Displays information about the filter system of the Sample-Rate Converter block:

- Overall Interpolation Factor

- Overall Decimation Factor
- Number of Filters
- Multiplication per Input Sample
- Number of Coefficients
- Filters

The button brings the functionality of the `info` method into the Simulink environment.

Simulate using

Type of simulation to run. You can set this parameter to:

- Code generation (default)

Simulate model using generated C code. The first time you run a simulation, Simulink generates C code for the block. The C code is reused for subsequent simulations, as long as the model does not change. This option requires additional startup time but provides faster simulation speed than Interpreted execution.

- Interpreted execution

Simulate model using the MATLAB interpreter. This option shortens startup time but has slower simulation speed than Code generation.

Supported Data Types

Port	Supported Data Types
Input	<ul style="list-style-type: none"> • Double-precision floating point • Single-precision floating point
Output	<ul style="list-style-type: none"> • Double-precision floating point • Single-precision floating point

Algorithms

This block brings the capabilities of the `dsp.SampleRateConverter` System object to the Simulink environment.

For information on the algorithms used by this block, see the “Algorithms” on page 4-1209 section of `dsp.SampleRateConverter`.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

The Sample-Rate Converter block supports SIMD code generation using Intel AVX2 technology under these conditions:

- For upsampling, the ratio of output sample rate to input sample rate must be an integer.
- For downsampling, the ratio of input sample rate to output sample rate must be an integer.
- Input signal has a data type of `single` or `double`.

The SIMD technology significantly improves the performance of the generated code.

Introduced in R2015b

Scalar Quantizer (Obsolete)

Convert input signal into set of quantized output values or index values, or convert set of index values into quantized output signal

Library

dspobslib

Description

Note The Scalar Quantizer block is still supported but is likely to be obsoleted in a future release. We strongly recommend replacing this block with the Scalar Quantizer Encoder block or the Scalar Quantizer Decoder block.

The Scalar Quantizer block has three modes of operation. In **Encoder** mode, the block maps each input value to a quantization region by comparing the input value to the quantizer boundary points defined in the **Boundary points** parameter. The block outputs the index of the associated region. In **Decoder** mode, the block transforms the input index values into quantized output values, defined in the **Codebook** parameter. In the **Encoder and Decoder** mode, the block performs both the encoding and decoding operations. The block outputs the index values and the quantized output values.

You can select how you want to enter the **Boundary points** and/or **Codebook** values using the **Source of quantizer** parameters. When you select **Specify via dialog**, type the parameters into the block parameters dialog box. Select **Input ports**, and port B and/or C appears on the block. In **Encoder** and **Encoder and decoder** mode, the input to port B is used as the **Boundary points**. In **Decoder** and **Encoder and decoder** mode, the input to port C is used as the **Codebook**.

In **Encoder** and **Encoder and decoder** mode, the **Boundary points** are the values used to break up the input signal into regions. Each region is specified by an index number. When your first boundary point is $-\infty$ and your last boundary point is ∞ , your quantizer is unbounded. When your first and last boundary point is finite, your quantizer is bounded. When only your first or last boundary point is $-\infty$ or ∞ , your quantizer is semi-bounded.

For instance, when your input signal ranges from 0 to 11, you can create a bounded quantizer using the following boundary points:

```
[0 0.5 3.7 5.8 6.0 11]
```

The boundary points can have equal or varied spacing. Any input values between 0 and 0.5 would correspond to index 0. Input values between 0.5 and 3.7 would correspond to index 1, and so on.

Suppose you wanted to create an unbounded quantizer with the following boundary points:

```
[-inf 0 2 5.5 7.1 10 inf]
```

When your input signal has values less than 0, these values would be assigned to index 0. When your input signal has values greater than 10, these values would be assigned to index 6.

When an input value is the same as a boundary point, the **Tie-breaking rule** parameter defines the index to which the value is assigned. When you want the input value to be assigned to the lower index value, select **Choose the lower index**. To assign the input value with the higher index, select **Choose the higher index**.

In **Decoder** and **Encoder** and **decoder** mode, the **Codebook** is a vector of quantized output values that correspond to each index value.

In **Encoder** and **Encoder** and **decoder** mode, the **Searching method** determines how the appropriate quantizer index is found. Select **Linear** and the Scalar Quantizer block compares the input value to the first region defined by the first two boundary points. When the input value does not fall within this region, the block then compares the input value to the next region. This process continues until the input value is determined to be within a region and is associated with the appropriate index value. The computational cost of this process is of the order P , where P is the number of boundary points.

Select **Binary** for the **Searching method** and the block compares the input value to the middle value of the boundary points vector. When the input value is larger than this boundary point, the block discards the boundary points that are lower than this middle value. The block then compares the input value to the middle boundary point of the new range, defined by the remaining boundary points. This process continues until the input value is associated with the appropriate index value. The computational cost of this process is of the order $\log_2 P$, where P is the number of boundary points. In most cases, the **Binary** option is faster than the **Linear** option.

In **Decoder** mode, the input to this block is a vector of index values, where $0 \leq \text{index} < N$ and N is the length of the codebook vector. Use the **Action for out of range input** parameter to determine what happens when an input index value is out of this range. When you want any index values less than 0 to be set to 0 and any index values greater than or equal to N to be set to $N - 1$, select **Clip**. When you want to be warned when any index values less than 0 are set to 0 and any index values greater than or equal to N are set to $N - 1$, select **Clip and warn**. When you want the simulation to stop and display an error when the index values are out of range, select **Error**.

In **Encoder** and **decoder** mode, you can select the **Output the quantization error** check box. The quantization error is the difference between the input value and the quantized output value. Select this check box to output the quantization error for each input value from the **Err** port on this block.

Data Type Support

In **Encoder** mode, the input data values and the boundary points can be the input to the block at ports **U** and **B**. Similarly, in **Encoder** and **decoder** mode, the codebook values can also be the input to the block at port **C**. The data type of the input data values, boundary points, and codebook values can be **double**, **single**, **uint8**, **uint16**, **uint32**, **int8**, **int16**, or **int32**. In **Decoder** mode, the input to the block can be the index values and the codebook values. The data type of the index input to the block at port **Idx** can be **uint8**, **uint16**, **uint32**, **int8**, **int16**, or **int32**. The data type of the codebook values can be **double**, **single**, **uint8**, **uint16**, **uint32**, **int8**, **int16**, or **int32**.

In Encoder mode, the output of the block is the index values. In Encoder and decoder mode, the output can also include the quantized output values and the quantization error. In Encoder and Encoder and decoder mode, use the **Output index data type** parameter to specify the data type of the index output from the block at port `Idx`. The data type of the index output can be `uint8`, `uint16`, `uint32`, `int8`, `int16`, or `int32`. The data type of the quantized output and the quantization error can be `double`, `single`, `uint8`, `uint16`, `uint32`, `int8`, `int16`, or `int32`. In Decoder mode, the output of the block is the quantized output values. Use the **Output data type** parameter to specify the data type of the quantized output values. The data type can be `double`, `single`, `uint8`, `uint16`, `uint32`, `int8`, `int16`, `int32`.

Note The input data, codebook values, boundary points, quantization error, and the quantized output values must have the same data type whenever they are present in any of the quantizer modes.

Parameters

Quantizer mode

Specify `Encoder`, `Decoder`, or `Encoder and decoder` as a mode of operation.

Source of quantizer parameters

Choose `Specify via dialog` to type the parameters into the block parameters dialog box. Select `Input ports` to specify the parameters using the block's input ports. In `Encoder and Encoder and decoder` mode, input the **Boundary points** using port B. In `Decoder and Encoder and decoder` mode, input the **Codebook** values using port C.

Boundary points

Enter a vector of values that represent the boundary points of the quantizer regions. Tunable (Simulink).

Codebook

Enter a vector of quantized output values that correspond to each index value. Tunable (Simulink).

Searching method

Select `Linear` and the block finds the region in which the input value is located using a linear search. Select `Binary` and the block finds the region in which the input value is located using a binary search.

Tie-breaking rule

Set this parameter to determine the behavior of the block when the input value is the same as the boundary point. When you select `Choose the lower index`, the input value is assigned to lower index value. When you select `Choose the higher index`, the value is assigned to the higher index.

Action for out of range input

Choose the block's behavior when an input index value is out of range, where $0 \leq \text{index} < N$ and N is the length of the codebook vector. Select `Clip`, when you want any index values less than 0 to be set to 0 and any index values greater than or equal to N to be set to $N - 1$. Select `Clip and warn`, when you want to be warned when any index values less than 0 are set to 0 and any index values greater than or equal to N are set to $N - 1$. Select `Error`, when you want the simulation to stop and display an error when the index values are out of range.

Output the quantization error

In Encoder and decoder mode, select this check box to output the quantization error from the Err port on this block.

Output index data type

In Encoder and Encoder and decoder mode, specify the data type of the index output from the block at port Idx. The data type can be uint8, uint16, uint32, int8, int16, or int32.

This parameter becomes visible when you select the **Show additional parameters** check box.

Output data type

In Decoder mode, specify the data type of the quantized output. The data type can be uint8, uint16, uint32, int8, int16, int32, single, or double. This parameter becomes visible when you select Specify via dialog for the **Source of quantizer parameters** and you select the **Show additional parameters** check box.

Supported Data Types

- Double-precision floating point
- Single-precision floating point
- Fixed point
- 8-, 16-, and 32-bit signed integers
- 8-, 16-, and 32-bit unsigned integers

For more information on what data types are supported for each quantizer mode, see “Data Type Support” on page 2-1183.

Scalar Quantizer Decoder

Convert each index value into quantized output value

Library

Quantizers

dspquant2

Description

The Scalar Quantizer Decoder block transforms the zero-based input index values into quantized output values. The set of all possible quantized output values is defined by the **Codebook values** parameter.

Use the **Codebook values** parameter to specify a matrix containing all possible quantized output values. You can select how you want to enter the codebook values using the **Source of codebook** parameter. When you select *Specify via dialog*, type the codebook values into the block parameters dialog box. When you select *Input port*, port C appears on the block. The block uses the input to port C as the **Codebook values** parameter.

The input to this block is a vector of integer index values, where $0 \leq \text{index} < N$ and N is the number of distinct codeword vectors in the codebook matrix. Use the **Action for out of range index value** parameter to determine what happens when an input index value is outside this range. When you want any index value less than 0 to be set to 0 and any index value greater than or equal to N to be set to $N - 1$, select *Clip*. When you want to be warned when clipping occurs, select *Clip and warn*. When you want the simulation to stop and the block to display an error when the index values are out of range, select *Error*.

Data Type Support

The data type of the index values input at port I can be `uint8`, `uint16`, `uint32`, `int8`, `int16`, or `int32`. The data type of the codebook values input at port C can be `double`, `single`, or `Fixed-point`.

The output of the block is the quantized output values. If, for the **Source of codebook** parameter, you select *Specify via dialog*, the **Codebook and output data type** parameter appears. You can use this parameter to specify the data type of the codebook and quantized output values. In this case, the data type of the output values can be *Same as input*, `double`, `single`, `Fixed-point`, or *User-defined*. If, for the **Source of codebook** parameter you select *Input port*, the quantized output values have the same data type as the codebook values input at port C.

Dialog Box

The **Main** pane of the Scalar Quantizer Decoder block dialog appears as follows.

Action for out of range index value

Use this parameter to determine the block's behavior when an input index value is out of range, where $0 \leq \text{index} < N$ and N is the length of the codebook vector. Select **Clip**, when you want any index values less than 0 to be set to 0 and any index values greater than or equal to N to be set to $N - 1$. Select **Clip and warn**, when you want to be warned when clipping occurs. Select **Error**, when you want the simulation to stop and the block to display an error when the index values are outside the range.

Source of codebook

Choose **Specify via dialog** to type the codebook values into the block parameters dialog box. Select **Input port** to specify the codebook using input port C.

Codebook values

Enter a vector of quantized output values that correspond to each index value. Tunable (Simulink).

The **Data Types** pane of the Scalar Quantizer Decoder block dialog appears as follows.

Codebook and output data type

Specify the data type of the codebook and quantized output values. You can select one of the following:

- A rule that inherits a data type, for example, `Inherit: Same as input`.
- A built in data type, such as `double`
- An expression that evaluates to a valid data type, for example, `fixdt(1,16)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the **Output data type** parameter.

See “Control Data Types of Signals” (Simulink) in *Simulink User's Guide* (Simulink) for more information.

This parameter is available only when you set the **Source of codebook** parameter to `Specify via dialog`. If you set the **Source of codebook** parameter to `Input port`, the output values have the same data type as the input codebook values.

Scalar Quantizer Design

(Removed) Start Scalar Quantizer Design Tool (SQDTool) to design scalar quantizer using Lloyd algorithm

Note The Scalar Quantizer Design block and the associated SQDTool have been removed. For more information, see “Compatibility Considerations”.

Library

Quantizers

dspquant2

Description

Double-click on the Scalar Quantizer Design block to start SQDTool, a GUI that allows you to design and implement a scalar quantizer. Based on your input values, SQDTool iteratively calculates the codebook values that minimize the mean squared error until the stopping criteria for the design process is satisfied. The block uses the resulting quantizer codebook values and boundary points to implement your scalar quantizer encoder and/or decoder.

For the **Training Set** parameter, enter a set of observations, or samples, of the signal you want to quantize. This data can be any variable defined in the MATLAB workspace including a variable created using a MATLAB function, such as the default value `randn(10000,1)`.

You have two choices for the **Source of initial codebook** parameter. Select **Auto-generate** to have the block choose the values of the initial codebook vector. In this case, the minimum training set value becomes the first codeword, and the maximum training set value becomes the last codeword. Then, the remaining initial codewords are equally spaced between these two values to form a codebook vector of length N , where N is the **Number of levels** parameter. When you select **User defined**, enter the initial codebook values in the **Initial codebook** field. Then, set the **Source of initial boundary points** parameter. You can select **Mid-points** to locate the boundary points at the midpoint between the codewords. To calculate the mid-points, the block internally arranges the initial codebook values in ascending order. You can also choose **User defined** and enter your own boundary points in the **Initial boundary points (unbounded)** field. Only one boundary point can be located between two codewords. When you select **User defined** for the **Source of initial boundary points** parameter, the values you enter in the **Initial codebook** and **Initial boundary points (unbounded)** fields must be arranged in ascending order.

Note This block assumes that you are designing an unbounded quantizer. Therefore, the first and last boundary points are always `-inf` and `inf` regardless of any other boundary point values you might enter.

After you have specified the quantization parameters, the block performs an iterative process to design the optimal scalar quantizer. Each step of the design process involves using the Lloyd algorithm to calculate codebook values and quantizer boundary points. Then, the block calculates the squared quantization error and checks whether the stopping criteria has been satisfied.

The two possible options for the **Stopping criteria** parameter are `Relative threshold` and `Maximum iteration`. When you want the design process to stop when the fractional drop in the squared quantization error is below a certain value, select `Relative threshold`. Then, for **Relative threshold**, type the maximum acceptable fractional drop. When you want the design process to stop after a certain number of iterations, choose `Maximum iteration`. Then, enter the maximum number of iterations you want the block to perform in the **Maximum iteration** field. For **Stopping criteria**, you can also choose `Whichever comes first` and enter a **Relative threshold** and **Maximum iteration** value. The block stops iterating as soon as one of these conditions is satisfied.

With each iteration, the block quantizes the training set values based on the newly calculated codebook values and boundary points. When the training point lies on a boundary point, the algorithm uses the **Tie-breaking rules** parameter to determine which region the value is associated with. When you want the training point to be assigned to the lower indexed region, select `Lower indexed codeword`. To assign the training point with the higher indexed region, select `Higher indexed codeword`.

The **Searching methods** parameter determines how the block compares the training points to the boundary points. Select `Linear search` and SQDTool compares each training point to each quantization region sequentially. This process continues until all the training points are associated with the appropriate regions.

Select `Binary search` for the **Searching methods** parameter and the block compares the training point to the middle value of the boundary points vector. When the training point is larger than this boundary point, the block discards the lower boundary points. The block then compares the training point to the middle boundary point of the new range, defined by the remaining boundary points. This process continues until the training point is associated with the appropriate region.

Click **Design and Plot** to design the quantizer with the parameter values specified on the left side of the GUI. The performance curve and the staircase character of the quantizer are updated and displayed in the figures on the right side of the GUI.

Note You must click **Design and Plot** to apply any changes you make to the parameter values in the SQDTool dialog box.

SQDTool can export parameter values that correspond to the figures displayed in the GUI. Click the **Export Outputs** button, or press **Ctrl+E**, to export the **Final Codebook**, **Final Boundary Points**, and **Error** values to the workspace, a text file, or a MAT-file. The **Error** values represent the mean squared error for each iteration.

In the **Model** section of the GUI, specify the destination of the block that will contain the parameters of your quantizer. For **Destination**, select `Current model` to create a block with your parameters in the model you most recently selected. Type `gcs` in the MATLAB Command Window to display the name of your current model. Select `New model` to create a block in a new model file.

From the **Block type** list, select `Encoder` to design a Scalar Quantizer Encoder block. Select `Decoder` to design a Scalar Quantizer Decoder block. Select `Both` to design a Scalar Quantizer Encoder block and a Scalar Quantizer Decoder block.

In the **Encoder block name** field, enter a name for the Scalar Quantizer Encoder block. In the **Decoder block name** field, enter a name for the Scalar Quantizer Decoder block. When you have a Scalar Quantizer Encoder and/or Decoder block in your destination model with the same name, select

the **Overwrite target block(s)** check box to replace the block's parameters with the current parameters. When you do not select this check box, a new Scalar Quantizer Encoder and/or Decoder block is created in your destination model.

Click **Generate Model**. SQDTool uses the parameters that correspond to the current plots to set the parameters of the Scalar Quantizer Encoder and/or Decoder blocks.

Parameters

Training Set

Enter the samples of the signal you would like to quantize. This data set can be a MATLAB function or a variable defined in the MATLAB workspace. The typical length of this data vector is $1e6$.

Source of initial codebook

Select `Auto-generate` to have the block choose the initial codebook values. Select `User defined` to enter your own initial codebook values.

Number of levels

Enter the length of the codebook vector. For a b -bit quantizer, the length should be $N = 2^b$.

Initial codebook

Enter your initial codebook values. From the **Source of initial codebook** list, select `User defined` in order to activate this parameter.

Source of initial boundary points

Select `Mid-points` to locate the boundary points at the midpoint between the codebook values. Choose `User defined` to enter your own boundary points. From the **Source of initial codebook** list, select `User defined` in order to activate this parameter.

Initial boundary points (unbounded)

Enter your initial boundary points. This block assumes that you are designing an unbounded quantizer. Therefore, the first and last boundary point are `-inf` and `inf`, regardless of any other boundary point values you might enter. From the **Source of initial boundary points** list, select `User defined` in order to activate this parameter.

Stopping criteria

Choose `Relative threshold` to enter the maximum acceptable fractional drop in the squared quantization error. Choose `Maximum iteration` to specify the number of iterations at which to stop. Choose `Whichever comes first` and the block stops the iteration process as soon as the relative threshold or maximum iteration value is attained.

Relative threshold

Type the value that is the maximum acceptable fractional drop in the squared quantization error.

Maximum iteration

Enter the maximum number of iterations you want the block to perform. From the **Stopping criteria** list, select `Maximum iteration` in order to activate this parameter.

Searching methods

Choose `Linear search` to use a linear search method when comparing the training points to the boundary points. Choose `Binary search` to use a binary search method when comparing the training points to the boundary points.

Tie-breaking rules

When a training point lies on a boundary point, choose **Lower indexed codeword** to assign the training point to the lower indexed quantization region. Choose **Higher indexed codeword** to assign the training point to the higher indexed region.

Design and Plot

Click this button to display the performance curve and the staircase character of the quantizer in the figures on the right side of the GUI. These plots are based on the current parameter settings.

You must click **Design and Plot** to apply any changes you make to the parameter values in the SQDTool GUI.

Export Outputs

Click this button, or press **Ctrl+E**, to export the **Final Codebook**, **Final Boundary Points**, and **Error** values to the workspace, a text file, or a MAT-file.

Destination

Choose **Current model** to create a Scalar Quantizer block in the model you most recently selected. Type `gcs` in the MATLAB Command Window to display the name of your current model. Choose **New model** to create a block in a new model file.

Block type

Select **Encoder** to design a Scalar Quantizer Encoder block. Select **Decoder** to design a Scalar Quantizer Decoder block. Select **Both** to design a Scalar Quantizer Encoder block and a Scalar Quantizer Decoder block.

Encoder block name

Enter a name for the Scalar Quantizer Encoder block.

Decoder block name

Enter a name for the Scalar Quantizer Decoder block.

Overwrite target block(s)

When you do not select this check box and a Scalar Quantizer Encoder and/or Decoder block with the same block name exists in the destination model, a new Scalar Quantizer Encoder and/or Decoder block is created in the destination model. When you select this check box and a Scalar Quantizer Encoder and/or Decoder block with the same block name exists in the destination model, the parameters of these blocks are overwritten by new parameters.

Generate Model

Click this button and SQDTool uses the parameters that correspond to the current plots to set the parameters of the Scalar Quantizer Encoder and/or Decoder blocks.

Scalar Quantizer Encoder

Encode each input value by associating it with index value of quantization region

Library

Quantizers

dspquant2

Description

The Scalar Quantizer Encoder block maps each input value to a quantization region by comparing the input value to the quantizer boundary points defined in the **Boundary points** parameter. The block outputs the zero-based index of the associated region.

You can select how you want to enter the **Boundary points** using the **Source of quantizer parameters**. When you select *Specify via dialog*, type the boundary points into the block parameters dialog box. When you select *Input port*, port B appears on the block. The block uses the input to port B as the **Boundary points** parameter.

Use the **Boundary points** parameter to specify the boundary points for your quantizer. These values are used to break up the set of input numbers into regions. Each region is specified by an index number.

Let N be the number of quantization regions. When the codebook is defined as $[c_1 \ c_2 \ c_3 \ \dots \ c_N]$, and the **Boundary points** parameter is defined as $[p_0 \ p_1 \ p_2 \ p_3 \ \dots \ p_N]$, then $p_0 < c_1 < p_1 < c_2 \ \dots \ p_{(N-1)} < c_N < p_N$ for a regular quantizer. When your quantizer is bounded, from the **Partitioning** list, select *Bounded*. You need to specify $N+1$ boundary points, or $[p_0 \ p_1 \ p_2 \ p_3 \ \dots \ p_N]$. When your quantizer is unbounded, from the **Partitioning** list, select *Unbounded*. You need to specify $N-1$ boundary points, or $[p_1 \ p_2 \ p_3 \ \dots \ p_{(N-1)}]$; the block sets p_0 equal to $-\infty$ and p_N equal to ∞ .

The block uses the **Partitioning** parameter to interpret the boundary points you enter. For instance, to create a bounded quantizer, from the **Partitioning** list, select *Bounded* and enter the following boundary points:

```
[0 0.5 3.7 5.8 6.0 11]
```

The block assigns any input values between 0 and 0.5 to index 0, input values between 0.5 and 3.7 to index 1, and so on. The block assigns any values that are less than 0 to index 0, the lowest index value. The block assigns any values that are greater than 11 to index 4, the highest index value.

To create an unbounded quantizer, from the **Partitioning** list, select Unbounded and enter the following boundary points:

```
[0 0.5 3.7 5.8 6.0 11]
```

The block assigns any input values between 0 and 0.5 to index 1, input values between 0.5 and 3.7 to index 2, and so on. The block assigns any input values less than 0 to index 0 and any values greater than 11 to index 6.

The **Searching method** parameter determines how the appropriate quantizer index is found. When you select **Linear**, the Scalar Quantizer Encoder block compares the input value to the first region defined by the first two boundary points. When the input value does not fall within this region, the block then compares the input value to the next region. This process continues until the input value is determined to be within a region and is associated with the appropriate index value. The computational cost of this process is of the order P , where P is the number of boundary points.

When you select **Binary** for the **Searching method**, the block compares the input value to the middle value of the boundary points vector. When the input value is larger than this boundary point, the block discards the boundary points that are lower than this middle value. The block then compares the input value to the middle boundary point of the new range, defined by the remaining boundary points. This process continues until the input value is associated with the appropriate index value. The computational cost of this process is of the order $\log_2 P$, where P is the number of boundary points. In most cases, the **Binary** option is faster than the **Linear** option.

When an input value is the same as a boundary point, the **Tie-breaking rule** parameter determines the region to which the value is assigned. When you want the input value to be assigned to the lower indexed region, select **Choose the lower index**. To assign the input value with the higher indexed region, select **Choose the higher index**.

Select the **Output codeword** check box to output the codeword values that correspond to each index value at port Q(U).

Select the **Output the quantization error** check box to output the quantization error for each input value from the Err port on this block. The quantization error is the difference between the input value and the quantized output value.

When you select either the **Output codeword** check box or the **Output quantization error** check box, you must also enter your codebook values. If, from the **Source of quantizer parameters** list, you choose **Specify via dialog**, use the **Codebook** parameter to enter a vector of quantized output values that correspond to each region. If, from the **Source of quantizer parameters** list, you choose **Input port**, use input port C to specify your codebook values.

If, for the **Partitioning** parameter, you select **Bounded**, the **Output clipping status** check box and the **Action for out of range input** parameter appear. When you select the **Output clipping status** check box, port S appears on the block. Any time an input value is outside the range defined by the **Boundary points** parameter, the block outputs a 1 at the S port. When the value is inside the range, the blocks outputs a 0.

You can use the **Action for out of range input** parameter to determine the block's behavior when an input value is outside the range defined by the **Boundary points** parameter. Suppose the boundary points for a bounded quantizer are defined as $[p_0 \ p_1 \ p_2 \ p_3 \ \dots \ p_N]$ and the possible index values are defined as $[i_0 \ i_1 \ i_2 \ \dots \ i_{(N-1)}]$, where $i_0=0$ and $i_0 < i_1 < i_2 < \dots < i_{(N-1)}$. When you want any input value less than p_0 to be assigned to index value i_0 and any input values greater than p_N to be assigned to index value $i_{(N-1)}$, select **Clip**. When you want to be warned

when clipping occurs, select `Clip` and `warn`. When you want the simulation to stop and the block to display an error when the index values are out of range, select `Error`.

The Scalar Quantizer Encoder block accepts real floating-point and fixed-point inputs. For more information on the data types accepted by each port, see “Data Type Support” on page 2-1197 or “Supported Data Types” on page 2-1199.

Data Type Support

The input data values, boundary points, and codebook values can be input to the block at ports U, B, and C, respectively. The data type of the inputs can be `double`, `single`, or `Fixed-point`.

The outputs of the block can be the index values, the quantized output values, the quantization error, and the clipping status. Use the **Index output data type** parameter to specify the data type of the index output from the block at port I. You can choose `int8`, `uint8`, `int16`, `uint16`, `int32`, or `uint32`. The data type of the quantized output and the quantization error can be `double`, `single`, or `Fixed-point`. The clipping status values output at port S are Boolean values.

Note The input data, boundary points, codebook values, quantized output values, and the quantization error must have the same data type whenever they are present.

Dialog Box

Main Tab

Source of quantizer parameters

Choose `Specify via dialog` to enter the boundary points and codebook values using the block parameters dialog box. Select `Input port` to specify the parameters using the block's input ports. Input the boundary points and codebook values using ports B and C, respectively.

Partitioning

When your quantizer is bounded, select `Bounded`. When your quantizer is unbounded, select `Unbounded`.

Boundary points

Enter a vector of values that represent the boundary points of the quantizer regions. This parameter is visible when you select `Specify via dialog` from the **Source of quantizer parameters** list. Tunable (Simulink).

Searching method

When you select `Linear`, the block finds the region in which the input value is located using a linear search. When you select `Binary`, the block finds the region in which the input value is located using a binary search.

Tie-breaking rule

Set this parameter to determine the behavior of the block when the input value is the same as the boundary point. When you select `Choose the lower index`, the input value is assigned to lower indexed region. When you select `Choose the higher index`, the value is assigned to the higher indexed region.

Output codeword

Select this check box to output the codeword values that correspond to each index value at port Q(U).

Output quantization error

Select this check box to output the quantization error for each input value at port Err.

Codebook

Enter a vector of quantized output values that correspond to each index value. If, for the **Partitioning** parameter, you select **Bounded** and your boundary points vector has length N , then you must specify a codebook of length $N-1$. If, for the **Partitioning** parameter, you select **Unbounded** and your boundary points vector has length N , then you must specify a codebook of length $N+1$.

This parameter is visible when you select **Specify** via dialog from the **Source of quantizer parameters** list and you select either the **Output codeword** or **Output quantization error** check box. Tunable (Simulink).

Output clipping status

When you select this check box, port S appears on the block. Any time an input value is outside the range defined by the **Boundary points** parameter, the block outputs a 1 at this port. When the value is inside the range, the block outputs a 0. This parameter is visible when you select **Bounded** from the **Partitioning** list.

Action for out of range input

Use this parameter to determine the behavior of the block when an input value is outside the range defined by the **Boundary points** parameter. Suppose the boundary points are defined as $[p_0 p_1 p_2 p_3 \dots p_N]$ and the index values are defined as $[i_0 i_1 i_2 \dots i_{(N-1)}]$. When you want any input value less than p_0 to be assigned to index value i_0 and any input values greater than p_N to be assigned to index value $i_{(N-1)}$, select **Clip**. When you want to be warned when clipping occurs, select **Clip and warn**. When you want the simulation to stop and the block to display an error when the index values are out of range, select **Error**. This parameter is visible when you select **Bounded** from the **Partitioning** list.

Index output data type

Specify the data type of the index output from the block at port I. You can choose `int8`, `uint8`, `int16`, `uint16`, `int32`, `uint32`, or `Inherit` via back propagation.

Data Types Tab**Rounding mode**

Specify the rounding mode for fixed-point operations as one of the following:

- Floor
- Ceiling
- Convergent
- Nearest
- Round
- Simplest
- Zero

For more details, see rounding mode.

Saturate on integer overflow

When you select this parameter, the block saturates the result of its fixed-point operation. When you clear this parameter, the block wraps the result of its fixed-point operation. For details on `saturate` and `wrap`, see overflow mode for fixed-point operations.

Short-Time FFT

Nonparametric estimate of spectrum using short-time, fast Fourier transform (FFT) method

Library

Transforms

dspxfm3

Description

The Short-Time FFT block computes a nonparametric estimate of the spectrum. The block buffers, applies a window, and zero pads the input signal. The block then takes the FFT of the signal, transforming it into the frequency domain.

Connect your single-channel analysis window to the $w(n)$ port. For the **Analysis window length** parameter, enter the length of the analysis window, W . The block buffers the input signal such that it has a frame length of W

Connect your single-channel or multichannel input signal to the $x(n)$ port. After the block buffers and windows this signal, it zero-pads the signal before computing the FFT. For the **FFT length** parameter, enter the length to which the block pads the input signal. For the **Overlap between consecutive windows (in samples)** parameter, enter the number of samples to overlap each frame of the input signal.

The block outputs the complex-valued, single-channel or multichannel short-time FFT at port $X(n,k)$.

Fixed-Point Data Types

The following diagram shows the data types used within the Short-Time FFT subsystem block for fixed-point signals.

The settings for the fixed-point parameters of the Array-Vector Multiply block in the diagram above are as follows:

- **Rounding Mode** — Floor

- **Saturate on integer overflow** — Wrap
- **Product output** — Inherit via internal rule
- **Accumulator** — Inherit via internal rule
- **Output** — Same as first input

The settings for the fixed-point parameters of the FFT block in the diagram above are as follows:

- **Rounding Mode** — Floor
- **Saturate on integer overflow** — Wrap
- **Sine table** — Same word length as input
- **Product output** — Inherit via internal rule
- **Accumulator** — Inherit via internal rule
- **Output** — Inherit via internal rule

See the FFT and Array-Vector Multiply block reference pages for more information.

Examples

The `dspstsa` example illustrates how to use the Short-Time FFT and Inverse Short-Time FFT blocks to remove the background noise from a speech signal. To open the `dspstsa` model, type `dspstsa` in the MATLAB command prompt.

Parameters

Analysis window length

Specify the frame length of the analysis window. The **Analysis window length** must be a positive integer value greater than one.

Overlap between consecutive windows (in samples)

Enter the number of samples of overlap for each frame of the input signal.

FFT length

Enter the length to which the block pads the input signal.

Supported Data Types

Port	Supported Data Types
x(n)	<ul style="list-style-type: none"> • Double-precision floating point • Single-precision floating point • Fixed point (signed only) • 8-, 16-, and 32-bit signed integers
w(n)	<ul style="list-style-type: none"> • Double-precision floating point • Single-precision floating point • Fixed point (signed only) • 8-, 16-, and 32-bit signed integers

Port	Supported Data Types
X(n,k)	<ul style="list-style-type: none"> • Double-precision floating point • Single-precision floating point • Fixed point (signed only) • 8-, 16-, and 32-bit signed integers

References

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Usage notes and limitations:

- Generated code relies on memcpy or memset functions (`string.h`) under certain conditions.
- When the FFT length is not a power of two, the executable generated from this block relies on prebuilt dynamic library files (`.dll` files) included with MATLAB. Use the `packNGo` function to package the code generated from this block and all the relevant files in a compressed zip file. Using this zip file, you can relocate, unpack, and rebuild your project in another development environment where MATLAB is not installed. For more details, see “How To Run a Generated Executable Outside MATLAB”.

When the FFT length is a power of two, you can generate standalone C and C++ code from this block.

Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

If the input is fixed point, it must be signed integer or signed fixed point with power-of-two slope and zero bias.

Signal From Workspace

Import signal from MATLAB workspace

Library: DSP System Toolbox / Sources

Description

The Signal From Workspace block imports a signal from the MATLAB workspace into the Simulink model. The **Signal** parameter specifies the name of a MATLAB workspace variable containing the signal to import, or any valid MATLAB expression defining a matrix or 3-D array.

Unlike the Simulink From Workspace block, the Signal From Workspace block holds the output value constant between successive output frames (that is, no linear interpolation takes place). Also, the initial signal values are always produced immediately at $t=0$.

Ports

Output

Port_1 — Signal imported from workspace

scalar | vector | matrix | 3-D array

Signal imported from workspace, as a scalar, vector, matrix, or 3-D array.

When the **Signal** parameter specifies an M -by- N matrix ($M \neq 1$), each of the N columns is treated as a distinct channel. You specify the frame size in the **Samples per frame** parameter, M_o . The output is an M_o -by- N matrix containing M_o consecutive samples from each signal channel. You specify the output sample period in the **Sample time** parameter, T_s , and the output frame period is $M_o T_s$. For convenience, an imported row vector ($M=1$) is treated as a single channel, so the output dimension is M_o -by-1.

When the **Signal** parameter specifies an M -by- N -by- P array, each of the P pages (an M -by- N matrix) is output in sequence with period T_s . The **Samples per frame** parameter must be set to 1.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point

Parameters

Signal — Signal to import

1:10 (default) | MATLAB workspace variable | MATLAB expression

The name of the MATLAB workspace variable from which to import the signal, or a valid MATLAB expression specifying the signal.

Sample time — Output sample period

1 (default) | scalar | vector

The sample period, T_s , of the output, specified as a scalar or vector. The output frame period is $M_o T_s$.

Samples per frame — Samples per frame

1 (default) | positive integer

The number of samples, M_o , to buffer into each output frame, specified as a positive integer scalar. This value must be 1 when you specify a 3-D array in the **Signal** parameter.

Form output after final data value by — Values to output after final imported signal value

Setting to zero (default) | Holding final value | Cyclic repetition

Specifies the output after all of the specified signal samples have been generated.

- When you specify **Setting To Zero**, the block generates zero-valued outputs for the duration of the simulation after generating the last frame of the signal.
- When you specify **Holding Final Value**, the block repeats the final sample for the duration of the simulation after generating the last frame of the signal.
- When you specify **Cyclic Repetition**, the block repeats the signal from the beginning after it reaches the last sample in the signal. If the frame size you specify in the **Samples per frame** parameter does not evenly divide the input length, a buffer block is inserted into the Signal From Workspace subsystem, and the model becomes multirate. If you do not want your model to become multirate, make sure that the frame size evenly divides the input signal length.

The block does not extrapolate the imported signal beyond the last sample.

Warn when frame size does not evenly divide input length — Warn when input length is not an integer multiple of frame size

off (default) | on

Select the **Warn when frame size does not evenly divide input length** parameter to be alerted when the input length is not an integer multiple of the frame size. When the input length is not an integer multiple of the frame size, the model becomes multirate. Use the Model Explorer to turn these warnings on or off model-wide:

- In the **Modeling** tab, click **Model Explorer**.
- In the **Search** bar of the Model Explorer, search by **Property Name** for the `ignoreOrWarnInputAndFrameLengths` property. Each block with the **Warn when frame size does not evenly divide input length** check box appears in the list in the **Contents** pane.
- Select each of the blocks for which you want to toggle the warning parameter, and select or clear the check box in the `ignoreOrWarnInputAndFrameLengths` column.

Dependencies

To enable this parameter set **Form output after final data value by** to **Cyclic Repetition**.

Block Characteristics

Signal To Workspace

Write data to MATLAB workspace

Compatibility

Note The Signal To Workspace block has been replaced by the To Workspace block in Simulink. Replace existing instances of the Signal To Workspace block with To Workspace block. For new models, use the To Workspace block.

Library

Sinks

dspsnks4

Description

The Signal To Workspace block writes data from your simulation into an array or structure in the main MATLAB workspace. You can specify a name for the workspace variable as well as whether the data is saved as an array, structure, or structure with time.

When the **Save format** is set to Array or Structure, the dimensions of the output depend on the input dimensions and the setting of the **Save 2-D signals as** parameter. The following table summarizes the output dimensions under various conditions. In the table, K represents the value of the **Limit data points to last** parameter.

Input Signal Dimensions	Save 2-D Signals as ...	Signal To Workspace Output Dimension
M -by- N matrix	2-D array (concatenate along first dimension)	<p>K-by-N matrix.</p> <p>If you set the Limit data points to last parameter to ∞, K represents the total number of samples acquired in each column by the end of simulation. This is equivalent to multiplying the input frame size (M) by the total number of M-by-N inputs acquired by the block.</p>

Input Signal Dimensions	Save 2-D Signals as ...	Signal To Workspace Output Dimension
M -by- N matrix	3-D array (concatenate along third dimension)	M -by- N -by- K array. If you set the Limit data points to last parameter to inf , K represents the total number of M -by- N inputs acquired by the end of the simulation.
Length- N unoriented vector	Any setting	K -by- N matrix
N -dimensional array where $N > 2$	Any setting	Array with $N+1$ dimensions, where the size of the last dimension is equal to K . If you set the Limit data points to last parameter to inf , K represents the total number of M -by- N inputs acquired by the end of simulation

Examples

Example 1: Save 2-D Signals as a 2-D Array

In the `ex_signaltoworkspace_ref2` model, the Signal To Workspace block receives a 2-by-4 matrix input and logs 11 frames (two samples per frame) by the end of the simulation. Because the **Save 2-D signals as** parameter is set to 2-D array (concatenate along first dimension), the block concatenates the input along the first dimension to create a 22-by-4 matrix, A , in the MATLAB workspace.

The following figure illustrates the behavior of the Signal to Workspace block in this example.

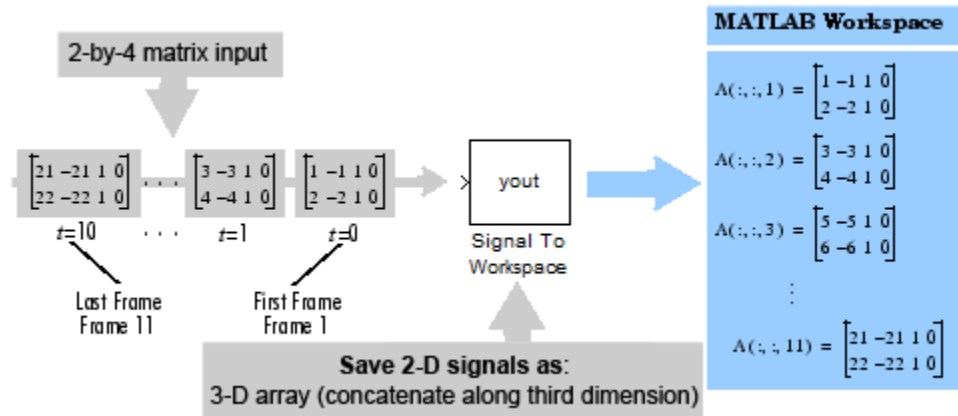

In the 2-D output mode, there is no indication of where one frame ends and another begins. To log input frames separately, set the **Save 2-D signals as** parameter to 3-D array (concatenate along third dimension), as shown in Example 2.

Example 2: Save 2-D Signals as a 3-D Array

In the `ex_signaltoworkspace_ref1` model, the input to the Signal To Workspace block is a 2-by-4 matrix. The **Save 2-D signals as** parameter is set to 3-D array (concatenate along third dimension), so by the end of the simulation the Signal To Workspace block logs 11 frames of data as a 2-by-4-by-11 array, *A*, in the MATLAB workspace.

The following figure illustrates the behavior of the Signal to Workspace block in this example.

Parameters

Variable name

Specify the name of the array or structure into which the block logs the simulation data. The block creates this variable in the MATLAB workspace only after the simulation stops running. When you enter the name of an existing workspace variable, the block overwrites that variable with the simulation data.

Limit data points to last

Specify the maximum number of samples or frames the block will save. When the simulation generates more than the specified maximum number of samples or frames, the simulation saves only the most recently generated data. To capture all data, set this parameter to `inf`. See the table in the Description on page 2-1207 section for more information on how this parameter affects the dimensions of the logged data.

Decimation

Specify a positive integer *d* to determine how often the block writes data to the workspace array or structure. The block writes data to the array or structure every *d*th sample. With the default decimation value of 1, the block writes data at every time step.

Save format

Specify the format in which to save simulation output to the workspace. You can select one of the following options:

- **Array** — Select this option to save the data as an N-dimensional array. If the input signal is an unoriented vector, the resulting workspace array is 2-D. Each input vector is saved in a row of the output matrix, vertically concatenated onto the previous vector. If the input signal is 2-dimensional, the dimensions of the resulting workspace array depend on the setting of the **Save 2-D signals as** parameter.

- **Structure** — Select this option to save the data as a structure consisting of three fields: `time`, `signals` and `blockName`. In this mode, the `time` field is empty, and the `blockName` field contains the name of the Signal To Workspace block. The `signals` field contains a structure with three additional fields: `values`, `dimensions`, and `label`. The `values` field contains the array of signal values, the `dimensions` field specifies the dimensions of the values array, and the `label` field contains the label of the input line.
- **Structure with time** — This option is the same as **Structure**, except that the `time` field contains a vector of simulation time steps. This is the only output format that can be read directly by a From Workspace block. When you select this option, the **Save 2-D signals as** parameter is not available. In this mode, the block always saves 2-D input arrays as a 3-D array.

The default setting of this parameter is **Array**.

Save 2-D signals as

Specify whether the block outputs 2-D signals as a 2-D or 3-D array in the MATLAB workspace:

- **2-D array (concatenate along first dimension)** — When you select this option, the block saves an M -by- N input signal as a $(K*M)$ -by- N matrix, where $K*M$ is the total number of samples acquired by the end of the simulation. The block vertically concatenates each M -by- N matrix input with the previous input to produce the 2-D output array. See “Example 1: Save 2-D Signals as a 2-D Array” on page 2-1208 for more information about this mode.
- **3-D array (concatenate along third dimension)** — When you select this option, the block saves an M -by- N input signal as an M -by- N -by- K array, where K is the number of M -by- N inputs logged by the end of the simulation. K has an upper bound equal to the value of the **Limit data points to last** parameter. See “Example 2: Save 2-D Signals as a 3-D Array” on page 2-1209 for more information about this mode.

This parameter is visible only when you set the **Save format** parameter to **Array** or **Structure**. When you set the **Save format** parameter to **Structure with time**, the block outputs the 2-D input signal as a 3-D array.

Note The **Inherit from input** (this choice will be removed - see release notes) option will be removed in a future release. See “Signal To Workspace Block Changes” in the *DSP System Toolbox Release Notes* for more information.

Log fixed-point data as a fi object

Select this check box to log fixed-point data to the MATLAB workspace as a Fixed-Point Designer `fi` object. Otherwise, fixed-point data is logged to the workspace as `double`.

Supported Data Types

- Double-precision floating point
- Single-precision floating point
- Fixed point (signed and unsigned)
- 8-, 16-, and 32-bit signed integers
- 8-, 16-, and 32-bit unsigned integers

Sine Wave

Generate continuous or discrete sine wave

Library: DSP System Toolbox / Sources
 DSP System Toolbox HDL Support / Sources

Description

The Sine Wave block generates a multichannel real or complex sinusoidal signal, with independent amplitude, frequency, and phase in each output channel. The block supports floating point and signed fixed-point data types.

The block generates a real sinusoidal signal when you set the **Output complexity** parameter to **Real**. The real sinusoidal output is defined by an expression of the type

$$y = A\sin(2\pi ft + \phi)$$

where you specify A in the **Amplitude** parameter, f in hertz in the **Frequency** parameter, and ϕ in radians in the **Phase offset** parameter.

The block generates a complex exponential signal when you set the **Output complexity** parameter to **Complex**. This complex exponential signal is defined by an expression of the type

$$y = Ae^{j(2\pi ft + \phi)} = A\{\cos(2\pi ft + \phi) + j\sin(2\pi ft + \phi)\}$$

Generating Multichannel Outputs

For both real and complex sinusoids, the **Amplitude**, **Frequency**, and **Phase offset** parameter values (A , f , and ϕ) can be scalars or length- N vectors, where N is the desired number of channels in the output. When you specify at least one of these parameters as a length- N vector, scalar values specified for the other parameters are applied to every channel.

For example, to generate the three-channel output containing the following real sinusoids, set the block parameters as shown:

$$y = \begin{cases} \sin(2000\pi t) & \text{(channel 1)} \\ 2\sin(1000\pi t) & \text{(channel 2)} \\ 3\sin\left(500\pi t + \frac{\pi}{2}\right) & \text{(channel 3)} \end{cases}$$

- **Output complexity** = Real
- **Amplitude** = [1 2 3]
- **Frequency** = [1000 500 250]
- **Phase offset** = [0 0 pi/2]

Ports

Output

Port_1 — Sinusoidal signal

scalar | vector | matrix

Output a sinusoidal signal as a scalar or vector. For more information about output complexity, see “Description” on page 2-1212. For information about multichannel support, see “Generating Multichannel Outputs” on page 2-1212.

Tip To output fixed-point data types, you must set **Sample mode** to **Discrete** and **Computation method** to **Table lookup**.

Data Types: single | double | fixed point
Complex Number Support: Yes

Parameters

Main

Amplitude — Amplitude of sine waves

1 (default) | scalar | vector

A length- N vector containing the amplitudes of the sine waves in each of N output channels, or a scalar to be applied to all N channels. The vector length must be the same as that specified for the **Frequency** and **Phase offset** parameters.

Tip This parameter is tunable (Simulink) only when the **Computation method** is **Trigonometric fcn** or **Differential**.

Tunable: Yes

Frequency (Hz) — Frequency of each sine wave

100 (default) | scalar | vector

A length- N vector containing frequencies, in hertz, of the sine waves in each of N output channels, or a scalar to be applied to all N channels. The vector length must be the same as that specified for the **Amplitude** and **Phase offset** parameters. You can specify positive, zero, or negative frequencies.

Tip This parameter is tunable (Simulink) when you set either:

- **Sample mode** to **Continuous**.
 - **Sample mode** to **Discrete** and **Computation method** to **Trigonometric fcn**.
-

Tunable: Yes

Phase offset (rad) — Phase offset

0 (default) | scalar | vector

A length- N vector containing the phase offsets, in radians, of the sine waves in each of N output channels, or a scalar to be applied to all N channels. The vector length must be the same as that specified for the **Amplitude** and **Frequency** parameters.

Tip This parameter is tunable (Simulink) when you set either:

- **Sample mode** to Continuous.
 - **Sample mode** to Discrete and **Computation method** to Trigonometric fcn.
-

Tunable: Yes

Sample mode — Continuous or discrete sampling mode

Discrete (default) | Continuous

Specify the sampling mode as Continuous or Discrete:

- Continuous

In continuous mode, the sinusoid in the i th channel, y_i , is computed as a continuous function,

$$y_i = A_i \sin(2\pi f_i t + \phi_i) \quad (\text{real})$$

or

$$y_i = A_i e^{j(2\pi f_i t + \phi_i)} \quad (\text{complex})$$

and the block's output is continuous. In this mode, the block operates the same as the Simulink Sine Wave block with **Sample time** set to 0. This mode offers high accuracy, but requires trigonometric function evaluations at each simulation step, which is computationally expensive. Also, because this method tracks absolute simulation time, a discontinuity will eventually occur when the time value reaches its maximum limit.

Note also that many DSP System Toolbox blocks do not accept continuous-time inputs.

- Discrete

In discrete mode, the block can generate discrete-time output by directly evaluating the trigonometric function, by table lookup, or by a differential method. For more information on these computation methods, see “Algorithms” on page 2-1216.

Output complexity — Real or complex waveform

Real (default) | Complex

The type of waveform to generate: Real specifies a real sine wave, Complex specifies a complex exponential.

Computation method — Method for computing discrete-time sinusoids

Trigonometric fcn (default) | Table lookup | Differential

The method by which discrete-time sinusoids are generated: `Trigonometric fcn`, `Table lookup`, or `Differential`. For more information on each of the available options, see “Algorithms” on page 2-1216.

Dependencies

This parameter is only visible when you set the **Sample mode** to `Discrete`.

Note To generate fixed-point sinusoids, you must set the **Computation method** to `Table lookup`.

Optimize table for — Optimize for speed or memory

Speed (default) | Memory

Optimizes the table of sine values for `Speed` or `Memory`. When optimized for speed, the table contains k elements, and when optimized for memory, the table contains $k/4$ elements, where k is the number of input samples in one full period of the sine wave.

Dependencies

This parameter is only visible when you set the **Computation method** parameter to `Table lookup`.

Sample time — Sample period

1/1000 (default) | scalar

The period with which the sine wave is sampled, T_s , as a finite scalar, greater than zero. The output frame period of the block is MT_s , where you specify M in the **Samples per frame** parameter.

Dependencies

To enable this parameter, set **Sample mode** to `Discrete`.

Samples per frame — Samples per frame

1 (default) | positive integer

The number of consecutive samples from each sinusoid to buffer into the output frame, M , specified as a positive scalar integer. This parameter is not tunable.

The block output is an M -by- N matrix with frame period MT_s , where you specify T_s in the **Sample time** parameter.

Dependencies

To enable this parameter, set **Sample mode** to `Discrete`.

Resetting states when re-enabled — State behavior inside enabled subsystems

Restart at time zero (default) | Catch up to simulation time

This parameter determines the behavior of the Sine Wave block when an enabled subsystem is reenabled. The block can either reset itself to its starting state (`Restart at time zero`), or resume generating the sinusoid based on the current simulation time (`Catch up to simulation time`).

Dependencies

This parameter only applies when the Sine Wave block is located inside an enabled subsystem and the **States when enabling** parameter of the Enable block is set to `reset`.

Data Types

Output data type — Output data type

double (default) | single | fixdt(1,16) | fixdt(1,16,0) | <data type expression> |
 Inherit: Inherit via back propagation

Select how you would like to specify the data type properties of the **Output data type**. You can choose:

- **Inherit** — Lets you specify a rule for inheriting a data type, for example, `Inherit: Inherit via back propagation`
- **Built in**— Lets you specify a built in data type, for example, `double`
- **Fixed point** — Lets you specify the fixed-point attributes of the data type.
- **Expression** — Lets you specify an expression that evaluates to a valid data type, for example, `fixdt(1,16)`

Block Characteristics

Data Types	double fixed point integer single
Direct Feedthrough	no
Multidimensional Signals	no
Variable-Size Signals	no
Zero-Crossing Detection	no

Algorithms

When you select **Discrete** from the **Sample mode** parameter, the secondary **Computation method** parameter provides three options for generating the discrete sinusoid: **Trigonometric fcn**, **Table lookup**, and **Differential**.

Trigonometric Fcn

The trigonometric function method computes the sinusoid in the i th channel, y_i , by sampling the continuous function

$$y_i = A_i \sin(2\pi f_i t + \phi_i) \quad (\text{real})$$

or

$$y_i = A_i e^{j(2\pi f_i t + \phi_i)} \quad (\text{complex})$$

with a period of T_s , where you specify T_s in the **Sample time** parameter. This mode of operation has the same benefits and liabilities as the **Continuous** sample mode.

At each sample time, the block evaluates the sine function at the appropriate time value *within the first cycle* of the sinusoid. By constraining trigonometric evaluations to the first cycle of each sinusoid, the block avoids the imprecision of computing the sine of very large numbers, and eliminates the possibility of discontinuity during extended operations (when an absolute time variable

might overflow). This method therefore avoids the memory demands of the table lookup method at the expense of many more floating-point operations.

Table Lookup

The table lookup method precomputes the *unique* samples of every output sinusoid at the start of the simulation, and recalls the samples from memory as needed. Because a table of finite length can only be constructed when all output sequences repeat, the method requires that the period of every sinusoid in the output be evenly divisible by the sample period. That is, $1/(f_i T_s) = k_i$ must be an integer value for every channel $i = 1, 2, \dots, N$.

When the **Optimize table for** parameter is set to **Speed**, the table constructed for each channel contains k_i elements. When the **Optimize table for** parameter is set to **Memory**, the table constructed for each channel contains $k_i/4$ elements.

For long output sequences, the table lookup method requires far fewer floating-point operations than any of the other methods, but can demand considerably more memory, especially for high sample rates (long tables). This method is recommended for models that are intended to emulate or generate code for DSP hardware, and that therefore must be optimized for execution speed.

Note The lookup table for this block is constructed from double-precision floating-point values. Thus, when you use the **Table lookup** computation mode, the maximum amount of precision you can achieve in your output is 53 bits. Setting the word length of the **Output** or **User-defined** data type to values greater than 53 bits does not improve the precision of your output.

Tip To generate fixed-point sinusoids, you must select **Table Lookup**.

Differential

The differential method uses an incremental algorithm. This algorithm computes the output samples based on the output values computed at the previous sample time (and precomputed update terms) by using the following identities.

$$\begin{aligned}\sin(t + T_s) &= \sin(t)\cos(T_s) + \cos(t)\sin(T_s) \\ \cos(t + T_s) &= \cos(t)\cos(T_s) - \sin(t)\sin(T_s)\end{aligned}$$

The update equations for the sinusoid in the i th channel, y_i , can therefore be written in matrix form as

$$\begin{bmatrix} \sin\{2\pi f_i(t + T_s) + \phi_i\} \\ \cos\{2\pi f_i(t + T_s) + \phi_i\} \end{bmatrix} = \begin{bmatrix} \cos(2\pi f_i T_s) & \sin(2\pi f_i T_s) \\ -\sin(2\pi f_i T_s) & \cos(2\pi f_i T_s) \end{bmatrix} \begin{bmatrix} \sin(2\pi f_i t + \phi_i) \\ \cos(2\pi f_i t + \phi_i) \end{bmatrix}$$

where you specify T_s in the **Sample time** parameter. Since T_s is constant, the right-hand matrix is a constant and can be computed once at the start of the simulation. The value of $A_i \sin[2\pi f_i(t + T_s) + \phi_i]$ is then computed from the values of $\sin(2\pi f_i t + \phi_i)$ and $\cos(2\pi f_i t + \phi_i)$ by a simple matrix multiplication at each time step.

This mode offers reduced computational load, but is subject to drift over time due to cumulative quantization error. Because the method is not contingent on an absolute time value, there is no danger of discontinuity during extended operations (when an absolute time variable might overflow).

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

The Sine Wave block references absolute simulation time when configured in continuous sample mode.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic.

HDL Architecture

This block has a single, default HDL architecture.

Restrictions

For HDL code generation, you must select the following Sine Wave block settings:

- **Computation method:** Table lookup
- **Sample mode:** Discrete

Output:

- The output port cannot have data types `single` or `double`.

Complex Data Support

This block supports code generation for complex signals.

Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

If the input is fixed point, it must be signed integer or signed fixed point with power-of-two slope and zero bias.

Singular Value Decomposition

Factor matrix using singular value decomposition

Library

Math Functions / Matrices and Linear Algebra / Matrix Factorizations

dspfactors

Description

The Singular Value Decomposition block factors the M -by- N input matrix A such that

$$A = U \cdot \text{diag}(S) \cdot V^*$$

where

- U is an M -by- P matrix
- V is an N -by- P matrix
- S is a length- P vector
- P is defined as $\min(M,N)$

When

- $M = N$, U and V are both M -by- M unitary matrices
- $M > N$, V is an N -by- N unitary matrix, and U is an M -by- N matrix whose columns are the first N columns of a unitary matrix
- $N > M$, U is an M -by- M unitary matrix, and V is an N -by- M matrix whose columns are the first M columns of a unitary matrix

In all cases, S is an unoriented vector of positive singular values having length P .

Length- N row inputs are treated as length- N columns.

Note that the first (maximum) element of output S is equal to the 2-norm of the matrix A .

Parameters

Show singular vector ports

Select to enable the U and V output ports.

Show error status port

Select to enable the E output port, which reports a failure to converge. The possible values you can receive on the port are:

- 0 — The singular value decomposition calculation converges.
- 1 — The singular value decomposition calculation does not converge.

If the singular value decomposition calculation fails to converge, the output at ports U, S, and V are undefined matrices of the correct size.

Simulate using

Type of simulation to run. You can set this parameter to:

- Interpreted execution (default)

Simulate model using the MATLAB interpreter. This option shortens startup time.

- Code generation

Simulate model using generated C code. The first time you run a simulation, Simulink generates C code for the block. The C code is reused for subsequent simulations, as long as the model does not change. This option requires additional startup time.

Introduced before R2006a

Sort

Sort input elements by value

Library: DSP System Toolbox / Statistics

Description

The Sort block ranks the values of the input elements along each channel (column) in an **Ascending** or a **Descending** order, based on the **Sort order** you specify. Complex inputs are sorted by their magnitude, which is the sum of the squares of the real and imaginary components of the input. You can choose the **Sort algorithm** to be either **Quick sort** or **Insertion sort**. The quick sort algorithm uses a recursive sort method and is faster at sorting more than 32 elements. The insertion sort algorithm uses a nonrecursive method and is faster at sorting fewer than 32 elements. When you generate code, use the insertion sort algorithm to avoid recursive function calls.

The **Mode** parameter specifies the block's mode of operation, which you can set to **Value**, **Index**, or **Value and Index**.

Ports

Input

Port_1 — Data input

vector | matrix

The block accepts real-valued or complex-valued multichannel inputs. The input data type must be double precision, single precision, integer, or fixed point, with power-of-two slope and zero bias.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point

Output

Val — Sorted data

vector | matrix

The block sorts the data along each channel and outputs the sorted data through this port. The size, data type, and complexity of the sorted data matches that of the input data. The block sorts complex inputs according to their magnitude.

Dependencies

To enable this port, set the **Mode** parameter to **Value** and **index** or **Value**.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point

Idx — Index of the sorted data

vector | matrix

The output at this port contains the indices of the sorted data.

Dependencies

To enable this port, set the **Mode** parameter to `Value` and `index` or `Index`.

Data Types: `uint32`

Parameters

Main Tab

Mode — Specify whether block returns values, indices, or both

`Value` and `Index` (default) | `Value` | `Index`

When the **Mode** parameter is set to:

- `Value` — The block sorts the elements in each channel of the M -by- N input matrix in an ascending or descending order, based on what you specify in the **Sort order** parameter. The output at each sample time, *Val*, is an M -by- N matrix that contains the sorted columns of the input.

The block sorts complex inputs according to their magnitude.

- `Index` — The block sorts the elements in each channel of the M -by- N input matrix, and outputs the index array, *I*. Each element in *I* is an integer of type `uint32` that indexes the sorted value in the corresponding column of the input.
- `Value` and `index` — The block outputs the sorted values of the input data, *Val*, and the corresponding indices in the index array, *I*.

Sort order — Order of sorting

`Ascending` (default) | `Descending`

Specify to sort the input data in either ascending or descending order.

Sort algorithm — Sort method

`Quick sort` (default) | `Insertion sort`

The quick sort algorithm uses a recursive sort method and is faster at sorting more than 32 elements. The insertion sort algorithm uses a nonrecursive method and is faster at sorting fewer than 32 elements. When you generate code, to avoid recursive function calls, use the insertion sort algorithm.

Data Types Tab

Note To use these parameters, the data input must be complex and fixedpoint. For all other inputs, the parameters on the **Data Types** tab are ignored.

Rounding mode — Method of rounding operation

`Floor` (default) | `Ceiling` | `Convergent` | `Nearest` | `Round` | `Simplest` | `Zero`

Specify the rounding mode for fixed-point operations. For more details, see rounding mode.

Saturate on integer overflow — Method of overflow action

`off` (default) | `on`

When you select this parameter, the block saturates the result of its fixed-point operation. When you clear this parameter, the block wraps the result of its fixed-point operation. For details on `saturate` and `wrap`, see `overflow mode for fixed-point operations`.

Product output — Product output data type

Inherit: Same as input (default) | `fixdt([],16,0)`

The squares of the real and imaginary parts of the complex input are stored in the **Product output** data type.

You can set this parameter to:

- `Inherit: Same as input` — The product output data type is the same as the input data type.
- `fixdt([],16,0)` — The product output data type is an autosigned, binary-point, scaled, fixed-point data type with a word length of 16 bits and a fraction length of 0.

Alternatively, you can set the **Product output** data type by using the **Data Type Assistant**. To use the assistant, click the **Show data type assistant** button .

For more information on the data type assistant, see “Specify Data Types Using Data Type Assistant” (Simulink) in *Simulink User's Guide* (Simulink).

Accumulator — Accumulator data type

Inherit: Same as product output (default) | Inherit: Same as input | `fixdt([],16,0)`

The result of the sum of the squares of the real and imaginary parts of the complex input are stored in the **Accumulator** data type.

You can set this parameter to:

- `Inherit: Same as product output` — The accumulator data type is the same as the product output data type.
- `Inherit: Same as input` — The accumulator data type is the same as the input data type.
- `fixdt([],16,0)` — The accumulator data type is an autosigned, binary-point, scaled, fixed-point data type with a word length of 16 bits and a fraction length of 0.

Alternatively, you can set the **Accumulator** data type by using the **Data Type Assistant**. To use the assistant, click the **Show data type assistant** button .

For more information on the data type assistant, see “Specify Data Types Using Data Type Assistant” (Simulink) in *Simulink User's Guide* (Simulink).

Lock data type settings against changes by the fixed-point tools — Prevent fixed-point tools from overriding data types

off (default) | on

Select this parameter to prevent the fixed-point tools from overriding the data types you specify on the block.

Block Characteristics

Data Types	double fixed point integer single
Direct Feedthrough	no
Multidimensional Signals	no
Variable-Size Signals	no
Zero-Crossing Detection	no

Algorithms

Sort

The block produces results identical to the MATLAB `sort` function.

The output of the block is equivalent to the following MATLAB code, when **Sort order** is set to:

- Ascending — `[Val,I] = sort(u,'ascend')`
- Descending — `[Val,I] = sort(u,'descend')`

where:

- `u` is the data input.
- `Val` is the sorted output.
- `I` is the index of the sorted output.

When the input is complex, the block sorts the data according to the magnitude. The block computes the magnitude by taking the sum of the squares of the real and imaginary components of the complex input. This is identical to calling the `sort` function as `[Val,I] = sort(u,...,'ComparisonMethod','abs')`.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Generated code relies on `memcpy` or `memset` functions (`string.h`) under certain conditions.

Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

The parameters on the **Data Types** tab are used only for complex fixed-point inputs. Complex inputs are sorted by their magnitude, which is the sum of the squares of the real and imaginary components of the input. The results of the squares of the real and imaginary parts are stored in the **Product output** data type. The result of the sum of the squares is stored in the **Accumulator** data type. The parameters on the **Data Types** tab are ignored for all other inputs.

Spectrum Analyzer

Display frequency spectrum

Library: DSP System Toolbox / Sinks
 DSP System Toolbox HDL Support / Sinks

Description

The Spectrum Analyzer block, referred to here as the scope, displays the frequency spectra of signals.

You can use the Spectrum Analyzer block in models running in Normal or Accelerator simulation modes. You can also use the Spectrum Analyzer block in models running in Rapid Accelerator or External simulation modes, with some limitations.

You can use the Spectrum Analyzer block inside all subsystems and conditional subsystems. Conditional subsystems include enabled subsystems, triggered subsystems, enabled and triggered subsystems, and function-call subsystems. See “Conditionally Executed Subsystems Overview” (Simulink) for more information.

Measurements

- Cursors — Measure signal values using vertical and horizontal cursors.

- **Peak Finder** — Find maxima, showing the x-axis values at which they occur.
- **Channel Measurements** — Measure the occupied bandwidth or adjacent channel power ratio (ACPR).
- **Distortion Measurements** — Measure harmonic distortion and intermodulation distortion.
- **CCDF Measurements** — Measure the complimentary cumulative distribution function. CCDF measurements show the probability of a signal’s instantaneous power being a specified level above the signal’s average power.
- **“Spectral Masks”** — Visualize spectrum limits and compare spectrum values to specification values.

Programmatic Control

You can configure and display Spectrum Analyzer settings from the command line with the `SpectrumAnalyzerConfiguration` object.

Ports

Input

Port_1 — Signals to visualize

scalar | vector | matrix | array

Connect the signals you want to visualize. You can have up to 96 input ports. Input signals can have these characteristics:

- **Signal Domain** — Frequency or time signals
- **Type** — Discrete (sample-based and frame-based).
- **Data type** — Any data type that Simulink supports. See “Data Types Supported by Simulink” (Simulink).
- **Dimension** — One dimensional (vector), two dimensional (matrix), or multidimensional (array). Input must have fixed number of channels. See “Signal Dimensions” (Simulink) and “Determine Signal Dimensions” (Simulink).

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point

Parameters

Spectrum Settings

The **Spectrum Settings** pane appears at the right side of the Spectrum Analyzer window. These settings control how the spectrum is calculated. To show the Spectrum Settings, in the Spectrum

Analyzer menu, select **View > Spectrum Settings** or use the  button in the toolbar.

Main options

Input domain — Domain of the input signal

Time (default) | Frequency

The domain of the input signal you want to visualize. If you visualize time-domain signals, the signal is transformed to the frequency spectrum based on the algorithm specified by the `Method` parameter.

Programmatic Use

See InputDomain.

Type — Type of spectrum to display

Power (default) | Power density | RMS

Power — Spectrum Analyzer shows the power spectrum.

Power density — Spectrum Analyzer shows the power spectral density. The power spectral density is the magnitude of the spectrum normalized to a bandwidth of 1 hertz.

RMS — Spectrum Analyzer shows the root mean squared spectrum.

Tunable: Yes

Dependency

To use this parameter, set “Input domain” on page 2-0 to Time.

Programmatic Use

See SpectrumType.

View — Spectrum view

Spectrum (default) | Spectrogram | Spectrum and spectrogram

Spectrum — Spectrum Analyzer shows the spectrum.

Spectrogram — Spectrum Analyzer shows the spectrogram, which displays frequency content over time. The most recent spectrogram update is at the bottom of the display, and time scrolls from the bottom to the top of the display.

Spectrum and spectrogram — Spectrum Analyzer shows both the spectrum and spectrogram.

Tunable: Yes

Programmatic Use

See ViewType.

Sample rate — Sample rate of the input signal in hertz

Inherited (default) | positive scalar

Sample rate of the input signal in hertz, specified as either

- Inherited to use the same sample rate as the input signal.
- Positive scalar. The specified sample rate must be at least twice the input signal sample rate. Otherwise, you might see unexpected behavior in your signal visualization due to aliasing.

Programmatic Use

See SampleRate.

Method — Spectrum estimation method

Filter Bank (default) | Welch

Select `Welch` or `Filter Bank` as the spectrum estimation method. For more details about the two spectrum estimation algorithms, see “Algorithms” on page 2-1245.

Tunable: No

Dependency

To use this parameter, set “Input domain” on page 2-0 to `Time`.

Programmatic Use

See `Method`.

Full frequency span — Use entire Nyquist frequency interval

`on` (default) | `off`

Select this check box to compute and plot the spectrum over the entire “Nyquist frequency interval” on page 2-1249.

Tunable: Yes

Dependency

To use this parameter, set “Input domain” on page 2-0 to `Time`.

Programmatic Use

See `FrequencySpan`.

Span (Hz) — Frequency span in hertz

`10e3` (default) | real positive scalar

Specify the frequency span in hertz. Use this parameter with the `CF (Hz)` parameter to define the frequency span around a center frequency. This parameter defines the range of values shown on the Frequency axis in the Spectrum Analyzer window.

Tunable: Yes

Dependencies

To use this parameter, you must:

- Set “Input domain” on page 2-0 to `Time`.
- Clear the “Full frequency span” on page 2-0 check box.
- Set the **Span (Hz)/Fstart (Hz)** drop-down to `Span (Hz)`.

Programmatic Use

See `FrequencySpan` and `Span`.

CF (Hz) — Center frequency in hertz

`0` (default) | scalar

Specify the center frequency, in hertz. Use this parameter with the “Span (Hz)” on page 2-0 parameter to define the frequency span around a center frequency. This parameter defines the value shown at the middle point of the Frequency axis on the Spectrum Analyzer window.

Tunable: Yes

Dependencies

To use this parameter, you must:

- Set “Input domain” on page 2-0 to Time.
- Clear the “Full frequency span” on page 2-0 check box.
- Set the **Span (Hz)/Fstart (Hz)** drop-down to “Span (Hz)” on page 2-0 .

Programmatic Use

See CenterFrequency.

FStart (Hz) — Start frequency in hertz

-5e3 (default) | scalar

Specify the start frequency in hertz. Use this parameter with the “FStop (Hz)” on page 2-0 parameter to define the range of frequency-axis values using start frequency and stop frequency. This parameter defines the value shown at the leftmost side of the Frequency axis on the Spectrum Analyzer window.

Tunable: Yes

Dependencies

To use this parameter, you must:

- Set “Input domain” on page 2-0 to Time.
- Clear the “Full frequency span” on page 2-0 check box.
- Set the **Span (Hz)/Fstart (Hz)** drop-down to FStart (Hz).

Programmatic Use

See StartFrequency.

FStop (Hz) — Stop frequency in hertz

5e3 (default) | scalar

Specify the stop frequency, in hertz. Use this parameter with the “FStart (Hz)” on page 2-0 parameter to define the range of Frequency axis values. This parameter defines the value shown at the rightmost side of the Frequency axis on the Spectrum Analyzer window.

Tunable: Yes

Dependencies

To use this parameter, you must:

- Set “Input domain” on page 2-0 to Time.
- Clear the “Full frequency span” on page 2-0 check box.
- Set the **Span (Hz)/Fstart (Hz)** drop-down to “FStart (Hz)” on page 2-0 .

Programmatic Use

See StopFrequency.

Frequency (Hz) — Frequency vector

Auto (default) | Input port | monotonically increasing vector

Set the frequency vector which determines the x-axis of the display.

- **Auto** — The frequency vector is calculated from the length of the input. See “Frequency Vector” on page 4-1304.
- **Input port** — When selected, an input port appears on the block for the frequency vector input.
- **Custom vector** — Enter a custom vector as the frequency vector. The length of the custom vector must be equal to the frame size of the input signal.

Tunable: No**Dependency**

To use this parameter, set “Input domain” on page 2-0 to Frequency.

Programmatic Use

See FrequencyVector.

RBW (Hz) — Resolution bandwidth

Auto (default) | Input port | positive scalar

The resolution bandwidth in hertz. This parameter defines the smallest positive frequency that can be resolved. By default, this parameter is set to **Auto**. In this case, the Spectrum Analyzer determines the appropriate value to ensure that there are 1024 RBW intervals over the specified frequency span.

If you set this parameter to a numeric value, the value must allow at least two RBW intervals over the specified frequency span. In other words, the ratio of the overall frequency span to RBW must be greater than two:

$$\frac{span}{RBW} > 2$$

For frequency input only, you can use an input port to set the RBW value.

Tunable: Yes**Dependency**

To use this parameter, set either:

- “Input domain” on page 2-0 to Time and the **RBW (Hz)/Window length/Number of frequency bands** drop-down to RBW (Hz).
- “Input domain” on page 2-0 to Frequency.

Programmatic Use

See RBW.

Input units — Units of frequency input

Auto (default) | dBm | dBV | dBW | Vrms | Watts

Select the units of the frequency-domain input. This property allows the Spectrum Analyzer to scale frequency data if you choose a different display unit with the “Units” on page 2-0 property.

Tunable: No

Dependency

This option is only available when “Input domain” on page 2-0 is set to Frequency.

Programmatic Use

See InputUnits.

Window length — Length of window in samples

1024 (default) | integer greater than 2

The length of the window, in samples. The window length used to control the frequency resolution and compute the spectral estimates. The window length must be an integer greater than 2.

Dependencies

To use this parameter, set:

- “Method” on page 2-0 to Welch
- Set the **RBW (Hz)/Window length/Number of frequency bands** drop-down to Window Length

Dependency

To use this parameter, set “Input domain” on page 2-0 to Time.

Programmatic Use

See WindowLength.

Number of frequency bands — FFT length

Auto (default) | positive integer

Specify the fast Fourier transform (FFT) length to control the number of frequency bands. If the value is Auto, the Spectrum Analyzer uses the entire frame size to estimate the spectrum. If you specify the number of frequency bands, you set the input buffer size.

Dependencies

To use this parameter, set:

- “Method” on page 2-0 to Filter Bank
- Set the **RBW (Hz)/Window length/Number of frequency bands** drop-down to Number of frequency bands

Programmatic Use

See FFTLength

Taps per band — Number of filter taps

12 (default) | positive even integer

Specify the number of filter taps or coefficients for each frequency band. This number must be a positive even integer. This value corresponds to the number of filter coefficients per polyphase branch. The total number of filter coefficients is equal to *Taps Per Band + FFT Length*.

Dependency

To use this parameter, you must set the **RBW (Hz)/Window length/Number of frequency bands** drop-down to “Number of frequency bands” on page 2-0 .

Programmatic Use

See NumTapsPerBand.

NFFT — Number of FFT points

Auto (default) | positive integer

Specify the length of the FFT that Spectrum Analyzer uses to compute spectral estimates. Acceptable options are Auto or a positive integer.

The **NFFT** value must be greater than or equal to the value of the **Window length** parameter. By default, when **NFFT** is set to Auto, the Spectrum Analyzer sets **NFFT** equal to the value of **Window length**. When in RBW mode, the specified RBW value is used to calculate an FFT length that equals the window length.

When this parameter is set to a positive integer, this parameter is equivalent to the n parameter of the fft function.

Dependencies

To use this parameter, you must set the **RBW (Hz)/Window length/Number of frequency bands** drop-down to “Window length” on page 2-0 .

Programmatic Use

See FFTLength.

Samples/update — Required number of input samples

positive scalar

This property is read-only.

The number of input samples required to compute one spectral update. You cannot modify this parameter; it is shown in the spectrum analyzer for informational purposes only. This parameter is directly related to **RBW (Hz)/Window length/Number of frequency bands**. For more details, see “Algorithms” on page 2-1245.

If the input does not have enough samples to achieve the resolution bandwidth that you specify, Spectrum Analyzer produces a message on the display.

**Spectrogram Settings****Channel — Spectrogram channel**

channel name

Select the signal channel for which the spectrogram settings apply.

Dependencies

To use this option, set “View” on page 2-0 to Spectrogram or Spectrum and spectrogram.

Programmatic Use

See SpectrogramChannel.

Time res. (s) – Time resolution in seconds

Auto (default) | positive number

Time resolution is the amount of data, in seconds, used to compute a spectrogram line. The minimum attainable resolution is the amount of time it takes to compute a single spectral estimate. The tooltip displays the minimum attainable resolution given the current settings.

The time resolution value is determined based on frequency resolution method, the RBW setting, and the time resolution setting.

Method	Frequency Resolution Method	Frequency Resolution Setting	Time Resolution Setting	Resulting Time Resolution in Seconds
Welch or Filter Bank	RBW (Hz)	Auto	Auto	1/RBW
Welch or Filter Bank	RBW (Hz)	Auto	Manually entered	Time Resolution
Welch or Filter Bank	RBW (Hz)	Manually entered	Auto	1/RBW
Welch or Filter Bank	RBW (Hz)	Manually entered	Manually entered	Must be equal to or greater than the minimum attainable time resolution, 1/RBW. Several spectral estimates are combined into one spectrogram line to obtain the desired time resolution. Interpolation is used to obtain time resolution values that are not integer multiples of 1/RBW.
Welch	Window length	—	Auto	1/RBW

Method	Frequency Resolution Method	Frequency Resolution Setting	Time Resolution Setting	Resulting Time Resolution in Seconds
Welch	Window length	—	Manually entered	Must be equal to or greater than the minimum attainable time resolution. Several spectral estimates are combined into one spectrogram line to obtain the desired time resolution. Interpolation is used to obtain time resolution values that are not integer multiples of 1/RBW.
Filter Bank	Number of frequency bands	—	Auto	1/RBW
Filter Bank	Number of frequency bands	—	Manually entered	Must be equal to or greater than the minimum attainable time resolution, 1/RBW.

Tunable: Yes

Dependency

To use this option, set “View” on page 2-0 to Spectrogram or Spectrum and spectrogram.

Programmatic Use

See TimeResolution.

Time span — Time span in seconds

Auto (default) | positive scalar

The time span over which the Spectrum Analyzer displays the spectrogram specified in seconds. The time span is the product of the desired number of spectral lines and the time resolution. The tooltip displays the minimum allowable time span, given the current settings. If the time span is set to Auto, 100 spectral lines are used.

Tunable: Yes

Dependency

To use this option, set “View” on page 2-0 to Spectrogram or Spectrum and spectrogram.

Programmatic Use

See TimeSpan.

Window Options

Overlap (%) — Segment overlap percentage

0 (default) | scalar between 0 and 100

This parameter defines the amount of overlap between the previous and current buffered data segments. The overlap creates a window segment that is used to compute a spectral estimate. The value must be greater than or equal to zero and less than 100.

Tunable: Yes

Programmatic Use

See `OverlapPercent`.

Window — Windowing method

Hann (default) | Rectangular | Blackman-Harris | Chebyshev | Flat Top | Hamming | Kaiser | custom window function name

The windowing method to apply to the spectrum. Windowing is used to control the effect of sidelobes in spectral estimation. The window you specify affects the window length required to achieve a resolution bandwidth and the required number of samples per update. For more information about windowing, see “Windows”.

Tunable: Yes

Programmatic Use

See `Window`.

Attenuation — Sidelobe attenuation

60 (default) | scalar greater than or equal to 45

The sidelobe attenuation in decibels (dB). The value must be greater than or equal to 45.

Dependency

This parameter applies only when you set the **Window** parameter to Chebyshev or Kaiser.

Programmatic Use

See `SidelobeAttenuation`.

NENBW — Normalized effective noise bandwidth

scalar

This property is read-only.

The normalized effective noise bandwidth of the window. You cannot modify this parameter; it is shown for informational purposes only. This parameter is a measure of the noise performance of the window. The value is the width of a rectangular filter that accumulates the same noise power with the same peak power gain.

The rectangular window has the smallest NENBW, with a value of 1. All other windows have a larger NENBW value. For example, the Hann window has an NENBW value of approximately 1.5.

Trace Options

Units — Spectrum units

dBm (default) | dBW | Watts | Vrms | dBV | dBFS

The units of the spectrum. The available values depend on the value of the “Type” on page 2-0 parameter.

Tunable: Yes

Programmatic Use

See `SpectrumUnits`.

Full scale — Full scale for dBFS units

Auto (default) | positive real scalar

The full scale used for the decibel full scale (dBFS) units. By default, the Spectrum Analyzer uses the entire spectrum scale. Specify a positive real scalar for the dBFS full scale.

Tunable: Yes

Dependencies

To enable this parameter, set:

- “Input domain” on page 2-0 to Time
- “Units” on page 2-0 to dBFS

Programmatic Use

See `FullScale`.

Averaging method — Smoothing method

Exponential (default) | Running

Specify the smoothing method as:

- `Exponential` — Weighted average of samples. Use the `Forgetting factor` property to specify the weighted forgetting factor.
- `Running` — Running average of the last n samples. Use the `Averages` property to specify n .

For more information about the averaging methods, see “Averaging Method” on page 2-1253.

Programmatic Use

See `AveragingMethod`.

Averages — Number of spectral averages

1 (default) | positive integer

Specify the number of spectral averages as a positive integer. The spectrum analyzer computes the current power spectrum estimate by computing a running average of the last N power spectrum estimates. This parameter defines the number of spectral averages, N .

Dependencies

This parameter applies only when:

- **View** is `Spectrum` or `Spectrum` and `spectrogram`.
- **Averaging method** is `Running`.

Programmatic Use

See `SpectralAverages`.

Forgetting factor — Weighting forgetting factor

0.9 (default) | scalar in the range (0,1]

Specify the exponential weighting as a scalar value greater than 0 and less than or equal to 1.

Dependency

This parameter applies only when the **Averaging method** is Exponential.

Programmatic Use

See ForgettingFactor.

Reference load — Reference load

1 (default) | positive real scalar

The reference load in ohms that the Spectrum Analyzer uses as a reference to compute power values.

Programmatic Use

See ReferenceLoad.

Scale — Scale of frequency axis

Linear (default) | Logarithmic

Choose a linear or logarithm scale for the frequency axis. When the frequency span contains negative frequency values, you cannot choose the logarithmic option.

Programmatic Use

See FrequencyScale.

Offset — Constant frequency offset

0 (default) | scalar

The constant frequency offset to apply to the entire spectrum, or a vector of frequencies to apply to each spectrum for multiple inputs. The offset parameter is added to the values on the Frequency axis in the Spectrum Analyzer window. This parameter is not used in any spectral computations. You must take the parameter into consideration when you set the **Span (Hz)** and **CF (Hz)** parameters to ensure that the frequency span is within the “Nyquist frequency interval” on page 2-1249.

Dependency

To use this parameter, set “Input domain” on page 2-0 to Time.

Programmatic Use

See FrequencyOffset.

Normal trace — Normal trace view

on (default) | off

When this check box is selected, the Spectrum Analyzer calculates and plots the power spectrum or power spectrum density. Spectrum Analyzer performs a smoothing operation by averaging several spectral estimates.

Dependencies

To clear this check box, you must first select either the “Max hold trace” on page 2-0 or the “Min hold trace” on page 2-0 parameter. This parameter applies only when “View” on page 2-0 is Spectrum or Spectrum and spectrogram.

Programmatic Use

See PlotNormalTrace.

Max hold trace — Maximum hold trace view

off (default) | on

Select this check box to enable Spectrum Analyzer to plot the maximum spectral values of all the estimates obtained.

Dependency

This parameter applies only when “View” on page 2-0 is Spectrum or Spectrum and spectrogram.

Programmatic Use

See PlotMaxHoldTrace.

Min hold trace — Minimum hold trace view

off (default) | on

Select this check box to enable Spectrum Analyzer to plot the minimum spectral values of all the estimates obtained.

Dependency

This parameter applies only when “View” on page 2-0 is Spectrum or Spectrum and spectrogram.

Programmatic Use

See PlotMinHoldTrace.

Two-sided spectrum — Enable two-sided spectrum view

off (default) | on

Select this check box to enable a two-sided spectrum view. In this view, both negative and positive frequencies are shown. If you clear this check box, Spectrum Analyzer shows a one-sided spectrum with only positive frequencies. Spectrum Analyzer requires that this parameter is selected when the input signal is complex-valued.

Programmatic Use

See PlotAsTwoSidedSpectrum.

Configuration Properties

The **Configuration Properties** dialog box controls visual aspects of the Spectrum Analyzer. To open the Configuration Properties, in the Spectrum Analyzer menu, select **View > Configuration**

Properties or select the  button in the toolbar drop-down.

Title – Display title

character vector | string

Specify the display title. Enter %<SignalLabel> to use the signal labels in the Simulink model as the axes titles.

Tunable: Yes

Programmatic Use

See Title.

Show Legend – Display signal legend

off (default) | on

Show signal legend. The names listed in the legend are the signal names from the model. For signals with multiple channels, a channel index is appended after the signal name. Continuous signals have straight lines before their names and discrete signals have step-shaped lines.

From the legend, you can control which signals are visible. This control is equivalent to changing the visibility in the **Style** parameters. In the scope legend, click a signal name to hide the signal in the scope. To show the signal, click the signal name again. To show only one signal, right-click the signal name, which hides all other signals. To show all signals, press **ESC**.

Note The legend only shows the first 20 signals. Any additional signals cannot be viewed or controlled from the legend.

Dependency

To enable this parameter, set “View” on page 2-0 to Spectrum or Spectrum and spectrogram.

Programmatic Use

See ShowLegend.

Show grid – Show internal grid lines

on (default) | off

Show internal grid lines on the Spectrum Analyzer

Programmatic Use

See ShowGrid.

Y-limits (minimum) – Y-axis minimum

-80 (default) | scalar

Specify the minimum value of the y-axis.

Programmatic Use

See YLimits.

Y-limits (maximum) – Y-axis maximum

20 (default) | scalar

Specify the maximum value of the y-axis.

Programmatic Use

See YLimits.

Y-label — Y-axis label

character vector | string

To display signal units, add (%<SignalUnits>) to the label. At the beginning of a simulation, Simulink replaces (%SignalUnits) with the units associated with the signals. For example, if you have a signal for velocity with units of m/s enter

Velocity (%<SignalUnits>)

Programmatic Use

See YLabel.

Color map — Spectrogram colormap

jet(256) (default) | hot(256) | bone(256) | cool(256) | copper(256) | gray(256) | parula(256) | 3-column matrix

Select the colormap for the spectrogram, or enter a three-column matrix expression for the colormap. For more information about colormaps, see colormap.

Tunable: Yes

Dependency

To use this parameter, set “View” on page 2-0 to Spectrogram or Spectrum and spectrogram.

Color-limits (minimum) — Spectrogram minimum

-80 (default) | scalar

Specify the signal power for the minimum color value of the spectrogram.

Tunable: Yes

Dependency

To use this parameter, set “View” on page 2-0 to Spectrogram or Spectrum and spectrogram.

Programmatic Use

See ColorLimits.

Color-limits (maximum) — Spectrogram maximum

20 (default) | scalar

Specify the signal power for the maximum color value of the spectrogram.

Tunable: Yes

Dependency

To use this parameter, set “View” on page 2-0 to **Spectrogram** or **Spectrum** and **spectrogram**.

Programmatic Use

See `ColorLimits`.

Style

The **Style** dialog box controls how to Spectrum Analyzer appears. To open the Style properties, in the Spectrum Analyzer menu, select **View > Style** or select the  button in the toolbar drop-down.

Figure color — Window background

gray (default) | color picker

Specify the color that you want to apply to the background of the scope figure.

Plot type — Plot type

Line (default) | Stem

Specify whether to display a Line or Stem plot.

Programmatic Use

See `PlotType`.

Axes colors — Axes background color

black (default) | color picker

Specify the color that you want to apply to the background of the axes.

Properties for line — Channel for visual property settings

channel names

Specify the channel for which you want to modify the visibility, line properties, and marker properties.

Visible — Channel visibility

on (default) | off

Specify whether the selected channel is visible. If you clear this check box, the line disappears. You can also change signal visibility using the scope legend.

Line — Line style

line, 0.5, yellow (default)

Specify the line style, line width, and line color for the selected channel.

Marker — Data point markers

none (default)

Specify marks for the selected channel to show at its data points. This parameter is similar to the 'Marker' property for plots. You can choose any of the marker symbols from the drop-down.

Axes Scaling

The **Axes Scaling** dialog box controls the axes limits of the Spectrum Analyzer. To open the Axes Scaling properties, in the Spectrum Analyzer menu, select **Tools > Axes Scaling > Axes Scaling Properties**.

Axes scaling/Color scaling — Automatic axes scaling

Auto (default) | Manual | After N Updates

Specify when the scope automatically scales the y-axis. If the spectrogram is displayed, specify when the scope automatically scales the color axis. By default, this parameter is set to **Auto**, and the scope does not shrink the y-axis limits when scaling the axes or color. You can select one of the following options:

- **Auto** — The scope scales the axes or color as needed, both during and after simulation. Selecting this option shows the **Do not allow Y-axis limits to shrink** or **Do not allow color limits to shrink**.
- **Manual** — When you select this option, the scope does not automatically scale the axes or color. You can manually scale the axes or color in any of the following ways:
 - Select **Tools > Scaling Properties**.
 - Press one of the **Scale Axis Limits** toolbar buttons.
 - When the scope figure is the active window, press **Ctrl+A**.
- **After N Updates** — Selecting this option causes the scope to scale the axes or color after a specified number of updates. This option is useful, and most efficient, when your frequency signal values quickly reach steady-state after a short period. Selecting this option shows the **Number of updates** edit box where you can modify the number of updates to wait before scaling.

Tunable: Yes

Programmatic Use

See `AxesScaling`.

Do not allow Y-axis/color limits to shrink — Axes scaling limits

on (default) | off

When you select this parameter, the y-axis is allowed to grow during axes scaling operations. If the spectrogram is displayed, selecting this parameter allows the color limits to grow during axis scaling. If you clear this check box, the y-axis or color limits can shrink during axes scaling operations.

Dependency

This parameter appears only when you select **Auto** for the **Axis scaling** or **Color scaling** parameter. When you set the **Axis scaling** or **Color scaling** parameter to **Manual** or **After N Updates**, the y-axis or color limits can shrink.

Number of updates — Number of updates before scaling

10 (default) | positive number

The number of updates after which the axes scale, specified as a positive integer. If the spectrogram is displayed, this parameter specifies the number of updates after which the color axes scales.

Tunable: Yes

Dependency

This parameter appears only when you set “Axes scaling/Color scaling” on page 2-0 to After N Updates.

Programmatic Use

See AxesScalingNumUpdates.

Scale limits at stop — Scale axes at stop

off (default) | on

Select this check box to scale the axes when the simulation stops. If the spectrogram is displayed, select this check box to scale the color when the simulation stops. The y-axis is always scaled. The x-axis limits are only scaled if you also select the **Scale X-axis limits** check box.

Data range (%) — Percent of axes

100 (default) | number in the range [1,100]

Set the percentage of the axis that the scope uses to display the data when scaling the axes. If the spectrogram is displayed, set the percentage of the power values range within the colormap. Valid values are from 1 through 100. For example, if you set this parameter to 100, the scope scales the axis limits such that your data uses the entire axis range. If you then set this parameter to 30, the scope increases the y-axis or color range such that your data uses only 30% of the axis range.

Tunable: Yes

Align — Alignment along axes

Center (default) | Bottom | Top | Left | Right

Specify where the scope aligns your data along the axis when it scales the axes. If the spectrogram is displayed, specify where the scope aligns your data along the axis when it scales the color. If you are using CCDF Measurements, the x axis is also configurable.

Tunable: Yes

Block Characteristics

Data Types	Boolean double enumerated fixed point integer single
Direct Feedthrough	no
Multidimensional Signals	yes
Variable-Size Signals	yes
Zero-Crossing Detection	no

Algorithms**Spectrum Estimation — Welch's Method**

When you choose the Welch method, the power spectrum estimate is averaged modified periodograms.

Given the signal input, x , the Spectrum Analyzer does the following:

- 1 Multiplies x by the given window and scales the result by the window power. The Spectrum Analyzer uses the RBW or the Window Length setting in the **Spectrum Settings** pane to determine the data window length.
- 2 Computes the FFT of the signal, Y , and takes the square magnitude using $Z = Y.*conj(Y)$.
- 3 Computes the current power spectrum estimate by taking the moving average of the last N number of Z 's, and scales the answer by the sample rate. For details on the moving average methods, see "Averaging Method" on page 2-1253.

Spectrum Analyzer requires that a minimum number of samples to compute a spectral estimate. This number of input samples required to compute one spectral update is shown as **Samples/update** in the **Main options** pane. This value is directly related to resolution bandwidth, RBW , by the following equation, or to the window length, by the equation shown in step 2.

$$N_{samples} = \frac{\left(1 - \frac{O_p}{100}\right) \times NENBW \times F_s}{RBW}$$

The normalized effective noise bandwidth, $NENBW$, is a factor that depends on the windowing method. Spectrum Analyzer shows the value of $NENBW$ in the **Window Options** pane of the **Spectrum Settings** pane. Overlap percentage, O_p , is the value of the **Overlap %** parameter in the **Window Options** pane of the **Spectrum Settings** pane. F_s is the sample rate of the input signal. Spectrum Analyzer shows sample rate in the **Main Options** pane of the **Spectrum Settings** pane.

- 1 When in **RBW (Hz)** mode, the window length required to compute one spectral update, N_{window} , is directly related to the resolution bandwidth and normalized effective noise bandwidth:

$$N_{window} = \frac{NENBW \times F_s}{RBW}$$

When in **Window Length** mode, the window length is used as specified.

- 2 The number of input samples required to compute one spectral update, $N_{samples}$, is directly related to the window length and the amount of overlap by the following equation.

$$N_{samples} = \left(1 - \frac{O_p}{100}\right) N_{window}$$

When you increase the overlap percentage, fewer new input samples are needed to compute a new spectral update. For example, if the window length is 100, then the number of input samples required to compute one spectral update is given as shown in the following table.

O_p	$N_{samples}$
0%	100
50%	50
80%	20

- 3 The normalized effective noise bandwidth, $NENBW$, is a window parameter determined by the window length, N_{window} , and the type of window used. If $w(n)$ denotes the vector of N_{window} window coefficients, then $NENBW$ is given by the following equation.

$$NENBW = N_{window} \times \frac{\sum_{n=1}^{N_{window}} w^2(n)}{\left[\sum_{n=1}^{N_{window}} w(n) \right]^2}$$

- 4 When in **RBW (Hz)** mode, you can set the resolution bandwidth using the value of the **RBW (Hz)** parameter on the **Main options** pane of the **Spectrum Settings** pane. You must specify a value to ensure that there are at least two RBW intervals over the specified frequency span. The ratio of the overall span to RBW must be greater than two:

$$\frac{span}{RBW} > 2$$

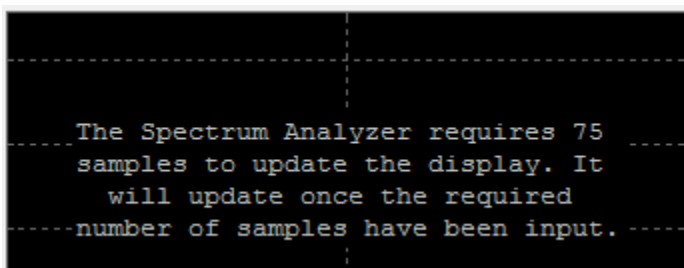

By default, the **RBW (Hz)** parameter on the **Main options** pane is set to Auto. In this case, the Spectrum Analyzer determines the appropriate value to ensure that there are 1024 RBW intervals over the specified frequency span. When you set **RBW (Hz)** to Auto, *RBW* is calculated as:

$$RBW_{auto} = \frac{span}{1024}$$

- 5 When in **Window Length** mode, you specify N_{window} and the resulting *RBW* is:

$$\frac{NENBW \times F_s}{N_{window}}$$

Sometimes, the number of input samples provided are not sufficient to achieve the resolution bandwidth that you specify. When this situation occurs, Spectrum Analyzer displays a message:

Spectrum Analyzer removes this message and displays a spectral estimate when enough data has been input.

Note The number of FFT points (N_{fft}) is independent of the window length (N_{window}). You can set them to different values if N_{fft} is greater than or equal to N_{window} .

Spectrum Estimation — Filter Bank

When you choose the Filter Bank method, the Spectrum Analyzer uses an analysis filter bank to estimate the power spectrum.

The filter bank splits the broadband input signal, $x(n)$, of sample rate fs , into multiple narrow band signals, $y_0(m)$, $y_1(m)$, ..., $y_{M-1}(m)$, of sample rate fs/M .

The variable M represents the number of frequency bands in the filter bank. When the frequency resolution method is set to NumFrequencyBands, M is equal to the value you specify for the number of frequency bands. When the frequency resolution method is set to RBW, M is equal to the number of data points that are needed to achieve the specified RBW value or 1024, whichever is larger. The number of taps per frequency band specifies the number of filter coefficients for each frequency band of the filter bank. The total number of filter coefficients is equal to number of taps per band times the number of frequency bands, M . For more information on the analysis filter bank and how it is implemented, see the “More About” on page 4-218 and the “Algorithm” on page 4-220 sections in dsp.Channelizer.

After the broadband input signal is split into multiple narrow bands, the Spectrum Analyzer computes the power in each narrow band using the following equation. Each Z_i value becomes the estimate of the power over that narrow frequency band.

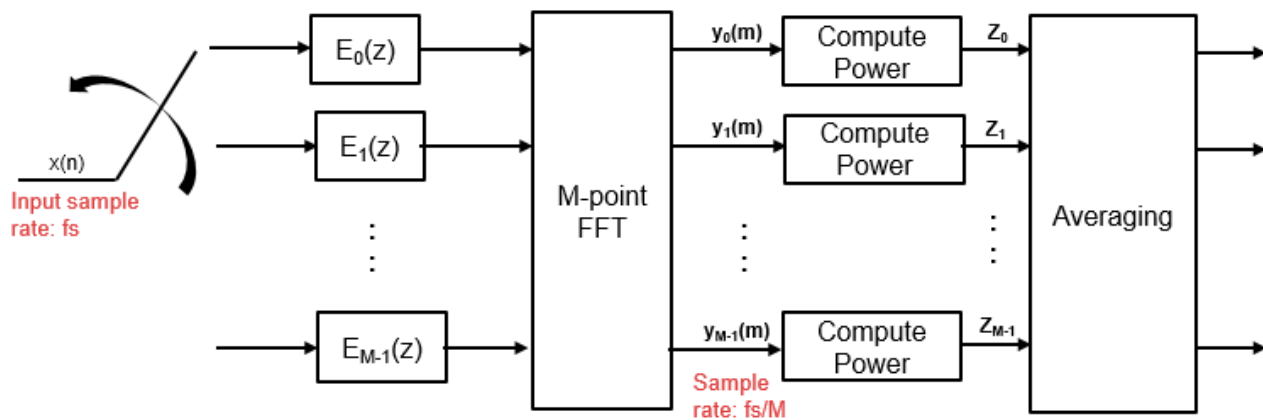

$$Z_i = \frac{1}{L} \sum_{m=0}^{L-1} |y_i[m]|^2$$

L is length of the narrow band signal, $y_i(m)$, and $i = 1, 2, \dots, M-1$.

The power values in all the narrow bands (denoted by the Z_i) form the Z vector.

$$Z = [Z_0, Z_1, Z_2, \dots, Z_{M-1}]$$

The current Z vector is averaged with the previous Z vectors using one of the two moving average methods: Running or Exponential weighting. The output of the averaging operation forms the spectral estimate vector. For details on the two averaging methods, see “Averaging Method” on page 2-1253.

The Spectrum Analyzer uses the **RBW (Hz)** or the **Number of frequency band** property in the **Spectrum Settings** pane to determine the input frame length.

Spectrum Analyzer requires a minimum number of samples to compute a spectral estimate. This number of input samples required to compute one spectral update is shown as **Samples/update** in the **Main options** pane. This value is directly related to resolution bandwidth, RBW , by the following equation.

$$N_{samples} = \frac{F_s}{RBW}$$

F_s is the sample rate of the input signal. Spectrum Analyzer shows sample rate in the **Main Options** pane of the **Spectrum Settings** pane.

- 1 When in **RBW (Hz)** mode, you can set the resolution bandwidth using the value of the **RBW (Hz)** parameter on the **Main options** pane of the **Spectrum Settings** pane. You must specify a value to ensure that there are at least two RBW intervals over the specified frequency span. The ratio of the overall span to RBW must be greater than two:

$$\frac{span}{RBW} > 2$$

By default, the **RBW** parameter on the **Main options** pane is set to **Auto**. In this case, the Spectrum Analyzer determines the appropriate value to ensure that there are 1024 RBW intervals over the specified frequency span. Thus, when you set **RBW** to **Auto**, it is calculated by the following equation. $RBW_{auto} = \frac{span}{1024}$

- 2 When in **Number of frequency bands** mode, you specify the input frame size. When the number of frequency bands is **Auto**, the resulting RBW is:

$$RBW = \frac{F_s}{\text{Input Frame Size}}$$

When the number of frequency bands is manually specified, the resulting RBW is:

$$RBW = \frac{F_s}{\text{FFTLength}}$$

Sometimes, the number of input samples provided are not sufficient to achieve the resolution bandwidth that you specify. When this situation occurs, Spectrum Analyzer displays a message:

Spectrum Analyzer removes this message and displays a spectral estimate when enough data has been input.

Nyquist frequency interval

When the `PlotAsTwoSidedSpectrum` property is set to `true`, the interval is

$$\left[-\frac{\text{SampleRate}}{2}, \frac{\text{SampleRate}}{2} \right] + \text{FrequencyOffset hertz.}$$

When the `PlotAsTwoSidedSpectrum` property is set to `false`, the interval is

$$\left[0, \frac{\text{SampleRate}}{2} \right] + \text{FrequencyOffset hertz.}$$

Periodogram and Spectrogram

Spectrum Analyzer calculates and plots the power spectrum, power spectrum density, and RMS computed by the modified Periodogram estimator. For more information about the Periodogram method, see [periodogram](#).

Power Spectral Density — The power spectral density (PSD) is given by the following equation.

$$\text{PSD}(f) = \frac{1}{P} \sum_{p=1}^P \frac{\left| \sum_{n=1}^{N_{FFT}} x^{(p)}[n] e^{-j2\pi f(n-1)T} \right|^2}{F_s \times \sum_{n=1}^{N_{window}} w^2[n]}$$

In this equation, $x[n]$ is the discrete input signal. On every input signal frame, Spectrum Analyzer generates as many overlapping windows as possible, with each window denoted as $x^{(p)}[n]$, and computes their periodograms. Spectrum Analyzer displays a running average of the P most current periodograms.

Power Spectrum — The power spectrum is the product of the power spectral density and the resolution bandwidth, as given by the following equation.

$$P_{\text{spectrum}}(f) = \text{PSD}(f) \times \text{RBW} = \text{PSD}(f) \times \frac{F_s \times N_{ENBW}}{N_{\text{window}}} = \frac{1}{P} \sum_{p=1}^P \frac{\left| \sum_{n=1}^{N_{FFT}} x^{(p)}[n] e^{-j2\pi f(n-1)T} \right|^2}{\left[\sum_{n=1}^{N_{\text{window}}} w[n] \right]^2}$$

Spectrogram — You can plot any power as a spectrogram. Each line of the spectrogram is one periodogram. The time resolution of each line is $1/\text{RBW}$, which is the minimum attainable resolution. Achieving the resolution you want may require combining several periodograms. You then use interpolation to calculate noninteger values of $1/\text{RBW}$. In the spectrogram display, time scrolls from top to bottom, so the most recent data is shown at the top of the display. The offset shows the time value at which the center of the most current spectrogram line occurred.

Frequency Vector

When set to **Auto**, the frequency vector for frequency-domain input is calculated by the software.

When the `PlotAsTwoSidedSpectrum` property is set to true, the frequency vector is:

$$\left[-\frac{\text{SampleRate}}{2}, \frac{\text{SampleRate}}{2} \right]$$

When the `PlotAsTwoSidedSpectrum` property is set to false, the frequency vector is:

$$\left[0, \frac{\text{SampleRate}}{2} \right]$$

Occupied BW

The *Occupied BW* is calculated as follows.

- 1 Calculate the total power in the measured frequency range.
- 2 Determine the lower frequency value. Starting at the lowest frequency in the range and moving upward, the power distributed in each frequency is summed until this result is

$$\frac{100 - \text{OccupiedBW}\%}{2}$$

of the total power.

- 3 Determine the upper frequency value. Starting at the highest frequency in the range and moving downward, the power distributed in each frequency is summed until the result reaches

$$\frac{100 - \text{OccupiedBW}\%}{2}$$

of the total power.

- 4 The bandwidth between the lower and upper power frequency values is the occupied bandwidth.
- 5 The frequency halfway between the lower and upper frequency values is the center frequency.

Distortion Measurements

The *Distortion Measurements* are computed as follows.

- 1 Spectral content is estimated by finding peaks in the spectrum. When the algorithm detects a peak, it records the width of the peak and clears all monotonically decreasing values. That is, the algorithm treats all these values as if they belong to the peak. Using this method, all spectral content centered at DC (0 Hz) is removed from the spectrum and the amount of bandwidth cleared (W_0) is recorded.
- 2 The fundamental power (P_1) is determined from the remaining maximum value of the displayed spectrum. A local estimate (Fe_1) of the fundamental frequency is made by computing the central moment of the power near the peak. The bandwidth of the fundamental power content (W_1) is recorded. Then, the power from the fundamental is removed as in step 1.
- 3 The power and width of the higher-order harmonics (P_2, W_2, P_3, W_3 , etc.) are determined in succession by examining the frequencies closest to the appropriate multiple of the local estimate (Fe_1). Any spectral content that decreases monotonically about the harmonic frequency is removed from the spectrum first before proceeding to the next harmonic.
- 4 Once the DC, fundamental, and harmonic content is removed from the spectrum, the power of the remaining spectrum is examined for its sum ($P_{remaining}$), peak value ($P_{maxspur}$), and median value ($P_{estnoise}$).
- 5 The sum of all the removed bandwidth is computed as $W_{sum} = W_0 + W_1 + W_2 + \dots + W_n$.

The sum of powers of the second and higher-order harmonics are computed as $P_{harmonic} = P_2 + P_3 + P_4 + \dots + P_n$.

- 6 The sum of the noise power is estimated as:

$$P_{noise} = (P_{remaining} \cdot dF + P_{est.noise} \cdot W_{sum})/RBW$$

Where dF is the absolute difference between frequency bins, and RBW is the resolution bandwidth of the window.

- 7 The metrics for SNR, THD, SINAD, and SFDR are then computed from the estimates.

$$THD = 10 \cdot \log_{10} \left(\frac{P_{\text{harmonic}}}{P_1} \right)$$

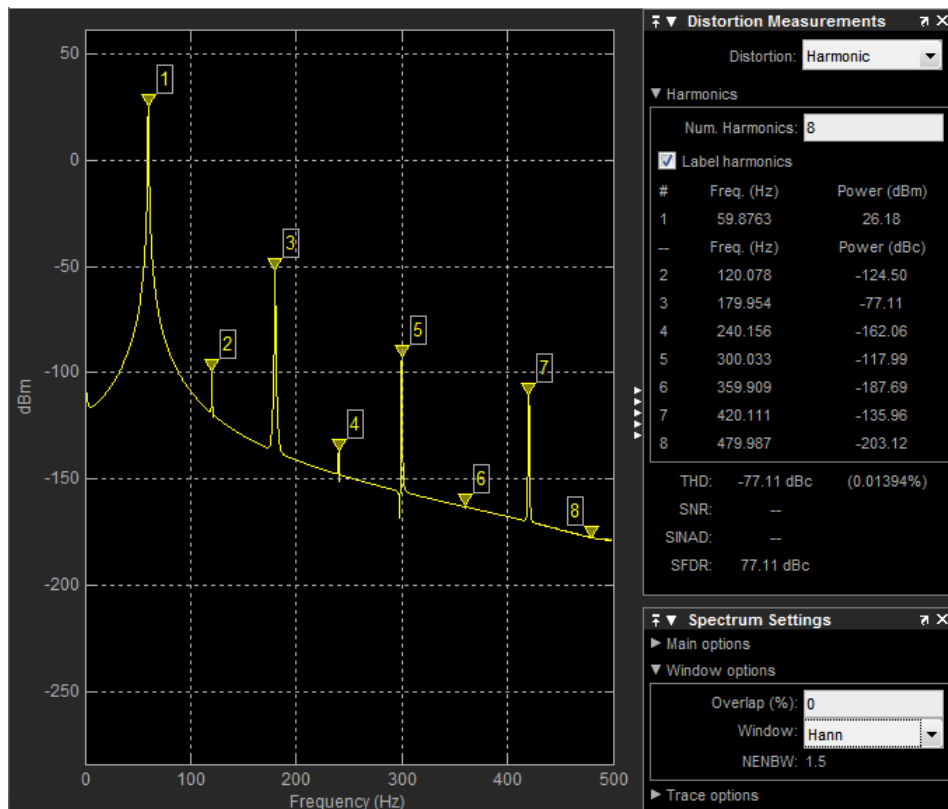

$$SINAD = 10 \cdot \log_{10} \left(\frac{P_1}{P_{\text{harmonic}} + P_{\text{noise}}} \right)$$

$$SNR = 10 \cdot \log_{10} \left(\frac{P_1}{P_{\text{noise}}} \right)$$

$$SFDR = 10 \cdot \log_{10} \left(\frac{P_1}{\max(P_{\text{maxspur}}, \max(P_2, P_3, \dots, P_n))} \right)$$

Harmonic Measurements

- The harmonic distortion measurements use the spectrum trace shown in the display as the input to the measurements. The default Hann window setting of the Spectrum Analyzer may exhibit leakage that can completely mask the noise floor of the measured signal.

The harmonic measurements attempt to correct for leakage by ignoring all frequency content that decreases monotonically away from the maximum of harmonic peaks. If the window leakage covers more than 70% of the frequency bandwidth in your spectrum, you may see a blank reading (-) reported for **SNR** and **SINAD**. If your application can tolerate the increased equivalent noise bandwidth (ENBW), consider using a Kaiser window with a high attenuation (up to 330 dB) to minimize spectral leakage.

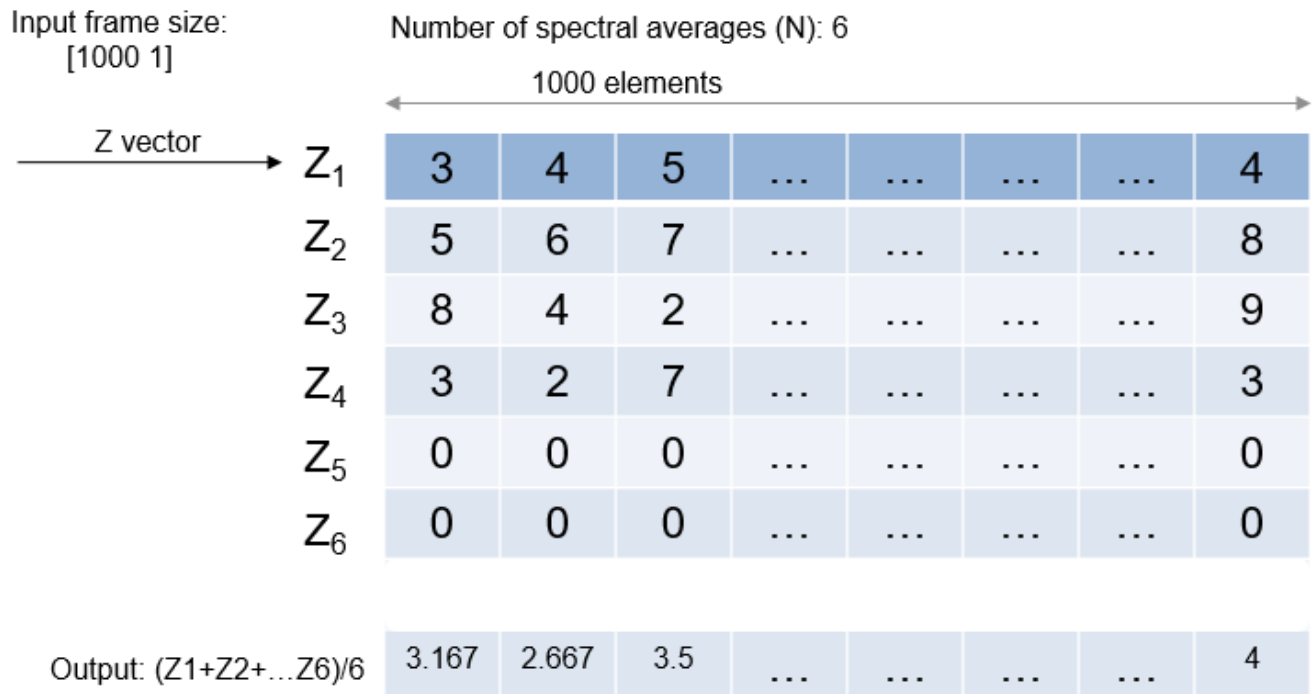

- 2 The DC component is ignored.
- 3 After windowing, the width of each harmonic component masks the noise power in the neighborhood of the fundamental frequency and harmonics. To estimate the noise power in each region, Spectrum Analyzer computes the median noise level in the nonharmonic areas of the spectrum. It then extrapolates that value into each region.
- 4 N^{th} order intermodulation products occur at $A*F1 + B*F2$,
 where $F1$ and $F2$ are the sinusoid input frequencies and $|A| + |B| = N$. A and B are integer values.
- 5 For intermodulation measurements, the third-order intercept (TOI) point is computed as follows, where P is power in decibels of the measured power referenced to 1 milliwatt (dBm):

- $TOI_{\text{lower}} = P_{F1} + (P_{F2} - P_{(2F1-F2)})/2$
- $TOI_{\text{upper}} = P_{F2} + (P_{F1} - P_{(2F2-F1)})/2$
- $TOI = (TOI_{\text{lower}} + TOI_{\text{upper}})/2$

Averaging Method

The moving average is calculated using one of the two methods:

- Running — For each frame of input, average the last N -scaled Z vectors, which are computed by the algorithm. The variable N is the value you specify for the number of spectral averages. If the algorithm does not have enough Z vectors, the algorithm uses zeros to fill the empty elements.

- **Exponential** – The moving average algorithm using the exponential weighting method updates the weights and computes the moving average recursively for each Z vector that comes in by using the following recursive equations:

$$w_N = \lambda w_{N-1} + 1$$

$$\bar{z}_N = \left(1 - \frac{1}{w_N}\right)\bar{z}_{N-1} + \left(\frac{1}{w_N}\right)z_N$$

- λ – Forgetting factor
- w_N – Weighting factor applied to the current Z vector
- z_N – Current Z vector
- \bar{z}_{N-1} – Moving average until the previous Z vector
- $\left(1 - \frac{1}{w_N}\right)\bar{z}_{N-1}$ – Effect of the previous Z vectors on the average
- \bar{z}_N – Moving average including the current Z vector

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

This block can be used for simulation visibility in systems that generate code, but is not included in the generated code.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

This block can be used for simulation visibility in subsystems that generate HDL code, but is not included in the hardware implementation.

PLC Code Generation

Generate Structured Text code using Simulink® PLC Coder™.

This block can be used for simulation visibility in systems that generate PLC code, but is not included in the generated code.

Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

This block accepts fixed-point input, but converts it to `double` for display.

Spectrum Estimator

Estimate power spectrum or power-density spectrum

Library

Estimation / Power Spectrum Estimation

dspspect3

Description

The Spectrum Estimator block outputs the power spectrum or power-density spectrum of a real or complex input signal, using the Welch method of averaged modified periodograms and the filter bank approach.

When you choose the filter bank approach, the block uses an analysis filter bank to estimate the power spectrum. The filter bank approach produces a spectral estimate with a higher resolution, a more accurate noise floor, and more precise peaks than the Welch method, with low or no spectral leakage. They come at the expense of increased computation and slower tracking.

When you choose the Welch method, the block computes the averaged modified periodograms to compute the spectral estimate. The block buffers the input data into overlapping segments. Use the block parameters to set the length of the data segments, the amount of data overlap between consecutive segments, and other features of the power spectrum.

For more information on the Welch method and the filter bank method, see “Algorithms” on page 2-1263.

Each column of the input signal is treated as a separate channel. If the input is a two-dimensional signal, the first dimension represents the channel length (or frame size) and the second dimension represents the number of channels. If the input is a one-dimensional signal, then it is interpreted as a single channel.

Parameters

Main Tab

Method

Specify the spectral estimation method.

- **Filter bank** (default) — An analysis filter bank splits the broadband input signal into multiple narrow subbands. The block computes the power in each narrow frequency band, and the computed value is the spectral estimate over the respective frequency band.

- **Welch** — The block uses the Welch averaged modified periodograms method to compute the power spectrum over the narrow subbands.

Number of taps per band

Specify the number of filter coefficients, or taps, for each frequency band. This value corresponds to the number of filter coefficients per polyphase branch. The total number of filter coefficients is equal to **Number of taps per band** times the FFT length.

This parameter applies when you set **Method** to `Filter bank`. The default is 12.

Spectrum type

Type of spectrum to compute. You can set this parameter to:

- **Power** (default) — Compute the power spectrum.
- **Power density** — Compute the power spectral density.

This parameter is nontunable.

Frequency resolution method

Frequency resolution method. You can set this parameter to:

- **Auto** (default) — The Spectrum Estimator block computes the resolution bandwidth (RBW) so that the frequency span fits 1024 RBW intervals.
 - **Welch method** — The window length, *winLen*, is calculated using $winLen = NENBW \times Fs/RBW$. *NENBW* is the equivalent noise bandwidth of the window and *Fs* is the sample rate.
 - **Filter bank method** — The FFT length is the ceiling of the ratio of **Sample rate (Hz)** to the computed resolution bandwidth.
- **RBW** — Specify the resolution bandwidth, which is used to determine the window length (Welch method) or the FFT length (filter bank method). When the block uses the Welch method, the behavior is equivalent to that of the Spectrum Analyzer block. The window length is calculated using $winLen = NENBW \times Fs/RBW$. *NENBW* is the equivalent noise bandwidth of the window and *Fs* is the sample rate. The FFT length is equal to the ceiling of the ratio of **Sample rate (Hz)** to **RBW (Hz)**.
- **Window length** — Specify the window or segment length to use in the Welch algorithm. This option appears when you set **Method** to `Welch`.
- **Number of frequency bands** — Specify the number of polyphase branches of the analysis filter bank. This value corresponds to the FFT length that the filter bank uses. This option appears when you set **Method** to `Filter bank`.

This parameter is nontunable.

RBW (Hz)

Resolution bandwidth, specified as a positive scalar in Hz. The default is 5. This parameter applies when you set **Frequency resolution method** to `RBW`. The ceiling of the ratio of the frequency span to RBW must be greater than 2.

This parameter is nontunable.

Number of bands source

Source of the number of frequency bands. This parameter applies when you set **Method** to `Filter bank` and **Frequency resolution method** to `Number of frequency bands`. You can set this parameter to:

- Same as input frame length (default) — The FFT length is set to the frame size of the input.
- Specify on dialog — The FFT length is the value you specify in **Number of bands**.

This parameter is nontunable.

Number of bands

Number of frequency bands, or the FFT length the filter bank uses to compute the power spectral estimate, specified as a positive scalar. The default is 1024. This parameter applies when you set **Method** to Filter bank, **Frequency resolution method** to Number of frequency bands, and **Number of bands source** to Specify on dialog. This parameter is nontunable.

Window length source

Source of the window length value. This parameter applies when you set **Method** to Welch and **Frequency resolution method** to Window length. You can set this parameter to:

- Same as input frame length (default) — Window length is set to the frame size of the input. Specify this option to obtain behavior equivalent to that of the Periodogram block.
- Specify on dialog — Window length is the value you specify in the **Window length** parameter.

This parameter is nontunable.

Window length

Length of the window used to compute the spectrum estimate, specified as a positive integer scalar greater than 2. The default is 1024. This parameter applies when you set **Method** to Welch, **Frequency resolution method** to Window length, and **Window length source** to Specify on dialog. This parameter is nontunable.

FFT length source

Source of the FFT length value. This parameter applies when you set **Method** to Welch and **Frequency resolution method** to Window length. You can set this parameter to:

- Auto (default) — The block sets the FFT length to the frame size of the input.
- Property — The block sets the FFT length to the value you specify in **FFT length**.

This parameter is nontunable.

FFT length

Length of the FFT used to compute the spectrum estimates, specified as a positive integer scalar. This parameter applies when you set **Method** to Welch, **Frequency resolution method** to Window length, and **FFT length source** to Property. The default is 1024. This parameter is nontunable.

Inherit sample rate from input

When you select this check box, the block sample rate is computed as N/T_s , where N is the frame size of the input signal and T_s is the sample time of the input signal.

This check box applies when you do one of the following:

- Set **Method** to Welch and **Frequency resolution method** to Window length.
- Set **Method** to Filter bank and **Frequency resolution method** to Number of frequency bands.

When you clear this check box, the block sample rate is the value you specify in **Sample rate (Hz)**. By default, this check box is selected. This parameter is nontunable.

Sample rate (Hz)

Sample rate of the input signal, specified as a positive scalar. The default is 44100. This parameter applies when you do one of the following:

- Set **Frequency resolution method** to Auto or RBW.
- Set **Method** to Welch, **Frequency resolution method** to Window length, and clear the **Inherit sample rate from input** check box.
- Set **Method** to Filter bank, **Frequency resolution method** to Number of frequency bands, and clear the **Inherit sample rate from input** check box.

This parameter is nontunable.

Window function

Window function the Welch algorithm uses, specified as one of Chebyshev | Flat Top | Hamming | Hann | Kaiser | Rectangular. This parameter appears when you set **Method** to Welch. The default is Hann. This parameter is nontunable.

Sidelobe attenuation of window (dB)

Sidelobe attenuation of the window, specified as a real positive scalar greater than or equal to 45, in dB. The default is 60. This parameter appears when you set **Method** to Welch and **Window function** to Chebyshev or Kaiser. This parameter is nontunable.

Averaging method

Specify the averaging method as Exponential (default) or Running. In the exponential method, the block computes the average over samples weighted by an exponentially decaying forgetting factor. In the running averaging method, the block computes an equally weighted average of specified number of spectrum estimates defined by **Number of spectral averages** parameter.

Number of spectral averages

Number of spectral averages, specified as a positive integer scalar. The default is 1. The spectrum estimator computes the current power spectrum estimate by averaging the last N power spectrum estimates, where N is the number of spectral averages defined in **Number of spectral averages**. This parameter is nontunable.

This parameter applies when **Averaging method** is set to Running.

Specify forgetting factor from input port

Select this check box to specify the forgetting factor from an input port. When you do not select this check box, the forgetting factor is specified through the **Forgetting factor** parameter.

This parameter applies when **Averaging method** is set to Exponential.

Forgetting factor

Specify the exponential weighting forgetting factor as a scalar value greater than zero and smaller than or equal to one. The default is 0.9.

This parameter applies when you set **Averaging method** to Exponential and clear the **Specify forgetting factor from input port** parameter.

Advanced Tab

Window overlap (%)

Percentage of overlap between successive data windows, specified as a scalar from 0 and 100. The default value is 0. To enable this parameter, on the **Main Tab**, set **Method** to **Welch**. This parameter is nontunable.

Reference load (ohms)

Load used as a reference to compute the power values, specified as a real positive scalar expressed in ohms. The default value is 1. This parameter is nontunable.

Frequency range

Frequency range of the spectrum estimator. You can set this parameter to:

- **One-sided** — The spectrum estimator computes the one-sided spectrum of a real input signal. When the FFT length, `NFFT`, is even, the spectrum estimate has length $(NFFT/2) + 1$ and is computed over the frequency range $[0 \text{ SampleRate}/2]$. `SampleRate` is the sample rate of the input signal. When `NFFT` is odd, the spectrum estimate has length $(NFFT + 1)/2$ and is computed over the frequency range $[0 \text{ SampleRate}/2]$.
- **Two-sided** — The spectrum estimator computes the two-sided spectrum of a complex or real input signal. The length of the spectrum estimate is equal to the FFT length. The spectrum estimate is computed over the frequency range $[0 \text{ SampleRate})$, where `SampleRate` is the sample rate of the input signal.
- **Centered (default)** — The spectrum estimator computes the centered two-sided spectrum of a complex or real input signal. The length of the spectrum estimate is equal to the FFT length. The spectrum estimate is computed over the frequency range $(-\text{SampleRate}/2 \text{ SampleRate}/2]$ when the FFT length is even and $(-\text{SampleRate}/2 \text{ SampleRate}/2)$ when the FFT length is odd.

This parameter is nontunable.

Power units

Units used to measure power. You can set this parameter to:

- **'Watts'** (default) — The spectrum estimator measures power in watts.
- **'dBw'** — The spectrum estimator measures power in decibel-watts.
- **'dBm'** — The spectrum estimator measures power in decibel-milliwatts.

This parameter is nontunable.

Output max-hold spectrum

When you select this check box, the block computes the max-hold spectrum of the input signal by keeping, at each frequency bin, the maximum value of all the power spectrum estimates. By default, this check box is not selected. This parameter is nontunable.

Output min-hold spectrum

When you select this check box, the block computes the min-hold spectrum of the input signal by keeping, at each frequency bin, the minimum value of all the power spectrum estimates. By default, this check box is not selected. This parameter is nontunable.

Output frequency vector

When you select this check box, the block outputs the frequency vector. By default, this check box is not selected. This parameter is nontunable.

Output effective RBW

When you select this check box, the block computes the effective resolution bandwidth. By default, this check box is not selected. This parameter is nontunable.

Simulate using

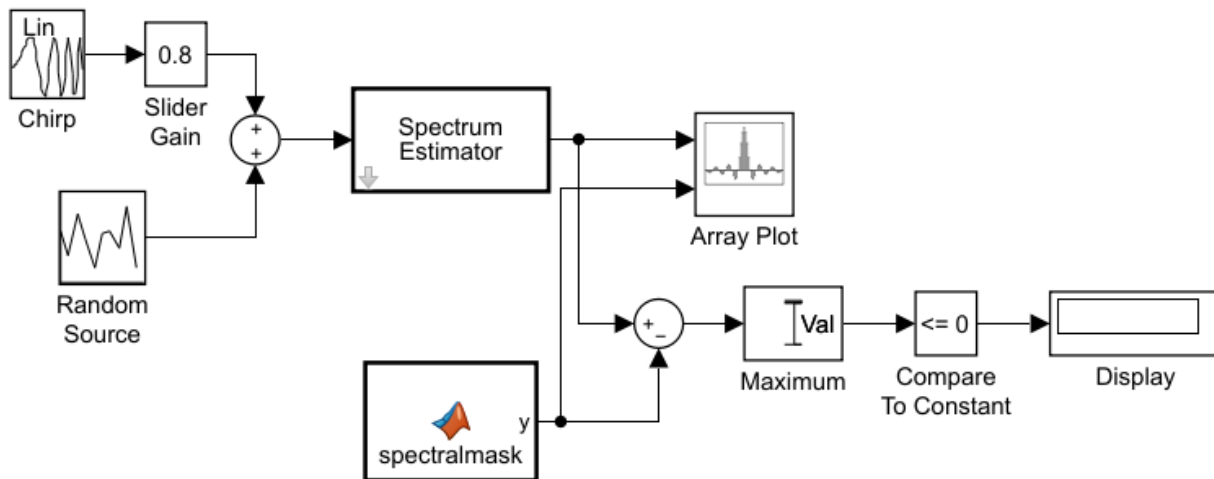

Type of simulation to run. You can set this parameter to:

- **Code generation** (default) — Simulate model using generated C code. The first time you run a simulation, Simulink generates C code for the block. The C code is reused for subsequent simulations, as long as the model does not change. This option requires additional startup time but provides faster simulation speed than **Interpreted execution**.
- **Interpreted execution** — Simulate model using the MATLAB interpreter. This option shortens startup time but has slower simulation speed than **Code generation**.

Example

Estimate the Power Spectral Density (PSD) of a chirp signal using the Spectrum Estimator block. Compare the PSD data with a Bluetooth[®] spectral mask and determine if the PSD data complies with the mask.

Estimate the Power Spectral Density

Copyright 2015 the Mathworks, Inc.

To view the complete model, enter `ex_psd_spectralmask` in the MATLAB command prompt.

Input Signal

The input to the Spectrum Estimator block is a chirp signal embedded in Gaussian noise with zero mean and a variance of 0.01 . The chirp signal is amplified with a gain factor in the range $[0 \ 1]$.

Spectral Mask

The Spectral mask is created using the MATLAB Function block. The mask is based on the Bluetooth standard described in [5].

Live Processing

The Spectrum Estimator block estimates the PSD of the chirp. In this example, the PSD data is compared with the spectral mask. The Display block shows a 1 or 0, depending on whether the spectral data is within the mask or not. During simulation, you can change the power in the input signal by moving the slider in the Slider Gain block. Simultaneously, you can view this change in the Array Plot block.

Supported Data Types

Port	Supported Data Types
Input	<ul style="list-style-type: none"> • Double-precision floating point • Single-precision floating point
Output	<ul style="list-style-type: none"> • Double-precision floating point • Single-precision floating point

Algorithms

Welch's Method of Averaged Modified Periodograms

When you choose the Welch method, the power spectrum estimate is averaged modified periodograms.

Given the signal input, x :

- 1 Multiply x by the window and scale the result by the window power.
- 2 Compute the FFT of the signal, Y , and take the square magnitude using $Z = Y.*\text{conj}(Y)$.
- 3 Compute the current power spectrum estimate by taking the moving average of the last N number of Z 's, and scaling the answer by the sample rate. For details on the moving average methods, see "Averaging Method" on page 2-1264.

Filter Bank

The filter-bank-based spectrum estimator uses an analysis filter bank to estimate the power spectrum. The filter bank splits a broadband input signal, $x(n)$, of sample rate fs into multiple narrow band signals, $y_0(m), y_1(m), \dots, y_{M-1}(m)$, of sample rate fs/M .

The variable M represents the number of frequency bands in the filter bank. When you specify FFT length, M equals the FFT length. When you do not specify FFT length, M is equal to the number of rows in the input signal. The number of taps per frequency band sets the number of filter coefficients for each frequency band of the filter bank. The total number of filter coefficients is equal to number of taps per band times the number of frequency bands M . For more information on the analysis filter bank and how it is implemented, see the "More About" on page 4-218 and the "Algorithm" on page 4-220 sections in `dsp.Channelizer`.

After the broadband input signal is split into multiple narrow bands, the spectrum estimator computes the power in each narrow band using the following equation. Each Z_i value becomes the estimate of the power over that narrow frequency band.

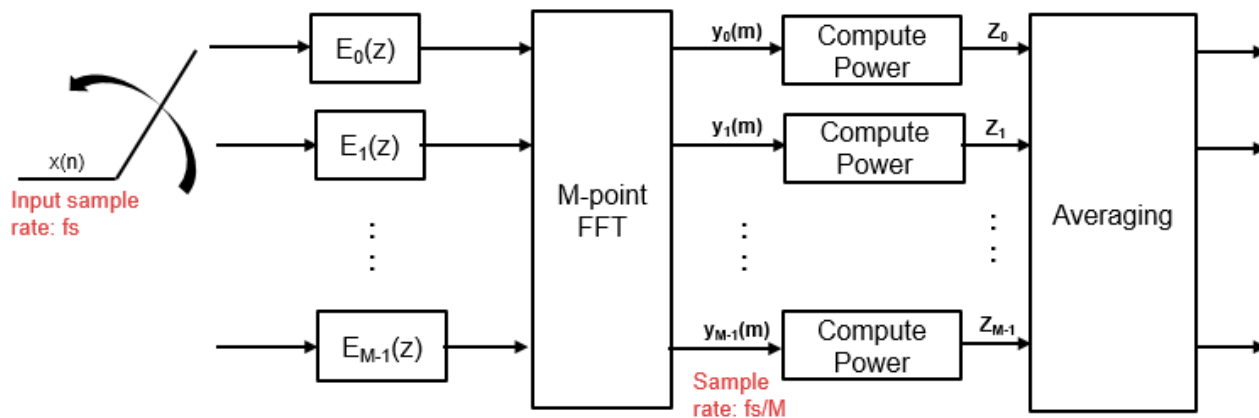

$$Z_i = \frac{1}{L} \sum_{m=0}^{L-1} |y_i[m]|^2$$

L is length of the narrow band signal $y_i(m)$, where $i = 1, 2, \dots, M-1$.

The power values in all the narrow bands (denoted by Z_i) form the Z vector.

$$Z = [Z_0, Z_1, Z_2, \dots, Z_{M-1}]$$

The filter bank estimator algorithm averages the current Z vector with the previous Z vectors using one of the two moving average methods: running or exponential weighting. The output of the averaging operation forms the spectral estimate vector. For details on the two averaging methods, see "Averaging Method" on page 2-1264.

Averaging Method

The moving average is calculated using one of the two methods:

- **Running** — For each frame of input, average the last N -scaled Z vectors, which are computed by the algorithm. The variable N is the value you specify for the number of spectral averages. If the algorithm does not have enough Z vectors, the algorithm uses zeros to fill the empty elements.

Input frame size:
[1000 1]

Number of spectral averages (N): 6

1000 elements

Z vector	Z_1	3	4	5	4
	Z_2	5	6	7	8
	Z_3	8	4	2	9
	Z_4	3	2	7	3
	Z_5	0	0	0	0
	Z_6	0	0	0	0

Output: $(Z_1+Z_2+...Z_6)/6$	3.167	2.667	3.5	4
------------------------------	-------	-------	-----	-----	-----	-----	-----	---

- **Exponential** — The moving average algorithm using the exponential weighting method updates the weights and computes the moving average recursively for each Z vector that comes in by using the following recursive equations:

$$w_N = \lambda w_{N-1} + 1$$

$$\bar{z}_N = \left(1 - \frac{1}{w_N}\right)\bar{z}_{N-1} + \left(\frac{1}{w_N}\right)z_N$$

- λ – Forgetting factor
- w_N – Weighting factor applied to the current Z vector
- z_N – Current Z vector
- \bar{z}_{N-1} – Moving average until the previous Z vector
- $\left(1 - \frac{1}{w_N}\right)\bar{z}_{N-1}$ – Effect of the previous Z vectors on the average
- \bar{z}_N – Moving average including the current Z vector

Stack

Store inputs into LIFO register

Library

Signal Management / Buffers

dspbuff3

Description

The Stack block stores a sequence of input samples in a last in, first out (LIFO) register. The register capacity is set by the **Stack depth** parameter, and inputs can be scalars, vectors, or matrices.

The block *pushes* the input at the In port onto the top of the stack when a trigger event is received at the Push port. When a trigger event is received at the Pop port, the block *pops* the top element off the stack and holds the Out port at that value. The last input to be pushed onto the stack is always the first to be popped off.

A trigger event at the optional Rst port empties the stack contents. When you select **Clear output port on reset**, then a trigger event at the Rst port empties the stack *and* sets the value at the Out port to zero. This setting also applies when a disabled subsystem containing the Stack block is reenabled; the Out port value is only reset to zero in this case when you select **Clear output port on reset**.

When two or more of the control input ports are triggered at the same time step, the operations are executed in the following order:

- 1 Rst
- 2 Push
- 3 Pop

The rate of the trigger signal must be the same as the rate of the data signal input. You specify the triggering event for the Push, Pop, and Rst ports in the **Trigger type** pop-up menu:

- **Rising edge** — Triggers execution of the block when the trigger input does one of the following:
 - Rises from a negative value to a positive value or zero
 - Rises from zero to a positive value, where the rise is not a continuation of a rise from a negative value to zero (see the following figure)

- **Falling edge** — Triggers execution of the block when the trigger input does one of the following:
 - Falls from a positive value to a negative value or zero
 - Falls from zero to a negative value, where the fall is not a continuation of a fall from a positive value to zero (see the following figure)

- **Either edge** — Triggers execution of the block when the trigger input is a **Rising edge** or **Falling edge** (as described above).
- **Non-zero sample** — Triggers execution of the block at each sample time that the trigger input is not zero.

Note If your model contains any referenced models that use a Stack block with the **Push full stack** parameter set to `Dynamic reallocation`, you cannot simulate your top-level model in Simulink Accelerator mode.

The **Push full stack** parameter specifies the block's behavior when a trigger is received at the Push port but the register is full. The **Pop empty stack** parameter specifies the block's behavior when a trigger is received at the Pop port but the register is empty. The following options are available for both cases:

- **Ignore** — Ignore the trigger event, and continue the simulation.
- **Warning** — Ignore the trigger event, but display a warning message in the MATLAB command window.
- **Error** — Display an error dialog box and terminate the simulation.

Note The **Push full stack** and **Pop empty stack** parameters are diagnostic parameters. Like all diagnostic parameters on the Configuration Parameters dialog box, they are set to `Ignore` in the code generated for this block by Simulink Coder code generation software.

The **Push full stack** parameter additionally offers the **Dynamic reallocation** option, which dynamically resizes the register to accept as many additional inputs as memory permits. To find out how many elements are on the stack at a given time, enable the Num output port by selecting the **Show number of stack entries port** parameter.

Note When `Dynamic reallocation` is selected, the **System target file** parameter on the **Code Generation** pane of the Model Configuration Parameters dialog box must be set to `grt_malloc.tlc` – Generic Real-Time Target with dynamic memory allocation.

Examples

Example 1

The table below illustrates the Stack block's operation for a **Stack depth** of 4, **Trigger type** of `Either edge`, and **Clear output port on reset** enabled. Because the block triggers on both rising and falling edges in this example, each transition from 1 to 0 or 0 to 1 in the Push, Pop, and Rst columns below represents a distinct trigger event. A 1 in the Empty column indicates an empty buffer, while a 1 in the Full column indicates a full buffer.

In	Push	Pop	Rst	Stack	Out	Empty	Full	Num
1	0	0	0	top  bottom	0	1	0	0
2	1	0	0	top  bottom	0	0	0	1
3	0	0	0	top  bottom	0	0	0	2
4	1	0	0	top  bottom	0	0	0	3
5	0	0	0	top  bottom	0	0	1	4

In	Push	Pop	Rst	Stack	Out	Empty	Full	Num
6	0	1	0	top  bottom	5	0	0	3
7	0	0	0	top  bottom	4	0	0	2
8	0	1	0	top  bottom	3	0	0	1
9	0	0	0	top  bottom	2	1	0	0
10	1	0	0	top  bottom	2	0	0	1
11	0	0	0	top  bottom	2	0	0	2
12	1	0	1	top  bottom	0	0	0	1

Note that at the last step shown, the Push and Rst ports are triggered simultaneously. The Rst trigger takes precedence, and the stack is first cleared and then pushed.

Parameters

Stack depth

The number of entries that the LIFO register can hold.

Trigger type

The type of event that triggers the block's execution. The rate of the trigger signal must be the same as the rate of the data signal input.

Push full stack

Response to a trigger received at the Push port when the register is full. Inputs to this port must have the same built-in data type as inputs to the Pop and Rst input ports.

When Dynamic reallocation is selected, the **System target file** parameter on the **Code Generation** pane of the Model Configuration Parameters dialog box must be set to `grt_malloc.tlc` – Generic Real-Time Target with dynamic memory allocation.

Pop empty stack

Response to a trigger received at the Pop port when the register is empty. Inputs to this port must have the same built-in data type as inputs to the Push and Rst input ports.

Show empty stack indicator port

Enable the Empty output port, which is high (1) when the stack is empty, and low (0) otherwise.

Show full stack indicator port

Enable the Full output port, which is high (1) when the stack is full, and low (0) otherwise. The Full port remains low when you select **Dynamic reallocation** from the **Push full stack** parameter.

Show number of stack entries port

Enable the Num output port, which tracks the number of entries currently on the stack. When inputs to the In port are double-precision values, the outputs from the Num port are double-precision values. Otherwise, the outputs from the Num port are 32-bit unsigned integer values.

Show reset port to clear internal stack buffer

Enable the Rst input port, which empties the stack when the trigger specified by the **Trigger type** is received. Inputs to this port must have the same built-in data type as inputs to the Push and Pop input ports.

Clear output port on reset

Reset the Out port to zero (in addition to clearing the stack) when a trigger is received at the Rst input port.

Supported Data Types

Port	Supported Data Types
In	<ul style="list-style-type: none"> • Double-precision floating point • Single-precision floating point • Fixed point (signed and unsigned) • Boolean • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

The following limitations apply:

- Generated code relies on memcpy or memset functions (`string.h`) under certain conditions.
- When Dynamic reallocation is selected, the **System target file** parameter on the **Code Generation** pane of the Configuration Parameters dialog box must be set to `grt_malloc.tlc` - Generic Real-Time Target with dynamic memory allocation.

Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

Standard Deviation

Standard deviation of input or sequence of inputs

Library: DSP System Toolbox / Statistics

Description

The Standard Deviation block computes the standard deviation of each row or column of the input, or along vectors of a specified dimension of the input. It can also compute the standard deviation of the entire input. You can specify the dimension using the **Find the standard deviation value over** parameter. The Standard Deviation block can also track the standard deviation in a sequence of inputs over a period of time. To track the standard deviation in a sequence of inputs, select the **Running standard deviation** parameter.

Note The **Running** mode in the Standard Deviation block will be removed in a future release. To compute the running standard deviation in Simulink, use the Moving Standard Deviation block instead.

Ports

Input

In — Data input

vector | matrix | N -D array

The block accepts real-valued or complex-valued multichannel and multidimensional inputs.

This port is unnamed until you select the **Running standard deviation** parameter and set the **Reset port** parameter to any option other than None.

Data Types: single | double

Rst — Reset port

scalar

Specify the reset event that causes the block to reset the running standard deviation. The sample time of the **Rst** input must be a positive integer multiple of the input sample time.

Dependencies

To enable this port, select the **Running standard deviation** parameter and set the **Reset port** parameter to any option other than None.

Data Types: single | double | int8 | int16 | int32 | uint8 | uint16 | uint32 | Boolean

Output

Port_1 — Standard deviation along the specified dimension

scalar | vector | matrix | N -D array

The data type of the output matches the data type of the input.

When you do not select the **Running standard deviation** parameter, the block computes the standard deviation in each row or column of the input, or along vectors of a specified dimension of the input. It can also compute the standard deviation of the entire input at each individual sample time. Each element in the output array y is the standard deviation of the corresponding column, row, or entire input. The output array y depends on the setting of the **Find the standard deviation value over** parameter. Consider a three-dimensional input signal of size M -by- N -by- P . When you set **Find the standard deviation value over** to:

- **Entire input** — The output at each sample time is a scalar that contains the standard deviation of the M -by- N -by- P input matrix.
- **Each row** — The output at each sample time consists of an M -by-1-by- P array, where each element contains the standard deviation of each vector over the second dimension of the input. For an M -by- N matrix input, the output at each sample time is an M -by-1 column vector.
- **Each column** — The output at each sample time consists of a 1-by- N -by- P array, where each element contains the standard deviation of each vector over the first dimension of the input. For an M -by- N matrix input, the output at each sample time is a 1-by- N row vector.

In this mode, the block treats length- M unoriented vector inputs as M -by-1 column vectors.

- **Specified dimension** — The output at each sample time depends on the value of the **Dimension** parameter. If you set the **Dimension** to 1, the output is the same as when you select **Each column**. If you set the **Dimension** to 2, the output is the same as when you select **Each row**. If you set the **Dimension** to 3, the output at each sample time is an M -by- N matrix containing the standard deviation of each vector over the third dimension of the input.

When you select **Running standard deviation**, the block tracks the standard deviation of each channel in a time sequence of inputs. In this mode, you must also specify a value for the **Input processing** parameter.

- **Elements as channels (sample based)** — The block treats each element of the input as a separate channel. For a three-dimensional input signal of size M -by- N -by- P , the block outputs an M -by- N -by- P array. Each element y_{ijk} of the output contains the standard deviation of the element u_{ijk} for all inputs since the last reset.

When a reset event occurs, the running standard deviation y_{ijk} in the current frame is reset to the element u_{ijk} .

- **Columns as channels (frame based)** — The block treats each column of the input as a separate channel. This option does not support input signals with more than two dimensions. For a two-dimensional input signal of size M -by- N , the block outputs an M -by- N matrix. Each element y_{ij} of the output contains the standard deviation of the elements in the j th column of all inputs since the last reset, up to and including the element u_{ij} of the current input.

When a reset event occurs, the running standard deviation for each channel becomes the standard deviation of all the samples in the current input frame, up to and including the current input sample.

Data Types: single | double

Parameters

Main Tab

Running standard deviation — Option to select running standard deviation

off (default) | on

When you select the **Running standard deviation** parameter, the block tracks the standard deviation value of each channel in a time sequence of inputs.

Find the standard deviation value over — Dimension over which the block computes the standard deviation

Each column (default) | Entire input | Each row | Specified dimension

- **Each column** — The block outputs the standard deviation over each column.
- **Each row** — The block outputs the standard deviation over each row.
- **Entire input** — The block outputs the standard deviation over the entire input.
- **Specified dimension** — The block outputs the standard deviation over the dimension, specified in the **Dimension** parameter.

Dependencies

To enable this parameter, clear the **Running standard deviation** parameter.

Dimension — Custom dimension

1 (default) | scalar

Specify the dimension (one-based value) of the input signal over which the standard deviation is computed. The value of this parameter must be greater than 0 and less than the number of dimensions in the input signal.

Dependencies

To enable this parameter, set **Find the standard deviation value over** to **Specified dimension**.

Input processing — Method to process the input in running mode

Columns as channels (frame based) (default) | Elements as channels (sample based)

- **Columns as channels (frame based)** — The block treats each column of the input as a separate channel. This option does not support input signals with more than two dimensions. For a two-dimensional input signal of size M -by- N , the block outputs an M -by- N matrix. Each element y_{ij} of the output contains the standard deviation of the elements in the j th column of all inputs since the last reset, up to and including the element u_{ij} of the current input.

When a reset event occurs, the running standard deviation for each channel becomes the standard deviation of all the samples in the current input frame, up to and including the current input sample.

- **Elements as channels (sample based)** — The block treats each element of the input as a separate channel. For a three-dimensional input signal of size M -by- N -by- P , the block outputs an M -by- N -by- P array. Each element y_{ijk} of the output contains the standard deviation of the element u_{ijk} for all inputs since the last reset.

When a reset event occurs, the running standard deviation y_{ijk} in the current frame is reset to the element u_{ijk} .

Variable-Size Inputs

When your inputs are of variable size, and you select the **Running standard deviation** parameter, then:

- If you set the **Input processing** parameter to **Elements as channels (sample based)**, the state is reset.
- If you set the **Input processing** parameter to **Columns as channels (frame based)**, then:
 - When the input size difference is in the number of channels (number of columns), the state is reset.
 - When the input size difference is in the length of channels (number of rows), no reset occurs and the running operation is carried out as usual.

Dependencies

To enable this parameter, select the **Running standard deviation** parameter.

Reset port — Reset event

None (default) | Rising edge | Falling edge | Either edge | Non-zero sample

The block resets the running standard deviation whenever a reset event is detected at the optional **Rst** port. The reset sample time must be a positive integer multiple of the input sample time.

When a reset event occurs while the **Input processing** parameter is set to **Elements as channels (sample based)**, the running standard deviation for each channel is initialized to the value in the corresponding channel of the current input. Similarly, when the **Input processing** parameter is set to **Columns as channels (frame based)**, the running standard deviation for each channel becomes the standard deviation of all the samples in the current input frame, up to and including the current input sample.

Use this parameter to specify the reset event.

- **None** — Disables the **Rst** port.
- **Rising edge** — Triggers a reset operation when the **Rst** input does one of the following:
 - Rises from a negative value to either a positive value or zero.
 - Rises from zero to a positive value, where the rise is not a continuation of a rise from a negative value to zero.

- **Falling edge** — Triggers a reset operation when the **Rst** input does one of the following:
 - Falls from a positive value to a negative value or zero.
 - Falls from zero to a negative value, where the fall is not a continuation of a fall from a positive value to zero.

- **Either edge** — Triggers a reset operation when the **Rst** input is a Rising edge or Falling edge.
- **Non-zero sample** — Triggers a reset operation at each sample time, when the **Rst** input is not zero.

Note When running simulations in the Simulink multitasking mode, reset signals have a one-sample latency. Therefore, when the block detects a reset event, there is a one-sample delay at the reset port rate before the block applies the reset. For more information on latency and the Simulink tasking modes, see “Excess Algorithmic Delay (Tasking Latency)” and “Time-Based Scheduling and Code Generation” (Simulink Coder).

Dependencies

To enable this parameter, select the **Running standard deviation** parameter.

More About

Standard Deviation

The standard deviation of a discrete-time signal is the square root of the variance of the signal.

Standard deviation gives a measure of deviation of the signal from its mean value.

For purely real or imaginary input, u , of size M -by- N , the standard deviation is given by the following equation:

$$y = \sigma = \sqrt{\frac{\sum_{i=1}^M \sum_{j=1}^N |u_{ij}|^2 - \frac{\left| \sum_{i=1}^M \sum_{j=1}^N u_{ij} \right|^2}{M*N}}{M*N - 1}}$$

- u_{ij} is the input data element at indices i, j .
- M is the length of the j th column.
- N is the number of columns.

For complex inputs, the standard deviation is given by the following equation:

$$\sigma = \sqrt{\sigma_{Re}^2 + \sigma_{Im}^2}$$

- σ_{Re}^2 is the variance of the real part of the complex input.
- σ_{Im}^2 is the variance of the imaginary part of the complex input.

Algorithms

Standard Deviation

When you clear the **Running standard deviation** parameter in the block and specify a dimension, the block produces results identical to the MATLAB `std` function, when it is called as `y = std(u, D)`.

- u is the data input.
- D is the dimension.
- y is the standard deviation along the specified dimension.

The standard deviation along the entire input is identical to calling the `std` function as `y = std(u(:))`.

For a complex input signal, the standard deviation is the square root of the sum of the variances of the real and imaginary parts.

$$\sigma = \sqrt{\sigma_{Re}^2 + \sigma_{Im}^2}$$

Submatrix

Select subset of elements (submatrix) from matrix input

Library: DSP System Toolbox / Signal Management / Indexing
 DSP System Toolbox / Math Functions / Matrices and Linear
 Algebra / Matrix Operations

Description

The Submatrix block extracts a contiguous submatrix, y , from the M -by- N input matrix u . For more information about selecting the rows and columns to extract, see “Range Specification Options” on page 2-1283.

Ports

Input

Port_1 — Input signal

vector | matrix

Input signal, from which the block extracts the specified submatrix.

This block supports Simulink virtual buses.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point | enumerated

Output

Port_1 — Selected submatrix

vector | matrix

Submatrix selected from the input signal. The data type of the output is the same as the input.

This block supports Simulink virtual buses.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point | enumerated

Parameters

For more information about selecting the subset of elements to form the submatrix, see “Range Specification Options” on page 2-1283.

Row span — Range of rows

All rows (default) | One row | Range of rows

The range of input rows to be retained in the output.

Row — First row of output

First (default) | Index | Offset from last | Last | Offset from middle | Middle

The input row to be used as the first and only row of the output.

Dependencies

To enable this parameter, set **Row span** to One row.

Starting row — First row of output

First (default) | Index | Offset from last | Last | Offset from middle | Middle

The input row to be used as the first row of the output.

Dependencies

To enable this parameter, set **Row span** to Range of rows.

Row index — Index of first row

1 (default) | positive integer

The index of the input row to be used as the first and only row of the output, specified as an integer greater than or equal to one.

Dependencies

To enable this parameter, set **Row span** to One row and **Row** to Index.

Starting row index — Index of first row

1 (default) | positive integer

The index of the input row to be used as the first row of the output, specified as an integer greater than or equal to one.

Dependencies

To enable this parameter, set **Row span** to Range of rows and **Starting row** to Index.

Row offset — Offset of first row

1 (default) | positive integer

The offset of the input row to be used as the first and only row of the output, specified as an integer greater than or equal to one.

Dependencies

To enable this parameter, set **Row span** to One row and **Row** to Offset from last or Offset from middle.

Starting row offset — Offset of first row

1 (default) | positive integer

The offset of the input row to be used as the first row of the output, specified as an integer greater than or equal to one.

Dependencies

To enable this parameter, set **Row span** to Range of rows and **Starting row** to Offset from last or Offset from middle.

Ending row — Last row

Last (default) | Index | Offset from last | Offset from middle | Middle

The input row to be used as the last row of the output.

Dependencies

To enable this parameter, set **Row span** to Range of rows and set **Starting row** to any value except Last.

Ending row index — Index of last row

1 (default) | positive integer

The index of the input row to be used as the last row of the output, specified as an integer greater than or equal to one.

Dependencies

To enable this parameter, set **Ending row** to Index.

Ending row offset — Offset of last row

1 (default) | positive integer

The offset of the input row to be used as the last row of the output.

Dependencies

To enable this parameter, set **Ending row** to Offset from middle or Offset from last.

Column span — Range of input columns

All columns (default) | One column | Range of columns

The range of input columns to be retained in the output.

Column — First column

First (default) | Index | Offset from last | Last | Offset from middle | Middle

The input column to be used as the first and only column of the output.

Dependencies

To enable this parameter, set **Column span** to One column.

Starting column — First column

First (default) | Index | Offset from last | Last | Offset from middle | Middle

The input column to be used as the first column of the output.

Dependencies

To enable this parameter, set **Column span** to Range of columns.

Starting column index — Index of first column

1 (default) | positive integer

The index of the input column to be used as the first column of the output, specified as an integer greater than or equal to one.

Dependencies

To enable this parameter, set **Column span** to Range of columns and **Starting column** to Index.

Column index — Index of first column

1 (default) | positive integer

The index of the input column to be used as the first and only column of the output, specified as an integer greater than or equal to one.

Dependencies

To enable this parameter, set **Column span** to One column and **Column** to Index.

Column offset — Offset of first column

1 (default) | positive integer

The offset of the input column to be used as the first and only column of the output, specified as an integer greater than or equal to one.

Dependencies

To enable this parameter, set **Column span** to One column and **Column** to Offset from last or Offset from middle.

Starting column offset — Offset of first column

1 (default) | positive integer

The offset of the input column to be used as the first column of the output, specified as an integer greater than or equal to one.

Dependencies

To enable this parameter, set **Column span** to Range of columns and **Starting column** to Offset from last or Offset from middle.

Ending column — Last column

Last (default) | Index | Offset from last | Offset from middle | Middle

The input column to be used as the last column of the output.

Dependencies

To enable this parameter, set **Column span** to Range of columns and set **Starting column** to any value except Last.

Ending column index — Index of last column

1 (default) | positive integer

The index of the input column to be used as the last column of the output, specified as an integer greater than or equal to one.

Dependencies

To enable this parameter, set **Ending column** to Index.

Ending column offset — Offset of last column

1 (default) | positive integer

The offset of the input column to be used as the last column of the output.

Dependencies

To enable this parameter, set **Ending column** to `Offset from middle` or `Offset from last`.

More About

Range Specification Options

The block treats length- M unoriented vector input as an M -by-1 matrix. The **Row span** parameter provides three options for specifying the range of rows in u to be retained in submatrix output y :

- **All rows**
Specifies that y contains all M rows of u .
- **One row**
Specifies that y contains only one row from u . Selecting **One row** enables the **Row** parameter to allow selection of the desired row.
- **Range of rows**
Specifies that y contains a range of rows from u . Selecting **Range of rows** enables the **Starting row** and **Ending row** parameters to allow selection of the desired range of rows.

The **Column span** parameter contains a corresponding set of three options for specifying the range of columns in u to be retained in submatrix y : **All columns**, **One column**, or **Range of columns**. The **One column** option enables the **Column** parameter, and **Range of columns** options enable the **Starting column** and **Ending column** parameters.

When you select **One row** or **Range of rows** from the **Row span** parameter, you specify the desired row or range of rows in the **Row** parameter, or the **Starting row** and **Ending row** parameters. Similarly, when you select **One column** or **Range of columns** from the **Column span** parameter, you specify the desired column or range of columns in the **Column** parameter, or the **Starting column** and **Ending column** parameters.

The **Row**, **Column**, **Starting row**, or **Starting column** can be specified in six ways:

- **First**
For rows, this specifies that the first row of u should be used as the first row of y . When all columns are to be included, this is equivalent to $y(1, :) = u(1, :)$.

For columns, this specifies that the first column of u should be used as the first column of y . When all rows are to be included, this is equivalent to $y(:,1) = u(:,1)$.

- Index

For rows, this specifies that the row of u , `firstrow`, forward-indexed by the **Row index** parameter or the **Starting row index** parameter, should be used as the first row of y . When all columns are to be included, this is equivalent to $y(1,:) = u(\text{firstrow},:)$.

For columns, this specifies that the column of u , forward-indexed by the **Column index** parameter or the **Starting column index** parameter, `firstcol`, should be used as the first column of y . When all rows are to be included, this is equivalent to $y(:,1) = u(:,\text{firstcol})$.

- Offset from last

For rows, this specifies that the row of u offset from row M by the **Row offset** or **Starting row offset** parameter, `firstrow`, should be used as the first row of y . When all columns are to be included, this is equivalent to $y(1,:) = u(M-\text{firstrow},:)$.

For columns, this specifies that the column of u offset from column N by the **Column offset** or **Starting column offset** parameter, `firstcol`, should be used as the first column of y . When all rows are to be included, this is equivalent to $y(:,1) = u(:,N-\text{firstcol})$.

- Last

For rows, this specifies that the last row of u should be used as the only row of y . When all columns are to be included, this is equivalent to $y = u(M,:)$.

For columns, this specifies that the last column of u should be used as the only column of y . When all rows are to be included, this is equivalent to $y = u(:,N)$.

- Offset from middle

When you select this option, the block selects the first row or column of the output y by adding the specified offset to the middle row or column of the input u . When the number, X , of input rows or columns is even, the block defines the middle as $X/2 + 1$. When the number of input rows or columns is odd, the block defines the middle as $\text{ceil}(X/2)$.

When all columns are to be included, the following code defines the starting row: $y(1,:) = u(\text{MiddleRow}+\text{Offset},:)$, where `Offset` is the value of the **Row offset** or **Starting row offset** parameter. When all rows are to be included, the following code defines the starting column: $y(1,:) = u(:,\text{MiddleColumn}+\text{Offset})$, where `Offset` is the value of the **Column offset** or **Starting column offset** parameter.

- Middle

When you select this option, the block uses the middle row or column of the input u as the first row or column of the output y . When the number, X , of input rows or columns is even, the block defines the middle as $X/2 + 1$. When the number of input rows or columns is odd, the block defines the middle as $\text{ceil}(X/2)$.

When all columns are to be included, the following code defines the starting row: $y = u(\text{MiddleRow},:)$. When all rows are to be included, the following code defines the starting column: $y = u(:,\text{MiddleColumn})$.

The **Ending row** or **Ending column** can similarly be specified in five ways:

- Index

For rows, this specifies that the row of u forward-indexed by the **Ending row index** parameter, `lastrow`, should be used as the last row of y . When all columns are to be included, this is equivalent to `y(end,:) = u(lastrow,:)`.

For columns, this specifies that the column of u forward-indexed by the **Ending column index** parameter, `lastcol`, should be used as the last column of y . When all rows are to be included, this is equivalent to `y(:,end) = u(:,lastcol)`.

- Offset from last

For rows, this specifies that the row of u offset from row M by the **Ending row offset** parameter, `lastrow`, should be used as the last row of y . When all columns are to be included, this is equivalent to `y(end,:) = u(M-lastrow,:)`.

For columns, this specifies that the column of u offset from column N by the **Ending column offset** parameter, `lastcol`, should be used as the last column of y . When all rows are to be included, this is equivalent to `y(:,end) = u(:,N-lastcol)`.

- Last

For rows, this specifies that the last row of u should be used as the last row of y . When all columns are to be included, this is equivalent to `y(end,:) = u(M,:)`.

For columns, this specifies that the last column of u should be used as the last column of y . When all rows are to be included, this is equivalent to `y(:,end) = u(:,N)`.

- Offset from middle

When you select this option, the block selects the last row or column of the output y by adding the specified offset to the middle row or column of the input u . When the number, X , of input rows or columns is even, the block defines the middle as $X/2 + 1$. When the number of input rows or columns is odd, the block defines the middle as `ceil(X/2)`.

When all columns are to be included, the following code defines the ending row: `y(end,:) = u(MiddleRow+Offset,:)`, where `Offset` is the value of the **Ending row offset** parameter. When all rows are to be included, the following code defines the ending column: `y(:,end) = u(:,MiddleColumn+Offset)`, where `Offset` is the value of the **Ending column offset** parameter.

- Middle

When you select this option, the block uses the middle row or column of the input u as the last row or column of the output y . When the number, X , of input rows or columns is even, the block defines the middle as $X/2 + 1$. When the number of input rows or columns is odd, the block defines the middle as `ceil(X/2)`.

When all columns are to be included, the following code defines the ending row: `y(end,:) = u(MiddleRow,:)`. When all rows are to be included, the following code defines the ending column: `y(:,end) = u(:,MiddleColumn)`.

SVD Solver

Solve $AX=B$ using singular value decomposition

Library

Math Functions / Matrices and Linear Algebra / Linear System Solvers

dsp solvers

Description

The SVD Solver block solves the linear system $AX=B$, which can be overdetermined, underdetermined, or exactly determined. The system is solved by applying singular value decomposition (SVD) factorization to the M -by- N matrix A , at the A port. The input to the B port is the right side M -by- L matrix, B . The block treats length- M unoriented vector input as an M -by-1 matrix.

The output at the X port is the N -by- L matrix, X . X is chosen to minimize the sum of the squares of the elements of $B-AX$ (the residual). When B is a vector, this solution minimizes the vector 2-norm of the residual. When B is a matrix, this solution minimizes the matrix Frobenius norm of the residual. In this case, the columns of X are the solutions to the L corresponding systems $AX_k=B_k$, where B_k is the k th column of B , and X_k is the k th column of X .

X is known as the minimum-norm-residual solution to $AX=B$. The minimum-norm-residual solution is unique for overdetermined and exactly determined linear systems, but it is not unique for underdetermined linear systems. Thus when the SVD Solver block is applied to an underdetermined system, the output X is chosen such that the number of nonzero entries in X is minimized.

Parameters

Show error status port

Select to enable the E output port, which reports a failure to converge. The possible values you can receive on the port are:

- 0 — The singular value decomposition calculation converges.
- 1 — The singular value decomposition calculation does not converge.

If the singular value decomposition calculation fails to converge, the output at port X is an undefined matrix of the correct size.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Generated code relies on `memcpy` or `memset` functions (`string.h`) under certain conditions.

Introduced before R2006a

Time Scope

Display and analyze signals generated during simulation and log signal data to MATLAB

Library: DSP System Toolbox / Sinks
DSP System Toolbox HDL Support / Sinks

Description

The Simulink Scope block and DSP System Toolbox Time Scope block display time domain signals.

The two blocks have identical functionality, but different default settings. The Time Scope is optimized for discrete time processing. The Scope is optimized for general time-domain simulation. For a side-by-side comparison, see “Simulink Scope Versus DSP System Toolbox Time Scope” (Simulink).

Oscilloscope features:

- Triggers — Set triggers to sync repeating signals and pause the display when events occur.
- Cursor Measurements — Measure signal values using vertical and horizontal cursors.
- Signal Statistics — Display the maximum, minimum, peak-to-peak difference, mean, median, and RMS values of a selected signal.
- Peak Finder — Find maxima, showing the x-axis values at which they occur.
- Bilevel Measurements — Measure transitions, overshoots, undershoots, and cycles.

You must have a Simscape™ or DSP System Toolbox license to use the Peak Finder, Bilevel Measurements, and Signal Statistics.

Scope display features:

- Simulation control — Debug models from a Scope window using **Run**, **Step Forward**, and **Step Backward** toolbar buttons.
- Multiple signals — Plot multiple signals on the same y-axis (display) using multiple input ports.
- Multiple y-axes (displays) — Display multiple y-axes. All the y-axes have a common time range on the x-axis.
- Modify parameters — Modify scope parameter values before and during a simulation.
- Axis autoscaling — Autoscale axes during or at the end of a simulation. Margins are drawn at the top and bottom of the axes.
- Display data after simulation — Scope data is saved during a simulation. If a scope is closed at the start of a simulation, when you open the scope after a simulation, the scope displays simulation results for attached input signals.

Note If you have a high sample rate or long simulation time, you may run into issues with memory or system performance because the scope saves data internally. To limit the amount of data saved for scope visualization, use the Limit data points to last property.

For information on controlling a scope programmatically, see “Control Scope Blocks Programmatically” (Simulink).

Limitations

- Do not use scope blocks in a Library. If you place a scope block inside a library block with a locked link or in a locked library, Simulink displays an error when trying to open the scope window. To display internal data from a library block, add an output port to the library block, and then connect the port to a Scope block in your model.
- If you step through a model, the scope only updates when the scope block runs. This means that the time shown in the status bar may not match the model time.
- When connected to a constant signal, a scope block may plot a single point.
- The scope shows gaps in the display when the signal value is NaN.

- When you visualize multiple frame-based signals in the scope, some samples of signals with a frame size of 1 might not be displayed. To visualize these signals, move the signals with frame size of 1 to a separate scope.
- Scope displays have limitations in Rapid Accelerator mode. See “Behavior of Scopes and Viewers with Rapid Accelerator Mode” (Simulink)
- When the Scope is in a ForEach subsystem, the scope only displays the last index.

Ports

Input

Port_1 — Signal or signals to visualize

scalar | vector | matrix | array | bus | nonvirtual bus

Connect the signals you want to visualize. You can have up to 96 input ports. Input signals can have these characteristics:

- **Type** — Continuous (sample-based) or discrete (sample-based and frame-based).
- **Data type** — Any data type that Simulink supports. See “Data Types Supported by Simulink” (Simulink).
- **Dimension** — Scalar, one dimensional (vector), two dimensional (matrix), or multidimensional (array). Display multiple channels within one signal depending on the dimension. See “Signal Dimensions” (Simulink) and “Determine Signal Dimensions” (Simulink).

Input Limitations

- When the input is a constant signal, the scope plots a single point.
- The scope shows gaps in the display when the signal value is NaN.
- When you visualize multiple frame-based signals in the scope, some samples of signals with a frame size of 1 might not be displayed. To visualize these signals, move the signals with frame size of 1 to a separate scope.

Bus Support

You can connect nonvirtual bus and arrays of bus signals to a scope. To display the bus signals, use normal or accelerator simulation mode. The scope displays each bus element signal in the order the elements appear in the bus, from the top to the bottom. Nested bus elements are flattened.

To log nonvirtual bus signals with a scope, set the **Save format** parameter to **Dataset**. You can use any **Save format** to log virtual bus signals.

Data Types: single | double | half | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point | enumerated | bus

Properties

Configuration Properties

The Configuration Properties dialog box controls various properties about the scope displays. From the scope menu, select **View > Configuration Properties**.

Main**Open at simulation start — Specify when scope window opens**

off (default for Scope) | on (default for Time Scope)

Select this check box to open the scope window when simulation starts.

Programmatic Use

See `OpenAtSimulationStart`.

Display the full path — Display block path on scope title bar

off (default) | on

Select this check box to display the block path in addition to the block name.

Number of input ports — Number of input ports on scope block

1 (default) | integer

Specify number of input ports on a Scope block, specified as an integer. The maximum number of input ports is 96.

Programmatic Use

See `NumInputPorts`.

Layout — Number and arrangement of displays

1-by-1 display (default) | an arrangement of m-by-n axes

Specify number and arrangement of displays. The maximum layout is 16 rows by 16 columns.

To expand the layout grid beyond 4 by 4, click within the dialog box and drag. Maximum of 16 rows by 16 columns.

If the number of displays is equal to the number of ports, signals from each port appear on separate displays. If the number of displays is less than the number of ports, signals from additional ports appear on the last display. For layouts with multiple columns and rows, ports are mapped down then across.

Programmatic Use

See `LayoutDimensions`.

Sample time — Simulation interval between scope updates

-1 (for inherited) (default) | positive real number

Specify the time interval between updates of the scope display. This property does not apply to floating scopes and scope viewers. For a more detailed explanation of sample time with the scope, see “Sample Time with Scope Blocks” (Simulink)

Programmatic Use

See `SampleTime`.

Input processing — Channel or element signal processing

`Elements as channels (sample based)` (default for Scope) | `Columns as channels (frame based)` (default for Time Scope)

- `Elements as channels (sample based)` - Process each element as a unique sample.
- `Columns as channels (frame based)` - Process signal values in a channel as a group of values from multiple time intervals. Frame-based processing is available only with discrete input signals.

Programmatic Use

See `FrameBasedProcessing`.

Maximize axes — Maximize size of plots

`Off` (default for Scope) | `Auto` (default for Time Scope) | `On`

- `Auto` - If “Title” on page 2-0 and “Y-label” on page 2-0 properties are not specified, maximize all plots.
- `On` - Maximize all plots. Values in **Title** and **Y-label** are hidden.
- `Off` - Do not maximize plots.

Programmatic Use

See `MaximizeAxes`.

Time**Time span — Length of x-axis to display**

`Auto` (default) | `User defined` | `One frame period`

- `Auto` — Difference between the simulation start and stop times.

The block calculates the beginning and end times of the time range using the “Time display offset” on page 2-0 and “Time span” on page 2-0 properties. For example, if you set the **Time display offset** to 10 and the **Time span** to 20, the scope sets the time range from 10 to 30.

- `User defined` — Enter any value less than the total simulation time.
- `One frame period` — Use the frame period of the input signal to the Time Scope block. This option is only available when the **Input processing** parameter is set to `Columns as channels (frame based)`.

Programmatic Use

See `TimeSpan`.

Time span overrun action — Display data beyond visible x-axis

Wrap (default) | Scroll

Specify how to display data beyond the visible x-axis range.

You can see the effects of this option only when plotting is slow with large models or small step sizes.

- **Wrap** — Draw a full screen of data from left to right, clear the screen, and then restart drawing the data from the left.
- **Scroll** — Move data to the left as new data is drawn on the right. This mode is graphically intensive and can affect run-time performance.

Programmatic Use

See `TimeSpanOverrunAction`.

Time units — x-axis units

None (default for Scope) | Metric (default for Time Scope) | Seconds

- **Metric** — Display time units based on the length of “Time span” on page 2-0 .
- **Seconds** — Display time in seconds.
- **None** — Do not display time units.

Programmatic Use

See `TimeUnits`.

Time display offset — x-axis offset

0 (default) | scalar | vector

Offset the x-axis by a specified time value, specified as a real number or vector of real numbers.

For input signals with multiple channels, you can enter a scalar or vector:

- **Scalar** — Offset all channels of an input signal by the same time value.
- **Vector** — Independently offset the channels.

Programmatic Use

See `TimeDisplayOffset`.

Time-axis labels — Display of x-axis labels

Bottom Displays Only (default for Scope) | All (default for Time Scope) | None

Specify how x-axis (time) labels display:

- **All** — Display x-axis labels on all y-axes.
- **None** — Do not display labels. Selecting None also clears the **Show time-axis label** check box.
- **Bottom displays only** — Display x-axis label on the bottom y-axis.

Dependencies

To enable this property, set:

- “Show time-axis label” on page 2-0 to on.
- “Maximize axes” on page 2-0 to off.

The “Active display” on page 2-0 property determines which display is affected.

Programmatic Use

See `TimeAxisLabels`.

Show time-axis label — Display or hide x-axis labels

off (default for Scope) | on (default for Time Scope)

Select this check box to show the x-axis label for the active display

Dependencies

To enable this property, set “Time-axis labels” on page 2-0 to **All or Bottom Displays Only**.

The “Active display” on page 2-0 property determines which display is affected.

Programmatic Use

See `ShowTimeAxisLabel`.

Display**Active display — Selected display**

1 (default) | positive integer

Selected display. Use this property to control which display is changed when changing style properties and axes-specific properties.

Specify the desired display using a positive integer that corresponds to the column-wise placement index. For layouts with multiple columns and rows, display numbers are mapped down and then across.

Programmatic Use

See `ActiveDisplay`.

Title — Display name

%<SignalLabel> (default) | string

Title for a display. The default value %<SignalLabel> uses the input signal name for the title.

Dependency

The “Active display” on page 2-0 property determines which display is affected.

Programmatic Use

See `Title`.

Show legend — Display signal legend

off (default) | on

Toggle signal legend. The names listed in the legend are the signal names from the model. For signals with multiple channels, a channel index is appended after the signal name. Continuous signals have straight lines before their names, and discrete signals have step-shaped lines.

From the legend, you can control which signals are visible. This control is equivalent to changing the visibility in the **Style** properties. In the scope legend, click a signal name to hide the signal in the scope. To show the signal, click the signal name again. To show only one signal, right-click the signal name, which hides all other signals. To show all signals, press **Esc**.

Note The legend only shows the first 20 signals. Any additional signals cannot be controlled from the legend.

Dependency

The “Active display” on page 2-0 property determines which display is affected.

Programmatic Use

See ShowLegend.

Show grid — Show internal grid lines

on (default) | off

Select this check box to show grid lines.

Dependency

The “Active display” on page 2-0 property determines which display is affected.

Programmatic Use

See ShowGrid.

Plot signals as magnitude and phase — Split display into magnitude and phase plots

off (default) | on

- On — Display magnitude and phase plots. If the signal is real, plots the absolute value of the signal for the magnitude. The phase is 0 degrees for positive values and 180 degrees for negative values. This feature is useful for complex-valued input signals. If the input is a real-valued signal, selecting this check box returns the absolute value of the signal for the magnitude.
- Off — Display signal plot. If the signal is complex, plots the real and imaginary parts on the same y-axis.

Dependency

The “Active display” on page 2-0 property determines which display is affected.

Programmatic Use

See PlotAsMagnitudePhase.

Y-limits (Minimum) — Minimum y-axis value

-10 (default) | real scalar

Specify the minimum value of the y-axis as a real number.

Tunable: Yes

Dependency

If you select **Plot signals as magnitude and phase**, this property only applies to the magnitude plot. The y-axis limits of the phase plot are always [-180 180].

The “Active display” on page 2-0 property determines which display is affected.

Programmatic Use

See YLimits.

Y-limits (Maximum) — Maximum y-axis value

10 (default) | real scalar

Specify the maximum value of the y-axis as a real number.

Tunable: Yes

Dependency

If you select **Plot signals as magnitude and phase**, this property only applies to the magnitude plot. The y-axis limits of the phase plot are always [-180 180].

The “Active display” on page 2-0 property determines which display is affected.

Programmatic Use

See YLimits.

Y-label — Y-axis label

none (default for Scope) | Amplitude (default for Time Scope) | string

Specify the text to display on the y-axis. To display signal units, add (%<SignalUnits>) to the label. At the beginning of a simulation, Simulink replaces (%SignalUnits) with the units associated with the signals.

Example: For a velocity signal with units of m/s, enter Velocity (%<SignalUnits>).

Dependency

If you select **Plot signals as magnitude and phase**, this property does not apply. The y-axes are labeled Magnitude and Phase.

The “Active display” on page 2-0 property determines which display is affected.

Programmatic Use

See YLabel.

Logging**Limit data points to last — Limit buffered data values**

off and 5000 (default) | on | positive integer

Limit data saved by the scope internally. By default all data points are saved so that you can view the scope visualization after the simulation finishes. For simulations with **Stop time** set to `inf`, consider selecting **Limit data points to last**.

Note If you do not select **Limit data points to last** and you have a high sample rate or long simulation time, you may run into issues with memory or system performance.

When you select this property, the scope saves the latest n data points, where n the specified number of data points.

- Off — Save and plot all data values.
- On — Save specified number of data values for each signal. If the signal is frame-based, the number of buffered data values is the specified number of data values multiplied by the frame size.

In some cases, selecting this property can have the effect of plotting signals for less than the entire time range of a simulation (for example if your sample time is small). If the scope plots a portion of your signals, consider increasing the number of data points to save.

This property limits the data values plotted in the scope and the data values saved to a MATLAB variable specified in “Variable name” on page 2-0 .

Programmatic Use

See `DataLoggingLimitDataPoints` and `DataLoggingMaxPoints`.

Decimation — Reduce amount of scope data to display and save

off, 2 (default) | on | positive integer

- On — Plot and log (save) scope data every Nth data point, where N is the decimation factor entered in the text box. A value of 1 buffers all data values.
- Off — Save all scope data values.

Dependency

To enable this property, select “Log data to workspace” (Simulink).

This property limits the data values plotted in the scope and the data values saved to a MATLAB variable specified in “Variable name” on page 2-0 .

Programmatic Use

See `DataLoggingDecimateData` and `DataLoggingDecimation`.

Log data to workspace — Save data to MATLAB workspace

off (default) | on

Select this check box to enable logging and enable the **Variable name**, **Save format**, and **Decimation** properties. This property does not apply to floating scopes and scope viewers.

For an example of saving signals to the MATLAB Workspace using a Scope block, see “Save Simulation Data Using Scope Block” (Simulink).

Programmatic Use

See `DataLogging`.

Variable name — Name of saved data variable

`ScopeData` (default) | string

Specify a variable name for saving scope data in the MATLAB workspace. This property does not apply to floating scopes and scope viewers.

Dependency

To enable this property, select “Log data to workspace” (Simulink).

Programmatic Use

See `DataLoggingVariableName`.

Save format — MATLAB variable format

`Dataset` (default) | `Structure With Time` | `Structure` | `Array`

Select variable format for saving data to the MATLAB workspace. This property does not apply to floating scopes and scope viewers.

- `Dataset` — Save data as a `Dataset` object, by default a `timeseries` object.
- `Structure With Time` — Save data as a structure with associated time information.
- `Structure` — Save data as a structure.
- `Array` — Save data as an array with associated time information. This format does not support variable-size data.

Dependency

To enable this property, select “Log data to workspace” (Simulink).

Programmatic Use

See `DataLoggingSaveFormat`.

Axes Scaling Properties

The **Axes Scaling** dialog controls the axes limits of the scope. To open the Axes Scaling properties, in the scope menu, select **Tools > Axes Scaling > Axes Scaling Properties**.

Axes scaling — Y-axis scaling mode

`Manual` (default) | `Auto` | `After N Updates`

- `Manual` — Manually scale the y-axis range with the **Scale Y-axis Limits** toolbar button.
- `Auto` — Scale the y-axis range during and after simulation. Selecting this option displays the **Do not allow Y-axis limits to shrink** check box. If you want the y-axis range to increase and decrease with the maximum value of a signal, set **Axes scaling** to `Auto` and clear the **Do not allow Y-axis limits to shrink** check box.
- `After N Updates` — Scale y-axis after the number of time steps specified in the **Number of updates** text box (10 by default). Scaling occurs only once during each run.

Programmatic Use

See `AxesScaling`.

Do not allow Y-axis limits to shrink — When y-axis limits can change

`on` (default) | `off`

Allow y-axis range limits to increase but not decrease during a simulation.

Dependency

To use this property, set **Axes scaling** to Auto.

Number of updates — Number of updates before scaling

10 (default) | integer

Set this property to delay auto scaling the y-axis.

Dependency

To use this property, set **Axes scaling** to After N Updates.

Programmatic Use

See `AxesScalingNumUpdates`.

Scale axes limits at stop — When y-axis limits can change

on (default) | off

- On — Scale axes when simulation stops.
- Off — Scale axes continually.

Dependency

To use this property, set **Axes scaling** to Auto.

Y-axis Data range (%) — Percent of y-axis to use for plotting

80 (default) | integer between [1, 100]

Specify the percentage of the y-axis range used for plotting data. If you set this property to 100, the plotted data uses the entire y-axis range.

Y-axis Align — Alignment along y-axis

Center (default) | Top | Bottom

Specify where to align plotted data along the y-axis data range when **Y-axis Data range** is set to less than 100 percent.

- Top — Align signals with the maximum values of the y-axis range.
- Center — Center signals between the minimum and maximum values.
- Bottom — Align signals with the minimum values of the y-axis range.

Autoscale X-axis limits — Scale x-axis range limits

off (default) | on

Scale x-axis range to fit all signal values. If **Axes scaling** is set to Auto, the data currently within the axes is scaled, not the entire signal in the data buffer.

X-axis Data range (%) — Percent of x-axis to use for plotting

100 (default) | integer in the range [1, 100]

Specify the percentage of the x-axis range to plot data on. For example, if you set this property to 100, plotted data uses the entire x-axis range.

X-axis Align — Alignment along x-axis

Center (default) | Top | Bottom

Specify where to align plotted data along the x-axis data range when **X-axis Data range** is set to less than 100 percent.

- Top — Align signals with the maximum values of the x-axis range.
- Center — Center signals between the minimum and maximum values.
- Bottom — Align signals with the minimum values of the x-axis range.

Style Properties

To open the Style dialog box, from the scope menu, select **View > Style**.

Figure color — Background color for window

black (default) | color

Background color for the scope.

Plot type — How to plot signal

Auto (default for Scope) | Line (default for Time Scope) | Stairs | Stem

When you select **Auto**, the plot type is a line graph for continuous signals, a stair-step graph for discrete signals, and a stem graph for Simulink message signals.

Axes colors — Background and axes color for individual displays

black (default) | color

Select the background color for axes (displays) with the first color palette. Select the grid and label color with the second color palette.

Preserve colors for copy to clipboard — Copy scope without changing colors

off (default) | on

Specify whether to use the displayed color of the scope when copying.

When you select **File > Copy to Clipboard**, the software changes the color of the scope to be printer friendly (white background, visible lines). If you want to copy and paste the scope with the colors displayed, select this check box.

Properties for line — Line to change

Channel 1 (default)

Select active line for setting line style properties.

Visible — Line visibility

on (default) | off

Show or hide a signal on the plot.

Dependency

The values of “Active display” on page 2-0 and “Properties for line” on page 2-0 determine which line is affected.

Line — Line style

solid line (default style) | 0.75 (default width) | yellow (default color)

Select line style, width, and color.

Dependency

The values of “Active display” on page 2-0 and “Properties for line” on page 2-0 determine which line is affected.

Marker — Data point marker style

None (default) | marker shape

Select marker shape.

Dependency

The values of “Active display” on page 2-0 and “Properties for line” on page 2-0 determine which line is affected.

Block Characteristics

Data Types	Boolean bus ^a double enumerated fixed point half integer single
Direct Feedthrough	no
Multidimensional Signals	yes
Variable-Size Signals	yes
Zero-Crossing Detection	no

a. Virtual bus not supported. Nonvirtual bus supported only in normal and accelerator mode simulation. Data logging for nonvirtual bus supported only in the dataset format

Tips

If you run your simulation for a long time, you may run into out-of-memory issues because the scope saves data. To limit the amount of data saved for scope visualization, use the Limit data points to last property.

Extended Capabilities**C/C++ Code Generation**

Generate C and C++ code using Simulink® Coder™.

This block can be used for simulation visibility in systems that generate code, but is not included in the generated code.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

This block can be used for simulation visibility in subsystems that generate HDL code, but is not included in the hardware implementation.

PLC Code Generation

Generate Structured Text code using Simulink® PLC Coder™.

This block can be used for simulation visibility in systems that generate code, but is not included in the generated code.

Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

This block accepts fixed-point input, but converts it to double for display.

Toeplitz

Generate matrix with Toeplitz symmetry

Library

Math Functions / Matrices and Linear Algebra / Matrix Operations

dspmtx3

Description

The Toeplitz block generates a Toeplitz matrix from inputs defining the first column and first row. The top input (*Col*) is a vector containing the values to be placed in the first *column* of the matrix, and the bottom input (*Row*) is a vector containing the values to be placed in the first *row* of the matrix.

```
y = toeplitz(Col,Row) % Equivalent MATLAB code
```

The other elements of the matrix obey the relationship

$$y(i,j) = y(i-1,j-1)$$

and the output has dimension $[\text{length}(\text{Col}) \ \text{length}(\text{Row})]$. The $y(1,1)$ element is inherited from the *Col* input. For example, the following inputs

```
Col = [1 2 3 4 5]
Row = [7 7 3 3 2 1 3]
```

produce the Toeplitz matrix

$$\begin{bmatrix} 1 & 7 & 3 & 3 & 2 & 1 & 3 \\ 2 & 1 & 7 & 3 & 3 & 2 & 1 \\ 3 & 2 & 1 & 7 & 3 & 3 & 2 \\ 4 & 3 & 2 & 1 & 7 & 3 & 3 \\ 5 & 4 & 3 & 2 & 1 & 7 & 3 \end{bmatrix}$$

When you select the **Symmetric** check box, the block generates a symmetric (Hermitian) Toeplitz matrix from a single input, *u*, defining both the first row and first column of the matrix.

```
y = toeplitz(u) % Equivalent MATLAB code
```

The output has dimension $[\text{length}(u) \ \text{length}(u)]$. For example, the Toeplitz matrix generated from the input vector $[1 \ 2 \ 3 \ 4]$ is

$$\begin{bmatrix} 1 & 2 & 3 & 4 \\ 2 & 1 & 2 & 3 \\ 3 & 2 & 1 & 2 \\ 4 & 3 & 2 & 1 \end{bmatrix}$$

The Toeplitz block supports real and complex floating-point and fixed-point inputs.

Parameters

Symmetric

When selected, enables the single-input configuration for symmetric Toeplitz matrix output.

Saturate on integer overflow

When you generate a symmetric Toeplitz matrix with this block, if the input vector is complex, the output is a symmetric Hermitian matrix whose elements satisfy the relationship

$$y(i, j) = \text{conj}(y(j, i))$$

For fixed-point signals the conjugate operation could result in an overflow. When you select this parameter, overflows saturate. This parameter is only visible with the **Symmetric** parameter is selected. This parameter is ignored for floating-point signals.

Supported Data Types

Port	Supported Data Types
Input	<ul style="list-style-type: none"> • Double-precision floating point • Single-precision floating point • Fixed point (signed and unsigned) • Boolean • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers (real signals only)
Toep Col	<ul style="list-style-type: none"> • Double-precision floating point • Single-precision floating point • Fixed point (signed and unsigned) • Boolean • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers
Toep Row	<ul style="list-style-type: none"> • Double-precision floating point • Single-precision floating point • Fixed point (signed and unsigned) • Boolean • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers

Port	Supported Data Types
Output	<ul style="list-style-type: none">• Double-precision floating point• Single-precision floating point• Fixed point (signed and unsigned)• Boolean• 8-, 16-, and 32-bit signed integers• 8-, 16-, and 32-bit unsigned integers

To Audio Device

Write audio data to computer's audio device

Compatibility

Note The To Audio Device block will be removed in a future release. Existing instances of the block continue to run. For new models, use the Audio Device Writer block instead.

Library

Sinks

dspsnks4

Description

The To Audio Device block sends audio data to your computer's audio device. This block is not supported for use with the Simulink Model block.

Use the **Device** parameter to specify the device to which you want to send the audio data. This parameter is automatically populated based on the audio devices installed on your system.

Select the **Inherit sample rate from input** check box if you want the block to inherit the sample rate of the audio signal from the input to the block. If you clear this check box, the **Sample rate (Hz)** parameter appears on the block. Use this parameter to specify the number of samples per second in the signal.

The range of supported audio device sample rates and data type formats, depend on both the sound card and the API which is chosen for the sound card.

Use the **Device data type** to specify the data type of the audio data that is sent to the device. You can choose:

- 8-bit integer
- 16-bit integer
- 24-bit integer
- 32-bit float
- Determine from input data type

If you choose Determine from input data type, the following table summarizes the block's behavior.

Input Data Type	Device Data Type
Double-precision floating point or single-precision floating point	32-bit floating point
32-bit integer	24-bit integer
16-bit integer	16-bit integer
8-bit integer	8-bit integer

If you choose **Determine** from **input data type** and the device does not support the input data type, the block uses the next lowest-precision data type supported by the device.

The generated code for this block relies on prebuilt .dll files. You can run this code outside the MATLAB environment, or redeploy it, but be sure to account for these extra .dll files when doing so. The packNGo function creates a single zip file containing all of the pieces required to run or rebuild this code. See packNGo for more information.

Buffering

The To Audio Device block buffers the data from a Simulink signal using the process illustrated by the following figure.

- 1 At the start of the simulation, the queue is filled with silence. Specify the size of this queue using the **Queue duration (seconds)** parameter. As Simulink runs, the block appends Simulink frames to the bottom of the queue.
- 2 At each time step, the blocks sends a buffer of samples from the top of the queue to the audio device. Select the **Automatically determine buffer size** check box to allow the block to use a conservative buffer size. See the From Audio Device block reference page for the equation the block uses to calculate this buffer size. If you clear this check box, the **Buffer size (samples)** parameter appears on the block. Use this parameter to specify the size of the buffer in samples.
- 3 The block writes the buffer of audio data to the device. If the queue did not contain enough data to completely fill the buffer, the block fills the remaining portion of the buffer with zeros. This data has a the data type specified by the **Device data type** parameter.

When the simulation throughput rate is lower than the hardware throughput rate, the queue, which is initially full, becomes empty. If the queue is empty, the block sends zeros (silence) to the audio device. You can monitor inserted zeroes using the optional **Under run** output port. When the simulation throughput rate is higher than the hardware throughput rate, the To Audio Device block waits to write data to the queue.

To minimize the chance of dropouts, the block checks to make sure the queue duration is at least as large as the maximum of the buffer size and the frame size. If it is not, the queue duration is automatically set to this maximum value.

Channel Mapping

The term Channel Mapping refers to a 1-to-1 mapping that associates channels on the selected audio device to channels of the data. When you play audio, channel mapping allows you to specify which channel of the audio device directs input to a specific channel of audio data. You can specify channel mapping as a vector of output channel indices corresponding to each output channel of data being written. The default value in the **Device Output Channels** parameter is 1:MAXOUTPUTCHANNELS. If you do not select the default mapping, you must specify the **Device Output Channels** parameter in the dialog box.

Example: The selected output audio device contains 8 channels. The data being output has dimensions $N \times 3$ (3-channel data). You want the output to be redirected as follows:

- First data channel to Audio Device channel 3
- Second data channel to Audio Device channel 1
- Third data channel to Audio Device channel 8

Thus, you would specify the **Device Output Channels** as [3 1 8].

Troubleshooting

Not Keeping Up in Real Time

When Simulink cannot keep up with an audio device that is operating in real time, the queue becomes empty and gaps occur in the audio data that the block sends to the device. Select the **Output number of samples by which the queue was underrun** check box to add an output port indicating when the queue was empty. Here are several ways to deal with this situation:

- *Increase the queue duration.*

The **Queue duration (seconds)** parameter specifies the duration of the signal, in seconds, that can be buffered during the simulation. This is the maximum length of time that the block's data supply can lag the hardware's data demand.

- *Increase the buffer size.*

The size of the buffer processed in each interrupt from the audio device affects the performance of your model. If the buffer is too small, a large portion of hardware resources are used to write data to the device. If the buffer is too big, Simulink must wait for the device to empty the buffer before it can write the data to the queue, which introduces latency.

- *Increase the simulation throughput rate.*

Two useful methods for improving simulation throughput rates are increasing the signal frame size and compiling the simulation into native code:

- Increase frame sizes and use frame-based processing throughout the model to reduce the amount of block-to-block communication overhead. This can increase throughput rates in many cases. However, larger frame sizes generally result in greater model latency due to initial buffering operations.
- Generate executable code with Simulink Coder code generation software. Native code runs much faster than Simulink and should provide rates adequate for real-time audio processing.

Other ways to improve throughput rates include simplifying the model and running the simulation on a faster PC processor. For other ideas on improving simulation performance, see “Delay and Latency” and “Optimize Performance” (Simulink).

Running an Executable Outside MATLAB

To run your generated standalone executable application in Shell, you need to set your environment to the following:

Platform	Command
Mac	<pre>setenv DYLD_LIBRARY_PATH \$LD_LIBRARY_PATH: \$MATLABROOT/bin/ maci64 (csh/tcsh) export DYLD_LIBRARY_PATH \$LD_LIBRARY_PATH: \$MATLABROOT/bin/ maci64 (Bash)</pre>
Linux	<pre>setenv LD_LIBRARY_PATH \$LD_LIBRARY_PATH: \$MATLABROOT/bin/ glnxa64 (csh/tcsh) export LD_LIBRARY_PATH \$LD_LIBRARY_PATH: \$MATLABROOT/bin/ glnxa64 (Bash)</pre>
Windows	<pre>set PATH = \$MATLABROOT\bin\win64;%PATH %</pre>

Channel-to-Speaker Mapping on Windows Operating Systems

The To Audio Device and From Audio Device blocks can support multiple channels. On Windows operating systems, the channel-to-speaker mapping is defined as listed below. This mapping only applies when your sound card is properly configured and capable of receiving the audio data you send. If the number of channels on the card does not match the number of channels on the block, or if you specify a data type for the **Device data type** parameter that is not supported by your device, the Windows mixer intervenes to translate from one format to another. If the Windows mixer does intervene, the channel-to-speaker mapping might differ from what is specified here.

- Single channel input — Front center speaker

On systems with two speakers, the front center channel is split between the right and left speakers.

- Multichannel input — Channels are assigned to speakers as follows:
 - One channel — Front center
 - Two channels — Front left, front right
 - Four channels — Front left, front right, rear left, rear right
 - Six channels — Front left, front right, front center, low frequency, rear left, rear right
 - Eight channels — Front left, front right, front center, low frequency, rear left, rear right, front left center, front right center
 - For all other channel combinations, the channel assignment is dictated by the audio card.

Audio Hardware API

The To Audio Device and From Audio Device blocks use the open-source PortAudio library in order to communicate with the audio hardware on a given computer. The PortAudio library supports a range of API's designed to communicate with the audio hardware on a given platform. The following API choices were made when building the PortAudio library for the DSP System Toolbox product:

- Windows: DirectSound, WDM-KS, ASIO
- Linux: ALSA, OSS
- Mac: CoreAudio

For Windows, the default is DirectSound, for Linux, the default is ALSA, and for Mac there is only one choice.

To determine the audio hardware API currently selected, type the following command in the MATLAB command prompt.

```
getpref('dsp','portaudioHostApi')
```

The output is a scalar indicating the choice of the API.

- 1 — DirectSound
- 3 — ASIO
- 7 — OSS
- 8 — ALSA
- 11 — WDM-KS

To select a particular API, type the following command in the MATLAB command prompt.

```
setpref('dsp','portaudioHostApi',N)
```

where N is a scalar. Choose N based on the API choice above.

Parameters

Device

Specify which device to send the audio data to.

Inherit sample rate from input

Select this check box if you want the block to inherit the sample rate of the audio signal from the input to the block.

Sample rate (Hz)

Specify the number of samples per second in the signal. This parameter is visible when the **Inherit sample rate from input** check box is cleared.

Device data type

Specify the data type of the audio data sent to the device.

Automatically determine buffer size

Select this check box to allow the block to calculate a conservative buffer size.

Buffer size (samples)

Specify the size of the buffer. This parameter is visible when the **Automatically determine buffer size** check box is cleared.

Queue duration (seconds)

Specify the size of the queue in seconds.

Use default mapping between Data and Device Output Channels

Select this check box to have the default mapping, where the data from the first channel of audio device is sent to the first channel of the input data, data from second channel of audio device is sent to second channel of data and so on. The maximum number of channels in the input data is determined by the **Number of channels** property.

Device Output Channels

Specify the channel mapping. This parameter is visible when the **Use default mapping between Device Input Channels and Data** check box is disabled.

Output number of samples by which the queue was underrun

Select this check box to output the number of zero samples inserted into the audio stream due to queue underrun since the last transfer of a frame to the audio device. You can use this value to debug throughput problems and adjust the queues and buffers in your model. To learn how to improve throughput, see “Troubleshooting” on page 2-1310.

Supported Data Types

Port	Supported Data Types
Input	<ul style="list-style-type: none"> • Double-precision floating point • Single-precision floating point • 32-bit signed integers • 16-bit signed integers • 8-bit unsigned integers
Underrun	32-bit unsigned integer

To Multimedia File

Stream video frames and audio samples to multimedia file

Library

Sinks

dspsnks4

Description

The To Multimedia File block writes video frames, audio samples, or both to a multimedia (.avi, .wav, .wma, .mp4, .ogg, .flac, or .wmv) file.

You can compress the video frames or audio samples by selecting a compression algorithm. You can connect as many of the input ports as you want. Therefore, you can control the type of video and/or audio the multimedia file receives.

Note This block supports code generation for platforms that have file I/O available. You cannot use this block with Simulink Desktop Real-Time software, because that product does not support file I/O.

This block performs best on platforms with Version 11 or later of Windows Media Player software. This block supports only uncompressed RGB24 AVI files on Linux and Mac platforms.

Windows 7 UAC (User Account Control), may require administrative privileges to encode WMV and WMA files.

The generated code for this block relies on prebuilt library files. You can run this code outside the MATLAB environment, or redeploy it, but be sure to account for these extra library files when doing so. The packNGo function creates a single zip file containing all of the pieces required to run or rebuild this code. See packNGo for more information.

To run an executable file that was generated from a model containing this block, you may need to add precompiled shared library files to your system path. See “Understanding C Code Generation in DSP System Toolbox” for details.

Cross-Platform Supported File Formats for Audio Files

Audio files can be of the following formats on all platforms:

- WAV
- FLAC

- OGG
- MPEG4 (only on Windows 7 and macOS)

The default format is WAV. This block supports MPEG-4 AAC audio files on Windows 7, and macOS. You can use both M4A and MP4 extensions. The following platform specific restrictions apply when writing these files:

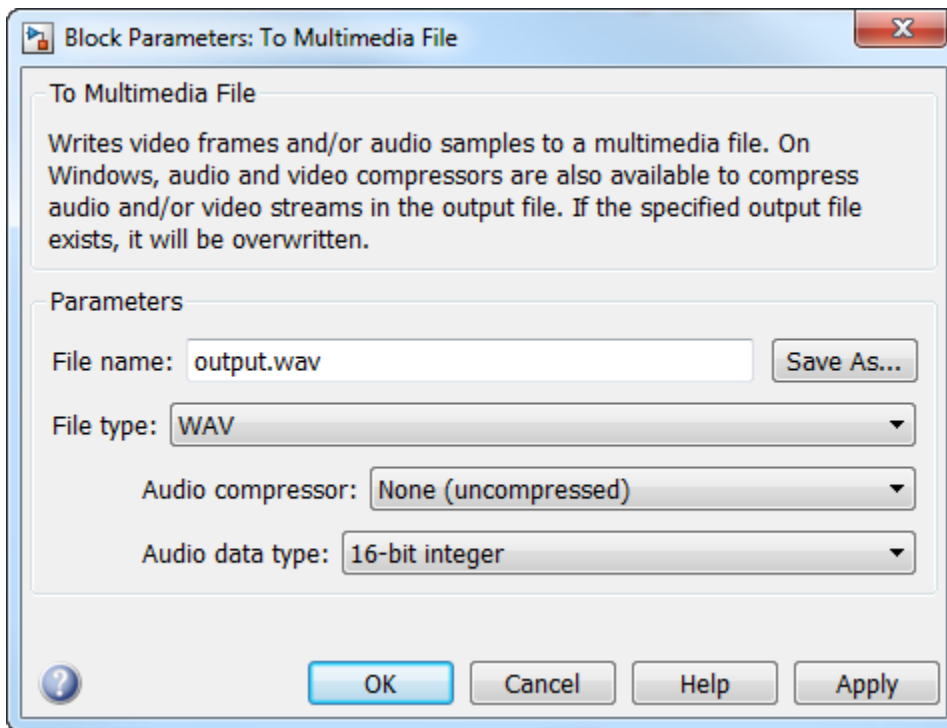

Windows 7	macOS
<ul style="list-style-type: none"> • Only sample rates of 44100 and 48000 Hz are supported. 	<ul style="list-style-type: none"> • Only mono or stereo outputs are allowed for MPEG-4 AAC file format. For all other formats, more than two audio output channels are allowed.
<ul style="list-style-type: none"> • Only mono or stereo outputs are allowed for MPEG-4 AAC file format. For all other formats, more than two audio output channels are allowed. 	
<ul style="list-style-type: none"> • The output data is padded on both the front and back of the signal, with extra samples of silence. <p>Windows AAC encoder places sharp fade-in and fade-out on audio signal, causing signal to be slightly longer in samples when written to disk.</p>	<ul style="list-style-type: none"> • Not all sampling rates are supported, although the Mac Audio Toolbox API do not explicitly specify a restriction.
<ul style="list-style-type: none"> • A minimum of 1025 samples per channel must be written to the MPEG-4 AAC file. 	

Ports

Port	Description
Image	M -by- N -by-3 matrix RGB, Intensity, or YCbCr 4:2:2 signal.
R, G, B	Matrix that represents one plane of the RGB video stream. Inputs to the R, G, or B port must have the same dimensions and data type.
Audio	M -by- N matrix. M is the number of samples in each channel, and N is the number of channels.
Y, Cb, Cr	Matrix that represents one frame of the YCbCr video stream. The Y, Cb, and Cr ports use the following dimensions: $Y: M \times N$ $Cb: M \times \frac{N}{2}$ $Cr: M \times \frac{N}{2}$

Dialog Box

The **Main** pane of the To Multimedia File block dialog appears as follows.

File name

Specify the name of the multimedia file. The block saves the file in your current folder. To specify a different file or location, click the **Save As...** button.

File type

Specify the file type of the multimedia file. You can select AVI, WAV, MJ2000, WMA, WMV, MPEG4, FLACC, or OGG. By default, the **File type** is set to WAV.

Write

Specify whether the block writes video frames, audio samples, or both to the multimedia file. You can select **Video and audio**, **Video only**, or **Audio only**. This parameter is visible only when you set **File type** to AVI, MPEG4, or OGG.

Audio compressor

Select the type of compression algorithm to use to compress the audio data. This compression reduces the size of the multimedia file. Choose **None (uncompressed)** to save uncompressed audio data to the multimedia file.

Note The other items available in this parameter list are the audio compression algorithms installed on your system. For information about a specific audio compressor, see the documentation for that compressor.

Audio data type

Select the audio data type. You can use the **Audio data type** parameter only for uncompressed wave files.

Video compressor

Select the type of compression algorithm to use to compress the video data. This compression reduces the size of the multimedia file. Choose **None (uncompressed)** to save uncompressed video data to the multimedia file.

Note The other items available in this parameter list are the video compression algorithms installed on your system. For information about a specific video compressor, see the documentation for that compressor.

Compression Factor (>1)

Specify the compression factor as an integer scalar greater than 1. This parameter is applicable only when the **File type** is set to MJ2000 and **Video compressor** is set to Lossy. By default, this parameter is set to 10.

File color format

Select the color format of the data stored in the file. You can select either RGB or YCbCr 4:2:2.

Image signal

Specify how the block accepts a color video signal. If you select **One multidimensional signal**, the block accepts an *M*-by-*N*-by-*P* color video signal, where *P* is the number of color planes, at one port. If you select **Separate color signals**, additional ports appear on the block. Each port accepts one *M*-by-*N* plane of an RGB video stream.

Video Quality (0-100)

Quality of the video specified as an integer scalar in the range [0 100]. This parameter is applicable only when **File name** is set to MPEG4 and **Write** is set to Video only. By default, this parameter is set to 75.

Troubleshooting**Running an Executable Outside MATLAB**

To run your generated standalone executable application in Shell, you need to set your environment to the following:

Platform	Command
Mac	<pre>setenv DYLD_LIBRARY_PATH "\$ {DYLD_LIBRARY_PATH}:\$MATLABROOT/bin/ maci64" (csh/tcsh) export DYLD_LIBRARY_PATH= \$DYLD_LIBRARY_PATH:\$MATLABROOT/bin/ maci64 (Bash)</pre> <p>For more information, see Append library path to "DYLD_LIBRARY_PATH" in MAC.</p>

Platform	Command
Linux	<pre>setenv LD_LIBRARY_PATH \$ {LD_LIBRARY_PATH}:\$MATLABROOT/bin/ glnxa64 (csh/tcsh) export LD_LIBRARY_PATH= \$LD_LIBRARY_PATH:\$MATLABROOT/bin/ glnxa64 (Bash)</pre>
Windows	<pre>set PATH=%PATH%;%MATLABROOT%\bin\win64</pre>

Supported Data Types

For the block to display video data properly, double- and single-precision floating-point pixel values must be between 0 and 1. Any other data type requires the pixel values between the minimum and maximum values supported by their data type.

Check the specific codecs you are using for supported audio rates.

Port	Supported Data Types	Supports Complex Values?
Image	<ul style="list-style-type: none"> • Double-precision floating point • Single-precision floating point • Boolean • 8-, 16- 32-bit signed integers • 8-, 16- 32-bit unsigned integers 	No
R, G, B	Same as Image port	No
Audio	<ul style="list-style-type: none"> • Double-precision floating point • Single-precision floating point • 16-bit signed integers • 32-bit signed integers • 8-bit unsigned integers 	No
Y, Cb, Cr	Same as Image port	No

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Usage notes and limitations:

- Host computer only. Excludes Simulink Desktop Real-Time code generation.
- The executable generated from this block relies on prebuilt dynamic library files (.dll files) included with MATLAB. Use the packNGo function to package the code generated from this block and all the relevant files in a compressed zip file. Using this zip file, you can relocate, unpack, and rebuild your project in another development environment where MATLAB is not installed. For more details, see “How To Run a Generated Executable Outside MATLAB”.

To Wave Device (Obsolete)

Send audio data to standard Windows audio device in real time

Library

dspwin32

Description

Note The To Wave Device block is still supported but is likely to be obsoleted in a future release. We strongly recommend replacing this block with the To Audio Device block.

The To Wave Device block sends audio data to a standard Windows audio device in real time. It is compatible with most popular Windows hardware, including Sound Blaster cards. The data is sent to the hardware in uncompressed pulse code modulation (PCM) format, and should typically be sampled at one of the standard Windows audio device rates: 8000, 11025, 22050, or 44100 Hz. Some hardware might support other rates in addition to these.

Note Models that contain both the To Wave Device block and the From Wave Device block require a duplex-capable sound card.

The **Use default audio device** check box allows the To Wave Device block to detect and use the system's default audio hardware. You should select this option for systems that have a single sound device installed, or when the default sound device on a multiple-device system is your desired target. When the default sound device is *not* your desired output device, clear **Use default audio device**, and set the desired hardware in the **Audio device** parameter. This parameter lists the names of the installed audio devices.

The block input can contain audio data from a mono or stereo signal. A mono signal is represented as either a sample-based scalar or a frame-based length- M vector, where M is frame size. A stereo signal is represented as a sample-based length-2 vector or a frame-based M -by-2 matrix.

When the input data type is `uint8`, the block conveys the signal samples to the audio device using 8 bits. When the input data type is `double`, `single`, `int16`, or fixed point with a word length of 16 and a fraction length of 15, the block conveys the signal samples to the audio device using 16 bits by default. For inputs of data type `double` and `single`, you can also set the block to convey the signal samples using 24 bits by selecting the **Enable 24-bit output for double- and single-precision input signals** check box. The 24-bit sample width requires more memory but in general yields better fidelity.

The amplitude of the input must be in a valid range that depends on the input data type, as shown in the following table. Amplitudes outside the valid range are clipped to the nearest allowable value.

Input Data Type	Valid Input Amplitude Range
double	$-1 \leq \textit{amplitude} < 1$
single	$-1 \leq \textit{amplitude} < 1$
int16	$-32768 \leq \textit{amplitude} \leq 32767$
uint8	$0 \leq \textit{amplitude} \leq 255$
Fixed point with a word length of 16 and a fraction length of 15	$-1 \leq \textit{amplitude} \leq 1 - 2^{-15}$

Buffering

Because audio devices generate real-time audio output, the Simulink environment must maintain a continuous flow of data to a device throughout simulation. Delays in passing data to the audio hardware can result in hardware errors or distortion of the output. This means that the To Wave Device block must in principle supply data to the audio hardware as quickly as the hardware reads the data. However, the To Wave Device block often *cannot* match the throughput rate of the audio hardware, especially when the simulation is running within Simulink rather than as generated code. Simulink execution speed can vary during the simulation as the host operating system services other processes. The block must therefore rely on a buffering strategy to ensure that signal data is available to the hardware on demand.

Note This block requires real-time execution of the parent model for best performance.

The following block parameters control the memory management for this block:

- **Queue duration**
- **Automatically determine internal buffer size** or **User-defined internal buffer size**
- **Initial output delay**

The **Queue duration** parameter defines the overall size of the block's buffer. The block reads in chunks of data in the size of the input dimensions and stores them in the buffer. The internal buffer size defines the dimensions of the block output to the hardware. You can define the internal buffer size yourself in the **User-defined internal buffer size parameter**. If you select **Automatically determine internal buffer size** instead, the internal buffer size is calculated for you according to the following rules:

- If the input to the block has a frame size of 32 samples or larger, the internal buffer size be the same as the input frame size.
- If the input to the block has a frame size smaller than 32 samples, the internal buffer size is based on the input sample rate according to the following table, where

$$F_s = \textit{samplingfrequency} = \frac{1}{\textit{samptime}}$$

F_s (Hz)	Internal Buffer Size (samples)
$F_s < 8000$	$\min(64, 2 * F_s)$
$8000 \leq F_s < 22,050$	128
$22,050 \leq F_s < 44,100$	256
$44,100 \leq F_s < 96,000$	512
$F_s \geq 96,000$	1024

To minimize the chance of dropouts, the block checks to make sure that the queue duration is at least as big as twice the internal buffer size. If it is not, the queue duration is automatically set to twice the internal buffer size.

The **Initial output delay** parameter enables you to preload the buffer before the block starts to output data to the audio device, which can be helpful for models that do not run in real time. However, for real-time applications, it is best to set the initial output delay to zero (one frame of delay), or as close to zero as possible.

Troubleshooting

If you are getting undesirable audio output using the To Wave Device block, first determine whether your model can run in real time. Replace the To Wave Device block with a To Wave File block, run the model, and compare the model's simulation stop time to the elapsed time on your watch. If the model simulation stop time is less than the elapsed time on your watch, your model can probably run in real time. Then,

- If your model can run in real time,
 - 1 Select **Automatically determine internal buffer size**. This alone might solve the problem. If not,
 - 2 Try increasing the **Queue duration** parameter to a relatively large value, such as 0.5 s.

If one or both of these options restores desirable audio output, you can try reducing the internal buffer size and/or queue duration until the quality of the audio output again degrades.

- If your model is not running in real time, try to make it run in real time by
 - 1 Optimizing the model (using a more efficient implementation), or
 - 2 Using a Simulink "Acceleration" (Simulink) mode, or
 - 3 Generating stand-alone code

If none of these are possible, but the model only runs for a short period of time, set the **Queue duration** parameter to a size equal to a significant fraction of the model stop time and use a similarly large initial delay. This is not an optimal solution, but might work in some cases.

Parameters

Queue duration (seconds)

Specify the overall buffer size. To minimize the chance of dropouts, the block checks to make sure that the queue duration is at least as large as twice the internal buffer size. If it is not, the queue duration is automatically set to twice the internal buffer size.

Automatically determine internal buffer size

Select to have the block automatically select the internal buffer size for you. For details, see “Buffering” on page 2-1321.

User-defined internal buffer size (samples)

Define the internal buffer size, or the size of the chunks of data sent by the block to the audio hardware device.

This parameter is only visible when **Automatically determine internal buffer size** is not selected.

Initial output delay (seconds)

Specify the amount of time by which to delay the initial output to the audio device. During this time data accumulates in the block's buffer. Any value less than or equal to the queue duration specifies the smallest possible initial delay, which is a single frame.

Use default audio device

Select to direct audio output to the system's default audio device.

Audio device

This parameter lists the names of the installed audio devices. Specify the name of the audio device to receive the audio output. Select **Use default audio device** when the system has only a single audio card installed.

This parameter is only enabled when the **Use default audio device** check box is not selected.

Enable 24-bit output for double and single precision input signals

Select to output 24-bit data when inputs are double- or single-precision. Otherwise, the block outputs 16-bit data for double- and single-precision inputs.

Supported Data Types

Port	Supported Data Types
Input	<ul style="list-style-type: none"> • Double-precision floating point • Single-precision floating point • Signed fixed point with a word length of 16 and a fraction length of 15 • 16-bit signed integers • 8-bit unsigned integers

To Wave File (Obsolete)

Write audio data to file in Microsoft Wave (.wav) format

Library

dspwin32

Description

Note The To Wave File block is still supported but is likely to be obsoleted in a future release. We strongly recommend replacing this block with the To Multimedia File block.

The To Wave File block streams audio data to a Microsoft Wave (.wav) file in the uncompressed pulse code modulation (PCM) format. For compatibility reasons, the sample rate of the discrete-time input signal should typically be one of the standard Windows audio device rates (8000, 11025, 22050, or 44100 Hz), although the block supports arbitrary rates.

The input to the block, u , can contain audio data with one or more channels. A signal with C channels is represented as a sample-based length- C vector or a frame-based M -by- C matrix. The amplitude of the input should be in the range ± 1 . Values outside this range are clipped to the nearest allowable value.

```
wavwrite(u,Fs,bits,'filename')    % Equivalent MATLAB code
```

Note AVI files are the only supported file type for non-Windows platforms.

Parameters

File name

Specify the path and name of the file to write. Paths can be relative or absolute. You do not need to specify the .wav extension.

Sample width (bits)

Specify the number of bits used to represent the signal samples in the file. The higher sample width settings require more memory but yield better fidelity for double- and single-precision inputs:

- 8 — Allocates 8 bits to each sample, allowing a resolution of 256 levels
- 16 — Allocates 16 bits to each sample, allowing a resolution of 65536 levels
- 24 — Allocates 24 bits to each sample, allowing a resolution of 16777216 levels

- 32 — Allocates 32 bits to each sample, allowing a resolution of 2^{32} levels ranging from -1 to 1

The 8-, 16-, and 24-bit modes output integer data, while the 32-bit mode outputs single-precision floating-point data.

Minimum number of samples for each write to file

Specify the number of consecutive samples, L , to write with each file access. To reduce the required number of file accesses, the block writes L consecutive samples to the file during each access for $L \geq M$. For $L < M$, the block instead writes M consecutive samples during each access. Larger values of L result in fewer file accesses, which reduces run-time overhead.

Supported Data Types

Port	Supported Data Types
Input	<ul style="list-style-type: none"> • Double-precision floating point • Single-precision floating point • Signed fixed point with a word length of 16 and a fraction length of 15 • 16-bit signed integers • 8-bit unsigned integers

Introduced in R2010a

Triggered Delay Line (Obsolete)

Buffer sequence of inputs into frame-based output

Library

dspobslib

Description

Note The Triggered Delay Line block is still supported but is likely to be obsoleted in a future release. We strongly recommend replacing this block with the Delay Line block.

The Triggered Delay Line block acquires a collection of M_o input samples into a frame, where you specify M_o in the **Delay line size** parameter. The block buffers a single sample from input 1 whenever it is triggered by the control signal at input 2 (⚡). When the next triggering event occurs, the newly acquired input sample is appended to the output frame so that the new output overlaps the previous output by M_o-1 samples. Between triggering events the block ignores input 1 and holds the output at its last value.

You specify the triggering event at input 2 in the **Trigger type** pop-up menu:

- **Rising edge** triggers execution of the block when the trigger input rises from a negative value to zero or a positive value, or from zero to a positive value.
- **Falling edge** triggers execution of the block when the trigger input falls from a positive value to zero or a negative value, or from zero to a negative value.
- **Either edge** triggers execution of the block when either a rising or falling edge (as described above) occurs.

The Triggered Delay Line block has zero latency, so the new input appears at the output in the same simulation time step. The output frame period is the same as the input sample period, $T_{fo}=T_{si}$.

Sample-Based Operation

In sample-based operation, the Triggered Delay Line block buffers a sequence of sample-based length- N vector inputs (1-D, row, or column) into a sequence of overlapping sample-based M_o -by- N matrix outputs, where you specify M_o in the **Delay line size** parameter ($M_o>1$). That is, each input vector becomes a *row* in the sample-based output matrix. When $M_o=1$, the input is simply passed through to the output, and retains the same dimension. Sample-based full-dimension matrix inputs are not accepted.

Frame-Based Operation

In frame-based operation, the Triggered Delay Line block rebuffers a sequence of frame-based M_f -by- N matrix inputs into an sequence of overlapping frame-based M_o -by- N matrix outputs, where M_o is

the output frame size specified by the **Delay line size** parameter (that is, the number of consecutive samples from the input frame to rebuffer into the output frame). M_o can be greater or less than the input frame size, M_i . Each of the N input channels is rebuffered independently.

Initial Conditions

The Triggered Delay Line block's buffer is initialized to the value specified by the **Initial condition** parameter. The block always outputs this buffer at the first simulation step ($t=0$). When the block's output is a vector, the **Initial condition** can be a vector of the same size or a scalar value to be repeated across all elements of the initial output. When the block's output is a matrix, the **Initial condition** can be a matrix of the same size or a scalar to be repeated across all elements of the initial output.

Parameters

Trigger type

The type of event that triggers the block's execution.

Delay line size

The length of the output frame (number of rows in output matrix), M_o .

Initial condition

The value of the block's initial output, a scalar, vector, or matrix.

Supported Data Types

Port	Supported Data Types
Input	<ul style="list-style-type: none"> • Double-precision floating point • Single-precision floating point • Fixed point (signed and unsigned) • Boolean • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers
Trigger	<ul style="list-style-type: none"> • Any data type supported by the Trigger block
Output	<ul style="list-style-type: none"> • Double-precision floating point • Single-precision floating point • Fixed point (signed and unsigned) • Boolean • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers

Triggered Signal From Workspace

Import signal samples from MATLAB workspace when triggered

Library: DSP System Toolbox / Signal Operations

Description

The Triggered Signal From Workspace block imports signal samples from the MATLAB workspace into the Simulink model when triggered by the control signal at the input port (⚡). The **Signal** parameter specifies the name of a MATLAB workspace variable containing the signal to import, or any valid MATLAB expression defining a matrix or 3-D array.

Ports

Input

trigger — Trigger signal

scalar | vector | matrix

Triggering input signal, specified as a scalar, vector, or matrix. This port is labelled with ⚡.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point

Output

Port_1 — Signal imported from workspace

scalar | vector | matrix | 3-D array

The block outputs the signal imported from the workspace when triggered by the control signal at the input port.

When the **Signal** parameter specifies an M -by- N matrix ($M \neq 1$), each of the N columns is treated as a distinct channel. You specify the frame size in the **Samples per frame** parameter, M_0 . When triggered, the block outputs an M_0 -by- N matrix containing M_0 consecutive samples from each signal channel. For convenience, an imported row vector ($M=1$) is treated as a single channel, so the output dimension is M_0 -by-1.

When the **Signal** parameter specifies an M -by- N -by- P array, the block generates a single page of the array (an M -by- N matrix) at each trigger time. The **Samples per frame** parameter must be set to 1.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point

Parameters

Signal — Signal to import

1:10 (default) | MATLAB workspace variable | MATLAB expression

The name of the MATLAB workspace variable from which to import the signal, or a valid MATLAB expression specifying the signal.

When the **Signal** parameter specifies an M -by- N matrix ($M \neq 1$), each of the N columns is treated as a distinct channel. You specify the frame size in the **Samples per frame** parameter, M_0 . When triggered, the block outputs an M_0 -by- N matrix containing M_0 consecutive samples from each signal channel. For convenience, an imported row vector ($M=1$) is treated as a single channel, so the output dimension is M_0 -by-1.

When the **Signal** parameter specifies an M -by- N -by- P array, the block generates a single page of the array (an M -by- N matrix) at each trigger time. The **Samples per frame** parameter must be set to 1.

Trigger type — Type of triggering event

Rising edge (default) | Falling edge | Either edge

The type of event that triggers the block to execute.

- **Rising edge** triggers execution of the block when the trigger input rises from a negative value to zero or a positive value, or from zero to a positive value.
- **Falling edge** triggers execution of the block when the trigger input falls from a positive value to zero or a negative value, or from zero to a negative value.
- **Either edge** triggers execution of the block when either a rising or falling edge occurs.

Initial output — Initial output value

0 (default) | scalar | vector | matrix

The value to output until the first trigger event is received. Between trigger events, the block holds the output value constant at its most recent value (that is, no linear interpolation takes place). For single-channel signals, the **Initial output** can be a vector of length M_0 or a scalar to repeat across the M_0 elements of the initial output frames. For matrix outputs (M_0 -by- N or M -by- N), the **Initial output** parameter value can be a matrix of the same size or a scalar to be repeated across all elements of the initial output.

Samples per frame — Samples per frame

1 (default) | positive integer

The number of samples, M_0 , to buffer into each output frame specified as a positive integer scalar. This value must be 1 when you specify a 3-D array in the **Signal** parameter.

Form output after final data value by — Values to output after final imported signal value

Setting to zero (default) | Holding final value | Cyclic repetition

Specifies the output after all of the specified signal samples have been generated.

- When you specify **Setting To Zero**, the block generates zero-valued outputs for the duration of the simulation after generating the last frame of the signal.
- When you specify **Holding Final Value**, the block repeats the final sample for the duration of the simulation after generating the last frame of the signal.
- When you specify **Cyclic Repetition**, the block repeats the signal from the beginning after generating the last frame. When there are not enough samples at the end of the signal to fill the final frame, the block zero-pads the final frame as necessary to ensure that the output for each cycle is identical. For example, the i th frame of one cycle contains the same samples as the i th frame of any other cycle.

The block does not extrapolate the imported signal beyond the last sample.

Block Characteristics

Data Types	double fixed point integer single
Direct Feedthrough	no
Multidimensional Signals	no
Variable-Size Signals	no
Zero-Crossing Detection	no

Blocks

Signal From Workspace | To Workspace | Triggered To Workspace

Introduced before R2006a

Triggered To Workspace

Write input sample to MATLAB workspace when triggered

Library

Sinks

dspsnks4

Description

The Triggered To Workspace block creates a matrix or array variable in the MATLAB workspace, where it stores the acquired inputs at the end of a simulation. The block overwrites an existing variable with the same name.

When you set the **Save 2-D signals as** parameter to 2-D array (concatenate along first dimension, the block saves an M -by- N input as a P -by- N matrix, where P is the **Maximum number of rows** parameter. When the simulation progresses long enough for the block to acquire more than P samples, the block stores only the most recent P samples. The **Decimation factor**, D , allows you to store only every D th input matrix.

When you set the **Save 2-D signals as** parameter to 3-D array (concatenate along third dimension, the block saves an M -by- N input as a three-dimensional array in which each M -by- N page represents a single sample from each of the $M*N$ channels (the most recent input matrix occupies the last page). The maximum size of this variable is limited to M -by- N -by- P , where P is the **Maximum number of rows** parameter. When the simulation progresses long enough for the block to acquire more than P inputs, it stores only the last P inputs. The **Decimation factor**, D , allows you to store only every D th input matrix.

The block acquires and buffers a single frame from input 1 whenever it is triggered by the control signal at input 2 (↗). At all other times, the block ignores input 1. You specify the triggering event at input 2 in the **Trigger type** pop-up menu:

- **Rising edge** triggers execution of the block when the trigger input rises from a negative value to zero or a positive value, or from zero to a positive value.
- **Falling edge** triggers execution of the block when the trigger input falls from a positive value to zero or a negative value, or from zero to a negative value.
- **Either edge** triggers execution of the block when either a rising or falling edge (as described above) occurs.

To save a record of the sample time corresponding to each sample value, open the Configuration Parameters dialog box. In the **Select** pane, click **Data Import/Export** and select the **Time** check box.

The nontriggered version of this block is the To Workspace block.

Parameters

Trigger type

The type of event that triggers the block's execution.

Variable name

The name of the workspace variable in which to store the data.

Maximum number of rows

The maximum number of rows (one row per time step) to be saved, P .

Decimation

The decimation factor, D .

Save 2-D signals as

Specify whether the block saves 2-D signals as a 2-D or 3-D array in the MATLAB workspace:

- **2-D array (concatenate along first dimension)** — When you select this option, the block vertically concatenates each M -by- N matrix input with the previous input to produce a 2-D output array.
- **3-D array (concatenate along third dimension)** — When you select this option, the block saves an M -by- N input signal as a 3-D array. The maximum size of this 3-D array is limited to M -by- N -by- P , where P is the **Maximum number of rows** parameter. When the simulation progresses long enough for the block to acquire more than P inputs, the block stores only the last P inputs. The **Decimation factor**, D , allows you to store only every D th input matrix.

Log fixed-point data as a fi object

Select to log fixed-point data to the MATLAB workspace as a Fixed-Point Designer `fi` object. Otherwise, fixed-point data is logged to the workspace as `double`.

Supported Data Types

Port	Supported Data Types
Input	• Any data type supported by the To Workspace block
Trigger	• Any data type supported by the Trigger block

Two-Channel Analysis Subband Filter

Decompose signal into high-frequency and low-frequency subbands

Library

Filtering / Multirate Filters

dspmlti4

Description

The Two-Channel Analysis Subband Filter block decomposes the input into high-frequency and low-frequency subbands, each with half the bandwidth and half the sample rate of the input.

The block filters the input with a pair of highpass and lowpass FIR filters, and then downsamples the results by 2, as illustrated in the following figure.

The block implements the FIR filtering and downsampling steps together using a polyphase filter structure, which is more efficient than the straightforward filter-then-decimate algorithm shown in the preceding figure. Each subband is the first phase of the respective polyphase filter. You can implement a multilevel dyadic analysis filter bank by connecting multiple copies of this block or by using the Dyadic Analysis Filter Bank block. See “Creating Multilevel Dyadic Analysis Filter Banks” on page 2-1337 for more information.

You must provide a vector of filter coefficients for the lowpass and highpass FIR filters. Each filter should be a half-band filter that passes the frequency band that the other filter stops.

See the following topics for more information about this block:

- “Specifying the FIR Filters” on page 2-1335
- “Frame-Based Processing” on page 2-1336
- “Sample-Based Processing” on page 2-1336
- “Latency” on page 2-1336
- “Creating Multilevel Dyadic Analysis Filter Banks” on page 2-1337

Specifying the FIR Filters

You must provide the vector of numerator coefficients for the lowpass and highpass filters in the **Lowpass FIR filter coefficients** and **Highpass FIR filter coefficients** parameters.

For example, to specify a filter with the following transfer function, enter the vector $[b(1) \ b(2) \ \dots \ b(m)]$.

$$H(z) = B(z) = b_1 + b_2z^{-1} + \dots + b_mz^{-(m-1)}$$

Each filter should be a half-band filter that passes the frequency band that the other filter stops. You can use the Two-Channel Synthesis Subband Filter block to reconstruct the input to this block. To do so, you must design perfect reconstruction filters to use in the synthesis subband filter.

The best way to design perfect reconstruction filters is to use the Wavelet Toolbox `wfilters` function in to design both the filters both in this block and in the Two-Channel Synthesis Subband Filter block. You can also use other DSP System Toolbox and Signal Processing Toolbox functions.

The Two-Channel Analysis Subband Filter block initializes all filter states to zero.

Frame-Based Processing

When you set the **Input processing** parameter to `Columns as channels (frame based)`, the block accepts an M -by- N matrix. The block treats each column of the input as the high- or low-frequency subbands of the corresponding output channel. You can use the **Rate options** parameter to specify how the block resamples the input:

- When you set the **Rate options** parameter to `Enforce single-rate processing`, the input to the block can be an M -by- N matrix, where M is a multiple of two. The block treats each column of the input as an independent channel and decomposes each channel over time. The block outputs two matrices, where each column of the output is the high- or low-frequency subband of the corresponding input column. To maintain the input sample rate, the block decreases the output frame size by a factor of two.
- When you set the **Rate options** parameter to `Allow multirate processing`, the block treats an M_i -by- N matrix input as N independent channels and decomposes each channel over time. The block outputs two M -by- N matrices, where each column of the output is the high- or low-frequency subband of the corresponding input column. The input and output frame sizes are the same, but the frame rate of the output is half that of the input. Thus, the overall sample rate of the output is half that of the input.

In this mode, the block has one frame of latency, as described in the “Latency” on page 2-1336 section.

Sample-Based Processing

When you set the **Input processing** parameter to `Elements as channels (sample based)`, the block treats an M -by- N matrix input as $M \cdot N$ independent channels. The block decomposes each channel over time and outputs two M -by- N matrices whose sample rates are half the input sample rate. Each element in the output matrix is the high- or low-frequency subband output of the corresponding element of the input matrix.

Depending on the setting of your Simulink configuration parameters, the output may have one sample of latency, as described in the “Latency” on page 2-1336 section.

Latency

When you set the **Input processing** parameter to `Columns as channels (frame based)` and the **Rate options** parameter to `Enforce single-rate processing`, the Two-Channel Analysis

Subband Filter block always has zero-tasking latency. Zero-tasking latency means that the block propagates the first input sample (received at time $t=0$) as the first output sample.

When you set the **Rate options** parameter to `Allow multirate processing`, the Two-Channel Analysis Subband Filter block may exhibit latency. The amount of latency depends on the setting of the **Input processing** parameter of this block, and the setting of the Simulink **Treat each discrete rate as a separate task** configuration parameter. The following table summarizes the conditions that produce latency when the block is performing multirate processing.

Input processing	Treat each discrete rate as a separate task	Latency
Elements as channels (sample based)	Off	None.
	On	One sample. The first output sample in each channel always has a value of 0.
Columns as channels (frame based)	On or Off	One frame. All samples in the first output frame have a value of 0.

Note For more information on latency and the Simulink tasking modes, see “Excess Algorithmic Delay (Tasking Latency)” and “Time-Based Scheduling and Code Generation” (Simulink Coder).

Creating Multilevel Dyadic Analysis Filter Banks

The Two-Channel Analysis Subband Filter block is the basic unit of a dyadic analysis filter bank. You can connect several of these blocks to implement an n -level filter bank, as illustrated in the following figure. For a review of dyadic analysis filter banks, see the Dyadic Analysis Filter Bank block reference page.

When you create a filter bank by connecting multiple copies of this block, the output values of the filter bank differ depending on whether there is latency. Though the output values differ, both sets of values are valid; the difference arises from changes in latency. See the “Latency” on page 2-1336 section for more information about when latency can occur in the Two-Channel Analysis Subband Filter block.

In some cases, rather than connecting several Two-Channel Analysis Subband Filter blocks, you can use the Dyadic Analysis Filter Bank block, which is faster and requires less memory. In particular, the Dyadic Analysis Filter Bank block is more efficient under the following conditions:

- The frame size of the signal you are decomposing is a multiple of 2^n .
- You are decomposing the signal into $n+1$ or 2^n subbands.

In all other cases, use Two-Channel Analysis Subband Filter blocks to implement your filter banks.

3-Level Dyadic Analysis Filter Banks

Conceptual illustration

Two-Channel Analysis Subband Filter block implementation

Both implementations of the dyadic analysis filter bank decompose a frame-based signal with frame size a multiple of 2^n into $n+1$ subbands, where $n = 3$.
 In this case, the Dyadic Analysis Filter Bank block's implementation is more efficient.
 Use the Two-Channel Analysis Subband Filter block implementation for other cases, such as to handle sample-based inputs, or to handle frame-based inputs whose frame size is not a multiple of 2^n .

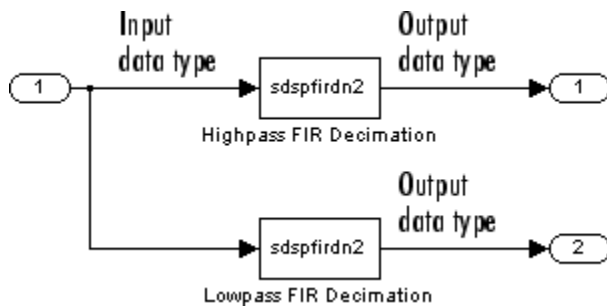

Dyadic Analysis Filter Bank block implementation

The Dyadic Analysis Filter Bank block allows you to specify the filter bank filters by providing vectors of filter coefficients, just as this block does. The Dyadic Analysis Filter Bank block provides an additional option of using wavelet-based filters that the block designs by using a wavelet you specify.

Fixed-Point Data Types

The Two-Channel Analysis Subband Filter Bank block is composed of two FIR Decimation blocks as shown in the following diagram.

For fixed-point signals, you can set the coefficient, product output, accumulator, and output data types of the FIR Decimation blocks as discussed in "Parameters" on page 2-1338. For a diagram showing the usage of these data types, see the FIR Decimation block reference page.

Parameters

Main Tab

Lowpass FIR filter coefficients

Specify a vector of lowpass FIR filter coefficients, in descending powers of z . The lowpass filter should be a half-band filter that passes the frequency band stopped by the filter specified in the **Highpass FIR filter coefficients** parameter. The default values of this parameter specify a filter

based on a third-order Daubechies wavelet. When you use the Two-Channel Synthesis Subband Filter block to reconstruct the input to this block, you need to design perfect reconstruction filters to use in the synthesis subband filter. For more information, see “Specifying the FIR Filters” on page 2-1335.

Highpass FIR filter coefficients

Specify a vector of highpass FIR filter coefficients, in descending powers of z . The highpass filter should be a half-band filter that passes the frequency band stopped by the filter specified in the **Lowpass FIR filter coefficients** parameter. The default values of this parameter specify a filter based on a third-order Daubechies wavelet. When you use the Two-Channel Synthesis Subband Filter block to reconstruct the input to this block, you need to design perfect reconstruction filters to use in the synthesis subband filter. For more information, see “Specifying the FIR Filters” on page 2-1335.

Input processing

Specify how the block should process the input. You can set this parameter to one of the following options:

- **Columns as channels (frame based)** (default) — When you select this option, the block treats each column of the input as a separate channel.
- **Elements as channels (sample based)** — When you select this option, the block treats each element of the input as a separate channel.

Rate options

Specify the rate processing rule for the block. You can set this parameter to one of the following options:

- **Enforce single-rate processing** — When you select this option, the block treats each column of the input as an independent channel and decomposes each channel over time. The output has the same sample rate as the input, but the output frame size is half that of the input frame size. To select this option, you must set the **Input processing** parameter to **Columns as channels (frame based)**.
- **Allow multirate processing** — When you select this option, the input and output of the block are the same size, but the sample rate of the output is half that of the input.

Some settings of this parameter cause the block to have nonzero latency. See “Latency” on page 2-1336 for more information.

Data Types Tab

Rounding mode

Select the rounding mode for fixed-point operations. The filter coefficients do not obey this parameter; they are always rounded to **Nearest**.

Note The **Rounding mode** and **Saturate on integer overflow** settings have no effect on numerical results when all the following conditions exist:

- **Product output** is **Inherit**: **Inherit via internal rule**
- **Accumulator** is **Inherit**: **Inherit via internal rule**
- **Output** is **Inherit**: **Same as accumulator**

With these data type settings, the block is effectively operating in full precision mode.

Saturate on integer overflow

When you select this parameter, the block saturates the result of its fixed-point operation. When you clear this parameter, the block wraps the result of its fixed-point operation. For details on saturate and wrap, see overflow mode for fixed-point operations.

Note The **Rounding mode** and **Saturate on integer overflow** parameters have no effect on numeric results when all these conditions are met:

- **Product output** data type is `Inherit: Inherit via internal rule`.
- **Accumulator** data type is `Inherit: Inherit via internal rule`.

With these data type settings, the block operates in full-precision mode.

Coefficients

Specify the coefficients data type. See “Fixed-Point Data Types” on page 2-1338 and “Multiplication Data Types” for illustrations depicting the use of the coefficients data type in this block. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Same word length as input`
- An expression that evaluates to a valid data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the **Coefficients** parameter.

See “Specify Data Types Using Data Type Assistant” (Simulink) in *Simulink User's Guide* (Simulink) for more information.

Coefficients Minimum

Specify the minimum value of the filter coefficients. The default value is [] (unspecified). Simulink software uses this value to perform:

- Automatic scaling of fixed-point data types

Coefficients Maximum

Specify the maximum value of the filter coefficients. The default value is [] (unspecified). Simulink software uses this value to perform:

- Automatic scaling of fixed-point data types

Product output

Specify the product output data type. See “Fixed-Point Data Types” on page 2-1338 and “Multiplication Data Types” for illustrations depicting the use of the product output data type in this block. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Inherit via internal rule`. For more information on this rule, see “Inherit via Internal Rule”.

Note The actual product output word length may be equal to or greater than the calculated ideal product output word length, depending on the settings on the **Hardware Implementation** pane of the Configuration Parameters dialog box.

- An expression that evaluates to a valid data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the **Product output** parameter.

See “Specify Data Types Using Data Type Assistant” (Simulink) in *Simulink User's Guide* (Simulink) for more information.

Accumulator

Specify the accumulator data type. See “Fixed-Point Data Types” on page 2-1338 for illustrations depicting the use of the accumulator data type in this block. You can set this parameter to:

- A rule that inherits a data type, for example, `Inherit: Inherit via internal rule`. For more information on this rule, see “Inherit via Internal Rule”.
- An expression that evaluates to a valid data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the **Accumulator** parameter.

See “Specify Data Types Using Data Type Assistant” (Simulink) in *Simulink User's Guide* (Simulink) for more information.

Output

Specify the output data type. See “Fixed-Point Data Types” on page 2-1338 for illustrations depicting the use of the output data type in this block. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Same as accumulator`
- An expression that evaluates to a valid data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the **Output** parameter.

See “Control Data Types of Signals” (Simulink) in *Simulink User's Guide* (Simulink) for more information.

Output Minimum

Specify the minimum value that the block should output. The default value is `[]` (unspecified). Simulink software uses this value to perform:

- Simulation range checking (see “Specify Signal Ranges” (Simulink))
- Automatic scaling of fixed-point data types

Output Maximum

Specify the maximum value that the block should output. The default value is `[]` (unspecified). Simulink software uses this value to perform:

- Simulation range checking (see “Specify Signal Ranges” (Simulink))
- Automatic scaling of fixed-point data types

Lock data type settings against changes by the fixed-point tools

Select this parameter to prevent the fixed-point tools from overriding the data types you specify on the block mask.

Supported Data Types

- Double-precision floating point
- Single-precision floating point
- Fixed point (signed only)
- 8-, 16-, and 32-bit signed integers

Two-Channel Synthesis Subband Filter

Reconstruct signal from high-frequency and low-frequency subbands

Library

Filtering / Multirate Filters

`dspmlti4`

Description

The Two-Channel Synthesis Subband Filter block reconstructs a signal from its high-frequency and low-frequency subbands, each with half the bandwidth and half the sample rate of the original signal. Use this block to reconstruct signals decomposed by the Two-Channel Analysis Subband Filter block.

The block upsamples the high- and low-frequency subbands by 2, and then filters the results with a pair of highpass and lowpass FIR filters, as illustrated in the following figure.

The block implements the FIR filtering and downsampling steps together using a polyphase filter structure, which is more efficient than the straightforward interpolate-then-filter algorithm shown in the preceding figure. You can implement a multilevel dyadic synthesis filter bank by connecting multiple copies of this block or by using the Dyadic Synthesis Filter Bank block. For more information, see “Creating Multilevel Dyadic Synthesis Filter Banks” on page 2-1345.

You must provide a vector of filter coefficients for the lowpass and highpass FIR filters. Each filter should be a half-band filter that passes the frequency band that the other filter stops. You can use this block to reconstruct the output of a Two-Channel Analysis Subband Filter block. To do so, you must design the filters in this block such that they perfectly reconstruct the outputs of the analysis filters.

See the following topics for more information about this block:

- “Specifying the FIR Filters” on page 2-1344
- “Frame-Based Processing” on page 2-1344
- “Sample-Based Processing” on page 2-1344
- “Latency” on page 2-1345
- “Creating Multilevel Dyadic Synthesis Filter Banks” on page 2-1345

Specifying the FIR Filters

You must provide the vector of numerator coefficients for the lowpass and highpass filters in the **Lowpass FIR filter coefficients** and **Highpass FIR filter coefficients** parameters.

For example, to specify a filter with the following transfer function, enter the vector $[b(1) \ b(2) \ \dots \ b(m)]$.

$$H(z) = B(z) = b_1 + b_2z^{-1} + \dots + b_mz^{-(m-1)}$$

Each filter should be a half-band filter that passes the frequency band that the other filter stops. You can use this block to reconstruct the output of a Two-Channel Analysis Subband Filter block. To do so, you must design the filters in this block such that they perfectly reconstruct the outputs of the analysis filters.

The best way to design perfect reconstruction filters is to use the Wavelet Toolbox `wfilters` function for the filters in both this block *and* in the corresponding Two-Channel Analysis Subband Filter block. You can also use DSP System Toolbox and Signal Processing Toolbox functions.

The Two-Channel Synthesis Subband Filter block initializes all filter states to zero.

Frame-Based Processing

When you set the **Input processing** parameter to `Columns as channels (frame based)`, the block accepts any two M -by- N matrices with the same frame rates. The block treats each column of the input as the high- or low-frequency subbands of the corresponding output channel. You can use the **Rate options** parameter to specify how the block resamples the input:

- When you set the **Rate options** parameter to `Enforce single-rate processing`, the input to the block can be any two M -by- N matrices with the same frame rate. The block treats each input column as the high- or low-frequency subbands of the corresponding output channel. The input to the topmost input port should contain the high-frequency subbands. The block outputs one matrix, where each column is reconstructed from the corresponding columns of each input matrix. The input and output frame *rates* are the same, but the frame *size* of the output is twice that of the input.
- When you set the **Rate options** parameter to `Allow multirate processing`, the block treats each column of the input as the high- or low-frequency subbands of the corresponding output channel. The input to the topmost input port should contain the high-frequency subbands. The block outputs one matrix, where each column is reconstructed from the corresponding columns of the input matrices. The input and output frame *sizes* are the same, but the frame *rate* of the output is twice that of the input. Thus, the overall sample rate of the output is twice that of the input sample rate.

In this mode, the block has one frame of latency, as described in the “Latency” on page 2-1345 section.

Sample-Based Processing

When you set the **Input processing** parameter to `Elements as channels (sample based)`, the block accepts any two M -by- N matrices with the same sample rates. The block treats each M -by- N matrix as $M \cdot N$ independent subbands. Each element of the input matrices is the high- or low-frequency subband of the corresponding channel in the output matrix. The input to the topmost input port should contain the high-frequency subbands. The block outputs one matrix with the same

dimensions as the input matrices, but a sample rate that is twice that of the input. The block reconstructs each element of the output from the corresponding elements in the input matrices.

Depending on the setting of your Simulink configuration parameters, the output may have one sample of latency, as described in the “Latency” on page 2-1345 section.

Latency

When you set the **Input processing** parameter to `Columns as channels (frame based)` and the **Rate options** parameter to `Enforce single-rate processing`, the Two-Channel Synthesis Subband Filter block always has zero-tasking latency. Zero-tasking latency means that the block propagates the first input sample (received at time $t=0$) as the first output sample.

When you set the **Rate options** parameter to `Allow multirate processing`, the Two-Channel Synthesis Subband Filter block may exhibit latency. The amount of latency depends on the setting of the **Input processing** parameter of this block and the setting of the Simulink **Treat each discrete rate as a separate task** configuration parameter. The following table summarizes the conditions that produce latency when the block is performing multirate processing.

Input processing	Treat each discrete rate as a separate task	Latency
Elements as channels (sample based)	Off	None.
	On	One sample. The first output sample in each channel always has a value of 0.
Columns as channels (frame based)	Off or On	One frame. All samples in the first output frame have a value of 0.

Note For more information on latency and the Simulink tasking modes, see “Excess Algorithmic Delay (Tasking Latency)” and “Time-Based Scheduling and Code Generation” (Simulink Coder).

Creating Multilevel Dyadic Synthesis Filter Banks

The Two-Channel Synthesis Subband Filter block is the basic unit of a dyadic synthesis filter bank. You can connect several of these blocks to implement an n -level filter bank, as illustrated in the following figure. For a review of dyadic synthesis filter banks, see the Dyadic Synthesis Filter Bank block reference page.

When you create a filter bank by connecting multiple copies of this block, the output values of the filter bank differ depending on whether there is latency. Though the output values differ, both sets of values are valid; the difference arises from changes in latency. See the “Latency” on page 2-1345 section for more information about when latency can occur in the Two-Channel Analysis Subband Filter block.

In some cases, rather than connecting several Two-Channel Analysis Subband Filter blocks, you can use the Dyadic Analysis Filter Bank block, which is faster and requires less memory. In particular, the Dyadic Analysis Filter Bank block is more efficient under the following conditions:

- You are reconstructing a signal from 2^n or $n+1$ subbands.
- The frame size of the signal you are reconstructing is a multiple of 2^n .

- The properties of the subbands you are working with match those of the outputs of the Dyadic Analysis Filter Bank block. These properties are described in the Dyadic Analysis Filter Bank reference page.

3-Level Dyadic Synthesis Filter Banks

Conceptual illustration

Both implementations of the dyadic analysis filter bank reconstruct a frame-based signal from $n+1$ subbands, where $n = 3$.

In this case, the Dyadic Synthesis Filter Bank block's implementation is more efficient, since the input subbands have the properties of the outputs of a Dyadic Analysis Filter Bank block.

Use the Two-Channel Synthesis Subband Filter block implementation for other cases, such as to handle separate sample-based vectors or matrices of subbands (rather than a single sample-based vector or matrix of concatenated subbands), or to output sample-based signals.

Two-Channel Synthesis Subband Filter block implementation

Dyadic Synthesis Filter Bank block implementation

The Dyadic Synthesis Filter Bank block allows you to specify the filter bank filters by providing vectors of filter coefficients, just as this block does. The Dyadic Synthesis Filter Bank block provides an additional option of using wavelet-based filters that the block designs by using a wavelet you specify.

Fixed-Point Data Types

The Two-Channel Synthesis Subband Filter block is composed of two FIR Interpolation blocks as shown in the following diagram.

For fixed-point signals, you can set the coefficient, product output, accumulator, and output data types used in the FIR Interpolation blocks as discussed in "Parameters" on page 2-1347. For a diagram showing the usage of these data types within the FIR blocks, see the FIR Interpolation block reference page.

In addition, the inputs to the Sum block shown in the previous diagram are accumulated using the accumulator data type. The output of the Sum block is then cast from the accumulator data type to the output data type. Therefore the output of the Two-Channel Synthesis Subband Filter block is in

the output data type. You also set these data types in the block dialog box as discussed in the “Parameters” on page 2-1347 section.

Parameters

Main Tab

Lowpass FIR filter coefficients

A vector of lowpass FIR filter coefficients, in descending powers of z . The lowpass filter should be a half-band filter that passes the frequency band stopped by the filter specified in the **Highpass FIR filter coefficients** parameter. To use this block to reconstruct the output of a Two-Channel Analysis Subband Filter block, you must design the filters in this block to perfectly reconstruct the outputs of the analysis filters. For more information, see “Specifying the FIR Filters” on page 2-1344.

Highpass FIR filter coefficients

A vector of highpass FIR filter coefficients, in descending powers of z . The highpass filter should be a half-band filter that passes the frequency band stopped by the filter specified in the **Lowpass FIR filter coefficients** parameter. To use this block to reconstruct the output of a Two-Channel Analysis Subband Filter block, you must design the filters in this block to perfectly reconstruct the outputs of the analysis filters. For more information, see “Specifying the FIR Filters” on page 2-1344.

Input processing

Specify how the block should process the input. You can set this parameter to one of the following options:

- **Columns as channels (frame based)** (default) — When you select this option, the block treats each column of the input as a separate channel.
- **Elements as channels (sample based)** — When you select this option, the block treats each element of the input as a separate channel.

Rate options

Specify the rate processing rule for the block. You can set this parameter to one of the following options:

- **Enforce single-rate processing** — When you select this option, the block treats each column of the input as an independent channel and reconstructs each channel over time. The output has the same sample rate as the input, but the output frame size is twice that of the input frame size. To select this option, you must set the **Input processing** parameter to **Columns as channels (frame based)**.
- **Allow multirate processing** — When you select this option, the input and output of the block are the same size, but the sample rate of the output is twice that of the input.

Some settings of this parameter cause the block to have nonzero latency. See “Latency” on page 2-1345 for more information.

Data Types Tab

Rounding mode

Select the rounding mode for fixed-point operations. The filter coefficients do not obey this parameter; they always round to Nearest.

Note The **Rounding mode** and **Saturate on integer overflow** settings have no effect on numerical results when all the following conditions exist:

- **Product output** is Inherit: Inherit via internal rule
- **Accumulator** is Inherit: Inherit via internal rule
- **Output** is Inherit: Same as accumulator

With these data type settings, the block is effectively operating in full precision mode.

Saturate on integer overflow

When you select this parameter, the block saturates the result of its fixed-point operation. When you clear this parameter, the block wraps the result of its fixed-point operation. For details on saturate and wrap, see overflow mode for fixed-point operations.

Note The **Rounding mode** and **Saturate on integer overflow** parameters have no effect on numeric results when all these conditions are met:

- **Product output** data type is Inherit: Inherit via internal rule.
- **Accumulator** data type is Inherit: Inherit via internal rule.

With these data type settings, the block operates in full-precision mode.

Coefficients

Specify the coefficients data type. See “Fixed-Point Data Types” on page 2-1346 and “Multiplication Data Types” for illustrations depicting the use of the coefficients data type in this block. You can set it to:

- A rule that inherits a data type, for example, Inherit: Same word length as input
- An expression that evaluates to a valid data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the **Coefficients** parameter.

See “Specify Data Types Using Data Type Assistant” (Simulink) in *Simulink User's Guide* (Simulink) for more information.

Coefficients Minimum

Specify the minimum value of the filter coefficients. The default value is [] (unspecified). Simulink software uses this value to perform:

- Automatic scaling of fixed-point data types

Coefficients Maximum

Specify the maximum value of the filter coefficients. The default value is [] (unspecified). Simulink software uses this value to perform:

- Automatic scaling of fixed-point data types

Product output

Specify the product output data type. See “Fixed-Point Data Types” on page 2-1346 and “Multiplication Data Types” for illustrations depicting the use of the product output data type in this block. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Inherit via internal rule`. For more information on this rule, see “Inherit via Internal Rule”.

Note The actual product output word length may be equal to or greater than the calculated ideal product output word length, depending on the settings on the **Hardware Implementation** pane of the Configuration Parameters dialog box.

- An expression that evaluates to a valid data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the **Product output** parameter.

See “Specify Data Types Using Data Type Assistant” (Simulink) in *Simulink User's Guide* (Simulink) for more information.

Accumulator

Specify the accumulator data type. See “Fixed-Point Data Types” on page 2-1346 for illustrations depicting the use of the accumulator data type in this block. You can set this parameter to:

- A rule that inherits a data type, for example, `Inherit: Inherit via internal rule`. For more information on this rule, see “Inherit via Internal Rule”.
- An expression that evaluates to a valid data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the **Accumulator** parameter.

See “Specify Data Types Using Data Type Assistant” (Simulink) in *Simulink User's Guide* (Simulink) for more information.

Output

Specify the output data type. See “Fixed-Point Data Types” on page 2-1346 for illustrations depicting the use of the output data type in this block. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Same as accumulator`
- An expression that evaluates to a valid data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the **Output** parameter.

See “Control Data Types of Signals” (Simulink) in *Simulink User's Guide* (Simulink) for more information.

Output Minimum

Specify the minimum value that the block should output. The default value is `[]` (unspecified). Simulink software uses this value to perform:

- Simulation range checking (see “Specify Signal Ranges” (Simulink))
- Automatic scaling of fixed-point data types

Output Maximum

Specify the maximum value that the block should output. The default value is [] (unspecified). Simulink software uses this value to perform:

- Simulation range checking (see “Specify Signal Ranges” (Simulink))
- Automatic scaling of fixed-point data types

Lock data type settings against changes by the fixed-point tools

Select this parameter to prevent the fixed-point tools from overriding the data types you specify on the block mask.

Supported Data Types

- Double-precision floating point
- Single-precision floating point
- Fixed point (signed only)
- 8-, 16-, and 32-bit signed integers

UDP Receive

Receive uint8 vector as UDP message

Library

Sources

dspsrcs4

Description

The UDP Receive block receives UDP packets from an IP network port and saves them to its buffer. With each sample, the block outputs the contents of a single UDP packet as a data vector. The local IP port number on which the block receives the UDP packets is tunable in the generated code.

The generated code for this block relies on prebuilt `.dll` files. You can run this code outside the MATLAB environment or redeploy it, but you must account for the extra `.dll` files. The `packNGo` function creates a ZIP file that contains the pieces required to run or rebuild this code. For more details, see “How To Run a Generated Executable Outside MATLAB”.

Parameters

Local IP port — Number of IP port

25000 (default) | scalar in the range [1, 65535]

Specify the IP port number on which to receive UDP packets. This parameter is tunable in the generated code but is not tunable during simulation.

On Linux, to set the IP port number below 1024, run MATLAB with root privileges. For example, at the Linux command line, enter:

```
sudo matlab
```

Remote IP address ('0.0.0.0' to accept all) — IP address from which to accept packets

'0.0.0.0' (default) | IP address

Specify the IP address from which to accept UDP packets. Specify a specific IP address to block UDP packets from other addresses. To accept packets from any IP address, specify '0.0.0.0'.

Receive buffer size (bytes) — Size of buffer that receives UDP packets

8192 (default) | scalar in the range [1, 67108864]

Specify the size of the buffer, in bytes, that receives the UDP packets. Make the buffer large enough to avoid data loss caused by buffer overflows.

Maximum length for Message — Maximum length of output data

255 (default) | scalar

Specify the maximum length, in vector elements, of the data output vector. Set this parameter to a value equal or greater than the data size of a UDP packet. The system truncates data that exceeds this length.

Parameter Dependencies

If you disable **Output variable-size signal**, the block output is the length specified by this parameter.

Data type for Message — Data type of message

uint8 (default) | single | double | int8 | int16 | int32 | int64 | uint16 | uint32 | uint64 | boolean | fixed point | enumerated | bus

Specify the data type of the vector elements in the message output. Match the data type to the data input used to create the UDP packets.

Message is complex — Message data complexity

off (default) | on

Specify whether the block receives a message as complex data. Select this parameter to receive a message as complex data. Clear this parameter if a received message is real data.

Output variable-size signal — Message output that varies in length

on (default) | off

Specify whether your model supports signals of varying length. If your model supports signals of varying length, select this parameter. In that case:

- The output vector varies in length, depending on the amount of data in the UDP packet.
- The block emits the data vector from a single unlabeled output.

If your model does not support signals of varying length, clear this parameter. In that case:

- The block emits a fixed-length output that is the same length as specified by **Maximum length for Message**.
- If the UDP packet contains less data than the fixed-length output, the difference contains invalid data.
- The block emits the data vector from the **Message** output.
- The block emits the length of the valid data from the **Length** output.
- The **Data type for Length** parameter is enabled.

Parameter Dependencies

If you disable this parameter, the block emits output that is the length specified by **Maximum length for Message**.

Blocking time (seconds) — Number of seconds to wait for UDP packet

inf (default) | scalar

For each sample, specify the number of seconds to wait for a UDP packet before returning control to the scheduler. To wait indefinitely, specify `inf`.

Note This parameter applies to the Embedded Coder® UDP Receive block only.

Sample time (seconds) — Frequency of calls to block

0.01 (default) | scalar

Specify the frequency at which the scheduler calls the UDP Receive block, in seconds. Enter a value greater than zero. In real-time operation, setting this parameter to a smaller value reduces the likelihood of dropped UDP messages.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Usage notes and limitations:

- The executable generated from this block relies on prebuilt dynamic library files (.dll files) included with MATLAB. Use the `packNGo` function to package the code generated from this block and all the relevant files in a compressed zip file. Using this zip file, you can relocate, unpack, and rebuild your project in another development environment where MATLAB is not installed. For more details, see “How To Run a Generated Executable Outside MATLAB”.
- The **Local IP port** parameter is tunable in the generated code, but not tunable during simulation. You can control the parameter tunability in the generated code through several ways. One of the ways is to configure the parameter as a tunable field of a global structure in the generated code. Other ways include applying a built-in storage class or custom storage class to a `Simulink.Parameter` object and using this object to set the value of the block parameter. For details, see “Create Tunable Calibration Parameter in the Generated Code” (Simulink Coder).

Blocks

UDP Send

Introduced in R2010a

UDP Send

Send UDP message

Library

Sinks

dspsnks4

Description

The UDP Send block transmits an input data vector as a UDP packet to a remote IP network port. The remote IP port number to which the block sends the UDP packets is tunable in the generated code.

Some Simulink blocks and .exe files built from models that contain those blocks require shared libraries, such as .dll files on Windows. The UDP Send block requires the `networkdevice.dll` library file. To meet this requirement, follow the example on the `packNGo` function page to package the code files for your model. The resulting compressed folder contains the .dll files that the model requires, including `networkdevice.dll`. To run this type of .exe file outside of a MATLAB environment, place the required .dll files in the same folder as the .exe file or place them in a folder on the Windows system path. For more details, see “How To Run a Generated Executable Outside MATLAB”.

Parameters

Remote IP address ('255.255.255.255' for broadcast) — IP address from which to accept UDP packets

'255.255.255.255' (default) | IP address | string

Specify the IP address or host name to which to send UDP packets. If you specify a host name, specify it as a string. To broadcast a UDP packet, specify '255.255.255.255'.

Remote IP port — Number of remote IP port

25000 (default) | scalar in the range [1, 65535] |

Specify the IP port number to which to send UDP packets. This parameter is tunable in the generated code but is not tunable during simulation.

On Linux, to set the IP port number below 1024, run MATLAB with root privileges. For example, at the Linux command line, enter:

```
sudo matlab
```

Local IP port source — Source of local IP port

Automatically determine (default) | Specify via dialog

Specify whether the block uses a local port number that the system assigns or that you specify by using the **Local IP port** parameter. For the system to assign the port number, select **Automatically determine**. If the receiving address expects UDP packets from a specific port number, select **Specify via dialog** and specify the port number by using the **Local IP port** parameter.

Parameter Dependencies

To enable the **Local IP port** parameter, select **Specify via dialog**.

Local IP port — Number of local IP port

-1 (default) | scalar in the range [1, 65535]

Specify the IP port number from which the block sends UDP packets. Use this parameter when the receiving address expects messages from a specific port number.

Parameter Dependencies

To enable this parameter, set **Local IP port source** to **Specify via dialog**.

Send buffer size (bytes) — Size of buffer that sends UDP packets

8192 (default) | scalar in the range [1, 67108864]

Specify the size of the buffer, in bytes, that sends the UDP packets. Make the buffer large enough to avoid data loss caused by buffer overflows.

Extended Capabilities**C/C++ Code Generation**

Generate C and C++ code using Simulink® Coder™.

Usage notes and limitations:

- The executable generated from this block relies on prebuilt dynamic library files (.dll files) included with MATLAB. Use the `packNGo` function to package the code generated from this block and all the relevant files in a compressed zip file. Blocks

UDP Receive

Introduced in R2010a

Unbuffer

Unbuffer input frame into sequence of scalar outputs

Library

Signal Management / Buffers

dspbuff3

Description

The Unbuffer block unbuffers an M_i -by- N input into a 1-by- N output. That is, inputs are unbuffered row-wise so that each matrix row becomes an independent time-sample in the output. The rate at which the block receives inputs is generally less than the rate at which the block produces outputs.

The block adjusts the output rate so that the *sample period* is the same at both the input and output, $T_{so} = T_{si}$. Therefore, the output sample period for an input of frame size M_i and frame period T_{fi} is T_{fi}/M_i , which represents a *rate* M_i times higher than the input frame rate. In the example above, the block receives inputs only once every three sample periods, but produces an output once every sample period. To rebuffer inputs to a larger or smaller frame size, use the Buffer block.

In the model below, the block unbuffers a four-channel input with a frame size of three. The **Initial conditions** parameter is set to zero and the tasking mode is set to multitasking, so the first three outputs are zero vectors.

Zero Latency

The Unbuffer block has *zero-tasking latency* in Simulink single-tasking mode. Zero-tasking latency means that the first input sample (received at $t=0$) appears as the first output sample.

Nonzero Latency

For *multitasking* operation, the Unbuffer block's buffer is initialized with the value specified by the **Initial conditions** parameter, and the block begins unbuffering this frame at the start of the simulation. Inputs to the block are therefore delayed by one buffer length, or M_i samples.

The **Initial conditions** parameter can be one of the following:

- A scalar to be repeated for the first M_i output samples of every channel
- A length- M_i vector containing the values of the first M_i output samples for every channel
- An M_i -by- N matrix containing the values of the first M_i output samples in each of N channels

Note For more information on latency and the Simulink tasking modes, see “Excess Algorithmic Delay (Tasking Latency)” and “Time-Based Scheduling and Code Generation” (Simulink Coder).

Parameters

Initial conditions

The value of the block's initial output for cases of nonzero latency. You can specify a scalar, vector, or matrix.

Supported Data Types

Port	Supported Data Types
Input	<ul style="list-style-type: none"> • Double-precision floating point • Single-precision floating point • Fixed point (signed and unsigned) • Boolean • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers
Output	<ul style="list-style-type: none"> • Double-precision floating point • Single-precision floating point • Fixed point (signed and unsigned) • Boolean • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers

Uniform Decoder

Decode integer input into floating-point output

Library

Quantizers

dspquant2

Description

The Uniform Decoder block performs the inverse operation of the Uniform Encoder block, and reconstructs quantized floating-point values from encoded integer input. The block adheres to the definition for uniform decoding specified in ITU-T Recommendation G.701.

Inputs can be real or complex values of the following six integer data types: `uint8`, `uint16`, `uint32`, `int8`, `int16`, or `int32`.

The block first casts the integer input values to floating-point values, and then uniquely maps (decodes) them to one of 2^B uniformly spaced floating-point values in the range $[-V, (1-2^{1-B})V]$, where you specify B in the **Bits** parameter (as an integer between 2 and 32) and V is a floating-point value specified by the **Peak** parameter. The smallest input value representable by B bits (0 for an unsigned input data type; -2^{B-1} for a signed input data type) is mapped to the value $-V$. The largest input value representable by B bits (2^B-1 for an unsigned input data type; $2^{B-1}-1$ for a signed input data type) is mapped to the value $(1-2^{1-B})V$. Intermediate input values are linearly mapped to the intermediate values in the range $[-V, (1-2^{1-B})V]$.

To correctly decode values encoded by the Uniform Encoder block, the **Bits** and **Peak** parameters of the Uniform Decoder block should be set to the same values as the **Bits** and **Peak** parameters of the Uniform Encoder block. The **Overflow mode** parameter specifies the Uniform Decoder block's behavior when the integer input is outside the range representable by B bits. When you select **Saturate**, *unsigned* input values greater than 2^B-1 saturate at 2^B-1 ; *signed* input values greater than $2^{B-1}-1$ or less than -2^{B-1} saturate at those limits. The real and imaginary components of complex inputs saturate independently.

When you select **Wrap**, *unsigned* input values, u , greater than 2^B-1 are wrapped back into the range $[0, 2^B-1]$ using $\text{mod-}2^B$ arithmetic.

$$u = \text{mod}(u, 2^B)$$

Signed input values, u , greater than $2^{B-1}-1$ or less than -2^{B-1} are wrapped back into that range using $\text{mod-}2^B$ arithmetic.

$$u = (\text{mod}(u+2^B/2, 2^B) - (2^B/2))$$

The real and imaginary components of complex inputs wrap independently.

The **Output type** parameter specifies whether the decoded floating-point output is single or double precision. Either level of output precision can be used with any of the six integer input data types.

Examples

See example model `ex_uniform_decoder`.

In this example, the input to the block is the `uint8` output of a Uniform Encoder block. This block has comparable settings: **Peak** = 2, **Bits** = 3, and **Output type** = `Unsigned`. (Comparable settings ensure that inputs to the Uniform Decoder block do not saturate or wrap. See the example on the Uniform Encoder block reference page for more about these settings.)

The real and complex components of each input are independently mapped to one of 2^3 distinct levels in the range `[-2.0, 1.5]`.

0	is mapped to	-2.0
1	is mapped to	-1.5
2	is mapped to	-1.0
3	is mapped to	-0.5
4	is mapped to	0.0
5	is mapped to	0.5
6	is mapped to	1.0
7	is mapped to	1.5

Parameters

Peak

Specify the largest amplitude represented in the encoded input. To correctly decode values encoded with the Uniform Encoder block, set the **Peak** parameters in both blocks to the same value.

Bits

Specify the number of input bits, `B`, used to encode the data. (This can be less than the total number of bits supplied by the input data type.) To correctly decode values encoded with the Uniform Encoder block, set the **Bits** parameters in both blocks to the same value.

Overflow mode

Specify the block's behavior when the integer input is outside the range representable by `B` bits. Out-of-range inputs can either saturate at the extreme value, or wrap back into range.

Output type

Specify the precision of the floating-point output, `single` or `double`.

Uniform Encoder

Quantize and encode floating-point input into integer output

Library

Quantizers

dspquant2

Description

The Uniform Encoder block performs the following two operations on each floating-point sample in the input vector or matrix:

- 1 Quantizes the value using the same precision
- 2 Encodes the quantized floating-point value to an integer value

In the first step, the block quantizes an input value to one of 2^B uniformly spaced levels in the range $[-V, (1-2^{1-B})V]$, where you specify B in the **Bits** parameter and you specify V in the **Peak** parameter. The quantization process rounds both positive and negative inputs *downward* to the nearest quantization level, with the exception of those that fall exactly on a quantization boundary. The real and imaginary components of complex inputs are quantized independently.

The number of bits, B , can be any integer value between 2 and 32, inclusive. Inputs greater than $(1-2^{1-B})V$ or less than $-V$ saturate at those respective values. The real and imaginary components of complex inputs saturate independently.

In the second step, the quantized floating-point value is uniquely mapped (encoded) to one of 2^B integer values. When the **Output type** is set to **Unsigned integer**, the smallest quantized floating-point value, $-V$, is mapped to the integer 0, and the largest quantized floating-point value, $(1-2^{1-B})V$, is mapped to the integer 2^B-1 . Intermediate quantized floating-point values are linearly (uniformly) mapped to the intermediate integers in the range $[0, 2^B-1]$. For efficiency, the block automatically selects an *unsigned* output data type (`uint8`, `uint16`, or `uint32`) with the minimum number of bits equal to or greater than B .

When the **Output type** is set to **Signed integer**, the smallest quantized floating-point value, $-V$, is mapped to the integer -2^{B-1} , and the largest quantized floating-point value, $(1-2^{1-B})V$, is mapped to the integer $2^{B-1}-1$. Intermediate quantized floating-point values are linearly mapped to the intermediate integers in the range $[-2^{B-1}, 2^{B-1}-1]$. The block automatically selects a *signed* output data type (`int8`, `int16`, or `int32`) with the minimum number of bits equal to or greater than B .

Inputs can be real or complex, double or single precision. The output data types that the block uses are shown in the table below. Note that most of the DSP System Toolbox blocks accept only double-precision inputs. Use the Simulink Data Type Conversion block to convert integer data types to double precision. See “About Data Types in Simulink” (Simulink) for a complete discussion of data types, as well as a list of Simulink blocks capable of reduced-precision operations.

Bits	Unsigned Integer	Signed Integer
2 to 8	uint8	int8
9 to 16	uint16	int16
17 to 32	uint32	int32

The Uniform Encoder block operations adhere to the definition for uniform encoding specified in ITU-T Recommendation G.701.

Examples

See example model `ex_uniform_encoder`.

In this example, the following parameters are set:

- **Peak** = 2
- **Bits** = 3
- **Output type** = Unsigned

The following figure illustrates uniform encoding.

The real and complex components of each input (horizontal axis) are independently quantized to one of 2^3 distinct levels in the range $[-2, 1.5]$. These components are then mapped to one of 2^3 integer values in the range $[0, 7]$.

-2.0 is mapped to 0
 -1.5 is mapped to 1
 -1.0 is mapped to 2
 -0.5 is mapped to 3
 0.0 is mapped to 4
 0.5 is mapped to 5
 1.0 is mapped to 6
 1.5 is mapped to 7

This table shows the results for a few particular inputs.

Input	Quantized Input	Output	Notes
1.6	1.5+0.0i	7+4i	

Input	Quantized Input	Output	Notes
-0.4	-0.5+0.0i	3+4i	
-3.2	-2.0+0.0i	4i	Saturation (real)
0.4-1.2i	0.0-1.5i	4+i	
0.4-6.0i	0.0-2.0i	4	Saturation (imaginary)
-4.2+3.5i	-2.0+2.0i	7i	Saturation (real and imaginary)

The output data type is automatically set to `uint8`, the most efficient format for this input range.

Parameters

Peak

The largest input amplitude to be encoded, V . Real or imaginary input values greater than $(1-2^{1-B})V$ or less than $-V$ saturate (independently for complex inputs) at those limits.

Bits

Specify the number of bits, B , needed to represent the integer output. The number of levels at which the block quantizes the floating-point input is 2^B .

Output type

The data type of the block's output, `Unsigned integer` or `Signed integer`. Unsigned outputs are `uint8`, `uint16`, or `uint32`, while signed outputs are `int8`, `int16`, or `int32`.

Unwrap

Unwrap signal phase

Library: DSP System Toolbox / Signal Operations

Description

The Unwrap block unwraps each channel of the input by adding or subtracting appropriate multiples of 2π to each channel element. The block recognizes phase discontinuities larger than the value of the **Tolerance** parameter. For more information on phase unwrapping, see “Definition of Phase Unwrap” on page 2-1370.

Ports

Input

Port_1 — Signal input

scalar | vector | matrix

Signal input to unwrap, specified as a scalar, vector, or matrix. The input must have radian phase entries.

Data Types: single | double

Output

Port_1 — Signal output

scalar | vector | matrix

Unwrapped signal output, returned as a scalar, vector, or matrix.

The block preserves the input size and dimension, and the output port rate equals the input port rate.

Data Types: single | double

Parameters

Tolerance (radians) — Jump size

π (default) | scalar value

The jump size that the block recognizes as a true phase discontinuity. The default is set to π (rather than a smaller value) to avoid altering legitimate signal features. To increase the block's sensitivity, set the **Tolerance** to a value slightly less than π .

Data Types: single | double | int8 | int16 | int32 | uint8 | uint16 | uint32

Input processing — Method to process the input

Columns as channels (frame based) (default) | Elements as channels (sample based)

Specify how the block should process the input. You can set this parameter to one of these options:

- **Columns as channels (frame based) (default)** — When you select this option, the block treats each column of the input as a separate channel.
- **Elements as channels (sample based)** — When you select this option, the block treats each element of the input as a separate channel.

Do not unwrap phase discontinuities between successive frames — Checking successive frames

off (default) | on

When you clear this check box, the block ignores boundaries between input frames and does not reset the initial phase value to zero each time a new input is received. In this mode, the block continuously unwraps the data in each column of the input.

This figure illustrates how the block unwraps data in this mode.

Default Frame-Based Unwrap Mode

Do not unwrap phase discontinuities between successive frames

When you select this check box, the block treats each frame of input data independently and resets the initial phase value for each new input frame.

This figure illustrates how the block unwraps data in this mode.

Nondefault Frame-Based Unwrap Mode

Do not unwrap phase discontinuities between successive frames

For more information, see “Frame-Based Processing” on page 2-1372.

Dependencies

To enable this parameter, set the **Input processing** parameter to **Columns as channels** (frame based). In sample-based processing mode, the block does not reset the initial phase value to zero for each new input. See “Sample-Based Processing” on page 2-1373 for more information.

Block Characteristics

Data Types	double single
Direct Feedthrough	no
Multidimensional Signals	no
Variable-Size Signals	no
Zero-Crossing Detection	no

More About

Definition of Phase Unwrap

Phase unwrap or unwrap is a process often used to reconstruct a signal's original phase. Unwrap algorithms add appropriate multiples of 2π to each phase input to restore original phase values, as illustrated in the diagram. For more information on the unwrap algorithm used by this block, see “Unwrap Method” on page 2-1371.

Algorithms that compute the phase of a signal often only output phases between $-\pi$ and π . For instance, such algorithms compute the phase of $\sin(2\pi + 3)$ to be 3, since $\sin(3) = \sin(2\pi + 3)$, and since the actual phase, $2\pi + 3$, is not between $-\pi$ and π . Such algorithms compute the phases of $\sin(-4\pi + 3)$ and $\sin(16\pi + 3)$ to be 3 as well.

Unwrap Method

The Unwrap block unwraps each channel of its input matrix or input vector by adding $2\pi k$ to each successive channel element, and updating k at each *phase jump*. A phase jump occurs when the difference between two adjacent phase value entries exceeds the value of the **Tolerance** parameter.

This code shows how the block unwraps the data in a given input channel u .

```
k=0; % initialize k to 0
i=1; % initialize the counter to 1
alpha=pi; % set alpha to the desired Tolerance. In this case, pi
```

```

for i = 1:(size(u)-1)
    yout(i,:) = u(i) + (2*pi*k); % add 2*pi*k to ui
    if((abs(u(i+1)-u(i))) > (abs(alpha))) % if diff is greater than alpha, increment or decrement k
        if u(i+1) < u(i) % if the phase jump is negative, increment k
            k = k + 1;
        else % if the phase jump is positive, decrement k
            k = k - 1;
        end
    end
end
end
yout((i+1), :) = u(i+1) + (2*pi*k); % add 2*pi*k to the last element of the input

```

Frame-Based Processing

When you configure the block to perform frame-based processing, by setting the **Input processing** parameter to **Columns as channels (frame based)**, the block supports two different unwrap modes. In both modes, the block adds $2\pi k$ to each input channel's elements, and updates k at each phase discontinuity. The difference between the two modes is how often the block resets the initial phase value (k) to zero. You can choose to unwrap data across frame boundaries (default), or to unwrap only within input frames, by resetting the initial phase value each time a new input frame is received.

Unwrapping Across Frame Boundaries

In the default mode, the block ignores boundaries between input frames, and continues to unwrap the data in each channel without resetting the initial phase value to zero. To specify this mode, clear the **Do not unwrap phase discontinuities between successive frames** check box. This figure illustrates how the block unwraps data in this mode.

Default Frame-Based Unwrap Mode

Do not unwrap phase discontinuities between successive frames

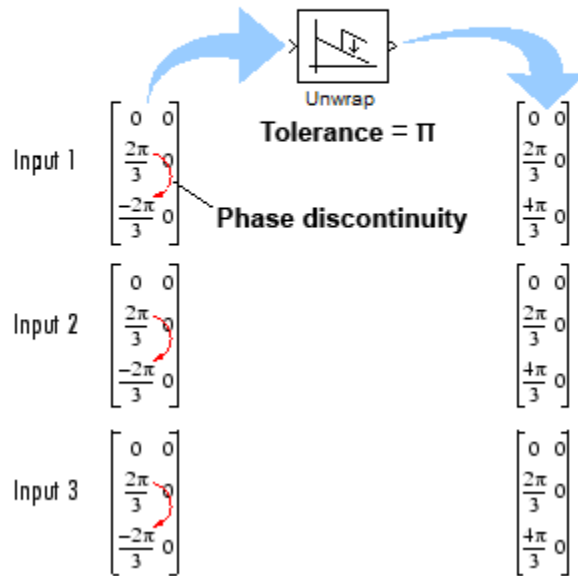

Unwrapping Within Frames

When you select the **Do not unwrap phase discontinuities between successive frames** check box, the block treats each frame of input data independently. In this mode, the block resets the initial phase value to zero each time a new input frame is received. This figure illustrates how the block unwraps data in this mode.

Nondefault Frame-Based Unwrap Mode

Do not unwrap phase discontinuities between successive frames

Sample-Based Processing

When you configure the block to perform sample-based processing, by setting the **Input processing** parameter to **Elements as channels (sample based)**, the block treats each element of the input as an individual channel. The block unwraps the data in each channel of the input, and does not reset the initial phase to zero each time a new input is received. This figure illustrates how the block unwraps data when performing sample-based processing.

Upsample

Resample input at higher rate by inserting zeros

Library

Signal Operations

dspsigops

Description

The Upsample block resamples each channel of the M_I -by- N input at a rate L times higher than the input sample rate by inserting $L-1$ zeros between consecutive samples. You specify the integer L in the **Upsample factor** parameter. The **Sample offset** parameter, D , allows you to delay the output samples by an integer number of sample periods. Doing so enables you to select any of the L possible output phases. The value you specify for the **Sample offset** parameter must be in the range $0 \leq D < (L - 1)$.

You can use this block inside of triggered subsystems when you set the **Rate options** parameter to Enforce single-rate processing.

Frame-Based Processing

When you set the **Input processing** parameter to Columns as channels (frame based), the block upsamples each column of the input over time. In this mode, the block can perform either single-rate or multirate processing. You can use the **Rate options** parameter to specify how the block upsamples the input:

- When you set the **Rate options** parameter to Enforce single-rate processing, the input and output of the block have the same sample rate. In this mode, the block outputs a signal with a proportionally larger frame size than the input. For upsampling by a factor of L , the output frame size is L times larger than the input frame size ($M_o = M_i * L$), but the input and output frame rates are equal.

For an example of single-rate upsampling, see the **Single-Rate Processing** example.

- When you set the **Rate options** parameter to Allow multirate processing, the block treats an M_I -by- N matrix input as N independent channels. The block upsamples each column of the input over time by keeping the frame size constant ($M_i = M_o$), and making the output frame period (T_{fo}) L times shorter than the input frame period ($T_{fi} = T_{fo} / L$).

See the **Multirate, Frame-Based Processing** example to see the Upsample block in this mode.

Sample-Based Processing

When you set the **Input processing** parameter to Elements as channels (sample based), the block treats an M -by- N matrix input as $M * N$ independent channels, and upsamples each channel over

time. In this mode, the block always performs multirate processing. The output sample rate is L times higher than the input sample rate ($T_{so} = T_{si}/L$), and the input and output sizes are identical.

Zero Latency

The Upsample block has *zero-tasking latency* for all single-rate operations. The block is in a single-rate mode if you set the **Upsample factor** parameter to 1 or if you set the **Input processing** parameter to `Columns as channels` (frame based) and the **Rate options** parameter to `Enforce single-rate processing`.

The Upsample block also has zero-tasking latency for multirate operations if you run your model in Simulink single-tasking mode.

Zero-tasking latency means that the block propagates the first input (received at $t=0$) immediately following the D consecutive zeros specified by the **Sample offset** parameter. This output ($D+1$) is followed in turn by the $L-1$ inserted zeros and the next input sample.

Nonzero Latency

The Upsample block has tasking latency for multirate, multitasking operation:

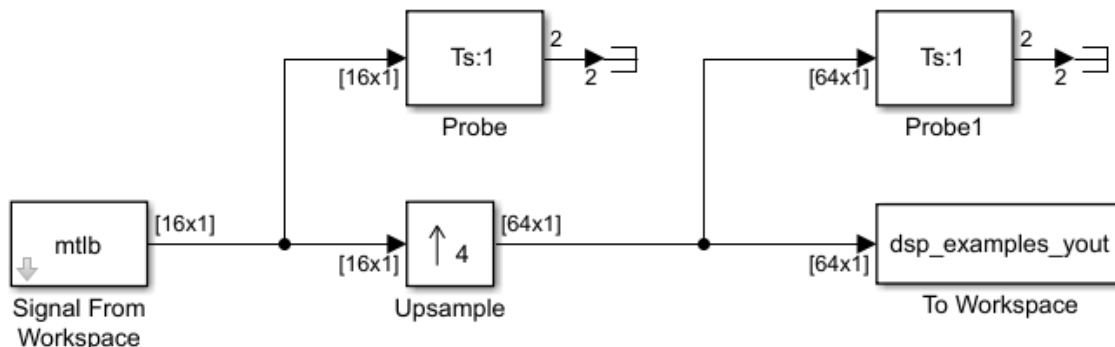

- In multirate, sample-based processing mode, the initial condition for each channel appears as output sample $D+1$, and is followed by $L-1$ inserted zeros. The channel's first input appears as output sample $D+L+1$. The **Initial conditions** parameter can be an M_i -by- N matrix containing one value for each channel, or a scalar to be applied to all signal channels.
- In multirate, frame-based processing mode, the first row of the initial condition matrix appears as output sample $D+1$, and is followed by $L-1$ inserted rows of zeros, the second row of the initial condition matrix, and so on. The first row of the first input matrix appears in the output as sample $M_i L + D + 1$. The **Initial conditions** parameter can be an M_i -by- N matrix, or a scalar to be repeated across all elements of the input matrix.

Note For more information on latency and the Simulink tasking modes, see “Excess Algorithmic Delay (Tasking Latency)” and “Time-Based Scheduling and Code Generation” (Simulink Coder).

Examples

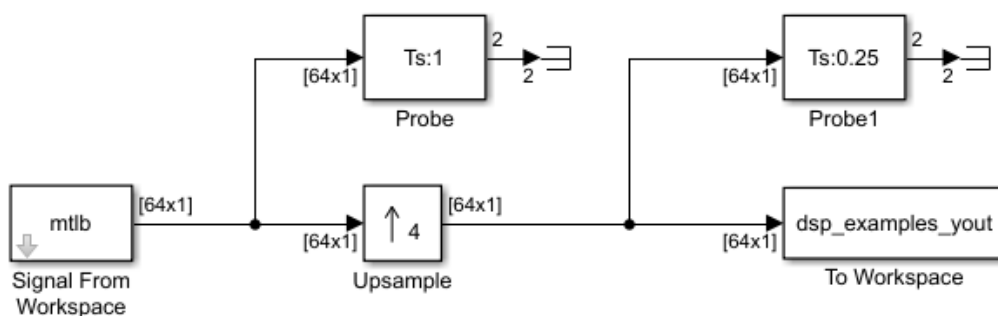

Example 2.3. Example: Single-Rate Processing

In the `ex_upsample_ref2` model, the Upsample block resamples a single-channel input with a frame size of 16. The block upsamples the input by a factor of 4. Thus, the output of the block has a frame size of 64. Because the block is in single-rate processing mode, the input and output frame rates are identical.

Example 2.4. Example: Multirate, Frame-Based Processing

In the `ex_upsample_ref1` model, the Upsample block resamples a single-channel input with a frame period of 1 second. The block upsamples the input by a factor of 4. Thus, the output of the block has a frame period of 0.25 seconds. Because the block is in multirate processing mode, the input and output frame sizes are identical.

Parameters

Upsample factor

The integer factor, L , by which to increase the input sample rate.

Sample offset

The sample offset, D , which must be an integer in the range $[0, L-1]$.

Input processing

Specify how the block should process the input. You can set this parameter to one of the following options:

- **Columns as channels (frame based)** — When you select this option, the block treats each column of the input as a separate channel. In this mode, the block can perform single-rate or multirate processing.
- **Elements as channels (sample based)** — When you select this option, the block treats each element of the input as a separate channel. In this mode, the block always performs multirate processing.

Rate options

Specify the method by which the block upsamples the input. You can select one of the following options:

- **Enforce single-rate processing** — When you select this option, the block maintains the input sample rate by increasing the output frame size by a factor of L . To select this option, you must set the **Input processing** parameter to **Columns as channels (frame based)**.
- **Allow multirate processing** — When you select this option, the block resamples the signal such that the output sample rate is L times faster than the input sample rate.

Initial conditions

The value with which the block is initialized for cases of nonzero latency, a scalar or matrix. This value appears in the output as sample $D+1$. This parameter appears only when you configure the block to perform multirate processing.

Supported Data Types

Port	Supported Data Types
Input	<ul style="list-style-type: none"> • Double-precision floating point • Single-precision floating point • Fixed point (signed and unsigned) • Boolean • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers
Output	<ul style="list-style-type: none"> • Double-precision floating point • Single-precision floating point • Fixed point (signed and unsigned) • Boolean • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Generated code relies on `memcpy` or `memset` functions (`string.h`) under certain conditions.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic.

Best Practices

Consider whether your model can use the Repeat block instead of the Upsample block. The Repeat block uses fewer hardware resources, so it is a best practice to use Upsample only when your algorithm requires zero-padding upsampling.

See also “Multirate Model Requirements for HDL Code Generation” (HDL Coder).

HDL Architecture

This block has a single, default HDL architecture.

HDL Block Properties

ConstrainedOutputPipeline	Number of registers to place at the outputs by moving existing delays within your design. Distributed pipelining does not redistribute these registers. The default is 0. For more details, see “ConstrainedOutputPipeline” (HDL Coder).
InputPipeline	Number of input pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “InputPipeline” (HDL Coder).
OutputPipeline	Number of output pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “OutputPipeline” (HDL Coder).

Restrictions

Input processing set to Columns as channels (frame based) is not supported.

Complex Data Support

This block supports code generation for complex signals.

Variable Bandwidth FIR Filter

Design tunable bandwidth FIR filter

Library

Filtering / Filter Designs

dspfdesign

Description

The Variable Bandwidth FIR Filter block filters each channel of the input signal over time using specified FIR filter specifications. This block offers tunable filter design parameters, which enable you to tune the filter characteristics while the simulation is running.

The block designs the FIR filter according to the filter parameters set in the block dialog box. The output port properties, such as datatype, complexity, and dimension, are identical to the input port properties.

Each column of the input signal is treated as a separate channel. If the input is a two-dimensional signal, the first dimension represents the channel length (or frame size) and the second dimension represents the number of channels. If the input is a one-dimensional signal, then it is interpreted as a single channel.

This block supports variable-size input, enabling you to change the channel length during simulation. To enable variable-size input, clear the **Inherit sample rate from input** check box. The number of channels must remain constant.

This block also supports SIMD code generation. For details, see “Code Generation” on page 2-1386.

Algorithms

This block brings the capabilities of `dsp.VariableBandwidthFIRFilter` System object to the Simulink environment.

The FIR filter is designed using the window method. For information on the algorithms used by the Variable Bandwidth FIR Filter block, see the “Algorithms” on page 4-1435 section of `dsp.VariableBandwidthFIRFilter`.

Examples

- “System Identification Using RLS Adaptive Filtering”

Parameters

FIR filter order

Order of the FIR filter, specified as a positive integer scalar. The default is 30. This parameter is nontunable.

Filter type

Type of FIR filter. You can set this parameter to:

- Lowpass (default)
- Highpass
- Bandpass
- Bandstop

This parameter is nontunable.

Specify cutoff frequency from input port

When you select this check box, the cutoff frequency is input through the **Fcut** port. When you clear this check box, the cutoff frequency is specified on the block dialog through the **Filter Cutoff frequency (Hz)** parameter.

This parameter applies when you set **Filter type** to Lowpass or Highpass.

Filter Cutoff frequency (Hz)

Cutoff frequency of the FIR filter, specified as a real positive scalar that is less than half the sample rate of the input signal. This parameter applies when you set **Filter type** to Lowpass or Highpass, and clear the **Specify cutoff frequency from input port** parameter. The default is 1000. This parameter is tunable.

Specify center frequency from input port

When you select this check box, the center frequency is input through the **Fc** port. When you clear this check box, the center frequency is specified on the block dialog through the **Filter center frequency (Hz)** parameter.

This parameter applies when you set **Filter type** to Bandpass or Bandstop.

Filter center frequency (Hz)

Center frequency of the FIR filter, specified as a real positive scalar that is less than half the sample rate of the input signal. This parameter applies when you set **Filter type** to Bandpass or Bandstop, and clear the **Specify center frequency from input port** parameter. The default is 10000. This parameter is tunable.

Specify bandwidth from input port

When you select this check box, the filter bandwidth is input through the **BW** port. When you clear this check box, the filter bandwidth is specified on the block dialog through the **Filter bandwidth (Hz)** parameter.

This parameter applies when you set **Filter type** to Bandpass or Bandstop.

Filter bandwidth (Hz)

Bandwidth of the FIR filter, specified as a real positive scalar that is less than half the sample rate of the input signal. This parameter applies when you set **Filter type** to Bandpass or Bandstop, and clear the **Specify bandwidth from input port** parameter. The default is 2000. This parameter is tunable.

Window function

Window function used to design the FIR filter. You can set this parameter to:

- Hann (default)
- Hamming
- Chebyshev
- Kaiser

This parameter is nontunable.

Chebyshev window sidelobe attenuation (dB)

Sidelobe attenuation of chebyshev window, specified as a real positive scalar. This parameter applies when you set **Window function** to Chebyshev. The default is 60. This parameter is nontunable.

Kaiser window parameter

Kaiser window parameter, specified as a real scalar. This parameter applies when you set **Window function** to Kaiser. The default is 0.5. This parameter is nontunable.

Inherit sample rate from input

When you select this check box, the block's sample rate is computed as N / T_s , where N is the frame size of the input signal and T_s is the sample time of the input signal. When you clear this check box, the block's sample rate is the value specified in **Input sample rate (Hz)**. By default, this check box is selected.

Input sample rate (Hz)

Sample rate of the input signal, specified as a positive scalar. The default is 44100. This parameter applies when you clear the **Inherit sample rate from input** check box. This parameter is nontunable.

View Filter Response

Opens the dynamic filter visualizer and displays the magnitude response of the variable bandwidth FIR filter. The response is based on the parameters you select in the Block Parameters dialog box. To update the magnitude response while the dynamic filter visualizer is running, modify the parameters in the dialog box and click **Apply**.

You can configure the plot settings and the signal measurements from the interface of the visualizer.

On the **Plot** tab, the **Configuration** section allows you to modify the plot settings.

On the **Measurements** tab, you can measure the signal statistics, place data cursors, and display the peak values of the selected signal.

For more details on the dynamic filter visualizer interface and its tools, see `dsp.DynamicFilterVisualizer`.

Simulate using

Type of simulation to run. You can set this parameter to:

- Code generation (default)

Simulate model using generated C code. The first time you run a simulation, Simulink generates C code for the block. The C code is reused for subsequent simulations, as long as the model does not change. This option requires additional startup time but provides faster simulation speed than Interpreted execution.

- Interpreted execution

Simulate model using the MATLAB interpreter. This option shortens startup time but has slower simulation speed than Code generation.

Supported Data Types

Port	Supported Data Types
Input	<ul style="list-style-type: none"> • Double-precision floating point • Single-precision floating point
Output	<ul style="list-style-type: none"> • Double-precision floating point • Single-precision floating point

Variable Bandwidth IIR Filter

Design tunable bandwidth IIR filter

Library

Filtering / Filter Designs

dspfdesign

Description

The Variable Bandwidth IIR Filter block filters each channel of the input signal over time using specified IIR filter specifications. This block offers tunable filter design parameters, which enable you to tune the filter characteristics while the simulation is running.

The block designs the IIR filter according to the filter parameters set in the block dialog box. The output port properties, such as datatype, complexity, and dimension, are identical to the input port properties.

Each column of the input signal is treated as a separate channel. If the input is a two-dimensional signal, the first dimension represents the channel length (or frame size) and the second dimension represents the number of channels. If the input is a one-dimensional signal, then it is interpreted as a single channel.

This block supports variable-size input, enabling you to change the channel length during simulation. To enable variable-size input, clear the **Inherit sample rate from input** check box. The number of channels must remain constant.

Algorithms

This block brings the capabilities of `dsp.VariableBandwidthIIRFilter` System object to the Simulink environment.

The IIR filter is designed using the elliptical method. The IIR filter is tuned using IIR spectral transformations based on allpass filters. For more information on the algorithms used by the Variable Bandwidth IIR Filter block, see the “Algorithms” on page 4-1443 section of `dsp.VariableBandwidthIIRFilter`.

Examples

- “Tunable Lowpass Filtering of Noisy Input in Simulink”

Parameters

Filter type

Type of IIR filter. You can set this parameter to:

- Lowpass (default)
- Highpass
- Bandpass
- Bandstop

This parameter is nontunable.

IIR filter order

Order of the IIR filter, specified as a positive integer scalar. The default is 8. This parameter is nontunable.

Specify passband frequency from input port

When you select this check box, the filter passband frequency is input through the **Fp** port. When you clear this check box, the passband frequency is specified on the block dialog through the **Filter passband frequency (Hz)** parameter.

This parameter applies when you set **Filter type** to Lowpass or Highpass.

Filter passband frequency (Hz)

Passband frequency of the IIR filter, specified as a real positive scalar that is less than half the sample rate of the input signal. This parameter applies when you set **Filter type** to Lowpass or Highpass, and clear the **Specify passband frequency from input port** parameter. The default is 1000. This parameter is tunable.

Specify center frequency from input port

When you select this check box, the center frequency of the IIR filter is input through the **Fc** port. When you clear this check box, the center frequency is specified on the block dialog through the **Filter center frequency (Hz)** parameter.

This parameter applies when you set **Filter type** to Bandpass or Bandstop.

Filter center frequency (Hz)

Center frequency of the IIR filter, specified as a real positive scalar that is less than half the sample rate of the input signal. This parameter applies when you set **Filter type** to Bandpass or Bandstop, and clear the **Specify center frequency from input port** parameter. The default is 10000. This parameter is tunable.

Specify bandwidth from input port

When you select this check box, the bandwidth of the IIR filter is input through the **BW** port. When you clear this check box, the filter bandwidth is specified on the block dialog through the **Filter bandwidth (Hz)** parameter.

This parameter applies when you set **Filter type** to Bandpass or Bandstop.

Filter bandwidth (Hz)

Bandwidth of the IIR filter, specified as a real positive scalar that is less than half the sample rate of the input signal. This parameter applies when you set **Filter type** to Bandpass or Bandstop, and clear the **Specify bandwidth from input port** parameter. The default is 2000. This parameter is tunable.

Filter passband ripple (dB)

Passband ripple of the IIR filter, specified as a real positive scalar. The default is 1. This parameter is nontunable.

Filter Stopband attenuation (dB)

Stopband attenuation of the IIR filter, specified as a real positive scalar. The default is 60. This parameter is nontunable.

Inherit sample rate from input

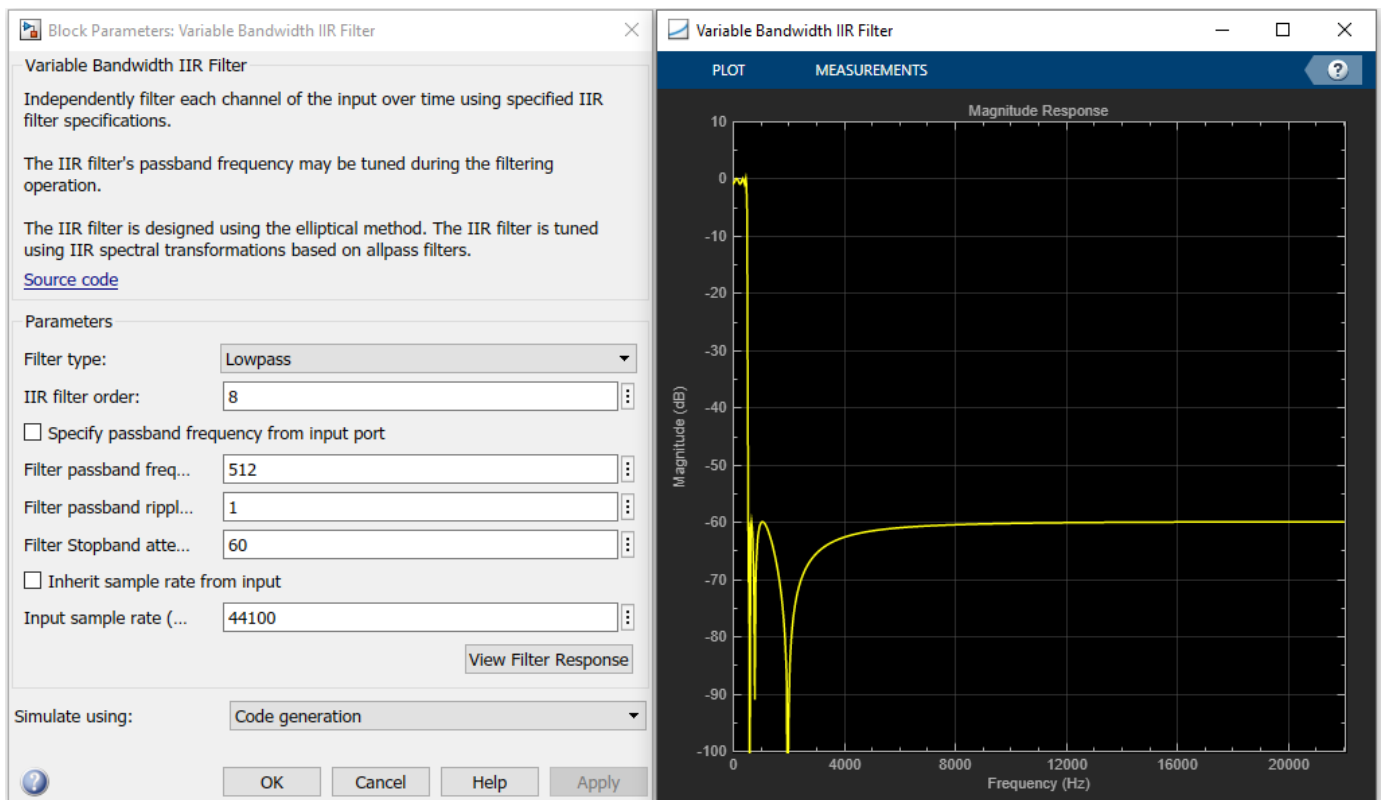

When you select this check box, the block's sample rate is computed as N / T_s , where N is the frame size of the input signal and T_s is the sample time of the input signal. When you clear this check box, the block's sample rate is the value specified in **Input sample rate (Hz)**. By default, this check box is selected.

Input sample rate (Hz)

Sample rate of the input signal, specified as a positive scalar. The default is 44100. This parameter applies when you clear the **Inherit sample rate from input** check box. This parameter is nontunable.

View Filter Response

Opens the dynamic filter visualizer and displays the magnitude response of the variable bandwidth IIR filter. The response is based on the parameters you select in the Block Parameters dialog box. To update the magnitude response while the dynamic filter visualizer is running, modify the parameters in the dialog box and click **Apply**.

You can configure the plot settings and the signal measurements from the interface of the visualizer.

On the **Plot** tab, the **Configuration** section allows you to modify the plot settings.

On the **Measurements** tab, you can measure the signal statistics, place data cursors, and display the peak values of the selected signal.

For more details on the dynamic filter visualizer interface and its tools, see `dsp.DynamicFilterVisualizer`.

Simulate using

Type of simulation to run. You can set this parameter to:

- Code generation (default)

Simulate model using generated C code. The first time you run a simulation, Simulink generates C code for the block. The C code is reused for subsequent simulations, as long as the model does not change. This option requires additional startup time but provides faster simulation speed than Interpreted execution.

- Interpreted execution

Simulate model using the MATLAB interpreter. This option shortens startup time but has slower simulation speed than Code generation.

Supported Data Types

Port	Supported Data Types
Input	<ul style="list-style-type: none">• Double-precision floating point• Single-precision floating point
Output	<ul style="list-style-type: none">• Double-precision floating point• Single-precision floating point

Variable Fractional Delay

Delay input by time-varying fractional number of sample periods

Library: DSP System Toolbox / Signal Operations

Description

The Variable Fractional Delay block delays the input signal by a specified number of fractional samples along each channel of the input. The block can also concurrently compute multiple delayed versions (taps) of the same signal. For an example, see “Delay Signal Using Multitap Fractional Delay”.

When the delay has a fractional value, the block interpolates the input signal to obtain new samples at noninteger sampling intervals. You can set **Interpolation mode** parameter to one of **Linear**, **FIR**, or **Farrow**. The block supports time-varying delay values. That is, the delay value can vary within a frame from sample to sample.

The block assumes that the input values at the **Delay** port are between D_{min} and D_{max} , where D_{min} appears in the **Valid delay range** section on the **Main** tab of the block dialog, and D_{max} is the value of the **Maximum delay (Dmax) in samples** parameter. The block clips delay values less than D_{min} to D_{min} and delay values greater than D_{max} to D_{max} .

You must consider additional factors when selecting valid **Delay** values for the **FIR** and **Farrow** interpolation modes. For details, see “Algorithms” on page 2-1406.

Ports

Input

In — Data input

vector | matrix

Specify the data input as a vector or matrix. The data input must have the same data type as the delay input.

This block supports variable-size input signal. That is, you can change the number of input rows during the simulation. However, the number of channels must remain constant.

Example: [1 2 3 4;5 1 4 2;2 6 2 3;1 2 3 2;3 4 5 6;1 2 3 1]

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point

Delay — Delay input

scalar | vector | matrix | N-D array

Specify the delay input as a scalar, vector, matrix, or N-D array. The delay can be an integer or a fractional value. The block interpolates the signal to obtain new samples at noninteger sampling intervals. The delay input must have the same data type as the data input.

This block supports variable-size delay signal. That is, you can change one or both of the dimensions of the delay signal during simulation. However, the block must make sure that the resulting number of output channels remains constant throughout the simulation.

When the **Input processing** parameter is set to `Columns as channels (frame based)`, the table below shows the effect of the dimension of the delay input on the data input. For an example, see “Delay Signal Using Multitap Fractional Delay”.

Data Input	Delay Input	Output	Effect of Delay Input on Data Input
N (unoriented, one channel)	scalar	Unoriented (N)	One delay value applied to the input channel
N (unoriented, one channel)	Unoriented (N)	Unoriented (N)	Delay value varies within the frame from sample to sample
N (unoriented, one channel)	1-by- P	N -by- P	P taps. Each column in the output is a delayed version of the input. The delay value is specified by the corresponding element in the delay input vector.
N (unoriented, one channel)	N -by- P	N -by- P	P taps. In addition, delay varies within each frame from sample to sample.
N -by-1 (one channel with frame size equal to N)	scalar	N -by-1	One delay value applied to the input channel
N -by-1 (one channel with frame size equal to N)	Unoriented (N)	N -by-1	Delay value varies within the frame from sample to sample
N -by-1 (one channel with frame size equal to N)	N -by-1	N -by-1	Delay value varies within the frame from sample to sample
N -by-1 (one channel with frame size equal to N)	1-by- P	N -by- P	P taps. Each column in the output is a delayed version of the input. The delay value is specified by the corresponding element in the delay input vector.
N -by-1 (one channel with frame size equal to N)	N -by- P	N -by- P	P taps. In addition, delay varies within each frame from sample to sample.
N -by- L (L channels with frame size equal to N)	scalar	N -by- L	One delay value applied to all input channels

Data Input	Delay Input	Output	Effect of Delay Input on Data Input
N -by- L (L channels with frame size equal to N)	1-by- L	N -by- L	Unique delay value for each input channel
N -by- L (L channels with frame size equal to N)	N -by-1	N -by- L	Delay value varies within the frame from sample to sample. Same set of delay values for all channels.
N -by- L (L channels with frame size equal to N)	N -by- L	N -by- L	Delay value varies within the frame from sample to sample. Different delay values for each input channel.
N -by- L (L channels with frame size equal to N)	1-by-1-by- P	N -by- L -by- P	L channels. P taps per channel. Same delay for all channels.
N -by- L (L channels with frame size equal to N)	1-by- L -by- P	N -by- L -by- P	L channels. P taps per channel. Taps vary across channels.
N -by- L (L channels with frame size equal to N)	N -by-1-by- P	N -by- L -by- P	L channels. P taps per channel. Delay varies within the frame from sample to sample. Same set of delay values for each channel.
N -by- L (L channels with frame size equal to N)	N -by- L -by- P	N -by- L -by- P	L channels. P taps per channel. Delay varies within the frame from sample to sample. Different set of delay values for each channel.

When the **Input processing** parameter is set to `Elements as channels (sample based)`, the table below shows the effect of the dimension of the delay input on the data input.

Data Input	Delay Input	Output	Effect of Delay Input on Data Input
N (unoriented, one channel)	scalar	Unoriented (N)	One delay value applied to the input channel
N (unoriented, one channel)	Unoriented (N)	Unoriented (N)	Delay value varies within the frame from sample to sample
N -by-1 (one channel with frame size equal to N)	scalar	N -by-1	One delay value applied to the input channel

Data Input	Delay Input	Output	Effect of Delay Input on Data Input
N -by-1 (one channel with frame size equal to N)	Unoriented (N)	N -by-1	Delay value varies within the frame from sample to sample
N -by-1 (one channel with frame size equal to N)	N -by-1	N -by-1	Delay value varies within the frame from sample to sample
N -by- L (L channels with N samples in each channel)	scalar	N -by- L	One delay value applied to all input channels
N -by- L (L channels with N samples in each channel)	1-by- L	N -by- L	Unique delay value for each input channel
N -by- L (L channels with N samples in each channel)	N -by-1	N -by- L	Delay value varies within the frame from sample to sample. Same set of delay values for all channels.
N -by- L (L channels with N samples in each channel)	N -by- L	N -by- L	Delay value varies within the frame from sample to sample. Different delay values for each input channel.

Example: [2 3 4 5]

Example: [2.5]

Example: [5.6]

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point

Output

Port_1 – Delayed output

vector | matrix

Delayed output, returned as a vector or matrix. The data type and complexity of the output match the data type and complexity of the data input.

When the **Input processing** parameter is set to `Columns as channels (frame based)`, the table below shows the effect of the dimension of the delay input on the data input.

Data Input	Delay Input	Output	Effect of Delay Input on Data Input
N (unoriented, one channel)	scalar	Unoriented (N)	One delay value applied to the input channel

Data Input	Delay Input	Output	Effect of Delay Input on Data Input
N (unoriented, one channel)	Unoriented (N)	Unoriented (N)	Delay value varies within the frame from sample to sample
N (unoriented, one channel)	1-by- P	N -by- P	P taps. Each column in the output is a delayed version of the input. The delay value is specified by the corresponding element in the delay input vector.
N (unoriented, one channel)	N -by- P	N -by- P	P taps. In addition, delay varies within each frame from sample to sample.
N -by-1 (one channel with frame size equal to N)	scalar	N -by-1	One delay value applied to the input channel
N -by-1 (one channel with frame size equal to N)	Unoriented (N)	N -by-1	Delay value varies within the frame from sample to sample
N -by-1 (one channel with frame size equal to N)	N -by-1	N -by-1	Delay value varies within the frame from sample to sample
N -by-1 (one channel with frame size equal to N)	1-by- P	N -by- P	P taps. Each column in the output is a delayed version of the input. The delay value is specified by the corresponding element in the delay input vector.
N -by-1 (one channel with frame size equal to N)	N -by- P	N -by- P	P taps. In addition, delay varies within each frame from sample to sample.
N -by- L (L channels with frame size equal to N)	scalar	N -by- L	One delay value applied to all input channels
N -by- L (L channels with frame size equal to N)	1-by- L	N -by- L	Unique delay value for each input channel
N -by- L (L channels with frame size equal to N)	N -by-1	N -by- L	Delay value varies within the frame from sample to sample. Same set of delay values for all channels.

Data Input	Delay Input	Output	Effect of Delay Input on Data Input
N -by- L (L channels with frame size equal to N)	N -by- L	N -by- L	Delay value varies within the frame from sample to sample. Different delay values for each input channel.
N -by- L (L channels with frame size equal to N)	1-by-1-by- P	N -by- L -by- P	L channels. P taps per channel. Same delay for all channels.
N -by- L (L channels with frame size equal to N)	1-by- L -by- P	N -by- L -by- P	L channels. P taps per channel. Taps vary across channels.
N -by- L (L channels with frame size equal to N)	N -by-1-by- P	N -by- L -by- P	L channels. P taps per channel. Delay varies within the frame from sample to sample. Same set of delay values for each channel.
N -by- L (L channels with frame size equal to N)	N -by- L -by- P	N -by- L -by- P	L channels. P taps per channel. Delay varies within the frame from sample to sample. Different set of delay values for each channel.

When the **Input processing** parameter is set to **Elements as channels (sample based)**, the table below shows the effect of the dimension of the delay input on the data input.

Data Input	Delay Input	Output	Effect of Delay Input on Data Input
N (unoriented, one channel)	scalar	Unoriented (N)	One delay value applied to the input channel
N (unoriented, one channel)	Unoriented (N)	Unoriented (N)	Delay value varies within the frame from sample to sample
N -by-1 (one channel with frame size equal to N)	scalar	N -by-1	One delay value applied to the input channel
N -by-1 (one channel with frame size equal to N)	Unoriented (N)	N -by-1	Delay value varies within the frame from sample to sample
N -by-1 (one channel with frame size equal to N)	N -by-1	N -by-1	Delay value varies within the frame from sample to sample

Data Input	Delay Input	Output	Effect of Delay Input on Data Input
N -by- L (L channels with N samples in each channel)	scalar	N -by- L	One delay value applied to all input channels
N -by- L (L channels with N samples in each channel)	1-by- L	N -by- L	Unique delay value for each input channel
N -by- L (L channels with N samples in each channel)	N -by-1	N -by- L	Delay value varies within the frame from sample to sample. Same set of delay values for all channels.
N -by- L (L channels with N samples in each channel)	N -by- L	N -by- L	Delay value varies within the frame from sample to sample. Different delay values for each input channel.

Example: [0 0 0 0;0 0 0 0;1 0 0 0;5 2 0 0;2 1 3 0;1 6 4 4]

Example: [0 0 0 0;0 0 0 0;0.5 1.0 1.5 2.0;3 1.5 3.5 3.0;3.5 3.5 3.0 2.5;1.5 4.0 2.5 2.5]

Example: [0 0 0 0;0 0 0 0;0 0 0 0;0 0 0 0;0.4 0.8 1.2 1.6]

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point

Parameters

Interpolation mode — Method of interpolation

Linear (default) | FIR | Farrow

Specify the method of interpolation. Using this method, the block interpolates the signal to obtain new samples at noninteger sampling intervals.

- **Linear** -- Linear interpolation. In this mode, the block stores the $\mathbf{D}_{\max}+1$ most recent samples the **In** port receives for each channel. \mathbf{D}_{\max} is the value you specify in the **Maximum delay (Dmax) in samples** parameter.
- **FIR** -- Polyphase FIR interpolation. In this mode, the block stores the $\mathbf{D}_{\max}+\mathbf{P}+1$ most recent samples the **In** port receives for each channel. \mathbf{P} is the value you specify in the **Interpolation filter half-length (P)** parameter.
- **Farrow** -- LaGrange method. In this mode, the block stores the $\mathbf{D}_{\max}+\frac{\mathbf{N}}{2}+1$ most recent samples the **In** port receives for each channel. \mathbf{N} is the value you specify in the **Farrow filter length (N)** parameter.

For more details on these methods, see “Algorithms” on page 2-1406.

Interpolation filter half-length (P) — Half length of interpolation filter

4 (default) | positive integer in the range [1 65535]

Half-length of the FIR interpolation filter. For periodic signals, a larger value of this property, which indicates a higher order filter, yields a better estimate of the delayed output sample. A property value of 4 to 6, which corresponds to a 7th-order to 11th-order filter, is usually adequate.

Example: 6

Example: 10

Dependencies

This parameter applies only when you set **Interpolation mode** to FIR.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `Boolean` | `fixed point`

Interpolation points per input sample — Number of interpolation points per input sample

10 (default) | positive integer in the range [2, 65,535]

Number of interpolation points per input sample at which a unique FIR interpolation filter is computed.

Example: 20

Example: 5

Dependencies

This parameter applies only when you set **Interpolation mode** to FIR.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

Normalized input bandwidth (0 to 1) — Normalized input bandwidth

1 (default) | real scalar in the range (0, 1]

Normalized input bandwidth at which to constrain the interpolated output samples. A value of 1 equals the Nyquist frequency, or half the sampling frequency, F_s . Use this property to take advantage of the bandlimited frequency content of the input. For example, if the input signal does not have frequency content above $F_s/4$, you can specify a value of 0.5.

Example: 0.5

Example: 0.8

Dependencies

This parameter applies only when you set **Interpolation mode** to FIR.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `Boolean` | `fixed point`

Farrow filter length (N) — Length of Farrow filter

4 (default) | integer greater than or equal to 2

Length of the FIR filter implemented using the Farrow structure. If the length equals 2, the filter performs linear interpolation.

Example: 4

Example: 10

Dependencies

This parameter applies only when you set **Interpolation mode** to Farrow.

Data Types: single | double | int8 | int16 | int32 | uint8 | uint16 | uint32

Maximum delay (Dmax) in samples — Maximum delay

100 (default) | integer in the range [0 65535]

Maximum delay the block can produce, D_{max} . Input delay values exceeding this maximum are clipped to D_{max} .

Example: 200

Example: 500

Data Types: single | double | int8 | int16 | int32 | uint8 | uint16 | uint32

Input processing — Method to process the input

Columns as channels (frame based) (default) | Elements as channels (sample based)

Specify how the block should process the input. You can set this parameter to one of the following options:

- **Columns as channels (frame based) (default)** — When you select this option, the block treats each column of the input as a separate channel. The block treats each of the R input columns as independent channels containing M_i sequential time samples.

The input to the **Delay** port, v , contains floating-point values that specify the number of sample intervals to delay the current input.

The input to the **Delay** port can be a scalar value to uniformly delay every sample in every channel. It can also be a length- M column vector, containing one delay for each sample in the input frame. The block applies the set of delays contained in the vector identically to every channel of a multichannel input. The **Delay** port entry can also be a length- R row vector, containing one delay for each channel. Finally, the **Delay** port entry can be an M -by- R matrix, containing a different delay for each corresponding element of the input.

For example, if v is the M_i -by-1 matrix $[v(1) \ v(2) \ \dots \ v(M_i)]'$, the earliest sample in the current frame is delayed by $v(1)$ fractional sample intervals, the following sample in the frame is delayed by $v(2)$ fractional sample intervals, and so on. The block applies the set of fractional delays contained in v identically to every channel of a multichannel input.

- **Elements as channels (sample based)** -- When you select this option, the block treats each element of the input as a separate channel. The block treats each element of the N-D input array, u , as an independent channel. The input to the **Delay** port, v , must either be an N-D array of the same size and dimension as the input u , or be a scalar value, such that $D_{min} \leq v \leq D_{max}$.

For example, consider an M -by- R input matrix. The block treats each of the $M \times R$ matrix elements as independent channels. The input to the **Delay** port can be an M -by- R matrix of floating-point values in the range $D_{min} \leq v \leq D_{max}$ that specifies the number of sample intervals to delay each channel of the input, or it can be a scalar floating-point value, $D_{min} \leq v \leq D_{max}$, by which to equally delay all channels.

In sample-based processing mode, the block treats an unoriented vector input as an M -by-1 matrix. In this mode, the output is also an unoriented vector.

InitialConditions – Initial values in the memory0 (default) | scalar | 1-by- R -by- D array | 1-by- R -by- $(D+L)$ array

Specify the values within the block's memory at the start of the simulation. The dimensions of this parameter can vary depending on whether you want fixed or time-varying initial conditions. The block treats each of the R input columns as a frame containing M sequential time samples from an independent channel.

For an M -by- R input matrix, u , you can set this parameter as follows:

- To specify fixed initial conditions, set this parameter to a scalar value. The block initializes every sample of every channel in memory using the value you specify.
- The dimensions you specify for time-varying initial conditions depend on the interpolation method. To specify different time-varying initial conditions for each channel, set this parameter as follows:
 - If you set the **Interpolation mode** to Linear, set the **Initial conditions** to an array of size 1-by- R -by- D , where D is the value in **Maximum delay (Dmax) in samples** parameter.
 - If you set the **Interpolation mode** to FIR or Farrow, set the **Initial conditions** to an array of size 1-by- R -by- $(D+L)$, where D is the value of the maximum delay. For FIR interpolation, L is the value of the interpolation filter half length. For Farrow interpolation, L equals floor of half the value of the farrow filter length (`floor(farrow filter length/2)`).

Example: 1

Example: `randn(1,3,104)`

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32`

Disable direct feedthrough by increasing minimum possible delay by one – Disable direct feedthrough

off (default) | on

Select this box to disable direct feedthrough by increasing the minimum possible delay value. When you set the **Input processing** parameter to Columns as channels (frame based), the block increases the minimum possible delay value by `frame size - 1`. Similarly, when you set the **Input processing** parameter to Elements as channels (sample based), the block increases the minimum possible delay value by one sample.

Checking this box allows you to use the Variable Fractional Delay block in feedback loops.

For small input delay values – Action to take for small input delay values

Clip to the minimum value necessary for centered kernel (default) | Use off-centered kernel | Switch to linear interpolation if kernel cannot be centered

Specify the block's behavior when the input delay values are too small to center the kernel.

You can specify how the block handles input delay values that are too small for the kernel to be centered using one of the following choices:

- In both FIR and Farrow interpolation modes, you can select `Clip to the minimum value necessary for centered kernel`. This option forces the block to increase D_{min} to the smallest value necessary to keep the kernel centered.
- In FIR interpolation mode, you can select `Switch to linear interpolation if kernel cannot be centered`. This option forces the block to preserve the value of D_{min} and compute all interpolated values using Linear interpolation.

- In Farrow interpolation mode, you can select Use off-centered kernel. This option forces the block to preserve the value of D_{min} and compute the interpolated values using a farrow filter with an off-centered kernel.

Dependencies

This parameter applies only when **Interpolation mode** is set to FIR or Farrow.

Valid delay range (in samples) — Range of valid delay values

[0 100] (default) | [D_{min} D_{max}]

This property is read-only.

The delay range values [D_{min} D_{max}] are calculated (in samples) by the block based on the current parameter settings. D_{min} is the smallest possible valid delay value (in samples). The block clips all input delay values less than D_{min} to D_{min} . D_{max} is the maximum valid delay value (in samples). The block clips all input delay values greater than D_{max} to D_{max} .

When the **Interpolation mode** is set to one of the following:

- **Linear** -- D_{min} equal 0. D_{max} equals the value you specify in the **Maximum delay (Dmax) in samples** parameter.
- **FIR** -- D_{min} equals $P - 1$, where P is the value you specify in **Interpolation filter half-length (P)**. D_{max} equals the value you specify in the **Maximum delay (Dmax) in samples** parameter.
- **Farrow** -- D_{min} equals $N/2 - 1$, where N is the value you specify in **Farrow filter length (N)**. D_{max} equals the value you specify in the **Maximum delay (Dmax) in samples** parameter.

Example: [1 100]

Example: [2 100]

Example: [3 100]

Fixed-Point Properties

Fixed-Point Properties

Rounding mode — Rounding method for fixed-point operations

Zero (default) | Ceiling | Convergent | Floor | Nearest | Round | Simplest

Specify the rounding mode for fixed-point operations as one of the following:

- Zero
- Ceiling
- Convergent
- Floor
- Nearest
- Round
- Simplest

For more details, see rounding mode.

Saturate on integer overflow — Method of overflow action

off (default) | on

When you select this parameter, the block saturates the result of its fixed-point operation. When you clear this parameter, the block wraps the result of its fixed-point operation. For details on `saturate` and `wrap`, see `overflow mode for fixed-point operations`.

Coefficients — Data type of the coefficients

Same word length as input (default) | Specify word length

Specify the data type of the filter coefficients as one of the following:

- `Same word length as input` -- The word length of the filter coefficients matches that of the input to the block. The fraction length of the coefficients is automatically set to the binary-point only scaling that provides you with the best precision possible given the value and word length of the coefficients.
- `Specify word length` -- Specify the word length of the coefficients, in bits. In this mode, the fraction length of the coefficients is automatically set to the binary-point only scaling that provides you with the best precision possible given the value and word length of the coefficients.

For more information on the coefficients data type this block uses, see the “Fixed Point” on page 2-1408 section.

Product output — Data type of the product output

Same as first input (default) | Binary point scaling

Specify the data type of the product output as one of the following:

- `Same as first input` -- The block specifies the product output data type to be the same as that of the data input.
- `Binary point scaling` -- Specify the word length and the fraction length of the product output, in bits.

For more information on the product output data type, see “Multiplication Data Types” and the “Fixed Point” on page 2-1408 section.

Accumulator — Data type of accumulation operation

Same as product output (default) | Same as first input | Binary point scaling

Specify the data type of an accumulation operation as one of the following:

- `Same as product output` -- The block specifies the accumulator data type to be the same as that of the product output data type.
- `Same as first input` -- The block specifies the accumulator data type to be the same as that of the data input.
- `Binary point scaling` -- Specify the word length and the fraction length of the accumulator output, in bits.

For more information on the accumulator data type this block uses, see the “Fixed Point” on page 2-1408.

Product output polyval — Data type of the product polynomial value

Same as first input (default) | Binary point scaling

Specify the data type of the product polynomial value as one of the following:

- `Same as first input` -- The block specifies the product polynomial value data type to be the same as that of the data input.
- `Binary point scaling` -- Specify the word length and the fraction length of the product output polynomial, in bits.

For more information on the product polynomial value data type this block uses, see the “Fixed Point” on page 2-1408 section.

Dependencies

This property applies when you set **Interpolation mode** to Farrow.

Accumulator polyval — Data type of the accumulator polynomial value

`Same as first input (default)` | `Binary point scaling`

Specify the data type of the accumulator polynomial value as one of the following:

- `Same as first input` -- The block specifies the accumulator polynomial value data type to be the same as that of the data input.
- `Binary point scaling` -- Specify the word length and the fraction length of the accumulator polynomial value, in bits.

For more information on the accumulator polynomial value data type that this block uses, see the “Fixed Point” on page 2-1408 section.

Dependencies

This property applies when you set **Interpolation mode** to Farrow.

Multiplicand polyval — Data type of multiplicand polynomial value

`Same as first input (default)` | `Binary point scaling`

Specify the data type of the multiplicand polynomial value as one of the following:

- `Same as first input` -- The block specifies the multiplicand polynomial value data type to be the same as that of the data input.
- `Binary point scaling` -- Specify the word length and the fraction length of the multiplicand polynomial value, in bits.

For more information on the multiplicand polynomial value data type this block uses, see the “Fixed Point” on page 2-1408 section.

Dependencies

This property applies when you set **Interpolation mode** to Farrow.

Output — Data type of block output

`Same as accumulator (default)` | `Same as first input` | `Binary point scaling`

Specify the data type of the block output as one of the following:

- `Same as accumulator` -- The block specifies the output data type to be the same as that of the accumulator output data type.
- `Same as first input` -- The block specifies the output data type to be the same as that of the data input.

- `Binary point scaling` -- Specify the word length and the fraction length of the block output, in bits.

For more information on the output data type this block uses, see the “Fixed Point” on page 2-1408 section.

Lock data type settings against changes by the fixed-point tools – Prevent fixed-point tools from overriding data types

`off (default) | on`

Select this parameter to prevent the fixed-point tools from overriding the data types you specify in the block dialog box.

Block Characteristics

Data Types	<code>double fixed point integer single</code>
Direct Feedthrough	<code>no</code>
Multidimensional Signals	<code>no</code>
Variable-Size Signals	<code>yes</code>
Zero-Crossing Detection	<code>no</code>

Algorithms

The delay value specified at the **Delay** port serves as an index into the block's memory, U , which stores, at a minimum, the $D_{\max} + 1$ most recent samples received at the **In** port for each channel. For example, an integer delay of 5 on a scalar input sequence retrieves and outputs the fifth most recent input sample from the block's memory, $U(6)$. The block computes fractional delays by interpolating between stored samples. The block uses a linear, FIR, or farrow interpolation method to interpolate signal values at noninteger sample intervals.

Linear Interpolation Mode

For noninteger delays, at each sample time, the linear interpolation method uses the two samples in memory nearest to the specified delay to compute a value for the sample at that time.

For a vector data input, the output vector, y , is computed using the following relation:

$$\begin{aligned} v_i &= \text{floor}(v) \\ v_f &= v - v_i \\ y(i) &= U(i - v_i - 1) * v_f + U(i - v_i) * (1 - v_f) \end{aligned}$$

where,

- i -- Index of the current sample
- v -- Fractional delay
- v_i -- Integer part of the delay
- v_f -- Fractional part of the delay
- U -- Input data vector

- y -- Output data vector
- $U(i-v_i), U(i-v_i-1)$ -- Two samples in memory nearest to the specified delay
- $i-v_i$ -- Distance, in samples, between the current index and the nearest point in the interpolation line.

The variable fractional delay stores the $D_{max}+1$ most recent samples received at the input for each channel, where D_{max} is the maximum delay specified. U represents the stored samples.

FIR Interpolation Mode

In the FIR interpolation mode, the block stores the $D_{max}+P+1$ most recent samples received at the input for each channel, where P is the specified interpolation filter half-length.

In this mode, the block provides a discrete set of fractional delays:

$$v + \frac{i}{L}, \quad v \geq P - 1, \quad i = 0, 1, \dots, L - 1$$

If v is less than $P - 1$, the behavior depends on the **For small input delay values** parameter. You can specify the block's behavior when the input delay value is too small to center the kernel (less than $P-1$), by setting the **For small input delay values** parameter:

- **Clip to the minimum value necessary for centered kernel** -- The FIR interpolation method remains in use. The small input delay values are clipped to the smallest value necessary to center the kernel.
- **Switch to linear interpolation if kernel cannot be centered** -- Fractional delays are computed using linear interpolation when the input delay value is less than $P-1$.

In the FIR interpolation mode, the algorithm implements a polyphase structure to compute a value for each sample at the specified delay. Each arm of the structure corresponds to a different delay value. The output computed for each sample corresponds to the output of the arm with a delay value nearest to the specified input delay. Therefore, only a discrete set of delays is actually possible. The number of coefficients in each of the L filter arms of the polyphase structure is $2P$. In most cases, using values of P between 4 and 6 provides you with reasonably accurate interpolation values.

The `designMultirateFIR` function designs the FIR interpolation filter.

For example, when you set the following values:

- Interpolation filter half-length (P) to 4
- Interpolation points per input sample to 10
- Normalized input bandwidth to 1
- Stopband attenuation to 80 dB

The filter coefficients are given by:

```
b = designMultirateFIR(10,1,4,80);
```

The algorithm then implements this filter as a polyphase structure.

Increasing the filter half length (P) increases the accuracy of the interpolation, but also increases the number of computations performed per input sample. The amount of memory needed to store the filter coefficients increases too. Increasing the interpolation points per sample (L) increases the

number of representable discrete delay points, but also increases the simulation's memory requirements. The computational load per sample is not affected.

The normalized input bandwidth from 0 to 1 allows you to take advantage of the bandlimited frequency content of the input. For example, if you know that the input signal does not have frequency content above $F_s/4$, you can specify 0.5 normalized bandwidth to constrain the frequency content of the output to that range.

Note You can consider each of the L interpolation filters to correspond to one output phase of an upsample-by- L FIR filter. Therefore, the normalized input value improves the stopband in critical regions and relaxes the stopband requirements in frequency regions without signal energy.

Farrow Interpolation Mode

In the farrow interpolation mode, the block stores the $D_{max}+N/2+1$ most recent samples received at the input for each channel, where N is the specified farrow filter length.

The algorithm uses the LaGrange method to interpolate values.

To increase the minimum possible delay value, select the **Disable direct feedthrough by increasing minimum possible delay by one** check box. Checking this box prevents algebraic loops from occurring when you use the block inside a feedback loop.

To specify the behavior when the input delay value is too small to center the kernel (less than $\frac{N}{2} - 1$), use the Farrow small delay action setting.

- **Clip to the minimum value necessary for centered kernel** -- The block clips small input delay values to the smallest value necessary to keep the kernel centered. This increases D_{min} but yields more accurate interpolation values.
- **Use off-centered kernel** -- The fractional delays are computed using a Farrow filter with an off-centered kernel. This mode does not increase D_{min} , but the results for input delay values less than $\frac{N}{2} - 1$ are less accurate than the results achieved by keeping the kernel centered.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

The diagrams in the following sections show the data types used within the Variable Fractional Delay for fixed-point signals.

Although you can specify most of these data types, the following data types are computed internally by the block and cannot be directly specified on the block dialog box.

Data Type	Word Length	Fraction Length
vf data type	Same word length as the coefficients	Same as the word length
HoldInteger data type	Same word length as the input delay value	0 bits
Integer data type	32 bits	0 bits

Note When the input is fixed point, all internal data types are signed fixed point.

To compute the integer (v_i) and fractional (v_f) parts of the input delay value (v), the Variable Fractional Delay block uses the following equations:

$$D_{min} < v < D_{max} \Rightarrow \begin{cases} v_i = \text{floor}(v) \\ v_f = v - v_i \end{cases}$$

$$v \leq D_{min} \Rightarrow \begin{cases} v_i = D_{min} \\ v_f = 0 \end{cases}$$

$$v \geq D_{max} \Rightarrow \begin{cases} v_i = D_{max} \\ v_f = 0 \end{cases}$$

Linear Interpolation Mode

The following diagram shows the fixed-point data types used by the Linear interpolation mode of the Variable Fractional Delay block.

FIR Interpolation Mode

The following diagram illustrates how the Variable Fractional Delay block selects the arm of the polyphase filter structure that most closely matches the fractional delay value (v_f).

The following diagram shows the fixed-point data types used by the variable fractional delay algorithm in the FIR interpolation mode.

You can set the coefficient, product output, accumulator, and output data types in the block. This diagram shows that input data is stored in the input buffer with the same data type and scaling as the input. The block stores filtered data and any initial conditions in the output buffer using the output data type and scaling that you set.

When at least one of the inputs to the multiplier is real, the output of the multiplier is in the product output data type. When both inputs to the multiplier are complex, the result of the multiplication is in the accumulator data type. For details on the complex multiplication, see “Multiplication Data Types”.

Farrow Interpolation Mode

The following diagram shows the fixed-point data types used by the Farrow interpolation mode when:

- Farrow filter length is set to 4
- Farrow small delay action is set to Clip to the minimum value necessary for centered kernel

The following diagram shows the fixed-point data types used by the Farrow interpolation mode when:

- Farrow filter length is set to 4.
- Farrow small delay action is set to Use off-centered kernel.

Diff is computed from the integer part of the delay value (v_i) and the farrow filter length (N) according to the following equation:

$$Diff = v_i - \left(\frac{N - 1}{2}\right)$$

$$Diff \geq 0 \Rightarrow Diff = 0$$

$$Diff < 0 \Rightarrow Diff = -Diff$$

The following diagram shows the fixed-point data types used by the Digital Filter's FIR direct form filter.

Description

Note The Variable Integer Delay block has been replaced with the Simulink Variable Integer Delay block. Existing instances of the DSP block will continue to operate, but certain functionality will be disabled in future releases. See “Functionality being removed or replaced for blocks and System objects”.

The Variable Integer Delay block delays the discrete-time input at the In port by the integer number of sample intervals specified by the input to the Delay port. The sample rate of the input signal at the Delay port must be the same as the sample rate of the input signal at the In port. When these sample rates are not the same, you need to insert a Zero-Order Hold or Rate Transition block in order to make the sample rates identical. When you set the **Input processing** parameter to **Elements as channels (sample based)**, the delay for an N-D input can be a scalar value to uniformly delay every sample in every channel, or a matrix containing one delay value for each channel of the input. When you set the **Input processing** parameter to **Columns as channels (frame based)**, the delay can be a scalar value to uniformly delay every sample in every channel, a vector containing one delay value for each sample in the input frame, or a vector containing one delay value for each channel in the input frame.

The delay values should be in the range of 0 to D , where D is the **Maximum delay**. Delay values greater than D or less than 0 are clipped to those respective values and noninteger delays are rounded to the nearest integer value.

The Variable Integer Delay block differs from the Delay block in the following ways.

Variable Integer Delay Block	Delay Block
The delay is provided as an input to the Delay port.	You specify the delay as a parameter setting in the dialog box.
Delay can vary with time; for example, when the block performs frame-based processing, the n th element's delay in the first input frame can differ from the n th element's delay in the second input frame.	Delay cannot vary with time; for example, when the block performs frame-based processing, the n th element's delay is the same for every input frame.

Variable Integer Delay Block	Delay Block
When you use the Variable Integer Delay block in a feedback loop, you must check the Disable direct feedthrough by increasing minimum possible delay by one check box. This prevents the occurrence of an algebraic loop when the delay of the Variable Integer Delay block is driven to zero.	You can use the Delay block to break an algebraic loop.

Sample-Based Processing

When you set the **Input processing** parameter to **Elements as channels (sample based)**, the Variable Integer Delay block supports N-D input arrays. When the input is an M -by- N -by- P array, the block treats each of the $M*N*P$ elements as independent channels, and applies the delay at the Delay port to each channel.

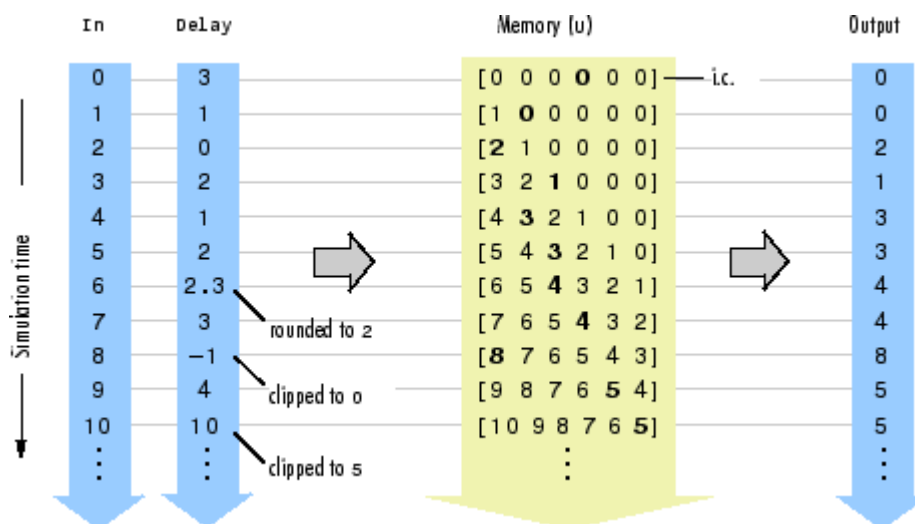

The Variable Integer Delay block stores the $D+1$ most recent samples received at the In port for each channel. At each sample time the block outputs the stored sample(s) indexed by the input to the Delay port.

For example, when the input to the In port, u , is a scalar signal, the block stores a vector, U , of the $D+1$ most recent signal samples. When the current input sample is $U(1)$, the previous input sample is $U(2)$, and so on, then the block's output is

```
y = U(v+1); % Equivalent MATLAB code
```

where v is the input to the Delay port. A delay value of 0 ($v=0$) causes the block to pass through the sample at the In port in the same simulation step that it is received. The block's memory is initialized to the **Initial conditions** value at the start of the simulation (see below).

The next figure shows the block output for a scalar ramp sequence at the In port, a **Maximum delay** of 5, an **Initial conditions** of 0, and a variety of different delays at the Delay port.

The current input at each time step is immediately stored in memory as $U(1)$. This allows the current input to be available at the output for a delay of 0 ($v=0$).

The **Initial conditions** parameter specifies the values in the block's memory at the start of the simulation. Unlike the Delay block, the Variable Integer Delay block does not have a fixed initial delay period during which the initial conditions appear at the output. Instead, the initial conditions are propagated to the output only when they are indexed in memory by the value at the Delay port. Both fixed and time-varying initial conditions can be specified in a variety of ways to suit the dimensions of the input sequence.

Fixed Initial Conditions

The settings in this section specify fixed initial conditions. For a fixed initial condition, the block initializes each of D samples in memory to the value entered in the **Initial conditions** parameter. A fixed initial condition in sample-based mode can be specified in one of the following ways:

- Scalar value with which to initialize every sample of every channel in memory. For a general M -by- N input and the parameter settings in this figure,

the block initializes 100 M -by- N matrices in memory with zeros.

- Array of size M -by- N -by- D . In this case, you can specify different fixed initial conditions for each channel. See the Array bullet in “Time-Varying Initial Conditions” on page 2-1416 below for details.

Time-Varying Initial Conditions

The following settings specify time-varying initial conditions. For a time-varying initial condition, the block initializes each of D samples in memory to one of the values entered in the **Initial conditions** parameter. This allows you to specify a unique output value for each sample in memory. A time-varying initial condition in sample-based mode can be specified in one of the following ways:

- Vector containing D elements with which to initialize memory samples $U(2:D+1)$, where D is the **Maximum delay**. For a scalar input and the parameters in the next figure, the block initializes $U(2:6)$ with values $[-1, -1, -1, 0, 1]$.

- Array of dimension M -by- N -by- D with which to initialize memory samples $U(2:D+1)$, where D is the **Maximum delay** and M and N are the number of rows and columns, respectively, in the input matrix. For a 2-by-3 input and the following parameters, the block initializes memory locations $U(2:5)$ with values

$$\mathbf{U}(2) = \begin{bmatrix} 1 & 1 & 1 \\ 1 & 1 & 1 \end{bmatrix}, \quad \mathbf{U}(3) = \begin{bmatrix} 2 & 2 & 2 \\ 2 & 2 & 2 \end{bmatrix}, \quad \mathbf{U}(4) = \begin{bmatrix} 3 & 3 & 3 \\ 3 & 3 & 3 \end{bmatrix}, \quad \mathbf{U}(5) = \begin{bmatrix} 4 & 4 & 4 \\ 4 & 4 & 4 \end{bmatrix}$$

An M -by- N -by- P -by- D array can be entered for the **Initial Conditions** parameter when the input is an M -by- N -by- P array. The (M,N,P,T) th sample of the **Initial Conditions** matrix provides the initial condition value for the (M,N,P) th channel of the input matrix at delay = $D-t+1$ samples.

Frame-Based Processing

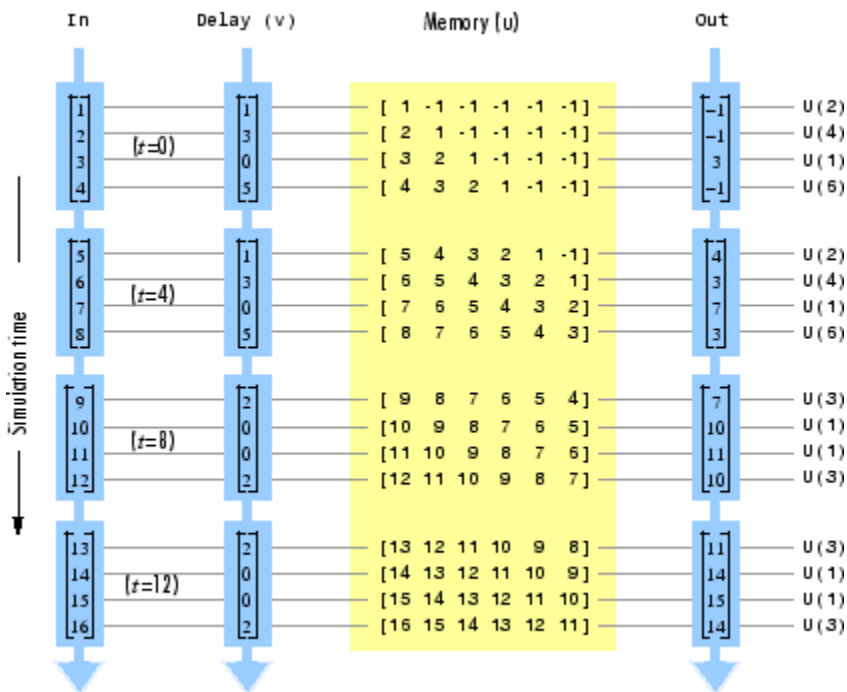

When you set the **Input processing** parameter to `Columns as channels (frame based)`, the input can be an M -by- N matrix. The block treats each of the N input columns as independent channels containing M sequential time samples.

In this mode, the input at the Delay port can be a scalar value to uniformly delay every sample in every channel. It can also be a length- M column vector containing one delay value for each sample in the input frame(s). The set of delays contained in the vector is applied identically to every channel of a multichannel input. The Delay port entry can also be a length- N row vector, containing one delay for each channel. Finally, the Delay port entry can be an M -by- N matrix, containing a different delay for each corresponding element of the input.

Vector v does not specify when the samples in the current input frame will appear in the output. Rather, v indicates which previous input samples (stored in memory) should be included in the current output frame. The first sample in the current output frame is the input sample $v(1)$ intervals earlier in the sequence, the second sample in the current output frame is the input sample $v(2)$ intervals earlier in the sequence, and so on.

The illustration below shows how this works for an input with a sample period of 1 and frame size of 4. The **Maximum delay** (D_{max}) is 5, and the **Initial conditions** parameter is set to -1. The delay input changes from $[1 \ 3 \ 0 \ 5]$ to $[2 \ 0 \ 0 \ 2]$ after the second input frame. The samples in each output frame are the values in memory indexed by the elements of v :

$$\begin{aligned} y(1) &= U(v(1)+1) \\ y(2) &= U(v(2)+1) \\ y(3) &= U(v(3)+1) \\ y(4) &= U(v(4)+1) \end{aligned}$$

The **Initial conditions** parameter specifies the values in the block's memory at the start of the simulation. Both fixed and time-varying initial conditions can be specified.

Fixed Initial Conditions

The settings shown in this section specify fixed initial conditions. For a fixed initial condition, the block initializes each of D samples in memory to the value entered in the **Initial conditions** parameter. A fixed initial condition in frame-based mode can be one of the following:

- Scalar value with which to initialize every sample of every channel in memory. For a general M -by- N input with the parameter settings below, the block initializes five samples in memory with zeros.

Maximum delay (samples):	5
Initial conditions:	0

- Array of size 1-by- N -by- D . In this case, you can specify different fixed initial conditions for each channel. See the Array bullet in “Time-Varying Initial Conditions” on page 2-1418 below for details.

Time-Varying Initial Conditions

The following setting specifies a time-varying initial condition. For a time-varying initial condition, the block initializes each of D samples in memory to one of the values entered in the **Initial conditions** parameter. This allows you to specify a unique output value for each sample in memory. When the block is performing frame-based processing, you can specify a time-varying initial condition in the following ways:

- Vector containing D elements. In this case, all channels have the same set of time-varying initial conditions specified by the entries of the vector. For the ramp input $[1:100; 1:100]'$ with a

frame size of 4, delay of 5, and the following parameter settings, the block outputs the following sequence of frames at the start of the simulation:

$$\begin{bmatrix} -1 & -1 \\ -2 & -2 \\ -3 & -3 \\ -4 & -4 \end{bmatrix}, \begin{bmatrix} -5 & -5 \\ 1 & 1 \\ 2 & 2 \\ 3 & 3 \end{bmatrix}, \begin{bmatrix} 4 & 4 \\ 5 & 5 \\ 6 & 6 \\ 7 & 7 \end{bmatrix}, \dots$$

- Array of size 1-by- N -by- D . In this case, you can specify different time-varying initial conditions for each channel. For the ramp input `[1:100; 1:100]'` with a frame size of 4, delay of 5, and the following parameter settings, the block outputs the following sequence of frames at the start of the simulation:

$$\begin{bmatrix} -1 & -11 \\ -2 & -22 \\ -3 & -33 \\ -4 & -44 \end{bmatrix}, \begin{bmatrix} -5 & -55 \\ 1 & 1 \\ 2 & 2 \\ 3 & 3 \end{bmatrix}, \begin{bmatrix} 4 & 4 \\ 5 & 5 \\ 6 & 6 \\ 7 & 7 \end{bmatrix}, \dots$$

By specifying a 1-by- N -by- D initial condition array such that each 1-by- N vector entry is identical, you can implement different fixed initial conditions for each channel.

Examples

See “Basic Algorithmic Delay” in the *DSP System Toolbox User's Guide*.

Parameters

Maximum delay

The maximum delay that the block can produce for any sample. Delay input values exceeding this maximum are clipped at the maximum.

Initial conditions

The values with which the block's memory is initialized.

Input processing

Specify how the block should process the input. You can set this parameter to one of the following options:

- **Columns as channels (frame based)** — When you select this option, the block treats each column of the input as a separate channel.
- **Elements as channels (sample based)** — When you select this option, the block treats each element of the input as a separate channel.

Note The Inherited (this choice will be removed - see release notes) option will be removed in a future release. See “Frame-Based Processing” in the *DSP System Toolbox Release Notes* for more information.

Disable direct feedthrough by increasing minimum possible delay by one

Select this box to disable direct feedthrough by adding one to the minimum possible delay value. When you set the **Input processing** parameter to Columns as channels (frame based), the block increases the minimum possible delay value by *frame size* - 1. Similarly, when you set the **Input processing** parameter to Elements as channels (sample based), the block increases the minimum possible delay value by one sample.

Checking this box allows you to use the Variable Integer Delay block in feedback loops.

Supported Data Types

Port	Supported Data Types
In	<ul style="list-style-type: none"> • Double-precision floating point • Single-precision floating point • Fixed point (signed and unsigned) • Boolean • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers
Delay	<ul style="list-style-type: none"> • Double-precision floating point • Single-precision floating point • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers
Out	<ul style="list-style-type: none"> • Double-precision floating point • Single-precision floating point • Fixed point (signed and unsigned) • Boolean • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers

Variable Selector

Select subset of rows or columns from input

Library: DSP System Toolbox / Signal Management / Indexing
 DSP System Toolbox HDL Support / Signal Management

Description

The Variable Selector block extracts a subset of rows or columns from the M -by- N input matrix u at each input port. You specify the number of input and output ports in the **Number of input signals** parameter.

When an element of the indexing vector references a nonexistent row or column of the input, the block implements the action that you specify by using the **Invalid index** parameter.

When the indexing vector elements are of the Boolean data type, the block performs logical indexing. Select **Fill empty spaces in outputs (for logical indexing)** to access the **Fill values** parameter. These values are appended to the output to make it as long as the input elements.

Note The Variable Selector block always copies the selected input rows or columns to a contiguous block of memory (unlike the Simulink Selector block).

Ports

Input

InN — Nth input signal

scalar | vector | matrix

Nth input signal, where N is the number of inputs specified in the “Number of input signals” on page 2-0 parameter.

When the input is an unoriented vector, the “Select” on page 2-0 parameter is ignored and the output is an unoriented vector of length L containing those elements specified by the length- L indexing vector.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | Boolean | fixed point | enumerated

Idx — Index vector

scalar | vector

Specify a scalar value or vector containing the indices of the input rows or columns that appear in the output matrix.

Dependencies

This port appears only when you set the “Selector mode” on page 2-0 to **Variable**.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `Boolean` | `fixed point` | `enumerated`

Output**OutN – Nth Output signal**

`scalar` | `vector` | `matrix`

Nth output signal, corresponding to the Nth input signal, where *N* is the number of inputs specified in the “Number of input signals” on page 2-0 parameter. The output is returned as a scalar, vector, or matrix as the same type, size, and complexity as the corresponding input.

For variable and fixed indexing modes, the row selection operation is equivalent to

```
y = u(idx,:) % Equivalent MATLAB code
```

and the column selection operation is equivalent to

```
y = u(:,idx) % Equivalent MATLAB code
```

where `idx` is the length-*L* indexing vector. The row selection output size is *L*-by-*N* and the column selection output size is *M*-by-*L*. Input rows or columns can appear any number of times in the output, or not at all.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `Boolean` | `fixed point` | `enumerated`

Parameters**Number of input signals – Number of inputs**

1 (default) | positive integer

Specify the number of input signals as a positive integer. An input port is created on the block for each input signal.

Select – Select dimension

`Rows` (default) | `Columns`

Specify the dimension of the input to select, `Rows` or `Columns`.

When **Select** is set to:

- `Rows` -- The block extracts rows from each input matrix.
- `Columns` -- The block extracts columns from each input matrix.

When the input is an unoriented vector, the **Select** parameter is ignored. The output is an unoriented vector of length *L* containing those elements specified by the length-*L* indexing vector.

Selector mode – Indexing mode

`Variable` (default) | `Fixed`

Specify the type of indexing operation to perform, `Variable` or `Fixed`.

When **Selector mode** is set to:

- **Variable** -- The length- L vector input to the “Idx” on page 2-0 port selects L rows or columns of each input to pass through to the output. You can update the elements of the indexing vector at each sample time, but the vector length must remain the same throughout the simulation.
- **Fixed** -- The **Idx** port is disabled. The length- L vector that you specified in the “Elements” on page 2-0 parameter selects L rows or columns of each input to pass through to the output. The **Elements** parameter is tunable, so you can change the values of the indexing vector elements at any time during the simulation but the vector length must remain the same.

Elements — Selected elements

[1 3] (default) | scalar | vector

Specify a vector containing the indices of the input rows or columns that appear in the output matrix.

Tunable: Yes

Dependencies

This parameter appears only when you set the “Selector mode” on page 2-0 to Fixed.

Index mode — Index mode

Zero-based (default) | One-based

When set to One-based, an index value of 1 refers to the first row or column of the input. When set to Zero-based, an index value of 0 refers to the first row or column of the input.

Invalid index — Error handling

Clip Index (default) | Clip and Warn | Generate Error

Specify how the block handles an invalid index value. You can select one of these options:

- **Clip index** — Clip the index to the nearest valid value and do not issue an alert.

For example, if the block receives a 64-by-4 input and the “Select” on page 2-0 parameter is set to:

- **Rows** -- The block clips an index of 72 to 64.
- **Columns** -- The block clips an index of 72 to 4.

In both cases, the block clips an index of -2 to 1.

- **Clip and warn** — Clip the index to the nearest valid value and display a warning message at the MATLAB command line.
- **Generate error** — Display an error dialog box and terminate the simulation.

Tunable: Yes

Fill empty spaces in outputs (for logical indexing) — Fill in empty spaces in outputs

on (default) | off

When the indexing vector elements are of a Boolean data type, the block performs logical indexing. Logical indexing can cause empty spaces in the output. Select this parameter to designate values to be appended to the output in the “Fill values” on page 2-0 parameter.

Fill values – Fill values

0 (default) | scalar value | integer

Specify the fill values when the block performs logical indexing.

Dependencies

This parameter appears only when you select the “Fill empty spaces in outputs (for logical indexing)” on page 2-0 parameter.

Block Characteristics

Data Types	Boolean double enumerated fixed point integer single
Direct Feedthrough	no
Multidimensional Signals	no
Variable-Size Signals	no
Zero-Crossing Detection	no

Extended Capabilities**C/C++ Code Generation**

Generate C and C++ code using Simulink® Coder™.

Generated code relies on memcpy or memset functions (string.h) under certain conditions.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic.

HDL Architecture

This block has a single, default HDL architecture.

HDL Block Properties

ConstrainedOutputPipeline	Number of registers to place at the outputs by moving existing delays within your design. Distributed pipelining does not redistribute these registers. The default is 0. For more details, see “ConstrainedOutputPipeline” (HDL Coder).
InputPipeline	Number of input pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “InputPipeline” (HDL Coder).
OutputPipeline	Number of output pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “OutputPipeline” (HDL Coder).

Complex Data Support

[Multiport Selector](#) | [Permute Matrix](#) | [Selector](#) | [Submatrix](#)

Introduced before R2006a

Variance

Variance of input or sequence of inputs

Library: DSP System Toolbox / Statistics

Description

The Variance block computes the unbiased variance of each row or column of the input, or along vectors of a specified dimension of the input. It can also compute the variance of the entire input. You can specify the dimension using the **Find the variance value over** parameter. The Variance block can also track the variance in a sequence of inputs over a period of time. To track the variance in a sequence of inputs, select the **Running variance** parameter.

Note The **Running** mode in the Variance block will be removed in a future release. To compute the running variance in Simulink, use the Moving Variance block instead.

Ports

Input

In — Data input

vector | matrix | N -D array

The block accepts real-valued or complex-valued multichannel and multidimensional inputs.

This port is unnamed until you select the **Running variance** parameter and set the **Reset port** parameter to any option other than None.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point

Rst — Reset port

scalar

Specify the event that causes the block to reset the running variance. The sample time of the **Rst** input must be a positive integer multiple of the input sample time.

Dependencies

To enable this port, select the **Running variance** parameter and set the **Reset port** parameter to any option other than None.

Data Types: single | double | int8 | int16 | int32 | uint8 | uint16 | uint32 | Boolean

Output

Port_1 — Variance along the specified dimension

scalar | vector | matrix | N -D array

When you do not select the **Running variance** parameter, the block computes the variance in each row or column of the input, or along vectors of a specified dimension of the input. It can also compute the variance of the entire input at each individual sample time. Each element in the output array y is the variance of the corresponding column, row, or entire input. The output array y depends on the setting of the **Find the variance value over** parameter.

Consider a three-dimensional input signal of size M -by- N -by- P . When you set **Find the variance value over** to:

- **Entire input** — The output at each sample time is a scalar that contains the variance of the M -by- N -by- P input matrix.
- **Each row** — The output at each sample time consists of an M -by-1-by- P array, where each element contains the variance of each vector over the second dimension of the input. For an M -by- N matrix input, the output at each sample time is an M -by-1 column vector.
- **Each column** — The output at each sample time consists of a 1-by- N -by- P array, where each element contains the variance of each vector over the first dimension of the input. For an M -by- N matrix input, the output at each sample time is a 1-by- N row vector.

In this mode, the block treats length- M unoriented vector inputs as M -by-1 column vectors.

- **Specified dimension** — The output at each sample time depends on the value of the **Dimension** parameter. If you set the **Dimension** to 1, the output is the same as when you select **Each column**. If you set the **Dimension** to 2, the output is the same as when you select **Each row**. If you set the **Dimension** to 3, the output at each sample time is an M -by- N matrix containing the variance of each vector over the third dimension of the input.

When you select **Running variance**, the block tracks the variance of each channel in a time sequence of inputs. In this mode, you must also specify a value for the **Input processing** parameter. When you set **Input processing** to:

- **Elements as channels (sample based)** — The block treats each element of the input as a separate channel. For a three-dimensional input signal of size M -by- N -by- P , the block outputs an M -by- N -by- P array. Each element y_{ijk} of the output contains the variance of the element u_{ijk} for all inputs since the last reset.

When a reset event occurs, the running variance y_{ijk} in the current frame is reset to the element u_{ijk} .

- **Columns as channels (frame based)** — The block treats each column of the input as a separate channel. This option does not support input signals with more than two dimensions. For a two-dimensional input signal of size M -by- N , the block outputs an M -by- N matrix. Each element y_{ij} of the output contains the variance of the elements in the j th column of all inputs since the last reset, up to and including the element u_{ij} of the current input.

When a reset event occurs, the running variance for each channel becomes the variance of all the samples in the current input frame, up to and including the current input sample.

The data type of the output matches the data type of the input.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixed point

Parameters

Main Tab

Running variance — Option to select running variance

off (default) | on

When you select the **Running variance** parameter, the block tracks the variance value of each channel in a time sequence of inputs.

Find the variance value over — Dimension over which variance is computed

Each column (default) | Entire input | Each row | Specified dimension

- **Each column** — The block outputs the variance over each column.
- **Each row** — The block outputs the variance over each row.
- **Entire input** — The block outputs the variance over the entire input.
- **Specified dimension** — The block outputs the variance over the dimension specified in the **Dimension** parameter.

Dependencies

To enable this parameter, clear the **Running variance** parameter.

Dimension — Custom dimension

1 (default) | scalar

Specify the dimension (one-based value) of the input signal over which the variance is computed. The value of this parameter must be greater than 0 and less than or equal to the number of dimensions in the input signal.

Dependencies

To enable this parameter, set **Find the variance value over** to **Specified dimension**.

Input processing — Method to process the input in running mode

Columns as channels (frame based) (default) | Elements as channels (sample based)

- **Columns as channels (frame based)** — The block treats each column of the input as a separate channel. This option does not support input signals with more than two dimensions. For a two-dimensional input signal of size M -by- N , the block outputs an M -by- N matrix. Each element y_{ij} of the output contains the variance of the elements in the j th column of all inputs since the last reset, up to and including the element u_{ij} of the current input.

When a reset event occurs, the running variance for each channel becomes the variance of all the samples in the current input frame, up to and including the current input sample.

- **Elements as channels (sample based)** — The block treats each element of the input as a separate channel. For a three-dimensional input signal of size M -by- N -by- P , the block outputs an M -by- N -by- P array. Each element y_{ijk} of the output contains the variance of the element u_{ijk} for all inputs since the last reset.

When a reset event occurs, the running variance y_{ijk} in the current frame is reset to the element u_{ijk} .

Variable-Size Inputs

When your inputs are of variable size, and you select the **Running variance** parameter, then:

- If you set the **Input processing** parameter to `Elements as channels (sample based)`, the state is reset.
- If you set the **Input processing** parameter to `Columns as channels (frame based)`, then:
 - When the input size difference is in the number of channels (number of columns), the state is reset.
 - When the input size difference is in the length of channels (number of rows), the state is not reset, and the running operation is carried out as usual.

Dependencies

To enable this parameter, select the **Running variance** parameter.

Reset port — Reset event

None (default) | Rising edge | Falling edge | Either edge | Non-zero sample

The block resets the running variance whenever a reset event is detected at the optional **Rst** port. The reset sample time must be a positive integer multiple of the input sample time.

When a reset event occurs while the **Input processing** parameter is set to `Elements as channels (sample based)`, the running variance for each channel is initialized to the value in the corresponding channel of the current input. Similarly, when the **Input processing** parameter is set to `Columns as channels (frame based)`, the running variance for each channel becomes the variance of all the samples in the current input frame, up to and including the current input sample.

Use this parameter to specify the reset event.

- `None` — Disables the **Rst** port.
- `Rising edge` — Triggers a reset operation when the **Rst** input does one of the following:
 - Rises from a negative value to either a positive value or zero.
 - Rises from zero to a positive value, where the rise is not a continuation of a rise from a negative value to zero.

- `Falling edge` — Triggers a reset operation when the **Rst** input does one of the following:
 - Falls from a positive value to a negative value or zero.
 - Falls from zero to a negative value, where the fall is not a continuation of a fall from a positive value to zero.

- **Either edge** — Triggers a reset operation when the **Rst** input is a Rising edge or Falling edge.
- **Non-zero sample** — Triggers a reset operation at each sample time, when the **Rst** input is not zero.

Note When running simulations in the Simulink multitasking mode, reset signals have a one-sample latency. Therefore, when the block detects a reset event, there is a one-sample delay at the reset port rate before the block applies the reset. For more information on latency and the Simulink tasking modes, see “Excess Algorithmic Delay (Tasking Latency)” and “Time-Based Scheduling and Code Generation” (Simulink Coder).

Dependencies

To enable this parameter, select the **Running variance** parameter.

Data Types Tab

Note To use these parameters, the data input must be fixed point. For all other inputs, the parameters on the **Data Types** tab are ignored.

Rounding mode — Method of rounding operation

Floor (default) | Ceiling | Convergent | Nearest | Round | Simplest | Zero

Specify the rounding mode for fixed-point operations. For more details, see rounding mode.

Saturate on integer overflow — Method of overflow action

off (default) | on

When you select this parameter, the block saturates the result of its fixed-point operation. When you clear this parameter, the block wraps the result of its fixed-point operation. For details on saturate and wrap, see overflow mode for fixed-point operations.

Input-squared product output — Data type of the input-squared term

Same as input (default) | Binary point scaling

The squares of the input elements are stored in the **Input-squared product output** data type. If the input is complex, the squares of the real and imaginary parts of the input are stored in this data type. For more details, see “Fixed Point” on page 2-1433.

You can set this parameter to:

- **Inherit**: Same as input — The data type is same as the input data type.
- **Binary point scaling** — The **Input-squared product output** data type uses binary point scaling. If you select this option, the block displays the fields to specify the **Word length** and **Fraction length**. The **Signedness** is inherited from the input.

Input-sum-squared product — Data type of the input-sum-squared term

Same as input-squared product (default) | Binary point scaling

The squares of the sum of the input elements are stored in the **Input-sum-squared product** data type. If the input is complex, the squares of the sum of the real parts and the squares of the sum of the imaginary parts are stored in this data type. For more details, see “Fixed Point” on page 2-1433.

You can set this parameter to:

- **Same as input-squared product** — The data type is the same as the input squared-product data type.
- **Binary point scaling** — The **Input-sum-squared product** data type uses binary point scaling. If you select this option, the block displays the fields to specify the **Word length** and **Fraction length**. The **Signedness** is inherited from the input.

Accumulator — Accumulator data type

Same as input-squared product (default) | Same as input | Binary point scaling

Accumulator specifies the data type of the output of an accumulation operation in the Variance block. See “Fixed Point” on page 2-1433 for illustrations depicting the use of the accumulator data type in this block.

You can set this parameter to:

- **Same as input-squared product** — The accumulator data type is the same as the input-squared product data type.
- **Same as input** — The accumulator data type is the same as the input data type.
- **Binary point scaling** — The **Accumulator** data type uses binary point scaling. If you select this option, the block displays the fields to specify the **Word length** and **Fraction length**. The **Signedness** is inherited from the input.

Output — Output data type

Same as input-squared product (default) | Same as accumulator | Same as input | Binary point scaling

Output specifies the data type of the output of the Variance block. See “Fixed Point” on page 2-1433 for information about the use of the output data type in this block. You can set it to:

- **Same as input-squared product** — The output data type is the same as the input-squared product data type.
- **Same as accumulator** — The output data type is the same as the accumulator data type.
- **Same as input** — The output data type is the same as the input data type.
- **Binary point scaling** — The **Output** data type uses binary point scaling. If you select this option, the block displays the fields to specify the **Word length** and **Fraction length**. The **Signedness** is inherited from the input.

Lock data type settings against changes by the fixed-point tools – Prevent fixed-point tools from overriding data types

off (default) | on

Select this parameter to prevent the fixed-point tools from overriding the data types you specify on the block.

Block Characteristics

Data Types	double fixed point integer single
Direct Feedthrough	no
Multidimensional Signals	no
Variable-Size Signals	yes
Zero-Crossing Detection	no

More About

Variance

The variance of a discrete-time signal is the square of the standard deviation of the signal. Variance gives a measure of deviation of the signal from its mean value.

For purely real or imaginary input, u , of size M -by- N , the variance is given by:

$$\sigma^2 = \frac{\sum_{i=1}^M \sum_{j=1}^N |u_{ij}|^2 - \frac{\left| \sum_{i=1}^M \sum_{j=1}^N u_{ij} \right|^2}{M*N}}{M*N - 1}.$$

where,

- u_{ij} is the input data element at indices i, j .
- M is the length of the j th column.
- N is the number of columns.

For complex inputs, the variance is given by the following equation:

$$\sigma^2 = \sigma_{\text{Re}}^2 + \sigma_{\text{Im}}^2$$

where,

- σ_{Re}^2 is the variance of the real part of the complex input.
- σ_{Im}^2 is the variance of the imaginary part of the complex input.

Algorithms

Variance

When you clear the **Running variance** parameter in the block and specify a dimension, the block produces results identical to the MATLAB `var` function when it is called as $y = \text{var}(u, \theta, D)$, where,

- u is the data input.
- D is the dimension.
- y is the variance along the specified dimension.

When this block calculates the variance along the entire input, the result is identical to calling the `var` function as $y = \text{var}(u(:))$.

For a complex input signal, the variance is the sum of the variances of the real and imaginary parts.

$$\sigma^2 = \sigma_{\text{Re}}^2 + \sigma_{\text{Im}}^2$$

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

For purely real or imaginary input u of size M -by- N , the variance is given by:

$$y = \sigma^2 = \frac{\sum_{i=1}^M \sum_{j=1}^N |u_{ij}|^2 - \frac{\left| \sum_{i=1}^M \sum_{j=1}^N u_{ij} \right|^2}{M*N}}{M*N - 1}.$$

The following diagram shows the data types used within the Variance block when the input is fixed-point.

For complex inputs, the variance is given by the following equation:

$$\sigma^2 = \sigma_{\text{Re}}^2 + \sigma_{\text{Im}}^2$$

Moving Variance

Introduced before R2006a

Vector Quantizer Decoder

Find vector quantizer codeword that corresponds to given, zero-based index value

Library

Quantizers

dspquant2

Description

The Vector Quantizer Decoder block associates each input index value with a codeword, a column vector of quantized output values defined in the **Codebook values** parameter. When you input multiple index values into this block, the block outputs a matrix of quantized output vectors. This matrix is created by horizontally concatenating the codeword vectors that correspond to each index value.

You can select how you want to enter the codebook values using the **Source of codebook** parameter. When you select **Specify via dialog**, you can type the codebook values into the block parameters dialog box. Select **Input port** and port C appears on the block. The block uses the input to port C as the **Codebook values** parameter.

The **Codebook values** parameter is a k -by- N matrix of values, where $k \geq 1$ and $N \geq 1$. Each column of this matrix is a codeword vector, and each codeword vector corresponds to an index value. The index values are zero based; therefore, the first codeword vector corresponds to an index value of 0, the second codeword vector corresponds to an index value of 1, and so on.

The input to this block is a vector of index values, where $0 \leq \text{index} < N$ and N is the number of columns of the codebook matrix. Use the **Action for out of range index value** parameter to determine how the block behaves when an input index value is out of this range. When you want any index values less than 0 to be set to 0 and any index values greater than or equal to N to be set to $N-1$, select **Clip**. When you want to be warned when any index values less than 0 are set to 0 and any index values greater than or equal to N are set to $N-1$, select **Clip and warn**. When you want the simulation to stop and display an error when the index values are out of range, select **Error**.

Data Type Support

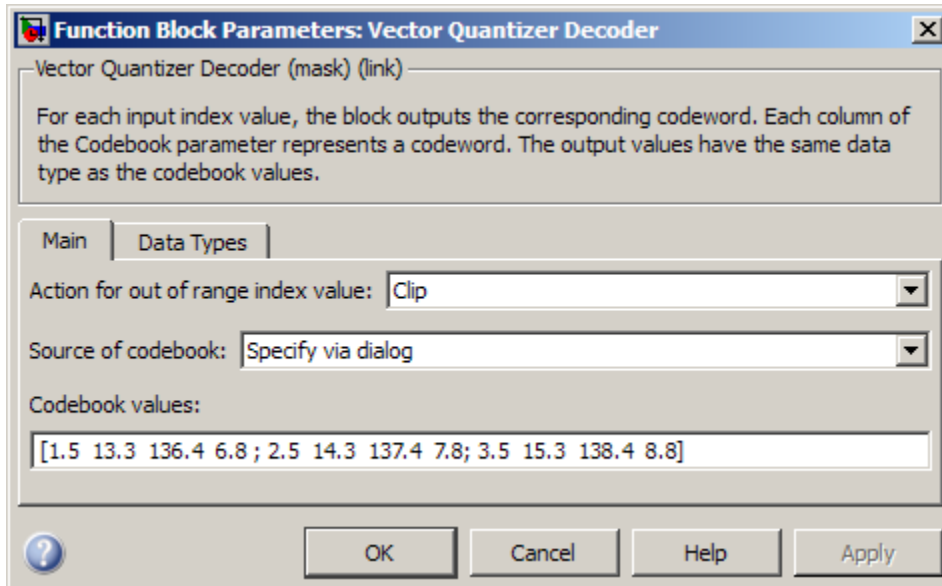

The input to the block can be the index values and the codebook values. The data type of the index input to the block at port I can be `uint8`, `uint16`, `uint32`, `int8`, `int16`, or `int32`. The data type of the codebook values can be `double`, `single`, or `Fixed-point`.

The output of the block is the quantized output values. These quantized output values always have the same data type as the codebook values. When the codebook values are specified via an input port,

the block assigns the same data type to the Q(U) output port. When the codebook values are specified via the dialog, use the **Codebook and output data type** parameter to specify the data type of the Q(U) output port. The data type of the codebook and quantized output can be `Same as input`, `double`, `single`, `Fixed-point`, `User-defined`, or `Inherit via back propagation`.

Dialog Box

The **Main** pane of the Vector Quantizer Decoder block dialog appears as follows.

Action for out of range index value

Choose the behavior of the block when an input index value is out of range, where $0 \leq \text{index} < N$ and N is the length of the codebook vector. Select `Clip` when you want any index values less than 0 to be set to 0 and any index values greater than or equal to N to be set to $N-1$. Select `Clip and warn` when you want to be warned when any index values less than 0 are set to 0 and any index values greater than or equal to N are set to $N-1$. Select `Error` when you want the simulation to stop and display an error when the index values are out of range.

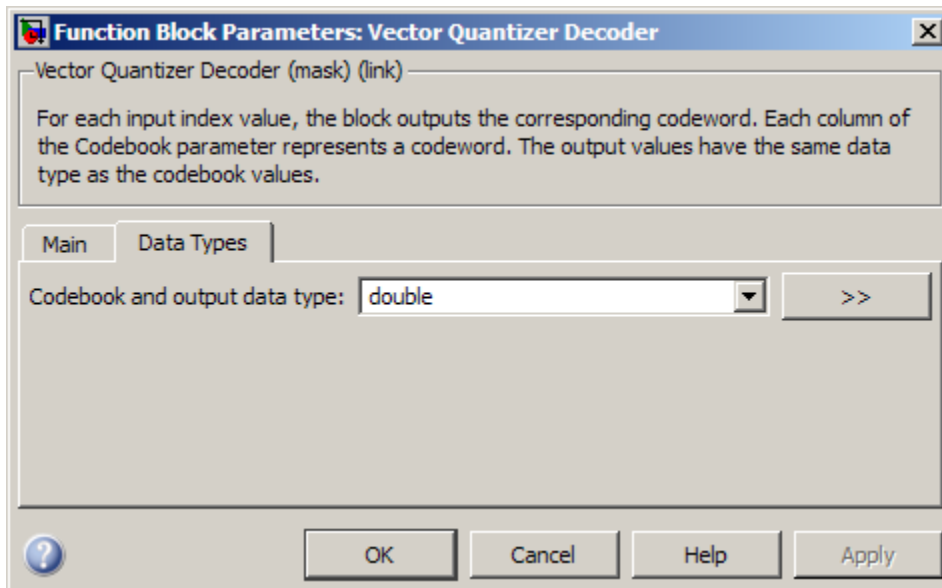

Source of codebook

Choose `Specify via dialog` to type the codebook values into the block parameters dialog box. Select `Input port` to specify the codebook values using the block's input port, `C`.

Codebook values

Enter a k -by- N matrix of quantized output values, where $1 \leq k$ and $1 \leq N$. Each column of your matrix corresponds to an index value. This parameter is visible if, from the **Source of codebook** list, you select `Specify via dialog`.

The **Data Types** pane of the Vector Quantizer Decoder block dialog appears as follows.

Codebook and output data type

Specify the data type of the codebook and quantized output values. You can select one of the following:

- A rule that inherits a data type, for example, `Inherit: Same as input`.
- A built in data type, such as `double`
- An expression that evaluates to a valid data type, for example, `fixdt(1,16)`

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the **Output data type** parameter.

See “Control Data Types of Signals” (Simulink) in *Simulink User's Guide* (Simulink) for more information.

This parameter is available only when you set the **Source of codebook** parameter to `Specify via dialog`. If you set the **Source of codebook** parameter to `Input port`, the output values have the same data type as the input codebook values.

Vector Quantizer Design

(Removed) Design vector quantizer using Vector Quantizer Design Tool (VQDTool)

Note The Vector Quantizer Design block has been removed.

Library

Quantizers

dspquant2

Description

Double-click on the Vector Quantizer Design block to start VQDTool, a GUI that allows you to design and implement a vector quantizer. You can also start VQDTool by typing `vqdttool` at the MATLAB command prompt. Based on your specifications, VQDTool iteratively calculates the codebook values that minimize the mean squared error between the training set and the codebook until the stopping criteria for the design process is satisfied. The block uses the resulting codebook values to implement your vector quantizer.

For the **Training Set** parameter, enter a k -by- M matrix of values you want to use to train the quantizer codebook. The variable k , where $k \geq 1$, is the length of each training vector. It also represents the dimension of your quantizer. The variable M , where $M \geq 2$, is the number of training vectors. This data can be created using a MATLAB function, such as the default value `randn(10,1000)`, or it can be any variable defined in the MATLAB workspace.

You have two choices for the **Source of initial codebook** parameter. Select **Auto-generate** to have the block choose the values of the initial codebook. In this case, the block picks N random training vectors as the initial codebook, where N is the **Number of levels** parameter and $N \geq 2$. When you select **User defined**, enter the initial codebook values in the **Initial codebook** field. The initial codebook matrix must have the same number of rows as the training set. Each column of the codebook is a codeword, and your codebook must have at least two codewords.

For the given training set and initial codebook, the block performs an iterative process, using the Generalized Lloyd Algorithm (GLA), to design a final codebook. For each iteration of the GLA, the block first associates each training vector with its nearest codeword by calculating the distortion. You can specify one of the two possible methods for calculating distortion using the **Distortion measure** parameter.

When you select **Squared error** for the **Distortion measure** parameter, the block finds the nearest codeword by calculating the squared error (unweighted). Consider the codebook $CB = [CW_1 \ CW_2 \ \dots \ CW_N]$. This codebook has N codewords; each codeword has k elements. The i -th codeword is defined as $CW_i = [a_{1i} \ a_{2i} \ \dots \ a_{ki}]$. The training set has M columns and is defined as $U = [U_1 \ U_2 \ \dots \ U_M]$, where the p -th training vector is $U_p = [u_{1p} \ u_{2p} \ \dots \ u_{kp}]'$. The squared error (unweighted) is calculated using the equation

$$D = \sum_{j=1}^k (a_{ji} - u_{jp})^2$$

When you select **Weighted squared error** for the **Distortion measure** parameter, enter a vector or matrix for the **Weighting factor** parameter. When the weighting factor is a vector, its length must be equal to the number of rows in the training set. This weighting factor is used for each training vector. When the weighting factor is a matrix, it must be the same size as the training set matrix. The block finds the nearest codeword by calculating the weighted squared error. If the weighting factor for the p -th column of the training vector, U_p , is defined as $W_p = [w_{1p} \ w_{2p} \ \dots \ w_{kp}]$, then the weighted squared error is defined by the equation

$$D = \sum_{j=1}^k w_{jp}(a_{ji} - u_{jp})^2$$

Once the block has associated all the training vectors with their nearest codeword vectors, the block calculates the mean squared error for the codebook and checks to see if the stopping criteria for the process has been satisfied.

The two possible options for the **Stopping criteria** parameter are **Relative threshold** and **Maximum iteration**. When you want the design process to stop when the fractional drop in the squared error is below a certain value, select **Relative threshold**. Then, type the maximum acceptable fractional drop in the **Relative threshold** field. The fraction drop in the squared error is defined as

$$\frac{\text{error at previous iteration} - \text{error at current iteration}}{\text{error at previous iteration}}$$

When you want the design process to stop after a certain number of iterations, choose **Maximum iteration**. Then, enter the maximum number of iterations you want the block to perform in the **Maximum iteration** field. For **Stopping criteria**, you can also choose **Whichever comes first** and enter **Relative threshold** and **Maximum iteration** values. The block stops iterating as soon as one of these conditions is satisfied.

When a training vector has the same distortion for two different codeword vectors, the algorithm uses the **Tie-breaking rule** parameter to determine which codeword vector the training vector is associated with. When you want the training vector to be associated with the lower indexed codeword, select **Lower indexed codeword**. To associate the training vector with the higher indexed codeword, select **Higher indexed codeword**.

With each iteration, the block updates the codeword values in order to minimize the distortion. The **Codebook update method** parameter defines the way the block calculates these new codebook values.

Note If, for the **Distortion measure** parameter, you choose **Squared error**, the **Codebook update method** parameter is set to **Mean**.

If, for the **Distortion measure** parameter, you choose **Weighted squared error** and you choose **Mean** for the **Codebook update method** parameter, the new codeword vector is found as follows. Suppose there are three training vectors associated with one codeword vector. The training vectors are

$$TS_1 = \begin{bmatrix} 1 \\ 2 \end{bmatrix}, \quad TS_3 = \begin{bmatrix} 10 \\ 12 \end{bmatrix}, \quad \text{and} \quad TS_7 = \begin{bmatrix} 11 \\ 12 \end{bmatrix}.$$

The new codeword vector is calculated as $CW_{new} = \begin{bmatrix} \frac{1 + 10 + 11}{3} \\ \frac{2 + 12 + 12}{3} \end{bmatrix}$

where the denominator is the number of training vectors associated with this codeword. If, for the **Codebook update method** parameter, you choose **Centroid** and you specify the weighting factors $W_1 = \begin{bmatrix} 0.1 \\ 0.2 \end{bmatrix}$, $W_3 = \begin{bmatrix} 1 \\ 0.6 \end{bmatrix}$, and $W_7 = \begin{bmatrix} 0.3 \\ 0.4 \end{bmatrix}$, the new codeword vector is calculated as

$$CW_{new} = \begin{bmatrix} \frac{(0.1)(1) + (1)(10) + (0.3)(11)}{0.1 + 1 + 0.3} \\ \frac{(0.2)(2) + (0.6)(12) + (0.4)(12)}{0.2 + 0.6 + 0.4} \end{bmatrix}$$

Click **Design and Plot** to design the quantizer with the parameter values specified on the left side of the GUI. The performance curve and the entropy of the quantizer are updated and displayed in the figures on the right side of the GUI.

Note You must click **Design and Plot** to apply any changes you make to the parameter values in the VQDTool dialog box.

The following is an example of how the block calculates the entropy of the quantizer at each iteration. Suppose you have a codebook with four codewords and a training set with 200 training vectors. Also suppose that, at the i -th iteration, 40 training vectors are associated with the first codeword, 60 training vectors are associated with the second codeword, 20 training vectors are associated with the third codeword, and 80 training vectors are associated with the fourth codeword. The probability that a training vector is associated with the first codeword is $\frac{40}{200}$. The probabilities that training vectors are associated with the second, third, and fourth codewords are $\frac{60}{200}$, $\frac{20}{200}$, and $\frac{80}{200}$, respectively. The GUI uses these probabilities to calculate the entropy according to the equation

$$H = \sum_{i=1}^N -p_i \log_2 p_i$$

where N is the number of codewords. Based on these probabilities, the GUI calculates the entropy of the quantizer at the i -th iteration as

$$H = -\left(\frac{40}{200} \log_2 \frac{40}{200} + \frac{60}{200} \log_2 \frac{60}{200} + \frac{20}{200} \log_2 \frac{20}{200} + \frac{80}{200} \log_2 \frac{80}{200}\right)$$

$$H = 1.8464$$

VQDTool can export parameter values that correspond to the figures displayed in the GUI. Click the **Export Outputs** button, or press **Ctrl+E**, to export the **Final Codebook**, **Mean Square Error**, and **Entropy** values to the workspace, a text file, or a MAT-file.

In the **Model** section of the GUI, specify the destination of the block that will contain the parameters of your quantizer. For **Destination**, select **Current model** to create a block with your parameters in the model you most recently selected. Type `gcs` in the MATLAB Command Window to display the name of your current model. Select **New model** to create a block in a new model file.

From the **Block type** list, select **Encoder** to design a Vector Quantizer Encoder block. Select **Decoder** to design a Vector Quantizer Decoder block. Select **Both** to design a Vector Quantizer Encoder block and a Vector Quantizer Decoder block.

In the **Encoder block name** field, enter a name for the Vector Quantizer Encoder block. In the **Decoder block name** field, enter a name for the Vector Quantizer Decoder block. When you have a Vector Quantizer Encoder and/or Decoder block in your destination model with the same name, select the **Overwrite target block** check box to replace the block's parameters with the current parameters. When you do not select this check box, a new Vector Quantizer Encoder and/or Decoder block is created in your destination model.

Click **Generate Model**. VQDTool uses the parameters that correspond to the current plots to set the parameters of the Vector Quantizer Encoder and/or Decoder blocks.

Parameters

Training Set

Enter the samples of the signal you would like to quantize. This data set can be a MATLAB function or a variable defined in the MATLAB workspace. The typical length of this data vector is $1e5$.

Source of initial codebook

Select **Auto-generate** to have the block choose the initial codebook values. Choose **User defined** to enter your own initial codebook values.

Number of levels

Enter the number of codeword vectors, N , in your codebook matrix, where $N \geq 2$.

Initial codebook

Enter your initial codebook values. From the **Source of initial codebook** list, select **User defined** in order to activate this parameter. The codebook must have the same number of rows as the training set. You must provide at least two codeword vectors.

Distortion measure

When you select **Squared error**, the block finds the nearest codeword by calculating the squared error (unweighted). When you select **Weighted squared error**, the block finds the nearest codeword by calculating the weighted squared error.

Weighting factor

Enter a vector or matrix. The block uses these values to compute the weighted squared error. When the weighting factor is a vector, its length must be equal to the number of rows in the training set. This weighting factor is used for each training vector. When the weighting factor is a matrix, it must be the same size as the training set matrix. The individual weighting factors cannot be negative. The weighting factor vector or matrix cannot contain all zeros.

Stopping criteria

Choose **Relative threshold** to enter the maximum acceptable fractional drop in the squared quantization error. Choose **Maximum iteration** to specify the number of iterations at which to stop. Choose **Whichever comes first** and the block stops the iteration process as soon as the relative threshold or maximum iteration value is attained.

Relative threshold

This parameter is available when you choose **Relative threshold** or **Whichever comes first** for the **Stopping criteria** parameter. Enter the value that is the maximum acceptable fractional drop in the squared quantization error.

Maximum iteration

This parameter is available when you choose **Maximum iteration** or **Whichever comes first** for the **Stopping criteria** parameter. Enter the maximum number of iterations you want the block to perform.

Tie-breaking rules

When a training vector has the same distortion for two different codeword vectors, select **Lower indexed codeword** to associate the training vector with the lower indexed codeword. Select **Higher indexed codeword** to associate the training vector with the higher indexed codeword.

Codebook update method

When you choose **Mean**, the new codeword vector is calculated by taking the average of all the training vector values that were associated with the original codeword vector. When you choose **Centroid**, the block calculates the new codeword vector by taking the weighted average of all the training vector values that were associated with the original codeword vector. Note that if, for the **Distortion measure** parameter, you choose **Squared error**, the **Codebook update method** parameter is set to **Mean**.

Destination

Choose **Current model** to create a Vector Quantizer block in the model you most recently selected. Type `gcs` in the MATLAB Command Window to display the name of your current model. Choose **New model** to create a block in a new model file.

Block type

Select **Encoder** to design a Vector Quantizer Encoder block. Select **Decoder** to design a Vector Quantizer Decoder block. Select **Both** to design a Vector Quantizer Encoder block and a Vector Quantizer Decoder block.

Encoder block name

Enter a name for the Vector Quantizer Encoder block.

Decoder block name

Enter a name for the Vector Quantizer Decoder block.

Overwrite target block

When you do not select this check box and a Vector Quantizer Encoder and/or Decoder block with the same block name exists in the destination model, a new Vector Quantizer Encoder and/or Decoder block is created in the destination model. When you select this check box and a Vector Quantizer Encoder and/or Decoder block with the same block name exists in the destination model, the parameters of these blocks are overwritten by new parameters.

Generate Model

Click this button and VQDTool uses the parameters that correspond to the current plots to set the parameters of the Vector Quantizer Encoder and/or Decoder blocks.

Design and Plot

Click this button to design a quantizer using the parameters on the left side of the GUI and to update the performance curve and entropy plots on the right side of the GUI.

You must click **Design and Plot** to apply any changes you make to the parameter values in the VQDTool GUI.

Export Outputs

Click this button, or press **Ctrl+E**, to export the **Final Codebook**, **Mean Squared Error**, and **Entropy** values to the workspace, a text file, or a MAT-file.

Supported Data Types

- Double-precision floating point

Compatibility Considerations

Vector Quantizer Design block has been removed

The Vector Quantizer Design block has been removed.

Vector Quantizer Encoder

For given input, find index of nearest codeword based on Euclidean or weighted Euclidean distance measure

Library

Quantizers

dspquant2

Description

The Vector Quantizer Encoder block compares each input column vector to the codeword vectors in the codebook matrix. Each column of this codebook matrix is a codeword. The block finds the codeword vector nearest to the input column vector and returns its zero-based index. This block supports real floating-point and fixed-point signals on all input ports.

The block finds the nearest codeword by calculating the distortion. The block uses two methods for calculating distortion: Euclidean squared error (unweighted) and weighted Euclidean squared error. Consider the codebook, $CB = [CW_1 \ CW_2 \ \dots \ CW_N]$. This codebook has N codewords; each codeword has k elements. The i -th codeword is defined as a column vector, $CW_i = [a_{1i} \ a_{2i} \ \dots \ a_{ki}]$. The multichannel input has M columns and is defined as $U = [U_1 \ U_2 \ \dots \ U_M]$, where the p -th input column vector is $U_p = [u_{1p} \ u_{2p} \ \dots \ u_{kp}]$. The squared error (unweighted) is calculated using the equation

$$D = \sum_{j=1}^k (a_{ji} - u_{jp})^2$$

The weighted squared error is calculated using the equation

$$D = \sum_{j=1}^k w_j (a_{ji} - u_{jp})^2$$

where the weighting factor is defined as $W = [w_1 \ w_2 \ \dots \ w_k]$. The index of the codeword that is associated with the minimum distortion is assigned to the input column vector.

You can select how you want to enter the codebook values using the **Source of codebook** parameter. When you select **Specify via dialog**, you can type the codebook values into the block parameters dialog box. Select **Input port** and port C appears on the block. The block uses the input to port C as the **Codebook** parameter.

The **Codebook** parameter is an k -by- N matrix of values, where $k \geq 1$ and $N \geq 1$. Each input column vector is compared to this codebook. Each column of the codebook matrix is a codeword, and each

codeword has an index value. The first codeword vector corresponds to an index value of 0, the second codeword vector corresponds to an index value of 1, and so on. The codeword vectors must have the same number of rows as the input, U.

For the **Distortion measure** parameter, select **Squared error** when you want the block to calculate the distortion by evaluating the Euclidean distance between the input column vector and each codeword in the codebook. Select **Weighted squared error** when you want to use a weighting factor to emphasize or deemphasize certain input values.

For the **Source of weighting factor** parameter, select **Specify via dialog** to enter a weighting factor vector in the dialog box. Choose **Input port** to specify the weighting factor using port W.

Use the **Weighting factor** parameter to emphasize or deemphasize certain input values when calculating the distortion measure. For example, consider the p -th input column vector, U_p , as previously defined. When you want to neglect the effect of the first element of this vector, enter $[0 \ 1 \ 1 \ \dots \ 1]$ as the **Weighting factor** parameter. This weighting factor is used to calculate the weighted squared error using the equation

$$D = \sum_{j=1}^k w_j (a_{ji} - u_{jp})^2$$

Because of the weighting factor used in this example, the weighted squared error is not affected by the first element of the input matrix. Therefore, the first element of the input column vector no longer impacts the choice of index value output by the Vector Quantizer Encoder block.

Use the **Index output data type** parameter to specify the data type of the index values output at port I. The data type of the index values can be `int8`, `uint8`, `int16`, `uint16`, `int32`, or `uint32`.

When an input vector is equidistant from two codewords, the block uses the **Tie-breaking rule** parameter to determine which index value the block chooses. When you want the input vector to be represented by the lower index valued codeword, select **Choose the lower index**. To represent the input column vector by the higher index valued codeword, select **Choose the higher index**.

Select the **Output codeword** check box to output at port Q(U) the codeword vectors that correspond to each index value. When the input is a matrix, the corresponding codeword vectors are horizontally concatenated into a matrix.

Select the **Output quantization error** check box to output at port D the quantization error that results when the block represents the input column vector by its nearest codeword. When the input is a matrix, the quantization error values are horizontally concatenated.

The Vector Quantizer Encoder block accepts real floating-point and fixed-point inputs. For more information on the data types accepted by each port, see “Data Type Support” on page 2-1446 or “Supported Data Types” on page 2-1449.

Data Type Support

The input data values, codebook values, and weighting factor values are input to the block at ports U, C, and W, respectively. The data type of the input data values, codebook values, and weighting factor values can be `double`, `single`, or `Fixed-point`. The input data, codebook values, and weighting factor must be the same data type.

The outputs of the block are the index values, output codewords, and quantization error. Use the **Index output data type** parameter to specify the data type of the index output from the block at

port I. The data type of the index can be `int8`, `uint8`, `int16`, `uint16`, `int32`, or `uint32`. The data type of the output codewords and the quantization error can be `double`, `single`, or `Fixed-point`. The block assigns the data type of the output codewords and the quantization error based on the data type of the input data.

Fixed-Point Data Types

The following diagram shows the data types used within the Vector Quantizer Encoder block for fixed-point signals.

You can set the product output, accumulator, and index output data types in the block dialog as discussed below.

Dialog Box

Main Tab

Source of codebook

Choose `Specify via dialog` to type the codebook values into the block parameters dialog box. Select `Input port` to specify the codebook values using the block's input port, `C`.

Codebook

Enter a k -by- N matrix of values, where $1 \leq k$ and $1 \leq N$, to which your input column vector or matrix is compared. This parameter is visible if, from the **Source of codebook** list, you select `Specify via dialog`.

Distortion measure

Select `Squared error` when you want the block to calculate the distortion by evaluating the Euclidean distance between the input column vector and each codeword in the codebook. Select `Weighted squared error` when you want the block to calculate the distortion by evaluating a weighted Euclidean distance using a weighting factor to emphasize or deemphasize certain input values.

Source of weighting factor

Select `Specify via dialog` to enter a value for the weighting factor in the dialog box. Choose `Input port` and specify the weighting factor using port `W` on the block. This parameter is visible if, for the **Distortion measure** parameter, you select `Weighted squared error`.

Weighting factor

Enter a vector of values. This vector must have length equal to the number of rows of the input, `U`. This parameter is visible if, for the **Source of weighting factor** parameter, you select `Specify via dialog`.

Tie-breaking rule

Set this parameter to determine the behavior of the block when an input column vector is equidistant from two codewords. When you want the input column vector to be represented by the lower index valued codeword, select `Choose the lower index`. To represent the input column vector by the higher index valued codeword, select `Choose the higher index`.

Output codeword

Select this check box to output the codeword vectors nearest to the input column vectors.

Output quantization error

Select this check box to output the quantization error value that results when the block represents the input column vector by the nearest codeword.

Index output data type

Select `int8`, `uint8`, `int16`, `uint16`, `int32`, or `uint32` as the data type of the index output at port I. To inherit the index output data type, select `Inherit via back propagation`.

Data Types Tab**Rounding mode**

Specify the rounding mode for fixed-point operations as one of the following:

- Floor
- Ceiling
- Convergent
- Nearest
- Round
- Simplest
- Zero

For more details, see rounding mode.

Overflow mode

When you select this parameter, the block saturates the result of its fixed-point operation. When you clear this parameter, the block wraps the result of its fixed-point operation. For details on saturate and wrap, see overflow mode for fixed-point operations.

Product output

As depicted above, the output of the multiplier is placed into the product output data type and scaling. Use this parameter to specify how you would like to designate this product output word and fraction lengths.

- When you select `Same as input`, these characteristics match those of the input to the block.
- When you select `Binary point scaling`, you can enter the word length and the fraction length of the product output, in bits.

Accumulator

As depicted above, inputs to the accumulator are cast to the accumulator data type. The output of the adder remains in the accumulator data type as each element of the input is added to it. Use this parameter to specify how you would like to designate the accumulator word and fraction lengths.

- When you select `Same as product output`, these characteristics match those of the product output.
- When you select `Same as input`, these characteristics match those of the input to the block.
- When you select `Binary point scaling`, you can enter the word length and the fraction length of the accumulator, in bits.

Waterfall

(To be removed) View vectors of data over time

Note The Waterfall block will be removed in a future release. Use a different scope instead, see “Scopes and Data Logging”.

Library: DSP System Toolbox / Obsolete Blocks

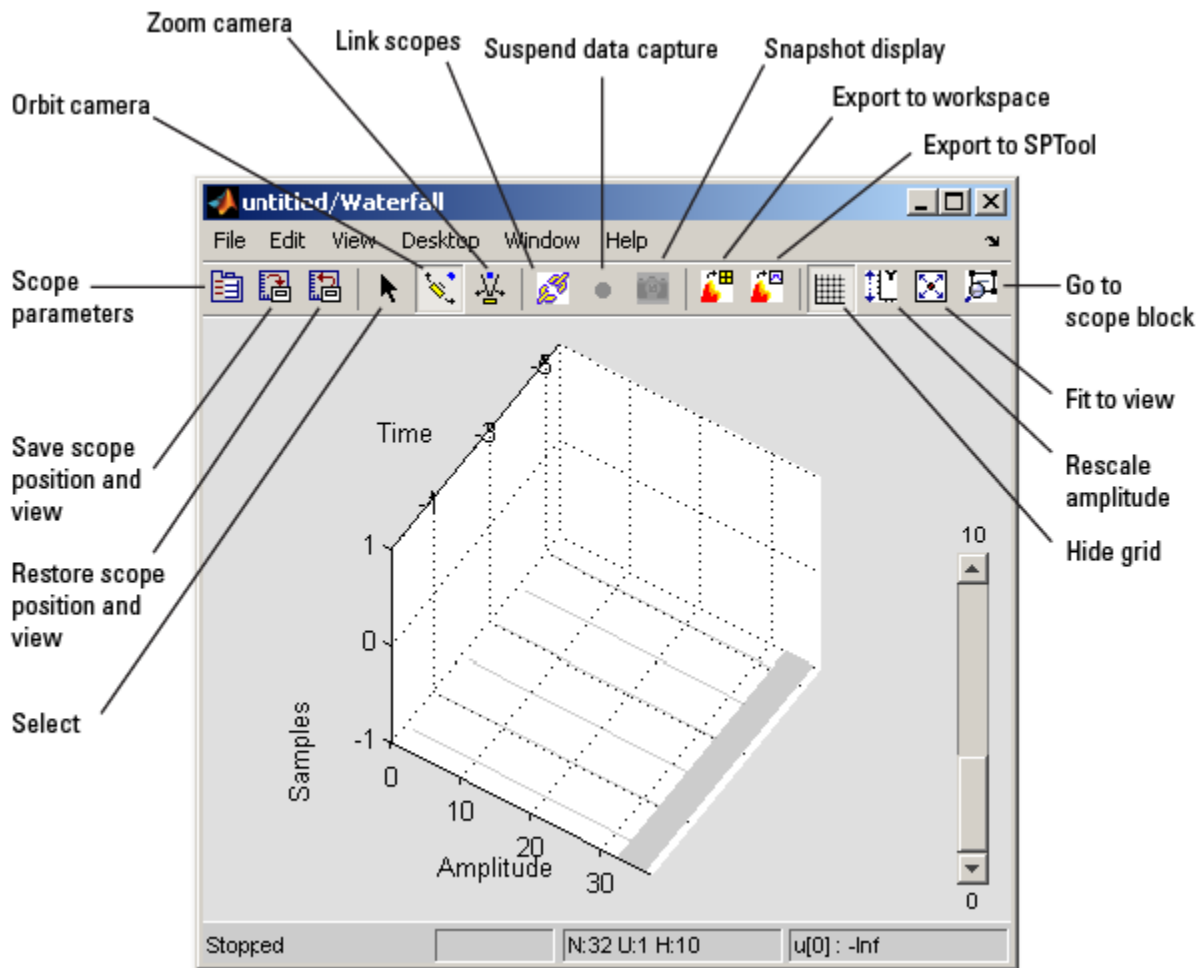

Description

The Waterfall block displays multiple vectors of data at one time. These vectors represent the input data at consecutive sample times.

The data is displayed in 3D in the Waterfall window. By default, the x -axis represents amplitude, the y -axis represents samples, and the z -axis represents time. You can adjust the number of sample vectors that the block displays, move and resize the Waterfall window, and modify block parameter values during the simulation. The Waterfall window has toolbar buttons that enable you to zoom in on the displayed data, suspend the data capture, freeze the scope display, save the scope position, and export data to the workspace.

The toolbar buttons are labeled on the Waterfall window as it appears when you double-click a Waterfall block.

Ports

Input

Port_1 — Signal or signals to visualize

scalar | vector | matrix | array

The Waterfall block accepts most numeric data types as input. However, the input is converted to double-precision before the block processes the data. The Waterfall block displays only real-valued, double-precision vectors of data.

Data Types: single | double | int8 | int16 | int32 | uint8 | uint16 | uint32 | fixed point

Parameters

You can control the display and behavior of the Waterfall window using the Parameters dialog box. To open the Parameters dialog box, click the Scope parameters button.

You can alter the Waterfall parameters while the simulation is running. However, when you make changes to values in text boxes, you must click **Enter** or click outside the text box for the block to accept your changes.

Display

These parameters control the Waterfall display.

Display traces — Number of data vectors to display

6 (default) | positive integer

Number of data vectors to display in the Waterfall window, specified as a positive integer.

Programmatic Use

Control this parameter from the command-line using `set_param` and `get_param`.

Block Parameter: NumTraces

Type: positive scalar specified as a character vector

Update interval — Number of vectors to store

1 (default) | positive integer

Number of vectors the block should store before it displays them to the window, specified as a positive integer.

Programmatic Use

Control this parameter from the command-line using `set_param` and `get_param`.

Block Parameter: UpdateInterval

Type: positive scalar specified as a character vector

Colormap — Colors of display

autumn (default) | gray | hot | pink | jet | copper | red | white

Colors for the displayed data, specified as a valid colormap.

Programmatic Use

Control this parameter from the command-line using `set_param` and `get_param`.

Block Parameter: CMapStr

Type: character vector

Type: valid colormap name, see `map`

Transparency — Transparency of oldest and newest data vectors

newest: opaque, oldest: transparent (default)

Transparency of the oldest and newest data vectors, specified with the sliders. The leftmost position makes the data vector transparent. The rightmost position makes the data vector opaque. The intermediate data vectors transition between the two chosen transparency values.

Programmatic Use

Control this parameter from the command-line using `set_param` and `get_param`.

Block Parameter: TNewest and TOldest

Type: number between [0,1] specified as a character vector

Axes

These parameters control the axes in the Waterfall window.

Y Min — Minimum value of y-axis

-1 (default) | integer

Minimum value of the y-axis specified as an integer.

Programmatic Use

Control this parameter from the command-line using `set_param` and `get_param`.

Block Parameter: YMin

Type: character vector

Y Max — Maximum value of y-axis

1 (default) | integer

Maximum value of the y-axis specified as an integer

Programmatic Use

Control this parameter from the command-line using `set_param` and `get_param`.

Block Parameter: YMax

Type: character vector

Axis color — Color of axes

'w' (default) | RGB triplet | specified color name | hexadecimal color code

Color of the axes, specified as a RGB triplet, specified color name, or hexadecimal color code.

RGB triplets and hexadecimal color codes are useful for specifying custom colors.

- An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range $[0, 1]$; for example, $[0.4 \ 0.6 \ 0.7]$.
- A hexadecimal color code is a character vector or a string scalar that starts with a hash symbol (#) followed by three or six hexadecimal digits, which can range from 0 to F. The values are not case sensitive. Thus, the color codes '#FF8800', '#ff8800', '#F80', and '#f80' are equivalent.

Alternatively, you can specify some common colors by name. This table lists the named color options, the equivalent RGB triplets, and hexadecimal color codes.

Color Name	Short Name	RGB Triplet	Hexadecimal Color Code	Appearance
'red'	'r'	[1 0 0]	'#FF0000'	
'green'	'g'	[0 1 0]	'#00FF00'	
'blue'	'b'	[0 0 1]	'#0000FF'	
'cyan'	'c'	[0 1 1]	'#00FFFF'	
'magenta'	'm'	[1 0 1]	'#FF00FF'	
'yellow'	'y'	[1 1 0]	'#FFFF00'	
'black'	'k'	[0 0 0]	'#000000'	
'white'	'w'	[1 1 1]	'#FFFFFF'	

Here are the RGB triplets and hexadecimal color codes for the default colors MATLAB uses in many types of plots.

RGB Triplet	Hexadecimal Color Code	Appearance
[0 0.4470 0.7410]	'#0072BD'	
[0.8500 0.3250 0.0980]	'#D95319'	
[0.9290 0.6940 0.1250]	'#EDB120'	
[0.4940 0.1840 0.5560]	'#7E2F8E'	
[0.4660 0.6740 0.1880]	'#77AC30'	
[0.3010 0.7450 0.9330]	'#4DBEEE'	
[0.6350 0.0780 0.1840]	'#A2142F'	

Programmatic Use

Control this parameter from the command-line using `set_param` and `get_param`.

Block Parameter: `AxisColor`

Type: character vector within a character vector

Example: `set_param(block, 'AxisColor', char("b"))`

X Axis — x-axis label

`Samples (default) | string`

Enter the x-axis label.

Programmatic Use

Control this parameter from the command-line using `set_param` and `get_param`.

Block Parameter: `XLabel`

Type: character vector

Y Axis — y-axis label

`Amplitude (default) | string`

Enter the y-axis label.

Programmatic Use

Control this parameter from the command-line using `set_param` and `get_param`.

Block Parameter: `YLabel`

Type: character vector

Z Axis — z-axis label

`Time (default) | string`

Enter the z-axis label.

Programmatic Use

Control this parameter from the command-line using `set_param` and `get_param`.

Block Parameter: `ZLabel`

Type: character vector

Data History

These parameters control how many input data vectors the Waterfall block stores. They also control how the data is exported to the MATLAB workspace.

History traces — Number of vectors to store

10 (default) | positive integer

Number of vectors (traces) that you want the block to store, specified as a positive integer.

Programmatic Use

Control this parameter from the command-line using `set_param` and `get_param`.

Block Parameter: HistoryLength**Type:** positive integer specified as a character vector**When the buffer is full — Behavior of full buffer**

Overwrite (default) | Suspend | Extend

Use this parameter to control the behavior of the block when the buffer is full:

- **Overwrite** — The old data is replaced with the new data.
- **Suspend** — The block stops storing data in the buffer; but the simulation continues to run.
- **Extend** — The block extends the buffer so that it can continue to store all the input data.

Programmatic Use

Control this parameter from the command-line using `set_param` and `get_param`.

Block Parameter: HistoryFull**Type:** character vector**Data logging — Export data from block**

Selected (default) | All visible | All history

Use this parameter to control which data is exported from the block:

- **Selected** — The selected data vector is exported.
- **All visible** — All of the data vectors displayed in the Waterfall window are exported.
- **All history** — All of the data vectors stored in the history buffer of the block are exported.

Programmatic Use

Control this parameter from the command-line using `set_param` and `get_param`.

Block Parameter: ExportMode**Type:** character vector**Export variable — Variable name of exported data**

ExportData (default) | valid MATLAB variable name

Name of the variable that represents your data in the MATLAB workspace.

Programmatic Use

Control this parameter from the command-line using `set_param` and `get_param`.

Block Parameter: MLExportName**Type:** character vector**Export at end of simulation — Automatically export data**

off (default) | on

Select this check box to automatically export the data to the MATLAB workspace when the simulation stops.

Programmatic Use

Control this parameter from the command-line using `set_param` and `get_param`.

Block Parameter: AutoExport

Values: 'off' | 'on'

Triggering

These parameters control when the Waterfall block starts and stops capturing data.

Begin recording — When to start capturing data

Immediately (default) | After T seconds | After N inputs | User-defined

This parameter controls when the Waterfall block starts capturing data:

- **Immediately** — The Waterfall window captures the input data as soon as the simulation starts.
- **After T seconds** — The **Time, T** parameter appears in the dialog box. Enter the number of seconds the block should wait before it begins capturing data.
- **After N inputs** — The **Count, N** parameter appears in the dialog box. Enter the number of inputs the block should receive before it begins capturing data.
- **User-defined** — The **Function name** parameter appears in the dialog box. Enter the name of a MATLAB function that defines when the block should begin capturing data. For more information about how you define this function, see “Scope Trigger Function”.

Programmatic Use

Control this parameter from the command-line using `set_param` and `get_param`.

Block Parameter: TrigStartMode | TrigStartT | TrigStartN | TrigStartFcn

Type: character vector

Stop recording — When to stop capturing data

Never (default) | After T seconds | After N inputs | User-defined

This parameter controls when the Waterfall block stops capturing data:

- **Never** — The block captures the input data as long as the simulation is running.
- **After T seconds** — The **Time, T** parameter appears in the dialog box. Enter the number of seconds the block should wait before it stops capturing data.
- **After N inputs** — The **Count, N** parameter appears in the dialog box. Enter the number of inputs the block should receive before it stops capturing data.
- **User-defined** — The **Function name** parameter appears in the dialog box. Enter the name of a MATLAB function that defines when the block should stop capturing data. For more information about how you define this function, see “Scope Trigger Function”.

Programmatic Use

Control this parameter from the command-line using `set_param` and `get_param`.

Block Parameter: TrigStopMode | TrigStopT | TrigStopN | TrigStopFcn

Type: character vector

Re-arm trigger — When to capture data

Never (default) | After T seconds | After N inputs | User-defined

This parameter controls when the Waterfall block begins waiting to capture data.

- **Never** — The Waterfall Scope block starts and stops capturing data as defined by the **Begin recording** and **Stop recording** parameters.
- **After T seconds** — The **Time, T** parameter appears in the dialog box. Enter the number of seconds the block should wait before it begins waiting to capture data.
- **After N inputs** — The **Count, N** parameter appears in the dialog box. Enter the number of inputs the block should receive before it begins waiting to capture data.
- **User-defined** — The **Function name** parameter appears in the dialog box. Enter the name of a MATLAB function that defines when the block should begin waiting to capture data. For more information about how you define this function, see “Scope Trigger Function”.

Dependency

To enable this parameter, set **Stop recording** to **After T seconds**, **After N inputs**, or **User-defined**.

Programmatic Use

Control this parameter from the command-line using `set_param` and `get_param`.

Block Parameter: TrigRearmMode | TrigRearmT | TrigRearmN | TrigRearmFcn

Type: character vector

Transform

These parameters transform the input data to the Waterfall block. The result of the transform is displayed in the Waterfall window.

The block assumes that the input to the block corresponds to the **Transform** parameter you select. For example, when you choose **Complex-> Angle**, the block assumes that the input is complex. But the block does not produce an error when the input is not complex. Therefore, you must verify the format of your input data to guarantee that a meaningful result is displayed in the Waterfall window.

Transform — Transformation to apply to input

None (default) | Amplitude-> dB | Complex-> Mag Lin | Complex-> Mag dB | ...

Choose a transform that you would like to apply to the input of the Waterfall block:

- **None** — The input is displayed as it is received by the block.
- **Amplitude-> dB** — The block converts the input amplitude into decibels.
- **Complex-> Mag Lin** — The block converts the complex input into linear magnitude.
- **Complex-> Mag dB** — The block converts the complex input into magnitude in decibels.
- **Complex-> Angle** — The block converts the complex input into phase.
- **FFT-> Mag Lin Fs/2** — The block takes the linear magnitude of the FFT input and plots it from 0 to the Nyquist frequency.
- **FFT-> Mag dB Fs/2** — The block takes the magnitude of the FFT input, converts it to decibels, and plots it from 0 to the Nyquist frequency.
- **FFT-> Angle Fs/2** — The block converts the FFT input into phase and plots it from 0 to the Nyquist frequency.

- Power -> dB — The block converts the input power into decibels.
- User-defined fcn — see “Function” on page 2-0 .
- User-defined expr — see “Expression” on page 2-0 .

Programmatic Use

Control this parameter from the command-line using `set_param` and `get_param`.

Block Parameter: XFormMode

Type: character vector

Function — Custom transformation function

abs (default)

Enter a function that you would like to apply to the input of the Waterfall block. For more information about how you define this function, see “Scope Transform Function”.

Dependency

To enable this parameter, set **Transform** to User-defined fcn.

Programmatic Use

Control this parameter from the command-line using `set_param` and `get_param`.

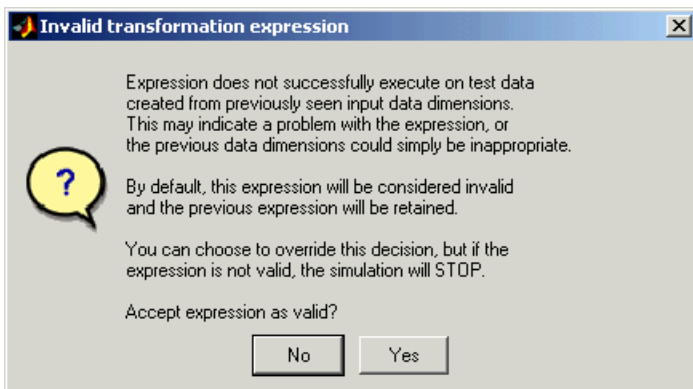

Block Parameter: XFormFcn

Type: character vector

Expression — Custom transformation expression

(u+1)/2 (default) | expression with real-valued output

Enter an expression that you would like to apply to the input of the Waterfall block. The result of this expression must be real-valued. When you write the expression, be sure to include only one unknown variable. The block assumes this unknown variable represents the input to the block. When the block believes your expression is invalid, this window appears.

When you click **No**, your expression is not applied to the input. When you click **Yes** and your expression is invalid, your simulation stops and Simulink displays an error.

Dependency

To enable this parameter, set **Transform** to User-defined expr.

Programmatic Use

Control this parameter from the command-line using `set_param` and `get_param`.

Block Parameter: XFormExpr

Type: character vector

Block Characteristics

Data Types	double fixed point integer single
Direct Feedthrough	no
Multidimensional Signals	no
Variable-Size Signals	no
Zero-Crossing Detection	no

Compatibility Considerations**Waterfall block will be removed**

Not recommended starting in R2020b

The Waterfall block will be removed in a future release. Use a different scope instead, see “Scopes and Data Logging”.

Extended Capabilities**C/C++ Code Generation**

Generate C and C++ code using Simulink® Coder™.

This block can be used for simulation visibility in systems that generate code, but is not included in the generated code.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

This block can be used for simulation visibility in subsystems that generate HDL code, but is not included in the hardware implementation.

PLC Code Generation

Generate Structured Text code using Simulink® PLC Coder™.

This block can be used for simulation visibility in systems that generate code, but is not included in the generated code.

Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

This block accepts fixed-point input, but converts it to `double` for display.

Window Function

Compute and apply window to input signal

Library: DSP System Toolbox / Signal Operations

Description

The Window Function block has three modes of operation that enable you to apply a window, or compute a window, or compute and apply a window to an input signal. You can select the mode via the **Operation** parameter. In each mode, the block first creates a window vector w by sampling the window specified in the **Window type** parameter.

Ports

Input

In — Input signal

vector | matrix | N -D array

Input signal, specified as a vector, matrix, or an N -D array. When the input is fixed point, it can be signed only.

This port is enabled only when you set **Operation** to either `Apply window to input` or `Generate and apply window`.

This port is unnamed when you set **Operation** to `Apply window to input`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `fixed point`

Output

Out — Output

vector | matrix | N -D array

Output signal, returned as a vector, matrix, or an N -D array.

The **Out** port is enabled only when **Operation** is set to:

- `Apply window to input` -- The block computes an M -by-1 window vector w and applies it to the M -by- N input, where M is the number of rows in the input signal.

- **Generate and apply window** -- The block generates an M -by-1 window vector w and applies it to the input.

The output signal has the same dimensions as the input signal. For more details, see “Operation” on page 2-0 .

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `fixed point`

Win — Window output

vector

Window output, returned as a vector. When **Operation** is set to `Apply window to input` or `Generate and apply window`, the window vector is of the same length as the number of rows in the input signal. When **Operation** is set to `Generate window`, the length of window vector is determined by the **Window length** parameter.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `fixed point`

Parameters

Main

Operation — Modes of operation

`Apply window to input` (default) | `Generate window` | `Generate and apply window`

The Window Function block has three modes of operation that you can select through the **Operation** parameter. In each mode, the block first creates a window vector w by sampling the window specified in the **Window type** parameter at M discrete points. The operation modes are:

- **Apply window to input**

In this mode, the block computes an M -by-1 window vector w and applies it to the input. The output y always has the same dimension as the input.

When the input is an M -by- N matrix u , the window is multiplied element-wise with each of the N channels in the input matrix u . This is equivalent to the following MATLAB code:

```
y = repmat(w,1,N) .* u % Equivalent MATLAB code
```

The window is always applied to the first dimension:

$$y(i, j, \dots, k) = w(i) * u(i, j, \dots, k) \quad i = 1, \dots, M, \quad j = 1, \dots, N, \quad \dots, \quad k = 1, \dots, P$$

A length- M unoriented vector input is treated as an M -by-1 vector.

- **Generate window**

In this mode, the block generates an unoriented window vector w with length M specified by the **Window length** parameter. The **In** port is disabled for this mode.

- **Generate and apply window**

In this mode, the block generates an M -by-1 window vector w and applies it to the input. The block produces two outputs:

- At the **Out** port, the block produces the result of the multiplication y , which has the same dimension as the input.

- At the **Win** port, the block produces the M -by-1 window vector w .

When the input is an M -by- N matrix u , the window is multiplied element-wise with each of the N channels in the input matrix u . This is equivalent to the following MATLAB code:

```
y = repmat(w,1,N) .* u % Equivalent MATLAB code
```

The window is always applied to the first dimension:

$$y(i, j, \dots, k) = w(i) * u(i, j, \dots, k) \quad i = 1, \dots, M, \quad j = 1, \dots, N, \quad \dots, \quad k = 1, \dots, P$$

A length- M 1-D vector input is treated as an M -by-1 vector.

Window type — Type of window

Hamming (default) | Bartlett | Blackman | ...

This table lists the available window types.

Window Type	Description
Bartlett	Computes a Bartlett window. $w = \text{bartlett}(M)$
Blackman	Computes a Blackman window. $w = \text{blackman}(M)$
Boxcar	Computes a rectangular window. $w = \text{rectwin}(M)$
Chebyshev	Computes a Chebyshev window with stopband ripple R . $w = \text{chebwin}(M, R)$
Hamming	Computes a Hamming window. $w = \text{hamming}(M)$
Hann	Computes a Hann window (also known as a Hanning window). $w = \text{hann}(M)$
Hanning	Obsolete. This window type is included only for compatibility with older models. Use the Hann Window type instead of Hanning whenever possible.
Kaiser	Computes a Kaiser window with the Kaiser parameter β . $w = \text{kaiser}(M, \beta)$
Taylor	Computes a Taylor window. $w = \text{taylorwin}(M)$
Triang	Computes a triangular window. $w = \text{triang}(M)$

Window Type	Description
User Defined	<p>Computes the user-defined window function specified by the entry in the Window function name parameter, <code>usrwin</code>.</p> <pre>w = usrwin(M) % Window takes no extra parameters w = usrwin(M,x₁,...,x_n) % Window takes extra parameters {x₁ ... x_n}</pre>

Sampling — Type of sampling

Symmetric (default) | Periodic

Specify the window sampling for generalized-cosine windows.

For the generalized-cosine windows (Blackman, Hamming, Hann, and Hanning), the **Sampling** parameter determines whether the window samples are computed in a periodic or a symmetric manner. For example, when **Sampling** is set to **Symmetric**, a Hamming window of length M is computed as:

```
w = hamming(M) % Symmetric (aperiodic) window
```

When **Sampling** is set to **Periodic**, the same window is computed as:

```
w = hamming(M+1) % Periodic (asymmetric) window
w = w(1:M)
```

Tunable (Simulink) in simulation only.

Dependencies

This parameter is visible only when you select Blackman, Hamming, Hann, or Hanning for the **Window type** parameter.

Sample mode — Sample mode

Continuous (default) | Discrete

Specify the sample mode for the block, **Continuous** or **Discrete**, when it is in the **Generate window mode**. In the **Apply window to input** and **Generate and apply window modes**, the block inherits the sample mode from its driving block.

Dependencies

This parameter is visible only when you select **Generate window** for the **Operation** parameter.

Sample time — Sample time

1 (default) | real scalar

Specify the sample time for the block when **Operation** is set to **Generate window** and **Sample mode** is set to **Discrete**. When **Operation** is set to **Apply window to input** and **Generate and apply window**, the block inherits the sample time from its driving block.

Dependencies

This parameter is visible only when you set **Sample mode** to **Discrete**.

Window length — Length of window

64 (default) | positive integer

Specify the length of the window to apply.

Dependencies

This parameter is visible only when you select `Generate window` for the **Operation** parameter. Otherwise, the window vector length is computed to match the length of the first dimension of the input.

Stopband attenuation in dB — Stopband attenuation in dB

50 (default) | nonnegative scalar

Specify the level of stopband attenuation R_s in decibels.

Tunable (Simulink) in simulation only.

Dependencies

This parameter is visible only when you select `Chebyshev` for the **Window type** parameter.

Beta — Kaiser window β parameter

10 (default) | real scalar

Specify the Kaiser window β parameter. Increasing β widens the mainlobe and decreases the amplitude of the window sidelobes in the window's frequency magnitude response.

Tunable (Simulink) in simulation only.

Dependencies

This parameter is visible only when you select `Kaiser` for the **Window type** parameter.

Number of sidelobes — Number of sidelobes

4 (default) | positive integer

Specify the number of sidelobes as a scalar integer value greater than zero.

Dependencies

This parameter is visible only when you select `Taylor` for the **Window type** parameter.

Maximum sidelobe level relative to mainlobe (dB) — Maximum sidelobe level relative to mainlobe

-30 (default) | scalar less than or equal to zero

Specify in decibels the maximum sidelobe level relative to the mainlobe. This parameter must be a scalar less than or equal to zero. The default value of -30 produces sidelobes with peaks 30 dB down from the mainlobe peak.

Dependencies

This parameter is visible only when you select `Taylor` for the **Window type** parameter.

Window function name — Window function name

hamming (default) | character vector

Specify the name of the user-defined window function to be calculated by the block. The output window vector returned by the custom window function must be of data type `double`.

Dependencies

This parameter is visible only when you select `User` defined for the **Window type** parameter.

Specify additional arguments to the hamming function – Specify additional arguments to the window function

off (default) | on

Select to enable the **Cell array of additional arguments** parameter, when the user-defined window requires parameters other than the window length.

Dependencies

This parameter is visible only when you select `User` defined for the **Window type** parameter.

Cell array of additional arguments – Additional arguments

{'symmetric'} (default) | cell array

Specify the extra parameters required by the user-defined window function, besides the window length.

Dependencies

This parameter is only available when you select the **Specify additional arguments to the hamming function** parameter. The entry must be a cell array.

Data Types

When the **Operation** parameter on the **Main** tab is set to `Generate window`, the following parameters appear.

Window data type – Window data type

double (default) | single | Fixed-point | User-defined | Inherit via back propagation

Specify the window data type in one of the following ways:

- double
- single
- Fixed-point -- To specify the window data type and scaling in the **Signed**, **Word length**, **Set fraction length in output to**, and **Fraction length** parameters.
- User-defined -- To specify the window data type and scaling in the **User-defined data type**, **Set fraction length in output to**, and **Fraction length** parameters.
- Inherit via back propagation -- To set the window data type and scaling to match the following block.

Signed – Window output is signed

on (default) | off

Select to output a signed fixed-point signal. Otherwise, the signal is unsigned.

Dependencies

This parameter appears only when you set **Window data type** to `Fixed-point`.

Word length – Word length

16 (default) | positive integer in the range [2 128]

Specify the word length of the fixed-point window data type in bits.

Dependencies

This parameter is visible only when you set **Window data type** to Fixed-point.

User-defined data type (e.g. `sfix(16)`, `float('single')`) — user-defined data type

`sfix(16)` (default) | built-in data type | fixed-point data type

Specify any built-in or fixed-point data type. You can specify fixed-point data types using the Fixed-Point Designer functions `sfix`, `ufix`, `sint`, `uint`, `sfrac`, and `ufrac`.

Dependencies

This parameter is only visible when you set **Window data type** to User-defined.

Set fraction length in output to — Scaling of fixed-point window data type

`Best precision` (default) | User-defined

Specify the scaling of the fixed-point window data type by using either of these methods:

- Choose `Best precision` to have the window data type scaling automatically set such that the output signal has the best possible precision.
- Choose `User-defined` to specify the window data type scaling in the **Fraction length** parameter.

Dependencies

This parameter is visible only when you set **Window data type** to Fixed-point or User-defined, and when the specified window data type is a fixed-point data type.

Fraction length — User-defined fraction length

15 (default) | integer

Specify the fraction length of the fixed-point window data type in bits.

Dependencies

This parameter is visible only when you set **Window data type** to Fixed-point or User-defined, and when you set **Set fraction length in output to** to User-defined.

When the **Operation** parameter on the **Main** tab is set to either `Apply window to input` or `Generate and apply window`, the following parameters appear.

Rounding mode — Rounding mode

`Floor` (default) | `Ceiling` | `Convergent` | `Nearest` | `Round` | `Simplest` | `Zero`

Select the rounding mode for fixed-point operations.

The window vector w does not obey this parameter. It always rounds to `Nearest`.

Note The **Rounding mode** and **Overflow mode** settings have no effect on numerical results when both of these conditions exist:

- **Product output** is `Inherit via internal rule`

- **Output** is Same as product output

With these data type settings, the block is effectively operating in a full-precision mode.

Overflow mode — Overflow mode

Wrap (default) | Saturate

Select the overflow mode for fixed-point operations.

The window vector w does not obey this parameter. It is always saturated.

Window — Window data type

Same word length as input (default) | Specify word length | Binary point scaling | Slope and bias scaling

Choose how you specify the word length and fraction length of the window vector w .

When you select:

- **Same word length as input** -- The word length of the window vector elements is the same as the word length of the input. The fraction length is automatically set to the best precision possible.
- **Specify word length** -- You can enter the word length of the window vector elements in bits. The fraction length is automatically set to the best precision possible.
- **Binary point scaling** -- You can enter the word length and the fraction length of the window vector elements in bits.
- **Slope and bias scaling** -- You can enter the word length, in bits, and the slope of the window vector elements. This block requires power-of-two slope and a bias of zero.

The window vector does not obey the **Rounding mode** and **Overflow mode** parameters. It is always saturated and rounded to Nearest.

Product output — Product output data type

Inherit via internal rule (default) | Same as input | Binary point scaling | Slope and bias scaling

Use this parameter to specify how you want to designate the product output word and fraction lengths.

When you select:

- **Inherit via internal rule** -- The product output word length and fraction length are calculated automatically. For information on how the product output word and fraction lengths are calculated when an internal rule is used, see "Inherit via Internal Rule".
- **Same as input** -- These characteristics match those of the input to the block.
- **Binary point scaling** -- You can enter the word length and the fraction length of the product output in bits.
- **Slope and bias scaling** -- You can enter the word length in bits and the slope of the product output. This block requires power-of-two slope and a bias of zero.

Output — Output data type

Same as product output (default) | Same as input | Binary point scaling | Slope and bias scaling

Choose how you specify the word length and fraction length of the output of the block.

When you select:

- **Same as product output** -- These characteristics match those of the product output.
- **Same as input** -- These characteristics match those of the input to the block.
- **Binary point scaling** -- You can enter the word length and the fraction length of the output in bits.
- **Slope and bias scaling** -- You can enter the word length in bits and the slope of the output. This block requires power-of-two slope and a bias of zero.

Lock data type settings against changes by the fixed-point tools – Prevent fixed-point tools from overriding data types

off (default) | on

Select this parameter to prevent the fixed-point tools from overriding the data types you specify in the block dialog box.

Block Characteristics

Data Types	double fixed point integer single
Direct Feedthrough	no
Multidimensional Signals	no
Variable-Size Signals	yes
Zero-Crossing Detection	no

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Generated code relies on memcpy or memset functions (string.h) under certain conditions.

Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

If the input is fixed point, it must be signed integer or signed fixed point with power-of-two slope and zero bias.

The following diagram shows the data types used within the Window Function block for fixed-point signals for each of the three operating modes.

Apply window to input

The input data type comes from the driving block. You can set the window, product output, and output data types in the block dialog. In this mode, the window vector is not output from the block.

Generate window

In this mode, the block acts as a source. The window vector is output in the window data type you specify in the block dialog.

Generate and apply window

The input data type comes from the driving block. You can set the window, product output, and output data types in the block dialog. In this mode, the window vector is output from the block.

You can set the window, product output, and output data types in the block dialog box.

Introduced before R2006a

Yule-Walker AR Estimator

Compute estimate of autoregressive (AR) model parameters using Yule-Walker method

Library

Estimation / Parametric Estimation

dspparest3

Description

The Yule-Walker AR Estimator block uses the Yule-Walker AR method, also called the autocorrelation method, to fit an autoregressive (AR) model to the windowed input data by minimizing the forward prediction error in the least squares sense. This formulation leads to the Yule-Walker equations, which are solved by the Levinson-Durbin recursion. Block outputs are always nonsingular.

The Yule-Walker AR Estimator block can output the AR model coefficients as polynomial coefficients, reflection coefficients, or both. The input can be a row vector, a column vector, or an unoriented vector which is assumed to be the output of an AR system driven by white noise. The block accepts matrices, and treats each column of the matrix as a channel. If the input is a row vector of length N , the input is treated as N different channels. If the input is an unoriented vector, the input is treated as a single channel. The block computes the normalized estimate of the AR system parameters, $A(z)$, independently for each successive input frame.

$$H(z) = \frac{\sqrt{G}}{A(z)} = \frac{\sqrt{G}}{1 + a(2)z^{-1} + \dots + a(p+1)z^{-p}}$$

When you select **Inherit estimation order from input dimensions**, the order p of the all-pole model is one less than the length of each input channel. Otherwise, the order is the value specified by the **Estimation order** parameter. To guarantee a valid output, you must set the **Estimation order** parameter to be a scalar less than or equal to half the input channel length. The Yule-Walker AR Estimator and Burg AR Estimator blocks return similar results for large frame sizes.

When **Output(s)** is set to A, port A is enabled. For each channel, port A outputs a column of length $p + 1$ that contains the normalized estimate of the AR model coefficients in descending powers of z

[1 a(2) ... a(p+1)]

When **Output(s)** is set to K, port K is enabled. For each channel, port K outputs a length- p column whose elements are the AR model reflection coefficients. When **Output(s)** is set to A and K, both port A and K are enabled, and each port outputs the respective AR model coefficients for each channel.

The square of the model gain, G , is provided at port G. G is a scalar for each channel.

See the Burg AR Estimator block reference page for a comparison of the Burg AR Estimator, Covariance AR Estimator, Modified Covariance AR Estimator, and Yule-Walker AR Estimator blocks.

Parameters

Output(s)

The type of AR model coefficients output by the block. The block can output polynomial coefficients (A), reflection coefficients (K), or both (A and K).

Inherit estimation order from input dimensions

When selected, sets the estimation order p to one less than the length of each input channel.

Estimation order

The order of the AR model, p . This parameter is enabled when you do not select **Inherit estimation order from input dimensions**.

Yule-Walker Method

Power spectral density estimate using Yule-Walker method

Library

Estimation / Power Spectrum Estimation

dpspect3

Description

The Yule-Walker Method block estimates the power spectral density (PSD) of the input using the Yule-Walker AR method. This method, also called the autocorrelation method, fits an autoregressive (AR) model to the windowed input data. It does so by minimizing the forward prediction error in the least squares sense. This formulation leads to the Yule-Walker equations, which the Levinson-Durbin recursion solves. Block outputs are always nonsingular.

The input must be a column vector. This input represents a frame of consecutive time samples from a single-channel signal. The block outputs a column vector containing the estimate of the power spectral density of the signal at N_{fft} equally spaced frequency points. The frequency points are in the range $[0, F_s)$, where F_s is the sampling frequency of the signal.

When you select **Inherit estimation order from input dimensions**, the order of the all-pole model is one less than the input frame size. Otherwise, the **Estimation order** parameter value specifies the order. To guarantee a valid output, the **Estimation order** parameter must be less than or equal to half the input vector length. The block computes the spectrum from the FFT of the estimated AR model parameters.

Selecting the **Inherit FFT length from estimation order** parameter specifies that N_{fft} is one greater than the estimation order. Clearing the **Inherit FFT length from estimation order** parameter allows you to use the **FFT length** parameter to specify N_{fft} as a power of 2. The block zero-pads or wraps the input to N_{fft} before computing the FFT.

When you select the **Inherit sample time from input** check box, the block computes the frequency data from the sample period of the input signal. For the block to produce valid output, the following conditions must hold:

- The input to the block is the original signal, with no samples added or deleted (by insertion of zeros, for example).
- The sample period of the time-domain signal in the simulation equals the sample period of the original time series.

If these conditions do not hold, clear the **Inherit sample time from input** check box. You can then specify a sample time using the **Sample time of original time series** parameter.

See the Burg Method block reference for a comparison of the Burg Method, Covariance Method, Modified Covariance Method, and Yule-Walker AR Estimator blocks. The Yule-Walker AR Estimator and Burg Method blocks return similar results for large buffer lengths.

Parameters

Inherit estimation order from input dimensions

When you select this option, it sets the estimation order to one less than the length of the input vector.

Estimation order

Specify the order of the AR model. This parameter is only visible when you clear the **Inherit estimation order from input dimensions** check box.

Inherit FFT length from estimation order

When you select the **Inherit FFT length from estimation order** check box, the FFT length is one greater than the estimation order. To specify the number of points on which to perform the FFT, clear the **Inherit FFT length from estimation order** check box. You can then specify a power-of-two FFT length using the **FFT length** parameter.

FFT length

Enter the number of data points on which to perform the FFT, N_{fft} . When N_{fft} is larger than the input frame size, the block zero-pads each frame as needed. When N_{fft} is smaller than the input frame size, the block wraps each frame as needed. This parameter becomes visible only when you clear the **Inherit FFT length from input dimensions** check box.

Inherit sample time from input

When you select the **Inherit sample time from input** check box, the block computes the frequency data from the sample period of the input signal. For the block to produce valid output, the following conditions must hold:

- The input to the block is the original signal, with no samples added or deleted (by insertion of zeros, for example).
- The sample period of the time-domain signal in the simulation equals the sample period of the original time series.

If these conditions do not hold, clear the **Inherit sample time from input** check box. You can then specify a sample time using the **Sample time of original time series** parameter.

Sample time of original time series

Specify the sample time of the original time-domain signal. This parameter becomes visible only when you clear the **Inherit sample time from input** check box.

Zero Crossing

Count number of times signal crosses zero in single time step

Library

Signal Operations

dspsigops

Description

The Zero Crossing block concludes that a signal in a given channel has passed through zero if it meets any of the following criteria, where x_i is the current signal value, x_{i-1} is the previous signal value, and so on:

- $x_i < 0$ and $x_{i-1} > 0$
- $x_i > 0$ and $x_{i-1} < 0$
- For some positive integer L , $x_i < 0$, $x_{i-l} = 0$, and $x_{i-L-1} > 0$, where $0 \leq l \leq L$.
- For some positive integer L , $x_i > 0$, $x_{i-l} = 0$, and $x_{i-L-1} < 0$, where $0 \leq l \leq L$.

For the first input value, x_{i-1} and x_{i-2} are zero. The block outputs the number of times the signal crosses zero in a single time step at the Cnt port.

The input to this block must be a real-valued fixed-point or floating-point signal. If you set the **Input processing** parameter to `Elements as channels (sample based)`, the block treats each element of the input as a time-varying channel. If you set the **Input processing** parameter to `Columns as channels (frame based)`, the block treats each column of the input as an independent channel.

Examples

The following example, `ex_zero_crossing` illustrates the behavior of the Zero Crossing block.

To run the model for one time step, the **Stop time** is set to 0.

- 1 Run the model.

Because the signal passes through zero once during the first time step, the Zero Crossing block finds one zero crossing. The number of detected zero crossings in the first time step is shown in the Display block in the following figure.

- 2 To run the model for two time steps, change the simulation **Stop time** to 1. To do so, select **Modeling** tab and click **Model Settings**. In the **Solver** pane, set **Stop time** to 1.
- 3 Run the model.

The Zero Crossing block remembers that the last value of the last frame was 3. Therefore, the signal passes through zero twice during the second time step. It passes through zero while going from 3 to -3, and it passes through zero again while going from -3 to 3. The Zero Crossing block finds two zero crossings in the second time step as shown in the Display block in the following figure.

Parameters

Input processing

Specify how the block should process the input. You can set this parameter to one of the following options:

- **Columns as channels (frame based)** (default) — When you select this option, the block treats each column of the input as a separate channel.
- **Elements as channels (sample based)** — When you select this option, the block treats each element of the input as a separate channel.

Zoom FFT

High-resolution FFT of a portion of a spectrum

Library: DSP System Toolbox / Transforms

Description

The Zoom FFT block computes the fast Fourier Transform (FFT) of a signal over a portion of frequencies in the Nyquist interval. By setting an appropriate decimation factor D , and sampling rate F_s , you can choose the bandwidth of frequencies to analyze BW , where $BW = F_s/D$. You can also select a specific range of frequencies to analyze in the Nyquist interval by choosing the center frequency of the desired band.

The resolution of a signal is the ratio of F_s and the FFT length (L). Using zoom FFT, you can retain the same resolution you would achieve with a full-size FFT on your original signal by computing a small FFT on a shorter signal. The shorter signal comes from decimating the original signal. The savings come from being able to compute a much shorter FFT while achieving the same resolution. For a decimation factor of D , the new sampling rate, F_{sd} , is F_s/D , and the new frame size (and FFT length) is $L_d = L/D$. The resolution of the decimated signal is $F_{sd}/L_d = F_s/L$. To achieve a higher resolution of the shorter band, use the original FFT length, L , instead of the decimated FFT length, L_d .

Ports

Input

x — Data input

vector | matrix

Data input whose zoom FFT the block computes, specified as a vector or a matrix. The number of input rows must be a multiple of the decimation factor.

This block supports variable-size input signals, as long as the input frame size is a multiple of the decimation factor. That is, you can change the input frame size (number of rows) during the simulation. However, the number of channels (number of columns) must remain constant.

This port is unnamed until you select the **Specify center frequency from input port** parameter and click **Apply**.

Example: `randn(22,2)`

Data Types: `single` | `double`

Fc — Center frequency input

real scalar

Center frequency of the desired band in Hz, passed through this input port as a real scalar in the range $(-SampleRate/2, SampleRate/2)$. *SampleRate* is the input sample rate either inherited from the

input signal or specified through the **Input sample rate (Hz)** parameter. This port appears only when you select the **Specify center frequency from input port** check box.

This port appears only when you select the **Specify center frequency from input port** check box and click **Apply**.

Example: 0

Example: 1200

Data Types: single | double

Output Arguments

Port_1 — Zoom FFT output

vector | matrix

Zoom FFT output, returned as a vector or matrix. If you select the **Inherit FFT Length from input dimensions** check box, the output frame size equals the input frame size divided by the decimation factor. If you clear the **Inherit FFT Length from input dimensions** check box and specify the FFT length, the output frame size equals the specified FFT length. The output data type matches the input data type.

Example: `randn(11,2)`

Data Types: single | double

Parameters

Decimation factor — Decimation factor

2 (default) | positive integer

Decimation factor, specified as a positive integer. This value specifies the factor by which the block reduces the bandwidth of the input signal. The number of rows in the input signal must be a multiple of the decimation factor.

Example: 4

Example: 8

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

Specify center frequency from input port — Flag to specify center frequency from input port

'off' (default) | 'on'

When you select this option and click **Apply**, the input port **Fc** appears on the block icon. You can pass the center frequency through this input port as a scalar.

Center frequency (Hz) — Center frequency

0 (default) | real scalar

Center frequency of the desired band in Hz, specified as a real scalar in the range $(- \text{SampleRate}/2, \text{SampleRate}/2)$. *SampleRate* is the input sample rate either inherited from the input or specified through the **Input sample rate (Hz)** parameter.

Example: 0.5

Example: 10

Dependencies

This parameter applies when you clear the **Specify center frequency from input port** check box.

Data Types: single | double

Inherit FFT Length from input dimensions — Flag to inherit FFT length from input dimensions

'on' (default) | 'off'

When you select this option, the FFT length is the ratio of the input frame size (number of rows in the input) and the **Decimation factor**.

FFT length — FFT length

64 (default) | positive scalar

FFT length, specified as a positive integer. The FFT length must be greater than or equal to the ratio of the frame size (number of input rows) and the **Decimation factor**.

Example: 24

Example: 52

Dependencies

This parameter applies when you clear the **Inherit FFT Length from input dimensions** check box.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

Inherit Sample rate from input — Flag to inherit sample rate from input

'off' (default) | 'on'

When you clear this check box, the block inherits the sample rate from the input signal.

Input sample rate (Hz) — Input sample rate

44100 (default) | positive real scalar

Input sample rate in Hz, specified as positive real scalar.

Example: 44100

Example: 48000

Simulate using — Type of simulation to run

Interpreted execution (default) | Code generation

- **Interpreted execution** — Simulate model using the MATLAB interpreter. This option shortens startup time and has faster simulation speed than **Code generation**.
- **Code generation** — Simulate model using generated C code. The first time you run a simulation, Simulink generates C code for the block. The C code is reused for subsequent simulations, as long as the model does not change. This option requires additional startup time and provides slower simulation speed than **Interpreted execution**.

Multidimensional Signals	No
Variable-Size Signals	Yes

Algorithms

The zoom FFT algorithm leverages bandpass filtering before computing the FFT of the signal. The concept of bandpass filtering is that suppose you are interested in the band $[F1, F2]$ of the original input signal, sampled at the rate F_s Hz. If you pass this signal through a complex (one-sided) bandpass filter centered at $F_c = (F1+F2)/2$, with the bandwidth $BW = F2 - F1$, and then downsample the signal by a factor of $D = \text{floor}(F_s/BW)$, the desired band comes down to the baseband.

If F_c cannot be expressed in the form of $k \times F_s/D$, where k is an integer, then the shifted, decimated spectrum is not centered at DC. In this case, the center frequency gets translated to F_d .

$$F_d = F_c - (F_s/D) \times \text{floor}((D \times F_c + F_s/2)/F_s)$$

The complex bandpass filter is obtained by first designing a lowpass filter prototype and then multiplying the lowpass coefficients with a complex exponential. This algorithm uses a multirate,

multistage FIR filter as the lowpass filter prototype. To obtain the bandpass filter, the coefficients of each stage are frequency shifted. The decimation factor is the cumulative decimation factor of each stage. The complex bandpass filter followed by the decimator are implemented using an efficient polyphase structure. For more details on the design of the complex bandpass filter from the multirate multistage FIR filter prototype, see “Zoom FFT” and “Complex Bandpass Filter Design”.

isreal	True for discrete-time filter with real coefficients
isstable	True if the filter is stable
isfir	True if the filter is FIR
issos	True if filter is in second order sections form
specifyall	Specify all fixed-point properties

System Objects

powermeter

Measure power of voltage signal

Description

The `powermeter` System object computes the power measurements of a voltage signal. The power measurements include average power, peak power, and peak-to-average power ratio. The object uses the sliding window method to compute these measurements. For more details, see “Algorithms” on page 4-7.

To measure the power of a voltage signal:

- 1 Create the `powermeter` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

Creation

Syntax

```
meter = powermeter(len)
meter = powermeter(Len,Overlap)
meter = powermeter(Name,Value)
```

Description

`meter = powermeter(len)` returns a power meter object with the `WindowLength` property set to `len`.

`meter = powermeter(Len,Overlap)` sets the `WindowLength` property to `Len` and the `OverlapLength` property to `Overlap`.

`meter = powermeter(Name,Value)` returns a power meter object with each specified property set to the specified value. Enclose each property name in quotes. You can use this syntax with the previous input argument.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see [System Design in MATLAB Using System Objects](#).

Measurement — Desired power measurement

'Average power' (default) | 'Peak power' | 'Peak-to-average power ratio' | 'All'

Desired power measurement, specified as one of the following:

- 'Average power' (default)
- 'Peak power'
- 'Peak-to-average power ratio'
- 'All'

For details on how the object computes these measurements, see “Algorithms” on page 4-7.

WindowLength — Window length

256 (default) | positive integer

Window length over which the measurement is computed, specified as a positive integer.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

OverlapLength — Overlap length between windows

WindowLength - 1 (default) | nonnegative integer

Overlap length between sliding windows, specified as a nonnegative integer. The value of overlap length varies in the range [0, WindowLength - 1]. If not specified, the overlap length is WindowLength - 1.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

ReferenceLoad — Reference load in ohms

1 (default) | positive scalar in ohms

Reference load that the power meter uses to compute power values, specified as a real, positive scalar in ohms.

Tunable: Yes

Data Types: single | double

PowerUnits — Units of measured power values

'dBm' (default) | 'dBW' | 'Watts'

Units of the measured power values, specified as one of the following:

- 'dBm'
- 'dBW'
- 'Watts'

Usage**Syntax**

```
avgpwr = meter(x)
peakpwr = meter(x)
```

```
papr = meter(x)
[avgpwr,peakpwr,papr] = meter(x)
```

Description

`avgpwr = meter(x)` computes the average power of the input signal `x` when the `Measurement` property is set to 'Average power'. Each column of `x` is an independent channel. The object computes the average power of each channel of the input signal independently.

`peakpwr = meter(x)` computes the peak power of the input signal `x` when the `Measurement` property is set to 'Peak power'. Each column of `x` is an independent channel. The object computes the peak power of each channel of the input signal independently.

`papr = meter(x)` computes the peak-to-average power ratio of the input signal `x` when the `Measurement` property is set to 'Peak-to-average power ratio'. Each column of `x` is an independent channel. The object computes the peak-to-average power ratio of each channel of the input signal independently.

`[avgpwr,peakpwr,papr] = meter(x)` computes the average power, peak power, and the peak-to-average power ratio of the input signal `x` when the `Measurement` property is set to 'All'. Each column of `x` is an independent channel. The object computes the power measurements of each channel of the input signal independently.

Input Arguments

x — Input voltage signal

vector | matrix

Input voltage signal, specified as a vector or a matrix, and measured in volts. If `x` is a matrix, each column is treated as an independent channel. The power measurement is computed along each channel using the “Sliding Window Method” on page 4-7.

The object also accepts variable-size inputs. That is, once the object is locked, you can change the size of each input channel, but you cannot change the number of channels.

Data Types: `single` | `double`

Output Arguments

avgpwr — Average power

vector | matrix

Average power of the voltage signal, returned as a vector or a matrix, and measured in the units determined by the `PowerUnits` property. For details on how the object computes the average power, see “Average Power” on page 4-7.

Data Types: `single` | `double`

peakpwr — Peak power

vector | matrix

Peak power of the voltage signal, returned as a vector or a matrix, and measured in the units determined by the `PowerUnits` property. For details on how the object computes the peak power, see “Peak Power” on page 4-8.

Data Types: `single` | `double`

papr — Peak-to-average power ratio

vector | matrix

Peak-to-average power ratio of the voltage signal, returned as a vector or a matrix. For details on how the object computes the peak-to-average power ratio, see “Peak-to-Average Power Ratio” on page 4-8.

Data Types: single | double

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Common to All System Objects

<code>step</code>	Run System object algorithm
<code>release</code>	Release resources and allow changes to System object property values and input characteristics
<code>reset</code>	Reset internal states of System object

Examples**Compute Power Measurements of Voltage Signal**

Compute the power measurements of a noisy sinusoidal signal using a power meter. These measurements include average power, peak power, and peak-to-average power ratio.

Assume the maximum voltage of the signal to be 100 V. The instantaneous values of a sinusoidal waveform are given by the equation $V_i = V_{max} \times \sin(2\pi ft)$, where V_i is the instantaneous value, V_{max} is the maximum voltage of the signal, and f is the frequency of the signal in Hz.

Initialization

The input signal is a sum of two sine waves with frequencies set to 1 kHz and 10 kHz, respectively. The frame length and the sampling frequency of the generated signal is 512 samples and 44.1 kHz, respectively.

To measure the power in this signal, create a `powermeter` object. Set 'Measurement' to 'All'. This setting enables the object to measure the average power, peak power, and peak-to-average power ratio. Set the length of the sliding window to 16 samples and the reference load to 50 Ohms. Use this object to measure the power in dBm units. Visualize the power measurements using the `timescope` object.

```
FrameLength = 512;
Fs = 44.1e3;
A = 100;
sine1 = dsp.SinWave('Amplitude',A,...
    'Frequency',1e3,...
    'SampleRate',44.1e3,...
    'SamplesPerFrame',FrameLength);
sine2 = dsp.SinWave('Amplitude',A,...
```

```

    'Frequency',10e3,...
    'SampleRate',44.1e3,...
    'SamplesPerFrame',FrameLength);
pm = powermeter(16, 'Measurement', 'All', ...
    'ReferenceLoad', 50, ...
    'PowerUnits', 'dBm');
scope = timescope('NumInputPorts',4,'SampleRate',Fs,...
    'TimeSpanSource','property',...
    'TimeSpan',96,...
    'YLabel','dBm',...
    'YLimits',[-30 90]);
title = 'Power Measurements';
scope.ChannelNames = {'Average power',...
    'Peak power','Peak-to-average power ratio',...
    'Expected Average Power'};
scope.Title = title;

```

Compute the Power Measurements

Add zero-mean white Gaussian noise with a standard deviation of 0.001 to the sum of sine waves. Vary the amplitude of the sine waves. Measure the average power, peak power, and the peak-to-average power ratio of this noisy sinusoidal signal that has a varying amplitude. For details on how the object measures these power values, see “Algorithms” on page 4-7. Compare the measured values to the expected value of the average power.

The expected value of the average power P of the noisy sinusoidal signal is given by the following equation.

$$P = \frac{A_1^2}{2R} + \frac{A_2^2}{2R} + \text{var}(\text{noise}),$$

where,

- A_1 is the amplitude of the first sinusoidal signal.
- A_2 is the amplitude of the second sinusoidal signal.
- R is the reference load in Ohms.

In dBm, the expected power is computed using the following equation:

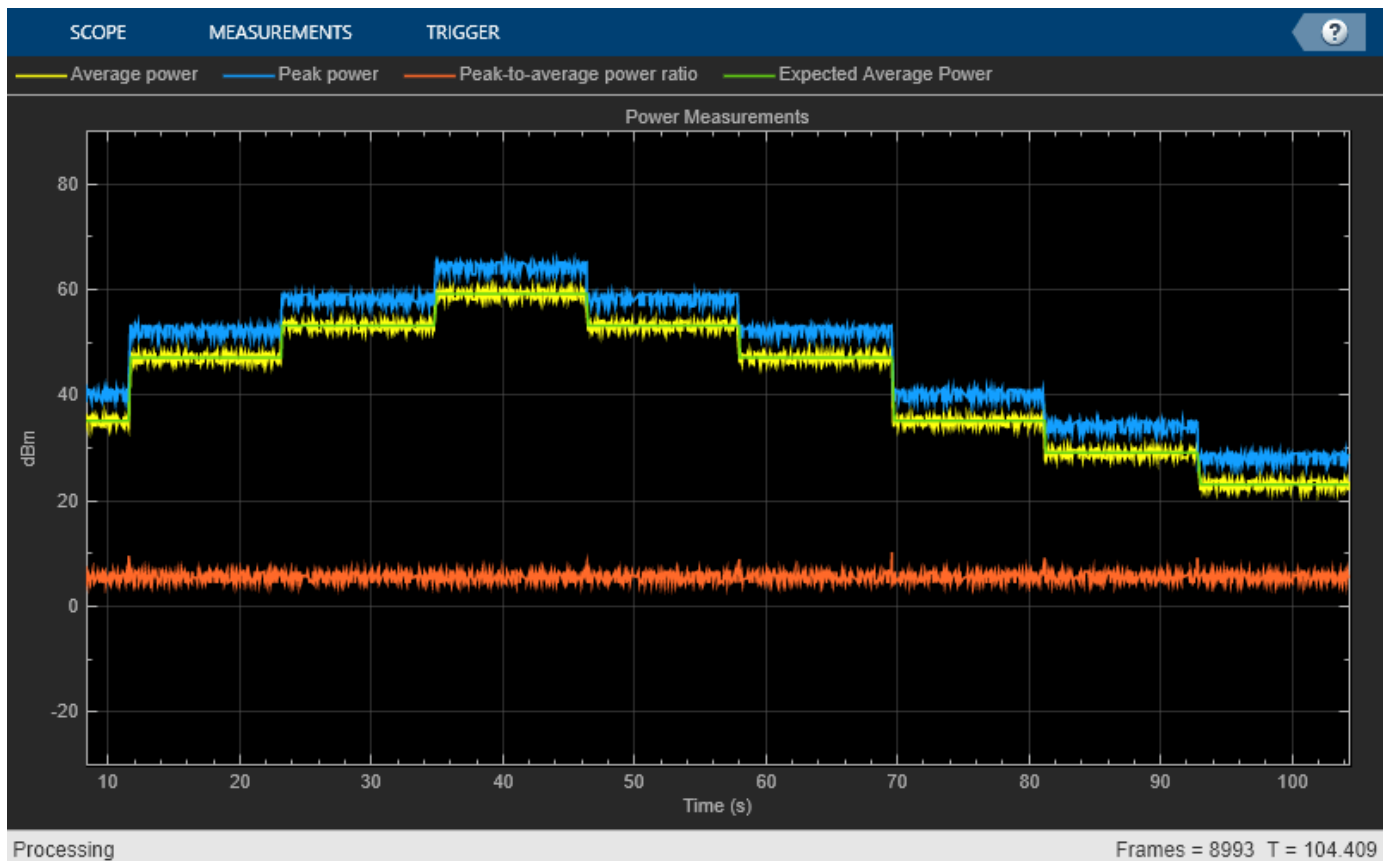

$$\text{expPwr}_{\text{dBm}} = 10\log_{10}(P) + 30.$$

Compare the expected value with the value computed by the object. All values are in dBm. These values match very closely. To verify, view the computed measurements using the `timescope` object.

```

Vect = [1/8 1/2 1 2 1 1/2 1/8 1/16 1/32];
for index = 1:length(Vect)
    V = Vect(index);
    for i = 1:1000
        x = V*sine1()+V*sine2()+0.001.*randn(FrameLength,1);
        P = (((V*A)^2)/100)+(((V*A)^2)/100)+(0.001)^2;
        expPwr = (10*log10(P)+30)*ones(FrameLength,1);
        [avgPwr,pkPwr,papr] = pm(x);
        scope(avgPwr,pkPwr,papr,expPwr);
    end
end

```

Algorithms

Sliding Window Method

In the sliding window method, the power measurement is computed over a finite duration of the signal. The window length defines the length of the data over which the algorithm computes the power value. The window moves as the new data comes in. The output for each input sample is the measurement done over the current sample and the $Len - 1$ previous samples. Len is the length of the sliding window in samples. To compute the first $Len - 1$ outputs, when the window does not have enough data yet, the algorithm fills the window with zeros. As an example, to compute the average power when the second input sample comes in, the algorithm fills the window with $Len - 2$ zeros. The input signal x is then the two data samples followed by $Len - 2$ zeros.

For a more detailed example, see “Sliding Window Method”.

If the window is large, the power computed is closer to the stationary power of the data. For data that does not change rapidly, use a long window to get a smoother measurement. For data that changes fast, use a smaller window.

Average Power

The average power of the voltage signal is computed using the Sliding Window Method on page 4-7 and is given by the following equations:

$$AvgPower_{dBm} = 10\log_{10}\left(\text{movAvg}\left(|x|^2\right)/R\right) + 30$$

$$AvgPower_{dBW} = 10\log_{10}(\text{movAvg}(|x|^2)/R)$$

$$AvgPower_{Watts} = \text{movAvg}(|x|^2)/R$$

where,

- x is the input voltage signal.
- R is the reference load (in ohms) that is used to compute the power value.
- `movAvg` computes the moving average using the sliding window method. The `powermeter` object in MATLAB uses the `dsp.MovingAverage` object and the Power Meter block in Simulink uses the Moving Average block.

Peak Power

The peak power of the voltage signal is computed using the Sliding Window Method on page 4-7 and is given by the following equations:

$$PeakPower_{dBm} = 10\log_{10}(\text{movMax}(|x|^2)/R) + 30$$

$$PeakPower_{dBW} = 10\log_{10}(\text{movMax}(|x|^2)/R)$$

$$PeakPower_{Watts} = \text{movMax}(|x|^2)/R$$

where,

- x is the input voltage signal.
- R is the reference load (in ohms) that is used to compute the power value.
- `movMax` computes the moving maximum using the sliding window method. The `powermeter` object in MATLAB uses the `dsp.MovingMaximum` object and the Power Meter block in Simulink uses the Moving Maximum block.

Peak-to-Average Power Ratio

The peak-to-average power ratio of the voltage signal is computed using the Sliding Window Method on page 4-7 and is given by the following equations:

$$pkAvgPwr_{dBm} = 10\log_{10}(\text{movMax}(|x|^2)/\text{movAvg}(|x|^2))$$

$$pkAvgPwr_{dBW} = 10\log_{10}(\text{movMax}(|x|^2)/\text{movAvg}(|x|^2))$$

$$pkAvgPwr_{Watts} = \text{movMax}(|x|^2)/\text{movAvg}(|x|^2)$$

where,

- x is the input voltage signal.
- `movAvg` computes the moving average using the sliding window method. The `powermeter` object in MATLAB uses the `dsp.MovingAverage` object and the Power Meter block in Simulink uses the Moving Average block.

- `movMax` computes the moving maximum using the sliding window method. The `powermeter` object in MATLAB uses the `dsp.MovingMaximum` object and the Power Meter block in Simulink uses the Moving Maximum block.

dsp.AdaptiveLatticeFilter

Package: dsp

Adaptive lattice filter

Description

The `dsp.AdaptiveLatticeFilter` System object computes output, error, and coefficients using a lattice-based FIR adaptive filter.

To implement the adaptive FIR filter object:

- 1** Create the `dsp.AdaptiveLatticeFilter` object and set its properties.
- 2** Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

Creation

Syntax

```
alf = dsp.AdaptiveLatticeFilter  
alf = dsp.AdaptiveLatticeFilter(len)  
alf = dsp.AdaptiveLatticeFilter(Name,Value)
```

Description

`alf = dsp.AdaptiveLatticeFilter` returns a lattice-based FIR adaptive filter System object, `alf`. This System object computes the filtered output and the filter error for a given input and desired signal.

`alf = dsp.AdaptiveLatticeFilter(len)` returns an `AdaptiveLatticeFilter` System object with the `Length` property set to `len`.

`alf = dsp.AdaptiveLatticeFilter(Name,Value)` returns an `AdaptiveLatticeFilter` System object with each specified property set to the specified value. Enclose each property name in single quotes. Unspecified properties have default values.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see [System Design in MATLAB Using System Objects](#).

Method — Method to calculate filter coefficients

'Least-squares Lattice' (default) | 'QR-decomposition Least-squares Lattice' | 'Gradient Adaptive Lattice'

Specify the method used to calculate filter coefficients as one of 'Least-squares Lattice', 'QR-decomposition Least-squares Lattice', 'Gradient Adaptive Lattice'. The default value is 'Least-squares Lattice'. For algorithms used to implement these three different methods, refer to [1] [2]. This property is nontunable.

Length — Length of filter coefficients vector

32 (default) | positive integer

Specify the length of the FIR filter coefficients vector as a positive integer value. This property is nontunable.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

ForgettingFactor — Least-squares lattice forgetting factor

1 (default) | positive scalar

Specify the least-squares lattice forgetting factor as a scalar positive numeric value less than or equal to 1. Setting this value to 1 denotes infinite memory during adaptation.

Tunable: Yes

Dependencies

This property applies only if the Method property is set to 'Least-squares Lattice' or 'QR-decomposition Least-squares Lattice'.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

StepSize — Joint process step size of gradient adaptive filter

0.1 (default) | positive scalar

Specify the joint process step size of the gradient adaptive lattice filter as a positive numeric scalar less than or equal to 1.

Tunable: Yes

Dependencies

This property applies only if the Method property is set to 'Gradient Adaptive Lattice'.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | logical

Offset — Offset for denominator of StepSize normalization term

1 (default) | nonnegative scalar

Specify an offset value for the denominator of the StepSize normalization term as a nonnegative numeric scalar. A nonzero offset helps avoid a divide-by-near-zero condition when the input signal amplitude is very small.

Tunable: Yes

Dependencies

This property applies only if the `Method` property is set to 'Gradient Adaptive Lattice'.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

ReflectionStepSize — Reflection process step size

`StepSize` property value (default) | positive scalar

Specify the reflection process step size of the gradient adaptive lattice filter as a scalar numeric value between 0 and 1, both inclusive. The default value is the `StepSize` property value.

Tunable: Yes

Dependencies

Use this property only if the `Method` property is set to 'Gradient Adaptive Lattice'.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical`

AveragingFactor — Averaging factor of energy estimator

`1 - StepSize` (default) | positive scalar

Specify the averaging factor as a positive numeric scalar less than 1. Use this property to compute the exponentially windowed forward and backward prediction error powers for the coefficient updates. The default is the value of `1 - StepSize`.

Tunable: Yes

Dependencies

This property applies only if the `Method` property is set to 'Gradient Adaptive Lattice'.

Data Types: `single` | `double`

InitialPredictionErrorPower — Initial prediction error power

`1.0` (default) | positive scalar

Specify the initial values for the prediction error vectors as a scalar positive numeric value.

If the `Method` property is set to 'Least-squares Lattice' or 'QR-decomposition Least-squares Lattice', the default value is `1.0`. If the `Method` property is set to 'Gradient Adaptive Lattice', the default value is `0.1`.

Tunable: Yes

Data Types: `single` | `double`

InitialCoefficients — Initial coefficients of filter

`0` (default) | scalar | vector

Specify the initial values of the FIR adaptive filter coefficients as a scalar or a vector of length equal to the value of the `Length` property.

Tunable: Yes

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

LockCoefficients — Locked status of coefficient updates

false (default) | true

Specify whether to lock the filter coefficient values. By default, the value of this property is `false`, and the object continuously updates the filter coefficients. If this property is set to `true`, the filter coefficients do not update and their values remain the same.

Tunable: Yes

Dependencies

This property is applicable only if the `Method` property is set to 'Gradient Adaptive Lattice'.

Usage**Syntax**

```
[y,err] = alf(x,d)
```

Description

`[y,err] = alf(x,d)` filters the input `x`, using `d` as the desired signal, and returns the filtered output in `y` and the filter error in `err`. The System object estimates the filter weights needed to minimize the error between the output signal and the desired signal. You can access these coefficients by accessing the `Coefficients` property of the object. This can be done only after calling the object. For example, to access the optimized coefficients of the `alf` filter, call `alf.Coefficients` after you pass the input and desired signal to the object.

Input Arguments**x — Data input**

scalar | column vector

The signal to be filtered by the adaptive lattice filter. The input, `x`, and the desired signal, `d`, must have the same size and data type.

The input can be a variable-size signal. You can change the number of elements in the column vector even when the object is locked. The System object locks when you call the object.

Data Types: `single` | `double`

d — Desired signal

scalar | column vector

The adaptive lattice filter adapts its coefficients to minimize the error, `err`, and converge the input signal `x` to the desired signal `d` as closely as possible.

The input, `x`, and the desired signal, `d`, must have the same size and data type.

The desired signal can be a variable-size signal. You can change the number of elements in the column vector even when the object is locked. The System object locks when you call the object.

Data Types: `single` | `double`

Complex Number Support: Yes

Output Arguments

y — Filtered output

scalar | column vector

Filtered output, returned as a scalar or a column vector. The object adapts its filter coefficients to converge the input signal x to match the desired signal d . The filter outputs the converged signal.

Data Types: `single` | `double`

err — Difference between output and desired signal

scalar | column vector

Difference between the output signal y and the desired signal d , returned as a scalar or a column vector. The objective of the adaptive lattice filter is to minimize this error. The object adapts its coefficients to converge towards optimal filter coefficients that produce an output signal that matches closely with the desired signal. To access the adaptive lattice filter coefficients, call `alf.Coefficients` after you pass the input and desired signal to the object algorithm.

Data Types: `single` | `double`

Complex Number Support: Yes

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Specific to `dsp.AdaptiveLatticeFilter`

`mseSim` Estimated mean squared error for adaptive filters

Common to All System Objects

`step` Run System object algorithm

`release` Release resources and allow changes to System object property values and input characteristics

`reset` Reset internal states of System object

Examples

QPSK Adaptive Equalization Using Adaptive Lattice Filter

Note: If you are using R2016a or an earlier release, replace each call to the object with the equivalent `step` syntax. For example, `obj(x)` becomes `step(obj,x)`.

Create the QPSK signal and the noise, filter them to obtain the received signal, and delay the received signal to obtain the desired signal.

```
D = 16;  
b = exp(1i*pi/4)*[-0.7 1];  
a = [1 -0.7];  
ntr = 1000;
```

```

s = sign(randn(1,ntr+D)) + 1i*sign(randn(1,ntr+D));
n = 0.1*(randn(1,ntr+D) + 1i*randn(1,ntr+D));
r = filter(b,a,s) + n;
x = r(1+D:ntr+D);
d = s(1:ntr);

```

Use the Adaptive Lattice Filter to compute the filtered output and the filter error for the input and desired signal.

```

lam = 0.995;
del = 1;
alf = dsp.AdaptiveLatticeFilter('Length', 32, ...
    'ForgettingFactor', lam, 'InitialPredictionErrorPower', del);
[y,e] = alf(x,d);

```

Plot the In-Phase and the Quadrature components of the desired, output, and the error signals.

```

subplot(2,2,1); plot(1:ntr,real([d;y;e]));
title('In-Phase Components');
legend('Desired','Output','Error');
xlabel('time index'); ylabel('signal value');
subplot(2,2,2); plot(1:ntr,imag([d;y;e]));
title('Quadrature Components');
legend('Desired','Output','Error');
xlabel('time index'); ylabel('signal value');

```

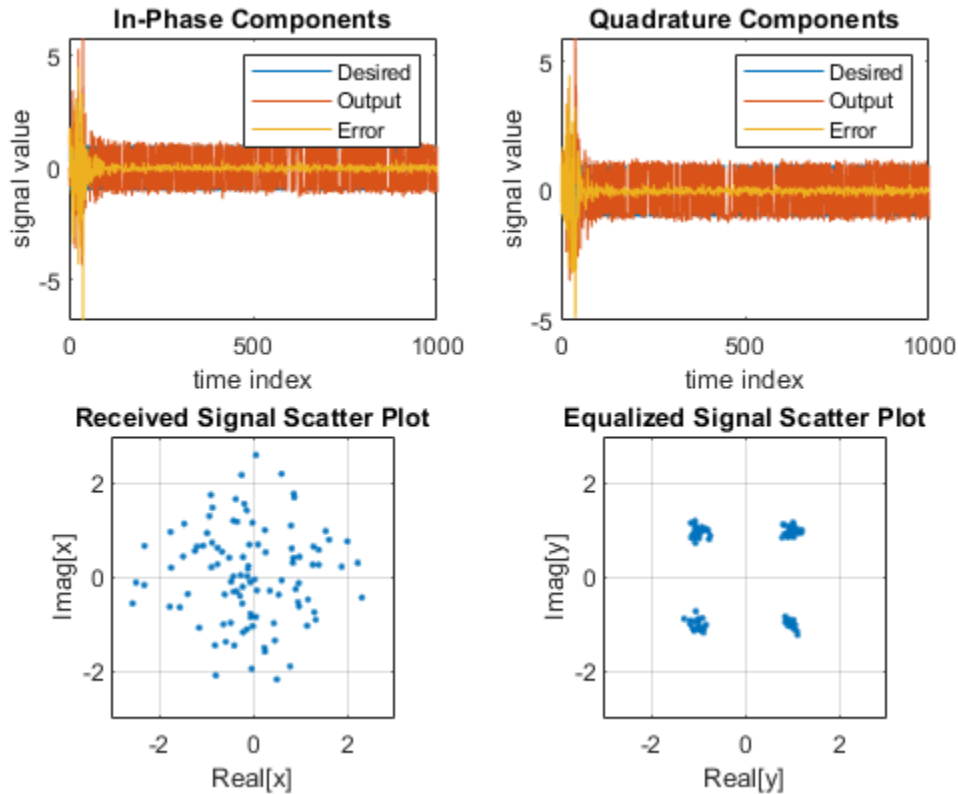

Plot the received and equalized signals' scatter plots.

```

subplot(2,2,3); plot(x(ntr-100:ntr),'.'); axis([-3 3 -3 3]);
title('Received Signal Scatter Plot'); axis('square');
xlabel('Real[x]'); ylabel('Imag[x]'); grid on;
subplot(2,2,4); plot(y(ntr-100:ntr),'.'); axis([-3 3 -3 3]);
title('Equalized Signal Scatter Plot'); axis('square');
xlabel('Real[y]'); ylabel('Imag[y]'); grid on;

```

System Identification of FIR Filter Using Adaptive Lattice Filter

Note: If you are using R2016a or an earlier release, replace each call to the object with the equivalent step syntax. For example, `obj(x)` becomes `step(obj,x)`.

```

ha = fir1(31,0.5);
% FIR system to be identified
fir = dsp.FIRFilter('Numerator',ha);
iir = dsp.IIRFilter('Numerator',sqrt(0.75),...
    'Denominator',[1 -0.5]);
x = iir(sign(randn(2000,25)));
% Observation noise signal
n = 0.1*randn(size(x));
% Desired signal
d = fir(x)+n;
% Filter length
l = 32;
% Decimation factor for analysis

```

```

% and simulation results
m = 5;
ha = dsp.AdaptiveLatticeFilter(l);
[simmse,meanWsim,Wsim,traceKsim] = msesim(ha,x,d,m);
plot(m*(1:length(simmse)),10*log10(simmse));
xlabel('Iteration');
ylabel('MSE (dB)');
% Plot the learning curve used for
% adaptive lattice filter used in system identification
title('Learning curve')

```

Introduced in R2013b

dsp.AffineProjectionFilter

Package: dsp

Compute output, error and coefficients using affine projection (AP) Algorithm

Description

The `dsp.AffineProjectionFilter` System object filters each channel of the input using AP filter implementations.

To filter each channel of the input:

- 1 Create the `dsp.AffineProjectionFilter` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

Creation

Syntax

```
apf = dsp.AffineProjectionFilter
apf = dsp.AffineProjectionFilter(len)
apf = dsp.AffineProjectionFilter(Name,Value)
```

Description

`apf = dsp.AffineProjectionFilter` returns an adaptive FIR filter System object, `apf`. This System object computes the filtered output and the filter error for a given input and desired signal using the affine projection (AP) algorithm.

`apf = dsp.AffineProjectionFilter(len)` returns an affine projection filter object with the `Length` property set to `len`.

`apf = dsp.AffineProjectionFilter(Name,Value)` returns an affine projection filter object with each specified property set to the specified value. Enclose each property name in single quotes. Unspecified properties have default values.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see [System Design in MATLAB Using System Objects](#).

Method — Method to calculate filter coefficients

Direct Matrix Inversion (default) | Recursive Matrix Update | Block Direct Matrix Inversion

Specify the method used to calculate filter coefficients as Direct Matrix Inversion, Recursive Matrix Update, Block Direct Matrix Inversion. This property is nontunable.

Length — Length of filter coefficients vector

32 (default) | positive integer

Specify the length of the FIR filter coefficients vector as a scalar positive integer value. This property is nontunable.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

ProjectionOrder — Projection order of affine projection algorithm

2 (default) | positive integer

Specify the projection order of the affine projection algorithm as a scalar positive integer value greater than or equal to 2. This property defines the size of the input signal covariance matrix. This property is nontunable.

Data Types: double

StepSize — Affine projection step size

1 (default) | nonnegative scalar

Specify the affine projection step size factor as a scalar nonnegative numeric value between 0 and 1, both inclusive. Setting the step size equal to one provides the fastest convergence during adaptation.

Tunable: Yes

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | logical

InitialCoefficients — Initial coefficients of filter

0 (default) | scalar | vector

Specify the initial values of the FIR adaptive filter coefficients as a scalar or a vector of length equal to the Length property value.

Tunable: Yes

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

InitialOffsetCovariance — Initial values of offset input covariance matrix

1 (default) | scalar | square matrix

Specify the initial values for the offset input covariance matrix. This property must be either a scalar positive numeric value or a positive-definite square matrix with each dimension equal to the ProjectionOrder property value. If it is a scalar value, the OffsetCovariance property is initialized to a diagonal matrix with the diagonal elements equal to that scalar value. If it is a square matrix, the OffsetCovariance property is initialized to the value of that square matrix.

Tunable: Yes

Dependencies

This property is applicable only if the `Method` property is set to `Direct Matrix Inversion` or `Block Direct Matrix Inversion`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

InitialInverseOffsetCovariance — Initial values of offset input covariance matrix inverse

20 (default) | scalar | square matrix

Specify the initial values for the offset input covariance matrix inverse. This property must be either a scalar positive numeric value or a positive-definite square matrix with each dimension equal to the `ProjectionOrder` property value. If it is a scalar value, the `InverseOffsetCovariance` property is initialized to a diagonal matrix with each diagonal element equal to that scalar value. If it is a square matrix, the `InverseOffsetCovariance` property is initialized to the values of that square matrix.

Tunable: Yes

Dependencies

This property is applicable only if the `Method` property is set to `Recursive Matrix Update`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

InitialCorrelationCoefficients — Initial correlation coefficients

0 (default) | scalar | vector

Specify the initial values of the correlation coefficients of the FIR filter as a scalar or a vector of length equal to `ProjectionOrder - 1`.

Tunable: Yes

Dependencies

This property is applicable only if the `Method` property is set to `Recursive Matrix Update`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

LockCoefficients — Lock coefficient updates

false (default) | true

Specify whether the filter coefficient values should be locked. When you set this property to `true`, the filter coefficients are not updated and their values remain the same. The default value is `false` (filter coefficients are continuously updated).

Tunable: Yes

Usage**Syntax**

```
[y,err] = apf(x,d)
```

Description

`[y, err] = apf(x, d)` filters the input `x`, using `d` as the desired signal, and returns the filtered output in `y` and the filter error in `err`. The System object estimates the filter weights needed to minimize the error between the output signal and the desired signal. You can access these coefficients by accessing the `Coefficients` property of the object. This can be done only after calling the object. For example, to access the optimized coefficients of the `apf` filter, call `apf.Coefficients` after you pass the input and desired signal to the object.

Input Arguments

x — Data input

scalar | column vector

The signal to be filtered by the affine projection filter. The input, `x`, and the desired signal, `d`, must have the same size and data type.

The input can be a variable-size signal. You can change the number of elements in the column vector even when the object is locked. The System object locks when you call the object to run its algorithm.

Data Types: `single` | `double`

d — Desired signal

scalar | column vector

The affine projection filter adapts its coefficients to minimize the error, `err`, and converge the input signal `x` to the desired signal `d` as closely as possible.

The input, `x`, and the desired signal, `d`, must have the same size and data type.

The desired signal can be a variable-size signal. You can change the number of elements in the column vector even when the object is locked. The System object locks when you call the object.

Data Types: `single` | `double`

Complex Number Support: Yes

Output Arguments

y — Filtered output

scalar | column vector

Filtered output, returned as a scalar or a column vector. The object adapts its filter coefficients to converge the input signal `x` to match the desired signal `d`. The filter outputs the converged signal.

Data Types: `single` | `double`

err — Difference between output and desired signal

scalar | column vector

Difference between the output signal `y` and the desired signal `d`, returned as a scalar or a column vector. The objective of the affine projection filter is to minimize this error. The object adapts its coefficients to converge towards optimal filter coefficients that produce an output signal that matches closely with the desired signal. To access the affine projection filter coefficients, call `apf.Coefficients` after you pass the input and desired signal to the object.

Data Types: `single` | `double`

Complex Number Support: Yes

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Specific to `dsp.AffineProjectionFilter`

`mssim` Estimated mean squared error for adaptive filters

Common to All System Objects

`step` Run System object algorithm

`release` Release resources and allow changes to System object property values and input characteristics

`reset` Reset internal states of System object

Examples

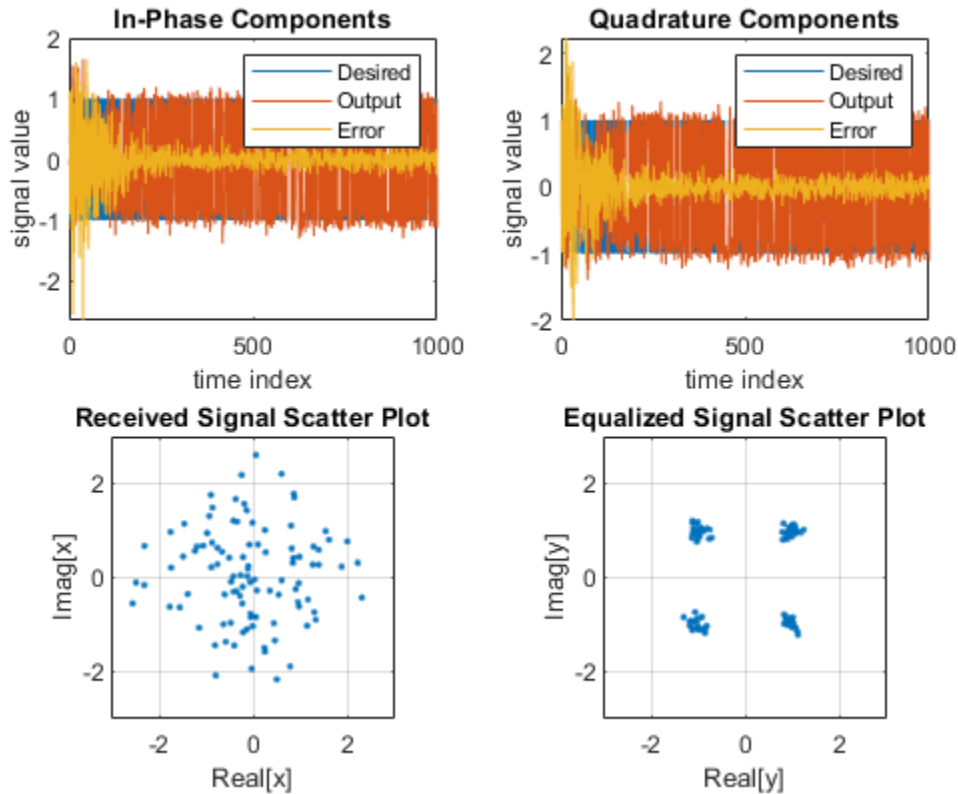

QPSK Adaptive Equalization

Note: If you are using R2016a or an earlier release, replace each call to the object with the equivalent `step` syntax. For example, `obj(x)` becomes `step(obj,x)`.

QPSK Adaptive Equalization Using a 32-Coefficient FIR Filter (1000 Iterations)

```
D = 16; % Number of samples of delay
b = exp(1i*pi/4)*[-0.7 1]; % Numerator coefficients of channel
a = [1 -0.7]; % Denominator coefficients of channel
ntr = 1000; % Number of iterations
s = sign(randn(1,ntr+D)) + 1i*sign(randn(1,ntr+D)); % Baseband signal
n = 0.1*(randn(1,ntr+D) + 1i*randn(1,ntr+D)); % Noise signal
r = filter(b,a,s)+n; % Received signal
x = r(1+D:ntr+D); % Input signal (received signal)
d = s(1:ntr); % Desired signal (delayed QPSK signal)
mu = 0.1; % Step size
po = 4; % Projection order
offset = 0.05; % Offset for covariance matrix
apf = dsp.AffineProjectionFilter('Length', 32, ...
    'StepSize', mu, 'ProjectionOrder', po, ...
    'InitialOffsetCovariance', offset);
[y,e] = apf(x,d);
subplot(2,2,1); plot(1:ntr,real([d;y;e]));
title('In-Phase Components');
legend('Desired','Output','Error');
xlabel('time index'); ylabel('signal value');
subplot(2,2,2); plot(1:ntr,imag([d;y;e]));
title('Quadrature Components');
legend('Desired','Output','Error');
xlabel('time index'); ylabel('signal value');
subplot(2,2,3); plot(x(ntr-100:ntr),'.'); axis([-3 3 -3 3]);
title('Received Signal Scatter Plot'); axis('square');
xlabel('Real[x]'); ylabel('Imag[x]'); grid on;
subplot(2,2,4); plot(y(ntr-100:ntr),'.'); axis([-3 3 -3 3]);
```

```
title('Equalized Signal Scatter Plot'); axis('square');
xlabel('Real[y]'); ylabel('Imag[y]'); grid on;
```

System Identification of FIR Filter Using Affine Projection Filter

Note: If you are using R2016a or an earlier release, replace each call to the object with the equivalent step syntax. For example, `obj(x)` becomes `step(obj,x)`.

```
ha = fir1(31,0.5);
% FIR system to be identified
fir = dsp.FIRFilter('Numerator',ha);
iir = dsp.IIRFilter('Numerator',sqrt(0.75),...
'Denominator',[1 -0.5]);
x = iir(sign(randn(2000,25)));
% Observation noise signal
n = 0.1*randn(size(x));
% Desired signal
d = fir(x)+n;
% Filter length
l = 32;
% Affine Projection filter Step size.
mu = 0.008;
% Decimation factor for analysis
% and simulation results
m = 5;
```

```

apf = dsp.AffineProjectionFilter(l,'StepSize',mu);
[simmse,meanWsim,Wsim,traceKsim] = msesim(apf,x,d,m);
plot(m*(1:length(simmse)),10*log10(simmse));
xlabel('Iteration'); ylabel('MSE (dB)');
% Plot the learning curve for affine projection filter
% used in system identification
title('Learning curve')

```

Algorithms

The affine projection algorithm (APA) is an adaptive scheme that estimates an unknown system based on multiple input vectors [1]. It is designed to improve the performance of other adaptive algorithms, mainly those that are LMS based. The affine projection algorithm reuses old data resulting in fast convergence when the input signal is highly correlated, leading to a family of algorithms that can make trade-offs between computation complexity with convergence speed [2].

The following equations describe the conceptual algorithm used in designing AP filters:

$$\mathbf{U}ap(n) = \begin{pmatrix} u(n) & \dots & u(n-L) \\ \vdots & \ddots & \vdots \\ u(n-N) & \dots & u(n-L-N) \end{pmatrix} = (\mathbf{u}(n) \ \mathbf{u}(n-1) \ \dots \ \mathbf{u}(n-L))$$

$$\mathbf{y}ap(n) = \mathbf{U}^T ap(n)\mathbf{w}(n) = \begin{pmatrix} y(n) \\ \cdot \\ \cdot \\ \cdot \\ y(n-L) \end{pmatrix}$$

$$\mathbf{d}ap(n) = \begin{pmatrix} d(n) \\ \cdot \\ \cdot \\ \cdot \\ d(n-L) \end{pmatrix}$$

$$\mathbf{e}ap(n) = \mathbf{d}ap(n) - \mathbf{y}ap(n) = \begin{pmatrix} e(n) \\ \cdot \\ \cdot \\ \cdot \\ e(n-L) \end{pmatrix}$$

$$\mathbf{w}(n) = \mathbf{w}(n-1) + \mu \mathbf{U}ap(n) \mathbf{e}ap$$

where \mathbf{C} is either $\varepsilon \mathbf{I}$ if the initial offset covariance is a scalar ε , or \mathbf{R} if the initial offset covariance is a matrix \mathbf{R} . The variables are as follows:

Variable	Description
n	The current time index
$u(n)$	The input sample at step n
$\mathbf{U}_{ap}(n)$	The matrix of the last $L+1$ input signal vectors
$\mathbf{w}(n)$	The adaptive filter coefficients vector
$y(n)$	The adaptive filter output
$d(n)$	The desired signal
$e(n)$	The error at step n
L	The projection order
N	The filter order (i.e., filter length = $N+1$)
μ	The step size

Introduced in R2013a

dsp.AllpassFilter

Package: dsp

Single section or cascaded allpass filter

Description

The `dsp.AllpassFilter` object filters each channel of the input using Allpass filter implementations. To import this object into Simulink, use the MATLAB System block.

Note Cell array support for `AllpassCoefficients`, `WDFCoefficients`, and `LatticeCoefficients` has been removed. Use an N -by-1 or N -by-2 numeric array instead. For more information, see “Compatibility Considerations” on page 4-35.

To filter each channel of the input:

- 1 Create the `dsp.AllpassFilter` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

Creation

Syntax

```
Allpass = dsp.AllpassFilter  
Allpass = dsp.AllpassFilter(Name,Value)
```

Description

`Allpass = dsp.AllpassFilter` returns an allpass filter System object, `Allpass`, that filters each channel of the input signal independently using an allpass filter, with the default structure and coefficients.

`Allpass = dsp.AllpassFilter(Name,Value)` returns an allpass filter System object, `Allpass`, with each property set to the specified value.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see [System Design in MATLAB Using System Objects](#).

Structure — Internal allpass filter structure

Minimum multiplier (default) | Lattice | Wave Digital Filter

You can specify the internal allpass filter implementation structure as one of | Minimum multiplier | Lattice | Wave Digital Filter. Each structure uses a different set of coefficients, independently stored in the corresponding object property.

AllpassCoefficients — Allpass polynomial coefficients[-2^(-1/2) 0.5] (default) | N-by-1 | N-by-2

Specify the real allpass polynomial filter coefficients. Specify this property as either an N-by-1 or N-by-2 matrix of N first-order or second-order allpass sections. The default value defines a stable second-order allpass filter with poles and zeros located at $\pm\pi/3$ in the Z plane.

Tunable: Yes**Dependencies**

This property is applicable only when the Structure property is set to Minimum multiplier.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

WDFCoefficients — Wave Digital Filter allpass coefficients[1/2, -2^(1/2)/3] (default) | N-by-1 | N-by-2

Specify the real allpass coefficients in the Wave Digital Filter form. Specify this property as either a N-by-1 or N-by-2 matrix of N first-order or second-order allpass sections. All elements must have absolute values less than or equal to 1. This value is a transformed version of the default value of AllpassCoefficients, computed using `allpass2wdf(AllpassCoefficients)`. These coefficients define the same stable second-order allpass filter as when Structure is set to 'Minimum multiplier'.

Tunable: Yes**Dependencies**

This property is only applicable when the Structure property is set to Wave Digital Filter.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

LatticeCoefficients — Lattice allpass coefficients[-2^(1/2)/3, 1/2] (default) | vector

Specify the real or complex allpass coefficients as lattice reflection coefficients. Specify this property as either a row vector (single-section configuration) or a column vector. This value is a transformed and transposed version of the default value of AllpassCoefficients, computed using `transpose(tf2latc([1 h.AllpassCoefficients]))`. These coefficients define the same stable second-order allpass filter as when Structure is set to 'Lattice'.

Tunable: Yes**Dependencies**

This property is applicable only if the Structure property is set to Lattice.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

TrailingFirstOrderSection — Indicate if last section is first order`false (default) | true`

Indicate if last section is first order or second order. When you set `TrailingFirstOrderSection` to `true`, the last section is considered to be first-order, and the second element of the last row of the N -by-2 matrix is ignored. When you set `TrailingFirstOrderSection` to `false`, the last section is considered to be second-order.

Usage**Syntax**`y = Allpass(x)`**Description**

`y = Allpass(x)` filters the input signal `x` using an allpass filter to produce the output `y`. Each column of `x` is filtered independently as a separate channel over time.

Input Arguments**x — Data input**`vector | matrix`

Data input, specified as a vector or a matrix. This object also accepts variable-size inputs. Once the object is locked, you can change the size of each input channel, but you cannot change the number of channels.

Data Types: `single` | `double`

Output Arguments**y — Filtered output**`vector | matrix`

Filtered output, returned as a vector or a matrix. The size, data type, and complexity of the output signal matches that of the input signal.

Data Types: `double` | `single`

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

`release(obj)`**Specific to `dsp.AllpassFilter`**

<code>freqz</code>	Frequency response of discrete-time filter System object
<code>fvtool</code>	Visualize frequency response of DSP filters
<code>impz</code>	Impulse response of discrete-time filter System object
<code>info</code>	Information about filter System object

coeffs Returns the filter System object coefficients in a structure
 cost Estimate cost of implementing filter System object
 grpdelay Group delay response of discrete-time filter System object

Common to All System Objects

step Run System object algorithm
 release Release resources and allow changes to System object property values and input characteristics
 reset Reset internal states of System object

Examples

Lowpass Filtering using Two Allpass Filters

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, `myObject(x)` becomes `step(myObject,x)`.

Construct the Allpass Filters

```

Fs = 48000;    % in Hz
FL = 1024;
APF1 = dsp.AllpassFilter('AllpassCoefficients',...
    [-0.710525516540603  0.208818210000029]);
APF2 = dsp.AllpassFilter('AllpassCoefficients',...
    [-0.940456403667957  0.6;...
    -0.324919696232907  0],...
    'TrailingFirstOrderSection',true);
  
```

    AP(db(A));
end
  
```

Algorithms

The transfer function of an allpass filter is given by

$$H(z) = \frac{c(n) + c(n-1)z^{-1} + \dots + z^{-n}}{1 + c(1)z^{-1} + \dots + c(n)z^{-n}}.$$

c is allpass polynomial coefficients vector. The order, n , of the transfer function is the length of vector c .

In the minimum multiplier form and wave digital form, the allpass filter is implemented as a cascade of either second-order (biquad) sections or first-order sections. When the coefficients are specified as an N -by-2 matrix, each row of the matrix specifies the coefficients of a second-order filter. The last element of the last row can be ignored based on the trailing first-order setting. When the coefficients are specified as an N -by-1 matrix, each element in the matrix specifies the coefficient of a first-order filter. The cascade of all the filter sections forms the allpass filter.

In the lattice form, the coefficients are specified as a vector.

These structures are computationally more economical and structurally more stable compared to the generic IIR filters, such as `df1`, `df1t`, `df2`, `df2t`. For all structures, the allpass filter can be a single-section or a multiple-section (cascaded) filter. The different sections can have different orders, but they are all implemented according to the same structure.

Minimum Multiplier

This structure realizes the allpass filter with the minimum number of required multipliers, equal to the order n . It also uses $2n$ delay units and $2n$ adders. The multipliers use the specified coefficients, which are equal to the polynomial vector c in the allpass transfer function. In this second-order section of the minimum multiplier structure, the coefficients vector, c , is equal to $[0.1 \ -0.7]$.

Wave Digital Filter

This structure uses n multipliers, but only n delay units, at the expense of requiring $3n$ adders. To use this structure, specify the coefficients in wave digital filter (WDF) form. Obtain the WDF equivalent of the conventional allpass coefficients using `allpass2wdf(allpass_coefficients)`. To convert WDF coefficients into the equivalent allpass polynomial form, use `wdf2allpass(WDF_coefficients)`. In this second-order section of the WDF structure, the coefficients vector w is equal to `allpass2wdf([0.1 -0.7])`.

Lattice

This lattice structure uses $2n$ multipliers, n delay units, and $2n$ adders. To use this structure, specify the coefficients as a vector.

You can obtain the lattice equivalent of the conventional allpass coefficients using `transpose(tf2latc(1, [1 allpass_coefficients]))`. In the following second-order section of the lattice structure, the coefficients vector is computed using `transpose(tf2latc(1, [1 0.1 -0.7]))`. Use these coefficients for a filter that is functionally equivalent to the minimum multiplier structure with coefficients $[0.1 \ -0.7]$.

Compatibility Considerations

Cell Array Support for dsp.AllpassFilter System object is removed

Errors starting in R2018b

The following properties of dsp.AllpassFilter System object have been removed in R2018b:

- LatticeCoefficients
- AllpassCoefficients
- WDFCoefficients

Use an N -by-1 or N -by-2 numeric array instead.

Update Code

This table shows typical usage of the System object and explains how to update your existing code.

If your code has this form:	Use this code instead:
<code>allpass = dsp.AllpassFilter; allpass.AllpassCoefficients = {0.5 0.7}</code>	<code>allpass = dsp.AllpassFilter; allpass.AllpassCoefficients = [0.5 0.7]</code>
<code>allpass = dsp.AllpassFilter('Structure', 'Lattice'); allpass.LatticeCoefficients = {-0.4714 0.5000}</code>	<code>allpass = dsp.AllpassFilter('Structure', 'Lattice'); allpass.LatticeCoefficients = [-0.4714 0.5000]</code>
<code>allpass = dsp.AllpassFilter('Structure', 'Wave Digital'); allpass.LatticeCoefficients = {0.5000 -0.4714}</code>	<code>allpass = dsp.AllpassFilter('Structure', 'Wave Digital'); allpass.LatticeCoefficients = [0.5000 -0.4714]</code>

dsp.AllpoleFilter

Package: dsp

IIR Filter with no zeros

Description

The `dsp.AllpoleFilter` object filters each channel of the input using allpole filter implementations.

To filter each channel of the input:

- 1 Create the `dsp.AllpoleFilter` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

Creation

Syntax

```
allpole = dsp.AllpoleFilter
allpole = dsp.AllpoleFilter(Name,Value)
```

Description

`allpole = dsp.AllpoleFilter` returns an allpole filter System object, `allpole`, which independently filters each channel of the input over successive calls to the algorithm. This System object uses a specified allpole filter implementation.

`allpole = dsp.AllpoleFilter(Name,Value)` returns an allpole filter System object, `allpole`, with each property set to the specified value.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see [System Design in MATLAB Using System Objects](#).

Structure — Filter structure

Direct form (default) | Direct form transposed | Lattice AR

Specify the filter structure as one of | `Direct form` | `Direct form transposed` | `Lattice AR`. Analysis methods are not supported for fixed-point processing if the structure is `Direct form` or `Direct form transposed`. This property is *nontunable*.

Denominator — Filter denominator coefficients

[1 0.1] (default) | row vector

Specify the denominator coefficients as a numeric row vector.

Tunable: Yes**Dependencies**

This property is applicable when the Structure property is set to one of Direct form | Direct form transposed.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

ReflectionCoefficients — Lattice filter coefficients

[0.2 0.4] (default) | row vector

Specify the lattice filter coefficients as a numeric row vector.

Tunable: Yes**Dependencies**

This property is applicable when the Structure property is set to Lattice AR.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

InitialConditions — Initial conditions for the filter states

0 (default) | scalar | vector | matrix

Specify the initial conditions of the filter states.

You can specify the initial conditions as a scalar, vector, or matrix. If you specify a scalar value, this System object initializes all delay elements in the filter to that value. You can also specify a vector whose length equals the number of delay elements in the filter. When you do so, each vector element specifies a unique initial condition for the corresponding delay element. The object applies the same vector of initial conditions to each channel of the input signal.

You can also specify a matrix with the same number of rows as the number of delay elements in the filter and one column for each channel of the input signal. In this case, each element specifies a unique initial condition for the corresponding delay element in the corresponding channel.

Tunable: Yes

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

CoefficientsDataType — Denominator coefficients word- and fraction-length designations

Same word length as input (default) | Custom

Specify the denominator coefficients fixed-point data type as one of Same word length as input | Custom. This property is nontunable.

ReflectionCoefficientsDataType — Reflection coefficients word- and fraction-length designations

Same word length as input (default) | Custom

Specify the reflection coefficients fixed-point data type as one of Same word length as input | Custom. This property is nontunable.

Fixed-Point Properties

ProductDataType — Product word- and fraction-length designations

Full precision (default) | Same as input | Custom

Specify the product fixed-point data type as one of | Full precision | Same as input | Custom |. This property is nontunable.

AccumulatorDataType — Accumulator word- and fraction-length designations

Full precision (default) | Same as input | Same as product | Custom

Specify the accumulator fixed-point data type to one of | Full precision | Same as input | Same as product | Custom |. This property is nontunable.

OutputDataType — Output word- and fraction-length designations

Same as input (default) | Same as accumulator | Custom

Specify the output fixed-point data type as one of | Same as accumulator | Same as input | Custom |. This property is nontunable.

StateDataType — State word- and fraction-length designations

Same as accumulator (default) | Same as input | Custom

Specify the state fixed-point data type as one of | Same as input | Same as accumulator | Custom. This property is nontunable.

CustomCoefficientsDataType — Custom denominator word- and fraction-lengths

numerictype ([], 16, 15) (default) | numerictype

Specify the denominator coefficients fixed-point type as an autosigned numerictype (Fixed-Point Designer) object. This property is nontunable.

Dependencies

This property is applicable when the CoefficientsDataType property is Custom.

CustomReflectionCoefficientsDataType — Custom reflection coefficients word- and fraction-lengths

numerictype ([], 16, 15) (default) | numerictype

Specify the denominator coefficients fixed-point type as an autosigned numerictype (Fixed-Point Designer) object. This property is nontunable.

Dependencies

This property is applicable when the ReflectionCoefficientsDataType property is Custom.

CustomProductDataType — Custom Product word- and fraction-lengths

numerictype ([], 32, 30) (default) | numerictype

Specify the product fixed-point type as an autosigned scaled numerictype object. This property is nontunable.

Dependencies

This property applies when you set the ProductDataType property to Custom.

CustomAccumulatorDataType — Custom accumulator word- and fraction-lengths`numericType([],32,30)` (default) | `numericType`

Specify the accumulator fixed-point type as an autosigned scaled `numericType` object. This property is nontunable.

Dependencies

This property applies when you set the `AccumulatorDataType` property to `Custom`.

CustomStateDataType — Custom state word- and fraction-lengths`numericType([],16,15)` (default) | `numericType`

Specify the state fixed-point type as an autosigned scaled `numericType` object. This property is nontunable.

Dependencies

This property applies when you set the `StateDataType` property to `Custom`.

CustomOutputDataType — Custom output word- and fraction-lengths`numericType([],16,15)` (default) | `numericType`

Specify the output fixed-point type as an autosigned scaled `numericType` object. This property is nontunable.

Dependencies

This property applies when you set the `OutputDataType` property to `Custom`.

Usage**Syntax**`y = allpole(x)`**Description**

`y = allpole(x)` filters the real or complex input signal `x` using an allpole filter to produce the output `y`.

Input Arguments**x — Data input**`vector` | `matrix`

Data input, specified as a vector or a matrix. This object also accepts variable-size inputs. Once the object is locked, you can change the size of each input channel, but you cannot change the number of channels.

When the input data is of a fixed-point type, it must be signed. The allpole filter object operates on each channel of the input signal independently over successive calls to the algorithm.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fi`

Output Arguments

y — Filtered output

vector | matrix

Filtered output, returned as a vector or a matrix. The size, data type, and complexity of the output signal matches that of the input signal.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fi`

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Specific to dsp.AllpoleFilter

<code>freqz</code>	Frequency response of discrete-time filter System object
<code>fvtool</code>	Visualize frequency response of DSP filters
<code>impz</code>	Impulse response of discrete-time filter System object
<code>info</code>	Information about filter System object
<code>coeffs</code>	Returns the filter System object coefficients in a structure
<code>cost</code>	Estimate cost of implementing filter System object
<code>grpdelay</code>	Group delay response of discrete-time filter System object
<code>phasez</code>	Phase response of discrete-time filter System object (unwrapped)

Common to All System Objects

<code>step</code>	Run System object algorithm
<code>release</code>	Release resources and allow changes to System object property values and input characteristics
<code>reset</code>	Reset internal states of System object

Examples

Lowpass filtering a waveform with two frequencies

Use an Allpole filter to apply a lowpass filter to a waveform with two sinusoidal frequencies.

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, `myObject(x)` becomes `step(myObject,x)`.

```
t = (0:1000)./8e3;
xin = sin(2*pi*1e3*t)+sin(2*pi*3e3*t);

src = dsp.SignalSource(xin', 4);
sink = dsp.SignalSink;
allpole = dsp.AllpoleFilter;
tt = (-25:25)';
xsinc = 0.4*sinc(0.4*tt);
asinc = lpc(xsinc,51);
allpole.Denominator = asinc;
```

```
sa = dsp.SpectrumAnalyzer('SampleRate',8e3,...  
    'PlotAsTwoSidedSpectrum',false,...  
    'OverlapPercent', 80,'PowerUnits','dBW',...  
    'YLimits', [-150 50]);  
  
while ~isDone(src)  
    input = src();  
    filteredOutput = allpole(input);  
    sink(filteredOutput);  
    sa(filteredOutput)  
end  
  
filteredResult = sink.Buffer;  
fvtool(allpole,'Fs',8000)
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the Allpole Filter block reference page. The object properties correspond to the block parameters.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- Only the Denominator property is tunable for code generation.

Introduced in R2012b

dsp.AnalyticSignal

Package: dsp

Analytic signals of discrete-time inputs

Description

The `dsp.AnalyticSignal` System object computes analytic signals of discrete-time inputs. The real part of the analytic signal in each channel is a replica of the real input in that channel, and the imaginary part is the Hilbert transform of the input. In the frequency domain, the analytic signal doubles the positive frequency content of the original signal while zeroing-out negative frequencies and retaining the DC component. The object computes the Hilbert transform using an equiripple FIR filter.

To compute the analytic signal of a discrete-time input:

- 1 Create the `dsp.AnalyticSignal` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

Creation

Syntax

```
anaSig = dsp.AnalyticSignal
anaSig = dsp.AnalyticSignal(order)
anaSig = dsp.AnalyticSignal(Name,Value)
```

Description

`anaSig = dsp.AnalyticSignal` returns an analytic signal object, `anaSig`, that computes the complex analytic signal corresponding to each channel of a real M -by- N input matrix.

`anaSig = dsp.AnalyticSignal(order)` returns an analytic signal object, `anaSig`, with the "FilterOrder" on page 4-0 property set to `order`.

`anaSig = dsp.AnalyticSignal(Name,Value)` returns an analytic signal object, `anaSig`, with each specified property set to the specified value.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see [System Design in MATLAB Using System Objects](#).

FilterOrder — Filter order used to compute Hilbert transform

100 (default) | scalar integer

Order of the equiripple FIR filter used in computing the Hilbert transform, specified as an even integer scalar greater than 3.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

Usage**Syntax**

```
y = anaSig(x)
```

Description

`y = anaSig(x)` computes the analytic signal, y , of the M -by- N input matrix x , according to the equation

$$\mathbf{Y} = \mathbf{X} + jH\{\mathbf{X}\}$$

where j is the imaginary unit and $H\{\mathbf{X}\}$ denotes the Hilbert transform.

Each of the N columns in x contains M sequential time samples from an independent channel. The method computes the analytic signal for each channel.

Input Arguments**x** — Data input

vector | matrix

Data input, specified as a vector or a matrix.

Data Types: single | double

Output Arguments**y** — Analytic signal output

vector | matrix

Analytic signal output, returned as a vector or a matrix.

Data Types: single | double

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Common to All System Objects

step Run System object algorithm

release Release resources and allow changes to System object property values and input characteristics
reset Reset internal states of System object

Examples

Compute The Analytic Signal

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, `myObject(x)` becomes `step(myObject,x)`.

Compute the analytic signal of a sinusoidal input.

```
t = (-1:0.01:1)';  
x = sin(4*pi*t);  
anaSig = dsp.AnalyticSignal(200);  
y = anaSig(x);
```

View the analytic signal.

```
subplot(2,1,1);  
plot(t, x)  
title('Original Signal');  
subplot(2,1,2), plot(t, [real(y) imag(y)]);  
title('Analytic signal of the input')  
legend('Real signal', 'Imaginary signal', ...  
       'Location', 'best');
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the Analytic Signal block reference page. The object properties correspond to the block parameters.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

See “System Objects in MATLAB Code Generation” (MATLAB Coder).

This object also supports SIMD code generation using Intel AVX2 technology under these conditions:

- Input signal is real-valued.
- Input signal has a data type of `single` or `double`.

The SIMD technology significantly improves the performance of the generated code.

Objects

`dsp.FFT` | `dsp.IFFT`

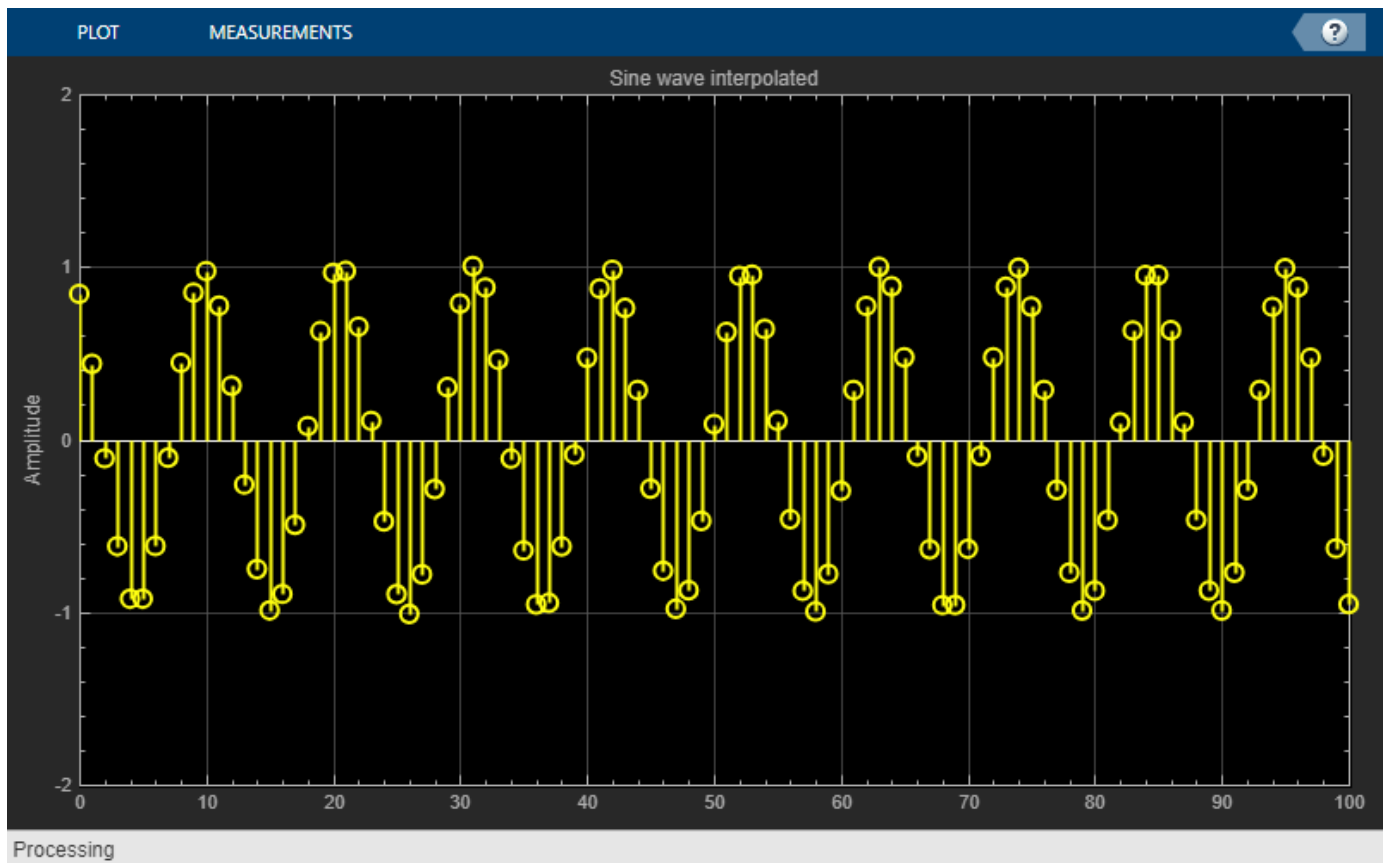

Introduced in R2012a

dsp.ArrayPlot

Display vectors or arrays

Description

Display vectors or arrays where the data is uniformly spaced along the x-axis.

Creation

Syntax

```
scope = dsp.ArrayPlot  
scope = dsp.ArrayPlot(Name,Value)
```

Description

`scope = dsp.ArrayPlot` creates an Array Plot object, `scope`.

`scope = dsp.ArrayPlot(Name, Value)` sets properties using one or more name-value pairs. Enclose each property name in quotes. For example, `scope = dsp.ArrayPlot("NumInputPorts", 3)`

Properties

Most properties can be changed from the `dsp.ArrayPlot` UI.

Plot Configuration

NumInputPorts — Number of input ports

1 (default) | integer between [1, 96]

Number of input ports, specified as a positive integer. Each signal coming through a separate input becomes a separate channel in the scope. You must invoke the scope with the same number of inputs as the value of this property.

XDataMode — Source of the x-data spacing

"Sample increment and X-offset" (default) | "Custom"

Specify whether to use the `SampleIncrement` and `XOffset` property values to determine spacing, or specify your own custom spacing. If you specify "Custom", you also must specify the `CustomXData` property values.

You can set this property only when creating the object.

Scope Window Use

Open the **Plot** tab, click **Settings**, and set **X-Data Mode**.

Data Types: char | string

CustomXData — X-data values

empty vector (default) | vector

Specify the desired x-data values as a row or column vector of length equal to the frame length of the individual inputs. If you use the default (empty vector) value, the x-data is uniformly spaced and set to $(0:L-1)$, where L is the frame length.

You can set this property only when creating the object.

Example: `scope = dsp.ArrayPlot("XDataMode", "Custom", "CustomXData", logspace(0, log10(44100/2), 1024))`

Scope Window Use

Open the **Plot** tab, click **Settings**, and set **X-Data Mode** to **Custom** and specify **Custom X-Data**.

Dependency

To use this property, set `XDataMode` to "Custom".

SampleIncrement — Sample increment of input

1 (default) | finite numeric scalar

Specify the spacing between samples along the x-axis as a finite numeric scalar. The input signal is only y-axis data. x-axis data is set automatically based on the `XOffset` and `SampleIncrement` properties.

Example: When `XOffset` is 0 and `SampleIncrement` is 1, the x-axis values are set to 0, 1, 2, 3, 4, ...

Example: When `XOffset` is -1 and `SampleIncrement` is 0.25, the x-axis values are set to -1, -0.75, -0.5, -0.25, 0, ...

Scope Window Use

Open the **Plot** tab, click **Settings**, and set **Sample Increment**.

Dependency

To use this property, set `XDataMode` to 'Sample increment and X-offset'.

XOffset — Display offset of x-axis

0 (default) | scalar

Display offset of x-axis, specified as a numeric scalar. x-axis data is set automatically based on both the `SampleIncrement` and `XOffset` values. The x-offset represents the first value on the x-axis.

Example: When `XOffset` is 0 and `SampleIncrement` is 1, the x-axis values are set to 0, 1, 2, 3, 4, ...

Example: When `XOffset` is -1 and `SampleIncrement` is 0.25, the x-axis values are set to -1, -0.75, -0.5, -0.25, 0, ...

Scope Window Use

Open the **Plot** tab, click **Settings**, and set **X-Offset**.

Dependency

To use this property, set `XDataMode` to 'Sample increment and X-offset'.

XScale — Scale of x-axis

"Linear" (default) | "Log"

Specify whether the scale of the x-axis is "Linear" or "Log". If `XOffset` is a negative value, you cannot set this property to "Log".

Scope Window Use

Open the **Plot** tab, click **Settings**, and set **XScale**.

Data Types: char | string

YScale — Scale of y-axis

"Linear" (default) | "Log"

Specify whether the scale of the y-axis is "Linear" or "Log".

Scope Window Use

Open the **Plot** tab, click **Settings**, and set **YScale**.

Data Types: char | string

PlotType — Control type of plot

"Stem" (default) | "Line" | "Stairs"

Specify the type of plot to use for all the input signals displayed in the scope window:

- "Stem" - The scope displays the input signal as circles with vertical lines extending down to the x-axis at each of the sampled values.
- "Line" - The scope displays the input signal as lines connecting each of the sampled values.
- "Stairs" - The scope displays the input signal as a stair-step graph. A stair-step graph is made up of only horizontal lines and vertical lines. Each horizontal line represents the signal value for a discrete sample period and is connected to two vertical lines. Each vertical line represents a change in values occurring at a sample. Stair-step graphs are useful for drawing time history graphs of digitally sampled data.

Scope Window Use

Open the **Settings** and set **Plot Type**.

AxesScaling — Axes scaling mode

"OnceAtStop" (default) | "Auto" | "Manual" | "Updates"

Specify when the scope scales the axes. Valid values are:

- "Auto" — The scope scales the axes as needed to fit the data, both during and after simulation.
- "Manual" — The scope does not scale the axes automatically.
- "OnceAtStop" — The scope scales the axes when the simulation stops.
- "Updates" — The scope scales the axes once and only once after 10 updates.

You can set this property only when creating the object.

Scope Window Use

Hover over the array plot to see the zoom  , pan  , and autoscale  buttons. You can also zoom and pan using your mouse.

Data Types: char | string

Visualization**Name — Window name**

'Array Plot' (default) | character vector | string scalar

Specify the name of the scope. This name appears as the title of the scope's figure window. To specify a title of a scope plot, use the **Title** property.

Data Types: char | string

Position — Scope window position and size in pixels

screen center (default) | [left bottom width height]

Specify, in pixels, the size and location of the scope window as a four-element vector of the form [left bottom width height]. By default, the scope window appears in the center of your screen with a width of 800 pixels and height of 450 pixels. The default values for this property may change depending on your screen resolution.

MaximizeAxes — Maximize axes control`"Auto" (default) | "On" | "Off"`

Specify whether to display the scope in maximized-axes mode. In this mode, the axes are expanded to fit into the entire display. To conserve space, labels do not appear in each display. Instead, tick-mark values appear on top of the plotted data. You can select one of the following options:

- "Auto" — The axes appear maximized in all displays only if the `Title` and `YLabel` properties are empty for every display. If you enter any value in any display for either of these properties, the axes are not maximized.
- "On" — The axes appear maximized in all displays. Any values entered into the `Title` and `YLabel` properties are hidden.
- "Off" — None of the axes appear maximized.

Scope Window Use

Hover over the array plot to see the maximize axes button .

Data Types: `char` | `string`

Title — Display title`'' (default) | character vector | string scalar`

Specify the display title as a character vector or string.

Scope Window Use

Open the **Plot** tab, click **Settings**, and set **Title**.

Data Types: `char` | `string`

ShowLegend — Show legend`false (default) | true`

To show a legend with the input names, set this property to `true`.

From the legend, you can control which signals are visible. This control is equivalent to changing the visibility in the **Style** dialog box. In the scope legend, click a signal name to hide the signal in the scope. To show the signal, click the signal name again. To show only one signal, right-click the signal name. To show all signals, press **Esc**.

Note The legend only shows the first 20 signals. Any additional signals cannot be viewed or controlled from the legend.

Scope Window Use

On the **Plot** tab, click **Legend**.

Data Types: `logical`

ChannelNames — Channel names`empty cell (default) | cell array of character vectors`

Specify the input channel names as a cell array of character vectors. The names appear in the legend, **Settings**, and **Measurements** panels. If you do not specify names, the channels are labeled as Channel 1, Channel 2, etc.

Dependency

To see channel names, set `ShowLegend` to `true`.

Data Types: `char`

ShowGrid — Display grid

`true` (default) | `false`

Set this property to `true` to show grid lines on the plot.

Scope Window Use

Open the **Plot** tab, click **Settings**, and select **Grid**.

PlotAsMagnitudePhase — Plot signal as magnitude and phase

`false` (default) | `true`

- `true` - The scope plots the magnitude and phase of the input signal on two separate axes within the same active display.
- `false` - The scope plots the real and imaginary parts of the input signal on two separate axes within the same active display.

This property is useful for complex-valued input signals. Turning on this property affects the phase for real-valued input signals. When the amplitude of the input signal is nonnegative, the phase is 0 degrees. When the amplitude of the input signal is negative, the phase is 180 degrees.

Scope Window Use

On the **Plot** tab, select the **Magnitude Phase** button.

XLabel — x-axis label

`""` (default) | character vector | string scalar

Specify the text for the scope to display below the x-axis.

Scope Window Use

Open the **Plot** tab, click **Settings**, and set **XLabel**.

Data Types: `char` | `string`

YLabel — y-axis label

"Amplitude" (default) | character vector | string scalar

Specify the text for the scope to display to the left of the y-axis.

Dependencies

This property applies only when `PlotAsMagnitudePhase` is `false`. When `PlotAsMagnitudePhase` is `true`, the two y-axis labels are read-only values "Magnitude" and "Phase", for the magnitude plot and the phase plot, respectively.

Scope Window Use

Open the **Plot** tab, click **Settings**, and set **YLabel**.

Data Types: `char` | `string`

YLimits — y-axis limits

`[-10,10]` (default) | `[ymin, ymax]`

Specify the y-axis limits as a two-element numeric vector, `[ymin, ymax]`.

If `PlotAsMagnitudePhase` is `false`, the default is `[-10,10]`. If `PlotAsMagnitudePhase` is `true`, the default is `[0,10]`.

Dependencies

When `PlotAsMagnitudePhase` is `true`, this property specifies the y-axis limits of only the magnitude plot. The y-axis limits of the phase plot are always `[-180,180]`.

Scope Window Use

Open the **Plot** tab, click **Settings**, and set **Y-Axis Limits** as a two-element numeric vector.

Usage**Syntax**

```
scope(signal)
scope(signal1,signal2,...,signalN)
```

Description

`scope(signal)` displays the signal in the Array Plot.

`scope(signal1,signal2,...,signalN)` displays multiple signals in the Array Plot. The signals can have a different number of channels and different frame lengths.

Input Arguments**signal — Input signal or signals to visualize**

`scalar` | `vector` | `matrix`

Specify one or more input signals to visualize in the `dsp.ArrayPlot`. Signals can have a different number of channels and different frame lengths.

Example: `scope(signal1,signal2)`

UI Customization

To customize the style of signals on the array plot, open the **Settings** and use the bottom row of options to select a signal and modify the style, width, color, and marker type.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fi`

Object Functions

To use an object function, specify the object as the first input argument.

generateScript	Generate MATLAB script to create scope with current settings
hide	Hide scope window
show	Display scope window
isVisible	Determine visibility of scope
step	Run System object algorithm
release	Release resources and allow changes to System object property values and input characteristics
reset	Reset internal states of System object

If you want to restart the simulation from the beginning, call `reset` to clear the scope window displays. Do not call `reset` after calling `release`.

Examples

Plot a Gaussian Distribution

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the object with the equivalent `step` syntax. For example, `myObject(x)` becomes `step(myObject,x)`.

Create a new Array Plot object.

```
scope = dsp.ArrayPlot;
```

Configure the properties of the Array Plot object for a Gaussian distribution.

```
scope.YLimits = [0 1];
scope.XOffset = -2.5;
scope.SampleIncrement = 0.1;
scope.Title = 'Gaussian distribution';
scope.XLabel = 'X';
scope.YLabel = 'f(X)';
```

Call the Array Plot object to plot a Gaussian distribution.

```
scope(exp(-(-2.5:.1:2.5).*(-2.5:.1:2.5)))
```

Plot Changing Filter Weights

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the object with the equivalent `step` syntax. For example, `myObject(x)` becomes `step(myObject,x)`.

View least mean squares (LMS) adaptive filter weights on the Array Plot figure. Watch the filter weights change as they adapt to filter a noisy input signal.

Create an LMS adaptive filter System object.

```
lmsFilter = dsp.LMSFilter(40,'Method',...
    'Normalized LMS',...
    'StepSize',0.002);
```

Create and configure a `dsp.AudioFileReader` System object to read the input signal from the specified audio file.

```
signalSource = dsp.AudioFileReader('dspafx_8000.wav',...
    'SamplesPerFrame',40, ...
    'PlayCount',Inf,...
    'OutputDataType','double');
```

Create and configure a `dsp.FIRFilter` System object to filter random white noise, creating colored noise.

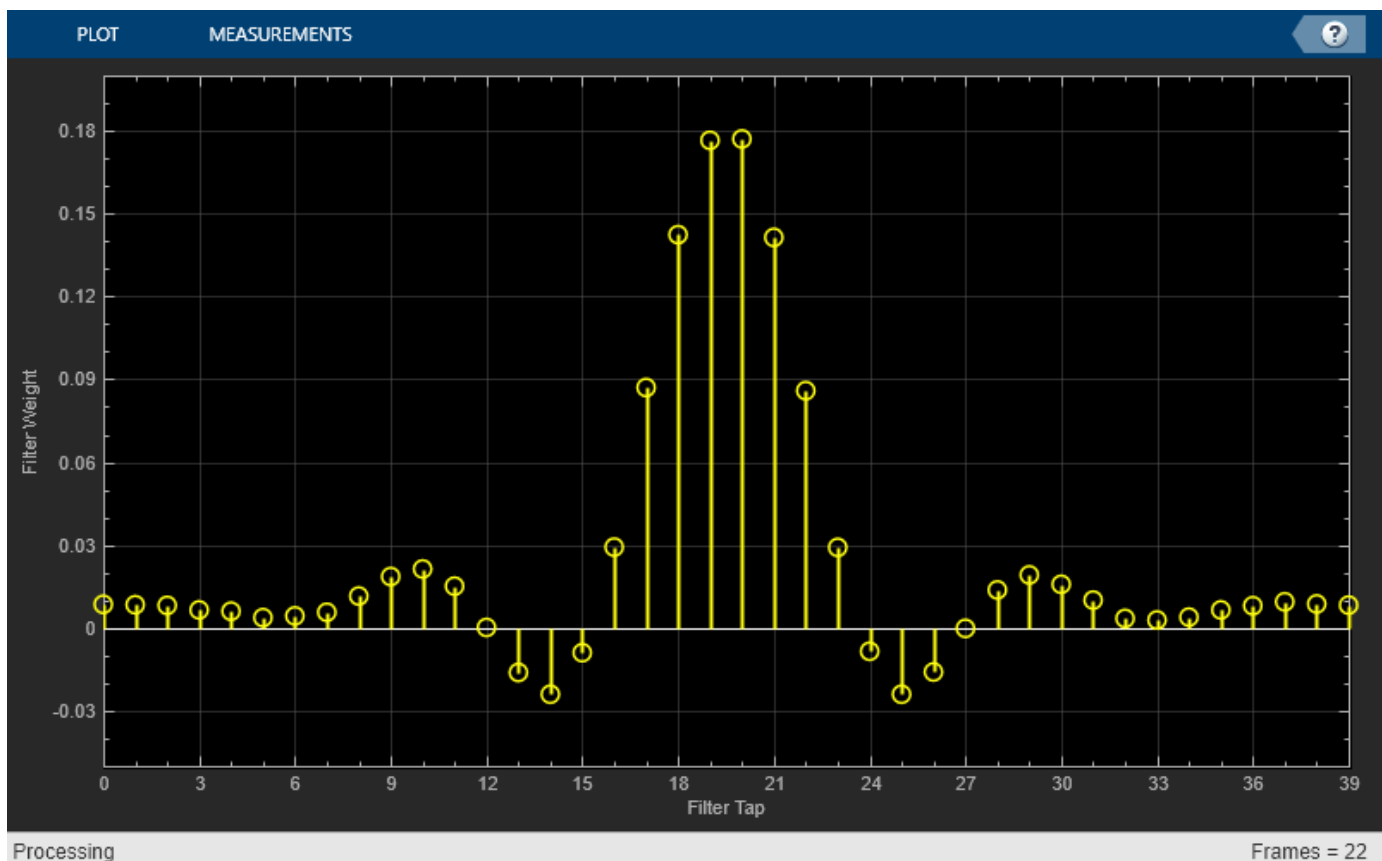

```
firFilter = dsp.FIRFilter('Numerator',fir1(39,0.25));
```

Create and configure an Array Plot System object to display the adaptive filter weights.

```
scope = dsp.ArrayPlot('XLabel','Filter Tap', ...
    'YLabel','Filter Weight', ...
    'YLimits',[-0.05 0.2]');
```

Plot the LMS filter weights as they adapt to a desired signal. Read from the audio file, produce random data, and filter the random data. Update the filter weights and plot the filter weights.

```
numplays = 0;
while numplays < 3
    [y, eof] = signalSource();
    noise = rand(40,1);
    noisefilt = firFilter(noise);
    desired = y + noisefilt;
    [~, ~, wts] = lmsFilter(noise,desired);
    scope(wts);
    numplays = numplays + eof;
end
```

Tips

- To close the Array Plot window and clear its associated data, use the MATLAB `clear` function.

- To hide or show the Array Plot window, use the `hide` and `show` functions.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- Supports MEX code generation by treating the calls to the object as extrinsic. Does not support code generation for standalone applications.
- See “System Objects in MATLAB Code Generation” (MATLAB Coder).

dsp.ArrayVectorAdder

Package: dsp

(To be removed) Add array to vector along specified dimension

Note dsp.ArrayVectorAdder will be removed in a future release. Use the + operator instead. For more information, see “Compatibility Considerations”.

Description

The ArrayVectorAdder object adds an N-D array to a vector along a specified dimension. The length of the vector must equal the size of the N-D array along the specified dimension.

To add an N-D array to a vector along a specified dimension:

- 1 Define and set up your array-vector addition object. See “Construction” on page 4-61.
- 2 Call `step` to add the N-D array according to the properties of dsp.ArrayVectorAdder. The behavior of `step` is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`ava = dsp.ArrayVectorAdder` returns an array-vector addition object, `ava`, that adds a vector to an N-D array along the first dimension.

`ava = dsp.ArrayVectorAdder('PropertyName',PropertyValue, ...)` returns an array-vector addition object, `ava`, with each property set to the specified value.

Properties

Dimension

Dimension along which to add vector elements to input

Specify the dimension along which to add the input array to the elements of the vector as a positive integer. The length of the vector must match the size of the N-D array along the specified dimension. The default is 1.

VectorSource

Source of vector

Specify the source of the vector values as |Input port | Property |. The default is Input port.

Vector

Vector values

Specify the vector values. This property applies only when you set the `VectorSource` property to `Property`. The default is `[0.5 0.25]`. This property is tunable.

Fixed-Point Properties**FullPrecisionOverride**

Full precision override for fixed-point arithmetic

Specify whether to use full precision rules. If you set `FullPrecisionOverride` to `true`, which is the default, the object computes all internal arithmetic and output data types using full precision rules. These rules provide the most accurate fixed-point numerics. It also turns off the display of other fixed-point properties because they do not apply individually. These rules guarantee that no quantization occurs within the object. Bits are added, as needed, to ensure that no roundoff or overflow occurs. If you set `FullPrecisionOverride` to `false`, fixed-point data types are controlled through individual fixed-point property settings. For more information, see “Full Precision for Fixed-Point System Objects”.

RoundingMethod

Rounding method for fixed-point operations

Specify the rounding method as `| Ceiling | Convergent | Floor | Nearest | Round | Simplest | Zero |`. The default is `Floor`. This property applies only if the object is not in full precision mode.

OverflowAction

Overflow action for fixed-point operations

Specify the overflow action as `| Wrap | Saturate |`. The default is `Wrap`. This property applies only if the object is not in full precision mode.

VectorDataType

Vector word and fraction lengths

Specify the vector fixed-point data type as `| Same word length as input | Custom |`. This property applies when you set the `VectorSource` property to `Property`. The default is `Same word length as input`.

CustomVectorDataType

Vector word and fraction lengths

Specify the vector fixed-point type as a `numericType` object with a `Signedness` of `Auto`. This property applies when you set the `VectorSource` property to `Property` and the `VectorDataType` property to `Custom`. The default is `numericType([], 16, 15)`.

AccumulatorDataType

Accumulator word and fraction lengths

Specify the accumulator fixed-point data type as | Full precision | Same as first input | Custom |. The default is Full precision.

CustomAccumulatorDataType

Accumulator word and fraction lengths

Specify the accumulator fixed-point type as a scaled `numericType` object with a `Signedness` of `Auto`. This property applies only when the `AccumulatorDataType` property is `Custom`. The default is `numericType([], 32, 30)`.

OutputDataType

Output word and fraction lengths

Specify the output fixed-point data type as | Same as accumulator | Same as first input | Custom |.

CustomOutputDataType

Output word and fraction lengths

Specify the output fixed-point type as a scaled `numericType` object with a `Signedness` of `Auto`. This property applies only when the “`OutputDataType`” on page 4-0 property is `Custom`. The default is `numericType([], 16, 15)`.

Methods

`step` Add vector to N-D array

Common to All System Objects	
<code>release</code>	Allow System object property value changes

Examples

Add a Vector To a Matrix

Note If you are using R2016a or an earlier release, replace each call to the object with the equivalent `step` syntax. For example, `obj(x)` becomes `step(obj, x)`.

Add a 2-by-1 vector to a 2-by-2 matrix along the first dimension of the array.

```
ava = dsp.ArrayVectorAdder;
a = ones(2);
```

```
x = [1 2]';
y = ava(a, x);
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the Array-Vector Add block reference page. The object properties correspond to the block parameters, except:

The array-vector addition object does not have **Minimum** or **Maximum** options for data output.

Compatibility Considerations

dsp.ArrayVectorAdder System object will be removed

Warns starting in R2021b

`dsp.ArrayVectorAdder` System object will be removed in a future release. Use the `+` operator instead.

Update Code

This table shows how the System object is typically used and explains how to update existing code to use the `+` operator.

Discouraged Usage	Recommended Replacement
<pre>ava = dsp.ArrayVectorAdder; a = ones(2); x = [1 2]'; y = ava(a, x) y = 2x2 2 2 3 3</pre>	<pre>y = a + x y = 2x2 2 2 3 3</pre>
<p>If you are using a release prior to R2016b, replace <code>ava(a, x)</code> with <code>step(ava, a, x)</code>.</p>	

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

See “System Objects in MATLAB Code Generation” (MATLAB Coder).

Introduced in R2012a

step

System object: dsp.ArrayVectorAdder

Package: dsp

Add vector to N-D array

Syntax

$Y = \text{step}(\text{ava}, A)$

$Y = \text{step}(\text{ava}, A, V)$

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, $y = \text{step}(\text{obj}, x)$ and $y = \text{obj}(x)$ perform equivalent operations.

$Y = \text{step}(\text{ava}, A)$ returns Y , the result of adding the input array A to the elements of the vector specified in the `Vector` property along the specified dimension when the `VectorSource` property is `Property`. The length of the vector specified in the `Vector` property must equal the length of the specified dimension of A .

$Y = \text{step}(\text{ava}, A, V)$ returns Y , the result of adding the input array A to the elements of the input vector V along the specified dimension when the `VectorSource` property is `Input port`. The length of the input V must equal the length of the specified dimension of A .

Note `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

dsp.ArrayVectorDivider

Package: dsp

(To be removed) Divide array by vector along specified dimension

Note dsp.ArrayVectorDivider will be removed in a future release. Use the ./ operator instead. For more information, see “Compatibility Considerations”.

Description

The ArrayVectorDivider object divides an array by a vector along a specified dimension.

To divide an array by a vector along a specified dimension:

- 1 Define and set up your array-vector division object. See “Construction” on page 4-66.
- 2 Call `step` to divide the array according to the properties of `dsp.ArrayVectorDivider`. The behavior of `step` is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`avd = dsp.ArrayVectorDivider` returns an array-vector division object, `avd`, that divides an input array by the elements of a vector along the first dimension of the array.

`avd = dsp.ArrayVectorDivider('PropertyName',PropertyValue,...)` returns an array-vector division object, `avd`, with each property set to the specified value.

Properties

Dimension

Dimension along which to divide input by vector elements

Specify the dimension along which to divide the input array by the elements of a vector as a positive integer. The default is 1.

VectorSource

Source of vector

Specify the source of the vector values as | Input port | Property |. The default is Input port.

Vector

Vector values

Specify the vector values. This property applies when you set the `VectorSource` property to `Property`. The default is `[0.5 0.25]`. This property is tunable.

Fixed-Point Properties

RoundingMethod

Rounding method for fixed-point operations

Specify the rounding method as `| Ceiling | Convergent | Floor | Nearest | Round | Simplest | Zero |`. The default is `Floor`.

OverflowAction

Overflow action for fixed-point operations

Specify the overflow action as `| Wrap | Saturate |`. The default is `Wrap`.

VectorDataType

Vector word and fraction lengths

Specify the vector fixed-point mode as `| Same word length as input | Custom |`. This property applies when you set the `VectorSource` property to `Property`. The default is `Same word length as input`.

CustomVectorDataType

Vector word and fraction lengths

Specify the vector fixed-point data type as a scaled `numericType` object with a `Signedness` of `Auto`. This property applies when you set the `VectorSource` property to `Property` and the `VectorDataType` property to `Custom`. The default is `numericType([], 16, 15)`.

OutputDataType

Output word and fraction lengths

Specify the output fixed-point data type as `| Same as first input | Custom |`. The default is `Same as first input`.

CustomOutputDataType

Output word and fraction lengths

Specify the output fixed-point type as a scaled `numericType` object with a `Signedness` of `Auto`. This property applies when you set the “`OutputDataType`” on page 4-0 property to `Custom`. The default is `numericType([], 16, 15)`.

Methods

`step` Divide array by vector

Common to All System Objects	
release	Allow System object property value changes

Examples

Divide a Matrix By a Vector

Note If you are using R2016a or an earlier release, replace each call to the object with the equivalent step syntax. For example, `obj(x)` becomes `step(obj,x)`.

```
avd = dsp.ArrayVectorDivider;
a = ones(2);
x = [2 3]';
y = avd(a, x)
```

```
y = 2x2
```

```
    0.5000    0.5000
    0.3333    0.3333
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the Array-Vector Divide block reference page. The object properties correspond to the block parameters, except:

The array-vector division object does not have **Minimum** or **Maximum** options for data output.

Compatibility Considerations

dsp.ArrayVectorDivider System object will be removed

Warns starting in R2021b

`dsp.ArrayVectorDivider` System object will be removed in a future release. Use the `./` operator instead.

Update Code

This table shows how the System object is typically used and explains how to update existing code to use the `./` operator.

Discouraged Usage	Recommended Replacement

dsp.ArrayVectorMultiplier

Package: dsp

(To be removed) Multiply array by vector along specified dimension

Note `dsp.ArrayVectorMultiplier` will be removed in a future release. Use the `.*` operator instead. For more information, see “Compatibility Considerations”.

Description

The `ArrayVectorMultiplier` object multiplies an array by a vector along a specified dimension.

To multiply an array by a vector along a specified:

- 1 Define and set up your array-vector multiplication object. See “Construction” on page 4-71.
- 2 Call `step` to multiply the array according to the properties of `dsp.ArrayVectorMultiplier`. The behavior of `step` is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`avm = dsp.ArrayVectorMultiplier` returns an array-vector multiplication object, `avm`, that multiplies an input N-D array by the elements of a vector along the second dimension.

`avm = dsp.ArrayVectorMultiplier('PropertyName',PropertyValue,...)` returns an array-vector multiplication object, `avm`, with each property set to the specified value.

Properties

Dimension

Dimension along which to multiply input by vector elements

Specify the dimension along which to multiply the input array by the elements of vector as a positive integer. The default is 2.

VectorSource

Source of vector

Specify the source of the vector values as one of `Input port` or `Property`. The default is `Input port`.

Vector

Vector to multiply array

Specify the vector by which to multiply the array. This property applies when you set the `VectorSource` property to `Property`. The default is `[0.5 0.25]`. This property is tunable.

Fixed-Point Properties**RoundingMethod**

Rounding method for fixed-point operations

Specify the rounding method as `Ceiling`, `Convergent`, `Floor`, `Nearest`, `Round`, `Simplest`, `Zero`. The default is `floor`.

OverflowAction

Overflow action for fixed-point operations

Specify the overflow action as `Wrap` or `Saturate`. The default is `Wrap`.

VectorDataType

Vector word and fraction lengths

Specify the vector fixed-point data type as `Same word length as input`, `Custom`. This property applies when you set the `VectorSource` property to `Property`. The default is `Same word length as input`.

CustomVectorDataType

Vector word and fraction lengths

Specify the vector fixed-point type as a `numericType` object with a `Signedness` of `Auto`. This property applies when you set the `VectorSource` property to `Property` and the `VectorDataType` property to `Custom`. The default is `numericType([],16,15)`.

ProductDataType

Product word and fraction lengths

Specify the product fixed-point data type as `Full precision`, `Same as first input`, or `Custom`. The default is `Full precision`.

CustomProductDataType

Product word and fraction lengths

Specify the product fixed-point type as a scaled `numericType` object with a `Signedness` of `Auto`. This property applies when you set the `ProductDataType` property to `Custom`. The default is `numericType([],32,30)`.

AccumulatorDataType

Accumulator word and fraction lengths

Specify the accumulator fixed-point data type as `Full precision`, `Same as product`, `Same as first input`, or `Custom`. The default is `Full precision`.

CustomAccumulatorDataType

Accumulator word and fraction lengths

Specify the accumulator fixed-point type as a scaled `numericType` object with a `Signedness` of `Auto`. This property applies when you set the `AccumulatorDataType` property to `Custom`. The default is `numericType([],32,30)`.

OutputDataType

Output word and fraction lengths

Specify the output fixed-point data type as `Same as product`, `Same as first input`, or `Custom`. The default is `Same as product`.

CustomOutputDataType

Output word and fraction lengths

Specify the output fixed-point type as a scaled `numericType` object with a `Signedness` of `Auto`. This property applies when you set the `OutputDataType` property to `Custom`. The default is `numericType([],16,15)`.

Methods

`step` Multiply array by vector

Common to All System Objects	
<code>release</code>	Allow System object property value changes

Examples

Multiply a Matrix by a Vector

Note If you are using R2016a or an earlier release, replace each call to the object with the equivalent `step` syntax. For example, `obj(x)` becomes `step(obj,x)`.

```
avm = dsp.ArrayVectorMultiplier;
a = ones(2);
x = [2 3]';
y = avm(a, x)
```

```
y = 2×2
```

```
    2    3
```

2 3

Algorithms

This object implements the algorithm, inputs, and outputs described on the Array-Vector Multiply block reference page. The object properties correspond to the block parameters, except:

- The array-vector multiplication object does not have **Minimum** or **Maximum** options for data output.

Compatibility Considerations

`dsp.ArrayVectorMultiplier` System object will be removed

Warns starting in R2021b

`dsp.ArrayVectorMultiplier` System object will be removed in a future release. Use the `.*` operator instead.

Update Code

Introduced in R2012a

step

System object: dsp.ArrayVectorMultiplier

Package: dsp

Multiply array by vector

Syntax

$Y = \text{step}(\text{avm}, A, V)$

$Y = \text{step}(\text{avm}, A)$

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, $y = \text{step}(\text{obj}, x)$ and $y = \text{obj}(x)$ perform equivalent operations.

$Y = \text{step}(\text{avm}, A, V)$ returns Y , the result of multiplying the input array A by the elements of input vector V along the specified dimension when the `VectorSource` property is `Input port`. The length of the input V must equal the length of the specified dimension of A .

$Y = \text{step}(\text{avm}, A)$ returns Y , the result of multiplying the input array A by the elements of vector specified in `Vector` property along the specified dimension when the `VectorSource` property is set to `Property`. The length of the vector specified in `Vector` property must equal the length of the specified dimension of A .

Note `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

dsp.ArrayVectorSubtractor

Package: dsp

(To be removed) Subtract vector from array along specified dimension

Note `dsp.ArrayVectorSubtractor` will be removed in a future release. Use the `-` operator instead. For more information, see “Compatibility Considerations”.

Description

The `ArrayVectorSubtractor` object subtracts a vector from an N-D array along a specified dimension.

To subtract a vector from an N-D array along a specified dimension:

- 1 Define and set up your array-vector subtraction object. See “Construction” on page 4-77.
- 2 Call `step` to subtract the vector according to the properties of `dsp.ArrayVectorSubtractor`. The behavior of `step` is specified to each object in the toolbox.

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`avs = dsp.ArrayVectorSubtractor` returns an array-vector subtraction object, `avs`, that subtracts the elements of a vector from an N-D input array along the first dimension.

`avs = dsp.ArrayVectorSubtractor('PropertyName',PropertyValue,...)` returns an array-vector subtraction object, `avs`, with each property set to the specified value.

Properties

Dimension

Dimension along which to subtract vector elements from input

Specify the dimension along which to subtract the elements of the vector from the input array as an integer-valued scalar greater than 0. The default is 1.

VectorSource

Source of vector

Specify the source of the vector values as one of `Input port` or `Property`. The default is `Input port`.

Vector

Vector values

Specify the vector values. This property applies when you set the `VectorSource` property to `Property`. The default is `[0.5 0.25]`. This property is tunable.

Fixed-Point Properties**FullPrecisionOverride**

Full precision override for fixed-point arithmetic

Specify whether to use full precision rules. If you set `FullPrecisionOverride` to `true`, which is the default, the object computes all internal arithmetic and output data types using full precision rules. These rules provide the most accurate fixed-point numerics. It also turns off the display of other fixed-point properties because they do not apply individually. These rules guarantee that no quantization occurs within the object. Bits are added, as needed, to ensure that no roundoff or overflow occurs. If you set `FullPrecisionOverride` to `false`, fixed-point data types are controlled through individual fixed-point property settings. For more information, see “Full Precision for Fixed-Point System Objects”.

RoundingMethod

Rounding method for fixed-point operations

Specify the rounding method as `Ceiling`, `Convergent`, `Floor`, `Nearest`, `Round`, `Simplest`, or `Zero`. This property applies only if the object is not in full precision mode.

OverflowAction

Overflow action for fixed-point operations

Specify the overflow action as one of `Wrap` or `Saturate`. The default is `Wrap`. This property applies only if the object is not in full precision mode.

VectorDataType

Vector word and fraction lengths

Specify the vector fixed-point data type as `Same word length as input` or `Custom`. This property applies when you set the `VectorSource` property to `Property`. The default is `Same word length as input`.

CustomVectorDataType

Vector word and fraction lengths

Specify the vector fixed-point type as a `numericType` object with a `Signedness` of `Auto`. This property applies when you set the `VectorSource` property to `Property` and the `VectorDataType` property to `Custom`. The default is `numericType([], 16, 15)`.

AccumulatorDataType

Accumulator word and fraction lengths

Specify the accumulator fixed-point data type as one of `Full precision`, `Same as first input`, or `Custom`. The default is `Full precision`.

CustomAccumulatorDataType

Accumulator word and fraction lengths

Specify the accumulator fixed-point type as a scaled `numericType` object with a `Signedness` of `Auto`. This property applies when you set the `AccumulatorDataType` property to `Custom`. The default is `numericType([],32,30)`.

OutputDataType

Output word and fraction lengths

Specify the output fixed-point data type as `Same as accumulator`, `Same as first input`, or `Custom`. The default is `Same as accumulator`.

CustomOutputDataType

Output word and fraction lengths

Specify the output fixed-point type as a scaled `numericType` object with a `Signedness` of `Auto`. This property applies when you set the “`OutputDataType`” on page 4-0 property to `Custom`. The default is `numericType([],16,15)`.

Methods

`step` Subtract vector from array along specified dimension

Common to All System Objects

<code>release</code>	Allow System object property value changes
----------------------	--

Examples

Subtract Vector From Matrix

Note If you are using R2016a or an earlier release, replace each call to the object with the equivalent `step` syntax. For example, `obj(x)` becomes `step(obj,x)`.

```
avs = dsp.ArrayVectorSubtractor;
a = ones(2);
x = [1 2]';
y = avs(a, x)
```

```
y = 2×2
```

```
    0    0
```

-1 -1

Algorithms

This object implements the algorithm, inputs, and outputs described on the Array-Vector Subtract block reference page. The object properties correspond to the block parameters, except:

The array-vector subtraction object does not have **Minimum** or **Maximum** options for data output.

Compatibility Considerations

dsp.ArrayVectorSubtractor System object will be removed

Warns starting in R2021b

`dsp.ArrayVectorSubtractor` System object will be removed in a future release. Use the `-` operator instead.

Update Code

This table shows how the System object is typically used and explains how to update existing code to use the `-` operator.

Discouraged Usage	Recommended Replacement
<pre> avs = dsp.ArrayVectorSubtractor; a = ones(2); x = [1 2]'; y = avs(a, x) y = 2x2 0 0 -1 -1 </pre> <p>If you are using a release prior to R2016b, replace <code>avs(a,x)</code> with <code>step(avs,a,x)</code>.</p>	<pre> y = a - x y = 2x2 0 0 -1 -1 </pre>

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

See “System Objects in MATLAB Code Generation” (MATLAB Coder).

Introduced in R2012a

step

System object: dsp.ArrayVectorSubtractor

Package: dsp

Subtract vector from array along specified dimension

Syntax

$Y = \text{step}(\text{avs}, A, V)$

$Y = \text{step}(\text{avs}, A)$

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, $y = \text{step}(\text{obj}, x)$ and $y = \text{obj}(x)$ perform equivalent operations.

$Y = \text{step}(\text{avs}, A, V)$ returns Y . The value of Y results from subtracting the elements of input vector V from the input array A along the specified dimension when the `VectorSource` property is `Input port`. The length of the input V must equal the length of the specified dimension of A .

$Y = \text{step}(\text{avs}, A)$ returns Y . The value of Y results from subtracting the elements of the vector specified in the `Vector` property from the input array A along the specified dimension when the `VectorSource` property is `Property`. The length of the vector specified in the `Vector` property must equal the length of the specified dimension of A .

Note `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

dsp.AsyncBuffer

Package: dsp

FIFO buffer

Description

The `dsp.AsyncBuffer` System object writes samples to and reads samples from a first-in, first-out (FIFO) buffer. The `write` method writes data to the buffer, and the `read` method reads data from the buffer. When creating the object, you can set the number of samples (rows) of the buffer using the `Capacity` property. The number of channels (columns) is set during the first call to `write`. Initialize the buffer by calling `write` or `setup` before the first call to `read`.

The data that you write occupies the next available space in the buffer. If the buffer is full and all the data within it is unread (`asyncBuff.NumUnreadSamples == asyncBuff.Capacity`), the object overwrites the oldest data with any new data that comes in. The buffer removes data only when the data is overwritten, so you can reread data from the past. The `dsp.AsyncBuffer` object supports writing and reading variable frame size signals. For examples, see “Read Variable Frame Sizes from Buffer” on page 4-84 and “Write Variable Frame Sizes to Buffer” on page 4-86.

To write and read samples from a FIFO buffer:

- Create a `dsp.AsyncBuffer` object and set the properties of the object.
- Call `write` to write samples to the buffer.
- Call `read` to read samples from the buffer.
- Call `peek` to read samples without changing the number of unread samples in the buffer.

Creation

Syntax

```
asyncBuff = dsp.AsyncBuffer  
asyncBuff = dsp.AsyncBuffer(cap)
```

Description

`asyncBuff = dsp.AsyncBuffer` returns an async buffer System object, `asyncBuff`, using the default properties.

`asyncBuff = dsp.AsyncBuffer(cap)` sets the `Capacity` property to `cap`.

Example: `asyncBuff = dsp.AsyncBuffer(200000);`

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects.

Capacity — Number of writable/readable rows in buffer

192000 (default) | positive integer

Number of writable/readable rows in the buffer, specified as a positive integer greater than or equal to 2. The number of rows during each write to the buffer must not exceed the capacity of the buffer. If the buffer is full and all the data within is unread, the object overwrites the oldest data with any new data that comes in. The `CumulativeOverrun` property returned by `info` gives the number of samples overrun per channel since the last call to `reset`. The number of samples overrun is the number of unread samples overwritten.

By default, this property has data type `int32`.

Example: `asyncBuff = dsp.AsyncBuffer(200000);`

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

NumUnreadSamples — Number of unread samples in each channel

0 (default) | integer

This property is read-only.

Number of unread samples in each channel (column) of the buffer, specified as an integer greater than or equal to 0. The total number of unread samples in the buffer is `NumUnreadSamples × numChann`. The variable `numChann` is the number of channels in the buffer. The number of channels in the buffer is the number of data columns in the first call to `write`.

The `CumulativeUnderrun` property returned by the `info` method gives the number of samples underrun per channel since the last call to `reset`. Underrun occurs if you attempt to read more samples than available.

Example: `asyncBuff = dsp.AsyncBuffer; input = randn(512,1); numUnreadSamples = write(asyncBuff,input)`

Data Types: `int32`

Usage

To write and read samples from the async buffer:

- Create a `dsp.AsyncBuffer` object and set the properties of the object.
- Call `write` to write samples to the buffer.
- Call `read` to read samples from the buffer.
- Call `peek` to read samples without changing the number of unread samples in the buffer.

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Specific to `dsp.AsyncBuffer`

`info` Get cumulative overrun and underrun
`read` Read data from buffer
`write` Write data to buffer
`peek` Read data from buffer without changing number of unread samples

Common to All System Objects

`step` Run System object algorithm
`release` Release resources and allow changes to System object property values and input characteristics
`reset` Reset internal states of System object

Examples

Read Variable Frame Sizes from Buffer

The `dsp.AsyncBuffer` System object™ supports reading variable frame sizes from the buffer.

Create a `dsp.AsyncBuffer` System object. The input is white Gaussian noise with a mean of 0, a standard deviation of 1, and a frame size of 512 samples. Write the input to the buffer using the `write` method.

```
asyncBuff = dsp.AsyncBuffer;  
input = randn(512,1);  
write(asyncBuff,input);  
plot(input)  
hold on
```

Store the data that is read from the buffer in `outTotal`.

Plot the input signal and data that is read from the buffer in the same plot. Read data from the buffer until all samples are read. In each iteration of the loop, `randi` determines the number of samples to read. Therefore, the signal is read in as a variable-size signal. The `prevIndex` variable keeps track of the previous index value that contains the data.

```

outTotal = zeros(size(input));
prevIndex = 0;
while asyncBuff.NumUnreadSamples ~= 0
    numToRead = randi([1,64]);
    out = read(asyncBuff,numToRead);
    outTotal(prevIndex+1:prevIndex+numToRead) = out;
    prevIndex = prevIndex+numToRead;
end
plot(outTotal,'r')
hold off

```

Verify that the input data and the data read from the buffer (excluding the underrun samples, if any) are the same. The cumulative number of overrun and underrun samples in the buffer is determined by the `info` function.

```
S = info(asyncBuff)
```

```
S = struct with fields:
    CumulativeOverrun: 0
    CumulativeUnderrun: 28
```

The `CumulativeUnderrun` field shows the number of samples underrun per channel. Underrun occurs if you attempt to read more samples than available.

Write Variable Frame Sizes to Buffer

Write a sine wave of variable frame size to the buffer. Compute the FFT of the sine wave and visualize the result on an array plot.

Initialize the `dsp.AsyncBuffer`, `dsp.ArrayPlot`, and `dsp.FFT` System objects.

```
asynBuff = dsp.AsyncBuffer;
plotter = dsp.ArrayPlot;
fftObj = dsp.FFT('FFTLengthSource','Property','FFTLength',256);
```

The sine wave is generated using the `sin` function in MATLAB. The `start` and `finish` variables mark the start and finish indices of each frame. If enough data is cached, read from the buffer and perform the FFT. View the FFT on an array plot.

```
start = 1;

for Iter = 1 : 2000
    numToWrite = randi([200,800]);
    finish = start + numToWrite;

    inputData = sin(start:finish)';
    start = finish + 1;

    write(asynBuff,inputData);
    while asynBuff.NumUnreadSamples >= 256
        x = read(asynBuff,256);
        X = abs(fftObj(x));
        plotter(log(X));
    end
end
```

Peek Data from Async Buffer

Read data from the async buffer without changing the number of unread samples using the `peek` function.

Create a `dsp.AsyncBuffer` System object™. The input is a column vector of 100 samples, 1 to 100. Write the data to the buffer.

```
asyncBuff = dsp.AsyncBuffer
asyncBuff =
  AsyncBuffer with properties:
      Capacity: 192000
  NumUnreadSamples: 0
```

```
input = (1:100)';
write(asyncBuff,input);
```

Peek at the first three samples. The output is [1 2 3]′.

```
out1 = peek(asyncBuff,3)
out1 = 3×1
     1
     2
     3
```

The `NumUnreadSamples` is 100, indicating that the peek function has not changed the number of unread samples in the buffer.

```
asyncBuff.NumUnreadSamples
ans = int32
    100
```

After peeking, read 50 samples using the read function. The output is [1:50]′.

```
out2 = read(asyncBuff,50)
out2 = 50×1
     1
     2
     3
     4
     5
     6
     7
     8
     9
    10
     :
```

The `NumUnreadSamples` is 50, indicating that the read function has changed the number of unread samples in the buffer.

```
asyncBuff.NumUnreadSamples
ans = int32
    50
```

Now peek again at the first three samples. The output is [51 52 53]'. Verify that the `NumUnreadSamples` is still 50.

```
out3 = peek(asyncBuff,3)
```

```
out3 = 3×1
```

```
51
52
53
```

```
asyncBuff.NumUnreadSamples
```

```
ans = int32
50
```

Read 50 samples again. The output now contains the sequence [51:100]'. Verify that `NumUnreadSamples` is 0.

```
out4 = read(asyncBuff)
```

```
out4 = 50×1
```

```
51
52
53
54
55
56
57
58
59
60
:
```

```
asyncBuff.NumUnreadSamples
```

```
ans = int32
0
```

Limitations

Before calling the `read` method, you must initialize the buffer by calling either the `write` or `setup` method. For an example, see “Why Does the `dsp.AsyncBuffer` Object Error When You Call `read` Before `write`?”

Extended Capabilities

audioDeviceWriter

Play to sound card

Description

The `audioDeviceWriter` System object writes audio samples to an audio output device. Properties of the audio device writer specify the driver, the device, and device attributes such as sample rate, bit depth, and buffer size.

Data Flow of Audio Device Writer

- Call the object to input an audio signal frame to the `audioDeviceWriter`.
- The `audioDeviceWriter` uses the specified driver to pass the frame (device input) to the buffer of your specified audio device.
- The audio device performs digital-to-analog conversion at the specified sample rate and bit depth.
- The audio device outputs an analog chunk to your speaker.

To stream data to an audio device:

- 1 Create the `audioDeviceWriter` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

Creation

Syntax

```
deviceWriter = audioDeviceWriter
deviceWriter = audioDeviceWriter(sampleRateValue)
deviceWriter = audioDeviceWriter( ___,Name,Value)
```

Description

`deviceWriter = audioDeviceWriter` returns a System object, `deviceWriter`, that writes audio samples to an audio output device in real time.

`deviceWriter = audioDeviceWriter(sampleRateValue)` sets the `SampleRate` property to `sampleRateValue`.

`deviceWriter = audioDeviceWriter(___, Name, Value)` sets each property `Name` to the specified `Value`. Unspecified properties have default values.

Example: `deviceWriter = audioDeviceWriter(48000, 'BitDepth', '8-bit integer')` creates a System object, `deviceWriter`, that operates at a 48 kHz sample rate and an 8-bit integer bit depth.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see *System Design in MATLAB Using System Objects*.

Driver — Driver used to access audio device (Windows only)

'DirectSound' (default) | 'ASIO' | 'WASAPI'

Driver used to access your audio device, specified as 'DirectSound', 'ASIO', or 'WASAPI'.

- ASIO drivers do not come pre-installed on Windows machines. To use the 'ASIO' driver option, install an ASIO driver outside of MATLAB.

Note If `Driver` is specified as 'ASIO', use `asiosettings` to set the sound card buffer size to the buffer size of your `audioDeviceWriter` System object.

- WASAPI drivers are supported for exclusive-mode only.

ASIO and WASAPI drivers do not provide sample rate conversion. For ASIO and WASAPI drivers, set `SampleRate` to a sample rate supported by your audio device.

This property applies only on Windows machines. Linux machines always use the ALSA driver. Mac machines always use the CoreAudio driver.

To specify nondefault `Driver` values, you must have an Audio Toolbox license. If the toolbox is not installed, specifying nondefault `Driver` values returns an error.

Data Types: `char` | `string`

Device — Device used to play audio samples

default audio device (default) | character vector | string scalar

Device used to play audio samples, specified as a character vector or string scalar. Use `getAudioDevices` to list available devices for the selected driver.

Data Types: `char` | `string`

SampleRate — Sample rate of signal sent to audio device (Hz)

44100 (default) | positive integer

Sample rate of signal sent to audio device, in Hz, specified as a positive integer. The range of `SampleRate` depends on your audio hardware.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`**BitDepth — Data type used by the device**

'16-bit integer' (default) | '8-bit integer' | '24-bit integer' | '32-bit float'

Data type used by the device, specified as a character vector or string scalar. Before performing digital-to-analog conversion, the input data is cast to a data type specified by `BitDepth`.

To specify a nondefault `BitDepth`, you must have an Audio Toolbox license. If the toolbox is not installed, specifying a nondefault `BitDepth` returns an error.

Data Types: `char` | `string`**SupportVariableSizeInput — Support variable frame size**`false` (default) | `true`

Option to support variable frame size, specified as `true` or `false`.

- `false` -- If the `audioDeviceWriter` object is locked, the input must have the same frame size at each call. The buffer size of your audio device is the same as the input frame size.
- `true` -- If the `audioDeviceWriter` object is locked, the input frame size can change at each call. The buffer size of your audio device is specified through the `BufferSize` property.

Data Types: `char`**BufferSize — Buffer size of audio device**

4096 (default) | positive integer

Buffer size of audio device, specified as a positive integer.

Note If `Driver` is specified as 'ASIO', open the ASIO UI to set the sound card buffer size to the `BufferSize` value of your `audioDeviceWriter` System object.

Dependencies

To enable this property, set `SupportVariableSizeInput` to `true`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`**ChannelMappingSource — Source of mapping between input matrix and device channels**

'Auto' (default) | 'Property'

Source of mapping between columns of input matrix and channels of audio output device, specified as 'Auto' or 'Property'.

- 'Auto' -- Default settings determine the mapping between columns of input matrix and channels of audio output device. For example, suppose that your input is a matrix with four columns, and your audio device has four channels available. Column 1 of your input data writes to channel 1 of your device, column 2 of your input data writes to channel 2 of your device, and so on.

- 'Property' -- The ChannelMapping property determines the mapping between columns of input matrix and channels of audio output device.

Data Types: char | string

ChannelMapping — Nondefault mapping between input matrix and device channels

[1:MaximumOutputChannels] (default) | scalar | vector

Nondefault mapping between columns of input matrix and channels of output device, specified as a scalar or vector of valid channel indices.

To selectively map between columns of the input matrix and your sound card's output channels, you must have an Audio Toolbox license. If the toolbox is not installed, specifying a nondefault ChannelMapping returns an error.

Note To ensure mono output on only one channel of a stereo device, use the default ChannelMapping setting and provide a stereo signal where one channel is all zeros.

Example: outputLeftOnly = [x(:,1) zeros(size(x,1),1)];

Example: outputRightOnly = [zeros(size(x,1),1) x(:,1)];

Dependencies

To enable this property, set ChannelMappingSource to 'Property'.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

Usage

Syntax

```
numUnderrun = deviceWriter(audioToDevice)
```

Description

numUnderrun = deviceWriter(audioToDevice) writes one frame of audio samples, audioToDevice, to the selected audio device and returns the number of audio samples underrun since the last call to deviceWriter.

Note: When you call the audioDeviceWriter System object, the audio device specified by the Device property is locked. An audio device can be locked by only one audioDeviceWriter at a time. To release the audio device, call release on your audioDeviceWriter System object.

Input Arguments

audioToDevice — Audio to device

matrix

Audio signal to write to device, specified as a matrix. The columns of the matrix are treated as independent audio channels.

If `audioToDevice` is of data type `'double'` or `'single'`, the audio device writer clips values outside the range `[-1, 1]`. For other data types, the allowed input range is `[min, max]` of the specified data type.

Data Types: `single` | `double` | `int16` | `int32` | `uint8`

Output Arguments

numUnderrun — Number of samples underrun

scalar

Number of samples by which the audio device writer queue was underrun since the last call to `deviceWriter`.

Data Types: `uint32`

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Specific to audioDeviceWriter

<code>getAudioDevices</code>	List available audio devices
<code>info</code>	Characteristic information about audio device writer

Common to All System Objects

<code>clone</code>	Create duplicate System object
<code>isLocked</code>	Determine if System object is in use
<code>release</code>	Release resources and allow changes to System object property values and input characteristics
<code>reset</code>	Reset internal states of System object
<code>step</code>	Run System object algorithm
<code>setup</code>	One-time set up tasks for System objects

Examples

Read from File and Write to Audio Device

Read an MP3 audio file and play it through your default audio output device.

Create a `dsp.AudioFileReader` object with default settings. Use the `audioinfo` function to return a structure containing information about the audio file.

```
fileReader = dsp.AudioFileReader('speech_dft.mp3');
fileInfo = audioinfo('speech_dft.mp3')

fileInfo = struct with fields:
    Filename: 'B:\matlab\toolbox\dsp\dsp\speech_dft.mp3'
    CompressionMethod: 'MP3'
    NumChannels: 1
```

```
SampleRate: 22050
TotalSamples: 112893
Duration: 5.1199
  Title: []
  Comment: []
  Artist: []
BitRate: 64
```

Create an `audioDeviceWriter` object and specify the sample rate.

```
deviceWriter = audioDeviceWriter('SampleRate', fileInfo.SampleRate);
```

Call `setup` to reduce the computational load of initialization in an audio stream loop.

```
setup(deviceWriter, zeros(fileReader.SamplesPerFrame, ...
    fileInfo.NumChannels))
```

Use the `info` function to obtain the characteristic information about the device writer.

```
info(deviceWriter)
ans = struct with fields:
    Driver: 'DirectSound'
    DeviceName: 'Primary Sound Driver'
    MaximumOutputChannels: 2
```

In an audio stream loop, read an audio signal frame from the file, and write the frame to your device.

```
while ~isDone(fileReader)
    audioData = fileReader();
    deviceWriter(audioData);
end
```

Close the input file and release the device.

```
release(fileReader)
release(deviceWriter)
```

Reduce Latency due to Output Device Buffer

Latency due to the output device buffer is the time delay of writing one frame of data. Modify default properties of your `audioDeviceWriter` System object™ to reduce latency due to device buffer size.

Create a `dsp.AudioFileReader` System object to read an audio file with default settings.

```
fileReader = dsp.AudioFileReader('speech_dft.mp3');
```

Create an `audioDeviceWriter` System object and specify the sample rate to match that of the audio file reader.

```
deviceWriter = audioDeviceWriter(...
    'SampleRate', fileReader.SampleRate);
```

Calculate the latency due to your device buffer, in seconds.

```
bufferLatency = fileReader.SamplesPerFrame/deviceWriter.SampleRate %#ok
bufferLatency = 0.0464
```

Set the `SamplesPerFrame` property of your `dsp.AudioFileReader` System object to 256. Calculate the buffer latency in seconds.

```
fileReader.SamplesPerFrame = 256;
bufferLatency = fileReader.SamplesPerFrame/deviceWriter.SampleRate
bufferLatency = 0.0116
```

Determine and Decrease Underrun

Underrun refers to output signal silence, which occurs when the audio stream loop does not keep pace with the output device. Determine the underrun of an audio stream loop, add artificial computational load to the audio stream loop, and then modify properties of your `audioDeviceWriter` object to decrease underrun. Your results depend on your computer.

Create a `dsp.AudioFileReader` object, and specify the file to read. Use the `audioinfo` function to return a structure containing information about the audio file.

```
fileReader = dsp.AudioFileReader('speech_dft.mp3');
fileInfo = audioinfo('speech_dft.mp3');
```

Create an `audioDeviceWriter` object. Use the `SampleRate` of the file reader as the `SampleRate` of the device writer. Call `setup` to reduce the computational load of initialization in an audio stream loop.

```
deviceWriter = audioDeviceWriter('SampleRate',fileReader.SampleRate);
setup(deviceWriter,zeros(fileReader.SamplesPerFrame,...
    fileInfo.NumChannels))
```

Run your audio stream loop with input from file and output to device. Print the total samples underrun and the underrun in seconds.

```
totalUnderrun = 0;
while ~isDone(fileReader)
    input = fileReader();
    numUnderrun = deviceWriter(input);
    totalUnderrun = totalUnderrun + numUnderrun;
end
fprintf('Total samples underrun: %d.\n',totalUnderrun)
```

```
Total samples underrun: 0.
```

```
fprintf('Total seconds underrun: %d.\n',double(totalUnderrun)/double(deviceWriter.SampleRate))
```

```
Total seconds underrun: 0.
```

Release your `dsp.AudioFileReader` and `audioDeviceWriter` objects and set your counter variable to zero.

```
release(fileReader)
release(deviceWriter)
totalUnderrun = 0;
```

Use `pause` to mimic an algorithm that takes 0.075 seconds to process. The pause causes the audio stream loop to go slower than the device, which results in periods of silence in the output audio signal.

```
while ~isDone(fileReader)
    input = fileReader();
    numUnderrun = deviceWriter(input);
    totalUnderrun = totalUnderrun + numUnderrun;
    pause(0.075)
end
fprintf('Total samples underrun: %d.\n',totalUnderrun)
```

Total samples underrun: 68608.

```
fprintf('Total seconds underrun: %d.\n',double(totalUnderrun)/double(deviceWriter.SampleRate))
```

Total seconds underrun: 3.111474e+00.

Release your `audioDeviceReader` and `dsp.AudioFileWriter` and set the counter variable to zero.

```
release(fileReader)
release(deviceWriter)
totalUnderrun = 0;
```

Set the frame size of your audio stream loop to 2048. Because the `SupportVariableSizeInput` property of your `audioDeviceWriter` System object is set to `false`, the buffer size of your audio device is the same size as the input frame size. Increasing your device buffer size decreases underrun.

```
fileReader = dsp.AudioFileReader('speech_dft.mp3');
fileReader.SamplesPerFrame = 2048;
fileInfo = audioinfo('speech_dft.mp3');
```

```
deviceWriter = audioDeviceWriter('SampleRate',fileReader.SampleRate);
setup(deviceWriter,zeros(fileReader.SamplesPerFrame,fileInfo.NumChannels))
```

Calculate the total underrun.

```
while ~isDone(fileReader)
    input = fileReader();
    numUnderrun = deviceWriter(input);
    totalUnderrun = totalUnderrun + numUnderrun;
    pause(0.075)
end
fprintf('Total samples underrun: %d.\n',totalUnderrun)
```

Total samples underrun: 0.

```
fprintf('Total seconds underrun: %d.\n',double(totalUnderrun)/double(deviceWriter.SampleRate))
```

Total seconds underrun: 0.

The increased frame size reduces the total underrun of your audio stream loop. However, increasing the frame size also increases latency. Other approaches to reduce underrun include:

- Increasing the buffer size independent of input frame size. To increase buffer size independent of input frame size, you must first set `SupportVariableSizeInput` to `true`. This approach also increases latency.

- Decreasing the sample rate. Decreasing the sample rate reduces both latency and underrun at the cost of signal resolution.
- Choosing an optimal driver and device for your system.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- “System Objects in MATLAB Code Generation” (MATLAB Coder)
- The executable generated from this System object relies on prebuilt dynamic library files (.dll files) included with MATLAB. Use the `packNGO` function to package the code generated from this object and all the relevant files in a compressed zip file. Using this zip file, you can relocate, unpack, and rebuild your project in another development environment where MATLAB is not installed. For more details, see “How To Run a Generated Executable Outside MATLAB”.

Topics

“How To Run a Generated Executable Outside MATLAB”

“Measure Audio Latency” (Audio Toolbox)

Introduced in R2016a

getAudioDevices

List available audio devices

Syntax

```
devices = getAudioDevices(deviceWriter)
```

Description

`devices = getAudioDevices(deviceWriter)` returns a list of audio devices that are available and compatible with your I/O audio object, `deviceWriter`.

Input Arguments

deviceWriter — Audio I/O object

`audioDeviceWriter` object

Audio I/O object, specified as an `audioDeviceWriter` object.

Data Types: `object`

Output Arguments

devices — List of available and compatible devices

`array`

List of available and compatible devices. The list of audio devices depends on the specified `Driver` property of your object.

Data Types: `cell`

Objects

`audioDeviceWriter`

Introduced in R2016a

dsp.AudioFileReader

Package: dsp

Stream from audio file

Description

The `dsp.AudioFileReader` System object reads audio samples from an audio file.

To read audio samples from an audio file:

- 1 Create the `dsp.AudioFileReader` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

Creation

Syntax

```
afr = dsp.AudioFileReader
afr = dsp.AudioFileReader(File name)
afr = dsp.AudioFileReader(Name,Value)
```

Description

`afr = dsp.AudioFileReader` returns an audio file reader System object, `afr` that reads audio from an audio file.

`afr = dsp.AudioFileReader(File name)` returns an audio file reader object, `afr`, with `Filename` property set to `File name`.

`afr = dsp.AudioFileReader(Name,Value)` returns an audio file reader System object, `afr`, with each specified property set to the specified value. Enclose each property name in single quotes. Unspecified properties have default values.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see [System Design in MATLAB Using System Objects](#).

Filename — Name of audio file from which to read

'speech_dft.mp3' (default) | character vector | string scalar

Specify the name of an audio file as a character vector or a string scalar. If `FilenameIsTunableInCodegen` is set to `false` and the file is on MATLAB path, then you do not need to specify the full name of the file. If `FilenameIsTunableInCodegen` is set to `true`, then the file name must either exist in the current directory, or you must specify the full file path. The file name can be an http web address like `'http://audio.wgbh.org:8004/'`. For an example, see “Read and Play Back Audio File from http Web Address” on page 4-105.

The `Filename` property is tunable in generated code. That is, you can pass the name of the audio file as an input while running the code generated from this object. File attributes such as the audio format, the number of audio channels, the sample rate, and the bit rate are not tunable and must match the attributes of the prototype audio file you specify through the `CodegenPrototypeFile` property. The specified prototype audio file determines the attributes and the type of audio files that can be read by the generated code. For an example, see “Tunable Audio File Name in Generated Code” on page 4-106.

The following table lists the supported audio file formats.

Platforms	File Name Extensions
Windows	.wav, .wma, .avi, .aif, .aifc, .aiff, .mp3, .au, .snd, .mp4, .m4a, .flac, .ogg, .mov
Non-Windows	.avi, .mp3, .mp4, .m4a, .wav, .flac, .ogg, .aif, .aifc, .aiff, .au, .snd, .mov

PlayCount — Number of times to play file

1 (default) | positive integer

Specify a positive integer as the number of times to play the file.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

SamplesPerFrame — Number of samples in audio frame

1024 (default) | positive integer

Specify the number of samples in an audio frame as a positive, scalar integer value.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

OutputDataType — Data type of output

'double' (default) | 'single' | 'int16' | 'uint8'

Set the data type of the audio data output from the audio file reader object. Specify the data type as 'double', 'single', 'int16', or 'uint8'.

FilenameIsTunableInCodegen — Enable file name tunability in generated code

false (default) | true

Set this property to true to enable tunability of `Filename` in generated C/C++ code. The file with the specified `Filename` must either exist in the current directory, or you must specify the full file path.

If `FilenameIsTunableInCodegen` is set to `true`, file attributes such as the audio format, the number of audio channels, the sample rate, and the bit rate are not tunable and must match the attributes of the prototype audio file you specify through the `CodegenPrototypeFile` property. The specified prototype audio file determines the attributes and the type of audio files that can be read by the generated code. For example, if the specified prototype file is a `.wav` file, then the generated

code can only read .wav files. If the specified prototype file sample rate is 44100 Hz, then the generated code can read files with a sample rate of 44100 Hz.

Data Types: `logical`

CodegenPrototypeFile — Prototype audio file for code generation

'speech_dft.mp3' (default) | character vector | string scalar

Specify the name of the prototype audio file used in code generation as a character vector or a string scalar. Specify the full path for the file only if the file is not on the MATLAB path. The file name can be an http web address, like 'http://audio.wgbh.org:8004/'.

The attributes of the audio file specified in `Filename` (such as the audio format, the number of audio channels, the sample rate, and the bite rate) must match the attributes of the audio file specified in `CodegenPrototypeFile`. The specified prototype audio file determines the attributes and the type of audio files that can be read by the generated code. For example, if the specified prototype file is a .wav file, then the generated code can only read .wav files. If the specified prototype file sample rate is 44100 Hz, then the generated code can read files with a sample rate of 44100 Hz.

The following table lists the supported audio file formats:

Platforms	File Name Extensions
Windows	.wav, .wma, .avi, .aif, .aifc, .aiff, .mp3, .au, .snd, .mp4, .m4a, .flac, .ogg, .mov
Non-Windows	.avi, .mp3, .mp4, .m4a, .wav, .flac, .ogg, .aif, .aifc, .aiff, .au, .snd, .mov

Dependencies

This property applies only when the `FilenameIsTunableInCodegen` property is set to `true`.

SampleRate — Sampling rate of audio file

positive scalar

This property is read-only.

This property displays the sample rate, in Hz, of the audio file.

Data Types: `double`

ReadRange — Range of samples to be read

[1 inf] (default) | two-element row vector

Specify the sample range from which to read, as a vector in the form of [`StartSample` `EndSample`], where `StartSample` is the sample at which file reading starts, and `EndSample` is the sample at which file reading stops.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

Usage

Syntax

```
audio = afr()
```

```
[audio,eof] = afr()
```

Description

`audio = afr()` outputs one frame of audio samples, `audio`. You can specify the number of times to play the file using the `PlayCount` property. After playing the file for the number of times you specify, `audio` contains silence.

`[audio,eof] = afr()` returns an end-of-file indicator, `eof`. `eof` is true each time the output `audio` contains the last audio sample in the file.

Output Arguments**audio — Audio samples**

column vector

One frame of audio samples, returned as a column vector of length equal to the value you specify in the `SamplesPerFrame` property. The data type of the audio output is specified in the `OutputDataType` property.

Data Types: `single` | `double` | `int16` | `uint8`

eof — End-of-file indicator

1 | 0

End-of-file indicator, returned as either a 1 or a 0. A value of 1 is output when `audio` contains the last audio sample in the file.

Data Types: `logical`

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Specific to `dsp.AudioFileReader`

`info` Information about specific audio file

`isDone` End-of-file status (logical)

Common to All System Objects

`step` Run System object algorithm

`release` Release resources and allow changes to System object property values and input characteristics

`reset` Reset internal states of System object

Examples**Read and Play Back Audio File**

Read and play back an audio file using the standard audio output device.

Note: If you are using R2016a or an earlier release, replace each call to the object with the equivalent `step` syntax. For example, `obj()` becomes `step(obj)`.

You can choose to read the entire data or specify a range of data to read from using the `ReadRange` property. By default, `ReadRange` is set to `[1 inf]`, indicating the file reader to read the entire data from the source. In this example, set `ReadRange` to `3Fs`, indicating the file reader to read the first 3 seconds of the data.

```
afr = dsp.AudioFileReader('speech_dft.mp3','ReadRange',[1 3*22050]);
adw = audioDeviceWriter('SampleRate', afr.SampleRate);

while ~isDone(afr)
    audio = afr();
    adw(audio);
end
release(afr);
release(adw);
```

Read and Play Back Audio File from http Web Address

Read audio data from an http web address using the `dsp.AudioFileReader` System object™. Play back the data using the `audioDeviceWriter` System object.

Initialization

Create an audio file reader which reads data from `http://audio.wgbh.org:8004/`. Set the sample rate of the audio device writer to be the same as that of the audio file reader.

```
afr = dsp.AudioFileReader('http://audio.wgbh.org:8004/')
```

```
afr =
    dsp.AudioFileReader with properties:

        Filename: 'http://audio.wgbh.org:8004/'
        PlayCount: 1
        SamplesPerFrame: 1024
        OutputDataType: 'double'
        SampleRate: 44100
        ReadRange: [1 Inf]
```

```
adw = audioDeviceWriter(afr.SampleRate)
```

```
adw =
    audioDeviceWriter with properties:

        Driver: 'DirectSound'
        Device: 'Default'
        SampleRate: 44100

    Show all properties
```

Read and Play Back

Read a specific amount of data from the web address directly and play the data back using the audio device writer.

```
for i = 1:1000
    audio = afr();
    adw(audio);
end
```

Close the input file and the audio output device.

```
release(afr)
release(adw)
```

Tunable Audio File Name in Generated Code

Generate a MEX file from a function named `writeAudio`. This function reads an audio signal from the `funky-stereo.wav` file, decimates the signal by a factor of 2, and writes the decimated signal to a specified output file.

The `dsp.AudioFileReader` object reads the audio signal from `funky-stereo.wav` file. The `funky-stereo.wav` file has two channels, a sample rate of 44100 Hz, and a bit rate of 1411 kbps. The `CodegenPrototypeFile` property of the object is set to `rock-stereo.wav` file. The `rock-stereo.wav` file has the same file attributes, such as the number of audio channels, sample rate, and bit rate, as the `funky-stereo.wav` file. The `dsp.FIRDecimator` object decimates the input audio signal by a factor of 2. The `dsp.AudioFileWriter` object writes the decimated signal to the output file `myoutput.wav`. Due to the decimation process, the output file has a sample rate of 22050 Hz and a bit rate of 2822 kbps.

```
type writeAudio.m

function writeAudio(readfile,writefile)

afr = dsp.AudioFileReader('FilenameIsTunableInCodegen',true,...
    'CodegenPrototypeFile','rock-stereo.wav');
afr.Filename = readfile;
% Filename is funky-stereo.wav and CodegenPrototypeFile is
% rock-stereo.wav.

firdec = dsp.FIRDecimator(2,'auto'); % decimate by 2

afw = dsp.AudioFileWriter('SampleRate',22050);
afw.Filename = writefile;
while ~isDone(afr)
    audio = afr();
    audiod = firdec(audio);
    afw(audiod);
end

release(afr);
release(afw);
end
```

For generating code, specify file names to be variable-length character vectors of maximum length 500.

```
readfilename = coder.typeof('a',[1 500],[0 1]);
writefilename = coder.typeof('b',[1 500],[0 1]);
```

Generate a MEX file using the `codegen` function.

```
codegen writeAudio -args {readfilename,writefilename}
```

Code generation successful.

```
writeAudio_mex('funky-stereo.wav','myoutput.wav');
```

Limitations

For MP3, MPEG-4 AAC, and AVI audio files on Windows 7 or later and Linux platforms, `dsp.AudioFileReader` object can read fewer samples than expected. On Windows platforms, this is due to a limitation in the underlying Media Foundation framework. On Linux platforms, this is due to a limitation in the underlying GStreamer framework. If you require sample-accurate reading, work with WAV or FLAC files.

Algorithms

This object implements the algorithm, inputs, and outputs described on the From Multimedia File block reference page. The object properties correspond to the block parameters, except:

- The object has no corresponding property for the **Inherit sample time from file** block parameter. The object always inherits the sample time from the file.
- The object has no corresponding property for the **Output end-of-file indicator** parameter. The object always outputs EOF as the last output.
- The object has no corresponding property for the **Multimedia Outputs** parameter because audio is the only supported output.
- The object has no corresponding property for the **Image signal** block parameter.
- The object has no corresponding property for the **Output color format** parameter.
- The object has no corresponding property for the **Video output data type** parameter.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- See “System Objects in MATLAB Code Generation” (MATLAB Coder).
- The executable generated from this System object relies on prebuilt dynamic library files (.dll files) included with MATLAB. Use the `packNGo` function to package the code generated from this object and all the relevant files in a compressed zip file. Using this zip file, you can relocate, unpack, and rebuild your project in another development environment where MATLAB is not installed. Objects

dsp.AudioFileWriter

Topics

“How To Run a Generated Executable Outside MATLAB”

Introduced in R2012a

dsp.AudioFileWriter

Package: dsp

Stream to audio file

Description

The `dsp.AudioFileWriter` System object writes audio samples to an audio file.

To write audio samples to an audio file:

- 1 Create the `dsp.AudioFileWriter` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

Creation

Syntax

```
afw = dsp.AudioFileWriter
afw = dsp.AudioFileWriter(File name)
afw = dsp.AudioFileWriter(Name,Value)
```

Description

`afw = dsp.AudioFileWriter` returns an audio file writer System object, `afw`. This object writes audio samples to an audio file.

`afw = dsp.AudioFileWriter(File name)` returns an audio file writer System object, `afw`. This object has the `Filename` property set to `File name`.

`afw = dsp.AudioFileWriter(Name,Value)` returns an audio file writer object with each specified property set to the specified value. Enclose each property name in single quotes. Unspecified properties have default values.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see [System Design in MATLAB Using System Objects](#).

Filename — Name of audio file to which to write

'output.wav' (default) | character vector | string scalar

Specify the name of the audio file as a character vector or a string scalar.

The `Filename` property is tunable in generated code. That is, you can pass the name of the audio file as an input while running the code generated from this object. For an example, see “Tunable Audio File Name in Generated Code” on page 4-106.

FileFormat — Audio file format

'WAV' (default) | 'AVI' | 'FLAC' | 'OGG' | 'MPEG4' | 'WMA'

Specify which audio file format the object writes. On Microsoft platforms, select one of 'AVI', 'WAV', 'FLAC', 'OGG', 'MPEG4', 'WMA'. On Linux platforms, select one of 'AVI', 'WAV', 'FLAC', or 'OGG'. On macOS platforms, select one of 'AVI', 'WAV', 'FLAC', 'OGG', or 'MPEG4'. These abbreviations correspond to the following file formats:

- 'AVI': Audio-Video Interleave
- 'WAV': Microsoft WAVE Files
- 'WMA': Windows Media Audio
- 'FLAC': Free Lossless Audio Codec
- 'OGG': Ogg/Vorbis Compressed Audio File
- 'MPEG4': MPEG-4 AAC File — You can use both `.m4a` and `.mp4` extensions

The default is 'WAV'.

SampleRate — Sampling rate of audio data stream

44100 (default) | positive scalar

Specify the sample rate of the input audio data as a positive, numeric scalar value.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

Compressor — Algorithm that compresses audio data

'None (uncompressed)' (default) | 'CCITT A-Law' | 'CCITT u-Law' | 'GSM 6.10' | 'IMA ADPCM' | 'Microsoft ADPCM' | 'PCM'

Specify the type of compression algorithm the audio file writer uses to compress the audio data. Compression reduces the size of the audio file. Select 'None (uncompressed)' to save uncompressed audio data to the file. The other options available reflect the audio compression algorithms installed on your system. You can use tab completion to query valid Compressor options for your computer by typing `H.Compressor = '` and then pressing the tab key.

Dependencies

This property applies when writing WAV or AVI files on Windows platforms.

Data Type — Data type of the uncompressed audio

'int16' (default) | 'double' | 'single' | 'inherit' | 'int24' | 'int32' | 'uint8'

Specify the type of uncompressed audio data written to the file as 'int16', 'double', 'single', 'inherit', 'int24', 'int32', or 'uint8'.

Dependencies

This property only applies when writing uncompressed WAV files.

Usage

Syntax

```
afw(audio)
```

Description

`afw(audio)` writes one frame of audio samples, `audio`, to the output file specified by `Filename`. `audio` is either a vector for mono audio input or an M -by- N matrix for N -channel audio input respectively.

Input Arguments

audio — Audio samples

column vector | matrix

One frame of audio samples, returned as a column vector or a matrix. A column vector input indicates a mono audio input. An M -by- N matrix indicates an N -channel audio input.

If the input is fixed-point, the input must be a signed fixed-point input with power-of-two slope and zero bias.

Data Types: `single` | `double` | `int16` | `int32` | `uint8` | `fi`

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Common to All System Objects

<code>step</code>	Run System object algorithm
<code>release</code>	Release resources and allow changes to System object property values and input characteristics
<code>reset</code>	Reset internal states of System object

Examples

Write an Audio Signal to WAV File

Note: If you are using R2016a or an earlier release, replace each call to the object with the equivalent `step` syntax. For example, `obj()` becomes `step(obj)`.

Decimate an audio signal, and write it to disk as a WAV file.

```
afr = dsp.AudioFileReader('OutputDataType',...
    'double');
firdec = dsp.FIRDecimator; % decimate by 2
afw = dsp.AudioFileWriter...
    ('speech_dft.wav', ...
```

```
    'SampleRate', afr.SampleRate/2);  
  
while ~isDone(afr)  
    audio = afr();  
    audiod = firdec(audio);  
    afw(audiod);  
end  
  
release(afr);  
release(afw);
```

Tunable Audio File Name in Generated Code

Generate a MEX file from a function named `writeAudio`. This function reads an audio signal from the `funky-stereo.wav` file, decimates the signal by a factor of 2, and writes the decimated signal to a specified output file.

The `dsp.AudioFileReader` object reads the audio signal from `funky-stereo.wav` file. The `funky-stereo.wav` file has two channels, a sample rate of 44100 Hz, and a bit rate of 1411 kbps. The `CodegenPrototypeFile` property of the object is set to `rock-stereo.wav` file. The `rock-stereo.wav` file has the same file attributes, such as the number of audio channels, sample rate, and bit rate, as the `funky-stereo.wav` file. The `dsp.FIRDecimator` object decimates the input audio signal by a factor of 2. The `dsp.AudioFileWriter` object writes the decimated signal to the output file `myoutput.wav`. Due to the decimation process, the output file has a sample rate of 22050 Hz and a bit rate of 2822 kbps.

```
type writeAudio.m  
  
function writeAudio(readfile,writefile)  
  
afr = dsp.AudioFileReader('FilenameIsTunableInCodegen',true,...  
    'CodegenPrototypeFile','rock-stereo.wav');  
afr.FileName = readfile;  
% Filename is funky-stereo.wav and CodegenPrototypeFile is  
% rock-stereo.wav.  
  
firdec = dsp.FIRDecimator(2,'auto'); % decimate by 2  
  
afw = dsp.AudioFileWriter('SampleRate',22050);  
afw.FileName = writefile;  
while ~isDone(afr)  
    audio = afr();  
    audiod = firdec(audio);  
    afw(audiod);  
end  
  
release(afr);  
release(afw);  
end
```

For generating code, specify file names to be variable-length character vectors of maximum length 500.

```
readfilename = coder.typeof('a',[1 500],[0 1]);  
writefilename = coder.typeof('b',[1 500],[0 1]);
```

Generate a MEX file using the `codegen` function.

```
codegen writeAudio -args {readfilename,writefilename}
```

Code generation successful.

```
writeAudio_mex('funky-stereo.wav','myoutput.wav');
```

Limitations

The following platform-specific restrictions apply when writing these files:

Windows 7	macOS
<ul style="list-style-type: none"> Only sample rates of 44100 Hz and 48000 Hz are supported for the MPEG-4 AAC file format. For other file formats, there is no restriction on the sample rate. 	<ul style="list-style-type: none"> Only mono or stereo outputs are allowed for MPEG-4 AAC file format. For all other formats, more than two audio output channels are allowed.
<ul style="list-style-type: none"> Only mono or stereo outputs are allowed for the MPEG-4 AAC file format. For all other formats, more than two audio output channels are allowed. 	
<ul style="list-style-type: none"> The output data is padded on both the front and back of the signal, with extra samples of silence. <p>Windows AAC encoder places sharp fade-in and fade-out on audio signals, causing the signals to be slightly longer in samples when written to disk.</p>	<ul style="list-style-type: none"> Not all sampling rates are supported, although the Mac Audio Toolbox API does not explicitly specify a restriction.
<ul style="list-style-type: none"> A minimum of 1025 samples per channel must be written to the MPEG-4 AAC file. 	

Algorithms

This object implements the algorithm, inputs, and outputs described on the To Multimedia File block reference page. The object properties correspond to the block parameters, except:

- The object **FileFormat** property does not support video-only file formats.
- The object has no corresponding property for the **Write** parameter. The object writes only audio content to files.
- The object has no corresponding property for the **Video compressor** parameter.
- The object has no corresponding property for the **File color format** parameter.
- The object has no corresponding property for the **Image signal** parameter.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- See “System Objects in MATLAB Code Generation” (MATLAB Coder).
- The executable generated from this System object relies on prebuilt dynamic library files (.dll files) included with MATLAB. Use the `packNGo` function to package the code generated from this object and all the relevant files in a compressed zip file. Using this zip file, you can relocate, unpack, and rebuild your project in another development environment where MATLAB is not installed. For more details, see “How To Run a Generated Executable Outside MATLAB”.

Topics

“How To Run a Generated Executable Outside MATLAB”

Introduced in R2012a

dsp.AudioPlayer

Package: dsp

(Removed) Play audio data using computer's audio device

Compatibility

The `dsp.AudioPlayer` object has been removed. Existing instances of the object error out. Replace with `audioDeviceWriter` object. For more information, see “Compatibility Considerations” on page 4-118.

Description

The `AudioPlayer` object plays audio data using the computer's audio device.

To play audio data using the computer's audio device:

- 1 Define and set up your audio player object. See “Construction” on page 4-115.
- 2 Call `step` to play audio data according to the properties of `dsp.AudioPlayer`. The behavior of `step` is specific to each object in the toolbox.

This System object buffers the data from the audio device using the process illustrated by the following figure.

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj, x)` and `y = obj(x)` perform equivalent operations.

Construction

`H = dsp.AudioPlayer` returns an audio player object, `H`, that plays audio samples using an audio output device in real-time.

`H = dsp.AudioPlayer('PropertyName', PropertyValue, ...)` returns an audio player object, `H`, with each property set to the specified value.

`H = dsp.AudioPlayer(SAMPLERATE, 'PropertyName', PropertyValue, ...)` returns an audio player object, `H`, with the `SampleRate` property set to `SAMPLERATE` and other specified properties set to the specified values. This System object supports variable-size input. If you use variable-size signals with this System object, you may experience sound dropouts when the size of the input frame increases. To avoid this behavior, use a signal of maximum expected size when you first call `step` to start running through this System object.

Properties

DeviceName

Device to which to send audio data

Specify the device to which to send the audio data. The default is `Default`, which is the computer's standard output device. You can use tab completion to query valid `DeviceName` assignments for your computer by typing `H.DeviceName = '` and then pressing the tab key.

SampleRate

Number of samples per second sent to audio device

Specify the number of samples per second in the signal as an integer. The default is `44100`. This property is tunable.

DeviceDataType

Data type used by device

Specify the data type used by the audio device to acquire audio data as `Determine from input data type`, `8-bit integer`, `16-bit integer`, `24-bit integer`, or `32-bit float`. The default is `Determine from input data type`.

BufferSizeSource

Source of Buffer Size

Specify how to determine the buffer size as `Auto` or `Property`. The default is `Auto`. When this property is set to `Auto`, an appropriate buffer size based on the `SampleRate` gets computed.

BufferSize

Buffer size

Specify the size of the buffer that the audio player object uses to communicate with the audio device as an integer. `BufferSize` is half the size of the sound card buffer. A frame of data cannot be passed to the queue until the device empties the buffer, which introduces latency. Latency is the time it takes the device to empty the queue and the buffer. `BufferSize` has to be smaller than the effective queue duration. This property is tunable. Tuning this property involves a balance between device latency and the possibility of dropping data (buffer underrun).

This property applies when you set the `BufferSizeSource` property to `Property`. The default is `4096`. To set the `BufferSize` to a value other than the default, first change the `BufferSizeSource` to `'Property'`. You can select `BufferSize` in the list of properties.

QueueDuration

Size of queue in seconds

Specify the length of the audio queue, in seconds. The default is 1.0. This property is tunable. The purpose of the queue is to control the trade-off between latency and data dropout. Latency is calculated by the following equation: $latency = \frac{QueueDuration \times SampleRate + 2 \times BufferSize}{SampleRate}$.

To minimize latency, lower the `QueueDuration` or set it to 0. However, be aware that data dropouts or loss of system robustness may result. The `QueueDuration` property specifies the duration of the signal, in seconds, that can be buffered during the simulation. This value is the maximum length of time that the System object data supply can lag the device's data demand. If the MATLAB data throughput rate is lower than the device throughput rate, a buffer underrun occurs. You can use `OutputNumUnderrunSamples` to monitor underrun. To correct the underrun, make the queue duration larger than the buffer. If the MATLAB data throughput rate is higher than the device throughput rate, a buffer overrun occurs, causing the System object to wait before writing data to the queue. To minimize the chance of dropouts, the System object checks to verify the queue duration is at least as large as the maximum of the buffer size and the frame size. If it is not, the queue duration is automatically set to this maximum value. At the start of the simulation, the queue is filled with silence. At each time step, the System object sends a buffer of samples from the top of the queue to the audio device. If the queue does not contain enough data to completely fill the buffer, the System object fills the remaining portion of the buffer with zeros.

OutputNumUnderrunSamples

Enable output of underrun count

Set to `true` to output the number of zero samples inserted due to queue underrun since the last call to the `step` method. The default is `false`.

ChannelMappingSource

Source of device channel mapping

Specify whether to determine the channel mapping as 'Auto' or as 'Property'. If you set the value of `ChannelMappingSource` to 'Auto', the `ChannelMapping` field is rendered inactive. If you set this property to 'Property', the vector specified in the `ChannelMapping` field is used to route the output.

ChannelMapping

Data-to-device channel mapping

Vector of valid channel indices to represent the mapping between data and device output channels. The term Channel Mapping refer to a 1-to-1 mapping that associates channels on the selected audio device to channels of the data. When you play audio, channel mapping allows you to specify which channel of the audio data to output a specific channel of audio data. By default, the `ChannelMapping` field is [1:MAXOUTPUTCHANNELS], where MAXOUTPUTCHANNELS depends upon the selected device.

Methods

step Write audio to audio output device

Common to All System Objects	
release	Allow System object property value changes

Troubleshooting

Running an Executable Outside MATLAB

To run your generated standalone executable application in Shell, you need to set your environment to the following:

Platform	Command
Mac	<pre>setenv DYLD_LIBRARY_PATH \$LD_LIBRARY_PATH: \$MATLABROOT/bin/ maci64 (csh/tcsh) export DYLD_LIBRARY_PATH \$LD_LIBRARY_PATH: \$MATLABROOT/bin/ maci64 (Bash)</pre>
Linux	<pre>setenv LD_LIBRARY_PATH \$LD_LIBRARY_PATH: \$MATLABROOT/bin/ glnxa64 (csh/tcsh) export LD_LIBRARY_PATH \$LD_LIBRARY_PATH: \$MATLABROOT/bin/ glnxa64 (Bash)</pre>
Windows	<pre>set PATH = \$MATLABROOT\bin\win64;%PATH %</pre>

Algorithms

This object implements the algorithm, inputs, and outputs described on the To Audio Device block reference page. The object properties correspond to the block parameters.

Compatibility Considerations

dsp.AudioPlayer System object has been removed

Errors starting in R2020a

dsp.AudioPlayer System object has been removed. Use audioDeviceWriter instead.

Update Code

This table shows typical usage of the System object and explains how to update existing code to use the equivalent function.

Discouraged Usage	Recommended Replacement
<pre> AFR = dsp.AudioFileReader; AP = dsp.AudioPlayer('SampleRate',22050); while ~isDone(AFR) audio = AFR(); AP(audio); end % Wait until audio is played to the end pause(AP.QueueDuration); % close the input file release(AFR); % close the audio output device release(AP); If you are using a release prior to R2016b, replace AP(audio) with step(AP, audio). </pre>	<pre> fileReader = dsp.AudioFileReader; devWriter = audioDeviceWriter('SampleRate',... fileReader.SampleRate); fileInfo = audioinfo(fileReader.FileName); % Initialize audio device setup(devWriter, zeros(fileReader.SamplesPerFrame, .. fileInfo.NumChannels)); while ~isDone(fileReader) audioSamples = fileReader(); play(devWriter, audioSamples); end % close the input file release(fileReader); % close the audio output device release(devWriter); </pre>

Topics

Set the Audio Hardware API on page 2-1312

Introduced in R2012a

step

System object: dsp.AudioPlayer

Package: dsp

Write audio to audio output device

Compatibility

The dsp.AudioPlayer object has been removed. Existing instances of the object error out. Replace with audioDeviceWriter object. For more information, see “Compatibility Considerations” on page 4-118.

Syntax

step(H,AUDIO)

Underrun = step(H,AUDIO)

Description

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, $y = \text{step}(\text{obj}, x)$ and $y = \text{obj}(x)$ perform equivalent operations.

step(H,AUDIO) writes one frame of AUDIO samples to the audio output device.

Underrun = step(H,AUDIO) writes one frame of AUDIO samples to the audio output device. The output Underrun indicates the number of zero samples inserted due to queue underrun since the last call to the step method. This syntax applies when you set the OutputNumUnderrunSamples property to true.

Note obj specifies the System object on which to run this step method.

The object performs an initialization the first time the step method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the release method to unlock the object.

dsp.AudioRecorder

Package: dsp

(Removed) Record audio data using computer's audio device

Compatibility

The `dsp.AudioRecorder` object has been removed. Existing instances of the object error out. Replace with `audioDeviceReader` object from Audio Toolbox. For more information, see “Compatibility Considerations” on page 4-124.

Description

The `AudioRecorder` object records audio data using the computer's audio device.

To record audio data using the computer's audio device:

- 1 Define and set up your audio recorder object. See “Construction” on page 4-121.
- 2 Call `step` to record audio data according to the properties of `dsp.AudioRecorder`. The behavior of `step` is specific to each object in the toolbox.

This System object buffers the data from a frame of data using the process illustrated by the following figure.

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj, x)` and `y = obj(x)` perform equivalent operations.

Construction

`H = dsp.AudioRecorder` returns an audio recorder object, `H`, that records audio samples using an audio input device in real-time.

`H = dsp.AudioRecorder('PropertyName', PropertyValue, ...)` returns an audio recorder object, `H`, with each property set to the specified value.

Properties

DeviceName

Device from which to acquire audio data

Specify the device from which to acquire audio data. The default is `Default`, which is the computer's standard input device. You can use tab completion to query valid `DeviceName` assignments for your computer by typing `H.DeviceName = '` and then pressing the tab key. The tab completion functionality shows all valid audio device names for your computer.

SampleRate

Number of samples per second read from audio device

Specify the number of samples per second in the signal as an integer. The default is 44100. This property is tunable.

NumChannels

Number of audio channels

Specify the number of audio channels as an integer. The default is 2.

DeviceDataType

Data type used by device

Specify the data type used by the device to acquire audio data as `Determine from output data type`, `8-bit integer`, `16-bit integer`, `24-bit integer`, or `32-bit float`. The default is `Determine from output data type`.

BufferSizeSource

Source of Buffer Size

Specify how to determine the buffer size as `Auto` or `Property`. The default is `Auto`.

BufferSize

Buffer size

Specify as an integer the size of the buffer that the audio recorder object uses to communicate with the audio device. This property applies when you set the `BufferSizeSource` property to `Property`. The default is 4096. This property is tunable. Tuning this property involves a balance between device latency and the possibility of dropping data (buffer underrun). The instant you receive the buffer from a device, you have samples that are relatively new and samples that are at least as old as the size of the buffer. Therefore, the buffer size introduces latency, which is the time required for the device to fill the queue and the buffer. `BufferSize` is half the size of the sound card buffer. The size of the buffer processed in each interrupt from the audio device affects the performance of the system. A frame of data cannot pass through the queue until the buffer is filled by the device, thus introducing latency. `BufferSize` has to be smaller than the effective queue duration. To set the `BufferSize` to a value other than the default, first change the `BufferSizeSource` to 'Property'. You can select `BufferSize` from the list of properties.

QueueDuration

Size of queue in seconds

Specify the length of the audio queue, in seconds. The default is 1.0. This property is tunable. The purpose of the queue is to control the trade-off between latency and data dropout. Latency is calculated by the following equation: $latency = \frac{QueueDuration \times SampleRate + 2 \times BufferSize}{SampleRate}$.

To minimize latency, lower the `QueueDuration` or set it to 0. However, be aware that data dropouts or loss of system robustness may result. The `QueueDuration` property specifies the duration of the signal, in seconds, that can be buffered during the simulation. This value is the maximum length of time that the System object data supply can lag the device's data demand. If the MATLAB data throughput rate is lower than the device throughput rate, a buffer overrun occurs. You can use `OutputNumOverrunSamples` to monitor overrun. To correct the overrun, make the queue duration larger than the buffer. If the MATLAB data throughput rate is higher than the device throughput rate, a buffer underrun occurs, causing the System object to wait for new samples to become available. To minimize the chance of dropouts, the System object checks to verify the queue duration is at least as large as the maximum of the buffer size and the frame size. If it is not, the queue duration is automatically set to this maximum value. At the start of the simulation, the queue is filled with silence. At each time step, the audio device sends a buffer of samples to the top of the queue.

SamplesPerFrame

Number of samples in the output signal

Specify the number of samples in the audio recorder's output as an integer. The default is 1024.

OutputDataType

Data type of the output

Select the output data type as `uint8`, `int16`, `int32`, `single`, or `double`. The default is `double`.

OutputNumOverrunSamples

Enable output of overrun count

Set to `true` to output the number of samples dropped due to queue overrun since the last call to the `step` method. The default is `false`.

ChannelMappingSource

Source of device channel mapping

Specify whether to determine the channel mapping as `'Auto'` or as `'Property'`. If you set the value of `ChannelMappingSource` to `'Auto'`, the `ChannelMapping` field is rendered inactive. If you set this property to `'Property'`, the vector specified in the `ChannelMapping` field is used to route the input. Additionally, the `NumChannels` field is rendered inactive, because the channel map contains information about the number of data channels that the user is attempting to read.

ChannelMapping

Device-to-data channel mapping

Vector of valid channel indices to represent the mapping between device input channels and the data. The term Channel Mapping refers to a 1-to-1 mapping that associates channels on the selected audio device to channels of the data. When you record audio, channel mapping allows you to specify which channel of the audio data directs input to a specific channel of audio. By default, the ChannelMapping field is [1:MAXNUMINPUTCHANNELS], where MAXNUMINPUTCHANNELS depends upon the selected device.

Methods

step Record audio from recording device

Common to All System Objects	
release	Allow System object property value changes

Troubleshooting

Running an Executable Outside MATLAB

To run your generated standalone executable application in Shell, you need to set your environment to the following:

Platform	Command

Topics

Set the Audio Hardware API on page 2-627

Introduced in R2012a

step

System object: dsp.AudioRecorder

Package: dsp

Record audio from recording device

Compatibility

The dsp.AudioRecorder object has been removed. Existing instances of the object error out. Replace with audioDeviceReader object from Audio Toolbox. For more information, see “Compatibility Considerations” on page 4-124.

Syntax

```
AUDIO = step(H)  
[AUDIO,Overrun] = step(H)
```

Description

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`AUDIO = step(H)` reads one frame of audio samples from the selected audio input device.

`[AUDIO,Overrun] = step(H)` reads one frame of audio samples from the selected audio input device. The output `Overrun` indicates the number of samples dropped due to queue overrun since the last call to the `step` method. This syntax applies when you set the “OutputNumOverrunSamples” on page 4-0 property to `true`.

dsp.Autocorrelator

Package: dsp

(To be removed) Autocorrelation sequence

Note `dsp.Autocorrelator` will be removed in a future release. Use `xcorr` instead. For more information, see “Compatibility Considerations”.

Description

The `Autocorrelator` object returns the autocorrelation sequence for a discrete-time, deterministic input, or the autocorrelation sequence estimate for a discrete-time, wide-sense stationary (WSS) random process at positive lags.

To obtain the autocorrelation sequence:

- 1 Create the `dsp.Autocorrelator` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

Creation

Syntax

```
ac = dsp.Autocorrelator
ac = dsp.Autocorrelator(Name,Value)
```

Description

`ac = dsp.Autocorrelator` returns an autocorrelator, `ac`, that computes the autocorrelation along the first dimension of an N -D array. By default, the autocorrelator computes the autocorrelation at lags from zero to $N - 1$, where N is the length of the input vector or the row dimension of the input matrix. Inputting a row vector results in a row of zero-lag autocorrelation sequence values, one for each column of the row vector. The default autocorrelator returns the unscaled autocorrelation and performs the computation in the time domain.

`ac = dsp.Autocorrelator(Name,Value)` returns an autocorrelator, `ac`, with each property set to the specified value.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see *System Design in MATLAB Using System Objects*.

MaximumLagSource — Source of maximum lag

Auto (default) | Property

Specify how to determine the range of lags for the autocorrelation as `Auto` or `Property`. If the value of `MaximumLagSource` is `Auto`, the autocorrelator computes the autocorrelation over all nonnegative lags in the interval $[0, N-1]$, where N is the length of the first dimension of the input. Otherwise, the object computes the autocorrelation using lags in the range $[0, \text{MaximumLag}]$.

MaximumLag — Maximum positive lag

1 (default) | 0 | positive integer

Specify the maximum lag as an integer greater than or equal to 0. The `MaximumLag` must be less than the length of the input data.

Dependencies

This property applies only when the `MaximumLagSource` property is `Property`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

Scaling — Autocorrelation function scaling

None (default) | Biased | Unbiased | Unity at zero-lag

Specify the scaling to apply to the output as `None`, `Biased`, `Unbiased`, or `Unity at zero-lag`. Set this property to `None` to generate the autocorrelation function without scaling. This option is appropriate if you are computing the autocorrelation of a nonrandom (deterministic) input.

The `Biased` option scales the autocorrelation by $1/N$, where N is the length of the input data. Scaling by $1/N$ yields a biased, finite-sample approximation to the theoretical autocorrelation of a WSS random process. In spite of the bias, scaling by $1/N$ has the desirable property that the sample autocorrelation matrix is nonnegative definite, a property possessed by the theoretical autocorrelation matrices of all wide-sense stationary random processes. The Fourier transform of the biased autocorrelation estimate is the *periodogram*, a widely used estimate of the power spectral density of a WSS process.

The `Unbiased` option scales the estimate of the autocorrelation by $1/N - 1$. Scaling by $N - 1$ produces an unbiased estimate of the theoretical autocorrelation. However, using the unbiased option, you can obtain an estimate of the autocorrelation function that fails to have the nonnegative definite property.

Use the `Unity at zero-lag` option to normalize the autocorrelation estimate as identically one at lag zero. The default is `None`.

Method — Domain for computing autocorrelations

Time Domain (default) | Frequency Domain

Specify the domain for computing autocorrelations as `Time Domain` or `Frequency Domain`. You must set this property to `Time Domain` for fixed-point signals.

Fixed-Point Properties

FullPrecisionOverride — Full precision override for fixed-point arithmetic

true (default) | false

Specify whether to use full precision rules. If you set `FullPrecisionOverride` to `true`, which is the default, the object computes all internal arithmetic and output data types using full precision rules. These rules provide the most accurate fixed-point numerics. It also turns off the display of other fixed-point properties because they do not apply individually. These rules guarantee that no quantization occurs within the object. Bits are added, as needed, to ensure that no roundoff or overflow occurs. If you set `FullPrecisionOverride` to `false`, fixed-point data types are controlled through individual fixed-point property settings. For more information, see “Full Precision for Fixed-Point System Objects”.

RoundingMethod — Rounding method for fixed-point operations

Floor (default) | Ceiling | Convergent | Nearest | Round | Simplest | Zero

Specify the rounding method as `Ceiling`, `Convergent`, `Floor`, `Nearest`, `Round`, `Simplest`, or `Zero`.

Dependencies

This property applies only when you set the `Method` property to `Time Domain` and the object is not in full precision mode.

OverflowAction — Overflow action for fixed-point operations

Wrap (default) | Saturate

Specify the overflow action as `Wrap` or `Saturate`.

Dependencies

This property applies only when you set the `Method` property to `Time Domain` and the object is not in full precision mode.

ProductDataType — Product word and fraction lengths

Full precision (default) | Same as input | Custom

Specify the product fixed-point data type as one of `Full precision`, `Same as input`, or `Custom`.

Dependencies

This property applies only when you set the `Method` property to `Time Domain`.

CustomProductDataType — Product word and fraction lengths

`numericType([,32,30])` (default) | `numericType`

Specify the product fixed-point type as a scaled `numericType` object with a `Signedness` of `Auto`.

Dependencies

This property applies only when you set the `Method` property to `Time Domain` and the `ProductDataType` property to `Custom`.

AccumulatorDataType — Accumulator word and fraction lengths

Full precision (default) | Same as product | Same as input | Custom

Specify the accumulator fixed-point data type as one of `Full precision`, `Same as product`, `Same as input`, or `Custom`.

Dependencies

This property applies only when the `Method` property is `Time Domain`.

CustomAccumulatorDataType — Accumulator word and fraction lengths`numerictype([],32,30) (default) | numerictype`

Specify the accumulator fixed-point type as a scaled `numerictype` object with a Signedness of `Auto`.

Dependencies

This property applies only when you set the `Method` property to `Time Domain` and the `AccumulatorDataType` property to `Custom`.

OutputDataType — Output word and fraction lengths`Same as accumulator (default) | Same as product | Same as input | Custom`

Specify the output fixed-point data type as `Same as accumulator`, `Same as product`, `Same as input`, or `Custom`.

Dependencies

This property applies only when the `Method` property is `Time Domain`.

CustomOutputDataType — Output word and fraction lengths`numerictype([],16,15) (default) | numerictype`

Specify the output fixed-point type as a scaled `numerictype` object with a Signedness of `Auto`.

Dependencies

This property applies only when you set the `Method` property to `Time Domain` and the `OutputDataType` property to `Custom`.

Usage**Syntax**`y = ac(x)`**Description**

`y = ac(x)` computes the autocorrelation sequence `y` for the columns of the input `x`.

Input Arguments**x — Data input**`vector | matrix | N-D array`

Data input, specified as a vector, matrix, or an *N*-D array. The object accepts real-valued or complex-valued multichannel and multidimensional inputs. The input can be a fixed-point signal when you set the `Method` property to `'Time Domain'`. When the input signal is complex, the output signal is complex.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fi`

Output Arguments

y — Autocorrelated output

vector | matrix | *N*-D array

Autocorrelated output of the two input signals. The size, data type, and complexity of the output matches that of the input signal.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fi`

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Common to All System Objects

`step` Run System object algorithm
`release` Release resources and allow changes to System object property values and input characteristics
`reset` Reset internal states of System object

Examples

Autocorrelation of Noisy Sine Wave

Note If you are using R2016a or an earlier release, replace each call to the object with the equivalent step syntax. For example, `obj(x)` becomes `step(obj,x)`.

Compute the autocorrelation of a sine wave in white Gaussian noise with approximate 95% upper and lower confidence limits.

```
S = rng('default');
% Sine wave with period N=4
x = 1.4*cos(pi/2*(1:100))'+randn(100,1);
MaxLag = 20;
ac = dsp.Autocorrelator('MaximumLagSource',...
'Property','MaximumLag',MaxLag,'Scaling','Unity at zero-lag');
SigAutocorr = ac(x);
stem(SigAutocorr,'b','markerfacecolor',[0 0 1]);
line(1:MaxLag+1,1.96/sqrt(100)*ones(MaxLag+1,1),...
'linestyle','-','linewidth',2);
line(1:MaxLag+1,-1.96/sqrt(100)*ones(MaxLag+1,1),...
'linestyle','-','linewidth',2);
axis([1 20 -1 1]);
title('Sine Wave + Noise Autocorrelation'); xlabel('Lag');
```

As the generated figure shows, the autocorrelation estimate demonstrates the four sample periodic sine wave with excursions outside the 95% white Gaussian noise confidence limits every two samples.

More About

Autocorrelation

Autocorrelation is the correlation of a signal with itself at different points in time.

For a deterministic discrete-time sequence, $x(n)$, the autocorrelation is computed using the following relationship:

$$r_x(h) = \sum_{n=0}^{N-h-1} x^*(n)x(n+h) \quad h = 0, 1, \dots, N-1$$

where h is the lag and $*$ denotes the complex conjugate. If the input is a length N realization of a WSS stationary random process, $r_x(h)$ is an estimate of the theoretical autocorrelation:

$$\rho_x(h) = E\{x^*(n)x(n+h)\}$$

where $E\{ \}$ is the expectation operator. The Unity at zero-lag normalization divides each sequence value by the autocorrelation or autocorrelation estimate at zero lag.

$$\frac{\rho_x(h)}{\rho_x(0)} = \frac{E\{x^*(n)x(n+h)\}}{E\{|x(0)|^2\}}$$

The most commonly used estimate of the theoretical autocorrelation of a WSS random process is the biased estimate:

$$\hat{\rho}_x(h) = \frac{1}{N} \sum_{k=0}^{N-h-1} x^*(k)x(k+h)$$

Algorithms

Time-Domain Computation

When you set the computation domain to time, the algorithm computes the autocorrelation of the input signal in the time domain. The input signal can be a fixed-point signal in this domain.

The autocorrelation sequence, y , is computed using this equation:

$$y_{i,j} = \sum_{k=0}^{M-l-1} u_{k,j}^* u_{(k+i),j} \quad 0 \leq i \leq l$$

- $y_{0,j}$ is the zero-lag element in the j th column of the input.
- i is the index of the lag.
- j is the index of the input data column.
- $*$ denotes the complex conjugate.
- M is the number of elements in each column.

- l is the maximum positive lag for autocorrelation. When you choose to compute the autocorrelation with all nonnegative lags, $l=M-1$. Otherwise, l is the maximum nonnegative integer lag value specified.
- u is an M -by- N input matrix.

Frequency-Domain Computation

When you set the computation domain to frequency, the algorithm computes the autocorrelation in the frequency domain.

In this domain, the algorithm computes the autocorrelation sequence by taking the Fourier transform of the input signal, multiplying the Fourier transform with its complex conjugate, and taking the inverse Fourier transform of the product. In this domain, depending on the input length, the algorithm can require fewer computations.

Compatibility Considerations

dsp.Autocorrelator System object will be removed

Warns starting in R2021b

`dsp.Autocorrelator` System object will be removed in a future release. Use the `xcorr` function instead.

Update Code

This table shows how the System object is typically used and explains how to update existing code to use the `xcorr` function.

Discouraged Usage	Recommended Replacement
<p>The function computes the correlation over nonnegative lags.</p> <p>No maximum lag specified</p> <p>When no maximum lag is specified, the object computes the autocorrelation using nonnegative lags $[0 (M - 1)]$, where M is the length of the first dimension of the input.</p> <pre>acObj = dsp.Autocorrelator; % x is a column vector x = (1:100)'; yObj = acObj(x); figure; stem(yObj)</pre> <p>Specify maximum lag</p> <p>When the maximum lag $MaxLag$ is specified, the object computes the autocorrelation using lags in the range $[0 MaxLag]$.</p> <pre>MaxLag = 20; acObjLag = dsp.Autocorrelator('MaximumLagSource', ... 'Property', 'MaximumLag', MaxLag); % x is a column vector x = (1:100)'; yObjLag = acObjLag(x); figure; stem(yObjLag)</pre> <p>If you are using a release prior to R2016b, replace <code>acObj(x)</code> with <code>step(acObj,x)</code> and <code>acObjLag(x)</code> with <code>step(acObjLag,x)</code>.</p>	<p>The function computes the correlation over both positive and negative lags.</p> <p>No maximum lag specified</p> <p>When no maximum lag is specified, the function computes the autocorrelation using lags in the range $[-(M - 1) (M - 1)]$.</p> <pre>[yfn,lags] = xcorr(x); figure; stem(lags,yfn)</pre> <p>Specify maximum lag</p> <p>When the maximum lag $MaxLag$ is specified, the function computes the autocorrelation using lags in the range $[-MaxLag MaxLag]$.</p> <pre>[yfnLag,lags] = xcorr(x,MaxLag); figure; stem(lags,yfnLag)</pre>

dsp.BinaryFileReader

Package: dsp

Read data from binary file

Description

The `dsp.BinaryFileReader` System object reads multichannel signal data from a binary file. If the header is not empty, then the header precedes the signal data. The System object specifies the prototype of the header, and the type, size, and complexity of the data. The first time you read the file, the reader reads the header, followed by the data. On subsequent calls, the reader reads the remaining data. Once the end of file is reached, the reader returns zeros of the specified data type, size, and complexity. The reader can read signal data from a binary file that is not created by the `dsp.BinaryFileWriter` System object.

The object accepts floating-point data or integer data. To read character data and fixed-point data, see the “Write and Read Character Data” on page 4-146 and “Write and Read Fixed-Point Data” on page 4-145 examples. The input data can be real or complex. When the data is complex, the object reads the data as interleaved real and imaginary components. For an example, see “Read Complex Data” on page 4-144. The reader assumes the default endianness of the host machine. To change the endianness, you can use the `swapbytes` function. For an example, see “Change Endianness of Data” on page 4-147.

To read data from a binary file:

- 1 Create the `dsp.BinaryFileReader` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

Creation

Syntax

```
reader = dsp.BinaryFileReader
reader = dsp.BinaryFileReader(fname)
reader = dsp.BinaryFileReader(fname,Name,Value)
```

Description

`reader = dsp.BinaryFileReader` creates a binary file reader object, `reader`, using the default properties.

`reader = dsp.BinaryFileReader(fname)` sets the `Filename` property to `fname`.

`reader = dsp.BinaryFileReader(fname,Name,Value)` with `Filename` set to `fname`, and each specified property set to the specified value. Unspecified properties have default values.

```
Example: reader =  
dsp.BinaryFileReader('myFilename.bin','SamplesPerFrame',1000,'NumChannels',2)  
;
```

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see *System Design in MATLAB Using System Objects*.

Filename — Name of file

'Untitled.bin' (default) | character vector | string scalar

Name of the file from which the object reads the data, specified as a character vector. If the file is not on the MATLAB path, then specify the full path for the file.

HeaderStructure — Size of header

struct('Field1',[]) (default) | structure

The structure specifies the prototype of the file header, that is, the size of the header and the data type of the field values. The structure can have an arbitrary number of fields. Each field of the structure must be a real matrix of a built-in type. For example, if `HeaderStructure` is set to `struct('field1',1:10,'field2',single(1))`, the object assumes that the header is formed by 10 real double-precision values followed by 1 single-precision value. If the file contains no header, you can set this property to an empty structure, `struct([])`. To retrieve the file header, call the `readHeader` method on the reader object.

SamplesPerFrame — Number of samples per output frame

1024 (default) | positive integer

Number of samples per output frame, specified as a positive integer. `SamplesPerFrame` specifies the number of rows of the output matrix that the object returns. The size of the data is `SamplesPerFrame-by-NumChannels`. Once the end of file is reached, the reader returns zeros of the specified data type, size, and complexity.

NumChannels — Number of channels

1 (default) | positive integer

Number of channels, specified as a positive integer. `NumChannels` specifies the number of columns of the output matrix that the object returns. This property defines the number of consecutive interleaved data samples stored in the file for each time instant. The size of the data is `SamplesPerFrame-by-NumChannels`. Once the end of file is reached, if the output matrix is not full, the object fills the matrix with zeros to make it a full-sized matrix.

DataType — Type of data in file

'double' (default) | 'single' | 'int8' | 'int16' | 'int32' | 'int64' | 'uint8' | 'uint16' | 'uint32' | 'uint64'

Type of data in file, specified as a character vector. This property defines the data type of the matrix returned by the object algorithm.

IsDataComplex — Specify data complexity`false` (default) | `true`

Option to specify data complexity, specified as `false` or `true`. When this property is set to `true`, the reader treats the data as complex. The object reads the data as interleaved real and imaginary components. Consider a reader object configured to read the data as a 2-by-2 matrix. The object reads `[1 5 2 6 3 7 4 8]` as `[1 2; 3 4]+1j*[5 6; 7 8]`. If this property is set to `false`, the same object reads the data as `[1 5; 2 6]`.

Usage**Syntax**`data = reader()`**Description**

`data = reader()` reads data from the binary file in a row-major format. The data type, size, and complexity of the data are determined by the properties of the reader object. Once the end of file is reached, the output contains zeros of the specified data type, size, and complexity.

Output Arguments**data — Data output**`vector` | `matrix`

Data read by the binary file reader, returned as a vector or a matrix. The size of the data is given by `SamplesPerFrame-by-NumChannels`, where `SamplesPerFrame` and `NumChannels` are the properties of the `dsp.BinaryFileReader` object.

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

`release(obj)`**Specific to dsp.BinaryFileReader**`isDone` End-of-data status`readHeader` Read file header**Common to All System Objects**`step` Run System object algorithm`release` Release resources and allow changes to System object property values and input characteristics`reset` Reset internal states of System object**Examples**

Write and Read Binary Files

Create a binary file with a custom header using the `dsp.BinaryFileWriter` System object. Write data to this file. Read the header and data using the `dsp.BinaryFileReader` System object.

Write the Data

Specify the file header as a structure with the following fields:

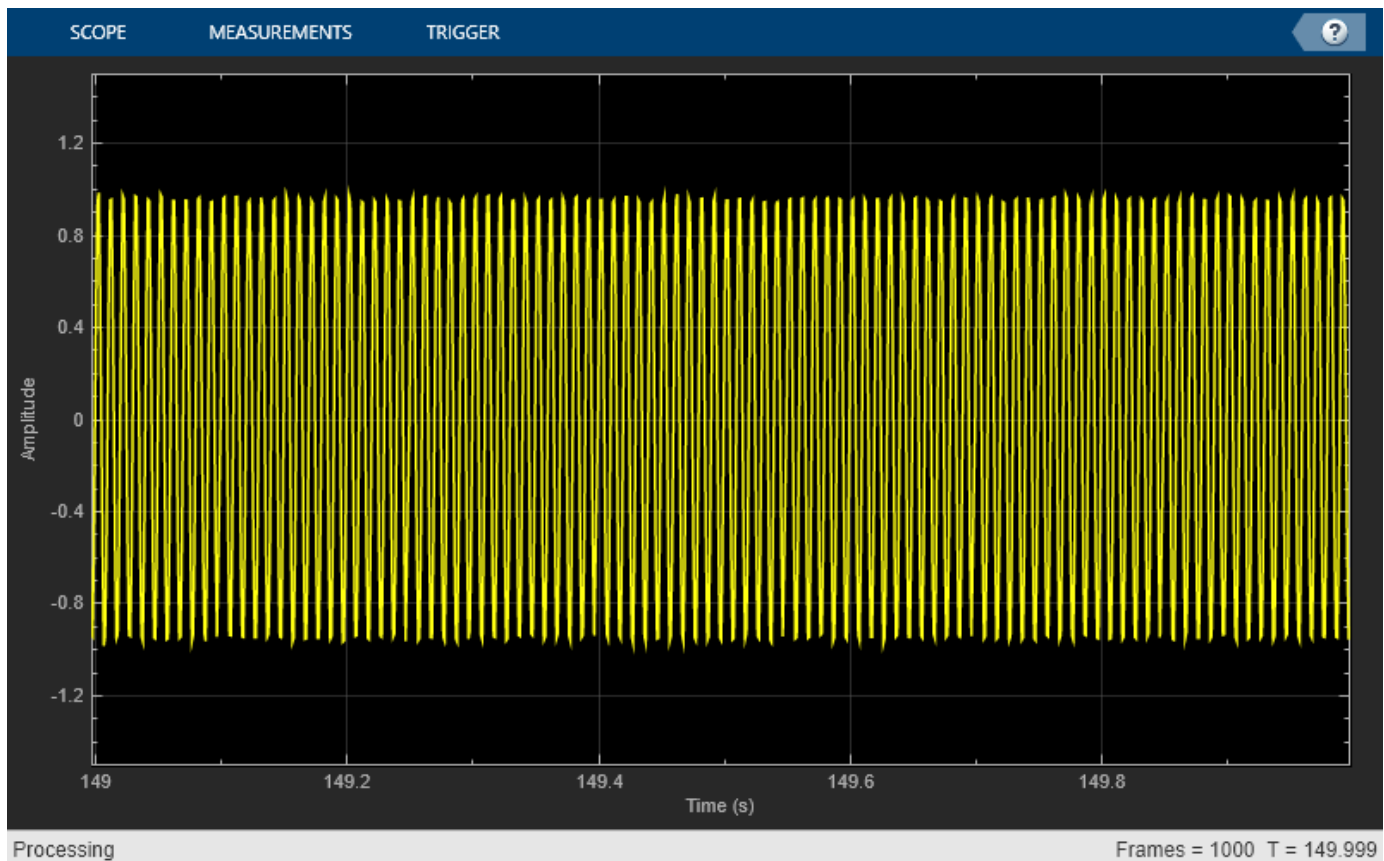

- `DataType` set to `double`.
- `Complexity` set to `false`.
- `FrameSize` (number of rows in the data matrix) set to 150.
- `NumChannels` (number of columns in the data matrix) set to 1.

Create a `dsp.BinaryFileWriter` object using this header. The object writes the header first, followed by the data, to `ex_file.bin`. The data is a noisy sine wave signal. View the data in a time scope.

```
L = 150;
header = struct('DataType','double',...
    'Complexity',false,...
    'FrameSize',L,...
    'NumChannels',1);
writer = dsp.BinaryFileWriter('ex_file.bin',...
    'HeaderStructure',header);

sine = dsp.SineWave('SamplesPerFrame',L);
scopewriter = timescope('YLimits',[-1.5 1.5],...
    'SampleRate',sine.SampleRate,...
    'TimeSpanSource','Property',...
    'TimeSpan',1);

for i = 1:1000
    data = sine() + 0.01*randn(L,1);
    writer(data);
    scopewriter(data)
end
```

Release the writer so that the reader can access the data from this file.

```
release(writer);
```

Read the Data

Read the data from the binary file, `ex_file.bin`, using the `dsp.BinaryFileReader` object. The file contains the header data followed by the actual data. The object reads the binary data until the end of file is reached. Specify the header to the reader using the `HeaderStructure` property of the reader object.

If the exact header is not known on the reader side, you must at least specify the prototype of the header. That is, the number of fields, and the data type, size, and complexity of each field in the prototype must match with the header data written to the binary file. When the `readHeader` function reads the data from the binary file, the function extracts the header information based on how the fields are specified in the header prototype. For example, a header field set to `'double'` on the writer side can be specified as any string of 6 characters on the reader side. The `readHeader` function reads this field as a string of 6 characters from the binary file, which matches with `'double'`.

```
headerPrototype = struct('DataType','datatype',...
    'Complexity',false,...
    'FrameSize',1,...
    'NumChannels',10);
reader = dsp.BinaryFileReader(...
    'ex_file.bin',...
```

```
'HeaderStructure',headerPrototype);  
headerReader = readHeader(reader)
```

```
headerReader =  
  
    struct with fields:  
  
        DataType: 'double'  
        Complexity: 0  
        FrameSize: 150  
        NumChannels: 1
```

The header data extracted by the `readHeader` function is assigned to the corresponding properties of the reader object.

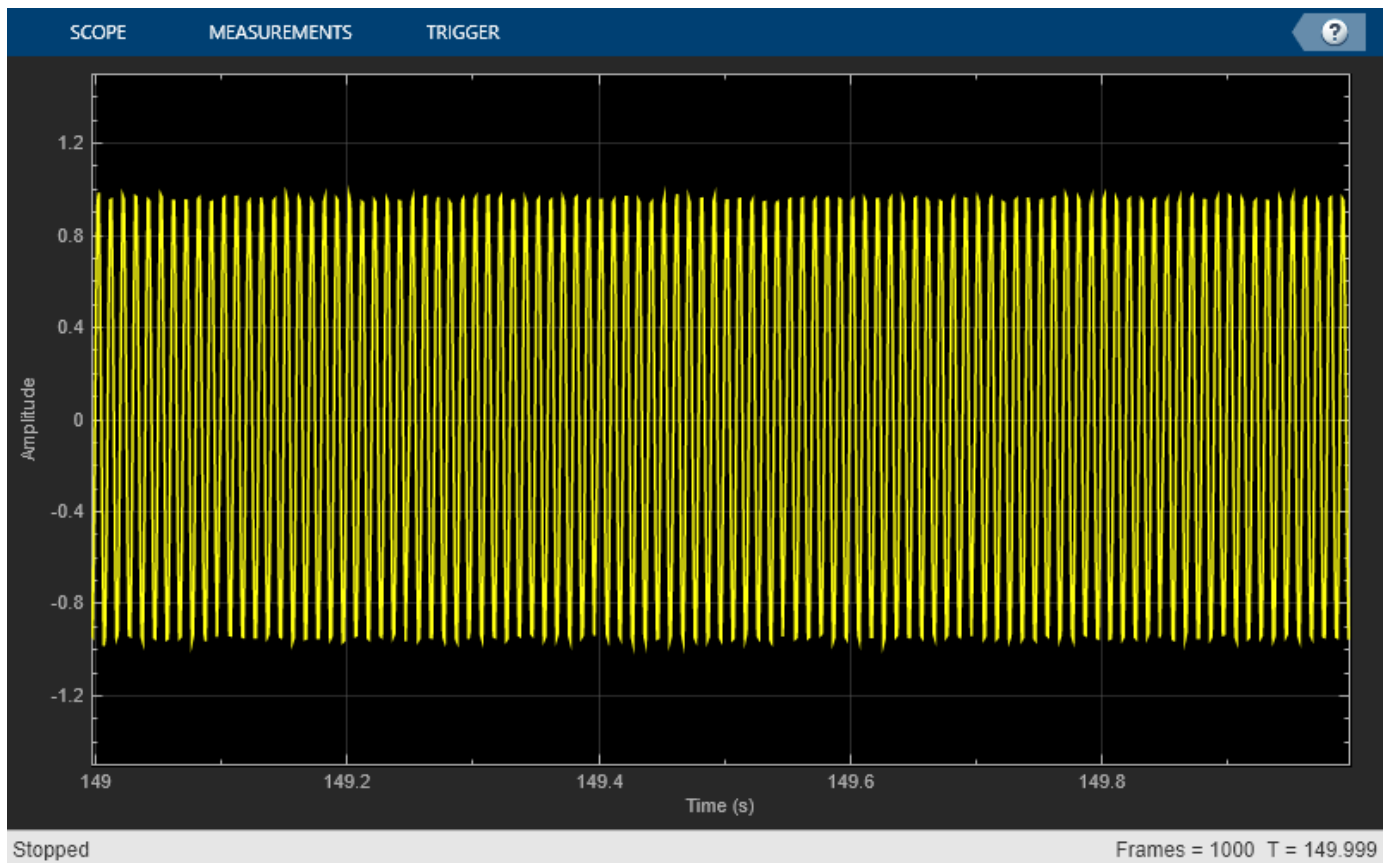

```
reader.IsDataComplex = headerReader.Complexity;  
reader.DataType = headerReader.DataType;  
reader.NumChannels = headerReader.NumChannels;  
reader.SamplesPerFrame = headerReader.FrameSize;
```

Initialize a scope on the reader side to view the extracted binary file data.

```
scopereader = timescope('YLimits',[-1.5 1.5],...  
    'SampleRate',sine.SampleRate,...  
    'TimeSpanSource','Property',...  
    'TimeSpan',1);
```

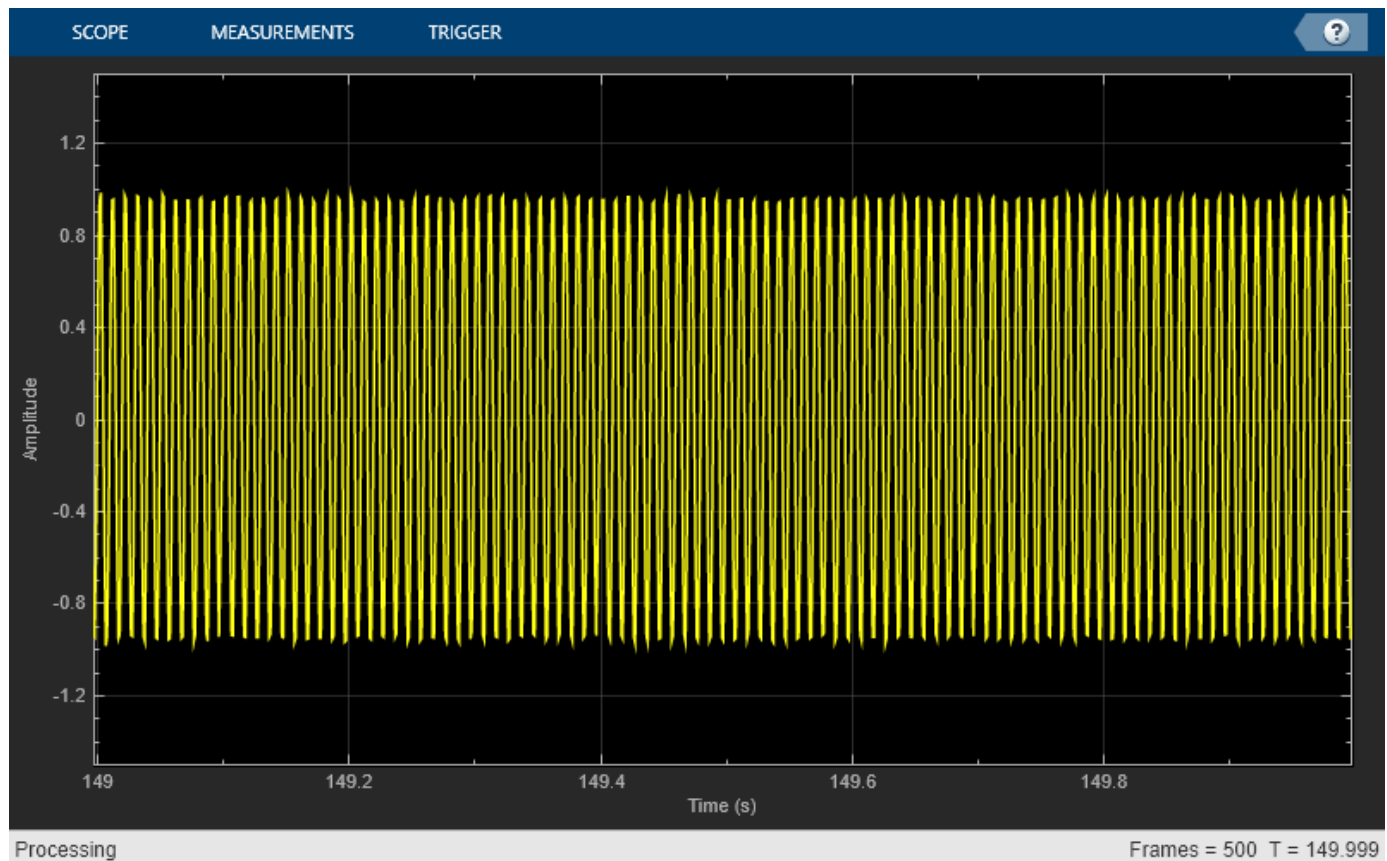

The data is read into a single channel (column) containing multiple frames, where each frame has 150 samples. View the data in a time scope.

```
while ~isDone(reader)  
    out = reader();  
    scopereader(out)  
end  
release(reader);  
release(scopereader);
```

Set the reader to read data in frames of size 300. Verify that the data read matches the data written to the file.

```
reader.SamplesPerFrame = 300;  
while ~isDone(reader)  
    out = reader();  
    scopereader(out)  
end  
release(reader);
```

Even when the reader reads data with a different frame size, the output in both time scopes matches exactly.

Write and Read Matrix Data

Use a `dsp.BinaryFileReader` System object™ to read data from a binary file in a row-major format.

Write the Data

Write the matrix `A` to the binary file `Matdata.bin` using a `dsp.BinaryFileWriter` object. The object writes the specified header followed by the data.

The header has the following format:

- `DataType` set to `double`.
- `Complexity` set to `false`.
- `FrameSize` (number of rows in the data matrix) set to 3.
- `NumChannels` (number of columns in the data matrix) set to 4.

```
A = [1 2 3 8; 4 5 6 10; 7 8 9 11];
header = struct('DataType','double',...
    'Complexity',false,...
```

```

        'FrameSize',3,...
        'NumChannels',4);
writer = dsp.BinaryFileWriter('Matdata.bin',...
    'HeaderStructure',header);
writer(A);

```

Release the writer so that the reader can access the data.

```
release(writer);
```

Read the Data

Specify the header using the `HeaderStructure` property of the reader object. If the exact header is not known, you must at least specify the prototype of the header. That is, the number of fields, and the data type, size, and complexity of each field in the prototype must match with the header data written to the binary file. The `dsp.BinaryFileReader` object reads the binary file `Matdata.bin` until the end of file is reached. Configure the System object to read the data into 4 channels, with each channel containing 5 samples. Each loop of the iteration reads a channel (or frame) of data.

```

headerPrototype = struct('DataType','double',...
    'Complexity',false,...
    'FrameSize',5,...
    'NumChannels',4);
reader = dsp.BinaryFileReader('Matdata.bin',...
    'HeaderStructure',headerPrototype,...
    'NumChannels',4,...
    'SamplesPerFrame',5);
while ~isDone(reader)
    out = reader();
    display(out)
end

```

```
out = 5×4
```

1	2	3	8
4	5	6	10
7	8	9	11
0	0	0	0
0	0	0	0

Each frame of `out` contains frames of the matrix `A`, followed by zeros to complete the frame. The original matrix `A` contains 4 channels with 3 samples in each channel. The reader is configured to read data into 4 channels, with each channel containing 5 samples. Because there are not enough samples to complete the frame, the reader object appends zeros at the end of each frame.

Read Header Data

Read the header data from a binary file using the `readHeader` function.

Write a header, followed by the data to a binary file named `myfile.dat`. The header is a 1-by-4 matrix of double precision values, followed by a 5-by-1 vector of single-precision values. The data is a sequence of 1000 double-precision values.

```

fid = fopen('myfile.dat','w');
fwrite(fid,[1 2 3 4],'double');

```

```
fwrite(fid, single((1:5).'), 'single');  
fwrite(fid, (1:1000).', 'double');  
fclose(fid);
```

Read the header using a `dsp.BinaryFileReader` object. Specify the expected header structure. This structure specifies only the format of the expected binary file header and does not contain the exact values.

```
reader = dsp.BinaryFileReader('myfile.dat');  
s = struct('A', zeros(1,4), 'B', ones(5,1, 'single'));  
reader.HeaderStructure = s;
```

Read the header using the `readHeader` function.

```
H = readHeader(reader);  
fprintf('H.A: ')  
  
H.A:  
  
fprintf('%d ', H.A);  
  
1 2 3 4  
  
fprintf('\nH.A datatype: %s\n', class(H.A))  
  
H.A datatype: double  
  
fprintf('H.B: ')  
  
H.B:  
  
fprintf('%d ', H.B);  
  
1 2 3 4 5  
  
fprintf('\nH.B datatype: %s\n', class(H.B))  
  
H.B datatype: single
```

Read Complex Data

Read complex data from a binary file using the `dsp.BinaryFileReader` object.

Write a sequence of numbers to a binary file named `myfile.dat`. There is no header. The data is a 2-by-4 matrix of double-precision values. `fwrite` writes the data in a column-major format. That is, the 2-by-4 matrix `[1 2 3 4; 9 10 11 12]` is written as `[1 9 2 10 3 11 4 12]` in the binary file.

```
fid = fopen('myfile.dat', 'w');  
fwrite(fid, [1 2 3 4; 9 10 11 12], 'double');  
fclose(fid);
```

Specify the data to be complex using the `IsDataComplex` property. The object reads the data as interleaved real and imaginary components. The `SamplesPerFrame` and `NumChannels` properties specify the number of rows and columns of the output data. The header structure is specified as empty.

```
reader = dsp.BinaryFileReader('myfile.dat', 'SamplesPerFrame', 2, ...  
    'NumChannels', 2, 'IsDataComplex', true);
```

```

s = struct([]);
reader.HeaderStructure = s;
data = reader();
display(data);

data = 2x2 complex

    1.0000 + 9.0000i    2.0000 +10.0000i
    3.0000 +11.0000i    4.0000 +12.0000i

release(reader);

```

Alternatively, if you do not specify the data as complex, the reader reads the data as a SamplesPerFrame-by- NumChannel matrix of real values.

```

reader.IsDataComplex = false;
data = reader();
display(data);

data = 2x2

     1     9
     2    10

release(reader);

```

Write and Read Fixed-Point Data

The `dsp.BinaryFileWriter` and `dsp.BinaryFileReader` System objects do not support writing and reading fixed-point data. As a workaround, you can write the stored integer portion of the `fi` data, read the data, and use this value to reconstruct the `fi` data.

Write the Fixed-Point Data

Create an `fi` object to represent 100 signed random numbers with a word length of 14 and a fraction length of 12. Write the stored integer portion of the `fi` object to the data file `myFile.dat`. The built-in data type is `int16`, which can be computed using `class(storeIntData)`.

```

data = randn(100,1);
fiDataWriter = fi(data,1,14,12);
storeIntData = storedInteger(fiDataWriter);

writer = dsp.BinaryFileWriter('myFile.dat');
writer(storeIntData);

```

Release the writer so that the reader can access the data.

```
release(writer);
```

Read the Fixed-Point Data

Specify the reader to read the stored integer data as `int16` data with 100 samples per data frame. The real-world value of the fixed-point number can be represented using

$2^{(-fractionLength)(storedInteger)}$. If you know the signedness, word length, and fraction length of the fixed-point data, you can reconstruct the `fi` data using `fi(realValue, signedness, wordLength, fractionLength)`. In this example, the data is signed with a word length of 14 and a fraction length of 12.

```
reader = dsp.BinaryFileReader('Filename', 'myFile.dat', ...
    'SamplesPerFrame', 100, ...
    'DataType', 'int16');
data = reader();
fractionLength = 12;
wordLength = 14;
realValue = 2^(-fractionLength)*double(data);

fiDataReader = fi(realValue, 1, ...
    wordLength, fractionLength);
```

Verify that the writer data is the same as the reader data.

```
isequal(fiDataWriter, fiDataReader)

ans = logical
     1
```

Write and Read Character Data

The `dsp.BinaryFileWriter` and `dsp.BinaryFileReader` System objects do not support writing and reading characters. As a workaround, cast character data to one of the built-in data types and write the integer data. After the reader reads the data, convert the data to a character using the `char` function.

Write the Character Data

Cast a character into `uint8` using the `cast` function. Write the cast data to the data file `myFile.dat`.

```
data = 'binary_file';
castData = cast(data, 'uint8');
writer = dsp.BinaryFileWriter('myFile.dat');
writer(castData);
```

Release the writer so that the reader can access the data.

```
release(writer);
```

Read the uint8 Data

Configure the reader to read the cast data as `uint8` data.

```
reader = dsp.BinaryFileReader('myFile.dat', ...
    'DataType', 'uint8', ...
    'SamplesPerFrame', 11);
readerData = reader();
charData = char(readerData);
```

Verify that the writer data is the same as the reader data. By default, the reader returns the data in a column-major format.

```
strcmp(data,charData.')
```

```
ans = logical
     1
```

Change Endianness of Data

By default, the dsp.BinaryFileReader System object™ uses the endianness of the host machine. To change the endianness, such as when the host machine that writes the data does not have the same endianness as the host machine that reads the data, use the `swapbytes` function.

Write a numeric array into `myfile.dat` in big endian format. Read the data using the dsp.BinaryFileReader object. The reader object reads the data in little endian format.

```
fid = fopen('myfile.dat','w','b');
fwrite(fid,[1 2 3 4 5 6 7 8],'double');
fclose(fid);
reader = dsp.BinaryFileReader('myfile.dat','SamplesPerFrame',8);
x = reader();
display(x);
```

```
x = 8×1
10-318 ×
```

```
0.3039
0.0003
0.0104
0.0206
0.0256
0.0307
0.0357
0.0408
```

`x` does not match the original data. Change the endianness of `x` using the `swapbytes` function.

```
y = swapbytes(x);
display(y);
```

```
y = 8×1
```

```
1
2
3
4
5
6
7
8
```

`y` matches the original data.

Write data to binary files

Description

The `dsp.BinaryFileWriter` System object writes multichannel signal data to a binary file. If the header is not empty, then the header precedes the signal data. The object specifies the file name and the structure of the header. The first time you write to the file, the object writes the header, followed by the data. On subsequent calls, the object writes the remaining data. If the header is empty, then no header is written.

The object can write floating-point data and integer data. To write character data and fixed-point data, see “Write and Read Character Data” on page 4-158 and “Write and Read Fixed-Point Data” on page 4-157. The input data can be real or complex. When the data is complex, the object writes the data as interleaved real and imaginary components. For an example, see “Write and Read Fixed-Point Data” on page 4-157. By default, the writer uses the endianness of the host machine. To change the endianness, you can use the `swapbytes` function. For an example, see “Change Endianness of Data Before Writing” on page 4-158 .

To write data to a binary file:

- 1 Create the `dsp.BinaryFileWriter` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

Creation

Syntax

```
writer = dsp.BinaryFileWriter
writer = dsp.BinaryFileWriter(fname)
writer = dsp.BinaryFileWriter(fname,Name,Value)
```

Description

`writer = dsp.BinaryFileWriter` creates a binary file writer object, `writer`, using the default properties.

`writer = dsp.BinaryFileWriter(fname)` sets the `Filename` property to `fname`.

`writer = dsp.BinaryFileWriter(fname,Name,Value)` with `Filename` set to `fname` and each property `Name` set to the specified `Value`. Unspecified properties have default values.

Example: `writer = dsp.BinaryFileWriter('myFilename.bin','HeaderStructure',struct('field1',1:10,'field2',single(1)));`

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects.

Filename — Name of file

'untitled.bin' (default) | character vector | string scalar

Name of the file to which the object writes the data, specified as a character vector or a string scalar. You must specify the full path for the file.

HeaderStructure — Header to write at beginning of file

struct([]) (default) | structure

Header to write at the beginning of the file, specified as a structure. The structure can have an arbitrary number of fields. Each field of the structure must be a real matrix of a built-in type. For example, if `HeaderStructure` is set to `struct('field1',1:10,'field2',single(1))`, the object writes a header formed by 10 double-precision values, (1:10), followed by one single precision value, `single(1)`. If you do not specify a header, the object sets this property to an empty structure, `struct([])`.

Usage

Syntax

```
writer(data)
```

Description

`writer(data)` writes data to the binary file in a row-major format. Each call to the algorithm writes the elements of `data` at the end of the file. At the first call to the algorithm, the object writes the header first, followed by the data. If the header is empty, then no header is written.

The input data can be real or complex. For complex data, real and imaginary parts are interleaved. For example, if the data equals `[1 2; 3 4]+1j*[5 6; 7 8]`, then the object writes the elements as `1 5 2 6 3 7 4 8`.

Input Arguments

data — Data to be written to file

vector | matrix

Data to be written to the binary file in a row-major format, specified as a vector or a matrix. The object writes the data in row-major format. For example, if the input array is `[1 2 4 5; 8 7 9 2]`, the object writes the data as `[1 2 4 5 8 7 9 2]`.

The input data can be real or complex. For complex data, real and imaginary parts are interleaved. For example, if the data equals `[1 2; 3 4]+1j*[5 6; 7 8]`, then the object writes the elements as `[1 5 2 6 3 7 4 8]`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Common to All System Objects

<code>step</code>	Run System object algorithm
<code>release</code>	Release resources and allow changes to System object property values and input characteristics
<code>reset</code>	Reset internal states of System object

Examples

Write and Read Binary Files

Create a binary file with a custom header using the `dsp.BinaryFileWriter` System object. Write data to this file. Read the header and data using the `dsp.BinaryFileReader` System object.

Write the Data

Specify the file header as a structure with the following fields:

- `DataType` set to `double`.
- `Complexity` set to `false`.
- `FrameSize` (number of rows in the data matrix) set to 150.
- `NumChannels` (number of columns in the data matrix) set to 1.

Create a `dsp.BinaryFileWriter` object using this header. The object writes the header first, followed by the data, to `ex_file.bin`. The data is a noisy sine wave signal. View the data in a time scope.

```
L = 150;
header = struct('DataType','double',...
    'Complexity',false,...
    'FrameSize',L,...
    'NumChannels',1);
writer = dsp.BinaryFileWriter('ex_file.bin',...
    'HeaderStructure',header);

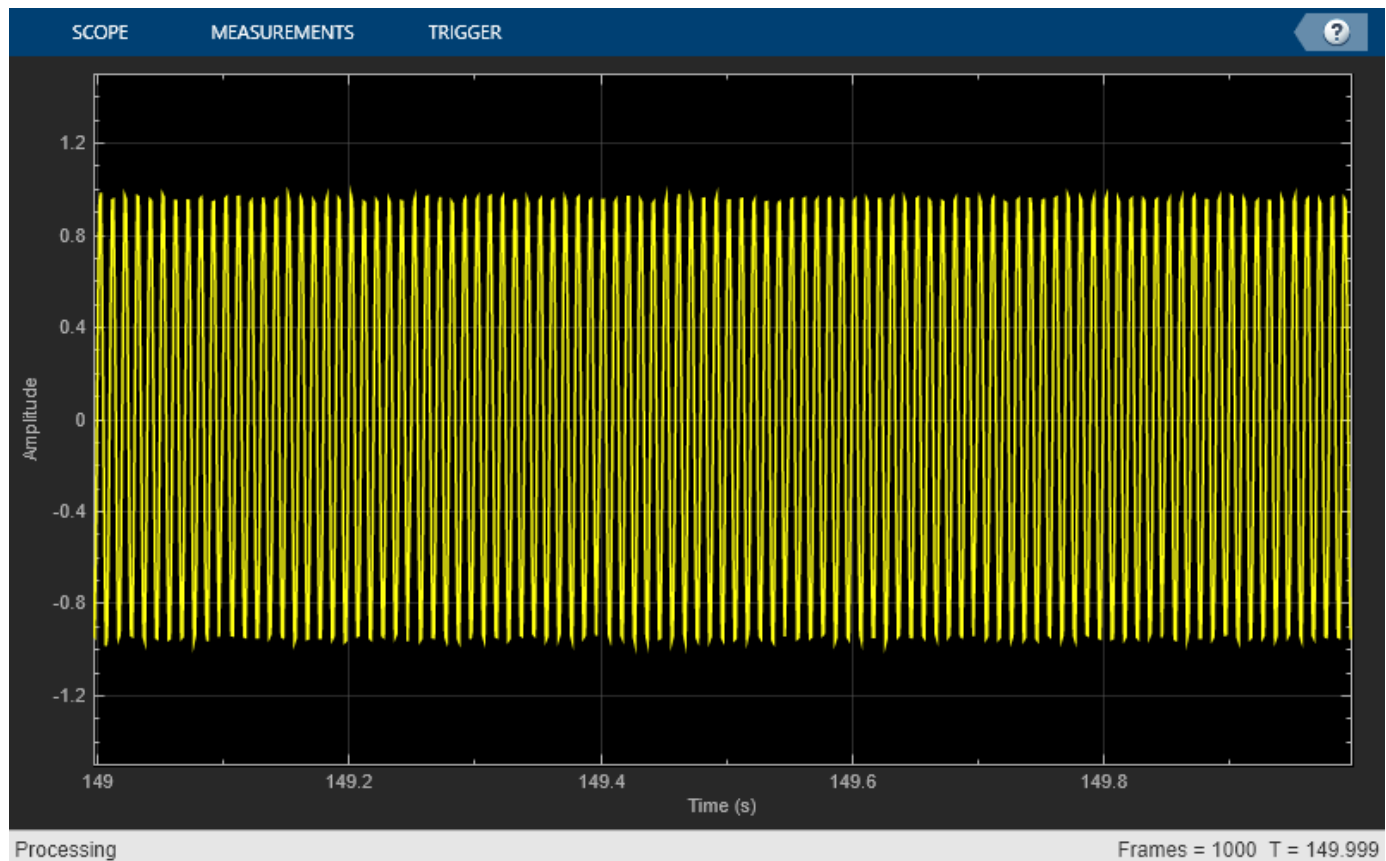

sine = dsp.SineWave('SamplesPerFrame',L);
scopewriter = timescope('YLimits',[-1.5 1.5],...
    'SampleRate',sine.SampleRate,...
    'TimeSpanSource','Property',...
    'TimeSpan',1);

for i = 1:1000
    data = sine() + 0.01*randn(L,1);
    writer(data);
end
```

```

        scopewriter(data)
    end

```

Release the writer so that the reader can access the data from this file.

```
release(writer);
```

Read the Data

Read the data from the binary file, `ex_file.bin`, using the `dsp.BinaryFileReader` object. The file contains the header data followed by the actual data. The object reads the binary data until the end of file is reached. Specify the header to the reader using the `HeaderStructure` property of the reader object.

If the exact header is not known on the reader side, you must at least specify the prototype of the header. That is, the number of fields, and the data type, size, and complexity of each field in the prototype must match with the header data written to the binary file. When the `readHeader` function reads the data from the binary file, the function extracts the header information based on how the fields are specified in the header prototype. For example, a header field set to `'double'` on the writer side can be specified as any string of 6 characters on the reader side. The `readHeader` function reads this field as a string of 6 characters from the binary file, which matches with `'double'`.

```

headerPrototype = struct('DataType','datatype',...
    'Complexity',false,...
    'FrameSize',1,...

```

```

        'NumChannels',10);
reader = dsp.BinaryFileReader(...
    'ex_file.bin',...
    'HeaderStructure',headerPrototype);
headerReader = readHeader(reader)

```

```
headerReader =
```

```

    struct with fields:
        DataType: 'double'
        Complexity: 0
        FrameSize: 150
        NumChannels: 1

```

The header data extracted by the `readHeader` function is assigned to the corresponding properties of the reader object.

```

reader.IsDataComplex = headerReader.Complexity;
reader.DataType = headerReader.DataType;
reader.NumChannels = headerReader.NumChannels;
reader.SamplesPerFrame = headerReader.FrameSize;

```

Initialize a scope on the reader side to view the extracted binary file data.

```

scopereader = timescope('YLimits',[-1.5 1.5],...
    'SampleRate',sine.SampleRate,...
    'TimeSpanSource','Property',...
    'TimeSpan',1);

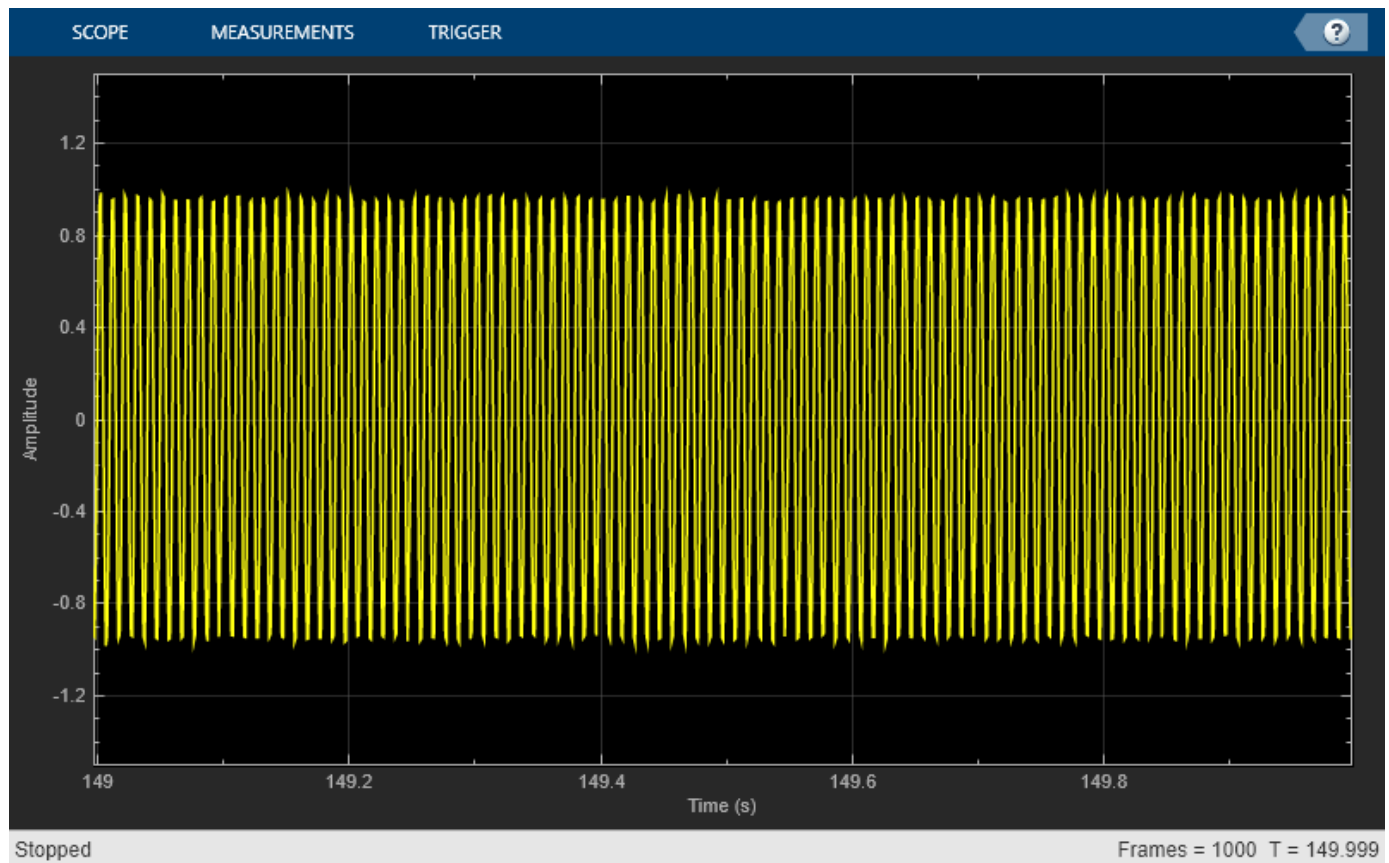

```

The data is read into a single channel (column) containing multiple frames, where each frame has 150 samples. View the data in a time scope.

```

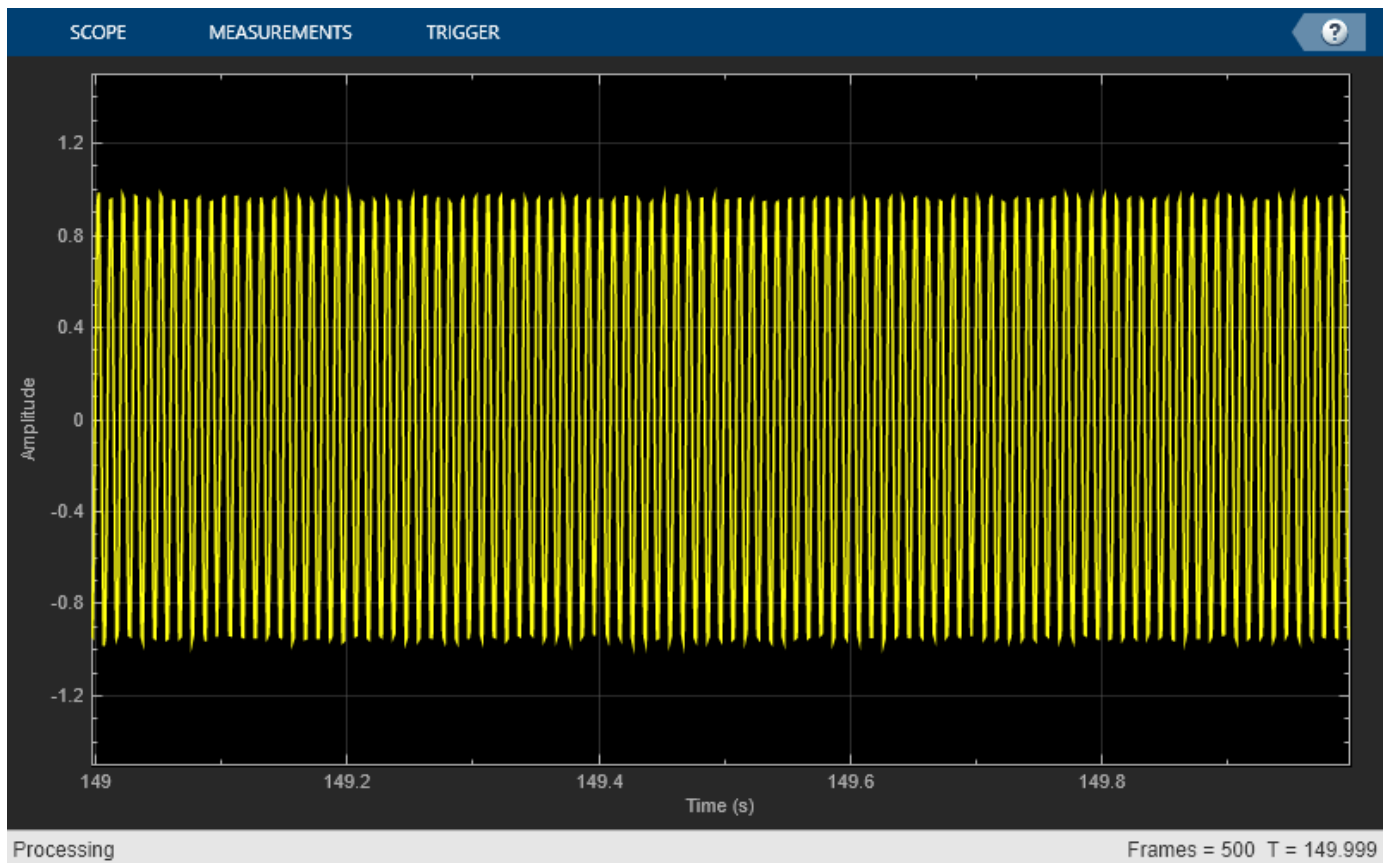

while ~isDone(reader)
    out = reader();
    scopereader(out)
end
release(reader);
release(scopereader);

```

Set the reader to read data in frames of size 300. Verify that the data read matches the data written to the file.

```
reader.SamplesPerFrame = 300;  
while ~isDone(reader)  
    out = reader();  
    scopereader(out)  
end  
release(reader);
```

Even when the reader reads data with a different frame size, the output in both time scopes matches exactly.

Write and Read Matrix Data

Use a `dsp.BinaryFileReader` System object™ to read data from a binary file in a row-major format.

Write the Data

Write the matrix `A` to the binary file `Matdata.bin` using a `dsp.BinaryFileWriter` object. The object writes the specified header followed by the data.

The header has the following format:

- `DataType` set to `double`.
- `Complexity` set to `false`.
- `FrameSize` (number of rows in the data matrix) set to 3.
- `NumChannels` (number of columns in the data matrix) set to 4.

```
A = [1 2 3 8; 4 5 6 10; 7 8 9 11];
header = struct('DataType','double',...
    'Complexity',false,...
```

```

        'FrameSize',3,...
        'NumChannels',4);
writer = dsp.BinaryFileWriter('Matdata.bin',...
    'HeaderStructure',header);
writer(A);

```

Release the writer so that the reader can access the data.

```
release(writer);
```

Read the Data

Specify the header using the `HeaderStructure` property of the reader object. If the exact header is not known, you must at least specify the prototype of the header. That is, the number of fields, and the data type, size, and complexity of each field in the prototype must match with the header data written to the binary file. The `dsp.BinaryFileReader` object reads the binary file `Matdata.bin` until the end of file is reached. Configure the System object to read the data into 4 channels, with each channel containing 5 samples. Each loop of the iteration reads a channel (or frame) of data.

```

headerPrototype = struct('DataType','double',...
    'Complexity',false,...
    'FrameSize',5,...
    'NumChannels',4);
reader = dsp.BinaryFileReader('Matdata.bin',...
    'HeaderStructure',headerPrototype,...
    'NumChannels',4,...
    'SamplesPerFrame',5);
while ~isDone(reader)
    out = reader();
    display(out)
end

```

```
out = 5x4
```

```

     1     2     3     8
     4     5     6    10
     7     8     9    11
     0     0     0     0
     0     0     0     0

```

Each frame of `out` contains frames of the matrix `A`, followed by zeros to complete the frame. The original matrix `A` contains 4 channels with 3 samples in each channel. The reader is configured to read data into 4 channels, with each channel containing 5 samples. Because there are not enough samples to complete the frame, the reader object appends zeros at the end of each frame.

Write Complex Data

Create a `dsp.BinaryFileWriter` object which writes to a file named `myfile.dat`. There is no header. The data is complex.

```

writer = dsp.BinaryFileWriter('myfile.dat');
data = [1 2 3 4]+1i*[5 6 7 8];
writer(data);
release(writer);

```

Read the data using the `dsp.BinaryFileReader` System object™. To view data in the format it is written to the file, set the `IsDataComplex` property to `false`. The reader object reads the data as a sequence of numbers in a row major format. Set `SamplesPerFrame` to 1 and `NumChannels` to 8.

```
reader = dsp.BinaryFileReader('myfile.dat','SamplesPerFrame',1,...
    'NumChannels',8);
s = struct([]);
reader.HeaderStructure = s;
dataRead = reader();
```

You can see that the real and imaginary components of the original data are sample interleaved.

```
display(dataRead);
```

```
dataRead = 1×8
```

```
    1    5    2    6    3    7    4    8
```

Write and Read Fixed-Point Data

The `dsp.BinaryFileWriter` and `dsp.BinaryFileReader` System objects do not support writing and reading fixed-point data. As a workaround, you can write the stored integer portion of the `fi` data, read the data, and use this value to reconstruct the `fi` data.

Write the Fixed-Point Data

Create an `fi` object to represent 100 signed random numbers with a word length of 14 and a fraction length of 12. Write the stored integer portion of the `fi` object to the data file `myFile.dat`. The built-in data type is `int16`, which can be computed using `class(storeIntData)`.

```
data = randn(100,1);
fiDataWriter = fi(data,1,14,12);
storeIntData = storedInteger(fiDataWriter);

writer = dsp.BinaryFileWriter('myFile.dat');
writer(storeIntData);
```

Release the writer so that the reader can access the data.

```
release(writer);
```

Read the Fixed-Point Data

Specify the reader to read the stored integer data as `int16` data with 100 samples per data frame. The real-world value of the fixed-point number can be represented using $2^{(-fractionLength)(storedInteger)}$. If you know the signedness, word length, and fraction length of the fixed-point data, you can reconstruct the `fi` data using `fi(realValue,signedness,wordLength,fractionLength)`. In this example, the data is signed with a word length of 14 and a fraction length of 12.

```
reader = dsp.BinaryFileReader('Filename','myFile.dat',...
    'SamplesPerFrame',100,...
    'DataType','int16');
```

```
data = reader();
fractionLength = 12;
wordLength = 14;
realValue = 2^(-fractionLength)*double(data);
```

```
fiDataReader = fi(realValue,1,...
    wordLength,fractionLength);
```

Verify that the writer data is the same as the reader data.

```
isequal(fiDataWriter,fiDataReader)
```

```
ans = logical
     1
```

Write and Read Character Data

The `dsp.BinaryFileWriter` and `dsp.BinaryFileReader` System objects do not support writing and reading characters. As a workaround, cast character data to one of the built-in data types and write the integer data. After the reader reads the data, convert the data to a character using the `char` function.

Write the Character Data

Cast a character into `uint8` using the `cast` function. Write the cast data to the data file `myFile.dat`.

```
data = 'binary_file';
castData = cast(data,'uint8');
writer = dsp.BinaryFileWriter('myFile.dat');
writer(castData);
```

Release the writer so that the reader can access the data.

```
release(writer);
```

Read the uint8 Data

Configure the reader to read the cast data as `uint8` data.

```
reader = dsp.BinaryFileReader('myFile.dat',...
    'DataType','uint8',...
    'SamplesPerFrame',11);
readerData = reader();
charData = char(readerData);
```

Verify that the writer data is the same as the reader data. By default, the reader returns the data in a column-major format.

```
strcmp(data,charData.')
```

```
ans = logical
     1
```

Change Endianness of Data Before Writing

By default, the `dsp.BinaryFileWriter` System object™ uses the endianness of the host machine. To change the endianness, use the `swapbytes` function.

Write a numeric array into `myfile.dat` using the `dsp.BinaryFileWriter` object. Before writing the data, change the endianness of the data using the `swapbytes` function.

```
data = [1 2 3 4 2 2];  
swapData = swapbytes(data);  
writer = dsp.BinaryFileWriter('myfile.dat');  
writer(swapData);
```

dsp.BiquadFilter

Package: dsp

IIR filter using biquadratic structures

Description

The `dsp.BiquadFilter` object implements a cascade of biquadratic sections, where the coefficients for each section are supplied by a separate row of an N -by-6 second-order sections (SOS) matrix. Each row of the SOS matrix contains the numerator and denominator coefficients of the corresponding section of the filter. The resulting filter can be applied to a vector or matrix input, where each column represents a channel of data that is processed independently.

To implement an IIR filter structure using biquadratic or SOS:

- 1 Create the `dsp.BiquadFilter` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

Creation

Syntax

```
biquad = dsp.BiquadFilter
biquad = dsp.BiquadFilter(sosmatrix,scalevalues)
biquad = dsp.BiquadFilter(Name,Value)
```

Description

`biquad = dsp.BiquadFilter` returns a biquadratic IIR (SOS) filter System object, `biquad`, which independently filters each channel (column) of the input over time using the SOS section `[1 0.3 0.4 1 0.1 0.2]` with a direct-form II transposed structure.

`biquad = dsp.BiquadFilter(sosmatrix,scalevalues)` returns a biquadratic filter object, with the `SOSMatrix` property set to `sosmatrix` and the `ScaleValues` property set to `scalevalues`.

`biquad = dsp.BiquadFilter(Name,Value)` returns a biquadratic filter object, `biquad`, with each property set to the specified value.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects.

Structure — Filter structure

'Direct form II transposed' (default) | 'Direct form I' | 'Direct form I transposed' | 'Direct form II'

Specify the filter structure as 'Direct form I', 'Direct form I transposed', 'Direct form II', 'Direct form II transposed'.

SOSMatrixSource — SOS matrix source

'Property' (default) | 'Input port'

Specify the source of the SOS matrix as 'Property' or 'Input port'.

SOSMatrix — SOS matrix

[1 0.3 0.4 1 0.1 0.2] (default) | N-by-6 matrix

Specify the second-order section (SOS) matrix as an N-by-6 matrix, where N is the number of sections in the filter. Each row of the SOS matrix contains the numerator and denominator coefficients of the corresponding section of the filter. The system function, $H(z)$, of a biquad filter is:

$$H(z) = \frac{\sum_{k=0}^2 b_k z^{-k}}{1 - \sum_{l=1}^2 a_l z^{-l}}$$

The coefficients are ordered in the rows of the SOS matrix as $(b_0, b_1, b_2, 1, -a_1, -a_2)$. You can use coefficients of real or complex values. This property applies only when you set the `SOSMatrixSource` property to `Property`. The leading denominator coefficient of the biquad filter, a_0 , equals 1 for each filter section, regardless of the specified value.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fi`

ScaleValues — Scale values for each biquad section

1 (default) | scalar | vector

Specify the scale values to apply before and after each section of a biquad filter. `ScaleValues` must be either a scalar or a vector of length N+1, where N is the number of sections. If you set this property to a scalar, the scalar value is used as the gain value only before the first filter section. The remaining gain values are set to 1. If you set this property to a vector of N+1 values, each value is used for a separate section of the filter.

Dependencies

This property applies only when you set the `SOSMatrixSource` property to `Property`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

InitialConditions — Initial conditions for direct form II structures

0 (default) | scalar | vector | matrix

Specify the initial conditions of the filter states when the `Structure` property is one of `Direct form II` | `Direct form II transposed`. The number of states or delay elements (zeros and

poles) in a direct-form II biquad filter equals twice the number of filter sections. You can specify the initial conditions as a scalar, vector, or matrix.

When you specify a scalar value, the biquad filter initializes all delay elements in the filter to that value. When you specify a vector of length equal to the number of delay elements in the filter, each vector element specifies a unique initial condition for the corresponding delay element.

The biquad filter applies the same vector of initial conditions to each channel of the input signal. When you specify a vector of length equal to the product of the number of input channels and the number of delay elements in the filter, each element specifies a unique initial condition for the corresponding delay element in the corresponding channel. When you specify a matrix with the same number of rows as the number of delay elements in the filter, and one column for each channel of the input signal, each element specifies a unique initial condition for the corresponding delay element in the corresponding channel.

Dependencies

This property applies only when you set the `Structure` property to one of `Direct form II` or `Direct form II transposed`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

NumeratorInitialConditions — Initial conditions on zeros side

0 (default) | `scalar` | `vector` | `matrix`

Specify the initial conditions of the filter states on the side of the filter structure with the zeros. The number of states or delay elements in the numerator of a direct-form I biquad filter equals twice the number of filter sections. You can specify the initial conditions as a scalar, vector, or matrix. When you specify a scalar, the biquad filter initializes all delay elements on the zeros side in the filter to that value. When you specify a vector of length equal to the number of delay elements on the zeros side in the filter, each vector element specifies a unique initial condition for the corresponding delay element on the zeros side.

The biquad filter applies the same vector of initial conditions to each channel of the input signal. When you specify a vector of length equal to the product of the number of input channels and the number of delay elements on the zeros side in the filter, each element specifies a unique initial condition for the corresponding delay element on the zeros side in the corresponding channel. When you specify a matrix with the same number of rows as the number of delay elements on the zeros side in the filter, and one column for each channel of the input signal, each element specifies a unique initial condition for the corresponding delay element on the zeros side in the corresponding channel.

Dependencies

This property applies only when you set the `Structure` property to one of `Direct form I` or `Direct form I transposed`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

DenominatorInitialConditions — Initial conditions on poles side

0 (default) | `scalar` | `vector` | `matrix`

Specify the initial conditions of the filter states on the side of the filter structure with the poles. The number of denominator states, or delay elements, in a direct-form I (noncanonic) biquad filter equals twice the number of filter sections. You can specify the initial conditions as a scalar, vector, or matrix. When you specify a scalar, the biquad filter initializes all delay elements on the poles side of the filter to that value. When you specify a vector of length equal to the number of delay elements on the poles

side in the filter, each vector element specifies a unique initial condition for the corresponding delay element on the poles side.

The object applies the same vector of initial conditions to each channel of the input signal. When you specify a vector of length equal to the product of the number of input channels and the number of delay elements on the poles side in the filter, each element specifies a unique initial condition for the corresponding delay element on the poles side in the corresponding channel. When you specify a matrix with the same number of rows as the number of delay elements on the poles side in the filter, and one column for each channel of the input signal, each element specifies a unique initial condition for the corresponding delay element on the poles side in the corresponding channel.

Dependencies

This property only applies when you set the `Structure` property to one of `Direct form I` or `Direct form I transposed`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

OptimizeUnityScaleValues — Optimize unity scale values

`true` (default) | `false`

When this Boolean property is set to `true`, the biquad filter removes all unity scale gain computations. This reduces the number of computations and increases the fixed-point accuracy.

Dependencies

This property applies only when you set the `SOSMatrixSource` property to `Property`.

ScaleValuesInputPort — How to specify scale values

`true` (default) | `false`

Select how to specify scale values. By default, this property is `true`, and the scale values are specified via the input port. When this property is `false`, all scale values are 1.

Dependencies

This property applies only when the `SOSMatrixSource` property is `Input port`.

Fixed-Point Properties

RoundingMethod — Rounding method for fixed-point operations

`Floor` (default) | `Ceiling` | `Convergent` | `Nearest` | `Round` | `Simplest` | `Zero`

Specify the rounding method.

OverflowAction — Overflow action for fixed-point operations

`Wrap` (default) | `Saturate`

Specify the overflow action as one of `Wrap` or `Saturate`.

MultiplicandDataType — Multiplicand word and fraction lengths

`Same as output` (default) | `Custom`

Specify the multiplicand fixed-point data type as one of `Same as output` or `Custom`.

Dependencies

This property applies only when you set the `Structure` property to `Direct form I transposed`.

CustomMultiplicandDataType — Custom multiplicand word and fraction lengths`numerictype([],32,30)` (default) | `numerictype`

Specify the multiplicand fixed-point type as a scaled `numerictype` object with a Signedness of `Auto`.

Dependencies

This property applies only when you set the `MultiplicandDataType` property to `Custom`.

SectionInputDataType — Section input word and fraction lengths`Same as input` (default) | `Custom`

Specify the section input fixed-point data type as either `Same as input` or `Custom`.

CustomSectionInputDataType — Custom section input word and fraction lengths`numerictype([],16,15)` (default) | `numerictype`

Specify the section input fixed-point type as a scaled `numerictype` object with a Signedness of `Auto`.

Dependencies

This property applies only when you set the `SectionInputDataType` property to `Custom`.

SectionOutputDataType — Section output word and fraction lengths`Same as section input` (default) | `Custom`

Specify the section output fixed-point data type as either `Same as section input` or `Custom`.

CustomSectionOutputDataType — Custom section output word and fraction lengths`numerictype([],16,15)` (default) | `numerictype`

Specify the section output fixed-point type as a signed, scaled `numerictype` object with a Signedness of `Auto`.

Dependencies

This property applies only when you set the `SectionOutputDataType` property to `Custom`.

NumeratorCoefficientsDataType — Numerator coefficients word and fraction lengths`Same word length as input` (default) | `Custom`

Specify the numerator coefficients fixed-point data type as `Same word length as input` or `Custom`. Setting this property also sets the `DenominatorCoefficientsDataType` and `ScaleValuesDataType` properties to the same value.

Dependencies

This property applies only when you set the `SOSMatrixSource` property to `Property`.

CustomNumeratorCoefficientsDataType — Custom numerator coefficients word and fraction lengths`numerictype([],16,15)` (default) | `numerictype`

Specify the numerator coefficients fixed-point type as a `numerictype` object with a Signedness of `Auto`. The word length of the `CustomNumeratorCoefficientsDataType`,

CustomDenominatorCoefficientsDataType, and CustomScaleValuesDataType properties must be the same.

Dependencies

This property applies only when you set the SOSMatrixSource property to Property and the NumeratorCoefficientsDataType property to Custom.

DenominatorCoefficientsDataType — Denominator coefficients word and fraction lengths

Same word length as input (default) | Custom

Specify the denominator coefficients fixed-point data type as Same word length as input or Custom. Setting this property also sets the NumeratorCoefficientsDataType and ScaleValuesDataType properties to the same value.

Dependencies

This property applies only when you set the SOSMatrixSource property to Property.

CustomDenominatorCoefficientsDataType — Custom denominator coefficients word and fraction lengths

numericType([],16,15) (default) | numericType

Specify the denominator coefficients fixed-point type as a numericType object with a Signedness of Auto. The CustomNumeratorCoefficientsDataType, CustomDenominatorCoefficientsDataType, and CustomScaleValuesDataType properties must have the same word lengths.

Dependencies

This property applies only when you set the SOSMatrixSource property to Property and the DenominatorCoefficientsDataType property to Custom.

ScaleValuesDataType — Scale values word and fraction lengths

Same word length as input (default) | Custom

Specify the scale values fixed-point data type as Same word length as input or Custom. Setting this property also sets the NumeratorCoefficientsDataType and DenominatorCoefficientsDataType properties to the same value.

Dependencies

This property applies only when you set the SOSMatrixSource property to Property.

CustomScaleValuesDataType — Custom scale values word and fraction lengths

numericType([],16,15) (default) | numericType

Specify the scale values fixed-point type as a numericType object with a Signedness of Auto. The CustomNumeratorCoefficientsDataType, CustomDenominatorCoefficientsDataType, and CustomScaleValuesDataType properties must have the same word lengths.

Dependencies

This property applies only when you set the SOSMatrixSource property to Property and the ScaleValuesDataType property to Custom.

NumeratorProductDataType — Numerator product word and fraction lengths

Same as input (default) | Custom | Full precision

Specify the mode to determine the numerator product fixed-point data type as:

- `Same as input` (default) — The numerator product word and fraction lengths are same as that of the input.
- `Custom` — Enables the `CustomNumeratorProductDataType` property, which you can use to specify the custom numerator product data type. Specify the data type as a `numericType` object.
- `Full precision` — Use full-precision rules to specify the data type. These rules provide the most accurate fixed-point numerics. The rules prevent quantization from occurring within the object. Bits are added, as needed, so that no roundoff or overflow occurs. For more information, see “Full Precision for Fixed-Point System Objects”.

Setting this property also sets the `DenominatorProductDataType` property to the same value.

CustomNumeratorProductDataType — Custom numerator product word and fraction lengths

`numericType([], 32, 30)` (default) | `numericType`

Specify the product fixed-point type as a scaled `numericType` object with a `Signedness` of `Auto`. The `CustomNumeratorProductDataType` and `CustomDenominatorProductDataType` properties must have the same word lengths.

Dependencies

This property applies only when you set the `NumeratorProductDataType` property to `Custom`.

DenominatorProductDataType — Denominator product word and fraction lengths

`Same as input` (default) | `Custom` | `Full precision`

Specify the mode to determine the denominator product fixed-point data type as:

- `Same as input` (default) — The denominator product word and fraction lengths are same as that of the input.
- `Custom` — Enables the `CustomDenominatorProductDataType` property, which you can use to specify the custom denominator product data type. Specify the data type as a `numericType` object.
- `Full precision` — Use full-precision rules to specify the data type. These rules provide the most accurate fixed-point numerics. The rules prevent quantization from occurring within the object. Bits are added, as needed, so that no roundoff or overflow occurs. For more information, see “Full Precision for Fixed-Point System Objects”.

Setting this property also sets the `NumeratorProductDataType` property to the same value.

CustomDenominatorProductDataType — Custom denominator product word and fraction lengths

`numericType([], 32, 30)` (default) | `numericType`

Specify the product fixed-point type as a scaled `numericType` object with a `Signedness` of `Auto`. The `CustomNumeratorProductDataType` and `CustomDenominatorProductDataType` properties must have the same word lengths.

Dependencies

This property applies only when you set the `DenominatorProductDataType` to `Custom`.

NumeratorAccumulatorDataType — Numerator accumulator word and fraction lengths

Same as product (default) | Same as input | Custom

Specify the numerator accumulator fixed-point data type as Same as input, Same as product, or Custom. Setting this property also sets the DenominatorAccumulatorDataType property to the same value.

CustomNumeratorAccumulatorDataType — Custom numerator accumulator word and fraction lengths

numericitytype([],32,30) (default) | numericitytype

Specify the numerator accumulator fixed-point type as a scaled numericitytype object with a Signedness of Auto. The CustomNumeratorAccumulatorDataType and CustomDenominatorAccumulatorDataType properties must have the same word lengths.

Dependencies

This property applies only when you set the NumeratorAccumulatorDataType property to Custom.

DenominatorAccumulatorDataType — Denominator accumulator word and fraction lengths

Same as product (default) | Same as input | Custom

Specify the denominator accumulator fixed-point data type as Same as input, Same as product, or Custom. Setting this property also sets the NumeratorAccumulatorDataType property to the same value.

CustomDenominatorAccumulatorDataType — Custom denominator accumulator word and fraction lengths

numericitytype([],32,30) (default) | numericitytype

Specify the denominator accumulator fixed-point type as a scaled numericitytype object with a Signedness of Auto. The CustomNumeratorAccumulatorDataType and CustomDenominatorAccumulatorDataType properties must have the same word lengths.

Dependencies

This property applies only when you set the DenominatorAccumulatorDataType property to Custom.

StateDataType — State word and fraction lengths

Same as accumulator (default) | Same as input | Custom

Specify the state fixed-point data type as Same as input, Same as accumulator, or Custom.

Dependencies

This property applies when you set the “Structure” on page 4-0 property to Direct form II or Direct form II transposed.

CustomStateDataType — Custom state word and fraction lengths

numericitytype([],16,15) (default) | numericitytype

Specify the state fixed-point type as a scaled numericitytype object with a Signedness of Auto.

Dependencies

This property applies only when you set the StateDataType property to Custom.

NumeratorStateDataType — Numerator state word and fraction lengths

Same as accumulator (default) | Same as input | Custom

Specify the numerator state fixed-point data type as Same as input, Same as accumulator, or Custom. Setting this property also sets the DenominatorStateDataType property to the same value.

Dependencies

This property applies only when you set the “Structure” on page 4-0 property to Direct form I transposed.

CustomNumeratorStateDataType — Custom numerator state word and fraction lengths

numericType([],16,15) (default) | numericType

Specify the numerator state fixed-point type as a scaled numericType object with a Signedness of Auto. The CustomNumeratorProductDataType and CustomDenominatorProductDataType properties must have the same word lengths.

Dependencies

This property applies only when you set the StateDataType property to Custom.

DenominatorStateDataType — Denominator state word and fraction lengths

Same as accumulator (default) | Same as input | Custom

Specify the denominator state fixed-point data type as Same as input, Same as accumulator, or Custom. Setting this property also sets the NumeratorStateDataType property to the same value.

Dependencies

This property applies only when you set the “Structure” on page 4-0 property to Direct form I transposed.

CustomDenominatorStateDataType — Custom denominator state word and fraction lengths

numericType([],16,15) (default) | numericType

Specify the denominator state fixed-point type as a scaled numericType object with a Signedness of Auto. The CustomNumeratorStateDataType and CustomDenominatorStateDataType properties must have the same word lengths.

Dependencies

This property applies only when you set the StateDataType property to Custom.

OutputDataType — Output word and fraction lengths

Same as accumulator (default) | Same as input | Custom

Specify the output fixed-point data type as Same as input, Same as accumulator, or Custom.

CustomOutputDataType — Custom output word and fraction lengths

numericType([],16,15) (default) | numericType

Specify the output fixed-point type as a scaled numericType object with a Signedness of Auto.

Dependencies

This property applies only when you set the “OutputDataType” on page 4-0 property to Custom.

Usage

Syntax

```
y = biquad(x)
y = biquad(x,num,den)
y = biquad(x,num,den,g)
```

Description

`y = biquad(x)` filters the input signal `x`, and outputs the filtered values, `y`. The biquad filter object filters each channel of the input signal over successive calls to the algorithm.

`y = biquad(x,num,den)` filters the input using `num` as the numerator coefficients, and `den` as the denominator coefficients of the biquad filter. This configuration applies when the `SOSMatrixSource` property is `Input port` and the `ScaleValuesInputPort` property is `false`.

`y = biquad(x,num,den,g)` specifies the scale values, `g`, of the biquad filter. This configuration applies when the `SOSMatrixSource` property is `Input Port` and the `ScaleValuesInputPort` property is `true`.

Input Arguments

x — Data input

vector | matrix

Data input, specified as a vector or a matrix. This object also accepts variable-size inputs. Once the object is locked, you can change the size of each input channel, but you cannot change the number of channels.

The data type of all the inputs must be the same. If the input is fixed-point, it must be signed fixed point with power-of-two slope and zero bias.

The complexity of `x`, `num`, and `den` must be the same.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `fi`

num — Numerator coefficients

3-by-*N* matrix

Numerator coefficients, specified as a 3-by-*N* numeric matrix, where *N* is the number of biquad filter sections. The complexity of `x`, `num`, and `den` must be the same.

The data type of all the inputs must be the same. If `num` is fixed point, it must be signed fixed point with power-of-two slope and zero bias.

Dependencies

This input applies only when you set `SOSMatrixSource` property is `Input port`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `fi`

Complex Number Support: Yes

den — Denominator coefficients

2-by-*N* matrix

Denominator coefficients, specified as a 2-by- N numeric matrix, where N is the number of biquad filter sections. The object assumes that the first denominator coefficient of each section is 1.

The data type of all the inputs must be the same. If `den` is fixed point, it must be signed fixed point with power-of-two slope and zero bias.

The complexity of `x`, `num`, and `den` must be the same.

Dependencies

This input applies only when you set `SOSMatrixSource` property is `InputPort`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `fi`
Complex Number Support: Yes

g — Scale values

1-by- $(N + 1)$ vector

Scale values of the biquad filter, specified as a 1-by- $(N + 1)$ numeric vector, where N is the number of biquad filter sections.

The data type of all the inputs must be the same. If `g` is fixed point, it must be signed fixed point with power-of-two slope and zero bias.

Dependencies

This input applies when the `SOSMatrixSource` property is `InputPort` and the `ScaleValuesInputPort` property is `true`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `fi`

Output Arguments

y — Filtered output

vector | matrix

Filtered output, returned as a vector or a matrix. The size, data type, and complexity of the output signal matches that of the input signal.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `fi`

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Specific to `dsp.BiquadFilter`

<code>freqz</code>	Frequency response of discrete-time filter System object
<code>fvtool</code>	Visualize frequency response of DSP filters
<code>impz</code>	Impulse response of discrete-time filter System object
<code>info</code>	Information about filter System object
<code>coeffs</code>	Returns the filter System object coefficients in a structure
<code>cost</code>	Estimate cost of implementing filter System object

scale	Scale second-order sections
scaleopts	Create an options object for second-order section scaling
scalecheck	Check scaling of biquadratic filter
cumsec	Cumulative second-order section of the biquadratic filter
generatehdl	Generate HDL code for quantized DSP filter (requires Filter Design HDL Coder)
tf	Convert discrete-time filter System object to transfer function
reorder	Reorder second-order sections of biquadratic filter System object

Common to All System Objects

step	Run System object algorithm
release	Release resources and allow changes to System object property values and input characteristics
reset	Reset internal states of System object

Examples

Filter a Signal Using Biquadratic Filter

Note: If you are using R2016a or an earlier release, replace each call to the object with the equivalent step syntax. For example, `obj(x)` becomes `step(obj,x)`.

Use a fourth order, lowpass biquadratic filter object with a normalized cutoff frequency of 0.4 to filter high frequencies from an input signal. Display the result as a power spectrum using the Spectrum Analyzer.

```
t = (0:1000)'/8e3;
xin = sin(2*pi*0.3e3*t)+sin(2*pi*3e3*t); % Input is 0.3 &
                                         % 3kHz sinusoids
src = dsp.SignalSource(xin, 100);
sink = dsp.SignalSink;

[z,p,k] = ellip(4,1,60,.4); % Set up the filter
[s,g] = zp2sos(z,p,k);
biquad = dsp.BiquadFilter(s,g,'Structure','Direct form I');

sa = dsp.SpectrumAnalyzer('SampleRate',8e3,...
    'PlotAsTwoSidedSpectrum',false,...
    'OverlapPercent', 80,'PowerUnits','dBW',...
    'YLimits', [-160 -10]);

while ~isDone(src)
    input = src();
    filteredOutput = biquad(input);
    sink(filteredOutput);
    sa(filteredOutput)
end

filteredResult = sink.Buffer;
fvtool(biquad,'Fs',8000)
```

Design and apply a lowpass biquad filter System object using the design function.

```
lpSpec = fdesign.lowpass('Fp,Fst,Ap,Ast',500,550,0.5,60,10000);
lpfilter = design(lpSpec,'butter','systemobject',true)
fvtool(lpfilter);
```

lpfilter =

dsp.BiquadFilter with properties:

```
    Structure: 'Direct form II'
    SOSMatrixSource: 'Property'
    SOSMatrix: [42x6 double]
    ScaleValues: [43x1 double]
    InitialConditions: 0
    OptimizeUnityScaleValues: true
```

Use get to show all properties

Linf-norm Scaling of a Biquad Filter

Demonstrate the Linf-norm scaling of a biquad filter using the `scale` function.

```

Fs = 8000; Fcutoff = 2000;
[z,p,k] = butter(10,Fcutoff/(Fs/2)); [s,g] = zp2sos(z,p,k);
biquad = dsp.BiquadFilter('Structure', 'Direct form I', ...
    'SOSMatrix', s, 'ScaleValues', g);
scale(biquad, 'linf', 'scalevalueconstraint', 'none', 'maxscalevalue', 2)

```

Options for scaling SOS filter

Create an options scaling object that contains the scaling options settings you require.

```

EllipI = design(fdesign.lowpass('N,Fp,Ap,Ast', 10, 0.5, 0.5, 20), ...
    'ellip', ...
    'FilterStructure', 'df1sos', ...
    'SystemObject', true)

```

```

EllipI =
    dsp.BiquadFilter with properties:

```

```

    Structure: 'Direct form I'

```

```

        SOSMatrixSource: 'Property'
            SOSMatrix: [5x6 double]
            ScaleValues: [6x1 double]
    NumeratorInitialConditions: 0
    DenominatorInitialConditions: 0
        OptimizeUnityScaleValues: true

```

Show all properties

```
opts = scaleopts(EllipI)
```

```
opts =
```

```

        sosReorder: 'auto'
        MaxNumerator: 2
    NumeratorConstraint: 'none'
        OverflowMode: 'wrap'
    ScaleValueConstraint: 'unit'
        MaxScaleValue: 'Not used'

```

Algorithms

This object implements the algorithm, inputs, and outputs described on the Biquad Filter block reference page. The object properties correspond to the block parameters, except:

- **Coefficient source**
- **Action when the a0 values of the SOS matrix are not one** – the biquad filter object assumes the zero-th-order denominator coefficient equals 1 regardless of the specified value. The biquad filter object does not support the **Error** or **Warn** options found in the corresponding block.

Both this object and its corresponding block support variable-size input. When you call the object, it can handle an input argument which is changing in size.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

See “System Objects in MATLAB Code Generation” (MATLAB Coder).

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

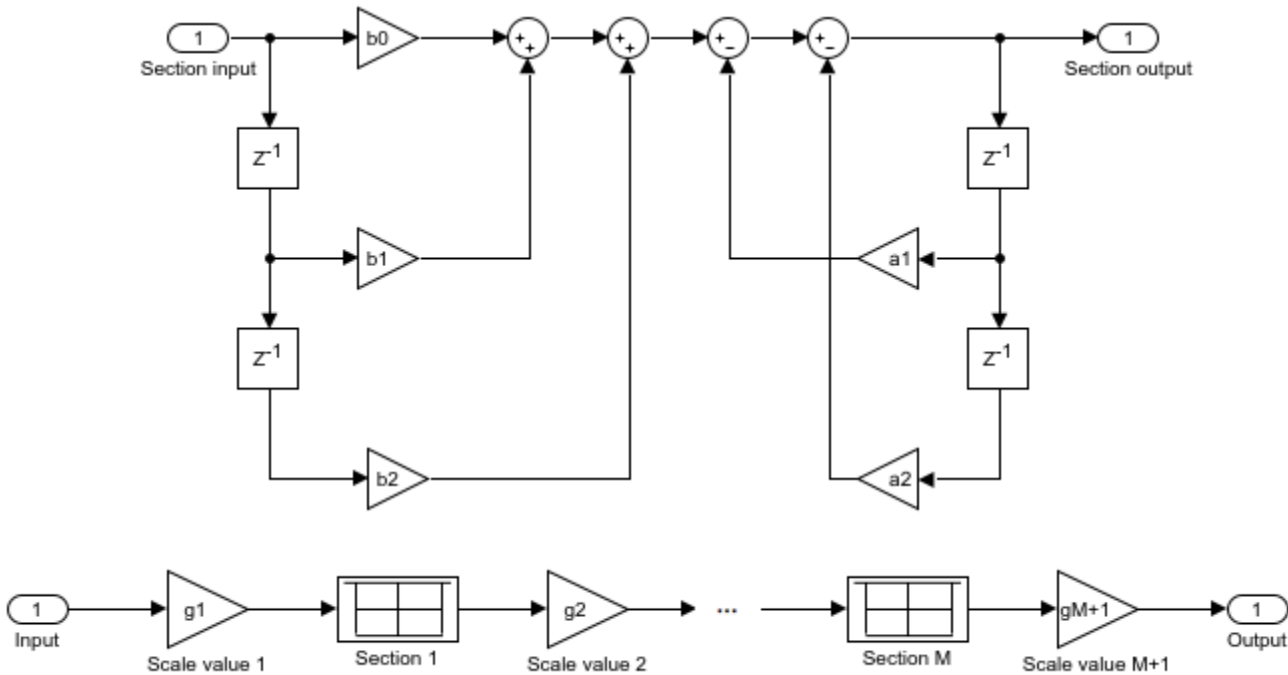

This object supports HDL code generation with the HDL Coder or Filter Design HDL Coder™ products. For HDL Coder workflows and limitations, see “HDL Code Generation for System Objects” (HDL Coder). For Filter Design HDL Coder workflows and limitations, see “Generate HDL Code for Filter System Objects” (Filter Design HDL Coder).

Fixed-Point Conversion

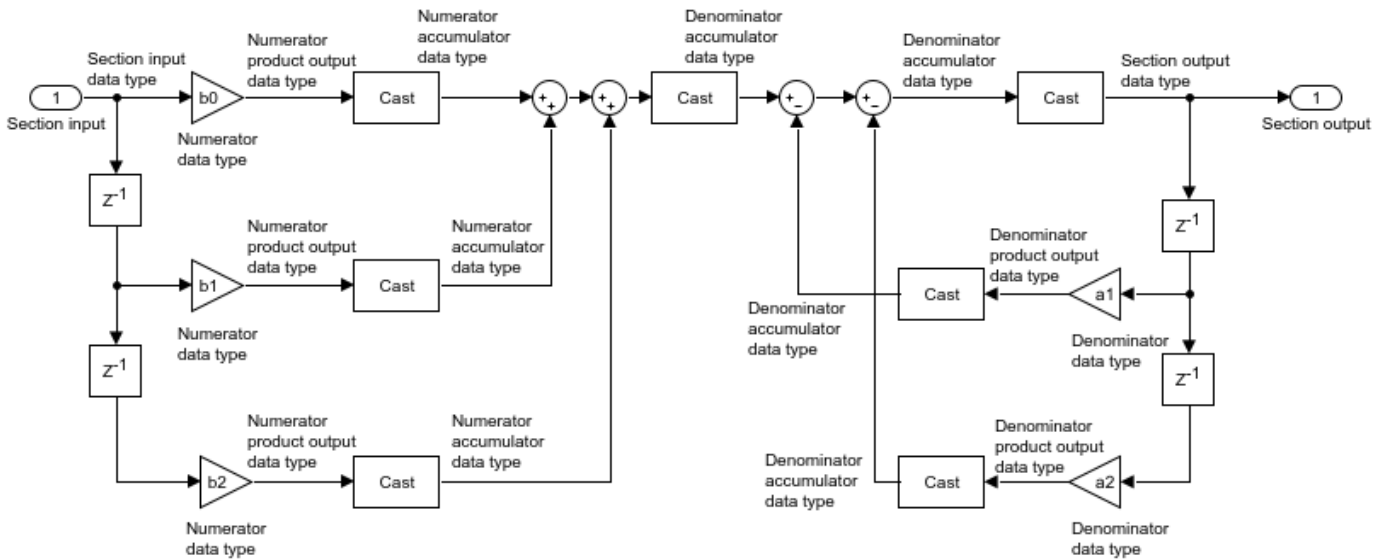

Design and simulate fixed-point systems using Fixed-Point Designer™.

The following diagrams show the data types used in the `dsp.BiquadFilter` object when the input is fixed-point. For each filter structure the object supports, the data types shown in the diagrams can be set through the respective fixed-point properties of the object.

Direct Form I

The following diagram shows the data types for one section of the filter for fixed-point signals.

The following diagrams show the fixed-point data types between filter sections.

When the data is not optimized:

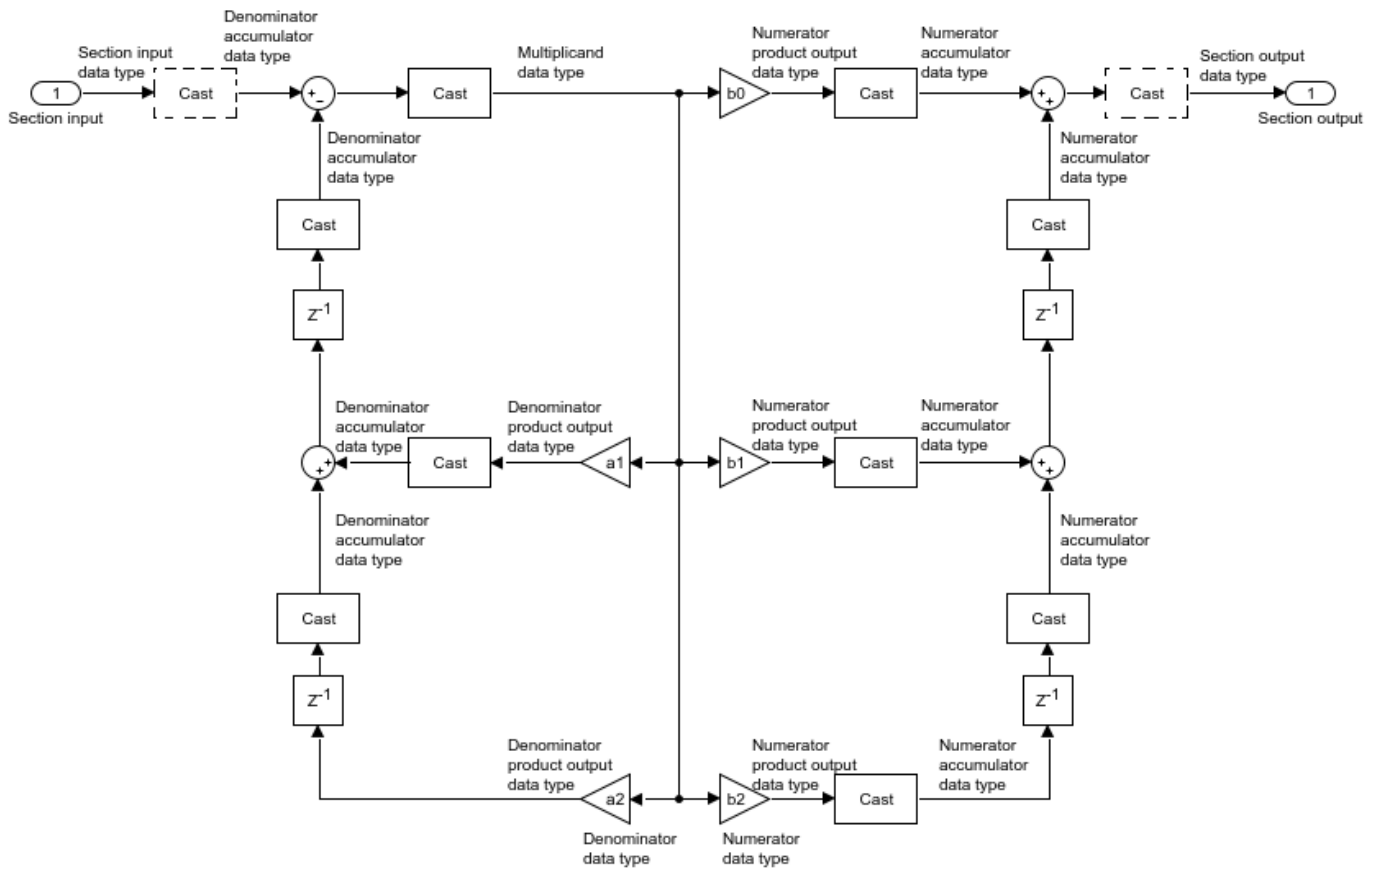

When you specify `OptimizeUnityScaleValues` to `true`, and scale values to 1:

Direct Form I Transposed

The following diagram shows the data types for one section of the filter for fixed-point signals.

The dashed casts are omitted when you specify `OptimizeUnityScaleValues` to true, and scale values to 1.

dsp.BlockLMSFilter

Package: dsp

Compute output, error, and weights using block LMS adaptive algorithm

Description

The `dsp.BlockLMSFilter` System object computes output, error, and weights using the block LMS adaptive algorithm.

To compute the output, error, and weights:

- 1 Create the `dsp.BlockLMSFilter` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

Creation

Syntax

```
blms = dsp.BlockLMSFilter
blms = dsp.BlockLMSFilter(length,blocksize)
blms = dsp.BlockLMSFilter(Name,Value)
```

Description

`blms = dsp.BlockLMSFilter` returns an adaptive FIR filter, `blms`, that filters the input signal and computes filter weights based on the block least mean squares (LMS) algorithm.

`blms = dsp.BlockLMSFilter(length,blocksize)` returns an adaptive FIR filter, `blms`, with the `Length` property set to `length` and the `BlockSize` property set to `blocksize`.

`blms = dsp.BlockLMSFilter(Name,Value)` returns an adaptive FIR filter, `blms`, with each specified property set to the specified value. Enclose each property name in single quotes. Unspecified properties have default values.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see [System Design in MATLAB Using System Objects](#).

Length — Length of FIR filter weights vector

32 (default) | positive integer

Specify the length of the FIR filter weights vector as a positive integer scalar.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

BlockSize — Number of samples acquired before weight adaptation

32 (default) | positive integer

Specify the number of samples of the input signal to acquire before the object updates the filter weights. The input frame length must be an integer multiple of the block size.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

StepSizeSource — Source of adaptation step size

Property (default) | Input port

Specify the source of the adaptation step size factor as Property or Input port.

StepSize — Adaptation step size

0.1 (default) | nonnegative scalar

Specify the adaptation step size factor as a scalar, nonnegative numeric value.

Tunable: Yes

Dependencies

This property applies only when you set the “StepSizeSource” on page 4-0 property to 'Property'.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

LeakageFactor — Leakage factor used in leaky LMS algorithm

1 (default) | scalar

Specify the leakage factor used in leaky LMS algorithm as a scalar numeric value between 0 and 1, both inclusive. When the value is less than 1, the System object implements a leaky LMS algorithm. The default is 1, providing no leakage in the adapting algorithm.

Tunable: Yes

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

InitialWeights — Initial values of filter weights

0 (default) | scalar | vector

Specify the initial values of the filter weights as a scalar or a vector of length equal to the “Length” on page 4-0 property value.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

AdaptInputPort — Additional input to enable adaptation of filter weights

false (default) | true

Specify when the object should adapt the filter weights. By default, the value of this property is `false`, and the filter continuously updates the filter weights. When this property is set to `true`, an adaptation control input is provided to the object. If the value of this input is nonzero, the filter continuously updates the filter weights. If the input is zero, the filter weights remain at their current value.

WeightsResetInputPort — Additional input to enable weights reset`false (default) | true`

Specify whether the FIR filter can reset the filter weights. By default, the value of this property is `false`, and the object does not reset the weights. When this property is set to `true`, you must provide a reset control input to the object, and the `WeightsResetCondition` property applies. The object resets the filter weights based on the values of the `WeightsResetCondition` property and the reset input to the object algorithm.

WeightsResetCondition — Condition that triggers the resetting of filter weights`Non-zero (default) | Rising edge | Falling edge | Either edge`

Specify the event to reset the filter weights as one of `Rising edge`, `Falling edge`, `Either edge`, or `Non-zero`. The object resets the filter weights based on the values of this property and the reset signal input to the object algorithm.

Dependencies

This property applies only when you set the `WeightsResetInputPort` property to `true`.

WeightsOutputPort — Output filter weights`true (default) | false`

Set this property to `true` to output the adapted filter weights. The default is `true`.

Usage**Syntax**

```
[y,err,wts] = blms(x,d)
[y,err] = blms(x,d)
[___] = blms(x,d,mu)
[___] = blms(x,d,a)
[___] = blms(x,d,r)
[y,err,wts] = blms(x,d,mu,a,r)
```

Description

`[y,err,wts] = blms(x,d)` filters the input `x`, using `d` as the desired signal, and returns the filtered output in `y`. The filter error is `err`, and the estimated filter weights is `wts`. The filter weights update once for every block of data that the object processes.

`[y,err] = blms(x,d)` returns only the filtered output `y` and the filter error `err` when the `WeightsOutputPort` property is `false`.

`[___] = blms(x,d,mu)` uses `mu` as the step size when you set the `StepSizeSource` property to `Input port`. These input arguments can be used with any of the previous sets of output arguments.

`[___] = blms(x,d,a)` uses `a` as the adaptation control when you set the `AdaptInputPort` property to `true`. When `a` is nonzero, the filter continuously updates the filter weights. When `a` is zero, the filter weights remain constant.

[___] = `blms(x,d,r)` uses `r` as a reset signal when you set the `WeightsResetInputPort` property to `true`. Use the `WeightsResetCondition` property to set the reset trigger condition. If a reset event occurs, the filter resets the filter weights to their initial values.

[`y,err,wts`] = `blms(x,d,mu,a,r)` filters input `x`, using `d` as the desired signal, `mu` as the step size, `a` as the adaptation control, and `r` as the reset signal. The object returns the filtered output `y`, the filter error `err`, and the adapted filter weights `wts`. Set the properties appropriately to provide all possible inputs.

Input Arguments

x — Data input

scalar | column vector

The signal to be filtered by the block LMS filter. The input, `x`, and the desired signal, `d`, must have the same size and data type.

The input length must be an integer multiple of the `BlockSize` property value.

Data Types: `single` | `double`

d — Desired signal

scalar | column vector

The LMS filter adapts its filter weights, `wts`, to minimize the error, `err`, and converge the input signal `x` to the desired signal `d` as closely as possible.

The input, `x`, and the desired signal, `d`, must have the same size and data type.

Data Types: `single` | `double`

mu — Step size

nonnegative scalar

Adaptation step size factor, specified as a scalar, nonnegative numeric value. The data type of the step size input must match the data type of `x` and `d`.

A small step size ensures a small steady state error between the output `y` and the desired signal `d`. If the step size is small, the convergence speed of the filter decreases. To improve the convergence speed, increase the step size. Note that if the step size is large, the filter can become unstable. To compute the maximum step size the filter can accept without becoming unstable, use the `maxstep` function.

Dependencies

This property applies only when you set the “StepSizeSource” on page 4-0 property to 'Input port'.

Data Types: `single` | `double`

a — Adaptation control

scalar

Adaptation control input that controls how the filter weights are updated. If the value of this input is nonzero, the object continuously updates the filter weights. If the value of this input is zero, the filter weights remain at their current value.

Dependencies

This input is required when the `AdaptInputPort` property is set to `true`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `logical`

r — Reset signal

scalar

Reset signal that resets the filter weights based on the values of the `WeightsResetInputPort` property.

Dependencies

This input is required when the `WeightsResetInputPort` property is set to `true`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `logical`

Output Arguments**y — Filtered output**

scalar | column vector

Filtered output, returned as a scalar or a column vector. The object adapts its filter weights to converge the input signal `x` to match the desired signal `d`. The filter outputs the converged signal.

Data Types: `single` | `double`

err — Difference between output and desired signal

scalar | column vector

Difference between the output signal `y` and the desired signal `d`, returned as a scalar or a column vector. The data type of `err` matches the data type of `y`. The objective of the adaptive filter is to minimize this error. The object adapts its weights to converge towards optimal filter weights that produce an output signal that matches closely with the desired signal.

Data Types: `single` | `double`

wts — Adaptive filter weights

scalar | column vector

Adaptive filter weights, returned as a scalar or a column vector of length specified by the value in the `Length` property.

The data type of `wts` matches the data type of `y`.

Data Types: `single` | `double`

Object Functions

To use an object function, specify the `System` object as the first input argument. For example, to release system resources of a `System` object named `obj`, use this syntax:

```
release(obj)
```

Specific to `dsp.BlockLMSFilter`

`mse` Estimated mean squared error for adaptive filters
`maxstep` Maximum step size for LMS adaptive filter convergence

Common to All System Objects

`step` Run System object algorithm
`release` Release resources and allow changes to System object property values and input characteristics
`reset` Reset internal states of System object

Examples

Remove Noise Using Block LMS Adaptive Algorithm

Note: If you are using R2016a or an earlier release, replace each call to the object with the equivalent `step` syntax. For example, `obj(x)` becomes `step(obj,x)`.

```
blms = dsp.BlockLMSFilter(10,5);
blms.StepSize = 0.01;
blms.WeightsOutputPort = false;
filt = dsp.FIRFilter;
filt.Numerator = fir1(10,[.5, .75]);
x = randn(1000,1); % Noise
d = filt(x) + sin(0:.05:49.95)'; % Noise + Signal
[y, err] = blms(x, d);
subplot(2,1,1);
plot(d);
title('Noise + Signal');
subplot(2,1,2);
plot(err);
title('Signal');
```

System Identification of FIR Filter Using Block LMS Filter

Note: If you are using R2016a or an earlier release, replace each call to the object with the equivalent step syntax. For example, `obj(x)` becomes `step(obj,x)`.

```

fir = fir1(31,0.5);
% FIR system to be identified
firFilter = dsp.FIRFilter('Numerator',fir);
iirFilter = dsp.IIRFilter('Numerator',sqrt(0.75),...
    'Denominator',[1 -0.5]);
x = iirFilter(sign(randn(2000,25)));
% Observation noise signal
n = 0.1*randn(size(x));
% Desired signal
d = firFilter(x)+n;
% Filter length
l = 32;
% Block LMS Step size
mu = 0.008;
% Decimation factor for analysis
% and simulation results
m = 32;
fir = dsp.BlockLMSFilter(l,'StepSize',mu);
[simmse,meanWsim,Wsim,traceKsim] = msesim(fir,x,d,m);
plot(m*(1:length(simmse)),10*log10(simmse));

```

```
xlabel('Iteration'); ylabel('MSE (dB)');  
% Plot the learning curve for  
% block LMS filter used in system identification  
title('Learning curve')
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the Block LMS Filter block reference page. The object properties correspond to the block parameters.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

See “System Objects in MATLAB Code Generation” (MATLAB Coder).

Objects

`dsp.LMSFilter` | `dsp.FIRFilter`

Introduced in R2012a

dsp.Buffer

Package: dsp

(Removed) Buffer input signal

Note The `dsp.Buffer` System object™ has been removed. Use `dsp.AsyncBuffer` instead. For more details, see “Compatibility Considerations”.

Description

The `Buffer` object buffers an input signal. The number of samples per channel in the input must equal the difference between the output buffer size and buffer overlap (i.e., `Length - OverlapLength`).

To buffer an input signal:

- 1 Create the `dsp.Buffer` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

Creation

Syntax

```
buff = dsp.Buffer  
buff = dsp.Buffer(len,overlap,ics)
```

Description

`buff = dsp.Buffer` returns a buffer System object, `buff`, used to buffer input signals with overlap.

`buff = dsp.Buffer(len,overlap,ics)` returns a buffer object, `buff`, with `Length` property set to `len`, `OverlapLength` property set to `overlap`, and `InitialConditions` property set to `ics`.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see [System Design in MATLAB Using System Objects](#).

Length — Number of samples to buffer

64 (default) | positive integer

Specify the number of consecutive samples from each input channel to buffer. You can set this property to any scalar integer greater than 0.

Data Types: `double` | `int32`

OverlapLength — Amount of overlap between outputs

0 (default) | positive integer

Specify the number of samples by which consecutive output frames overlap. You can set this property to any scalar integer in the range $0 \leq L < M_o$, where M_o is the output frame size specified by the `Length` property.

The object takes L samples (rows) from the current output and repeats them in the next output. The object acquires $M_o - L$ new input samples before propagating the buffered data to the output.

Data Types: `double` | `int32`

InitialConditions — Initial output

0 (default) | scalar | vector | matrix

Specify the value of the object's initial output for cases of nonzero latency as a scalar, vector, or matrix.

When there is nonzero latency, the buffer is initialized to the value(s) specified by the `InitialConditions` property. The object reads from the buffer to generate the first D output samples, where

$$D = \begin{cases} M_o + L & (L \geq 0) \\ M_o & (L < 0) \end{cases}$$

The dimensions of the `InitialConditions` property depend on the `OverlapLength`, L , and whether the input contains a single channel or multiple channels:

- When $L \neq 0$, the `InitialConditions` property must be a scalar.
- When $L = 0$, the `InitialConditions` property can be a scalar, or it can be a vector with the following constraints:
 - For single-channel inputs, the `InitialConditions` property can be a vector of length M_o if M_i is 1, or a vector of length M_i if M_o is 1.
 - For multichannel inputs, the `InitialConditions` property can be a vector of length $M_o * N$ if M_i is 1, or a vector of length $M_i * N$ if M_o is 1.

For general buffering between arbitrary frame sizes, the `InitialConditions` property must be a scalar value, which is then repeated across all elements of the initial output(s). However, in the special case where the input is a 1-by- N row vector, and the output of the block is an M_o -by- N matrix, `InitialConditions` can be:

- An M_o -by- N matrix.
- A length- M_o vector to be repeated across all columns of the initial output(s).
- A scalar to be repeated across all elements of the initial output(s).

In the special case where the output is a 1-by- N row vector, which is the result of unbuffering an M_i -by- N matrix, the `InitialConditions` can be:

- A vector containing M_i samples to output sequentially for each channel during the first M_i sample times.
- A scalar to be repeated across all elements of the initial output(s).

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical`

Usage

Syntax

`y = buff(x)`

Description

`y = buff(x)` creates output `y` based on current input and stored past values of `x`. Output length equals the `Length` property.

Input Arguments

x — Data input

column vector | matrix

Data input, specified as a column vector or a matrix. The number of input rows must be equal to `Length - OverlapLength`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical` | `fi`

Output Arguments

y — Buffer output

column vector | matrix

Buffer output, returned as a column vector or a matrix.

The following table shows the output dimensions of the `dsp.Buffer System` object when the input is a single-channel signal. M_i is the input frame size and M_o is the output frame size specified by the `Length` property.

Input Dimensions	Output Dimensions
1-by-1 (scalar)	M_o -by-1
M_i -by-1 (column vector)	M_o -by-1

The following table shows the output dimensions of the `dsp.Buffer System` object when the input is a multichannel signal. The output frame size, M_o can be greater or less than the input frame size, M_i . The object buffers each of the N input channels independently.

Input Dimensions	Output Dimensions
1-by- N (row vector)	M_o -by- N
M_i -by- N (matrix)	M_o -by- N

The data type and complexity of the output matches that of the input signal.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical` | `fi`

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Common to All System Objects

<code>step</code>	Run System object algorithm
<code>release</code>	Release resources and allow changes to System object property values and input characteristics
<code>reset</code>	Reset internal states of System object

Examples

Create a Buffer

Note: If you are using R2016a or an earlier release, replace each call to the object with the equivalent `step` syntax. For example, `obj(x)` becomes `step(obj,x)`.

Create a buffer of 256 samples with 128 sample overlap.

```
reader = dsp.SignalSource(randn(1024,1),128);
buff = dsp.Buffer(256,128);
```

```
for i = 1:8
    y = buff(reader());
end
```

`y` is of length 256 with 128 samples from previous input.

Algorithms

This object implements the algorithm, inputs, and outputs described on the Buffer block reference page. The object properties correspond to the block properties, except as noted.

Compatibility Considerations

dsp.Buffer System object has been removed

Errors starting in R2021a

The `dsp.Buffer` System object has been removed. Use the `dsp.AsyncBuffer` object instead.

Update Code

This table shows typical usage of the System object and explains how to update existing code to use the equivalent function.

Discouraged Usage	Recommended Replacement
<p>Buffer with no overlap</p> <pre>signal = randn(512,1); buff = dsp.Buffer(512) y = buff(signal);</pre> <p>Buffer with 25% overlap</p> <pre>overlapLen = 128; buffCap = 512; buff = dsp.Buffer(buffCap,overlapLen) y = buff(signal(1:(512-128))); % Number of input samples must equal % Length - OverlapLength.</pre> <p>If you are using a release prior to R2016b, replace <code>buff(signal)</code> with <code>step(buff,signal)</code> and <code>buff(signal(1:(512-128)))</code> with <code>step(buff,signal(1:(512-128)))</code>.</p>	<p>Async buffer with no overlap</p> <pre>abuff = dsp.AsyncBuffer; write(abuff,signal) % Write the signal yabuff = read(abuff,512); % Read the entire signal from the buffer</pre> <p>Buffer with 25% overlap</p> <pre>abuff = dsp.AsyncBuffer; write(abuff,signal); yabuff = read(abuff,512,128);</pre>

Objects

`dsp.AsyncBuffer`

Introduced in R2012a

dsp.BurgAREstimator

Package: dsp

(Removed) Estimate of autoregressive (AR) model parameters using Burg method

Note The `dsp.BurgAREstimator` System object™ has been removed. Use `arburg` instead. For more information, see “Compatibility Considerations”.

Description

The `BurgAREstimator` object computes the estimate of the autoregressive (AR) model parameters using the Burg method.

To compute the estimate of the AR model parameters:

- 1 Define and set up your System object. See “Construction” on page 4-197.
- 2 Call `step` to compute the estimate according to the properties of `dsp.BurgAREstimator`. The behavior of `step` is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj, x)` and `y = obj(x)` perform equivalent operations.

Construction

`burgarest = dsp.BurgAREstimator` returns a Burg `BurgAREstimator` System object, `burgarest`, that performs parametric AR estimation using the Burg maximum entropy method.

`burgarest = dsp.BurgAREstimator('PropertyName', PropertyValue, ...)` returns a Burg AR estimator object, `burgarest`, with each specified property set to the specified value.

Properties

AOutputPort

Enable output of polynomial coefficients

Set this property to `true` to output the polynomial coefficients, *A*, of the AR model the object computes. The default is `true`. Either the `AOutputPort` property, the `KOutputPort` property, or both must be `true`.

KOutputPort

Enable output of reflection coefficients

Set this property to `true` to output the reflection coefficients, *K*, for the AR model that the object computes. The default is `false`. Either the `AOutputPort` property, the `KOutputPort` property, or both must be `true`.

EstimationOrderSource

Source of estimation order

Specify how to determine estimator order as `Auto` or `Property`. When you set this property to `Auto`, the object assumes the estimation order is one less than the length of the input vector. When you set this property to `Property`, the value in `EstimationOrder` is used. The default is `Auto`.

EstimationOrder

Order of AR model

Set the AR model estimation order to a real positive integer. This property applies when you set the `EstimationOrderSource` to `Property`. The default is 4.

Methods

`step` Normalized estimate of AR model parameter

Common to All System Objects	
<code>release</code>	Allow System object property value changes

Examples

Estimate the parameters of an AR model

Note This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, `myObject(x)` becomes `step(myObject,x)`.

Use the `dsp.BurgAREstimator` System object to estimate the parameters of an AR model.

```

rng default; % Use default random number generator and seed
noise = randn(100,1); % Normalized white Gaussian noise
x = filter(1,[1 1/2 1/3 1/4 1/5],noise);
burgarest = dsp.BurgAREstimator(...
    'EstimationOrderSource', 'Property', ...
    'EstimationOrder', 4);
[a, g] = burgarest(x);
x_est = filter(g, a, x);
plot(1:100,[x x_est]);
title('Original and estimated signals');
legend('Original', 'Estimated');

```

Algorithms

This object implements the algorithm, inputs, and outputs described on the Burg AR Estimator block reference page. The object properties correspond to the block parameters, except:

Output(s) block parameter corresponds to the `AOutputPort` and the `KOutputPort` object properties.

Compatibility Considerations

dsp.BurgAREstimator System object has been removed

Errors starting in R2021a

The dsp.BurgAREstimator System object has been removed. Use arburg instead.

Update Code

This table shows typical usage of the System object and explains how to update existing code to use the equivalent function.

Discouraged Usage	Recommended Replacement
<pre>% Use default random number % generator and seed rng default; % Normalized white Gaussian noise noise = randn(100,1); x = filter(1,[1 1/2 1/3 1/4 1/5],noise); burgarest = dsp.BurgAREstimator(... Functions

arburg

Introduced in R2012a

step

System object: dsp.BurgAREstimator

Package: dsp

Normalized estimate of AR model parameter

Syntax

```
[A,G] = step(burgarest,X)
[K,G] = step(burgarest,X)
[A,K,G] = step(burgarest,X)
```

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`[A,G] = step(burgarest,X)` computes the normalized estimate of the AR model parameters to fit the input, `X`, in the least square sense. The input `X` must be a column vector. Output `A` is a column vector that contains the normalized estimate of the AR model polynomial coefficients in descending powers of `z`. The scalar `G` is the AR model gain.

`[K,G] = step(burgarest,X)` returns `K`, a column vector containing the AR model reflection coefficients when you set the `KOutputPort` property to `true` and the `AOutputPort` property to `false`.

`[A,K,G] = step(burgarest,X)` returns the AR model polynomial coefficients `A`, reflection coefficients `K`, and the scalar gain `G` when the `AOutputPort` and `KOutputPort` properties are both `true`.

Note `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

dsp.BurgSpectrumEstimator

Package: dsp

(Removed) Parametric spectral estimate using Burg method

Note The `dsp.BurgSpectrumEstimator` System object™ has been removed. Use `pburg` instead. For more information, see “Compatibility Considerations”.

Description

The `BurgSpectrumEstimator` object computes a parametric spectral estimate of the input using the Burg method. The object fits an autoregressive (AR) model to the signal by minimizing the forward and backward prediction errors (via least-squares). The AR parameters are constrained to satisfy the Levinson-Durbin recursion.

To compute the parametric spectral estimate of the input:

- 1 Define and set up your System object. See “Construction” on page 4-202.
- 2 Call `step` to compute the estimate according to the properties of `dsp.BurgSpectrumEstimator`. The behavior of `step` is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`burgspecest = dsp.BurgSpectrumEstimator` returns an object, `burgspecest`, that estimates the power spectral density (PSD) of the input frame using the Burg method.

`burgspecest = dsp.BurgSpectrumEstimator('PropertyName',PropertyValue,...)` returns a spectrum estimator, `burgspecest`, with each specified property set to the specified value.

Properties

EstimationOrderSource

Source of estimation order

Specify the source of the estimation order as `Auto` or `Property`. If you set this property to `Auto`, the object assumes the estimation order is one less than the length of the input vector. The default value is `Property`.

EstimationOrder

Order of AR model

Specify the order of AR model as a real positive integer. This property applies only when you set the `EstimationOrderSource` property to `Property`. The default value is 6.

FFTLengthSource

Source of FFT length

Specify the source of the FFT length as `Auto` or `Property`. When you set this property to `Auto`, the objects assumes the FFT length is one more than the estimation order. When you set this property to `Property`, the “FFTLength” on page 4-0 property value must be an integer power of two.

FFTLength

FFT length as power-of-two integer value

Specify the FFT length as a power-of-two numeric scalar. This property applies when you set the `FFTLengthSource` property to `Property`. The default value is 256.

SampleRate

Sample rate of input time series

Specify the sampling rate of the original input time series as a positive numeric scalar in hertz. The default value is 1.

Methods

`step` Estimate of power spectral density

Common to All System Objects	
<code>release</code>	Allow System object property value changes

Examples

Estimate PSD Using the Burg Method

Note This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, `myObject(x)` becomes `step(myObject,x)`.

```
x = randn(100,1);
burgspecest = dsp.BurgSpectrumEstimator('EstimationOrder', 4);
y = filter(1,[1 1/2 1/3 1/4 1/5],x); % Fourth order AR filter
p = burgspecest(y); % Uses default FFT length of 256

plot((0:255)/256, p);
```

```
title('Burg Method Spectral Density Estimate');
xlabel('Normalized frequency'); ylabel('Power/frequency');
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the Burg Method block reference page. The object properties correspond to the block properties.

Compatibility Considerations

dsp.BurgSpectrumEstimator System object has been removed

Errors starting in R2021a

The dsp.BurgSpectrumEstimator System object has been removed. Use pburg instead.

Update Code

This table shows typical usage of the System object and explains how to update existing code to use the equivalent function.

Discouraged Usage	Recommended Replacement
<pre>x = randn(100,1); burgspecest = dsp.BurgSpectrumEstimator(... 'EstimationOrder', 4); % Fourth order AR filter y = filter(1,[1 1/2 1/3 1/4 1/5],x); % Uses default FFT length of 256 p = burgspecest(y);</pre> <p>If you are using a release prior to R2016b, replace burgspecest(y) with step(burgspecest,y).</p>	<pre>x = randn(100,1); % Fourth order AR filter y = filter(1,[1 1/2 1/3 1/4 1/5],x); % Uses default FFT length of 256 pFn = pburg(y,4,256,1,'twosided');</pre> <p>The pburg function is in this format Pxx = pburg(y,order,nfft,fs,'twosided').</p>

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- “System Objects in MATLAB Code Generation” (MATLAB Coder)
- When the FFT length is not a power of two, the executable generated from this System object relies on prebuilt dynamic library files (.dll files) included with MATLAB. Use the packNGo function to package the code generated from this object and all the relevant files in a compressed zip file. Using this zip file, you can relocate, unpack, and rebuild your project in another development environment where MATLAB is not installed. For more details, see “How To Run a Generated Executable Outside MATLAB”.
- When the FFT length is a power of two, you can generate standalone C and C++ code from this System object.

Package: dsp

Estimate of power spectral density

Syntax

$Y = \text{step}(\text{burgspecest}, X)$

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, $y = \text{step}(\text{obj}, x)$ and $y = \text{obj}(x)$ perform equivalent operations.

$Y = \text{step}(\text{burgspecest}, X)$ outputs Y , a spectral estimate of input X , using the Burg method.

Note `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

dsp.CepstralToLPC

Package: dsp

(Removed) Convert cepstral coefficients to linear prediction coefficients

Note dsp.CepstralToLPC has been removed. For more information, see “Compatibility Considerations”.

Description

The CepstralToLPC object converts cepstral coefficients to linear prediction coefficients (LPC).

To convert cepstral coefficients to LPC:

- 1 Define and set up your System object. See “Construction” on page 4-207.
- 2 Call `step` to convert the coefficients according to the properties of dsp.CepstralToLPC. The behavior of `step` is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`cc2lpc = dsp.CepstralToLPC` returns a System object, `cc2lpc`, that converts the cepstral coefficients (CCs) to linear prediction coefficients (LPCs).

`cc2lpc = dsp.CepstralToLPC('PropertyName',PropertyValue,...)` returns a Cepstral to LPC object, `cc2lpc`, with each specified property set to the specified value.

Properties

PredictionErrorOutputPort

Enable prediction error power output

Set this property to `true` to output the prediction error power. The prediction error power is the power of the error output of an FIR analysis filter represented by the LPCs for a given input signal. The default is `false`.

Methods

`step` LPC coefficients from column of cepstral coefficients

step

System object: dsp.CepstralToLPC

Package: dsp

LPC coefficients from column of cepstral coefficients

Syntax

```
A = step(cc2lpc,CC)
[A,P]=step(cc2lpc,CC)
```

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`A = step(cc2lpc,CC)` computes the linear prediction coefficients (LPC) coefficients, `A`, from the columns of cepstral coefficients, `CC`.

`[A,P]=step(cc2lpc,CC)` converts the columns of the cepstral coefficients `CC` to the LPCs and returns the prediction error power `P` when the `PredictionErrorOutputPort` property is `true`.

Note `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

dsp.Channelizer

Package: dsp

Polyphase FFT analysis filter bank

Description

The `dsp.Channelizer` System object separates a broadband input signal into multiple narrow subbands using a fast Fourier transform (FFT)-based analysis filter bank. The filter bank uses a prototype lowpass filter and is implemented using a polyphase structure. You can specify the filter coefficients directly or through design parameters.

To separate a broadband signal into multiple narrow subbands:

- 1 Create the `dsp.Channelizer` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

Creation

Syntax

```
channelizer = dsp.Channelizer
channelizer = dsp.Channelizer(M)
channelizer = dsp.Channelizer(Name,Value)
```

Description

`channelizer = dsp.Channelizer` creates a polyphase FFT analysis filter bank System object that separates a broadband input signal into multiple narrowband output signals. This object implements the inverse operation of the `dsp.ChannelSynthesizer` System object.

`channelizer = dsp.Channelizer(M)` creates an M -band polyphase FFT analysis filter bank, with the "NumFrequencyBands" on page 4-0 property set to M .

Example: `channelizer = dsp.Channelizer(16);`

`channelizer = dsp.Channelizer(Name,Value)` creates a polyphase FFT analysis filter bank with each specified property set to the specified value. Enclose each property name in single quotes.

Example: `channelizer = dsp.Channelizer('NumTapsPerBand',20,'StopbandAttenuation',140);`

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects.

NumFrequencyBands — Number of frequency bands

8 (default) | positive integer greater than 1

Number of frequency bands M into which the object separates the input broadband signal, specified as a positive integer greater than 1. This property corresponds to the number of polyphase branches and the FFT length used in the filter bank.

Example: 16

Example: 64

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

DecimationFactor — Decimation factor

8 (default) | positive integer

Decimation factor D specified as a positive integer less than or equal to the number of frequency bands M . The default value of this property equals the number of frequency bands specified.

If the decimation factor D equals the number of frequency bands M , then the M/D ratio equals 1, and the channelizer is known as the maximally decimated channelizer.

If the M/D ratio is greater than 1, the output sample rate is different from the channel spacing, and the channelizer is known as the non-maximally decimated channelizer. If the ratio is an integer, the channelizer is known as the integer-oversampled channelizer. If the ratio is not an integer, say $4/3$, the channelizer is known as the rationally oversampled channelizer. For more details, see “Algorithm” on page 4-220.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

Specification — Filter design parameters or coefficients

'Number of taps per band and stopband attenuation' (default) | 'Coefficients'

Filter design parameters or filter coefficients, specified as one of these options:

- 'Number of taps per band and stopband attenuation' — Specify the filter design parameters through the NumTapsPerBand and “Stopband attenuation (dB)” on page 2-0 properties.
- 'Coefficients' — Specify the filter coefficients directly using the “LowpassCoefficients” on page 4-0 property.

NumTapsPerBand — Number of filter coefficients per frequency band

12 (default) | positive integer

Number of filter coefficients each polyphase branch uses, specified as a positive integer. The number of polyphase branches matches the number of frequency bands. The total number of filter coefficients for the prototype lowpass filter is given by NumFrequencyBands \times NumTapsPerBand. For a given stopband attenuation, increasing the number of taps per band narrows the transition width of the filter. As a result, there is more usable bandwidth for each frequency band at the expense of increased computation.

Example: 8

Example: 16

Dependencies

This property applies when you set `Specification` to 'Number of taps per band and stopband attenuation'.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

StopbandAttenuation — Stopband attenuation

80 (default) | positive real scalar

Stopband attenuation of the lowpass filter, specified as a positive real scalar in dB. This value controls the maximum amount of aliasing from one frequency band to the next. When the stopband attenuation increases, the passband ripple decreases. For a given stopband attenuation, increasing the number of taps per band narrows the transition width of the filter. As a result, there is more usable bandwidth for each frequency band at the expense of increased computation.

Example: 80

Dependencies

This property applies when you set `Specification` to 'Number of taps per band and stopband attenuation'.

Data Types: `single` | `double`

LowpassCoefficients — Coefficients of prototype lowpass filter

[1×49 double] (default) | row vector

Coefficients of the prototype lowpass filter, specified as a row vector. The default vector of coefficients is obtained using `rcosdesign(0.25,6,8,'sqrt')`. There must be at least one coefficient per frequency band. If the length of the lowpass filter is less than the number of frequency bands, the object zero-pads the coefficients.

If you specify complex coefficients, the object designs a prototype filter that is centered at a nonzero frequency, also known as a bandpass filter. The modulated versions of the prototype bandpass filter appear with respect to the prototype filter and are wrapped around the frequency range $[-F_s, F_s]$. For an example, see “Channelizer with Complex Coefficients” on page 4-216.

Tunable: Yes

Dependencies

This property applies when you set `Specification` to 'Coefficients'.

Data Types: `single` | `double`

Usage**Syntax**

```
channOut = channelizer(input)
```

Description

`channOut = channelizer(input)` separates the broadband input signal into a number of narrow band signals contained in the columns of the channelizer output.

Input Arguments

input — Data input

vector | matrix

Data input, specified as a vector or a matrix. The number of rows in the input signal must be a multiple of the number of frequency bands of the filter bank. Each column of the input corresponds to a separate channel. If M is the number of frequency bands, and the input is an L -by-1 matrix, then the output signal has dimensions L/M -by- M . Each narrowband signal forms a column in the output. If the input has more than one channel, that is, it has dimensions L -by- N with $N > 1$, then the output has dimensions L/M -by- M -by- N .

This object supports variable-size input signals. You can change the input frame size (number of rows) even after calling the algorithm. However, the number of channels (number of columns) must remain constant.

Example: `randn(64,4)`

Data Types: `single` | `double`

Output Arguments

channOut — Channelizer output

matrix | 3-D array

Channelizer output, returned as a matrix or a 3-D array. If the input is an L -by-1 matrix, then the output signal has dimensions L/M -by- M , where M is the number of frequency bands. Each narrowband signal forms a column in the output. If the input has more than one channel, that is, it has dimensions L -by- N with $N > 1$, then the output has dimensions L/M -by- M -by- N .

Data Types: `single` | `double`

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Specific to `dsp.Channelizer`

<code>coeffs</code>	Coefficients of prototype lowpass filter
<code>tf</code>	Return transfer function of overall prototype lowpass filter
<code>polyphase</code>	Return polyphase matrix
<code>freqz</code>	Frequency response of filters in channelizer
<code>fvtool</code>	Visualize the filters in the channelizer
<code>bandedgeFrequencies</code>	Compute the bandedge frequencies
<code>centerFrequencies</code>	Compute center frequencies
<code>getFilters</code>	Return matrix of channelizer FIR filters

Common to All System Objects

<code>step</code>	Run System object algorithm
<code>release</code>	Release resources and allow changes to System object property values and input characteristics

reset Reset internal states of System object

Examples

Channelize and Synthesize Sine Wave in MATLAB

Channelize and synthesize a sine wave signal with multiple frequencies using an M -channel filter bank.

The M -channel filter bank contains an analysis filter bank section and a synthesis filter bank section. The `dsp.Channelizer` object implements the analysis filter bank section. The `dsp.ChannelSynthesizer` object implements the synthesis filter bank section. These objects use an efficient polyphase structure to implement the filter bank. For more details, see **Polyphase Implementation** under **Algorithms** on the object reference pages.

Initialization

Initialize the `dsp.Channelizer` and `dsp.ChannelSynthesizer` System objects. Each object is set up with 8 frequency bands, 8 polyphase branches in each filter, 12 coefficients per polyphase branch, and a stopband attenuation of 140 dB. Use a sine wave with multiple frequencies as the input signal. View the input spectrum and the output spectrum using a spectrum analyzer.

```
offsets = [-40, -30, -20, 10, 15, 25, 35, -15];
sinewave = dsp.SineWave('ComplexOutput', true, 'Frequency', ...
    offsets+(-375:125:500), 'SamplesPerFrame', 800);

channelizer = dsp.Channelizer('StopbandAttenuation', 140);
synthesizer = dsp.ChannelSynthesizer('StopbandAttenuation', 140);
spectrumAnalyzer = dsp.SpectrumAnalyzer('ShowLegend', true, ...
    'SampleRate', sinewave.SampleRate, ...
    'NumInputPorts', 2, 'ChannelNames', {'Input', 'Output'}, ...
    'Title', 'Input and Output Spectra');
```

Streaming

Use the channelizer to split the broadband input signal into multiple narrow bands. Then pass the multiple narrowband signals into the synthesizer, which merges these signals to form the broadband signal. Compare the spectra of the input and output signals. The input and output spectra match very closely.

```
for i = 1:5000
    x = sum(sinewave(), 2);
    y = channelizer(x);
    v = synthesizer(y);
    spectrumAnalyzer(x, v)
end
```

Channelizer with Complex Coefficients

Create a `dsp.Channelizer` object and set the `LowpassCoefficients` property to a vector of complex coefficients.

Complex Coefficients

Using `firpm`, determine the coefficients of a Park-McClellan's optimal equiripple FIR filter of order 30, and frequency and amplitude characteristics described by $F = [0 \ 0.2 \ 0.4 \ 1.0]$ and $A = [1 \ 1 \ 0 \ 0]$ vectors, respectively.

Create a complex version of these coefficients by multiplying with a complex exponential. The resultant frequency response is that of a bandpass filter at the specified frequency, in this case 0.4.

```
blowpass = firpm(30,[0 .2 .4 1],[1 1 0 0]);
N = length(blowpass)-1;
Fc = 0.4;
j = complex(0,1);
bbandpass = blowpass.*exp(j*Fc*pi*(0:N));
```

Channelizer

Create a `dsp.Channelizer` object with 4 frequency bands and set the `Specification` property to `'Coefficients'`.

```
chann = dsp.Channelizer('NumFrequencyBands',4,...  
    'Specification','Coefficients');
```

Pass the complex coefficients to the channelizer. The prototype filter is a bandpass filter with a center frequency of 0.4. The modulated versions of this filter appear with respect to the prototype filter and are wrapped around the frequency range $[-F_s F_s]$.

```
chann.LowpassCoefficients = bbandpass
```

```
chann =  
    dsp.Channelizer with properties:  
        NumFrequencyBands: 4  
        DecimationFactor: 4  
        Specification: 'Coefficients'  
        LowpassCoefficients: [0.0019 + 0.0000i 0.0005 + 0.0016i ... ]
```

Visualize the frequency response of the channelizer.

```
fvtool(chann)
```

More About

Analysis Filter Bank

The generic analysis filter bank consists of a series of parallel bandpass filters that split an input broadband signal, $x[n]$, into a series of narrow subbands. Each bandpass filter retains a different portion of the input signal. After the bandwidth is reduced by one of the bandpass filters, the signal is downsampled to a lower sampling rate commensurate with the new bandwidth.

Conceptual Diagram of Generic Analysis Filter Bank

Prototype Lowpass Filter

To implement the analysis filter bank efficiently, the channelizer uses a prototype lowpass filter.

The prototype lowpass filter has an impulse response of $h[n]$, a normalized two-sided bandwidth of $2\pi/M$, and a cutoff frequency of π/M . M is the number of frequency bands, that is, the branches of the analysis filter bank. This value corresponds to the FFT length that the filter bank uses. M can be high on the order of 2048 or more. The stopband attenuation determines the minimum level of interference (aliasing) from one frequency band to another. The passband ripple must be small so that the input signal is not distorted in the passband.

The prototype lowpass filter corresponds to $H_0(z)$ in the filter bank. The first branch of the filter bank contains $H_0(z)$ followed by the decimator. The other $M - 1$ branches contain filters that are modulated versions of the prototype filter. The modulation factor is given by the following equation:

$$e^{-jw_k n}, \quad w_k = 2\pi k/M, \quad k = 0, 1, \dots, M - 1$$

Using the Prototype Lowpass Filter

The transfer function of the modulated k th bandpass filter is given by:

$$H_k(z) = H_0(z e^{-jw_k}), \quad w_k = 2\pi k/M, \quad k = 1, 2, \dots, M - 1$$

This figure shows the frequency response of M filters.

To obtain the frequency response characteristics of the filter $H_k(z)$, where $k = 1, \dots, M-1$, uniformly shift the frequency response of the prototype filter, $H_0(z)$, by multiples of $2\pi/M$. Each subband filter, $H_k(z)$, $\{k = 1, \dots, M - 1\}$, is derived from the prototype filter.

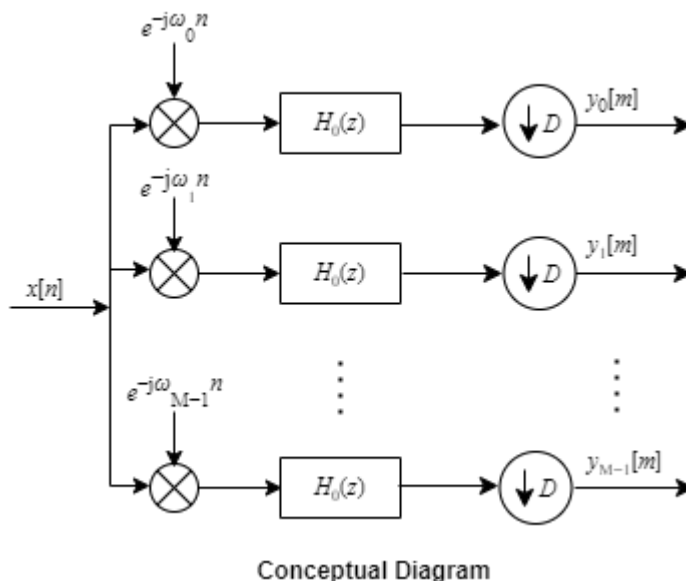

Following is an equivalent representation of the frequency response diagram with ω ranging from $[-\pi, \pi]$.

Shift Narrow Subbands to Baseband

The frequency components in the input signal, $x[n]$, are translated in frequency to baseband by multiplying $x[n]$ with the complex exponentials, $e^{-j\omega_k n}$, $\omega_k = 2\pi k/M$, $k = 1, 2, \dots, M-1$, where $\omega_k = 2\pi k/M$, and $k = 1, 2, \dots, M-1$. The resulting product signals are passed through the lowpass filters, $H_0(z)$. The output of the lowpass filter is relatively narrow in bandwidth. Downsample the signal commensurate with the new bandwidth. Choose a decimation factor, $D \leq M$, where M is the number of branches of the analysis filter bank. When $D < M$, the channelizer is known as oversampled or non-maximally decimated channelizer.

The figure shows an analysis filter bank that uses the prototype lowpass filter.

$y_1[m], y_2[m], \dots, y_{M-1}[m]$ are narrow subband signals translated into baseband.

Algorithms

Polyphase Implementation

The analysis filter bank can be implemented efficiently using the polyphase structure. For more details on the analysis filter bank, see Analysis Filter Bank on page 4-218.

To derive the polyphase structure, start with the transfer function of the prototype lowpass filter:

$$H_0(z) = b_0 + b_1 z^{-1} + \dots + b_N z^{-N}$$

$N + 1$ is the length of the prototype filter.

You can rearrange this equation as follows:

$$H_0(z) = \begin{aligned} & (b_0 + b_M z^{-M} + b_{2M} z^{-2M} + \dots + b_{N-M+1} z^{-(N-M+1)}) + \\ & z^{-1} (b_1 + b_{M+1} z^{-M} + b_{2M+1} z^{-2M} + \dots + b_{N-M+2} z^{-(N-M+1)}) + \\ & \quad \vdots \\ & z^{-(M-1)} (b_{M-1} + b_{2M-1} z^{-M} + b_{3M-1} z^{-2M} + \dots + b_N z^{-(N-M+1)}) \end{aligned}$$

M is the number of polyphase components.

You can write this equation as:

$$H_0(z) = E_0(z^M) + z^{-1} E_1(z^M) + \dots + z^{-(M-1)} E_{M-1}(z^M)$$

$E_0(z^M), E_1(z^M), \dots, E_{M-1}(z^M)$ are polyphase components of the prototype lowpass filter $H_0(z)$.

The other filters in the filter bank, $H_k(z)$, where $k = 1, \dots, M-1$, are modulated versions of this prototype filter.

You can write the transfer function of the k^{th} modulated bandpass filter as $H_k(z) = H_0(z e^{-jw_k})$.

Replacing z with $z e^{jw_k}$,

$$H_k(z) = h_0 + h_1 e^{-jw_k} z^{-1} + h_2 e^{-j2w_k} z^{-2} \dots + h_N e^{-jNw_k} z^{-N}$$

$N + 1$ is the length of the k^{th} filter.

In polyphase form, the equation is as follows:

$$H_k(z) = \begin{bmatrix} 1 & e^{-jw_k} & e^{-j2w_k} & \dots & e^{-j(M-1)w_k} \end{bmatrix} \begin{bmatrix} E_0(z^M) \\ z^{-1} E_1(z^M) \\ \vdots \\ z^{-(M-1)} E_{M-1}(z^M) \end{bmatrix}$$

For all M channels in the filter bank, the transfer function $H(z)$ is given by:

$$H(z) = \begin{bmatrix} 1 & 1 & 1 & \dots & 1 \\ 1 & e^{-jw_1} & e^{-j2w_1} & \dots & e^{-j(M-1)w_1} \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ 1 & e^{-jw_{M-1}} & e^{-j2w_{M-1}} & \dots & e^{-j(M-1)w_{M-1}} \end{bmatrix} \begin{bmatrix} E_0(z^M) \\ z^{-1} E_1(z^M) \\ \vdots \\ z^{-(M-1)} E_{M-1}(z^M) \end{bmatrix}$$

Maximally decimated channelizer

When $D = M$, the channelizer is known as the maximally decimated channelizer or critically sampled channelizer.

Here is the multirate noble identity for decimation, assuming that $D = M$.

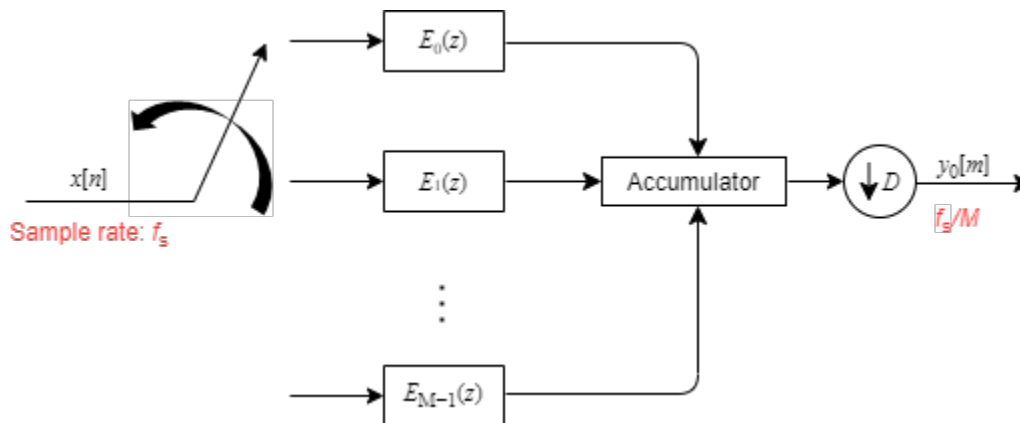

For example, consider the first branch of the filter bank that contains the lowpass filter.

Replace $H_0(z)$ with its polyphase representation on page 4-220.

After applying the noble identity for decimation, you can replace the delays and the decimation factor with a commutator switch. The switch starts on the first branch 0 and moves in the counterclockwise direction as shown in the following diagram. The accumulator at the output receives the processed input samples from each branch of the polyphase structure and accumulates these processed samples until the switch goes to branch 0. When the switch goes to branch 0, the accumulator outputs the accumulated value.

For all M channels in the filter bank, the transfer function $H(z)$ is given by:

$$H(z) = \begin{bmatrix} 1 & 1 & 1 & \dots & 1 \\ 1 & e^{-jw_1} & e^{-j2w_1} & \dots & e^{-j(M-1)w_1} \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ 1 & e^{-jw_{M-1}} & e^{-j2w_{M-1}} & \dots & e^{-j(M-1)w_{M-1}} \end{bmatrix} \begin{bmatrix} E_0(z) \\ E_1(z) \\ \vdots \\ E_{M-1}(z) \end{bmatrix}$$

The matrix on the left is a discrete Fourier transform (DFT) matrix. With the DFT matrix, the efficient implementation of the lowpass prototype-based filter bank looks like this.

When the first input sample is delivered, the switch feeds this input to the branch 0 and the channelizer computes the first set of output values. As more input samples come in, the switch moves in the counterclockwise direction through branches $M-1$, $M-2$, all the way up to branch 0, delivering one sample at a time to each branch. When the switch comes to branch 0, the channelizer outputs the next set of output values. This process continues as the data keeps coming in. Every time the switch comes to the first branch 0, the channelizer outputs $y_0[m]$, $y_1[m]$, ..., $y_{M-1}[m]$. Each branch in the channelizer effectively outputs one sample for every M samples it receives. Hence, the sample rate at the output of the channelizer is f_s/M .

Non-maximally decimated or oversampled channelizer

When $D < M$, the channelizer is known as the non-maximally decimated channelizer or oversampled channelizer. In this configuration, the output sample rate is different from the channel spacing. The non-maximally decimated channelizers offer increased design freedom, but at the expense of increasing computational cost.

If the ratio M/D equals an integer that is greater than 1 and is less than or equal to $M-1$, the channelizer is known as integer-oversampled channelizer. If the ratio M/D is not an integer, then the channelizer is known as rationally-oversampled channelizer.

In this configuration, when the first input sample is delivered, the switch feeds this input to branch 0 and the channelizer computes the first set of output values. As more input samples come in, the switch moves in the counterclockwise direction through branches $D-1$, $D-2$, all the way up to branch 0, delivering one sample at a time to each branch. When the switch comes to branch 0, the channelizer outputs the next set of output values. This process continues as the data keeps coming in. Every time the switch comes to the first branch 0, the channelizer outputs $y_0[m]$, $y_1[m]$, ..., $y_{M-1}[m]$.

As more data keeps coming in and the switch feeds these samples to the first D addresses, the formal contents of these addresses are shifted to the next set of D addresses, and this process of data shift continues every time there is a new set of D input samples.

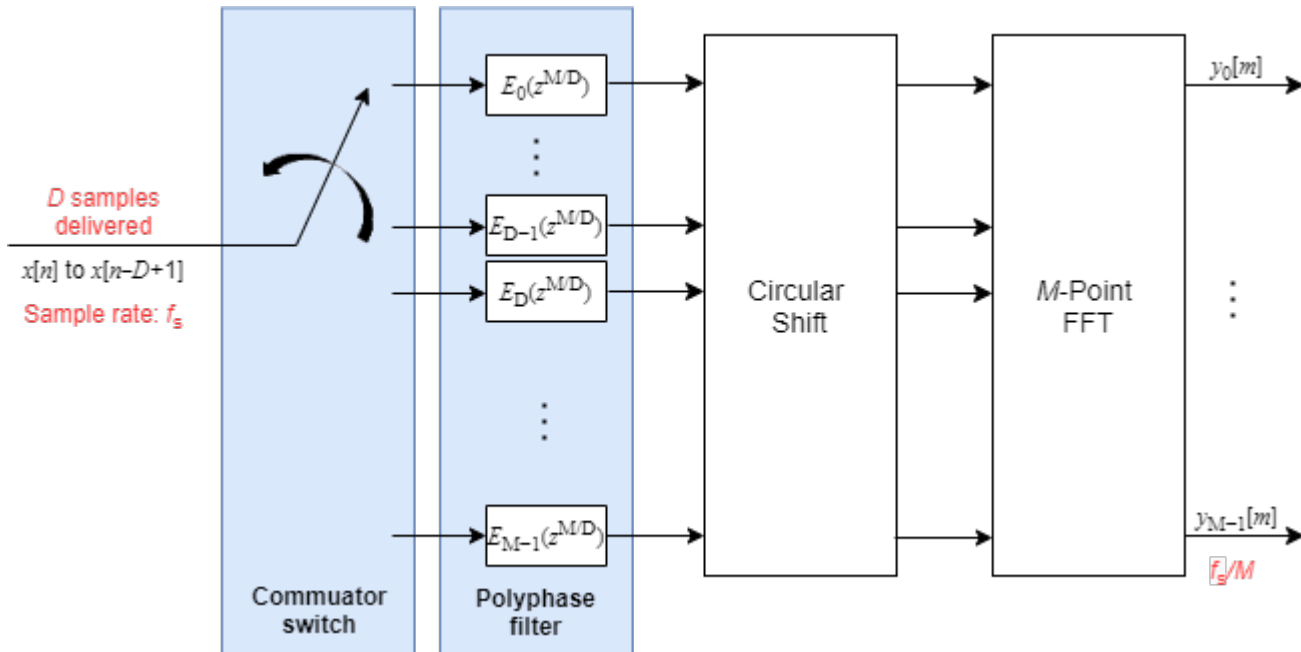

For every D input samples that are fed to the polyphase structure, the channelizer outputs M samples, $y_0[m]$, $y_1[m]$, ..., $y_{M-1}[m]$. This process increases the output sample rate from f_s/M in the case of a maximally decimated channelizer, to f_s/D in the case of a non-maximally decimated channelizer.

For more details, see [2].

After each D -point data sequence is delivered to the partitioned M -stage polyphase filter, the outputs of the M stages are computed and conditioned for delivery to the M -point FFT. The data shifting

through the filter introduces frequency-dependent phase shift. To correct for this phase shift and alias all bands to DC, a circular shift buffer is inserted after the polyphase filters and before the M -point FFT.

With the commutator switch followed by M -stage polyphase filter, circular shift buffer, and a DFT matrix, the efficient implementation of the lowpass prototype-based filter bank looks like this.

Package: dsp

Polyphase FFT synthesis filter bank

Description

The `dsp.ChannelSynthesizer` System object merges multiple narrowband signals into a broadband signal by using an FFT based synthesis filter bank. The filter bank uses a prototype lowpass filter and is implemented using a polyphase structure. You can specify the filter coefficients directly or through design parameters.

To merge multiple narrowband signals into a broadband signal:

- 1 Create the `dsp.ChannelSynthesizer` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

Creation

Syntax

```
synthesizer = dsp.ChannelSynthesizer  
synthesizer = dsp.ChannelSynthesizer(Name,Value)
```

Description

`synthesizer = dsp.ChannelSynthesizer` creates a synthesizer object, using the default properties.

`synthesizer = dsp.ChannelSynthesizer(Name,Value)` specifies additional properties using `Name,Value` pairs. Unspecified properties have default values.

Example: `synthesizer = dsp.ChannelSynthesizer('NumTapsPerBand',20,'StopbandAttenuation',140)`

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see [System Design in MATLAB Using System Objects](#).

Specification — Filter design parameters or coefficients

'Number of taps per band and stopband attenuation' (default) | 'Coefficients'

Filter design parameters or filter coefficients, specified as one of these options:

- 'Number of taps per band and stopband attenuation' — Specify the filter design parameters through the NumTapsPerBand and StopbandAttenuation properties.
- 'Coefficients' — Specify the filter coefficients directly using LowpassCoefficients.

NumTapsPerBand — Number of filter coefficients per frequency band

12 (default) | positive integer

Number of filter coefficients each polyphase branch uses, specified as a positive integer. The number of polyphase branches matches the number of frequency bands. The total number of filter coefficients for the prototype lowpass filter is given by product of the number of frequency bands and NumTapsPerBand. For a given stopband attenuation, increasing the number of taps per band narrows the transition width of the filter. As a result, there is more usable bandwidth for each frequency band at the expense of increased computation.

Dependencies

This property applies when you set Specification to 'Number of taps per band and stopband attenuation'.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

StopbandAttenuation — Stopband attenuation

80 (default) | positive real scalar

Stopband attenuation of the lowpass filter, specified as a positive real scalar in dB. This value controls the maximum amount of aliasing from one frequency band to the next. Larger is the stopband attenuation, smaller is the passband ripple.

Dependencies

This property applies when you set Specification to 'Number of taps per band and stopband attenuation'.

Data Types: single | double

LowpassCoefficients — Coefficients of the prototype lowpass filter

[1×49 double] (default) | row vector

Coefficients of the prototype lowpass filter, specified as a row vector. The default vector of coefficients is obtained using `rcosdesign(0.25,6,8,'sqrt')`. There must be at least one coefficient per frequency band. If the length of the lowpass filter is less than the number of frequency bands, the object zero-pads the coefficients.

If you specify complex coefficients, the object designs a prototype filter that is centered at a nonzero frequency, also known as a bandpass filter. The modulated versions of the prototype bandpass filter appear with respect to the prototype filter and are wrapped around the frequency range $[-F_s, F_s]$.

Tunable: Yes

Dependencies

This property applies when you set Specification to 'Coefficients'.

Data Types: single | double

Usage

Syntax

```
synthOut = synthesizer(input)
```

Description

`synthOut = synthesizer(input)` merges the narrowband input signals contained as columns in `input` into broadband signal, `synthOut`.

Input Arguments

input — Narrowband signals

matrix | 3-D array

Narrowband signals, specified as a matrix or a 3-D array. Each narrowband signal is stored as a column in the input signal. The number of columns in `input` corresponds to the number of frequency bands of the filter bank. If `input` is three-dimensional, each matrix corresponds to a separate channel. If M is the number of frequency bands, and `input` is an L -by- M matrix, then the output signal, `synthOut`, has dimensions $L \times M$ -by-1. If `input` has more than one channel, that is, it has dimensions L -by- M -by- N , then `synthOut` has dimensions $L \times M$ -by- N .

This object also accepts variable-size inputs. That is, once the object is locked, you can change the size of each input channel. The number of channels cannot change.

Data Types: `single` | `double`

Output Arguments

synthOut — Merged broadband signal

matrix | 3-D array

Merged broadband signal, returned as a matrix or a 3-D array. If M is the number of frequency bands, and `input` is an L -by- M matrix, then the output signal, `synthOut`, has dimensions $L \times M$ -by-1. If `input` has more than one channel, that is, it has dimensions L -by- M -by- N , then `synthOut` has dimensions $L \times M$ -by- N .

Data Types: `single` | `double`

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Specific to `dsp.ChannelSynthesizer`

<code>coeffs</code>	Coefficients of prototype lowpass filter
<code>tf</code>	Return transfer function of overall prototype lowpass filter
<code>polyphase</code>	Return polyphase matrix

Common to All System Objects

step	Run System object algorithm
release	Release resources and allow changes to System object property values and input characteristics

Examples

Channelize and Synthesize Sine Wave in MATLAB

Channelize and synthesize a sine wave signal with multiple frequencies using an M -channel filter bank.

The M -channel filter bank contains an analysis filter bank section and a synthesis filter bank section. The `dsp.Channelizer` object implements the analysis filter bank section. The `dsp.ChannelSynthesizer` object implements the synthesis filter bank section. These objects use an efficient polyphase structure to implement the filter bank. For more details, see **Polyphase Implementation** under **Algorithms** on the object reference pages.

Initialization

Initialize the `dsp.Channelizer` and `dsp.ChannelSynthesizer` System objects. Each object is set up with 8 frequency bands, 8 polyphase branches in each filter, 12 coefficients per polyphase branch, and a stopband attenuation of 140 dB. Use a sine wave with multiple frequencies as the input signal. View the input spectrum and the output spectrum using a spectrum analyzer.

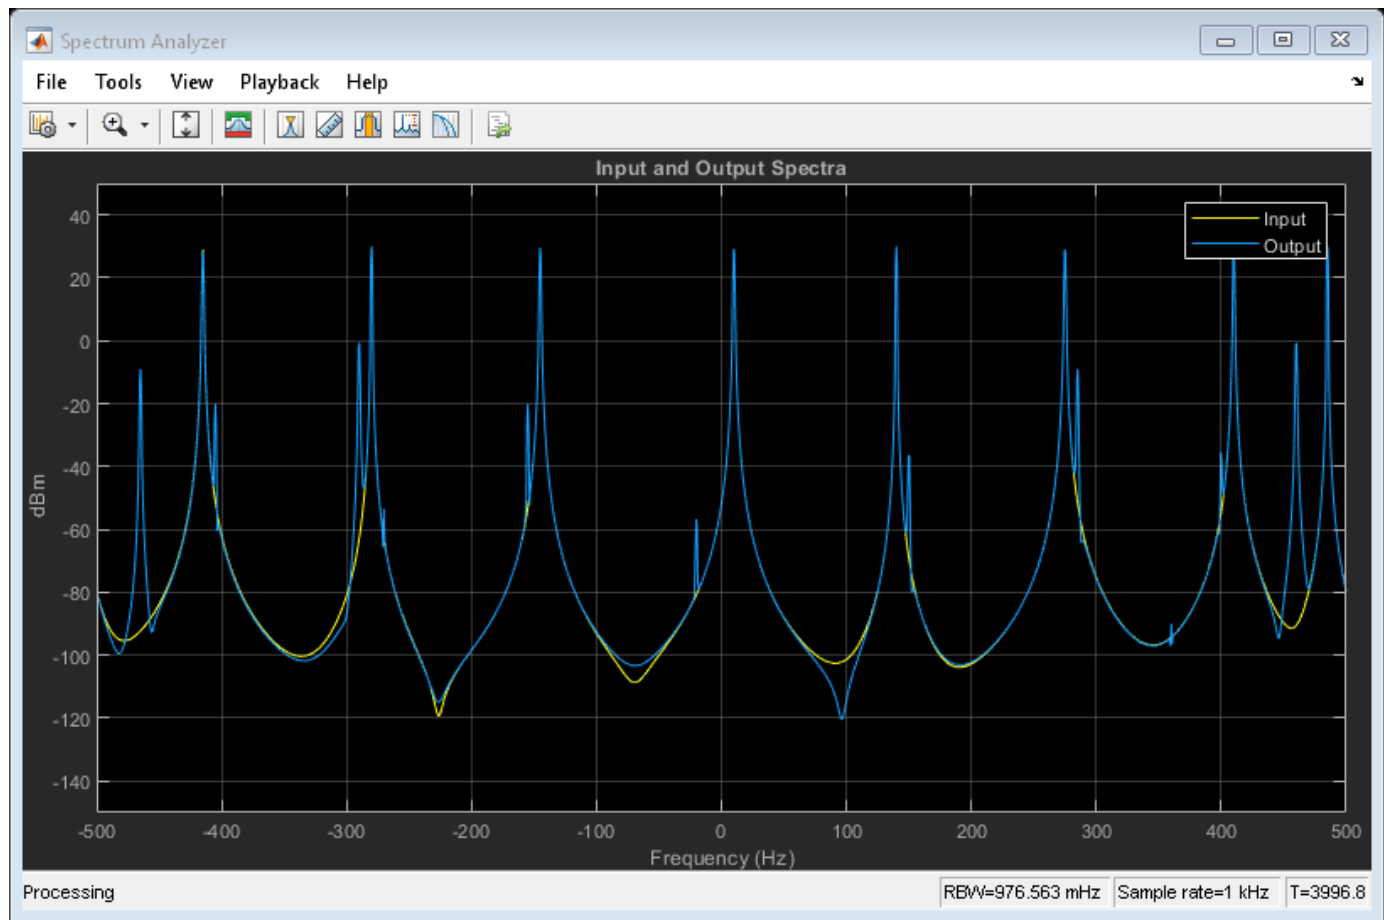

```
offsets = [-40, -30, -20, 10, 15, 25, 35, -15];
sinewave = dsp.SineWave('ComplexOutput', true, 'Frequency', ...
    offsets+(-375:125:500), 'SamplesPerFrame', 800);

channelizer = dsp.Channelizer('StopbandAttenuation', 140);
synthesizer = dsp.ChannelSynthesizer('StopbandAttenuation', 140);
spectrumAnalyzer = dsp.SpectrumAnalyzer('ShowLegend', true, ...
    'SampleRate', sinewave.SampleRate, ...
    'NumInputPorts', 2, 'ChannelNames', {'Input', 'Output'}, ...
    'Title', 'Input and Output Spectra');
```

Streaming

Use the channelizer to split the broadband input signal into multiple narrow bands. Then pass the multiple narrowband signals into the synthesizer, which merges these signals to form the broadband signal. Compare the spectra of the input and output signals. The input and output spectra match very closely.

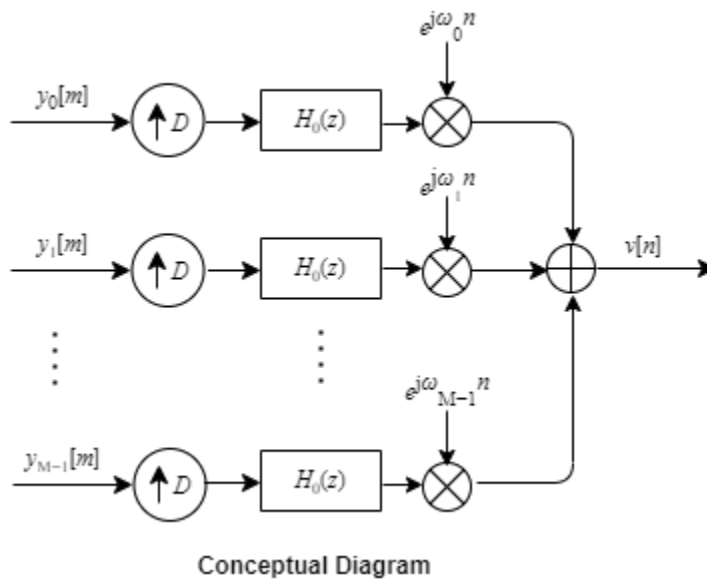

```
for i = 1:5000
    x = sum(sinewave(), 2);
    y = channelizer(x);
    v = synthesizer(y);
    spectrumAnalyzer(x, v)
end
```

More About

Synthesis Filter Bank

The synthesis filter bank consists of a set of parallel bandpass filters that merge multiple input narrowband signals, $y_0[m]$, $y_1[m]$, ..., $y_{M-1}[m]$ into a single broadband signal, $v[n]$. The input narrowband signals are in the baseband. Each narrowband signal is interpolated to a higher sampling rate by using the upsampler, and then filtered by the lowpass filter. A complex exponential that follows the lowpass filter centers the baseband signal around w_k .

Prototype Lowpass Filter

To implement the synthesis filter bank efficiently, the synthesizer uses a prototype lowpass filter. This filter has an impulse response of $h[n]$, a normalized two-sided bandwidth of $2\pi/M$, and a cutoff frequency of π/M . M is the number of frequency bands, that is, the branches of the synthesis filter bank. This value corresponds to the FFT length that the filter bank uses. M can be high, in the order of 2048 or more. The stopband attenuation determines the minimum level of interference (aliasing) from one frequency band to another. The passband ripple must be small so that the input signal is not distorted in the passband.

The prototype lowpass filter models the first branch of the filter bank. The other $M - 1$ branches are modeled by filters that are modulated versions of the prototype filter. The modulation factor is given by $e^{jw_k n}$, $w_k = 2\pi k/M$, $k = 0, 1, \dots, M - 1$.

The output of each bandpass filter forms a specific portion of the broadband signal. The output of all the branches are added to form the broadband signal, $v[n]$.

Algorithms

Polyphase Implementation

The synthesis filter bank can be implemented efficiently using the polyphase structure.

To derive the polyphase structure, start with the transfer function of the prototype lowpass filter.

$$H_0(z) = b_0 + b_1 z^{-1} + \dots + b_N z^{-N}$$

$N + 1$ is the length of the prototype filter.

You can rearrange this equation as follows:

$$H_0(z) = \begin{aligned} & (b_0 + b_M z^{-M} + b_{2M} z^{-2M} + \dots + b_{N-M+1} z^{-(N-M+1)}) + \\ & z^{-1} (b_1 + b_{M+1} z^{-M} + b_{2M+1} z^{-2M} + \dots + b_{N-M+2} z^{-(N-M+1)}) + \\ & \quad \vdots \\ & z^{-(M-1)} (b_{M-1} + b_{2M-1} z^{-M} + b_{3M-1} z^{-2M} + \dots + b_N z^{-(N-M+1)}) \end{aligned}$$

M is the number of polyphase components.

You can write this equation as:

$$H_0(z) = E_0(z^M) + z^{-1} E_1(z^M) + \dots + z^{-(M-1)} E_{M-1}(z^M)$$

$E_0(z^M), E_1(z^M), \dots, E_{M-1}(z^M)$ are polyphase components of the prototype lowpass filter, $H_0(z)$.

The other filters in the filter bank, $H_k(z)$, where $k = 1, \dots, M-1$, are modulated versions of this prototype filter.

You can write the transfer function of the k th modulated bandpass filter as $H_k(z) = H_0(z e^{jw_k})$. Replacing z with $z e^{jw_k}$,

$$H_k(z) = h_0 + h_1 e^{jw_k} z^{-1} + h_2 e^{j2w_k} z^{-2} \dots + h_N e^{jNw_k} z^{-N}$$

$N + 1$ is the length of the k th filter.

In polyphase form, the equation is as follows:

$$H_k(z) = \begin{bmatrix} 1 & e^{jw_k} & e^{j2w_k} & \dots & e^{j(M-1)w_k} \end{bmatrix} \begin{bmatrix} E_0(z^M) \\ z^{-1} E_1(z^M) \\ \vdots \\ z^{-(M-1)} E_{M-1}(z^M) \end{bmatrix}$$

For all M channels in the filter bank, the MIMO transfer function, $H(z)$, is given by:

$$H(z) = \begin{bmatrix} 1 & 1 & 1 & \dots & 1 \\ 1 & e^{jw_1} & e^{j2w_1} & \dots & e^{j(M-1)w_1} \\ & & \vdots & & \\ 1 & e^{jw_{M-1}} & e^{j2w_{M-1}} & \dots & e^{j(M-1)w_{M-1}} \end{bmatrix} \begin{bmatrix} E_0(z^M) \\ z^{-1} E_1(z^M) \\ \vdots \\ z^{-(M-1)} E_{M-1}(z^M) \end{bmatrix}$$

Here is the multirate noble identity for interpolation, assuming that $D = M$:

For illustration, consider the first branch of the filter bank that contains the lowpass filter.

Replace $H_0(z)$ with its polyphase representation.

After applying the noble identity for interpolation, you can replace the delays, interpolation factor, and the adder with a commutator switch.

For all the M channels in the filter bank, the MIMO transfer function, $H(z)$, is given by:

$$H(z) = \begin{bmatrix} 1 & 1 & 1 & \dots & 1 \\ 1 & e^{jw_1} & e^{j2w_1} & \dots & e^{j(M-1)w_1} \\ & & & \vdots & \\ 1 & e^{jw_{M-1}} & e^{j2w_{M-1}} & \dots & e^{j(M-1)w_{M-1}} \end{bmatrix} \begin{bmatrix} E_0(z) \\ E_1(z) \\ \vdots \\ E_{M-1}(z) \end{bmatrix}$$

The matrix on the left is an IDFT matrix. With the IDFT matrix, the efficient implementation of the lowpass prototype based filter bank looks like the following.

dsp.Chirp

Package: dsp

Generate swept-frequency cosine (chirp) signal

Description

The `Chirp` object generates a swept-frequency cosine (chirp) signal.

To generate the chirp signal:

- 1 Create the `dsp.Chirp` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

Creation

Syntax

```
chirp = dsp.Chirp
chirp = dsp.Chirp(Name,Value)
```

Description

`chirp = dsp.Chirp` returns a chirp signal, `chirp`, with unity amplitude.

`chirp = dsp.Chirp(Name,Value)` returns a chirp signal, `chirp`, with each specified property set to the specified value.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see [System Design in MATLAB Using System Objects](#).

Type — Frequency sweep type

`Linear` (default) | `Swept cosine` | `Logarithmic` | `Quadratic`

Specify the frequency sweep type as `Swept cosine`, `Linear`, `Logarithmic`, or `Quadratic`. This property specifies how the output instantaneous frequency sweep varies over time.

SweepDirection — Sweep direction

`Unidirectional` (default) | `Bidirectional`

Specify the sweep direction as either `Unidirectional` or `Bidirectional`.

InitialFrequency — Initial frequency (hertz)

1000 (default) | scalar greater than or equal to 0

When you set the `Type` property to `Linear`, `Quadratic`, or `Logarithmic`, this property specifies the initial instantaneous frequency in hertz of the output chirp signal. When you set the `Type` property to `Logarithmic`, the value of this property is one less than the actual initial frequency of the sweep. Also, when the sweep is logarithmic, the initial frequency must be less than the target frequency, specified by the `TargetFrequency` property.

Tunable: Yes

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

TargetFrequency — Target frequency (hertz)

4000 (default) | scalar greater than or equal to 0

When you set the `Type` property to `Linear`, `Quadratic`, or `Logarithmic`, this property specifies the instantaneous frequency of the output signal in hertz at the target time. When you set the `Type` property to `Swept Cosine`, the target frequency is the instantaneous frequency of the output at half the target time. Also, when the sweep is logarithmic, the target frequency must be greater than the initial frequency, specified by the `InitialFrequency` property.

Tunable: Yes

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

TargetTime — Target time

1 (default) | scalar greater than or equal to 0

When you set the `Type` property to `Linear`, `Quadratic`, or `Logarithmic`, this property specifies the target time in seconds at which the target frequency is reached. When you set the `Type` property to `Swept cosine`, this property specifies the time at which the sweep reaches $2f_{tgt} - f_{init}$ Hz, where f_{tgt} is the `TargetFrequency` and f_{init} is the `InitialFrequency`. The target time should not be greater than the sweep time, specified by the `SweepTime` property.

Tunable: Yes

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

SweepTime — Sweep time

1 (default) | scalar greater than or equal to 0

When you set the `SweepDirection` property to `Unidirectional`, the sweep time in seconds is the period of the output frequency sweep. When you set the `SweepDirection` property to `Bidirectional`, the sweep time is half the period of the output frequency sweep. The sweep time should be no less than the target time, specified by the `TargetTime`. This property must be a positive numeric scalar.

Tunable: Yes

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

InitialPhase — Initial phase

0 (default) | scalar greater than or equal to 0

Specify initial phase of the output in radians at time $t = 0$.

Tunable: Yes

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

SampleRate — Sample rate

8000 (default) | positive scalar

Specify the sampling rate of the output in hertz as a positive numeric scalar.

Data Types: `single` | `double` | `logical`

SamplesPerFrame — Samples per output frame

1 (default) | positive integer

Specify the number of samples to buffer into each output as a positive integer. The default value is 1.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

OutputDataType — Output data type

`double` (default) | `single`

Specify the output data type as `double` or `single`. The default value is `double`.

Usage

Syntax

```
y = chirp()
```

Description

`y = chirp()` returns a swept-frequency cosine output, `y`.

Output Arguments

y — Swept-frequency cosine output

scalar | column vector

Swept-frequency cosine output, returned as a scalar or a column vector. The length of the output vector equals the value you specify in the `SamplesPerFrame` property.

Data Types: `double`

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Common to All System Objects

`step` Run System object algorithm

release Release resources and allow changes to System object property values and input characteristics
reset Reset internal states of System object

Examples

Generate a Bidirectional Swept Chirp Signal

Note: If you are using R2016a or earlier, replace each call to the object with the equivalent `step` syntax. For example, `obj(x)` becomes `step(obj,x)`.

```
chirp = dsp.Chirp(...  
    'SweepDirection', 'Bidirectional', ...  
    'TargetFrequency', 25, ...  
    'InitialFrequency', 0,...  
    'TargetTime', 1, ...  
    'SweepTime', 1, ...  
    'SamplesPerFrame', 400, ...  
    'SampleRate', 400);
```

```
plot(chirp());
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the Chirp block reference page. The object properties correspond to the block parameters.

dsp.CICCompensationDecimator

Package: dsp

Compensate for CIC decimation filter using FIR decimator

Description

You can compensate for the shortcomings of a CIC decimator, namely its passband droop and wide transition region, by following it with a compensation decimator. This System object lets you design and use such a filter.

To compensate for the shortcomings of a CIC filter using an FIR decimator:

- 1 Create the `dsp.CICCompensationDecimator` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

Creation

Syntax

```
ciccompdec = dsp.CICCompensationDecimator
ciccompdec = dsp.CICCompensationDecimator(decim)
ciccompdec = dsp.CICCompensationDecimator(cic)
ciccompdec = dsp.CICCompensationDecimator(cic,decim)
ciccompdec = dsp.CICCompensationDecimator( ____,Name,Value)
```

Description

`ciccompdec = dsp.CICCompensationDecimator` returns a System object, `ciccompdec`, that applies an FIR decimator to each channel of an input signal. Using the properties of the object, the decimation filter can be designed to compensate for a preceding CIC filter.

`ciccompdec = dsp.CICCompensationDecimator(decim)` returns a CIC compensation decimator System object, with the `DecimationFactor` property set to `decim`.

`ciccompdec = dsp.CICCompensationDecimator(cic)` returns a CIC compensation decimator System object, with the `CICRateChangeFactor`, `CICNumSections`, and `CICDifferentialDelay` properties specified in the `dsp.CICDecimator` System object, `cic`.

`ciccompdec = dsp.CICCompensationDecimator(cic,decim)` returns a CIC compensation decimator System object, `ciccompdec`, with the `CICRateChangeFactor`, `CICNumSections`, and `CICDifferentialDelay` properties specified in the `dsp.CICDecimator` System object `cic`, and the `DecimationFactor` property set to `decim`.

`ciccompdec = dsp.CICCompensationDecimator(____,Name,Value)` returns a CIC compensation decimator object with each specified property set to the specified value. Enclose each property name in quotes. You can use this syntax with any previous input argument combinations.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects.

CICDifferentialDelay — Differential delay of the CIC filter being compensated

1 (default) | positive integer scalar

Specify the differential delay of the CIC filter being compensated as a positive integer scalar.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

CICNumSections — Number of sections of the CIC filter being compensated

2 (default) | positive integer scalar

Specify the number of sections of the CIC filter being compensated as a positive integer scalar.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

CICRateChangeFactor — Rate-change factor of the CIC filter being compensated

2 (default) | positive integer scalar

Specify the rate-change factor of the CIC filter being compensated as a positive integer scalar.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

DecimationFactor — Decimation factor of compensator

2 (default) | positive integer scalar

Specify the decimation factor of the compensator System object as a positive integer scalar.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

DesignForMinimumOrder — Design filter of minimum order or of specified order

`true` (default) | `false`

Specify whether to design a filter of minimum order or a filter of specified order as a logical scalar. The default is `true`, which corresponds to a filter of minimum order.

FilterOrder — Order of decimation compensator filter

12 (default) | positive integer scalar

Specify the order of the decimation compensator filter as a positive integer scalar.

Dependencies

This property applies only when you set the `DesignForMinimumOrder` property to `false`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

PassbandFrequency — Passband edge frequency in hertz

100000 (default) | positive real scalar

Specify the passband edge frequency as a positive real scalar expressed in hertz. PassbandFrequency must be less than $F_s/2$, where F_s is the input sample rate.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

PassbandRipple — Filter passband ripple in decibels

0.1 (default) | positive real scalar

Specify the filter passband ripple as a positive real scalar expressed in decibels.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

SampleRate — Input sample rate in hertz

1200000 (default) | positive real scalar

Specify the input sample rate as a positive real scalar expressed in hertz.

Data Types: single | double

StopbandAttenuation — Filter stopband attenuation in decibels

60 (default) | positive real scalar

Specify the filter stopband attenuation as a positive real scalar expressed in decibels.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

StopbandFrequency — Stopband edge frequency in hertz

400000 (default) | positive real scalar

Specify the stopband edge frequency as a positive real scalar expressed in hertz. StopbandFrequency must be less than $F_s/2$, where F_s is the input sample rate.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

Fixed-Point Properties**CoefficientsDataType — Word and fraction lengths of coefficients**

numericType(1,16) (default) | numericType object

Word and fraction lengths of coefficients, specified as a signed or unsigned numericType object. The default, numericType(1,16) corresponds to a signed numeric type object with 16-bit coefficients and a fraction length determined based on the coefficient values, to give the best possible precision.

This property is not tunable.

Word length of the output is same as the word length of the input. Fraction length of the output is computed such that the entire dynamic range of the output can be represented without overflow. For details on how the fraction length of the output is computed, see “Fixed-Point Precision Rules for Avoiding Overflow in FIR Filters”.

RoundingMethod — Rounding method for output fixed-point operations

'Floor' (default) | 'Ceiling' | 'Convergent' | 'Nearest' | 'Round' | 'Simplest' | 'Zero'

Rounding method for output fixed-point operations, specified as a character vector. For more information on the rounding modes, see “Precision and Range”.

Usage

Syntax

```
y = ciccompdecim(x)
```

Description

`y = ciccompdecim(x)` returns the filtered and downsampled values, y , of the input signal, x .

Input Arguments

x — Data input

vector | matrix

Data input, specified as a vector or a matrix. The System object treats a $K_i \times N$ input matrix as N independent channels, decimating each channel over the first dimension. The number of input rows, K_i , must be a multiple of the decimation factor.

This object does not support complex unsigned fixed-point data.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fi

Output Arguments

y — Filtered and downsampled signal

vector | matrix

Filtered and downsampled signal, returned as a vector or matrix. For a $K_i \times N$ input matrix, the result is a $K_o \times N$ output matrix, where $K_o = K_i / M$ and M is the decimation factor.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fi

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Specific to dsp.CICCompensationDecimator

freqz	Frequency response of discrete-time filter System object
fvtool	Visualize frequency response of DSP filters
info	Information about filter System object
cost	Estimate cost of implementing filter System object
coeffs	Returns the filter System object coefficients in a structure
polyphase	Polyphase decomposition of multirate filter
generatehdl	Generate HDL code for quantized DSP filter (requires Filter Design HDL Coder)

Common to All System Objects

step Run System object algorithm
 release Release resources and allow changes to System object property values and input characteristics
 reset Reset internal states of System object

Examples

Impulse and Frequency Response of CIC Compensation Decimator

Design an CIC compensation decimator. Specify the decimation factor to be 2, passband frequency to be 4 kHz, stopband frequency to be 4.5 kHz, and the input sample rate to be 16 kHz.

```
fs = 16e3;
fPass = 4e3;
fStop = 4.5e3;
```

```
CICCompDecim = dsp.CICCompensationDecimator('DecimationFactor',2,...
    'PassbandFrequency',fPass,...
    'StopbandFrequency',fStop,...
    'SampleRate',fs);
```

Plot the impulse response. The group delay of the filter is 45.5.

```
fvtool(CICCompDecim,'Analysis','impulse')
```

Plot the magnitude and Phase response.

```
fvtool(CICCompDecim,'Analysis','freq')
```

Compensation Decimator Design

Note: If you are using R2016a or an earlier release, replace each call to the object with the equivalent step syntax. For example, `obj(x)` becomes `step(obj,x)`.

Design a compensation decimator for an existing CIC decimator having six sections and a decimation factor of 6.

```
CICDecim = dsp.CICDecimator('DecimationFactor',6, ...
    'NumSections',6);
```

Construct the compensation decimator. Specify a decimation factor of 2, an input sample rate of 16 kHz, a passband frequency of 4 kHz, and a stopband frequency of 4.5 kHz.

```
fs = 16e3;
fPass = 4e3;
fStop = 4.5e3;
```

```
CICCompDecim = dsp.CICCompensationDecimator(CICDecim, ...
    'DecimationFactor',2,'PassbandFrequency',fPass, ...
    'StopbandFrequency',fStop,'SampleRate',fs);
```

Visualize the frequency response of the cascade. Normalize all magnitude responses to 0 dB.

```
filtCasc = dsp.FilterCascade(CICDecim,CICCompDecim);

f = fvtool(CICDecim, CICCompDecim, filtCasc, ...
    'Fs', [fs*6 fs fs*6]);

f.NormalizeMagnitudeto1 = 'on';
legend(f, 'CIC Decimator', 'CIC Compensation Decimator', ...
    'Overall Response');
```

Apply the design to a 1200-sample random input signal. Store the decimated output along the first dimension of the `y` array.

```
x = dsp.SignalSource(fi(rand(1200,1),1,16,15), 'SamplesPerFrame', 120);

y = fi(zeros(100,1),1,32,20);

for ind = 1:10
    x2 = CICDecim(x());
    y(((ind-1)*10)+1:ind*10,1) = CICCompDecim(x2);
end
```

Algorithms

The response of a CIC filter is given by:

$$H_{cic}(\omega) = \left[\frac{\sin\left(\frac{RD\omega}{2}\right)}{\sin\left(\frac{\omega}{2}\right)} \right]^N$$

R , D , and N are the rate change factor, the differential delay, and the number of sections of the CIC filter, respectively.

After decimation, the cic response has the form:okay

$$H_{cic}(\omega) = \left[\frac{\sin\left(\frac{D\omega}{2}\right)}{\sin\left(\frac{\omega}{2R}\right)} \right]^N$$

The normalized version of this last response is the one that the CIC compensator needs to compensate. Hence, the passband response of the CIC compensator should take the following form:

$$H_{ciccomp}(\omega) = \left[RD \frac{\sin\left(\frac{\omega}{2R}\right)}{\sin\left(\frac{D\omega}{2}\right)} \right]^N \text{ for } \omega \leq \omega_p < \pi$$

where ω_p is the passband frequency of the CIC compensation filter.

Notice that when $\omega/2R \ll \pi$, the previous equation for $H_{ciccomp}(\omega)$ can be simplified using the fact that $\sin(x) \cong x$:

$$H_{ciccomp}(\omega) \approx \left[\frac{\left(\frac{D\omega}{2}\right)}{\sin\left(\frac{D\omega}{2}\right)} \right]^N = \left[\text{sinc}\left(\frac{D\omega}{2}\right) \right]^{-N} \text{ for } \omega \leq \omega_p < \pi$$

This previous equation is the inverse sinc approximation to the true inverse passband response of the CIC filter.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

See “System Objects in MATLAB Code Generation” (MATLAB Coder).

This object supports code generation for ARM Cortex-M and ARM Cortex-A processors.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

This object supports HDL code generation with the Filter Design HDL Coder product. For workflows and limitations, see “Generate HDL Code for Filter System Objects” (Filter Design HDL Coder).

dsp.CICCompensationInterpolator

Package: dsp

Compensate for CIC interpolation filter using FIR interpolator

Description

You can compensate for the shortcomings of a CIC interpolator, namely its passband droop and wide transition region, by preceding it with a compensation interpolator. This System object lets you design and use such a filter.

To compensate for the shortcomings of a CIC filter using an FIR interpolator:

- 1 Create the `dsp.CICCompensationInterpolator` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

Creation

Syntax

```
ciccompint = dsp.CICCompensationInterpolator
ciccompint = dsp.CICCompensationInterpolator(interp)
ciccompint = dsp.CICCompensationInterpolator(cic)
ciccompint = dsp.CICCompensationInterpolator(cic,interp)
ciccompint = dsp.CICCompensationInterpolator( ___,Name,Value)
```

Description

`ciccompint = dsp.CICCompensationInterpolator` returns a System object, `ciccompint`, that applies an FIR interpolator to each channel of an input signal. Using the properties of the object, the interpolation filter can be designed to compensate for a subsequent CIC filter.

`ciccompint = dsp.CICCompensationInterpolator(interp)` returns a CIC compensation interpolator System object, `ciccompint`, with the `InterpolationFactor` property set to `interp`.

`ciccompint = dsp.CICCompensationInterpolator(cic)` returns a CIC compensation interpolator System object, `ciccompint`, with the `CICRateChangeFactor`, `CICNumSections`, and `CICDifferentialDelay` properties specified in the `dsp.CICInterpolator` System object `cic`.

`ciccompint = dsp.CICCompensationInterpolator(cic,interp)` returns a CIC compensation interpolator System object, `ciccompint`, with the `CICRateChangeFactor`, `CICNumSections`, and `CICDifferentialDelay` properties specified in the `dsp.CICInterpolator` System object `cic`, and the `InterpolationFactor` property set to `interp`.

`ciccompint = dsp.CICCompensationInterpolator(___,Name,Value)` returns a CIC compensation interpolator object with each specified property set to the specified value. Enclose each property name in quotes. You can use this syntax with any previous input argument combinations.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects.

CICDifferentialDelay — Differential delay of the CIC filter being compensated

1 (default) | positive integer scalar

Specify the differential delay of the CIC filter being compensated as a positive integer scalar.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

CICNumSections — Number of sections of the CIC filter being compensated

2 (default) | positive integer scalar

Specify the number of sections of the CIC filter being compensated as a positive integer scalar.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

CICRateChangeFactor — Rate-change factor of the CIC filter being compensated

2 (default) | positive integer scalar

Specify the rate-change factor of the CIC filter being compensated as a positive integer scalar. The default is 2.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

DesignForMinimumOrder — Design filter of minimum order or of specified order

`true` (default) | `false`

Specify whether to design a filter of minimum order or a filter of specified order as a logical scalar. The default is `true`, which corresponds to a filter of minimum order.

FilterOrder — Order of interpolation compensator filter

12 (default) | positive integer scalar

Specify the order of the interpolation compensator filter as a positive integer scalar.

Dependencies

This property applies only when you set the `DesignForMinimumOrder` property to `false`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

InterpolationFactor — Interpolation factor of compensator

2 (default) | positive integer scalar

Specify the interpolation factor of the compensator System object as a positive integer scalar.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

PassbandFrequency — Passband edge frequency in hertz

100000 (default) | positive real scalar

Specify the passband edge frequency as a positive real scalar expressed in hertz. PassbandFrequency must be less than $F_s/2$, where F_s is the output sample rate.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

PassbandRipple — Filter passband ripple in decibels

0.1 (default) | positive real scalar

Specify the filter passband ripple as a positive real scalar expressed in decibels.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

SampleRate — Input sample rate in hertz

600000 (default) | positive real scalar

Specify the input sample rate as a positive real scalar expressed in hertz.

Data Types: `single` | `double`

StopbandAttenuation — Filter stopband attenuation in decibels

60 (default) | positive real scalar

Specify the filter stopband attenuation as a positive real scalar expressed in decibels.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

StopbandFrequency — Stopband edge frequency in hertz

400000 (default) | positive real scalar

Specify the stopband edge frequency as a positive real scalar expressed in hertz. StopbandFrequency must be less than $F_s/2$, where F_s is the output sample rate.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

Fixed-Point Properties

CoefficientsDataType — Word and fraction lengths of coefficients

`numericType(1,16)` (default) | `numericType` object

Word and fraction lengths of coefficients, specified as a signed or unsigned `numericType` object. The default, `numericType(1,16)` corresponds to a signed numeric type object with 16-bit coefficients and a fraction length determined based on the coefficient values, to give the best possible precision.

This property is not tunable.

Word length of the output is same as the word length of the input. Fraction length of the output is computed such that the entire dynamic range of the output can be represented without overflow. For details on how the fraction length of the output is computed, see “Fixed-Point Precision Rules for Avoiding Overflow in FIR Filters”.

RoundingMethod — Rounding method for output fixed-point operations

'Floor' (default) | 'Ceiling' | 'Convergent' | 'Nearest' | 'Round' | 'Simplest' | 'Zero'

Rounding method for output fixed-point operations, specified as a character vector. For more information on the rounding modes, see “Precision and Range”.

Usage

Syntax

```
y = ciccompint(x)
```

Description

`y = ciccompint(x)` outputs the upsampled and filtered values, y , of the input signal, x .

Input Arguments

x — Data input

vector | matrix

Data input, specified as a vector or a matrix. The System object treats a $K_i \times N$ input matrix as N independent channels, interpolating each channel over the first dimension.

This object does not support complex unsigned fixed-point data.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fi`

Output Arguments

y — Upsampled and filtered signal

vector | matrix

Upsampled and filtered signal, returned as a vector or matrix. For a $K_i \times N$ input matrix, the result is a $K_o \times N$ output matrix, where $K_o = K_i \times L$ and L is the interpolation factor.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fi`

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Specific to `dsp.CICCompensationInterpolator`

<code>freqz</code>	Frequency response of discrete-time filter System object
<code>fvtool</code>	Visualize frequency response of DSP filters
<code>info</code>	Information about filter System object
<code>cost</code>	Estimate cost of implementing filter System object
<code>coeffs</code>	Returns the filter System object coefficients in a structure
<code>polyphase</code>	Polyphase decomposition of multirate filter
<code>generatehdl</code>	Generate HDL code for quantized DSP filter (requires Filter Design HDL Coder)

Common to All System Objects

step Run System object algorithm
release Release resources and allow changes to System object property values and input characteristics
reset Reset internal states of System object

Examples

Impulse and Frequency Response of CIC Compensation Interpolator

Design an CIC compensation interpolator. Specify the interpolation factor to be 2, passband frequency to be 200 Hz, stopband frequency to be 500 Hz, and the input sample rate to be 600 Hz.

```
fs = 600;  
fPass = 200;  
fStop = 500;
```

```
CICCompInterp = dsp.CICCompensationInterpolator(...  
    'InterpolationFactor',2,...  
    'PassbandFrequency',fPass,...  
    'StopbandFrequency',fStop,...  
    'SampleRate',fs);
```

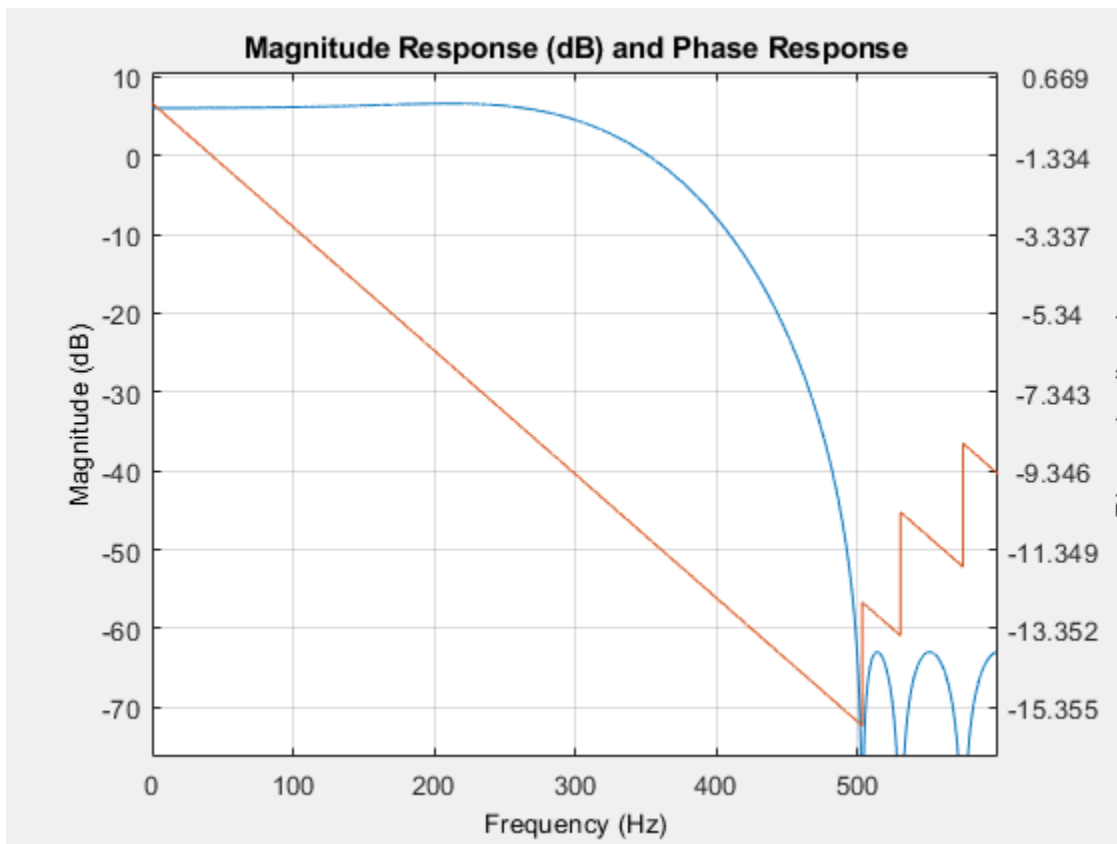

Plot the impulse response. The zeroth order coefficient is delayed 6 samples, which is equal to the group delay of the filter.

```
fvtool(CICCompInterp,'Analysis','impulse')
```

Plot the magnitude and Phase response.

```
fvtool(CICCompInterp, 'Analysis', 'freq')
```

Compensation Interpolator Design

Note: If you are using R2016a or an earlier release, replace each call to the object with the equivalent step syntax. For example, `obj(x)` becomes `step(obj,x)`.

Design a compensation interpolator for an existing CIC interpolator having six sections and an interpolation factor of 16.

```
CICInterp = dsp.CICInterpolator('InterpolationFactor',16, ...
    'NumSections',6);
```

Construct the compensation interpolator. Specify an interpolation factor of 2, an input sample rate of 600 Hz, a passband frequency of 100 Hz, and a stopband frequency of 250 Hz. Set the minimum attenuation of alias components in the stopband to be at least 80 dB.

```
fs = 600;
fPass = 100;
fStop = 250;
ast = 80;
```

```
CICCompInterp = dsp.CICCompensationInterpolator(CICInterp, ...
    'InterpolationFactor',2,'PassbandFrequency',fPass, ...
    'StopbandFrequency',fStop,'StopbandAttenuation',ast, ...
    'SampleRate',fs);
```

Visualize the frequency response of the cascade. Normalize all magnitude responses to 0 dB.

```
FC = dsp.FilterCascade(CICCompInterp, CICInterp);

f = fvtool(CICCompInterp,CICInterp,FC, ...
    'Fs', [fs*2 fs*16*2 fs*16*2]);

f.NormalizeMagnitudeto1 = 'on';
legend(f, 'CIC Compensation Interpolator', 'CIC Interpolator', ...
    'Overall Response');
```

Apply the design to a 1000-sample random input signal.

```
x = dsp.SignalSource(fi(rand(1000,1),1,16,15), 'SamplesPerFrame', 100);

y = fi(zeros(32000,1),1,32,20);
for ind = 1:10
    x2 = CICCompInterp(x());
    y(((ind-1)*3200)+1:ind*3200) = CICInterp(x2);
end
```

Algorithms

The response of a CIC filter is given by:

$$H_{cic}(\omega) = \left[\frac{\sin\left(\frac{RD\omega}{2}\right)}{\sin\left(\frac{\omega}{2}\right)} \right]^N$$

R , D , and N are the rate change factor, the differential delay, and the number of sections of the CIC filter, respectively.

After decimation, the cic response has the form:okay

$$H_{cic}(\omega) = \left[\frac{\sin\left(\frac{D\omega}{2}\right)}{\sin\left(\frac{\omega}{2R}\right)} \right]^N$$

The normalized version of this last response is the one that the CIC compensator needs to compensate. Hence, the passband response of the CIC compensator should take the following form:

$$H_{ciccomp}(\omega) = \left[RD \frac{\sin\left(\frac{\omega}{2R}\right)}{\sin\left(\frac{D\omega}{2}\right)} \right]^N \text{ for } \omega \leq \omega_p < \pi$$

where ω_p is the passband frequency of the CIC compensation filter.

Notice that when $\omega/2R \ll \pi$, the previous equation for $H_{ciccomp}(\omega)$ can be simplified using the fact that $\sin(x) \cong x$:

$$H_{ciccomp}(\omega) \approx \left[\frac{\left(\frac{D\omega}{2}\right)}{\sin\left(\frac{D\omega}{2}\right)} \right]^N = \left[\text{sinc}\left(\frac{D\omega}{2}\right) \right]^{-N} \text{ for } \omega \leq \omega_p < \pi$$

This previous equation is the inverse sinc approximation to the true inverse passband response of the CIC filter.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

See “System Objects in MATLAB Code Generation” (MATLAB Coder).

This object supports code generation for ARM Cortex-M and ARM Cortex-A processors.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

This object supports HDL code generation with the Filter Design HDL Coder product. For workflows and limitations, see “Generate HDL Code for Filter System Objects” (Filter Design HDL Coder).

Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

This object does not support complex unsigned fixed-point data.

dsp.CICDecimator

Package: dsp

Decimate signal using cascaded integrator-comb (CIC) filter

Description

The `dsp.CICDecimator` System object decimates an input signal using a cascaded integrator-comb (CIC) decimation filter. The CIC decimation filter structure consists of N sections of cascaded integrators, followed by a rate change by a factor of R , followed by N sections of cascaded comb filters. For details, see “Algorithms” on page 4-271. The `NumSections` property specifies N , the number of sections in the CIC filter. The `DecimationFactor` property specifies R , the decimation factor. The `getFixedPointInfo` function returns the word lengths and fraction lengths of the fixed-point sections and the output for the `dsp.CICDecimator` System object. You can also generate HDL code for this System object using the `generatehdl` function.

Note This object requires a Fixed-Point Designer license.

To decimate a signal using a CIC filter:

- 1 Create the `dsp.CICDecimator` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

Creation

Syntax

```
cicDecim = dsp.CICDecimator
cicDecim = dsp.CICDecimator(R,M,N)
cicDecim = dsp.CICDecimator(Name,Value)
```

Description

`cicDecim = dsp.CICDecimator` creates a CIC decimation System object that applies a CIC decimation filter to the input signal.

`cicDecim = dsp.CICDecimator(R,M,N)` creates a CIC decimation object with the `DecimationFactor` property set to R , the `DifferentialDelay` property set to M , and the `NumSections` property set to N .

`cicDecim = dsp.CICDecimator(Name,Value)` creates a CIC decimation object with each specified property set to the specified value. Enclose each property name in single quotes. You can use this syntax with any previous input argument combination.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects.

DecimationFactor — Decimation factor

2 (default) | positive integer

Factor by which the input signal is decimated, specified as a positive integer.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

DifferentialDelay — Differential delay of filter comb sections

1 (default) | positive integer

Differential delay value used in each of the comb sections of the filter, specified as a positive integer. For details, see “Algorithms” on page 4-271. If the differential delay is a built-in integer data type, the decimation factor must be the same integer data type or `double`. For example, if the differential delay is an `int8`, then the decimation factor must be an `int8` or `double`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

NumSections — Number of integrator and comb sections

2 (default) | positive integer

Number of integrator and comb sections of the CIC filter, specified as a positive integer. This number indicates the number of sections in either the comb part or the integrator part of the filter. The total number of sections in the CIC filter is twice the number of sections given by this property.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

FixedPointDataType — Fixed-point property designations

Full precision (default) | Minimum section word lengths | Specify word lengths | Specify word and fraction lengths

Fixed-point property designations, specified as one of the following:

- **Full precision** - The word length and fraction length of the CIC filter sections and the object output operate in full precision.
- **Minimum section word lengths** - Specify the output word length through the `OutputWordLength` property. The object determines the filter section data type and the output fraction length that give the best possible precision. For details, see `getFixedPointInfo` and `cicDecimOut` argument.
- **Specify word lengths** - Specify the word lengths of the CIC filter sections and the object output through the `SectionWordLengths` and `OutputWordLength` properties. The object determines the corresponding fraction lengths to give the best possible precision. For details, see `getFixedPointInfo` and the `cicDecimOut` argument.
- **Specify word and fraction lengths** - Specify the word length and fraction length of the CIC filter sections and the object output through the `SectionWordLengths`, `SectionFractionLengths`, `OutputWordLength`, and `OutputFractionLength` properties.

SectionWordLengths — Fixed-point word lengths for each filter section

[16 16 16 16] (default) | scalar | vector

Fixed-point word lengths to use for each filter section, specified as a scalar or a row vector of integers. The word length must be greater than or equal to 2. If you specify a scalar, the value applies to all the sections of the filter. If you specify a vector, the vector must be of length $2 \times \text{NumSections}$.

Example: 32

Example: [32 32 32 32]

Dependencies

This property applies when you set the `FixedPointDataType` property to 'Specify word lengths' or 'Specify word and fraction lengths'.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

SectionFractionLengths — Fixed-point fraction lengths for each filter section

0 (default) | scalar | vector

Fixed-point fraction lengths to use for each filter section, specified as a scalar or a row vector of integers. The fraction length can be negative, 0, or positive. If you specify a scalar, the value applies to all the sections of the filter. If you specify a vector, the vector must be of length $2 \times \text{NumSections}$.

Example: -2

Example: [-2 0 5 8]

Dependencies

This property applies when you set the `FixedPointDataType` property to 'Specify word and fraction lengths'.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

OutputWordLength — Fixed-point word length for filter output

32 (default) | scalar integer

Fixed-point word length to use for the filter output, specified as a scalar integer greater than or equal to 2.

Dependencies

This property applies when you set the `FixedPointDataType` property to 'Minimum section word lengths', 'Specify word lengths', or 'Specify word and fraction lengths'.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

OutputFractionLength — Fixed-point fraction length for filter output

0 (default) | scalar integer

Fixed-point fraction length to use for the filter output, specified as a scalar integer.

Dependencies

This property applies when you set `FixedPointDataType` property to 'Specify word and fraction lengths'.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

Usage

Syntax

```
cicDecimOut = cicDecim(input)
```

Description

`cicDecimOut = cicDecim(input)` decimates the input using a CIC decimator.

Input Arguments

input — Data input

vector | matrix

Data input, specified as a vector or matrix. The number of rows in the input must be a multiple of the “DecimationFactor” on page 4-0 . If the input is of `single` or `double` data type, property settings related to the fixed-point data types are ignored.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fi`

Output Arguments

cicDecimOut — CIC decimator output

vector | matrix

Decimated output, returned as a vector or a matrix. The output frame size equals $(1 / \text{DecimationFactor}) \times$ input frame size. The complexity of the output data matches that of the input data. If the input is `single` or `double`, the output data type matches the input data type.

If the input is of built-in integer data type or of fixed-point data type, the output word length and fraction length depend on the fixed-point data type setting you choose through the “FixedPointDataType” on page 4-0 property.

Full precision

When the `FixedPointDataType` is set to 'Full precision', the following relationship applies:

$$WL_{\text{output}} = WL_{\text{input}} + \text{NumSect}$$

$$FL_{\text{output}} = FL_{\text{input}}$$

where,

- WL_{output} -- Word length of the output data.
- FL_{output} -- Fraction length of the output data.
- WL_{input} -- Word length of the input data.
- FL_{input} -- Fraction length of the input data.
- NumSect -- Number of sections in the CIC filter specified through the “NumSections” on page 4-0 property.

The WL_{input} and FL_{input} are inherited from the data input you pass to the object algorithm. For built-in integer inputs, the fraction length is 0.

Minimum section word lengths

When the `FixedPointDataType` property is set to 'Minimum section word lengths', the output word length is the value you specify in the “OutputWordLength” on page 4-0 property. The output fraction length, FL_{output} , is given by:

$$FL_{\text{output}} = WL_{\text{output}} - (WL_{\text{input}} - FL_{\text{input}} + \text{NumSect})$$

Specify word and fraction lengths

When the `FixedPointDataType` property is set to 'Specify word and fraction lengths', the output word length and fraction length are the values you specify in the “OutputWordLength” on page 4-0 and “OutputFractionLength” on page 4-0 properties.

Specify word lengths

When the `FixedPointDataType` property is set to 'Specify word lengths', the output word length is the value you specify in the `OutputWordLength` property. The output fraction length, FL_{output} , is given by:

$$FL_{\text{output}} = WL_{\text{output}} - (WL_{\text{input}} - FL_{\text{input}} + \text{NumSect})$$

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fi`

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Specific to dsp.CICDecimator

<code>generatehdl</code>	Generate HDL code for quantized DSP filter (requires Filter Design HDL Coder)
<code>impz</code>	Impulse response of discrete-time filter System object
<code>freqz</code>	Frequency response of discrete-time filter System object
<code>phasez</code>	Phase response of discrete-time filter System object (unwrapped)
<code>fvtool</code>	Visualize frequency response of DSP filters
<code>gain</code>	Gain of CIC filter System object
<code>getFixedPointInfo</code>	Get fixed-point word and fraction lengths
<code>info</code>	Information about filter System object

Common to All System Objects

<code>step</code>	Run System object algorithm
<code>release</code>	Release resources and allow changes to System object property values and input characteristics
<code>reset</code>	Reset internal states of System object

For a list of filter analysis methods this object supports, type `dsp.CICDecimator.helpFilterAnalysis` in the MATLAB command prompt. For the corresponding function reference pages, see “Analysis Methods for Filter System Objects” on page 3-2.

Examples

Decimate a Signal Using a CICDecimator Object

Note: If you are using R2016a or an earlier release, replace each call to the object with the equivalent step syntax. For example, `obj(x)` becomes `step(obj,x)`.

Create a `dsp.CICDecimator System` object™ with `DecimationFactor` set to 4. Decimate a signal from 44.1 kHz to 11.025 kHz.

```
cicdec = dsp.CICDecimator(4);
cicdec.FixedPointDataType = 'Minimum section word lengths';
cicdec.OutputWordLength = 16;
```

Create a fixed-point sinusoidal input signal of 1024 samples, with a sampling frequency of 44.1e3 Hz.

```
Fs = 44.1e3;
% 0.0232 sec signal
n = (0:1023)';
x = fi(sin(2*pi*1e3/Fs*n),true,16,15);
```

Create a `dsp.SignalSource` object.

```
src = dsp.SignalSource(x,64);
```

Decimate the output with 16 samples per frame.

```
y = zeros(16,16);
for ii = 1:16
    y(ii,:) = cicdec(src());
end
```

Plot the first frame of the original and decimated signals. Output latency is 2 samples.

```
D = cicdec.DecimationFactor;
diffDelay = cicdec.DifferentialDelay;
NumSect = cicdec.NumSections;
gainCIC = ...
    (D*diffDelay)^NumSect;
stem(n(1:56)/Fs,double(x(4:59)))
hold on;
stem(n(1:14)/(Fs/D),double(y(1,3:end))/gainCIC,...
    'r','filled')
xlabel('Time (sec)')
ylabel('Signal Amplitude')
legend('Original signal',...
    'Decimated signal',...
    'Location','north')
hold off;
```

Using the `info` method in 'long' format, obtain the word lengths and fraction lengths of the fixed-point filter sections and the filter output.

```
info(cicdec, 'long')
```

```
ans =
'Discrete-Time FIR Multirate Filter (real)
-----
Filter Structure      : Cascaded Integrator-Comb Decimator

Determine the Section and Output Word Lengths and Fraction Lengths

Using the `getFixedPointInfo` function, you can determine the word lengths and fraction lengths of the fixed-point sections and the output of the `dsp.CICDecimator` and `dsp.CICInterpolator` System objects. The data types of the filter sections and the output depend on the `FixedPointDataType` property of the filter System object™.

Full precision

Create a `dsp.CICDecimator` object. The default value of the `NumSections` property is 2. This value indicates that there are two integrator and comb sections. The WLS and FLs vectors returned by the `getFixedPointInfo` function contain five elements each. The first two elements represent the two integrator sections. The third and fourth elements represent the two comb sections. The last element represents the filter output.

```
cicD = dsp.CICDecimator

cicD =
  dsp.CICDecimator with properties:

    DecimationFactor: 2
    DifferentialDelay: 1
    NumSections: 2
    FixedPointDataType: 'Full precision'
```

By default, the `FixedPointDataType` property of the object is set to 'Full precision'. Calling the `getFixedPointInfo` function on this object with the input numeric type, `nt`, yields the following word length and fraction length vectors.

```
nt = numericType(1,16,15)

nt =

    DataTypeMode: Fixed-point: binary point scaling
    Signedness: Signed
    WordLength: 16
    FractionLength: 15

[WLs,FLs] = getFixedPointInfo(cicD,nt) %#ok

WLs = 1x5

    18    18    18    18    18

FLs = 1x5

    15    15    15    15    15
```

For details on how the word lengths and fraction lengths are computed, see the description for *Output Arguments*.

If you lock the `cicD` object by passing an input to its algorithm, you do not need to pass the `nt` argument to the `getFixedPointInfo` function.

```
input = int64(randn(8,1))
input = 8x1 int64 column vector

     1
     2
    -2
     1
     0
    -1
     0
     0

output = cicD(input)
output =
     0
     1
     3
     0

        DataTypeMode: Fixed-point: binary point scaling
          Signedness: Signed
          WordLength: 66
        FractionLength: 0

[WLs,FLs] = getFixedPointInfo(cicD) %#ok
WLs = 1x5
    66    66    66    66    66

FLs = 1x5
     0     0     0     0     0
```

The output and section word lengths are the sum of input word length, 64 in this case, and the number of sections, 2. The output and section fraction lengths are 0 since the input is a built-in integer.

Minimum section word lengths

Release the object and change the `FixedPointDataType` property to 'Minimum section word lengths'. Determine the section and output fixed-point information when the input is fixed-point data, `fi(randn(8,2),1,24,15)`.

```
release(cicD);
cicD.FixedPointDataType = 'Minimum section word lengths'

cicD =
    dsp.CICDecimator with properties:
```

```

    DecimationFactor: 2
    DifferentialDelay: 1
        NumSections: 2
    FixedPointDataType: 'Minimum section word lengths'
    OutputWordLength: 32

```

```
inputF = fi(randn(8,2),1,24,15)
```

```
inputF =
    3.5784   -0.1241
    2.7694    1.4897
   -1.3499    1.4090
    3.0349    1.4172
    0.7254    0.6715
   -0.0630   -1.2075
    0.7148    0.7172
   -0.2050    1.6302

```

```

    DataTypeMode: Fixed-point: binary point scaling
    Signedness: Signed
    WordLength: 24
    FractionLength: 15

```

```
[WLs, FLs] = getFixedPointInfo(cicD,numericType(inputF)) %#ok
```

```
WLs = 1x5
    26    26    26    26    32

```

```
FLs = 1x5
    15    15    15    15    21

```

Specify word and fraction lengths

Change the `FixedPointDataType` property to 'Specify word and fraction lengths'. Determine the fixed-point information using the `getFixedPointInfo` function.

```
cicD.FixedPointDataType = 'Specify word and fraction lengths'
```

```

cicD =
    dsp.CICDecimator with properties:

        DecimationFactor: 2
        DifferentialDelay: 1
            NumSections: 2
        FixedPointDataType: 'Specify word and fraction lengths'
        SectionWordLengths: [16 16 16 16]
        SectionFractionLengths: 0
        OutputWordLength: 32
        OutputFractionLength: 0

```

```
[WLs, FLs] = getFixedPointInfo(cicD,numericType(inputF)) %#ok
```

```

WLs = 1x5
    16    16    16    16    32

```

```

FLs = 1x5
     0     0     0     0     0

```

The section and output word lengths and fraction lengths are assigned as per the respective fixed-point properties of the `cicD` object. These values are not determined by the input numeric type. To confirm, call the `getFixedPointInfo` function without passing the `numericType` input argument.

```
[WLs, FLs] = getFixedPointInfo(cicD) %#ok
```

```

WLs = 1x5
    16    16    16    16    32

```

```

FLs = 1x5
     0     0     0     0     0

```

Specify word lengths

To specify the word lengths of the filter section and output, set the `FixedPointDataType` property to `'Specify word lengths'`.

```
cicD.FixedPointDataType = 'Specify word lengths'
```

```

cicD =
  dsp.CICDecimator with properties:
    DecimationFactor: 2
    DifferentialDelay: 1
    NumSections: 2
    FixedPointDataType: 'Specify word lengths'
    SectionWordLengths: [16 16 16 16]
    OutputWordLength: 32

```

The `getFixedPointInfo` function requires the input numeric type because that information is used to compute the section and word fraction lengths.

```
[WLs, FLs] = getFixedPointInfo(cicD,numericType(inputF))
```

```

WLs = 1x5
    16    16    16    16    32

```

```

FLs = 1x5
     5     5     5     5    21

```

For more details on how the function computes the word and fraction lengths, see the description for *Output Arguments*.

More About

CIC Filter

CIC filters are an optimized class of linear phase FIR filters composed of a comb part and an integrator part.

The CIC decimation filter is conceptually given by a single rate CIC filter, $H(z)$ which is a lowpass anti-imaging filter, followed by a downsampler. The CIC decimation filter decreases the sample rate of an input signal by an integer factor using a cascaded integrator-comb (CIC) filter.

In a more efficient implementation, the single rate CIC filter $H(z)$ is factorized this way:

$$H(z) = \left[\sum_{k=0}^{RM-1} z^{-k} \right]^N = \frac{(1 - z^{-RM})^N}{(1 - z^{-1})^N} = \frac{1}{(1 - z^{-1})^N} \cdot \frac{(1 - z^{-RM})^N}{1} = H_I^N(z) \cdot H_C^N(z)$$

where,

- H_I is the transfer function of the integrator part of the filter containing N stages of integrators.
- H_C is the transfer function of the N sections of the cascaded comb filters, each with a width of RM .
- N is the number of sections. The number of sections in a CIC filter is defined as the number of sections in either the comb part *or* the integrator part of the filter. This value does not represent the total number of sections throughout the entire filter.
- R is the decimation factor.
- M is the differential delay.

In the overall multirate realization, the algorithm applies the noble identity for decimation and moves the rate change factor, R , to follow after the N sections of the cascaded integrators. The transfer function of the resulting filter is given by the following equation:

$$H(z) = \frac{(1 - z^{-M})^N}{(1 - z^{-1})^N}$$

For a block diagram that shows the multirate implementation, see "Algorithms" on page 4-271.

Algorithms

CIC Decimation Filter

The CIC decimation filter in “More About” on page 4-270 is realized as a cascade of N sections of the integrators followed by a rate change factor of R , followed by N sections of comb filters.

This diagram shows two sections of cascaded integrators and two sections of cascaded comb filters. The unit delay in the integrator portion of the CIC filter can be located in either the feedforward or the feedback path. These two configurations yield identical filter frequency response. However, the numerical outputs from these two configurations are different due to the latency. This block puts the unit delay in the feedforward path of the integrator because it is a preferred configuration for HDL implementation.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

See “System Objects in MATLAB Code Generation” (MATLAB Coder).

HDL Code Generation

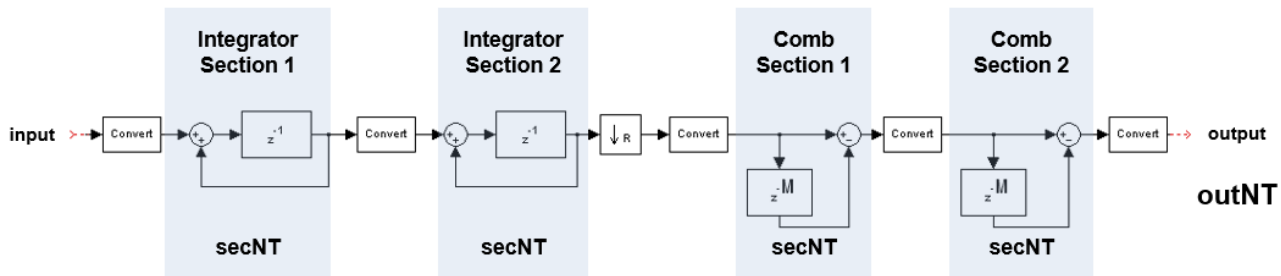

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

This object supports HDL code generation with the Filter Design HDL Coder product. For workflows and limitations, see “Generate HDL Code for Filter System Objects” (Filter Design HDL Coder).

Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

The fixed-point signal diagram shows the data types that the `dsp.CICDecimator` object uses for fixed-point signals.

where,

- `secNT = numerictype(1,secWL,secFL)`
- `outNT = numerictype(1,outWL,outFL)`
- `secWL` is the section word length you specify through the “SectionWordLengths” on page 4-0 property.
- `secFL` is the section fraction length you specify through the “SectionFractionLengths” on page 4-0 property.
- `outWL` is the output word length you specify through the “OutputWordLength” on page 4-0 property.
- `outFL` is the output fraction length you specify through the “OutputFractionLength” on page 4-0 property.

The value of NumSections in this diagram is 2.

dsp.CICInterpolator

Package: dsp

Interpolate signal using cascaded integrator-comb filter

Description

The `dsp.CICInterpolator` System object interpolates an input signal using a cascaded integrator-comb (CIC) interpolation filter. The CIC interpolation filter structure consists of N sections of cascaded comb filters, followed by a rate change by a factor of R , followed by N sections of cascaded integrators. For details, see “Algorithms” on page 4-286. The `NumSections` property specifies N , the number of sections in the CIC filter. The `InterpolationFactor` property specifies R , the interpolation factor. The `getFixedPointInfo` function returns the word lengths and fraction lengths of the fixed-point sections and the output for the `dsp.CICInterpolator` System object. You can also generate HDL code for this System object using the `generatehdl` function.

Note This object requires a Fixed-Point Designer license.

To interpolate a signal using a CIC filter:

- 1 Create the `dsp.CICInterpolator` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

Creation

Syntax

```
cicInterp = dsp.CICInterpolator
cicInterp = dsp.CICInterpolator(R,M,N)
cicInterp = dsp.CICInterpolator(Name,Value)
```

Description

`cicInterp = dsp.CICInterpolator` creates a CIC interpolation System object that applies a CIC interpolation filter to the input signal.

`cicInterp = dsp.CICInterpolator(R,M,N)` creates a CIC interpolation object with the `InterpolationFactor` property set to R , the `DifferentialDelay` property set to M , and the `NumSections` property set to N .

`cicInterp = dsp.CICInterpolator(Name,Value)` creates a CIC interpolation object with each specified property set to the specified value. Enclose each property name in single quotes. You can use this syntax with any previous input argument combinations.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects.

InterpolationFactor — Interpolation factor

2 (default) | positive integer

Factor by which the input signal is interpolated, specified as a positive integer.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

DifferentialDelay — Differential delay of filter comb sections

1 (default) | positive integer

Differential delay value used in each of the comb sections of the filter, specified as a positive integer. For details, see “Algorithms” on page 4-286. If the differential delay is of built-in integer class data type, the interpolation factor must be the same integer data type or `double`. For example, if the differential delay is an `int8`, then the interpolation factor must be an `int8` or `double`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

NumSections — Number of integrator and comb sections

2 (default) | positive integer

Number of integrator and comb sections of the CIC filter, specified as a positive integer. This number indicates the number of sections in either the comb part or the integrator part of the filter. The total number of sections in the CIC filter is twice the number of sections given by this property.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

FixedPointDataType — Fixed-point property designations

Full precision (default) | Minimum section word lengths | Specify word lengths | Specify word and fraction lengths

Fixed-point property designations, specified as one of the following:

- `Full precision` - The word length and fraction length of the CIC filter sections and the object output operate in full precision.
- `Minimum section word lengths` - Specify the output word length through the `OutputWordLength` property. The object determines the filter section data type and the output fraction length that give the best possible precision. For details, see `getFixedPointInfo` and `cicInterpOut` argument.
- `Specify word lengths` - Specify the word lengths of the CIC filter sections and the object output through the `SectionWordLengths` and `OutputWordLength` properties. The object determines the corresponding fraction lengths to give the best possible precision. For details, see `getFixedPointInfo` and the `cicInterpOut` argument.
- `Specify word and fraction lengths` - Specify the word length and fraction length of the CIC filter sections and the object output through the `SectionWordLengths`, `SectionFractionLengths`, `OutputWordLength`, and `OutputFractionLength` properties.

SectionWordLengths — Fixed-point word lengths for each filter section

[16 16 16 16] (default) | scalar | vector

Fixed-point word lengths to use for each filter section, specified as a scalar or a row vector of integers. The word length must be greater than or equal to 2. If you specify a scalar, the value applies to all the sections of the filter. If you specify a vector, the vector must be of length $2 \times \text{NumSections}$.

Example: 32

Example: [32 32 32 32]

Dependencies

This property applies when you set the `FixedPointDataType` property to 'Specify word lengths' or 'Specify word and fraction lengths'.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

SectionFractionLengths — Fixed-point fraction lengths for each filter section

0 (default) | scalar | vector

Fixed-point fraction lengths to use for each filter section, specified as a scalar or a row vector of integers. The fraction length can be negative, 0, or positive. If you specify a scalar, the value applies to all the sections of the filter. If you specify a vector, the vector must be of length $2 \times \text{NumSections}$.

Example: -2

Example: [-2 0 5 8]

Dependencies

This property applies when you set the `FixedPointDataType` property to 'Specify word and fraction lengths'.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

OutputWordLength — Fixed-point word length for filter output

32 (default) | scalar integer

Fixed-point word length to use for the filter output, specified as a scalar integer greater than or equal to 2.

Dependencies

This property applies when you set the `FixedPointDataType` property to one of 'Minimum section word lengths', 'Specify word lengths', or 'Specify word and fraction lengths'.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

OutputFractionLength — Fixed-point fraction length for filter output

0 (default) | scalar integer

Fixed-point fraction length to use for the filter output, specified as a scalar integer.

Dependencies

This property applies when you set the `FixedPointDataType` property to 'Specify word and fraction lengths'.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

Usage

Syntax

```
cicInterpOut = cicInterp(input)
```

Description

`cicInterpOut = cicInterp(input)` interpolates the input using a CIC interpolator.

Input Arguments

input — Data input

vector | matrix

Data input, specified as a vector or matrix. If the input is of `single` or `double` data type, property settings related to the fixed-point data types are ignored.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fi`

Output Arguments

cicInterpOut — CIC interpolator output

vector | matrix

Interpolated output, returned as a vector or a matrix. The output frame size equals (“InterpolationFactor” on page 4-0) \times input frame size. The complexity of the output data matches that of the input data. If the input is `single` or `double`, the output data type matches the input data type.

If the input is of built-in integer data type or of fixed-point data type, the output word length and fraction length depend on the fixed-point data type setting you choose through the “FixedPointDataType” on page 4-0 property.

Full precision

When the `FixedPointDataType` property is set to 'Full precision', the following relationship applies:

$$WL_{\text{output}} = WL_{\text{input}} + NumSect$$

$$FL_{\text{output}} = FL_{\text{input}}$$

where,

- WL_{output} -- Word length of the output data.
- FL_{output} -- Fraction length of the output data.
- WL_{input} -- Word length of the input data.
- FL_{input} -- Fraction length of the input data.
- $NumSect$ -- Number of sections in the CIC filter specified through the “NumSections” on page 4-0 property.

WL_{input} and FL_{input} are inherited from the data input you pass to the object algorithm. For built-in integer inputs, the fraction length is 0.

Minimum section word lengths

When the `FixedPointDataType` property is set to 'Minimum section word lengths', the output word length is the value you specify in "OutputWordLength" on page 4-0 property. The output fraction length, FL_{output} is given by the following equation:

$$FL_{output} = WL_{output} - (WL_{input} - FL_{input} + NumSect)$$

Specify word and fraction lengths

When the `FixedPointDataType` is set to 'Specify word and fraction lengths', the output word length and fraction length are the values you specify in the "OutputWordLength" on page 4-0 and "OutputFractionLength" on page 4-0 properties.

Specify word lengths

When the `FixedPointDataType` is set to 'Specify word lengths', the output word length is the value you specify in the `OutputWordLength` property. The output fraction length, FL_{output} is given by the following equation:

$$FL_{output} = WL_{output} - (WL_{input} - FL_{input} + NumSect)$$

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fi`

Object Functions

To use an object function, specify the `System` object as the first input argument. For example, to release system resources of a `System` object named `obj`, use this syntax:

```
release(obj)
```

Specific to dsp.CICInterpolator

<code>generatehdl</code>	Generate HDL code for quantized DSP filter (requires Filter Design HDL Coder)
<code>impz</code>	Impulse response of discrete-time filter System object
<code>freqz</code>	Frequency response of discrete-time filter System object
<code>phasez</code>	Phase response of discrete-time filter System object (unwrapped)
<code>fvtool</code>	Visualize frequency response of DSP filters
<code>gain</code>	Gain of CIC filter System object
<code>getFixedPointInfo</code>	Get fixed-point word and fraction lengths
<code>info</code>	Information about filter System object

Common to All System Objects

<code>step</code>	Run System object algorithm
<code>release</code>	Release resources and allow changes to System object property values and input characteristics
<code>reset</code>	Reset internal states of System object

For a list of filter analysis methods this object supports, type `dsp.CICInterpolator.helpFilterAnalysis` in the MATLAB command prompt. For the

corresponding function reference pages, see “Analysis Methods for Filter System Objects” on page 3-2.

Examples

Interpolate Signal Using CICInterpolator System object

Note: If you are using R2016a or an earlier release, replace each call to the object with the equivalent `step` syntax. For example, `obj(x)` becomes `step(obj,x)`.

Create a `dsp.CICInterpolator` System object™ with `InterpolationFactor` set to 2. Interpolate a fixed-point signal by a factor of 2 from 22.05 kHz to 44.1 kHz.

```
cicint = dsp.CICInterpolator(2)

cicint =
    dsp.CICInterpolator with properties:

        InterpolationFactor: 2
        DifferentialDelay: 1
        NumSections: 2
        FixedPointDataType: 'Full precision'
```

Create a `dsp.SineWave` object with `SampleRate` set to 22.05 kHz, `SamplesPerFrame` set to 32, and `OutputDataType` set to 'Custom'. To generate a fixed-point signal, set the `CustomOutputDataType` property to a `numericType` object. For the purpose of this example, set the value to `numericType([],16)`. The fraction length is computed based on the values of the generated sinusoidal signal to give the best possible precision.

To generate a fixed-point signal, set the `Method` property of the `dsp.SineWave` object to 'Table lookup'. This method of generating the sinusoidal signal requires that the period of every sinusoid in the output be evenly divisible by the sample period. That is, $1/f_i T_s = k_i$ must be an integer value for every channel $i = 1, 2, \dots, N$. The value of T_s equals $1/F_s$, the variable f_i is the frequency of the sinusoidal signal, and F_s is the sample rate of the signal. In other words, the ratio F_s/f_i must be an integer. For more details, see the “Algorithms” on page 4-1239 section on the `dsp.SineWave` object page.

In this example, F_s is set to 22050 Hz and f_i is set to 1050 Hz.

```
Fs = 22.05e3;
sine = dsp.SineWave('Frequency',1050,...
    'SampleRate',Fs,...
    'SamplesPerFrame',32,...
    'Method','Table lookup',...
    'OutputDataType','Custom')

sine =
    dsp.SineWave with properties:

        Amplitude: 1
        Frequency: 1050
        PhaseOffset: 0
        ComplexOutput: false
```

```

        Method: 'Table lookup'
    TableOptimization: 'Speed'
        SampleRate: 22050
    SamplesPerFrame: 32
    OutputDataType: 'Custom'

```

Show all properties

In each loop of the iteration, stream in a frame of the fixed-point sinusoidal signal sampled at 22.05 kHz. Interpolate the streamed signal by a factor of 2. The interpolated output has 64 samples per frame.

```

for i = 1:16
    x = sine();
    y = cicint(x);
end

```

The output of the CIC interpolation filter is amplified by a specific gain value. You can determine this value using the `gain` function. This gain equals the gain of the $2N^{\text{th}}$ stage of the CIC interpolation filter and equals $(I \times D)^N / I$, where I is the interpolation factor, D is the differential delay, and N is the number of sections of the CIC interpolator.

```

gainCIC = gain(cicint)

gainCIC = 2

```

To adjust this amplified output and to match it to the amplitude of the original signal, divide the CIC interpolated signal with the computed gain value.

Compare the last frames of the original and the interpolated signals. While plotting, account for the output latency of 2 samples.

```

n = (0:63)';
stem(n(1:31)/Fs,double(x(1:31)),'r','filled')
hold on;
I = cicint.InterpolationFactor;
stem(n(1:61)/(Fs*I), ...
     double(y(4:end))/gainCIC,'b')
xlabel('Time (sec)')
ylabel('Signal Amplitude')
legend('Original Signal',...
       'Interpolated Signal',...
       'location','north')
hold off;

```

Using the `info` function in the 'long' format, obtain the word lengths and fraction lengths of the fixed-point filter sections and the filter output.

```
info(cicint, 'long')
```

```

Determine the Section and Output Word Lengths and Fraction Lengths

Using the `getFixedPointInfo` function, you can determine the word lengths and fraction lengths of the fixed-point sections and the output of the `dsp.CICDecimator` and `dsp.CICInterpolator` System objects. The data types of the filter sections and the output depend on the `FixedPointDataType` property of the filter System object™.

Full precision

Create a `dsp.CICDecimator` object. The default value of the `NumSections` property is 2. This value indicates that there are two integrator and comb sections. The WLS and FLs vectors returned by the `getFixedPointInfo` function contain five elements each. The first two elements represent the two integrator sections. The third and fourth elements represent the two comb sections. The last element represents the filter output.

```
cicD = dsp.CICDecimator
cicD =
    dsp.CICDecimator with properties:
        DecimationFactor: 2
        DifferentialDelay: 1
        NumSections: 2
        FixedPointDataType: 'Full precision'
```

By default, the `FixedPointDataType` property of the object is set to 'Full precision'. Calling the `getFixedPointInfo` function on this object with the input numeric type, `nt`, yields the following word length and fraction length vectors.

```
nt = numerictype(1,16,15)
nt =
    DataTypeMode: Fixed-point: binary point scaling
    Signedness: Signed
    WordLength: 16
    FractionLength: 15

[WLs,FLs] = getFixedPointInfo(cicD,nt) %#ok
WLs = 1x5
    18    18    18    18    18
FLs = 1x5
    15    15    15    15    15
```

For details on how the word lengths and fraction lengths are computed, see the description for *Output Arguments*.

If you lock the `cicD` object by passing an input to its algorithm, you do not need to pass the `nt` argument to the `getFixedPointInfo` function.

```
input = int64(randn(8,1))
input = 8x1 int64 column vector

     1
     2
    -2
     1
     0
    -1
     0
     0

output = cicD(input)
output =
     0
     1
     3
     0

        DataTypeMode: Fixed-point: binary point scaling
           Signedness: Signed
          WordLength: 66
        FractionLength: 0

[WLs,FLs] = getFixedPointInfo(cicD) %#ok
WLs = 1x5
     66     66     66     66     66

FLs = 1x5
     0     0     0     0     0
```

The output and section word lengths are the sum of input word length, 64 in this case, and the number of sections, 2. The output and section fraction lengths are 0 since the input is a built-in integer.

Minimum section word lengths

Release the object and change the `FixedPointDataType` property to 'Minimum section word lengths'. Determine the section and output fixed-point information when the input is fixed-point data, `fi(randn(8,2),1,24,15)`.

```
release(cicD);
cicD.FixedPointDataType = 'Minimum section word lengths'

cicD =
    dsp.CICDecimator with properties:
```

```

    DecimationFactor: 2
    DifferentialDelay: 1
        NumSections: 2
    FixedPointDataType: 'Minimum section word lengths'
    OutputWordLength: 32

```

```
inputF = fi(randn(8,2),1,24,15)
```

```

inputF =
    3.5784   -0.1241
    2.7694    1.4897
   -1.3499    1.4090
    3.0349    1.4172
    0.7254    0.6715
   -0.0630   -1.2075
    0.7148    0.7172
   -0.2050    1.6302

    DataTypeMode: Fixed-point: binary point scaling
    Signedness: Signed
    WordLength: 24
    FractionLength: 15

```

```
[WLs, FLs] = getFixedPointInfo(cicD,numericType(inputF)) %#ok
```

```

WLs = 1x5
    26    26    26    26    32

```

```

FLs = 1x5
    15    15    15    15    21

```

Specify word and fraction lengths

Change the `FixedPointDataType` property to 'Specify word and fraction lengths'. Determine the fixed-point information using the `getFixedPointInfo` function.

```
cicD.FixedPointDataType = 'Specify word and fraction lengths'
```

```

cicD =
    dsp.CICDecimator with properties:

        DecimationFactor: 2
        DifferentialDelay: 1
            NumSections: 2
        FixedPointDataType: 'Specify word and fraction lengths'
        SectionWordLengths: [16 16 16 16]
        SectionFractionLengths: 0
        OutputWordLength: 32
        OutputFractionLength: 0

```

```
[WLs, FLs] = getFixedPointInfo(cicD,numericType(inputF)) %#ok
```

```

WLs = 1x5
    16    16    16    16    32

```

```

FLs = 1x5
    0     0     0     0     0

```

The section and output word lengths and fraction lengths are assigned as per the respective fixed-point properties of the `cicD` object. These values are not determined by the input numeric type. To confirm, call the `getFixedPointInfo` function without passing the `numericType` input argument.

```
[WLs, FLs] = getFixedPointInfo(cicD) %#ok
```

```

WLs = 1x5
    16    16    16    16    32

```

```

FLs = 1x5
    0     0     0     0     0

```

Specify word lengths

To specify the word lengths of the filter section and output, set the `FixedPointDataType` property to `'Specify word lengths'`.

```
cicD.FixedPointDataType = 'Specify word lengths'
```

```

cicD =
  dsp.CICDecimator with properties:
    DecimationFactor: 2
    DifferentialDelay: 1
    NumSections: 2
    FixedPointDataType: 'Specify word lengths'
    SectionWordLengths: [16 16 16 16]
    OutputWordLength: 32

```

The `getFixedPointInfo` function requires the input numeric type because that information is used to compute the section and word fraction lengths.

```
[WLs, FLs] = getFixedPointInfo(cicD,numericType(inputF))
```

```

WLs = 1x5
    16    16    16    16    32

```

```

FLs = 1x5
    5     5     5     5    21

```

For more details on how the function computes the word and fraction lengths, see the description for *Output Arguments*.

More About

CIC Filter

CIC filters are an optimized class of linear phase FIR filters composed of a comb part and an integrator part.

The CIC interpolation filter is conceptually given by an upsampler followed by a single rate CIC filter, $H(z)$, which is a lowpass anti-imaging filter. The CIC interpolation filter increases the sample rate of an input signal by an integer factor using a cascaded integrator-comb (CIC) filter.

In a more efficient implementation, the single rate CIC filter $H(z)$ is factorized this way:

$$H(z) = \left[\sum_{k=0}^{RM-1} z^{-k} \right]^N = \frac{(1 - z^{-RM})^N}{(1 - z^{-1})^N} = \frac{(1 - z^{-RM})^N}{1} \cdot \frac{1}{(1 - z^{-1})^N} = H_C^N(z) \cdot H_I^N(z)$$

where,

- H_C is the transfer function of the N sections of the cascaded comb filters, each with a width of RM .
- H_I is the transfer function of the integrator part of the filter containing N stages of integrators.
- N is the number of sections. The number of sections in a CIC filter is defined as the number of sections in either the comb part *or* the integrator part of the filter. This value does not represent the total number of sections throughout the entire filter.
- R is the interpolation factor.
- M is the differential delay.

In the overall multirate realization, the algorithm applies the noble identity for interpolation and moves the rate change factor, R , to follow after the N sections of the cascaded comb filters.

The transfer function of the resulting filter is given by the following equation:

$$H(z) = \frac{(1 - z^{-M})^N}{(1 - z^{-1})^N}$$

For a block diagram that shows the multirate implementation, see “Algorithms” on page 4-286.

Algorithms

CIC Interpolation Filter

The CIC interpolation filter in “More About” on page 4-285 is realized as a cascade of N sections of comb filters followed by a rate change by a factor R , followed by N sections of cascaded integrators.

This diagram shows two sections of cascaded comb filters and two sections of cascaded integrators. The unit delay in the integrator portion of the CIC filter can be located in either the feedforward or the feedback path. These two configurations yield identical filter frequency response. However, the numerical outputs from these two configurations are different due to the latency. This algorithm puts the unit delay in the feedforward path of the integrator since it is a preferred configuration for HDL implementation.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

See “System Objects in MATLAB Code Generation” (MATLAB Coder).

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

This object supports HDL code generation with the Filter Design HDL Coder product. For workflows and limitations, see “Generate HDL Code for Filter System Objects” (Filter Design HDL Coder).

Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

The fixed-point signal diagram shows the data types that the `dsp.CICInterpolator` object uses for fixed-point signals.

where,

- `secNT = numerictype(1,secWL,secFL)`
- `outNT = numerictype(1,outWL,outFL)`
- `secWL` is the section word length you specify through the “SectionWordLengths” on page 4-0 property.
- `secFL` is the section fraction length you specify through the “SectionFractionLengths” on page 4-0 property.
- `outWL` is the output word length you specify through the “OutputWordLength” on page 4-0 property.
- `outFL` is the output fraction length you specify through the “OutputFractionLength” on page 4-0 property.

The value of NumSections in this diagram is 2.

dsp.HDLCICDecimation

Package: dsp

Decimate signal using cascaded integrator-comb filter — optimized for HDL code generation

Description

The `dsp.HDLCICDecimation` System object decimates an input signal by using a cascaded integrator-comb (CIC) decimation filter. CIC filters are a class of linear phase FIR filters consisting of a comb part and an integrator part. The CIC decimation filter structure consists of N sections of cascaded integrators, a rate change factor of R , and then N sections of cascaded comb filters. For more information about CIC decimation filters, see “Algorithms” on page 4-296.

The System object supports fixed and variable decimation rates for scalar inputs and only fixed decimation for vector inputs. For both types of inputs, the System object provides a scalar output. The System object provides an architecture suitable for HDL code generation and hardware deployment.

The System object supports real and complex fixed-point inputs.

To filter input data with an HDL-optimized CIC decimation filter:

- 1 Create the `dsp.HDLCICDecimation` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

Creation

Syntax

```
cicDecFilt = dsp.HDLCICDecimation
cicDecFilt = dsp.HDLCICDecimation(Name,Value)
```

Description

`cicDecFilt = dsp.HDLCICDecimation` creates an HDL-optimized CIC decimation filter System object, `cicDecFilt`, with default properties.

`cicDecFilt = dsp.HDLCICDecimation(Name,Value)` creates the filter with properties set using one or more name-value pairs. Enclose each property name in single quotes.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects.

VariableDownsample — Variable decimation rate

(0) false (default) | (1) true

Set this property to `true` (1) to operate the System object with a variable decimation rate specified by the `decimFactor` input argument. Set this property to `false` (0) to operate the object with a fixed decimation rate, specified by the `DecimationFactor` property.

For vector inputs, the object does not support variable decimation rate.

DecimationFactor — Decimation factor

2 (default) | integer from 2 to 2048

Specify the decimation factor as an integer from 2 to 2048. This value represents the rate with which you want to decimate the input.

When you set the `VariableDownsample` property to `true`, this property sets the upper bound of the range of valid values for the `decimFactor` argument.

DifferentialDelay — Differential delay

1 (default) | 2

Specify the differential delay of the comb part of the filter as either 1 or 2 cycles.

NumSections — Number of integrator or comb sections

2 (default) | integer from 1 to 6

Specify the number of sections in either the integrator or the comb part of the filter as an integer from 1 to 6.

OutputDataType — Data type of output

'Full precision' (default) | 'Same word length as input' | 'Minimum section word lengths'

Choose the data type of the filtered output data.

- 'Full precision' — The output data type has a word length equal to the input word length plus gain bits.
- 'Same word length as input' — The output data type has a word length equal to the input word length.
- 'Minimum section word lengths' — The output data type uses the word length you specify in the `OutputWordLength` property. When you choose this option, the System object applies a Pruning algorithm internally. For more information about Pruning, see “Output Data Type” on page 4-298. This option is not supported when `VariableDownsample` is `true`.

OutputWordLength — Word length of output

16 (default) | integer from 2 to 104

Word length of the output, specified as an integer from 2 to 104.

Note When this value is less than 7 the output data values might overflow.

Dependencies

To enable this property, set the `OutputDataType` property to 'Minimum section word lengths'.

GainCorrection — Compensate output gain

false (default) | true

Set this property to `true` to compensate for the output gain of the filter.

Depending on the type of decimation you specify and the value of this property, the latency of the object changes. Here, N means the number of sections and $vecLen$ means the length of the vector.

For a scalar input with fixed decimation (`VariableDownsample` is `false`):

- With gain correction off, the latency of the object is $3 + N$ clock cycles.
- With gain correction on, the latency of the object is $3 + N + 9$ clock cycles.

For a scalar input with variable decimation (`VariableDownsample` is `true`):

- With gain correction off, the latency of the object is $4 + N$ clock cycles.
- With gain correction on, the latency of the object is $4 + N + 9$ clock cycles.

For a vector input with fixed decimation (`VariableDownsample` is `false`):

- With gain correction off, the latency of the object is $\text{floor}((vecLen - 1) * (N/vecLen)) + 1 + N + (2 + (vecLen + 1) * N)$ clock cycles.
- With gain correction on, the latency of the object is $\text{floor}((vecLen - 1) * (N/vecLen)) + 1 + N + (2 + (vecLen + 1) * N) + 9$ clock cycles.

Note For vector inputs, the object does not support variable decimation.

ResetIn — Enable reset argument

false (default) | true

When you set this property to `true`, the System object expects a reset input argument.

Usage

Syntax

```
[dataOut,validOut] = cicDecFilt(dataIn,validIn)
[dataOut,validOut] = cicDecFilt(dataIn,validIn,decimFactor)
[dataOut,validOut] = cicDecFilt(dataIn,validIn,reset)
[dataOut,validOut] = cicDecFilt(dataIn,validIn,decimFactor,reset)
```

Description

`[dataOut,validOut] = cicDecFilt(dataIn,validIn)` filters and decimates the input data using a fixed decimation factor only when `validIn` is `true`.

`[dataOut,validOut] = cicDecFilt(dataIn,validIn,decimFactor)` filters the input data using the specified variable decimation factor, `decimFactor`. The `VariableDownsample` property must be set to `true`.

`[dataOut,validOut] = cicDecFilt(dataIn,validIn,reset)` filters the input data when `reset` is `false` and clears filter internal states when `reset` is `true`. The System object expects the `reset` argument only when you set the `ResetIn` property to `true`.

`[dataOut,validOut] = cicDecFilt(dataIn,validIn,decimFactor,reset)` filters the input data when `reset` is `false` and clears filter internal states when `reset` is `true`. The System object expects the `reset` argument only when you set the `ResetIn` property to `true`. The `VariableDownsample` property is set to `true`.

Input Arguments

dataIn — Input data

scalar | column vector

Specify input data as a scalar or a column vector of length 1 to 64. The input data must be a signed integer or signed fixed point with a word length less than or equal to 32. `DecimationFactor` property must be an integer multiple of the input frame size.

Data Types: `int8` | `int16` | `int32` | `fi`

validIn — Indication of valid input data

logical scalar

Control signal that indicates if the input data is valid.

When `validIn` is 1 (`true`), the System object captures the value from the `dataIn` input argument. When `validIn` is 0 (`false`), the System object ignores the `dataIn` input value.

Data Types: `logical`

decimFactor — Variable decimation rate

scalar

Specifies the decimation rate.

The `decimFactor` value must be of data type `ufix12` data type and an integer in the range from 2 to the `DecimationFactor` property value.

Dependencies

To enable this argument, set the `VariableDownsample` property to `true`.

Data Types: `fi(0,12,0)`

reset — Clear internal states

logical scalar

Clear internal states, specified as a logical scalar.

When this value is 1 (`true`), the System object stops the current calculation and clears all internal states. When this value is 0 (`false`) and `validIn` is 1 (`true`), the System object starts a new filtering operation.

Dependencies

To enable this argument, set the `ResetIn` property to `true`.

Data Types: `logical`

Output Arguments

dataOut — CIC-decimated output data

scalar

CIC decimated output data, returned as a scalar.

The `OutputDataType` property sets the output data type of this argument. See “`OutputDataType`” on page 4-0 .

Data Types: `int8 | int16 | int32 | fi`

Complex Number Support: Yes

validOut — Indication of valid output data

logical scalar

Control signal that indicates if the data from the `dataOut` output argument is valid. When this value is `1` (`true`), the System object returns valid data from the `dataOut` output argument. When this value is `0` (`false`), the values of the `dataOut` output argument are not valid.

Data Types: `logical`

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Specific to `dsp.HDLCICDecimation`

`getLatency` Latency of CIC decimation filter

Common to All System Objects

`step` Run System object algorithm

`release` Release resources and allow changes to System object property values and input characteristics

`reset` Reset internal states of System object

Examples

Create CIC Decimation Filter for HDL Code Generation

This example shows how to use a `dsp.HDLCICDecimation` System object™ to filter and downsample the data. This object supports scalar and vector inputs. In this example, two functions are provided to work with scalar and vector input data separately. You can generate the HDL code from these functions.

Generate Frames of Random Input Samples

Set up these workspace variables for the object to use. The object supports fixed and variable decimation rates for scalar inputs and only a fixed decimation rate for vector inputs. The example runs the HDLCIC_maxR8 function when you set the scalar variable to `true` and runs the HDLCIC_vec function when you set the scalar variable to `false`. For scalar inputs, choose a range of the input varRValue values and set the decimation factor value, R, to the maximum expected decimation factor. For vector inputs, the input data must be a column vector of size 1 to 64 and R must be an integer multiple of the input frame size.

```
R = 8; % decimation factor
M = 1; % differential delay
N = 3; % number of sections
scalar = false; % true for scalar; false for vector
if scalar
    varRValue = [2, 4, 5, 6, 7, 8];
    vecSize = 1;
else
    varRValue = R;
    fac = (factor(R));
    vecSize = fac(randi(length(fac),1,1));
end

numFrames = length(varRValue);
dataSamples = cell(1,numFrames);
varRtemp = cell(1,numFrames);
framesize = zeros(1,numFrames);
refOutput = [];
WL = 0; % Word length
FL = 0; % Fraction length
```

Generate Reference Output from dsp.CICDecimation System Object™

Generate frames of random input samples and apply the samples to the dsp.CICDecimation System object. The output generated from this System object is used as a reference data for comparison. The System object does not support a variable decimation rate, so you must create and release the object for each change in decimation factor value.

```
totalsamples = 0;
for i = 1:numFrames
    framesize(i) = varRValue(i)*randi([5 20],1,1);
    dataSamples{i} = fi(randn(vecSize,framesize(i)),1,16,8);
    ref_cic = dsp.CICDecimator('DifferentialDelay',M,...
        'NumSections',N,...
        'DecimationFactor',varRValue(i));
    refOutput = [refOutput,ref_cic(dataSamples{i}(:)).'];
    release(ref_cic);
end
```

Run a Function that contains dsp.HDLCICDecimation System Object

Set the properties of the System object to match the input data parameters and run the respective function based on the input type. These functions operate on a stream of data samples rather than a frame. You can generate HDL code from these functions.

The example uses the HDLCIC_maxR8 function for a scalar input.

```

function [dataOut,validOut] = HDLCIC_maxR8(dataIn,validIn,R)
%HDLCIC_maxR8
% Performs CIC decimation with an input decimation factor up to 8.
% sampleIn is a scalar fixed-point value.
% validIn is a logical scalar value.
% You can generate HDL code from this function.

persistent cic8;
if isempty(cic8)
    cic8 = dsp.HDLCICDecimation('DecimationFactor',8,...
                               'VariableDownsample',true,...
                               'DifferentialDelay',1,...
                               'NumSections',3);
end
[dataOut,validOut] = cic8(dataIn,validIn,R);
end

```

The example uses the HDLCIC_vec function for a vector input.

```

function [dataOut,validOut] = HDLCIC_vec(dataIn,validIn)
%HDLCIC_vec
% Performs CIC decimation with an input vector.
% sampleIn is a fixed-point vector.
% validIn is a logical scalar value.
% You can generate HDL code from this function.

persistent cicVec;
if isempty(cicVec)
    cicVec = dsp.HDLCICDecimation('DecimationFactor',8,...
                                  'VariableDownsample',false,...
                                  'DifferentialDelay',1,...
                                  'NumSections',3);
end
[dataOut,validOut] = cicVec(dataIn,validIn);
end

```

To flush remaining data, run the object by inserting the required number of idle cycles after each frame through latency variable. For more information, see “GainCorrection” on page 4-0 property.

Initialize the output to a size large enough to accommodate the output data. The final size is expected to be smaller than totalsamples due to decimation.

```

latency = floor((vecSize - 1)*(N/vecSize))+ 1+ N +(2+(vecSize + 1)*N)+ 9;
dataOut = zeros(1,totalsamples+numFrames*latency);
validOut = zeros(1,totalsamples+numFrames*latency);
idx=0;
for ij = 1:numFrames
    if scalar
        % scalar input with variable decimation
        for ii = 1:length(dataSamples{ij})
            idx = idx+1;
            [dataOut(idx),validOut(idx)] = HDLCIC_maxR8(...
                dataSamples{ij}(ii),...

```

```

        true,...
        fi(varRValue(ij),0,12,0));
    end
    for ii = 1:latency
        idx = idx+1;
        [dataOut(idx),validOut(idx)] = HDLCIC_maxR8(...
            fi(0,1,16,8),...
            false,...
            fi(varRValue(ij),0,12,0));
    end

else
    % vector input with fixed decimation
    for ii = 1:size(dataSamples{ij},2)
        idx = idx+1;
        [dataOut(idx),validOut(idx)] = HDLCIC_vec(...
            dataSamples{ij}{:,ii},...
            true);
    end
    for ii = 1:latency
        idx = idx+1;
        [dataOut(idx),validOut(idx)] = HDLCIC_vec(...
            fi(zeros(vecSize,1),1,16,8),...
            false);
    end
end
end
end

```

Compare the Function Output with the Reference Data

Compare the function results against the output from the `dsp.CICDecimation` object.

```

cicOutput = dataOut(validOut==1);

fprintf('\nHDL CIC Decimation\n');
difference = (abs(cicOutput-refOutput(1:length(cicOutput)))>0);
fprintf('\nTotal number of samples differed between Behavioral and HDL simulation: %d \n',sum(difference));

```

```
HDL CIC Decimation
```

```
Total number of samples differed between Behavioral and HDL simulation: 0
```

Explore Latency of HDL CIC Decimation Object

The latency of the `dsp.HDLCICDecimation` System object™ varies depending on how many integrator and comb sections your filter has, input vector size, and whether you enable gain correction. Use the `getLatency` function to find the latency of a particular filter configuration. The latency is the number of cycles between the first valid input and the first valid output, assuming the input is continuously valid.

Create a `dsp.HDLCICDecimation` System object™ and request the latency. The default filter has two sections, and gain correction is disabled.

```
hdlcic = dsp.HDLCICDecimation
```

```
hdlcic =
  dsp.HDLCICDecimation with properties:

  VariableDownsample: false
  DecimationFactor: 2
  DifferentialDelay: 1
  NumSections: 2
  OutputDataType: 'Full precision'
  GainCorrection: false
  ResetIn: false
```

```
L_def = getLatency(hdlcic)
```

```
L_def = 5
```

Modify the filter object to have three integrator and comb sections. Check the resulting change in latency.

```
hdlcic.NumSections = 3;
L_3sec = getLatency(hdlcic)
```

```
L_3sec = 6
```

Enable the gain correction on the filter object with vector input size 2. Check the resulting change in latency.

```
hdlcic.GainCorrection = true;
vecSize = 2;
L_wgain = getLatency(hdlcic,vecSize)
```

```
L_wgain = 25
```

Algorithms

CIC Decimation Filter

The transfer function of a CIC decimation filter is

$$H(z) = \left[\sum_{k=0}^{RM-1} z^{-k} \right]^N = \frac{(1 - z^{-RM})^N}{(1 - z^{-1})^N} = \frac{1}{(1 - z^{-1})^N} \cdot \frac{(1 - z^{-RM})^N}{1} = H_I^N(z) \cdot H_C^N(z),$$

where

- H_I is the transfer function of the integrator part of the CIC filter.
- H_C is the transfer function of the comb part of the CIC filter.
- N is the number of sections. The number of sections in a CIC filter is defined as the number of sections in either the comb part or the integrator part of the filter. This value does not represent the total number of sections throughout the entire filter.
- R is the decimation factor.
- M is the differential delay.

CIC Filter Structure

The `dsp.HDLCICDecimation` System object has the CIC filter structure shown in this figure. The structure consists of N sections of cascaded integrators, a rate change factor of R , and N sections of cascaded comb filters [1].

Designs can put the unit delay in the integrator part of the CIC filter in either the feed-forward or feedback path. These two configurations yield an identical filter frequency response. However, the numerical outputs from these two configurations are different due to the latency of the paths. This System object puts the unit delay in the feed-forward path of the integrator.

Fixed and Variable Decimation

The System object downsamples the integrator stage output using R , either the fixed decimation rate provided using the `DecimationFactor` property or the variable decimation rate provided using the `decimFactor` input argument. At the downsampler stage, the System object uses a counter to count the valid input samples, which depend on the decimation rate. Whenever the decimation rate changes, the object resets and starts a new calculation from the next sample. This mechanism prevents the System object from accumulating invalid values. Then, the System object provides the decimated output to the comb part.

Gain Correction

The gain of the System object is given by $Gain = (R \times M)^N$.

where:

- R is the `DecimationFactor` property value.
- M is the `DifferentialDelay` property value.
- N is the `NumSections` property value.

The System object implements gain correction in two parts: coarse gain and fine gain. In coarse gain correction, the System object calculates the shift value, adds the shift value to the fractional bits to create a numeric type, and then performs bit-shift left. In fine gain correction, the System object divides the remaining gain with the coarse gain if the gain is not a power of 2 and then multiplies the coarse gain corrected value with the inverse value of fine gain. All possible shift and fine gain values are precalculated initially and stored in an array before the System object starts processing.

You can modify this equation as $Gain = 2^{cGain} \times fGain$, where $cGain$ means coarse gain and $fGain$ means fine gain.

- $cGain = \text{floor}(\log_2 Gain)$
- $fGain = Gain / 2^{cGain} = Gain \times 2^{-cGain}$

To perform `GainCorrection` when the `VariableDownsample` property is enabled, the System object sets the output data type configured with the maximum decimation rate and bit-shifts left for all the values under the maximum decimation rate. The bit-shift value is equal to $\text{Maximum gain} - \log_2(\text{current gain})$.

Output Data Type

This section explains how the System object determines the output data type. For example, consider a filter with `DecimationFactor`, `DifferentialDelay`, and `NumSections` values 8, 1, and 3, respectively, with an input width of 16 bits.

The output word length is calculated as: $B_{OUT} = B_{IN} + \lceil \log_2(Gain) \rceil$,

where:

- $Gain = (R \times M)^N$
- B_{IN} is the input word length.
- B_{OUT} is the output word length.

When you set the `OutputDataType` property to 'Full precision', the System object returns data with a word length of 25 bits, by adding nine gain bits to the input word length.

When you set the `OutputDataType` property to 'Same word length as input', the object outputs data with a word length of 16, which is the same length as the input word length. The internal integrator and comb stages use the full-precision data type with 25 bits.

When you set the `OutputDataType` property to 'Minimum section word lengths' and the `OutputWordLength` property to 16, the System object returns data with a word length of 16 bits. In this case, the object changes the bit width at each stage, based on the Pruning algorithm.

If the `OutputWordLength` property value is less than the number of bits requested at the output, the least significant bits (LSBs) at the earlier stages are pruned. The Hogenauer algorithm provides the number of LSBs to discard at each stage. This algorithm minimizes the loss of information in the output data [1].

Latency

This section shows the latencies of the System object for a scalar input when the System object is operated with fixed and variable decimation rates and for a vector input when the System object is operated with a fixed decimation rate.

Scalar Input

This figure shows the output of the System object for the default configuration, that is, with a fixed decimation rate and DecimationFactor, DifferentialDelay, and NumSections values of 2, 1, and 2, respectively. The System object returns valid output data at every second cycle based on the fixed DecimationFactor value of 2. The latency of the System object is 5 clock cycles, calculated as $3 + N$.

This figure shows the output of the System object with a fixed decimation rate, DecimationFactor, DifferentialDelay, and NumSections values of 8, 1, and 3, respectively and GainCorrection set to true. The System object returns valid output data at every eighth cycle based on the fixed DecimationFactor value of 8. The latency of the object is 15 clock cycles and is calculated as $3 + N + 9$.

This figure shows the output of the System object for variable decimFactor values 2, 4, and 8 along with M and N values 1 and 3. The GainCorrection property is set to false. The System object returns valid output data at the second, fourth, and eighth cycles corresponding to the decimFactor values 2, 4, and 8, respectively. The System object accepts decimFactor argument value changes only when input validIn is 1 (true). The latency of the System object is 7 clock cycles, calculated as $4 + N$.

Vector Input

The latency of the System object for a vector input is calculated using this formula: $\text{floor}((\text{vecLen} - 1) * (N/\text{vecLen})) + 1 + N + 9 * \text{GainCorrection} + (2 + (\text{vecLen} + 1) * N)$, where *vecLen* is the length of the vector and *N* is the number of sections.

This figure shows the output of the System object for a two-element column vector input with default configuration, that is, with a fixed decimation rate and DecimationFactor, DifferentialDelay, and NumSections values of 2, 1, and 2, respectively. The latency of the block is 12 clock cycles.

This figure shows the output of the System object for an eight-element column vector input with a fixed decimation rate and *R*, *M*, and *N* values of 8, 1, and 3, respectively and GainCorrection set to true. The latency of the block is 44 clock cycles.

Performance

The performance of the synthesized HDL code varies with your target and synthesis options. This table shows the resource and performance data synthesis results of the block for a scalar input with fixed and variable decimation rates and for a two-element column vector input with fixed decimation rate DecimationFactor, DifferentialDelay, and NumSections values are 2, 1, and 2, respectively. The generated HDL is targeted to the Xilinx Zynq-7000 ZC706 evaluation board.

Input Data	Decimation Type	Slice LUTs	Slice Registers	Maximum Frequency in MHz
Scalar	Fixed rate	101	166	711.74
	Variable rate	206	186	441.70
Vector	Fixed rate	218	627	624.61

The resources and frequencies vary based on the type of input data and R , M , and N values and other selected property values. Using a vector input can increase the throughput, however this option also increases the number of hardware resources that the System object uses.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

This System object supports C/C++ code generation for accelerating MATLAB simulations, and for DPI component generation.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

`double` and `single` data types are supported for simulation, but not for HDL code generation.

To generate HDL code from predefined System objects, see "HDL Code Generation from Viterbi Decoder System Object" (HDL Coder).

dsp.ColoredNoise

Package: dsp

Generate colored noise signal

Description

The `dsp.ColoredNoise` System object generates a colored noise signal with a power spectral density (PSD) of $1/|f|^\alpha$ over its entire frequency range. The inverse frequency power, α , can be any value in the interval $[-2, 2]$. The type of colored noise the object generates depends on the “Color” on page 4-0 you choose. When you set `Color` to 'custom', you can specify the power density of the noise through the “InverseFrequencyPower” on page 4-0 property.

The size and data type properties of the generated signal depend on “SamplesPerFrame” on page 4-0, “NumChannels” on page 4-0, and the “OutputDataType” on page 4-0 properties.

This object uses the default MATLAB random stream, `RandStream`. Reset the default stream for repeatable simulations.

To generate colored noise signal:

- 1 Create the `dsp.ColoredNoise` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

Creation

Syntax

```
cn = dsp.ColoredNoise
cn = dsp.ColoredNoise(Name,Value)
cn = dsp.ColoredNoise(pow,samp,numChan,Name,Value)
cn = dsp.ColoredNoise(color,samp,numChan,Name,Value)
```

Description

`cn = dsp.ColoredNoise` creates a colored noise object, `cn`, that outputs a noise signal one sample or frame at a time, with a $1/|f|^\alpha$ spectral characteristic over its entire frequency range. Typical values for α are $\alpha = 1$ (pink noise) and $\alpha = 2$ (brownian noise).

`cn = dsp.ColoredNoise(Name,Value)` creates a colored noise object with each specified property set to the specified value. Enclose each property name in single quotes.

Example: `dsp.ColoredNoise('Color','pink');`

`cn = dsp.ColoredNoise(pow,samp,numChan,Name,Value)` creates a colored noise object with the `InverseFrequencyPower` property set to `pow`, the `SamplesPerFrame` property set to `samp`, and the `NumChannels` property set to `numChan`.

Example: `dsp.ColoredNoise(1,44.1e3,1,'OutputDataType','single');`

`cn = dsp.ColoredNoise(color,samp,numChan,Name,Value)` creates a colored noise object with the `Color` property set to `color`, the `SamplesPerFrame` property set to `samp`, and the `NumChannels` property set to `numChan`.

Example: `dsp.ColoredNoise('pink',1024,2,'OutputDataType','single');`

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects.

Color — Noise color

'custom' (default) | 'pink' | 'white' | 'brown' | 'blue' | 'purple'

Noise color, specified as one of the following. Each color is associated with a specific inverse frequency power of the generated noise sequence.

- 'pink' -- The inverse frequency power, α equals 1.
- 'white' -- $\alpha = 0$.
- 'brown' -- $\alpha = 2$. Also known as red or Brownian noise.
- 'blue' -- $\alpha = -1$. Also known as azure noise.
- 'purple' -- $\alpha = -2$. Also known as violet noise.
- 'custom' -- For noise with a custom inverse frequency power, α equals the value of the "InverseFrequencyPower" on page 4-0 property.

InverseFrequencyPower, α can be any value in the interval $[-2, 2]$.

InverseFrequencyPower — Inverse frequency power

1 (default) | real scalar in $[-2, 2]$

Inverse frequency power, α , specified as a real scalar in the interval $[-2, 2]$. The inverse exponent defines the PSD of the random process as $1/|f|^\alpha$. Values of "InverseFrequencyPower" on page 4-0 greater than 0 generate lowpass noise with a singularity (pole) at $f = 0$. These processes exhibit long memory. Values of InverseFrequencyPower less than 0 generate highpass noise with increments that are negatively correlated. These processes are referred to as anti-persistent. Special cases include:

- 1 -- Pink noise
- 2 -- Brown, red, or Brownian noise
- 0 -- White noise process with a flat PSD
- -1 -- Blue or azure noise
- -2 -- Purple or violet noise

In a log-log plot of power as a function of frequency, processes generated by this object exhibit an approximate linear relationship with slope equal to $-\alpha$.

Example: 1.2

Example: -1.4

Dependencies

This property applies only when you set “Color” on page 4-0 to 'custom'.

SamplesPerFrame — Number of samples per output channel

1024 (default) | positive integer

Number of samples per output channel, specified as a positive integer. This property determines the number of rows of the signal.

Example: 512

NumChannels — Number of output channels

1 (default) | positive integer

Number of output channels, specified as an integer. This property determines the number of columns of the signal.

Example: 5

Example: 25

RandomStream — Source of random number stream

'Global stream' (default) | 'mt19937ar with seed'

Source of the random number stream, specified as one of the following:

- 'Global stream' -- The current global random number stream is used for normally distributed random number generation.
- 'mt19937ar with seed' -- The mt19937ar algorithm is used for normally distributed random number generation. The `reset` function reinitializes the random number stream to the value of the `Seed` property.

Seed — Initial seed

67 (default) | nonnegative integer

Initial seed of mt19937ar random number stream generator algorithm, specified as a nonnegative integer. The `reset` function reinitializes the random number stream to the value of the `Seed` property.

Example: 3

Example: 34

Dependencies

This property applies only when you set the `RandomStream` property to 'mt19937ar with seed'.

Data Types: double

BoundedOutput — Set output bounds to +1 and -1

false (default) | true

Specify the output to be bounded between +1 and -1, specified as:

- `true` -- The internal random source that generates the noise is uniform. If `Color` is set to `'white'`, there is no color filter applied to the output of the random source. The output is uniform noise of amplitude between +1 and -1. If `Color` is set to any other option, then a coloring filter is applied to the output of the random source, followed by a gain ensures that the absolute maximum output never exceeds 1.
- `false` -- The internal random source is Gaussian. The output is not bounded.

Data Types: `logical`

OutputDataType — Output data type

`'double'` (default) | `'single'`

Output data type, specified as either `'double'` or `'single'`.

Usage

Syntax

```
noiseOut = cn()
```

Description

`noiseOut = cn()` outputs one sample or one frame of colored noise data.

Output Arguments

noiseOut — Colored noise output

`vector` | `matrix`

Colored noise output, returned as a vector or matrix. The `"SamplesPerFrame"` on page 4-0 , `"NumChannels"` on page 4-0 , and the `"OutputDataType"` on page 4-0 properties specify the size and data type of the output.

Example:

```
[0.5377;2.1027;-1.1403;0.5885;0.6229;-0.8971;-0.7435;-0.0588;3.458;4.4537]
```

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Common to All System Objects

<code>step</code>	Run System object algorithm
<code>release</code>	Release resources and allow changes to System object property values and input characteristics
<code>reset</code>	Reset internal states of System object

Examples

Measure Pink Noise Power in Octave Bands

Note: If you are using R2016a or an earlier release, replace each call to the object with the equivalent `step` syntax. For example, `obj(x)` becomes `step(obj,x)`.

The output from this example shows that pink noise has approximately equal power in octave bands.

Generate a single-channel signal of pink noise that is 44,100 samples in length. Set the random number generator to the default settings for reproducible results.

```
pinkNoise = dsp.ColoredNoise(1,44.1e3,1);
rng default;
x = pinkNoise();
```

Set the sampling frequency to 44.1 kHz. Measure the power in octave bands beginning with 100-200 Hz and ending with 6.400-12.8 kHz. Display the results in a table.

```
beginfreq = 100;
endfreq = 200;
count = 1;
freqinterval = zeros(7,2);
Pwr = zeros(7,1);
while(endfreq<=44.1e3/2)
    freqinterval(count,:) = [beginfreq endfreq];
    Pwr(count) = bandpower(x,44.1e3,[beginfreq endfreq]);
    beginfreq = endfreq;
    endfreq = 2*endfreq;
    count = count+1;
end
Pwr = Pwr(:);
table(freqinterval,Pwr)
```

```
ans=7x2 table
    freqinterval      Pwr
    _____      _____
    100           200      0.17549
    200           400      0.20313
    400           800      0.2438
    800          1600      0.2503
    1600         3200      0.25233
    3200         6400      0.26828
    6400        12800      0.25211
```

The pink noise has roughly equal power in octave bands.

Rerun the preceding code with 'InverseFrequencyPower' equal to 0, which generates a white noise signal. A white noise signal has a flat power spectral density, or equal power per unit frequency. Set the random number generator to the default settings for reproducible results.

```
whiteNoise = dsp.ColoredNoise(0,44.1e3,1);
rng default;
x = whiteNoise();
```

Set the sampling frequency is 44.1 kHz. Measure the power in octave bands beginning with 100-200 Hz and ending with 6.400-12.8 kHz. Display the results in a table.

```

beginfreq = 100;
endfreq = 200;
count = 1;
while(endfreq<=44.1e3/2)
    freqinterval(count,:) = [beginfreq endfreq];
    Pwr(count) = bandpower(x,44.1e3,[beginfreq endfreq]);
    beginfreq = endfreq;
    endfreq = 2*endfreq;
    count = count+1;
end
Pwr = Pwr(:);
table(freqinterval,Pwr)

```

```

ans=7x2 table
    freqinterval      Pwr
    _____      _____
    100           200      0.0031417
    200           400      0.0073833
    400           800      0.017421
    800          1600      0.035926
    1600         3200      0.071139
    3200         6400      0.15183
    6400        12800      0.28611

```

White noise has approximately equal power per unit frequency, so octave bands have an unequal distribution of power. Because the width of an octave band increases with increasing frequency, the power per octave band increases for white noise.

PSD of Pink Noise Realization

Note: If you are using R2016a or an earlier release, replace each call to the object with the equivalent `step` syntax. For example, `obj(x)` becomes `step(obj,x)`.

Generate a pink noise signal 2048 samples in length. The sampling frequency is 1 Hz. Obtain an estimate of the power spectral density using Welch's overlapped segment averaging.

```

cn = dsp.ColoredNoise('pink','SamplesPerFrame',2048);
x = cn();
Fs = 1;
[Pxx,F] = pwelch(x,hamming(128),[],[],Fs,'psd');

```

Construct the theoretical PSD of the pink noise process.

```

PSDPink = 1./F(2:end);

```

Display the Welch PSD estimate of the noise along with the theoretical PSD on a log-log plot. Plot the frequency axis with a base-2 logarithmic scale to clearly show the octaves. Plot the PSD estimate in dB, $10\log_{10}$.

```

plot(log2(F(2:end)),10*log10(Pxx(2:end)))
hold on
plot(log2(F(2:end)),10*log10(PSDPink),'r','linewidth',2)
xlabel('log_2(Hz)')

```

```

ylabel('dB')
title('Pink Noise')
grid on
legend('PSD estimate','Theoretical pink noise PSD')
hold off

```

Two-Channel Brownian Noise

Note: If you are using R2016a or an earlier release, replace each call to the object with the equivalent `step` syntax. For example, `obj(x)` becomes `step(obj,x)`.

Generate two channels of Brownian noise by setting `Color` to `'brown'` and `NumChannels` to 2.

```

cn = dsp.ColoredNoise('brown','SamplesPerFrame',2048,...
    'NumChannels',2);
x = cn();
subplot(2,1,1)
plot(x(:,1)); title('Channel 1'); axis tight;
subplot(2,1,2)
plot(x(:,2)); title('Channel 2'); axis tight;

```

The sampling frequency is 1 Hz. Obtain Welch PSD estimates for both channels. The fourth argument of `pwelch`, `NFFT`, which is the number of FFT points, is empty. Hence, `NFFT` is set to 256. For even `NFFT`, The number of FFT points used to calculate the PSD estimate is $(NFFT/2+1)$, which equals 129.

```
Fs = 1;
Pxx = zeros(129,size(x,2));
for nn = 1:size(x,2)
[Pxx(:,nn),F] = pwelch(x(:,nn),hamming(128),[],[],Fs,'psd');
end
```

Construct the theoretical PSD of a Brownian process. Plot the theoretical PSD along with both realizations on a log-log plot. Use a base-2 logarithmic scale for the frequency axis and plot the power spectral densities in dB.

```
PSDBrownian = 1./F(2:end).^2;
figure;
plot(log2(F(2:end)),10*log10(PSDBrownian),'k-.','linewidth',2);
hold on;
plot(log2(F(2:end)),10*log10(Pxx(2:end,:)));
xlabel('log_2(Hz)'); ylabel('dB');
grid on;
legend('Theoretical PSD','Channel 1', 'Channel 2');
```

Add Pink Noise at 0 dB SNR

Note: If you are using R2016a or an earlier release, replace each call to the object with the equivalent `step` syntax. For example, `obj(x)` becomes `step(obj,x)`.

Note: The `audioDeviceWriter` System object™ is not supported in MATLAB Online.

This example shows how to stream in an audio file and add pink noise at a 0 dB signal-to-noise ratio (SNR). The example reads in frames of an audio file 1024 samples in length, measures the root mean square (RMS) value of the audio frame, and adds pink noise with the same RMS value as the audio frame.

Set up the System objects. Set `'SamplesPerFrame'` for both the file reader and the colored noise generator to 1024 samples. Set `Color` to `'pink'` to generate pink noise with a $1/|f|$ power spectral density.

```
N = 1024;
afr = dsp.AudioFileReader('Filename','speech_dft.mp3',...
    'SamplesPerFrame',N);
adw = audioDeviceWriter('SampleRate',afr.SampleRate);
cn = dsp.ColoredNoise('pink','SamplesPerFrame',N);
```

Stream the audio file in 1024 samples at a time. Measure the signal RMS value for each frame, generate a frame of pink noise equal in length, and scale the RMS value of the pink noise to match the signal. Add the scaled noise to the signal and play the output.

```
while ~isDone(afr)
    audio = afr();
    speechRMS = rms(audio);
    noise = cn();
    noiseRMS = rms(noise);
    noise = noise*(speechRMS/noiseRMS);
    sigPlusNoise = audio+noise;
    adw(sigPlusNoise);
end
release(afr);
release(adw);
```

Averaged Power Spectrum of Pink Noise

Note: If you are using R2016a or an earlier release, replace each call to the object with the equivalent `step` syntax. For example, `obj(x)` becomes `step(obj,x)`.

Generate two-channels of pink noise and compute the power spectrum based on a running average of 50 PSD estimates.

Set up the colored noise generator to generate two channels of pink noise with 1024 samples. Set up the spectrum analyzer to compute modified periodograms using a Hamming window and 50% overlap. Obtain a running average of the PSD using 50 spectral averages.

```
pinkNoise = dsp.ColoredNoise('pink',1024,2);
sa = dsp.SpectrumAnalyzer('SpectrumType','Power density', ...
    'OverlapPercent',50,'Window','Hamming', ...
    'SpectralAverages',50,'PlotAsTwoSidedSpectrum',false, ...
    'FrequencyScale','log','YLimits',[-50 30]);
```

Run the simulation for 30 seconds.

```
tic
while toc < 30
    pink = pinkNoise();
    sa(pink);
end
```

More About

Colored Noise Processes

Many phenomena in diverse fields, such as hydrology and finance, produce time series with PSD functions that follow a power law of the form

$$S(f) = \frac{L(f)}{|f|^\alpha}$$

where α is a real number in the interval $[-2, 2]$ and $L(f)$ is a positive, slowly-varying or constant function. Plotting the PSD of such processes on a log-log plot displays an approximate linear relationship between the log frequency and log PSD with slope equal to $-\alpha$

$$\ln S(f) = -\alpha \ln |f| + \ln L(f).$$

It is often convenient to plot the PSD in dB as a function of the frequency on a base-2 logarithmic scale. The slope of the plot is then dB/octave. Rewriting the preceding equation, you obtain

$$10 \log S(f) = -10\alpha \frac{\ln(2) \log_2(f)}{\ln(10)} + 10 \frac{\ln(L(f))}{\ln(10)}$$

with the slope in dB/octave given by

$$-10\alpha \frac{\ln(2)\log_2(f)}{\ln(10)}$$

If $\alpha > 0$, $S(f)$ goes to infinity as the frequency, f , approaches 0. Stochastic processes with PSDs of this form exhibit long memory. Long-memory processes have autocorrelations that persist for a long time as opposed to decaying exponentially like many common time-series models. If $\alpha < 0$, the process is antipersistent and exhibits negative correlation between increments [1].

Special examples of $\frac{1}{|f|^\alpha}$ processes include:

- $\alpha = 0$ — White noise, where $L(f)$ is a constant proportional to the process variance.
- $\alpha = 1$ — Pink, or flicker noise. Pink noise has equal energy per octave. See “Measure Pink Noise Power in Octave Bands” on page 4-305 for a demonstration. The power spectral density of pink noise decreases 3 dB per octave.
- $\alpha = 2$ — brown noise, or Brownian motion. Brownian motion is a nonstationary process with stationary increments. You can think of Brownian motion as the integral of a white noise process. Even though Brownian motion is nonstationary, you can still define a generalized power spectrum, which behaves like $\frac{1}{|f|^2}$. Accordingly, power in a brown noise decreases 6 dB per octave.
- $\alpha = -1$ — blue noise. The power spectral density of blue noise increases 3 dB per octave.
- $\alpha = -2$ — violet, or purple noise. The power spectral density of violet noise increases 6 dB per octave. You can think of violet noise as the derivative of white noise process.

Algorithms

The figure shows the overall process of generating the colored noise.

The random stream generator produces a stream of white noise that is either Gaussian or uniform in distribution. A coloring filter applied to the white noise generates colored noise with a power spectral density (PSD) function given by:

$$S(f) = \frac{L(f)}{|f|^\alpha}$$

When α , the inverse frequency power, equals 0, no coloring filter is applied to the output of the random stream generator. If the bounded option is enabled, the output is uniform white noise with amplitude between +1 and -1. If the bounded output is not enabled, the output is a Gaussian white noise and the values are not bounded between +1 and -1. If α is set to any other value, then a coloring filter is applied to the output of the random stream generator. If the bounded output option is enabled, a gain g is applied to the output of the coloring filter to ensure that the absolute maximum output never exceeds 1.

For details on colored noise processes and how the value of α affects the PSD of the colored noise, see “Colored Noise Processes” on page 4-312.

When the inverse frequency power α is positive, the colored noise is generated using an autoregressive (AR) model of order 63. The AR coefficients are:

$$a_0 = 1,$$

$$a_k = (k - 1 - \frac{\alpha}{2}) \frac{a_{k-1}}{k}, \quad k = 1, 2, \dots, 63$$

Pink and brown noises are special cases, which are generated from specially tuned SOS filters of orders 12 and 10, respectively. These filters are optimized for better performance.

When the inverse frequency power α is negative, the colored noise is generated using a moving average (MA) model of order 255. The MA coefficients are:

$$b_0 = 1,$$

$$b_k = (k - 1 + \frac{\alpha}{2}) \frac{b_{k-1}}{k}, \quad k = 1, 2, \dots, 255$$

Purple noise is generated from a first order filter, $B = [1 \ -1]$.

The coloring filters applied (except pink, brown, and purple) are detailed on pp. 820-822 in [2].

dsp.ComplexBandpassDecimator

Package: dsp

Extract a frequency subband using a one-sided (complex) bandpass decimator

Description

The `dsp.ComplexBandpassDecimator` System object extracts a specific sub-band of frequencies using a one-sided, multistage, complex bandpass decimator. The object determines the bandwidth of interest using the specified `CenterFrequency`, `DecimationFactor` and `Bandwidth` values.

To extract a frequency subband using a complex bandpass decimator:

- 1 Create the `dsp.ComplexBandpassDecimator` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

Creation

Syntax

```
bpdecim = dsp.ComplexBandpassDecimator
bpdecim = dsp.ComplexBandpassDecimator(d)
bpdecim = dsp.ComplexBandpassDecimator(d,Fc)
bpdecim = dsp.ComplexBandpassDecimator(d,Fc,Fs)
bpdecim = dsp.ComplexBandpassDecimator(Name,Value)
```

Description

`bpdecim = dsp.ComplexBandpassDecimator` creates a System object that filters each channel of the input over time using a one-sided, multistage, complex bandpass decimation filter. The object determines the bandwidth of interest using the default center frequency, decimation factor, and bandwidth values.

`bpdecim = dsp.ComplexBandpassDecimator(d)` creates a complex bandpass decimator object with the `DecimationFactor` property set to `d`.

`bpdecim = dsp.ComplexBandpassDecimator(d,Fc)` creates a complex bandpass decimator object with the `DecimationFactor` property set to `d`, and the `CenterFrequency` property set to `Fc`.

`bpdecim = dsp.ComplexBandpassDecimator(d,Fc,Fs)` creates a complex bandpass decimator object with the `DecimationFactor` property set to `d`, the `CenterFrequency` property set to `Fc`, and the `SampleRate` property set to `Fs`.

Example: `dsp.ComplexBandpassDecimator(48e3/1e3,2e3,48e3);`

`bpdecim = dsp.ComplexBandpassDecimator(Name, Value)` creates a complex bandpass decimator object with each specified property set to the specified value. Enclose each property name in quotes. You can use this syntax with any previous input argument combinations.

Example: `dsp.ComplexBandpassDecimator(48e3/1e3, 2e3, 48e3, 'CenterFrequency', 1e3);`

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see *System Design in MATLAB Using System Objects*.

CenterFrequency — Center frequency in Hz

0 (default) | real scalar

Center frequency of the desired band in Hz, specified as a real, finite numeric scalar in the range $[-\text{SampleRate}/2, \text{SampleRate}/2]$.

Tunable: Yes

Data Types: `single` | `double`

Specification — Filter design parameters

'Decimation factor' (default) | 'Bandwidth' | 'Decimation factor and bandwidth'

Filter design parameters, specified as:

- 'Decimation factor' -- The object specifies the decimation factor through the `DecimationFactor` property. The bandwidth of interest (BW) is computed using the following equation:

$$BW = Fs/D$$

where

- Fs -- Sample rate specified through `SampleRate` property.
- D -- Decimation factor.
- 'Bandwidth' -- The object specifies the bandwidth through the `Bandwidth` property. The decimation factor (D) is computed using the following equation:

$$D = \text{floor}\left(\frac{Fs}{BW + TW}\right)$$

where

- Fs -- Sample rate specified through `SampleRate` property.
- BW -- Bandwidth of interest.
- TW -- Transition width specified through the `TransitionWidth` property.
- 'Decimation factor and bandwidth' -- The decimation factor and the bandwidth of interest are specified through the `DecimationFactor` and `Bandwidth` properties.

DecimationFactor — Decimation factor

2 (default) | positive integer

Factor by which to reduce the bandwidth of the input signal, specified as a positive integer. The frame size (number of rows) of the input signal must be a multiple of the decimation factor.

Dependencies

This property applies when you set `Specification` to either 'Decimation factor' or 'Decimation factor and bandwidth'.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

StopbandAttenuation — Stopband attenuation in dB

80 (default) | positive scalar

Stopband attenuation of the filter in dB, specified as finite positive scalar.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

TransitionWidth — Transition width in Hz

100 (default) | positive scalar

Transition width of the filter in Hz, specified as a positive scalar.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

Bandwidth — Bandwidth (Hz)

5000 (default) | real positive scalar

Width of the frequency band of interest, specified as a real positive scalar in Hz.

Dependencies

This property applies when you set `Specification` to either 'Bandwidth' or 'Decimation factor and bandwidth'.

Data Types: `single` | `double`

PassbandRipple — Passband ripple (dB)

1 (default) | positive scalar

Passband ripple of the filter, specified as a positive scalar in dB.

Dependencies

This property applies when you set `Specification` to either 'Bandwidth' or 'Decimation factor and bandwidth'.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

MinimizeComplexCoefficients — Flag to minimize number of complex coefficients`true` (default) | `false`

Flag to minimize the number of complex filter coefficients, specified as:

- `true` -- The first stage of the multistage filter is bandpass (complex coefficients) centered at the specified center frequency. The first stage is followed by a mixing stage that heterodynes the signal to DC. The remaining filter stages, all with real coefficients, follow.

- `false` -- The input signal is first passed through the different stages of the multistage filter. All stages are bandpass (complex coefficients). The signal is then heterodyned to DC if `MixToBaseband` is `true`, and the frequency offset resulting from the decimation is nonzero.

MixToBaseband — Flag to mix signal to baseband

`true` (default) | `false`

Flag to mix the signal to baseband, specified as:

- `true` -- The object heterodynes the filtered, decimated signal to DC. This mixing stage runs at the output sample rate of the filter.
- `false` -- The object skips the mixing stage.

Dependencies

This property applies when you set `MinimizeComplexCoefficients` to `false`.

SampleRate — Input sample rate in Hz

44100 (default) | real positive scalar

Sampling rate of the input signal in Hz, specified as a real positive scalar.

Data Types: `single` | `double`

Usage

Syntax

```
y = bpdecim(x)
```

Description

`y = bpdecim(x)` filters the real or complex input signal, `x`, to produce the output, `y`. The output contains the subband of frequencies specified by the System object properties. The System object filters each channel of the input signal independently over time. The frame size (first dimension) of `x` must be a multiple of the decimation factor.

Input Arguments

x — Data input

vector | matrix

Data input, specified as a vector or a matrix. The number of rows in the input must be a multiple of the decimation factor.

Data Types: `single` | `double`

Output Arguments

y — Filtered output

vector | matrix

Output of the complex bandpass decimator, returned as a vector or a matrix. The output contains the subband of frequencies specified by the System object properties. The number of rows (frame size) in

the output signal is $1/D$ times the number of rows in the input signal, where D is the decimation factor. The number of channels (columns) does not change.

The data type of the output is same as the data type of the input. The output signal is always complex.

Data Types: `single` | `double`

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Specific to dsp.ComplexBandpassDecimator

<code>cost</code>	Implementation cost of the complex bandpass decimator
<code>freqz</code>	Frequency response of the multirate multistage filter
<code>info</code>	Information about filter System object
<code>visualizeFilterStages</code>	Visualize filter stages

Common to All System Objects

<code>step</code>	Run System object algorithm
<code>release</code>	Release resources and allow changes to System object property values and input characteristics
<code>reset</code>	Reset internal states of System object

Examples

Compute Cost of Complex Bandpass Decimator

Compute the implementation cost of a complex bandpass decimator using the `cost` function.

Create a `dsp.ComplexBandpassDecimator` object. Set the `DecimationFactor` to 12, the `CenterFrequency` to 5000 Hz, and the `SampleRate` to 44,100 Hz.

```
cbp = dsp.ComplexBandpassDecimator(12,5000,44100)
```

```
cbp =
  dsp.ComplexBandpassDecimator with properties:
      CenterFrequency: 5000
      Specification: 'Decimation factor'
      DecimationFactor: 12
      StopbandAttenuation: 80
      TransitionWidth: 100
      MinimizeComplexCoefficients: true
      SampleRate: 44100
```

Compute the implementation cost of `cbp` using the `cost` function.

```
c = cost(cbp)
```

```
c = struct with fields:
    NumCoefficients: 201
    NumStates: 379
    RealMultiplicationsPerInputSample: 44.3333
    RealAdditionsPerInputSample: 43.8333
```

Compute Frequency Response of Complex Bandpass Decimator

Compute the complex frequency response of a complex bandpass decimator using the `freqz` function.

Create a `dsp.ComplexBandpassDecimator` object. Set the `DecimationFactor` to 12, the `CenterFrequency` to 5000 Hz, and the `SampleRate` to 44100 Hz. Compute and display the frequency response.

```
cbp = dsp.ComplexBandpassDecimator(12,5000,44100);
[h,f] = freqz(cbp);
plot(f,20*log10(abs(h)))
grid on
xlabel('Frequency (Hz)')
ylabel('h (dB)')
```

Filter Signal Through Complex Bandpass Decimator

Filter an input signal through a complex bandpass decimator and visualize the filtered spectrum in a spectrum analyzer.

Initialization

Create a `dsp.ComplexBandpassDecimator` System object™ with center frequency set to 2000 Hz, bandwidth of interest set to 1000 Hz, and sample rate set to 48 kHz. The decimation factor is computed as the ratio of the sample rate to the bandwidth of interest. The input to the decimator is a sine wave with a frame length of 1200 samples with tones at 1625 Hz, 2000 Hz, and 2125 Hz. Create a `dsp.SpectrumAnalyzer` scope to visualize the signal spectrum.

```
Fs = 48e3;
CF = 2000;
BW = 1000;
D = Fs/BW;
FrameLength = 1200;
bpdecim = dsp.ComplexBandpassDecimator(D,CF,Fs);

sa = dsp.SpectrumAnalyzer('SampleRate',Fs/D,...
    'YLimits',[-120 40],...
    'FrequencyOffset',CF);

tones = [1625 2000 2125];
sin = dsp.SineWave('SampleRate',Fs,'Frequency',tones,...
    'SamplesPerFrame',FrameLength);
```

Visualize Filter Stages

Using the `visualizeFilterStages` function, you can visualize the response of each individual filter stage using FVTool.

```
visualizeFilterStages(bpdecim)
```

Display Filter info

The `info` function displays information about the bandpass decimator.

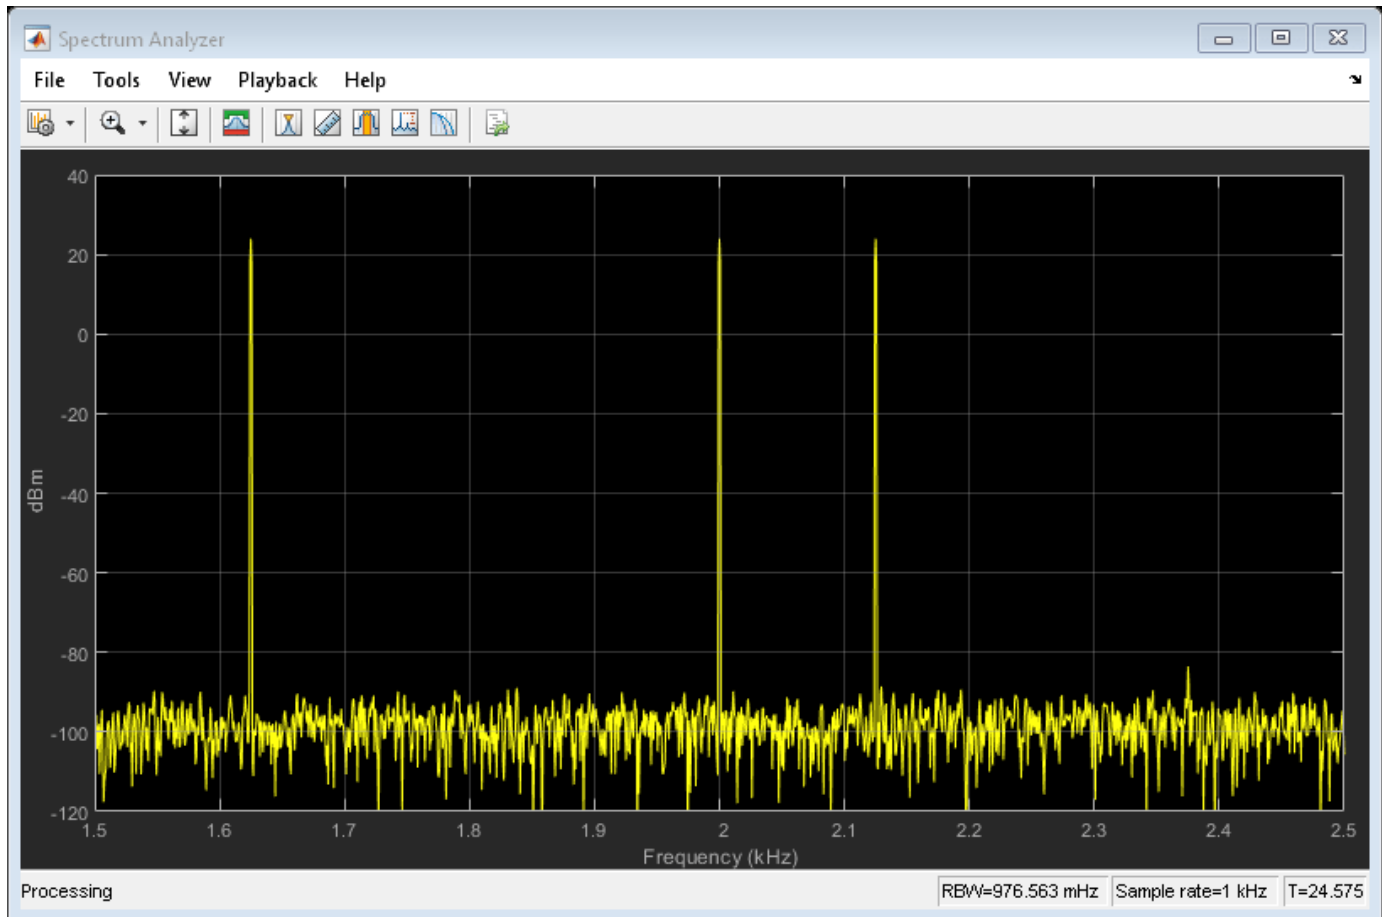

```
fprintf('%s',info(bpdecim))
```

```
Overall Decimation Factor      : 48
Bandwidth                      : 1000 Hz
Number of Filters              : 5
Real multiplications per Input Sample: 14.708333
Real additions per Input Sample  : 13.833333
Number of Coefficients         : 89
Filters:
  Filter 1:
  dsp.FIRDecimator - Decimation Factor : 2
  Filter 2:
  dsp.FIRDecimator - Decimation Factor : 2
  Filter 3:
  dsp.FIRDecimator - Decimation Factor : 2
  Filter 4:
  dsp.FIRDecimator - Decimation Factor : 3
  Filter 5:
  dsp.FIRDecimator - Decimation Factor : 2
```

Stream In and Filter Signal

Construct a for-loop to run for 1000 iterations. In each iteration, stream in 1200 samples (one frame) of the noisy sine wave and apply the complex bandpass decimator on each frame of the input signal. Visualize the input and output spectrum in the spectrum analyzer, sa.

```
for index = 1:1000
    x = sum(sin(),2) + 1e-4*randn(FrameLength,1);
    z = bpdecim(x);
    sa(z);
end
```

The bandpass decimator with center frequency at 2000 Hz and a bandwidth of 1000 Hz passes the three sine wave tones at 1625 Hz, 2000 Hz, and 2125 Hz.

Change the center frequency of the decimator to 2400 Hz and filter the signal.

```
release(bpdecim);
bpdecim.CenterFrequency = 2400
```

```
bpdecim =
```

```
    dsp.ComplexBandpassDecimator with properties:
```

```

CenterFrequency: 2400
Specification: 'Decimation factor'
DecimationFactor: 48
StopbandAttenuation: 80
TransitionWidth: 100
MinimizeComplexCoefficients: true
SampleRate: 48000

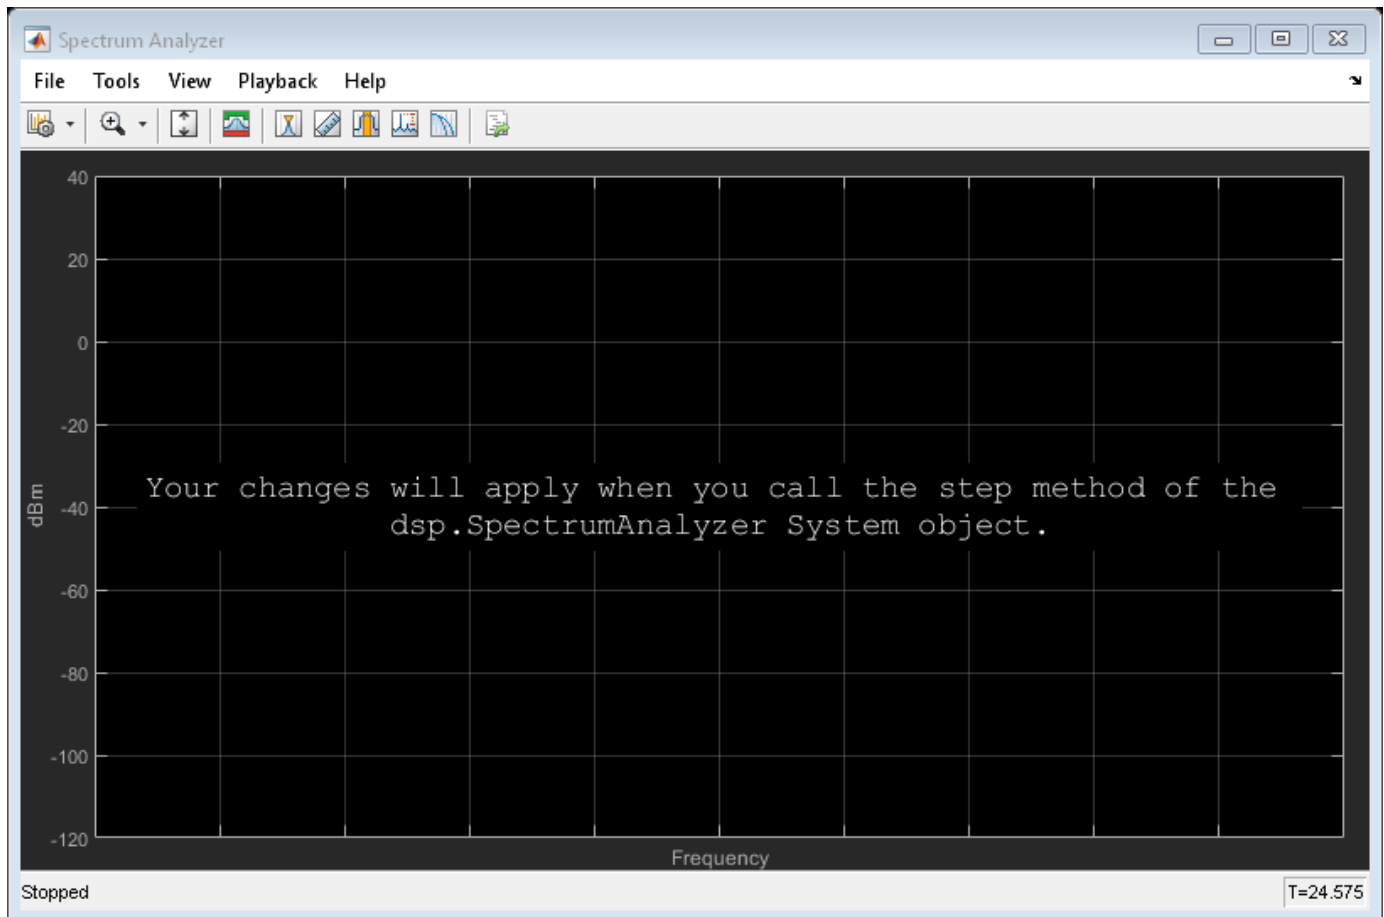

```

Configure the spectrum analyzer to show the bandwidth of interest, [-1900, 2900] Hz.

```

release(sa)
sa.FrequencyOffset = 2400;

```

Stream in the data and filter the signal.

```

for index = 1:1000
    x = sum(sin(),2) + 1e-4 * randn(FrameLength,1);
    z = bpdecim(x);
    sa(z);
end

```

The tones at 2000 Hz and 2125 Hz are passed through the decimator, while the tone at 1625 Hz is filtered out.

Algorithms

The complex bandpass decimator is designed by applying a complex frequency shift transformation on a lowpass prototype filter. The lowpass prototype in this case is a multirate, multistage finite impulse response (FIR) filter. The desired frequency shift applies only to the first stage. Subsequent stages scale the desired frequency shift by their respective cumulative decimation factors. For details, see “Complex Bandpass Filter Design” and “Zoom FFT”.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

See “System Objects in MATLAB Code Generation” (MATLAB Coder).

This object also supports SIMD code generation using Intel AVX2 technology under these conditions:

- Input signal is complex-valued.
- Input signal has a data type of `single` or `double`.

The SIMD technology significantly improves the performance of the generated code.

dsp.Convolver

Package: dsp

(To be removed) Convolution of two signals

Note `dsp.Convolver` will be removed in a future release. Use `conv` instead. For more information, see “Compatibility Considerations”.

Description

The `dsp.Convolver` System object convolves the first dimension of an N -D input array, u , with the first dimension of an N -D input array, v . You can convolve the inputs in the time domain or frequency domain. In the time domain, the object convolves the first input with the second input. In the frequency domain, the object multiplies the Fourier transforms of both the inputs, and computes the inverse Fourier transform of the product. In this domain, depending on the input length, the object can require fewer computations. For more information on the two computation methods, see “Algorithms” on page 4-332.

To convolve two inputs:

- 1 Create the `dsp.Convolver` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

Creation

Syntax

```
cnv = dsp.Convolver
cnv = dsp.Convolver(Name, Value)
```

Description

`cnv = dsp.Convolver` creates a convolution System object, `cnv`, to convolve two inputs in the time domain or frequency domain.

`cnv = dsp.Convolver(Name, Value)` creates a convolution System object, `cnv`, with each specified property set to the specified value. Enclose each property name in single quotes.

Example: `cnv = dsp.Convolver('Method', 'Frequency Domain')`

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects.

Method — Domain for computing convolutions

'Time Domain' (default) | 'Frequency Domain' | 'Fastest'

Domain in which the System object computes convolutions, specified as one of the following:

- 'Time Domain' -- Computes the convolutions in the time domain, which minimizes memory usage. For more information, see “Time-Domain Computation” on page 4-332.
- 'Frequency Domain' -- Computes the convolutions in the frequency domain, which can require fewer computations depending on the input length. For more information, see “Frequency-Domain Computation” on page 4-333.
- 'Fastest' -- Computes the convolutions in the domain that minimizes the number of computations.

Note Fixed-point signals are supported for the time domain only. To use the following fixed-point properties, set Method to 'Time Domain'.

Fixed-Point Properties

FullPrecisionOverride — Full-precision override for fixed-point arithmetic

true (default) | false

Flag to use full-precision rules for fixed-point arithmetic, specified as one of the following:

- true -- The object computes all internal arithmetic and output data types using the full-precision rules. These rules provide the most accurate fixed-point numerics. In this mode, other fixed-point properties do not apply. No quantization occurs within the object. Bits are added, as needed, to ensure that no roundoff or overflow occurs.
- false -- Fixed-point data types are controlled through individual fixed-point property settings.

For more information, see “Full Precision for Fixed-Point System Objects” and “Set System Object Fixed-Point Properties”.

RoundingMethod — Rounding method

'Floor' (default) | 'Ceiling' | 'Convergent' | 'Nearest' | 'Round' | 'Simplest' | 'Zero'

Select the rounding mode for fixed-point operations.

Dependencies

This property applies when you set the FullPrecisionOverride property to false and at least one of the ProductDataType, AccumulatorDataType, and OutputDataType properties to any option other than 'Full precision'.

OverflowAction — Overflow action

'Wrap' (default) | 'Saturate'

The overflow action for fixed-point operations, specified as one of the following:

- 'Wrap' -- The object wraps the result of its fixed-point operations.

- 'Saturate' -- The object saturates the result of its fixed-point operations.

For more details on overflow actions, see overflow mode for fixed-point operations.

Dependencies

This property applies when you set the `FullprecisionOverride` property to `false` and at least one of the `ProductDataType`, `AccumulatorDataType`, and `OutputDataType` properties to any option other than 'Full precision'.

ProductDataType — Product output data type

'Full precision' (default) | 'Custom' | 'Same as first input'

Data type of the output of a product operation in the `dsp.Convolver` object, specified as one of the following:

- 'Full precision' -- The object computes the product output data type using the full-precision rules. These rules provide the most accurate fixed-point numerics. No quantization occurs. Bits are added, as needed, to ensure that no roundoff or overflow occurs.
- 'Custom' -- The product output data type is specified as a custom numeric type through the `CustomProductDataType` property. The rounding method and the overflow action are specified through the `RoundingMethod` and `OverflowAction` properties.
- 'Same as first input' -- The object specifies the product output data type to be the same as the first input data type.

For more information on the product output data type, see the “Fixed Point” on page 4-334 section.

CustomProductDataType — Product word and fraction lengths

`numericType([],32,30)` (default)

The product output data type, specified as an autosigned numeric type with a word length of 32 and a fraction length of 30.

Dependencies

This property applies only when you set `ProductDataType` to 'Custom'.

AccumulatorDataType — Accumulator data type

'Full precision' (default) | 'Custom' | 'Same as first input' | 'Same as product'

Data type of the output of an accumulation operation in the `dsp.Convolver` object, specified as one of the following:

- 'Full precision' -- The object computes the accumulator data type using the full precision rules. These rules provide the most accurate fixed-point numerics. No quantization occurs. Bits are added, as needed, to ensure that no roundoff or overflow occurs.
- 'Custom' -- The accumulator data type is specified as a custom numeric type through the `CustomAccumulatorDataType` property. The rounding method and the overflow action are specified through the `RoundingMethod` and the `OverflowAction` properties.
- 'Same as first input' -- The object specifies the accumulator data type to be the same as the first input data type.
- 'Same as product' -- The object specifies the accumulator data type to be the same as the product data type.

For more information on the accumulator data type, see the “Fixed Point” on page 4-334 section.

CustomAccumulatorDataType — Accumulator word and fraction lengths

`numericType([],32,30)` (default)

The accumulator data type, specified as an auto signed numeric type with a word length of 32 and a fraction length of 30.

Dependencies

This property applies only when you set `AccumulatorDataType` to 'Custom'.

OutputDataType — Output data type

'Same as accumulator' (default) | 'Custom' | 'Same as first input' | 'Same as product'

Data type of the output of the `dsp.Convolver` object, specified as one of the following:

- 'Same as accumulator' -- The object specifies the output data type to be the same as the accumulator data type. For more details on the accumulator data type, see the “AccumulatorDataType” on page 4-0 property.
- 'Custom' -- The output data type is specified as a custom numeric type through the `CustomOutputDataType` property. The rounding method and the overflow action are specified through the `RoundingMethod` and the `OverflowAction` properties.
- 'Same as first input' -- The object specifies the output data type to be the same as the first input data type.
- 'Same as product' -- The object specifies the output data type to be the same as the product data type.

For more information on the output data type, see the “Fixed Point” on page 4-334 section.

CustomOutputDataType — Output word and fraction lengths

`numericType([],16,15)` (default)

The output data type, specified as an autosigned numeric type with a word length of 16 and a fraction length of 15.

Dependencies

This property applies only when you set `OutputDataType` to 'Custom'.

Usage**Syntax**

```
cnvOut = cnv(input1, input2)
```

Description

`cnvOut = cnv(input1, input2)` convolves the two inputs, `input1` and `input2`, along their first dimensions, and returns the convolved output, `cnvOut`.

Input Arguments

input1 — First data input

vector | matrix | N -D array

First data input, specified as a vector, matrix, or N -D array. If the input is a matrix or an array, all the dimensions of both the inputs, except for the first dimension, must be the same.

Example: `ones(10,3,2)`

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fi`

input2 — Second data input

vector | matrix | N -D array

Second data input, specified as a vector, matrix, or N -D array. If the input is a matrix or an array, all the dimensions of both the inputs, except for the first dimension, must be the same.

Example: `randn(4,3,2)`

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fi`

Output Arguments

cnvOut — Convolved output

vector | matrix | N -D array

The convolved output of the two inputs, returned as a vector, matrix, or N -D array.

- When both inputs are N -D arrays, the size of their first dimension can differ, but the size of all other dimensions must be equal. For example, when u is an M_u -by- N -by- P array, and v is an M_v -by- N -by- P array, the output is an (M_u+M_v-1) -by- N -by- P array.
- When one input is a column vector and the other is an N -D array, the object independently convolves the vector with the first dimension of the N -D input array. For example, when u is an M_u -by-1 column vector and v is an M_v -by- N matrix, the output is an (M_u+M_v-1) -by- N matrix.
- When u and v are column vectors with lengths M_u and M_v , the object performs the vector convolution. The output is an (M_u+M_v-1) -by-1 column vector.

When both the inputs are real, the output is real. When one or both inputs are complex, the output is complex.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fi`

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Common to All System Objects

<code>step</code>	Run System object algorithm
<code>release</code>	Release resources and allow changes to System object property values and input characteristics

reset Reset internal states of System object

Examples

Convolve Two Rectangular Sequences

Note If you are using R2016a or an earlier release, replace each call to the object with the equivalent step syntax. For example, `obj(x)` becomes `step(obj,x)`.

Create a `dsp.Convolver` object.

```
conv = dsp.Convolver
conv =
  dsp.Convolver with properties:
    Method: 'Time Domain'
  Show all properties
```

Convolve two rectangular sequences.

```
x = ones(10,1);
y = conv(x,x);
```

Plot the resulting convolved sequence, which is a triangular sequence.

```
plot(y)
```

More About

Convolution

The convolution of two signals is the integral that measures the amount of overlap of one signal as it is shifted over another signal.

The convolution of two discrete time sequences, $u[n]$ and $v[n]$, is given by the following equation:

$$y(k) = \sum_n u(n-k)v(k)$$

Algorithms

Time-Domain Computation

When you set the computation domain to *time*, the algorithm computes the convolution of the two inputs in the time domain.

When the two inputs, u and v , are of size M_u -by- N and M_v -by- N respectively, the j th column of the convolution output is given by the following equation:

$$y_{i,j} = \sum_{k=0}^{\max(M_u, M_v) - 1} u_{k,j} v_{(i-k),j} \quad 0 \leq i \leq (M_u + M_v - 2)$$

Inputs u and v are zero when they are indexed outside their valid ranges.

When u is an M_u -by-1 column and v an M_v -by- N matrix, the output is an $(M_u + M_v - 1)$ -by- N matrix whose j th column is computed using the following equation:

$$y_{i,j} = \sum_{k=0}^{\max(M_u, M_v) - 1} u_k v_{(i-k),j} \quad 0 \leq i \leq (M_u + M_v - 2)$$

When both the inputs are column vectors with lengths M_u and M_v , the object performs the vector convolution given by the following equation:

$$y_i = \sum_{k=0}^{\max(M_u, M_v) - 1} u_k v_{(i-k)} \quad 0 \leq i \leq (M_u + M_v - 2)$$

The output is an $(M_u + M_v - 1)$ -by-1 column vector.

Frequency-Domain Computation

When you set the computation domain to *frequency*, the algorithm computes the convolution in the frequency domain.

In this domain, the algorithm computes the convolution sequence by taking the Fourier transform of both the input signals, multiplying the Fourier transforms, and taking the inverse Fourier transform of the product. In this domain, depending on the input length, the algorithm can require fewer computations.

Compatibility Considerations

dsp.Convolver System object will be removed

Warns starting in R2021b

`dsp.Convolver System` object will be removed in a future release. Use the `conv` function instead.

Update Code

This table shows how the System object is typically used and explains how to update existing code to use the `conv` function.

Discouraged Usage	Recommended Replacement
<pre>cv = dsp.Convolver; x = ones(10,1); yobj = cv(x,x);</pre> <p>If you are using a release prior to R2016b, replace <code>cv(x)</code> with <code>step(cv,x)</code>.</p>	<pre>yfn = conv(x,x); isequal(yobj,yfn)</pre> <pre>ans = logical 1</pre> <p>Run the code and plot the vectors <i>yobj</i> and <i>yfn</i> using the <code>plot</code> function. Verify that the plots match.</p>

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

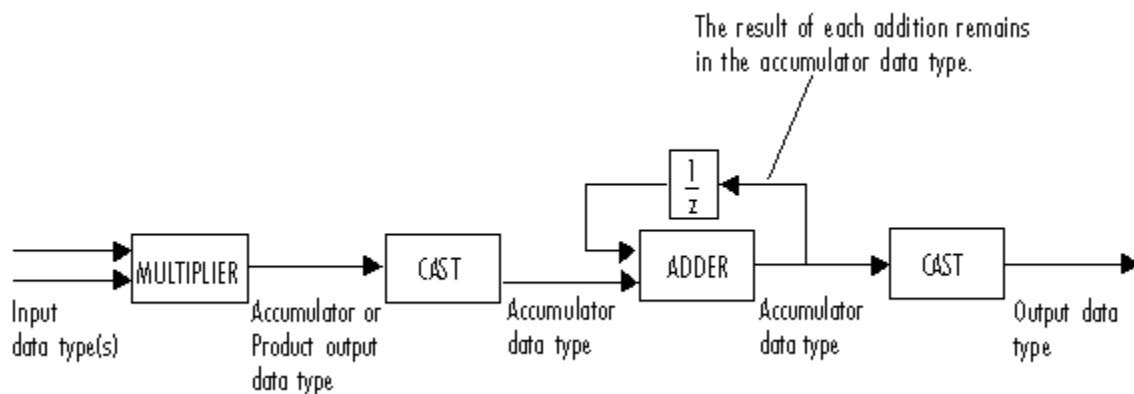

See “System Objects in MATLAB Code Generation” (MATLAB Coder).

Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

The following diagram shows the data types used within the `dsp.Convolver` System object for fixed-point signals.

Fixed-point signals are supported for the time domain only.

The output of the multiplier is in the product output data type when the input is real. When the input is complex, the result of the multiplication is in the accumulator data type. For details on the complex multiplication performed, see “Multiplication Data Types”.

When one or both of the inputs are signed fixed-point signals, all internal object data types are signed fixed point. The internal data types are unsigned fixed point only when *both* inputs are unsigned fixed-point signals.

dsp.Counter

Package: dsp

(To be removed) Count up or down through specified range of numbers

Note dsp.Counter will be removed in a future release. Alternatively, you can create a variable in MATLAB® and increment the variable by 1.

Description

The Counter object counts up or down through a specified range of numbers.

To count up or down through a specified range of numbers:

- 1 Create the dsp.Counter object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

Creation

Syntax

```
count = dsp.Counter  
count = dsp.Counter(Name, Value)
```

Description

count = dsp.Counter returns a counter System object, count, that counts up when the input is nonzero.

count = dsp.Counter(Name, Value) returns a counter System object, count, with each specified property set to the specified value.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see [System Design in MATLAB Using System Objects](#).

Direction — Count up or down

Up (default) | Down

Specify the counter direction as Up or Down.

Tunable: Yes

CountEventInputPort — Add input to specify a count event

true (default) | false

Set this property to true to enable a count event input for the internal counter. The internal counter increments or decrements whenever the count event input satisfies the condition you specify in the CountEventCondition property. When you set this property to false, the internal counter is free running, that is, the counter increments or decrements on every call to the object algorithm.

CountEventCondition — Condition that increments, decrements, or resets internal counter

Non-zero (default) | Rising edge | Falling edge | Either edge

Specify the event at the count event input that increments or decrements the counter as Rising edge, Falling edge, Either edge or Non-zero.

If you set the ResetInputPort and CountEventInputPort properties to true, the counter is reset when the event you specify for the CountEventCondition occurs.

Dependencies

This property applies only when you set the CountEventInputPort property to true.

CounterSizeSource — Source of counter size data type

Property (default) | Input port

Specify the source of the counter size data type as Property or Input port.

CounterSize — Range of integer values to count through

Maximum (default) | 8 bits | 16 bits | 32 bits

Specify the range of integer values to count through before recycling to zero as 8 bits, 16 bits, 32 bits or Maximum.

MaximumCount — Counter's maximum value

255 (default) | 0 | positive integer

Specify the counter's maximum value as a numeric scalar value.

Tunable: Yes

Dependencies

This property applies only when you set the CounterSizeSource property to Property and the CounterSize property to Maximum.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

InitialCount — Counter initial value

0 (default) | 0 | positive integer

Specify the initial value for the counter.

Tunable: Yes

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

CountOutputPort — Output count`true (default) | false`

Set this property to `true` to enable output of the internal count. The default is `true`. You cannot set both `CountOutputPort` and `HitOutputPort` to `false` at the same time.

HitOutputPort — Output hit events`true (default) | false`

Set this property to `true` to enable output of the hit events. You cannot set both `CountOutputPort` and `HitOutputPort` to `false` at the same time.

HitValues — Values whose occurrence in count produce a true hit output`32 (default) | scalar integer | vector of integers`

Specify an integer scalar or a vector of integers, whose occurrences in the count you want flagged as a hit.

Dependencies

This property applies only when you set the `HitOutputPort` property to `true`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

ResetInputPort — Add input to enable internal counter reset`true (default) | false`

When you set this property to `true`, specify a reset input to the object algorithm. When the reset input receives the event you specify for the `CountEventCondition` property, the counter resets. If you set the `CountEventInputPort` property to `false`, the counter resets whenever the reset input is not zero.

SamplesPerFrame — Number of samples in each output frame`1 (default) | positive integer`

Specify the number of samples in each output frame.

Dependencies

This property applies only when you set the `CountEventInputPort` property to `false`, indicating a free-running counter.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

CountOutputDataType — Data type of count output`double (default) | single | int8 | uint8 | int16 | uint16 | int32 | uint32`

Specify the data type of the count output, `cnt`, as `double`, `single`, `int8`, `uint8`, `int16`, `uint16`, `int32` or `uint32`.

Dependencies

This property applies when you set the `CountOutputPort` property to `true`.

Usage

Syntax

```
[cnt, hit] = count(event, reset)
cnt = count(event, reset)
hit = count(event, reset)
[ ___ ] = count()
[ ___ ] = count(event)
```

Description

`[cnt, hit] = count(event, reset)` increments, decrements, or resets the internal counter as specified by the values of the `event` and `reset` inputs. The output argument `cnt` denotes the present value of the counter. A trigger event at the `event` input causes the counter to increment or decrement. A trigger event at the `reset` input resets the counter to its initial state.

`cnt = count(event, reset)` returns the current value of the count when you set the `CountOutputPort` property to `true` and the `HitOutputPort` property to `false`.

`hit = count(event, reset)` returns a Boolean value indicating whether the count has reached any of the values specified by the `HitValues` property. This condition applies when you set the `HitOutputPort` property to `true` and the `CountOutputPort` property to `false`.

`[___] = count()` increments or decrements the free-running internal counter when you set the `CountEventInputPort` property to `false` and the `ResetInputPort` property to `false`.

`[___] = count(event)` increments or decrements the internal counter when the `event` input matches the event you specify for the `CountEventCondition` property and you set the `ResetInputPort` property to `false`.

Input Arguments

event — Event that causes counter to increment or decrement

scalar

Event that causes the counter to increment or decrement, specified as a scalar. The `CountEventCondition` property specifies the event under which the counter value changes.

Dependencies

This input is valid only when `CountEventInputPort` is set to `true`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `logical`

reset — Reset of internal counter

scalar

A trigger event at the reset input resets the counter to the initial state.

Dependencies

This input is valid only when `ResetInputPort` is set to `true`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `logical`

Output Arguments

cnt — Present value of counter

scalar | column vector

Current value of the count, returned as a scalar. The data type of this output is set by the `CountOutputDataType` property. If `CountEventInputPort` is `false`, the number of elements in this output vector is determined by the value you specify in the `SamplesPerFrame` property.

Dependencies

This output is enabled only when you set the `CountOutputPort` property to `true`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32`

hit — Indicates if counter matches hit values

scalar | column vector

Boolean value indicating whether the count has reached any of the values specified by the `HitValues` property. If `CountEventInputPort` is `false`, the number of elements in this output vector is determined by the value you specify in the `SamplesPerFrame` property.

Dependencies

This output is enabled when you set the `HitOutputPort` property to `true`.

Data Types: `logical`

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Common to All System Objects

<code>step</code>	Run System object algorithm
<code>release</code>	Release resources and allow changes to System object property values and input characteristics
<code>reset</code>	Reset internal states of System object

Examples

Count the Rising Edges

Note: If you are using R2016a or earlier, replace each call to the object with the equivalent `step` syntax. For example, `obj(x)` becomes `step(obj,x)`.

Use `dsp.Counter` System object to count at every rising edge of the input signal.

```
count = dsp.Counter('MaximumCount', 5, ...  
    'CountOutputPort', true, ...  
    'HitOutputPort', false, ...  
    'ResetInputPort', false);
```

```

sgnl = [0 1 0 1 0 1 0 1 0 1 0 1 ];
cnt = zeros(1,12);
for ii = 1:length(sgnl)
    cnt(ii) = count(sgnl(ii));
end
disp(cnt);

```

```

    0     1     1     2     2     3     3     4     4     5     5     0

```

Algorithms

This object implements the algorithm, inputs, and outputs described on the Counter block reference page. The object properties correspond to the block parameters.

- The CountEventCondition object property does not have a free-running option. Set the CountEventInputPort property to `false` to obtain the free-running option.
- The CounterSizeSource and CounterSize object properties correspond to the **Counter size** block parameter.
- The CountOutputPort and HitOutputPort correspond to the **Output** block parameter.
- There is no object property that corresponds to the **Hit data type** block parameter. The output type is logical in MATLAB. (This logical is different from the popup logical in the block. For the object, logical corresponds to Boolean in the block.)

Compatibility Considerations

dsp.Counter System object will be removed

Warns starting in R2021b

dsp.Counter System object will be removed in a future release. Alternatively, you can create a variable in MATLAB and increment the variable by 1.

dsp.CoupledAllpassFilter

Package: dsp

Coupled allpass IIR filter

Description

The `dsp.CoupledAllpassFilter` object implements a coupled allpass filter structure composed of two allpass filters connected in parallel. Each allpass branch can contain multiple sections. The overall filter output is computed by adding the output of the two respective branches. An optional second output can also be returned, which is power complementary to the first. For example, from the frequency domain perspective, if the first output implements a lowpass filter, the second output implements the power complementary highpass filter. For real signals, the power complementary output is computed by subtracting the output of the second branch from the first.

`dsp.CoupledAllpassFilter` supports double- and single-precision floating point and allows you to choose between different realization structures. This System object also supports complex coefficients, multichannel variable length input, and tunable filter coefficient values.

To filter each channel of the input:

- 1 Create the `dsp.CoupledAllpassFilter` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

Creation

Syntax

```
caf = dsp.CoupledAllpassFilter
caf = dsp.CoupledAllpassFilter(AllpassCoeffs1,AllpassCoeffs2)
caf = dsp.CoupledAllpassFilter(struc,AllpassCoeffs1,AllpassCoeffs2)
caf = dsp.CoupledAllpassFilter(Name,Value)
```

Description

`caf = dsp.CoupledAllpassFilter` returns a coupled allpass filter System object, `caf`, that filters each channel of the input signal independently. The coupled allpass filter uses the default inner structures and coefficients.

`caf = dsp.CoupledAllpassFilter(AllpassCoeffs1,AllpassCoeffs2)` returns a coupled allpass filter System object, `caf`, with `Structure` set to 'Minimum multiplier', `AllpassCoefficients1` set to `AllpassCoeffs1`, and `AllpassCoefficients2` set to `AllpassCoeffs2`.

`caf = dsp.CoupledAllpassFilter(struc,AllpassCoeffs1,AllpassCoeffs2)` returns a coupled allpass filter System object, `caf`, with `Structure` set to `struc` and the relevant coefficients set to `AllpassCoeffs1` and `AllpassCoeffs2`. `struc` can be 'Minimum multiplier' | 'Wave Digital Filter' | 'Lattice'.

`caf = dsp.CoupledAllpassFilter(Name,Value)` returns a Coupled allpass filter System object, `caf`, with each property set to the specified value.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see *System Design in MATLAB Using System Objects*.

Structure — Internal structure of allpass branches

'Minimum multiplier' (default) | 'Wave Digital Filter' | 'Lattice'

Specify the internal structure of allpass branches as one of 'Minimum multiplier', 'Wave Digital Filter', or 'Lattice'. Each structure uses a different pair of coefficient values, independently stored in the relevant object property.

AllpassCoefficients1 — Allpass polynomial coefficients of branch 1

[0 0.5] (default) | row vector | cell array

Specify the polynomial filter coefficients for the first allpass branch. This property can accept values either in the form of a row vector (single-section configuration) or a cell array with as many cells as filter sections.

Tunable: Yes

Dependencies

This property is applicable only if you set the Structure property to 'Minimum multiplier'.

Data Types: `single` | `double`

WDFCoefficients1 — Wave Digital Filter coefficients of branch 1

[0.5 0] (default) | row vector | cell array

Specify the Wave Digital Filter coefficients for the first allpass branch. This property can accept values either in the form of a row vector (single-section configuration) or a cell array with as many cells as filter sections.

Tunable: Yes

Dependencies

This property is applicable only if you set the Structure property to 'Wave Digital Filter'.

Data Types: `single` | `double`

LatticeCoefficients1 — Lattice coefficients of branch 1

[0.5 0] (default) | row vector | cell array

Specify the allpass lattice coefficients for the first allpass branch. This property can accept values either in the form of a row vector (single-section configuration) or a cell array with as many cells as filter sections.

Tunable: Yes

Dependencies

This property is applicable only if you set the Structure property to 'Lattice'.

Data Types: `single` | `double`

Delay — Length in samples for branch 1

0 (default) | positive integer scalar

Integer number of the delay taps in the top branch, specified as a positive integer scalar.

Tunable: Yes

Dependencies

This property is applicable only if you set the PureDelayBranch property to `true`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

Gain1 — Independent Branch 1 Phase Gain

1 (default) | '-1' | '0+i' | '0-i'

Gain1 is the individual branch phase gain. This property can accept only values equal to '1', '-1', '0+i', or '0-i'. This property is nontunable.

Data Types: `char`

AllpassCoefficients2 — Allpass polynomial coefficients of branch 2

{[]} (default) | row vector | cell array

Specify the polynomial filter coefficients for the second allpass branch. This property can accept values either in the form of a row vector (single-section configuration) or a cell array with as many cells as filter sections.

Tunable: Yes

Dependencies

This property is applicable only if you set the Structure property to 'Minimum multiplier'.

Data Types: `single` | `double`

WDFCoefficients2 — Wave Digital Filter coefficients of branch 2

{[]} (default) | row vector | cell array

Specify the Wave Digital Filter coefficients for the second allpass branch. This property can accept values either in the form of a row vector (single-section configuration) or a cell array with as many cells as filter sections.

Tunable: Yes

Dependencies

This property is applicable only if you set the Structure property to 'Wave Digital Filter'.

Data Types: `single` | `double`

LatticeCoefficients2 — Lattice coefficients of branch 2

{[]} (default) | row vector | cell array

Specify the allpass lattice coefficients for the second allpass branch. This property can accept values either in the form of a row vector (single-section configuration) or a cell array with as many cells as filter sections.

Tunable: Yes

Dependencies

This property is applicable only if you set the Structure property to 'Lattice'.

Data Types: single | double

Gain2 — Independent Branch 2 Phase Gain

'1' (default) | '-1' | '0+1i' | '0-1i'

Specify the value of the independent phase gain applied to branch 2. This property can accept only values equal to '1', '-1', '0+i', or '0-i'. This property is nontunable.

Data Types: char

Beta — Coupled phase gain

1 (default) | complex value with magnitude equal to 1

Specify the value of the phasor gain in complex conjugate form, in each of the two branches, and in complex coefficient configuration. The absolute value of this property should be 1 and its default value is 1.

Tunable: Yes

Dependencies

This property is applicable only when the selected Structure property supports complex coefficients.

Data Types: single | double

PureDelayBranch — Replace allpass filter in first branch with pure delay

false (default) | true

If you set PureDelayBranch to true, the property holding the coefficients for the first allpass branch is disabled and Delay becomes enabled. You can use this property to improve performance, when one of the two allpass branches is known to be a pure delay (e.g. for halfband filter designs)

Data Types: logical

ComplexConjugateCoefficients — Allow inferring coefficients of second allpass branch as complex conjugate of first

false (default) | true

When the input signal is real, this property triggers the use of an optimized structural realization. This property enables providing complex coefficients for only the first branch. The coefficients for the second branch are automatically inferred as complex conjugate values of the first branch coefficients

Dependencies

This property is only enabled if the currently selected structure supports complex coefficients. Use it only if the filter coefficients are actually complex.

Data Types: `logical`

Usage

Syntax

```
y = caf(x)
[y, ypc] = caf(x)
```

Description

`y = caf(x)` filters the input signal `x` to produce the output `y`. When `x` is a matrix, each column is filtered independently as a separate channel over time.

`[y, ypc] = caf(x)` also returns `ypc`, the power complementary signal to the primary output `y`.

Input Arguments

x — Data input

vector | matrix

Data input, specified as a vector or a matrix. This object also accepts variable-size inputs. Once the object is locked, you can change the size of each input channel, but you cannot change the number of channels.

Data Types: `single` | `double`

Output Arguments

y — Lowpass filtered output

vector | matrix

Lowpass filtered output, returned as a vector or a matrix. The size and data type of the output signal matches that of the input signal.

Data Types: `double` | `single`

ypc — Highpass filtered output

vector | matrix

Power complimentary highpass filtered output, returned as a vector or a matrix. The size and data type of the output signal matches that of the input signal.

Data Types: `double` | `single`

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Specific to dsp.CoupledAllpassFilter

fvtool	Visualize frequency response of coupled allpass filter
getBranches	Return internal allpass branches
freqz	Frequency response of discrete-time filter System object
impz	Impulse response of discrete-time filter System object
info	Information about filter System object
coeffs	Returns the filter System object coefficients in a structure
cost	Estimate cost of implementing filter System object
grpdelay	Group delay response of discrete-time filter System object

Common to All System Objects

step	Run System object algorithm
release	Release resources and allow changes to System object property values and input characteristics
reset	Reset internal states of System object

Examples

Allpass Realization of a Butterworth Lowpass Filter

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, `myObject(x)` becomes `step(myObject,x)`.

Realize a Butterworth lowpass filter of order 3. Use a coupled allpass structure with inner minimum multiplier structure.

```

Fs = 48000;    % in Hz
Fc = 12000;   % in Hz
frameLength = 1024;
[b, a] = butter(3,2*Fc/Fs);
AExp = [freqz(b,a,frameLength/2); NaN];
[c1, c2] = tf2ca(b,a);
caf = dsp.CoupledAllpassFilter(c1(2:end),c2(2:end));
tfe = dsp.TransferFunctionEstimator('FrequencyRange', 'onesided',...
    'SpectralAverages', 2);
aplot = dsp.ArrayPlot('PlotType', 'Line',...
    'YLimits', [-40 5],...
    'YLabel', 'Magnitude (dB)',...
    'SampleIncrement', Fs/frameLength,...
    'XLabel', 'Frequency (Hz)',...
    'Title', 'Magnitude Response',...
    'ShowLegend', true,'ChannelNames',{'Actual','Expected'});
Niter = 200;
for k = 1:Niter
    in = randn(frameLength,1);
    out = caf(in);
    A = tfe(in,out);
    aplot(db([A,AExp]));
end

```

Allpass Realization of an Elliptic Highpass Filter

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, `myObject(x)` becomes `step(myObject,x)`.

Remove a low-frequency sinusoid using an elliptic highpass filter design implemented through a coupled allpass structure.

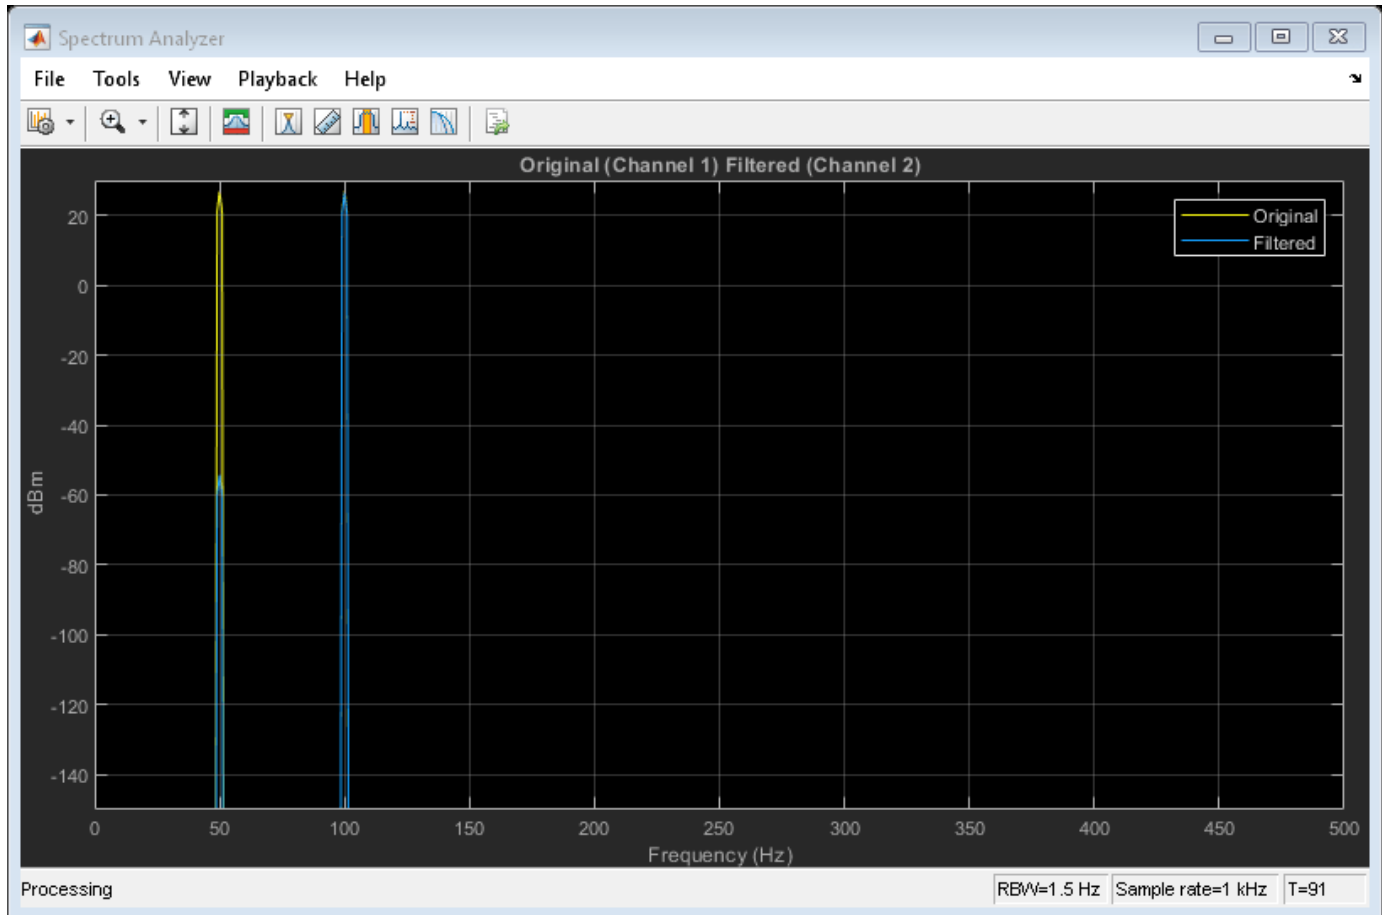

Initialize

```
Fs = 1000;
f1 = 50; f2 = 100;
Fpass = 70; Apass = 1;
Fstop = 60; Astop = 80;
filtSpecs = fdesign.highpass(Fstop,Fpass,Astop,Apass,Fs);
hpSpec = design(filtSpecs,'ellip','FilterStructure','cascadeallpass',...
    'SystemObject',true);
frameLength = 1000;
nFrames = 100;
sine = dsp.SineWave('Frequency',[f1,f2],'SampleRate',Fs,...
    'SamplesPerFrame',frameLength); % Input composed of two sinusoids.
sa = dsp.SpectrumAnalyzer('SampleRate',Fs,'YLimits',[-150 30],...
    'PlotAsTwoSidedSpectrum',false,'ShowLegend',true,...
    'FrequencyResolutionMethod','WindowLength','WindowLength',1000,...
    'FFTLengthSource','Property','FFTLength',1000,...
```

```
'Title','Original (Channel 1) Filtered (Channel 2)',...
'ChannelNames',{'Original','Filtered'});
```

Simulate

```
for k = 1:nFrames
    original = sum(sine(),2); % Add the two sinusoids together
    filtered = hpSpec(original);
    sa([original,filtered]);
end
```

View Power Complementary Output of Coupled Allpass Filter

Design a Butterworth lowpass filter of order 3. Use a coupled allpass structure with inner minimum multiplier structure.

```
Fs = 48000; % in Hz
Fc = 12000; % in Hz
frameLength = 1024;
[b,a] = butter(3,2*Fc/Fs);
AExp = [freqz(b,a,frameLength/2); NaN];
[c1,c2] = tf2ca(b,a);
caf = dsp.CoupledAllpassFilter(c1(2:end),c2(2:end));
```

Using the 'SubbandView' option of the `dsp.CoupledAllpassFilter`, you can visualize the lowpass filter output, the power complementary highpass filter output, or both using the `fvtool`.

To view the lowpass filter output, set 'SubbandView' to 1.

```
fvtool(caf, 'SubbandView', 1, 'Fs', Fs)
```

To view the highpass filter output, set 'SubbandView' to 2.

```
fvtool(caf, 'SubbandView', 2, 'Fs', Fs)
```

To view both the outputs, set 'SubbandView' to 'all', [1 2] or [1;2].

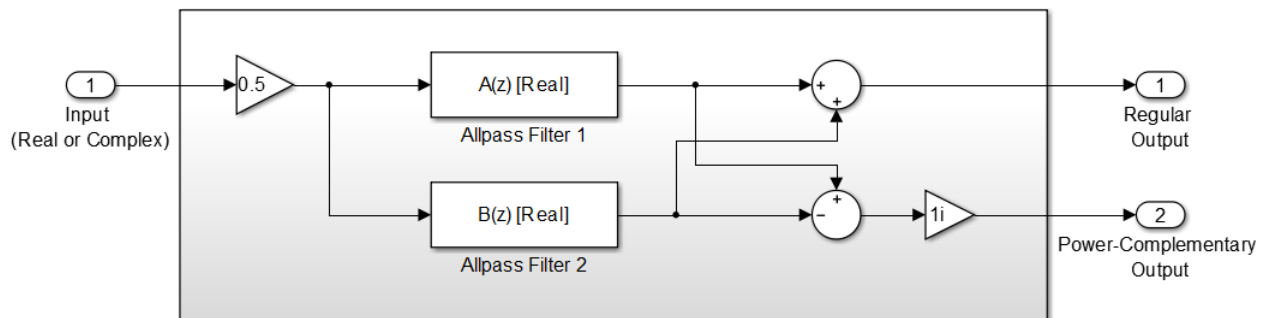

```
fvtool(caf, 'SubbandView', 'all', 'Fs', Fs);
```

Algorithms

The following three figures summarize the main structures supported by `dsp.CoupledAllpassFilter`.

- Minimum Multiplier and WDF

- Lattice

- Lattice with Complex Conjugate Coefficients

Estimate cross-spectral density

Description

The `dsp.CrossSpectrumEstimator` System object computes the cross-spectrum density of a signal, using the Welch's averaged periodogram method.

To implement the cross-spectrum estimation object:

- 1 Create the `dsp.CrossSpectrumEstimator` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

Creation

Syntax

```
cse = dsp.CrossSpectrumEstimator  
cse = dsp.CrossSpectrumEstimator(Name, Value)
```

Description

`cse = dsp.CrossSpectrumEstimator` returns a System object, `cse`, that computes the cross-power spectrum of real or complex signals using the periodogram method and Welch's averaged, modified periodogram method.

`cse = dsp.CrossSpectrumEstimator(Name, Value)` returns a `dsp.CrossSpectrumEstimator` System object, `cse`, with each specified property name set to the specified value. Unspecified properties have default values.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see [System Design in MATLAB Using System Objects](#).

FFTLengthSource — Source of FFT length value

'Auto' (default) | 'Property'

Specify the source of the FFT length value as either 'Auto' or 'Property'. If you set this property to 'Auto', the cross-spectrum estimator sets the FFT length to the input frame size. If you set this property to 'Property', then specify the number of FFT points using the FFTLength property.

FFTLength — FFT Length

128 (default) | positive integer

Specify the length of the FFT that the cross-spectrum estimator uses to compute cross-spectral estimates as a positive, integer scalar.

Dependencies

This property applies when you set the FFTLengthSource property to 'Property'.

Data Types: double

Window — Window function

'Hann' (default) | 'Rectangular' | 'Chebyshev' | 'Flat Top' | 'Hamming' | 'Kaiser'

Specify a window function for the cross-spectrum estimator as one of 'Rectangular', 'Chebyshev', 'Flat Top', 'Hamming', 'Hann', or 'Kaiser'.

SidelobeAttenuation — Side lobe attenuation of window

60 (default) | positive scalar

Specify the side lobe attenuation of the window as a real, positive scalar, in decibels (dB).

Dependencies

This property applies when you set the Window property to 'Chebyshev' or 'Kaiser'.

Data Types: double

FrequencyRange — Frequency range of the cross-spectrum estimate

'Twosided' (default) | 'onesided' | 'centered'

Specify the frequency range of the cross-spectrum estimator as one of 'twosided', 'onesided', or 'centered'.

If you set the FrequencyRange to 'onesided', the cross-spectrum estimator computes the one-sided spectrum of real input signals, x and y . If the FFT length, N_{FFT} , is even, the length of the cross-spectral estimate is $N_{FFT}/2+1$ and is computed over the interval $[0, \text{SampleRate}/2]$. If N_{FFT} is odd, the length of the cross-spectrum estimate is equal to $(N_{FFT}+1)/2$, and the interval is $[0, \text{SampleRate}/2]$.

If you set the FrequencyRange to 'twosided', the cross-spectrum estimator computes the two-sided spectrum of complex or real input signals, x and y . The length of the cross-spectrum estimate is equal to N_{FFT} . This value is computed over $[0, \text{SampleRate}]$.

If you set the FrequencyRange to 'centered', the cross-spectrum estimator computes the centered two-sided spectrum of complex or real input signals, x and y . The length of the cross-spectrum estimate is equal to N_{FFT} , and the estimate is computed between $[-\text{SampleRate}/2, \text{SampleRate}/2]$ and $(-\text{SampleRate}/2, \text{SampleRate}/2)$ for even and odd lengths, respectively.

AveragingMethod — Averaging method

'Running' (default) | 'Exponential'

Specify the averaging method as 'Running' or 'Exponential'. In the running averaging method, the object computes an equally weighted average of a specified number of spectrum estimates defined by the `SpectralAverages` property. In the exponential method, the object computes the average over samples weighted by an exponentially decaying forgetting factor.

SpectralAverages — Number of spectral averages

8 (default) | positive integer

Specify the number of spectral averages as a positive, integer scalar. The object computes the current cross-spectral estimate by averaging the last N estimates. N is the number of spectral averages defined in the `SpectralAverages` property.

Dependencies

This property applies when you set `AveragingMethod` to 'Running'.

Data Types: double

ForgettingFactor — Forgetting factor

0.9 (default) | scalar in the range (0,1]

Specify the exponential weighting forgetting factor as a scalar value greater than zero and smaller than or equal to one.

Tunable: Yes

Dependencies

This property applies when you set `AveragingMethod` to 'Exponential'.

Data Types: single | double

SampleRate — Sample rate of input

1 (default) | positive scalar

Specify the sample rate of the input, in hertz, as a finite numeric scalar. The sample rate is the rate at which the signal is sampled in time.

Data Types: single | double

Usage**Syntax**

`pxy = cse(x,y)`

Description

`pxy = cse(x,y)` computes the cross power spectrum density, `pxy`, of the input signals, `x` and `y`.

Input Arguments**x — First data input**

vector | matrix

First data input, specified as a vector or a matrix. The inputs, `x` and `y` must have the same size and data type.

Data Types: `single` | `double`

y — Second data input

vector | matrix

Second data input, specified as a vector or a matrix. The inputs, `x` and `y` must have the same size and data type.

Data Types: `single` | `double`

Output Arguments

pxy — Cross-power spectrum density output

vector | matrix

Cross-power spectrum density output, returned as a vector or a matrix. The output has the same size and data type as the input signals.

Data Types: `single` | `double`

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Specific to dsp.CrossSpectrumEstimator

`getFrequencyVector` Vector of frequencies at which estimation is done

`getRBW` Resolution bandwidth of spectrum

Common to All System Objects

`step` Run System object algorithm

`release` Release resources and allow changes to System object property values and input characteristics

`reset` Reset internal states of System object

Examples

Compute Cross-Power Spectrum of Two Noisy Sine Waves

Note: If you are using R2016a or an earlier release, replace each call to the object with the equivalent `step` syntax. For example, `obj(x)` becomes `step(obj,x)`.

Generate two sine waves.

```
sin1 = dsp.SineWave('Frequency',200, 'SampleRate', 1000);
sin1.SamplesPerFrame = 1000;
sin2 = dsp.SineWave('Frequency',100, 'SampleRate', 1000);
sin2.SamplesPerFrame = 1000;
```

Use the `dsp.CrossSpectrumEstimator` System object™ to compute the cross-spectrum of the signals. Also, use the `dsp.ArrayPlot` object to display the spectra.

```

cse = dsp.CrossSpectrumEstimator('SampleRate', sin1.SampleRate,...
    'FrequencyRange','centered');
aplot = dsp.ArrayPlot('PlotType','Line','XOffset',-500,'YLimits',...
    [-150 -60],'YLabel','Power Spectrum Density (Watts/Hz)',...
    'XLabel','Frequency (Hz)',...
    'Title','Cross Power Spectrum of Two Signals');

```

Add random noise to the sine waves. Stream in the data, and plot the cross-power spectrum of the two signals.

```

for ii = 1:10
x = sin1() + 0.05*randn(1000,1);
y = sin2() + 0.05*randn(1000,1);
Pxy = cse(x, y);
aplot(20*log10(abs(Pxy)));
end

```

Algorithms

Welch's Method of Averaged Modified Periodograms

Give two signal inputs, x and y :

- 1 Multiply the inputs by the window and scale the result by the window power.
- 2 Compute FFT of the signals, X and Y , and multiply X with $\text{conj}(Y)$ using $Z = X.\text{*conj}(Y)$.

- 3 Compute the current cross power spectrum estimate by taking the moving average of the last N number of Z 's and scaling the answer by the sample rate. For details on the moving average methods, see "Averaging Method" on page 4-1321.

For further information on the algorithms, refer to the "Algorithms" on page 2-1245 section in Spectrum Analyzer.

dsp.Crosscorrelator

Package: dsp

(To be removed) Cross-correlation of two inputs

Note `dsp.Crosscorrelator` will be removed in a future release. Use `xcorr` instead. For more information, see “Compatibility Considerations”.

Description

The `dsp.Crosscorrelator` System object computes the cross-correlation of two N -D input arrays along the first dimension. The computation can be done in the time domain or frequency domain. You can specify the domain through the “Method” on page 4-0 property. In the time domain, the object convolves the first input signal, u , with the time-reversed complex conjugate of the second input signal, v . To compute the cross-correlation in the frequency domain, the object:

- 1 Takes the Fourier transform of both input signals, resulting in U and V .
- 2 Multiplies U and V^* , where $*$ denotes the complex conjugate.
- 3 Computes the inverse Fourier transform of the product.

If you set `Method` to 'Fastest', the object chooses the domain that minimizes the number of computations. For information on these computation methods, see “Algorithms” on page 4-366.

To obtain the cross-correlation for two discrete-time deterministic inputs:

- 1 Create the `dsp.Crosscorrelator` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see What Are System Objects?

Creation

Syntax

```
xcorr = dsp.Crosscorrelator
xcorr = dsp.Crosscorrelator(Name, Value)
```

Description

`xcorr = dsp.Crosscorrelator` returns a cross-correlator object, `xcorr`, that computes the cross-correlation of two inputs in the time domain or frequency domain.

`xcorr = dsp.Crosscorrelator(Name, Value)` returns a cross-correlator object with each specified property set to the specified value. Enclose each property name in single quotes.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see *System Design in MATLAB Using System Objects*.

Method — Domain for computing correlations

'Time Domain' (default) | 'Frequency Domain' | 'Fastest'

Domain in which the System object computes the correlation, specified as one of the following:

- 'Time Domain' -- Computes the cross-correlation in the time domain, which minimizes the memory usage.
- 'Frequency Domain' -- Computes the cross-correlation in the frequency domain. For more information, see “Algorithms” on page 4-366.
- 'Fastest' -- Computes the cross-correlation in the domain that minimizes the number of computations.

To cross-correlate fixed-point signals, set this property to 'Time Domain'.

Fixed-Point Properties

Note Fixed-point signals are supported for the time domain only. To use these properties, set `Method` to 'Time Domain'.

FullPrecisionOverride — Full-precision override for fixed-point arithmetic

true (default) | false

Flag to use full-precision rules for fixed-point arithmetic, specified as one of the following:

- `true` -- The object computes all internal arithmetic and output data types using the full-precision rules. These rules provide the most accurate fixed-point numerics. In this mode, other fixed-point properties do not apply. No quantization occurs within the object. Bits are added, as needed, to ensure that no roundoff or overflow occurs.
- `false` -- Fixed-point data types are controlled through individual fixed-point property settings.

For more information, see “Full Precision for Fixed-Point System Objects” and “Set System Object Fixed-Point Properties”.

RoundingMethod — Rounding method for fixed-point operations

'Floor' (default) | 'Ceiling' | 'Convergent' | 'Nearest' | 'Round' | 'Simplest' | 'Zero'

Rounding method for fixed-point operations. For more details, see rounding mode.

Dependencies

This property is not visible and has no effect on the numerical results when the following conditions are met:

- FullPrecisionOverride set to true.
- FullPrecisionOverride set to false, OutputDataType set to 'Same as accumulator', ProductDataType set to 'Full precision', and AccumulatorDataType set to 'Full precision'

Under these conditions, the object operates in full precision mode.

In addition, if Method is set to either 'Frequency Domain' or 'Fastest', the RoundingMethod property does not apply.

OverflowAction — Overflow action for fixed-point operations

'Wrap' (default) | 'Saturate'

Overflow action for fixed-point operations, specified as one of the following:

- 'Wrap' -- The object wraps the result of its fixed-point operations.
- 'Saturate' -- The object saturates the result of its fixed-point operations.

For more details on overflow actions, see overflow mode for fixed-point operations.

Dependencies

This property is not visible and has no effect on the numerical results when the following conditions are met:

- FullPrecisionOverride set to true.
- FullPrecisionOverride set to false, OutputDataType set to 'Same as accumulator', ProductDataType set to 'Full precision', and AccumulatorDataType set to 'Full precision'

Under these conditions, the object operates in full precision mode.

In addition, if Method is set to either 'Frequency Domain' or 'Fastest', the OverflowAction property does not apply.

ProductDataType — Data type of product output

'Full precision' (default) | 'Custom' | 'Same as first input'

Data type of the product output in this object, specified as one of the following:

- 'Full precision' -- The product output data type has full precision.
- 'Same as first input' -- The object specifies the product output data type to be the same as that of the first input data type.
- 'Custom' -- The product output data type is specified as a custom numeric type through the "CustomProductDataType" on page 4-0 property.

For more information on the product output data type, see "Multiplication Data Types" and the "Fixed Point" on page 4-368 section.

Dependencies

This property applies when you set FullPrecisionOverride to false.

CustomProductDataType — Word and fraction lengths of product data type

numericType([],32,30) (default)

Word and fraction lengths of the product data type, specified as an autosigned numeric type with a word length of 32 and a fraction length of 30.

Dependencies

This property applies only when you set `FullPrecisionOverride` to `false` and “`ProductDataType`” on page 4-0 to `'Custom'`.

AccumulatorDataType — Data type of accumulation operation

`'Full precision' (default) | 'Same as first input' | 'Same as product' | 'Custom'`

Data type of an accumulation operation in this object, specified as one of the following:

- `'Full precision'` -- The accumulation operation has full precision.
- `'Same as product'` -- The object specifies the accumulator data type to be the same as that of the product output data type.
- `'Same as first input'` -- The object specifies the accumulator data type to be the same as that of the first input data type.
- `'Custom'` -- The accumulator data type is specified as a custom numeric type through the “`CustomAccumulatorDataType`” on page 4-0 property.

For more information on the accumulator data type this object uses, see the “Fixed Point” on page 4-368 section.

Dependencies

This property applies when you set `FullPrecisionOverride` to `false`.

CustomAccumulatorDataType — Word and fraction lengths of accumulator data type

`numericType([],32,30) (default)`

Word and fraction lengths of the accumulator data type, specified as an autosigned numeric type with a word length of 32 and a fraction length of 30.

Dependencies

This property applies only when you set `FullPrecisionOverride` to `false` and “`AccumulatorDataType`” on page 4-0 to `'Custom'`.

OutputDataType — Data type of object output

`'Same as accumulator' (default) | 'Same as first input' | 'Same as product' | 'Custom'`

Data type of the object output, specified as one of the following:

- `'Same as accumulator'` -- The output data type is the same as that of the accumulator output data type.
- `'Same as first input'` -- The output data type is the same as that of the first input data type.
- `'Same as product'` -- The output data type is the same as that of the product output data type.
- `'Custom'` -- The output data type is specified as a custom numeric type through the “`CustomOutputDataType`” on page 4-0 property.

For more information on the output data type this object uses, see the “Fixed Point” on page 4-368 section.

Dependencies

This property applies when you set `FullPrecisionOverride` to `false`.

CustomOutputDataType — Word and fraction lengths of output data type

`numericType([],16,15)` (default)

Word and fraction lengths of the output data type, specified as an autosigned numeric type with a word length of 16 and a fraction length of 15.

Dependencies

This property applies only when you set `FullPrecisionOverride` to `false` and “`OutputDataType`” on page 4-0 to 'Custom'.

Usage**Syntax**

```
y = xcorr(u,v)
```

Description

`y = xcorr(u,v)` computes the cross-correlation of the two input signals, `u` and `v`.

Input Arguments**u — First data input signal**

vector | matrix | *N*-D array

First data input signal, specified as a vector, matrix, or an *N*-D array. The object accepts real-valued or complex-valued multichannel and multidimensional inputs. The input can be a fixed-point signal when you set the `Method` property to 'Time Domain'. When one or both of the input signals are complex, the output signal is also complex. Both data inputs must have the same data type.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fi`

v — Second data input signal

scalar | column vector | matrix

Second data input signal, specified as a vector, matrix, or an *N*-D array. The object accepts real-valued or complex-valued multichannel and multidimensional inputs. The input can be a fixed-point signal when you set the `Method` property to 'Time Domain'. When one or both of the input signals are complex, the output signal is also complex. Both data inputs must have the same data type.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fi`

Output Arguments**y — Cross-correlated output**

vector | matrix | *N*-D array

Cross-correlated output of the two input signals.

When the inputs are N -D arrays, the object outputs an N -D array. All the dimensions of the output array, except for the first dimension, match the input array. For example:

- When the inputs u and v have dimensions M_u -by- N -by- P and M_v -by- N -by- P , respectively, the object outputs an $(M_u + M_v - 1)$ -by- N -by- P array.
- When the inputs u and v have the dimensions M_u -by- N and M_v -by- N , the object outputs an $(M_u + M_v - 1)$ -by- N matrix.

If one input is a column vector and the other input is an N -D array, the object computes the cross-correlation of the vector with each column in the N -D array. For example:

- When the input u is an M_u -by-1 column vector and v is an M_v -by- N matrix, the object outputs an $(M_u + M_v - 1)$ -by- N matrix.
- Similarly, when u and v are column vectors with lengths M_u and M_v , respectively, the object performs the vector cross-correlation.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fi`

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Common to All System Objects

<code>step</code>	Run System object algorithm
<code>release</code>	Release resources and allow changes to System object property values and input characteristics
<code>reset</code>	Reset internal states of System object

Examples

Cross-Correlation of Input Noise and Delayed Version

Note If you are using R2016a or an earlier release, replace each call to the object with the equivalent `step` syntax. For example, `obj(x)` becomes `step(obj,x)`.

Compute the cross-correlation of a noisy input signal with its delayed version. The peak of the correlation output occurs at the lag, which corresponds to the delay between the signals.

Use `randn` to create the white Gaussian noisy input, `x`. Create a delayed version of this input, `x1`, using the `dsp.Delay` object.

```
S = rng('default');
x = randn(100,1);
delay = dsp.Delay(10);
x1 = delay(x);
```

Compute the cross-correlation between the two inputs. Plot the correlation output with respect to the lag between the inputs.

```
xcorr = dsp.Crosscorrelator;
y = xcorr(x1,x);
lags = 0:99;
stem(lags,y(100:end),'markerfacecolor',[0 0 1])
axis([0 99 -125 125])
xlabel('Lags')
title('Cross-Correlation of Input Noise and Delayed Version')
```

The correlation sequence peaks when the lag is 10, indicating that the correct delay between the two signals is 10 samples.

More About

Cross-Correlation

Cross-correlation is the measure of similarity of two discrete-time sequences as a function of the lag of one relative to the other.

For two length- N deterministic inputs or realizations of jointly wide-sense stationary (WSS) random processes, x and y , the cross-correlation is computed using the following relationship:

$$r_{xy}(h) = \begin{cases} \sum_{n=0}^{N-h-1} x(n+h)y^*(n) & 0 \leq h \leq N-1 \\ r_{yx}^*(h) & -(N-1) \leq h \leq 0 \end{cases}$$

where h is the lag and $*$ denotes the complex conjugate. If the inputs are realizations of jointly WSS stationary random processes, $r_{xy}(h)$ is an unnormalized estimate of the theoretical cross-correlation:

$$\rho_{xy}(h) = E\{x(n+h)y^*(n)\}$$

where $E\{ \}$ is the expectation operator.

Algorithms

Time-Domain Computation

When you set the computation domain to time, the algorithm computes the cross-correlation of two signals in the time domain. The input signals can be fixed-point signals in this domain.

Correlate Two 2-D Arrays

When the inputs are two 2-D arrays, the j th column of the output, y_{uv} , has these elements:

$$y_{uv}(i, j) = \sum_{k=0}^{\max(M_u, M_v) - 1} u_{k, j}^* v_{(k+i), j} \quad 0 \leq i < M_v$$

$$y_{uv}(i, j) = y_{vu}^*(-i, j) \quad -M_u < i < 0$$

where:

- * denotes the complex conjugate.
- u is an M_u -by- N input matrix.
- v is an M_v -by- N input matrix.
- $y_{u,v}$ is an $(M_u + M_v - 1)$ -by- N matrix.

Inputs u and v are zero when indexed outside their valid ranges.

Correlate a Column Vector with a 2-D Array

When one input is a column vector and the other input is a 2-D array, the algorithm independently cross-correlates the input vector with each column of the 2-D array. The j th column of the output, $y_{u,v}$, has these elements:

$$y_{uv}(i, j) = \sum_{k=0}^{\max(M_u, M_v) - 1} u_k^* v_{(k+i), j} \quad 0 \leq i < M_v$$

$$y_{uv}(i, j) = y_{vu}^*(-i, j) \quad -M_u < i < 0$$

where:

- * denotes the complex conjugate.
- u is an M_u -by-1 column vector.
- v is an M_v -by- N matrix.
- y_{uv} is an $(M_u + M_v - 1)$ -by- N matrix.

Inputs u and v are zero when indexed outside their valid ranges.

Correlate Two Column Vectors

When the inputs are two column vectors, the j th column of the output, y_{uv} , has these elements:

$$y_{uv}(i) = \sum_{k=0}^{\max(M_u, M_v) - 1} u_k^* v_{(k+i)} \quad 0 \leq i < M_v$$

$$y_{uv}(i) = y_{vu}^*(-i) \quad -M_u < i < 0$$

where:

- * denotes the complex conjugate.
- u is an M_u -by-1 column vector.
- v is an M_v -by-1 column vector.
- y_{uv} is an $(M_u + M_v - 1)$ -by-1 column vector.

Inputs u and v are zero when indexed outside their valid ranges.

Frequency-Domain Computation

When you set the computation domain to frequency, the algorithm computes the cross-correlation in the frequency domain.

To compute the cross-correlation, the algorithm:

- 1 Takes the Fourier transform of both input signals, U and V .
- 2 Multiplies U and V^* , where $*$ denotes the complex conjugate.
- 3 Computes the inverse Fourier transform of the product.

In this domain, depending on the input length, the algorithm can require fewer computations.

Compatibility Considerations

dsp.Crosscorrelator System object will be removed

Warns starting in R2021b

`dsp.Crosscorrelator` System object will be removed in a future release. Use the `xcorr` function instead.

Update Code

This table shows how the System object is typically used and explains how to update existing code to use the `xcorr` function.

Discouraged Usage	Recommended Replacement
<pre>xcObj = dsp.Crosscorrelator; t = 0:0.001:1; x1 = sin(2*pi*2*t) + 0.05*sin(2*pi*50*t); x2 = sin(2*pi*2*t); % computes cross-correlation of x1 and x2 y = xcObj(x1',x2'); figure; plot(t,x1,'b',t,x2,'g'); legend('Input signal 1', 'Input signal 2') figure; plot(y); title('Correlated output')</pre> <p>If you are using a release prior to R2016b, replace <code>xcObj(x)</code> with <code>step(xcObj,x)</code>.</p>	<pre>[yfn,lags] = xcorr(x1',x2'); figure; plot(yfn)</pre> <p>Plot with respect to the lags.</p> <pre>figure; plot(lags,yfn)</pre>

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

See “System Objects in MATLAB Code Generation” (MATLAB Coder).

Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

The diagram shows the data types the `dsp.Crosscorrelator` object uses for fixed-point signals (time domain only).

You can set the product output, accumulator, and output data types using the corresponding fixed-point properties of the object.

When the input is real, the output of the multiplier is in the product output data type. When the input is complex, the output of the multiplier is in the accumulator data type. For details on the complex multiplication performed, see "Multiplication Data Types".

Note When one or both of the inputs are signed fixed-point signals, all internal object data types are signed fixed point. The internal object data types are unsigned fixed point only when both inputs are unsigned fixed-point signals.

dsp.CumulativeProduct

Package: dsp

(To be removed) Cumulative product of channel, column, or row elements

Note `dsp.CumulativeProduct` will be removed in a future release. Use the `cumprod` function instead. For more information, see “Compatibility Considerations”.

Description

The `dsp.CumulativeProduct` System object computes the cumulative product of channel, column, or row elements.

To compute the cumulative product of channel, column, or row elements:

- 1 Create the `dsp.CumulativeProduct` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

Creation

Syntax

```
cprod = dsp.CumulativeProduct  
cprod = dsp.CumulativeProduct(Name,Value)
```

Description

`cprod = dsp.CumulativeProduct` returns a cumulative product object, `cprod`, that computes the cumulative product of input matrix or input vector elements along the default dimension.

`cprod = dsp.CumulativeProduct(Name,Value)` returns a cumulative product object with each specified property set to the specified value.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see [System Design in MATLAB Using System Objects](#).

Dimension — Computation dimension for cumulative product

Channels (running product) (default) | Rows | Columns

Specify the computation dimension as `Channels (running product)`, `Rows`, or `Columns`.

ResetInputPort — Enable resetting cumulative product through input port

`false` (default) | `true`

Set this property to `true` to enable resetting the cumulative product. When you set this property to `true`, specify a reset signal to the object algorithm to reset the cumulative product.

Dependencies

You can access this property when the “Dimension” on page 4-0 property is set to `Channels (running product)`.

ResetCondition — Reset condition for cumulative product

`Rising edge` (default) | `Falling edge` | `Either edge` | `Non-zero`

Specify the event on the reset input port that causes resetting the cumulative product to `Rising edge`, `Falling edge`, `Either edge`, or `Non-zero`.

Dependencies

This property applies when you set the “ResetInputPort” on page 4-0 property to `true` and the “Dimension” on page 4-0 property to `Channels (running product)`.

Fixed-Point Properties

RoundingMethod — Rounding method for fixed-point operations

`Floor` (default) | `Ceiling` | `Convergent` | `Nearest` | `Round` | `Simplest` | `Zero`

Specify the rounding method as one of `Ceiling`, `Convergent`, `Floor`, `Nearest`, `Round`, `Simplest`, or `Zero`.

OverflowAction — Overflow action for fixed-point operations

`Wrap` (default) | `Saturate`

Specify the overflow action as one of `Wrap` or `Saturate`.

IntermediateProductDataType — Intermediate product word and fraction lengths

`Same as input` (default) | `Custom`

Specify the intermediate product fixed-point data type as `Same as input` or `Custom`.

CustomIntermediateProductDataType — Intermediate product word and fraction lengths

`numerictype([], 16, 15)` (default) | `numerictype`

Specify the intermediate product fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`.

Dependencies

This property applies when you set the `IntermediateProductDataType` property to `Custom`.

ProductDataType — Product output word and fraction lengths

`Same as input` (default) | `Custom`

Specify the product output fixed-point data type as one of | `Same as input` | `Custom` |.

CustomProductDataType — Custom product output word and fraction lengths`numericity([], 32, 30) (default) | numericity`

Specify the product output fixed-point type as a scaled `numericity` object with a `Signedness` of `Auto`.

Dependencies

This property applies when you set the `ProductDataType` property to `Custom`.

AccumulatorDataType — Accumulator word and fraction lengths`Same as input (default) | Same as product output | Custom`

Specify the accumulator fixed-point data type as `Same as product output`, `Same as input`, or `Custom`.

CustomAccumulatorDataType — Custom accumulator word and fraction lengths`numericity([], 32, 30) (default) | numericity`

Specify the accumulator fixed-point type as a scaled `numericity` object with a `Signedness` of `Auto`.

Dependencies

This property applies when you set the `AccumulatorDataType` property to `Custom`.

OutputDataType — Output word and fraction lengths`Same as input (default) | Same as product output | Custom`

Specify the output fixed-point data type as one of `| Same as product output | Same as input | Custom |`.

CustomOutputDataType — Custom output word and fraction lengths`numericity([], 16, 15) (default) | numericity`

Specify the output fixed-point type as a scaled `numericity` object with a `Signedness` of `Auto`.

Dependencies

This property applies when you set the “`OutputDataType`” on page 4-0 property to `Custom`.

Usage**Syntax**

```
y = cprod(x)
y = cprod(x,r)
```

Description

`y = cprod(x)` computes the cumulative product along the specified dimension for the input `x`.

`y = cprod(x,r)` resets the cumulative product object's state based on the `ResetCondition` property value and the value of the reset signal, `r`, when the `ResetInputPort` property is `true`.

Input Arguments

x — Data input

vector | matrix

Data input, specified as a vector or a matrix.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fi`

r — Reset signal

scalar

Reset signal used to reset the running cumulative product, specified as a scalar. The object resets the running cumulative product if the reset signal satisfies the `ResetCondition`.

Dependencies

This input is applicable only when `Dimension` is set to `'Channels (running product)'` and `ResetInputPort` is set to `true`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `logical` | `fi`

Output Arguments

y — Cumulative product

vector | matrix

Cumulative product of the input signal, returned as a vector or a matrix.

The size, data type, and complexity characteristics of the output signal match that of the input signal.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fi`

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Common to All System Objects

<code>step</code>	Run System object algorithm
<code>release</code>	Release resources and allow changes to System object property values and input characteristics
<code>reset</code>	Reset internal states of System object

Examples

Cumulative Product of Matrix

Note If you are using R2016a or an earlier release, replace each call to the object with the equivalent step syntax. For example, `obj(x)` becomes `step(obj,x)`.

Use the `dsp.CumulativeProduct` object to compute the cumulative product of a matrix.

```
cprod = dsp.CumulativeProduct;  
x = magic(2)
```

$x = 2 \times 2$

```
 1  3  
 4  2
```

```
y = cprod(x)
```

$y = 2 \times 2$

```
 1  3  
 4  6
```

The cumulative product is computed column-wise along each channel.

Algorithms

This object implements the algorithm, inputs, and outputs described on the Cumulative Product block reference page. The object properties correspond to the block parameters, except the **Reset port** block parameter corresponds to both the `ResetCondition` and `ResetInputPort` object properties.

Compatibility Considerations

dsp.CumulativeProduct System object will be removed

Warns starting in R2021b

`dsp.CumulativeProduct` System object will be removed in a future release. Use the `cumprod` function instead.

Update Code

This table shows how the System object is typically used and explains how to update existing code to use the `cumprod` function.

Discouraged Usage	Recommended Replacement

Introduced in R2012a

dsp.CumulativeSum

Package: dsp

(To be removed) Cumulative sum of channel, column, or row elements

Note dsp.CumulativeSum will be removed in a future release. Use the cumsum function instead. For more information, see “Compatibility Considerations”.

Description

The dsp.CumulativeSum System object computes the cumulative sum of channel, column, or row elements.

To compute the cumulative sum of channel, column, or row elements:

- 1 Create the dsp.CumulativeSum object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see What Are System Objects?

Creation

Syntax

```
csum = dsp.CumulativeSum
csum = dsp.CumulativeSum(Name,Value)
```

Description

csum = dsp.CumulativeSum returns a cumulative sum System object, csum, which computes the running cumulative sum for each channel in the input.

csum = dsp.CumulativeSum(Name,Value) returns a cumulative sum object, csum, with each specified property set to the specified value. Enclose each property name in single quotes. Unspecified properties have default values.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the release function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects.

Dimension — Computation dimension for cumulative sum

Channels (running sum) (default) | Rows | Columns

Specify the computation dimension as `Channels` (running sum), `Rows`, or `Columns`.

ResetInputPort — Enable resetting cumulative sum through input port

`false` (default) | `true`

Set this property to `true` to enable resetting the cumulative sum. When you set this property to `true`, you also specify a reset input to the object algorithm to reset the cumulative sum.

ResetCondition — Reset condition for cumulative sum

`Rising edge` (default) | `Falling edge` | `Either edge` | `Non-zero`

Specify the event on the reset input port that resets the cumulative sum as `Rising edge`, `Falling edge`, `Either edge`, or `Non-zero`.

Dependencies

This property applies when you set the “ResetInputPort” on page 4-0 property to `true`.

Fixed-Point Properties**RoundingMethod — Rounding method for fixed-point operations**

`Floor` (default) | `Ceiling` | `Convergent` | `Nearest` | `Round` | `Simplest` | `Zero`

Specify the rounding method as one of `Ceiling`, `Convergent`, `Floor`, `Nearest`, `Round`, `Simplest`, or `Zero`.

OverflowAction — Overflow action for fixed-point operations

`Wrap` (default) | `Saturate`

Specify the overflow action as one of `Wrap` or `Saturate`.

AccumulatorDataType — Accumulator word and fraction lengths

`Same as input` (default) | `Custom`

Specify the accumulator fixed-point data type as `Same as input` or `Custom`.

CustomAccumulatorDataType — Custom accumulator word and fraction lengths

`numerictype([], 32, 30)` (default) | `numerictype`

Specify the accumulator fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`.

Dependencies

This property applies when you set the `AccumulatorDataType` property to `Custom`.

OutputDataType — Output word and fraction lengths

`Same as accumulator` (default) | `Same as input` | `Custom`

Specify the output fixed-point data type as `Same as accumulator`, `Same as input`, or `Custom`.

CustomOutputDataType — Custom output word and fraction lengths

`numerictype([], 16, 15)` (default) | `numerictype`

Specify the output fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`.

Dependencies

This property applies when you set the “OutputDataType” on page 4-0 property to Custom.

Usage**Syntax**

```
y = csum(x)
y = csum(x, r)
```

Description

$y = \text{csum}(x)$ computes the cumulative sum along the specified dimension for the input x .

$y = \text{csum}(x, r)$ resets the System object state based on the ResetCondition property value and the value of the reset signal, r . You can only reset the state if the ResetInputPort property is true.

Input Arguments**x — Data input**

vector | matrix

Data input, specified as a vector or a matrix.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fi

r — Reset signal

scalar

Reset signal used to reset the running cumulative sum, specified as a scalar. The object resets the running cumulative sum if the reset signal satisfies the ResetCondition.

Dependencies

This input is applicable only when Dimension is set to 'Channels (running sum)' and ResetInputPort is set to true.

Data Types: single | double | int8 | int16 | int32 | uint8 | uint16 | uint32 | logical | fi

Output Arguments**y — Cumulative sum**

vector | matrix

Cumulative sum of the input signal, returned as a vector or a matrix.

The size, data type, and complexity characteristics of the output signal match that of the input signal.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fi

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Common to All System Objects

<code>step</code>	Run System object algorithm
<code>release</code>	Release resources and allow changes to System object property values and input characteristics
<code>reset</code>	Reset internal states of System object

Examples

Cumulative Sum of Matrix

Note If you are using R2016a or an earlier release, replace each call to the object with the equivalent step syntax. For example, `obj(x)` becomes `step(obj,x)`.

Use the `dsp.CumulativeSum` object to compute the cumulative sum of a matrix.

```
csum = dsp.CumulativeSum;  
x = magic(2)
```

```
x = 2×2
```

```
    1    3  
    4    2
```

```
y = csum(x)
```

```
y = 2×2
```

```
    1    3  
    5    5
```

The cumulative sum is computed column-wise along each channel.

Algorithms

This object implements the algorithm, inputs, and outputs described on the Cumulative Sum block reference page. The object properties correspond to the block properties, except the **Reset port** block parameter corresponds to both the `ResetCondition` and the `ResetInputPort` object properties.

Compatibility Considerations

dsp.CumulativeSum System object will be removed

Warns starting in R2021b

dsp.CumulativeSum System object will be removed in a future release. Use the cumsum function instead.

Update Code

This table shows how the System object is typically used and explains how to update existing code to use the cumsum function.

Discouraged Usage	Recommended Replacement
<p>Column-wise cumulative sum</p> <p>By default, the object computes the running sum along the columns (channels) since the Dimension property of the object is set to 'Channels (running sum)'.</p> <pre>csum = dsp.CumulativeSum; x = magic(2)</pre> <p>$x = 2 \times 2$</p> <pre> 1 3 4 2</pre> <p>$y = \text{csum}(x)$</p> <p>$y = 2 \times 2$</p> <pre> 1 3 5 5</pre> <p>Row-wise cumulative sum</p> <p>To compute row-wise cumulative sum, set the Dimension property to 'Rows' and rerun the object algorithm.</p> <pre>release(csum); csum.Dimension = 'Rows'; y = csum(x)</pre> <p>$y = 2 \times 2$</p> <pre> 1 4 4 6</pre> <p>If you are using a release prior to R2016b, replace <code>csum(x)</code> with <code>step(csum,x)</code>.</p>	<p>Column-wise cumulative sum</p> <pre>y = cumsum(x,1)</pre> <p>$y = 2 \times 2$</p> <pre> 1 3 5 5</pre> <p>Row-wise cumulative sum</p> <pre>y = cumsum(x,2)</pre> <p>$y = 2 \times 2$</p> <pre> 1 4 4 6</pre>

cumsum

Introduced in R2012a

dsp.DCBlocker

Package: dsp

Block DC component (offset) from input signal

Description

The `dsp.DCBlocker` System object removes the DC offset from each channel (column) of the input signal. The operation runs over time to continually estimate and remove the DC offset.

To block the DC component of the input signal:

- 1 Create the `dsp.DCBlocker` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

Creation

Syntax

```
dcblk = dsp.DCBlocker
dcblk = dsp.DCBlocker(Name, Value)
```

Description

`dcblk = dsp.DCBlocker` creates a DC blocker System object, `dcblk`, to block the DC component from each channel (column) of the input signal.

`dcblk = dsp.DCBlocker(Name, Value)` creates a DC blocker System object, `dcblk`, with each specified property set to the specified value. Enclose each property name in single quotes.

Example: `dcblk = dsp.DCBlocker('Algorithm','FIR')`

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see [System Design in MATLAB Using System Objects](#).

Algorithm — Algorithm for estimating DC offset

'IIR' (default) | 'FIR' | 'CIC' | 'Subtract mean'

Algorithm for estimating DC offset, specified as one of the following:

- 'IIR' -- The object uses a recursive estimate based on a narrow, lowpass elliptic filter. The "Order" on page 4-0 property sets the order of the filter, and the "NormalizedBandwidth" on page 4-0 property sets its bandwidth. This algorithm typically uses less memory than the FIR algorithm and is more efficient.
- 'FIR' -- The object uses a nonrecursive, moving average estimate based on a finite number of past input samples. The "Length" on page 4-0 property sets the number of samples. The FIR filter has a linear phase response and does not cause any phase distortion to the signal. The IIR filter requires less memory and is more efficient to implement.
- 'CIC' -- The object uses a CIC decimator, with a decimation factor of 1, whose differential delay is calculated using the NormalizedBandwidth property. It uses two sections to ensure that the first sidelobe attenuation is at least 25 dB below the main lobe of the filter. This algorithm requires fixed-point inputs and can be used for HDL code generation.
- 'Subtract mean' -- The object computes the means of the columns of the input matrix, and subtracts the means from the input. This method does not retain state between inputs.

You can visualize the IIR, FIR, and CIC responses by using the `fvtool` function.

NormalizedBandwidth — Normalized bandwidth of lowpass IIR or CIC filter

0.001 (default) | real scalar greater than 0 and less than 1

Normalized bandwidth of the IIR or CIC filter, specified as a real scalar greater than 0 or less than 1. The normalized bandwidth is used to estimate the DC component of the input signal.

Dependencies

This property applies only when you set the "Algorithm" on page 4-0 property to 'IIR' or 'CIC'.

Order — Order of lowpass IIR elliptic filter

6 (default) | integer greater than 3

Order of the lowpass IIR elliptic filter that is used to estimate the DC level, specified as an integer greater than 3.

Dependencies

This property applies only when you set the "Algorithm" on page 4-0 property to 'IIR'.

Length — Number of past input samples used in FIR algorithm

50 (default) | positive integer

Number of past input samples used in the FIR algorithm to estimate the running mean, specified as a positive integer.

Dependencies

This property applies only when you set the "Algorithm" on page 4-0 property to 'FIR'.

Usage

Syntax

```
dcblkOut = dcblk(input)
```

Description

`dcblkerOut = dcblker(input)` removes the DC component from each channel (column) of the input and returns the output.

Input Arguments

input — Input signal

vector | matrix | *N*-D array

Data input to the DC blocker object, specified as a vector, matrix, or *N*-D array.

Example: `t = (0:0.001:100)'`; `x = sin(30*pi*t) + 1`;

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `fi`

Output Arguments

dcblkerOut — Signal with DC component removed

vector | matrix | *N*-D array

Signal with DC component removed, returned as a vector, matrix, or *N*-D array. The output dimensions match the input dimensions.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `fi`

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Visualization Specific to DSP System Toolbox

`fvtool` Visualize frequency response of DSP filters

Common to All System Objects

<code>step</code>	Run System object algorithm
<code>release</code>	Release resources and allow changes to System object property values and input characteristics
<code>reset</code>	Reset internal states of System object

Examples

Remove DC Component and Display Results

Note: If you are using R2016a or earlier, replace each call to the object with the equivalent `step` syntax. For example, `obj(x)` becomes `step(obj,x)`.

Remove the DC component of an input signal using the IIR, FIR, and subtract mean estimation algorithms.

Create a signal composed of a 15 Hz tone, a 25 Hz tone, and a DC offset.

```
t = (0:0.001:100)';  
x = sin(30*pi*t) + 0.33*cos(50*pi*t) + 1;
```

Create three DC blocker objects for the three estimation algorithms.

```
dc1 = dsp.DCBlocker('Algorithm','IIR','Order', 6);  
dc2 = dsp.DCBlocker('Algorithm','FIR','Length', 100);  
dc3 = dsp.DCBlocker('Algorithm','Subtract mean');
```

For each second of time, pass the input signal through the DC blockers. By implementing the DC blockers in 1-second increments, you can observe differences in the convergence times.

```
for idx = 1 : 100  
    range = (1:1000) + 1000*(idx-1);  
    y1 = dc1(x(range));           % IIR estimate  
    y2 = dc2(x(range));           % FIR estimate  
    y3 = dc3(x(range));           % Subtract mean  
end
```

Plot the input and output data for the three DC blockers for the first second of time, and show the mean value for each signal. The mean values for the three algorithm types show that the FIR and Subtract mean algorithms converge more quickly.

```
plot(t(1:1000),x(1:1000), ...  
     t(1:1000),y1, ...  
     t(1:1000),y2, ...  
     t(1:1000),y3);  
xlabel('Time (sec)')  
ylabel('Amplitude')  
legend(sprintf('Input DC:%.3f',mean(x)), ...  
        sprintf('IIR DC:%.3f',mean(y1)), ...  
        sprintf('FIR DC:%.3f',mean(y2)), ...  
        sprintf('Subtract mean DC:%.3f',mean(y3)));
```

Frequency Response Before and After DC Blocker

Note: If you are using R2016a or earlier, replace each call to the object with the equivalent step syntax. For example, `obj(x)` becomes `step(obj,x)`.

Compare the spectrum of an input signal with a DC offset to the spectrum of the same signal after applying a DC blocker. Enable the DC blocker to use the FIR estimation algorithm.

Create an input signal composed of three tones and that has a DC offset of 1. Set the sampling frequency to 1 kHz and set the signal duration to 100 seconds.

```
fs = 1000;
t = (0:1/fs:100)';
x = sin(30*pi*t) + 0.67*sin(40*pi*t) + 0.33*sin(50*pi*t) + 1;
```

Create a DC blocker object that uses the FIR algorithm to estimate the DC offset.

```
dcblker = dsp.DCBlocker('Algorithm','FIR','Length',100);
```

Create a spectrum analyzer with power units set to dBW and a frequency range of `[-30 30]` to display the frequency response of the input signal. Using the `clone` function, create a second spectrum analyzer to display the response of the output. Then, use the `Title` property of the spectrum analyzers to label them.

```
hsa = dsp.SpectrumAnalyzer('SampleRate',fs, ...
    'PowerUnits','dBW','FrequencySpan','Start and stop frequencies',...
    'StartFrequency',-30,'StopFrequency',30,'YLimits',[-200 20],...
    'Title','Signal Spectrum');
```

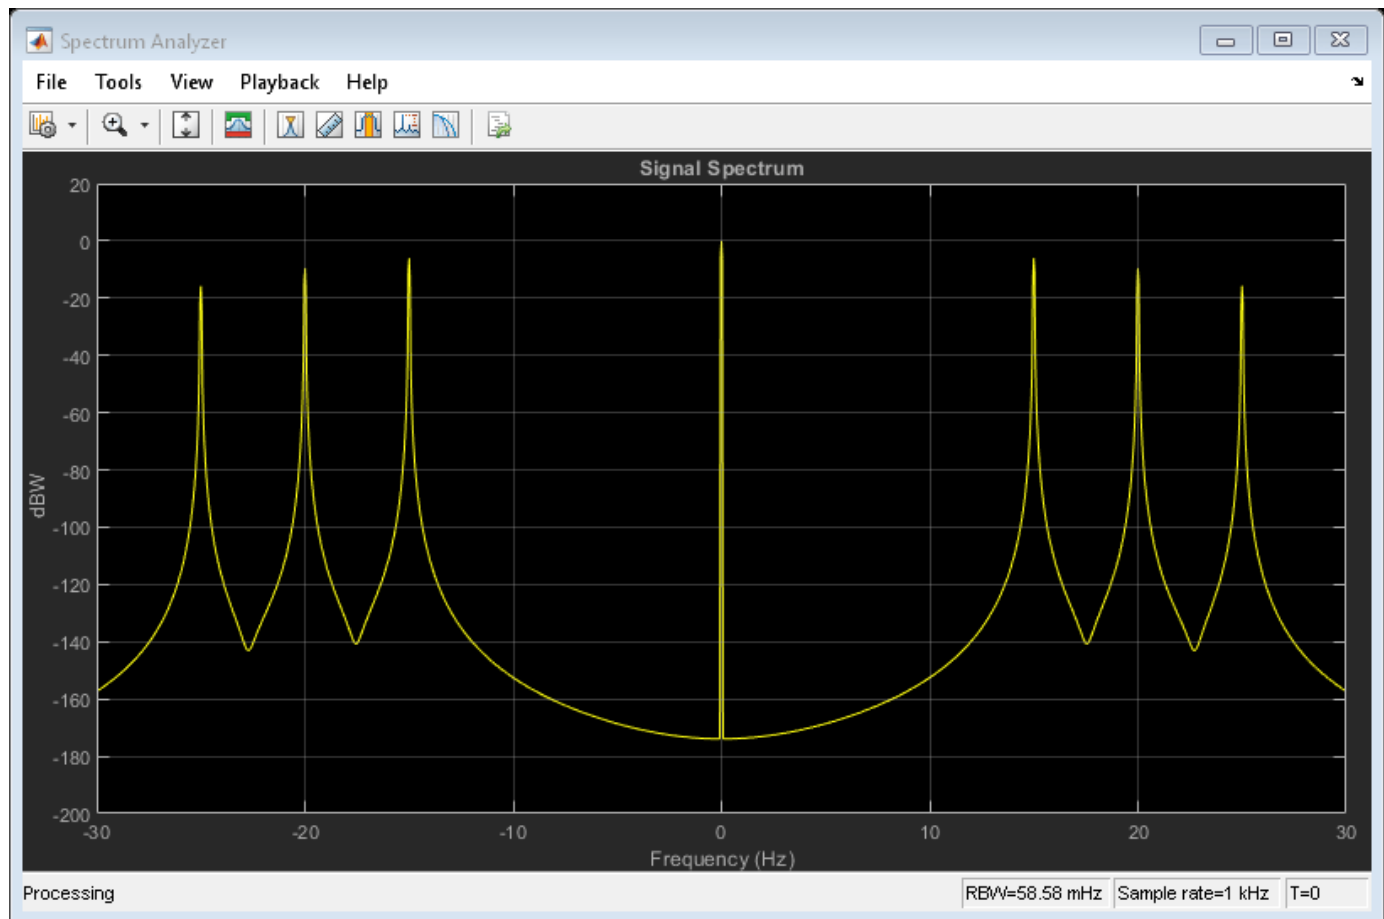

```
hsb = clone(hsa);
hsb.Title = 'Signal Spectrum After DC Blocker';
```

Pass the input signal, x , through the DC blocker to generate the output signal, y .

```
y = dcblkcr(x);
```

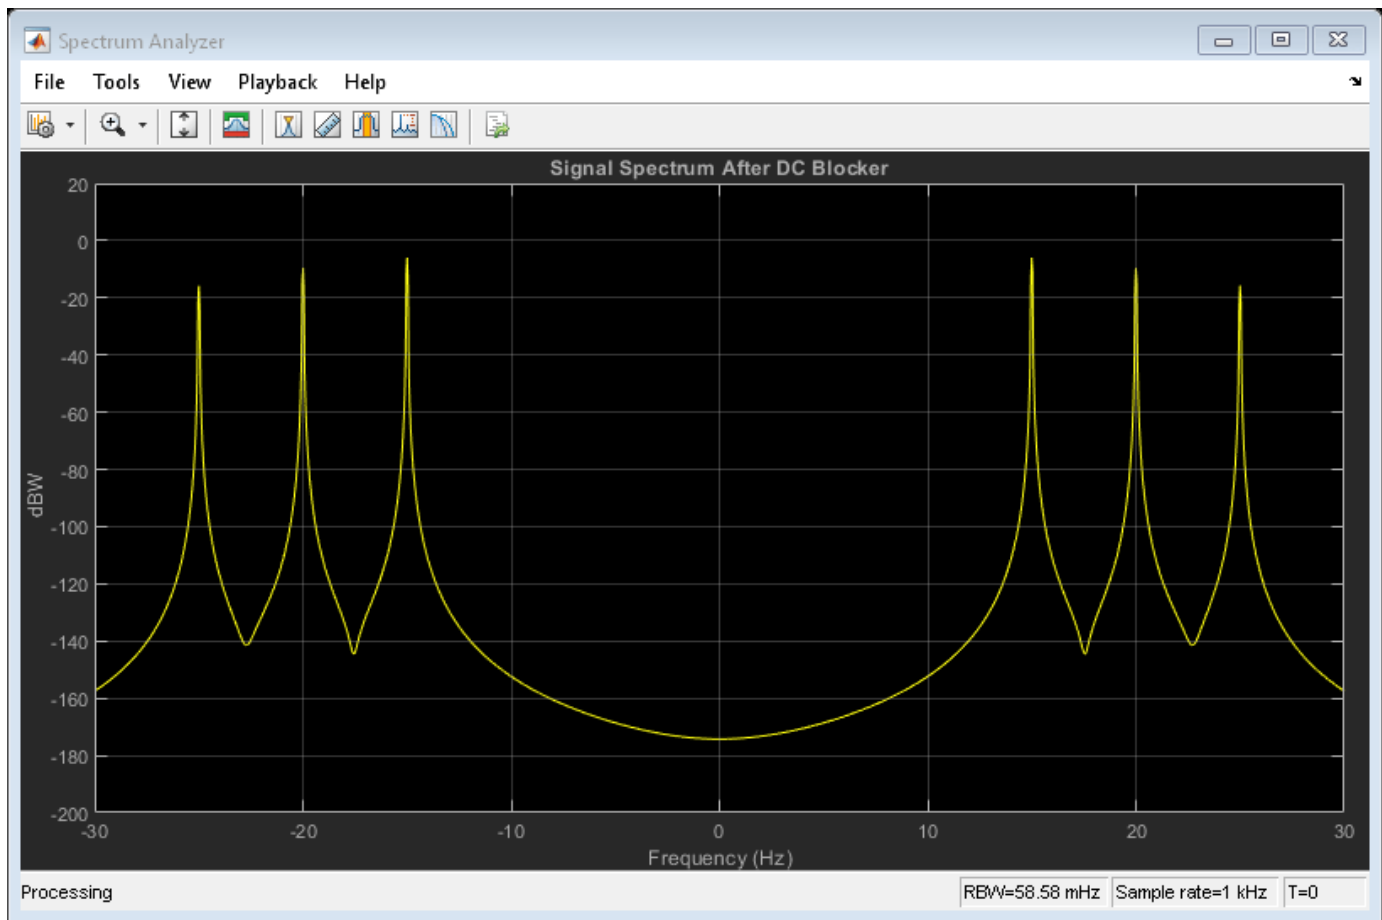

Use the first spectrum analyzer to display the frequency characteristics of the input signal. The tones at 15, 20, and 25 Hz, and the DC component, are clearly visible.

```
hsa(x)
```

Use the second spectrum analyzer to display the frequency characteristics of the output signal. The DC component has been removed.

```
hsb(y)
```

Algorithms

The DC blocker subtracts the DC component from the input signal. You can estimate the DC component by using the IIR, FIR, CIC, or subtract mean algorithm.

IIR

Pass the input signal through an IIR lowpass elliptical filter.

The elliptical IIR filter has a passband ripple of 0.1 dB and a stopband attenuation of 60 dB. You specify the normalized bandwidth and the filter order.

FIR

Pass the input signal through an FIR filter that uses a nonrecursive moving average from a finite number of past input samples.

The FIR filter coefficients are given as $(1, \text{Length}) / \text{Length}$, where you specify the Length. The FIR filter structure is a direct form I transposed structure.

CIC

Pass the input signal through a CIC filter. Because the CIC filter amplifies the signal, the filter gain is estimated and subtracted from the DC estimate.

The Cascaded Integrator-Comb (CIC) filter consists of two integrator-comb pairs. These pairs help to ensure that the peak of the first sidelobe of the filter response is attenuated by at least 25 dB relative to the peak of the main lobe. The normalized 3-dB bandwidth is used to calculate the differential delay. The delay is used to determine the gain of the CIC filter. The inverse of the filter gain is used as a multiplier, which is applied to the output of the CIC filter. This ensures that the aggregate gain of the DC estimate is 0 dB.

The following equation characterizes the aggregate magnitude response of the filter and the multiplier:

$$|H(e^{j\omega})| = \left| \frac{\sin(M\frac{\pi}{2}B_{norm})}{M\sin(\frac{\pi}{2}B_{norm})} \right|^N$$

- B_{norm} is the normalized bandwidth such that $0 < B_{norm} < 1$.
- M is the differential delay in samples.
- N is the number of sections, equal to 2.

Set the differential delay, M , to the smallest integer such that $|H(e^{j\omega})| < 1/\sqrt{2}$. Once M is known, the gain of the CIC filter is calculated as M^N . Therefore, to precisely compensate for the filter gain, the multiplier is set to $(1/M)^N$.

Subtract Mean

Compute the mean value of each column of the input signal and subtract the mean from the input. For example, if the input is [1 2 3 4; 3 4 5 6], then a DC Blocker set to this mode outputs [-1 -1 -1 -1; 1 1 1 1].

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

See "System Objects in MATLAB Code Generation" (MATLAB Coder).

This object also supports SIMD code generation using Intel AVX2 technology when the input signal has a data type of `single` or `double`.

The SIMD technology significantly improves the performance of the generated code.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

`double` and `single` data types are supported for simulation, but not for HDL code generation.

To generate HDL code from predefined System objects, see “HDL Code Generation from Viterbi Decoder System Object” (HDL Coder).

Blocks

DC Blocker

Introduced in R2014a

dsp.DCT

Package: dsp

(Removed) Discrete cosine transform (DCT)

Note The `dsp.DCT` System object™ has been removed. Use `dct` instead. For more information, see “Compatibility Considerations”.

Description

The DCT object computes the discrete cosine transform (DCT) of input.

To compute the DCT of input:

- 1 Define and set up your DCT object. See “Construction” on page 4-392.
- 2 Call `step` to compute the DCT according to the properties of `dsp.DCT`. The behavior of `step` is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`dct = dsp.DCT` returns a discrete cosine transform (DCT) object, `dct`, used to compute the DCT of a real or complex input signal.

`dct = dsp.DCT('PropertyName',PropertyValue, ...)` returns a DCT object, `dct`, with each property set to the specified value.

Properties

SineComputation

Method to compute sines and cosines

Specify how the DCT object computes the trigonometric values as `Trigonometric function` or `Table lookup`. This property must be set to `Table lookup` for fixed-point inputs. The default is `Table lookup`.

Fixed-Point Properties

RoundingMethod

Rounding method for fixed-point operations

Specify the rounding method as one of `Ceiling`, `Convergent`, `Floor`, `Nearest`, `Round`, `Simplest`, or `Zero`. This property applies when you set the `SineComputation` property to `Table lookup`.

OverflowAction

Overflow action for fixed-point operations

Specify the overflow action as one of `Wrap` or `Saturate`. This property applies when you set the `SineComputation` property to `Table lookup`.

SineTableDataType

Sine table word-length designation

Specify the sine table fixed-point data type as one of `Same word length as input` or `Custom`. This property applies when you set the `SineComputation` property to `Table lookup`.

CustomSineTableDataType

Sine table word length

Specify the sine table fixed-point type as an unscaled `numericType` object with a `Signedness` of `Auto`. This property applies when you set the `SineComputation` property to `Table lookup` and the `SineTableDataType` property to `Custom`. The default is `numericType([],16)`.

ProductDataType

Product word and fraction lengths

Specify the product fixed-point data type as one of `Full precision`, `Same as input`, `Custom`. This property applies when you set the `SineComputation` property to `Table lookup`.

CustomProductDataType

Product word and fraction lengths

Specify the product fixed-point type as a scaled `numericType` object with a `Signedness` of `Auto`. This property applies when you set the `SineComputation` property to `Table lookup` and the `ProductDataType` property to `Custom`. The default is `numericType([],32,30)`.

AccumulatorDataType

Accumulator word and fraction lengths

Specify the accumulator fixed-point data type as one of `Full precision`, `Same as input`, `Same as product`, or `Custom`. This property applies when you set the `SineComputation` property to `Table lookup`.

CustomAccumulatorDataType

Accumulator word and fraction lengths

Specify the accumulator fixed-point type as a scaled `numericType` object with a `Signedness` of `Auto`. This property applies when you set the `SineComputation` property to `Table lookup` and the `AccumulatorDataType` property to `Custom`. The default is `numericType([],32,30)`.

OutputDataType

Output word and fraction lengths

Specify the output fixed-point data type as one of `Full precision`, `Same as input`, `Custom`. This property applies when you set the `SineComputation` property to `Table lookup`. The default is `Full precision`.

CustomOutputDataType

Output word and fraction lengths

Specify the output fixed-point type as a scaled `numericType` object with a `Signedness` of `Auto`. This property applies when you set the `SineComputation` property to `Table lookup` and the “`OutputDataType`” on page 4-0 property to `Custom`. The default is `numericType([],16,15)`.

Methods

`step` Discrete cosine transform (DCT) of input

Common to All System Objects

<code>release</code>	Allow System object property value changes
----------------------	--

Examples

Analyze the Energy Content in a Sequence

Note This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, `myObject(x)` becomes `step(myObject,x)`.

Use DCT to analyze the energy content in a sequence:

```
x = (1:128).' + 50*cos((1:128).'*2*pi/40);
dct = dsp.DCT;
X = dct(x);
```

Set the DCT coefficients which represent less than 0.1% of the total energy to 0 and reconstruct the sequence using IDCT.

```
[XX, ind] = sort(abs(X),1, 'descend');
ii = 1;
while (norm([XX(1:ii);zeros(128-ii,1)]) <= 0.999*norm(XX))
    ii = ii+1;
end
disp(['Number of DCT coefficients that represent 99.9%',...
    'of the total energy in the sequence: ',num2str(ii)]);
```

Number of DCT coefficients that represent 99.9%of the total energy in the sequence: 10

```
XXt = zeros(128,1);
XXt(ind(1:ii)) = X(ind(1:ii));
idct = dsp.IDCT;
xt = idct(XXt);
plot(1:128,[x xt]);
```

```
legend('Original signal','Reconstructed signal',...
      'location','best');
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the DCT block reference page. The object properties correspond to the block parameters.

Compatibility Considerations

dsp.DCT System object has been removed

Errors starting in R2021a

The dsp.DCT System object has been removed. Use `dct` instead.

Update Code

This table shows typical usage of the System object and explains how to update existing code to use the equivalent function.

Discouraged Usage	Recommended Replacement
<pre>x = (1:128).' + 50*cos((1:128).'*2*pi/40); dctObj = dsp.DCT; X = dctObj(x);</pre> <p>If you are using a release prior to R2016b, replace <code>dctObj(x)</code> with <code>step(dctObj,x)</code>.</p>	<pre>x = (1:128).' + 50*cos((1:128).'*2*pi/40); X = dct(x);</pre>

Functions

`dct`

Objects

`dsp.FFT` | `dsp.IFFT`

Introduced in R2012a

step

System object: dsp.DCT

Package: dsp

Discrete cosine transform (DCT) of input

Syntax

$Y = \text{step}(\text{dct}, X)$

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, $y = \text{step}(\text{obj}, x)$ and $y = \text{obj}(x)$ perform equivalent operations.

$Y = \text{step}(\text{dct}, X)$ computes the DCT of the input X .

Note `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

dsp.Delay

Package: dsp

Delay input signal by fixed samples

Description

Note The `Units` property no longer supports the `'Frames'` option. Use `'Samples'` instead. The `InitialConditions` property no longer supports a cell array format. Use a `Length-by-numChans` matrix instead, where `numChans` is the number of input channels. For more details, see “Compatibility Considerations” on page 4-403.

The `dsp.Delay` System object delays the input by a specified number of samples along each channel (column) of the input. You can specify the initial output of the object through the “`InitialConditions`” on page 4-0 property. To reset the delay, enable the “`ResetCondition`” on page 4-0 through the “`ResetInputPort`” on page 4-0 .

To delay the input:

- 1 Create the `dsp.Delay` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

Creation

Syntax

```
delay = dsp.Delay
delay = dsp.Delay(Name,Value)
delay = dsp.Delay(len,Name,Value)
```

Description

`delay = dsp.Delay` creates a System object that delays the input by 1 sample.

`delay = dsp.Delay(Name,Value)` creates a delay System object with each specified property set to the specified value. Enclose each property name in single quotes.

Example: `delay = dsp.Delay('InitialConditionsPerChannel',true);`

`delay = dsp.Delay(len,Name,Value)` creates a delay System object, `delay`, with the `Length` property set to `len`, and other specified properties set to the specified values. Enclose each property name in single quotes.

Example: `delay = dsp.Delay(10,'ResetInputPort',true,'ResetCondition','Rising edge');`

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects.

Units — Units of delay

'Samples'

Units of delay, specified as 'Samples'.

Length — Amount of delay to apply to input signal

1 (default) | scalar positive integer | vector of positive integers

Amount of delay in samples to apply to the input signal, specified as one of the following:

- Scalar positive integer -- The object applies equal delay to all the channels.
- Vector of positive integers -- The length of the vector must equal the number of input channels (columns). The object delays each channel by the amount specified by the respective element in the delay vector.

InitialConditionsPerChannel — Enable different initial conditions per channel

false (default) | true

Enable different initial conditions per channel, specified as either:

- `false` -- The object applies the same initial conditions for all channels.
- `true` -- The object applies different initial conditions for each channel.

The value of this property must be the same as the value you choose for the `InitialConditionsPerSample` property. This value determines the size of the initial conditions array. For more details, see the “InitialConditions” on page 4-0 property.

InitialConditionsPerSample — Enables different initial conditions per sample

false (default) | true

Different initial conditions per sample, specified as either:

- `false` -- The object applies the same initial conditions for all samples.
- `true` -- The object applies different initial conditions for each sample.

The value of this property must be the same as the value you choose for the `InitialConditionsPerChannel` property. This value determines the size of the initial conditions array. For more details, see the “InitialConditions” on page 4-0 property.

InitialConditions — Initial output of the object

0 (default) | scalar | vector | matrix

Initial output of System object, specified as a scalar, vector, or a matrix. The dimensions of the initial condition matrix must be (Length property value)-by-(number of input channels).

If the input is an M -by- N matrix, the dimensions of the `InitialConditions` property value must be as follows:

<code>InputConditionsPerChannel</code>	<code>InputConditionsPerSample</code>	<code>InitialConditions</code>
false	false	scalar
true	true	Length-by- N matrix

ResetInputPort — Enable reset condition

false (default) | true

Enable the reset condition so that you can pass the reset control input to the object, specified as either:

- `false` -- The object does not reset the delay states.
- `true` -- You must pass a reset control input to the object by using the “ResetCondition” on page 4-0 property. The object resets the delay states based on the values of the `ResetCondition` property and the reset control that is input to the object.

ResetCondition — Event that triggers reset of delay

'Non-zero' (default) | 'Rising edge' | 'Falling edge' | 'Either edge'

Event that triggers the reset of the delay, specified as one of the following. The object resets the delay whenever a reset event is detected in its reset input.

- 'Non-zero' -- Triggers a reset operation at each sample, when the reset input is not zero.
- 'Rising edge' -- Triggers a reset operation when the reset input does one of the following:
 - Rises from a negative value to either a positive value or zero.
 - Rises from zero to a positive value, where the rise is not a continuation of a rise from a negative value to zero.

- 'Falling edge' -- Triggers a reset operation when the reset input does one of the following:
 - Falls from a positive value to a negative value or zero.
 - Falls from zero to a negative value, where the fall is not a continuation of a fall from a positive value to zero.

- 'Either edge' -- Triggers a reset operation when the reset input is a rising edge or a falling edge.

Dependencies

This property applies only when you set the `ResetInputPort` property to `true`.

Usage

Syntax

```
delayOut = delay(dataInput)
delayOut = delay(dataInput, resetInput)
```

Description

`delayOut = delay(dataInput)` adds delay to the data input and returns the delayed output. Each column of the input is treated as an independent channel.

`delayOut = delay(dataInput, resetInput)` adds delay to the data input and selectively resets the state of the System object based on the value of the reset input and the value of the "ResetCondition" on page 4-0 property.

To pass the reset input, set "ResetInputPort" on page 4-0 property to `true`.

```
delay = dsp.Delay('ResetInputPort',true);
...
delayOut = delay(dataInput,resetInput);
```

Input Arguments

dataInput — Data input

vector | matrix

Data input that is delayed by the object, specified as a vector or a matrix.

Example: `[1;2;3;4;5]`

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical` | `fi`

resetInput — Reset input

scalar

Reset input, specified as a scalar.

Example: 2

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `logical`

Output Arguments

delayOut — Delayed output

`vector` | `matrix`

Delayed output, returned as a vector or matrix. The size and data type of the output match the size and data type of the data input.

Example: `[0;0;1;2;3]`

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical` | `fi`

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Common to All System Objects

<code>step</code>	Run System object algorithm
<code>release</code>	Release resources and allow changes to System object property values and input characteristics
<code>reset</code>	Reset internal states of System object

Examples

Delay Input

Delay input by five samples by using the `dsp.Delay` System object™. By default, the initial conditions are 0.

Note: If you are using R2016a or earlier, replace each call to the object with the equivalent step syntax. For example, `obj(x)` becomes `step(obj,x)`.

Delay input by 4 samples.

```
delay = dsp.Delay(4);
input = [(1:10)' (11:20)'];
delayOut = delay(input) %#ok
```

```
delayOut = 10x2
```

```
0     0
0     0
0     0
0     0
1    11
```

```
2    12
3    13
4    14
5    15
6    16
```

```
release(delay);
```

Specify initial conditions for each channel and for each sample. The `InitialConditions` property must be a (*Length*)-by-(*NumChannels*) matrix.

```
delay.InitialConditionsPerChannel = true;
delay.InitialConditionsPerSample = true;
delay.InitialConditions = [(0.1:0.1:0.4)' (0.5:0.1:0.8)'];
delayOut = delay(input) %#ok
```

```
delayOut = 10x2
```

```
0.1000    0.5000
0.2000    0.6000
0.3000    0.7000
0.4000    0.8000
1.0000   11.0000
2.0000   12.0000
3.0000   13.0000
4.0000   14.0000
5.0000   15.0000
6.0000   16.0000
```

```
release(delay);
```

Reset the delay by setting the reset event to 'Rising edge'. In this mode, a reset event occurs when the reset input:

- Rises from a negative value to 0.
- Rises from a negative value to a positive value.
- Rises from 0 to a positive value, where the rise is not a continuation from a negative value to 0.

Pass an initial reset input of 0.

```
delay.ResetInputPort = true;
delay.ResetCondition = 'Rising edge';
delayOut = delay(input,0) %#ok
```

```
delayOut = 10x2
```

```
0.1000    0.5000
0.2000    0.6000
0.3000    0.7000
0.4000    0.8000
1.0000   11.0000
2.0000   12.0000
3.0000   13.0000
4.0000   14.0000
5.0000   15.0000
```

```
6.0000 16.0000
```

Continue to run the delay. The delay samples now contain the rest of the input vector.

```
delayOut = delay(input,0) %#ok
```

```
delayOut = 10x2
```

```
7 17
8 18
9 19
10 20
1 11
2 12
3 13
4 14
5 15
6 16
```

Change the reset input to 2, indicating a rising edge.

```
delayOut = delay(input,2)
```

```
delayOut = 10x2
```

```
0.1000 0.5000
0.2000 0.6000
0.3000 0.7000
0.4000 0.8000
1.0000 11.0000
2.0000 12.0000
3.0000 13.0000
4.0000 14.0000
5.0000 15.0000
6.0000 16.0000
```

The delay values are reset to the initial conditions.

Compatibility Considerations

Setting delay Units to 'Frames' is no longer supported

Errors starting in R2018a

Starting in R2018a, setting the delay Units to 'Frames' errors. To resolve the error, set Units to 'Samples' and specify Length in samples instead of frames. Calculate the number of samples by multiplying the frame delay value by the frame size.

Initial conditions are not supported in a cell array format

Errors starting in R2018a

The InitialConditions vector no longer supports cell array format. Specify the initial conditions as a Length-by-numChans matrix instead, where numChans is the number of input channels.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

See “System Objects in MATLAB Code Generation” (MATLAB Coder).

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

double and single data types are supported for simulation, but not for HDL code generation.

dsp.DelayLine

Package: dsp

(To be removed) Rebuffer sequence of inputs with one-sample shift

Note dsp.DelayLine will be removed in a future release. There is no direct replacement. You can use the dsp.AsyncBuffer object to achieve a delay line.

Description

The dsp.DelayLine System object rebuffers a sequence of inputs with one-sample shift.

To rebuffer a sequence of inputs with one-sample shift:

- 1 Create the dsp.DelayLine object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

Creation

Syntax

```
dline = dsp.DelayLine
dline = dsp.DelayLine(delaysize,initial)
dline = dsp.DelayLine(Name,Value)
```

Description

dline = dsp.DelayLine returns a delay line System object, dline, that buffers the input samples into a sequence of overlapping or underlapping matrix outputs.

dline = dsp.DelayLine(delaysize,initial) returns a delay line System object, dline, with the Length property set to delaysize and the InitialConditions property set to initial.

dline = dsp.DelayLine(Name,Value) returns a delay line object with each specified property set to the specified value. Enclose each property name in single quotes. Unspecified properties have default values.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see [System Design in MATLAB Using System Objects](#).

Length — Number of rows in output matrix

64 (default) | positive integer

Specify the number of rows in the output matrix as a scalar positive integer.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

InitialConditions — Initial delay line output

0 (default) | scalar | vector | matrix

Set the value of the object's initial output as one of `scalar`, `vector`, or `matrix`.

For vector outputs, you can use these options for the `InitialConditions` property:

- A vector of the same size
- A scalar value that you want repeated across all elements of the initial output

For matrix outputs, you can use these options for the `InitialConditions` property:

- A matrix of the same size
- A vector (equal to the length of the number of matrix rows) that repeats across all columns of the initial output
- A scalar that repeats across all elements of the initial output

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

DirectFeedthrough — Enable passing input data to output without extra frame delay

`false` (default) | `true`

When you set this property to `true`, the input data is available immediately at the output. When you set this property to `false`, the output has a delay of one frame.

EnableOutputInputPort — Enable selective output linearization

`false` (default) | `true`

The object uses a circular buffer, even though the output is linear. To obtain a valid output, the object must linearize the circular buffer. When this property is `true`, the object uses an additional Boolean input to determine if a valid output calculation is needed. If the input value is `true`, the object's output is linearized and thus valid. If the input value is `false`, the output is not linearized and is invalid. This allows the object to be more efficient when each step does not require the tapped delay line output. When you set this property to `false`, the output is always linearized and valid.

HoldPreviousValue — Hold previous valid value for invalid output

`false` (default) | `true`

If you set this property to `true`, the most recent, valid value is held on the output. If you set this property to `false`, the signal on the output is invalid data.

Dependencies

This property applies only when you set the `EnableOutputInputPort` property to `true`.

Usage

Syntax

```
y = dline(x)
y = dline(x,en)
```

Description

`y = dline(x)` returns the delayed version of input `x`. `y` is an output matrix with the same number of rows as the delay line size. Each column of `x` is treated as a separate channel.

`y = dline(x,en)` selectively outputs the delayed version of input `x` depending on the Boolean input `en`. This occurs only when you set the `EnableOutputInputPort` property to `true`. If `en` is `false`, use the `HoldPreviousValue` property to specify if the object should hold the previous output value(s).

Input Arguments

x — Data input

vector | matrix

Data input, specified as a vector or a matrix.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical` | `fi`

en — Enable output input port

`true` | `false`

Enable output input port signal, specified as a logical value.

If `en` is `false`, use the `HoldPreviousValue` property to specify if the object should hold the previous output value(s).

Dependencies

This input is valid only when you set the `EnableOutputInputPort` property to `true`.

Data Types: `logical`

Output Arguments

y — Delay line output

vector | matrix

Delay line output, returned as a vector or a matrix.

When the input is an M_i -by- N matrix, the System object rebuffers the input into a sequence of M_o -by- N matrix outputs, where M_o is the output frame size specified by the `Length` property. Depending on whether M_o is greater than, less than, or equal to the input frame size, M_i , the output frames can be underlapped or overlapped. Each of the N input channels is rebuffered independently:

- When $M_o > M_i$, the output frame overlap is the difference between the output and input frame size, $M_o - M_i$.

- When $Mo < Mi$, the output is overlapped; the object discards the first $Mi - Mo$ samples of each input frame so that only the last Mo samples are buffered into the corresponding output frame.
- When $Mo = Mi$, the output data is identical to the input data, but is delayed by the latency of the object.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical` | `fi`

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Common to All System Objects

`step` Run System object algorithm
`release` Release resources and allow changes to System object property values and input characteristics
`reset` Reset internal states of System object

Examples

Delay Line

Note: If you are using R2016a or earlier, replace each call to the object with the equivalent `step` syntax. For example, `obj(x)` becomes `step(obj,x)`.

Use a delay line object with a delay line size of 4 samples.

```
delayline = dsp.DelayLine( ...
    'Length', 4, ...
    'DirectFeedthrough', true, ...
    'InitialConditions', -2, ...
    'EnableOutputInputPort', true, ...
    'HoldPreviousValue', true);
en = logical([1 1 0 1 0]);
y = zeros(4,5);
for ii = 1:5
    y(:,ii) = delayline(ii, en(ii));
end
disp(y)
```

```
-2    -2    -2     1     1
-2    -2    -2     2     2
-2     1     1     3     3
 1     2     2     4     4
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the Delay Line block reference page. The object properties correspond to the block properties.

Compatibility Considerations

dsp.DelayLine System object will be removed

Warns starting in R2021b

dsp.DelayLine System object will be removed in a future release. There is no direct replacement for this object. You can use the dsp.AsyncBuffer object to achieve a delay line.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

See “System Objects in MATLAB Code Generation” (MATLAB Coder).

Objects

dsp.AsyncBuffer

Introduced in R2012a

dsp.Differentiator

Package: dsp

Direct form FIR fullband differentiator filter

Description

The `dsp.Differentiator` System object applies a fullband differentiator filter on the input signal to differentiate all its frequency components. This object uses an FIR equiripple filter design to design the differentiator filter. The ideal frequency response of the differentiator is $D(\omega) = j\omega$ for $-\pi \leq \omega \leq \pi$. You can design the filter with minimum order with a specified order. This object supports fixed-point operations.

To filter each channel of your input:

- 1 Create the `dsp.Differentiator` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

Creation

Syntax

```
DF = dsp.Differentiator
DF = dsp.Differentiator(Name,Value)
```

Description

`DF = dsp.Differentiator` returns a differentiator, `DF`, which independently filters each channel of the input over time using the given design specifications.

`DF = dsp.Differentiator(Name,Value)` sets each property name to the specified value. Unspecified properties have default values.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see [System Design in MATLAB Using System Objects](#).

DesignForMinimumOrder — Design minimum order filter

true (default) | false

Option to design a minimum-order filter, specified as a logical scalar. The filter has 2 degrees of freedom. When you set this property to

- `true` — The object designs the filter with the minimum order that meets the `PassbandRipple` value.
- `false` — The object designs the filter with order that you specify in the `FilterOrder` property.

This property is not tunable.

FilterOrder — Order of the filter

31 (default) | odd positive integer

Order of the filter, specified as an odd positive integer.

This property is not tunable.

Dependencies

You can specify the filter order only when `'DesignForMinimumOrder'` is set to `false`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

PassbandRipple — Maximum passband ripple

0.1 (default) | positive real scalar

Maximum passband ripple in dB, specified as a positive real scalar.

This property is not tunable.

Dependencies

You can specify the passband ripple only when `'DesignForMinimumOrder'` is set to `true`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

ScaleCoefficients — Scale filter coefficients

`false` (default) | `true`

Option to scale the filter coefficients, specified as a logical scalar. When you set this property to `true`, the object scales the filter coefficients to preserve the input dynamic range.

This property is not tunable.

Fixed-Point Properties

CoefficientsDataType — Word and fraction lengths of coefficients

`numericType(1,16)` (default) | `numericType` object

Word and fraction lengths of coefficients, specified as a signed or unsigned `numericType` object. The default, `numericType(1,16)`, corresponds to a signed numeric type object with 16-bit coefficients. To give the best possible precision, the fraction length is computed based on the coefficient values.

This property is not tunable.

The word length of the output is the same as the word length of the input. The object computes the fraction length of the output such that the entire dynamic range of the output can be represented

without overflow. For details on how the object computes the fraction length of the output, see “Fixed-Point Precision Rules for Avoiding Overflow in FIR Filters”.

RoundingMethod — Rounding method for output fixed-point operations

'Floor' (default) | 'Ceiling' | 'Convergent' | 'Nearest' | 'Round' | 'Simplest' | 'Zero'

Rounding method for output fixed-point operations, specified as a character vector. For more information on the rounding modes, see “Precision and Range”.

This property is not tunable.

Usage

Syntax

$y = DF(x)$

Description

$y = DF(x)$ applies a fullband differentiator filter to the input signal, x . y is a differentiated version of x .

Input Arguments

x — Data input

vector | matrix

Data input, specified as a vector or a matrix. If the input signal is a matrix, each column of the matrix is treated as an independent channel. The number of rows in the input signal denotes the channel length. The data type characteristics (double, single, or fixed-point) and the real-complex characteristics (real or complex valued) must be the same for the input data and output data.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fi

Output Arguments

y — Differentiated signal

vector | matrix

Differentiated signal, returned as a vector or matrix of the same size, data type, and complexity as the input signal, x .

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fi

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Specific to dsp.Differentiator

getFilter Get underlying FIR filter

Common to All System Objects

step Run System object algorithm
 release Release resources and allow changes to System object property values and input characteristics
 reset Reset internal states of System object

Examples

Group Delay Estimation

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, `myObject(x)` becomes `step(myObject,x)`.

Estimate the group delay of a linear phase FIR filter using a `dsp.TransferFunctionEstimator` object followed by `dsp.PhaseExtractor` and `dsp.Differentiator` objects. The group delay of a linear phase FIR filter is given by $GD = -(d\theta(\omega)/d\omega) = -\frac{N}{2}$, where $\theta(\omega)$ is the phase information of the filter, ω is the frequency vector, and N is the order of the filter.

Set Up the Objects

Create a linear phase FIR lowpass filter. Set the order to 200, the passband frequency to 255 Hz, the passband ripple to 0.1 dB, and the stopband attenuation to 80 dB. Specify a sample rate of 512 Hz.

```
Fs = 512;
LPF = dsp.LowpassFilter('SampleRate',Fs,'PassbandFrequency',255,...
    'DesignForMinimumOrder',false,'FilterOrder',200);
```

To estimate the transfer function of the lowpass filter, create a transfer function estimator. Specify the window to be Hann. Set the FFT length to 1024 and the number of spectral averages to 200.

```
TFE = dsp.TransferFunctionEstimator('FrequencyRange','twosided',...
    'SpectralAverages',200,'FFTLengthSource','Property',...
    'FFTLength',1024);
```

To extract the unwrapped phase from the frequency response of the filter, create a phase extractor.

```
PE = dsp.PhaseExtractor;
```

To differentiate the phase θ , create a differentiator filter. This value is used in computing the group delay.

```
DF = dsp.Differentiator;
```

To smoothen the input, create a variable bandwidth FIR filter.

```
Gain1 = 512/pi;
Gain2 = -1;
VBFilter = dsp.VariableBandwidthFIRFilter('CutoffFrequency',10,...
    'SampleRate',Fs);
```

To view the group delay of the filter, create an array plot object.

```
AP = dsp.ArrayPlot('PlotType','Line','YLimits',[-500 400],...
    'YLabel','Amplitude','XLabel','Number of samples');
```

Run the Algorithm

The for-loop is the streaming loop that estimates the group delay of the filter. In the loop, the algorithm filters the input signal, estimates the transfer function of the filter, and differentiates the phase of the filter to compute the group delay.

```
Niter = 1000; % Number of iterations
for k = 1:Niter
    x = randn(512,1); % Input signal = white Gaussian noise
    y = LPF(x); % Filter noise with Lowpass FIR filter
    H = TFE(x,y); % Compute transfer function estimate
    Phase = PE(H); % Extract the Unwrapped phase
    phaseaftergain1 = Gain1*Phase;
    DiffOut = DF(phaseaftergain1); % Differentiate the phase
    phaseaftergain2 = Gain2 * DiffOut;
    VBFOut = VBFiter(phaseaftergain2); % Smooth the group delay
    AP(VBFOut); % Display the group delay
end
```

As you can see, the group delay of the lowpass filter is 100.

Convert FM Signal to AM Signal

Create an FM wave on a 100 Hz carrier signal sampled at 1.5 kHz.

```
Fc = 1e2; % Carrier
Fs = 1.5e3; % Sample rate
sinewave = dsp.SineWave('Frequency',10,...
                        'SamplesPerFrame',1e3,...
                        'SampleRate',Fs);
```

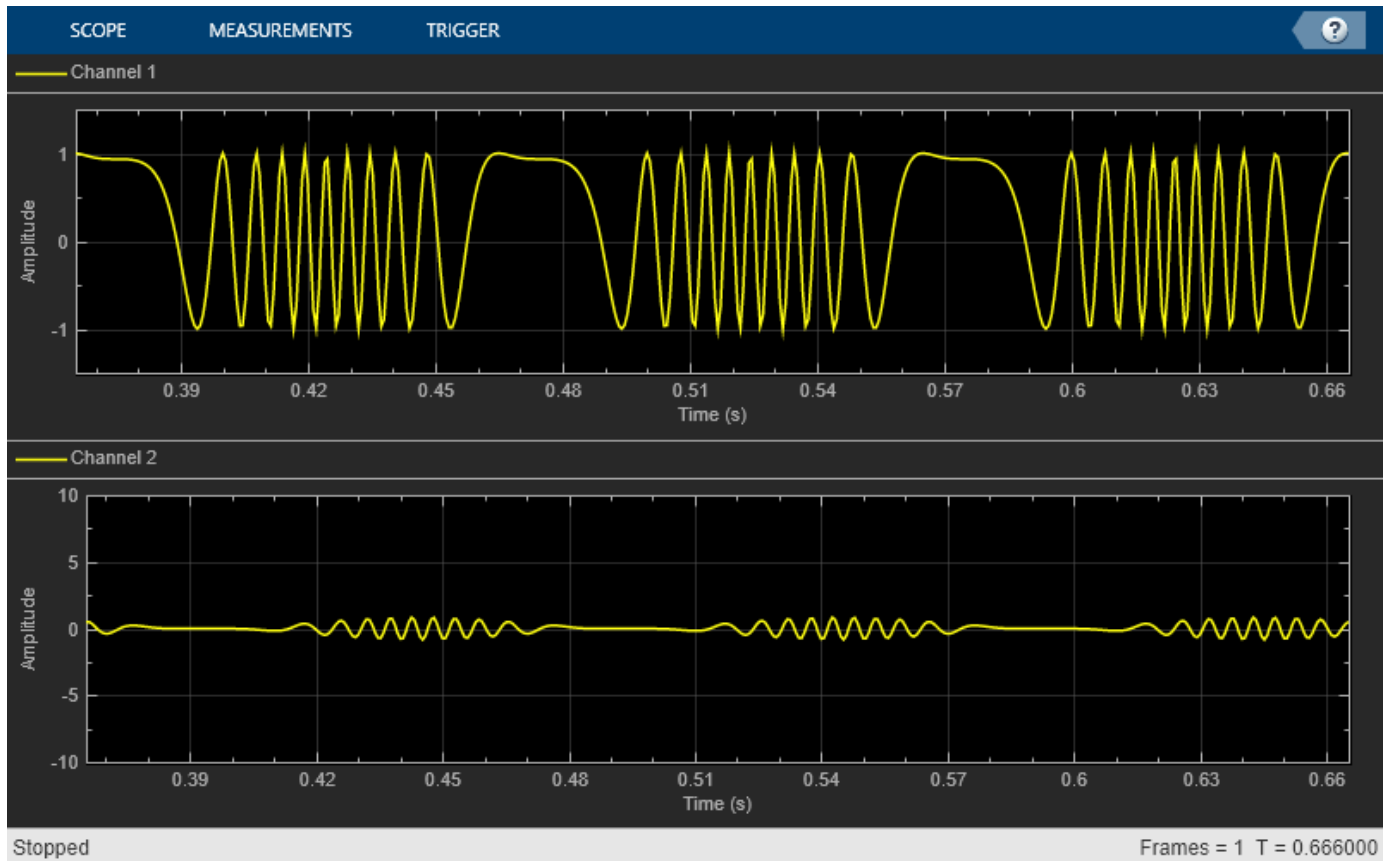

Convert the FM signal to an AM signal.

```
ts = timescope('TimeSpanSource','Property',...
              'TimeSpan',0.3,...
              'BufferLength',10*Fs,...
              'SampleRate',Fs,...
              'ShowGrid',true,...
              'YLimits',[-1.5 1.5],...
              'LayoutDimensions',[2 1]);
```

```
df = dsp.Differentiator;
```

```
tic
while toc<2.2
    x = step(sinewave);
    fm_y = modulate(x,Fc,Fs,'fm');
    am_y = step(df,fm_y);
    step(ts,fm_y,am_y);
end
```

```
release(df);
release(ts);
```

Algorithms

Differentiator Filter

Differentiator computes the derivative of a signal. The frequency response of an ideal differentiator filter is given by $D(\omega) = j\omega$, defined over the Nyquist interval $-\pi \leq \omega \leq \pi$.

The frequency response is antisymmetric and is linearly proportional to the frequency.

`dsp.Differentiator` object acts as a differentiator filter. This object condenses the two-step process into one. For the minimum order design, the object uses generalized Remez FIR filter design algorithm. For the specified order design, the object uses the Parks-McClellan optimal equiripple FIR filter design algorithm. The filter is designed as a linear phase Type-IV FIR filter with a Direct form structure.

The ideal differentiator has an antisymmetric impulse response given by $d(n) = -d(-n)$. Hence $d(0) = 0$. The differentiator must have zero response at zero frequency.

Linear-Phase FIR Differentiator Filter

The impulse response of an antisymmetric linear-phase FIR filter is given by $h(n) = -h(M-1-n)$, where M is the length of the filter. Because the filter is antisymmetric, you can use this type of FIR filter to design the linear-phase FIR differentiators.

Consider the design of linear-phase FIR differentiators based on the Chebyshev approximation criterion.

If M is odd, the real-valued frequency response of the FIR filter, $H_r(\omega)$, has the characteristics that $H_r(0) = 0$ and $H_r(\pi) = 0$. This filter satisfies the condition of zero response at zero frequency. However, it is not fullband because $H_r(\pi) = 0$. This differentiator has a linear response over the limited frequency range $[0, 2\pi f_p]$, where f_p is the bandwidth of the differentiator. The absolute error between the desired response and the Chebyshev approximation increases as ω increases from 0 to $2\pi f_p$.

If M is even, the real-valued frequency response of the FIR filter, $H_r(\omega)$, has the characteristics that $H_r(0) = 0$ and $H_r(\pi) \neq 0$. This filter satisfies the condition of zero response at zero frequency. It is fullband and this design results in a significantly smaller approximation error than comparable odd-length differentiators. Hence, even-length (odd order) differentiators are preferred in practical systems.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

See “System Objects in MATLAB Code Generation” (MATLAB Coder).

This object also supports SIMD code generation using Intel AVX2 technology when the input signal has a data type of `single` or `double`.

The SIMD technology significantly improves the performance of the generated code.

Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

dsp.DigitalDownConverter

Package: dsp

Translate digital signal from intermediate frequency (IF) band to baseband and decimate it

Description

The `dsp.DigitalDownConverter` object translates digital signal from intermediate frequency (IF) band to baseband and decimates it.

To digitally downconvert the input signal:

- 1 Create the `dsp.DigitalDownConverter` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

Creation

Syntax

```
dwnConv = dsp.DigitalDownConverter
dwnConv = dsp.DigitalDownConverter(Name, Value)
```

Description

`dwnConv = dsp.DigitalDownConverter` returns a digital downconverter (DDC) System object, `dwnConv`.

`dwnConv = dsp.DigitalDownConverter(Name, Value)` returns a DDC object, `dwnConv`, with the specified property `Name` set to the specified `Value`. You can specify additional name-value pair arguments in any order as `(Name1, Value1, ..., NameN, ValueN)`.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see [System Design in MATLAB Using System Objects](#).

SampleRate — Sample rate of input signal

30000000 (default) | positive scalar

Set this property to a positive scalar value, greater than or equal to twice the value of the `CenterFrequency` property.

Data Types: `single` | `double`

DecimationFactor — Decimation factor

100 (default) | positive integer scalar | vector of positive integers

Set this property to a positive integer scalar, or to a 1-by-2 or 1-by-3 vector of positive integers.

When you set this property to a scalar, the object automatically chooses the decimation factors for each of the three filtering stages.

When you set this property to a 1-by-2 vector, the object bypasses the third filter stage and sets the decimation factor of the first and second filtering stages to the values in the first and second vector elements respectively. Both elements of the `DecimationFactor` vector must be greater than one.

When you set this property to a 1-by-3 vector, the i th element of the vector specifies the decimation factor for the i th filtering stage. The first and second elements of the `DecimationFactor` vector must be greater than one, and the third element must be 1 or 2.

Data Types: `double`

MinimumOrderDesign — Minimum order filter design

`true` (default) | `false`

When you set this property to `true`, the object designs filters with the minimum order that meets the passband ripple, stopband attenuation, passband frequency, and stopband frequency specifications that you set using the `PassbandRipple`, `StopbandAttenuation`, `Bandwidth`, `StopbandFrequencySource`, and `StopbandFrequency` properties.

When you set this property to `false`, the object designs filters with orders that you specify in the `NumCICSections`, `SecondFilterOrder`, and `ThirdFilterOrder` properties. The filter designs meet the passband and stopband frequency specifications that you set using the `Bandwidth`, `StopbandFrequencySource`, and `StopbandFrequency` properties.

Data Types: `logical`

NumCICSections — Number of sections of CIC decimator

3 (default) | positive integer scalar

Number of sections of CIC decimator, specified as a positive integer scalar.

Dependencies

This property applies when you set the `MinimumOrderDesign` property to `false`.

Data Types: `double`

SecondFilterOrder — Order of CIC compensation filter stage

12 (default) | positive integer scalar

Order of CIC compensation filter stage, specified as a positive integer scalar.

Dependencies

This property applies when you set the `MinimumOrderDesign` property to `false`.

Data Types: `double`

ThirdFilterOrder — Order of third filter stage

10 (default) | even positive integer

Order of third filter stage, specified as an even positive integer scalar. When you set the `DecimationFactor` property to a 1-by-2 vector, the object ignores the `ThirdFilterOrder` property because the third filter stage is bypassed.

Dependencies

This property applies when you set the `MinimumOrderDesign` property to `false`.

Data Types: `double`

Bandwidth — Two-sided bandwidth of input signal in Hz

200000 (default) | positive integer scalar

Two-sided bandwidth of input signal in Hz, specified as a positive integer scalar. The object sets the passband frequency of the cascade of filters to one-half of the value that you specify in the `Bandwidth` property. Set the value of this property to less than `SampleRate/DecimationFactor`.

Data Types: `double`

StopbandFrequencySource — Source of stopband frequency

Auto (default) | Property

Specify the source of the stopband frequency as one of `Auto` | `Property`. When you set this property to `Auto`, the object places the cutoff frequency of the cascade filter response at approximately $F_c = \text{SampleRate}/M/2$ Hz, where M is the total decimation factor that you specify in the `DecimationFactor` property. The object computes the stopband frequency as $F_{stop} = F_c + TW/2$. TW is the transition bandwidth of the cascade response computed as $2 \times (F_c - F_p)$, and the passband frequency, F_p , equals `Bandwidth/2`.

StopbandFrequency — Stopband frequency in Hz

150000 (default) | positive scalar

Stopband frequency in Hz, specified as a positive scalar.

Dependencies

This property applies when you set the `StopbandFrequencySource` property to `Property`.

Data Types: `double`

PassbandRipple — Passband ripple of cascade response in dB

0.1 (default) | positive scalar

Passband ripple of cascade response in dB, specified as a positive scalar. When you set the `MinimumOrderDesign` property to `true`, the object designs the filters so that the cascade response meets the passband ripple that you specify in the `PassbandRipple` property.

Dependencies

This property applies when you set the `MinimumOrderDesign` property to `true`.

Data Types: `double`

StopbandAttenuation — Stopband attenuation of cascade response in dB

60 (default) | positive scalar

Stopband attenuation of cascade response in dB, specified as a positive scalar. When you set the `MinimumOrderDesign` property to `true`, the object designs the filters so that the cascade response meets the stopband attenuation that you specify in the `StopbandAttenuation` property.

Dependencies

This property applies when you set the `MinimumOrderDesign` property to `true`.

Data Types: `double`

Oscillator — Type of oscillator

`Sine wave` (default) | `NCO` | `Input port` | `None`

Specify the oscillator as one of `Sine wave` | `NCO` | `Input port` | `None`. When you set this property to `Sine wave`, the object frequency down converts the input signal using a complex exponential obtained from samples of a sinusoidal trigonometric function. When you set this property to `NCO`, the object performs frequency down conversion with a complex exponential obtained using a numerically controlled oscillator (NCO). When you set this property to `Input port`, the object performs frequency down conversion using the complex oscillator signal, `z`, that you pass as an input to the object. When you set this property to `None`, the mixer stage in the object is not present and the object acts as three stage cascaded decimator.

CenterFrequency — Center frequency of input signal in Hz

`14000000` (default) | positive scalar

Center frequency of input signal in Hz, specified as a positive scalar that is less than or equal to half the value of the `SampleRate` property. The object down converts the input signal from the passband center frequency you specify in the `CenterFrequency` property, to 0 Hz.

Dependencies

This property applies when you set the `Oscillator` property to `Sine wave` or `NCO`.

Data Types: `double`

NumAccumulatorBits — Number of NCO accumulator bits

`16` (default) | positive integer

Number of NCO accumulator bits, specified as a positive integer in the range [1 128].

Dependencies

This property applies when you set the `Oscillator` property to `NCO`.

Data Types: `double`

NumQuantizedAccumulatorBits — Number of NCO quantized accumulator bits

`12` (default) | positive integer

Number of NCO quantized accumulator bits, specified as an integer scalar in the range [1 128]. The value you specify in this property must be less than the value you specify in the `NumAccumulatorBits` property.

Dependencies

This property applies when you set the `Oscillator` property to `NCO`.

Data Types: `double`

Dither — Dither control for NCO

true (default) | false

When you set this property to `true`, a number of dither bits specified in the `NumDitherBits` property will be used to apply dither to the NCO signal.

Dependencies

This property applies when you set the `Oscillator` property to `NCO`.

NumDitherBits — Number of NCO dither bits

4 (default) | positive integer

Specify this property as an integer scalar smaller than the number of accumulator bits that you specify in the `NumAccumulatorBits` property.

Dependencies

This property applies when you set the `Oscillator` property to `NCO` and the `Dither` property to `true`.

Data Types: double

Fixed-Point Properties**FiltersInputDataType — Data type of input of each filter stage**

Same as input (default) | Custom

Specify the data type at the input of the first, second, and third (if it has not been bypassed) filter stages as one of `Same as input` | `Custom`. The object casts the data at the input of each filter stage according to the value you set in this property.

CustomFiltersInputDataType — Fixed-point data type of input of each filter stage

numericType([], 16, 15) (default) | numeric type

Specify the filters input fixed-point type as a scaled `numericType` object with a `Signedness` of `Auto`.

Dependencies

This property applies when you set the `FiltersInputDataType` property to `Custom`.

OutputDataType — Data type of output

Same as input (default) | Custom

Specify the data type of output as `Same as input` | `Custom`.

CustomOutputDataType — Fixed-point data type of output

numericType([], 16, 15) (default) | numeric type

Specify the output fixed-point type as a scaled `numericType` object with a `Signedness` of `Auto`.

Dependencies

This property applies when you set the `OutputDataType` property to `Custom`.

Usage

Syntax

```
y = dwnConv(x)  
y = dwnConv(x,z)
```

Description

`y = dwnConv(x)` takes an input `x` and outputs a signal, `y` that is frequency downconverted and downsampled.

`y = dwnConv(x,z)` uses the complex input, `z`, as the oscillator signal used to frequency down convert input `x` when you set the `Oscillator` property to `Input port`.

Input Arguments

x — Data input

column vector | matrix

Data input, specified as a column vector or a matrix. The length of input `x` must be a multiple of the decimation factor. When the data type of `x` is `double` or `single` precision, the data type of `y` is the same as that of `x`. When the data type of `x` is of a fixed-point type, the data type of `y` is defined by the `OutputDataType` property.

The input can have multiple channels only if its data type is `double` or `single`. The input can be of data type `double`, `single`, signed integer, or signed fixed-point (`fi` objects).

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `fi`

z — Oscillator signal

column vector | matrix

Oscillator signal used to frequency down convert the input signal, specified as a column vector or a matrix. This input must be complex. The length of `z` must be equal to the length of `x`. `z` can be `double`, `single`, signed integer, or signed fixed-point (`fi` objects).

Dependencies

This input applies when you set the `Oscillator` property to `Input port`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `fi`

Output Arguments

y — Down converted and down sampled signal

column vector | matrix

Down converted and down sampled signal, returned as a column vector or a matrix. The length of `y` is equal to the length of `x` divided by the `DecimationFactor`. When the data type of `x` is `double` or `single` precision, the data type of `y` is the same as that of `x`. When the data type of `x` is of a fixed point type, the data type of `y` is defined by the `OutputDataType` property.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `fi`

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Specific to dsp.DigitalDownConverter

<code>getDecimationFactors</code>	Get decimation factors of each filter stage of a digital down converter
<code>getFilterOrders</code>	Get orders of digital down converter or digital up converter filter cascade
<code>getFilters</code>	Get handles to digital down converter or digital up converter filter cascade objects
<code>fvtool</code>	Visualize frequency response of digital down converter or digital up converter filter cascade
<code>groupDelay</code>	Group delay of digital down converter or digital up converter filter cascade
<code>visualizeFilterStages</code>	Display response of digital down converter or digital up converter filter cascade
<code>generatehdl</code>	Generate HDL code for quantized DSP filter (requires Filter Design HDL Coder)

Common to All System Objects

<code>step</code>	Run System object algorithm
<code>release</code>	Release resources and allow changes to System object property values and input characteristics
<code>reset</code>	Reset internal states of System object

Examples

Upconvert and Downconvert a Sine Wave Signal

Create a digital up converter object that up samples a 1 KHz sinusoidal signal by a factor of 20 and up converts it to 50 KHz. Create a digital down converter object that down converts the signal to 0 Hz and down samples it by a factor of 20.

Note: If you are using R2016a or an earlier release, replace each call to the object with the equivalent step syntax. For example, `obj(x)` becomes `step(obj,x)`.

Create a sine wave generator to obtain the 1 KHz sinusoidal signal with a sample rate of 6 KHz.

```
Fs = 6e3; % Sample rate
sine = dsp.SineWave('Frequency',1000,'SampleRate',...
Fs,'SamplesPerFrame',1024);
x = sine(); % generate signal
```

Create a `DigitalUpConverter` object. Use minimum order filter designs and set passband ripple to 0.2 dB and the stopband attenuation to 55 dB. Set the double sided signal bandwidth to 2 KHz.

```
upConv = dsp.DigitalUpConverter(...
'InterpolationFactor', 20,...
'SampleRate', Fs,...
'Bandwidth', 2e3,...
'StopbandAttenuation', 55,...
```

```
'PassbandRipple',0.2,...
'CenterFrequency',50e3);
```

Create a `DigitalDownConverter` object. Use minimum order filter designs and set the passband ripple to 0.2 dB and the stopband attenuation to 55 dB.

```
dwnConv = dsp.DigitalDownConverter(...
'DecimationFactor',20,...
'SampleRate', Fs*20,...
'Bandwidth', 3e3,...
'StopbandAttenuation', 55,...
'PassbandRipple',0.2,...
'CenterFrequency',50e3);
```

Create a spectrum estimator to visualize the signal spectrum before up converting, after up converting, and after down converting.

```
window = hamming(floor(length(x)/10));
figure; pwelch(x>window, [], [], Fs, 'centered')
title('Spectrum of baseband signal x')
```

Up convert the signal and visualize the spectrum

```
xUp = upConv(x); % up convert
window = hamming(floor(length(xUp)/10));
figure; pwelch(xUp>window, [], [], 20*Fs, 'centered');
title('Spectrum of up converted signal xUp')
```

Down convert the signal and visualize the spectrum

```
xDown = dwnConv(xUp); % down convert  
window = hamming(floor(length(xDown)/10));  
figure; pwelch(xDown,window,[],[],Fs,'centered')  
title('Spectrum of down converted signal xDown')
```

Visualize the response of the decimation filters

```
visualizeFilterStages(dwnConv)
```

Get Decimation Factors

Get decimation factors of each filter stage of the `dsp.DigitalDownConverter` System object™.

Create a `dsp.DigitalDownConverter` System object with the default settings. Using the `getDecimationFactors` function, obtain the decimation factors of each stage of the object.

```
dwnConv = dsp.DigitalDownConverter
```

```
dwnConv =  
dsp.DigitalDownConverter with properties:
```

```
    DecimationFactor: 100  
    MinimumOrderDesign: true  
        Bandwidth: 200000  
StopbandFrequencySource: 'Auto'  
    PassbandRipple: 0.1000  
StopbandAttenuation: 60  
    Oscillator: 'Sine wave'  
    CenterFrequency: 14000000  
    SampleRate: 30000000
```

```
Show all properties
```

```
M = getDecimationFactors(dwnConv) %#ok
```

```
M = 1×3
```

```
    25     2     2
```

The `DecimationFactor` property of the object is set to 100. The output `M` is by default a 1-by-3 vector, where each element in the vector is a factor of the overall decimation factor.

When you set the `DecimationFactor` to a 1-by-2 vector, the object bypasses the third filter stage and sets the decimation factor of the first and second filtering stages to the values in the first and second vector elements respectively.

```
dwnConv.DecimationFactor = [10 10]
```

```
dwnConv =  
  dsp.DigitalDownConverter with properties:
```

```
    DecimationFactor: [10 10]  
    MinimumOrderDesign: true  
           Bandwidth: 200000  
StopbandFrequencySource: 'Auto'  
    PassbandRipple: 0.1000  
StopbandAttenuation: 60  
           Oscillator: 'Sine wave'  
    CenterFrequency: 14000000  
           SampleRate: 30000000
```

```
Show all properties
```

```
M = getDecimationFactors(dwnConv)
```

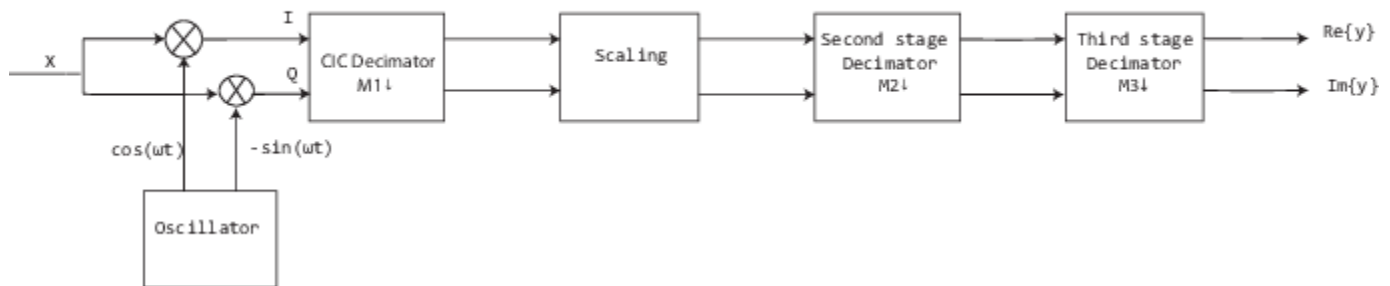

```
M = 1×2
```

```
    10    10
```

The output of the `getDecimationFactors` function is now a 1-by-2 vector.

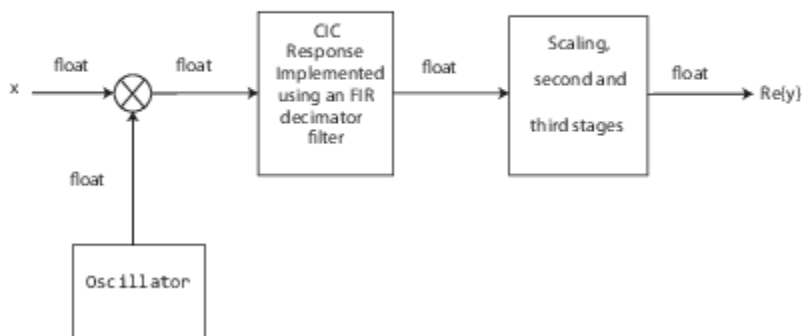

Algorithms

The object downconverts the input signal by multiplying it with a complex exponential with center frequency equal to the value in the `CenterFrequency` property. The object downsamples the frequency downconverted signal using a cascade of three decimation filters. In this case, the filter cascade consists of a CIC decimator, a CIC compensator, and a third FIR decimation stage. The following block diagram shows the architecture of the digital down converter.

The scaling section normalizes the CIC gain and the oscillator power. It may also contain a correction factor to achieve the desired ripple specification. When you set the **Oscillator** property to **InputPort**, the normalization factor does not include the oscillator power factor. Depending on the setting of the **DecimationFactor** property, you may be able to bypass the third filter stage. When the input data type is double or single, the object implements an N -section CIC decimation filter as an FIR filter with a response that corresponds to a cascade of N boxcar filters. A true CIC filter with actual comb and integrator sections is implemented when the input data is of a fixed-point type. The CIC filter is emulated with an FIR filter so that you can run simulations with floating-point data.

The following block diagram represents the DDC arithmetic with single or double-precision, floating-point inputs.

For details of fixed-point operation, see “Fixed Point” on page 4-432.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

See “System Objects in MATLAB Code Generation” (MATLAB Coder).

This object also supports SIMD code generation using Intel AVX2 technology when the input signal has a data type of `single` or `double`.

The SIMD technology significantly improves the performance of the generated code.

HDL Code Generation

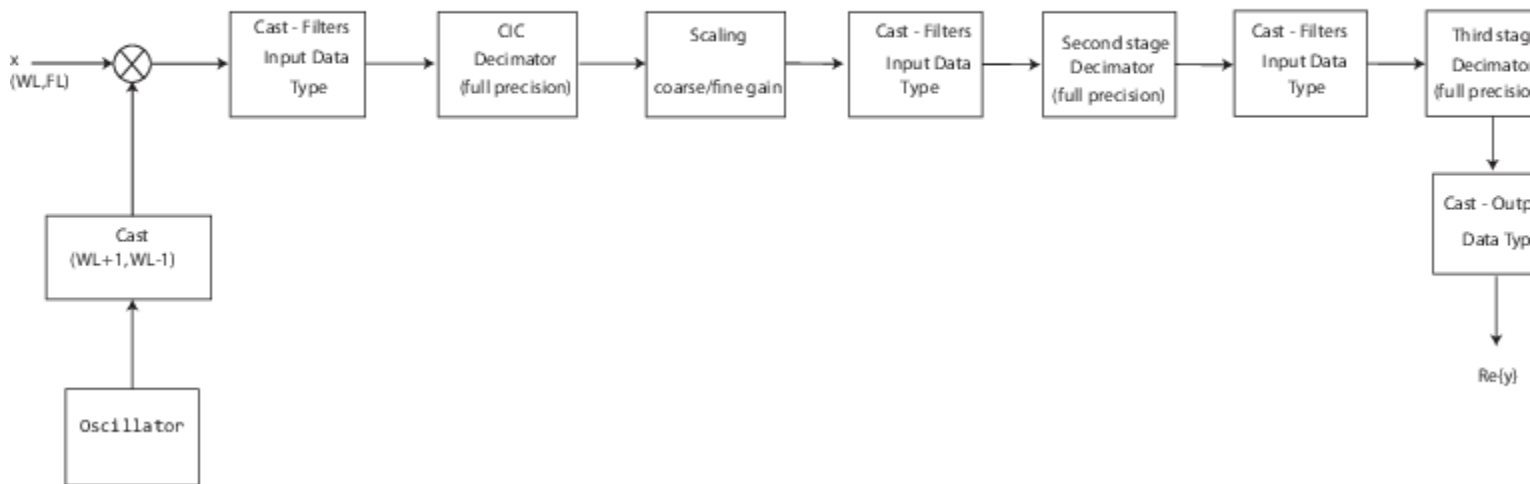

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

This object supports HDL code generation with the Filter Design HDL Coder product. For workflows and limitations, see “Generate HDL Code for Filter System Objects” (Filter Design HDL Coder).

Fixed-Point Conversion

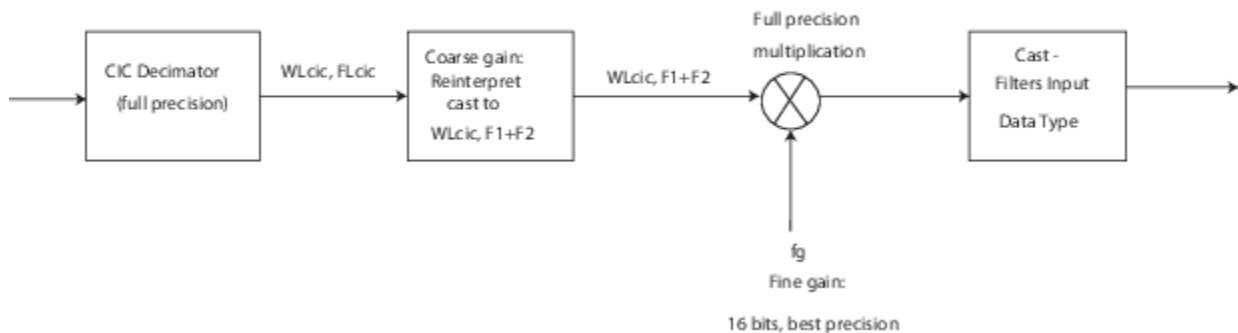

Design and simulate fixed-point systems using Fixed-Point Designer™.

The following block diagram represents the DDC arithmetic with signed fixed-point inputs.

- WL is the word length of the input, and FL is the fraction length of the input.
- The input of each filter is cast to the data type specified in the **FiltersInputDataType** and **CustomFiltersInputDataType** properties.
- The oscillator output is cast to a word length equal to the input word length plus one. The fraction length is equal to the input word length minus one.
- The scaling at the output of the CIC decimator consists of coarse- and fine-gain adjustments. The coarse gain is achieved using the `reinterpretcast` function on the CIC decimator output. The fine gain is achieved using full-precision multiplication.

The following figure depicts the coarse- and fine-gain operations.

If the normalization gain is G (where $0 < G \leq 1$), then:

- $WLCic$ is the word length of the CIC decimator output and $FLCic$ is the fraction length of the CIC decimator output
- $F1 = \text{abs}(\text{nextpow2}(G))$, indicating the part of G achieved using bit shifts (coarse gain)
- $F2 =$ fraction length specified by the **FiltersInputDataType** and **CustomFiltersInputDataType** properties
- $fg = \text{fi}((2^{F1}) * G, \text{true}, 16)$, indicating that the remaining gain cannot be achieved with a bit shift (fine gain)

dsp.DigitalUpConverter

Package: dsp

Interpolate digital signal and translate it from baseband to IF band

Description

The `dsp.DigitalUpConverter` System object interpolates a digital signal, and translates it from baseband to intermediate frequency (IF) band.

To digitally upconvert the input signal:

- 1 Create the `dsp.DigitalUpConverter` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

Creation

Syntax

```
upConv = dsp.DigitalUpConverter
upConv = dsp.DigitalUpConverter(Name,Value)
```

Description

`upConv = dsp.DigitalUpConverter` returns a digital up-converter (DUC) System object, `upConv`.

`upConv = dsp.DigitalUpConverter(Name,Value)` returns a DUC System object with the specified property `Name` set to the specified value `Value`. You can specify one or more name-value pair arguments in any order as `(Name1,Value1,...,NameN,ValueN)`. Enclose each property name in single quotes. For example, create an object that upsamples the input signal by a factor of 20, using a filter with the specified qualities.

```
upConv = dsp.DigitalUpConverter('InterpolationFactor',20,...
    'SampleRate',Fs,...
    'Bandwidth',2e3,...
    'StopbandAttenuation',55,...
    'PassbandRipple',0.2,...
    'CenterFrequency',50e3);
```

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects.

SampleRate — Sample rate of input signal

30000000 (default) | positive scalar

Set this property to a positive scalar value. The value of this property multiplied by the total interpolation factor must be greater than or equal to twice the value of the `CenterFrequency` property.

Data Types: `single` | `double`

InterpolationFactor — Interpolation factor

100 (default) | positive integer | vector of positive integers

Interpolation factor, specified as a positive integer, or a 1-by-2 or 1-by-3 vector of positive integers.

When you set this property to a scalar the object automatically chooses the interpolation factors for each of the three filtering stages.

When you set this property to a 1-by-2 vector, the object bypasses the first filter stage and sets the interpolation factor of the second and third filtering stages to the values in the first and second vector elements, respectively. Both elements of this `InterpolationFactor` vector must be greater than 1.

When you set this property to a 1-by-3 vector, the *i*th element of the vector specifies the interpolation factor for the *i*th filtering stage. The second and third elements of this `InterpolationFactor` vector must be greater than 1 and the first element must equal 1 or 2.

Data Types: `double`

MinimumOrderDesign — Minimum order filter design

`true` (default) | `false`

Minimum order filter design, specified as `true` or `false`.

When you set this property to `true`, the object designs filters with the minimum order that meets the passband ripple, stopband attenuation, passband frequency, and stopband frequency specifications that you set using the `PassbandRipple`, `StopbandAttenuation`, `Bandwidth`, `StopbandFrequencySource`, and `StopbandFrequency` properties.

When you set this property to `false`, the object designs filters with orders that you specify in the `FirstFilterOrder`, `SecondFilterOrder`, and `NumCICSections` properties. The filter designs meet the passband and stopband frequency specifications that you set using the `Bandwidth`, `StopbandFrequencySource`, and `StopbandFrequency` properties.

Data Types: `logical`

SecondFilterOrder — Order of CIC compensation filter stage

12 (default) | positive integer

Order of CIC compensation filter stage, specified as a positive integer.

Dependencies

To enable this property, set the `MinimumOrderDesign` property to `false`.

Data Types: `double`

FirstFilterOrder — Order of first filter stage

10 (default) | positive even integer

Order of first filter stage, specified as a positive even integer.

Dependencies

To enable this property, set the `MinimumOrderDesign` property to `false`. When you set the `InterpolationFactor` property to a 1-by-2 vector, the object ignores the `FirstFilterOrder` property, because the first filter stage is bypassed.

Data Types: `double`

NumCICSections — Number of sections of CIC interpolator

3 (default) | positive integer

Number of sections of CIC interpolator, specified as a positive integer.

Dependencies

To enable this property, set the `MinimumOrderDesign` property to `false`.

Data Types: `double`

Bandwidth — Two-sided bandwidth of input signal in Hz

200000 (default) | positive integer

Two-sided bandwidth of input signal in Hz, specified as a positive integer. The object sets the passband frequency of the cascade of filters to half of the value that you specify in this `Bandwidth` property.

Data Types: `double`

StopbandFrequencySource — Source of stopband frequency

Auto (default) | Property

Source of stopband frequency, specified as `Auto` or `Property`. When you set this property to `Auto`, the object places the cutoff frequency of the cascade filter response at approximately $F_c = \text{SampleRate}/2$ Hz and computes the stopband frequency as $F_{\text{stop}} = F_c + TW/2$. TW is the transition bandwidth of the cascade response, computed as $2 \times (F_c - F_p)$. F_p is the passband frequency computed by `Bandwidth/2`.

StopbandFrequency — Stopband frequency in Hz

150000 (default) | positive scalar

Stopband frequency in Hz, specified as a positive scalar.

Dependencies

To enable this property, set the `StopbandFrequencySource` property to `Property`.

Data Types: `double`

PassbandRipple — Passband ripple of cascade response in dB

0.1 (default) | positive scalar

Passband ripple of cascade response in dB, specified as a positive scalar. When you set the `MinimumOrderDesign` property to `true`, the object designs the filters so that the cascade response meets the passband ripple that you specify in this `PassbandRipple` property.

Dependencies

To enable this property, set the `MinimumOrderDesign` property to `true`.

Data Types: `double`

StopbandAttenuation — Stopband attenuation of cascade response in dB

60 (default) | positive scalar

Stopband attenuation of cascade response in dB, specified as a positive scalar. When you set the `MinimumOrderDesign` property to `true`, the object designs the filters so that the cascade response meets the stopband attenuation that you specify in this `StopbandAttenuation` property.

Dependencies

To enable this property, set the `MinimumOrderDesign` property to `true`.

Data Types: `double`

Oscillator — Type of oscillator

Sine wave (default) | NCO

Type of oscillator, specified as `Sine wave` or `NCO`. When you set this property to `Sine wave`, the object frequency-upconverts the output of the interpolation filter cascade by using a complex exponential signal obtained from samples of a sinusoidal trigonometric function. When you set this property to `NCO`, the object frequency-upconverts the output by using a complex exponential obtained from a numerically controlled oscillator (NCO).

CenterFrequency — Center frequency of output signal in Hz

14000000 (default) | positive scalar

Center frequency of output signal in Hz, specified as a positive scalar. The value of this property must be less than or equal to half the product of the `SampleRate` property and the total interpolation factor. The object up converts the input signal so that the output spectrum centers at this frequency you specify in the `CenterFrequency` property.

Data Types: `double`

NCO Properties**NumAccumulatorBits — Number of NCO accumulator bits**

16 (default) | integer in the range [1, 128]

Number of NCO accumulator bits, specified as an integer in the range [1, 128]. For more details, see the `dsp.NCO System` object.

Dependencies

To enable this property, set the `Oscillator` property to `NCO`.

Data Types: `double`

NumQuantizedAccumulatorBits — Number of NCO accumulator bits

12 (default) | integer in the range [1, 128]

Number of NCO accumulator bits, specified as an integer in the range [1, 128]. The value you specify for this property must be less than the value you specify in the `NumAccumulatorBits` property. For more details, see the `dsp.NCO System` object.

Dependencies

To enable this property, set the `Oscillator` property to `NCO`.

Data Types: `double`

Dither — Dither control for NCO

`true` (default) | `false`

Dither control for NCO, specified as `true` or `false`. When you set this property to `true`, the object uses the number of dither bits specified in the `NumDitherBits` property when applying dither to the NCO signal. When this property is `false`, the NCO does not apply dither to the signal. For more details, see the `dsp.NCO` System object.

Dependencies

To enable this property, set the `Oscillator` property to `NCO`.

Data Types: `logical`

NumDitherBits — Number of NCO dither bits

4 (default) | positive integer

Number of NCO dither bits, specified as a positive integer scalar smaller than the number of accumulator bits that you specify in the `NumAccumulatorBits` property. For more details, see the `dsp.NCO` System object.

Dependencies

To enable this property, set the `Oscillator` property to `NCO` and the `Dither` property to `true`.

Data Types: `double`

Fixed-Point Properties**FiltersOutputDataType — Data type at output of each filter stage**

Same as input (default) | `Custom`

Data type at the output of the first (if it has not been bypassed), second, and third filter stages, specified as `Same as input` or `Custom`. The object casts the data at the output of each filter stage according to the value you set in this property. For the CIC stage, the casting is done after the signal is scaled by the normalization factor.

CustomFiltersOutputDataType — Fixed-point data type at output of each filter stage

`numericType([],16,15)` (default) | `numericType` object

Fixed-point data type at output of each filter stage, specified as a scaled `numericType` object with the `Signedness` property set to `Auto`.

Dependencies

To enable this property, set the `FiltersOutputDataType` property to `Custom`.

OutputDataType — Data type of output

Same as input (default) | `Custom`

Data type of output, specified as `Same as input` or `Custom`.

CustomOutputDataType — Fixed-point data type of output

numericType([],16,15) (default) | numericType object

Fixed-point data type of output, specified as a scaled numericType object the Signedness property set to Auto.

Dependencies

To enable this property, set the OutputDataType property to Custom.

Usage**Syntax**

$y = \text{upConv}(x)$

Description

$y = \text{upConv}(x)$ returns an upsampled and frequency-upconverted signal y , for a real or complex input column vector x .

Input Arguments **x — Input signal**

real or complex column vector

Input signal, specified as a column vector of real or complex values. The length of input x must be a multiple of the decimation factor. When the data type of x is `double` or `single`, the data type of y is the same as that of x . When the data type of x is of a fixed-point type, the data type of y is defined by the `OutputDataType` property.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `fi`

Output Arguments **y — Upconverted and upsampled signal**

column vector

Upconverted and upsampled signal, returned as a column vector. The length of y is equal to the length of x divided by the `InterpolationFactor`. When the data type of x is `double` or `single`, the data type of y is the same as that of x . When the data type of x is of a fixed-point type, the data type of y is defined by the `OutputDataType` property.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `fi`

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

`release(obj)`

Specific to dsp.DigitalUpConverter

getInterpolationFactors	Get interpolation factors of each filter stage of digital upconverter
getFilterOrders	Get orders of digital down converter or digital up converter filter cascade
getFilters	Get handles to digital down converter or digital up converter filter cascade objects
fvtool	Visualize frequency response of digital down converter or digital up converter filter cascade
groupDelay	Group delay of digital down converter or digital up converter filter cascade
visualizeFilterStages	Display response of digital down converter or digital up converter filter cascade
generatehdl	Generate HDL code for quantized DSP filter (requires Filter Design HDL Coder)

Common to All System Objects

step	Run System object algorithm
release	Release resources and allow changes to System object property values and input characteristics
reset	Reset internal states of System object

Examples

Upconvert Sine Wave Signal

Create a DUC System object™ that upsamples a 1-kHz sinusoidal signal by a factor of 20 and upconverts it to 50 kHz.

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, `myObject(x)` becomes `step(myObject,x)`.

Create a sine wave generator to obtain the 1-kHz sinusoidal signal with a sample rate of 6 kHz.

```
Fs = 6e3; % Sample rate
sine = dsp.SinWave('Frequency',1000,...
    'SampleRate',Fs,...
    'SamplesPerFrame',1024);
x = sine(); % generate signal
```

Create a DUC System object. Use minimum order filter designs and set the passband ripple to 0.2 dB and stopband attenuation to 55 dB. Set the double-sided signal bandwidth to 2 kHz.

```
upConv = dsp.DigitalUpConverter(...
    'InterpolationFactor',20,...
    'SampleRate',Fs,...
    'Bandwidth',2e3,...
    'StopbandAttenuation',55,...
    'PassbandRipple',0.2,...
    'CenterFrequency',50e3);
```

Create a spectrum estimator to visualize the signal spectrum before and after upconverting.

```
window = hamming(floor(length(x)/10));  
figure; pwelch(x>window,[],[],Fs,'centered')  
title('Spectrum of baseband signal x')
```

Upconvert the signal and visualize the spectrum.

```
xUp = upConv(x);  
window = hamming(floor(length(xUp)/10));  
figure;  
pwelch(xUp>window,[],[],20*Fs,'centered')  
title('Spectrum of upconverted signal xUp')
```

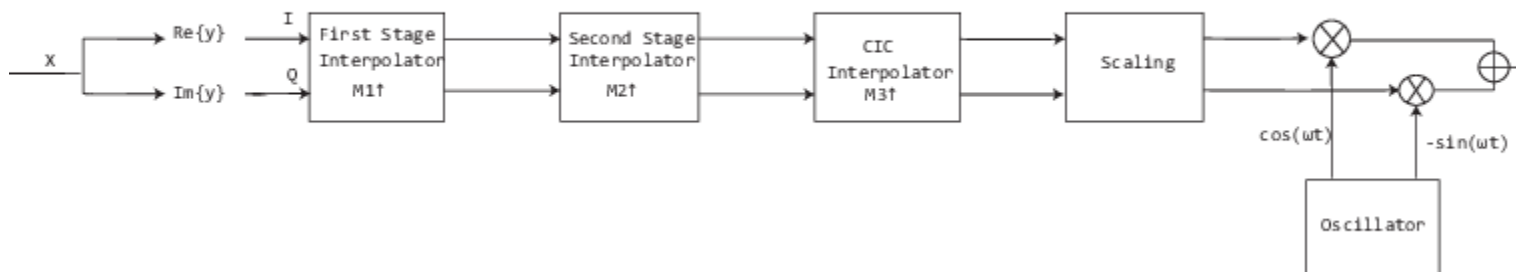

Visualize the response of the interpolation filters.

```
visualizeFilterStages(upConv)
```

Algorithms

The object up samples the input signal using a cascade of three interpolation filters. This object frequency-upconverts the upsampled signal by multiplying it by a complex exponential with center frequency equal to the value in the `CenterFrequency` property. In this case, the filter cascade consists of a FIR interpolation stage, a second stage for CIC compensation, and a CIC interpolator. The block diagram shows the architecture of the digital up converter.

The scaling section normalizes the CIC gain and the oscillator power. It can also contain a correction factor to achieve the desired ripple specification. Depending on the setting of the `InterpolationFactor` property, you might be able to bypass the first filter stage. When the input

data type is floating point, the object implements an N -section CIC interpolation filter as a FIR filter with a response that corresponds to a cascade of N boxcar filters. The CIC filter is emulated with a FIR filter so that you can run simulations with floating-point data. When the input data is fixed-point type, the object implements a true CIC filter with actual comb and integrator sections.

The diagram represents the DUC arithmetic with floating-point inputs.

For details of fixed-point operation, see “Fixed Point” on page 4-444.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

See “System Objects in MATLAB Code Generation” (MATLAB Coder).

This object also supports SIMD code generation using Intel AVX2 technology when the input signal has a data type of `single` or `double`.

The SIMD technology significantly improves the performance of the generated code.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

This object supports HDL code generation with the Filter Design HDL Coder product. For workflows and limitations, see “Generate HDL Code for Filter System Objects” (Filter Design HDL Coder).

Fixed-Point Conversion

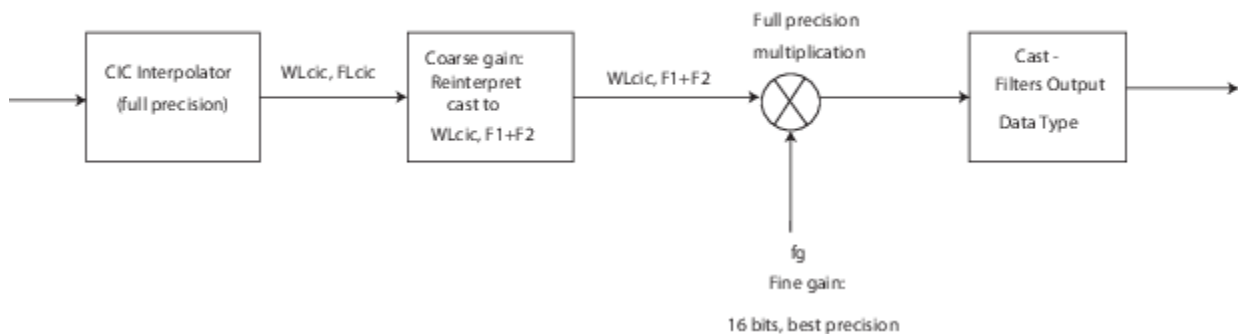

Design and simulate fixed-point systems using Fixed-Point Designer™.

The block diagram represents the DUC arithmetic with signed fixed-point inputs.

- WL is the word length of the input, and FL is the fraction length of the input.
- The output of each filter is cast to the data type specified in the `FiltersOutputDataType` and `CustomFiltersOutputDataType` properties. The casting of the CIC output occurs after the scaling factor is applied.
- The oscillator output is cast to a word length equal to the `FiltersOutputDataType` word length plus one. The fraction length is equal to the `FiltersOutputDataType` word length minus one.
- The scaling at the output of the CIC interpolator consists of coarse-gain and fine-gain adjustments. The coarse gain is achieved using the `reinterpretcast` function on the CIC interpolator output. The fine gain is achieved using full-precision multiplication.

The figure shows the coarse-gain and fine-gain operations.

If the normalization gain is G (where $0 < G \leq 1$), then:

- WL_{cic} is the word length of the CIC interpolator output, and FL_{cic} is the fraction length of the CIC interpolator output.
- $F1 = \text{abs}(\text{nextpow2}(G))$, indicating the part of G achieved by using bit shifts (coarse gain).
- $F2$ is the fraction length specified by the `FiltersOutputDataType` and `CustomFiltersOutputDataType` properties.

- $fg = fi((2^{F1}) * G, true, 16)$, indicating that the remaining gain cannot be achieved with a bit shift (fine gain).

getInterpolationFactors

Package: dsp

Get interpolation factors of each filter stage of digital upconverter

Syntax

```
M = getInterpolationFactors(upConv)
```

Description

`M = getInterpolationFactors(upConv)` returns a vector, `M`, with the interpolation factors of each filter stage of digital up converter `upConv`. If the first filter stage is bypassed, then `M` is a 1-by-2 vector that contains the interpolation factors of the second and third stages. If the first filter stage is not bypassed, then `M` is a 1-by-3 vector containing the interpolation factors of the first, second, and third filter stages.

Examples

Get Interpolation Factors

Get interpolation factors of each filter stage of a `dsp.DigitalUpConverter` System object™.

Create a `dsp.DigitalUpConverter` System object with the default settings. Using the `getInterpolationFactors` function, obtain the interpolation factors of each stage of the object.

```
upConv = dsp.DigitalUpConverter

upConv =
  dsp.DigitalUpConverter with properties:

    InterpolationFactor: 100
    MinimumOrderDesign: true
    Bandwidth: 200000
    StopbandFrequencySource: 'Auto'
    PassbandRipple: 0.1000
    StopbandAttenuation: 60
    Oscillator: 'Sine wave'
    CenterFrequency: 14000000
    SampleRate: 300000
```

Show all properties

```
M = getInterpolationFactors(upConv) %#ok
```

```
M = 1×3
    2    2   25
```

The `InterpolationFactor` property of the object is set to 100. By default, the output `M` is a 1-by-3 vector, where each element in the vector is a factor of the overall interpolation factor.

When you set the `InterpolationFactor` property to a 1-by-2 vector, the object bypasses the first filter stage and sets the interpolation factor of the second and third filtering stages to the values in the first and second vector elements, respectively. The output of the `getInterpolationFactors` function is now a 1-by-2 vector.

```
upConv.InterpolationFactor = [10 10]
```

```
upConv =  
  dsp.DigitalUpConverter with properties:
```

```
    InterpolationFactor: [10 10]  
    MinimumOrderDesign: true  
           Bandwidth: 200000  
StopbandFrequencySource: 'Auto'  
    PassbandRipple: 0.1000  
StopbandAttenuation: 60  
           Oscillator: 'Sine wave'  
    CenterFrequency: 14000000  
           SampleRate: 300000
```

```
Show all properties
```

```
M = getInterpolationFactors(upConv)
```

```
M = 1×2  
    10    10
```

Input Arguments

upConv — Digital up converter

`dsp.DigitalUpConverter` System object

Digital up converter, specified as a `dsp.DigitalUpConverter` System object.

Output Arguments

M — Interpolation factors

vector

Interpolation factors of each filter stage, returned as a 1-by-2 or 1-by-3 vector. If the first filter stage is bypassed, then `M` is a 1-by-2 vector containing the interpolation factors of the second and third stages. If the first filter stage is not bypassed, then `M` is a 1-by-3 vector containing the interpolation factors of the first, second, and third filter stages.

Introduced in R2012a

dsp.DyadicAnalysisFilterBank

Package: dsp

Dyadic analysis filter bank

Description

The `dsp.DyadicAnalysisFilterBank` System object decomposes a broadband signal into a collection of subbands with smaller bandwidths and slower sample rates. The System object uses a series of highpass and lowpass FIR filters to provide approximate octave band frequency decompositions of the input. Each filter output is downsampled by a factor of two. With the appropriate analysis filters and tree structure, the dyadic analysis filter bank is a discrete wavelet transform (DWT) or discrete wavelet packet transform (DWPT).

To obtain approximate octave band frequency decompositions of the input:

- 1 Create the `dsp.DyadicAnalysisFilterBank` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

Creation

Syntax

```
dydan = dsp.DyadicAnalysisFilterBank  
dydan = dsp.DyadicAnalysisFilterBank(Name, Value)
```

Description

`dydan = dsp.DyadicAnalysisFilterBank` constructs a dyadic analysis filter bank object, `dydan`, that computes the level-two discrete wavelet transform (DWT) of a column vector input. For a 2-D matrix input, the object transforms the columns using the Daubechies third-order extremal phase wavelet. The length of the input along the first dimension must be a multiple of 4.

`dydan = dsp.DyadicAnalysisFilterBank(Name, Value)` returns a dyadic analysis filter bank object, with each property set to the specified value.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see [System Design in MATLAB Using System Objects](#).

Filter — Type of filter used in subband decomposition

Custom (default) | Biorthogonal | Coiflets | Daubechies | Discrete Meyer | Haar | Reverse Biorthogonal | Symlets

Specify the type of filter used to determine the high and lowpass FIR filters in the dyadic analysis filter bank as Custom, Haar, Daubechies, Symlets, Coiflets, Biorthogonal, Reverse Biorthogonal, or Discrete Meyer. All property values except Custom require Wavelet Toolbox software. If the value of this property is Custom, the filter coefficients are specified by the values of the CustomLowpassFilter and CustomHighpassFilter properties. Otherwise, the dyadic analysis filter bank object uses the Wavelet Toolbox function wfilters to construct the filters. The following table lists supported wavelet filters and example syntax to construct the filters:

Filter	Example Setting	Syntax for Analysis Filters
Haar	N/A	[Lo_D,Hi_D]=wfilters('haar');
Daubechies extremal phase	WaveletOrder=3;	[Lo_D,Hi_D]=wfilters('db3');
Symlets (Daubechies least-asymmetric)	WaveletOrder=4;	[Lo_D,Hi_D]=wfilters('sym4');
Coiflets	WaveletOrder=1;	[Lo_D,Hi_D]=wfilters('coif1');
Biorthogonal	FilterOrder='[3/1]';	[Lo_D,Hi_D,Lo_R,Hi_R]=... wfilters('bior3.1');
Reverse biorthogonal	FilterOrder='[3/1]';	[Lo_D,Hi_D,Lo_R,Hi_R]=... wfilters('rbior3.1');
Discrete Meyer	N/A	[Lo_D,Hi_D]=wfilters('dmey');

CustomLowpassFilter — Lowpass FIR filter coefficients

[0.0352 -0.0854 -0.1350 0.4599 0.8069 0.3327] (default) | row vector

Specify a vector of lowpass FIR filter coefficients, in powers of z^{-1} . Use a half-band filter that passes the frequency band stopped by the filter specified in the CustomHighpassFilter property. The default specifies a Daubechies third-order extremal phase scaling (lowpass) filter.

Dependencies

This property applies when you set the Filter property to Custom.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

CustomHighpassFilter — Highpass FIR filter coefficients

[-0.3327 0.8069 -0.4599 -0.1350 0.0854 0.0352] (default) | row vector

Specify a vector of highpass FIR filter coefficients, in powers of z^{-1} . Use a half-band filter that passes the frequency band stopped by the filter specified in the CustomLowpassFilter property. The default specifies a Daubechies 3rd-order extremal phase wavelet (highpass) filter.

Dependencies

This property applies when you set the Filter property to Custom.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

WaveletOrder — Order for orthogonal wavelets

2 (default) | positive integer

Specify the order of the wavelet selected in the `Filter` property.

Dependencies

This property applies when you set the `Filter` property to an orthogonal wavelet: `Daubechies` (Daubechies extremal phase), `Symlets` (Daubechies least-asymmetric), or `Coiflets`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical` | `fi`

FilterOrder — Analysis and synthesis filter orders for biorthogonal filters

1 / 1 (default) | 1 / 3 | 1 / 5 | 2 / 2 | 2 / 4 | 2 / 6 | 2 / 8 | 3 / 1 | 3 / 3 | 3 / 5 | 3 / 7 | 3 / 9 | 4 / 4 | 5 / 5 | 6 / 8

Specify the order of the analysis and synthesis filter orders for biorthogonal filter banks as 1 / 1, 1 / 3, 1 / 5, 2 / 2, 2 / 4, 2 / 6, 2 / 8, 3 / 1, 3 / 3, 3 / 5, 3 / 7, 3 / 9, 4 / 4, 5 / 5, or 6 / 8. Unlike orthogonal wavelets, biorthogonal wavelets require different filters for the analysis (decomposition) and synthesis (reconstruction) of an input. The first number indicates the order of the synthesis (reconstruction) filter. The second number indicates the order of the analysis (decomposition) filter.

Dependencies

This property applies when you set the `Filter` property to `Biorthogonal` or `ReverseBiorthogonal`.

Data Types: `char`

NumLevels — Number of filter bank levels used in analysis (decomposition)

2 (default) | integer greater than or equal to 1

Specify the number of filter bank analysis levels a positive integer greater than or equal to 1. A level- N asymmetric structure produces $N+1$ output subbands. A level- N symmetric structure produces 2^N output subbands. The size of the input along the first dimension must be a multiple of 2^N , where N is the number of levels.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

TreeStructure — Structure of filter bank

`Asymmetric` (default) | `Symmetric`

Specify the structure of the filter bank as `Asymmetric` or `Symmetric`. The asymmetric structure decomposes only the lowpass filter output from each level. The symmetric structure decomposes the highpass and lowpass filter outputs from each level. If the analysis filters are scaling (lowpass) and wavelet (highpass) filters, the asymmetric structure is the discrete wavelet transform, while the symmetric structure is the discrete wavelet packet transform.

When this property is `Symmetric`, the output has 2^N subbands each of size $M/2^N$. In this case, M is the length of the input along the first dimension and N is the value of the `NumLevels` property. When this property is `Asymmetric`, the output has $N+1$ subbands. The following equation gives the length of the output in the k th subband in the asymmetric case:

$$M_k = \begin{cases} \frac{M}{2^k} & 1 \leq k \leq N \\ \frac{M}{2^N} & k = N + 1 \end{cases}$$

Usage

Syntax

```
y = dydan(x)
```

Description

`y = dydan(x)` computes the subband decomposition of the input `x` and outputs the dyadic subband decomposition in `y` as a single concatenated column vector or matrix of coefficients.

Input Arguments

x — Data input

column vector | matrix

Data input, specified as a column vector or a matrix. Each column of `x` is treated as an independent input, and the number of rows of `x` must be a multiple of 2^N , where N is the number of levels specified by the `NumLevels` property.

Data Types: `single` | `double`

Output Arguments

y — Dyadic subband decomposition output

column vector | matrix

Dyadic subband decomposition output, returned as a column vector or a matrix. The elements of `y` are ordered with the highest-frequency subband first followed by subbands in decreasing frequency.

When `TreeStructure` is set to `Symmetric`, the output has 2^N subbands each of size $M/2^N$. In this case, M is the length of the input along the first dimension, and N is the value of the `NumLevels` property. When `TreeStructure` is set to `Asymmetric`, the output has $N+1$ subbands. The following equation gives the length of the output in the k th subband in the asymmetric case:

$$M_k = \begin{cases} \frac{M}{2^k} & 1 \leq k \leq N \\ \frac{M}{2^N} & k = N + 1 \end{cases}$$

Data Types: `single` | `double`

Object Functions

To use an object function, specify the `System` object as the first input argument. For example, to release system resources of a `System` object named `obj`, use this syntax:

```
release(obj)
```

Common to All System Objects

`step` Run System object algorithm

release Release resources and allow changes to System object property values and input characteristics
reset Reset internal states of System object

Examples

Filter Square Wave Using Dyadic Filter Banks

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, `myObject(x)` becomes `step(myObject,x)`.

Denoise square wave input using dyadic analysis and synthesis filter banks.

```
t = 0:.0001:.0511;  
x = square(2*pi*30*t);  
xn = x' + 0.08*randn(length(x),1);  
dydanl = dsp.DyadicAnalysisFilterBank;
```

The filter coefficients correspond to a haar wavelet.

```
dydanl.CustomLowpassFilter = [1/sqrt(2) 1/sqrt(2)];  
dydanl.CustomHighpassFilter = [-1/sqrt(2) 1/sqrt(2)];  
dydsyn = dsp.DyadicSynthesisFilterBank;  
dydsyn.CustomLowpassFilter = [1/sqrt(2) 1/sqrt(2)];  
dydsyn.CustomHighpassFilter = [1/sqrt(2) -1/sqrt(2)];  
C = dydanl(xn);
```

Subband outputs.

```
C1 = C(1:256); C2 = C(257:384); C3 = C(385:512);
```

Set higher frequency coefficients to zero to remove the noise.

```
x_den = dydsyn([zeros(length(C1),1);...  
zeros(length(C2),1);C3]);
```

Plot the original and denoised signals.

```
subplot(2,1,1), plot(xn); title('Original noisy Signal');  
subplot(2,1,2), plot(x_den); title('Denoised Signal');
```

Subband Ordering For Asymmetric Tree Structure Using Dyadic Analysis Filter Bank

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, `myObject(x)` becomes `step(myObject,x)`.

Sampling frequency 1 kHz input length 1024

```
t = 0:.001:1.023;
x = square(2*pi*30*t);
xn = x' + 0.08*randn(length(x),1);
```

Default asymmetric structure with order 3 extremal phase wavelet

```
dydan = dsp.DyadicAnalysisFilterBank;
Y = dydan(xn);
```

Level 2 yields 3 subbands (two detail-one approximation) Nyquist frequency is 500 Hz

```
D1 = Y(1:512); % subband approx. [250, 500] Hz
D2 = Y(513:768); % subband approx. [125, 250] Hz
Approx = Y(769:1024); % subband approx. [0,125] Hz
```

Subband Ordering For Symmetric Tree Structure Using Dyadic Analysis Filter Bank

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, `myObject(x)` becomes `step(myObject,x)`.

Sampling frequency 1 kHz input length 1024.

```
t = 0:.001:1.023;
x = square(2*pi*30*t);
xn = x' + 0.08*randn(length(x),1);

dydan = dsp.DyadicAnalysisFilterBank('TreeStructure',...
'Symmetric');
Y = dydan(xn);
D1 = Y(1:256); % subband approx. [375,500] Hz
D2 = Y(257:512); % subband approx. [250,375] Hz
D3 = Y(513:768); % subband approx. [125,250] Hz
Approx = Y(769:1024); % subband approx. [0, 125] Hz
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the Dyadic Analysis Filter Bank block reference page. The object properties correspond to the block parameters, except: The dyadic analysis filter bank object always concatenates the subbands into a single column vector for a column vector input, or into the columns of a matrix for a matrix input. This behavior corresponds to the block's behavior when you set the **Output** parameter to `Single port`.

Objects

`dsp.DyadicSynthesisFilterBank` | `dsp.SubbandAnalysisFilter`

Introduced in R2012a

dsp.DyadicSynthesisFilterBank

Package: dsp

Reconstruct signals from subbands

Description

The `dsp.DyadicSynthesisFilterBank` System object reconstructs signals from subbands with smaller bandwidths and lower sample rates. The filter bank uses a series of highpass and lowpass FIR filters to repeatedly reconstruct the signal.

To reconstruct signals from subbands with smaller bandwidths and lower sample rates:

- 1 Create the `dsp.DyadicSynthesisFilterBank` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

Creation

Syntax

```
dydsyn = dsp.DyadicSynthesisFilterBank
dydsyn = dsp.DyadicSynthesisFilterBank(Name, Value)
```

Description

`dydsyn = dsp.DyadicSynthesisFilterBank` returns a synthesis filter bank, `dydsyn`, that reconstructs a signal from its subbands with smaller bandwidths and smaller sample rates.

`dydsyn = dsp.DyadicSynthesisFilterBank(Name, Value)` returns a dyadic synthesis filter bank object, with each property set to the specified value.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see [System Design in MATLAB Using System Objects](#).

Filter — Type of filter used in filter bank

Custom (default) | Biorthogonal | Coiflets | Daubechies | Discrete Meyer | Haar | Reverse Biorthogonal | Symlets

Specify the type of filter used to determine the highpass and lowpass FIR filters in the filter bank as one of Custom, Haar, Daubechies, Symlets, Coiflets, Biorthogonal, Reverse

Biorthogonal, or Discrete Meyer. If you set this property to Custom, the CustomLowpassFilter and CustomHighpassFilter properties specify the filter coefficients. Otherwise, the object uses the wfilters function to construct the filters. Depending on the filter, the WaveletOrder or “FilterOrder” on page 4-0 property might apply. For a list of the supported wavelets, see the following table.

Filter	Sample Setting for Related Filter Specification Properties	Corresponding Wavelet Toolbox Function Syntax
Haar	None	wfilters('haar')
Daubechies	H.WaveletOrder = 4	wfilters('db4')
Symlets	H.WaveletOrder = 3	wfilters('sym3')
Coiflets	H.WaveletOrder = 1	wfilters('coif1')
Biorthogonal	H.FilterOrder = '[3/1]'	wfilters('bior3.1')
Reverse Biorthogonal	H.FilterOrder = '[3/1]'	wfilters('rbior3.1')
Discrete Meyer	None	wfilters('dmey')

In order to automatically design wavelet-based filters, install the Wavelet Toolbox product. Otherwise, use the CustomLowpassFilter and CustomHighpassFilter properties to specify lowpass and highpass FIR filters.

CustomLowpassFilter — Lowpass FIR filter coefficients

[0.3327 0.8069 0.4599 -0.1350 -0.0854 0.0352] (default) | row vector

Specify a vector of lowpass FIR filter coefficients, in descending powers of z . Use a half-band filter that passes the frequency band stopped by the filter specified in the CustomHighpassFilter property. To perfectly reconstruct a signal decomposed by the dsp.DyadicAnalysisFilterBank object, design the filters in the synthesis filter bank to perfectly reconstruct the outputs of the analysis filter bank. Otherwise, the reconstruction is imperfect. The default values of this property specify a perfect reconstruction filter for the default settings of the analysis filter bank (based on a third-order Daubechies wavelet).

Dependencies

This property applies when you set the Filter property to Custom.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

CustomHighpassFilter — Highpass FIR filter coefficients

[0.0352 0.0854 -0.1350 -0.4599 0.8069 -0.3327] (default) | row vector

Specify a vector of highpass FIR filter coefficients, in descending powers of z . Use a half-band filter that passes the frequency band stopped by the filter specified in the CustomLowpassFilter property. To perfectly reconstruct a signal decomposed by the dsp.DyadicAnalysisFilterBank object, design the filters in the synthesis filter bank to perfectly reconstruct the outputs of the analysis filter bank. Otherwise, the reconstruction is imperfect. The default values of this property specify a perfect reconstruction filter for the default settings of the analysis filter bank (based on a third-order Daubechies wavelet).

Dependencies

This property applies when you set the Filter property to Custom.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

WaveletOrder — Wavelet order

2 (default) | positive integer

Specify the order of the wavelet selected in the `Filter` property.

Dependencies

This property applies when you set the `Filter` property to an orthogonal wavelet: `Daubechies` (Daubechies extremal phase), `Symlets` (Daubechies least-asymmetric), or `Coiflets`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical` | `fi`

FilterOrder — Wavelet order for synthesis filter stage

1 / 1 (default) | 1 / 3 | 1 / 5 | 2 / 2 | 2 / 4 | 2 / 6 | 2 / 8 | 3 / 1 | 3 / 3 | 3 / 5 | 3 / 7 | 3 / 9 | 4 / 4 | 5 / 5 | 6 / 8

Specify the order of the wavelet for the synthesis filter stage as:

- First order: `'[1/1]'`, `'[1/3]'`, or `'[1/5]'`.
- Second order: `'[2/2]'`, `'[2/4]'`, `'[2/6]'`, or `'[2/8]'`.
- Third order: `'[3/1]'`, `'[3/3]'`, `'[3/5]'`, `'[3/7]'`, or `'[3/9]'`.
- Fourth order: `'[4/4]'`.
- Fifth order: `'[5/5]'`.
- Sixth order: `'[6/8]'`.

Dependencies

This property applies when you set the `Filter` property to `Biorthogonal` or `ReverseBiorthogonal`.

Data Types: `char`

NumLevels — Number of filter bank levels

2 (default) | integer greater than or equal to 1

Specify the number of filter bank levels as a scalar integer. An N -level asymmetric structure has $N + 1$ input subbands, and an N -level symmetric structure has 2^N input subbands.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

TreeStructure — Structure of filter bank

`Asymmetric` (default) | `Symmetric`

Specify the structure of the filter bank as `Asymmetric` or `Symmetric`. In the asymmetric structure, the low-frequency subband input to each level is the output of the previous level, while the high-frequency subband input to each level is an input to the filter bank. In the symmetric structure, both the low- and high-frequency subband inputs to each level are outputs from the previous level.

Usage

Syntax

```
y = dydsyn(x)
```

Description

`y = dydsyn(x)` reconstructs the concatenated subband input `x` to output `y`. Each column of input `x` contains the subbands for an independent signal. Upper rows contain the high-frequency subbands, and lower rows contain the low-frequency subbands.

Input Arguments

x — Data input

column vector | matrix

Data input, specified as a column vector or a matrix. Each column of input `x` contains the subbands for an independent signal. Upper rows contain the high-frequency subbands, and lower rows contain the low-frequency subbands. The number of rows of `x` must be a multiple of 2^N , where N is the value of the `NumLevels` property.

Data Types: `single` | `double`

Output Arguments

y — Reconstructed signal

column vector | matrix

Reconstructed signal, returned as a column vector or a matrix.

Data Types: `single` | `double`

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Common to All System Objects

<code>step</code>	Run System object algorithm
<code>release</code>	Release resources and allow changes to System object property values and input characteristics
<code>reset</code>	Reset internal states of System object

Examples

Filter Square Wave Using Dyadic Filter Banks

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, `myObject(x)` becomes `step(myObject,x)`.

Denoise square wave input using dyadic analysis and synthesis filter banks.

```
t = 0:.0001:.0511;
x= square(2*pi*30*t);
xn = x' + 0.08*randn(length(x),1);
dydanl = dsp.DyadicAnalysisFilterBank;
```

The filter coefficients correspond to a haar wavelet.

```
dydanl.CustomLowpassFilter = [1/sqrt(2) 1/sqrt(2)];
dydanl.CustomHighpassFilter = [-1/sqrt(2) 1/sqrt(2)];
dydsyn = dsp.DyadicSynthesisFilterBank;
dydsyn.CustomLowpassFilter = [1/sqrt(2) 1/sqrt(2)];
dydsyn.CustomHighpassFilter = [1/sqrt(2) -1/sqrt(2)];
C = dydanl(xn);
```

Subband outputs.

```
C1 = C(1:256); C2 = C(257:384); C3 = C(385:512);
```

Set higher frequency coefficients to zero to remove the noise.

```
x_den = dydsyn([zeros(length(C1),1);...
               zeros(length(C2),1);C3]);
```

Plot the original and denoised signals.

```
subplot(2,1,1), plot(xn); title('Original noisy Signal');
subplot(2,1,2), plot(x_den); title('Denoised Signal');
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the Dyadic Synthesis Filter Bank block reference page. The object properties correspond to the block parameters, except: The object only receives data as a vector or matrix of concatenated subbands.

Objects

`dsp.DyadicAnalysisFilterBank` | `dsp.SubbandSynthesisFilter`

Introduced in R2012a

dsp.FarrowRateConverter

Package: dsp

Polynomial sample rate converter with arbitrary conversion factor

Description

The `dsp.FarrowRateConverter` System object implements a polynomial-fit sample rate conversion filter using a Farrow structure. You can use this object to convert the sample rate of a signal up or down by an arbitrary factor. This object supports fixed-point operations.

To convert the sample rate of a signal:

- 1 Create the `dsp.FarrowRateConverter` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

Creation

Syntax

```
frc = dsp.FarrowRateConverter
frc = dsp.FarrowRateConverter(Name,Value)
frc = dsp.FarrowRateConverter(fsIn,fsOut,tol,np)
```

Description

`frc = dsp.FarrowRateConverter` creates a polynomial filter-based sample rate converter System object, `frc`. For each channel of an input signal, `frc` converts the input sample rate to the output sample rate.

`frc = dsp.FarrowRateConverter(Name,Value)` sets properties using one or more name-value pairs. Enclose each property name in single quotes.

Example: `frc = dsp.FarrowRateConverter('Specification','Coefficients','Coefficients',[1 2; 3 4])` returns a filter that converts from 44.1 kHz to 48 kHz using custom coefficients that implement a 2nd-order polynomial filter.

`frc = dsp.FarrowRateConverter(fsIn,fsOut,tol,np)` returns a sample rate converter System object, `frc`, with `InputSampleRate` property set to `fsIn`, `OutputSampleRate` property set to `fsOut`, `OutputRateTolerance` property set to `tol`, and `PolynomialOrder` property set to `np`.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects.

Filter Properties

InputSampleRate — Sample rate of input signal

44100 (default) | positive scalar in Hz

Sample rate of the input signal, specified as a positive scalar in Hz. The input sample rate must be greater than the bandwidth of interest.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

OutputSampleRate — Sample rate of output signal

48000 (default) | positive scalar in Hz

Sample rate of the output signal, specified as a positive scalar in Hz. The output sample rate can represent an upsample or downsample of the input signal.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

OutputRateTolerance — Maximum tolerance for output sample rate

0 (default) | positive scalar

Maximum tolerance for the output sample rate, specified as a positive scalar from 0 through 0.5, inclusive.

The actual output sample rate varies but is within the specified range. For example, if `OutputRateTolerance` is specified as `0.01`, then the actual output sample rate is in the range `OutputSampleRate ± 1%`. This flexibility often enables a simpler filter design.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

Specification — Method for specifying filter coefficients

'Polynomial order' (default) | 'Coefficients'

Method for specifying filter coefficients for the interpolator filter, specified as one of the following:

- 'Polynomial order' — Use the `PolynomialOrder` property to specify the order of the Lagrange-interpolation-filter polynomial. The object calculates coefficients that meet the rate and tolerance properties.
- 'Coefficients' — Use the `Coefficients` property to specify the polynomial coefficients directly.

PolynomialOrder — Order of Lagrange-interpolation-filter polynomial

3 (default) | positive integer less than or equal to 4

Order of the Lagrange-interpolation-filter polynomial, specified as a positive integer less than or equal to 4. The object calculates coefficients that meet the rate and tolerance properties.

Dependencies

This property applies only when you set `Specification` to 'Polynomial order'.

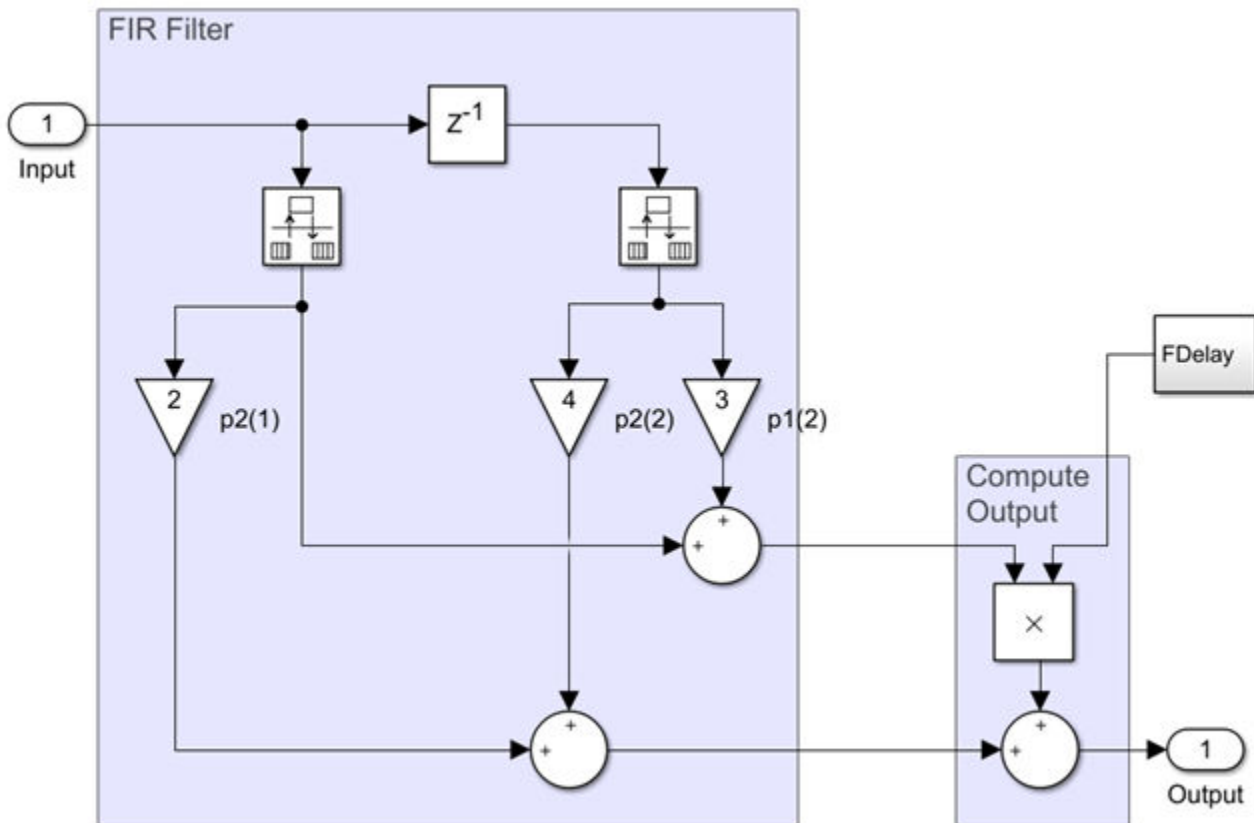

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

Coefficients — Filter polynomial coefficients

`[-1 1; 1 0]` (default) | real-valued square matrix

Filter polynomial coefficients, specified as a real-valued M -by- M matrix, where M is the polynomial order.

The diagram shows the signal flow graph for a `dsp.FarrowRateConverter` object with coefficients set to `[1 2; 3 4]`.

Each branch of the FIR filter corresponds to a row of the coefficient matrix.

Dependencies

This property applies only when you set `Specification` to `'Coefficients'`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

Fixed-Point Properties**RoundingMethod — Rounding method for fixed-point operations**

`'Floor'` (default) | `'Ceiling'` | `'Convergent'` | `'Nearest'` | `'Round'` | `'Zero'`

Rounding method for fixed-point operations, specified as a character vector. For more information on the rounding methods see “Rounding Modes”.

OverflowAction — Overflow action for fixed-point operations

`'Wrap'` (default) | `'Saturate'`

Overflow action for fixed-point operations, specified as either 'Wrap' or 'Saturate'. For more details on the overflow actions, see “Overflow Handling”.

CoefficientsDataType — Data type of filter coefficients

`numericType(1,16)` (default) | `numericType` object

Data type of the filter coefficients, specified as a signed `numericType` object. The default data type is a signed, 16-bit `numericType` object. You must specify a `numericType` object without specific binary-point scaling. To maximize precision, the object determines the fraction length of this data type based on the coefficient values.

FractionalDelayDataType — Data type of fractional delay

`numericType(0,8)` (default) | `numericType` object

Data type of the fractional delay, specified as an unsigned `numericType` object. The default data type is an unsigned, 8-bit `numericType` object. You must specify a `numericType` object without specific binary-point scaling. To maximize precision, the object determines the fraction length of this data type based on the fractional delay values.

MultiplicandDataType — Data type of multiplicand

`numericType(1,16,13)` (default) | `numericType` object

Data type of the multiplicand, specified as a signed `numericType` object. The default data type is a signed 16-bit `numericType` object with 13-bit fraction length. You must specify a `numericType` object that has a specific binary point scaling.

OutputDataType — Data type of output

'Same word length as input' (default) | 'Same as accumulator' | `numericType` object

Data type of the output, specified as one of the following:

- 'Same word length as input' — Output word length and fraction length are the same as the input.
- 'Same as accumulator' — Output word length and fraction length are the same as the accumulator.
- `numericType` object — Signed fixed-point output data type. If you do not specify a fraction length, the object computes the fraction length based on the input range. The object preserves the dynamic range of the input.

Usage

Syntax

```
y = frc(x)
```

Description

`y = frc(x)` resamples input `x` to create output `y` according to the rate conversion defined by `frc`.

Input Arguments

x — Input signal

vector | matrix

Input signal, specified as a vector or a matrix. Each column of the input is treated as a separate channel.

Output Arguments

y — Resampled signal

vector | matrix

Resampled signal, returned as a vector or matrix.

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Specific to dsp.FarrowRateConverter

<code>getPolynomialCoefficients</code>	Get polynomial coefficients of farrow rate conversion filter
<code>getActualOutputRate</code>	Get actual output rate
<code>getRateChangeFactors</code>	Get overall interpolation and decimation factors
<code>generatehdl</code>	Generate HDL code for quantized DSP filter (requires Filter Design HDL Coder)

Filter Analysis

<code>freqz</code>	Frequency response of discrete-time filter System object
<code>fvtool</code>	Visualize frequency response of DSP filters
<code>info</code>	Information about filter System object
<code>cost</code>	Estimate cost of implementing filter System object

Common to All System Objects

<code>step</code>	Run System object algorithm
<code>release</code>	Release resources and allow changes to System object property values and input characteristics
<code>reset</code>	Reset internal states of System object

Examples

Upsample an Audio Signal Using dsp.FarrowRateConverter

Note: If you are using R2016a or an earlier release, replace each call to the object with the equivalent `step` syntax. For example, `obj(x)` becomes `step(obj,x)`.

Note: The `dsp.AudioFileWriter` System object™ is not supported in MATLAB Online.

Create a `dsp.FarrowRateConverter` System object™ to convert an audio signal from 44.1 kHz to 96 kHz. Set the polynomial order for the filter.

```
fs1 = 44.1e3;
fs2 = 96e3;
```

```

LagrangeOrder = 2; % 1 = linear interpolation
frc = dsp.FarrowRateConverter('InputSampleRate',fs1,...
                             'OutputSampleRate',fs2,...
                             'PolynomialOrder',LagrangeOrder);
ar = dsp.AudioFileReader('guitar10min.ogg','SamplesPerFrame',14700);
aw = dsp.AudioFileWriter('guitar10min_96kHz.wav','SampleRate',fs2);

```

Check the resulting interpolation and decimation factors.

```
[interp,decim] = getRateChangeFactors(frc)
```

```
interp = 320
```

```
decim = 147
```

Display the polynomial that the object uses to fit the input samples.

```
coeffs = getPolynomialCoefficients(frc)
```

```
coeffs = 3×3
```

```

    0.5000    -0.5000         0
   -1.0000         0    1.0000
    0.5000     0.5000         0

```

Convert 100 frames of the audio signal. Write the result to a file.

```

for n = 1:1:100
    x = ar();
    y = frc(x);
    aw(y);
end

```

Release the AudioFileWriter System object™ to complete creation of the output file.

```

release(aw)
release(ar)

```

Plot the input and output signals of the 100th frame of data. Delay the input to compensate for the latency of the filter.

```

t1 = 0:1/fs1:1/30-1/fs1;
t2 = 0:1/fs2:1/30-1/fs2;

```

```

delay = ceil((LagrangeOrder+1)/2)/fs1;
e11 = 1:length(t1)-delay;
e12 = 1:length(t2);
e12(1:delay) = [];

```

```
figure
```

```

subplot(2,1,1)
plot(t1(1:length(e11)),x(e11,1))
hold on
plot(t1(1:length(e11)),x(e11,2))
xlabel('Time (s)')
title('Input Channels')

```

```

subplot(2,1,2)
plot(t2(1:length(e12)),y(e12,1))
hold on
plot(t2(1:length(e12)),y(e12,2))
xlabel('Time (s)')
title('Output Channels')

```

Zoom in to see the difference in sample rates.

figure

```

subplot(2,1,1)
plot(t1(1:length(e11)),x(e11,1),'o-')
hold on
plot(t2(1:length(e12)),y(e12,1),'d--')
xlim([0.0104 0.0107])
title('First Channel')
xlabel('Time (s)')
legend('Input','Output')

```

```

subplot(2,1,2)
plot(t1(1:length(e11)),x(e11,2),'o-')
hold on
plot(t2(1:length(e12)),y(e12,2),'d--')
xlim([0.0104 0.0107])
xlabel('Time (s)')
title('Second Channel')
legend('Input','Output')

```

Reduce Input Size Restriction by Adjusting Tolerance

Create a `dsp.FarrowRateConverter` System object™ with 0% tolerance. The output rate is equal to the `OutputSampleRate` property. The input size must be a multiple of the decimation factor, `M`. In this case `M` is 320.

```
frc = dsp.FarrowRateConverter('InputSampleRate',96e3,...
    'OutputSampleRate',44.1e3);
FsOut = getActualOutputRate(frc)

FsOut = 44100

[L,M] = getRateChangeFactors(frc)

L = 147
M = 320
```

Allow a 1% tolerance on the output rate and observe the difference in decimation factor.

```
frc.OutputRateTolerance = 0.01;
FsOut2 = getActualOutputRate(frc)

FsOut2 = 4.4308e+04

[L2,M2] = getRateChangeFactors(frc)
```

L2 = 6

M2 = 13

The decimation factor is now only 13. The lower the decimation factor, the more flexibility in input size. The output rate is within the range $\text{OutputSampleRate} \pm 1\%$.

Frequency Response of dsp.FarrowRateConverter

Create a dsp.FarrowRateConverter System object™ with default properties. Compute and display the frequency response.

```
frc = dsp.FarrowRateConverter;
[h,f] = freqz(frc);
plot(f,20*log10(abs(h)))
ylabel('Filter Response')
xlabel('Frequency (rad/s)')
```

Determine Computational Cost of dsp.FarrowRateConverter

Create a dsp.FarrowRateConverter System object™ with default values. Determine its computational cost: the number of coefficients, number of states, multiplications per input sample, and additions per input sample.

```
frc = dsp.FarrowRateConverter;
cst = cost(frc)
```

```
cst = struct with fields:
    NumCoefficients: 16
    NumStates: 3
    MultiplicationsPerInputSample: 13.0612
    AdditionsPerInputSample: 11.9728
```

Repeat the computation, allowing for a 10% tolerance in the output sample rate.

```
frc.OutputRateTolerance = 0.1;
ctl = cost(frc)

ctl = struct with fields:
    NumCoefficients: 16
    NumStates: 3
    MultiplicationsPerInputSample: 12
    AdditionsPerInputSample: 11
```

Algorithms

Farrow filters implement piecewise polynomial interpolation using Horner's rule to compute samples from the polynomial. The polynomial coefficients used to fit the input samples correspond to the Lagrange interpolation coefficients.

Once a polynomial is fitted to the input data, the value of the polynomial can be calculated at any point. Therefore, a polynomial filter enables interpolation at arbitrary locations between input samples.

You can use a polynomial of any order to fit to the existing samples. However, since large-order polynomials frequently oscillate, polynomials of order 1, 2, 3, or 4 are used in practice.

The block computes interpolated values at the desired locations by varying only the fractional delay, μ . This value is the interval between the previous input sample and the current output sample. All filter coefficients remain constant.

- The input samples are filtered using $M + 1$ FIR filters, where M is the polynomial order.
- The outputs of these filters are multiplied by the fractional delay, μ .
- The output is the sum of the multiplication results.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

See "System Objects in MATLAB Code Generation" (MATLAB Coder).

The `getRateChangeFactors` function supports C and C++ code generation.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

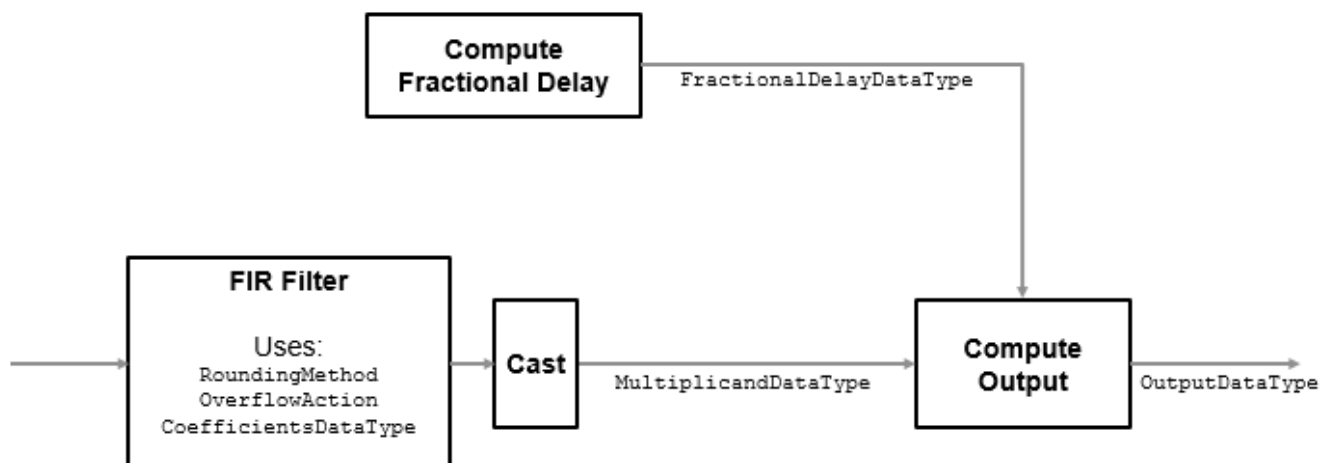

This object supports HDL code generation with the Filter Design HDL Coder product. For workflows and limitations, see “Generate HDL Code for Filter System Objects” (Filter Design HDL Coder).

Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

If the input is fixed point, it must be signed integer or signed fixed point with power-of-two slope and zero bias.

The diagram shows the data types that the `dsp.FarrowRateConverter` object uses for fixed-point signals and floating-point signals. You can specify these data types using the properties of the object, see “Fixed-Point Properties” on page 4-0 . If the input is floating point, all data types in filter are the same as the input data type, `single` or `double`.

If the input is fixed point, the FIR filter defines internal data types using the `RoundingMode`, `OverflowMode`, and `CoefficientsDataType` properties. The accumulators and products within the FIR filter use full precision data types. The object casts the output of the FIR filter to `MultiplicandDataType`.

dsp.FastTransversalFilter

Package: dsp

Fast transversal least-squares FIR adaptive filter

Description

The `dsp.FastTransversalFilter` computes output, error and coefficients using a fast transversal least-squares FIR adaptive filter.

To implement the adaptive FIR filter object:

- 1 Create the `dsp.FastTransversalFilter` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

Creation

Syntax

```
ftf = dsp.FastTransversalFilter
ftf = dsp.FastTransversalFilter(len)
ftf = dsp.FastTransversalFilter(Name,Value)
```

Description

`ftf = dsp.FastTransversalFilter` returns a System object, `ftf`, which is a fast transversal, least-squares FIR adaptive filter. This System object computes the filtered output and the filter error for a given input and desired signal.

`ftf = dsp.FastTransversalFilter(len)` returns a `dsp.FastTrasversalFilter` System object with the `Length` property set to `len`.

`ftf = dsp.FastTransversalFilter(Name,Value)` returns a `dsp.FastTransversalFilter` System object with each specified property set to the specified value.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see [System Design in MATLAB Using System Objects](#).

Method — Method to calculate filter coefficients

'Fast transversal least-squares' (default) | 'Sliding-window fast transversal least-squares'

Specify the method used to calculate filter coefficients as either 'Fast transversal least-squares' or 'Sliding-window fast transversal least-squares'. For algorithms used to implement these two different methods, refer to [1]. This property is nontunable.

Length — Length of filter coefficients vector

32 (default) | positive integer

Specify the length of the FIR filter coefficients vector as a positive integer value.

Data Types: double

SlidingWindowBlockLength — Width of sliding window

32 (default) | positive integer

Specify the width of the sliding window as a positive integer value greater than or equal to the Length property value. The default value is the value of the Length property.

Dependencies

This property applies only if the Method property is set to 'Sliding-window fast transversal least-squares'.

Data Types: double

ForgettingFactor — Fast transversal filter forgetting factor

1 (default) | positive scalar

Specify the fast transversal filter forgetting factor as a positive scalar in the range (0,1]. Setting this value to 1 denotes infinite memory while filter adaptation. Setting this property value to 1 denotes infinite memory while adapting to find the new filter. For best results, set this property to a value that lies in the range $[1 - 0.5/L, 1]$, where L is the Length property value.

Tunable: Yes

Dependencies

This property applies only if the Method property is set to 'Fast transversal least-squares'.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | logical

InitialPredictionErrorPower — Initial prediction error power

10 (default) | positive scalar

Specify the initial value of the forward and backward prediction error vectors as a positive numeric scalar. This scalar should be sufficiently large to maintain stability and prevent an excessive number of Kalman gain rescues.

Tunable: Yes

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

InitialConversionFactor — Initial conversion factor (gamma)

1 (default) | scalar | 2-element row vector

Specify the initial value of the conversion factor of the fast transversal filter.

The value of this property depends on the `Method` property. If `Method` is set to:

- 'Fast transversal least-squares' -- This property must be a positive numeric value less than or equal to 1
- 'Sliding-window fast transversal least-squares' -- This property must be a two-element numeric vector. The first element of this vector must lie within the range $[0, 1]$, and the second element must be less than or equal to -1. In this case, the default value is $[1, -1]$.

Tunable: Yes

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical`

InitialCoefficients — Initial coefficients of filter

0 (default) | scalar | vector

Specify the initial values of the FIR adaptive filter coefficients as a scalar or a vector of length equal to the value of the `Length` property.

Tunable: Yes

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

LockCoefficients — Locked status of coefficient updates

false (default) | true

Specify whether to lock the filter coefficient values. By default, the value of this property is `false`, and the object continuously updates the filter coefficients. If this property is set to `true`, the filter coefficients do not update, and their values remain the same.

Tunable: Yes

Usage

Syntax

```
[y,err] = ftf(x,d)
```

Description

`[y,err] = ftf(x,d)` filters the input `x`, using `d` as the desired signal, and returns the filtered output in `y` and the filter error in `err`. The System object estimates the filter weights needed to minimize the error between the output signal and the desired signal.

Input Arguments

x — Data input

scalar | column vector

The signal to be filtered by the fast transversal filter. The input, `x`, and the desired signal, `d` must have the same size and data type.

The data input can be a variable-size signal. You can change the number of elements in the column vector even when the object is locked. The System object locks when you call the object to run its algorithm.

Data Types: `single` | `double`

d — Desired signal

scalar | column vector

The fast transversal filter adapts its filter weights, `wts`, to minimize the error, `err`, and converge the input signal `x` to the desired signal `d` as closely as possible. You can access the current filter weights by calling `ftf.Coefficients`, where `ftf` is the fast transversal filter object.

The input and the desired signal must have the same size and data type.

The desired signal can be a variable-size signal. You can change the number of elements in the column vector even when the object is locked. The System object locks when you call the object to run its algorithm.

Data Types: `single` | `double`

Output Arguments

y — Filtered output

scalar | column vector

Filtered output, returned as a scalar or a column vector. The object adapts its filter weights to converge the input signal `x` to match the desired signal `d`. The filter outputs the converged signal.

Data Types: `single` | `double`

err — Difference between output and desired signal

scalar | column vector

Difference between the output signal `y` and the desired signal `d`, returned as a scalar or a column vector. The data type of `err` matches the data type of `y`. The objective of the adaptive filter is to minimize this error. The object adapts its weights to converge toward optimal filter weights that produce an output signal that matches closely with the desired signal.

Data Types: `single` | `double`

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Specific to `dsp.FastTransversalFilter`

`mseSim` Estimated mean squared error for adaptive filters

Common to All System Objects

`step` Run System object algorithm

release Release resources and allow changes to System object property values and input characteristics
 reset Reset internal states of System object

Examples

System Identification of FIR Filter Using Fast Transversal Filter

System identification is the process of identifying the coefficients of an unknown system using an adaptive filter. The general overview of the process is shown in “System Identification -- Using an Adaptive Filter to Identify an Unknown System”. The main components involved are:

- The adaptive filter algorithm.
- An unknown system or process to adapt to. In this example, the filter designed by `fir1` is the unknown system.
- Appropriate input data to exercise the adaptation process. In a generic system identification model, the desired signal $d(k)$ and the input signal $x(k)$ are used to exercise the adaptation process.

The objective of the adaptive filter is to minimize the error signal between the output of the adaptive filter $y(k)$ and the output of the unknown system (or the system to be identified) $d(k)$. Once the error signal is minimized, the adapted filter resembles the unknown system. The coefficients of both the filters match closely.

Note: If you are using R2016a or earlier, replace each call to the object with the equivalent `step` syntax. For example, `obj(x)` becomes `step(obj,x)`.

Unknown System

Create a `dsp.FIRFilter` object that represents the system to be identified. Use the `fir1` function to design the filter coefficients. The designed filter is a 10th order lowpass digital filter with a cutoff frequency of 0.25.

```
filt = dsp.FIRFilter;
filt.Numerator = fir1(10,.25)

filt =
  dsp.FIRFilter with properties:
      Structure: 'Direct form'
  NumeratorSource: 'Property'
      Numerator: [-0.0039 1.7585e-18 0.0321 0.1167 0.2207 0.2687 ... ]
  InitialConditions: 0

  Show all properties
```

Pass the signal x to the FIR filter. The desired signal d is the sum of the output of the unknown system (FIR filter) and an additive noise signal n .

```
x = randn(1000,1);
d = filt(x) + 0.01*randn(1000,1);
```

Adaptive Filter

With the unknown filter designed and the desired signal in place, create and apply the fast transversal filter object to identify the unknown filter.

Create a `dsp.FastTransversalFilter` object to represent an adaptive filter. Set the length of the adaptive filter to 11 taps and a forgetting factor of 0.99.

```
ftf1 = dsp.FastTransversalFilter(11,...
    'ForgettingFactor',0.99)

ftf1 =
    dsp.FastTransversalFilter with properties:

                Method: 'Fast transversal least-squares'
                Length: 11
    ForgettingFactor: 0.9900
InitialPredictionErrorPower: 10
    InitialCoefficients: 0
    InitialConversionFactor: 1
    LockCoefficients: false
```

Pass the primary input signal `x` and the desired signal `d` to the fast transversal filter. Run the adaptive filter to determine the unknown system. The output `y` of the adaptive filter is the signal converged to the desired signal `d`, thereby minimizing the error `e` between the two signals.

```
[y,e] = ftf1(x,d);
w = ftf1.Coefficients

w = 1×11

    -0.0043    0.0016    0.0308    0.1171    0.2204    0.2677    0.2210    0.1181    0.0323    0.0000
```

Plot the results. The output signal matches the desired signal very closely making the error between the two close to zero.

```
subplot(2,1,1);
plot(1:1000,[d,y,e])
title('System Identification of an FIR filter');
legend('Desired','Output','Error');
xlabel('time index');
ylabel('signal value');
```

The coefficients of the FIR filter match very closely with the coefficients of the adapted filter, thereby confirming the convergence.

```
subplot(2,1,2);
stem([filt.Numerator; w].');
legend('Actual','Estimated');
xlabel('coefficient #');
ylabel('coefficient value');
```

Introduced in R2013b

dsp.FFT

Package: dsp

Discrete Fourier transform

Description

The `dsp.FFT` System object computes the discrete Fourier transform (DFT) of an input using fast Fourier transform (FFT). The object uses one or more of the following fast Fourier transform (FFT) algorithms depending on the complexity of the input and whether the output is in linear or bit-reversed order:

- Double-signal algorithm
- Half-length algorithm
- Radix-2 decimation-in-time (DIT) algorithm
- Radix-2 decimation-in-frequency (DIF) algorithm
- An algorithm chosen from FFTW [1] , [2]

To compute the DFT of an input:

- 1 Create the `dsp.FFT` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

Creation

Syntax

```
ft = dsp.FFT  
ft = dsp.FFT(Name,Value)
```

Description

`ft = dsp.FFT` returns a FFT object, `ft`, that computes the DFT of an N -D array. For column vectors or multidimensional arrays, the FFT object computes the DFT along the first dimension. If the input is a row vector, the FFT object computes a row of single-sample DFTs and issues a warning.

`ft = dsp.FFT(Name,Value)` returns a FFT object with each specified property set to the specified value. Enclose each property name in single quotes. Unspecified properties have default values.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects.

FFTImplementation — FFT implementation

Auto (default) | Radix-2 | FFTW

Specify the implementation used for the FFT as one of Auto, Radix-2, or FFTW. When you set this property to Radix-2, the FFT length must be a power of two.

BitReversedOutput — Order of output elements relative to input elements

false (default) | true

Designate order of output channel elements relative to order of input elements. Set this property to true to output the frequency indices in bit-reversed order. The default is false, which corresponds to a linear ordering of frequency indices.

Normalize — Divide butterfly outputs by two

false (default) | true

Set this property to true if the output of the FFT should be divided by the FFT length. This option is useful when you want the output of the FFT to stay in the same amplitude range as its input. This is particularly useful when working with fixed-point data types.

The default value of this property is false with no scaling.

FFTLengthSource — Source of FFT length

Auto (default) | Property

Specify how to determine the FFT length as Auto or Property. When you set this property to Auto, the FFT length equals the number of rows of the input signal.

FFTLength — FFT length

64 (default) | integer

FFT length, specified as an integer greater than or equal to 2.

This property must be a power of two if any of these conditions apply:

- The input is a fixed-point data type.
- The BitReversedOutput property is true.
- The FFTImplementation property is Radix-2.

Dependencies

This property applies when you set the FFTLengthSource property to Property.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

WrapInput — Boolean value of wrapping or truncating input

true (default) | false

Wrap input data when FFT length is shorter than input length. If this property is set to true, modulo-length data wrapping occurs before the FFT operation, given FFT length is shorter than the input length. If this property is set to false, truncation of the input data to the FFT length occurs before the FFT operation.

Fixed-Point Properties**RoundingMethod — Rounding method for fixed-point operations**

Floor (default) | Ceiling | Convergent | Nearest | Round | Simplest | Zero

Specify the rounding method.

OverflowAction — Overflow action for fixed-point operations

Wrap (default) | Saturate

Specify the overflow action as Wrap or Saturate.

SineTableDataType — Sine table word and fraction lengths

Same word length as input (default) | Custom

Specify the sine table data type as Same word length as input or Custom.

CustomSineTableDataType — Sine table word and fraction lengths

numerictype([],16) (default) | numerictype

Specify the sine table fixed-point type as an unscaled numerictype object with a Signedness of Auto.

Dependencies

This property applies when you set the SineTableDataType property to Custom.

ProductDataType — Product word and fraction lengths

Full precision (default) | Same as input | Custom

Specify the product data type as Full precision, Same as input, or Custom.

CustomProductDataType — Product word and fraction lengths

numerictype([],32,30) (default) | numerictype

Specify the product fixed-point type as a scaled numerictype object with a Signedness of Auto.

Dependencies

This property applies when you set the ProductDataType property to Custom.

AccumulatorDataType — Accumulator word and fraction lengths

Full precision (default) | Same as input | Same as product | Custom

Specify the accumulator data type as Full precision, Same as input, Same as product, or Custom.

CustomAccumulatorDataType — Accumulator word and fraction lengths

numerictype([],32,30) (default) | numerictype

Specify the accumulator fixed-point type as a scaled numerictype object with a Signedness of Auto.

Dependencies

This property applies when you set the AccumulatorDataType property to Custom.

OutputDataType — Output word and fraction lengths

Full precision (default) | Same as input | Custom

Specify the output data type as one of Full precision, Same as input, Custom.

CustomOutputDataType — Output word and fraction lengths

numericitytype([],16,15) (default) | numericitytype

Specify the output fixed-point type as a scaled numericitytype object with a Signedness of Auto.

Dependencies

This property applies when you set the “OutputDataType” on page 4-0 property to Custom.

Usage**Syntax**

$$y = \text{ft}(x)$$
Description

$y = \text{ft}(x)$ computes the DFT, y , of the input x along the first dimension of x .

Input Arguments**x — Time-domain input signal**vector | matrix | N -D array

Time-domain input signal, specified as a vector, matrix, or N -D array.

When the FFTLengthSource property is set to 'Auto', the length of x along the first dimension must be a positive integer power of two. This length is also the FFT length. When the FFTLengthSource property is 'Property', the value you specify in FFTLength property must be a positive integer power of two.

Variable-size input signals are only supported when the FFTLengthSource property is set to 'Auto'.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fi

Output Arguments**y — Discrete Fourier transform of input signal**vector | matrix | N -D array

Discrete Fourier transform of input signal, returned as a vector, matrix, or an N -D array. When FFTLengthSource property is set to 'Auto', the FFT length is same as the number of rows in the input signal. When FFTLengthSource property is set to 'Property', the FFT length is specified through the FFTLength property.

To support non-power-of-two transform lengths with variable-size data, set the FFTImplementation property to 'FFTW'.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fi`

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Common to All System Objects

<code>step</code>	Run System object algorithm
<code>release</code>	Release resources and allow changes to System object property values and input characteristics
<code>reset</code>	Reset internal states of System object

Examples

Single-Sided Amplitude Spectrum of Signal

Find frequency components of a signal in additive noise.

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, `myObject(x)` becomes `step(myObject,x)`.

```
Fs = 800; L = 1000;  
t = (0:L-1)/Fs;  
x = sin(2*pi*250*t) + 0.75*cos(2*pi*340*t);  
y = x + .5*randn(size(x)); % noisy signal  
ft = dsp.FFT('FFTLengthSource','Property', ...  
            'FFTLength',1024);  
Y = ft(y);
```

Plot the single-sided amplitude spectrum

```
plot(Fs/2*linspace(0,1,512), 2*abs(Y(1:512)/1024))  
title('Single-sided amplitude spectrum of noisy signal y(t)')  
xlabel('Frequency (Hz)'); ylabel('|Y(f)|')
```

Construct a Sinusoidal Signal Using High Energy FFT Coefficients

Compute the FFT of a noisy sinusoidal input signal. The energy of the signal is stored as the magnitude square of the FFT coefficients. Determine the FFT coefficients which occupy 99.99% of the signal energy and reconstruct the time-domain signal by taking the IFFT of these coefficients. Compare the reconstructed signal with the original signal.

Note: If you are using R2016a or an earlier release, replace each call to the object with the equivalent `step` syntax. For example, `obj(x)` becomes `step(obj(x))`.

Consider a time-domain signal $x[n]$, which is defined over the finite time interval $0 \leq n \leq N - 1$. The energy of the signal $x[n]$ is given by the following equation:

$$E_N = \sum_{n=0}^{N-1} |x[n]|^2$$

FFT coefficients, $X[k]$, are considered signal values in the frequency domain. The energy of the signal $x[n]$ in the frequency-domain is therefore the sum of the squares of the magnitude of the FFT coefficients:

$$E_N = \frac{1}{N} \sum_{k=0}^{N-1} |X[k]|^2$$

According to Parseval's theorem, the total energy of the signal in time or frequency-domain is the same.

$$E_N = \sum_{n=0}^{N-1} |x[n]|^2 = \frac{1}{N} \sum_{k=0}^{N-1} |X[k]|^2$$

Initialization

Initialize a `dsp.SineWave` System object to generate a sine wave sampled at 44.1 kHz and has a frequency of 1000 Hz. Construct a `dsp.FFT` and `dsp.IFFT` objects to compute the FFT and the IFFT of the input signal.

The `'FFTLenghSource'` property of each of these transform objects is set to `'Auto'`. The FFT length is hence considered as the input frame size. The input frame size in this example is 1020, which is not a power of 2, so select the `'FFTImplementation'` as `'FFTW'`.

```
L = 1020;
Sineobject = dsp.SineWave('SamplesPerFrame',L,...
    'PhaseOffset',10,...
    'SampleRate',44100,...
    'Frequency',1000);
ft = dsp.FFT('FFTImplementation','FFTW');
ift = dsp.IFFT('FFTImplementation','FFTW',...
    'ConjugateSymmetricInput',true);
rng(1);
```

Streaming

Stream in the noisy input signal. Compute the FFT of each frame and determine the coefficients that constitute 99.99% energy of the signal. Take IFFT of these coefficients to reconstruct the time-domain signal.

```
numIter = 1000;
for Iter = 1:numIter
    Sinewave1 = Sineobject();
    Input = Sinewave1 + 0.01*randn(size(Sinewave1));
    FFTCoeff = ft(Input);
    FFTCoeffMagSq = abs(FFTCoeff).^2;

    EnergyFreqDomain = (1/L)*sum(FFTCoeffMagSq);
    [FFTCoeffSorted, ind] = sort((1/L)*FFTCoeffMagSq), ...
        1, 'descend');

    CumFFTCoeffs = cumsum(FFTCoeffSorted);
    EnergyPercent = (CumFFTCoeffs/EnergyFreqDomain)*100;
    Vec = find(EnergyPercent > 99.99);
    FFTCoeffsModified = zeros(L,1);
    FFTCoeffsModified(ind(1:Vec(1))) = FFTCoeff(ind(1:Vec(1)));
    ReconstrSignal = ift(FFTCoeffsModified);
end
```

99.99% of the signal energy can be represented by the number of FFT coefficients given by `Vec(1)`:

```
Vec(1)
ans = 296
```

The signal is reconstructed efficiently using these coefficients. If you compare the last frame of the reconstructed signal with the original time-domain signal, you can see that the difference is very small and the plots match closely.

```
max(abs(Input-ReconstrSignal))
```

```
ans = 0.0431
```

```
plot(Input, '*');
hold on;
plot(ReconstrSignal, 'o');
hold off;
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the FFT block reference page. The object properties correspond to the block parameters.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- “System Objects in MATLAB Code Generation” (MATLAB Coder).
- When the following conditions apply, the executable generated from this System object relies on prebuilt dynamic library files (.dll files) included with MATLAB:
 - `FFTImplementation` is set to 'FFTW'.
 - `FFTImplementation` is set to 'Auto', `FFTLengthSource` is set to 'Property', and `FFTLength` is not a power of two.

Use the `packNGo` function to package the code generated from this System object and all the relevant files in a compressed zip file. Using this zip file, you can relocate, unpack, and rebuild your project in another development environment where MATLAB is not installed. For more details, see “How To Run a Generated Executable Outside MATLAB”.

- When the FFT length is a power of two, you can generate standalone C and C++ code from this System object.

Objects

`dsp.IFFT`

Introduced in R2012a

dsp.FilterCascade

Package: dsp

Create cascade of filter System objects

Description

The `dsp.FilterCascade` object creates a multistage System object that enables cascading of filter System objects, delays, and scalar gains. This object operates similar to the `cascade` function. However, the `cascade` function does not support delay as a filter stage.

You can pass the `dsp.FilterCascade` System object as a stage to another `dsp.FilterCascade` System object. You can also pass `dsp.FilterCascade` System object as an input to the `cascade` function.

When you call the object, the size, data type, and complexity of the input signal must be supported by all of the stages in the filter cascade. This object supports variable-size signals if the filter stages within the object support variable-size signals.

To filter a signal with a cascade of filters:

- 1 Create the `dsp.FilterCascade` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

Alternatively, you can generate a MATLAB function from the filter cascade object, and call that function to filter a signal. The generated function supports C/C++ code generation. For more details, see the `generateFilteringCode` function.

Creation

Syntax

```
FC = dsp.FilterCascade
FC = dsp.FilterCascade(filt1, filt2, ..., filtn)
```

Description

`FC = dsp.FilterCascade` returns a System object, `FC` that has a single stage, a `dsp.FIRFilter` System object with default properties.

`FC = dsp.FilterCascade(filt1, filt2, ..., filtn)` returns a multistage System object, `FC`, with the first stage set to `filt1`, the second stage set to `filt2`, and so on. Each stage can be a filter System object, a `dsp.FilterCascade` System object, a `dsp.Delay` System object, or a scalar gain value.

For example, create a filter cascade that includes a lowpass filter, a highpass filter, and a gain stage.

```
lpFilt = dsp.LowpassFilter('StopbandFrequency',15000,...  
                           'PassbandFrequency',12000);  
hpFilt = dsp.HighpassFilter('StopbandFrequency',5000,...  
                            'PassbandFrequency',8000);  
gain = 2;  
bpFilt = dsp.FilterCascade(lpFilt, hpFilt, 2);
```

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see [System Design in MATLAB Using System Objects](#).

Stage*i* — Filter stage

`dsp.FIRFilter` System object with default properties (default) | filter System object | delay System object | scalar gain value

Filter stage, specified as a filter System object, delay System object, or a scalar gain value. To see which System objects you can add to a filter cascade, use:

```
dsp.FilterCascade.helpSupportedSystemObjects
```

You can modify an existing stage by modifying the associated property. For example:

```
FC = dsp.FilterCascade(dsp.FIRFilter,5)
```

```
FC =
```

```
    dsp.FilterCascade with properties:
```

```
    Stage1: [1×1 dsp.FIRFilter]  
    Stage2: 5
```

```
K>> FC.Stage2 = dsp.FIRDecimator
```

```
FC =
```

```
    dsp.FilterCascade with properties:
```

```
    Stage1: [1×1 dsp.FIRFilter]  
    Stage2: [1×1 dsp.FIRDecimator]
```

To change the number of stages in a cascade, use the `addStage` and `removeStage` functions.

Usage

Syntax

```
y = FC(x)
```

Description

$y = FC(x)$ filters input signal x by using the filter cascade defined in FC and returns filtered output y . The size, data type, and complexity of the input signal must be supported by all of the stages in the filter cascade. This object supports variable-size signals if the filter stages within the object support variable-size signals.

Input Arguments

x — Data input

vector | matrix

Data input, specified as a vector or a matrix. When the input is a matrix, each column of the matrix represents an independent data channel.

Data Types: `single` | `double`

Output Arguments

y — Filtered output data

vector | matrix

Filtered output data, returned as a vector or a matrix. The size, data type, and complexity of the output signal matches that of the input signal.

Data Types: `double` | `single`

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Specific to `dsp.FilterCascade`

<code>addStage</code>	Add filter stage to cascade
<code>generateFilteringCode</code>	Generate MATLAB code for a filter cascade
<code>getNumStages</code>	Get number of stages in filter cascade
<code>releaseStages</code>	Release locked state of all stages in cascade
<code>removeStage</code>	Remove stage from filter cascade

Common to All System Objects

<code>step</code>	Run System object algorithm
<code>release</code>	Release resources and allow changes to System object property values and input characteristics
<code>reset</code>	Reset internal states of System object

Examples

Filter Signal Using Cascaded Lowpass and Highpass Filters

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, `myObject(x)` becomes `step(myObject,x)`.

Design a bandpass filter by cascading:

- A highpass filter with a stopband frequency of 5000 Hz and a passband frequency of 8000 Hz
- A lowpass filter with a passband frequency of 12,000 Hz and a stopband frequency of 15,000 Hz

Visualize the frequency response using `fvtool`.

```
lpFilt = dsp.LowpassFilter('StopbandFrequency',15000,...
    'PassbandFrequency',12000);
hpFilt = dsp.HighpassFilter('StopbandFrequency',5000,...
    'PassbandFrequency',8000);

bpFilt = dsp.FilterCascade(lpFilt,hpFilt);

fvtool(bpFilt);
legend('Bandpass filter');
```

Pass a noisy sine wave as the input to the bandpass filter. The input is a sum of three sine waves with frequencies at 3 kHz, 10 kHz, and 15 kHz. The sampling frequency is 48 kHz. View the input and the filtered output on a spectrum analyzer.

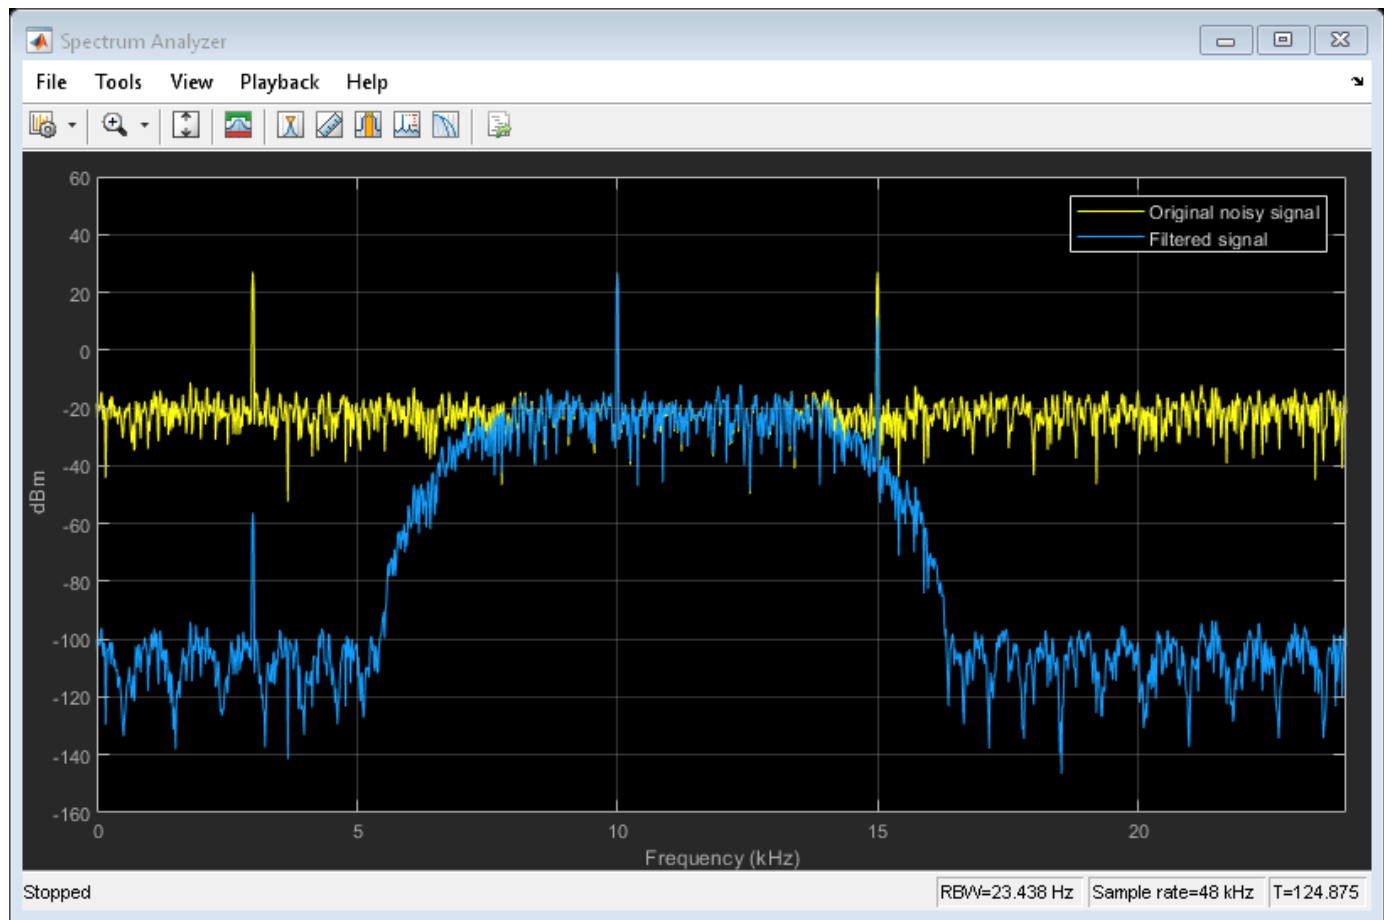

The tones at 3 kHz and 15 kHz are attenuated, and the tone at 10 kHz is preserved by the bandpass filter.

```
Sine1 = dsp.SinWave('Frequency',3e3,...
    'SampleRate',48e3,...
    'SamplesPerFrame',6000);
Sine2 = dsp.SinWave('Frequency',10e3,...
    'SampleRate',48e3,...
    'SamplesPerFrame',6000);
Sine3 = dsp.SinWave('Frequency',15e3,...
    'SampleRate',48e3,...
    'SamplesPerFrame',6000);

SpecAna = dsp.SpectrumAnalyzer(...
    'PlotAsTwoSidedSpectrum',false,...
    'SampleRate',Sine1.SampleRate, ...
    'NumInputPorts',2,...
    'ShowLegend',true, ...
    'YLimits',[-160,60]);

SpecAna.ChannelNames = {'Original noisy signal','Filtered signal'};

for i = 1:1000
    x = Sine1()+Sine2()+Sine3()+0.1.*randn(Sine1.SamplesPerFrame,1);
    y = bpFilt(x);
    SpecAna(x,y);
end
release(SpecAna)
```

Design Compensation Decimator for CIC Decimator

Create a CIC decimator. Cascade the decimator with a gain.

```
cicdecim = dsp.CICDecimator(...
    'DecimationFactor',6,...
    'NumSections',6);
decimcasc = dsp.FilterCascade(cicdecim,...
    1/gain(cicdecim));
```

Design a compensation decimator and cascade it with the filter cascade, `decimcasc`. This operation nests a `dsp.FilterCascade` object as a stage in another filter cascade. The CIC compensation decimator has an inherent gain, `gain(cicdecim)`. The factor of `1/gain(cicdecim)` from the decimation filter cascade, `decimcasc`, compensates for the compensation filter gain.

```
% Sample rate of input of compensation decimator
fs = 16e3;
% Passband frequency
fPass = 4e3;
% Stopband frequency
fStop = 4.5e3;
ciccomp = dsp.CICCompensationDecimator(cicdecim,...
    'DecimationFactor',2, ...
```

```

    'PassbandFrequency', fPass, ...
    'StopbandFrequency', fStop, ...
    'SampleRate', fs);
filtchain = dsp.FilterCascade(decimcasc,ciccomp);

```

Visualize the frequency response of the cascade of cascades.

```

f = fvtool(decimcasc,ciccomp,...
    filtchain,'Fs',[fs*6,fs,fs*6],...
    'Arithmetic','fixed');
legend(f,'CIC Decimator',...
    'CIC Compensation Decimator',...
    'Overall Response');

```

Generate Code to Filter Using Cascade

Design a two-stage decimator with a 100-Hz transition width, a 2-kHz sampling frequency, and 60-dB attenuation in the stopband. The decimator needs to downsample by a factor of 4.

```

decimSpec = fdesign.decimator(4,'Nyquist',...
    4,'Tw,Ast',...
    100,60,2000);
filtCasc = design(decimSpec,'multistage',...
    'SystemObject',true);

```

Verify your design by using `fvtool`.

```
info(filtCasc)
```

```
ans =

```

Generate code to filter data using this design. You cannot generate C/C++ code from the `dsp.FilterCascade` object directly, but you can generate C/C++ code from the generated function. The function defines the filter stages and calls them in sequence. The function is saved in a file called `myDecimator.m` in the current directory.

```
generateFilteringCode(filtCasc, 'myDecimator');
```

The `myDecimator` function creates a filter cascade and calls each stage object in turn.

```
type myDecimator
```

```
function y = myDecimator(x)
%MYDECIMATOR Construct filter cascade and process each stage
```

```

Functions

`cascade`

Introduced in R2014b

addStage

Package: dsp

Add filter stage to cascade

Syntax

```
addStage(FC,newFilt)
addStage(FC,newFilt,stageId)
```

Description

`addStage(FC,newFilt)` adds a filter stage represented by the `newFilt` System object as the final stage of the `dsp.FilterCascade` System object, `FC`. To see which System objects you can add to a filter cascade, use:

```
dsp.FilterCascade.helpSupportedSystemObjects
```

`addStage(FC,newFilt,stageId)` adds `newFilt` at stage position `stageId` of the filter cascade `FC`. All existing filters from `stageId` to the end of the cascade are shifted up in the cascade when `newFilt` is added.

Examples

Add Filter Stage to Filter Cascade

Call `addStage` with only the System object™ arguments. The function adds the new filter stage as the final stage in the filter cascade.

```
FC = dsp.FilterCascade
```

```
FC =
    dsp.FilterCascade with properties:
```

```
    Stage1: [1x1 dsp.FIRFilter]
```

```
addStage(FC,dsp.IIRFilter)
```

```
FC
```

```
FC =
    dsp.FilterCascade with properties:
```

```
    Stage1: [1x1 dsp.FIRFilter]
    Stage2: [1x1 dsp.IIRFilter]
```

Call `addStage` with an index argument. The function adds the new filter stage at the specified index. This example creates a filter cascade with three stages, and then adds a filter as the second stage of the cascade.

```
FC = dsp.FilterCascade(dsp.CICDecimator,dsp.FIRDecimator,dsp.FIRFilter)
```

```
FC =  
    dsp.FilterCascade with properties:  
  
    Stage1: [1x1 dsp.CICDecimator]  
    Stage2: [1x1 dsp.FIRDecimator]  
    Stage3: [1x1 dsp.FIRFilter]
```

```
addStage(FC,dsp.IIRFilter,2)
```

```
FC
```

```
FC =  
    dsp.FilterCascade with properties:  
  
    Stage1: [1x1 dsp.CICDecimator]  
    Stage2: [1x1 dsp.IIRFilter]  
    Stage3: [1x1 dsp.FIRDecimator]  
    Stage4: [1x1 dsp.FIRFilter]
```

Input Arguments

FC — Filter cascade

`dsp.FilterCascade` System object

Filter cascade, specified as a `dsp.FilterCascade` System object.

newFilt — Filter stage to add

filter System object | delay System object | scalar gain value

Filter stage to add, specified as one of the supported System objects or a scalar gain value. Each stage can be a filter or delay object, or a scalar gain value. To see which System objects you can add to a filter cascade, use:

```
dsp.FilterCascade.helpSupportedSystemObjects
```

stageId — Index of filter stage to be added

positive integer

Index of filter stage to be added, specified as a positive integer. The object adds this stage to the filter cascade. All existing filters from `stageId` to the end of the cascade are shifted up in the cascade when the new filter is added.

generateFilteringCode

Package: dsp

Generate MATLAB code for a filter cascade

Syntax

```
generateFilteringCode(FC)
generateFilteringCode(FC, fileName)
```

Description

`generateFilteringCode(FC)` creates a MATLAB function that contains code to create the stages of a filter cascade, `FC`, and calls each stage in sequence. If the filters in each stage support code generation, you can generate C/C++ code from the function returned by `generateFilteringCode`.

`generateFilteringCode(FC, fileName)` generates code and saves the resulting function to the file specified in `fileName`.

Examples

Generate Code to Filter Using Cascade

Design a two-stage decimator with a 100-Hz transition width, a 2-kHz sampling frequency, and 60-dB attenuation in the stopband. The decimator needs to downsample by a factor of 4.

```
decimSpec = fdesign.decimator(4, 'Nyquist', ...
    4, 'Tw,Ast', ...
    100,60,2000);
filtCasc = design(decimSpec, 'multistage', ...
    'SystemObject', true);
```

Verify your design by using `fvtool`.

getNumStages

Package: dsp

Get number of stages in filter cascade

Syntax

```
getNumStages(FC)
```

Description

getNumStages(FC) returns the number of stages in the dsp.FilterCascade object, FC.

Examples

Find Number of Stages

This example shows how to query the number of stages in a filter cascade.

Create a filter cascade with two stages and call getNumStages on the cascade object.

```
FC = cascade(dsp.FIRFilter,dsp.IIRFilter)
FC =
  dsp.FilterCascade with properties:
    Stage1: [1x1 dsp.FIRFilter]
    Stage2: [1x1 dsp.IIRFilter]

FCstages = getNumStages(FC)
FCstages = 2
```

Input Arguments

FC — Filter cascade

dsp.FilterCascade System object

Filter cascade, specified as a dsp.FilterCascade System object.

Objects

dsp.FilterCascade

Functions

addStage | generateFilteringCode | getNumStages | releaseStages | removeStage

Introduced in R2014b

releaseStages

Package: dsp

Release locked state of all stages in cascade

Syntax

```
releaseStages(FC)
```

Description

`releaseStages(FC)` calls the `release` function of each individual stage in the `dsp.FilterCascade` System object `FC`.

For instance, if a `dsp.FilterCascade` object consists of a `dsp.FIRFilter` and a `dsp.FIRInterpolator` object, the `releaseStages` function calls the:

- `release` function of the `dsp.FIRFilter` object
- `release` function of the `dsp.FIRInterpolator` object

Examples

Release Stages of a Filter Cascade

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, `myObject(x)` becomes `step(myObject,x)`.

Create and release stages of a filter cascade.

```
firfilt = dsp.FIRFilter;  
y = firfilt(randn);  
FC = dsp.FilterCascade(dsp.FIRInterpolator, firfilt);  
isLocked(FC.Stage2)
```

```
ans = logical  
     1
```

```
releaseStages(FC);  
isLocked(FC.Stage2)
```

```
ans = logical  
     0
```

Input Arguments

FC — Filter cascade

`dsp.FilterCascade` System object

Filter cascade, specified as a `dsp.FilterCascade` System object.

See Also

Objects

`dsp.FilterCascade`

Functions

`addStage` | `generateFilteringCode` | `getNumStages` | `releaseStages` | `removeStage`

Introduced in R2014b

removeStage

Package: dsp

Remove stage from filter cascade

Syntax

```
removeStage(FC)
removeStage(FC, stageId)
```

Description

`removeStage(FC)` removes the final stage of the `dsp.FilterCascade` System object `FC`.

`removeStage(FC, stageId)` removes the stage from stage position `stageId` of the filter cascade `FC`. All existing filter stages from `stageId` to the end of the cascade are shifted down in the cascade when the stage is removed.

Examples

Remove Filter Stage

Call `removeStage` with no arguments other than the filter cascade System object™. The function removes the last stage in the filter cascade.

```
FC2= dsp.FilterCascade(dsp.FIRFilter,...
    dsp.IIRFilter)
```

```
FC2 =
    dsp.FilterCascade with properties:
```

```
    Stage1: [1x1 dsp.FIRFilter]
    Stage2: [1x1 dsp.IIRFilter]
```

```
removeStage(FC2);
FC2
```

```
FC2 =
    dsp.FilterCascade with properties:
```

```
    Stage1: [1x1 dsp.FIRFilter]
```

To remove a specific stage of the cascade, specify the index for that stage as an input argument. This example creates a filter cascade that has four stages, and then removes the third stage.

```
FC4 = cascade(dsp.FIRInterpolator,...
    dsp.FIRInterpolator,...
    dsp.FIRDecimator,...
    dsp.FIRDecimator)
```

```
FC4 =  
    dsp.FilterCascade with properties:  
  
        Stage1: [1x1 dsp.FIRInterpolator]  
        Stage2: [1x1 dsp.FIRInterpolator]  
        Stage3: [1x1 dsp.FIRDecimator]  
        Stage4: [1x1 dsp.FIRDecimator]  
  
removeStage(FC4,3);  
FC4  
  
FC4 =  
    dsp.FilterCascade with properties:  
  
        Stage1: [1x1 dsp.FIRInterpolator]  
        Stage2: [1x1 dsp.FIRInterpolator]  
        Stage3: [1x1 dsp.FIRDecimator]
```

Input Arguments

FC — Filter cascade

`dsp.FilterCascade` System object

Filter cascade, specified as a `dsp.FilterCascade` System object.

stageId — Index of filter stage to be removed

positive integer

Index of filter stage to be removed, specified as a positive integer. The function removes this stage from the filter cascade. All existing filters from `stageId` to the end of the cascade are shifted up in the cascade when the filter is removed.

dsp.FilteredXLMSFilter

Package: dsp

Filtered XLMS filter

Description

The `dsp.FilteredXLMSFilter` System object computes output, error and coefficients using filtered-x least mean square FIR adaptive filter.

To implement the adaptive FIR filter object:

- 1 Create the `dsp.FilteredXLMSFilter` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

Creation

Syntax

```
fxlms = dsp.FilteredXLMSFilter  
fxlms = dsp.FilteredXLMSFilter(len)  
fxlms = dsp.FilteredXLMSFilter(Name,Value)
```

Description

`fxlms = dsp.FilteredXLMSFilter` returns a filtered-x least mean square FIR adaptive filter System object, `fxlms`. This System object is used to compute the filtered output and the filter error for a given input and desired signal.

`fxlms = dsp.FilteredXLMSFilter(len)` returns a `FilteredXLMSFilter` System object, `fxlms`, with the `Length` property set to `len`.

`fxlms = dsp.FilteredXLMSFilter(Name,Value)` returns a `FilteredXLMSFilter` System object, `fxlms`, with each specified property set to the specified value. Enclose each property name in single quotes. Unspecified properties have default values.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see [System Design in MATLAB Using System Objects](#).

Length — Length of filter coefficients vector

10 (default) | positive integer

Specify the length of the FIR filter coefficients vector as a positive integer value. This property is nontunable.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

StepSize — Adaptation step size

0.1 (default) | positive scalar

Specify the adaptation step size factor as a positive numeric scalar.

Tunable: Yes

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

LeakageFactor — Adaptation leakage factor

1 (default) | scalar

Specify the leakage factor used in a leaky adaptive filter as a numeric value between 0 and 1, both inclusive. When the value is less than 1, the System object implements a leaky adaptive algorithm. The default value is 1, providing no leakage in the adapting method.

Tunable: Yes

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | logical

SecondaryPathCoefficients — Coefficients of the secondary path filter model

[0.0051 -3.2506e-18 -0.0419 1.3210e-17 0.2885 0.4968 0.2885 1.3210e-17 -0.0419 -3.2506e-18 0.0051] (default) | vector

Specify the coefficients of the secondary path filter model as a numeric vector. The secondary path connects the output actuator and the error sensor. The default value is a vector that represents the coefficients of a 10th-order FIR lowpass filter.

Tunable: Yes

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

SecondaryPathEstimate — Estimate of secondary path filter model

[0.0051 -3.2506e-18 -0.0419 1.3210e-17 0.2885 0.4968 0.2885 1.3210e-17 -0.0419 -3.2506e-18 0.0051] (default) | vector

Specify the estimate of the secondary path filter model as a numeric vector. The secondary path connects the output actuator and the error sensor. The default value equals to the SecondaryPathCoefficients property value. This property is not tunable.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

InitialCoefficients — Initial coefficients of filter

0 (default) | scalar | vector

Specify the initial values of the FIR adaptive filter coefficients as a scalar or a vector of length equal to the value of the Length property.

Tunable: Yes

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

LockCoefficients — Locked status of coefficient updates

`false` (default) | `true`

Specify whether to lock the filter coefficient values. By default, the value of this property is `false`, and the object continuously updates the filter coefficients. If this property is set to `true`, the filter coefficients do not update and their values remain the same.

Tunable: Yes

Usage

Syntax

```
[y,err] = fxlms(x,d)
```

Description

`[y,err] = fxlms(x,d)` filters the input `x`, using `d` as the desired signal, and returns the filtered output `y` and the filter error `err`. The System object estimates the filter weights needed to minimize the error between the output signal and the desired signal. You can access these coefficients by accessing the `Coefficients` property of the object. This can be done only after calling the object. For example, to access the optimized coefficients of the `fxlms` filter, call `fxlms.Coefficients` after you pass the input and desired signal to the object.

Input Arguments

x — Data input

scalar | column vector

The signal to be filtered by the filtered XLMS filter. The input, `x`, and the desired signal, `d`, must have the same size and data type.

The input, `x` can be a variable-size signal. You can change the number of elements in the column vector even when the object is locked. The System object locks when you call the object to run its algorithm.

Data Types: `single` | `double`

d — Desired signal

scalar | column vector

The filtered XLMS filter adapts its coefficients to minimize the error, `err`, and converge the input signal `x` to the desired signal `d` as closely as possible.

The input, `x`, and the desired signal, `d`, must have the same size and data type.

The desired signal, `d`, can be a variable-size signal. You can change the number of elements in the column vector even when the object is locked. The System object locks when you call the object to run its algorithm.

Data Types: `single` | `double`

Complex Number Support: Yes

Output Arguments

y — Filtered output

scalar | column vector

Filtered output, returned as a scalar or a column vector. The object adapts its filter coefficients to converge the input signal x to match the desired signal d . The filter outputs the converged signal.

Data Types: `single` | `double`

err — Difference between output and desired signal

scalar | column vector

Difference between the output signal y and the desired signal d , returned as a scalar or a column vector. The objective of the filtered XLMS filter is to minimize this error. The object adapts its coefficients to converge towards optimal filter coefficients that produce an output signal that matches closely with the desired signal. To access the filtered XLMS filter coefficients, call `fxlms.Coefficients` after you pass the input and desired signal to the object.

Data Types: `single` | `double`

Complex Number Support: Yes

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Specific to `dsp.FilteredXLMSFilter`

`msesim` Estimated mean squared error for adaptive filters

Common to All System Objects

`step` Run System object algorithm

`release` Release resources and allow changes to System object property values and input characteristics

`reset` Reset internal states of System object

Examples

Active Noise Control of Random Noise Signal

Note: If you are using R2016a or an earlier release, replace each call to the object with the equivalent `step` syntax. For example, `obj(x)` becomes `step(obj,x)`.

Generate noise, create FIR primary path system model, generate observation noise, filter the primary path system model output with added noise, and create FIR secondary path system model.

```
x = randn(1000,1);
g = fir1(47,0.4);
n = 0.1*randn(1000,1);
d = filter(g,1,x) + n;
b = fir1(31,0.5);
```

Use the `dsp.FilteredXLMSFilter` System object™ to compute the filtered output and the filter error for the input and the signal to be canceled.

```
mu = 0.008;
fxlms = dsp.FilteredXLMSFilter(32, 'StepSize', mu, 'LeakageFactor', ...
    1, 'SecondaryPathCoefficients', b);
[y,e] = fxlms(x,d);
```

Plot the results.

```
plot(1:1000,d,'b',1:1000,e,'r');
title('Active Noise Control of a Random Noise Signal');
legend('Original','Attenuated');
xlabel('Time Index'); ylabel('Signal Value'); grid on;
```

System Identification of FIR Filter Using Filtered XLMS Filter

Identify an unknown system by performing active noise control using a filtered-x LMS algorithm. The objective of the adaptive filter is to minimize the error signal between the output of the adaptive filter and the output of the unknown system (or the system to be identified). Once the error signal is minimal, the unknown system converges to the adaptive filter.

Note: If you are using R2016a or an earlier release, replace each call to the object with the equivalent step syntax. For example, `obj(x)` becomes `step(obj,x)`.

Initialization

Create a `dsp.FIRFilter` System object that represents the system to be identified. Pass the signal, `x`, to the FIR filter. The output of the unknown system is the desired signal, `d`, which is the sum of the output of the unknown system (FIR filter) and an additive noise signal, `n`.

```
num = fir1(31,0.5);
fir = dsp.FIRFilter('Numerator',num);
iir = dsp.IIRFilter('Numerator',sqrt(0.75),...
    'Denominator',[1 -0.5]);
x = iir(sign(randn(2000,25)));
n = 0.1*randn(size(x));
d = fir(x) + n;
```

Adaptive Filter

Create a `dsp.FilteredXLMSFilter` System object to create an adaptive filter that uses the filtered-`x` LMS algorithm. Set the length of the adaptive filter to 32 taps, step size to 0.008, and the decimation factor for analysis and simulation to 5. The variable `simmse` represents the error between the output of the unknown system, `d`, and the output of the adaptive filter.

```
l = 32;
mu = 0.008;
m = 5;
fxlms = dsp.FilteredXLMSFilter(l,'StepSize',mu);
[simmse,meanWsim,Wsim,traceKsim] = msesim(fxlms,x,d,m);
plot(m*(1:length(simmse)),10*log10(simmse))
xlabel('Iteration')
ylabel('MSE (dB)')
% Plot the learning curve for filtered-x LMS filter
% used in system identification
title('Learning curve')
```

With each iteration of adaptation, the value of `simmse` decreases to a minimal value, indicating that the unknown system has converged to the adaptive filter.

dsp.FIRDecimator

Package: dsp

Polyphase FIR decimator

Description

The `dsp.FIRDecimator` System object resamples vector or matrix inputs along the first dimension. The FIR decimator (as shown in the schematic) conceptually consists of an anti-aliasing FIR filter followed by a downsampler.

The FIR filter filters the data in each channel of the input using a direct-form FIR filter. The FIR filter coefficients can be specified through the `Numerator` property, or can be automatically designed by the object using the `designMultirateFIR` function. The `designMultirateFIR` function designs an anti-aliasing FIR filter. The downsampler that follows the FIR filter downsamples each channel of filtered data by taking every M -th sample and discarding the $M - 1$ samples that follow. M is the value of the decimation factor that you specify. The resulting discrete-time signal has a sample rate that is $1/M$ times the original sample rate.

Note that the actual object algorithm implements a direct-form FIR polyphase structure, an efficient equivalent of the combined system depicted in the diagram. For more details, see "Algorithms" on page 4-533.

To resample vector or matrix inputs along the first dimension:

- 1 Create the `dsp.FIRDecimator` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

Under specific conditions, this System object also supports SIMD code generation. For details, see "Code Generation" on page 4-536.

Creation

Syntax

```
firdecim = dsp.FIRDecimator
firdecim = dsp.FIRDecimator(M)
firdecim = dsp.FIRDecimator(M,'Auto')
firdecim = dsp.FIRDecimator(M,num)
firdecim = dsp.FIRDecimator( ____,Name,Value)
firdecim = dsp.FIRDecimator(M,'legacy')
```

Description

`firdecim = dsp.FIRDecimator` returns an FIR decimator object with a decimation factor of 2. The object designs the FIR filter coefficients using the `designMultirateFIR(1,2)` function.

`firdecim = dsp.FIRDecimator(M)` returns an FIR decimator with the integer-valued `DecimationFactor` property set to M . The object designs its filter coefficients based on the decimation factor M that you specify while creating the object, using the `designMultirateFIR(1,M)` function. The designed filter corresponds to a lowpass with a cutoff at π/M in radial frequency units.

`firdecim = dsp.FIRDecimator(M,'Auto')` returns an FIR decimator with the `NumeratorSource` property set to 'Auto'. In this mode, every time there is an update in the decimation factor, the object redesigns the filter using `designMultirateFIR(1,M)`.

`firdecim = dsp.FIRDecimator(M,num)` returns an FIR decimator with the `DecimationFactor` property set to M and the `Numerator` property set to `num`.

`firdecim = dsp.FIRDecimator(____,Name,Value)` returns an FIR decimator object with each specified property set to the specified value. Enclose each property name in quotes. You can use this syntax with any previous input argument combinations.

`firdecim = dsp.FIRDecimator(M,'legacy')` returns an FIR decimator where the filter coefficients are designed using `fir1(35,0.4)`. The designed filter has a cutoff frequency of 0.4π radians/sample.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see [System Design in MATLAB Using System Objects](#).

DecimationFactor – Decimation factor

2 (default) | positive integer

Decimation factor M , specified as a positive integer. The FIR decimator reduces the sampling rate of the input by this factor. The number of input rows must be a multiple of the decimation factor.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

NumeratorSource — FIR filter coefficient source

'Property' (default) | 'Input port' | 'Auto'

FIR filter coefficient source, specified as one of the following:

- 'Property' -- The numerator coefficients are specified through the Numerator property.
- 'Input port' -- The numerator coefficients are specified as an input to the object algorithm.
- 'Auto' -- The numerator coefficients are designed automatically using the `designMultirateFIR(1,M)` function.

Numerator — FIR filter coefficients

`designMultirateFIR(1,M)` (default) | row vector

Numerator coefficients of the FIR filter, specified as a row vector in powers of z^{-1} . The following equation defines the system function for a filter of length $N+1$:

$$H(z) = \sum_{l=0}^N b_l z^{-l}$$

The vector $\mathbf{b} = [b_0, b_1, \dots, b_N]$ represents the vector of filter coefficients.

To prevent aliasing as a result of downsampling, the filter transfer function should have a normalized cutoff frequency no greater than $1/M$. To design an effective anti-aliasing filter, use the `designMultirateFIR` function. For an example, see “Decimate Sum of Sine Waves” on page 4-526.

Dependencies

This property is visible only when you set `NumeratorSource` to 'Property'.

When `NumeratorSource` is set to 'Auto', the numerator coefficients are automatically redesigned using `designMultirateFIR(1,M)`. To access the filter coefficients in the automatic design mode, type `objName.Numerator` in the MATLAB command prompt.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

Structure — Filter structure

'Direct form' (default) | 'Direct form transposed'

Specify the implementation of the FIR filter as either `Direct form` or `Direct form transposed`.

Fixed-Point Properties

FullPrecisionOverride — Full-precision override for fixed-point arithmetic

`true` (default) | `false`

Flag to use full-precision rules for fixed-point arithmetic, specified as one of the following:

- `true` -- The object computes all internal arithmetic and output data types using the full-precision rules. These rules provide the most accurate fixed-point numerics. In this mode, other fixed-point properties do not apply. No quantization occurs within the object. Bits are added, as needed, to ensure that no roundoff or overflow occurs.
- `false` -- Fixed-point data types are controlled through individual fixed-point property settings.

For more information, see “Full Precision for Fixed-Point System Objects” and “Set System Object Fixed-Point Properties”.

RoundingMethod — Rounding method for fixed-point operations

'Floor' (default) | 'Ceiling' | 'Convergent' | 'Nearest' | 'Round' | 'Simplest' | 'Zero'

Rounding method for fixed-point operations. For more details, see rounding mode.

Dependencies

This property is not visible and has no effect on the numerical results when the following conditions are met:

- FullPrecisionOverride set to true.
- FullPrecisionOverride set to false, ProductDataType set to 'Full precision', AccumulatorDataType set to 'Full precision', and OutputDataType set to 'Same as accumulator'.

Under these conditions, the object operates in full precision mode.

OverflowAction — Overflow action for fixed-point operations

'Wrap' (default) | 'Saturate'

Overflow action for fixed-point operations, specified as one of the following:

- 'Wrap' -- The object wraps the result of its fixed-point operations.
- 'Saturate' -- The object saturates the result of its fixed-point operations.

For more details on overflow actions, see overflow mode for fixed-point operations.

Dependencies

This property is not visible and has no effect on the numerical results when the following conditions are met:

- FullPrecisionOverride set to true.
- FullPrecisionOverride set to false, OutputDataType set to 'Same as accumulator', ProductDataType set to 'Full precision', and AccumulatorDataType set to 'Full precision'

Under these conditions, the object operates in full precision mode.

CoefficientsDataType — Data type of FIR filter coefficients

Same word length as input (default) | Custom

Data type of the FIR filter coefficients, specified as:

- Same word length as input -- The word length of the coefficients is the same as that of the input. The fraction length is computed to give the best possible precision.
- Custom -- The coefficients data type is specified as a custom numeric type through the CustomCoefficientsDataType property.

CustomCoefficientsDataType — Word and fraction lengths of coefficients data type

numerictype([], 16, 15) (default) | custom numeric type

Word and fraction lengths of the coefficients data type, specified as an autosigned numeric type with a word length of 16 and a fraction length of 15.

Dependencies

This property applies when you set the `CoefficientsDataType` property to `Custom`.

ProductDataType — Data type of product output

'Full precision' (default) | 'Custom' | 'Same as input'

Data type of the product output in this object, specified as one of the following:

- 'Full precision' -- The product output data type has full precision.
- 'Same as input' -- The object specifies the product output data type to be the same as that of the input data type.
- 'Custom' -- The product output data type is specified as a custom numeric type through the `CustomProductDataType` property.

For more information on the product output data type, see “Multiplication Data Types”.

Dependencies

This property applies when you set `FullPrecisionOverride` to `false`.

CustomProductDataType — Word and fraction lengths of product data type

numeric type([], 32, 30) (default) | custom numeric type

Word and fraction lengths of the product data type, specified as an autosigned numeric type with a word length of 32 and a fraction length of 30.

Dependencies

This property applies only when you set `FullPrecisionOverride` to `false` and `ProductDataType` to `'Custom'`.

AccumulatorDataType — Data type of accumulation operation

'Full precision' (default) | 'Same as input' | 'Same as product' | 'Custom'

Data type of an accumulation operation in this object, specified as one of the following:

- 'Full precision' -- The accumulation operation has full precision.
- 'Same as product' -- The object specifies the accumulator data type to be the same as that of the product output data type.
- 'Same as input' -- The object specifies the accumulator data type to be the same as that of the input data type.
- 'Custom' -- The accumulator data type is specified as a custom numeric type through the `CustomAccumulatorDataType` property.

Dependencies

This property applies when you set `FullPrecisionOverride` to `false`.

CustomAccumulatorDataType — Word and fraction lengths of accumulator data type

numeric type([], 32, 30) (default) | custom numeric type

Word and fraction lengths of the accumulator data type, specified as an autosigned numeric type with a word length of 32 and a fraction length of 30.

Dependencies

This property applies only when you set `FullPrecisionOverride` to `false` and `AccumulatorDataType` to `'Custom'`.

OutputDataType — Data type of object output

`'Same as accumulator'` (default) | `'Same as input'` | `'Same as product'` | `'Custom'`

Data type of the object output, specified as one of the following:

- `'Same as accumulator'` -- The output data type is the same as that of the accumulator output data type.
- `'Same as input'` -- The output data type is the same as that of the input data type.
- `'Same as product'` -- The output data type is the same as that of the product output data type.
- `'Custom'` -- The output data type is specified as a custom numeric type through the `CustomOutputDataType` property.

Dependencies

This property applies when you set `FullPrecisionOverride` to `false`.

CustomOutputDataType — Word and fraction lengths of output data type

`numerictype([],16,15)` (default) | custom numeric type

Word and fraction lengths of the output data type, specified as an autosigned numeric type with a word length of 16 and a fraction length of 15.

Dependencies

This property applies only when you set `FullPrecisionOverride` to `false` and `OutputDataType` to `'Custom'`.

Usage

Syntax

```
y = firdecim(x)
y = firdecim(x,num)
```

Description

`y = firdecim(x)` outputs the filtered and downsampled values, `y`, of the input signal, `x`.

`y = firdecim(x,num)` uses the FIR filter, `num`, to decimate the input signal. This configuration is valid only when the `'NumeratorSource'` property is set to `'Input port'`.

Input Arguments

x — Data input

column vector | matrix

Data input, specified as a column vector or a matrix of size P -by- Q . The number of input rows, P , must be a multiple of the DecimationFactor property. The input columns represent the Q independent channels.

This object supports variable-size input and does not support complex unsigned fixed-point inputs.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fi

num — FIR filter coefficients

row vector

FIR filter coefficients, specified as a row vector.

Dependencies

This input is accepted only when the 'NumeratorSource' property is set to 'Input port'.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fi

Output Arguments

y — FIR decimator output

column vector | matrix

FIR decimated output, returned as a column vector or a matrix of size P/M -by- Q , where M is the decimation factor.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fi

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Specific to dsp.FIRDecimator

freqz	Frequency response of discrete-time filter System object
fvtool	Visualize frequency response of DSP filters
info	Information about filter System object
cost	Estimate cost of implementing filter System object
polyphase	Polyphase decomposition of multirate filter
generatehdl	Generate HDL code for quantized DSP filter (requires Filter Design HDL Coder)
impz	Impulse response of discrete-time filter System object
coeffs	Returns the filter System object coefficients in a structure

Common to All System Objects

step	Run System object algorithm
release	Release resources and allow changes to System object property values and input characteristics
reset	Reset internal states of System object

Examples

Decimate Sum of Sine Waves

Decimate a sum of sine waves by a factor of 2 and by a factor of 4.

Note: If you are using R2016a or an earlier release, replace each call to the object with the equivalent `step` syntax. For example, `obj(x)` becomes `step(obj,x)`.

Start with a cosine wave that has an angular frequency of $\frac{\pi}{4}$ radians/sample.

```
x = cos(pi/4*(0:95)');
```

Design Default Filter

Create a `dsp.FIRDecimator` object. To prevent aliasing, the object uses an anti-aliasing lowpass filter before downsampling. By default, the anti-aliasing lowpass filter is designed using the `designMultirateFIR` function. The function designs the filter based on the decimation factor that you specify, and stores the coefficients in the `Numerator` property. For a decimation factor of 2, the object designs the coefficients using `designMultirateFIR(1,2)`.

```
firdecim = dsp.FIRDecimator(2)
```

```
firdecim =
```

```
  dsp.FIRDecimator with properties:
```

```
    DecimationFactor: 2
```

```
    NumeratorSource: 'Property'
```

```
        Numerator: [0 -1.0054e-04 0 3.8704e-04 0 -0.0010 0 0.0022 0 ... ]
```

```
        Structure: 'Direct form'
```

```
  Show all properties
```

Visualize the filter response using `fvtool`. The designed filter meets the ideal filter constraints that are marked in red. The cutoff frequency is approximately half the spectrum.

```
fvtool(firdecim)
```

Decimate by 2

Decimate the cosine signal by a factor of 2.

```
y = firdecim(x);
```

Plot the original and the decimated signals. In order to plot the two signals on the same plot, obtain the time affine transformation parameters. Use these parameters to compute the output sample times. The n^{th} output sample time equals $\text{scale} \times n + \text{delay}$.

```
scale = 1/firdecim.DecimationFactor;
delay = length(firdecim.Numerator)/(2*firdecim.DecimationFactor);
```

```
nx = (0:length(x)-1);
ty = ((0:length(y)-1)-delay)/scale;
```

After a short transition, the output converges to a cosine of frequency $\frac{\pi}{2}$ as expected, which is twice the frequency of the input signal $\frac{\pi}{4}$. Due to the decimation factor of 2, the output samples coincide with every other input sample.

```
stem(ty,y,'filled',MarkerSize=4); hold on;
stem(nx,x); hold off;
xlim([-10,22])
ylim([-2.5 2.5])
legend('Decimated by 2 (y)', 'Input signal (x)');
```

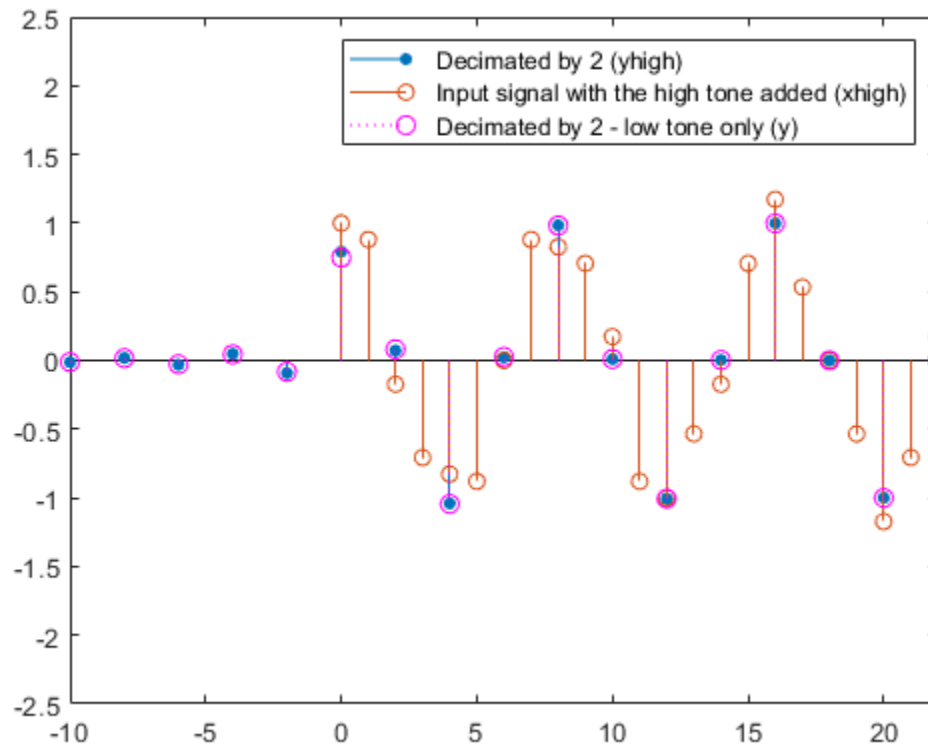

Add a High Frequency Component to Input and Decimate

Add another frequency component to the input signal, a sine with an angular frequency of $\frac{2\pi}{3}$ radians/sample. Since $\omega = \frac{2\pi}{3}$ is above the FIR lowpass cutoff, $\frac{\pi}{2}$, the frequency $\frac{2\pi}{3}$ radians/sample is filtered out from the signal.

```
xhigh = x + 0.2*sin(2*pi/3*(0:95)');
release(firdecim)
yhigh = firdecim(xhigh);
```

Plot the input signal, decimated signal, and the output of the low frequency component. The decimated signal `yhigh` has the high frequency component filtered out. `yhigh` is almost identical to the output of the low frequency component `y`.

```
stem(ty,yhigh,'filled',MarkerSize=4); hold on;
stem(nx,xhigh);
stem(ty,y,':m',MarkerSize=7);
hold off;
xlim([-10,22])
ylim([-2.5 2.5])
legend('Decimated by 2 (yhigh)',...
       'Input signal with the high tone added (xhigh)',...
       'Decimated by 2 - low tone only (y)');
```

Decimate by 4 in Automatic Filter Design Mode

Now decimate by a factor of 4. In order for the filter design to be updated automatically based on the new decimation factor, set the `NumeratorSource` property to `'Auto'`. Alternately, you can pass `'auto'` as the keyword while creating the object. The object then operates in the automatic filter design mode. Every time there is a change in the decimation factor, the object updates the filter design.

```
release(firdecim)
firdecim.NumeratorSource = 'Auto';
firdecim.DecimationFactor = 4
```

```
firdecim =
  dsp.FIRDecimator with properties:

    DecimationFactor: 4
    NumeratorSource: 'Auto'
    Structure: 'Direct form'
```

Show all properties

To access the filter coefficients in the automatic mode, type `firdecim.Numerator` in the MATLAB command prompt.

The designed filter occupies a narrower passband that is approximately a quarter of the spectrum.

```
fvtool(firdecim)
```

Decimate the cosine signal by a factor of 4. After a short transition, the output converges to a cosine of frequency π as expected, which is four times the lower frequency component of the input signal $\frac{\pi}{4}$. This time, the amplitude of the output is half the amplitude of the input since the gain of the FIR at $\omega = \frac{\pi}{4}$ is exactly $\frac{1}{2}$. The high frequency component $\frac{2\pi}{3}$ diminishes by the lowpass FIR whose cutoff frequency is $\frac{\pi}{4}$.

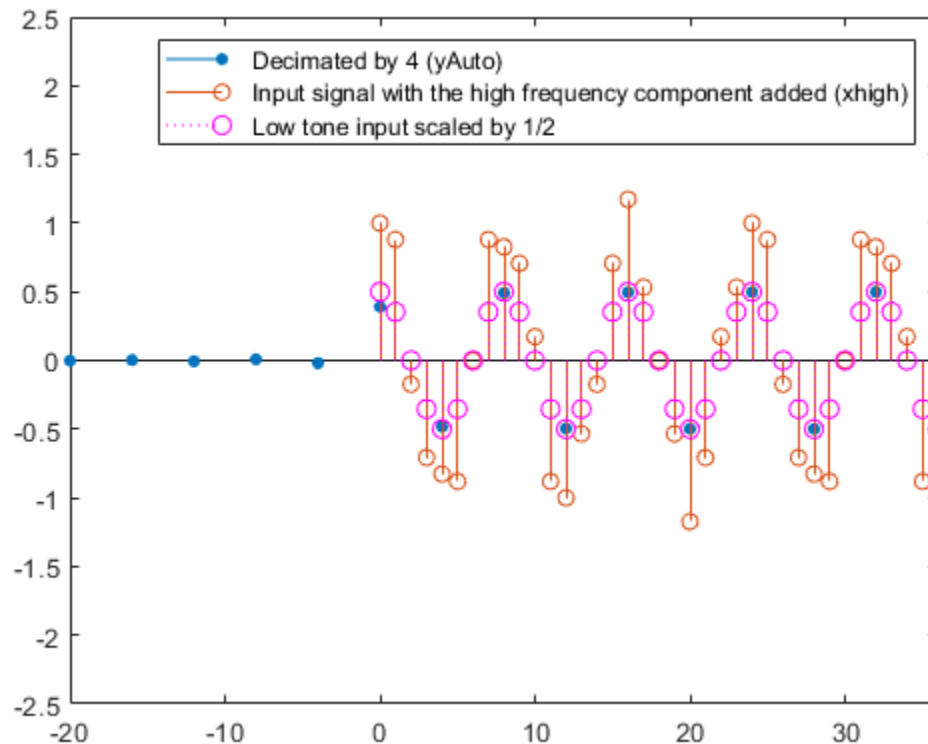

```
yAuto = firdecim(xhigh);
```

Plot the input signal with the high frequency component added, low frequency component scaled by 1/2, and the decimated signal. Recalculate the time affine transformation parameters since the decimation factor has changed.

```
scale = 1/firdecim.DecimationFactor;
delay = length(firdecim.Numerator)/(2*firdecim.DecimationFactor);
tyAuto = ((0:length(yAuto)-1)-delay)/scale;

stem(tyAuto,yAuto,'filled',MarkerSize=4); hold on;
stem(nx,xhigh);
stem(nx,x/2,'m:',MarkerSize=7); hold off;

xlim([-20,36])
ylim([-2.5 2.5])
legend('Decimated by 4 (yAuto)',...
       'Input signal with the high frequency component added (xhigh)',...
       'Low tone input scaled by 1/2');
```

Reduce Sample Rate of Audio Signal

Reduce the sample rate of an audio signal by a factor of 2 and play the decimated signal using the `audioDeviceWriter` object.

Note: If you are using R2016a or an earlier release, replace each call to the object with the equivalent `step` syntax. For example, `obj(x)` becomes `step(obj,x)`.

Note: The `audioDeviceWriter` System object™ is not supported in MATLAB Online.

Create a `dsp.AudioFileReader` object. The default audio file read by the object has a sample rate of 22050 Hz.

```
afr = dsp.AudioFileReader('OutputDataType',...
    'single');
```

Create a `dsp.FIRDecimator` object and specify the decimation factor to be 2. The object designs the filter using `designMultirateFIR(1,2)` and stores the coefficients in the `Numerator` property of the object.

```
firdecim = dsp.FIRDecimator(2)
```

```
firdecim =
    dsp.FIRDecimator with properties:
```

```
DecimationFactor: 2
  NumeratorSource: 'Property'
    Numerator: [0 -1.0054e-04 0 3.8704e-04 0 -0.0010 0 0.0022 0 ... ]
    Structure: 'Direct form'
```

Show all properties

Create an `audioDeviceWriter` object. Specify the sample rate to be 22050/2.

```
adw = audioDeviceWriter(22050/2)
```

```
adw =
  audioDeviceWriter with properties:
```

```
  Driver: 'DirectSound'
  Device: 'Default'
  SampleRate: 11025
```

Show all properties

Read the audio signal using the file reader object, decimate the signal by a factor of 2, and play the decimated signal.

```
while ~isDone(afr)
    frame = afr();
    y = firdecim(frame);
    adw(y);
end

release(afr);
pause(0.5);
release(adw);
```

More About

Polyphase Subfilters

A polyphase implementation of an FIR decimator *splits* the lowpass FIR filter impulse response into M different subfilters, where M is the downsampling or decimation factor. For more details on the polyphase implementation, see “Algorithms” on page 4-533.

Let $h(n)$ denote the FIR filter impulse response of length $N+1$ and $x(n)$ the input signal. Decimating the filter output by a factor of M is equivalent to the downsampled convolution:

$$y(n) = \sum_{l=0}^N h(l)x(nM - l)$$

The key to the efficiency of polyphase filtering is that specific input values are only multiplied by select values of the impulse response in the downsampled convolution. For example, letting $M = 2$, the input values $x(0), x(2), x(4), \dots$ are combined only with the filter coefficients $h(0), h(2), h(4), \dots$, and the input values $x(1), x(3), x(5), \dots$ are combined only with the filter coefficients $h(1), h(3), h(5), \dots$. By splitting the filter coefficients into two polyphase subfilters, no unnecessary computations are

performed in the convolution. The outputs of the convolutions with the polyphase subfilters are interleaved and summed to yield the filter output.

The following code demonstrates how to construct the two polyphase subfilters for the default order 35 filter.

```
M = 2;
Num = fir1(35,0.4);
FiltLength = length(Num);
Num = flipud(Num(:));

if (rem(FiltLength, M) ~= 0)
    nzeros = M - rem(FiltLength, M);
    Num = [zeros(nzeros,1); Num]; % Appending zeros
end

len = length(Num);
nrows = len / M;
PolyphaseFilt = flipud(reshape(Num, M, nrows).');
```

The columns of `PolyphaseFilt` are subfilters containing the two *phases* of the filter in `Num`. For a general downsampling factor of M , there are M phases and therefore M subfilters.

Algorithms

The FIR decimation filter is implemented efficiently using a polyphase structure. For more details on polyphase filters, see Polyphase Subfilters on page 4-532.

To derive the polyphase structure, start with the transfer function of the FIR filter:

$$H(z) = b_0 + b_1z^{-1} + \dots + b_Nz^{-N}$$

$N+1$ is the length of the FIR filter.

You can rearrange this equation as follows:

$$H(z) = \begin{aligned} & (b_0 + b_Mz^{-M} + b_{2M}z^{-2M} + \dots + b_{N-M+1}z^{-(N-M+1)}) + \\ & z^{-1}(b_1 + b_{M+1}z^{-M} + b_{2M+1}z^{-2M} + \dots + b_{N-M+2}z^{-(N-M+1)}) + \\ & \quad \vdots \\ & z^{-(M-1)}(b_{M-1} + b_{2M-1}z^{-M} + b_{3M-1}z^{-2M} + \dots + b_Nz^{-(N-M+1)}) \end{aligned}$$

M is the number of polyphase components, and its value equals the decimation factor that you specify.

You can write this equation as:

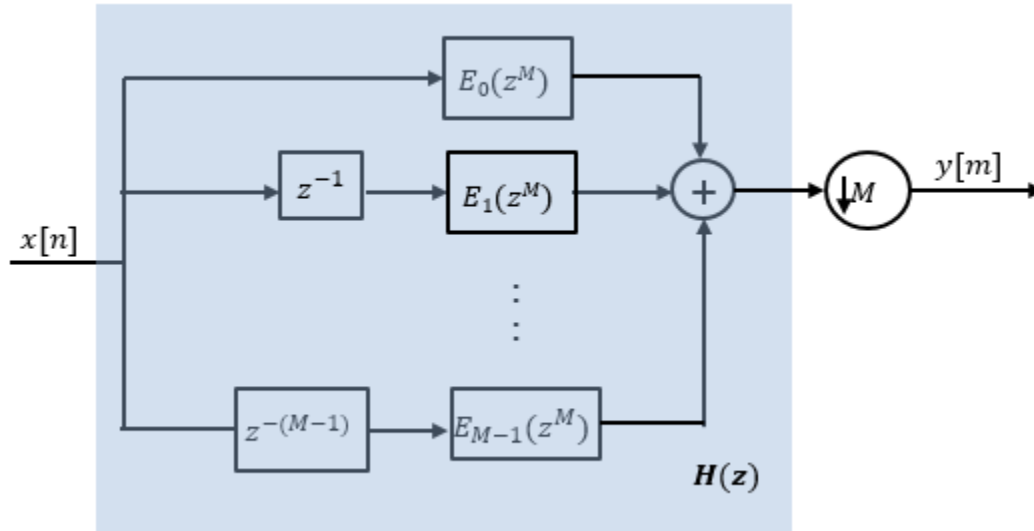

$$H(z) = E_0(z^M) + z^{-1}E_1(z^M) + \dots + z^{-(M-1)}E_{M-1}(z^M)$$

$E_0(z^M)$, $E_1(z^M)$, ..., $E_{M-1}(z^M)$ are the polyphase components of the FIR filter $H(z)$.

Conceptually, the FIR decimation filter contains a lowpass FIR filter followed by a downsampler.

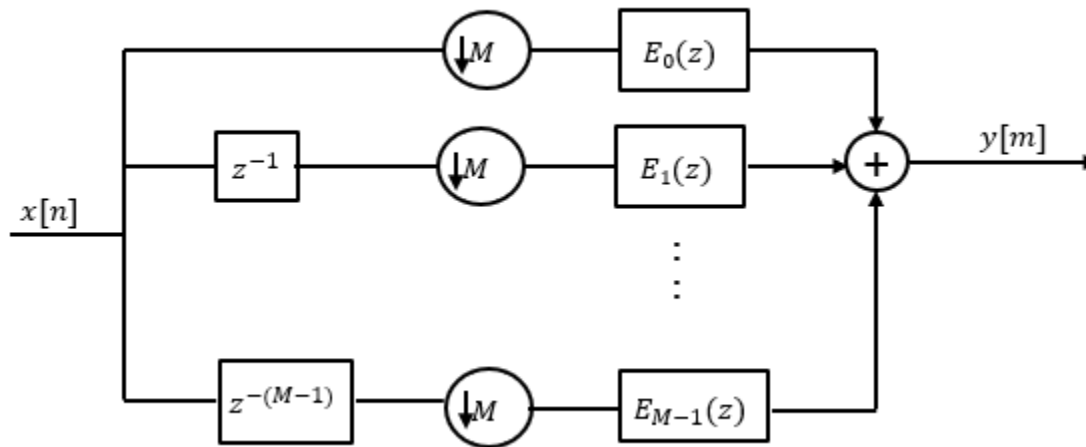

Replace $H(z)$ with its polyphase representation.

Here is the multirate noble identity for decimation.

Applying the noble identity for decimation moves the downsampling operation to before the filtering operation. This move enables you to filter the signal at a lower rate.

You can replace the delays and the decimation factor at the input with a commutator switch. The switch starts on the first branch 0 and moves in the counterclockwise direction as shown in this diagram. The accumulator at the output receives the processed input samples from each branch of the polyphase structure and accumulates these processed samples until the switch goes to branch 0. When the switch goes to branch 0, the accumulator outputs the accumulated value.

When the first input sample is delivered, the switch feeds this input to the branch 0 and the decimator computes the first output value. As more input samples come in, the switch moves in the counter clockwise direction through branches $M-1$, $M-2$, and all the way up to branch 0, delivering one sample at a time to each branch. When the switch comes to branch 0, the decimator outputs the next set of output values. This process continues as data keeps coming in. Every time the switch comes to the branch 0, the decimator outputs $y[m]$. The decimator effectively outputs one sample for every M samples it receives. Hence the sample rate at the output of the FIR decimation filter is fs/M .

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

See “System Objects in MATLAB Code Generation” (MATLAB Coder).

The `dsp.FIRDecimator` System object supports SIMD code generation using Intel AVX2 technology under these conditions:

- Filter structure is set to 'Direct form'.
- Input signal is real-valued with real filter coefficients.
- Input signal is complex-valued with real or complex filter coefficients.
- Input signal has a data type of `single` or `double`.

The SIMD technology significantly improves the performance of the generated code.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

This object supports HDL code generation with the Filter Design HDL Coder product. For workflows and limitations, see “Generate HDL Code for Filter System Objects” (Filter Design HDL Coder).

Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

dsp.FIRFilter

Package: dsp

Static or time-varying FIR filter

Description

The `dsp.FIRFilter` System object filters each channel of the input using static or time-varying FIR filter implementations.

To filter each channel of the input:

- 1 Create the `dsp.FIRFilter` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

Under specific conditions, this System object also supports SIMD code generation. For details, see “Code Generation” on page 4-547.

Creation

Syntax

```
fir = dsp.FIRFilter
fir = dsp.FIRFilter(num)
fir = dsp.FIRFilter(Name,Value)
```

Description

`fir = dsp.FIRFilter` returns a finite impulse response (FIR) filter object, `fir`, which independently filters each channel of the input over time using a specified FIR filter implementation.

`fir = dsp.FIRFilter(num)` returns an FIR filter System object, `fir`, with the `Numerator` property set to `num`.

`fir = dsp.FIRFilter(Name,Value)` returns an FIR filter System object, `fir`, with each property set to the specified value.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see [System Design in MATLAB Using System Objects](#).

Structure – Filter structure

Direct form (default) | Direct form symmetric | Direct form antisymmetric | Direct form transposed | Lattice MA

Specify the filter structure. You can specify the filter structure as one of Direct form | Direct form symmetric | Direct form antisymmetric | Direct form transposed | Lattice MA.

NumeratorSource – Source of filter coefficients

Property (default) | Input port

Specify the source of the filter coefficients as Property or Input port. When you specify Input port, the filter object updates the time-varying filter once every frame.

Dependencies

This applies when you set the Structure to Direct form | Direct form symmetric | Direct form antisymmetric | Direct form transposed.

ReflectionCoefficientsSource – Source of filter coefficients

Property (default) | Input port

Specify the source of the Lattice filter coefficients as Property or Input port. When you specify Input port, the filter object updates the time-varying filter once every frame.

Dependencies

This applies when you set the Structure to Lattice MA.

Numerator – Numerator coefficients

[0.5 0.5] (default) | row vector

Specify the filter coefficients as a real or complex numeric row vector.

Tunable: Yes

Dependencies

This property applies when you set the NumeratorSource property to Property, and the “Structure” on page 4-0 property is set to Direct form, Direct form symmetric, Direct form antisymmetric, or Direct form transposed.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

ReflectionCoefficients – Reflection coefficients of lattice filter structure

[0.5 0.5] (default) | row vector

Specify the reflection coefficients of a lattice filter as a real or complex numeric row vector.

Tunable: Yes

Dependencies

This property applies when you set the “Structure” on page 4-0 property to Lattice MA, and the ReflectionCoefficientsSource property to Property.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

InitialConditions — Initial conditions for the FIR filter

0 (default) | scalar | vector | matrix

Specify the initial conditions of the filter states. The number of states or delay elements equals the number of reflection coefficients for the lattice structure, or the number of filter coefficients-1 for the other direct form structures.

You can specify the initial conditions as a scalar, vector, or matrix. If you specify a scalar value, the FIR filter object initializes all delay elements in the filter to that value. If you specify a vector whose length equals the number of delay elements in the filter, each vector element specifies a unique initial condition for the corresponding delay element. The object applies the same vector of initial conditions to each channel of the input signal.

If you specify a vector whose length equals the product of the number of input channels and the number of delay elements in the filter, each element specifies a unique initial condition for the corresponding delay element in the corresponding channel.

If you specify a matrix with the same number of rows as the number of delay elements in the filter, and one column for each channel of the input signal, each element specifies a unique initial condition for the corresponding delay element in the corresponding channel.

Tunable: Yes

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

Fixed-Point Properties**FullPrecisionOverride — Full precision override for fixed-point arithmetic**

true (default) | false

Specify whether to use full precision rules. If you set `FullPrecisionOverride` to `true`, which is the default, the object computes all internal arithmetic and output data types using full precision rules. These rules provide the most accurate fixed-point numerics. It also turns off the display of other fixed-point properties because they do not apply individually. These rules guarantee that no quantization occurs within the object. Bits are added, as needed, to ensure that no roundoff or overflow occurs. If you set `FullPrecisionOverride` to `false`, fixed-point data types are controlled through individual fixed-point property settings. For more information, see “Full Precision for Fixed-Point System Objects”.

RoundingMethod — Rounding method for fixed-point operations

Floor (default) | Ceiling | Convergent | Nearest | Round | Simplest | Zero

Specify the rounding method.

Dependencies

This property applies only if the object is not in full precision mode.

OverflowAction — Overflow action for fixed-point operations

Wrap (default) | Saturate

Specify the overflow action as `Wrap` or `Saturate`.

Dependencies

This property applies only if the object is not in full precision mode.

CoefficientsDataType — Coefficients word and fraction lengths

Same word length as input (default) | Custom

Specify the coefficients fixed-point data type as Same word length as input or Custom.

Dependencies

This property applies when you set the NumeratorSource property to Property.

CustomCoefficientsDataType — Custom coefficients word and fraction lengths

numerictype(true,16,15) (default) | numerictype

Specify the coefficients fixed-point type as a signed or unsigned numerictype object.

Dependencies

This property applies when you set the CoefficientsDataType property to Custom.

ReflectionCoefficientsDataType — Reflection coefficients word and fraction lengths

Same word length as input (default) | Custom

Specify the reflection coefficients fixed-point data type as Same word length as input or Custom.

Dependencies

This property applies when you set the ReflectionCoefficientsSource property to Property.

CustomReflectionCoefficientsDataType — Custom reflection coefficients word and fraction lengths

numerictype(true,16,15) (default) | numerictype

Specify the reflection coefficients fixed-point type as a signed or unsigned numerictype object.

Dependencies

This property applies when you set the ReflectionCoefficientsDataType property to Custom.

ProductDataType — Product word and fraction lengths

Full precision (default) | Same as input | Custom

Specify the product fixed-point data type as Full precision, Same as input, or Custom.

CustomProductDataType — Custom product word and fraction lengths

numerictype(true,32,30) (default) | numerictype

Specify the product fixed-point type as a signed or unsigned scaled numerictype object.

Dependencies

This property applies when you set the ProductDataType property to Custom.

AccumulatorDataType — Accumulator word and fraction lengths

Full precision (default) | Same as input | Same as product | Custom

Specify the accumulator fixed-point data type to Full precision, Same as input, Same as product, or Custom.

CustomAccumulatorDataType — Custom accumulator word and fraction lengths

`numerictype(true,32,30)` (default) | `numerictype`

Specify the accumulator fixed-point type as a signed or unsigned scaled `numerictype` object.

Dependencies

This property applies when you set the `AccumulatorDataType` property to `Custom`.

StateDataType — State word and fraction lengths

Same as `accumulator` (default) | Same as `input` | `Custom`

Specify the state fixed-point data type as one of `Same as input`, `Same as accumulator`, or `Custom`.

Dependencies

This property does not apply to any of the direct form or direct form I filter structures.

CustomStateDataType — Custom state word and fraction lengths

`numerictype(true,16,15)` (default) | `numerictype`

Specify the state fixed-point type as a signed or unsigned scaled `numerictype` object.

Dependencies

This property applies when you set the `StateDataType` property to `Custom`.

OutputDataType — Output word and fraction lengths

Same as `accumulator` (default) | Same as `input` | `Custom`

Specify the output fixed-point data type as one of `Same as input`, `Same as accumulator`, or `Custom`.

CustomOutputDataType — Custom output word and fraction lengths

`numerictype(true,16,15)` (default) | `numerictype`

Specify the output fixed-point type as a signed or unsigned scaled `numerictype` object.

Dependencies

This property applies when you set the “`OutputDataType`” on page 4-0 property to `Custom`.

Usage**Syntax**

```
y = fir(x)
y = fir(x,coeff)
```

Description

`y = fir(x)` applies an FIR filter to the real or complex input signal `x` to produce the output `y`.

`y = fir(x,coeff)` uses the time-varying coefficients, `coeff`, to filter the input signal `x` and produce the output `y`. You can use this option when you set the `NumeratorSource` or `ReflectionCoefficientsSource` property to `Input port`.

Input Arguments

x — Data input

vector | matrix

Data input, specified as a vector or a matrix. When the input data is of a fixed-point type, it must be signed when the structure is set to `Direct form symmetric` or `Direct form antisymmetric`. The FIR filter object operates on each channel of the input signal independently over successive calls to the object.

This System object supports variable-size input.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fi`

coeff — Filter coefficients

row vector

Time-varying filter coefficients, specified as a row vector. The data and coefficient inputs must have the same data type.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fi`

Complex Number Support: Yes

Output Arguments

y — Filtered output

vector | matrix

Filtered output, returned as a vector or a matrix. The output has the same size and data type as the input.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fi`

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Specific to `dsp.FIRFilter`

<code>freqz</code>	Frequency response of discrete-time filter System object
<code>fvtool</code>	Visualize frequency response of DSP filters
<code>impz</code>	Impulse response of discrete-time filter System object
<code>info</code>	Information about filter System object
<code>coeffs</code>	Returns the filter System object coefficients in a structure
<code>cost</code>	Estimate cost of implementing filter System object
<code>grpdelay</code>	Group delay response of discrete-time filter System object
<code>generatehdl</code>	Generate HDL code for quantized DSP filter (requires Filter Design HDL Coder)

Common to All System Objects

step Run System object algorithm
 release Release resources and allow changes to System object property values and input characteristics
 reset Reset internal states of System object

Examples

Lowpass Filter a Sinusoid Signal Using FIRFilter object

Use an FIR filter to apply a low pass filter to a waveform with two sinusoidal components.

```

t = (0:1000)'/8e3;
xin = sin(2*pi*0.3e3*t)+sin(2*pi*3e3*t);

sr = dsp.SignalSource;
sr.Signal = xin;
sink = dsp.SignalSink;

fir = dsp.FIRFilter(fir1(10,0.5));

sa = dsp.SpectrumAnalyzer(...
    'SampleRate',8e3,...
    'PlotAsTwoSidedSpectrum',false,...
    'OverlapPercent', 80,...
    'PowerUnits','dBW',...
    'YLimits', [-150 -10]);

while ~isDone(sr)
    input = sr();
    filteredOutput = fir(input);
    sink(filteredOutput);
    sa(filteredOutput)
end

filteredResult = sink.Buffer;
fvtool(fir,'Fs',8000)
  
```

Design an FIR filter as a System object.

```
N = 10;  
Fc = 0.4;  
B = fir1(N,Fc);  
fir1 = dsp.FIRFilter(B);  
fvtool(fir1)
```

This can also be achieved by using `fdesign` as a constructor and `design` to design the filter.

```
N = 10;
Fc = 0.4;
specLowpass = fdesign.lowpass('N,Fc',...
    N,Fc);
fir2 = design(specLowpass,...
    'systemobject',true)
fvtool(fir2);
```

```
fir2 =
```

```
  dsp.FIRFilter with properties:
```

```
      Structure: 'Direct form'
  NumeratorSource: 'Property'
      Numerator: [-1.2414e-18 -0.0126 -0.0247 0.0635 0.2748 0.3981 ... ]
  InitialConditions: 0
```

```
Use get to show all properties
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the Discrete FIR Filter block reference page. The object properties correspond to the block parameters.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- Only the `Numerator` property is tunable for code generation.
- See “System Objects in MATLAB Code Generation” (MATLAB Coder).

The `dsp.FIRFilter` System object supports SIMD code generation using Intel AVX2 technology under these conditions:

- Filter structure is set to 'Direct form' or 'Direct form transposed'.
- Input signal is real-valued with real filter coefficients.
- Input signal is complex-valued with real or complex filter coefficients.
- Input signal has a data type of `single` or `double`.

The SIMD technology significantly improves the performance of the generated code.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

This object supports HDL code generation with the HDL Coder or Filter Design HDL Coder products. For HDL Coder workflow and limitations, see “HDL Code Generation for System Objects” (HDL Coder). dsp.HDLFIRFilter

Package: dsp

Finite impulse response filter—optimized for HDL code generation

Description

The `dsp.HDLFIRFilter` System object models finite-impulse response filter architectures optimized for HDL code generation. The object accepts one input sample at a time, and provides an option for programmable coefficients. It provides a hardware-friendly interface with input and output control signals. To provide a cycle-accurate simulation of the generated HDL code, the object models architectural latency including pipeline registers and resource sharing.

The object provides three filter structures. The direct form systolic architecture provides a fully parallel implementation that makes efficient use of Intel and Xilinx DSP blocks. The direct form transposed architecture is a fully parallel implementation and is suitable for FPGA and ASIC applications. The partly-serial systolic architecture provides a configurable serial implementation that makes efficient use of FPGA DSP blocks. For a filter implementation that matches multipliers, pipeline registers, and pre-adders to the DSP configuration of your FPGA vendor, specify your target device when you generate HDL code.

All three structures optimize hardware resources by sharing multipliers for symmetric or antisymmetric filters. The parallel implementations also remove the multipliers for zero-valued coefficients such as in half-band filters and Hilbert transforms.

The latency between valid input data and the corresponding valid output data depends on the filter structure, serialization options, the number of coefficients and whether the coefficient values provide optimization opportunities.

For a FIR filter with multichannel or frame-based inputs, use the `dsp.FIRFilter` System object instead of this System object.

To filter input data with an HDL-optimized FIR filter:

- 1 Create the `dsp.HDLFIRFilter` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

Creation

Syntax

```
firFilt = dsp.HDLFIRFilter
firFilt = dsp.HDLFIRFilter(num)
firFilt = dsp.HDLFIRFilter( ___, Name, Value)
```

Description

`firFilt = dsp.HDLFIRFilter` creates an HDL-optimized discrete FIR filter System object, `firFilt`, with default properties.

`firFilt = dsp.HDLFIRFilter(num)` creates a filter with the `Numerator` property set to `num`.

`firFilt = dsp.HDLFIRFilter(___, Name, Value)` sets properties using one or more name-value pairs. Enclose each property name in single quotes.

For example:

```
Numerator = firpm(10,[0,0.1,0.5,1],[1,1,0,0]);  
fir = dsp.HDLFIRFilter(Numerator,'FilterStructure','Direct form transposed');  
...  
[dataOut,validOut] = fir(dataIn,validIn);
```

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see [System Design in MATLAB Using System Objects](#).

Main

NumeratorSource — Source of filter coefficients

'Property' (default) | 'Input port (Parallel interface)'

You can enter constant filter coefficients as a property or provide time-varying filter coefficients using an input argument.

Setting this property to 'Input port (Parallel interface)' enables the `coeff` argument, and the `NumeratorPrototype` property. Specify a prototype to enable the object to optimize the filter implementation according to the symmetry of your coefficients. To use 'Input port (Parallel interface)', set the `FilterStructure` property to 'Direct form systolic'.

Numerator — Discrete FIR filter coefficients

[0.5 0.5] (default) | real or complex vector

Discrete FIR filter coefficients, specified as a vector of real or complex values. You can also specify the vector as a workspace variable, or as a call to a filter design function. When the input data type is a floating-point type, the object casts the coefficients to the same data type as the input. When the input data type is an integer type or a fixed-point type, you can modify the coefficient data type by using the `CoefficientsDataType` property.

Example: `dsp.HDLFIRFilter('Numerator',firpm(30,[0 0.1 0.2 0.5]*2,[1 1 0 0]))` defines coefficients using a linear-phase filter design function.

Dependencies

To enable this property, set `NumeratorSource` to 'Property'.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32`

NumeratorPrototype — Prototype filter coefficients

`[]` (default) | real or complex vector

Prototype filter coefficients, specified as a vector of real or complex values. The prototype specifies a sample coefficient vector that is representative of the symmetry and zero-value locations of the expected input coefficients. If all of your input coefficient vectors have the same symmetry and zero-value coefficient locations, set `NumeratorPrototype` to one of those vectors. If your coefficients are unknown or not expected to share symmetry or zero-value locations, set `NumeratorPrototype` to `[]`. The object uses the prototype to optimize the filter by sharing multipliers for symmetric or antisymmetric coefficients, and removing multipliers for zero-value coefficients.

Coefficient optimizations affect the expected size of the `coeff` input argument. Provide only the nonduplicate coefficients as the argument. For example, if you set the `NumeratorPrototype` property to a symmetric 14-tap filter, the object shares one multiplier between each pair of duplicate coefficients, so the object expects a vector of 7 values for the `coeff` argument. You must still provide zeros in the input `coeff` vector for the nonduplicate zero-value coefficients.

Dependencies

To enable this property, set `NumeratorSource` to `'Input port (Parallel interface)'`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32`

FilterStructure — HDL filter architecture

`'Direct form systolic'` (default) | `'Direct form transposed'` | `'Partly serial systolic'`

HDL filter architecture, specified as one of these structures:

- `'Direct form systolic'` — This architecture provides a fully parallel filter implementation that makes efficient use of Intel and Xilinx DSP blocks. For architecture and performance details, see “Fully Parallel Systolic Architecture” on page 2-463.
- `'Direct form transposed'` — This architecture is a fully parallel implementation that is suitable for FPGA and ASIC applications. For architecture and performance details, see “Fully Parallel Transposed Architecture” on page 2-464.
- `'Partly serial systolic'` — This architecture provides a serial filter implementation and options for tradeoffs between throughput and resource utilization. It makes efficient use of Intel and Xilinx DSP blocks. The object implements a serial L -coefficient filter with M multipliers and requires input samples that are at least N cycles apart, such that $L = N \times M$. You can specify either M or N . For this implementation, the object provides an output signal, `ready`, that indicates when the object is ready for new input data. For architecture and performance details, see “Partly Serial Systolic Architecture ($1 < N < L$)” on page 2-464 and “Fully Serial Systolic Architecture ($N \geq L$)” on page 2-465.

All implementations share multipliers for symmetric and antisymmetric coefficients. The `'Direct form systolic'` and `'Direct form transposed'` structures also remove multipliers for zero-valued coefficients.

SerializationOption — Rule to define serial implementation

`'Minimum number of cycles between valid input samples'` (default) | `'Maximum number of multipliers'`

Specify the rule that the object uses to serialize the filter as one of:

- 'Minimum number of cycles between valid input samples' - Specify a requirement for input data timing by using the `NumberOfCycles` property.
- 'Maximum number of multipliers' - Specify a requirement for resource usage by using the `NumberOfMultipliers` property.

For a filter with L coefficients, the object implements a serial filter with not more than M multipliers and requires input samples that are at least N cycles apart, such that $L = N \times M$. The object applies coefficient optimizations after serialization, so the M or N values of the final filter implementation can be lower than the value that you specified.

Dependencies

To enable this property, set `FilterStructure` to 'Partly serial systolic'.

NumberOfCycles — Serialization requirement for input timing

2 (default) | positive integer

Serialization requirement for input timing, specified as a positive integer. This property represents N , the minimum number of cycles between valid input samples. In this case, the object calculates $M = L/N$. To implement a fully-serial architecture, set `NumberOfCycles` to a value greater than the filter length, L , or to `Inf`.

The object applies coefficient optimizations after serialization, so the M and N values of the final filter can be lower than the value you specified.

Dependencies

To enable this property, set `FilterStructure` to 'Partly serial systolic' and set `SerializationOption` to 'Minimum number of cycles between valid input samples'.

NumberOfMultipliers — Serialization requirement for resource usage

2 (default) | positive integer

Serialization requirement for resource usage, specified as a positive integer. This property represents M , the maximum number of multipliers in the filter implementation. In this case, the object calculates $N = L/M$. If the input data is complex, the object allocates $\text{floor}(M/2)$ multipliers for the real part of the filter and $\text{floor}(M/2)$ multipliers for the imaginary part of the filter. To implement a fully-serial architecture, set `NumberOfMultipliers` to 1 for real input, or 2 for complex input.

The object applies coefficient optimizations after serialization, so the M and N values of the final filter can be lower than the value you specified.

Dependencies

To enable this property, set the `FilterStructure` to 'Partly serial systolic', and set `SerializationOption` to 'Maximum number of multipliers'.

Data Types

Rounding — Rounding method for type-casting the output

'Floor' (default) | 'Ceiling' | 'Convergent' | 'Nearest' | 'Round' | 'Zero'

Rounding method for type-casting the output, specified as 'Floor', 'Ceiling', 'Convergent', 'Nearest', 'Round', or 'Zero'. The rounding method is used when casting the output to the data type specified by the `OutputDataType` property. When the input data type is floating point, the object ignores the `RoundingMethod` property. For more details, see "Rounding Modes".

OverflowAction — Overflow handling for type-casting the output

'Wrap' (default) | 'Saturate'

Overflow handling for type-casting the output, specified as 'Wrap' or 'Saturate'. Overflow handling is used when casting the output to the data type specified by the `OutputDataType` property. When the input data type is floating point, the object ignores the `OverflowAction` property. For more details, see “Overflow Handling”.

CoefficientsDataType — Data type of discrete FIR filter coefficients'Same word length as input' (default) | `numericType` object

Data type of discrete FIR filter coefficients, specified as 'Same word length as input' or a `numericType` object. To specify a `numericType` object, call `numericType(s,w,f)`, where:

- `s` is 1 for signed and 0 for unsigned.
- `w` is the word length in bits.
- `f` is the number of fractional bits.

The object type-casts the filter coefficients of the discrete FIR filter to the specified data type. The quantization rounds to the nearest representable value and saturates on overflow. When the input data type is floating point, the object ignores the `Coefficients` property.

Dependencies

To enable this property, set `NumeratorSource` to 'Property'.

OutputDataType — Data type of discrete FIR filter output'Full precision' (default) | 'Same word length as input' | `numericType` object

Data type of discrete FIR filter output, specified as 'Same word length as input', 'Full precision', or a `numericType` object. To specify a `numericType` object, call `numericType(s,w,f)`, where:

- `s` is 1 for signed and 0 for unsigned.
- `w` is the word length in bits.
- `f` is the number of fractional bits.

The object type-casts the output of the discrete FIR filter to the specified data type. The quantization uses the settings of the `RoundingMethod` and `OverflowAction` properties. When the input data type is floating point, the object ignores the `OutputDataType` property.

The object increases the word length for full precision inside each filter tap and casts the final output to the specified type. The maximum final internal data type (WF) depends on the input data type (WI), the coefficient data type (WC), and the number of coefficients (L) and is given by

$$WF = WI + WC + \text{ceil}(\log_2(L)).$$

When you specify a fixed set of coefficients, usually the actual full-precision internal word length is smaller than WF because the values of the coefficients limit the potential growth. When you use programmable coefficients, the object cannot calculate the dynamic range, and the internal data type is always WF .

Control Arguments

ResetInputPort — Option to enable reset input argument

false (default) | true

Option to enable reset input argument, specified as `true` or `false`. When you set this property to `true`, the object expects a value for the reset input argument. The reset signal implements a local synchronous reset of the data path registers.

For more reset considerations, see “Tips” on page 4-563.

HDLGlobalReset — Option to connect data path registers to generated HDL global reset signal

false (default) | true

Option to connect data path registers to generated HDL global reset signal, specified as `true` or `false`. Set this property to `true` to connect the generated HDL global reset signal to the data path registers. This property does not change the arguments of the object or modify simulation behavior in MATLAB. When you set this property to `false`, the generated HDL global reset clears only the control path registers. The generated HDL global reset can be synchronous or asynchronous depending on your HDL code generation settings.

For more reset considerations, see “Tips” on page 4-563.

Usage

Syntax

```
[dataOut,validOut] = firFilt(dataIn,validIn)
[dataOut,validOut,ready] = firFilt(dataIn,validIn)
[dataOut,validOut] = firFilt(dataIn,validIn,coeff)
[dataOut,validOut] = firFilt(dataIn,validIn,reset)
```

Description

`[dataOut,validOut] = firFilt(dataIn,validIn)` filters the input data only when `validIn` is `true`.

`[dataOut,validOut,ready] = firFilt(dataIn,validIn)` returns `ready` set to `true` when the object is ready to accept new input data on the next call.

The object returns the `ready` argument only when you set the `FilterStructure` property to `'Partly serial systolic'`. For example:

```
firFilt = dsp.HDLFIRFilter(Numerator,...
    'FilterStructure','Partly serial systolic',...
    'SerializationOption','Minimum number of cycles between valid input samples',...
    'NumberOfCycles',8)
...
for k=1:length(dataIn)
    [dataOut,validOut,ready] = firFilt(dataIn(k),validIn(k));
```

`[dataOut,validOut] = firFilt(dataIn,validIn,coeff)` filters data using the coefficients, `coeff`. The object expects the `coeff` argument only when you set the `NumeratorSource` property to `'Input port (Parallel interface)'`. For example:

```
firFilt = dsp.HDLFIRFilter(NumeratorSource,'Input Port (Parallel interface)')
...
```

```

for k=1:length(dataIn)
    Numerator = myGetNumerator(); %calculate coefficients
    [dataOut,validOut] = firFilt(dataIn(k),validIn(k),Numerator);

```

[dataOut,validOut] = firFilt(dataIn,validIn,reset) filters data when reset is false. When reset is true, the object resets the filter registers. The object expects the reset argument only when you set the ResetInputPort property to true. For example:

```

firFilt = dsp.HDLFIRFilter(Numerator,'ResetInputPort',true)
...
% reset the filter
firFilt(0,false,true);
for k=1:length(dataIn)
    [dataOut,validOut] = firFilt(dataIn(k),validIn(k),false);

```

For more reset considerations, see “Tips” on page 4-563.

Input Arguments

dataIn — Input data

real or complex scalar

Input data, specified as a real or complex scalar. When the input data type is an integer type or fixed-point type, the object uses fixed-point arithmetic for internal calculations.

double and single data types are supported for simulation, but not for HDL code generation.

Data Types: fi | single | double | int8 | int16 | int32 | uint8 | uint16 | uint32

Complex Number Support: Yes

validIn — Validity of input data

logical scalar

Validity of the input data, specified as a logical scalar. The dataIn argument is valid only when validIn is 1 (true).

Data Types: logical

coeff — Filter coefficients

real or complex vector

Filter coefficients, specified as a vector of real or complex values. You can change the input coefficients at any time. The size of the vector depends on the size and symmetry of the sample coefficients specified in the NumeratorPrototype property. The prototype specifies a sample coefficient vector that is representative of the symmetry and zero-value locations of the expected input coefficients. The object uses the prototype to optimize the filter by sharing multipliers for symmetric or antisymmetric coefficients, and removing multipliers for zero-value coefficients. Therefore, provide only the nonduplicate coefficients in the argument. For example, if you set the NumeratorPrototype property to a symmetric 14-tap filter, the object expects a vector of 7 values for the coeff argument. You must still provide zeros in the input coeff vector for the nonduplicate zero-value coefficients.

double and single data types are supported for simulation, but not for HDL code generation.

Dependencies

To enable this argument, set the NumeratorSource property to 'Input port (Parallel interface)'.

Data Types: `fi | single | double | int8 | int16 | int32 | uint8 | uint16 | uint32`

reset — Clear data path state

logical scalar

When the `reset` argument is `true`, the object stops the current calculation and clears the internal state of the filter. The reset signal is synchronous and clears the data path and control path states. For more reset considerations, see “Tips” on page 4-563.

Dependencies

To enable this argument, set the `ResetInputPort` property to `true`.

Data Types: `logical`

Output Arguments**dataOut — Filtered output data**

real or complex scalar

Filtered output data, returned as a real or complex scalar. When the input data is floating point, the output data inherits the data type of the input data. When the input data is an integer type or fixed-point type, the `OutputDataType` property determines the output data type.

Data Types: `fi | single | double`

validOut — Validity of output data

logical scalar

Validity of the output data, returned as a logical scalar. The object sets `validOut` to `1 (true)` with each valid output data in the `dataOut` argument.

Data Types: `logical`

ready — Indication object is ready for new input data

logical scalar

Indication of whether the object is ready for new input data, returned as a logical scalar. The object sets this value to `true` to indicate that it is ready to accept new input data on the next call.

When using the partly-serial architecture, the object processes one sample at a time. If your design waits for the object to return `ready` set to `false` before de-asserting `validIn`, then one extra data input value arrives at the object. The object stores this extra data while processing the current data, and then does not set `ready` to `true` until the extra input is processed.

Dependencies

The object returns this value only when the `FilterStructure` property is set to `'Partly serial systolic'`.

Data Types: `logical`

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Specific to dsp.HDLFIRFilter

getLatency Latency of FIR filter

Common to All System Objects

step Run System object algorithm
 release Release resources and allow changes to System object property values and input characteristics
 reset Reset internal states of System object

Examples

Create HDL FIR Filter System Object with Default Settings

Create an HDL FIR filter System object with default settings.

```
firFilt = dsp.HDLFIRFilter;
```

Create an input signal of random noise, and allocate memory for outputs.

```
L = 100;
dataIn = randn(L,1);
dataOut = zeros(L,1);
validOut = false(L,1);
```

Call the object on the input signal, asserting that the input data is always valid. The object processes one data sample at a time.

```
for k=1:L
    [dataOut(k),validOut(k)] = firFilt(dataIn(k),true);
end
```

Implement a Partly-Serial Streaming FIR Filter

This example shows how to configure the dsp.HDLFIRFilter System object™ as a partly-serial 31-tap lowpass filter.

Design the filter coefficients. Then create an HDL FIR filter System object. Set the FilterStructure to 'Partly serial systolic'. By default, the SerializationOption property is 'Minimum number of cycles between valid input samples', and so you must specify the serialization rule using the NumberOfCycles property. To share each multiplier between 10 coefficients, set the NumberOfCycles to 10.

```
numerator = firpm(30,[0 0.1 0.2 0.5]*2,[1 1 0 0]);
numCycles = 10;
firFilt = dsp.HDLFIRFilter('Numerator',numerator, ...
    'FilterStructure','Partly serial systolic','NumberOfCycles',numCycles);
```

This serial filter implementation requires 10 time steps to calculate each output. Create input signals dataIn and validIn such that new data is applied only every NumberOfCycles time steps.

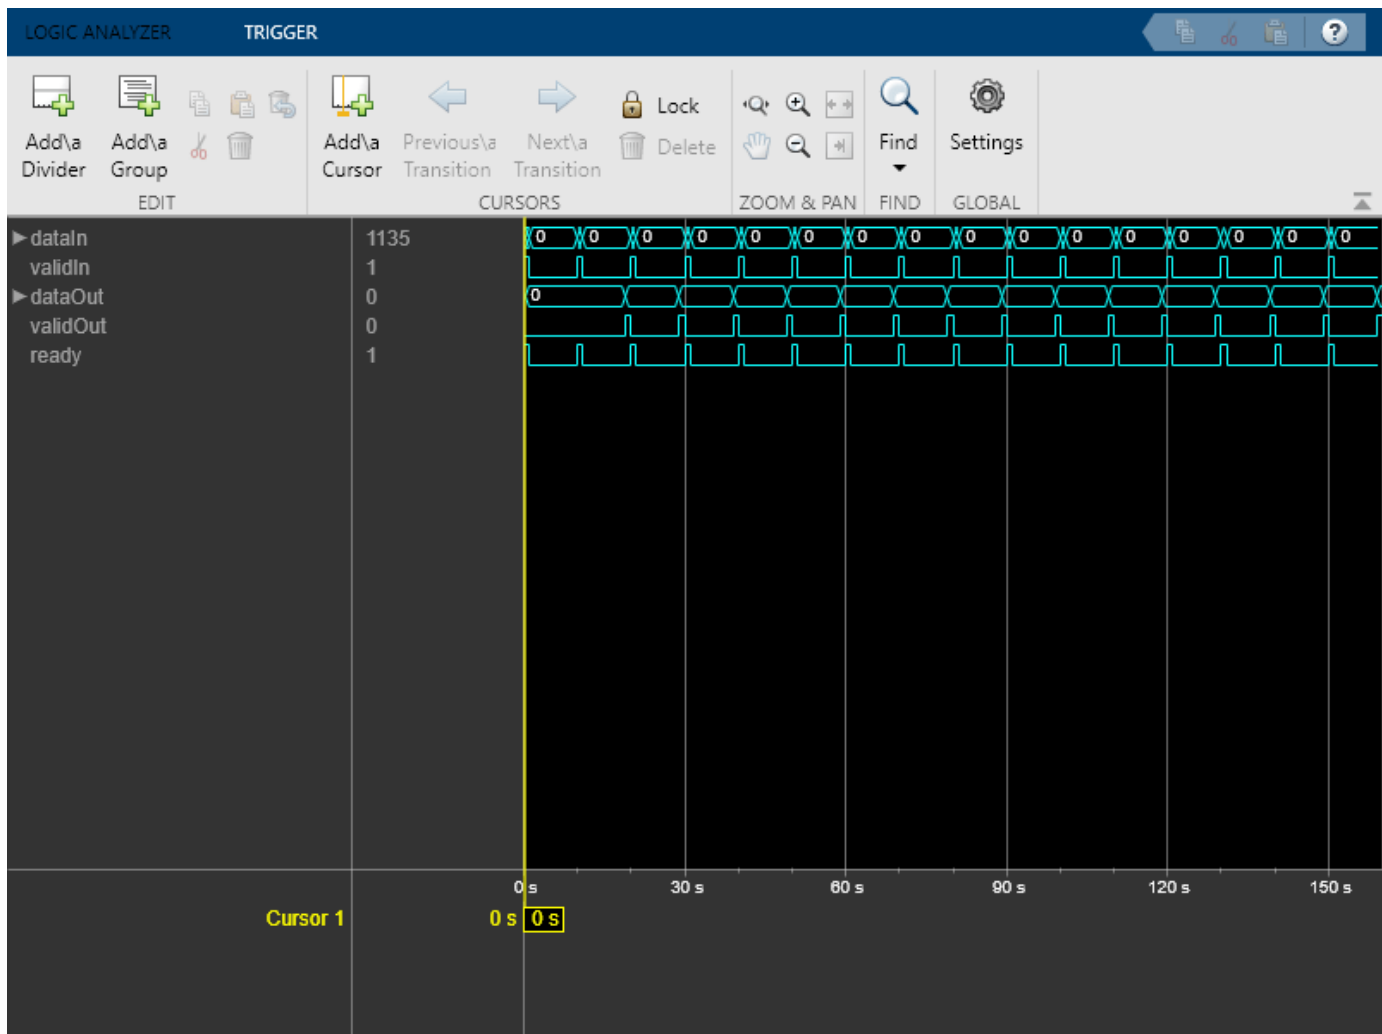

```
L = 16;  
x = fi(randn(L,1),1,16);  
dataIn = zeros(L*numCycles,1,'like',x);  
dataIn(1:numCycles:end) = x;  
validIn = false(L*numCycles,1);  
validIn(1:numCycles:end) = true;
```

Create a LogicAnalyzer object to view the inputs and output signals.

```
la = dsp.LogicAnalyzer('NumInputPorts',5, ...  
    'SampleTime',1,'TimeSpan',length(dataIn));  
tags = getDisplayChannelTags(la);  
modifyDisplayChannel(la,tags{1},'Name','dataIn');  
modifyDisplayChannel(la,tags{2},'Name','validIn');  
modifyDisplayChannel(la,tags{3},'Name','dataOut');  
modifyDisplayChannel(la,tags{4},'Name','validOut');  
modifyDisplayChannel(la,tags{5},'Name','ready');
```

Call the filter System object on the input signals, and view the results in the Logic Analyzer. The object models HDL pipeline registers and resource sharing, so the waveform shows an initial delay before the object returns valid output samples.

```
for k=1:length(dataIn)  
    [dataOut,validOut,ready] = firFilt(dataIn(k),validIn(k));  
    la(dataIn(k),validIn(k),dataOut,validOut,ready)  
end
```

Create HDL FIR Filter System Object for HDL Code Generation

To generate HDL code from a System object™, create a function that contains and calls the object.

Create Function

Write a function that creates and calls an 11-tap HDL FIR filter System object. You can generate HDL code from this function.

```
function [dataOut,validOut] = HDLFIR11Tap(dataIn, validIn)
%HDLFIR11Tap
% Process one sample of data by using the dsp.HDLFIRFilter System
% object.
% dataIn is a fixed-point scalar value.
% You can generate HDL code from this function.
    persistent fir
    if isempty(fir)
```

```
        Numerator = firpm(10,[0 0.1 0.5 1],[1 1 0 0]);
        fir = dsp.HDLFIRFilter('Numerator',Numerator);
    end
    [dataOut,validOut] = fir(dataIn,validIn);
end
```

Create Test Bench for Function

Clear the workspace, create an input signal of random noise, and allocate memory for outputs.

```
clear variables
clear HDLFIR11Tap
L = 200;
dataIn = fi(randn(L,1),1,16);
validIn = ones(L,'logical');
dataOut = zeros(L,1);
validOut = false(L,1);
```

Call the function on the input signal.

```
for k = 1:L
    [dataOut(k),validOut(k)] = HDLFIR11Tap(dataIn(k), validIn(k));
end
```

Plot the signals with the Logic Analyzer.

```
la = dsp.LogicAnalyzer('NumInputPorts',3,'SampleTime',1,'TimeSpan',L);
tags = getDisplayChannelTags(la);
modifyDisplayChannel(la,tags{1},'Name','dataIn','Format','Analog','Height',50);
modifyDisplayChannel(la,tags{2},'Name','dataOut','Format','Analog','Height',50);
modifyDisplayChannel(la,tags{3},'Name','validOut');
la(dataIn,dataOut,validOut)
```

Explore Latency of HDL FIR Object

The latency of the `dsp.HDLFIRFilter` System object™ varies with filter structure, serialization options, and whether the coefficient values provide optimization opportunities. Use the `getLatency` function to find the latency of a particular configuration. The latency is the number of cycles between the first valid input and the first valid output.

Create a `dsp.HDLFIRFilter` System object™ and request the latency. The default architecture is fully parallel systolic. The default data type for the coefficients is 'Same word length as input'. Therefore, when you call the `getLatency` object function, you must specify an input data type. The object casts the coefficient values to the input data type, and then checks for symmetric coefficients. This Numerator has 31 symmetric coefficients, so the object optimizes for the shared coefficients, and implements 16 multipliers.

```
Numerator = firpm(30,[0 0.1 0.2 0.5]*2,[1 1 0 0]);
Input_type = numeric(1,16,15); % object uses only the word length for coefficient type cast
hdlfir = dsp.HDLFIRFilter('Numerator',Numerator);
L_sysp = getLatency(hdlfir,Input_type)
```

```
L_sysp = 23
```

Check the latency for a partly serial systolic implementation of the same filter. By default, the `SerializationOption` property is 'Minimum number of cycles between valid input samples', and so you must specify the serialization rule using the `NumberOfCycles` property. To share each multiplier between 8 coefficients, set the `NumberOfCycles` to 8. The object then optimizes based on the coefficient symmetry, so there are 16 unique coefficients shared 8 times each over 2 multipliers. This serial filter implementation requires input samples that are valid every 8 cycles.

```
hdlfir = dsp.HDLFIRFilter('Numerator',Numerator,'FilterStructure','Partly serial systolic','NumberOfCycles',8);
L_sysp = getLatency(hdlfir,Input_type)
```

```
L_sysp = 19
```

Check the latency of a nonsymmetric fully parallel systolic filter. The Numerator has 31 coefficients.

```
Numerator = sinc(0.4*[-30:0]);
hdlfir = dsp.HDLFIRFilter('Numerator',Numerator);
L_sysp = getLatency(hdlfir,Input_type)

L_sysp = 37
```

Check the latency of the same nonsymmetric filter implemented as a partly serial systolic filter. In this case, specify the `SerializationOption` by the number of multipliers. The object implements a filter that has 2 multipliers and requires 8 cycles between input samples.

```
hdlfir = dsp.HDLFIRFilter('Numerator',Numerator,'FilterStructure','Partly serial systolic',...
                        'SerializationOption','Maximum number of multipliers','NumberOfMultipliers',2);
L_sysp = getLatency(hdlfir,Input_type)

L_sysp = 37
```

Check the latency of a fully parallel transposed architecture. The latency for this filter structure is always 6 cycles.

```
hdlfir = dsp.HDLFIRFilter('Numerator',Numerator,'FilterStructure','Direct form transposed');
L_trans = getLatency(hdlfir,Input_type)

L_trans = 6
```

Tips

Reset Behavior

- By default, the `dsp.HDLFIRFilter` object connects the generated HDL global reset to only the control path registers. The two reset properties, `ResetInputPort` and `HDLGlobalReset`, connect a reset signal to the data path registers. Because of the additional routing and loading on the reset signal, resetting data path registers can reduce synthesis performance.
- The `ResetInputPort` property enables the `reset` argument of the object. The reset signal implements a local synchronous reset of the data path registers. For optimal use of FPGA resources, this option does not connect the reset signal to registers targeted to the DSP blocks of the FPGA.
- The `HDLGlobalReset` property connects the generated HDL global reset signal to the data path registers. This property does not change the arguments of the object or modify simulation behavior in MATLAB. The generated HDL global reset can be synchronous or asynchronous depending on your HDL code generation settings. Depending on your device, using the global reset might move registers out of the DSP blocks and increase resource use.
- When you set both the `ResetInputPort` and `HDLGlobalReset` properties to `true`, the global and local reset signals clear the control and data path registers.

Algorithms

This System object implements the algorithms described on the Discrete FIR Filter HDL Optimized block reference page.

Compatibility Considerations

Changes to Serial Filter Properties

Behavior changed in R2019a

The options for configuring a serial filter architecture have changed. Prior to R2019a, you specified the serial implementation by setting a requirement for input timing. Now, you can specify the serialization requirement based on either input timing (N) or resource usage (M).

Serial Filter Requirement	Configuration Prior to R2019a	Configuration After R2019a
Specify a serialization rule based on input timing, that is, N cycles.	<ul style="list-style-type: none"> • Set the FilterStructure property to 'Direct form systolic'. • Set the Sharing property to true. • Set the SharingFactor property to N. 	<ul style="list-style-type: none"> • Set the FilterStructure property to 'Partly serial systolic'. • Set the SerializationOption property to 'Minimum number of cycles between valid input samples'. • Set the NumberOfCycles property to N.
Specify a serialization rule based on resource usage, that is, M multipliers.	<p>Serialization by resource usage is not supported prior to R2019a. However, you can calculate N based on your multiplier requirement.</p> <ul style="list-style-type: none"> • Set the FilterStructure property to 'Direct form systolic'. • Set the Sharing property to true. • Set the SharingFactor property to $\text{ceil}(\text{NumCoeffs}/M)$. 	<ul style="list-style-type: none"> • Set the FilterStructure property to 'Partly serial systolic'. • Set the SerializationOption property to 'Maximum number of multipliers'. • Set the NumberOfMultipliers property to M.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

This System object supports C/C++ code generation for accelerating MATLAB simulations, and for DPI component generation.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

`double` and `single` data types are supported for simulation, but not for HDL code generation.

To generate HDL code from predefined System objects, see “HDL Code Generation from Viterbi Decoder System Object” (HDL Coder).

Introduced in R2017a

dsp.HDLFIRDecimation

Package: dsp

Finite impulse response (FIR) decimation filter—optimized for HDL code generation

Description

The `dsp.HDLFIRDecimation` System object implements a polyphase FIR decimation filter that is optimized for HDL code generation. It provides a hardware-friendly interface with input and output control signals. To provide a cycle-accurate simulation of the generated HDL code, the object models architectural latency including pipeline registers and resource sharing.

The object accepts scalar or vector input. When you use vector input, the decimation factor must be an integer multiple of the vector size. The object uses a single-rate implementation. The output is scalar and a valid signal indicates which samples are valid after decimation. The waveform shows an input vector of four samples and a decimation factor of eight. The output sample is valid every second cycle.

The object provides two filter structures. The direct form systolic architecture provides a fully parallel implementation that makes efficient use of Intel and Xilinx DSP blocks. The direct form transposed architecture is a fully parallel implementation that is suitable for FPGA and ASIC applications. For a filter implementation that matches multipliers, pipeline registers, and pre-adders to the DSP configuration of your FPGA vendor, specify your target device when you generate HDL code.

The object implements one filter for each sample in the input vector. The object then shares this filter between the polyphase subfilters by interleaving the subfilter coefficients in time.

To filter and decimate input data with an HDL-optimized algorithm:

- 1 Create the `dsp.HDLFIRDecimation` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

Creation

Syntax

```
firDecim = dsp.HDLFIRDecimation
firDecim = dsp.HDLFIRDecimation(dec,num)
firDecim = dsp.HDLFIRDecimator( ___,Name,Value)
```

Description

`firDecim = dsp.HDLFIRDecimation` creates a default HDL-optimized FIR decimation filter System object.

`firDecim = dsp.HDLFIRDecimation(dec,num)` sets the `DecimationFactor` property to `dec` and the `Numerator` property to `num`.

`firDecim = dsp.HDLFIRDecimator(___,Name,Value)` sets properties using one or more name-value pairs in addition to any input argument combination from previous syntaxes. Enclose each property name in quotes. For example, `'FilterStructure','Direct form transposed'` specifies the filter architecture as a fully parallel implementation that is suitable for FPGA and ASIC applications.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see [System Design in MATLAB Using System Objects](#).

Main

Numerator — FIR filter coefficients

`fir1(35,0.4)` (default) | real- or complex-valued vector

FIR filter coefficients, specified as a real- or complex-valued vector. You can specify the vector as a workspace variable or as a call to a filter design function. When the input data type is a floating-point type, the object casts the coefficients to the same data type as the input. When the input data type is an integer type or a fixed-point type, you can modify the coefficient data type by using the `CoefficientsDataType` property.

Example: `firpm(30,[0 0.1 0.2 0.5]*2,[1 1 0 0])` defines coefficients using a linear-phase filter design function.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32`

FilterStructure — HDL filter architecture

`'Direct form systolic'` (default) | `'Direct form transposed'`

HDL filter architecture, specified as one of these structures:

- `'Direct form systolic'` — This architecture provides a fully parallel filter implementation that makes efficient use of Intel and Xilinx DSP blocks.
- `'Direct form transposed'` — This architecture is a fully parallel implementation that is suitable for FPGA and ASIC applications.

Both implementations share resources by interleaving the subfilter coefficients over one filter implementation for each sample in the input vector.

The object implements a polyphase decomposition filter using `dsp.HDLFIRFilter` System objects. For architecture details, see the “Fully Parallel Systolic Architecture” on page 2-463 and the “Fully

Parallel Transposed Architecture” on page 2-464 sections on the Discrete FIR Filter HDL Optimized block reference page.

DecimationFactor — Decimation factor

2 (default) | integer greater than two

Decimation factor, specified as integer greater than two. When you use vector input, the decimation factor must be an integer multiple of the vector size.

Data Types**RoundingMethod — Rounding method for type-casting output**

'Floor' (default) | 'Ceiling' | 'Convergent' | 'Nearest' | 'Round' | 'Zero'

Rounding method for type-casting the output, specified as 'Floor', 'Ceiling', 'Convergent', 'Nearest', 'Round', or 'Zero'. The object uses this property when casting the output to the data type specified by the `OutputDataType` property. When the input data type is floating point, the object ignores this property. For more details, see “Rounding Modes”.

OverflowAction — Overflow handling for type-casting the output

'Wrap' (default) | 'Saturate'

Overflow handling for type-casting the output, specified as 'Wrap' or 'Saturate'. The object uses this property when casting the output to the data type specified by the `OutputDataType` property. When the input data type is floating point, the object ignores this property. For more details, see “Overflow Handling”.

CoefficientsDataType — Data type of filter coefficients

'Same word length as input' (default) | `numericType` object

Data type of filter coefficients, specified as 'Same word length as input' or a `numericType` object. To specify a `numericType` object, call `numericType(s, w, f)`, where:

- s is 1 for signed and 0 for unsigned.
- w is the word length in bits.
- f is the number of fractional bits.

The object casts the filter coefficients to the specified data type. The quantization rounds to the nearest representable value and saturates on overflow. When the input data type is floating point, the object ignores this property.

OutputDataType — Data type of filter output

'Full precision' (default) | 'Same word length as input' | `numericType` object

Data type of the filter output, specified as 'Same word length as input', 'Full precision', or a `numericType` object. To specify a `numericType` object, call `numericType(s, w, f)`, where:

- s is 1 for signed and 0 for unsigned.
- w is the word length in bits.
- f is the number of fractional bits.

The object casts the output of the filter to the specified data type. The quantization uses the settings of the `RoundingMethod` and `OverflowAction` properties. When the input data type is floating point, the object ignores this property.

The object increases the word length for full precision inside each filter tap and casts the final output to the specified type. The maximum final internal data type (WF) depends on the input data type (WI), the coefficient data type (WC), and the number of coefficients (L) and is given by

$$WF = WI + WC + \text{ceil}(\log_2(L)).$$

Because the coefficient values limit the potential growth, usually the actual full-precision internal word length is smaller than WF .

Control Arguments

ResetInputPort — Option to enable reset input argument

false (default) | true

Option to enable reset input argument, specified as `true` or `false`. When you set this property to `true`, the object expects a value for the reset input argument. The reset signal implements a local synchronous reset of the data path registers.

For more reset considerations, see “Tips” on page 4-571.

HDLGlobalReset — Option to connect data path registers to generated HDL global reset signal

false (default) | true

Option to connect data path registers to generated HDL global reset signal, specified as `true` or `false`. Set this property to `true` to connect the generated HDL global reset signal to the data path registers. This property does not change the arguments of the object or modify simulation behavior in MATLAB. When you set this property to `false`, the generated HDL global reset clears only the control path registers. The generated HDL global reset can be synchronous or asynchronous depending on your HDL code generation settings.

For more reset considerations, see “Tips” on page 4-571.

Usage

Syntax

```
[dataOut,validOut] = firDecim(dataIn,validIn)
[dataOut,validOut] = firDecim(dataIn,validIn,reset)
```

Description

`[dataOut,validOut] = firDecim(dataIn,validIn)` filters the input data only when `validIn` is `true`.

`[dataOut,validOut] = firDecim(dataIn,validIn,reset)` filters data when `reset` is `false`. When `reset` is `true`, the object resets the filter registers. The object expects the reset argument only when you set the `ResetInputPort` property to `true`. For more reset considerations, see “Tips” on page 4-571.

Input Arguments

dataIn — Input data

scalar | vector

Input data, specified as a real- or complex-valued scalar or vector. When you use vector input, the decimation factor must be an integer multiple of the vector size. The vector size must be less than or equal to 64.

When the input data type is an integer type or fixed-point type, the object uses fixed-point arithmetic for internal calculations.

`double` and `single` data types are supported for simulation, but not for HDL code generation.

Data Types: `fi` | `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32`

Complex Number Support: Yes

validIn — Validity of input data

logical scalar

Validity of the input data, specified as a logical scalar. The `dataIn` argument is valid only when this argument is 1 (`true`).

Data Types: `logical`

reset — Control signal that clears data path state

logical scalar

Control signal that clears data path state, specified as a logical scalar. When this argument is 1, the object stops the current calculation and clears the internal state of the filter. The reset signal is synchronous and clears the data path and control path states. For more reset considerations, see “Tips” on page 4-571.

Dependencies

To enable this argument, set the `ResetInputPort` property to `true`.

Data Types: `logical`

Output Arguments

dataOut — Filtered output data

scalar

Filtered output data, returned as a real- or complex-valued scalar. When the input data is floating point, the output data inherits the data type of the input data. When the input data is an integer type or fixed-point type, the `OutputDataType` property specifies the output data type.

The output `valid` signal indicates which samples are valid after decimation.

Data Types: `fi` | `single` | `double`

validOut — Validity of output data

logical scalar

Validity of the output data, returned as a logical scalar. The object sets this argument to 1 (`true`) with each valid output data in the `dataOut` argument.

Data Types: `logical`

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Specific to dsp.HDLFIRDecimation

`getLatency` Latency of FIR decimation filter

Common to All System Objects

`step` Run System object algorithm

`release` Release resources and allow changes to System object property values and input characteristics

`reset` Reset internal states of System object

Tips

Reset Behavior

- By default, the `dsp.HDLFIRDecimation` object connects the generated HDL global reset to only the control path registers. The two reset properties, `ResetInputPort` and `HDLGlobalReset`, connect a reset signal to the data path registers. Because of the additional routing and loading on the reset signal, resetting data path registers can reduce synthesis performance.
- The `ResetInputPort` property enables the `reset` argument of the object. The reset signal implements a local synchronous reset of the data path registers. For optimal use of FPGA resources, this option does not connect the reset signal to registers targeted to the DSP blocks of the FPGA.
- The `HDLGlobalReset` property connects the generated HDL global reset signal to the data path registers. This property does not change the arguments of the object or modify simulation behavior in MATLAB. The generated HDL global reset can be synchronous or asynchronous depending on your HDL code generation settings. Depending on your device, using the global reset might move registers out of the DSP blocks and increase resource use.
- When you set both the `ResetInputPort` and `HDLGlobalReset` properties to `true`, the global and local reset signals clear the control and data path registers.

Algorithms

This System object implements the algorithms described on the FIR Decimation HDL Optimized block reference page.

Note The output of the `dsp.HDLFIRDecimation` object does not match the output from the `dsp.FIRDecimation` object sample-for-sample. This difference is mainly because of the phase that the samples are applied across the subfilters. To match the `dsp.FIRDecimation` object, apply `DecimationFactor - 1` zeroes to the `dsp.HDLFIRDecimation` object at the start of the data stream.

The `dsp.HDLFIRDecimation` object also uses slightly different data types for full-precision calculations. The different data types can also introduce differences in output values if the values overflow the internal datatypes.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

This System object supports C/C++ code generation for accelerating MATLAB simulations, and for DPI component generation.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

double and single data types are supported for simulation, but not for HDL code generation.

To generate HDL code from predefined System objects, see “HDL Code Generation from Viterbi Decoder System Object” (HDL Coder).

dsp.FIRHalfbandDecimator

Package: dsp

Halfband decimator

Description

The `dsp.FIRHalfbandDecimator` System object performs an efficient polyphase decimation of the input signal by a factor of two. You can use `dsp.FIRHalfbandDecimator` to implement the analysis portion of a two-band filter bank to filter a signal into lowpass and highpass subbands.

`dsp.FIRHalfbandDecimator` uses an FIR equiripple design to construct the halfband filters and a polyphase implementation to filter the input.

To filter and downsample your data:

- 1 Create the `dsp.FIRHalfbandDecimator` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

Creation

Syntax

```
firhalfbanddecim = dsp.FIRHalfbandDecimator  
firhalfbanddecim = dsp.FIRHalfbandDecimator(Name,Value)
```

Description

`firhalfbanddecim = dsp.FIRHalfbandDecimator` returns a halfband decimator, `firhalfbanddecim`, with the default settings. Under the default settings, the System object filters and downsamples the input data with a halfband frequency of 11025 Hz, a transition width of 4.1 kHz, and a stopband attenuation of 80 dB.

`firhalfbanddecim = dsp.FIRHalfbandDecimator(Name,Value)` returns a halfband decimator, with additional properties specified by one or more `Name,Value` pair arguments.

Example: `firhalfbanddecim = dsp.FIRHalfbandDecimator('Specification','Filter order and stopband attenuation')` creates an FIR halfband decimator object with filter order set to 52 and stopband attenuation set to 80 dB.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects.

Specification — Filter design parameters

'Transition width and stopband attenuation' (default) | 'Filter order and stopband attenuation' | 'Filter order and transition width' | 'Coefficients'

Filter design parameters, specified as a character vector. When you set `Specification` to one of the following, you choose two of the three available design parameters to design the FIR Halfband filter.

- 'Transition width and stopband attenuation' -- Transition width and stopband attenuation are the design parameters.
- 'Filter order and stopband attenuation' -- Filter order and stopband attenuation are the design parameters.
- 'Filter order and transition width' -- Filter order and transition width are the design parameters.

The filter is designed using the optimal equiripple filter design method.

When you set `Specification` to 'Coefficients', you specify the halfband filter coefficients directly through the `Numerator` property.

FilterOrder — Filter order

52 (default) | even positive integer

Filter order, specified as an even positive integer.

Dependencies

This property applies when you set `Specification` to either 'Filter order and stopband attenuation' or 'Filter order and transition width'.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

StopbandAttenuation — Stopband attenuation

80 (default) | positive real scalar

Stopband attenuation in dB, specified as a positive real scalar.

Dependencies

This property applies when you set `Specification` to either 'Filter order and stopband attenuation' or 'Transition width and stopband attenuation'.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

TransitionWidth — Transition width

4100 (default) | positive real scalar

Transition width in Hz, specified as a positive real scalar. The value of the transition width in Hz must be less than 1/2 the input sample rate.

Dependencies

This property applies when you set `Specification` to either 'Transition width and stopband attenuation' or 'Filter order and transition width'.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

Numerator — FIR halfband filter coefficients

`firhalfband('minororder',0.407,1e-4)` (default) | row vector

FIR halfband filter coefficients, specified as a row vector. The coefficients must comply with the FIR halfband impulse response format. For details on this format, see “Halfband Filters” on page 4-583 and “FIR Halfband Filter Design”. If half the order of the filter, $(\text{length}(\text{Numerator}) - 1)/2$, is even, every other coefficient starting from the first coefficient must be a zero except for the center coefficient which must be a 0.5. If half the order of the filter is odd, the sequence of alternating zeros with a 0.5 at the center starts at the second coefficient.

Dependencies

This property applies when you set `Specification` to `'Coefficients'`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

SampleRate — Input sample rate

44100 (default) | positive real scalar

Input sample rate in Hz, specified as a positive real scalar. The input sample rate defaults to 44100 Hz. If you specify transition width as one of your filter design parameters, the transition width cannot exceed 1/2 the input sample rate.

Data Types: `single` | `double`

Fixed-Point Properties

CoefficientsDataType — Word and fraction lengths of coefficients

`numerictype(1,16)` (default) | `numerictype` object

Word and fraction lengths of coefficients, specified as a signed or unsigned `numerictype` object. The default, `numerictype(1,16)` corresponds to a signed numeric type object with 16-bit coefficients and a fraction length determined based on the coefficient values, to give the best possible precision.

This property is not tunable.

Word length of the output is same as the word length of the input. Fraction length of the output is computed such that the entire dynamic range of the output can be represented without overflow. For details on how the fraction length of the output is computed, see “Fixed-Point Precision Rules for Avoiding Overflow in FIR Filters”.

RoundingMethod — Rounding method for output fixed-point operations

`'Floor'` (default) | `'Ceiling'` | `'Convergent'` | `'Nearest'` | `'Round'` | `'Simplest'` | `'Zero'`

Rounding method for output fixed-point operations, specified as a character vector. For more information on the rounding modes, see “Precision and Range”.

Usage

Syntax

```
y_low = firhalfbanddecim(x)
[y_low,y_high] = firhalfbanddecim(x)
```

Description

`yLow = firhalfbanddecim(x)` filters the input signal `x` using the FIR halfband filter, `firhalfbanddecim`, and downsamples the output by a factor of 2.

`[yLow,yHigh] = firhalfbanddecim(x)` computes the `yLow` and `yHigh`, of the analysis filter bank, `firhalfbanddecim` for input `x`. A K_i -by- N input matrix is treated as N independent channels. The System object generates two power-complementary output signals by adding and subtracting the two polyphase branch outputs respectively. `yLow` and `yHigh` are of the same size (K_o -by- N) and data type. $K_o = K_i/2$, where 2 is the decimation factor.

Input Arguments

x — Data input

column vector | matrix

Data input, specified as a column vector or a matrix. If the input signal is a matrix, each column of the matrix is treated as an independent channel. The number of rows in the input signal must be a multiple of 2.

This object supports variable-size input signal.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fi`

Output Arguments

yLow — Lowpass subband of decimator output

column vector | matrix

Lowpass subband of decimator output, returned as a column vector or a matrix. The output, `yLow` is a lowpass halfband filtered and downsampled version of the input `x`. Due to the halfband nature of the filter, the downsampling factor is always 2.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fi`

yHigh — Highpass subband of decimator output

column vector | matrix

Highpass subband of decimator output, returned as a column vector or a matrix. The output, `yHigh` is a highpass halfband filtered and downsampled version of the input `x`. Due to the halfband nature of the filter, the downsampling factor is always 2.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fi`

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Specific to dsp.FIRHalfbandDecimator

freqz	Frequency response of discrete-time filter System object
fvtool	Visualize frequency response of DSP filters
info	Information about filter System object
cost	Estimate cost of implementing filter System object
coeffs	Returns the filter System object coefficients in a structure
polyphase	Polyphase decomposition of multirate filter

Common to All System Objects

step	Run System object algorithm
release	Release resources and allow changes to System object property values and input characteristics
reset	Reset internal states of System object

Examples

Impulse and Frequency Response of Halfband Decimation Filter

Create a lowpass halfband decimation filter for data sampled at 44.1 kHz. The output data rate is 1/2 the input sampling rate, or 22.05 kHz. Specify the filter order to be 52 with a transition width of 4.1 kHz.

```
Fs = 44.1e3;
filterspec = 'Filter order and transition width';
Order = 52;
TW = 4.1e3;
firhalfbanddecim = dsp.FIRHalfbandDecimator(...
    'Specification',filterspec, ...
    'FilterOrder',Order, ...
    'TransitionWidth',TW, ...
    'SampleRate',Fs);
```

Plot the impulse response. The zeroth-order coefficient is delayed 26 samples, which is equal to the group delay of the filter. This yields a causal halfband filter.

```
fvtool(firhalfbanddecim,...
    'Analysis','impulse')
```

Plot the magnitude and phase response.

```
fvtool(firhalfbanddecim,...  
       'Analysis','freq')
```

Extract Low Frequency Subband From Speech

Use a halfband analysis filter bank and interpolation filter to extract the low frequency subband from a speech signal.

Note: If you are using R2016a or an earlier release, replace each call to the object with the equivalent `step` syntax. For example, `obj(x)` becomes `step(obj,x)`.

Note: The `audioDeviceWriter` System object™ is not supported in MATLAB Online.

Set up the audio file reader, the analysis filter bank, audio device writer, and interpolation filter. The sampling rate of the audio data is 22050 Hz. The order of the halfband filter is 52, with a transition width of 2 kHz.

```
afr = dsp.AudioFileReader(...
    'speech_dft.mp3',...
    'SamplesPerFrame',1024);

filtSpec = 'Filter order and transition width';
Order = 52;
TW = 2000;

firhalfbanddecim = dsp.FIRHalfbandDecimator(...
    'Specification',filtSpec,...
```

```

    'FilterOrder',Order,...
    'TransitionWidth',TW,...
    'SampleRate',afr.SampleRate);

firhalfbandinterp = dsp.FIRHalfbandInterpolator(...
    'Specification',filtSpec,...
    'FilterOrder',Order,...
    'TransitionWidth',TW,...
    'SampleRate',afr.SampleRate/2);

adw = audioDeviceWriter('SampleRate',...
    afr.SampleRate);

```

View the magnitude response of the halfband filter.

```
fvtool(firhalfbanddecim)
```

Read the speech signal from the audio file in frames of 1024 samples. Filter the speech signal into lowpass and highpass subbands with a halfband frequency of 5512.5 Hz. Reconstruct a lowpass approximation of the speech signal by interpolating the lowpass subband. Play the filtered output.

```

while ~isDone(afr)
    audioframe = afr();
    xlo = firhalfbanddecim(audioframe);
    ylow = firhalfbandinterp(xlo);
    adw(ylow);
end

```

Wait until the audio file is played to the end, then close the input file and release the audio output resource.

```
release(afr);
release(adw);
```

Two-Channel Filter Bank

Use a halfband decimator and interpolator to implement a two-channel filter bank. This example uses an audio file input and shows that the power spectrum of the filter bank output does not differ significantly from the input.

Note: If you are using R2016a or an earlier release, replace each call to the object with the equivalent step syntax. For example, `obj(x)` becomes `step(obj,x)`.

Note: The `audioDeviceWriter` System object™ is not supported in MATLAB Online.

Set up the audio file reader and device writer. Construct the FIR halfband decimator and interpolator. Finally, set up the spectrum analyzer to display the power spectra of the filter-bank input and output.

```
AF = dsp.AudioFileReader('speech_dft.mp3','SamplesPerFrame',1024);
AP = audioDeviceWriter('SampleRate',AF.SampleRate);
```

```
filterspec = 'Filter order and transition width';
Order = 52;
TW = 2000;
```

```
firhalfbanddecim = dsp.FIRHalfbandDecimator(...
    'Specification',filterspec,'FilterOrder',Order,...
    'TransitionWidth',TW,'SampleRate',AF.SampleRate);
```

```
firhalfbandinterp = dsp.FIRHalfbandInterpolator(...
    'Specification',filterspec,'FilterOrder',Order,...
    'TransitionWidth',TW,'SampleRate',AF.SampleRate/2,...
    'FilterBankInputPort',true);
```

```
SpecAna = dsp.SpectrumAnalyzer('SampleRate',AF.SampleRate,...
    'PlotAsTwoSidedSpectrum',false,'ReducePlotRate',false,...
    'ShowLegend',true,...
    'ChannelNames',{'Input signal','Filtered output signal'});
```

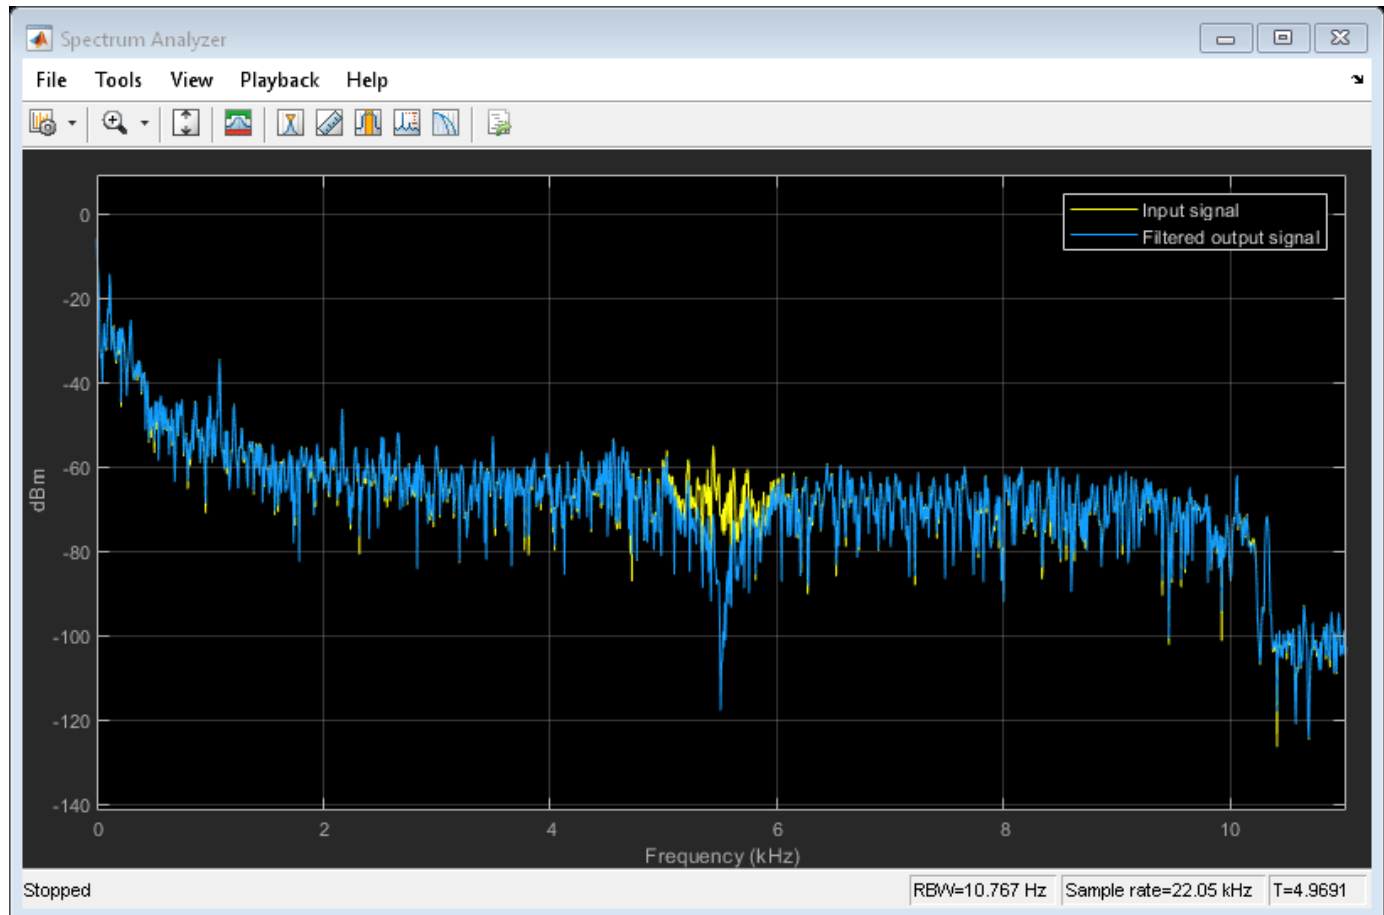

Read the audio 1024 samples at a time. Filter the input to obtain the lowpass and highpass subband signals decimated by a factor of two. This is the analysis filter bank. Use the halfband interpolator as the synthesis filter bank. Display the running power spectrum of the audio input and the output of the synthesis filter bank. Play the output.

```
while ~isDone(AF)
    audioInput = AF();
    [xlo,xhigh] = firhalfbanddecim(audioInput);
    audioOutput = firhalfbandinterp(xlo,xhigh);
    spectrumInput = [audioInput audioOutput];
    SpecAna(spectrumInput);
    AP(audioOutput);
end
```

```

release(AF);
release(AP);
release(SpecAna);

```

Filter Input into Lowpass and Highpass Subbands Using FIR Halfband Decimator

Create a halfband decimator for data sampled at 44.1 kHz. Use a minimum-order design with a transition width of 2 kHz and a stopband attenuation of 60 dB.

```

hfirhalfbanddecim = dsp.FIRHalfbandDecimator(...
    'Specification',...
    'Transition width and stopband attenuation',...
    'TransitionWidth',2000,...
    'StopbandAttenuation',60,...
    'SampleRate',44.1e3);

```

Filter a two-channel input into low and highpass subbands.

```

x = randn(1024,2);
[ylow,yhigh] = hfirhalfbanddecim(x);

```

More About

Halfband Filters

The ideal lowpass halfband filter is given by

$$h(n) = \frac{1}{2\pi} \int_{-\pi/2}^{\pi/2} e^{j\omega n} d\omega = \frac{\sin(\frac{\pi}{2}n)}{\pi n}.$$

The ideal filter is not realizable because the impulse response is noncausal and not absolutely summable. However, the impulse response of the ideal lowpass filter possesses some important properties that are required of a realizable approximation. Specifically, the ideal lowpass halfband filter's impulse response is:

- equal to 0 for all even-indexed samples
- equal to 1/2 at $n=0$. You can see this by using L'Hopital's rule on the continuous-valued equivalent of the discrete-time impulse response.

The ideal highpass halfband filter is given by

$$g(n) = \frac{1}{2\pi} \int_{-\pi}^{-\pi/2} e^{j\omega n} d\omega + \frac{1}{2\pi} \int_{\pi/2}^{\pi} e^{j\omega n} d\omega.$$

Evaluating the preceding integral gives the following impulse response

$$g(n) = \frac{\sin(\pi n)}{\pi n} - \frac{\sin(\frac{\pi}{2}n)}{\pi n}.$$

The ideal highpass halfband filter's impulse is:

- equal to 0 for all even-indexed samples
- equal to 1/2 at $n=0$.

`dsp.FIRHalfbandDecimator` uses a causal FIR approximation to the ideal halfband response, which is based on minimizing the ℓ^∞ norm of the error (minimax). See "Algorithms" on page 4-583 for more details.

Algorithms

Halfband Equiripple Design

`dsp.FIRHalfbandDecimator` uses a minimax FIR design to design a fullband linear phase filter with the desired specifications. The fullband filter is upsampled so that the even-indexed samples of the filter are replaced with zeros. The upsampling of the filter produces a halfband filter. Finally, the filter tap corresponding to the group delay of the filter in samples is set equal to 1/2. This yields a causal linear-phase FIR filter approximation to the ideal halfband filter defined in "Halfband Filters" on page 4-583. See [1] for a description of this filter design method using the Remez exchange algorithm.

Polyphase Implementation with Halfband Filters

`dsp.FIRHalfbandDecimator` uses an efficient polyphase implementation for halfband filters when you filter the input signal. The chief advantage of the polyphase implementation is that you can downsample the signal prior to filtering. This allows you to filter at the lower sampling rate.

Splitting a filter's impulse response, $h(n)$, into two polyphase components results in an even polyphase component with z -transform

$$H_0(z) = \sum_n h(2n)z^{-n}.$$

and an odd polyphase component with z -transform

$$H_1(z) = \sum_n h(2n+1)z^{-n}.$$

The z -transform of the filter can be written in terms of the even and odd polyphase components as

$$H(z) = H_0(z^2) + z^{-1}H_1(z^2).$$

Graphically, you can represent filtering and input followed by downsampling by two with the following figure

Using the multirate noble identity for downsampling, you can move the downsampling operation before filtering. This allows you to filter at the lower rate.

For a halfband filter, the only nonzero coefficient in the even polyphase component is the coefficient corresponding to z^0 . Implementing the halfband filter as a causal FIR filter shifts the nonzero coefficient to approximately $z^{-N/4}$ where N is the number of filter taps. This process is illustrated in the following figure.

The top plot shows a halfband filter of order 52. The bottom plot shows the even polyphase component. Both of these filters are noncausal. Delaying the even polyphase component by 13 samples creates a causal FIR filter.

To efficiently implement the halfband decimator, `dsp.FIRHalfbandDecimator` replaces the delay block and downsampling operator with a commutator switch. This is illustrated in the following figure where one polyphase component is replaced by a gain and delay.

The commutator switch takes input samples from a single branch and supplies every other sample to one of the two polyphase components for filtering. This halves the sampling rate of the input signal. Which polyphase component reduces to a simple delay depends on whether the half order of the filter is even or odd. This is because the delay required to make the even polyphase component causal can be odd or even depending on the filter half order. You can see this by inspecting the polyphase components of the following filters.

```
filterspec = 'Filter order and stopband attenuation' ;
halfOrderEven = dsp.FIRHalfbandDecimator('Specification',filterspec,...
    'FilterOrder',64,'StopbandAttenuation',80);
halfOrderOdd = dsp.FIRHalfbandDecimator('Specification',filterspec,...
    'FilterOrder', 54,'StopbandAttenuation',80);
polyphase(halfOrderEven)
polyphase(halfOrderOdd)
```

To summarize, `dsp.FIRHalfbandDecimator`

- decimates the input prior to filtering and filters the even and odd polyphase components of the input separately with the even and odd polyphase components of the filter.
- exploits the fact that one filter polyphase component is a simple delay for a halfband filter.

dsp.FIRHalfbandInterpolator

Package: dsp

Halfband interpolator

Description

The `dsp.FIRHalfbandInterpolator` System object performs efficient polyphase interpolation of the input signal using an upsampling factor of two. You can use `dsp.FIRHalfbandInterpolator` to implement the synthesis portion of a two-band filter bank to synthesize a signal from lowpass and highpass subbands. `dsp.FIRHalfbandInterpolator` uses an FIR equiripple design to construct the halfband filters and a polyphase implementation to filter the input.

To upsample and interpolate your data:

- 1 Create the `dsp.FIRHalfbandInterpolator` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

Creation

Syntax

```
firhalfbandinterp = dsp.FIRHalfbandInterpolator  
firhalfbandinterp = dsp.FIRHalfbandInterpolator(Name,Value)
```

Description

`firhalfbandinterp = dsp.FIRHalfbandInterpolator` returns a FIR halfband interpolation filter, `firhalfbandinterp`, with the default settings. Under the default settings, the System object upsamples and interpolates the input data using a halfband frequency of 11025 Hz, a transition width of 4.1 kHz, and a stopband attenuation of 80 dB.

`firhalfbandinterp = dsp.FIRHalfbandInterpolator(Name,Value)` returns a halfband interpolator, with additional properties specified by one or more `Name,Value` pair arguments.

Example: `firhalfbandinterp = dsp.FIRHalfbandInterpolator('Specification','Filter order and stopband attenuation')` creates an FIR halfband interpolator object with filter order set to 52 and stopband attenuation set to 80 dB.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects.

Specification — Filter design parameters

'Transition width and stopband attenuation' (default) | 'Filter order and stopband attenuation' | 'Filter order and transition width' | 'Coefficients'

Filter design parameters, specified as a character vector. When you set `Specification` to one of the following, you choose two of the three available design parameters to design the FIR Halfband filter.

- 'Transition width and stopband attenuation' -- Transition width and stopband attenuation are the design parameters.
- 'Filter order and stopband attenuation' -- Filter order and stopband attenuation are the design parameters.
- 'Filter order and transition width' -- Filter order and transition width are the design parameters.

The filter is designed using optimal equiripple filter design method.

When you set `Specification` to 'Coefficients', you specify the halfband filter coefficients directly through the `Numerator` property.

FilterOrder — Filter order

52 (default) | even positive integer

Filter order, specified as an even positive integer.

Dependencies

This property applies when you set `Specification` to either 'Filter order and stopband attenuation' or 'Filter order and transition width'.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

StopbandAttenuation — Stopband attenuation

80 (default) | positive real scalar

Stopband attenuation in dB, specified as a positive real scalar.

Dependencies

This property applies when you set `Specification` to either 'Filter order and stopband attenuation' or 'Transition width and stopband attenuation'.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

TransitionWidth — Transition width

4100 (default) | positive real scalar

Transition width in Hz, specified as a positive real scalar. The value of the transition width in Hz must be less than 1/2 the input sample rate.

Dependencies

This property applies when you set `Specification` to either 'Transition width and stopband attenuation' or 'Filter order and transition width'.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

Numerator — FIR halfband filter coefficients

`2*firhalfband('minororder',0.407,1e-4)` (default) | row vector

FIR halfband filter coefficients, specified as a row vector. The coefficients must comply with the FIR halfband impulse response format. For details on this format, see “Halfband Filters” on page 4-598 and “FIR Halfband Filter Design”. If half the order of the filter, $(\text{length}(\text{Numerator}) - 1)/2$ is even, every other coefficient starting from the first coefficient must be a zero except for the center coefficient which must be a 1.0. If half the order of the filter is odd, the sequence of alternating zeros with a 1.0 at the center starts at the second coefficient.

Dependencies

This property applies when you set `Specification` to `'Coefficients'`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

SampleRate — Input sample rate

`44100` (default) | positive real scalar

Input sample rate in Hz, specified as a positive real scalar. The input sample rate defaults to 44100 Hz. If you specify a transition width as one of your filter design parameters, the transition width cannot exceed 1/2 the input sample rate.

Data Types: `single` | `double`

FilterBankInputPort — Synthesis filter bank

`false` (default) | `true`

Synthesis filter bank, specified as either `false` or `true`. If this property is `false`, `dsp.FIRHalfbandInterpolator` is an interpolation filter for a single vector- or matrix-valued input when you call the algorithm. If this property is `true`, `dsp.FIRHalfbandInterpolator` is a synthesis filter bank and the algorithm accepts two inputs, the lowpass and highpass subbands to `synthesize`.

Fixed-Point Properties

CoefficientsDataType — Word and fraction lengths of coefficients

`numerictype(1,16)` (default) | `numerictype` object

Word and fraction lengths of coefficients, specified as a signed or unsigned `numerictype` object. The default, `numerictype(1,16)` corresponds to a signed numeric type object with 16-bit coefficients and a fraction length determined based on the coefficient values, to give the best possible precision.

This property is not tunable.

Word length of the output is same as the word length of the input. Fraction length of the output is computed such that the entire dynamic range of the output can be represented without overflow. For details on how the fraction length of the output is computed, see “Fixed-Point Precision Rules for Avoiding Overflow in FIR Filters”.

RoundingMethod — Rounding method for output fixed-point operations

`'Floor'` (default) | `'Ceiling'` | `'Convergent'` | `'Nearest'` | `'Round'` | `'Simplest'` | `'Zero'`

Rounding method for output fixed-point operations, specified as a character vector. For more information on the rounding modes, see “Precision and Range”.

Usage

Syntax

```
y = firhalfbandinterp(x1)
y = firhalfbandinterp(x1,x2)
```

Description

`y = firhalfbandinterp(x1)` upsamples by two and interpolates the input signal `x1` using the FIR halfband interpolator, `firhalfbandinterp`.

`y = firhalfbandinterp(x1,x2)` implements a halfband synthesis filter bank for the inputs `x1` and `x2`. `x1` is the lowpass output of a halfband analysis filter bank and `x2` is the highpass output of a halfband analysis filter bank. `dsp.FIRHalfbandInterpolator` implements a synthesis filter bank only when the 'FilterBankInputPort' property is set to `true`.

Input Arguments

x1 — Data input

column vector | matrix

Data input to the FIR halfband interpolator, specified as a column vector or a matrix. This signal is the lowpass output of a halfband analysis filter bank. If the input signal is a matrix, each column of the matrix is treated as an independent channel.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fi`

x2 — Second data input

column vector | matrix

Second data input to the synthesis filter bank, specified as a column vector or a matrix. This signal is the highpass output of a halfband analysis filter bank. If the input signal is a matrix, each column of the matrix is treated as an independent channel.

The size, data type, and complexity of both the inputs must be the same.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fi`

Output Arguments

y — Output of interpolator

column vector | matrix

Output of the interpolator, returned as a column vector or a matrix. The number of rows in the interpolator output is twice the number of rows in the input signal.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fi`

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Specific to `dsp.FIRHalfbandInterpolator`

<code>freqz</code>	Frequency response of discrete-time filter System object
<code>fvtool</code>	Visualize frequency response of DSP filters
<code>info</code>	Information about filter System object
<code>cost</code>	Estimate cost of implementing filter System object
<code>coeffs</code>	Returns the filter System object coefficients in a structure
<code>polyphase</code>	Polyphase decomposition of multirate filter

Common to All System Objects

<code>step</code>	Run System object algorithm
<code>release</code>	Release resources and allow changes to System object property values and input characteristics
<code>reset</code>	Reset internal states of System object

Examples

Impulse and Frequency Response of Halfband Interpolation Filter

Create a lowpass halfband interpolation filter for upsampling data to 44.1 kHz. Specify a filter order of 52 and a transition width of 4.1 kHz.

```
Fs = 44.1e3;  
InputSampleRate = Fs/2;  
Order = 52;  
TW = 4.1e3;  
filterspec = 'Filter order and transition width';  
  
firhalfbandinterp = dsp.FIRHalfbandInterpolator(...  
    'Specification',filterspec,'FilterOrder',Order,...  
    'TransitionWidth',TW,'SampleRate',InputSampleRate);
```

Plot the impulse response. The 0th order coefficient is delayed 26 samples, which is equal to the group delay of the filter. This yields a causal halfband filter.

```
fvtool(firhalfbandinterp,'Analysis','Impulse');
```

Plot the magnitude and phase response.

```
fvtool(firhalfbandinterp, 'Analysis', 'freq');
```

Extract Low Frequency Subband From Speech

Use a halfband analysis filter bank and interpolation filter to extract the low frequency subband from a speech signal.

Note: If you are using R2016a or an earlier release, replace each call to the object with the equivalent `step` syntax. For example, `obj(x)` becomes `step(obj,x)`.

Note: The `audioDeviceWriter` System object™ is not supported in MATLAB Online.

Set up the audio file reader, the analysis filter bank, audio device writer, and interpolation filter. The sampling rate of the audio data is 22050 Hz. The order of the halfband filter is 52, with a transition width of 2 kHz.

```
afr = dsp.AudioFileReader(...
    'speech_dft.mp3',...
    'SamplesPerFrame',1024);

filtSpec = 'Filter order and transition width';
Order = 52;
TW = 2000;

firhalfbanddecim = dsp.FIRHalfbandDecimator(...
    'Specification',filtSpec,...
```

```

    'FilterOrder',Order,...
    'TransitionWidth',TW,...
    'SampleRate',afr.SampleRate);

firhalfbandinterp = dsp.FIRHalfbandInterpolator(...
    'Specification',filtSpec,...
    'FilterOrder',Order,...
    'TransitionWidth',TW,...
    'SampleRate',afr.SampleRate/2);

adw = audioDeviceWriter('SampleRate',...
    afr.SampleRate);

```

View the magnitude response of the halfband filter.

```
fvtool(firhalfbanddecim)
```

Read the speech signal from the audio file in frames of 1024 samples. Filter the speech signal into lowpass and highpass subbands with a halfband frequency of 5512.5 Hz. Reconstruct a lowpass approximation of the speech signal by interpolating the lowpass subband. Play the filtered output.

```

while ~isDone(afr)
    audioframe = afr();
    xlo = firhalfbanddecim(audioframe);
    ylow = firhalfbandinterp(xlo);
    adw(ylow);
end

```

Wait until the audio file is played to the end, then close the input file and release the audio output resource.

```
release(afr);  
release(adw);
```

Two-Channel Filter Bank

Use a halfband decimator and interpolator to implement a two-channel filter bank. This example uses an audio file input and shows that the power spectrum of the filter bank output does not differ significantly from the input.

Note: If you are using R2016a or an earlier release, replace each call to the object with the equivalent step syntax. For example, `obj(x)` becomes `step(obj,x)`.

Note: The `audioDeviceWriter` System object™ is not supported in MATLAB Online.

Set up the audio file reader and device writer. Construct the FIR halfband decimator and interpolator. Finally, set up the spectrum analyzer to display the power spectra of the filter-bank input and output.

```
AF = dsp.AudioFileReader('speech_dft.mp3','SamplesPerFrame',1024);  
AP = audioDeviceWriter('SampleRate',AF.SampleRate);
```

```
filterspec = 'Filter order and transition width';  
Order = 52;  
TW = 2000;
```

```
firhalfbanddecim = dsp.FIRHalfbandDecimator(...  
    'Specification',filterspec,'FilterOrder',Order,...  
    'TransitionWidth',TW,'SampleRate',AF.SampleRate);
```

```
firhalfbandinterp = dsp.FIRHalfbandInterpolator(...  
    'Specification',filterspec,'FilterOrder',Order,...  
    'TransitionWidth',TW,'SampleRate',AF.SampleRate/2,...  
    'FilterBankInputPort',true);
```

```
SpecAna = dsp.SpectrumAnalyzer('SampleRate',AF.SampleRate,...  
    'PlotAsTwoSidedSpectrum',false,'ReducePlotRate',false,...  
    'ShowLegend',true,...  
    'ChannelNames',{'Input signal','Filtered output signal'});
```

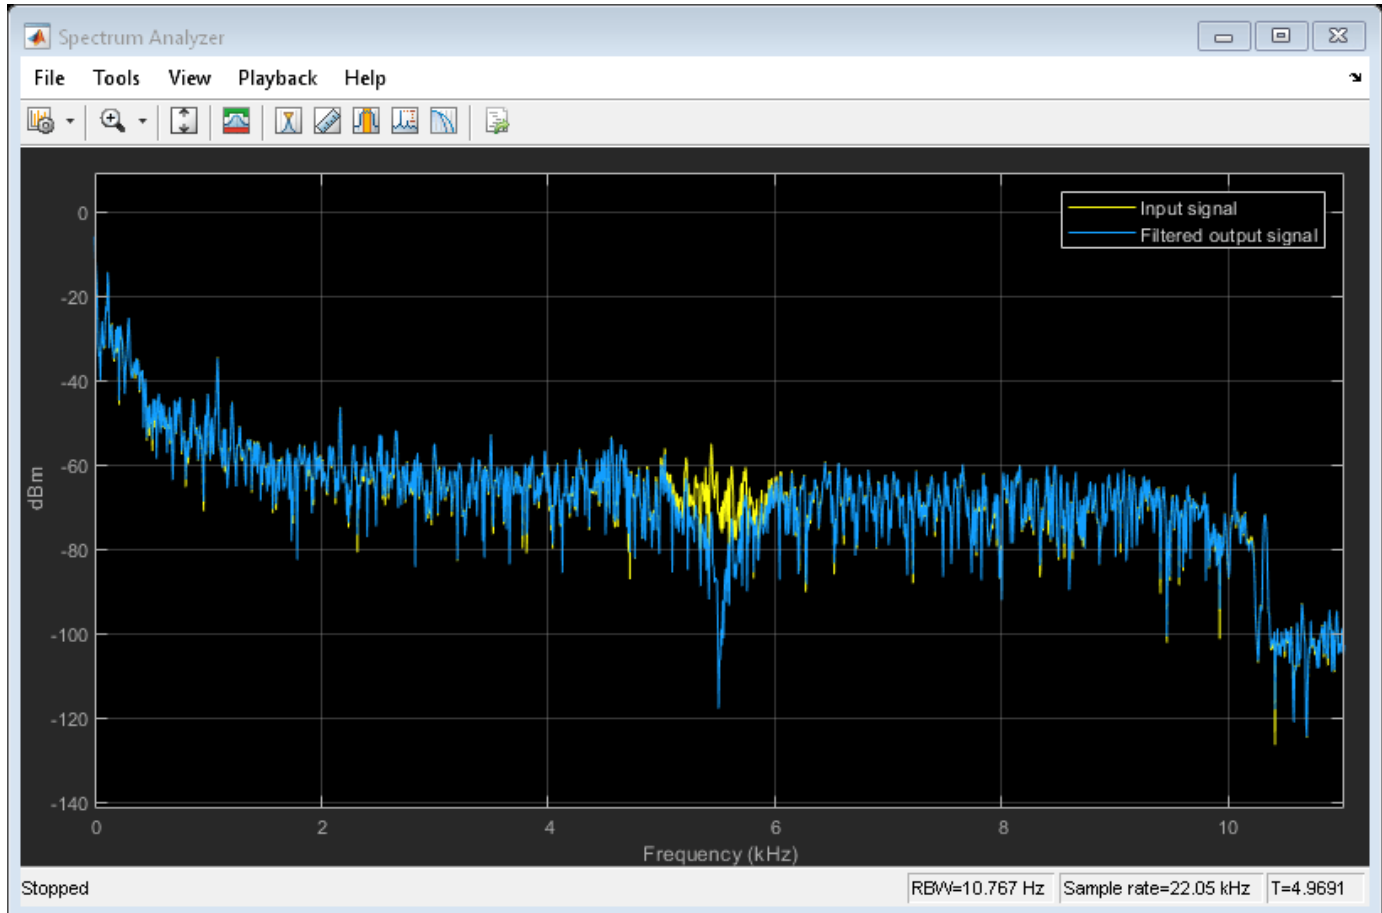

Read the audio 1024 samples at a time. Filter the input to obtain the lowpass and highpass subband signals decimated by a factor of two. This is the analysis filter bank. Use the halfband interpolator as the synthesis filter bank. Display the running power spectrum of the audio input and the output of the synthesis filter bank. Play the output.

```
while ~isDone(AF)  
    audioInput = AF();  
    [xlo,xhigh] = firhalfbanddecim(audioInput);  
    audioOutput = firhalfbandinterp(xlo,xhigh);  
    spectrumInput = [audioInput audioOutput];  
    SpecAna(spectrumInput);  
    AP(audioOutput);  
end
```

```

release(AF);
release(AP);
release(SpecAna);

```

Upsample and Interpolate Multichannel Input Using FIR Halfband Interpolator

Create a half-band interpolation filter for data sampled at 44.1 kHz. The filter order is 52 with a transition width of 4.1 kHz. Use the filter to upsample and interpolate a multichannel input.

```

Fs = 44.1e3;
filterspec = 'Filter order and transition width';
Order = 52;
TW = 4.1e3;
firhalfbandinterp = dsp.FIRHalfbandInterpolator(...
    'Specification',filterspec,...
    'FilterOrder',Order,...
    'TransitionWidth',TW,...
    'SampleRate',Fs);

x = randn(1024,4);
y = firhalfbandinterp(x);

```

More About

Halfband Filters

The ideal lowpass halfband filter is given by

$$h(n) = \frac{1}{2\pi} \int_{-\pi/2}^{\pi/2} e^{j\omega n} d\omega = \frac{\sin(\frac{\pi}{2}n)}{\pi n}.$$

The ideal filter is not realizable because the impulse response is noncausal and not absolutely summable. However, the impulse response of the ideal lowpass filter possesses some important properties that are required of a realizable approximation. Specifically, the ideal lowpass halfband filter's impulse response is:

- equal to 0 for all even-indexed samples
- equal to 1/2 at $n=0$. You can see this by using L'Hopital's rule on the continuous-valued equivalent of the discrete-time impulse response.

The ideal highpass halfband filter is given by

$$g(n) = \frac{1}{2\pi} \int_{-\pi}^{-\pi/2} e^{j\omega n} d\omega + \frac{1}{2\pi} \int_{\pi/2}^{\pi} e^{j\omega n} d\omega.$$

Evaluating the preceding integral gives the following impulse response

$$g(n) = \frac{\sin(\pi n)}{\pi n} - \frac{\sin(\frac{\pi}{2}n)}{\pi n}.$$

The ideal highpass halfband filter's impulse is:

- Equal to 0 for all even-indexed samples
- Equal to 1/2 at $n=0$.

`dsp.FIRHalfbandInterpolator` uses a causal FIR approximation to the ideal halfband response, which is based on minimizing the ℓ^∞ norm of the error (minimax). See "Algorithms" on page 4-598 for more details.

Algorithms

Halfband Equiripple Design

`dsp.FIRHalfbandInterpolator` uses a minimax FIR design to design a fullband linear phase filter with the desired specifications. The fullband filter is upsampled so that the even-indexed samples of the filter are replaced with zeros. The upsampling of the filter produces a halfband filter. Finally, the filter tap corresponding to the group delay of the filter in samples is set equal to 1/2. This yields a causal linear-phase FIR filter approximation to the ideal halfband filter defined in "Halfband Filters" on page 4-598. See [1] for a description of this filter design method using the Remez exchange algorithm.

The coefficients of the halfband interpolation filter are scaled by the interpolation factor, two, to preserve the output power of the signal.

Polyphase Implementation with Halfband Filters

`dsp.FIRHalfbandInterpolator` uses an efficient polyphase implementation for halfband filters when you filter the input signal. You can use a polyphase implementation to move the upsampling operation after filtering. This allows you to filter at the lower sampling rate.

Splitting a filter's impulse response, $h(n)$, into two polyphase components results in an even polyphase component with z -transform

$$H_0(z) = \sum_n h(2n)z^{-n}.$$

and an odd polyphase component with z -transform

$$H_1(z) = \sum_n h(2n + 1)z^{-n}.$$

The z -transform of the filter can be written in terms of the even and odd polyphase components as

$$H(z) = H_0(z^2) + z^{-1}H_1(z^2).$$

Graphically, you can represent upsampling by two followed by filtering with the following figure

Using the multirate noble identity for upsampling, you can move the upsampling operation after filtering. This enables you to filter at the lower rate.

For a halfband filter, the only nonzero coefficient in the even polyphase component is the coefficient corresponding to z^0 . Implementing the halfband filter as a causal FIR filter shifts the nonzero coefficient to approximately $z^{-N/4}$, where N is the number of filter taps. This process is shown in the following figure.

The top plot shows a halfband filter of order 52. The bottom plot shows the even polyphase component. Both of these filters are noncausal. Delaying the even polyphase component by 13 samples creates a causal FIR filter.

To efficiently implement the halfband interpolator, `dsp.FIRHalfbandInterpolator` replaces the upsampling operator, delay block, and adder with a commutator switch. This is shown in the following figure, where one polyphase component is replaced by a delay.

The commutator switch takes input samples from the two branches alternately, one sample at a time. This doubles the sampling rate of the input signal. The polyphase component that reduces to a simple delay depends on whether the half order of the filter is even or odd. This is because the delay required to make the even polyphase component causal can be odd or even, depending on the filter half order. For an example of this behavior, inspect the polyphase components of the following filters.

```
filterspec = 'Filter order and stopband attenuation';
halfOrderEven = dsp.FIRHalfbandInterpolator('Specification',filterspec,...
    'FilterOrder',64,'StopbandAttenuation',80);
halfOrderOdd = dsp.FIRHalfbandInterpolator('Specification',filterspec,...
    'FilterOrder', 54,'StopbandAttenuation',80);
polyphase(halfOrderEven)
polyphase(halfOrderOdd)
```

One of the polyphase components has a single nonzero coefficient indicating that it is a simple delay. To preserve the output power of the signal, the coefficients are scaled by the interpolation factor, two. To see this scaling, compare the polyphase components of a halfband interpolator with the coefficients of a halfband decimator.

```
hfirinterp = dsp.FIRHalfbandInterpolator;
hfirdecim = dsp.FIRHalfbandDecimator;
polyphase(hfirdecim)
polyphase(hfirinterp)
```

To summarize, `dsp.FIRHalfbandInterpolator`

- Filters the input before upsampling with the even and odd polyphase components of the filter.
- Exploits the fact that one filter polyphase component is a simple delay for a halfband filter.

dsp.FIRInterpolator

Package: dsp

Polyphase FIR interpolator

Description

The `dsp.FIRInterpolator` System object upsamples an input by the integer upsampling factor L along the first dimension. The FIR interpolator (as shown in the schematic) conceptually consists of an upsampler followed by an FIR anti-imaging filter, which is usually an approximation of an ideal band-limited interpolation filter. The coefficients of the anti-imaging filter can be specified through the `Numerator` property, or can be automatically designed by the object using the `designMultirateFIR` function.

The upsampler upsamples each channel of the input to a higher rate by inserting $L-1$ zeros between samples. The FIR filter that follows filters each channel of the upsampled data. The resulting discrete-time signal has a sample rate that is L times the original sample rate.

Note that the actual object algorithm implements a direct-form FIR polyphase structure, an efficient equivalent of the combined system depicted in the diagram. For more details, see "Algorithms" on page 4-618.

To upsample an input:

- 1 Create the `dsp.FIRInterpolator` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

Under specific conditions, this System object also supports SIMD code generation. For details, see "Code Generation" on page 4-620.

Creation

Syntax

```
firinterp = dsp.FIRInterpolator
firinterp = dsp.FIRInterpolator(L)
firinterp = dsp.FIRInterpolator(L, 'Auto')
```

```
firinterp = dsp.FIRInterpolator(L,num)
firinterp = dsp.FIRInterpolator(L,method)
firinterp = dsp.FIRInterpolator( ____,Name,Value)
firinterp = dsp.FIRInterpolator(L,'legacy')
```

Description

`firinterp = dsp.FIRInterpolator` returns an FIR interpolator with an interpolation factor of 3. The object designs the FIR filter coefficients using the `designMultirateFIR(3,1)` function.

`firinterp = dsp.FIRInterpolator(L)` returns an FIR interpolator with the integer-valued `InterpolationFactor` property set to L . The object designs its filter coefficients based on the interpolation factor L that you specify while creating the object using the `designMultirateFIR(L,1)` function. The designed filter corresponds to a lowpass with a cutoff at π/L in radial frequency units.

`firinterp = dsp.FIRInterpolator(L,'Auto')` returns an FIR interpolator with the `NumeratorSource` property set to 'Auto'. In this mode, every time there is an update in the interpolation factor, the object redesigns the filter using the design method specified in `DesignMethod`.

`firinterp = dsp.FIRInterpolator(L,num)` returns an FIR interpolator with the `InterpolationFactor` property set to L and the `Numerator` property set to `num`.

`firinterp = dsp.FIRInterpolator(L,method)` returns an FIR interpolator with the `InterpolationFactor` property set to L and the `DesignMethod` property set to `method`. When you pass the design method as an input, the `NumeratorSource` property is automatically set to 'Auto'.

`firinterp = dsp.FIRInterpolator(____,Name,Value)` returns an FIR interpolator object with each specified property set to the specified value. Enclose each property name in quotes. You can use this syntax with any previous input argument combinations.

`firinterp = dsp.FIRInterpolator(L,'legacy')` returns an FIR interpolator where the filter coefficients are designed using `fir1(15,0.25)`. The designed filter has a cutoff frequency of 0.25π radians/sample.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see *System Design in MATLAB Using System Objects*.

InterpolationFactor — Interpolation factor

3 (default) | positive integer

Specify the integer factor, L , by which to increase the sampling rate of the input signal. The polyphase implementation uses L polyphase subfilters to compute convolutions at the lower sample rate. The FIR interpolator delays and interleaves these lower-rate convolutions to obtain the higher-rate output.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

NumeratorSource — FIR filter coefficient source

'Property' (default) | 'Input port' | 'Auto'

FIR filter coefficient source, specified as either:

- 'Property' -- The numerator coefficients are specified through the `Numerator` property.
- 'Input port' -- The numerator coefficients are specified as an input to the object algorithm.
- 'Auto' -- The numerator coefficients are designed automatically using the design method specified in `DesignMethod`.

Numerator — FIR filter coefficients`designMultirateFIR(L,1)` (default) | row vector

Numerator coefficients of the anti-imaging FIR filter, specified as a row vector in powers of z^{-1} . The following equation defines the system function for a filter of length $N+1$:

$$H(z) = \sum_{n=0}^N b(n)z^{-n}$$

The vector $\mathbf{b} = [b(0), b(1), \dots, b(N)]$ represents the vector of filter coefficients.

To act as an effective anti-imaging filter, the coefficients usually correspond to a lowpass filter with a normalized cutoff frequency no greater than the reciprocal of the `InterpolationFactor`. Use `designMultirateFIR` to design such a filter. More generally, any complex bandpass filter can be used. For an example, see “Double the Sample Rate Using FIR Interpolator” on page 4-616.

The filter coefficients are scaled by the value of the `InterpolationFactor` property before filtering the signal. To form the L polyphase subfilters, `Numerator` is appended with zeros if necessary.

Dependencies

This property is visible only when you set `NumeratorSource` to 'Property'.

When `NumeratorSource` is set to 'Auto', the numerator coefficients are automatically redesigned using the design method specified in `DesignMethod`. To access the filter coefficients in the automatic design mode, type `objName.Numerator` in the MATLAB command prompt.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

DesignMethod — Auto design method

'Kaiser' (default) | 'ZOH' | 'Linear'

Design method of the FIR filter coefficients, specified as one of the following:

- 'Kaiser' -- Kaiser method. Approximate anti-imaging lowpass filter using the `designMultirateFIR` function.
- 'ZOH' -- Zero order hold method. Hold the input sequence values.
- 'Linear' -- Linear interpolation method.

Dependencies

This property is visible only when you set the `NumeratorSource` property to 'Auto', or if you pass the 'auto' keyword as an input while creating the object.

Fixed-Point Properties

FullPrecisionOverride — Full-precision override for fixed-point arithmetic

true (default) | false

Flag to use full-precision rules for fixed-point arithmetic, specified as one of the following:

- `true` -- The object computes all internal arithmetic and output data types using the full-precision rules. These rules provide the most accurate fixed-point numerics. In this mode, other fixed-point properties do not apply. No quantization occurs within the object. Bits are added, as needed, to ensure that no roundoff or overflow occurs.
- `false` -- Fixed-point data types are controlled through individual fixed-point property settings.

For more information, see “Full Precision for Fixed-Point System Objects” and “Set System Object Fixed-Point Properties”.

RoundingMethod — Rounding method for fixed-point operations

'Floor' (default) | 'Ceiling' | 'Convergent' | 'Nearest' | 'Round' | 'Simplest' | 'Zero'

Rounding method for fixed-point operations. For more details, see rounding mode.

Dependencies

This property is not visible and has no effect on the numerical results when the following conditions are met:

- FullPrecisionOverride set to `true`.
- FullPrecisionOverride set to `false`, ProductDataType set to 'Full precision', AccumulatorDataType set to 'Full precision', and OutputDataType set to 'Same as accumulator'.

Under these conditions, the object operates in full precision mode.

OverflowAction — Overflow action for fixed-point operations

'Wrap' (default) | 'Saturate'

Overflow action for fixed-point operations, specified as one of the following:

- `'Wrap'` -- The object wraps the result of its fixed-point operations.
- `'Saturate'` -- The object saturates the result of its fixed-point operations.

For more details on overflow actions, see overflow mode for fixed-point operations.

Dependencies

This property is not visible and has no effect on the numerical results when the following conditions are met:

- FullPrecisionOverride set to `true`.
- FullPrecisionOverride set to `false`, OutputDataType set to 'Same as accumulator', ProductDataType set to 'Full precision', and AccumulatorDataType set to 'Full precision'

Under these conditions, the object operates in full precision mode.

CoefficientsDataType — Data type of FIR filter coefficients

Same word length as input (default) | Custom

Data type of the FIR filter coefficients, specified as:

- `Same word length as input` -- The word length of the coefficients is the same as that of the input. The fraction length is computed to give the best possible precision.
- `Custom` -- The coefficients data type is specified as a custom numeric type through the `CustomCoefficientsDataType` property.

CustomCoefficientsDataType — Word and fraction lengths of coefficients data type

numericType([],16,15) (default) | custom numeric type

Word and fraction lengths of the coefficients data type, specified as an autosigned numeric type with a word length of 16 and a fraction length of 15.

DependenciesThis property applies when you set the `CoefficientsDataType` property to `Custom`.**ProductDataType — Data type of product output**

'Full precision' (default) | 'Custom' | 'Same as input'

Data type of the product output in this object, specified as one of the following:

- `'Full precision'` -- The product output data type has full precision.
- `'Same as input'` -- The object specifies the product output data type to be the same as that of the input data type.
- `'Custom'` -- The product output data type is specified as a custom numeric type through the `CustomProductDataType` property.

For more information on the product output data type, see “Multiplication Data Types”.

DependenciesThis property applies when you set `FullPrecisionOverride` to `false`.**CustomProductDataType — Word and fraction lengths of product data type**

numericType([],32,30) (default) | custom numeric type

Word and fraction lengths of the product data type, specified as an autosigned numeric type with a word length of 32 and a fraction length of 30.

DependenciesThis property applies only when you set `FullPrecisionOverride` to `false` and `ProductDataType` to `'Custom'`.**AccumulatorDataType — Data type of accumulation operation**

'Full precision' (default) | 'Same as input' | 'Same as product' | 'Custom'

Data type of an accumulation operation in this object, specified as one of the following:

- `'Full precision'` -- The accumulation operation has full precision.
- `'Same as product'` -- The object specifies the accumulator data type to be the same as that of the product output data type.

- 'Same as input' -- The object specifies the accumulator data type to be the same as that of the input data type.
- 'Custom' -- The accumulator data type is specified as a custom numeric type through the CustomAccumulatorDataType property.

Dependencies

This property applies when you set FullPrecisionOverride to false.

CustomAccumulatorDataType — Word and fraction lengths of accumulator data type

numericType([],32,30) (default) | custom numeric type

Word and fraction lengths of the accumulator data type, specified as an autosigned numeric type with a word length of 32 and a fraction length of 30.

Dependencies

This property applies only when you set FullPrecisionOverride to false and AccumulatorDataType to 'Custom'.

OutputDataType — Data type of object output

'Same as accumulator' (default) | 'Same as input' | 'Same as product' | 'Custom'

Data type of the object output, specified as one of the following:

- 'Same as accumulator' -- The output data type is the same as that of the accumulator output data type.
- 'Same as input' -- The output data type is the same as that of the input data type.
- 'Same as product' -- The output data type is the same as that of the product output data type.
- 'Custom' -- The output data type is specified as a custom numeric type through the CustomOutputDataType property.

Dependencies

This property applies when you set FullPrecisionOverride to false.

CustomOutputDataType — Word and fraction lengths of output data type

numericType([],16,15) (default) | custom numeric type

Word and fraction lengths of the output data type, specified as an autosigned numeric type with a word length of 16 and a fraction length of 15.

Dependencies

This property applies only when you set FullPrecisionOverride to false and OutputDataType to 'Custom'.

Usage

Syntax

```
y = firinterp(x)
y = firinterp(x,num)
```

Description

$y = \text{firinterp}(x)$ interpolates the input signal x along the first dimension, and outputs the upsampled and filtered values, y .

$y = \text{firinterp}(x, \text{num})$ uses the FIR filter, num , to interpolate the input signal. This configuration is valid only when the 'NumeratorSource' property is set to 'Input port'.

Input Arguments

x — Data input

vector | matrix

Data input, specified as a vector or a matrix. A P -by- Q input matrix is treated as Q independent channels, and the System object interpolates each channel over the first dimension and generates a $P*L$ -by- Q output matrix, where L is the interpolation factor.

This object supports variable-size input and does not support complex unsigned fixed-point inputs.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fi

num — FIR filter coefficients

row vector

FIR filter coefficients, specified as a row vector.

Dependencies

This input is accepted only when the 'NumeratorSource' property is set to 'Input port'.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fi

Output Arguments

y — FIR interpolator output

vector | matrix

FIR interpolator output, returned as a vector or a matrix of size $P*L$ -by- Q , where L is the interpolation factor.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fi

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Specific to dsp.FIRInterpolator

freqz	Frequency response of discrete-time filter System object
fvtool	Visualize frequency response of DSP filters

info	Information about filter System object
cost	Estimate cost of implementing filter System object
polyphase	Polyphase decomposition of multirate filter
generatehdl	Generate HDL code for quantized DSP filter (requires Filter Design HDL Coder)
impz	Impulse response of discrete-time filter System object
coeffs	Returns the filter System object coefficients in a structure

Common to All System Objects

step	Run System object algorithm
release	Release resources and allow changes to System object property values and input characteristics
reset	Reset internal states of System object

Examples

Interpolate a Cosine Wave

Interpolate a cosine wave by a factor of 2. In the automatic filter design mode, change the underlying D/A signal interpolation model to 'linear' and interpolate the signal by a factor of 4, change the underlying D/A signal interpolation model to 'ZOH' and interpolate the signal by a factor of 5.

The cosine wave has an angular frequency of $\frac{\pi}{4}$ radians/sample.

```
x = cos(pi/4*(0:39));
```

Design Default Filter

Create a `dsp.FIRInterpolator` object. The object uses an anti-imaging lowpass filter after upsampling. By default, the anti-imaging lowpass filter is designed using the `designMultirateFIR` function. The function designs the filter based on the interpolation factor that you specify, and stores the coefficients in the `Numerator` property. For an interpolation factor of 2, the object designs the coefficients using `designMultirateFIR(2,1)`.

```
firinterp = dsp.FIRInterpolator(2)
```

```
firinterp =  
dsp.FIRInterpolator with properties:  
    InterpolationFactor: 2  
    NumeratorSource: 'Property'  
    Numerator: [0 -2.0108e-04 0 7.7408e-04 0 -0.0020 0 0.0045 ... ]
```

```
Show all properties
```

Visualize the filter response using `fvtool`. The designed filter meets the ideal filter constraints that are marked in red. The cutoff frequency is approximately half the spectrum.

```
fvtool(firinterp)
```

Interpolate by 2

Interpolate the cosine signal by a factor of 2.

```
y = firinterp(x);
```

Plot the original and interpolated signals. In order to plot the two signals on the same plot, obtain the time affine transformation parameters. Use these parameters to compute the output sample times.

The n^{th} output sample time equals $\text{scale} \times n + \text{delay}$. The input and output values coincide every other sample, due to the interpolation factor of 2.

```
scale = firinterp.InterpolationFactor;
delay = length(firinterp.Numerator)/2;
nx = (0:length(x)-1);

% Calculate output times for vector y in input units
ty = ((0:length(y)-1)-delay)/scale;

stem(ty,y,'filled',MarkerSize=4); hold on;
stem(nx,x); hold off;
xlim([-5,20])
ylim([-2.5 2.5])
legend('Interpolated by 2','Input signal');
```

Interpolate by 4 in Automatic Filter Design Mode

Now interpolate by a factor of 4. In order for the filter design to be updated automatically based on the new interpolation factor, set the `NumeratorSource` property to `'Auto'`. Alternately, you can pass the keyword `'auto'` as an input while creating the object. The object then operates in the automatic filter design mode. Every time there is a change in the interpolation factor, the object updates the filter design.

```
release(firinterp)
firinterp.NumeratorSource = 'Auto';
firinterp.InterpolationFactor = 4

firinterp =
  dsp.FIRInterpolator with properties:

    InterpolationFactor: 4
    NumeratorSource: 'Auto'
    DesignMethod: 'Kaiser'

Show all properties
```

To access the filter coefficients in the automatic filter design mode, type `firinterp.Numerator` in the MATLAB command prompt.

The designed filter occupies a narrower passband that is approximately a quarter of the spectrum.

```
fvtool(firinterp)
```

Interpolate the cosine signal by a factor of 4.

```
yAuto = firinterp(x);
```

Plot the original and resampled signals. Recalculate the time affine transformation parameters since the interpolation factor has changed. The input and output values coincide every 4 output samples, owing to the interpolation factor of 4.

```
scale = firinterp.InterpolationFactor;
delay = length(firinterp.Numerator)/2;
nx = (0:length(x)-1);

% Calculate output times for vector yAuto in input units
tyAuto = ((0:length(yAuto)-1)-delay)/scale;

stem(tyAuto,yAuto,'filled',MarkerSize=4); hold on;
stem(nx,x); hold off;
xlim([-5,10])
ylim([-2.5 2.5])
legend('Interpolated by 4','Input signal');
```

Specify Signal Interpolation Model

In the automatic design mode, you can also specify the underlying D/A signal interpolation model through the `DesignMethod` property.

Set `DesignMethod` to 'linear'

If you set the `DesignMethod` to 'linear', the object uses the linear interpolation model.

```
release(firinterp)
firinterp.DesignMethod = 'linear'

firinterp =
  dsp.FIRInterpolator with properties:

    InterpolationFactor: 4
    NumeratorSource: 'Auto'
    DesignMethod: 'Linear'

Show all properties
```

Interpolate the signal using the linear interpolation model.

```
ylinear = firinterp(x);
```

Plot the original and the linearly interpolated signal.

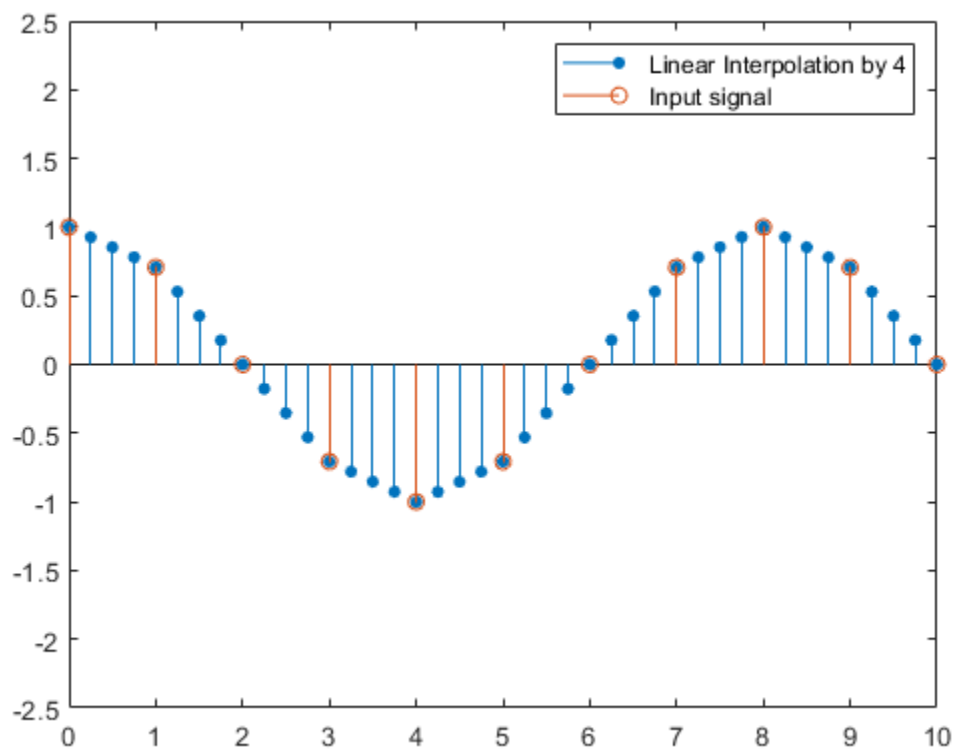

```

scale = firinterp.InterpolationFactor;
delay = (length(firinterp.Numerator)-1)/2;
nx = (0:length(x)-1);

% Calculate output times for vector ylinear in input units
tylinear = ((0:length(ylinear)-1)-delay)/scale;

stem(tylinear,ylinear,'filled',MarkerSize=4); hold on;
stem(nx,x);
hold off;
xlim([0,10])
ylim([-2.5 2.5])
legend('Linear Interpolation by 4','Input signal');

```

Set DesignMethod to 'ZOH' and Change InterpolationFactor to 5

If you set the `DesignMethod` to 'ZOH', the object uses the zero order hold method. Change the interpolation factor to 5.

```

release(firinterp)
firinterp.DesignMethod = 'ZOH';
firinterp.InterpolationFactor = 5

firinterp =
    dsp.FIRInterpolator with properties:

        InterpolationFactor: 5
        NumeratorSource: 'Auto'

```

```
DesignMethod: 'ZOH'
```

```
Show all properties
```

Interpolate the signal using the zero order hold method.

```
yzoh = firinterp(x);
```

Plot the original and ZOH interpolated signal.

```
scale = firinterp.InterpolationFactor;
delay = floor((length(firinterp.Numerator)-1)/2);
nx = (0:length(x)-1);

% Calculate output times for vector yzoh in input units
tyzoh = ((0:length(yzoh)-1)-delay)/scale;

stem(tyzoh,yzoh,'filled',MarkerSize=4); hold on;
stem(nx,x); hold off;
xlim([0,10])
ylim([-1.5 1.5])
legend('ZOH Interpolation by 4','Input signal');
```

Double the Sample Rate Using FIR Interpolator

Double the sample rate of an audio signal and play the interpolated signal using the `audioDeviceWriter` object.

Note: If you are using R2016a or an earlier release, replace each call to the object with the equivalent `step` syntax. For example, `obj(x)` becomes `step(obj,x)`.

Note: The `audioDeviceWriter` System object™ is not supported in MATLAB Online.

Create a `dsp.AudioFileReader` object. The default audio file ready by the object has a sample rate of 22050 Hz.

```
afr = dsp.AudioFileReader('OutputDataType',...
    'single');
```

Create a `dsp.FIRInterpolator` object and specify the interpolation factor to be 2. The object designs the filter using the `designMultirateFIR(2,1)` function and stores the coefficients in the `Numerator` property of the object.

```
firInterp = dsp.FIRInterpolator(2)
```

```
firInterp =
    dsp.FIRInterpolator with properties:
        InterpolationFactor: 2
        NumeratorSource: 'Property'
        Numerator: [0 -2.0108e-04 0 7.7408e-04 0 -0.0020 0 0.0045 ... ]
```

Show all properties

Create an `audioDeviceWriter` object. Specify the sample rate to be 22050×2 , which equals 44100 Hz.

```
adw = audioDeviceWriter(44100)
```

```
adw =
    audioDeviceWriter with properties:
        Driver: 'DirectSound'
        Device: 'Default'
        SampleRate: 44100
```

Show all properties

Read the audio signal using the file reader object, double the sample rate of the signal from 22050 Hz to 44100 Hz and play the interpolated signal.

```
while ~isDone(afr)
    frame = afr();
    y = firInterp(frame);
    adw(y);
end

pause(1);
```

```
release(afr);
release(adw);
```

Algorithms

The FIR interpolation filter is implemented efficiently using a polyphase structure.

To derive the polyphase structure, start with the transfer function of the FIR filter:

$$H(z) = b_0 + b_1z^{-1} + \dots + b_Nz^{-N}$$

$N+1$ is the length of the FIR filter.

You can rearrange this equation as follows:

$$\begin{aligned}
 H(z) = & (b_0 + b_Lz^{-L} + b_{2L}z^{-2L} + \dots + b_{N-L+1}z^{-(N-L+1)}) + \\
 & z^{-1}(b_1 + b_{L+1}z^{-L} + b_{2L+1}z^{-2L} + \dots + b_{N-L+2}z^{-(N-L+1)}) + \\
 & \vdots \\
 & z^{-(L-1)}(b_{L-1} + b_{2L-1}z^{-L} + b_{3L-1}z^{-2L} + \dots + b_Nz^{-(N-L+1)})
 \end{aligned}$$

L is the number of polyphase components, and its value equals the interpolation factor that you specify.

You can write this equation as:

$$H(z) = E_0(z^L) + z^{-1}E_1(z^L) + \dots + z^{-(L-1)}E_{L-1}(z^L)$$

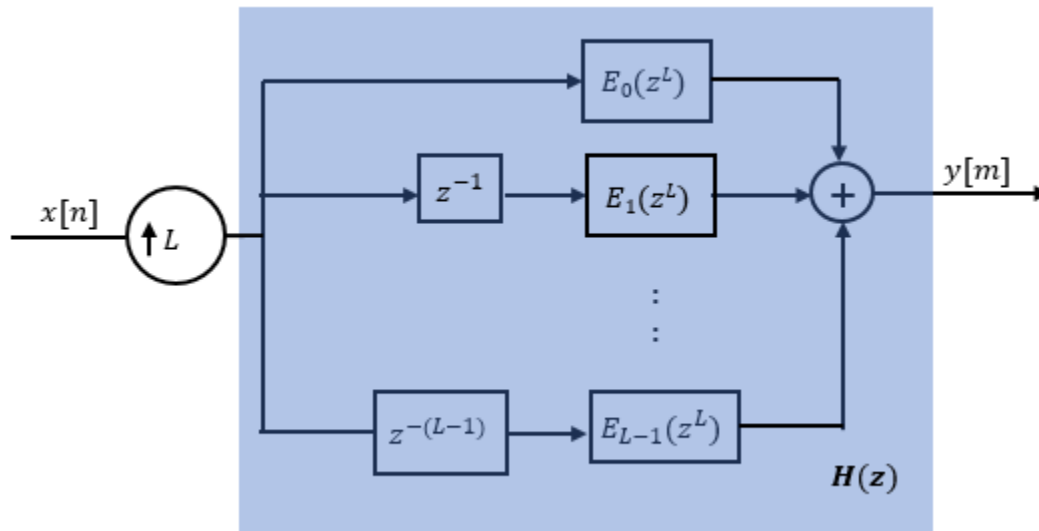

$E_0(z^L), E_1(z^L), \dots, E_{L-1}(z^L)$ are polyphase components of the FIR filter $H(z)$.

Conceptually, the FIR interpolation filter contains an upsampler followed by an FIR lowpass filter $H(z)$.

**Conceptual Operation
of FIR Interpolator**

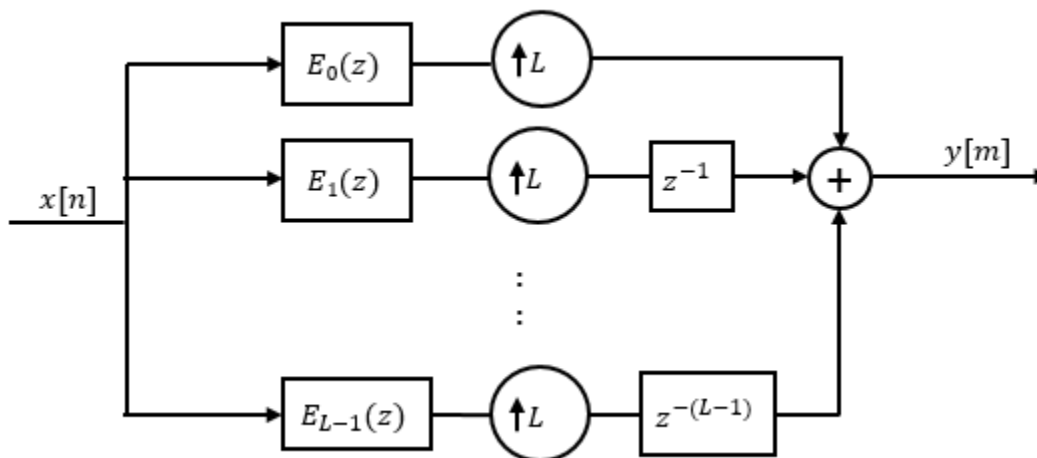

Replace $H(z)$ with its polyphase representation.

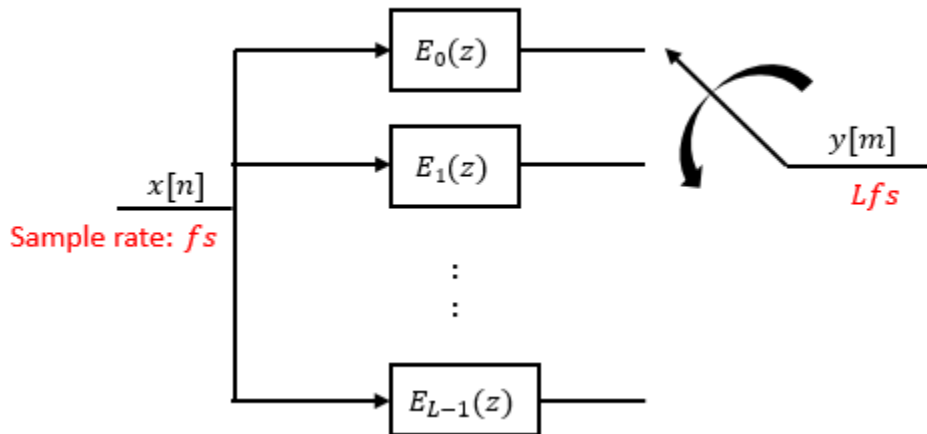

Here is the multirate noble identity for interpolation.

Applying the noble identity for interpolation moves the upsampling operation to after the filtering operation. This move enables you to filter the signal at a lower rate.

You can replace the upsampling operator, delay block, and adder with a commutator switch. The switch starts on the first branch 0 and moves in the counterclockwise direction, each time receiving one sample from each branch. The interpolator effectively outputs L samples for every one input sample it receives. Hence the sample rate at the output of the FIR interpolation filter is Lfs .

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

See “System Objects in MATLAB Code Generation” (MATLAB Coder).

The `dsp.FIRInterpolator` System object supports SIMD code generation using Intel AVX2 technology under these conditions:

- Input signal is real-valued with real filter coefficients.
- Input signal is complex-valued with real or complex filter coefficients.
- Input signal has a data type of `single` or `double`.

The SIMD technology significantly improves the performance of the generated code.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

This object supports HDL code generation with the Filter Design HDL Coder product. For workflows and limitations, see “Generate HDL Code for Filter System Objects” (Filter Design HDL Coder).

Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

Introduced in R2012a

`dsp.FIRRateConverter`

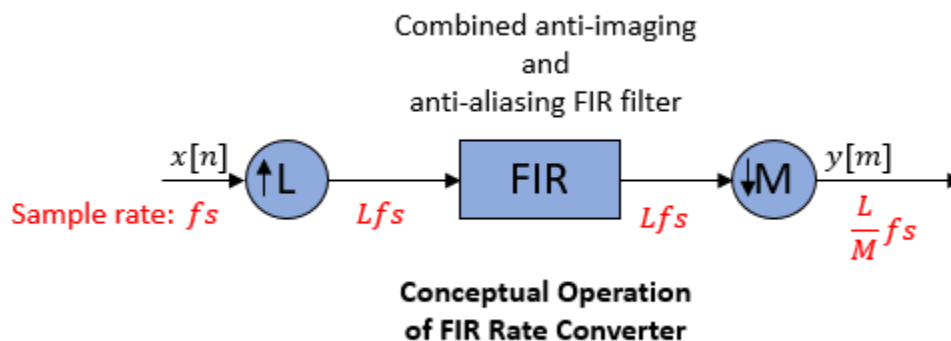

Package: dsp

Sample rate converter

Description

The `dsp.FIRRateConverter` System object performs sampling rate conversion by a rational factor on a vector or matrix input. The FIR rate converter cascades an interpolator with a decimator. The rate converter (as shown in the schematic) conceptually consists of an upsampler, followed by a combined anti-imaging and anti-aliasing FIR filter, followed by a downsampler. The coefficients of the anti-imaging and anti-aliasing FIR filter can be specified through the `Numerator` property, or can be automatically designed by the object using the `designMultirateFIR` function. For an example, see “Resample Signal Using FIR Rate Converter” on page 4-628.

The upsampler increases the sample rate of the signal by a factor L and the downsampler reduces the sample rate of the signal by a factor M . Use upsampling and downsampling factors that are relatively prime or coprime. The resulting discrete-time signal has a sample rate that is L/M times the original sample rate.

Note that the actual object algorithm implements a polyphase structure, an efficient equivalent of the combined system depicted in the diagram. For more details, see “Algorithms” on page 4-633.

To perform sampling rate conversion:

- 1 Create the `dsp.FIRRateConverter` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

Creation

Syntax

```
firrc = dsp.FIRRateConverter
firrc = dsp.FIRRateConverter(L,M)
firrc = dsp.FIRRateConverter(L,M,'Auto')
firrc = dsp.FIRRateConverter(L,M,num)
firrc = dsp.FIRRateConverter(L,M,method)
firrc = dsp.FIRRateConverter( ____,Name,Value)
firrc = dsp.FIRRateConverter(L,M,'legacy')
```

Description

`firrc = dsp.FIRRateConverter` returns an FIR sample rate converter object with an interpolation factor of 3 and a decimation factor of 2. The object designs the FIR filter coefficients using the `designMultirateFIR(3,2)` function.

`firrc = dsp.FIRRateConverter(L,M)` returns an FIR sample rate converter with the integer-valued `InterpolationFactor` property set to L and the `DecimationFactor` property set to M. The object designs its filter coefficients based on the rate conversion factors that you specify while creating the object, using the `designMultirateFIR(L,M)` function. The designed filter corresponds to a lowpass with normalized cutoff frequency no greater than $\min(\pi/L, \pi/M)$ in radial frequency units.

`firrc = dsp.FIRRateConverter(L,M,'Auto')` returns an FIR sample rate converter where the `NumeratorSource` property is set to 'Auto'. In this mode, every time there is an update in the rate conversion factors, the object redesigns the filter using the design method specified in `DesignMethod`.

`firrc = dsp.FIRRateConverter(L,M,num)` returns an FIR sample rate converter with the `InterpolationFactor` property set to L, the `DecimationFactor` property set to M, and the `Numerator` property set to num.

`firrc = dsp.FIRRateConverter(L,M,method)` returns an FIR sample rate converter with the `InterpolationFactor` property set to L, the `DecimationFactor` property set to M, and the `DesignMethod` property set to method. When you pass the design method as an input, the `NumeratorSource` property is automatically set to 'Auto'.

`firrc = dsp.FIRRateConverter(____,Name,Value)` returns an FIR sample rate converter with each specified property set to the specified value. Enclose each property name in quotes. You can use this syntax with any previous input argument combinations.

Example: `firrc = dsp.FIRRateConverter('FullPrecisionOverride','false')` enables the fixed-point data types to be controlled through the individual fixed-point property settings.

`firrc = dsp.FIRRateConverter(L,M,'legacy')` returns an FIR sample rate converter where the filter coefficients are designed using `firpm(70,[0 0.28 0.32 1],[1 1 0 0])`. The designed filter has a cutoff frequency of $\pi/3$ radians/sample.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects.

InterpolationFactor — Interpolation factor

3 (default) | positive integer

Interpolation factor L , specified as a positive integer.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

DecimationFactor — Decimation factor

2 (default) | positive integer

Decimation factor M , specified as a positive integer.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

NumeratorSource — FIR filter coefficient source

'Property' (default) | 'Auto'

FIR filter coefficient source, specified as one of the following:

- 'Property' -- The numerator coefficients are specified through the `Numerator` property.
- 'Auto' -- The numerator coefficients are designed automatically using the design method specified in `DesignMethod`.

Numerator — FIR filter coefficients

`designMultirateFIR(L,M)` (default) | row vector

Numerator coefficients of the FIR filter, specified as a row vector in powers of z^{-1} .

The following equation defines the transfer function of the filter:

$$H(z) = \sum_{n=0}^N b(n)z^{-n}$$

The vector $\mathbf{b} = [b(0), b(1), \dots, b(N)]$ represents the vector of filter coefficients.

Use a lowpass with normalized cutoff frequency no greater than $\min(1/L, 1/M)$, where L is the interpolation factor and M is the decimation factor. The gain of the lowpass filter should equal L , the interpolation factor. Choose the length of the filter to be a multiple of the interpolation factor. To design such a filter, use the `designMultirateFIR` function. For an example, see "Resample Signal Using FIR Rate Converter" on page 4-628. All initial filter states are zero.

Dependencies

This property is visible only when you set `NumeratorSource` to 'Property'.

When `NumeratorSource` is set to `'Auto'`, the numerator coefficients are automatically redesigned using the design method specified in `DesignMethod`. To access the filter coefficients in the automatic design mode, type `objName.Numerator` in the MATLAB command prompt.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

DesignMethod — Auto design method

`'Kaiser'` (default) | `'ZOH'` | `'Linear'`

Design method of the FIR filter coefficients, specified as one of the following:

- `'Kaiser'` -- Kaiser method. Approximate combined anti-aliasing and anti-imaging lowpass filter using the `designMultirateFIR` function.
- `'ZOH'` -- Zero order hold method. Hold the input sequence values.
- `'Linear'` -- Linear interpolation method.

Dependencies

This property is visible only when you set the `NumeratorSource` property to `'Auto'`, or if you pass the `'auto'` keyword as an input while creating the object.

Fixed-Point Properties

FullPrecisionOverride — Full precision override for fixed-point arithmetic

`true` (default) | `false`

Specify whether to use full precision rules. If you set `FullPrecisionOverride` to `true`, which is the default, the object computes all internal arithmetic and output data types using full precision rules. These rules provide the most accurate fixed-point numerics. It also turns off the display of other fixed-point properties because they do not apply individually. These rules guarantee that no quantization occurs within the object. Bits are added, as needed, to ensure that no roundoff or overflow occurs. If you set `FullPrecisionOverride` to `false`, fixed-point data types are controlled through individual fixed-point property settings. For more information, see “Full Precision for Fixed-Point System Objects”.

RoundingMethod — Rounding method for fixed-point operations

`Floor` (default) | `Ceiling` | `Convergent` | `Nearest` | `Round` | `Simplest` | `Zero`

Specify the rounding method as one of `Ceiling` | `Convergent` | `Floor` | `Nearest` | `Round` | `Simplest` | `Zero` |.

Dependencies

This property applies only if the object is not in full precision mode.

OverflowAction — Overflow action for fixed-point operations

`Wrap` (default) | `Saturate`

Specify the overflow action as one of `Wrap` | `Saturate` |.

Dependencies

This property applies only if the object is not in full precision mode.

CoefficientsDataType — Word and fraction lengths of filter coefficients

Same word length as `input` (default) | `Custom`

Specify the filter coefficient fixed-point data type as one of | Same word length as input | Custom |.

CustomCoefficientsDataType — Word and fraction lengths of filter coefficients

`numerictype([],16,15)` (default) | `numerictype`

Specify the filter coefficient fixed-point type as a `numerictype` object with a Signedness of Auto.

Dependencies

This property applies only when the `CoefficientsDataType` property is Custom.

ProductDataType — Product word and fraction lengths

`Full precision` (default) | `Same as input` | `Custom`

Specify the product fixed-point data type as one of | `Full precision` | `Same as input` | `Custom` |.

CustomProductDataType — Product word and fraction lengths

`numerictype([],32,30)` (default) | `numerictype`

Specify the product fixed-point type as a scaled `numerictype` object with a Signedness of Auto.

Dependencies

This property applies only when the `ProductDataType` property is Custom.

AccumulatorDataType — Accumulator word and fraction lengths

`Full precision` (default) | `Same as product` | `Same as input` | `Custom`

Specify the accumulator fixed-point data type as one of | `Full precision` | `Same as product` | `Same as input` | `Custom` |.

CustomAccumulatorDataType — Accumulator word and fraction lengths

`numerictype([],32,30)` (default) | `numerictype`

Specify the accumulator fixed-point type as a scaled `numerictype` object with a Signedness of Auto.

Dependencies

This property applies only when the `AccumulatorDataType` property is Custom.

OutputDataType — Output word and fraction lengths

`Same as accumulator` (default) | `Same as product` | `Same as input` | `Custom`

Specify the output fixed-point data type as one of | `Same as accumulator` | `Same as product` | `Same as input` | `Custom` |.

CustomOutputDataType — Output word and fraction lengths

`numerictype([],16,15)` (default) | `numerictype`

Specify the output fixed-point type as a scaled `numerictype` object with a Signedness of Auto.

Dependencies

This property applies only when the `OutputDataType` property is Custom.

Usage

Syntax

```
y = firrc(x)
```

Description

`y = firrc(x)` resamples the input `x` and returns the resampled signal `y`.

Input Arguments

x — Data input

column vector | matrix

Data input, specified as a column vector or a matrix. The number of input rows P must be a multiple of the decimation factor M . A P -by- Q matrix input is treated as Q independent channels.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fi`

Output Arguments

y — Resampled output

column vector | matrix

Resampled output, returned as a column vector or a matrix. The number of rows in the output signal is given by PL/M , where P is the number of input rows, L is the interpolation factor, and M is the decimation factor.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fi`

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Specific to `dsp.FIRRateConverter`

<code>freqz</code>	Frequency response of discrete-time filter System object
<code>fvtool</code>	Visualize frequency response of DSP filters
<code>info</code>	Information about filter System object
<code>cost</code>	Estimate cost of implementing filter System object
<code>coeffs</code>	Returns the filter System object coefficients in a structure
<code>polyphase</code>	Polyphase decomposition of multirate filter
<code>generatehdl</code>	Generate HDL code for quantized DSP filter (requires Filter Design HDL Coder)

Common to All System Objects

`step` Run System object algorithm

release Release resources and allow changes to System object property values and input characteristics
reset Reset internal states of System object

Examples

Resample Signal Using FIR Rate Converter

Resample a 100 Hz sine wave signal by a factor of 3/2.

Note: If you are using R2016a or an earlier release, replace each call to the object with the equivalent `step` syntax. For example, `obj(x)` becomes `step(obj,x)`.

Create a `dsp.SinWave` object which generates a sinusoidal signal with 54 samples per frame, contains a tone at 100 Hz, and has a sample rate of 1250 Hz.

```
sine = dsp.SinWave(1,100, 'SampleRate',1250, 'SamplesPerFrame',54);  
  
% Grab a frame  
x = sine();  
  
% Calculate input time vector  
tx = (0:length(x)-1)/sine.SampleRate;
```

Design Default Filter

Create a `dsp.FIRRateConverter` object. The object uses a combined anti-imaging and anti-aliasing FIR filter. By default, this filter is designed using the `designMultirateFIR` function. The function designs the filter based on the rate conversion factors that you specify, and stores the coefficients in the `Numerator` property. For an interpolation factor of 3 and a decimation factor of 2, the object designs the coefficients using `designMultirateFIR(3,2)`.

```
firrc = dsp.FIRRateConverter(3,2);
```

Resample by a Factor of 3/2

Resample the signal by a factor of 3/2.

```
y = firrc(x);
```

Plot the original and resampled signals. In order to plot the two signals on the same plot, obtain the time affine transformation parameters. Use these parameters to compute the output sample times. The n^{th} output sample time equals $\text{scale} \times n + \text{delay}$. The input and output values coincide every 3 output samples, and every other input sample, owing to the conversion rate of 3/2.

```
scale = firrc.InterpolationFactor/firrc.DecimationFactor;  
delay = length(firrc.Numerator)/(2*firrc.DecimationFactor);  
  
% Calculate output times for vector y in input units  
ty = (((0:length(y)-1)-delay)/scale)/sine.SampleRate;  
  
stem(tx, x, 'filled', MarkerSize=4); hold on;  
stem(ty, y);  
hold off;  
xlim([0.0 0.0145])
```

```
ylim([-1.5 1.5])
legend('Original input', 'Resampled');
```

Resample by a Factor of 5/3 in Automatic Filter Design Mode

Now change the interpolation factor to 5 and the decimation factor to 3. In order for the filter design to be updated automatically based on the new rate conversion factors, set the `NumeratorSource` property to `'Auto'`. Alternately, you can pass the keyword `'auto'` as an input while creating the object. The object then operates in the automatic filter design mode. Every time there is a change in the rate conversion factors, the object updates the filter design accordingly.

```
release(firrc)
firrc.NumeratorSource = 'Auto';
firrc.InterpolationFactor = 5;
firrc.DecimationFactor = 3

firrc =
  dsp.FIRRateConverter with properties:

    InterpolationFactor: 5
    DecimationFactor: 3
    NumeratorSource: 'Auto'
    DesignMethod: 'Kaiser'

Show all properties
```

To access the filter coefficients in the automatic filter design mode, type `firrc.Numerator` in the MATLAB command prompt.

Resample the signal with the updated rate conversion values.

```
yAuto = firrc(x);
```

Plot the original and resampled signals. Recalculate the time affine transformation parameters since the rate conversion factors have changed. Note the input and output coincide every 3 input samples, and every 5 output samples, owing to the 5/3 conversion factor.

```
scale = firrc.InterpolationFactor/firrc.DecimationFactor;
delay = length(firrc.Numerator)/(2*firrc.DecimationFactor);
```

```
% Calculate output times for vector yAuto in input units
tyAuto = ((0:length(yAuto)-1)-delay)/scale/sine.SampleRate;
```

```
stem(tx, x, 'filled', MarkerSize=4); hold on;
stem(tyAuto, yAuto, 'r');
hold off;
xlim([0.0 0.015])
ylim([-1.5 1.5])
legend('Original input', 'Resampled');
```

Specify Signal Interpolation Model

In the automatic design mode, you can also specify the underlying D/A signal interpolation model through the `DesignMethod` property.

Set `DesignMethod` to `'linear'` and change the interpolation factor to 11.

```
release(firrc)
firrc.DesignMethod = 'linear';
firrc.InterpolationFactor = 11;
```

Resample the signal using the linear interpolation model.

```
yLinear = firrc(x);
```

Plot the original and resampled signals. The output samples lie on a piecewise-linear curve. Note the input and output coincide every three input samples and every 11 output samples as expected from the ratio 11/3.

```
scale = firrc.InterpolationFactor/firrc.DecimationFactor;
delay = (length(firrc.Numerator)-1)/(2*firrc.DecimationFactor);

% Calculate output times for vector yLinear in input units
tyLinear = ((0:length(yLinear)-1)-delay)/scale/sine.SampleRate;

stem(tx, x, 'filled',MarkerSize=4); hold on;
stem(tyLinear, yLinear);
plot(tyLinear, yLinear,Color=[1 0 0 0.3]);
hold off;
xlim([0.0 0.009])
ylim([-1.5 1.5])
legend('Original input','Resampled');
```

Resample and Play Audio Signal

Resample an audio signal from 48 kHz to 44 kHz and play the resampled signal using the `audioDeviceWriter` object.

Note: If you are using R2016a or an earlier release, replace each call to the object with the equivalent `step` syntax. For example, `obj(x)` becomes `step(obj,x)`.

Note: The `audioDeviceWriter` System object™ is not supported in MATLAB Online.

Create a `dsp.AudioFileReader` object. The object reads an audio file that has a sample rate of 48 kHz.

```
L = 11;
M = 12;
afr = dsp.AudioFileReader('audio48kHz.wav', ...
    'OutputDataType', 'single', ...
    'SamplesPerFrame', 4*M);
```

Create a `dsp.FIRRateConverter` object with an interpolation factor of $L = 11$ and a decimation factor of $M = 12$ (the co-prime representation of the ratio $44k/48k$), a reasonable approximation of the standard 44.1 kHz rate. The object designs the filter using `designMultirateFIR(11,12)` and stores the coefficients in the `Numerator` property of the object.

```
firrc = dsp.FIRRateConverter(L,M)
```

```
firrc =
  dsp.FIRRateConverter with properties:

    InterpolationFactor: 11
    DecimationFactor: 12
    NumeratorSource: 'Property'
    Numerator: [0 2.3076e-05 5.4790e-05 9.3620e-05 1.3665e-04 ... ]

  Show all properties
```

Create an `audioDeviceWriter` object. Specify the sample rate to be 44100 Hz.

```
adw = audioDeviceWriter(44100);
```

Read the audio file, convert the sample rate of the audio signal, and play the resampled audio.

```
while ~isDone(afr)
    audio1 = afr();
    audio2 = firrc(audio1);
    adw(audio2);
end
release(afr);
release(adw);
```

Algorithms

The FIR rate converter is implemented efficiently using a polyphase structure.

To derive the polyphase structure, start with the transfer function of the FIR filter: This FIR filter is a combined anti-imaging and anti-aliasing filter.

$$H(z) = b_0 + b_1z^{-1} + \dots + b_Nz^{-N}$$

$N+1$ is the length of the FIR filter.

You can rearrange this equation as follows:

$$H(z) = \begin{aligned} & (b_0 + b_Lz^{-L} + b_{2L}z^{-2L} + \dots + b_{N-L+1}z^{-(N-L+1)}) + \\ & z^{-1}(b_1 + b_{L+1}z^{-L} + b_{2L+1}z^{-2L} + \dots + b_{N-L+2}z^{-(N-L+1)}) + \\ & \quad \vdots \\ & z^{-(L-1)}(b_{L-1} + b_{2L-1}z^{-L} + b_{3L-1}z^{-2L} + \dots + b_Nz^{-(N-L+1)}) \end{aligned}$$

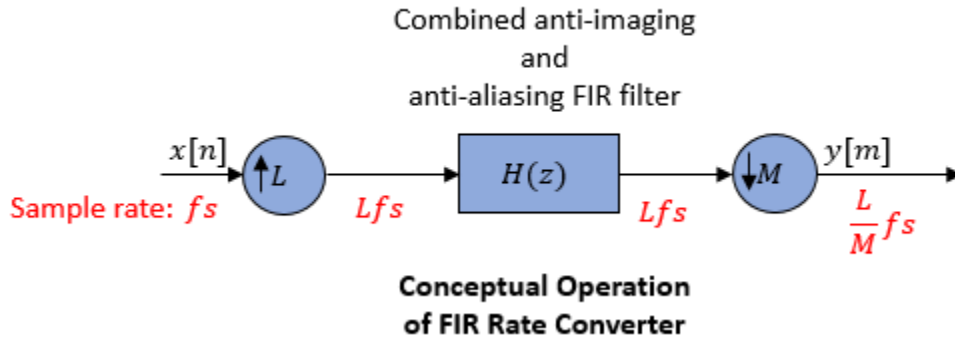

L is the number of polyphase components, and its value equals the interpolation factor that you specify.

You can write this equation as:

$$H(z) = E_0(z^L) + z^{-1}E_1(z^L) + \dots + z^{-(L-1)}E_{L-1}(z^L)$$

$E_0(z^L), E_1(z^L), \dots, E_{L-1}(z^L)$ are polyphase components of the FIR filter $H(z)$.

Conceptually, the FIR rate converter contains an upsampler, followed by a combined anti-imaging, anti-aliasing FIR filter $H(z)$, which is followed by a downsampler.

Replace $H(z)$ with its polyphase representation.

Here is the multirate noble identity for interpolation.

Applying the noble identity for interpolation moves the upsampling operation to after the filtering operation. This move enables you to filter the signal at a lower rate.

You can replace the upsampling operator, delay block, and the adder with a commutator switch. To account for the downsampler that follows, the switch moves in steps of size M . The switch receives the first sample from branch 0 and moves in the counter clockwise direction, each time skipping $M-1$ branches.

As an example, consider a rate converter with L set to 5 and M set to 3. The polyphase components are $E_0(z)$, $E_1(z)$, $E_2(z)$, $E_3(z)$, and $E_4(z)$. The switch starts on the first branch 0, skips branches 1 and 2, receives the next sample from branch 3, then skips branches 4 and 0, receives the next sample from branch 2, and so on. The sequence of branches from which the switch receives the data sample is [0, 3, 1, 4, 2, 0, 3, 1, ...].

The rate converter implements the L/M conversion by first applying the interpolation factor L to the incoming data, and using the commutator switch at the end to receive only 1 in M samples, effectively accounting for the downsampling factor M . Hence, the sample rate at the output of the FIR rate converter is Lfs/M .

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

See “System Objects in MATLAB Code Generation” (MATLAB Coder).

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

This object supports HDL code generation with the Filter Design HDL Coder product. For workflows and limitations, see “Generate HDL Code for Filter System Objects” (Filter Design HDL Coder).

Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

dsp.FrequencyDomainAdaptiveFilter

Package: dsp

Compute output, error, and coefficients using frequency-domain FIR adaptive filter

Description

The `dsp.FrequencyDomainAdaptiveFilter` System object implements an adaptive finite impulse response (FIR) filter in the frequency domain using the fast block least mean squares (LMS) algorithm. The “Length” on page 4-0 and the “BlockLength” on page 4-0 properties specify the filter length and the block length values the algorithm uses. The “FFTCoefficients” on page 4-0 property contains the discrete Fourier transform of the current filter coefficients. The object offers the constrained and unconstrained versions of the algorithm with partitioned and non-partitioned modes. For details, see “Algorithms” on page 4-650.

To filter a signal using frequency-domain FIR adaptive filter:

- 1 Create the `dsp.FrequencyDomainAdaptiveFilter` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

Creation

Syntax

```
fdaf = dsp.FrequencyDomainAdaptiveFilter
fdaf = dsp.FrequencyDomainAdaptiveFilter(len)
fdaf = dsp.FrequencyDomainAdaptiveFilter( ___,Name,Value)
```

Description

`fdaf = dsp.FrequencyDomainAdaptiveFilter` returns a frequency domain FIR adaptive filter System object, `fdaf`. This System object is used to compute the filtered output and the filter error for a given input and desired signal.

`fdaf = dsp.FrequencyDomainAdaptiveFilter(len)` returns a frequency domain FIR adaptive filter object with the `Length` property set to `len`.

`fdaf = dsp.FrequencyDomainAdaptiveFilter(___,Name,Value)` returns a frequency domain FIR adaptive filter object with each specified property set to the specified value. Enclose each property name in quotes. You can use this syntax with any previous input argument combinations.

Example: `fdaf = dsp.FrequencyDomainAdaptiveFilter('Length',32,'StepSize',0.1)` models a frequency-domain adaptive filter with a length of 32 taps and a step size of 0.1.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see *System Design in MATLAB Using System Objects*.

Method — Method to calculate filter coefficients

'Constrained FDAF' (default) | 'Unconstrained FDAF' | 'Partitioned constrained FDAF' | 'Partitioned unconstrained FDAF'

Method used to calculate the filter coefficients, specified as:

- 'Constrained FDAF' -- Imposes a gradient constraint on the filter tap weights.
- 'Unconstrained FDAF' -- No gradient constraint is imposed on the filter tap weights.
- 'Partitioned constrained FDAF' -- Partitions the impulse response of the filter to reduce latency.
- 'Partitioned unconstrained FDAF' -- Partitions the impulse response of the filter to reduce latency. No gradient constraint is imposed on the filter tap weights.

For more details, see “Algorithms” on page 4-650.

Length — Length of filter coefficients vector

32 (default) | positive, integer-valued scalar

Length of the FIR filter coefficients vector, specified as a positive, integer-valued scalar.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

BlockLength — Block length for coefficient updates

32 (default) | positive, integer-valued scalar

Block length for the coefficient updates, specified as a positive, integer-valued scalar. The adaptive filter processes the input data and the desired signal as a block of samples of length set by this property. For details on how this data is processed by the filter, see “Algorithms” on page 4-650. The length of the input vector must be divisible by the `BlockLength` property value. The default value of the `BlockLength` property is set to the value of the `Length` property.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

StepSize — Adaptation step size

1 (default) | real scalar in the range (0,1]

Adaptation step size factor, specified as a real scalar in the range (0,1]. Using a small step size ensures a small steady-state error. However, a small step size decreases the resulting convergence speed of the adaptive filter. Increasing the step size improves the convergence speed, at the cost of increased steady-state mean squared error. When the step size value is 1, the algorithm provides the optimal tradeoff between the convergence speed and the steady-state mean squared error.

Tunable: Yes

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | logical

LeakageFactor — Adaptation leakage factor

1 (default) | scalar in the range [0,1]

Leakage factor used when implementing a leaky adaptive filter, specified as a scalar numeric value in the range [0,1]. When the value is less than 1, the System object implements a leaky adaptive algorithm. When the value is 1, the object provides no leakage in the adapting method.

Tunable: Yes

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | logical

AveragingFactor — Averaging factor for signal power

0.9 (default) | real scalar in the range (0,1]

Averaging factor used to compute the exponentially windowed FFT input signal powers for the coefficient updates, specified as a real scalar in the range (0,1].

Tunable: Yes

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | logical

Offset — Offset for normalization terms

0 (default) | nonnegative real scalar

Offset for the normalization terms in the coefficient updates, specified as a nonnegative real scalar value. This property value is used to avoid division by zero or division by very small numbers if any of the FFT input signal powers become very small.

Tunable: Yes

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

InitialPower — Initial FFT input signal power

1 (default) | positive numeric scalar

Initial common value of all of the FFT input signal powers, specified as a positive numeric scalar.

If you change this value once the object is locked, the change takes effect only after you reset the object.

Tunable: Yes

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

InitialCoefficients — Initial time-domain coefficients of filter

0 (default) | scalar | vector

Initial time-domain coefficients of the adaptive filter, specified as a scalar or a vector of length equal to the `Length` property value. The adaptive filter object uses these coefficients to compute the initial frequency-domain filter coefficients.

If you change this value once the object is locked, the change takes effect only after you reset the object.

Tunable: Yes

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

LockCoefficients — Locked status of coefficient updates

`false` (default) | `true`

Locked status of the coefficient updates, specified as:

- `false` -- The object continuously updates the filter coefficients.
- `true` -- The filter coefficients do not get updated and their values remain at the current value.

Tunable: Yes

Data Types: `logical`

FFTCoefficients — Current FFT coefficients of filter

`[]` (default) | row vector

This property is read-only.

Current discrete Fourier transform of the filter coefficients, returned as a row vector. For 'Constrained FDAF' and 'Unconstrained FDAF' algorithms, the length of this vector is equal to the sum of the `Length` value and the `BlockLength` value. This property is initialized to the FFT values of the `InitialCoefficients` property. To get the discrete Fourier transform of the filter coefficients, call the object, and access the `FFTCoefficients` property of the object.

Data Types: `single` | `double`

Complex Number Support: Yes

Usage

Syntax

```
[y,err] = fdaf(x,d)
```

Description

`[y,err] = fdaf(x,d)` filters the input signal, `x`, using `d` as the desired signal, and returns the filtered output in `y` and the filter error in `err`. The System object estimates the filter weights needed to minimize the error between the output signal and the desired signal. The FFT of these filter weights can be obtained by accessing the `FFTCoefficients` property after calling the object algorithm.

Input Arguments

x — Data input

column vector

The signal to be filtered by the frequency-domain FIR adaptive filter. The input, `x`, and the desired signal, `d`, must have the same size and data type. The length of the input vector must be divisible by the “`BlockLength`” on page 4-0 property value.

The input, x , can be a variable-size signal as long as the frame length is a multiple of the `BlockLength`. You can change the number of elements in the column vector even when the object is locked. The System object locks when you call the object to run its algorithm.

Data Types: `single` | `double`

d — Desired signal

column vector

The frequency domain adaptive filter adapts its filter weights to minimize the error, `err`, and converge the input signal, x , to the desired signal, d , as closely as possible.

The input signal and the desired signal must have the same size and data type. The length of the desired signal vector must be divisible by the `BlockLength` property value.

The input signal can be a variable-size signal as long as the frame length is a multiple of the `BlockLength`. You can change the number of elements in the column vector even when the object is locked. The System object locks when you call the object to run its algorithm.

Data Types: `single` | `double`

Output Arguments

y — Filtered output

column vector

Filtered output, returned as a column vector. The object adapts its filter weights to converge the input signal, x , to match the desired signal, d . The filter outputs the converged signal.

Data Types: `single` | `double`

err — Difference between output and desired signal

column vector

Difference between the output signal and the desired signal, returned as a column vector. The objective of the adaptive filter is to minimize this error. The object adapts its weights to converge towards optimal filter weights which produce an output signal that matches the desired signal as closely as possible. For more details on how `err` is computed, see [2].

Data Types: `single` | `double`

Complex Number Support: Yes

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Common to All System Objects

<code>step</code>	Run System object algorithm
<code>release</code>	Release resources and allow changes to System object property values and input characteristics
<code>reset</code>	Reset internal states of System object

Examples

QPSK Adaptive Equalization With FIR Filter

Transmit a quadrature phase shift keying (QPSK) signal across a noisy transmission channel. Minimize the noise in the received signal using a frequency-domain adaptive filter.

Note: If you are using R2016a or an earlier release, replace each call to the object with the equivalent step syntax. For example, `obj(x)` becomes `step(obj,x)`.

The QPSK signal, s , is transmitted across a noisy channel. The numerator and the denominator coefficients of the channel are contained in the vectors b and a , respectively. The received signal, r , obtained at the end of the transmission channel contains the transmitted QPSK signal and the noise added to the channel, n . The adaptive filter is used to extract the QPSK signal from the received noisy input. The desired signal, d , is the delayed version of the QPSK signal.

```
D = 16;
b = exp(1i*pi/4)*[-0.7 1];
a = [1 -0.7];
ntr = 1024;
s = sign(randn(1,ntr+D)) + 1i*sign(randn(1,ntr+D));
n = 0.1*(randn(1,ntr+D) + 1i*randn(1,ntr+D));
r = filter(b,a,s) + n;
x = r(1+D:ntr+D);
d = s(1:ntr);
```

Create a `dsp.FrequencyDomainAdaptiveFilter` object to model a frequency-domain adaptive filter of length 32 taps and a step size of 0.1. The adaptive filter accepts the delayed version of the received signal and the desired signal as inputs. The output of the adaptive filter is compared to the desired signal. The error between the two signals represents the noise added to the transmission channel. The adaptive filter updates its coefficients until this error becomes minimal. To get the discrete Fourier transform of the filter coefficients, call the `fdaf` object, and access the `FFTCoefficients` property of this object.

```
mu = 0.1;
fdaf = dsp.FrequencyDomainAdaptiveFilter('Length',32,'StepSize',mu);
[y,e] = fdaf(x,d);
fftCoeffs = fdaf.FFTCoefficients

fftCoeffs = 1x64 complex

    0.6802 - 0.6847i   -0.2485 - 0.9427i   -0.9675 - 0.2123i   -0.5605 + 0.8002i    0.5748 + 0.7593i
```

Plot the In-Phase and the Quadrature components of the desired, output, and the error signals.

```
plot(1:ntr,real([d;y;e]))
legend('Desired','Output','Error')
title('In-Phase Components')
xlabel('Time Index'); ylabel('signal value')
```

```
plot(1:ntr,imag([d;y;e]))  
legend('Desired','Output','Error')  
title('Quadrature Components')  
xlabel('Time Index')  
ylabel('signal value')
```

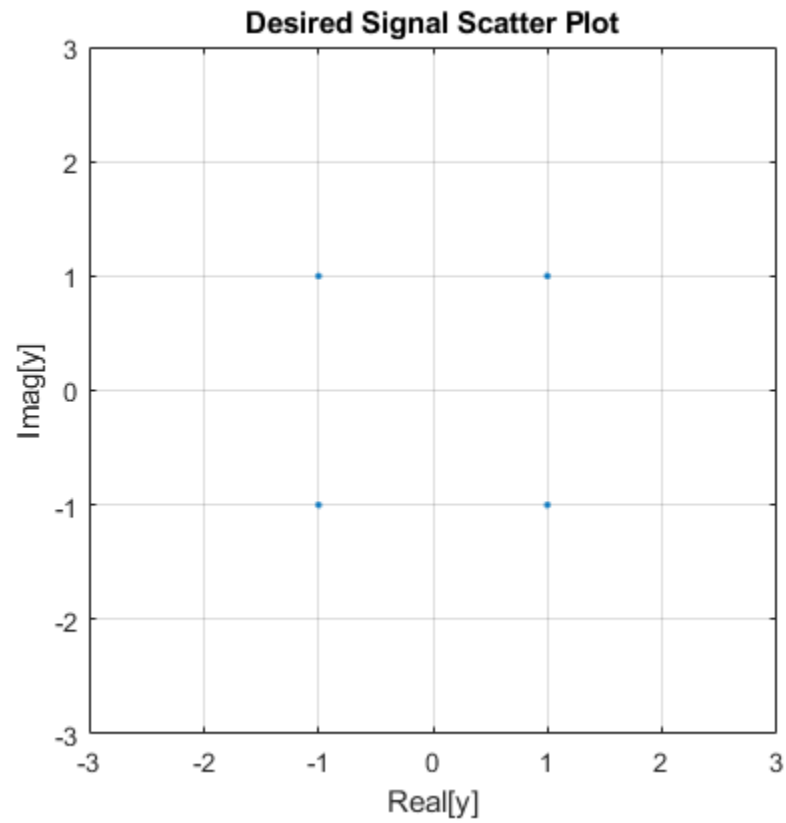

Create scatter plots of the received signal and the desired signal.

```
plot(x(ntr-100:ntr),'.')  
axis([-3 3 -3 3])  
title('Received Signal Scatter Plot')  
axis('square')  
xlabel('Real[x]')  
ylabel('Imag[x]')  
grid on
```

```
plot(d(ntr-100:ntr),'.')  
axis([-3 3 -3 3])  
title('Desired Signal Scatter Plot')  
axis('square')  
xlabel('Real[y]')

axis('square')
xlabel('Real[y]')
ylabel('Imag[y]')
grid on
```

Estimate Coefficients of long FIR Filter using Frequency-Domain Adaptive Filter

Use a frequency-domain adaptive filter to estimate the coefficients of a long FIR filter. The FIR filter models the impulse response of a room. Use the partitioned mode in the frequency-domain adaptive filter to reduce filter latency.

Note: This example runs only in R2018a or later.

Initialization

Generate a long FIR impulse response of 8192 samples and assign the impulse response to a `dsp.FIRFilter` object, `room`. This object models the impulse response of a room. Create a `dsp.FrequencyDomainAdaptiveFilter` filter, `lmsfilt`, in partitioned constrained mode. Set the length of the filter to one-fourth the length of the impulse response of the room. Set the block length of the filter to 128 samples. Set the step size to 0.025, initial power to 0.01, averaging factor to 0.98, offset to 1, and the leakage factor to 1. Initialize a `dsp.ArrayPlot` object to view the filter coefficients. Initialize a `timescope` object to show the mean-squared error between the filter output and the desired signal.

```
fs = 16e3;
m = 8192;
[b,a] = cheby2(4,20,[0.1 0.7]);
impulseResponseGenerator = dsp.IIRFilter(...
    'Numerator', [zeros(1,6) b], ...
```

```

    'Denominator', a);
roomImpulseResponse = impulseResponseGenerator( ...
    (log(0.99*rand(1,m)+0.01).*sign(randn(1,m)).*exp(-0.002*(1:m)))');
roomImpulseResponse = roomImpulseResponse/norm(roomImpulseResponse);
room = dsp.FIRFilter('Numerator',roomImpulseResponse');

lmsfilt = dsp.FrequencyDomainAdaptiveFilter(...
    'Method','Partitioned constrained FDAF',...
    'Length',m/4, ...
    'BlockLength',128,...
    'StepSize',0.025, ...
    'InitialPower',0.01, ...
    'AveragingFactor',0.98,...
    'Offset',1,...
    'LeakageFactor',1);

FrameSize = lmsfilt.BlockLength; NIter = 2000;

AP = dsp.ArrayPlot('YLimits',[-0.2 .2],'ShowLegend',true, ...
    'Position',[0 0 560 420],'ChannelNames', ...
    {'Actual Coefficients','Estimated Coefficients'});

TS = timescope('SampleRate',fs,'TimeSpanSource','property',...
    'TimeSpan',FrameSize*NIter/fs,...
    'TimeUnits','Seconds',...
    'YLimits',[-50 0],'Title','Learning curve',...
    'YLabel','dB', ...
    'BufferLength',FrameSize*NIter,...
    'ShowGrid',true);

signalmean = dsp.MovingAverage('SpecifyWindowLength',false);

```

Streaming

Generate a random input signal using the `randn` function. The frame size of the input matches the block length of the adaptive filter. The desired signal is the sum of the output of the FIR filter (`room`) and a white Gaussian noise signal. Pass the input signal and the desired signal to the adaptive filter. Compute the adaptive filter output and the error between the output and the desired signal.

Estimate the time-domain coefficients of the adaptive filter by taking the IFFT of the frequency-domain coefficients vector returned by the `lmsfilt.FFTCoefficients` property. Compare the estimated coefficients with the actual coefficients assigned to the FIR filter (`room`). Once the adaptive filter has converged its output to the desired signal, and minimized the error signal, the estimated coefficients match closely with the actual coefficients. This means that the adaptive filter has successfully adapted itself to model the impulse response of the FIR filter (`room`).

```

for k = 1:NIter
    x = randn(FrameSize,1);
    d = room(x) + 0.01*randn(FrameSize,1);
    [y,e] = lmsfilt(x,d);
    FFTCoeffs = lmsfilt.FFTCoefficients;
    w = ifft(FFTCoeffs,[],2,'symmetric');
    w = w(:,1:FrameSize) + w(:,FrameSize+1:end);
    w = reshape(w.',1,m/4);
    AP([roomImpulseResponse(1:m/4),w.']);
    TS(10*log10(signalmean(abs(e).^2)));
end

```

As the filter adapts with time, you can see in the time scope that the mean-squared error becomes minimal. Simultaneously, the estimated coefficients match the actual coefficients closely in the array plot.

Algorithms

Frequency-domain adaptive filtering consists of three steps - filtering, error estimation, and tap-weight adaptation. This algorithm implements FIR filtering in the frequency domain using the overlap-save or overlap-add method. For more implementation details of these two methods, see the “Algorithms” on page 4-663 section in the `dsp.FrequencyDomainFIRFilter` object page. The error estimation and the tap-weight adaptation are implemented using the fast block LMS algorithm (FBLMS).

Fast Block LMS Algorithm

The frequency-domain adaptive filter processes input data and the desired signal data as a block of samples using the fast block LMS (FBLMS) algorithm. Here is the block diagram of the frequency-domain adaptive filter using the FBLMS algorithm. The frequency-domain FIR filter in this diagram uses the overlap-save method.

where:

- N -- Filter length
- L -- Block length
- μ -- Step size parameter
- $x(n)$ -- Input signal
- $X(k)$ -- Transformed input signal in the frequency domain
- $d(n)$ -- Desired signal
- $e(n)$ -- Error between the desired signal and the filter output
- $E(k)$ -- Transformed error signal in the frequency domain
- $W(k)$ -- Tap-weights vector in the frequency domain

For more details on how the error is estimated and the tap-weights are adapted, see [2].

Constrained and Unconstrained FBLMS Algorithms

The previous diagram is the constrained version. If you remove the gradient constraint portion of the algorithm, you have the unconstrained FBLMS implementation. For details on the convergence behavior of both constrained and unconstrained variations, see [2].

Partitioned FBLMS Algorithm

The latency of the filter roughly equals the length of the FIR numerator. If the impulse response of the filter is very long, the latency becomes significantly large. The partitioned FBLMS algorithm reduces latency by partitioning the impulse response. The nonpartitioned frequency-domain FIR filtering is faster than the time-domain filtering for long impulse responses, at the cost of increased latency. To mitigate the latency and make the frequency domain filtering even more efficient, the algorithm partitions the impulse response into multiple short blocks and performs overlap-save or overlap-add on each block. The results of the different blocks are then combined to obtain the final output. The latency of this approach is of the order of the block length, rather than the entire impulse response length. This reduced latency comes at the cost of additional computation. For more details on the implementation, see [2].

dsp.FrequencyDomainFIRFilter

Package: dsp

Filter input signal in frequency domain

Description

The `dsp.FrequencyDomainFIRFilter` System object implements frequency-domain, fast Fourier transform (FFT)-based filtering to filter a streaming input signal. In the time domain, the filtering operation involves a convolution between the input and the impulse response of the finite impulse response (FIR) filter. In the frequency domain, the filtering operation involves the multiplication of the Fourier transform of the input and the Fourier transform of the impulse response. The frequency-domain filtering is efficient when the impulse response is very long. You can specify the filter coefficients directly in the frequency domain by setting `NumeratorDomain` to 'Frequency'.

This object uses the overlap-save and overlap-add methods to perform the frequency-domain filtering. For filters with a long impulse response length, the latency inherent to these two methods can be significant. To mitigate this latency, the `dsp.FrequencyDomainFIRFilter` object partitions the impulse response into shorter blocks and implements the overlap-save and overlap-add methods on these shorter blocks. To partition the impulse response, set the "PartitionForReducedLatency" on page 4-0 property to `true`. For more details on these two methods and on reducing latency through impulse response partitioning, see "Algorithms" on page 4-663.

To filter the input signal in the frequency domain:

- 1 Create the `dsp.FrequencyDomainFIRFilter` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

Creation

Syntax

```
fdf = dsp.FrequencyDomainFIRFilter
fdf = dsp.FrequencyDomainFIRFilter(num)
fdf = dsp.FrequencyDomainFIRFilter(Name,Value)
```

Description

`fdf = dsp.FrequencyDomainFIRFilter` creates a frequency domain FIR filter System object that filters each channel of the input signal independently over time in the frequency domain using the overlap-save or overlap-add method.

`fdf = dsp.FrequencyDomainFIRFilter(num)` creates a frequency domain FIR filter object with the "Numerator" on page 4-0 property set to `num`.

Example: `dsp.FrequencyDomainFIRFilter(fir1(400,2 * 2000 / 8000));`

`fdf = dsp.FrequencyDomainFIRFilter(Name,Value)` creates a frequency domain FIR filter System object with each specified property set to the specified value. Enclose each property name in single quotes. You can use this syntax with any previous input argument combinations.

Example: `dsp.FrequencyDomainFIRFilter('Method','Overlap-add');`

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects.

Method — Frequency-domain filter method

'Overlap-save' (default) | 'Overlap-add'

Frequency-domain filter method, specified as either 'Overlap-save' or 'Overlap-add'. For more details on these two methods, see “Algorithms” on page 4-663.

NumeratorDomain — Numerator domain

'Time' (default) | 'Frequency'

Domain of the filter coefficients, specified as one of the following:

- 'Time' -- Specify the time-domain filter numerator in the Numerator property.
- 'Frequency' -- Specify the filter's frequency response in the FrequencyResponse property.

Numerator — FIR filter coefficients

`fir1(100,0.3)` (default) | row vector

FIR filter coefficients, specified as a row vector.

Tunable: Yes

Dependencies

This property applies when NumeratorDomain is set to 'Time'.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`
Complex Number Support: Yes

FrequencyResponse — Filter frequency response

`fft(fir1(100,0.3),202)` (default) | row vector | matrix

Frequency response of the filter, specified as a row vector or a matrix. When `PartitionForReducedLatency` is `false`, `FrequencyResponse` must be a row vector. The FFT length is equal to the length of the `FrequencyResponse` vector. When `PartitionForReducedLatency` is `true`, `FrequencyResponse` must be a $2P$ -by- N matrix, where P is the partition size, and N is the number of partitions.

Tunable: Yes

Dependencies

This property applies when `NumeratorDomain` is set to 'Frequency'.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`
Complex Number Support: Yes

NumeratorLength — Time-domain numerator length

101 (default) | positive integer-valued scalar

Time-domain numerator length, specified as a positive integer-valued scalar.

Dependencies

This property applies when `NumeratorDomain` is set to 'Frequency' and `PartitionForReducedLatency` is set to `false`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

FilterIsReal — Flag to specify if filter is real

`true` (default) | `false`

Flag to specify if the filter coefficients are all real, specified as `true` or `false`.

Dependencies

This property applies when `NumeratorDomain` is set to 'Frequency'.

PartitionForReducedLatency — Flag to partition numerator to reduce latency

`false` (default) | `true`

Flag to partition numerator to reduce latency, specified as one of the following:

- `false` -- The filter uses the traditional overlap-save or overlap-add method. The latency in this case is “`FFTLength`” on page 4-0 - length(“`Numerator`” on page 4-0) + 1.
- `true` -- In this mode, the object partitions the numerator into segments of length specified by the “`PartitionLength`” on page 4-0 property. The filter performs overlap-save or overlap-add on each partition, and combines the partial results to form the overall output. The latency is now reduced to the partition length.

FFTLength — FFT length

[] (default) | positive integer

FFT length, specified as a positive integer. The default value of this property, [], indicates that the FFT length is equal to twice the numerator length. The FFT length must be greater than or equal to the numerator length.

Example: 64

Dependencies

This property applies when you set `NumeratorDomain` property to 'Time' and “`PartitionForReducedLatency`” on page 4-0 property to `false`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

PartitionLength — Numerator partition length

32 (default) | positive integer

Numerator partition length, specified as a positive integer less than or equal to the length of the numerator.

Example: 40

Example: 60

Dependencies

This property applies when you set the `NumeratorDomain` property to 'Time' and "PartitionForReducedLatency" on page 4-0 property to `true`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

Latency — Filter latency

102 (default) | positive integer

This property is read-only.

Filter latency in samples, returned as an integer greater than 0. When "PartitionForReducedLatency" on page 4-0 is `false`, the latency is equal to "FFTLength" on page 4-0 - length("Numerator" on page 4-0) + 1. When `PartitionForReducedLatency` is `true`, the latency is equal to the partition length.

Data Types: `uint32`

Usage

Syntax

```
fdfOut = fdf(input)
```

Description

`fdfOut = fdf(input)` filters the input signal and outputs the filtered signal. The object filters each channel of the input signal independently over time in the frequency domain.

Input Arguments

input — Data input

vector | matrix

Data input, specified as a vector or a matrix. This object supports variable-size input signals. That is, you can change the input frame size (number of rows) even after calling the algorithm. However, the number of channels (number of columns) must remain constant.

Example: `randn(164,4)`

Data Types: `single` | `double`

Output Arguments

fdfOut — Filtered output

vector | matrix

Filtered output, returned as a vector or matrix. The size, data type, and complexity of the output match those of the input.

Data Types: `single` | `double`

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Specific to `dsp.FrequencyDomainFIRFilter`

`fvtool` Visualize frequency response of DSP filters

Common to All System Objects

`step` Run System object algorithm
`release` Release resources and allow changes to System object property values and input characteristics
`reset` Reset internal states of System object

Examples

Frequency Domain Filtering Using Overlap-Add and Overlap-Save

Filter input signal using overlap-add and overlap-save methods, and compare the outputs to the output of a FIR filter.

Initialization

Design the FIR lowpass filter coefficients using the `fir1` function. The sampling frequency is 8 kHz, and the cutoff frequency of the filter is 2 kHz. The impulse response has a length of 400.

```
impL = 400;  
Fs = 8000;  
Fcutoff = 2000;  
imp = fir1(impL, 2*Fcutoff/Fs);
```

Create two `dsp.FrequencyDomainFIRFilter` objects and a `dsp.FIRFilter` object. Set the numerator of all the three filters to `imp`. Delay the FIR output by the latency of the frequency-domain filter.

```
fdf0A = dsp.FrequencyDomainFIRFilter(imp, 'Method', 'overlap-add');  
fdf0S = dsp.FrequencyDomainFIRFilter(imp, 'Method', 'overlap-save');  
fir = dsp.FIRFilter('Numerator', imp);  
dly = dsp.Delay('Length', fdf0A.Latency);
```

Create two `dsp.SineWave` objects. The sine waves generated have a sample rate of 8000 Hz, frame size of 256, and frequencies of 100 Hz and 3 kHz, respectively. Create a `timescope` object to view the filtered outputs.

```
frameLen = 256;  
sin_100Hz = dsp.SineWave('Frequency', 100, 'SampleRate', Fs, ...  
    'SamplesPerFrame', frameLen);
```

```

sin_3KHz = dsp.SineWave('Frequency',3e3,'SampleRate',Fs,...
    'SamplesPerFrame',frameLen);
ts = timescope('TimeSpanOvverrunAction','Scroll',...
    'ShowGrid',true,'TimeSpanSource','Property','TimeSpan',5 * frameLen/Fs,...
    'YLimits',[-1.1 1.1],...
    'ShowLegend',true,...
    'SampleRate',Fs,...
    'ChannelNames',{'Overlap-add','Overlap-save','Direct-form FIR'});

```

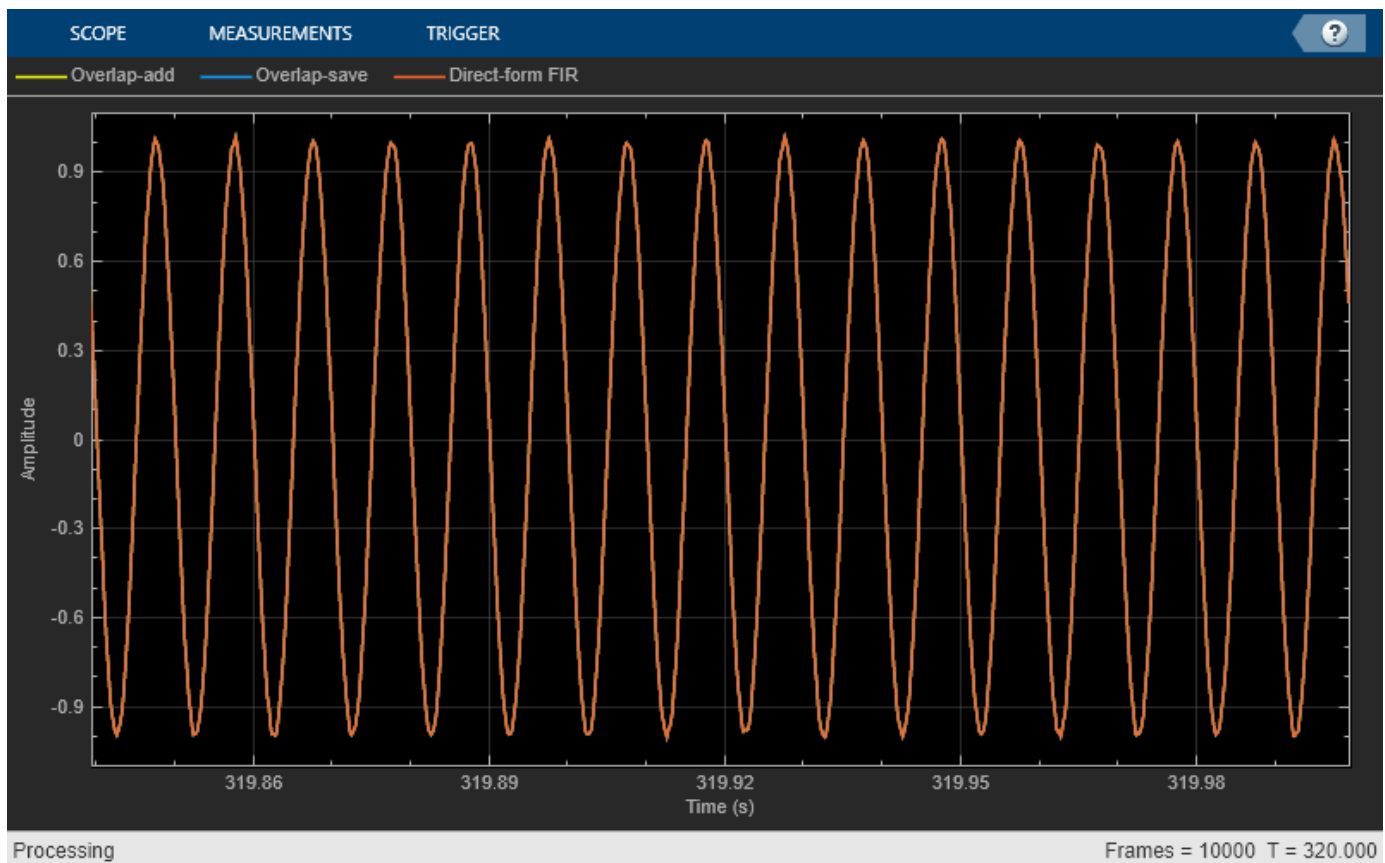

Streaming

Stream 1e4 frames of noisy input data. Pass this data through the frequency domain filters and the FIR filter. View the filtered outputs in the time scope.

```

numFrames = 1e4;
for idx = 1:numFrames
    x = sin_100Hz() + sin_3KHz() + 0.01*randn(frameLen,1);
    yOA = fdfOA(x);
    yOS = fdfOS(x);
    yFIR = fir(dly(x));
    ts([yOA,yOS,yFIR]);
end

```

The outputs of all the three filters match exactly.

Reduce Latency Through Partitioned Numerator

Partition the impulse response length of a frequency domain FIR filter. Compare the outputs of the partitioned filter and the original filter.

Design the FIR lowpass filter coefficients using the `fir1` function. The sampling frequency is 8 kHz and the cutoff frequency of the filter is 2 kHz. The impulse response is of length 4000.

```
impL    = 4000;
Fs      = 8000;
Fcutoff = 2000;
imp     = fir1(impL, 2 * Fcutoff / Fs);
```

Create a `dsp.FrequencyDomainFIRFilter` with coefficients set to the `imp` vector. The latency of this filter is given by $FFTLength - Length(Numerator) + 1$, which is equal to 4002. By default, FFT length is equal to twice the numerator length. This makes the latency proportional to the impulse response length.

```
fdf0S = dsp.FrequencyDomainFIRFilter(imp, 'Method', 'overlap-save');
fprintf('Frequency domain filter latency is %d samples\n', fdf0S.Latency);
```

```
Frequency domain filter latency is 4002 samples
```

Partition the impulse response to blocks of length 256. The latency after partitioning is proportional to the block length.

```
fdfRL = dsp.FrequencyDomainFIRFilter(imp, 'Method', 'overlap-save', ...
    'PartitionForReducedLatency', true, ...
    'PartitionLength', 256);
fprintf('Frequency domain filter latency is %d samples\n', fdfRL.Latency);
```

```
Frequency domain filter latency is 256 samples
```

Compare the outputs of the two frequency domain filters. The latency of `fdf0S` is 4002, and the latency of `fdfRL` is 256. To compare the two outputs, delay the input to `fdfRL` by 4002 - 256 samples.

```
dly = dsp.Delay('Length', (fdf0S.Latency - fdfRL.Latency));
```

Create two `dsp.SineWave` objects. The sine waves have a sample rate of 8000 Hz, frame size of 256, and frequencies of 100 Hz and 3 kHz, respectively. Create a `timescope` object to view the filtered outputs.

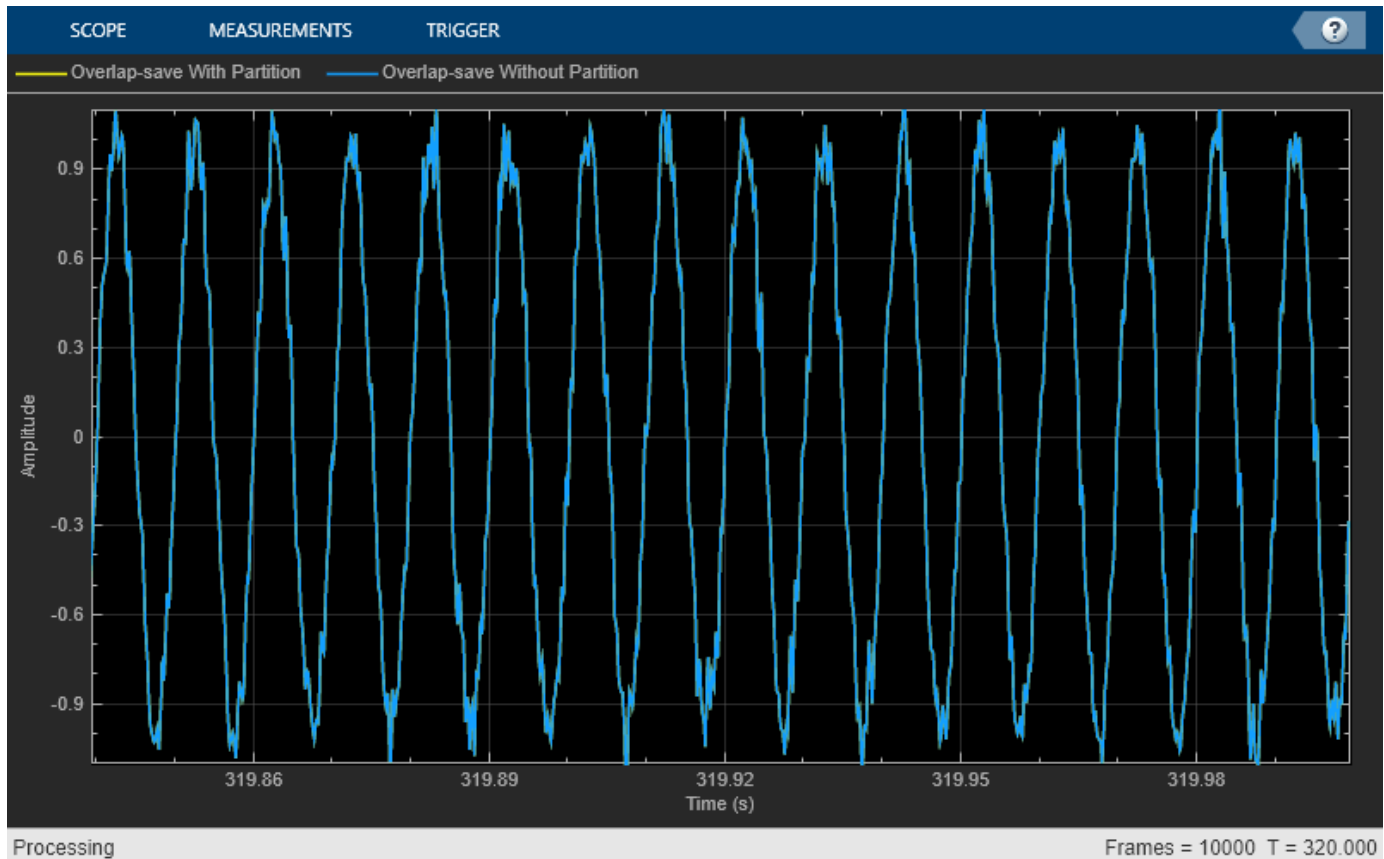

```
frameLen = 256;
sin_100Hz = dsp.SineWave('Frequency', 100, 'SampleRate', Fs, ...
    'SamplesPerFrame', frameLen);
sin_3KHz = dsp.SineWave('Frequency', 3e3, 'SampleRate', Fs, ...
    'SamplesPerFrame', frameLen);
ts = timescope('TimeSpanOvverrunAction', 'Scroll', 'ShowGrid', true, ...
    'TimeSpanSource', 'Property', 'TimeSpan', 5 * frameLen / Fs, ...
    'YLimits', [-1.1 1.1], ...
    'ShowLegend', true, ...
    'SampleRate', Fs, ...
    'ChannelNames', {'Overlap-save With Partition', 'Overlap-save Without Partition'});
```

Stream 1e4 frames of noisy input data. Pass this data through the two frequency domain filters. View the filtered outputs in the time scope.

```

numFrames = 1e4;
for idx = 1:numFrames
    x = sin_100Hz() + sin_3KHz() + .1 * randn(frameLen,1);
    yRL = fdfRL(dly(x));
    yOS = fdfOS(x);
    ts([yRL,yOS]);
end

```

The outputs match exactly.

Specify Frequency Response of the Frequency-Domain FIR Filter

Specify the numerator coefficients of the frequency-domain FIR filter in the frequency domain. Filter the input signal using the overlap-add method. Compare the frequency-domain FIR filter output to the corresponding time-domain FIR filter output.

Initialization

Design the FIR lowpass filter coefficients using the `fir1` function. The sampling frequency is 8 kHz, and the cutoff frequency of the filter is 2 kHz. The time-domain impulse response has a length of 400. Compute the FFT of this impulse response and specify this response as the frequency response of the frequency-domain FIR filter. Set the time-domain numerator length, specified by the `NumeratorLength` property, to the number of elements in the time-domain impulse response.

```

impL    = 400;
Fs      = 8000;
Fcutoff = 2000;
imp     = fir1(impL,2 * Fcutoff / Fs);
H       = fft(imp , 2 * numel(imp));
oa      = dsp.FrequencyDomainFIRFilter('NumeratorDomain','Frequency',...
    'FrequencyResponse', H,...
    'NumeratorLength',numel(imp),...
    'Method','overlap-add');
fprintf('Frequency domain filter latency is %d samples\n',oa.Latency);

```

```
Frequency domain filter latency is 402 samples
```

Create a `dsp.FIRFilter` System object? and specify the numerator as the time-domain coefficients computed using the `fir1` function, `imp`. Delay the FIR output by the latency of the frequency-domain FIR filter.

```

fir = dsp.FIRFilter('Numerator',imp);
dly = dsp.Delay('Length',oa.Latency);

```

Create two `dsp.SineWave` objects. The sine waves generated have a sample rate of 8000 Hz, frame size of 256, and frequencies of 100 Hz and 3 kHz, respectively. Create a `timescope` object to view the filtered outputs.

```

frameLen = 256;

sin_100Hz = dsp.SineWave('Frequency',100,'SampleRate',Fs,...
    'SamplesPerFrame',frameLen);
sin_3KHz  = dsp.SineWave('Frequency',3e3,'SampleRate',Fs,...
    'SamplesPerFrame',frameLen);

ts = timescope('TimeSpanOvrrunAction','Scroll',...
    'ShowGrid',true,'YLimits',[-1.1 1.1],...
    'TimeSpanSource','Property','TimeSpan',5 * frameLen/Fs,...
    'ShowLegend',true,...
    'SampleRate',Fs,...
    'ChannelNames',{'Overlap-add','Direct-form FIR'});

```

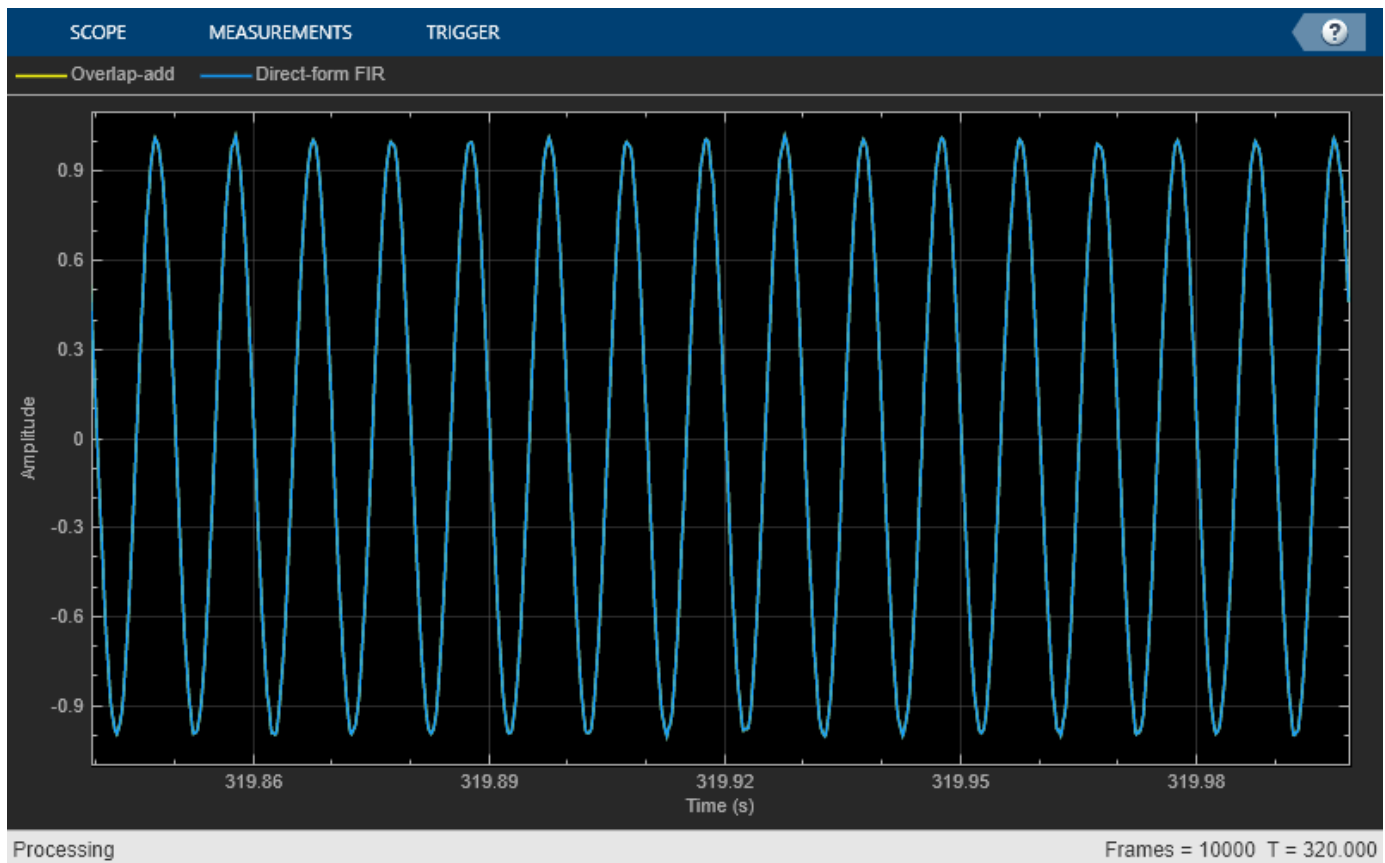

Streaming

Stream 1e4 frames of noisy input data. Pass this data through the frequency-domain FIR filter and the time-domain FIR filter. View the filtered outputs in the time scope.

```

numFrames = 1e4;
for idx = 1:numFrames
    x = sin_100Hz() + sin_3KHz() + 0.01 * randn(frameLen,1);
    y1 = oa(x);
    y2 = fir(dly(x));
    ts([y1,y2]);
end

```

The outputs of both the filters match exactly.

Algorithms

Overlap-save and overlap-add are the two frequency-domain FFT-based filtering methods this algorithm uses.

Overlap-Save

The overlap-save method is implemented using the following approach:

The input stream is partitioned into overlapping blocks of size $FFTLen$, with an overlap factor of $NumLen - 1$ samples. $FFTLen$ is the FFT length and $NumLen$ is the length of the FIR filter numerator. The FFT of each block of input samples is computed and multiplied with the length- $FFTLen$ FFT of

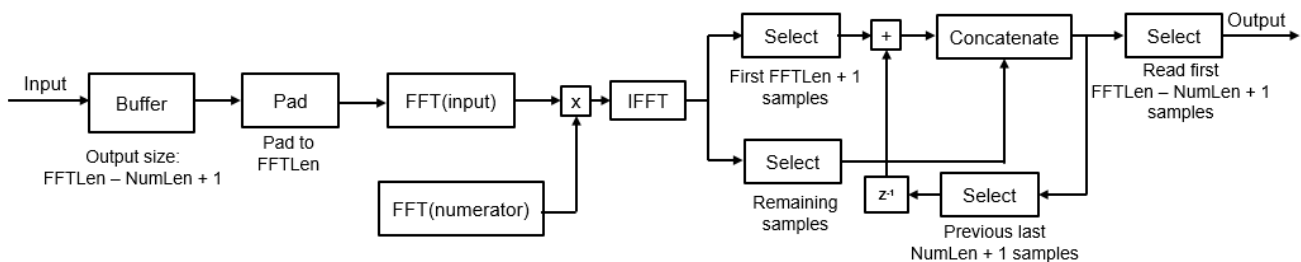

the FIR numerator. The inverse fast Fourier transform (IFFT) of the result is performed, and the last $FFTLen - NumLen + 1$ samples are saved. The remaining samples are dropped.

The latency of overlap-save is $FFTLen - NumLen + 1$. The first $FFTLen - NumLen + 1$ samples are equal to zero. The filtered value of the first input sample appears as the $FFTLen - NumLen + 2$ output sample.

Note that the FFT length must be larger than the numerator length, and is typically set to a value much greater than $NumLen$.

Overlap-Add

The overlap-add method is implemented using the following approach:

The input stream is partitioned into blocks of length $FFLen - NumLen + 1$, with no overlap between consecutive blocks. Similar to overlap-save, the FFT of the block is computed, and multiplied by the FFT of the FIR numerator. The IFFT of the result is then computed. The first $NumLen + 1$ samples are modified by adding the values of the last $NumLen + 1$ samples from the previous computed IFFT.

The latency of overlap-add is $FFTLen - NumLen + 1$. The first $FFTLen - NumLen + 1$ samples are equal to zero. The filtered value of the first input sample appears as the $FFTLen - NumLen + 2$ output sample.

Reduce Latency Through Impulse Response Partitioning

With an FFT length that is twice the length of the FIR numerator, the latency roughly equals the length of the FIR numerator. If the impulse response is very long, the latency becomes significantly large. However, frequency domain FIR filtering is still faster than the time-domain filtering. To mitigate the latency and make the frequency domain filtering even more efficient, the algorithm partitions the impulse response into multiple short blocks and performs overlap-save or overlap-add on each block. The results of the different blocks are then combined to obtain the final output. The latency of this approach is of the order of the block length, rather than the entire impulse response length. This reduced latency comes at the cost of additional computation. For more details, see [1].

Package: dsp

Filter outliers using Hampel identifier

Description

The `dsp.HampelFilter` System object detects and removes the outliers of the input signal by using the Hampel identifier. The Hampel identifier is a variation of the three-sigma rule of statistics that is robust against outliers. For each sample of the input signal, the object computes the median of a window composed of the current sample and $\frac{Len-1}{2}$ adjacent samples on each side of current sample. *Len* is the window length you specify through the `WindowLength` property. The object also estimates the standard deviation of each sample about its window median by using the median absolute deviation. If a sample differs from the median by more than the threshold multiplied by the standard deviation, the filter replaces the sample with the median. For more information, see “Algorithms” on page 4-673.

To filter the input signal using a Hampel identifier:

- 1 Create the `dsp.HampelFilter` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

Creation

Syntax

```
hampFilt = dsp.HampelFilter
hampFilt = dsp.HampelFilter(Len)
hampFilt = dsp.HampelFilter(Len, Lim)
hampFilt = dsp.HampelFilter(Name, Value)
```

Description

`hampFilt = dsp.HampelFilter` returns a Hampel filter object, `hampFilt`, using the default properties.

`hampFilt = dsp.HampelFilter(Len)` sets the `WindowLength` property to `Len`.

`hampFilt = dsp.HampelFilter(Len, Lim)` sets the `WindowLength` property to `Len` and the `Threshold` property to `Lim`.

Example: `hampFilt = dsp.HampelFilter(11,2);`

`hampFilt = dsp.HampelFilter(Name, Value)` specifies properties using `Name, Value` pairs. Unspecified properties have default values.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see *System Design in MATLAB Using System Objects*.

If a property is listed as *tunable*, then you can change its value even when the object is locked.

WindowLength — Length of the sliding window

11 (default) | positive odd scalar integer

Length of the sliding window, specified as a positive odd scalar integer. The window of finite length slides over the data, and the object computes the median and median absolute deviation of the data in the window.

Data Types: `single` | `double`

Threshold — Threshold for outlier detection

3 (default) | positive real scalar

Threshold for outlier detection, specified as a positive real scalar. For information on how this property is used to detect the outlier, see “Algorithms” on page 4-673.

Tunable: Yes

Data Types: `single` | `double`

Usage

Syntax

```
y = hampFilt(x)
[y,isOutlier] = hampFilt(x)
```

Description

`y = hampFilt(x)` detects and removes the outliers of each channel of the input signal, `x`, independently over time using the Hampel filter.

`[y,isOutlier] = hampFilt(x)` returns a logical array, `isOutlier`, in which each true element indicates that the corresponding element in the input is an outlier. `isOutlier` is the same size as the input and output vectors.

Input Arguments

x — Data input

vector | matrix

Data input, specified as a vector or a matrix. The object accepts multichannel inputs, that is, m -by- n size inputs, where $m \geq 1$, and $n > 1$. m is the number of samples in each frame (channel), and n is the

number of channels. The object also accepts variable-size inputs. After the object is locked, you can change the size of each input channel, but you cannot change the number of channels.

Data Types: `single` | `double`

Output Arguments

y — Filtered data

vector | matrix

Filtered data, returned as a vector or a matrix.

Data Types: `single` | `double`

isOutlier — Indicate outlier

`true` | `false`

Logical array whose elements indicate if the corresponding element in the input array is an outlier. If an element in `isOutlier` is `true`, the corresponding element in the input array is an outlier.

Data Types: `logical`

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Common to All System Objects

<code>step</code>	Run System object algorithm
<code>release</code>	Release resources and allow changes to System object property values and input characteristics
<code>reset</code>	Reset internal states of System object

Examples

Remove High-Frequency Noise Using Hampel Filter

Filter high-frequency noise from a noisy sine wave signal using a Hampel filter. Compare the performance of the Hampel filter with a median filter.

Initialization

Set up a `dsp.HampelFilter` and a `dsp.MedianFilter` object. These objects use the sliding window method with a window length of 7. Create a time scope for viewing the output.

```
Fs = 1000;  
hampFilt = dsp.HampelFilter(7);  
medFilt = dsp.MedianFilter(7);  
scope = timescope('SampleRate',Fs, ...  
    'TimeSpanOvverrunAction','Scroll', ...  
    'TimeSpanSource','Property',...  
    'TimeSpan',1,'ShowGrid',true, ...
```

```

        'LayoutDimensions',[3 1], ...
        'NumInputPorts',3);
scope.ActiveDisplay = 1;
scope.Title = 'Signal + Noise';
scope.YLimits = [-1 3];
scope.ActiveDisplay = 2;
scope.Title = 'Hampel Filter Output (Window Length = 7)';
scope.YLimits = [-1 1];
scope.ActiveDisplay = 3;
scope.Title = 'Median Filter Output (Window Length = 7)';
scope.YLimits = [-1 1];

```

Filter the Noisy Sine Wave Using a Window of Length 7

Generate a noisy sine wave signal with a frequency of 10 Hz. Apply the Hampel filter and the median filter object to the signal. View the output on the time scope.

```

FrameLength = 256;
sine = dsp.SineWave('SampleRate',Fs,'Frequency',10,...
    'SamplesPerFrame',FrameLength);

for i = 1:500
    hfn = 3 * (rand(FrameLength,1) < 0.02);
    x = sine() + 1e-2 * randn(FrameLength,1) + hfn;
    y1 = hampFilt(x);
    y2 = medFilt(x);
    scope(x,y1,y2);
end
release(scope)

```

Both filters remove the high-frequency noise. However, when you increase the window length, the Hampel filter is preferred. Unlike the median filter, the Hampel filter preserves the shape of the sine wave even with large window lengths.

Filter the Noisy Sine Wave Using a Window of Length 37

Increase the window length of both the filters to 37. Filter the noisy sine wave and view the filtered output on the time scope. To change the window length of the filters, you must release the filter objects at the start of the processing loop.

```
release(hampFilt);
release(medFilt);
hampFilt.WindowLength = 37;
medFilt.WindowLength = 37;
scope.ActiveDisplay = 1;
scope.Title = 'Signal + Noise';
scope.ActiveDisplay = 2;
scope.Title = 'Hampel Filter Output (Window Length = 37)';
scope.ActiveDisplay = 3;
scope.Title = 'Median Filter Output (Window Length = 37)';
for i = 1:500
    hfn = 3 * (rand(FrameLength,1) < 0.02);
    x = sine() + 1e-2 * randn(FrameLength,1) + hfn;
    y1 = hampFilt(x);
    y2 = medFilt(x);
    scope(x,y1,y2);
end
```

```
end
release(scope)
```

The median filter flattens the crests and troughs of the sine wave due to the median operation over a large window of data. The Hampel filter preserves the shape of the signal, in addition to removing the outliers.

Remove High-Frequency Noise from Gyroscope Data Using Hampel Filter

Remove the high-frequency outliers from a streaming signal using the `dsp.HampelFilter` System object™.

Use the `dsp.MatFileReader` System object to read the gyroscope MAT file. The file contains three columns of data, with each column containing 7140 samples. The three columns represent the x-axis, y-axis, and z-axis data from the gyroscope motion sensor. Choose a frame size of 714 samples so that each column of the data contains 10 frames. The `dsp.HampelFilter` System object uses a window length of 11. Create a `timescope` object to view the filtered output.

```
reader = dsp.MatFileReader('SamplesPerFrame',714,'Filename','LSM9DSHampelgyroData73.mat', ...
    'VariableName','data');
hampFilt = dsp.HampelFilter(11);
scope = timescope('NumInputPorts',1,'SampleRate',119,'YLimits',[-300 300], ...
    'ChannelNames',{'Input','Filtered Output'},...
    'TimeSpanSource','Property','TimeSpan',60,'ShowLegend',true);
```

Filter the gyroscope data using the `dsp.HampelFilter` System object. View the filtered z-axis data in the Time Scope.

```
for i = 1:10
    gyroData = reader();
    filteredData = hampFilt(gyroData);
    scope([gyroData(:,3), filteredData(:,3)]);
end
```

The Hampel filter removes all the outliers and preserves the shape of the signal.

More About

Hampel Identifier

The Hampel identifier is a variation of the three-sigma rule of statistics that is robust against outliers.

Given a sequence $x_1, x_2, x_3, \dots, x_n$ and a sliding window of length k , define point-to-point median and standard-deviation estimates using:

- Local median — $m_i = \text{median}(x_{i-k}, x_{i-k+1}, x_{i-k+2}, \dots, x_i, \dots, x_{i+k-2}, x_{i+k-1}, x_{i+k})$
- Standard deviation — $\sigma_i = \kappa \text{median}(|x_{i-k} - m_i|, \dots, |x_{i+k} - m_i|)$, where $\kappa = \frac{1}{\sqrt{2} \text{erfc}^{-1}(1/2)} \approx 1.4826$

The quantity σ_i / κ is known as the median absolute deviation (MAD).

If a sample x_i is such that

$$|x_i - m_i| > n_\sigma \sigma_i$$

for a given threshold n_σ , then the Hampel identifier declares x_i an outlier and replaces it with m_i . If n_σ is 0, then the Hampel filter behaves as a regular median filter.

Algorithms

For a given sample of data, x_s , the algorithm:

- Centers the window of odd length at the current sample.
- Computes the local median, m_i , and standard deviation, σ_i , over the current window of data.
- Compares the current sample with $n_\sigma \times \sigma_i$, where n_σ is the threshold value. If $|x_s - m_i| > n_\sigma \times \sigma_i$, the filter identifies the current sample, x_s , as an outlier and replaces it with the median value, m_i .

Consider a frame of data that is passed into the Hampel filter.

1	2	4	9	23	8	12	4	2
---	---	---	---	----	---	----	---	---

In this example, the Hampel filter slides a window of length 5 (Len) over the data. The filter has a threshold value of 2 (n_σ). To have a complete window at the beginning of the frame, the filter algorithm prepends the frame with $Len - 1$ zeros. To compute the first sample of the output, the window centers on the $\left[\frac{Len - 1}{2} + 1\right]^{\text{th}}$ sample in the appended frame, the third zero in this case. The filter computes the median, median absolute deviation, and the standard deviation over the data in the local window.

- Current sample: $x_s = 0$.
- Window of data: $win = [0\ 0\ 0\ 0\ 1]$.

- Local median: $m_i = \text{median}([0\ 0\ 0\ 0\ 1]) = 0$.
- Median absolute deviation: $mad_i = \text{median}(|x_i - k - m_i|, \dots, |x_i + k - m_i|)$. For this window of data, $mad = \text{median}(|0 - 0|, \dots, |1 - 0|) = 0$.
- Standard deviation: $\sigma_i = \kappa \times mad_i = 0$, where $\kappa = \frac{1}{\sqrt{2}\text{erfc}^{-1}(1/2)} \approx 1.4826$.
- The current sample, $x_s = 0$, does not obey the relation for outlier detection.
 $[|x_s - m_i| = 0] > [(n_\sigma \times \sigma_i) = 0]$

Therefore, the Hampel filter outputs the current input sample, $x_s = 0$.

Repeat this procedure for every succeeding sample until the algorithm centers the window on the $\left[\text{End} - \frac{\text{Len} - 1}{2} \right]^{\text{th}}$ sample, marked as End. Because the window centered on the last $\frac{\text{Len} - 1}{2}$ samples cannot be full, these samples are processed with the next frame of input data.

Here is the first output frame the Hampel filter generates:

The seventh sample of the appended input frame, 23, is an outlier. The Hampel filter replaces this sample with the median over the local window [4 9 23 8 12].

dsp.HDLChannelizer

Package: dsp

Polyphase filter bank and fast Fourier transform—optimized for HDL code generation

Description

The `dsp.HDLChannelizer` System object separates a broadband input signal into multiple narrowband output signals. It provides hardware speed and area optimization for streaming data applications. The object accepts scalar or vector input of real or complex data, provides hardware-friendly control signals, and has optional output frame control signals. You can achieve giga-sample-per-second (GSPS) throughput by using vector input. The object implements a polyphase filter, with one subfilter per input vector element. The hardware implementation interleaves the subfilters, which results in sharing each filter multiplier ($FFT\ Length / Input\ Size$) times. The object implements the same pipelined Radix 2^2 FFT algorithm as the `dsp.HDLFFT` System object.

To channelize input data:

- 1 Create the `dsp.HDLChannelizer` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

Creation

Syntax

```
channelizer = dsp.HDLChannelizer  
channelizer = dsp.HDLChannelizer(Name,Value)
```

Description

`channelizer = dsp.HDLChannelizer` returns a System object, `channelizer`, that implements a raised-cosine filter and an 8-point FFT.

`channelizer = dsp.HDLChannelizer(Name,Value)` sets properties using one or more name-value pairs. Enclose each property name in single quotes.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see [System Design in MATLAB Using System Objects](#).

NumFrequencyBands — FFT length

8 (default) | integer power of two

FFT length, specified as an integer power of two. For HDL code generation, the FFT length must be between 2^3 and 2^{16} , inclusive.

FilterCoefficients — Polyphase filter coefficients

[-0.032 0.121 0.318 0.482 0.546 0.482 0.318 0.121 -0.032] (default) | vector of numeric values

Polyphase filter coefficients, specified as a vector of numeric values. If the number of coefficients is not a multiple of NumFrequencyBands, the object pads this vector with zeros. The default filter specification is a raised-cosine FIR filter, `rcosdesign(0.25,2,4,'sqrt')`. You can specify a vector of coefficients or a call to a filter design function that returns the coefficient values. Complex coefficients are not supported. By default, the object casts the coefficients to the same data type as the input.

ComplexMultiplication — HDL implementation of complex multipliers

'Use 4 multipliers and 2 adders' (default) | 'Use 3 multipliers and 5 adders'

HDL implementation of complex multipliers, specified as either 'Use 4 multipliers and 2 adders' or 'Use 3 multipliers and 5 adders'. Depending on your synthesis tool and target device, one option may be faster or smaller.

Dependencies

This option applies only if you use the Radix 2^2 architecture.

OutputSize — Size of output data

'Same as number of frequency bands' (default) | 'Same as input size'

Size of output data, specified as:

- 'Same as number of frequency bands' — Output data is a 1-by- M vector, where M is the FFT length.
- 'Same as input size' — Output data is an M -by-1 vector, where M is the input vector size.

The output order is bit natural for both output sizes.

Normalize — FFT scaling

true (default) | false

FFT output scaling, specified as either:

- `true` — The FFT implements an overall $1/N$ scale factor by scaling the result of each pipeline stage by 2. This adjustment keeps the output of the FFT in the same amplitude range as its input.
- `false` — The FFT avoids overflow by increasing the word length by one bit at each stage.

RoundingMethod — Rounding mode used for internal fixed-point calculations

'Floor' (default) | 'Ceiling' | 'Convergent' | 'Nearest' | 'Round' | 'Zero'

Rounding mode used for fixed-point operations. The object uses fixed-point arithmetic for internal calculations when the input is any integer or fixed-point data type. This option does not apply when the input is `single` or `double`. Each FFT stage rounds after the twiddle factor multiplication but

before the butterflies. Rounding can also occur when casting the coefficients and the output of the polyphase filter to the data types you specify.

OverflowAction — Overflow handling for internal fixed-point calculations

'Wrap' (default) | 'Saturate'

“Overflow Handling” used for fixed-point operations. The object uses fixed-point arithmetic for internal calculations when the input is any integer or fixed-point data type. This option does not apply when the input is `single` or `double`. This option applies to casting the coefficients and the output of the polyphase filter to the data types you specify.

The FFT algorithm avoids overflow by either scaling the output of each stage (Normalize enabled), or by increasing the word length by 1 bit at each stage (Normalize disabled).

CoefficientsDataType — Data type of filter coefficients

'Same word length as input' (default) | `numericType` object

The object casts the polyphase filter coefficients to this data type, using the rounding and overflow settings you specify. When you select `Inherit: Same word length as input` (default), the object selects the binary point using `fi()` best-precision rules.

FilterOutputDataType — Data type of output of polyphase filter

'Same word length as input' (default) | 'Full precision' | `numericType` object

Data type of the output of the polyphase filter, specified as 'Same word length as input', 'Full precision', or a `numericType` object. The object casts the output of the polyphase filter (the input to the FFT) to this data type, using the rounding and overflow settings you specify. When you specify 'Same word length as input', the object selects a best-precision binary point by considering the values of your filter coefficients and the range of your input data type.

By default, the FFT logic does not change the data type. When you disable Normalize, the FFT algorithm avoids overflow by increasing the word length by 1 bit at each stage.

ResetInputPort — Enable reset argument

`false` (default) | `true`

Enable reset input argument to the object. When reset is 1 (true), the object stops calculation and clears all internal state.

StartOutputPort — Enable start output argument

`false` (default) | `true`

Enable `startOut` output argument of the object. When enabled, the object returns an additional output signal that is 1 (true) on the first cycle of each valid output frame.

EndOutputPort — Enable end output argument

`false` (default) | `true`

Enable `endOut` output argument of the object. When enabled, the object returns an additional output signal that is 1 (true) on the first cycle of each valid output frame.

Usage

Syntax

```
[dataOut,validOut] = channelizer(dataIn,validIn)
[dataOut,validOut] = channelizer(dataIn,validIn,reset)
[dataOut,startOut,endOut,validOut] = channelizer( ___ )
```

Description

`[dataOut,validOut] = channelizer(dataIn,validIn)` filters and computes a fast Fourier transform, and returns the frequency channels, `dataOut`, detected in the input signal, `dataIn`, when `validIn` is 1 (true). The `validIn` and `validOut` arguments are logical scalars that indicate the validity of the input and output signals, respectively.

`[dataOut,validOut] = channelizer(dataIn,validIn,reset)` returns the frequency channels, `dataOut`, detected in the input signal, `dataIn`, when `validIn` is 1 (true) and `reset` is 0 (false). When `reset` is 1 (true), the object stops the current calculation and clears all internal state.

To use this syntax, set the `ResetInputPort` property to `true`. For example:

```
channelizer = dsp.HDLChannelizer(...,'ResetInputPort',true);
...
[dataOut,validOut] = channelizer(dataIn,validIn,reset)
```

`[dataOut,startOut,endOut,validOut] = channelizer(___)` returns the frequency channels, `dataOut`, computed from the input arguments of any of the previous syntaxes. `startOut` is 1 (true) for the first sample of a frame of output data. `endOut` is 1 (true) for the last sample of a frame of output data.

To use this syntax, set the `StartOutputPort` and `EndOutputPort` properties to `true`. For example:

```
channelizer = dsp.HDLChannelizer(...,'StartOutputPort',true,'EndOutputPort',true);
...
[dataOut,startOut,endOut,validOut] = channelizer(dataIn,validIn)
```

Input Arguments

dataIn — Input data

scalar or column vector of real or complex values

Input data, specified as a scalar or column vector of real or complex values. The vector size must be a power of 2 between 1 and 64 that is not greater than the number of channels (FFT length).

`double` and `single` data types are supported for simulation, but not for HDL code generation.

The object does not accept `uint64` data.

Data Types: `fi` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `single` | `double`

validIn — Validity of input data

logical scalar

Validity of input data, specified as a logical scalar. When `validIn` is 1 (true), the object captures the value on `dataIn`.

Data Types: `logical`

reset — Reset internal state

logical scalar

Reset internal state, specified as a logical scalar. When `reset` is 1 (true), the object stops the current calculation and clears internal state.

Dependencies

To enable this argument, set `ResetInputPort` to `true`.

Data Types: `logical`

Output Arguments**dataOut — Frequency channel output data**

row vector

Frequency channel output data, returned as a row vector.

- If you set `OutputSize` to 'Same as number of frequency bands' (default), the output data is a 1-by- M vector, where M is the FFT length.
- If you set `OutputSize` to 'Same as input size', the output data is an M -by-1 vector, where M is the input vector size.

The output order is bit natural for either output size. The data type is a result of the `FilterOutputDataType` and the FFT bit growth necessary to avoid overflow.

validOut — Validity of output data

logical scalar

Validity of output data, returned as a logical scalar. The object sets `validOut` to 1 (true) with each valid sample on `dataOut`.

Data Types: `logical`

startOut — First valid cycle of output data

logical scalar

First sample of output frame, returned as a logical scalar. The object sets `startOut` to 1 (true) during the first valid sample on `dataOut`.

Dependencies

To enable this argument, set `StartOutputPort` to `true`.

Data Types: `logical`

endOut — Last valid cycle of output data

logical scalar

Last sample of output frame, returned as a logical scalar. The object sets `endOut` to 1 (true) during the last valid sample on `dataOut`.

Dependencies

To enable this argument, set `EndOutputPort` to `true`.

Data Types: `logical`

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Specific to dsp.HDLChannelizer

`getLatency` Latency of FFT or channelizer calculation

Common to All System Objects

`step` Run System object algorithm
`release` Release resources and allow changes to System object property values and input characteristics
`reset` Reset internal states of System object

Examples

Create Channelizer for HDL Generation

Create a function that contains a channelizer object and supports HDL code generation.

Create the specifications and input signal. The signal has 8 frequency channels.

```
N = 8;
loopCount = 1024;
offsets = [-40 -30 -20 10 15 25 35 -15];
sinewave = dsp.SineWave('ComplexOutput',true,'Frequency', ...
    offsets+(-375:125:500),'SamplesPerFrame',loopCount);
spectrumAnalyzer = dsp.SpectrumAnalyzer('ShowLegend',true, ...
    'SampleRate',sinewave.SampleRate/N);
```

Write a function that creates and calls the channelizer System object™. You can generate HDL from this function.

```
function [yOut,validOut] = HDLChannelizer8(yIn,validIn)
%HDLChannelizer8
% Process one sample of data using the dsp.HDLChannelizer System object
% yIn is a fixed-point scalar or column vector.
% validIn is a logical scalar value.
% You can generate HDL code from this function.

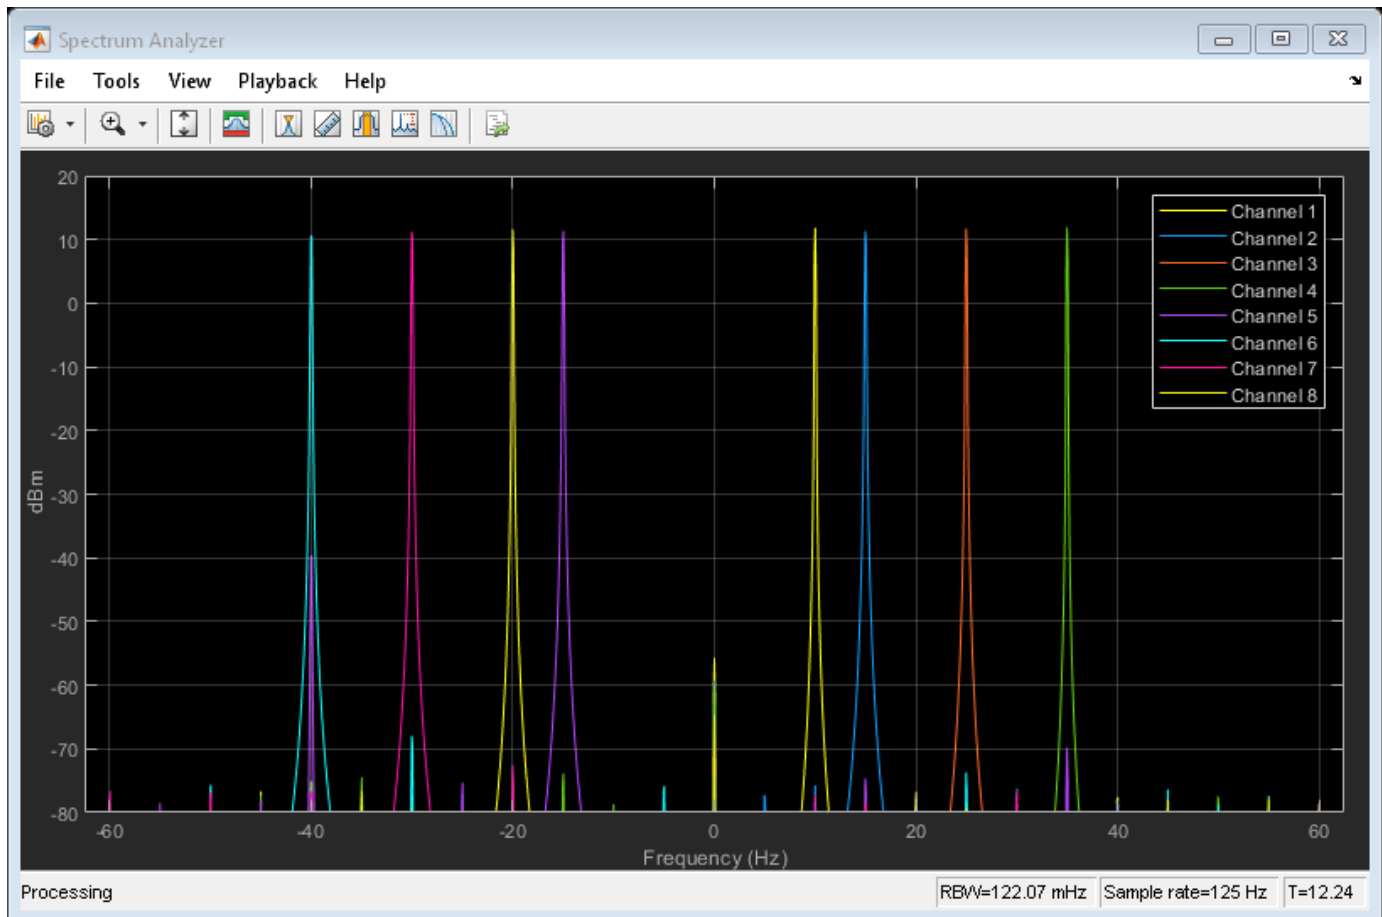

persistent channelize8;
coder.extrinsic('tf');
coder.extrinsic('dsp.Channelizer');

if isempty(channelize8)
    % Use filter coeffs from non-HDL channelizer, or supply your own.
    channelizer = coder.const(dsp.Channelizer('NumFrequencyBands',8));
    coeff = coder.const(tf(channelizer));
    channelize8 = dsp.HDLChannelizer('NumFrequencyBands',8,'FilterCoefficients',coeff);
end
```

```
[yOut,validOut] = channelize8(yIn,validIn);
end
```

Channelize the input data by calling the object for each data sample.

```
y = zeros(loopCount/N,N);
validOut = false(loopCount/N,1);
yValid = zeros(loopCount/(N*N),N);
for reps=1:20
    x = fi(sum(sinwave(),2),1,18);
    for loop=1:length(x)
        [y(loop,:),validOut(loop)]= HDLChannelizer8(x(loop),true);
    end
    yValid = y(validOut == 1,:);
    spectrumAnalyzer(yValid);
end
```

Explore Latency of the HDL Channelizer Object

The latency of the `dsp.HDLChannelizer` object varies with the FFT length and the vector size. Use the `getLatency` function to find the latency of a particular configuration. The latency is measured as

the number of cycles between the first valid input and the first valid output, assuming that the input is contiguous. The number of filter coefficients does not affect the latency. Setting the output size equal to the input size reduces the latency because the samples are not saved and reordered.

Create a `dsp.HDLChannelizer` object and request the latency.

```
channelize = dsp.HDLChannelizer('NumFrequencyBands',512);
L512 = getLatency(channelize)
```

```
L512 = 1118
```

Request hypothetical latency information about a similar object with a different number of frequency bands (FFT length). The properties of the original object do not change.

```
L256 = getLatency(channelize,256)
```

```
L256 = 592
```

```
N = channelize.NumFrequencyBands
```

```
N = 512
```

Request hypothetical latency information of a similar object that accepts eight-sample vector input.

```
L256v8 = getLatency(channelize,256,8)
```

```
L256v8 = 132
```

Enable scaling at each stage of the FFT. The latency does not change.

```
channelize.Normalize = true;
L512n = getLatency(channelize)
```

```
L512n = 1118
```

Request the same output size and order as the input data. The latency decreases because the object does not need to store and reorder the data before output. The default input size is scalar.

```
channelize.OutputSize = 'Same as input size';
L512r = getLatency(channelize)
```

```
L512r = 1084
```

Check the latency of a vector input implementation where the input and output are the same size. Specify the current value of the FFT length and a vector size of 8 samples. The latency decreases because the object computes results in parallel when the input is a vector.

```
L256rv8 = getLatency(channelize,channelize.NumFrequencyBands,8)
```

```
L256rv8 = 218
```

Algorithms

This object implements the algorithm described on the Channelizer HDL Optimized block reference page.

Latency

The latency varies with the FFT length and the vector size. Use the `getLatency` function to find the latency of a particular configuration. The latency is the number of cycles between the first valid input and the first valid output, assuming that the input is contiguous. The filter coefficients do not affect the latency. Setting the output size equal to the input size reduces the latency, because the samples are not saved and reordered.

Control Signals

This diagram shows `validIn` and `validOut` signals for contiguous input data with a vector size of 16 and an FFT length of 512.

The diagram also shows the optional `startOut` and `endOut` signals that indicate frame boundaries. When enabled, `startOut` pulses for one cycle with the first `validOut` of the frame, and `endOut` pulses for one cycle with the last `validOut` of the frame.

If you apply continuous input frames (no gap in `validIn` between frames), the output will also be continuous, after the initial latency.

The `validIn` signal can be noncontiguous. Data accompanied by a `validIn` signal is stored until a frame is filled. Then the data is output in a contiguous frame of N (FFT length) cycles. This diagram shows noncontiguous input and contiguous output for an FFT length of 512 and a vector size of 16 samples.

Performance

These resource and performance data are the place-and-route results from the generated HDL targeted to a Xilinx Virtex 6 (XC6VLX240-1ff784) FPGA. The three examples in the tables use this configuration:

- FFT length (default) — 8
- Filter length — 96 coefficients
- 16-bit complex input data
- Coefficient and filter output data types (default) — Same as number of frequency bands

- Complex multiplication (default) — 4 multipliers, 2 adders
- Output scaling — Enabled
- Minimize clock enables (HDL Coder parameter)

Performance of the synthesized HDL code varies with your target and synthesis options.

For scalar input, the design achieves a clock frequency of 346 MHz. The latency is 53 cycles. The subfilters share each multiplier eight (N) times. The design uses these resources.

Resource	Number Used
LUT	1591
FFS	2681
Xilinx LogiCORE DSP48	16

For four-sample vector input, the design achieves a clock frequency of 333 MHz. The latency is 31 cycles. The subfilters share each multiplier twice (N/M). The design uses these resources.

Resource	Number Used
LUT	1912
FFS	3986
Xilinx LogiCORE DSP48	56

For eight-sample vector input, the design achieves a clock frequency of 292 MHz. The latency is 20 cycles. When the input size is the same as the FFT length, the subfilters do not share any multipliers. The design uses these resources.

Resource	Number Used
LUT	1388
FFS	2302
Xilinx LogiCORE DSP48	110

Extended Capabilities

dsp.HDLComplexToMagnitudeAngle

Package: dsp

Magnitude and phase angle of complex signal—optimized for HDL code generation

Description

The `dsp.HDLComplexToMagnitudeAngle` System object computes the magnitude and phase angle of a complex signal. It provides hardware-friendly control signals. The System object uses a pipelined coordinate rotation digital computer (CORDIC) algorithm to achieve an HDL-optimized implementation.

To compute the magnitude and phase angle of a complex signal:

- 1 Create the `dsp.HDLComplexToMagnitudeAngle` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

Creation

Syntax

```
HCMA = dsp.HDLComplexToMagnitudeAngle
HCMA = dsp.HDLComplexToMagnitudeAngle(Name,Value)
```

Description

`HCMA = dsp.HDLComplexToMagnitudeAngle` returns a `dsp.HDLComplexToMagnitudeAngle` System object, `HCMA`, that computes the magnitude and phase angle of a complex input signal.

`HCMA = dsp.HDLComplexToMagnitudeAngle(Name,Value)` sets properties of `HCMA` using one or more name-value pairs. Enclose each property name in single quotes.

Example: `cma = dsp.HDLComplexToMagnitudeAngle('AngleFormat','Radians')`

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see [System Design in MATLAB Using System Objects](#).

OutputValue — Type of values to return

'Magnitude and angle' (default) | 'Magnitude' | 'Angle'

Type of output values to return, specified as 'Magnitude and angle', 'Magnitude', or 'Angle'. You can choose for the object to return the magnitude of the input signal, or the phase angle of the input signal, or both.

AngleFormat — Format of phase angle output value

'Normalized' (default) | 'Radians'

Format of the phase angle output value from the object, specified as:

- 'Normalized' — Fixed-point format that normalizes the angle in the range [-1,1].
- 'Radians' — Fixed-point values in the range [π , $-\pi$].

ScaleOutput — Scale output by inverse of CORDIC gain factor

true (default) | false

Scale output by the inverse of the CORDIC gain factor, specified as true or false.

Note If your design includes a gain factor later in the datapath, you can set `ScaleOutput` to false, and include the CORDIC gain factor in the later gain. For calculation of this gain factor, see “Algorithm” on page 4-693. The object replaces the first CORDIC iteration by mapping the input value onto the angle range $[0, \pi/4]$. Therefore, the initial rotation does not contribute a gain term.

NumIterationsSource — Source of NumIterations

'Auto' (default) | 'Property'

Source of the `NumIterations` property for the CORDIC algorithm, specified as:

- 'Auto' — Sets the number of iterations to one less than the input word length. If the input is double or single, the number of iterations is 16.
- 'Property' — Uses the `NumIterations` property.

For details of the CORDIC algorithm, see “Algorithm” on page 4-693.

NumIterations — Number of CORDIC iterations

integer less than or equal to one less than the input word length

Number of CORDIC iterations that the object executes, specified as an integer. The number of iterations must be less than or equal to one less than the input word length.

For details of the CORDIC algorithm, see “Algorithm” on page 4-693.

Dependencies

To enable this property, set `NumIterationsSource` to 'Property'.

Usage**Syntax**

```
[mag,angle,validOut] = HCMA(X,validIn)
[mag,validOut] = HCMA(X,validIn)
[angle,validOut] = HCMA(X,validIn)
```

Description

`[mag,angle,validOut] = HCMA(X,validIn)` converts a scalar or vector of complex values `X` into their component magnitude and phase angles. `validIn` and `validOut` are logical scalars that indicate the validity of the input and output signals, respectively.

`[mag,validOut] = HCMA(X,validIn)` returns only the component magnitudes of `X`.

To use this syntax, set `OutputValue` to `'Magnitude'`.

Example: `HCMA = dsp.HDLComplexToMagnitudeAngle('OutputValue','Magnitude');`

`[angle,validOut] = HCMA(X,validIn)` returns only the component phase angles of `X`.

To use this syntax, set `OutputValue` to `'Angle'`.

Example: `HCMA = dsp.HDLComplexToMagnitudeAngle('OutputValue','Angle');`

Input Arguments

X — Input signal

complex scalar or vector

Input signal, specified as a scalar, a column vector representing samples in time, or a row vector representing channels. Using vector input increases data throughput while using more hardware resources. The object implements the conversion logic in parallel for each element of the vector. The input vector can contain up to 64 elements.

`double` and `single` data types are supported for simulation, but not for HDL code generation.

Data Types: `fi` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `single` | `double`

validIn — Validity of input signal

scalar

When `validIn` is `true`, the block captures the data from the `dataIn` input argument. The `validIn` argument applies to all samples in a vector input argument.

Data Types: `logical`

Output Arguments

mag — Magnitude component of input signal

scalar | vector

Magnitude calculated from the complex input signal, returned as a scalar, a column vector representing samples in time, or a row vector representing channels. The dimensions and data type of this argument match the dimensions of the `dataIn` argument.

Dependencies

To enable this argument, set the `OutputValue` property to `'Magnitude and Angle'` or `'Magnitude'`.

angle — Phase angle component of input signal

scalar | vector

Angle calculated from the complex input signal, returned as a scalar, a column vector representing samples in time, or a row vector representing channels. The dimensions and data type of this argument match the dimensions of the `dataIn` argument. The format of this value depends on the `AngleFormat` property.

Dependencies

To enable this argument, set the `OutputValue` property to 'Magnitude and Angle' or 'Angle'.

`validOut` — Validity of output components

scalar

The object sets `validOut` to `true` with each valid data returned on the magnitude or angle output arguments. The `validOut` argument applies to all samples in a vector output argument.

Data Types: `logical`

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Common to All System Objects

<code>step</code>	Run System object algorithm
<code>release</code>	Release resources and allow changes to System object property values and input characteristics
<code>reset</code>	Reset internal states of System object

Examples

Compute Magnitude and Phase Angle of Complex Signal

Use the `dsp.HDLComplexToMagnitudeAngle` object to compute the magnitude and phase angle of a complex signal. The object uses a CORDIC algorithm for an efficient hardware implementation.

Choose word lengths and create random complex input signal. Then, convert the input signal to fixed-point.

```
a = -4;  
b = 4;  
inputWL = 16;  
inputFL = 12;  
numSamples = 10;  
reData = ((b-a).*rand(numSamples,1)+a);  
imData = ((b-a).*rand(numSamples,1)+a);  
dataIn = (fi(reData+imData*1i,1,inputWL,inputFL));  
figure  
plot(dataIn)  
title('Random Complex Input Data')  
xlabel('Real')  
ylabel('Imaginary')
```

Write a function that creates and calls the System object™. You can generate HDL from this function.

Note: This object syntax runs only in R2016b or later. If you are using an earlier release, replace each call of an object with the equivalent `step` syntax. For example, replace `myObject(x)` with `step(myObject,x)`.

```
function [mag,angle,validOut] = Complex2MagAngle(yIn,validIn)
%Complex2MagAngle
% Converts one sample of complex data to magnitude and angle data.
% yIn is a fixed-point complex number.
% validIn is a logical scalar value.
% You can generate HDL code from this function.

persistent cma;
if isempty(cma)
    cma = dsp.HDLComplexToMagnitudeAngle('AngleFormat','Radians');
end
[mag,angle,validOut] = cma(yIn,validIn);
end
```

The number of CORDIC iterations determines the latency that the object takes to compute the answer for each input sample. The latency is `NumIterations+4`. In this example, `NumIterationsSource` is set to the default, 'Auto', so the object uses `inputWL - 1` iterations. The latency is `inputWL+3`.

```

latency = inputWL+3;
mag = zeros(1,numSamples+latency);
ang = zeros(1,numSamples+latency);
validOut = false(1,numSamples+latency);

```

Call the function to convert each sample. After you apply all input samples, continue calling the function with invalid input to flush remaining output samples.

```

for ii = 1:1:numSamples
    [mag(ii),ang(ii),validOut] = Complex2MagAngle(dataIn(ii),true);
end
for ii = (numSamples+1):1:(numSamples+latency)
    [mag(ii),ang(ii),validOut(ii)] = Complex2MagAngle(fi(0+0*1i,1,inputWL,inputFL),false);
end
end
% Remove invalid output values
mag = mag(validOut == 1);
ang = ang(validOut == 1);
figure
polar(ang,mag,'--r') % Red is output from HDL-optimized System object
title('Output from dsp.HDLComplexToMagnitudeAngle')
magD = abs(dataIn);
angD = angle(dataIn);
figure
polar(angD,magD,'--b') % Blue is output from abs and angle functions
title('Output from abs and angle Functions')

```

Output from dsp.HDLComplexToMagnitudeAngle

Algorithms

CORDIC Algorithm

The CORDIC algorithm is a hardware-friendly method for performing trigonometric functions. It is an iterative algorithm that approximates the solution by converging toward the ideal point. The object uses CORDIC vectoring mode to iteratively rotate the input onto the real axis.

The Givens method for rotating a complex number $x+iy$ by an angle θ is as follows. The direction of rotation, d , is $+1$ for counterclockwise and -1 for clockwise.

$$x_r = x \cos \theta - d y \sin \theta$$

$$y_r = y \cos \theta + d x \sin \theta$$

For a hardware implementation, factor out the $\cos \theta$ to leave a $\tan \theta$ term.

$$x_r = \cos \theta (x - d y \tan \theta)$$

$$y_r = \cos \theta (y + d x \tan \theta)$$

To rotate the vector onto the real axis, choose a series of rotations of θ_n so that $\tan \theta_n = 2^{-n}$. Remove the $\cos \theta$ term so each iterative rotation uses only shift and add operations.

$$R x_n = x_{n-1} - d_n y_{n-1} 2^{-n}$$

$$R y_n = y_{n-1} + d_n x_{n-1} 2^{-n}$$

Combine the missing $\cos\theta$ terms from each iteration into a constant, and apply it with a single multiplier to the result of the final rotation. The output magnitude is the scaled final value of x . The output angle, z , is the sum of the rotation angles.

$$x_r = (\cos\theta_0 \cos\theta_1 \dots \cos\theta_n) R x_N$$

$$z = \sum_0^N d_n \theta_n$$

Modified CORDIC Algorithm

The convergence region for the standard CORDIC rotation is $\approx \pm 99.7^\circ$. To work around this limitation, before doing any rotation, the object maps the input into the $[0, \pi/4]$ range using the following algorithm.

```
if abs(x) > abs(y)
  input_mapped = [abs(x), abs(y)];
else
  input_mapped = [abs(y), abs(x)];
end
```

At each iteration, the object rotates the vector towards the real axis. The rotation is counterclockwise when y is negative, and clockwise when y is positive.

Quadrant mapping saves hardware resources and reduces latency by reducing the number of CORDIC pipeline stages by one. The CORDIC gain factor, K_n , therefore does not include the $n=0$, or $\cos(\pi/4)$ term.

$$K_n = \cos\theta_1 \dots \cos\theta_n = \cos(26.565) \cdot \cos(14.036) \cdot \cos(7.125) \cdot \cos(3.576)$$

After the CORDIC iterations are complete, the object corrects the angle back to its original location. First it adjusts the angle to the correct side of $\pi/4$.

```
if abs(x) > abs(y)
  angle_unmapped = CORDIC_out;
else
  angle_unmapped = (pi/2) - CORDIC_out;
end
```

Then it flips the angle to the original quadrant.

```
if (x < 0)
  if (y < 0)
    output_angle = - pi + angle_unmapped;
  else
    output_angle = pi - angle_unmapped;
else
  if (y < 0)
    output_angle = -angle_unmapped;
```

Architecture

The object generates a pipelined HDL architecture to maximize throughput. Each CORDIC iteration is done in one pipeline stage. The gain multiplier, if enabled, is implemented with Canonical Signed Digit (CSD) logic.

If you use vector input, this object replicates this architecture in parallel for each element of the vector.

Input Word Length	Output Magnitude Word Length
fixdt(0,WL,FL)	fixdt(0,WL+2,FL)
fixdt(1,WL,FL)	fixdt(1,WL+1,FL)

Input Word Length	Output Angle Word Length	
fixdt([],WL,FL)	Radians	fixdt(1,WL+3,WL)
	Normalized	fixdt(1,WL+3,WL+2)

The CORDIC logic at each pipeline stage implements one iteration. For each pipeline stage, the shift and angle rotation are constants.

When you set `OutputValue` to 'Magnitude', the object does not generate HDL code for the angle accumulation and quadrant correction logic.

Normalized Angle Format

This format normalizes the fixed-point radian angle values around the unit circle. This is a more efficient use of bits than a range of $[0, 2\pi]$ radians. Normalized angle format also enables wraparound at $0/2\pi$ without additional detect and correct logic.

For example, representing the angle with 3 bits results in the following normalized values.

Using the mapping described in “Modified CORDIC Algorithm” on page 2-687, the object normalizes the angles across $[0, \pi/4]$ and maps them to the correct octant at the end of the calculation.

Delay

The latency is $\text{NumIterations} + 4$ cycles from input to output. Each call to the object models one clock cycle.

When you set `NumIterationsSource` to 'Auto', the number of iterations is one less than the input word length and the latency is three more than the input word length. If the data type of the input is `double` or `single`, the number of iterations is 16 and the latency is 20.

Performance

Performance was measured for the default configuration, with output scaling disabled and `fixdt(1, 16, 12)` input. When the generated HDL code is synthesized into a Xilinx Virtex-6 (XC6VLX240T-1FFG1156) FPGA, the design achieves 260 MHz clock frequency. It uses the following resources.

Resource	Number Used
LUT	882
FFS	792
Xilinx LogiCORE DSP48	0
Block RAM (16K)	0

Performance of the synthesized HDL code varies depending on your target and synthesis options. When you use vector input, the resource usage is about *VectorSize* times the scalar resource usage.

Extended Capabilities

Introduced in R2014b

dsp.HDLFIRRateConverter

Package: dsp

Upsample, filter, and downsample—optimized for HDL code generation

Description

The `dsp.HDLFIRRateConverter` System object upsamples, filters, and downsamples input signals. It is optimized for HDL code generation and operates on one sample of each channel at a time. The object implements an efficient polyphase architecture to avoid unnecessary arithmetic operations and high intermediate sample rates.

The object upsamples by an integer factor of L , applies an FIR filter, and downsamples by an integer factor of M . The object accepts and returns control signal arguments for pacing the flow of samples. For detail of the flow control interface, see “Flow Control” on page 4-712.

To resample and filter input data:

- 1 Create the `dsp.HDLFIRRateConverter` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

Creation

Syntax

```

HDLFIRRC = dsp.HDLFIRRateConverter
HDLFIRRC = dsp.HDLFIRRateConverter(L,M,num)
HDLFIRRC = dsp.HDLFIRRateConverter( ___,Name,Value)
  
```

Description

`HDLFIRRC = dsp.HDLFIRRateConverter` returns a System object, `HDLFIRRC`, that resamples each channel of the input. The object upsamples by an integer factor of L , applies an FIR filter, and downsamples by an integer factor of M . The default L/M is $3/2$.

`HDLFIRRC = dsp.HDLFIRRateConverter(L,M,num)` sets the `InterpolationFactor` property to L , the `DecimationFactor` property to M , and the `Numerator` property to `num`.

`HDLFIRRC = dsp.HDLFIRRateConverter(____, Name, Value)` sets properties using one or more name-value pairs. Enclose each property name in single quotes. For example:

```
HDLFIRRC = dsp.HDLFIRRateConverter(L,M,Num, 'ReadyPort', true, 'RequestPort', true);
```

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see *System Design in MATLAB Using System Objects*.

InterpolationFactor — Upsampling factor

3 (default) | positive integer scalar

Upsampling factor, L , specified as a positive integer.

DecimationFactor — Downsampling factor

2 (default) | positive integer scalar

Downsampling factor, M , specified as a positive integer scalar.

Numerator — FIR filter coefficients

`firpm(70,[0 .28 .32 1],[1 1 0 0])` (default) | vector in descending powers of z^{-1}

FIR filter coefficients, specified as a vector in descending powers of z^{-1} .

You can generate filter coefficients by using the Signal Processing Toolbox filter design functions, such as `fir1`. Design a lowpass filter with normalized cutoff frequency no greater than $\min(1/L, 1/M)$. The object initializes internal filter states to zero.

ReadyPort — Enable ready argument

false (default) | true

Enable ready output argument of the object. When enabled, the object returns a logical scalar value, `ready`, when you call the object. When `ready` is 1 (true), the object is ready for a new input sample the next time you call it.

RequestPort — Enable request argument

false (default) | true

Enable request input argument of the object. When `request` is 1 (true), the object returns a new output sample on the current call to the object.

RoundingMethod — Rounding mode used for fixed-point operations

'Floor' (default) | 'Ceiling' | 'Convergent' | 'Nearest' | 'Round' | 'Zero'

Rounding mode used for fixed-point operations. This property does not apply when the input is single or double type. 'Simplest' mode is not supported.

OverflowAction — Overflow mode used for fixed-point operations

'Wrap' (default) | 'Saturate'

Overflow mode used for fixed-point operations. This property does not apply when the input is single or double type.

CoefficientsDataType — Data type of the FIR filter coefficients

`numericType(1,16,16)` (default) | `numericType(s,wl,fl)`

Data type of the FIR filter coefficients, specified as a `numericType(s,wl,fl)` object with `signedness`, `word length`, and `fractional length` properties.

OutputDataType — Data type of the output data samples

'Same word length as input' (default) | `numericType(s,wl,fl)` | 'Full precision'

Data type of the output data samples, specified as 'Same word length as input', 'Full precision', or as a `numericType(s,wl,fl)` object with `signedness`, `word length`, and `fractional length` properties.

Usage

Syntax

```
[dataOut,validOut] = HDLFIRRC(dataIn,validIn)
[dataOut,ready,validOut] = HDLFIRRC(dataIn,validIn)
[dataOut,ready,validOut] = HDLFIRRC(dataIn,validIn,request)
```

Description

`[dataOut,validOut] = HDLFIRRC(dataIn,validIn)` resamples `dataIn` according to the `InterpolationFactor` (L) and `DecimationFactor` (M) properties. To avoid dropped samples when using this syntax, apply new valid input samples, with `validIn` set to `true`, only every `ceil(L/M)` calls to the object. The object sets `validOut` to `true` when `dataOut` is a new valid sample.

`[dataOut,ready,validOut] = HDLFIRRC(dataIn,validIn)` resamples the input data and returns `ready` to indicate whether the object can accept a new sample on the next call.

This syntax applies when you set the `ReadyPort` property to `true`. For example:

```
HDLFIRRC = dsp.HDLFIRRateConverter(...,'ReadyPort',true);
...
[dataOut,validOut,ready] = rateConverter(dataIn,validIn);
```

`[dataOut,ready,validOut] = HDLFIRRC(dataIn,validIn,request)` resamples the input data, indicates whether the object can accept a new sample, and, if `request` is `true`, returns the next available sample.

This syntax applies when you set the `RequestPort` property to `true`. For example:

```
HDLFIRRC = dsp.HDLFIRRateConverter(...,'RequestPort',true);
...
[dataOut,validOut] = rateConverter(dataIn,validIn,request);
```

You can connect the `ready` output of a downstream object to the `request` input of an upstream object.

Input Arguments

dataIn — Data input

scalar or row vector

Data input, specified as a scalar, or as a row vector where each element represents an independent channel.

The data can be real or complex.

`double` and `single` data types are supported for simulation, but not for HDL code generation.

Data Types: `fi` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `single` | `double`

validIn — Validity of input data

logical scalar

Validity of the input data, specified as a logical scalar.

When `validIn` is 1 (true), the object captures the value on `dataIn`. You can apply a valid data sample every `ceil(L/M)` calls to the object. You can use the optional `ready` output signal to indicate when the object can accept a new sample.

Data Types: `logical`

request — Request for a new output sample

logical scalar

Request for a new output sample, specified as a logical scalar.

When `request` is 1 (true), and a new output data sample is available, the object returns the sample with `validOut` set to 1 (true). If no sample is available, the object returns `validOut` set to 0 (false). The object accepts this argument when you set the `RequestPort` property to `true`.

Data Types: `logical`

Output Arguments

dataOut — Resampled and filtered data sample

scalar or row vector

Resampled and filtered data sample, returned as a scalar, or as a vector in which each element represents an independent channel.

`double` and `single` data types are supported for simulation, but not for HDL code generation.

Data Types: `fi` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `single` | `double`

validOut — Validity of output data

logical scalar

Validity of the output data, returned as a logical scalar.

When `validOut` is 1 (true), the data output is valid. When `validOut` is 0 (false), the data output is not valid.

Data Types: `logical`

ready — Ready for a new input sample

logical scalar

Indicator that the object is ready for a new input sample, returned as a logical scalar.

The object returns `ready = 1` (true) to indicate that the object can accept a new input data sample on the next call. The object returns this additional output when you set the `ReadyPort` property to `true`.

Data Types: `logical`

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Common to All System Objects

<code>step</code>	Run System object algorithm
<code>release</code>	Release resources and allow changes to System object property values and input characteristics
<code>reset</code>	Reset internal states of System object

Examples**Downsample Signal**

Convert a signal from 48 kHz to 32 kHz by using the `dsp.HDLFIRRateConverter` System object™.

Define the sample rate and length of the input signal, and a 2 kHz cosine waveform. Set `validIn = true` for every sample.

```
Fs = 48e3;
Ns = 100;
t = (0:Ns-1) ./ Fs;
dataIn = cos(2*pi*2e3*t);
validIn = true(Ns,1);
```

Preallocate `dataOut` and `validOut` signals for faster simulation.

```
dataOut = zeros(Ns,1);
validOut = false(Ns,1);
```

Create the System object. Configure it to perform rate conversion by a factor of 2/3, using an equiripple filter.

```
Numerator = firpm(70,[0 0.25 0.32 1],[1 1 0 0]);
firrc = dsp.HDLFIRRateConverter(2,3,Numerator);
```

Call the System object to perform the rate conversion and obtain each output sample.

Note: This object syntax runs only in R2016b or later. If you are using an earlier release, replace each call of an object with the equivalent `step` syntax. For example, replace `myObject(x)` with `step(myObject,x)`.

```

for k = 1:Ns
    [dataOut(k),validOut(k)] = firrc(dataIn(k),validIn(k));
end

```

Because the input sample rate is higher than the output sample rate, not every member of `dataOut` is valid. Use `validOut` to extract the valid samples from `dataOut`.

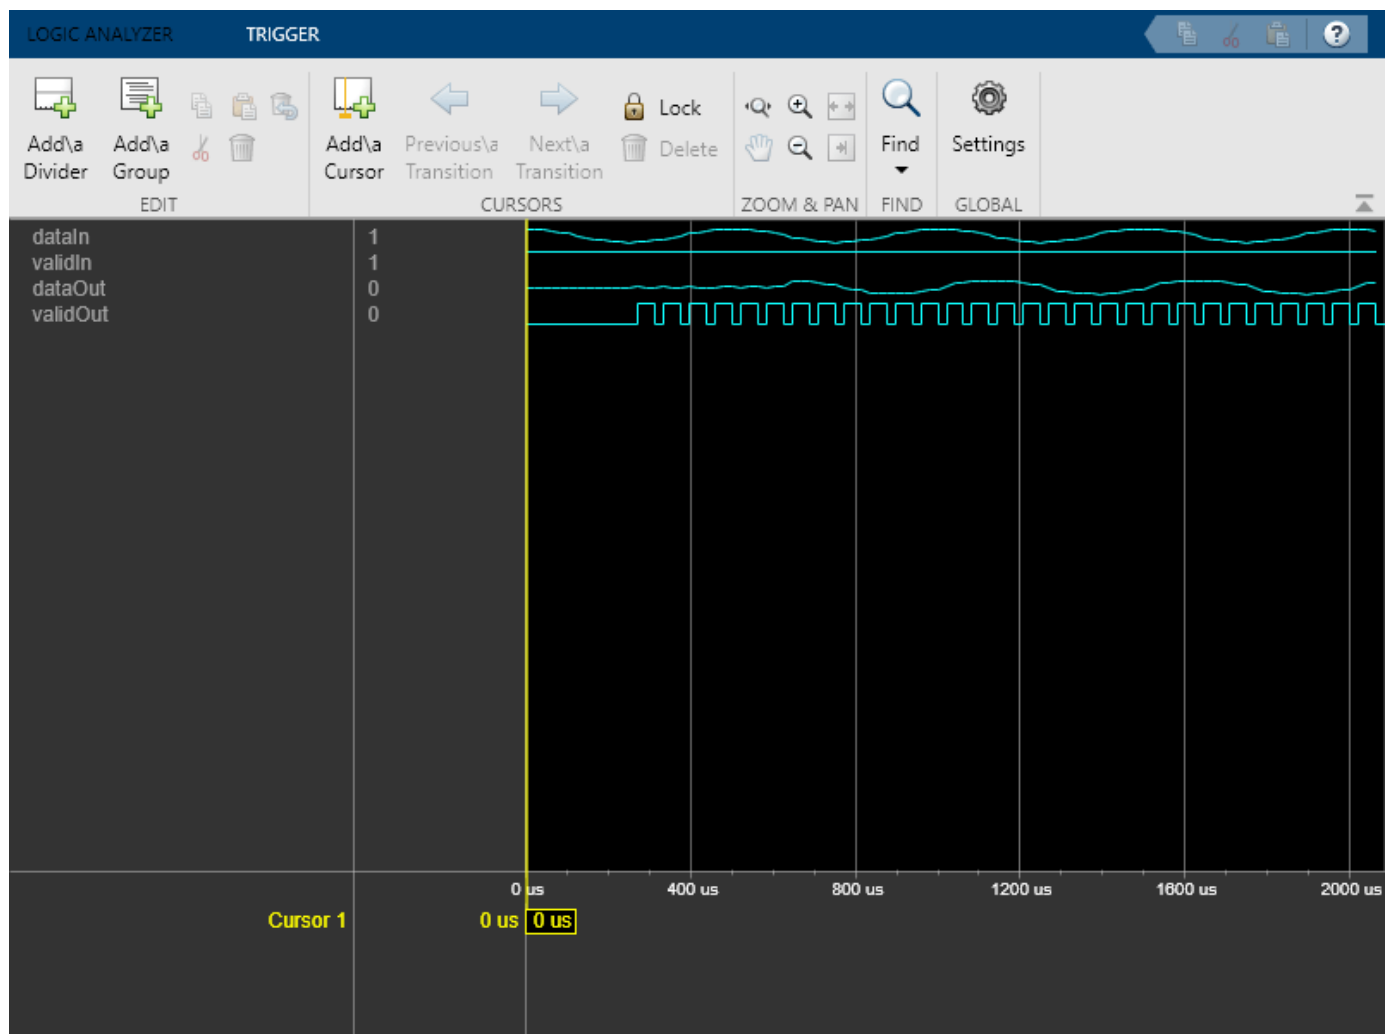

```
y = dataOut(validOut);
```

View the input and output signals with the Logic Analyzer.

```

la = dsp.LogicAnalyzer('NumInputPorts',4,'SampleTime',1/Fs,'TimeSpan',Ns/Fs);
modifyDisplayChannel(la,1,'Name','dataIn','Format','Analog','Height',8)
modifyDisplayChannel(la,2,'Name','validIn')
modifyDisplayChannel(la,3,'Name','dataOut','Format','Analog','Height',8)
modifyDisplayChannel(la,4,'Name','validOut')
la(dataIn,validIn,dataOut,validOut)

```

Upsample Signal

Convert a signal from 40 MHz to 100 MHz by using the `dsp.HDLFIRRateConverter` System object™. To avoid overrunning the object as the signal is upsampled, control the input rate manually.

Define the sample rate and length of the input signal, and a fixed-point cosine waveform.

```
Fs = 40e6;
Ns = 50;
t = (0:Ns-1) ./ Fs;
x = fi(cos(2*pi*1.2e6*t), 1, 16, 14);
```

Define the rate conversion parameters. Use an interpolation factor of 5 and a decimation factor of 2. Calculate how often the object can accept a new input sample.

```
L = 5;
M = 2;
stepsPerInput = ceil(L/M);
numSteps = stepsPerInput*Ns;
```

Generate `dataIn` and `validIn` based on how often the object can accept a new sample.

```
dataIn = zeros(numSteps, 1, 'like', x);
dataIn(1:stepsPerInput:end) = x;
validIn = false(numSteps, 1);
validIn(1:stepsPerInput:end) = true;
```

Create the System object. Configure it to perform rate conversion using the specified factors and an equiripple FIR filter.

```
Numerator = firpm(70, [0 0.15 0.25 1], [1 1 0 0]);
rateConverter = dsp.HDLFIRRateConverter(L, M, Numerator);
```

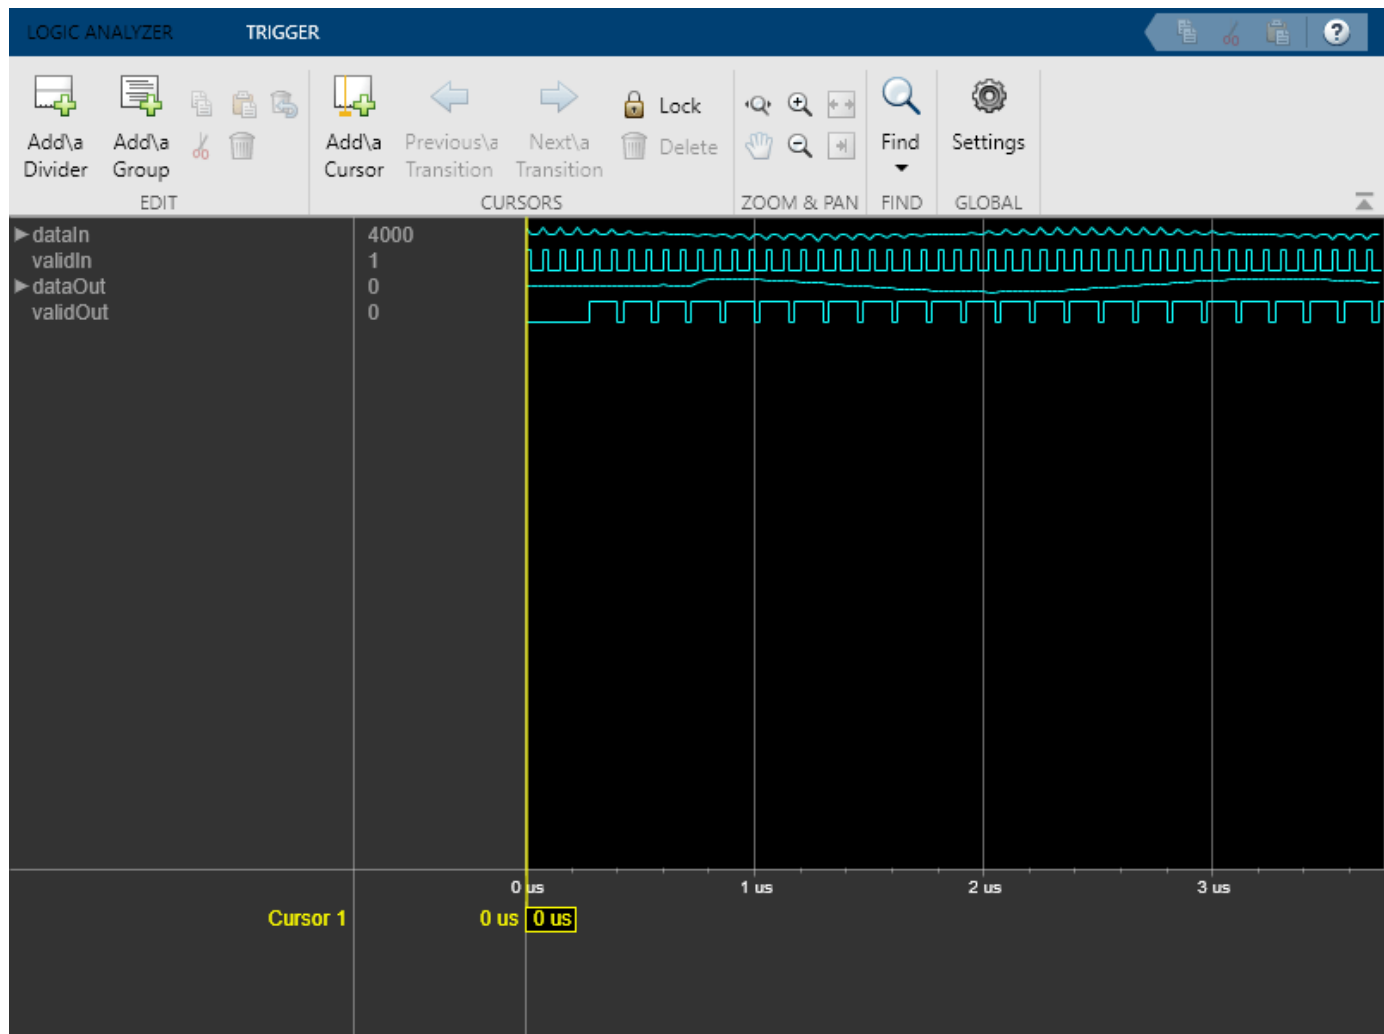

Create a Logic Analyzer to capture and view the input and output signals.

```
la = dsp.LogicAnalyzer('NumInputPorts', 4, 'SampleTime', 1/Fs, 'TimeSpan', numSteps/Fs);
modifyDisplayChannel(la, 1, 'Name', 'dataIn', 'Format', 'Analog', 'Height', 8)
modifyDisplayChannel(la, 2, 'Name', 'validIn')
modifyDisplayChannel(la, 3, 'Name', 'dataOut', 'Format', 'Analog', 'Height', 8)
modifyDisplayChannel(la, 4, 'Name', 'validOut')
```

Call the System object to perform the rate conversion and obtain each output sample. Call the Logic Analyzer to add each sample to the waveform display.

Note: This object syntax runs only in R2016b or later. If you are using an earlier release, replace each call of an object with the equivalent `step` syntax. For example, replace `myObject(x)` with `step(myObject, x)`.

```
for k = 1:numSteps
    [dataOut, validOut] = rateConverter(dataIn(k), validIn(k));
    la(dataIn(k), validIn(k), dataOut, validOut)
end
```

Control Input Rate When Upsampling

Convert a signal from 40 MHz to 100 MHz by using the `dsp.HDLFIRRateConverter` System object™. Use the optional ready output signal to avoid overrunning the object as the data is upsampled. The ready signal indicates the object can accept a new data sample on the next call to the object.

Define the sample rate and length of the input signal, and a fixed-point cosine waveform. Create a `SignalSource` object to provide data samples on demand.

```
Fs = 40e6;
Ns = 50;
t = (0:Ns-1) ./ Fs;
x = fi(cos(2*pi*1.2e6*t), 1, 16, 14);
inputSource = dsp.SignalSource(x);
```

Define the rate conversion parameters. Use an interpolation factor of 5 and a decimation factor of 2. Determine the number of calls to the object needed to convert `Ns` samples.

```
L = 5;
M = 2;
numSteps = floor(Ns*L/M);
```

Create the HDL FIR rate converter System object. Configure it to perform rate conversion using the specified factors and an equiripple FIR filter. Enable the optional ready output port.

```
Numerator = firpm(70,[0 0.15 0.25 1],[1 1 0 0]);
rateConverter = dsp.HDLFIRRateConverter(L,M,Numerator,'ReadyPort',true);
```

Create a Logic Analyzer to capture and view the input and output signals.

```
la = dsp.LogicAnalyzer('NumInputPorts',5,'SampleTime',1/Fs,'TimeSpan',numSteps/Fs);
modifyDisplayChannel(la,1,'Name','dataIn','Format','Analog','Height',8)
modifyDisplayChannel(la,2,'Name','validIn')
modifyDisplayChannel(la,3,'Name','dataOut','Format','Analog','Height',8)
modifyDisplayChannel(la,4,'Name','validOut')
modifyDisplayChannel(la,5,'Name','ready')
```

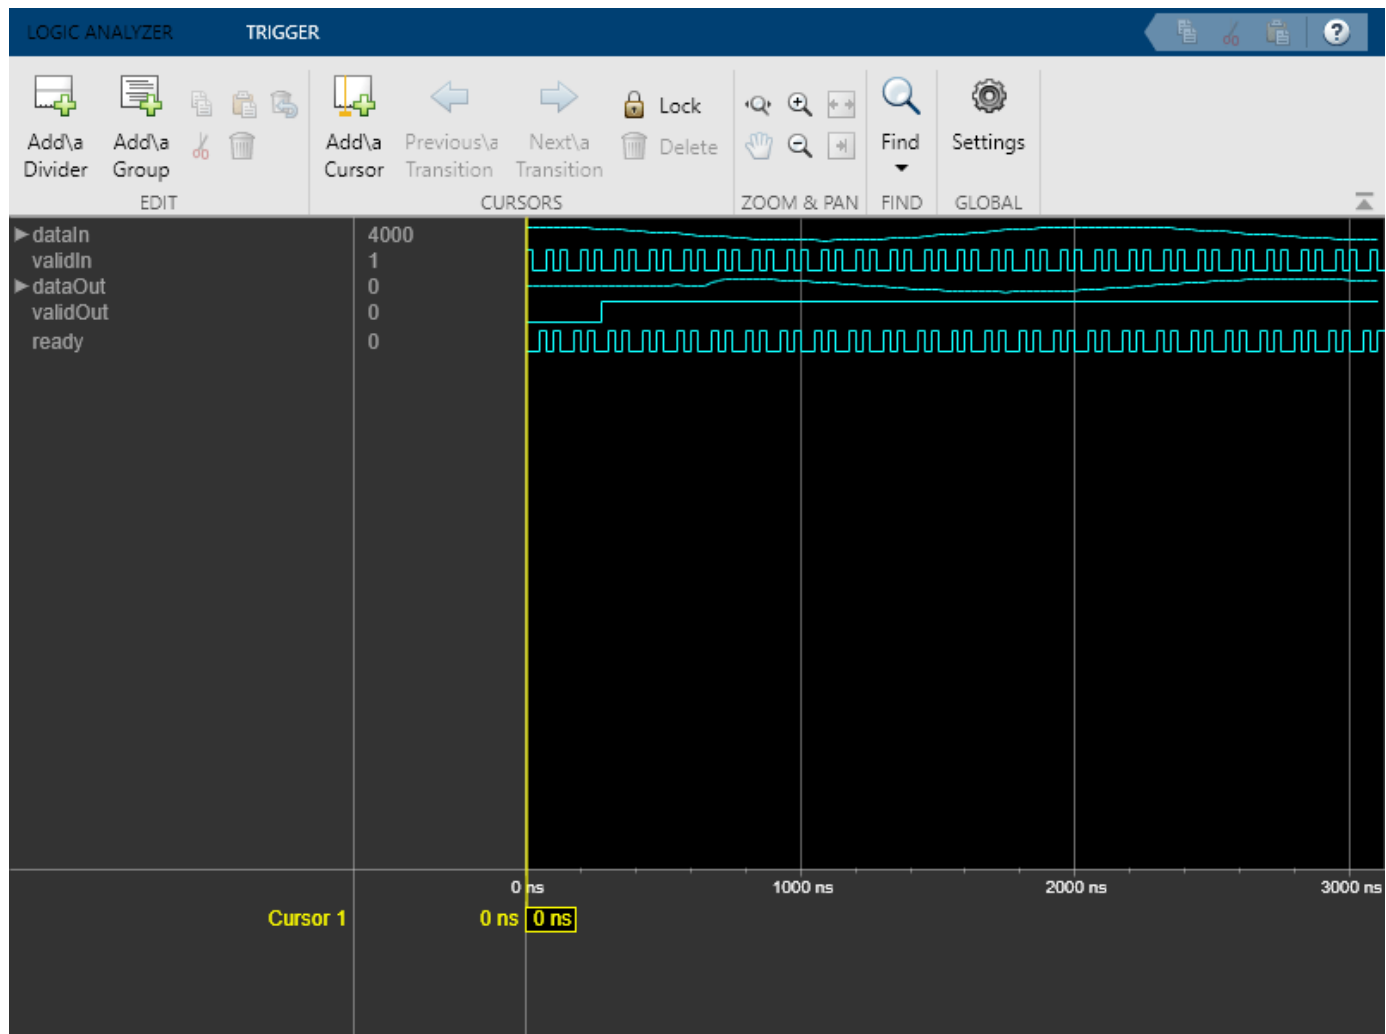

Initialize the ready signal. The object is always ready for input data on the first call.

```
ready = true;
```

Call the System object to perform the rate conversion and obtain each output sample. Apply a new input sample when the object indicates it is ready. Otherwise, set validIn to false.

Note: This object syntax runs only in R2016b or later. If you are using an earlier release, replace each call of an object with the equivalent step syntax. For example, replace myObject(x) with step(myObject,x).

```
for k = 1:numSteps
    if ready
        dataIn = inputSource();
    end
    validIn = ready;
    [dataOut,validOut,ready] = rateConverter(dataIn,validIn);
    la(dataIn,validIn,dataOut,validOut,ready)
end
```

Control Output Rate When Upsampling

Convert a signal from 40 MHz to 100 MHz by using the `dsp.HDLFIRRateConverter System` object™. Use the optional `request` input signal to control the output data rate. When the object receives the `request` signal, it returns a new output data sample. This example models a clock rate of 200 MHz by requesting an output sample every second call to the object.

Define the sample rate and length of the input signal, and a fixed-point cosine waveform. Create a `SignalSource` object to provide data samples on demand.

```
Fs = 40e6;
Ns = 50;
t = (0:Ns-1) ./ Fs;
x = fi(cos(2*pi*1.2e6*t), 1, 16, 14);
inputSource = dsp.SignalSource(x);
```

Define the rate conversion parameters. Use an interpolation factor of 5 and a decimation factor of 2. Determine the number of calls to the object needed to convert `Ns` samples.

```
L = 5;
M = 2;
numSteps = floor(2*Ns*L/M);
```

Create the HDL FIR rate converter System object. Configure it to perform rate conversion using the specified factors and an equiripple FIR filter. Enable the optional ready and request ports.

```
Numerator = firpm(70,[0 0.15 0.25 1],[1 1 0 0]);
rateConverter = dsp.HDLFIRRateConverter(L,M,Numerator,...
    'ReadyPort',true,...
    'RequestPort',true);
```

Create a **Logic Analyzer** to capture and view the input and output signals.

```
la = dsp.LogicAnalyzer('NumInputPorts',6,'SampleTime',1/Fs,'TimeSpan',numSteps/Fs);
modifyDisplayChannel(la,1,'Name','dataIn','Format','Analog','Height',8)
modifyDisplayChannel(la,2,'Name','validIn')
modifyDisplayChannel(la,3,'Name','request')
modifyDisplayChannel(la,4,'Name','dataOut','Format','Analog','Height',8)
modifyDisplayChannel(la,5,'Name','validOut')
modifyDisplayChannel(la,6,'Name','ready')
```

Generate a signal that requests a new output sample every second call to the object.

```
request = false(numSteps,1);
request(1:2:end) = true;
```

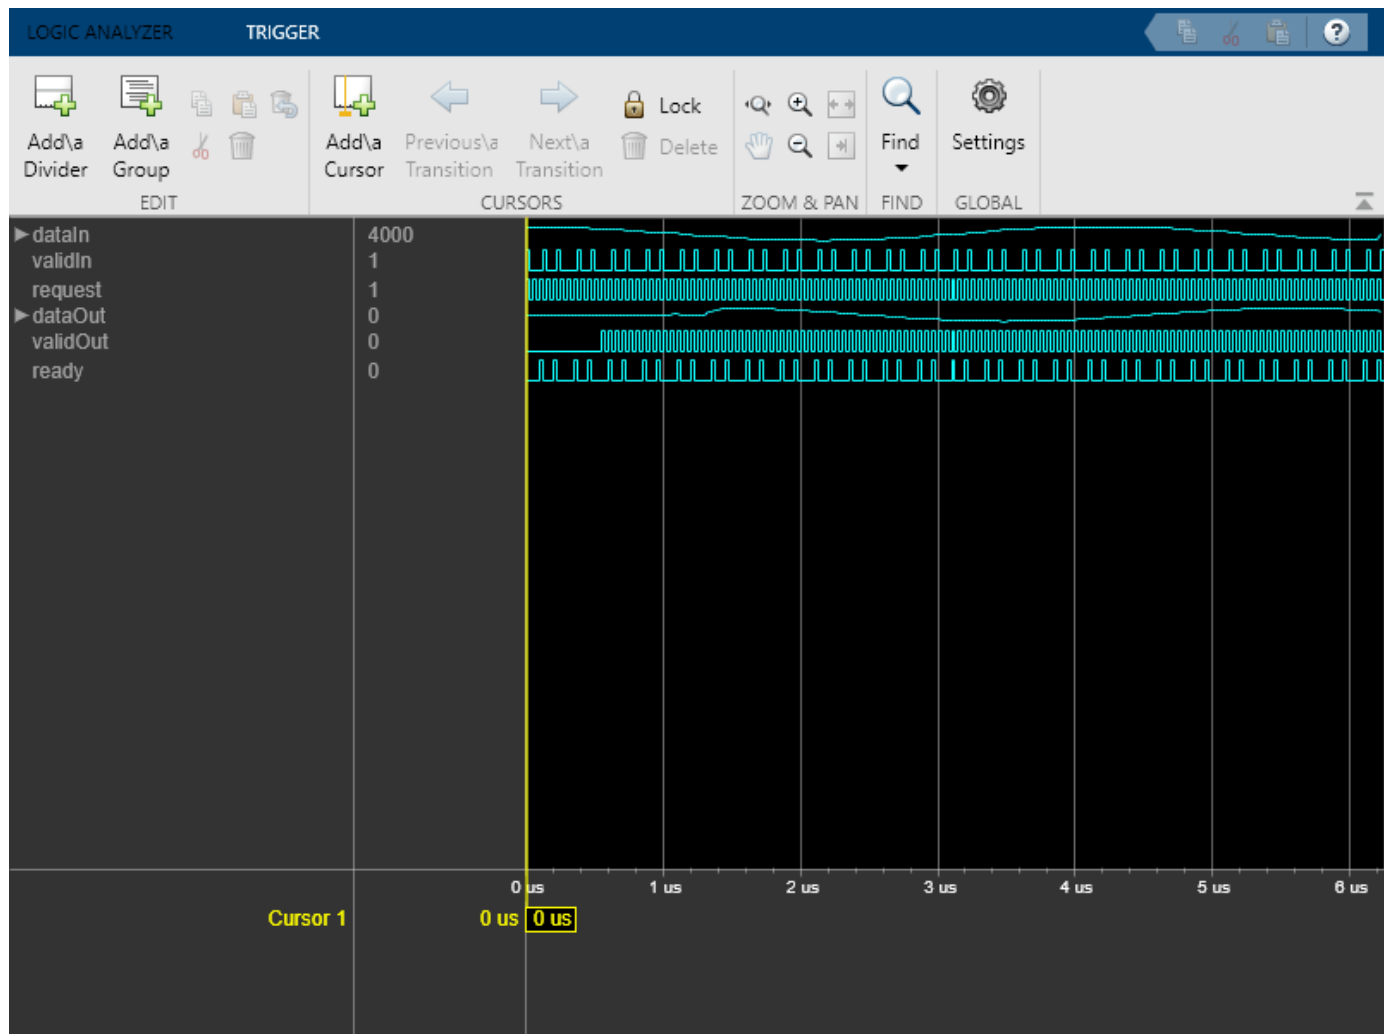

Initialize the ready signal. The object is always ready for input data on the first call.

```
ready = true;
```

Call the System object to perform the rate conversion and obtain each output sample. Apply a new input sample when the object indicates it is ready. Otherwise, set `validIn` to `false`. The object returns valid output samples when `request` is set to `true`.

Note: This object syntax runs only in R2016b or later. If you are using an earlier release, replace each call of an object with the equivalent `step` syntax. For example, replace `myObject(x)` with `step(myObject,x)`.

```
for k = 1:numSteps
    if ready
        dataIn = inputSource();
    end
    validIn = ready;
    [dataOut,validOut,ready] = rateConverter(dataIn,validIn,request(k));
    la(dataIn,validIn,request(k),dataOut,validOut,ready)
end
```

Design for HDL Code Generation from HDL FIR Rate Converter

Create a rate conversion function targeted for HDL code generation, and a test bench to exercise it. The function converts a signal from 40 MHz to 100 MHz. To avoid overrunning the object, the test bench manually controls the input rate.

Define the sample rate and length of the input signal, and a fixed-point cosine waveform.

```

Fs = 40e6;
Ns = 50;
t = (0:Ns-1) ./ Fs;
x = fi(cos(2*pi*1.2e6*t), 1, 16, 14);

```

Define the rate conversion parameters. Use an interpolation factor of 5 and a decimation factor of 2. Calculate how often the object can accept a new data sample.

```

L = 5;
M = 2;

```

```
stepsPerInput = ceil(L/M);
numSteps = stepsPerInput*Ns;
```

Generate `dataIn` and `validIn` based on how often the object can accept a new sample.

```
dataIn = zeros(numSteps,1,'like',x);
dataIn(1:stepsPerInput:end) = x;
validIn = false(numSteps,1);
validIn(1:stepsPerInput:end) = true;
```

Create a Logic Analyzer to capture and view the input and output signals.

```
la = dsp.LogicAnalyzer('NumInputPorts',4,'SampleTime',1/Fs,'TimeSpan',numSteps/Fs);
modifyDisplayChannel(la,1,'Name','dataIn','Format','Analog','Height',8)
modifyDisplayChannel(la,2,'Name','validIn')
modifyDisplayChannel(la,3,'Name','dataOut','Format','Analog','Height',8)
modifyDisplayChannel(la,4,'Name','validOut')
```

Write a function that creates and calls the System object.

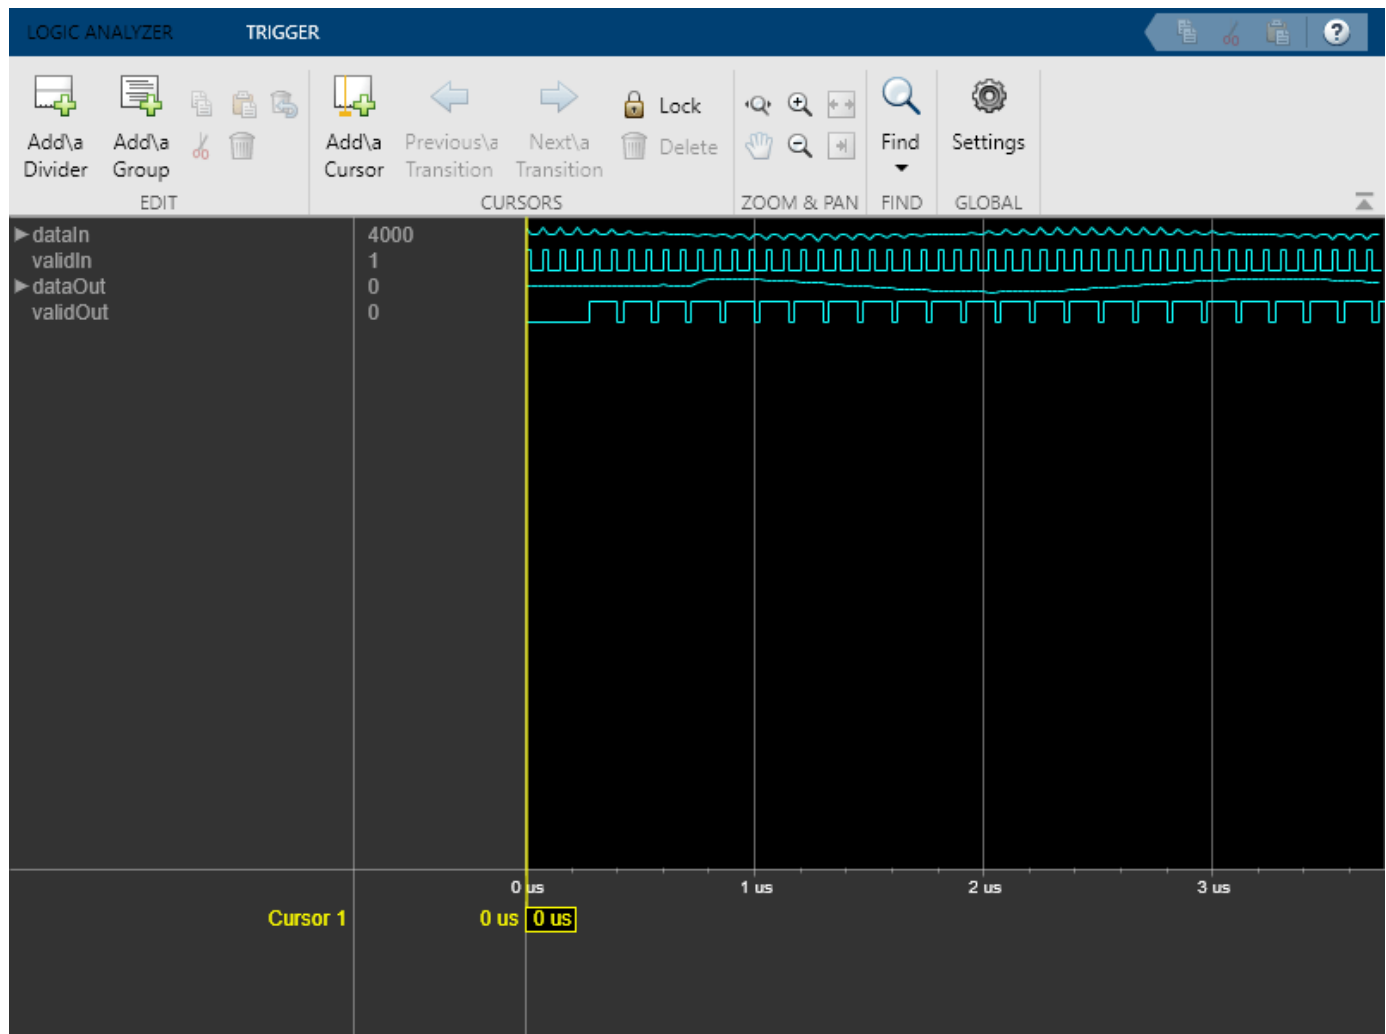

Note: This object syntax runs only in R2016b or later. If you are using an earlier release, replace each call of an object with the equivalent `step` syntax. For example, replace `myObject(x)` with `step(myObject,x)`.

```
function [dataOut,validOut] = HDLFIRRC5_2(dataIn,validIn)
%HDLFIRRC5_2
% Processes one sample of data using the dsp.HDLFIRRateConverter System
% object. dataIn is a fixed-point scalar value. validIn is a logical scalar value.
% You can generate HDL code from this function.

persistent firrc5_2;
if isempty(firrc5_2)
    Numerator = firpm(70,[0,.15,.25,1],[1,1,0,0]);
    firrc5_2 = dsp.HDLFIRRateConverter(5,2,Numerator);
end
[dataOut,validOut] = firrc5_2(dataIn,validIn);
end
```

Resample the signal by calling the function for each data sample.

```
for k = 1:numSteps
    [dataOut,validOut] = HDLFIRRC5_2(dataIn(k),validIn(k));
    la(dataIn(k),validIn(k),dataOut,validOut)
end
```

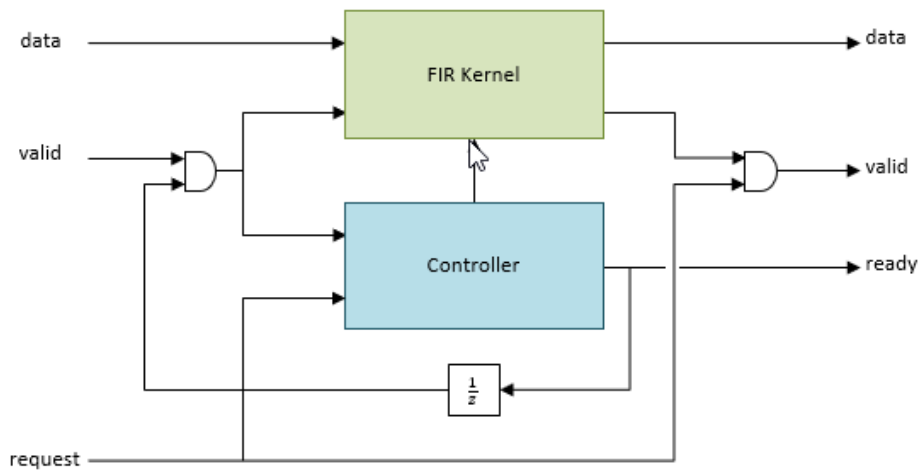

Algorithms

This object implements the algorithms described on the FIR Rate Conversion HDL Optimized block reference page.

Flow Control

The object accepts and returns control signal arguments for pacing the flow of samples. By default, the object uses `validIn` and `validOut` control signals. You can also enable a `ready` output signal and a `request` input signal.

The `ready` output indicates that the object can accept a new input data sample on the next call to the object. When $L \geq M$, you can use the `ready` argument to achieve continuous output data samples. If you apply a new input sample after each time object returns `ready = true`, each call to the object returns a data output sample with `validOut = true`.

When you do not enable the `ready` argument, you can apply a valid data sample only every `ceil(L/M)` calls to the object. For example:

- $L/M = 4/5$ — You can apply a new input sample on every call.
- $L/M = 3/2$ — You can apply a new input sample on every other call.

When you enable the `request` input, the object returns the next output sample when `request` is `true` and a valid output sample is available. When you do not use `request`, the object returns output samples when they are available. Calls to the object that do not return a new sample return `validOut = false`.

You can connect `request` to the `ready` output of a downstream object.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

This System object supports C/C++ code generation for accelerating MATLAB simulations, and for DPI component generation.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

`double` and `single` data types are supported for simulation, but not for HDL code generation.

To generate HDL code from predefined System objects, see “HDL Code Generation from Viterbi Decoder System Object” (HDL Coder).

`dsp.FIRRateConverter`

Introduced in R2015b

dsp.HDLFFT

Package: dsp

Fast Fourier transform — optimized for HDL code generation

Description

The HDL FFT System object provides two architectures to optimize either throughput or area. Use the streaming Radix 2² architecture for high-throughput applications. This architecture supports scalar or vector input data. You can achieve giga-sample-per-second (GSPS) throughput using vector input. Use the burst Radix 2 architecture for a minimum resource implementation, especially with large FFT sizes. Your system must be able to tolerate bursty data and higher latency. This architecture supports only scalar input data. The object accepts real or complex data, provides hardware-friendly control signals, and has optional output frame control signals.

To calculate the fast Fourier transform:

- 1 Create the `dsp.HDLFFT` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

Creation

Syntax

```
FFT_N = dsp.HDLFFT  
FFT_N = dsp.HDLFFT(Name, Value)
```

Description

`FFT_N = dsp.HDLFFT` returns an HDL FFT System object, `FFT_N`, that performs a fast Fourier transform.

`FFT_N = dsp.HDLFFT(Name, Value)` sets properties using one or more name-value pairs. Enclose each property name in single quotes.

Example: `fft128 = dsp.HDLFFT('FFTLength', 128)`

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see [System Design in MATLAB Using System Objects](#).

Architecture — Hardware implementation`'Streaming Radix 2^2' (default) | 'Burst Radix 2'`

Hardware implementation, specified as either:

- `'Streaming Radix 2^2'` — Low-latency architecture. Supports giga-sample-per-second (GSPS) throughput when you use vector input.
- `'Burst Radix 2'` — Minimum resource architecture. Vector input is not supported when you select this architecture. When you use this architecture, your input data must comply with the ready backpressure signal. For a waveform that shows this protocol, see the third diagram in the “Timing Diagram” on page 2-709 section.

ComplexMultiplication — HDL implementation of complex multipliers`'Use 4 multipliers and 2 adders' (default) | 'Use 3 multipliers and 5 adders'`

HDL implementation of complex multipliers, specified as either `'Use 4 multipliers and 2 adders'` or `'Use 3 multipliers and 5 adders'`. Depending on your synthesis tool and target device, one option may be faster or smaller.

BitReversedOutput — Order of the output data`true (default) | false`

Order of the output data, specified as either:

- `true` — The output channel elements are bit reversed relative to the input order.
- `false` — The output channel elements are in linear order.

The FFT algorithm calculates output in the reverse order to the input. When you request output in the same order as the input, the algorithm performs an extra reversal operation. For more information on ordering of the output, see “Linear and Bit-Reversed Output Order”.

BitReversedInput — Expected order of the input data`false (default) | true`

Expected order of the input data, specified as either:

- `true` — The input channel elements are in bit-reversed order.
- `false` — The input channel elements are in linear order.

The FFT algorithm calculates output in the reverse order to the input. When you request output in the same order as the input, the algorithm performs an extra reversal operation. For more information on ordering of the output, see “Linear and Bit-Reversed Output Order”.

Normalize — Output scaling`false (default) | true`

Output scaling, specified as either:

- `true` — The object implements an overall $1/N$ scale factor by dividing the output of each butterfly multiplication by 2. This adjustment keeps the output of the FFT in the same amplitude range as its input.
- `false` — The object avoids overflow by increasing the word length by one bit after each butterfly multiplication. The bit growth is the same for both architectures.

FFTLength — Number of data points used for one FFT calculation1024 (default) | integer power of 2 between 2^3 and 2^{16}

Number of data points used for one FFT calculation, specified as an integer power of 2 between 2^3 and 2^{16} . The object accepts FFT lengths outside this range, but they are not supported for HDL code generation.

ResetInputPort — Enable reset argument

false (default) | true

Enable reset input argument to the object. When reset is true, the object stops calculation and clears all internal state.

StartOutputPort — Enable start output argument

false (default) | true

Enable startOut output argument of the object. When enabled, the object returns an additional output signal that is true on the first cycle of each valid output frame.

EndOutputPort — Enable end output argument

false (default) | true

Enable endOut output argument of the object. When enabled, the object returns an additional output signal that is true on the first cycle of each valid output frame.

RoundingMethod — Rounding mode used for fixed-point operations

'Floor' (default) | 'Ceiling' | 'Convergent' | 'Nearest' | 'Round' | 'Zero'

Rounding mode used for fixed-point operations. When the input is any integer or fixed-point data type, the FFT algorithm uses fixed-point arithmetic for internal calculations. This option does not apply when the input is single or double type. Rounding applies to twiddle factor multiplication and scaling operations.

Usage**Syntax**

```
[Y,validOut] = FFT_N(X,validIn)
[Y,validOut,ready] = FFT_N(X,validIn)
[Y,startOut,endOut,validOut] = FFT_N(X,validIn)
[Y,validOut] = FFT_N(X,validIn,resetIn)
[Y,startOut,endOut,validOut] = FFT_N(X,validIn,resetIn)
```

Description

`[Y,validOut] = FFT_N(X,validIn)` returns the FFT, Y, of the input, X, when validIn is true. validIn and validOut are logical scalars that indicate the validity of the input and output signals, respectively.

`[Y,validOut,ready] = FFT_N(X,validIn)` returns the fast Fourier transform (FFT) when using the burst Radix 2 architecture. The ready signal indicates when the object has memory available for new input samples. You must apply input data and valid signals only when ready is 1 (true). The object ignores any input data and valid signals when ready is 0 (false).

To use this syntax, set the `Architecture` property to `'Burst Radix 2'`. For example:

```
FFT_N = dsp.HDLFFT(___, 'Architecture', 'Burst Radix 2');
...
[y, validOut, ready] = FFT_N(x, validIn)
```

`[Y, startOut, endOut, validOut] = FFT_N(X, validIn)` also returns frame control signals `startOut` and `endOut`. `startOut` is true on the first sample of a frame of output data. `endOut` is true for the last sample of a frame of output data.

To use this syntax, set the `StartOutputPort` and `EndOutputPort` properties to true. For example:

```
FFT_N = dsp.HDLFFT(___, 'StartOutputPort', true, 'EndOutputPort', true);
...
[y, startOut, endOut, validOut] = FFT_N(x, validIn)
```

`[Y, validOut] = FFT_N(X, validIn, resetIn)` returns the FFT when `validIn` is true and `resetIn` is false. When `resetIn` is true, the object stops the current calculation and clears all internal state.

To use this syntax set the `ResetInputPort` property to true. For example:

```
FFT_N = dsp.HDLFFT(___, 'ResetInputPort', true);
...
[y, validOut] = FFT_N(x, validIn, resetIn)
```

`[Y, startOut, endOut, validOut] = FFT_N(X, validIn, resetIn)` returns the FFT, `Y`, using all optional control signals. You can use any combination of the optional port syntaxes.

Input Arguments

X — Input data

scalar or column vector of real or complex values

Input data, specified as a scalar or column vector of real or complex values, in fixed-point or integer format. Vector input is supported with `'Streaming Radix 2^2'` architecture only. The vector size must be a power of 2 between 1 and 64, and not greater than the FFT length.

`double` and `single` data types are supported for simulation, but not for HDL code generation.

Data Types: `fi` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `single` | `double`

validIn — Validity of input data

logical scalar

Validity of input data, specified as a logical scalar.

Data Types: `logical`

resetIn — Reset internal state

logical scalar

Reset internal state, specified as a logical scalar. To enable this argument, set the `ResetInputPort` property to true.

Data Types: `logical`

Output Arguments

Y — Output data

scalar or column vector of real or complex values

Output data, returned as a scalar or column vector of real or complex values. The output format matches the format of the input data.

ready — Memory available for input data

logical scalar

Indication that the object has memory available for new input data, returned as a logical scalar. This output is returned when you select 'Burst Radix 2' architecture. When you use this architecture, you must apply input data and valid signals only when ready is 1 (true). The object ignores any input data and valid signals when ready is 0 (false). For a waveform that shows this protocol, see the third diagram in the “Timing Diagram” on page 2-709 section.

Data Types: `logical`

startOut — First sample of output frame

logical scalar

First sample of output frame, returned as a logical scalar. To enable this argument, set the `StartOutputPort` property to `true`.

Data Types: `logical`

endOut — Last sample of output frame

logical scalar

Last sample of output frame, returned as a logical scalar. To enable this argument, set the `EndOutputPort` property to `true`.

Data Types: `logical`

validOut — Validity of output data

logical scalar

Validity of output data, returned as a logical scalar.

Data Types: `logical`

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Specific to dsp.HDLFFT

`getLatency` Latency of FFT or channelizer calculation

Common to All System Objects

`step` Run System object algorithm

release Release resources and allow changes to System object property values and input characteristics
reset Reset internal states of System object

Examples

Create FFT for HDL Generation

Create the specifications and input signal.

```
N = 128;  
Fs = 40;  
t = (0:N-1)'/Fs;  
x = sin(2*pi*15*t) + 0.75*cos(2*pi*10*t);  
y = x + .25*randn(size(x));  
y_fixed = sfi(y,32,24);
```

Write a function that creates and calls the System object™. You can generate HDL from this function.

Note: This object syntax runs only in R2016b or later. If you are using an earlier release, replace each call of an object with the equivalent step syntax. For example, replace `myObject(x)` with `step(myObject,x)`.

```
function [yOut,validOut] = HDLFFT128(yIn,validIn)  
%HDLFFT128  
% Processes one sample of FFT data using the dsp.HDLFFT System object(TM)  
% yIn is a fixed-point scalar or column vector.  
% validIn is a logical scalar value.  
% You can generate HDL code from this function.  
  
persistent fft128;  
if isempty(fft128)  
    fft128 = dsp.HDLFFT('FFTLength',128);  
end  
[yOut,validOut] = fft128(yIn,validIn);  
end
```

Compute the FFT by calling the function for each data sample.

```
Yf = zeros(1,3*N);  
validOut = false(1,3*N);  
for loop = 1:1:3*N  
    if (mod(loop, N) == 0)  
        i = N;  
    else  
        i = mod(loop, N);  
    end  
    [Yf(loop),validOut(loop)] = HDLFFT128(complex(y_fixed(i)),(loop <= N));  
end
```

Discard invalid data samples. Then plot the frequency channel results from the FFT.

```
Yf = Yf(validOut == 1);  
Yr = bitrevorder(Yf);
```

```

plot(Fs/2*linspace(0,1,N/2), 2*abs(Yr(1:N/2)/N))
title('Single-Sided Amplitude Spectrum of Noisy Signal y(t)')
xlabel('Frequency (Hz)')
ylabel('Output of FFT (f)')

```

Create Vector-Input FFT for HDL Generation

Create specifications and input signal. This example uses a 128-point FFT and computes the transform over 16 samples at a time.

```

N = 128;
V = 16;
Fs = 40;
t = (0:N-1)'/Fs;
x = sin(2*pi*15*t) + 0.75*cos(2*pi*10*t);
y = x + .25*randn(size(x));
y_fixed = sfi(y,32,24);
y_vect = reshape(y_fixed,V,N/V);

```

Write a function that creates and calls the System object™. The function does not need to know the vector size. The object saves the size of the input signal the first time you call it.

Note: This object syntax runs only in R2016b or later. If you are using an earlier release, replace each call of an object with the equivalent `step` syntax. For example, replace `myObject(x)` with `step(myObject,x)`.

```

function [yOut,validOut] = HDLFFT128V16(yIn,validIn)
%HDLFFT128V16
% Processes 16-sample vectors of FFT data
% yIn is a fixed-point column vector.
% validIn is a logical scalar value.
% You can generate HDL code from this function.

persistent fft128v16;
if isempty(fft128v16)
    fft128v16 = dsp.HDLFFT('FFTLenght',128);
end
[yOut,validOut] = fft128v16(yIn,validIn);
end

```

Compute the FFT by passing 16-element vectors to the object. Use the `getLatency` function to find out when the first output data sample will be ready. Then, add the frame length to determine how many times to call the object. Because the object variable is inside the function, use a second object to call `getLatency`. Use the loop counter to flip `validIn` to false after N input samples.

```

tempfft = dsp.HDLFFT;
loopCount = getLatency(tempfft,N,V)+N/V;
Yf = zeros(V,loopCount);
validOut = false(V,loopCount);
for loop = 1:1:loopCount
    if ( mod(loop,N/V) == 0 )
        i = N/V;
    else
        i = mod(loop,N/V);
    end
    [Yf(:,loop),validOut(loop)] = HDLFFT128V16(complex(y_vect(:,i)),(loop<=N/V));
end

```

Discard invalid output samples.

```

C = Yf(:,validOut==1);
Yf_flat = C(:);

```

Plot the frequency channel data from the FFT. The FFT output is in bit-reversed order. Reorder it before plotting.

```

Yr = bitrevorder(Yf_flat);
plot(Fs/2*linspace(0,1,N/2),2*abs(Yr(1:N/2)/N))
title('Single-Sided Amplitude Spectrum of Noisy Signal y(t)')
xlabel('Frequency (Hz)')
ylabel('Output of FFT (f)')

```

Explore Latency of HDL FFT Object

The latency of the object varies with the FFT length and the vector size. Use the `getLatency` function to find the latency of a particular configuration. The latency is the number of cycles between the first valid input and the first valid output, assuming that the input is contiguous.

Create a new `dsp.HDLFFT` object and request the latency.

```
hdlfft = dsp.HDLFFT('FFTLength',512);
L512 = getLatency(hdlfft)
```

```
L512 = 599
```

Request hypothetical latency information about a similar object with a different FFT length. The properties of the original object do not change.

```
L256 = getLatency(hdlfft,256)
```

```
L256 = 329
```

```
N = hdlfft.FFTLength
```

```
N = 512
```

Request hypothetical latency information of a similar object that accepts eight-sample vector input.

```
L256v8 = getLatency(hdlfft,256,8)
```

```
L256v8 = 93
```

Enable scaling at each stage of the FFT. The latency does not change.

```
hdlfft.Normalize = true;  
L512n = getLatency(hdlfft)
```

```
L512n = 599
```

Request the same output order as the input order. The latency increases because the object must collect the output before reordering.

```
hdlfft.BitReversedOutput = false;  
L512r = getLatency(hdlfft)
```

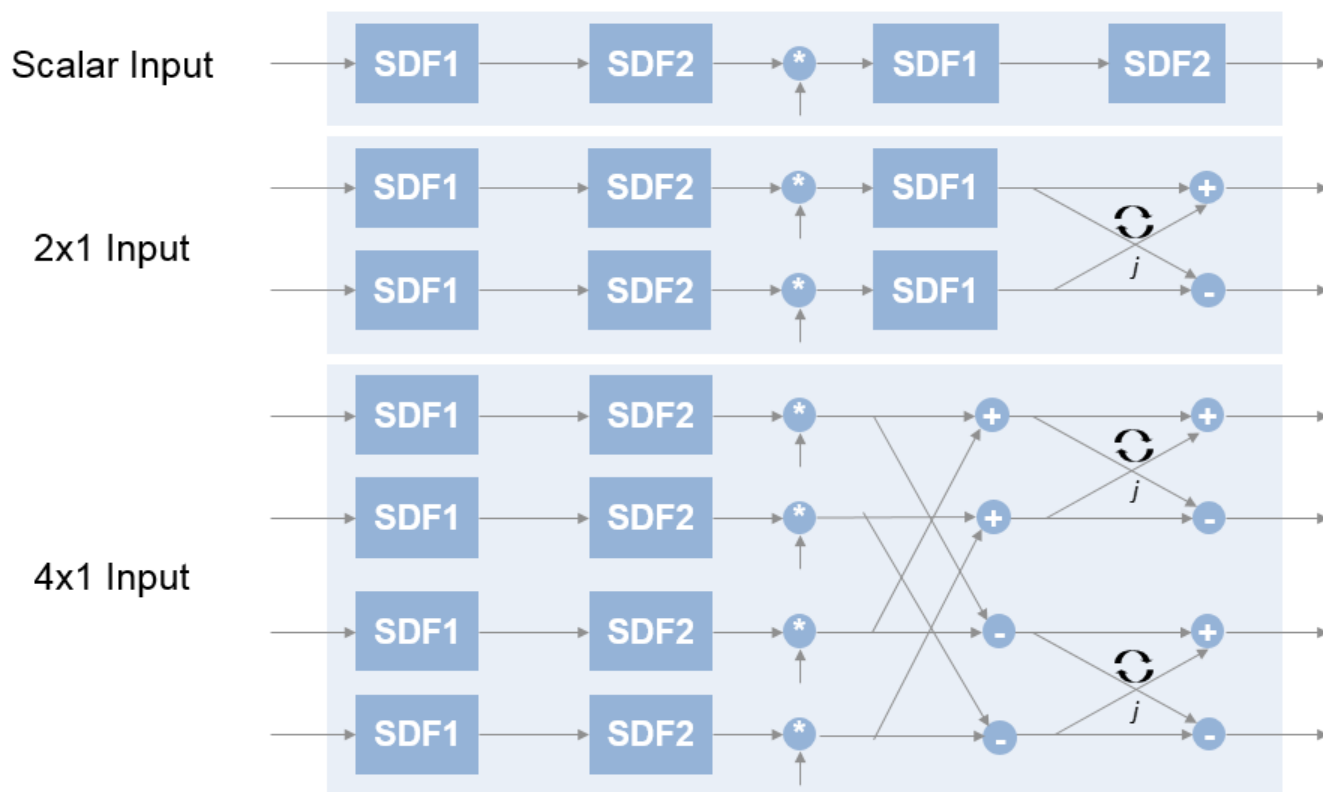

```
L512r = 1078
```

Algorithms

Streaming Radix 2²

The streaming Radix 2² architecture implements a low-latency architecture. It saves resources compared to a streaming Radix 2 implementation by factoring and grouping the FFT equation. The architecture has $\log_4(N)$ stages. Each stage contains two single-path delay feedback (SDF) butterflies with memory controllers. When you use vector input, each stage operates on fewer input samples, so some stages reduce to a simple butterfly, without SDF.

16-Point FFT

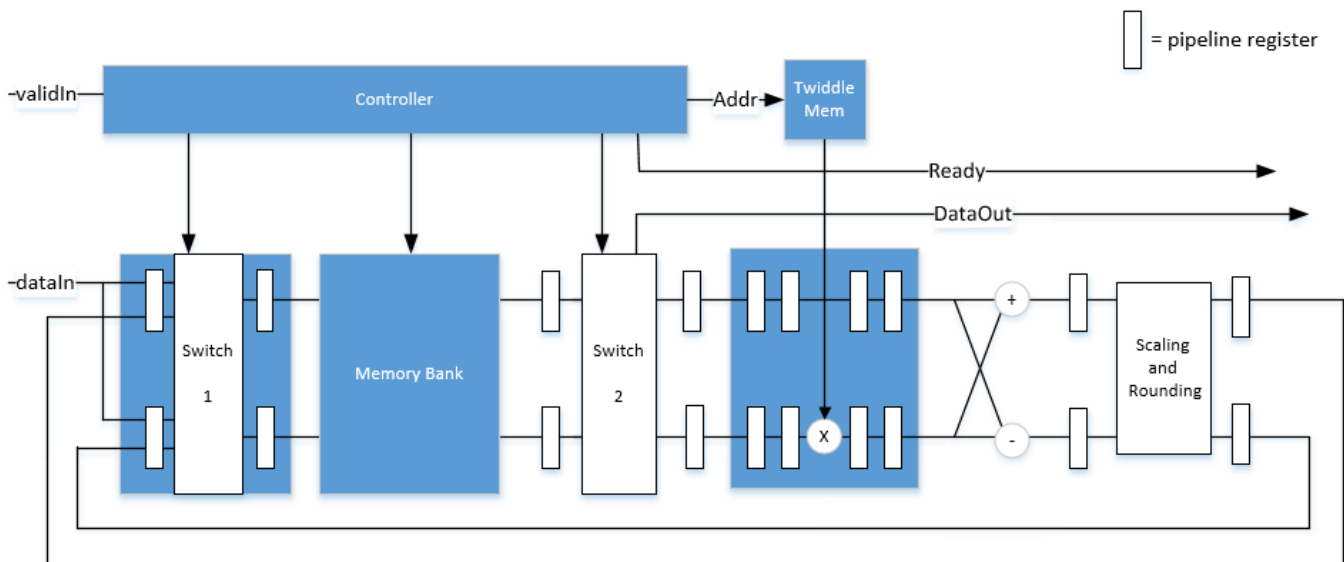

The first SDF stage is a regular butterfly. The second stage multiplies the outputs of the first stage by $-j$. To avoid a hardware multiplier, the block swaps the real and imaginary parts of the inputs, and again swaps the imaginary parts of the resulting outputs. Each stage rounds the result of the twiddle factor multiplication to the input word length. The twiddle factors have two integer bits, and the rest of the bits are used for fractional bits. The twiddle factors have the same bit width as the input data, WL . The twiddle factors have two integer bits, and $WL-2$ fractional bits.

If you enable scaling, the algorithm divides the result of each butterfly stage by 2. Scaling at each stage avoids overflow, keeps the word length the same as the input, and results in an overall scale factor of $1/N$. If scaling is disabled, the algorithm avoids overflow by increasing the word length by 1 bit at each stage. The diagram shows the butterflies and internal word lengths of each stage, not including the memory.

Burst Radix 2

The burst Radix 2 architecture implements the FFT by using a single complex butterfly multiplier. The algorithm cannot start until it has stored the entire input frame, and it cannot accept the next frame until computations are complete. The output **ready** port indicates when the algorithm is ready for new data. The diagram shows the burst architecture, with pipeline registers.

When you use this architecture, your input data must comply with the **ready** backpressure signal. For a waveform that shows this protocol, see the third diagram in the “Timing Diagram” on page 2-709 section.

Control Signals

The algorithm processes input data only when the input **valid** port is 1. Output data is valid only when the output **valid** port is 1.

When the optional input **reset** port is 1, the algorithm stops the current calculation and clears all internal states. The algorithm begins new calculations when **reset** port is 0 and the input **valid** port starts a new frame.

Timing Diagram

This diagram shows the input and output **valid** port values for contiguous scalar input data, streaming Radix 2^2 architecture, an FFT length of 1024, and a vector size of 16.

The diagram also shows the optional **start** and **end** port values that indicate frame boundaries. If you enable the **start** port, the **start** port value pulses for one cycle with the first valid output of the frame. If you enable the **end** port, the **start** port value pulses for one cycle with the last valid output of the frame.

If you apply continuous input frames, the output will also be continuous after the initial latency.

The input **valid** port can be noncontiguous. Data accompanied by an input **valid** port is processed as it arrives, and the resulting data is stored until a frame is filled. Then the algorithm returns contiguous output samples in a frame of N (**FFT length**) cycles. This diagram shows noncontiguous input and contiguous output for an FFT length of 512 and a vector size of 16.

When you use the burst architecture, you cannot provide the next frame of input data until memory space is available. The **ready** signal indicates when the algorithm can accept new input data. You must apply input **data** and **valid** signals only when **ready** is 1 (true). The algorithm ignores any input **data** and **valid** signals when **ready** is 0 (false).

Latency

The latency varies with the FFT length and the vector size. Use the `getLatency` function to find the latency of a particular configuration. The latency is the number of cycles between the first valid input and the first valid output, assuming that the input is contiguous.

When using the burst architecture with a contiguous input, if your design waits for **ready** to output 0 before de-asserting the input **valid**, then one extra cycle of data arrives at the input. This data sample

is the first sample of the next frame. The algorithm can save one sample while processing the current frame. Due to this one sample advance, the observed latency of the later frames (from input **valid** to output **valid**) is one cycle shorter than the reported latency. The latency is measured from the first cycle, when input **valid** is 1 to the first cycle when output **valid** is 1. The number of cycles between when **ready** port is 0 and the output **valid** port is 1 is always *latency - FFTLength*.

Performance

This resource and performance data is the synthesis result from the generated HDL targeted to a Xilinx Virtex-6 (XC6VLX75T-1FF484) FPGA. The examples in the tables have this configuration:

- 1024 FFT length (default)
- Complex multiplication using 4 multipliers, 2 adders
- Output scaling enabled
- Natural order input, Bit-reversed output
- 16-bit complex input data
- Clock enables minimized (HDL Coder parameter)

Performance of the synthesized HDL code varies with your target and synthesis options. For instance, reordering for a natural-order output uses more RAM than the default bit-reversed output, and real input uses less RAM than complex input.

For a scalar input Radix 2² configuration, the design achieves 326 MHz clock frequency. The latency is 1116 cycles. The design uses these resources.

Resource	Number Used
LUT	4597
FFS	5353
Xilinx LogiCORE DSP48	12
Block RAM (16K)	6

When you vectorize the same Radix 2² implementation to process two 16-bit input samples in parallel, the design achieves 316 MHz clock frequency. The latency is 600 cycles. The design uses these resources.

Resource	Number Used
LUT	7653
FFS	9322
Xilinx LogiCORE DSP48	24

Resource	Number Used
Block RAM (16K)	8

The block supports scalar input data only when implementing burst Radix 2 architecture. The burst design achieves 309 MHz clock frequency. The latency is 5811 cycles. The design uses these resources.

Resource	Number Used
LUT	971
FFS	1254
Xilinx LogiCORE DSP48	3
Block RAM (16K)	6

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

This System object supports C/C++ code generation for accelerating MATLAB simulations, and for DPI component generation.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

double and single data types are supported for simulation, but not for HDL code generation.

To generate HDL code from predefined System objects, see “HDL Code Generation from Viterbi Decoder System Object” (HDL Coder).

dsp.HDLIFFT

Package: dsp

Inverse fast Fourier transform — optimized for HDL code generation

Description

The HDL IFFT System object provides two architectures to optimize either throughput or area. Use the streaming Radix 2² architecture for high-throughput applications. This architecture supports scalar or vector input data. You can achieve giga-sample-per-second (GSPS) throughput using vector input. Use the burst Radix 2 architecture for a minimum resource implementation, especially with large FFT sizes. Your system must be able to tolerate bursty data and higher latency. This architecture supports only scalar input data. The object accepts real or complex data, provides hardware-friendly control signals, and has optional output frame control signals.

To calculate the inverse fast Fourier transform:

- 1 Create the `dsp.HDLIFFT` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

Creation

Syntax

```
IFFT_N = dsp.HDLIFFT  
IFFT_N = dsp.HDLIFFT(Name, Value)
```

Description

`IFFT_N = dsp.HDLIFFT` returns an HDL IFFT System object, `IFFT_N`, that performs a fast Fourier transform.

`IFFT_N = dsp.HDLIFFT(Name, Value)` sets properties using one or more name-value pairs. Enclose each property name in single quotes.

Example: `ifft128 = dsp.HDLIFFT('FFTLength', 128)`

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see [System Design in MATLAB Using System Objects](#).

Architecture — Hardware implementation`'Streaming Radix 2^2' (default) | 'Burst Radix 2'`

Hardware implementation, specified as either:

- `'Streaming Radix 2^2'` — Low-latency architecture. Supports giga-sample-per-second (GSPS) throughput when you use vector input.
- `'Burst Radix 2'` — Minimum resource architecture. Vector input is not supported when you select this architecture. When you use this architecture, your input data must comply with the ready backpressure signal. For a waveform that shows this protocol, see the third diagram in the “Timing Diagram” on page 2-709 section.

ComplexMultiplication — HDL implementation of complex multipliers`'Use 4 multipliers and 2 adders' (default) | 'Use 3 multipliers and 5 adders'`

HDL implementation of complex multipliers, specified as either `'Use 4 multipliers and 2 adders'` or `'Use 3 multipliers and 5 adders'`. Depending on your synthesis tool and target device, one option may be faster or smaller.

BitReversedOutput — Order of the output data`true (default) | false`

Order of the output data, specified as either:

- `true` — The output channel elements are bit reversed relative to the input order.
- `false` — The output channel elements are in linear order.

The IFFT algorithm calculates output in the reverse order to the input. When you request output in the same order as the input, the algorithm performs an extra reversal operation. For more information on ordering of the output, see “Linear and Bit-Reversed Output Order”.

BitReversedInput — Expected order of the input data`false (default) | true`

Expected order of the input data, specified as either:

- `true` — The input channel elements are in bit-reversed order.
- `false` — The input channel elements are in linear order.

The IFFT algorithm calculates output in the reverse order to the input. When you request output in the same order as the input, the algorithm performs an extra reversal operation. For more information on ordering of the output, see “Linear and Bit-Reversed Output Order”.

Normalize — Output scaling`true (default) | false`

Output scaling, specified as either:

- `true` — The object implements an overall $1/N$ scale factor by dividing the output of each butterfly multiplication by 2. This adjustment keeps the output of the IFFT in the same amplitude range as its input.
- `false` — The object avoids overflow by increasing the word length by one bit after each butterfly multiplication. The bit growth is the same for both architectures.

FFTLength — Number of data points used for one FFT calculation

1024 (default) | integer power of 2 between 2^3 and 2^{16}

Number of data points used for one FFT calculation, specified as an integer power of 2 between 2^3 and 2^{16} . The object accepts FFT lengths outside this range, but they are not supported for HDL code generation.

ResetInputPort — Enable reset argument

false (default) | true

Enable reset input argument to the object. When reset is true, the object stops calculation and clears all internal state.

StartOutputPort — Enable start output argument

false (default) | true

Enable startOut output argument of the object. When enabled, the object returns an additional output signal that is true on the first cycle of each valid output frame.

EndOutputPort — Enable end output argument

false (default) | true

Enable endOut output argument of the object. When enabled, the object returns an additional output signal that is true on the first cycle of each valid output frame.

RoundingMethod — Rounding mode used for fixed-point operations

'Floor' (default) | 'Ceiling' | 'Convergent' | 'Nearest' | 'Round' | 'Zero'

Rounding mode used for fixed-point operations. When the input is any integer or fixed-point data type, the IFFT algorithm uses fixed-point arithmetic for internal calculations. This option does not apply when the input is single or double type. Rounding applies to twiddle factor multiplication and scaling operations.

Usage

Syntax

```
[Y,validOut] = IFFT_N(X,validIn)
[Y,validOut,ready] = IFFT_N(X,validIn)
[Y,startOut,endOut,validOut] = IFFT_N(X,validIn)
[Y,validOut] = IFFT_N(X,validIn,resetIn)
[Y,startOut,endOut,validOut] = IFFT_N(X,validIn,resetIn)
```

Description

`[Y,validOut] = IFFT_N(X,validIn)` returns the inverse fast Fourier transform (IFFT), Y, of the input, X, when validIn is true. validIn and validOut are logical scalars that indicate the validity of the input and output signals, respectively.

`[Y,validOut,ready] = IFFT_N(X,validIn)` returns the inverse fast Fourier transform (IFFT) when using the burst Radix 2 architecture. The ready signal indicates when the object has memory available to accept new input samples. You must apply input data and valid signals only when ready is 1 (true). The object ignores the input data and valid signals when ready is 0 (false).

To use this syntax, set the Architecture property to 'Burst Radix 2'. For example:

```
IFFT_N = dsp.HDLIFFT(__, 'Architecture', 'Burst Radix 2');
...
[y, validOut, ready] = IFFT_N(x, validIn)
```

[Y, startOut, endOut, validOut] = IFFT_N(X, validIn) also returns frame control signals startOut and endOut. startOut is true on the first sample of a frame of output data. endOut is true for the last sample of a frame of output data.

To use this syntax, set the StartOutputPort and EndOutputPort properties to true. For example:

```
IFFT_N = dsp.HDLIFFT(__, 'StartOutputPort', true, 'EndOutputPort', true);
...
[y, startOut, endOut, validOut] = IFFT_N(x, validIn)
```

[Y, validOut] = IFFT_N(X, validIn, resetIn) returns the IFFT, Y, when validIn is true and resetIn is false. When resetIn is true, the object stops the current calculation and clears all internal state.

To use this syntax, set the ResetInputPort property to true. For example:

```
IFFT_N = dsp.HDLIFFT(__, 'ResetInputPort', true);
...
[y, validOut] = IFFT_N(x, validIn, resetIn)
```

[Y, startOut, endOut, validOut] = IFFT_N(X, validIn, resetIn) returns the IFFT, Y, using all optional control signals. You can use any combination of the optional port syntaxes.

Input Arguments

X — Input data

scalar or column vector of real or complex values

Input data, specified as a scalar or column vector of real or complex values, in fixed-point or integer format. Vector input is supported with 'Streaming Radix 2²' architecture only. The vector size must be a power of 2 between 1 and 64 that is not greater than the FFT length.

double and single data types are supported for simulation, but not for HDL code generation.

Data Types: fi | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | single | double

validIn — Validity of input data

logical scalar

Validity of input data, specified as a logical scalar.

Data Types: logical

resetIn — Reset internal state

logical scalar

Reset internal state, specified as a logical scalar. To enable this argument, set the ResetInputPort property to true.

Data Types: logical

Output Arguments

Y — Output data

scalar or column vector of real or complex values

Output data, returned as a scalar or column vector of real or complex values. The output format matches the format of the input data.

ready — Memory available for input data

logical scalar

Indication that the object has memory available for input data, returned as a logical scalar. This output is returned when you select 'Burst Radix 2' architecture. When you use this architecture, you must apply input data and valid signals only when ready is 1 (true). The object ignores any input data and valid signals when ready is 0 (false). For a waveform that shows this protocol, see the third diagram in the “Timing Diagram” on page 2-709 section.

Data Types: `logical`

startOut — First sample of output frame

logical scalar

First sample of output frame, returned as a logical scalar. To enable this argument, set the StartOutputPort property to `true`.

Data Types: `logical`

endOut — Last sample of output frame

logical scalar

Last sample of output frame, returned as a logical scalar. To enable this argument, set the EndOutputPort property to `true`.

Data Types: `logical`

validOut — Validity of output data

logical scalar

Validity of output data, returned as a logical scalar.

Data Types: `logical`

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Specific to dsp.HDLIFFT

`getLatency` Latency of FFT or channelizer calculation

Common to All System Objects

`step` Run System object algorithm

release Release resources and allow changes to System object property values and input characteristics

reset Reset internal states of System object

Examples

Create IFFT for HDL Code Generation

Create the specifications and input signal. This example uses a 128-point FFT.

```
N = 128;
Fs = 40;
t = (0:N-1)/Fs;
x = sin(2*pi*15*t) + 0.75*cos(2*pi*10*t);
y = x + .25*randn(size(x));
y_fixed = sfi(y,32,16);
no0p = zeros(1,'like',y_fixed);
```

Compute the FFT of the signal to use as the input to the IFFT object.

Note: This object syntax runs only in R2016b or later. If you are using an earlier release, replace each call of an object with the equivalent `step` syntax. For example, replace `myObject(x)` with `step(myObject,x)`.

```
hdlfft = dsp.HDLFFT('FFTLength',N,'BitReversedOutput',false);
Yf = zeros(1,4*N);
validOut = false(1,4*N);
for loop = 1:1:N
    [Yf(loop),validOut(loop)] = hdlfft(complex(y_fixed(loop)),true);
end
for loop = N+1:1:4*N
    [Yf(loop),validOut(loop)] = hdlfft(complex(no0p),false);
end
Yf = Yf(validOut == 1);
```

Plot the single-sided amplitude spectrum.

```
plot(Fs/2*linspace(0,1,N/2),2*abs(Yf(1:N/2)/N))
title('Single-Sided Amplitude Spectrum of Noisy Signal y(t)')
xlabel('Frequency (Hz)')
ylabel('Output of FFT (f)')
```

Select frequencies that hold the majority of the energy in the signal. The `cumsum` function does not accept fixed-point arguments, so convert the data back to `double`.

```
[Ysort,i] = sort(abs(double(transpose(Yf(1:N))))),1,'descend');
Ysort_d = double(Ysort);
CumEnergy = sqrt(cumsum(Ysort_d.^2))/norm(Ysort_d);
j = find(CumEnergy > 0.9, 1);
    disp(['Number of FFT coefficients that represent 90% of the ', ...
        'total energy in the sequence: ', num2str(j)])
Yin = zeros(N,1);
Yin(i(1:j)) = Yf(i(1:j));
```

Number of FFT coefficients that represent 90% of the total energy in the sequence: 4

Write a function that creates and calls the IFFT System object™. You can generate HDL from this function.

```
function [yOut,validOut] = HDLIFFT128(yIn,validIn)
%HDLIFFT128
% Processes one sample of data using the dsp.HDLIFFT System object(TM)
% yIn is a fixed-point scalar or column vector.
% validIn is a logical scalar.
% You can generate HDL code from this function.

persistent ifft128;
if isempty(ifft128)
    ifft128 = dsp.HDLIFFT('FFTLength',128);
```

```

    end
    [yOut,validOut] = ifft128(yIn,validIn);
end

```

Compute the IFFT by calling the function for each data sample.

```

Xt = zeros(1,3*N);
validOut = false(1,3*N);
for loop = 1:1:N
    [Xt(loop),validOut(loop)] = HDLIFFT128(complex(Yin(loop)),true);
end
for loop = N+1:1:3*N
    [Xt(loop),validOut(loop)] = HDLIFFT128(complex(0),false);
end

```

Discard invalid output samples. Then inspect the output and compare it with the input signal. The original input is in green.

```

Xt = Xt(validOut==1);
Xt = bitrevorder(Xt);
norm(x-transpose(Xt(1:N)))
figure
stem(real(Xt))
figure
stem(real(x), '--g')

```

ans =

```

    0.7863

```

Create a Vector-Input IFFT for HDL Code Generation

Create the specifications and input signal. This example uses a 128-point FFT and computes the transform over 16 samples at a time.

```
N = 128;
V = 16;
Fs = 40;
t = (0:N-1)'/Fs;
x = sin(2*pi*15*t) + 0.75*cos(2*pi*10*t);
y = x + .25*randn(size(x));
y_fixed = sfi(y,32,24);
y_vect = reshape(y_fixed,V,N/V);
```

Compute the FFT of the signal, to use as the input to the IFFT object.

Note: This object syntax runs only in R2016b or later. If you are using an earlier release, replace each call of an object with the equivalent `step` syntax. For example, replace `myObject(x)` with `step(myObject,x)`.

```
hdlfft = dsp.HDLIFFT('FFTLength',N);
loopCount = getLatency(hdlfft,N,V)+N/V;
Yf = zeros(V,loopCount);
validOut = false(V,loopCount);
for loop = 1:1:loopCount
```

```

if ( mod(loop,N/V) == 0 )
    i = N/V;
else
    i = mod(loop,N/V);
end
[Yf(:,loop),validOut(loop)] = hdlfft(complex(y_vect(:,i)),(loop<=N/V));
end

```

Plot the single-sided amplitude spectrum.

```

C = Yf(:,validOut==1);
Yf_flat = C(:);
Yr = bitrevorder(Yf_flat);
plot(Fs/2*linspace(0,1,N/2),2*abs(Yr(1:N/2)/N))
title('Single-Sided Amplitude Spectrum of Noisy Signal y(t)')
xlabel('Frequency (Hz)')
ylabel('Output of FFT(f)')

```

Select frequencies that hold the majority of the energy in the signal. The `cumsum` function doesn't accept fixed-point arguments, so convert the data back to `double`.

```

[Ysort,i] = sort(abs(double(Yr(1:N))),1,'descend');
CumEnergy = sqrt(cumsum(Ysort.^2))/norm(Ysort);
j = find(CumEnergy > 0.9, 1);
disp(['Number of FFT coefficients that represent 90% of the ', ...
    'total energy in the sequence: ', num2str(j)])
Yin = zeros(N,1);

```

```
Yin(i(1:j)) = Yr(i(1:j));
YinVect = reshape(Yin,V,N/V);
```

Number of FFT coefficients that represent 90% of the total energy in the sequence: 4

Write a function that creates and calls the IFFT System object™. You can generate HDL from this function.

```
function [yOut,validOut] = HDLIFFT128V16(yIn,validIn)
%HDLFFT128V16
% Processes 16-sample vectors of FFT data
% yIn is a fixed-point column vector.
% validIn is a logical scalar value.
% You can generate HDL code from this function.

persistent ifft128v16;
if isempty(fft128v16)
    ifft128v16 = dsp.HDLIFFT('FFTLenght',128)
end
[yOut,validOut] = ifft128v16(yIn,validIn);
end
```

Compute the IFFT by calling the function for each data sample.

```
Xt = zeros(V,loopCount);
validOut = false(V,loopCount);
for loop = 1:1:loopCount
    if ( mod(loop,N/V) == 0 )
        i = N/V;
    else
        i = mod(loop,N/V);
    end
    [Xt(:,loop),validOut(loop)] = HDLIFFT128V16(complex(YinVect(:,i)),(loop<=N/V));
end
```

```
ifft128v16 =

Explore Latency of HDL IFFT Object

The latency of the object varies with the FFT length and the vector size. Use the `getLatency` function to find the latency of a particular configuration. The latency is the number of cycles between the first valid input and the first valid output, assuming that the input is contiguous.

Create a new `dsp.HDLIFFT` object and request the latency.

```
hdlifft = dsp.HDLIFFT('FFTLength',512);  
L512 = getLatency(hdlifft)
```

```
L512 = 599
```

Request hypothetical latency information about a similar object with a different FFT length. The properties of the original object do not change. When you do not specify a vector length, the function assumes scalar input data.

```
L256 = getLatency(hdlifft,256)
```

```
L256 = 329
```

```
N = hdlifft.FFTLength
```

```
N = 512
```

Request hypothetical latency information of a similar object that accepts eight-sample vector input.

```
L256v8 = getLatency(hdlifft,256,8)
```

```
L256v8 = 93
```

Enable scaling at each stage of the IFFT. The latency does not change.

```
hdlifft.Normalize = true;  
L512n = getLatency(hdlifft)
```

```
L512n = 599
```

Request the same output order as the input order. This setting increases the latency because the object must collect the output before reordering.

```
hdlifft.BitReversedOutput = false;  
L512r = getLatency(hdlifft)
```

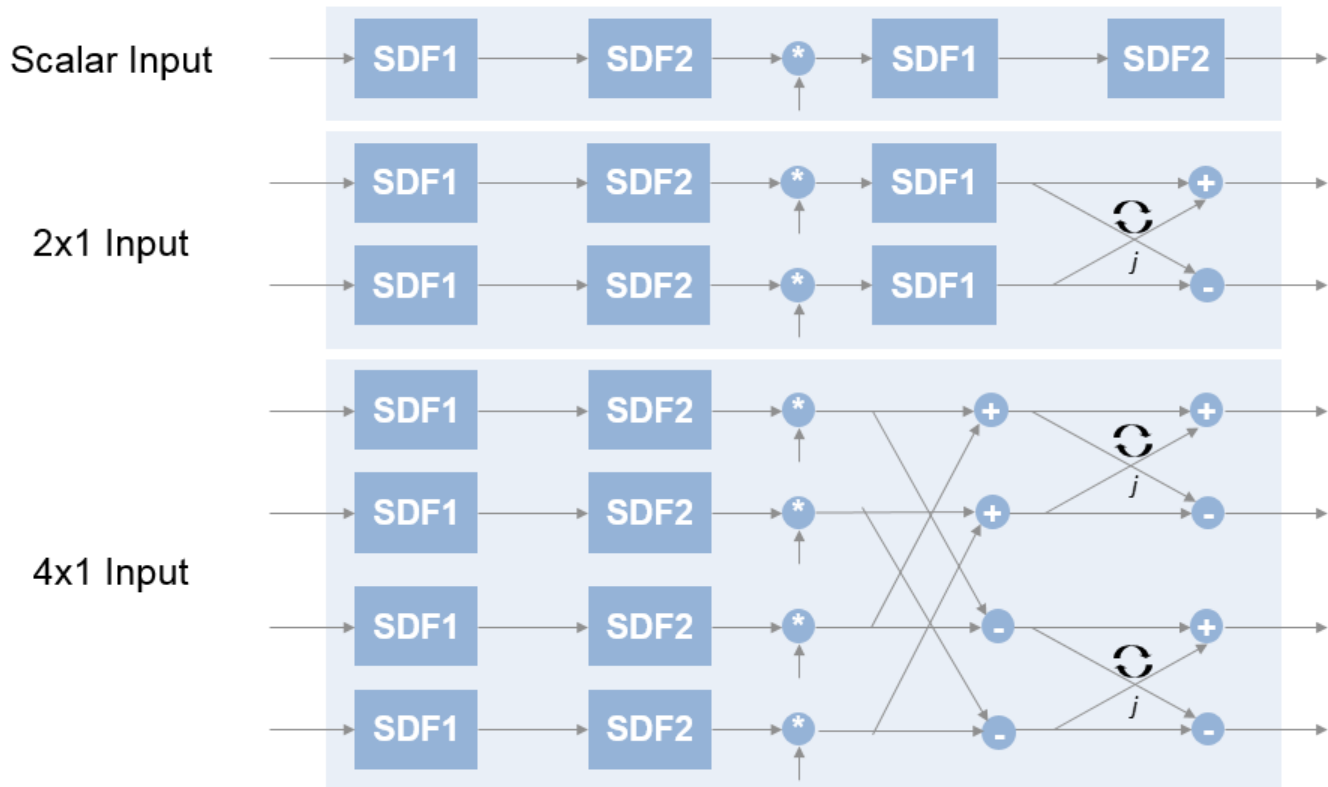

```
L512r = 1078
```

Algorithms

Streaming Radix 2²

The streaming Radix 2² architecture implements a low-latency architecture. It saves resources compared to a streaming Radix 2 implementation by factoring and grouping the FFT equation. The architecture has $\log_4(N)$ stages. Each stage contains two single-path delay feedback (SDF) butterflies with memory controllers. When you use vector input, each stage operates on fewer input samples, so some stages reduce to a simple butterfly, without SDF.

16-Point FFT

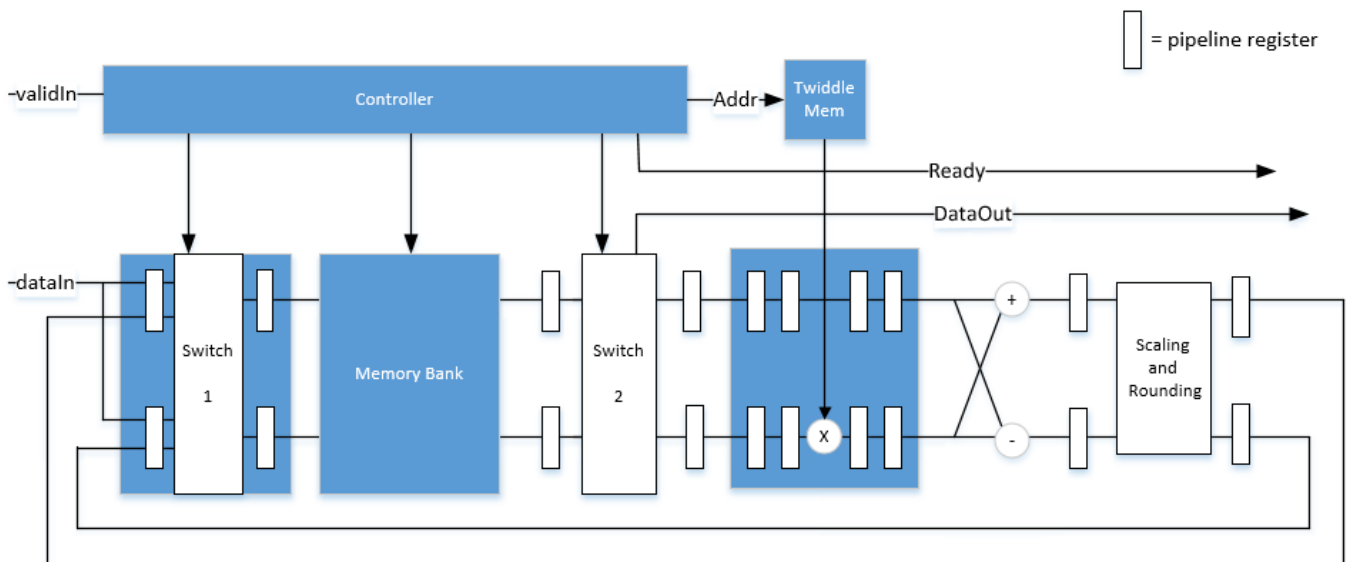

The first SDF stage is a regular butterfly. The second stage multiplies the outputs of the first stage by $-j$. To avoid a hardware multiplier, the block swaps the real and imaginary parts of the inputs, and again swaps the imaginary parts of the resulting outputs. Each stage rounds the result of the twiddle factor multiplication to the input word length. The twiddle factors have two integer bits, and the rest of the bits are used for fractional bits. The twiddle factors have the same bit width as the input data, WL . The twiddle factors have two integer bits, and $WL-2$ fractional bits.

If you enable scaling, the algorithm divides the result of each butterfly stage by 2. Scaling at each stage avoids overflow, keeps the word length the same as the input, and results in an overall scale factor of $1/N$. If scaling is disabled, the algorithm avoids overflow by increasing the word length by 1 bit at each stage. The diagram shows the butterflies and internal word lengths of each stage, not including the memory.

Burst Radix 2

The burst Radix 2 architecture implements the FFT by using a single complex butterfly multiplier. The algorithm cannot start until it has stored the entire input frame, and it cannot accept the next frame until computations are complete. The output **ready** port indicates when the algorithm is ready for new data. The diagram shows the burst architecture, with pipeline registers.

When you use this architecture, your input data must comply with the **ready** backpressure signal. For a waveform that shows this protocol, see the third diagram in the "Timing Diagram" on page 2-709 section.

Control Signals

The algorithm processes input data only when the input **valid** port is 1. Output data is valid only when the output **valid** port is 1.

When the optional input **reset** port is 1, the algorithm stops the current calculation and clears all internal states. The algorithm begins new calculations when **reset** port is 0 and the input **valid** port starts a new frame.

Timing Diagram

This diagram shows the input and output **valid** port values for contiguous scalar input data, streaming Radix 2^2 architecture, an FFT length of 1024, and a vector size of 16.

The diagram also shows the optional **start** and **end** port values that indicate frame boundaries. If you enable the **start** port, the **start** port value pulses for one cycle with the first valid output of the frame. If you enable the **end** port, the **start** port value pulses for one cycle with the last valid output of the frame.

If you apply continuous input frames, the output will also be continuous after the initial latency.

The input **valid** port can be noncontiguous. Data accompanied by an input **valid** port is processed as it arrives, and the resulting data is stored until a frame is filled. Then the algorithm returns contiguous output samples in a frame of N (**FFT length**) cycles. This diagram shows noncontiguous input and contiguous output for an FFT length of 512 and a vector size of 16.

When you use the burst architecture, you cannot provide the next frame of input data until memory space is available. The **ready** signal indicates when the algorithm can accept new input data. You must apply input **data** and **valid** signals only when **ready** is 1 (true). The algorithm ignores any input **data** and **valid** signals when **ready** is 0 (false).

Latency

The latency varies with the FFT length and the vector size. Use the `getLatency` function to find the latency of a particular configuration. The latency is the number of cycles between the first valid input and the first valid output, assuming that the input is contiguous.

When using the burst architecture with a contiguous input, if your design waits for **ready** to output 0 before de-asserting the input **valid**, then one extra cycle of data arrives at the input. This data sample

is the first sample of the next frame. The algorithm can save one sample while processing the current frame. Due to this one sample advance, the observed latency of the later frames (from input **valid** to output **valid**) is one cycle shorter than the reported latency. The latency is measured from the first cycle, when input **valid** is 1 to the first cycle when output **valid** is 1. The number of cycles between when **ready** port is 0 and the output **valid** port is 1 is always *latency - FFTLength*.

Performance

This resource and performance data is the synthesis result from the generated HDL targeted to a Xilinx Virtex-6 (XC6VLX75T-1FF484) FPGA. The examples in the tables have this configuration:

- 1024 FFT length (default)
- Complex multiplication using 4 multipliers, 2 adders
- Output scaling enabled
- Natural order input, Bit-reversed output
- 16-bit complex input data
- Clock enables minimized (HDL Coder parameter)

Performance of the synthesized HDL code varies with your target and synthesis options. For instance, reordering for a natural-order output uses more RAM than the default bit-reversed output, and real input uses less RAM than complex input.

For a scalar input Radix 2² configuration, the design achieves 326 MHz clock frequency. The latency is 1116 cycles. The design uses these resources.

Resource	Number Used
LUT	4597
FFS	5353
Xilinx LogiCORE DSP48	12
Block RAM (16K)	6

When you vectorize the same Radix 2² implementation to process two 16-bit input samples in parallel, the design achieves 316 MHz clock frequency. The latency is 600 cycles. The design uses these resources.

Resource	Number Used
LUT	7653
FFS	9322
Xilinx LogiCORE DSP48	24

Resource	Number Used
Block RAM (16K)	8

The block supports scalar input data only when implementing burst Radix 2 architecture. The burst design achieves 309 MHz clock frequency. The latency is 5811 cycles. The design uses these resources.

Resource	Number Used
LUT	971
FFS	1254
Xilinx LogiCORE DSP48	3
Block RAM (16K)	6

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

This System object supports C/C++ code generation for accelerating MATLAB simulations, and for DPI component generation.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

double and single data types are supported for simulation, but not for HDL code generation.

To generate HDL code from predefined System objects, see “HDL Code Generation from Viterbi Decoder System Object” (HDL Coder).

Generate real or complex sinusoidal signals—optimized for HDL code generation

Description

The HDL NCO System object generates real or complex sinusoidal signals, while providing hardware-friendly control signals. A numerically-controlled oscillator (NCO) accumulates a phase increment and uses the quantized output of the accumulator as the index to a lookup table that contains the sine wave values. The wrap around of the fixed-point accumulator and quantizer data types provide periodicity of the sine wave, and quantization reduces the necessary size of the table for a given frequency resolution.

For an example of how to generate a sine wave using this System object, see “Design a HDL-Compatible NCO Source” on page 4-758. For more information on configuration and implementation, refer to the “Algorithms” on page 2-1033 section.

The HDL NCO System object provides these features.

- Optional frame-based output.
- A lookup table compression option to reduce the lookup table size. This compression results in less than one LSB loss in precision. See “Lookup Table Compression” on page 4-761 for more information.
- An optional input argument for external dither.
- An optional reset argument that resets the phase accumulator to its initial value.
- An optional output argument for the current NCO phase.

To generate real or complex sinusoidal signals:

- 1 Create the `dsp.HDLNCO` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

Creation

Syntax

```
hdlnco = dsp.HDLNCO
hdlnco = dsp.HDLNCO(Name,Value)
hdlnco = dsp.HDLNCO(Inc,'PhaseIncrementSource','Property')
```

Description

`hdlnco = dsp.HDLNCO` creates a numerically controlled oscillator (NCO) System object, `hdlnco`, that generates a real or complex sinusoidal signal. The amplitude of the generated signal is always 1.

`hdlnco = dsp.HDLNCO(Name,Value)` sets properties using one or more name-value pairs. Enclose each property name in single quotes. For example,

```
hdlnco = dsp.HDLNCO('NumQuantizerAccumulatorBits',12, ...
    'AccumulatorWL',16);
```

`hdlnco = dsp.HDLNCO(Inc,'PhaseIncrementSource','Property')` creates an NCO with the `PhaseIncrement` property set to `Inc`, an integer scalar. To use the `PhaseIncrement` property, set the `PhaseIncrementSource` property to `'Property'`. You can add other `Name,Value` pairs before or after `PhaseIncrementSource`.

Properties

Note This object supports floating-point types for simulation but not for HDL code generation. When all input values are fixed-point type or all input arguments are disabled, the object determines the output type using the `OutputDataType` property. When any input value is floating-point type, the object ignores the `OutputDataType` property. In this case, the object returns the waveform and optional `Phase` as floating-point values.

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see [System Design in MATLAB Using System Objects](#).

Waveform Generation

PhaseIncrementSource — Source of phase increment

'Input port' (default) | 'Property'

You can set the phase increment with an input argument or by specifying a value for the property. Specify `'Property'` to configure the phase increment using the `PhaseIncrement` property. Specify `'Input port'` to set the phase increment using the `inc` argument.

PhaseIncrement — Phase increment for generated waveform

100 (default) | integer

Phase increment for generated waveform, specified as an integer. The object casts this value to match the accumulator word length.

Dependencies

To enable this property, set the `PhaseIncrementSource` property to `'Property'`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fixdt([],N,0)`

PhaseOffsetSource — Source of phase offset

`'Input port'` (default) | `'Property'`

You can set the phase offset with an input argument or by specifying a value for the property. Specify `'Property'` to configure the phase increment using the `PhaseOffset` property. Specify `'Input port'` to set the phase increment using the `offset` argument.

PhaseOffset — Phase offset for generated waveform

`0` (default) | integer

Phase offset for the generated waveform, specified as an integer.

Dependencies

To enable this property, set the `PhaseOffsetSource` property to `'Property'`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fixdt([],N,0)`

DitherSource — Source of number of dither bits

`'Input port'` (default) | `'Property'` | `'None'`

You can set the number of dither bits from an input argument or from a property, or you can disable dither. Specify `'Property'` to configure the number of dither bits using the `NumDitherBits` property. Specify `'Input port'` to set the number of dither bits using the `dither` argument. Specify `'None'` to disable dither.

NumDitherBits — Bits used to express dither

`4` (default) | positive integer

Number of dither bits, specified as a positive integer.

Dependencies

To enable this property, set the `DitherSource` property to `'Property'`.

SamplesPerFrame — Vector size for frame-based output

`1` (default) | positive integer

Vector size for frame-based output, specified as a positive integer. When you set this value to `1`, the object has scalar input and output. When this value is greater than `1`, the `Dither` input argument must be a column vector of length `SamplesPerFrame` and the `Y` and `Phase` output arguments return column vectors of length `SamplesPerFrame`.

LUTCompress — Lookup table compression

`false` or `0` (default) | `true` or `1`

Lookup table compression, specified as a logical `0` (`false`) or `1` (`true`). By default, the object implements a noncompressed lookup table, and the output matches the output of the `dsp.NCO`

System object. When you enable this option, the object implements a compressed lookup table. The Sunderland compression method reduces the size of the lookup table, losing less than one LSB of precision. The spurious free dynamic range (SFDR) is empirically 1-3 dB lower than the noncompressed case. The hardware savings of the compressed lookup table allow room to improve performance by increasing the word length of the accumulator and the number of quantize bits. For details of the compression method, see “Algorithms” on page 4-760.

Waveform — Type of output waveform

'Sine' (default) | 'Cosine' | 'Complex exponential' | 'Sine and cosine'

Type of output waveform. If you select 'Sine' or 'Cosine', the object returns a sin or cos value. If you select 'Complex exponential', the output value, exp , is of the form $\cosine + j*sine$. If you select 'Sine and cosine', the object returns two values, sin and cos.

PhasePort — Return current phase

false or 0 (default) | true or 1

Set this property to 1 (true) to return the current NCO phase in the phase output argument. The phase is the output of the quantized accumulator with offset and increment applied. If quantization is disabled, this argument returns the output of the accumulator with offset and increment applied.

ResetAction — Enable reset accumulator input argument

false or 0 (default) | true or 1

When this property is 1 (true), the object accepts a ResetAccum input argument. When the ResetAccum argument is 1 (true), the object resets the accumulator to its initial value.

Data Types

OverflowAction — Overflow mode for fixed-point operations

'Wrap' (default)

This property is read-only.

Overflow mode for fixed-point operations.

RoundingMethod — Rounding mode for fixed-point operations

'Floor' (default)

This property is read-only.

Rounding mode for fixed-point operations.

AccumulatorDataType — Accumulator data type

'Binary point scaling' (default)

This property is read-only.

Accumulator data type description. The object defines the fixed-point data type using the AccumulatorSigned, AccumulatorWL, and AccumulatorFL properties.

AccumulatorSigned — Signed or unsigned accumulator data format

'Signed' (default)

This property is read-only.

Signed or unsigned accumulator data format. All output is signed format.

AccumulatorWL — Accumulator word length

16 (default) | integer

Accumulator word length, in bits, specified as an integer. This value must include the sign bit.

When the `PhaseQuantization` property is `0`, then `AccumulatorWL` determines the LUT size. For HDL code generation, the LUT size must be between 2 and 2^{17} entries. When you set the `LUTCompress` property to `1` (`true`), `AccumulatorWL` must be an integer in the range [5,21]. When you set the `LUTCompress` property to `0` (`false`), `AccumulatorWL` must be an integer in the range [3,19]. For more information on how this parameter affects the LUT size, see the “Lookup Table Compression” on page 4-761 section.

When you set the `PhaseQuantization` property to `1`, there is no limit to the accumulator word length property value.

AccumulatorFL — Accumulator fraction length

0 (default)

This property is read-only.

Accumulator fraction length, in bits. The accumulator operates on integers. If the phase increment is fixed-point type with a fractional part, the object returns an error.

PhaseQuantization — Quantize accumulated phase

false or 0 (default) | true or 1

Whether to quantize accumulated phase, specified as `1` (`true`) or `0` (`false`). When this property is enabled, the object quantizes the result of the phase accumulator to a fixed bit-width. The object uses this quantized value to select a waveform value from the lookup table. Quantizing the output of the phase accumulator enables you to reduce the lookup table size without lowering the frequency resolution. Select the size of the lookup table by using the `NumQuantizerAccumulatorBits` property.

When you disable this property, the object uses the full accumulator value as the address of the lookup table.

NumQuantizerAccumulatorBits — Number of quantizer accumulator bits

12 (default) | integer

Number of quantizer accumulator bits, specified as an integer greater than 4 and less than the `AccumulatorWL` property value. For HDL code generation, this parameter value must result in a LUT size between 2 and 2^{17} entries.

When you set the `LUTCompress` property to `1` (`true`), `AccumulatorWL` must be an integer in the range [5,21]. When you set the `LUTCompress` property to `0` (`false`), `AccumulatorWL` must be an integer in the range [3,19]. For more information on how this parameter affects the LUT size, see the “Lookup Table Compression” on page 4-761 section.

When you set the `QuantizePhase` property to `true`, there is no limit to the `NumQuantizerAccumulatorBits` property value.

Dependencies

To enable this property, set the `PhaseQuantization` property to `1` (`true`).

OutputDataType — Output data type

'Binary point scaling' (default) | 'double' | 'single'

Output data type. If you specify 'Binary point scaling', the object defines the fixed-point data type using the `OutputSigned`, `OutputWL`, and `OutputFL` properties.

This parameter is ignored if any input is of floating-point type. In that case, the output data type is `double`.

OutputSigned — Signed or unsigned output data format

'Signed' (default)

This property is read-only.

Signed or unsigned output data format. All output is signed format.

OutputWL — Output word length

16 (default) | integer

Output word length, in bits, specified as an integer. This value must include the sign bit.

OutputFL — Output fraction length

14 (default) | scalar integer

Output fraction length, in bits, specified as a scalar integer.

Usage**Syntax**

```
[Y,ValidOut] = hdlnc(Inc,ValidIn)
[Y,ValidOut] = hdlnc (ValidIn)
[Y,ValidOut] = hdlnc(Inc,Offset,Dither,ValidIn)
[Y,Phase,ValidOut] = hdlnc(____)
[____] = hdlnc(____,ResetAccum,ValidIn)
```

Description

The object returns the waveform value, *Y*, as a sine value, a cosine value, a complex exponential value, or a [*Sine*, *Cosine*] pair of values, depending on the `Waveform` property.

`[Y,ValidOut] = hdlnc(Inc,ValidIn)` returns a sinusoidal signal, *Y*, generated by the HDLNCO System object, using the phase increment, *Inc*. When `ValidIn` is `true`, *Inc* is added to the accumulator. The *Inc* argument is optional. Alternatively, you can specify the phase increment as a property.

`[Y,ValidOut] = hdlnc (ValidIn)` returns a waveform, *Y*, using waveform parameters from properties rather than input arguments.

To use this syntax, set the `PhaseIncrementSource`, `PhaseOffsetSource`, and `DitherSource` properties to 'Property'. These properties are independent of each other. For example:

```
hdlnc = dsp.HDLNCO('PhaseIncrementSource','Property', ...
    'PhaseIncrement',phIncr,...
```

```
'PhaseOffset',phOffset,...
'NumDitherBits',4)
```

[Y,ValidOut] = hdlnco(Inc,Offset,Dither,ValidIn) returns a waveform, Y, with phase increment, Inc, phase offset, Offset, and dither, Dither.

This syntax applies when you set the PhaseIncrementSource, PhaseOffsetSource, and DitherSource properties to 'Input port'. These properties are independent of each other. You can mix and match the activation of these arguments. PhaseIncrementSource is 'Input port' by default. For example:

```
hdlnco = dsp.HDLNCO('PhaseOffsetSource','Input port',...
                  'DitherSource','Input port')
for k = 1:1/Ts
    y(k) = hdlnco(phIncr,phOffset,ditherBits,true);
end
```

[Y,Phase,ValidOut] = hdlnco(___) returns a waveform, Y, and current phase, Phase. The phase is the output of the quantized accumulator.

To use this syntax, set the PhasePort property to true. This syntax can include any of the arguments from other syntaxes.

[___] = hdlnco(___ ,ResetAccum,ValidIn) resets the accumulator value, but does not reset the output samples in the pipeline. If ValidIn is true, then the object continues to generate the output waveform starting from the reset accumulator value.

To use this syntax, set the ResetAction property to 1 (true). This syntax can include any of the arguments from other syntaxes.

Input Arguments

Inc — Phase increment (optional)

scalar integer

Phase increment, specified as a scalar integer. The object casts this value to match the accumulator word length.

double and single data types are supported for simulation, but not for HDL code generation.

Dependencies

To enable this argument, set the PhaseIncrementSource property to 'Input port'.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | fixdt([],N,0)

ValidIn — Control signal that enables NCO operation

logical scalar

Control signal that enables NCO operation, specified as a logical scalar. When ValidIn is true, the object increments the phase and captures any input values. When ValidIn is false, the object holds the phase accumulator and ignores any input values.

When the SamplesPerFrame property value is greater than 1, this signal enables processing of SamplesPerFrame samples.

Data Types: `logical`

Offset — Phase offset

scalar integer

Phase offset, specified as a scalar integer.

`double` and `single` data types are supported for simulation but not for HDL code generation.

Dependencies

To enable this argument, set the `PhaseOffsetSource` property to `'Input port'`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fixdt([],N,0)`

Dither — Dither

scalar integer | column vector of integers

Dither, specified as an integer or as a column vector of integers. The length of the vector must equal the `SamplesPerFrame` property value.

`double` and `single` data types are supported for simulation, but not for HDL code generation.

Dependencies

To enable this argument, set the `DitherSource` property to `'Input port'`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fixdt([],N,0)`

ResetAccum — Control signal that resets the accumulator (optional)

logical scalar

Control signal that resets the accumulator, specified as a logical scalar. When this signal is `true`, the object resets the accumulator to its initial value. This signal does not reset the output samples in the pipeline.

Dependencies

To enable this argument, set the `ResetAction` property to `1` (`true`).

Data Types: `logical`

Output Arguments

Y — Generated waveform

scalar | [*Sine*,*Cosine*] pair | vector

Generated waveform, returned as a scalar or a vector of length `SamplesPerFrame`. This argument can be a `sin` or `cos` value, an `exp` value representing `cosine + j*sine`, or a pair of arguments in the form [*Sine*,*Cosine*].

If any input is of floating-point type, the object returns floating-point values for the waveform and `Phase` arguments, otherwise the object returns values using the type defined by the `OutputDataType` property.

`double` and `single` data types are supported for simulation, but not for HDL code generation.

Dependencies

By default, the output waveform is a sine wave. The format of the output waveform depends on the Waveform property.

ValidOut — Control signal that indicates validity of output data

logical scalar

Control signal that indicates validity of output data, specified as a logical scalar. When validOut is true, the values of Y and Phase are valid. When validOut is false, the values of Y and Phase are not valid.

When the SamplesPerFrame property value is greater than 1, this signal indicates the validity of all elements in the output vectors.

Data Types: logical

Phase — Current phase of NCO

scalar | column vector

Current phase of the NCO, returned as a scalar or as a vector of length SamplesPerFrame. The phase is the output of the quantized accumulator with offset and increment applied. If quantization is disabled, this port returns the output of the accumulator with offset and increment applied.

The values are of type `fixdt(1,N,0)`, where N is the NumQuantizerAccumulatorBits property value. If quantization is disabled, then N is the AccumulatorWL property value.

If any input argument is floating-point type, the object returns the Phase argument as a floating point value. Floating-point types are supported for simulation but not for HDL code generation.

Dependencies

To enable this argument, set the PhasePort property to 1 (true).

Data Types: single | double | `fixdt(1,N,0)`

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Common to All System Objects

step	Run System object algorithm
release	Release resources and allow changes to System object property values and input characteristics
reset	Reset internal states of System object

Examples**Design a HDL-Compatible NCO Source**

This example shows how to design an HDL-compatible NCO source.

Write a function that creates and calls the System object™, based on the waveform requirements. You can generate HDL from this function.

Note: This object syntax runs only in R2016b or later. If you are using an earlier release, replace each call of an object with the equivalent `step` syntax. For example, replace `myObject(x)` with `step(myObject,x)`.

```
function yOut = HDLNC0510(validIn)
%HDLNC0510
% Generates one sample of NCO waveform using the dsp.HDLNCO System object(TM)
% validIn is a logical scalar value
% phase increment, phase offset, and dither are fixed.
% You can generate HDL code from this function.

persistent nco510;

if isempty(nco510)
% Since calculation of the object parameters results in constant values, this
% code is not included in the generated HDL. The generated HDL code for
% the NCO object is initialized with the constant property values.

F0 = 510;      % Target output frequency in Hz
dphi = pi/2;  % Target phase offset
df = 0.05;    % Frequency resolution in Hz
minSFDR = 96; % Spurious free dynamic range(SFDR) in dB
Ts = 1/4000;  % Sample period in seconds

% Calculate the number of accumulator bits required for the frequency
% resolution and the number of quantized accumulator bits to satisfy the SFDR
% requirement.
Nacc = ceil(log2(1/(df*Ts)));
% Actual frequency resolution achieved = 1/(Ts*2^Nacc)
Nqacc = ceil((minSFDR-12)/6);
% Calculate the phase increment and offset to achieve the target frequency
% and offset.
phIncr = round(F0*Ts*2^Nacc);
phOffset = 2^Nacc*dphi/(2*pi);
nco510 = dsp.HDLNCO('PhaseIncrementSource','Property', ...
    'PhaseIncrement',phIncr,...
    'PhaseOffset',phOffset,...
    'NumDitherBits',4, ...
    'NumQuantizerAccumulatorBits',Nqacc,...
    'AccumulatorWL',Nacc);
end

yOut = nco510(validIn);

end
```

Call the object to generate data points in a sine wave. The input to the object is a valid control signal.

```
Ts = 1/4000;
y = zeros(1,1/Ts);
for k = 1:1/Ts
    y(k) = HDLNC0510(true);
end
```

Plot the mean-square spectrum of the 510 Hz sine wave generated by the NCO.

```
sa = dsp.SpectrumAnalyzer('SampleRate',1/Ts);
sa.SpectrumType = 'Power density';
sa.PlotAsTwoSidedSpectrum = false;
sa(y')
```

Algorithms

The frequency resolution of the sine wave depends on the size of the accumulator. Given a sample time, T_s , and the desired output frequency resolution Δf , calculate the necessary accumulator word length, N .

$$N = \text{ceil}\left(\log_2\left(\frac{1}{T_s \cdot \Delta f}\right)\right)$$

For a desired output frequency F_o , calculate the *phase increment*.

$$\text{phaseincrement} = \text{round}(F_o T_s 2^N)$$

Quantizing the output of the phase accumulator enables you to reduce the lookup table size without lowering the frequency resolution. Calculate the quantized word length to achieve a desired spurious free dynamic range (*SFDR*).

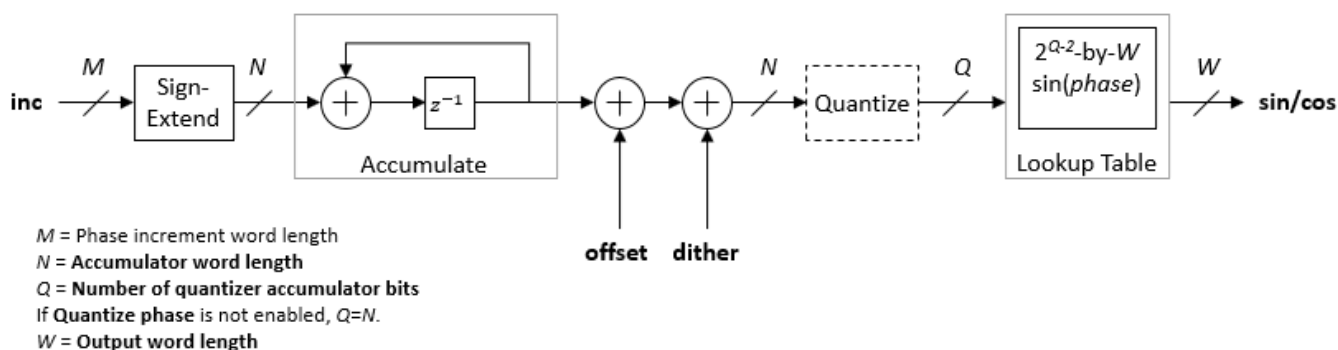

$$Q = \text{ceil}\left(\frac{SFDR - 12}{6}\right)$$

Phase offset and dither are optionally added at the accumulator stage. For a desired phase offset (in radians) of the output waveform, calculate the *phase offset* value that the object adds in the accumulator.

$$\text{phaseoffset} = \frac{2^N \cdot \text{desiredphaseoffset}}{2\pi}$$

The NCO implementation depends on whether you enable the LUTCompress property.

Without lookup table compression, the object uses the same quarter-sine lookup table as the NCO block. The size of the LUT is $2^{Q-2} \times W$ bits, where Q is NumQuantizerAccumulatorBits and W is OutputWL.

The object casts the phase increment value to match the accumulator word length.

If you do not enable PhaseQuantization, then $Q=N$, where N is AccumulatorWL. Consider the impact on simulator memory and hardware resources when you select these parameters.

For an example of how to generate a sine wave using this System object, see “Design a HDL-Compatible NCO Source” on page 4-758.

Lookup Table Compression

When you select lookup table (LUT) compression, the object applies the Sunderland compression method. Sunderland techniques use trigonometric identities to divide each phase of the quarter sine wave into three components and express it as:

$$\sin(A + B + C) = \sin(A + B)\cos(C) + \cos(A)\cos(B)\sin(C) - \sin(A)\sin(B)\sin(C)$$

If the quarter-sine phase has $Q-2$ bits, then the phase components A and B have a word length of $LA=LB=\text{ceil}((Q-2)/3)$. Phase component C contains the remaining phase bits. If the phase has 12 bits, then the quarter sine phase has 10 bits, and the components are defined as:

- A , the four most significant bits

$$(0 \leq A \leq \frac{\pi}{2})$$

- B , the next four bits

$$(0 \leq B \leq \frac{\pi}{2} \times 2^{-4})$$

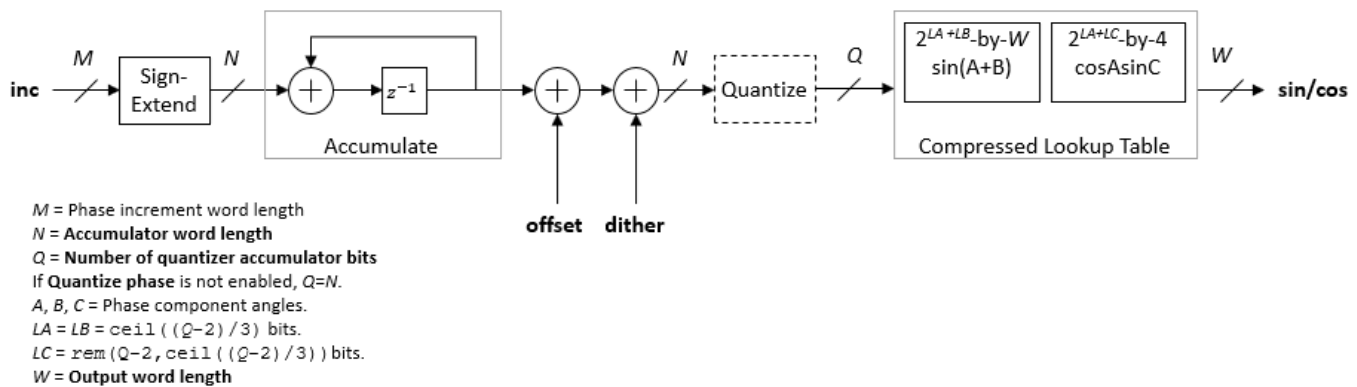

- C , the remaining two least significant bits

$$(0 \leq C \leq \frac{\pi}{2} \times 2^{-8})$$

Given the relative sizes of A , B , and C , the equation can be approximated by:

$$\sin(A + B + C) \approx \sin(A + B) + \cos(A)\sin(C)$$

The object implements this equation with one LUT for $\sin(A + B)$ and one LUT for $\cos(A)\sin(C)$. The second term is a fine correction factor that you can truncate to fewer bits without losing precision. Therefore, the second LUT returns a four-bit result.

With the default accumulator size of 16 bits, and the default quantized phase width of 12 bits, the LUTs use $2^8 \times 16$ plus $2^6 \times 4$ bits (4.5 kb). For comparison, a quarter-sine lookup table without compression uses $2^{10} \times 16$ bits (16 kb). The compression approximation is accurate within one LSB, resulting in an SNR of at least 60 dB on the output. See [1].

Compatibility Considerations

HDL-optimized NCO requires valid input argument

Behavior changed in R2020a

In previous releases, the input `validIn` argument of the `dsp.HDLNCO` System object was optional. It is now required. If you are using no other input ports, the object uses the `validIn` argument as an enable signal.

HDL-optimized NCO with floating-point inputs applies phase quantization

Behavior changed in R2020a

The output waveform returned from floating-point input values has changed. The output waveform now matches that returned from the same input values specified in fixed-point types.

Prior to R2020a, when using floating-point input types, the `dsp.HDLNCO` System object did not quantize the phase internally. The object expected floating-point phase increment and phase offset

inputs specified in radians. Now, the object quantizes the phase internally, and you must specify the input phase increment and offset in terms of the quantized size, for both floating-point and fixed-point input types.

For example, prior to R2020a, for a floating-point HDL NCO to generate output samples with a desired output frequency of F_0 and sample frequency of F_s , you had to specify the phase increment as $2\pi(F_0/F_s)$ and phase offset as $\pi/2$.

Starting in R2020a, you must specify the phase increment and phase offset in terms of the quantized size, N . These input values are the same as the input values you use with fixed-point types. Specify the phase increment as $(F_0*2^N)/F_s$, and the phase offset as $(\pi/2)*2^N/2\pi$, or $2^N/4$.

dsp.HighpassFilter

Package: dsp

FIR or IIR highpass filter

Description

The `dsp.HighpassFilter` System object independently filters each channel of the input over time using the given design specifications. You can set the `FilterType` property of `dsp.HighpassFilter` to 'FIR' or 'IIR' to implement the object as an FIR or IIR highpass filter.

To filter each channel of your input:

- 1 Create the `dsp.HighpassFilter` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

Creation

Syntax

```
HPF = dsp.HighpassFilter  
HPF = dsp.HighpassFilter(Name,Value)
```

Description

`HPF = dsp.HighpassFilter` returns a minimum order FIR highpass filter, `HPF`, with the default filter settings. Calling the object with the default property settings filters the input data with a stopband frequency of 8 kHz, a passband frequency of 12 kHz, a stopband attenuation of 80 dB, and a passband ripple of 0.1 dB.

`HPF = dsp.HighpassFilter(Name,Value)` returns a highpass filter, with additional properties specified by one or more `Name,Value` pair arguments. `Name` is the property name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name-value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see [System Design in MATLAB Using System Objects](#).

SampleRate — Input sample rate

44100 (default) | positive real scalar

Input sample rate in Hz, specified as the comma-separated pair consisting of 'SampleRate' and a positive real scalar.

Data Types: `single` | `double`

FilterType — Filter type

'FIR' (default) | 'IIR'

Filter type, specified as one of the following options:

- 'FIR' — The object designs an FIR highpass filter.
- 'IIR' — The object designs an IIR highpass (biquad) filter.

DesignForMinimumOrder — Minimum order filter design

`true` (default) | `false`

Minimum order filter design, specified as the comma-separated pair consisting of 'DesignForMinimumOrder' and a logical value. If this property is `true`, then `dsp.HighpassFilter` designs filters with the minimum order that meets the passband frequency, stopband frequency, passband ripple, and stopband attenuation specifications. Set these specifications using the corresponding properties. If this property is `false`, then the object designs filters with the order that you specify in the `FilterOrder` property. This filter design meets the passband frequency, passband ripple, and stopband attenuation specifications that you set using the respective properties.

FilterOrder — Order of the FIR or IIR filter

50 (default) | positive integer scalar

Order of the FIR or IIR filter, specified as the comma-separated pair consisting of 'FilterOrder' and a positive integer scalar.

Dependencies

Specifying a filter order is only valid when the value of 'DesignForMinimumOrder' is `false`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

StopbandFrequency — Filter stopband edge frequency

8000 (default) | real positive scalar

Filter stopband edge frequency in Hz, specified as the comma-separated pair consisting of 'StopbandFrequency' and a real positive scalar. The value of the stopband edge frequency in Hz must be less than the passband frequency.

Dependencies

You can specify the stopband edge frequency only when 'DesignForMinimumOrder' is `true`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

PassbandFrequency — Filter passband edge frequency

12000 (default) | real positive scalar

Filter passband edge frequency in Hz, specified as the comma-separated pair consisting of 'PassbandFrequency' and a real positive scalar. The value of the passband edge frequency in Hz must be less than half the `SampleRate` and greater than `StopbandFrequency`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

StopbandAttenuation — Minimum attenuation in the stopband

80 (default) | real positive scalar

Minimum attenuation in the stopband in dB, specified as the comma-separated pair consisting of 'StopbandAttenuation' and a real positive scalar. Minimum attenuation in the stopband defaults to 80 dB.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

PassbandRipple — Maximum ripple of filter response in the passband

0.1 (default) | real positive scalar

Maximum ripple of filter response in the passband, in dB, specified as the comma-separated pair consisting of 'PassbandRipple' and a real positive scalar. Maximum ripple of filter response defaults to 0.1 dB.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

Fixed-Point Properties

RoundingMethod — Rounding method for output fixed-point operations

'Floor' (default) | 'Ceiling' | 'Convergent' | 'Nearest' | 'Round' | 'Simplest' | 'Zero'

Rounding method for output fixed-point operations, specified as a character vector. For more information on the rounding modes, see “Precision and Range”.

CoefficientsDataType — Word and fraction lengths of coefficients

`numericType([],16)` (default) | `numericType` object

Word and fraction lengths of coefficients, specified as a `numericType` object. The default, `numericType(1,16)` corresponds to a signed numeric type object with 16-bit coefficients and a fraction length determined based on the coefficient values, to give the best possible precision.

This property is not tunable.

Word length of the output is same as the word length of the input. Fraction length of the output is computed such that the entire dynamic range of the output can be represented without overflow. For details on how the fraction length of the output is computed, see “Fixed-Point Precision Rules for Avoiding Overflow in FIR Filters”.

Usage

Syntax

$y = \text{HPF}(x)$

Description

$y = \text{HPF}(x)$ highpass filters the input signal, x . y is a highpass-filtered version of x .

Input Arguments

x — Noisy data input

vector | matrix

Noisy data input, specified as a vector or a matrix. If the input signal is a matrix, each column of the matrix is treated as an independent channel. The number of rows in the input signal denote the channel length. This object accepts variable-size inputs. After the object is locked, you can change the size of each input channel, but you cannot change the number of channels.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fi`

Output Arguments

y — Filtered output

vector | matrix

Filtered output, returned as a vector or a matrix. The output has the same size, data type, and complexity characteristics as the input.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fi`

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Specific to `dsp.HighpassFilter`

<code>freqz</code>	Frequency response of discrete-time filter System object
<code>fvtool</code>	Visualize frequency response of DSP filters
<code>impz</code>	Impulse response of discrete-time filter System object
<code>info</code>	Information about filter System object
<code>coeffs</code>	Returns the filter System object coefficients in a structure
<code>cost</code>	Estimate cost of implementing filter System object
<code>grpdelay</code>	Group delay response of discrete-time filter System object
<code>generatehdl</code>	Generate HDL code for quantized DSP filter (requires Filter Design HDL Coder)
<code>measure</code>	Measure frequency response characteristics of filter System object

Common to All System Objects

<code>step</code>	Run System object algorithm
<code>release</code>	Release resources and allow changes to System object property values and input characteristics
<code>reset</code>	Reset internal states of System object

Examples

Impulse and Frequency Response of FIR and IIR Highpass Filters

Create a minimum order FIR highpass filter for data sampled at 44.1 kHz. Specify a passband frequency of 12 kHz, a stopband frequency of 8 kHz, a passband ripple of 0.1 dB, and a stopband attenuation of 80 dB.

```
Fs = 44.1e3;  
filtertype = 'FIR';  
Fpass = 12e3;  
Fstop = 8e3;  
Rp = 0.1;  
Astop = 80;  
FIRHPF = dsp.HighpassFilter('SampleRate',Fs,...  
                             'FilterType',filtertype,...  
                             'PassbandFrequency',Fpass,...  
                             'StopbandFrequency',Fstop,...  
                             'PassbandRipple',Rp,...  
                             'StopbandAttenuation',Astop);
```

Design a minimum order IIR highpass filter with the same properties as the FIR highpass filter. Use `clone` to create a system object with the same properties as the FIR Highpass filter. Change the `FilterType` property of the cloned filter to IIR.

```
IIRHPF = clone(FIRHPF);  
IIRHPF.FilterType = 'IIR';
```

Plot the impulse response of the FIR highpass filter. The zeroth order coefficient is delayed by 19 samples, which is equal to the group delay of the filter. The FIR highpass filter is a causal FIR filter

```
fvtool(FIRHPF,'Analysis','impulse')
```

Plot the impulse response of the IIR highpass filter.

```
fvtool(IIRHPF,'Analysis','impulse')
```

Plot the magnitude and phase response of the FIR highpass filter.

```
fvtool(FIRHPF, 'Analysis', 'freq')
```

Plot the magnitude and phase response of the IIR highpass filter.

```
fvtool(IIRHPF, 'Analysis', 'freq')
```

Calculate the cost of implementing the FIR highpass filter.

```
cost(FIRHPF)
```

```
ans = struct with fields:
    NumCoefficients: 39
    NumStates: 38
    MultiplicationsPerInputSample: 39
    AdditionsPerInputSample: 38
```

Calculate the cost of implementing the IIR highpass filter. The IIR filter is more efficient to implement than its FIR counterpart.

```
cost(IIRHPF)
```

```
ans = struct with fields:
    NumCoefficients: 18
    NumStates: 14
    MultiplicationsPerInputSample: 18
    AdditionsPerInputSample: 14
```

Calculate the group delay of the FIR highpass filter.

```
grpdelay(FIRHPF)
```

Calculate the group delay of the IIR highpass filter. The FIR filter has a constant group delay (linear phase) while its IIR counterpart does not.

```
grpdelay(IIRHPF)
```

Filter White Gaussian Noise with an IIR Highpass filter

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, `myObject(x)` becomes `step(myObject,x)`.

Set up the IIR highpass filter. The sampling rate of the white Gaussian noise is 44,100 Hz. The passband frequency of the filter is 12 kHz, the stopband frequency is 8 kHz, the passband ripple is 0.1 dB, and the stopband attenuation is 80 dB.

```
Fs = 44.1e3;
filtertype = 'IIR';
Fpass = 12e3;
Fstop = 8e3;
Rp = 0.1;
Astop = 80;
hpf = dsp.HighpassFilter('SampleRate',Fs,...
                        'FilterType',filtertype,...
                        'PassbandFrequency',Fpass,...
                        'StopbandFrequency',Fstop,...
                        'PassbandRipple',Rp,...
                        'StopbandAttenuation',Astop);
```

View the magnitude response of the highpass filter.

```
fvtool(hpf)
```

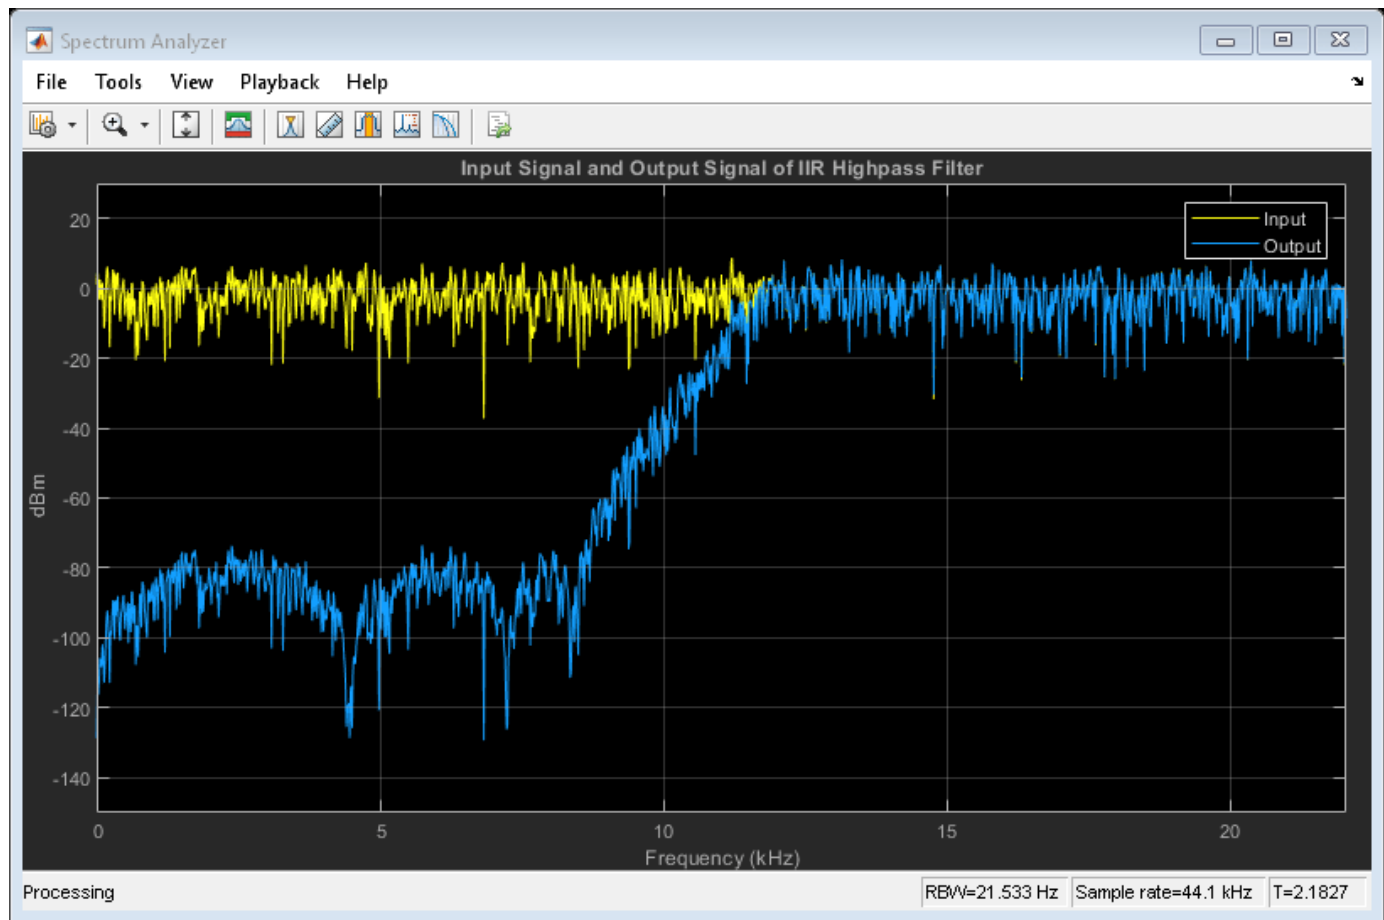

Create a spectrum analyzer object.

```
sa = dsp.SpectrumAnalyzer('SampleRate',44.1e3,...
    'PlotAsTwoSidedSpectrum',false,'ShowLegend',true,'YLimits',...
    [-150 30],...
    'Title',...
    'Input Signal and Output Signal of IIR Highpass Filter');
sa.ChannelNames = {'Input','Output'};
```

Filter the white Gaussian noisy input signal. View the input and output signals using the spectrum analyzer.

```
for k = 1:100
    Input = randn(1024,1);
    Output = hpf(Input);
    sa([Input,Output]);
end
```

Measure Frequency Response Characteristics of Highpass Filter

Measure the frequency response characteristics of a highpass filter. Create a `dsp.HighpassFilter` System object with default properties. Measure the frequency response characteristics of the filter.

```
HPF = dsp.HighpassFilter
```

```
HPF =  
    dsp.HighpassFilter with properties:
```

```
        FilterType: 'FIR'  
    DesignForMinimumOrder: true  
        StopbandFrequency: 8000  
        PassbandFrequency: 12000  
    StopbandAttenuation: 80  
        PassbandRipple: 0.1000  
        SampleRate: 44100
```

```
Show all properties
```

```
HPFMeas = measure(HPF)
```

```

HPFMeas =
Sample Rate      : 44.1 kHz
Stopband Edge    : 8 kHz
6-dB Point       : 10.418 kHz
3-dB Point       : 10.8594 kHz
Passband Edge    : 12 kHz
Stopband Atten.  : 81.8558 dB
Passband Ripple  : 0.08066 dB
Transition Width  : 4 kHz

```

Algorithms

FIR Highpass Filter

When the `FilterType` property is set to 'FIR', the `dsp.HighpassFilter` object acts as a FIR highpass filter. In this configuration, `dsp.HighpassFilter` is an alternative to using `firceqrip` and `firgr` with `dsp.FIRFilter`. This object condenses the two-step process into one. For the minimum order design, the object uses generalized Remez FIR filter design algorithm. For the specified order design, the object uses constrained equiripple FIR filter design algorithm. The designed filter is then implemented as a linear phase Type-1 filter with a `Direct form` structure. You can use `measure` to verify that the design meets the prescribed specifications.

IIR Highpass Filter

When the `FilterType` property is set to 'IIR', the `dsp.HighpassFilter` object acts as an IIR highpass filter. In this configuration, this object uses the elliptic design method to compute the SOS and scale values required to meet the filter design specifications. The object uses the SOS and scale values to set up a `Direct form I` biquadratic IIR filter, which forms the basis of the IIR version of the `dsp.HighpassFilter` System object. You can use `measure` to verify that the design meets the prescribed specifications.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

See "System Objects in MATLAB Code Generation" (MATLAB Coder).

This object supports code generation for ARM Cortex-M and ARM Cortex-A processors. To learn more about ARM Cortex code generation, see "Code Generation for ARM Cortex-M and ARM Cortex-A Processors".

This object also supports SIMD code generation using Intel AVX2 technology under these conditions:

- `FilterType` is set to 'FIR'.
- Input signal has a data type of `single` or `double`.

The SIMD technology significantly improves the performance of the generated code.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

This object supports HDL code generation with the Filter Design HDL Coder product. For workflows and limitations, see “Generate HDL Code for Filter System Objects” (Filter Design HDL Coder).

Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

Topics

“Analysis Methods for Filter System Objects” on page 3-2

Introduced in R2015a

dsp.Histogram

Package: dsp

(Removed) Histogram of input or sequence of inputs

Note The `dsp.Histogram System` object™ has been removed. Use the `histcounts` function instead. For more information, see “Compatibility Considerations”.

Description

The `Histogram` object generates a histogram for an input or a sequence of inputs.

To generate a histogram for an input or a sequence of inputs:

- 1 Create the `dsp.Histogram` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

Creation

Syntax

```
hist = dsp.Histogram
hist = dsp.Histogram(min,max,numbins)
hist = dsp.Histogram(Name,Value)
```

Description

`hist = dsp.Histogram` returns a histogram object, `hist`, that computes the frequency distribution of the elements in each input matrix.

`hist = dsp.Histogram(min,max,numbins)` returns a histogram object, `hist`, with the `LowerLimit` property set to `min`, `UpperLimit` property set to `max`, and `NumBins` property set to `numbins`.

`hist = dsp.Histogram(Name,Value)` returns a histogram object, `hist`, with each specified property set to the specified value. Enclose each property name in single quotes. Unspecified properties have default values.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects.

LowerLimit — Lower boundary

0 (default) | real scalar

Specify the lower boundary of the lowest-valued bin as a real-valued scalar. NaN and Inf are not valid values for this property.

Tunable: Yes

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

UpperLimit — Upper boundary

10 (default) | real scalar

Specify the upper boundary of the highest-valued bin as a real-valued scalar. NaN and Inf are not valid values for this property.

Tunable: Yes

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

NumBins — Number of bins in histogram

11 (default) | positive integer

Specify the number of bins in the histogram.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

Dimension — Dimension

Column (default) | All

Specify how the histogram calculation is performed over the data as All or Column.

Normalize — Enable output vector normalization

false (default) | true

Specify whether the histogram object normalizes the output vector, v , so that $sum(v) = 1$. When you set this property to true, the output vector is normalized. When you set it to false, the object supports fixed-point operations and does not use this property for normalization.

RunningHistogram — Enable calculation over successive calls to algorithm

false (default) | true

Set this property to true to enable running histogram calculations for the input elements over successive calls to the algorithm. Set this property to false to compute a histogram for the current input.

ResetInputPort — Enable resetting in running histogram mode

false (default) | true

Set this property to true to enable resetting the running histogram. When you set the property to true, specify a reset input to the object algorithm that resets the running histogram. When this property is false, the histogram object does not reset.

Dependencies

This property applies when you set the `RunningHistogram` property to `true`.

ResetCondition — Reset condition for running histogram mode

`Non-zero` (default) | `Rising edge` | `Falling edge` | `Either edge`

Specify the event that resets the running histogram as `Rising edge`, `Falling edge`, `Either edge`, or `Non-zero`.

Dependencies

This property applies when you set the `ResetInputPort` property to `true`.

Fixed-Point Properties**RoundingMethod — Rounding method for fixed-point operations**

`Floor` (default) | `Ceiling` | `Convergent` | `Nearest` | `Round` | `Simplest` | `Zero`

Specify the rounding method.

OverflowAction — Overflow action for fixed-point operations

`Wrap` (default) | `Saturate`

Specify the overflow action as `Wrap` or `Saturate`.

ProductDataType — Product word and fraction lengths

`Same as input` (default) | `Custom`

Specify the product fixed-point data type as `Same as input` or `Custom`.

CustomProductDataType — Custom product word and fraction lengths

`numerictype([],32,30)` (default) | `numerictype`

Specify the product fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`.

Dependencies

This property applies when you set the `ProductDataType` property to `Custom`.

AccumulatorDataType — Accumulator word and fraction lengths

`Same as input` (default) | `Same as product` | `Custom`

Specify the accumulator fixed-point data type as one of `Same as product`, `Same as input`, or `Custom`.

CustomAccumulatorDataType — Custom accumulator word and fraction lengths

`numerictype([],32,30)` (default) | `numerictype`

Specify the accumulator fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`.

Dependencies

This property applies when you set the `AccumulatorDataType` property to `Custom`.

Usage

Syntax

```
y = hist(x)  
y = hist(x,r)
```

Description

`y = hist(x)` returns a histogram `y` for the input data `x`. When the `RunningHistogram` property is `true`, `y` corresponds to the histogram of the input elements over successive calls to the algorithm.

`y = hist(x,r)` resets the histogram state based on the reset signal, `r` and the object's `ResetCondition` property. You can reset the histogram state only when the `RunningHistogram` and the `ResetInputPort` properties are `true`.

Input Arguments

x — Data input

vector | matrix | *N*-D array

Data input, specified as a vector, matrix, or *N*-D array. If `x` is a matrix, each column is treated as an independent channel.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fi`

r — Reset signal

scalar

Reset signal, specified as a scalar. The reset signal resets the histogram state based on the value of `r` and the object's `ResetCondition` property.

Dependencies

You can reset the histogram state only when the `RunningHistogram` and the `ResetInputPort` properties are `true`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `logical`

Output Arguments

y — Histogram output

scalar | vector

Histogram output of the input signal, returned as a scalar, vector, or matrix. The output depends on the setting of `Dimension`:

- `'Column'` -- The object computes the histogram value of each input channel. If the input is a column vector, the output is a scalar. If the input is a multichannel signal, the output signal is 1-by-*N* vector, where *N* is the number of input channels.
- `'All'` -- The object computes the histogram value over all input channels.

Data Types: `single` | `double` | `uint32`

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Common to All System Objects

<code>step</code>	Run System object algorithm
<code>release</code>	Release resources and allow changes to System object property values and input characteristics
<code>reset</code>	Reset internal states of System object

Examples

Compute Histogram of Sequence

Note: If you are using R2016a or an earlier release, replace each call to the object with the equivalent `step` syntax. For example, `obj(x)` becomes `step(obj,x)`.

Compute a histogram with four bins, for possible input values 1 through 4.

```
hist = dsp.Histogram(1,4,4);
y = hist([1 2 2 3 3 3 4 4 4 4]')
```

```
y = 4x1
```

```
1
2
3
4
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the Histogram block reference page. The object properties correspond to the block parameters, except:

- The **Reset port** block parameter corresponds to both the `ResetCondition` and the `ResetInputPort` object properties.
- The **Find histogram over** block parameter corresponds to the “Dimension” on page 4-0 property of the object.

Compatibility Considerations

dsp.Histogram System object has been removed

Errors starting in R2021a

The `dsp.Histogram` System object has been removed. Use the `histcounts` function instead.

Update Code

This table shows typical usage of the System object and explains how to update existing code to use the equivalent function.

Discouraged Usage	Recommended Replacement

dsp.IDCT

Package: dsp

(Removed) Inverse discrete cosine transform (IDCT)

Note The `dsp.IDCT` System object™ has been removed. Use `idct` instead. For more information, see “Compatibility Considerations”.

Description

The IDCT object computes the inverse discrete cosine transform (IDCT) of an input.

To compute the IDCT of an input:

- 1 Define and set up your IDCT object. See “Construction” on page 4-785.
- 2 Call `step` to compute the IDCT of an input according to the properties of `dsp.IDCT`. The behavior of `step` is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`idct = dsp.IDCT` returns a inverse discrete cosine transform (IDCT) object, `idct`. This object computes the IDCT of a real or complex input signal using the `Table lookup` method.

`idct = dsp.IDCT('PropertyName',PropertyValue,...)` returns an inverse discrete cosine transform (IDCT) object, `idct`, with each property set to the specified value.

Properties

SineComputation

Method to compute sines and cosines

Specify how the IDCT object computes the trigonometric function values as `Trigonometric function` or `Table lookup`. You must set this property to `Table lookup` for fixed-point inputs. The default is `Table lookup`.

Fixed-Point Properties

RoundingMethod

Rounding method for fixed-point operations

Specify the rounding method as one of `Ceiling`, `Convergent`, `Floor`, `Nearest`, `Round`, `Simplest`, or `Zero`. This property applies when you set the `SineComputation` property to `Table lookup`.

OverflowAction

Overflow action for fixed-point operations

Specify the overflow action as one of `Wrap` or `Saturate`. This property applies when you set the `SineComputation` property to `Table` lookup.

SineTableDataType

Sine table word-length designation

Specify the sine table fixed-point data type as one of `Same word length as input` or `Custom`. This property applies when you set the `SineComputation` property to `Table` lookup.

CustomSineTableDataType

Sine table word length

Specify the sine table fixed-point type as a signed, unscaled `numeric` object. This property applies when you set the `SineComputation` property to `Table` lookup and the `SineTableDataType` property to `Custom`. The default is `numeric(true, 16)`.

ProductDataType

Product word and fraction lengths

Specify the product fixed-point data type as one of `Full precision`, `Same as input`, `Custom`. This property applies when you set the `SineComputation` property to `Table` lookup.

CustomProductDataType

Product word and fraction lengths

Specify the product fixed-point type as a signed, scaled `numeric` object. This property applies when you set the `SineComputation` property to `Table` lookup and the `ProductDataType` property to `Custom`. The default is `numeric(true, 32, 30)`.

AccumulatorDataType

Accumulator word and fraction lengths

Specify the accumulator fixed-point data type as one of `Full precision`, `Same as input`, `Same as product`, or `Custom`. This property applies when you set the `SineComputation` property to `Table` lookup.

CustomAccumulatorDataType

Accumulator word and fraction lengths

Specify the accumulator fixed-point type as a signed, scaled `numeric` object. This property applies when you set the `SineComputation` property to `Table` lookup and the `AccumulatorDataType` property to `Custom`. The default is `numeric(true, 32, 30)`.

OutputDataType

Output word and fraction lengths

Specify the output fixed-point data type as one of `Full precision`, `Same as input`, `Custom`. This property applies when you set the `SineComputation` property to `Table lookup`. The default is `Full precision`.

CustomOutputDataType

Output word and fraction lengths

Specify the output fixed-point type as a signed, scaled `numericType` object. This property applies when you set the `SineComputation` property to `Table lookup` and the “OutputDataType” on page 4-0 property to `Custom`. The default is `numericType(true,16,15)`.

Methods

`step` Inverse discrete cosine transform (IDCT) of input

Common to All System Objects

<code>release</code>	Allow System object property value changes
----------------------	--

Examples

Analyze the Energy Content in a Sequence

Note This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, `myObject(x)` becomes `step(myObject,x)`.

Use DCT to analyze the energy content in a sequence:

```
x = (1:128).' + 50*cos((1:128).'*2*pi/40);
dct = dsp.DCT;
X = dct(x);
```

Set the DCT coefficients which represent less than 0.1% of the total energy to 0 and reconstruct the sequence using IDCT.

```
[XX, ind] = sort(abs(X),1, 'descend');
ii = 1;
while (norm([XX(1:ii);zeros(128-ii,1)]) <= 0.999*norm(XX))
    ii = ii+1;
end
disp(['Number of DCT coefficients that represent 99.9%',...
    'of the total energy in the sequence: ',num2str(ii)]);
```

Number of DCT coefficients that represent 99.9%of the total energy in the sequence: 10

```
XXt = zeros(128,1);
XXt(ind(1:ii)) = X(ind(1:ii));
idct = dsp.IDCT;
xt = idct(XXt);
plot(1:128,[x xt]);
```

```
legend('Original signal','Reconstructed signal',...
      'location','best');
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the IDCT block reference page. The object properties correspond to the block parameters.

Compatibility Considerations

dsp.IDCT System object has been removed

Errors starting in R2021a

The dsp.IDCT System object has been removed. Use `idct` instead.

Update Code

This table shows typical usage of the System object and explains how to update existing code to use the equivalent function.

Discouraged Usage	Recommended Replacement
<pre>idctObj = dsp.IDCT; xt = idctObj(X);</pre> <p>The variable, <i>X</i> represents the DCT of a time-domain signal.</p> <p>If you are using a release prior to R2016b, replace <code>idctObj(X)</code> with <code>step(idctObj,X)</code>.</p>	<pre>xt = idct(X);</pre>

Functions

`idct`

Objects

`dsp.FFT` | `dsp.IFFT`.

Introduced in R2012a

step

System object: dsp.IDCT

Package: dsp

Inverse discrete cosine transform (IDCT) of input

Syntax

$Y = \text{step}(\text{idct}, X)$

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, $y = \text{step}(\text{obj}, x)$ and $y = \text{obj}(x)$ perform equivalent operations.

$Y = \text{step}(\text{idct}, X)$ computes the inverse discrete cosine transform, Y , of input X .

Note `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

dsp.IFFT

Package: dsp

Inverse discrete Fourier transform (IDFT)

Description

The `dsp.IFFT` System object computes the inverse discrete Fourier transform (IDFT) of the input. The object uses one or more of the following fast Fourier transform (FFT) algorithms depending on the complexity of the input and whether the output is in linear or bit-reversed order:

- Double-signal algorithm
- Half-length algorithm
- Radix-2 decimation-in-time (DIT) algorithm
- Radix-2 decimation-in-frequency (DIF) algorithm
- An algorithm chosen from FFTW [1], [2]

To compute the IFFT of the input:

- 1** Create the `dsp.IFFT` object and set its properties.
- 2** Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

Creation

Syntax

```
ift = dsp.IFFT  
ift = dsp.IFFT(Name,Value)
```

Description

`ift = dsp.IFFT` returns an IFFT object, `ift`, that computes the IDFT of a column vector or N -D array. For column vectors or N -D arrays, the IFFT object computes the IDFT along the first dimension of the array. If the input is a row vector, the IFFT object computes a row of single-sample IDFTs and issues a warning.

`ift = dsp.IFFT(Name,Value)` returns an IFFT object, `ift`, with each property set to the specified value. Enclose each property name in single quotes. Unspecified properties have default values.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects.

FFTImplementation — FFT implementation

Auto (default) | Radix-2 | FFTW

Specify the implementation used for the FFT as Auto, Radix-2, or FFTW. When you set this property to Radix-2, the FFT length must be a power of two.

BitReversedInput — Enable bit-reversed order interpretation of input elements

false (default) | true

Set this property to true if the order of Fourier transformed input elements to the IFFT object are in bit-reversed order. The default is false, which denotes linear ordering.

Dependencies

This property applies only when the FFTLengthSource property is Auto.

ConjugateSymmetricInput — Enable conjugate symmetric interpretation of input

false (default) | true

Set this property to true if the input is conjugate symmetric to yield real-valued outputs. The discrete Fourier transform of a real valued sequence is conjugate symmetric, and setting this property to true optimizes the IDFT computation method. Setting this property to false for conjugate symmetric inputs may result in complex output values with nonzero imaginary parts. This occurs due to rounding errors. Setting this property to true for nonconjugate symmetric inputs results in invalid outputs.

Dependencies

This property applies only when the FFTLengthSource property is Auto.

Normalize — Enable dividing output by FFT length

true (default) | false

Specify whether to divide the IFFT output by the FFT length. The default is true and each element of the output is divided by the FFT length.

FFTLengthSource — Source of FFT length

Auto (default) | Property

Specify how to determine the FFT length as Auto or Property. When you set this property to Auto, the FFT length equals the number of rows of the input signal.

Dependencies

This property applies only when both the BitReversedInput and ConjugateSymmetricInput properties are false.

FFTLength — FFT length

64 (default) | integer

Specify the FFT length as an integer greater than or equal to 2.

This property must be a power of two if any of these conditions apply:

- The input is a fixed-point data type.
- The FFTImplementation property is Radix-2.

Dependencies

This property applies when you set the BitReversedInput and ConjugateSymmetricInput properties to false, and the FFTLengthSource property to 'Property'.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

WrapInput — Boolean value of wrapping or truncating input

true (default) | false

Wrap input data when FFTLength is shorter than input length. If this property is set to true, modulo-length data wrapping occurs before the FFT operation, given FFTLength is shorter than the input length. If this property is set to false, truncation of the input data to the FFTLength occurs before the FFT operation.

Fixed-Point Properties**RoundingMethod — Rounding method for fixed-point operations**

Floor (default) | Ceiling | Convergent | Nearest | Round | Simplest | Zero

Specify the rounding method.

OverflowAction — Overflow action for fixed-point operations

Wrap (default) | Saturate

Specify the overflow action as Wrap or Saturate.

SineTableDataType — Sine table word and fraction lengths

Same word length as input (default) | Custom

Specify the sine table data type as Same word length as input or Custom.

CustomSineTableDataType — Sine table word and fraction lengths

numerictype([],16) (default) | numerictype

Specify the sine table fixed-point type as an unscaled numerictype object with a Signedness of Auto.

Dependencies

This property applies when you set the SineTableDataType property to Custom.

ProductDataType — Product word and fraction lengths

Full precision (default) | Same as input | Custom

Specify the product data type as Full precision, Same as input, or Custom.

CustomProductDataType — Product word and fraction lengths

numerictype([],32,30) (default) | numerictype

Specify the product fixed-point type as a scaled numerictype object with a Signedness of Auto.

Dependencies

This property applies when you set the `ProductDataType` property to `Custom`.

AccumulatorDataType — Accumulator word and fraction lengths

`Full precision (default) | Same as input | Same as product | Custom`

Specify the accumulator data type as `Full precision`, `Same as input`, `Same as product`, or `Custom`.

CustomAccumulatorDataType — Accumulator word and fraction lengths

`numerictype([],32,30) (default) | numerictype`

Specify the accumulator fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`.

Dependencies

This property applies when you set the `AccumulatorDataType` property to `Custom`.

OutputDataType — Output word and fraction lengths

`Full precision (default) | Same as input | Custom`

Specify the output data type as `Full precision`, `Same as input`, or `Custom`.

CustomOutputDataType — Output word and fraction lengths

`numerictype([],16,15) (default) | numerictype`

Specify the output fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`.

Dependencies

This property applies when you set the `OutputDataType` property to `Custom`.

Usage**Syntax**

`y = ift(x)`

Description

`y = ift(x)` computes the inverse discrete Fourier transform (IDFT) , `y`, of the input `x` along the first dimension of `x`.

Input Arguments**x — Data input**

`vector | matrix | N-D array`

Data input, specified as a vector, matrix, or *N*-D array.

When the `FFTLengthSource` property is `Auto`, the length of `x` along the first dimension must be a positive integer power of two. When the `FFTLengthSource` property is `'Property'`, the length of `x` along the first dimension can be any positive integer and the `FFTLength` property must be a positive integer power of two.

Variable-size input signals are only supported when the `FFTLengthSource` property is set to `'Auto'`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fi`

Output Arguments

y — Inverse discrete Fourier transform of input signal

vector | matrix | *N*-D array

Inverse discrete Fourier transform of input signal, returned as a vector, matrix, or *N*-D array.

When `FFTLengthSource` property is set to `'Auto'`, the FFT length is same as the number of rows in the input signal. When `FFTLengthSource` property is set to `'Property'`, the FFT length is specified through the `FFTLength` property.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `fi`

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Common to All System Objects

<code>step</code>	Run System object algorithm
<code>release</code>	Release resources and allow changes to System object property values and input characteristics
<code>reset</code>	Reset internal states of System object

Examples

Construct a Sinusoidal Signal Using High Energy FFT Coefficients

Compute the FFT of a noisy sinusoidal input signal. The energy of the signal is stored as the magnitude square of the FFT coefficients. Determine the FFT coefficients which occupy 99.99% of the signal energy and reconstruct the time-domain signal by taking the IFFT of these coefficients. Compare the reconstructed signal with the original signal.

Note: If you are using R2016a or an earlier release, replace each call to the object with the equivalent `step` syntax. For example, `obj(x)` becomes `step(obj(x))`.

Consider a time-domain signal $x[n]$, which is defined over the finite time interval $0 \leq n \leq N - 1$. The energy of the signal $x[n]$ is given by the following equation:

$$E_N = \sum_{n=0}^{N-1} |x[n]|^2$$

FFT coefficients, $X[k]$, are considered signal values in the frequency domain. The energy of the signal $x[n]$ in the frequency-domain is therefore the sum of the squares of the magnitude of the FFT coefficients:

$$E_N = \frac{1}{N} \sum_{k=0}^{N-1} |X[k]|^2$$

According to Parseval's theorem, the total energy of the signal in time or frequency-domain is the same.

$$E_N = \sum_{n=0}^{N-1} |x[n]|^2 = \frac{1}{N} \sum_{k=0}^{N-1} |X[k]|^2$$

Initialization

Initialize a `dsp.SineWave` System object to generate a sine wave sampled at 44.1 kHz and has a frequency of 1000 Hz. Construct a `dsp.FFT` and `dsp.IFFT` objects to compute the FFT and the IFFT of the input signal.

The `'FFTLengthSource'` property of each of these transform objects is set to `'Auto'`. The FFT length is hence considered as the input frame size. The input frame size in this example is 1020, which is not a power of 2, so select the `'FFTImplementation'` as `'FFTW'`.

```
L = 1020;
Sineobject = dsp.SineWave('SamplesPerFrame',L,...
    'PhaseOffset',10,...
    'SampleRate',44100,...
    'Frequency',1000);
ft = dsp.FFT('FFTImplementation','FFTW');
ift = dsp.IFFT('FFTImplementation','FFTW',...
    'ConjugateSymmetricInput',true);
rng(1);
```

Streaming

Stream in the noisy input signal. Compute the FFT of each frame and determine the coefficients that constitute 99.99% energy of the signal. Take IFFT of these coefficients to reconstruct the time-domain signal.

```
numIter = 1000;
for Iter = 1:numIter
    Sinewave1 = Sineobject();
    Input = Sinewave1 + 0.01*randn(size(Sinewave1));
    FFTCoeff = ft(Input);
    FFTCoeffMagSq = abs(FFTCoeff).^2;

    EnergyFreqDomain = (1/L)*sum(FFTCoeffMagSq);
    [FFTCoeffSorted, ind] = sort(((1/L)*FFTCoeffMagSq),...
        1, 'descend');

    CumFFTCoeffs = cumsum(FFTCoeffSorted);
    EnergyPercent = (CumFFTCoeffs/EnergyFreqDomain)*100;
    Vec = find(EnergyPercent > 99.99);
    FFTCoeffsModified = zeros(L,1);
    FFTCoeffsModified(ind(1:Vec(1))) = FFTCoeff(ind(1:Vec(1)));
    ReconstrSignal = ift(FFTCoeffsModified);
end
```

99.99% of the signal energy can be represented by the number of FFT coefficients given by `Vec(1)`:

```
Vec(1)
```

```
ans = 296
```

The signal is reconstructed efficiently using these coefficients. If you compare the last frame of the reconstructed signal with the original time-domain signal, you can see that the difference is very small and the plots match closely.

```
max(abs(Input-ReconstrSignal))
```

```
ans = 0.0431
```

```
plot(Input, '*');  
hold on;  
plot(ReconstrSignal, 'o');  
hold off;
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the IFFT block reference page. The object properties correspond to the block parameters, except the **Output sampling mode** parameter is not supported by `dsp.IFFT`.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- See "System Objects in MATLAB Code Generation" (MATLAB Coder).
- When the following conditions apply, the executable generated from this System object relies on prebuilt dynamic library files (.dll files) included with MATLAB:
 - `FFTImplementation` is set to 'FFTW'.
 - `FFTImplementation` is set to 'Auto', `FFTLengthSource` is set to 'Property', and `FFTLength` is not a power of two.

Use the `packNGo` function to package the code generated from this System object and all the relevant files in a compressed zip file. Using this zip file, you can relocate, unpack, and rebuild your project in another development environment where MATLAB is not installed. For more details, see "How To Run a Generated Executable Outside MATLAB".

- When the FFT length is a power of two, you can generate standalone C and C++ code from this System object.

Objects

`dsp.FFT`

Introduced in R2012a

dsp.IIRFilter

Package: dsp

Infinite impulse response (IIR) filter

Description

The `dsp.IIRFilter` System object filters each channel of the input using the specified filter. You can specify the filter to have a 'Direct form I', 'Direct form I transposed', 'Direct form II', or 'Direct form II transposed' structure.

Use the “Numerator” on page 4-0 and “Denominator” on page 4-0 properties to specify the coefficients of the filter numerator and denominator coefficients. In addition to these coefficients, you can also specify nonzero initial filter states through the “InitialConditions” on page 4-0 property.

To filter a signal using an IIR filter:

- 1 Create the `dsp.IIRFilter` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

Creation

Syntax

```
iir = dsp.IIRFilter  
iir = dsp.IIRFilter(Name,Value)
```

Description

`iir = dsp.IIRFilter` creates an infinite impulse response (IIR) filter System object that independently filters each channel of the input over time using a specified IIR filter implementation.

`iir = dsp.IIRFilter(Name,Value)` creates an IIR filter object with each specified property set to the specified value. Enclose each property name in single quotes.

Example: `iir = dsp.IIRFilter('Structure','Direct form I');`

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see [System Design in MATLAB Using System Objects](#).

Structure — IIR filter structure

'Direct form II transposed' (default) | 'Direct form I' | 'Direct form I transposed' | 'Direct form II'

IIR filter structure, specified as 'Direct form I', 'Direct form I transposed', 'Direct form II', or 'Direct form II transposed'.

Numerator — Numerator coefficients

[1 1] (default) | row vector

Numerator coefficients, specified as a row vector.

Example: [0.0296 0.1775 0.4438 0.5918 0.4438 0.1775 0.0296]

Tunable: Yes

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64
Complex Number Support: Yes

Denominator — Denominator coefficients

[1 0.1] (default) | row vector

Denominator coefficients, specified as a row vector. The leading denominator coefficient must equal 1.

Example: [1.0000 -0.0000 0.7777 -0.0000 0.1142 -0.0000 0.0018]

Tunable: Yes

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64
Complex Number Support: Yes

InitialConditions — Initial conditions

0 (default) | scalar | vector | matrix

Initial conditions of the filter states, specified as one of the following:

- scalar -- The object initializes all delay elements in the filter to the scalar value.
- vector -- The length of the vector equals the number of delay elements in the filter. Each vector element specifies a unique initial condition for the corresponding delay element. The object applies the same vector to each channel of the input signal.
- matrix -- The number of rows in the matrix must equal the number of delay elements in the filter. The number of columns in the matrix must equal the number of channels in the input. Each element specifies a unique initial condition for the corresponding delay element in the corresponding channel.

The number of filter states equals $\max(N,M) - 1$, where N is the number of poles, and M is the number of zeros.

Tunable: Yes

Dependencies

This property applies only when you set the "Structure" on page 4-0 property to 'Direct form II' or 'Direct form II transposed'.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

Complex Number Support: Yes

NumeratorInitialConditions — Initial conditions on zeros side

0 (default) | scalar | vector | matrix

Initial conditions of the filter states on the side of the filter structure with the zeros, specified as one of the following:

- scalar -- The object initializes all delay elements on the zeros side in the filter to the scalar value.
- vector -- The length of the vector equals the number of delay elements on the zeros side in the filter. Each vector element specifies a unique initial condition for the corresponding delay element on the zeros side. The object applies the same vector of initial conditions to each channel of the input signal.
- matrix -- The number of rows in the matrix must equal the number of delay elements on the zeros side in the filter. The number of columns in the matrix must equal the number of channels in the input signal. Each element specifies a unique initial condition for the corresponding delay element on the zeros side in the corresponding channel.

The number of filter states equals $\max(N,M) - 1$, where N is the number of poles, and M is the number of zeros, respectively.

Tunable: Yes

Dependencies

This property applies only when you set the “Structure” on page 4-0 property to 'Direct form I' or 'Direct form I transposed'.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64
Complex Number Support: Yes

DenominatorInitialConditions — Initial conditions on poles side

0 (default) | scalar | vector | matrix

Initial conditions of the filter states on the side of the filter structure with the poles, specified as one of the following:

- scalar -- The object initializes all delay elements on the poles side in the filter to the scalar value.
- vector -- The length of the vector equals the number of delay elements on the poles side in the filter. Each vector element specifies a unique initial condition for the corresponding delay element on the poles side. The object applies the same vector of initial conditions to each channel of the input signal.
- matrix -- The number of rows in the matrix must equal the number of delay elements on the poles side in the filter. The number of columns in the matrix must equal the number of channels in the input signal. Each element specifies a unique initial condition for the corresponding delay element on the poles side in the corresponding channel.

The number of filter states equals $\max(N,M) - 1$, where N is the number of poles, and M is the number of zeros, respectively.

Tunable: Yes

Dependencies

This property applies only when you set the “Structure” on page 4-0 property to 'Direct form I' or 'Direct form I transposed'.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`
 Complex Number Support: Yes

Fixed-Point Properties**RoundingMethod — Rounding method**

'Floor' (default) | 'Ceiling' | 'Convergent' | 'Nearest' | 'Round' | 'Simplest' | 'Zero'

Select the rounding mode for fixed-point operations.

OverflowAction — Overflow action

'Wrap' (default) | 'Saturate'

Overflow action for fixed-point operations, specified as one of the following:

- 'Wrap' -- The object wraps the result of its fixed-point operations.
- 'Saturate' -- The object saturates the result of its fixed-point operations.

For more details on overflow actions, see overflow mode for fixed-point operations.

StateDataType — State data type

'Same as input' (default) | 'Custom'

State data type, specified as one of the following:

- 'Same as input' -- The state data type is same as the input data type.
- 'Custom' -- The state output data type is an autosigned numeric type through the “CustomStateDataType” on page 4-0 property.

CustomStateDataType — State word and fraction lengths

`numericType([],16,15)` (default)

State word and fraction lengths, specified as an autosigned numeric type with a word length of 16 and a fraction length of 15.

Dependencies

This property applies only when you set “StateDataType” on page 4-0 to 'Custom'.

NumeratorCoefficientsDataType — Data type of numerator coefficients

'Same word length as input' (default) | 'Custom'

Data type of numerator coefficients, specified as one of the following:

- 'Same word length as input' -- The word length of the numerator coefficients is the same as the input word length. The fraction length is chosen to give the best possible precision.
- 'Custom' -- The data type of the numerator coefficients is the autosigned numeric type specified by the “CustomNumeratorCoefficientsDataType” on page 4-0 property.

CustomNumeratorCoefficientsDataType — Word and fraction lengths of the numerator coefficients`numerictype([],16,15)` (default)

Word and fraction lengths of the numerator coefficients, specified as an autosigned numeric type with a word length of 16 and a fraction length of 15.

Dependencies

This property applies only when you set “NumeratorCoefficientsDataType” on page 4-0 to 'Custom'.

DenominatorCoefficientsDataType — Data type of the denominator coefficients`'Same word length as input'` (default) | 'Custom'

Data type of the denominator coefficients, specified as one of the following:

- 'Same word length as input' -- The word length of the denominator coefficients is the same as that of the input word length. The fraction length is chosen to give the best possible precision.
- 'Custom' -- The data type of the denominator coefficients is the autosigned numeric type specified by the “CustomDenominatorCoefficientsDataType” on page 4-0 property.

CustomDenominatorCoefficientsDataType — Word and fraction lengths of denominator coefficients`numerictype([],16,15)` (default)

Word and fraction lengths of denominator coefficients, specified as an autosigned numeric type with a word length of 16 and a fraction length of 15.

Dependencies

This property applies only when you set “DenominatorCoefficientsDataType” on page 4-0 to 'Custom'.

NumeratorProductDataType — Numerator product data type`'Full precision'` (default) | 'Same as input' | 'Custom'

Data type of the output of a product operation in the numerator polynomial of the IIR filter, specified as one of the following:

- 'Full precision' -- The object computes the numerator product output data type using the full-precision rules. These rules provide the most accurate fixed-point numerics. No quantization occurs. Bits are added, as needed, to ensure that no roundoff or overflow occurs.
- 'Same as input' -- The product output data type is the same as the input data type.
- 'Custom' -- The product output data type is the custom numeric type specified by the “CustomNumeratorProductDataType” on page 4-0 property. The rounding method and the overflow action are specified by the “RoundingMethod” on page 4-0 and “OverflowAction” on page 4-0 properties.

CustomNumeratorProductDataType — Numerator product word and fraction lengths`numerictype([],32,30)` (default)

Numerator product word and fraction lengths, specified as an autosigned numeric type with a word length of 32 and a fraction length of 30.

Dependencies

This property applies only when you set “NumeratorProductDataType” on page 4-0 to 'Custom'.

DenominatorProductDataType — Denominator product data type

'Full precision' (default) | 'Same as input' | 'Custom'

Data type of the output of a product operation in the denominator polynomial of the IIR filter, specified as one of the following:

- 'Full precision' -- The object computes the denominator product output data type using the full-precision rules. These rules provide the most accurate fixed-point numerics. No quantization occurs. Bits are added, as needed, to ensure that no roundoff or overflow occurs.
- 'Same as input' -- The product output data type is the same as the input data type.
- 'Custom' -- The product output data type is custom numeric type specified by the “CustomDenominatorProductDataType” on page 4-0 property. The rounding method and the overflow action are specified by the “RoundingMethod” on page 4-0 and “OverflowAction” on page 4-0 properties.

CustomDenominatorProductDataType — Denominator product word and fraction lengths

numericType([],32,30) (default)

Denominator product word and fraction lengths, specified as an autosigned numeric type with a word length of 32 and a fraction length of 30.

Dependencies

This property applies only when you set “DenominatorProductDataType” on page 4-0 to 'Custom'.

NumeratorAccumulatorDataType — Numerator accumulator data type

'Full precision' (default) | 'Same as input' | 'Same as product' | 'Custom'

Data type of the output of an accumulation operation in the numerator polynomial of the IIR filter, specified as one of the following:

- 'Full precision' -- The object computes the numerator accumulator data type using the full-precision rules. These rules provide the most accurate fixed-point numerics. No quantization occurs. Bits are added, as needed, to ensure that no roundoff or overflow occurs.
- 'Same as input' -- The accumulator data type is the same as the input data type.
- 'Same as product' -- The accumulator data type is the same as the product output data type.
- 'Custom' -- The accumulator data type is the custom numeric type specified by the “CustomNumeratorAccumulatorDataType” on page 4-0 property. The rounding method and the overflow action are specified by the “RoundingMethod” on page 4-0 and “OverflowAction” on page 4-0 properties.

CustomNumeratorAccumulatorDataType — Numerator accumulator word and fraction lengths

numericType([],32,30) (default)

Numerator accumulator word and fraction lengths, specified as an autosigned numeric type with a word length of 32 and a fraction length of 30.

Dependencies

This property applies only when you set “NumeratorAccumulatorDataType” on page 4-0 to 'Custom'.

DenominatorAccumulatorDataType — Denominator accumulator data type

'Full precision' (default) | 'Same as input' | 'Same as product' | 'Custom'

Data type of the output of an accumulation operation in the denominator polynomial of the IIR filter, specified as one of the following:

- 'Full precision' -- The object computes the denominator accumulator data type using the full-precision rules. These rules provide the most accurate fixed-point numerics. No quantization occurs. Bits are added, as needed, to ensure that no roundoff or overflow occurs.
- 'Same as input' -- The accumulator data type is the same as the input data type.
- 'Same as product' -- The accumulator data type is the same as the product output data type.
- 'Custom' -- The accumulator data type is the custom numeric type specified by the “CustomDenominatorAccumulatorDataType” on page 4-0 property. The rounding method and the overflow action are specified by the “RoundingMethod” on page 4-0 and “OverflowAction” on page 4-0 properties.

CustomDenominatorAccumulatorDataType — Denominator accumulator word and fraction lengths

numericType([],32,30) (default)

Denominator accumulator word and fraction lengths, specified as an autosigned numeric type with a word length of 32 and a fraction length of 30.

Dependencies

This property applies only when you set “DenominatorAccumulatorDataType” on page 4-0 to 'Custom'.

OutputDataType — Output data type

'Same as input' (default) | 'Full precision' | 'Custom'

Data type of the output of the dsp.IIRFilter object, specified as one of the following:

- 'Same as input' -- The output data type is the same as the input data type.
- 'Full precision' -- The object computes the output data type using the full-precision rules. These rules provide the most accurate fixed-point numerics. No quantization occurs. Bits are added, as needed, to ensure that no roundoff or overflow occurs.
- 'Custom' -- The output data type is the custom numeric type specified by the “CustomOutputDataType” on page 4-0 property. The rounding method and the overflow action are specified by the “RoundingMethod” on page 4-0 and “OverflowAction” on page 4-0 properties.

CustomOutputDataType — Output word and fraction lengths

numericType([],16,15) (default)

Output word and fraction lengths, specified as an autosigned numeric type with a word length of 16 and a fraction length of 15.

Dependencies

This property applies only when you set “OutputDataType” on page 4-0 to 'Custom'.

MultiplicandDataType — Multiplicand data type

'Same as input' (default) | 'Custom'

Multiplicand data type, specified as one of the following:

- 'Same as input' -- The multiplicand data type is the same as the input data type.
- 'Custom' -- The multiplicand data type is the autosigned numeric type specifies by the “CustomMultiplicandDataType” on page 4-0 property.

CustomMultiplicandDataType — Multiplicand output word and fraction lengths

numericType([],16,15) (default)

Multiplicand output word and fraction lengths, specified as an autosigned numeric type with a word length of 16 and a fraction length of 15.

Dependencies

This property applies only when you set “MultiplicandDataType” on page 4-0 to 'Custom'.

Usage

Syntax

```
iirOut = iir(input)
```

Description

`iirOut = iir(input)` filters the input signal using the specified filter to produce the filtered output. The System object filters each column of the input signal independently over time.

Input Arguments

input — Data input

vector | matrix

Data input that is filtered, specified as a vector or matrix.

Example: `randn(34,24)`

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `fi`

Output Arguments

iirOut — Filtered output

vector | matrix

Filtered output, returned as a vector or a matrix. The size, data type, and complexity of the output match that of the input.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `fi`

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Specific to `dsp.IIRFilter`

<code>freqz</code>	Frequency response of discrete-time filter System object
<code>fvtool</code>	Visualize frequency response of DSP filters
<code>impz</code>	Impulse response of discrete-time filter System object
<code>phasez</code>	Phase response of discrete-time filter System object (unwrapped)
<code>sos</code>	Convert to second order sections

Common to All System Objects

<code>step</code>	Run System object algorithm
<code>release</code>	Release resources and allow changes to System object property values and input characteristics
<code>reset</code>	Reset internal states of System object

For a list of filter analysis methods this object supports, type `dsp.IIRFilter.helpFilterAnalysis` in the MATLAB command prompt. For the corresponding function reference pages, see “Analysis Methods for Filter System Objects” on page 3-2.

Examples

Filter Noisy Signal Using IIR Filter

Filter a noisy sinusoidal signal using a lowpass butterworth IIR filter.

Note: If you are using R2016a or an earlier release, replace each call to the object with the equivalent step syntax. For example, `obj(x)` becomes `step(obj,x)`.

Input Signal

The input signal has three tones, 1 kHz, 5 kHz, and 12 kHz.

```
Sine1 = dsp.SineWave('Frequency',1e3,...  
    'SampleRate',44.1e3);  
Sine2 = dsp.SineWave('Frequency',5e3,...  
    'SampleRate',44.1e3);  
Sine3 = dsp.SineWave('Frequency',12e3,...  
    'SampleRate',44.1e3);
```

Filter Design

Use the `butter` function to design a 10th order lowpass Butterworth filter.

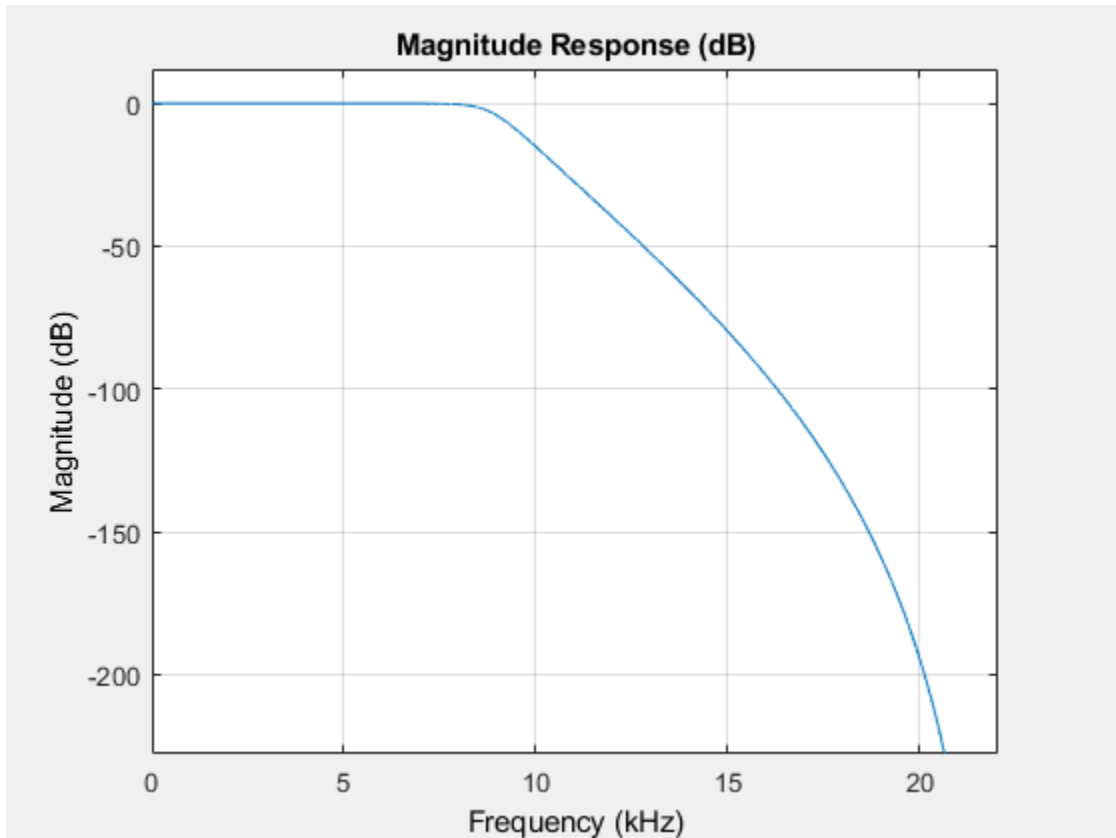

```
N = 10;  
Fc = 0.4;  
[b,a] = butter(N,Fc);
```

Create a `dsp.IIRFilter` object and assign the designed coefficients to the `Numerator` and the `Denominator` properties.

```
iir = dsp.IIRFilter('Numerator',b,...
    'Denominator',a);
```

View the magnitude response of the filter. The cutoff frequency is at 0.4 rad/sample, which, with a sample rate of 44.1 kHz, translates to $0.4 \times 44100/2$ or 8.82 kHz.

```
fvtool(iir,'Fs',Sine1.SampleRate)
```

View the power spectrum of the input and output signal using the Spectrum Analyzer.

```
sa = dsp.SpectrumAnalyzer('SampleRate',...
    Sine1.SampleRate,...
    'NumInputPorts',2,...
    'PlotAsTwoSidedSpectrum',false,...
    'OverlapPercent',80,...
    'PowerUnits','dBW',...
    'YLimits',[-220 -10]);
```

Streaming

Add zero-mean white Gaussian noise with a standard deviation of 0.01 to the sum of sine waves. Filter the signal using the IIR filter.

The tones at 1 kHz and 5 kHz are unaffected since they fall in the passband. The frequency at 12 kHz is attenuated since it falls in the transition band of the filter.

```

for i = 1:1000
    input = Sine1()+Sine2()+Sine3()+...
           0.01*randn(Sine1.SamplesPerFrame,1);
    output = iir(input);
    sa(input,output)
end

```

Design an IIR Filter

Design a notching comb filter with 8 notches, and a notch bandwidth of 0.02 referenced to a -3 dB level.

Create a comb filter design specification object using the `fdesign.comb` function and specify these design parameters.

```
combSpecs = fdesign.comb('notch','N,BW',8,0.02);
```

Design the notching comb filter using the `design` function. The resulting filter is a `dsp.IIRFilter` System object™. For details on how to apply this filter on streaming data, refer to `dsp.IIRFilter`.

```
iirFilt = design(combSpecs,'Systemobject',true)
```

```
iirFilt =
    dsp.IIRFilter with properties:
```

```

Structure: 'Direct form II'
Numerator: [0.8878 0 0 0 0 0 0 0 -0.8878]
Denominator: [1 0 0 0 0 0 0 0 -0.7757]
InitialConditions: 0

```

Show all properties

View magnitude response of the designed filter using `fvtool`.

```
fvtool(iirFilt)
```

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- Only the `Numerator` and `Denominator` properties are tunable for code generation.
- See “System Objects in MATLAB Code Generation” (MATLAB Coder).

Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

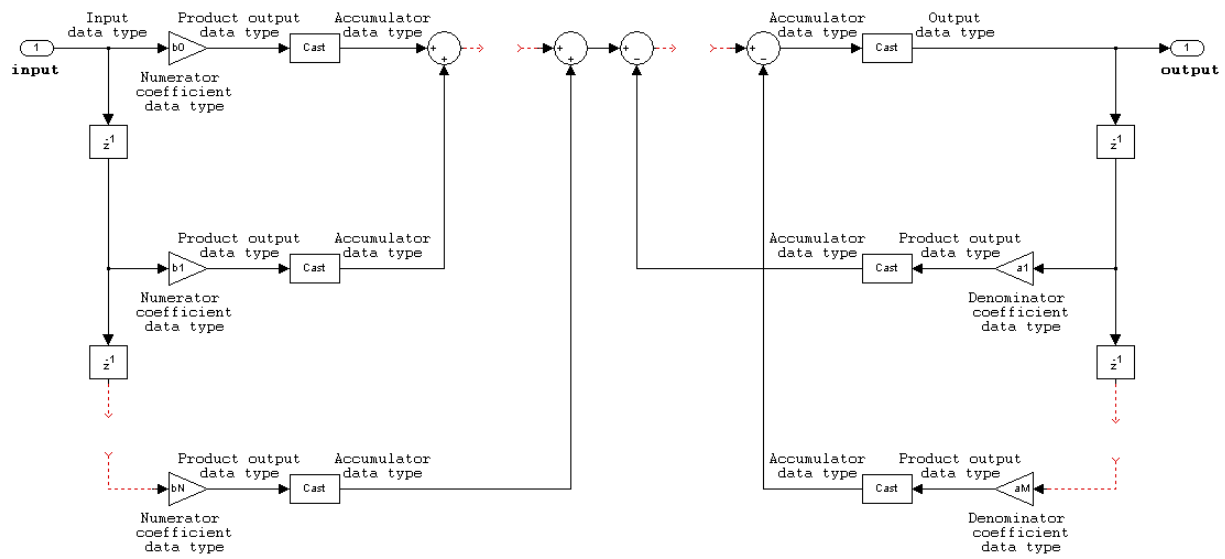

The `dsp.IIRFilter` System object supports the following filter structures. The diagrams in each section show the data types used in the filter structures for fixed-point signals. You can set the data types using the fixed-point properties of the object.

Direct form I

The following constraints apply when the Structure property is set to 'Direct form I':

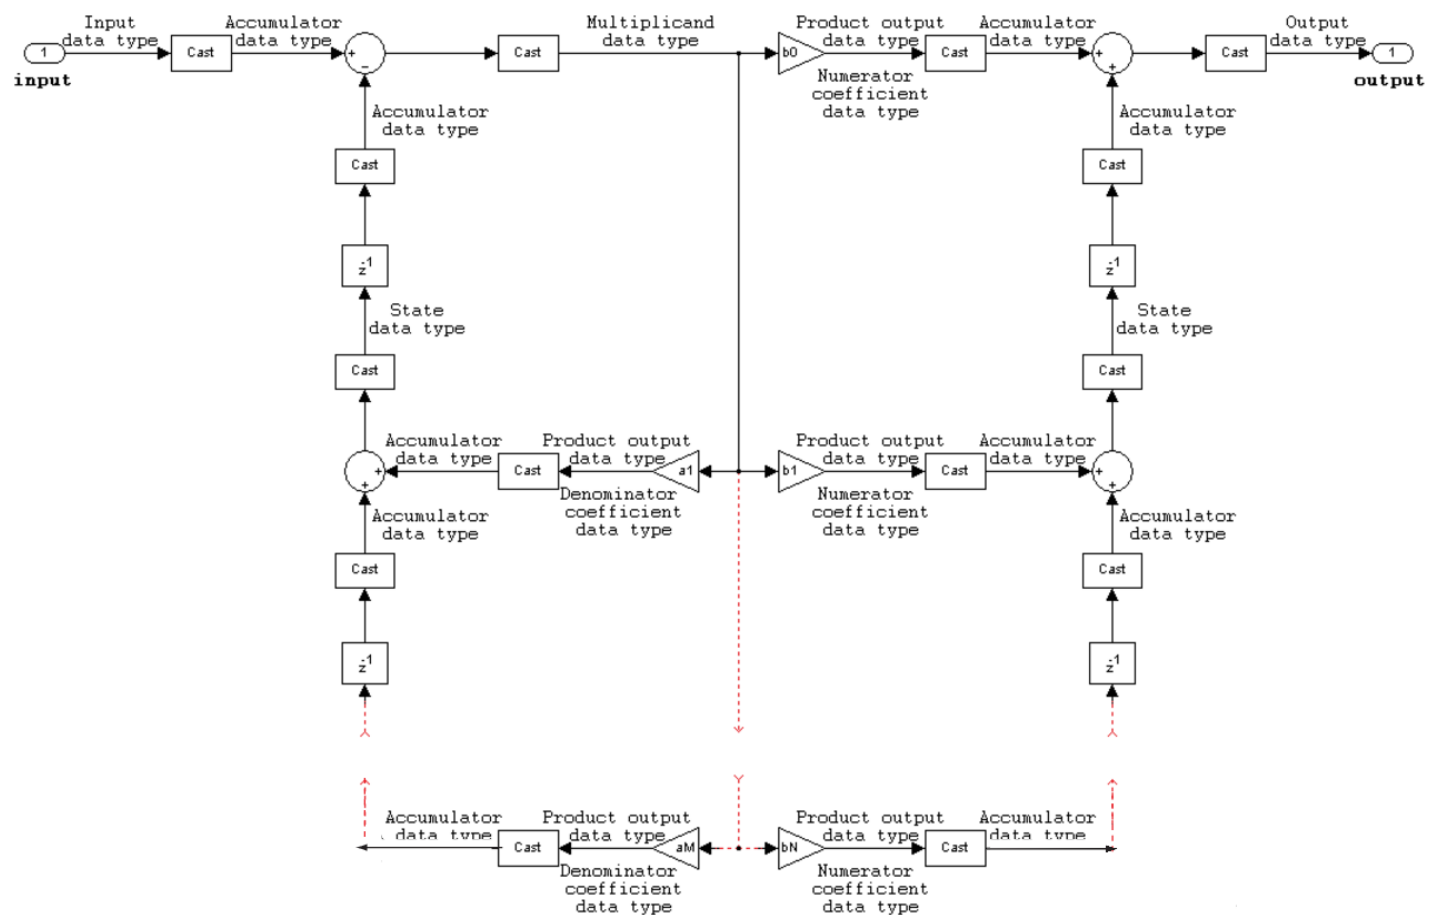

- Inputs can be real or complex.
- Numerator and denominator coefficients can be real or complex.
- Numerator and denominator coefficients must have the same complexity characteristics. When the numerator and denominator coefficients have different complexities from each other, the object processes the filter as if two sets of complex coefficients are provided. The real-valued coefficient set is treated as if it is a complex vector with zero-valued imaginary parts.
- The State data type cannot be specified for this structure. Doing so is not possible because the input and output states have the same data types as the input and output buffers.

Direct form I transposed

The following constraints apply when the Structure property is set to 'Direct form I transposed':

- Inputs can be real or complex.
- Numerator and denominator coefficients can be real or complex.
- Numerator and denominator coefficients must have the same complexity characteristics. When the numerator and denominator coefficients have different complexities from each other, the object processes the filter as if two sets of complex coefficients are provided. The real-valued coefficient set is treated as if it is a complex vector with zero-valued imaginary parts.
- States are complex when either the input or the coefficients are complex.

Direct form II

The following constraints apply when the Structure property is set to 'Direct form II':

- Inputs can be real or complex.
- Numerator and denominator coefficients can be real or complex.
- Numerator and denominator coefficients must have the same complexity characteristics. When the numerator and denominator coefficients have different complexities from each other, the object processes the filter as if two sets of complex coefficients are provided. The real-valued coefficient set is treated as if it is a complex vector with zero-valued imaginary parts.
- States are complex when either the inputs or the coefficients are complex.

Direct form II transposed

The following constraints apply when the Structure property is set to 'Direct form II transposed':

- Inputs can be real or complex.
- Numerator and denominator coefficients can be real or complex.
- Numerator and denominator coefficients must have the same complexity characteristics. When the numerator and denominator coefficients have different complexities from each other, the object processes the filter as if two sets of complex coefficients are provided. The real-valued coefficient set is treated as if it is a complex vector with zero-valued imaginary parts.
- States are complex when either the inputs or the coefficients are complex.

dsp.IIRHalfbandDecimator

Package: dsp

Decimate by factor of two using polyphase IIR

Description

The `dsp.IIRHalfbandDecimator` System object performs efficient polyphase decimation of the input signal by a factor of two. To design the halfband filter, you can specify the object to use an elliptic design or a quasi-linear phase design. The object uses these design methods to compute the filter coefficients. To filter the inputs, the object uses a polyphase structure. The allpass filters in the polyphase structure are in a minimum multiplier form.

Elliptic design introduces nonlinear phase and creates the filter using fewer coefficients than quasi linear design. Quasi-linear phase design overcomes phase nonlinearity at the cost of additional coefficients.

Alternatively, instead of designing the halfband filter using a design method, you can specify the filter coefficients directly. When you choose this option, the allpass filters in the two branches of the polyphase implementation can be in a minimum multiplier form or in a wave digital form.

You can also use the `dsp.IIRHalfbandDecimator` object to implement the analysis portion of a two-band filter bank to filter a signal into lowpass and highpass subbands.

To filter and downsample your data:

- 1 Create the `dsp.IIRHalfbandDecimator` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

Creation

Syntax

```
iirhalfbanddecim = dsp.IIRHalfbandDecimator  
iirhalfbanddecim = dsp.IIRHalfbandDecimator(Name, Value)
```

Description

`iirhalfbanddecim = dsp.IIRHalfbandDecimator` returns a halfband decimator, `iirhalfbanddecim`, with the default settings. Under the default settings, the System object filters and downsamples the input data with a halfband frequency of 22050 Hz, a transition width of 4100 Hz, and a stopband attenuation of 80 dB.

`iirhalfbanddecim = dsp.IIRHalfbandDecimator(Name, Value)` returns an IIR halfband decimator, with additional properties specified by one or more `Name, Value` pair arguments.

Example: `iirhalfbanddecim = dsp.IIRHalfbandDecimator('Specification','Filter order and stopband attenuation')` creates an IIR halfband decimator object with filter order set to 9 and stopband attenuation set to 80 dB.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see *System Design in MATLAB Using System Objects*.

Specification — Filter design parameters

'Transition width and stopband attenuation' (default) | 'Filter order and stopband attenuation' | 'Filter order and transition width' | 'Coefficients'

Filter design parameters, specified as a character vector. When you set `Specification` to one of the filter design options, you can specify the filter design parameters using the corresponding `FilterOrder`, `StopbandAttenuation`, and `TransitionWidth` properties. Also, you can specify the design method using `DesignMethod`. When you set `Specification` to 'Coefficients', you can specify the coefficients directly.

FilterOrder — Order of the IIR halfband filter

9 (default) | positive scalar integer

Order of the IIR halfband filter, specified as a positive scalar integer. If you set `DesignMethod` to 'Elliptic', then `FilterOrder` must be an odd integer greater than one. If you set `DesignMethod` to 'Quasi-linear phase', then `FilterOrder` must be a multiple of four.

Dependencies

This property applies when you set `Specification` to 'Filter order and stopband attenuation' or 'Filter order and transition width'.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

StopbandAttenuation — Minimum attenuation needed in stopband

80 (default) | positive real scalar

Minimum attenuation needed in the stopband of the IIR halfband filter, specified as a positive real scalar. Units are in dB.

Dependencies

This property applies only when you set `Specification` to 'Filter order and stopband attenuation' or 'Transition width and stopband attenuation'.

Data Types: `single` | `double`

TransitionWidth — Transition width

4100 (default) | positive real scalar

Transition width of the IIR halfband filter, specified as a positive real scalar. Units are in Hz. The value of the transition width must be less than half the input sample rate.

Dependencies

This property applies only when you set `Specification` to 'Transition width and stopband attenuation' or 'Filter order and transition width'.

Data Types: `single` | `double`

DesignMethod — Design method

'Elliptic' (default) | 'Quasi-linear phase'

Design method for the IIR halfband filter, specified as 'Elliptic' or 'Quasi-linear phase'. When the property is set to 'Quasi-linear phase', the first branch of the polyphase structure is a pure delay, which results in an approximately linear phase response.

Dependencies

This property applies only when you set `Specification` to any accepted value except 'Coefficients'.

SampleRate — Input sample rate

44100 (default) | positive real scalar

Input sample rate, specified as a positive real scalar. Units are in Hz.

Dependencies

This property applies only when you set `Specification` to any accepted value except 'Coefficients'.

Data Types: `single` | `double`

Structure — Internal allpass filter implementation structure

'Minimum multiplier' (default) | 'Wave Digital Filter'

Internal allpass filter implementation structure, specified as 'Minimum multiplier' or 'Wave Digital Filter'.

This property is not tunable.

Dependencies

This property applies only when you set 'Specification' to 'Coefficients'. Each structure uses a different coefficients set, independently stored in the corresponding object property.

AllpassCoefficients1 — Allpass polynomial filter coefficients of first branch

[0.1284563; 0.7906755] (default) | [0.1284563 0.1534; 0.7906755 0.6745]

Allpass polynomial filter coefficients of the first branch, specified as an N -by-1 or N -by-2 matrix. N is the number of first-order or second-order allpass sections.

Tunable: Yes

Dependencies

This property applies only when you set `Specification` to 'Coefficients' and `Structure` to 'Minimum multiplier'.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

AllpassCoefficients2 — Allpass polynomial filter coefficients of second branch

[0.4295667] (default) | [0.7906755 0.1534]

Allpass polynomial filter coefficients of the second branch, specified as an N -by-1 or N -by-2 matrix. N is the number of first-order or second-order allpass sections.

Tunable: Yes

Dependencies

This property applies only when you set Specification to 'Coefficients' and Structure to 'Minimum multiplier'.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

WDFCoefficients1 — Allpass filter coefficients of first branch in Wave Digital Filter form

[0.1284563; 0.7906755] (default) | [0.1284563 0.1534; 0.7906755 0.6745]

Allpass filter coefficients of the first branch in Wave Digital Filter form, specified as an N -by-1 or N -by-2 matrix. N is the number of first-order or second-order allpass sections. Each element must have an absolute value less than or equal to 1.

This property is not tunable.

Dependencies

This property applies only when you set Specification to 'Coefficients' and Structure to 'Wave Digital Filter'.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

WDFCoefficients2 — Allpass filter coefficients of second branch in Wave Digital Filter form

[0.4295667] (default) | [0.7906755 0.1534]

Allpass filter coefficients of the second branch in Wave Digital Filter form, specified as the comma-separated pair consisting of 'WDFCoefficients2' and a N -by-1 or N -by-2 matrix. N is the number of first-order or second-order allpass sections. Each element must have an absolute value less than or equal to 1.

This property is not tunable.

Dependencies

This property applies only when you set 'Specification' to 'Coefficients' and 'Structure' to 'Wave Digital Filter'.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

HasPureDelayBranch — Make first branch a pure delay

false (default) | true

Flag to make the first allpass branch a delay, specified as a logical scalar. When this property is true, the first branch is treated as a pure delay and the properties AllpassCoefficients1 and WDFCoefficients1 do not apply.

This property is not tunable.

Dependencies

This property applies only when you set `Specification` to `'Coefficients'`.

Delay — Length of delay

1 (default) | finite positive scalar

Length of the first branch delay, specified as a finite positive scalar. The value of this property specifies the number of samples by which you can delay the input to the first branch.

This property is not tunable.

Dependencies

This property applies only when you set `Specification` to `'Coefficients'` and `HasPureDelayBranch` to 1.

Data Types: `single` | `double`

HasTrailingFirstOrderSection — Treat the last section of the second branch as first order

false (default) | true

Option to treat the last section of the second branch as first order, specified as a logical scalar. When this property is 1 and the coefficients of the second branch are in an N -by-2 matrix, the object ignores the second element of the last row of the matrix. The last section of the second branch then becomes a first-order section. When this property is set to 0, the last section of the second branch is a second-order section. When the coefficients of the second branch are in an N -by-1 matrix, this property is ignored.

This property is not tunable.

Dependencies

This property applies only when you set `Specification` to `'Coefficients'`.

Usage**Syntax**

```
y_low = iirhalfbanddecim(x)  
[y_low,y_high] = iirhalfbanddecim(x)
```

Description

`y_low = iirhalfbanddecim(x)` filters the input signal, `x`, using the IIR halfband filter, `iirhalfbanddecim`, and downsamples the output by a factor of 2.

`[y_low,y_high] = iirhalfbanddecim(x)` computes the `y_low` and `y_high`, of the analysis filter bank, `iirhalfbanddecim` for input `x`. A K_i -by- N input matrix is treated as N independent channels. The System object generates two power-complementary output signals by adding and subtracting the two polyphase branch outputs respectively. `y_low` and `y_high` are of the same size (K_o -by- N) and data type. $K_o = K_i/2$, where 2 is the decimation factor.

Input Arguments

x — Data input

column vector | matrix

Data input, specified as a column vector or a matrix. The number of rows in the input signal must be even since the decimation factor is always 2 for this object. If the input is a matrix, each column is treated as an independent channel.

Data Types: `single` | `double`

Output Arguments

y_{low} — Lowpass subband of decimator output

column vector | matrix

Lowpass subband of decimator output, returned as a column vector or a matrix. The output, `ylow` is a lowpass halfband filtered and downsampled version of the input `x`. Due to the halfband nature of the filter, the downsampling factor is always 2.

Data Types: `single` | `double`

y_{high} — Highpass subband of decimator output

column vector | matrix

Highpass subband of decimator output, returned as a column vector or a matrix. The output, `yhigh` is a highpass halfband filtered and downsampled version of the input `x`. Due to the halfband nature of the filter, the downsampling factor is always 2.

Data Types: `single` | `double`

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Specific to dsp.IIRHalfbandDecimator

<code>freqz</code>	Frequency response of discrete-time filter System object
<code>fvtool</code>	Visualize frequency response of DSP filters
<code>info</code>	Information about filter System object
<code>cost</code>	Estimate cost of implementing filter System object
<code>polyphase</code>	Polyphase decomposition of multirate filter

Common to All System Objects

<code>step</code>	Run System object algorithm
<code>release</code>	Release resources and allow changes to System object property values and input characteristics
<code>reset</code>	Reset internal states of System object

Examples

Frequency Response of Quasi-Linear Phase IIR Halfband Decimator

Create a minimum-order lowpass IIR halfband decimation filter for data sampled at 44.1 kHz. The filter has a transition width of 4.1 kHz, and a stopband attenuation of 80 dB.

```
IIRHalfbandDecim = dsp.IIRHalfbandDecimator(...
    'DesignMethod', 'Quasi-linear phase');
```

Obtain the filter coefficients.

```
c = coeffs(IIRHalfbandDecim);
```

Plot the magnitude and phase response.

```
fvtool(IIRHalfbandDecim, 'Analysis', 'freq')
```

Extract Low Frequency Subband from Speech

Use a halfband analysis filter bank and interpolation filter to extract the low frequency subband from a speech signal.

Note: If you are using R2016a or an earlier release, replace each call to the object with the equivalent `step` syntax. For example, `obj(x)` becomes `step(obj, x)`.

Note: The `audioDeviceWriter` System object™ is not supported in MATLAB Online.

Set up the audio file reader, the analysis filter bank, the audio device writer, and the interpolation filter. The sampling rate of the audio data is 22050 Hz. The halfband filter has an order of 21 and a transition width of 2 kHz.

```
afr = dsp.AudioFileReader('speech_dft.mp3','SamplesPerFrame',1024);
```

```
filterspec = 'Filter order and transition width';
Order = 21;
TW = 2000;
```

```
IIRHalfbandDecim = dsp.IIRHalfbandDecimator(...
    'Specification',filterspec,'FilterOrder',Order,...
    'TransitionWidth',TW,'SampleRate',afr.SampleRate);
```

```
IIRHalfbandInterp = dsp.IIRHalfbandInterpolator(...
    'Specification',filterspec,'FilterOrder',Order,...
    'TransitionWidth',TW,'SampleRate',afr.SampleRate/2);
```

```
ap = audioDeviceWriter('SampleRate',afr.SampleRate);
```

View the magnitude response of the halfband filter.

```
fvtool(IIRHalfbandDecim)
```

Read the speech signal from the audio file in frames of 1024 samples. Filter the speech signal into lowpass and highpass subbands with a halfband frequency of 5512.5 Hz. Reconstruct a lowpass approximation of the speech signal by interpolating the lowpass subband. Play the filtered output.

```
while ~isDone(afr)
    audioframe = afr();
    xlo = IIRHalfbandDecim(audioframe);
    ylow = IIRHalfbandInterp(xlo);
    ap(ylow);
end
```

Wait until the audio file ends, and then close the input file and release the audio output resource.

```
release(afr);
release(ap);
```

Two-Channel Filter Bank

Use a halfband decimator and interpolator to implement a two-channel filter bank. This example uses an audio file input and shows that the power spectrum of the filter bank output does not differ significantly from the input.

Note: If you are using R2016a or an earlier release, replace each call to the object with the equivalent step syntax. For example, `obj(x)` becomes `step(obj,x)`.

Note: The `audioDeviceWriter` System object™ is not supported in MATLAB Online.

Set up the audio file reader and audio device writer. Construct the IIR halfband decimator and interpolator. Finally, set up the spectrum analyzer to display the power spectra of the filter-bank input and output.

```
AF = dsp.AudioFileReader('speech_dft.mp3','SamplesPerFrame',1024);
AP = audioDeviceWriter('SampleRate',AF.SampleRate);
```

```
filterspec = 'Filter order and transition width';
Order = 51;
TW = 2000;
```

```
IIRHalfbandDecim = dsp.IIRHalfbandDecimator(...
    'Specification',filterspec,'FilterOrder',Order,...
    'TransitionWidth',TW,'SampleRate',AF.SampleRate);
```

```
IIRHalfbandInterp = dsp.IIRHalfbandInterpolator(...
    'Specification',filterspec,'FilterOrder',Order,...
    'TransitionWidth',TW,'SampleRate',AF.SampleRate/2,...
    'FilterBankInputPort',true);
```

```
SpecAna = dsp.SpectrumAnalyzer('SampleRate',AF.SampleRate,...
    'PlotAsTwoSidedSpectrum',false,'ReducePlotRate',false,...
    'ShowLegend',true,...
    'ChannelNames',{'Input signal','Filtered output signal'});
```

Read the audio 1024 samples at a time. Filter the input to obtain the lowpass and highpass subband signals decimated by a factor of two. This is the analysis filter bank. Use the halfband interpolator as the synthesis filter bank. Display the running power spectrum of the audio input and the output of the synthesis filter bank. Play the output.

```
while ~isDone(AF)
    audioInput = AF();
```

```

[xlo,xhigh] = IIRHalfbandDecim(audioInput);
audioOutput = IIRHalfbandInterp(xlo,xhigh);
spectrumInput = [audioInput audioOutput];
SpecAna(spectrumInput);
AP(audioOutput);
end

release(AF);
release(AP);
release(SpecAna);

```

Filter Input into Lowpass and Highpass Subbands

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, `myObject(x)` becomes `step(myObject,x)`.

Create a halfband decimator for data sampled at 44.1 kHz. Use a minimum-order design with a transition width of 2 kHz and a stopband attenuation of 60 dB.

```

IIRHalfbanddecim = dsp.IIRHalfbandDecimator(...
    'Specification','Transition width and stopband attenuation',...
    'TransitionWidth',2000,'StopbandAttenuation',60,'SampleRate',44.1e3);

```

Filter a two-channel input into lowpass and highpass subbands.

```
x = randn(1024,2);
[yLow,yHigh] = IIRHalfbandDecim(x);
```

Algorithms

Polyphase Implementation with Halfband Filters

When you filter your signal, `dsp.IIRHalfbandDecimator` uses an efficient polyphase implementation for halfband filters. You can use the polyphase implementation to move the downsample operation before filtering. This change enables you to filter at the lower sampling rate.

IIR halfband filters are generally modeled using two parallel allpass filter branches.

$$H(z) = 0.5 * [A_1(z^2) + z^{-1}A_2(z^2)]$$

Elliptic Design

The allpass filters for elliptic IIR halfband filter are given as

$$A_1(z) = \prod_{k=1}^{K_1} \frac{a_k^{(1)} + z^{-1}}{1 + a_k^{(1)}z^{-1}}$$

$$A_2(z) = \prod_{k=1}^{K_2} \frac{a_k^{(2)} + z^{-1}}{1 + a_k^{(2)}z^{-1}}$$

Quasi-Linear Phase Design

To achieve a near-linear phase response for IIR halfband filters, make one of the branches a pure delay. In this design, the cost of the filter increases.

The allpass filters for the quasi-linear phase IIR halfband filter are

$$A_1(z) = z^{-k}$$

where k is the length of the delay.

$$A_2(z) = \prod_{k=1}^{K_2^{(1)}} \frac{a_k + z^{-1}}{1 + a_k z^{-1}} \prod_{k=1}^{K_2^{(2)}} \frac{c_k + b_k z^{-1} + z^{-2}}{1 + b_k z^{-1} + c_k z^{-2}}$$

where N is the order of the IIR halfband filter.

This figure represents filtering and downsampling the input by two.

Using the multirate noble identity for downsampling, you can move the downsampling operation before filtering. This change enables you to filter at the lower rate.

To implement the halfband decimator efficiently, `dsp.IIRHalfbandDecimator` replaces the delay block and downsampling operator with a commutator switch.

Analysis Filter Bank

The transfer function of the complementary highpass filter branch of the analysis filter bank is given by

$$G(z) = 0.5 * [A_1(z^2) - z^{-1}A_2(z^2)]$$

Graphically, you can represent the analysis filter bank as follows.

`dsp.IIRHalfbandDecimator` generates two power-complementary output signals by adding and subtracting the two polyphase branch outputs respectively.

To summarize, `dsp.IIRHalfbandDecimator`

- Decimates the input prior to filtering.
- Acts as an analysis filter bank.
- Has non-linear phase response and uses few coefficients with elliptic design method.

- Has near-linear phase response at the cost of additional coefficients with quasi-linear phase design method. One of the branches in this design is a pure delay.

dsp.IIRHalfbandInterpolator

Package: dsp

Interpolate by a factor of two using polyphase IIR

Description

The `dsp.IIRHalfbandInterpolator` System object performs efficient polyphase interpolation of the input signal by a factor of two. To design the halfband filter, you can specify the object to use an elliptic design or a quasi-linear phase design. The object uses these design methods to compute the filter coefficients. To filter the inputs, the object uses a polyphase structure. The allpass filters in the polyphase structure are in a minimum multiplier form.

Elliptic design introduces nonlinear phase and creates the filter using fewer coefficients than quasi linear design. Quasi-linear phase design overcomes phase nonlinearity at the cost of additional coefficients.

Alternatively, instead of designing the halfband filter using a design method, you can specify the filter coefficients directly. When you choose this option, the allpass filters in the two branches of the polyphase implementation can be in a minimum multiplier form or in a wave digital form.

You can also use `dsp.IIRHalfbandInterpolator` object to implement the synthesis portion of a two-band filter bank to synthesize a signal from lowpass and highpass subbands.

To upsample and interpolate your data:

- 1 Create the `dsp.IIRHalfbandInterpolator` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

Creation

Syntax

```
iirhalfbandinterp = dsp.IIRHalfbandInterpolator
iirhalfbandinterp = dsp.IIRHalfbandInterpolator(Name,Value)
```

Description

`iirhalfbandinterp = dsp.IIRHalfbandInterpolator` returns an IIR halfband interpolation filter, `iirhalfbandinterp`, with the default settings. Under the default settings, the System object upsamples and interpolates the input data using a halfband frequency of 22050 Hz, a transition width of 4100 Hz, and a stopband attenuation of 80 dB.

`iirhalfbandinterp = dsp.IIRHalfbandInterpolator(Name,Value)` returns an IIR halfband interpolator, with additional properties specified by one or more `Name, Value` pair arguments.

Example: `iirhalfbandinterp = dsp.IIRHalfbandInterpolator('Specification','Filter order and stopband`

`attenuation'`) creates an IIR halfband interpolator object with filter order set to 9 and stopband attenuation set to 80 dB.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects.

Specification — Filter design parameters

'Transition width and stopband attenuation' (default) | 'Filter order and stopband attenuation' | 'Filter order and transition width' | 'Coefficients'

Filter design parameters, specified as a character vector. When you set `Specification` to one of the filter design options, you can specify the filter design parameters using the corresponding `FilterOrder`, `StopbandAttenuation`, and `TransitionWidth` properties. Also, you can specify the design method using `DesignMethod`. When you set `Specification` to 'Coefficients', you can specify the coefficients directly.

FilterOrder — Order of the IIR halfband filter

9 (default) | positive scalar integer

Order of the IIR halfband filter, specified as a positive scalar integer. If you set `DesignMethod` to 'Elliptic', then `FilterOrder` must be an odd integer greater than one. If you set `DesignMethod` to 'Quasi-linear phase', then `FilterOrder` must be a multiple of four.

Dependencies

This property applies when you set `Specification` to 'Filter order and stopband attenuation' or 'Filter order and transition width'.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

StopbandAttenuation — Minimum attenuation needed in stopband

80 (default) | positive real scalar

Minimum attenuation needed in the stopband of the IIR halfband filter, specified as a positive real scalar. Units are in dB.

Dependencies

This property applies only when you set `Specification` to 'Filter order and stopband attenuation' or 'Transition width and stopband attenuation'.

Data Types: `single` | `double`

TransitionWidth — Transition width

4100 (default) | positive real scalar

Transition width of the IIR halfband filter, specified as a positive real scalar. Units are in Hz. The value of the transition width must be less than half the input sample rate.

Dependencies

This property applies only when you set `Specification` to 'Transition width and stopband attenuation' or 'Filter order and transition width'.

Data Types: `single` | `double`

DesignMethod — Design method

'Elliptic' (default) | 'Quasi-linear phase'

Design method for the IIR halfband filter, specified as 'Elliptic' or 'Quasi-linear phase'. When the property is set to 'Quasi-linear phase', the first branch of the polyphase structure is a pure delay, which results in an approximately linear phase response.

Dependencies

This property applies only when you set `Specification` to any accepted value except 'Coefficients'.

SampleRate — Input sample rate

44100 (default) | positive real scalar

Input sample rate, specified as a positive real scalar. Units are in Hz.

Dependencies

This property applies only when you set `Specification` to any accepted value except 'Coefficients'.

Data Types: `single` | `double`

FilterBankInputPort — Option to use object as synthesis filter bank

false (default) | true

Option to use object as synthesis filter bank, specified as a logical value. If this property is false, `dsp.IIRHalfbandInterpolator` acts as an interpolator. If this property is true, then `dsp.IIRHalfbandInterpolator` acts as a synthesis filter bank and the algorithm accepts two inputs: the lowpass and highpass subbands.

Dependencies

This property applies only when you set `Specification` to any accepted value except 'Coefficients'.

Structure — Filter structure used in coefficient mode

'Minimum multiplier' (default) | 'Wave Digital Filter'

Internal allpass filter implementation structure, specified as 'Minimum multiplier' or 'Wave Digital Filter'. Each structure uses a different coefficients set, independently stored in the corresponding object property.

This property is not tunable.

Dependencies

This property applies only when you set 'Specification' to 'Coefficients'.

AllpassCoefficients1 — Allpass polynomial filter coefficients of first branch

[0.1284563; 0.7906755] (default) | [0.1284563 0.1534; 0.7906755 0.6745]

Allpass polynomial filter coefficients of the first branch, specified as an N -by-1 or N -by-2 matrix. N is the number of first-order or second-order allpass sections.

Tunable: Yes

Dependencies

This property applies only when you set Specification to 'Coefficients' and Structure to 'Minimum multiplier'.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

AllpassCoefficients2 — Allpass polynomial filter coefficients of second branch

[0.4295667] (default) | [0.7906755 0.1534]

Allpass polynomial filter coefficients of the second branch, specified as an N -by-1 or N -by-2 matrix. N is the number of first-order or second-order allpass sections.

Tunable: Yes

Dependencies

This property applies only when you set Specification to 'Coefficients' and Structure to 'Minimum multiplier'.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

WDFCoefficients1 — Allpass filter coefficients of first branch in Wave Digital Filter form

[0.1284563; 0.7906755] (default) | [0.1284563 0.1534; 0.7906755 0.6745]

Allpass filter coefficients of the first branch in Wave Digital Filter form, specified as an N -by-1 or N -by-2 matrix. N is the number of first-order or second-order allpass sections. All elements must have an absolute value less than or equal to 1.

This property is not tunable.

Dependencies

This property applies only when you set Specification to 'Coefficients' and Structure to 'Wave Digital Filter'.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

WDFCoefficients2 — Allpass filter coefficients of second branch in Wave Digital Filter form

[0.4295667] (default) | [0.7906755 0.1534]

Allpass filter coefficients of the second branch in Wave Digital Filter form, specified as an N -by-1 or N -by-2 matrix. N is the number of first-order or second-order allpass sections. All elements must have an absolute value less than or equal to 1.

This property is not tunable.

Dependencies

This property applies only when you set Specification to 'Coefficients' and Structure to 'Wave Digital Filter'.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

HasPureDelayBranch — Make the first branch a pure delay

`false` (default) | `true`

Flag to make the first allpass branch a delay, specified as a logical scalar. When this property is true, the first branch is treated as a pure delay and the properties `AllpassCoefficients1` and `WDFCoefficients1` do not apply.

This property is not tunable.

Dependencies

This property applies only when you set `Specification` to `'Coefficients'`.

Delay — Length of the delay

1 (default) | finite positive scalar

Length of the first branch delay, specified as a finite positive scalar. The value of this property specifies the number of samples by which you can delay the input to the first branch.

This property is not tunable.

Dependencies

This property is applicable only when you set `'Specification'` to `'Coefficients'` and `HasPureDelayBranch` to 1.

Data Types: `single` | `double`

HasTrailingFirstOrderSection — Make the last section of the second branch as first order

`false` (default) | `true`

Option to treat the last section of the second branch as first order, specified as a logical scalar. When this property is 1 and the coefficients of the second branch are in an N -by-2 matrix, the object ignores the second element of the last row of the matrix. The last section of the second branch then becomes a first-order section. When this property is set to 0, the last section of the second branch is a second-order section. When the coefficients of the second branch are in an N -by-1 matrix, this property is ignored.

This property is not tunable.

Dependencies

This property applies only when you set `Specification` to `'Coefficients'`.

Usage

Syntax

```
y = iirhalfbandinterp(x1)
y = iirhalfbandinterp(x1,x2)
```

Description

`y = iirhalfbandinterp(x1)` upsamples by two and interpolates the input signal `x1` using the IIR halfband interpolator, `iirhalfbandinterp`.

`y = iirhalfbandinterp(x1,x2)` implements a halfband synthesis filter bank for the inputs `x1` and `x2`. `x1` is the lowpass output of a halfband analysis filter bank and `x2` is the highpass output of a halfband analysis filter bank. `dsp.IIRHalfbandInterpolator` implements a synthesis filter bank only when the `FilterBankInputPort` property is `true`.

Input Arguments

x1 — Data input

column vector | matrix

Data input to the IIR halfband interpolator, specified as a column vector or a matrix. This signal is the lowpass output of a halfband analysis filter bank. If the input signal is a matrix, each column of the matrix is treated as an independent channel.

Data Types: `single` | `double`

x2 — Second data input

column vector | matrix

Second data input to the synthesis filter bank, specified as a column vector or a matrix. This signal is the highpass output of a halfband analysis filter bank. If the input signal is a matrix, each column of the matrix is treated as an independent channel.

The size, data type, and complexity of both the inputs must be the same.

Data Types: `single` | `double`

Output Arguments

y — Output of interpolator

column vector | matrix

Output of the interpolator, returned as a column vector or a matrix. The number of rows in the interpolator output is twice the number of rows in the input signal.

Data Types: `single` | `double`

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Specific to `dsp.IIRHalfbandInterpolator`

Examples

Frequency response of Quasi-linear Phase IIR Halfband Interpolator

Create a minimum order lowpass IIR half-band interpolation filter for data sampled at 44.1 kHz. The filter has a transition width of 4.1 kHz, and a stopband attenuation of 80 dB.

```
IIRHalfbandInterp = dsp.IIRHalfbandInterpolator(...
    'DesignMethod', 'Quasi-linear phase');
```

Obtain filter coefficients

```
c = coeffs(IIRHalfbandInterp);
```

Plot the Magnitude and Phase response

```
fvtool(IIRHalfbandInterp, 'Analysis', 'freq')
```

Extract Low Frequency Subband from Speech

Use a halfband analysis filter bank and interpolation filter to extract the low frequency subband from a speech signal.

Note: If you are using R2016a or an earlier release, replace each call to the object with the equivalent `step` syntax. For example, `obj(x)` becomes `step(obj,x)`.

Note: The `audioDeviceWriter` System object™ is not supported in MATLAB Online.

Set up the audio file reader, the analysis filter bank, the audio device writer, and the interpolation filter. The sampling rate of the audio data is 22050 Hz. The halfband filter has an order of 21 and a transition width of 2 kHz.

```
afr = dsp.AudioFileReader('speech_dft.mp3','SamplesPerFrame',1024);
```

```
filterspec = 'Filter order and transition width';  
Order = 21;  
TW = 2000;
```

```
IIRHalfbandDecim = dsp.IIRHalfbandDecimator(...  
    'Specification',filterspec,'FilterOrder',Order,...  
    'TransitionWidth',TW,'SampleRate',afr.SampleRate);
```

```
IIRHalfbandInterp = dsp.IIRHalfbandInterpolator(...  
    'Specification',filterspec,'FilterOrder',Order,...  
    'TransitionWidth',TW,'SampleRate',afr.SampleRate/2);
```

```
ap = audioDeviceWriter('SampleRate',afr.SampleRate);
```

View the magnitude response of the halfband filter.

```
fvtool(IIRHalfbandDecim)
```

Read the speech signal from the audio file in frames of 1024 samples. Filter the speech signal into lowpass and highpass subbands with a halfband frequency of 5512.5 Hz. Reconstruct a lowpass approximation of the speech signal by interpolating the lowpass subband. Play the filtered output.

```
while ~isDone(afr)
    audioframe = afr();
    xlo = IIRHalfbandDecim(audioframe);
    ylow = IIRHalfbandInterp(xlo);
    ap(ylow);
end
```

Wait until the audio file ends, and then close the input file and release the audio output resource.

```
release(afr);
release(ap);
```

Two-Channel Filter Bank

Use a halfband decimator and interpolator to implement a two-channel filter bank. This example uses an audio file input and shows that the power spectrum of the filter bank output does not differ significantly from the input.

Note: If you are using R2016a or an earlier release, replace each call to the object with the equivalent step syntax. For example, `obj(x)` becomes `step(obj,x)`.

Note: The `audioDeviceWriter` System object™ is not supported in MATLAB Online.

Set up the audio file reader and audio device writer. Construct the IIR halfband decimator and interpolator. Finally, set up the spectrum analyzer to display the power spectra of the filter-bank input and output.

```
AF = dsp.AudioFileReader('speech_dft.mp3','SamplesPerFrame',1024);
AP = audioDeviceWriter('SampleRate',AF.SampleRate);

filterspec = 'Filter order and transition width';
Order = 51;
TW = 2000;

IIRHalfbandDecim = dsp.IIRHalfbandDecimator(...
    'Specification',filterspec,'FilterOrder',Order,...
    'TransitionWidth',TW,'SampleRate',AF.SampleRate);

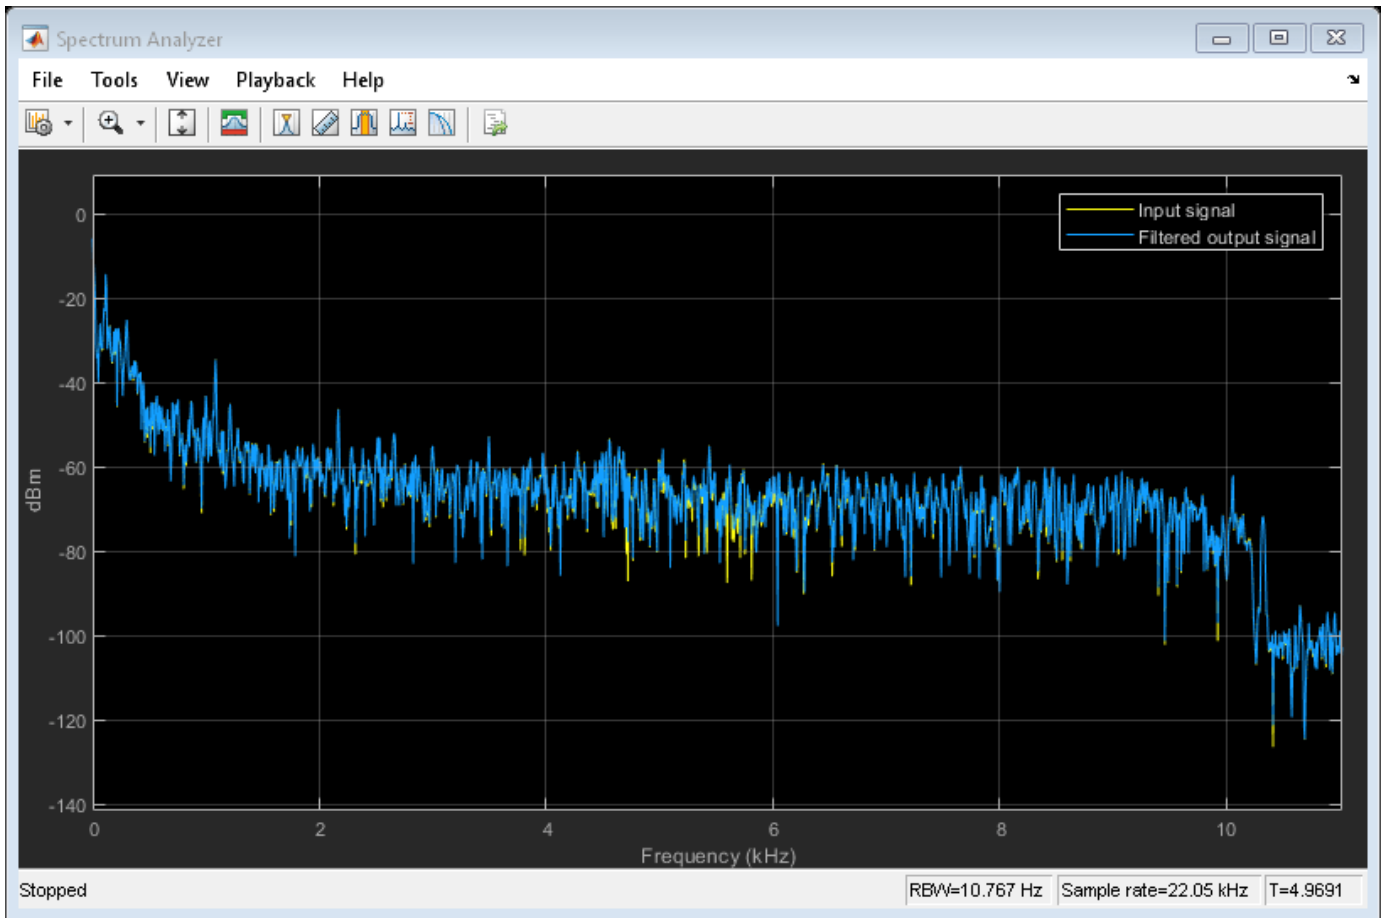

IIRHalfbandInterp = dsp.IIRHalfbandInterpolator(...
    'Specification',filterspec,'FilterOrder',Order,...
    'TransitionWidth',TW,'SampleRate',AF.SampleRate/2,...
    'FilterBankInputPort',true);

SpecAna = dsp.SpectrumAnalyzer('SampleRate',AF.SampleRate,...
    'PlotAsTwoSidedSpectrum',false,'ReducePlotRate',false,...
    'ShowLegend',true,...
    'ChannelNames',{'Input signal','Filtered output signal'});
```

Read the audio 1024 samples at a time. Filter the input to obtain the lowpass and highpass subband signals decimated by a factor of two. This is the analysis filter bank. Use the halfband interpolator as the synthesis filter bank. Display the running power spectrum of the audio input and the output of the synthesis filter bank. Play the output.

```
while ~isDone(AF)
    audioInput = AF();
    [xlo,xhigh] = IIRHalfbandDecim(audioInput);
    audioOutput = IIRHalfbandInterp(xlo,xhigh);
    spectrumInput = [audioInput audioOutput];
    SpecAna(spectrumInput);
    AP(audioOutput);
end

release(AF);
release(AP);
release(SpecAna);
```

Upsample and Interpolate Multichannel Input with IIR Halfband Interpolator

Note: This example runs only in R2016b or later. If you are using an earlier release, replace each call to the function with the equivalent `step` syntax. For example, `myObject(x)` becomes `step(myObject,x)`.

Create a half-band interpolation filter for data sampled at 44.1 kHz. The filter order is 51 with a transition width of 4.1 kHz. Use the filter to upsample and interpolate a multichannel input.

```
Fs = 44.1e3;
filterspec = 'Filter order and transition width';
Order = 51;
TW = 4.1e3;
iirhalfbandinterp = dsp.IIRHalfbandInterpolator(...
    'Specification',filterspec,...
    'FilterOrder',Order,...
    'TransitionWidth',TW,...
    'SampleRate',Fs);

x = randn(1024,4);
y = iirhalfbandinterp(x);
```

Algorithms

Polyphase Implementation with Halfband Filters

When you filter your signal, `dsp.IIRHalfbandInterpolator` uses an efficient polyphase implementation for halfband filters. You can use a polyphase implementation to move the upsampling operation after filtering. This change enables you to filter at the lower sampling rate.

IIR halfband filters are generally modeled using two parallel allpass filter branches.

$$H(z) = 0.5 * [A_1(z^2) + z^{-1}A_2(z^2)]$$

Elliptic Design

The allpass filters for elliptic IIR halfband filter are given as

$$A_1(z) = \prod_{k=1}^{K_1} \frac{a_k^{(1)} + z^{-1}}{1 + a_k^{(1)}z^{-1}}$$

$$A_2(z) = \prod_{k=1}^{K_2} \frac{a_k^{(2)} + z^{-1}}{1 + a_k^{(2)}z^{-1}}$$

Quasi-Linear Phase Design

A near-linear phase response for IIR halfband filters is achieved by making one of the branches a pure delay. In this design, the cost of the filter increases.

The allpass filters for quasi-linear phase IIR halfband filter are

$$A_1(z) = z^{-k}$$

where, k is the length of the delay.

$$A_2(z) = \prod_{K=1}^{K_2^{(1)}} \frac{a_k + z^{-1}}{1 + a_k z^{-1}} \prod_{K=1}^{K_2^{(2)}} \frac{c_k + b_k z^{-1} + z^{-2}}{1 + b_k z^{-1} + c_k z^{-2}}$$

where N is the order of the IIR halfband filter.

Graphically, you can represent upsampling by two followed by filtering with the following figure

Using the multirate noble identity for upsampling, you can move the upsampling operation after filtering. This enables you to filter at the lower rate.

To efficiently implement the halfband interpolator, `dsp.IIRHalfbandInterpolator` replaces the upsampling operator, delay block, and adder with a commutator switch. This is shown in the following figure:

The commutator switch takes input samples from the two branches alternately, one sample at a time. This doubles the sampling rate of the input signal.

Synthesis Filter Bank

Transfer function of the complementary high-pass filter branch of the synthesis filter bank is given by

$$G(z) = 0.5 * [A_1(z^2) - z^{-1}A_2(z^2)]$$

Graphically, you can represent the synthesis filter bank as

`dsp.IIRHalfbandInterpolator` to implement the synthesis portion of a two-band filter bank to synthesize a signal from lowpass and highpass subbands.

To summarize, `dsp.IIRHalfbandInterpolator`

- Filters the input before upsampling
- acts as a synthesis filter bank
- has non-linear phase response and uses few coefficients with elliptic design method

- has near-linear phase response at the cost of additional coefficients with quasi-linear phase design method. One of the branches in this design is a pure delay.

dsp.Interpolator

Package: dsp

(To be removed) Linear or polyphase FIR interpolation

Note dsp.Interpolator will be removed in a future release. Use dsp.FIRInterpolator, interp1 instead. For more information, see “Compatibility Considerations”.

Description

The dsp.Interpolator System object interpolates values between real-valued input samples using linear or polyphase FIR interpolation. Specify which values to interpolate by providing a vector of interpolation points. An interpolation point of 1 refers to the first sample in the input. To interpolate the value halfway between the second and third sample in the input, specify an interpolation point of 2.5. Interpolation points that are not within the valid range are replaced with the closest value in the valid range.

To interpolate a real-valued input signal:

- 1 Create the dsp.Interpolator object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

Creation

Syntax

```
interp = dsp.Interpolator  
interp = dsp.Interpolator(Name, Value)
```

Description

interp = dsp.Interpolator creates an interpolation System object, interp, to interpolate values between real-valued input samples using linear interpolation.

interp = dsp.Interpolator(Name, Value) creates an interpolation System object, interp, with each specified property set to the specified value. Enclose each property name in single quotes.

Example: `interp = dsp.Interpolator('InterpolationPointsSource', 'Input port')`

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects.

InterpolationPointsSource — Source of interpolation points

'Property' (default) | 'Input port'

Method to specify the interpolation points, specified as one of the following:

- 'Property' — Specify the interpolation points through the “InterpolationPoints” on page 4-0 property.
- 'Input port' — Pass the interpolation points as an input to the System object algorithm.

InterpolationPoints — Interpolation points

[1.1;4.8;2.67;1.6;3.2] (default) | vector | matrix | N -D array

Interpolation points, specified as a vector, matrix, or an N -D array. The valid range of the values in the interpolation vector is from 1 to the number of samples in each channel of the input. If you specify interpolation points outside the valid range, the object *clips* the point to the nearest point in the valid range. For example, if the input is [2;3.1;-2.1], the valid range of interpolation points is from 1 to 3. If you specify a [-1;1.5;2;2.5;3;3.5] vector of interpolation points, the interpolator object clips -1 to 1 and 3.5 to 3. This clipping results in the interpolation points [1 1.5 2 2.5 3 3].

For details on the dimension of the interpolation points array and how that influences the dimension of the output, see the tables in the “*ipts*” on page 4-0 input of the System object.

Tunable: Yes

Dependencies

This property applies only when you set the “InterpolationPointsSource” on page 4-0 property to 'Property'.

Method — Interpolation method

'Linear' (default) | 'FIR'

Interpolation method, specified as one of the following:

- 'Linear' -- The object interpolates data values by assuming that the data varies linearly between samples taken at adjacent sample times.
- 'FIR' -- The object uses polyphase interpolation to replace filtering (convolution) at the upsampled rate with a series of convolutions at the lower rate. If the input has insufficient low-rate samples to perform FIR interpolation, the interpolator object performs linear interpolation. For more details, see the “FilterHalfLength” on page 4-0 property.

FilterHalfLength — Half-length of interpolation filter

3 (default) | integer scalar greater than 0

For a filter half-length of P , the polyphase FIR subfilters have length $2P$. FIR interpolation always requires $2P$ low-rate samples for every interpolation point.

- If the interpolation point does not correspond to a low-rate sample, FIR interpolation requires P low-rate samples below and P low-rate samples above the interpolation point.
- If the interpolation point corresponds to a low-rate sample, the $2P$ -sample requirement includes the low-rate sample.

- If the input has less than $2P$ neighboring low-rate samples, the interpolator object uses linear interpolation.

For example, for an input [1 4 1 4 1 4 1 4], upsampling by a factor of 4 results in equally spaced interpolation points, `InterP = [1:0.25:8]`. The points `InterP(9:12)` are [3.0 3.25 3.5 3.75]. If you set `FilterHalfLength` to 2, interpolating at these points uses the 4 low-rate samples from the input with indices (2,3,4,5). If you set `FilterHalfLength` to 4, the interpolator object uses linear interpolation, because the input does not have enough low-rate samples to perform FIR interpolation.

The longer the `FilterHalfLength` property, the better the quality of the interpolation. However, increasing the filter half-length increases computation time and requires more low-rate samples below and above the interpolation point. In general, setting the `FilterHalfLength` property between 4 and 6 provides a reasonably accurate interpolation.

Dependencies

This property applies only when you set the “Method” on page 4-0 property to 'FIR'.

InterpolationPointsPerSample — Upsampling factor

3 (default) | integer scalar greater than 0

Upsampling factor, specified as an integer scalar greater than 0. An upsampling factor of L inserts $L - 1$ zeros between low-rate samples. Interpolation results from filtering the upsampled sequence with a lowpass anti-imaging filter. The interpolator object uses a polyphase FIR implementation with `InterpolationPointsPerSample` subfilters of length $2P$, where P is the value you specify in the “FilterHalfLength” on page 4-0 property. For nL low-rate samples in the upsampled input, where $n=1,2,\dots$, the interpolator object uses exactly one of the `InterpolationPointsPerSample` subfilters to interpolate at the points $nL+i/L$, where $i = 0, 1, 2, \dots, L - 1$.

If you specify interpolation points that do not correspond to a polyphase subfilter, the object rounds the point down to the nearest interpolation point associated with a polyphase subfilter. Suppose you set the `InterpolationPointsPerSample` property to 4 and interpolate at the points [3 3.2 3.4 3.6 3.8]. The interpolator object uses the first polyphase subfilter for the points [3.0 3.2], the second subfilter for the point 3.4, the third subfilter for the point 3.6, and the fourth subfilter for the point 3.8.

Dependencies

This property applies only when you set the “Method” on page 4-0 property to 'FIR'.

Bandwidth — Normalized input bandwidth

0.5 (default) | real scalar greater than 0 and less than or equal to 1

Bandwidth to which the interpolated output samples must be constrained, specified as a real scalar greater than 0 and less than or equal to 1. A value of 1 equals the Nyquist frequency, or half the sampling frequency, F_s . Use this property to take advantage of the bandlimited frequency content of the input. For example, if the input signal does not have frequency content above $F_s/4$, you can specify a value of 0.5 for the `Bandwidth` property.

Dependencies

This property applies only when you set the “Method” on page 4-0 property to 'FIR'.

Usage

Syntax

```
interpOut = interp(input)
interpOut = interp(input, ipts)
```

Description

`interpOut = interp(input)` outputs the interpolated sequence, `interpOut`, of the input vector or matrix `input`, as specified in the “InterpolationPoints” on page 4-0 property. Each column of `input` is treated as an independent channel of the input.

`interpOut = interp(input, ipts)` outputs the interpolated sequence as specified by `ipts`.

To specify the interpolation points, set the “InterpolationPointsSource” on page 4-0 property to ‘Input port’.

```
t = 0:.0001:.0511;
x = sin(2*pi*20*t);
x1 = x(1:50:end);
ipts = 1:0.1:length(x1);
interp = dsp.Interpolator('InterpolationPointsSource', 'Input port');
interpOut = interp(x1', ipts');
```

Input Arguments

input — Data input

vector | matrix | N -D array

Input that is interpolated by the object, specified as a vector, matrix, or N -D array.

Example: `t = 0:0.0001:0.0511; input = sin(2*pi*20*t);`

Data Types: `single` | `double`

ipts — Interpolation points

vector | matrix | N -D array

Interpolation array I_{pts} , specified as a vector, matrix, or N -D array. The interpolation array represents the points in time at which to interpolate values of the input signal. An entry of 1 in I_{pts} refers to the first sample of the input, an entry of 2.5 refers to the sample halfway between the second and third input sample, and so on. In most cases, when I_{pts} is a vector, it can be of any length.

Valid values in the interpolation array I_{pts} range from 1 to the number of samples in each channel of the input. For instance, given a length-5 input vector D , all entries of I_{pts} must range from 1 to 5. I_{pts} cannot contain entries such as 7 or -9, because D does not have a seventh or ninth entry.

The algorithm replaces any out-of-range values in I_{pts} with the closest value in the valid range (from 1 to the number of input samples). Then it performs the interpolation using the clipped version of I_{pts} .

Consider the following input data and interpolation points vector:

- `D = [11 22 33 44]'`

- $I_{pts} = [10 \ 2.6 \ -3]'$

Because D has four samples, valid interpolation points range from 1 to 4. The algorithm clips interpolation point 10 down to 4 and the point -3 up to 1. The result is the clipped interpolation vector $I_{ptsClipped} = [4 \ 2.6 \ 1]'$.

Depending on the dimension of the input and the dimension of I_{pts} , the algorithm applies I_{pts} to the input in one of the following ways:

- If I_{pts} is an array, the object applies I_{pts} across the first dimension of an N -D array, resulting in an N -D array output.
- If I_{pts} is a vector, the object applies I_{pts} to each input vector (as if the input vector were a single channel), resulting in a vector output with the same orientation as the input (row or column).

The following tables summarize how the object applies the interpolation array I_{pts} to all the possible types of inputs. The table also shows the resulting output dimensions.

This table describes the behavior when `InterpolationPointsSource` is set to 'Property'.

Input Dimensions	Valid Dimensions of Interpolation Array I_{pts}	How Object Applies I_{pts} to Input	Output Dimensions
M -by- N -by- K matrix	P -by-1 column	Applies I_{pts} to the first dimension of the input	P -by- N -by- K array
	P -by- N -by- K matrix	Applies each column element of I_{pts} to the corresponding column of the input matrix	P -by- N -by- K array
M -by- N matrix	1-by- N row	Applies each column element of I_{pts} to the corresponding column of the input matrix	1-by- N row
	P -by-1 column	Applies I_{pts} to each input column	P -by- N matrix
	P -by- N matrix	Applies the columns of I_{pts} to the corresponding columns of the input matrix	
M -by-1 column	1-by- P row (the algorithm treats I_{pts} as a column)	Applies I_{pts} to the input column	P -by-1 column
	P -by-1 column		
1-by- N row (not recommended)	1-by- N row	Not applicable. Object copies input vector.	1-by- N row, a copy of the input vector
	P -by-1 column		P -by- N matrix, where each row is a copy of the input vector
	P -by- N matrix		

This table describes the behavior when `InterpolationPointsSource` is set to 'Input port'.

Input Dimensions	Valid Dimensions of Interpolation Array I_{pts}	How Object Applies I_{pts} to Input	Output Dimensions
M -by- N -by- K matrix	Column vector of length P	Applies I_{pts} to the first dimension of the input	P -by- N -by- K array
	P -by- N -by- K matrix	Applies each column element of I_{pts} to the corresponding column of the input matrix	P -by- N -by- K array
M -by- N matrix	1-by- N row	Applies each column element of I_{pts} to the corresponding column of the input matrix	1-by- N row
	P -by-1 column	Applies I_{pts} to each input column	P -by- N matrix
	P -by- N matrix	Applies the columns of I_{pts} to the corresponding columns of the input matrix	
M -by-1 column	1-by- P row	Applies I_{pts} to the input column	P -by-1 column
	P -by-1 column		
1-by- N row (not recommended)	1-by- N row	Not applicable. Object copies input vector.	1-by- N row, a copy of the input vector
	P -by-1 column		P -by- N matrix, where each row is a copy of the input vector
	P -by- N matrix		

Example: `ipts = [1:10];`

Data Types: `single` | `double`

Output Arguments

interpOut – Interpolated sequence

vector | matrix | N -D array

Interpolated sequence, returned as a vector, matrix, or N -D array. The dimension of the output depends on the dimensions of the input and the interpolation points array. For more details on the dimensions, see the tables in “`ipts`” on page 4-0 .

Data Types: `single` | `double`

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Common to All System Objects

step	Run System object algorithm
release	Release resources and allow changes to System object property values and input characteristics
reset	Reset internal states of System object

Examples

Interpolate a Sum of Sinusoids

Note If you are using R2016a or an earlier release, replace each call to the object with the equivalent step syntax. For example, `obj(x)` becomes `step(obj,x)`.

Interpolate a sum of sinusoids with FIR interpolation, and with 'Input port' as the source of interpolation points.

```

Fs = 1000;
t = 0:(1/Fs):0.1-(1/Fs);
x = cos(2*pi*50*t)+0.5*sin(2*pi*100*t);
x1 = x(1:4:end);
I = 1:(1/4):length(x1);
interp = dsp.Interpolator('Method','FIR',...
'FilterHalfLength',3,'InterpolationPointsSource','Input Port');
y = interp(x1,I);
stem(I,y,'r');
hold on;
axis([0 25 -2 2]);
stem(x1,'b','linewidth',2);
legend('Interpolated Signal','Original',...
'Location','Northeast');

```

Algorithms

Linear Interpolation Mode

In the linear interpolation mode, the algorithm interpolates data values by assuming that the data varies linearly between samples taken at adjacent sample times.

Suppose the input signal is $D = [1 \ 2 \ 1.5 \ 3 \ 0.25]'$. The left plot shows the samples in D and the right plot shows the linearly interpolated values between the samples in D .

When the interpolation points are out of range, the algorithm clips the invalid interpolation points. Consider an input signal, $D = [1 \ 2 \ 1.5 \ 3 \ 0.25]'$, and an interpolation vector, $I_{pts} = [-4 \ 2.7 \ 4.3 \ 10]'$. The interpolated output is given by $[1 \ 1.65 \ 2.175 \ 0.25]'$.

Interpolated Values of D at Clipped Interpolation Points

FIR Interpolation Mode

In the FIR interpolation mode, the algorithm interpolates data values using an FIR interpolation filter. The FIR filter is implemented using a polyphase structure. A polyphase implementation *splits* the lowpass FIR filter impulse response into a number of different subfilters.

Let L represent the number of interpolation points per sample, or the upsampling factor. Let P represent the half length of the polyphase subfilters. Indexing from zero, if $h(n)$ is the impulse response of the FIR filter, the k th subfilter is:

$$h_k(n) = h(k + nL) \quad k = 0, 1, \dots, L - 1 \quad n = 0, 1, \dots, 2P - 1$$

The table describes the decomposition of an 18-coefficient FIR filter into 3 polyphase subfilters of length 6, the defaults for the FIR interpolator object.

Coefficients	Polyphase Subfilter
$h(0), h(3), h(6), \dots, h(15)$	$h_0(n)$
$h(1), h(4), h(7), \dots, h(16)$	$h_1(n)$
$h(2), h(5), h(8), \dots, h(17)$	$h_2(n)$

An upsampling factor of L inserts $L - 1$ zeros between low-rate samples. Interpolation results from filtering the upsampled sequence with a lowpass anti-imaging filter.

Compatibility Considerations

dsp.Interpolator System object will be removed

Warns starting in R2021b

dsp.Interpolator System object will be removed in a future release. Use dsp.FIRInterpolator, interp1 instead.

Update Code

This table shows how the System object is typically used and explains how to update existing code to use the replacement features.

Discouraged Usage	Replacement using dsp.FIRInterpolator
<p>Linear interpolation</p> <p>Set up the input signal.</p> <pre>n = 0:11; x = sin(2*pi*n/length(n));</pre> <p>Create the dsp.Interpolator object and pass the input signal to the object.</p> <pre>L = 10; t = (n(1):1/L:n(end)+1-1/L)+1/L; interpolator = dsp.Interpolator('Interpolator', 't'); y = interpolator(x');</pre> <p>If you are using a release prior to R2016b, replace interpolator(x) with step(interpolator,x) and firInterpolator(x) with step(firInterpolator,x).</p>	<p>Linear interpolation</p> <p>Create a triangle interpolation filter. This filter yields a linear interpolation template. dsp.KalmanFilter

Package: dsp

(To be removed) Estimate system measurements and states using Kalman filter

Note `dsp.KalmanFilter` will be removed in a future release. Use the Kalman filter functionality in Sensor Fusion and Tracking Toolbox™ instead.

Description

The `dsp.KalmanFilter` System object is an estimator used to recursively obtain a solution for linear optimal filtering. This estimation is made without precise knowledge of the underlying dynamic system. The Kalman filter implements the following linear discrete-time process with state, x , at the k^{th} time-step: $x(k) = Ax(k-1) + Bu(k-1) + w(k-1)$ (state equation). This measurement, z , is given as: $z(k) = Hx(k) + v(k)$ (measurement equation).

The Kalman filter algorithm computes the following two steps recursively:

- Prediction: Process parameters x (state) and P (state error covariance) are estimated using the previous state.
- Correction: The state and error covariance are corrected using the current measurement.

To filter each channel of the input:

- 1 Create the `dsp.KalmanFilter` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

Creation

Syntax

```
kalman = dsp.KalmanFilter
kalman = dsp.KalmanFilter(STMatrix, MMatrix, PNCovariance, MNCovariance,
CIMatrix)
kalman = dsp.KalmanFilter(Name,Value)
```

Description

`kalman = dsp.KalmanFilter` returns the Kalman filter System object, `kalman`, with default values for the parameters.

`kalman = dsp.KalmanFilter(STMatrix, MMatrix, PNCovariance, MNCovariance, CIMatrix)` returns a Kalman filter System object, `kalman`. The `StateTransitionMatrix` property is set to `STMatrix`, the `MeasurementMatrix` property is set to `MMatrix`, the `ProcessNoiseCovariance` property is set to `PNCovariance`, the

MeasurementNoiseCovariance property is set to MNCovariance, and the ControlInputMatrix property is set to CIMatrix.

`kalman = dsp.KalmanFilter(Name, Value)` returns an Kalman filter System object, `kalman`, with each property set to the specified value. Enclose each property name in single quotes. Unspecified properties have default values.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects.

StateTransitionMatrix — Model of state transition

1 (default) | scalar | square matrix

Specify A in the state equation that relates the state at the previous time step to the state at current time step. A is a square matrix with each dimension equal to the number of states.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

ControlInputMatrix — Model of relation between control input and states

1 (default) | column vector

Specify B in the state equation that relates the control input to the state. B is a column vector with a number of rows equal to the number of states.

Dependencies

This property is activated only when the `ControlInputPort` property value is `true`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

MeasurementMatrix — Model of relation between states and measurement output

1 (default) | row vector

Specify H in the measurement equation that relates the states to the measurements. H is a row vector with a number of columns equal to the number of measurements.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

ProcessNoiseCovariance — Covariance of process noise

0.1 (default) | scalar | square matrix

Specify Q as a square matrix with each dimension equal to the number of states. Q is the covariance of the white Gaussian process noise, w , in the state equation.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

MeasurementNoiseCovariance — Covariance of measurement noise

0.1 (default) | scalar | square matrix

Specify R as a square matrix with each dimension equal to the number of states. R is the covariance of the white Gaussian process noise, v , in the measurement equation.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

InitialStateEstimate — Initial value for states

0 (default) | scalar | column vector

Specify an initial estimate of the states of the model as a column vector with length equal to the number of states.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

InitialErrorCovarianceEstimate — Initial value for state error covariance

0.1 (default) | scalar | square matrix

Specify an initial estimate for covariance of the state error, as a square matrix with each dimension equal to the number of states.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

DisableCorrection — Disable port for filters

false (default) | true

Specify as a scalar logical value, disabling System object filters from performing the correction step after the prediction step in the Kalman filter algorithm.

ControlInputPort — Presence of a control input

true (default) | false

Specify if the control input is present, using a scalar logical value. The default value is true.

Usage

Syntax

```
[zEst, xEst, MSE_Est, zPred, xPred, MSE_Pred] = kalman(z,u)
```

Description

`[zEst, xEst, MSE_Est, zPred, xPred, MSE_Pred] = kalman(z,u)` carries out the iterative Kalman filter algorithm over measurements z and control inputs u . The columns in z and u are treated as inputs to separate parallel filters, whose correction (or update) step can be disabled by the `DisableCorrection` property. The values returned are estimated measurements `zEst`, estimated states `xEst`, MSE of estimated states `MSE_Est`, predicted measurements `zPred`, predicted states `xPred`, and MSE of predicted states `MSE_Pred`.

Input Arguments

z — Measurement input

vector | matrix

Measurement input, specified as a vector or a matrix.

The ratio of the number of rows of the measurement input to the number of rows of the `MeasurementMatrix` property must be equal to the ratio of the number of rows of the control input to the number of columns of the `ControlInputMatrix` property.

The measurement signal can be a variable-size input. Once the object is locked, you can change the size of each input channel, but the number of channels cannot change.

Data Types: `single` | `double`

u — Control input

vector | matrix

Control input, specified as a vector or a matrix.

The ratio of the number of rows of the control input to the number of columns of the `ControlInputMatrix` property must be equal to the ratio of the number of rows of the measurement input to the number of rows of the `MeasurementMatrix` property.

The control signal can be a variable-size input. Once the object is locked, you can change the size of each input channel, but the number of channels cannot change.

Data Types: `single` | `double`

Output Arguments

zEst — Estimated measurements

vector | matrix

Estimated measurements, returned as a vector or matrix.

Data Types: `single` | `double`

xEst — Estimated state

vector | matrix

Estimated state, returned as a vector or matrix.

Data Types: `single` | `double`

MSE_Est — MSE of estimated states

scalar | column vector

Mean-squared error of estimated states, returned as a scalar or column vector. If the input is a row vector, the MSE of the estimated states is a scalar.

Data Types: `single` | `double`

zPred — Predicted measurements

vector | matrix

Predicted measurements, returned as a vector or a matrix.

Data Types: `single` | `double`

xPred — Predicted states

vector | matrix

Predicted states, returned as a vector or a matrix.

Data Types: `single` | `double`

MSE_Pred — MSE of predicted states

scalar | column vector

Mean-squared error of predicted states, returned as a scalar or a column vector. If the input is a row vector, the MSE of the estimated states is a scalar.

Data Types: `single` | `double`

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Common to All System Objects

`step` Run System object algorithm

`release` Release resources and allow changes to System object property values and input characteristics

`reset` Reset internal states of System object

Examples

Estimate Changing Scalar

Note: If you are using R2016a or an earlier release, replace each call to the object with the equivalent `step` syntax. For example, `obj(x)` becomes `step(obj,x)`.

Create the System objects for the changing scalar input, the Kalman filter, and the scope (for plotting).

```
numSamples = 4000;
R = 0.02;
src = dsp.SignalSource;
src.Signal = [ones(numSamples/4,1); -3*ones(numSamples/4,1); ...
    4*ones(numSamples/4,1); -0.5*ones(numSamples/4,1)];
tScope = timescope('NumInputPorts',3,...
    'TimeSpanSource','Property','TimeSpan',numSamples, ...
    'TimeUnits','Seconds','YLimits',[-5 5], ...
    'ShowLegend',true); % Create the Time Scope
kalman = dsp.KalmanFilter('ProcessNoiseCovariance', 0.0001,...
    'MeasurementNoiseCovariance',R,...
    'InitialStateEstimate',5,...
    'InitialErrorCovarianceEstimate',1,...
    'ControlInputPort',false); %Create Kalman filter
```

Add noise to the scalar, and pass the result to the Kalman filter. Stream the data, and plot the filtered signal.

```
while(~isDone(src))
    trueVal = src();
    noisyVal = trueVal + sqrt(R)*randn;
```

```
    estVal = kalman(noisyVal);  
    tScope(noisyVal,trueVal,estVal);  
end
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the Kalman Filter block reference page. The object properties correspond to the block parameters.

Compatibility Considerations

dsp.KalmanFilter System object will be removed

Warns starting in R2021b

dsp.KalmanFilter System object will be removed in a future release. Use the Kalman filter functionality in the Sensor Fusion and Tracking Toolbox instead.

Blocks

Kalman Filter

Introduced in R2013b

dsp.LDLFactor

Package: dsp

(To be removed) Factor square Hermitian positive definite matrices into components

Note dsp.LDLFactor will be removed in a future release. Use `ldl` instead. For more information, see “Compatibility Considerations”.

Description

The LDLFactor object factors square Hermitian positive definite matrices into lower, upper, and diagonal components. The object uses only the lower triangle of S.

To factor these matrices into lower, upper, and diagonal components:

- 1 Define and set up your LDL factor object. See “Construction” on page 4-862.
- 2 Call `step` to factor the matrices according to the properties of dsp.LDLFactor. The behavior of `step` is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj, x)` and `y = obj(x)` perform equivalent operations.

Construction

`ldl = dsp.LDLFactor` returns an LDL factor System object, `ldl`, that computes unit lower triangular L and diagonal D such that $S = LDL$ for square, symmetric/Hermitian, positive definite input matrix S.

`ldl = dsp.LDLFactor('PropertyName', PropertyValue, ...)` returns an LDL factor System object, `ldl`, with each specified property set to the specified value.

Properties

Fixed-Point Properties

AccumulatorDataType

Accumulator word and fraction lengths

Specify the accumulator fixed-point data type as `Full` precision, `Same as input`, `Same as product` or `Custom`. The default is `Full` precision

CustomAccumulatorDataType

Accumulator word and fraction lengths

Specify the accumulator fixed-point type as a scaled `numericType` object with a `Signedness` of `Auto`. This property applies when you set the `AccumulatorDataType` property to `Custom`. The default is `numericType([], 32, 30)`.

CustomIntermediateProductDataType

Intermediate product word and fraction lengths

Specify the intermediate product fixed-point type as a signed, scaled `numericType` object. This property applies when you set the `IntermediateProductDataType` property to `Custom`. The default is `numericType(true, 16, 15)`.

CustomOutputDataType

Output word and fraction lengths

Specify the output fixed-point type as a scaled `numericType` object with a `Signedness` of `Auto`. This property applies when you set the `OutputDataType` property to `Custom`. The default is `numericType([], 16, 15)`.

CustomProductDataType

Product word and fraction lengths

Specify the product fixed-point type as a scaled `numericType` object with a `Signedness` of `Auto`. This property applies when you set the `ProductDataType` property to `Custom`. The default is `numericType([], 32, 30)`.

IntermediateProductDataType

Intermediate product word and fraction lengths

Specify the intermediate product fixed-point data type as `Same as input` or `Custom`. The default is `Same as input`.

OutputDataType

Output word and fraction lengths

Specify the output fixed-point data type as `Same as input` or `Custom`. The default is `Same as input`.

OverflowAction

Overflow action for fixed-point operations

Specify the overflow action as one of `Wrap` or `Saturate`. The default is `Wrap`.

ProductDataType

Product word and fraction lengths

Specify the product fixed-point data type as `Full precision`, `Same as input` or `Custom`. The default is `Full precision`.

RoundingMethod

Rounding method for fixed-point operations

Specify the rounding method as: Ceiling, Convergent, Floor, Nearest, Round, Simplest or Zero. The default is Floor.

Methods

step Decompose matrix into components

Common to All System Objects

release	Allow System object property value changes
---------	--

Examples

Decompose a Matrix

Note If you are using R2016a or an earlier release, replace each call to the object with the equivalent step syntax. For example, `obj(x)` becomes `step(obj,x)`.

Decompose a square Hermitian positive definite matrix using LDL factor.

```
A = gallery('randcorr',5);
ldl = dsp.LDLFactor;
y = ldl(A)
```

```
y = 5x5
    1.0000    -0.3884     0.0296    -0.6152    -0.3903
   -0.3884     0.8491    -0.6386    -0.4901     0.3137
    0.0296    -0.6386     0.6529     0.3611     0.5770
   -0.6152    -0.4901     0.3611     0.3324     0.5660
   -0.3903     0.3137     0.5770     0.5660     0.4403
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the LDL Factorization block reference page. The object properties correspond to the block parameters, except: No object property that corresponds to the **Non-positive definite input** block parameter. The object does not issue any alerts for nonpositive definite inputs. The output is not a valid factorization. A partial factorization is in the upper left corner of the output.

Compatibility Considerations

dsp.LDLFactor System object will be removed

Warns starting in R2021b

`dsp.LDLFactor` System object will be removed in a future release. Use the `ldl` function instead.

Update Code

This table shows how the System object is typically used and explains how to update existing code to use the `ldl` function.

Discouraged Usage	Recommended Replacement

Usage notes and limitations:

See “System Objects in MATLAB Code Generation” (MATLAB Coder).

See Also

`ldl`

Introduced in R2012a

step

System object: dsp.LDLFactor

Package: dsp

Decompose matrix into components

Syntax

```
Y = step(ldl,S)
```

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(ldl,S)` decomposes the matrix `S` into lower, upper, and diagonal components. The output `Y` is a composite matrix with the `L` as its lower triangular part and `D` as the diagonal and `L'` as its upper triangular part. If `S` is not positive definite the output `Y` is not a valid factorization.

Note `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

dsp.LevinsonSolver

Package: dsp

(To be removed) Solve linear system of equations using Levinson-Durbin recursion

Note dsp.LevinsonSolver will be removed in a future release. Use levinson instead. For more information, see “Compatibility Considerations”.

Description

The LevinsonSolver object solves linear systems of equations using Levinson-Durbin recursion.

To solve linear systems of equations using Levinson-Durbin recursion:

- 1 Define and set up your System object. See “Construction” on page 4-867.
- 2 Call step to solve the system of equations according to the properties of dsp.LevinsonSolver. The behavior of step is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, $y = \text{step}(\text{obj}, x)$ and $y = \text{obj}(x)$ perform equivalent operations.

Construction

levinson = dsp.LevinsonSolver returns a System object, levinson, that solves a Hermitian Toeplitz system of equations using the Levinson-Durbin recursion.

levinson = dsp.LevinsonSolver('PropertyName', PropertyValue, ...) returns a Levinson-Durbin object, levinson, with each specified property set to the specified value.

Properties

AOutputPort

Enable polynomial coefficients output

Set this property to true to output the polynomial coefficients A . Both AOutputPort and KOutputPort properties cannot be false at the same time. For scalar inputs, set the AOutputPort property to true. The default is false.

KOutputPort

Enable reflection coefficients output

Set this property to true to output the reflection coefficients K . You cannot set both the AOutputPort and KOutputPort properties to false at the same time. For scalar inputs, you must set the KOutputPort property to false. The default is true.

PredictionErrorOutputPort

Enable prediction error output

Set this property to `true` to output the prediction error. The default is `false`.

ZerothLagZeroAction

Action when value of lag zero is zero

Specify the output for an input with the first coefficient as zero. Select `Ignore` or `Use zeros`. The default is `Use zeros`.

Fixed-Point Properties**RoundingMethod**

Rounding method for fixed-point operations

Specify the rounding method as `Ceiling`, `Convergent`, `Floor`, `Nearest`, `Round`, `Simplest`, or `Zero`. The default is `Floor`.

OverflowAction

Overflow action for fixed-point operations

Specify the overflow action as `Wrap`, `Saturate`. The default is `Wrap`.

ACoefficientDataType

A coefficient word and fraction lengths

This constant property has a value of `Custom`.

CustomACoefficientDataType

A coefficient word and fraction lengths

Specify the A coefficient fixed-point type as a scaled `numericType` object with a `Signedness` of `Auto`. The default is `numericType([], 16, 15)`.

KCoefficientDataType

K coefficient word and fraction lengths

This constant property has a value of `Custom`.

CustomKCoefficientDataType

K coefficient word and fraction lengths

Specify the K coefficient fixed-point type as a scaled `numericType` object with a `Signedness` of `Auto`. The default is `numericType([], 16, 15)`.

PredictionErrorDataType

Prediction error power word and fraction lengths

Specify the prediction error power fixed-point data type as `Same as input` or `Custom`. The default is `Same as input`.

CustomPredictionErrorDataType

Prediction error power word and fraction lengths

Specify the prediction error power fixed-point type as a scaled `numericType` object with a `Signedness` of `Auto`. This property applies only when the `PredictionErrorDataType` property is `Custom`. The default is `numericType([], 16, 15)`.

ProductDataType

Product word and fraction lengths

Specify the product fixed-point data type as `Same as input` or `Custom`. The default is `Custom`

CustomProductDataType

Product word and fraction lengths

Specify the product fixed-point type as a scaled `numericType` object with a `Signedness` of `Auto`. This property applies only when the `ProductDataType` property is `Custom`. The default is `numericType([], 32, 30)`.

AccumulatorDataType

Accumulator word and fraction lengths

Specify the Accumulator fixed-point data type as `Same as input`, `Same as product`, or `Custom`. The default is `Custom`.

CustomAccumulatorDataType

Accumulator word and fraction lengths

Specify the accumulator fixed-point type as a scaled `numericType` object with a `Signedness` of `Auto`. This property applies only when the `AccumulatorDataType` property is `Custom`. The default is `numericType([], 32, 30)`.

Methods

`step` Reflection coefficients corresponding to columns of input

Common to All System Objects	
<code>release</code>	Allow System object property value changes

Examples

Compute Polynomial Coefficients

Note If you are using R2016a or an earlier release, replace each call to the object with the equivalent step syntax. For example, `obj(x)` becomes `step(obj,x)`.

Use the Levinson solver to compute polynomial coefficients from autocorrelation coefficients.

```
lev = dsp.LevinsonSolver;
lev.AOutputPort = true;
lev.KOutputPort = false;
x = (1:100)';
a = xcorr(x,10);
% Consider the autocorrelation computed over nonnegative lags [0 10].
c = lev(a(11:end)); % Compute polynomial coefficients
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the Levinson-Durbin block reference page. The object properties correspond to the block parameters, except:

Output(s) block parameter corresponds to the AOutputPort and the KOutputPort object properties.

Compatibility Considerations

dsp.LevinsonSolver System object will be removed

Warns starting in R2021b

`dsp.LevinsonSolver` System object will be removed in a future release. Use the `levinson` function instead.

Update Code

This table shows how the System object is typically used and explains how to update existing code to use the `levinson` function.

Discouraged Usage	Recommended Replacement
<pre>lev = dsp.LevinsonSolver; lev.AOutputPort = true; lev.KOutputPort = false; x = (1:100)';</pre> <p>Autocorrelation is computed over the lags [-10 10].</p> <pre>a = xcorr(x,10);</pre> <p>Consider the autocorrelation computed over nonnegative lags [0 10].</p> <pre>c = lev(a(11:end));</pre> <pre>c = 10x1 1.0000 -0.9920 0.0001 0.0001 0.0001 0.0001 0.0001 0.0001 0.0001 0.0001 0.0001 0.0070</pre> <p>If you are using a release prior to R2016b, replace <code>lev(x)</code> with <code>step(lev,x)</code>.</p>	<p>Polynomial coefficients returned by the function are in the form of a row vector.</p> <pre>cfn = levinson(a(11:end))</pre> <pre>cfn = 1x10 1.0000 -0.9920 0.0001 0.0001 0.0001 0.0001 0.0001... 0.0001 0.0001 0.0001 0.0001 0.0070</pre>

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

See “System Objects in MATLAB Code Generation” (MATLAB Coder).

See Also

levinson

Introduced in R2012a

step

System object: dsp.LevinsonSolver

Package: dsp

Reflection coefficients corresponding to columns of input

Syntax

```
K = step(levinson,X)
A = step(levinson,X)
[A, K] = step(levinson,X)
[... , P] = step(levinson,X)
```

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`K = step(levinson,X)` returns reflection coefficients `K` corresponding to the columns of input `X`. `X` is typically a column or matrix of autocorrelation coefficients with lag θ as the first element.

`A = step(levinson,X)` returns polynomial coefficients `A` when the `AOutputPort` property is `true` and the `KOutputPort` property is `false`.

`[A, K] = step(levinson,X)` returns polynomial coefficients `A` and reflection coefficients `K` when both the `AOutputPort` and `KOutputPort` properties are `true`.

`[... , P] = step(levinson,X)` also returns the error power `P` when the `PredictionErrorOutputPort` property is `true`.

Note `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

dsp.LMSFilter

Package: dsp

Compute output, error, and weights of LMS adaptive filter

Description

The `dsp.LMSFilter` System object implements an adaptive finite impulse response (FIR) filter that converges an input signal to the desired signal using one of the following algorithms:

- LMS
- Normalized LMS
- Sign-Data LMS
- Sign-Error LMS
- Sign-Sign LMS

For more details on each of these methods, see “Algorithms” on page 4-913.

The filter adapts its weights until the error between the primary input signal and the desired signal is minimal. The mean square of this error (MSE) is computed using the `mseim` function. The predicted version of the MSE is determined using a Wiener filter in the `msepred` function. The `maxstep` function computes the maximum adaptation step size, which controls the speed of convergence.

For an overview of the adaptive filter methodology, and the most common applications the adaptive filters are used in, see “Overview of Adaptive Filters and Applications”.

To filter a signal using an adaptive FIR filter:

- 1 Create the `dsp.LMSFilter` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

Under specific conditions, this System object also supports SIMD code generation. For details, see “Code Generation” on page 4-914.

Creation

Syntax

```
lms = dsp.LMSFilter
lms = dsp.LMSFilter(L)
lms = dsp.LMSFilter(Name,Value)
```

Description

`lms = dsp.LMSFilter` returns an LMS filter object, `lms`, that computes the filtered output, filter error, and the filter weights for a given input and a desired signal using the least mean squares (LMS) algorithm.

`lms = dsp.LMSFilter(L)` returns an LMS filter object with the “Length” on page 4-0 property set to `L`.

`lms = dsp.LMSFilter(Name, Value)` returns an LMS filter object with each specified property set to the specified value. Enclose each property name in single quotes. You can use this syntax with the previous input argument.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects.

Method — Method to calculate filter weights

'LMS' (default) | 'Normalized LMS' | 'Sign-Data LMS' | 'Sign-Error LMS' | 'Sign-Sign LMS'

Method to calculate filter weights, specified as one of the following:

- 'LMS' -- Solves the Weiner-Hopf equation and finds the filter coefficients for an adaptive filter.
- 'Normalized LMS' -- Normalized variation of the LMS algorithm.
- 'Sign-Data LMS' -- Correction to the filter weights at each iteration depends on the sign of the input `x`.
- 'Sign-Error LMS' -- Correction applied to the current filter weights for each successive iteration depends on the sign of the error, `err`.
- 'Sign-Sign LMS' -- Correction applied to the current filter weights for each successive iteration depends on both the sign of `x` and the sign of `err`.

For more details on the algorithms, see “Algorithms” on page 4-913.

Length — Length of FIR filter weights vector

32 (default) | positive integer

Length of the FIR filter weights vector, specified as a positive integer.

Example: 64

Example: 16

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

StepSizeSource — Method to specify adaptation step size

'Property' (default) | 'Input port'

Method to specify the adaptation step size, specified as one of the following:

- 'Property' -- The property "StepSize" on page 4-0 specifies the size of each adaptation step.
- 'Input port' -- Specify the adaptation step size as one of the inputs to the object.

StepSize — Adaptation step size

0.1 (default) | non-negative scalar

Adaptation step size factor, specified as a non-negative scalar. For convergence of the normalized LMS method, the step size must be greater than 0 and less than 2.

A small step size ensures a small steady state error between the output "y" on page 4-0 and the desired signal "d" on page 4-0. If the step size is small, the convergence speed of the filter decreases. To improve the convergence speed, increase the step size. Note that if the step size is large, the filter can become unstable. To compute the maximum step size the filter can accept without becoming unstable, use the `maxstep` function.

Tunable: Yes

Dependencies

This property applies when you set "StepSizeSource" on page 4-0 to 'Property'.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

LeakageFactor — Leakage factor used in leaky LMS method

1 (default) | [0 1]

Leakage factor used when implementing the leaky LMS method, specified as a scalar in the range [0 1]. When the value equals 1, there is no leakage in the adapting method. When the value is less than 1, the filter implements a leaky LMS method.

Example: 0.5

Tunable: Yes

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

InitialConditions — Initial conditions of filter weights

0 (default) | scalar | vector

Initial conditions of filter weights, specified as a scalar or a vector of length equal to the value of the "Length" on page 4-0 property. When the input is real, the value of this property must be real.

Example: 0

Example: [1 3 1 2 7 8 9 0 2 2 8 2]

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

Complex Number Support: Yes

AdaptInputPort — Flag to adapt filter weights

false (default) | true

Flag to adapt filter weights, specified as one of the following:

- false -- The object continuously updates the filter weights.

- `true` -- An adaptation control input is provided to the object when you call its algorithm. If the value of this input is non-zero, the object continuously updates the filter weights. If the value of this input is zero, the filter weights remain at their current value.

WeightsResetInputPort — Flag to reset filter weights

`false` (default) | `true`

Flag to reset filter weights, specified as one of the following:

- `false` -- The object does not reset weights.
- `true` -- A reset control input is provided to the object when you call its algorithm. This setting enables the “WeightsResetCondition” on page 4-0 property. The object resets the filter weights based on the values of the `WeightsResetCondition` property and the reset input provided to the object algorithm.

WeightsResetCondition — Event to reset filter weights

`'Non-zero'` (default) | `'Rising edge'` | `'Falling edge'` | `'Either edge'`

Event that triggers the reset of the filter weights, specified as one of the following. The object resets the filter weights whenever a reset event is detected in its reset input.

- `'Non-zero'` -- Triggers a reset operation at each sample, when the reset input is not zero.
- `'Rising edge'` -- Triggers a reset operation when the reset input does one of the following:
 - Rises from a negative value to either a positive value or zero.
 - Rises from zero to a positive value, where the rise is not a continuation of a rise from a negative value to zero.

- `'Falling edge'` -- Triggers a reset operation when the reset input does one of the following:
 - Falls from a positive value to a negative value or zero.
 - Falls from zero to a negative value, where the fall is not a continuation of a fall from a positive value to zero.

- 'Either edge' -- Triggers a reset operation when the reset input is a rising edge or a falling edge.

The object resets the filter weights based on the value of this property and the reset input `r` provided to the object algorithm.

Dependencies

This property applies when you set the “WeightsResetInputPort” on page 4-0 property to `true`.

WeightsOutput — Method to output adapted filter weights

'Last' (default) | 'None' | 'All'

Method to output adapted filter weights, specified as one of the following:

- 'Last' (default) — The object returns a column vector of weights corresponding to the last sample of the data frame. The length of the weights vector is the value given by the “Length” on page 4-0 property.
- 'All' — The object returns a *FrameLength*-by-*Length* matrix of weights. The matrix corresponds to the full sample-by-sample history of weights for all *FrameLength* samples of the input values. Each row in the matrix corresponds to a set of LMS filter weights calculated for the corresponding input sample.
- 'None' — This setting disables the weights output.

Fixed-Point Properties

RoundingMethod — Rounding method for fixed-point operations

'Floor' (default) | 'Ceiling' | 'Convergent' | 'Nearest' | 'Round' | 'Simplest' | 'Zero'

Specify the rounding mode for fixed-point operations. For more details, see rounding mode.

OverflowAction — Overflow action for fixed-point operations

'Wrap' (default) | 'Saturate'

Overflow action for fixed-point operations, specified as one of the following:

- 'Wrap' -- The object wraps the result of its fixed-point operations.
- 'Saturate' -- The object saturates the result of its fixed-point operations.

For more details on overflow actions, see overflow mode for fixed-point operations.

StepSizeDataType — Step size word length and fraction length settings

'Same word length as first input' (default) | 'Custom'

Step size word length and fraction length settings, specified as one of the following:

- 'Same word length as first input' -- The object specifies the word length of step size to be the same as that of the first input. The fraction length is computed to get the best possible precision.
- 'Custom' -- The step size data type is specified as a custom numeric type through the "CustomStepSizeDataType" on page 4-0 property.

For more information on the step size data type this object uses, see the "Fixed Point" on page 4-915 section.

CustomStepSizeDataType — Word and fraction lengths of step size

numericity([],16,15) (default)

Word and fraction lengths of the step size, specified as an autosigned numeric type with a word length of 16 and a fraction length of 15.

Example: numericity([],32)

Dependencies

This property applies under the following conditions:

- "StepSizeSource" on page 4-0 property set to 'Property' and "StepSizeDataType" on page 4-0 set to 'Custom'.
- StepSizeSource property set to 'Input port'.

LeakageFactorDataType — Leakage factor word length and fraction length settings

'Same word length as first input' (default) | 'Custom'

Leakage factor word length and fraction length settings, specified as one of the following:

- 'Same word length as first input' -- The object specifies the word length of leakage factor to be the same as that of the first input. The fraction length is computed to get the best possible precision.
- 'Custom' -- The leakage factor data type is specified as a custom numeric type through the "CustomLeakageFactorDataType" on page 4-0 property.

For more information on the leakage factor data type this object uses, see the "Fixed Point" on page 4-915 section.

CustomLeakageFactorDataType — Word and fraction lengths of the leakage factor

numericity([],16,15) (default)

Word and fraction lengths of the leakage factor, specified as an autosigned numeric type with a word length of 16 and a fraction length of 15.

Example: numericity([],32)

Dependencies

This property applies when you set the "LeakageFactorDataType" on page 4-0 property to 'Custom'.

WeightsDataType — Weights word length and fraction length settings

'Same as first input' (default) | 'Custom'

Weights word length and fraction length settings, specified as one of the following:

- 'Same as first input' -- The object specifies the data type of the filter weights to be the same as that of the first input.
- 'Custom' -- The data type of filter weights is specified as a custom numeric type through the "CustomWeightsDataType" on page 4-0 property.

For more information on the filter weights data type this object uses, see the "Fixed Point" on page 4-915 section.

CustomWeightsDataType — Word and fraction lengths of filter weights

`numericType([],16,15)` (default)

Word and fraction lengths of the filter weights, specified as an autosigned numeric type with a word length of 16 and a fraction length of 15.

Example: `numericType([],32,20)`

Dependencies

This property applies when you set the "WeightsDataType" on page 4-0 property to 'Custom'.

EnergyProductDataType — Energy product word length and fraction length settings

'Same as first input' (default) | 'Custom'

Energy product word length and fraction length settings, specified as one of the following:

- 'Same as first input' -- The object specifies the data type of the energy product to be the same as that of the first input.
- 'Custom' -- The data type of the energy product is specified as a custom numeric type through the "CustomEnergyProductDataType" on page 4-0 property.

For more information on the energy product data type this object uses, see the "Fixed Point" on page 4-915 section.

Dependencies

This property applies when you set the "Method" on page 4-0 property to 'Normalized LMS'.

CustomEnergyProductDataType — Word and fraction lengths of energy product

`numericType([],32,20)` (default)

Word and fraction lengths of the energy product, specified as an autosigned numeric type with a word length of 32 and a fraction length of 20.

Dependencies

This property applies when you set the "Method" on page 4-0 property to 'Normalized LMS' and "EnergyProductDataType" on page 4-0 property to 'Custom'.

EnergyAccumulatorDataType — Energy accumulator word length and fraction length settings

'Same as first input' (default) | 'Custom'

Energy accumulator word length and fraction length settings, specified as one of the following:

- 'Same as first input' -- The object specifies the data type of the energy accumulator to be the same as that of the first input.
- 'Custom' -- The data type of the energy accumulator is specified as a custom numeric type through the “CustomEnergyAccumulatorDataType” on page 4-0 property.

For more information on the energy accumulator data type this object uses, see the “Fixed Point” on page 4-915 section.

Dependencies

This property applies when you set the “Method” on page 4-0 property to 'Normalized LMS'.

CustomEnergyAccumulatorDataType — Word and fraction lengths of energy accumulator
numericity([],32,20) (default)

Word and fraction lengths of the energy accumulator, specified as an autosigned numeric type with a word length of 32 and a fraction length of 20.

Dependencies

This property applies when you set the “Method” on page 4-0 property to 'Normalized LMS' and “EnergyAccumulatorDataType” on page 4-0 property to 'Custom'.

ConvolutionProductDataType — Convolution product word length and fraction length settings

'Same as first input' (default) | 'Custom'

Convolution product word length and fraction length settings, specified as one of the following:

- 'Same as first input' -- The object specifies the data type of the convolution product to be the same as that of the first input.
- 'Custom' -- The data type of the convolution product is specified as a custom numeric type through the “CustomConvolutionProductDataType” on page 4-0 property.

For more information on the convolution product data type this object uses, see the “Fixed Point” on page 4-915 section.

CustomConvolutionProductDataType — Word and fraction lengths of convolution product
numericity([],32,20) (default)

Word and fraction lengths of the convolution product, specified as an autosigned numeric type with a word length of 32 and a fraction length of 20.

Dependencies

This property applies when you set the “ConvolutionProductDataType” on page 4-0 property to 'Custom'.

ConvolutionAccumulatorDataType — Convolution accumulator word length and fraction length settings

'Same as first input' (default) | 'Custom'

Convolution accumulator word length and fraction length settings, specified as one of the following:

- 'Same as first input' -- The object specifies the data type of the convolution accumulator to be the same as that of the first input.

- 'Custom' -- The data type of the convolution accumulator is specified as a custom numeric type through the “CustomConvolutionAccumulatorDataType” on page 4-0 property.

For more information on the convolution accumulator data type this object uses, see the “Fixed Point” on page 4-915 section.

CustomConvolutionAccumulatorDataType — Word and fraction lengths of convolution accumulator

`numericType([],32,20)` (default)

Word and fraction lengths of the convolution accumulator, specified as an autosigned numeric type with a word length of 32 and a fraction length of 20.

Dependencies

This property applies when you set the “ConvolutionAccumulatorDataType” on page 4-0 property to 'Custom'.

StepSizeErrorProductDataType — Step size error product word length and fraction length settings

'Same as first input' (default) | 'Custom'

Step size error product word length and fraction length settings, specified as one of the following:

- 'Same as first input' -- The object specifies the data type of the step size error product to be the same as that of the first input.
- 'Custom' -- The data type of the step size error product is specified as a custom numeric type through the “CustomStepSizeErrorProductDataType” on page 4-0 property.

For more information on the step size error product data type this object uses, see the “Fixed Point” on page 4-915 section.

CustomStepSizeErrorProductDataType — Word and fraction lengths of step size error product

`numericType([],32,20)` (default)

Word and fraction lengths of the step size error product, specified as an autosigned numeric type with a word length of 32 and a fraction length of 20.

Dependencies

This property applies when you set the “StepSizeErrorProductDataType” on page 4-0 property to 'Custom'.

WeightsUpdateProductDataType — Filter weights update product word length and fraction length settings

'Same as first input' (default) | 'Custom'

Word and fraction length settings of the filter weights update product, specified as one of the following:

- 'Same as first input' -- The object specifies the data type of the filter weights update product to be the same as that of the first input.
- 'Custom' -- The data type of the filter weights update product is specified as a custom numeric type through the “CustomWeightsUpdateProductDataType” on page 4-0 property.

For more information on the filter weights update product data type this object uses, see the “Fixed Point” on page 4-915 section.

CustomWeightsUpdateProductDataType — Word and fraction lengths of filter weights update product

`numericType([],32,20)` (default)

Word and fraction lengths of the filter weights update product, specified as an autosigned numeric type with a word length of 32 and a fraction length of 20.

Dependencies

This property applies when you set the “WeightsUpdateProductDataType” on page 4-0 property to 'Custom'.

QuotientDataType — Quotient word length and fraction length settings

'Same as first input' (default) | 'Custom'

Quotient word length and fraction length settings, specified as one of the following:

- 'Same as first input' -- The object specifies the quotient data type to be the same as that of the first input.
- 'Custom' -- The quotient data type is specified as a custom numeric type through the “CustomQuotientDataType” on page 4-0 property.

For more information on the quotient data type this object uses, see the “Fixed Point” on page 4-915 section.

Dependencies

This property applies when you set the “Method” on page 4-0 property to 'Normalized LMS'.

CustomQuotientDataType — Word and fraction lengths of quotient

`numericType([],32,20)` (default)

Word and fraction lengths of the filter weights update product, specified as an autosigned numeric type with a word length of 32 and a fraction length of 20.

Dependencies

This property applies when you set the “Method” on page 4-0 property to 'Normalized LMS' and “QuotientDataType” on page 4-0 property to 'Custom'.

Usage

Syntax

```
[y,err,wts] = lms(x,d)
[y,err] = lms(x,d)
[___] = lms(x,d,mu)
[___] = lms(x,d,a)
[___] = lms(x,d,r)
[y,err,wts] = lms(x,d,mu,a,r)
```

Description

`[y,err,wts] = lms(x,d)` filters the input signal, `x`, using `d` as the desired signal, and returns the filtered output in `y`, the filter error in `err`, and the estimated filter weights in `wts`. The LMS filter object estimates the filter weights needed to minimize the error between the output signal and the desired signal.

`[y,err] = lms(x,d)` filters the input signal, `x`, using `d` as the desired signal, and returns the filtered output in `y` and the filter error in `err` when the “WeightsOutput” on page 4-0 property is set to 'None'.

`[___] = lms(x,d,mu)` filters the input signal, `x`, using `d` as the desired signal and `mu` as the step size, when the “StepSizeSource” on page 4-0 property is set to 'Input port'. These inputs can be used with either of the previous sets of outputs.

`[___] = lms(x,d,a)` filters the input signal, `x`, using `d` as the desired signal and `a` as the adaptation control when the “AdaptInputPort” on page 4-0 property is set to `true`. When `a` is nonzero, the System object continuously updates the filter weights. When `a` is zero, the filter weights remain constant.

`[___] = lms(x,d,r)` filters the input signal, `x`, using `d` as the desired signal and `r` as a reset signal when the “WeightsResetInputPort” on page 4-0 property is set to `true`. The “WeightsResetCondition” on page 4-0 property can be used to set the reset trigger condition. If a reset event occurs, the System object resets the filter weights to their initial values.

`[y,err,wts] = lms(x,d,mu,a,r)` filters the input signal, `x`, using `d` as the desired signal, `mu` as the step size, `a` as the adaptation control, and `r` as the reset signal, and returns the filtered output in `y`, the filter error in `err`, and the adapted filter weights in `wts`.

Input Arguments

x — Data input

scalar | column vector

The signal to be filtered by the LMS filter. The input, `x`, and the desired signal, `d` must have the same size, data type, and complexity. If the input is fixed-point, the data type must be signed and must have the same word length as the desired signal.

The input, `x` can be a variable-size signal. You can change the number of elements in the column vector even when the object is locked. The System object locks when you call the object to run its algorithm.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `fi`

d — Desired signal

scalar | column vector

The LMS filter adapts its filter weights, `wts`, to minimize the error, `err`, and converge the input signal `x` to the desired signal `d` as closely as possible.

The input, `x`, and the desired signal, `d`, must have the same size, data type, and complexity. If the desired signal is fixed-point, the data type must be signed and must have the same word length as the data input.

The input, `d` can be a variable-size signal. You can change the number of elements in the column vector even when the object is locked. The System object locks when you call the object to run its algorithm.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `fi`

mu — Step size

nonnegative scalar

Adaptation step size factor, specified as a scalar, nonnegative numeric value. For convergence of the normalized LMS method, the step size should be greater than 0 and less than 2. The data type of the step size input must match the data type of `x` and `d`. If the data type is fixed-point, the data type must be signed.

A small step size ensures a small steady state error between the output `y` and the desired signal `d`. If the step size is small, the convergence speed of the filter decreases. To improve the convergence speed, increase the step size. Note that if the step size is large, the filter can become unstable. To compute the maximum step size the filter can accept without becoming unstable, use the `maxstep` function.

Dependencies

This input is required when the “StepSizeSource” on page 4-0 property is set to `'Input port'`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `fi`

a — Adaptation control

scalar

Adaptation control input that controls how the filter weights are updated. If the value of this input is non-zero, the object continuously updates the filter weights. If the value of this input is zero, the filter weights remain at their current value.

Dependencies

This input is required when the “AdaptInputPort” on page 4-0 property is set to `true`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `logical`

r — Reset signal

scalar

Reset signal that resets the filter weights based on the values of the “WeightsResetCondition” on page 4-0 property.

Dependencies

This input is required when the “WeightsResetInputPort” on page 4-0 property is set to `true`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `logical`

Output Arguments**y — Filtered output**

scalar | column vector

Filtered output, returned as a scalar or a column vector. The object adapts its filter weights to converge the input signal `x` to match the desired signal `d`. The filter outputs the converged signal.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `fi`

err — Difference between output and desired signal

scalar | column vector

Difference between the output signal `y` and the desired signal `d`, returned as a scalar or a column vector. The data type of `err` matches the data type of `y`. The objective of the adaptive filter is to minimize this error. The object adapts its weights to converge towards optimal filter weights that produce an output signal that matches closely with the desired signal. For more details on how `err` is computed, see “Algorithms” on page 4-913.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `fi`

wts — Adaptive filter weights

scalar | column vector

Adaptive filter weights, returned as a scalar or a column vector of length specified by the value in “Length” on page 4-0 .

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `fi`

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Specific to dsp.LMSFilter

<code>maxstep</code>	Maximum step size for LMS adaptive filter convergence
<code>msepred</code>	Predicted mean squared error for LMS adaptive filter
<code>msestim</code>	Estimated mean squared error for adaptive filters

Common to All System Objects

<code>step</code>	Run System object algorithm
<code>release</code>	Release resources and allow changes to System object property values and input characteristics
<code>reset</code>	Reset internal states of System object

Examples

Predict Mean Squared Error for LMS Filter

The mean squared error (MSE) measures the average of the squares of the errors between the desired signal and the primary signal input to the adaptive filter. Reducing this error converges the primary input to the desired signal. Determine the predicted value of MSE and the simulated value of MSE at each time instant using the `msepred` and `msestim` functions. Compare these MSE values with each other and with respect to the minimum MSE and steady-state MSE values. In addition, compute the sum of the squares of the coefficient errors given by the trace of the coefficient covariance matrix.

Note: If you are using R2016a or an earlier release, replace each call to the object with the equivalent step syntax. For example, `obj(x)` becomes `step(obj,x)`.

Initialization

Create a `dsp.FIRFilter` System object™ that represents the unknown system. Pass the signal, `x`, to the FIR filter. The output of the unknown system is the desired signal, `d`, which is the sum of the output of the unknown system (FIR filter) and an additive noise signal, `n`.

```
num = fir1(31,0.5);
fir = dsp.FIRFilter('Numerator',num);
iir = dsp.IIRFilter('Numerator',sqrt(0.75),...
    'Denominator',[1 -0.5]);
x = iir(sign(randn(2000,25)));
n = 0.1*randn(size(x));
d = fir(x) + n;
```

LMS Filter

Create a `dsp.LMSFilter` System object to create a filter that adapts to output the desired signal. Set the length of the adaptive filter to 32 taps, step size to 0.008, and the decimation factor for analysis and simulation to 5. The variable `simmse` represents the simulated MSE between the output of the unknown system, `d`, and the output of the adaptive filter. The variable `mse` gives the corresponding predicted value.

```
l = 32;
mu = 0.008;
m = 5;

lms = dsp.LMSFilter('Length',l,'StepSize',mu);
[mmse,emse,meanW,mse,traceK] = msepred(lms,x,d,m);
[simmse,meanWsim,Wsim,traceKsim] = msesim(lms,x,d,m);
```

Plot the MSE Results

Compare the values of simulated MSE, predicted MSE, minimum MSE, and the final MSE. The final MSE value is given by the sum of minimum MSE and excess MSE.

```
nn = m:m:size(x,1);
semilogy(nn,simmse,[0 size(x,1)],[(emse+mmse)...
    (emse+mmse)],nn,mse,[0 size(x,1)],[mmse mmse])
title('Mean Squared Error Performance')
axis([0 size(x,1) 0.001 10])
legend('MSE (Sim.)','Final MSE','MSE','Min. MSE')
xlabel('Time Index')
ylabel('Squared Error Value')
```

The predicted MSE follows the same trajectory as the simulated MSE. Both these trajectories converge with the steady-state (final) MSE.

Plot the Coefficient Trajectories

meanWsim is the mean value of the simulated coefficients given by msesim. meanW is the mean value of the predicted coefficients given by msepred.

Compare the simulated and predicted mean values of LMS filter coefficients 12,13,14, and 15.

```
plot(nn,meanWsim(:,12),'b',nn,meanW(:,12),'r',nn,...
meanWsim(:,13:15),'b',nn,meanW(:,13:15),'r')
PlotTitle ={'Average Coefficient Trajectories for';...
            'W(12), W(13), W(14), and W(15)'};
```

```
PlotTitle = 2x1 cell
            {'Average Coefficient Trajectories for'}
            {'W(12), W(13), W(14), and W(15)'}      }
```

```
title(PlotTitle)
legend('Simulation','Theory')
xlabel('Time Index')
ylabel('Coefficient Value')
```

In steady state, both the trajectories converge.

Sum of Squared Coefficient Errors

Compare the sum of the squared coefficient errors given by `msepred` and `msesim`. These values are given by the trace of the coefficient covariance matrix.

```
semilogy(nn,traceKsim,nn,traceK,'r')
title('Sum-of-Squared Coefficient Errors')
axis([0 size(x,1) 0.0001 1])
legend('Simulation','Theory')
xlabel('Time Index')
ylabel('Squared Error Value')
```

Compute Maximum Step of LMS Adaptive Filter

The `maxstep` function computes the maximum step size of the adaptive filter. This step size keeps the filter stable at the maximum possible speed of convergence. Create the primary input signal, `x`, by passing a signed random signal to an IIR filter. Signal `x` contains 50 frames of 2000 samples each frame. Create an LMS filter with 32 taps and a step size of 0.1.

```
x = zeros(2000,50);
IIRFilter = dsp.IIRFilter('Numerator',sqrt(0.75),...
    'Denominator',[1 -0.5]);
for k = 1:size(x,2)
    x(:,k) = IIRFilter(sign(randn(size(x,1),1)));
end
mu = 0.1;
LMSFilter = dsp.LMSFilter('Length',32,...
    'StepSize',mu);
```

Compute the maximum adaptation step size and the maximum step size in mean-squared sense using the `maxstep` function.

```
[mumax,mumaxmse] = maxstep(LMSFilter,x)

mumax = 0.0625
mumaxmse = 0.0536
```

System Identification of FIR Filter Using LMS Algorithm

System identification is the process of identifying the coefficients of an unknown system using an adaptive filter. The general overview of the process is shown in “System Identification -- Using an Adaptive Filter to Identify an Unknown System”. The main components involved are:

- The adaptive filter algorithm. In this example, set the `Method` property of `dsp.LMSFilter` to 'LMS' to choose the LMS adaptive filter algorithm.
- An unknown system or process to adapt to. In this example, the filter designed by `firband` is the unknown system.
- Appropriate input data to exercise the adaptation process. For the generic LMS model, these are the desired signal $d(k)$ and the input signal $x(k)$.

The objective of the adaptive filter is to minimize the error signal between the output of the adaptive filter $y(k)$ and the output of the unknown system (or the system to be identified) $d(k)$. Once the error signal is minimized, the adapted filter resembles the unknown system. The coefficients of both the filters match closely.

Note: If you are using R2016a or an earlier release, replace each call to the object with the equivalent step syntax. For example, `obj(x)` becomes `step(obj,x)`.

Unknown System

Create a `dsp.FIRFilter` object that represents the system to be identified. Use the `firband` function to design the filter coefficients. The designed filter is a lowpass filter constrained to 0.2 ripple in the stopband.

```
filt = dsp.FIRFilter;
filt.Numerator = firband(12,[0 0.4 0.5 1],[1 1 0 0],[1 0.2],...
{'w' 'c'});
```

Pass the signal x to the FIR filter. The desired signal d is the sum of the output of the unknown system (FIR filter) and an additive noise signal n .

```
x = 0.1*randn(250,1);
n = 0.01*randn(250,1);
d = filt(x) + n;
```

Adaptive Filter

With the unknown filter designed and the desired signal in place, create and apply the adaptive LMS filter object to identify the unknown filter.

Preparing the adaptive filter object requires starting values for estimates of the filter coefficients and the LMS step size (μ). You can start with some set of nonzero values as estimates for the filter coefficients. This example uses zeros for the 13 initial filter weights. Set the `InitialConditions` property of `dsp.LMSFilter` to the desired initial values of the filter weights. For the step size, 0.8 is a good compromise between being large enough to converge well within 250 iterations (250 input sample points) and small enough to create an accurate estimate of the unknown filter.

Create a `dsp.LMSFilter` object to represent an adaptive filter that uses the LMS adaptive algorithm. Set the length of the adaptive filter to 13 taps and the step size to 0.8.

```
mu = 0.8;
lms = dsp.LMSFilter(13, 'StepSize', mu)
```

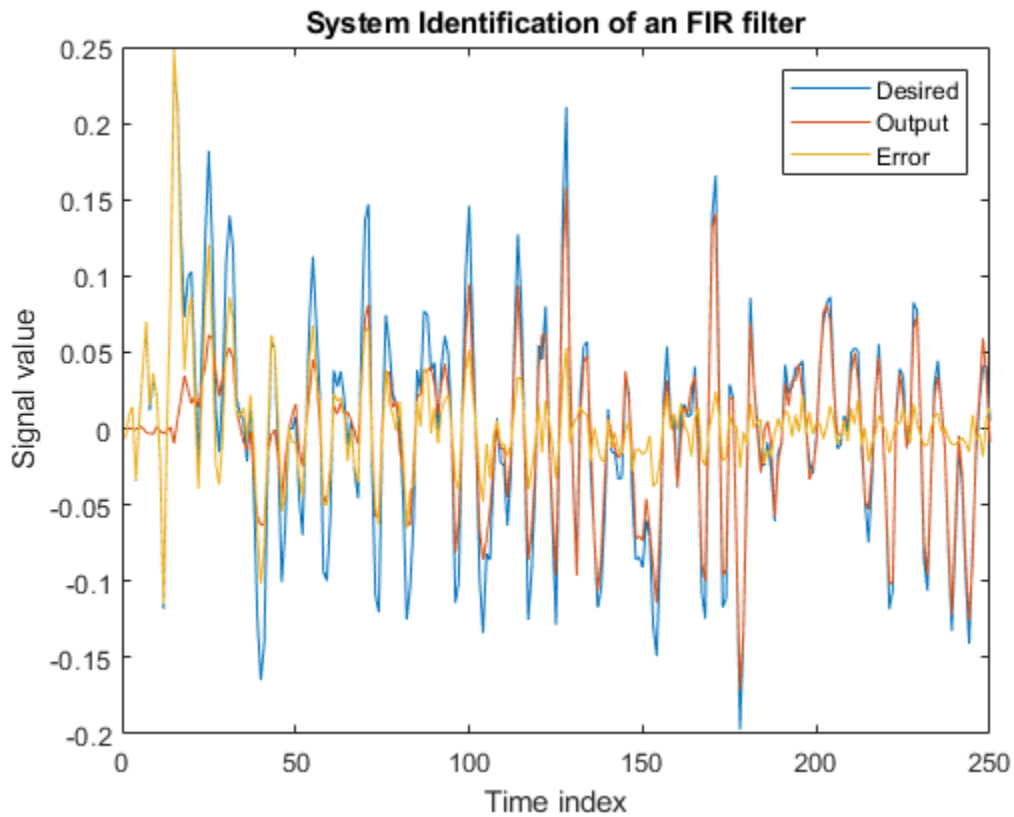

```
lms =
  dsp.LMSFilter with properties:
        Method: 'LMS'
        Length: 13
  StepSizeSource: 'Property'
        StepSize: 0.8000
        LeakageFactor: 1
  InitialConditions: 0
        AdaptInputPort: false
  WeightsResetInputPort: false
        WeightsOutput: 'Last'
```

Show all properties

Pass the primary input signal x and the desired signal d to the LMS filter. Run the adaptive filter to determine the unknown system. The output y of the adaptive filter is the signal converged to the desired signal d thereby minimizing the error e between the two signals.

Plot the results. The output signal does not match the desired signal as expected, making the error between the two nontrivial.

```
[y,e,w] = lms(x,d);
plot(1:250, [d,y,e])
title('System Identification of an FIR filter')
legend('Desired','Output','Error')
xlabel('Time index')
ylabel('Signal value')
```

Compare the Weights

The weights vector w represents the coefficients of the LMS filter that is adapted to resemble the unknown system (FIR filter). To confirm the convergence, compare the numerator of the FIR filter and the estimated weights of the adaptive filter.

The estimated filter weights do not closely match the actual filter weights, confirming the results seen in the previous signal plot.

```
stem([(filt.Numerator). ' w'])
title('System Identification by Adaptive LMS Algorithm')
legend('Actual filter weights', 'Estimated filter weights', ...
       'Location', 'NorthEast')
```

Changing the Step Size

As an experiment, change the step size to 0.2. Repeating the example with $\mu = 0.2$ results in the following stem plot. The filters do not converge, and the estimated weights are not good approximations of the actual weights.

```
mu = 0.2;
lms = dsp.LMSFilter(13, 'StepSize', mu);
[~,~,w] = lms(x,d);
stem([(filt.Numerator).' w])
title('System Identification by Adaptive LMS Algorithm')
legend('Actual filter weights', 'Estimated filter weights', ...
       'Location', 'NorthEast')
```

Increase the Number of Data Samples

Increase the frame size of the desired signal. Even though this increases the computation involved, the LMS algorithm now has more data that can be used for adaptation. With 1000 samples of signal data and a step size of 0.2, the coefficients are aligned closer than before, indicating an improved convergence.

```
release(filt);
x = 0.1*randn(1000,1);
n = 0.01*randn(1000,1);
d = filt(x) + n;
[y,e,w] = lms(x,d);
stem([filt.Numerator.' w])
title('System Identification by Adaptive LMS Algorithm')
legend('Actual filter weights','Estimated filter weights',...
       'Location','NorthEast')
```

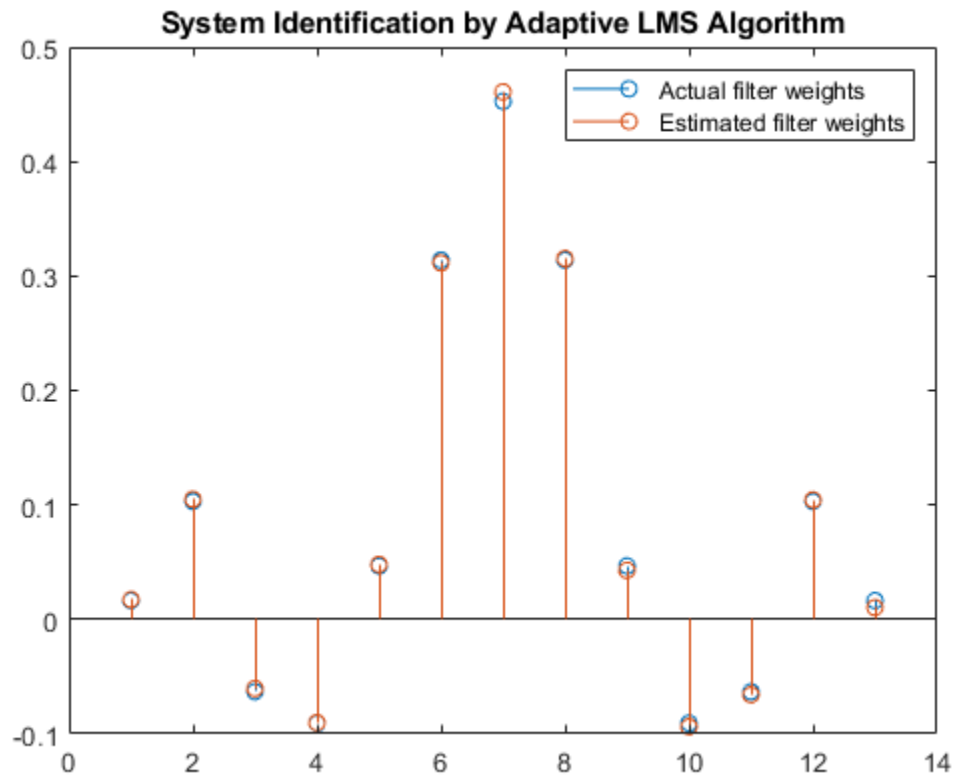

Increase the number of data samples further by inputting the data through iterations. Run the algorithm on 4000 samples of data, passed to the LMS algorithm in batches of 1000 samples over 4 iterations.

Compare the filter weights. The weights of the LMS filter match the weights of the FIR filter very closely, indicating a good convergence.

```

release(filt);
n = 0.01*randn(1000,1);
for index = 1:4
    x = 0.1*randn(1000,1);
    d = filt(x) + n;
    [y,e,w] = lms(x,d);
end
stem([(filt.Numerator).' w])
title('System Identification by Adaptive LMS Algorithm')
legend('Actual filter weights','Estimated filter weights',...
       'Location','NorthEast')

```

The output signal matches the desired signal very closely, making the error between the two close to zero.

```
plot(1:1000, [d,y,e])  
title('System Identification of an FIR filter')  
legend('Desired', 'Output', 'Error')  
xlabel('Time index')  
ylabel('Signal value')
```

System Identification of FIR Filter Using Normalized LMS Algorithm

To improve the convergence performance of the LMS algorithm, the normalized variant (NLMS) uses an adaptive step size based on the signal power. As the input signal power changes, the algorithm calculates the input power and adjusts the step size to maintain an appropriate value. The step size changes with time, and as a result, the normalized algorithm converges faster with fewer samples in many cases. For input signals that change slowly over time, the normalized LMS algorithm can be a more efficient LMS approach.

For an example using the LMS approach, see “System Identification of FIR Filter Using LMS Algorithm”.

Note: If you are using R2016a or an earlier release, replace each call to the object with the equivalent step syntax. For example, `obj(x)` becomes `step(obj,x)`.

Unknown System

Create a `dsp.FIRFilter` object that represents the system to be identified. Use the `firband` function to design the filter coefficients. The designed filter is a lowpass filter constrained to 0.2 ripple in the stopband.

```
filt = dsp.FIRFilter;
filt.Numerator = firband(12,[0 0.4 0.5 1],[1 1 0 0],[1 0.2],...
{'w' 'c'});
```

Pass the signal x to the FIR filter. The desired signal d is the sum of the output of the unknown system (FIR filter) and an additive noise signal n .

```
x = 0.1*randn(1000,1);
n = 0.001*randn(1000,1);
d = filt(x) + n;
```

Adaptive Filter

To use the normalized LMS algorithm variation, set the `Method` property on the `dsp.LMSFilter` to 'Normalized LMS'. Set the length of the adaptive filter to 13 taps and the step size to 0.2.

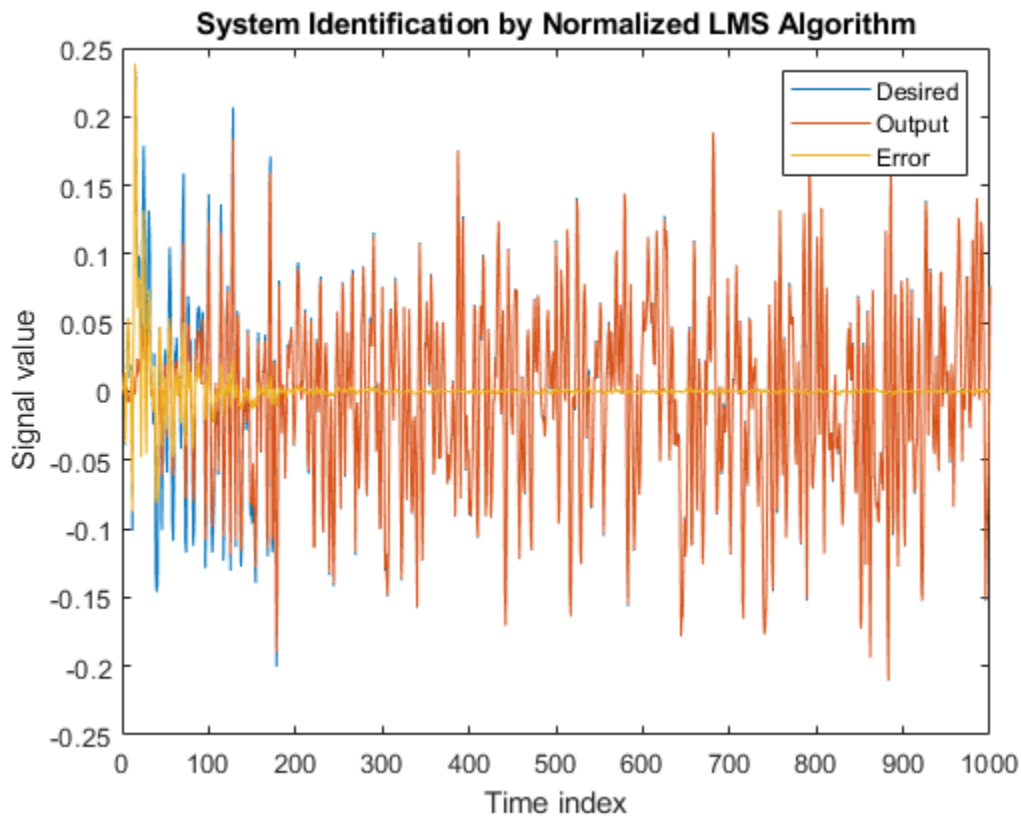

```
mu = 0.2;
lms = dsp.LMSFilter(13, 'StepSize', mu, 'Method', ...
    'Normalized LMS');
```

Pass the primary input signal x and the desired signal d to the LMS filter.

```
[y,e,w] = lms(x,d);
```

The output y of the adaptive filter is the signal converged to the desired signal d thereby minimizing the error e between the two signals.

```
plot(1:1000, [d,y,e])
title('System Identification by Normalized LMS Algorithm')
legend('Desired', 'Output', 'Error')
xlabel('Time index')
ylabel('Signal value')
```

Compare the Adapted Filter to the Unknown System

The weights vector w represents the coefficients of the LMS filter that is adapted to resemble the unknown system (FIR filter). To confirm the convergence, compare the numerator of the FIR filter and the estimated weights of the adaptive filter.

```
stem([filt.Numerator.' w])
title('System Identification by Normalized LMS Algorithm')
legend('Actual filter weights', 'Estimated filter weights', ...
       'Location', 'NorthEast')
```

Compare Convergence Performance Between LMS Algorithm and Normalized LMS Algorithm

An adaptive filter adapts its filter coefficients to match the coefficients of an unknown system. The objective is to minimize the error signal between the output of the unknown system and the output of the adaptive filter. When these two outputs converge and match closely for the same input, the coefficients are said to match closely. The adaptive filter at this state resembles the unknown system. This example compares the rate at which this convergence happens for the normalized LMS (NLMS) algorithm and the LMS algorithm with no normalization.

Unknown System

Create a `dsp.FIRFilter` that represents the unknown system. Pass the signal x as an input to the unknown system. The desired signal d is the sum of the output of the unknown system (FIR filter) and an additive noise signal n .

```
filt = dsp.FIRFilter;  
filt.Numerator = fircband(12,[0 0.4 0.5 1],[1 1 0 0],[1 0.2],...  
{'w' 'c'});  
x = 0.1*randn(1000,1);  
n = 0.001*randn(1000,1);  
d = filt(x) + n;
```

Adaptive Filter

Create two `dsp.LMSFilter` objects, with one set to the LMS algorithm, and the other set to the normalized LMS algorithm. Choose an adaptation step size of 0.2 and set the length of the adaptive filter to 13 taps.

```
mu = 0.2;  
lms_nonnormalized = dsp.LMSFilter(13,'StepSize',mu,...  
'Method','LMS');  
lms_normalized = dsp.LMSFilter(13,'StepSize',mu,...  
'Method','Normalized LMS');
```

Pass the primary input signal `x` and the desired signal `d` to both the variations of the LMS algorithm. The variables `e1` and `e2` represent the error between the desired signal and the output of the normalized and nonnormalized filters, respectively.

```
[~,e1,~] = lms_normalized(x,d);  
[~,e2,~] = lms_nonnormalized(x,d);
```

Plot the error signals for both variations. The error signal for the NLMS variant converges to zero much faster than the error signal for the LMS variant. The normalized version adapts in far fewer iterations to a result almost as good as the nonnormalized version.

```
plot([e1,e2]);  
title('Comparing the LMS and NLMS Conversion Performance');  
legend('NLMS derived filter weights', ...  
'LMS derived filter weights','Location','NorthEast');  
xlabel('Time index')  
ylabel('Signal value')
```

Cancel Noise Using LMS Filter

Cancel additive noise, n , added to an unknown system using an LMS adaptive filter. The LMS filter adapts its coefficients until its transfer function matches the transfer function of the unknown system as closely as possible. The difference between the output of the adaptive filter and the output of the unknown system represents the error signal, e . Minimizing this error signal is the objective of the adaptive filter.

The unknown system and the LMS filter process the same input signal, x , and produce outputs d and y , respectively. If the coefficients of the adaptive filter match the coefficients of the unknown system, the error, e , in effect represents the additive noise.

Note: If you are using R2016a or an earlier release, replace each call to the object with the equivalent step syntax. For example, `obj(x)` becomes `step(obj,x)`.

Create a `dsp.FIRFilter` System object to represent the unknown system. Create a `dsp.LMSFilter` object and set the length to 11 taps and the step size to 0.05. Create a sine wave to represent the noise added to the unknown system. View the signals in a time scope.

```
FrameSize = 100;
NIter = 10;
lmsfilt2 = dsp.LMSFilter('Length',11,'Method','Normalized LMS', ...
    'StepSize',0.05);
firfilt2 = dsp.FIRFilter('Numerator', fir1(10,[.5, .75]));
```

```

sinewave = dsp.SineWave('Frequency',0.01, ...
    'SampleRate',1,'SamplesPerFrame',FrameSize);
scope = timescope('TimeUnits','Seconds',...
    'YLimits',[-3 3],'BufferLength',2*FrameSize*NIter, ...
    'ShowLegend',true,'ChannelNames', ...
    {'Noisy signal', 'Error signal'});

```

Create a random input signal, x and pass the signal to the FIR filter. Add a sine wave to the output of the FIR filter to generate the noisy signal, d . The signal, d is the output of the unknown system. Pass the noisy signal and the primary input signal to the LMS filter. View the noisy signal and the error signal in the time scope.

```

for k = 1:NIter
    x = randn(FrameSize,1);
    d = firfilt2(x) + sinewave();
    [y,e,w] = lmsfilt2(x,d);
    scope([d,e])
end
release(scope)

```

The error signal, e , is the sinusoidal noise added to the unknown system. Minimizing the error signal minimizes the noise added to the system.

Noise Cancellation Using Sign-Data LMS Algorithm

When the amount of computation required to derive an adaptive filter drives your development process, the sign-data variant of the LMS (SDLMS) algorithm might be a very good choice, as demonstrated in this example.

In the standard and normalized variations of the LMS adaptive filter, coefficients for the adapting filter arise from the mean square error between the desired signal and the output signal from the unknown system. The sign-data algorithm changes the mean square error calculation by using the sign of the input data to change the filter coefficients.

When the error is positive, the new coefficients are the previous coefficients plus the error multiplied by the step size μ . If the error is negative, the new coefficients are again the previous coefficients minus the error multiplied by μ — note the sign change.

When the input is zero, the new coefficients are the same as the previous set.

In vector form, the sign-data LMS algorithm is:

$$w(k+1) = w(k) + \mu e(k) \text{sgn}(x(k)),$$

where

$$\text{sgn}(x(k)) = \begin{cases} 1, & x(k) > 0 \\ 0, & x(k) = 0 \\ -1, & x(k) < 0 \end{cases}$$

with vector w containing the weights applied to the filter coefficients and vector x containing the input data. The vector e is the error between the desired signal and the filtered signal. The objective of the SDLMS algorithm is to minimize this error. Step size is represented by μ .

With a smaller μ , the correction to the filter weights gets smaller for each sample, and the SDLMS error falls more slowly. A larger μ changes the weights more for each step, so the error falls more rapidly, but the resulting error does not approach the ideal solution as closely. To ensure a good convergence rate and stability, select μ within the following practical bounds.

$$0 < \mu < \frac{1}{N\{\text{InputSignalPower}\}},$$

where N is the number of samples in the signal. Also, define μ as a power of two for efficient computing.

Note: How you set the initial conditions of the sign-data algorithm profoundly influences the effectiveness of the adaptation process. Because the algorithm essentially quantizes the input signal, the algorithm can become unstable easily.

A series of large input values, coupled with the quantization process might result in the error growing beyond all bounds. Restrain the tendency of the sign-data algorithm to get out of control by choosing a small step size ($\mu \ll 1$) and setting the initial conditions for the algorithm to nonzero positive and negative values.

In this noise cancellation example, set the Method property of `dsp.LMSFilter` to 'Sign-Data LMS'. This example requires two input data sets:

- Data containing a signal corrupted by noise. In the block diagram under “Noise or Interference Cancellation -- Using an Adaptive Filter to Remove Noise from an Unknown System”, this is the desired signal $d(k)$. The noise cancellation process removes the noise from the signal.
- Data containing random noise. In the block diagram under “Noise or Interference Cancellation -- Using an Adaptive Filter to Remove Noise from an Unknown System”, this is $x(k)$. The signal $x(k)$ is correlated with the noise that corrupts the signal data. Without the correlation between the noise data, the adapting algorithm cannot remove the noise from the signal.

For the signal, use a sine wave. Note that `signal` is a column vector of 1000 elements.

```
signal = sin(2*pi*0.055*(0:1000-1)');
```

Now, add correlated white noise to `signal`. To ensure that the noise is correlated, pass the noise through a lowpass FIR filter and then add the filtered noise to the signal.

```
noise = randn(1000,1);
filt = dsp.FIRFilter;
filt.Numerator = fir1(11,0.4);
fnoise = filt(noise);
d = signal + fnoise;
```

`fnoise` is the correlated noise and `d` is now the desired input to the sign-data algorithm.

To prepare the `dsp.LMSFilter` object for processing, set the initial conditions of the filter weights and `mu` (`StepSize`). As noted earlier in this section, the values you set for `coeffs` and `mu` determine whether the adaptive filter can remove the noise from the signal path.

In “System Identification of FIR Filter Using LMS Algorithm” on page 4-890, you constructed a default filter that sets the filter coefficients to zeros. In most cases that approach does not work for the sign-data algorithm. The closer you set your initial filter coefficients to the expected values, the more likely it is that the algorithm remains well behaved and converges to a filter solution that removes the noise effectively.

For this example, start with the coefficients used in the noise filter (`filt.Numerator`), and modify them slightly so the algorithm has to adapt.

```
coeffs = (filt.Numerator).'-0.01; % Set the filter initial conditions.
mu = 0.05; % Set the step size for algorithm updating.
```

With the required input arguments for `dsp.LMSFilter` prepared, construct the LMS filter object, run the adaptation, and view the results.

```
lms = dsp.LMSFilter(12,'Method','Sign-Data LMS',...
    'StepSize',mu,'InitialConditions',coeffs);
[~,e] = lms(noise,d);
L = 200;
plot(0:L-1,signal(1:L),0:L-1,e(1:L));
title('Noise Cancellation by the Sign-Data Algorithm');
legend('Actual signal','Result of noise cancellation',...
    'Location','NorthEast');
xlabel('Time index')
ylabel('Signal values')
```

When `dsp.LMSFilter` runs, it uses far fewer multiplication operations than either of the standard LMS algorithms. Also, performing the sign-data adaptation requires only multiplication by bit shifting when the step size is a power of two.

Although the performance of the sign-data algorithm as shown in this plot is quite good, the sign-data algorithm is much less stable than the standard LMS variations. In this noise cancellation example, the processed signal is a very good match to the input signal, but the algorithm could very easily grow without bound rather than achieve good performance.

Changing the weight initial conditions (`InitialConditions`) and μ (`StepSize`), or even the lowpass filter you used to create the correlated noise, can cause noise cancellation to fail.

Noise Cancellation Using Sign-Error LMS Algorithm

In the standard and normalized variations of the LMS adaptive filter, the coefficients for the adapting filter arise from calculating the mean square error between the desired signal and the output signal from the unknown system, and applying the result to the current filter coefficients. The sign-error LMS (SELMS) algorithm replaces the mean square error calculation by using the sign of the error to modify the filter coefficients.

When the error is positive, the new coefficients are the previous coefficients plus the error multiplied by the step size μ . If the error is negative, the new coefficients are the previous coefficients minus the error multiplied by μ — note the sign change. When the input is zero, the new coefficients are the same as the previous set.

In vector form, the sign-error LMS algorithm is:

$$w(k+1) = w(k) + \mu \text{sgn}(e(k))x(k),$$

where

$$\text{sgn}(e(k)) = \begin{cases} 1, & e(k) > 0 \\ 0, & e(k) = 0 \\ -1, & e(k) < 0 \end{cases}$$

with vector w containing the weights applied to the filter coefficients and vector x containing the input data. The vector e is the error between the desired signal and the filtered signal. The objective of the SELMS algorithm is to minimize this error.

With a smaller μ , the correction to the filter weights gets smaller for each sample and the SELMS error falls more slowly. A larger μ changes the weights more for each step so the error falls more rapidly, but the resulting error does not approach the ideal solution as closely. To ensure a good convergence rate and stability, select μ within the following practical bounds.

$$0 < \mu < \frac{1}{N\{\text{InputSignalPower}\}}$$

where N is the number of samples in the signal. Also, define μ as a power of two for efficient computation.

Note: How you set the initial conditions of the sign-error algorithm profoundly influences the effectiveness of the adaptation process. Because the algorithm essentially quantizes the error signal, the algorithm can become unstable easily.

A series of large error values, coupled with the quantization process might result in the error growing beyond all bounds. Restrain the tendency of the sign-error algorithm to become unstable by choosing a small step size ($\mu \ll 1$) and setting the initial conditions for the algorithm to nonzero positive and negative values.

In this noise cancellation example, set the Method property of `dsp.LMSFilter` to 'Sign-Error LMS'. This example requires two input data sets:

- Data containing a signal corrupted by noise. In the block diagram under “Noise or Interference Cancellation -- Using an Adaptive Filter to Remove Noise from an Unknown System”, this is the desired signal $d(k)$. The noise cancellation process removes the noise from the signal.
- Data containing random noise. In the block diagram under “Noise or Interference Cancellation -- Using an Adaptive Filter to Remove Noise from an Unknown System”, this is $x(k)$. The signal $x(k)$ is correlated with the noise that corrupts the signal data. Without the correlation between the noise data, the adapting algorithm cannot remove the noise from the signal.

For the signal, use a sine wave. Note that `signal` is a column vector of 1000 elements.

```
signal = sin(2*pi*0.055*(0:1000-1)');
```

Now, add correlated white noise to `signal`. To ensure that the noise is correlated, pass the noise through a lowpass FIR filter and then add the filtered noise to the signal.

```
noise = randn(1000,1);
filt = dsp.FIRFilter;
```

```
filt.Numerator = fir1(11,0.4);
fnoise = filt(noise);
d = signal + fnoise;
```

fnoise is the correlated noise and d is now the desired input to the sign-error algorithm.

To prepare the dsp.LMSFilter object for processing, set the initial conditions of the filter weights (InitialConditions) and mu (StepSize). As noted earlier in this section, the values you set for coeffs and mu determine whether the adaptive filter can remove the noise from the signal path.

In “System Identification of FIR Filter Using LMS Algorithm” on page 4-890, you constructed a default filter that sets the filter coefficients to zeros. In most cases that approach does not work for the sign-error algorithm. The closer you set your initial filter coefficients to the expected values, the more likely it is that the algorithm remains well behaved and converges to a filter solution that removes the noise effectively.

For this example, start with the coefficients used in the noise filter (filt.Numerator) and modify them slightly so the algorithm has to adapt.

```
coeffs = (filt.Numerator).'-0.01; % Set the filter initial conditions.
mu = 0.05; % Set the step size for algorithm updating.
```

With the required input arguments for dsp.LMSFilter prepared, run the adaptation and view the results.

```
lms = dsp.LMSFilter(12,'Method','Sign-Error LMS',...
    'StepSize',mu,'InitialConditions',coeffs);
[~,e] = lms(noise,d);
L = 200;
plot(0:199,signal(1:200),0:199,e(1:200));
title('Noise cancellation performance by the sign-error LMS algorithm');
legend('Actual signal','Error after noise reduction',...
    'Location','NorthEast')
xlabel('Time index')
ylabel('Signal value')
```

When the sign-error LMS algorithm runs, it uses far fewer multiplication operations than either of the standard LMS algorithms. Also, performing the sign-error adaptation requires only bit shifting multiples when the step size is a power of two.

Although the performance of the sign-error algorithm as shown in this plot is quite good, the sign-error algorithm is much less stable than the standard LMS variations. In this noise cancellation example, the adapted signal is a very good match to the input signal, but the algorithm could very easily become unstable rather than achieve good performance.

Changing the weight initial conditions (`InitialConditions`) and μ (`StepSize`), or even the lowpass filter you used to create the correlated noise, can cause noise cancellation to fail and the algorithm to become useless.

Noise Cancellation Using Sign-Sign LMS Algorithm

The sign-sign LMS algorithm (SSLMS) replaces the mean square error calculation by using the sign of the input data to change the filter coefficients. When the error is positive, the new coefficients are the previous coefficients plus the error multiplied by the step size μ . If the error is negative, the new coefficients are the previous coefficients minus the error multiplied by μ — note the sign change. When the input is zero, the new coefficients are the same as the previous set.

In essence, the algorithm quantizes both the error and the input by applying the sign operator to them.

In vector form, the sign-sign LMS algorithm is:

$$w(k+1) = w(k) + \mu \text{sgn}(e(k)) \text{sgn}(x(k)),$$

where

$$\text{sgn}(z(k)) = \begin{cases} 1, & z(k) > 0 \\ 0, & z(k) = 0 \\ -1, & z(k) < 0 \end{cases}$$

$$z(k) = e(k) \text{sgn}(x(k))$$

Vector w contains the weights applied to the filter coefficients and vector x contains the input data. The vector e is the error between the desired signal and the filtered signal. The objective of the SSLMS algorithm is to minimize this error.

With a smaller μ , the correction to the filter weights gets smaller for each sample and the SSLMS error falls more slowly. A larger μ changes the weights more for each step, so the error falls more rapidly, but the resulting error does not approach the ideal solution as closely. To ensure a good convergence rate and stability, select μ within the following practical bounds.

$$0 < \mu < \frac{1}{N\{\text{InputSignalPower}\}}$$

where N is the number of samples in the signal. Also, define μ as a power of two for efficient computation

Note:

How you set the initial conditions of the sign-sign algorithm profoundly influences the effectiveness of the adaptation process. Because the algorithm essentially quantizes the input signal and the error signal, the algorithm can become unstable easily.

A series of large error values, coupled with the quantization process might result in the error growing beyond all bounds. Restrain the tendency of the sign-sign algorithm to become unstable by choosing a small step size ($\mu \ll 1$) and setting the initial conditions for the algorithm to nonzero positive and negative values.

In this noise cancellation example, set the Method property of `dsp.LMSFilter` to 'Sign-Sign LMS'. This example requires two input data sets:

- Data containing a signal corrupted by noise. In the block diagram under "Noise or Interference Cancellation -- Using an Adaptive Filter to Remove Noise from an Unknown System", this is the desired signal $d(k)$. The noise cancellation process removes the noise from the signal.
- Data containing random noise. In the block diagram under "Noise or Interference Cancellation -- Using an Adaptive Filter to Remove Noise from an Unknown System", this is $x(k)$. The signal $x(k)$ is correlated with the noise that corrupts the signal data. Without the correlation between the noise data, the adapting algorithm cannot remove the noise from the signal.

For the signal, use a sine wave. Note that `signal` is a column vector of 1000 elements.

```
signal = sin(2*pi*0.055*(0:1000-1)');
```

Now, add correlated white noise to `signal`. To ensure that the noise is correlated, pass the noise through a lowpass FIR filter, then add the filtered noise to the signal.

```
noise = randn(1000,1);
filt = dsp.FIRFilter;
filt.Numerator = fir1(11,0.4);
fnoise = filt(noise);
d = signal + fnoise;
```

`fnoise` is the correlated noise and `d` is now the desired input to the sign-sign algorithm.

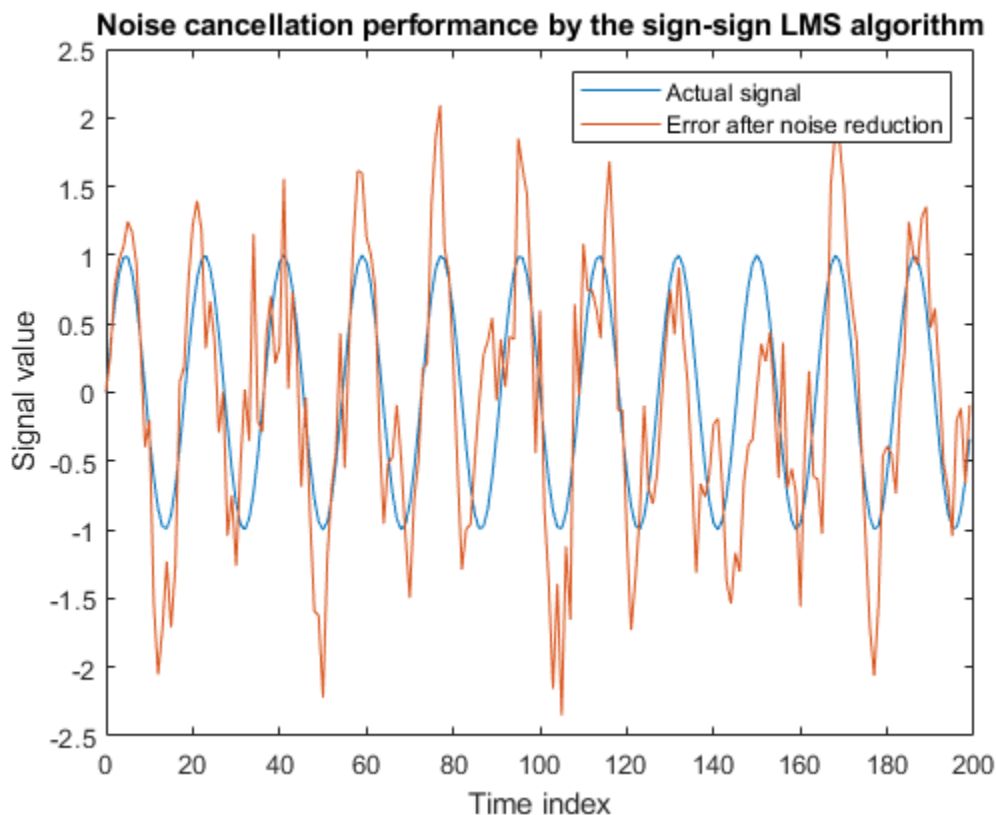

To prepare the `dsp.LMSFilter` object for processing, set the initial conditions of the filter weights (`InitialConditions`) and `mu` (`StepSize`). As noted earlier in this section, the values you set for `coeffs` and `mu` determine whether the adaptive filter can remove the noise from the signal path. In “System Identification of FIR Filter Using LMS Algorithm” on page 4-890, you constructed a default filter that sets the filter coefficients to zeros. Usually that approach does not work for the sign-sign algorithm.

The closer you set your initial filter coefficients to the expected values, the more likely it is that the algorithm remains well behaved and converges to a filter solution that removes the noise effectively. For this example, you start with the coefficients used in the noise filter (`filt.Numerator`), and modify them slightly so the algorithm has to adapt.

```
coeffs = (filt.Numerator).' -0.01; % Set the filter initial conditions.
mu = 0.05;
```

With the required input arguments for `dsp.LMSFilter` prepared, run the adaptation and view the results.

```
lms = dsp.LMSFilter(12,'Method','Sign-Sign LMS',...
    'StepSize',mu,'InitialConditions',coeffs);
[~,e] = lms(noise,d);
L = 200;
plot(0:199,signal(1:200),0:199,e(1:200));
title('Noise cancellation performance by the sign-sign LMS algorithm');
legend('Actual signal','Error after noise reduction',...
    'Location','NorthEast')
xlabel('Time index')
ylabel('Signal value')
```

When `dsp.LMSFilter` runs, it uses far fewer multiplication operations than either of the standard LMS algorithms. Also, performing the sign-sign adaptation requires only bit shifting multiples when the step size is a power of two.

Although the performance of the sign-sign algorithm as shown in this plot is quite good, the sign-sign algorithm is much less stable than the standard LMS variations. In this noise cancellation example, the adapted signal is a very good match to the input signal, but the algorithm could very easily become unstable rather than achieve good performance.

Changing the weight initial conditions (`InitialConditions`) and `mu` (`StepSize`), or even the lowpass filter you used to create the correlated noise, can cause noise cancellation to fail and the algorithm to become useless.

Access Full History of LMS Filter Weights

Note: This example runs only in R2017a or later. If you are using a release earlier than R2017a, the object does not output a full sample-by-sample history of filter weights. If you are using a release earlier than R2016b, replace each call to the function with the equivalent `step` syntax. For example, `myObject(x)` becomes `step(myObject,x)`.

Initialize the `dsp.LMSFilter` System object and set the `WeightsOutput` property to `'All'`. This setting enables the LMS filter to output a matrix of weights with dimensions `[FrameLength Length]`, corresponding to the full sample-by-sample history of weights for all `FrameLength` samples of input values.

```
FrameSize = 15000;
lmsfilt3 = dsp.LMSFilter('Length',63,'Method','LMS', ...
    'StepSize',0.001,'LeakageFactor',0.99999, ...
    'WeightsOutput','All'); % full Weights history

w_actual = fir1(64,[0.5 0.75]);
firfilt3 = dsp.FIRFilter('Numerator',w_actual);
sinewave = dsp.SineWave('Frequency',0.01, ...
    'SampleRate',1,'SamplesPerFrame',FrameSize);

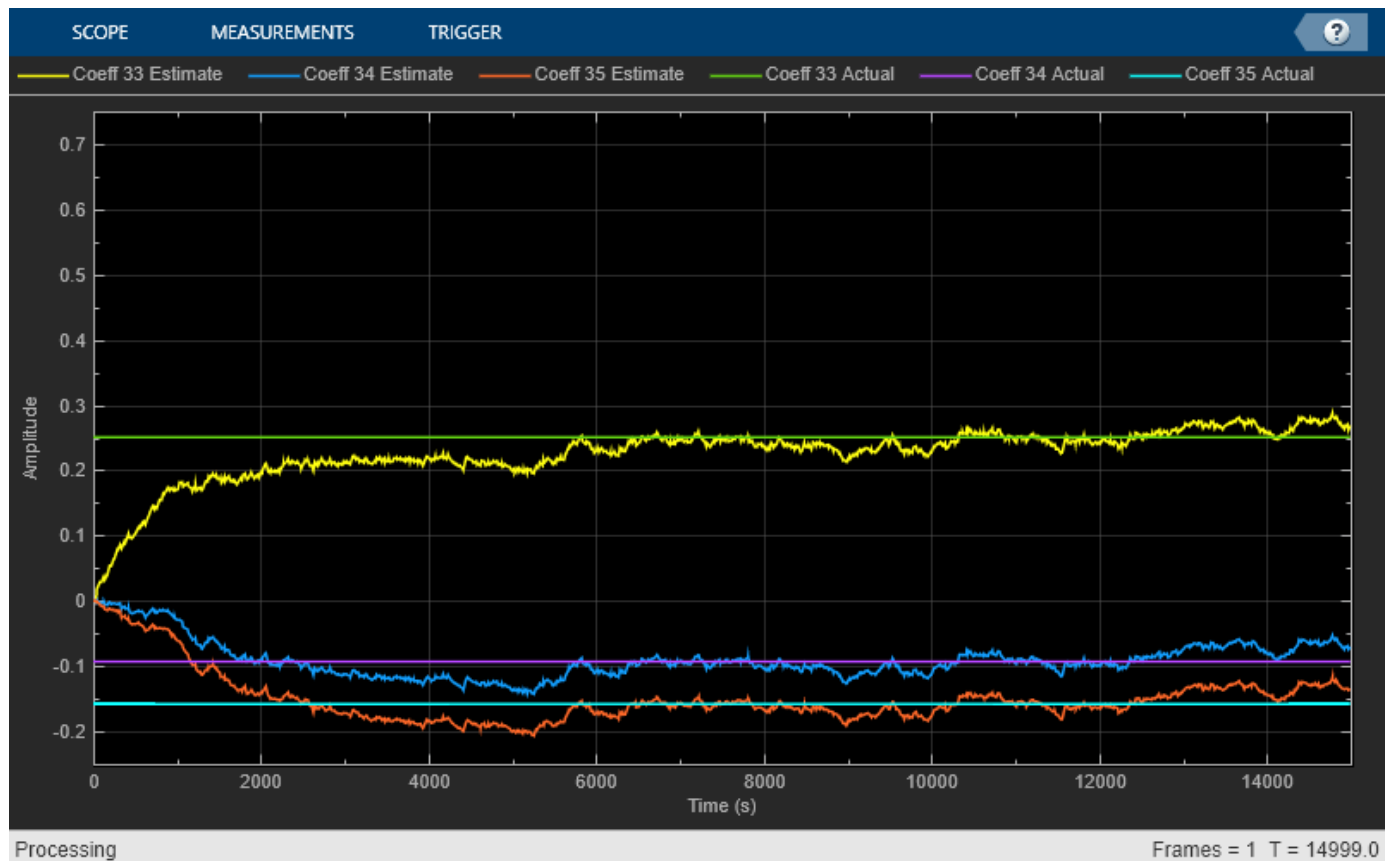

scope = timescope('TimeUnits','Seconds', ...
    'YLimits',[-0.25 0.75],'BufferLength',2*FrameSize, ...
    'ShowLegend',true,'ChannelNames', ...
    {'Coeff 33 Estimate','Coeff 34 Estimate','Coeff 35 Estimate', ...
    'Coeff 33 Actual','Coeff 34 Actual','Coeff 35 Actual'});
```

Run one frame and output the full adaptive weights history, w.

```
x = randn(FrameSize,1); % Input signal
d = firfilt3(x) + sinewave(); % Noise + Signal
[~,~,w] = lmsfilt3(x,d);
```

Each row in w is a set of weights estimated for the respective input sample. Each column in w gives the complete history of a specific weight. Plot the actual weight and the entire history of the 33rd, 34th, and 35th weight. In the plot, you can see that the estimated weight output eventually converges with the actual weight as the adaptive filter receives input samples and continues to adapt.

```
idxBeg = 33;
idxEnd = 35;
scope([w(:,idxBeg:idxEnd), repmat(w_actual(idxBeg:idxEnd),FrameSize,1)])
```

Algorithms

The LMS filter algorithm is defined by the following equations.

$$\begin{aligned}
 y(n) &= \mathbf{w}^T(n-1)\mathbf{u}(n) \\
 e(n) &= d(n) - y(n) \\
 \mathbf{w}(n) &= \alpha\mathbf{w}(n-1) + f(\mathbf{u}(n), e(n), \mu)
 \end{aligned}$$

The various LMS adaptive filter algorithms available in this System object are defined as:

- LMS -- Solves the Weiner-Hopf equation and finds the filter coefficients for an adaptive filter.

$$f(\mathbf{u}(n), e(n), \mu) = \mu e(n)\mathbf{u}^*(n)$$

- Normalized LMS -- Normalized variation of the LMS algorithm.

$$f(\mathbf{u}(n), e(n), \mu) = \mu e(n) \frac{\mathbf{u}^*(n)}{\varepsilon + \mathbf{u}^H(n)\mathbf{u}(n)}$$

In Normalized LMS, to overcome potential numerical instability in the update of the weights, a small positive constant, ε , has been added in the denominator. For double-precision floating-point input, ε is 2.2204460492503131e-016. For single-precision floating-point input, ε is 1.192092896e-07. For fixed-point input, ε is 0.

- Sign-Data LMS -- Correction to the filter weights at each iteration depends on the sign of the input $\mathbf{u}(n)$.

$$f(\mathbf{u}(n), e(n), \mu) = \mu e(n) \text{sign}(\mathbf{u}(n))$$

where $\mathbf{u}(n)$ is real.

- Sign-Error LMS -- Correction applied to the current filter weights for each successive iteration depends on the sign of the error, $e(n)$.

$$f(\mathbf{u}(n), e(n), \mu) = \mu \text{sign}(e(n)) \mathbf{u}^*(n)$$

- Sign-Sign LMS -- Correction applied to the current filter weights for each successive iteration depends on both the sign of $\mathbf{u}(n)$ and the sign of $e(n)$.

$$f(\mathbf{u}(n), e(n), \mu) = \mu \text{sign}(e(n)) \text{sign}(\mathbf{u}(n))$$

where $\mathbf{u}(n)$ is real.

The variables are as follows:

Variable	Description
n	The current time index
$\mathbf{u}(n)$	The vector of buffered input samples at step n
$\mathbf{u}^*(n)$	The complex conjugate of the vector of buffered input samples at step n
$\mathbf{w}(n)$	The vector of filter weight estimates at step n
$y(n)$	The filtered output at step n
$e(n)$	The estimation error at step n
$d(n)$	The desired response at step n
μ	The adaptation step size
α	The leakage factor ($0 < \alpha \leq 1$)
ε	A constant that corrects any potential numerical instability that occurs during the update of weights.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

See “System Objects in MATLAB Code Generation” (MATLAB Coder).

The `dsp.LMSFilter` System object supports SIMD code generation using Intel AVX2 technology under these conditions:

- Method is set to 'LMS' or 'Normalized LMS'.
- WeightsOutput is set to 'None' or 'Last'.

- Input signal is real-valued.
- Input signal has a data type of `single` or `double`.

The SIMD technology significantly improves the performance of the generated code.

Fixed-Point Conversion

Design and simulate fixed-point systems using Fixed-Point Designer™.

The following diagrams show the data types used within the `dsp.LMSFilter` object for fixed-point signals. The table summarizes the definitions of the variables used in the diagrams:

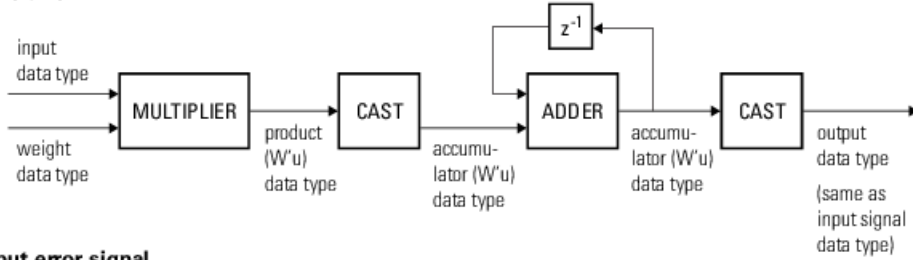

Variable	Definition
u	Input vector
W	Vector of filter weights
μ	Step size
e	Error
Q	Quotient, $Q = \frac{\mu \cdot e}{\mathbf{u}'\mathbf{u}}$
Product $\mathbf{u}'\mathbf{u}$	Product data type in Energy calculation diagram
Accumulator $\mathbf{u}'\mathbf{u}$	Accumulator data type in Energy calculation diagram
Product $\mathbf{W}'\mathbf{u}$	Product data type in Convolution diagram
Accumulator $\mathbf{W}'\mathbf{u}$	Accumulator data type in Convolution diagram
Product $\mu \cdot e$	Product data type in Product of step size and error diagram
Product $Q \cdot \mathbf{u}$	Product and accumulator data type in Weight update diagram. ¹

¹The accumulator data type for this quantity is automatically set to be the same as the product data type. The minimum, maximum, and overflow information for this accumulator is logged as part of the product information. Autoscaling treats this product and accumulator as one data type.

Energy calculation (for normalized LMS algorithm only)

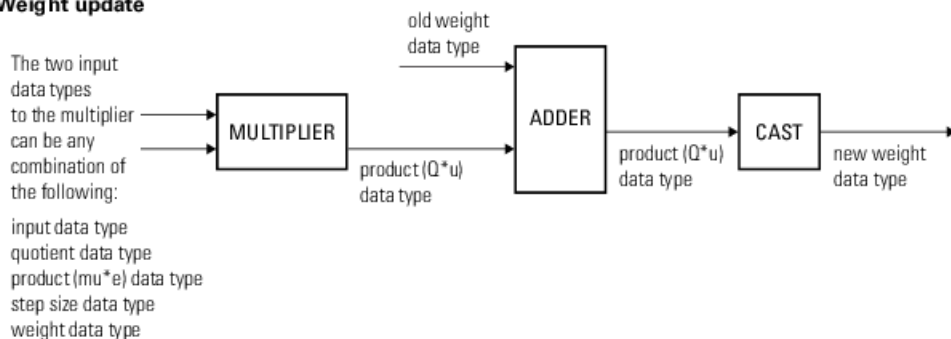

Convolution

Output error signal

Product of step size and error (for LMS and Sign-Data LMS algorithms only)**Quotient (for normalized LMS only)****Weight update**

You can set the data type of the properties, weights, products, quotient, and accumulators in the System object properties. Fixed-point inputs, outputs, and System object properties must have the following characteristics:

- The input signal and the desired signal must have the same word length, but their fraction lengths can differ.
- The step size and leakage factor must have the same word length, but their fraction lengths can differ.
- The output signal and the error signal have the same word length and the same fraction length as the desired signal.
- The quotient and the product output of the $\mathbf{u}'\mathbf{u}$, $\mathbf{W}'\mathbf{u}$, $\mu \cdot e$, and $Q \cdot \mathbf{u}$ operations must have the same word length, but their fraction lengths can differ.
- The accumulator data type of the $\mathbf{u}'\mathbf{u}$ and $\mathbf{W}'\mathbf{u}$ operations must have the same word length, but their fraction lengths can differ.

The output of the multiplier is in the product output data type if at least one of the inputs to the multiplier is real. If both of the inputs to the multiplier are complex, the result of the multiplication is in the accumulator data type. For details on the complex multiplication performed, see “Multiplication Data Types”.

dsp.LogicAnalyzer

Package: dsp

Visualize, measure, and analyze transitions and states over time

Description

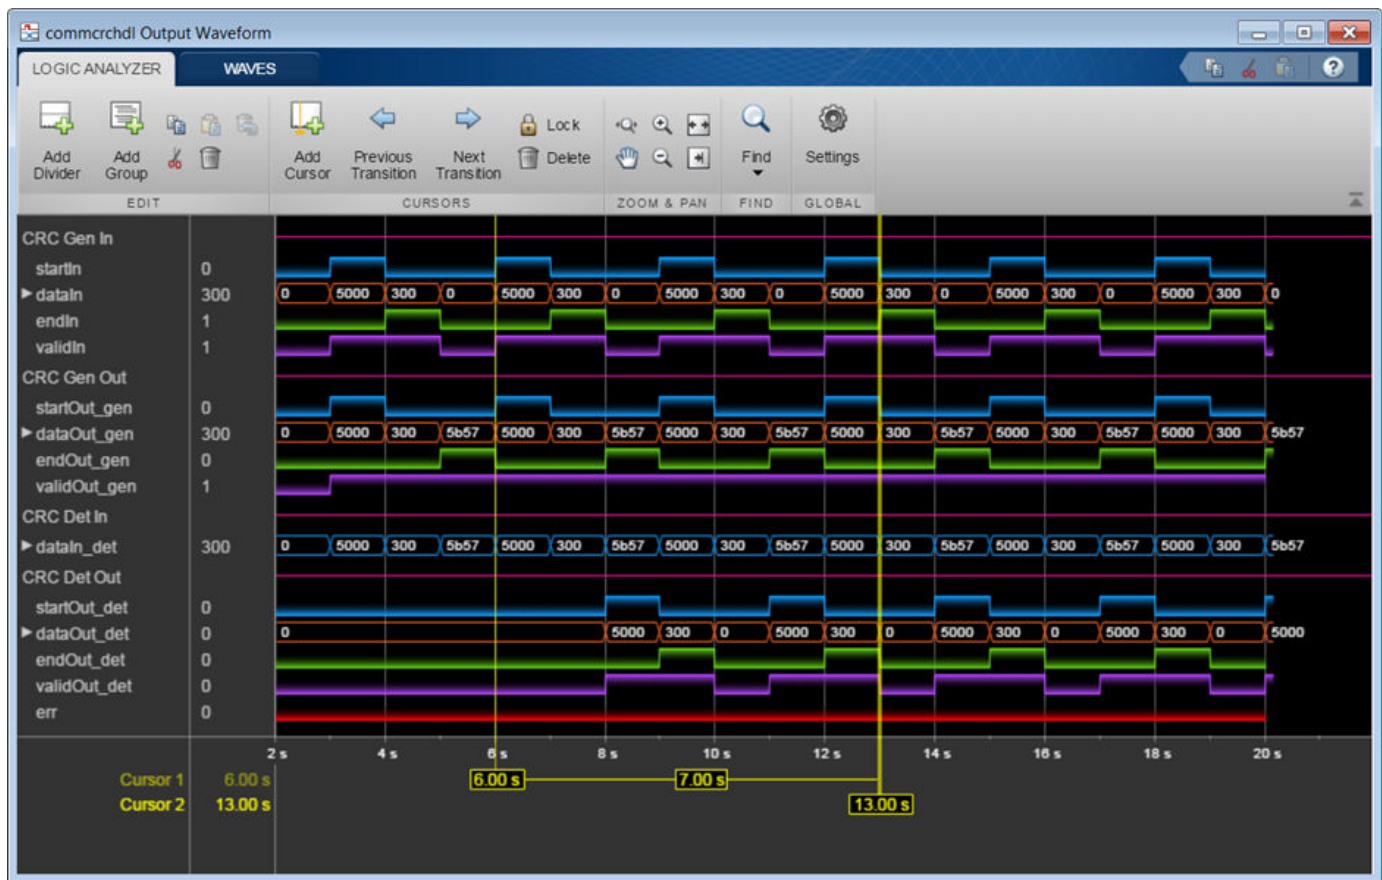

The Logic Analyzer System object displays the transitions in time-domain signals. Using `dsp.LogicAnalyzer`, you can:

- Debug and analyze models
- Trace and correlate 96 signals simultaneously
- Detect and analyze timing violations
- Trace system execution
- Detect signal changes using triggers

To display the transitions of signals in the Logic Analyzer:

- 1** Create the `dsp.LogicAnalyzer` object and set its properties.
- 2** Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

For more information about how to configure and customize the Logic Analyzer, see **Logic Analyzer**.

Creation

Syntax

```
scope = dsp.LogicAnalyzer
scope = dsp.LogicAnalyzer(Name,Value)
```

Description

`scope = dsp.LogicAnalyzer` creates a Logic Analyzer System object, `scope`.

`scope = dsp.LogicAnalyzer(Name,Value)` sets properties using one or more name-value pairs. Enclose each property name in single quotes. For example, `scope = dsp.LogicAnalyzer('BackgroundColor','White','NumInputPorts',4)`.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects.

BackgroundColor — Background color for display

'Black' (default) | 'White'

Background color of the display, specified as 'Black' or 'White'.

Tunable: Yes

Data Types: char | string

DisplayChannelColor — Color for channels in display

[0.0588 1 1] (default) | RGB triplet

Color for channels in the display, specified as an RGB triplet.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range [0,1]; for example, [0.4 0.6 0.7].

Tunable: Yes

Data Types: double | single | uint8 | uint16 | uint32 | uint64 | int8 | int16 | int32 | int64

DisplayChannelFontSize — Font size for channels in display

10 (default) | nonnegative scalar integer

Font size for channels in the display, in points, specified as a nonnegative integer.

Tunable: Yes

Data Types: double | single | uint8 | uint16 | uint32 | uint64 | int8 | int16 | int32 | int64

DisplayChannelFormat — Format for channels in display

'Automatic' (default) | 'Analog' | 'Digital'

Format for channels in the display, specified as one of the following:

- 'Automatic' — Displays floating-point signals in `Analog` format and integer and fixed-point signals in `Digital` format. Boolean signals are displayed as zero or one.
- 'Analog' — Shows values as an analog plot.
- 'Digital' — Shows values as digital transitions.

Tunable: Yes

Data Types: char | string

DisplayChannelHeight — Channel height in display

12 (default) | positive real scalar

Channel height in the display, in pixels, specified as a positive real scalar in the range [8, 200].

Tunable: Yes

Data Types: double | single | uint8 | uint16 | uint32 | uint64 | int8 | int16 | int32 | int64

DisplayChannelRadix — Base used to display values

'Hexadecimal' (default) | 'Binary' | 'Octal' | 'Signed decimal' | 'Unsigned decimal'

This property applies only to fixed-point (fi) values.

Tunable: Yes

Data Types: char | string

DisplayChannelSpacing — Spacing between channels in display (pixels)

4 (default) | positive integer

Spacing between channels in the display, in pixels, specified as a positive scalar integer.

Tunable: Yes

Data Types: double | single | uint8 | uint16 | uint32 | uint64 | int8 | int16 | int32 | int64

Name — Caption to display on scope window

'Logic Analyzer' (default) | character vector | string scalar

Caption to display on the scope window, specified as a character vector or string.

Tunable: Yes

Data Types: char | string

NumInputPorts — Number of input ports

1 (default) | integer between [1, 96]

Number of input ports, specified as a positive integer. Each signal coming through a separate input becomes a separate channel in the scope. You must invoke the scope with the same number of inputs as the value of this property.

Position — Scope window position

[left bottom width height] vector

Position of the scope window on your screen, in pixels, specified as a [left bottom width height] vector. The default position depends on your screen resolution. By default, the scope window appears in the center of your screen, with a width of 800 pixels and height of 600 pixels.

Tunable: Yes

Data Types: double | single | uint8 | uint16 | uint32 | uint64 | int8 | int16 | int32 | int64

SampleTime — Input sample time

1 (default) | scalar

Sample time of inputs in seconds, specified as a finite numeric scalar. The same sample time is used for all inputs.

Data Types: double | single | uint8 | uint16 | uint32 | uint64 | int8 | int16 | int32 | int64

TimeDisplayOffset — Time display offset

0 (default) | nonnegative scalar

Time display offset in seconds, specified as a nonnegative scalar.

Tunable: Yes

Data Types: double | single | uint8 | uint16 | uint32 | uint64 | int8 | int16 | int32 | int64

TimeSpan — Time span

10 | positive scalar

Time span in seconds, specified as a positive scalar. The x-axis limits are calculated as follows:

- Minimum x-axis limit = `min(TimeDisplayOffset)`
- Maximum x-axis limit = `max(TimeDisplayOffset) + TimeSpan`

`TimeDisplayOffset` and `TimeSpan` are the values of their respective properties.

Tunable: Yes

Data Types: double | single | uint8 | uint16 | uint32 | uint64 | int8 | int16 | int32 | int64

Usage

Syntax

```
scope(signal)
scope(signal1,signal2,...signalN)
```

Description

`scope(signal)` displays the signal `signal` in the Logic Analyzer scope.

`scope(signal1,signal2,...signalN)` displays multiple signals in the Logic Analyzer when you set the `NumInputPorts` property to `N`. Each signal can have different data types and dimensions.

Input Arguments

signal — Input signal or signals to visualize

scalar | vector | matrix

Specify one or more input signals to visualize in the `dsp.LogicAnalyzer`. Signals can have different data types and dimensions.

Integers are supported up to 64 bits and fixed-point signals are supported up to 128 bits.

Example: `scope(signal1,signal2)`

Data Types: single | double | int8 | int16 | int32 | uint8 | uint16 | uint32 | logical | struct | table | cell

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Specific to dsp.LogicAnalyzer

addCursor	Add cursor to Logic Analyzer
addDivider	Add divider to Logic Analyzer
addWave	Add wave to Logic Analyzer
deleteCursor	Delete Logic Analyzer cursor
deleteDisplayChannel	Delete Logic Analyzer channel
getCursorInfo	Return settings for Logic Analyzer cursor
getCursorTags	Return all Logic Analyzer cursor tags
getDisplayChannelInfo	Return settings for Logic Analyzer display channel
getDisplayChannelTags	Return all Logic Analyzer display channel tags
modifyCursor	Modify properties of Logic Analyzer cursor
modifyDisplayChannel	Modify properties of Logic Analyzer display channel
moveDisplayChannel	Move position of Logic Analyzer display channel

Specific to Scopes

show	Display scope window
hide	Hide scope window
isVisible	Determine visibility of scope

Common to All System Objects

step	Run System object algorithm
release	Release resources and allow changes to System object property values and input characteristics
reset	Reset internal states of System object

Examples

Display Simple Ramp Signals

Create a dsp.LogicAnalyzer object. Call the scope in a loop to display the signals.

```
scope = dsp.LogicAnalyzer('NumInputPorts',3);  
for ii = 1:20  
    scope(ii,10*ii,20*ii);  
end
```

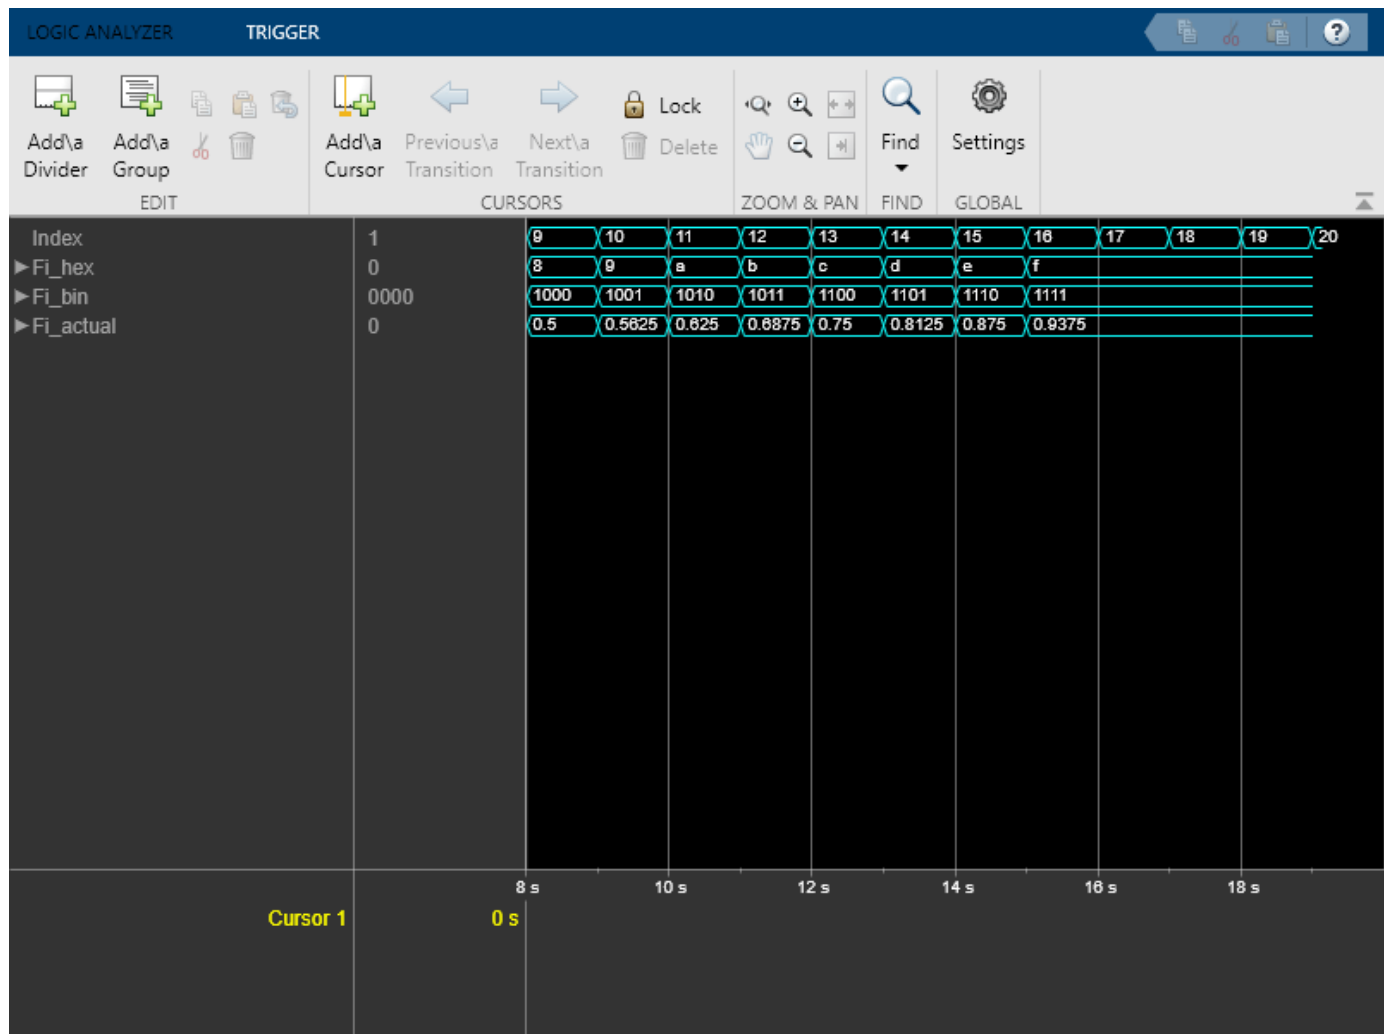

Display Fixed-Point Signals

Create a `dsp.LogicAnalyzer` object with four channels. Call `modifyDisplayChannel` to set the radix of each of the channels. Run the scope in a loop to display the waves.

```
scope = dsp.LogicAnalyzer('NumInputPorts',4,'DisplayChannelFormat','Digital');
scope.TimeSpan = 12;
```

```
modifyDisplayChannel(scope,1,'Name','Index','Radix','Unsigned decimal');
modifyDisplayChannel(scope,2,'Name','Fi_hex','Radix','Hexadecimal');
modifyDisplayChannel(scope,3,'Name','Fi_bin','Radix','Binary');
modifyDisplayChannel(scope,4,'Name','Fi_actual','Radix','Signed decimal');
```

```
for ii = 1:20
    fival = fi((ii-1)/16,0,4,4);
    scope(ii,fival,fival,fival);
end
```

Display Vector, Complex, and Enumerated Signals

Define a `WeekDaysInt` class to hold an enumerated list of weekday values. Create and save the following class definition file.

```
classdef WeekDaysInt < int32
    enumeration
        Monday(1), Tuesday(2), Wednesday(3), Thursday(4), Friday(5)
    end
end
```

Create a `dsp.LogicAnalyzer` object and configure the vector, complex, and enumerated data signals.

```
scope = dsp.LogicAnalyzer('NumInputPorts',6);
waves = getDisplayChannelTags(scope);

modifyDisplayChannel(scope,waves{1}, 'InputChannel',1, 'Name', 'Vector Digital');
```

```

modifyDisplayChannel(scope,waves{2},'InputChannel',2,'Name','Vector Analog',...
    'Format','Analog','Height',80);
modifyDisplayChannel(scope,waves{3},'InputChannel',3,'Name','Complex Digital');
modifyDisplayChannel(scope,waves{4},'InputChannel',4,'Name','Complex Analog',...
    'Format','Analog','Height',80,'Color','Green');
modifyDisplayChannel(scope,waves{5},'InputChannel',5,'Name','Enum Digital');
modifyDisplayChannel(scope,waves{6},'InputChannel',6,'Name','Enum Analog',...
    'Format','Analog','Height',80);

```

Call the scope object in a loop to display the signals.

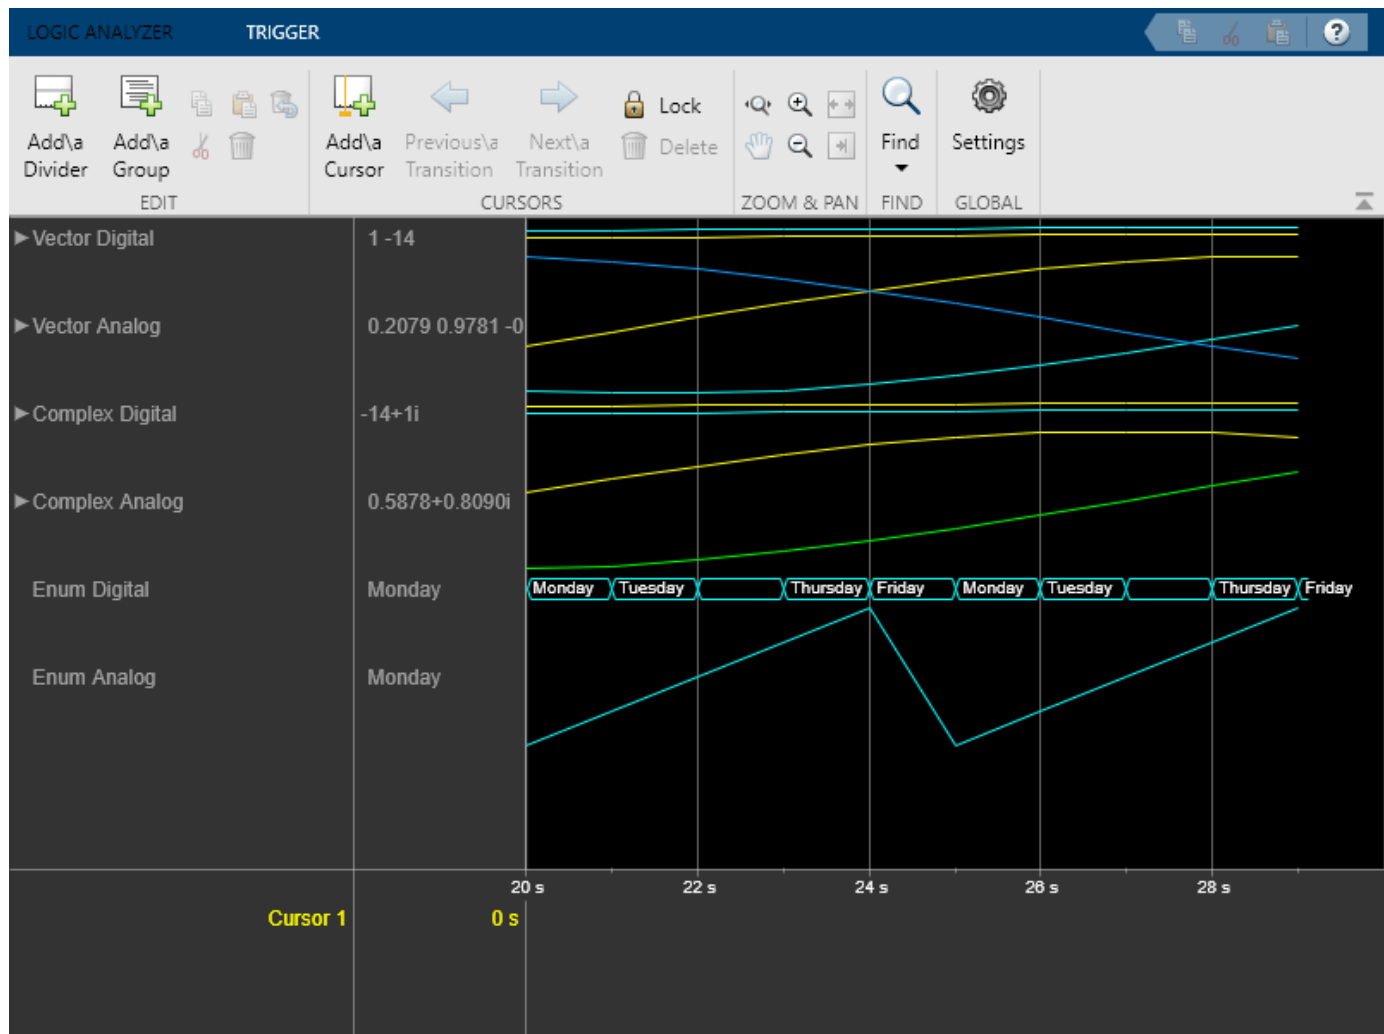

```

stop = 30;
for count = 1:stop
    sinValVec      = sin(count/stop*2*pi);
    cosValVec      = cos(count/stop*2*pi);
    cosValVecOffset = cos((count+10)/stop*2*pi);
    sinValReal     = sin((count+2)/stop*2*pi);
    cosValImag     = cos((count+2)/stop*2*pi);

    % Create a weekday enumerated value by wrapping the index
    day = WeekDaysInt(1+mod(count-1,5));

    scope(...
        [count (count-(stop/2))],...           % digital vector
        [sinValVec cosValVec cosValVecOffset],... % analog vector
        complex((count-(stop/2)),count),...   % digital complex
        complex(sinValReal, cosValImag),...   % analog complex
        day,...                               % digital enum
        day...                                 % analog enum
    )
end

```

Tips

To close the logic analyzer window and clear its associated data, use the MATLAB `clear` function.

dsp.LowerTriangularSolver

Package: dsp

(To be removed) Solve lower-triangular matrix equation

Note `dsp.LowerTriangularSolver` will be removed in a future release. Use the `mldivide` function or the `\` operator instead. For more information, see “Compatibility Considerations”.

Description

The `LowerTriangularSolver` object solves $LX = B$ for X when L is a square, lower-triangular matrix with the same number of rows as B .

To solve $LX = B$ for X :

- 1 Create the `dsp.LowerTriangularSolver` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

Creation

Syntax

```
lowtriang = dsp.LowerTriangularSolver  
lowtriang = dsp.LowerTriangularSolver(Name,Value)
```

Description

`lowtriang = dsp.LowerTriangularSolver` returns a linear system solver, `lowtriang`, used to solve the linear system $LX = B$, where L is a lower (or unit-lower) triangular matrix.

`lowtriang = dsp.LowerTriangularSolver(Name,Value)` returns a linear system solver, `lowtriang`, with each specified property set to the specified value.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see [System Design in MATLAB Using System Objects](#).

OverwriteDiagonal — Replace diagonal elements of input with ones

false (default) | true

When you set this property to `true`, the linear system solver replaces the elements on the diagonal of the input, L , with ones. This property is useful when matrix L is the result of another operation, such as an LDL decomposition, that uses the diagonal elements to represent the D matrix.

RealDiagonalElements — Indicate that diagonal of complex input is real

`false` (default) | `true`

When you set this property to `true`, the linear system solver optimizes computation speed if the input L is complex, but its diagonal elements are real. Set this property to either `true` or `false`.

Dependencies

This property applies only when you set the `OverwriteDiagonal` property to `false`.

Fixed-Point Properties

RoundingMethod — Rounding method for fixed-point operations

`Floor` (default) | `Ceiling` | `Convergent` | `Nearest` | `Round` | `Simplest` | `Zero`

Specify the rounding method as `Ceiling`, `Convergent`, `Floor`, `Nearest`, `Round`, `Simplest`, or `Zero`.

OverflowAction — Overflow action for fixed-point operations

`Wrap` (default) | `Saturate`

Specify the overflow action as `Wrap` or `Saturate`.

ProductDataType — Data type of product

`Full precision` (default) | `Same as input` | `Custom`

Specify the product data type as `Full precision`, `Same as input`, or `Custom`.

CustomProductDataType — Product word and fraction lengths

`numerictype([],32,30)` (default) | `numerictype`

Specify the product fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`.

Dependencies

This property applies only when you set the `ProductDataType` property to `Custom`.

AccumulatorDataType — Data type of accumulator

`Full precision` (default) | `Same as first input` | `Same as product` | `Custom`

Specify the accumulator data type as `Full precision`, `Same as first input`, `Same as product`, or `Custom`.

CustomAccumulatorDataType — Accumulator word and fraction lengths

`numerictype([],32,30)` (default) | `numerictype`

Specify the accumulator fixed-point type as a scaled `numerictype` object with a `Signedness` of `Auto`.

Dependencies

This property applies only when you set the `AccumulatorDataType` property to `Custom`.

OutputDataType — Data type of output

Same as first input (default) | Custom

Specify the output data type as Same as first input or Custom.

CustomOutputDataType — Output word and fraction lengths

numerictype([],16,15) (default) | numerictype

Specify the output fixed-point type as a scaled numerictype object with a Signedness of Auto.

Dependencies
