- Resize the RGB images and masks using the `imresize` function and rescale the bounding boxes using the `bboxresize` (Computer Vision Toolbox) function. The helper function selects a homogenous scale factor such that the smaller dimension of the image, bounding box, or mask is equal to the target network input size.
- Crop the RGB images and masks using the `imcrop` (Image Processing Toolbox) function and crop the bounding boxes using the `bboxcrop` (Computer Vision Toolbox) function. The helper function crops the image, bounding box, or mask such that the larger dimension is equal to the target network input size.
- Zero center the images using the COCO data set image mean. (The standard deviation normalization factor is included in the weights of the first convolutional layer.)

```
dsTrain = transform(ds,@(x)helper.preprocessData(x,imageSizeTrain));
```

Preview the data returned by the transformed datastore.

```
data = preview(dsTrain)
```

```
data=1×4 cell array
    {800×800×3 single}    {14×4 double}    {14×1 categorical}    {800×800×14 logical}
```

Create Mask R-CNN Network Layers

The Mask R-CNN builds upon a Faster R-CNN with a ResNet-50 base network. To transfer learn on the pretrained Mask R-CNN network, use the `maskrcnn` object to load the pretrained network and customize the network for the new set of classes and input size. By default, the `maskrcnn` object uses the same anchor boxes as the COCO data set.

```
net = maskrcnn("resnet50-coco",trainClassNames,"InputSize",imageSizeTrain)
```

```
net =
  maskrcnn with properties:

      ModelName: 'maskrcnn'
     ClassNames: {'person'  'car'}
      InputSize: [800 800 3]
    AnchorBoxes: [15×2 double]
```

Create a structure containing configuration paramaters for the Mask R-CNN network.

```
params = createMaskRCNNConfig(imageSizeTrain,numClasses,[trainClassNames {'background'}]);
params.ClassAgnosticMasks = false;
params.AnchorBoxes = net.AnchorBoxes;
params.FreezeBackbone = true;
```

Specify Training Options

Specify the options for SGDM optimization. Train the network for 10 epochs.

```
initialLearnRate = 0.0012;
momentum = 0.9;
decay = 0.01;
velocity = [];
maxEpochs = 10;
miniBatchSize = 2;
```

Batch Training Data

Create a `minibatchqueue` object that manages the mini-batching of observations in a custom training loop. The `minibatchqueue` object also casts data to a `dlarray` object that enables automatic differentiation in deep learning applications.

Define a custom batching function named `miniBatchFcn`. The images are concatenated along the fourth dimension to get an *H*-by-*W*-by-*C*-by-*miniBatchSize* shaped batch. The other ground truth data is configured a cell array of length equal to the mini-batch size.

```
miniBatchFcn = @(img,boxes,labels,masks) deal(cat(4,img{:}),boxes,labels,masks);
```

Specify the mini-batch data extraction format for the image data as `"SSCB"` (spatial, spatial, channel, batch). If a supported GPU is available for computation, then the `minibatchqueue` object preprocesses mini-batches in the background in a parallel pool during training.

```
mbqTrain = minibatchqueue(dsTrain,4, ...
    "MiniBatchFormat",["SSCB","","",""], ...
    "MiniBatchSize",miniBatchSize, ...
    "OutputCast",["single","","",""], ...
    "OutputAsDlArray",[true,false,false,false], ...
    "MiniBatchFcn",miniBatchFcn, ...
    "OutputEnvironment",["auto","cpu","cpu","cpu"]);
```

Train Network

To train the network, set the `doTraining` variable in the following code to `true`. Train the model in a custom training loop. For each iteration:

- Read the data for the current mini-batch using the `next` function.
- Evaluate the model gradients using the `dlfeval` function and the `networkGradients` helper function. The function `networkGradients`, listed as a supporting function, returns the gradients of the loss with respect to the learnable parameters, the corresponding mini-batch loss, and the state of the current batch.
- Update the network parameters using the `sgdmupdate` function.
- Update the `state` parameters of the network with the moving average.
- Update the training progress plot.

Train on a GPU if one is available. Using a GPU requires Parallel Computing Toolbox™ and a CUDA® enabled NVIDIA® GPU. For more information, see “GPU Support by Release” (Parallel Computing Toolbox).

```
doTraining = true;
if doTraining

    iteration = 1;
    start = tic;
```

```
        % Create subplots for the learning rate and mini-batch loss
        fig = figure;
        [lossPlotter, learningratePlotter] = helper.configureTrainingProgressPlotter(fig);

        % Initialize verbose output
        helper.initializeVerboseOutput([]);

        % Custom training loop
        for epoch = 1:maxEpochs
            reset(mbqTrain)
            shuffle(mbqTrain)

            while hasdata(mbqTrain)
                % Get next batch from minibatchqueue
                [X,gtBox,gtClass,gtMask] = next(mbqTrain);

                % Evaluate the model gradients and loss using dlfeval
                [gradients,loss,state,learnables] = dlfeval(@networkGradients,X,gtBox,gtClass,gtMask
                %dlnet.State = state;

                % Compute the learning rate for the current iteration
                learnRate = initialLearnRate/(1 + decay*(epoch-1));

                if(~isempty(gradients) && ~isempty(loss))
                    [net.AllLearnables,velocity] = sgdmupdate(learnables,gradients,velocity,learnRate
                else
                    continue;
                end

                % Plot loss/accuracy metric every 10 iterations
                if(mod(iteration,10)==0)
                    helper.displayVerboseOutputEveryEpoch(start,learnRate,epoch,iteration,loss);
                    D = duration(0,0,toc(start),'Format','hh:mm:ss');
                    addpoints(learningratePlotter,iteration,learnRate)
                    addpoints(lossPlotter,iteration,double(gather(extractdata(loss))))
                    subplot(2,1,2)
                    title(strcat("Epoch: ",num2str(epoch),", Elapsed: "+string(D)))
                    drawnow
                end

                iteration = iteration + 1;
            end

        end

        % Save the trained network
        modelDateTime = string(datetime('now','Format',"yyyy-MM-dd-HH-mm-ss"));
        save(strcat("trainedMaskRCNN-",modelDateTime,"-Epoch-",num2str(epoch),".mat"),'net');

    end
```

Using the trained network, you can perform instance segmentation on test images, such as demonstrated in the section Perform Instance Segmentation Using Pretrained Mask R-CNN on page 8-0 .

Estimate Body Pose Using Deep Learning

This example shows how to estimate the body pose of one or more people using the OpenPose algorithm and a pretrained network.

The goal of body pose estimation is to identify the location of people in an image and the orientation of their body parts. When multiple people are present in a scene, pose estimation can be more difficult because of occlusion, body contact, and proximity of similar body parts.

There are two strategies to estimating body pose. A top-down strategy first identifies individual people using object detection and then estimates the pose of each person. A bottom-up strategy first identifies body parts in an image, such as noses and left elbows, and then assembles individuals based on likely pairings of body parts. The bottom-up strategy is more robust to occlusion and body contact, but the strategy is more difficult to implement. OpenPose is a multi-person human pose estimation algorithm that uses a bottom-up strategy [1 on page 8-0].

To identify body parts in an image, OpenPose uses a pretrained neural network that predicts heatmaps and part affinity fields (PAFs) for body parts in an input image [2 on page 8-0]. Each heatmap shows the probability that a particular type of body part is located at each pixel in the image. The PAFs are vector fields that indicate whether two body parts are connected. For each defined type of body part pairing, such as neck to left shoulder, there are two PAFs that show the x- and y-component of the vector field between instances of the body parts.

To assemble body parts into individual people, the OpenPose algorithm performs a series of post-processing operations. The first operation identifies and localized body parts using the heatmaps returned by the network. Subsequent operations identify actual connections between body parts, resulting in the individual poses. For more details about the algorithm, see Identify Poses from Heatmaps and PAFs on page 8-0 .

Import the Network

Import a pretrained network from an ONNX file.

```
dataDir = fullfile(tempdir,'OpenPose');
trainedOpenPoseNet_url = 'https://ssd.mathworks.com/supportfiles/vision/data/human-pose-estimatio
downloadTrainedOpenPoseNet(trainedOpenPoseNet_url,dataDir)
unzip(fullfile(dataDir,'human-pose-estimation.zip'),dataDir);
```

Download and install the Deep Learning Toolbox™ Converter for ONNX Model Format support package.

If Deep Learning Toolbox Converter™ for ONNX Model Format is not installed, then the function provides a link to the required support package in the Add-On Explorer. To install the support package, click the link, and then click Install. If the support package is installed, then the `importONNXLayers` function returns a `LayerGraph` object.

```
modelfile = fullfile(dataDir,'human-pose-estimation.onnx');
layers = importONNXLayers(modelfile,"ImportWeights",true);
```

Remove the unused output layers.

```
layers = removeLayers(layers,["Output_node_95" "Output_node_98" "Output_node_147" "Output_node_15
net = dlnetwork(layers);
```

Predict Heatmaps and PAFs of Test Image

Read and display a test image.

```
im = imread("visionteam.jpg");
imshow(im)
```

The network expects image data of data type `single` in the range [-0.5, 0.5]. Shift and rescale the data to this range.

```
netInput = im2single(im)-0.5;
```

The network expects the color channels in the order blue, green, red. Switch the order of the image color channels.

```
netInput = netInput(:,:,[3 2 1]);
```

Store the image data as a `dlarray`.

```
netInput = dlarray(netInput,"SSC");
```

Predict the heatmaps, which are output from the 2-D convolutional layer named 'node_147'.

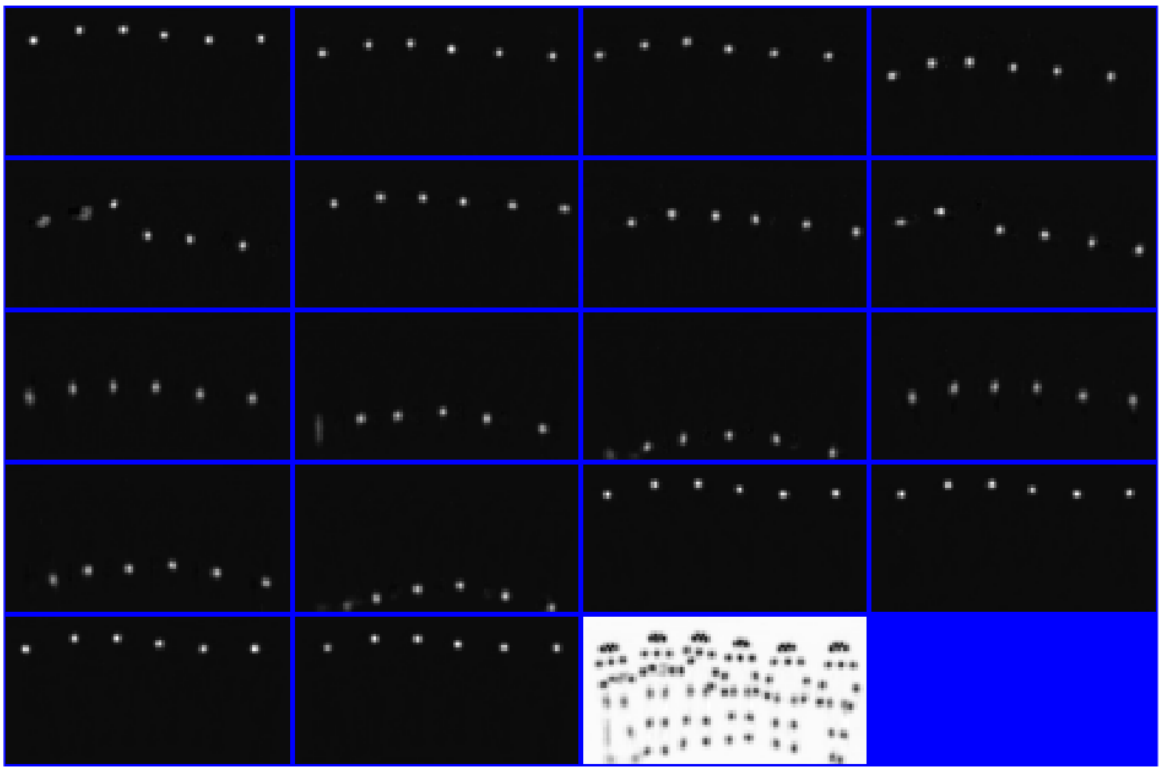
```
heatmaps = predict(net,netInput,"Outputs","node_147");
```

Get the numeric heatmap data stored in the `dlarray`. The data has 19 channels. Each channel corresponds to a heatmap for a unique body part, with one additional heatmap for the background.

```
heatmaps = extractdata(heatmaps);
```

Display the heatmaps in a montage, rescaling the data to the range [0, 1] expected of images of data type `single`. The scene has six people, and there are six bright spots in each heatmap.

```
montage(rescale(heatmaps),"BackgroundColor","b","BorderSize",3)
```



To visualize the correspondence of bright spots with the bodies, display the first heatmap in falsecolor over the test image.

```
idx = 1;
hmap = heatmaps(:,:,idx);
hmap = imresize(hmap,size(im,[1 2]));
imshowpair(hmap,im);
```

The OpenPose algorithm does not use the background heatmap to determine the location of body parts. Remove the background heatmap.

```
heatmaps = heatmaps(:,:,1:end-1);
```

Predict the PAFs, which are output from the 2-D convolutional layer named 'node_150'.

```
pafs = predict(net,netInput,"Outputs","node_150");
```

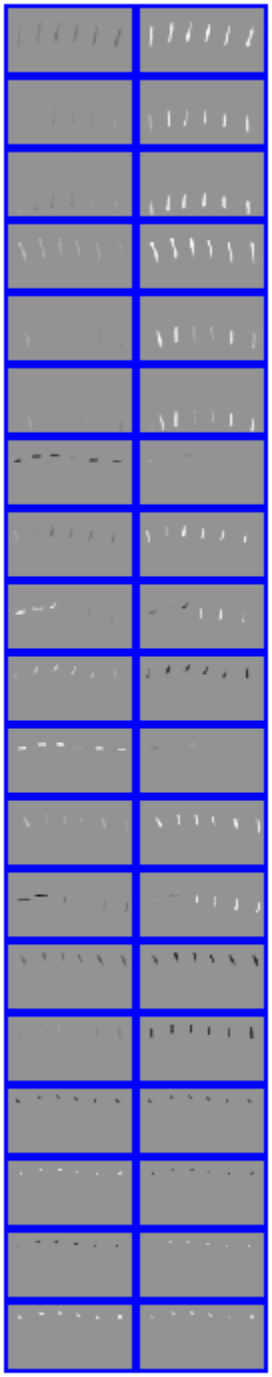
Get the numeric PAF data stored in the `dlarray`. The data has 38 channels. There are two channels for each type of body part pairing, which represent the x- and y-component of the vector field.

```
pafs = extractdata(pafs);
```

Display the PAFs in a montage, rescaling the data to the range [0, 1] expected of images of data type `single`. The two columns show the x- and y-components of the vector field, respectively. The body part pairings are in the order determined by the `params.PAF_INDEX` value.

- Pairs of body parts with a mostly vertical connection have large magnitudes for the y-component pairings and negligible values for the x-component pairings. One example is the right hip to right knee connection, which appears in the second row. Note that the PAFs depend on the actual poses in the image. An image with a body in a different orientation, such as lying down, will not necessarily have a large y-component magnitude for the right hip to right knee connection.
- Pairs of body parts with a mostly horizontal connection have large magnitudes for the x-component pairings and negligible values for the y-component pairings. One example is the neck to left shoulder connection, which appears in the seventh row.
- Pairs of body part at an angle have values for both x- and y-components of the vector field. One example is the neck to left hip, which appears in the first row.

```
montage(rescale(pafs),"Size",[19 2],"BackgroundColor","b","BorderSize",3)
```



To visualize the correspondence of the PAFs with the bodies, display the x- and y-component of the first type of body part pair in falsecolor over the test image.

```
idx = 1;
impair = horzcat(im,im);
pafpair = horzcat(pafs(:,:,2*idx-1),pafs(:,:,2*idx));
pafpair = imresize(pafpair,size(impair,[1 2]));
imshowpair(pafpair,impair);
```

Identify Poses from Heatmaps and PAFs

The post-processing part of the algorithm identifies the individual poses of the people in the image using the heatmaps and PAFs returned by the neural network.

Get parameters of the OpenPose algorithm using the `getBodyPoseParameters` helper function. The function is attached to the example as a supporting file. The function returns a struct with parameters such as the number of body parts and connections between body part types to consider. The parameters also include thresholds that you can adjust to improve the performance of the algorithm.

```
params = getBodyPoseParameters;
```

Identify individual people and their poses by using the `getBodyPoses` helper function. This function is attached to the example as a supporting file. The helper function performs all post-processing steps for pose estimation:

1. Detect the precise body part locations from the heatmaps using nonmaximum suppression.
2. For each type of body part pairing, generate all possible pairs between detected body parts. For instance, generate all possible pairs between the six necks and the six left shoulders. The result is a bipartite graph.
3. Score the pairs by computing the line integral of the straight line connecting the two detected body parts through the PAF vector field. A large score indicates a strong connection between detected body parts.
4. Sort the possible pairs by their scores and find the valid pairs. Valid body part pairs are pairs that connect two body parts that belong to the same person. Typically, pairs with the largest score are considered first because they are most likely to be a valid pair. However, the algorithm compensates for occlusion and proximity using additional constraints. For example, the same person cannot have duplicate pairs of body parts, and one body part cannot belong to two different people.
5. Knowing which body parts are connected, assemble the body parts into separate poses for each individual person.

The helper function returns a 3-D matrix. The first dimension represents the number of identified people in the image. The second dimension represents the number of body part types. The third dimension indicates the x- and y-coordinates for each body part of each person. If a body part is not detected in the image, then the coordinates for that part are [NaN NaN].

```
poses = getBodyPoses(heatmaps,pafs,params);
```

Display the body poses using the `renderBodyPoses` helper function. This function is attached to the example as a supporting file.

```
renderBodyPoses(im,poses,size(heatmaps,1),size(heatmaps,2),params);
```

Generate Image from Segmentation Map Using Deep Learning

This example shows how to generate a synthetic image of a scene from a semantic segmentation map using a pix2pixHD conditional generative adversarial network (CGAN).

Pix2pixHD [1 on page 8-0] consists of two networks that are trained simultaneously to maximize the performance of both.

1. The generator is an encoder-decoder style neural network that generates a scene image from a semantic segmentation map. A CGAN network trains the generator to generate a scene image that the discriminator misclassifies as real.
2. The discriminator is a fully convolutional neural network that compares a generated scene image and the corresponding real image and attempts to classify them as fake and real, respectively. A CGAN network trains the discriminator to correctly distinguish between generated and real image.

The generator and discriminator networks compete against each other during training. The training converges when neither network can improve further.

Download CamVid Data Set

This example uses the CamVid data set [2 on page 8-0] from the University of Cambridge for training. This data set is a collection of 701 images containing street-level views obtained while driving. The data set provides pixel labels for 32 semantic classes including car, pedestrian, and road.

Download the CamVid data set from these URLs. The download time depends on your internet connection.

```
imageURL = 'http://web4.cs.ucl.ac.uk/staff/g.brostow/MotionSegRecData/files/701_StillsRaw_full.zi
labelURL = 'http://web4.cs.ucl.ac.uk/staff/g.brostow/MotionSegRecData/data/LabeledApproved_full.z

dataDir = fullfile(tempdir,'CamVid');
downloadCamVidData(dataDir,imageURL,labelURL);
imgDir = fullfile(dataDir,"images","701_StillsRaw_full");
labelDir = fullfile(dataDir,'labels');
```

Preprocess Training Data

Create an `imageDatastore` to store the images in the CamVid data set.

```
imds = imageDatastore(imgDir);
imageSize = [576 768];
```

Define the class names and pixel label IDs of the 32 classes in the CamVid data set using the helper function `defineCamVid32ClassesAndPixelLabelIDs`. Get a standard colormap for the CamVid data set using the helper function `camvid32ColorMap`. The helper functions are attached to the example as supporting files.

```
numClasses = 32;
[classes,labelIDs] = defineCamVid32ClassesAndPixelLabelIDs;
cmap = camvid32ColorMap;
```

Create a `pixelLabelDatastore` (Computer Vision Toolbox) to store the pixel label images.

```
pxds = pixelLabelDatastore(labelDir,classes,labelIDs);
```

Preview a pixel label image and the corresponding ground truth scene image. Convert the labels from categorical labels to RGB colors by using the `label2rgb` (Image Processing Toolbox) function, then display the pixel label image and ground truth image in a montage.

```
im = preview(imds);
px = preview(pxds);
px = label2rgb(px,cmap);
montage({px,im})
```

Partition the data into training and test sets using the helper function `partitionCamVidForPix2PixHD`. This function is attached to the example as a supporting file. The helper function splits the data into 648 training files and 32 test files.

```
[imdsTrain,imdsTest,pxdsTrain,pxdsTest] = partitionCamVidForPix2PixHD(imds,pxds,classes,labelIDs)
```

Use the `combine` function to combine the pixel label images and ground truth scene images into a single datastore.

```
dsTrain = combine(pxdsTrain,imdsTrain);
```

Augment the training data by using the `transform` function with custom preprocessing operations specified by the helper function `preprocessCamVidForPix2PixHD`. This helper function is attached to the example as a supporting file.

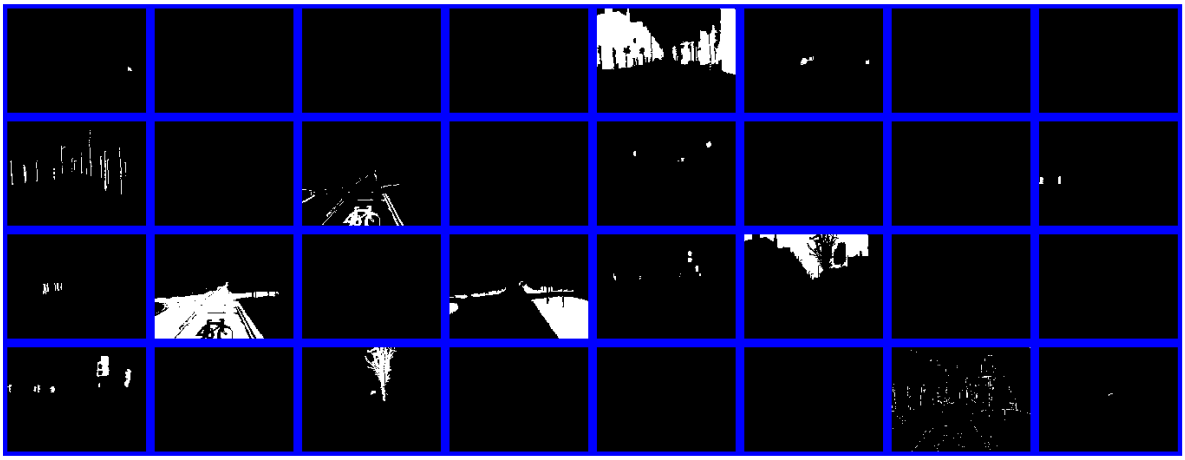
The `preprocessCamVidForPix2PixHD` function performs these operations:

1. Scale the ground truth data to the range [-1, 1]. This range matches the range of the final `tanhLayer` in the generator network.
2. Resize the image and labels to the output size of the network, 576-by-768 pixels, using bicubic and nearest neighbor downsampling, respectively.
3. Convert the single channel segmentation map to a 32-channel one-hot encoded segmentation map using the `onehotencode` function.
4. Randomly flip image and pixel label pairs in the horizontal direction.

```
dsTrain = transform(dsTrain,@(x) preprocessCamVidForPix2PixHD(x,imageSize));
```

Preview the channels of a one-hot encoded segmentation map in a montage. Each channel represents a one-hot map corresponding to pixels of a unique class.

```
map = preview(dsTrain);
montage(map{1},'Size',[4 8],'Bordersize',5,'BackgroundColor','b')
```



Create Generator Network

Define a pix2pixHD generator network that generates a scene image from a depth-wise one-hot encoded segmentation map. This input has same height and width as the original segmentation map and the same number of channels as classes.

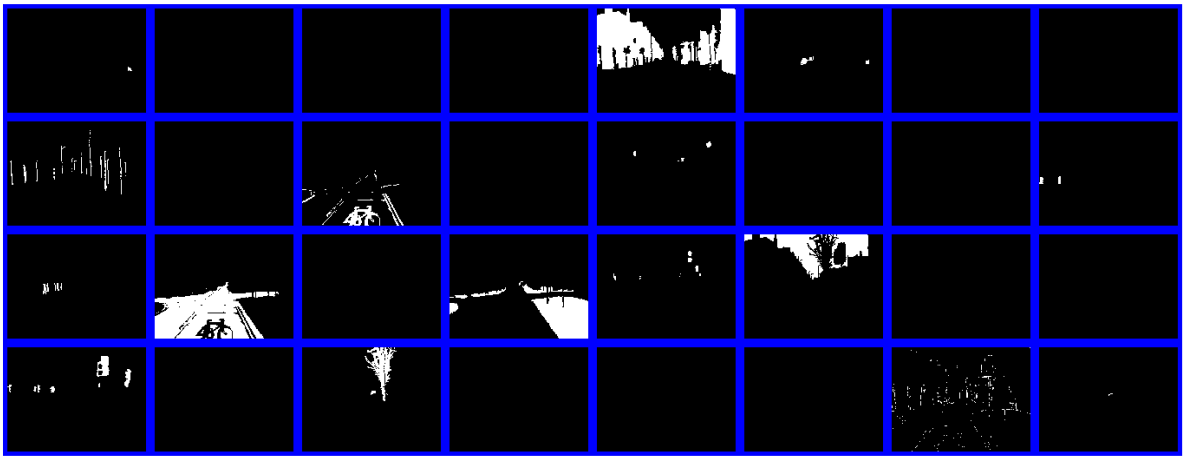
```
generatorInputSize = [imageSize numClasses];
```

Create the pix2pixHD generator network using the `pix2pixHDGlobalGenerator` (Image Processing Toolbox) function.

```
dlnetGenerator = pix2pixHDGlobalGenerator(generatorInputSize);
```

Display the network architecture.

```
analyzeNetwork(dlnetGenerator)
```



Note that this example shows the use of pix2pixHD global generator for generating images of size 576-by-768 pixels. To create local enhancer networks that generate images at higher resolution such as 1152-by-1536 pixels or even higher, you can use the `addPix2PixHDLocalEnhancer` (Image Processing Toolbox) function. The local enhancer networks help generate fine level details at very high resolutions.

Create Discriminator Network

Define the patch GAN discriminator networks that classifies an input image as either real (1) or fake (0). This example uses two discriminator networks at different input scales, also known as multiscale discriminators. The first scale is the same size as the image size, and the second scale is half the size of image size.

The input to the discriminator is the depth-wise concatenation of the one-hot encoded segmentation maps and the scene image to be classified. Specify the number of channels input to the discriminator as the total number of labeled classes and image color channels.

```
numImageChannels = 3;
numChannelsDiscriminator = numClasses + numImageChannels;
```

Specify the input size of the first discriminator. Create the patch GAN discriminator with instance normalization using the `patchGANDiscriminator` (Image Processing Toolbox) function.

```
discriminatorInputSizeScale1 = [imageSize numChannelsDiscriminator];
dlnetDiscriminatorScale1 = patchGANDiscriminator(discriminatorInputSizeScale1,"NormalizationLaye
```

Specify the input size of the second discriminator as half the image size, then create the second patch GAN discriminator.

```
discriminatorInputSizeScale2 = [floor(imageSize)./2 numChannelsDiscriminator];
dlnetDiscriminatorScale2 = patchGANDiscriminator(discriminatorInputSizeScale2,"NormalizationLaye
```

Visualize the networks.

```
analyzeNetwork(dlnetDiscriminatorScale1);
analyzeNetwork(dlnetDiscriminatorScale2);
```

Define Model Gradients and Loss Functions

The helper function `modelGradients` calculates the gradients and adversarial loss for the generator and discriminator. The function also calculates the feature matching loss and VGG loss for the generator. This function is defined in Supporting Functions on page 8-0 section of this example.

Generator Loss

The objective of the generator is to generate images that the discriminator classifies as real (1). The generator loss consists of three losses.

- The adversarial loss is computed as the squared difference between a vector of ones and the discriminator predictions on the generated image. $\widehat{Y}_{generated}$ are discriminator predictions on the image generated by the generator. This loss is implemented using part of the `pix2pixhdAdversarialLoss` helper function defined in the Supporting Functions on page 8-0 section of this example.

  $$lossAdversarialGenerator = (1 - \widehat{Y}_{generated})^2$$

- The feature matching loss penalises the L^1 distance between the real and generated feature maps obtained as predictions from the discriminator network. T is total number of discriminator feature layers. Y_{real} and $\widehat{Y}_{generated}$ are the ground truth images and generated images, respectively. This loss is implemented using the `pix2pixhdFeatureMatchingLoss` helper function defined in the Supporting Functions on page 8-0 section of this example

  $$lossFeatureMatching = \sum_{i=1}^{T} ||Y_{real} - \widehat{Y}_{generated}||_1$$

- The perceptual loss penalises the L^1 distance between real and generated feature maps obtained as predictions from a feature extraction network. T is total number of feature layers. $Y_{VggReal}$ and $\widehat{Y}_{VggGenerated}$ are network predictions for ground truth images and generated images, respectively. This loss is implemented using the `pix2pixhdVggLoss` helper function defined in the Supporting Functions on page 8-0 section of this example. The feature extraction network is created in Load Feature Extraction Network on page 8-0 .

  $$lossVgg = \sum_{i=1}^{T} ||Y_{VggReal} - \widehat{Y}_{VggGenerated}||_1$$

The overall generator loss is a weighted sum of all three losses. λ_1, λ_2, and λ_3 are the weight factors for adversarial loss, feature matching loss, and perceptual loss, respectively.

$$lossGenerator = \lambda_1 * lossAdversarialGenerator + \lambda_2 * lossFeatureMatching + \lambda_3 * lossPerceptual$$

Note that the adversarial loss and feature matching loss for the generator are computed for two different scales.

Discriminator Loss

The objective of the discriminator is to correctly distinguish between ground truth images and generated images. The discriminator loss is a sum of two components:

- The squared difference between a vector of ones and the predictions of the discriminator on real images
- The squared difference between a vector of zeros and the predictions of the discriminator on generated images

$$lossDiscriminator = (1 - Y_{real})^2 + (0 - \hat{Y}_{generated})^2$$

The discriminator loss is implemented using part of the `pix2pixhdAdversarialLoss` helper function defined in the Supporting Functions on page 8-0 section of this example. Note that adversarial loss for the discriminator is computed for two different discriminator scales.

Load Feature Extraction Network

This example modifies a pretrained VGG-19 deep neural network to extract the features of the real and generated images at various layers. These multilayer features are used to compute the perceptual loss of the generator.

To get a pretrained VGG-19 network, install `vgg19`. If you do not have the required support packages installed, then the software provides a download link.

```
netVGG = vgg19;
```

Visualize the network architecture using the Deep Network Designer app.

```
deepNetworkDesigner(netVGG)
```

To make the VGG-19 network suitable for feature extraction, keep the layers up to 'pool5' and remove all of the fully connected layers from the network. The resulting network is a fully convolutional network.

```
netVGG = layerGraph(netVGG.Layers(1:38));
```

Create a new image input layer with no normalization. Replace the original image input layer with the new layer.

```
inp = imageInputLayer([imageSize 3],"Normalization","None","Name","Input");
netVGG = replaceLayer(netVGG,"input",inp);
netVGG = dlnetwork(netVGG);
```

Specify Training Options

Specify the options for Adam optimization. Train for 60 epochs. Specify identical options for the generator and discriminator networks.

- Specify an equal learning rate of 0.0002.
- Initialize the trailing average gradient and trailing average gradient-square decay rates with `[]`.
- Use a gradient decay factor of 0.5 and a squared gradient decay factor of 0.999.
- Use a mini-batch size of 1 for training.

```
numEpochs = 60;
learningRate = 0.0002;
trailingAvgGenerator = [];
trailingAvgSqGenerator = [];
trailingAvgDiscriminatorScale1 = [];
trailingAvgSqDiscriminatorScale1 = [];
```

```
trailingAvgDiscriminatorScale2 = [];
trailingAvgSqDiscriminatorScale2 = [];
gradientDecayFactor = 0.5;
squaredGradientDecayFactor = 0.999;
miniBatchSize = 1;
```

Create a `minibatchqueue` object that manages the mini-batching of observations in a custom training loop. The `minibatchqueue` object also casts data to a `dlarray` object that enables auto differentiation in deep learning applications.

Specify the mini-batch data extraction format as `SSCB` (spatial, spatial, channel, batch). Set the `DispatchInBackground` name-value pair argument as the boolean returned by `canUseGPU`. If a supported GPU is available for computation, then the `minibatchqueue` object preprocesses mini-batches in the background in a parallel pool during training.

```
mbqTrain = minibatchqueue(dsTrain,"MiniBatchSize",miniBatchSize, ...
   "MiniBatchFormat","SSCB","DispatchInBackground",canUseGPU);
```

Train the Network

By default, the example downloads a pretrained version of the pix2pixHD generator network for the CamVid data set by using the helper function `downloadTrainedPix2PixHDNet`. The helper function is attached to the example as a supporting file. The pretrained network enables you to run the entire example without waiting for training to complete.

To train the network, set the `doTraining` variable in the following code to `true`. Train the model in a custom training loop. For each iteration:

- Read the data for current mini-batch using the `next` function.
- Evaluate the model gradients using the `dlfeval` function and the `modelGradients` helper function.
- Update the network parameters using the `adamupdate` function.
- Update the training progress plot for every iteration and display various computed losses.

Train on a GPU if one is available. Using a GPU requires Parallel Computing Toolbox™ and a CUDA® enabled NVIDIA® GPU. For more information, see “GPU Support by Release” (Parallel Computing Toolbox).

Training takes about 22 hours on an NVIDIA™ Titan RTX and can take even longer depending on your GPU hardware. If your GPU device has less memory, try reducing the size of the input images by specifying the `imageSize` variable as [480 640] in the Preprocess Training Data on page 8-0 section of the example.

```
doTraining = false;
if doTraining
    fig = figure;

    lossPlotter = configureTrainingProgressPlotter(fig);
    iteration = 0;

    % Loop over epochs
    for epoch = 1:numEpochs

        % Reset and shuffle the data
        reset(mbqTrain);
```

```
            shuffle(mbqTrain);

            % Loop over each image
            while hasdata(mbqTrain)
                iteration = iteration + 1;

                % Read data from current mini-batch
                [dlInputSegMap,dlRealImage] = next(mbqTrain);

                % Evaluate the model gradients and the generator state using
                % dlfeval and the GANLoss function listed at the end of the
                % example
                [gradParamsG,gradParamsDScale1,gradParamsDScale2,lossGGAN,lossGFM,lossGVGG,lossD] = d
                    @modelGradients,dlInputSegMap,dlRealImage,dlnetGenerator,dlnetDiscriminatorScale1

                % Update the generator parameters
                [dlnetGenerator,trailingAvgGenerator,trailingAvgSqGenerator] = adamupdate( ...
                    dlnetGenerator,gradParamsG, ...
                    trailingAvgGenerator,trailingAvgSqGenerator,iteration, ...
                    learningRate,gradientDecayFactor,squaredGradientDecayFactor);

                % Update the discriminator scale1 parameters
                [dlnetDiscriminatorScale1,trailingAvgDiscriminatorScale1,trailingAvgSqDiscriminatorSc
                    dlnetDiscriminatorScale1,gradParamsDScale1, ...
                    trailingAvgDiscriminatorScale1,trailingAvgSqDiscriminatorScale1,iteration, ...
                    learningRate,gradientDecayFactor,squaredGradientDecayFactor);

                % Update the discriminator scale2 parameters
                [dlnetDiscriminatorScale2,trailingAvgDiscriminatorScale2,trailingAvgSqDiscriminatorSc
                    dlnetDiscriminatorScale2,gradParamsDScale2, ...
                    trailingAvgDiscriminatorScale2,trailingAvgSqDiscriminatorScale2,iteration, ...
                    learningRate,gradientDecayFactor,squaredGradientDecayFactor);

                % Plot and display various losses
                lossPlotter = updateTrainingProgressPlotter(lossPlotter,iteration, ...
                    epoch,numEpochs,lossD,lossGGAN,lossGFM,lossGVGG);
            end
        end
        save('trainedPix2PixHDNet.mat','dlnetGenerator');

    else
        trainedPix2PixHDNet_url = 'https://ssd.mathworks.com/supportfiles/vision/data/trainedPix2PixH
        netDir = fullfile(tempdir,'CamVid');
        downloadTrainedPix2PixHDNet(trainedPix2PixHDNet_url,netDir);
        load(fullfile(netDir,'trainedPix2PixHDv2.mat'));
    end
```

Evaluate Generated Images from Test Data

The performance of this trained Pix2PixHD network is limited because the number of CamVid training images is relatively small. Additionally, some images belong to an image sequence and therefore are correlated with other images in the training set. To improve the effectiveness of the Pix2PixHD network, train the network using a different data set that has a larger number of training images without correlation.

Because of the limitations, this Pix2PixHD network generates more realistic images for some test images than for others. To demonstrate the difference in results, compare the generated images for

the first and third test image. The camera angle of the first test image has an uncommon vantage point that faces more perpendicular to the road than the typical training image. In contrast, the camera angle of the third test image has a typical vantage point that faces along the road and shows two lanes with lane markers. The network has significantly better performance generating a realistic image for the third test image than for the first test image.

Get the first ground truth scene image from the test data. Resize the image using bicubic interpolation.

```
idxToTest = 1;
gtImage = readimage(imdsTest,idxToTest);
gtImage = imresize(gtImage,imageSize,"bicubic");
```

Get the corresponding pixel label image from the test data. Resize the pixel label image using nearest neighbor interpolation.

```
segMap = readimage(pxdsTest,idxToTest);
segMap = imresize(segMap,imageSize,"nearest");
```

Convert the pixel label image to a multichannel one-hot segmentation map by using the `onehotencode` function.

```
segMapOneHot = onehotencode(segMap,3,'single');
```

Create `dlarray` objects that inputs data to the generator. If a supported GPU is available for computation, then perform inference on a GPU by converting the data to a `gpuArray` object.

```
dlSegMap = dlarray(segMapOneHot,'SSCB');
if canUseGPU
    dlSegMap = gpuArray(dlSegMap);
end
```

Generate a scene image from the generator and one-hot segmentation map using the `predict` function.

```
dlGeneratedImage = predict(dlnetGenerator,dlSegMap);
generatedImage = extractdata(gather(dlGeneratedImage));
```

The final layer of the generator network produces activations in the range [-1, 1]. For display, rescale the activations to the range [0, 1].

```
generatedImage = rescale(generatedImage);
```

For display, convert the labels from categorical labels to RGB colors by using the `label2rgb` (Image Processing Toolbox) function.

```
coloredSegMap = label2rgb(segMap,cmap);
```

Display the RGB pixel label image, generated scene image, and ground truth scene image in a montage.

```
figure
montage({coloredSegMap generatedImage gtImage},'Size',[1 3])
title(['Test Pixel Label Image ',num2str(idxToTest),' with Generated and Ground Truth Scene Image
```

Get the third ground truth scene image from the test data. Resize the image using bicubic interpolation.

```
idxToTest = 3;
gtImage = readimage(imdsTest,idxToTest);
gtImage = imresize(gtImage,imageSize,"bicubic");
```

To get the third pixel label image from the test data and to generate the corresponding scene image, you can use the helper function `evaluatePix2PixHD`. This helper function is attached to the example as a supporting file.

The `evaluatePix2PixHD` function performs the same operations as the evaluation of the first test image:

- Get a pixel label image from the test data. Resize the pixel label image using nearest neighbor interpolation.
- Convert the pixel label image to a multichannel one-hot segmentation map using the `onehotencode` function.
- Create a `dlarray` object to input data to the generator. For GPU inference, convert the data to a `gpuArray` object.
- Generate a scene image from the generator and one-hot segmentation map using the `predict` function.
- Rescale the activations to the range [0, 1].

```
[generatedImage,segMap] = evaluatePix2PixHD(pxdsTest,idxToTest,imageSize,dlnetGenerator);
```

For display, convert the labels from categorical labels to RGB colors by using the `label2rgb` (Image Processing Toolbox) function.

```
coloredSegMap = label2rgb(segMap,cmap);
```

Display the RGB pixel label image, generated scene image, and ground truth scene image in a montage.

```
figure
montage({coloredSegMap generatedImage gtImage},'Size',[1 3])
title(['Test Pixel Label Image ',num2str(idxToTest),' with Generated and Ground Truth Scene Image
```

Evaluate Generated Images from Custom Pixel Label Images

To evaluate how well the network generalizes to pixel label images outside the CamVid data set, generate scene images from custom pixel label images. This example uses pixel label images that were created using the Image Labeler (Computer Vision Toolbox) app. The pixel label images are attached to the example as supporting files. No ground truth images are available.

Create a pixel label datastore that reads and processes the pixel label images in the current example directory.

```
cpxds = pixelLabelDatastore(pwd,classes,labelIDs);
```

For each pixel label image in the datastore, generate a scene image using the helper function `evaluatePix2PixHD`.

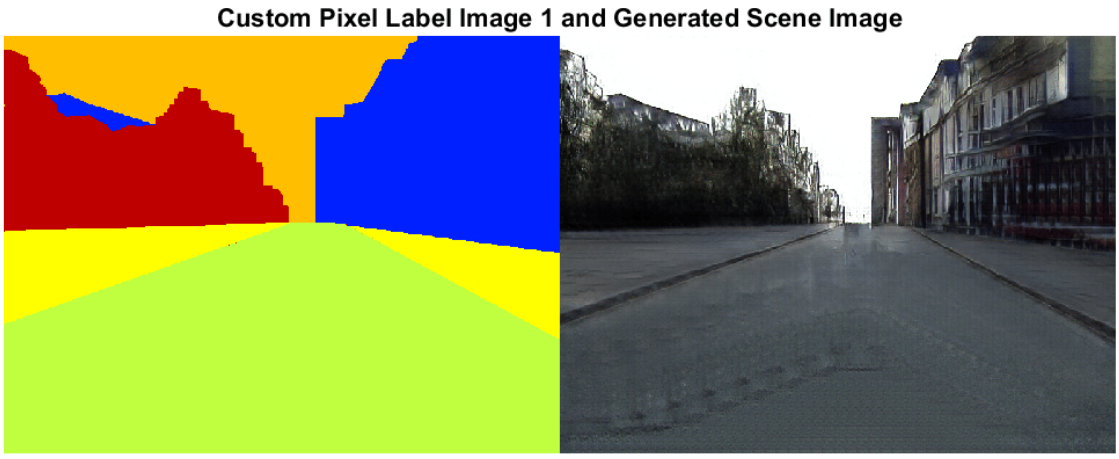
```
for idx = 1:length(cpxds.Files)

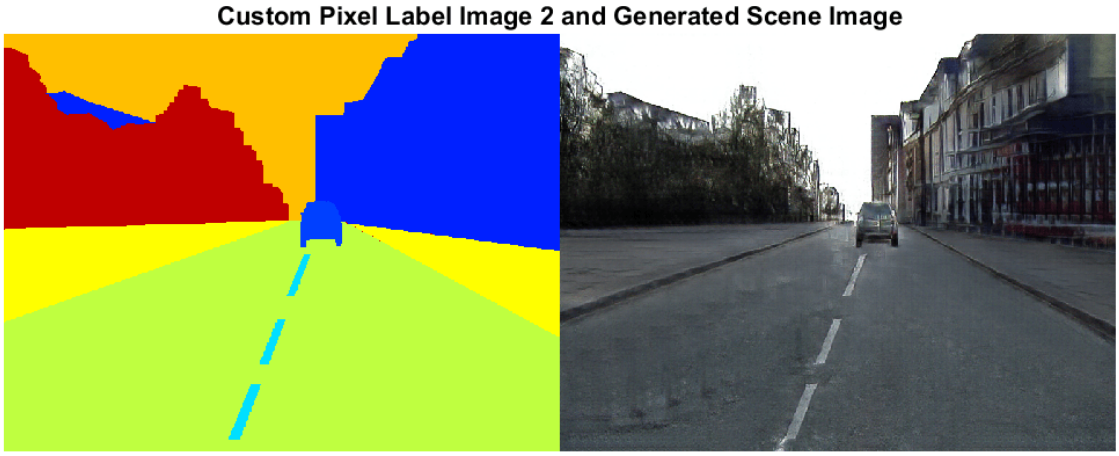
    % Get the pixel label image and generated scene image
    [generatedImage,segMap] = evaluatePix2PixHD(cpxds,idx,imageSize,dlnetGenerator);

    % For display, convert the labels from categorical labels to RGB colors
    coloredSegMap = label2rgb(segMap);

    % Display the pixel label image and generated scene image in a montage
    figure
    montage({coloredSegMap generatedImage})
    title(['Custom Pixel Label Image ',num2str(idx),' and Generated Scene Image'])

end
```





Supporting Functions

Model Gradients Function

The `modelGradients` helper function calculates the gradients and adversarial loss for the generator and discriminator. The function also calculates the feature matching loss and VGG loss for the generator.

```
function [gradParamsG,gradParamsDScale1,gradParamsDScale2,lossGGAN,lossGFM,lossGVGG,lossD] = mode

    % Compute the image generated by the generator given the input semantic
    % map.
    generatedImage = forward(generator,inputSegMap);

    % Define the loss weights
    lambdaDiscriminator = 1;
```

```
lambdaGenerator = 1;
lambdaFeatureMatching = 5;
lambdaVGG = 5;

% Concatenate the image to be classified and the semantic map
inpDiscriminatorReal = cat(3,inputSegMap,realImage);
inpDiscriminatorGenerated = cat(3,inputSegMap,generatedImage);

% Compute the adversarial loss for the discriminator and the generator
% for first scale.
[DLossScale1,GLossScale1,realPredScale1D,fakePredScale1G] = pix2pixHDAdverserialLoss(inpDisc

% Scale the generated image, the real image, and the input semantic map to
% half size
resizedRealImage = dlresize(realImage, 'Scale',0.5, 'Method',"linear");
resizedGeneratedImage = dlresize(generatedImage,'Scale',0.5,'Method',"linear");
resizedinputSegMap = dlresize(inputSegMap,'Scale',0.5,'Method',"nearest");

% Concatenate the image to be classified and the semantic map
inpDiscriminatorReal = cat(3,resizedinputSegMap,resizedRealImage);
inpDiscriminatorGenerated = cat(3,resizedinputSegMap,resizedGeneratedImage);

% Compute the adversarial loss for the discriminator and the generator
% for second scale.
[DLossScale2,GLossScale2,realPredScale2D,fakePredScale2G] = pix2pixHDAdverserialLoss(inpDisc

% Compute the feature matching loss for first scale.
FMLossScale1 = pix2pixHDFeatureMatchingLoss(realPredScale1D,fakePredScale1G);
FMLossScale1 = FMLossScale1 * lambdaFeatureMatching;

% Compute the feature matching loss for second scale.
FMLossScale2 = pix2pixHDFeatureMatchingLoss(realPredScale2D,fakePredScale2G);
FMLossScale2 = FMLossScale2 * lambdaFeatureMatching;

% Compute the VGG loss
VGGLoss = pix2pixHDVGGLoss(realImage,generatedImage,netVGG);
VGGLoss = VGGLoss * lambdaVGG;

% Compute the combined generator loss
lossGCombined = GLossScale1 + GLossScale2 + FMLossScale1 + FMLossScale2 + VGGLoss;
lossGCombined = lossGCombined * lambdaGenerator;

% Compute gradients for the generator
gradParamsG = dlgradient(lossGCombined,generator.Learnables,'RetainData',true);

% Compute the combined discriminator loss
lossDCombined = (DLossScale1 + DLossScale2)/2 * lambdaDiscriminator;

% Compute gradients for the discriminator scale1
gradParamsDScale1 = dlgradient(lossDCombined,discriminatorScale1.Learnables,'RetainData',true

% Compute gradients for the discriminator scale2
gradParamsDScale2 = dlgradient(lossDCombined,discriminatorScale2.Learnables);

% Log the values for displaying later
lossD = gather(extractdata(lossDCombined));
lossGGAN = gather(extractdata(GLossScale1 + GLossScale2));
lossGFM  = gather(extractdata(FMLossScale1 + FMLossScale2));
```

```
    lossGVGG = gather(extractdata(VGGLoss));
end
```

Adversarial Loss Function

The helper function `pix2pixHDAdverserialLoss` computes the adversarial loss gradients for the generator and the discriminator. The function also returns feature maps of the real image and synthetic images.

```
function [DLoss,GLoss,realPredFtrsD,genPredFtrsD] = pix2pixHDAdverserialLoss(inpReal,inpGenerated

    % Discriminator layer names containing feature maps
    featureNames = {'act_top','act_mid_1','act_mid_2','act_tail','conv2d_final'};

    % Get the feature maps for the real image from the discriminator
    realPredFtrsD = cell(size(featureNames));
    [realPredFtrsD{:}] = forward(discriminator,inpReal,"Outputs",featureNames);

    % Get the feature maps for the generated image from the discriminator
    genPredFtrsD = cell(size(featureNames));
    [genPredFtrsD{:}] = forward(discriminator,inpGenerated,"Outputs",featureNames);

    % Get the feature map from the final layer to compute the loss
    realPredD = realPredFtrsD{end};
    genPredD = genPredFtrsD{end};

    % Compute the discriminator loss
    DLoss = (1 - realPredD).^2 + (genPredD).^2;
    DLoss = mean(DLoss,"all");

    % Compute the generator loss
    GLoss = (1 - genPredD).^2;
    GLoss = mean(GLoss,"all");
end
```

Feature Matching Loss Function

The helper function `pix2pixHDFeatureMatchingLoss` computes the feature matching loss between a real image and a synthetic image generated by the generator.

```
function featureMatchingLoss = pix2pixHDFeatureMatchingLoss(realPredFtrs,genPredFtrs)

    % Number of features
    numFtrsMaps = numel(realPredFtrs);

    % Initialize the feature matching loss
    featureMatchingLoss = 0;

    for i = 1:numFtrsMaps
        % Get the feature maps of the real image
        a = extractdata(realPredFtrs{i});
        % Get the feature maps of the synthetic image
        b = genPredFtrs{i};

        % Compute the feature matching loss
        featureMatchingLoss = featureMatchingLoss + mean(abs(a - b),"all");
    end
end
```

Perceptual VGG Loss Function

The helper function `pix2pixHDVGGLoss` computes the perceptual VGG loss between a real image and a synthetic image generated by the generator.

```
function vggLoss = pix2pixHDVGGLoss(realImage,generatedImage,netVGG)

    featureWeights = [1.0/32 1.0/16 1.0/8 1.0/4 1.0];

    % Initialize the VGG loss
    vggLoss = 0;

    % Specify the names of the layers with desired feature maps
    featureNames = ["relu1_1","relu2_1","relu3_1","relu4_1","relu5_1"];

    % Extract the feature maps for the real image
    activReal = cell(size(featureNames));
    [activReal{:}] = forward(netVGG,realImage,"Outputs",featureNames);

    % Extract the feature maps for the synthetic image
    activGenerated = cell(size(featureNames));
    [activGenerated{:}] = forward(netVGG,generatedImage,"Outputs",featureNames);

    % Compute the VGG loss
    for i = 1:numel(featureNames)
        vggLoss = vggLoss + featureWeights(i)*mean(abs(activReal{i} - activGenerated{i}),"all");
    end
end
```

Image Processing Examples

Remove Noise from Color Image Using Pretrained Neural Network

This example shows how to remove Gaussian noise from an RGB image using a denoising convolutional neural network.

Read a color image into the workspace and convert the data to data type `double`. Display the pristine color image.

```
pristineRGB = imread('lighthouse.png');
pristineRGB = im2double(pristineRGB);
imshow(pristineRGB)
title('Pristine Image')
```

Add zero-mean Gaussian white noise with a variance of 0.01 to the image. The `imnoise` function adds noise to each color channel independently. Display the noisy color image.

```
noisyRGB = imnoise(pristineRGB,'gaussian',0,0.01);
imshow(noisyRGB)
title('Noisy Image')
```

The pretrained denoising convolutional neural network, DnCNN, operates on single-channel images. Split the noisy RGB image into its three individual color channels.

```
[noisyR,noisyG,noisyB] = imsplit(noisyRGB);
```

Load the pretrained DnCNN network.

```
net = denoisingNetwork('dncnn');
```

Use the DnCNN network to remove noise from each color channel.

```
denoisedR = denoiseImage(noisyR,net);
denoisedG = denoiseImage(noisyG,net);
denoisedB = denoiseImage(noisyB,net);
```

Recombine the denoised color channels to form the denoised RGB image. Display the denoised color image.

```
denoisedRGB = cat(3,denoisedR,denoisedG,denoisedB);
imshow(denoisedRGB)
title('Denoised Image')
```

Calculate the peak signal-to-noise ratio (PSNR) for the noisy and denoised images. A larger PSNR indicates that noise has a smaller relative signal, and is associated with higher image quality.

```
noisyPSNR = psnr(noisyRGB,pristineRGB);
fprintf('\n The PSNR value of the noisy image is %0.4f.',noisyPSNR);
```

```
 The PSNR value of the noisy image is 20.6395.
```

```
denoisedPSNR = psnr(denoisedRGB,pristineRGB);
fprintf('\n The PSNR value of the denoised image is %0.4f.',denoisedPSNR);
```

```
 The PSNR value of the denoised image is 29.6857.
```

Calculate the structural similarity (SSIM) index for the noisy and denoised images. An SSIM index close to 1 indicates good agreement with the reference image, and higher image quality.

```
noisySSIM = ssim(noisyRGB,pristineRGB);
fprintf('\n The SSIM value of the noisy image is %0.4f.',noisySSIM);
```

```
 The SSIM value of the noisy image is 0.7393.
```

```
denoisedSSIM = ssim(denoisedRGB,pristineRGB);
fprintf('\n The SSIM value of the denoised image is %0.4f.',denoisedSSIM);
```

```
 The SSIM value of the denoised image is 0.9507.
```

In practice, image color channels frequently have correlated noise. To remove correlated image noise, first convert the RGB image to a color space with a luminance channel, such as the L*a*b* color space. Remove noise on the luminance channel only, then convert the denoised image back to the RGB color space.

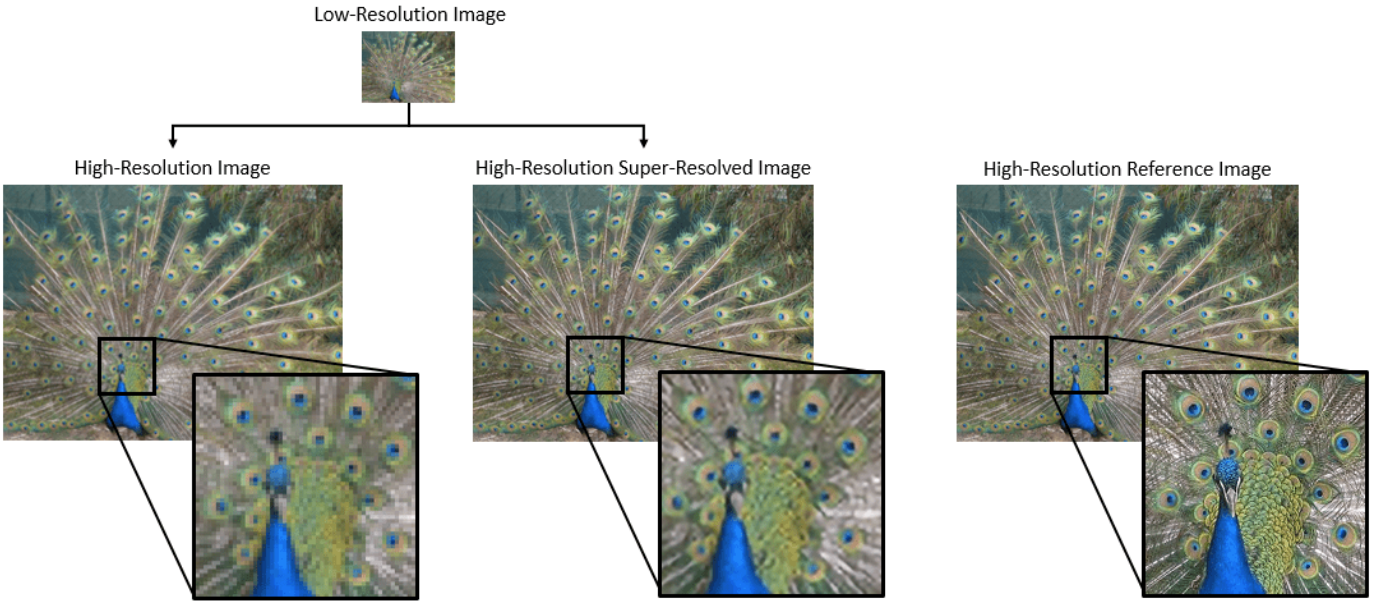
Single Image Super-Resolution Using Deep Learning

This example shows how to estimate a high-resolution image from a low-resolution image using a very-deep super-resolution (VDSR) neural network.

Super-resolution is the process of creating high-resolution images from low-resolution images. This example considers single image super-resolution (SISR), where the goal is to recover one high-resolution image from one low-resolution image. SISR is challenging because high-frequency image content typically cannot be recovered from the low-resolution image. Without high-frequency information, the quality of the high-resolution image is limited. Further, SISR is an ill-posed problem because one low-resolution image can yield several possible high-resolution images.



Several techniques, including deep learning algorithms, have been proposed to perform SISR. This example explores one deep learning algorithm for SISR, called very-deep super-resolution (VDSR) [1 on page 9-0].

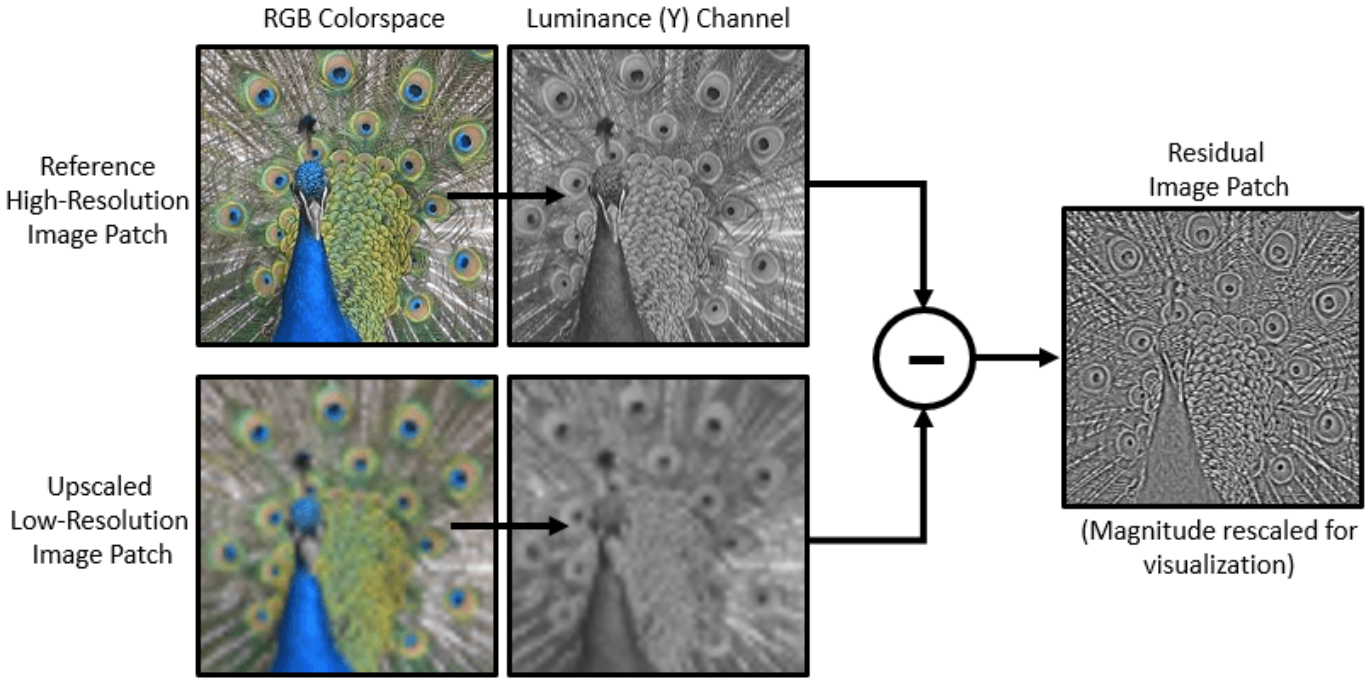
The VDSR Network

VDSR is a convolutional neural network architecture designed to perform single image super-resolution [1 on page 9-0]. The VDSR network learns the mapping between low- and high-resolution images. This mapping is possible because low-resolution and high-resolution images have similar image content and differ primarily in high-frequency details.

VDSR employs a residual learning strategy, meaning that the network learns to estimate a residual image. In the context of super-resolution, a residual image is the difference between a high-resolution reference image and a low-resolution image that has been upscaled using bicubic interpolation to match the size of the reference image. A residual image contains information about the high-frequency details of an image.

The VDSR network detects the residual image from the luminance of a color image. The luminance channel of an image, Y, represents the brightness of each pixel through a linear combination of the red, green, and blue pixel values. In contrast, the two chrominance channels of an image, *Cb* and *Cr*, are different linear combinations of the red, green, and blue pixel values that represent color-

difference information. VDSR is trained using only the luminance channel because human perception is more sensitive to changes in brightness than to changes in color.



If Y_{highres} is the luminance of the high-resolution image and Y_{lowres} is the luminance a low-resolution image that has been upscaled using bicubic interpolation, then the input to the VDSR network is Y_{lowres} and the network learns to predict $Y_{\text{residual}} = Y_{\text{highres}} - Y_{\text{lowres}}$ from the training data.

After the VDSR network learns to estimate the residual image, you can reconstruct high-resolution images by adding the estimated residual image to the upsampled low-resolution image, then converting the image back to the RGB color space.

A scale factor relates the size of the reference image to the size of the low-resolution image. As the scale factor increases, SISR becomes more ill-posed because the low-resolution image loses more information about the high-frequency image content. VDSR solves this problem by using a large receptive field. This example trains a VDSR network with multiple scale factors using scale augmentation. Scale augmentation improves the results at larger scale factors because the network can take advantage of the image context from smaller scale factors. Additionally, the VDSR network can generalize to accept images with noninteger scale factors.

Download Training and Test Data

Download the IAPR TC-12 Benchmark, which consists of 20,000 still natural images [2 on page 9-0]. The data set includes photos of people, animals, cities, and more. The size of the data file is ~1.8 GB. If you do not want to download the training data set, then you can load the pretrained VDSR network by typing `load('trainedVDSR-Epoch-100-ScaleFactors-234.mat');` at the command line. Then, go directly to the Perform Single Image Super-Resolution Using VDSR Network on page 9-0 section in this example.

Use the helper function, `downloadIAPRTC12Data`, to download the data. This function is attached to the example as a supporting file.

```
imagesDir = tempdir;
url = 'http://www-i6.informatik.rwth-aachen.de/imageclef/resources/iaprtc12.tgz';
downloadIAPRTC12Data(url,imagesDir);
```

This example will train the network with a small subset of the IAPR TC-12 Benchmark data. Load the imageCLEF training data. All images are 32-bit JPEG color images.

```
trainImagesDir = fullfile(imagesDir,'iaprtc12','images','02');
exts = {'.jpg','.bmp','.png'};
pristineImages = imageDatastore(trainImagesDir,'FileExtensions',exts);
```

List the number of training images.

```
numel(pristineImages.Files)
```

```
ans = 616
```

Prepare Training Data

To create a training data set, generate pairs of images consisting of upsampled images and the corresponding residual images.

The upsampled images are stored on disk as MAT files in the directory `upsampledDirName`. The computed residual images representing the network responses are stored on disk as MAT files in the directory `residualDirName`. The MAT files are stored as data type `double` for greater precision when training the network.

```
upsampledDirName = [trainImagesDir filesep 'upsampledImages'];
residualDirName = [trainImagesDir filesep 'residualImages'];
```

Use the helper function `createVDSRTrainingSet` to preprocess the training data. This function is attached to the example as a supporting file.

The helper function performs these operations for each pristine image in `trainImages`:

- Convert the image to the YCbCr color space
- Downsize the luminance (Y) channel by different scale factors to create sample low-resolution images, then resize the images to the original size using bicubic interpolation
- Calculate the difference between the pristine and resized images.
- Save the resized and residual images to disk.

```
scaleFactors = [2 3 4];
createVDSRTrainingSet(pristineImages,scaleFactors,upsampledDirName,residualDirName);
```

Define Preprocessing Pipeline for Training Set

In this example, the network inputs are low-resolution images that have been upsampled using bicubic interpolation. The desired network responses are the residual images. Create an image datastore called `upsampledImages` from the collection of input image files. Create an image datastore called `residualImages` from the collection of computed residual image files. Both datastores require a helper function, `matRead`, to read the image data from the image files. This function is attached to the example as a supporting file.

```
upsampledImages = imageDatastore(upsampledDirName,'FileExtensions','.mat','ReadFcn',@matRead);
residualImages = imageDatastore(residualDirName,'FileExtensions','.mat','ReadFcn',@matRead);
```

Create an `imageDataAugmenter` that specifies the parameters of data augmentation. Use data augmentation during training to vary the training data, which effectively increases the amount of available training data. Here, the augmenter specifies random rotation by 90 degrees and random reflections in the *x*-direction.

```
augmenter = imageDataAugmenter( ...
    'RandRotation',@()randi([0,1],1)*90, ...
    'RandXReflection',true);
```

Create a `randomPatchExtractionDatastore` (Image Processing Toolbox) that performs randomized patch extraction from the upsampled and residual image datastores. Patch extraction is the process of extracting a large set of small image patches, or tiles, from a single larger image. This type of data augmentation is frequently used in image-to-image regression problems, where many network architectures can be trained on very small input image sizes. This means that a large number of patches can be extracted from each full-sized image in the original training set, which greatly increases the size of the training set.

```
patchSize = [41 41];
patchesPerImage = 64;
dsTrain = randomPatchExtractionDatastore(upsampledImages,residualImages,patchSize, ...
    "DataAugmentation",augmenter,"PatchesPerImage",patchesPerImage);
```

The resulting datastore, `dsTrain`, provides mini-batches of data to the network at each iteration of the epoch. Preview the result of reading from the datastore.

```
inputBatch = preview(dsTrain);
disp(inputBatch)
```

```
      InputImage      ResponseImage
    ______________    ______________

    {41×41 double}    {41×41 double}
    {41×41 double}    {41×41 double}
    {41×41 double}    {41×41 double}
    {41×41 double}    {41×41 double}
    {41×41 double}    {41×41 double}
    {41×41 double}    {41×41 double}
    {41×41 double}    {41×41 double}
    {41×41 double}    {41×41 double}
```

Set Up VDSR Layers

This example defines the VDSR network using 41 individual layers from Deep Learning Toolbox™, including:

- `imageInputLayer` - Image input layer
- `convolution2dLayer` - 2-D convolution layer for convolutional neural networks
- `reluLayer` - Rectified linear unit (ReLU) layer
- `regressionLayer` - Regression output layer for a neural network

The first layer, `imageInputLayer`, operates on image patches. The patch size is based on the network receptive field, which is the spatial image region that affects the response of the top-most layer in the network. Ideally, the network receptive field is the same as the image size so that the field can see all the high-level features in the image. In this case, for a network with D convolutional layers, the receptive field is $(2D+1)$-by-$(2D+1)$.

VDSR has 20 convolutional layers so the receptive field and the image patch size are 41-by-41. The image input layer accepts images with one channel because VDSR is trained using only the luminance channel.

```
networkDepth = 20;
firstLayer = imageInputLayer([41 41 1],'Name','InputLayer','Normalization','none');
```

The image input layer is followed by a 2-D convolutional layer that contains 64 filters of size 3-by-3. The mini-batch size determines the number of filters. Zero-pad the inputs to each convolutional layer so that the feature maps remain the same size as the input after each convolution. He's method [3 on page 9-0] initializes the weights to random values so that there is asymmetry in neuron learning. Each convolutional layer is followed by a ReLU layer, which introduces nonlinearity in the network.

```
convLayer = convolution2dLayer(3,64,'Padding',1, ...
    'WeightsInitializer','he','BiasInitializer','zeros','Name','Conv1');
```

Specify a ReLU layer.

```
relLayer = reluLayer('Name','ReLU1');
```

The middle layers contain 18 alternating convolutional and rectified linear unit layers. Every convolutional layer contains 64 filters of size 3-by-3-by-64, where a filter operates on a 3-by-3 spatial region across 64 channels. As before, a ReLU layer follows every convolutional layer.

```
middleLayers = [convLayer relLayer];
for layerNumber = 2:networkDepth-1
    convLayer = convolution2dLayer(3,64,'Padding',[1 1], ...
        'WeightsInitializer','he','BiasInitializer','zeros', ...
        'Name',['Conv' num2str(layerNumber)]);

    relLayer = reluLayer('Name',['ReLU' num2str(layerNumber)]);
    middleLayers = [middleLayers convLayer relLayer];
end
```

The penultimate layer is a convolutional layer with a single filter of size 3-by-3-by-64 that reconstructs the image.

```
convLayer = convolution2dLayer(3,1,'Padding',[1 1], ...
    'WeightsInitializer','he','BiasInitializer','zeros', ...
    'NumChannels',64,'Name',['Conv' num2str(networkDepth)]);
```

The last layer is a regression layer instead of a ReLU layer. The regression layer computes the mean-squared error between the residual image and network prediction.

```
finalLayers = [convLayer regressionLayer('Name','FinalRegressionLayer')];
```

Concatenate all the layers to form the VDSR network.

```
layers = [firstLayer middleLayers finalLayers];
```

Alternatively, you can use the `vdsrLayers` helper function to create VDSR layers. This function is attached to the example as a supporting file.

```
layers = vdsrLayers;
```

Specify Training Options

Train the network using stochastic gradient descent with momentum (SGDM) optimization. Specify the hyperparameter settings for SGDM by using the `trainingOptions` function. The learning rate is initially `0.1` and decreased by a factor of 10 every 10 epochs. Train for 100 epochs.

Training a deep network is time-consuming. Accelerate the training by specifying a high learning rate. However, this can cause the gradients of the network to explode or grow uncontrollably, preventing the network from training successfully. To keep the gradients in a meaningful range, enable gradient clipping by specifying `'GradientThreshold'` as `0.01`, and specify `'GradientThresholdMethod'` to use the L2-norm of the gradients.

```
maxEpochs = 100;
epochIntervals = 1;
initLearningRate = 0.1;
learningRateFactor = 0.1;
l2reg = 0.0001;
miniBatchSize = 64;
options = trainingOptions('sgdm', ...
    'Momentum',0.9, ...
    'InitialLearnRate',initLearningRate, ...
    'LearnRateSchedule','piecewise', ...
    'LearnRateDropPeriod',10, ...
    'LearnRateDropFactor',learningRateFactor, ...
    'L2Regularization',l2reg, ...
    'MaxEpochs',maxEpochs, ...
    'MiniBatchSize',miniBatchSize, ...
    'GradientThresholdMethod','l2norm', ...
    'GradientThreshold',0.01, ...
    'Plots','training-progress', ...
    'Verbose',false);
```

Train the Network

By default, the example loads a pretrained version of the VDSR network that has been trained to super-resolve images for scale factors 2, 3 and 4. The pretrained network enables you to perform super-resolution of test images without waiting for training to complete.

To train the VDSR network, set the `doTraining` variable in the following code to `true`. Train the network using the `trainNetwork` function.

Train on a GPU if one is available. Using a GPU requires Parallel Computing Toolbox™ and a CUDA® enabled NVIDIA® GPU. For more information, see “GPU Support by Release” (Parallel Computing Toolbox). Training takes about 6 hours on an NVIDIA Titan X.

```
doTraining = false;
if doTraining
    net = trainNetwork(dsTrain,layers,options);
    modelDateTime = string(datetime('now','Format',"yyyy-MM-dd-HH-mm-ss"));
    save(strcat("trainedVDSR-",modelDateTime,"-Epoch-",num2str(maxEpochs),"-ScaleFactors-234.mat'
else
    load('trainedVDSR-Epoch-100-ScaleFactors-234.mat');
end
```

Perform Single Image Super-Resolution Using VDSR Network

To perform single image super-resolution (SISR) using the VDSR network, follow the remaining steps of this example. The remainder of the example shows how to:

- Create a sample low-resolution image from a high-resolution reference image.
- Perform SISR on the low-resolution image using bicubic interpolation, a traditional image processing solution that does not rely on deep learning.
- Perform SISR on the low-resolution image using the VDSR neural network.
- Visually compare the reconstructed high-resolution images using bicubic interpolation and VDSR.
- Evaluate the quality of the super-resolved images by quantifying the similarity of the images to the high-resolution reference image.

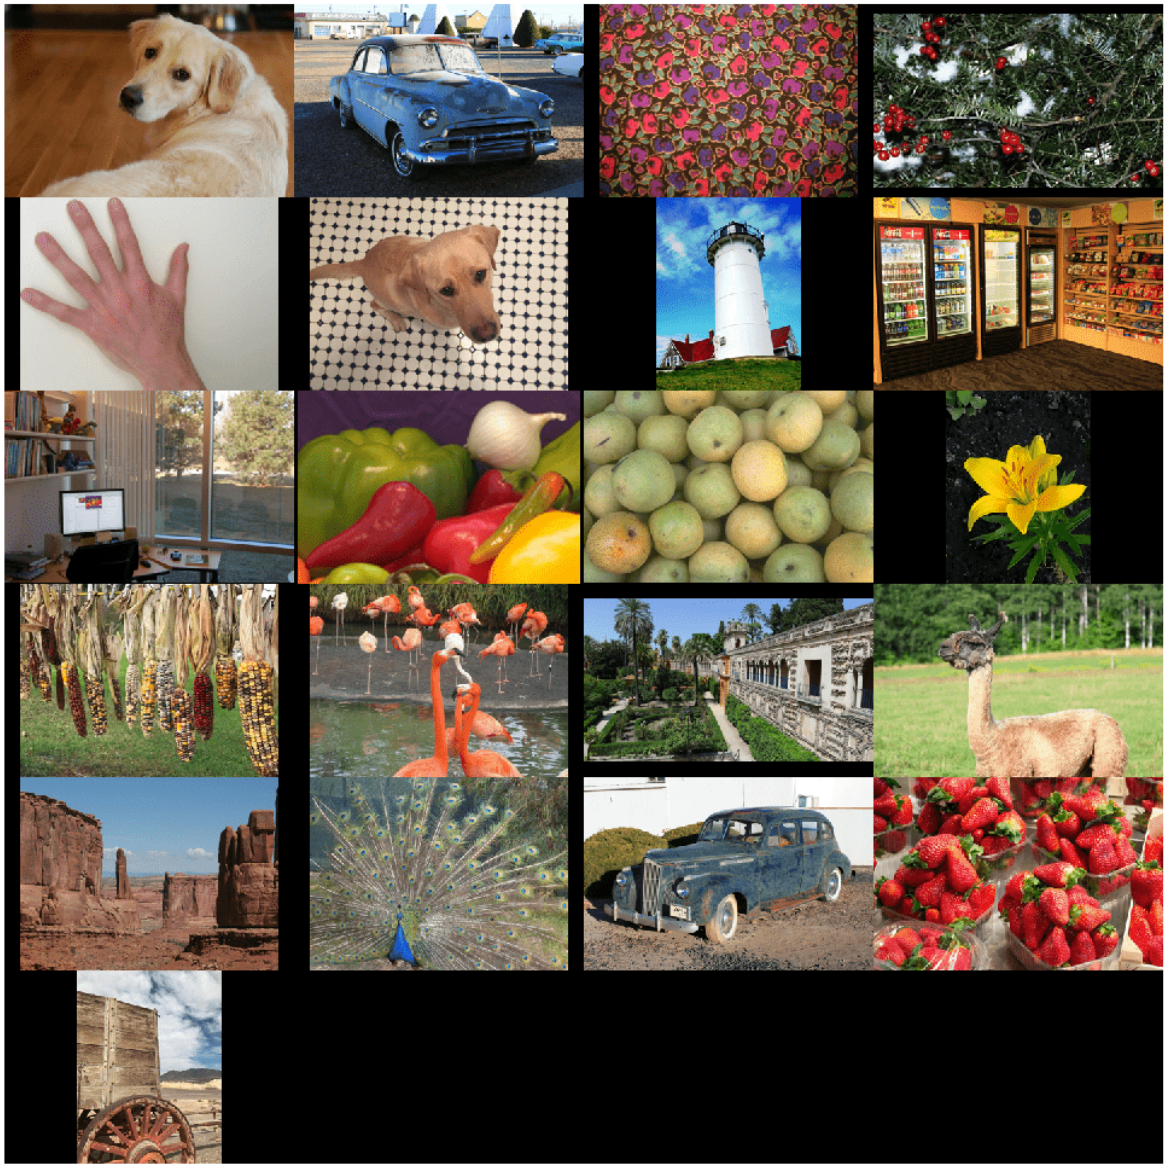
Create Sample Low-Resolution Image

Create a low-resolution image that will be used to compare the results of super-resolution using deep-learning to the result using traditional image processing techniques such as bicubic interpolation. The test data set, `testImages`, contains 21 undistorted images shipped in Image Processing Toolbox™. Load the images into an `imageDatastore`.

```
exts = {'.jpg','.png'};
fileNames = {'sherlock.jpg','car2.jpg','fabric.png','greens.jpg','hands1.jpg','kobi.png', ...
    'lighthouse.png','micromarket.jpg','office_4.jpg','onion.png','pears.png','yellowlily.jpg', ...
    'indiancorn.jpg','flamingos.jpg','sevilla.jpg','llama.jpg','parkavenue.jpg', ...
    'peacock.jpg','car1.jpg','strawberries.jpg','wagon.jpg'};
filePath = [fullfile(matlabroot,'toolbox','images','imdata') filesep];
filePathNames = strcat(filePath,fileNames);
testImages = imageDatastore(filePathNames,'FileExtensions',exts);
```

Display the testing images as a montage.

```
montage(testImages)
```



Select one of the images to use as the reference image for super-resolution. You can optionally use your own high-resolution image as the reference image.

```
indx = 1; % Index of image to read from the test image datastore
Ireference = readimage(testImages,indx);
Ireference = im2double(Ireference);
imshow(Ireference)
title('High-Resolution Reference Image')
```

Create a low-resolution version of the high-resolution reference image by using `imresize` with a scaling factor of 0.25. The high-frequency components of the image are lost during the downscaling.

```
scaleFactor = 0.25;
Ilowres = imresize(Ireference,scaleFactor,'bicubic');
imshow(Ilowres)
title('Low-Resolution Image')
```

Improve Image Resolution Using Bicubic Interpolation

A standard way to increase image resolution without deep learning is to use bicubic interpolation. Upscale the low-resolution image using bicubic interpolation so that the resulting high-resolution image is the same size as the reference image.

```
[nrows,ncols,np] = size(Ireference);
Ibicubic = imresize(Ilowres,[nrows ncols],'bicubic');
imshow(Ibicubic)
title('High-Resolution Image Obtained Using Bicubic Interpolation')
```

Improve Image Resolution Using Pretrained VDSR Network

Recall that VDSR is trained using only the luminance channel of an image because human perception is more sensitive to changes in brightness than to changes in color.

Convert the low-resolution image from the RGB color space to luminance (`Iy`) and chrominance (`Icb` and `Icr`) channels by using the `rgb2ycbcr` (Image Processing Toolbox) function.

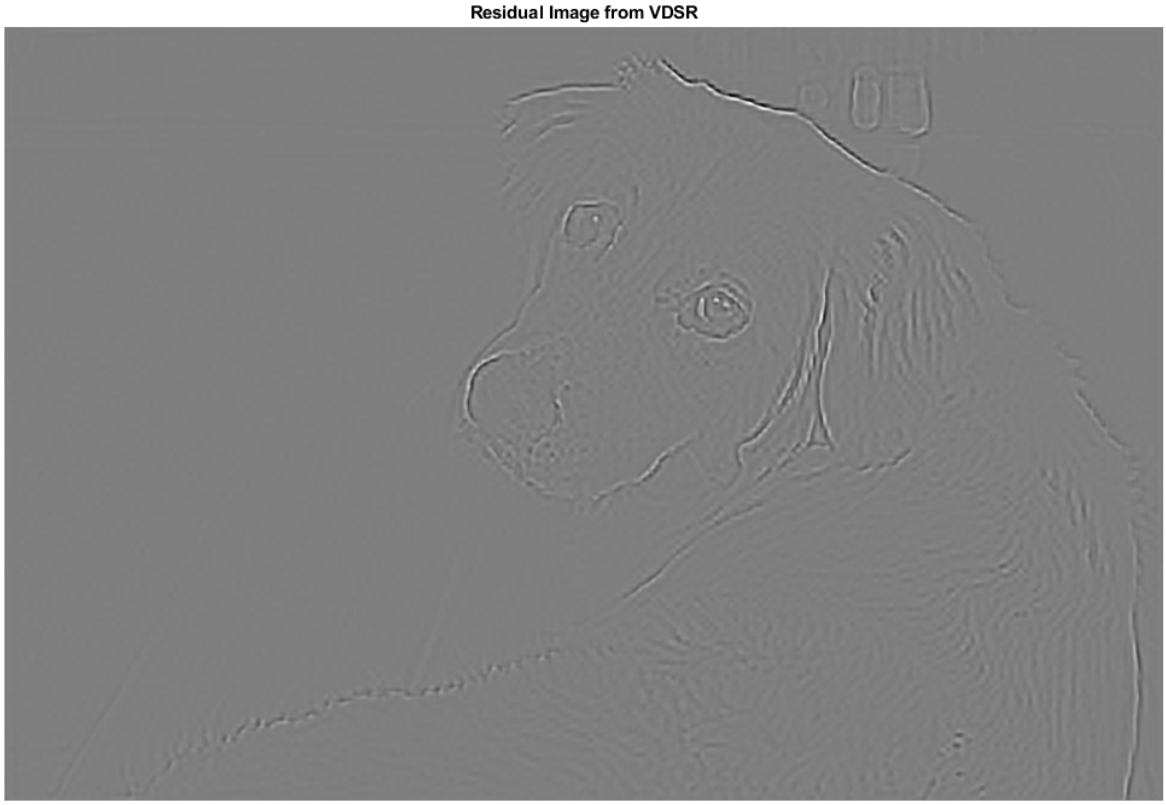
```
Iycbcr = rgb2ycbcr(Ilowres);
Iy = Iycbcr(:,:,1);
Icb = Iycbcr(:,:,2);
Icr = Iycbcr(:,:,3);
```

Upscale the luminance and two chrominance channels using bicubic interpolation. The upsampled chrominance channels, `Icb_bicubic` and `Icr_bicubic`, require no further processing.

```
Iy_bicubic = imresize(Iy,[nrows ncols],'bicubic');
Icb_bicubic = imresize(Icb,[nrows ncols],'bicubic');
Icr_bicubic = imresize(Icr,[nrows ncols],'bicubic');
```

Pass the upscaled luminance component, `Iy_bicubic`, through the trained VDSR network. Observe the `activations` from the final layer (a regression layer). The output of the network is the desired residual image.

```
Iresidual = activations(net,Iy_bicubic,41);
Iresidual = double(Iresidual);
imshow(Iresidual,[])
title('Residual Image from VDSR')
```



Add the residual image to the upscaled luminance component to get the high-resolution VDSR luminance component.

```
Isr = Iy_bicubic + Iresidual;
```

Concatenate the high-resolution VDSR luminance component with the upscaled color components. Convert the image to the RGB color space by using the `ycbcr2rgb` (Image Processing Toolbox) function. The result is the final high-resolution color image using VDSR.

```
Ivdsr = ycbcr2rgb(cat(3,Isr,Icb_bicubic,Icr_bicubic));
imshow(Ivdsr)
title('High-Resolution Image Obtained Using VDSR')
```

Visual and Quantitative Comparison

To get a better visual understanding of the high-resolution images, examine a small region inside each image. Specify a region of interest (ROI) using vector `roi` in the format [*x y width height*]. The elements define the x- and y-coordinate of the top left corner, and the width and height of the ROI.

```
roi = [320 30 480 400];
```

Crop the high-resolution images to this ROI, and display the result as a montage. The VDSR image has clearer details and sharper edges than the high-resolution image created using bicubic interpolation.

```
montage({imcrop(Ibicubic,roi),imcrop(Ivdsr,roi)})
title('High-Resolution Results Using Bicubic Interpolation (Left) vs. VDSR (Right)');
```

Use image quality metrics to quantitatively compare the high-resolution image using bicubic interpolation to the VDSR image. The reference image is the original high-resolution image, `Ireference`, before preparing the sample low-resolution image.

Measure the peak signal-to-noise ratio (PSNR) of each image against the reference image. Larger PSNR values generally indicate better image quality. See `psnr` (Image Processing Toolbox) for more information about this metric.

```
bicubicPSNR = psnr(Ibicubic,Ireference)
```

```
bicubicPSNR = 38.4747
```

```
vdsrPSNR = psnr(Ivdsr,Ireference)
```

```
vdsrPSNR = 39.2346
```

Measure the structural similarity index (SSIM) of each image. SSIM assesses the visual impact of three characteristics of an image: luminance, contrast and structure, against a reference image. The closer the SSIM value is to 1, the better the test image agrees with the reference image. See `ssim` (Image Processing Toolbox) for more information about this metric.

```
bicubicSSIM = ssim(Ibicubic,Ireference)
```

```
bicubicSSIM = 0.9861
```

```
vdsrSSIM = ssim(Ivdsr,Ireference)
```

```
vdsrSSIM = 0.9874
```

Measure perceptual image quality using the Naturalness Image Quality Evaluator (NIQE). Smaller NIQE scores indicate better perceptual quality. See `niqe` (Image Processing Toolbox) for more information about this metric.

```
bicubicNIQE = niqe(Ibicubic)
```

```
bicubicNIQE = 5.1721
```

```
vdsrNIQE = niqe(Ivdsr)

vdsrNIQE = 4.7611
```

Calculate the average PSNR and SSIM of the entire set of test images for the scale factors 2, 3, and 4. For simplicity, you can use the helper function, `superResolutionMetrics`, to compute the average metrics. This function is attached to the example as a supporting file.

```
scaleFactors = [2 3 4];
superResolutionMetrics(net,testImages,scaleFactors);

Results for Scale factor 2

Average PSNR for Bicubic = 31.809683
Average PSNR for VDSR = 31.921784
Average SSIM for Bicubic = 0.938194
Average SSIM for VDSR = 0.949404

Results for Scale factor 3

Average PSNR for Bicubic = 28.170441
Average PSNR for VDSR = 28.563952
Average SSIM for Bicubic = 0.884381
Average SSIM for VDSR = 0.895830

Results for Scale factor 4

Average PSNR for Bicubic = 27.010839
Average PSNR for VDSR = 27.837260
Average SSIM for Bicubic = 0.861604
Average SSIM for VDSR = 0.877132
```

VDSR has better metric scores than bicubic interpolation for each scale factor.

JPEG Image Deblocking Using Deep Learning

This example shows how to train a denoising convolutional neural network (DnCNN), then use the network to reduce JPEG compression artifacts in an image.

Image compression is used to reduce the memory footprint of an image. One popular and powerful compression method is employed by the JPEG image format, which uses a quality factor to specify the amount of compression. Reducing the quality value results in higher compression and a smaller memory footprint, at the expense of visual quality of the image.

JPEG compression is *lossy*, meaning that the compression process causes the image to lose information. For JPEG images, this information loss appears as blocking artifacts in the image. As shown in the figure, more compression results in more information loss and stronger artifacts. Textured regions with high-frequency content, such as the grass and clouds, look blurry. Sharp edges, such as the roof of the house and the guardrails atop the lighthouse, exhibit ringing.

JPEG deblocking is the process of reducing the effects of compression artifacts in JPEG images. Several JPEG deblocking methods exist, including more effective methods that use deep learning. This example implements one such deep learning-based method that attempts to minimize the effect of JPEG compression artifacts.

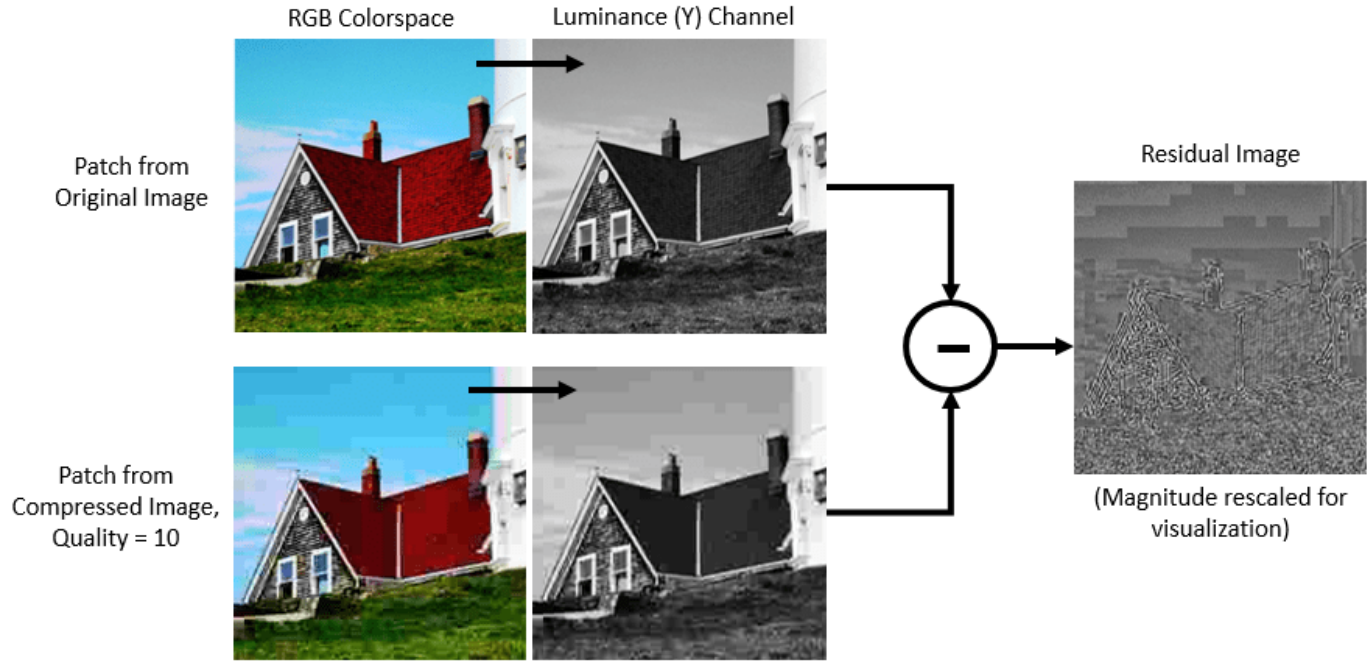
The DnCNN Network

This example uses a built-in deep feed-forward convolutional neural network, called `DnCNN`. The network was primarily designed to remove noise from images. However, the DnCNN architecture can also be trained to remove JPEG compression artifacts or increase image resolution.

The reference paper [1 on page 9-0] employs a residual learning strategy, meaning that the DnCNN network learns to estimate the residual image. A residual image is the difference between a pristine image and a distorted copy of the image. The residual image contains information about the image distortion. For this example, distortion appears as JPEG blocking artifacts.

The DnCNN network is trained to detect the residual image from the luminance of a color image. The luminance channel of an image, *Y*, represents the brightness of each pixel through a linear combination of the red, green, and blue pixel values. In contrast, the two chrominance channels of an

image, *Cb* and *Cr*, are different linear combinations of the red, green, and blue pixel values that represent color-difference information. DnCNN is trained using only the luminance channel because human perception is more sensitive to changes in brightness than changes in color.



If Y_{Original} is the luminance of the pristine image and $Y_{\text{Compressed}}$ is the luminance of the image containing JPEG compression artifacts, then the input to the DnCNN network is $Y_{\text{Compressed}}$ and the network learns to predict $Y_{\text{Residual}} = Y_{\text{Compressed}} - Y_{\text{Original}}$ from the training data.

Once the DnCNN network learns how to estimate a residual image, it can reconstruct an undistorted version of a compressed JPEG image by adding the residual image to the compressed luminance channel, then converting the image back to the RGB color space.

Download Training Data

Download the IAPR TC-12 Benchmark, which consists of 20,000 still natural images [2 on page 9-0]. The data set includes photos of people, animals, cities, and more. The size of the data file is ~1.8 GB. If you do not want to download the training data set needed to train the network, then you can load the pretrained DnCNN network by typing `load('pretrainedJPEGDnCNN.mat')` at the command line. Then, go directly to the Perform JPEG Deblocking Using DnCNN Network on page 9-0 section in this example.

Use the helper function, `downloadIAPRTC12Data`, to download the data. This function is attached to the example as a supporting file.

```
imagesDir = tempdir;
url = "http://www-i6.informatik.rwth-aachen.de/imageclef/resources/iaprtc12.tgz";
downloadIAPRTC12Data(url,imagesDir);
```

This example will train the network with a small subset of the IAPR TC-12 Benchmark data. Load the imageCLEF training data. All images are 32-bit JPEG color images.

```
trainImagesDir = fullfile(imagesDir,'iaprtc12','images','00');
exts = {'.jpg','.bmp','.png'};
imdsPristine = imageDatastore(trainImagesDir,'FileExtensions',exts);
```

List the number of training images.

```
numel(imdsPristine.Files)
```

```
ans = 251
```

Prepare Training Data

To create a training data set, read in pristine images and write out images in the JPEG file format with various levels of compression.

Specify the JPEG image quality values used to render image compression artifacts. Quality values must be in the range [0, 100]. Small quality values result in more compression and stronger compression artifacts. Use a denser sampling of small quality values so the training data has a broad range of compression artifacts.

```
JPEGQuality = [5:5:40 50 60 70 80];
```

The compressed images are stored on disk as MAT files in the directory `compressedImagesDir`. The computed residual images are stored on disk as MAT files in the directory `residualImagesDir`. The MAT files are stored as data type `double` for greater precision when training the network.

```
compressedImagesDir = fullfile(imagesDir,'iaprtc12','JPEGDeblockingData','compressedImages');
residualImagesDir = fullfile(imagesDir,'iaprtc12','JPEGDeblockingData','residualImages');
```

Use the helper function `createJPEGDeblockingTrainingSet` to preprocess the training data. This function is attached to the example as a supporting file.

For each pristine training image, the helper function writes a copy of the image with quality factor 100 to use as a reference image and copies of the image with each quality factor to use as the network inputs. The function computes the luminance (Y) channel of the reference and compressed images in data type `double` for greater precision when calculating the residual images. The compressed images are stored on disk as .MAT files in the directory `compressedDirName`. The computed residual images are stored on disk as .MAT files in the directory `residualDirName`.

```
[compressedDirName,residualDirName] = createJPEGDeblockingTrainingSet(imdsPristine,JPEGQuality);
```

Create Random Patch Extraction Datastore for Training

Use a random patch extraction datastore to feed the training data to the network. This datastore extracts random corresponding patches from two image datastores that contain the network inputs and desired network responses.

In this example, the network inputs are the compressed images. The desired network responses are the residual images. Create an image datastore called `imdsCompressed` from the collection of compressed image files. Create an image datastore called `imdsResidual` from the collection of computed residual image files. Both datastores require a helper function, `matRead`, to read the image data from the image files. This function is attached to the example as a supporting file.

```
imdsCompressed = imageDatastore(compressedDirName,'FileExtensions','.mat','ReadFcn',@matRead);
imdsResidual = imageDatastore(residualDirName,'FileExtensions','.mat','ReadFcn',@matRead);
```

Create an `imageDataAugmenter` that specifies the parameters of data augmentation. Use data augmentation during training to vary the training data, which effectively increases the amount of

available training data. Here, the augmenter specifies random rotation by 90 degrees and random reflections in the x-direction.

```
augmenter = imageDataAugmenter( ...
    'RandRotation',@()randi([0,1],1)*90, ...
    'RandXReflection',true);
```

Create the `randomPatchExtractionDatastore` (Image Processing Toolbox) from the two image datastores. Specify a patch size of 50-by-50 pixels. Each image generates 128 random patches of size 50-by-50 pixels. Specify a mini-batch size of 128.

```
patchSize = 50;
patchesPerImage = 128;
dsTrain = randomPatchExtractionDatastore(imdsCompressed,imdsResidual,patchSize, ...
    'PatchesPerImage',patchesPerImage, ...
    'DataAugmentation',augmenter);
dsTrain.MiniBatchSize = patchesPerImage;
```

The random patch extraction datastore `dsTrain` provides mini-batches of data to the network at iteration of the epoch. Preview the result of reading from the datastore.

```
inputBatch = preview(dsTrain);
disp(inputBatch)
```

```
      InputImage       ResponseImage
    _______________    _______________

```

Set up DnCNN Layers

Create the layers of the built-in DnCNN network by using the `dnCNNLayers` (Image Processing Toolbox) function. By default, the network depth (the number of convolution layers) is 20.

```
layers = dnCNNLayers
```

```
layers =
  1x59 Layer array with layers:

     1   'InputLayer'            Image Input           50x50x1 images
     2   'Conv1'                 Convolution           64 3x3x1 convolutions with stride [1  1]
     3   'ReLU1'                 ReLU                  ReLU
     4   'Conv2'                 Convolution           64 3x3x64 convolutions with stride [1  1]

 59   'FinalRegressionLayer'  Regression Output     mean-squared-error
```

Select Training Options

Train the network using stochastic gradient descent with momentum (SGDM) optimization. Specify the hyperparameter settings for SGDM by using the `trainingOptions` function.

Training a deep network is time-consuming. Accelerate the training by specifying a high learning rate. However, this can cause the gradients of the network to explode or grow uncontrollably, preventing the network from training successfully. To keep the gradients in a meaningful range,

enable gradient clipping by setting `'GradientThreshold'` to `0.005`, and specify `'GradientThresholdMethod'` to use the absolute value of the gradients.

```
maxEpochs = 30;
initLearningRate = 0.1;
l2reg = 0.0001;
batchSize = 64;

options = trainingOptions('sgdm', ...
    'Momentum',0.9, ...
    'InitialLearnRate',initLearningRate, ...
    'LearnRateSchedule','piecewise', ...
    'GradientThresholdMethod','absolute-value', ...
    'GradientThreshold',0.005, ...
    'L2Regularization',l2reg, ...
    'MiniBatchSize',batchSize, ...
    'MaxEpochs',maxEpochs, ...
    'Plots','training-progress', ...
    'Verbose',false);
```

Train the Network

By default, the example loads a pretrained DnCNN network. The pretrained network enables you to perform JPEG deblocking without waiting for training to complete.

To train the network, set the `doTraining` variable in the following code to `true`. Train the DnCNN network using the `trainNetwork` function.

Train on a GPU if one is available. Using a GPU requires Parallel Computing Toolbox™ and a CUDA® enabled NVIDIA® GPU. For more information, see “GPU Support by Release” (Parallel Computing Toolbox). Training takes about 40 hours on an NVIDIA™ Titan X.

```
doTraining = false;
if doTraining
    modelDateTime = string(datetime('now','Format',"yyyy-MM-dd-HH-mm-ss"));
    [net,info] = trainNetwork(dsTrain,layers,options);
    save(strcat("trainedJPEGDnCNN-",modelDateTime,"-Epoch-",num2str(maxEpochs),".mat"),'net');
else
    load('pretrainedJPEGDnCNN.mat');
end
```

You can now use the DnCNN network to remove JPEG compression artifacts from images.

Perform JPEG Deblocking Using DnCNN Network

To perform JPEG deblocking using DnCNN, follow the remaining steps of this example. The remainder of the example shows how to:

- Create sample test images with JPEG compression artifacts at three different quality levels.
- Remove the compression artifacts using the DnCNN network.
- Visually compare the images before and after deblocking.
- Evaluate the quality of the compressed and deblocked images by quantifying their similarity to the undistorted reference image.

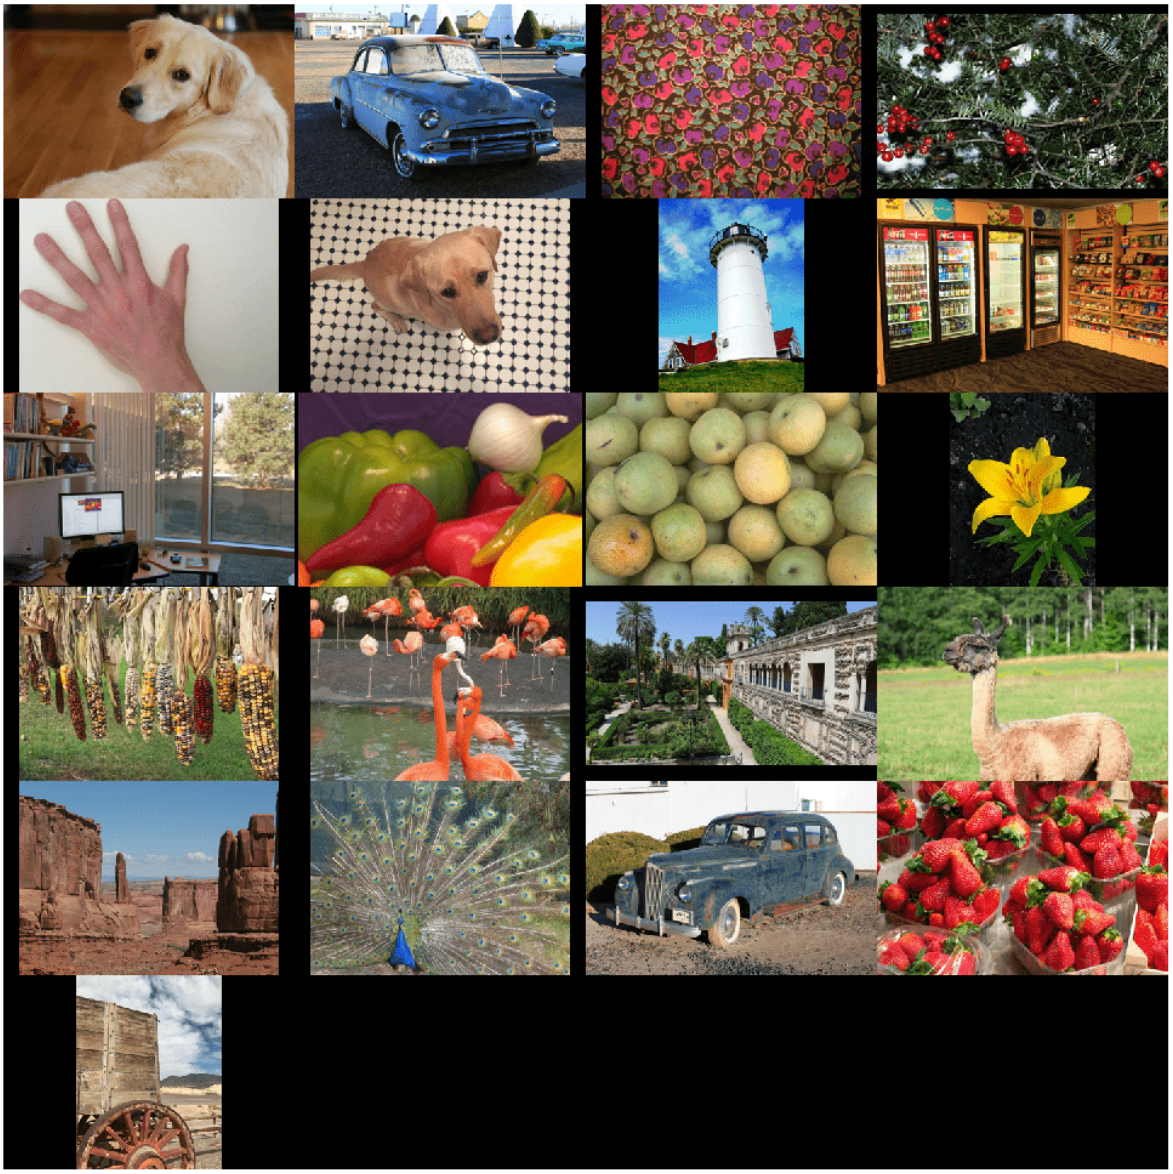
Create Sample Images with Blocking Artifacts

Create sample images to evaluate the result of JPEG image deblocking using the DnCNN network. The test data set, `testImages`, contains 21 undistorted images shipped in Image Processing Toolbox™. Load the images into an `imageDatastore`.

```
exts = {'.jpg','.png'};
fileNames = {'sherlock.jpg','car2.jpg','fabric.png','greens.jpg','hands1.jpg','kobi.png',...
    'lighthouse.png','micromarket.jpg','office_4.jpg','onion.png','pears.png','yellowlily.jpg',...
    'indiancorn.jpg','flamingos.jpg','sevilla.jpg','llama.jpg','parkavenue.jpg',...
    'peacock.jpg','car1.jpg','strawberries.jpg','wagon.jpg'};
filePath = [fullfile(matlabroot,'toolbox','images','imdata') filesep];
filePathNames = strcat(filePath,fileNames);
testImages = imageDatastore(filePathNames,'FileExtensions',exts);
```

Display the testing images as a montage.

```
montage(testImages)
```



Select one of the images to use as the reference image for JPEG deblocking. You can optionally use your own uncompressed image as the reference image.

```
indx = 7; % Index of image to read from the test image datastore
Ireference = readimage(testImages,indx);
imshow(Ireference)
title('Uncompressed Reference Image')
```

Create three compressed test images with the JPEG `Quality` values of 10, 20, and 50.

```
imwrite(Ireference,fullfile(tempdir,'testQuality10.jpg'),'Quality',10);
imwrite(Ireference,fullfile(tempdir,'testQuality20.jpg'),'Quality',20);
imwrite(Ireference,fullfile(tempdir,'testQuality50.jpg'),'Quality',50);
```

Preprocess Compressed Images

Read the compressed versions of the image into the workspace.

```
I10 = imread(fullfile(tempdir,'testQuality10.jpg'));
I20 = imread(fullfile(tempdir,'testQuality20.jpg'));
I50 = imread(fullfile(tempdir,'testQuality50.jpg'));
```

Display the compressed images as a montage.

```
montage({I50,I20,I10},'Size',[1 3])
title('JPEG-Compressed Images with Quality Factor: 50, 20 and 10 (left to right)')
```

Recall that DnCNN is trained using only the luminance channel of an image because human perception is more sensitive to changes in brightness than changes in color. Convert the JPEG-compressed images from the RGB color space to the YCbCr color space using the `rgb2ycbcr` (Image Processing Toolbox) function.

```
I10ycbcr = rgb2ycbcr(I10);
I20ycbcr = rgb2ycbcr(I20);
I50ycbcr = rgb2ycbcr(I50);
```

Apply the DnCNN Network

In order to perform the forward pass of the network, use the `denoiseImage` (Image Processing Toolbox) function. This function uses exactly the same training and testing procedures for denoising an image. You can think of the JPEG compression artifacts as a type of image noise.

```
I10y_predicted = denoiseImage(I10ycbcr(:,:,1),net);
I20y_predicted = denoiseImage(I20ycbcr(:,:,1),net);
I50y_predicted = denoiseImage(I50ycbcr(:,:,1),net);
```

The chrominance channels do not need processing. Concatenate the deblocked luminance channel with the original chrominance channels to obtain the deblocked image in the YCbCr color space.

```
I10ycbcr_predicted = cat(3,I10y_predicted,I10ycbcr(:,:,2:3));
I20ycbcr_predicted = cat(3,I20y_predicted,I20ycbcr(:,:,2:3));
I50ycbcr_predicted = cat(3,I50y_predicted,I50ycbcr(:,:,2:3));
```

Convert the deblocked YCbCr image to the RGB color space by using the `ycbcr2rgb` (Image Processing Toolbox) function.

```
I10_predicted = ycbcr2rgb(I10ycbcr_predicted);
I20_predicted = ycbcr2rgb(I20ycbcr_predicted);
I50_predicted = ycbcr2rgb(I50ycbcr_predicted);
```

Display the deblocked images as a montage.

```
montage({I50_predicted,I20_predicted,I10_predicted},'Size',[1 3])
title('Deblocked Images with Quality Factor 50, 20 and 10 (Left to Right)')
```

To get a better visual understanding of the improvements, examine a smaller region inside each image. Specify a region of interest (ROI) using vector `roi` in the format [*x y width height*]. The elements define the x- and y-coordinate of the top left corner, and the width and height of the ROI.

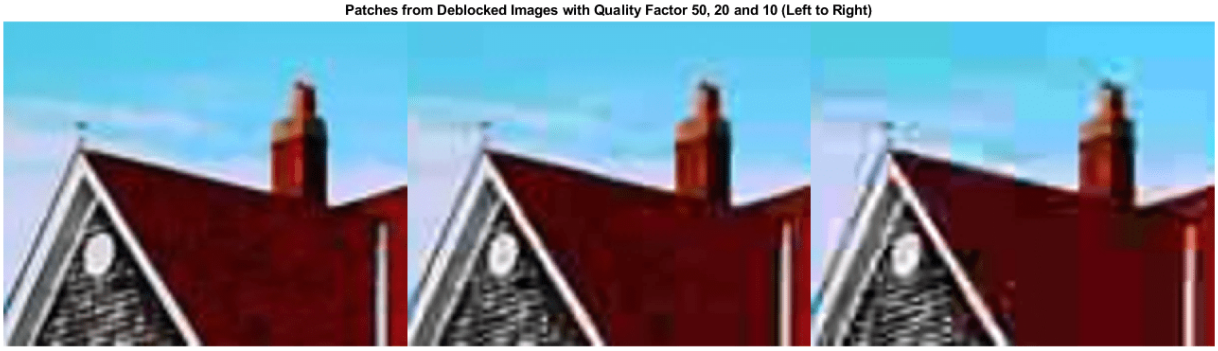
```
roi = [30 440 100 80];
```

Crop the compressed images to this ROI, and display the result as a montage.

```
i10 = imcrop(I10,roi);
i20 = imcrop(I20,roi);
i50 = imcrop(I50,roi);
montage({i50 i20 i10},'Size',[1 3])
title('Patches from JPEG-Compressed Images with Quality Factor 50, 20 and 10 (Left to Right)')
```

Crop the deblocked images to this ROI, and display the result as a montage.

```
i10predicted = imcrop(I10_predicted,roi);
i20predicted = imcrop(I20_predicted,roi);
i50predicted = imcrop(I50_predicted,roi);
montage({i50predicted,i20predicted,i10predicted},'Size',[1 3])
title('Patches from Deblocked Images with Quality Factor 50, 20 and 10 (Left to Right)')
```



Quantitative Comparison

Quantify the quality of the deblocked images through four metrics. You can use the `displayJPEGResults` helper function to compute these metrics for compressed and deblocked images at the quality factors 10, 20, and 50. This function is attached to the example as a supporting file.

- Structural Similarity Index (SSIM). SSIM assesses the visual impact of three characteristics of an image: luminance, contrast and structure, against a reference image. The closer the SSIM value is to 1, the better the test image agrees with the reference image. Here, the reference image is the undistorted original image, `Ireference`, before JPEG compression. See `ssim` (Image Processing Toolbox) for more information about this metric.
- Peak signal-to-noise ratio (PSNR). The larger the PSNR value, the stronger the signal compared to the distortion. See `psnr` (Image Processing Toolbox) for more information about this metric.
- Naturalness Image Quality Evaluator (NIQE). NIQE measures perceptual image quality using a model trained from natural scenes. Smaller NIQE scores indicate better perceptual quality. See `niqe` (Image Processing Toolbox) for more information about this metric.

- Blind/Referenceless Image Spatial Quality Evaluator (BRISQUE). BRISQUE measures perceptual image quality using a model trained from natural scenes with image distortion. Smaller BRISQUE scores indicate better perceptual quality. See `brisque` (Image Processing Toolbox) for more information about this metric.

```
displayJPEGResults(Ireference,I10,I20,I50,I10_predicted,I20_predicted,I50_predicted)
```

```
----------------------------------------
SSIM Comparison
===============
I10: 0.90624    I10_predicted: 0.91286
I20: 0.94904    I20_predicted: 0.95444
I50: 0.97238    I50_predicted: 0.97482
----------------------------------------
PSNR Comparison
===============
I10: 26.6046    I10_predicted: 27.0793
I20: 28.8015    I20_predicted: 29.3378
I50: 31.4512    I50_predicted: 31.8584
----------------------------------------
NIQE Comparison
===============
I10: 7.2194    I10_predicted: 3.9478
I20: 4.5158    I20_predicted: 3.0685
I50: 2.8874    I50_predicted: 2.4106
NOTE: Smaller NIQE score signifies better perceptual quality
----------------------------------------
BRISQUE Comparison
==================
I10: 52.372    I10_predicted: 38.9271
I20: 45.3772    I20_predicted: 30.8991
I50: 27.7093    I50_predicted: 24.3845
NOTE: Smaller BRISQUE score signifies better perceptual quality
```

Image Processing Operator Approximation Using Deep Learning

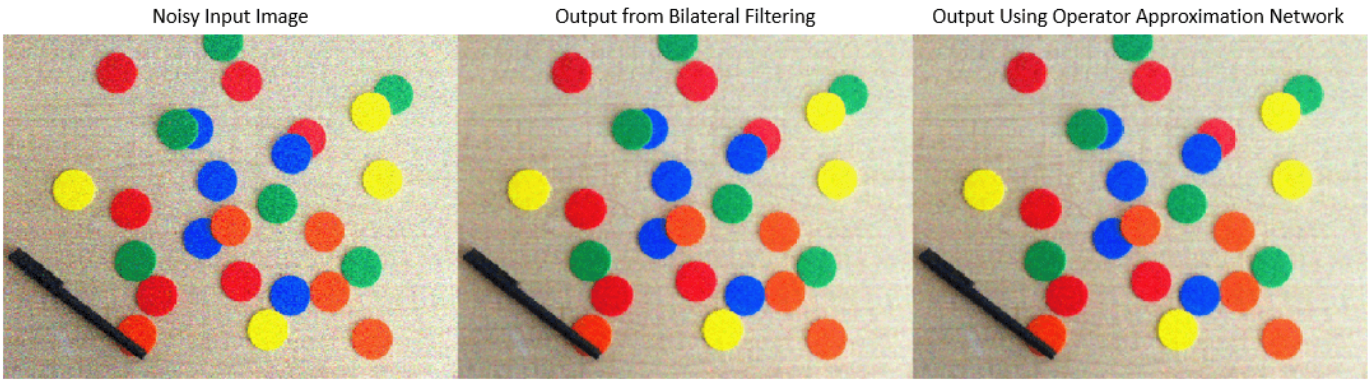
This example shows how to approximate an image filtering operation using a multiscale context aggregation network (CAN).

Operator approximation finds alternative ways to process images such that the result resembles the output from a conventional image processing operation or pipeline. The goal of operator approximation is often to reduce the time required to process an image.

Several classical and deep learning techniques have been proposed to perform operator approximation. Some classical techniques improve the efficiency of a single algorithm but cannot be generalized to other operations. Another common technique approximates a wide range of operations by applying the operator to a low resolution copy of an image, but the loss of high-frequency content limits the accuracy of the approximation.

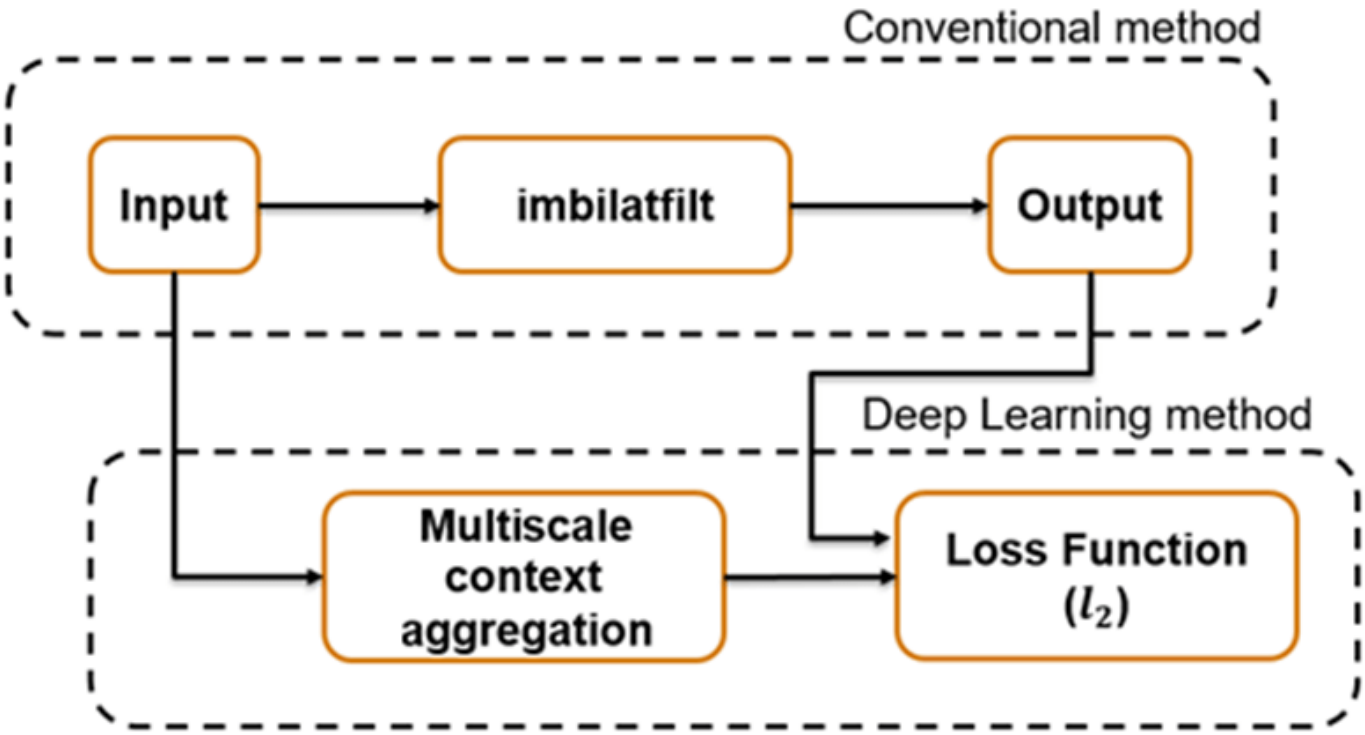
Deep learning solutions enable the approximation of more general and complex operations. For example, the multiscale context aggregation network (CAN) presented by Q. Chen [1 on page 9-0] can approximate multiscale tone mapping, photographic style transfer, nonlocal dehazing, and pencil drawing. Multiscale CAN trains on full-resolution images for greater accuracy in processing high-frequency details. After the network is trained, the network can bypass the conventional processing operation and process images directly.

This example explores how to train a multiscale CAN to approximate a bilateral image filtering operation, which reduces image noise while preserving edge sharpness. The example presents the complete training and inference workflow, which includes the process of creating a training datastore, selecting training options, training the network, and using the network to process test images.



The Operator Approximation Network

The multiscale CAN is trained to minimize the l_2 loss between the conventional output of an image processing operation and the network response after processing the input image using multiscale context aggregation. Multiscale context aggregation looks for information about each pixel from across the entire image, rather than limiting the search to a small neighborhood surrounding the pixel.



To help the network learn global image properties, the multiscale CAN architecture has a large receptive field. The first and last layers have the same size because the operator should not change the size of the image. Successive intermediate layers are dilated by exponentially increasing scale factors (hence the "multiscale" nature of the CAN). Dilation enables the network to look for spatially separated features at various spatial frequencies, without reducing the resolution of the image. After each convolution layer, the network uses adaptive normalization to balance the impact of batch normalization and the identity mapping on the approximated operator.

Download Training and Test Data

Download the IAPR TC-12 Benchmark, which consists of 20,000 still natural images [2 on page 9-0]. The data set includes photos of people, animals, cities, and more. The size of the data file is ~1.8 GB. If you do not want to download the training data set needed to train the network, then you can load the pretrained CAN by typing `load('trainedOperatorLearning-Epoch-181.mat');` at the command line. Then, go directly to the Perform Bilateral Filtering Approximation Using Multiscale CAN on page 9-0 section in this example.

```
imagesDir = tempdir;
url_1 = 'http://www-i6.informatik.rwth-aachen.de/imageclef/resources/iaprtc12.tgz';
downloadIAPRTC12Data(url_1,imagesDir);
```

This example trains the network with small subset of the IAPRTC-12 Benchmark data.

```
trainImagesDir = fullfile(imagesDir,'iaprtc12','images','39');
exts = {'.jpg','.bmp','.png'};
pristineImages = imageDatastore(trainImagesDir,'FileExtensions',exts);
```

List the number of training images.

```
numel(pristineImages.Files)
```

```
ans = 916
```

Prepare Training Data

To create a training data set, read in pristine images and write out images that have been bilateral filtered. The filtered images are stored on disk in the directory specified by `preprocessDataDir`.

```
preprocessDataDir = [trainImagesDir filesep 'preprocessedDataset'];
```

Use the helper function `bilateralFilterDataset` to preprocess the training data. This function is attached to the example as a supporting file.

The helper function performs these operations for each pristine image in `inputImages`:

- Calculate the degree of smoothing for bilateral filtering. Smoothing the filtered image reduces image noise.
- Perform bilateral filtering using `imbilatfilt` (Image Processing Toolbox).
- Save the filtered image to disk using `imwrite`.

```
bilateralFilterDataset(pristineImages,preprocessDataDir);
```

Define Random Patch Extraction Datastore for Training

Use a random patch extraction datastore to feed the training data to the network. This datastore extracts random corresponding patches from two image datastores that contain the network inputs and desired network responses.

In this example, the network inputs are the pristine images in `pristineImages`. The desired network responses are the processed images after bilateral filtering. Create an image datastore called `bilatFilteredImages` from the collection of bilateral filtered image files.

```
bilatFilteredImages = imageDatastore(preprocessDataDir,'FileExtensions',exts);
```

Create a `randomPatchExtractionDatastore` (Image Processing Toolbox) from the two image datastores. Specify a patch size of 256-by-256 pixels. Specify '`PatchesPerImage`' to extract one randomly-positioned patch from each pair of images during training. Specify a mini-batch size of one.

```
miniBatchSize = 1;
patchSize = [256 256];
dsTrain = randomPatchExtractionDatastore(pristineImages,bilatFilteredImages,patchSize, ....
    'PatchesPerImage',1);
dsTrain.MiniBatchSize = miniBatchSize;
```

The `randomPatchExtractionDatastore` provides mini-batches of data to the network at each iteration of the epoch. Perform a read operation on the datastore to explore the data.

```
inputBatch = read(dsTrain);
disp(inputBatch)
```

```
       InputImage          ResponseImage
    ________________    ________________

    {256×256×3 uint8}    {256×256×3 uint8}
```

Set Up Multiscale CAN Layers

This example defines the multiscale CAN using layers from Deep Learning Toolbox™, including:

- `imageInputLayer` - Image input layer
- `convolution2dLayer` - 2D convolution layer for convolutional neural networks
- `batchNormalizationLayer` - Batch normalization layer
- `leakyReluLayer` - Leaky rectified linear unit layer
- `regressionLayer` - Regression output layer for a neural network

Two custom scale layers are added to implement an adaptive batch normalization layer. These layers are attached as supporting files to this example.

- **adaptiveNormalizationMu** - Scale layer that adjusts the strengths of the batch-normalization branch
- **adaptiveNormalizationLambda** - Scale layer that adjusts the strengths of the identity branch

The first layer, `imageInputLayer`, operates on image patches. The patch size is based on the network receptive field, which is the spatial image region that affects the response of top-most layer in the network. Ideally, the network receptive field is the same as the image size so that it can see all the high level features in the image. For a bilateral filter, the approximation image patch size is fixed to 256-by-256.

```
networkDepth = 10;
numberOfFilters = 32;
firstLayer = imageInputLayer([256 256 3],'Name','InputLayer','Normalization','none');
```

The image input layer is followed by a 2-D convolution layer that contains 32 filters of size 3-by-3. Zero-pad the inputs to each convolution layer so that feature maps remain the same size as the input after each convolution. Initialize the weights to the identity matrix.

```
Wgts = zeros(3,3,3,numberOfFilters);
for ii = 1:3
    Wgts(2,2,ii,ii) = 1;
end
convolutionLayer = convolution2dLayer(3,numberOfFilters,'Padding',1, ...
    'Weights',Wgts,'Name','Conv1');
```

Each convolution layer is followed by a batch normalization layer and an adaptive normalization scale layer that adjusts the strengths of the batch-normalization branch. Later, this example will create the corresponding adaptive normalization scale layer that adjusts the strength of the identity branch. For now, follow the `adaptiveNormalizationMu` layer with an addition layer. Finally, specify a leaky ReLU layer with a scalar multiplier of `0.2` for negative inputs.

```
batchNorm = batchNormalizationLayer('Name','BN1');
adaptiveMu = adaptiveNormalizationMu(numberOfFilters,'Mu1');
addLayer = additionLayer(2,'Name','add1');
leakyrelLayer = leakyReluLayer(0.2,'Name','Leaky1');
```

Specify the middle layers of the network following the same pattern. Successive convolution layers have a dilation factor that scales exponentially with the network depth.

```
middleLayers = [convolutionLayer batchNorm adaptiveMu addLayer leakyrelLayer];

Wgts = zeros(3,3,numberOfFilters,numberOfFilters);
for ii = 1:numberOfFilters
    Wgts(2,2,ii,ii) = 1;
end
```

```
for layerNumber = 2:networkDepth-2
    dilationFactor = 2^(layerNumber-1);
    padding = dilationFactor;
    conv2dLayer = convolution2dLayer(3,numberOfFilters, ...
        'Padding',padding,'DilationFactor',dilationFactor, ...
        'Weights',Wgts,'Name',['Conv' num2str(layerNumber)]);
    batchNorm = batchNormalizationLayer('Name',['BN' num2str(layerNumber)]);
    adaptiveMu = adaptiveNormalizationMu(numberOfFilters,['Mu' num2str(layerNumber)]);
    addLayer = additionLayer(2,'Name',['add' num2str(layerNumber)]);
    leakyrelLayer = leakyReluLayer(0.2, 'Name', ['Leaky' num2str(layerNumber)]);
    middleLayers = [middleLayers conv2dLayer batchNorm adaptiveMu addLayer leakyrelLayer];
end
```

Do not apply a dilation factor to the second-to-last convolution layer.

```
conv2dLayer = convolution2dLayer(3,numberOfFilters, ...
    'Padding',1,'Weights',Wgts,'Name','Conv9');

batchNorm = batchNormalizationLayer('Name','AN9');
adaptiveMu = adaptiveNormalizationMu(numberOfFilters,'Mu9');
addLayer = additionLayer(2,'Name','add9');
leakyrelLayer = leakyReluLayer(0.2,'Name','Leaky9');
middleLayers = [middleLayers conv2dLayer batchNorm adaptiveMu addLayer leakyrelLayer];
```

The last convolution layer has a single filter of size 1-by-1-by-32-by-3 that reconstructs the image.

```
Wgts = sqrt(2/(9*numberOfFilters))*randn(1,1,numberOfFilters,3);
conv2dLayer = convolution2dLayer(1,3,'NumChannels',numberOfFilters, ...
    'Weights',Wgts,'Name','Conv10');
```

The last layer is a regression layer instead of a leaky ReLU layer. The regression layer computes the mean-squared error between the bilateral-filtered image and the network prediction.

```
finalLayers = [conv2dLayer
    regressionLayer('Name','FinalRegressionLayer')
];
```

Concatenate all the layers.

```
layers = [firstLayer middleLayers finalLayers'];
lgraph = layerGraph(layers);
```

Create skip connections, which act as the identity branch for the adaptive normalization equation. Connect the skip connections to the addition layers.

```
skipConv1 = adaptiveNormalizationLambda(numberOfFilters,'Lambda1');
skipConv2 = adaptiveNormalizationLambda(numberOfFilters,'Lambda2');
skipConv3 = adaptiveNormalizationLambda(numberOfFilters,'Lambda3');
skipConv4 = adaptiveNormalizationLambda(numberOfFilters,'Lambda4');
skipConv5 = adaptiveNormalizationLambda(numberOfFilters,'Lambda5');
skipConv6 = adaptiveNormalizationLambda(numberOfFilters,'Lambda6');
skipConv7 = adaptiveNormalizationLambda(numberOfFilters,'Lambda7');
skipConv8 = adaptiveNormalizationLambda(numberOfFilters,'Lambda8');
skipConv9 = adaptiveNormalizationLambda(numberOfFilters,'Lambda9');

lgraph = addLayers(lgraph,skipConv1);
lgraph = connectLayers(lgraph,'Conv1','Lambda1');
lgraph = connectLayers(lgraph,'Lambda1','add1/in2');
```

```
lgraph = addLayers(lgraph,skipConv2);
lgraph = connectLayers(lgraph,'Conv2','Lambda2');
lgraph = connectLayers(lgraph,'Lambda2','add2/in2');

lgraph = addLayers(lgraph,skipConv3);
lgraph = connectLayers(lgraph,'Conv3','Lambda3');
lgraph = connectLayers(lgraph,'Lambda3','add3/in2');

lgraph = addLayers(lgraph,skipConv4);
lgraph = connectLayers(lgraph,'Conv4','Lambda4');
lgraph = connectLayers(lgraph,'Lambda4','add4/in2');

lgraph = addLayers(lgraph,skipConv5);
lgraph = connectLayers(lgraph,'Conv5','Lambda5');
lgraph = connectLayers(lgraph,'Lambda5','add5/in2');

lgraph = addLayers(lgraph,skipConv6);
lgraph = connectLayers(lgraph,'Conv6','Lambda6');
lgraph = connectLayers(lgraph,'Lambda6','add6/in2');

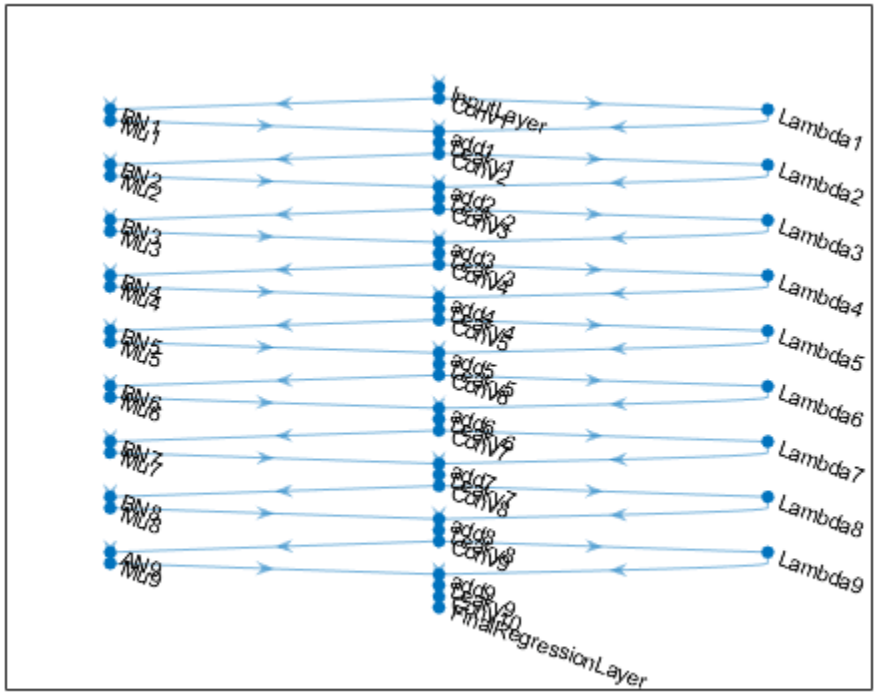
lgraph = addLayers(lgraph,skipConv7);
lgraph = connectLayers(lgraph,'Conv7','Lambda7');
lgraph = connectLayers(lgraph,'Lambda7','add7/in2');

lgraph = addLayers(lgraph,skipConv8);
lgraph = connectLayers(lgraph,'Conv8','Lambda8');
lgraph = connectLayers(lgraph,'Lambda8','add8/in2');

lgraph = addLayers(lgraph,skipConv9);
lgraph = connectLayers(lgraph,'Conv9','Lambda9');
lgraph = connectLayers(lgraph,'Lambda9','add9/in2');
```

Plot the layer graph.

```
plot(lgraph)
```



Specify Training Options

Train the network using the Adam optimizer. Specify the hyperparameter settings by using the `trainingOptions` function. Use the default values of `0.9` for '`Momentum`' and `0.0001` for '`L2Regularization`' (weight decay). Specify a constant learning rate of `0.0001`. Train for 181 epochs.

```
maxEpochs = 181;
initLearningRate = 0.0001;
miniBatchSize = 1;

options = trainingOptions('adam', ...
    'InitialLearnRate',initLearningRate, ...
    'MaxEpochs',maxEpochs, ...
    'MiniBatchSize',miniBatchSize, ...
    'Plots','training-progress', ...
    'Verbose',false);
```

Train the Network

By default, the example loads a pretrained multiscale CAN that approximates a bilateral filter. The pretrained network enables you to perform an approximation of bilateral filtering without waiting for training to complete.

To train the network, set the `doTraining` variable in the following code to `true`. Train the multiscale CAN using the `trainNetwork` function.

Train on a GPU if one is available. Using a GPU requires Parallel Computing Toolbox™ and a CUDA® enabled NVIDIA® GPU. For more information, see “GPU Support by Release” (Parallel Computing Toolbox). Training takes about 15 hours on an NVIDIA™ Titan X.

```
doTraining = false;
if doTraining
    modelDateTime = string(datetime('now','Format',"yyyy-MM-dd-HH-mm-ss"));
    net = trainNetwork(dsTrain,lgraph,options);
    save(strcat("trainedOperatorLearning-",modelDateTime,"-Epoch-",num2str(maxEpochs),".mat"),'ne
else
    load('trainedOperatorLearning-Epoch-181.mat');
end
```

Perform Bilateral Filtering Approximation Using Multiscale CAN

To process an image using a trained multiscale CAN network that approximates a bilateral filter, follow the remaining steps of this example. The remainder of the example shows how to:

- Create a sample noisy input image from a reference image.
- Perform conventional bilateral filtering of the noisy image using the `imbilatfilt` (Image Processing Toolbox) function.
- Perform an approximation to bilateral filtering on the noisy image using the CAN.
- Visually compare the denoised images from operator approximation and conventional bilateral filtering.
- Evaluate the quality of the denoised images by quantifying the similarity of the images to the pristine reference image.

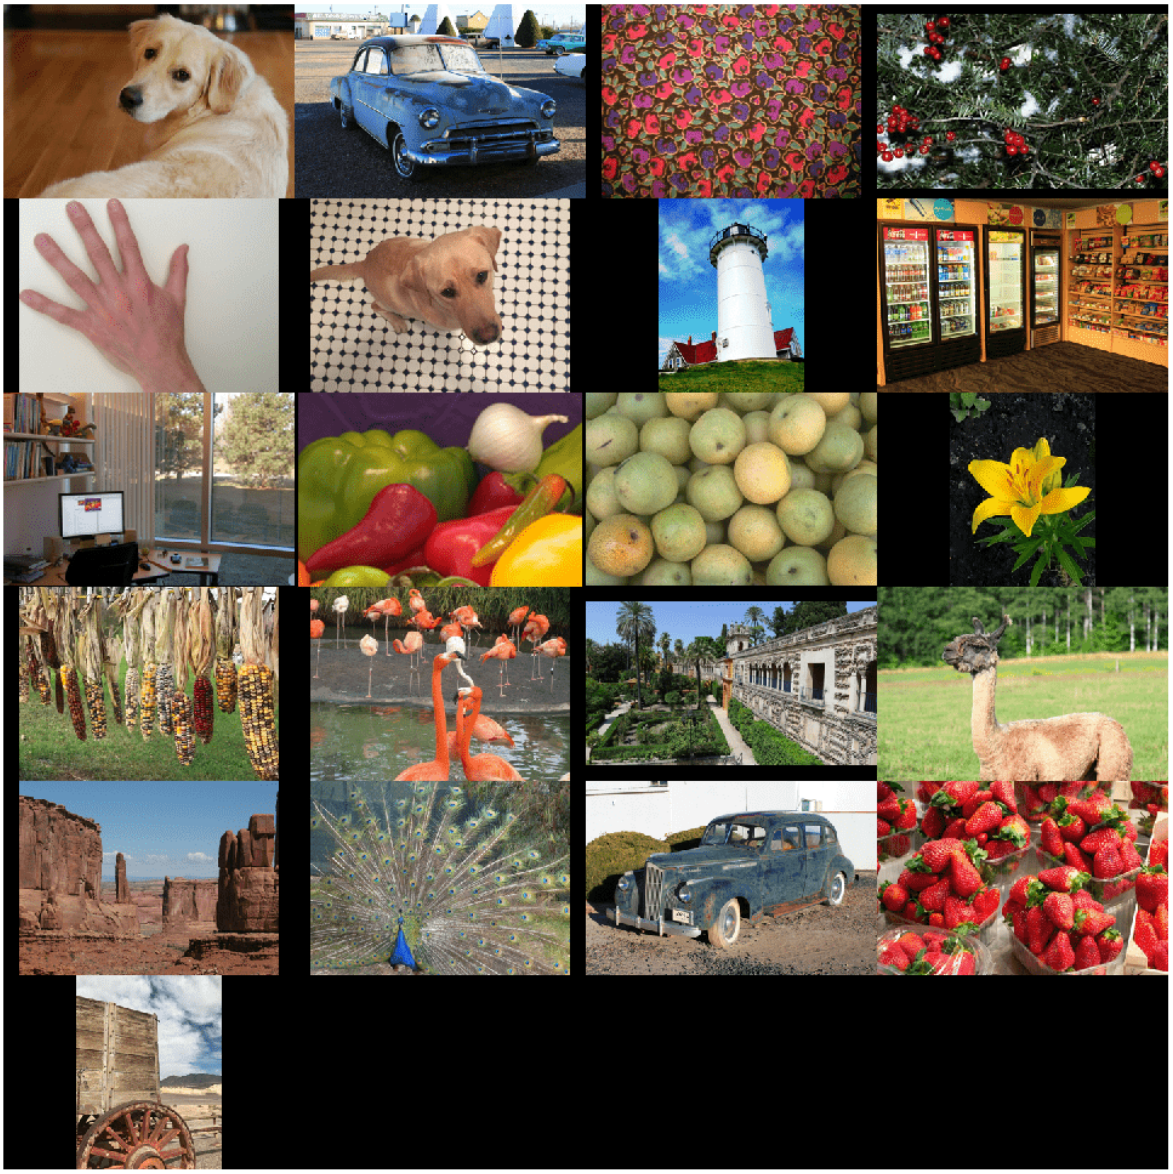
Create Sample Noisy Image

Create a sample noisy image that will be used to compare the results of operator approximation to conventional bilateral filtering. The test data set, `testImages`, contains 21 pristine images shipped in Image Processing Toolbox™. Load the images into an `imageDatastore`.

```
exts = {'.jpg','.png'};
fileNames = {'sherlock.jpg','car2.jpg','fabric.png','greens.jpg','hands1.jpg','kobi.png',...
    'lighthouse.png','micromarket.jpg','office_4.jpg','onion.png','pears.png','yellowlily.jpg',.
    'indiancorn.jpg','flamingos.jpg','sevilla.jpg','llama.jpg','parkavenue.jpg',...
    'peacock.jpg','car1.jpg','strawberries.jpg','wagon.jpg'};
filePath = [fullfile(matlabroot,'toolbox','images','imdata') filesep];
filePathNames = strcat(filePath,fileNames);
testImages = imageDatastore(filePathNames,'FileExtensions',exts);
```

Display the test images as a montage.

```
montage(testImages)
```



Select one of the images to use as the reference image for bilateral filtering. Convert the image to data type `uint8`.

```
indx = 3; % Index of image to read from the test image datastore
Ireference = readimage(testImages,indx);
Ireference = im2uint8(Ireference);
```

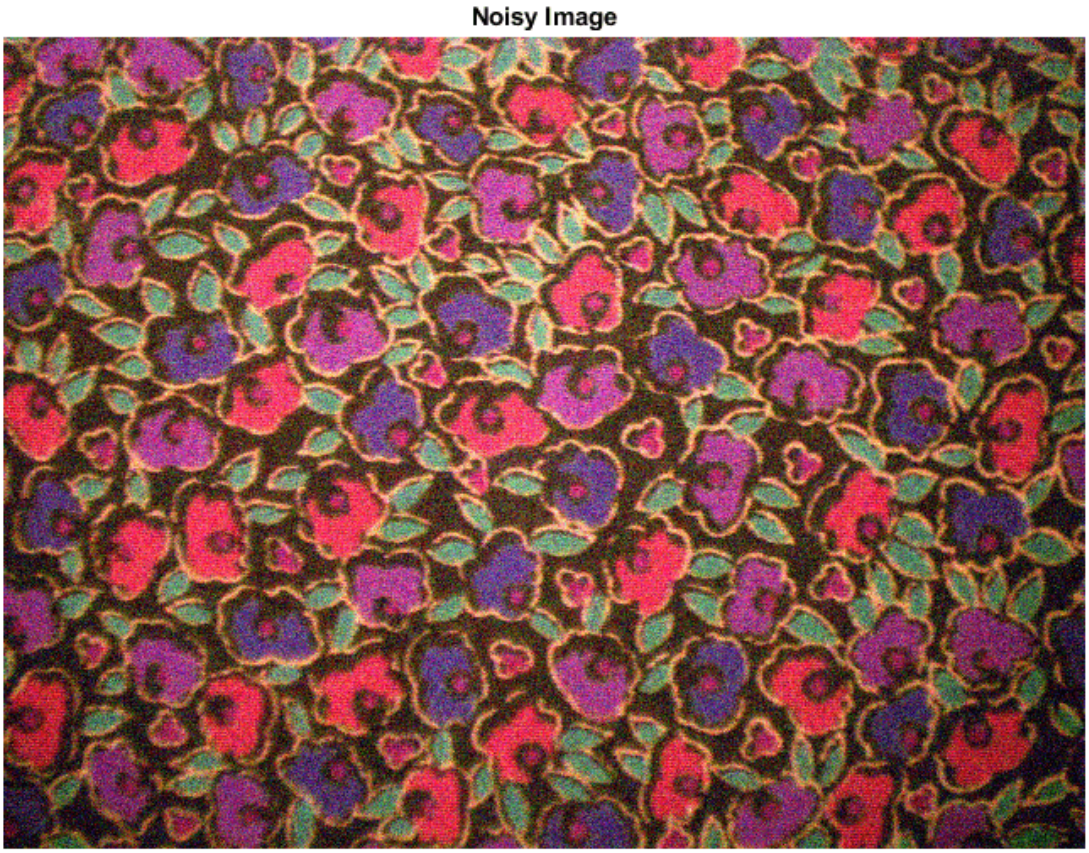
You can optionally use your own image as the reference image. Note that the size of the test image must be at least 256-by-256. If the test image is smaller than 256-by-256, then increase the image size by using the `imresize` function. The network also requires an RGB test image. If the test image is grayscale, then convert the image to RGB by using the `cat` function to concatenate three copies of the original image along the third dimension.

Display the reference image.

```
imshow(Ireference)
title('Pristine Reference Image')
```

Use the `imnoise` (Image Processing Toolbox) function to add zero-mean Gaussian white noise with a variance of 0.00001 to the reference image.

```
Inoisy = imnoise(Ireference,'gaussian',0.00001);
imshow(Inoisy)
title('Noisy Image')
```



Filter Image Using Bilateral Filtering

Conventional bilateral filtering is a standard way to reduce image noise while preserving edge sharpness. Use the `imbilatfilt` (Image Processing Toolbox) function to apply a bilateral filter to the noisy image. Specify a degree of smoothing equal to the variance of pixel values.

```
degreeOfSmoothing = var(double(Inoisy(:)));
Ibilat = imbilatfilt(Inoisy,degreeOfSmoothing);
imshow(Ibilat)
title('Denoised Image Obtained Using Bilateral Filtering')
```

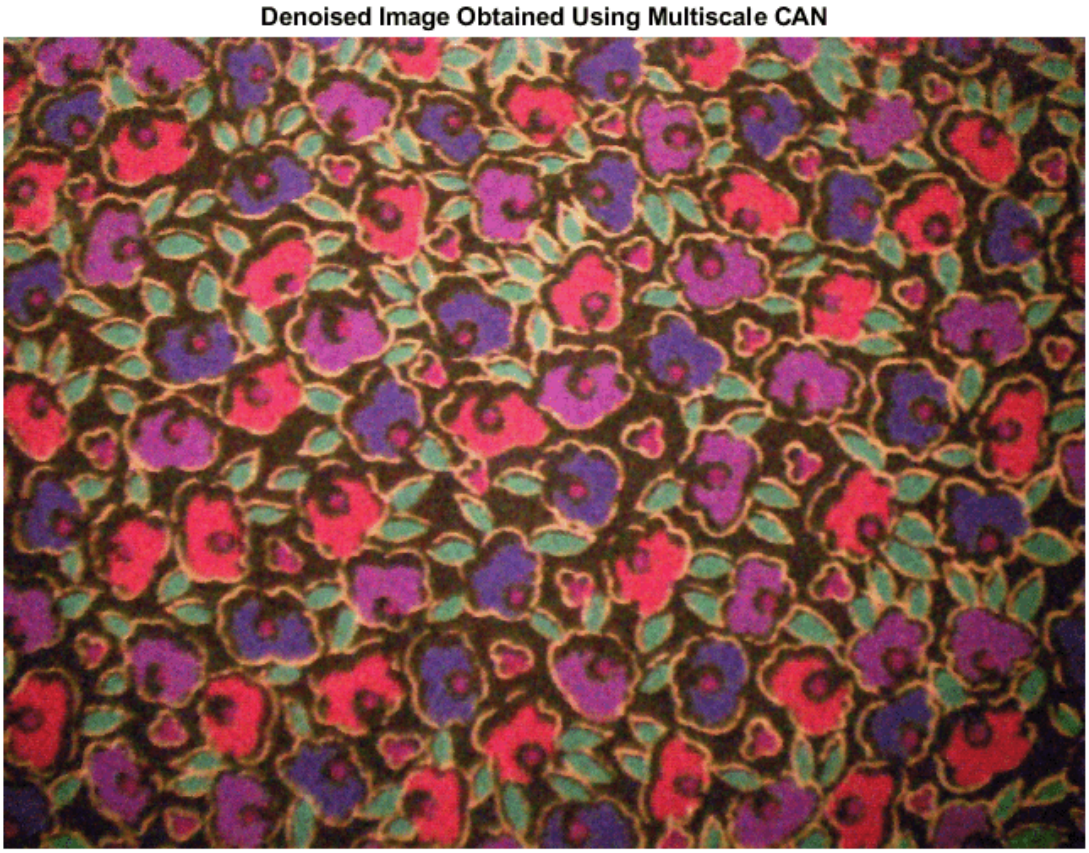
Process Image Using Trained Network

Pass the normalized input image through the trained network and observe the `activations` from the final layer (a regression layer). The output of the network is the desired denoised image.

```
Iapprox = activations(net,Inoisy,'FinalRegressionLayer');
```

Image Processing Toolbox™ requires floating point images to have pixel values in the range [0, 1]. Use the `rescale` function to scale the pixel values to this range, then convert the image to `uint8`.

```
Iapprox = rescale(Iapprox);
Iapprox = im2uint8(Iapprox);
imshow(Iapprox)
title('Denoised Image Obtained Using Multiscale CAN')
```



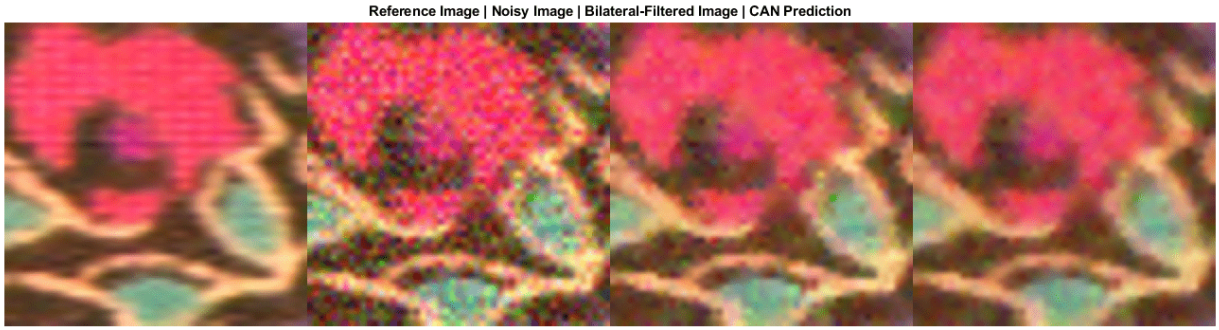
Visual and Quantitative Comparison

To get a better visual understanding of the denoised images, examine a small region inside each image. Specify a region of interest (ROI) using vector `roi` in the format [*x y width height*]. The elements define the x- and y-coordinate of the top left corner, and the width and height of the ROI.

```
roi = [300 30 50 50];
```

Crop the images to this ROI, and display the result as a montage.

```
montage({imcrop(Ireference,roi),imcrop(Inoisy,roi), ...
    imcrop(Ibilat,roi),imcrop(Iapprox,roi)}, ...
    'Size',[1 4]);
title('Reference Image | Noisy Image | Bilateral-Filtered Image | CAN Prediction');
```



The CAN removes more noise than conventional bilateral filtering. Both techniques preserve edge sharpness.

Use image quality metrics to quantitatively compare the noisy input image, the bilateral-filtered image, and the operator-approximated image. The reference image is the original reference image, `Ireference`, before adding noise.

Measure the peak signal-to-noise ratio (PSNR) of each image against the reference image. Larger PSNR values generally indicate better image quality. See `psnr` (Image Processing Toolbox) for more information about this metric.

```
noisyPSNR = psnr(Inoisy,Ireference);
bilatPSNR = psnr(Ibilat,Ireference);
approxPSNR = psnr(Iapprox,Ireference);
disp(['PSNR of: Noisy Image / Bilateral-Filtered Image / Operator Approximated Image = ', ...
    num2str([noisyPSNR bilatPSNR approxPSNR])])
```

```
PSNR of: Noisy Image / Bilateral-Filtered Image / Operator Approximated Image = 20.2857      25.7
```

Measure the structural similarity index (SSIM) of each image. SSIM assesses the visual impact of three characteristics of an image: luminance, contrast and structure, against a reference image. The closer the SSIM value is to 1, the better the test image agrees with the reference image. See `ssim` (Image Processing Toolbox) for more information about this metric.

```
noisySSIM = ssim(Inoisy,Ireference);
bilatSSIM = ssim(Ibilat,Ireference);
approxSSIM = ssim(Iapprox,Ireference);
disp(['SSIM of: Noisy Image / Bilateral-Filtered Image / Operator Approximated Image = ', ...
    num2str([noisySSIM bilatSSIM approxSSIM])])
```

```
SSIM of: Noisy Image / Bilateral-Filtered Image / Operator Approximated Image = 0.76251     0.915
```

Measure perceptual image quality using the Naturalness Image Quality Evaluator (NIQE). Smaller NIQE scores indicate better perceptual quality. See `niqe` (Image Processing Toolbox) for more information about this metric.

```
noisyNIQE = niqe(Inoisy);
bilatNIQE = niqe(Ibilat);
approxNIQE = niqe(Iapprox);
disp(['NIQE score of: Noisy Image / Bilateral-Filtered Image / Operator Approximated Image = ',
    num2str([noisyNIQE bilatNIQE approxNIQE])])
```

```
NIQE score of: Noisy Image / Bilateral-Filtered Image / Operator Approximated Image = 12.1865
```

Compared to conventional bilateral filtering, the operator approximation produces better metric scores.

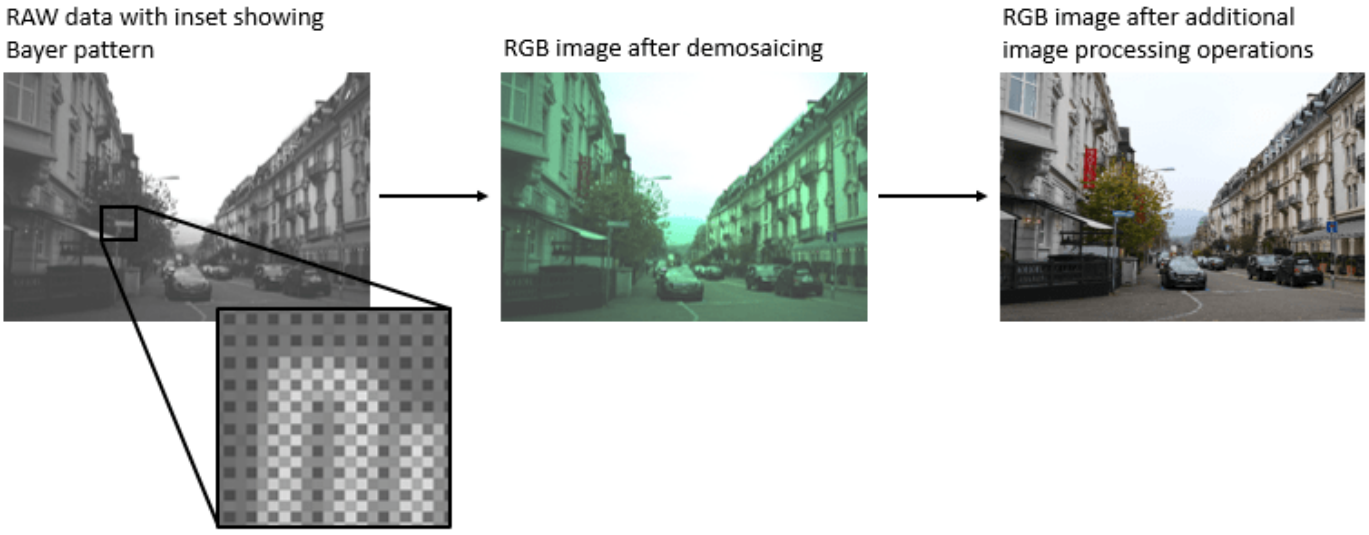
Develop RAW Camera Processing Pipeline Using Deep Learning

This example shows how to convert RAW camera data to an aesthetically pleasing color image using a U-Net.

DSLRs and many modern phone cameras offer the ability to save data collected directly from the camera sensor as a RAW file. Each pixel of RAW data corresponds directly to the amount of light captured by a corresponding camera photosensor. The data depends on fixed characteristics of the camera hardware, such as the sensitivity of each photosensor to a particular range of wavelengths of the electromagnetic spectrum. The data also depends on camera acquisition settings such as exposure time, and factors of the scene such as the light source.

Demosaicing is the only required operation to convert single-channel RAW data to a three-channel RGB image. However, without additional image processing operations, the resulting RGB image has subjectively poor visual quality.

A traditional image processing pipeline performs a combination of additional operations including denoising, linearization, white-balancing, color correction, brightness adjustment, and contrast adjustment [1 on page 9-0]. The challenge of designing a pipeline lies in refining algorithms to optimize the subjective appearance of the final RGB image regardless of variations in the scene and acquisition settings.



Deep learning techniques enable direct RAW to RGB conversion without the necessity of developing a traditional processing pipeline. For instance, one technique compensates for underexposure when converting RAW images to RGB [2 on page 9-0]. This example shows how to convert RAW images from a lower end phone camera to RGB images that approximate the quality of a higher end DSLR camera.

Download Zurich RAW to RGB Data Set

This example uses the Zurich RAW to RGB data set [3 on page 9-0]. The size of the data set is 22 GB. The data set contains 48,043 spatially registered pairs of RAW and RGB training image patches of size 448-by-448. The data set contains two separate test sets. One test set consists of 1,204 spatially registered pairs of RAW and RGB image patches of size 448-by-448. The other test set consists of unregistered full-resolution RAW and RGB images.

Create a directory to store the data set.

```
imageDir = fullfile(tempdir,'ZurichRAWToRGB');
if ~exist(imageDir,'dir')
    mkdir(imageDir);
end
```

To download the data set, request access using the Zurich RAW to RGB dataset form. Extract the data into the directory specified by the `imageDir` variable. When extracted successfully, `imageDir` contains three directories named `full_resolution`, `test`, and `train`.

Create Datastores for Training, Validation, and Testing

Create Datastore for RGB Image Patch Training Data

Create an `imageDatastore` that reads the target RGB training image patches acquired using a high-end Canon DSLR.

```
trainImageDir = fullfile(imageDir,'train');
dsTrainRGB = imageDatastore(fullfile(trainImageDir,'canon'),'ReadSize',16);
```

Preview an RGB training image patch.

```
groundTruthPatch = preview(dsTrainRGB);
imshow(groundTruthPatch)
```

Create Datastore for RAW Image Patch Training Data

Create an `imageDatastore` that reads the input RAW training image patches acquired using a Huawei phone camera. The RAW images are captured with 10-bit precision and are represented as both 8-bit and 16-bit PNG files. The 8-bit files provide a compact representation of patches with data in the range [0, 255]. No scaling has been done on any of the RAW data.

```
dsTrainRAW = imageDatastore(fullfile(trainImageDir,'huawei_raw'),'ReadSize',16);
```

Preview an input RAW training image patch. The datastore reads this patch as an 8-bit `uint8` image because the sensor counts are in the range [0, 255]. To simulate the 10-bit dynamic range of the training data, divide the image intensity values by 4. If you zoom in on the image, then you can see the RGGB Bayer pattern.

```
inputPatch = preview(dsTrainRAW);
inputPatchRAW = inputPatch/4;
imshow(inputPatchRAW)
```

To simulate the minimal traditional processing pipeline, demosaic the RGGB Bayer pattern of the RAW data using the `demosaic` (Image Processing Toolbox) function. Display the processed image and brighten the display. Compared to the target RGB image, the minimally-processed RGB image is dark and has imbalanced colors and noticeable artifacts. A trained RAW-to-RGB network performs preprocessing operations so that the output RGB image resembles the target image.

```
inputPatchRGB = demosaic(inputPatch,'rggb');
imshow(rescale(inputPatchRGB))
```

Partition Test Images into Validation and Test Sets

The test data contains RAW and RGB image patches and full-sized images. This example partitions the test image patches into a validation set and test set. The example uses the full-sized test images for qualitative testing only. See Evaluate Trained Image Processing Pipeline on Full-Sized Images on page 9-0 .

Create image datastores that read the RAW and RGB test image patches.

```
testImageDir = fullfile(imageDir,'test');
dsTestRAW = imageDatastore(fullfile(testImageDir,'huawei_raw'),'ReadSize',16);
dsTestRGB = imageDatastore(fullfile(testImageDir,'canon'),'ReadSize',16);
```

Randomly split the test data into two sets for validation and training. The validation data set contains 200 images. The test set contains the remaining images.

```
numTestImages = dsTestRAW.numpartitions;
numValImages = 200;
```

```
testIdx = randperm(numTestImages);
validationIdx = testIdx(1:numValImages);
testIdx = testIdx(numValImages+1:numTestImages);

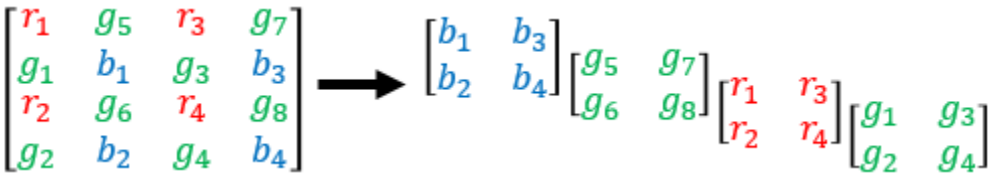
dsValRAW = subset(dsTestRAW,validationIdx);
dsValRGB = subset(dsTestRGB,validationIdx);

dsTestRAW = subset(dsTestRAW,testIdx);
dsTestRGB = subset(dsTestRGB,testIdx);
```

Preprocess and Augment Data

The sensor acquires color data in a repeating Bayer pattern that includes one red, two green, and one blue photosensor. Preprocess the data into a four-channel image expected of the network using the `transform` function. The `transform` function processes the data using the operations specified in the `preprocessRAWDataForRAWToRGB` helper function. The helper function is attached to the example as a supporting file.

The `preprocessRAWDataForRAWToRGB` helper function converts an *H*-by-*W*-by-1 RAW image to an *H*/2-by-*W*/2-by-4 multichannel image consisting of one red, two green, and one blue channel.



The function also casts the data to data type `single` scaled to the range [0, 1].

```
dsTrainRAW = transform(dsTrainRAW,@preprocessRAWDataForRAWToRGB);
dsValRAW = transform(dsValRAW,@preprocessRAWDataForRAWToRGB);
dsTestRAW = transform(dsTestRAW,@preprocessRAWDataForRAWToRGB);
```

The target RGB images are stored on disk as unsigned 8-bit data. To make the computation of metrics and the network design more convenient, preprocess the target RGB training images using the `transform` function and the `preprocessRGBDataForRAWToRGB` helper function. The helper function is attached to the example as a supporting file.

The `preprocessRGBDataForRAWToRGB` helper function casts images to data type `single` scaled to the range [0, 1].

```
dsTrainRGB = transform(dsTrainRGB,@preprocessRGBDataForRAWToRGB);
dsValRGB = transform(dsValRGB,@preprocessRGBDataForRAWToRGB);
```

Combine the input RAW and target RGB data for the training, validation, and test image sets by using the `combine` function.

```
dsTrain = combine(dsTrainRAW,dsTrainRGB);
dsVal = combine(dsValRAW,dsValRGB);
dsTest = combine(dsTestRAW,dsTestRGB);
```

Randomly augment the training data using the `transform` function and the `augmentDataForRAWToRGB` helper function. The helper function is attached to the example as a supporting file.

The `augmentDataForRAWToRGB` helper function randomly applies 90 degree rotation and horizontal reflection to pairs of input RAW and target RGB training images.

```
dsTrainAug = transform(dsTrain,@augmentDataForRAWToRGB);
```

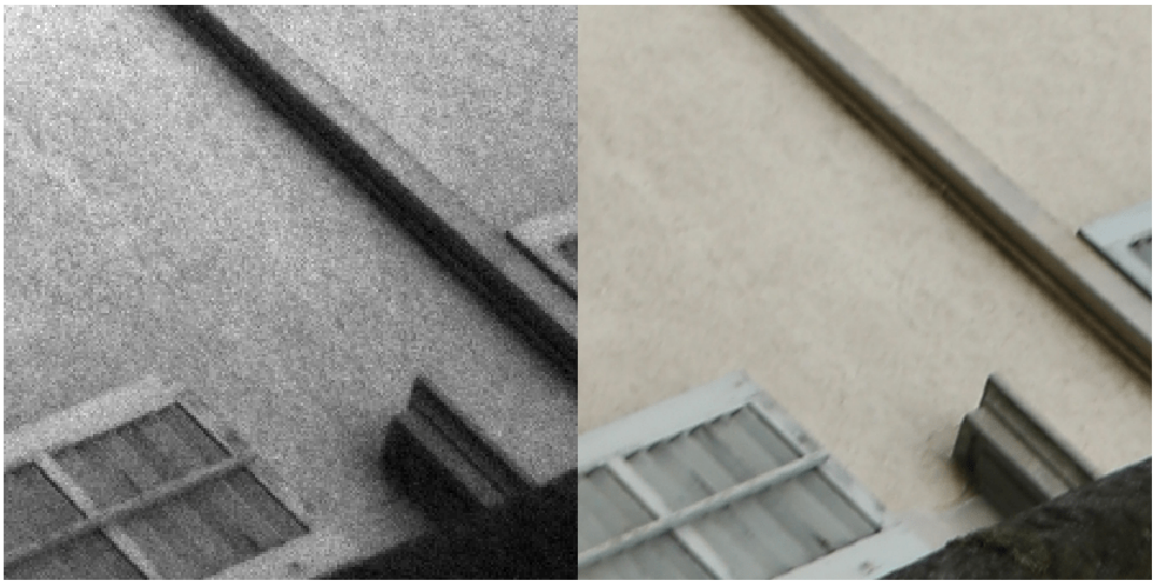
Preview the augmented training data.

```
exampleAug = preview(dsTrainAug)
```

```
exampleAug=8×2 cell array
    {224×224×4 single}    {448×448×3 single}
    {224×224×4 single}    {448×448×3 single}
    {224×224×4 single}    {448×448×3 single}
    {224×224×4 single}    {448×448×3 single}
    {224×224×4 single}    {448×448×3 single}
    {224×224×4 single}    {448×448×3 single}
    {224×224×4 single}    {448×448×3 single}
    {224×224×4 single}    {448×448×3 single}
```

Display the network input and target image in a montage. The network input has four channels, so display the first channel rescaled to the range [0, 1]. The input RAW and target RGB images have identical augmentation.

```
exampleInput = exampleAug{1,1};
exampleOutput = exampleAug{1,2};
montage({rescale(exampleInput(:,:,1)),exampleOutput})
```



Batch Training and Validation Data During Training

This example uses a custom training loop. The `minibatchqueue` object is useful for managing the mini-batching of observations in custom training loops. The `minibatchqueue` object also casts data to a `dlarray` object that enables auto differentiation in deep learning applications.

```
miniBatchSize = 12;
valBatchSize = 10;
trainingQueue = minibatchqueue(dsTrainAug,'MiniBatchSize',miniBatchSize,'PartialMiniBatch','disca
validationQueue = minibatchqueue(dsVal,'MiniBatchSize',valBatchSize,'MiniBatchFormat','SSCB');
```

The `next` function of `minibatchqueue` yields the next mini-batch of data. Preview the outputs from one call to the `next` function. The outputs have data type `dlarray`. The data is already cast to `gpuArray`, on the GPU, and ready for training.

```
[inputRAW,targetRGB] = next(trainingQueue);
whos inputRAW
```

```
  Name            Size                    Bytes  Class      Attributes

  inputRAW      224x224x4x12            9633800  dlarray
```

```
whos targetRGB
```

```
  Name             Size                     Bytes  Class      Attributes

  targetRGB      448x448x3x12            28901384  dlarray
```

Set Up U-Net Network Layers

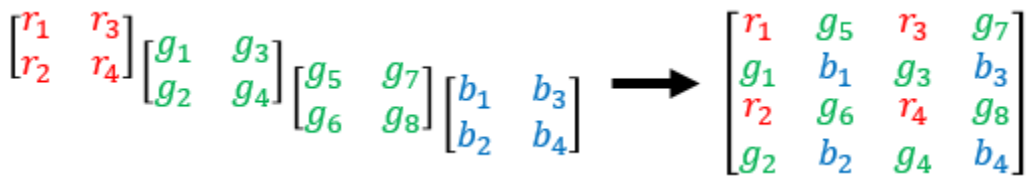
This example uses a variation of the U-Net network. In U-Net, the initial series of convolutional layers are interspersed with max pooling layers, successively decreasing the resolution of the input image. These layers are followed by a series of convolutional layers interspersed with upsampling operators, successively increasing the resolution of the input image. The name U-Net comes from the fact that the network can be drawn with a symmetric shape like the letter U.

This example uses a simple U-Net architecture with two modifications. First, the network replaces the final transposed convolution operation with a custom pixel shuffle upsampling (also known as a depth-to-space) operation. Second, the network uses a custom hyperbolic tangent activation layer as the final layer in the network.

Pixel Shuffle Upsampling

Convolution followed by pixel shuffle upsampling can define subpixel convolution for super resolution applications. Subpixel convolution prevents the checkboard artifacts that can arise from transposed convolution [6 on page 9-0]. Because the model needs to map *H*/2-by-*W*/2-by-4 RAW inputs to *W*-by-*H*-by-3 RGB outputs, the final upsampling stage of the model can be thought of similarly to super resolution where the number of spatial samples grows from the input to the output.

The figure shows how pixel shuffle upsampling works for a 2-by-2-by-4 input. The first two dimensions are spatial dimensions and the third dimension is a channel dimension. In general, pixel shuffle upsampling by a factor of *S* takes an *H*-by-*W*-by-*C* input and yields an *S***H*-by-*S***W*-by-$\frac{C}{S^2}$ output.

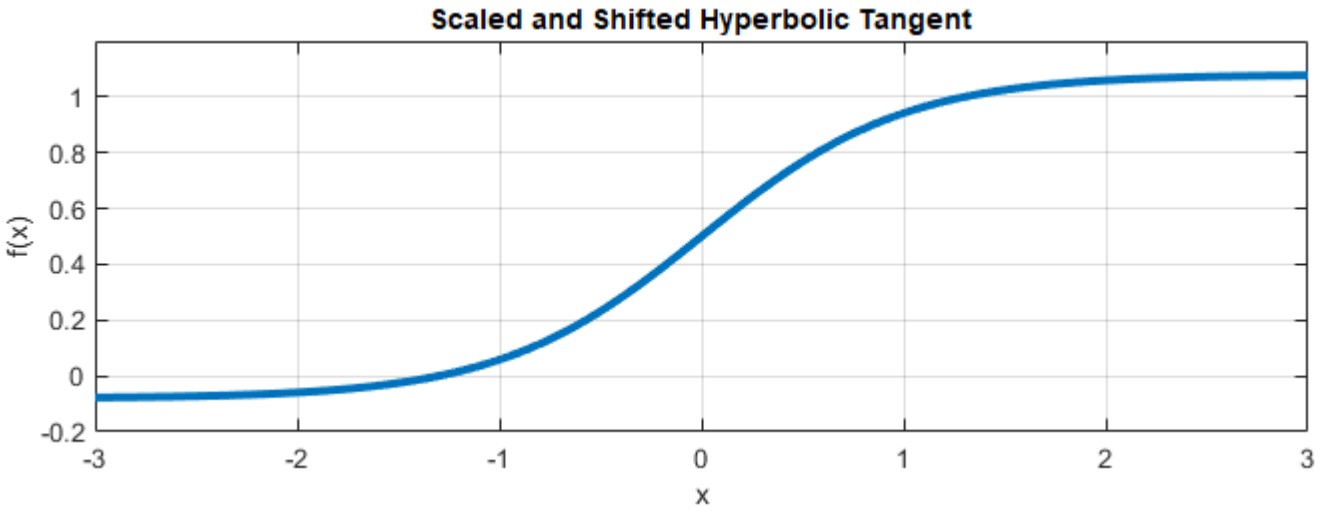


The pixel shuffle function grows the spatial dimensions of the output by mapping information from channel dimensions at a given spatial location into *S*-by-*S* spatial blocks in the output in which each channel contributes to a consistent spatial position relative to its neighbors during upsampling.

Scaled and Hyperbolic Tangent Activation

A hyperbolic tangent activation layer applies the `tanh` function on the layer inputs. This example uses a scaled and shifted version of the `tanh` function, which encourages but does not strictly enforce that the RGB network outputs are in the range [0, 1].

$$f(x) = 0.58 * \tanh(x) + 0.5$$



Calculate Training Set Statistics for Input Normalization

Use `tall` to compute per-channel mean reduction across the training data set. The input layer of the network performs mean centering of inputs during training and testing using the mean statistics.

```
dsIn = copy(dsTrainRAW);
dsIn.UnderlyingDatastore.ReadSize = 1;
t = tall(dsIn);
perChannelMean = gather(mean(t,[1 2]));
```

```
Evaluating tall expression using the Parallel Pool 'LocalProfile12':
- Pass 1 of 1: 0% complete
Evaluation 0% complete

- Pass 1 of 1: Completed in 1 min 1 sec
Evaluation completed in 1 min 2 sec
```

Create U-Net

Create layers of the initial subnetwork, specifying the per-channel mean.

```
inputSize = [256 256 4];
initialLayer = imageInputLayer(inputSize,"Normalization","zerocenter","Mean",perChannelMean, ...
    "Name","ImageInputLayer");
```

Add layers of the first encoding subnetwork. The first encoder has 32 convolutional filters.

```
numEncoderStages = 4;
numFiltersFirstEncoder = 32;
encoderNamePrefix = "Encoder-Stage-";

encoderLayers = [
    convolution2dLayer([3 3],numFiltersFirstEncoder,"Padding","same","WeightsInitializer","narrow
        "Name",strcat(encoderNamePrefix,"1-Conv-1"))
    leakyReluLayer(0.2,"Name",strcat(encoderNamePrefix,"1-ReLU-1"))
    convolution2dLayer([3 3],numFiltersFirstEncoder,"Padding","same","WeightsInitializer","narrow
        "Name",strcat(encoderNamePrefix,"1-Conv-2"))
    leakyReluLayer(0.2,"Name",strcat(encoderNamePrefix,"1-ReLU-2"))
    maxPooling2dLayer([2 2],"Stride",[2 2], ...
        "Name",strcat(encoderNamePrefix,"1-MaxPool"));
    ];
```

Add layers of additional encoding subnetworks. These subnetworks add channel-wise instance normalization after each convolutional layer using a `groupNormalizationLayer`. Each encoder subnetwork has twice the number of filters as the previous encoder subnetwork.

```
cnIdx = 1;
for stage = 2:numEncoderStages

    numFilters = numFiltersFirstEncoder*2^(stage-1);
    layerNamePrefix = strcat(encoderNamePrefix,num2str(stage));

    encoderLayers = [
        encoderLayers
        convolution2dLayer([3 3],numFilters,"Padding","same","WeightsInitializer","narrow-normal"
            "Name",strcat(layerNamePrefix,"-Conv-1"))
        groupNormalizationLayer("channel-wise","Name",strcat("cn",num2str(cnIdx)))
        leakyReluLayer(0.2,"Name",strcat(layerNamePrefix,"-ReLU-1"))
        convolution2dLayer([3 3],numFilters,"Padding","same","WeightsInitializer","narrow-normal"
            "Name",strcat(layerNamePrefix,"-Conv-2"))
        groupNormalizationLayer("channel-wise","Name",strcat("cn",num2str(cnIdx+1)))
        leakyReluLayer(0.2,"Name",strcat(layerNamePrefix,"-ReLU-2"))
        maxPooling2dLayer([2 2],"Stride",[2 2],"Name",strcat(layerNamePrefix,"-MaxPool"))
        ];

    cnIdx = cnIdx + 2;
end
```

Add bridge layers. The bridge subnetwork has twice the number of filters as the final encoder subnetwork and first decoder subnetwork.

```
numFilters = numFiltersFirstEncoder*2^numEncoderStages;
bridgeLayers = [
    convolution2dLayer([3 3],numFilters,"Padding","same","WeightsInitializer","narrow-normal", .
        "Name","Bridge-Conv-1")
    groupNormalizationLayer("channel-wise","Name","cn7")
    leakyReluLayer(0.2,"Name","Bridge-ReLU-1")
    convolution2dLayer([3 3],numFilters,"Padding","same","WeightsInitializer","narrow-normal", .
        "Name","Bridge-Conv-2")
    groupNormalizationLayer("channel-wise","Name","cn8")
    leakyReluLayer(0.2,"Name","Bridge-ReLU-2")];
```

Add layers of the first three decoder subnetworks.

```
numDecoderStages = 4;
cnIdx = 9;
```

```
decoderNamePrefix = "Decoder-Stage-";

decoderLayers = [];
for stage = 1:numDecoderStages-1

    numFilters = numFiltersFirstEncoder*2^(numDecoderStages-stage);
    layerNamePrefix = strcat(decoderNamePrefix,num2str(stage));

    decoderLayers = [
        decoderLayers
        transposedConv2dLayer([3 3],numFilters,"Stride",[2 2],"Cropping","same","WeightsInitiali
            "Name",strcat(layerNamePrefix,"-UpConv"))
        leakyReluLayer(0.2,"Name",strcat(layerNamePrefix,"-UpReLU"))
        depthConcatenationLayer(2,"Name",strcat(layerNamePrefix,"-DepthConcatenation"))
        convolution2dLayer([3 3],numFilters,"Padding","same","WeightsInitializer","narrow-normal
            "Name",strcat(layerNamePrefix,"-Conv-1"))
        groupNormalizationLayer("channel-wise","Name",strcat("cn",num2str(cnIdx)))
        leakyReluLayer(0.2,"Name",strcat(layerNamePrefix,"-ReLU-1"))
        convolution2dLayer([3 3],numFilters,"Padding","same","WeightsInitializer","narrow-normal
            "Name",strcat(layerNamePrefix,"-Conv-2"))
        groupNormalizationLayer("channel-wise","Name",strcat("cn",num2str(cnIdx+1)))
        leakyReluLayer(0.2,"Name",strcat(layerNamePrefix,"-ReLU-2"))
        ];

    cnIdx = cnIdx + 2;
end
```

Add layers of the last decoder subnetwork. This subnetwork excludes the channel-wise instance normalization performed by the other decoder subnetworks. Each decoder subnetwork has half the number of filters as the previous subnetwork.

```
numFilters = numFiltersFirstEncoder;
layerNamePrefix = strcat(decoderNamePrefix,num2str(stage+1));

decoderLayers = [
    decoderLayers
    transposedConv2dLayer([3 3],numFilters,"Stride",[2 2],"Cropping","same","WeightsInitializer"
       "Name",strcat(layerNamePrefix,"-UpConv"))
    leakyReluLayer(0.2,"Name",strcat(layerNamePrefix,"-UpReLU"))
    depthConcatenationLayer(2,"Name",strcat(layerNamePrefix,"-DepthConcatenation"))
    convolution2dLayer([3 3],numFilters,"Padding","same","WeightsInitializer","narrow-normal", .
        "Name",strcat(layerNamePrefix,"-Conv-1"))
    leakyReluLayer(0.2,"Name",strcat(layerNamePrefix,"-ReLU-1"))
    convolution2dLayer([3 3],numFilters,"Padding","same","WeightsInitializer","narrow-normal", .
        "Name",strcat(layerNamePrefix,"-Conv-2"))
    leakyReluLayer(0.2,"Name",strcat(layerNamePrefix,"-ReLU-2"))];
```

Add the final layers of the U-Net. The pixel shuffle layer moves from the *H*/2-by-*W*/2-by-12 channel size of the activations from the final convolution to *H*-by-*W*-by-3 channel activations using pixel shuffle upsampling. The final layer encourages outputs to the desired range [0, 1] using a hyperbolic tangent function.

```
finalLayers = [
    convolution2dLayer([3 3],12,"Padding","same","WeightsInitializer","narrow-normal", ...
       "Name","Decoder-Stage-4-Conv-3")
    pixelShuffleLayer("pixelShuffle",2)
    tanhScaledAndShiftedLayer("tanhActivation")];
```

```
layers = [initialLayer;encoderLayers;bridgeLayers;decoderLayers;finalLayers];
lgraph = layerGraph(layers);
```

Connect layers of the encoding and decoding subnetworks.

```
lgraph = connectLayers(lgraph,"Encoder-Stage-1-ReLU-2","Decoder-Stage-4-DepthConcatenation/in2");
lgraph = connectLayers(lgraph,"Encoder-Stage-2-ReLU-2","Decoder-Stage-3-DepthConcatenation/in2");
lgraph = connectLayers(lgraph,"Encoder-Stage-3-ReLU-2","Decoder-Stage-2-DepthConcatenation/in2");
lgraph = connectLayers(lgraph,"Encoder-Stage-4-ReLU-2","Decoder-Stage-1-DepthConcatenation/in2");
net = dlnetwork(lgraph);
```

Visualize the network architecture using the Deep Network Designer app.

```
%deepNetworkDesigner(lgraph)
```

Load the Feature Extraction Network

This function modifies a pretrained VGG-16 deep neural network to extract image features at various layers. These multilayer features are used to compute content loss.

To get a pretrained VGG-16 network, install `vgg16`. If you do not have the required support package installed, then the software provides a download link.

```
vggNet = load('vgg16');
vggNet = vggNet.net;
%vggNet = vgg16;
```

To make the VGG-16 network suitable for feature extraction, use the layers up to `'relu5_3'`.

```
vggNet = vggNet.Layers(1:31);
vggNet = dlnetwork(layerGraph(vggNet));
```

Define Model Gradients and Loss Functions

The helper function `modelGradients` calculates the gradients and overall loss for batches of training data. This function is defined in the Supporting Functions on page 9-0 section of this example.

The overall loss is a weighted sum of two losses: mean of absolute error (MAE) loss and content loss. The content loss is weighted such that the MAE loss and content loss contribute approximately equally to the overall loss:

$$lossOverall = lossMAE + weightFactor * lossContent$$

The MAE loss penalises the L^1 distance between samples of the network predictions and samples of the target image. L^1 is often a better choice than L^2 for image processing applications because it can help reduce blurring artifacts [4 on page 9-0]. This loss is implemented using the `maeLoss` helper function defined in the Supporting Functions on page 9-0 section of this example.

The content loss helps the network learn both high-level structural content and low-level edge and color information. The loss function calculates a weighted sum of the mean square error (MSE) between predictions and targets for each activation layer. This loss is implemented using the `contentLoss` helper function defined in the Supporting Functions on page 9-0 section of this example.

Calculate Content Loss Weight Factor

The `modelGradients` helper function requires the content loss weight factor as an input argument. Calculate the weight factor for a sample batch of training data such that the MAE loss is equal to the weighted content loss.

Preview a batch of training data, which consists of pairs of RAW network inputs and RGB target outputs.

```
trainingBatch = preview(dsTrainAug);
networkInput = dlarray((trainingBatch{1,1}),'SSC');
targetOutput = dlarray((trainingBatch{1,2}),'SSC');
```

Predict the response of the untrained U-Net network using the `forward` function.

```
predictedOutput = forward(net,networkInput);
```

Calculate the MAE and content losses between the predicted and target RGB images.

```
sampleMAELoss = maeLoss(predictedOutput,targetOutput);
sampleContentLoss = contentLoss(vggNet,predictedOutput,targetOutput);
```

Calculate the weight factor.

```
weightContent = sampleMAELoss/sampleContentLoss;
```

Specify Training Options

Define the training options that are used within the custom training loop to control aspects of Adam optimization. Train for 20 epochs.

```
learnRate = 5e-5;
numEpochs = 20;
```

Train Network

By default, the example downloads a pretrained version of the RAW-to-RGB network by using the helper function `downloadTrainedRAWToRGBNet`. The helper function is attached to the example as a supporting file. The pretrained network enables you to run the entire example without waiting for training to complete.

To train the network, set the `doTraining` variable in the following code to `true`. Train the model in a custom training loop. For each iteration:

- Read the data for current mini-batch using the `next` function.
- Evaluate the model gradients using the `dlfeval` function and the `modelGradients` helper function.
- Update the network parameters using the `adamupdate` function and the gradient information.
- Update the training progress plot for every iteration and display various computed losses.

Train on a GPU if one is available. Using a GPU requires Parallel Computing Toolbox™ and a CUDA® enabled NVIDIA® GPU. For more information, see “GPU Support by Release” (Parallel Computing Toolbox). Training takes about 88 hours on an NVIDIA™ Titan RTX and can take even longer depending on your GPU hardware.

```
doTraining = false;
if doTraining
```

```
    % Create a directory to store checkpoints
    checkpointDir = fullfile(imageDir,'checkpoints',filesep);
    if ~exist(checkpointDir,'dir')
        mkdir(checkpointDir);
    end

    % Initialize training plot
    [hFig,batchLine,validationLine] = initializeTrainingPlotRAWPipeline;

    % Initialize Adam solver state
    [averageGrad,averageSqGrad] = deal([]);
    iteration = 0;

    start = tic;
    for epoch = 1:numEpochs
        reset(trainingQueue);
        shuffle(trainingQueue);
        while hasdata(trainingQueue)
            [inputRAW,targetRGB] = next(trainingQueue);

            [grad,loss] = dlfeval(@modelGradients,net,vggNet,inputRAW,targetRGB,weightContent);

            iteration = iteration + 1;

            [net,averageGrad,averageSqGrad] = adamupdate(net, ...
                grad,averageGrad,averageSqGrad,iteration,learnRate);

            updateTrainingPlotRAWPipeline(batchLine,validationLine,iteration,loss,start,epoch,..
                validationQueue,numValImages,valBatchSize,net,vggNet,weightContent);
        end
        % Save checkpoint of network state
        save(checkpointDir + "epoch" + epoch,'net');
    end
    % Save the final network state
    save(checkpointDir + "trainedRAWToRGBNet.mat",'net');

else
    trainedRAWToRGBNet_url = 'https://ssd.mathworks.com/supportfiles/vision/data/trainedRAWToRGBI
    downloadTrainedRAWToRGBNet(trainedRAWToRGBNet_url,imageDir);
    load(fullfile(imageDir,'trainedRAWToRGBNet.mat'));
end
```

```
Pretrained RAW-to-RGB network already exists.
```

Calculate Image Quality Metrics

Reference-based quality metrics such as MSSIM or PSNR enable a quantitative measure of image quality. You can calculate the MSSIM and PSNR of the patched test images because they are spatially registered and the same size.

Iterate through the test set of patched images using a `minibatchqueue` object.

```
patchTestSet = combine(dsTestRAW,dsTestRGB);
testPatchQueue = minibatchqueue(patchTestSet,'MiniBatchSize',16,'MiniBatchFormat','SSCB');
```

Iterate through the test set and calculate the MSSIM and PSNR for each test image using the `multissim` (Image Processing Toolbox) and `psnr` (Image Processing Toolbox) functions. Compute

MSSIM for color images by using a mean of the metric for each color channel as an approximation since the metric isn't well defined for multi-channel inputs.

```
totalMSSIM = 0;
totalPSNR = 0;
while hasdata(testPatchQueue)
    [inputRAW,targetRGB] = next(testPatchQueue);
    outputRGB = forward(net,inputRAW);
    targetRGB = targetRGB ./ 255;
    mssimOut = sum(mean(multissim(outputRGB,targetRGB),3),4);
    psnrOut = sum(psnr(outputRGB,targetRGB),4);
    totalMSSIM = totalMSSIM + mssimOut;
    totalPSNR = totalPSNR + psnrOut;
end
```

Calculate the mean MSSIM and mean PSNR over the test set. This result is consistent with the similar U-Net approach from [3 on page 9-0] for mean MSSIM and competitive with the PyNet approach in [3 on page 9-0] in mean PSNR. The differences in loss functions and use of pixel shuffle upsampling compared to [3 on page 9-0] likely account for these differences.

```
numObservations = dsTestRGB.numpartitions;
meanMSSIM = totalMSSIM / numObservations
```

```
meanMSSIM =
  1(S) × 1(S) × 1(C) × 1(B) single dlarray

    0.8425
```

```
meanPSNR = totalPSNR / numObservations
```

```
meanPSNR =
  1(S) × 1(S) × 1(C) × 1(B) single dlarray

   21.1213
```

Evaluate Trained Image Processing Pipeline on Full-Sized Images

Because of sensor differences between the phone camera and DSLR used to acquire the full-resolution test images, the scenes are not registered and are not the same size. Reference-based comparison of the full-resolution images from the network and the DSLR ISP is difficult. However, a qualitative comparison of the images is useful because a goal of image processing is to create an aesthetically pleasing image.

Create an image datastore that contains full-sized RAW images acquired by a phone camera.

```
testImageDir = fullfile(imageDir,'test');
testImageDirRAW = "huawei_full_resolution";
dsTestFullRAW = imageDatastore(fullfile(testImageDir,testImageDirRAW));
```

Get the names of the image files in the full-sized RAW test set.

```
targetFilesToInclude = extractAfter(string(dsTestFullRAW.Files),fullfile(testImageDirRAW,filesep)
targetFilesToInclude = extractBefore(targetFilesToInclude,".png");
```

Preprocess the RAW data by converting the data to the form expected by the network using the `transform` function. The `transform` function processes the data using the operations specified in

the `preprocessRAWDataForRAWToRGB` helper function. The helper function is attached to the example as a supporting file.

```
dsTestFullRAW = transform(dsTestFullRAW,@preprocessRAWDataForRAWToRGB);
```

Create an image datastore that contains full-sized RGB test images captured from the high-end DSLR. The Zurich RAW-to-RGB data set contains more full-sized RGB images than RAW images, so include only the RGB images with a corresponding RAW image.

```
dsTestFullRGB = imageDatastore(fullfile(imageDir,'full_resolution','canon'));
dsTestFullRGB.Files = dsTestFullRGB.Files(contains(dsTestFullRGB.Files,targetFilesToInclude));
```

Read in the target RGB images. Get a sense of the overall output by looking at a montage view.

```
targetRGB = readall(dsTestFullRGB);
montage(targetRGB,"Size",[5 2],"Interpolation","bilinear")
```

Iterate through the test set of full-sized images using a `minibatchqueue` object. If you have a GPU device with sufficient memory to process full-resolution images, then you can run prediction on a GPU by specifying the output environment as `"gpu"`.

```
testQueue = minibatchqueue(dsTestFullRAW,"MiniBatchSize",1, ...
    "MiniBatchFormat","SSCB","OutputEnvironment","cpu");
```

For each full-sized RAW test image, predict the output RGB image by calling `forward` on the network.

```
outputSize = 2*size(preview(dsTestFullRAW),[1 2]);
outputImages = zeros([outputSize,3,dsTestFullRAW.numpartitions],'uint8');

idx = 1;
while hasdata(testQueue)
    inputRAW = next(testQueue);
    rgbOut = forward(net,inputRAW);
    rgbOut = gather(extractdata(rgbOut));
    outputImages(:,:,:,idx) = im2uint8(rgbOut);
    idx = idx+1;
end
```

Get a sense of the overall output by looking at a montage view. The network produces images that are aesthetically pleasing, with similar characteristics.

```
montage(outputImages,"Size",[5 2],"Interpolation","bilinear")
```

Compare one target RGB image with the corresponding image predicted by the network. The network produces colors which are more saturated than the target DSLR images. Although the colors from the simple U-Net architecture are not the same as the DSLR targets, the images are still qualitatively pleasing in many cases.

```
imgIdx = 1;
imTarget = targetRGB{imgIdx};
imPredicted = outputImages(:,:,:,imgIdx);
figure
montage({imTarget,imPredicted},"Interpolation","bilinear")
```

To improve the performance of the RAW-to-RGB network, a network architecture would learn detailed localized spatial features using multiple scales from global features that describe color and contrast [3 on page 9-0].

Supporting Functions

Model Gradients Function

The `modelGradients` helper function calculates the gradients and overall loss. The gradient information is returned as a table which includes the layer, parameter name and value for each learnable parameter in the model.

```
function [gradients,loss] = modelGradients(dlnet,vggNet,Xpatch,Target,weightContent)
    Y = forward(dlnet,Xpatch);
    lossMAE = maeLoss(Y,Target);
    lossContent = contentLoss(vggNet,Y,Target);
    loss = lossMAE + weightContent.*lossContent;
    gradients = dlgradient(loss,dlnet.Learnables);
end
```

Mean Absolute Error Loss Function

The helper function `maeLoss` computes the mean absolute error between network predictions, `Y`, and target images, `T`.

```
function loss = maeLoss(Y,T)
    loss = mean(abs(Y-T),'all');
end
```

Content Loss Function

The helper function `contentLoss` calculates a weighted sum of the MSE between network predictions, `Y`, and target images, `T`, for each activation layer. The `contentLoss` helper function

calculates the MSE for each activation layer using the `mseLoss` helper function. Weights are selected such that the loss from each activation layers contributes roughly equally to the overall content loss.

```
function loss = contentLoss(net,Y,T)

    layers = ["relu1_1","relu1_2","relu2_1","relu2_2","relu3_1","relu3_2","relu3_3","relu4_1"];
    [T1,T2,T3,T4,T5,T6,T7,T8] = forward(net,T,'Outputs',layers);
    [X1,X2,X3,X4,X5,X6,X7,X8] = forward(net,Y,'Outputs',layers);

    l1 = mseLoss(X1,T1);
    l2 = mseLoss(X2,T2);
    l3 = mseLoss(X3,T3);
    l4 = mseLoss(X4,T4);
    l5 = mseLoss(X5,T5);
    l6 = mseLoss(X6,T6);
    l7 = mseLoss(X7,T7);
    l8 = mseLoss(X8,T8);

    layerLosses = [l1 l2 l3 l4 l5 l6 l7 l8];
    weights = [1 0.0449 0.0107 0.0023 6.9445e-04 2.0787e-04 2.0118e-04 6.4759e-04];
    loss = sum(layerLosses.*weights);
end
```

Mean Square Error Loss Function

The helper function `mseLoss` computes the MSE between network predictions, `Y`, and target images, `T`.

```
function loss = mseLoss(Y,T)
    loss = mean((Y-T).^2,'all');
end
```

Recover Images from Extreme Low-Light Conditions Using Deep Learning

This example shows how to recover brightened RGB images from RAW camera data collected in extreme low-light conditions using a U-Net.

Low-light image recovery in cameras is a challenging problem. A typical solution is to increase the exposure time, which allows more light in the scene to hit the sensor and increases the brightness of the image. However, longer exposure times can result in motion blur artifacts when objects in the scene move or when the camera is perturbed during acquisition.

Deep learning offers solutions that recover reasonable images for RAW data collected from DSLRs and many modern phone cameras despite low light conditions and short exposure times. These solutions take advantage of the full information present in RAW data to outperform brightening techniques performed in postprocessed RGB data [1].

Low Light Image (Left) and Recovered Image (Right)

This example shows how to train a network to implement a low-light camera pipeline using data from a particular camera sensor. This example shows how to recover well exposed RGB images from very low light, underexposed RAW data from the same type of camera sensor.

Download See-in-the-Dark Data Set

This example uses the Sony camera data from the See-in-the-Dark (SID) data set [1]. The SID data set provides registered pairs of RAW images of the same scene. In each pair, one image has a short exposure time and is underexposed, and the other image has a longer exposure time and is well exposed. The size of the Sony camera data from the SID data set is 25 GB.

Set `dataDir` as the desired location of the data set.

```
dataDir = fullfile(tempdir,"SID");
if ~exist(dataDir,"dir")
    mkdir(dataDir);
end
```

To download the data set, go to this link: https://storage.googleapis.com/isl-datasets/SID/Sony.zip. Extract the data into the directory specified by the `dataDir` variable. When extraction is successful,

`dataDir` contains the directory `Sony` with two subdirectories: `long` and `short`. The files in the `long` subdirectory have a long exposure and are well exposed. The files in the `short` subdirectory have a short exposure and are quite underexposed and dark.

The data set also provides text files that describe how to partition the files into training, validation, and test data sets. Move the files `Sony_train_list.txt`, `Sony_val_list.txt`, and `Sony_test_list.txt` to the directory specified by the `dataDir` variable.

Create Datastores for Training, Validation, and Testing

Import the list of files to include in the training, validation, and test data sets using the `importSonyFileInfo` helper function. This function is attached to the example as a supporting file.

```
trainInfo = importSonyFileInfo(fullfile(dataDir,"Sony_train_list.txt"));
valInfo = importSonyFileInfo(fullfile(dataDir,"Sony_val_list.txt"));
testInfo = importSonyFileInfo(fullfile(dataDir,"Sony_test_list.txt"));
```

Combine and Preprocess RAW and RGB Data Using Datastores

Create combined datastores that read and preprocess pairs of underexposed and well exposed RAW images using the `createCombinedDatastoreForLowLightRecovery` helper function. This function is attached to the example as a supporting file.

The `createCombinedDatastoreForLowLightRecovery` helper function performs these operations:

- Create an `imageDatastore` that reads the short exposure RAW images using a custom read function. The read function reads a RAW image using the `rawread` (Image Processing Toolbox) function, then separates the RAW Bayer pattern into separate channels for each of the four sensors using the `raw2planar` (Image Processing Toolbox) function. Normalize the data to the range [0, 1] by transforming the `imageDatastore` object.
- Create an `imageDatastore` object that reads long-exposure RAW images and converts the data to an RGB image in one step using the `raw2rgb` (Image Processing Toolbox) function. Normalize the data to the range [0, 1] by transforming the `imageDatastore` object.
- Combine the `imageDatastore` objects using the `combine` function.
- Apply a simple multiplicative gain to the pairs of images. The gain corrects for the exposure time difference between the shorter exposure time of the dark inputs and the longer exposure time of the output images. This gain is defined by taking the ratio of the long and short exposure times provided in the image file names.
- Associate the images with metadata such as exposure time, ISO, and aperture.

```
dsTrainFull = createCombinedDatastoreForLowLightRecovery(dataDir,trainInfo);
dsValFull = createCombinedDatastoreForLowLightRecovery(dataDir,valInfo);
dsTestFull = createCombinedDatastoreForLowLightRecovery(dataDir,testInfo);
```

Use a subset of the validation images to make computation of validation metrics quicker. Do not apply additional augmentation.

```
numVal = 30;
dsValFull = shuffle(dsValFull);
dsVal = subset(dsValFull,1:numVal);
```

Preprocess Training and Validation Data

Preprocess the training data set using the `transform` function and the `extractRandomPatch` helper function. The helper function is attached to the example as a supporting file. The

`extractRandomPatch` helper function crops multiple random patches of size 512-by-512-by-4 pixels from a planar RAW image and corresponding patches of size 1024-by-1024-by-3 pixels from an RGB image. The scene content in the patches matches. Extract 12 patches per training image.

```
inputSize = [512,512,4];
patchesPerImage = 12;
dsTrain = transform(dsTrainFull,@(data) extractRandomPatch(data,inputSize,patchesPerImage));
```

Preview an original full-sized image and a random training patch.

```
previewFull = preview(dsTrainFull);
previewPatch = preview(dsTrain);
montage({previewFull{1,2},previewPatch{1,2}},BackgroundColor="w");
```

Preprocess the validation data set using the `transform` function and the `extractCenterPatch` helper function. The helper function is attached to the example as a supporting file. The `extractCenterPatch` helper function crops a single patch of size 512-by-512-by-4 pixels from the center of a planar RAW image and corresponding patches of size 1024-by-1024-by-3 pixels from an RGB image. The scene content in the patches matches.

```
dsVal = transform(dsVal,@(data) extractCenterPatch(data,inputSize));
```

The testing data set does not require preprocessing. Test images are fed at full size into the network.

Augment Training Data

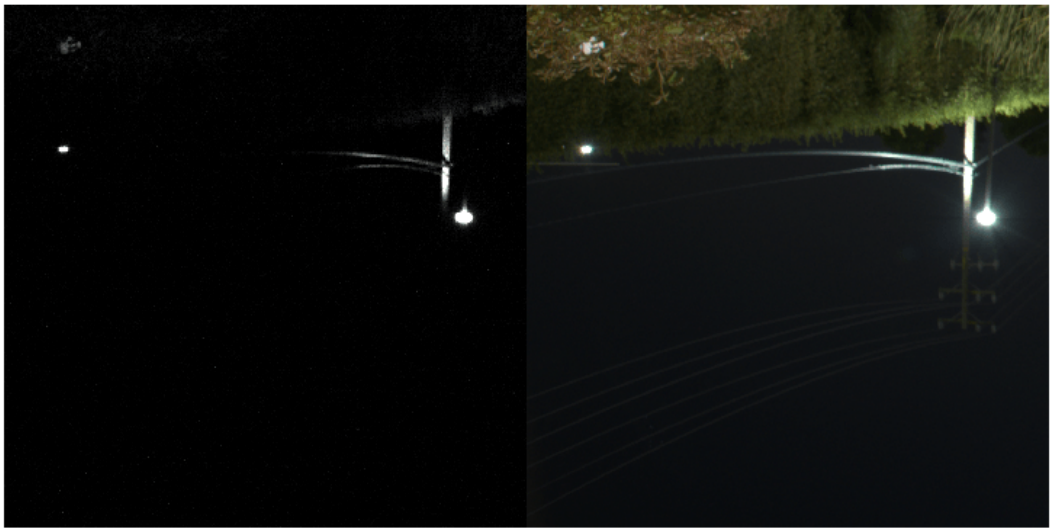
Augment the training data by adding random horizontal and vertical reflection and randomized 90-degree rotations.

```
dsTrain = transform(dsTrain,@(data) augmentPatchesForLowLightRecovery(data));
```

Verify that the preprocessing and augmentation operations work as expected by previewing one channel from the planar RAW image patch and the corresponding RGB decoded patch. The planar RAW data and the target RGB data depict patches of the same scene, randomly extracted from the original source image. Significant noise is visible in the RAW patch because of the short acquisition time of the RAW data, causing a low signal-to-noise ratio.

```
imagePairs = read(dsTrain);
rawImage = imagePairs{1,1};
```

```
rgbPatch = imagePairs{1,2};
montage({rawImage(:,:,1),rgbPatch});
```



Define Network

Use a network architecture similar to U-Net. The example creates the encoder and decoder subnetworks using the `blockedNetwork` (Image Processing Toolbox) function. This function creates the encoder and decoder subnetworks programmatically using the `buildEncoderBlock` and `buildDecoderBlock` helper functions, respectively. The helper functions are defined at the end of this example. The example uses instance normalization between convolution and activation layers in all network blocks except the first and last, and uses a leaky ReLU layer as the activation layer.

Create an encoder subnetwork that consists of four encoder modules. The first encoder module has 32 channels, or feature maps. Each subsequent module doubles the number of feature maps from the previous encoder module.

```
numModules = 4;
numChannelsEncoder = 2.^(5:8);
encoder = blockedNetwork(@(block) buildEncoderBlock(block,numChannelsEncoder), ...
    numModules,NamePrefix="encoder");
```

Create a decoder subnetwork that consists of four decoder modules. The first decoder module has 256 channels, or feature maps. Each subsequent decoder module halves the number of feature maps from the previous decoder module.

```
numChannelsDecoder = fliplr(numChannelsEncoder);
decoder = blockedNetwork(@(block) buildDecoderBlock(block,numChannelsDecoder), ...
    numModules,NamePrefix="decoder");
```

Specify the bridge layers that connect the encoder and decoder subnetworks.

```
bridgeLayers = [
    convolution2dLayer(3,512,Padding="same",PaddingValue="replicate")
    groupNormalizationLayer("channel-wise")
    leakyReluLayer(0.2)
    convolution2dLayer(3,512,Padding="same",PaddingValue="replicate")
    groupNormalizationLayer("channel-wise")
    leakyReluLayer(0.2)];
```

Specify the final layers of the network.

```
finalLayers = [
    convolution2dLayer(1,12)
    depthToSpace2dLayer(2)];
```

Combine the encoder subnetwork, bridge layers, decoder subnetwork, and final layers using the `encoderDecoderNetwork` (Image Processing Toolbox) function.

```
net = encoderDecoderNetwork(inputSize,encoder,decoder, ...
    LatentNetwork=bridgeLayers, ...
    SkipConnections="concatenate", ...
    FinalNetwork=finalLayers);
net = layerGraph(net);
```

Use mean centering normalization on the input as part of training.

```
net = replaceLayer(net,"encoderImageInputLayer",imageInputLayer(inputSize,Normalization="zerocent
```

Define the overall loss using the custom layer `ssimLossLayerGray`. This layer definition is attached to this example as a supporting file. The `ssimLossLayerGray` layer uses a loss of the form

$$lossOverall = \alpha \times lossSSIM + (1 - \alpha) \times lossL_1$$

The layer calculates a multiscale structural similarity (SSIM) loss for the grayscale representations of the predicted and target RGB images using the `multissim` (Image Processing Toolbox) function. The layer specifies the weighting factor α as 7/8 and uses five scales.

```
finalLayerName = net.Layers(end).Name;
lossLayer = ssimLossLayerGray;
net = addLayers(net,lossLayer);
net = connectLayers(net,finalLayerName,lossLayer.Name);
```

Specify Training Options

For training, use the Adam solver with an initial learning rate of 1e-3. Train for 30 epochs.

```
miniBatchSize = 12;
maxEpochs = 30;
options = trainingOptions("adam", ...
    Plots="training-progress", ...
    MiniBatchSize=miniBatchSize, ...
    InitialLearnRate=1e-3, ...
    MaxEpochs=maxEpochs, ...
    ValidationFrequency=400);
```

Train Network or Download Pretrained Network

By default, the example loads a pretrained version of the low-light recovery network. The pretrained network enables you to run the entire example without waiting for training to complete.

To train the network, set the `doTraining` variable in the following code to `true`. Train the model using the `trainNetwork` function.

Train on a GPU if one is available. Using a GPU requires Parallel Computing Toolbox™ and a CUDA® enabled NVIDIA® GPU. For more information, see “GPU Support by Release” (Parallel Computing Toolbox).

```
doTraining = false;

if doTraining
    checkpointsDir = fullfile(dataDir,"checkpoints");
    if ~exist(checkpointsDir,"dir")
        mkdir(checkpointsDir);
    end
    options.CheckpointPath=checkpointsDir;

    netTrained = trainNetwork(dsTrain,net,options);
    modelDateTime = string(datetime("now",Format="yyyy-MM-dd-HH-mm-ss"));
    save(dataDir+"trainedLowLightCameraPipelineNet-"+modelDateTime+".mat",'netTrained');

else
    trainedNet_url = "https://ssd.mathworks.com/supportfiles/vision/data/trainedLowLightCameraPi
    trainedNet_filename = "trainedLowLightCameraPipelineNet.mat";
    downloadTrainedLowLightRecoveryNet(trainedNet_url,dataDir);
    load(fullfile(dataDir,trainedNet_filename));
end
```

Examine Results from Trained Network

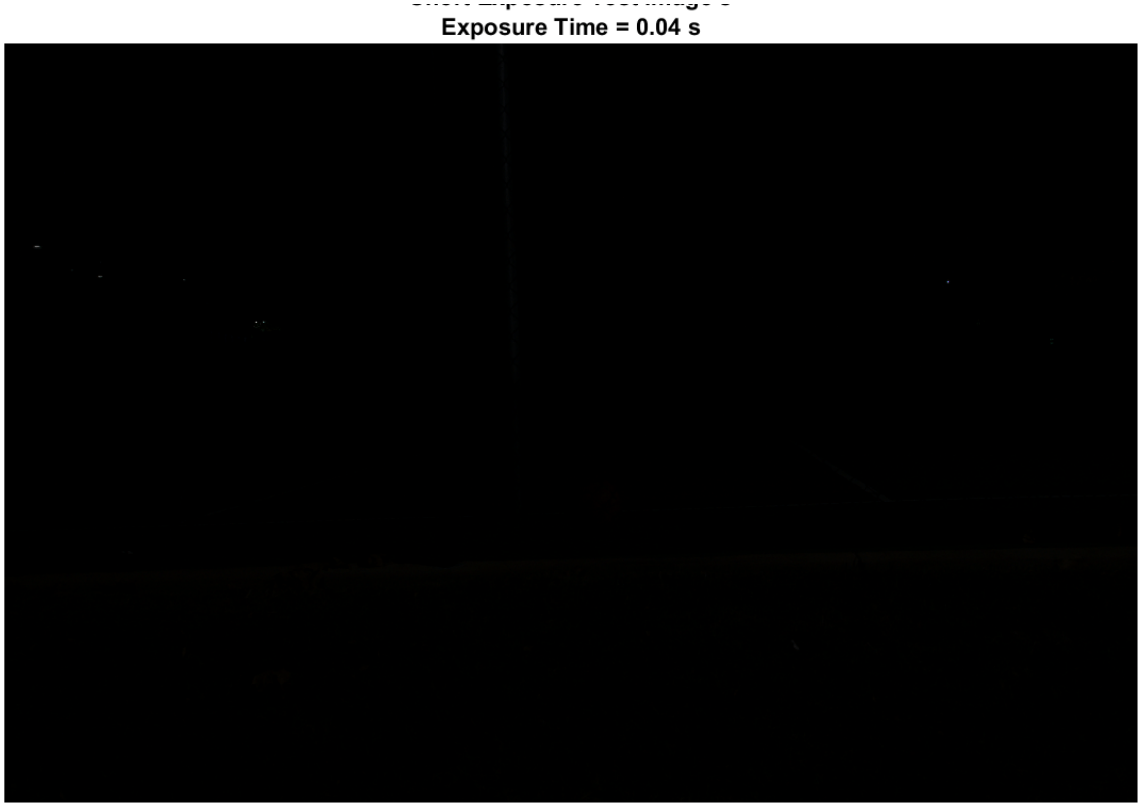
Visually examine the results of the trained low-light camera pipeline network.

Read a pair of images and accompanying metadata from the test set. Get the file names of the short and long exposure images from the metadata.

```
[testPair,info] = read(dsTestFull);
testShortFilename = info.ShortExposureFilename;
testLongFilename = info.LongExposureFilename;
```

Convert the original underexposed RAW image to an RGB image in one step using the `raw2rgb` (Image Processing Toolbox) function. Display the result, scaling the display range to the range of pixel values. The image looks almost completely black, with only a few bright pixels.

```
testShortImage = raw2rgb(testShortFilename);
testShortTime = info.ShortExposureTime;
imshow(testShortImage,[])
title(["Short Exposure Test Image";"Exposure Time = "+num2str(testShortTime)]+" s")
```



Convert the original well exposed RAW image to an RGB image in one step using the `raw2rgb` (Image Processing Toolbox) function. Display the result.

```
testLongImage = raw2rgb(testLongFilename);
testLongTime = info.LongExposureTime;
imshow(testLongImage)
title(["Long Exposure Target Image";"Exposure Time = "+num2str(testLongTime)]+" s")
```

Display the network prediction. The trained network recovers an impressive image under challenging acquisition conditions with very little noise or other visual artifacts. The colors of the network prediction are less saturated and vibrant than in the ground truth long-exposure image of the scene.

```
outputFromNetwork = im2uint8(activations(netTrained,testPair{1},'FinalNetworkLayer2'));
imshow(outputFromNetwork)
title("Low-Light Recovery Network Prediction")
```

Supporting Functions

The `extractRandomPatch` helper function crops multiple random patches from a planar RAW image and corresponding patches from an RGB image. The RAW data patch has size *m*-by-*n*-by-4 and the RGB image patch has size 2*m*-by-2*n*-by-3, where [*m n*] is the value of the `targetRAWSize` input argument. Both patches have the same scene content.

```
function dataOut = extractRandomPatch(data,targetRAWSize,patchesPerImage)
    dataOut = cell(patchesPerImage,2);
    raw = data{1};
    rgb = data{2};
    for idx = 1:patchesPerImage
        windowRAW = randomCropWindow3d(size(raw),targetRAWSize);
        windowRGB = images.spatialref.Rectangle(2*windowRAW.XLimits+[-1,0],2*windowRAW.YLimits+[
        dataOut(idx,:) = {imcrop3(raw,windowRAW),imcrop(rgb,windowRGB)};
    end
end
```

The `extractCenterPatch` helper function crops a single patch from the center of a planar RAW image and the corresponding patch from an RGB image. The RAW data patch has size *m*-by-*n*-by-4 and the RGB image patch has size 2*m*-by-2*n*-by-3, where [*m n*] is the value of the `targetRAWSize` input argument. Both patches have the same scene content.

```
function dataOut = extractCenterPatch(data,targetRAWSize)
    raw = data{1};
```

```
    rgb = data{2};
    windowRAW = centerCropWindow3d(size(raw),targetRAWSize);
    windowRGB = images.spatialref.Rectangle(2*windowRAW.XLimits+[-1,0],2*windowRAW.YLimits+[-1,0
    dataOut = {imcrop3(raw,windowRAW),imcrop(rgb,windowRGB)};
end
```

The `buildEncoderBlock` helper function defines the layers of a single encoder module within the encoder subnetwork.

```
function block = buildEncoderBlock(blockIdx,numChannelsEncoder)

    if blockIdx < 2
        instanceNorm = [];
    else
        instanceNorm = instanceNormalizationLayer;
    end

    filterSize = 3;
    numFilters = numChannelsEncoder(blockIdx);
    block = [
        convolution2dLayer(filterSize,numFilters,Padding="same",PaddingValue="replicate",Weights
        instanceNorm
        leakyReluLayer(0.2)
        convolution2dLayer(filterSize,numFilters,Padding="same",PaddingValue="replicate",Weights
        instanceNorm
        leakyReluLayer(0.2)
        maxPooling2dLayer(2,Stride=2,Padding="same")];
end
```

The `buildDecoderBlock` helper function defines the layers of a single encoder module within the decoder subnetwork.

```
function block = buildDecoderBlock(blockIdx,numChannelsDecoder)

    if blockIdx < 4
        instanceNorm = instanceNormalizationLayer;
    else
        instanceNorm = [];
    end

    filterSize = 3;
    numFilters = numChannelsDecoder(blockIdx);
    block = [
        transposedConv2dLayer(filterSize,numFilters,Stride=2,WeightsInitializer="he",Cropping="sa
        convolution2dLayer(filterSize,numFilters,Padding="same",PaddingValue="replicate",Weights
        instanceNorm
        leakyReluLayer(0.2)
        convolution2dLayer(filterSize,numFilters,Padding="same",PaddingValue="replicate",Weights
        instanceNorm
        leakyReluLayer(0.2)];
end
```

Classify Tumors in Multiresolution Blocked Images

This example shows how to classify multiresolution whole slide images (WSIs) that might not fit in memory using an Inception-v3 deep neural network.

Deep learning methods for tumor classification rely on digital pathology, in which whole tissue slides are imaged and digitized. The resulting WSIs have high resolution, on the order of 200,000-by-100,000 pixels. WSIs are frequently stored in a multiresolution format to facilitate efficient display, navigation, and processing of images.

The example outlines an architecture to use block based processing to train large WSIs. The example trains an Inception-v3 based network using transfer learning techniques to classify individual blocks as `normal` or `tumor`.

If you do not want to download the training data and train the network, then continue to the Train or Download Network on page 9-0 section of this example.

Prepare Training Data

Prepare the training and validation data by following the instructions in “Preprocess Multiresolution Images for Training Classification Network” (Image Processing Toolbox). The preprocessing example saves the preprocessed training and validation datastores in the a file called `trainingAndValidationDatastores.mat`.

Set the value of the `dataDir` variable as the location where the `trainingAndValidationDatastores.mat` file is located. Load the training and validation datastores into variables called `dsTrainLabeled` and `dsValLabeled`.

```
dataDir = fullfile(tempdir,"Camelyon16");
load(fullfile(dataDir,"trainingAndValidationDatastores.mat"))
```

Set Up Inception-v3 Network Layers For Transfer Learning

This example uses an Inception-v3 network [2], a convolutional neural network that is trained on more than a million images from the ImageNet database [3]. The network is 48 layers deep and can classify images into 1,000 object categories, such as keyboard, mouse, pencil, and many animals.

The `inceptionv3` function returns a pretrained Inception-v3 network. Inception-v3 requires the Deep Learning Toolbox™ Model for Inception-v3 Network support package. If this support package is not installed, then the function provides a download link.

```
net = inceptionv3;
lgraph = layerGraph(net);
```

The convolutional layers of the network extract image features. The last learnable layer and the final classification layer classify an input image using the image features. These two layers contain information on how to combine the features into class probabilities, a loss value, and predicted labels. To retrain a pretrained network to classify new images, replace these two layers with new layers adapted to the new data set. For more information, see “Train Deep Learning Network to Classify New Images” on page 3-6.

Find the names of the two layers to replace using the helper function `findLayersToReplace`. This function is attached to the example as a supporting file. In Inception-v3, these two layers are named `'predictions'` and `'ClassificationLayer_predictions'`.

```
[learnableLayer,classLayer] = findLayersToReplace(lgraph);
```

The goal of this example is to perform binary segmentation between two classes, `tumor` and `normal`. Create a new fully connected layer for two classes. Replace the final fully connected layer with the new layer.

```
numClasses = 2;
newLearnableLayer = fullyConnectedLayer(numClasses,Name="predictions");
lgraph = replaceLayer(lgraph,learnableLayer.Name,newLearnableLayer);
```

Create a new classification layer for two classes. Replace the final classification layer with the new layer.

```
newClassLayer = classificationLayer(Name="ClassificationLayer_predictions");
lgraph = replaceLayer(lgraph,classLayer.Name,newClassLayer);
```

Specify Training Options

Train the network using root mean squared propagation (RMSProp) optimization. Specify the hyperparameter settings for RMSProp by using the `trainingOptions` function.

Reduce `MaxEpochs` to a small number because the large amount of training data enables the network to reach convergence sooner. Specify a `MiniBatchSize` according to your available GPU memory. While larger mini-batch sizes can make the training faster, larger sizes can reduce the ability of the network to generalize. Set `ResetInputNormalization` to `false` to prevent a full read of the training data to compute normalization stats.

```
checkpointsDir = fullfile(dataDir,'checkpoints');
if ~exist(checkpointsDir,'dir')
    mkdir(checkpointsDir);
end

options = trainingOptions("rmsprop", ...
    MaxEpochs=1, ...
    MiniBatchSize=256, ...
    Shuffle="every-epoch", ...
    ValidationFrequency=250, ...
    InitialLearnRate=1e-4, ...
    SquaredGradientDecayFactor=0.99, ...
    ResetInputNormalization=false, ...
    ExecutionEnvironment="auto", ...
    Plots="training-progress", ...
    CheckpointPath=checkpointsDir);
```

Train Network or Download Pretrained Network

By default, this example downloads a pretrained version of the trained classification network using the helper function `downloadTrainedCamelyonNet`. The pretrained network can be used to run the entire example without waiting for training to complete.

To train the network, set the `doTraining` variable in the following code to `true`. Train the network using the `trainNetwork` function.

Train on one or more GPUs, if available. Using a GPU requires Parallel Computing Toolbox™ and a CUDA® enabled NVIDIA® GPU. For more information, see “GPU Support by Release” (Parallel Computing Toolbox).

```
doTraining = false;
if doTraining
    options.ValidationData=dsValLabeled;
    trainedNet = trainNetwork(dsTrainLabeled,lgraph,options);
    modelDateTime = string(datetime("now",Format="yyyy-MM-dd-HH-mm-ss"));
    save(dataDir+"trainedCamelyonNet-"+modelDateTime+".mat","trainedNet");

else
    trainedCamelyonNet_url = "https://www.mathworks.com/supportfiles/vision/data/trainedCamelyonN
    dataDir = fullfile(tempdir,"Camelyon16");
    downloadTrainedCamelyonNet(trainedCamelyonNet_url,dataDir);
    load(fullfile(dataDir,"trainedCamelyonNet.mat"));
end
```

Download Test Data

The Camelyon16 test data set consists of 130 WSIs. These images have both normal and tumor tissue. The size of each file is approximately 2 GB.

To download the test data, go to the Camelyon17 website and click the first "CAMELYON16 data set" link. Open the "testing" directory, then follow these steps.

- Download the "lesion_annotations.zip" file. Extract all files to the directory specified by the `testAnnotationDir` variable.
- Open the "images" directory. Download the files to the directory specified by the `testImageDir` variable.

```
testDir = fullfile(dataDir,"testing");
testImageDir = fullfile(testDir,"images");
testAnnotationDir = fullfile(testDir,"lesion_annotations");
if ~exist(testDir,"dir")
    mkdir(testDir);
    mkdir(fullfile(testDir,"images"));
    mkdir(fullfile(testDir,"lesion_annotations"));
end
```

Preprocess Test Data

Create `blockedImage` Objects to Manage Test Images

Get the file names of the test images. Then, create an array of `blockedImage` (Image Processing Toolbox) objects that manage the test images. Each `blockedImage` object points to the corresponding image file on disk.

```
testFileSet = matlab.io.datastore.FileSet(testImageDir+filesep+"test*");
testImages = blockedImage(testFileSet);
```

Set the spatial referencing for all training data by using the `setSpatialReferencingForCamelyon16` helper function. This function is attached to the example as a supporting file. The `setSpatialReferencingForCamelyon16` function sets the `WorldStart` and `WorldEnd` properties of each `blockedImage` object using the spatial referencing information from the TIF file metadata.

```
testImages = setSpatialReferencingForCamelyon16(testImages);
```

Create Tissue Masks

To process the WSI data efficiently, create a tissue mask for each test image. This process is the same as the one used for the preprocessing the normal training images. For more information, see "Preprocess Multiresolution Images for Training Classification Network" (Image Processing Toolbox).

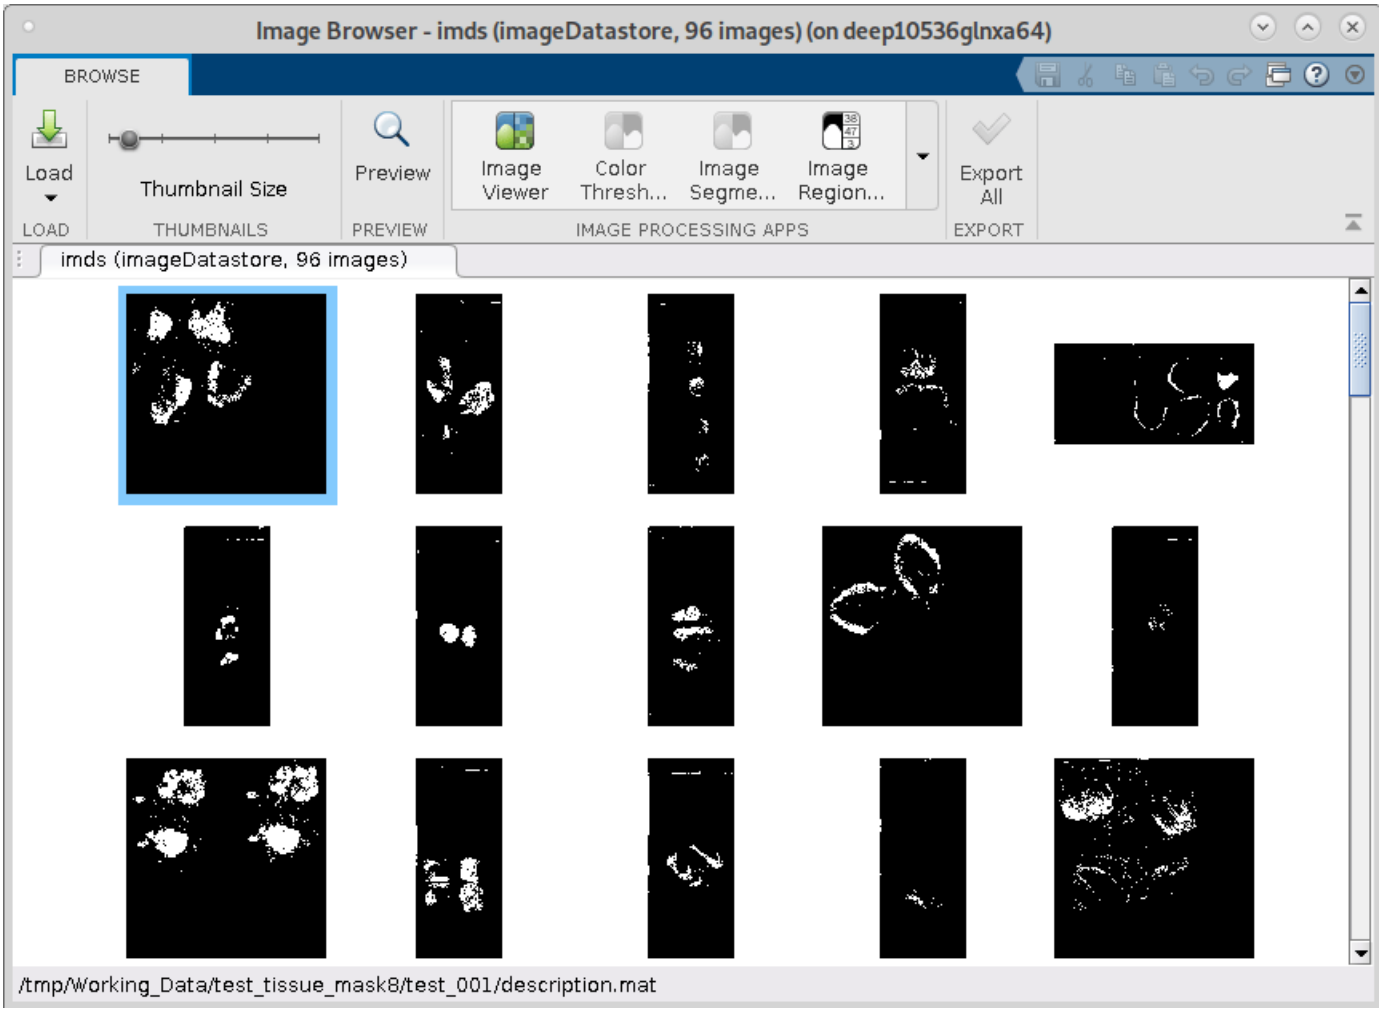
```
normalMaskLevel = 8;

testTissueMaskDir = fullfile(testDir,"test_tissue_mask_level"+num2str(normalMaskLevel));

if ~isfolder(testTissueMaskDir)
    testTissueMasks = apply(testImages, @(bs)im2gray(bs.Data)<150, ...
        BlockSize=[512 512], ...
        Level=normalMaskLevel, ...
        UseParallel=canUseGPU, ...
        DisplayWaitbar=false, ...
        OutputLocation=testTissueMaskDir);
    save(fullfile(testTissueMaskDir,"testTissueMasks.mat"),"testTissueMasks")
else
    % Load previously saved data
    load(fullfile(testTissueMaskDir,"testTissueMasks.mat"),"testTissueMasks");
end
```

The tissue masks have only one level and are small enough to fit in memory. Display the tissue masks in the **Image Browser** app using the `browseBlockedImages` helper function. This helper function is attached to the example as a supporting file.

```
browseBlockedImages(testTissueMasks,1);
```



Preprocess Tumor Ground Truth Images

Specify the resolution level of the tumor masks.

```
tumorMaskLevel = 8;
```

Create a tumor mask for each ground truth tumor image using the `createMaskForCamelyon16TumorTissue` helper function. This helper function is attached to the example as a supporting file. The function performs these operations for each image:

- Read the (*x*, *y*) boundary coordinates for all ROIs in the annotated XML file.
- Separate the boundary coordinates for tumor and normal tissue ROIs into separate cell arrays.
- Convert the cell arrays of boundary coordinates to a binary blocked image using the `polyToBlockedImage` (Image Processing Toolbox) function. In the binary image, the ROI indicates tumor pixels and the background indicates normal tissue pixels. Pixels that are within both tumor and normal tissue ROIs are classified as background.

```
testTumorMaskDir = fullfile(testDir,['test_tumor_mask_level' num2str(tumorMaskLevel)]);
if ~isfolder(testTumorMaskDir)
    testTumorMasks = createMaskForCamelyon16TumorTissue(testImages,testAnnotationDir,testTumorMas
    save(fullfile(testTumorMaskDir,"testTumorMasks.mat"),"testTumorMasks")
```

```
else
    load(fullfile(testTumorMaskDir,"testTumorMasks.mat"),"testTumorMasks");
end
```

Predict Heatmaps of Tumor Probability

Use the trained classification network to predict a heatmap for each test image. The heatmap gives a probability score that each block is of the `tumor` class. The example performs these operations for each test image to create a heatmap:

- Select blocks using the `selectBlockLocations` (Image Processing Toolbox) function. Include all blocks that have at least one tissue pixel by specifying the `InclusionThreshold` name-value argument as `0`.
- Process batches of blocks using the `apply` (Image Processing Toolbox) function with the processing operations defined by the `predictBlock` helper function. The helper function is attached to the example as a supporting file. The `predictBlock` helper function calls the `predict` function on a block of data and returns the probability score that the block is `tumor`.
- Write the heatmap data to a TIF file using the `write` (Image Processing Toolbox) function. The final output after processing all blocks is a heatmap showing the probability of finding tumors over the entire WSI.

```
numTest = numel(testImages);
outputHeatmapsDir = fullfile(testDir,"heatmaps");
networkBlockSize = [299,299,3];
tic
for ind = 1:numTest
    % Check if TIF file already exists
    [~,id] = fileparts(testImages(ind).Source);
    outFile = fullfile(outputHeatmapsDir,id+".tif");
    if ~exist(outFile,"file")
        bls = selectBlockLocations(testImages(ind),Levels=1, ...
            BlockSize=networkBlockSize, ...
            Mask=testTissueMasks(ind),InclusionThreshold=0);

        % Resulting heat maps are in-memory blockedImage objects
        bhm = apply(testImages(ind),@(x)predictBlockForCamelyon16(x,trainedNet), ...
            Level=1,BlockLocationSet=bls,BatchSize=128, ...
            PadPartialBlocks=true,DisplayWaitBar=false);

        % Write results to a TIF file
        write(bhm,outFile,BlockSize=[512 512]);
    end
end
toc
```

Collect all of the written heatmaps as an array of `blockedImage` objects.

```
heatMapFileSet = matlab.io.datastore.FileSet(outputHeatmapsDir,FileExtensions=".tif");
bheatMapImages = blockedImage(heatMapFileSet);
```

Visualize Heatmap

Select a test image to display. On the left side of a figure, display the ground truth boundary coordinates as freehand ROIs using the `showCamelyon16TumorAnnotations` helper function. This helper function is attached to the example as a supporting file. Normal regions (shown with a green boundary) can occur inside tumor regions (shown with a red boundary).

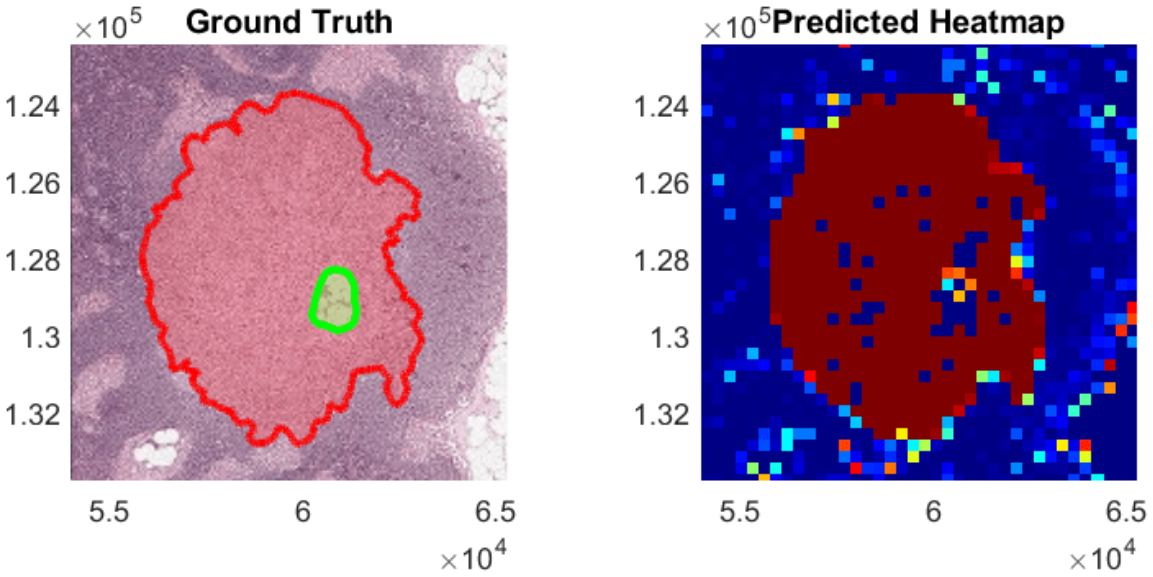
```
idx = 27;
figure
tiledlayout(1,2)
nexttile
hBim1 = showCamelyon16TumorAnnotations(testImages(idx),testAnnotationDir);
title("Ground Truth")
```

On the right side of the figure, display the heatmap for the test image.

```
nexttile
hBim2 = bigimageshow(bheatMapImages(idx),Interpolation="nearest");
colormap(jet)
```

Link the axes and zoom in to an area of interest.

```
linkaxes([hBim1.Parent,hBim2.Parent])
xlim([53982, 65269])
ylim([122475, 133762])
title("Predicted Heatmap")
```



Classify Test Images at Specific Threshold

To classify blocks as `tumor` or `normal`, apply a threshold to the heatmap probability values.

Pick a threshold probability above which blocks are classified as `tumor`. Ideally, you would calculate this threshold value using receiver operating characteristic (ROC) or precision-recall curves on the validation data set.

```
thresh = 0.8;
```

Classify the blocks in each test image and calculate the confusion matrix using the `apply` (Image Processing Toolbox) function with the processing operations defined by the `computeBlockConfusionMatrixForCamelyon16` helper function. The helper function is attached to the example as a supporting file.

The `computeBlockConfusionMatrixForCamelyon16` helper function performs these operations on each heatmap:

- Resize and refine the ground truth mask to match the size of the heatmap.
- Apply the threshold on the heatmap.
- Calculate a confusion matrix for all of the blocks at the finest resolution level. The confusion matrix gives the number of true positive (TP), false positive (FP), true negative (TN), and false negative (FN) classification predictions.
- Save the total counts of TP, FP, TN, and FN blocks as a structure in a blocked image. The blocked image is returned as an element in the array of blocked images, `bcmatrix`.
- Save a numeric labeled image of the classification predictions in a blocked image. The values 0, 1, 2, and 3 correspond to TN, FP, FN, and TP results, respectively. The blocked image is returned as an element in the array of blocked images, `bcmatrixImage`.

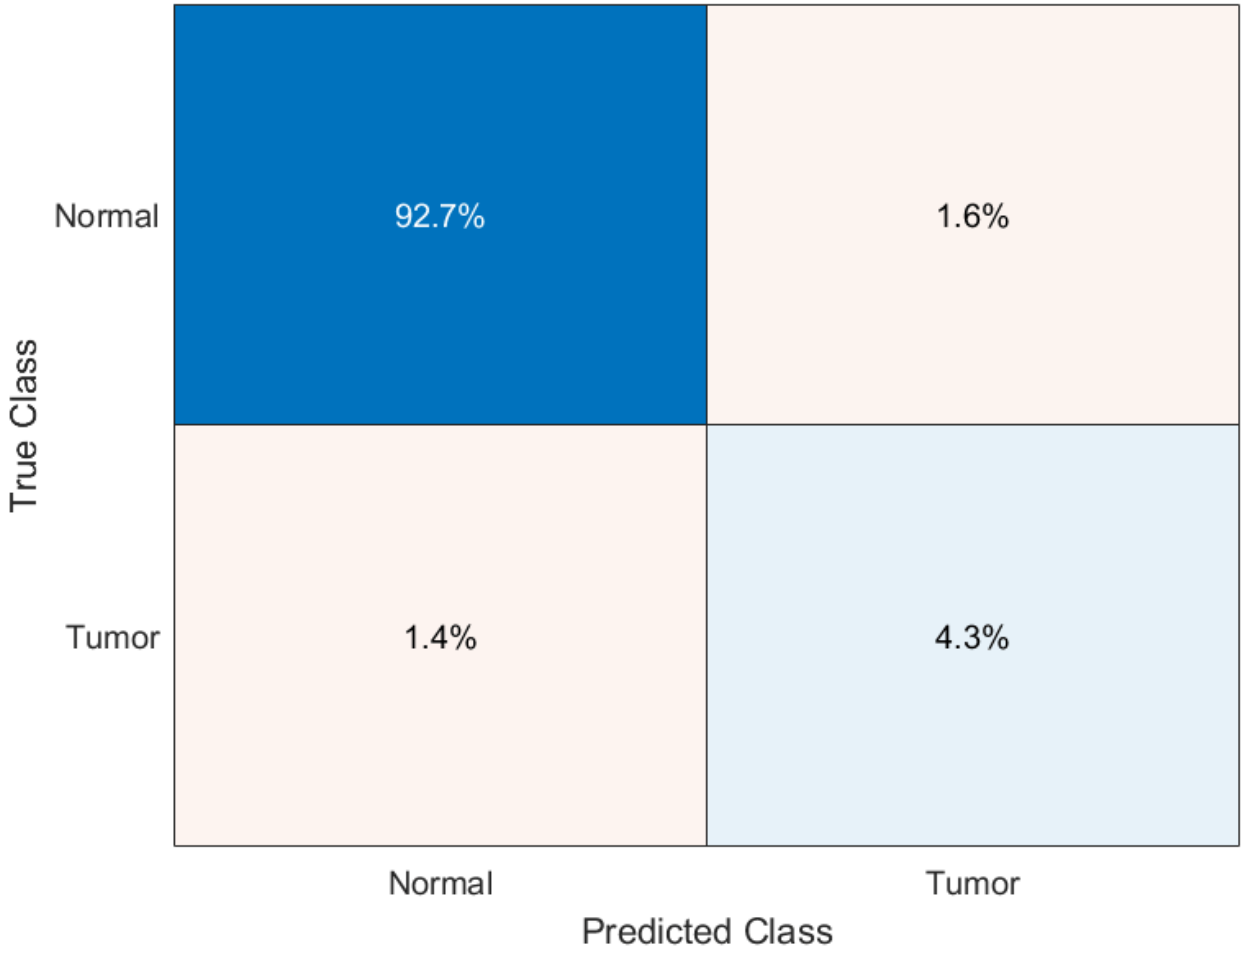
```
for ind = 1:numTest
    [bcmatrix(ind),bcmatrixImage{ind}] = apply(bheatMapImages(ind), ...
        @(bs,tumorMask,tissueMask)computeBlockConfusionMatrixForCamelyon16(bs,tumorMask,tissueMas
        ExtraImages=[testTumorMasks(ind),testTissueMasks(ind)]);
end
```

Calculate the global confusion matrix over all test images.

```
cmArray = arrayfun(@(c)gather(c),bcmatrix);
cm = [sum([cmArray.tp]),sum([cmArray.fp]);
    sum([cmArray.fn]),sum([cmArray.tn])];
```

Display the confusion chart of the normalized global confusion matrix. The majority of blocks in the WSI images are of normal tissue, resulting in a high percentage of true negative predictions.

```
figure
confusionchart(cm,["Tumor","Normal"],Normalization="total-normalized")
```



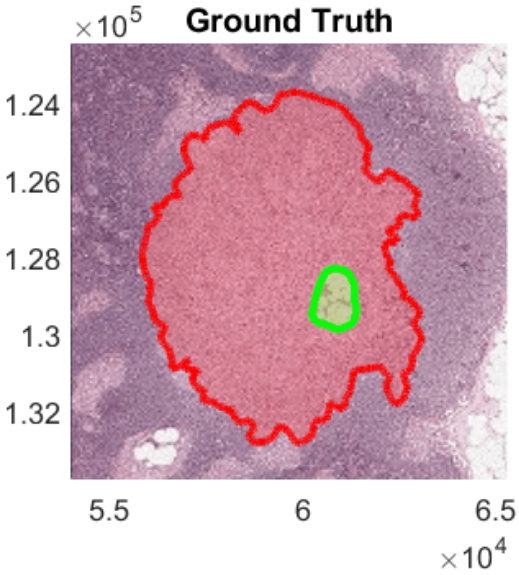
Visualize Classification Results

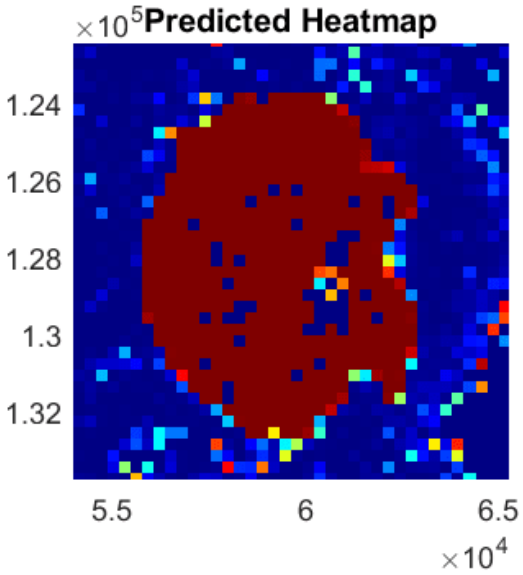
Compare the ground truth ROI boundary coordinates with the classification results. On the left side of a figure, display the ground truth boundary coordinates as freehand ROIs. On the right side of the figure, display the test image and overlay a color on each block based on the confusion matrix. Display true positives as red, false positives as cyan, false negatives as yellow, and true negatives with no color.

False negatives and false positives appear around the edges of the tumor region, which indicates that the network has difficulty classifying blocks with partial classes.

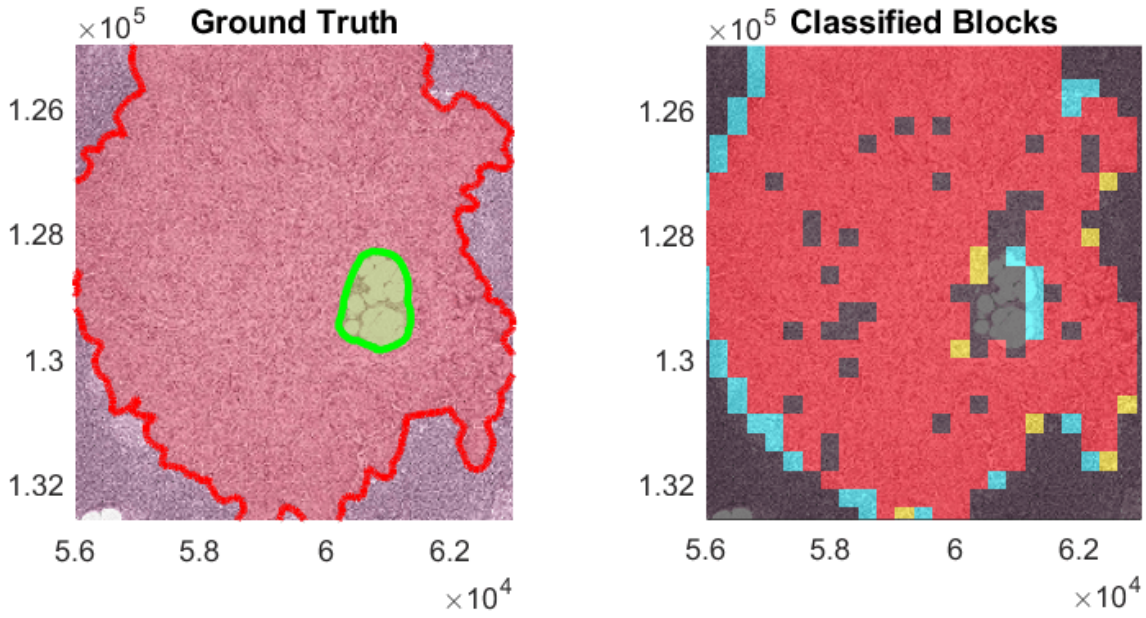
```
idx = 27;
figure
tiledlayout(1,2)
nexttile
hBim1 = showCamelyon16TumorAnnotations(testImages(idx),testAnnotationDir);
title("Ground Truth")
nexttile
hBim2 = bigimageshow(testImages(idx));
cmColormap = [0 0 0; 0 1 1; 1 1 0; 1 0 0];
```

```
showlabels(hBim2,bcmatrixImage{idx}, ...
    Colormap=cmColormap,AlphaData=bcmatrixImage{idx})
```





```
title("Classified Blocks")
linkaxes([hBim1.Parent,hBim2.Parent])
xlim([56000 63000])
ylim([125000 132600])
```



Note: To reduce the classification error around the perimeter of the tumor, you can retrain the network with less homogenous blocks. When preprocessing the `Tumor` blocks of the training data set, reduce the value of the `InclusionThreshold` name-value argument.

Quantify Network Prediction with AUC-ROC Curve

Calculate the ROC curve values at different thresholds by using the `computeROCCurvesForCamelyon16` helper function. This helper function is attached to the example as a supporting file.

```
threshs = [1 0.99 0.9:-.1:.1 0.05 0];
[tpr,fpr,ppv] = computeROCCurvesForCamelyon16(bheatMapImages,testTumorMasks,testTissueMasks,thres
```

Calculate the area under the curve (AUC) metric using the `trapz` function. The metric returns a value in the range [0, 1], where 1 indicates perfect model performance. The AUC for this data set is close to 1. You can use the AUC to fine-tune the training process.

```
figure
stairs(fpr,tpr,"-");
ROCAUC = trapz(fpr,tpr);
```

```
title(["Area Under Curve: " num2str(ROCAUC)]);
xlabel("False Positive Rate")
ylabel("True Positive Rate")
```

Unsupervised Day-to-Dusk Image Translation Using UNIT

This example shows how to translate images between daytime and dusk lighting conditions using an unsupervised image-to-image translation network (UNIT).

Domain translation is the task of transferring styles and characteristics from one image domain to another. This technique can be extended to other image-to-image learning operations, such as image enhancement, image colorization, defect generation, and medical image analysis.

UNIT [1] on page 9-0 is a type of generative adversarial network (GAN) that consists of one generator network and two discriminator networks that you train simultaneously to maximize the overall performance. For more information about UNIT, see “Get Started with GANs for Image-to-Image Translation” (Image Processing Toolbox).

Download Data Set

This example uses the CamVid data set [2] on page 9-0 from the University of Cambridge for training. This data set is a collection of 701 images containing street-level views obtained while driving.

Download the CamVid data set. The download time depends on your internet connection.

```
imageURL = 'http://web4.cs.ucl.ac.uk/staff/g.brostow/MotionSegRecData/files/701_StillsRaw_full.z

dataDir = fullfile(tempdir,'CamVid');
downloadCamVidImageData(dataDir,imageURL);
imgDir = fullfile(dataDir,"images","701_StillsRaw_full");
```

Load Day and Dusk Data

The CamVid image data set includes 497 images acquired in daytime and 124 images acquired at dusk. The performance of the trained UNIT network is limited because the number of CamVid training images is relatively small, which limits the performance of the trained network. Further, some images belong to an image sequence and therefore are correlated with other images in the data set. To minimize the impact of these limitations, this example manually partitions the data into training and test data sets in a way that maximizes the variability of the training data.

Get the file names of the day and dusk images for training and testing by loading the file `camvidDayDuskDatasetFileNames.mat`. The training data sets consist of 263 day images and 107 dusk images. The test data sets consist of 234 day images and 17 dusk images.

```
load('camvidDayDuskDatasetFileNames.mat');
```

Create `imageDatastore` objects that manage the day and dusk images for training and testing.

```
imdsDayTrain = imageDatastore(fullfile(imgDir,trainDayNames));
imdsDuskTrain = imageDatastore(fullfile(imgDir,trainDuskNames));
imdsDayTest = imageDatastore(fullfile(imgDir,testDayNames));
imdsDuskTest = imageDatastore(fullfile(imgDir,testDuskNames));
```

Preview a training image from the day and dusk training data sets.

```
day = preview(imdsDayTrain);
dusk = preview(imdsDuskTrain);
montage({day,dusk})
```

Preprocess and Augment Training Data

Specify the image input size for the source and target images.

```
inputSize = [256,256,3];
```

Augment and preprocess the training data by using the `transform` function with custom preprocessing operations specified by the helper function `augmentDataForDayToDusk`. This function is attached to the example as a supporting file.

The `augmentDataForDayToDusk` function performs these operations:

1. Resize the image to the specified input size using bicubic interpolation.
2. Randomly flip the image in the horizontal direction.
3. Scale the image to the range [-1, 1]. This range matches the range of the final `tanhLayer` used in the generator.

```
imdsDayTrain = transform(imdsDayTrain, @(x)augmentDataForDayToDusk(x,inputSize));
imdsDuskTrain = transform(imdsDuskTrain, @(x)augmentDataForDayToDusk(x,inputSize));
```

Create Generator Network

Create a UNIT generator network using the `unitGenerator` (Image Processing Toolbox) function. The source and target encoder sections of the generator each consist of two downsampling blocks and five residual blocks. The encoder sections share two of the five residual blocks. Similarly, the source and target decoder sections of the generator each consist of two downsampling blocks and five residual blocks, and the decoder sections share two of the five residual blocks.

```
gen = unitGenerator(inputSize,'NumResidualBlocks',5,'NumSharedBlocks',2);
```

Visualize the generator network.

```
analyzeNetwork(gen)
```

Create Discriminator Networks

Create two discriminator networks, one for each of the source and target domains, using the `patchGANDiscriminator` (Image Processing Toolbox) function. Day is the source domain and dusk is the target domain.

```
discDay = patchGANDiscriminator(inputSize,"NumDownsamplingBlocks",4,"FilterSize",3, ...
    "ConvolutionWeightsInitializer","narrow-normal","NormalizationLayer","none");
discDusk = patchGANDiscriminator(inputSize,"NumDownsamplingBlocks",4,"FilterSize",3, ...
    "ConvolutionWeightsInitializer","narrow-normal","NormalizationLayer","none");
```

Visualize the discriminator networks.

```
analyzeNetwork(discDay);
analyzeNetwork(discDusk);
```

Define Model Gradients and Loss Functions

The `modelGradientsDisc` and `modelGradientGen` helper functions calculate the gradients and losses for the discriminators and generator, respectively. These functions are defined in the Supporting Functions on page 9-0 section of this example.

The objective of each discriminator is to correctly distinguish between real images (1) and translated images (0) for images in its domain. Each discriminator has a single loss function.

The objective of the generator is to generate translated images that the discriminators classify as real. The generator loss is a weighted sum of five types of losses: self-reconstruction loss, cycle consistency loss, hidden KL loss, cycle hidden KL loss, and adversarial loss.

Specify the weight factors for the various losses.

```
lossWeights.selfReconLossWeight = 10;
lossWeights.hiddenKLLossWeight = 0.01;
lossWeights.cycleConsisLossWeight = 10;
lossWeights.cycleHiddenKLLossWeight = 0.01;
lossWeights.advLossWeight = 1;
lossWeights.discLossWeight = 0.5;
```

Specify Training Options

Specify the options for Adam optimization. Train the network for 35 epochs. Specify identical options for the generator and discriminator networks.

- Specify an equal learning rate of 0.0001.
- Initialize the trailing average gradient and trailing average gradient-square decay rates with `[]`.
- Use a gradient decay factor of 0.5 and a squared gradient decay factor of 0.999.
- Use weight decay regularization with a factor of 0.0001.
- Use a mini-batch size of 1 for training.

```
learnRate = 0.0001;
gradDecay = 0.5;
sqGradDecay = 0.999;
weightDecay = 0.0001;

genAvgGradient = [];
genAvgGradientSq = [];
```

```
discDayAvgGradient = [];
discDayAvgGradientSq = [];

discDuskAvgGradient = [];
discDuskAvgGradientSq = [];

miniBatchSize = 1;
numEpochs = 35;
```

Batch Training Data

Create a `minibatchqueue` object that manages the mini-batching of observations in a custom training loop. The `minibatchqueue` object also casts data to a `dlarray` object that enables automatic differentiation in deep learning applications.

Specify the mini-batch data extraction format as `"SSCB"` (spatial, spatial, channel, batch). Set the `"DispatchInBackground"` name-value argument as the boolean returned by `canUseGPU`. If a supported GPU is available for computation, then the `minibatchqueue` object preprocesses mini-batches in the background in a parallel pool during training.

```
mbqDayTrain = minibatchqueue(imdsDayTrain,"MiniBatchSize",miniBatchSize, ...
    "MiniBatchFormat","SSCB","DispatchInBackground",canUseGPU);
mbqDuskTrain = minibatchqueue(imdsDuskTrain,"MiniBatchSize",miniBatchSize, ...
    "MiniBatchFormat","SSCB","DispatchInBackground",canUseGPU);
```

Train Network

By default, the example downloads a pretrained version of the UNIT generator for the CamVid data set by using the helper function `downloadTrainedDayDuskGeneratorNet`. The helper function is attached to the example as a supporting file. The pretrained network enables you to run the entire example without waiting for training to complete.

To train the network, set the `doTraining` variable in the following code to `true`. Train the model in a custom training loop. For each iteration:

- Read the data for the current mini-batch using the `next` function.
- Evaluate the model gradients using the `dlfeval` function and the `modelGradientsDisc` and `modelGradientGen` helper functions.
- Update the network parameters using the `adamupdate` function.
- Display the input and translated images for both the source and target domains after each epoch.

Train on a GPU if one is available. Using a GPU requires Parallel Computing Toolbox™ and a CUDA® enabled NVIDIA® GPU. For more information, see “GPU Support by Release” (Parallel Computing Toolbox). Training takes about 88 hours on an NVIDIA Titan RTX.

```
doTraining = false;
if doTraining
    % Create a figure to show the results
    figure("Units","Normalized");
    for iPlot = 1:4
        ax(iPlot) = subplot(2,2,iPlot);
    end

    iteration = 0;
```

```
% Loop over epochs
for epoch = 1:numEpochs

    % Shuffle data every epoch
    reset(mbqDayTrain);
    shuffle(mbqDayTrain);
    reset(mbqDuskTrain);
    shuffle(mbqDuskTrain);

    % Run the loop until all the images in the mini-batch queue mbqDayTrain are processed
    while hasdata(mbqDayTrain)
        iteration = iteration + 1;

        % Read data from the day domain
        imDay = next(mbqDayTrain);

        % Read data from the dusk domain
        if hasdata(mbqDuskTrain) == 0
            reset(mbqDuskTrain);
            shuffle(mbqDuskTrain);
        end
        imDusk = next(mbqDuskTrain);

        % Calculate discriminator gradients and losses
        [discDayGrads,discDuskGrads,discDayLoss,disDuskLoss] = dlfeval(@modelGradientDisc, .
            gen,discDay,discDusk,imDay,imDusk,lossWeights.discLossWeight);

        % Apply weight decay regularization on day discriminator gradients
        discDayGrads = dlupdate(@(g,w) g+weightDecay*w,discDayGrads,discDay.Learnables);

        % Update parameters of day discriminator
        [discDay,discDayAvgGradient,discDayAvgGradientSq] = adamupdate(discDay,discDayGrads,
            discDayAvgGradient,discDayAvgGradientSq,iteration,learnRate,gradDecay,sqGradDeca

        % Apply weight decay regularization on dusk discriminator gradients
        discDuskGrads = dlupdate(@(g,w) g+weightDecay*w,discDuskGrads,discDusk.Learnables);

        % Update parameters of dusk discriminator
        [discDusk,discDuskAvgGradient,discDuskAvgGradientSq] = adamupdate(discDusk,discDuskG
            discDuskAvgGradient,discDuskAvgGradientSq,iteration,learnRate,gradDecay,sqGradDe

        % Calculate generator gradient and loss
        [genGrad,genLoss,images] = dlfeval(@modelGradientGen,gen,discDay,discDusk,imDay,imDus

        % Apply weight decay regularization on generator gradients
        genGrad = dlupdate(@(g,w) g+weightDecay*w,genGrad,gen.Learnables);

        % Update parameters of generator
        [gen,genAvgGradient,genAvgGradientSq] = adamupdate(gen,genGrad,genAvgGradient, ...
            genAvgGradientSq,iteration,learnRate,gradDecay,sqGradDecay);
    end

    % Display the results
    updateTrainingPlotDayToDusk(ax,images{:});
end

% Save the trained network
modelDateTime = string(datetime('now','Format',"yyyy-MM-dd-HH-mm-ss"));
```

```
    save(strcat("trainedDayDuskUNITGeneratorNet-",modelDateTime,"-Epoch-",num2str(numEpochs),".ma

else
    net_url = 'https://ssd.mathworks.com/supportfiles/vision/data/trainedDayDuskUNITGeneratorNet
    downloadTrainedDayDuskGeneratorNet(net_url,dataDir);
    load(fullfile(dataDir,'trainedDayDuskUNITGeneratorNet.mat'));
end
```

Evaluate Source-to-Target Translation

Source-to-target image translation uses the UNIT generator to generate an image in the target domain (dusk) from an image in the source domain (day).

Read an image from the datastore of day test images.

```
idxToTest = 1;
dayTestImage = readimage(imdsDayTest,idxToTest);
```

Convert the image to data type `single` and normalize the image to the range [-1, 1].

```
dayTestImage = im2single(dayTestImage);
dayTestImage = (dayTestImage-0.5)/0.5;
```

Create a `dlarray` object that inputs data to the generator. If a supported GPU is available for computation, then perform inference on a GPU by converting the data to a `gpuArray` object.

```
dlDayImage = dlarray(dayTestImage,'SSCB');
if canUseGPU
    dlDayImage = gpuArray(dlDayImage);
end
```

Translate the input day image to the dusk domain using the `unitPredict` (Image Processing Toolbox) function.

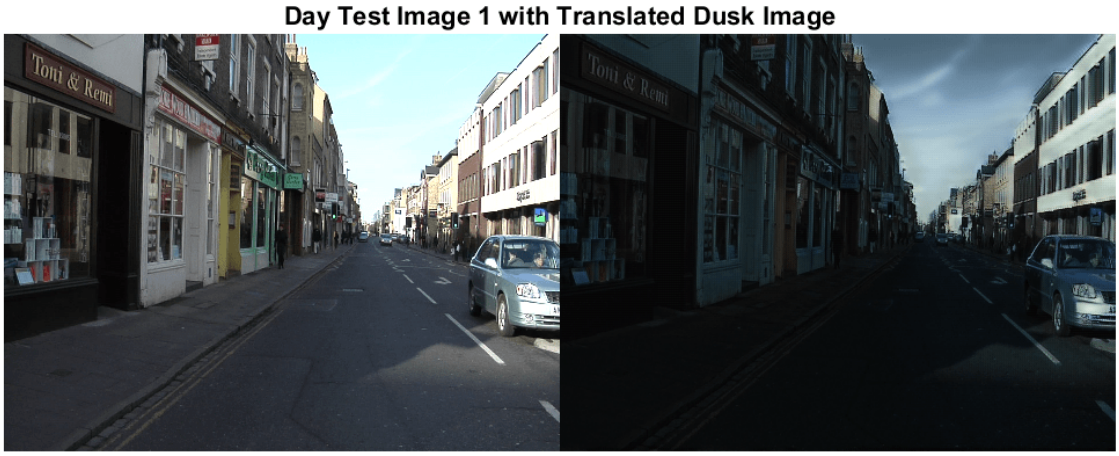
```
dlDayToDuskImage = unitPredict(gen,dlDayImage);
dayToDuskImage = extractdata(gather(dlDayToDuskImage));
```

The final layer of the generator network produces activations in the range [-1, 1]. For display, rescale the activations to the range [0, 1]. Also, rescale the input day image before display.

```
dayToDuskImage = rescale(dayToDuskImage);
dayTestImage = rescale(dayTestImage);
```

Display the input day image and its translated dusk version in a montage.

```
figure
montage({dayTestImage dayToDuskImage})
title(['Day Test Image ',num2str(idxToTest),' with Translated Dusk Image'])
```



Evaluate Target-to-Source Translation

Target-to-source image translation uses the UNIT generator to generate an image in the source domain (day) from an image in the target domain (dusk).

Read an image from the datastore of dusk test images.

```
idxToTest = 1;
duskTestImage = readimage(imdsDuskTest,idxToTest);
```

Convert the image to data type `single` and normalize the image to the range [-1, 1].

```
duskTestImage = im2single(duskTestImage);
duskTestImage = (duskTestImage-0.5)/0.5;
```

Create a `dlarray` object that inputs data to the generator. If a supported GPU is available for computation, then perform inference on a GPU by converting the data to a `gpuArray` object.

```
dlDuskImage = dlarray(duskTestImage,'SSCB');
if canUseGPU
    dlDuskImage = gpuArray(dlDuskImage);
end
```

Translate the input dusk image to the day domain using the `unitPredict` (Image Processing Toolbox) function.

```
dlDuskToDayImage = unitPredict(gen,dlDuskImage,"OutputType","TargetToSource");
duskToDayImage = extractdata(gather(dlDuskToDayImage));
```

For display, rescale the activations to the range [0, 1]. Also, rescale the input dusk image before display.

```
duskToDayImage = rescale(duskToDayImage);
duskTestImage = rescale(duskTestImage);
```

Display the input dusk image and its translated day version in a montage.

```
montage({duskTestImage duskToDayImage})
title(['Test Dusk Image ',num2str(idxToTest),' with Translated Day Image'])
```

Supporting Functions

Model Gradients Functions

The `modelGradientDisc` helper function calculates the gradients and loss for the two discriminators.

```
function [discAGrads,discBGrads,discALoss,discBLoss] = modelGradientDisc(gen, ...
    discA,discB,ImageA,ImageB,discLossWeight)

    [~,fakeA,fakeB,~] = forward(gen,ImageA,ImageB);

    % Calculate loss of the discriminator for X_A
    outA = forward(discA,ImageA);
    outfA = forward(discA,fakeA);
    discALoss = discLossWeight*computeDiscLoss(outA,outfA);

    % Update parameters of the discriminator for X
    discAGrads = dlgradient(discALoss,discA.Learnables);

    % Calculate loss of the discriminator for X_B
    outB = forward(discB,ImageB);
    outfB = forward(discB,fakeB);
    discBLoss = discLossWeight*computeDiscLoss(outB,outfB);

    % Update parameters of the discriminator for Y
    discBGrads = dlgradient(discBLoss,discB.Learnables);

    % Convert the data type from dlarray to single
    discALoss = extractdata(discALoss);
    discBLoss = extractdata(discBLoss);
end
```

The `modelGradientGen` helper function calculates the gradients and loss for the generator.

```
function [genGrad,genLoss,images] = modelGradientGen(gen,discA,discB,ImageA,ImageB,lossWeights)

    [ImageAA,ImageBA,ImageAB,ImageBB] = forward(gen,ImageA,ImageB);
    hidden = forward(gen,ImageA,ImageB,'Outputs','encoderSharedBlock');

    [~,ImageABA,ImageBAB,~] = forward(gen,ImageBA,ImageAB);
    cycle_hidden = forward(gen,ImageBA,ImageAB,'Outputs','encoderSharedBlock');

    % Calculate different losses
    selfReconLoss = computeReconLoss(ImageA,ImageAA) + computeReconLoss(ImageB,ImageBB);
    hiddenKLLoss = computeKLLoss(hidden);
    cycleReconLoss = computeReconLoss(ImageA,ImageABA) + computeReconLoss(ImageB,ImageBAB);
    cycleHiddenKLLoss = computeKLLoss(cycle_hidden);

    outA = forward(discA,ImageBA);
    outB = forward(discB,ImageAB);
    advLoss = computeAdvLoss(outA) + computeAdvLoss(outB);

    % Calculate the total loss of generator as a weighted sum of five
    % losses
    genTotalLoss = ...
        selfReconLoss*lossWeights.selfReconLossWeight + ...
        hiddenKLLoss*lossWeights.hiddenKLLossWeight + ...
        cycleReconLoss*lossWeights.cycleConsisLossWeight + ...
        cycleHiddenKLLoss*lossWeights.cycleHiddenKLLossWeight + ...
        advLoss*lossWeights.advLossWeight;

    % Update the parameters of generator
    genGrad = dlgradient(genTotalLoss,gen.Learnables);

    % Convert the data type from dlarray to single
    genLoss = extractdata(genTotalLoss);
    images = {ImageA,ImageAB,ImageB,ImageBA};
end
```

Loss Functions

The `computeDiscLoss` helper function calculates the discriminator loss. Each discriminator loss is a sum of two components:

- The squared difference between a vector of ones and the predictions of the discriminator on real images, Y_{real}
- The squared difference between a vector of zeros and the predictions of the discriminator on generated images, $\widehat{Y}_{translated}$

$$discriminatorLoss = (1 - Y_{real})^2 + \left(0 - \widehat{Y}_{translated}\right)^2$$

```
function discLoss = computeDiscLoss(Yreal,Ytranslated)
    discLoss = mean(((1-Yreal).^2),"all") + ...
               mean(((0-Ytranslated).^2),"all");
end
```

The `computeAdvLoss` helper function calculates the adversarial loss for the generator. Adversarial loss is the squared difference between a vector of ones and the discriminator predictions on the translated image.

$$adversarialLoss = \left(1 - \widehat{Y}_{translated}\right)^2$$

```
function advLoss = computeAdvLoss(Ytranslated)
    advLoss = mean(((Ytranslated-1).^2),"all");
end
```

The `computeReconLoss` helper function calculates the self-reconstruction loss and cycle-consistency loss for the generator. Self-reconstruction loss is the L^1 distance between the input images and their self-reconstructed versions. Cycle-consistency loss is the L^1 distance between the input images and their cycle-reconstructed versions.

$$selfReconstructionLoss = \left\|\left(Y_{real} - Y_{self-reconstructed}\right)\right\|_1$$

$$cycleConsistencyLoss = \left\|\left(Y_{real} - Y_{cycle-reconstructed}\right)\right\|_1$$

```
function reconLoss = computeReconLoss(Yreal,Yrecon)
    reconLoss = mean(abs(Yreal-Yrecon),"all");
end
```

The `computeKLLoss` helper function calculates the hidden KL loss and cycle-hidden KL loss for the generator. Hidden KL loss is the squared difference between a vector of zeros and the `encoderSharedBlock` activation for the self-reconstruction stream. Cycle-hidden KL loss is the squared difference between a vector of zeros and the `encoderSharedBlock` activation for the cycle-reconstruction stream.

$$hiddenKLLoss = \left(0 - Y_{encoderSharedBlockActivation}\right)^2$$

$$cycleHiddenKLLoss = \left(0 - Y_{encoderSharedBlockActivation}\right)^2$$

```
function klLoss = computeKLLoss(hidden)
    klLoss = mean(abs(hidden.^2),"all");
end
```

Quantify Image Quality Using Neural Image Assessment

This example shows how to analyze the aesthetic quality of images using a Neural Image Assessment (NIMA) convolutional neural network (CNN).

Image quality metrics provide an objective measure of image quality. An effective metric provides quantitative scores that correlate well with a subjective perception of quality by a human observer. Quality metrics enable the comparison of image processing algorithms.

NIMA [1] on page 9-0 is a no-reference technique that predicts the quality of an image without relying on a pristine reference image, which is frequently unavailable. NIMA uses a CNN to predict a distribution of quality scores for each image.

Evaluate Image Quality Using Trained NIMA Model

Download a pretrained NIMA neural network by using the helper function `downloadTrainedNIMANet`. The helper function is attached to the example as a supporting file. This model predicts a distribution of quality scores for each image in the range [1, 10], where 1 and 10 are the lowest and the highest possible values for the score, respectively. A high score indicates good image quality.

```
imageDir = fullfile(tempdir,"LIVEInTheWild");
if ~exist(imageDir,'dir')
    mkdir(imageDir);
end
trainedNIMA_url = 'https://ssd.mathworks.com/supportfiles/image/data/trainedNIMA.zip';
downloadTrainedNIMANet(trainedNIMA_url,imageDir);
load(fullfile(imageDir,'trainedNIMA.mat'));
```

You can evaluate the effectiveness of the NIMA model by comparing the predicted scores for a high-quality and lower quality image.

Read a high-quality image into the workspace.

```
imOriginal = imread('kobi.png');
```

Reduce the aesthetic quality of the image by applying a Gaussian blur. Display the original image and the blurred image in a montage. Subjectively, the aesthetic quality of the blurred image is worse than the quality of the original image.

```
imBlur = imgaussfilt(imOriginal,5);
montage({imOriginal,imBlur})
```

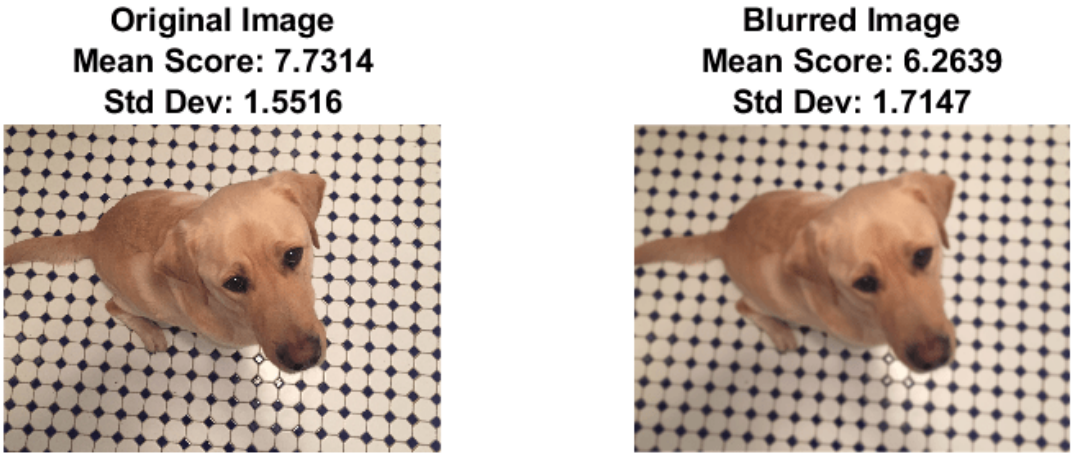
Predict the NIMA quality score distribution for the two images using the `predictNIMAScore` helper function. This function is attached to the example as a supporting file.

The `predictNIMAScore` function returns the mean and standard deviation of the NIMA score distribution for an image. The predicted mean score is a measure of the quality of the image. The standard deviation of scores can be considered a measure of the confidence level of the predicted mean score.

```
[meanOriginal,stdOriginal] = predictNIMAScore(dlnet,imOriginal);
[meanBlur,stdBlur] = predictNIMAScore(dlnet,imBlur);
```

Display the images along with the mean and standard deviation of the score distributions predicted by the NIMA model. The NIMA model correctly predicts scores for these images that agree with the subjective visual assessment.

```
figure
t = tiledlayout(1,2);
displayImageAndScoresForNIMA(t,imOriginal,meanOriginal,stdOriginal,"Original Image")
displayImageAndScoresForNIMA(t,imBlur,meanBlur,stdBlur,"Blurred Image")
```



The rest of this example shows how to train and evaluate a NIMA model.

Download LIVE In the Wild Data Set

This example uses the LIVE In the Wild data set [2] on page 9-0 , which is a public-domain subjective image quality challenge database. The data set contains 1162 photos captured by mobile devices, with 7 additional images provided to train the human scorers. Each image is rated by an average of 175 individuals on a scale of [1, 100]. The data set provides the mean and standard deviation of the subjective scores for each image.

Download the data set by following the instructions outlined in LIVE In the Wild Image Quality Challenge Database. Extract the data into the directory specified by the `imageDir` variable. When extraction is successful, `imageDir` contains two directories: `Data` and `Images`.

Load LIVE In the Wild Data

Get the file paths to the images.

```
imageData = load(fullfile(imageDir,'Data','AllImages_release.mat'));
imageData = imageData.AllImages_release;
```

```
nImg = length(imageData);
imageList(1:7) = fullfile(imageDir,'Images','trainingImages',imageData(1:7));
imageList(8:nImg) = fullfile(imageDir,'Images',imageData(8:end));
```

Create an image datastore that manages the image data.

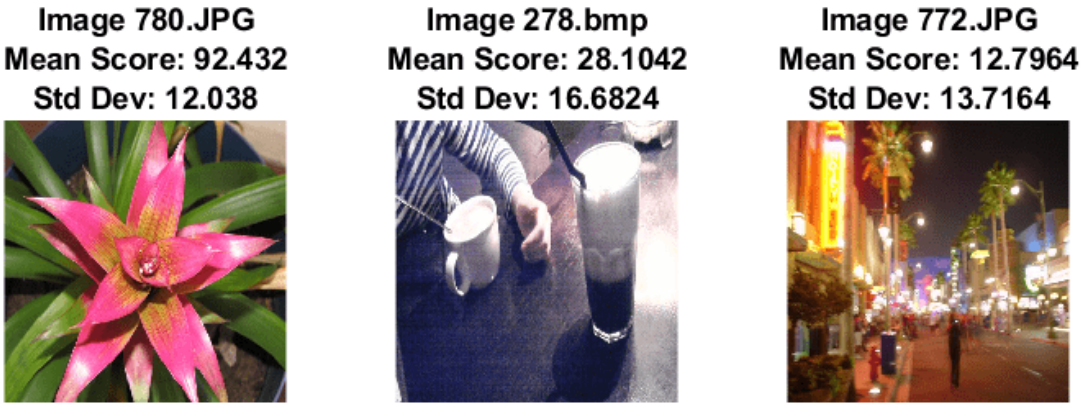
```
imds = imageDatastore(imageList);
```

Load the mean and standard deviation data corresponding to the images.

```
meanData = load(fullfile(imageDir,'Data','AllMOS_release.mat'));
meanData = meanData.AllMOS_release;
stdData = load(fullfile(imageDir,'Data','AllStdDev_release.mat'));
stdData = stdData.AllStdDev_release;
```

Optionally, display a few sample images from the data set with the corresponding mean and standard deviation values.

```
figure
t = tiledlayout(1,3);
idx1 = 785;
displayImageAndScoresForNIMA(t,readimage(imds,idx1), ...
    meanData(idx1),stdData(idx1),"Image "+imageData(idx1))
idx2 = 203;
displayImageAndScoresForNIMA(t,readimage(imds,idx2), ...
    meanData(idx2),stdData(idx2),"Image "+imageData(idx2))
idx3 = 777;
displayImageAndScoresForNIMA(t,readimage(imds,idx3), ...
    meanData(idx3),stdData(idx3),"Image "+imageData(idx3))
```



Preprocess and Augment Data

Preprocess the images by resizing them to 256-by-256 pixels.

```
rescaleSize = [256 256];
imds = transform(imds,@(x)imresize(x,rescaleSize));
```

The NIMA model requires a distribution of human scores, but the LIVE data set provides only the mean and standard deviation of the distribution. Approximate an underlying distribution for each image in the LIVE data set using the `createNIMAScoreDistribution` helper function. This function is attached to the example as a supporting file.

The `createNIMAScoreDistribution` rescales the scores to the range [1, 10], then generates maximum entropy distribution of scores from the mean and standard deviation values.

```
newMaxScore = 10;
prob = createNIMAScoreDistribution(meanData,stdData);
cumProb = cumsum(prob,2);
```

Create an `arrayDatastore` that manages the score distributions.

```
probDS = arrayDatastore(cumProb','IterationDimension',2);
```

Combine the datastores containing the image data and score distribution data.

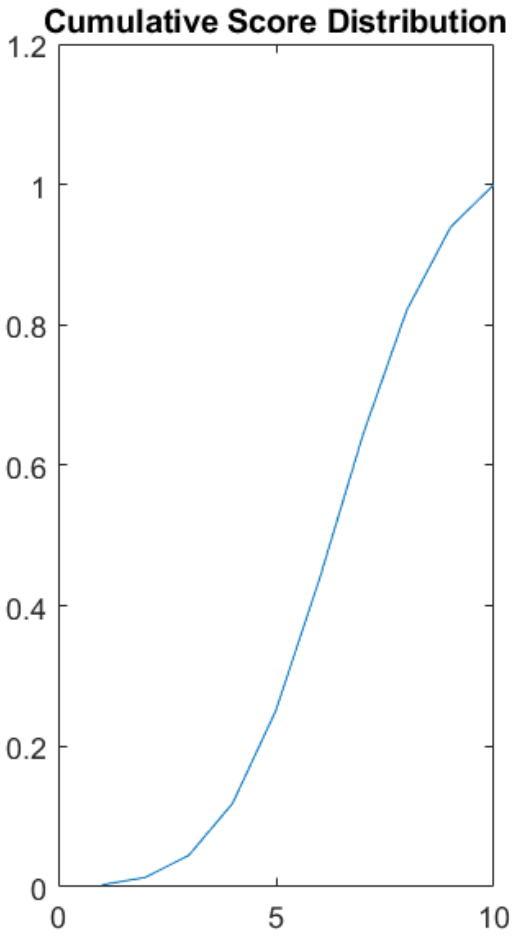
```
dsCombined = combine(imds,probDS);
```

Preview the output of reading from the combined datastore.

```
sampleRead = preview(dsCombined)
```

```
sampleRead=1×2 cell array
    {256×256×3 uint8}    {10×1 double}
```

```
figure
tiledlayout(1,2)
nexttile
imshow(sampleRead{1})
title("Sample Image from Data Set")
nexttile
plot(sampleRead{2})
title("Cumulative Score Distribution")
```



Split Data for Training, Validation, and Testing

Partition the data into training, validation, and test sets. Allocate 70% of the data for training, 15% for validation, and the remainder for testing.

```
numTrain = floor(0.70 * nImg);
numVal = floor(0.15 * nImg);

Idx = randperm(nImg);
idxTrain = Idx(1:numTrain);
idxVal = Idx(numTrain+1:numTrain+numVal);
idxTest = Idx(numTrain+numVal+1:nImg);

dsTrain = subset(dsCombined,idxTrain);
dsVal = subset(dsCombined,idxVal);
dsTest = subset(dsCombined,idxTest);
```

Augment Training Data

Augment the training data using the `augmentImageTest` helper function. This function is attached to the example as a supporting file. The `augmentDataForNIMA` function performs these augmentation operations on each training image:

- Crop the image to 224-by-244 pixels to reduce overfitting.
- Flip the image horizontally with 50% probability.

```
inputSize = [224 224];
dsTrain = transform(dsTrain,@(x)augmentDataForNIMA(x,inputSize));
```

Calculate Training Set Statistics for Input Normalization

The input layer of the network performs z-score normalization of the training images. Calculate the mean and standard deviation of the training images for use in z-score normalization.

```
meanImage = zeros([inputSize 3]);
meanImageSq = zeros([inputSize 3]);
while hasdata(dsTrain)
    dat = read(dsTrain);
    img = double(dat{1});
    meanImage = meanImage + img;
    meanImageSq = meanImageSq + img.^2;
end
meanImage = meanImage/numTrain;
meanImageSq = meanImageSq/numTrain;
varImage = meanImageSq - meanImage.^2;
stdImage = sqrt(varImage);
```

Reset the datastore to its initial state.

```
reset(dsTrain);
```

Batch Training Data

Create a `minibatchqueue` object that manages the mini-batching of observations in a custom training loop. The `minibatchqueue` object also casts data to a `dlarray` object that enables automatic differentiation in deep learning applications.

Specify the mini-batch data extraction format as `'SSCB'` (spatial, spatial, channel, batch). Set the `'DispatchInBackground'` name-value argument to the boolean returned by `canUseGPU`. If a supported GPU is available for computation, then the `minibatchqueue` object preprocesses mini-batches in the background in a parallel pool during training.

```
miniBatchSize = 128;
mbqTrain = minibatchqueue(dsTrain,'MiniBatchSize',miniBatchSize, ...
    'PartialMiniBatch','discard','MiniBatchFormat',{'SSCB',''}, ...
    'DispatchInBackground',canUseGPU);
mbqVal = minibatchqueue(dsVal,'MiniBatchSize',miniBatchSize, ...
    'MiniBatchFormat',{'SSCB',''},'DispatchInBackground',canUseGPU);
```

Load and Modify MobileNet-v2 Network

This example starts with a MobileNet-v2 [3] on page 9-0 CNN trained on ImageNet [4] on page 9-0 . The example modifies the network by replacing the last layer of the MobileNet-v2 network with a fully connected layer with 10 neurons, each representing a discrete score from 1 through 10. The network predicts the probability of each score for each image. The example normalizes the outputs of the fully connected layer using a softmax activation layer.

The `mobilenetv2` function returns a pretrained MobileNet-v2 network. This function requires the Deep Learning Toolbox™ Model *for MobileNet-v2 Network* support package. If this support package is not installed, then the function provides a download link.

```
net = mobilenetv2;
```

Convert the network into a `layerGraph` object.

```
lgraph = layerGraph(net);
```

The network has an image input size of 224-by-224 pixels. Replace the input layer with an image input layer that performs z-score normalization on the image data using the mean and standard deviation of the training images.

```
inLayer = imageInputLayer([inputSize 3],'Name','input','Normalization','zscore','Mean',meanImage
lgraph = replaceLayer(lgraph,'input_1',inLayer);
```

Replace the original final classification layer with a fully connected layer with 10 neurons. Add a softmax layer to normalize the outputs. Set the learning rate of the fully connected layer to 10 times the learning rate of the baseline CNN layers. Apply a dropout of 75%.

```
lgraph = removeLayers(lgraph,{'ClassificationLayer_Logits','Logits_softmax','Logits'});
newFinalLayers = [
    dropoutLayer(0.75,'Name','drop')
    fullyConnectedLayer(newMaxScore,'Name','fc','WeightLearnRateFactor',10,'BiasLearnRateFactor'
    softmaxLayer('Name','prob')];
lgraph = addLayers(lgraph,newFinalLayers);
lgraph = connectLayers(lgraph,'global_average_pooling2d_1','drop');
dlnet = dlnetwork(lgraph);
```

Visualize the network using the Deep Network Designer app.

```
deepNetworkDesigner(lgraph)
```

Define Model Gradients and Loss Functions

The `modelGradients` helper function calculates the gradients and losses for each iteration of training the network. This function is defined in the Supporting Functions on page 9-0 section of this example.

The objective of the NIMA network is to minimize the earth mover's distance (EMD) between the ground truth and predicted score distributions. EMD loss considers the distance between classes when penalizing misclassification. Therefore, EMD loss performs better than a typical softmax cross-entropy loss used in classification tasks [5] on page 9-0 . This example calculates the EMD loss using the `earthMoverDistance` helper function, which is defined in the Supporting Functions on page 9-0 section of this example.

For the EMD loss function, use an r-norm distance with $r = 2$. This distance allows for easy optimization when you work with gradient descent.

Specify Training Options

Specify the options for SGDM optimization. Train the network for 150 epochs.

```
numEpochs = 150;
momentum = 0.9;
initialLearnRate = 3e-3;
decay = 0.95;
```

Train Network

By default, the example loads a pretrained version of the NIMA network. The pretrained network enables you to run the entire example without waiting for training to complete.

To train the network, set the `doTraining` variable in the following code to `true`. Train the model in a custom training loop. For each iteration:

- Read the data for the current mini-batch using the `next` function.
- Evaluate the model gradients using the `dlfeval` function and the `modelGradients` helper function.
- Update the network parameters using the `sgdmupdate` function.

Train on a GPU if one is available. Using a GPU requires Parallel Computing Toolbox™ and a CUDA® enabled NVIDIA® GPU. For more information, see “GPU Support by Release” (Parallel Computing Toolbox).

```
doTraining = false;
if doTraining
    iteration = 0;
    velocity = [];
    start = tic;

    [hFig,lineLossTrain,lineLossVal] = initializeTrainingPlotNIMA;

    for epoch = 1:numEpochs

        shuffle (mbqTrain);
        learnRate = initialLearnRate/(1+decay*floor(epoch/10));

        while hasdata(mbqTrain)
```

```
            iteration = iteration + 1;
            [dlX,cdfY] = next(mbqTrain);
            [grad,loss] = dlfeval(@modelGradients,dlnet,dlX,cdfY);
            [dlnet,velocity] = sgdmupdate(dlnet,grad,velocity,learnRate,momentum);

            updateTrainingPlotNIMA(lineLossTrain,loss,epoch,iteration,start)

        end

        % Add validation data to plot
        [~,lossVal,~] = modelPredictions(dlnet,mbqVal);
        updateTrainingPlotNIMA(lineLossVal,lossVal,epoch,iteration,start)

    end

    % Save the trained network
    modelDateTime = string(datetime('now','Format',"yyyy-MM-dd-HH-mm-ss"));
    save(strcat("trainedNIMA-",modelDateTime,"-Epoch-",num2str(numEpochs),".mat"),'dlnet');

else
    load(fullfile(imageDir,'trainedNIMA.mat'));
end
```

Evaluate NIMA Model

Evaluate the performance of the model on the test data set using three metrics: EMD, binary classification accuracy, and correlation coefficients. The performance of the NIMA network on the test data set is in agreement with the performance of the reference NIMA model reported by Talebi and Milanfar [1] on page 9-0 .

Create a `minibatchqueue` object that manages the mini-batching of test data.

```
mbqTest = minibatchqueue(dsTest,'MiniBatchSize',miniBatchSize,'MiniBatchFormat',{'SSCB',''});
```

Calculate the predicted probabilities and ground truth cumulative probabilities of mini-batches of test data using the `modelPredictions` function. This function is defined in the Supporting Functions on page 9-0 section of this example.

```
[YPredTest,~,cdfYTest] = modelPredictions(dlnet,mbqTest);
```

Calculate the mean and standard deviation values of the ground truth and predicted distributions.

```
meanPred = extractdata(YPredTest)' * (1:10)';
stdPred = sqrt(extractdata(YPredTest)'*((1:10).^2)' - meanPred.^2);
origCdf = extractdata(cdfYTest);
origPdf = [origCdf(1,:); diff(origCdf)];
meanOrig = origPdf' * (1:10)';
stdOrig = sqrt(origPdf'*((1:10).^2)' - meanOrig.^2);
```

Calculate EMD

Calculate the EMD of the ground truth and predicted score distributions. For prediction, use an r-norm distance with $r = 1$. The EMD value indicates the closeness of the predicted and ground truth rating distributions.

```
EMDTest = earthMoverDistance(YPredTest,cdfYTest,1)
```

```
EMDTest =
  1×1 single gpuArray dlarray
```

```
    0.1158
```

Calculate Binary Classification Accuracy

For binary classification accuracy, convert the distributions to two classifications: high-quality and low-quality. Classify images with a mean score greater than a threshold as high-quality.

```
qualityThreshold = 5;
binaryPred = meanPred > qualityThreshold;
binaryOrig = meanOrig > qualityThreshold;
```

Calculate the binary classification accuracy.

```
binaryAccuracy = 100 * sum(binaryPred==binaryOrig)/length(binaryPred)
```

```
binaryAccuracy =

   84.6591
```

Calculate Correlation Coefficients

Large correlation values indicate a large positive correlation between the ground truth and predicted scores. Calculate the linear correlation coefficient (LCC) and Spearman's rank correlation coefficient (SRCC) for the mean scores.

```
meanLCC = corr(meanOrig,meanPred)
```

```
meanLCC =

  gpuArray single

    0.7265
```

```
meanSRCC = corr(meanOrig,meanPred,'type','Spearman')
```

```
meanSRCC =

  gpuArray single

    0.6451
```

Supporting Functions

Model Gradients Function

The `modelGradients` function takes as input a `dlnetwork` object `dlnet` and a mini-batch of input data `dlX` with corresponding target cumulative probabilities `cdfY`. The function returns the gradients of the loss with respect to the learnable parameters in `dlnet` as well as the loss. To compute the gradients automatically, use the `dlgradient` function.

```
function [gradients,loss] = modelGradients(dlnet,dlX,cdfY)
    dlYPred = forward(dlnet,dlX);
    loss = earthMoverDistance(dlYPred,cdfY,2);
    gradients = dlgradient(loss,dlnet.Learnables);
end
```

Loss Function

The `earthMoverDistance` function calculates the EMD between the ground truth and predicted distributions for a specified *r*-norm value. The `earthMoverDistance` uses the `computeCDF` helper function to calculate the cumulative probabilities of the predicted distribution.

```
function loss = earthMoverDistance(YPred,cdfY,r)
    N = size(cdfY,1);
    cdfYPred = computeCDF(YPred);
    cdfDiff = (1/N) * (abs(cdfY - cdfYPred).^r);
    lossArray = sum(cdfDiff,1).^(1/r);
    loss = mean(lossArray);

end
function cdfY = computeCDF(Y)
% Given a probability mass function Y, compute the cumulative probabilities
    [N,miniBatchSize] = size(Y);
    L = repmat(triu(ones(N)),1,1,miniBatchSize);
    L3d = permute(L,[1 3 2]);
    prod = Y.*L3d;
    prodSum = sum(prod,1);
    cdfY = reshape(prodSum(:)',miniBatchSize,N)';
end
```

Model Predictions Function

The `modelPredictions` function calculates the estimated probabilities, loss, and ground truth cumulative probabilities of mini-batches of data.

```
function [dlYPred,loss,cdfYOrig] = modelPredictions(dlnet,mbq)
    reset(mbq);
    loss = 0;
    numObservations = 0;
    dlYPred = [];
    cdfYOrig = [];

    while hasdata(mbq)
        [dlX,cdfY] = next(mbq);
        miniBatchSize = size(dlX,4);

        dlY = predict(dlnet,dlX);
        loss = loss + earthMoverDistance(dlY,cdfY,2)*miniBatchSize;
        dlYPred = [dlYPred dlY];
        cdfYOrig = [cdfYOrig cdfY];

        numObservations = numObservations + miniBatchSize;

    end
    loss = loss / numObservations;
end
```

Neural Style Transfer Using Deep Learning

This example shows how to apply the stylistic appearance of one image to the scene content of a second image using a pretrained VGG-19 network [1] on page 9-0 .

Load Data

Load the style image and content image. This example uses the distinctive Van Gogh painting "Starry Night" as the style image and a photograph of a lighthouse as the content image.

```
styleImage = im2double(imread('starryNight.jpg'));
contentImage = imread('lighthouse.png');
```

Display the style image and content image as a montage.

```
imshow(imtile({styleImage,contentImage},'BackgroundColor','w'));
```

Load Feature Extraction Network

In this example, you use a modified pretrained VGG-19 deep neural network to extract the features of the content and style image at various layers. These multilayer features are used to compute respective content and style losses. The network generates the stylized transfer image using the combined loss.

To get a pretrained VGG-19 network, install `vgg19`. If you do not have the required support packages installed, then the software provides a download link.

```
net = vgg19;
```

To make the VGG-19 network suitable for feature extraction, remove all of the fully connected layers from the network.

```
lastFeatureLayerIdx = 38;
layers = net.Layers;
layers = layers(1:lastFeatureLayerIdx);
```

The max pooling layers of the VGG-19 network cause a fading effect. To decrease the fading effect and increase the gradient flow, replace all max pooling layers with average pooling layers [1] on page 9-0 .

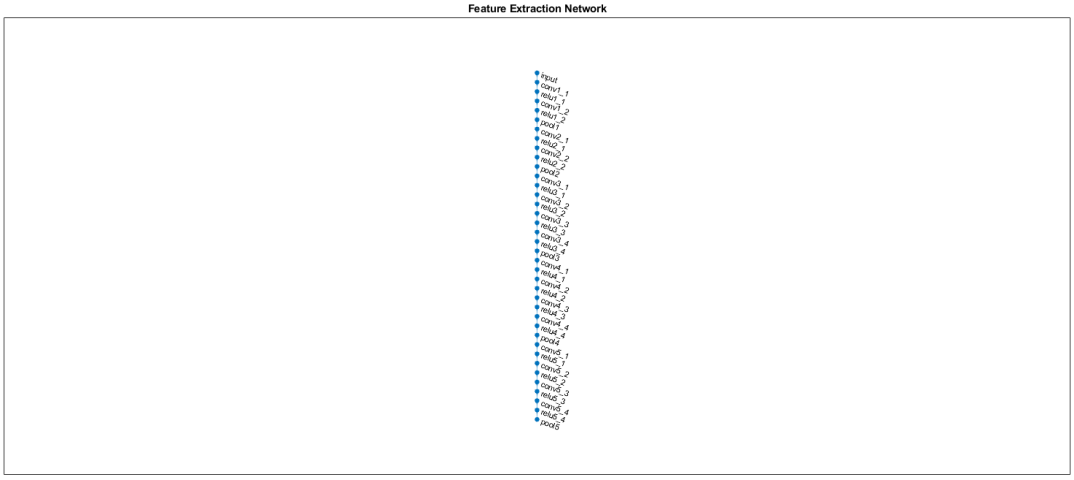
```
for l = 1:lastFeatureLayerIdx
    layer = layers(l);
    if isa(layer,'nnet.cnn.layer.MaxPooling2DLayer')
        layers(l) = averagePooling2dLayer(layer.PoolSize,'Stride',layer.Stride,'Name',layer.Name
    end
end
```

Create a layer graph with the modified layers.

```
lgraph = layerGraph(layers);
```

Visualize the feature extraction network in a plot.

```
plot(lgraph)
title('Feature Extraction Network')
```



To train the network with a custom training loop and enable automatic differentiation, convert the layer graph to a `dlnetwork` object.

```
dlnet = dlnetwork(lgraph);
```

Preprocess Data

Resize the style image and content image to a smaller size for faster processing.

```
imageSize = [384,512];
styleImg = imresize(styleImage,imageSize);
contentImg = imresize(contentImage,imageSize);
```

The pretrained VGG-19 network performs classification on a channel-wise mean subtracted image. Get the channel-wise mean from the image input layer, which is the first layer in the network.

```
imgInputLayer = lgraph.Layers(1);
meanVggNet = imgInputLayer.Mean(1,1,:);
```

The values of the channel-wise mean are appropriate for images of floating point data type with pixel values in the range [0, 255]. Convert the style image and content image to data type `single` with range [0, 255]. Then, subtract the channel-wise mean from the style image and content image.

```
styleImg = rescale(single(styleImg),0,255) - meanVggNet;
contentImg = rescale(single(contentImg),0,255) - meanVggNet;
```

Initialize Transfer Image

The transfer image is the output image as a result of style transfer. You can initialize the transfer image with a style image, content image, or any random image. Initialization with a style image or content image biases the style transfer process and produces a transfer image more similar to the input image. In contrast, initialization with white noise removes the bias but takes longer to converge on the stylized image. For better stylization and faster convergence, this example initializes the output transfer image as a weighted combination of the content image and a white noise image.

```
noiseRatio = 0.7;
randImage = randi([-20,20],[imageSize 3]);
transferImage = noiseRatio.*randImage + (1-noiseRatio).*contentImg;
```

Define Loss Functions and Style Transfer Parameters

Content Loss

The objective of content loss is to make the features of the transfer image match the features of the content image. The content loss is computed as the mean squared difference between content image features and transfer image features for each content feature layer [1] on page 9-0 . $\widehat{Y}$ is the predicted feature map for the transfer image and Y is the predicted feature map for the content image. W_c^l is the content layer weight for the l^{th} layer. $H, W, C$are the height, width, and channels of the feature maps, respectively.

$$L_{content} = \sum_l W_c^l \times \frac{1}{HWC} \sum_{i,j} (\widehat{Y}_{i,j}^l - Y_{i,j}^l)^2$$

Specify the content feature extraction layer names. The features extracted from these layers are used to compute the content loss. In the VGG-19 network, training is more effective using features from deeper layers rather than features from shallow layers. Therefore, specify the content feature extraction layer as the fourth convolutional layer.

```
styleTransferOptions.contentFeatureLayerNames = {'conv4_2'};
```

Specify the weights of the content feature extraction layers.

```
styleTransferOptions.contentFeatureLayerWeights = 1;
```

Style Loss

The objective of style loss is to make the texture of the transfer image match the texture of the style image. The style representation of an image is represented as a Gram matrix. Therefore, the style loss is computed as the mean squared difference between the Gram matrix of the style image and the Gram matrix of the transfer image [1] on page 9-0 . Z and $\widehat{Z}$ are the predicted feature maps for the style and transfer image, respectively. G_Z and $G_{\widehat{Z}}$ are Gram matrices for style features and transfer features, respectively. W_s^l is the style layer weight for the l^{th} style layer.

$$G_{\hat{Z}} = \sum_{i,j} \hat{Z}_{i,j} \times \hat{Z}_{j,i}$$

$$G_Z = \sum_{i,j} Z_{i,j} \times Z_{j,i}$$

$$L_{style} = \sum_l W_s^l \times \frac{1}{(2HWC)^2} \sum (G_{\hat{Z}}^l - G_Z^l)^2$$

Specify the names of the style feature extraction layers. The features extracted from these layers are used to compute style loss.

```
styleTransferOptions.styleFeatureLayerNames = {'conv1_1','conv2_1','conv3_1','conv4_1','conv5_1'}
```

Specify the weights of the style feature extraction layers. Specify small weights for simple style images and increase the weights for complex style images.

```
styleTransferOptions.styleFeatureLayerWeights = [0.5,1.0,1.5,3.0,4.0];
```

Total Loss

The total loss is a weighted combination of content loss and style loss. α and β are weight factors for content loss and style loss, respectively.

$$L_{total} = \alpha \times L_{content} + \beta \times L_{style}$$

Specify the weight factors `alpha` and `beta` for content loss and style loss. The ratio of `alpha` to `beta` should be around 1e-3 or 1e-4 [1] on page 9-0 .

```
styleTransferOptions.alpha = 1;
styleTransferOptions.beta = 1e3;
```

Specify Training Options

Train for 2500 iterations.

```
numIterations = 2500;
```

Specify options for Adam optimization. Set the learning rate to 2 for faster convergence. You can experiment with the learning rate by observing your output image and losses. Initialize the trailing average gradient and trailing average gradient-square decay rates with `[]`.

```
learningRate = 2;
trailingAvg = [];
trailingAvgSq = [];
```

Train the Network

Convert the style image, content image, and transfer image to `dlarray` objects with underlying type `single` and dimension labels `'SSC'`.

```
dlStyle = dlarray(styleImg,'SSC');
dlContent = dlarray(contentImg,'SSC');
dlTransfer = dlarray(transferImage,'SSC');
```

Train on a GPU if one is available. Using a GPU requires Parallel Computing Toolbox™ and a CUDA® enabled NVIDIA® GPU. For more information, see “GPU Support by Release” (Parallel Computing Toolbox). For GPU training, convert the data into a `gpuArray`.

```
if canUseGPU
    dlContent = gpuArray(dlContent);
    dlStyle = gpuArray(dlStyle);
    dlTransfer = gpuArray(dlTransfer);
end
```

Extract the content features from the content image.

```
numContentFeatureLayers = numel(styleTransferOptions.contentFeatureLayerNames);
contentFeatures = cell(1,numContentFeatureLayers);
[contentFeatures{:}] = forward(dlnet,dlContent,'Outputs',styleTransferOptions.contentFeatureLaye
```

Extract the style features from the style image.

```
numStyleFeatureLayers = numel(styleTransferOptions.styleFeatureLayerNames);
styleFeatures = cell(1,numStyleFeatureLayers);
[styleFeatures{:}] = forward(dlnet,dlStyle,'Outputs',styleTransferOptions.styleFeatureLayerNames
```

Train the model using a custom training loop. For each iteration:

- Calculate the content loss and style loss using the features of the content image, style image, and transfer image. To calculate the loss and gradients, use the helper function `imageGradients` (defined in the Supporting Functions on page 9-0 section of this example).
- Update the transfer image using the `adamupdate` function.
- Select the best style transfer image as the final output image.

```
figure

minimumLoss = inf;

for iteration = 1:numIterations
    % Evaluate the transfer image gradients and state using dlfeval and the
    % imageGradients function listed at the end of the example.
    [grad,losses] = dlfeval(@imageGradients,dlnet,dlTransfer,contentFeatures,styleFeatures,styleT
    [dlTransfer,trailingAvg,trailingAvgSq] = adamupdate(dlTransfer,grad,trailingAvg,trailingAvgSq

    if losses.totalLoss < minimumLoss
        minimumLoss = losses.totalLoss;
        dlOutput = dlTransfer;
    end

    % Display the transfer image on the first iteration and after every 50
    % iterations. The postprocessing steps are described in the "Postprocess
    % Transfer Image for Display" section of this example.
    if mod(iteration,50) == 0 || (iteration == 1)

        transferImage = gather(extractdata(dlTransfer));
        transferImage = transferImage + meanVggNet;
        transferImage = uint8(transferImage);
        transferImage = imresize(transferImage,size(contentImage,[1 2]));

        image(transferImage)
        title(['Transfer Image After Iteration ',num2str(iteration)])
```

```
        axis off image
        drawnow
    end

end
```

Postprocess Transfer Image for Display

Get the updated transfer image.

```
transferImage = gather(extractdata(dlOutput));
```

Add the network-trained mean to the transfer image.

```
transferImage = transferImage + meanVggNet;
```

Some pixel values can exceed the original range [0, 255] of the content and style image. You can clip the values to the range [0, 255] by converting the data type to `uint8`.

```
transferImage = uint8(transferImage);
```

Resize the transfer image to the original size of the content image.

```
transferImage = imresize(transferImage,size(contentImage,[1 2]));
```

Display the content image, transfer image, and style image in a montage.

```
imshow(imtile({contentImage,transferImage,styleImage}, ...
    'GridSize',[1 3],'BackgroundColor','w'));
```

Supporting Functions

Compute Image Loss and Gradients

The `imageGradients` helper function returns the loss and gradients using features of the content image, style image, and transfer image.

```
function [gradients,losses] = imageGradients(dlnet,dlTransfer,contentFeatures,styleFeatures,paran

    % Initialize transfer image feature containers.
    numContentFeatureLayers = numel(params.contentFeatureLayerNames);
    numStyleFeatureLayers = numel(params.styleFeatureLayerNames);

    transferContentFeatures = cell(1,numContentFeatureLayers);
    transferStyleFeatures = cell(1,numStyleFeatureLayers);

    % Extract content features of transfer image.
    [transferContentFeatures{:}] = forward(dlnet,dlTransfer,'Outputs',params.contentFeatureLayerN

    % Extract style features of transfer image.
    [transferStyleFeatures{:}] = forward(dlnet,dlTransfer,'Outputs',params.styleFeatureLayerNames

    % Compute content loss.
    cLoss = contentLoss(transferContentFeatures,contentFeatures,params.contentFeatureLayerWeights

    % Compute style loss.
    sLoss = styleLoss(transferStyleFeatures,styleFeatures,params.styleFeatureLayerWeights);

    % Compute final loss as weighted combination of content and style loss.
    loss = (params.alpha * cLoss) + (params.beta * sLoss);

    % Calculate gradient with respect to transfer image.
    gradients = dlgradient(loss,dlTransfer);

    % Extract various losses.
```

```
    losses.totalLoss = gather(extractdata(loss));
    losses.contentLoss = gather(extractdata(cLoss));
    losses.styleLoss = gather(extractdata(sLoss));

end
```

Compute Content Loss

The `contentLoss` helper function computes the weighted mean squared difference between the content image features and the transfer image features.

```
function loss = contentLoss(transferContentFeatures,contentFeatures,contentWeights)

    loss = 0;
    for i=1:numel(contentFeatures)
        temp = 0.5 .* mean((transferContentFeatures{1,i} - contentFeatures{1,i}).^2,'all');
        loss = loss + (contentWeights(i)*temp);
    end
end
```

Compute Style Loss

The `styleLoss` helper function computes the weighted mean squared difference between the Gram matrix of the style image features and the Gram matrix of the transfer image features.

```
function loss = styleLoss(transferStyleFeatures,styleFeatures,styleWeights)

    loss = 0;
    for i=1:numel(styleFeatures)

        tsf = transferStyleFeatures{1,i};
        sf = styleFeatures{1,i};
        [h,w,c] = size(sf);

        gramStyle = computeGramMatrix(sf);
        gramTransfer = computeGramMatrix(tsf);
        sLoss = mean((gramTransfer - gramStyle).^2,'all') / ((h*w*c)^2);

        loss = loss + (styleWeights(i)*sLoss);
    end
end
```

Compute Gram Matrix

The `computeGramMatrix` helper function is used by the `styleLoss` helper function to compute the Gram matrix of a feature map.

```
function gramMatrix = computeGramMatrix(featureMap)
    [H,W,C] = size(featureMap);
    reshapedFeatures = reshape(featureMap,H*W,C);
    gramMatrix = reshapedFeatures' * reshapedFeatures;
end
```

Unsupervised Medical Image Denoising Using CycleGAN

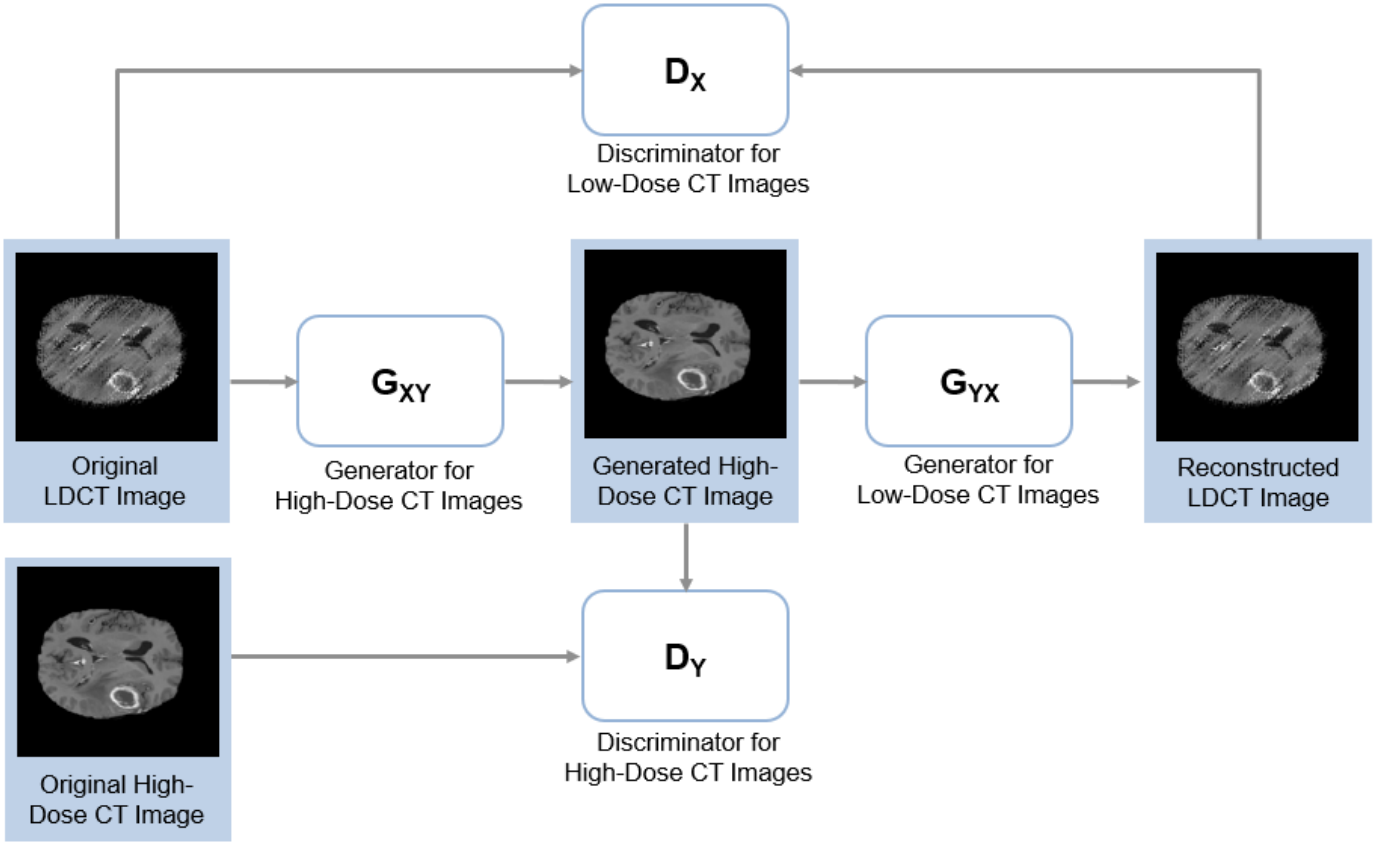
This example shows how to generate high-quality high-dose computed tomography (CT) images from noisy low-dose CT images using a CycleGAN neural network.

This example uses a cycle-consistent generative adversarial network (CycleGAN) trained on patches of image data from a large sample of data. For a similar approach using a UNIT neural network trained on full images from a limited sample of data, see “Unsupervised Medical Image Denoising Using CycleGAN” (Image Processing Toolbox).

X-ray CT is a popular imaging modality used in clinical and industrial applications because it produces high-quality images and offers superior diagnostic capabilities. To protect the safety of patients, clinicians recommend a low radiation dose. However, a low radiation dose results in a lower signal-to-noise ratio (SNR) in the images, and therefore reduces the diagnostic accuracy.

Deep learning techniques offer solutions to improve the image quality for low-dose CT (LDCT) images. Using a generative adversarial network (GAN) for image-to-image translation, you can convert noisy LDCT images to images of the same quality as regular-dose CT images. For this application, the source domain consists of LDCT images and the target domain consists of regular-dose images.

CT image denoising requires a GAN that performs unsupervised training because clinicians do not typically acquire matching pairs of low-dose and regular-dose CT images of the same patient in the same session. This example uses a CycleGAN architecture that supports unsupervised training. For more information, see “Get Started with GANs for Image-to-Image Translation” (Image Processing Toolbox).



Download LDCT Data Set

This example uses data from the Low Dose CT Grand Challenge [2, 3, 4]. The data includes pairs of regular-dose CT images and simulated low-dose CT images for 99 head scans (labeled N for neuro), 100 chest scans (labeled C for chest), and 100 abdomen scans (labeled L for liver). The size of the data set is 1.2 TB.

Set `dataDir` as the desired location of the data set.

```
dataDir = fullfile(tempdir,"LDCT","LDCT-and-Projection-data");
```

To download the data, go to the Cancer Imaging Archive website. This example uses only images from the chest. Download the chest files from the "Images (DICOM, 952 GB)" data set into the directory specified by `dataDir` using the NBIA Data Retriever. When the download is successful, `dataDir` contains 50 subfolders with names such as "C002" and "C004", ending with "C296".

Create Datastores for Training, Validation, and Testing

The LDCT data set provides pairs of low-dose and high-dose CT images. However, the CycleGAN architecture requires unpaired data for unsupervised learning. This example simulates unpaired training and validation data by partitioning images such that the patients used to obtain low-dose CT and high-dose CT images do not overlap. The example retains pairs of low-dose and regular-dose images for testing.

Split the data into training, validation, and test data sets using the `createLDCTFolderList` helper function. This function is attached to the example as a supporting file. The helper function splits the

data such that there is roughly good representation of the two types of images in each group. Approximately 80% of the data is used for training, 15% is used for testing, and 5% is used for validation.

```
maxDirsForABodyPart = 25;
[filesTrainLD,filesTrainHD,filesTestLD,filesTestHD,filesValLD,filesValHD] = ...
    createLDCTFolderList(dataDir,maxDirsForABodyPart);
```

Create image datastores that contain training and validation images for both domains, namely low-dose CT images and high-dose CT images. The data set consists of DICOM images, so use the custom `ReadFcn` name-value argument in `imageDatastore` to enable reading the data.

```
exts = {'.dcm'};
readFcn = @(x)dicomread(x);
imdsTrainLD = imageDatastore(filesTrainLD,FileExtensions=exts,ReadFcn=readFcn);
imdsTrainHD = imageDatastore(filesTrainHD,FileExtensions=exts,ReadFcn=readFcn);
imdsValLD = imageDatastore(filesValLD,FileExtensions=exts,ReadFcn=readFcn);
imdsValHD = imageDatastore(filesValHD,FileExtensions=exts,ReadFcn=readFcn);
imdsTestLD = imageDatastore(filesTestLD,FileExtensions=exts,ReadFcn=readFcn);
imdsTestHD = imageDatastore(filesTestHD,FileExtensions=exts,ReadFcn=readFcn);
```

The number of low-dose and high-dose images can differ. Select a subset of the files such that the number of images is equal.

```
numTrain = min(numel(imdsTrainLD.Files),numel(imdsTrainHD.Files));
imdsTrainLD = subset(imdsTrainLD,1:numTrain);
imdsTrainHD = subset(imdsTrainHD,1:numTrain);

numVal = min(numel(imdsValLD.Files),numel(imdsValHD.Files));
imdsValLD = subset(imdsValLD,1:numVal);
imdsValHD = subset(imdsValHD,1:numVal);

numTest = min(numel(imdsTestLD.Files),numel(imdsTestHD.Files));
imdsTestLD = subset(imdsTestLD,1:numTest);
imdsTestHD = subset(imdsTestHD,1:numTest);
```

Preprocess and Augment Data

Preprocess the data by using the `transform` function with custom preprocessing operations specified by the `normalizeCTImages` helper function. This function is attached to the example as a supporting file. The `normalizeCTImages` function rescales the data to the range [-1, 1].

```
timdsTrainLD = transform(imdsTrainLD,@(x){normalizeCTImages(x)});
timdsTrainHD = transform(imdsTrainHD,@(x){normalizeCTImages(x)});
timdsValLD = transform(imdsValLD,@(x){normalizeCTImages(x)});
timdsValHD  = transform(imdsValHD,@(x){normalizeCTImages(x)});
timdsTestLD = transform(imdsTestLD,@(x){normalizeCTImages(x)});
timdsTestHD  = transform(imdsTestHD,@(x){normalizeCTImages(x)});
```

Combine the low-dose and high-dose training data by using a `randomPatchExtractionDatastore` (Image Processing Toolbox). When reading from this datastore, augment the data using random rotation and horizontal reflection.

```
inputSize = [128,128,1];
augmenter = imageDataAugmenter(RandRotation=@()90*(randi([0,1],1)),RandXReflection=true);
dsTrain = randomPatchExtractionDatastore(timdsTrainLD,timdsTrainHD, ...
    inputSize(1:2),PatchesPerImage=16,DataAugmentation=augmenter);
```

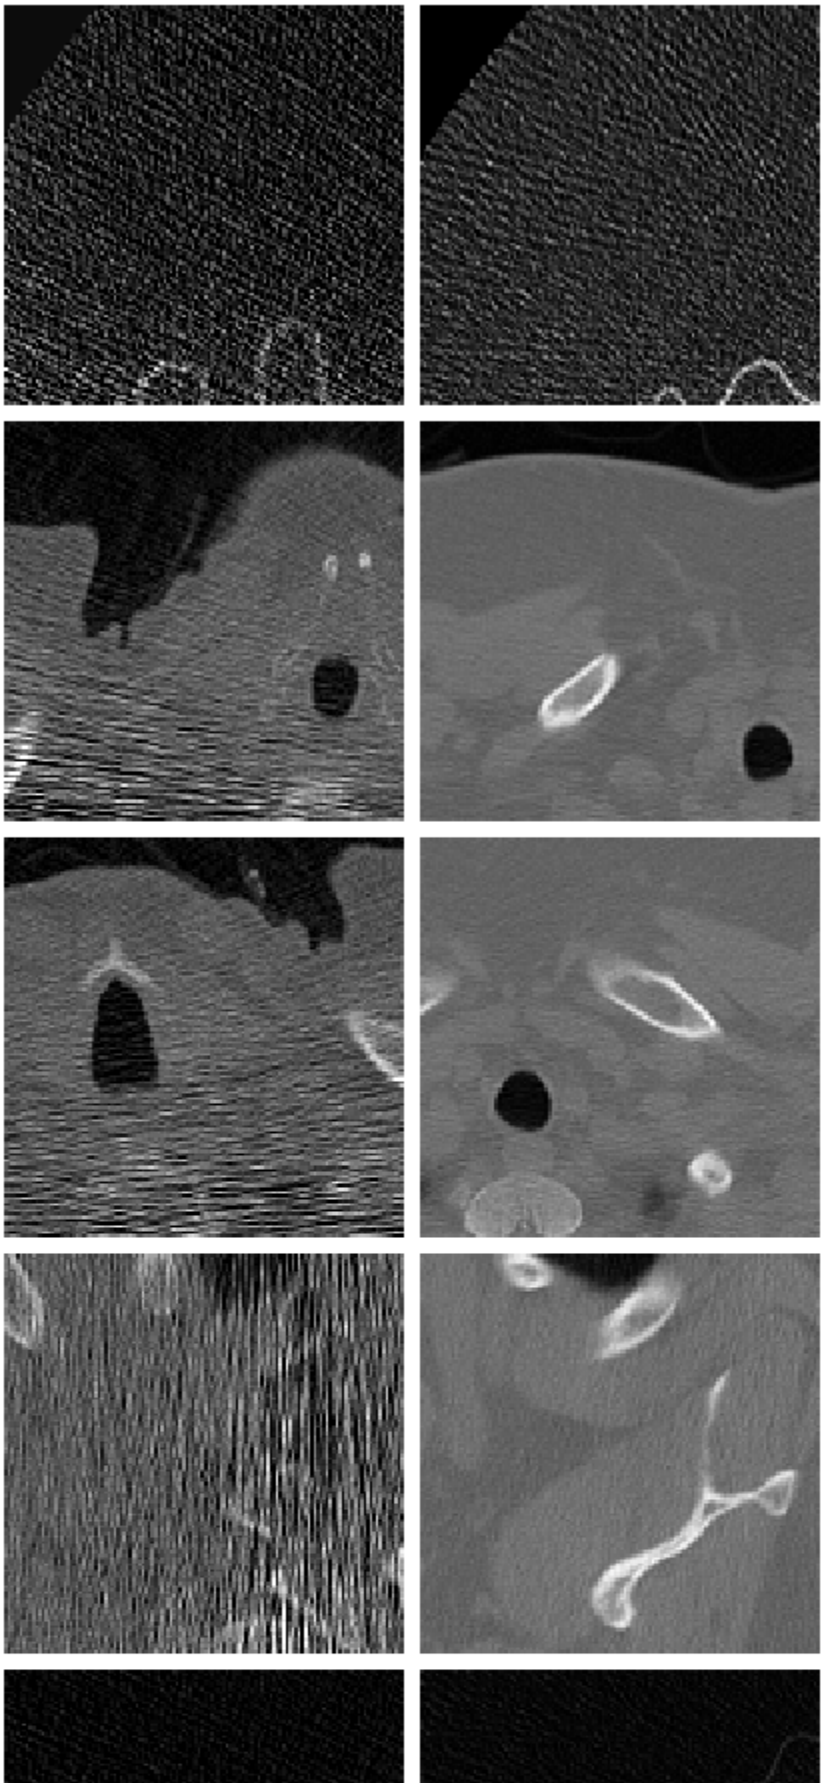
Combine the validation data by using a `randomPatchExtractionDatastore`. You do not need to perform augmentation when reading validation data.

```
dsVal = randomPatchExtractionDatastore(timdsValLD,timdsValHD,inputSize(1:2));
```

Visualize Data Set

Look at a few low-dose and high-dose image patch pairs from the training set. Notice that the image pairs of low-dose (left) and high-dose (right) images are unpaired, as they are from different patients.

```
numImagePairs = 6;
imagePairsTrain = [];
for i = 1:numImagePairs
    imLowAndHighDose = read(dsTrain);
    inputImage = imLowAndHighDose.InputImage{1};
    inputImage = rescale(im2single(inputImage));
    responseImage = imLowAndHighDose.ResponseImage{1};
    responseImage = rescale(im2single(responseImage));
    imagePairsTrain = cat(4,imagePairsTrain,inputImage,responseImage);
end
montage(imagePairsTrain,Size=[numImagePairs 2],BorderSize=4,BackgroundColor="w")
```



Batch Training and Validation Data During Training

This example uses a custom training loop. The `minibatchqueue` object is useful for managing the mini-batching of observations in custom training loops. The `minibatchqueue` object also casts data to a `dlarray` object that enables auto differentiation in deep learning applications.

Process the mini-batches by concatenating image patches along the batch dimension using the helper function `concatenateMiniBatchLD2HDCT`. This function is attached to the example as a supporting file. Specify the mini-batch data extraction format as `"SSCB"` (spatial, spatial, channel, batch). Discard any partial mini-batches with less than `miniBatchSize` observations.

```
miniBatchSize = 32;

mbqTrain = minibatchqueue(dsTrain, ...
    MiniBatchSize=miniBatchSize, ...
    MiniBatchFcn=@concatenateMiniBatchLD2HDCT, ...
    PartialMiniBatch="discard", ...
    MiniBatchFormat="SSCB");
mbqVal = minibatchqueue(dsVal, ...
    MiniBatchSize=miniBatchSize, ...
    MiniBatchFcn=@concatenateMiniBatchLD2HDCT, ...
    PartialMiniBatch="discard", ...
    MiniBatchFormat="SSCB");
```

Create Generator and Discriminator Networks

The CycleGAN consists of two generators and two discriminators. The generators perform image-to-image translation from low-dose to high-dose and vice versa. The discriminators are PatchGAN networks that return the patch-wise probability that the input data is real or generated. One discriminator distinguishes between the real and generated low-dose images and the other discriminator distinguishes between real and generated high-dose images.

Create each generator network using the `cycleGANGenerator` (Image Processing Toolbox) function. For an input size of 256-by-256 pixels, specify the `NumResidualBlocks` argument as `9`. By default, the function has 3 encoder modules and uses 64 filters in the first convolutional layer.

```
numResiduals = 6;
genHD2LD = cycleGANGenerator(inputSize,NumResidualBlocks=numResiduals,NumOutputChannels=1);
genLD2HD = cycleGANGenerator(inputSize,NumResidualBlocks=numResiduals,NumOutputChannels=1);
```

Create each discriminator network using the `patchGANDiscriminator` (Image Processing Toolbox) function. Use the default settings for the number of downsampling blocks and number of filters in the first convolutional layer in the discriminators.

```
discLD = patchGANDiscriminator(inputSize);
discHD = patchGANDiscriminator(inputSize);
```

Define Loss Functions and Scores

The `modelGradients` helper function calculates the gradients and losses for the discriminators and generators. This function is defined in the Supporting Functions on page 9-0 section of this example.

The objective of the generator is to generate translated images that the discriminators classify as real. The generator loss is a weighted sum of three types of losses: adversarial loss, cycle consistency loss, and fidelity loss. Fidelity loss is based on structural similarity (SSIM) loss.

$$L_{\text{Total}} = L_{\text{Adversarial}} + \lambda * L_{\text{Cycle consistency}} + L_{\text{Fidelity}}$$

Specify the weighting factor λ that controls the relative significance of the cycle consistency loss with the adversarial and fidelity losses.

```
lambda = 10;
```

The objective of each discriminator is to correctly distinguish between real images (1) and translated images (0) for images in its domain. Each discriminator has a single loss function that relies on the mean squared error (MSE) between the expected and predicted output.

Specify Training Options

Train with a mini-batch size of 32 for 3 epochs.

```
numEpochs = 3;
miniBatchSize = 32;
```

Specify the options for Adam optimization. For both generator and discriminator networks, use:

- A learning rate of 0.0002
- A gradient decay factor of 0.5
- A squared gradient decay factor of 0.999

```
learnRate = 0.0002;
gradientDecay = 0.5;
squaredGradientDecayFactor = 0.999;
```

Initialize Adam parameters for the generators and discriminators.

```
avgGradGenLD2HD = [];
avgSqGradGenLD2HD = [];
avgGradGenHD2LD = [];
avgSqGradGenHD2LD = [];
avgGradDiscLD = [];
avgSqGradDiscLD = [];
avgGradDiscHD = [];
avgSqGradDiscHD = [];
```

Display the generated validation images every 100 iterations.

```
validationFrequency = 100;
```

Train or Download Model

By default, the example downloads a pretrained version of the CycleGAN generator for low-dose to high-dose CT by using the helper function `downloadTrainedLD2HDCTCycleGANNet`. The helper function is attached to the example as a supporting file. The pretrained network enables you to run the entire example without waiting for training to complete.

To train the network, set the `doTraining` variable in the following code to `true`. Train the model in a custom training loop. For each iteration:

- Read the data for the current mini-batch using the `next` function.
- Evaluate the model gradients using the `dlfeval` function and the `modelGradients` helper function.

- Update the network parameters using the `adamupdate` function.
- Display the input and translated images for both the source and target domains after each epoch.

Train on a GPU if one is available. Using a GPU requires Parallel Computing Toolbox™ and a CUDA® enabled NVIDIA® GPU. For more information, see "GPU Support by Release" (Parallel Computing Toolbox). Training takes about 30 hours on an NVIDIA™ Titan X with 24 GB of GPU memory.

```
doTraining = false;
if doTraining

    iteration = 0;
    start = tic;

    % Create a directory to store checkpoints
    checkpointDir = fullfile(dataDir,"checkpoints");
    if ~exist(checkpointDir,"dir")
        mkdir(checkpointDir);
    end

    % Initialize plots for training progress
    [figureHandle,tileHandle,imageAxes,scoreAxesX,scoreAxesY, ...
        lineScoreGenLD2HD,lineScoreGenD2LD, ...
        lineScoreDiscHD,lineScoreDiscLD] = initializeTrainingPlotLD2HDCT;

    for epoch = 1:numEpochs

        shuffle(mbqTrain);

        % Loop over mini-batches
        while hasdata(mbqTrain)
            iteration = iteration + 1;

            % Read mini-batch of data
            [imageLD,imageHD] = next(mbqTrain);

            % Convert mini-batch of data to dlarray and specify the dimension labels
            % "SSCB" (spatial, spatial, channel, batch)
            imageLD = dlarray(imageLD,"SSCB");
            imageHD = dlarray(imageHD,"SSCB");

            % If training on a GPU, then convert data to gpuArray
            if canUseGPU
                imageLD = gpuArray(imageLD);
                imageHD = gpuArray(imageHD);
            end

            % Calculate the loss and gradients

```

```
    load(fullfile(netDir,"trainedLD2HDCTCycleGANNet.mat"));
end
```

Generate New Images Using Test Data

Define the number of test images to use for calculating quality metrics. Randomly select two test images to display.

```
numTest = timdsTestLD.numpartitions;
numImagesToDisplay = 2;
idxImagesToDisplay = randi(numTest,1,numImagesToDisplay);
```

Initialize variables to calculate PSNR and SSIM.

```
origPSNR = zeros(numTest,1);
generatedPSNR = zeros(numTest,1);
origSSIM = zeros(numTest,1);
generatedSSIM = zeros(numTest,1);
```

To generate new translated images, use the `predict` function. Read images from the test data set and use the trained generators to generate new images.

```
for idx = 1:numTest
    imageTestLD = read(timdsTestLD);
    imageTestHD = read(timdsTestHD);

    imageTestLD = cat(4,imageTestLD{1});
    imageTestHD = cat(4,imageTestHD{1});

    % Convert mini-batch of data to dlarray and specify the dimension labels
    % 'SSCB' (spatial, spatial, channel, batch)
    imageTestLD = dlarray(imageTestLD,'SSCB');
    imageTestHD = dlarray(imageTestHD,'SSCB');

    % If running on a GPU, then convert data to gpuArray
    if canUseGPU
        imageTestLD = gpuArray(imageTestLD);
        imageTestHD = gpuArray(imageTestHD);
    end

    % Generate translated images
    generatedImageHD = predict(generatorLowDoseToHighDose,imageTestLD);
    generatedImageLD = predict(generatorHighDoseToLowDose,imageTestHD);

    % Display a few images to visualize the network responses
     if ismember(idx,idxImagesToDisplay)
         figure
         origImLD = rescale(extractdata(imageTestLD));
         genImHD = rescale(extractdata(generatedImageHD));
         montage({origImLD,genImHD},Size=[1 2],BorderSize=5)
         title("Original LDCT Test Image "+idx+" (Left), Generated HDCT Image (Right)")
    end

    origPSNR(idx) = psnr(imageTestLD,imageTestHD);
    generatedPSNR(idx) = psnr(generatedImageHD,imageTestHD);

```

```
Average SSIM of original images: 0.76651
```

```
disp("Average SSIM of generated images: "+mean(generatedSSIM,"all"));
```

```
Average SSIM of generated images: 0.90194
```

Supporting Functions

Model Gradients Function

The function `modelGradients` takes as input the two generator and discriminator `dlnetwork` objects and a mini-batch of input data. The function returns the gradients of the loss with respect to the learnable parameters in the networks and the scores of the four networks. Because the discriminator outputs are not in the range [0, 1], the `modelGradients` function applies the sigmoid function to convert discriminator outputs into probability scores.

```
function [genHD2LDGrad,genLD2HDGrad,discLDGrad,discHDGrad, ...
    genHD2LDState,genLD2HDState,scores,imagesOutLDAndHDGenerated,imagesOutHDAndLDGenerated] = ..
    modelGradients(genLD2HD,genHD2LD,discLD,discHD,imageHD,imageLD,lambda)

% Translate images from one domain to another: low-dose to high-dose and
% vice versa
[imageLDGenerated,genHD2LDState] = forward(genHD2LD,imageHD);
[imageHDGenerated,genLD2HDState] = forward(genLD2HD,imageLD);

% Calculate predictions for real images in each domain by the corresponding
% discriminator networks
predRealLD = forward(discLD,imageLD);
predRealHD = forward(discHD,imageHD);

% Calculate predictions for generated images in each domain by the
% corresponding discriminator networks
predGeneratedLD = forward(discLD,imageLDGenerated);
predGeneratedHD = forward(discHD,imageHDGenerated);

% Calculate discriminator losses for real images
discLDLossReal = lossReal(predRealLD);
discHDLossReal = lossReal(predRealHD);

% Calculate discriminator losses for generated images
discLDLossGenerated = lossGenerated(predGeneratedLD);
discHDLossGenerated = lossGenerated(predGeneratedHD);

% Calculate total discriminator loss for each discriminator network
discLDLossTotal = 0.5*(discLDLossReal + discLDLossGenerated);
discHDLossTotal = 0.5*(discHDLossReal + discHDLossGenerated);

% Calculate generator loss for generated images
genLossHD2LD = lossReal(predGeneratedLD);
```

```
genLossLD2HD = lossReal(predGeneratedHD);

% Complete the round-trip (cycle consistency) outputs by applying the
% generator to each generated image to get the images in the corresponding
% original domains
cycleImageLD2HD2LD = forward(genHD2LD,imageHDGenerated);
cycleImageHD2LD2HD = forward(genLD2HD,imageLDGenerated);

% Calculate cycle consistency loss between real and generated images
cycleLossLD2HD2LD = cycleConsistencyLoss(imageLD,cycleImageLD2HD2LD,lambda);
cycleLossHD2LD2HD = cycleConsistencyLoss(imageHD,cycleImageHD2LD2HD,lambda);

% Calculate identity outputs
identityImageLD = forward(genHD2LD,imageLD);
identityImageHD = forward(genLD2HD,imageHD);

% Calculate fidelity loss (SSIM) between the identity outputs
fidelityLossLD = mean(1-multissim(identityImageLD,imageLD),"all");
fidelityLossHD = mean(1-multissim(identityImageHD,imageHD),"all");

% Calculate total generator loss
genLossTotal = genLossHD2LD + cycleLossHD2LD2HD + ...
    genLossLD2HD + cycleLossLD2HD2LD + fidelityLossLD + fidelityLossHD;

% Calculate scores of generators
genHD2LDScore = mean(sigmoid(predGeneratedLD),"all");
genLD2HDScore = mean(sigmoid(predGeneratedHD),"all");

% Calculate scores of discriminators
discLDScore = 0.5*mean(sigmoid(predRealLD),"all") + ...
    0.5*mean(1-sigmoid(predGeneratedLD),"all");
discHDScore = 0.5*mean(sigmoid(predRealHD),"all") + ...
    0.5*mean(1-sigmoid(predGeneratedHD),"all");

% Combine scores into cell array
scores = {genHD2LDScore,genLD2HDScore,discLDScore,discHDScore};

% Calculate gradients of generators
genLD2HDGrad = dlgradient(genLossTotal,genLD2HD.Learnables,'RetainData',true);
genHD2LDGrad = dlgradient(genLossTotal,genHD2LD.Learnables,'RetainData',true);

% Calculate gradients of discriminators
discLDGrad = dlgradient(discLDLossTotal,discLD.Learnables,'RetainData',true);
discHDGrad = dlgradient(discHDLossTotal,discHD.Learnables);

% Return mini-batch of images transforming low-dose CT into high-dose CT
imagesOutLDAndHDGenerated = {imageLD,imageHDGenerated};

% Return mini-batch of images transforming high-dose CT into low-dose CT
imagesOutHDAndLDGenerated = {imageHD,imageLDGenerated};
end
```

Loss Functions

Specify MSE loss functions for real and generated images.

```
function loss = lossReal(predictions)
    loss = mean((1-predictions).^2,"all");
```

```
end

function loss = lossGenerated(predictions)
    loss = mean((predictions).^2,"all");
end
```

Specify cycle consistency loss functions for real and generated images.

```
function loss = cycleConsistencyLoss(imageReal,imageGenerated,lambda)
    loss = mean(abs(imageReal-imageGenerated),"all") * lambda;
end
```

Unsupervised Medical Image Denoising Using UNIT

This example shows how to generate high-quality computed tomography (CT) images from noisy low-dose CT images using a UNIT neural network.

This example uses an unsupervised image-to-image translation (UNIT) neural network trained on full images from a limited sample of data. For a similar approach using a CycleGAN neural network trained on patches of image data from a large sample of data, see “Unsupervised Medical Image Denoising Using CycleGAN” (Image Processing Toolbox).

X-ray CT is a popular imaging modality used in clinical and industrial applications because it produces high-quality images and offers superior diagnostic capabilities. To protect the safety of patients, clinicians recommend a low radiation dose. However, a low radiation dose results in a lower signal-to-noise ratio (SNR) in the images, and therefore reduces the diagnostic accuracy.

Deep learning techniques offer solutions to improve the image quality for low-dose CT (LDCT) images. Using a generative adversarial network (GAN) for image-to-image translation, you can convert noisy LDCT images to images of the same quality as regular-dose CT images. For this application, the source domain consists of LDCT images and the target domain consists of regular-dose images.

CT image denoising requires a GAN that performs unsupervised training because clinicians do not typically acquire matching pairs of low-dose and regular-dose CT images of the same patient in the same session. This example uses a UNIT architecture that supports unsupervised training. For more information, see “Get Started with GANs for Image-to-Image Translation” (Image Processing Toolbox).

Download LDCT Data Set

This example uses data from the Low Dose CT Grand Challenge [2, 3, 4]. The data includes pairs of regular-dose CT images and simulated low-dose CT images for 99 head scans (labeled N for neuro), 100 chest scans (labeled C for chest), and 100 abdomen scans (labeled L for liver).

Set `dataDir` as the desired location of the data set. The data for this example requires 52 GB of memory.

```
dataDir = fullfile(tempdir,"LDCT","LDCT-and-Projection-data");
```

To download the data, go to the Cancer Imaging Archive website. This example uses ony two patient scans from the chest. Download the chest files "C081" and "C120" from the "Images (DICOM, 952 GB)" data set using the NBIA Data Retriever. Specify the `dataFolder` variable as the location of the downloaded data. When the download is successful, `dataFolder` contains two subfolders named "C081" and "C120".

Create Datastores for Training, Validation, and Testing

Specify the patient scans that are the source of each data set.

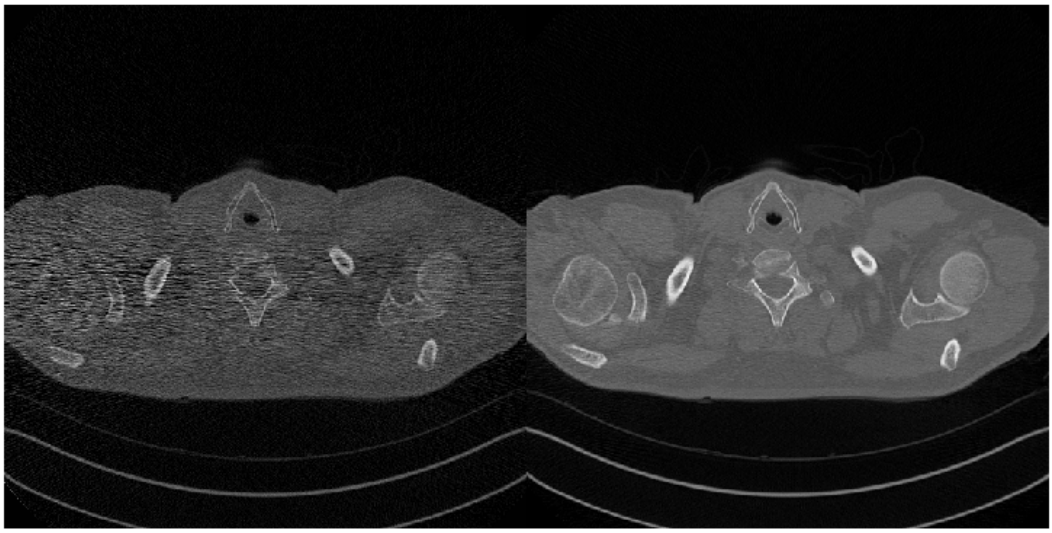
```
scanDirTrain = fullfile(dataDir,"C120","08-30-2018-97899");
scanDirTest = fullfile(dataDir,"C081","08-29-2018-10762");
```

Create `imageDatastore` objects that manage the low-dose and high-dose CT images for training and testing. The data set consists of DICOM images, so use the custom `ReadFcn` name-value argument in `imageDatastore` to enable reading the data.

```
exts = {'.dcm'};
readFcn = @(x)rescale(dicomread(x));
imdsLDTrain = imageDatastore(fullfile(scanDirTrain,"1.000000-Low Dose Images-71581"), ...
    FileExtensions=exts,ReadFcn=readFcn);
imdsHDTrain = imageDatastore(fullfile(scanDirTrain,"1.000000-Full dose images-34601"), ...
    FileExtensions=exts,ReadFcn=readFcn);
imdsLDTest = imageDatastore(fullfile(scanDirTest,"1.000000-Low Dose Images-32837"), ...
    FileExtensions=exts,ReadFcn=readFcn);
imdsHDTest = imageDatastore(fullfile(scanDirTest,"1.000000-Full dose images-95670"), ...
    FileExtensions=exts,ReadFcn=readFcn);
```

Preview a training image from the low-dose and high-dose CT training data sets.

```
lowDose = preview(imdsLDTrain);
highDose = preview(imdsHDTrain);
montage({lowDose,highDose})
```



Preprocess and Augment Training Data

Specify the image input size for the source and target images.

```
inputSize = [256,256,1];
```

Augment and preprocess the training data by using the `transform` function with custom preprocessing operations specified by the `augmentDataForLD2HDCT` helper function. This function is attached to the example as a supporting file.

The `augmentDataForLD2HDCT` function performs these operations:

1. Resize the image to the specified input size using bicubic interpolation.
2. Randomly flip the image in the horizontal direction.

3 Scale the image to the range [-1, 1]. This range matches the range of the final `tanhLayer` used in the generator.

```
imdsLDTrain = transform(imdsLDTrain, @(x)augmentDataForLD2HDCT(x,inputSize));
imdsHDTrain = transform(imdsHDTrain, @(x)augmentDataForLD2HDCT(x,inputSize));
```

The LDCT data set provides pairs of low-dose and high-dose CT images. However, the UNIT architecture requires unpaired data for unsupervised learning. This example simulates unpaired training and validation data by shuffling the data in each iteration of the training loop.

Batch Training and Validation Data During Training

This example uses a custom training loop. The `minibatchqueue` object is useful for managing the mini-batching of observations in custom training loops. The `minibatchqueue` object also casts data to a `dlarray` object that enables auto differentiation in deep learning applications.

Specify the mini-batch data extraction format as `SSCB` (spatial, spatial, channel, batch). Set the `DispatchInBackground` name-value argument as the boolean returned by `canUseGPU`. If a supported GPU is available for computation, then the `minibatchqueue` object preprocesses mini-batches in the background in a parallel pool during training.

```
miniBatchSize = 1;
mbqLDTrain = minibatchqueue(imdsLDTrain,MiniBatchSize=miniBatchSize, ...
    MiniBatchFormat="SSCB",DispatchInBackground=canUseGPU);
mbqHDTrain = minibatchqueue(imdsHDTrain,MiniBatchSize=miniBatchSize, ...
    MiniBatchFormat="SSCB",DispatchInBackground=canUseGPU);
```

Create Generator Network

The UNIT consists of one generator and two discriminators. The generator performs image-to-image translation from low dose to high dose. The discriminators are PatchGAN networks that return the patch-wise probability that the input data is real or generated. One discriminator distinguishes between the real and generated low-dose images and the other discriminator distinguishes between real and generated high-dose images.

Create a UNIT generator network using the `unitGenerator` (Image Processing Toolbox) function. The source and target encoder sections of the generator each consist of two downsampling blocks and five residual blocks. The encoder sections share two of the five residual blocks. Likewise, the source and target decoder sections of the generator each consist of two downsampling blocks and five residual blocks, and the decoder sections share two of the five residual blocks.

```
gen = unitGenerator(inputSize);
```

Visualize the generator network.

```
analyzeNetwork(gen)
```

Create Discriminator Networks

There are two discriminator networks, one for each of the image domains (low-dose CT and high-dose CT). Create the discriminators for the source and target domains using the `patchGANDiscriminator` (Image Processing Toolbox) function.

```
discLD = patchGANDiscriminator(inputSize,NumDownsamplingBlocks=4,FilterSize=3, ...
    ConvolutionWeightsInitializer="narrow-normal",NormalizationLayer="none");
discHD = patchGANDiscriminator(inputSize,"NumDownsamplingBlocks",4,FilterSize=3, ...
    ConvolutionWeightsInitializer="narrow-normal",NormalizationLayer="none");
```

Visualize the discriminator networks.

```
analyzeNetwork(discLD);
analyzeNetwork(discHD);
```

Define Model Gradients and Loss Functions

The `modelGradientDisc` and `modelGradientGen` helper functions calculate the gradients and losses for the discriminators and generator, respectively. These functions are defined in the Supporting Functions on page 9-0 section of this example.

The objective of each discriminator is to correctly distinguish between real images (1) and translated images (0) for images in its domain. Each discriminator has a single loss function.

The objective of the generator is to generate translated images that the discriminators classify as real. The generator loss is a weighted sum of five types of losses: self-reconstruction loss, cycle consistency loss, hidden KL loss, cycle hidden KL loss, and adversarial loss.

Specify the weight factors for the various losses.

```
lossWeights.selfReconLossWeight = 10;
lossWeights.hiddenKLLossWeight = 0.01;
lossWeights.cycleConsisLossWeight = 10;
lossWeights.cycleHiddenKLLossWeight = 0.01;
lossWeights.advLossWeight = 1;
lossWeights.discLossWeight = 0.5;
```

Specify Training Options

Specify the options for Adam optimization. Train the network for 26 epochs.

```
numEpochs = 26;
```

Specify identical options for the generator and discriminator networks.

- Specify a learning rate of 0.0001.
- Initialize the trailing average gradient and trailing average gradient-square decay rates with `[]`.
- Use a gradient decay factor of 0.5 and a squared gradient decay factor of 0.999.
- Use weight decay regularization with a factor of 0.0001.
- Use a mini-batch size of 1 for training.

```
learnRate = 0.0001;
gradDecay = 0.5;
sqGradDecay = 0.999;
weightDecay = 0.0001;

genAvgGradient = [];
genAvgGradientSq = [];
discLDAvgGradient = [];
discLDAvgGradientSq = [];
discHDAvgGradient = [];
discHDAvgGradientSq = [];
```

Train Model or Download Pretrained UNIT Network

By default, the example downloads a pretrained version of the UNIT generator for the NIH-AAPM-Mayo Clinic Low-Dose CT data set by using the helper function

`downloadTrainedLD2HDCTUNITNet`. The helper function is attached to the example as a supporting file. The pretrained network enables you to run the entire example without waiting for training to complete.

To train the network, set the `doTraining` variable in the following code to `true`. Train the model in a custom training loop. For each iteration:

- Read the data for the current mini-batch using the `next` function.
- Evaluate the discriminator model gradients using the `dlfeval` function and the `modelGradientDisc` helper function.
- Update the parameters of the discriminator networks using the `adamupdate` function.
- Evaluate the generator model gradients using the `dlfeval` function and the `modelGradientGen` helper function.
- Update the parameters of the generator network using the `adamupdate` function.
- Display the input and translated images for both the source and target domains after each epoch.

Train on a GPU if one is available. Using a GPU requires Parallel Computing Toolbox™ and a CUDA® enabled NVIDIA® GPU. For more information, see “GPU Support by Release” (Parallel Computing Toolbox). Training takes about 58 hours on an NVIDIA Titan RTX.

```
doTraining = false;
if doTraining

    % Create a figure to show the results
    figure("Units","Normalized");
    for iPlot = 1:4
        ax(iPlot) = subplot(2,2,iPlot);
    end

    iteration = 0;

    % Loop over epochs
    for epoch = 1:numEpochs

        % Shuffle data every epoch
        reset(mbqLDTrain);
        shuffle(mbqLDTrain);
        reset(mbqHDTrain);
        shuffle(mbqHDTrain);

        % Run the loop until all the images in the mini-batch queue
        % mbqLDTrain are processed
        while hasdata(mbqLDTrain)
            iteration = iteration + 1;

            % Read data from the low-dose domain
            imLowDose = next(mbqLDTrain);

            % Read data from the high-dose domain
            if hasdata(mbqHDTrain) == 0
                reset(mbqHDTrain);
                shuffle(mbqHDTrain);
            end
            imHighDose = next(mbqHDTrain);
```

```
            % Calculate discriminator gradients and losses
            [discLDGrads,discHDGrads,discLDLoss,discHDLoss] = dlfeval(@modelGradientDisc, ...
                gen,discLD,discHD,imLowDose,imHighDose,lossWeights.discLossWeight);

            % Apply weight decay regularization on low-dose discriminator gradients
            discLDGrads = dlupdate(@(g,w) g+weightDecay*w,discLDGrads,discLD.Learnables);

            % Update parameters of low-dose discriminator
            [discLD,discLDAvgGradient,discLDAvgGradientSq] = adamupdate(discLD,discLDGrads, ...
                discLDAvgGradient,discLDAvgGradientSq,iteration,learnRate,gradDecay,sqGradDecay)

            % Apply weight decay regularization on high-dose discriminator gradients
            discHDGrads = dlupdate(@(g,w) g+weightDecay*w,discHDGrads,discHD.Learnables);

            % Update parameters of high-dose discriminator
            [discHD,discHDAvgGradient,discHDAvgGradientSq] = adamupdate(discHD,discHDGrads, ...
                discHDAvgGradient,discHDAvgGradientSq,iteration,learnRate,gradDecay,sqGradDecay)

            % Calculate generator gradient and loss
            [genGrad,genLoss,images] = dlfeval(@modelGradientGen,gen,discLD,discHD,imLowDose,imH

            % Apply weight decay regularization on generator gradients
            genGrad = dlupdate(@(g,w) g+weightDecay*w,genGrad,gen.Learnables);

            % Update parameters of generator
            [gen,genAvgGradient,genAvgGradientSq] = adamupdate(gen,genGrad,genAvgGradient, ...
                genAvgGradientSq,iteration,learnRate,gradDecay,sqGradDecay);
        end

        % Display the results
        updateTrainingPlotLowDoseToHighDose(ax,images{:});
    end

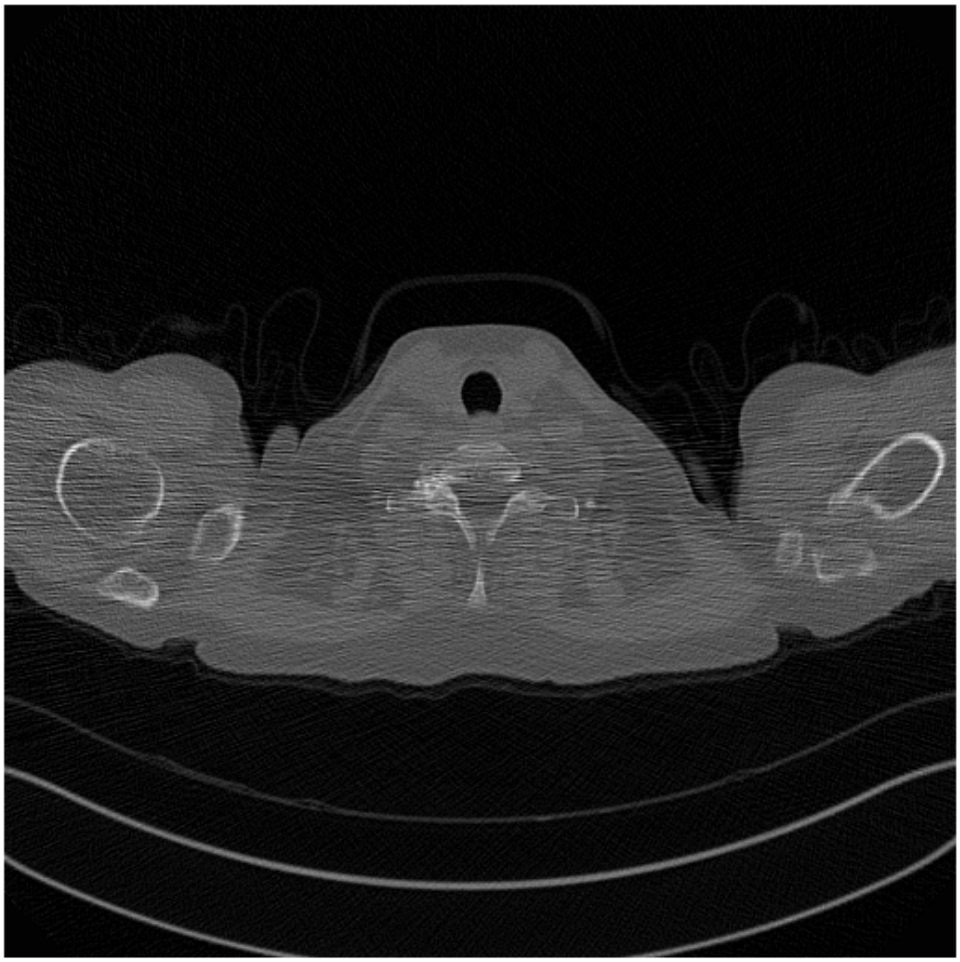
    % Save the trained network
    modelDateTime = string(datetime("now",Format="yyyy-MM-dd-HH-mm-ss"));
    save(strcat("trainedLowDoseHighDoseUNITGeneratorNet-",modelDateTime,"-Epoch-",num2str(numEpo

else
    net_url = "https://ssd.mathworks.com/supportfiles/vision/data/trainedLowDoseHighDoseUNITGene
    downloadTrainedLD2HDCTUNITNet(net_url,dataDir);
    load(fullfile(dataDir,"trainedLowDoseHighDoseUNITGeneratorNet.mat"));
end
```

Generate High-Dose Image Using Trained Network

Read and display an image from the datastore of low-dose test images.

```
idxToTest = 1;
imLowDoseTest = readimage(imdsLDTest,idxToTest);
figure
imshow(imLowDoseTest)
```



Convert the image to data type `single`. Rescale the image data to the range [-1, 1] as expected by the final layer of the generator network.

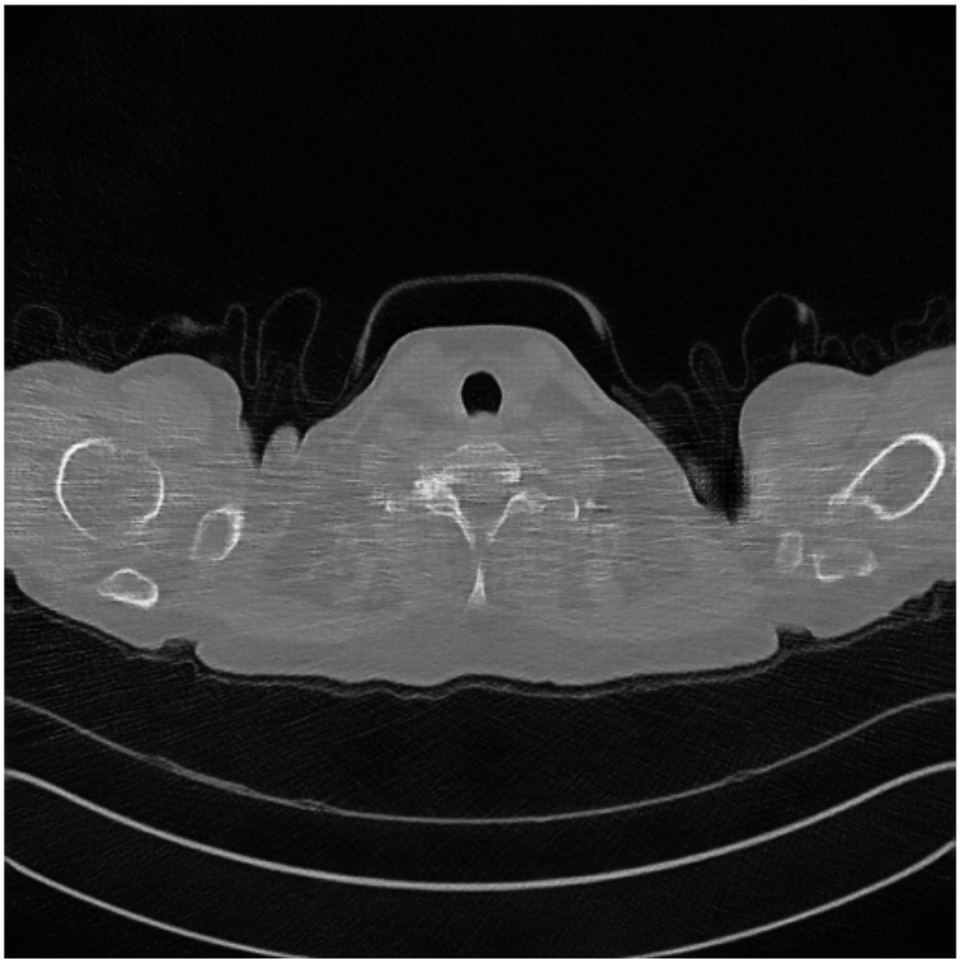
```
imLowDoseTest = im2single(imLowDoseTest);
imLowDoseTestRescaled = (imLowDoseTest-0.5)/0.5;
```

Create a `dlarray` object that inputs data to the generator. If a supported GPU is available for computation, then perform inference on a GPU by converting the data to a `gpuArray` object.

```
dlLowDoseImage = dlarray(imLowDoseTestRescaled,'SSCB');
if canUseGPU
    dlLowDoseImage = gpuArray(dlLowDoseImage);
end
```

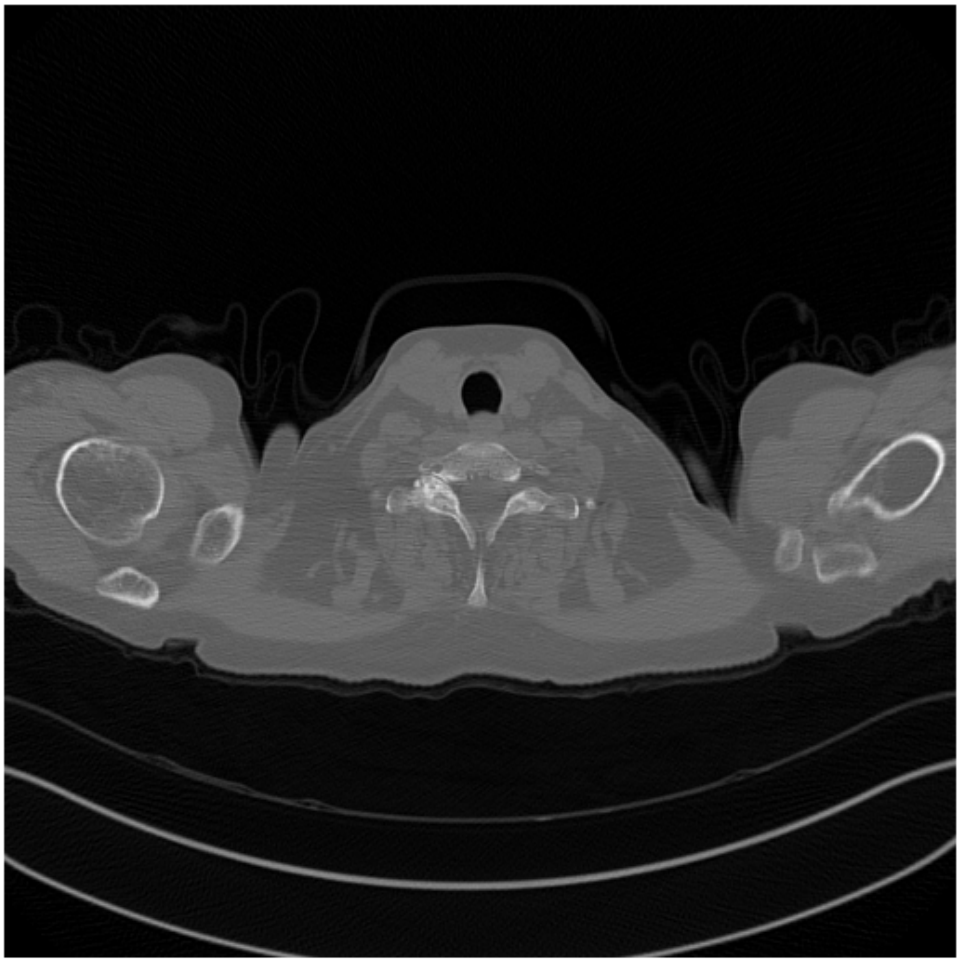
Translate the input low-dose image to the high-dose domain using the `unitPredict` (Image Processing Toolbox) function. The generated image has pixel values in the range [-1, 1]. For display, rescale the activations to the range [0, 1].

```
dlImLowDoseToHighDose = unitPredict(gen,dlLowDoseImage);
imHighDoseGenerated = extractdata(gather(dlImLowDoseToHighDose));
imHighDoseGenerated = rescale(imHighDoseGenerated);
imshow(imHighDoseGenerated)
```



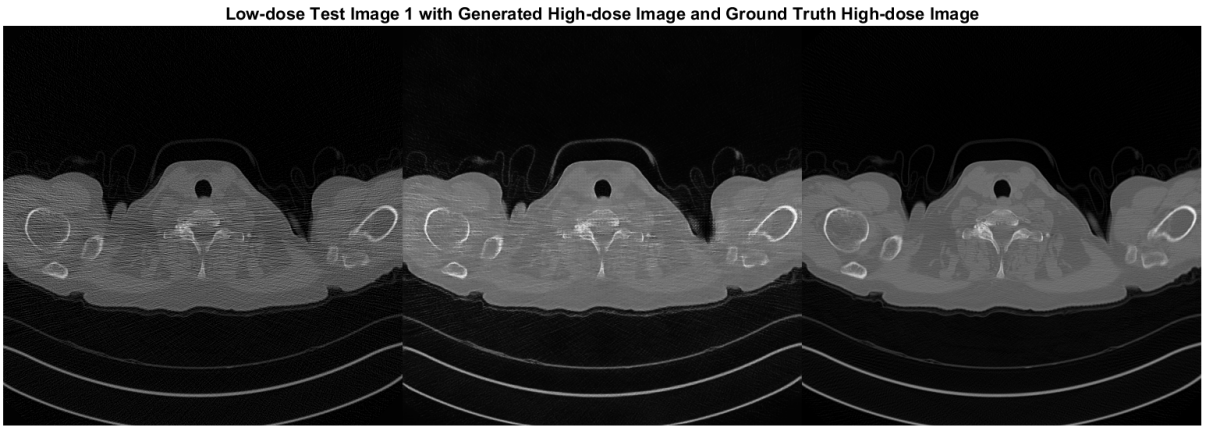
Read and display the ground truth high-dose image. The high-dose and low-dose test datastores are not shuffled, so the ground truth high-dose image corresponds directly to the low-dose test image.

```
imHighDoseGroundTruth = readimage(imdsHDTest,idxToTest);
imshow(imHighDoseGroundTruth)
```



Display the input low-dose CT, the generated high-dose version, and the ground truth high-dose image in a montage. Although the network is trained on data from a single patient scan, the network generalizes well to test images from other patient scans.

```
imshow([imLowDoseTest imHighDoseGenerated imHighDoseGroundTruth])
title(['Low-dose Test Image ',num2str(idxToTest),' with Generated High-dose Image and Ground Tru
```



Supporting Functions

Model Gradients Function

The `modelGradientGen` helper function calculates the gradients and loss for the generator.

```
function [genGrad,genLoss,images] = modelGradientGen(gen,discLD,discHD,imLD,imHD,lossWeights)

    [imLD2LD,imHD2LD,imLD2HD,imHD2HD] = forward(gen,imLD,imHD);
    hidden = forward(gen,imLD,imHD,Outputs="encoderSharedBlock");

    [~,imLD2HD2LD,imHD2LD2HD,~] = forward(gen,imHD2LD,imLD2HD);
    cycle_hidden = forward(gen,imHD2LD,imLD2HD,Outputs="encoderSharedBlock");

    % Calculate different losses
    selfReconLoss = computeReconLoss(imLD,imLD2LD) + computeReconLoss(imHD,imHD2HD);
    hiddenKLLoss = computeKLLoss(hidden);
    cycleReconLoss = computeReconLoss(imLD,imLD2HD2LD) + computeReconLoss(imHD,imHD2LD2HD);
    cycleHiddenKLLoss = computeKLLoss(cycle_hidden);

    outA = forward(discLD,imHD2LD);
    outB = forward(discHD,imLD2HD);
    advLoss = computeAdvLoss(outA) + computeAdvLoss(outB);

    % Calculate the total loss of generator as a weighted sum of five losses
    genTotalLoss = ...
        selfReconLoss*lossWeights.selfReconLossWeight + ...
        hiddenKLLoss*lossWeights.hiddenKLLossWeight + ...
        cycleReconLoss*lossWeights.cycleConsisLossWeight + ...
        cycleHiddenKLLoss*lossWeights.cycleHiddenKLLossWeight + ...
        advLoss*lossWeights.advLossWeight;

    % Update the parameters of generator
    genGrad = dlgradient(genTotalLoss,gen.Learnables);

    % Convert the data type from dlarray to single
    genLoss = extractdata(genTotalLoss);
    images = {imLD,imLD2HD,imHD,imHD2LD};
end
```

The `modelGradientDisc` helper function calculates the gradients and loss for the two discriminators.

```
function [discLDGrads,discHDGrads,discLDLoss,discHDLoss] = modelGradientDisc(gen, ...
    discLD,discHD,imRealLD,imRealHD,discLossWeight)

    [~,imFakeLD,imFakeHD,~] = forward(gen,imRealLD,imRealHD);

    % Calculate loss of the discriminator for low-dose images
    outRealLD = forward(discLD,imRealLD);
    outFakeLD = forward(discLD,imFakeLD);
    discLDLoss = discLossWeight*computeDiscLoss(outRealLD,outFakeLD);

    % Update parameters of the discriminator for low-dose images
    discLDGrads = dlgradient(discLDLoss,discLD.Learnables);

    % Calculate loss of the discriminator for high-dose images
    outRealHD = forward(discHD,imRealHD);
    outFakeHD = forward(discHD,imFakeHD);
    discHDLoss = discLossWeight*computeDiscLoss(outRealHD,outFakeHD);

    % Update parameters of the discriminator for high-dose images
    discHDGrads = dlgradient(discHDLoss,discHD.Learnables);

    % Convert the data type from dlarray to single
    discLDLoss = extractdata(discLDLoss);
    discHDLoss = extractdata(discHDLoss);
end
```

Loss Functions

The `computeDiscLoss` helper function calculates discriminator loss. Each discriminator loss is a sum of two components:

- The squared difference between a vector of ones and the predictions of the discriminator on real images, Y_{real}
- The squared difference between a vector of zeros and the predictions of the discriminator on generated images, $\widehat{Y}_{translated}$

$$discriminatorLoss = (1 - Y_{real})^2 + \left(0 - \widehat{Y}_{translated}\right)^2$$

```
function discLoss = computeDiscLoss(Yreal,Ytranslated)
    discLoss = mean(((1-Yreal).^2),"all") + ...
               mean(((0-Ytranslated).^2),"all");
end
```

The `computeAdvLoss` helper function calculates adversarial loss for the generator. Adversarial loss is the squared difference between a vector of ones and the discriminator predictions on the translated image.

$$adversarialLoss = \left(1 - \widehat{Y}_{translated}\right)^2$$

```
function advLoss = computeAdvLoss(Ytranslated)
    advLoss = mean(((Ytranslated-1).^2),"all");
end
```

The `computeReconLoss` helper function calculates self-reconstruction loss and cycle consistency loss for the generator. Self reconstruction loss is the L^1 distance between the input images and their self-reconstructed versions. Cycle consistency loss is the L^1 distance between the input images and their cycle-reconstructed versions.

$$selfReconstructionLoss = \left\|\left(Y_{real} - Y_{self-reconstructed}\right)\right\|_1$$

$$cycleConsistencyLoss = \left\|\left(Y_{real} - Y_{cycle-reconstructed}\right)\right\|_1$$

```
function reconLoss = computeReconLoss(Yreal,Yrecon)
    reconLoss = mean(abs(Yreal-Yrecon),"all");
end
```

The `computeKLLoss` helper function calculates hidden KL loss and cycle-hidden KL loss for the generator. Hidden KL loss is the squared difference between a vector of zeros and the '`encoderSharedBlock`' activation for the self-reconstruction stream. Cycle-hidden KL loss is the squared difference between a vector of zeros and the '`encoderSharedBlock`' activation for the cycle-reconstruction stream.

$$hiddenKLLoss = (0 - Y_{encoderSharedBlockActivation})^2$$

$$cycleHiddenKLLoss = (0 - Y_{encoderSharedBlockActivation})^2$$

```
function klLoss = computeKLLoss(hidden)
    klLoss = mean(abs(hidden.^2),"all");
end
```

Detect Image Anomalies Using Explainable One-Class Classification Neural Network

This example shows how to detect and localize anomalies such as cracks in concrete using explainable single-class classification.

In one-class approaches to anomaly detection, training is semi-supervised, meaning that the network trains on data consisting only of examples of images without anomalies [1 on page 9-0]. Despite training on samples only of normal scenes, the model learns how to distinguish between normal and anamalous scenes. One-class learning offers many advantages for anomaly detection problems:

1. Representations of anomalies can be scarce.
2. Anomalies can represent expensive or catastophic outcomes.
3. There can be many kinds of anomalies, and the kinds of anomalies can change over the lifetime of the model. Describing what "good" looks like than is often more feasable than providing data that represents all posssible anomalies in real world settings.

A crucial part of anomaly detection is for a human observer to be able to understand why a trained network classifies images as anomalies. Explainable classification supplements the class prediction with information that justifies how the neural network reached its classification decision.

This example explores how one-class deep learning can be used to create accurate anomaly detection classifiers. The example also implements explainable classification using a network that returns a heatmap with the probability that each pixel is anomalous.

Download Concrete Crack Images for Classification Data Set

This example works with the Concrete Crack Images for Classification data set. The data set contains images of two classes: `Negative` images without cracks present in the road and `Positive` images with cracks. The data set provides 20,000 images of each class. The size of the data set is 235 MB.

Set `dataDir` as the desired location of the data set.

```
dataDir = fullfile(tempdir,"ConcreteCracks");
if ~exist(dataDir,"dir")
    mkdir(dataDir);
end
```

To download the data set, go to this link: https://md-datasets-cache-zipfiles-prod.s3.eu-west-1.amazonaws.com/5y9wdsg2zt-2.zip. Extract the ZIP file to obtain a RAR file, then extract the contents of the RAR file into the directory specified by the `dataDir` variable. When extracted successfully, `dataDir` contains two subdirectories: `Negative` and `Positive`.

Load and Preprocess Data

Create an `imageDatastore` that reads and manages the image data. Label each image as `Positive` or `Negative` according to the name of its directory.

```
imdsP = imageDatastore(fullfile(dataDir,"Positive"),LabelSource="foldernames");
imdsN = imageDatastore(fullfile(dataDir,"Negative"),LabelSource="foldernames");
```

Display an example of each class. Display a negative, or good, image without crack anomalies on the left. In the good image, imperfections and deviations in texture are small. Display a positive, or anomalous, image on the right. The anomalous image shows a large black crack oriented vertically.

```
samplePositive = preview(imdsP);
sampleNegative = preview(imdsN);
montage({sampleNegative,samplePositive})
title("Road Images Without (Left) and With (Right) Crack Anomalies")
```

Partition Data into Training, Validation, and Test Sets

To simulate a more typical semi-supervised workflow, create a training set of only 250 good images. Include a small collection of anomalous training images to provide better classification results. Create a balanced test set using 1000 images from each class. Create a balanced validation set using 100 images of each class.

```
numTrainNormal = 250;
numTrainAnomaly = 10;
numTest = 1000;
numVal = 100;

[dsTrainPos,dsTestPos,dsValPos,~] = splitEachLabel(imdsP,numTrainAnomaly,numTest,numVal);
[dsTrainNeg,dsTestNeg,dsValNeg,~] = splitEachLabel(imdsN,numTrainNormal,numTest,numVal);

dsTrain = imageDatastore(cat(1,dsTrainPos.Files,dsTrainNeg.Files),LabelSource="foldernames");
dsTest = imageDatastore(cat(1,dsTestPos.Files,dsTestNeg.Files),LabelSource="foldernames");
dsVal = imageDatastore(cat(1,dsValPos.Files,dsValNeg.Files),LabelSource="foldernames");
```

Define an anonymous function, `addLabelFcn`, that creates a one-hot encoded representation of label information from an input image. Then, transform the datastores using the `transform` function such that the datastores return a cell array of image data and corresponding one-hot encoded array. The `transform` function applies the operations specified by the anonymous `addLabelFcn` function.

```
addLabelFcn = @(x,info) deal({x,onehotencode(info.Label,1)},info);
dsTrain = transform(dsTrain,addLabelFcn,IncludeInfo=true);
```

```
dsVal = transform(dsVal,addLabelFcn,IncludeInfo=true);
dsTest = transform(dsTest,addLabelFcn,IncludeInfo=true);
```

Augment Training Data

Augment the training data by using the `transform` function with custom preprocessing operations specified by the helper function `augmentDataForConcreteClassification`. The helper function is attached to the example as a supporting file.

The `augmentDataForConcreteClassification` function randomly applies 90 degree rotation and horizontal and vertical reflection to each input image.

```
dsTrain = transform(dsTrain,@augmentDataForConcreteClassification);
```

Batch Training Data

Create a `minibatchqueue` object that manages the mini-batching of observations in a custom training loop. The `minibatchqueue` object also casts data to a `dlarray` object that enables automatic differentiation in deep learning applications.

Specify the mini-batch data extraction format as `"SSCB"` (spatial, spatial, channel, batch). Set the `DispatchInBackground` name-value argument as the boolean returned by `canUseGPU`. If a supported GPU is available for computation, then the `minibatchqueue` object preprocesses mini-batches in the background in a parallel pool during training.

```
mbSize = 128;
mbqTrain = minibatchqueue(dsTrain,PartialMiniBatch="discard", ...
    MiniBatchFormat=["SSCB","CB"],MiniBatchSize=mbSize);

mbqVal = minibatchqueue(dsVal,MiniBatchFormat=["SSCB","CB"],MiniBatchSize=mbSize);
```

Calculate Training Set Statistics for Input Normalization

Calculate the per-channel mean of the training images for use in zero-mean normalization.

```
queue = copy(mbqTrain);
queue.PartialMiniBatch = "return";

X = next(queue);
sumImg = sum(X,4);

while hasdata(queue)
    X = next(queue);
    sumImg = sumImg + sum(X,4);
end
trainSetMean = sumImg ./ dsTrain.numpartitions;
trainSetMean = mean(trainSetMean,[1 2]);
```

Create FCDD Model

This example uses a fully convolutional data description (FCDD) model [1 on page 9-0]. The basic idea of FCDD is to train a network to produce a heatmap from an input image.

This example uses a VGG-16 network [3 on page 9-0] trained on ImageNet [4 on page 9-0] as the base fully convolutional network architecture. The example freezes the majority of the model and randomly initializes and trains the final convolutional stages. This approach enables quick training with small amounts of input training data.

The `vgg16` function returns a pretrained VGG-16 network. This function requires the Deep Learning Toolbox™ Model *for VGG-16 Network* support package. If this support package is not installed, then the function provides a download link.

```
pretrainedVGG = vgg16;
```

Freeze the first 24 layers of the network by setting the weights and bias to `0`.

```
numLayersToFreeze = 24;
net = pretrainedVGG.Layers(1:numLayersToFreeze);
for idx = 1:numLayersToFreeze
    if isprop(net(idx),"Weights")
        net(idx) = setLearnRateFactor(net(idx),Weights=0);
        net(idx) = setLearnRateFactor(net(idx),Bias=0);
    end
end
```

Add a final convolutional stage. This stage is similar to the next convolutional stage of VGG-16 but with randomly initialized and trainable convolutional layers and with batch normalization. A final 1-by-1 convolution compresses the network output into a one-channel heatmap. The final layer is a Pseudo-Huber loss function used to stabilize training with the FCDD loss [1 on page 9-0] [2 on page 9-0].

```
finalLayers = [
    convolution2dLayer(3,512,Padding="same")
    batchNormalizationLayer
    reluLayer
    convolution2dLayer(3,512,Padding="same")
    batchNormalizationLayer
    reluLayer
    convolution2dLayer(1,1)
    functionLayer(@(x)sqrt(x.^2+1)-1,Name="pseudoHuber")];
```

Assemble the complete network.

```
net = dlnetwork([net;finalLayers]);
lgraph = layerGraph(net);
```

Replace the image input layer in the encoder with a new input layer that performs zero-center normalization using the computed mean. Set the input size of the network equal to the size of the images in the data set.

```
inputSize = size(sampleNegative);
newInputLayer = imageInputLayer(inputSize,Normalization="zerocenter", ...
    Mean=extractdata(trainSetMean),Name="inputLayer");
lgraph = replaceLayer(lgraph,lgraph.Layers(1).Name,newInputLayer);
```

Specify Training Options

Specify the training options for Adam optimization. Train the network for 70 epochs.

```
learnRate = 1e-4;
averageGrad = [];
averageSqGrad = [];
numEpochs = 70;
```

Train Network or Download Pretrained Network

By default, this example downloads a pretrained version of the VGG-16 network using the helper function `downloadTrainedConcreteClassificationNet`. The pretrained network can be used to run the entire example without waiting for training to complete.

To train the network, set the `doTraining` variable in the following code to `true`. Train the model in a custom training loop. For each iteration:

- Read the data for the current mini-batch using the `next` function.
- Evaluate the model gradients using the `dlfeval` function and the `modelGradients` helper function. This function is defined at the end of this example.
- Update the network parameters using the `adamupdate` function.
- Update a plot of the loss.

Train on one or more GPUs, if available. Using a GPU requires Parallel Computing Toolbox™ and a CUDA® enabled NVIDIA® GPU. For more information, see “GPU Support by Release” (Parallel Computing Toolbox). Training takes about 7 minutes on an NVIDIA™ Titan X.

```
doTraining = false;
if doTraining

    [hFig,batchLine] = initializeTrainingPlotConcreteClassification;
    start = tic;

    iteration = 0;
    for epoch = 1:numEpochs
        reset(mbqTrain);
        shuffle(mbqTrain);

        while hasdata(mbqTrain)
            [X,T] = next(mbqTrain);
            [grad,loss,state] = dlfeval(@modelGradients,net,X,T);

            iteration = iteration + 1;

            [net,averageGrad,averageSqGrad] = adamupdate(net, ...
                grad,averageGrad,averageSqGrad,iteration,learnRate);

            net.State = state;

            % Update the plot
            updateTrainingPlotConcreteClassification(batchLine,iteration,loss,start,epoch);
        end
    end
else
    trainedConcreteClassificationNet_url = 'https://www.mathworks.com/supportfiles/vision/data/t
    downloadTrainedConcreteClassificationNet(trainedConcreteClassificationNet_url,dataDir);
    load(fullfile(dataDir,"trainedAnomalyDetectionNet.mat"));
end
```

Create Classification Model

Classify an image as good or anomalous using the anomaly heatmap predicted by the network in two steps. First, create a classifier that returns the probability that an image has an anomaly based on the

heatmap predicted by the trained network. Then, you can assign a class label to test images based on the probability returned by the classifier.

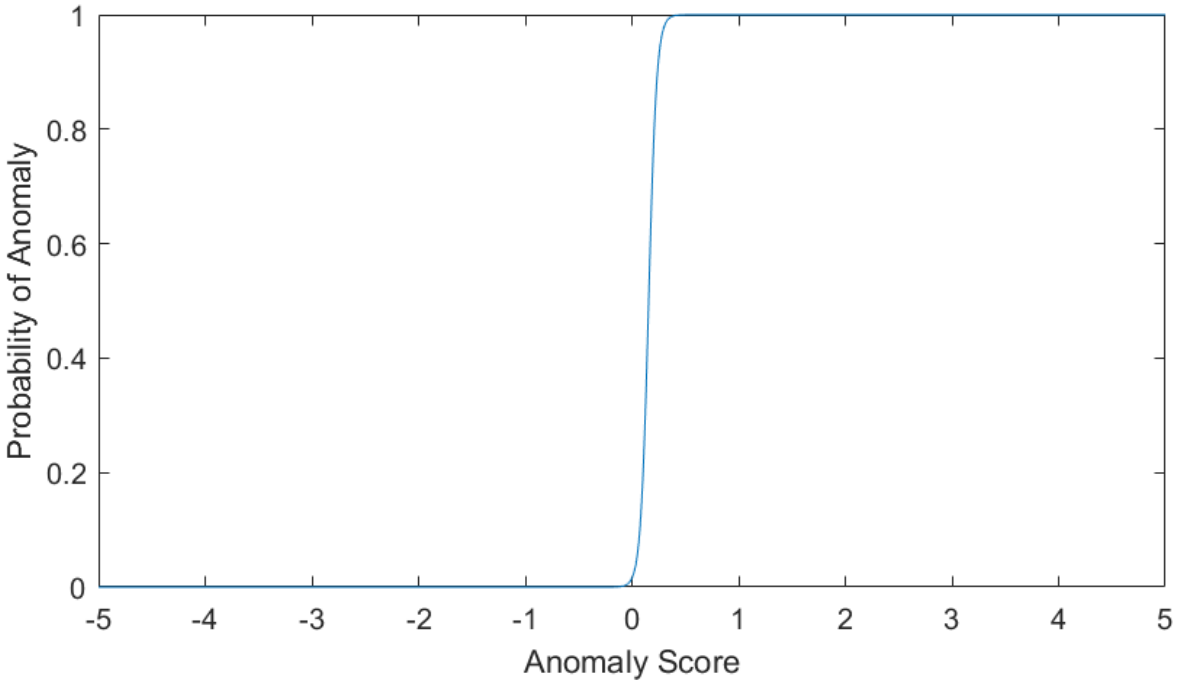
Calculate the mean anomaly score and the known ground truth label (`Positive` or `Negative`) for each image in the validation set. This example chooses the anomaly score threshold using the validation set to avoid leaking information from the test set into the design of the classifier.

```
reset(mbqVal);

scores = zeros(dsVal.numpartitions,1);
labels = zeros(dsVal.numpartitions,1);
idx = 1;
while hasdata(mbqVal)
    [X,T] = next(mbqVal);
    batchSize = size(X,4);
    Y = predict(net,X);
    Y = mean(Y,[1 2]);
    T = onehotdecode(T,[0 1],1,"double");
    scores(idx:idx+batchSize-1) = Y;
    labels(idx:idx+batchSize-1) = T;
    idx = idx+batchSize;
end
```

Fit a sigmoid to the anomaly scores and associated class labels. The resulting anonymous function, `anomalyProbability`, takes an input anomaly score predicted by the network and returns a probability that the score describes an anomaly. Outputs from `anomalyProbability` greater than 0.5 are considered anomalies.

```
coeff = glmfit(scores,labels,"binomial","link","logit");
sigmoid = @(x) 1./(1+exp(-x));
anomalyProbability = @(x) sigmoid(coeff(2).*x + coeff(1));
fplot(anomalyProbability)
xlabel("Anomaly Score")
ylabel("Probability of Anomaly")
```



The default sigmoid has a value of 0.5 at a score of 0. Calculate the anomaly score at which the fitted sigmoid defined by the `anomalyProbability` function has a value of 0.5.

```
threshold = -coeff(1)/coeff(2)
```

```
threshold = 0.1567
```

Evaluate Classification Model

Predict the anomaly heatmap and calculate the mean anomaly score for each image in the test set. Also get the ground truth labels of each test image.

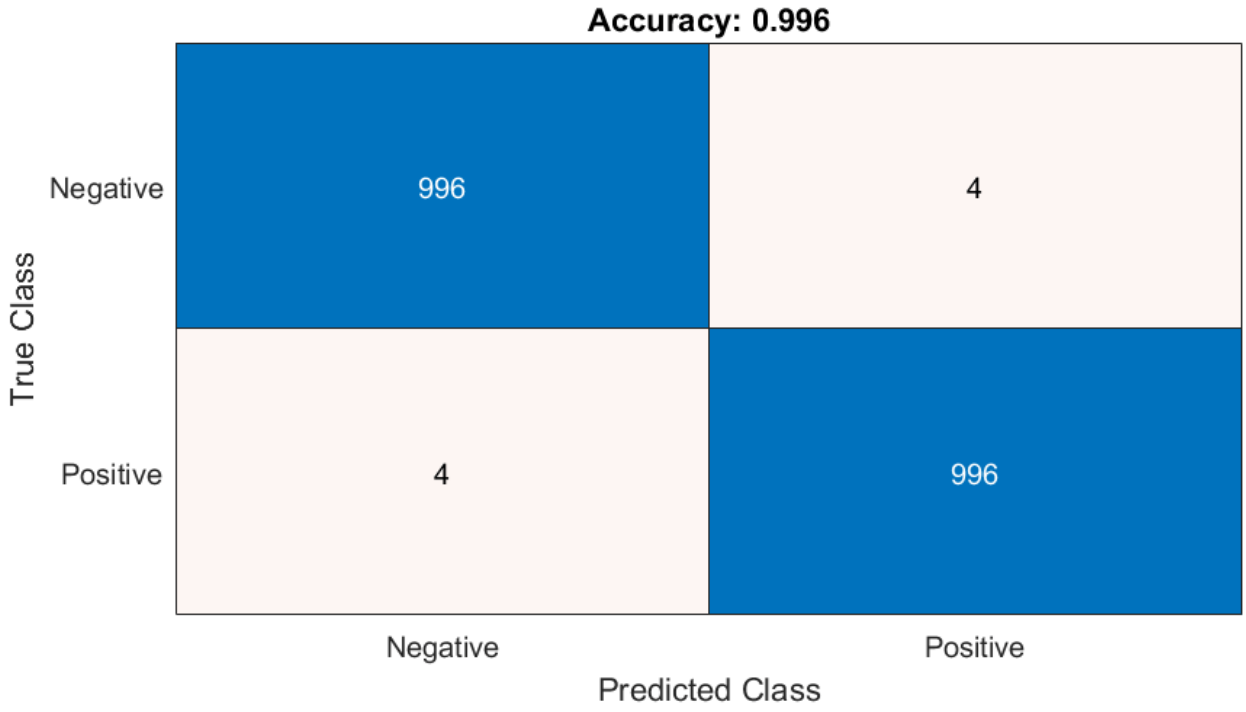
```
q = minibatchqueue(dsTest,MiniBatchSize=64,MiniBatchFormat=["SSCB","CB"]);
scores = zeros(dsTest.numpartitions,1);
labels = zeros(dsTest.numpartitions,1);
idx = 1;
while hasdata(q)
    [X,T] = next(q);
    batchSize = size(X,4);
    Y = predict(net,X);
    Y = mean(Y,[1 2]);
    T = onehotdecode(T,[0 1],1,"double");
    scores(idx:idx+batchSize-1) = Y;
    labels(idx:idx+batchSize-1) = T;
    idx = idx+batchSize;
end
```

Predict class labels for the test set using the classification model defined by the `anomalyProbability` function.

```
predictedLabels = anomalyProbability(scores) > 0.5;
```

Calculate the confusion matrix and the classification accuracy for the test set. The classification model in this example is very accurate and predicts a small percentage of false positives and false negatives.

```
targetLabels = logical(labels);
M = confusionmat(targetLabels,predictedLabels);
confusionchart(M,["Negative","Positive"])
acc = sum(diag(M)) / sum(M,'all');
title(sprintf("Accuracy: %g",acc));
```



Explain Classification Decisions

View Heatmap of Anomaly

Select and display an image of a correctly classified anomaly. This result is a true positive classification.

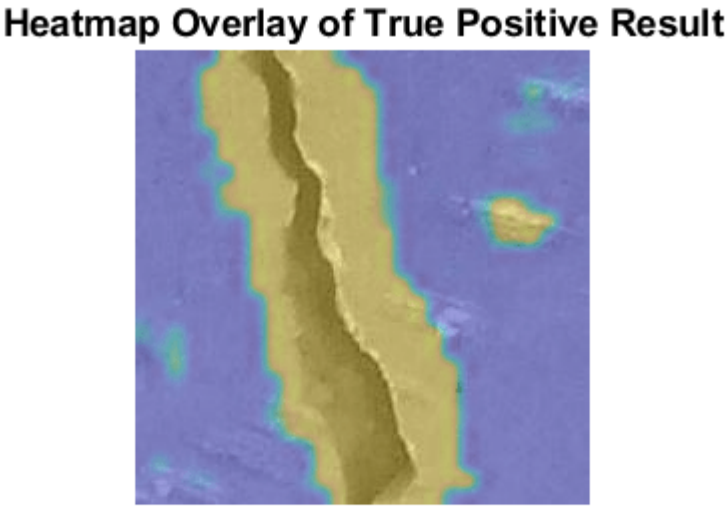
```
idxTruePositive = find(targetLabels & predictedLabels,1);
dsExample = subset(dsTest,idxTruePositive);
dataTP = preview(dsExample);
imgTP = dataTP{1};
imshow(imgTP)
title("True Positive Test Image")
```

Obtain a heatmap of an anomaly image by calling the `predict` function on the trained network. The network returns a heatmap with a smaller size than the input image, so resize the heatmap to the size of the input image.

```
hmapTP = predict(net,gpuArray(dlarray(single(imgTP),"SSCB")));
hmapTP = gather(extractdata(hmapTP));
hmapTP = anomalyProbability(hmapTP);
hmapTP = imresize(hmapTP,OutputSize=size(imgTP,[1 2]));
```

Display an overlay of a colored heatmap on a grayscale representation of the color image using the `heatmapOverlay` helper function. This function is defined at the end of the example. Adjust the opacity of the overlaid heatmap by setting `alpha` to a number in the range [0, 1]. For a fully opaque heatmap, specify `alpha` as `1`. For a fully transparent heatmap, specify `alpha` as `0`.

```
alpha = 0.4;
imshow(heatmapOverlay(imgTP,hmapTP,alpha))
title("Heatmap Overlay of True Positive Result")
```



To quantitatively confirm the result, display the mean heatmap anomaly score of the true positive test image as predicted by the network.

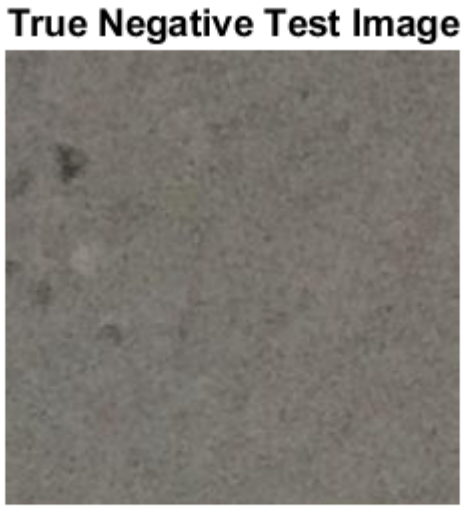
```
disp("Mean heatmap anomaly score of test image: "+scores(idxTruePositive(1)))
```

```
Mean heatmap anomaly score of test image: 1.2185
```

View Heatmap of Normal Image

Select and display an image of a correctly classified normal image. This result is a true negative classification.

```
idxTrueNegative = find(~targetLabels & ~predictedLabels);
dsTestTN = subset(dsTest,idxTrueNegative);
dataTN = read(dsTestTN);
imgTN = dataTN{1};
imshow(imgTN)
title("True Negative Test Image")
```

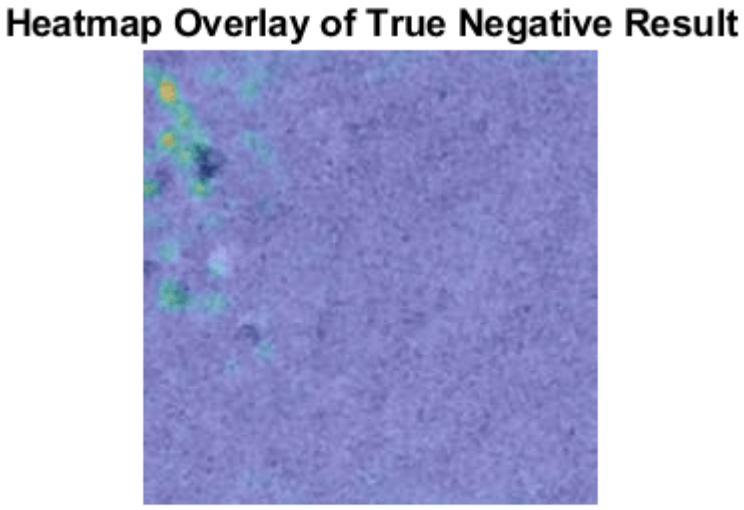


Obtain a heatmap of the correctly predicted negative image by calling the `predict` function on the trained network. Resize the heatmap to the size of the input image.

```
hmapTN = predict(net,gpuArray(dlarray(single(imgTN),"SSCB")));
hmapTN = gather(extractdata(hmapTN));
hmapTN = anomalyProbability(hmapTN);
hmapTN = imresize(hmapTN,OutputSize=size(imgTN,[1 2]));
```

Display an overlay of a colored heatmap on a grayscale representation of the color image using the `heatmapOverlay` helper function. This function is defined at the end of the example. Many true negative test images, such as this test image, either have small anomaly scores across the entire image or large anomaly scores in a localized portion of the image.

```
imshow(heatmapOverlay(imgTN,hmapTN,alpha))
title("Heatmap Overlay of True Negative Result")
```



Display the mean heatmap anomaly score of the true negative test image as predicted by the network.

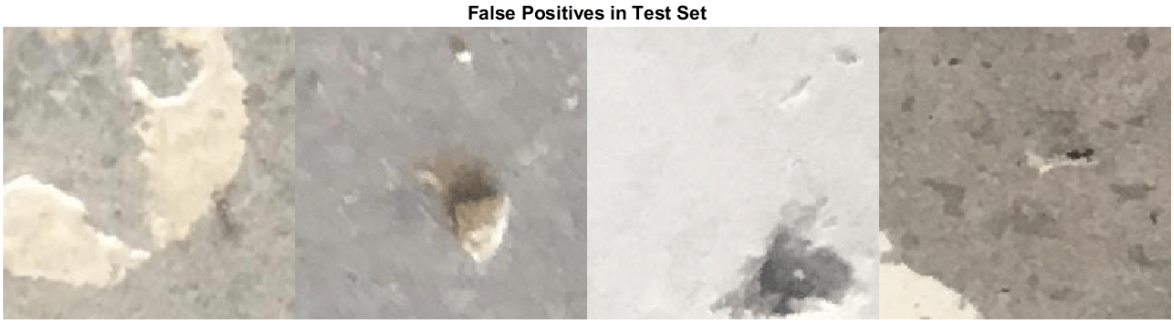
```
disp("Mean heatmap anomaly score of test image: "+scores(idxTrueNegative(1)))
```

```
Mean heatmap anomaly score of test image: 0.0022878
```

Visualize False Positives

False positives are images without crack anomalies that the network classifies as anomalous. Display any false positive images from the test set in a montage.

```
falsePositiveIdx = find(predictedLabels & ~targetLabels);
dataFP = readall(subset(dsTest,falsePositiveIdx));
numFP = length(falsePositiveIdx);
if numFP>0
    montage(dataFP(:,1),Size=[1,numFP]);
    title("False Positives in Test Set")
end
```



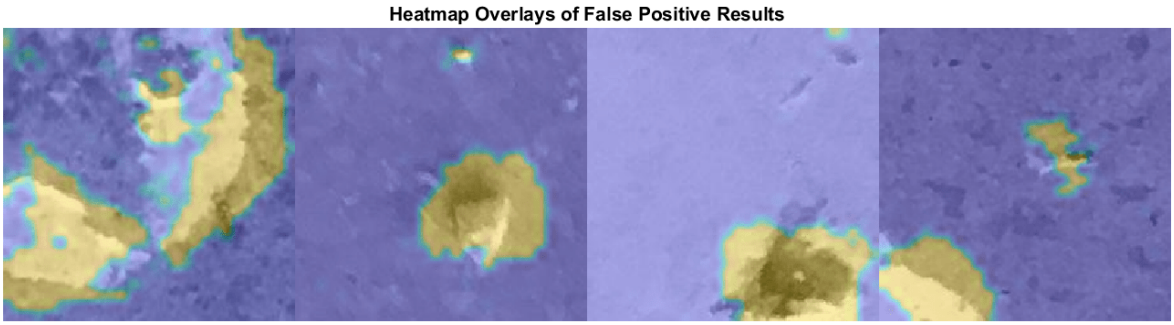
Use the explanation from the network to gain insights into the misclassifications.

Calculate the heatmap overlays.

```
hmapOverlay = cell(1,numFP);
for idx = 1:numFP
    img = dataFP{idx,1};
    map = predict(net,gpuArray(dlarray(single(img),"SSCB")));
    map = gather(extractdata(map));
    mapProb = anomalyProbability(map);
    hmap = imresize(mapProb,OutputSize=size(img,[1 2]));
    hmapOverlay{idx} = heatmapOverlay(img,hmap,alpha);
end
```

The false positive images show features such as rocks that have similar visual characteristics to cracks. In all cases, these are hard classification problems in which the explainable nature of the network architecture is useful for gaining insights.

```
if numFP>0
    montage(hmapOverlay,Size=[1,numFP])
    title("Heatmap Overlays of False Positive Results")
end
```



Display the mean anomaly heatmap scores of the false positive test images as predicted by the network. The mean scores are larger than the threshold used by the classification model, resulting in misclassifications.

```
disp("Mean heatmap anomaly scores:"); scores(falsePositiveIdx)
```

```
Mean heatmap anomaly scores:

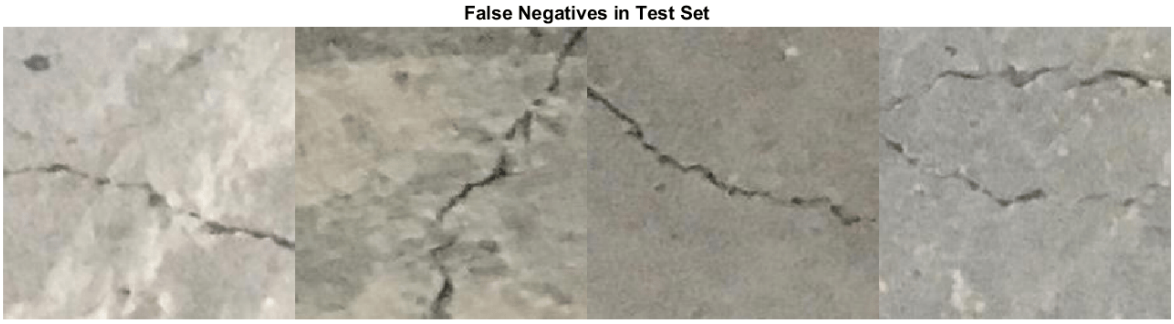
ans = 4×1

    0.3218
    0.1700
    0.2516
    0.1862
```

Visualize False Negatives

False negatives are images with anomalies that the network classifies as good. Display any false negative images from the test set in a montage. The false negative images show relatively thin visible cracks.

```
falseNegativeIdx = find(~predictedLabels & targetLabels);
dataFN = readall(subset(dsTest,falseNegativeIdx));
numFN = length(falseNegativeIdx);
if numFN>0
    montage(dataFN(:,1),Size=[1,numFN])
    title("False Negatives in Test Set")
end
```



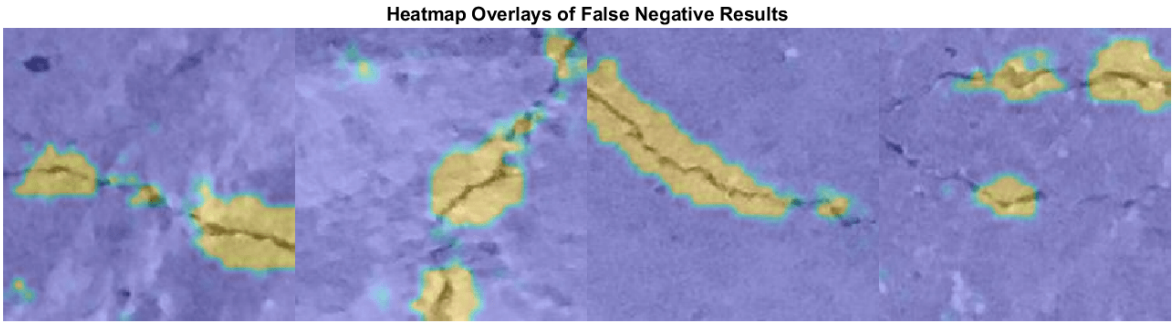
Calculate the heatmap overlays.

```
hmapOverlay = cell(1,numFN);
for idx = 1:numFN
    img = dataFN{idx,1};
    map = predict(net,gpuArray(dlarray(single(img),"SSCB")));
    map = gather(extractdata(map));
    mapProb = anomalyProbability(map);
    hmap = imresize(mapProb,OutputSize=size(img,[1 2]));
    hmapOverlay{idx} = heatmapOverlay(img,hmap,alpha);
end
```

Display the heatmap overlays. The network assigns a large anomaly score along cracks, as expected.

```
if numFN>0
    montage(hmapOverlay,Size=[1,numFN])
```

```
    title("Heatmap Overlays of False Negative Results")
end
```



Display the mean heatmap anomaly scores of the negative positive test images as predicted by the network. The mean scores are smaller than the threshold used by the sigmoid classification model, resulting in misclassifications.

```
disp("Mean heatmap anomaly scores:"); scores(falseNegativeIdx)
```

```
Mean heatmap anomaly scores:

ans = 4×1

    0.1477
    0.1186
    0.1241
    0.0920
```

Supporting Functions

The `modelGradients` helper function calculates the gradients and loss for the network.

```
function [grad,loss,state] = modelGradients(net,X,T)
    [Y,state] = forward(net,X);
    loss = fcddLoss(Y,T);
    grad = dlgradient(loss,net.Learnables);
end
```

The `fcddLoss` helper function calculates the FDCC loss.

```
function loss = fcddLoss(Y,T)
    normalTerm = mean(Y,[1 2 3]);
    anomalyTerm = log(1-exp(-normalTerm));

    isNegative = T(1,:) == 1;
    loss = mean(single(isNegative) .* normalTerm-single(~isNegative) .* anomalyTerm);
end
```

The `heatmapOverlay` helper function overlays a colored heatmap `hmap` on a grayscale representation of the image `img`. Adjust the transparency of the heatmap overlay by specifying the `alpha` argument as a number in the range [0, 1].

```
function out = heatmapOverlay(img,hmap,alpha)

    % Normalize to the range [0, 1]
    img = mat2gray(img);
    hmap = mat2gray(hmap);

    % Convert image to a 3-channel grayscale representation
    imgGray = im2gray(img);
    imgGray = repmat(imgGray,[1 1 3]);

    % Convert heatmap to an RGB image using a colormap
    cmap = parula(256);
    hmapRGB = ind2rgb(gray2ind(hmap,size(cmap,1)),cmap);

    % Blend results
    hmapWeight = alpha;
    grayWeight = 1-hmapWeight;
    out = im2uint8(grayWeight.*imgGray + hmapWeight.*hmapRGB);
end
```

Automated Driving Examples

Train a Deep Learning Vehicle Detector

This example shows how to train a vision-based vehicle detector using deep learning.

Overview

Vehicle detection using computer vision is an important component for tracking vehicles around the ego vehicle. The ability to detect and track vehicles is required for many autonomous driving applications, such as for forward collision warning, adaptive cruise control, and automated lane keeping. Automated Driving Toolbox™ provides pretrained vehicle detectors (`vehicleDetectorFasterRCNN` (Automated Driving Toolbox) and `vehicleDetectorACF` (Automated Driving Toolbox)) to enable quick prototyping. However, the pretrained models might not suit every application, requiring you to train from scratch. This example shows how to train a vehicle detector from scratch using deep learning.

Deep learning is a powerful machine learning technique that you can use to train robust object detectors. Several deep learning techniques for object detection exist, including Faster R-CNN and you only look once (YOLO) v2. This example trains a Faster R-CNN vehicle detector using the `trainFasterRCNNObjectDetector` function. For more information, see “Object Detection” (Computer Vision Toolbox).

Download Pretrained Detector

Download a pretrained detector to avoid having to wait for training to complete. If you want to train the detector, set the `doTrainingAndEval` variable to true.

```
doTrainingAndEval = false;
if ~doTrainingAndEval && ~exist('fasterRCNNResNet50EndToEndVehicleExample.mat','file')
    disp('Downloading pretrained detector (118 MB)...');
    pretrainedURL = 'https://www.mathworks.com/supportfiles/vision/data/fasterRCNNResNet50EndToE
    websave('fasterRCNNResNet50EndToEndVehicleExample.mat',pretrainedURL);
end
```

Load Dataset

This example uses a small labeled dataset that contains 295 images. Many of these images come from the Caltech Cars 1999 and 2001 data sets, available at the Caltech Computational Vision website, created by Pietro Perona and used with permission. Each image contains one or two labeled instances of a vehicle. A small dataset is useful for exploring the Faster R-CNN training procedure, but in practice, more labeled images are needed to train a robust detector. Unzip the vehicle images and load the vehicle ground truth data.

```
unzip vehicleDatasetImages.zip
data = load('vehicleDatasetGroundTruth.mat');
vehicleDataset = data.vehicleDataset;
```

The vehicle data is stored in a two-column table, where the first column contains the image file paths and the second column contains the vehicle bounding boxes.

Split the data set into a training set for training the detector and a test set for evaluating the detector. Select 60% of the data for training. Use the rest for evaluation.

```
rng(0)
shuffledIdx = randperm(height(vehicleDataset));
idx = floor(0.6 * height(vehicleDataset));
```

```
trainingDataTbl = vehicleDataset(shuffledIdx(1:idx),:);
testDataTbl = vehicleDataset(shuffledIdx(idx+1:end),:);
```

Use `imageDatastore` and `boxLabelDatastore` to create datastores for loading the image and label data during training and evaluation.

```
imdsTrain = imageDatastore(trainingDataTbl{:,'imageFilename'});
bldsTrain = boxLabelDatastore(trainingDataTbl(:,'vehicle'));

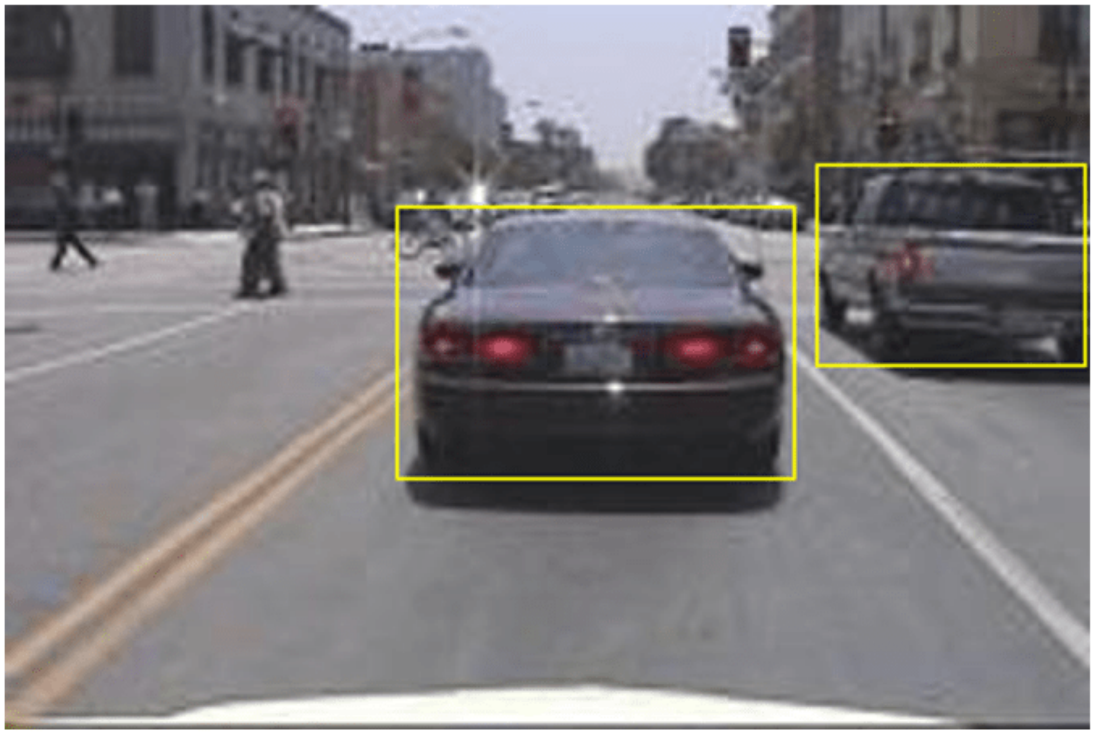
imdsTest = imageDatastore(testDataTbl{:,'imageFilename'});
bldsTest = boxLabelDatastore(testDataTbl(:,'vehicle'));
```

Combine image and box label datastores.

```
trainingData = combine(imdsTrain,bldsTrain);
testData = combine(imdsTest,bldsTest);
```

Display one of the training images and box labels.

```
data = read(trainingData);
I = data{1};
bbox = data{2};
annotatedImage = insertShape(I,'Rectangle',bbox);
annotatedImage = imresize(annotatedImage,2);
figure
imshow(annotatedImage)
```



Create Faster R-CNN Detection Network

A Faster R-CNN object detection network is composed of a feature extraction network followed by two subnetworks. The feature extraction network is typically a pretrained CNN, such as ResNet-50 or Inception v3. The first subnetwork following the feature extraction network is a region proposal network (RPN) trained to generate object proposals - areas in the image where objects are likely to exist. The second subnetwork is trained to predict the actual class of each object proposal.

The feature extraction network is typically a pretrained CNN (for details, see “Pretrained Deep Neural Networks” on page 1-8). This example uses ResNet-50 for feature extraction. You can also use other pretrained networks such as MobileNet v2 or ResNet-18, depending on your application requirements.

Use `fasterRCNNLayers` to create a Faster R-CNN network automatically given a pretrained feature extraction network. `fasterRCNNLayers` requires you to specify several inputs that parameterize a Faster R-CNN network:

- Network input size
- Anchor boxes
- Feature extraction network

First, specify the network input size. When choosing the network input size, consider the minimum size required to run the network itself, the size of the training images, and the computational cost incurred by processing data at the selected size. When feasible, choose a network input size that is close to the size of the training image and larger than the input size required for the network. To reduce the computational cost of running the example, specify a network input size of [224 224 3], which is the minimum size required to run the network.

```
inputSize = [224 224 3];
```

Note that the training images used in this example are bigger than 224-by-224 and vary in size, so you must resize the images in a preprocessing step prior to training.

Next, use `estimateAnchorBoxes` to estimate anchor boxes based on the size of objects in the training data. To account for the resizing of the images prior to training, resize the training data for estimating anchor boxes. Use `transform` to preprocess the training data, then define the number of anchor boxes and estimate the anchor boxes.

```
preprocessedTrainingData = transform(trainingData, @(data)preprocessData(data,inputSize));
numAnchors = 4;
anchorBoxes = estimateAnchorBoxes(preprocessedTrainingData,numAnchors)
```

```
anchorBoxes = 4×2

    96    91
    68    65
   150   125
    38    29
```

For more information on choosing anchor boxes, see “Estimate Anchor Boxes From Training Data” (Computer Vision Toolbox) (Computer Vision Toolbox™) and “Anchor Boxes for Object Detection” (Computer Vision Toolbox).

Now, use `resnet50` to load a pretrained ResNet-50 model.

```
featureExtractionNetwork = resnet50;
```

Select `'activation_40_relu'` as the feature extraction layer. This feature extraction layer outputs feature maps that are downsampled by a factor of 16. This amount of downsampling is a good trade-off between spatial resolution and the strength of the extracted features, as features extracted further down the network encode stronger image features at the cost of spatial resolution. Choosing the optimal feature extraction layer requires empirical analysis. You can use `analyzeNetwork` to find the names of other potential feature extraction layers within a network.

```
featureLayer = 'activation_40_relu';
```

Define the number of classes to detect.

```
numClasses = width(vehicleDataset)-1;
```

Create the Faster R-CNN object detection network.

```
lgraph = fasterRCNNLayers(inputSize,numClasses,anchorBoxes,featureExtractionNetwork,featureLayer
```

You can visualize the network using `analyzeNetwork` or Deep Network Designer from Deep Learning Toolbox™.

If more control is required over the Faster R-CNN network architecture, use Deep Network Designer to design the Faster R-CNN detection network manually. For more information, see “Getting Started with R-CNN, Fast R-CNN, and Faster R-CNN” (Computer Vision Toolbox).

Data Augmentation

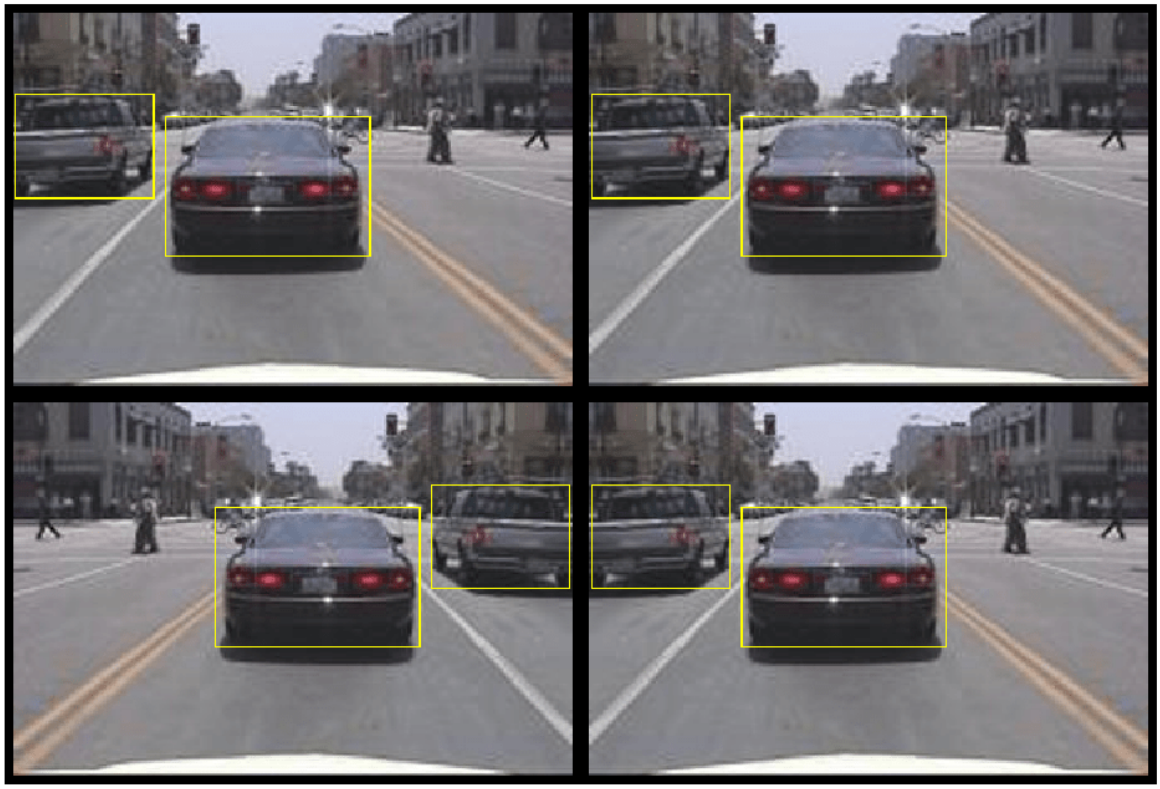
Data augmentation is used to improve network accuracy by randomly transforming the original data during training. By using data augmentation, you can add more variety to the training data without actually having to increase the number of labeled training samples.

Use `transform` to augment the training data by randomly flipping the image and associated box labels horizontally. Note that data augmentation is not applied to test data. Ideally, test data is representative of the original data and is left unmodified for unbiased evaluation.

```
augmentedTrainingData = transform(trainingData,@augmentData);
```

Read the same image multiple times and display the augmented training data.

```
augmentedData = cell(4,1);
for k = 1:4
    data = read(augmentedTrainingData);
    augmentedData{k} = insertShape(data{1},'Rectangle',data{2});
    reset(augmentedTrainingData);
end
figure
montage(augmentedData,'BorderSize',10)
```



Preprocess Training Data

Preprocess the augmented training data to prepare for training.

```
trainingData = transform(augmentedTrainingData,@(data)preprocessData(data,inputSize));
```

Read the preprocessed data.

```
data = read(trainingData);
```

Display the image and box bounding boxes.

```
I = data{1};
bbox = data{2};
annotatedImage = insertShape(I,'Rectangle',bbox);
annotatedImage = imresize(annotatedImage,2);
figure
imshow(annotatedImage)
```

Train Faster R-CNN

Use `trainingOptions` to specify network training options. Set `'CheckpointPath'` to a temporary location. This enables the saving of partially trained detectors during the training process. If training is interrupted, such as by a power outage or system failure, you can resume training from the saved checkpoint.

```
options = trainingOptions('sgdm',...
    'MaxEpochs',7,...
    'MiniBatchSize',1,...
    'InitialLearnRate',1e-3,...
    'CheckpointPath',tempdir);
```

Use `trainFasterRCNNObjectDetector` to train Faster R-CNN object detector if `doTrainingAndEval` is true. Otherwise, load the pretrained network.

```
if doTrainingAndEval
    % Train the Faster R-CNN detector.
    % * Adjust NegativeOverlapRange and PositiveOverlapRange to ensure
```

```
    %   that training samples tightly overlap with ground truth.
    [detector, info] = trainFasterRCNNObjectDetector(trainingData,lgraph,options, ...
        'NegativeOverlapRange',[0 0.3], ...
        'PositiveOverlapRange',[0.6 1]);
else
    % Load pretrained detector for the example.
    pretrained = load('fasterRCNNResNet50EndToEndVehicleExample.mat');
    detector = pretrained.detector;
end
```

This example was verified on an Nvidia(TM) Titan X GPU with 12 GB of memory. Training the network took approximately 20 minutes. The training time varies depending on the hardware you use.

As a quick check, run the detector on one test image. Make sure you resize the image to the same size as the training images.

```
I = imread(testDataTbl.imageFilename{1});
I = imresize(I,inputSize(1:2));
[bboxes,scores] = detect(detector,I);
```

Display the results.

```
I = insertObjectAnnotation(I,'rectangle',bboxes,scores);
figure
imshow(I)
```

Evaluate Detector Using Test Set

Evaluate the trained object detector on a large set of images to measure the performance. Computer Vision Toolbox™ provides object detector evaluation functions to measure common metrics such as average precision (`evaluateDetectionPrecision`) and log-average miss rates (`evaluateDetectionMissRate`). For this example, use the average precision metric to evaluate performance. The average precision provides a single number that incorporates the ability of the detector to make correct classifications (precision) and the ability of the detector to find all relevant objects (recall).

Apply the same preprocessing transform to the test data as for the training data.

```
testData = transform(testData,@(data)preprocessData(data,inputSize));
```

Run the detector on all the test images.

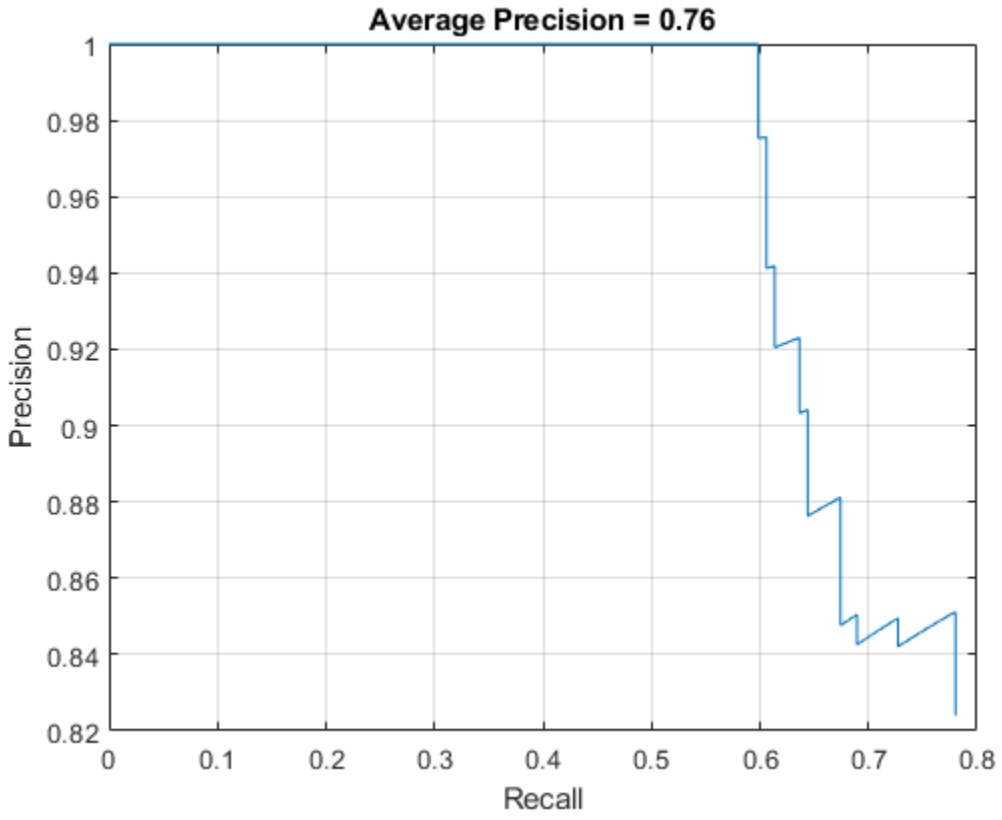
```
if doTrainingAndEval
    detectionResults = detect(detector,testData,'MinibatchSize',4);
else
    % Load pretrained detector for the example.
    pretrained = load('fasterRCNNResNet50EndToEndVehicleExample.mat');
    detectionResults = pretrained.detectionResults;
end
```

Evaluate the object detector using the average precision metric.

```
[ap, recall, precision] = evaluateDetectionPrecision(detectionResults,testData);
```

The precision/recall (PR) curve highlights how precise a detector is at varying levels of recall. The ideal precision is 1 at all recall levels. The use of more data can help improve the average precision but might require more training time. Plot the PR curve.

```
figure
plot(recall,precision)
xlabel('Recall')
ylabel('Precision')
grid on
title(sprintf('Average Precision = %.2f', ap))
```



Supporting Functions

```
function data = augmentData(data)
% Randomly flip images and bounding boxes horizontally.
tform = randomAffine2d('XReflection',true);
sz = size(data{1},[1 2]);
rout = affineOutputView(sz, tform);
data{1} = imwarp(data{1},tform,'OutputView',rout);

% Sanitize box data, if needed.
data{2} = helperSanitizeBoxes(data{2}, sz);

% Warp boxes.
data{2} = bboxwarp(data{2},tform,rout);
end

function data = preprocessData(data,targetSize)
% Resize image and bounding boxes to targetSize.
sz = size(data{1},[1 2]);
scale = targetSize(1:2)./sz;
data{1} = imresize(data{1},targetSize(1:2));

% Sanitize box data, if needed.
data{2} = helperSanitizeBoxes(data{2}, sz);

% Resize boxes.
data{2} = bboxresize(data{2},scale);
end
```

Create Occupancy Grid Using Monocular Camera and Semantic Segmentation

This example shows how to estimate free space around a vehicle and create an occupancy grid using semantic segmentation and deep learning. You then use this occupancy grid to create a vehicle costmap, which can be used to plan a path.

About Free Space Estimation

Free space estimation identifies areas in the environment where the ego vehicle can drive without hitting any obstacles such as pedestrians, curbs, or other vehicles. A vehicle can use a variety of sensors to estimate free space such as radar, lidar, or cameras. This example focuses on estimating free space from an image sensor using semantic segmentation.

In this example, you learn how to:

- Use semantic image segmentation to estimate free space.
- Create an occupancy grid using the free space estimate.
- Visualize the occupancy grid on a bird's-eye plot.
- Create a vehicle costmap using the occupancy grid.
- Check whether locations in the world are occupied or free.

Download Pretrained Network

This example uses a pretrained semantic segmentation network, which can classify pixels into 11 different classes, including `Road`, `Pedestrian`, `Car`, and `Sky`. The free space in an image can be estimated by defining image pixels classified as `Road` as free space. All other classes are defined as non-free space or obstacles.

The complete procedure for training this network is shown in the “Semantic Segmentation Using Deep Learning” (Computer Vision Toolbox) example. Download the pretrained network.

```
% Download the pretrained network.
pretrainedURL = 'https://www.mathworks.com/supportfiles/vision/data/segnetVGG16CamVid.mat';
pretrainedFolder = fullfile(tempdir,'pretrainedSegNet');
pretrainedSegNet = fullfile(pretrainedFolder,'segnetVGG16CamVid.mat');
if ~exist(pretrainedFolder,'dir')
    mkdir(pretrainedFolder);
    disp('Downloading pretrained SegNet (107 MB)...');
    websave(pretrainedSegNet,pretrainedURL);
    disp('Download complete.');
end

% % Load the network.
data = load(pretrainedSegNet);
net = data.net;
```

Note: Download time of the data depends on your Internet connection. The commands used above block MATLAB® until the download is complete. Alternatively, you can use your web browser to first download the data set to your local disk. In this case, to use the file you downloaded from the web, change the `pretrainedFolder` variable above to the location of the downloaded file.

Estimate Free Space

Estimate free space by processing the image using downloaded semantic segmentation network. The network returns classifications for each image pixel in the image. The free space is identified as image pixels that have been classified as `Road`.

The image used in this example is a single frame from an image sequence in the CamVid data set[1]. The procedure shown in this example can be applied to a sequence of frames to estimate free space as a vehicle drives along. However, because a very deep convolutional neural network architecture is used in this example (SegNet with a VGG-16 encoder), it takes about 1 second to process each frame. Therefore, for expediency, process a single frame.

```
% Read the image.
I = imread('seq05vd_snap_shot.jpg');

% Segment the image.
[C,scores,allScores] = semanticseg(I,net);

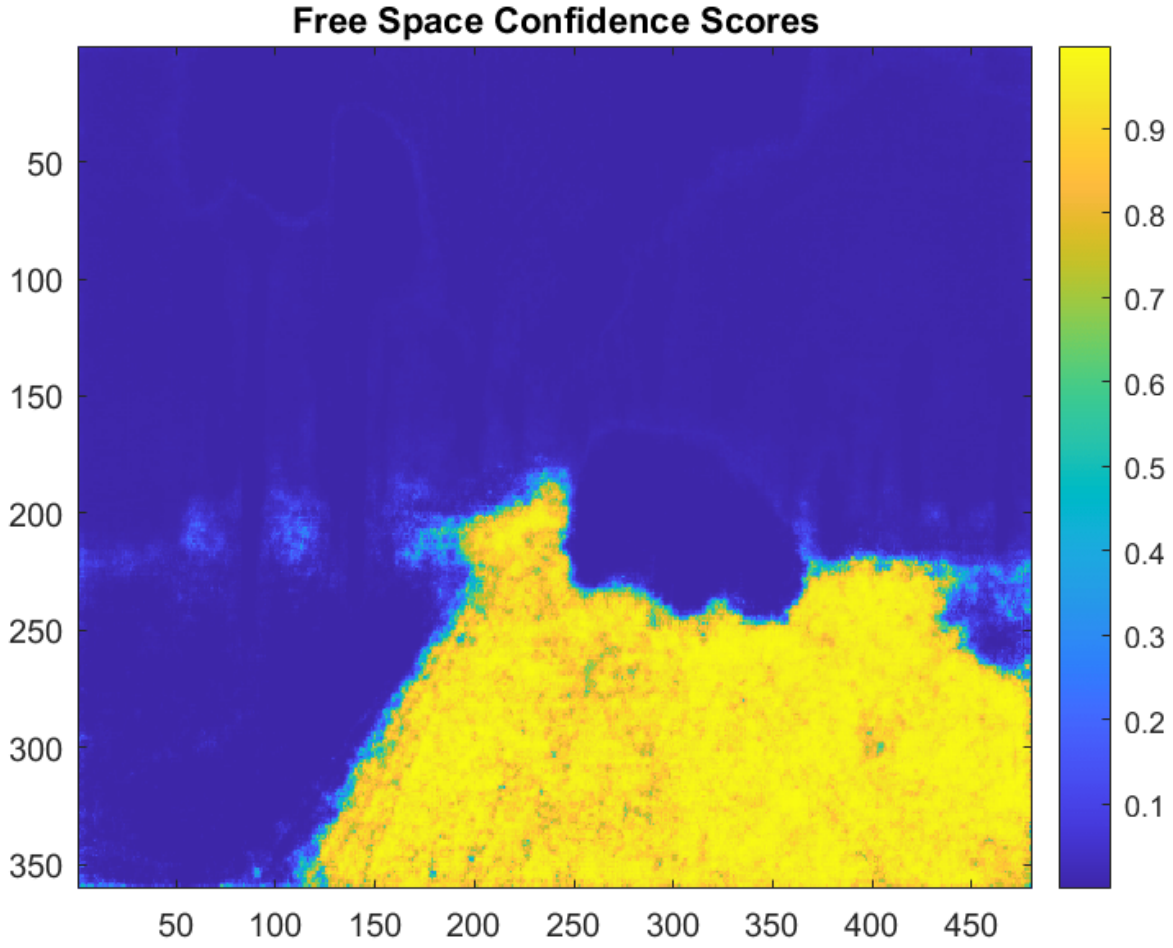
% Overlay free space onto the image.
B = labeloverlay(I,C,'IncludedLabels',"Road");

% Display free space and image.
figure
imshow(B)
```

To understand the confidence in the free space estimate, display the output score for the Road class for every pixel. The confidence values can be used to inform downstream algorithms of the estimate's validity. For example, even if the network classifies a pixel as Road, the confidence score may be low enough to disregard that classification for safety reasons.

```
% Use the network's output score for Road as the free space confidence.
roadClassIdx = 4;
freeSpaceConfidence = allScores(:,:,roadClassIdx);

% Display the free space confidence.
figure
imagesc(freeSpaceConfidence)
title('Free Space Confidence Scores')
colorbar
```



Although the initial segmentation result for `Road` pixels showed most pixels on the road were classified correctly, visualizing the scores provides richer detail on the classifier's confidence in those classifications. For example, the confidence decreases as you get closer to the boundary of the car.

Create Bird's-Eye-View Image

The free space estimate is generated in the image space. To facilitate generation of an occupancy grid that is useful for navigation, the free space estimate needs to be transformed into the vehicle coordinate system. This can be done by transforming the free space estimate to a bird's-eye-view image.

To create the bird's-eye-view image, first define the camera sensor configuration. The supporting function listed at the end of this example, `camvidMonoCameraSensor`, returns a `monoCamera` (Automated Driving Toolbox) object representing the monocular camera used to collect the CamVid[1] data. Configuring the `monoCamera` (Automated Driving Toolbox) requires the camera intrinsics and extrinsics, which were estimated using data provided in the CamVid data set. To estimate the camera intrinsics, the function used CamVid checkerboard calibration images and the Camera Calibrator (Computer Vision Toolbox) app. Estimates of the camera extrinsics, such as height and pitch, were derived from the extrinsic data estimated by the authors of the CamVid data set.

```
% Create monoCamera for CamVid data.
sensor = camvidMonoCameraSensor();
```

Given the camera setup, the `birdsEyeView` (Automated Driving Toolbox) object transforms the original image to the bird's-eye view. This object lets you specify the area that you want transformed using vehicle coordinates. Note that the vehicle coordinate units were established by the `monoCamera` (Automated Driving Toolbox) object, when the camera mounting height was specified in meters. For example, if the height was specified in millimeters, the rest of the simulation would use millimeters.

```
% Define bird's-eye-view transformation parameters.
distAheadOfSensor = 20; % in meters, as previously specified in monoCamera height input
spaceToOneSide    = 3;  % look 3 meters to the right and left
bottomOffset      = 0;
outView = [bottomOffset, distAheadOfSensor, -spaceToOneSide, spaceToOneSide];

outImageSize = [NaN, 256]; % output image width in pixels; height is chosen automatically to pres

birdsEyeConfig = birdsEyeView(sensor,outView,outImageSize);
```

Generate bird's-eye-view image for the image and free space confidence.

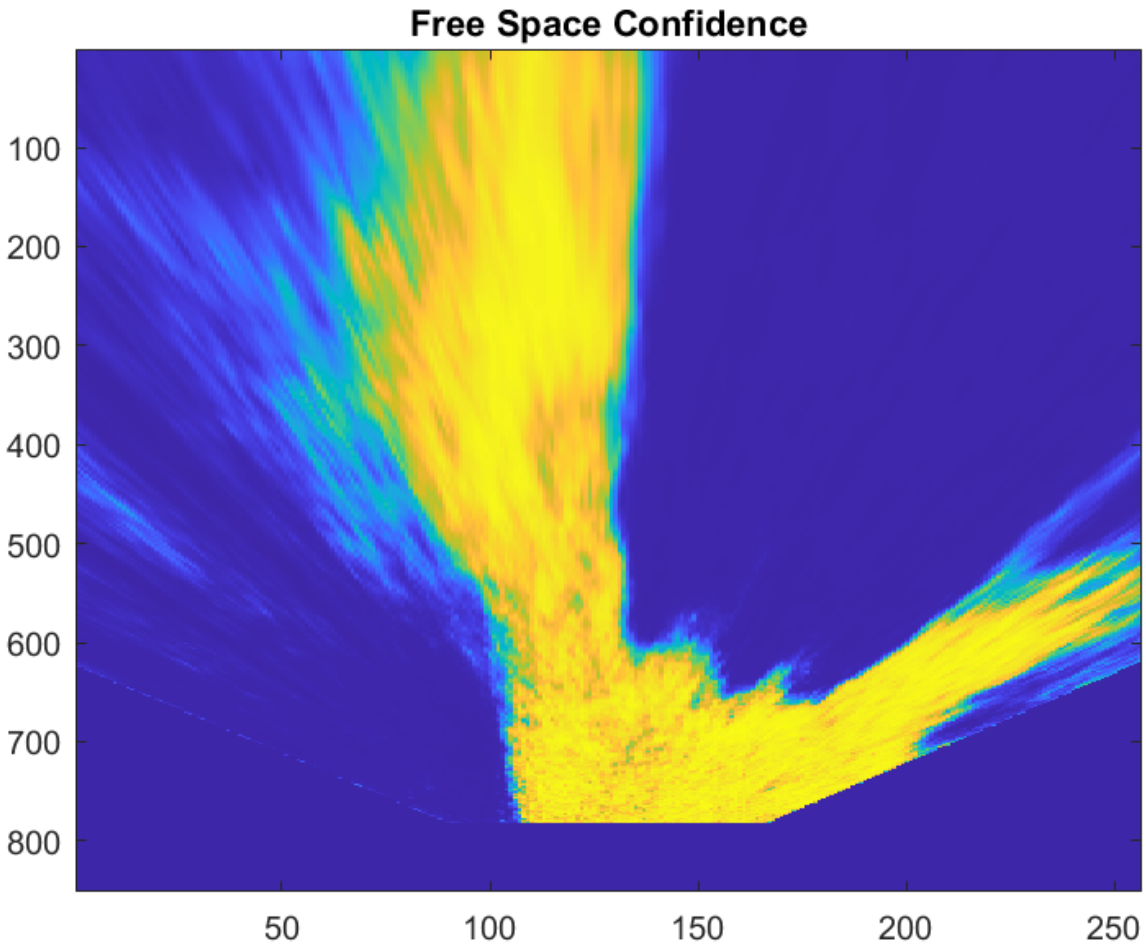
```
% Resize image and free space estimate to size of CamVid sensor.
imageSize = sensor.Intrinsics.ImageSize;
I = imresize(I,imageSize);
freeSpaceConfidence = imresize(freeSpaceConfidence,imageSize);

% Transform image and free space confidence scores into bird's-eye view.
imageBEV = transformImage(birdsEyeConfig,I);
freeSpaceBEV = transformImage(birdsEyeConfig,freeSpaceConfidence);

% Display image frame in bird's-eye view.
figure
imshow(imageBEV)
```

Transform the image into a bird's-eye view and generate the free space confidence.

```
figure
imagesc(freeSpaceBEV)
title('Free Space Confidence')
```



The areas farther away from the sensor are more blurry, due to having fewer pixels and thus requiring greater amount of interpolation.

Create Occupancy Grid Based on Free Space Estimation

Occupancy grids are used to represent a vehicle's surroundings as a discrete grid in vehicle coordinates and are used for path planning. Each cell in the occupancy grid has a value representing the probability of the occupancy of that cell. The estimated free space can be used to fill in values of the occupancy grid.

The procedure to fill the occupancy grid using the free space estimate is as follows:

1. Define the dimensions of the occupancy grid in vehicle coordinates.
2. Generate a set of (X,Y) points for each grid cell. These points are in the vehicle's coordinate system.

3. Transform the points from the vehicle coordinate space (X,Y) into the bird's-eye-view image coordinate space (x,y) using the `vehicleToImage` (Automated Driving Toolbox) transform.
4. Sample the free space confidence values at (x,y) locations using `griddedInterpolant` to interpolate free space confidence values that are not exactly at pixel centers in the image.
5. Fill the occupancy grid cell with the average free space confidence value for all (x,y) points that correspond to that grid cell.

For brevity, the procedure shown above is implemented in the supporting function, `createOccupancyGridFromFreeSpaceEstimate`, which is listed at the end of this example. Define the dimensions of the occupancy grid in terms of the bird's-eye-view configuration and create the occupancy grid by calling `createOccupancyGridFromFreeSpaceEstimate`.

```
% Define dimensions and resolution of the occupancy grid.
gridX = distAheadOfSensor;
gridY = 2 * spaceToOneSide;
cellSize = 0.25; % in meters to match units used by CamVid sensor

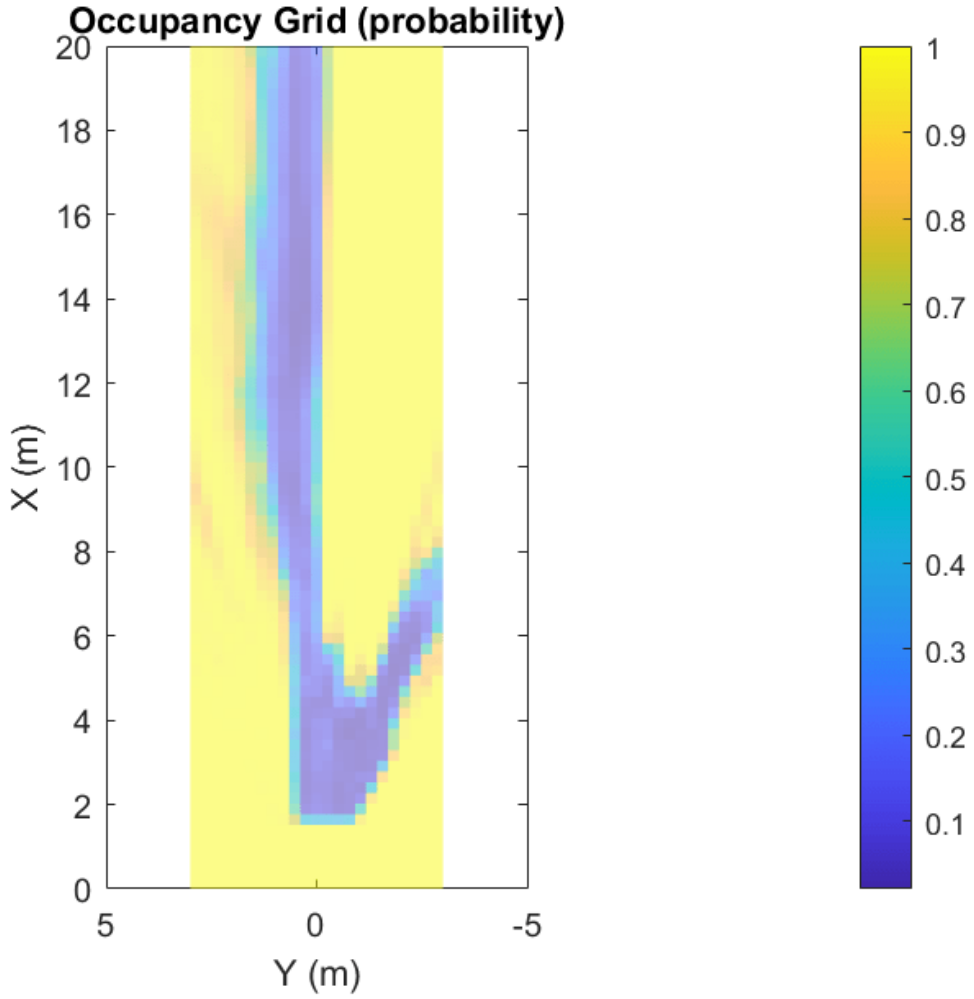
% Create the occupancy grid from the free space estimate.
occupancyGrid = createOccupancyGridFromFreeSpaceEstimate(...
    freeSpaceBEV, birdsEyeConfig, gridX, gridY, cellSize);
```

Visualize the occupancy grid using `birdsEyePlot` (Automated Driving Toolbox). Create a `birdsEyePlot` (Automated Driving Toolbox) and add the occupancy grid on top using `pcolor`.

```
% Create bird's-eye plot.
bep = birdsEyePlot('XLimits',[0 distAheadOfSensor],'YLimits', [-5 5]);

% Add occupancy grid to bird's-eye plot.
hold on
[numCellsY,numCellsX] = size(occupancyGrid);
X = linspace(0, gridX, numCellsX);
Y = linspace(-gridY/2, gridY/2, numCellsY);
h = pcolor(X,Y,occupancyGrid);
title('Occupancy Grid (probability)')
colorbar
delete(legend)

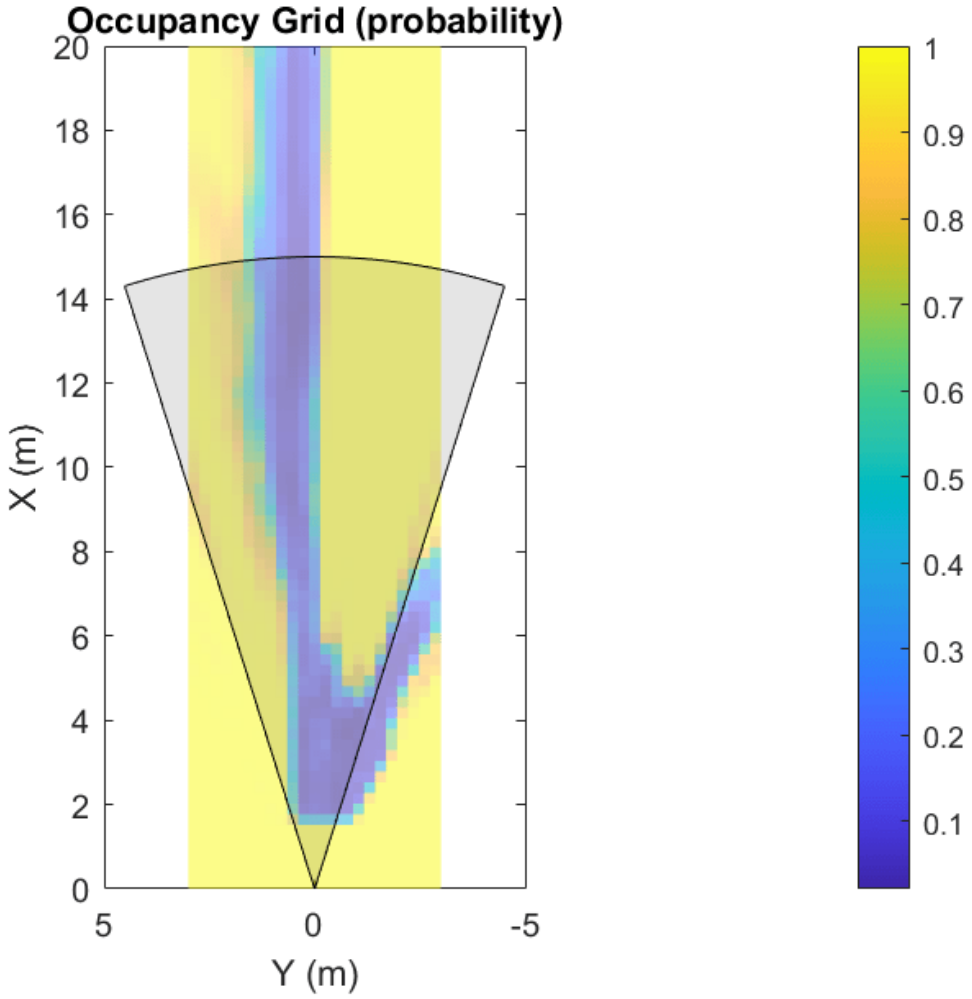
% Make the occupancy grid visualization transparent and remove grid lines.
h.FaceAlpha = 0.5;
h.LineStyle = 'none';
```



The bird's-eye plot can also display data from multiple sensors. For example, add the radar coverage area using `coverageAreaPlotter` (Automated Driving Toolbox).

```
% Add coverage area to plot.
caPlotter = coverageAreaPlotter(bep, 'DisplayName', 'Coverage Area');

% Update it with a field of view of 35 degrees and a range of 60 meters
mountPosition = [0 0];
range = 15;
orientation = 0;
fieldOfView = 35;
plotCoverageArea(caPlotter, mountPosition, range, orientation, fieldOfView);
hold off
```



Displaying data from multiple sensors is useful for diagnosing and debugging decisions made by autonomous vehicles.

Create Vehicle Costmap Using the Occupancy Grid

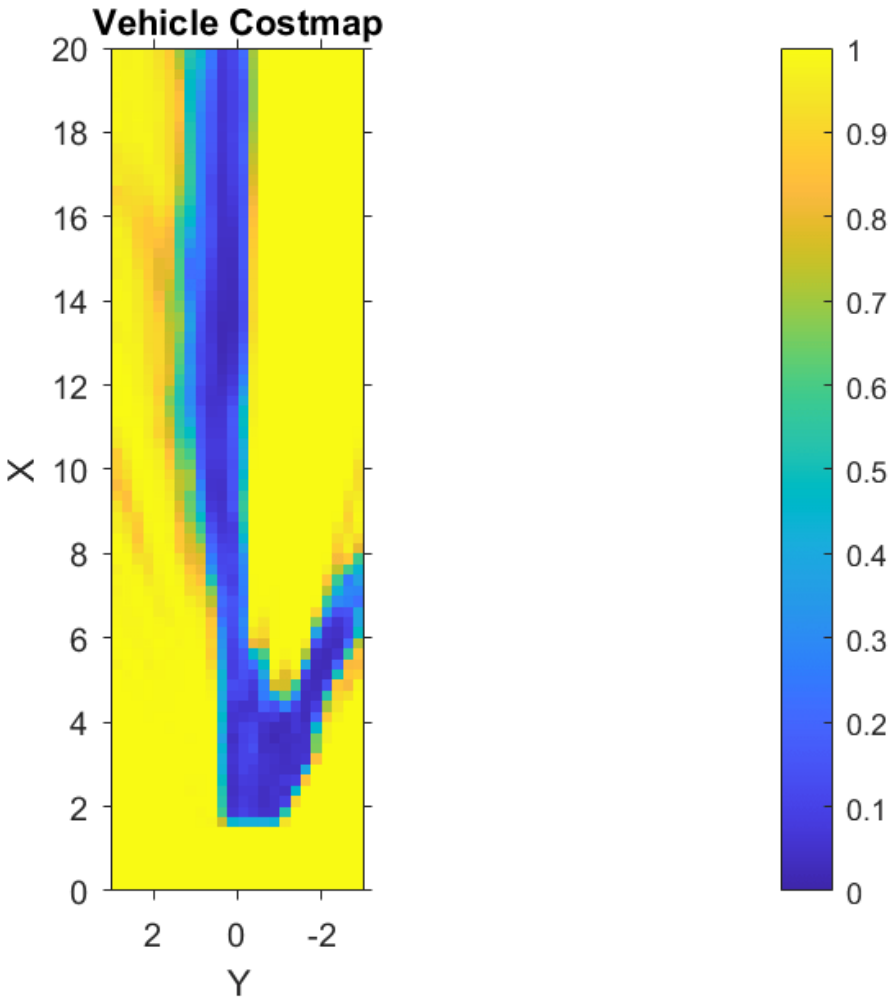
The `vehicleCostmap` (Automated Driving Toolbox) provides functionality to check if locations, in vehicle or world coordinates, are occupied or free. This check is required for any path-planning or decision-making algorithm. Create the `vehicleCostmap` (Automated Driving Toolbox) using the generated `occupancyGrid`.

```
% Create the costmap.
costmap = vehicleCostmap(flipud(occupancyGrid), ...
    'CellSize',cellSize, ...
    'MapLocation',[0,-spaceToOneSide]);
costmap.CollisionChecker.InflationRadius = 0;

% Display the costmap.
figure
plot(costmap,'Inflation','off')
colormap(parula)
```

```
colorbar
title('Vehicle Costmap')

% Orient the costmap so that it lines up with the vehicle coordinate
% system, where the X-axis points in front of the ego vehicle and the
% Y-axis points to the left.
view(gca,-90,90)
```



To illustrate how to use the `vehicleCostmap` (Automated Driving Toolbox), create a set of locations in world coordinates. These locations represent a path the vehicle could traverse.

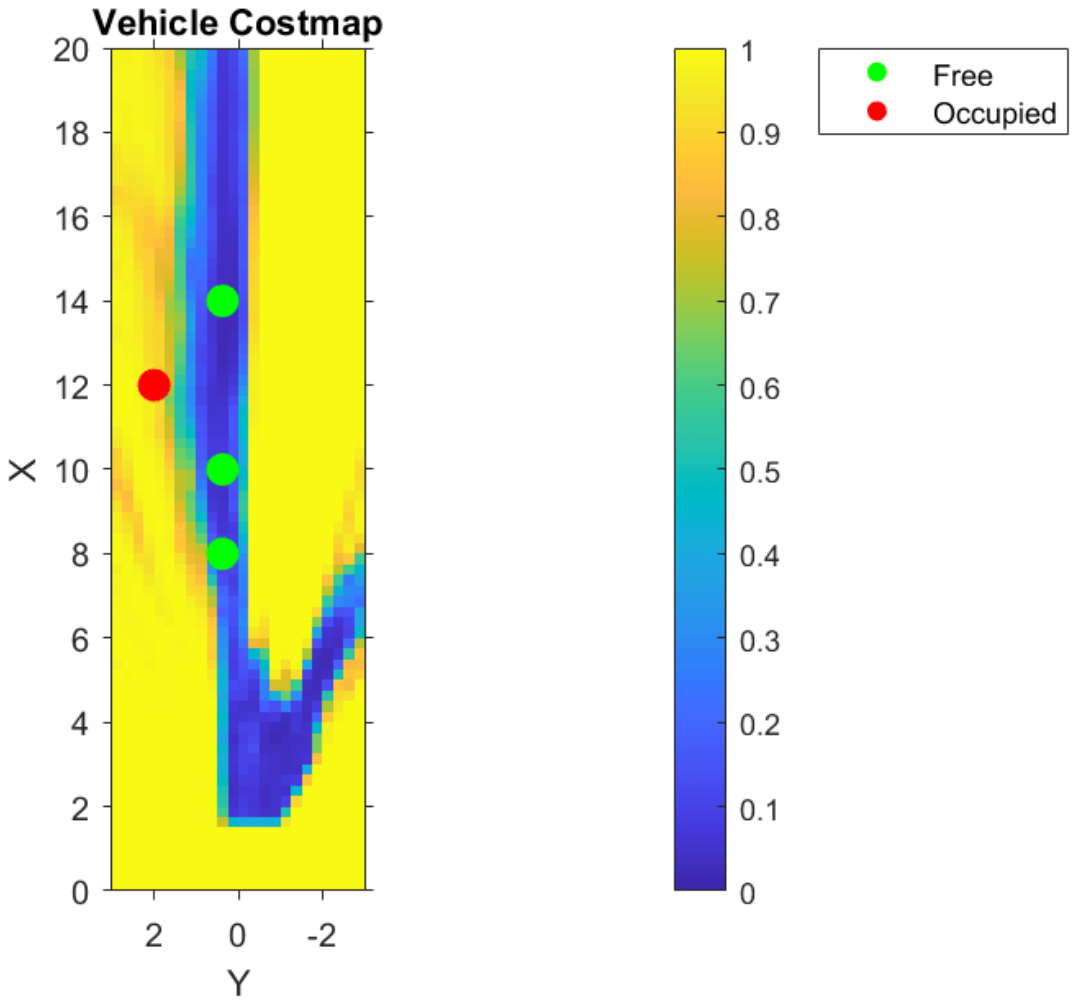
```
% Create a set of locations in vehicle coordinates.
candidateLocations = [
    8 0.375
    10 0.375
    12 2
    14 0.375
    ];
```

Use `checkOccupied` (Automated Driving Toolbox) to check whether each location is occupied or free. Based on the results, a potential path might be impossible to follow because it collides with obstacles defined in the `costmap`.

```
% Check if locations are occupied.
isOccupied = checkOccupied(costmap,candidateLocations);

% Partition locations into free and occupied for visualization purposes.
occupiedLocations = candidateLocations(isOccupied,:);
freeLocations = candidateLocations(~isOccupied,:);

% Display free and occupied points on top of costmap.
hold on
markerSize = 100;
scatter(freeLocations(:,1),freeLocations(:,2),markerSize,'g','filled')
scatter(occupiedLocations(:,1),occupiedLocations(:,2),markerSize,'r','filled');
legend(["Free" "Occupied"])
hold off
```



The use of `occupancyGrid`, `vehicleCostmap` (Automated Driving Toolbox), and `checkOccupied` (Automated Driving Toolbox) shown above illustrate the basic operations used by path planners such

as `pathPlannerRRT` (Automated Driving Toolbox). Learn more about path planning in the "Automated Parking Valet" (Automated Driving Toolbox) example.

% Camera pitch was computed using camera extrinsics provided in data set.
pitch = 0;  % pitch of the camera, towards the ground, in degrees

camIntrinsics = cameraIntrinsics(focalLength,principalPoint,imageSize);
sensor = monoCamera(camIntrinsics,height,'Pitch',pitch);
end

function occupancyGrid = createOccupancyGridFromFreeSpaceEstimate(...
    freeSpaceBEV,birdsEyeConfig,gridX,gridY,cellSize)
% Return an occupancy grid that contains the occupancy probability over
% a uniform 2-D grid.

% Number of cells in occupancy grid.
numCellsX = ceil(gridX / cellSize);
numCellsY = ceil(gridY / cellSize);

% Generate a set of (X,Y) points for each grid cell. These points are in
```

```
% the vehicle's coordinate system. Start by defining the edges of each grid
% cell.

% Define the edges of each grid cell in vehicle coordinates.
XEdges = linspace(0,gridX,numCellsX);
YEdges = linspace(-gridY/2,gridY/2,numCellsY);

% Next, specify the number of sample points to generate along each
% dimension within a grid cell. Use these to compute the step size in the
% X and Y direction. The step size will be used to shift the edge values of
% each grid to produce points that cover the entire area of a grid cell at
% the desired resolution.

% Sample 20 points from each grid cell. Sampling more points may produce
% smoother estimates at the cost of additional computation.
numSamplePoints = 20;

% Step size needed to sample number of desired points.
XStep = (XEdges(2)-XEdges(1)) / (numSamplePoints-1);
YStep = (YEdges(2)-YEdges(1)) / (numSamplePoints-1);

% Finally, slide the set of points across both dimensions of the grid
% cells. Sample the occupancy probability along the way using
% griddedInterpolant.

% Create griddedInterpolant for sampling occupancy probability. Use 1
% minus the free space confidence to represent the probability of occupancy.
occupancyProb = 1 - freeSpaceBEV;
sz = size(occupancyProb);
[y,x] = ndgrid(1:sz(1),1:sz(2));
F = griddedInterpolant(y,x,occupancyProb);

% Initialize the occupancy grid to zero.
occupancyGrid = zeros(numCellsY*numCellsX,1);

% Slide the set of points XEdges and YEdges across both dimensions of the
% grid cell.
for j = 1:numSamplePoints

    % Increment sample points in the X-direction
    X = XEdges + (j-1)*XStep;

    for i = 1:numSamplePoints

        % Increment sample points in the Y-direction
        Y = YEdges + (i-1)*YStep;

        % Generate a grid of sample points in bird's-eye-view vehicle coordinates
        [XGrid,YGrid] = meshgrid(X,Y);

        % Transform grid of sample points to image coordinates
        xy = vehicleToImage(birdsEyeConfig,[XGrid(:) YGrid(:)]);

        % Clip sample points to lie within image boundaries
        xy = max(xy,1);
        xq = min(xy(:,1),sz(2));
        yq = min(xy(:,2),sz(1));
```

```
            % Sample occupancy probabilities using griddedInterpolant and keep
            % a running sum.
            occupancyGrid = occupancyGrid + F(yq,xq);
        end

    end

    % Determine mean occupancy probability.
    occupancyGrid = occupancyGrid / numSamplePoints^2;
    occupancyGrid = reshape(occupancyGrid,numCellsY,numCellsX);
    end
```

Train Deep Learning Semantic Segmentation Network Using 3-D Simulation Data

This example shows how to use 3-D simulation data to train a semantic segmentation network and fine-tune it to real-world data using generative adversarial networks (GANs).

This example uses 3-D simulation data generated by Driving Scenario Designer and the Unreal Engine®. For an example showing how to generate such simulation data, see “Depth and Semantic Segmentation Visualization Using Unreal Engine Simulation” (Automated Driving Toolbox). The 3-D simulation environment generates the images and the corresponding ground truth pixel labels. Using the simulation data avoids the annotation process, which is both tedious and requires a large amount of human effort. However, domain shift models trained on only simulation data do not perform well on real-world data sets. To address this, you can use domain adaptation to fine-tune the trained model to work on a real-world data set.

This example uses AdaptSegNet [1 on page 10-0], a network that adapts the structure of the output segmentation predictions, which look alike irrespective of the input domain. The AdaptSegNet network is based on the GAN model and consists of two networks that are trained simultaneously to maximize the performance of both:

1. Generator — Network trained to generate high-quality segmentation results from real or simulated input images
2. Discriminator — Network that compares and attempts to distinguish whether the segmentation predictions of the generator are from real or simulated data

To fine-tune the AdaptSegNet model for real-world data, this example uses a subset of the CamVid data [2 on page 10-0] and adapts the model to generate high-quality segmentation predictions on the CamVid data.

Download Pretrained Network

Download the pretrained network. The pretrained model allows you to run the entire example without having to wait for training to complete. If you want to train the network, set the `doTraining` variable to `true`.

```
doTraining = false;
if ~doTraining
    pretrainedURL = 'https://ssd.mathworks.com/supportfiles/vision/data/trainedAdaptSegGANNet.ma
    pretrainedFolder = fullfile(tempdir,'pretrainedNetwork');
    pretrainedNetwork = fullfile(pretrainedFolder,'trainedAdaptSegGANNet.mat');
    if ~exist(pretrainedNetwork,'file')
        mkdir(pretrainedFolder);
        disp('Downloading pretrained network (57 MB)...');
        websave(pretrainedNetwork,pretrainedURL);
    end
    pretrained = load(pretrainedNetwork);
    dlnetGenerator = pretrained.dlnetGenerator;
end
```

Download Data Sets

Download the simulation and real data sets by using the `downloadDataset` function, defined in the Supporting Functions section of this example. The `downloadDataset` function downloads the entire CamVid data set and partition the data into training and test sets.

The simulation data set was generated by Driving Scenario Designer. The generated scenarios, which consist of 553 photorealistic images with labels, were rendered by the Unreal Engine. You use this data set to train the model.

The real data set is a subset of the CamVid data set from the University of Cambridge. To adapt the model to real-world data, 69 CamVid images. To evaluate the trained model, you use 368 CamVid images.

The download time depends on your internet connection.

```
simulationDataURL = 'https://ssd.mathworks.com/supportfiles/vision/data/SimulationDrivingDataset
realImageDataURL = 'http://web4.cs.ucl.ac.uk/staff/g.brostow/MotionSegRecData/files/701_StillsRa
realLabelDataURL = 'http://web4.cs.ucl.ac.uk/staff/g.brostow/MotionSegRecData/data/LabeledApprove

simulationDataLocation = fullfile(tempdir,'SimulationData');
realDataLocation = fullfile(tempdir,'RealData');
[simulationImagesFolder, simulationLabelsFolder, realImagesFolder, realLabelsFolder, ...
    realTestImagesFolder, realTestLabelsFolder] = ...
    downloadDataset(simulationDataLocation,simulationDataURL,realDataLocation,realImageDataURL,re
```

The downloaded files include the pixel labels for the real domain, but note that you do not use these pixel labels in the training process. This example uses the real domain pixel labels only to calculate the mean intersection over union (IoU) value to evaluate the efficacy of the trained model.

Load Simulation and Real Data

Use `imageDatastore` to load the simulation and real data sets for training. By using an image datastore, you can efficiently load a large collection of images on disk.

```
simData = imageDatastore(simulationImagesFolder);
realData = imageDatastore(realImagesFolder);
```

Preview images from the simulation data set and real data set.

```
simImage = preview(simData);
realImage = preview(realData);
montage({simImage,realImage})
```

The real and simulated images look very different. Consequently, models trained on simulated data and evaluated on real data perform poorly due to domain shift.

Load Pixel-Labeled Images for Simulation Data and Real Data

Load the simulation pixel label image data by using `pixelLabelDatastore` (Computer Vision Toolbox). A pixel label datastore encapsulates the pixel label data and the label ID to a class name mapping.

For this example, specify five classes useful for an automated driving application: road, background, pavement, sky, and car.

```
classes = [
    "Road"
    "Background"
    "Pavement"
    "Sky"
    "Car"
    ];
numClasses = numel(classes);
```

The simulation data set has eight classes. Reduce the number of classes from eight to five by grouping the building, tree, traffic signal, and light classes from the original data set into a single background class. Return the grouped label IDs by using the helper function `simulationPixelLabelIDs`. This helper function is attached to the example as a supporting file.

```
labelIDs = simulationPixelLabelIDs;
```

Use the classes and label IDs to create a pixel label datastore of the simulation data.

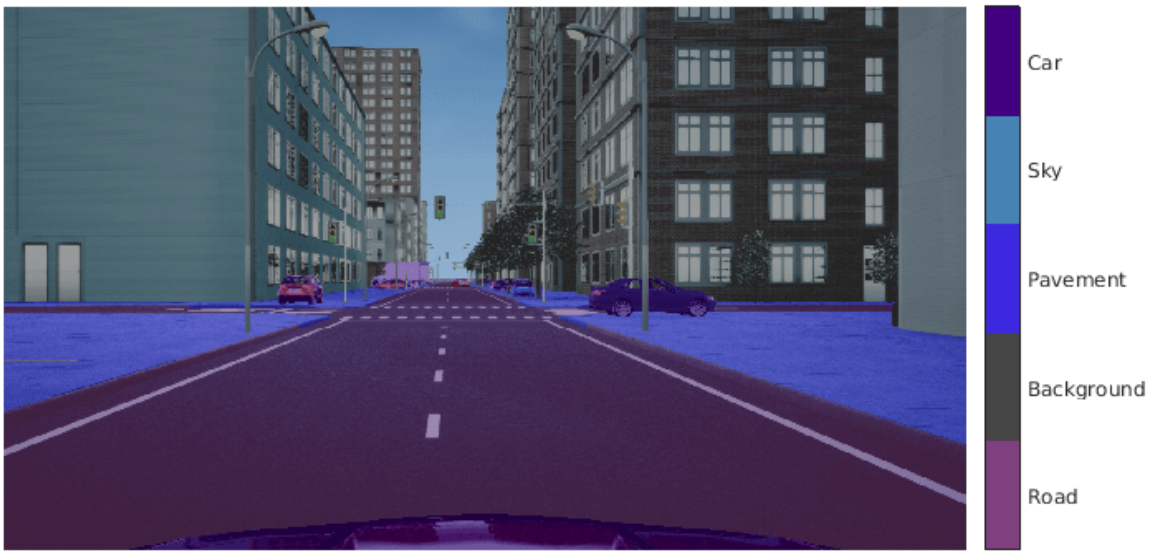
```
simLabels = pixelLabelDatastore(simulationLabelsFolder,classes,labelIDs);
```

Initialize the colormap for the segmented images using the helper function `domainAdaptationColorMap`, defined in the Supporting Functions section.

```
dmap = domainAdaptationColorMap;
```

Preview a pixel-labeled image by overlaying the label on top of the image using the `labeloverlay` (Image Processing Toolbox) function.

```
simImageLabel = preview(simLabels);
overlayImageSimulation = labeloverlay(simImage,simImageLabel,'ColorMap',dmap);
figure
imshow(overlayImageSimulation)
labelColorbar(dmap,classes);
```



Shift the simulation and real data used for training to zero center, to center the data around the origin, by using the `transform` function and the `preprocessData` helper function, defined in the Supporting Functions section.

```
preprocessedSimData = transform(simData, @(simdata)preprocessData(simdata));
preprocessedRealData = transform(realData, @(realdata)preprocessData(realdata));
```

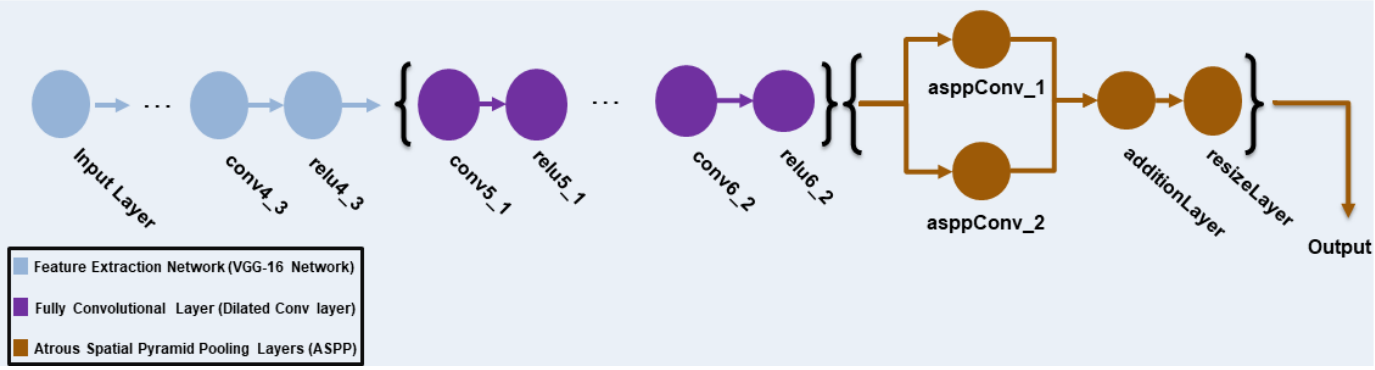
Use the `combine` function to combine the transformed image datastore and pixel label datastores of the simulation domain. The training process does not use the pixel labels of real data.

```
combinedSimData = combine(preprocessedSimData,simLabels);
```

Define AdaptSegNet Generator

This example modifies the VGG-16 network pretrained on ImageNet to a fully convolutional network. To enlarge the receptive fields, dilated convolutional layers with strides of 2 and 4 are added. This makes the output feature map resolution one-eighth of the input size. Atrous spatial pyramid pooling (ASPP) is used to provide multiscale information and is followed by a `resize2dlayer` with an upsampling factor of 8 to resize the output to the size of the input.

The AdaptSegNet generator network used in this example is illustrated in the following diagram.



To get a pretrained VGG-16 network, install the `vgg16`. If the support package is not installed, then the software provides a download link.

```
net = vgg16;
```

To make the VGG-16 network suitable for semantic segmentation, remove all VGG layers after `'relu4_3'`.

```
vggLayers = net.Layers(2:24);
```

Create an image input layer of size 1280-by-720-by-3 for the generator.

```
inputSizeGenerator = [1280 720 3];
inputLayer = imageInputLayer(inputSizeGenerator,'Normalization','None','Name','inputLayer');
```

Create fully convolutional network layers. Use dilation factors of 2 and 4 to enlarge the respective fields.

```
fcnlayers = [
    convolution2dLayer([3 3], 360,'DilationFactor',[2 2],'Padding',[2 2 2 2],'Name','conv5_1','We
    reluLayer('Name','relu5_1')
    convolution2dLayer([3 3], 360,'DilationFactor',[2 2],'Padding',[2 2 2 2] ,'Name','conv5_2','W
    reluLayer('Name','relu5_2')
    convolution2dLayer([3 3], 360,'DilationFactor',[2 2],'Padding',[2 2 2 2],'Name','conv5_3','We
    reluLayer('Name','relu5_3')
    convolution2dLayer([3 3], 480,'DilationFactor',[4 4],'Padding',[4 4 4 4],'Name','conv6_1','We
    reluLayer('Name','relu6_1')
    convolution2dLayer([3 3], 480,'DilationFactor',[4 4],'Padding',[4 4 4 4] ,'Name','conv6_2','W
    reluLayer('Name','relu6_2')
    ];
```

Combine the layers and create the layer graph.

```
layers = [
    inputLayer
    vggLayers
    fcnlayers
    ];
lgraph = layerGraph(layers);
```

ASPP is used to provide multiscale information. Add the ASPP module to the layer graph with a filter size equal to the number of channels by using the `addASPPToNetwork` helper function, defined in the Supporting Functions section.

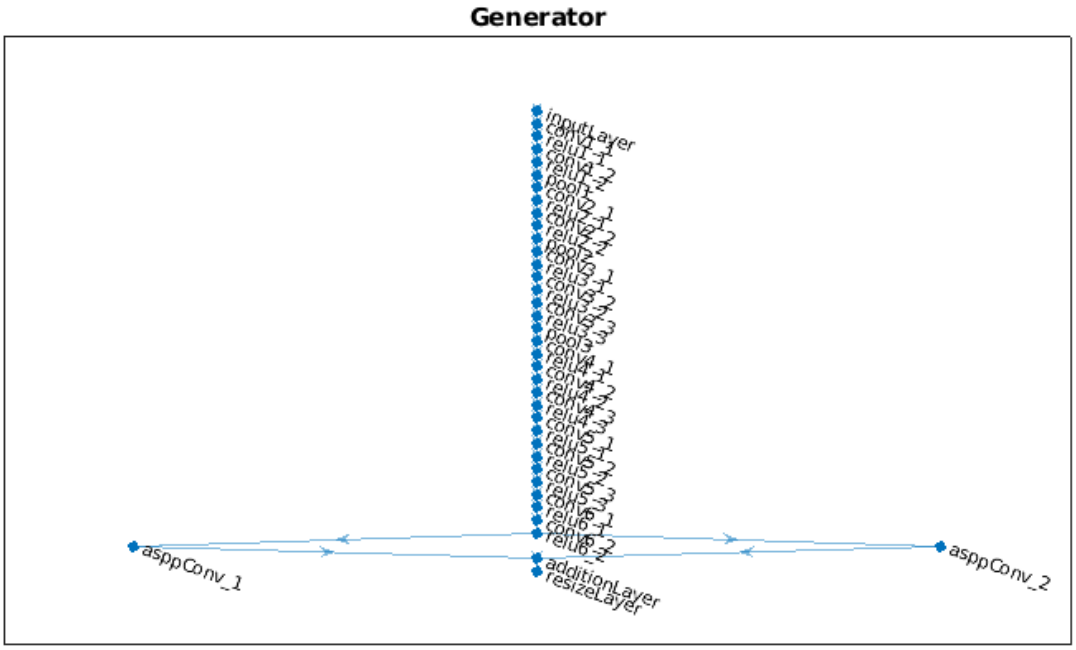
```
lgraph  = addASPPToNetwork(lgraph, numClasses);
```

Apply `resize2dLayer` with an upsampling factor of 8 to make the output match the size of the input.

```
upSampleLayer = resize2dLayer('Scale',8,'Method','bilinear','Name','resizeLayer');
lgraphGenerator = addLayers(lgraph,upSampleLayer);
lgraphGenerator = connectLayers(lgraphGenerator,'additionLayer','resizeLayer');
```

Visualize the generator network in a plot.

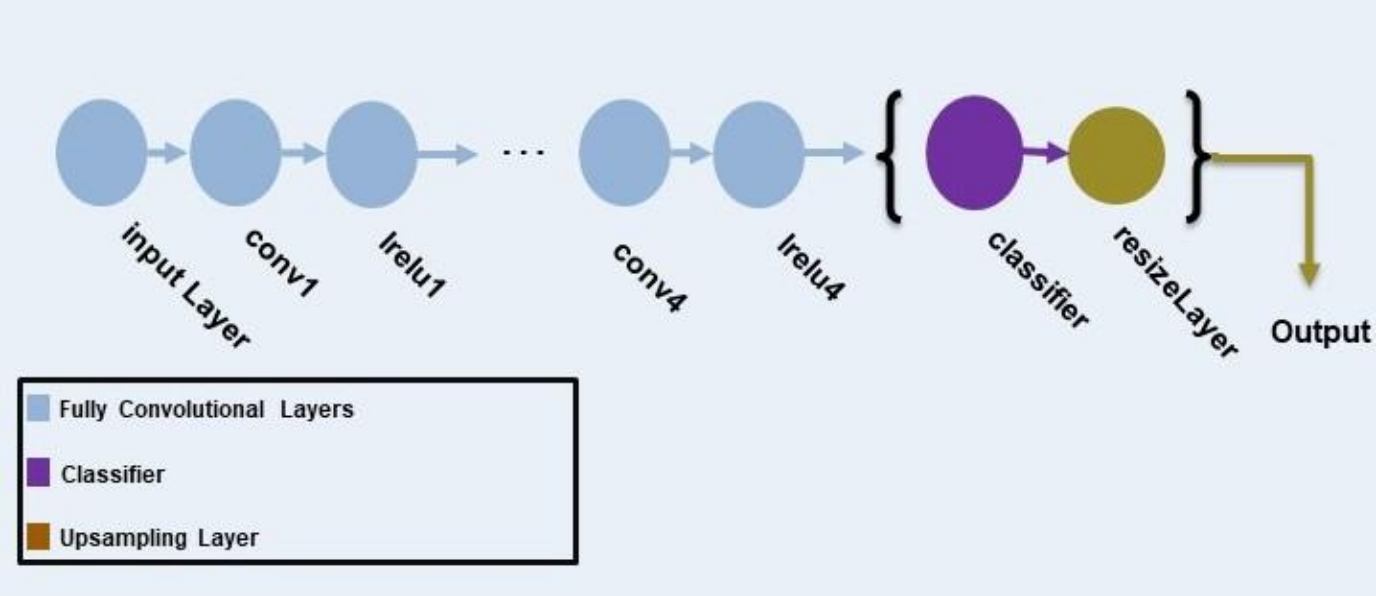
```
plot(lgraphGenerator)
title("Generator")
```



Define AdaptSeg Discriminator

The discriminator network consists of five convolutional layers with a kernel size of 3 and a stride of 2, where the number of channels is {64, 128, 256, 512, 1}. Each layer is followed by a leaky ReLU layer parameterized by a scale of 0.2, except for the last layer. `resize2dLayer` is used to resize the output of the discriminator. Note that this example does not use batch normalization, as the discriminator is jointly trained with the segmentation network using a small batch size.

The AdaptSegNet discriminator network in this example is illustrated in the following diagram.



Create an image input layer of size 1280-by-720-by-`numClasses` that takes in the segmentation predictions of the simulation and real domains.

```
inputSizeDiscriminator = [1280 720 numClasses];
```

Create fully convolutional layers and generate the discriminator layer graph.

```
% Factor for number of channels in convolution layer.
numChannelsFactor = 64;

% Scale factor to resize the output of the discriminator.
resizeScale = 64;

% Scalar multiplier for leaky ReLU layers.
leakyReLUScale = 0.2;

% Create the layers of the discriminator.
layers = [
    imageInputLayer(inputSizeDiscriminator,'Normalization','none','Name','inputLayer')
    convolution2dLayer(3,numChannelsFactor,'Stride',2,'Padding',1,'Name','conv1','WeightsInitial
    leakyReluLayer(leakyReLUScale,'Name','lrelu1')
    convolution2dLayer(3,numChannelsFactor*2,'Stride',2,'Padding',1,'Name','conv2','WeightsInitia
    leakyReluLayer(leakyReLUScale,'Name','lrelu2')
    convolution2dLayer(3,numChannelsFactor*4,'Stride',2,'Padding',1,'Name','conv3','WeightsInitia
    leakyReluLayer(leakyReLUScale,'Name','lrelu3')
    convolution2dLayer(3,numChannelsFactor*8,'Stride',2,'Padding',1,'Name','conv4','WeightsInitia
    leakyReluLayer(leakyReLUScale,'Name','lrelu4')
    convolution2dLayer(3,1,'Stride',2,'Padding',1,'Name','classifer','WeightsInitializer','narrow
    resize2dLayer('Scale', resizeScale,'Method','bilinear','Name','resizeLayer');
    ];

% Create the layer graph of the discriminator.
lgraphDiscriminator  = layerGraph(layers);
```

Visualize the discriminator network in a plot.

```
plot(lgraphDiscriminator)
title("Discriminator")
```

Specify Training Options

Specify these training options.

- Set the total number of iterations to `5000`. By doing so, you train the network for around 10 epochs.
- Set the learning rate for the generator to `2.5e-4`.
- Set the learning rate for the discriminator to `1e-4`.
- Set the L2 regularization factor to `0.0005`.
- The learning rate exponentially decreases based on the formula *learningrate* × $\left[\frac{iteration}{total\ \ iterations}\right]^{power}$. This decrease helps to stabilize the gradients at higher iterations. Set the power to `0.9`.
- Set the weight of the adversarial loss to `0.001`.
- Initialize the velocity of the gradient as `[ ]`. This value is used by SGDM to store the velocity of the gradients.
- Initialize the moving average of the parameter gradients as `[ ]`. This value is used by Adam initializer to store the average of parameter gradients.
- Initialize the moving average of squared parameter gradients as `[ ]`. This value is used by Adam initializer to store the average of the squared parameter gradients.
- Set the mini-batch size to `1`.

```
numIterations = 5000;
learnRateGenBase = 2.5e-4;
```

```
learnRateDisBase = 1e-4;
l2Regularization = 0.0005;
power = 0.9;
lamdaAdv = 0.001;
vel= [];
averageGrad = [];
averageSqGrad = [];
miniBatchSize = 1;
```

Train on a GPU, if one is available. Using a GPU requires Parallel Computing Toolbox™ and a CUDA® enabled NVIDIA® GPU. To automatically detect if you have a GPU available, set `executionEnvironment` to `"auto"`. If you do not have a GPU, or do not want to use one for training, set `executionEnvironment` to `"cpu"`. To ensure the use of a GPU for training, set `executionEnvironment` to `"gpu"`. For information about the supported compute capabilities, see "GPU Support by Release" (Parallel Computing Toolbox).

```
executionEnvironment = "auto";
```

Create the `minibatchqueue` object from the combined datastore of the simulation domain.

```
mbqTrainingDataSimulation =  minibatchqueue(combinedSimData,"MiniBatchSize",miniBatchSize, ...
    "MiniBatchFormat","SSCB","OutputEnvironment",executionEnvironment);
```

Create the `minibatchqueue` object from the input image datastore of the real domain.

```
mbqTrainingDataReal = minibatchqueue(preprocessedRealData,"MiniBatchSize",miniBatchSize, ...
    "MiniBatchFormat","SSCB","OutputEnvironment",executionEnvironment);
```

Train Model

Train the model using a custom training loop. The helper function `modelGradients`, defined in the Supporting Functions section of this example, calculate the gradients and losses for the generator and discriminator. Create the training progress plot using `configureTrainingLossPlotter`, attached to this example as a supporting file, and update the training progress using `updateTrainingPlots`. Loop over the training data and update the network parameters at each iteration.

For each iteration:

- Read the image and label information from the `minibatchqueue` object of the simulation data using the `next` function.
- Read the image information from the `minibatchqueue` object of the real data using the `next` function.
- Evaluate the model gradients using `dlfeval` and the `modelGradients` helper function, defined in the Supporting Functions section. `modelGradients` returns the gradients of the loss with respect to the learnable parameters.
- Update the generator network parameters using the `sgdmupdate` function.
- Update the discriminator network parameters using the `adamupdate` function.
- Update the training progress plot for every iteration and display various computed losses.

```
if doTraining

    % Create the dlnetwork object of the generator.
    dlnetGenerator = dlnetwork(lgraphGenerator);
```

```
        % Create the dlnetwork object of the discriminator.
        dlnetDiscriminator = dlnetwork(lgraphDiscriminator);

        % Create the subplots for the generator and discriminator loss.
        fig = figure;
        [generatorLossPlotter, discriminatorLossPlotter] = configureTrainingLossPlotter(fig);

        % Loop through the data for the specified number of iterations.
        for iter = 1:numIterations

            % Reset the minibatchqueue of simulation data.
            if ~hasdata(mbqTrainingDataSimulation)
                reset(mbqTrainingDataSimulation);
            end

            % Retrieve the next mini-batch of simulation data and labels.
            [dlX,label] = next(mbqTrainingDataSimulation);

            % Reset the minibatchqueue of real data.
            if ~hasdata(mbqTrainingDataReal)
                reset(mbqTrainingDataReal);
            end

            % Retrieve the next mini-batch of real data.
            dlZ = next(mbqTrainingDataReal);

            % Evaluate the model gradients and loss using dlfeval and the modelGradients function.
            [gradientGenerator,gradientDiscriminator, lossSegValue, lossAdvValue, lossDisValue] = ..
                dlfeval(@modelGradients,dlnetGenerator,dlnetDiscriminator,dlX,dlZ,label,lamdaAdv);

            % Apply L2 regularization.
            gradientGenerator  = dlupdate(@(g,w) g + l2Regularization*w, gradientGenerator, dlnetGene

            % Adjust the learning rate.
            learnRateGen = piecewiseLearningRate(iter,learnRateGenBase,numIterations,power);
            learnRateDis = piecewiseLearningRate(iter,learnRateDisBase,numIterations,power);

             % Update the generator network learnable parameters using the SGDM optimizer.
            [dlnetGenerator.Learnables, vel] = ...
                sgdmupdate(dlnetGenerator.Learnables,gradientGenerator,vel,learnRateGen);

             % Update the discriminator network learnable parameters using the Adam optimizer.
            [dlnetDiscriminator.Learnables, averageGrad, averageSqGrad] = ...
                adamupdate(dlnetDiscriminator.Learnables,gradientDiscriminator,averageGrad,averageSq

            % Update the training plot with loss values.
            updateTrainingPlots(generatorLossPlotter,discriminatorLossPlotter,iter, ...
                double(gather(extractdata(lossSegValue + lamdaAdv * lossAdvValue))),double(gather(ex

        end

        % Save the trained model.
        save('trainedAdaptSegGANNet.mat','dlnetGenerator');
    end
```

The discriminator can now identify whether the input is from the simulation or real domain. In turn, the generator can now generate segmentation predictions that are similar across the simulation and real domains.

Evaluate Model on Real Test Data

Evaluate the performance of the trained AdaptSegNet network by computing the mean IoU for the test data predictions.

Load the test data using `imageDatastore`.

```
realTestData = imageDatastore(realTestImagesFolder);
```

The CamVid data set has 32 classes. Use the `realpixelLabelIDs` helper function to reduce the number of classes to five, as for the simulation data set. The `realpixelLabelIDs` helper function is attached to this example as a supporting file.

```
labelIDs = realPixelLabelIDs;
```

Use `pixelLabelDatastore` (Computer Vision Toolbox) to load the ground truth label images for the test data.

```
realTestLabels = pixelLabelDatastore(realTestLabelsFolder,classes,labelIDs);
```

Shift the data to zero center to center the data around the origin, as for the training data, by using the `transform` function and the `preprocessData` helper function, defined in the Supporting Functions section.

```
preprocessedRealTestData = transform(realTestData, @(realtestdata)preprocessData(realtestdata));
```

Use `combine` to combine the transformed image datastore and pixel label datastores of the real test data.

```
combinedRealTestData = combine(preprocessedRealTestData,realTestLabels);
```

Create the `minibatchqueue` object from the combined datastore of the test data. Set `"MiniBatchSize"` to `1` for ease of evaluating the metrics.

```
mbqimdsTest = minibatchqueue(combinedRealTestData,"MiniBatchSize",1,...
    "MiniBatchFormat","SSCB","OutputEnvironment",executionEnvironment);
```

To generate the confusion matrix cell array, use the helper function `predictSegmentationLabelsOnTestSet` on `minibatchqueue` object of test data. The helper function `predictSegmentationLabelsOnTestSet` is listed below in Supporting Functions section.

```
imageSetConfusionMat = predictSegmentationLabelsOnTestSet(dlnetGenerator,mbqimdsTest);
```

Use `evaluateSemanticSegmentation` (Computer Vision Toolbox) to measure semantic segmentation metrics on the test set confusion matrix.

```
metrics = evaluateSemanticSegmentation(imageSetConfusionMat,classes,'Verbose',false);
```

To see the data set level metrics, inspect `metrics.DataSetMetrics`.

```
metrics.DataSetMetrics
```

```
ans=1×4 table
    GlobalAccuracy    MeanAccuracy    MeanIoU    WeightedIoU
```

```
    _____________    _____________    _______    ___________

      0.86883            0.769        0.64487      0.78026
```

The data set metrics provide a high-level overview of network performance. To see the impact each class has on the overall performance, inspect the per-class metrics using `metrics.ClassMetrics`.

```
metrics.ClassMetrics
```

```
ans=5×2 table
                 Accuracy      IoU
                 ________    _______

    Road          0.9147     0.81301
    Background    0.93418    0.85518
    Pavement      0.33373    0.27105
    Sky           0.82652    0.81109
    Car           0.83586    0.47399
```

The data set performance is good, but the class metrics show that the car and pavement classes are not segmented well. Training the network using additional data can yield improved results.

Segment Image

Run the trained network on one test image to check the segmented output prediction.

```
% Read the image from the test data.
data = readimage(realTestData,350);

% Perform the preprocessing step of zero shift on the image.
processeddata = preprocessData(data);

% Convert the data to dlarray.
processeddata = dlarray(processeddata,'SSCB');

% Predict the output of the network.
[genPrediction, ~] = forward(dlnetGenerator,processeddata);

% Get the label, which is the index with the maximum value in the channel dimension.
[~, labels] = max(genPrediction,[],3);

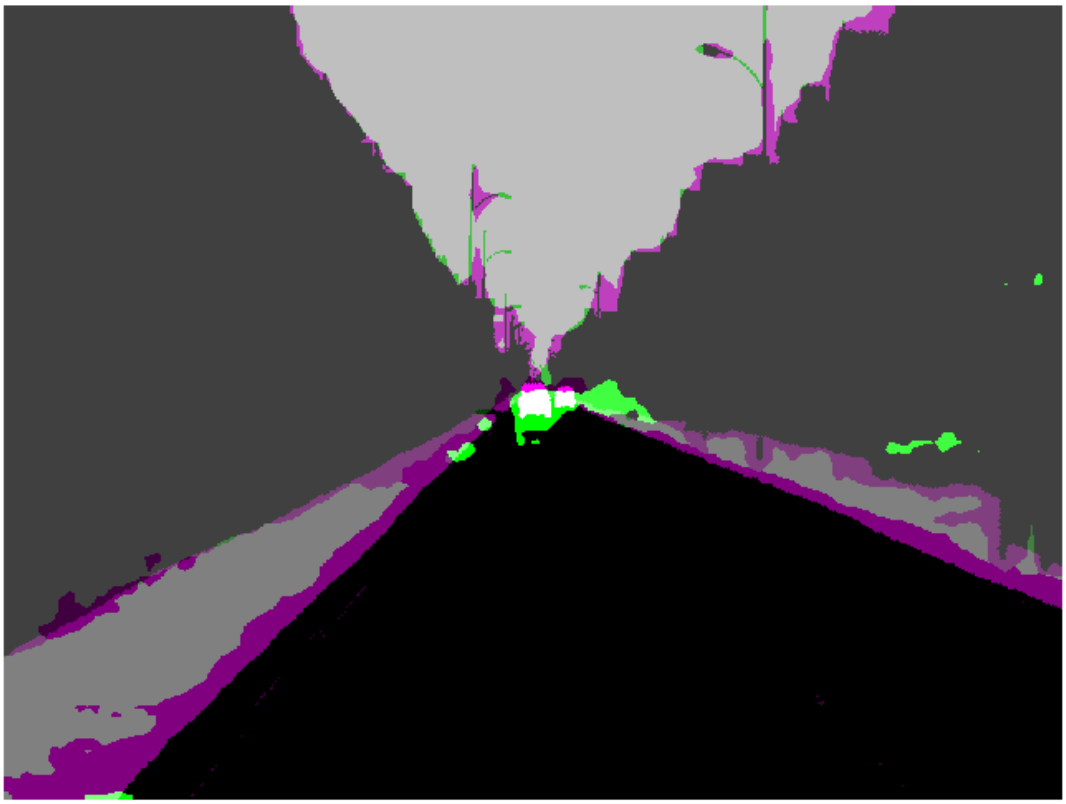
% Overlay the predicted labels on the image.
segmentedImage = labeloverlay(data,uint8(gather(extractdata(labels))),'Colormap',dmap);
```

Display the results.

```
figure
imshow(segmentedImage);
labelColorbar(dmap,classes);
```

Compare the label results with the expected ground truth stored in `realTestLabels`. The green and magenta regions highlight areas where the segmentation results differ from the expected ground truth.

```
expectedResult = readimage(realTestLabels,350);
actual = uint8(gather(extractdata(labels)));
expected = uint8(expectedResult);
figure
imshowpair(actual,expected)
```



Visually, the semantic segmentation results overlap well for the road, sky, and building classes. However, the results do not overlap well for the car and pavement classes.

Supporting Functions

Model Gradients Function

The helper function `modelGradients` calculates the gradients and adversarial loss for the generator and discriminator. The function also calculates the segmentation loss for the generator and the cross-entropy loss for the discriminator. As no state information is required to be remembered between the iterations for both generator and discriminator networks, the states are not updated.

```
function [gradientGenerator, gradientDiscriminator, lossSegValue, lossAdvValue, lossDisValue] = m

% Labels for adversarial training.
simulationLabel = 0;
realLabel = 1;

% Extract the predictions of the simulation from the generator.
[genPredictionSimulation, ~] = forward(dlnetGenerator,dlX);

% Compute the generator loss.
lossSegValue = segmentationLoss(genPredictionSimulation,label);
```

```
% Extract the predictions of the real data from the generator.
[genPredictionReal, ~] = forward(dlnetGenerator,dlZ);

% Extract the softmax predictions of the real data from the discriminator.
disPredictionReal = forward(dlnetDiscriminator,softmax(genPredictionReal));

% Create a matrix of simulation labels of real prediction size.
Y = simulationLabel * ones(size(disPredictionReal));

% Compute the adversarial loss to make the real distribution close to the simulation label.
lossAdvValue = mse(disPredictionReal,Y)/numel(Y(:));

% Compute the gradients of the generator with regard to loss.
gradientGenerator = dlgradient(lossSegValue + lamdaAdv*lossAdvValue,dlnetGenerator.Learnables);

% Extract the softmax predictions of the simulation from the discriminator.
disPredictionSimulation = forward(dlnetDiscriminator,softmax(genPredictionSimulation));

% Create a matrix of simulation labels of simulation prediction size.
Y = simulationLabel * ones(size(disPredictionSimulation));

% Compute the discriminator loss with regard to simulation class.
lossDisValueSimulation = mse(disPredictionSimulation,Y)/numel(Y(:));

% Extract the softmax predictions of the real data from the discriminator.
disPredictionReal = forward(dlnetDiscriminator,softmax(genPredictionReal));

% Create a matrix of real labels of real prediction size.
Y = realLabel * ones(size(disPredictionReal));

% Compute the discriminator loss with regard to real class.
lossDisValueReal = mse(disPredictionReal,Y)/numel(Y(:));

% Compute the total discriminator loss.
lossDisValue = lossDisValueSimulation + lossDisValueReal;

% Compute the gradients of the discriminator with regard to loss.
gradientDiscriminator = dlgradient(lossDisValue,dlnetDiscriminator.Learnables);

end
```

Segmentation Loss Function

The helper function `segmentationLoss` computes the feature segmentation loss, which is defined as the cross-entropy loss for the generator using the simulation data and its respective ground truth. The helper function computes the loss by using the `crossentropy` function.

```
function loss = segmentationLoss(predict, target)

% Generate the one-hot encodings of the ground truth.
oneHotTarget = onehotencode(categorical(extractdata(target)),4);

% Convert the one-hot encoded data to dlarray.
oneHotTarget = dlarray(oneHotTarget,'SSBC');

% Compute the softmax output of the predictions.
predictSoftmax = softmax(predict);
```

```
% Compute the cross-entropy loss.
loss =  crossentropy(predictSoftmax,oneHotTarget,'TargetCategories','exclusive')/(numel(oneHotTa
end
```

The helper function `downloadDataset` downloads both the simulation and real data sets from the specified URLs to the specified folder locations if they do not exist. The function returns the paths of the simulation, real training data, and real testing data. The function downloads the entire CamVid data set and partition the data into training and test sets using the `subsetCamVidDatasetFileNames` mat file, attached to the example as a supporting file.

```
function [simulationImagesFolder, simulationLabelsFolder, realImagesFolder, realLabelsFolder,...
    realTestImagesFolder, realTestLabelsFolder] = ...
    downloadDataset(simulationDataLocation, simulationDataURL, realDataLocation, realImageDataURI

% Build the training image and label folder location for simulation data.
simulationDataZip = fullfile(simulationDataLocation,'SimulationDrivingDataset.zip');

% Get the simulation data if it does not exist.
if ~exist(simulationDataZip,'file')
    mkdir(simulationDataLocation)

    disp('Downloading the simulation data');
    websave(simulationDataZip,simulationDataURL);
    unzip(simulationDataZip,simulationDataLocation);
end

simulationImagesFolder = fullfile(simulationDataLocation,'SimulationDrivingDataset','images');
simulationLabelsFolder = fullfile(simulationDataLocation,'SimulationDrivingDataset','labels');

camVidLabelsZip = fullfile(realDataLocation,'CamVidLabels.zip');
camVidImagesZip = fullfile(realDataLocation,'CamVidImages.zip');

if ~exist(camVidLabelsZip,'file') || ~exist(camVidImagesZip,'file')
    mkdir(realDataLocation)

    disp('Downloading 16 MB CamVid dataset labels...');
    websave(camVidLabelsZip, realLabelDataURL);
    unzip(camVidLabelsZip, fullfile(realDataLocation,'CamVidLabels'));

    disp('Downloading 587 MB CamVid dataset images...');
    websave(camVidImagesZip, realImageDataURL);
    unzip(camVidImagesZip, fullfile(realDataLocation,'CamVidImages'));
end

% Build the training image and label folder location for real data.
realImagesFolder = fullfile(realDataLocation,'train','images');
realLabelsFolder = fullfile(realDataLocation,'train','labels');

% Build the testing image and label folder location for real data.
realTestImagesFolder = fullfile(realDataLocation,'test','images');
realTestLabelsFolder = fullfile(realDataLocation,'test','labels');

% Partition the data into training and test sets if they do not exist.
if ~exist(realImagesFolder,'file') || ~exist(realLabelsFolder,'file') || ...
        ~exist(realTestImagesFolder,'file') || ~exist(realTestLabelsFolder,'file')

    mkdir(realImagesFolder);
```

```
    mkdir(realLabelsFolder);
    mkdir(realTestImagesFolder);
    mkdir(realTestLabelsFolder);

    % Load the mat file that has the names for testing and training.
    partitionNames = load('subsetCamVidDatasetFileNames.mat');

    % Extract the test images names.
    imageTestNames = partitionNames.imageTestNames;

    % Remove the empty cells.
    imageTestNames = imageTestNames(~cellfun('isempty',imageTestNames));

    % Extract the test labels names.
    labelTestNames = partitionNames.labelTestNames;

    % Remove the empty cells.
    labelTestNames = labelTestNames(~cellfun('isempty',labelTestNames));

    % Copy the test images to the respective folder.
    for i = 1:size(imageTestNames,1)
        labelSource = fullfile(realDataLocation,'CamVidLabels',labelTestNames(i));
        imageSource = fullfile(realDataLocation,'CamVidImages','701_StillsRaw_full',imageTestName
        copyfile(imageSource{1}, realTestImagesFolder);
        copyfile(labelSource{1}, realTestLabelsFolder);
    end

    % Extract the train images names.
    imageTrainNames = partitionNames.imageTrainNames;

    % Remove the empty cells.
    imageTrainNames = imageTrainNames(~cellfun('isempty',imageTrainNames));

    % Extract the train labels names.
    labelTrainNames = partitionNames.labelTrainNames;

    % Remove the empty cells.
    labelTrainNames = labelTrainNames(~cellfun('isempty',labelTrainNames));

    % Copy the train images to the respective folder.
    for i = 1:size(imageTrainNames,1)
        labelSource = fullfile(realDataLocation,'CamVidLabels',labelTrainNames(i));
        imageSource = fullfile(realDataLocation,'CamVidImages','701_StillsRaw_full',imageTrainNa
        copyfile(imageSource{1},realImagesFolder);
        copyfile(labelSource{1},realLabelsFolder);
    end
end
end
```

The helper function `addASPPToNetwork` creates the atrous spatial pyramid pooling (ASPP) layers and adds them to the input layer graph. The function returns the layer graph with ASPP layers connected to it.

```
function lgraph  = addASPPToNetwork(lgraph, numClasses)

% Define the ASPP dilation factors.
asppDilationFactors = [6,12];
```

```
% Define the ASPP filter sizes.
asppFilterSizes = [3,3];

% Extract the last layer of the layer graph.
lastLayerName = lgraph.Layers(end).Name;

% Define the addition layer.
addLayer = additionLayer(numel(asppDilationFactors),'Name','additionLayer');

% Add the addition layer to the layer graph.
lgraph = addLayers(lgraph,addLayer);

% Create the ASPP layers connected to the addition layer
% and connect the layer graph.
for i = 1: numel(asppDilationFactors)
    asppConvName = "asppConv_" + string(i);
    branchFilterSize = asppFilterSizes(i);
    branchDilationFactor = asppDilationFactors(i);
    asspLayer  = convolution2dLayer(branchFilterSize, numClasses,'DilationFactor', branchDilatio
        'Padding','same','Name',asppConvName,'WeightsInitializer','narrow-normal','BiasInitializ
    lgraph = addLayers(lgraph,asspLayer);
    lgraph = connectLayers(lgraph,lastLayerName,asppConvName);
    lgraph = connectLayers(lgraph,asppConvName,strcat(addLayer.Name,'/',addLayer.InputNames{i}))
end
end
```

The helper function `predictSegmentationLabelsOnTestSet` calculates the confusion matrix of the predicted and ground truth labels using the `segmentationConfusionMatrix` (Computer Vision Toolbox) function.

```
function confusionMatrix =  predictSegmentationLabelsOnTestSet(net, minbatchTestData)

confusionMatrix = {};
i = 1;
while hasdata(minbatchTestData)

    % Use next to retrieve a mini-batch from the datastore.
    [dlX, gtlabels] = next(minbatchTestData);

    % Predict the output of the network.
    [genPrediction, ~] = forward(net,dlX);

    % Get the label, which is the index with maximum value in the channel dimension.
    [~, labels] = max(genPrediction,[],3);

    % Get the confusion matrix of each image.
    confusionMatrix{i}  = segmentationConfusionMatrix(double(gather(extractdata(labels))),double

    i = i+1;
end

confusionMatrix = confusionMatrix';

end
```

The helper function `piecewiseLearningRate` computes the current learning rate based on the iteration number.

```
function lr = piecewiseLearningRate(i, baseLR, numIterations, power)

fraction = i/numIterations;
factor = (1 - fraction)^power * 1e1;
lr = baseLR * factor;

end
```

The helper function `preprocessData` performs a zero center shift by subtracting the number of the image channels by the respective mean.

```
function data = preprocessData(data)

% Extract respective channels.
rc = data(:,:,1);
gc = data(:,:,2);
bc = data(:,:,3);

% Compute the respective channel means.
r = mean(rc(:));
g = mean(gc(:));
b = mean(bc(:));

% Shift the data by the mean of respective channel.
data = single(data) - single(shiftdim([r g b],-1));
end
```

Lidar Examples

Aerial Lidar Semantic Segmentation Using PointNet++ Deep Learning

This example shows how to train a PointNet++ deep learning network to perform semantic segmentation on aerial lidar data.

Lidar data acquired from airborne laser scanning systems is used in applications such as topographic mapping, city modeling, biomass measurement, and disaster management. Extracting meaningful information from this data requires semantic segmentation, a process where each point in the point cloud is assigned a unique class label.

In this example, you train a PointNet++ network to perform semantic segmentation by using the Dayton Annotated Lidar Earth Scan (DALES) dataset [1 on page 11-0]. The dataset contains scenes of dense, labeled aerial lidar data from urban, suburban, rural, and commercial settings. The dataset provides semantic segmentation labels for 8 classes such as buildings, cars, trucks, poles, power lines, fences, ground, and vegetation.

Load DALES Data

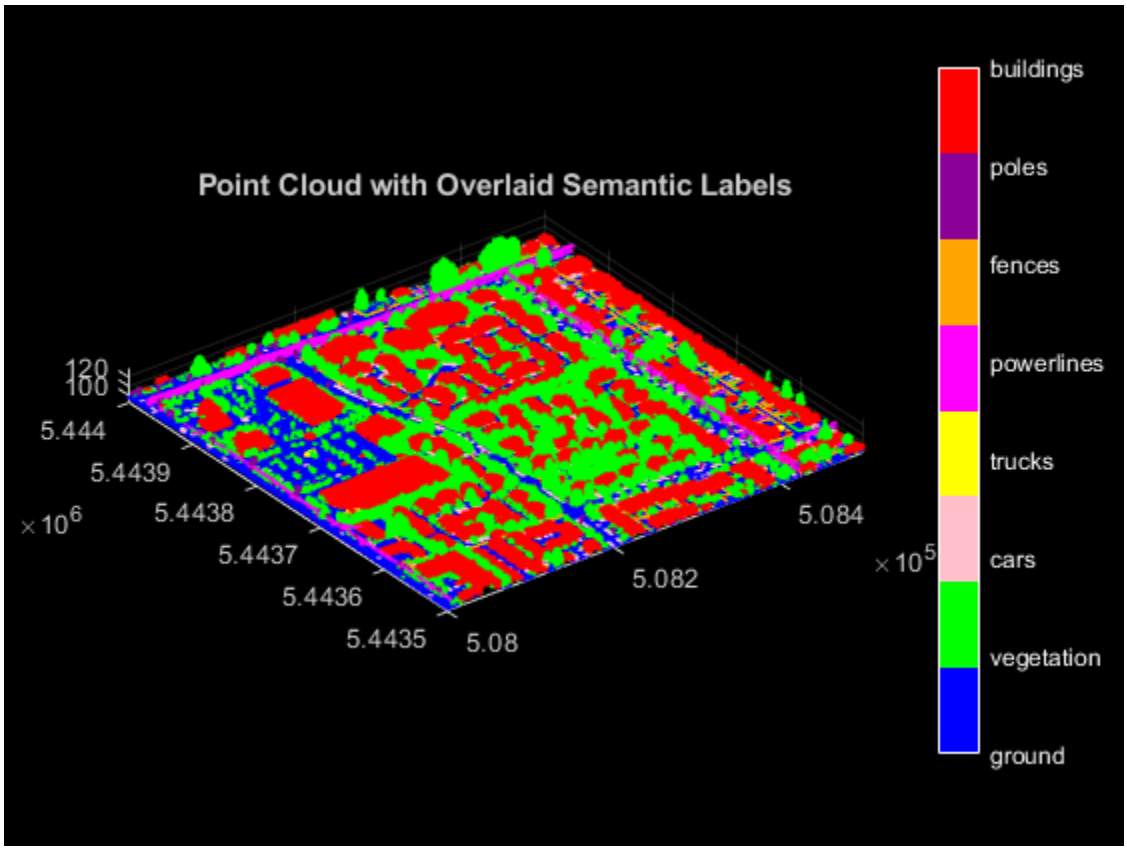
The DALES dataset contains 40 scenes of aerial lidar data. Out of the 40 scenes, 29 scenes are used for training and the remaining 11 scenes are used for testing. Each pixel in the data has a class label. Follow the instructions on the DALES website to download the dataset to the folder specified by the `dataFolder` variable. Create folders to store training and test data.

```
dataFolder = fullfile(tempdir,'DALES');
trainDataFolder = fullfile(dataFolder,'dales_las','train');
testDataFolder = fullfile(dataFolder,'dales_las','test');
```

Preview a point cloud from the training data.

```
lasReader = lasFileReader(fullfile(trainDataFolder,'5080_54435.las'));
[pc,attr] = readPointCloud(lasReader,'Attributes','Classification');
labels = attr.Classification;

% Select only labeled data.
pc = select(pc,labels~=0);
labels = labels(labels~=0);
classNames = [
    "ground"
    "vegetation"
    "cars"
    "trucks"
    "powerlines"
    "fences"
    "poles"
    "buildings"
    ];
figure;
ax = pcshow(pc.Location,labels);
helperLabelColorbar(ax,classNames);
title('Point Cloud with Overlaid Semantic Labels');
```



Preprocess Data

Each point cloud in the DALES dataset covers an area of 500-by-500 meters, which is much larger than the typical area covered by terrestrial rotating lidar point clouds. For efficient memory processing, divide the point cloud into small, non-overlapping grids.

Use the `helperCropPointCloudsAndMergeLabels` function, attached to this example as a supporting file, to:

- Crop the point clouds into non-overlapping grids of size 50-by-50 meters.
- Downsample the point cloud to a fixed size.
- Normalize the point clouds to range [0 1].
- Save the cropped grids and semantic labels as PCD and PNG files, respectively.

Define the grid dimensions and set a fixed number of points per grid to enable faster training.

```
gridSize = [50,50];
numPoints = 8192;
```

If the training data is already divided into grids, set `writeFiles` to `false`. Please note that the training data must be in a format supported by the `pcread` (Computer Vision Toolbox) function.

```
writeFiles = true;
numClasses = numel(classNames);
[pcCropTrainPath,labelsCropTrainPath,weights] = helperCropPointCloudsAndMergeLabels( ...
    gridSize,trainDataFolder,numPoints,writeFiles,numClasses);
```

Note: Processing can take some time. The code suspends MATLAB® execution until processing is complete.

The point distribution in the training dataset across all the classes is captured in `weights`. Normalize the `weights` using the `maxWeight`.

```
[maxWeight,maxLabel] = max(weights);
weights = sqrt(maxWeight./weights);
```

Create Datastore Objects for Training

Create a `fileDatastore` object to load PCD files using the `pcread` (Computer Vision Toolbox) function.

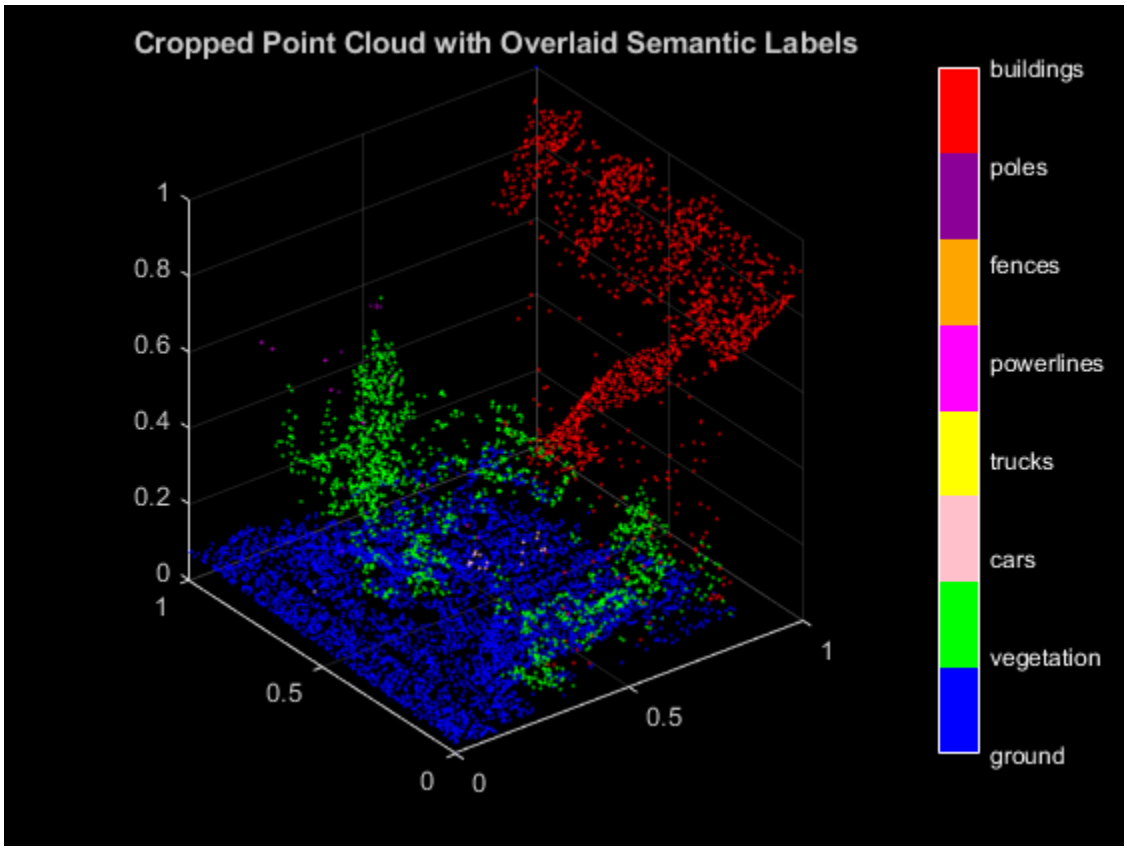
```
ldsTrain = fileDatastore(pcCropTrainPath,'ReadFcn',@(x) pcread(x));
```

Use a `pixelLabelDatastore` (Computer Vision Toolbox) object to store pixel-wise labels from the pixel label images. The object maps each pixel label to a class name and assigns a unique label ID to each class.

```
% Specify label IDs from 1 to the number of classes.
labelIDs = 1 : numClasses;
pxdsTrain = pixelLabelDatastore(labelsCropTrainPath,classNames,labelIDs);
```

Load and display the point cloud.

```
ptcld = preview(ldsTrain);
labels = preview(pxdsTrain);
figure;
ax = pcshow(ptcld.Location,uint8(labels));
helperLabelColorbar(ax,classNames);
title('Cropped Point Cloud with Overlaid Semantic Labels');
```



Use the `helperConvertPointCloud` function, defined at the end of this example, to convert the point cloud to cell array. This function also permutes the dimensions of the point cloud to make it compatible with the input layer of the network.

```
ldsTransformed = transform(ldsTrain,@(x) helperConvertPointCloud(x));
```

Use the `combine` function to combine the point clouds and pixel labels into a single datastore for training.

```
dsTrain = combine(ldsTransformed,pxdsTrain);
```

Define PointNet++ Model

The PointNet++ [2 on page 11-0] segmentation model consists of two main components:

- Set abstraction modules
- Feature propagation modules

The series of set abstraction modules progressively subsamples points of interest by hierarchically grouping points, and uses a custom PointNet architecture to encode points into feature vectors. Because semantic segmentation tasks require point features for all the original points, a series of feature propagation modules are used to hierarchically interpolate features to original points using an inverse-distance based interpolation scheme.

Define the PointNet++ architecture using the `pointnetplusLayers` (Lidar Toolbox) function.

```
lgraph = pointnetplusLayers(numPoints,3,numClasses);
```

To handle the class-imbalance on the DALES dataset, the weighted cross-entropy loss from the `pixelClassificationLayer` (Computer Vision Toolbox) function is used. This will penalize the network more if a point belonging to a class with lower weight is misclassified.

```
% Replace the FocalLoss layer with pixelClassificationLayer.
larray = pixelClassificationLayer('Name','SegmentationLayer','ClassWeights', ...
    weights,'Classes',classNames);
lgraph = replaceLayer(lgraph,'FocalLoss',larray);
```

Specify Training Options

Use the `Adam` optimization algorithm to train the network. Use the `trainingOptions` function to specify the hyperparameters.

```
learningRate = 0.0005;
l2Regularization = 0.01;
numEpochs = 20;
miniBatchSize = 6;
learnRateDropFactor = 0.1;
learnRateDropPeriod = 10;
gradientDecayFactor = 0.9;
squaredGradientDecayFactor = 0.999;

options = trainingOptions('adam', ...
    'InitialLearnRate',learningRate, ...
    'L2Regularization',l2Regularization, ...
    'MaxEpochs',numEpochs, ...
    'MiniBatchSize',miniBatchSize, ...
    'LearnRateSchedule','piecewise', ...
    'LearnRateDropFactor',learnRateDropFactor, ...
    'LearnRateDropPeriod',learnRateDropPeriod, ...
    'GradientDecayFactor',gradientDecayFactor, ...
    'SquaredGradientDecayFactor',squaredGradientDecayFactor, ...
    'Plots','training-progress');
```

Note: Reduce the `miniBatchSize` value to control memory usage when training.

Train Model

You can train the network yourself by setting the `doTraining` argument to `true`. If you train the network, you can use a CPU or GPU. Using a GPU requires Parallel Computing Toolbox™ and a CUDA® enabled NVIDIA® GPU. For more information, see “GPU Support by Release” (Parallel Computing Toolbox). Otherwise, load a pretrained network.

```
doTraining = false;
if doTraining
    % Train the network on the dsTrain datastore using the trainNetwork function.
    [net, info] = trainNetwork(dsTrain,lgraph,options);
else
    % Load the pretrained network.
    load('pointnetplusTrained.mat','net');
end
```

Segment Aerial Point Cloud

The network is trained on downsampled point clouds. To perform segmentation on a test point cloud, first downsample the test point cloud, similar to how training data is downsampled. Perform inference

on this downsampled test point cloud to compute prediction labels. Interpolate the prediction labels, to obtain prediction labels on the dense point cloud.

Define `numNearestNeighbors` and `radius` to find the nearest points in the downsampled point cloud for each point in the dense point cloud and to perform interpolation effectively.

```
numNearestNeighbors = 20;
radius = 0.05;
```

Read the full test point cloud.

```
lasReader = lasFileReader(fullfile(testDataFolder,'5080_54470.las'));
[pc,attr] = readPointCloud(lasReader,'Attributes','Classification');
labelsDenseTarget = attr.Classification;

% Select only labeled data.
pc = select(pc,labelsDenseTarget~=0);
labelsDenseTarget = labelsDenseTarget(labelsDenseTarget~=0);

% Initialize prediction labels
labelsDensePred = zeros(size(labelsDenseTarget));
```

Calculate the number of non-overlapping grids based on `gridSize`, `XLimits`, and `YLimits` of the point cloud.

```
numGridsX = round(diff(pc.XLimits)/gridSize(1));
numGridsY = round(diff(pc.YLimits)/gridSize(2));
[~,edgesX,edgesY,indx,indy] = histcounts2(pc.Location(:,1),pc.Location(:,2), ...
    [numGridsX,numGridsY],'XBinLimits',pc.XLimits,'YBinLimits',pc.YLimits);
ind = sub2ind([numGridsX,numGridsY],indx,indy);
```

Iterate over all the non-overlapping grids and predict the labels using the `semanticseg` (Computer Vision Toolbox) function.

```
for num=1:numGridsX*numGridsY
    idx = ind==num;
    ptCloudDense = select(pc,idx);
    labelsDense = labelsDenseTarget(idx);

    % Use the helperDownsamplePoints function, attached to this example as a
    % supporting file, to extract a downsampled point cloud from the
    % dense point cloud.
    ptCloudSparse = helperDownsamplePoints(ptCloudDense, ...
        labelsDense,numPoints);

    % Make the spatial extent of the dense point cloud and the sparse point
    % cloud same.
    limits = [ptCloudDense.XLimits;ptCloudDense.YLimits;ptCloudDense.ZLimits];
    ptCloudSparseLocation = ptCloudSparse.Location;
    ptCloudSparseLocation(1:2,:) = limits(:,1:2)';
    ptCloudSparse = pointCloud(ptCloudSparseLocation,'Color',ptCloudSparse.Color, ...
        'Intensity',ptCloudSparse.Intensity, ...
        'Normal',ptCloudSparse.Normal);

    % Use the helperNormalizePointCloud function, attached to this example as
    % a supporting file, to normalize the point cloud between 0 and 1.
    ptCloudSparseNormalized = helperNormalizePointCloud(ptCloudSparse);
    ptCloudDenseNormalized = helperNormalizePointCloud(ptCloudDense);
```

```
    % Use the helperConvertPointCloud function, defined at the end of this
    % example, to convert the point cloud to a cell array and to permute the
    % dimensions of the point cloud to make it compatible with the input layer
    % of the network.
    ptCloudSparseForPrediction = helperConvertPointCloud(ptCloudSparseNormalized);

    % Get the output predictions.
    labelsSparsePred = semanticseg(ptCloudSparseForPrediction{1,1}, ...
        net,'OutputType','uint8');

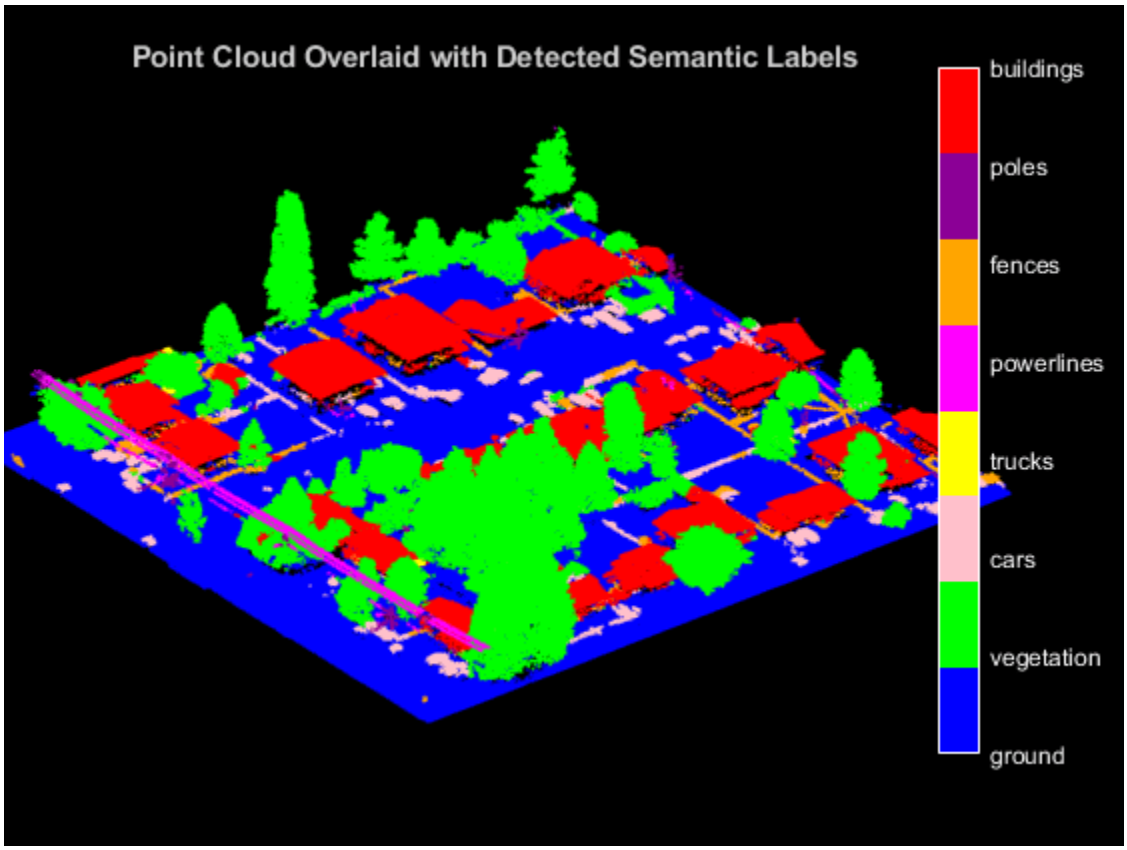
    % Use the helperInterpolate function, attached to this example as a
    % supporting file, to calculate labels for the dense point cloud,
    % using the sparse point cloud and labels predicted on the sparse point cloud.
    interpolatedLabels = helperInterpolate(ptCloudDenseNormalized, ...
        ptCloudSparseNormalized,labelsSparsePred,numNearestNeighbors, ...
        radius,maxLabel,numClasses);

    labelsDensePred(idx) = interpolatedLabels;
end
```

```
Starting parallel pool (parpool) using the 'local' profile ...
Connected to the parallel pool (number of workers: 6).
```

For better visualisation, select a region of interest from the point cloud data. Modify the limits in the `roi` variable according to the point cloud data.

```
roi = [edgesX(5) edgesX(8) edgesY(8) edgesY(11) pc.ZLimits];
indices = findPointsInROI(pc,roi);
figure;
ax = pcshow(select(pc,indices).Location, labelsDensePred(indices));
axis off;
zoom(ax,1.5);
helperLabelColorbar(ax,classNames);
title('Point Cloud Overlaid with Detected Semantic Labels');
```



Evaluate Network

Evaluate the network performance on the test data. Use the `evaluateSemanticSegmentation` (Computer Vision Toolbox) function to compute the semantic segmentation metrics from the test set results. The target and predicted labels are computed previously and are stored in the `labelsDensePred` and the `labelsDenseTarget` variables respectively.

```
confusionMatrix = segmentationConfusionMatrix(labelsDensePred, ...
    double(labelsDenseTarget),'Classes',1:numClasses);
metrics = evaluateSemanticSegmentation({confusionMatrix},classNames,'Verbose',false);
```

You can measure the amount of overlap per class using the intersection-over-union (IoU) metric.

The `evaluateSemanticSegmentation` (Computer Vision Toolbox) function returns metrics for the entire data set, for individual classes, and for each test image. To see the metrics at the data set level, use the `metrics.DataSetMetrics` property.

```
metrics.DataSetMetrics
```

```
ans=1×4 table
    GlobalAccuracy    MeanAccuracy    MeanIoU    WeightedIoU
    ______________    ____________    _______    ___________

       0.93191           0.64238      0.52709      0.88198
```

The data set metrics provide a high-level overview of network performance. To see the impact each class has on the overall performance, inspect the metrics for each class using the `metrics.ClassMetrics` property.

```
metrics.ClassMetrics
```

```
ans=8×2 table
                 Accuracy       IoU
                 ________    _________

    ground         0.98874      0.93499
    vegetation     0.85948      0.81865
    cars           0.61847      0.36659
    trucks        0.018676    0.0070006
    powerlines      0.7758       0.6904
    fences          0.3753      0.21718
    poles           0.5741      0.28528
    buildings      0.92843      0.89662
```

Although the overall network performance is good, the class metrics for some classes like `Trucks` indicate that more training data is required for better performance.

Supporting Functions

The `helperLabelColorbar` function adds a colorbar to the current axis. The colorbar is formatted to display the class names with the color.

```
function helperLabelColorbar(ax,classNames)
% Colormap for the original classes.
cmap = [[0,0,255];
    [0,255,0];
    [255,192,203];
    [255,255,0];
    [255,0,255];
    [255,165,0];
    [139,0,150];
    [255,0,0]];
cmap = cmap./255;
cmap = cmap(1:numel(classNames),:);
colormap(ax,cmap);

% Add colorbar to current figure.
c = colorbar(ax);
c.Color = 'w';

% Center tick labels and use class names for tick marks.
numClasses = size(classNames, 1);
c.Ticks = 1:1:numClasses;
c.TickLabels = classNames;

% Remove tick mark.
c.TickLength = 0;
end
```

The `helperConvertPointCloud` function converts the point cloud to a cell array and permutes the dimensions of the point cloud to make it compatible with the input layer of the network.

```
function data = helperConvertPointCloud(data)
if ~iscell(data)
    data = {data};
end
numObservations = size(data,1);
for i = 1:numObservations
    tmp = data{i,1}.Location;
    data{i,1} = permute(tmp,[1,3,2]);
end
end
```

Code Generation For Aerial Lidar Semantic Segmentation Using PointNet++ Deep Learning

This example shows how to generate CUDA® MEX code for a PointNet++ [1 on page 11-0] network for lidar semantic segmentation. This example uses a pretrained PointNet++ network that can segment unorganized lidar point clouds belonging to eight classes (buildings, cars, trucks, poles, power lines, fences, ground, and vegetation). For more information on PointNet++ network, see "Getting started with PointNet++" (Lidar Toolbox).

Third-Party Prerequisites

Required

- CUDA enabled NVIDIA® GPU and compatible driver.

Optional

For non-MEX builds such as static libraries, dynamic libraries, or executables, this example has the following additional requirements.

- NVIDIA toolkit.
- NVIDIA cuDNN library.
- Environment variables for the compilers and libraries. For more information, see "Third-Party Hardware" (GPU Coder) and "Setting Up the Prerequisite Products" (GPU Coder).

Verify GPU Environment

To verify that the compilers and libraries for running this example are set up correctly, use the `coder.checkGpuInstall` (GPU Coder) function.

```
envCfg = coder.gpuEnvConfig('host');
envCfg.DeepLibTarget = 'cudnn';
envCfg.DeepCodegen = 1;
envCfg.Quiet = 1;
coder.checkGpuInstall(envCfg);
```

Load PointNet++ Network

Use the getPointnetplusNet function, attached as a supporting file to this example, to load the pretrained PointNet++ network. For more information on how to train this network, see "Aerial Lidar Semantic Segmentation Using PointNet++ Deep Learning" (Lidar Toolbox).

```
net = getPointnetplusNet;
```

The pretrained network is a DAG network. To display an interactive visualization of the network architecture, use the `analyzeNetwork` function.

The sampling and grouping layer, and the interpolation layer are implemented using the `functionLayer` function, that does not support code generation. So, replace the function layers in the network with custom layers that support code generation using the `helperReplaceFunctionLayers` helper function and save the network as a MAT file with the name `pointnetplusCodegenNet.mat`.

```
net = helperReplaceFunctionLayers(net);
```

`pointnetplusPredict` Entry-Point Function

The `pointnetplusPredict` entry-point function takes a point cloud data matrix as input and performs prediction on it by using the deep learning network saved in the `pointnetplusCodegenNet.mat` file. The function loads the network object from the `pointnetplusCodegenNet.mat` file into a persistent variable `mynet` and reuses the persistent variable in subsequent prediction calls.

```
type('pointnetplusPredict.m');
```

```
function out = pointnetplusPredict(in)
%#codegen

% A persistent object mynet is used to load the DAG network object. At
% the first call to this function, the persistent object is constructed and
% setup. When the function is called subsequent times, the same object is
% reused to call predict on inputs, thus avoiding reconstructing and
% reloading the network object.

% Copyright 2021 The MathWorks, Inc.

persistent mynet;

if isempty(mynet)
    mynet = coder.loadDeepLearningNetwork('pointnetplusCodegenNet.mat');
end

% pass in input
out = predict(mynet,in);
```

Generate CUDA MEX Code

To generate CUDA® code for the `pointnetplusPredict` entry-point function, create a GPU code configuration object for a MEX target and set the target language to C++. Use the `coder.DeepLearningConfig` (GPU Coder) function to create a CuDNN deep learning configuration object and assign it to the `DeepLearningConfig` property of the GPU code configuration object. Run the `codegen` command with the size of point cloud data in the input layer of the network, which in this case is [8192 1 3].

```
cfg = coder.gpuConfig('mex');
cfg.TargetLang = 'C++';
cfg.DeepLearningConfig = coder.DeepLearningConfig(TargetLibrary='cudnn');
codegen -config cfg pointnetplusPredict -args {randn(8192,1,3,'single')} -report
```

```
Code generation successful: View report
```

To generate CUDA® code for the TensorRT target, create and use a TensorRT deep learning configuration object instead of the CuDNN configuration object.

Segment Aerial Point Cloud Using Generated MEX Code

The network in this example is trained on the DALES data set [2 on page 11-0]. Follow the instructions on the DALES website to download the data set to the folder specified by the `dataFolder` variable. Create folders to store training and test data.

```
dataFolder = fullfile(tempdir,'DALES');
testDataFolder = fullfile(dataFolder,'dales_las','test');
```

Since the network is trained on downsampled point clouds, to perform segmentation on a test point cloud, first downsample the test point cloud, similar to how training data is downsampled. Perform inference on this downsampled test point cloud to compute prediction labels. Interpolate the prediction labels to obtain prediction labels on the dense point cloud.

Define `numNearestNeighbors` and `radius` to find the nearest points in the downsampled point cloud for each point in the dense point cloud and to perform interpolation effectively. Define the parameters `gridSize`, `numPoints`, and `maxLabel`, used to train the network.

```
numNearestNeighbors = 20;
radius = 0.05;
gridSize = [50,50];
numPoints = 8192;
maxLabel = 1;
```

Store the interpolated labels and the target labels in the `DensePredictedLabels`, and `DenseTargetLabels` directories, respectively.

```
densePcTargetLabelsPath = fullfile(testDataFolder,'DenseTargetLabels');
densePcPredLabelsPath =  fullfile(testDataFolder,'DensePredictedLabels');
```

Read the full test point cloud.

```
lasReader = lasFileReader(fullfile(testDataFolder,'5080_54470.las'));
[pc,attr] = readPointCloud(lasReader,'Attributes','Classification');
labelsDenseTarget = attr.Classification;

% Select only labeled data.
pc = select(pc,labelsDenseTarget~=0);
labelsDenseTarget = labelsDenseTarget(labelsDenseTarget~=0);

% Initialize prediction labels.
labelsDensePred = zeros(size(labelsDenseTarget));
classNames = [
    "ground"
    "vegetation"
    "cars"
    "trucks"
    "powerlines"
    "fences"
    "poles"
    "buildings"
    ];
numClasses = numel(classNames);
```

Calculate the number of non-overlapping grids based on the `gridSize`, `XLimits`, and `YLimits` values of the point cloud.

```
numGridsX = round(diff(pc.XLimits)/gridSize(1));
numGridsY = round(diff(pc.YLimits)/gridSize(2));
[~,edgesX,edgesY,indx,indy] = histcounts2(pc.Location(:,1),pc.Location(:,2), ...
    [numGridsX,numGridsY],'XBinLimits',pc.XLimits,'YBinLimits',pc.YLimits);
ind = sub2ind([numGridsX,numGridsY],indx,indy);
```

Iterate over all the non-overlapping grids and predict the labels using the `pointnetplusPredict_mex` function.

```
for num=1:numGridsX*numGridsY
    idx = ind==num;
```

```
    ptCloudDense = select(pc,idx);
    labelsDense = labelsDenseTarget(idx);

    % Use the helperDownsamplePoints function, attached to this example as a
    % supporting file, to extract a downsampled point cloud from the
    % dense point cloud.
    ptCloudSparse = helperDownsamplePoints(ptCloudDense, ...
        labelsDense,numPoints);

    % Make the spatial extent of the dense point cloud and the sparse point
    % cloud the same.
    limits = [ptCloudDense.XLimits;ptCloudDense.YLimits;ptCloudDense.ZLimits];
    ptCloudSparseLocation = ptCloudSparse.Location;
    ptCloudSparseLocation(1:2,:) = limits(:,1:2)';
    ptCloudSparse = pointCloud(ptCloudSparseLocation,'Color',ptCloudSparse.Color, ...
        'Intensity',ptCloudSparse.Intensity, ...
        'Normal',ptCloudSparse.Normal);

    % Use the helperNormalizePointCloud function, attached to this example as
    % a supporting file, to normalize the point cloud between 0 and 1.
    ptCloudSparseNormalized = helperNormalizePointCloud(ptCloudSparse);
    ptCloudDenseNormalized = helperNormalizePointCloud(ptCloudDense);

    % Use the helperConvertPointCloud function, defined at the end of this
    % example, to convert the point cloud to a cell array and to permute the
    % dimensions of the point cloud to make it compatible with the input layer
    % of the network.
    ptCloudSparseForPrediction = helperConvertPointCloud(ptCloudSparseNormalized);

    % Get the output predictions.
    scoresPred = pointnetplusPredict_mex(ptCloudSparseForPrediction{1,1});
    [~,labelsSparsePred] = max(scoresPred,[],3);
    labelsSparsePred = uint8(labelsSparsePred);

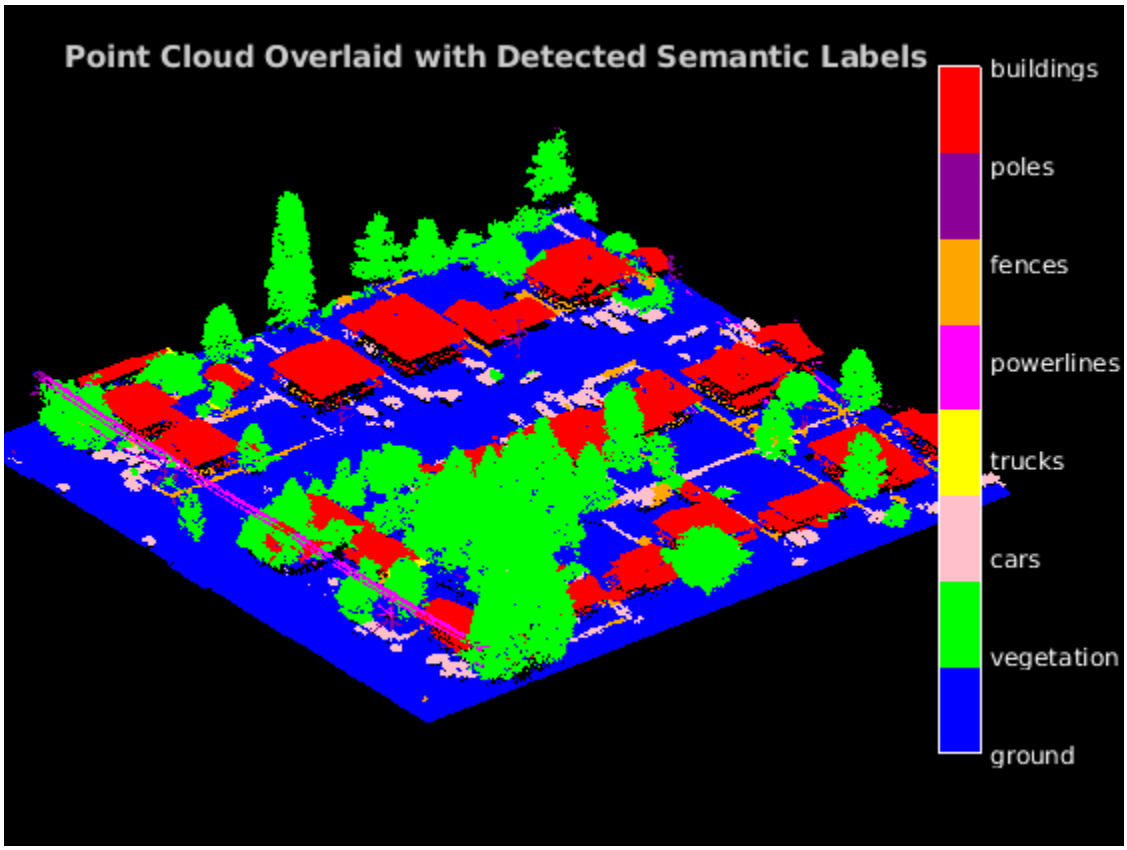
    % Use the helperInterpolate function, attached to this example as a
    % supporting file, to calculate labels for the dense point cloud,
    % using the sparse point cloud and labels predicted on the sparse point cloud.
    interpolatedLabels = helperInterpolate(ptCloudDenseNormalized, ...
        ptCloudSparseNormalized,labelsSparsePred,numNearestNeighbors, ...
        radius,maxLabel,numClasses);

    labelsDensePred(idx) = interpolatedLabels;
end

Starting parallel pool (parpool) using the 'local' profile ...
Connected to the parallel pool (number of workers: 8).
```

For better visualization, select a region of interest from the point cloud data. Modify the limits in the `roi` variable according to the point cloud data.

```
roi = [edgesX(5) edgesX(8) edgesY(8) edgesY(11) pc.ZLimits];
indices = findPointsInROI(pc,roi);
figure;
ax = pcshow(select(pc,indices).Location, labelsDensePred(indices));
axis off;
zoom(ax,1.5);
helperLabelColorbar(ax,classNames);
title('Point Cloud Overlaid with Detected Semantic Labels');
```



Supporting Functions

The `helperLabelColorbar` function adds a colorbar to the current axis. The colorbar is formatted to display the class names with the color.

```
function helperLabelColorbar(ax,classNames)
% Colormap for the original classes.
cmap = [[0,0,255];
    [0,255,0];
    [255,192,203];
    [255,255,0];
    [255,0,255];
    [255,165,0];
    [139,0,150];
    [255,0,0]];
cmap = cmap./255;
cmap = cmap(1:numel(classNames),:);
colormap(ax,cmap);

% Add colorbar to current figure.
c = colorbar(ax);
c.Color = 'w';

% Center tick labels and use class names for tick marks.
numClasses = size(classNames, 1);
c.Ticks = 1:1:numClasses;
c.TickLabels = classNames;
```

```
% Remove tick mark.
c.TickLength = 0;
end
```

The `helperConvertPointCloud` function converts the point cloud to a cell array and permutes the dimensions of the point cloud to make it compatible with the input layer of the network.

```
function data = helperConvertPointCloud(data)
if ~iscell(data)
    data = {data};
end
numObservations = size(data,1);
for i = 1:numObservations
    tmp = data{i,1}.Location;
    data{i,1} = permute(tmp,[1,3,2]);
end
end
```

Lidar Point Cloud Semantic Segmentation Using PointSeg Deep Learning Network

This example shows how to train a PointSeg semantic segmentation network on 3-D organized lidar point cloud data.

PointSeg [1 on page 11-0] is a convolutional neural network (CNN) for performing end-to-end semantic segmentation of road objects based on an organized lidar point cloud. By using methods such as atrous spatial pyramid pooling (ASPP) and squeeze-and-excitation blocks, the network provides improved segmentation results. The training procedure shown in this example requires 2-D spherical projected images as inputs to the deep learning network.

This example uses a highway scene data set collected using an Ouster OS1 sensor. It contains organized lidar point cloud scans of highway scenes and corresponding ground truth labels for car and truck objects. The size of the data file is approximately 760 MB.

Download Lidar Data Set

Execute this code to download the highway scene data set. The data set contains 1617 point clouds stored as `pointCloud` objects in a cell array. Corresponding ground truth data, which is attached to the example, contains bounding box information of cars and trucks in each point cloud.

```
url = 'https://www.mathworks.com/supportfiles/lidar/data/WPI_LidarData.tar.gz';

outputFolder = fullfile(tempdir,'WPI');
lidarDataTarFile = fullfile(outputFolder,'WPI_LidarData.tar.gz');

if ~exist(lidarDataTarFile, 'file')
    mkdir(outputFolder);

    disp('Downloading WPI Lidar driving data (760 MB)...');
    websave(lidarDataTarFile, url);
    untar(lidarDataTarFile,outputFolder);
end

% Check if tar.gz file is downloaded, but not uncompressed.
if ~exist(fullfile(outputFolder, 'WPI_LidarData.mat'), 'file')
    untar(lidarDataTarFile,outputFolder);
end
lidarData = load(fullfile(outputFolder, 'WPI_LidarData.mat'));

groundTruthData = load('WPI_LidarGroundTruth.mat');
```

Note: Depending on your Internet connection, the download process can take some time. The code suspends MATLAB® execution until the download process is complete. Alternatively, you can download the data set to your local disk using your web browser, and then extract `WPI_LidarData`. To use the file you downloaded from the web, change the `outputFolder` variable in the code to the location of the downloaded file.

Download Pretrained Network

Download the pretrained network to avoid having to wait for training to complete. If you want to train the network, set the `doTraining` variable to true.

```
doTraining = false;
if ~doTraining && ~exist('trainedPointSegNet.mat','file')
```

```
    disp('Downloading pretrained network (14 MB)...');
    pretrainedURL = 'https://www.mathworks.com/supportfiles/lidar/data/trainedPointSegNet.mat';
    websave('trainedPointSegNet.mat', pretrainedURL);
end
```

```
Downloading pretrained network (14 MB)...
```

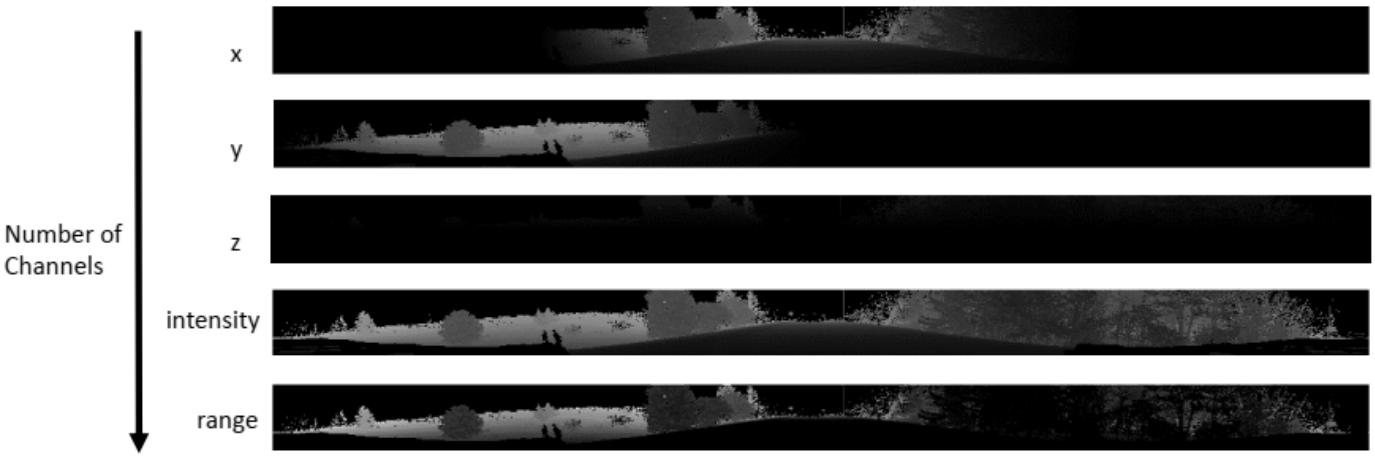
Prepare Data for Training

Load Lidar Point Clouds and Class Labels

Use the `helperGenerateTrainingData` supporting function, attached to this example, to generate training data from the lidar point clouds. The function uses point cloud and bounding box data to create five-channel input images and pixel label images. To create the pixel label images, the function selects points inside the bounding box and labels them with the bounding box class ID. Each training image is specified as a 64-by-1024-by-5 array:

- The height of each image is 64 pixels.
- The width of each image is 1024 pixels.
- The width of each image is 1024 pixels.
- Each image has 5 channels. The five channels specify the 3-D coordinates of the point cloud, intensity, and range: $r = \sqrt{x^2 + y^2 + z^2}$.

A visual representation of the training data follows.



Generate the five-channel training images and pixel label images.

```
imagesFolder = fullfile(outputFolder, 'images');
labelsFolder = fullfile(outputFolder, 'labels');

helperGenerateTrainingData(lidarData, groundTruthData, imagesFolder, labelsFolder);
```

```
Preprocessing data 100.00% complete
```

The five-channel images are saved as MAT files. Pixel labels are saved as PNG files.

Note: Processing can take some time. The code suspends MATLAB® execution until processing is complete.

Create ImageDatastore and PixelLabelDatastore

Use the `imageDatastore` object to extract and store the five channels of the 2-D spherical images using the `helperImageMatReader` supporting function, which is a custom MAT file reader. This function is attached to this example as a supporting file.

```
imds = imageDatastore(imagesFolder, ...
          'FileExtensions', '.mat', ...
          'ReadFcn', @helperImageMatReader);
```

Use the `pixelLabelDatastore` (Computer Vision Toolbox) object to store pixel-wise labels from the label images. The object maps each pixel label to a class name. In this example, cars and trucks are the only objects of interest; all other pixels are the background. Specify these classes (car, truck, and background) and assign a unique label ID to each class.

```
classNames = [
    "background"
    "car"
    "truck"
];

numClasses = numel(classNames);

% Specify label IDs from 1 to the number of classes.
labelIDs = 1 : numClasses;

pxds = pixelLabelDatastore(labelsFolder, classNames, labelIDs);
```

Load and display one of the labeled images by overlaying it on the corresponding intensity image using the `helperDisplayLidarOverlayImage` function, defined in the Supporting Functions on page 11-0 section of this example.

```
imageNumber = 225;

% Point cloud (channels 1, 2, and 3 are for location, channel 4 is for intensity).
I = readimage(imds, imageNumber);

labelMap = readimage(pxds, imageNumber);
figure;
helperDisplayLidarOverlayImage(I, labelMap, classNames);
title('Ground Truth');
```

Prepare Training, Validation, and Test Sets

Use the `helperPartitionLidarData` supporting function, attached to this example, to split the data into training, validation, and test sets that contain 970, 216, and 431 images, respectively.

```
[imdsTrain, imdsVal, imdsTest, pxdsTrain, pxdsVal, pxdsTest] = ...
    helperPartitionLidarData(imds, pxds);
```

Use the `combine` function to combine the pixel and image datastores for the training and validation data sets.

```
trainingData = combine(imdsTrain, pxdsTrain);
validationData = combine(imdsVal, pxdsVal);
```

Data Augmentation

Data augmentation is used to improve network accuracy by randomly transforming the original data during training. By using data augmentation, you can add more variety to the training data without actually having to increase the number of labeled training samples.

Augment the training data using the `transform` function with custom preprocessing operations specified by the `augmentData` function, defined in the Supporting Functions on page 11-0 section of this example. This function randomly flips the spherical 2-D image and associated labels in the horizontal direction. Apply data augmentation to only the training data set.

```
augmentedTrainingData = transform(trainingData, @(x) augmentData(x));
```

Balance Classes Using Class Weighting

To see the distribution of class labels in the data set, use the `countEachLabel` (Computer Vision Toolbox) function.

```
tbl = countEachLabel(pxds);
tbl(:,{'Name','PixelCount','ImagePixelCount'})
```

```
ans=3×3 table
         Name         PixelCount    ImagePixelCount
    ______________    __________    _______________

    {'background'}    1.0473e+08      1.0597e+08
    {'car'       }    9.7839e+05      8.4738e+07
    {'truck'     }    2.6017e+05      1.9726e+07
```

The classes in this data set are imbalanced, which is a common issue in automotive data sets containing street scenes. The background class covers more area than the car and truck classes. If not handled correctly, this imbalance can be detrimental to the learning process because the learning is biased in favor of the dominant classes.

Use these weights to correct the class imbalance. Use the pixel label counts from the `tbl.PixelCount` property and calculate the median frequency class weights.

```
imageFreq = tbl.PixelCount ./ tbl.ImagePixelCount;
classWeights = median(imageFreq) ./ imageFreq
```

```
classWeights = 3×1

    0.0133
    1.1423
    1.0000
```

Define Network Architecture

Create a PointSeg network using the `createPointSeg` supporting function, which is attached to the example. The code returns the layer graph that you use to train the network.

```
inputSize = [64 1024 5];

lgraph = createPointSeg(inputSize, classNames, classWeights);
```

Use the `analyzeNetwork` function to display an interactive visualization of the network architecture.

```
analyzeNetwork(lgraph)
```

Specify Training Options

Use the `rmsprop` optimization algorithm to train the network. Specify the hyperparameters for the algorithm by using the `trainingOptions` function.

```
maxEpochs = 30;
initialLearningRate= 5e-4;
miniBatchSize = 8;
l2reg = 2e-4;

options = trainingOptions('rmsprop', ...
    'InitialLearnRate', initialLearningRate, ...
    'L2Regularization', l2reg, ...
    'MaxEpochs', maxEpochs, ...
    'MiniBatchSize', miniBatchSize, ...
    'LearnRateSchedule', 'piecewise', ...
    'LearnRateDropFactor', 0.1, ...
    'LearnRateDropPeriod', 10, ...
    'ValidationData', validationData, ...
    'Plots', 'training-progress', ...
    'VerboseFrequency', 20);
```

Note: Reduce `miniBatchSize` to control memory usage when training.

Train Network

Use the `trainNetwork` function to train a PointSeg network if `doTraining` is `true`. Otherwise, load the pretrained network.

If you train the network, you can use a CPU or a GPU. Using a GPU requires Parallel Computing Toolbox™ and a CUDA® enabled NVIDIA® GPU. For more information, see “GPU Support by Release” (Parallel Computing Toolbox).

```
if doTraining
    [net, info] = trainNetwork(trainingData, lgraph, options);
else
    pretrainedNetwork = load('trainedPointSegNet.mat');
    net = pretrainedNetwork.net;
end
```

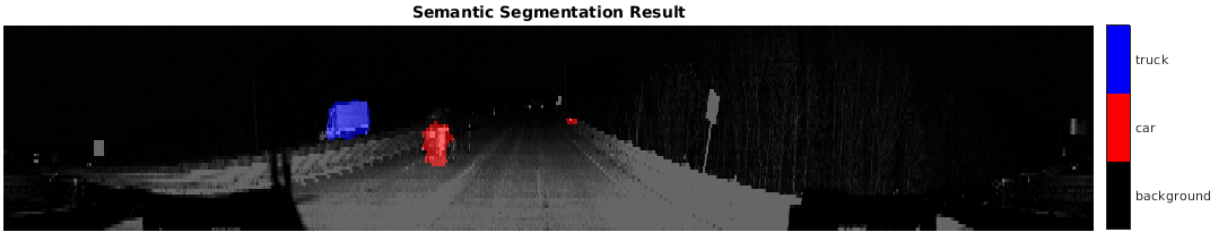
Predict Results on Test Point Cloud

Use the trained network to predict results on a test point cloud and display the segmentation result.

First, read a PCD file and convert the point cloud to a five-channel input image. Predict the labels using the trained network. Display the figure with the segmentation as an overlay.

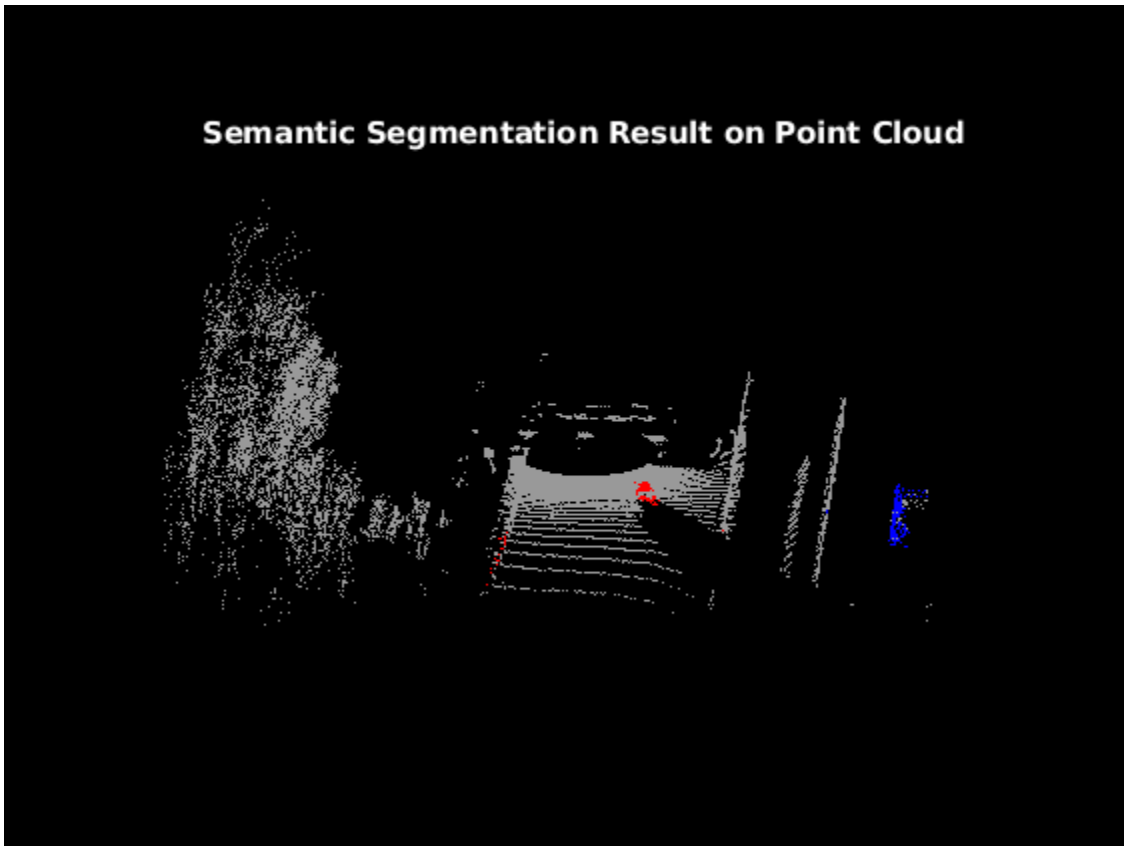
```
ptCloud = pcread('ousterLidarDrivingData.pcd');
I = helperPointCloudToImage(ptCloud);
predictedResult = semanticseg(I, net);

figure;
helperDisplayLidarOverlayImage(I, predictedResult, classNames);
title('Semantic Segmentation Result');
```



Use the `helperDisplayLidarOverlayPointCloud` helper function, defined in the Supporting Functions on page 11-0 section of this example, to display the segmentation result over the 3-D point cloud object `ptCloud` .

```
figure;
helperDisplayLidarOverlayPointCloud(ptCloud, predictedResult, numClasses);
view([95.71 24.14])
title('Semantic Segmentation Result on Point Cloud');
```



Evaluate Network

Run the `semanticseg` function on the entire test set to measure the accuracy of the network. Set `MiniBatchSize` to a value of 8 to reduce memory usage when segmenting images. You can increase or decrease this value depending on the amount of GPU memory you have on your system.

```
outputLocation = fullfile(tempdir, 'output');
if ~exist(outputLocation,'dir')
    mkdir(outputLocation);
end
pxdsResults = semanticseg(imdsTest, net, ...
                'MiniBatchSize', 8, ...
                'WriteLocation', outputLocation, ...
                'Verbose', false);
```

The `semanticseg` function returns the segmentation results on the test data set as a `PixelLabelDatastore` object. The function writes the actual pixel label data for each test image in the `imdsTest` object to the disk in the location specified by the `'WriteLocation'` argument.

Use the `evaluateSemanticSegmentation` (Computer Vision Toolbox) function to compute the semantic segmentation metrics from the test set results.

```
metrics = evaluateSemanticSegmentation(pxdsResults, pxdsTest, 'Verbose', false);
```

You can measure the amount of overlap per class using the intersection-over-union (IoU) metric.

The `evaluateSemanticSegmentation` function returns metrics for the entire data set, for individual classes, and for each test image. To see the metrics at the data set level, use the `metrics.DataSetMetrics` property.

```
metrics.DataSetMetrics
```

```
ans=1×5 table
    GlobalAccuracy    MeanAccuracy    MeanIoU    WeightedIoU    MeanBFScore
    ______________    ____________    _______    ___________    ___________

       0.99209           0.83752      0.67895      0.98685        0.91654
```

The data set metrics provide a high-level overview of network performance. To see the impact each class has on the overall performance, inspect the metrics for each class using the `metrics.ClassMetrics` property.

```
metrics.ClassMetrics
```

```
ans=3×3 table
                  Accuracy      IoU      MeanBFScore
                  ________    _______    ___________

    background    0.99466     0.99212      0.98529
    car           0.75977     0.50096      0.82682
    truck         0.75814     0.54378      0.77119
```

Although the network overall performance is good, the class metrics show that biased classes (car and truck) are not segmented as well as the classes with abundant data (background). You can improve the network performance by training the network on more labeled data containing the car and truck classes.

Supporting Functions

Function to Augment Data

The `augmentData` function randomly flips the 2-D spherical image and associated labels in the horizontal direction.

```
function out = augmentData(inp)
%augmentData Apply random horizontal flipping.

out = cell(size(inp));

% Randomly flip the five-channel image and pixel labels horizontally.
I = inp{1};
sz = size(I);
tform = randomAffine2d('XReflection',true);
rout = affineOutputView(sz,tform,'BoundsStyle','centerOutput');

out{1} = imwarp(I,tform,'OutputView',rout);
out{2} = imwarp(inp{2},tform,'OutputView',rout);
end
```

Function to Display Lidar Segmentation Map Overlaid on 2-D Spherical Image

The `helperDisplayLidarOverlayImage` function overlays the semantic segmentation map over the intensity channel of the 2-D spherical image. The function also resizes the overlaid image for better visualization.

```
function helperDisplayLidarOverlayImage(lidarImage, labelMap, classNames)
%helperDisplayLidarOverlayImage Overlay labels over the intensity image.
%
%  helperDisplayLidarOverlayImage(lidarImage, labelMap, classNames)
%  displays the overlaid image. lidarImage is a five-channel lidar input.
%  labelMap contains pixel labels and classNames is an array of label
%  names.

% Read the intensity channel from the lidar image.
intensityChannel = uint8(lidarImage(:,:,4));

% Load the lidar color map.
cmap = helperLidarColorMap();

% Overlay the labels over the intensity image.
B = labeloverlay(intensityChannel,labelMap,'Colormap',cmap,'Transparency',0.4);

% Resize for better visualization.
B = imresize(B, 'Scale', [3 1], 'method', 'nearest');
imshow(B);

% Display the color bar.
helperPixelLabelColorbar(cmap, classNames);
end
```

Function To Display Lidar Segmentation Map Overlaid on 3-D Point Cloud

The `helperDisplayLidarOverPointCloud` function overlays the segmentation result over a 3-D organized point cloud.

```
function helperDisplayLidarOverlayPointCloud(ptCloud, labelMap, numClasses)
%helperDisplayLidarOverlayPointCloud Overlay labels over a point cloud object.
%
%  helperDisplayLidarOverlayPointCloud(ptCloud, labelMap, numClasses)
%  displays the overlaid pointCloud object. ptCloud is the organized
%  3-D point cloud input. labelMap contains pixel labels and numClasses
%  is the number of predicted classes.

sz = size(labelMap);

% Apply the color red to cars.
carClassCar = zeros(sz(1), sz(2), numClasses, 'uint8');
carClassCar(:,:,1) = 255*ones(sz(1), sz(2), 'uint8');

% Apply the color blue to trucks.
truckClassColor = zeros(sz(1), sz(2), numClasses, 'uint8');
truckClassColor(:,:,3) = 255*ones(sz(1), sz(2), 'uint8');

% Apply the color gray to the background.
backgroundClassColor = 153*ones(sz(1), sz(2), numClasses, 'uint8');

% Extract indices from the labels.
```

```
carIndices = labelMap == 'car';
truckIndices = labelMap == 'truck';
backgroundIndices = labelMap == 'background';

% Extract a point cloud for each class.
carPointCloud = select(ptCloud, carIndices, 'OutputSize','full');
truckPointCloud = select(ptCloud, truckIndices, 'OutputSize','full');
backgroundPointCloud = select(ptCloud, backgroundIndices, 'OutputSize','full');

% Apply colors to different classes.
carPointCloud.Color = carClassCar;
truckPointCloud.Color = truckClassColor;
backgroundPointCloud.Color = backgroundClassColor;

% Merge and add all the processed point clouds with class information.
coloredCloud = pcmerge(carPointCloud, truckPointCloud, 0.01);
coloredCloud = pcmerge(coloredCloud, backgroundPointCloud, 0.01);

% Plot the colored point cloud. Set an ROI for better visualization.
ax = pcshow(coloredCloud);
set(ax,'XLim',[-35.0 35.0],'YLim',[-32.0 32.0],'ZLim',[-3 8], ...
    'XColor','none','YColor','none','ZColor','none');
set(get(ax,'parent'), 'units','normalized');
end
```

Function to Define Lidar Colormap

The `helperLidarColorMap` function defines the colormap used by the lidar data set.

```
function cmap = helperLidarColorMap()

cmap = [
   0.00  0.00   0.00  % background
   0.98  0.00   0.00  % car
   0.00  0.00   0.98  % truck
   ];
end
```

Function to Display Pixel Label Colorbar

The `helperPixelLabelColorbar` function adds a colorbar to the current axis. The colorbar is formatted to display the class names with the color.

```
function helperPixelLabelColorbar(cmap, classNames)

colormap(gca, cmap);

% Add a colorbar to the current figure.
c = colorbar('peer', gca);

% Use class names for tick marks.
c.TickLabels = classNames;
numClasses = size(classNames, 1);

% Center tick labels.
c.Ticks = 1/(numClasses * 2):1/numClasses:1;

% Remove tick marks.
```

```
c.TickLength = 0;
end
```

References

[1] Wang, Yuan, Tianyue Shi, Peng Yun, Lei Tai, and Ming Liu. “PointSeg: Real-Time Semantic Segmentation Based on 3D LiDAR Point Cloud.” *ArXiv:1807.06288 [Cs]*, September 25, 2018. http://arxiv.org/abs/1807.06288.

Lidar Point Cloud Semantic Segmentation Using SqueezeSegV2 Deep Learning Network

This example shows how to train a SqueezeSegV2 semantic segmentation network on 3-D organized lidar point cloud data.

SqueezeSegV2 [1 on page 11-0] is a convolutional neural network (CNN) for performing end-to-end semantic segmentation of an organized lidar point cloud. The training procedure shown in this example requires 2-D spherical projected images as inputs to the deep learning network.

This example uses PandaSet data set from Hesai and Scale [2] on page 11-0 . The PandaSet contains 4800 unorganized lidar point cloud scans of the various city scenes captured using the Pandar 64 sensor. The data set provides semantic segmentation labels for 42 different classes including car, road, and pedestrian.

Download Lidar Data Set

This example uses a subset of PandaSet, that contains 2560 preprocessed organized point clouds. Each point cloud is specified as a 64-by-1856 matrix. The corresponding ground truth contains the semantic segmentation labels for 12 classes. The point clouds are stored in PCD format, and the ground truth data is stored in PNG format. The size of the data set is 5.2 GB. Execute this code to download the data set.

```
url = 'https://ssd.mathworks.com/supportfiles/lidar/data/Pandaset_LidarData.tar.gz';
outputFolder = fullfile(tempdir,'Pandaset');
lidarDataTarFile = fullfile(outputFolder,'Pandaset_LidarData.tar.gz');
if ~exist(lidarDataTarFile, 'file')
    mkdir(outputFolder);
    disp('Downloading Pandaset Lidar driving data (5.2 GB)...');
    websave(lidarDataTarFile, url);
    untar(lidarDataTarFile,outputFolder);
end
% Check if tar.gz file is downloaded, but not uncompressed.
if (~exist(fullfile(outputFolder,'Lidar'), 'file'))...
        &&(~exist(fullfile(outputFolder,'semanticLabels'), 'file'))
    untar(lidarDataTarFile,outputFolder);
end
lidarData =  fullfile(outputFolder,'Lidar');
labelsFolder = fullfile(outputFolder,'semanticLabels');
```

Depending on your Internet connection, the download process can take some time. The code suspends MATLAB® execution until the download process is complete. Alternatively, you can download the data set to your local disk using your web browser, and then extract `Pandaset_LidarData` folder. To use the file you downloaded from the web, change the `outputFolder` variable in the code to the location of the downloaded file.

The training procedure for this example is for organized point clouds. For an example showing how to convert unorganized to organized point clouds, see “Unorganized to Organized Conversion of Point Clouds Using Spherical Projection” (Lidar Toolbox).

Download Pretrained Network

Download the pretrained network to avoid having to wait for training to complete. If you want to train the network, set the `doTraining` variable to `true`.

```
doTraining = false;
pretrainedNetURL = ...
'https://ssd.mathworks.com/supportfiles/lidar/data/trainedSqueezeSegV2PandasetNet.zip';
if ~doTraining
    downloadPretrainedSqueezeSegV2Net(outputFolder, pretrainedNetURL);
end
```

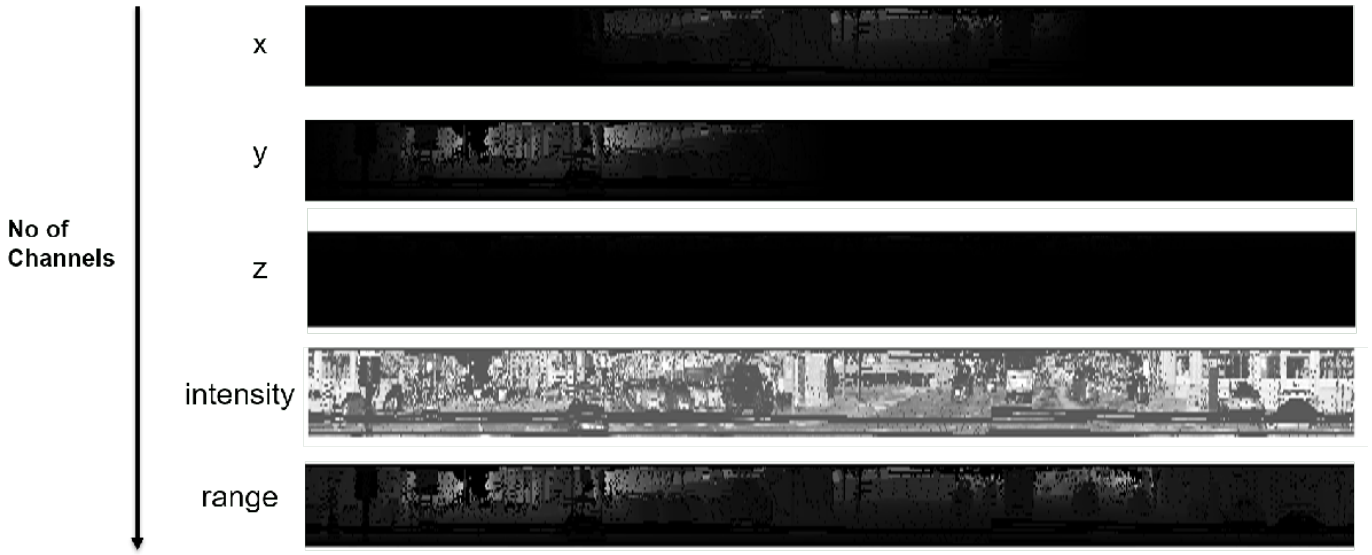
Prepare Data for Training

Load Lidar Point Clouds and Class Labels

Use the `helperTransformOrganizedPointCloudToTrainingData` supporting function, attached to this example, to generate training data from the lidar point clouds. The function uses point cloud data to create five-channel input images. Each training image is specified as a 64-by-1856-by-5 array:

- The height of each image is 64 pixels.
- The width of each image is 1856 pixels.
- Each image has five channels. The five channels specify the 3-D coordinates of the point cloud, intensity, and range: $r = \sqrt{x^2 + y^2 + z^2}$.

A visual representation of the training data follows.



Generate the five-channel training images.

```
imagesFolder = fullfile(outputFolder,'images');
helperTransformOrganizedPointCloudToTrainingData(lidarData,imagesFolder);
```

```
Preprocessing data 100% complete
```

The five-channel images are saved as MAT files.

Processing can take some time. The code suspends MATLAB® execution until processing is complete.

Create imageDatastore and pixelLabelDatastore

Create an `imageDatastore` to extract and store the five channels of the 2-D spherical images using imageDatastore and the helperImageMatReader supporting function, which is a custom MAT file reader. This function is attached to this example as a supporting file.

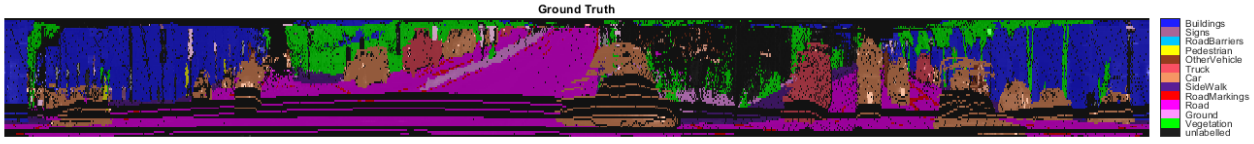
```
imds = imageDatastore(imagesFolder, ...
    'FileExtensions', '.mat', ...
    'ReadFcn', @helperImageMatReader);
```

Create a pixel label datastore using `pixelLabelDatastore` (Computer Vision Toolbox) to store pixel-wise labels from the pixel label images. The object maps each pixel label to a class name. In this example, the vegetation, ground, road, road markings, sidewalk, cars, trucks, other vehicles, pedestrian, road barrier, signs, and buildings are the objects of interest; all other pixels are the background. Specify these classes and assign a unique label ID to each class.

```
classNames = ["unlabelled"
              "Vegetation"
              "Ground"
              "Road"
              "RoadMarkings"
              "SideWalk"
              "Car"
              "Truck"
              "OtherVehicle"
              "Pedestrian"
              "RoadBarriers"
              "Signs"
              "Buildings"];
numClasses = numel(classNames);
% Specify label IDs from 1 to the number of classes.
labelIDs = 1 : numClasses;
pxds = pixelLabelDatastore(labelsFolder, classNames, labelIDs);
```

Load and display one of the labeled images by overlaying it on the corresponding intensity image using the `helperDisplayLidarOverlaidImage` function, defined in the Supporting Functions on page 11-0 section of this example.

```
% Point cloud (channels 1, 2, and 3 are for location, channel 4 is for intensity, and channel 5 i
I = read(imds);
labelMap = read(pxds);
figure;
helperDisplayLidarOverlaidImage(I, labelMap{1,1}, classNames);
title('Ground Truth');
```



Prepare Training, Validation, and Test Sets

Use the `helperPartitionLidarSegmentationDataset` supporting function, attached to this example, to split the data into training, validation, and test sets. You can split the training data

according to the percentage specified by the `trainingDataPercentage`. Divide the rest of the data in a 2:1 ratio into validation and testing data. Default value of `trainingDataPercentage` is `0.7`.

```
[imdsTrain, imdsVal, imdsTest, pxdsTrain, pxdsVal, pxdsTest] = ...
helperPartitionLidarSegmentationDataset(imds, pxds, 'trainingDataPercentage', 0.75);
```

Use the `combine` function to combine the pixel label and image datastores for the training and validation data.

```
trainingData = combine(imdsTrain, pxdsTrain);
validationData = combine(imdsVal, pxdsVal);
```

Data Augmentation

Data augmentation is used to improve network accuracy by randomly transforming the original data during training. By using data augmentation, you can add more variety to the training data without actually having to increase the number of labeled training samples.

Augment the training data by using the `transform` function with custom preprocessing operations specified by the `helperAugmentData` function, defined in the Supporting Functions on page 11-0 section of this example. This function randomly flips the multichannel 2-D image and associated labels in the horizontal direction. Apply data augmentation to only the training data set.

```
augmentedTrainingData = transform(trainingData, @(x) helperAugmentData(x));
```

Define Network Architecture

Create a standard SqueezeSegV2 [1 on page 11-0] network by using the `squeezesegv2Layers` (Lidar Toolbox) function. In the SqueezeSegV2 network, the encoder subnetwork consists of FireModules interspersed with max-pooling layers. This arrangement successively decreases the resolution of the input image. In addition, the SqueezeSegV2 network uses the *focal loss* function to mitigate the effect of the imbalanced class distribution on network accuracy. For more details on how to use the focal loss function in semantic segmentation, see `focalLossLayer` (Computer Vision Toolbox).

Execute this code to create a layer graph that can be used to train the network.

```
inputSize = [64 1856 5];
lgraph = squeezesegv2Layers(inputSize, ...
numClasses,'NumEncoderModules',4,'NumContextAggregationModules',2);
```

Use the `analyzeNetwork` function to display an interactive visualization of the network architecture.

```
analyzeNetwork(lgraph);
```

Specify Training Options

Use the Adam optimization algorithm to train the network. Use the `trainingOptions` function to specify the hyperparameters.

```
maxEpochs = 30;
initialLearningRate = 1e-3;
miniBatchSize = 8;
l2reg = 2e-4;
options = trainingOptions('adam', ...
    'InitialLearnRate', initialLearningRate, ...
    'L2Regularization', l2reg, ...
```

```
    'MaxEpochs', maxEpochs, ...
    'MiniBatchSize', miniBatchSize, ...
    'LearnRateSchedule', 'piecewise', ...
    'LearnRateDropFactor', 0.1, ...
    'LearnRateDropPeriod', 10, ...
    'ValidationData', validationData, ...
    'Plots', 'training-progress', ...
    'VerboseFrequency', 20);
```

Note: Reduce the `miniBatchSize` value to control memory usage when training.

Train Network

You can train the network yourself by setting the `doTraining` argument to `true`. If you train the network, you can use a CPU or a GPU. Using a GPU requires Parallel Computing Toolbox™ and a supported GPU device. For information on supported devices, see "GPU Support by Release" (Parallel Computing Toolbox). Otherwise, load a pretrained network.

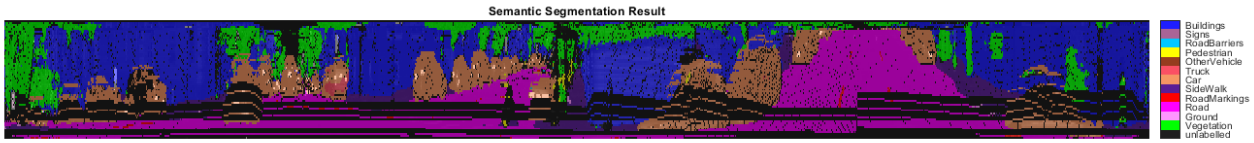
```
if doTraining
    [net, info] = trainNetwork(trainingData, lgraph, options);
else
    load(fullfile(outputFolder,'trainedSqueezeSegV2PandasetNet.mat'),'net');
end
```

Predict Results on Test Point Cloud

Use the trained network to predict results on a test point cloud and display the segmentation result. First, read a five-channel input image and predict the labels using the trained network.

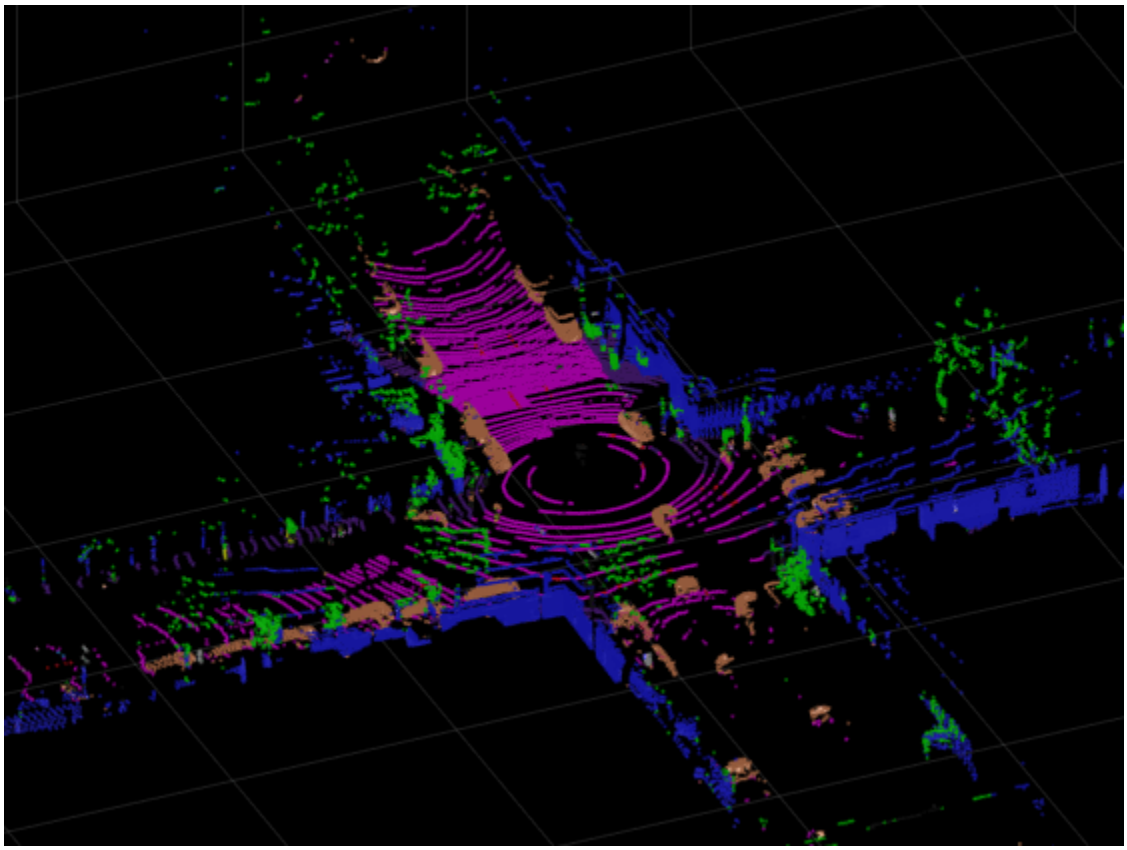
Display the figure with the segmentation as an overlay.

```
I = read(imdsTest);
predictedResult = semanticseg(I, net);
figure;
helperDisplayLidarOverlaidImage(I, predictedResult, classNames);
title('Semantic Segmentation Result');
```



Use the `helperDisplayLabelOverlaidPointCloud` function, defined in the Supporting Functions on page 11-0 section of this example, to display the segmentation result on the point cloud.

```
figure;
helperDisplayLabelOverlaidPointCloud(I, predictedResult);
view([39.2 90.0 60]);
title('Semantic Segmentation Result on Point Cloud');
```



Evaluate Network

Use the `evaluateSemanticSegmentation` (Computer Vision Toolbox) function to compute the semantic segmentation metrics from the test set results.

```
outputLocation = fullfile(tempdir, 'output');
if ~exist(outputLocation,'dir')
    mkdir(outputLocation);
end
pxdsResults = semanticseg(imdsTest, net, ...
    'MiniBatchSize', 4, ...
    'WriteLocation', outputLocation, ...
    'Verbose', false);
metrics = evaluateSemanticSegmentation(pxdsResults, pxdsTest, 'Verbose', false);
```

You can measure the amount of overlap per class using the intersection-over-union (IoU) metric.

The `evaluateSemanticSegmentation` function returns metrics for the entire data set, for individual classes, and for each test image. To see the metrics at the data set level, use the `metrics.DataSetMetrics` property.

```
metrics.DataSetMetrics
```

```
ans=1×5 table
    GlobalAccuracy    MeanAccuracy    MeanIoU    WeightedIoU    MeanBFScore
    ______________    ____________    _______    ___________    ___________
```

```
       0.89724          0.61685       0.54431      0.81806        0.74537
```

The data set metrics provide a high-level overview of network performance. To see the impact each class has on the overall performance, inspect the metrics for each class using the `metrics.ClassMetrics` property.

```
metrics.ClassMetrics
```

```
ans=13×3 table
                    Accuracy      IoU      MeanBFScore
                    ________    _______    ___________

    unlabelled         0.94       0.9005      0.99911
    Vegetation      0.77873      0.64819      0.95466
    Ground          0.69019      0.59089      0.60657
    Road            0.94045      0.83663      0.99084
    RoadMarkings    0.37802      0.34149      0.77073
    SideWalk         0.7874      0.65668      0.93687
    Car              0.9334      0.81065      0.95448
    Truck           0.30352      0.27401      0.37273
    OtherVehicle    0.64397      0.58108      0.47253
    Pedestrian      0.26214      0.20896      0.45918
    RoadBarriers    0.23955      0.21971      0.19433
    Signs           0.17276      0.15613      0.44275
    Buildings       0.94891      0.85117      0.96929
```

Although the overall network performance is good, the class metrics for some classes like `RoadMarkings` and `Truck` indicate that more training data is required for better performance.

Supporting Functions

Function to Augment Data

The `helperAugmentData` function randomly flips the spherical image and associated labels in the horizontal direction.

```
function out = helperAugmentData(inp)
% Apply random horizontal flipping.
out = cell(size(inp));
% Randomly flip the five-channel image and pixel labels horizontally.
I = inp{1};
sz = size(I);
tform = randomAffine2d('XReflection',true);
rout = affineOutputView(sz,tform,'BoundsStyle','centerOutput');
out{1} = imwarp(I,tform,'OutputView',rout);
out{2} = imwarp(inp{2},tform,'OutputView',rout);
end
```

Function to Display Lidar Segmentation Map Overlaid on 2-D Spherical Image

The `helperDisplayLidarOverlaidImage` function overlays the semantic segmentation map over the intensity channel of the 2-D spherical image. The function also resizes the overlaid image for better visualization.

```
function helperDisplayLidarOverlaidImage(lidarImage, labelMap, classNames)
% helperDisplayLidarOverlaidImage Overlay labels over the intensity image.
```

```
%
%  helperDisplayLidarOverlaidImage(lidarImage, labelMap, classNames)
%  displays the overlaid image. lidarImage is a five-channel lidar input.
%  labelMap contains pixel labels and classNames is an array of label
%  names.
% Read the intensity channel from the lidar image.
intensityChannel = uint8(lidarImage(:,:,4));
% Load the lidar color map.
cmap = helperPandasetColorMap;
% Overlay the labels over the intensity image.
B = labeloverlay(intensityChannel,labelMap,'Colormap',cmap,'Transparency',0.4);
% Resize for better visualization.
B = imresize(B,'Scale',[3 1],'method','nearest');
imshow(B);
helperPixelLabelColorbar(cmap, classNames);
end
```

Function to Display Lidar Segmentation Map Overlaid on 3-D Point Cloud

The `helperDisplayLabelOverlaidPointCloud` function overlays the segmentation result over a 3-D organized point cloud.

```
function helperDisplayLabelOverlaidPointCloud(I,predictedResult)
% helperDisplayLabelOverlaidPointCloud Overlay labels over point cloud object.
%  helperDisplayLabelOverlaidPointCloud(I, predictedResult)
%  displays the overlaid pointCloud object. I is the 5 channels organized
%  input image. predictedResult contains pixel labels.
ptCloud = pointCloud(I(:,:,1:3),'Intensity',I(:,:,4));
cmap = helperPandasetColorMap;
B = ...
labeloverlay(uint8(ptCloud.Intensity),predictedResult,'Colormap',cmap,'Transparency',0.4);
pc = pointCloud(ptCloud.Location,'Color',B);
figure;
ax = pcshow(pc);
set(ax,'XLim',[-70 70],'YLim',[-70 70]);
zoom(ax,3.5);
end
```

Function to Define Lidar Colormap

The `helperPandasetColorMap` function defines the colormap used by the lidar data set.

```
function cmap = helperPandasetColorMap
cmap = [[30,30,30];      % Unlabeled
        [0,255,0];       % Vegetation
        [255, 150, 255]; % Ground
        [255,0,255];     % Road
        [255,0,0];       % Road Markings
        [90, 30, 150];   % Sidewalk
        [245,150,100];   % Car
        [250, 80, 100];  % Truck
        [150, 60, 30];   % Other Vehicle
        [255, 255, 0];   % Pedestrian
        [0, 200, 255];   % Road Barriers
        [170,100,150];   % Signs
        [30, 30, 255]];  % Building
cmap = cmap./255;
end
```

Function to Display Pixel Label Colorbar

The `helperPixelLabelColorbar` function adds a colorbar to the current axis. The colorbar is formatted to display the class names with the color.

```
function helperPixelLabelColorbar(cmap, classNames)
colormap(gca, cmap);
% Add a colorbar to the current figure.
c = colorbar('peer', gca);
% Use class names for tick marks.
c.TickLabels = classNames;
numClasses = size(classNames, 1);
% Center tick labels.
c.Ticks = 1/(numClasses * 2):1/numClasses:1;
% Remove tick marks.
c.TickLength = 0;
end
```

Function to Download Pretrained Model

The `downloadPretrainedSqueezeSegV2Net` function downloads the pretrained model.

```
function downloadPretrainedSqueezeSegV2Net(outputFolder, pretrainedNetURL)
    preTrainedMATFile = fullfile(outputFolder,'trainedSqueezeSegV2PandasetNet.mat');
    preTrainedZipFile = fullfile(outputFolder,'trainedSqueezeSegV2PandasetNet.zip');

    if ~exist(preTrainedMATFile,'file')
        if ~exist(preTrainedZipFile,'file')
            disp('Downloading pretrained model (5 MB)...');
            websave(preTrainedZipFile, pretrainedNetURL);
        end
        unzip(preTrainedZipFile, outputFolder);
    end
end
```

Code Generation for Lidar Point Cloud Segmentation Network

This example shows how to generate CUDA® MEX code for a deep learning network for lidar semantic segmentation. This example uses a pretrained SqueezeSegV2 [1] network that can segment organized lidar point clouds belonging to three classes (*background*, *car*, and *truck*). For information on the training procedure for the network, see “Lidar Point Cloud Semantic Segmentation Using SqueezeSegV2 Deep Learning Network” (Lidar Toolbox). The generated MEX code takes a point cloud as input and performs prediction on the point cloud by using the `DAGNetwork` object for the SqueezeSegV2 network.

Third-Party Prerequisites

Required

This example generates CUDA MEX and has the following third-party requirements.

- CUDA enabled NVIDIA® GPU and compatible driver.

Optional

For non-MEX builds such as static, dynamic libraries or executables, this example has the following additional requirements.

- NVIDIA toolkit.
- NVIDIA cuDNN library.
- NVIDIA TensorRT library.
- Environment variables for the compilers and libraries. For details, see “Third-Party Hardware” (GPU Coder) and “Setting Up the Prerequisite Products” (GPU Coder).

Verify GPU Environment

To verify that the compilers and libraries for running this example are set up correctly, use the `coder.checkGpuInstall` (GPU Coder) function.

```
envCfg = coder.gpuEnvConfig('host');
envCfg.DeepLibTarget = 'cudnn';
envCfg.DeepCodegen = 1;
envCfg.Quiet = 1;
coder.checkGpuInstall(envCfg);
```

Segmentation Network

SqueezeSegV2 is a convolutional neural network (CNN) designed for the semantic segmentation of organized lidar point clouds. It is a deep encoder-decoder segmentation network trained on a lidar data set and imported into MATLAB® for inference. In SqueezeSegV2, the encoder subnetwork consists of convolution layers that are interspersed with max-pooling layers. This arrangement successively decreases the resolution of the input image. The decoder subnetwork consists of a series of transposed convolution layers, which successively increase the resolution of the input image. In addition, the SqueezeSegV2 network mitigates the impact of missing data by including context aggregation modules (CAMs). A CAM is a convolutional subnetwork with filterSize of value [7, 7] that aggregates contextual information from a larger receptive field, which improves the robustness of the network to missing data. The SqueezeSegV2 network in this example is trained to segment points belonging to three classes (background, car, and truck).

For more information on training a semantic segmentation network in MATLAB® by using the Mathworks lidar dataset, see “Lidar Point Cloud Semantic Segmentation Using PointSeg Deep Learning Network” (Lidar Toolbox).

Download the pretrained SqueezeSegV2 Network.

```
net = getSqueezeSegV2Net();
```

```
Downloading pretrained SqueezeSegV2 (2 MB)...
```

The DAG network contains 238 layers, including convolution, ReLU, and batch normalization layers, and a focal loss output layer. To display an interactive visualization of the deep learning network architecture, use the `analyzeNetwork` function.

```
analyzeNetwork(net);
```

`squeezesegv2_predict` Entry-Point Function

The `squeezesegv2_predict.m` entry-point function, which is attached to this example, takes a point cloud as input and performs prediction on it by using the deep learning network saved in the `SqueezeSegV2Net.mat` file. The function loads the network object from the `SqueezeSegV2Net.mat` file into a persistent variable `mynet` and reuses the persistent variable in subsequent prediction calls.

```
type('squeezesegv2_predict.m');
```

```
function out = squeezesegv2_predict(in)
%#codegen

% A persistent object mynet is used to load the DAG network object. At
% the first call to this function, the persistent object is constructed and
% setup. When the function is called subsequent times, the same object is
% reused to call predict on inputs, thus avoiding reconstructing and
% reloading the network object.

% Copyright 2020 The MathWorks, Inc.

persistent mynet;

if isempty(mynet)
    mynet = coder.loadDeepLearningNetwork('SqueezeSegV2Net.mat');
end

% pass in input
out = predict(mynet,in);
```

Generate CUDA MEX Code

To generate CUDA MEX code for the `squeezesegv2_predict.m` entry-point function, create a GPU code configuration object for a MEX target and set the target language to C++. Use the `coder.DeepLearningConfig` (GPU Coder) function to create a `CuDNN` deep learning configuration object and assign it to the `DeepLearningConfig` property of the GPU code configuration object. Run the `codegen` command, specifying an input size of [64, 1024, 5]. This value corresponds to the size of the input layer of the SqueezeSegV2 network.

```
cfg = coder.gpuConfig('mex');
cfg.TargetLang = 'C++';
```

```
cfg.DeepLearningConfig = coder.DeepLearningConfig('cudnn');
codegen -config cfg squeezesegv2_predict -args {ones(64,1024,5,'uint8')} -report

Code generation successful: View report
```

To generate CUDA C++ code that takes advantage of NVIDIA TensorRT libraries, in the code, specify `coder.DeepLearningConfig('tensorrt')` instead of `coder.DeepLearningConfig('cudnn')`.

For information on how to generate MEX code for deep learning networks on Intel® processors, see "Code Generation for Deep Learning Networks with MKL-DNN" (MATLAB Coder).

Prepare Data

Load an organized test point cloud in MATLAB®. Convert the point cloud to a five-channel image for prediction.

```
ptCloud = pcread('ousterLidarDrivingData.pcd');
I = pointCloudToImage(ptCloud);

% Examine converted data
whos I
```

```
  Name       Size                 Bytes  Class    Attributes

  I         64x1024x5            327680  uint8
```

The image has five channels. The *(x,y,z)* point coordinates comprise the first three channels. The fourth channel contains the lidar intensity measurement. The fifth channel contains the range information, which is computed as $r = \sqrt{x^2 + y^2 + z^2}$.

Visualize intensity channel of the image.

```
intensityChannel = I(:,:,4);

figure;
imshow(intensityChannel);
title('Intensity Image');
```

Run Generated MEX on Data

Call `squeezesegv2_predict_mex` on the five-channel image.

```
predict_scores = squeezesegv2_predict_mex(I);
```

The `predict_scores` variable is a three-dimensional matrix that has three channels corresponding to the pixel-wise prediction scores for every class. Compute the channel by using the maximum prediction score to get the pixel-wise labels

```
[~,argmax] = max(predict_scores,[],3);
```

Overlay the segmented labels on the intensity channel image and display the segmented region. Resize the segmented output and add a colorbar for better visualization.

```
classes = [
    "background"
    "car"
    "truck"
    ];

cmap = lidarColorMap();
SegmentedImage = labeloverlay(intensityChannel,argmax,'ColorMap',cmap);
SegmentedImage = imresize(SegmentedImage, 'Scale', [2 1], 'method', 'nearest');
figure;
imshow(SegmentedImage);

N = numel(classes);
ticks = 1/(N*2):1/N:1;
colorbar('TickLabels',cellstr(classes),'Ticks',ticks,'TickLength',0,'TickLabelInterpreter','none
colormap(cmap)
title('Semantic Segmentation Result');
```

Run Generated MEX Code on Point Cloud Sequence

Read an input point cloud sequence. The sequence contains 10 organized `pointCloud` frames collected using an Ouster OS1 lidar sensor. The input data has a height of 64 and a width of 1024, so each pointCloud object is of size 64-by-1024.

```
dataFile = 'highwaySceneData.mat';

% Load data in workspace.
load(dataFile);
```

Setup different colors to visualize point-wise labels for different classes of interest.

```
% Apply the color red to cars.
carClassCar = zeros(64, 1024, 3, 'uint8');
carClassCar(:,:,1) = 255*ones(64, 1024, 'uint8');

% Apply the color blue to trucks.
truckClassColor = zeros(64, 1024, 3, 'uint8');
truckClassColor(:,:,3) = 255*ones(64, 1024, 'uint8');

% Apply the color gray to background.
backgroundClassColor = 153*ones(64, 1024, 3, 'uint8');
```

Set the `pcplayer` function properties to display the sequence and the output predictions. Read the input sequence frame by frame and detect classes of interest using the model.

```
xlimits = [0 120.0];
ylimits = [-80.7 80.7];
zlimits = [-8.4 27];

player = pcplayer(xlimits, ylimits, zlimits);
set(get(player.Axes,'parent'), 'units','normalized','outerposition',[0 0 1 1]);
zoom(get(player.Axes,'parent'),2);
set(player.Axes,'XColor','none','YColor','none','ZColor','none');

for i = 1 : numel(inputData)
    ptCloud = inputData{i};

    % Convert point cloud to five-channel image for prediction.
    I = pointCloudToImage(ptCloud);

    % Call squeezesegv2_predict_mex on the 5-channel image.
    predict_scores = squeezesegv2_predict_mex(I);

    % Convert the numeric output values to categorical labels.
    [~,predictedOutput] = max(predict_scores,[],3);
    predictedOutput = categorical(predictedOutput, 1:3, classes);

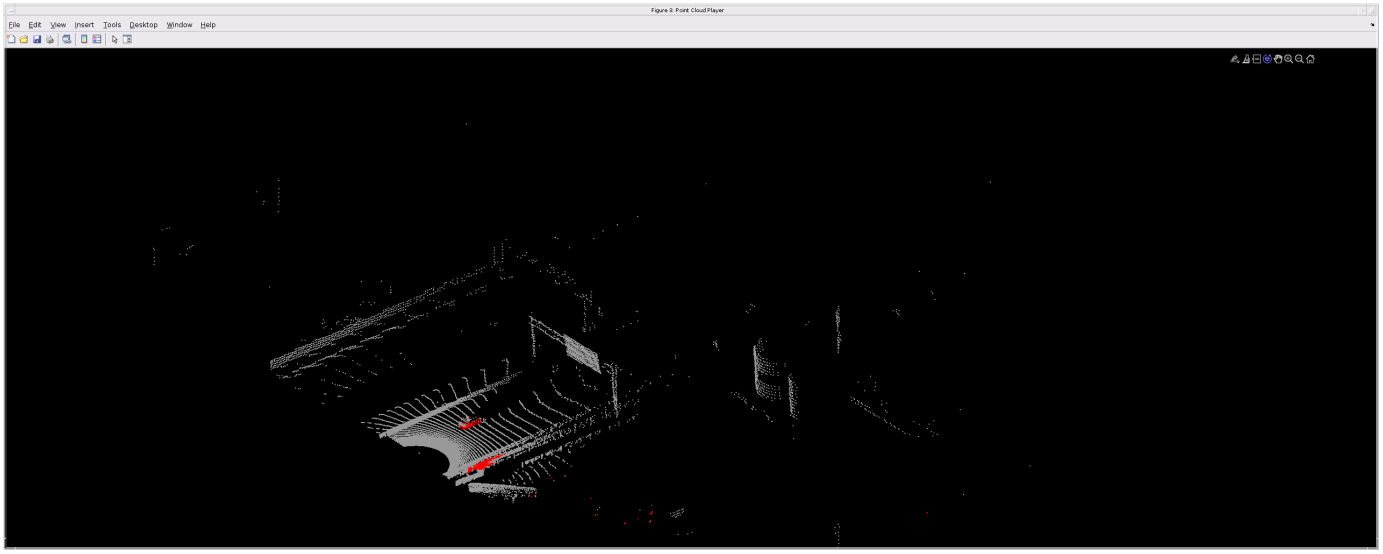
    % Extract the indices from labels.
    carIndices = predictedOutput == 'car';
    truckIndices = predictedOutput == 'truck';
    backgroundIndices = predictedOutput == 'background';

    % Extract a point cloud for each class.
    carPointCloud = select(ptCloud, carIndices, 'OutputSize','full');
    truckPointCloud = select(ptCloud, truckIndices, 'OutputSize','full');
    backgroundPointCloud = select(ptCloud, backgroundIndices, 'OutputSize','full');

    % Fill the colors to different classes.
    carPointCloud.Color = carClassCar;
    truckPointCloud.Color = truckClassColor;
    backgroundPointCloud.Color = backgroundClassColor;

    % Merge and add all the processed point clouds with class information.
    coloredCloud = pcmerge(carPointCloud, truckPointCloud, 0.01);
    coloredCloud = pcmerge(coloredCloud, backgroundPointCloud, 0.01);

    % View the output.
    view(player, coloredCloud);
    drawnow;
end
```



Helper Functions

The helper functions used in this example follow.

```
type pointCloudToImage.m
```

```
function image = pointCloudToImage(ptcloud)
%pointCloudToImage Converts organized 3-D point cloud to 5-channel
%   2-D image.

image = ptcloud.Location;
image(:,:,4) = ptcloud.Intensity;
rangeData = iComputeRangeData(image(:,:,1),image(:,:,2),image(:,:,3));
image(:,:,5) = rangeData;

% Cast to uint8.
image = uint8(image);
end

%--------------------------------------------------------------------------
function rangeData = iComputeRangeData(xChannel,yChannel,zChannel)
rangeData = sqrt(xChannel.*xChannel+yChannel.*yChannel+zChannel.*zChannel);
end
```

```
type lidarColorMap.m
```

```
function cmap = lidarColorMap()

cmap = [
   0.00  0.00   0.00  % background
   0.98  0.00   0.00  % car
   0.00  0.00   0.98  % truck
   ];
end
```

Lidar 3-D Object Detection Using PointPillars Deep Learning

This example shows how to train a PointPillars network for object detection in point clouds.

Lidar point cloud data can be acquired by a variety of lidar sensors, including Velodyne®, Pandar, and Ouster sensors. These sensors capture 3-D position information about objects in a scene, which is useful for many applications in autonomous driving and augmented reality. However, training robust detectors with point cloud data is challenging because of the sparsity of data per object, object occlusions, and sensor noise. Deep learning techniques have been shown to address many of these challenges by learning robust feature representations directly from point cloud data. One deep learning technique for 3-D object detection is PointPillars [1 on page 11-0]. Using a similar architecture to PointNet, the PointPillars network extracts dense, robust features from sparse point clouds called pillars, then uses a 2-D deep learning network with a modified SSD object detection network to estimate joint 3-D bounding boxes, orientations, and class predictions.

This example uses the PandaSet [2 on page 11-0] data set from Hesai and Scale. PandaSet contains 8240 unorganized lidar point cloud scans of various city scenes captured using a Pandar64 sensor. The data set provides 3-D bounding box labels for 18 different object classes, including car, truck, and pedestrian.

Download Lidar Data Set

This example uses a subset of PandaSet that contains 2560 preprocessed organized point clouds. Each point cloud covers 360^o of view, and is specified as a 64-by-1856 matrix. The point clouds are stored in PCD format and their corresponding ground truth data is stored in the `PandaSetLidarGroundTruth.mat` file. The file contains 3-D bounding box information for three classes, which are car, truck, and pedestrian. The size of the data set is 5.2 GB.

Download the Pandaset dataset from the given URL using the `helperDownloadPandasetData` helper function, defined at the end of this example.

```
doTraining = false;

outputFolder = fullfile(tempdir,'Pandaset');

lidarURL = ['https://ssd.mathworks.com/supportfiles/lidar/data/' ...
    'Pandaset_LidarData.tar.gz'];
helperDownloadPandasetData(outputFolder,lidarURL);
```

Depending on your Internet connection, the download process can take some time. The code suspends MATLAB® execution until the download process is complete. Alternatively, you can download the data set to your local disk using your web browser and extract the file. If you do so, change the `outputFolder` variable in the code to the location of the downloaded file.

Load Data

Create a file datastore to load the PCD files from the specified path using the `pcread` (Computer Vision Toolbox) function.

```
path = fullfile(outputFolder,'Lidar');
lidarData = fileDatastore(path,'ReadFcn',@(x) pcread(x));
```

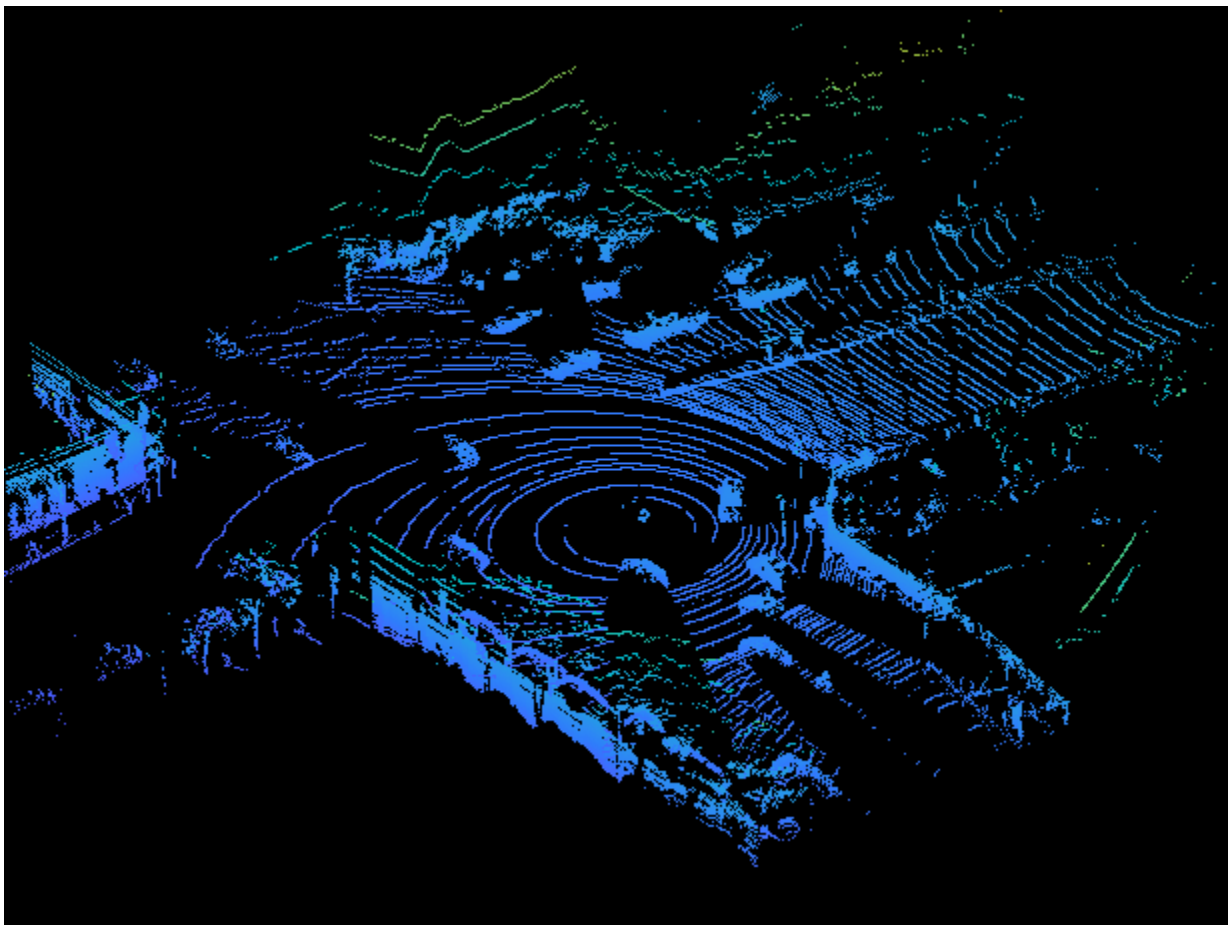
Load the 3-D bounding box labels of the car and truck objects.

```
gtPath = fullfile(outputFolder,'Cuboids','PandaSetLidarGroundTruth.mat');
data = load(gtPath,'lidarGtLabels');
```

```
Labels = timetable2table(data.lidarGtLabels);
boxLabels = Labels(:,2:3);
```

Display the full-view point cloud.

```
figure
ptCld = read(lidarData);
ax = pcshow(ptCld.Location);
set(ax,'XLim',[-50 50],'YLim',[-40 40]);
zoom(ax,2.5);
axis off;
```



```
reset(lidarData);
```

Preprocess Data

The PandaSet data consists of full-view point clouds. For this example, crop the full-view point clouds to front-view point clouds using the standard parameters [1 on page 11-0]. These parameters determine the size of the input passed to the network. Selecting a smaller range of point clouds along the x, y, and z-axis helps detect objects that are closer to the origin and also decreases the overall training time of the network.

```
xMin = 0.0;     % Minimum value along X-axis.
yMin = -39.68;  % Minimum value along Y-axis.
zMin = -5.0;    % Minimum value along Z-axis.
```

```
xMax = 69.12;   % Maximum value along X-axis.
yMax = 39.68;   % Maximum value along Y-axis.
zMax = 5.0;     % Maximum value along Z-axis.
xStep = 0.16;   % Resolution along X-axis.
yStep = 0.16;   % Resolution along Y-axis.
dsFactor = 2.0; % Downsampling factor.

% Calculate the dimensions for the pseudo-image.
Xn = round(((xMax - xMin) / xStep));
Yn = round(((yMax - yMin) / yStep));

% Define point cloud parameters.
pointCloudRange = [xMin,xMax,yMin,yMax,zMin,zMax];
voxelSize = [xStep,yStep];
```

Use the `cropFrontViewFromLidarData` helper function, attached to this example as a supporting file, to:

- Crop the front view from the input full-view point cloud.
- Select the box labels that are inside the ROI specified by `gridParams`.

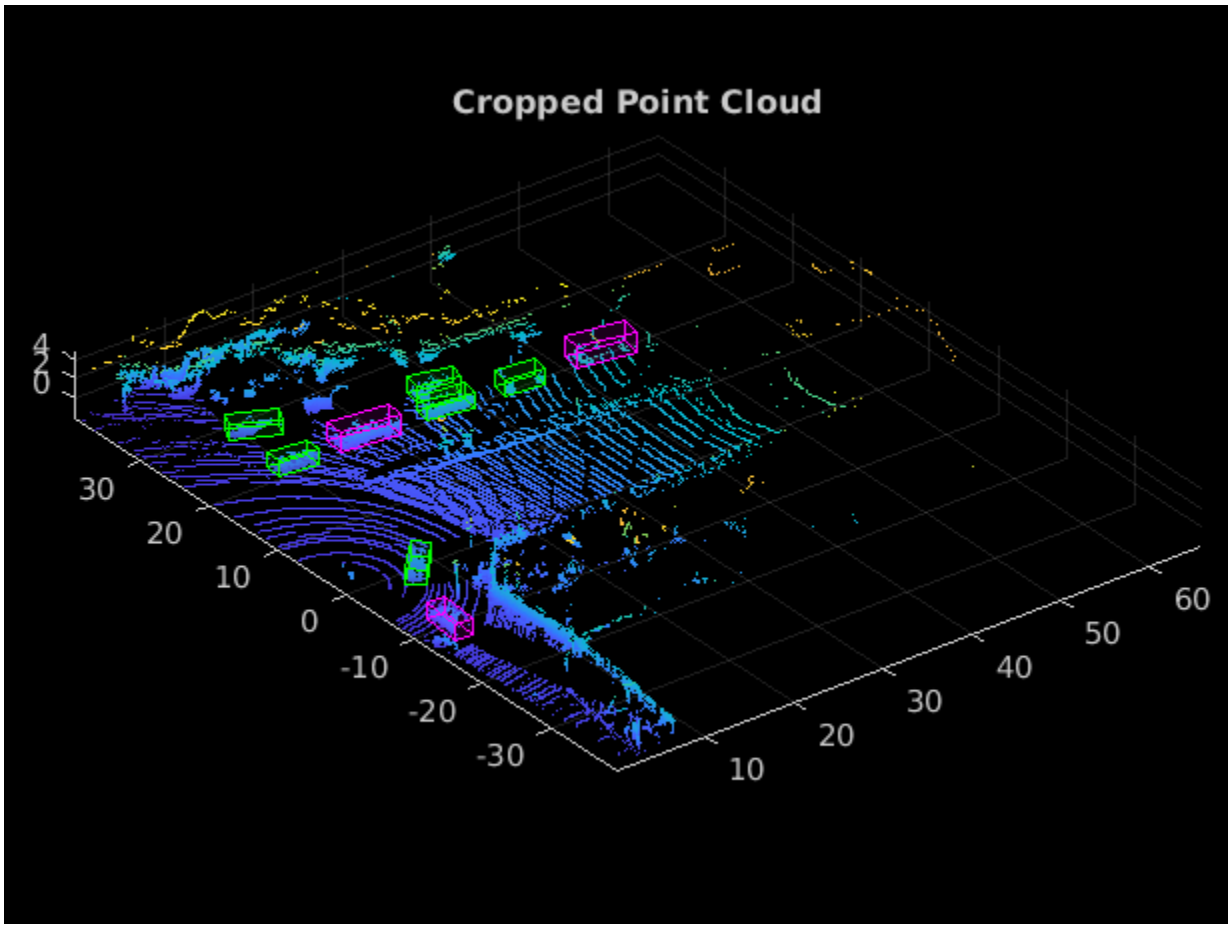
```
[croppedPointCloudObj,processedLabels] = cropFrontViewFromLidarData(...
    lidarData,boxLabels,pointCloudRange);
```

```
Processing data 100% complete
```

Display the cropped point cloud and the ground truth box labels using the `helperDisplay3DBoxesOverlaidPointCloud` helper function defined at the end of the example.

```
pc = croppedPointCloudObj{1,1};
gtLabelsCar = processedLabels.Car{1};
gtLabelsTruck = processedLabels.Truck{1};

helperDisplay3DBoxesOverlaidPointCloud(pc.Location,gtLabelsCar,...
   'green',gtLabelsTruck,'magenta','Cropped Point Cloud');
```



```
reset(lidarData);
```

Create Datastore Objects for Training

Split the data set into training and test sets. Select 70% of the data for training the network and the rest for evaluation.

```
rng(1);
shuffledIndices = randperm(size(processedLabels,1));
idx = floor(0.7 * length(shuffledIndices));

trainData = croppedPointCloudObj(shuffledIndices(1:idx),:);
testData = croppedPointCloudObj(shuffledIndices(idx+1:end),:);

trainLabels = processedLabels(shuffledIndices(1:idx),:);
testLabels = processedLabels(shuffledIndices(idx+1:end),:);
```

So that you can easily access the datastores, save the training data as PCD files by using the `saveptCldToPCD` helper function, attached to this example as a supporting file. You can set `writeFiles` to `"false"` if your training data is saved in a folder and is supported by the `pcread` function.

```
writeFiles = true;
dataLocation = fullfile(outputFolder,'InputData');
```

```
[trainData,trainLabels] = saveptCldToPCD(trainData,trainLabels,...
    dataLocation,writeFiles);
```

```
Processing data 100% complete
```

Create a file datastore using `fileDatastore` to load PCD files using the `pcread` (Computer Vision Toolbox) function.

```
lds = fileDatastore(dataLocation,'ReadFcn',@(x) pcread(x));
```

Createa box label datastore using `boxLabelDatastore` (Computer Vision Toolbox) for loading the 3-D bounding box labels.

```
bds = boxLabelDatastore(trainLabels);
```

Use the `combine` function to combine the point clouds and 3-D bounding box labels into a single datastore for training.

```
cds = combine(lds,bds);
```

Data Augmentation

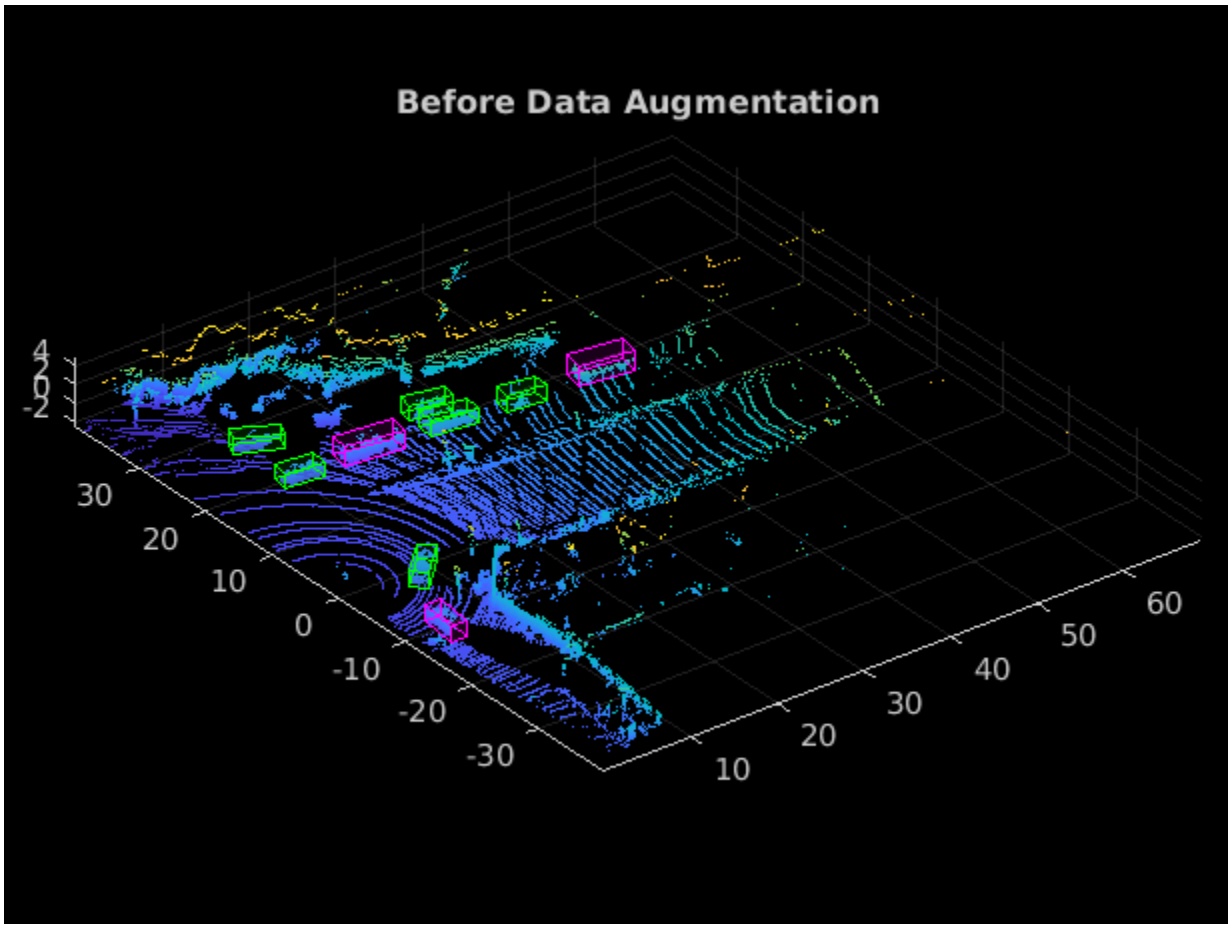
This example uses ground truth data augmentation and several other global data augmentation techniques to add more variety to the training data and corresponding boxes. For more information on typical data augmentation techniques used in 3-D object detection workflows with lidar data, see “Data Augmentations for Lidar Object Detection Using Deep Learning” (Lidar Toolbox).

Read and display a point cloud before augmentation using the `helperDisplay3DBoxesOverlaidPointCloud` helper function, defined at the end of the example..

```
augData = read(cds);
augptCld = augData{1,1};
augLabels = augData{1,2};
augClass = augData{1,3};

labelsCar = augLabels(augClass=='Car',:);
labelsTruck = augLabels(augClass=='Truck',:);

helperDisplay3DBoxesOverlaidPointCloud(augptCld.Location,labelsCar,'green',...
    labelsTruck,'magenta','Before Data Augmentation');
```



```
reset(cds);
```

Use the `sampleGroundTruthObjectsFromLidarData` helper function, attached to this example as a supporting file, to extract all the ground truth bounding boxes from the training data.

```
classNames = {'Car','Truck'};
sampleLocation = fullfile(tempdir,'GTsamples');
[sampledGTData,indices] = sampleGroundTruthObjectsFromLidarData(cds,classNames,...
    'MinPoints',20,'sampleLocation',sampleLocation);
```

Use the `augmentGroundTruthObjectsToLidarData` helper function, attached to this example as a supporting file, to randomly add a fixed number of car and truck class objects to every point cloud. Use the `transform` function to apply the ground truth and custom data augmentations to the training data.

```
numObjects = [10,10];
cdsAugmented = transform(cds,@(x) augmentGroundTruthObjectsToLidarData(x,...
    sampledGTData,indices,classNames,numObjects));
```

In addition, apply the following data augmentations to every point cloud.

- Random flipping along the x-axis
- Random scaling by 5 percent

- Random rotation along the z-axis from [-pi/4, pi/4]
- Random translation by [0.2, 0.2, 0.1] meters along the x-, y-, and z-axis respectively

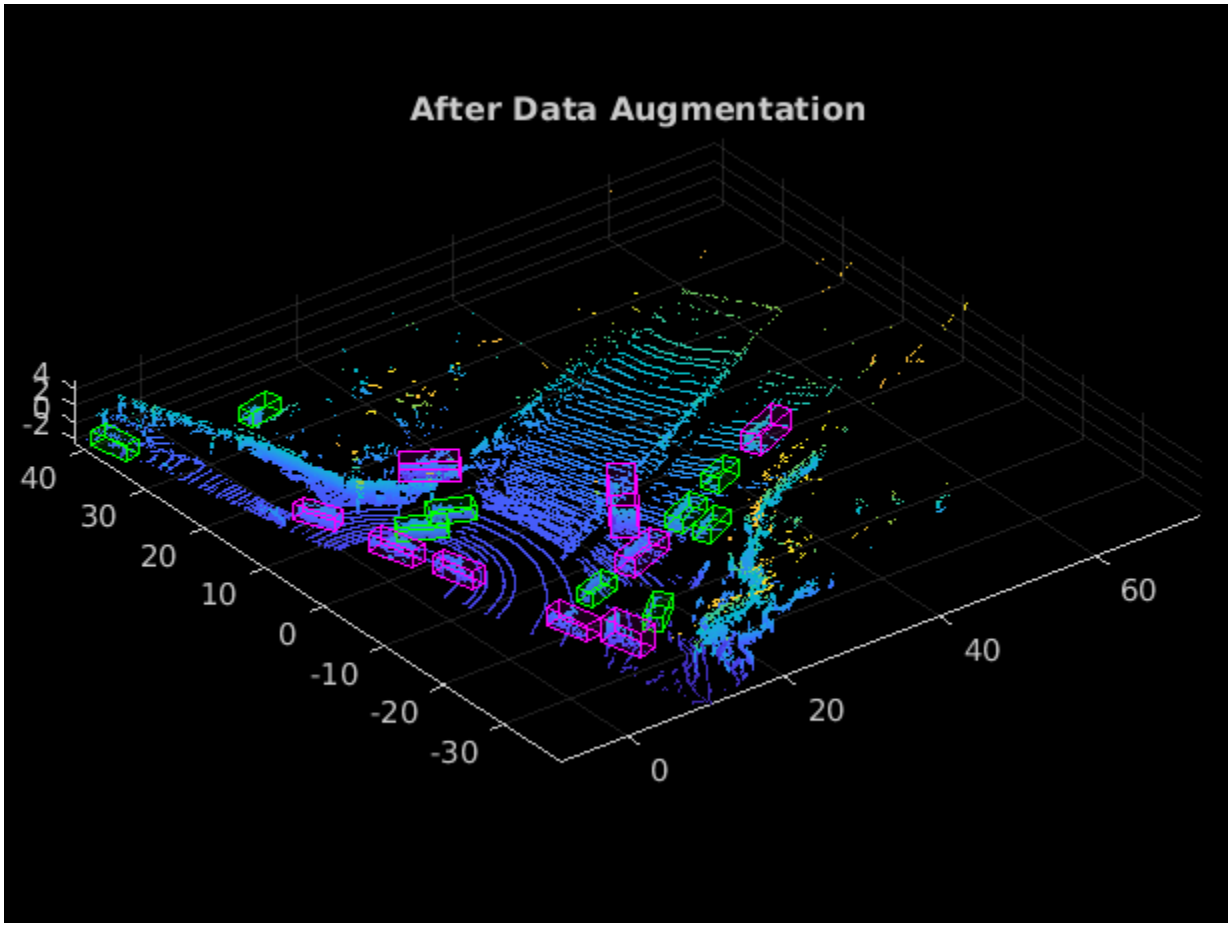
```
cdsAugmented = transform(cdsAugmented,@(x) augmentData(x));
```

Display an augmented point cloud along with ground truth augmented boxes using the `helperDisplay3DBoxesOverlaidPointCloud` helper function, defined at the end of the example.

```
augData = read(cdsAugmented);
augptCld = augData{1,1};
augLabels = augData{1,2};
augClass = augData{1,3};

labelsCar = augLabels(augClass=='Car',:);
labelsTruck = augLabels(augClass=='Truck',:);

helperDisplay3DBoxesOverlaidPointCloud(augptCld.Location,labelsCar,'green',...
    labelsTruck,'magenta','After Data Augmentation');
```



```
reset(cdsAugmented);
```

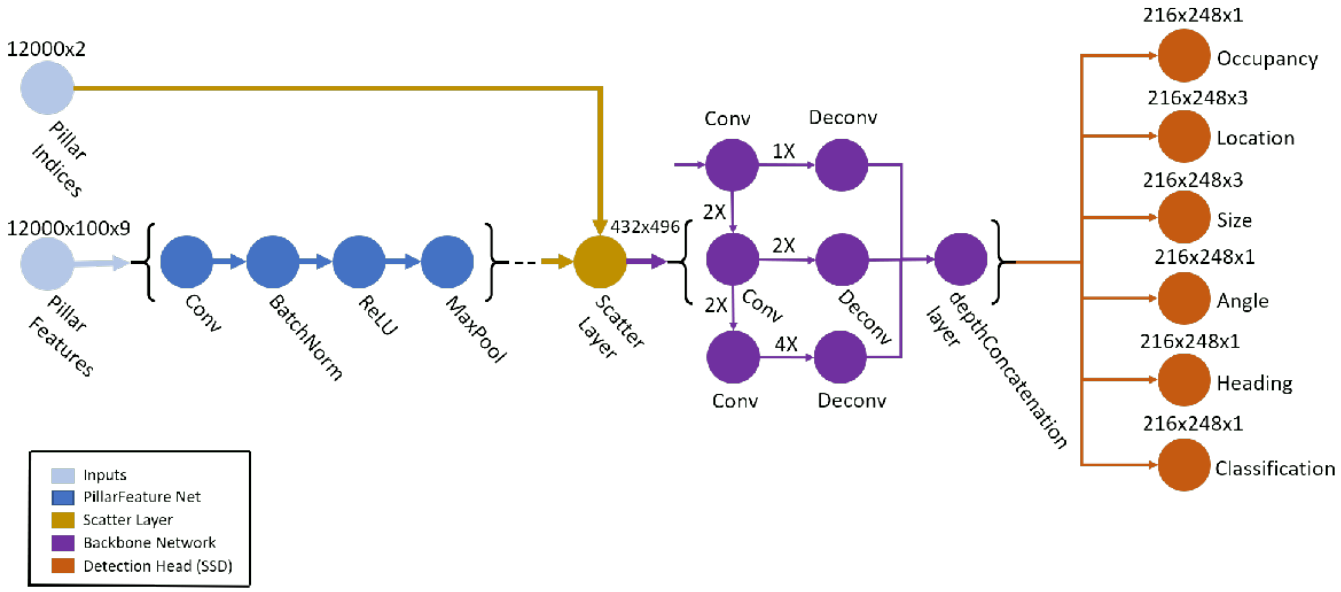
Create PointPillars Object Detector

Use the `pointPillarsObjectDetector` (Lidar Toolbox) function to create a PointPillars object detection network automatically. The PointPillars network uses a simplified version of the PointNet

network that takes pillar features as input. For each pillar feature, the network applies a linear layer, followed by batch normalization and ReLU layers. Finally, the network applies a max-pooling operation over the channels to get high-level encoded features. These encoded features are scattered back to the original pillar locations to create a pseudo-image. The network then processes the pseudo-image with a 2-D convolutional backbone followed by various SSD detection heads to predict the 3-D bounding boxes along with its classes.

The PointPillars network present in the PointPillars detector is illustrated in the following diagram.

You can use Deep Network Designer to create the network shown in the diagram.



The `pointPillarsObjectDetector` function requires you to specify several inputs that parameterize the PointPillars network:

- Class names
- Anchor boxes
- Point cloud range
- Voxel size
- Number of prominent pillars
- Number of points per pillar

```
% Define number of prominent pillars.
P = 12000;

% Define number of points per pillar.
N = 100;

% Estimate anchor boxes from training data.
anchorBoxes = calculateAnchorsPointPillars(trainLabels);
classNames = trainLabels.Properties.VariableNames;

% Define the PointPillars detector.
detector = pointPillarsObjectDetector(pointCloudRange,classNames,anchorBoxes,...
    'VoxelSize',voxelSize,'NumPillars',P,'NumPointsPerPillar',N);
```

If more control is required over the PointPillars network architecture, you can design the network manually. For more information, see Design a PointPillars Network.

Train Pointpillars Object Detector

Specify the network training parameters using `trainingOptions`. Set `'CheckpointPath'` to a temporary location to enable saving of partially trained detectors during the training process. If training is interrupted, you can resume training from the saved checkpoint.

Train the detector using a CPU or GPU. Using a GPU requires Parallel Computing Toolbox™ and a CUDA® enabled NVIDIA® GPU. For more information, see “GPU Support by Release” (Parallel Computing Toolbox). To automatically detect if you have a GPU available, set `executionEnvironment` to `"auto"`. If you do not have a GPU, or do not want to use one for training, set `executionEnvironment` to `"cpu"`. To ensure the use of a GPU for training, set `executionEnvironment` to `"gpu"`.

```
executionEnvironment = "auto";
if canUseParallelPool
    dispatchInBackground = true;
else
    dispatchInBackground = false;
end

options = trainingOptions('adam',...
    'Plots',"none",...
    'MaxEpochs',60,...
    'MiniBatchSize',3,...
    'GradientDecayFactor',0.9,...
    'SquaredGradientDecayFactor',0.999,...
    'LearnRateSchedule',"piecewise",...
    'InitialLearnRate',0.0002,...
    'LearnRateDropPeriod',15,...
    'LearnRateDropFactor',0.8,...
    'ExecutionEnvironment',executionEnvironment,...
    'DispatchInBackground',dispatchInBackground,...
    'BatchNormalizationStatistics','moving',...
    'ResetInputNormalization',false,...
    'CheckpointPath',tempdir);
```

Use `trainPointPillarsObjectDetector` (Lidar Toolbox) function to train the PointPillars object detector if `doTraining` is true. Otherwise, load the pretrained detector.

```
if doTraining
    [detector,info] = trainPointPillarsObjectDetector(cdsAugmented,detector,options);
else
    pretrainedDetector = load('pretrainedPointPillarsDetector.mat','detector');
    detector = pretrainedDetector.detector;
end
```

Generate Detections

Use the trained network to detect objects in the test data:

- Read the point cloud from the test data.
- Run the detector on the test point cloud to get the predicted bounding boxes and confidence scores.

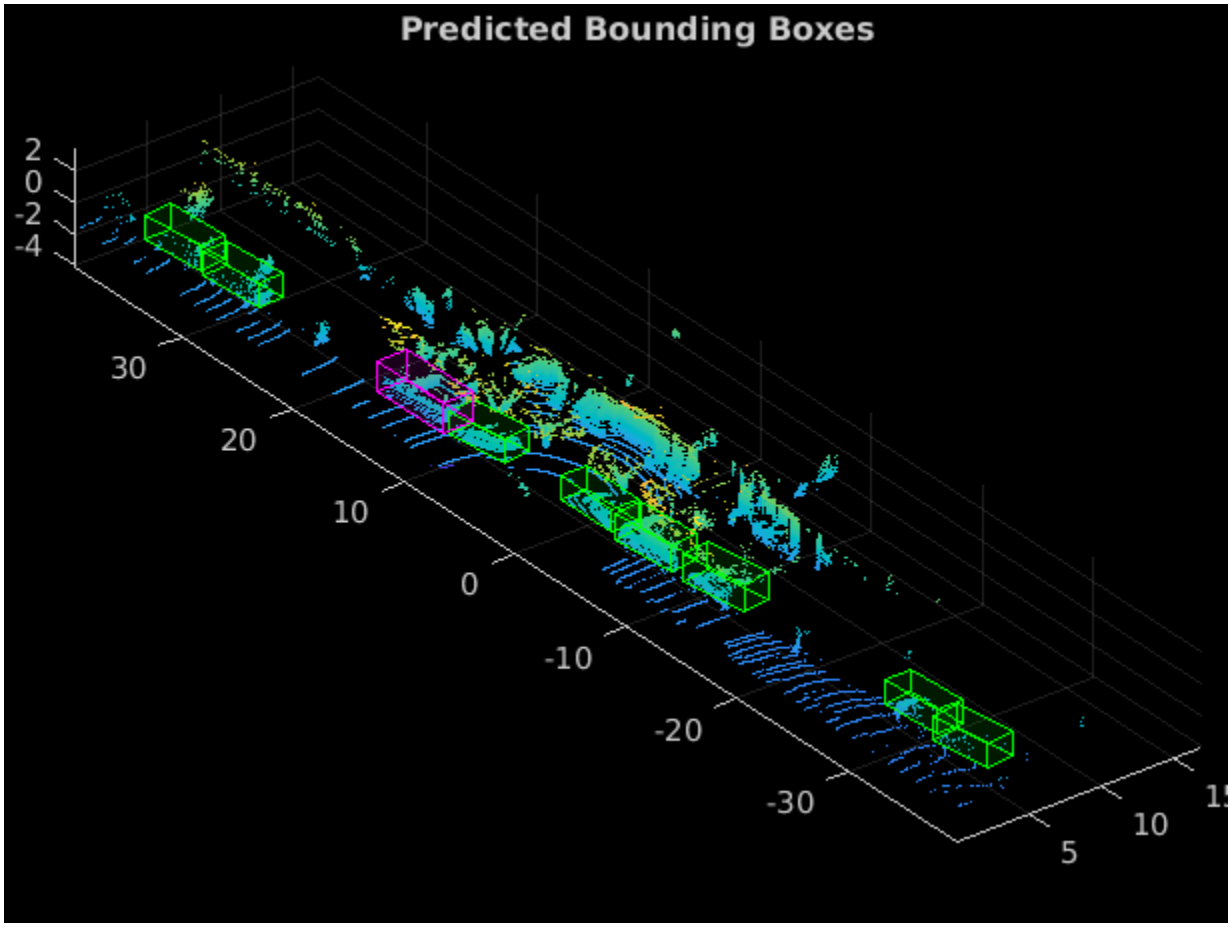
- Display the point cloud with bounding boxes using the `helperDisplay3DBoxesOverlaidPointCloud` helper function, defined at the end of the example.

```
ptCloud = testData{45,1};
gtLabels = testLabels(45,:);

% Specify the confidence threshold to use only detections with
% confidence scores above this value.
confidenceThreshold = 0.5;
[box,score,labels] = detect(detector,ptCloud,'Threshold',confidenceThreshold);

boxlabelsCar = box(labels'=='Car',:);
boxlabelsTruck = box(labels'=='Truck',:);

% Display the predictions on the point cloud.
helperDisplay3DBoxesOverlaidPointCloud(ptCloud.Location,boxlabelsCar,'green',...
    boxlabelsTruck,'magenta','Predicted Bounding Boxes');
```



Evaluate Detector Using Test Set

Evaluate the trained object detector on a large set of point cloud data to measure the performance.

```
numInputs = 50;
```

```
% Generate rotated rectangles from the cuboid labels.
bds = boxLabelDatastore(testLabels(1:numInputs,:));
groundTruthData = transform(bds,@(x) createRotRect(x));

% Set the threshold values.
nmsPositiveIoUThreshold = 0.5;
confidenceThreshold = 0.25;

detectionResults = detect(detector,testData(1:numInputs,:),...
    'Threshold',confidenceThreshold);

% Convert to rotated rectangles format for calculating metrics
for i = 1:height(detectionResults)
    box = detectionResults.Boxes{i};
    detectionResults.Boxes{i} = box(:,[1,2,4,5,7]);
end

metrics = evaluateDetectionAOS(detectionResults,groundTruthData,...
    nmsPositiveIoUThreshold);
disp(metrics(:,1:2))
```

```
              AOS        AP
            _______    _______

    Car     0.89735    0.89735
    Truck     0.758      0.758
```

Helper Functions

```
function helperDownloadPandasetData(outputFolder,lidarURL)
% Download the data set from the given URL to the output folder.

    lidarDataTarFile = fullfile(outputFolder,'Pandaset_LidarData.tar.gz');

    if ~exist(lidarDataTarFile,'file')
        mkdir(outputFolder);

        disp('Downloading PandaSet Lidar driving data (5.2 GB)...');
        websave(lidarDataTarFile,lidarURL);
        untar(lidarDataTarFile,outputFolder);
    end

    % Extract the file.
    if (~exist(fullfile(outputFolder,'Lidar'),'dir'))...
            &&(~exist(fullfile(outputFolder,'Cuboids'),'dir'))
        untar(lidarDataTarFile,outputFolder);
    end

end

function helperDisplay3DBoxesOverlaidPointCloud(ptCld,labelsCar,carColor,...
    labelsTruck,truckColor,titleForFigure)
% Display the point cloud with different colored bounding boxes for different
% classes.
    figure;
    ax = pcshow(ptCld);
    showShape('cuboid',labelsCar,'Parent',ax,'Opacity',0.1,...
        'Color',carColor,'LineWidth',0.5);
```

```
    hold on;
    showShape('cuboid',labelsTruck,'Parent',ax,'Opacity',0.1,...
        'Color',truckColor,'LineWidth',0.5);
    title(titleForFigure);
    zoom(ax,1.5);
end
```

Signal Processing Examples

Learn Pre-Emphasis Filter Using Deep Learning

This example shows how to use a convolutional deep network to learn a pre-emphasis filter for speech recognition. The example uses a learnable short-time Fourier transform (STFT) layer to obtain a time-frequency representation suitable for use with 2-D convolutional layers. The use of a learnable STFT enables a gradient-based optimization of the pre-emphasis filter weights.

Data

Clone or download the Free Spoken Digit Dataset (FSDD), available at https://github.com/Jakobovski/free-spoken-digit-dataset. FSDD is an open data set, which means that it can grow over time. This example uses the version committed on 08/20/2020 which consists of 3000 recordings of the English digits 0 through 9 obtained from six speakers. The data is sampled at 8000 Hz.

This example assumes that you have downloaded the data into the folder corresponding to the value of `tempdir` in MATLAB. If you use a different folder, substitute that folder name for `tempdir` in the following code. Use audioDatastore to manage data access and ensure random division of data into training and test sets.

```
tempdir = '/mathworks/devel/sandbox/wking';
pathToRecordingsFolder = fullfile(tempdir,'free-spoken-digit-dataset','recordings');
ads = audioDatastore(pathToRecordingsFolder);
```

The helper function `helpergenLabels` creates a categorical array of labels from the FSDD files. The source code for `helpergenLabels` is listed in the appendix. List the classes and the number of examples in each class. It may take a few minutes to generate all the labels for this dataset.

```
ads.Labels = helpergenLabels(ads);
summary(ads.Labels)
```

```
     0      300
     1      300
     2      300
     3      300
     4      300
     5      300
     6      300
     7      300
     8      300
     9      300
```

Split the FSDD into training and test sets maintaining equal class proportions in each subset. For reproducible results, set the random number generator to its default value. Eighty percent, or 2400 recordings, are used for training. The remaining 600 recordings, 20% of the total, are held out for testing. Shuffle the files in the datastore once before creating the training and test sets.

```
rng default;
ads = shuffle(ads);
[adsTrain,adsTest] = splitEachLabel(ads,0.8,0.2);
```

The recordings in FSDD are not equal in length. Use a transform so that each read from the datastore is padded or truncated to 8192 samples. The data are additionally cast to single-precision and a z-score normalization is applied.

```
transTrain = transform(adsTrain,@(x,info)helperReadData(x,info),'IncludeInfo',true);
transTest = transform(adsTest,@(x,info)helperReadData(x,info),'IncludeInfo',true);
```

Deep Convolutional Neural Network (DCNN) Architecture

This example uses a custom training loop with the following deep convolutional network.

```
numF = 12;
dropoutProb = 0.2;
layers = [
    sequenceInputLayer(1,'Name','input','MinLength',8192,...
         'Normalization',"none")

    convolution1dLayer(5,1,"name","pre-emphasis-filter",...
    "WeightsInitializer",@(sz)kronDelta(sz),"BiasLearnRateFactor",0)

    stftLayer('Window',hamming(1280),'OverlapLength',900,...
    'OutputMode','spatial','Name','STFT')

    convolution2dLayer(5,numF,'Padding','same')
    batchNormalizationLayer
    reluLayer

    maxPooling2dLayer(3,'Stride',2,'Padding','same')

    convolution2dLayer(3,2*numF,'Padding','same')
    batchNormalizationLayer
    reluLayer

    maxPooling2dLayer(3,'Stride',2,'Padding','same')

    convolution2dLayer(3,4*numF,'Padding','same')
    batchNormalizationLayer
    reluLayer

    maxPooling2dLayer(3,'Stride',2,'Padding','same')

    convolution2dLayer(3,4*numF,'Padding','same')
    batchNormalizationLayer
    reluLayer

    convolution2dLayer(3,4*numF,'Padding','same')
    batchNormalizationLayer
    reluLayer

    maxPooling2dLayer(2)

    dropoutLayer(dropoutProb)
    fullyConnectedLayer(numel(categories(ads.Labels)))
    softmaxLayer
    ];
dlnet = dlnetwork(layers);
```

The sequence input layer is followed by a 1-D convolution layer consisting of a single filter with 5 coefficients. This is a finite impulse response filter. Convolutional layers in deep learning networks by default implement an affine operation on the input features. To obtain a strictly linear (filtering) operation, use the default `'BiasInitializer'` which is `'zeros'` and set the bias learn rate factor of the layer to 0. This means that the bias is initialized to 0 and never changes during training. The network uses a custom initialization of the filter weights to be a scaled Kronecker delta sequence. This is an allpass filter, which performs no filtering of the input.

`stftLayer` takes the filtered batch of input signals and obtains their magnitude STFTs. The magnitude STFT is a 2-D representation of the signal, which is amenable to use in 2-D convolutional networks.

While the weights of the STFT are not changed here during training, the layer supports backpropagation, which enables the filter coefficients in the "pre-emphasis-filter" layer to be learned.

Network Training

Set the training options for the custom training loop. Use 25 epochs with a minbatch size of 128. Set the initial learn rate to 0.001.

```
NumEpochs = 25;
miniBatchSize = 128;
learnRate = 0.001;
```

In the custom training loop, use a `minibatchqueue` object. The `processSpeechMB` function reads in a minibatch and applies a one-hot encoding scheme to the labels.

```
mbqTrain = minibatchqueue(transTrain, 2,...
    'MiniBatchSize',miniBatchSize,...
    'MiniBatchFormat', {'CBT', 'CB'}, ...
    'MiniBatchFcn', @processSpeechMB);
```

Train the network and plot the loss for each iteration. Use an Adam optimizer to update the network learnable parameters. To plot the loss as training progress, set the value of `progress` in the following code to "training-progress".

```
progress = "final-loss";
if progress == "training-progress"
    figure
    lineLossTrain = animatedline;

```

Evaluate the classification accuracy on the 600 examples in the held-out test set.

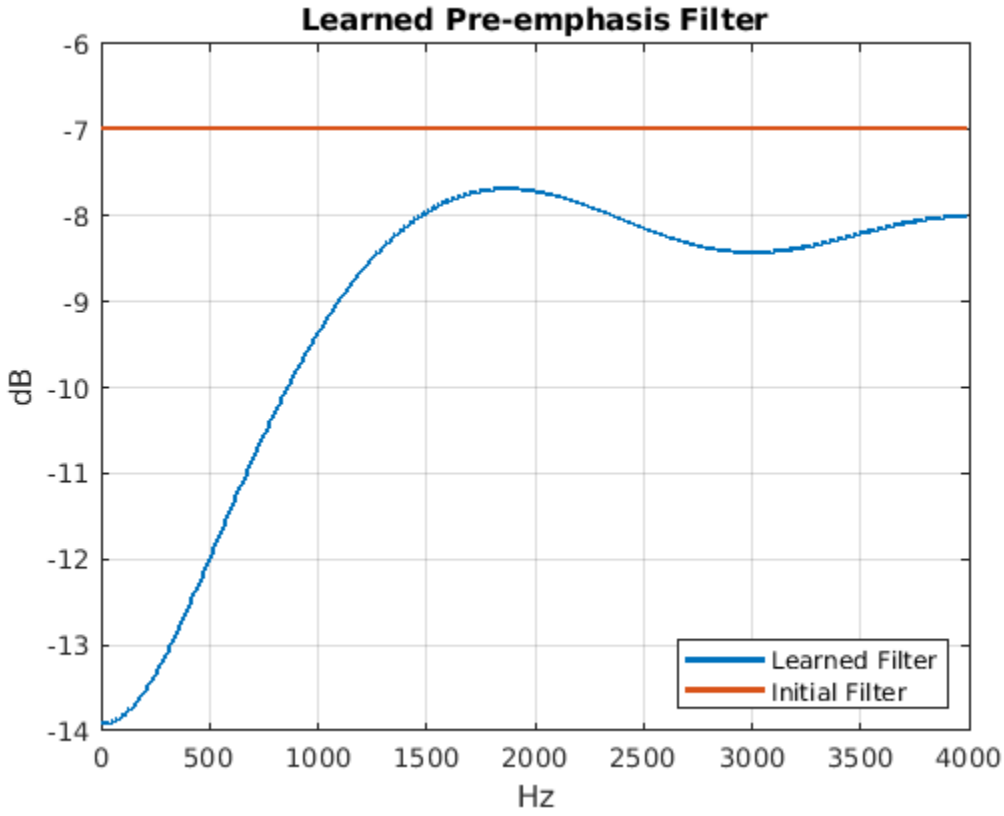
```
accuracy = mean(predictions' == categorical(adsTest.Labels))
```

```
accuracy = 0.9833
```

Test performance is approximately 98%. You can comment out the 1-D convolution layer and retrain the network without the pre-emphasis filter. The test performance without the pre-emphasis filter is also excellent at approximately 96%, but the use of the pre-emphasis filter makes a small improvement. It is noteworthy, that while the use of the learned pre-emphasis filter has only improved the test accuracy slightly, this was achieved by adding only 5 learnable parameters to the network.

To examine the learned pre-emphasis filter, extract the weights of the 1-D convolutional layer. Plot the frequency response. Recall that the sampling frequency of the data is 8 kHz. Because we initialized the filter to a scaled Kronecker delta sequence (allpass filter), we can easily compare the frequency response of the initialized filter with the learned response.

```
FIRFilter = dlnet.Layers(2).Weights;
[H,W] = freqz(FIRFilter,1,[],8000);
delta = kronDelta([5 1 1]);
Hinit = freqz(delta,1,[],4000);
plot(W,20*log10(abs([H Hinit])),'linewidth',2)
grid on
xlabel('Hz')
ylabel('dB')
legend('Learned Filter','Initial Filter','Location','SouthEast')
title('Learned Pre-emphasis Filter')
```



This example showed how to learn a pre-emphasis filter as a preprocessing step in a 2-D convolutional network based on short-time Fourier transforms of the signals. The ability of `stftLayer` to support backpropagation enabled gradient-based optimization of the filter weights inside the deep network. While this resulted in only a small improvement in the performance of the network on the test set, it achieved this improvement with a trivial increase in the number of learnable parameters.

Appendix: Helper Functions

```
function Labels = helpergenLabels(ads)
% This function is only for use in the "Learn Pre-Emphasis Filter using
% Deep Learning" example. It may change or be removed in a
% future release.

tmp = cell(numel(ads.Files),1);
expression = "[0-9]+_";
for nf = 1:numel(ads.Files)
    idx = regexp(ads.Files{nf},expression);
    tmp{nf} = ads.Files{nf}(idx);
end
Labels = categorical(tmp);
end

function [out,info] = helperReadData(x,info)
% This function is only for use in the "Learn Pre-Emphasis Filter using
% Deep Learning" example. It may change or be removed in a
% future release.
```

```
N = numel(x);
x = single(x);
if N > 8192
    x = x(1:8192);
elseif N < 8192
    pad = 8192-N;
    prepad = floor(pad/2);
    postpad = ceil(pad/2);
    x = [zeros(prepad,1) ; x ; zeros(postpad,1)];
end
x = (x-mean(x))./std(x);
x = x(:)';
out = {x,info.Label};
end

Denoise EEG Signals Using Deep Learning Regression

This example shows how to remove electro-oculogram (EOG) noise from electroencephalogram (EEG) signals using the *EEGdenoiseNet* benchmark dataset [1] on page 12-0 and deep learning regression. The *EEGdenoiseNet* dataset contains 4514 clean EEG segments and 3400 ocular artifact segments that can be used to synthesize noisy EEG segments with the ground-truth clean EEG (the dataset also contains muscular artifact segments, but these will not be used in this example).

This example uses clean and EOG-contaminated EEG signals to train a long short-term memory (LSTM) model to remove the EOG artifacts. The regression model was trained with raw input signals and with signals transformed by the short-time Fourier transform (STFT). The STFT model improves performance especially at degraded SNR values.

Create the Dataset

The EEGdenoiseNet dataset contains 4514 clean EEG segments and 3400 EOG segments that can be used to generate three datasets for training, validating, and testing a deep learning model. The sample rate of all the signal segments is 256 Hz. For convenience, the dataset has been uploaded to this location: https://ssd.mathworks.com/supportfiles/SPT/data/EEGEOGDenoisingData.zip

Download the dataset using the `downloadSupportFile` function.

```
% Download the data
datasetZipFile = matlab.internal.examples.downloadSupportFile('SPT','data/EEGEOGDenoisingData.zi
datasetFolder = fullfile(fileparts(datasetZipFile),'EEG_EOG_Denoising_Dataset');
if ~exist(datasetFolder,'dir')
    unzip(datasetZipFile,fileparts(datasetZipFile));
end
```

After downloading the data, the location in `datasetFolder` contains two MAT files:

- `EEG_all_epochs.mat` contains a matrix with 4514 clean EEG segments of length 512 samples
- `EOG_all_epochs.mat` contains a matrix with 3400 EOG segments of length 512 samples

Use the `createDataset` helper function to generate training, validation, and testing datasets. The function combines clean EEG and EOG signals to generate pairs of clean and noisy EEG segments with different signal-to-noise ratios (SNR). For any EEG and EOG pair you can use the following combination equation to obtain a noisy segment with a given SNR:

$$\text{noisyEEG} = \text{EEG} + \lambda \cdot \text{EOG}$$

$$\text{SNR} = 10 \cdot \log_{10}\left(\frac{\text{rms(EEG)}}{\text{rms}(\lambda \cdot \text{EOG})}\right)$$

You vary parameter λ to control the artifact power and achieve a particular SNR value.

To create the training dataset `createDataset` combines the first 2720 pairs of EEG and EOG segments ten times each with random SNRs in the [-7, 2] dB interval for a total of 27200 training pairs. Each training pair is stored in a MAT file inside a folder named `train`. Each MAT file includes:

- A clean EEG segment (stored under a variable named `EEG`)
- An EOG segment (stored under a variable named `EOG`)
- A noisy EEG segment (stored under a variable named `noisyEEG`)

- The SNR of the noisy segment (stored under a variable named `SNR`)
- The sample rate value of the signal segments (stored under a variable named `Fs`)

To create the validation dataset `createDataset` combines the next 340 pairs of the EEG and EOG segments ten times each with random SNRs in the [–7, 2] dB interval for a total of 3400 validation segments. Validation data is stored in MAT files inside a folder named `validate`. Each MAT file contains the same variables as the ones described for the training set.

Finally, to create the test dataset `createDataset` combines the next 340 pairs of EEG and EOG segments ten times each with deterministic SNR values of –7, –6, –5, –4, –3, –2, –1, 0, 1, and 2 dB. The test data is stored in MAT files inside a folder named `test`. Test MAT files with the same SNR value are grouped under a common subfolder to make it easier to analyze the denoising performance of the trained model for a given SNR. For example, files with test signals with an SNR of -3 dB are stored in a folder with name `data_SNR_-3`.

Call the `createDataset` function to create the dataset (this may take a few seconds). Set the `createDatasetFlag` to false if you already have the dataset in the `datasetFolder` and want to skip this step.

```
createDatasetFlag = True;
if createDatasetFlag
    createDataset(datasetFolder);
end
```

Prepare Datastores to Consume the Data

The generated dataset is quite large (~430 MB), so it is convenient to use datastores to access the data without having to read it all at once into memory. Create signal datastores to access the training and validation data. Use the `SignalVariableNames` parameter to specify the variables you want to read from the MAT files (in the order you want them read). Also specify the `ReadOutputOrientation` as "row" to ensure the data is compatible with the LSTM network.

```
ds_Train = signalDatastore(fullfile(datasetFolder,"train"),SignalVariableNames=["noisyEEG","EEG"]
```

```
ds_Train =
  signalDatastore with properties:

                      Files:{
                             ' .../supportfiles/SPT/data/EEG_EOG_Denoising_Dataset/train/data_1.m
                             ' .../supportfiles/SPT/data/EEG_EOG_Denoising_Dataset/train/data_10
                             ' .../supportfiles/SPT/data/EEG_EOG_Denoising_Dataset/train/data_100
                              ... and 27197 more
                            }
                    Folders: {'/home/fboucher/Documents/MATLAB/Examples/R2021b/supportfiles/SPT/
    AlternateFileSystemRoots: [0×0 string]
                   ReadSize: 1
         SignalVariableNames: ["noisyEEG"    "EEG"]
       ReadOutputOrientation: "row"
```

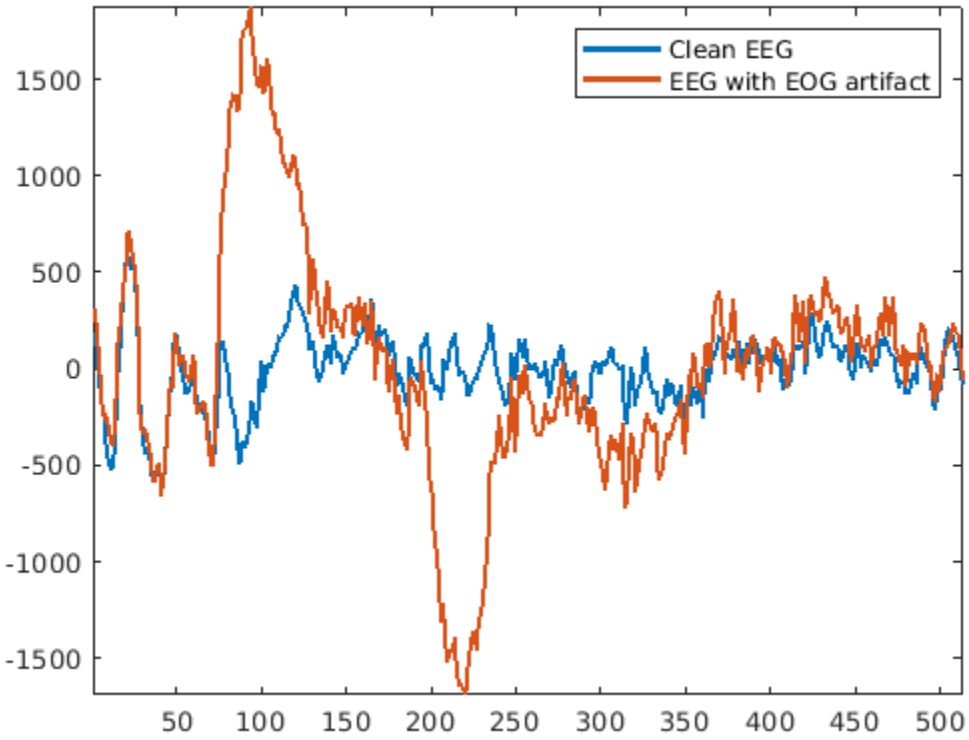
```
ds_Validate = signalDatastore(fullfile(datasetFolder,"validate"),SignalVariableNames=["noisyEEG"
```

Read the data from the first training file and plot the clean and noisy EEG signals. A call to preview or read methods of the datastore yields a 1x2 cell array with the first element containing a noisy EEG segment, and the second element containing a clean EEG segment.

```
data = preview(ds_Train)
```

```
data=1×2 cell array
    {[293.5459 312.8255 158.2003 54.3755 -122.9328 -245.2081 -263.6249 -231.0821 -265.4603 -326.4
```

```
plot([data{2}.' data{1}.'],LineWidth=2)
legend('Clean EEG','EEG with EOG artifact')
axis tight
```



The performance of a regression network is usually improved if the input and output signals are normalized. You can transform the signal datastores to apply normalization to each signal as it is read from disk. The `normalizeData helper` function is listed at the end of this example. It simply subtracts the signal mean and divides the result by the signal's standard deviation.

```
ds_Train_T = transform(ds_Train,@normalizeData);
ds_Validate_T = transform(ds_Validate,@normalizeData);
```

Train a Regression Model to Denoise EEG Signals

Train a network to denoise signals by passing noisy EEG signals into the network input and requesting the desired EEG clean ground-truth signals at the network output. A long-short term memory (LSTM) architecture is chosen because it is capable of learning features from time sequences.

Define the network architecture: the number of features is set to one as a single sequence is input to the network and a single sequence is output from the network. Use a dropout layer to reduce

overfitting of the model on the training data. Use a regression layer as the output layer since the model is being trained to perform regression. Note that normalization must be applied to input and output signals so it is more convenient to use transformed datastores than to use the `Normalization` option of the `sequenceInputLayer` that only normalizes the inputs.

```
numFeatures = 1;
numHiddenUnits = 100;

layers = [
    sequenceInputLayer(numFeatures)
    lstmLayer(numHiddenUnits)
    dropoutLayer(0.2)
    fullyConnectedLayer(numFeatures)
    regressionLayer];
```

Define the training option parameters: use an Adam optimizer and choose to shuffle the data at every epoch. Also, specify the validation datastore `ds_Validate_T` as the source for the validation data.

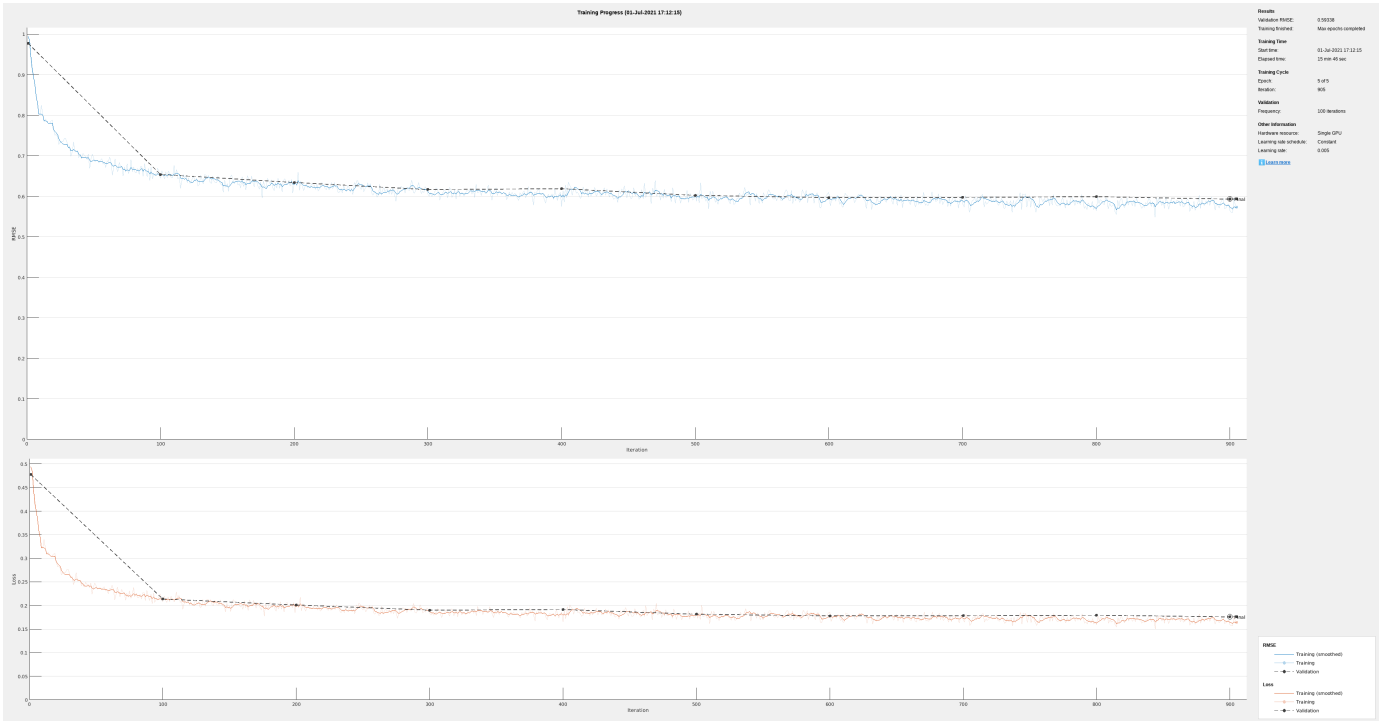
```
maxEpochs = 5;
miniBatchSize = 150;

options = trainingOptions('adam', ...
    MaxEpochs=maxEpochs, ...
    MiniBatchSize=miniBatchSize, ...
    InitialLearnRate=0.005, ...
    GradientThreshold=1, ...
    Plots="training-progress", ...
    Shuffle="every-epoch", ...
    Verbose=false,...
    ValidationData=ds_Validate_T ,...
    ValidationFrequency=100, ...
    OutputNetwork="best-validation-loss");
```

Use the `trainNetwork` function to train the model. You can directly pass the transformed train datastore into the function because the datastore outputs a 1x2 cell array, with input and output signals, at each call to the `read` method.

The training steps will take several minutes. You can skip these steps by downloading the pre-trained networks using the selector below. If you want to train the network as the example runs, select '`Train Networks`'. If you want to skip the training steps, select '`Download Networks`' and a MAT file containing two pre-trained networks -`rawNet`, and stft`Net`- will be downloaded into your machine.

```
trainingFlag = Train networks ;
if trainingFlag == "Train networks"
    rawNet = trainNetwork(ds_Train_T,layers,options);
else
    % Download the pre-trained networks
    modelsZipFile = matlab.internal.examples.downloadSupportFile('SPT','data/EEGEOGDenoisingNetwo
    modelsFolder = fullfile(fileparts(datasetZipFile),'EEG_EOG_Denoising_Networks');
    if ~exist(modelsFolder,'dir')
        unzip(modelsZipFile,fileparts(modelsZipFile));
    end
    modelsFile = fullfile(modelsFolder,'trainedNetworks.mat');
    load(modelsFile)
end
```



Analyze the Denoising Performance of the Trained Model

Use the test dataset to analyze the denoising performance of the `rawNet` network. Recall that the test dataset contains multiple test files for each SNR value in [-7, -6, -5, -4, -3, -2, -1, 0, 1, 2] dB. The performance metric is chosen as the mean-squared error (MSE) between the clean baseline EEG signal and the denoised EEG signal. The MSE of the clean EEG signal and the noisy EEG signal is also computed to show the worst-case MSE when no denoising is applied. At each SNR compute 340 MSE values for each of the 340 available test EEG segments and obtain the average MSE.

Create a `signalDatastore` to consume the test data and use a transformed datastore to setup data normalization. Since the data is now inside subfolders of the test folder, specify `IncludeSubfolders` as true. Further, use the folders2labels function to get the list of folder names for each file in the test dataset so that you can get data for each SNR.

```
ds_Test = signalDatastore(fullfile(datasetFolder,"test"),SignalVariableNames=["noisyEEG","EEG"],I
ds_Test_T = transform(ds_Test,@normalizeData);

% Get labels that contain the SNR value for each file in the datastore
labels = folders2labels(ds_Test)
```

```
labels = 3400×1 categorical
     data_SNR_-1
     data_SNR_-1
     data_SNR_-1
     data_SNR_-1
     data_SNR_-1
     data_SNR_-1
     data_SNR_-1
     data_SNR_-1
     data_SNR_-1
     data_SNR_-1
```

```
data_SNR_-1
data_SNR_-1
data_SNR_-1
data_SNR_-1
data_SNR_-1
data_SNR_-1
data_SNR_-1
data_SNR_-1
data_SNR_-1
data_SNR_-1
data_SNR_-1
data_SNR_-1
data_SNR_-1
data_SNR_-1
data_SNR_-1
data_SNR_-1
data_SNR_-1
data_SNR_-1
data_SNR_-1
  ⋮
```

For each SNR value, denoise the test signals and compute the average MSE value. Use the `subset` function of the datastore to get a datastore pointing to the data for each SNR. To denoise a signal call the `predict` function passing the trained network and the noisy data as inputs.

```
SNRs = (-7:2);
MSE_Denoised_rawNet = zeros(numel(SNRs),1); % Measure denoising performance
MSE_No_Denoise = zeros(numel(SNRs),1); % Measure worst-case MSE when no denoising is applied

for idx = 1:numel(SNRs)
    lblIdx = find(labels == "data_SNR_"+num2str(SNRs(idx)));
    ds_Test_SNR = subset(ds_Test_T,lblIdx); % New datastore pointing to files with current SNR va

    % Denoise the data using the predict function of the trained model
    pred = predict(rawNet,ds_Test_SNR);

    % Use an array datastore to loop over the 340 denoised signals for the
    % current SNR value. Transform the datastore to add the normalization
    % step.
    ds_Pred = transform(arrayDatastore(pred,OutputType="same"),@normalizeData);

    mse = 0;
    mseWorstCase = 0;
    cnt = 0;
    while hasdata(ds_Pred)

        testData = read(ds_Test_SNR);
        denoisedData = read(ds_Pred);

        % MSE performance of denoiser - testData{2} contains clean EEG,
        % testData{1} contains noisy EEG.
        mse = mse + sum((testData{2} - denoisedData{1}).^2)/numel(denoisedData{1});

        % Worst-case MSE performance when no denoising is applied.
        % Convert data to single precession as denoisedData is single
        % precision.
```

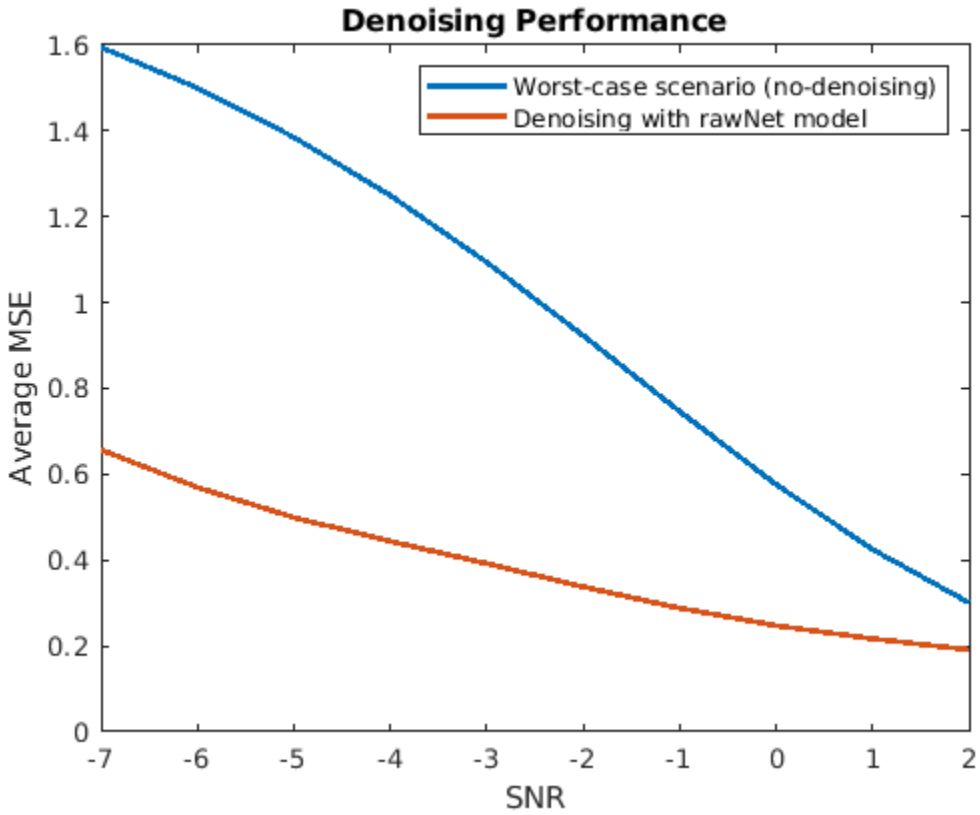
```
        mseWorstCase = mseWorstCase + sum((single(testData{2}) - single(testData{1})).^2)/numel(
        cnt = cnt+1;
    end

    % Average MSE of denoised signals
    MSE_Denoised_rawNet(idx) = mse/cnt;

    % Worst-case average MSE
    MSE_No_Denoise(idx) = mseWorstCase/cnt;
end
```

Plot the average MSE results.

```
plot(SNRs,[MSE_No_Denoise,MSE_Denoised_rawNet],LineWidth=2)
xlabel("SNR")
ylabel("Average MSE")
title("Denoising Performance")
legend("Worst-case scenario (no-denoising)","Denoising with rawNet model")
```



Improve Performance Using Short-Time Fourier Transform Feature Extraction

A common approach to improve performance of a deep learning model is to use extracted features in place of the original raw signal data. The features provide a representation of the input data that makes it easier for the network to learn the most important aspects of the signals.

Choose a short-time Fourier transformation (STFT) with a window length of 64 samples and overlap length of 63 samples. This transformation will effectively create 33 complex features with a length of

449 samples each. LSTM networks do not support complex inputs so the complex features can be separated into real and imaginary components by stacking the real part of the features on top of the imaginary part of the features to yield 66 real features each one of length 449 samples.

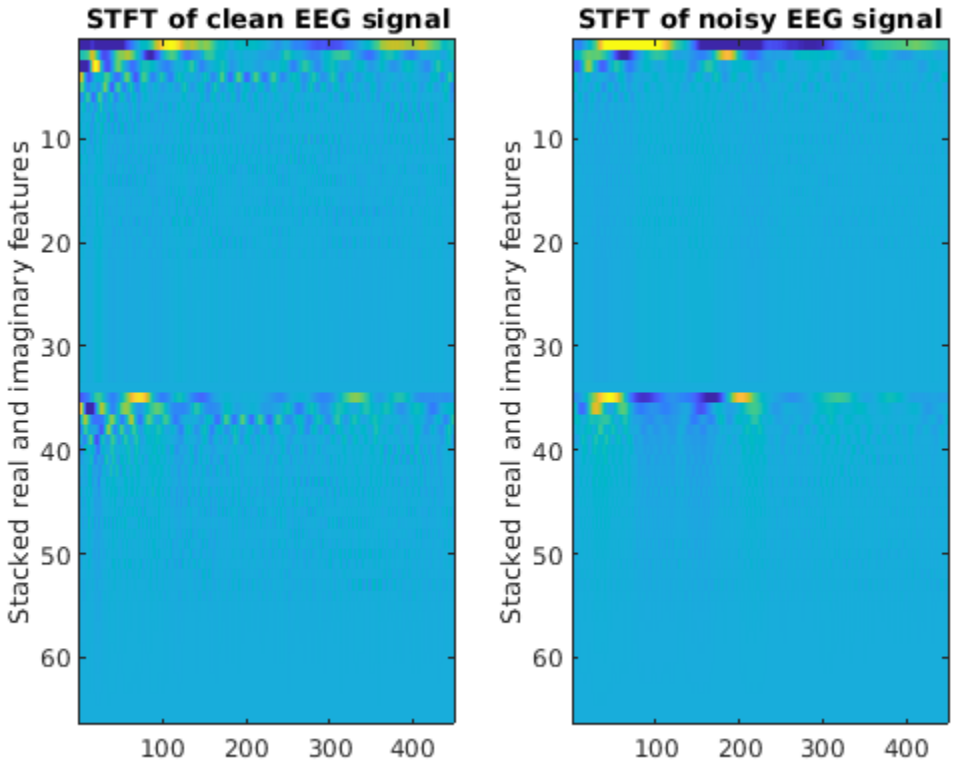
```
winLength = 64;
overlapLength = 63;
```

The `transformSTFT` helper function listed at the end of this example normalizes the input signal and then computes its STFT. The function stacks the real and imaginary components to create a real output matrix. Further, if a GPU is available, the function moves the data to the GPU to accelerate the STFT computations and mitigate the increased complexity of computing the transforms. If you do not wish to use the GPU, set `useGPUFlag` to `false`.

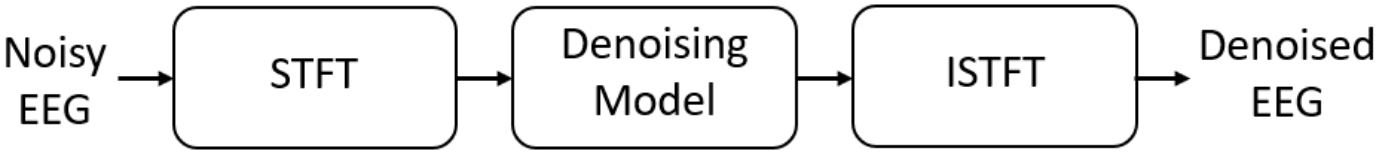
```
useGPUFlag = True;
```

Compute and plot the STFT of a pair of clean and noisy EEG signals using the `transformSTFT helper function.`

```
data = preview(ds_Train);
P = transformSTFT(data,winLength,overlapLength,useGPUFlag);
figure
subplot(1,2,1)
h = imagesc(P{2});
h.Parent.CLim = [-40 57];
title('STFT of clean EEG signal')
ylabel("Stacked real and imaginary features")
subplot(1,2,2)
h = imagesc(P{1});
h.Parent.CLim = [-40 57];
ylabel("Stacked real and imaginary features")
title('STFT of noisy EEG signal')
```



The idea is to train a network so that it can produce denoised STFT signal representations based on STFT inputs corresponding to noisy signals. Note that the target outcome is a denoised signal, not its denoised STFT representation, so a final step must be added to compute the inverse STFT (ISTFT) to recover the denoised signal as depicted on the block diagram below.



The helper function, `transformISTFT`, listed at the end of this example takes the denoised STFT network output, converts the stacked real and imaginary features back to complex features and computes the inverse STFT. As a final step the function normalizes the resulting signal. If a GPU is available and `useGPU`flag is true, the function performs all the computations in the GPU to reduce the processing time.

Create train, validation, and test datastores to apply STFT using the `transformSTFT` function.

```
ds_Train_STFT = transform(ds_Train,@(d,wl,ol,fl)transformSTFT(d,winLength,overlapLength,useGPUFla
ds_Validate_STFT = transform(ds_Validate,@(d,wl,ol,fl)transformSTFT(d,winLength,overlapLength,use
ds_Test_STFT = transform(ds_Test,@(d,wl,ol,fl)transformSTFT(d,winLength,overlapLength,useGPUFlag)
```

Update the network architecture to account for 66 input and output features and specify the new validation data in the training options. Every other network parameter or option is unchanged.

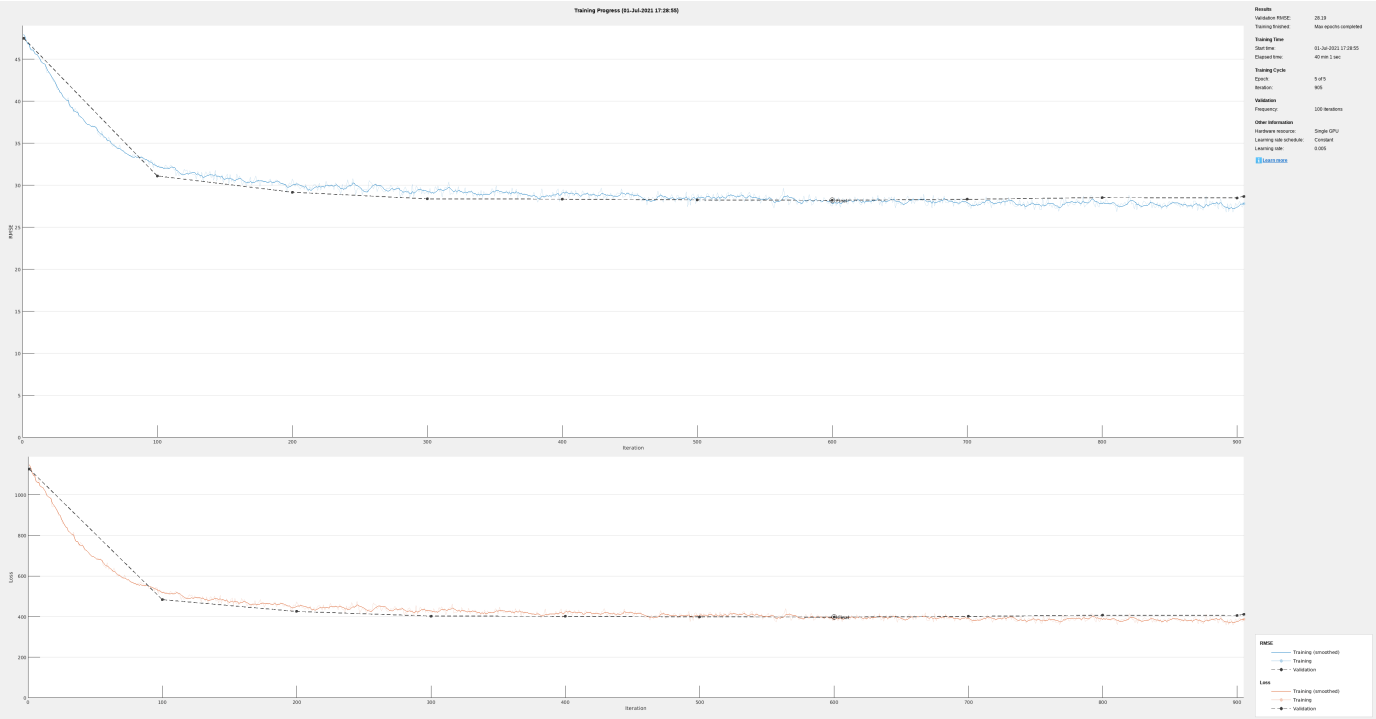
```
numFeatures = winLength + 2;

layers = [
    sequenceInputLayer(numFeatures)
    lstmLayer(numHiddenUnits)
    dropoutLayer(0.2)
    fullyConnectedLayer(numFeatures)
    regressionLayer];

options.ValidationData = ds_Validate_STFT;
```

Train the network if `trainingFlag` is `"Train networks"`.

```
if trainingFlag == "Train networks"
    stftNet = trainNetwork(ds_Train_STFT,layers,options);
end
```



Use the trained network to denoise EEG signals using the test data. Compute average MSE values by comparing denoised and clean baseline EEG signals.

```
MSE_Denoised_stftNet = zeros(numel(SNRs),1); % Measure denoising performance
for idx = 1:numel(SNRs)
    lblIdx = find(labels == "data_SNR_"+num2str(SNRs(idx)));
    % New datastores pointing to files with current SNR value
    ds_Test_SNR = subset(ds_Test_T,lblIdx); % Raw EEG signals to compute MSE
    ds_Test_STFT_SNR = subset(ds_Test_STFT,lblIdx); % STFT transforms

    % Denoise the data using the predict function of the trained model.
    pred = predict(stftNet,ds_Test_STFT_SNR);

    % Use an array datastore to loop over the 340 denoised signals for the
    % current SNR value. Transform the datastore to compute the inverse
```

```
    % STFT and recover the actual denoised signal.
    ds_Pred = transform(arrayDatastore(pred,OutputType="same"),@(P,wl,ol)transformISTFT(P,winLeng

    mse = 0;
    cnt = 0;
    while hasdata(ds_Pred)

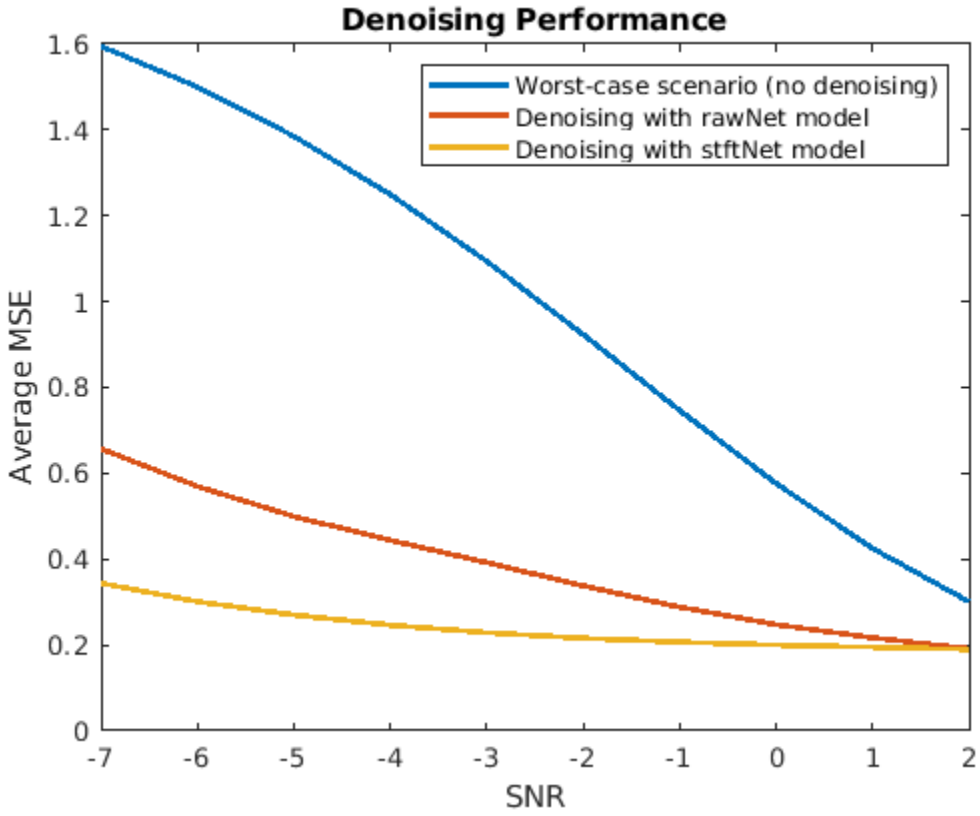
        testData = read(ds_Test_SNR);
        denoisedData = read(ds_Pred);

        % MSE performance of denoiser - testData{2} contains clean EEG
        mse = mse + sum((testData{2} - denoisedData).^2)/numel(denoisedData);
        cnt = cnt+1;
    end

    % Average MSE of denoised signals
    MSE_Denoised_stftNet(idx) = mse/cnt;
end
```

Plot the average MSE obtained with no denoising, denoising with a network trained with raw input signals, and denoising with a network trained with STFT transformed signals. You can see that the addition of the STFT step has improved the performance especially at the lower SNR values.

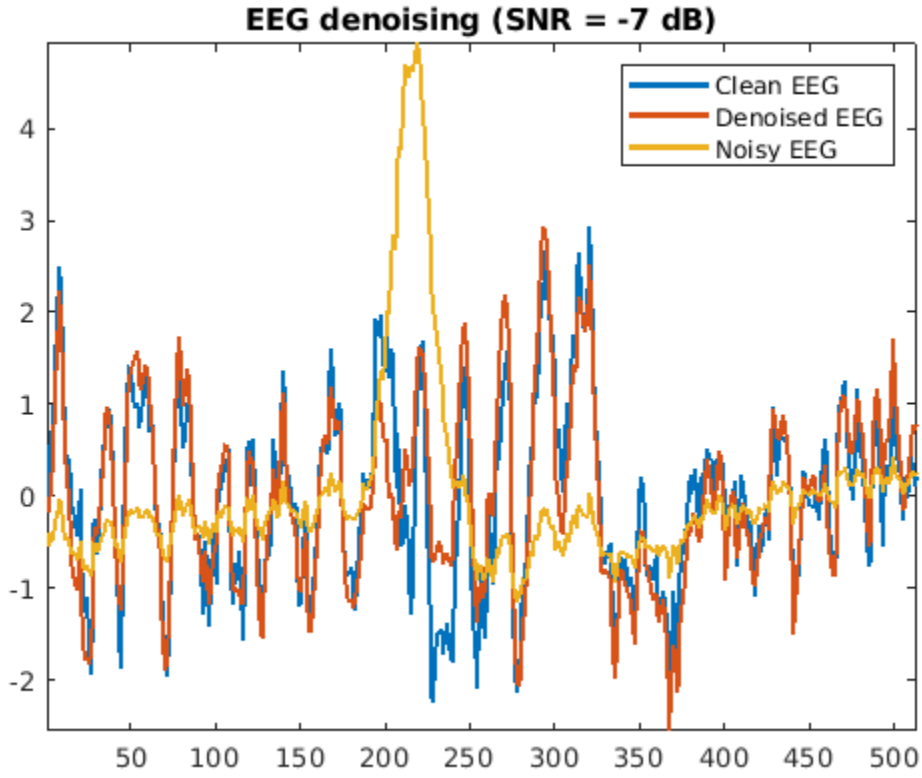
```
figure
plot(SNRs,[MSE_No_Denoise,MSE_Denoised_rawNet,MSE_Denoised_stftNet],LineWidth=2)
xlabel("SNR")
ylabel("Average MSE")
title("Denoising Performance")
legend("Worst-case scenario (no denoising)","Denoising with rawNet model","Denoising with stftNe
```



Plot noisy and denoised signals for different SNRs. The `getRandomEEG` helper function listed at the end of this example gets a random EEG signal with a specified SNR from the test dataset.

```
SNR = -7; % dB
data = getRandomEEG(datasetFolder,SNR);
noisyEEG = normalizeData(data{1});
cleanEEG = normalizeData(data{2});
stftInput = transformSTFT(noisyEEG,winLength,overlapLength,useGPUFlag);
denoisedEEG = transformISTFT(predict(stftNet,stftInput),winLength,overlapLength);

plot([cleanEEG.' denoisedEEG.' noisyEEG.'],LineWidth=2)
title("EEG denoising (SNR = " + SNR + " dB)")
legend("Clean EEG", "Denoised EEG","Noisy EEG")
axis tight
```



Conclusion

In this example you learned how to train a deep network to perform regression for signal denoising. You compared two models, one trained with raw clean and noisy EEG signals, the other trained with features extracted using a short-time Fourier transform. You learned that you can use complex features by stacking their real and imaginary components and treating them as independent real features. The use of STFT sequences provides greater performance improvement at worse SNRs and both approaches converge in performance as the SNR improves.

Helper Functions

`normalizeData` - this function normalizes input signals by subtracting the mean and dividing by the standard deviation.

```
function y = normalizeData(x)
% This function is only intended to support examples in the Signal
% Processing Toolbox. It may be changed or removed in a future release.

if iscell(x)
    y = cell(1,numel(x));
    y{1} = (x{1}-mean(x{1}))/std(x{1});
```

```
    if numel(x) == 2
        y{2} = (x{2}-mean(x{2}))/std(x{2});
    end
else
    y = (x - mean(x))/std(x);
end
end
```

`transformSTFT` - this function normalizes the signals in input `data` and computes their short-time Fourier transform. It converts the complex STFT results into a real matrix by stacking the real and imaginary components one on top of the other.

```
function P = transformSTFT(data,winLength,overlapLength,useGPUFlag)
% This function is only intended to support examples in the Signal
% Processing Toolbox. It may be changed or removed in a future release.

if ~iscell(data)
    data = {data};
end

P = cell(1,numel(data));

x = data{1};
if useGPUFlag
    x = gpuArray(x);
end
x = normalizeData(x);
y = stft(x,Window=rectwin(winLength),OverlapLength=overlapLength,FrequencyRange="onesided");
P{1} = [real(y);imag(y)];

if numel(data) == 2
    x = data{2};
    if useGPUFlag
        x = gpuArray(x);
    end
    x = normalizeData(x);
    y = stft(x,Window=rectwin(winLength),OverlapLength=overlapLength,FrequencyRange="onesided");
    P{2} = [real(y);imag(y)];
end
end
```

`transformISTFT` - this function takes a matrix with stacked real and imaginary STFT elements and combines them back to a complex STFT matrix. The function then computes the inverse STFT transform and normalizes the resulting reconstructed signals.

```
function data = transformISTFT(P,winLength,overlapLength)
% This function is only intended to support examples in the Signal
% Processing Toolbox. It may be changed or removed in a future release.
PP = P{1};
NumRows = size(PP,1);
X = PP(1:NumRows/2,:)+1i*PP(1+NumRows/2:end,:);
data = istft(X,Window=rectwin(winLength),OverlapLength=overlapLength,ConjugateSymmetric=true,Fre
data = normalizeData(data);
end
```

`createDataset` - this function combines clean EEG signal segments with EOG segments to create training, validation and testing datasets to train an EEG denoiser neural network.

```
function createDataset(dataDir)
% This function is only intended to support examples in the Signal
% Processing Toolbox. It may be changed or removed in a future release.

% Create training, validation, and testing datasets consisting of clean EEG
% signals and noisy EEG signals contaminated by EOG segments.

load(fullfile(dataDir,"EEG_all_epochs.mat"),"EEG_all_epochs");
load(fullfile(dataDir,"EOG_all_epochs.mat"),"EOG_all_epochs");

EEG_all_epochs = EEG_all_epochs(1:3400,:).';
EOG_all_epochs = EOG_all_epochs.';
Fs = 256;
trainingPercentage = 80;
validationPercentage = 10;
N = size(EEG_all_epochs,2);

% Create a training dataset consisting of mat files containing two signals
% - a clean EEG signal, and an EEG signal contaminated by EOG artifacts.
% Combine each of 2720 pairs of EEG and EOG segments ten times with random
% SNRs in the range -7dB to 2dB to obtain 27200 training segments.

EEG_training = EEG_all_epochs(:,1:N*trainingPercentage/100);
EOG_training = EOG_all_epochs(:,1:N*trainingPercentage/100);

M = size(EEG_training,2);
cnt = 0;
if ~exist(fullfile(dataDir,"train"),'dir')
    mkdir(fullfile(dataDir,"train"))
end

        cnt = cnt + 1;
        EEG = EEG_training(:,idx).';
        EOG = EOG_training(:,idx).';
        [noisyEEG,SNR] = createNoisySegment(EEG,EOG,[-7,2]);
        save(fullfile(dataDir,"train","data_" + num2str(cnt) + ".mat"),"EEG","EOG","noisyEEG","Fs
    end
end

% Create a validation dataset by combining 340 pairs of EEG and EOG
% segments ten times with random SNRs in (-7:2) dB

EEG_validation = EEG_all_epochs(:,1+N*trainingPercentage/100:N*trainingPercentage/100+N*validatio
EOG_validation = EOG_all_epochs(:,1+N*trainingPercentage/100:N*trainingPercentage/100+N*validatio

M = size(EEG_validation,2);
cnt = 0;
if ~exist(fullfile(dataDir,"validate"),'dir')
    mkdir(fullfile(dataDir,"validate"))
end
for idx = 1:M
    for kk = 1:10
        cnt = cnt + 1;
        EEG = EEG_validation(:,idx).';
        EOG = EOG_validation(:,idx).';
        [noisyEEG,SNR] = createNoisySegment(EEG,EOG,[-7,2]);
```

```
        save(fullfile(dataDir,"validate","data_" + num2str(cnt) + ".mat"),"EEG","EOG","noisyEEG",
    end
end

% Create a test dataset by combining 340 pairs of EEG and EOG segments ten
% times with 10 SNR values [-7 -6 -5 -4 -3 -2 -1 0 1 2] dB. Store the
% training sets in folders with names that identify the SNR value so that
% it is easy to analyze performance by accessing files with a specific SNR.

EEG_test = EEG_all_epochs(:,1+N*trainingPercentage/100+N*validationPercentage/100:end);
EOG_test = EOG_all_epochs(:,1+N*trainingPercentage/100+N*validationPercentage/100:end);

M = size(EEG_test,2);
SNRVect = (-7:2);
for kk = 1:numel(SNRVect)
    cnt = 0;
    if ~exist(fullfile(dataDir,"test","data_SNR_" + num2str(SNRVect(kk))),'dir')
        mkdir(fullfile(dataDir,"test","data_SNR_" + num2str(SNRVect(kk))));
    end
    for idx = 1:M
        cnt = cnt + 1;
        EEG = EEG_test(:,idx).';
        EOG = EOG_test(:,idx).';
        [noisyEEG,SNR] = createNoisySegment(EEG,EOG,SNRVect(kk));
        save(fullfile(dataDir,"test","data_SNR_" + num2str(SNR)+"/" + "data_"+num2str(cnt) + ".ma
    end
end
end

function [y,SNROut] = createNoisySegment(eeg,artifact,SNR)
% Combine EEG and artifact signals with a specified SNR in dB. If SNR is a
% two-element vector, its value is chosen randomly from a uniform
% distribution over the interval [SNR(1) SNR(2)]

if numel(SNR) == 2
    SNR = SNR(1) + (SNR(2)-SNR(1)).*rand(1,1);
end

k = 10^(SNR/10);
lambda = (1/k)*rms(eeg)/rms(artifact);

y = eeg + lambda * artifact;

SNROut = SNR;
end
```

getRandomEEG - this function reads the data from a random EEG test file with a specified SNR.

```
function data = getRandomEEG(datasetFolder,SNR)
sds  = signalDatastore(fullfile(datasetFolder,"test","data_SNR_"+num2str(SNR)),SignalVariableName
n = numel(sds.Files);
idx = randi(n,1);
```

```
data = read(subset(sds,idx));
end
```

Hand Gesture Classification Using Radar Signals and Deep Learning

This example shows how to classify ultra-wideband (UWB) impulse radar signal data using a multiple-input, single-output convolutional neural network (CNN).

Introduction

Movement-based signal data acquired using sensors, like UWB impulse radars, contain patterns specific to different gestures. Correlating motion data with movement benefits several avenues of work. For example, hand gesture recognition is important for contactless human-computer interaction. This example aims to use a deep learning solution to automate feature extraction from patterns within a hand gesture dataset and provide a label for every signal sample.

UWB-gestures is a publicly available dataset of dynamic hand gestures [1 on page 12-0]. It contains a total of 9600 samples gathered from 8 different human volunteers. To obtain each recording, the examiners placed a separate UWB impulse radar at the left, top, and right sides of their experimental setup, resulting in 3 received radar signal data matrices. Volunteers performed hand gestures from a gesture vocabulary consisting of 12 dynamic hand movements:

1. left-right swipe (L-R swipe)
2. right-left swipe (R-L swipe)
3. up-down swipe (U-D swipe)
4. down-up swipe (D-U swipe)
5. diagonal-left-right-up-down swipe (Diag-LR-UD swipe)
6. diagonal-left-right-down-up swipe (Diag-LR-DU swipe)
7. diagonal-right-left-up-down swipe (Diag-RL-UD swipe)
8. diagonal-right-left-down-up swipe (Diag-RL-DU swipe)
9. clockwise rotation
10. counterclockwise rotation
11. inward push
12. empty gesture

As each hand gesture motion is captured by 3 independent UWB impulse radars, we will use a CNN architecture that accepts 3 signals as separate inputs. The CNN model will extract feature information from each signal before combining it to make a final gesture label prediction. As such, a multiple-input, single-output CNN will use minimally pre-processed radar signal data matrices to classify different gestures.

Download the Data

Each radar signal data matrix is labeled as the hand gesture that generated it. 8 different human volunteers performed 12 separate hand gestures, for a total of 96 trials stored in 96 MAT-files. Each MAT-file contains 3 radar data matrices, corresponding to the 3 radars used in the experimental setup. They are named `Left`, `Top`, and `Right`. The files are available at the following location:

https://ssd.mathworks.com/supportfiles/SPT/data/uwb-gestures.zip

Download the data files into your MATLAB Examples directory.

```
datasetZipFolder = matlab.internal.examples.downloadSupportFile("SPT","data/uwb-gestures.zip");
datasetFolder = erase(datasetZipFolder,".zip");
if ~exist(datasetFolder,"dir")
    downloadLocation = fileparts(datasetZipFolder);
    unzip(datasetZipFolder,downloadLocation);
end
```

You can also choose to download a separate file which includes a pre-trained network, `misoNet`, stored in a MAT-file named `pretrainedNetwork.mat`. It is available at the following location:

https://ssd.mathworks.com/supportfiles/SPT/data/uwb-gestures-network.zip

You can skip the training steps and use the pre-trained network for classification by setting `doTraining` to `false`. If `doTraining` is set to `false`, the pre-trained network will be downloaded later in this example. If you want to train the network as the example runs, make sure to set `doTraining` to `true`.

```
doTraining = true;
```

Explore the Data

Create a signal datastore to access the data in the files. Specify the signal variable names you want to read from each file using the `SignalVariableNames` parameter. This example assumes the dataset has been stored in your MATLAB Examples directory under the *uwb-gestures* folder. If this is not the case, change the path to the data in the `datasetFolder` variable.

```
sds = signalDatastore(datasetFolder,...
                      "IncludeSubfolders",true,...
                      "SignalVariableNames",["Left","Top","Right"],...
                      "FileExtensions",".mat",...
                      "ReadOutputOrientation","row")
```

```
sds =
  signalDatastore with properties:

                       Files:{
                              ' .../R2021b/supportfiles/SPT/data/uwb-gestures/HV_01/HV_01_G10_RawD
                              ' .../R2021b/supportfiles/SPT/data/uwb-gestures/HV_01/HV_01_G11_RawD
                              ' .../R2021b/supportfiles/SPT/data/uwb-gestures/HV_01/HV_01_G12_RawD
                               ... and 93 more
                             }
                     Folders: {'/home/ejoshi/Documents/MATLAB/Examples/R2021b/supportfiles/SPT/da
    AlternateFileSystemRoots: [0×0 string]
                    ReadSize: 1
         SignalVariableNames: ["Left"    "Top"    "Right"]
       ReadOutputOrientation: "row"
```

The datastore returns a three-element cell array containing the radar signal matrices for the left, top, and right radars, in that order.

```
preview(sds)
```

```
ans=1×3 cell array
    {9000×189 double}    {9000×189 double}    {9000×189 double}
```

The rows and columns in each radar signal matrix represent the duration of the hand gesture (slow-time) and the distance of the hand from the radar (fast-time), respectively. During data acquisition,

examiners recorded a subject repeating a particular hand gesture for 450 seconds, corresponding to 9000 (slow-time) rows. There is 1 complete gesture motion in 90 slow-time frames. As such, each radar signal matrix contains 100 complete hand gesture motion samples.The range of each UWB radar is 1.2 meters, corresponding to 189 fast-time bins.

```
slowTimeFrames = 90;
recordedTimePerSample = 4.5;
radarRange = 1.2;
```

To visualize a hand gesture motion, specify a UWB radar location, gesture, and gesture sample (between 1 and 100).

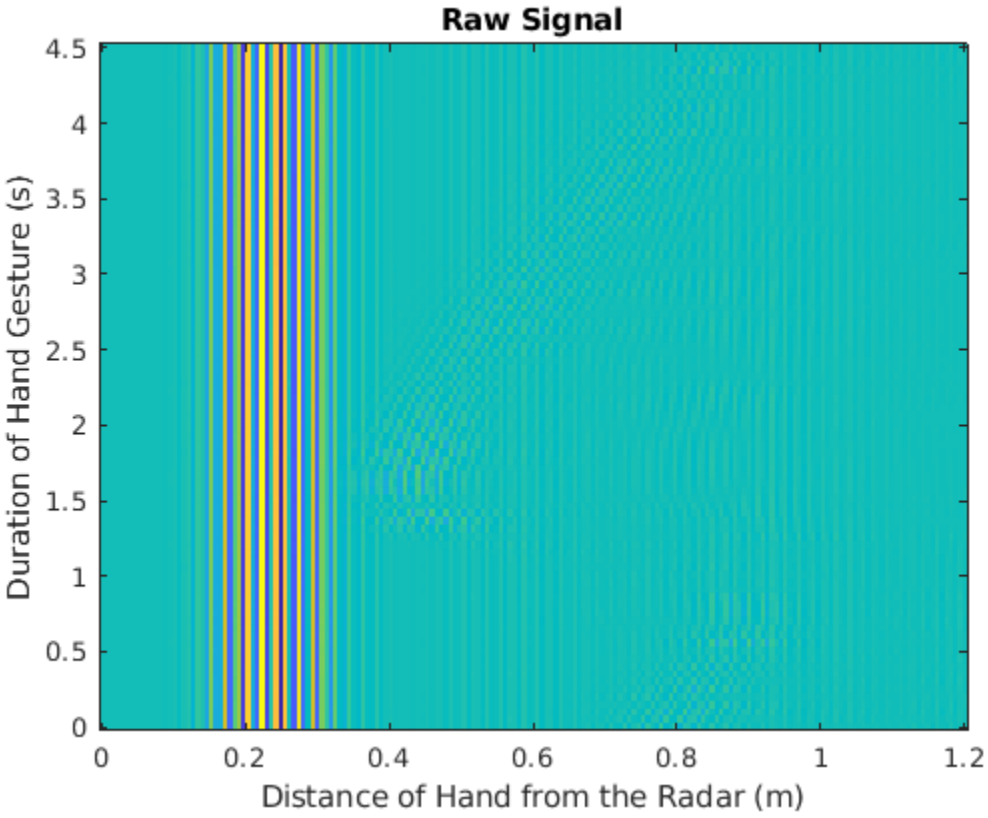
```
radarToPlot = left;
gestureToPlot = left-right swipe;
gestureSample = 50;
Visualize my choices
```

Obtain the radar signal matrix for the chosen hand gesture and radar location.

```
sdssubset = subset(sds,contains(sds.Files,gestureToPlot));
radarDataMatrix = read(sdssubset);
radarDataMatrix = radarDataMatrix{radarToPlot};
```

Use `normalize` to transform the gesture signal data to range between 0 and 1, and use `imagesc` to visualize the hand gesture motion sample.

```
normalizedRadarData = normalize(radarDataMatrix,2,"range",[0 1]);
imagesc([0 radarRange],...
        [0 recordedTimePerSample],...
        normalizedRadarData(slowTimeFrames*(gestureSample-1)+1:slowTimeFrames*gestureSample,:),.
        [0 1]);
set(gca,"YDir","normal")
title("Raw Signal")
xlabel("Distance of Hand from the Radar (m)")
ylabel("Duration of Hand Gesture (s)")
```



As you can see, it is difficult to discern a motion pattern.

The raw signal contains environmental reflections from body parts or other static objects present within the radar"s range. These unwanted reflections are known as "clutter" and can be removed using a pulse canceller that performs an exponential moving average. The transfer function for this operation is

$$H(z) = \frac{1 - z^{-1}}{1 - \alpha z^{-1}}$$

such that α is a value $0 \le \alpha \le 1$ that controls the amount of averaging [2 on page 12-0]. Use `filter` with the numerator coefficients and denominator coefficients set as [1 -1] and [1 -0.9], respectively, to remove clutter from the raw signal.

```
clutterRemovedSignal = filter([1 -1],[1 -0.9],radarDataMatrix,[],1);
```

Visualize the clutter-removed signal to see the difference.

```
normalizedClutterRemovedSignal = normalize(clutterRemovedSignal,2,"range",[0 1]);
imagesc([0 radarRange],...
        [0 recordedTimePerSample],...
        normalizedClutterRemovedSignal(slowTimeFrames*(gestureSample-1)+1:slowTimeFrames*gestureS
        [0 1]);
set(gca,"YDir","normal")
title("Clutter-Removed Signal")
xlabel("Distance of Hand from the Radar (m)")
ylabel("Duration of Hand Gesture (s)")
```

Note that the motion pattern is much more visible now. For example, if you choose to visualize a *left-right swipe* from the perspective of the left radar, you will see that the distance of the hand from the radar increases over the duration of the hand gesture.

Prepare Data for Training

The MAT-file names contain gesture codes (G1, G2,..., G12) corresponding to labels for each radar signal matrix. Convert these codes to labels within the gesture vocabulary, using a categorical array.

```
[~,filenames] = fileparts(sds.Files);
gestureLabels = extract(filenames,"G"+digitsPattern);
gestureCodes = ["G1","G2","G3","G4",...
                "G5","G6","G7","G8",...
                "G9","G10","G11","G12"];
gestureVocabulary = ["L-R swipe",       "R-L swipe",       "U-D swipe",       "D-U swipe",...
                     "Diag-LR-UD swipe","Diag-LR-DU swipe","Diag-RL-UD swipe","Diag-RL-DU swipe",
                     "clockwise",       "counterclockwise","inward push",     "empty"];
gestureLabels = categorical(gestureLabels,gestureCodes,gestureVocabulary);
```

Collect the labels in an array datastore.

```
labelDs = arrayDatastore(gestureLabels,"OutputType","cell");
```

Combine the signal datastore and array datastore to obtain a single datastore that contains the signal data from each radar and a categorical label. Shuffle the resulting datastore to randomize the order in which it stores the MAT-files.

```
allDataDs = combine(sds,labelDs);
allDataDs = shuffle(allDataDs);
preview(allDataDs)
```

```
ans=1×4 cell array
    {9000×189 double}    {9000×189 double}    {9000×189 double}    {[Diag-LR-UD swipe]}
```

The transform function allows the helper function, `processData`, to be applied to data as it is read by a datastore. `processData` performs the normalization and filtering that was described in the above section to standardize data and remove clutter. In addition, it divides the radar signal matrix into separate hand gesture motion samples.

```
allDataDs = transform(allDataDs,@processData);
preview(allDataDs)
```

```
ans=8×4 cell array
    {90×189 double}    {90×189 double}    {90×189 double}    {[Diag-LR-UD swipe]}
    {90×189 double}    {90×189 double}    {90×189 double}    {[Diag-LR-UD swipe]}
    {90×189 double}    {90×189 double}    {90×189 double}    {[Diag-LR-UD swipe]}
    {90×189 double}    {90×189 double}    {90×189 double}    {[Diag-LR-UD swipe]}
    {90×189 double}    {90×189 double}    {90×189 double}    {[Diag-LR-UD swipe]}
    {90×189 double}    {90×189 double}    {90×189 double}    {[Diag-LR-UD swipe]}
    {90×189 double}    {90×189 double}    {90×189 double}    {[Diag-LR-UD swipe]}
    {90×189 double}    {90×189 double}    {90×189 double}    {[Diag-LR-UD swipe]}
```

Neural network training is iterative. At every iteration, the datastore reads data from files and transforms the data before updating the network coefficients. Since the data is being read from individual samples, the data will need to be read into memory, before being re-shuffled and inserted into another datastore for training.

Because the entire training dataset fits in memory, it is possible to transform the data in parallel, if Parallel Computing Toolbox is available, and then gather it into the workspace. Use `readall` with the `UseParallel` flag set to true to utilize a parallel pool to read all of the signal data and labels into the workspace. If the data fits into the memory of your computer, importing the data into the workspace enables faster training because the data is read and transformed only once. Note that if the data does not fit in memory, you must to pass the datastore into the training function, and the transformations are performed at every training epoch.

```
allData = readall(allDataDs,"UseParallel",true);
```

```
Starting parallel pool (parpool) using the 'local' profile ...
Connected to the parallel pool (number of workers: 8).
```

The labels are returned as the last column in `allData`. Use `countlabels` to obtain proportions of label values in the dataset. Note that the gestures are balanced and well-represented across the dataset.

```
countlabels(allData(:,4))
```

```
ans=12×3 table
         Label          Count    Percent
    ________________    _____    _______

    D-U swipe            793     8.2664
    Diag-LR-DU swipe     800     8.3394
```

```
    Diag-LR-UD swipe     800     8.3394
    Diag-RL-DU swipe     800     8.3394
    Diag-RL-UD swipe     800     8.3394
    L-R swipe            800     8.3394
    R-L swipe            800     8.3394
    U-D swipe            800     8.3394
    clockwise            800     8.3394
    counterclockwise     800     8.3394
    empty                800     8.3394
    inward push          800     8.3394
```

Divide the data randomly into training and validation sets, while making sure to leave testing data for later. In this example, training, validation, and testing splits will be 70%, 15%, and 15%, respectively. Use `splitlabels` to split the data into training, validation, and testing sets that maintain the same label proportions as the original dataset. Specify the `randomized` option to shuffle the data randomly across the three sets.

```
idxs = splitlabels(allData(:,4),[0.7 0.15],"randomized");
trainIdx = idxs{1}; valIdx = idxs{2}; testIdx = idxs{3};
```

Avoid selecting samples from the same trial by randomizing the indices once more. Store the in-memory training and validation data in array datastores so that they can be used to train a multi-input network.

```
trainData = allData(trainIdx(randperm(length(trainIdx))),:);
valData = allData(valIdx(randperm(length(valIdx))),:);
trainDataDs = arrayDatastore(trainData,"OutputType","same");
valDataDs = arrayDatastore(valData,"OutputType","same");
```

Prepare Network for Training

Define the network architecture before training. Since each hand gesture motion is captured by 3 independent UWB impulse radars, we will use a CNN architecture that accepts 3 signals as separate inputs. The results achieved after training this proposed multiple-input, single-output CNN are considerably better than those achieved with an alternative single-input, single-output CNN whose input is a 90 x 189 x 3 stack of radar data matrices.

`repeatBranch` contains operations that will be performed separately on the three radar data signal matrices. The CNN model needs to combine the extracted feature information from each signal to make a final gesture label prediction. `mainBranch` contains operations that will concatenate the 3 `repeatBranch` outputs and estimate labels. Specify an `imageInputLayer` of size 90 x 189 to accept the hand gesture motion samples. Specify an `additionLayer` with number of inputs set to 3, to collect the outputs of the 3 branches and pass them into the classification section of the model. Specify a `fullyConnectedLayer` with an output size of 12, one for each of the hand gestures. Add a `softmaxLayer` and a `classificationLayer` to output the estimated labels.

```
repeatBranch = [
    imageInputLayer([90 189 1],"Normalization", "none")

    convolution2dLayer(3,8,"Padding",1)
    batchNormalizationLayer
    reluLayer
    maxPooling2dLayer(2,"Stride",2)

    convolution2dLayer(3,16,"Padding",1)
    batchNormalizationLayer
```

```
    reluLayer
    maxPooling2dLayer(2,"Stride",2)

    convolution2dLayer(3,32,"Padding",1)
    batchNormalizationLayer
    reluLayer
    maxPooling2dLayer(2,"Stride",2)

    convolution2dLayer(3,64,"Padding",1)
    batchNormalizationLayer
    reluLayer
    maxPooling2dLayer(2,"Stride",2)];

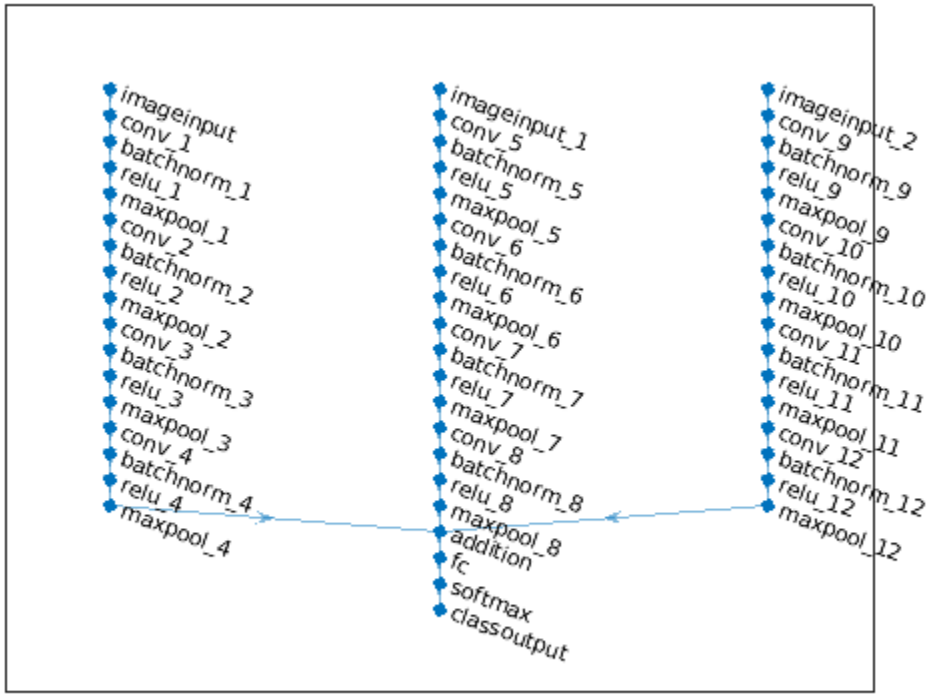
mainBranch = [
    additionLayer(3)
    fullyConnectedLayer(12)
    softmaxLayer
    classificationLayer];
```

Define a `layerGraph` to which `repeatBranch` is added 3 times and `mainBranch` is added once. Connect the outputs of the final `maxPooling2dLayer` in each `repeatBranch` to the inputs of `additionLayer`.

```
misoCNN = layerGraph();
misoCNN = addLayers(misoCNN, repeatBranch);
misoCNN = addLayers(misoCNN, repeatBranch);
misoCNN = addLayers(misoCNN, repeatBranch);
misoCNN = addLayers(misoCNN, mainBranch);
misoCNN = connectLayers(misoCNN, "maxpool_4", "addition/in1");
misoCNN = connectLayers(misoCNN, "maxpool_8", "addition/in2");
misoCNN = connectLayers(misoCNN, "maxpool_12", "addition/in3");
```

Visualize the multiple-input, single-output CNN.

```
plot(misoCNN);
```



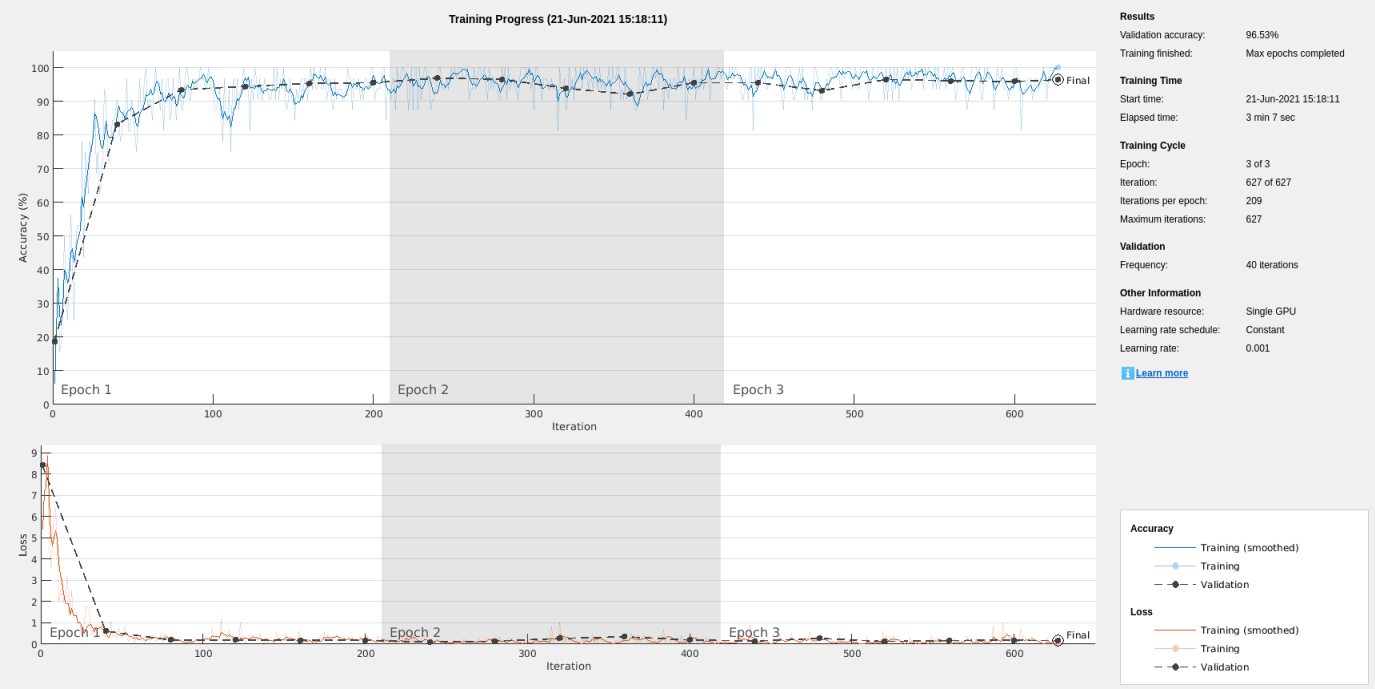
Choose options for the training process that ensure good network performance. Make sure to specify `valDataDs` as `ValidationData`, so that it is used for validation during training. Refer to the `trainingOptions` (Deep Learning Toolbox) documentation for a description of each parameter.

```
options = trainingOptions("adam", ...
    "InitialLearnRate",1e-3, ...
    "MaxEpochs",3,...
    "MiniBatchSize",32, ...
    "ValidationData",valDataDs,...
    "ValidationFrequency",40,...
    "Verbose",false,...
    "Plots","training-progress");
```

Train Network

Use the `trainNetwork` command to train the CNN.

```
if doTraining == true
    misoNet = trainNetwork(trainDataDs,misoCNN,options);
else
    pretrainedNetworkZipFolder = matlab.internal.examples.downloadSupportFile("SPT","data/uwb-ges
    pretrainedNetworkFolder = erase(pretrainedNetworkZipFolder,".zip");
    if ~exist(pretrainedNetworkFolder,"dir")
        downloadLocation = fileparts(pretrainedNetworkZipFolder);
        unzip(pretrainedNetworkZipFolder,downloadLocation);
    end
    load(fullfile(pretrainedNetworkFolder,"pretrainedNetwork.mat"),"misoNet");
end
```



Classify Testing Data

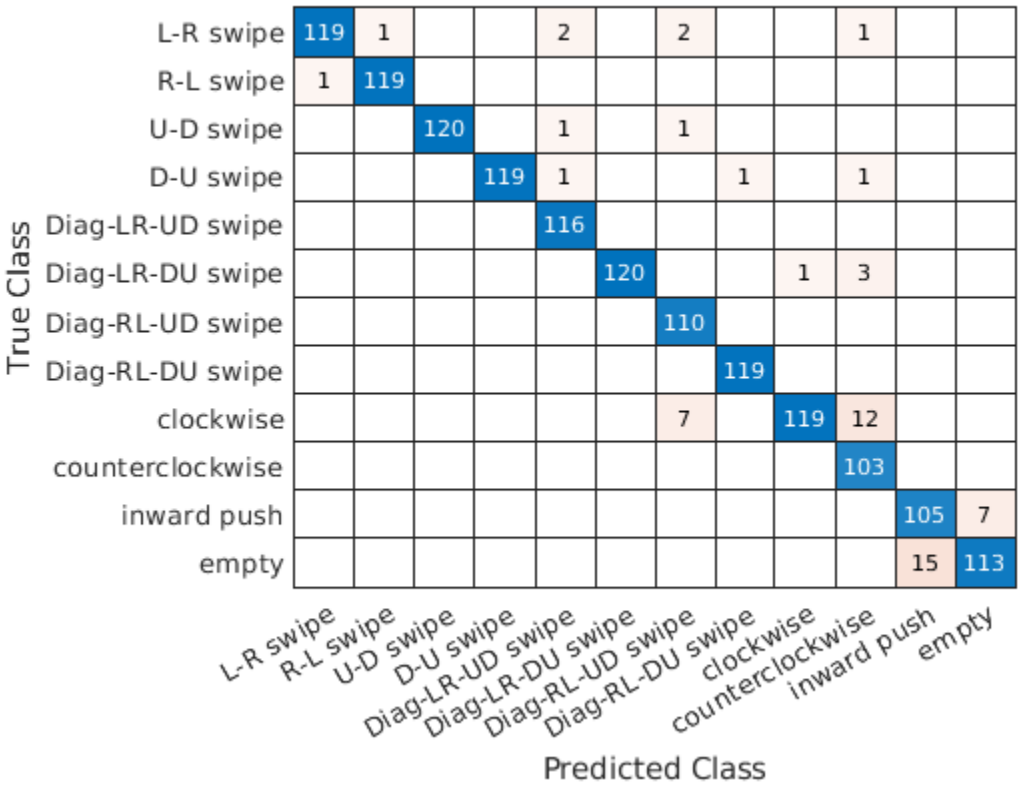
Classify the testing data using the trained CNN and the `classify` command.

```
testData = allData(testIdx,:);
testData = {cat(4,testData{:,1}),cat(4,testData{:,2}),cat(4,testData{:,3}),cat(1,testData{:,4})};
actualLabels = testData{4};
predictedLabels = classify(misoNet,testData{1},testData{2},testData{3});
accuracy = mean(predictedLabels==actualLabels);
fprintf("Accuracy on the test set is %0.2f%%",100*accuracy)
```

```
Accuracy on the test set is 96.04%
```

Visualize classification performance using a confusion matrix.

```
confusionchart(predictedLabels,actualLabels);
```



The largest confusion is between *counterclockwise* and *clockwise* movements and *inward push* and *empty* movements.

Explore Network Predictions

You can obtain the scores from the final max-pooling layers in each input branch to get a better understanding of how data from each radar contributed to final network confidence. The helper function, `getActivationData`, returns softmax-normalized scores (probabilities for class membership) and indices corresponding to the 3 highest scores.

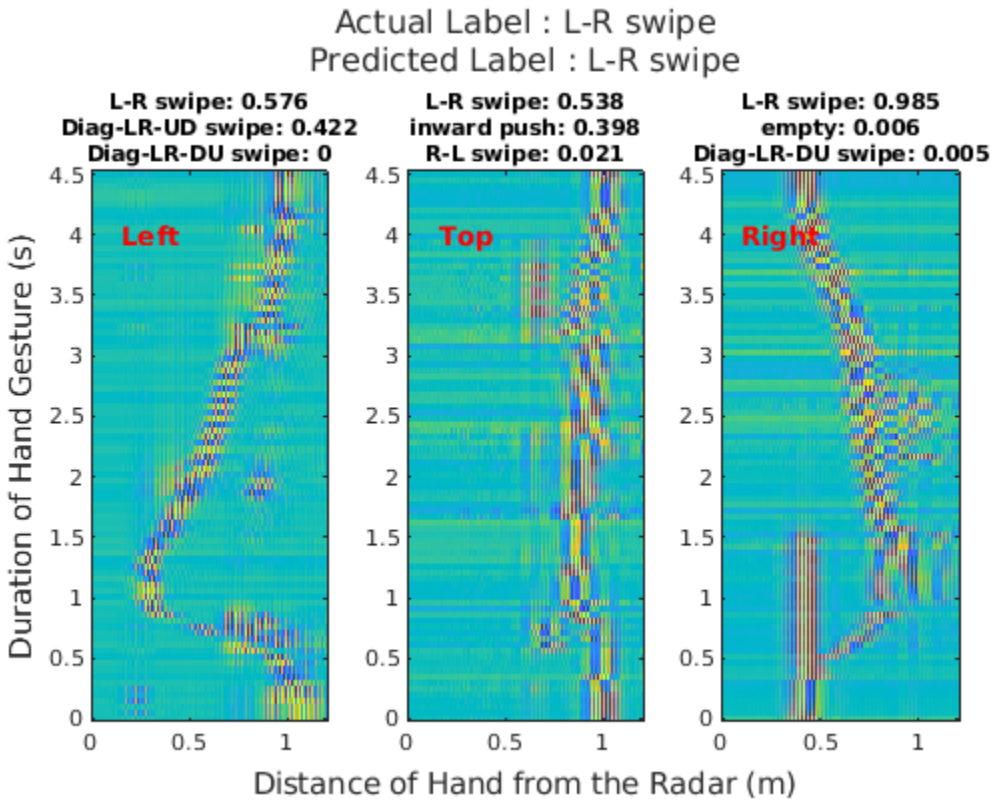
```
gestureToPlot = left-right swipe;
gestureToPlotIndices = find(matches(string(actualLabels),gestureToPlot));
gestureSelection = randsample(gestureToPlotIndices,1);
actualLabel = actualLabels(gestureSelection);
predictedLabel = predictedLabels(gestureSelection);
allLabels = categories(actualLabels);

[leftScores, leftClassIds] = getActivationData(misoNet,testData,gestureSelection,"maxpool_4");
[topScores, topClassIds] = getActivationData(misoNet,testData,gestureSelection,"maxpool_8");
[rightScores, rightClassIds] = getActivationData(misoNet,testData,gestureSelection,"maxpool_12")
```

Use the helper function `plotActivationData` to visualize the data from each radar and overlay the labels corresponding to the 3 highest scores after the operations in each input branch are completed.

```
t = tiledlayout(1,3);
plotActivationData(testData, allLabels, leftScores, leftClassIds,...
```

```
    gestureSelection, [0 radarRange],[0 recordedTimePerSample], "Left");
plotActivationData(testData, allLabels, topScores, topClassIds,...
    gestureSelection, [0 radarRange],[0 recordedTimePerSample], "Top");
plotActivationData(testData, allLabels, rightScores, rightClassIds,...
    gestureSelection, [0 radarRange],[0 recordedTimePerSample], "Right");
title(t,["Actual Label : "+string(actualLabel);"Predicted Label : "+string(predictedLabel)],"Fon
xlabel(t,"Distance of Hand from the Radar (m)","FontSize",11)
ylabel(t,"Duration of Hand Gesture (s)","FontSize",11)
```



Conclusion

In this example, you learned how to use a multiple-input CNN to extract information from 3 independent radar data matrices and classify hand gesture movements. The multiple-input architecture allowed us to take advantage of data generated by multiple sensors recording the same event.

Helper Functions

```
function dataOut = processData(dataIn)
    label = dataIn(end);
    dataIn(end) = [];
    dataOut = cellfun(@(x) filter([1 -1],[1 -0.9],x,[],1),dataIn,"UniformOutput",false);
    dataOut = cellfun(@(x) normalize(x,2,"range",[0 1]),dataOut,"UniformOutput",false);
    dataOut = cat(1,dataOut{:});
    dataOut = mat2cell(dataOut,90*ones(1,size(dataOut,1)/90));
    dataOut = reshape(dataOut,[],3);
    dataOut(:,4) = label;
end
```

```
function [scores, classIds] = getActivationData(net, testData, index, layer)
    activation = activations(net,testData{1}(:,:,index),testData{2}(:,:,index),testData{3}(:,:,in
    fcWeights = net.Layers(end-2).Weights;
    fcBias = net.Layers(end-2).Bias;
    scores = fcWeights*activation + fcBias;
    scores = exp(scores)/sum(exp(scores));
    [~,classIds] = maxk(scores,3);
end

function plotActivationData(testData, labels, scores, ids, sampleIdx, xlimits, ylimits, plotTitle
    if plotTitle == "Left"
        gesture = 1;
    elseif plotTitle == "Top"
        gesture = 2;
    elseif plotTitle == "Right"
        gesture = 3;
    end
    nexttile;
    imagesc(xlimits,ylimits,testData{gesture}(:,:,sampleIdx),[0 1])
    text(0.3,4,plotTitle,"Color","red","FontWeight","bold","HorizontalAlignment","center")
    set(gca,"YDir","normal")
    title(string(labels(ids)) + ": " + string(round(scores(ids),3)),"FontSize",8);
end
```

Waveform Segmentation Using Deep Learning

This example shows how to segment human electrocardiogram (ECG) signals using recurrent deep learning networks and time-frequency analysis.

Introduction

The electrical activity in the human heart can be measured as a sequence of amplitudes away from a baseline signal. For a single normal heartbeat cycle, the ECG signal can be divided into the following beat morphologies [1 on page 12-0]:

- P wave — A small deflection before the QRS complex representing atrial depolarization
- QRS complex — Largest-amplitude portion of the heartbeat
- T wave — A small deflection after the QRS complex representing ventricular repolarization

The segmentation of these regions of ECG waveforms can provide the basis for measurements useful for assessing the overall health of the human heart and the presence of abnormalities [2 on page 12-0]. Manually annotating each region of the ECG signal can be a tedious and time-consuming task. Signal processing and deep learning methods potentially can help streamline and automate region-of-interest annotation.

This example uses ECG signals from the publicly available QT Database [3 on page 12-0] [4 on page 12-0]. The data consists of roughly 15 minutes of ECG recordings, with a sample rate of 250 Hz, measured from a total of 105 patients. To obtain each recording, the examiners placed two electrodes on different locations on a patient's chest, resulting in a two-channel signal. The database provides signal region labels generated by an automated expert system [2 on page 12-0]. This example aims to use a deep learning solution to provide a label for every ECG signal sample according to the region where the sample is located. This process of labeling regions of interest across a signal is often referred to as *waveform segmentation*.

To train a deep neural network to classify signal regions, you can use a Long Short-Term Memory (LSTM) network. This example shows how signal preprocessing techniques and time-frequency analysis can be used to improve LSTM segmentation performance. In particular, the example uses the Fourier synchrosqueezed transform to represent the nonstationary behavior of the ECG signal.

Download and Prepare the Data

Each channel of the 105 two-channel ECG signals was labeled independently by the automated expert system and is treated independently, for a total of 210 ECG signals that were stored together with the region labels in 210 MAT-files. The files are available at the following location: https://www.mathworks.com/supportfiles/SPT/data/QTDatabaseECGData.zip.

Download the data files into your temporary directory, whose location is specified by MATLAB®'s `tempdir` command. If you want to place the data files in a folder different from `tempdir`, change the directory name in the subsequent instructions.

```
% Download the data
dataURL = 'https://www.mathworks.com/supportfiles/SPT/data/QTDatabaseECGData1.zip';
datasetFolder = fullfile(tempdir,'QTDataset');
zipFile = fullfile(tempdir,'QTDatabaseECGData.zip');
if ~exist(datasetFolder,'dir')
     websave(zipFile,dataURL);
     unzip(zipFile,tempdir);
end
```

The `unzip` operation creates the `QTDatabaseECGData` folder in your temporary directory with 210 MAT-files in it. Each file contains an ECG signal in variable `ecgSignal` and a table of region labels in variable `signalRegionLabels`. Each file also contains the sample rate of the signal in variable `Fs`. In this example all signals have a sample rate of 250 Hz.

Create a signal datastore to access the data in the files. This example assumes the dataset has been stored in your temporary directory under the `QTDatabaseECGData` folder. If this is not the case, change the path to the data in the code below. Specify the signal variable names you want to read from each file using the `SignalVariableNames` parameter.

```
sds = signalDatastore(datasetFolder,'SignalVariableNames',["ecgSignal","signalRegionLabels"])
```

```
sds =
  signalDatastore with properties:

                      Files:{
                             '/tmp/QTDataset/ecg1.mat';
                             '/tmp/QTDataset/ecg10.mat';
                             '/tmp/QTDataset/ecg100.mat'
                              ... and 207 more
                             }
    AlternateFileSystemRoots: [0×0 string]
                    ReadSize: 1
         SignalVariableNames: ["ecgSignal"    "signalRegionLabels"]
```

The datastore returns a two-element cell array with an ECG signal and a table of region labels each time you call the `read` function. Use the `preview` function of the datastore to see that the content of the first file is a 225,000 samples long ECG signal and a table containing 3385 region labels.

```
data = preview(sds)
```

```
data=2×1 cell array
    {225000×1 double}
    {  3385×2 table }
```

Look at the first few rows of the region labels table and observe that each row contains the region limit indices and the region class value (P, T, or QRS).

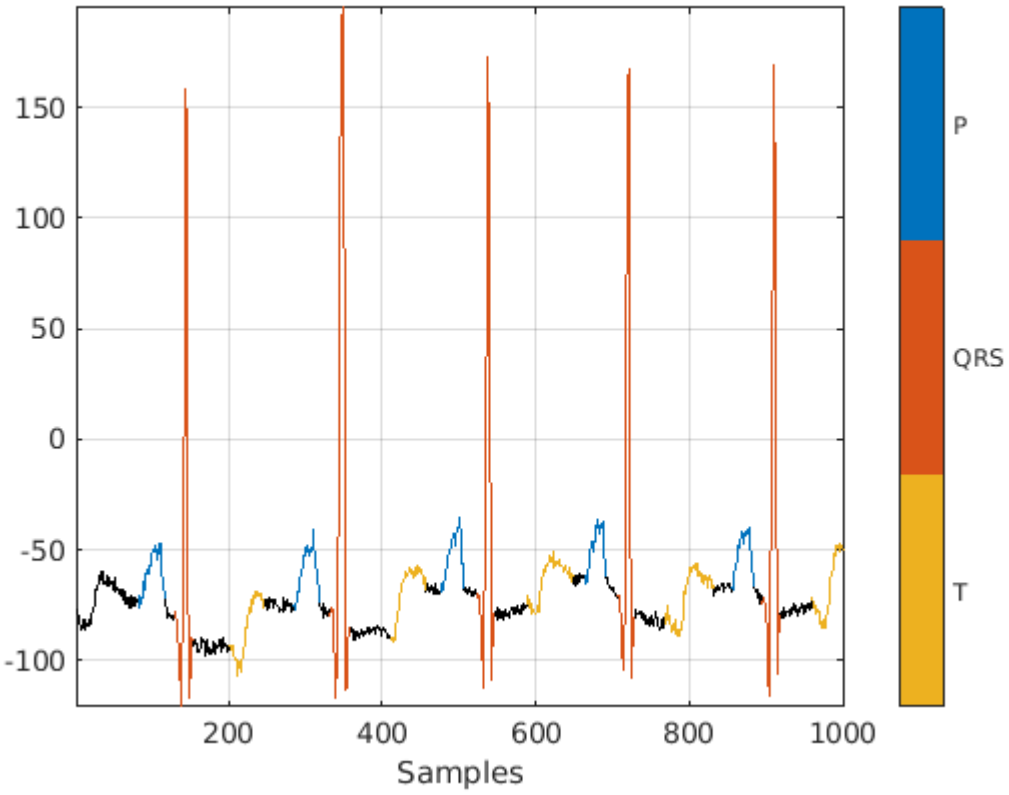
```
head(data{2})
```

```
ans=8×2 table
    ROILimits     Value
    _________    _____

     83    117     P
    130    153     QRS
    201    246     T
    285    319     P
    332    357     QRS
    412    457     T
    477    507     P
    524    547     QRS
```

Visualize the labels for the first 1000 samples using a `signalMask` object.

```
M = signalMask(data{2});
plotsigroi(M,data{1}(1:1000))
```



The usual machine learning classification procedure is the following:

1. Divide the database into training and testing datasets.
2. Train the network using the training dataset.
3. Use the trained network to make predictions on the testing dataset.

The network is trained with 70% of the data and tested with the remaining 30%.

For reproducible results, reset the random number generator. Use the `dividerand` function to get random indices to shuffle the files, and the `subset` function of `signalDatastore` to divide the data into training and testing datastores.

```
rng default
[trainIdx,~,testIdx] = dividerand(numel(sds.Files),0.7,0,0.3);
trainDs = subset(sds,trainIdx);
testDs = subset(sds,testIdx);
```

In this segmentation problem, the input to the LSTM network is an ECG signal and the output is a sequence or mask of labels with the same length as the input signal. The network task is to label each signal sample with the name of the region it belongs to. For this reason, it is necessary to transform the region labels on the dataset to sequences containing one label per signal sample. Use a transformed datastore and the `getmask` helper function to transform the region labels. The `getmask` function adds a label category, `"n/a"`, to label samples that do not belong to any region of interest.

```
type getmask.m
```

```
function outputCell = getmask(inputCell)
%GETMASK Convert region labels to a mask of labels of size equal to the
%size of the input ECG signal.
%
%   inputCell is a two-element cell array containing an ECG signal vector
%   and a table of region labels.
%
%   outputCell is a two-element cell array containing the ECG signal vector
%   and a categorical label vector mask of the same length as the signal.

% Copyright 2020 The MathWorks, Inc.

sig = inputCell{1};
roiTable = inputCell{2};
L = length(sig);
M = signalMask(roiTable);

% Get categorical mask and give priority to QRS regions when there is overlap
mask = catmask(M,L,'OverlapAction','prioritizeByList','PriorityList',[2 1 3]);

% Set missing values to "n/a"
mask(ismissing(mask)) = "n/a";

outputCell = {sig,mask};
end
```

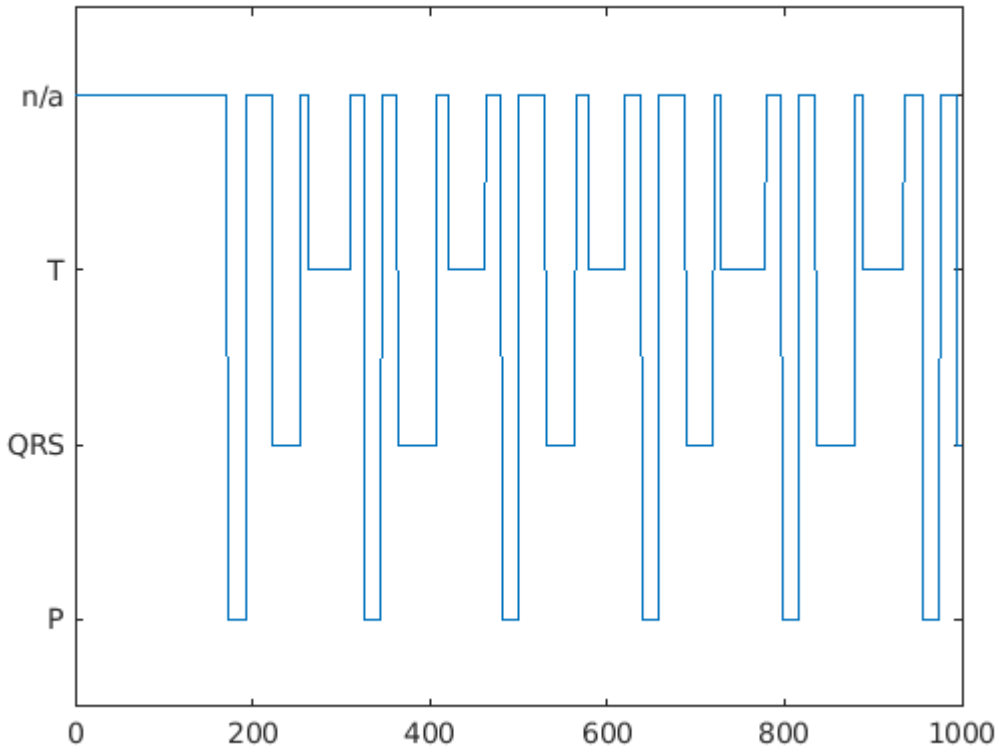
Preview the transformed datastore to observe that it returns a signal vector and a label vector of equal lengths. Plot the first 1000 element of the categorical mask vector.

```
trainDs = transform(trainDs, @getmask);
testDs = transform(testDs, @getmask);

transformedData = preview(trainDs)
```

```
transformedData=1×2 cell array
    {224993×1 double}    {224993×1 categorical}
```

```
plot(transformedData{2}(1:1000))
```



Passing very long input signals into the LSTM network can result in estimation performance degradation and excessive memory usage. To avoid these effects, break the ECG signals and their corresponding label masks using a transformed datastore and the `resizeData` helper function. The helper function creates as many 5000-sample segments as possible and discards the remaining samples. A preview of the output of the transformed datastore shows that the first ECG signal and its label mask are broken into 5000-sample segments. Note that preview of the transformed datastore only shows the first 8 elements of the otherwise `floor(224993/5000)` = 44 element cell array that would result if we called the datastore `read` function.

```
trainDs = transform(trainDs,@resizeData);
testDs = transform(testDs,@resizeData);
preview(trainDs)
```

```
ans=8×2 cell array
    {1×5000 double}    {1×5000 categorical}
    {1×5000 double}    {1×5000 categorical}
    {1×5000 double}    {1×5000 categorical}
    {1×5000 double}    {1×5000 categorical}
    {1×5000 double}    {1×5000 categorical}
    {1×5000 double}    {1×5000 categorical}
    {1×5000 double}    {1×5000 categorical}
    {1×5000 double}    {1×5000 categorical}
```

Choose to Train Networks or Download Pre-Trained Networks

The next sections of this example compare three different approaches to train LSTM networks. Due to the large size of the dataset, the training process of each network may take several minutes. If your machine has a GPU and Parallel Computing Toolbox™, then MATLAB automatically uses the GPU for faster training. Otherwise, it uses the CPU.

You can skip the training steps and download the pre-trained networks using the selector below. If you want to train the networks as the example runs, select 'Train Networks'. If you want to skip the training steps, select 'Download Networks' and a file containing all three pre-trained networks - `rawNet`, `filteredNet`, and `fsstNet-` will be downloaded into your temporary directory, whose location is specified by MATLAB®'s `tempdir` command. If you want to place the downloaded file in a folder different from `tempdir`, change the directory name in the subsequent instructions.

```
actionFlag = Train networks;
if actionFlag == "Download networks"
    % Download the pre-trained networks
    dataURL = 'https://ssd.mathworks.com/supportfiles/SPT/data/QTDatabaseECGSegmentationNetworks
    modelsFolder = fullfile(tempdir,'QTDatabaseECGSegmentationNetworks');
    modelsFile = fullfile(modelsFolder,'trainedNetworks.mat');
    zipFile = fullfile(tempdir,'QTDatabaseECGSegmentationNetworks.zip');
    if ~exist(modelsFolder,'dir')
        websave(zipFile,dataURL);
        unzip(zipFile,fullfile(tempdir,'QTDatabaseECGSegmentationNetworks'));
    end
    load(modelsFile)
end
```

Results between the downloaded networks and newly trained networks may vary slightly since the networks are trained using random initial weights.

Input Raw ECG Signals Directly into the LSTM Network

First, train an LSTM network using the raw ECG signals from the training dataset.

Define the network architecture before training. Specify a `sequenceInputLayer` of size 1 to accept one-dimensional time series. Specify an LSTM layer with the `'sequence'` output mode to provide classification for each sample in the signal. Use 200 hidden nodes for optimal performance. Specify a `fullyConnectedLayer` with an output size of 4, one for each of the waveform classes. Add a `softmaxLayer` and a `classificationLayer` to output the estimated labels.

```
layers = [ ...
    sequenceInputLayer(1)
    lstmLayer(200,'OutputMode','sequence')
    fullyConnectedLayer(4)
    softmaxLayer
    classificationLayer];
```

Choose options for the training process that ensure good network performance. Refer to the `trainingOptions` documentation for a description of each parameter.

```
options = trainingOptions('adam', ...
    'MaxEpochs',10, ...
    'MiniBatchSize',50, ...
    'InitialLearnRate',0.01, ...
    'LearnRateDropPeriod',3, ...
```

```
    'LearnRateSchedule','piecewise', ...
    'GradientThreshold',1, ...
    'Plots','training-progress',...
    'shuffle','every-epoch',...
    'Verbose',0,...
    'DispatchInBackground',true);
```

Because the entire training dataset fits in memory, it is possible to use the `tall` function of the datastore to transform the data in parallel, if Parallel Computing Toolbox™ is available, and then gather it into the workspace. Neural network training is iterative. At every iteration, the datastore reads data from files and transforms the data before updating the network coefficients. If the data fits into the memory of your computer, importing the data into the workspace enables faster training because the data is read and transformed only once. Note that if the data does not fit in memory, you must to pass the datastore into the training function, and the transformations are performed at every training epoch.

Create tall arrays for both the training and test sets. Depending on your system, the number of workers in the parallel pool that MATLAB creates may be different.

```
tallTrainSet = tall(trainDs);
```

```
Starting parallel pool (parpool) using the 'local' profile ...
Connected to the parallel pool (number of workers: 8).
```

```
tallTestSet = tall(testDs);
```

Now call the `gather` function of the tall arrays to compute the transformations over the entire dataset and obtain cell arrays with the training and test signals and labels.

```
 trainData = gather(tallTrainSet);
```

```
Evaluating tall expression using the Parallel Pool 'local':
- Pass 1 of 1: Completed in 11 sec
Evaluation completed in 12 sec
```

```
 trainData(1,:)
```

```
ans=1×2 cell array
    {1×5000 double}    {1×5000 categorical}
```

```
 testData = gather(tallTestSet);
```

```
Evaluating tall expression using the Parallel Pool 'local':
- Pass 1 of 1: Completed in 2.9 sec
Evaluation completed in 3.1 sec
```

Train Network

Use the `trainNetwork` command to train the LSTM network.

```
if actionFlag == "Train networks"
     rawNet = trainNetwork(trainData(:,1),trainData(:,2),layers,options);
end
```

The training accuracy and loss subplots in the figure track the training progress across all iterations. Using the raw signal data, the network correctly classifies about 77% of the samples as belonging to a P wave, a QRS complex, a T wave, or an unlabeled region `"n/a"`.

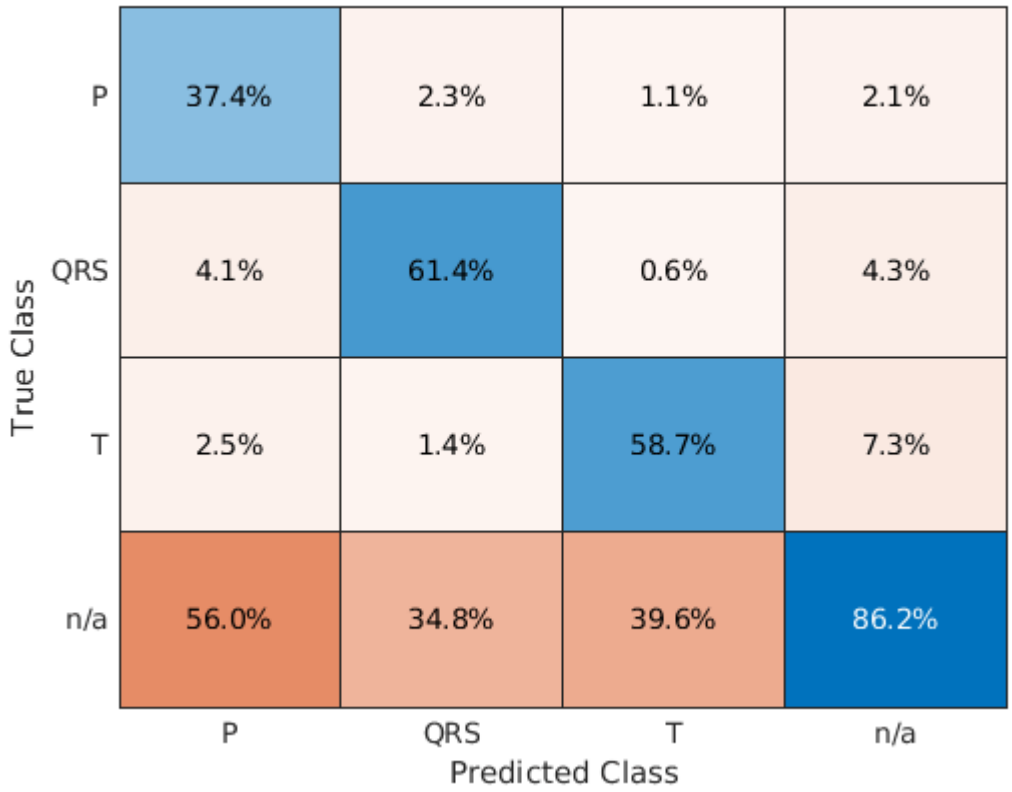
Classify Testing Data

Classify the testing data using the trained LSTM network and the `classify` command. Specify a mini-batch size of 50 to match the training options.

```
predTest = classify(rawNet,testData(:,1),'MiniBatchSize',50);
```

A confusion matrix provides an intuitive and informative means to visualize classification performance. Use the `confusionchart` command to calculate the overall classification accuracy for the testing data predictions. For each input, convert the cell array of categorical labels to a row vector. Specify a column-normalized display to view results as percentages of samples for each class.

```
confusionchart([predTest{:}],[testData{:,2}],'Normalization','column-normalized');
```



Using the raw ECG signal as input to the network, only about 60% of T-wave samples, 40% of P-wave samples, and 60% of QRS-complex samples were correct. To improve performance, apply some knowledge of the ECG signal characteristics prior to input to the deep learning network, for instance the baseline wandering caused by a patient's respiratory motion.

Apply Filtering Methods to Remove Baseline Wander and High-Frequency Noise

The three beat morphologies occupy different frequency bands. The spectrum of the QRS complex typically has a center frequency around 10–25 Hz, and its components lie below 40 Hz. The P and T waves occur at even lower frequencies: P-wave components are below 20 Hz, and T-wave components are below 10 Hz [5 on page 12-0].

Baseline wander is a low-frequency (< 0.5 Hz) oscillation caused by the patient's breathing motion. This oscillation is independent from the beat morphologies and does not provide meaningful information [6 on page 12-0].

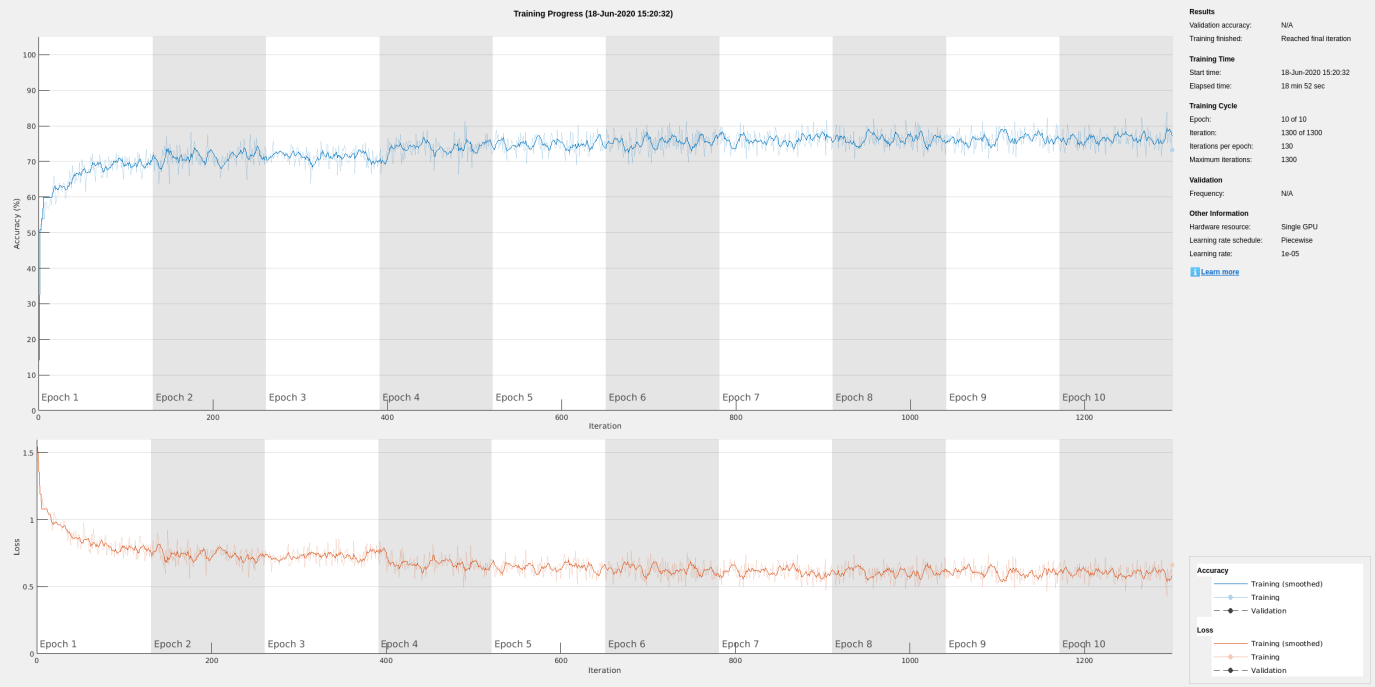
Design a bandpass filter with passband frequency range of [0.5, 40] Hz to remove the wander and any high frequency noise. Removing these components improves the LSTM training because the network does not learn irrelevant features. Use `cellfun` on the tall data cell arrays to filter the dataset in parallel.

```
% Bandpass filter design
hFilt = designfilt('bandpassiir', 'StopbandFrequency1',0.4215,'PassbandFrequency1', 0.5, ...
    'PassbandFrequency2',40,'StopbandFrequency2',53.345,...
    'StopbandAttenuation1',60,'PassbandRipple',0.1,'StopbandAttenuation2',60,...
    'SampleRate',250,'DesignMethod','ellip');
```

```
% Create tall arrays from the transformed datastores and filter the signals
tallTrainSet = tall(trainDs);
tallTestSet = tall(testDs);

filteredTrainSignals = gather(cellfun(@(x)filter(hFilt,x),tallTrainSet(:,1),'UniformOutput',false

Evaluating tall expression using the Parallel Pool 'local':
- Pass 1 of 1: 0% complete
Evaluation 0% complete
```



```
- Pass 1 of 1: Completed in 13 sec
Evaluation completed in 14 sec

trainLabels = gather(tallTrainSet(:,2));

Evaluating tall expression using the Parallel Pool 'local':
- Pass 1 of 1: Completed in 3.6 sec
Evaluation completed in 4 sec

filteredTestSignals = gather(cellfun(@(x)filter(hFilt,x),tallTestSet(:,1),'UniformOutput',false)

Evaluating tall expression using the Parallel Pool 'local':
- Pass 1 of 1: Completed in 2.4 sec
Evaluation completed in 2.5 sec

testLabels = gather(tallTestSet(:,2));

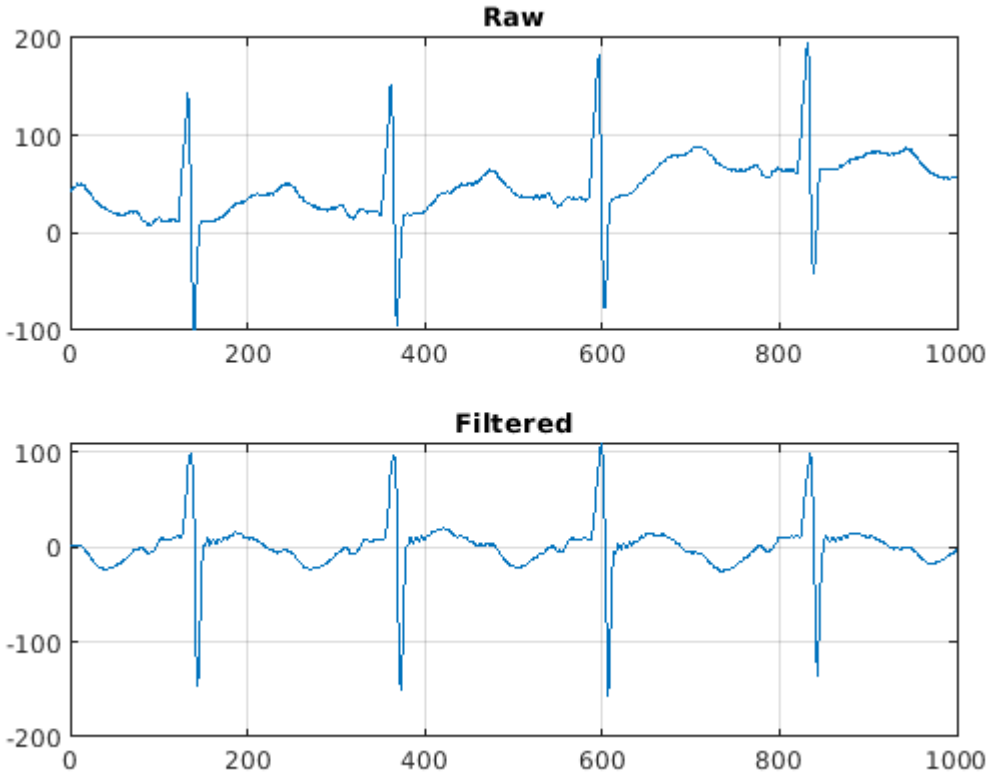
Evaluating tall expression using the Parallel Pool 'local':
- Pass 1 of 1: Completed in 1.9 sec
Evaluation completed in 2 sec
```

Plot the raw and filtered signals for a typical case.

```
trainData = gather(tallTrainSet);
```

```
Evaluating tall expression using the Parallel Pool 'local':
- Pass 1 of 1: Completed in 4 sec
Evaluation completed in 4.2 sec
```

```
figure
subplot(2,1,1)
plot(trainData{95,1}(2001:3000))
title('Raw')
grid
subplot(2,1,2)
plot(filteredTrainSignals{95}(2001:3000))
title('Filtered')
grid
```

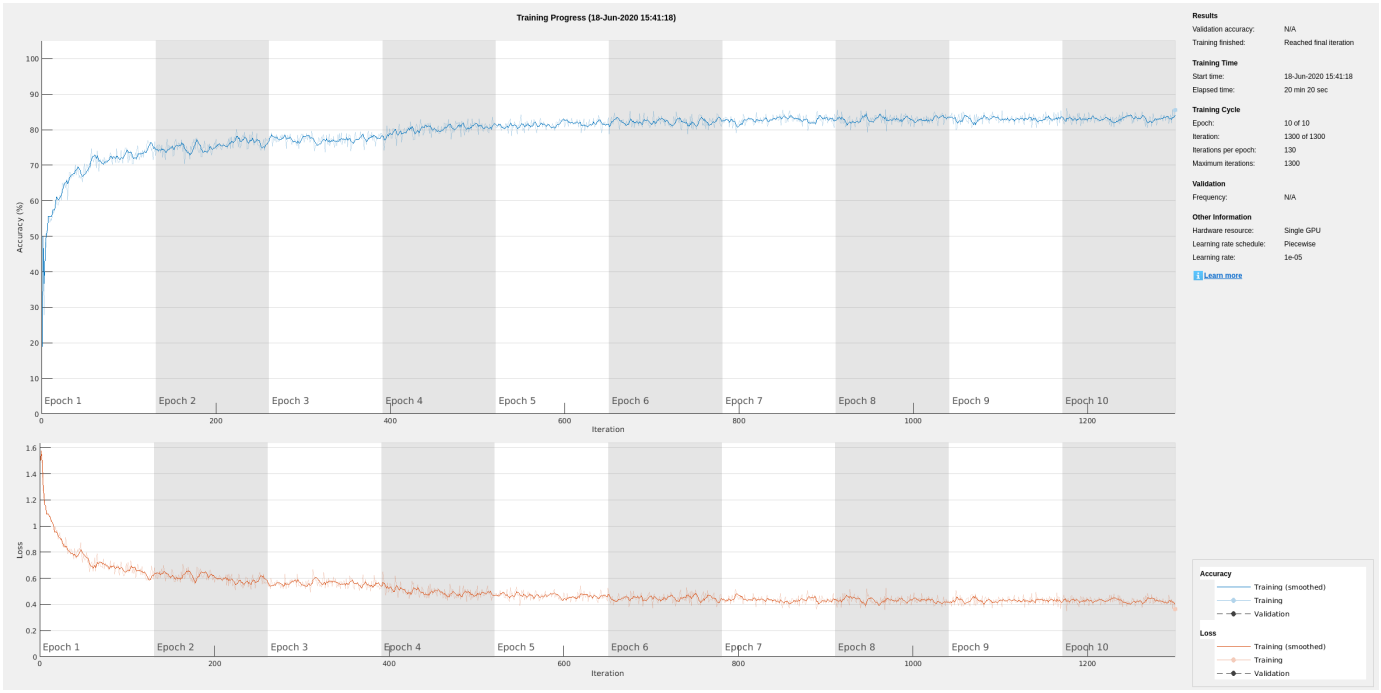


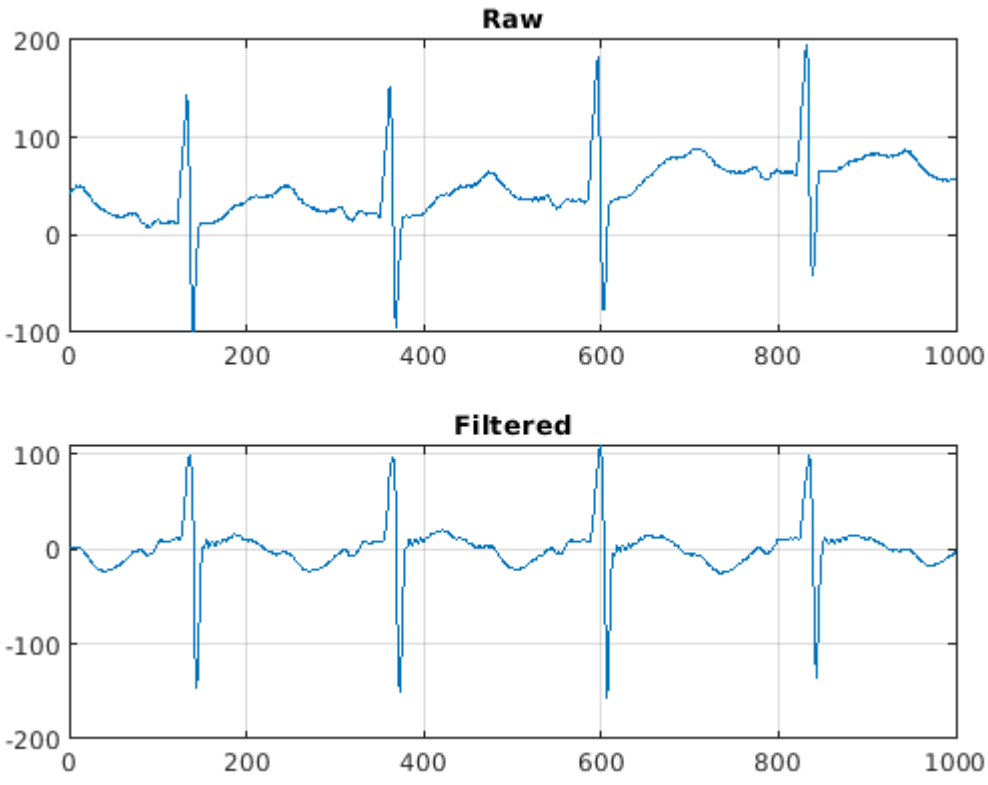
Even though the baseline of the filtered signals may confuse a physician that is used to traditional ECG measurements on medical devices, the network will actually benefit from the wandering removal.

Train Network with Filtered ECG Signals

Train the LSTM network on the filtered ECG signals using the same network architecture as before.

```
if actionFlag == "Train networks"
    filteredNet = trainNetwork(filteredTrainSignals,trainLabels,layers,options);
end
```





Preprocessing the signals improves the training accuracy to better than 80%.

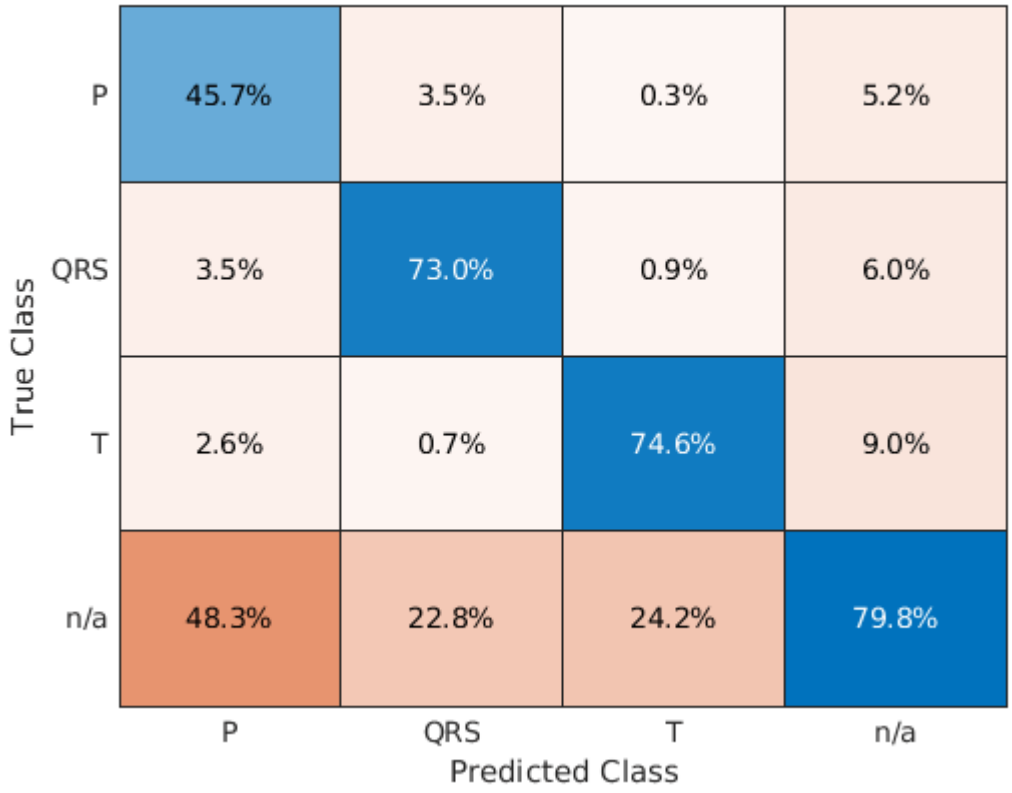
Classify Filtered ECG Signals

Classify the preprocessed test data with the updated LSTM network.

```
predFilteredTest = classify(filteredNet,filteredTestSignals,'MiniBatchSize',50);
```

Visualize the classification performance as a confusion matrix.

```
figure
confusionchart([predFilteredTest{:}],[testLabels{:}],'Normalization','column-normalized');
```



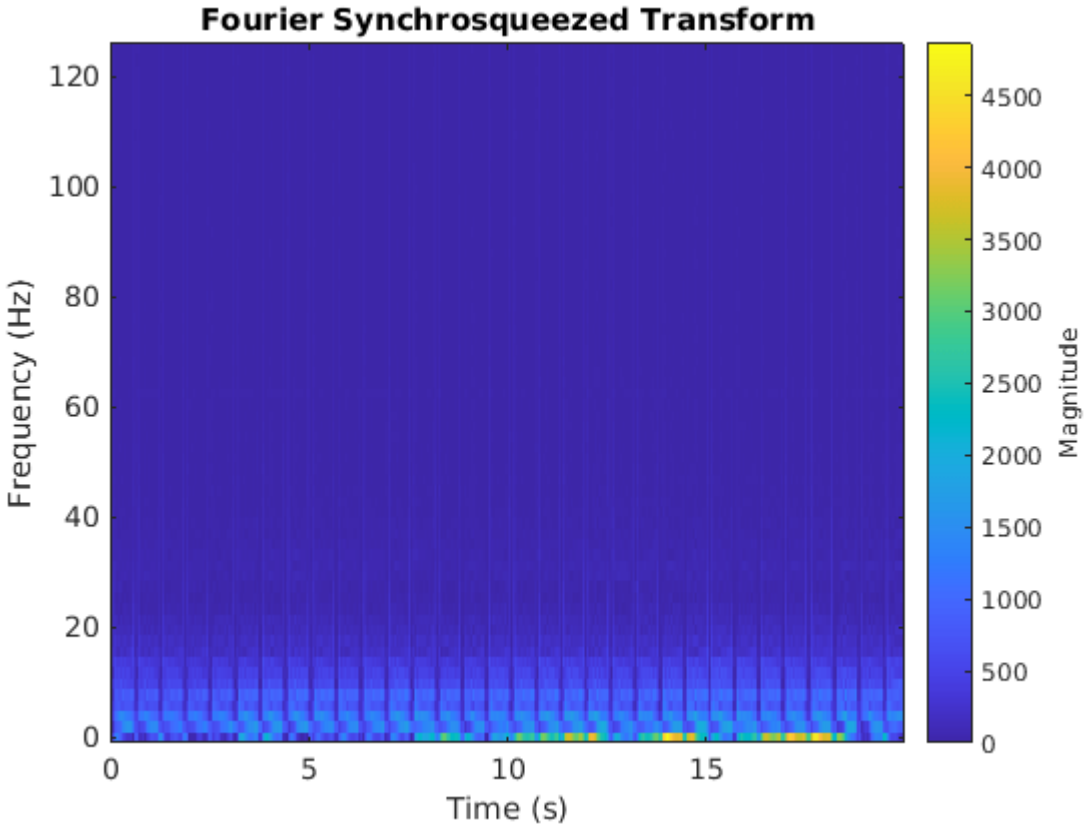
Simple preprocessing improves T-wave classification by about 15%, and QRS-complex and P-wave classification by about 10%.

Time-Frequency Representation of ECG Signals

A common approach for successful classification of time-series data is to extract time-frequency features and feed them to the network instead of the original data. The network then learns patterns across time and frequency simultaneously [7 on page 12-0].

The Fourier synchrosqueezed transform (FSST) computes a frequency spectrum for each signal sample so it is ideal for the segmentation problem at hand where we need to maintain the same time resolution as the original signals. Use the `fsst` function to inspect the transform of one of the training signals. Specify a Kaiser window of length 128 to provide adequate frequency resolution.

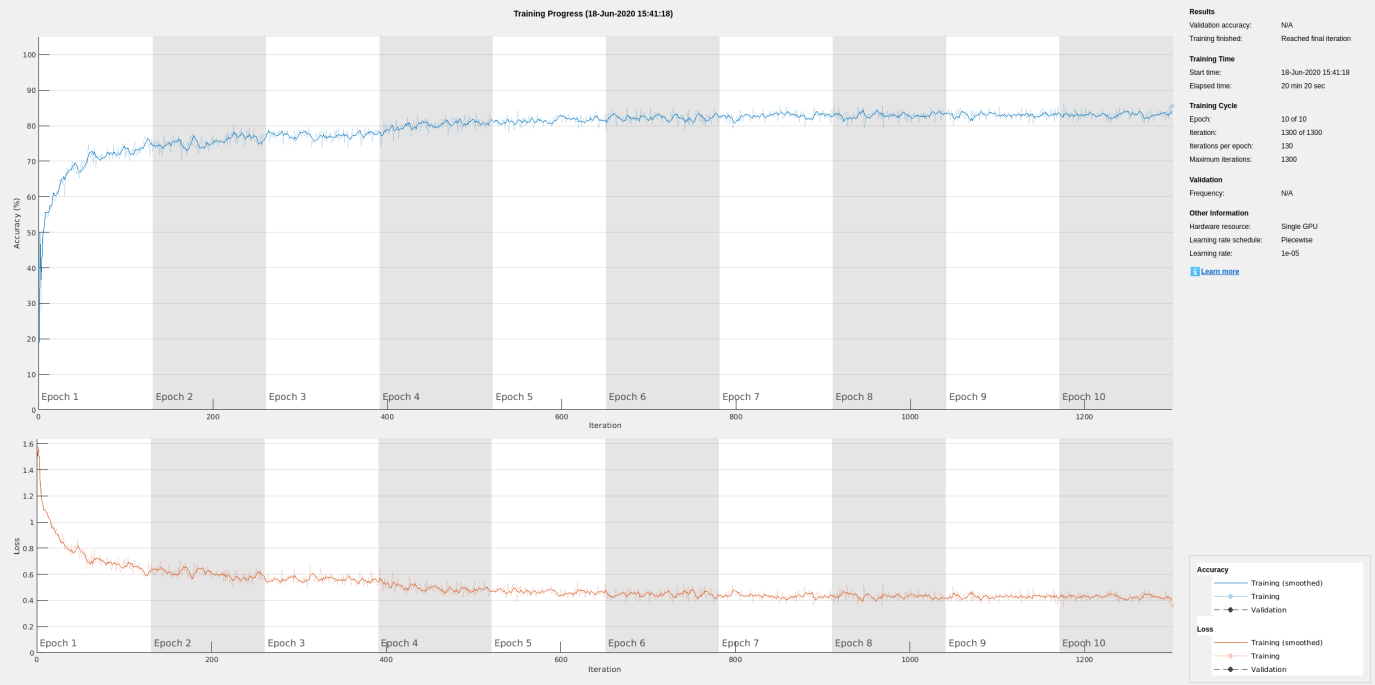
```
data =  preview(trainDs);
figure
fsst(data{1,1},250,kaiser(128),'yaxis')
```



Calculate the FSST of each signal in the training dataset over the frequency range of interest, [0.5, 40] Hz. Treat the real and imaginary parts of the FSST as separate features and feed both components into the network. Furthermore, standardize the training features by subtracting the mean and dividing by the standard deviation. Use a transformed datastore, the `extractFSSTFeatures` helper function, and the `tall` function to process the data in parallel.

```
fsstTrainDs = transform(trainDs,@(x)extractFSSTFeatures(x,250));
fsstTallTrainSet = tall(fsstTrainDs);
fsstTrainData = gather(fsstTallTrainSet);
```

```
Evaluating tall expression using the Parallel Pool 'local':
- Pass 1 of 1: 0% complete
Evaluation 0% complete
```



```
- Pass 1 of 1: Completed in 2 min 35 sec
Evaluation completed in 2 min 35 sec
```

Repeat this procedure for the testing data.

```
fsstTTestDs = transform(testDs,@(x)extractFSSTFeatures(x,250));
fsstTallTestSet = tall(fsstTTestDs);
fsstTestData = gather(fsstTallTestSet);
```

```
Evaluating tall expression using the Parallel Pool 'local':
- Pass 1 of 1: Completed in 1 min 4 sec
Evaluation completed in 1 min 4 sec
```

Adjust Network Architecture

Modify the LSTM architecture so that the network accepts a frequency spectrum for each sample instead of a single value. Inspect the size of the FSST to see the number of frequencies.

```
size(fsstTrainData{1,1})
```

```
ans = 1×2

          40        5000
```

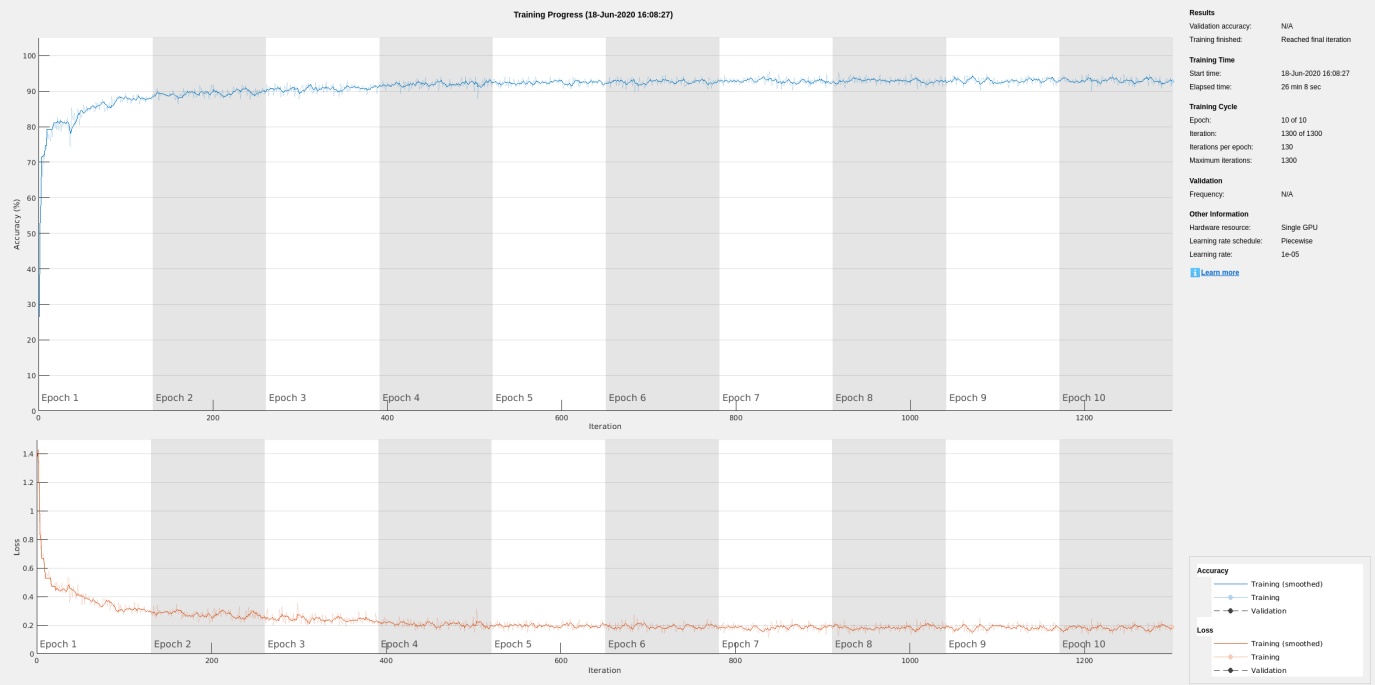
Specify a `sequenceInputLayer` of 40 input features. Keep the rest of the network parameters unchanged.

```
layers = [ ...
    sequenceInputLayer(40)
    lstmLayer(200,'OutputMode','sequence')
    fullyConnectedLayer(4)
    softmaxLayer
    classificationLayer];
```

Train Network with FSST of ECG Signals

Train the updated LSTM network with the transformed dataset.

```
if actionFlag == "Train networks"
    fsstNet = trainNetwork(fsstTrainData(:,1),fsstTrainData(:,2),layers,options);
end
```



Using time-frequency features improves the training accuracy, which now exceeds 90%.

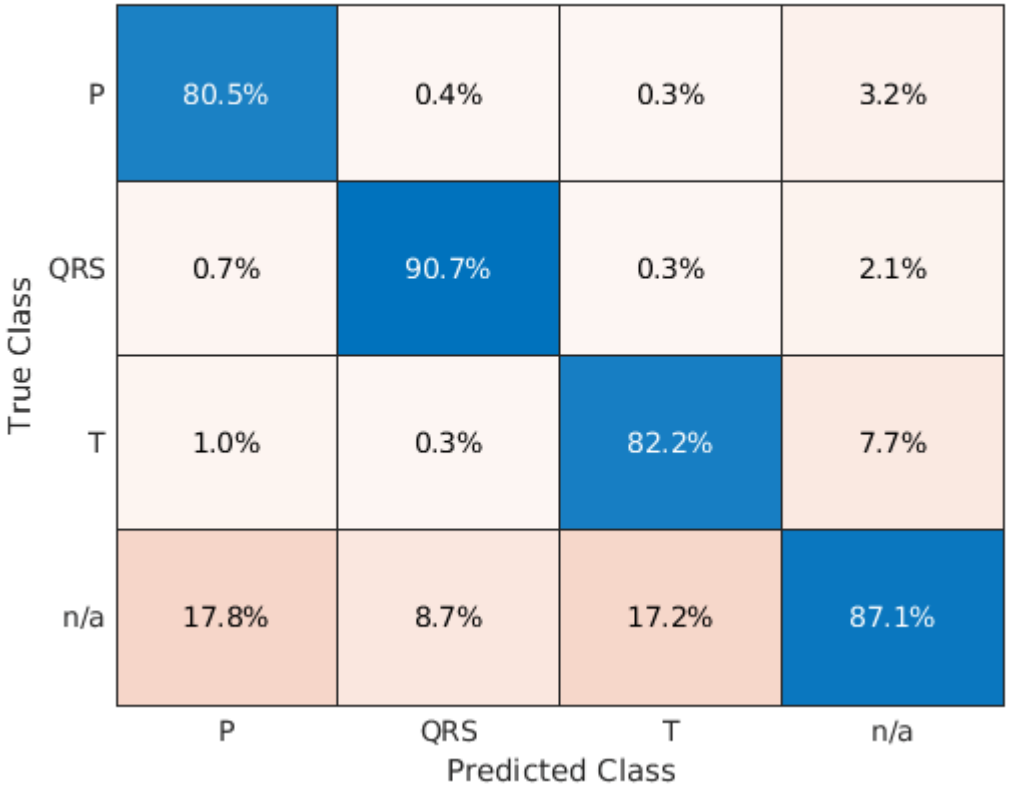
Classify Test Data with FSST

Using the updated LSTM network and extracted FSST features, classify the testing data.

```
predFsstTest = classify(fsstNet,fsstTestData(:,1),'MiniBatchSize',50);
```

Visualize the classification performance as a confusion matrix.

```
confusionchart([predFsstTest{:}],[fsstTestData{:,2}],'Normalization','column-normalized');
```

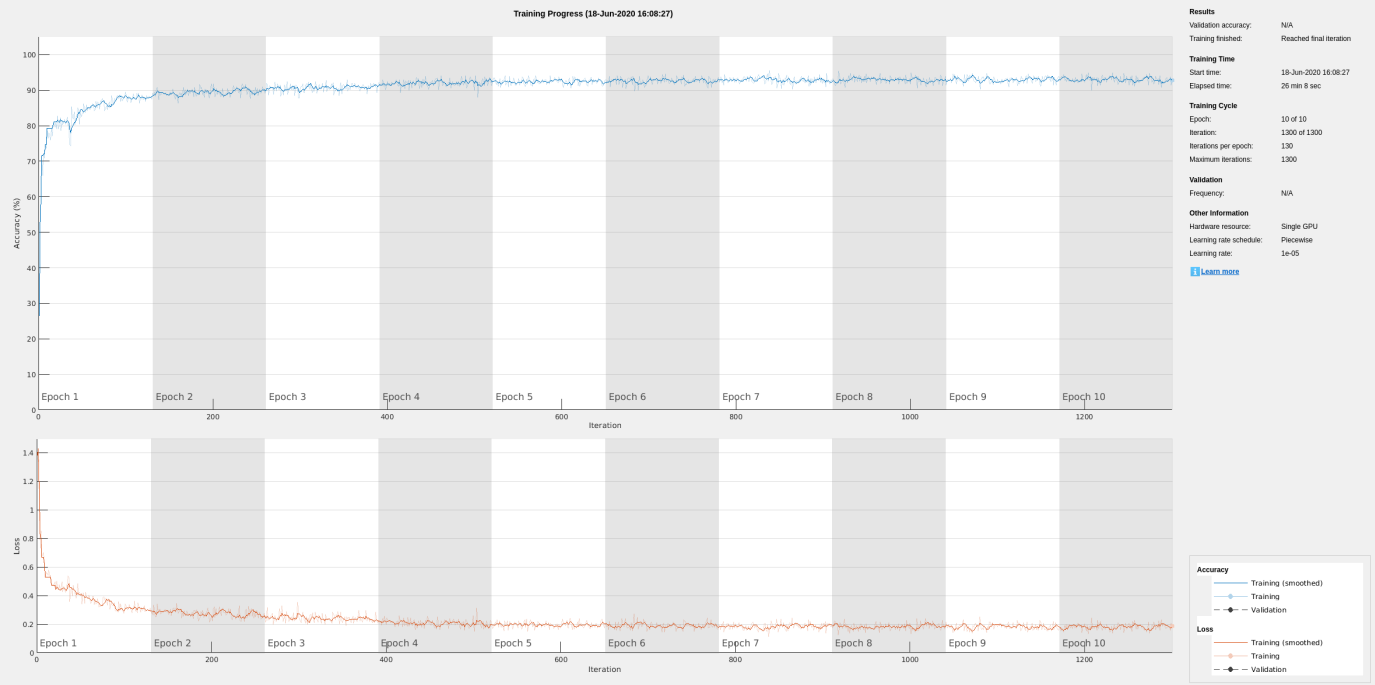


Using a time-frequency representation improves T-wave classification by about 25%, P-wave classification by about 40%, and QRS-complex classification by 30%, when compared to the raw data results.

Use a `signalMask` object to compare the network prediction to the ground truth labels for a single ECG signal. Ignore the `"n/a"` labels when plotting the regions of interest.

```
testData = gather(tall(testDs));
```

```
Evaluating tall expression using the Parallel Pool 'local':
- Pass 1 of 1: 0% complete
Evaluation 0% complete
```



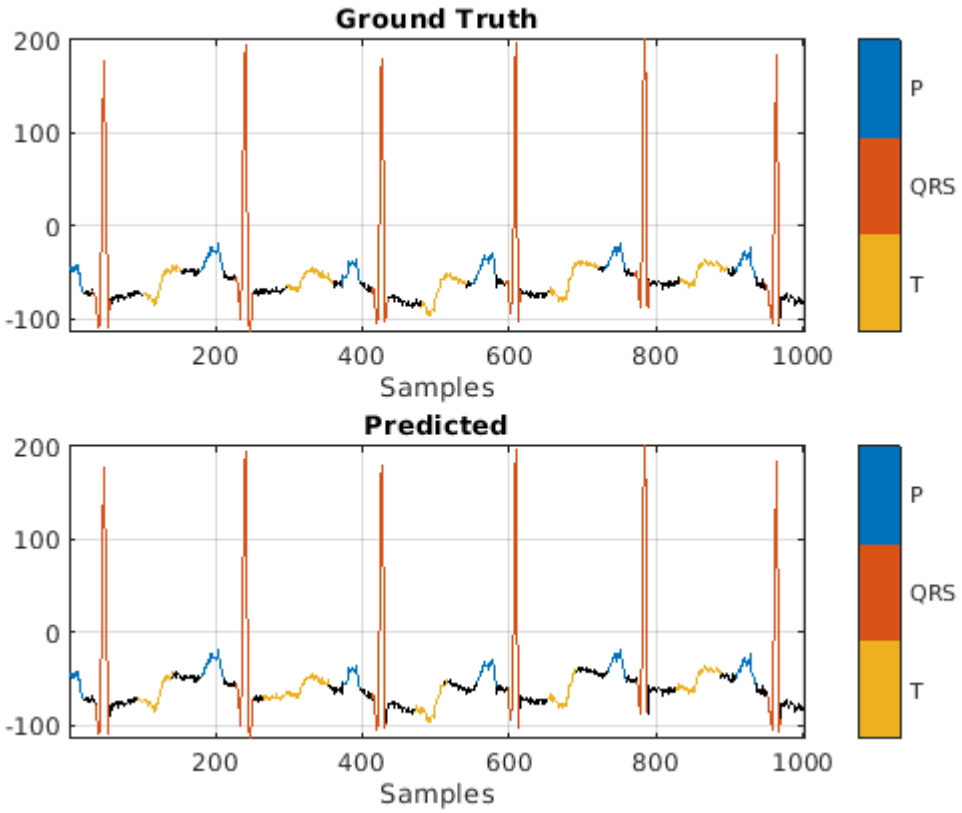
```
- Pass 1 of 1: Completed in 37 sec
Evaluation completed in 37 sec

Mtest = signalMask(testData{1,2}(3000:4000));
Mtest.SpecifySelectedCategories = true;
Mtest.SelectedCategories = find(Mtest.Categories ~= "n/a");

figure
subplot(2,1,1)
plotsigroi(Mtest,testData{1,1}(3000:4000))
title('Ground Truth')

Mpred = signalMask(predFsstTest{1}(3000:4000));
Mpred.SpecifySelectedCategories = true;
Mpred.SelectedCategories = find(Mpred.Categories ~= "n/a");

subplot(2,1,2)
plotsigroi(Mpred,testData{1,1}(3000:4000))
title('Predicted')
```



Conclusion

This example showed how signal preprocessing and time-frequency analysis can improve LSTM waveform segmentation performance. Bandpass filtering and Fourier-based synchrosqueezing result in an average improvement across all output classes from 55% to around 85%.

Classify ECG Signals Using Long Short-Term Memory Networks

This example shows how to classify heartbeat electrocardiogram (ECG) data from the PhysioNet 2017 Challenge using deep learning and signal processing. In particular, the example uses Long Short-Term Memory networks and time-frequency analysis.

Introduction

ECGs record the electrical activity of a person's heart over a period of time. Physicians use ECGs to detect visually if a patient's heartbeat is normal or irregular.

Atrial fibrillation (AFib) is a type of irregular heartbeat that occurs when the heart's upper chambers, the atria, beat out of coordination with the lower chambers, the ventricles.

This example uses ECG data from the PhysioNet 2017 Challenge [1 on page 12-0], [2 on page 12-0], [3 on page 12-0], which is available at https://physionet.org/challenge/2017/. The data consists of a set of ECG signals sampled at 300 Hz and divided by a group of experts into four different classes: Normal (N), AFib (A), Other Rhythm (O), and Noisy Recording (~). This example shows how to automate the classification process using deep learning. The procedure explores a binary classifier that can differentiate Normal ECG signals from signals showing signs of AFib.

This example uses long short-term memory (LSTM) networks, a type of recurrent neural network (RNN) well-suited to study sequence and time-series data. An LSTM network can learn long-term dependencies between time steps of a sequence. The LSTM layer (`lstmLayer`) can look at the time sequence in the forward direction, while the bidirectional LSTM layer (`bilstmLayer`) can look at the time sequence in both forward and backward directions. This example uses a bidirectional LSTM layer.

To accelerate the training process, run this example on a machine with a GPU. If your machine has a GPU and Parallel Computing Toolbox™, then MATLAB® automatically uses the GPU for training; otherwise, it uses the CPU.

Load and Examine the Data

Run the `ReadPhysionetData` script to download the data from the PhysioNet website and generate a MAT-file (`PhysionetData.mat`) that contains the ECG signals in the appropriate format. Downloading the data might take a few minutes. Use a conditional statement that runs the script only if `PhysionetData.mat` does not already exist in the current folder.

```
if ~isfile('PhysionetData.mat')
    ReadPhysionetData
end
load PhysionetData
```

The loading operation adds two variables to the workspace: `Signals` and `Labels`. `Signals` is a cell array that holds the ECG signals. `Labels` is a categorical array that holds the corresponding ground-truth labels of the signals.

```
Signals(1:5)
```

```
ans=5×1 cell array
    {1×9000  double}
    {1×9000  double}
    {1×18000 double}
    {1×9000  double}
```

```
    {1×18000 double}
```

```
Labels(1:5)
```

```
ans = 5×1 categorical
     N
     N
     N
     A
     A
```

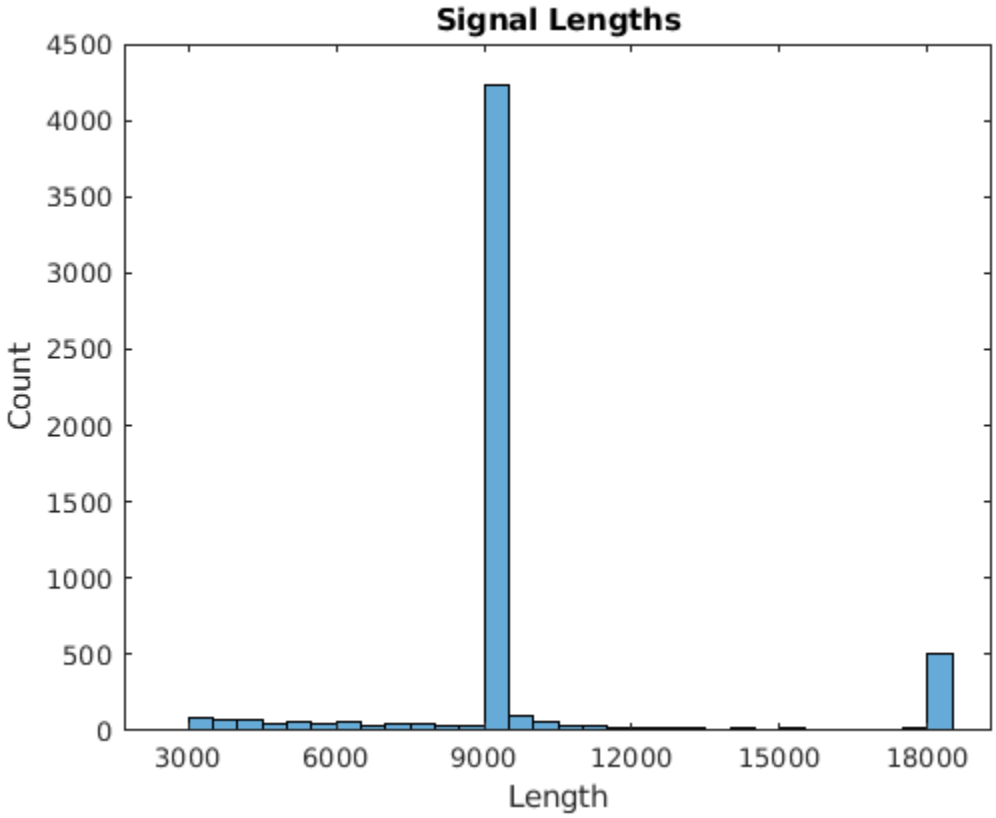
Use the `summary` function to see how many AFib signals and Normal signals are contained in the data.

```
summary(Labels)
```

```
     A       738
     N      5050
```

Generate a histogram of signal lengths. Most of the signals are 9000 samples long.

```
L = cellfun(@length,Signals);
h = histogram(L);
xticks(0:3000:18000);
xticklabels(0:3000:18000);
title('Signal Lengths')
xlabel('Length')
ylabel('Count')
```

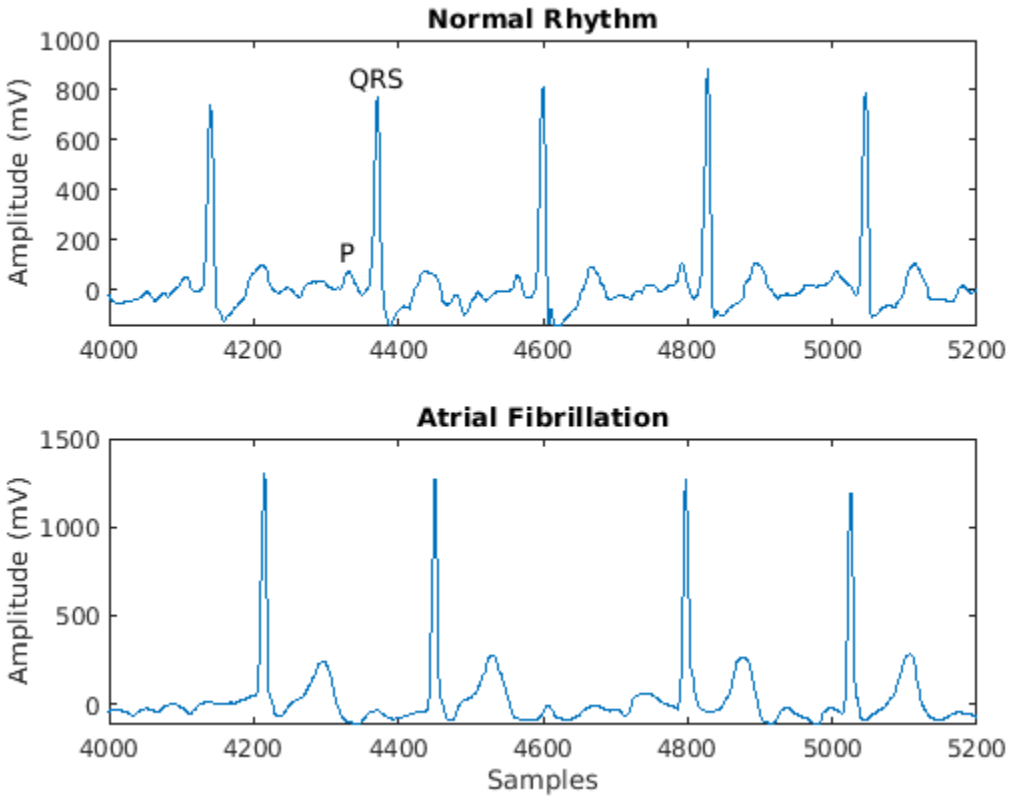


Visualize a segment of one signal from each class. AFib heartbeats are spaced out at irregular intervals while Normal heartbeats occur regularly. AFib heartbeat signals also often lack a P wave, which pulses before the QRS complex in a Normal heartbeat signal. The plot of the Normal signal shows a P wave and a QRS complex.

```
normal = Signals{1};
aFib = Signals{4};

subplot(2,1,1)
plot(normal)
title('Normal Rhythm')
xlim([4000,5200])
ylabel('Amplitude (mV)')
text(4330,150,'P','HorizontalAlignment','center')
text(4370,850,'QRS','HorizontalAlignment','center')

subplot(2,1,2)
plot(aFib)
title('Atrial Fibrillation')
xlim([4000,5200])
xlabel('Samples')
ylabel('Amplitude (mV)')
```



Prepare the Data for Training

During training, the `trainNetwork` function splits the data into mini-batches. The function then pads or truncates signals in the same mini-batch so they all have the same length. Too much padding or truncating can have a negative effect on the performance of the network, because the network might interpret a signal incorrectly based on the added or removed information.

To avoid excessive padding or truncating, apply the `segmentSignals` function to the ECG signals so they are all 9000 samples long. The function ignores signals with fewer than 9000 samples. If a signal has more than 9000 samples, `segmentSignals` breaks it into as many 9000-sample segments as possible and ignores the remaining samples. For example, a signal with 18500 samples becomes two 9000-sample signals, and the remaining 500 samples are ignored.

```
[Signals,Labels] = segmentSignals(Signals,Labels);
```

View the first five elements of the `Signals` array to verify that each entry is now 9000 samples long.

```
Signals(1:5)
```

```
ans=5×1 cell array
    {1×9000 double}
    {1×9000 double}
    {1×9000 double}
    {1×9000 double}
    {1×9000 double}
```

Train the Classifier Using Raw Signal Data

To design the classifier, use the raw signals generated in the previous section. Split the signals into a training set to train the classifier and a testing set to test the accuracy of the classifier on new data.

Use the `summary` function to show that the ratio of AFib signals to Normal signals is 718:4937, or approximately 1:7.

```
summary(Labels)
```

```
     A       718
     N      4937
```

Because about 7/8 of the signals are Normal, the classifier would learn that it can achieve a high accuracy simply by classifying all signals as Normal. To avoid this bias, augment the AFib data by duplicating AFib signals in the dataset so that there is the same number of Normal and AFib signals. This duplication, commonly called oversampling, is one form of data augmentation used in deep learning.

Split the signals according to their class.

```
afibX = Signals(Labels=='A');
afibY = Labels(Labels=='A');

normalX = Signals(Labels=='N');
normalY = Labels(Labels=='N');
```

Next, use `dividerand` to divide targets from each class randomly into training and testing sets.

```
[trainIndA,~,testIndA] = dividerand(718,0.9,0.0,0.1);
[trainIndN,~,testIndN] = dividerand(4937,0.9,0.0,0.1);

XTrainA = afibX(trainIndA);
YTrainA = afibY(trainIndA);

XTrainN = normalX(trainIndN);
YTrainN = normalY(trainIndN);

XTestA = afibX(testIndA);
YTestA = afibY(testIndA);

XTestN = normalX(testIndN);
YTestN = normalY(testIndN);
```

Now there are 646 AFib signals and 4443 Normal signals for training. To achieve the same number of signals in each class, use the first 4438 Normal signals, and then use `repmat` to repeat the first 634 AFib signals seven times.

For testing, there are 72 AFib signals and 494 Normal signals. Use the first 490 Normal signals, and then use `repmat` to repeat the first 70 AFib signals seven times. By default, the neural network randomly shuffles the data before training, ensuring that contiguous signals do not all have the same label.

```
XTrain = [repmat(XTrainA(1:634),7,1); XTrainN(1:4438)];
YTrain = [repmat(YTrainA(1:634),7,1); YTrainN(1:4438)];

XTest = [repmat(XTestA(1:70),7,1); XTestN(1:490)];
YTest = [repmat(YTestA(1:70),7,1); YTestN(1:490);];
```

The distribution between Normal and AFib signals is now evenly balanced in both the training set and the testing set.

```
summary(YTrain)
```

```
     A      4438
     N      4438
```

```
summary(YTest)
```

```
     A      490
     N      490
```

Define the LSTM Network Architecture

LSTM networks can learn long-term dependencies between time steps of sequence data. This example uses the bidirectional LSTM layer `bilstmLayer`, as it looks at the sequence in both forward and backward directions.

Because the input signals have one dimension each, specify the input size to be sequences of size 1. Specify a bidirectional LSTM layer with an output size of 100 and output the last element of the sequence. This command instructs the bidirectional LSTM layer to map the input time series into 100 features and then prepares the output for the fully connected layer. Finally, specify two classes by including a fully connected layer of size 2, followed by a softmax layer and a classification layer.

```
layers = [ ...
    sequenceInputLayer(1)
    bilstmLayer(100,'OutputMode','last')
    fullyConnectedLayer(2)
    softmaxLayer
    classificationLayer
    ]
```

```
layers =
  5x1 Layer array with layers:

     1   ''   Sequence Input          Sequence input with 1 dimensions
     2   ''   BiLSTM                 BiLSTM with 100 hidden units
     3   ''   Fully Connected         2 fully connected layer
     4   ''   Softmax                softmax
     5   ''   Classification Output   crossentropyex
```

Next specify the training options for the classifier. Set the `'MaxEpochs'` to 10 to allow the network to make 10 passes through the training data. A `'MiniBatchSize'` of 150 directs the network to look at 150 training signals at a time. An `'InitialLearnRate'` of 0.01 helps speed up the training process. Specify a `'SequenceLength'` of 1000 to break the signal into smaller pieces so that the machine does not run out of memory by looking at too much data at one time. Set '`GradientThreshold`' to 1 to stabilize the training process by preventing gradients from getting too large. Specify `'Plots'` as `'training-progress'` to generate plots that show a graphic of the training progress as the number of iterations increases. Set `'Verbose'` to `false` to suppress the table output that corresponds to the data shown in the plot. If you want to see this table, set `'Verbose'` to `true`.

This example uses the adaptive moment estimation (ADAM) solver. ADAM performs better with RNNs like LSTMs than the default stochastic gradient descent with momentum (SGDM) solver.

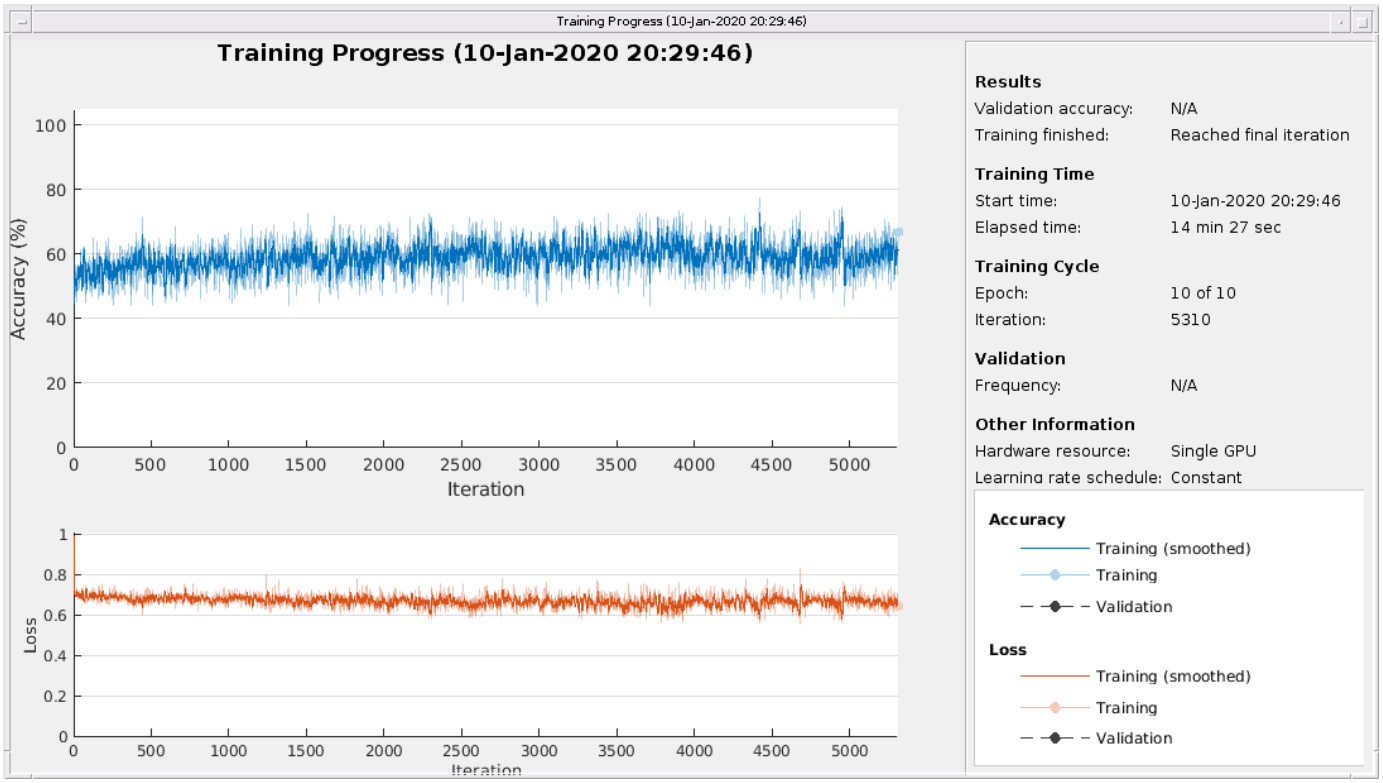
```
options = trainingOptions('adam', ...
    'MaxEpochs',10, ...
```

```
'MiniBatchSize', 150, ...
'InitialLearnRate', 0.01, ...
'SequenceLength', 1000, ...
'GradientThreshold', 1, ...
'ExecutionEnvironment',"auto",...
'plots','training-progress', ...
'Verbose',false);
```

Train the LSTM Network

Train the LSTM network with the specified training options and layer architecture by using `trainNetwork`. Because the training set is large, the training process can take several minutes.

```
net = trainNetwork(XTrain,YTrain,layers,options);
```



The top subplot of the training-progress plot represents the training accuracy, which is the classification accuracy on each mini-batch. When training progresses successfully, this value typically increases towards 100%. The bottom subplot displays the training loss, which is the cross-entropy loss on each mini-batch. When training progresses successfully, this value typically decreases towards zero.

If the training is not converging, the plots might oscillate between values without trending in a certain upward or downward direction. This oscillation means that the training accuracy is not improving and the training loss is not decreasing. This situation can occur from the start of training, or the plots might plateau after some preliminary improvement in training accuracy. In many cases, changing the training options can help the network achieve convergence. Decreasing `MiniBatchSize` or decreasing `InitialLearnRate` might result in a longer training time, but it can help the network learn better.

The classifier's training accuracy oscillates between about 50% and about 60%, and at the end of 10 epochs, it already has taken several minutes to train.

Visualize the Training and Testing Accuracy

Calculate the training accuracy, which represents the accuracy of the classifier on the signals on which it was trained. First, classify the training data.

```
trainPred = classify(net,XTrain,'SequenceLength',1000);
```

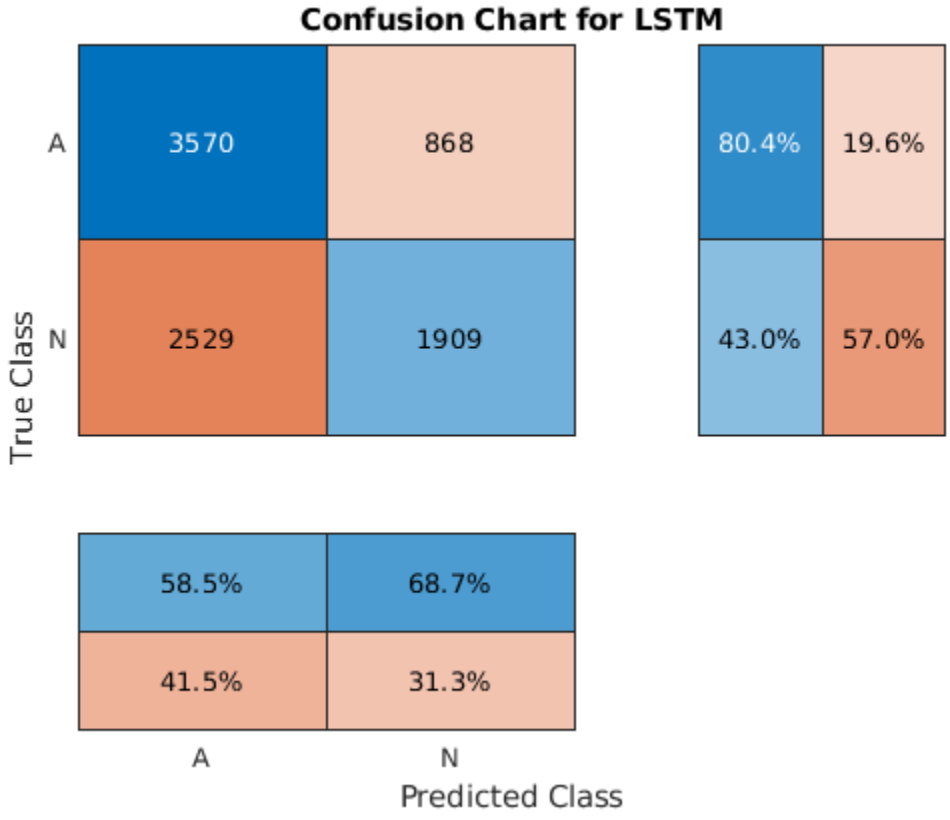
In classification problems, confusion matrices are used to visualize the performance of a classifier on a set of data for which the true values are known. The Target Class is the ground-truth label of the signal, and the Output Class is the label assigned to the signal by the network. The axes labels represent the class labels, AFib (A) and Normal (N).

Use the `confusionchart` command to calculate the overall classification accuracy for the testing data predictions. Specify `'RowSummary'` as `'row-normalized'` to display the true positive rates and false positive rates in the row summary. Also, specify `'ColumnSummary'` as `'column-normalized'` to display the positive predictive values and false discovery rates in the column summary.

```
LSTMAccuracy = sum(trainPred == YTrain)/numel(YTrain)*100
```

```
LSTMAccuracy = 61.7283
```

```
figure
confusionchart(YTrain,trainPred,'ColumnSummary','column-normalized',...
               'RowSummary','row-normalized','Title','Confusion Chart for LSTM');
```



Now classify the testing data with the same network.

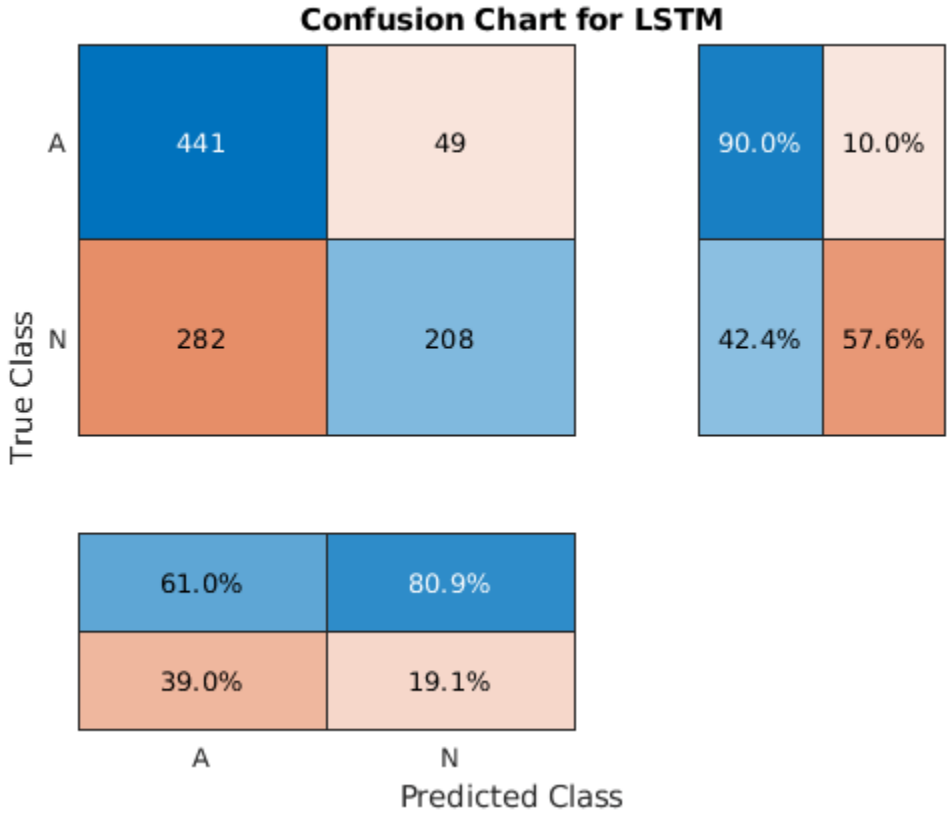
```
testPred = classify(net,XTest,'SequenceLength',1000);
```

Calculate the testing accuracy and visualize the classification performance as a confusion matrix.

```
LSTMAccuracy = sum(testPred == YTest)/numel(YTest)*100
```

```
LSTMAccuracy = 66.2245
```

```
figure
confusionchart(YTest,testPred,'ColumnSummary','column-normalized',...
               'RowSummary','row-normalized','Title','Confusion Chart for LSTM');
```



Improve the Performance with Feature Extraction

Feature extraction from the data can help improve the training and testing accuracies of the classifier. To decide which features to extract, this example adapts an approach that computes time-frequency images, such as spectrograms, and uses them to train convolutional neural networks (CNNs) [4 on page 12-0], [5 on page 12-0].

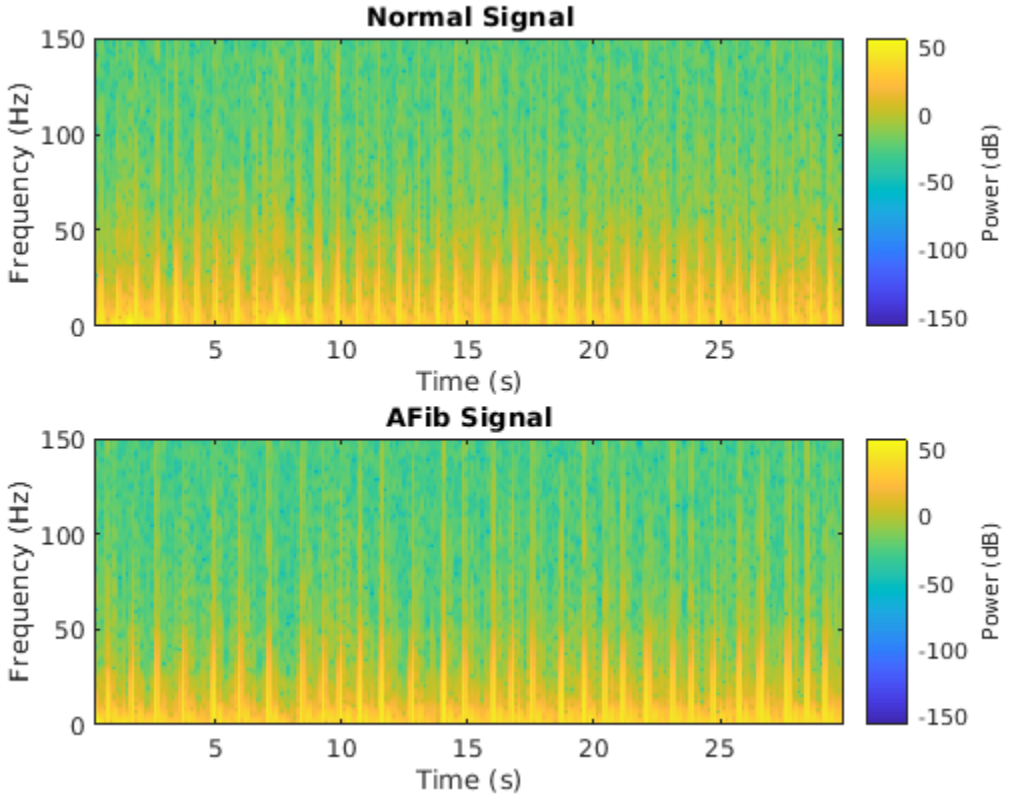
Visualize the spectrogram of each type of signal.

```
fs = 300;

figure
subplot(2,1,1);
pspectrum(normal,fs,'spectrogram','TimeResolution',0.5)
```

```
title('Normal Signal')

subplot(2,1,2);
pspectrum(aFib,fs,'spectrogram','TimeResolution',0.5)
title('AFib Signal')
```



Because this example uses an LSTM instead of a CNN, it is important to translate the approach so it applies to one-dimensional signals. Time-frequency (TF) moments extract information from the spectrograms. Each moment can be used as a one-dimensional feature to input to the LSTM.

Explore two TF moments in the time domain:

- Instantaneous frequency (`instfreq`)
- Spectral entropy (`pentropy`)

The `instfreq` function estimates the time-dependent frequency of a signal as the first moment of the power spectrogram. The function computes a spectrogram using short-time Fourier transforms over time windows. In this example, the function uses 255 time windows. The time outputs of the function correspond to the centers of the time windows.

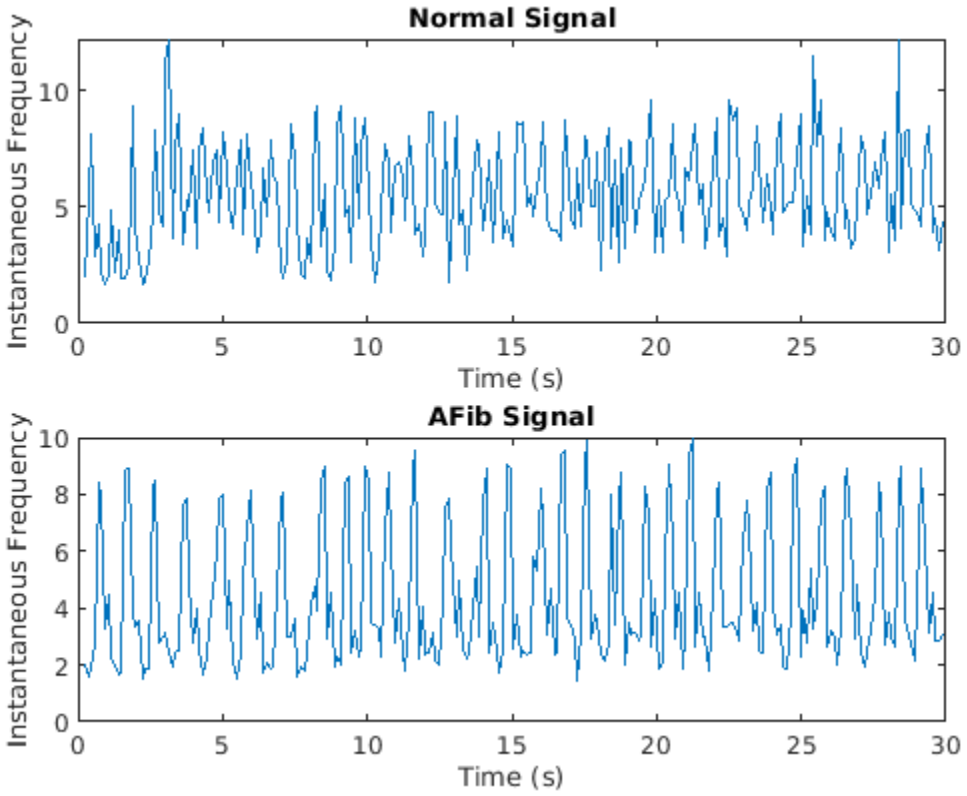
Visualize the instantaneous frequency for each type of signal.

```
[instFreqA,tA] = instfreq(aFib,fs);
[instFreqN,tN] = instfreq(normal,fs);

figure
subplot(2,1,1);
```

```
plot(tN,instFreqN)
title('Normal Signal')
xlabel('Time (s)')
ylabel('Instantaneous Frequency')

subplot(2,1,2);
plot(tA,instFreqA)
title('AFib Signal')
xlabel('Time (s)')
ylabel('Instantaneous Frequency')
```



Use `cellfun` to apply the `instfreq` function to every cell in the training and testing sets.

```
instfreqTrain = cellfun(@(x)instfreq(x,fs)',XTrain,'UniformOutput',false);
instfreqTest = cellfun(@(x)instfreq(x,fs)',XTest,'UniformOutput',false);
```

The spectral entropy measures how spiky flat the spectrum of a signal is. A signal with a spiky spectrum, like a sum of sinusoids, has low spectral entropy. A signal with a flat spectrum, like white noise, has high spectral entropy. The `pentropy` function estimates the spectral entropy based on a power spectrogram. As with the instantaneous frequency estimation case, `pentropy` uses 255 time windows to compute the spectrogram. The time outputs of the function correspond to the center of the time windows.

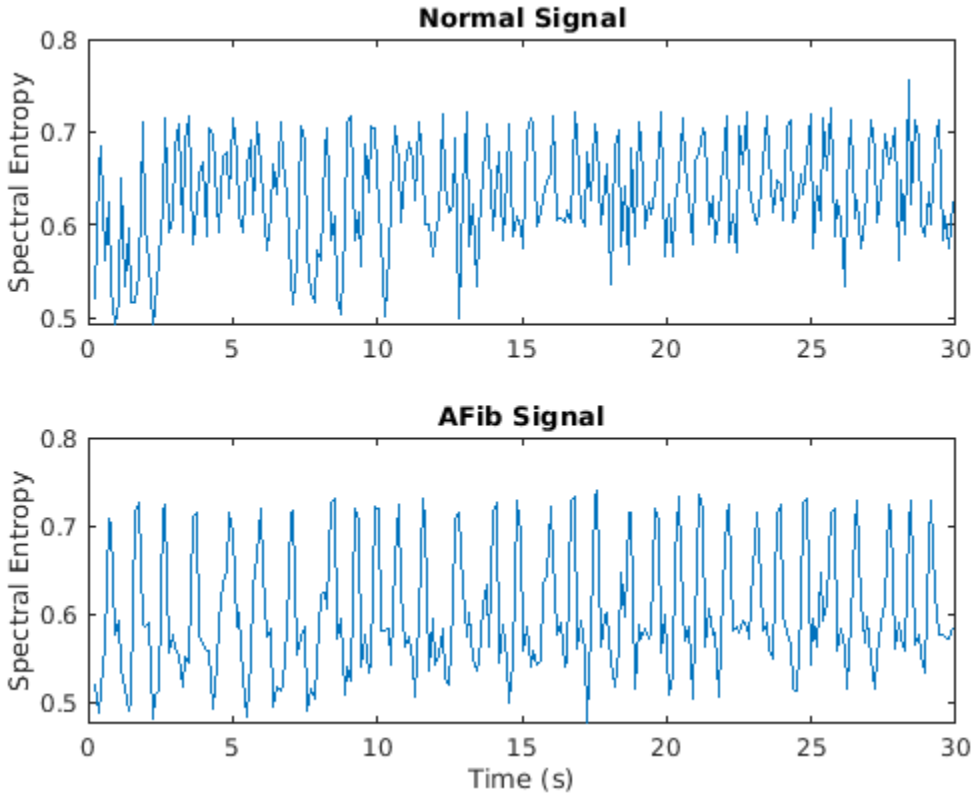
Visualize the spectral entropy for each type of signal.

```
[pentropyA,tA2] = pentropy(aFib,fs);
[pentropyN,tN2] = pentropy(normal,fs);
```

```
figure

subplot(2,1,1)
plot(tN2,pentropyN)
title('Normal Signal')
ylabel('Spectral Entropy')

subplot(2,1,2)
plot(tA2,pentropyA)
title('AFib Signal')
xlabel('Time (s)')
ylabel('Spectral Entropy')
```



Use `cellfun` to apply the `pentropy` function to every cell in the training and testing sets.

```
pentropyTrain = cellfun(@(x)pentropy(x,fs)',XTrain,'UniformOutput',false);
pentropyTest = cellfun(@(x)pentropy(x,fs)',XTest,'UniformOutput',false);
```

Concatenate the features such that each cell in the new training and testing sets has two dimensions, or two features.

```
XTrain2 = cellfun(@(x,y)[x;y],instfreqTrain,pentropyTrain,'UniformOutput',false);
XTest2 = cellfun(@(x,y)[x;y],instfreqTest,pentropyTest,'UniformOutput',false);
```

Visualize the format of the new inputs. Each cell no longer contains one 9000-sample-long signal; now it contains two 255-sample-long features.

```
XTrain2(1:5)
```

```
ans=5×1 cell array
    {2×255 double}
    {2×255 double}
    {2×255 double}
    {2×255 double}
    {2×255 double}
```

Standardize the Data

The instantaneous frequency and the spectral entropy have means that differ by almost one order of magnitude. Furthermore, the instantaneous frequency mean might be too high for the LSTM to learn effectively. When a network is fit on data with a large mean and a large range of values, large inputs could slow down the learning and convergence of the network [6 on page 12-0].

```
mean(instFreqN)
```

```
ans = 5.5615
```

```
mean(pentropyN)
```

```
ans = 0.6326
```

Use the training set mean and standard deviation to standardize the training and testing sets. Standardization, or z-scoring, is a popular way to improve network performance during training.

```
XV = [XTrain2{:}];
mu = mean(XV,2);
sg = std(XV,[],2);

XTrainSD = XTrain2;
XTrainSD = cellfun(@(x)(x-mu)./sg,XTrainSD,'UniformOutput',false);

XTestSD = XTest2;
XTestSD = cellfun(@(x)(x-mu)./sg,XTestSD,'UniformOutput',false);
```

Show the means of the standardized instantaneous frequency and spectral entropy.

```
instFreqNSD = XTrainSD{1}(1,:);
pentropyNSD = XTrainSD{1}(2,:);

mean(instFreqNSD)
```

```
ans = -0.3211
```

```
mean(pentropyNSD)
```

```
ans = -0.2416
```

Modify the LSTM Network Architecture

Now that the signals each have two dimensions, it is necessary to modify the network architecture by specifying the input sequence size as 2. Specify a bidirectional LSTM layer with an output size of 100, and output the last element of the sequence. Specify two classes by including a fully connected layer of size 2, followed by a softmax layer and a classification layer.

```
layers = [ ...
    sequenceInputLayer(2)
```

```
    bilstmLayer(100,'OutputMode','last')
    fullyConnectedLayer(2)
    softmaxLayer
    classificationLayer
    ]
```

```
layers =
  5x1 Layer array with layers:

     1   ''   Sequence Input          Sequence input with 2 dimensions
     2   ''   BiLSTM                 BiLSTM with 100 hidden units
     3   ''   Fully Connected         2 fully connected layer
     4   ''   Softmax                softmax
     5   ''   Classification Output   crossentropyex
```

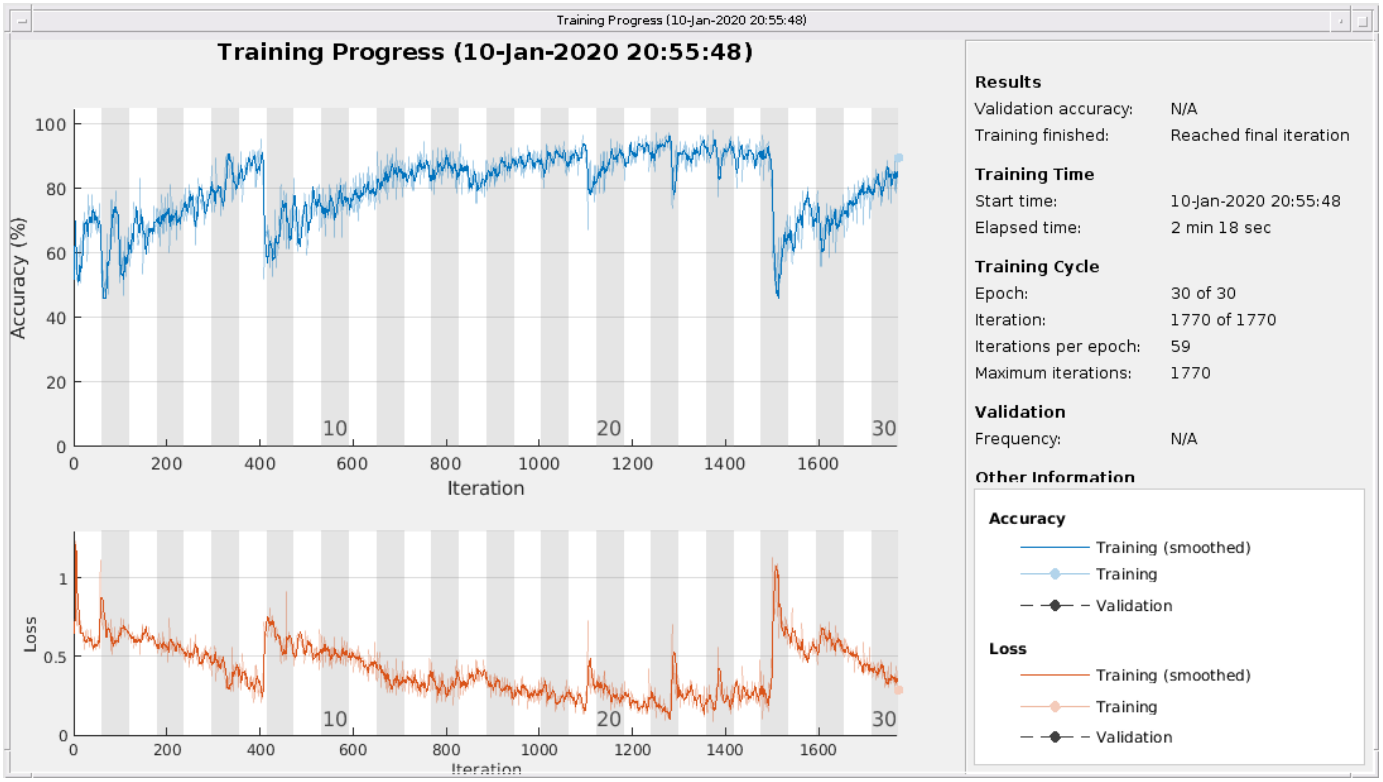
Specify the training options. Set the maximum number of epochs to 30 to allow the network to make 30 passes through the training data.

```
options = trainingOptions('adam', ...
    'MaxEpochs',30, ...
    'MiniBatchSize', 150, ...
    'InitialLearnRate', 0.01, ...
    'GradientThreshold', 1, ...
    'ExecutionEnvironment',"auto",...
    'plots','training-progress', ...
    'Verbose',false);
```

Train the LSTM Network with Time-Frequency Features

Train the LSTM network with the specified training options and layer architecture by using `trainNetwork`.

```
net2 = trainNetwork(XTrainSD,YTrain,layers,options);
```



There is a great improvement in the training accuracy. The cross-entropy loss trends towards 0. Furthermore, the time required for training decreases because the TF moments are shorter than the raw sequences.

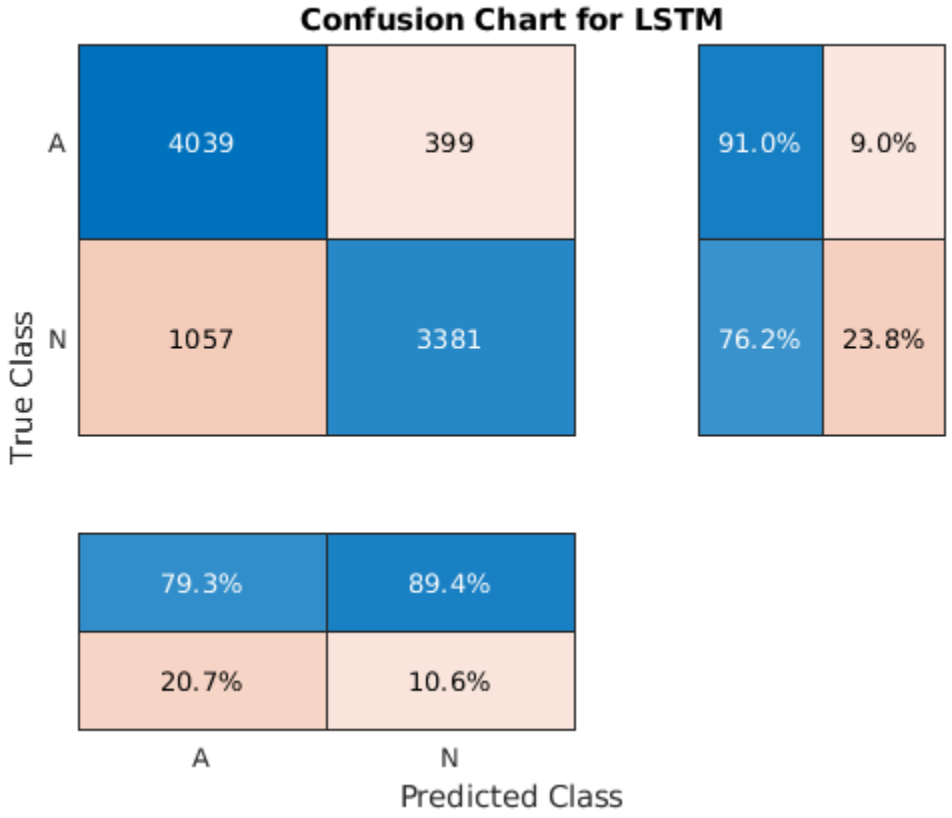
Visualize the Training and Testing Accuracy

Classify the training data using the updated LSTM network. Visualize the classification performance as a confusion matrix.

```
trainPred2 = classify(net2,XTrainSD);
LSTMAccuracy = sum(trainPred2 == YTrain)/numel(YTrain)*100
```

```
LSTMAccuracy = 83.5962
```

```
figure
confusionchart(YTrain,trainPred2,'ColumnSummary','column-normalized',...
              'RowSummary','row-normalized','Title','Confusion Chart for LSTM');
```



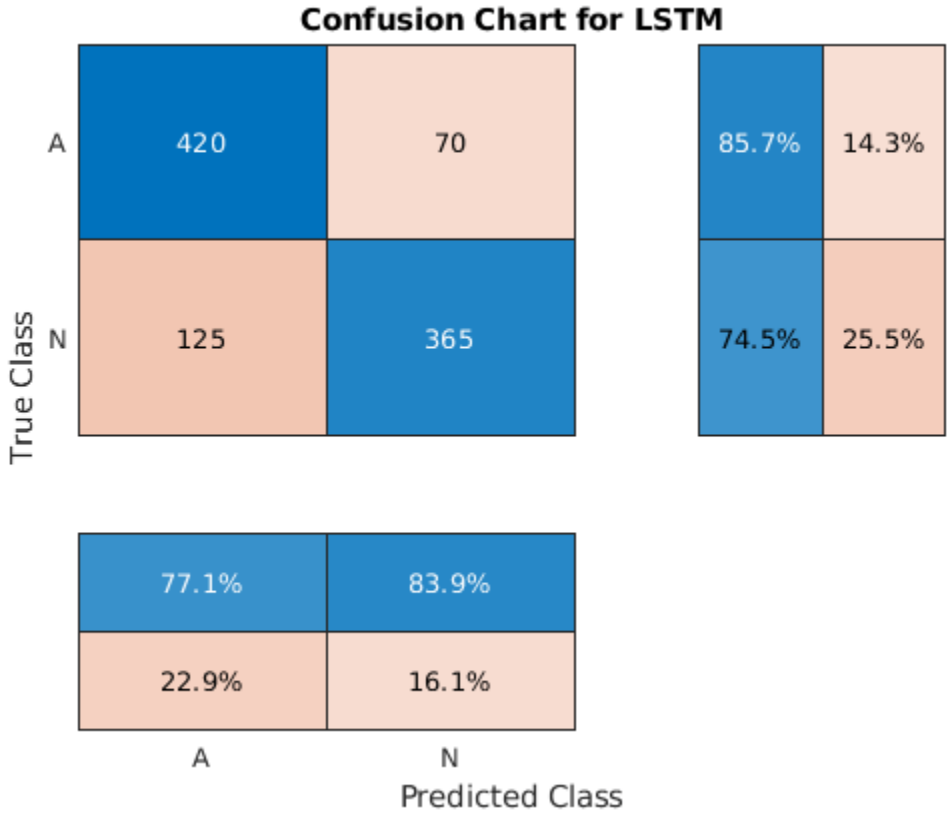
Classify the testing data with the updated network. Plot the confusion matrix to examine the testing accuracy.

```
testPred2 = classify(net2,XTestSD);

LSTMAccuracy = sum(testPred2 == YTest)/numel(YTest)*100
```

```
LSTMAccuracy = 80.1020
```

```
figure
confusionchart(YTest,testPred2,'ColumnSummary','column-normalized',...
               'RowSummary','row-normalized','Title','Confusion Chart for LSTM');
```



Conclusion

This example shows how to build a classifier to detect atrial fibrillation in ECG signals using an LSTM network. The procedure uses oversampling to avoid the classification bias that occurs when one tries to detect abnormal conditions in populations composed mainly of healthy patients. Training the LSTM network using raw signal data results in a poor classification accuracy. Training the network using two time-frequency-moment features for each signal significantly improves the classification performance and also decreases the training time.

Generate Synthetic Signals Using Conditional GAN

This example shows how to generate synthetic pump signals using a conditional generative adversarial network.

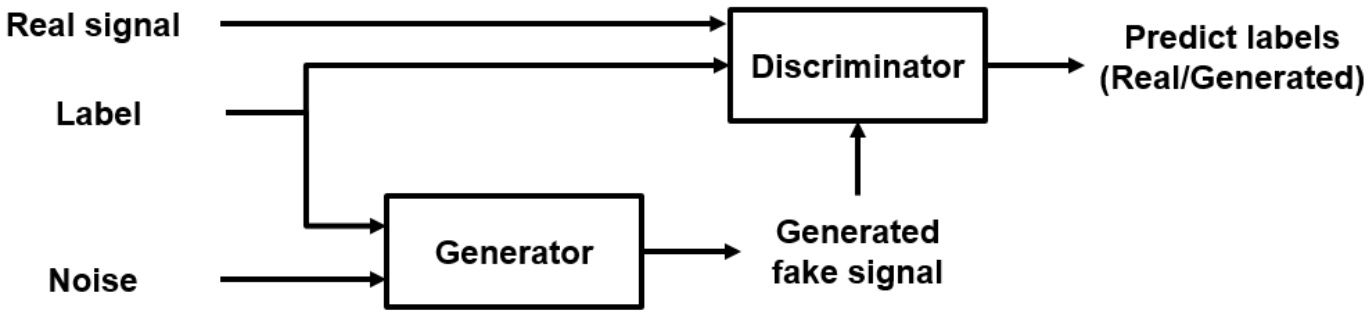
Generative adversarial networks (GANs) can be used to produce synthetic data that resembles real data input to the networks. GANs are useful when simulations are computationally expensive or experiments are costly. Conditional GANs (CGANs) can use data labels during the training process to generate data belonging to specific categories.

This example treats simulated signals obtained by a pump Simulink™ model as the "real" data that plays the role of training data set for a CGAN. The CGAN uses 1-D convolutional networks and is trained using a custom training loop and a deep learning array. In addition, this example uses principal component analysis (PCA) to visually compare the characteristics of generated and real signals.

CGAN for Signal Synthesis

CGANs consist of two networks that train together as adversaries:

1. *Generator* network — Given a label and random array as input, this network generates data with the same structure as the training data observations corresponding to the same label. The objective of the generator is to generate labeled data that the discriminator classifies as "real."
2. *Discriminator* network — Given batches of labeled data containing observations from both training data and generated data from the generator, this network attempts to classify the observations as "real" or "generated." The objective of the discriminator is to not be "fooled" by the generator when given batches of both real and generated labeled data.



Ideally, these strategies result in a generator that generates convincingly realistic data corresponding to the input labels and a discriminator that has learned strong features characteristic of the training data for each label.

Load Data

The simulated data is generated by the pump Simulink model presented in the “Multi-Class Fault Detection Using Simulated Data” (Predictive Maintenance Toolbox) example. The Simulink model is configured to model three types of faults: cylinder leaks, blocked inlets, and increased bearing friction. The data set contains 1575 pump output flow signals, of which 760 are healthy signals and 815 have a single fault, combinations of two faults, or combinations of three faults. Each signal has 1201 signal samples with a sample rate of 1000 Hz.

Download and unzip the data in your temporary directory, whose location is specified by MATLAB® `tempdir` command. If you have the data in a folder different from that specified by `tempdir`, change the directory name in the following code.

```
% Download the data
dataURL = 'https://ssd.mathworks.com/supportfiles/SPT/data/PumpSignalGAN.zip';
saveFolder = fullfile(tempdir,'PumpSignalGAN');
zipFile = fullfile(tempdir,'PumpSignalGAN.zip');
if ~exist(saveFolder,'dir')
    websave(zipFile,dataURL);
end

% Unzip the data
unzip(zipFile,saveFolder)
```

The zip file contains the training data set and a pretrained CGAN:

- `simulatedDataset` — Simulated signals and their corresponding categorical labels
- `GANModel` — Generator and discriminator trained on the simulated data

Load the training data set and standardize the signals to have zero mean and unit variance.

```
load(fullfile(saveFolder,'simulatedDataset.mat')) % load data set
meanFlow = mean(flow,2);
flowNormalized = flow-meanFlow;
stdFlow = std(flowNormalized(:));
flowNormalized = flowNormalized/stdFlow;
```

Healthy signals are labeled as 1 and faulty signals are labeled as 2.

Define Generator Network

Define the following two-input network, which generates flow signals given 1-by-1-by-100 arrays of random values and corresponding labels.

The network:

- Projects and reshapes the 1-by-1-by-100 arrays of noise to 4-by-1-by-1024 arrays by a custom layer.
- Converts the categorical labels to embedding vectors and reshapes them to a 4-by-1-by-1 arrays.
- Concatenates the results from the two inputs along the channel dimension. The output is a 4-by-1-by-1025 array.
- Upsamples the resulting arrays to 1201-by-1-by-1 arrays using a series of 1-D transposed convolution layers with batch normalization and ReLU layers.

To project and reshape the noise input, use the custom layer `projectAndReshapeLayer`, attached to this example as a supporting file. The `projectAndReshapeLayer` object upscales the input using a fully connected layer and reshapes the output to the specified size.

To input the labels into the network, use an `imageInputLayer` object and specify a size of 1-by-1. To embed and reshape the label input, use the custom layer `embedAndReshapeLayer`, attached to this example as a supporting file. The `embedAndReshapeLayer` object converts a categorical label to a one-channel array of the specified size using an embedding and a fully connected operation. For categorical inputs, use an embedding dimension of 100.

```
% Generator Network

numFilters = 64;
numLatentInputs = 100;
projectionSize = [4 1 1024];
numClasses = 2;
embeddingDimension = 100;

layersGenerator = [
    imageInputLayer([1 1 numLatentInputs],'Normalization','none','Name','in')
    projectAndReshapeLayer(projectionSize,numLatentInputs,'proj');
    concatenationLayer(3,2,'Name','cat');
    transposedConv2dLayer([5 1],8*numFilters,'Name','tconv1')
    batchNormalizationLayer('Name','bn1','Epsilon',5e-5)
    reluLayer('Name','relu1')
    transposedConv2dLayer([10 1],4*numFilters,'Stride',4,'Cropping',[1 0],'Name','tconv2')
    batchNormalizationLayer('Name','bn2','Epsilon',5e-5)
    reluLayer('Name','relu2')
    transposedConv2dLayer([12 1],2*numFilters,'Stride',4,'Cropping',[1 0],'Name','tconv3')
    batchNormalizationLayer('Name','bn3','Epsilon',5e-5)
    reluLayer('Name','relu3')
    transposedConv2dLayer([5 1],numFilters,'Stride',4,'Cropping',[1 0],'Name','tconv4')
    batchNormalizationLayer('Name','bn4','Epsilon',5e-5)
    reluLayer('Name','relu4')
    transposedConv2dLayer([7 1],1,'Stride',2,'Cropping',[1 0],'Name','tconv5')
    ];

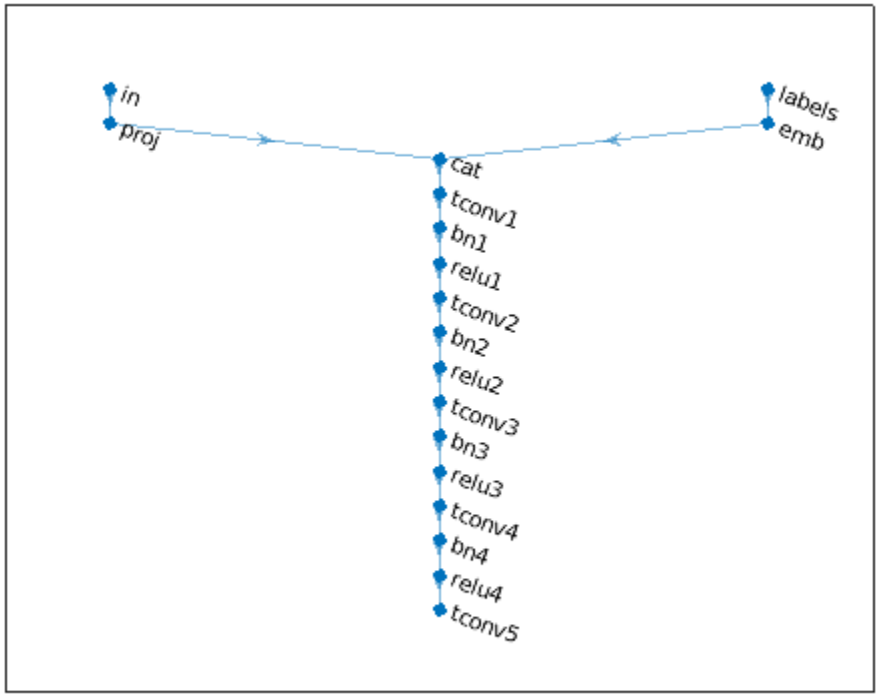
lgraphGenerator = layerGraph(layersGenerator);

layers = [
    imageInputLayer([1 1],'Name','labels','Normalization','none')
    embedAndReshapeLayer(projectionSize(1:2),embeddingDimension,numClasses,'emb')];

lgraphGenerator = addLayers(lgraphGenerator,layers);
lgraphGenerator = connectLayers(lgraphGenerator,'emb','cat/in2');
```

Plot the network structure for the generator.

```
plot(lgraphGenerator)
```



To train the network with a custom training loop and enable automatic differentiation, convert the layer graph to a `dlnetwork` object.

```
dlnetGenerator = dlnetwork(lgraphGenerator);
```

Define Discriminator Network

Define the following two-input network, which classifies real and generated 1201-by-1 signals given a set of signals and their corresponding labels.

This network:

- Takes 1201-by-1-by-1 signals as input.
- Converts categorical labels to embedding vectors and reshapes them to a 1201-by-1-by-1 arrays.
- Concatenates the results from the two inputs along the channel dimension. The output is a 1201-by-1-by-1025 array.
- Downsamples the resulting arrays to scalar prediction scores, which are 1-by-1-by-1 arrays, using a series of 1-D convolution layers with leaky ReLU layers with a scale of 0.2.

```
% Discriminator Network

scale = 0.2;
inputSize = [1201 1 1];

layersDiscriminator = [
    imageInputLayer(inputSize,'Normalization','none','Name','in')
```

```
    concatenationLayer(3,2,'Name','cat')
    convolution2dLayer([17 1],8*numFilters,'Stride',2,'Padding',[1 0],'Name','conv1')
    leakyReluLayer(scale,'Name','lrelu1')
    convolution2dLayer([16 1],4*numFilters,'Stride',4,'Padding',[1 0],'Name','conv2')
    leakyReluLayer(scale,'Name','lrelu2')
    convolution2dLayer([16 1],2*numFilters,'Stride',4,'Padding',[1 0],'Name','conv3')
    leakyReluLayer(scale,'Name','lrelu3')
    convolution2dLayer([8 1],numFilters,'Stride',4,'Padding',[1 0],'Name','conv4')
    leakyReluLayer(scale,'Name','lrelu4')
    convolution2dLayer([8 1],1,'Name','conv5')];

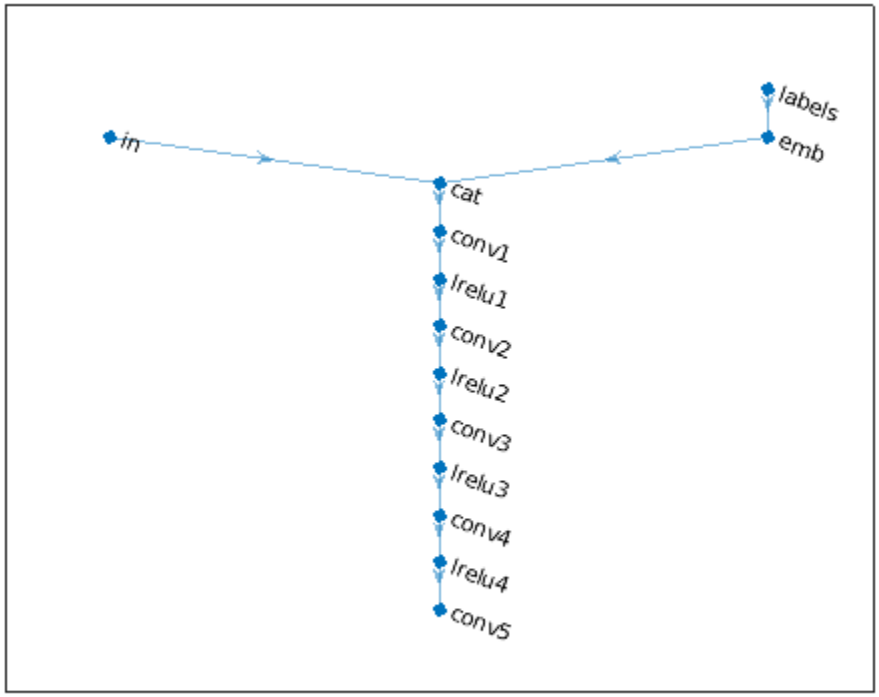
lgraphDiscriminator = layerGraph(layersDiscriminator);

layers = [
    imageInputLayer([1 1],'Name','labels','Normalization','none')
    embedAndReshapeLayer(inputSize,embeddingDimension,numClasses,'emb')];

lgraphDiscriminator = addLayers(lgraphDiscriminator,layers);
lgraphDiscriminator = connectLayers(lgraphDiscriminator,'emb','cat/in2');
```

Plot the network structure for the discriminator.

```
plot(lgraphDiscriminator)
```



To train the network with a custom training loop and enable automatic differentiation, convert the layer graph to a `dlnetwork` object.

```
dlnetDiscriminator = dlnetwork(lgraphDiscriminator);
```

Train Model

Train the CGAN model using a custom training loop. Loop over the training data and update the network parameters at each iteration. To monitor the training progress, display generated healthy and faulty signals using two fixed arrays of random values to input into the generator as well as a plot of the scores of the two networks.

For each epoch, shuffle the training data and loop over mini-batches of data.

For each mini-batch:

- Generate a `dlarray` object containing an array of random values for the generator network.
- For GPU training, convert the data to a `gpuArray` (Parallel Computing Toolbox) object.
- Evaluate the model gradients using `dlfeval` and the helper function `modelGradients`.
- Update the network parameters using the `adamupdate` function.

The helper function `modelGradients` takes as input the generator and discriminator networks, a mini-batch of input data, and an array of random values, and returns the gradients of the loss with respect to the learnable parameters in the networks and the scores of the two networks. The loss function is defined in the helper function `ganLoss`.

Specify Training Options

Set the training parameters.

```
params.numLatentInputs = numLatentInputs;
params.numClasses = numClasses;
params.sizeData = [inputSize length(labels)];
params.numEpochs = 1000;
params.miniBatchSize = 256;

% Specify the options for Adam optimizer
params.learnRate = 0.0002;
params.gradientDecayFactor = 0.5;
params.squaredGradientDecayFactor = 0.999;
```

Set the execution environment to run the CGANs on the CPU. To run the CGANs on the GPU, set `executionEnvironment` to "`gpu`" or select the "Run on GPU" option in Live Editor. Using a GPU requires Parallel Computing Toolbox™. To see which GPUs are supported, see “GPU Support by Release” (Parallel Computing Toolbox).

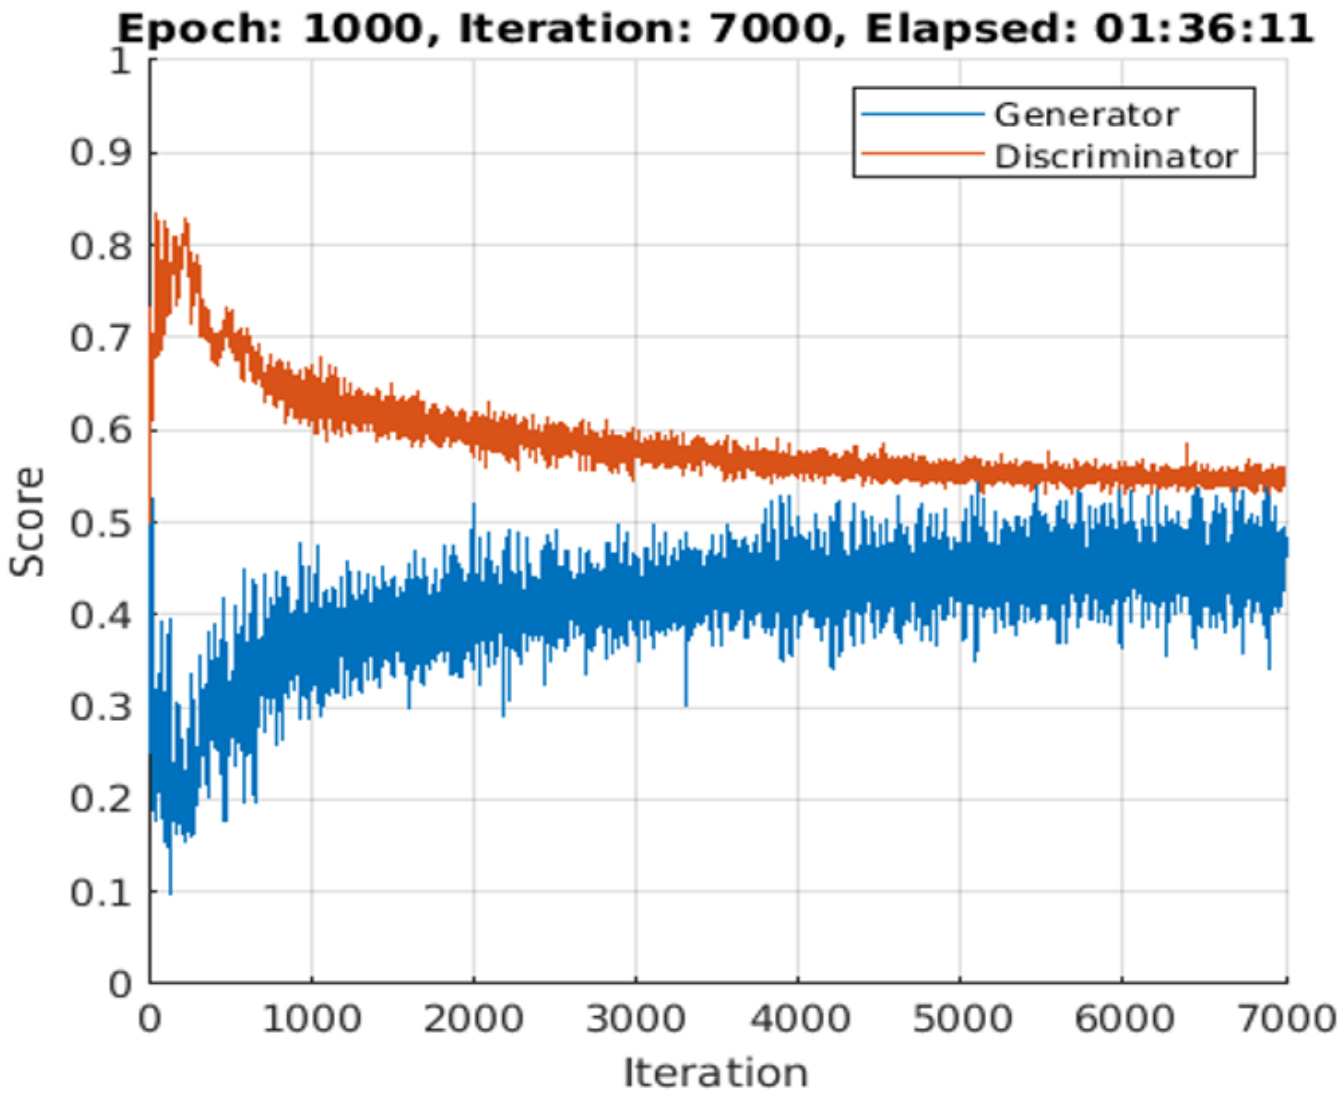
```
executionEnvironment = Run on CPU;
params.executionEnvironment = executionEnvironment;
```

Skip the training process by loading the pretrained network. To train the network on your computer, set `trainNow` to `true` or select the "Train CGAN now" option in Live Editor.

```
trainNow = Use trained CGAN;
if trainNow
    % Train the CGAN
    [dlnetGenerator,dlnetDiscriminator] = trainGAN(dlnetGenerator, ...
        dlnetDiscriminator,flowNormalized,labels,params); %#ok
else
    % Use pretrained CGAN (default)
```

```
    load(fullfile(tempdir,'PumpSignalGAN','GANModel.mat')) % load data set
end
```

The training plot below shows an example of scores of the generator and discriminator networks. To learn more about how to interpret the network scores, see “Monitor GAN Training Progress and Identify Common Failure Modes” on page 5-182. In this example, the scores of both the generator and discriminator converge close to 0.5, indicating that the training performance is good.



Synthesize Flow Signals

Create a `dlarray` object containing a batch of 2000 1-by-1-by-100 arrays of random values to input into the generator network. Reset the random number generator for reproducible results.

```
rng default

numTests = 2000;
```

```
ZNew = randn(1,1,numLatentInputs,numTests,'single');
dlZNew = dlarray(ZNew,'SSCB');
```

Specify that the first 1000 random arrays are healthy and the rest are faulty.

```
TNew = ones(1,1,1,numTests,'single');
TNew(1,1,1,numTests/2+1:end) = single(2);
dlTNew = dlarray(TNew,'SSCB');
```

To generate signals using the GPU, convert the data to `gpuArray` objects.

```
if executionEnvironment == "gpu"
    dlZNew = gpuArray(dlZNew);
    dlTNew = gpuArray(dlTNew);
end
```

Use the `predict` function on the generator with the batch of 1-by-1-by-100 arrays of random values and labels to generate synthetic signals and revert the standardization step that you performed on the original flow signals.

```
dlXGeneratedNew = predict(dlnetGenerator,dlZNew,dlTNew)*stdFlow+meanFlow;
```

Signal Feature Visualization

Unlike images and audio signals, general signals have characteristics that make them difficult for human perception to tell apart. To compare real and generated signals or healthy and faulty signals, you can apply principal component analysis (PCA) to the statistical features of the real signals and then project the features of the generated signals to the same PCA subspace.

Feature Extraction

Combine the original real signal and the generated signals in one data matrix. Use the helper function `extractFeatures` to extract the feature including common signal statistics such as the mean and variance as well as spectral characteristics.

```
idxGenerated = 1:numTests;
idxReal = numTests+1:numTests+size(flow,2);

XGeneratedNew = squeeze(extractdata(gather(dlXGeneratedNew)));
x = [XGeneratedNew single(flow)];

features = zeros(size(x,2),14,'like',x);

for ii = 1:size(x,2)
    features(ii,:) = extractFeatures(x(:,ii));
end
```

Each row of `features` corresponds to the features of one signal.

Modify the labels for the generated healthy and faulty signals as well as real healthy and faulty signals.

```
L = [squeeze(TNew)+2;labels.'];
```

The labels now have these definitions:

- 1 — Generated healthy signals

- 2 — Generated faulty signals
- 3 — Real healthy signals
- 4 — Real faulty signals

Principal Component Analysis

Perform PCA on the features of the real signals and project the features of the generated signals to the same PCA subspace. `W` is the coefficient and `Y` is the score.

```
% PCA via svd
featuresReal = features(idxReal,:);
mu = mean(featuresReal,1);
[~,S,W] = svd(featuresReal-mu);
S = diag(S);
Y = (features-mu)*W;
```

From the singular vector `S`, the first three singular values make up 99% of the energy in `S`. You can visualize the signal features by taking advantage of the first three principal components.

```
sum(S(1:3))/sum(S)
```

```
ans = single
    0.9923
```

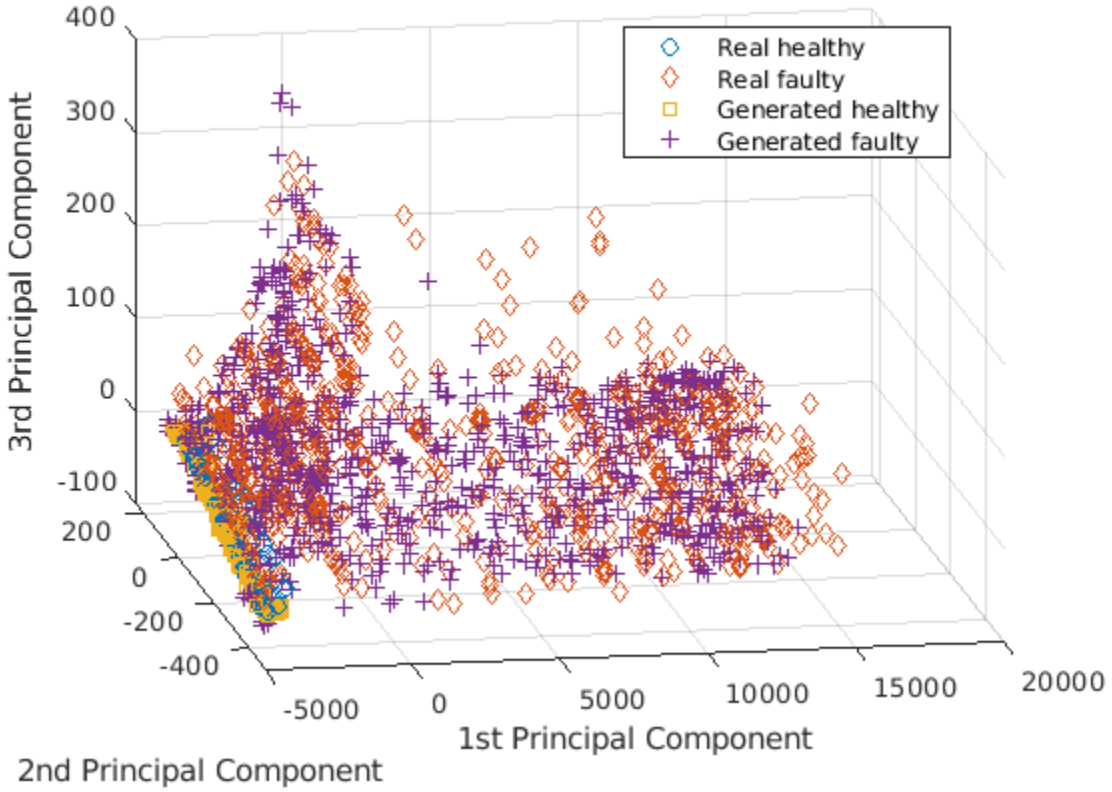
Plot the features of all the signals using the first three principal components. In the PCA subspace, the distribution of the generated signals is similar to the distribution of the real signals.

```
idxHealthyR = L==1;
idxFaultR = L==2;

idxHealthyG = L==3;
idxFaultG = L==4;

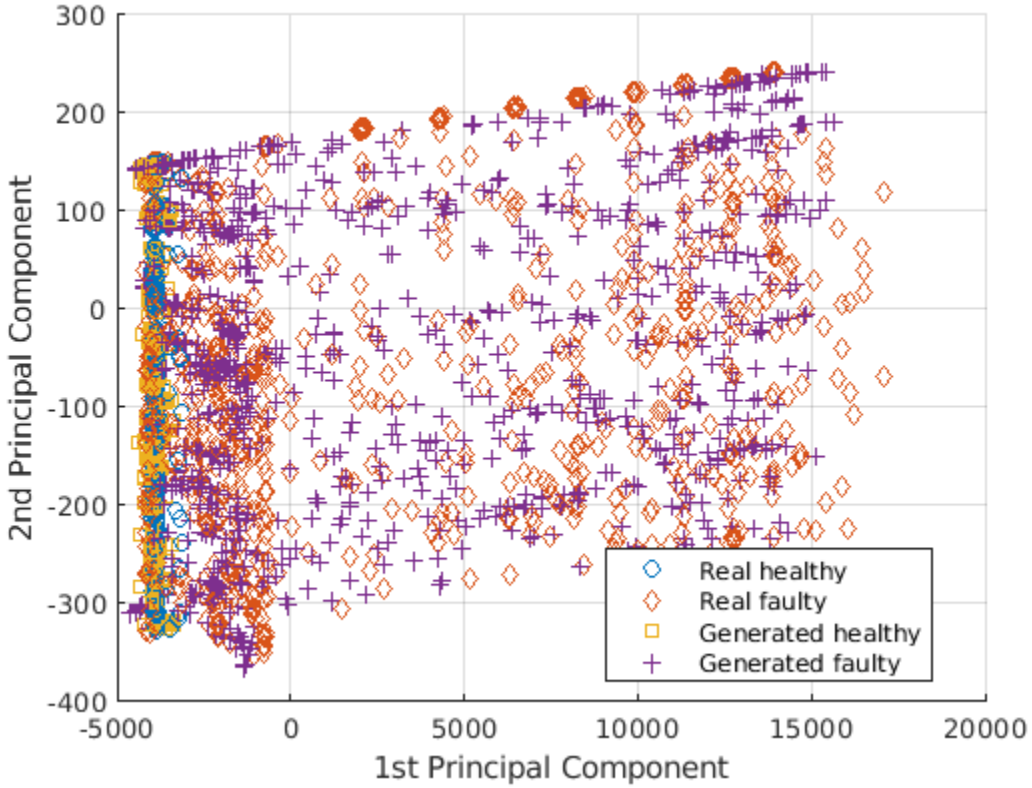
pp = Y(:,1:3);

figure
scatter3(pp(idxHealthyR,1),pp(idxHealthyR,2),pp(idxHealthyR,3),'o')
xlabel('1st Principal Component')
ylabel('2nd Principal Component')
zlabel('3rd Principal Component')
hold on
scatter3(pp(idxFaultR,1),pp(idxFaultR,2),pp(idxFaultR,3),'d')
scatter3(pp(idxHealthyG,1),pp(idxHealthyG,2),pp(idxHealthyG,3),'s')
scatter3(pp(idxFaultG,1),pp(idxFaultG,2),pp(idxFaultG,3),'+')
view(-10,20)
legend('Real healthy','Real faulty','Generated healthy','Generated faulty', ...
    'Location','Best')
hold off
```



To better capture the difference between the real signals and generated signals, plot the subspace using the first two principal components.

```
view(2)
```



Healthy and faulty signals lie in the same area of the PCA subspace regardless of their being real or generated, demonstrating that the generated signals have features similar to those of the real signals.

Predict Labels of Real Signals

To further illustrate the performance of the CGAN, train an SVM classifier based on the generated signals and then predict whether a real signal is healthy or faulty.

Set the generated signals as the training data set and the real signals as the test data set. Change the numeric labels to character vectors.

```
LABELS = {'Healthy','Faulty'};
strL = LABELS([squeeze(TNew);labels.']).';

dataTrain = features(idxGenerated,:);
dataTest = features(idxReal,:);

labelTrain = strL(idxGenerated);
labelTest = strL(idxReal);

predictors = dataTrain;
response = labelTrain;
cvp = cvpartition(size(predictors,1),'KFold',5);
```

Train an SVM classifier using the generated signals.

```
SVMClassifier = fitcsvm( ...
    predictors(cvp.training(1),:), ...
    response(cvp.training(1)),'KernelFunction','polynomial', ...
    'PolynomialOrder',2, ...
    'KernelScale','auto', ...
    'BoxConstraint',1, ...
    'ClassNames',LABELS, ...
    'Standardize',true);
```

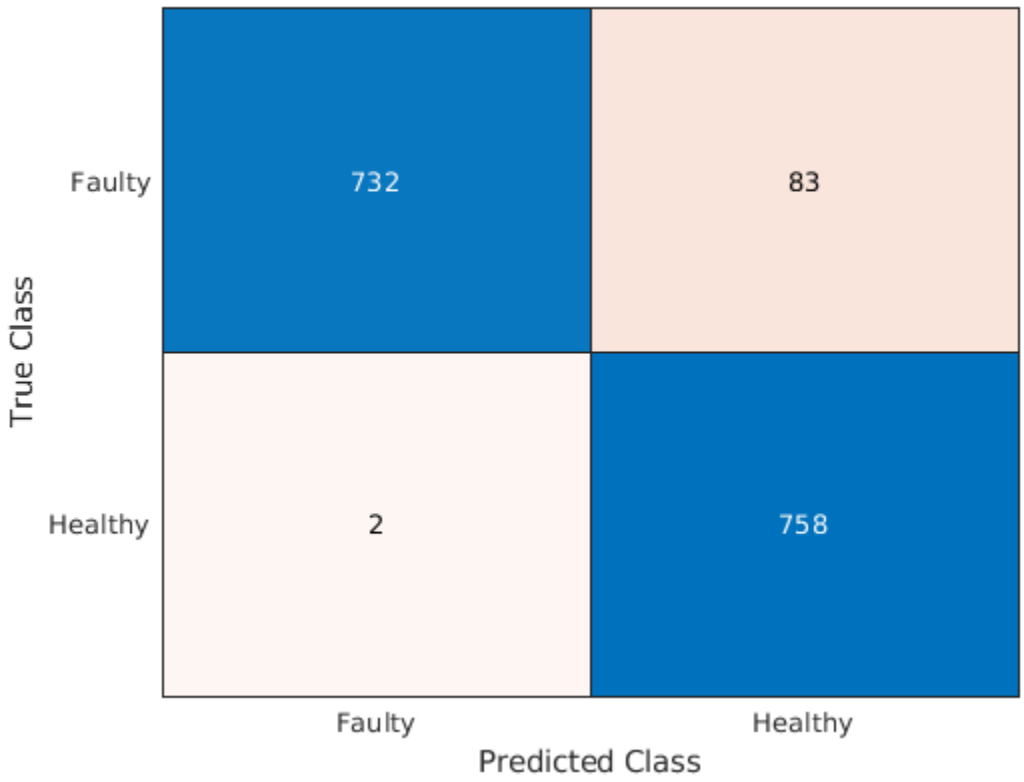
Use the trained classifier to obtain the predicted labels for the real signals. The classifier achieves a prediction accuracy above 90%.

```
actualValue = labelTest;
predictedValue = predict(SVMClassifier,dataTest);
predictAccuracy = mean(cellfun(@strcmp,actualValue,predictedValue))
```

```
predictAccuracy = 0.9460
```

Use a confusion matrix to view detailed information about prediction performance for each category. The confusion matrix shows that, in each category, the classifier trained based on the generated signals achieves a high degree of accuracy.

```
figure
confusionchart(actualValue,predictedValue)
```

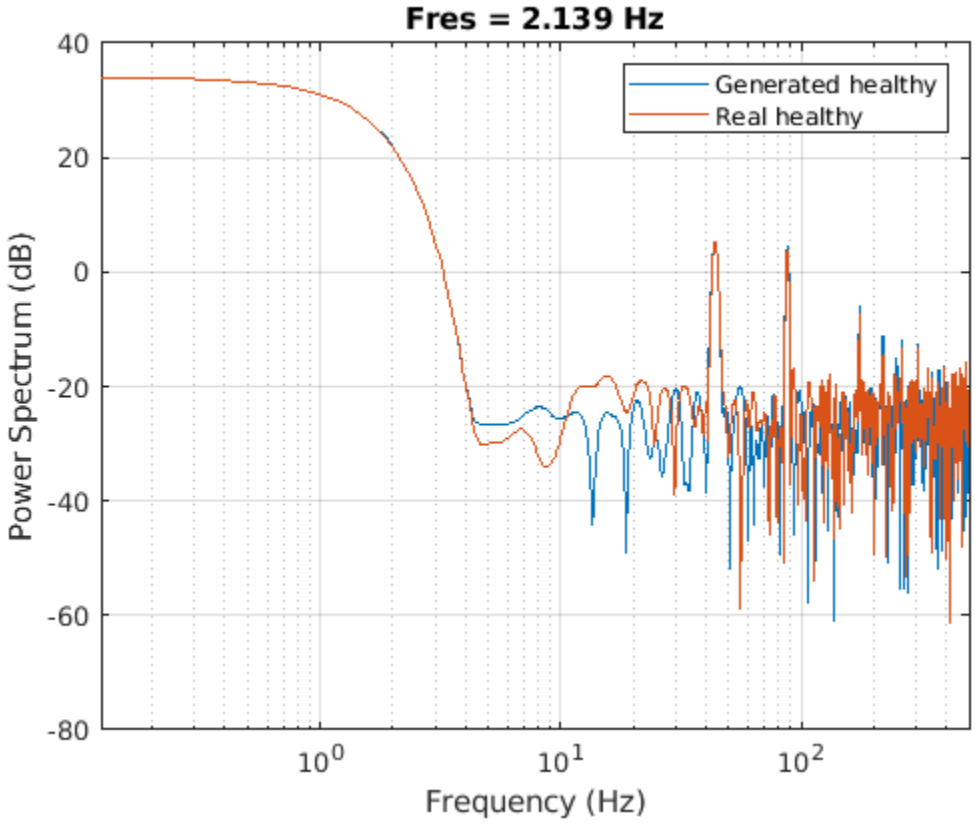


Case Study

Compare the spectral characteristics of real and generated signals. Due to the nondeterministic behavior of GPU training, if you train the CGAN model yourself, your results might differ from the results in this example.

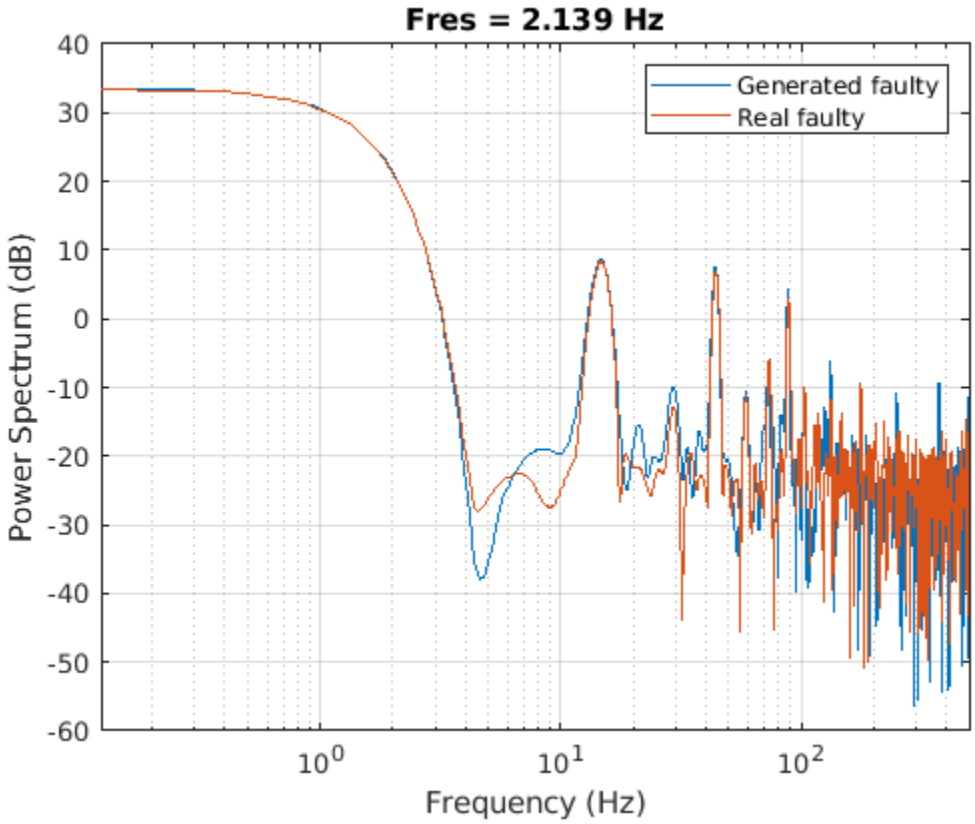
The pump motor speed is 950 rpm, or 15.833 Hz, and since the pump has three cylinders the flow is expected to have a fundamental at 3 times 15.833 Hz, or 47.5 Hz, and harmonics at multiples of 47.5 Hz. Plot the spectrum for one case of the real and generated healthy signals. From the plot, the generated healthy signal has relatively high power values at 47.5 Hz and 2 times 47.5 Hz, which is exactly the same as the real healthy signal.

```
Fs = 1000;
pspectrum([x(:,1) x(:,2006)],Fs)
set(gca,'XScale','log')
legend('Generated healthy','Real healthy')
```



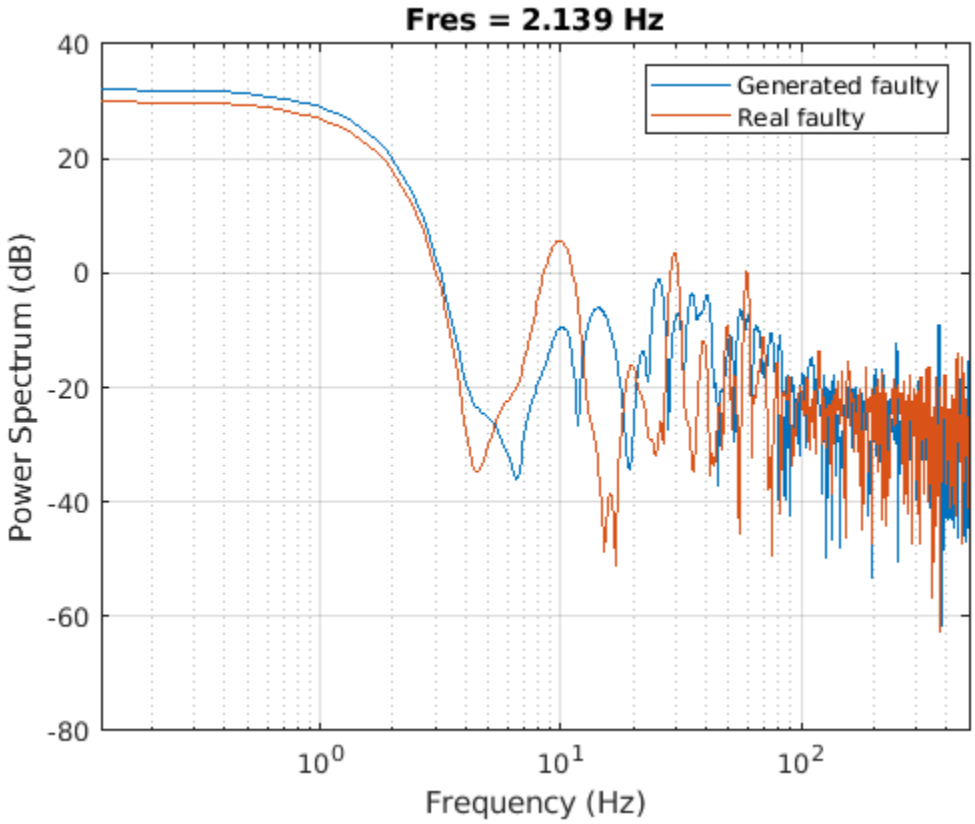
If faults exist, resonances will occur at the pump motor speed, 15.833 Hz, and its harmonics. Plot the spectra for one case of real and generated faulty signals. The generated signal has relatively high power values at around 15.833 Hz and its harmonics, which is similar to the real faulty signal.

```
pspectrum([x(:,1011) x(:,2100)],Fs)
set(gca,'XScale','log')
legend('Generated faulty','Real faulty')
```



Plot spectra for another case of real and generated faulty signals. The spectral characteristics of the generated faulty signals do not match the theoretical analysis very well and are different from the real faulty signal. The CGAN can still be possibly improved by tuning the network structure or hyperparameters.

```
pspectrum([x(:,1001) x(:,2600)],Fs)
set(gca,'XScale','log')
legend('Generated faulty','Real faulty')
```



Computation Time

The Simulink simulation takes about 14 hours to generate 2000 pump flow signals. This duration can be reduced to about 1.7 hours with eight parallel workers if you have Parallel Computing Toolbox™.

The CGAN takes 1.5 hours to train and 70 seconds to generate the same amount of synthetic data with an NVIDIA Titan V GPU.

Classify Time Series Using Wavelet Analysis and Deep Learning

This example shows how to classify human electrocardiogram (ECG) signals using the continuous wavelet transform (CWT) and a deep convolutional neural network (CNN).

Training a deep CNN from scratch is computationally expensive and requires a large amount of training data. In various applications, a sufficient amount of training data is not available, and synthesizing new realistic training examples is not feasible. In these cases, leveraging existing neural networks that have been trained on large data sets for conceptually similar tasks is desirable. This leveraging of existing neural networks is called transfer learning. In this example we adapt two deep CNNs, GoogLeNet and SqueezeNet, pretrained for image recognition to classify ECG waveforms based on a time-frequency representation.

GoogLeNet and SqueezeNet are deep CNNs originally designed to classify images in 1000 categories. We reuse the network architecture of the CNN to classify ECG signals based on images from the CWT of the time series data. The data used in this example are publicly available from PhysioNet.

Data Description

In this example, you use ECG data obtained from three groups of people: persons with cardiac arrhythmia (ARR), persons with congestive heart failure (CHF), and persons with normal sinus rhythms (NSR). In total you use 162 ECG recordings from three PhysioNet databases: MIT-BIH Arrhythmia Database [3][7], MIT-BIH Normal Sinus Rhythm Database [3], and The BIDMC Congestive Heart Failure Database [1][3]. More specifically, 96 recordings from persons with arrhythmia, 30 recordings from persons with congestive heart failure, and 36 recordings from persons with normal sinus rhythms. The goal is to train a classifier to distinguish between ARR, CHF, and NSR.

Download Data

The first step is to download the data from the GitHub repository. To download the data from the website, click `Code` and select `Download ZIP`. Save the file `physionet_ECG_data-main.zip` in a folder where you have write permission. The instructions for this example assume you have downloaded the file to your temporary directory, `tempdir`, in MATLAB. Modify the subsequent instructions for unzipping and loading the data if you choose to download the data in folder different from `tempdir`.

After downloading the data from GitHub, unzip the file in your temporary directory.

```
unzip(fullfile(tempdir,'physionet_ECG_data-main.zip'),tempdir)
```

Unzipping creates the folder `physionet-ECG_data-main` in your temporary directory. This folder contains the text file `README.md` and `ECGData.zip`. The `ECGData.zip` file contains

- `ECGData.mat`
- `Modified_physionet_data.txt`
- `License.txt`

`ECGData.mat` holds the data used in this example. The text file, `Modified_physionet_data.txt`, is required by PhysioNet's copying policy and provides the source attributions for the data as well as a description of the preprocessing steps applied to each ECG recording.

Unzip `ECGData.zip` in `physionet-ECG_data-main`. Load the data file into your MATLAB workspace.

```
unzip(fullfile(tempdir,'physionet_ECG_data-main','ECGData.zip'),...
    fullfile(tempdir,'physionet_ECG_data-main'))
load(fullfile(tempdir,'physionet_ECG_data-main','ECGData.mat'))
```

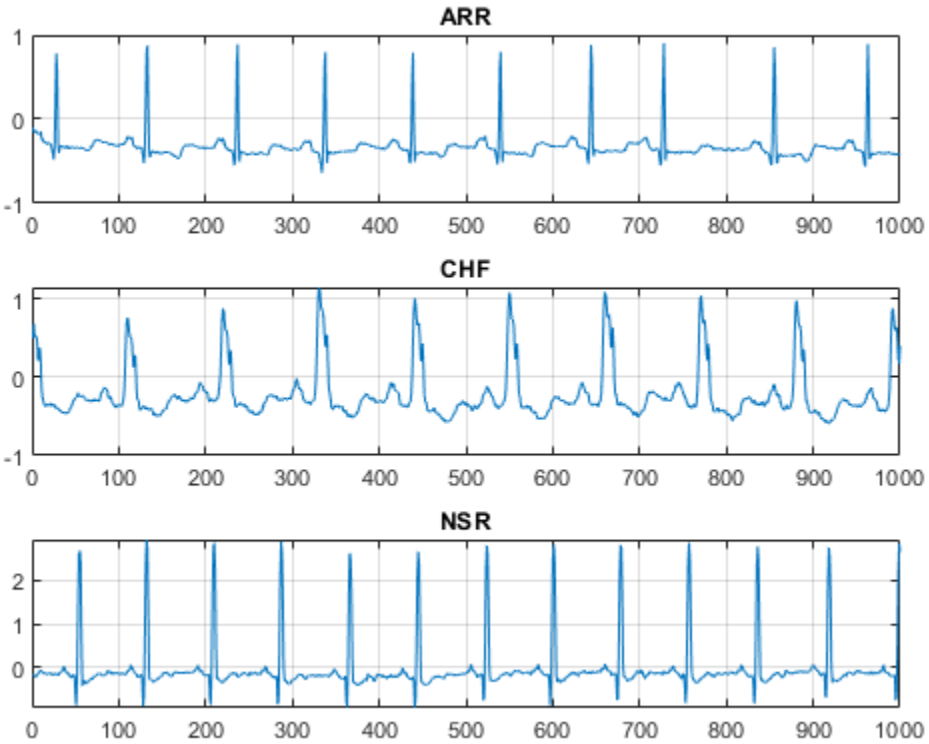
`ECGData` is a structure array with two fields: `Data` and `Labels`. The `Data` field is a 162-by-65536 matrix where each row is an ECG recording sampled at 128 hertz. `Labels` is a 162-by-1 cell array of diagnostic labels, one for each row of `Data`. The three diagnostic categories are: `'ARR'`, `'CHF'`, and `'NSR'`.

To store the preprocessed data of each category, first create an ECG data directory `dataDir` inside `tempdir`. Then create three subdirectories in `'data'` named after each ECG category. The helper function `helperCreateECGDirectories` does this. `helperCreateECGDirectories` accepts `ECGData`, the name of an ECG data directory, and the name of a parent directory as input arguments. You can replace `tempdir` with another directory where you have write permission. You can find the source code for this helper function in the Supporting Functions section at the end of this example.

```
parentDir = tempdir;
dataDir = 'data';
helperCreateECGDirectories(ECGData,parentDir,dataDir)
```

Plot a representative of each ECG category. The helper function `helperPlotReps` does this. `helperPlotReps` accepts `ECGData` as input. You can find the source code for this helper function in the Supporting Functions section at the end of this example.

```
helperPlotReps(ECGData)
```



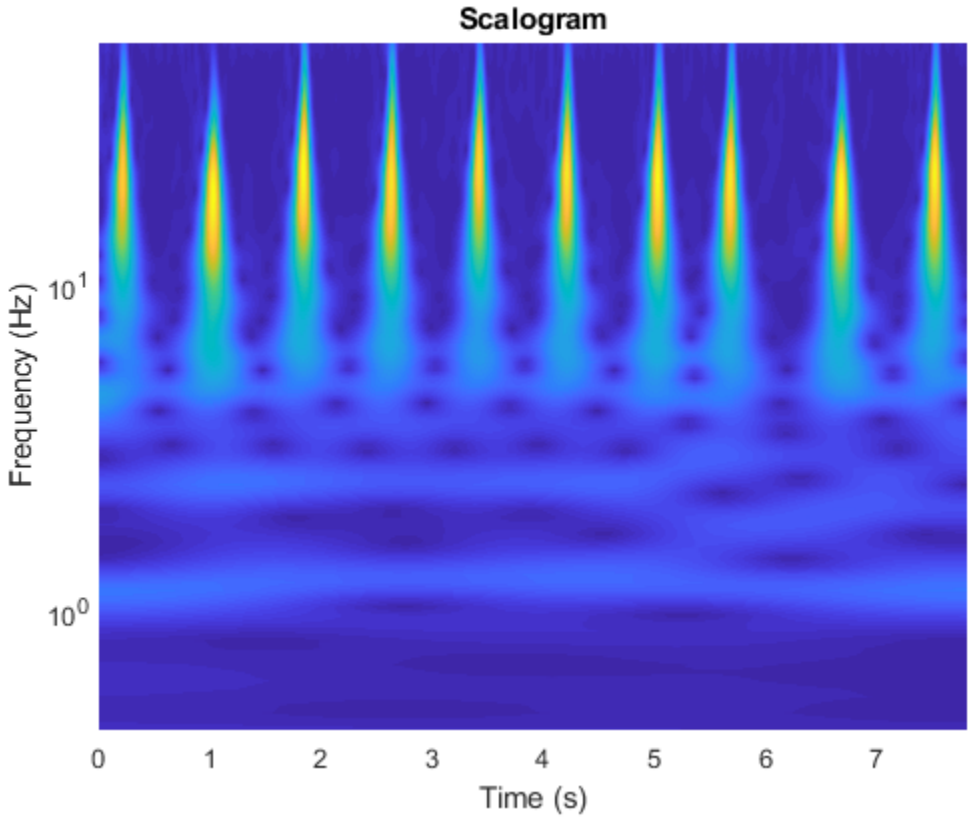
Create Time-Frequency Representations

After making the folders, create time-frequency representations of the ECG signals. These representations are called scalograms. A scalogram is the absolute value of the CWT coefficients of a signal.

To create the scalograms, precompute a CWT filter bank. Precomputing the CWT filter bank is the preferred method when obtaining the CWT of many signals using the same parameters.

Before generating the scalograms, examine one of them. Create a CWT filter bank using `cwtfilterbank` (Wavelet Toolbox) for a signal with 1000 samples. Use the filter bank to take the CWT of the first 1000 samples of the signal and obtain the scalogram from the coefficients.

```
Fs = 128;
fb = cwtfilterbank('SignalLength',1000,...
    'SamplingFrequency',Fs,...
    'VoicesPerOctave',12);
sig = ECGData.Data(1,1:1000);
[cfs,frq] = wt(fb,sig);
t = (0:999)/Fs;figure;pcolor(t,frq,abs(cfs))
set(gca,'yscale','log');shading interp;axis tight;
title('Scalogram');xlabel('Time (s)');ylabel('Frequency (Hz)')
```



Use the helper function `helperCreateRGBfromTF` to create the scalograms as RGB images and write them to the appropriate subdirectory in `dataDir`. The source code for this helper function is in the Supporting Functions section at the end of this example. To be compatible with the GoogLeNet architecture, each RGB image is an array of size 224-by-224-by-3.

```
helperCreateRGBfromTF(ECGData,parentDir,dataDir)
```

Divide into Training and Validation Data

Load the scalogram images as an image datastore. The `imageDatastore` function automatically labels the images based on folder names and stores the data as an ImageDatastore object. An image datastore enables you to store large image data, including data that does not fit in memory, and efficiently read batches of images during training of a CNN.

```
allImages = imageDatastore(fullfile(parentDir,dataDir),...
    'IncludeSubfolders',true,...
    'LabelSource','foldernames');
```

Randomly divide the images into two groups, one for training and the other for validation. Use 80% of the images for training, and the remainder for validation. For purposes of reproducibility, we set the random seed to the default value.

```
rng default
[imgsTrain,imgsValidation] = splitEachLabel(allImages,0.8,'randomized');
disp(['Number of training images: ',num2str(numel(imgsTrain.Files))]);
```

```
Number of training images: 130
```

```
disp(['Number of validation images: ',num2str(numel(imgsValidation.Files))]);
```

```
Number of validation images: 32
```

GoogLeNet

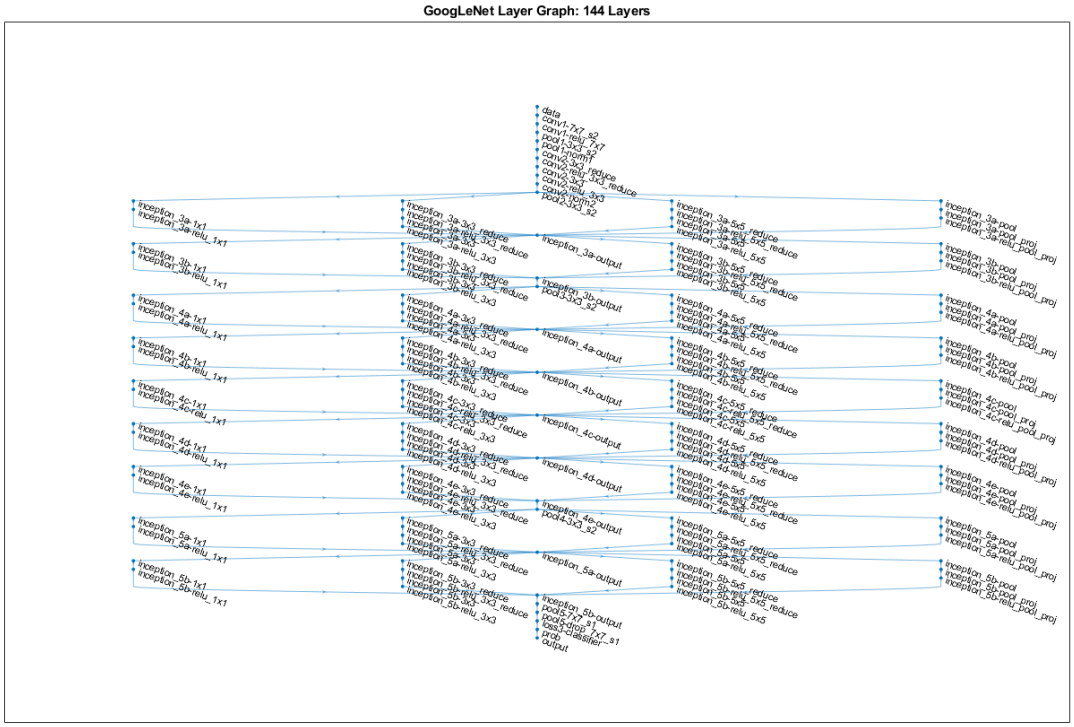
Load

Load the pretrained GoogLeNet neural network. If Deep Learning Toolbox™ Model *for GoogLeNet Network* support package is not installed, the software provides a link to the required support package in the Add-On Explorer. To install the support package, click the link, and then click **Install**.

```
net = googlenet;
```

Extract and display the layer graph from the network.

```
lgraph = layerGraph(net);
numberOfLayers = numel(lgraph.Layers);
figure('Units','normalized','Position',[0.1 0.1 0.8 0.8]);
plot(lgraph)
title(['GoogLeNet Layer Graph: ',num2str(numberOfLayers),' Layers']);
```



Inspect the first element of the network Layers property. Confirm that GoogLeNet requires RGB images of size 224-by-224-by-3.

```
net.Layers(1)
```

```
ans =
  ImageInputLayer with properties:

                 Name: 'data'
            InputSize: [224 224 3]

   Hyperparameters
    DataAugmentation: 'none'
       Normalization: 'zerocenter'
                Mean: [224×224×3 single]
```

Modify GoogLeNet Network Parameters

Each layer in the network architecture can be considered a filter. The earlier layers identify more common features of images, such as blobs, edges, and colors. Subsequent layers focus on more specific features in order to differentiate categories. GoogLeNet is pretrained to classify images into 1000 object categories. You must retrain GoogLeNet for our ECG classification problem.

To prevent overfitting, a dropout layer is used. A dropout layer randomly sets input elements to zero with a given probability. See `dropoutLayer` for more information. The default probability is 0.5.

Replace the final dropout layer in the network, `'pool5-drop_7x7_s1'`, with a dropout layer of probability 0.6.

```
newDropoutLayer = dropoutLayer(0.6,'Name','new_Dropout');
lgraph = replaceLayer(lgraph,'pool5-drop_7x7_s1',newDropoutLayer);
```

The convolutional layers of the network extract image features that the last learnable layer and final classification layer use to classify the input image. These two layers, `'loss3-classifier'` and `'output'` in GoogLeNet, contain information on how to combine the features that the network extracts into class probabilities, a loss value, and predicted labels. To retrain GoogLeNet to classify the RGB images, replace these two layers with new layers adapted to the data.

Replace the fully connected layer `'loss3-classifier'` with a new fully connected layer with the number of filters equal to the number of classes. To learn faster in the new layers than in the transferred layers, increase the learning rate factors of the fully connected layer.

```
numClasses = numel(categories(imgsTrain.Labels));
newConnectedLayer = fullyConnectedLayer(numClasses,'Name','new_fc',...
    'WeightLearnRateFactor',5,'BiasLearnRateFactor',5);
lgraph = replaceLayer(lgraph,'loss3-classifier',newConnectedLayer);
```

The classification layer specifies the output classes of the network. Replace the classification layer with a new one without class labels. `trainNetwork` automatically sets the output classes of the layer at training time.

```
newClassLayer = classificationLayer('Name','new_classoutput');
lgraph = replaceLayer(lgraph,'output',newClassLayer);
```

Set Training Options and Train GoogLeNet

Training a neural network is an iterative process that involves minimizing a loss function. To minimize the loss function, a gradient descent algorithm is used. In each iteration, the gradient of the loss function is evaluated and the descent algorithm weights are updated.

Training can be tuned by setting various options. `InitialLearnRate` specifies the initial step size in the direction of the negative gradient of the loss function. `MiniBatchSize` specifies how large of a subset of the training set to use in each iteration. One epoch is a full pass of the training algorithm over the entire training set. `MaxEpochs` specifies the maximum number of epochs to use for training. Choosing the right number of epochs is not a trivial task. Decreasing the number of epochs has the effect of underfitting the model, and increasing the number of epochs results in overfitting.

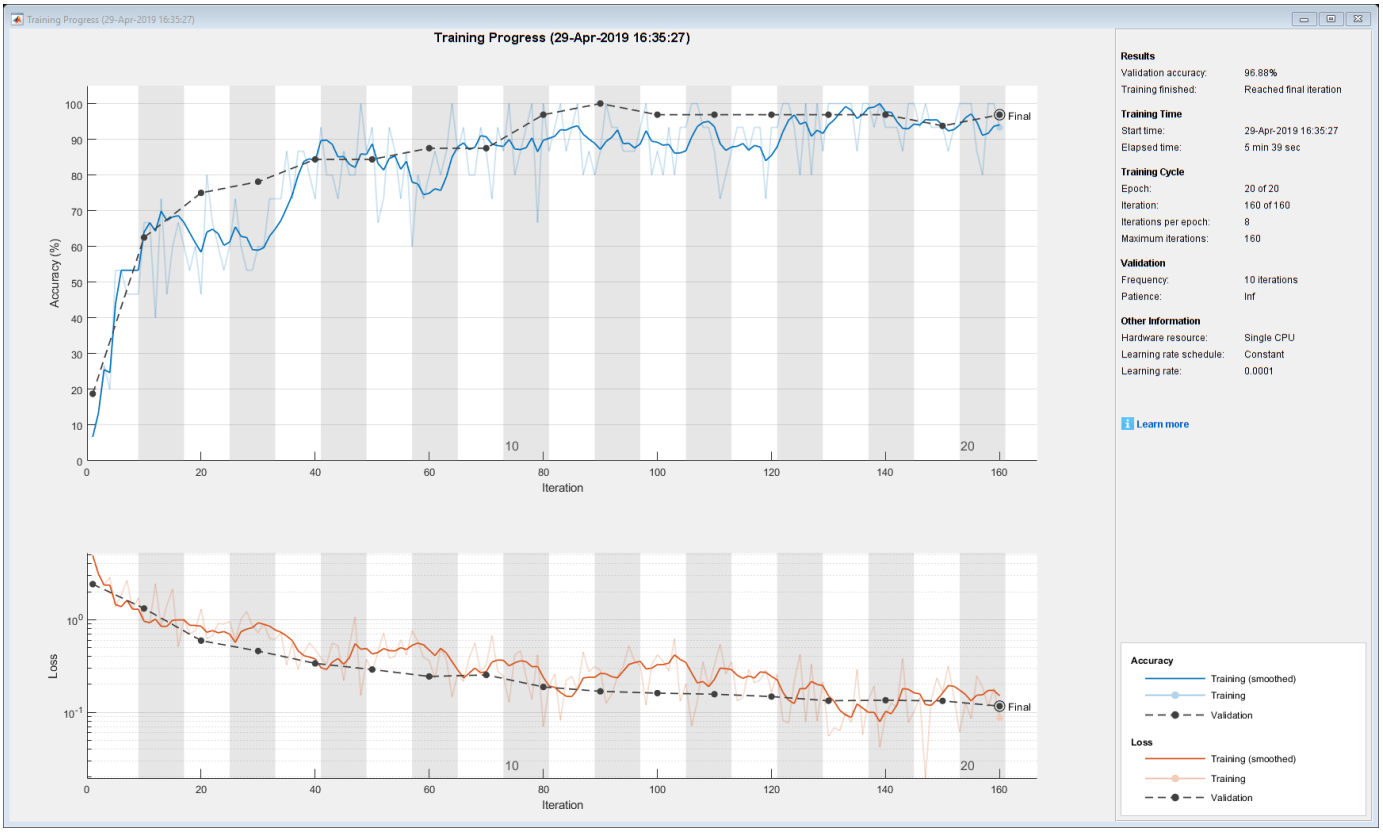
Use the `trainingOptions` function to specify the training options. Set `MiniBatchSize` to 10, `MaxEpochs` to 10, and `InitialLearnRate` to 0.0001. Visualize training progress by setting `Plots` to `training-progress`. Use the stochastic gradient descent with momentum optimizer. By default, training is done on a GPU if one is available. Using a GPU requires Parallel Computing Toolbox™. To see which GPUs are supported, see “GPU Support by Release” (Parallel Computing Toolbox). For purposes of reproducibility, set `ExecutionEnvironment` to `cpu` so that `trainNetwork` used the CPU. Set the random seed to the default value. Run times will be faster if you are able to use a GPU.

```
options = trainingOptions('sgdm',...
    'MiniBatchSize',15,...
    'MaxEpochs',20,...
    'InitialLearnRate',1e-4,...
    'ValidationData',imgsValidation,...
    'ValidationFrequency',10,...
    'Verbose',1,...
```

```
    'ExecutionEnvironment','cpu',...
    'Plots','training-progress');
rng default
```

Train the network. The training process usually takes 1-5 minutes on a desktop CPU. The command window displays training information during the run. Results include epoch number, iteration number, time elapsed, mini-batch accuracy, validation accuracy, and loss function value for the validation data.

```
trainedGN = trainNetwork(imgsTrain,lgraph,options);
```



```
Initializing input data normalization.

|=========================================================================================================
```

Inspect the last layer of the trained network. Confirm the Classification Output layer includes the three classes.

```
trainedGN.Layers(end)
```

```
ans =
  ClassificationOutputLayer with properties:

            Name: 'new_classoutput'
         Classes: [ARR    CHF    NSR]
      OutputSize: 3

   Hyperparameters
    LossFunction: 'crossentropyex'
```

Evaluate GoogLeNet Accuracy

Evaluate the network using the validation data.

```
[YPred,probs] = classify(trainedGN,imgsValidation);
accuracy = mean(YPred==imgsValidation.Labels);
disp(['GoogLeNet Accuracy: ',num2str(100*accuracy),'%'])
```

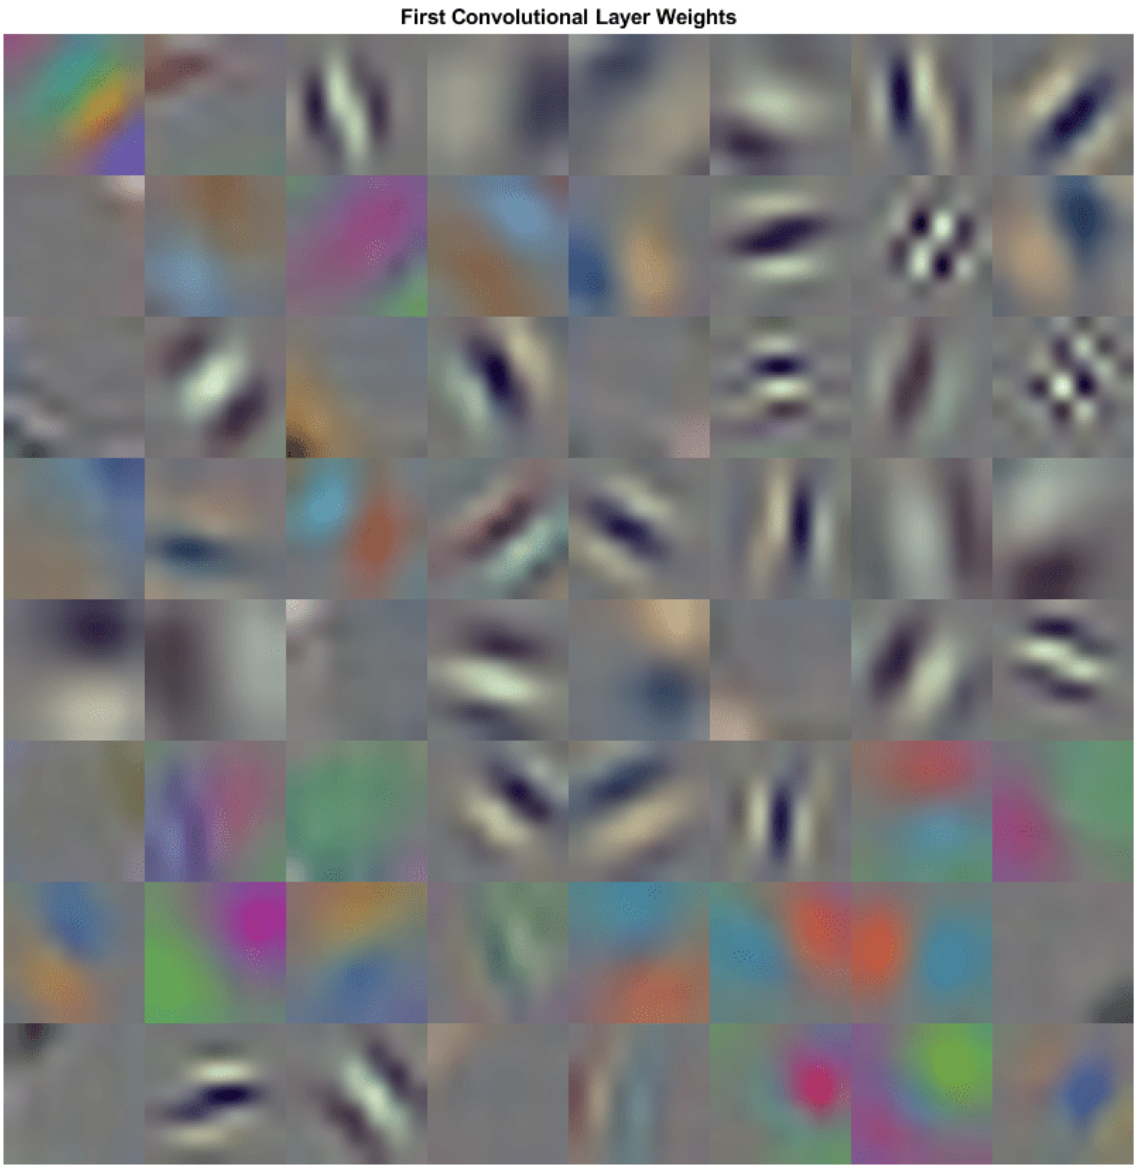
```
GoogLeNet Accuracy: 96.875%
```

The accuracy is identical to the validation accuracy reported on the training visualization figure. The scalograms were split into training and validation collections. Both collections were used to train GoogLeNet. The ideal way to evaluate the result of the training is to have the network classify data it has not seen. Since there is an insufficient amount of data to divide into training, validation, and testing, we treat the computed validation accuracy as the network accuracy.

Explore GoogLeNet Activations

Each layer of a CNN produces a response, or activation, to an input image. However, there are only a few layers within a CNN that are suitable for image feature extraction. The layers at the beginning of the network capture basic image features, such as edges and blobs. To see this, visualize the network filter weights from the first convolutional layer. There are 64 individual sets of weights in the first layer.

```
wghts = trainedGN.Layers(2).Weights;
wghts = rescale(wghts);
wghts = imresize(wghts,5);
figure
montage(wghts)
title('First Convolutional Layer Weights')
```



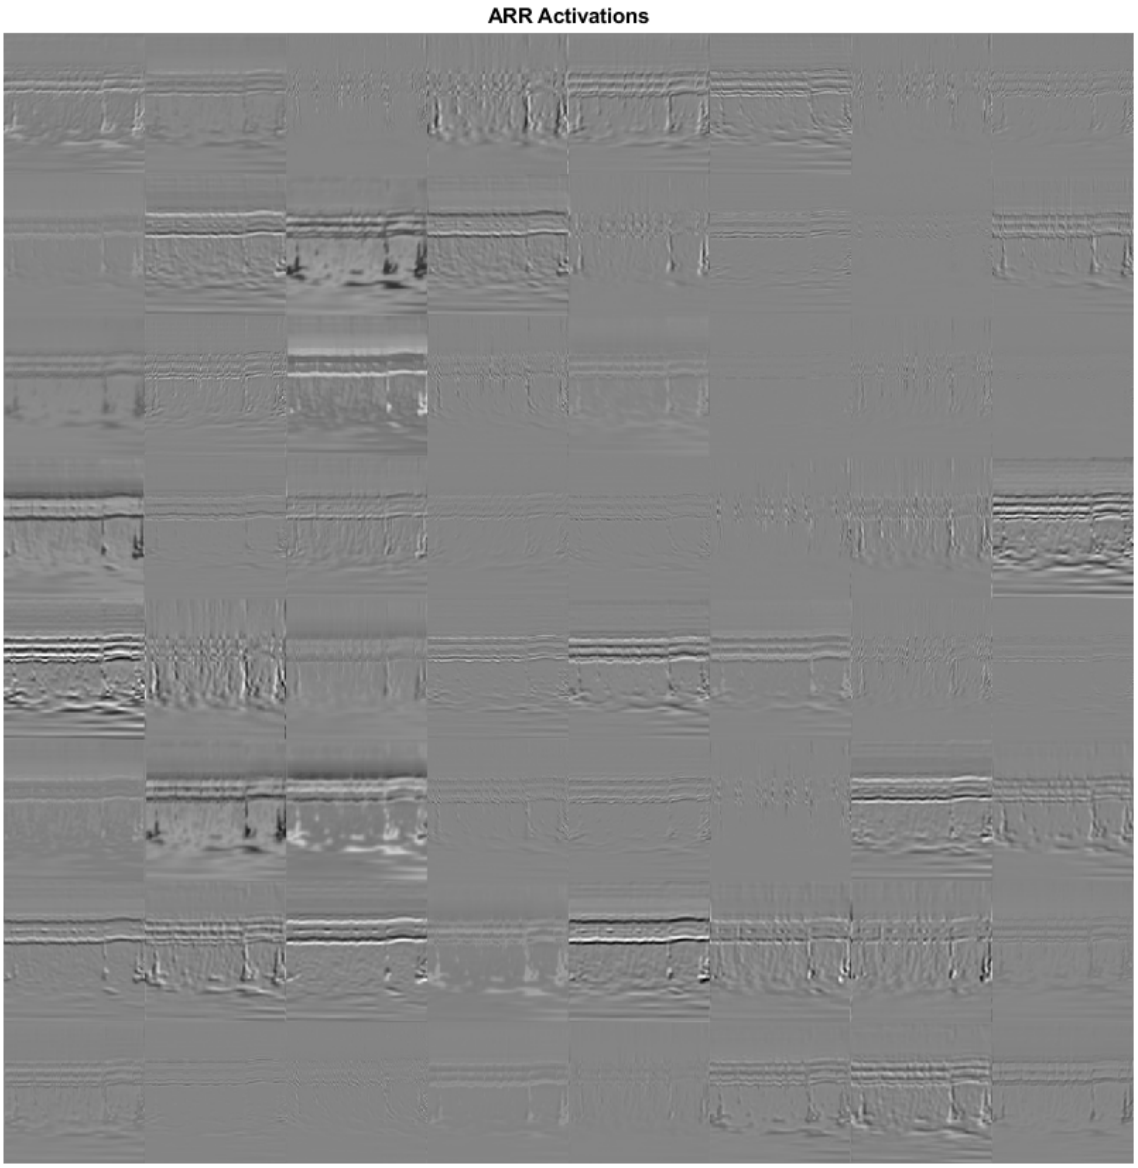
You can examine the activations and discover which features GoogLeNet learns by comparing areas of activation with the original image. For more information, see “Visualize Activations of a Convolutional Neural Network” on page 5-141 and “Visualize Features of a Convolutional Neural Network” on page 5-156.

Examine which areas in the convolutional layers activate on an image from the ARR class. Compare with the corresponding areas in the original image. Each layer of a convolutional neural network consists of many 2-D arrays called *channels*. Pass the image through the network and examine the output activations of the first convolutional layer, `'conv1-7x7_s2'`.

```
convLayer = 'conv1-7x7_s2';
```

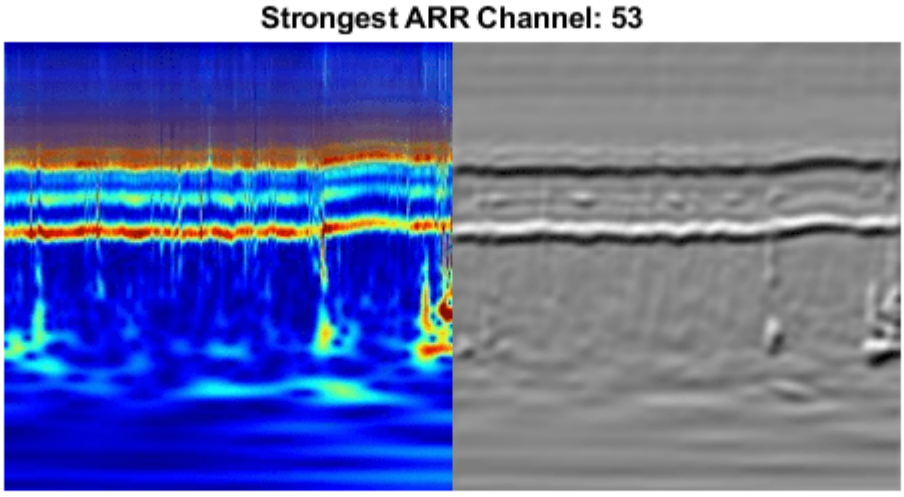
```
imgClass = 'ARR';
imgName = 'ARR_10.jpg';
imarr = imread(fullfile(parentDir,dataDir,imgClass,imgName));

trainingFeaturesARR = activations(trainedGN,imarr,convLayer);
sz = size(trainingFeaturesARR);
trainingFeaturesARR = reshape(trainingFeaturesARR,[sz(1) sz(2) 1 sz(3)]);
figure
montage(rescale(trainingFeaturesARR),'Size',[8 8])
title([imgClass,' Activations'])
```



Find the strongest channel for this image. Compare the strongest channel with the original image.

```
imgSize = size(imarr);
imgSize = imgSize(1:2);
[~,maxValueIndex] = max(max(max(trainingFeaturesARR)));
arrMax = trainingFeaturesARR(:,:,:,maxValueIndex);
arrMax = rescale(arrMax);
arrMax = imresize(arrMax,imgSize);
figure;
imshowpair(imarr,arrMax,'montage')
title(['Strongest ',imgClass,' Channel: ',num2str(maxValueIndex)])
```



SqueezeNet

SqueezeNet is a deep CNN whose architecture supports images of size 227-by-227-by-3. Even though the image dimensions are different for GoogLeNet, you do not have to generate new RGB images at the SqueezeNet dimensions. You can use the original RGB images.

Load

Load the pretrained SqueezeNet neural network. If Deep Learning Toolbox™ Model *for SqueezeNet Network* support package is not installed, the software provides a link to the required support package in the Add-On Explorer. To install the support package, click the link, and then click **Install**.

```
sqz = squeezenet;
```

Extract the layer graph from the network. Confirm SqueezeNet has fewer layers than GoogLeNet. Also confirm that SqueezeNet is configured for images of size 227-by-227-by-3

```
lgraphSqz = layerGraph(sqz);
disp(['Number of Layers: ',num2str(numel(lgraphSqz.Layers))])
```

```
Number of Layers: 68
```

```
disp(lgraphSqz.Layers(1).InputSize)
```

```
   227   227     3
```

Modify SqueezeNet Network Parameters

To retrain SqueezeNet to classify new images, make changes similar to those made for GoogLeNet.

Inspect the last six network layers.

```
lgraphSqz.Layers(end-5:end)
```

```
ans =
  6x1 Layer array with layers:

     1   'drop9'                               Dropout                 50% dropout
     2   'conv10'                              Convolution             1000 1x1x512 convolutions wi
     3   'relu_conv10'                         ReLU                    ReLU
     4   'pool10'                              Average Pooling         14x14 average pooling with s
     5   'prob'                                Softmax                 softmax
     6   'ClassificationLayer_predictions'     Classification Output   crossentropyex with 'tench'
```

Replace the `'drop9'` layer, the last dropout layer in the network, with a dropout layer of probability 0.6.

```
tmpLayer = lgraphSqz.Layers(end-5);
newDropoutLayer = dropoutLayer(0.6,'Name','new_dropout');
lgraphSqz = replaceLayer(lgraphSqz,tmpLayer.Name,newDropoutLayer);
```

Unlike GoogLeNet, the last learnable layer in SqueezeNet is a 1-by-1 convolutional layer, `'conv10'`, and not a fully connected layer. Replace the `'conv10'` layer with a new convolutional layer with the number of filters equal to the number of classes. As was done with GoogLeNet, increase the learning rate factors of the new layer.

```
numClasses = numel(categories(imgsTrain.Labels));
tmpLayer = lgraphSqz.Layers(end-4);
newLearnableLayer = convolution2dLayer(1,numClasses, ...
        'Name','new_conv', ...
        'WeightLearnRateFactor',10, ...
        'BiasLearnRateFactor',10);
lgraphSqz = replaceLayer(lgraphSqz,tmpLayer.Name,newLearnableLayer);
```

Replace the classification layer with a new one without class labels.

```
tmpLayer = lgraphSqz.Layers(end);
newClassLayer = classificationLayer('Name','new_classoutput');
lgraphSqz = replaceLayer(lgraphSqz,tmpLayer.Name,newClassLayer);
```

Inspect the last six layers of the network. Confirm the dropout, convolutional, and output layers have been changed.

```
lgraphSqz.Layers(63:68)
```

```
ans =
  6x1 Layer array with layers:

     1   'new_dropout'       Dropout                 60% dropout
     2   'new_conv'          Convolution             3 1x1 convolutions with stride [1  1] and pa
     3   'relu_conv10'       ReLU                    ReLU
     4   'pool10'            Average Pooling         14x14 average pooling with stride [1  1] and
     5   'prob'              Softmax                 softmax
     6   'new_classoutput'   Classification Output   crossentropyex
```

Prepare RGB Data for SqueezeNet

The RGB images have dimensions appropriate for the GoogLeNet architecture. Create augmented image datastores that automatically resize the existing RGB images for the SqueezeNet architecture. For more information, see `augmentedImageDatastore`.

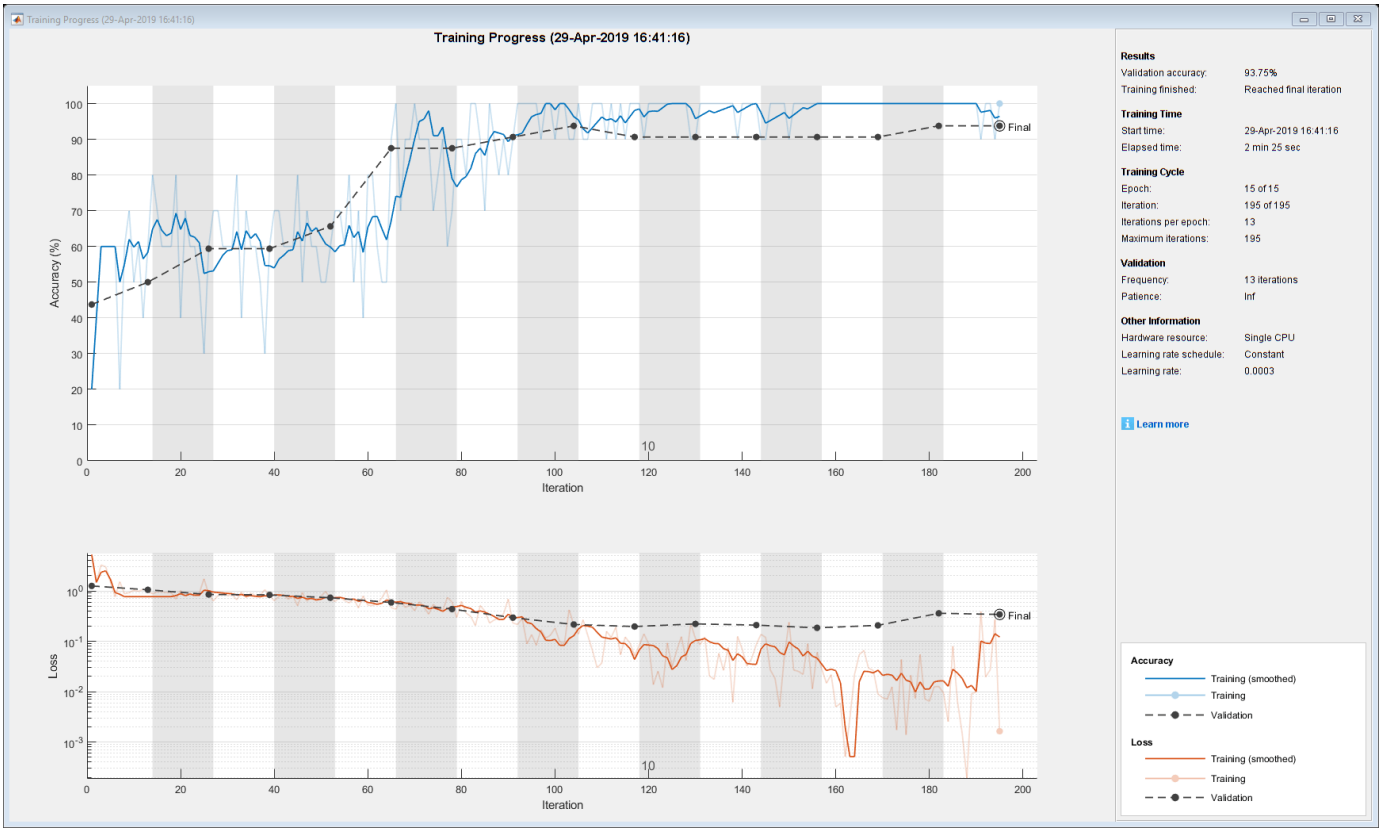
```
augimgsTrain = augmentedImageDatastore([227 227],imgsTrain);
augimgsValidation = augmentedImageDatastore([227 227],imgsValidation);
```

Set Training Options and Train SqueezeNet

Create a new set of training options to use with SqueezeNet. Set the random seed to the default value and train the network. The training process usually takes 1-5 minutes on a desktop CPU.

```
ilr = 3e-4;
miniBatchSize = 10;
maxEpochs = 15;
valFreq = floor(numel(augimgsTrain.Files)/miniBatchSize);
opts = trainingOptions('sgdm',...
    'MiniBatchSize',miniBatchSize,...
    'MaxEpochs',maxEpochs,...
    'InitialLearnRate',ilr,...
    'ValidationData',augimgsValidation,...
    'ValidationFrequency',valFreq,...
    'Verbose',1,...
    'ExecutionEnvironment','cpu',...
    'Plots','training-progress');

rng default
trainedSN = trainNetwork(augimgsTrain,lgraphSqz,opts);
```



```
Initializing input data normalization.

      OutputSize: 3

   Hyperparameters
    LossFunction: 'crossentropyex'
```

Evaluate SqueezeNet Accuracy

Evaluate the network using the validation data.

```
[YPred,probs] = classify(trainedSN,augimgsValidation);
accuracy = mean(YPred==imgsValidation.Labels);
disp(['SqueezeNet Accuracy: ',num2str(100*accuracy),'%'])
```

```
SqueezeNet Accuracy: 93.75%
```

Conclusion

This example shows how to use transfer learning and continuous wavelet analysis to classify three classes of ECG signals by leveraging the pretrained CNNs GoogLeNet and SqueezeNet. Wavelet-based time-frequency representations of ECG signals are used to create scalograms. RGB images of the scalograms are generated. The images are used to fine-tune both deep CNNs. Activations of different network layers were also explored.

This example illustrates one possible workflow you can use for classifying signals using pretrained CNN models. Other workflows are possible. “Deploy Signal Classifier on NVIDIA Jetson Using Wavelet Analysis and Deep Learning” (Wavelet Toolbox) and “Deploy Signal Classifier Using Wavelets and Deep Learning on Raspberry Pi” (Wavelet Toolbox) show how to deploy code onto hardware for signal classification. GoogLeNet and SqueezeNet are models pretrained on a subset of the ImageNet database [10], which is used in the ImageNet Large-Scale Visual Recognition Challenge (ILSVRC) [8]. The ImageNet collection contains images of real-world objects such as fish, birds, appliances, and fungi. Scalograms fall outside the class of real-world objects. In order to fit into the GoogLeNet and SqueezeNet architecture, the scalograms also underwent data reduction. Instead of fine-tuning pretrained CNNs to distinguish different classes of scalograms, training a CNN from scratch at the original scalogram dimensions is an option.

Supporting Functions

helperCreateECGDataDirectories creates a data directory inside a parent directory, then creates three subdirectories inside the data directory. The subdirectories are named after each class of ECG signal found in `ECGData`.

```
function helperCreateECGDirectories(ECGData,parentFolder,dataFolder)
% This function is only intended to support the ECGAndDeepLearningExample.
% It may change or be removed in a future release.

rootFolder = parentFolder;
localFolder = dataFolder;
mkdir(fullfile(rootFolder,localFolder))

folderLabels = unique(ECGData.Labels);
for i = 1:numel(folderLabels)
    mkdir(fullfile(rootFolder,localFolder,char(folderLabels(i))));
end
end
```

helperPlotReps plots the first thousand samples of a representative of each class of ECG signal found in `ECGData`.

```
function helperPlotReps(ECGData)
% This function is only intended to support the ECGAndDeepLearningExample.
% It may change or be removed in a future release.

folderLabels = unique(ECGData.Labels);

for k=1:3
    ecgType = folderLabels{k};
    ind = find(ismember(ECGData.Labels,ecgType));
    subplot(3,1,k)
    plot(ECGData.Data(ind(1),1:1000));
    grid on
```

```
    title(ecgType)
end
end
```

helperCreateRGBfromTF uses `cwtfilterbank` (Wavelet Toolbox) to obtain the continuous wavelet transform of the ECG signals and generates the scalograms from the wavelet coefficients. The helper function resizes the scalograms and writes them to disk as jpeg images.

```
function helperCreateRGBfromTF(ECGData,parentFolder,childFolder)
% This function is only intended to support the ECGAndDeepLearningExample.
% It may change or be removed in a future release.

imageRoot = fullfile(parentFolder,childFolder);

data = ECGData.Data;
labels = ECGData.Labels;

[~,signalLength] = size(data);

fb = cwtfilterbank('SignalLength',signalLength,'VoicesPerOctave',12);
r = size(data,1);

for ii = 1:r
    cfs = abs(fb.wt(data(ii,:)));
    im = ind2rgb(im2uint8(rescale(cfs)),jet(128));

    imgLoc = fullfile(imageRoot,char(labels(ii)));
    imFileName = strcat(char(labels(ii)),'_',num2str(ii),'.jpg');
    imwrite(imresize(im,[224 224]),fullfile(imgLoc,imFileName));
end
end
```

Deploy Signal Classifier on NVIDIA Jetson Using Wavelet Analysis and Deep Learning

This example shows how to generate and deploy a CUDA® executable that classifies human electrocardiogram (ECG) signals using features extracted by the continuous wavelet transform (CWT) and a pretrained convolutional neural network (CNN).

SqueezeNet is a deep CNN originally designed to classify images in 1000 categories. We reuse the network architecture of the CNN to classify ECG signals based on their scalograms. A scalogram is the absolute value of the CWT of the signal. After training SqueezeNet to classify ECG signals, you create a CUDA executable that generates a scalogram of an ECG signal and then uses the CNN to classify the signal. The executable and CNN are both deployed to the NVIDIA hardware.

This example uses the same data as used in “Classify Time Series Using Wavelet Analysis and Deep Learning” (Wavelet Toolbox). In that example, transfer learning with GoogLeNet and SqueezeNet are used to classify ECG waveforms into one of three categories. The description of the data and how to obtain it are repeated here for convenience.

ECG Data Description and Download

The ECG data is obtained from three groups of people: persons with cardiac arrhythmia (ARR), persons with congestive heart failure (CHF), and persons with normal sinus rhythms (NSR). In total there are 162 ECG recordings from three PhysioNet databases: MIT-BIH Arrhythmia Database [2][3], MIT-BIH Normal Sinus Rhythm Database [3], and The BIDMC Congestive Heart Failure Database [1] [3]. More specifically, 96 recordings from persons with arrhythmia, 30 recordings from persons with congestive heart failure, and 36 recordings from persons with normal sinus rhythms. The goal is to train a model to distinguish between ARR, CHF, and NSR.

You can obtain this data from the MathWorks GitHub repository. To download the data from the website, click `Code` and select `Download ZIP`. Save the file `physionet_ECG_data-main.zip` in a folder where you have write permission. The instructions for this example assume you have downloaded the file to your temporary directory, `tempdir`, in MATLAB. Modify the subsequent instructions for unzipping and loading the data if you choose to download the data in a folder different from `tempdir`.

After downloading the data from GitHub, unzip the file in your temporary directory.

```
unzip(fullfile(tempdir,'physionet_ECG_data-main.zip'),tempdir)
```

Unzipping creates the folder `physionet-ECG_data-main` in your temporary directory. This folder contains the text file `README.md` and `ECGData.zip`. The `ECGData.zip` file contains:

- `ECGData.mat`
- `Modified_physionet_data.txt`
- `License.txt`

`ECGData.mat` holds the data used in this example. The text file `Modified_physionet_data.txt` is required by PhysioNet's copying policy and provides the source attributions for the data as well as a description of the preprocessing steps applied to each ECG recording.

Unzip `ECGData.zip` in `physionet-ECG_data-main`. Load the data file into your MATLAB workspace.

```
unzip(fullfile(tempdir,'physionet_ECG_data-main','ECGData.zip'),...
    fullfile(tempdir,'physionet_ECG_data-main'))
load(fullfile(tempdir,'physionet_ECG_data-main','ECGData.mat'))
```

ECGData is a structure array with two fields: `Data` and `Labels`. The `Data` field is a 162-by-65536 matrix where each row is an ECG recording sampled at 128 hertz. `Labels` is a 162-by-1 cell array of diagnostic labels, one label for each row of `Data`. The three diagnostic categories are: `'ARR'`, `'CHF'`, and `'NSR'`.

Feature Extraction

After downloading the data, you must generate scalograms of the signals. The scalograms are the "input" images to the CNN.

To store the scalograms of each category, first create an ECG data directory `'data'` inside `tempdir`. Then create three subdirectories in `'data'` named after each ECG category. The helper function `helperCreateECGDirectories` does this for you. `helperCreateECGDirectories` accepts `ECGData`, the name of an ECG data directory, and the name of a parent directory as input arguments. You can replace `tempdir` with another directory where you have write permission. You can find the source code for this helper function in the Supporting Functions on page 12-0 section at the end of this example.

```
parentDir = tempdir;
dataDir = 'data';
helperCreateECGDirectories(ECGData,parentDir,dataDir)
```

After making the folders, create scalograms of the ECG signals as RGB images and write them to the appropriate subdirectory in `dataDir`. To create the scalograms, first precompute a CWT filter bank. Precomputing the filter bank is the preferred method when obtaining the CWT of many signals using the same parameters. The helper function `helperCreateRGBfromTF` does this.The source code for this helper function is in the Supporting Functions on page 12-0 section at the end of this example. To be compatible with the SqueezeNet architecture, each RGB image is an array of size 227-by-227-by-3.

```
helperCreateRGBfromTF(ECGData,parentDir,dataDir)
```

Divide Data Set into Training and Validation Data

Load the scalogram images as an image datastore. The `imageDatastore` function automatically labels the images based on folder names and stores the data as an `ImageDatastore` object. An image datastore enables you to store large image data, including data that does not fit in memory, and efficiently read batches of images when training a CNN.

```
allImages = imageDatastore(fullfile(tempdir,dataDir),...
    'IncludeSubfolders',true,...
    'LabelSource','foldernames');
```

Randomly divide the images into two groups, one for training and the other for validation. Use 80% of the images for training and the remainder for validation. For purposes of reproducibility, we set the random seed to the default value.

```
rng default
[imgsTrain,imgsValidation] = splitEachLabel(allImages,0.8,'randomized');
disp(['Number of training images: ',num2str(numel(imgsTrain.Files))]);
```

```
Number of training images: 130
```

```
disp(['Number of validation images: ',num2str(numel(imgsValidation.Files))]);
```

```
Number of validation images: 32
```

SqueezeNet

SqueezeNet is a pretrained CNN that can classify images into 1000 categories. You need to retrain SqueezeNet for our ECG classification problem. Prior to retraining, you modify several network layers and set various training options. After retraining is complete, you save the CNN in a `.mat` file. The CUDA executable will use the `.mat` file.

Specify an experiment trial index and a results directory. If necessary, create the directory.

```
trial = 1;
ResultDir = 'results';
if ~exist(ResultDir,'dir')
    mkdir(ResultDir)
end
MatFile = fullfile(ResultDir,sprintf('SqueezeNet_Trial%d.mat',trial));
```

Load SqeezeNet. Extract the layer graph and inspect the last five layers.

```
sqz = squeezenet;
lgraph = layerGraph(sqz);
lgraph.Layers(end-4:end)
```

```
ans =
  5×1 Layer array with layers:

     1   'conv10'                            Convolution              1000 1×1×512 convolutions w
     2   'relu_conv10'                       ReLU                     ReLU
     3   'pool10'                            Global Average Pooling   Global average pooling
     4   'prob'                              Softmax                  softmax
     5   'ClassificationLayer_predictions'   Classification Output    crossentropyex with 'tench
```

To retrain SqueezeNet to classify the three classes of ECG signals, replace the `'conv10'` layer with a new convolutional layer with the number of filters equal to the number of ECG classes. Replace the classification layer with a new one without class labels.

```
numClasses = numel(categories(imgsTrain.Labels));
new_conv10_WeightLearnRateFactor = 1;
new_conv10_BiasLearnRateFactor = 1;
newConvLayer = convolution2dLayer(1,numClasses,...
        'Name','new_conv10',...
        'WeightLearnRateFactor',new_conv10_WeightLearnRateFactor,...
        'BiasLearnRateFactor',new_conv10_BiasLearnRateFactor);
lgraph = replaceLayer(lgraph,'conv10',newConvLayer);
newClassLayer = classificationLayer('Name','new_classoutput');
lgraph = replaceLayer(lgraph,'ClassificationLayer_predictions',newClassLayer);
lgraph.Layers(end-4:end)
```

```
ans =
  5×1 Layer array with layers:

     1   'new_conv10'        Convolution              3 1×1 convolutions with stride [1  1] and p
     2   'relu_conv10'       ReLU                     ReLU
     3   'pool10'            Global Average Pooling   Global average pooling
     4   'prob'              Softmax                  softmax
     5   'new_classoutput'   Classification Output    crossentropyex
```

Create a set of training options to use with SqueezeNet.

```
OptimSolver = 'sgdm';
MiniBatchSize = 15;
MaxEpochs = 20;
InitialLearnRate = 1e-4;
Momentum = 0.9;
ExecutionEnvironment = 'cpu';

options = trainingOptions(OptimSolver,...
    'MiniBatchSize',MiniBatchSize,...
    'MaxEpochs',MaxEpochs,...
    'InitialLearnRate',InitialLearnRate,...
    'ValidationData',imgsValidation,...
    'ValidationFrequency',10,...
    'ExecutionEnvironment',ExecutionEnvironment,...
    'Momentum',Momentum);
```

Save all the parameters in a structure. The trained network and structure will be later saved in a `.mat` file.

```
TrialParameter.new_conv10_WeightLearnRateFactor = new_conv10_WeightLearnRateFactor;
TrialParameter.new_conv10_BiasLearnRateFactor = new_conv10_BiasLearnRateFactor;
TrialParameter.OptimSolver = OptimSolver;
TrialParameter.MiniBatchSize = MiniBatchSize;
TrialParameter.MaxEpochs = MaxEpochs;
TrialParameter.InitialLearnRate = InitialLearnRate;
TrialParameter.Momentum = Momentum;
TrialParameter.ExecutionEnvironment = ExecutionEnvironment;
```

Set the random seed to the default value and train the network. Save the trained network, trial parameters, training run time, and image datastore containing the validation images. The training process usually takes 1-5 minutes on a desktop CPU. If you want to use a trained CNN from a previous trial, set `trial` to the index number of that trial and `LoadModel` to `true`.

```
LoadModel = false;
if ~LoadModel
    rng default
    tic;
    trainedModel = trainNetwork(imgsTrain,lgraph,options);
    trainingTime = toc;
    fprintf('Total training time: %.2e sec\n',trainingTime);
    save(MatFile,'TrialParameter','trainedModel','trainingTime','imgsValidation');
else
    disp('Load ML model from the file')
    load(MatFile,'trainedModel','imgsValidation');
end
```

```
Initializing input data normalization.

Average prediction time (execution environment: cpu): 2.94e-02 sec
```

Save the results.

```
if ~LoadModel
    save(MatFile,'accuracy','confusionMat','PredTime','ModelMemSize', ...
        'AvgPredTimePerImage','-append')
end
```

GPU Code Generation — Define Functions

The scalogram of a signal is the input "image" to a deep CNN. Create a function, `cwt_ecg_jetson_ex`, that computes the scalogram of an input signal and returns an image at the user-specified dimensions. The image uses the `jet(128)` colormap. The `%#codegen` directive in the function indicates that the function is intended for code generation. When using the `coder.gpu.kernelfun` pragma, code generation attempts to map the computations in the `cwt_ecg_jetson_ex` function to the GPU.

```
type cwt_ecg_jetson_ex.m
```

```
function im = cwt_ecg_jetson_ex(TimeSeriesSignal, ImgSize) %#codegen
% This function is only intended to support wavelet deep learning examples.
% It may change or be removed in a future release.

coder.gpu.kernelfun();

%% Create Scalogram
cfs = cwt(TimeSeriesSignal, 'morse', 1, 'VoicesPerOctave', 12);
cfs = abs(cfs);

%% Image generation
cmapj128 = coder.load('cmapj128');
imx = ind2rgb_custom_ecg_jetson_ex(round(255*rescale(cfs))+1,cmapj128.cmapj128);

% resize to proper size and convert to uint8 data type
im = im2uint8(imresize(imx, ImgSize));

end
```

Create the entry-point function, `model_predict_ecg.m`, for code generation. The function takes an ECG signal as input and calls the `cwt_ecg_jetson_ex` function to create an image of the scalogram. The `model_predict_ecg` function uses the network contained in the `ecg_model.mat` file to classify the ECG signal.

```
type model_predict_ecg.m
```

```
function PredClassProb = model_predict_ecg(TimeSeriesSignal) %#codegen
% This function is only intended to support wavelet deep learning examples.
% It may change or be removed in a future release.
    coder.gpu.kernelfun();

    % parameters
    ModFile = 'ecg_model.mat'; % file that saves neural network model
    ImgSize = [227 227]; % input image size for the ML model
```

```
    % sanity check signal is a row vector of correct length
    assert(isequal(size(TimeSeriesSignal), [1 65536]))
    %% cwt transformation for the signal
    im = cwt_ecg_jetson_ex(TimeSeriesSignal, ImgSize);

    %% model prediction
    persistent model;
    if isempty(model)
        model = coder.loadDeepLearningNetwork(ModFile, 'mynet');
    end

    PredClassProb = predict(model, im);

end
```

To generate a CUDA executable that can be deployed to an NVIDIA target, create a custom main file (`main_ecg_jetson_ex.cu`) and a header file (`main_ecg_jetson_ex.h`). You can generate an example main file and use that as a template to rewrite new main and header files. For more information, see the `GenerateExampleMain` property of `coder.CodeConfig` (MATLAB Coder). The main file calls the code generated for the MATLAB entry-point function. The main file first reads the ECG signal from a text file, passes the data to the entry-point function, and writes the prediction results to a text file (`predClassProb.txt`). To maximize computation efficiency on the GPU, the executable processes single-precision data.

```
type main_ecg_jetson_ex.cu
```

```
//
// File: main_ecg_jetson_ex.cu
//
// This file is only intended to support wavelet deep learning examples.
// It may change or be removed in a future release.

GPU Code Generation — Specify Target

To create an executable that can be deployed to the target device, set `CodeGenMode` equal to 1. If you want to create an executable that runs locally and connects remotely to the target device, set `CodeGenMode` equal to 2.

The `main` function reads data from the text file specified by `signalFile` and writes the classification results to `resultFile`. Set `ExampleIndex` to choose a representative ECG signal. You will use this signal to test the executable against the `classify` function. `Jetson_BuildDir` specifies the directory for performing the remote build process on the target. If the specified build directory does not exist on the target, then the software creates a directory with the given name.

```
CodeGenMode = 1;
signalFile = 'signalData.txt';
resultFile = 'predClassProb.txt'; % consistent with "main_ecg_jetson_ex.cu"
Jetson_BuildDir = '~/projectECG';
ExampleIndex = 1; % 1,4: type ARR; 2,5: type CHF; 3,6: type NSR

Function_to_Gen = 'model_predict_ecg';
ModFile = 'ecg_model.mat'; % file that saves neural network model; consistent with "main_ecg_jets
ImgSize = [227 227]; % input image size for the ML model

switch ExampleIndex
    case 1 % ARR 7
        SampleSignalIdx = 7;
    case 2 % CHF 97
        SampleSignalIdx = 97;
    case 3 % NSR 132
        SampleSignalIdx = 132;
    case 4 % ARR 31
        SampleSignalIdx = 31;
    case 5 % CHF 101
```

```
        SampleSignalIdx = 101;
    case 6 % NSR 131
        SampleSignalIdx = 131;
end
signal_data = single(ECGData.Data(SampleSignalIdx,:));
ECGtype = ECGData.Labels{SampleSignalIdx};
```

GPU Code Generation — Connect to Hardware

To communicate with the NVIDIA hardware, you create a live hardware connection object using the `jetson` function. You must know the host name or IP address, username, and password of the target board to create a live hardware connection object.

Create a live hardware connection object for the Jetson hardware. During the hardware live object creation checking of hardware, IO server installation and gathering peripheral information on target are performed. This information is displayed in the Command Window.

```
hwobj = jetson('gpucoder-nano-2','ubuntu','ubuntu');
```

        deepcodeexec: 0
    tensorrtdatatype: 0
```

```
            profiling: 0
```

GPU Code Generation — Compile

Create a GPU code configuration object necessary for compilation. Use the `coder.hardware` function to create a configuration object for the Jetson platform and assign it to the `Hardware` property of the code configuration object `cfg`. Use `'NVIDIA Jetson'` for the Jetson TX1 or TX2 boards. The custom main file is a wrapper that calls the entry-point function in the generated code. The custom file is required for a deployed executable.

Use the `coder.DeepLearningConfig` (GPU Coder) function to create a `CuDNN` deep learning configuration object and assign it to the `DeepLearningConfig` property of the GPU code configuration object. The code generator takes advantage of NVIDIA® CUDA® deep neural network library (cuDNN) for NVIDIA GPUs. cuDNN is a GPU-accelerated library of primitives for deep neural networks.

```
if CodeGenMode == 1
    cfg = coder.gpuConfig('exe');
    cfg.Hardware = coder.hardware('NVIDIA Jetson');
    cfg.Hardware.BuildDir = Jetson_BuildDir;
    cfg.DeepLearningConfig = coder.DeepLearningConfig('cudnn');
    cfg.CustomSource = fullfile('main_ecg_jetson_ex.cu');
elseif CodeGenMode == 2
    cfg = coder.gpuConfig('lib');
    cfg.VerificationMode = 'PIL';
    cfg.Hardware = coder.hardware('NVIDIA Jetson');
    cfg.Hardware.BuildDir = Jetson_BuildDir;
    cfg.DeepLearningConfig = coder.DeepLearningConfig('cudnn');
end
```

To generate CUDA code, use the `codegen` function and pass the GPU code configuration along with the size and type of the input for the `model_predict_ecg` entry-point function. After code generation on the host is complete, the generated files are copied over and built on the target.

```
codegen('-config ',cfg,Function_to_Gen,'-args',{signal_data},'-report');
```

```
Code generation successful: View report
```

GPU Code Generation — Execute

If you compiled an executable to be deployed to the target, write the example ECG signal to a text file. Use the `putFile()` function of the hardware object to place the text file on the target. The `workspaceDir` property contains the path to the `codegen` folder on the target.

```
if CodeGenMode == 1
    fid = fopen(signalFile,'w');
    for i = 1:length(signal_data)
        fprintf(fid,'%f\n',signal_data(i));
    end
    fclose(fid);
    hwobj.putFile(signalFile,hwobj.workspaceDir);
end
```

Run the executable.

When running the deployed executable, delete the previous result file if it exists. Use the `runApplication()` function to launch the executable on the target hardware, and then the

`getFile()` function to retrieve the results. Because the results may not exist immediately after the `runApplication()` function call returns, and to allow for communication delays, set a maximum time for fetching the results to 90 seconds. Use the `evalc` function to suppress the command-line output.

```
if CodeGenMode == 1 % run deployed executable
    maxFetchTime = 90;
    resultFile_hw = fullfile(hwobj.workspaceDir,resultFile);
    if ispc
        resultFile_hw = strrep(resultFile_hw,'\','/');
    end

    ta = tic;

    hwobj.deleteFile(resultFile_hw)
    hwobj.runApplication(Function_to_Gen,signalFile);

    tf = tic;
    success = false;
    while toc(tf) < maxFetchTime
        try
            evalc('hwobj.getFile(resultFile_hw)');
            success = true;
        catch ME
        end
        if success
            break
        end
    end
    fprintf('Fetch time = %.3e sec\n',toc(tf));
    assert(success,'Unable to fetch the prediction')
    PredClassProb = readmatrix(resultFile);
    PredTime = toc(ta);
elseif CodeGenMode == 2 % run PIL executable
    ta = tic;
    eval(sprintf('PredClassProb = %s_pil(signal_data);',Function_to_Gen));
    PredTime = toc(ta);
    eval(sprintf('clear %s_pil;',Function_to_Gen)); % terminate PIL execution
end

### Launching the executable on the target...

Close the hardware connection.

```
clear hwobj
```

Summary

This example shows how to create and deploy a CUDA executable that uses a CNN to classify ECG signals. You also have the option to create an executable the runs locally and connects to the remote target. A complete workflow is presented in this example. After the data is downloaded, the CWT is used to extract features from the ECG signals. Then SqueezeNet is retrained to classify the signals based on their scalograms. Two user-defined functions are created and compiled on the target NVIDIA device. Results of the executable are compared with MATLAB.

More About

- “GPU Acceleration of Scalograms for Deep Learning” (Wavelet Toolbox)

Deploy Signal Classifier Using Wavelets and Deep Learning on Raspberry Pi

This example shows the workflow to classify human electrocardiogram (ECG) signals using the Continuous Wavelet Transform (CWT) and a deep convolutional neural network (CNN). This example also provides information on how to generate and deploy the code and CNN for prediction on a Raspberry Pi target (ARM®-based device).

SqueezeNet is a deep CNN originally designed to classify images in 1000 categories. In the example "Classify Time Series Using Wavelet Analysis and Deep Learning" (Wavelet Toolbox), SqueezeNet is retrained to classify ECG waveforms based on their *scalograms*. A scalogram is a time-frequency representation of the signal and is the absolute value of the CWT of the signal. We reuse the retrained SqueezeNet in this example.

ECG Data Description

In this example, ECG data from PhysioNet is used. The ECG data is obtained from three groups of people: persons with cardiac arrhythmia (ARR), persons with congestive heart failure (CHF), and persons with normal sinus rhythms (NSR). The data set includes 96 recordings from persons with ARR, 30 recordings from persons with CHF, and 36 recordings from persons with NSR. The 162 ECG recordings are from three PhysioNet databases: MIT-BIH Arrhythmia Database [2][3], MIT-BIH Normal Sinus Rhythm Database [3], and The BIDMC Congestive Heart Failure Database [1][3]. Shortened ECG data of the above references can be downloaded from the GitHub repository.

Prerequisites

- ARM processor that supports the NEON extension
- ARM Compute Library version 19.05 (on the target ARM hardware)
- Environment variables for the compilers and libraries
- MATLAB Support Package for Raspberry Pi Hardware
- MATLAB Coder Interface for Deep Learning Libraries support package

For supported versions of libraries and for information about setting up environment variables, see "Prerequisites for Deep Learning with MATLAB Coder" (MATLAB Coder). This example is not supported in MATLAB Online™.

Functionality of Generated Code

The core function in the generated executable, `processECG`, uses 65,536 samples of single-precision ECG data as input. The function:

1. Takes the CWT of the ECG data.
2. Obtains scalogram from wavelet coefficients.
3. Converts the scalogram to an RGB mage of dimension 227-by-227-by-3. This makes the image compatible with the SqueezeNet network architecture.
4. Performs prediction to classify the image using SqueezeNet.

```
type processECG
```

```
function [YPred] = processECG(input)
% processECG function - converts 1D ECG to image and predicts the syndrome
% of heart disease
```

```
%
% This function is only intended to support the example:
% Signal Classification Code Generation Using Wavelets and
% Deep Learning on Raspberry Pi. It may change or be removed in a
% future release.

% Copyright 2020 The MathWorks, Inc.

    % colourmap for image transformation
    persistent net jetdata;
    if(isempty(jetdata))
        jetdata = colourmap(128,class(input));
    end

    % Squeezenet trained network
    if(isempty(net))
        net = coder.loadDeepLearningNetwork('trainedNet.mat');
    end

    % Wavelet Transformation & Image conversion
    cfs = ecg_to_Image(input);
    image = ind2rgb(im2uint8(rescale(cfs)),single(jetdata));
    image = im2uint8(imresize(image,[227,227]));

    % figure
    if isempty(coder.target)
        imshow(image);
    end

    % Prediction
    [YPred] = predict(net,image);

    %% ECG to image conversion
    function cfs = ecg_to_Image(input)

        %Wavelet Transformation
        persistent filterBank
        [~,siglen] = size(input);
        if isempty(filterBank)
            filterBank = cwtfilterbank('SignalLength',siglen,'VoicesPerOctave',6);
        end
        %CWT conversion
        cfs = abs(filterBank.wt(input));
    end

    %% Colourmap
    function J = colourmap(m,class)

        n = ceil(m/4);
        u = [(1:1:n)/n ones(1,n-1) (n:-1:1)/n]';
        g = ceil(n/2) - (mod(m,4)==1) + (1:length(u))';
        r = g + n;
        b = g - n;
        r1 = r(r<=128);
        g1 = g(g<=128);
        b1 = b(b >0);
```

```
        J = zeros(m,3);
        J(r1,1) = u(1:length(r1));
        J(g1,2) = u(1:length(g1));
        J(b1,3) = u(end-length(b1)+1:end);
        feval = str2func(class);
        J = feval(J);
    end
end
```

Create Code Generation Configuration Object

Create a code generation configuration object for generation of an executable program. Specify generation of C++ code.

```
cfg = coder.config('exe');
cfg.TargetLang = 'C++';
```

Set Up Configuration Object for Deep Learning Code Generation

Create a `coder.ARMNEONConfig` object. Specify the same version of the ARM Compute library as the one on the Raspberry Pi. Specify the architecture of the Raspberry Pi.

```
dlcfg = coder.DeepLearningConfig('arm-compute');
dlcfg.ArmComputeVersion = '19.05';
dlcfg.ArmArchitecture = 'armv7';
```

Attach Deep Learning Configuration Object to Code Generation Configuration Object

Set the `DeepLearningConfig` property of the code generation configuration object to the deep learning configuration object. Make the MATLAB Source Comments visible in the configuration object at the time of code generation.

```
cfg.DeepLearningConfig = dlcfg;
cfg.MATLABSourceComments = 1;
```

Create a Connection to the Raspberry Pi

Use the MATLAB Support Package for Raspberry Pi Support Package function, `raspi`, to create a connection to the Raspberry Pi. In the following code, replace:

- `'raspiname'` with the name of your Raspberry Pi
- `'pi'` with your user name
- `'password'` with your password

```
r = raspi('172.18.76.69','pi','raspberry');
```

Configure Code Generation Hardware Parameters for Raspberry Pi

Create a `coder.Hardware` object for Raspberry Pi and attach it to the code generation configuration object.

```
hw = coder.hardware('Raspberry Pi');
cfg.Hardware = hw;
```

Specify the build folder on the Raspberry Pi.

```
buildDir = '~/remdirECG';
cfg.Hardware.BuildDir = buildDir;
```

Provide C++ Main File for Code Execution

The C++ main file reads the input ECG data, calls the `processECG` function to perform preprocessing and deep learning using CNN on the ECG data, and displays the classification probability.

Specify the main file in the code generation configuration object. To learn more about generating and customizing `main_ecg_raspi.cpp`, refer to “Generating Standalone C/C++ Executables from MATLAB Code” (MATLAB Coder).

```
cfg.CustomSource = 'main_ecg_raspi.cpp';
```

Generate Source C++ Code Using codegen

Use the `codegen` function to generate the C++ code. When `codegen` is used with the MATLAB Support Package for Raspberry Pi Hardware, the executable is built on the Raspberry Pi board.

Make sure to set the environment variables `ARM_COMPUTELIB` and `LD_LIBRARY_PATH` on the Raspberry Pi. See “Prerequisites for Deep Learning with MATLAB Coder” (MATLAB Coder).

```
codegen -config cfg processECG -args {ones(1,65536,'single')} -d arm_compute
```

```
 Deploying code. This may take a few minutes.
```

Fetch Generated Executable Directory

To test the generated code on the Raspberry Pi, copy the input ECG signal to the generated code directory. You can find this directory manually or by using the `raspi.utils.getRemoteBuildDirectory` API. This function lists the directories of the binary files that are generated by using `codegen`.

```
applicationDirPaths = raspi.utils.getRemoteBuildDirectory('applicationName','processECG')
```

```
applicationDirPaths=1×4 cell array
    {1×1 struct}    {1×1 struct}    {1×1 struct}    {1×1 struct}
```

The complete path to the remote build directory is derived from the present working directory. If you do not know which `applicationDirPaths` entry contains the generated code, use the helper function `helperFindTargetDir`. Otherwise, specify the proper directory.

```
directoryUnknown = true;

if directoryUnknown
    targetDirPath = helperFindTargetDir(applicationDirPaths);
else
    targetDirPath = applicationDirPaths{1}.directory;
end
```

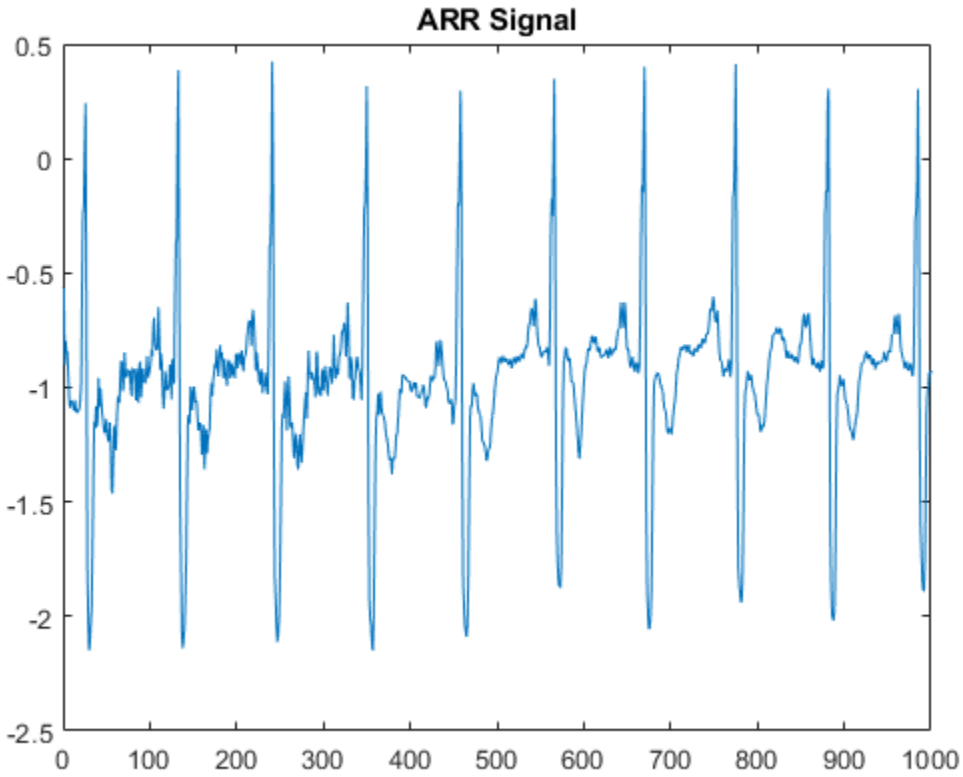
Copy Input File to Raspberry Pi

The text file `input_ecg_raspi.csv` contains the ECG samples of a representative ARR signal. To copy the file required to run the executable program, use `putFile`, which is available with the MATLAB Support Package for Raspberry Pi Hardware.

```
r.putFile('input_ecg_raspi.csv', targetDirPath);
```

For a pictorial representation, the first 1000 samples can be plotted by using these steps.

```
input = dlmread('input_ecg_raspi.csv');
plot(input(1:1000))
title('ARR Signal')
```



Run Executable on Raspberry Pi

Run the executable program on the Raspberry Pi from MATLAB and direct the output back to MATLAB. The input file name is passed as the command line argument for the executable.

```
exeName = 'processECG.elf';           % executable name
fileName = 'input_ecg_raspi.csv';     % Input ECG file that is pushed to target
command = ['cd ' targetDirPath ';./' exeName ' ' fileName];
output = system(r,command)
```

```
output =
    'Predicted Values on the Target Hardware
     ARR            CHF            NSR
     0.806078    0.193609    0.000313103
     '
```

Deploy Signal Segmentation Deep Network on Raspberry Pi

This example details the workflow for waveform segmentation of an electrocardiogram (ECG) signal using short-time Fourier transform and a bidirectional long short-term memory (BiLSTM) network. The example also provides information on how to generate and deploy the code and the trained BiLSTM network for segmentation on a Raspberry Pi™ target (ARM®-based device).

The pretrained network in the example is similar to the “Waveform Segmentation Using Deep Learning” (Signal Processing Toolbox) example.

This example details:

- Processor-in-the-loop (PIL) based workflow to verify generated code deployed and running on a Raspberry Pi from MATLAB™
- Generation of a standalone executable

The PIL verification process is a crucial part of the design cycle to check that the behavior of the generated code matches the design before deploying a standalone executable.

ECG Dataset

This example uses ECG signals from the publicly available QT Database [1 on page 12-0] [2 on page 12-0]. The data consists of roughly 15 minutes of labeled ECG recordings, with a sample rate of 250 Hz, measured from a total of 105 patients.

The ECG signal can be divided into the following beat morphologies [3 on page 12-0]:

- P wave — A small deflection before the QRS complex representing atrial depolarization
- QRS complex — Largest amplitude portion of the heartbeat
- T wave — A small deflection after the QRS complex representing ventricular repolarization

The segmentation of these regions of ECG waveforms can provide the basis for measurements that assess the overall health of the human heart and the presence of abnormalities.

Prerequisites

- ARM processor that supports the NEON extension
- ARM Compute Library (on the target ARM hardware)
- MATLAB® Coder™
- Embedded Coder™
- Deep Learning Toolbox™
- Deep Learning Support for MATLAB Coder
- MATLAB Support Package for Raspberry Pi™

For supported versions of libraries and for information about setting up environment variables, see “Prerequisites for Deep Learning with MATLAB Coder” (MATLAB Coder) (MATLAB Coder).

Functionality of Generated Code

The core function in the generated executable:

- Uses 15,000 samples of single-precision ECG data as input.
- Computes the short-time Fourier transform of the signal.
- Standardizes and normalizes the output.
- Labels regions of the signal using the pretrained BiLSTM network.
- Generates an output file with the labels.

`waveformSegmentation` Function

An *entry-point* function, also known as the *top-level* or *primary* function, is a function you define for code generation. You must define an entry-point function that calls code-generation-enabled functions and generates C/C++ code from the entry-point function. All functions within the entry-point function must support code generation.

In this example, w`aveformSegmentation` is the entry-point function. It takes an ECG signal as an input and passes it to the trained BiLSTM network for prediction. The `performPreprocessing` function preprocesses the raw signal and applies the short-time Fourier transform. The `genClassifiedResults` function passes the preprocessed signal to the network for prediction and displays the classification results.

```
type waveformSegmentation
```

```
function out = waveformSegmentation(in)
%#codegen
persistent net;

if isempty(net)
    net = coder.loadDeepLearningNetwork('trained-network-STFTBILSTM.mat', 'net');
end

preprocessedSignal = performPreprocessing(in);
out = cell(3,1);

for indx = 1:3
  out{indx,1} =  genClassifedResults(net.predict(preprocessedSignal{1,indx}));
end

end
```

Create a Connection to the Raspberry Pi

Use the MATLAB Support Package for Raspberry Pi function, `raspi`, to create a connection to the Raspberry Pi. In the following code, replace:

- `'raspiname'` with the name of your Raspberry Pi
- `'pi'` with your username
- `'password'` with your password

```
r = raspi('raspiname','pi','password');
```

The example shows the PIL-based workflow for verification of code and design and then creates and deploys a standalone executable. Optionally, if you want to directly deploy a standalone executable, you can skip PIL execution and go to creating a standalone execution.

Generate PIL MEX Function

The first step shows a PIL-based workflow to generate a MEX function for the `waveformSegmentation` function.

Set Up Code Generation Configuration Object for a Static Library

Create a code configuration object for a static library and set the verification mode to `'PIL'`. Set the target language to `'C++'`.

```
cfg = coder.config('lib','ecoder',true);
cfg.VerificationMode = 'PIL';
cfg.TargetLang = 'C++';
```

Set Up Configuration Object for Deep Learning Code Generation

Create a `coder.ARMNEONConfig` object. Specify the version of the ARM Compute library as the one on the Raspberry Pi. Specify the architecture of the Raspberry Pi. (This example requires ARM Compute Library v19.05).

```
dlcfg = coder.DeepLearningConfig('arm-compute');
dlcfg.ArmComputeVersion = '19.05';
dlcfg.ArmArchitecture = 'armv7';
```

Set the `DeepLearningConfig` property of the code generation configuration object to the deep learning configuration object. Set the configuration object with MATLAB Source Comments visible in the code generation.

```
cfg.DeepLearningConfig = dlcfg;
cfg.MATLABSourceComments = 1;
```

Configure Code Generation Hardware Parameters for Raspberry Pi

Create a `coder.Hardware` object for the Raspberry Pi and attach it to the code generation configuration object.

```
hw = coder.hardware('Raspberry Pi');
cfg.Hardware = hw;
```

Specify the build folder on the Raspberry Pi.

```
cfg.Hardware.BuildDir = '~/waveformSegmentation';
```

Generate Source C++ Code Using codegen Function

Use the `codegen` function to generate the C++ code. When `codegen` is used with MATLAB Support Package for Raspberry Pi Hardware, the generated code is downloaded to the board and compiled there. A PIL MEX function is generated to communicate between MATLAB and the generated code running on the Raspberry Pi.

Make sure to set the environment variables `ARM_COMPUTELIB` and `LD_LIBRARY_PATH` on the Raspberry Pi. See “Prerequisites for Deep Learning with MATLAB Coder” (MATLAB Coder) (MATLAB Coder).

```
codegen -config cfg waveformSegmentation -args {coder.typeof(single(ones(1,15000)),[1,15000],[0,0
```

```
### Target device has no native communication support. Checking connectivity configuration regist
 Deploying code. This may take a few minutes.
### Target device has no native communication support. Checking connectivity configuration regist
### Connectivity configuration for function 'waveformSegmentation': 'Raspberry Pi'
Location of the generated elf : /home/pi/waveformSegmentation/MATLAB_ws/R2020b/C/Users/eshashah/C
Code generation successful: View report
```

Run the Executable Program on Raspberry Pi

Load the MAT-file `ecgsignal_test`. The file stores a sample ECG signal on which you can test the generated code.

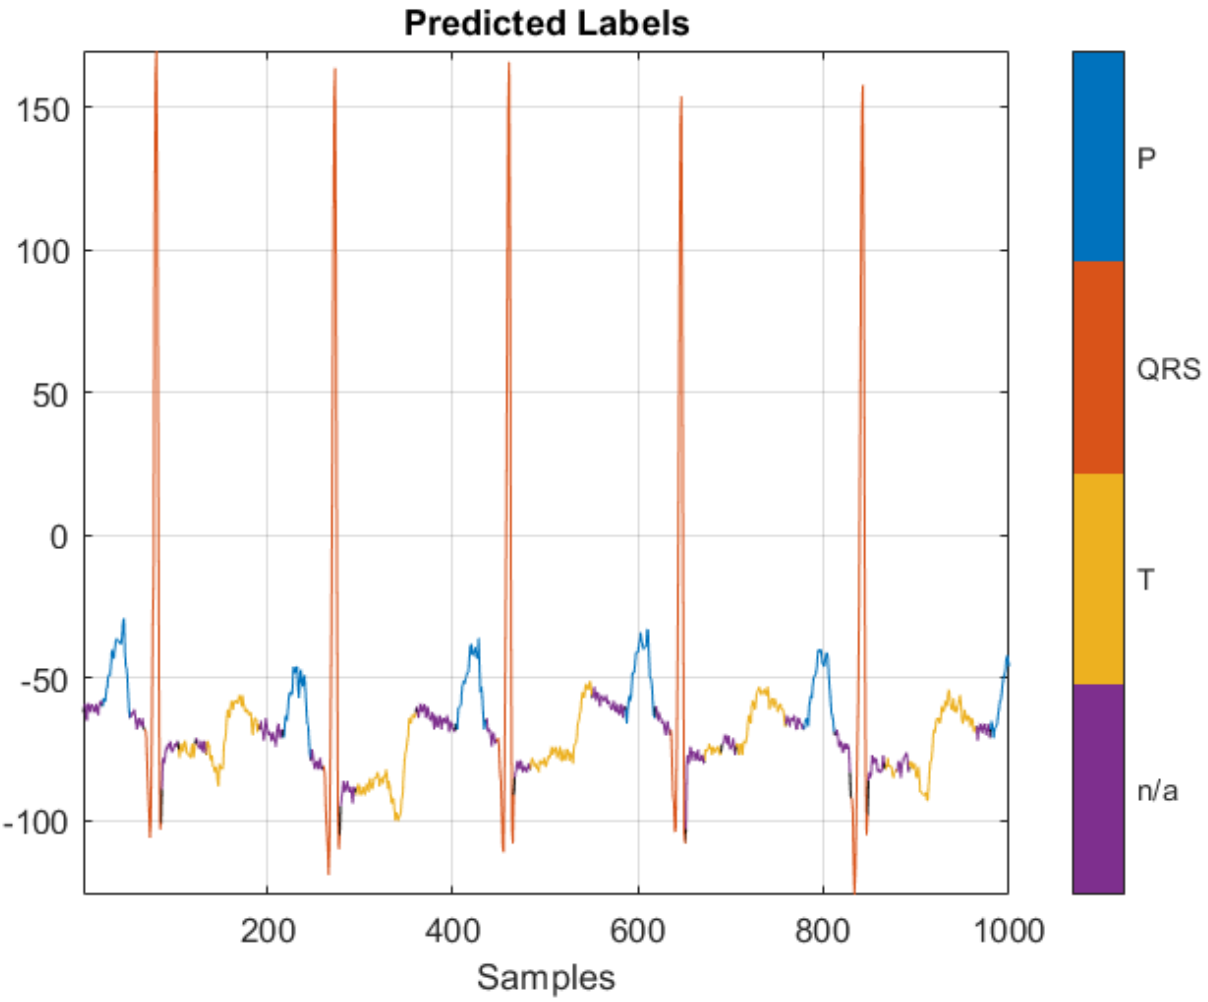
Run the generated `waveformSegmentation_pil` MEX function on the test signal.

```
load ecgsignal_test.mat;
out = waveformSegmentation_pil(test);
```

```
### Starting application: 'codegen\lib\waveformSegmentation\pil\waveformSegmentation.elf'
    To terminate execution: clear waveformSegmentation_pil
### Launching application waveformSegmentation.elf...
```

Display the signals with predicted labels.

```
labels = categorical(out{1}(1,2000:3000));
msk = signalMask(labels);
plotsigroi(msk,test(1,2000:3000))
title('Predicted Labels')
```



After the verifying the output of the PIL MEX function, you can create a standalone executable for the `waveformSegmentation` function.

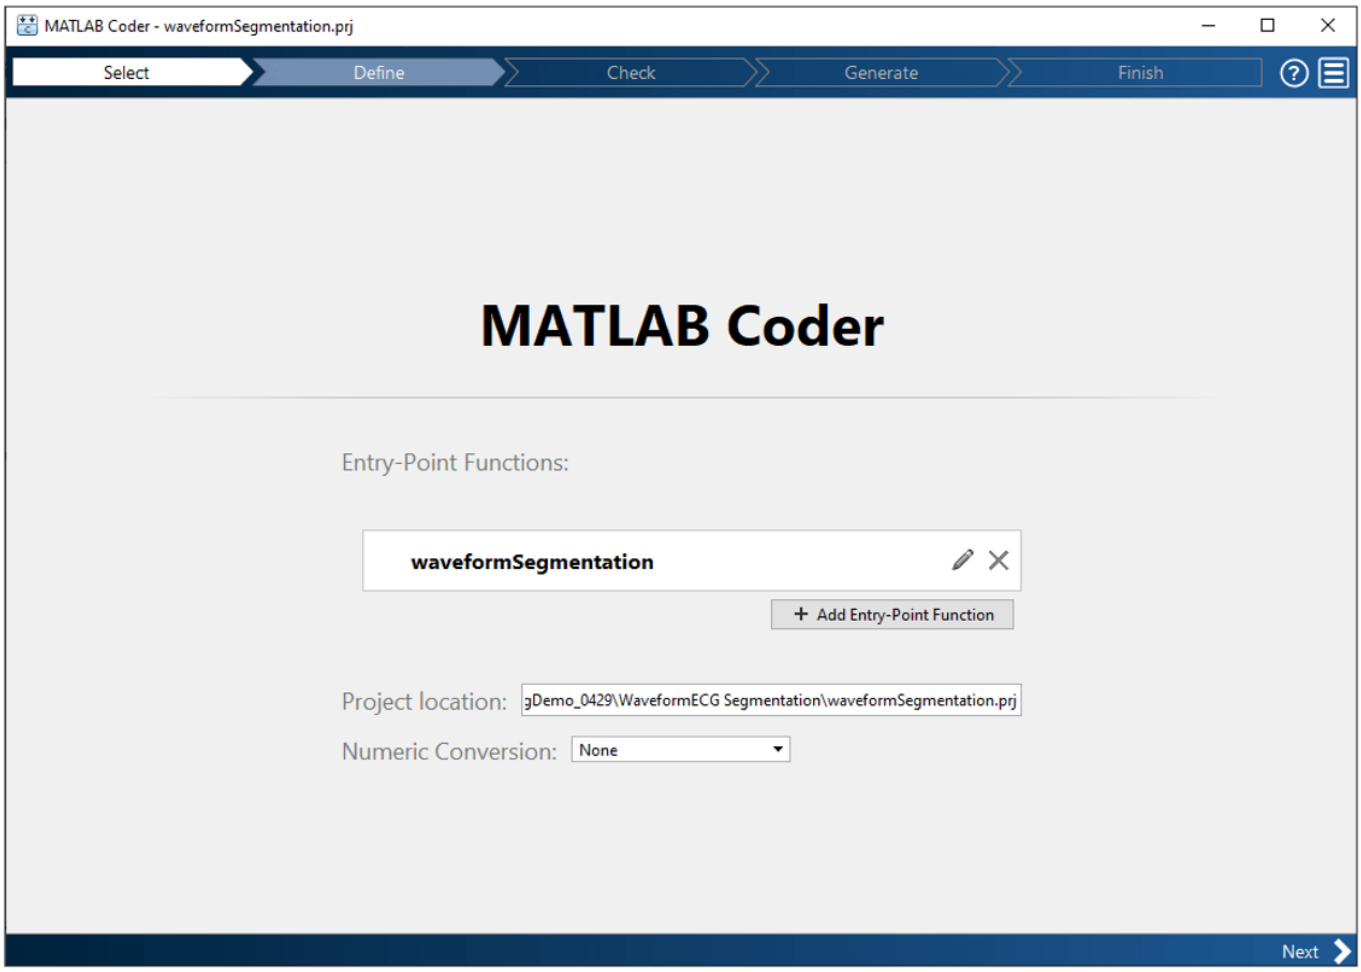
The next part shows the code generation workflow to create a generate and deploy a standalone executable in the code for prediction on a Raspberry Pi using the MATLAB Coder App.

Create a Standalone Executable Using the MATLAB Coder App

The **MATLAB Coder** app generates C or C++ code from MATLAB® code. The workflow-based user interface steps you through the code generation process. The following steps describe a brief workflow using the MATLAB Coder app. For more details, see MATLAB Coder (MATLAB Coder) and “Generate C Code by Using the MATLAB Coder App” (MATLAB Coder).

Select the Entry-Point Function File

On the **Apps** tab, click the down arrow on the far right of the toolstrip to expand the apps gallery. Under **Code Generation**, click **MATLAB Coder**. The app opens the **Select Source Files** page. Enter or select the name of the entry-point function, `waveformSegmentation`.



Click **Next** to go to the **Define Input Types** page.

Define Input Types

1. Select **Let me enter input or global types directly** and set the value of the input `in` as single `(1x15000)`.

2. Click **Next** to go to the **Generate Code** step. Skip the **Check for Run-Time Issues** step because MEX generation is not supported for code generation with the ARM Compute Library.

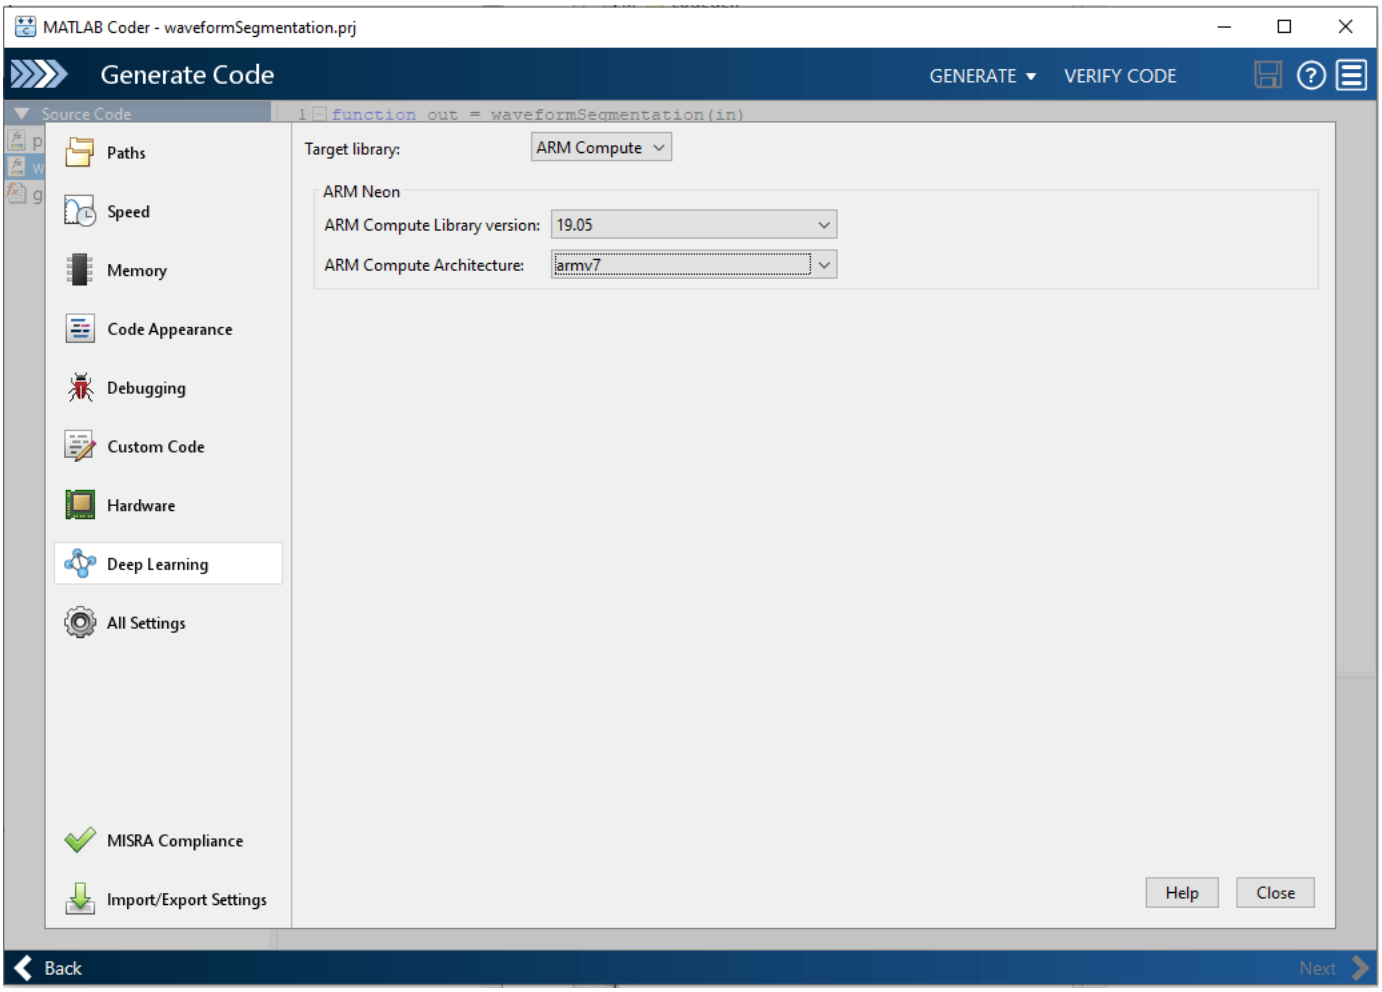
Generate Code

1. Set values in the generate code dialog box:

- Set **Build Type** to `Executable (.exe)`
- Set **Language** to `C++`
- Set **Hardware Board** as `Raspberry Pi`

2. Click the **More Settings** button:

- In the **Custom Code** pane, in additional source files, browse and select `ecgsegmentation_main.cpp`. For more information on writing a C/C++ main function, refer to "Structure of Generated Example C/C++ Main Function" (MATLAB Coder).
- In the **Hardware** pane, set the **username** and **password** for the Raspberry Pi board.
- In the **Deep Learning** pane, set **Target library** to `ARM Compute`. Specify **ARM Compute Library version** and **ARM Compute Architecture**.



3. Close the Settings window and generate code.

4. Click **Next** to go to the **Finish Workflow** page.

Fetch Generated Executable Directory

Once the code generation is completed the following lines of code to test the generated code on the Raspberry Pi, copy the input ECG signal to the generated code directory. You can find this directory manually or by using the `raspi.utils.getRemoteBuildDirectory` API. This function lists the directories of the binary files that are generated by using the `codegen` function. Assuming that the binary is found in only one directory, enter:

```
applicationDirPaths =...
```

```
raspi.utils.getRemoteBuildDirectory('applicationName','waveformSegmentation')
;

targetDirPath = applicationDirPaths{1}.directory;
```

Copy Input Files to the Raspberry Pi

To copy files required to run the executable program, use `putFile`, which is available with the MATLAB Support Package for Raspberry Pi Hardware. The `input.csv` file contains a sample ECG signal that is used to test the deployed code.

```
r.putFile('input.csv', targetDirPath);

input = dlmread('input.csv');
```

Run Executable program on Raspberry Pi

Run the executable program on the Raspberry Pi from MATLAB and get the output file to MATLAB. Input file name should be passed as the command line argument for the executable.

```
exeName = 'waveformSegmentation.elf'; % Executable name

command = ['cd ' targetDirPath ';./' exeName];

system(r,command)

outputPath = strcat(targetDirPath,'/*.txt');

getFile(r,outputPath)
```

Display the signals with predicted labels. The output is depicted in the figure.

```
load ecgsignal_test.mat;

labels = categorical(textread('out.txt','%s')');

msk = signalMask(labels(1,2000:3000));

plotsigroi(msk,test(1,2000:3000))

title('Predicted Labels')
```

Anomaly Detection Using Autoencoder and Wavelets

This example shows how wavelet features can be used to detect arc faults in a DC system. For the safe operation of DC distribution systems, it is important to identify arc faults and prefault signals that can be caused by deterioration of wire insulation due to aging, abrasion, or rodent bites. These arc faults can result in shock, fires, and system failures in the microgrid. Unlike the fault signals in AC distribution systems, these prefault arc flash signals are difficult to identify as they do not generate significant power to trigger the circuit breakers. As a result, these signals can exist in the system for hours without being detected.

Arc fault detection using the wavelet transform was studied in [1] on page 12-0 . This example follows the feature extraction procedure detailed in [1] on page 12-0 . The feature extraction involves filtering the load signals using the Daubechies `db3` wavelet followed by normalization. Further, an autoencoder trained with signal features under normal conditions is used to detect arc faults in load signals. The DC arc model used to generate the fault signal and the pretrained network used to detect the arc faults are provided in the example folder. As training the network and arc detection in larger signals can take significantly long simulation time, in this example we only report the detection results.

Training and Testing Setup

The autoencoder is trained using the load signal generated by the Simulink™ model `DCNoArc` under normal conditions, i.e., without arc faults. The model `DCNoArc` was built using components from the `Specialized Power System` library in `Simscape Electrical™`.

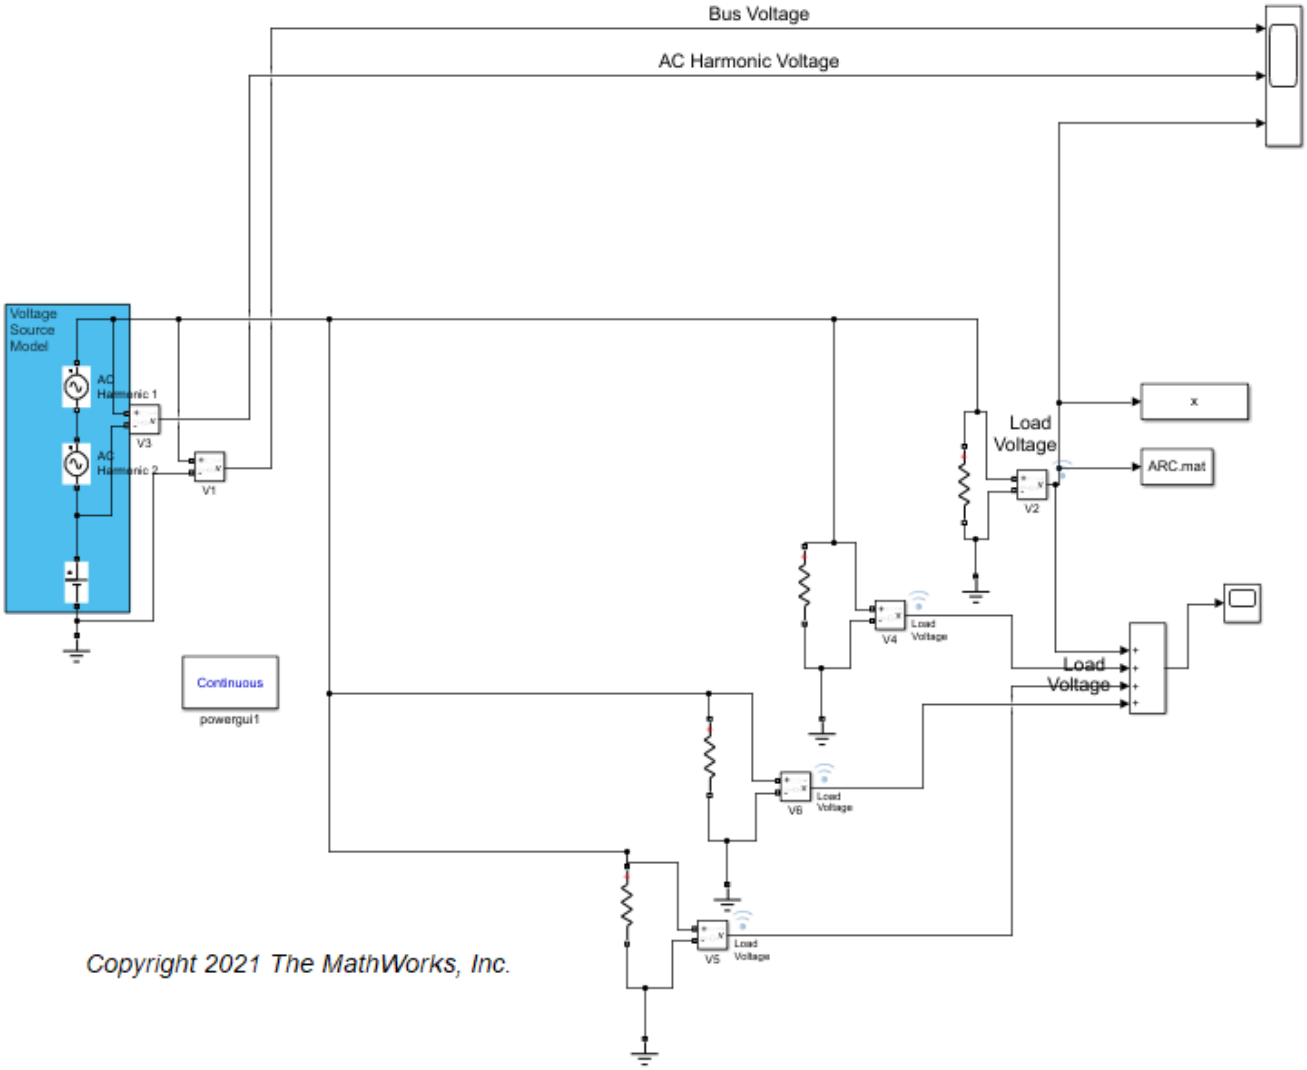

Figure 1: `DCNoArc` model for generating load signal under normal conditions.

The voltage sources are modeled using the following parameters:

- *AC Harmonic Source 1:* 10V ac voltage and 120 Hz frequency
- *AC Harmonic Source 2:* 20V ac voltage and 2000 Hz frequency
- *DC voltage source:* 1000V

In the model `DCArcModelFinal` we add arc fault generation in every load branch. The model uses the Cassie arc model for synthetic arc fault generation. The arc model works like an ideal conductance until the arc ignites at the contact separation time.

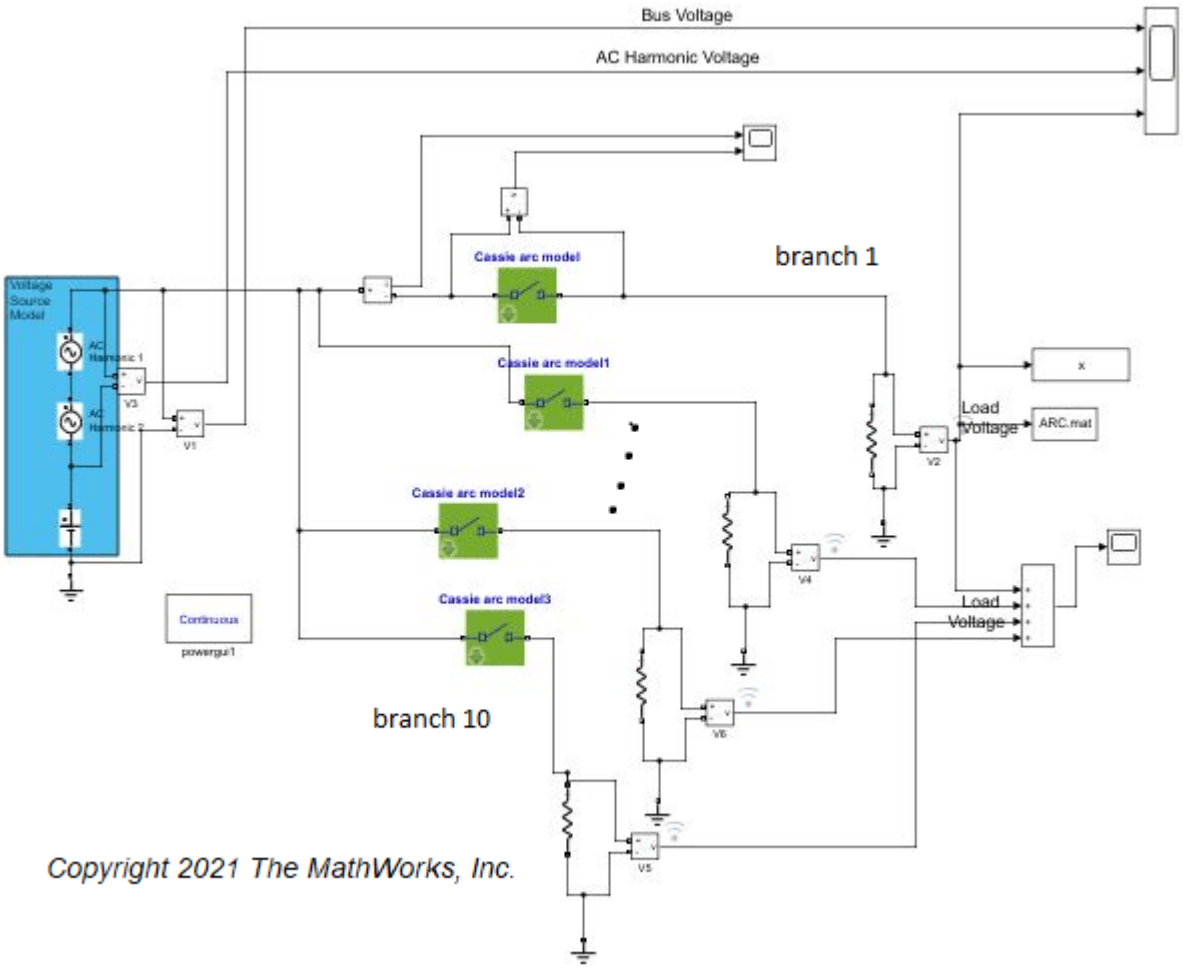

Figure 2: `DCArcModelFinal` model for generating load signal with arc fault.

Cassie Arc Model:

The Cassie arc model is one of the most studied black box models for generating synthetic arc. The model is described by the following differential equation:

$$\frac{dg}{dt} = \frac{g}{\tau}\left(\frac{u^2}{U_c^2} - 1\right)$$

where

- g is the conductance of the arc in siemens
- τ is the arc time constant in seconds
- u is the voltage across the arc in volts
- U_c is constant arc voltage in volts

The Cassie arc models were implemented in Simulink™ using the following parameter values:

- Initial conductance g(0) is 1e4 siemens
- Constant arc voltage U_c = 100 V
- Arc time constant 1.2e-6 seconds

The contact separation times for the arc models are chosen at random. All the parameters have been loaded in the `initFcn` callbacks in the **Model Properties** of the **Model Settings** tab. We use the `DCArcModelFinal` model to generate a faulty load signal to test the autoencoder.

Anomaly Detection with Autoencoder

Autoencoders are used to detect anomalies in a signal. To this end, the autoencoder accepts training data without anomalies as input and tries to reconstruct the input signal using a neural network. The network weights are calculated such that the reconstruction error is minimized. The statistics of the reconstruction error for the training data can be used to select the threshold in the anomaly detection block that determines the detection performance of the autoencoder. Every time the autoencoder encounters an anomaly in the testing data, it produces a large reconstruction error. If the error is above the threshold in the anomaly detection block, the encoder declares it to be an anomaly. In this example, we used root-mean-square error (RMSE) as the reconstruction error metric.

For this example, we trained two autoencoders using the load signal under normal conditions without arc fault. One autoencoder was trained using the raw load signal as training data. This encoder uses the raw faulty load signal to detect arc faults. The second autoencoder was trained using wavelet features. Arc fault detection is subsequently done on wavelet features as opposed to the raw data. For training and testing the network, we assume that the load consists of 10 parallel resistive branches with randomly chosen resistance values. For arc fault signal generation, we add a Cassie arc model in every load branch. The contact separation times of the models are such that they are triggered randomly throughout the simulation period. Just like in a real-time DC system, the load signals from both normal and faulty conditions have added white noise.

Feature Extraction

The wavelet-based autoencoder was trained and tested on signals filtered using the discrete wavelet transform (DWT). Following [1] on page 12-0 , the Daubechies `db3` wavelet was used.

The following figures show the wavelet-filtered load signals under normal and faulty conditions. The wavelet-filtered faulty signal captures the variation due to arc faults. For training and testing purposes, the wavelet-filtered signals are segmented into 100-sample frames.

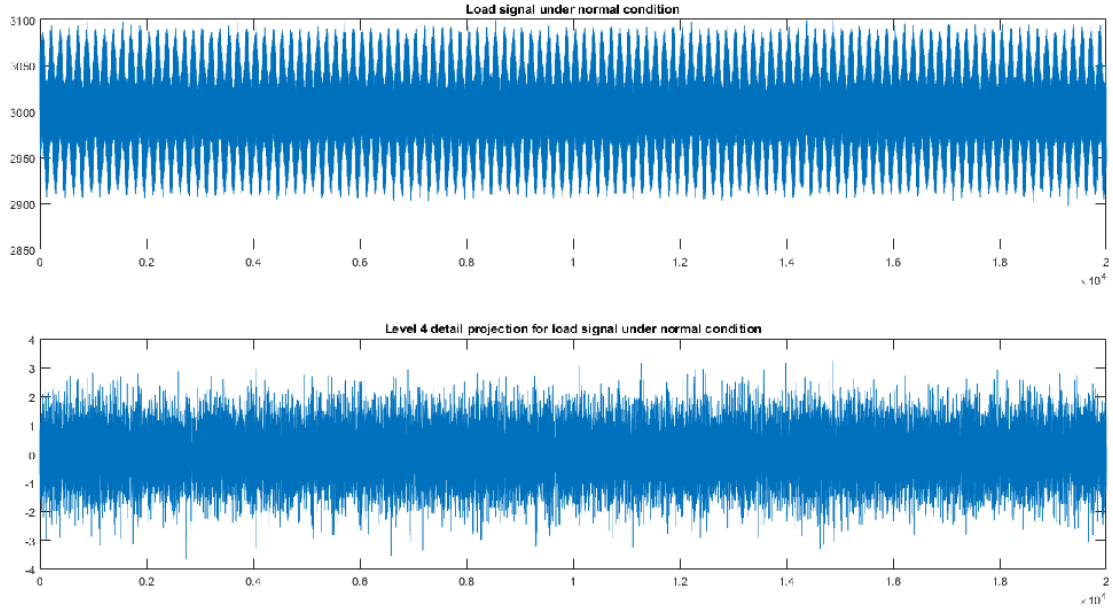

Figure 3: Raw load signal and wavelet-filtered feature under normal conditions.

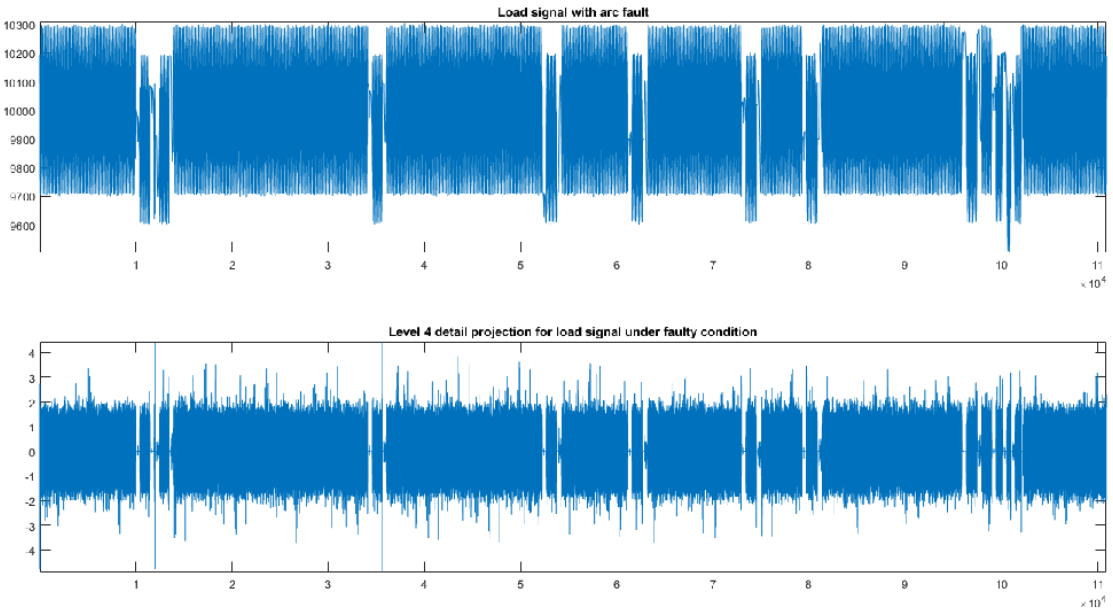

Figure 4: Raw load signal and wavelet-filtered feature under faulty conditions.

Model Training

The load signal under normal conditions is specified in the `normal.mat` file in the example folder. Use the normal load signal to obtain the training features that are used as the input of the autoencoder. Train the autoencoder using these layers and training options.

```
% Training data: load voltage under normal condition
featureDimension = 100;

% Create network layers
numHiddenUnits = 50;

layers = [ sequenceInputLayer(1, 'Name', 'in')
    bilstmLayer(32, 'Name', 'bilstm1')
    reluLayer('Name', 'relu1')
    bilstmLayer(16, 'Name', 'bilstm2')
    reluLayer('Name', 'relu2')
    bilstmLayer(32, 'Name', 'bilstm3')
    reluLayer('Name', 'relu3')
    fullyConnectedLayer(1, 'Name', 'fc')
    regressionLayer('Name', 'out') ];

% Set options
options = trainingOptions('adam', ...
    'MaxEpochs',20, ...
    'MiniBatchSize',16, ...
    'Plots','training-progress');
```

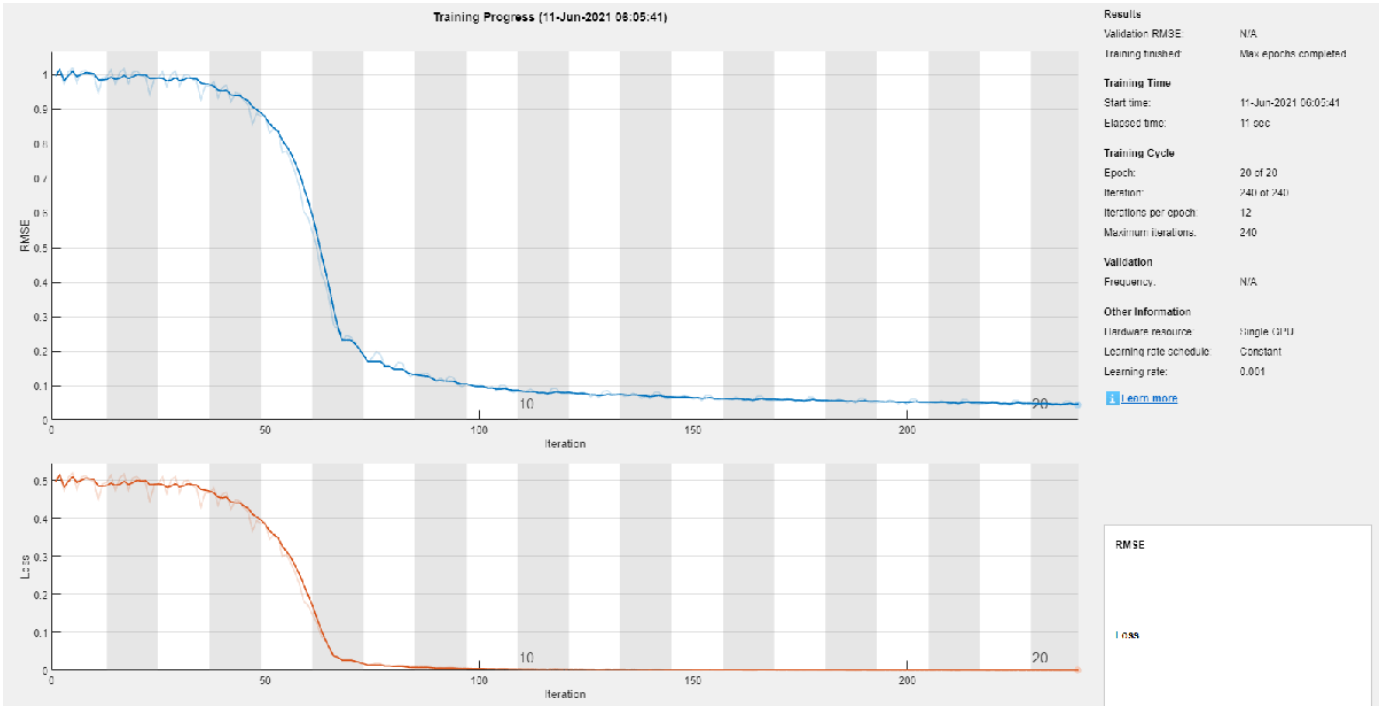

Figure 5: Training progress for the autoencoder.

The trained network is specified in the file `netData.mat` in the example folder. The trained network can be uploaded into the `Predict` block from Deep Learning Toolbox™ to detect the arc fault in the

load signal. The figure shows the histogram for the reconstruction error produced by the autoencoder when the input is the training data. You can use the statistics for the reconstruction error to choose the detection threshold. For instance, choose the detection threshold to be three times the standard deviation for the reconstruction error.

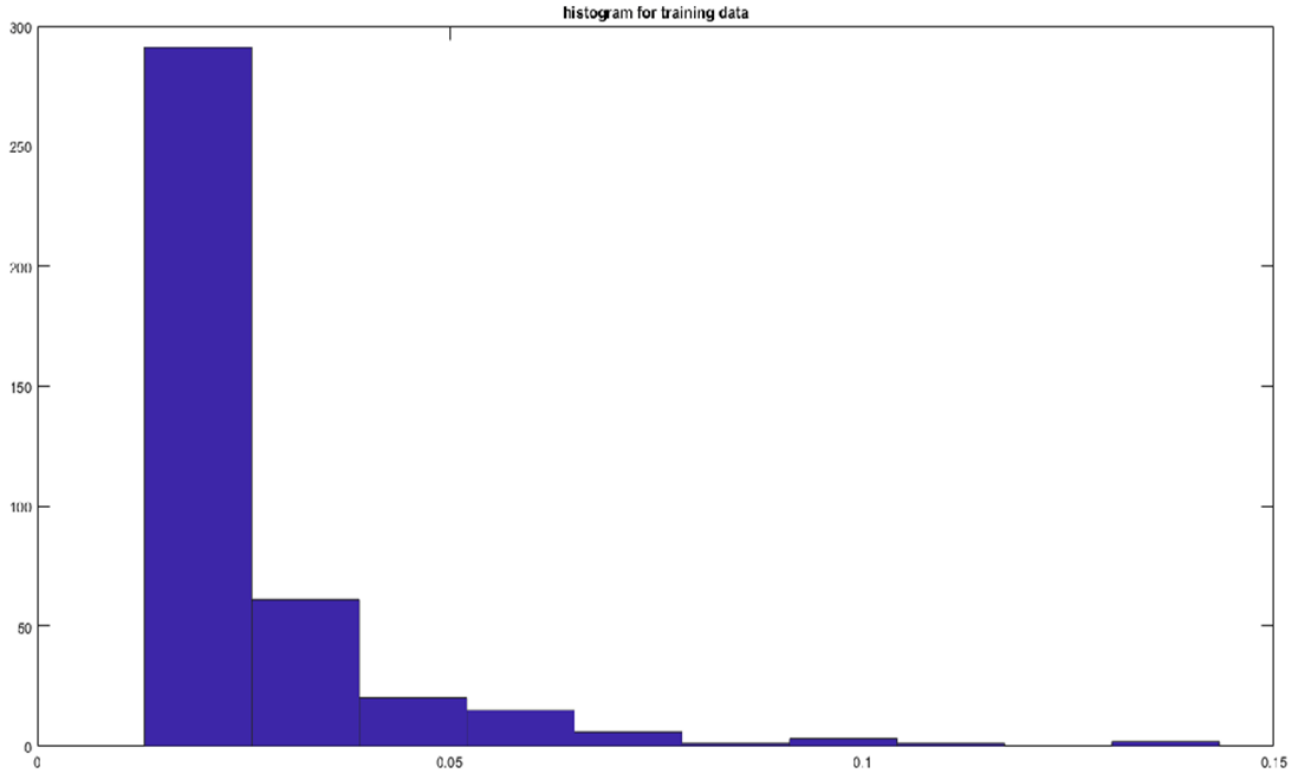

Figure 6: Histogram for the reconstruction error produced by the autoencoder when the input is the training data.

Model for Anomaly Detection Using Autoencoder

The `DCArcModelFinal` model is used for real-time detection of the arc fault in a DC load signal. Before running the model, you must specify the simulation stop time in seconds in the workspace variable `t`.

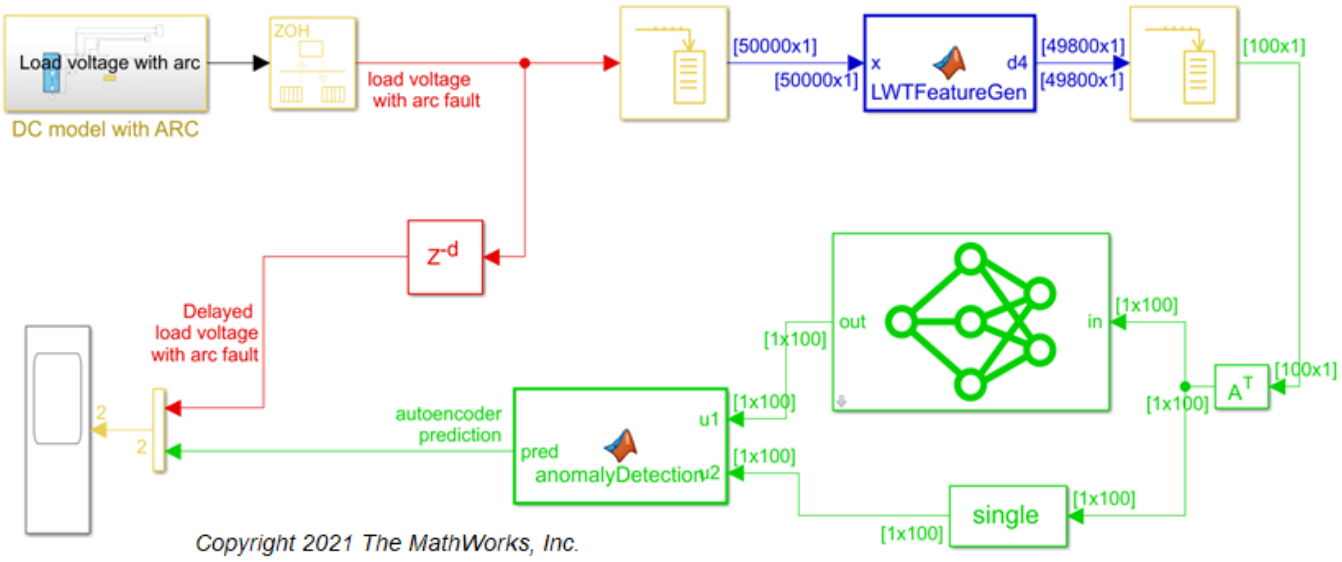

Figure 7: `DCArcModelFinal` for arc fault detection.

The first block generates noisy DC load signal with arc fault in continuous time. The load voltage is then converted into a discrete-time signal sampled at 20kHz by the `Rate transition` block in DSP System Toolbox™. The discrete time signal is then buffered to the `LWTFeatureGen` block that obtains the desired level 4 detail projection after preprocessing. The detail projection is then segmented in 100 sample frames that are the test features for the `Predict` block. The `Predict` block has been preloaded with the network pretrained using the load signal under normal conditions. The anomaly detection block then calculates the root-mean-square error (RMSE) for each frame and declares the presence of an arc fault if the error is above some predefined threshold. We can observe the prediction from the block adding a scope to the model. The red line in the plot indicates where the transition due to anomaly is detected. The autoencoder identified most of the arc faults.

Figure 8: Real-time arc fault detection as seen from scope.

This plot shows the regions predicted by the network when the wavelet-filtered features are used. The autoencoder was able to detect all 10 arc fault regions correctly. In other words, we obtained a 100% probability of detection in this case.

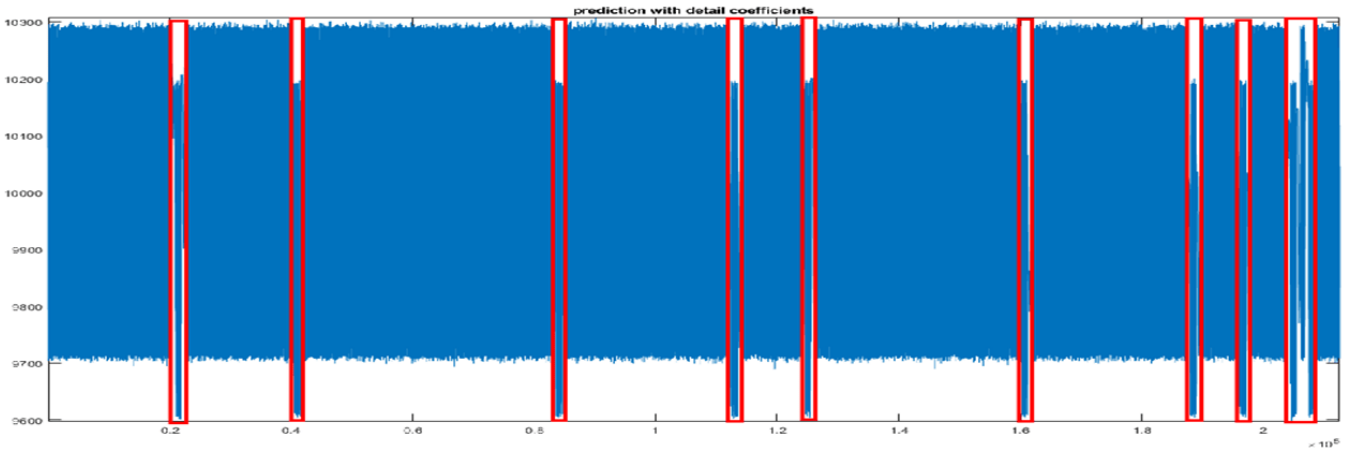

Figure 9: Detection performance for the autoencoder using wavelet-filtered features.

This plot shows the anomaly detection performance of the raw data trained autoencoder. When we used raw data for anomaly detection, the encoder was able to identify seven out of 10 regions correctly.

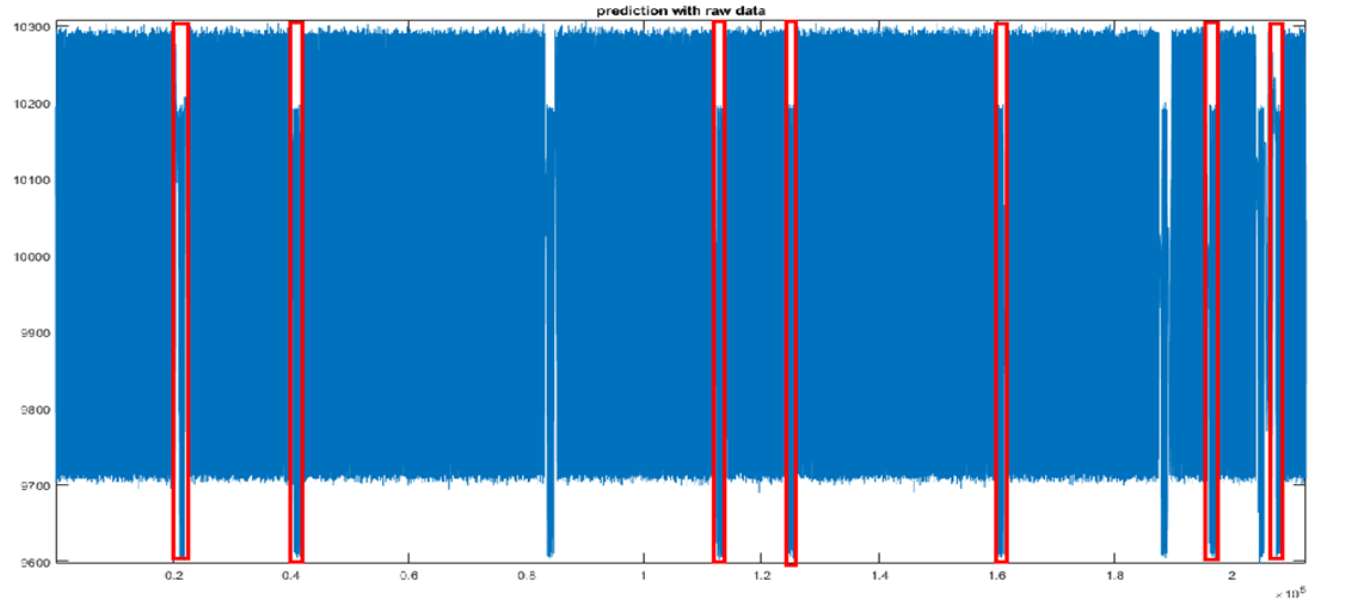

Figure 10: Detection performance for the autoencoder using raw load signal.

Finally, we generated a 50 second long anomalous signal with 40 arc fault regions (this data is not included with the example). When tested with the autoencoder trained with raw signals, the arc regions were detected with a 57.85% probability of detection. In contrast, the autoencoder trained with the wavelet-filtered signals, was able to detect the arc fault regions with a 97.52% probability of detection.

Summary

In this example, we demonstrated how autoencoders can be used to identify arc faults in DC systems. Both the raw and wavelet filtered load signals under normal conditions can be used as features to train the autoencoders. These anomaly detection mechanisms can be used to detect arc faults in a timely manner and thus protect a DC system from damages caused by the faults.

Fault Detection Using Wavelet Scattering and Recurrent Deep Networks

This example shows how to classify faults in acoustic recordings of air compressors using a wavelet scattering network paired with a recurrent neural network. The example provides the opportunity to use a GPU to accelerate the computation of the wavelet scattering transform. If you wish to utilize a GPU, you must have Parallel Computing Toolbox™ and a supported GPU. See “GPU Support by Release” (Parallel Computing Toolbox) for details.

Dataset

The dataset consists of acoustic recordings collected on a single stage reciprocating type air compressor [1 on page 12-0]. The data are sampled at 16 kHz. Specifications of the air compressor are as follows:

- Air Pressure Range: 0-500 lb/m2, 0-35 Kg/cm2
- Induction Motor: 5HP, 415V, 5Am, 50 Hz, 1440rpm
- Pressure Switch: Type PR-15, Range 100-213 PSI

Each recording represents one of 8 states which includes the healthy state and 7 faulty states. The 7 faulty states are:

1. Leakage inlet valve (LIV) fault
2. Leakage outlet valve (LOV) fault
3. Non-return valve (NRV) fault
4. Piston ring fault
5. Flywheel fault
6. Rider belt fault
7. Bearing fault

Download the dataset and unzip the data file in a folder where you have write permission. This example assumes you are downloading the data in the temporary directory designated as `tempdir` in MATLAB®. If you chose to use a different folder, substitute that folder for `tempdir` in the following. The recordings are stored as .wav files in folders named for their respective state.

```
url = 'https://www.mathworks.com/supportfiles/audio/AirCompressorDataset/AirCompressorDataset.zip
downloadFolder = fullfile(tempdir,'AirCompressorDataSet');
if ~exist(fullfile(tempdir,'AirCompressorDataSet'),'dir')
    loc = websave(downloadFolder,url);
    unzip(loc,fullfile(tempdir,'AirCompressorDataSet'))
end
```

Use an `audioDatastore` to manage data access. Each subfolder contains only recordings of the designated class. Use the folder names as the class labels.

```
datasetLocation = fullfile(tempdir,'AirCompressorDataSet','AirCompressorDataset');
ads = audioDatastore(datasetLocation,'IncludeSubfolders',true,...
    'LabelSource','foldernames');
```

Examine the number of examples in each class. There are 225 recordings in each class.

```
countcats(ads.Labels)
```

```
ans = 8×1

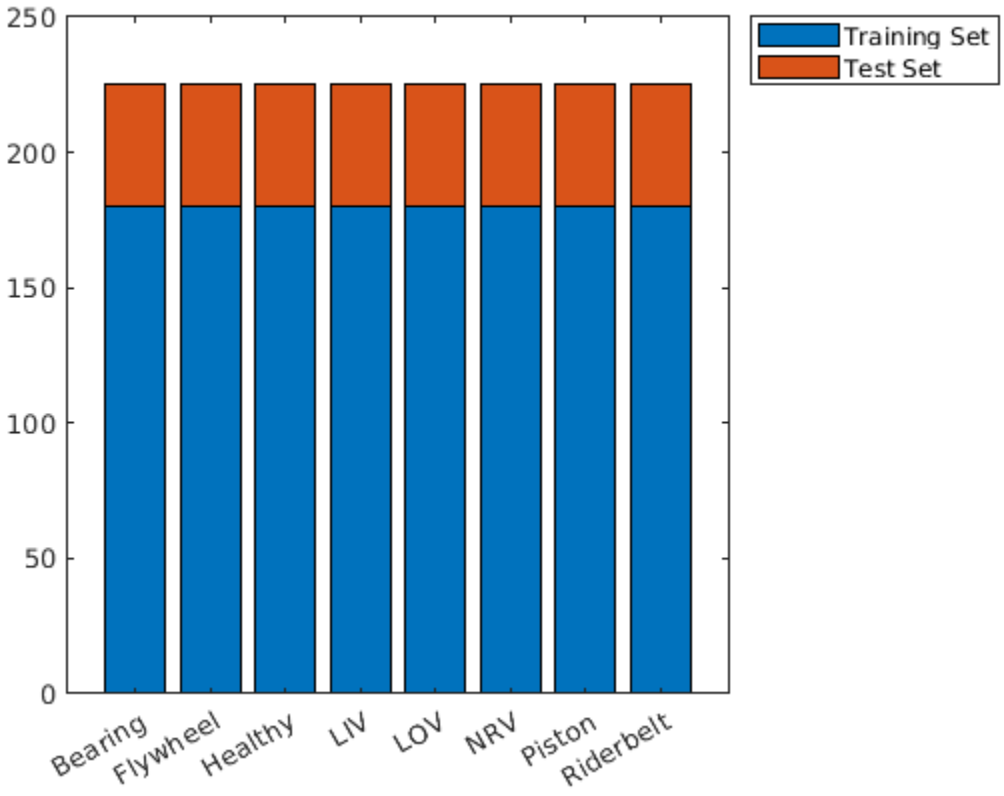
   225
   225
   225
   225
   225
   225
   225
   225
```

Split the data into training and test sets. Use 80% of the data for training and hold out the remaining 20% for testing. Shuffle the data once before splitting.

```
rng default
ads = shuffle(ads);
[adsTrain,adsTest] = splitEachLabel(ads,0.8,0.2);
```

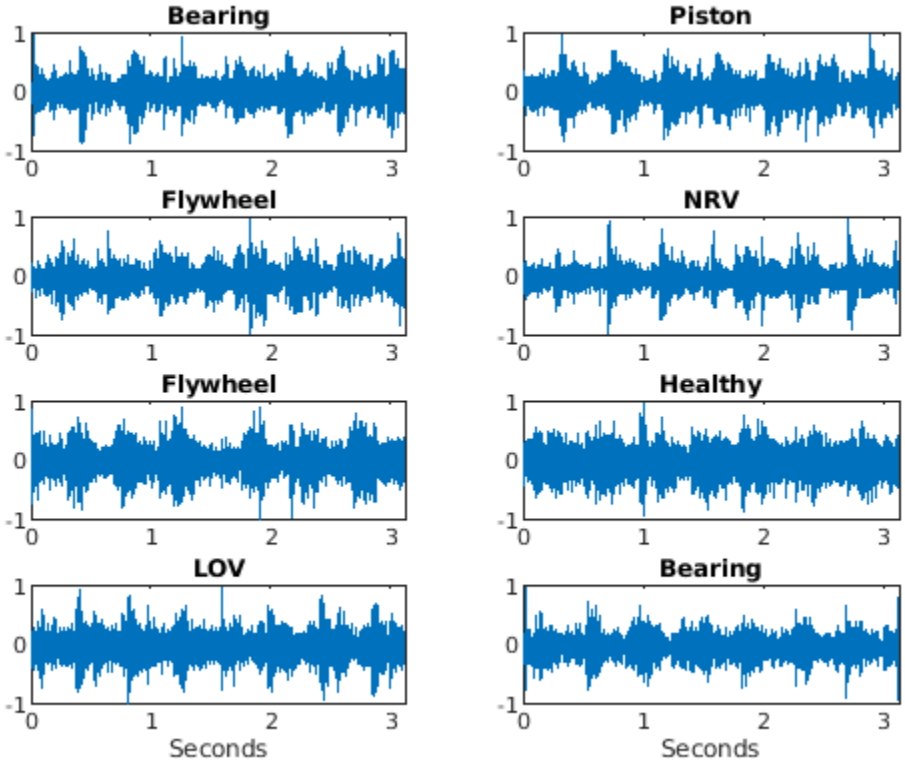
Verify that the number of examples in each class is the expected number.

```
uniqueLabels = unique(adsTrain.Labels);
tblTrain = countEachLabel(adsTrain);
tblTest = countEachLabel(adsTest);
H = bar(uniqueLabels,[tblTrain.Count, tblTest.Count],'stacked');
legend(H,["Training Set","Test Set"],'Location','NorthEastOutside')
```



Select some random examples from the training set for plotting.

```
idx = randperm(numel(adsTrain.Files),8);
Fs = 16e3;
for n = 1:numel(idx)
    x = audioread(adsTrain.Files{idx(n)});
    t = (0:size(x,1)-1)/Fs;
    subplot(4,2,n);
    plot(t,x);
    if n == 7 || n == 8
        xlabel('Seconds');
    end
    title(string(adsTrain.Labels(idx(n))));
end
```



Wavelet Scattering Network

Each record has 50,000 samples sampled at 16 kHz. Construct a wavelet scattering network based on the data characteristics. Set the invariance scale to be 0.5 seconds.

```
N = 5e4;
Fs = 16e3;
IS = 0.5;
sn = waveletScattering('SignalLength',N,'SamplingFrequency',Fs,...
    'InvarianceScale',0.5);
```

With these network settings, there are 330 scattering paths and 25 time windows per example. You can see this with the following code.

```
[~,npaths] = paths(sn);
Ncfs = numCoefficients(sn);
sum(npaths)
```

```
ans = 330
```

```
Ncfs
```

```
Ncfs = 25
```

Note this already represents a 6-fold reduction in the size of the data for each record. We reduced the data size from 50,000 samples to 8250 in total. Most importantly, we reduced the size of the data along the time dimension from 50,000 to 25 samples. This is crucial for our use of a recurrent network. Attempting to use a recurrent network on the original data with 50,000 samples would immediately result in memory problems.

Obtain the wavelet scattering features for the training and test sets. If you have a suitable GPU and Parallel Computing Toolbox, you can set `useGPU` to `true` to accelerate the scattering transform. The function `helperBatchScatFeatures` obtains the scattering transform of each example.

```
batchsize = 64;
useGPU = false;
scTrain = [];
while hasdata(adsTrain)
    sc = helperBatchScatFeatures(adsTrain,sn,N,batchsize,useGPU);
    scTrain = cat(3,scTrain,sc);
end
```

Repeat the process for the held out test set.

```
scTest = [];
while hasdata(adsTest)
   sc = helperBatchScatFeatures(adsTest,sn,N,batchsize,useGPU);
   scTest = cat(3,scTest,sc);
end
```

Remove the 0-th order scattering coefficients. For both the training and test sets, put each 330-by-25 scattering transform into an element of a cell array for use in training and testing the recurrent network.

```
TrainFeatures = scTrain(2:end,:,:);
TrainFeatures = squeeze(num2cell(TrainFeatures,[1 2]));
YTrain = adsTrain.Labels;
TestFeatures = scTest(2:end,:,:);
TestFeatures = squeeze(num2cell(TestFeatures,[1 2]));
YTest = adsTest.Labels;
```

Define Network

Recall there are 1440 training examples and 360 test set examples. Accordingly the `TrainFeatures` and `TestFeatures` cell arrays have 1440 and 360 elements respectively.

Use the number of scattering paths as the number of features. Create a recurrent network with a single LSTM layer having 512 hidden units. Follow the LSTM layer with a fully connected layer and finally a softmax layer. Use 'zscore' normalization across all scattering paths at the input to the network.

```
[inputSize, ~] = size(TrainFeatures{1});
```

```
numHiddenUnits = 512;
numClasses = numel(unique(YTrain));

layers = [ ...
    sequenceInputLayer(inputSize,'Normalization','zscore')
    lstmLayer(numHiddenUnits,'OutputMode','last')
    fullyConnectedLayer(numClasses)
    softmaxLayer
    classificationLayer];
```

Train Network

Train the network for 50 epochs with a mini batch size of 128. Use an Adam optimizer with an initial learn rate of 1e-4. Shuffle the data each epoch.

```
maxEpochs = 50;
miniBatchSize = 128;

options = trainingOptions('adam', ...
    'InitialLearnRate',1e-4,...
    'MaxEpochs',maxEpochs, ...
    'MiniBatchSize',miniBatchSize, ...
    'SequenceLength','shortest', ...
    'Shuffle','every-epoch',...
    'Plots','training-progress',...
    'Verbose',true);

net = trainNetwork(TrainFeatures,YTrain,layers,options);
```

```
Training on single CPU.
Initializing input data normalization.

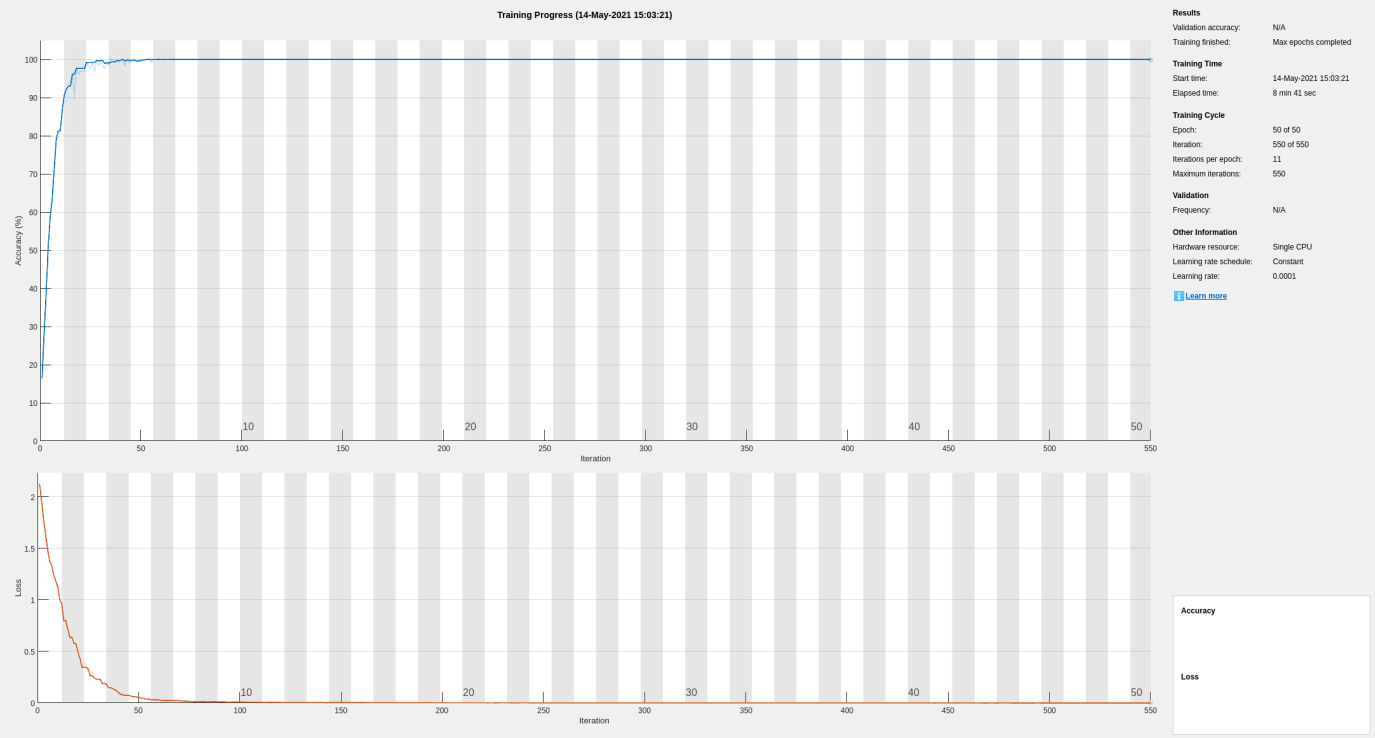
|      50 |         550 |       00:08:41 |      100.00% |       0.0004 |      1.0000e-04 |
|========================================================================================|
Training finished: Reached final iteration.
```



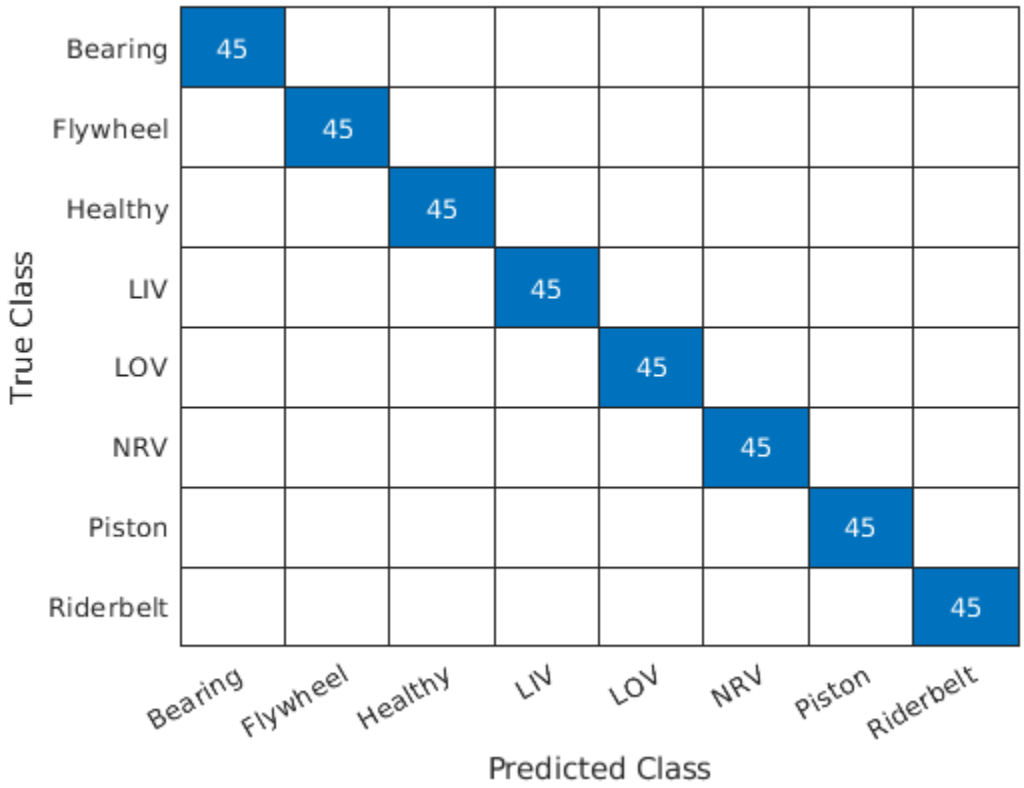
In training, the network has achieved near perfect performance. In order to ensure we have not overfit to the training data, use the held-out test set to determine how well our network generalizes to unseen data.

```
YPred = classify(net,TestFeatures);
accuracy = 100*sum(YPred == YTest) / numel(YTest)
```

```
accuracy = 100
```

In this case, we see that the performance on the held-out test set is also excellent.

```
figure
confusionchart(YTest, YPred)
```



Summary

In this example, the wavelet scattering transform was used with a simple recurrent network to classify faults in an air compressor. The scattering transform allowed us to extract robust features for our learning problem. Additionally, the data reduction achieved along the time dimension of the data by the use of the wavelet scattering transform was critical in order to create a computationally feasible problem for our recurrent network.

helperbatchscatfeatures - This function returns the wavelet time scattering feature matrix for a given input signal. If `useGPU` is set to `true`, the scattering transform is computed on the GPU.

```
function sc = helperBatchScatFeatures(ds,sn,N,batchsize,useGPU)
% This function is only intended to support examples in the Wavelet
% Toolbox. It may be changed or removed in a future release.

% Read batch of data from audio datastore
batch = helperReadBatch(ds,N,batchsize);
if useGPU
    batch = gpuArray(batch);
end
```

```
% Obtain scattering features
S = sn.featureMatrix(batch,'transform','log');
gather(batch);
S = gather(S);

% Subsample the features
%sc = S(:,1:6:end,:);
sc = S;
end
```

helperReadBatch - This function reads batches of a specified size from a datastore and returns the output in single precision. Each column of the output is a separate signal from the datastore. The output may have fewer columns than the batch size if the datastore does not have enough records.

```
function batchout = helperReadBatch(ds,N,batchsize)
% This function is only in support of Wavelet Toolbox examples. It may
% change or be removed in a future release.
%
% batchout = readReadBatch(ds,N,batchsize) where ds is the Datastore and
%   ds is the Datastore
%   batchsize is the batchsize

kk = 1;

while(hasdata(ds)) && kk <= batchsize
    tmpRead = read(ds);
    batchout(:,kk) = cast(tmpRead(1:N),'single'); %#ok<AGROW>
    kk = kk+1;
end

end
```

Parasite Classification Using Wavelet Scattering and Deep Learning

This example shows how to classify parasitic infections in Giemsa stain images using wavelet image scattering and deep learning. The dataset is challenging for deep networks because it contains only 48 images. The images are divided evenly into three categories of parasitic infections: babesiosis, plasmodium-gametocyte, and trypanosomiasis.

Data

Obtain the data from the MATLAB® file exchange: Deploying Deep Neural Networks to Embedded GPUs and unzip the file. The file is in the same folder as this example.

```
url = "https://www.mathworks.com/matlabcentral/mlc-downloads/downloads/" + ...
    "5918495a-0009-419e-8e10-77b06e3fe553/844e43fa-7c50-4f88-a435-f0afe04fc3a3/" + ...
    "packages/zip";
websave("classifyBloodSmearImages.zip",url);
unzip('classifyBloodSmearImages.zip')
```

Create an `ImageDatastore` to manage the access of the Giemsa stain images. The images are in RGB format with a common size of 300-by-300-by-3.

```
imagedir = fullfile('classifyBloodSmearImages','BloodSmearImages');
Imds = imageDatastore(imagedir,'IncludeSubFolders',true,'FileExtensions',...
    '.jpg','LabelSource','foldernames');
summary(Imds.Labels)
```

```
     babesiosis                16
     plasmodium-gametocyte     16
     trypanosomiasis           16
```

There are 16 images for each of the three parasite types. Split the data into training and hold-out test sets, with 70 percent of the images in the training set and 30 percent in the test set. Set the random number generator for reproducibility.

```
rng default
[trainImds,testImds] = splitEachLabel(Imds,0.7);
```

Verify that equal numbers of each parasite class are contained in both the training and test sets.

```
summary(trainImds.Labels)
```

```
     babesiosis                11
     plasmodium-gametocyte     11
     trypanosomiasis           11
```

```
% Perform the same for the test set.
summary(testImds.Labels)
```

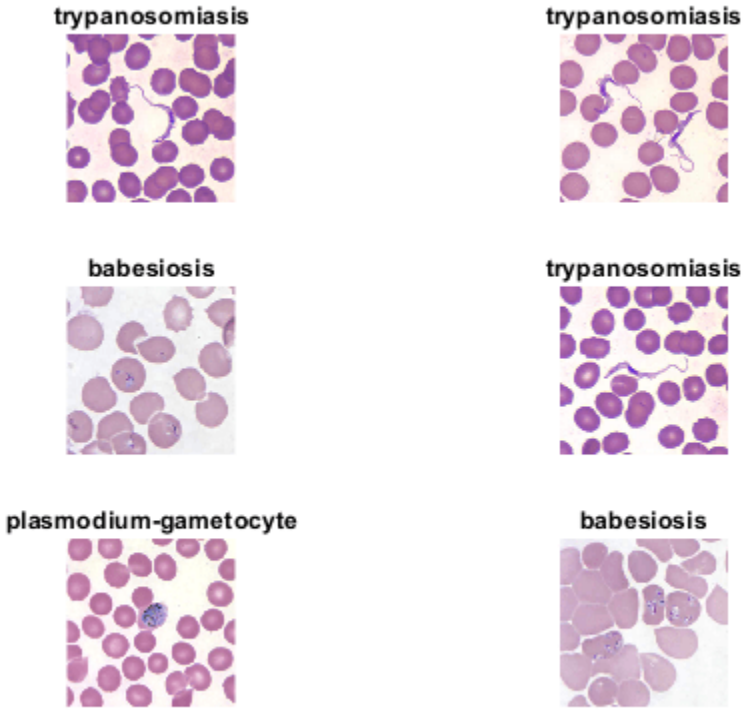
```
     babesiosis                5
     plasmodium-gametocyte     5
     trypanosomiasis           5
```

Because this is a small dataset, the entire training and test sets fit in memory. Read all images for both sets.

```
trainImages = readall(trainImds);
testImages = readall(testImds);
```

Plot some sample images from the training data.

```
idx = randperm(33,6);
figure
for ii = 1:length(idx)
    im = trainImages{idx(ii)};
    subplot(3,2,ii)
    imshow(im,[])
    title(string(trainImds.Labels(idx(ii))));
end
```



Wavelet Scattering Network

In this example, you use a wavelet scattering transform as the feature extractor for the machine learning approaches. The wavelet scattering transform helps to reduce the dimensionality of the data and increase the interclass dissimilarity. Construct a two-layer image scattering network with a 40-by-40 pixel invariance scale. Use two wavelets per octave in the first layer and one wavelet per octave in the second layer. Use two rotations of the wavelets per layer.

```
sn = waveletScattering2('ImageSize',[300 300],'InvarianceScale',40,...
    'QualityFactors',[2 1],'NumRotations',[2 2]);
[~,npaths] = paths(sn);
sum(npaths)
```

```
ans = 27
```

```
coefficientSize(sn)
```

```
ans = 1×2

    38    38
```

The specified wavelet scattering network has 27 paths. The image on each scattering path is reduced to 38-by-38-by-3. Even without further averaging of the scattering coefficients, this is a reduction in the size of each image's memory by more than a factor of 2. However, for classification we form a feature vector that averages the scattering coefficients over the spatial and channel dimensions. This results in feature vectors with only 27 elements, a real-valued scalar for each scattering path. This represents a reduction in the number of elements by a factor of 10,000 for each image.

The following code computes the wavelet scattering feature vectors for both the training and test sets. Concatenate the feature vectors so that you have *N*-by-27 matrices, where *N* is the number of examples in the training or test set and each row is a wavelet scattering feature vector for an example.

```
trainfeatures = cellfun(@(x)helperScatImages_mean(sn,x),trainImages,'Uni',0);
testfeatures = cellfun(@(x)helperScatImages_mean(sn,x),testImages,'Uni',0);
trainfeatures = cat(1,trainfeatures{:});
testfeatures = cat(1,testfeatures{:});
```

SVM Classification

Use an SVM classifier with the scattering features. Choose a cubic polynomial kernel. Use a one-vs-all coding scheme.

```
template = templateSVM(...
    'KernelFunction', 'polynomial', ...
    'PolynomialOrder', 3, ...
    'KernelScale', 1, ...
    'BoxConstraint', 314, ...
    'Standardize', true);
classificationSVM = fitcecoc(trainfeatures,trainImds.Labels,...
    'Learners', template, 'Coding', 'onevsall');
```

Estimate the accuracy on the training set using cross-validation with 5 folds.

```
kfoldmodel = crossval(classificationSVM, 'KFold', 5);
loss = kfoldLoss(kfoldmodel)*100;
crossvalAccuracy = 100-loss
```

```
crossvalAccuracy = single
    81.8182
```

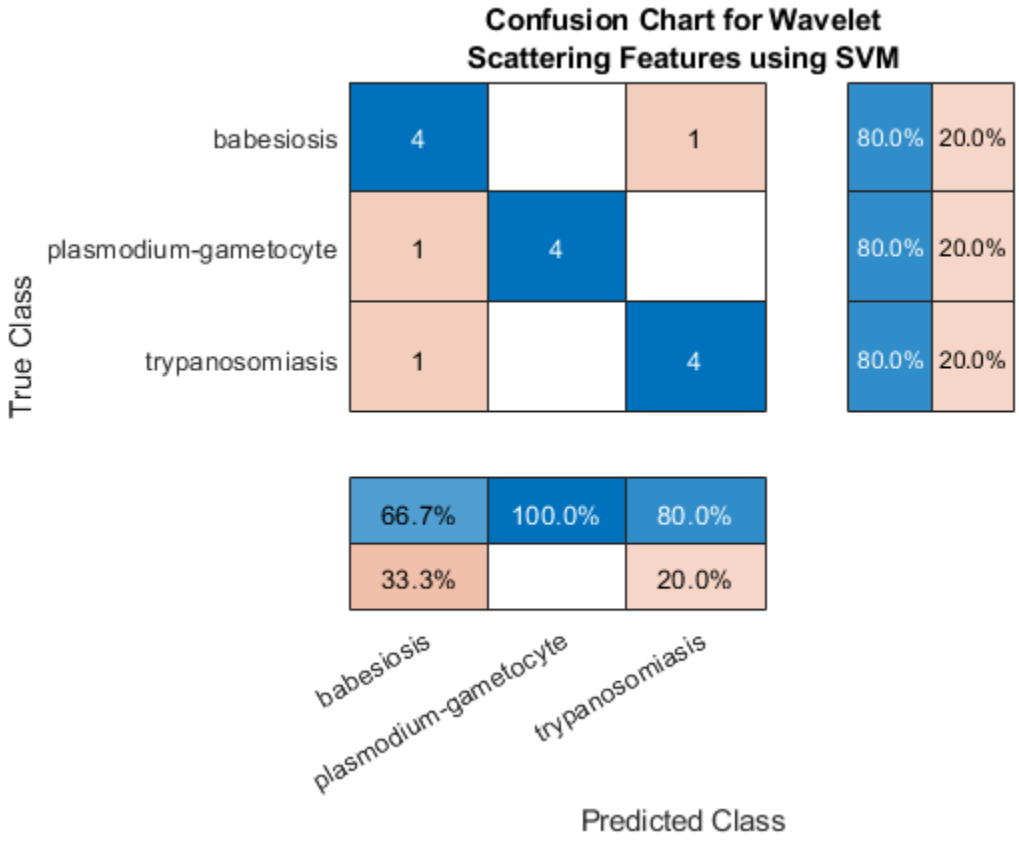
The cross-validation accuracy is approximately 80 percent. Now examine the accuracy on the held-out test set and plot the confusion chart.

```
[predLabels,scores] = predict(classificationSVM,testfeatures);
testAccuracy = ...
    sum(categorical(predLabels)== testImds.Labels)/numel(testImds.Labels)*100
```

```
testAccuracy = 80
```

```
figure
cchart = confusionchart(testImds.Labels,predLabels);
```

```
cchart.Title = ...
    {'Confusion Chart for Wavelet' ; 'Scattering Features using SVM'};
cchart.RowSummary = 'row-normalized';
cchart.ColumnSummary = 'column-normalized';
```



The overall test accuracy is 80 percent with the SVM model. The recall for each class is 80%. The precision is also good for the plasmodium-gametocyte and trypanosomiasis parasites, but worse for babesiosis. Examine the F1 scores for each class.

```
f1SVM = f1score(cchart.NormalizedValues);
disp(f1SVM)
```

```
                            F1
                          _______

    babesiosis            0.72727
    plasmodium-gametocyte 0.88889
    trypanosomiasis           0.8
```

All F1 scores are between approximately 0.7 and 0.9.

PCA classifier with scattering features

Support vector machines are powerful techniques for features that are not linearly separable, but they are designed for binary classification and may be suboptimal for multiclass problems. Here you complement the SVM analysis by using a simple PCA (linear) classifier with the same wavelet scattering features. The `helperPCAModel` function determines the `numcomp` eigenvectors

corresponding to the largest eigenvalues of the covariance matrix of the wavelet scattering features for each pathogen in the training set along with the class means.

`helperPCAClassifier` classifies each test sample. It does this by subtracting the model class means from each wavelet scattering feature vector in the test dataset and projecting the centered feature vectors onto the covariance-matrix eigenvectors for each class in the model. `helperPCAClassifier` assigns each test example to the pathogen with the smallest error, or residual. This is a principal components analysis (PCA) classifier.

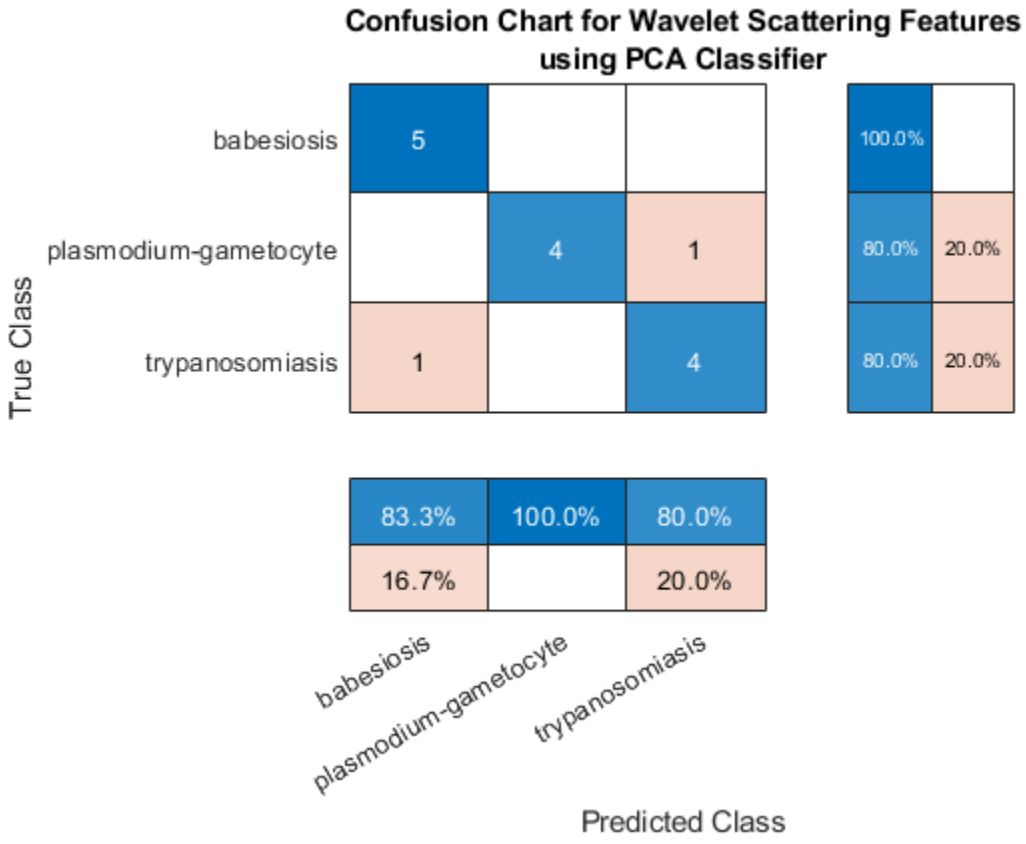
Remove the 0-th order scattering features from each feature vector. Set the number of principal components (eigenvectors) to 6.

```
numcomp = 6;
model = helperPCAModel(trainfeatures(:,2:end)',numcomp,trainImds.Labels);
PCALabels = helperPCAClassifier(testfeatures(:,2:end)',model);
testPCAacc = sum(PCALabels==testImds.Labels)/numel(testImds.Labels)*100
```

```
testPCAacc = 86.6667
```

The test accuracy is approximately 87% with the PCA classifier. Plot the confusion chart and calculate the F1 scores for each class.

```
figure
cchart = confusionchart(testImds.Labels,PCALabels);
cchart.Title = {'Confusion Chart for Wavelet Scattering Features' ; ...
    'using PCA Classifier'};
cchart.RowSummary = 'row-normalized';
cchart.ColumnSummary = 'column-normalized';
```



```
f1PCA = f1score(cchart.NormalizedValues);
disp(f1PCA)
```

```
                              F1
                            _______

    babesiosis              0.90909
    plasmodium-gametocyte   0.88889
    trypanosomiasis             0.8
```

The F1 scores for the PCA classifier with wavelet scattering features are quite strong, with all scores between 0.8 and 1.

Convolutional Deep Network

In this section, you attempt the same classification using deep convolutional networks. Deep networks provide state-of-art results for classification problems with large datasets and are capable of learning complicated nonlinear mappings, but their performance often suffers in small datasets. To mitigate this problem, use an image augmenter. `imageDataAugmenter` perturbs the data in each epoch, in effect creating new training examples.

```
augmenter = imageDataAugmenter('RandRotation',[0 180],'RandXTranslation', [-5 5], ...
    'RandYTranslation',[-5 5]);
augimds = augmentedImageDatastore([300 300 3],trainImds,'DataAugmentation',augmenter);
```

Define a small CNN consisting of two convolution layers followed by batch normalization layers and RELU activations. Follow the final RELU activation with max pooling, fully connected, and softmax layers.

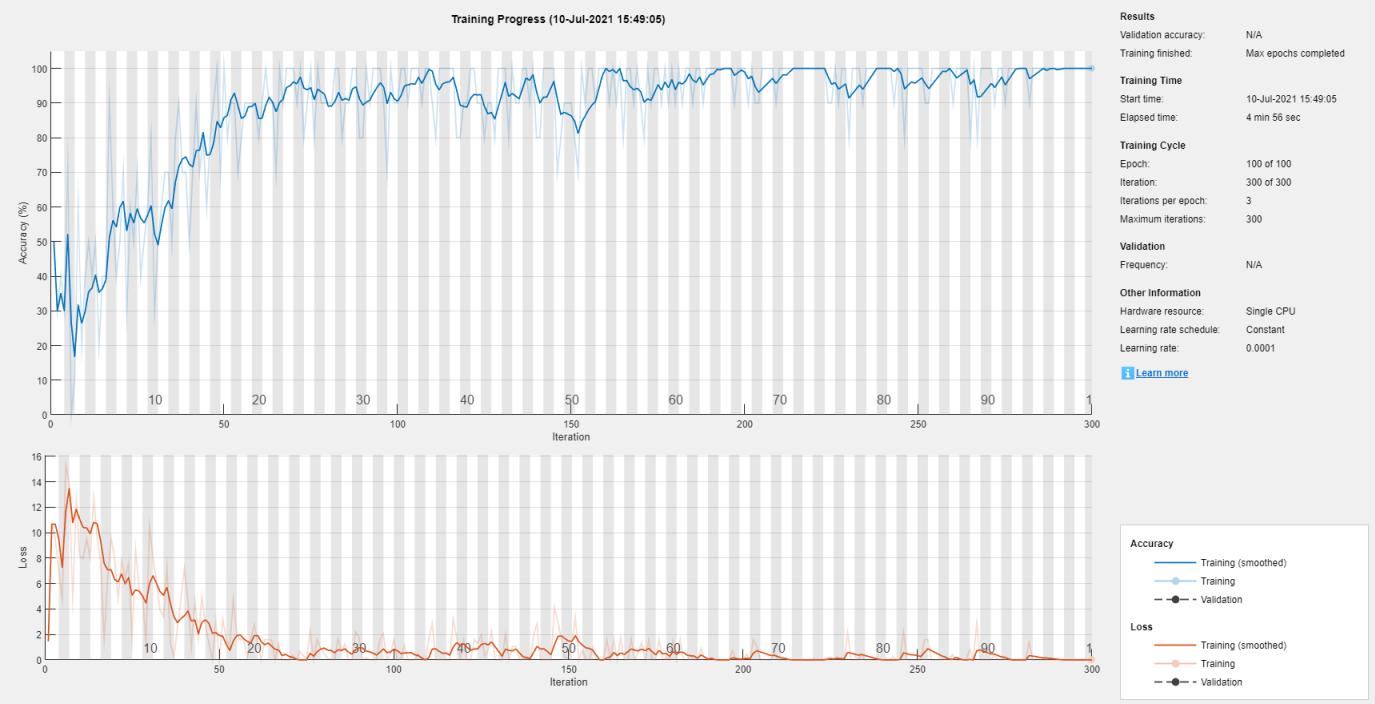
```
layers = [
    imageInputLayer([300 300 3])
    convolution2dLayer(7,16)
    batchNormalizationLayer
    reluLayer
    convolution2dLayer(3,20)
    batchNormalizationLayer
    reluLayer
    maxPooling2dLayer(4)
    fullyConnectedLayer(3)
    softmaxLayer
    classificationLayer];
```

Use stochastic gradient descent with a minibatch size of 10. Shuffle the data each epoch. Run the training for 100 epochs.

```
opts = trainingOptions('sgdm',...
    'InitialLearnRate',  0.0001, ...
    'MaxEpochs', 100, ...
    'MiniBatchSize',10,...
    'Shuffle','every-epoch',...
    'Plots', 'training-progress',...
    'Verbose',false,...
    'ExecutionEnvironment','cpu');
```

Train the network.

```
trainedNet = trainNetwork(augimds,layers,opts);
```

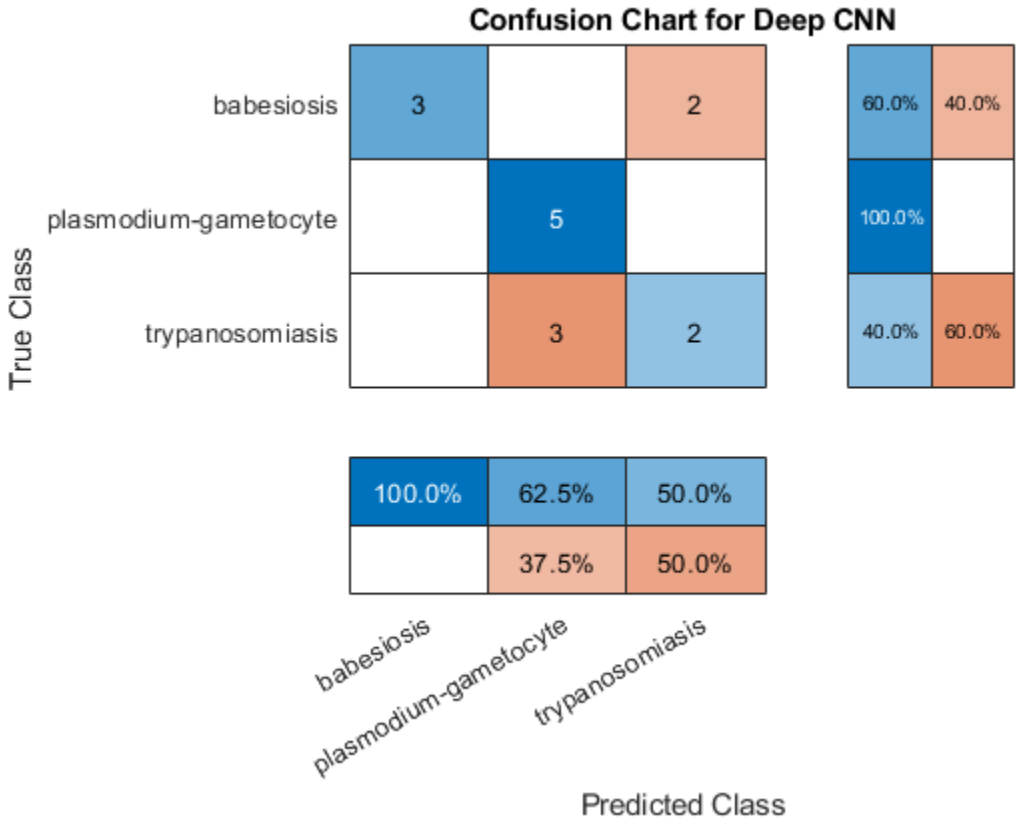


Examine the performance of the network on the held-out test set.

```
ypred = trainedNet.classify(testImds);
cnnAccuracy = sum(ypred == testImds.Labels)/numel(testImds.Labels)*100
```

```
cnnAccuracy = 66.6667
```

```
figure
cchart = confusionchart(testImds.Labels,ypred);
cchart.Title = 'Confusion Chart for Deep CNN';
cchart.RowSummary = 'row-normalized';
cchart.ColumnSummary = 'column-normalized';
```



```
f1CNN = f1score(cchart.NormalizedValues);
disp(f1CNN)
```

```
                            F1
                          _______

    babesiosis              0.75
    plasmodium-gametocyte  0.76923
    trypanosomiasis        0.44444
```

In spite of using an augmented dataset for training, the CNN has overfit the training set and the F1 scores are significantly worse than either the SVM or PCA model with the wavelet scattering features.

Next, use transfer learning with SqueezeNet. Modify the final convolutional layer to accommodate the fact that you have three classes of pathogens. SqueezeNet was constructed to recognize 1,000 classes.

```
net = squeezenet;
lgraphSQZ = layerGraph(net);
numClasses = numel(categories(trainImds.Labels));
oldFinalConv = lgraphSQZ.Layers(end-4);
newFinalConv = convolution2dLayer(1,numClasses, ...
        'Name','new_conv');
setLearnRateFactor(newFinalConv,'Weights',10);
setLearnRateFactor(newFinalConv,'Bias',10)
```

```
ans =
  Convolution2DLayer with properties:

             Name: 'new_conv'

   Hyperparameters
        FilterSize: [1 1]
       NumChannels: 'auto'
        NumFilters: 3
            Stride: [1 1]
    DilationFactor: [1 1]
       PaddingMode: 'manual'
       PaddingSize: [0 0 0 0]
      PaddingValue: 0

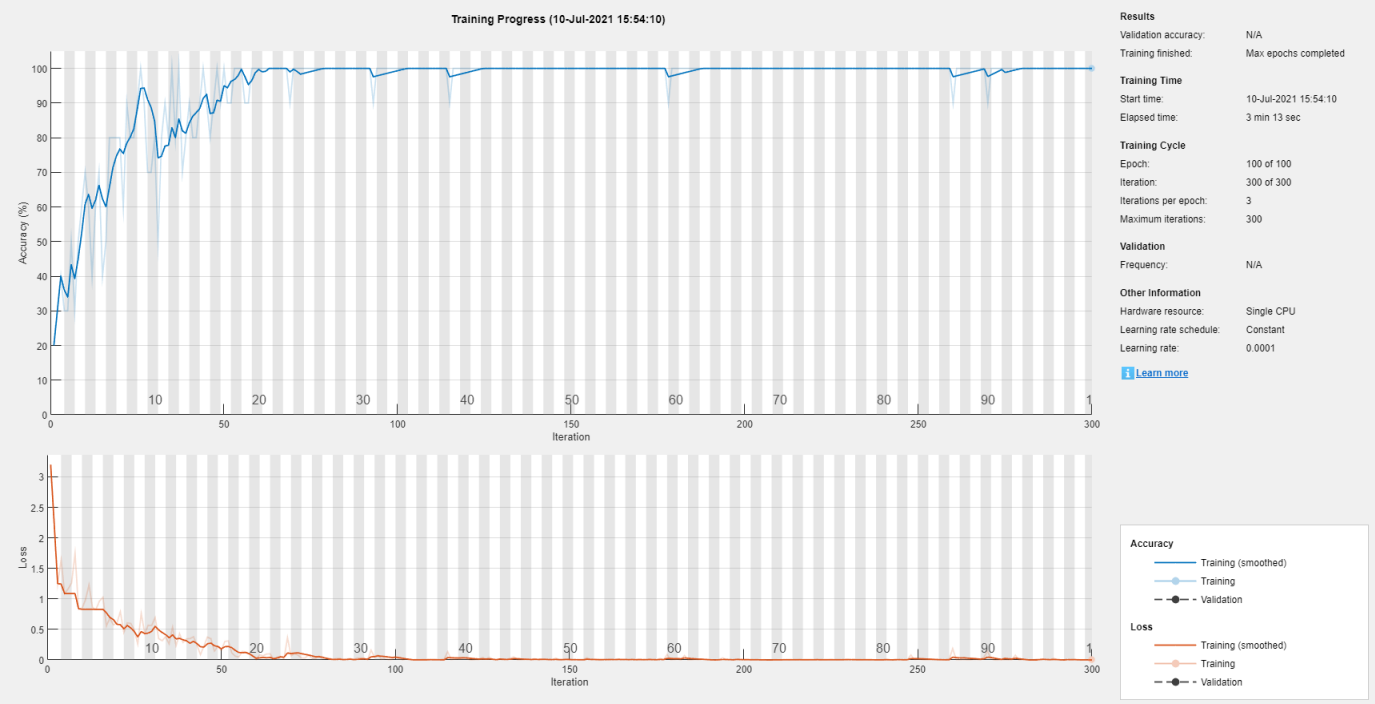
   Learnable Parameters
           Weights: []
              Bias: []

  Show all properties
```

```
lgraphSQZ = replaceLayer(lgraphSQZ,oldFinalConv.Name,newFinalConv);
oldClassLayer= lgraphSQZ.Layers(end);
newClassLayer = classificationLayer('Name','new_classoutput');
lgraphSQZ = replaceLayer(lgraphSQZ,oldClassLayer.Name,newClassLayer);
```

Reset the training and test datastores. Modify the datastore read function to resize images to be compatible with SqueezeNet, which expects 227-by-227-by-3 images. Set up the image augmenter and train the network.

```
reset(trainImds);
reset(testImds);
trainImds.ReadFcn = @(x)imresize(imread(x),'OutputSize',[227 227]);
testImds.ReadFcn = @(x)imresize(imread(x),'OutputSize',[227 227]);
augmenter = imageDataAugmenter('RandRotation',[0 180],'RandXTranslation', [-5 5], ...
    'RandYTranslation',[-5 5]);
augimds = augmentedImageDatastore([227 227 3],trainImds,...
    'DataAugmentation',augmenter);
trainedNet = trainNetwork(augimds,lgraphSQZ,opts);
```

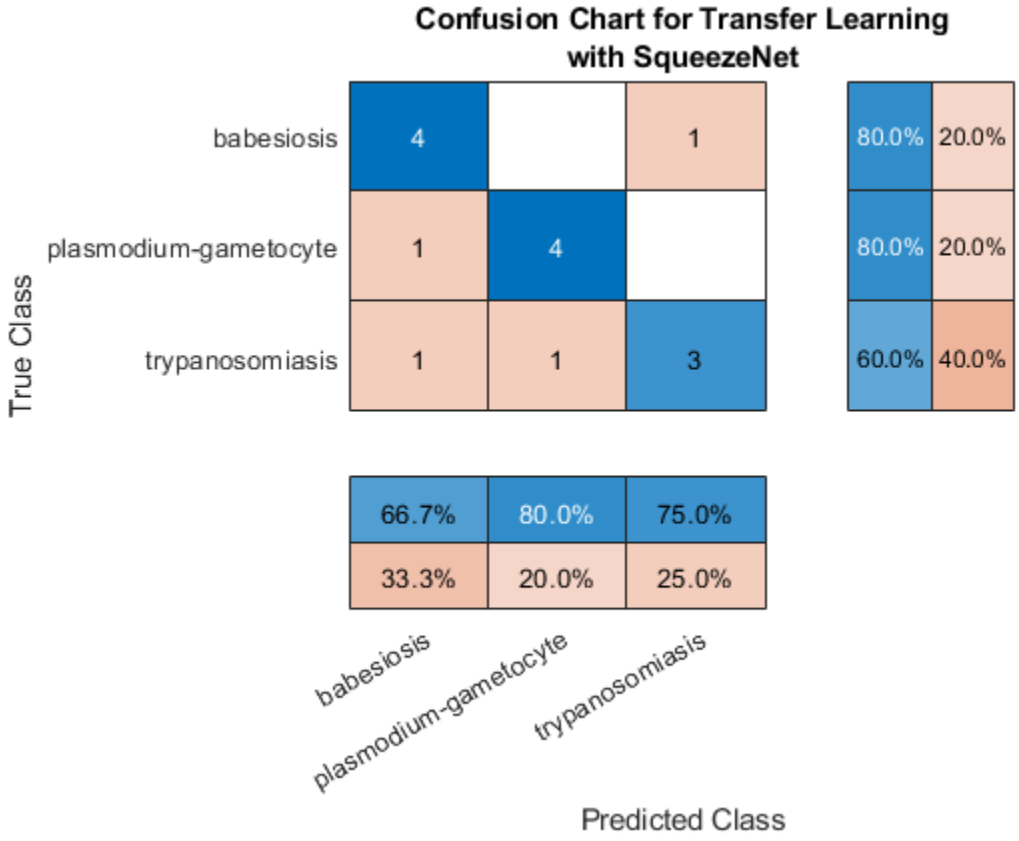


Obtain the SqueezeNet accuracy, plot the confusion chart, and compute the F1 scores.

```
ypred = trainedNet.classify(testImds);
sqznetAccuracy = sum(ypred == testImds.Labels)/numel(testImds.Labels)*100
```

```
sqznetAccuracy = 73.3333
```

```
figure
cchart = confusionchart(testImds.Labels,ypred);
cchart.Title = {'Confusion Chart for Transfer Learning' ; 'with SqueezeNet'};
cchart.RowSummary = 'row-normalized';
cchart.ColumnSummary = 'column-normalized';
```



```
f1SqueezeNet = f1score(cchart.NormalizedValues);
disp(f1SqueezeNet)
```

```
                            F1
                          _______

    babesiosis            0.72727
    plasmodium-gametocyte     0.8
    trypanosomiasis       0.66667
```

SqueezeNet performs better than the simpler CNN, particularly in terms of the F1 score for trypanosomiasis, but the performance does not match the accuracy of the simpler PCA classifier with the wavelet scattering features.

Summary

In this example, the wavelet scattering transform and deep learning frameworks were used to classify pathogens in Giemsa stain images. The limited dataset size provides challenges for training a deep learning classifier even when data augmentation is used. The example illustrated that the wavelet scattering transform can provide a useful alternative to deep networks in such cases. In forming feature vectors from the wavelet scattering transform, we reduced each transform output from a 27-by-38-by-38-by-3 tensor to a 27-element vector. Accordingly, we have used a global pooling of the scattering coefficients. It is possible to utilize other pooling schemes, which could yield better results.

Appendix — Supporting Functions

```
function features = helperScatImages_mean(sn,x)
smat = featureMatrix(sn,x);
features = mean(smat,2:4);
features = features';
end
function F1scores = f1score(cchartVal)
N = sum(cchartVal,'all');
probT = sum(cchartVal)./N;
classProbEst = diag(cchartVal)./N;
Prec = classProbEst'./probT;
probC = [5/15 5/15 5/15];

Spectrum Sensing with Deep Learning to Identify 5G and LTE Signals

This example shows how to train a semantic segmentation network using deep learning for spectrum monitoring. One of the uses of spectrum monitoring is to characterize spectrum occupancy. The neural network in this example is trained to identify 5G NR and LTE signals in a wideband spectrogram.

Introduction

Computer vision uses the semantic segmentation technique to identify objects and their locations in an image or a video. In wireless signal processing, the objects of interest are wireless signals, and the locations of the objects are the frequency and time occupied by the signals. In this example we apply the semantic segmentation technique to wireless signals to identify spectral content in a wideband spectrogram.

In the following, you will:

1. Generate training signals.
2. Apply transfer learning to a semantic segmentation network to identify 5G NR and LTE signals in time and frequency.
3. Test the trained network with synthetic signals.
4. Use an SDR to test the network with over the air (OTA) signals.

Generate Training Data

One advantage of wireless signals in the deep learning domain is the fact that the signals are synthesized. Also, we have highly reliable channel and RF impairment models. As a result, instead of collecting and manually labeling signals, you can generate 5G NR signals using 5G Toolbox™ and LTE signals using LTE Toolbox™ functions. You can pass these signals through standards-specified channel models to create the training data.

Train the network with frames that contain only 5G NR or LTE signals and then shift these signals in frequency randomly within the band of interest. Each frame is 40 ms long, which is the duration of 40 subframes. The network assumes that the 5G NR or LTE signal occupies the same band for the whole frame duration. To test the network performance, create frames that contain both 5G NR and LTE signals on distinct random bands within the band of interest.

Use a sampling rate of 61.44 MHz. This rate is high enough to process most of the latest standard signals and several low-cost software defined radio (SDR) systems can sample at this rate providing about 50 MHz of useful bandwidth. To monitor a wider band, you can increase the sample rate, regenerate training frames and retrain the network.

Use the `helperSpecSenseTrainingData` function to generate training frames. This function generates 5G NR signals using the `helperSpecSenseNRSignal` function and LTE signals using the `helperSpecSenseLTESignal` function. This table lists 5G NR variable signal parameters.

5G NR Parameter	Value	Units
Bandwidth	[10 15 20 25 30 40 50]	MHz
Sub-Carrier Spacing (SCS)	[15 30]	kHz
SSB Block Pattern	["Case A" "Case B"]	
SSB Period	[20]	ms

This table lists LTE variable signal parameters.

LTE Parameter	Value	Units
Reference Channel	["R.2","R.6","R.8","R.9"}	
Bandwidth	[10 5 15 20]	MHz
Duplex Mode	FDD	

Use the `nrCDLChannel` (5G Toolbox) and the `lteFadingChannel` (LTE Toolbox) functions to add channel impairments. For details of the channel configurations, see the `helperSpecSenseTrainingData` function. This table lists channel parameters.

Channel Parameter	Value	Units
SNR	[40 50 100]	dB
Doppler	[0 10 500]	Hz

The `helperSpecSenseTrainingData` function uses the `helperSpecSenseSpectrogramImage` function to create spectrogram images from complex baseband signals. Calculate the spectrograms using an FFT length of 4096. Generate 256 by 256 RGB images. This Image size allows a large enough batch of images to fit in memory during training while providing enough resolution in time and frequency. If your GPU does not have sufficient memory, you can resize the images to smaller sizes or reduce the training batch size.

The `generateTrainData` variable determines whether training data is to be downloaded or generated. Choosing "Use downloaded data" sets the `generateTrainData` variable to `false`. Choosing "Generate training data" sets the `generateTrainData` variable to `true` to generate the training data from scratch. Data generation may take several hours depending on the configuration of your computer. Using a PC with Intel® Xeon® W-2133 CPU @ 3.60GHz and creating a parallel pool with six workers with the Parallel Computing Toolbox, training data generation takes about an hour. Choose "Train network now" to train the network. This process takes about 20 minutes with the same PC and NVIDIA® Titan V GPU. Choose "Use trained network" to skip network training. Instead, the example downloads the trained network.

Use 900 frames from each set of signals: 5G NR only, LTE only and 5G NR and LTE both. If you increase the number of possible values for the system parameters, increase the number of training frames .

```
imageSize = [256 256];    % pixels
sampleRate = 61.44e6;     % Hz
numSubFrames = 40;        % corresponds to 40 ms
frameDuration = numSubFrames*1e-3;    % seconds
trainDir = fullfile(pwd,'TrainingData');
```

```
generateTrainData = Use downloaded data ;
trainNow = Use trained network ;
if ~generateTrainData || ~trainNow
  helperSpecSenseDownloadData()
end
```

```
Starting download of data files from:
    https://www.mathworks.com/supportfiles/spc/SpectrumSensing/SpectrumSenseTrainingDataNetwork.t
Download complete. Extracting files.
Extract complete.
```

```
if generateTrainData
  numFramesPerStandard = 900;
  helperSpecSenseTrainingData(numFramesPerStandard,imageSize,trainDir,numSubFrames,sampleRate);
end
```

Load Training Data

Use the `imageDatastore` function to load training images with the spectrogram of 5G NR and LTE signals. The `imageDatastore` function enables you to efficiently load a large collection of images from disk. Spectrogram images are stored in .png files.

```
imds = imageDatastore(trainDir,'IncludeSubfolders',false,'FileExtensions','.png');
```

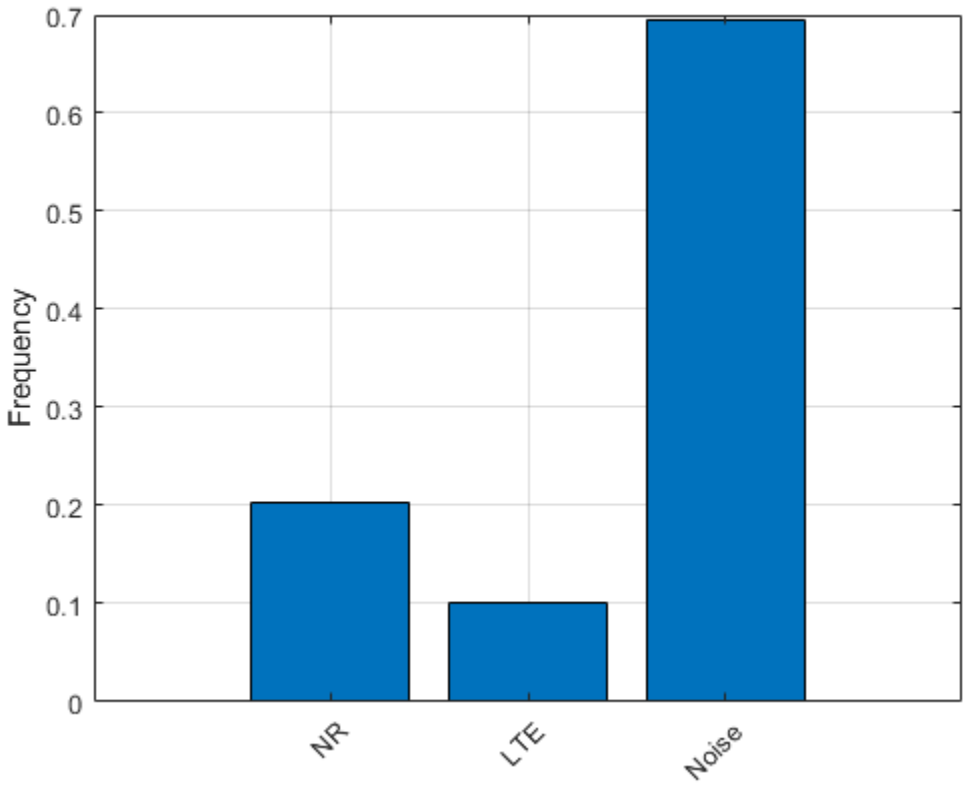
Use the `pixelLabelDatastore` (Computer Vision Toolbox) function to load spectrogram pixel label image data. Each pixel is labeled as one of "NR", "LTE" or "Noise". A pixel label datastore encapsulates the pixel label data and the label ID to a class name mapping. Pixel labels are stored in .hdf files.

```
classNames = ["NR" "LTE" "Noise"];
pixelLabelID = [127 255 0];
pxdsTruth = pixelLabelDatastore(trainDir,classNames,pixelLabelID,...
  'IncludeSubfolders',false,'FileExtensions','.hdf');
```

Analyze Dataset Statistics

To see the distribution of class labels in the training dataset, use the `countEachLabel` (Computer Vision Toolbox) function to count the number of pixels by class label, and plot the pixel counts by class.

```
tbl = countEachLabel(pxdsTruth);
frequency = tbl.PixelCount/sum(tbl.PixelCount);
figure
bar(1:numel(classNames),frequency)
grid on
xticks(1:numel(classNames))
xticklabels(tbl.Name)
xtickangle(45)
ylabel('Frequency')
```



Ideally, all classes would have an equal number of observations. However, with wireless signals it is common for the classes in the training set to be imbalanced. 5G NR signals may have larger bandwidth than LTE signals, and noise fills the background. Because the learning is biased in favor of the dominant classes, imbalance in the number of observations per class can be detrimental to the learning process. In the Balance Classes Using Class Weighting on page 13-0 section, class weighting is used to mitigate bias caused by imbalance in the number of observations per class.

Prepare Training, Validation, and Test Sets

The deep neural network uses 80% of the single signal images from the dataset for training and, 20% of the images for validation. The `helperSpecSensePartitionData` function randomly splits the image and pixel label data into training and validation sets.

```
[imdsTrain,pxdsTrain,imdsVal,pxdsVal] = helperSpecSensePartitionData(imds,pxdsTruth,[80 20]);
cdsTrain = pixelLabelImageDatastore(imdsTrain,pxdsTrain,'OutputSize',imageSize);
cdsVal = pixelLabelImageDatastore(imdsVal,pxdsVal,'OutputSize',imageSize);
```

Train Deep Neural Network

Use the `deeplabv3plusLayers` (Computer Vision Toolbox) function to create a semantic segmentation neural network. Choose `resnet50` as the base network and specify the input image size (number of pixels used to represent time and frequency axes) and the number of classes. If the Deep Learning Toolbox™ Model *for ResNet-50 Network* support package is not installed, then the function provides a link to the required support package in the Add-On Explorer. To install the support package, click the link, and then click **Install**. Check that the installation is successful by

typing `resnet50` at the command line. If the required support package is installed, then the function returns a `DAGNetwork` object.

```
baseNetwork = resnet50;
lgraph = deeplabv3plusLayers(imageSize,numel(classNames),baseNetwork);
```

Balance Classes Using Class Weighting

To improve training when classes in the training set are not balanced, you can use class weighting to balance the classes. Use the pixel label counts computed earlier with the `countEachLabel` function and calculate the median frequency class weights.

```
imageFreq = tbl.PixelCount ./ tbl.ImagePixelCount;
classWeights = median(imageFreq) ./ imageFreq;
```

Specify the class weights using a `pixelClassificationLayer` (Computer Vision Toolbox).

```
pxLayer = pixelClassificationLayer('Name','labels','Classes',tbl.Name,'ClassWeights',classWeights
lgraph = replaceLayer(lgraph,"classification",pxLayer);
```

Select Training Options

Configure training using the `trainingOptions` function to specify the stochastic gradient descent with momentum (SGDM) optimization algorithm and the hyper-parameters used for SGDM. To get the best performance from the network, you can use the Experiment Manager to optimize training options.

```
opts = trainingOptions("sgdm",...
  MiniBatchSize = 40,...
  MaxEpochs = 20, ...
  LearnRateSchedule = "piecewise",...
  InitialLearnRate = 0.02,...
  LearnRateDropPeriod = 10,...
  LearnRateDropFactor = 0.1,...
  ValidationData = cdsVal,...
  ValidationPatience = 5,...
  Shuffle="every-epoch",...
  OutputNetwork = "best-validation-loss",...
  Plots = 'training-progress')
```

```
opts =
  TrainingOptionsSGDM with properties:

                     Momentum: 0.9000
               InitialLearnRate: 0.0200
              LearnRateSchedule: 'piecewise'
            LearnRateDropFactor: 0.1000
            LearnRateDropPeriod: 10
               L2Regularization: 1.0000e-04
       GradientThresholdMethod: 'l2norm'
             GradientThreshold: Inf
                     MaxEpochs: 20
                 MiniBatchSize: 40
                       Verbose: 1
               VerboseFrequency: 50
                 ValidationData: [1×1 pixelLabelImageDatastore]
            ValidationFrequency: 50
```

```
              ValidationPatience: 5
                         Shuffle: 'every-epoch'
                  CheckpointPath: ''
            ExecutionEnvironment: 'auto'
                      WorkerLoad: []
                       OutputFcn: []
                           Plots: 'training-progress'
                  SequenceLength: 'longest'
              SequencePaddingValue: 0
          SequencePaddingDirection: 'right'
              DispatchInBackground: 0
           ResetInputNormalization: 1
      BatchNormalizationStatistics: 'population'
                   OutputNetwork: 'best-validation-loss'
```

Train the network using the combined training data store, `cdsTrain`. The combined training data store contains single signal frames and true pixel labels.

```
if trainNow
  [net,trainInfo] = trainNetwork(cdsTrain,lgraph,opts); %#ok<UNRCH>
else
  load specSenseTrainedNet net
end
```

Test with Synthetic Signals

Test the network signal identification performance using signals that contain both 5G NR and LTE signals. Use the `semanticseg` (Computer Vision Toolbox) function to get the pixel estimates of the spectrogram images in the test data set. Use the `evaluateSemanticSegmentation` (Computer Vision Toolbox) function to compute various metrics to evaluate the quality of the semantic segmentation results.

```
dataDir = fullfile(trainDir,'LTE_NR');
imds = imageDatastore(dataDir,'IncludeSubfolders',false,'FileExtensions','.png');
pxdsResults = semanticseg(imds,net,"WriteLocation",tempdir);
```

```
Running semantic segmentation network
-------------------------------------
* Processed 900 images.
```

```
pxdsTruth = pixelLabelDatastore(dataDir,classNames,pixelLabelID,...
  'IncludeSubfolders',false,'FileExtensions','.hdf');
metrics = evaluateSemanticSegmentation(pxdsResults,pxdsTruth);
```

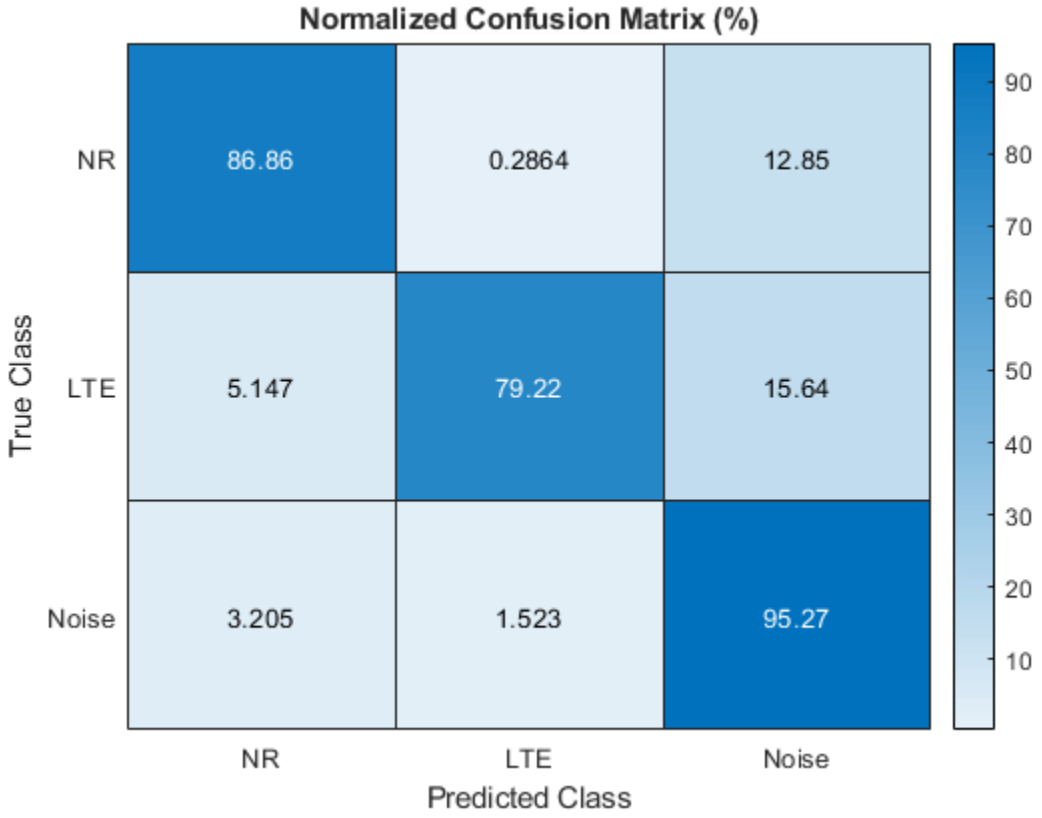
```
Evaluating semantic segmentation results
----------------------------------------
* Selected metrics: global accuracy, class accuracy, IoU, weighted IoU, BF score.
* Processed 900 images.
* Finalizing... Done.
* Data set metrics:

    GlobalAccuracy    MeanAccuracy    MeanIoU    WeightedIoU    MeanBFScore
    ______________    ____________    _______    ___________    ___________

       0.88609           0.87117       0.79066      0.79601        0.65624
```

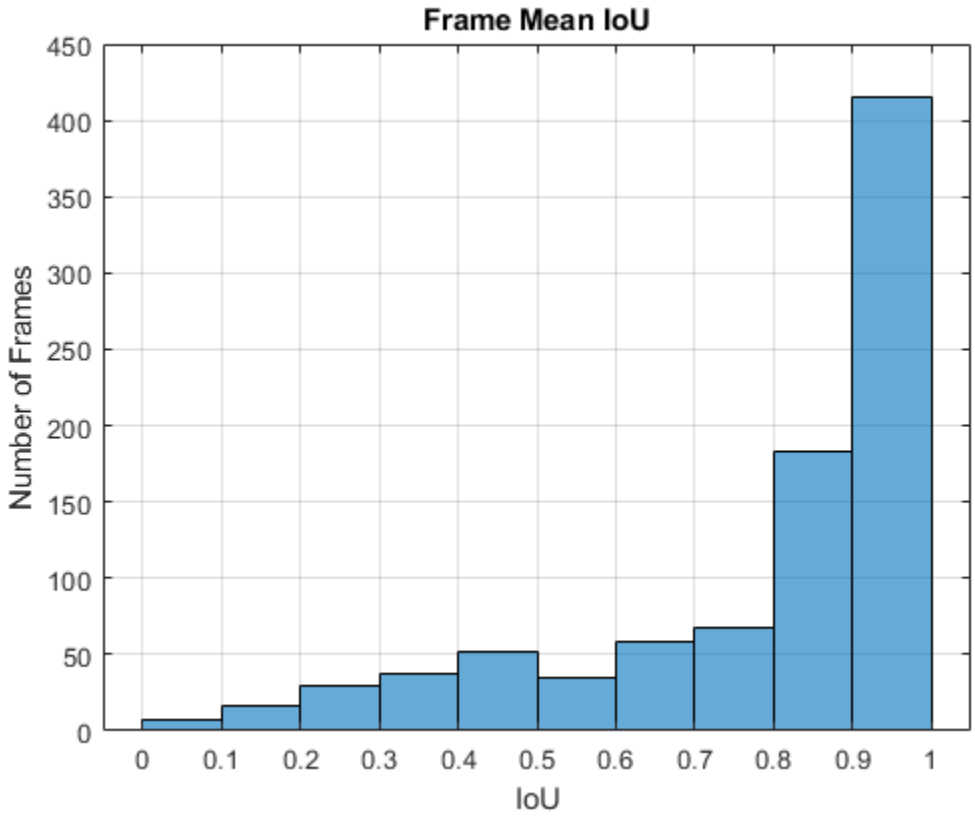
Plot the normalized confusion matrix for all test frames as a heat map.

```
normConfMatData = metrics.NormalizedConfusionMatrix.Variables;
figure
h = heatmap(classNames,classNames,100*normConfMatData);
h.XLabel = 'Predicted Class';
h.YLabel = 'True Class';
h.Title = 'Normalized Confusion Matrix (%)';
```



Plot the histogram of the per-image intersection over union (IoU). For each class, IoU is the ratio of correctly classified pixels to the total number of ground truth and predicted pixels in that class.

```
imageIoU = metrics.ImageMetrics.MeanIoU;
figure
histogram(imageIoU)
grid on
xlabel('IoU')
ylabel('Number of Frames')
title('Frame Mean IoU')
```



Inspecting low SNR frames shows that the spectrogram images do not contain visual features that can help the network identify the low SNR frames correctly. Repeat the same process, considering only the frames with average SNR of 50dB or 100dB and ignoring the frames with average SNR of 40dB.

```
files = dir(fullfile(dataDir,'*.mat'));
dataFiles = {};
labelFiles = {};
for p=1:numel(files)
  load(fullfile(files(p).folder,files(p).name),'params');
  if params.SNRdB > 40
    [~,name] = fileparts(files(p).name);
    dataFiles = [dataFiles; fullfile(files(p).folder,[name '.png'])]; %#ok<AGROW>
    labelFiles = [labelFiles; fullfile(files(p).folder,[name '.hdf'])]; %#ok<AGROW>
  end
end
imds = imageDatastore(dataFiles);
pxdsResults = semanticseg(imds,net,"WriteLocation",tempdir);
```

```
Running semantic segmentation network
-------------------------------------
* Processed 608 images.
```

```
pxdsTruth = pixelLabelDatastore(labelFiles,classNames,pixelLabelID);
metrics = evaluateSemanticSegmentation(pxdsResults,pxdsTruth);
```

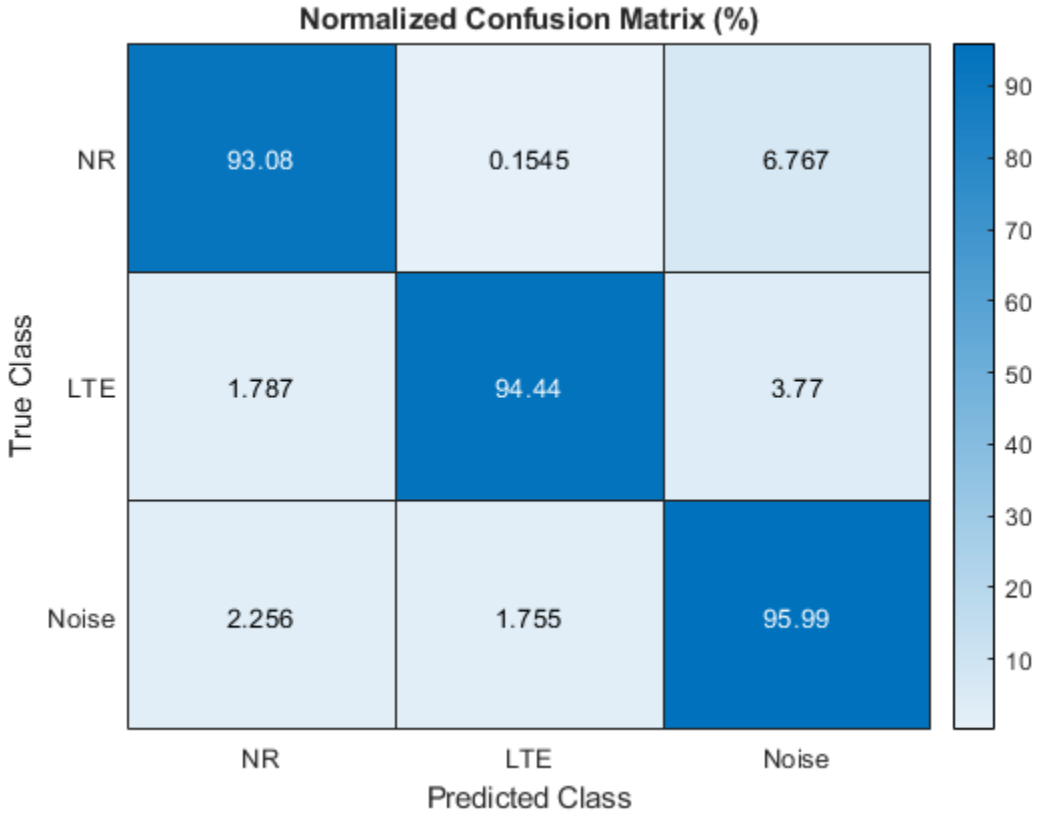
```
Evaluating semantic segmentation results
----------------------------------------
```

```
* Selected metrics: global accuracy, class accuracy, IoU, weighted IoU, BF score.
* Processed 608 images.
* Finalizing... Done.
* Data set metrics:
```

GlobalAccuracy	MeanAccuracy	MeanIoU	WeightedIoU	MeanBFScore
0.94487	0.94503	0.89799	0.89582	0.74699

Considering only the set of frames with higher SNR, replot the normalized confusion matrix and observe the improved network accuracy.

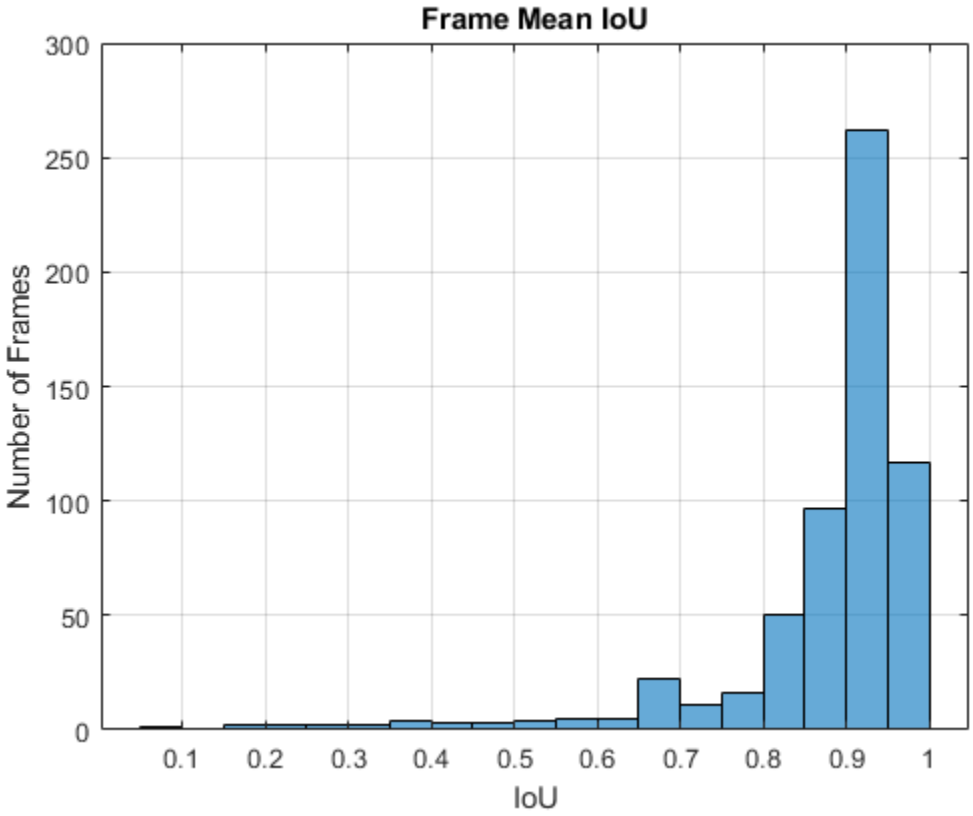
```
normConfMatData = metrics.NormalizedConfusionMatrix.Variables;
figure
h = heatmap(classNames,classNames,100*normConfMatData);
h.XLabel = 'Predicted Class';
h.YLabel = 'True Class';
h.Title = 'Normalized Confusion Matrix (%)';
```



Considering only the set of frames with higher SNR, replot the per-image IoU histogram and observe the improved distribution.

```
imageIoU = metrics.ImageMetrics.MeanIoU;
figure
histogram(imageIoU)
grid on
xlabel('IoU')
```

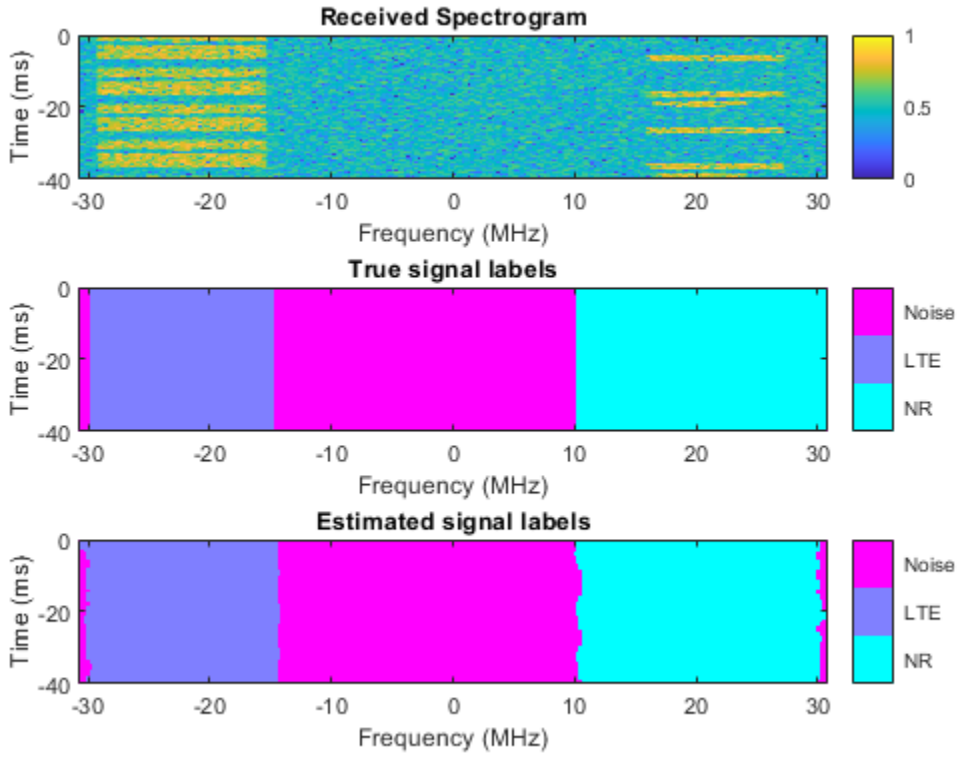
```
ylabel('Number of Frames')
title('Frame Mean IoU')
```



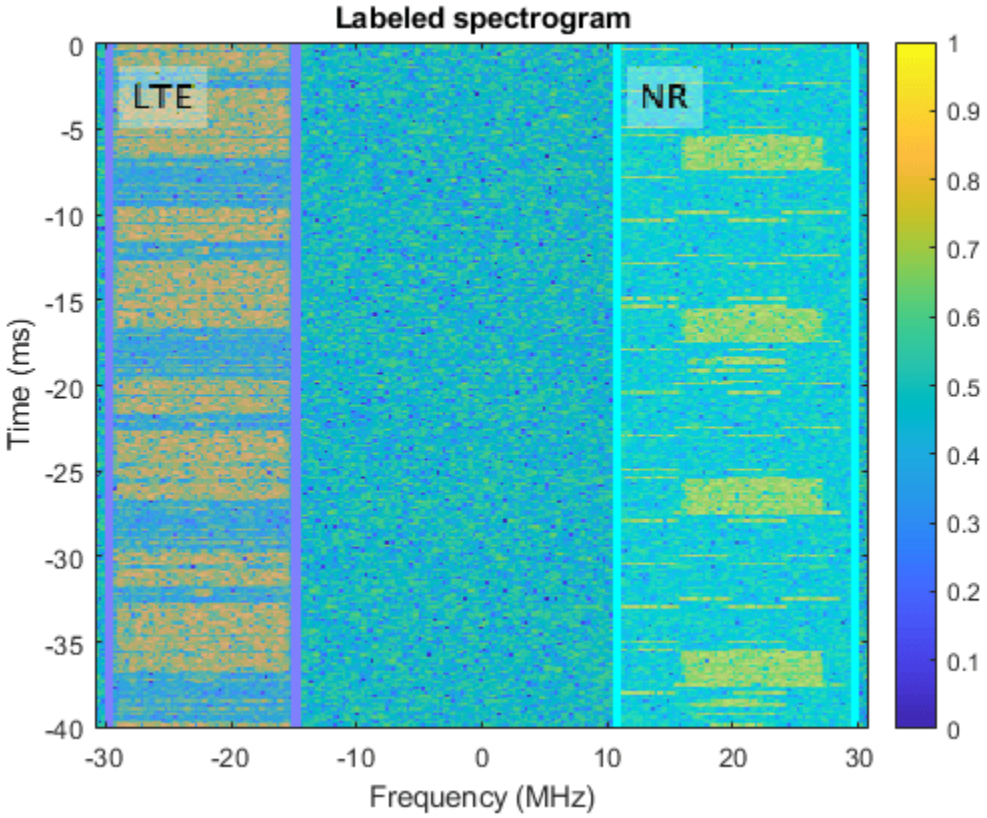
Identify 5G NR and LTE Signals in Spectrogram

Visualize the received spectrum, true labels, and predicted labels for the image with index 602.

```
imgIdx = 602;
rcvdSpectrogram = readimage(imds,imgIdx);
trueLabels = readimage(pxdsTruth,imgIdx);
predictedLabels = readimage(pxdsResults,imgIdx);
figure
helperSpecSenseDisplayResults(rcvdSpectrogram,trueLabels,predictedLabels, ...
  classNames,sampleRate,0,frameDuration)
```



```
figure
helperSpecSenseDisplayIdentifiedSignals(rcvdSpectrogram,predictedLabels, ...
  classNames,sampleRate,0,frameDuration)
```



Test with Over-the-Air Signals

Test the performance of the trained network using over-the-air signal captures. Find a nearby base station and tune the center frequency of your radio to cover the band of the signals you want to identify. This example sets the center frequency to 2.35 GHz. If you have at least one ADALM-PLUTO radio and have installed Communication Toolbox Support Package for ADALM-PLUTO Radio, you can run this section of the code. In case you do not have access to an ADALM-PLUTO radio, this example shows results of a test conducted using captured signals.

```
runSDRSection = false;
if helperIsPlutoSDRInstalled()
  radios = findPlutoRadio();
  if length(radios) >= 1
    runSDRSection = true;
  else
    disp("At least one ADALM-PLUTO radios is needed. Skipping SDR test.")
  end
else
    disp("Communications Toolbox Support Package for Analog Devices ADALM-PLUTO Radio not found.
    disp("Click Add-Ons in the Home tab of the MATLAB toolstrip to install the support package."
    disp("Skipping SDR test.")
end
```

```
Communications Toolbox Support Package for Analog Devices ADALM-PLUTO Radio not found.

Click Add-Ons in the Home tab of the MATLAB toolstrip to install the support package.

Skipping SDR test.
```

```
if runSDRSection
  % Set up PlutoSDR receiver
  rx = sdrrx('Pluto');
  rx.CenterFrequency = 2.35e9;
  rx.BasebandSampleRate = sampleRate;
  rx.SamplesPerFrame = frameDuration*rx.BasebandSampleRate;
  rx.OutputDataType = 'single';
  rx.EnableBurstMode = true;
  rx.NumFramesInBurst = 1;
  Nfft = 4096;
  overlap = 10;

  meanAllScores = zeros([imageSize numel(classNames)]);
  segResults = zeros([imageSize 10]);
  for frameCnt=1:10
    rxWave = rx();
    rxSpectrogram = helperSpecSenseSpectrogramImage(rxWave,Nfft,sampleRate,imageSize);

    [segResults(:,:,frameCnt),scores,allScores] = semanticseg(rxSpectrogram,net);
    meanAllScores = (meanAllScores*(frameCnt-1) + allScores) / frameCnt;
  end
  release(rx)

  [~,predictedLabels] = max(meanAllScores,[],3);
  figure
  helperSpecSenseDisplayResults(rxSpectrogram,[],predictedLabels,classNames,...
    sampleRate,rx.CenterFrequency,frameDuration)
  figure
  freqBand = helperSpecSenseDisplayIdentifiedSignals(rxSpectrogram,predictedLabels,...

Conclusions and Further Exploration

The trained network can distinguish 5G NR and LTE signals including two example captures from real base stations. The network may not be able to identify every captured signal correctly. In such cases, enhance the training data either by generating more representative synthetic signals or capturing over-the-air signals and including these in the training set.

You can use the LTE “Cell Search, MIB and SIB1 Recovery” (LTE Toolbox) and the “NR Cell Search and MIB and SIB1 Recovery” (5G Toolbox) examples to identify LTE and 5G NR base stations manually to capture training data, respectively.

If you need to monitor wider bands of spectrum, increase the `sampleRate`, regenerate the training data and retrain the network.

Autoencoders for Wireless Communications

This example shows how to model an end-to-end communications system with an autoencoder to reliably transmit information bits over a wireless channel.

Introduction

A traditional autoencoder is an unsupervised neural network that learns how to efficiently compress data, which is also called encoding. The autoencoder also learns how to reconstruct the data from the compressed representation such that the difference between the original data and the reconstructed data is minimal.

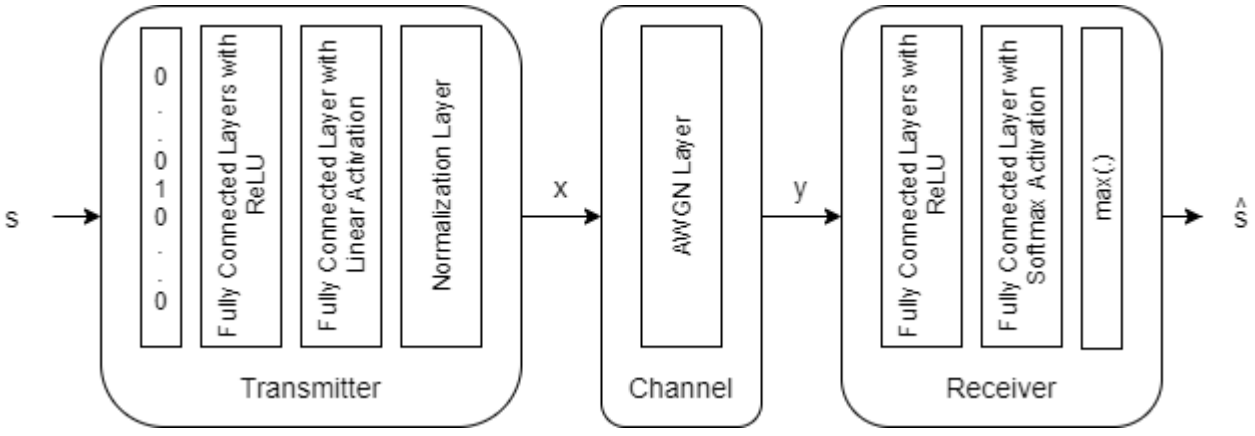
Traditional wireless communication systems are designed to provide reliable data transfer over a channel that impairs the transmitted signals. These systems have multiple components such as channel coding, modulation, equalization, synchronization, etc. Each component is optimized independently based on mathematical models that are simplified to arrive at closed form expressions. On the contrary, an autoencoder jointly optimizes the transmitter and the receiver as a whole. This joint optimization has the potential of providing a better performance than the traditional systems [1] on page 13-0 ,[2] on page 13-0 .

Traditional autoencoders are usually used to compress images, in other words remove redundancies in an image and reduce its dimension. A wireless communication system on the other hand uses channel coding and modulation techniques to add redundancy to the information bits. With this added redundancy, the system can recover the information bits that are impaired by the wireless channel. So, a wireless autoencoder actually adds redundancy and tries to minimize the number of errors in the received information for a given channel while learning to apply both channel coding and modulation in an unsupervised way.

Basic Autoencoder System

The following is the block diagram of a wireless auto encoder system. The encoder (transmitter) first maps k information bits into a message s such that $s \in \{1, \ldots, M\}$, where $M = 2^k$. Then message s is mapped to n real number to create $\mathbf{x} = f(s) \in \mathbb{R}^n$. The last layer of the encoder imposes constraints on $\mathbf{x}$ to further restrict the encoded symbols. The following are possible such constraints and are implemented using the normalization layer:

- Energy constraint: $\|x\|_2^2 \le n$
- Average power constraint: $\mathbb{E}[|x_i|^2] \le 1, \forall i$



Define the communication rate of this system as $R = k/n$ [bits/channel use], where (n,k) means that the system sends one of $M = 2^k$ messages using n channel uses. The channel impairs encoded (i.e. transmitted) symbols to generate $\mathbf{y} \in \mathbb{R}^n$. The decoder (i.e. receiver) produces an estimate, $\hat{s}$, of the transmitted message, s.

The input message is defined as a one-hot vector $\mathbf{1}_s \in \mathbb{R}^M$, which is defined as a vector whose elements are all zeros except the s^{th} one. The channel is additive white Gaussian noise (AWGN) that adds noise to achieve a given energy per bit to noise power density ratio, E_b/N_o.

Define a (7,4) autoencoder network with energy normalization and a training E_b/N_o of 3 dB. In [1] on page 13-0 , authors showed that two fully connected layers for both the encoder (transmitter) and the decoder (receiver) provides the best results with minimal complexity. Input layer (`featureInputLayer`) accepts a one-hot vector of length M. The encoder has two fully connected layers (`fullyConnectedLayer`). The first one has M inputs and M outputs and is followed by an ReLU layer (`reluLayer`). The second fully connected layer has M inputs and n outputs and is followed by the normalization layer (helperAEWNormalizationLayer.m). The encoder layers are followed by the AWGN channel layer (helperAEWAWGNLayer.m). The output of the channel is passed to the decoder layers. The first decoder layer is a fully connected layer that has n inputs and M outputs and is followed by an ReLU layer. Second fully connected layer has M inputs and M outputs and is followed by a softmax layer (`softmaxLayer`), which outputs the probability of each M symbols. The classification layer (`classificationLayer`) outputs the most probable transmitted symbol from 0 to M-1.

```
k = 4;    % number of input bits
M = 2^k;  % number of possible input symbols
n = 7;    % number of channel uses
EbNo = 3; % Eb/No in dB

wirelessAutoencoder = [
  featureInputLayer(M,"Name","One-hot input","Normalization","none")

  fullyConnectedLayer(M,"Name","fc_1")

```

The `helperAEWTrainWirelessAutoencoder.m` function defines such a network based on the (n,k), normalization method and the E_b/N_o values. The Wireless Autoencoder Training Function section on page 13-0 shows the contents of the `helperAEWTrainWirelessAutoencoder.m` function.

Train Autoencoder

Run the `helperAEWTrainWirelessAutoencoder.m` function to train a (2,2) autoencoder with energy normalization. This function uses the `trainingOptions` function to select

- Adam (adaptive moment estimation) optimizer,
- Initial learning rate of 0.01,
- Maximum epochs of 15,
- Minibatch size of 20*M,
- Piecewise learning schedule with drop period of 10 and drop factor of 0.1.

Then, the `helperAEWTrainWirelessAutoencoder.m` function runs the `trainNetwork` function to train the autoencoder network with the selected options. Finally, this function separates the network into encoder and decoder parts. Encoder starts with the input layer and ends after the normalization layer. Decoder starts after the channel layer and ends with the classification layer. A feature input layer is added at the beginning of the decoder.

Train the autoencoder with an E_b/N_o value that is low enough to result in some errors but not too low such that the training algorithm cannot extract any useful information from the received symbols, y. Set E_b/N_o to 3 dB.

Training an autoencoder may take several minutes. Set `trainNow` to false to use saved networks.

```
trainNow = false; %#ok<*NASGU>

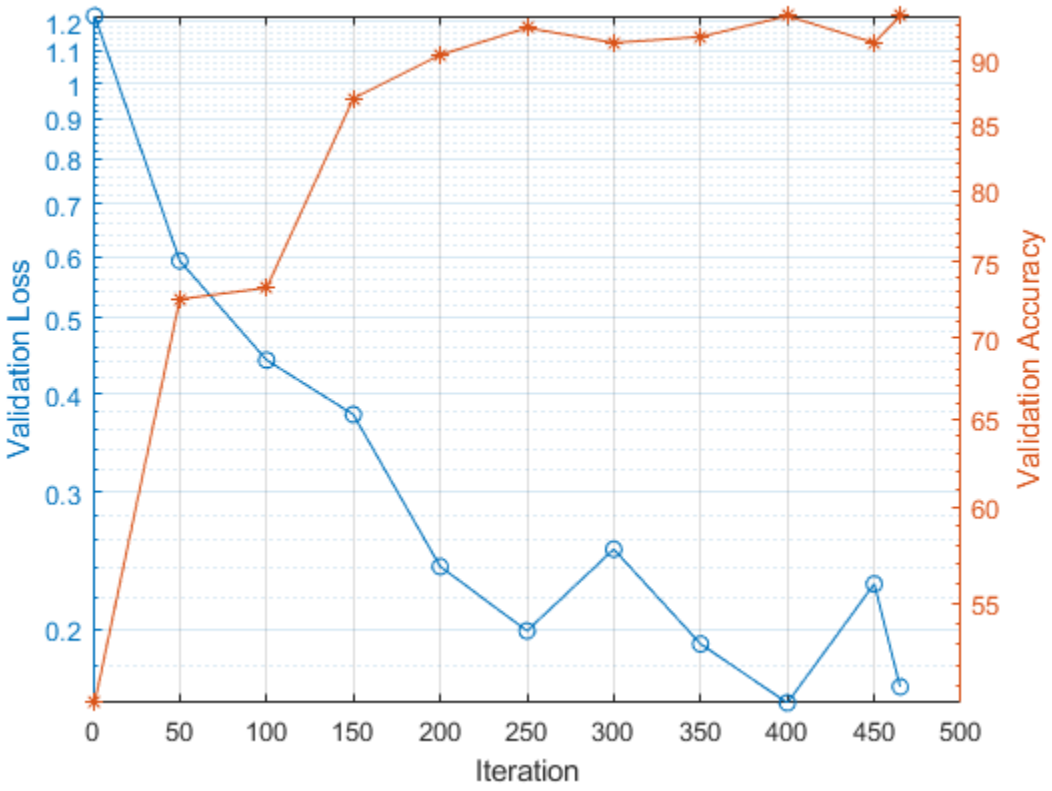
n = 2;                      % number of channel uses
k = 2;                      % bits per data symbol
EbNo = 3;                   % dB
normalization = "Energy";   % Normalization "Energy" | "Average power"

if trainNow
  [txNet22e,rxNet22e,info22e,wirelessAutoEncoder22e] = ...
    helperAEWTrainWirelessAutoencoder(n,k,normalization,EbNo); %#ok<*UNRCH>
else
  load trainedNet_n2_k2_energy txNet rxNet info trainedNet
  txNet22e = txNet;
  rxNet22e = rxNet;
  info22e = info;
```

```
  wirelessAutoEncoder22e = trainedNet;
end
```

Plot the traning progress. The validation accuracy quickly reaches more than 90% while the validation loss keeps slowly decreasing. This behavior shows that the training E_b/N_o value was low enough to cause some errors but not too low to avoid convergence. For definitions of validation accuracy and validation loss, see “Monitor Deep Learning Training Progress” on page 5-115 section.

```
figure
helperAEWPlotTrainingPerformance(info22e)
```



Use the plot object function of the trained network objects to show the layer graphs of the full autoencoder, the encoder network, i.e. the transmitter, and the decoder network, i.e. the receiver.

```

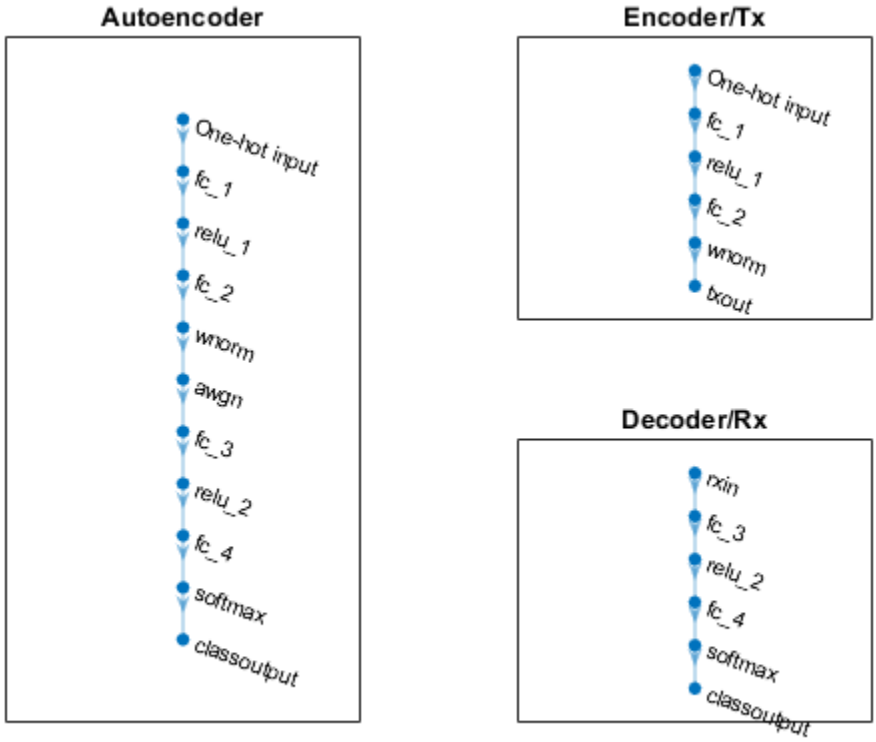
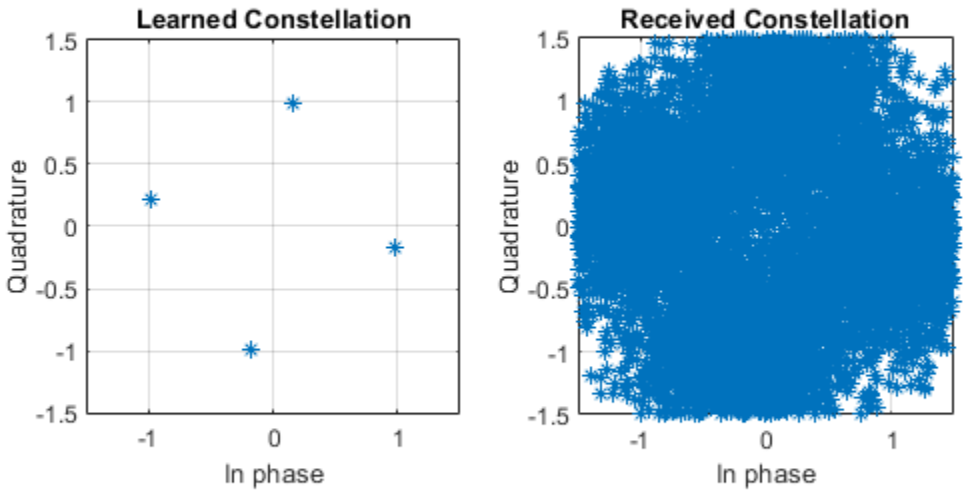
plot(txNet22e)
title('Encoder/Tx')
nexttile
plot(rxNet22e)
title('Decoder/Rx')
```



Plot Transmitted and Received Constellation

Plot the constellation learned by the autoencoder to send symbols through the AWGN channel together with the received constellation. For a (2,2) configuration, autoencoder learns a QPSK ($M = 2^k = 4$) constellation with a phase rotation. The received constellation is basically the activation values at the output of the channel layer obtained using the `activations` function and treated as interleaved complex numbers.

```
subplot(1,2,1)
helperAEWPlotConstellation(txNet22e)
title('Learned Constellation')
subplot(1,2,2)
helperAEWPlotReceivedConstellation(wirelessAutoEncoder22e)
title('Received Constellation')
```



Simulate BLER Performance

Simulate the block error rate (BLER) performance of the (2,2) autoencoder. Setup simulation parameters.

```
simParams.EbNoVec = 0:0.5:8;
simParams.MinNumErrors = 10;
simParams.MaxNumFrames = 300;
simParams.NumSymbolsPerFrame = 10000;
simParams.SignalPower = 1;
```

Generate random integers in the [0 M-1] range that represents k random information bits. Encode these information bits into complex symbols with `helperAEWEncode.m` function. The `helperAEWEncode` function runs the encoder part of the autoencoder then maps the real valued $\mathbf{x}$ vector into a complex valued $\mathbf{x_c}$ vector such that the odd and even elements are mapped into the in-phase and the quadrature component of a complex symbol, respectively, where $\mathbf{x}_c = \mathbf{x}(1:2:end) + j\mathbf{x}(2:2:end)$. In other words, treat the $\mathbf{x}$ array as an interleaved complex array.

Pass the complex symbols through an AWGN channel. Decode the channel impaired complex symbols with the `helperAEWDecode.m` function. The following code runs the simulation for each E_b/N_o point for at least 10 block errors. To obtain more accurate results, increase minimum number of errors to at least 100. If Parallel Computing Toolbox™ is installed and a license is available, the simulation will run on a parallel pool. Compare the results with that of an uncoded QPSK system with block length 2.

```
EbNoVec = simParams.EbNoVec;
R = k/n;
```

```
M = 2^k;
BLER = zeros(size(EbNoVec));
parfor EbNoIdx = 1:length(EbNoVec)
  EbNo = EbNoVec(EbNoIdx) + 10*log10(R);
  chan = comm.AWGNChannel("BitsPerSymbol",2, ...
    "EbNo", EbNo, "SamplesPerSymbol", 1, "SignalPower", 1);

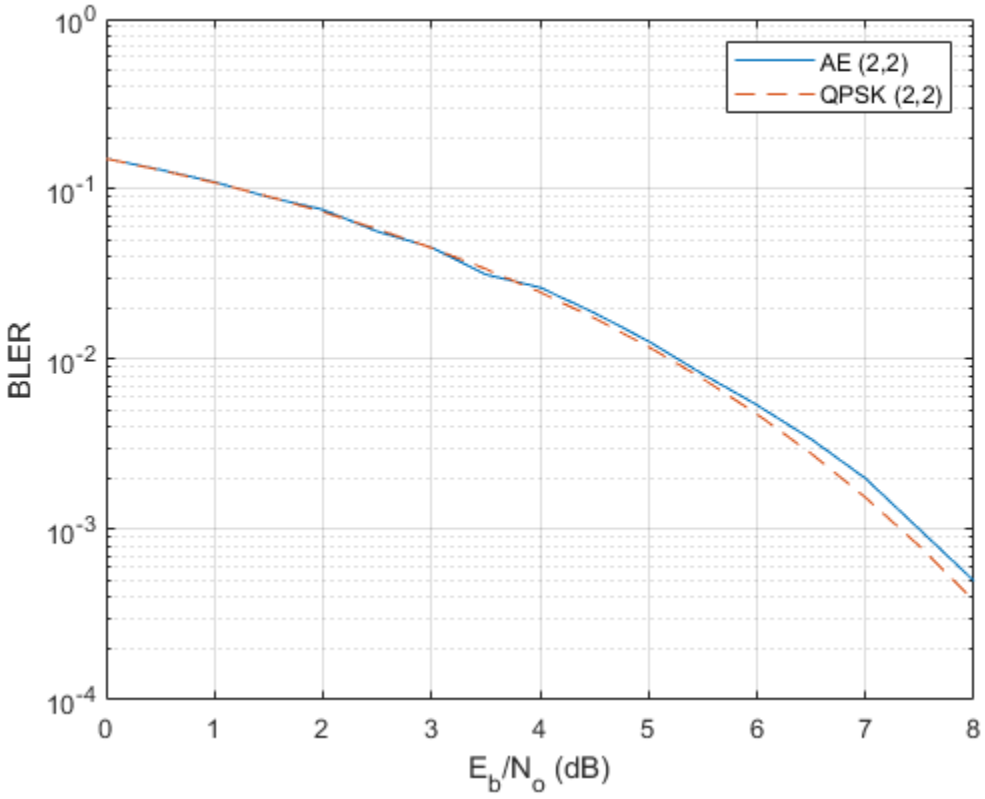
  numBlockErrors = 0;
  frameCnt = 0;
  while (numBlockErrors < simParams.MinNumErrors) ...
      && (frameCnt < simParams.MaxNumFrames) %#ok<PFBNS>

    d = randi([0 M-1],simParams.NumSymbolsPerFrame,1);    % Random information bits
    x = helperAEWEncode(d,txNet22e);                      % Encoder
    y = chan(x);                                          % Channel
    dHat = helperAEWDecode(y,rxNet22e);                   % Decoder

    numBlockErrors = numBlockErrors + sum(d ~= dHat);
    frameCnt = frameCnt + 1;
  end
  BLER(EbNoIdx) = numBlockErrors / (frameCnt*simParams.NumSymbolsPerFrame);
end
```

```
Starting parallel pool (parpool) using the 'local' profile ...
Connected to the parallel pool (number of workers: 6).
```

```
figure
semilogy(simParams.EbNoVec,BLER,'-')
hold on
qpsk22BLER = 1-(1-berawgn(simParams.EbNoVec,'psk',4,'nondiff')).^2;
semilogy(simParams.EbNoVec,qpsk22BLER,'--')
hold off
ylim([1e-4 1])
grid on
xlabel('E_b/N_o (dB)')
ylabel('BLER')
legend('AE (2,2)','QPSK (2,2)')
```



The well formed constellation together with the BLER results show that training for 15 epochs is enough to get a satisfactory convergence.

Compare Constellation Diagrams

Compare learned constellations of several autoencoders normalized to unit energy and unit average power. Train (2,4) autoencoder normalized to unit energy.

```
n = 2;      % number of channel uses
k = 4;      % bits per data symbol
EbNo = 3;   % dB
normalization = "Energy";
if trainNow
  [txNet24e,rxNet24e,info24e,wirelessAutoEncoder24e] = ...
    helperAEWTrainWirelessAutoencoder(n,k,normalization,EbNo);
else
  load trainedNet_n2_k4_energy txNet rxNet info trainedNet
  txNet24e = txNet;
  rxNet24e = rxNet;
  info24e = info;
  wirelessAutoEncoder24e = trainedNet;
end
```

Train (2,4) autoencoder normalized to unit average power.

```
n = 2;      % number of channel uses
k = 4;      % bits per data symbol
```

```
EbNo = 3;   % dB
normalization = "Average power";
if trainNow
  [txNet24p,rxNet24p,info24p,wirelessAutoEncoder24p] = ...
    helperAEWTrainWirelessAutoencoder(n,k,normalization,EbNo);
else
  load trainedNet_n2_k4_power txNet rxNet info trainedNet
  txNet24p = txNet;
  rxNet24p = rxNet;
  info24p = info;
  wirelessAutoEncoder24p = trainedNet;
end
```

Train (7,4) autoencoder normalized to unit energy.

```
n = 7;      % number of channel uses
k = 4;      % bits per data symbol
EbNo = 3;   % dB
normalization = "Energy";
if trainNow
  [txNet74e,rxNet74e,info74e,wirelessAutoEncoder74e] = ...
    helperAEWTrainWirelessAutoencoder(n,k,normalization,EbNo);
else
  load trainedNet_n7_k4_energy txNet rxNet info trainedNet
  txNet74e = txNet;
  rxNet74e = rxNet;
  info74e = info;
  wirelessAutoEncoder74e = trainedNet;
end
```

Plot the constellation using the `helperAEWPlotConstellation.m` function. The trained (2,2) autoencoder converges on a QPSK constellation with a phase shift as the optimal constellation for the channel conditions experienced. The (2,4) autoencoder with energy normalization converges to a 16PSK constellation with a phase shift. Note that, energy normalization forces every symbol to have unit energy and places the symbols on the unit circle. Given this constraint, best constellation is a PSK constellation with equal angular distance between symbols. The (2,4) autoencoder with average power normalization converges to a three-tier constellation of 1-6-9 symbols. Average power normalization forces the symbols to have unity average power over time. This constraint results in an APSK constellation, which is different than the conventional QAM or APSK schemes. Note that, this network configuration may also converge to a two-tier constellation with 7-9 symbols based on the random initial condition used during training. The last plot shows the 2-D mapping of the 7-D constellation generated by the (7,4) autoencoder with energy constraint. 2-D mapping is obtained using the t-Distributed Stochastic Neighbor Embedding (t-SNE) method (see `tsne` (Statistics and Machine Learning Toolbox) function).

```

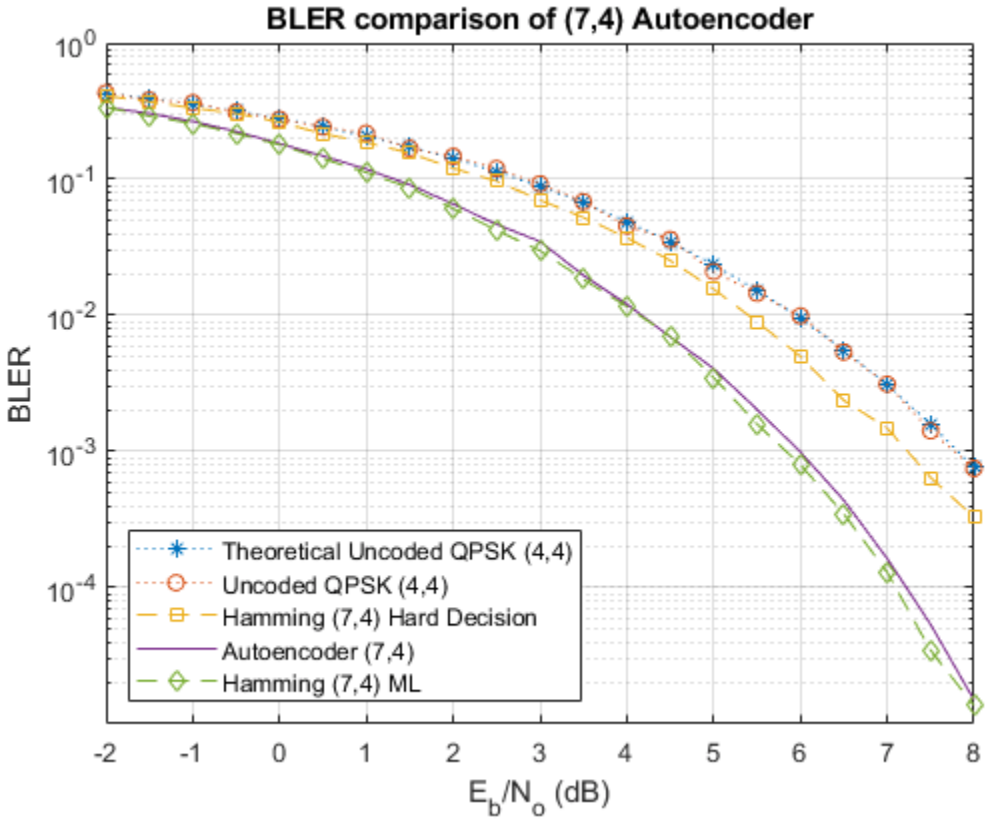
Compare BLER Performance of Autoencoders with Coded and Uncoded QPSK

Simulate the BLER performance of a (7,4) autoencoder with that of (7,4) Hamming code with QPSK modulation for both hard decision and maximum likelihood (ML) decoding. Use uncoded (4,4) QPSK as a baseline. (4,4) uncoded QPSK is basically a QPSK modulated system that sends blocks of 4 bits and measures BLER. The data for the following figures is obtained using helperAEWSimulateBLER.mlx and helperAEWPrepareAutoencoders.mlx files.

```
load codedBLERResults.mat
figure
qpsk44BLERTh = 1-(1-berawgn(simParams.EbNoVec,'psk',4,'nondiff')).^4;
semilogy(simParams.EbNoVec,qpsk44BLERTh,':*')
hold on
semilogy(simParams.EbNoVec,qpsk44BLER,':o')
semilogy(simParams.EbNoVec,hammingHard74BLER,'--s')
semilogy(simParams.EbNoVec,ae74eBLER,'-')
semilogy(simParams.EbNoVec,hammingML74BLER,'--d')
hold off
ylim([1e-5 1])
grid on
xlabel('E_b/N_o (dB)')
ylabel('BLER')
legend('Theoretical Uncoded QPSK (4,4)','Uncoded QPSK (4,4)','Hamming (7,4) Hard Decision',...
```

```
  'Autoencoder (7,4)','Hamming (7,4) ML','Location','southwest')
title('BLER comparison of (7,4) Autoencoder')
```

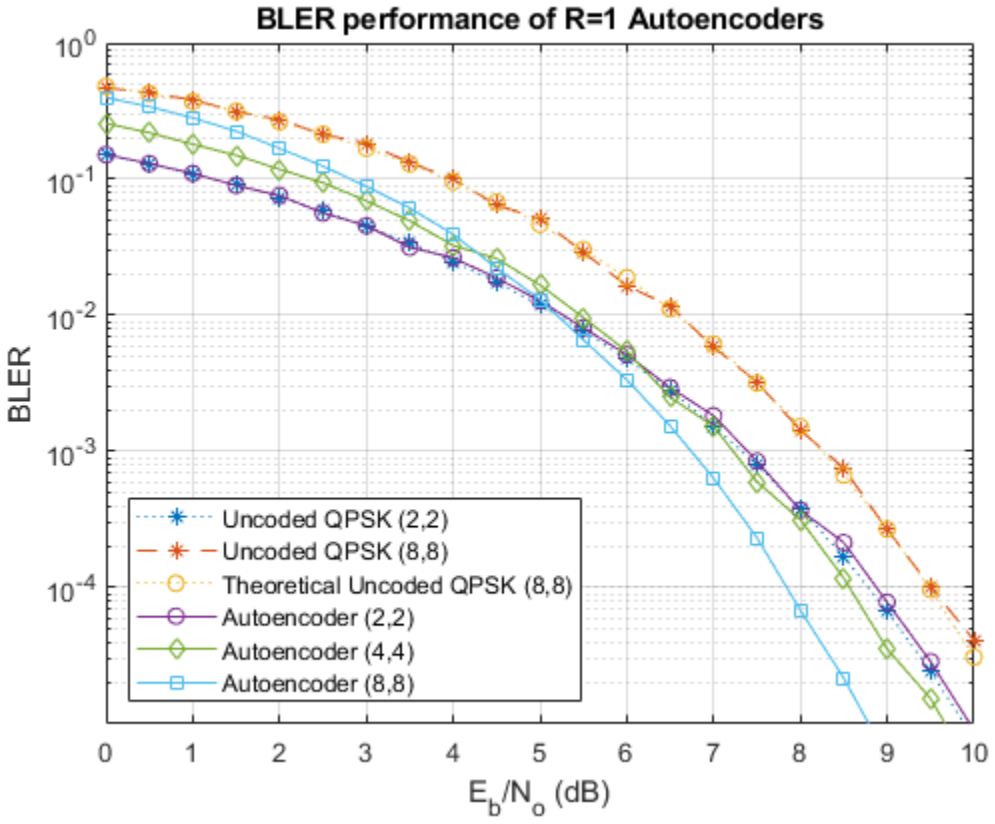


As expected, hard decision (7,4) Hamming code with QPSK modulation provides about 0.6 dB E_b/N_o advantage over uncoded QPSK, while the ML decoding of (7,4) Hamming code with QPSK modulation provides another 1.5 dB advantage for a BLER of 10^{-3}. The (7,4) autoencoder BLER performance approaches the ML decoding of (7,4) Hamming code, when trained with 3 dB E_b/N_o. This BLER performance shows that the autoencoder is able to learn not only modulation but also channel coding to achieve a coding gain of about 2 dB for a coding rate of R=4/7.

Next, simulate the BLER performance of autoencoders with R=1 with that of uncoded QPSK systems. Use uncoded (2,2) and (8,8) QPSK as baselines. Compare BLER performance of these systems with that of (2,2), (4,4) and (8,8) autoencoders.

```
load uncodedBLERResults.mat
qpsk22BLERTh = 1-(1-berawgn(simParams.EbNoVec,'psk',4,'nondiff')).^2;
semilogy(simParams.EbNoVec,qpsk22BLERTh,':*')
hold on
semilogy(simParams.EbNoVec,qpsk88BLER,'--*')
qpsk88BLERTh = 1-(1-berawgn(simParams.EbNoVec,'psk',4,'nondiff')).^8;
semilogy(simParams.EbNoVec,qpsk88BLERTh,':o')
semilogy(simParams.EbNoVec,ae22eBLER,'-o')
semilogy(simParams.EbNoVec,ae44eBLER,'-d')
semilogy(simParams.EbNoVec,ae88eBLER,'-s')
hold off
ylim([1e-5 1])
```

```
grid on
xlabel('E_b/N_o (dB)')
ylabel('BLER')
legend('Uncoded QPSK (2,2)','Uncoded QPSK (8,8)','Theoretical Uncoded QPSK (8,8)',...
  'Autoencoder (2,2)','Autoencoder (4,4)','Autoencoder (8,8)','Location','southwest')
title('BLER performance of R=1 Autoencoders')
```



Bit error rate of QPSK is the same for both (8,8) and (2,2) cases. However, the BLER depends on the block length, n, and gets worse as n increases as given by $BLER = 1 - (1 - BER)^n$. As expected, BLER performance of (8,8) QPSK is worse than the (2,2) QPSK system. The BLER performance of (2,2) autoencoder matches the BLER performance of (2,2) QPSK. On the other hand, (4,4) and (8,8) autoencoders optimize the channel coder and the constellation jointly to obtain a coding gain with respect to the corresponding uncoded QPSK systems.

Effect of Training Eb/No on BLER Performance

Train the (7,4) autoencoder with energy normalization under different E_b/N_o values and compare the BLER performance.

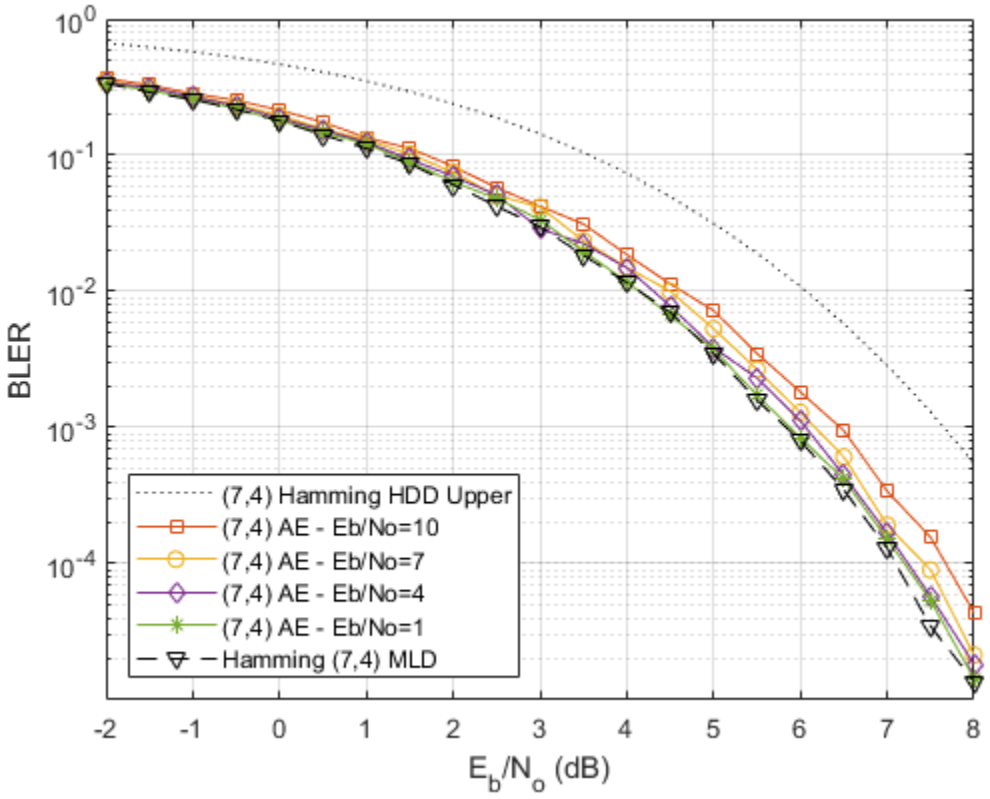
```
n = 7;
k = 4;
normalization = 'Energy';

EbNoVec = 1:3:10;
if trainNow
  for EbNoIdx = 1:length(EbNoVec)
    EbNo = EbNoVec(EbNoIdx);
```

```
    [txNetVec{EbNoIdx},rxNetVec{EbNoIdx},infoVec{EbNoIdx},trainedNetVec{EbNoIdx}] = ...
      helperAEWTrainWirelessAutoencoder(n,k,normalization,EbNo);
    BLERVec{EbNoIdx} = helperAEWAutoencoderBLER(txNetVec{EbNoIdx},rxNetVec{EbNoIdx},simParams);
  end
else
  load ae74TrainedEbNo1to10 BLERVec trainParams simParams txNetVec rxNetVec infoVec trainedNetVe
end
```

Plot the BLER performance together with theoretical upper bound for hard decision decoded Hamming (7,4) code and simulated BLER of maximum likelihood decoded (MLD) Hamming (7,4) code. The BLER performance of the (7,4) autoencoder gets closer to the Hamming (7,4) code with MLD as the training E_b/N_o decreases from 10 dB to 1 dB, at which point it almost matches the MLD Hamming (7,4) code.

```
berHamming = bercoding(simParams.EbNoVec,'hamming','hard',7);
blerHamming = 1-(1-berHamming).^7;
load codedBLERResults hammingML74BLER
figure
semilogy(simParams.EbNoVec,blerHamming,':k')
hold on
linespec = {'-*','-d','-o','-s',};
for EbNoIdx=length(EbNoVec):-1:1
  semilogy(simParams.EbNoVec,BLERVec{EbNoIdx},linespec{EbNoIdx})
end
semilogy(simParams.EbNoVec,hammingML74BLER,'--vk')
hold off
ylim([1e-5 1])
grid on
xlabel('E_b/N_o (dB)')
ylabel('BLER')
legend('(7,4) Hamming HDD Upper','(7,4) AE - Eb/No=10','(7,4) AE - Eb/No=7',...
  '(7,4) AE - Eb/No=4','(7,4) AE - Eb/No=1','Hamming (7,4) MLD','location','southwest')
```



Conclusions and Further Exploration

The BLER results show that it is possible for autoencoders to learn joint coding and modulation schemes in an unsupervised way. It is even possible to train an autoencoder with R=1 to obtain a coding gain as compared to traditional methods. The example also shows the effect of hyperparameters such as E_b/N_o on the BLER performance.

The results are obtained using the following default settings for training and BLER simulations:

```
trainParams.Plots = 'none';
trainParams.Verbose = false;
trainParams.MaxEpochs = 15;
trainParams.InitialLearnRate = 0.01;
trainParams.LearnRateSchedule = 'piecewise';
trainParams.LearnRateDropPeriod = 10;
trainParams.LearnRateDropFactor = 0.1;
trainParams.MiniBatchSize = 20*2^k;

simParams.EbNoVec = -2:0.5:8;
simParams.MinNumErrors = 100;
simParams.MaxNumFrames = 300;
simParams.NumSymbolsPerFrame = 10000;
simParams.SignalPower = 1;
```

Vary these parameters to train different autoencoders and test their BLER performance. Experiment with different n, k, normalization and E_b/N_o values. See the help for

helperAEWTrainWirelessAutoencoder.m, helperAEWPrepareAutoencoders.mlx and helperAEWAutoencoderBLER.m for more information.

Modulation Classification with Deep Learning

This example shows how to use a convolutional neural network (CNN) for modulation classification. You generate synthetic, channel-impaired waveforms. Using the generated waveforms as training data, you train a CNN for modulation classification. You then test the CNN with software-defined radio (SDR) hardware and over-the-air signals.

Predict Modulation Type Using CNN

The trained CNN in this example recognizes these eight digital and three analog modulation types:

- Binary phase shift keying (BPSK)
- Quadrature phase shift keying (QPSK)
- 8-ary phase shift keying (8-PSK)
- 16-ary quadrature amplitude modulation (16-QAM)
- 64-ary quadrature amplitude modulation (64-QAM)
- 4-ary pulse amplitude modulation (PAM4)
- Gaussian frequency shift keying (GFSK)
- Continuous phase frequency shift keying (CPFSK)
- Broadcast FM (B-FM)
- Double sideband amplitude modulation (DSB-AM)
- Single sideband amplitude modulation (SSB-AM)

```
modulationTypes = categorical(["BPSK", "QPSK", "8PSK", ...
  "16QAM", "64QAM", "PAM4", "GFSK", "CPFSK", ...
  "B-FM", "DSB-AM", "SSB-AM"]);
```

First, load the trained network. For details on network training, see the Training a CNN on page 13-0 section.

```
load trainedModulationClassificationNetwork
trainedNet
```

```
trainedNet = SeriesNetwork with properties:
         Layers: [28×1 nnet.cnn.layer.Layer]
     InputNames: {'Input Layer'}
    OutputNames: {'Output'}
```

The trained CNN takes 1024 channel-impaired samples and predicts the modulation type of each frame. Generate several PAM4 frames that are impaired with Rician multipath fading, center frequency and sampling time drift, and AWGN. Use following function to generate synthetic signals to test the CNN. Then use the CNN to predict the modulation type of the frames.

- `randi`: Generate random bits
- `pammod` (Communications Toolbox) PAM4-modulate the bits
- `rcosdesign` (Signal Processing Toolbox): Design a square-root raised cosine pulse shaping filter
- `filter`: Pulse shape the symbols
- `comm.RicianChannel` (Communications Toolbox): Apply Rician multipath channel

- `comm.PhaseFrequencyOffset` (Communications Toolbox): Apply phase and/or frequency shift due to clock offset
- `interp1`: Apply timing drift due to clock offset
- `awgn` (Communications Toolbox): Add AWGN

```
% Set the random number generator to a known state to be able to regenerate
% the same frames every time the simulation is run
rng(123456)
% Random bits
d = randi([0 3], 1024, 1);
% PAM4 modulation
syms = pammod(d,4);
% Square-root raised cosine filter
filterCoeffs = rcosdesign(0.35,4,8);
tx = filter(filterCoeffs,1,upsample(syms,8));

% Channel
SNR = 30;
maxOffset = 5;
fc = 902e6;
fs = 200e3;
multipathChannel = comm.RicianChannel(...
  'SampleRate', fs, ...
  'PathDelays', [0 1.8 3.4] / 200e3, ...
  'AveragePathGains', [0 -2 -10], ...
  'KFactor', 4, ...
  'MaximumDopplerShift', 4);

frequencyShifter = comm.PhaseFrequencyOffset(...
  'SampleRate', fs);

% Apply an independent multipath channel
reset(multipathChannel)
outMultipathChan = multipathChannel(tx);

% Determine clock offset factor
clockOffset = (rand() * 2*maxOffset) - maxOffset;
C = 1 + clockOffset / 1e6;

% Add frequency offset
frequencyShifter.FrequencyOffset = -(C-1)*fc;
outFreqShifter = frequencyShifter(outMultipathChan);

% Add sampling time drift
t = (0:length(tx)-1)' / fs;
newFs = fs * C;
tp = (0:length(tx)-1)' / newFs;
outTimeDrift = interp1(t, outFreqShifter, tp);

% Add noise
rx = awgn(outTimeDrift,SNR,0);

% Frame generation for classification
unknownFrames = helperModClassGetNNFrames(rx);

% Classification
[prediction1,score1] = classify(trainedNet,unknownFrames);
```

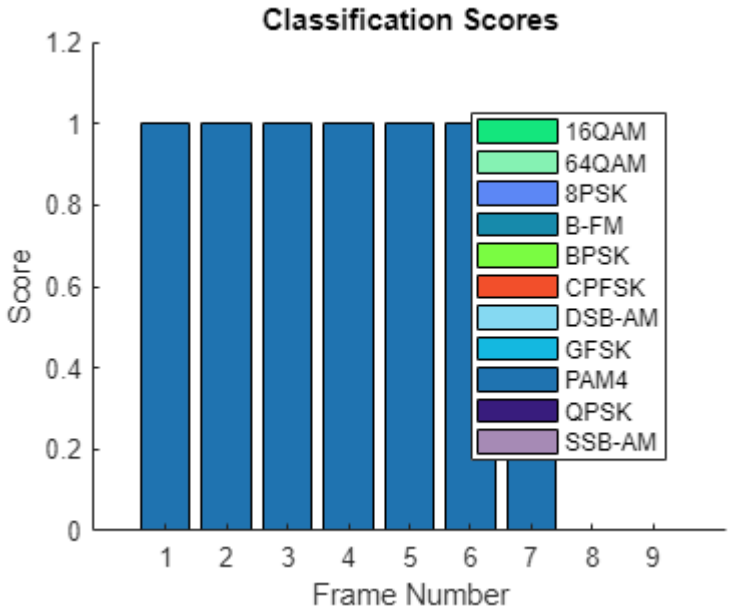
Return the classifier predictions, which are analogous to hard decisions. The network correctly identifies the frames as PAM4 frames. For details on the generation of the modulated signals, see helperModClassGetModulator function.

```
prediction1
```

```
prediction1 = 7×1 categorical
     PAM4
     PAM4
     PAM4
     PAM4
     PAM4
     PAM4
     PAM4
```

The classifier also returns a vector of scores for each frame. The score corresponds to the probability that each frame has the predicted modulation type. Plot the scores.

```
helperModClassPlotScores(score1,modulationTypes)
```



Before we can use a CNN for modulation classification, or any other task, we first need to train the network with known (or labeled) data. The first part of this example shows how to use Communications Toolbox features, such as modulators, filters, and channel impairments, to generate synthetic training data. The second part focuses on defining, training, and testing the CNN for the task of modulation classification. The third part tests the network performance with over-the-air signals using software defined radio (SDR) platforms.

Waveform Generation for Training

Generate 10,000 frames for each modulation type, where 80% is used for training, 10% is used for validation and 10% is used for testing. We use training and validation frames during the network training phase. Final classification accuracy is obtained using test frames. Each frame is 1024 samples long and has a sample rate of 200 kHz. For digital modulation types, eight samples represent

a symbol. The network makes each decision based on single frames rather than on multiple consecutive frames (as in video). Assume a center frequency of 902 MHz and 100 MHz for the digital and analog modulation types, respectively.

To run this example quickly, use the trained network and generate a small number of training frames. To train the network on your computer, choose the "Train network now" option (i.e. set trainNow to true).

```
trainNow = Use trained network ;
if trainNow == true
  numFramesPerModType = 10000;
else
  numFramesPerModType = 200;
end
percentTrainingSamples = 80;
percentValidationSamples = 10;
percentTestSamples = 10;

sps = 8;                % Samples per symbol
spf = 1024;             % Samples per frame
symbolsPerFrame = spf / sps;
fs = 200e3;             % Sample rate
fc = [902e6 100e6];     % Center frequencies
```

Create Channel Impairments

Pass each frame through a channel with

- AWGN
- Rician multipath fading
- Clock offset, resulting in center frequency offset and sampling time drift

Because the network in this example makes decisions based on single frames, each frame must pass through an independent channel.

AWGN

The channel adds AWGN with an SNR of 30 dB. Implement the channel using `awgn` (Communications Toolbox) function.

Rician Multipath

The channel passes the signals through a Rician multipath fading channel using the `comm.RicianChannel` (Communications Toolbox) System object. Assume a delay profile of [0 1.8 3.4] samples with corresponding average path gains of [0 -2 -10] dB. The K-factor is 4 and the maximum Doppler shift is 4 Hz, which is equivalent to a walking speed at 902 MHz. Implement the channel with the following settings.

Clock Offset

Clock offset occurs because of the inaccuracies of internal clock sources of transmitters and receivers. Clock offset causes the center frequency, which is used to downconvert the signal to baseband, and the digital-to-analog converter sampling rate to differ from the ideal values. The channel simulator uses the clock offset factor C, expressed as $C = 1 + \frac{\Delta_{\text{clock}}}{10^6}$, where Δ_{clock} is the clock

offset. For each frame, the channel generates a random Δ_{clock} value from a uniformly distributed set of values in the range $[-\max\Delta_{\text{clock}}\ \max\Delta_{\text{clock}}]$, where $\max\Delta_{\text{clock}}$ is the maximum clock offset. Clock offset is measured in parts per million (ppm). For this example, assume a maximum clock offset of 5 ppm.

```
maxDeltaOff = 5;
deltaOff = (rand()*2*maxDeltaOff) - maxDeltaOff;
C = 1 + (deltaOff/1e6);
```

Frequency Offset

Subject each frame to a frequency offset based on clock offset factor C and the center frequency. Implement the channel using `comm.PhaseFrequencyOffset` (Communications Toolbox).

Sampling Rate Offset

Subject each frame to a sampling rate offset based on clock offset factor C. Implement the channel using the `interp1` function to resample the frame at the new rate of $C \times f_s$.

Combined Channel

Use the helperModClassTestChannel object to apply all three channel impairments to the frames.

```
channel = helperModClassTestChannel(...
  'SampleRate', fs, ...
  'SNR', SNR, ...
  'PathDelays', [0 1.8 3.4] / fs, ...
  'AveragePathGains', [0 -2 -10], ...
  'KFactor', 4, ...
  'MaximumDopplerShift', 4, ...
  'MaximumClockOffset', 5, ...
  'CenterFrequency', 902e6)
```

```
channel = helperModClassTestChannel with properties:
                    SNR: 30
         CenterFrequency: 902000000
              SampleRate: 200000
              PathDelays: [0 9.0000e-06 1.7000e-05]
        AveragePathGains: [0 -2 -10]
                 KFactor: 4
     MaximumDopplerShift: 4
      MaximumClockOffset: 5
```

You can view basic information about the channel using the info object function.

```
chInfo = info(channel)
```

```
chInfo = struct with fields:
               ChannelDelay: 6
      MaximumFrequencyOffset: 4510
     MaximumSampleRateOffset: 1
```

Waveform Generation

Create a loop that generates channel-impaired frames for each modulation type and stores the frames with their corresponding labels in MAT files. By saving the data into files, you eliminate the need to generate the data every time you run this example. You can also share the data more effectively.

Remove a random number of samples from the beginning of each frame to remove transients and to make sure that the frames have a random starting point with respect to the symbol boundaries.

```
% Set the random number generator to a known state to be able to regenerate
% the same frames every time the simulation is run
rng(1235)
tic

numModulationTypes = length(modulationTypes);

channelInfo = info(channel);
transDelay = 50;
dataDirectory = fullfile(tempdir,"ModClassDataFiles");
disp("Data file directory is " + dataDirectory)
```

```
Data file directory is C:\TEMP\ModClassDataFiles
```

```
fileNameRoot = "frame";

% Check if data files exist
dataFilesExist = false;
if exist(dataDirectory,'dir')
  files = dir(fullfile(dataDirectory,sprintf("%s*",fileNameRoot)));
  if length(files) == numModulationTypes*numFramesPerModType
    dataFilesExist = true;
  end
end

if ~dataFilesExist
  disp("Generating data and saving in data files...")
  [success,msg,msgID] = mkdir(dataDirectory);
  if ~success
    error(msgID,msg)
  end
  for modType = 1:numModulationTypes
    elapsedTime = seconds(toc);
    elapsedTime.Format = 'hh:mm:ss';
    fprintf('%s - Generating %s frames\n', ...
      elapsedTime, modulationTypes(modType))

    label = modulationTypes(modType);
    numSymbols = (numFramesPerModType / sps);
    dataSrc = helperModClassGetSource(modulationTypes(modType), sps, 2*spf, fs);
    modulator = helperModClassGetModulator(modulationTypes(modType), sps, fs);
    if contains(char(modulationTypes(modType)), {'B-FM','DSB-AM','SSB-AM'})
      % Analog modulation types use a center frequency of 100 MHz
      channel.CenterFrequency = 100e6;
    else
      % Digital modulation types use a center frequency of 902 MHz
      channel.CenterFrequency = 902e6;
    end
```

```
    for p=1:numFramesPerModType
      % Generate random data
      x = dataSrc();

      % Modulate
      y = modulator(x);

      % Pass through independent channels
      rxSamples = channel(y);

      % Remove transients from the beginning, trim to size, and normalize
      frame = helperModClassFrameGenerator(rxSamples, spf, spf, transDelay, sps);

      % Save data file
      fileName = fullfile(dataDirectory,...
        sprintf("%s%s%03d",fileNameRoot,modulationTypes(modType),p));
      save(fileName,"frame","label")
    end
  end
else
  disp("Data files exist. Skip data generation.")
end
```

Create a Datastore

Use a `signalDatastore` object to manage the files that contain the generated complex waveforms. Datastores are especially useful when each individual file fits in memory, but the entire collection does not necessarily fit.

```
frameDS = signalDatastore(dataDirectory,'SignalVariableNames',["frame","label"]);
```

Transform Complex Signals to Real Arrays

The deep learning network in this example expects real inputs while the received signal has complex baseband samples. Transform the complex signals into real valued 4-D arrays. The output frames have size 1-by-spf-by-2-by-N, where the first page (3rd dimension) is in-phase samples and the second page is quadrature samples. When the convolutional filters are of size 1-by-spf, this approach ensures that the information in the I and Q gets mixed even in the convolutional layers and makes better use of the phase information. See helperModClassIQAsPages for details.

```
frameDSTrans = transform(frameDS,@helperModClassIQAsPages);
```

Split into Training, Validation, and Test

Next divide the frames into training, validation, and test data. See helperModClassSplitData for details.

```
splitPercentages = [percentTrainingSamples,percentValidationSamples,percentTestSamples];
[trainDSTrans,validDSTrans,testDSTrans] = helperModClassSplitData(frameDSTrans,splitPercentages);
```

```
Starting parallel pool (parpool) using the 'local' profile ...
Connected to the parallel pool (number of workers: 6).
```

Import Data Into Memory

Neural network training is iterative. At every iteration, the datastore reads data from files and transforms the data before updating the network coefficients. If the data fits into the memory of your computer, importing the data from the files into the memory enables faster training by eliminating this repeated read from file and transform process. Instead, the data is read from the files and transformed once. Training this network using data files on disk takes about 110 minutes while training using in-memory data takes about 50 min.

Import all the data in the files into memory. The files have two variables: `frame` and `label` and each `read` call to the datastore returns a cell array, where the first element is the `frame` and the second element is the `label`. Use the `transform` functions helperModClassReadFrame and helperModClassReadLabel to read frames and labels. Use `readall` with `"UseParallel"` option set to `true` to enable parallel processing of the transform functions, in case you have Parallel Computing Toolbox license. Since `readall` function, by default, concatenates the output of the `read` function over the first dimension, return the frames in a cell array and manually concatenate over the 4th dimension.

```
% Read the training and validation frames into the memory
pctExists = parallelComputingLicenseExists();
trainFrames = transform(trainDSTrans, @helperModClassReadFrame);
rxTrainFrames = readall(trainFrames,"UseParallel",pctExists);
rxTrainFrames = cat(4, rxTrainFrames{:});
validFrames = transform(validDSTrans, @helperModClassReadFrame);
rxValidFrames = readall(validFrames,"UseParallel",pctExists);
rxValidFrames = cat(4, rxValidFrames{:});

% Read the training and validation labels into the memory
trainLabels = transform(trainDSTrans, @helperModClassReadLabel);
rxTrainLabels = readall(trainLabels,"UseParallel",pctExists);
validLabels = transform(validDSTrans, @helperModClassReadLabel);
rxValidLabels = readall(validLabels,"UseParallel",pctExists);
```

Train the CNN

This example uses a CNN that consists of six convolution layers and one fully connected layer. Each convolution layer except the last is followed by a batch normalization layer, rectified linear unit (ReLU) activation layer, and max pooling layer. In the last convolution layer, the max pooling layer is replaced with an average pooling layer. The output layer has softmax activation. For network design guidance, see “Deep Learning Tips and Tricks” on page 1-67.

```
modClassNet = helperModClassCNN(modulationTypes,sps,spf);
```

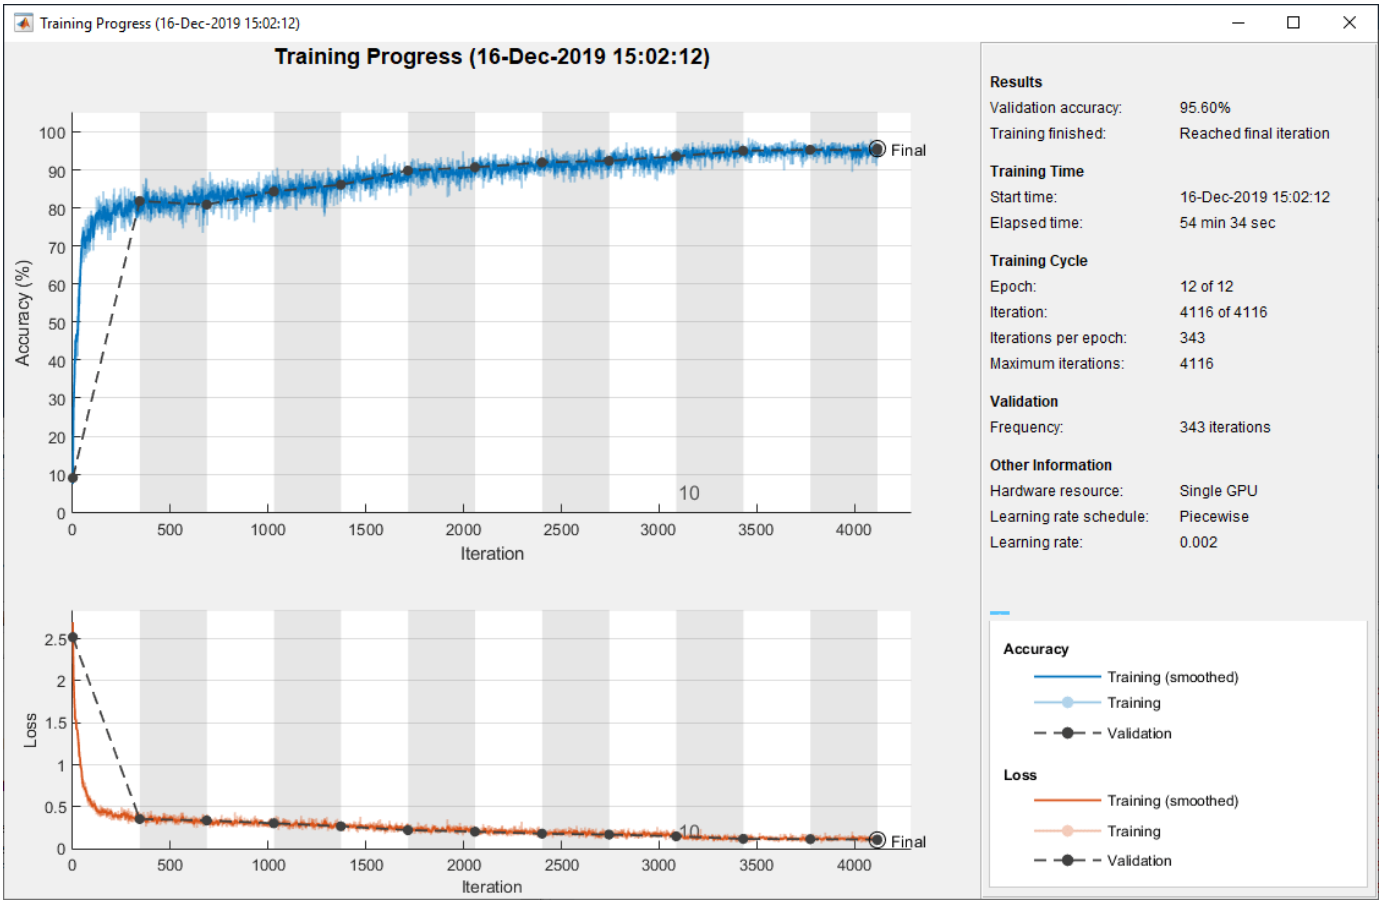
Next configure `TrainingOptionsSGDM` to use an SGDM solver with a mini-batch size of 256. Set the maximum number of epochs to 12, since a larger number of epochs provides no further training advantage. By default, the `'ExecutionEnvironment'` property is set to `'auto'`, where the `trainNetwork` function uses a GPU if one is available or uses the CPU, if not. To use the GPU, you must have a Parallel Computing Toolbox license. Set the initial learning rate to $2x10^{-2}$. Reduce the learning rate by a factor of 10 every 9 epochs. Set `'Plots'` to `'training-progress'` to plot the training progress. On an NVIDIA Titan Xp GPU, the network takes approximately 25 minutes to train. .

```
maxEpochs = 12;
miniBatchSize = 256;
options = helperModClassTrainingOptions(maxEpochs,miniBatchSize,...
  numel(rxTrainLabels),rxValidFrames,rxValidLabels);
```

Either train the network or use the already trained network. By default, this example uses the trained network.

```
if trainNow == true
  elapsedTime = seconds(toc);
  elapsedTime.Format = 'hh:mm:ss';
  fprintf('%s - Training the network\n', elapsedTime)
  trainedNet = trainNetwork(rxTrainFrames,rxTrainLabels,modClassNet,options);
else
  load trainedModulationClassificationNetwork
end
```

As the plot of the training progress shows, the network converges in about 12 epochs to more than 95% accuracy.



Evaluate the trained network by obtaining the classification accuracy for the test frames. The results show that the network achieves about 94% accuracy for this group of waveforms.

```
elapsedTime = seconds(toc);
elapsedTime.Format = 'hh:mm:ss';
fprintf('%s - Classifying test frames\n', elapsedTime)
```

```
00:01:25 - Classifying test frames
```

```
% Read the test frames into the memory
testFrames = transform(testDSTrans, @helperModClassReadFrame);
rxTestFrames = readall(testFrames,"UseParallel",pctExists);
rxTestFrames = cat(4, rxTestFrames{:});

% Read the test labels into the memory
testLabels = transform(testDSTrans, @helperModClassReadLabel);
rxTestLabels = readall(testLabels,"UseParallel",pctExists);

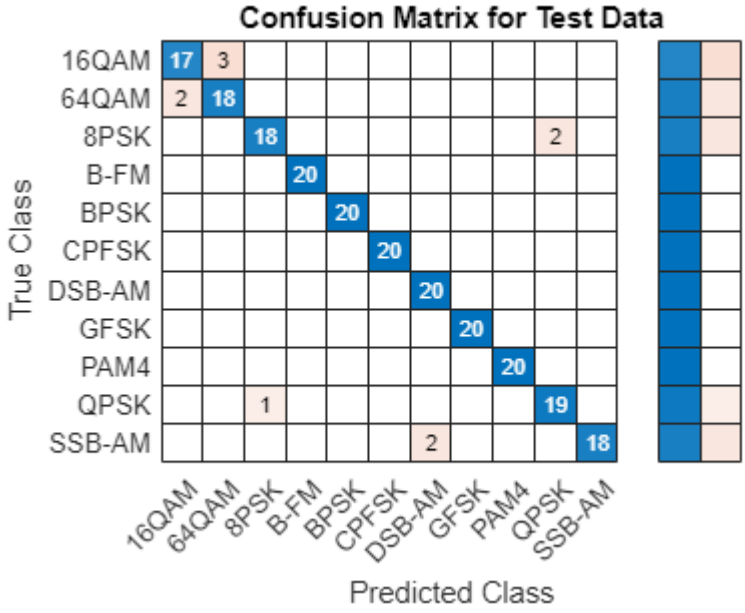
rxTestPred = classify(trainedNet,rxTestFrames);
testAccuracy = mean(rxTestPred == rxTestLabels);
disp("Test accuracy: " + testAccuracy*100 + "%")
```

```
Test accuracy: 95.4545%
```

Plot the confusion matrix for the test frames. As the matrix shows, the network confuses 16-QAM and 64-QAM frames. This problem is expected since each frame carries only 128 symbols and 16-QAM is a

subset of 64-QAM. The network also confuses QPSK and 8-PSK frames, since the constellations of these modulation types look similar once phase-rotated due to the fading channel and frequency offset.

```
figure
cm = confusionchart(rxTestLabels, rxTestPred);
cm.Title = 'Confusion Matrix for Test Data';
cm.RowSummary = 'row-normalized';
cm.Parent.Position = [cm.Parent.Position(1:2) 740 424];
```



Test with SDR

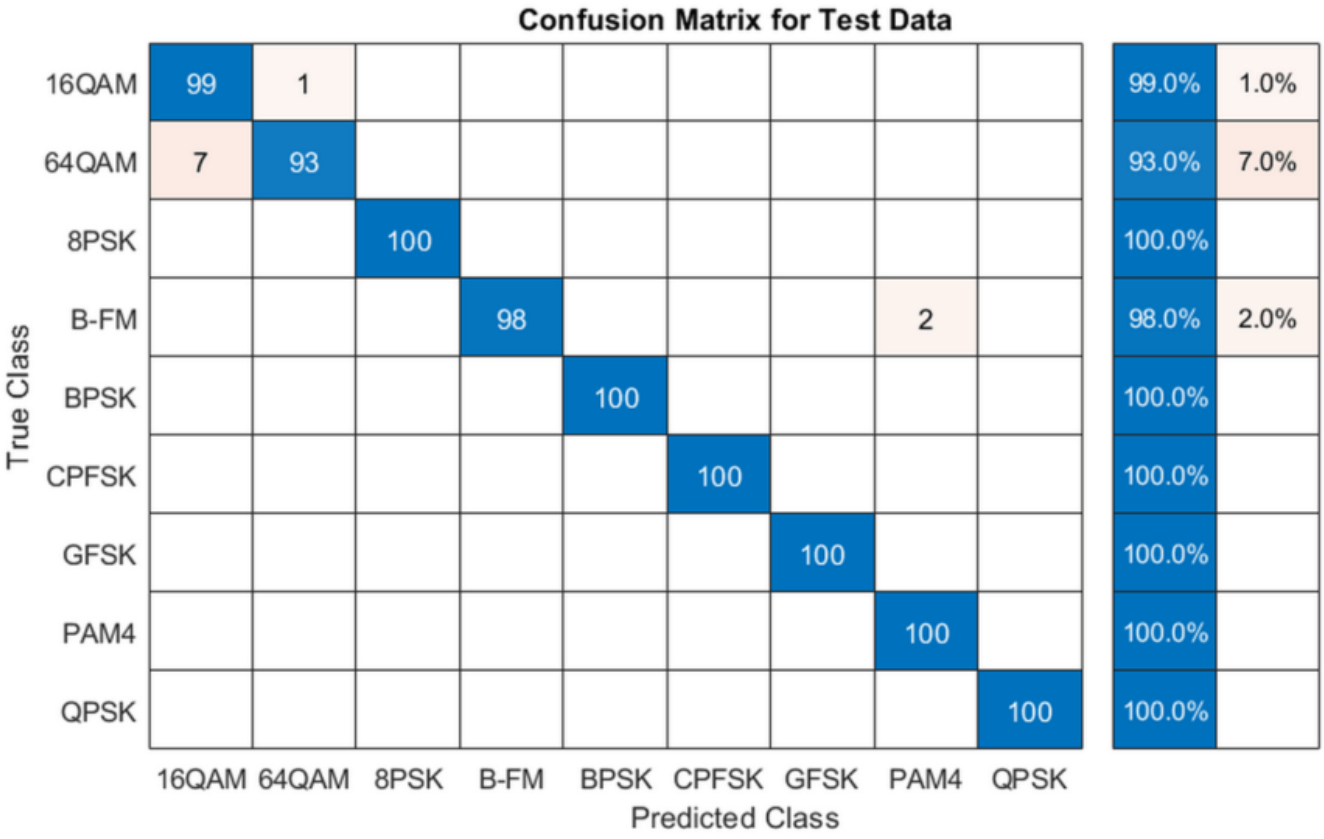
Test the performance of the trained network with over-the-air signals using the helperModClassSDRTest function. To perform this test, you must have dedicated SDRs for transmission and reception. You can use two ADALM-PLUTO radios, or one ADALM-PLUTO radio for transmission and one USRP® radio for reception. You must install Communications Toolbox Support Package for ADALM-PLUTO Radio. If you are using a USRP® radio, you must also install Communications Toolbox Support Package for USRP® Radio. The `helperModClassSDRTest` function uses the same modulation functions as used for generating the training signals, and then transmits them using an ADALM-PLUTO radio. Instead of simulating the channel, capture the channel-impaired signals using the SDR that is configured for signal reception (ADALM-PLUTO or USRP® radio). Use the trained network with the same `classify` function used previously to predict the modulation type. Running the next code segment produces a confusion matrix and prints out the test accuracy.

```
radioPlatform = "ADALM-PLUTO";

switch radioPlatform
  case "ADALM-PLUTO"
    if helperIsPlutoSDRInstalled() == true
      radios = findPlutoRadio();
      if length(radios) >= 2
        helperModClassSDRTest(radios);
```

```
      else
        disp('Selected radios not found. Skipping over-the-air test.')
      end
    end
  case {"USRP B2xx","USRP X3xx","USRP N2xx"}
    if (helperIsUSRPInstalled() == true) && (helperIsPlutoSDRInstalled() == true)
      txRadio = findPlutoRadio();
      rxRadio = findsdru();
      switch radioPlatform
        case "USRP B2xx"
          idx = contains({rxRadio.Platform}, {'B200','B210'});
        case "USRP X3xx"
          idx = contains({rxRadio.Platform}, {'X300','X310'});
        case "USRP N2xx"
          idx = contains({rxRadio.Platform}, 'N200/N210/USRP2');
      end
      rxRadio = rxRadio(idx);
      if (length(txRadio) >= 1) && (length(rxRadio) >= 1)
        helperModClassSDRTest(rxRadio);
      else
        disp('Selected radios not found. Skipping over-the-air test.')
      end
    end
end
```

When using two stationary ADALM-PLUTO radios separated by about 2 feet, the network achieves 99% overall accuracy with the following confusion matrix. Results will vary based on experimental setup.



Further Exploration

It is possible to optimize the hyperparameters parameters, such as number of filters, filter size, or optimize the network structure, such as adding more layers, using different activation layers, etc. to improve the accuracy.

Communication Toolbox provides many more modulation types and channel impairments. For more information see “Modulation” (Communications Toolbox) and “Propagation and Channel Models” (Communications Toolbox) sections. You can also add standard specific signals with LTE Toolbox, WLAN Toolbox, and 5G Toolbox. You can also add radar signals with Phased Array System Toolbox.

helperModClassGetModulator function provides the MATLAB functions used to generate modulated signals. You can also explore the following functions and System objects for more details:

- helperModClassGetModulator.m
- helperModClassTestChannel.m
- helperModClassGetSource.m
- helperModClassFrameGenerator.m
- helperModClassCNN.m

Training and Testing a Neural Network for LLR Estimation

This example shows how to generate signals and channel impairments to train a neural network, called LLRNet, to estimate exact log likelihood ratios (LLR).

Most modern communication systems, such as 5G New Radio (NR) and Digital Video Broadcasting for Satellite, Second Generation (DVB-S.2) use forward error correction algorithms that benefit from soft demodulated bit values. These systems calculate soft bit values using the LLR approach. LLR is defined as the log of the ratio of probability of a bit to be 0 to the probability of a bit to be 1 or

$$l_i \triangleq \log\left(\frac{P_r(c_i = 0 \,|\, \hat{s})}{P_r(c_i = 1 \,|\, \hat{s})}\right),\ i = 1, \ldots, k$$

where $\hat{s}$ is an k-bit received symbol, and c_i is the i^{th}bit of the symbol. Assuming an additive white Gaussian noise (AWGN) channel, the exact computation of the LLR expression is

$$l_i \triangleq \log\left(\frac{\sum_{s \in c_i^0} \exp\left(-\frac{\|\hat{s}-s\|_2^2}{\sigma^2}\right)}{\sum_{s \in c_i^1} \exp\left(-\frac{\|\hat{s}-s\|_2^2}{\sigma^2}\right)}\right)$$

where σ^2 is the noise variance. Exponential and logarithmic calculations are very costly especially in embedded systems. Therefore, most practical systems use the max-log approximation. For a given array x, the max-log approximation is

$$\log\left(\sum_j \exp\left(-x_j^2\right)\right) \approx \max_j\left(-x_j^2\right).$$

Substituting this in the exact LLR expression results in the max-log LLR approximation [1] on page 13-0

$$l_i \approx \frac{1}{\sigma^2}\left(\min_{s \in C_i^1} \|\hat{s}-s\|_2^2 - \min_{s \in C_i^0} \|\hat{s}-s\|_2^2\right).$$

LLRNet uses a neural network to estimate the exact LLR values given the baseband complex received symbol for a given SNR value. A shallow network with a small number of hidden layers has the potential to estimate the exact LLR values at a complexity similar to the approximate LLR algorithm [1] on page 13-0 .

Compare Exact LLR, Max-Log Approximate LLR and LLRNet for M-ary QAM

5G NR uses M-ary QAM modulation. This section explores the accuracy of LLRNet in estimating the LLR values for 16-, 64-, and 256-QAM modulation. Assume an M-ary QAM system that operates under AWGN channel conditions. This assumption is valid even when the channel is frequency selective but symbols are equalized. The following shows calculated LLR values for the following three algorithms:

- Exact LLR
- Max-log approximate LLR

- LLRNet

16-QAM LLR Estimation Performance

Calculate exact and approximate LLR values for symbol values that cover the 99.7% ($\pm 3\sigma$) of the possible received symbols. Assuming AWGN, 99.7% ($\pm 3\sigma$) of the received signals will be in the range $\left[\max_{s \in C}(Re(s) + 3\sigma) \min_{s \in C}(Re(s) - 3\sigma)\right] + i\left[\max_{s \in C}(Im(s) + 3\sigma) \min_{s \in C}(Im(s) - 3\sigma)\right]$. Generate uniformly distributed I/Q symbols over this space and use `qamdemod` (Communications Toolbox) function to calculate exact LLR and approximate LLR values.

```
M = 16;             % Modulation order
k = log2(M);        % Bits per symbols
SNRValues = -5:5:5; % in dB
numSymbols = 1e4;
numSNRValues = length(SNRValues);
symOrder = llrnetQAMSymbolMapping(M);

const = qammod(0:15,M,symOrder,'UnitAveragePower',1);
maxConstReal = max(real(const));
maxConstImag = max(imag(const));

numBits = numSymbols*k;
exactLLR = zeros(numBits,numSNRValues);
approxLLR = zeros(numBits,numSNRValues);
rxSym = zeros(numSymbols,numSNRValues);
for snrIdx = 1:numSNRValues
    SNR = SNRValues(snrIdx);
    noiseVariance = 10^(-SNR/10);
    sigma = sqrt(noiseVariance);

    maxReal = maxConstReal + 3*sigma;
    minReal = -maxReal;
    maxImag = maxConstImag + 3*sigma;
    minImag = -maxImag;

    r = (rand(numSymbols,1)*(maxReal-minReal)+minReal) + ...
        1i*(rand(numSymbols,1)*(maxImag-minImag)+minImag);
    rxSym(:,snrIdx) = r;

    exactLLR(:,snrIdx) = qamdemod(r,M,symOrder,...
        'UnitAveragePower',1,'OutputType','llr','NoiseVariance',noiseVariance);
    approxLLR(:,snrIdx) = qamdemod(r,M,symOrder,...
        'UnitAveragePower',1,'OutputType','approxllr','NoiseVariance',noiseVariance);
end
```

Set up and Train Neural Network

Set up a shallow neural network with one input layer, one hidden layer, and one output layer. Input a received symbol to the network and train it to estimate the exact LLR values. Since the network expects real inputs, create a two column vector, where the first column is the real values of the received symbol and the second column is the imaginary values of the received symbol. Also, the output must be a $k \times N$ vector, where k is the number of bits per symbol and N is the number of symbols.

```
nnInput = zeros(numSymbols,2,numSNRValues);
nnOutput = zeros(numSymbols,k,numSNRValues);
```

```
for snrIdx = 1:numSNRValues
    rxTemp = rxSym(:,snrIdx);
    rxTemp = [real(rxTemp) imag(rxTemp)];
    nnInput(:,:,snrIdx) = rxTemp;

    llrTemp = exactLLR(:,snrIdx);
    nnOutput(:,:,snrIdx) = reshape(llrTemp, k, numSymbols)';
end
```

For 16-QAM symbols, the hidden layer has 8 neurons and the output layer has 4 neurons, which corresponds to the number of bits per symbol. The llrnetNeuralNetwork function returns preconfigured neural network. Train the neural network for three different SNR values. Use the exact LLR values calculated using the `qamdemod` function as the expected output values.

```
hiddenLayerSize = 8;
trainedNetworks = cell(1,numSNRValues);
for snrIdx=1:numSNRValues
    fprintf('Training neural network for SNR = %1.1fdB\n', ...
        SNRValues(snrIdx))
    x = nnInput(:,:,snrIdx)';
    y = nnOutput(:,:,snrIdx)';

    MSExactLLR = mean(y(:).^2);
    fprintf('\tMean Square LLR = %1.2f\n', MSExactLLR)

    % Train the Network. Use parallel pool, if available. Train three times
    % and pick the best one.
    mse = inf;
    for p=1:3
        netTemp = llrnetNeuralNetwork(hiddenLayerSize);
        if parallelComputingLicenseExists()
            [netTemp,tr] = train(netTemp,x,y,'useParallel','yes');
        else
            [netTemp,tr] = train(netTemp,x,y);
        end
        % Test the Network
        predictedLLRSNR = netTemp(x);
        mseTemp = perform(netTemp,y,predictedLLRSNR);
        fprintf('\t\tTrial %d: MSE = %1.2e\n', p, mseTemp)
        if mse > mseTemp
            mse = mseTemp;
            net = netTemp;
        end
    end

    % Store the trained network
    trainedNetworks{snrIdx} = net;
    fprintf('\tBest MSE = %1.2e\n', mse)
end
```

```
Training neural network for SNR = -5.0dB

    Mean Square LLR = 4.42

        Trial 1: MSE = 1.95e-06
        Trial 2: MSE = 1.22e-04
        Trial 3: MSE = 4.54e-06

    Best MSE = 1.95e-06
```

```
Training neural network for SNR = 0.0dB

    Mean Square LLR = 15.63

        Trial 1: MSE = 1.90e-03
        Trial 2: MSE = 5.03e-03
        Trial 3: MSE = 8.95e-05

    Best MSE = 8.95e-05

Training neural network for SNR = 5.0dB

    Mean Square LLR = 59.29

        Trial 1: MSE = 2.25e-02
        Trial 2: MSE = 2.23e-02
        Trial 3: MSE = 7.40e-02

    Best MSE = 2.23e-02
```

Performance metric for this network is mean square error (MSE). The final MSE values show that the neural network converges to an MSE value that is at least 40 dB less than the mean square exact LLR values. Note that, as SNR increases so do the LLR values, which results in relatively higher MSE values.

Results for 16-QAM

Compare the LLR estimates of LLRNet to that of exact LLR and approximate LLR. Simulate 1e4 16-QAM symbols and calculate LLR values using all three methods. Do not use the symbols that we generated in the previous section so as not to give LLRNet an unfair advantage, since those symbols were used to train the LLRNet.

```
numBits = numSymbols*k;
d = randi([0 1], numBits, 1);

txSym = qammod(d,M,symOrder,'InputType','bit','UnitAveragePower',1);

exactLLR = zeros(numBits,numSNRValues);
approxLLR = zeros(numBits,numSNRValues);
predictedLLR = zeros(numBits,numSNRValues);
rxSym = zeros(length(txSym),numSNRValues);
for snrIdx = 1:numSNRValues
    SNR = SNRValues(snrIdx);
    sigmas = 10^(-SNR/10);
    r = awgn(txSym,SNR);
    rxSym(:,snrIdx) = r;

    exactLLR(:,snrIdx) = qamdemod(r,M,symOrder,...
        'UnitAveragePower',1,'OutputType','llr','NoiseVariance',sigmas);
    approxLLR(:,snrIdx) = qamdemod(r,M,symOrder,...
        'UnitAveragePower',1,'OutputType','approxllr','NoiseVariance',sigmas);

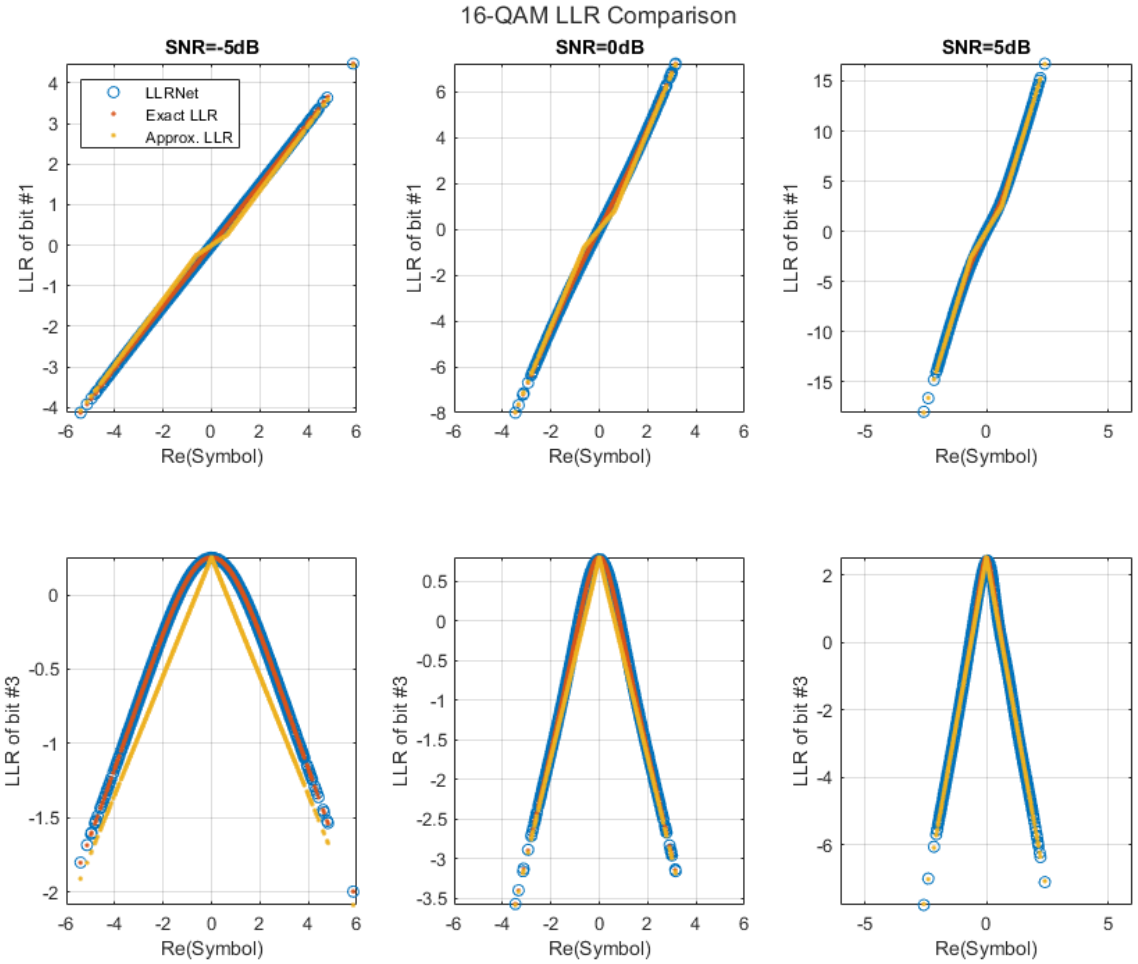
    net = trainedNetworks{snrIdx};
    x = [real(r) imag(r)]';
    tempLLR = net(x);
    predictedLLR(:,snrIdx) = reshape(tempLLR, numBits, 1);
end

qam16Results.exactLLR = exactLLR;
```

```
qam16Results.approxLLR = approxLLR;
qam16Results.predictedLLR = predictedLLR;
qam16Results.RxSymbols = rxSym;
qam16Results.M = M;
qam16Results.SNRValues = SNRValues;
qam16Results.HiddenLayerSize = hiddenLayerSize;
qam16Results.NumSymbols = numSymbols;
```

The following figure shows exact LLR, max-log approximate LLR, and LLRNet estimate of LLR values versus the real part of the received symbol for odd bits. LLRNet matches the exact LLR values even for low SNR values.

```
llrnetPlotLLR(qam16Results,'16-QAM LLR Comparison')
```



64-QAM and 256-QAM LLR Estimation Performance

Check if the LLRNet can estimate the LLR values for higher order QAM. Repeat the same process you followed for 16-QAM for 64-QAM and 256-QAM using the llrnetQAMLLR helper function. The following figures show exact LLR, max-log approximate LLR, and LLRNet estimate of LLR values versus the real part of the received symbol for odd bits.

```
trainNow = Show saved results;

DVB-S.2 Packet Error Rate

DVB-S.2 system uses a soft demodulator to generate inputs for the LDPC decoder. Simulate the packet error rate (PER) of a DVB-S.2 system with 16-APSK modulation and 2/3 LDPC code using exact LLR, approximate LLR, and LLRNet using llrNetDVBS2PER function. This function uses the `comm.PSKDemodulator` (Communications Toolbox) System object and the `dvbsapskdemod` (Communications Toolbox) function to calculate exact and approximate LLR values and the `comm.AWGNChannel` (Communications Toolbox) System object to simulate the channel.

Set `simulateNow` to true (or select "Simulate" in the dropdown) to run the PER simulations for the values of `subsystemType`, `EsNoValues`, and `numSymbols` using the llrnetDVBS2PER function. If Parallel Computing Toolbox™ is installed, this function uses the `parfor` command to run the simulations in parallel. On an Intel® Xeon® W-2133 CPU @ 3.6GHz and running a “Run Code on Parallel Pools” (Parallel Computing Toolbox) of size 6, the simulation takes about 40 minutes. Set `simulateNow` to `false` (or select "Plot saved results" in the dropdown), to load the PER results for the values of `subsystemType='16APSK 2/3'`, `EsNoValues=8.6:0.1:8.9`, and `numSymbols=10000`.

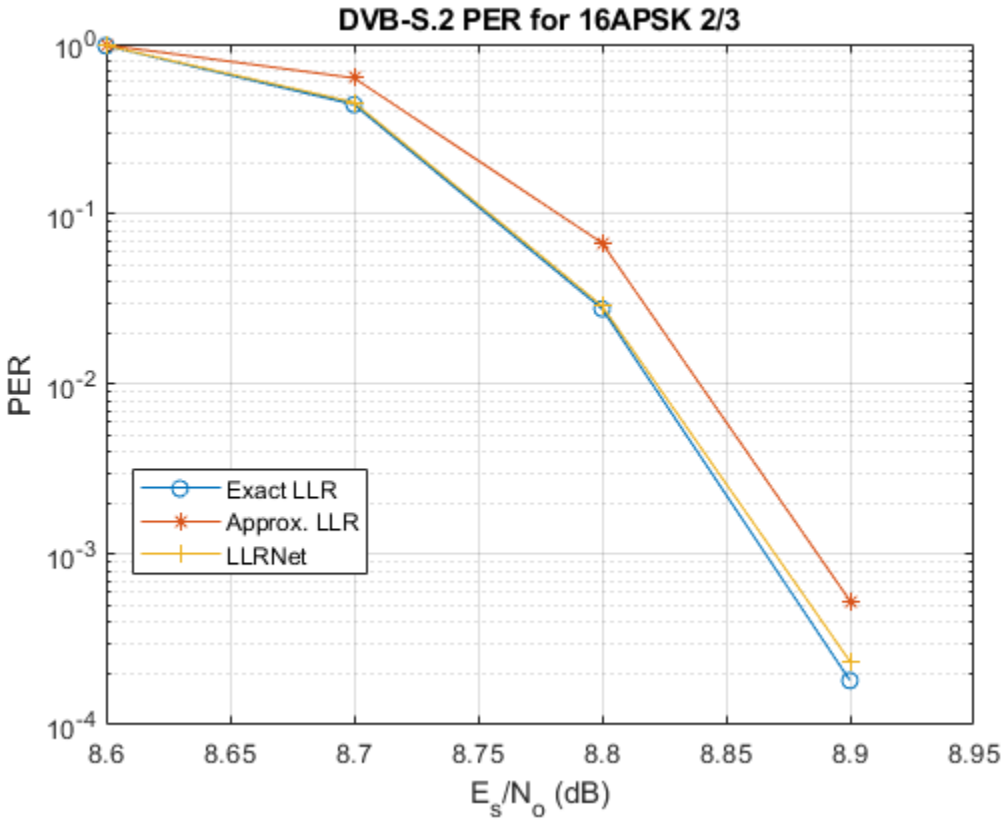
Set `trainNow` to `true` (or select "Train LLRNet" in the dropdown) to train LLR neural networks for each value of `EsNoValues`, for the given `subsystemType` and `numSymbols`. If Parallel Computing Toolbox™ is installed, the `train` function can be called with the optional name-value pair `'useParallel'` set to `'yes'` to run the simulations in parallel. On an Intel® Xeon® W-2133 CPU @ 3.6GHz and running a “Run Code on Parallel Pools” (Parallel Computing Toolbox) of size 6, the simulation takes about 21 minutes. Set `trainNow` to false (or select "Use saved networks" in the dropdown) to load LLR neural networks trained for `subsystemType='16APSK 2/3'`, `EsNoValues=8.6:0.1:8.9`.

For more information on the DVB-S.2 PER simulation, see the “DVB-S.2 Link, Including LDPC Coding in Simulink” (Communications Toolbox) example. For more information on training the network, refer to the llrnetTrainDVBS2LLRNetwork function and [1] on page 13-0 .

```
simulateNow = Plot saved results;
if simulateNow
    subsystemType = '16APSK 2/3'; %#ok<UNRCH>
    EsNoValues = 8.6:0.1:8.9;     % in dB
    numFrames = 10000;
    numErrors = 200;

    trainNow = Use saved networks;
    if trainNow && (~strcmp(subsystemType,'16APSK 2/3') || ~isequal(EsNoValues,8.6:0.1:9))
        % Train the networks for each EsNo value
        numTrainSymbols = 1e4;
        hiddenLayerSize = 64;
        llrNets = llrnetTrainDVBS2LLRNetwork(subsystemType, EsNoValues, numTrainSymbols, hiddenLa
    else
        load('llrnetDVBS2Networks','llrNets','subsystemType','EsNoValues');
    end

    % Simulate PER with exact LLR, approximate LLR, and LLRNet
    [perLLR,perApproxLLR,perLLRNet] = llrnetDVBS2PER(subsystemType,EsNoValues,llrNets,numFrames,n
    llrnetPlotLLRvsEsNo(perLLR,perApproxLLR,perLLRNet,EsNoValues,subsystemType)
else
    load('llrnetDVBS2PERResults.mat','perApproxLLR','perLLR','perLLRNet',...
        'subsystemType','EsNoValues');
    llrnetPlotLLRvsEsNo(perLLR,perApproxLLR,perLLRNet,EsNoValues,subsystemType)
end
```



The results show that the LLRNet almost matches the performance of exact LLR without using any expensive operations such as logarithm and exponential.

Further Exploration

Try different modulation and coding schemes for the DVB-S.2 system. The full list of modulation types and coding rates are given in the “DVB-S.2 Link, Including LDPC Coding in Simulink” (Communications Toolbox) example. You can also try different sizes for the hidden layer of the network to reduce the number of operations and measure the performance loss as compared to exact LLR.

The example uses these helper functions. Examine these files to learn about details of the implementation.

Design a Deep Neural Network with Simulated Data to Detect WLAN Router Impersonation

This example shows how to design a radio frequency (RF) fingerprinting convolutional neural network (CNN) with simulated data. You train the CNN with simulated wireless local area network (WLAN) beacon frames from known and unknown routers for RF fingerprinting. You then compare the media access control (MAC) address of received signals and the RF fingerprint detected by the CNN to detect WLAN router impersonators.

For more information on how to test the designed neural network with signals captured from real Wi-Fi routers, see the “Test a Deep Neural Network with Captured Data to Detect WLAN Router Impersonation” (Communications Toolbox) example.

Detect Router Impersonation Using RF Fingerprinting

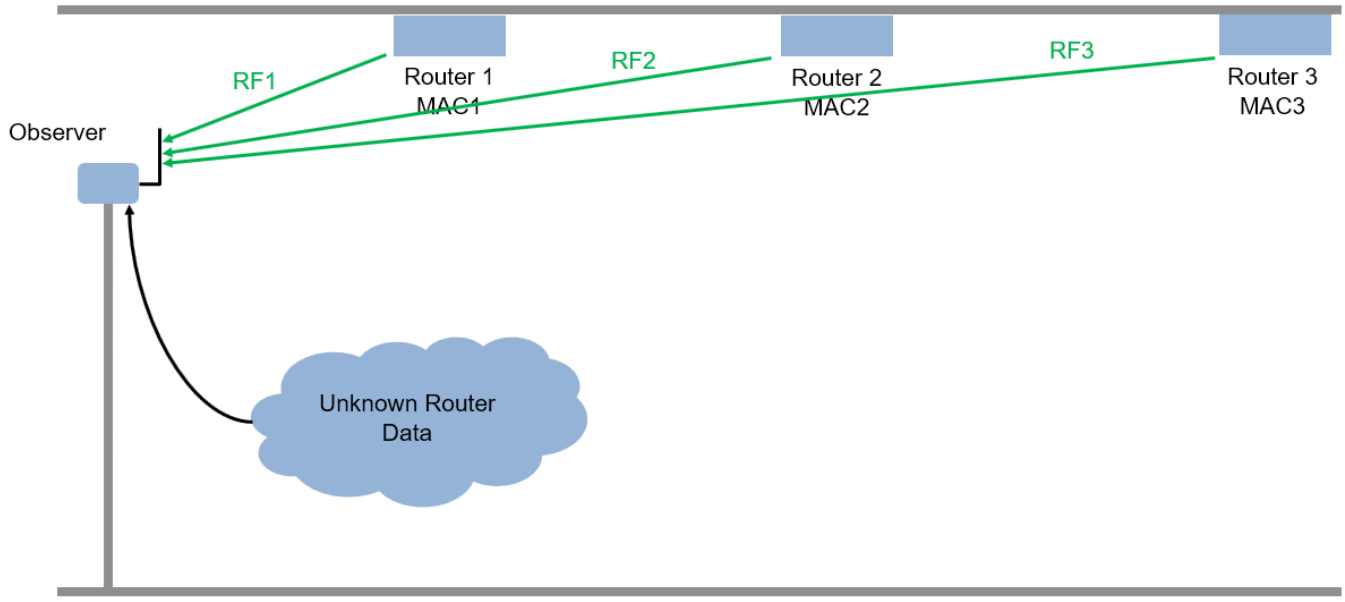
Router impersonation is a form of attack on a WLAN network where a malicious agent tries to impersonate a legitimate router and trick network users to connect to it. Security identification solutions based on simple digital identifiers, such as MAC addresses, IP addresses, and SSID, are not effective in detecting such an attack. These identifiers can be easily spoofed. Therefore, a more secure solution uses other information, such as the RF signature of the radio link, in addition to these simple digital identifiers.

A wireless transmitter-receiver pair creates a unique RF signature at the receiver that is a combination of the channel and RF impairments. *RF Fingerprinting* is the process of distinguishing transmitting radios in a shared spectrum through these signatures. In [1] on page 13-0 , authors designed a deep learning (DL) network that consumes raw baseband in-phase/quadrature (IQ) samples and identifies the transmitting radio. The network can identify the transmitting radios if the RF impairments are dominant or the channel profile stays constant during the operation time. Most WLAN networks have fixed routers that create a static channel profile when the receiver location is also fixed. In such a scenario, the deep learning network can identify router impersonators by comparing the received signal's RF fingerprint and MAC address pair to that of the known routers.

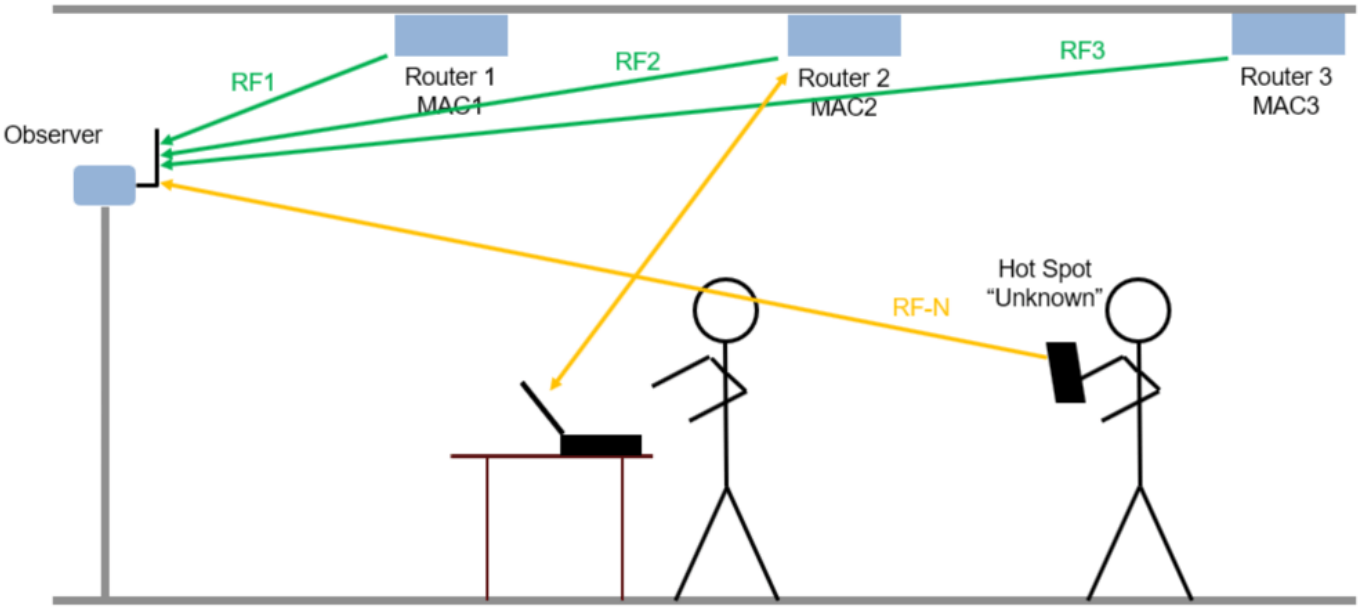
This example simulates a WLAN system with several fixed routers and a fixed observer using the WLAN Toolbox™ and trains a neural network (NN) with the simulated data using Deep Learning Toolbox™.

System Description

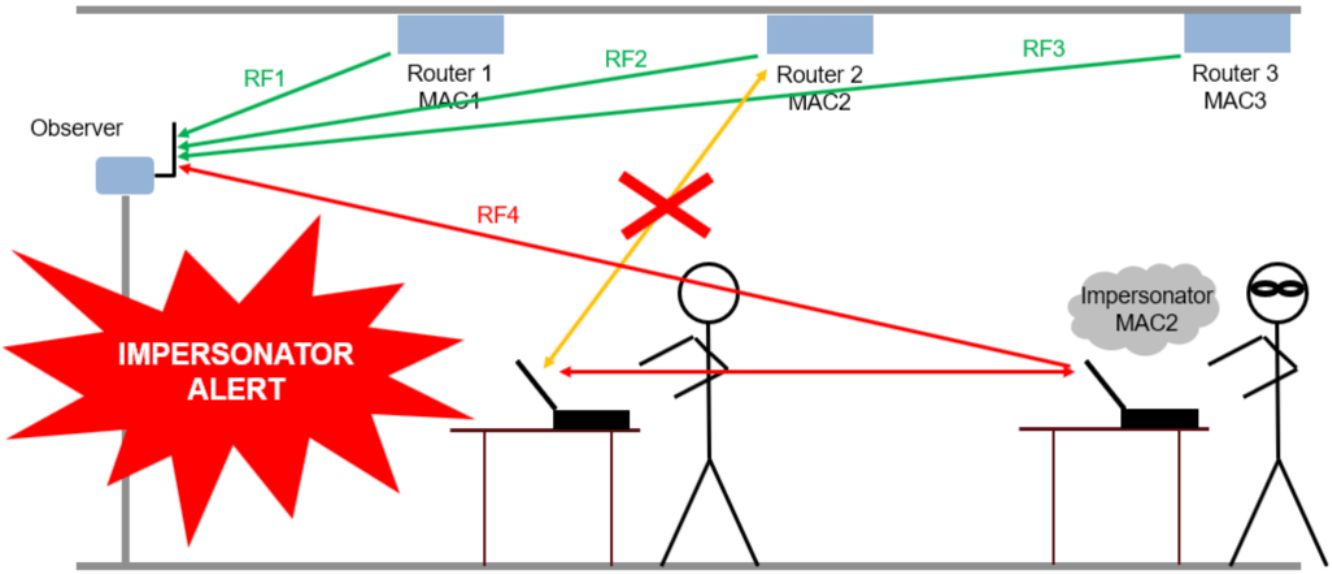
Assume an indoor space with a number of trusted routers with known MAC addresses, which we will refer to as known routers. Also, assume that unknown routers may enter the observation area, some of which may be router impersonators. The class "Unknown" represents any transmitting device that is not contained in the known set. The following figure shows a scenario where there are three known routers. The observer collects non-high throughput (non-HT) beacon signals from these routers and uses the (legacy) long training field (L-LTF) to identify the RF fingerprint. Transmitted L-LTF signals are the same for all routers that enables the algorithm to avoid any data dependency. Since the routers and the observer are fixed, the RF fingerprints (combination of multipath channel profile and RF impairments) RF1, RF2, and RF3 do not vary in time. Unknown router data is a collection of random RF fingerprints, which are different than the known routers.



The following figure shows a user connected to a router and a mobile hot spot. After training, the observer receives beacon frames and decodes the MAC address. Also, the observer extracts the L-LTF signal and uses this signal to classify the RF fingerprint of the source of the beacon frame. If the MAC address and the RF fingerprint matches, as in the case of Router 1, Router 2, and Router3, then the observer declares the source as a "known" router. If the MAC address of the beacon is not in the database and the RF fingerprint does not match any of the known routers, as in the case of a mobile hot spot, then the observer declares the source as an "unknown" router.



The following figure shows a router impersonator in action. A router impersonator (a.k.a. evil twin) can replicate the MAC address of a known router and transmit beacon frames. Then, the hacker can jam the original router and force the user to connect to the evil twin. The observer receives the beacon frames from the evil twin too and decodes the MAC address. The decoded MAC address matches the MAC address of a known router but the RF fingerprint does not match. The observer declares the source as a router impersonator.



Set System Parameters

Generate a dataset of 5,000 Non-HT WLAN beacon frames for each router. Use MAC addresses as labels for the known routers; the remaining are be labeled as "Unknown". A NN is trained to classify the known routers as well as to detect any unknown ones. Split the dataset into training, validation and test, where the splitting ratios are 80%, 10%, and 10%, respectively. Consider an SNR of 20 dB, working on the 5 GHz band. The number of simulated devices is set to 4 but it can be modified by choosing a different value for `numKnownRouters`. Set the number of unknown routers more than the known ones to represent in the dataset the variability in the unknown router RF fingerprints.

```
numKnownRouters = 4;
numUnknownRouters = 10;
numTotalRouters = numKnownRouters+numUnknownRouters;
SNR = 20;                   % dB
channelNumber = 153;        % WLAN channel number
channelBand = 5;            % GHz
frameLength = 160;          % L-LTF sequence length in samples
```

By default, this example downloads training data and trained network from https://www.mathworks.com/supportfiles/spc/RFFingerprinting/RFFingerprintingSimulatedData.tar.gz. If you do not have an Internet connection, you can download the file manually on a computer that is connected to the Internet and save to the same directory as the current example files.

To run this example quickly, download the pretrained trained network and generate a small number of frames, for example 10. To train the network on your computer, choose the "Train network now" option (i.e. set `trainNow` to true). Generating 5000 frames of data takes about 50 minutes on an Intel(R) Xeon(R) W-2133 CPU @ 3.6 GHz with 64 MB memory. Training this network takes about 5

minutes with an Nvidia(R) Titan Xp GPU. Training on a CPU may result in a very long training duration.

```
trainNow = Use trained network ;

if trainNow
  numTotalFramesPerRouter = 5000; %#ok<UNRCH>
else
  numTotalFramesPerRouter = 10;
  rfFingerprintingDownloadData('simulated')
end

Starting download of data files from:
    https://www.mathworks.com/supportfiles/spc/RFFingerprinting/RFFingerprintingSimulatedData.ta
Download and extracting files done

  numTrainingFramesPerRouter = numTotalFramesPerRouter*0.8;
  numValidationFramesPerRouter = numTotalFramesPerRouter*0.1;
  numTestFramesPerRouter = numTotalFramesPerRouter*0.1;
```

Generate WLAN Waveforms

Wi-Fi routers that implement 802.11a/g/n/ac protocols transmit beacon frames in the 5 GHz band to broadcast their presence and capabilities using the OFDM non-HT format. The beacon frame consists of two main parts: preamble (SYNC) and payload (DATA). The preamble has two parts: short training and long training. In this example, the payload contains the same bits except the MAC address for each router. The CNN uses the L-LTF part of the preamble as training units. Reusing the L-LTF signal for RF fingerprinting provides an overhead-free fingerprinting solution. Use `wlanMACFrameConfig` (WLAN Toolbox), `wlanMACFrame` (WLAN Toolbox), `wlanNonHTConfig` (WLAN Toolbox), and `wlanWaveformGenerator` (WLAN Toolbox) functions to generate WLAN beacon frames.

```
% Create Beacon frame-body configuration object
frameBodyConfig = wlanMACManagementConfig;

% Create Beacon frame configuration object
beaconFrameConfig = wlanMACFrameConfig('FrameType', 'Beacon', ...
  "ManagementConfig", frameBodyConfig);

% Generate Beacon frame bits
[~, mpduLength] = wlanMACFrame(beaconFrameConfig, 'OutputFormat', 'bits');

% Create a wlanNONHTConfig object, 20 MHz bandwidth and MCS 1 are used
nonHTConfig = wlanNonHTConfig(...
  'ChannelBandwidth', "CBW20",...
  "MCS", 1,...
  "PSDULength", mpduLength);
```

The rfFingerprintingNonHTFrontEnd object performs front-end processing including extracting the L-LTF signal. The object is configured with a channel bandwidth of 20 MHz to process non-HT signals.

```
rxFrontEnd = rfFingerprintingNonHTFrontEnd('ChannelBandwidth', 'CBW20');

fc = helperWLANChannelFrequency(channelNumber, channelBand);
fs = wlanSampleRate(nonHTConfig);
```

Setup Channel and RF Impairments

Pass each frame through a channel with

- Rayleigh multipath fading
- Radio impairments, such as phase noise, frequency offset and DC offset
- AWGN

Rayleigh Multipath and AWGN

The channel passes the signals through a Rayleigh multipath fading channel using the `comm.RayleighChannel` (Communications Toolbox) System object. Assume a delay profile of [0 1.8 3.4] samples with corresponding average path gains of [0 -2 -10] dB. Since the channel is static, set maximum Doppler shift to zero to make sure that the channel does not change for the same radio. Implement the multipath channel with these settings. Add noise using the `awgn` (Communications Toolbox) function,

```
multipathChannel = comm.RayleighChannel(...
  'SampleRate', fs, ...
  'PathDelays', [0 1.8 3.4]/fs, ...
  'AveragePathGains', [0 -2 -10], ...
  'MaximumDopplerShift', 0);
```

Radio Impairments

The RF impairments, and their corresponding range of values are:

- Phase noise [0.01, 0.3] rms (degrees)
- Frequency offset [-4, 4] ppm
- DC offset: [-50, -32] dBc

See helperRFImpairments on page 13-0 function for more details on RF impairment simulation. This function uses `comm.PhaseFrequencyOffset` (Communications Toolbox) and `comm.PhaseNoise` (Communications Toolbox) System objects.

```
phaseNoiseRange = [0.01, 0.3];
freqOffsetRange = [-4, 4];
dcOffsetRange = [-50, -32];

rng(123456)  % Fix random generator

% Assign random impairments to each simulated radio within the previously
% defined ranges
radioImpairments = repmat(...
  struct('PhaseNoise', 0, 'DCOffset', 0, 'FrequencyOffset', 0), ...
  numTotalRouters, 1);
for routerIdx = 1:numTotalRouters
  radioImpairments(routerIdx).PhaseNoise = ...
    rand*(phaseNoiseRange(2)-phaseNoiseRange(1)) + phaseNoiseRange(1);
  radioImpairments(routerIdx).DCOffset = ...
    rand*(dcOffsetRange(2)-dcOffsetRange(1)) + dcOffsetRange(1);
  radioImpairments(routerIdx).FrequencyOffset = ...
    fc/1e6*(rand*(freqOffsetRange(2)-freqOffsetRange(1)) + freqOffsetRange(1));
end
```

Apply Channel Impairments and Generate Data Frames for Training

Apply the RF and channel impairments defined previously. Reset the channel object for each radio to generate an independent channel. Use rfFingerprintingNonHTFrontEnd function to process the received frames. Finally, extract the L-LTF from every transmitted WLAN frame. Split the received L-LTF signals into training, validation and test sets.

```
% Create variables that will store the training, validation and testing
% datasets
xTrainingFrames = zeros(frameLength, numTrainingFramesPerRouter*numTotalRouters);
xValFrames = zeros(frameLength, numValidationFramesPerRouter*numTotalRouters);
xTestFrames = zeros(frameLength, numTestFramesPerRouter*numTotalRouters);

% Index vectors for train, validation and test data units
trainingIndices = 1:numTrainingFramesPerRouter;
validationIndices = 1:numValidationFramesPerRouter;
testIndices = 1:numTestFramesPerRouter;

tic
generatedMACAddresses = strings(numTotalRouters, 1);
rxLLTF = zeros(frameLength, numTotalFramesPerRouter);     % Received L-LTF sequences
for routerIdx = 1:numTotalRouters

  % Generate a 12-digit random hexadecimal number as a MAC address for
  % known routers. Set the MAC address of all unknown routers to
  % 'AAAAAAAAAAAA'.
  if (routerIdx<=numKnownRouters)
    generatedMACAddresses(routerIdx) = string(dec2hex(bi2de(randi([0 1], 12, 4)))');
  else
    generatedMACAddresses(routerIdx) = 'AAAAAAAAAAAA';
  end

  fprintf('%s - Generating frames for router %d with MAC address %s\n', ...
    datestr(toc/86400,'HH:MM:SS'), routerIdx, generatedMACAddresses(routerIdx))

  % Set MAC address into the wlanFrameConfig object
  beaconFrameConfig.Address2 = generatedMACAddresses(routerIdx);

  % Generate beacon frame bits
  beacon = wlanMACFrame(beaconFrameConfig, 'OutputFormat', 'bits');

  txWaveform = wlanWaveformGenerator(beacon, nonHTConfig);

  txWaveform = helperNormalizeFramePower(txWaveform);

  % Add zeros to account for channel delays
  txWaveform = [txWaveform; zeros(160,1)]; %#ok<AGROW>

  % Reset multipathChannel object to generate a new static channel
  reset(multipathChannel)

  frameCount= 0;
  while frameCount<numTotalFramesPerRouter

    rxMultipath = multipathChannel(txWaveform);

    rxImpairment = helperRFImpairments(rxMultipath, radioImpairments(routerIdx), fs);
```

```
    rxSig = awgn(rxImpairment,SNR,0);

    % Detect the WLAN packet and return the received L-LTF signal using
    % rfFingerprintingNonHTFrontEnd object
    [valid, ~, ~, ~, ~, LLTF] = rxFrontEnd(rxSig);

    % Save successfully received L-LTF signals
    if valid
      frameCount=frameCount+1;
      rxLLTF(:,frameCount) = LLTF;
    end

    if mod(frameCount,500) == 0
      fprintf('%s - Generated %d/%d frames\n', ...

yVal = repelem(labels, numValidationFramesPerRouter);
yTest = repelem(labels, numTestFramesPerRouter);
```

Create Real-Valued Input Matrices

The Deep Learning model only works on real numbers. Thus, I and Q are split into two separate columns. Then, the data is rearranged into a 2 x frameLength x 1 x numFrames matrix, as required

by the Deep Learning Toolbox. Additionally, the training set is shuffled, and the label variables are saved as categorical variables.

```
% Rearrange datasets into a one-column vector
xTrainingFrames = xTrainingFrames(:);
xValFrames = xValFrames(:);
xTestFrames = xTestFrames(:);

% Separate between I and Q
xTrainingFrames = [real(xTrainingFrames), imag(xTrainingFrames)];
xValFrames = [real(xValFrames), imag(xValFrames)];
xTestFrames = [real(xTestFrames), imag(xTestFrames)];

% Reshape training data into a 2 x frameLength x 1 x
% numTrainingFramesPerRouter*numTotalRouters matrix
xTrainingFrames = permute(...
  reshape(xTrainingFrames,[frameLength,numTrainingFramesPerRouter*numTotalRouters, 2, 1]),...
  [1 3 4 2]);

% Shuffle data
vr = randperm(numTotalRouters*numTrainingFramesPerRouter);
xTrainingFrames = xTrainingFrames(:,:,:,vr);

% Create label vector and shuffle
yTrain = categorical(yTrain(vr));

% Reshape validation data into a 2 x frameLength x 1 x
% numValidationFramesPerRouter*numTotalRouters matrix
xValFrames = permute(...
  reshape(xValFrames,[frameLength,numValidationFramesPerRouter*numTotalRouters, 2, 1]),...
  [1 3 4 2]);

% Create label vector
yVal = categorical(yVal);

% Reshape test dataset into a numTestFramesPerRouter*numTotalRouter matrix
xTestFrames = permute(...
  reshape(xTestFrames,[frameLength,numTestFramesPerRouter*numTotalRouters, 2, 1]),...
  [1 3 4 2]); %#ok<NASGU>

% Create label vector
yTest = categorical(yTest); %#ok<NASGU>
```

Train the Neural Network

This example uses a neural network (NN) architecture that consists of two convolutional and three fully connected layers. The intuition behind this design is that the first layer will learn features independently in I and Q. Note that the filter sizes are 1x7. Then, the next layer will use a filter size of 2x7 that will extract features combining I and Q together. Finally, the last three fully connected layers will behave as a classifier using the extracted features in the previous layers [1] on page 13-0 .

```
poolSize = [2 1];
strideSize = [2 1];
layers = [
  imageInputLayer([frameLength 2 1], 'Normalization', 'none', 'Name', 'Input Layer')

  convolution2dLayer([7 1], 50, 'Padding', [1 0], 'Name', 'CNN1')

```

Configure the training options to use the ADAM optimizer with a mini-batch size of 256. By default, '`ExecutionEnvironment`' is set to 'auto', which uses a GPU for training if one is available. Otherwise, `trainNetwork` uses a CPU for training. To explicitly set the execution environment, set '`ExecutionEnvironment`' to one of '`cpu`', '`gpu`', '`multi-gpu`', or '`parallel`'. Choosing '`cpu`' may result in a very long training duration.

```
if trainNow

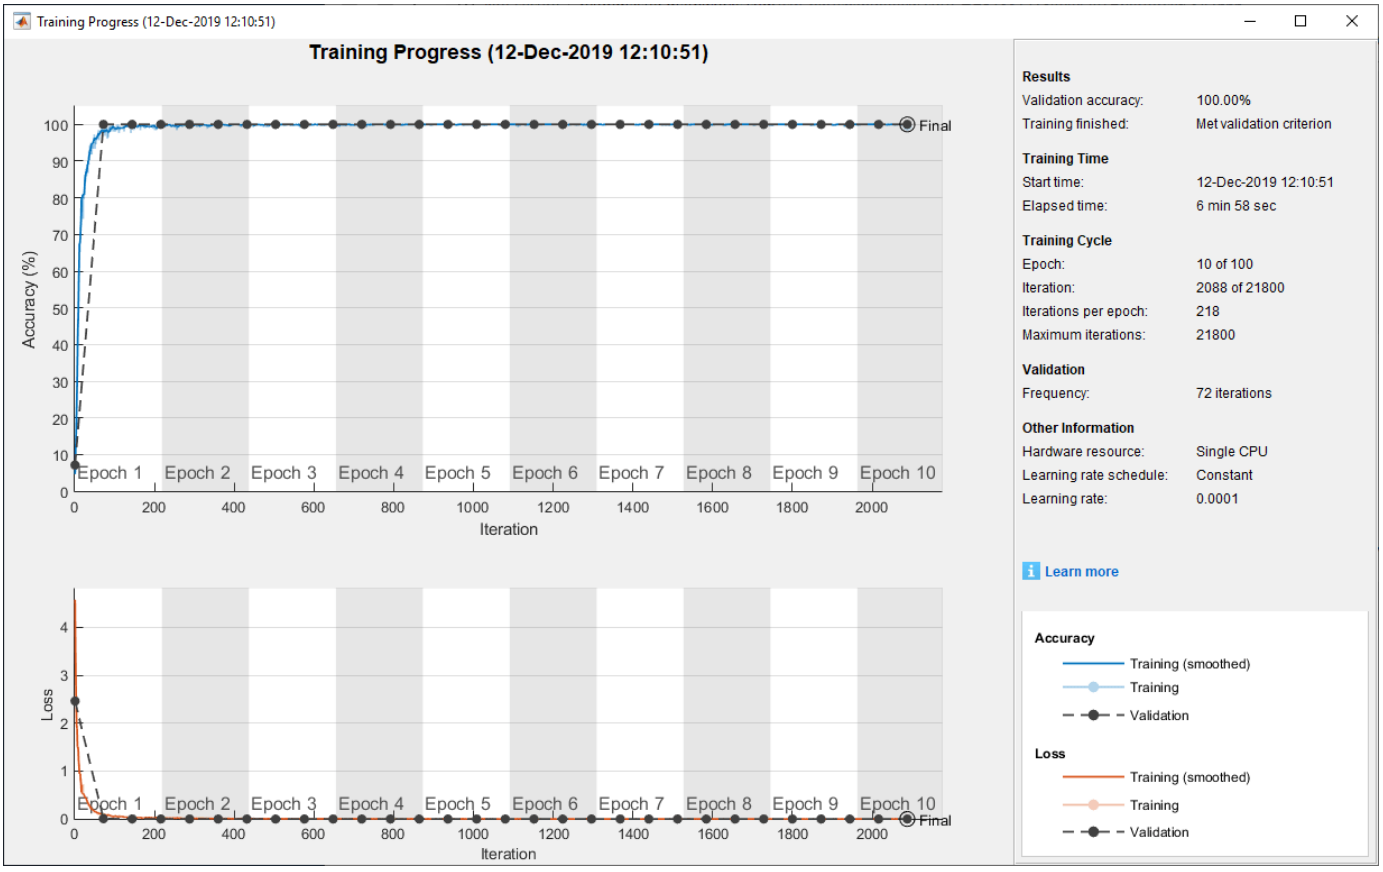
  miniBatchSize = 256; %#ok<UNRCH>

  % Training options
  options = trainingOptions('adam', ...
    'MaxEpochs',100, ...
    'ValidationData',{xValFrames, yVal}, ...
    'ValidationFrequency',floor(numTrainingFramesPerRouter*numTotalRouters/miniBatchSize/3), ...
```

```
    'Verbose',false, ...
    'L2Regularization', 0.0001, ...
    'InitialLearnRate', 0.0001, ...
    'MiniBatchSize', miniBatchSize, ...
    'ValidationPatience', 3, ...
    'Plots','training-progress', ...
    'Shuffle','every-epoch');

  % Train the network
  simNet = trainNetwork(xTrainingFrames, yTrain, layers, options);
else
  % Load trained network (simNet), testing dataset (xTestFrames and
  % yTest) and the used MACAddresses (generatedMACAddresses)
  load('rfFingerprintingSimulatedDataTrainedNN.mat',...
    'generatedMACAddresses',...
    'simNet',...
    'xTestFrames',...
    'yTest')
end
```

As the plot of the training progress shows, the network converges in about 2 epochs to almost 100% accuracy.



Classify test frames and calculate the final accuracy off the neural network.

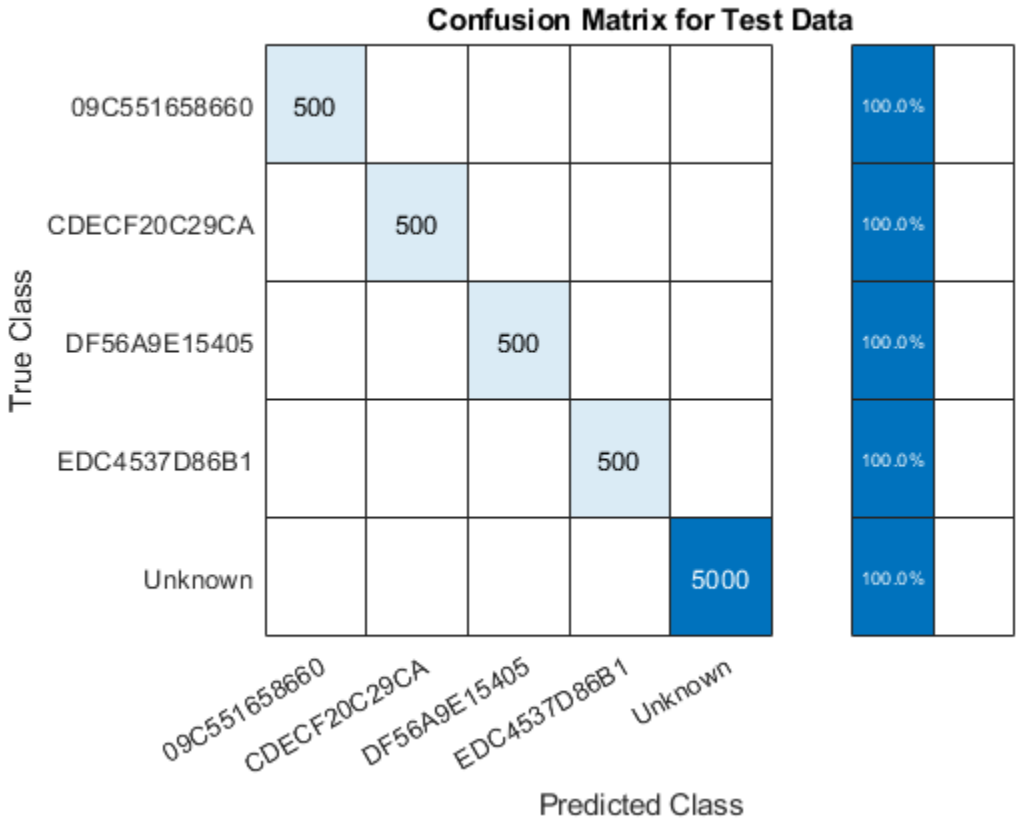
```
% Obtain predicted classes for xTestFrames
yTestPred = classify(simNet,xTestFrames);
```

```
% Calculate test accuracy
testAccuracy = mean(yTest == yTestPred);
disp("Test accuracy: " + testAccuracy*100 + "%")
```

```
Test accuracy: 100%
```

Plot the confusion matrix for the test frames. As mentioned before, perfect classification accuracy is achieved with the synthetic dataset.

```
figure
cm = confusionchart(yTest, yTestPred);
cm.Title = 'Confusion Matrix for Test Data';
cm.RowSummary = 'row-normalized';
```



Detect Router Impersonator

Generate beacon frames with the known MAC addresses and one unknown MAC address. Generate a new set of RF impairments and multipath channel. Since the impairments are all new, the RF fingerprint for these frames should be classified as "Unknown". The frames with known MAC addresses represent router impersonators while the frames with unknown MAC addresses are simply unknown routers.

```
framesPerRouter = 4;
knownMACAddresses = generatedMACAddresses(1:numKnownRouters);

% Assign random impairments to each simulated radio within the previously
% defined ranges
```

```
for routerIdx = 1:numTotalRouters
  radioImpairments(routerIdx).PhaseNoise = rand*( phaseNoiseRange(2)-phaseNoiseRange(1) ) + phase
  radioImpairments(routerIdx).DCOffset = rand*( dcOffsetRange(2)-dcOffsetRange(1) ) + dcOffsetRan
  radioImpairments(routerIdx).FrequencyOffset = fc/1e6*(rand*( freqOffsetRange(2)-freqOffsetRange
end
% Reset multipathChannel object to generate a new static channel
reset(multipathChannel)

% Run for all known routers and one unknown
for macIndex = 1:(numKnownRouters+1)

  beaconFrameConfig.Address2 = generatedMACAddresses(macIndex);

  % Generate Beacon frame bits
  beacon = wlanMACFrame(beaconFrameConfig, 'OutputFormat', 'bits');

  txWaveform = wlanWaveformGenerator(beacon, nonHTConfig);

  txWaveform = helperNormalizeFramePower(txWaveform);

  % Add zeros to account for channel delays
  txWaveform = [txWaveform; zeros(160,1)]; %#ok<AGROW>

  % Create an unseen multipath channel. In other words, create an unseen
  % RF fingerprint.
  reset(multipathChannel)

  frameCount= 0;
  while frameCount<framesPerRouter

    rxMultipath = multipathChannel(txWaveform);

    rxImpairment = helperRFImpairments(rxMultipath, radioImpairments(routerIdx), fs);

    rxSig = awgn(rxImpairment,SNR,0);

    % Detect the WLAN packet and return the received L-LTF signal using
    % rfFingerprintingNonHTFrontEnd object

Further Exploration

You can test the system under different channel and RF impairments by modifying the

- Multipath profile (`PathDelays` and `AveragePathGains` properties of Rayleigh channel object),
- Channel noise level (SNR input of `awgn` function),
- RF impairments (`phaseNoiseRange`, `freqOffsetRange`, and `dcOffsetRange` variables).

You can also modify the neural network structure by changing

- Convolutional layer parameters (filter size, number of filters, padding),
- Number of fully connected layers,
- Number of convolutional layers.

Appendix: Helper Functions

```
function [impairedSig] = helperRFImpairments(sig, radioImpairments, fs)
% helperRFImpairments Apply RF impairments
%   IMPAIREDSIG = helperRFImpairments(SIG, RADIOIMPAIRMENTS, FS) returns signal
%   SIG after applying the impairments defined by RADIOIMPAIRMENTS
%   structure at the sample rate FS.
```

```
% Apply frequency offset
fOff = comm.PhaseFrequencyOffset('FrequencyOffset', radioImpairments.FrequencyOffset,  'SampleRa

% Apply phase noise
phaseNoise = helperGetPhaseNoise(radioImpairments);
phNoise = comm.PhaseNoise('Level', phaseNoise, 'FrequencyOffset', abs(radioImpairments.FrequencyO

impFOff = fOff(sig);
impPhNoise = phNoise(impFOff);

% Apply DC offset
impairedSig = impPhNoise + 10^(radioImpairments.DCOffset/10);

end

function [phaseNoise] = helperGetPhaseNoise(radioImpairments)
% helperGetPhaseNoise Get phase noise value
load('Mrms.mat','Mrms','MyI','xI');
[~, iRms] = min(abs(radioImpairments.PhaseNoise - Mrms));
[~, iFreqOffset] = min(abs(xI - abs(radioImpairments.FrequencyOffset)));
phaseNoise = -abs(MyI(iRms, iFreqOffset));
end
```

Test a Deep Neural Network with Captured Data to Detect WLAN Router Impersonation

This example shows how to train a radio frequency (RF) fingerprinting convolutional neural network (CNN) with captured data. You capture wireless local area network (WLAN) beacon frames from real routers using a software defined radio (SDR). You program a second SDR to transmit unknown beacon frames and capture them. You train the CNN using these captured signals. You then program a software-defined radio (SDR) as a router impersonator that transmits beacon signals with the media access control (MAC) address of one of the known routers and use the CNN to identify it as an impersonator.

For more information on router impersonation and validation of the network design with simulated data, see the “Design a Deep Neural Network with Simulated Data to Detect WLAN Router Impersonation” (Communications Toolbox) example.

Train with Captured Data

Collect a dataset of 802.11a/g/n/ac OFDM non-high throughput (non-HT) beacon frames from real WLAN routers. As described in the “Design a Deep Neural Network with Simulated Data to Detect WLAN Router Impersonation” (Communications Toolbox) example, only the legacy long training field (L-LTF) field present in preambles are used as training units in order to avoid any data dependency.

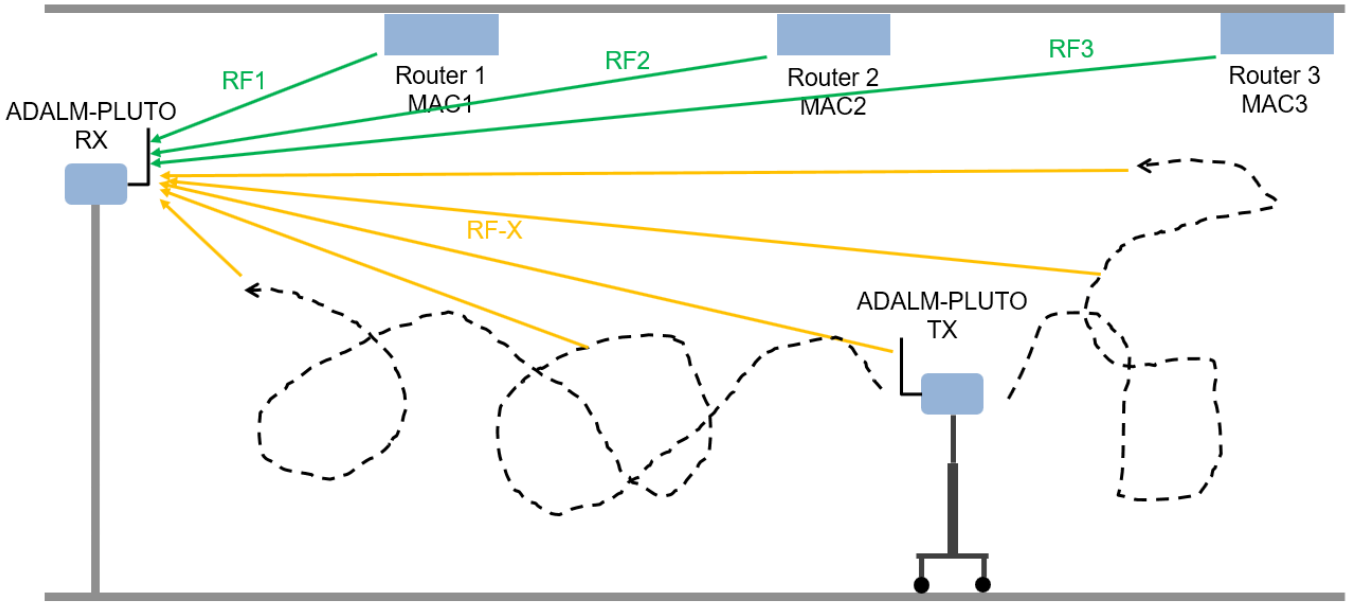
In this example, the data was collected using the scenario depicted in the following figure. The observer is a stationary ADALM-PLUTO radio. Known router data was collected as follows:

1. Set the observer's center frequency based on the WLAN channel used by the routers
2. Receive a beacon frame
3. Extract the L-LTF signal
4. Decode the MAC address to use as the label
5. Save the L-LTF signal together with its label
6. Repeat steps 2-5 to collect `numFramesPerRouter` frames from `numKnownRouters` routers.

Unknown router beacon frames are simulated using a mobile ADALM-PLUTO radio as a transmitter. This radio repeatedly transmits beacon frames with a random MAC address. Unknown router data was collected as follows:

1. Generate beacon frames with a random MAC address
2. Start transmitting the beacon frames repeatedly using the ADALM-PLUTO radio
3. Collect `NUMFRAMES` beacon frames
4. Extract the L-LTF signal
5. Save the L-LTF frames with label "Unknown"
6. Move the radio to another location
7. Repeat steps 3-6 to collect data from `NUMLOC` locations

This combined dataset of known and unknown routers is used to train the same DL model as in the “Design a Deep Neural Network with Simulated Data to Detect WLAN Router Impersonation” (Communications Toolbox) example.



This example downloads training data and trained network from https://www.mathworks.com/supportfiles/spc/RFFingerprinting/RFFingerprintingCapturedData.tar.gz. If you do not have an Internet connection, you can download the file manually on a computer that is connected to the Internet and save to the same directory as the current example files. For privacy reasons, MAC addresses have been anonymized in the downloaded data. To replicate the results of this example, capture your own data as described in Appendix: Known and Unknown Router Data Collection on page 13-0 .

```
rfFingerprintingDownloadData('captured')
```

```
Starting download of data files from:
    https://www.mathworks.com/supportfiles/spc/RFFingerprinting/RFFingerprintingCapturedData.tar
Download and extracting files done
```

To run this example quickly, use the downloaded pretrained network. To train the network on your computer, choose the "Train network now" option (i.e. set `trainNow` to true). Training this network takes about 5 minutes with an Nvidia(R) Titan Xp GPU. Training on a CPU may result in a very long training duration.

`trainNow =` Use trained network ; `%#ok<*UNRCH>`

This example uses data from four known routers. The dataset contains 3600 frames per router, where 90% is used as training frames and 10% is used as test frames.

```
numKnownRouters = 4;
numFramesPerRouter = 3600;
numTrainingFramesPerRouter = numFramesPerRouter * 0.9;
numTestFramesPerRouter = numFramesPerRouter * 0.1;
frameLength = 160;
```

Preprocess Known and Unknown Router Data

Separate collected complex baseband data into its in-phase and quadrature components and reshape it into a *2 x frameLength x 1 x numFramesPerRouter*numKnownRouters* matrix. Repeat the same process for the unknown router data. The following code uses previously collected and pre-processed data. To use your own data, first collect data as described in Appendix: Known and Unknown Router Data Collection on page 13-0 . Copy the new data files named `rfFingerprintingCapturedDataUser.mat` and `rfFingerprintingCapturedUnknownFramesUser.mat` to the same directory as this example. Then update the `load` commands to load these files.

```
if trainNow
  % Load known router data
  load('rfFingerprintingCapturedData.mat')

  % Create label vectors
  yTrain = repelem(MACAddresses, numTrainingFramesPerRouter);
  yTest = repelem(MACAddresses, numTestFramesPerRouter);

  % Separate between I and Q
  numTrainingSamples = numTrainingFramesPerRouter*numKnownRouters*frameLength;
  xTrainingFrames = xTrainingFrames(1:numTrainingSamples,1);
  xTrainingFrames = [real(xTrainingFrames), imag(xTrainingFrames)];
  numTestSamples = numTestFramesPerRouter*numKnownRouters*frameLength;
  xTestFrames = xTestFrames(1:numTestSamples,1);
  xTestFrames = [real(xTestFrames), imag(xTestFrames)];

  % Reshape dataset into an 2 x frameLength x 1 x numTrainingFramesPerRouter*numKnownRouters mat
  xTrainingFrames = permute(...
    reshape(xTrainingFrames,[frameLength,numTrainingFramesPerRouter*numKnownRouters, 2, 1]),...
    [1 3 4 2]);

  % Reshape dataset into an 2 x frameLength x 1 x numTestFramesPerRouter*numKnownRouters matrix
  xTestFrames = permute(...
    reshape(xTestFrames,[frameLength,numTestFramesPerRouter*numKnownRouters, 2, 1]),...
    [1 3 4 2]);

  % Load unknown router data
  load('rfFingerprintingCapturedUnknownFrames.mat')

  % Number of training units
  numUnknownFrames = size(unknownFrames, 4);

  % Split data into 90% training and 10% test
  numUnknownTrainingFrames = floor(numUnknownFrames*0.9);
  numUnknownTest = numUnknownFrames - numUnknownTrainingFrames;

  % Add ADALM-PLUTO data into training and test datasets
  xTrainingFrames(:,:,:,(1:numUnknownTrainingFrames) + numTrainingFramesPerRouter*numKnownRouters
    = unknownFrames(:,:,:, 1:numUnknownTrainingFrames);
  xTestFrames(:,:,:,(1:numUnknownTest) + numTestFramesPerRouter*numKnownRouters) ...
    = unknownFrames(:,:,:, (1:numUnknownTest) + numUnknownTrainingFrames);

  % Shuffle data
  vr = randperm(numKnownRouters*numTrainingFramesPerRouter+numUnknownTrainingFrames);
  xTrainingFrames = xTrainingFrames(:,:,:,vr);
```

```
  % Add "unknown" label and shuffle
  yTrain = [yTrain, repmat("Unknown", [1, numUnknownTrainingFrames])];
  yTrain = categorical(yTrain(vr));

  yTest = [yTest, repmat("Unknown", [1, numUnknownTest])];
  yTest = categorical(yTest);
end
```

Train the CNN

Use the same NN architecture and training options as in the training with simulated data example.

```
poolSize = [2 1];
strideSize = [2 1];
% Create network architecture
layers = [
  imageInputLayer([frameLength 2 1], 'Normalization', 'none', 'Name', 'Input Layer')

  convolution2dLayer([7 1], 50, 'Padding', [1 0], 'Name', 'CNN1')
  batchNormalizationLayer('Name', 'BN1')
  leakyReluLayer('Name', 'LeakyReLu1')
  maxPooling2dLayer(poolSize, 'Stride', strideSize, 'Name', 'MaxPool1')

  convolution2dLayer([7 2], 50, 'Padding', [1 0], 'Name', 'CNN2')
  batchNormalizationLayer('Name', 'BN2')
  leakyReluLayer('Name', 'LeakyReLu2')
  maxPooling2dLayer(poolSize, 'Stride', strideSize, 'Name', 'MaxPool2')

  fullyConnectedLayer(256, 'Name', 'FC1')
  leakyReluLayer('Name', 'LeakyReLu3')
  dropoutLayer(0.5, 'Name', 'DropOut1')

  fullyConnectedLayer(80, 'Name', 'FC2')
  leakyReluLayer('Name', 'LeakyReLu4')
  dropoutLayer(0.5, 'Name', 'DropOut2')

  fullyConnectedLayer(numKnownRouters+1, 'Name', 'FC3')
  softmaxLayer('Name', 'SoftMax')
  classificationLayer('Name', 'Output')
  ];
```

Configure the training options to use ADAM optimizer with a mini-batch size of 128. Use test frames for validation since optimization of hyperparameters were done in [1] on page 13-0 .

By default, `ExecutionEnvironment` is set to `'auto'`, which uses a GPU for training if one is available. Otherwise, `trainNetwork` uses the CPU for training. To explicitly set the execution environment, set `ExecutionEnvironment` to one of `'cpu'`, `'gpu'`, `'multi-gpu'`, or `'parallel'`. Choosing `'cpu'` may result in a very long training duration.

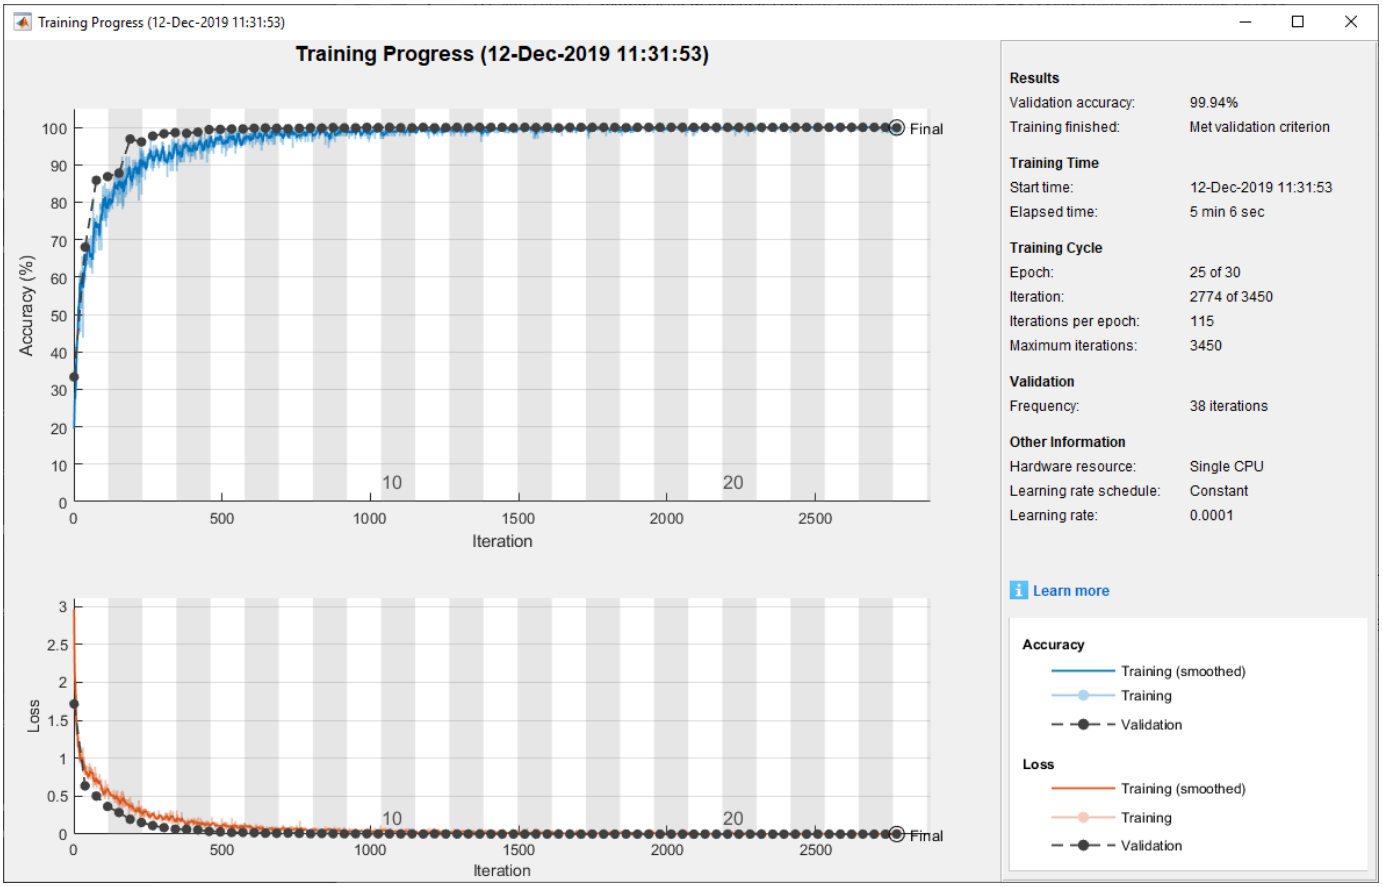
```
if trainNow
  miniBatchSize = 128;

  % Training options
  options = trainingOptions('adam', ...
    'MaxEpochs',30, ...
    'ValidationData',{xTestFrames, yTest}, ...
    'ValidationFrequency',floor((numTrainingFramesPerRouter*numKnownRouters + numUnknownTrainingF
    'Verbose',false, ...
```

```
    'L2Regularization', 0.0001, ...
    'InitialLearnRate', 0.0001, ...
    'MiniBatchSize', miniBatchSize, ...
    'ValidationPatience', 5, ...
    'Plots','training-progress', ...
    'Shuffle', 'every-epoch');

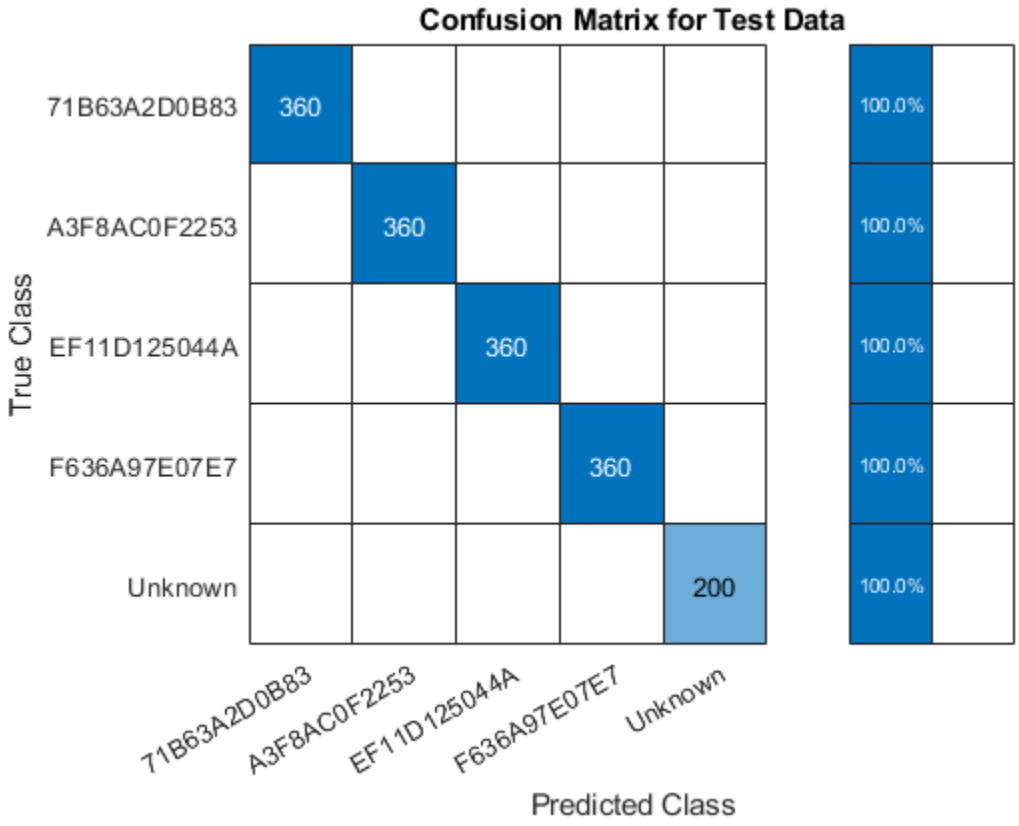
  % Train the network
  capturedDataNet = trainNetwork(xTrainingFrames, yTrain, layers, options);
else
  load('rfFingerprintingCapturedDataTrainedNN.mat','capturedDataNet','xTestFrames','yTest','MACAd
end
```

The following plot shows the training progress of the network run on a computer with a single Nvidia Titan Xp GPU, where the network converged in about 10 epochs to almost 100% accuracy. The final accuracy of the network is 100%.



Generate the confusion matrix.

```
figure
yTestPred = classify(capturedDataNet,xTestFrames);
cm = confusionchart(yTest, yTestPred);
cm.Title = 'Confusion Matrix for Test Data';
cm.RowSummary = 'row-normalized';
```



Test with SDR

Test the performance of the trained network on the class "Unknown". Generate beacon frames with MAC addresses of the known routers and one unknown router. Transmit these frames using an ADALM-PLUTO radio and receive using another ADALM-PLUTO radio. Since the channel and RF impairments created between these two radios are different than the ones created between the real routers and the observer, the neural network should classify all of the received signals as "Unknown". If the received MAC address is a known one, then the system declares the source as a router impersonator. If the received MAC address is an unknown one, then the system declares the source as an unknown router. To perform this test, you need two ADALM-PLUTO radios for transmission and reception. Also, you need to install Communication Toolbox Support Package for ADALM-PLUTO Radio.

Waveform Generation

Generate a transmission waveform consisting of beacon frames with different MAC addresses. The transmitter repeatedly transmits these WLAN frames. The receiver captures the WLAN frames and determines if it is a router impersonator using the received MAC address and RF fingerprint detected by the trained NN.

```
chanBW='CBW20';     % Channel Bandwidth
osf = 2;            % Oversampling Factor
frameLength=160;    % Frame Length in samples
% Create Beacon frame-body configuration object
frameBodyConfig = wlanMACManagementConfig;
```

```
% Create Beacon frame configuration object
beaconFrameConfig = wlanMACFrameConfig('FrameType', 'Beacon');
beaconFrameConfig.ManagementConfig = frameBodyConfig;

% Create interpolation and decimation objects
decimator = dsp.FIRDecimator('DecimationFactor',osf);

% Save known MAC addresses
knownMACAddresses = MACAddresses;
MACAddressesToSimulate = [MACAddresses, "ABCDEFABCDEF"];

% Create WLAN waveform with the MAC addresses of known routers and an
% unknown router
txWaveform = zeros(1540,5);
for i = 1:length(MACAddressesToSimulate)

  % Set MAC Address
  beaconFrameConfig.Address2 = MACAddressesToSimulate(i);

  % Generate Beacon frame bits
  [beacon, mpduLength] = wlanMACFrame(beaconFrameConfig, 'OutputFormat', 'bits');

  nonHTcfg = wlanNonHTConfig(...
    'ChannelBandwidth', chanBW,...
    "MCS", 1,...
    "PSDULength", mpduLength);
  txWaveform(:,i) = [wlanWaveformGenerator(beacon, nonHTcfg); zeros(20,1)];
end

txWaveform = txWaveform(:);

% Get center frequency for channel 153 in 5 GHz band
fc = helperWLANChannelFrequency(153, 5);
fs = wlanSampleRate(nonHTcfg);

txSig  = resample(txWaveform,osf,1);

% Samples per frame in Burst Mode
spf = length(txSig)/length(MACAddressesToSimulate);

  rxSDR.OutputDataType = 'double';
  rxSDR.EnableBurstMode=true;
  rxSDR.NumFramesInBurst = 20;
  rxSDR.SamplesPerFrame = osf*spf;
end
```

L-LTF for Classification

The L-LTF sequence present in each beacon frame preamble is used as input units to the NN. rfFingerprintingNonHTFrontEnd System object is used to detect the WLAN packets, perform synchronization tasks and, extract the L-LTF sequences and data. In addition, the MAC address is also decoded. In addition, the data is pre-processed and classified using the trained network.

```
if runSDRSection
  numLLTF = 20;       % Number of L-LTF captured for Testing

Further Exploration

Capture data from your own routers as explained in Appendix: Known and Unknown Router Data Collection, on page 13-0 train the neural network with this data, and test the performance of the network.

Appendix: Helper Functions

- rfFingerprintingRouterDataCollection
- rfFingerprintingUnknownClassDataCollectionTx
- rfFingerprintingUnknownClassDataCollectionRx
- rfFingerprintingNonHTFrontEnd
- rfFingerprintingNonHTReceiver

Appendix: Known and Unknown Router Data Collection

Use `rfFingerprintingRouterDataCollection` to collect data from known (i.e. trusted) routers. This function extracts L-LTF signals present in 802.11a/g/n/ac OFDM Non-HT beacons frames transmitted from commercial 802.11 hardware. For more information see the “IEEE® 802.11™ WLAN - OFDM Beacon Receiver with USRP® Hardware” (Communications Toolbox Support Package for USRP Radio) example. L-LTF signals and corresponding router MAC addresses are used to train the RF fingerprinting neural network. This method works best if the routers and their antennas are fixed and hard to move unintentionally. For example, in most office environments, routers are mounted on the ceiling. Follow these steps:

1. Connect an ADALM-PLUTO radio to your PC to use as the observer radio.
2. Place the radio in a central location where it can receive signals from as many routers as possible. Fix the radio so that it does not move. If possible, place the observer radio on the ceiling or high on a wall.
3. Determine the channel number of the routers. You can use a Wi-Fi analyzer app on your phone to find out the channel numbers.
4. Start data collection by running "`rfFingerprintingRouterDataCollection(channel)`" where channel is the Wi-Fi channel number
5. Monitor the "max(abs(LLTF))" value. If it is above 1.2 or smaller than 0.01, adjust the gain of the receiver using the GAIN input of `rfFingerprintingRouterDataCollection` function.

Use the helper functions `rfFingerprintingUnknownClassDataCollectionTx` and `rfFingerprintingUnknownClassDataCollectionRx` to collect data from unknown routers. These functions set two ADALM-PLUTO radios to transmit and receive L-LTF signals. The received signals are combined with the known router signals to train the neural network. You need two ADALM-PLUTO radios, preferably connected to two separate PCs. Follow these steps:

1. Connect an ADALM-PLUTO radio to a stationary PC to act as the unknown router
2. Start transmissions by running "`rfFingerprintingUnknownClassDataCollectionTx`"
3. Connect another ADALM-PLUTO radio to a mobile PC to act as the observer
4. Start data collection by running "`rfFingerprintingUnknownClassDataCollectionRx`". This function by default collects 200 frames per location. Each location represents a different unknown router.
5. When the function instructs you to move to a new location, move the observer radio to a new location. By default, this function collects data from 10 locations.
6. If the observer does not receive any beacons or it rarely receives beacons, move the observer closer to the transmitter.
7. Once the data collection is done, call "`release(sdrTransmitter)`" in the transmitting radio's MATLAB session.

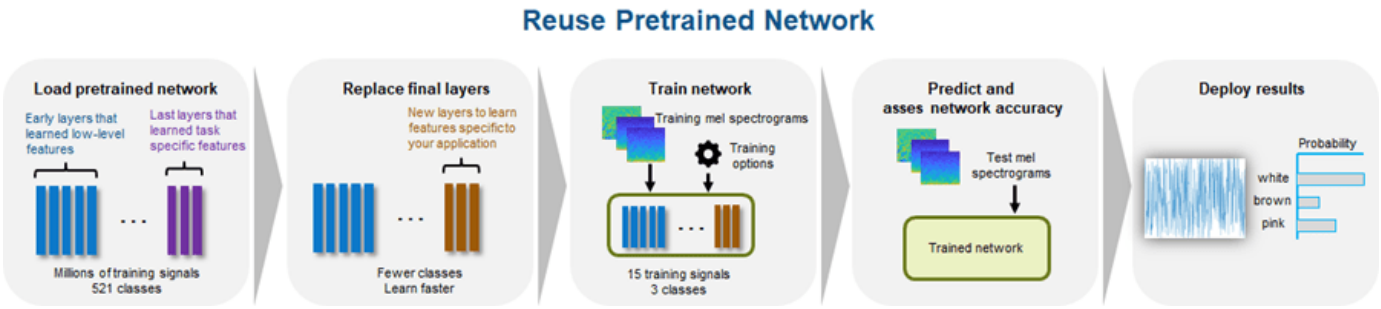
Audio Examples

Transfer Learning with Pretrained Audio Networks

This example shows how to use transfer learning to retrain YAMNet, a pretrained convolutional neural network, to classify a new set of audio signals. To get started with audio deep learning from scratch, see “Classify Sound Using Deep Learning” (Audio Toolbox).

Transfer learning is commonly used in deep learning applications. You can take a pretrained network and use it as a starting point to learn a new task. Fine-tuning a network with transfer learning is usually much faster and easier than training a network with randomly initialized weights from scratch. You can quickly transfer learned features to a new task using a smaller number of training signals.



Audio Toolbox™ additionally provides the `classifySound` (Audio Toolbox) function, which implements necessary preprocessing for YAMNet and convenient postprocessing to interpret the results. Audio Toolbox also provides the pretrained VGGish network (`vggish` (Audio Toolbox)) as well as the `vggishFeatures` (Audio Toolbox) function, which implements preprocessing and postprocessing for the VGGish network.

Create Data

Generate 100 white noise signals, 100 brown noise signals, and 100 pink noise signals. Each signal represents a duration of 0.98 seconds assuming a 16 kHz sample rate.

```
fs = 16e3;
duration = 0.98;
N = duration*fs;
numSignals = 100;

wNoise = 2*rand([N,numSignals]) - 1;
wLabels = repelem(categorical("white"),numSignals,1);

bNoise = filter(1,[1,-0.999],wNoise);
bNoise = bNoise./max(abs(bNoise),[],'all');
bLabels = repelem(categorical("brown"),numSignals,1);

pNoise = pinknoise([N,numSignals]);
pLabels = repelem(categorical("pink"),numSignals,1);
```

Split the data into training and test sets. Normally, the training set consists of most of the data. However, to illustrate the power of transfer learning, you will use only a few samples for training and the majority for validation.

```
K = 5 ;
```

```
trainAudio = [wNoise(:,1:K),bNoise(:,1:K),pNoise(:,1:K)];
trainLabels = [wLabels(1:K);bLabels(1:K);pLabels(1:K)];

validationAudio = [wNoise(:,K+1:end),bNoise(:,K+1:end),pNoise(:,K+1:end)];
validationLabels = [wLabels(K+1:end);bLabels(K+1:end);pLabels(K+1:end)];

fprintf("Number of samples per noise color in train set = %d\n" + ...
        "Number of samples per noise color in validation set = %d\n",K,numSignals-K);
```

```
Number of samples per noise color in train set = 5
Number of samples per noise color in validation set = 95
```

Extract Features

Use `melSpectrogram` (Audio Toolbox) to extract log-mel spectrograms from both the training set and the validation set using the same parameters as the YAMNet model was trained on.

```
FFTLength = 512;
numBands = 64;
frequencyRange = [125 7500];
windowLength = 0.025*fs;
overlapLength = 0.015*fs;

trainFeatures = melSpectrogram(trainAudio,fs, ...
    'Window',hann(windowLength,'periodic'), ...
    'OverlapLength',overlapLength, ...
    'FFTLength',FFTLength, ...
    'FrequencyRange',frequencyRange, ...
    'NumBands',numBands, ...
    'FilterBankNormalization','none', ...
    'WindowNormalization',false, ...
    'SpectrumType','magnitude', ...
    'FilterBankDesignDomain','warped');

trainFeatures = log(trainFeatures + single(0.001));
trainFeatures = permute(trainFeatures,[2,1,4,3]);

validationFeatures = melSpectrogram(validationAudio,fs, ...
    'Window',hann(windowLength,'periodic'), ...
    'OverlapLength',overlapLength, ...
    'FFTLength',FFTLength, ...
    'FrequencyRange',frequencyRange, ...
    'NumBands',numBands, ...
    'FilterBankNormalization','none', ...
    'WindowNormalization',false, ...
    'SpectrumType','magnitude', ...
    'FilterBankDesignDomain','warped');

validationFeatures = log(validationFeatures + single(0.001));
validationFeatures = permute(validationFeatures,[2,1,4,3]);
```

Transfer Learning

To load the pretrained network, call `yamnet` (Audio Toolbox). If the Audio Toolbox model for YAMNet is not installed, then the function provides a link to the location of the network weights. To download the model, click the link. Unzip the file to a location on the MATLAB path. The YAMNet model can classify audio into one of 521 sound categories, including white noise and pink noise (but not brown noise).

```
net = yamnet;
net.Layers(end).Classes

ans = 521×1 categorical
     Speech
     Child speech, kid speaking
     Conversation
     Narration, monologue
     Babbling
     Speech synthesizer
     Shout
     Bellow
     Whoop
     Yell
     Children shouting
     Screaming
     Whispering
     Laughter
     Baby laughter
     Giggle
     Snicker
     Belly laugh
     Chuckle, chortle
     Crying, sobbing
     Baby cry, infant cry
     Whimper
     Wail, moan
     Sigh
     Singing
     Choir
     Yodeling
     Chant
     Mantra
     Child singing
      ⋮
```

Prepare the model for transfer learning by first converting the network to a `layerGraph`. Use `replaceLayer` to replace the fully-connected layer with an untrained fully-connected layer. Replace the classification layer with a classification layer that classifies the input as "white", "pink", or "brown". See “List of Deep Learning Layers” on page 1-21 for deep learning layers supported in MATLAB®.

```
uniqueLabels = unique(trainLabels);
numLabels = numel(uniqueLabels);

lgraph = layerGraph(net.Layers);

lgraph = replaceLayer(lgraph,"dense",fullyConnectedLayer(numLabels,"Name","dense"));
lgraph = replaceLayer(lgraph,"Sound",classificationLayer("Name","Sounds","Classes",uniqueLabels))
```

To define training options, use `trainingOptions`.

```
options = trainingOptions('adam','ValidationData',{single(validationFeatures),validationLabels})
```

To train the network, use `trainNetwork`. The network achieves a validation accuracy of 100% using only 5 signals per noise type.

```
trainNetwork(single(trainFeatures),trainLabels,lgraph,options);
```

```
Training on single CPU.

Speech Command Recognition in Simulink

This example shows a Simulink model that detects the presence of speech commands in audio. The model uses a pretrained convolutional neural network to recognize a given set of commands.

Speech Command Recognition Model

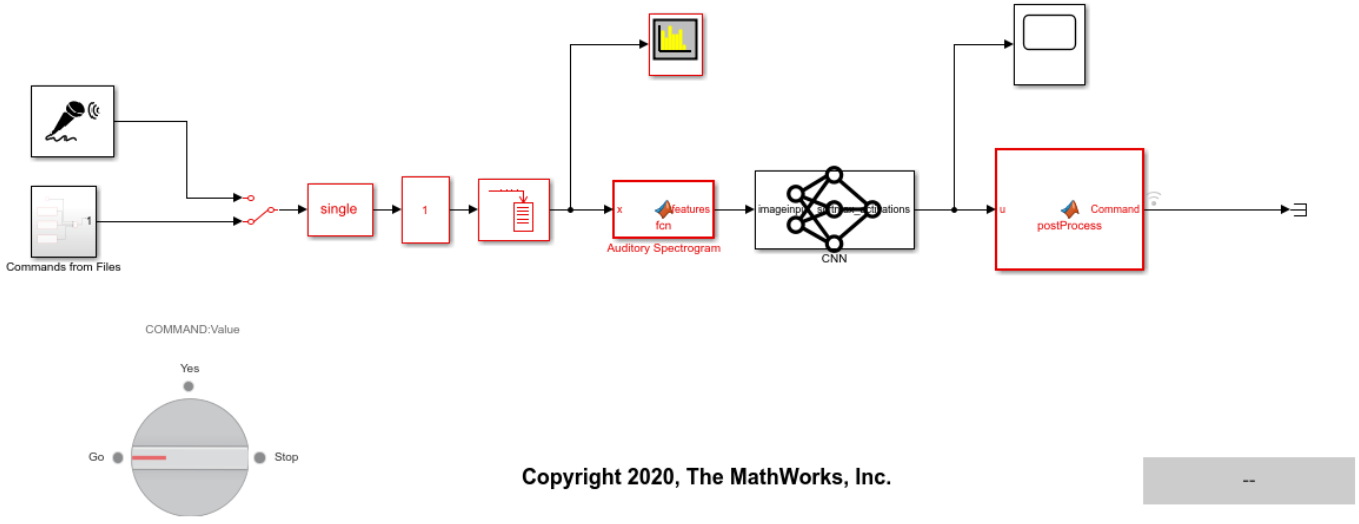
The model recognizes the following speech commands:

- "yes"
- "no"
- "up"
- "down"
- "left"
- "right"
- "on"
- "off"
- "stop"
- "go"

The model uses a pretrained convolutional deep learning network. Refer to the example “Speech Command Recognition Using Deep Learning” (Audio Toolbox) for details on the architecture of this network and how you train it.

Open the model.

```
model = 'speechCommandRecognition';
open_system(model)
```



The model breaks the audio stream into one-second overlapping segments. A mel spectrogram is computed from each segment. The spectrograms are fed to the pretrained network.

Use the manual switch to select either a live stream from your microphone or read commands stored in audio files. For commands on file, use the rotary switch to select one of three commands (Go, Yes and Stop).

Auditory Spectrogram Extraction

The deep learning network is trained on auditory spectrograms computed using an audioFeatureExtractor. For the model to classify commands properly, you must extract auditory spectrograms in a manner identical to the trainind stage.

Define the parameters of the feature extraction. `frameDuration` is the duration of each frame for spectrum calculation. `hopDuration` is the time step between each spectrum. `numBands` is the number of filters in the auditory spectrogram.

```
fs = 16000;
frameDuration = 0.025;
frameSamples = round(frameDuration*fs);
hopDuration = 0.010;
hopSamples = round(hopDuration*fs);
numBands = 50;
```

Define an audioFeatureExtractor object to perform the feature extraction. The object is identical to the one used in “Speech Command Recognition Using Deep Learning” (Audio Toolbox) to extract the training spectrograms.

```
afe = audioFeatureExtractor( ...
    'SampleRate',fs, ...
    'FFTLength',512, ...
    'Window',hann(frameSamples,'periodic'), ...
    'OverlapLength',frameSamples - hopSamples, ...
    'barkSpectrum',true);

setExtractorParams(afe,'barkSpectrum','NumBands',numBands,'WindowNormalization',false);
```

Call generateMATLABFunction to create a feature extraction function. This function is called from the `Auditory Spectrogram` MATLAB Function block in the model. This ensures that the feature extraction used in the model matches the one used in training.

```
generateMATLABFunction(afe,'extractSpeechFeatures')
```

Run the model

Simulate the model for 20 seconds. To run the model indefinitely, set the stop time to Inf.

```
set_param(model,'StopTime','20');
sim(model);
```

Speaker Identification Using Custom SincNet Layer and Deep Learning

In this example, you train three convolutional neural networks (CNNs) to perform speaker verification and then compare the performances of the architectures. The architectures of the three CNNs are all equivalent except for the first convolutional layer in each:

1. In the first architecture, the first convolutional layer is a "standard" convolutional layer, implemented using `convolution2dLayer`.
2. In the second architecture, the first convolutional layer is a constant sinc filterbank, implemented using a custom layer.
3. In the third architecture, the first convolutional layer is a trainable sinc filterbank, implemented using a custom layer. This architecture is referred to as *SincNet* [1] on page 14-0 .

[1] on page 14-0 shows that replacing the standard convolutional layer with a filterbank layer leads to faster training convergence and higher accuracy. [1] on page 14-0 also shows that making the parameters of the filter bank learnable yields additional performance gains.

Introduction

Speaker identification is a prominent research area with a variety of applications including forensics and biometric authentication. Many speaker identification systems depend on precomputed features such as i-vectors or MFCCs, which are then fed into machine learning or deep learning networks for classification. Other deep learning speech systems bypass the feature extraction stage and feed the audio signal directly to the network. In such end-to-end systems, the network directly learns low-level audio signal characteristics.

In this example, you first train a traditional end-to-end speaker identification CNN. The filters learned tend to have random shapes that do not correspond to perceptual evidence or knowledge of how the human ear works, especially in scenarios where the amount of training data is limited [1] on page 14-0 . You then replace the first convolutional layer in the network with a custom sinc filterbank layer that introduces structure and constraints based on perceptual evidence. Finally, you train the SincNet architecture, which adds learnability to the sinc filterbank parameters.

The three neural network architectures explored in the example are summarized as follows:

1. **Standard Convolutional Neural Network** - The input waveform is directly connected to a randomly initialized convolutional layer which attempts to learn features and capture characteristics from the raw audio frames.
2. **ConstantSincLayer** - The input waveform is convolved with a set of fixed-width sinc functions (bandpass filters) equally spaced on the mel scale.
3. **SincNetLayer** - The input waveform is convolved with a set of sinc functions whose parameters are learned by the network. In the SincNet architecture, the network tunes parameters of the sinc functions while training.

This example defines and trains the three neural networks proposed above and evaluates their performance on the LibriSpeech Dataset [2] on page 14-0 .

Data Set

Download Dataset

In this example, you use a subset of the LibriSpeech Dataset [2] on page 14-0 . The LibriSpeech Dataset is a large corpus of read English speech sampled at 16 kHz. The data is derived from audiobooks read from the LibriVox project.

```
downloadDatasetFolder = tempdir;

filename = "train-clean-100.tar.gz";
url = "http://www.openSLR.org/resources/12/" + filename;

datasetFolder = fullfile(downloadDatasetFolder,"LibriSpeech","train-clean-100");

if ~isfolder(datasetFolder)
    gunzip(url,downloadDatasetFolder);
    unzippedFile = fullfile(downloadDatasetFolder,filename);
    untar(unzippedFile{1}(1:end-3),downloadDatasetFolder);
end
```

Create an `audioDatastore` object to access the LibriSpeech audio data.

```
ADS = audioDatastore(datasetFolder,'IncludeSubfolders',1);
```

Extract the speaker label from the file path.

```
ADS.Labels = extractBetween(ADS.Files,fullfile(datasetFolder,filesep),filesep);
```

The full `dev-train-100` dataset is around 6 GB of data. To train the network with data from all 251 speakers, set `reduceDataset` to `false`. To run this example quickly with data from just six speakers, set `reduceDataset` to `true`.

```
reducedDataSet = false;
if reducedDataSet
    indices = cellfun(@(c)str2double(c)<50,ADS.Labels);  %#ok
    ADS = subset(ADS,indices);
end
ADS = splitEachLabel(ADS,0.1);
```

Split the audio files into training and test data. 80% of the audio files are assigned to the training set and 20% are assigned to the test set.

```
[ADSTrain,ADSTest] = splitEachLabel(ADS,0.8);
```

Sample Speech Signal

Plot one of the audio files and listen to it.

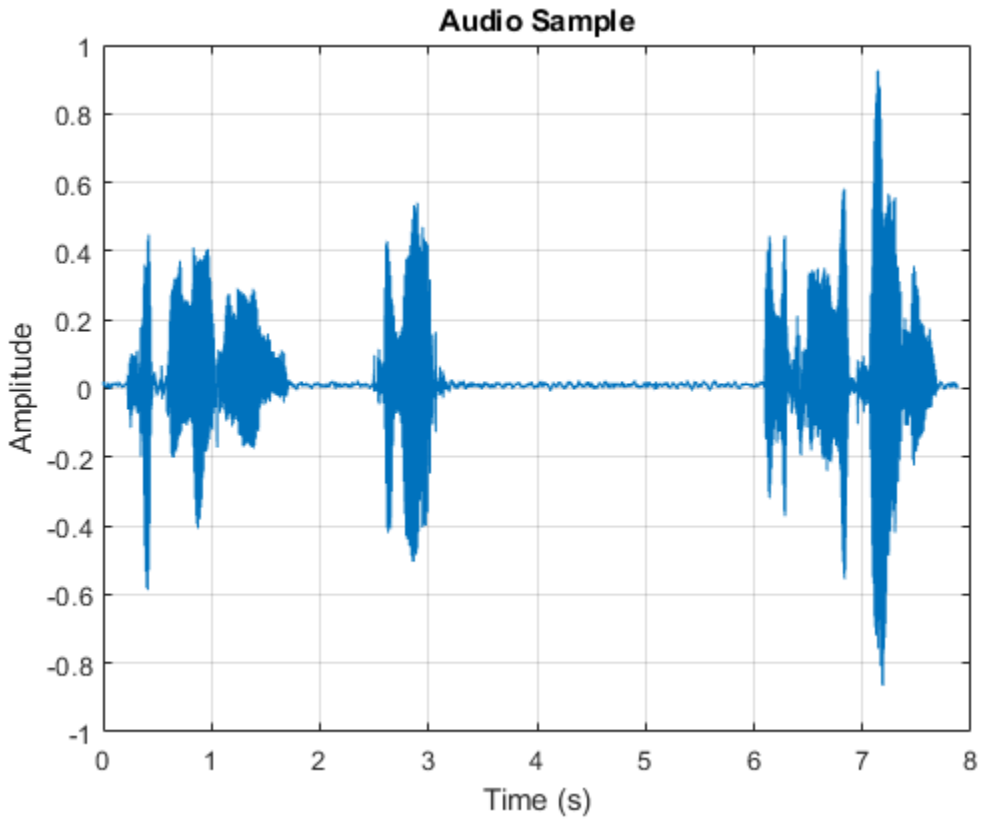
```
[audioIn,dsInfo] = read(ADSTrain);
Fs = dsInfo.SampleRate;

sound(audioIn,Fs)

t = (1/Fs)*(0:length(audioIn)-1);

plot(t,audioIn)
```

```
title("Audio Sample")
xlabel("Time (s)")
ylabel("Amplitude")
grid on
```



Reset the training datastore.

```
reset(ADSTrain)
```

Data Preprocessing

CNNs expect inputs to have consistent dimensions. You will preprocess the audio by removing regions of silence and then break the remaining speech into 200 ms frames with 40 ms overlap.

Set the parameters for preprocessing.

```
frameDuration = 200e-3;
overlapDuration = 40e-3;
frameLength = floor(Fs*frameDuration);
overlapLength = round(Fs*overlapDuration);
```

Use the supporting function, preprocessAudioData on page 14-0 , to preprocess the training and test data. `XTrain` and `XTest` contain the train and test speech frames, respectively. `YTrain` and `YTest` contain the train and test labels, respectively.

```
[XTrain,YTrain] = preprocessAudioData(ADSTrain,frameLength,overlapLength,Fs);
```

```
Starting parallel pool (parpool) using the 'local' profile ...
Connected to the parallel pool (number of workers: 6).
```

```
[XTest,YTest] = preprocessAudioData(ADSTest,frameLength,overlapLength,Fs);
```

Standard CNN

Define Layers

The standard CNN is inspired by the neural network architecture in [1] on page 14-0 .

```
numFilters = 80;
filterLength = 251;
numSpeakers = numel(unique(ADS.Labels));

layers = [
    imageInputLayer([1 frameLength 1])

    % First convolutional layer

    convolution2dLayer([1 filterLength],numFilters)
    batchNormalizationLayer
    leakyReluLayer(0.2)
    maxPooling2dLayer([1 3])

    % This layer is followed by 2 convolutional layers

    convolution2dLayer([1 5],60)
    batchNormalizationLayer
    leakyReluLayer(0.2)
    maxPooling2dLayer([1 3])

    convolution2dLayer([1 5],60)
    batchNormalizationLayer
    leakyReluLayer(0.2)
    maxPooling2dLayer([1 3])

    % This is followed by 3 fully-connected layers

    fullyConnectedLayer(256)
    batchNormalizationLayer
    leakyReluLayer(0.2)

    fullyConnectedLayer(256)
    batchNormalizationLayer
    leakyReluLayer(0.2)

    fullyConnectedLayer(256)
    batchNormalizationLayer
    leakyReluLayer(0.2)

    fullyConnectedLayer(numSpeakers)
    softmaxLayer
    classificationLayer];
```

Analyze the layers of the neural network using the `analyzeNetwork` function

```
analyzeNetwork(layers)
```

Train Network

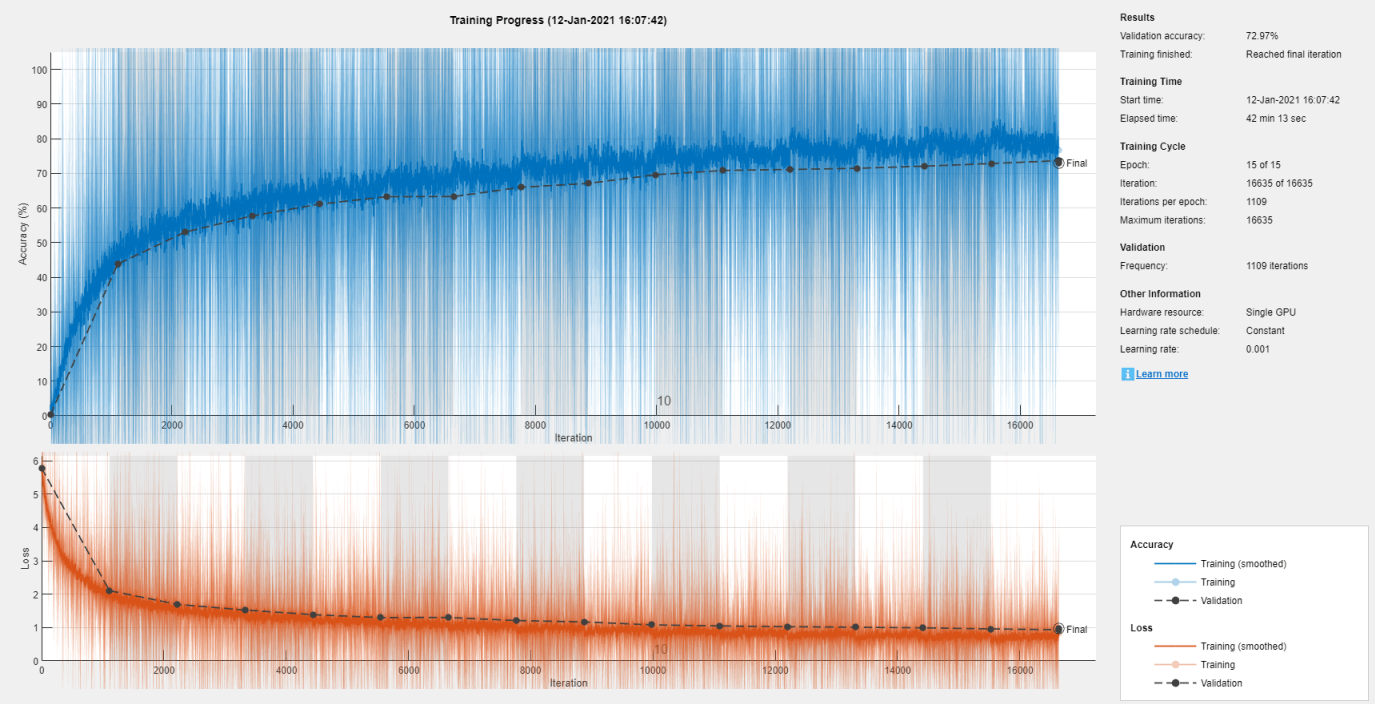
Train the neural network for 15 epochs using `adam` optimization. Shuffle the training data before every epoch. The training options for the neural network are set using `trainingOptions`. Use the test data as the validation data to observe how the network performance improves as training progresses.

```
numEpochs = 15;
miniBatchSize = 128;
validationFrequency = floor(numel(YTrain)/miniBatchSize);

options = trainingOptions("adam", ...
    "Shuffle","every-epoch", ...
    "MiniBatchSize",miniBatchSize, ...
    "Plots","training-progress", ...
    "Verbose",false,"MaxEpochs",numEpochs, ...
    "ValidationData",{XTest,categorical(YTest)}, ...
    "ValidationFrequency",validationFrequency);
```

To train the network, call `trainNetwork`.

```
[convNet,convNetInfo] = trainNetwork(XTrain,YTrain,layers,options);
```



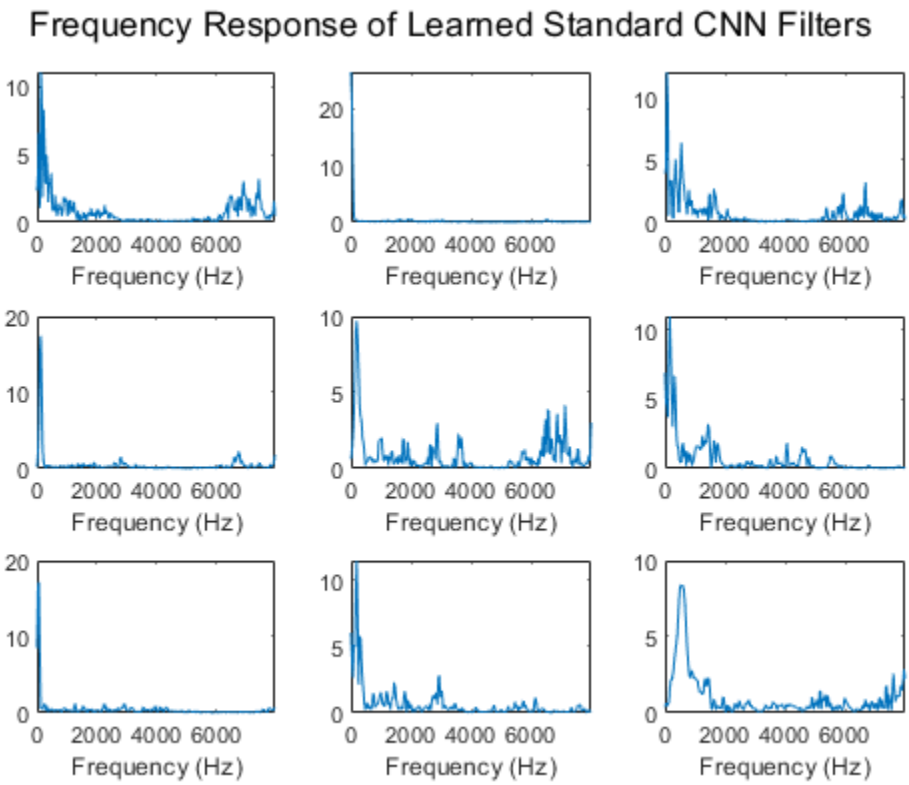
Inspect Frequency Response of First Convolutional Layer

Plot the magnitude frequency response of nine filters learned from the standard CNN network. The shape of these filters is not intuitive and does not correspond to perceptual knowledge. The next section explores the effect of using constrained filter shapes.

```
F = squeeze(convNet.Layers(2,1).Weights);
H = zeros(size(F));
Freq = zeros(size(F));
```

```
for ii = 1:size(F,2)
   [h,f] = freqz(F(:,ii),1,251,Fs);
    H(:,ii) = abs(h);
    Freq(:,ii) = f;
end
idx = linspace(1,size(F,2),9);
idx = round(idx);

figure
for jj = 1:9
   subplot(3,3,jj)
   plot(Freq(:,idx(jj)),H(:,idx(jj)))
   sgtitle("Frequency Response of Learned Standard CNN Filters")
   xlabel("Frequency (Hz)")
end
```



Constant Sinc Filterbank

In this section, you replace the first convolutional layer in the standard CNN with a constant sinc filterbank layer. The constant sinc filterbank layer convolves the input frames with a bank of fixed bandpass filters. The bandpass filters are a linear combination of two sinc filters in the time domain. The frequencies of the bandpass filters are spaced linearly on the mel scale.

Define Layers

The implementation for the constant sinc filterbank layer can be found in the `constantSincLayer.m` file (attached to this example). Define parameters for a `ConstantSincLayer`. Use 80 filters and a filter length of 251.

```
numFilters = 80;
filterLength = 251;
numChannels = 1;
name = 'constant_sinc';
```

Change the first convolutional layer from the standard CNN to the `ConstantSincLayer` and keep the other layers unchanged.

```
cSL = constantSincLayer(numFilters,filterLength,Fs,numChannels,name)
```

```
cSL =
  constantSincLayer with properties:

                Name: 'constant_sinc'
          NumFilters: 80
          SampleRate: 16000
        FilterLength: 251
         NumChannels: []
             Filters: [1×251×1×80 single]
    MinimumFrequency: 50
    MinimumBandwidth: 50
    StartFrequencies: [1×80 double]
          Bandwidths: [1×80 double]

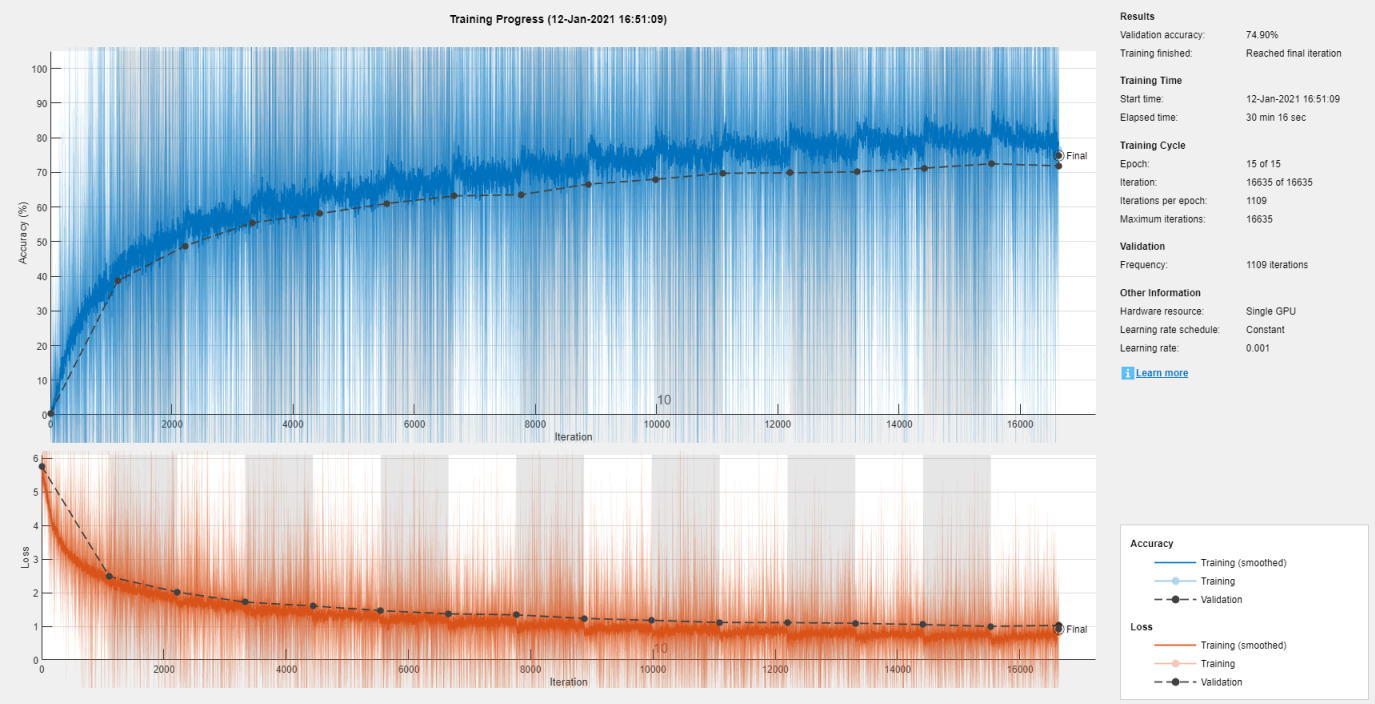
  Show all properties
```

```
layers(2) = cSL;
```

Train Network

Train the network using the `trainNetwork` function. Use the same training options defined previously.

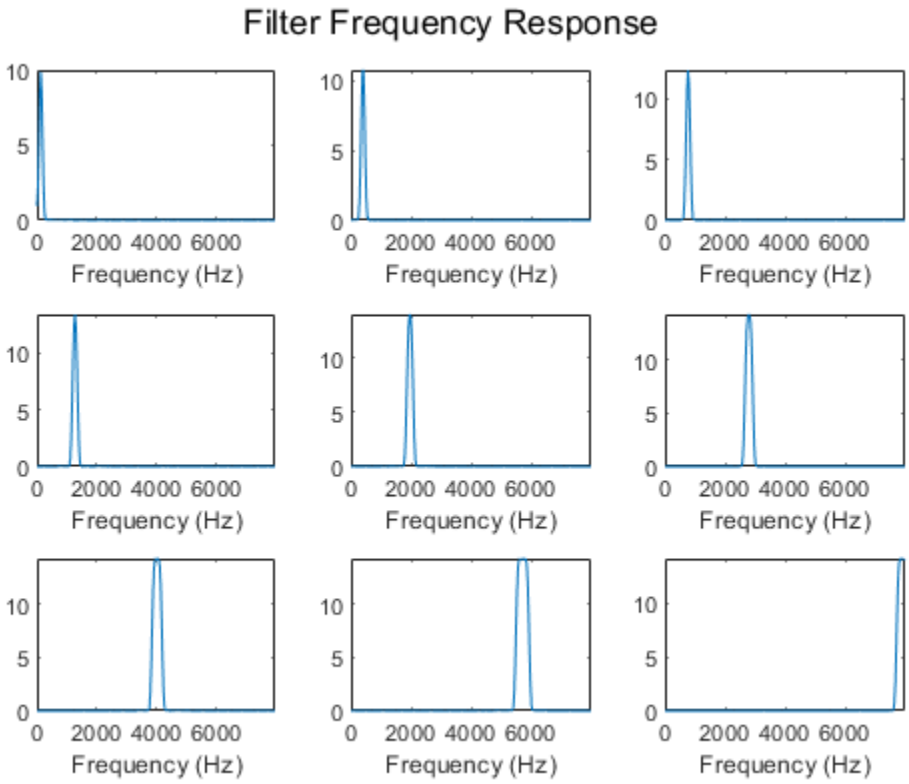
```
[constSincNet,constSincInfo] = trainNetwork(XTrain,YTrain,layers,options);
```



Inspect Frequency Response of First Convolutional Layer

The `plotNFilters` method plots the magnitude frequency response of `n` filters with equally spaced filter indices. Plot the magnitude frequency response of nine filters in the `ConstantSincLayer`.

```
figure
n = 9;
plotNFilters(constSincNet.Layers(2),n)
```



SincNet

In this section, you use a trainable SincNet layer as the first convolutional layer in your network. The SincNet layer convolves the input frames with a bank of bandpass filters. The bandwidth and the initial frequencies of the SincNet filters are initialized as equally spaced in the mel scale. The SincNet layer attempts to learn better parameters for these bandpass filters within the neural network framework.

Define Layers

The implementation for the SincNet layer filterbank layer can be found in the `sincNetLayer.m` file (attached to this example). Define parameters for a `SincNetLayer`. Use 80 filters and a filter length of 251.

```
numFilters = 80;
filterLength = 251;
numChannels = 1;
name = 'sinc';
```

Replace the `ConstantSincLayer` from the previous network with the `SincNetLayer`. This new layer has two learnable parameters: `FilterFrequencies` and `FilterBandwidths`.

```
sNL = sincNetLayer(numFilters,filterLength,Fs,numChannels,name)
```

```
sNL =
  sincNetLayer with properties:
```

```
                Name: 'sinc'
          NumFilters: 80
          SampleRate: 16000
        FilterLength: 251
         NumChannels: []
              Window: [1×251 double]
          TimeStamps: [1×251 double]
    MinimumFrequency: 50
    MinimumBandwidth: 50

  Learnable Parameters
    FilterFrequencies: [1×80 double]
    FilterBandwidths: [1×80 double]

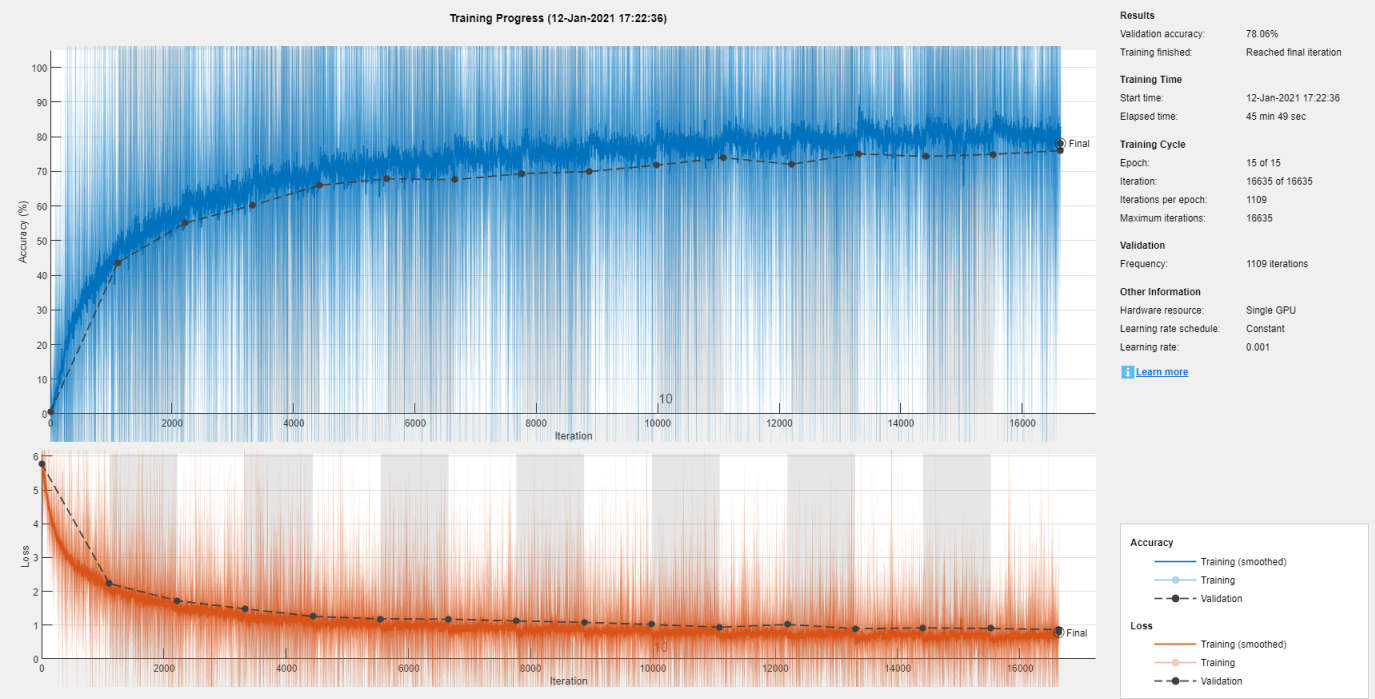
  Show all properties
```

```
layers(2) = sNL;
```

Train Network

Train the network using the `trainNetwork` function. Use the same training options defined previously.

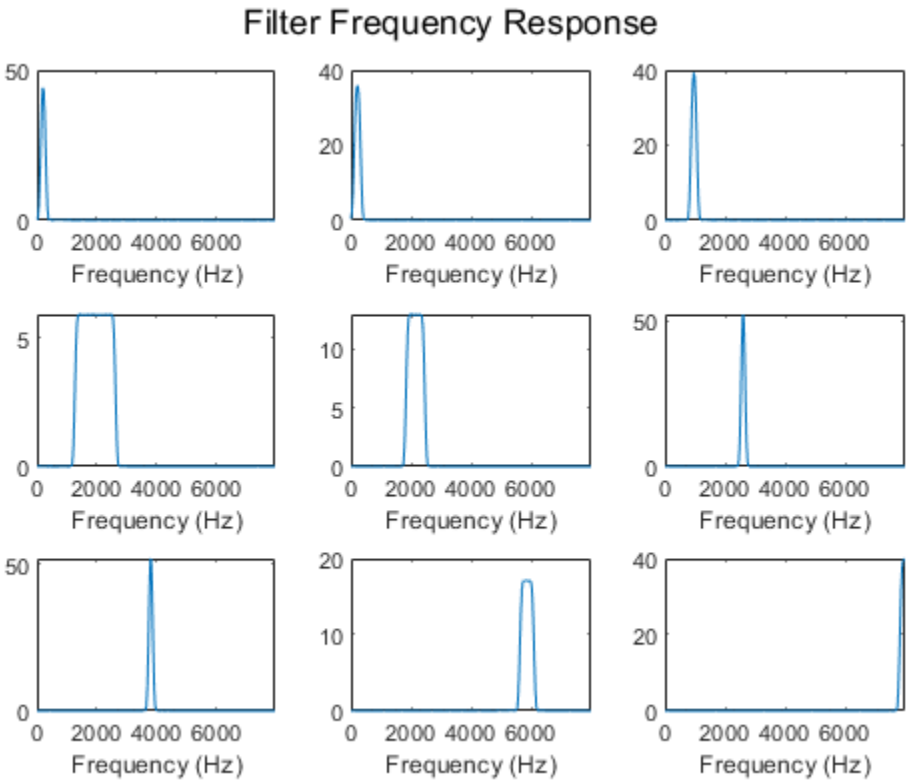
```
[sincNet,sincNetInfo] = trainNetwork(XTrain,YTrain,layers,options);
```



Inspect Frequency Response of First Convolutional Layer

Use the `plotNFilters` method of `SincNetLayer` to visualize the magnitude frequency response of nine filters with equally spaced indices learned by SincNet.

```
figure
plotNFilters(sincNet.Layers(2),9)
```



Results Summary

Accuracy

The table summarizes the frame accuracy for all three neural networks.

```
NetworkType = {'Standard CNN','Constant Sinc Layer','SincNet Layer'}';
Accuracy = [convNetInfo.FinalValidationAccuracy;constSincInfo.FinalValidationAccuracy;sincNetInfo
```

```
resultsSummary = table(NetworkType,Accuracy)
```

```
resultsSummary=3×2 table
          NetworkType          Accuracy
    ___________________________    ________

    {'Standard CNN'       }      72.97
    {'Constant Sinc Layer'}     74.902
    {'SincNet Layer'      }     78.062
```

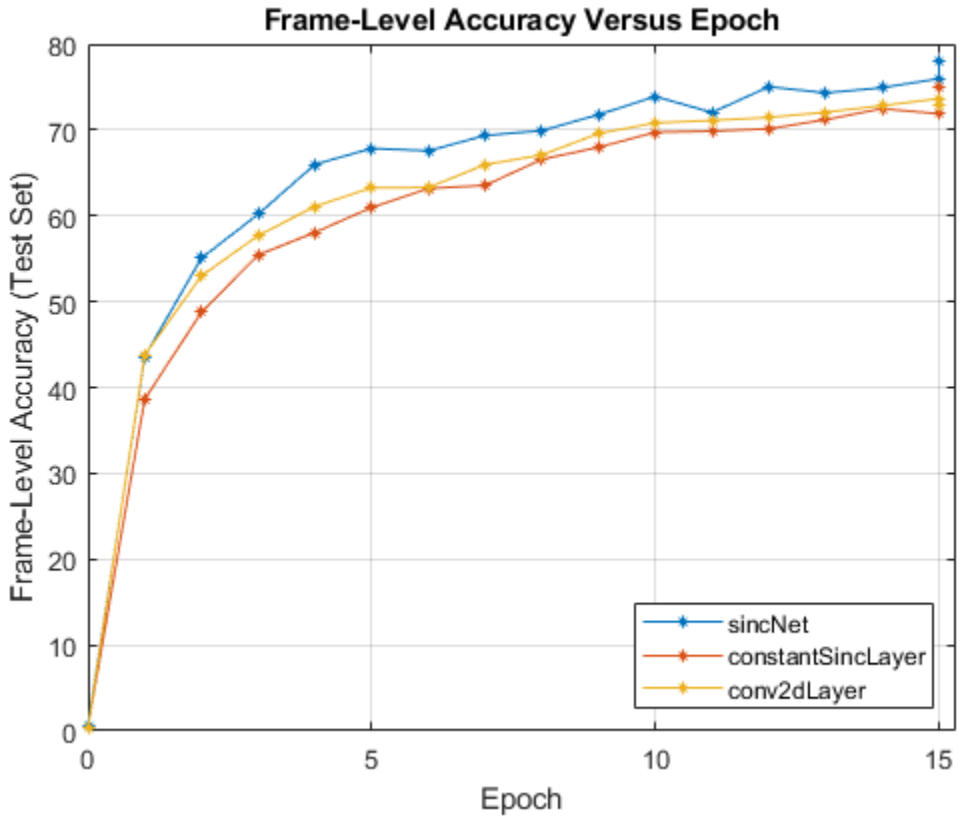
Performance with Respect to Epochs

Plot the accuracy on the test set against the epoch number to see how well the networks learn as the number of epochs increase. SincNet outperforms the `ConstantSincLayer` network, especially during the early stages of training. This shows that updating the parameters of the bandpass filters within the neural network framework leads to faster convergence. This behavior is only observed when the dataset is large enough, so it might not be seen when `reduceDataSet` is set to `true`.

```
epoch = linspace(0,numEpochs,numel(sincNetInfo.ValidationAccuracy(~isnan(sincNetInfo.ValidationA
epoch = [epoch,numEpochs];

sinc_valAcc = [sincNetInfo.ValidationAccuracy(~isnan(sincNetInfo.ValidationAccuracy)),...
    sincNetInfo.FinalValidationAccuracy];
const_sinc_valAcc = [constSincInfo.ValidationAccuracy(~isnan(constSincInfo.ValidationAccuracy)),
    constSincInfo.FinalValidationAccuracy];
conv_valAcc = [convNetInfo.ValidationAccuracy(~isnan(convNetInfo.ValidationAccuracy)),...
    convNetInfo.FinalValidationAccuracy];

figure
plot(epoch,sinc_valAcc,'-*','MarkerSize',4)
hold on
plot(epoch,const_sinc_valAcc,'-*','MarkerSize',4)
plot(epoch,conv_valAcc,'-*','MarkerSize',4)
ylabel('Frame-Level Accuracy (Test Set)')
xlabel('Epoch')
xlim([0 numEpochs+0.3])
title('Frame-Level Accuracy Versus Epoch')
legend("sincNet","constantSincLayer","conv2dLayer","Location","southeast")
grid on
```



In the figure above, the final frame accuracy is a bit different from the frame accuracy that is computed in the last iteration. While training, the batch normalization layers perform normalization over mini-batches. However, at the end of training, the batch normalization layers normalize over the entire training data, which results in a slight change in performance.

Supporting Functions

```
function [X,Y] = preprocessAudioData(ADS,SL,OL,Fs)

    if ~isempty(ver('parallel'))
        pool = gcp;
        numPar = numpartitions(ADS,pool);
    else
        numPar = 1;
    end

    parfor ii = 1:numPar

        X = zeros(1,SL,1,0);
        Y = zeros(0);
        subADS = partition(ADS,numPar,ii);

        while hasdata(subADS)
            [audioIn,dsInfo] = read(subADS);

            speechIdx = detectSpeech(audioIn,Fs);
            numChunks = size(speechIdx,1);
            audioData = zeros(1,SL,1,0);

            for chunk = 1:numChunks
                % Remove trail end audio
                audio_chunk = audioIn(speechIdx(chunk,1):speechIdx(chunk,2));
                audio_chunk = buffer(audio_chunk,SL,OL);
                q = size(audio_chunk,2);

                % Split audio into 200 ms chunks
                audio_chunk = reshape(audio_chunk,1,SL,1,q);

                % Concatenate with existing audio
                audioData = cat(4,audioData,audio_chunk);
            end

            audioLabel = str2double(dsInfo.Label{1});

            % Generate labels for training and testing by replecating matrix
            audioLabelsTrain = repmat(audioLabel,1,size(audioData,4));

            % Add data points for current speaker to existing data
            X = cat(4,X,audioData);
            Y = cat(2,Y,audioLabelsTrain);
        end

        XC{ii} = X;
        YC{ii} = Y;
    end

    X = cat(4,XC{:});
    Y = cat(2,YC{:});

    Y = categorical(Y);

end
```

Dereverberate Speech Using Deep Learning Networks

This example shows how to train a U-Net fully convolutional network (FCN) [1] on page 14-0 to dereverberate a speech signals.

Introduction

Reverberation occurs when a speech signal is reflected off objects in space, causing multiple reflections to build up and eventually leads to degradation of speech quality. Dereverberation is the process of reducing the reverberation effects in a speech signal.

Dereverberate Speech Signal Using Pretrained Network

Before going into the training process in detail, use a pretrained network to dereverberate a speech signal.

Download the pretrained network. This network was trained on 56-speaker versions of the training datasets. The example walks through training on the 28-speaker version.

```
url = 'https://ssd.mathworks.com/supportfiles/audio/dereverbnet.zip';
downloadFolder = tempdir;
networkDataFolder = fullfile(downloadFolder,'derevernet');

if ~exist(networkDataFolder,'dir')
    disp('Downloading pretrained network ...')
    unzip(url,downloadFolder)
end
load(fullfile(networkDataFolder,'dereverbNet.mat'))
```

Listen to a clean speech signal sampled at 16 kHz.

```
[cleanAudio,fs] = audioread('clean_speech_signal.wav');

sound(cleanAudio,fs)
```

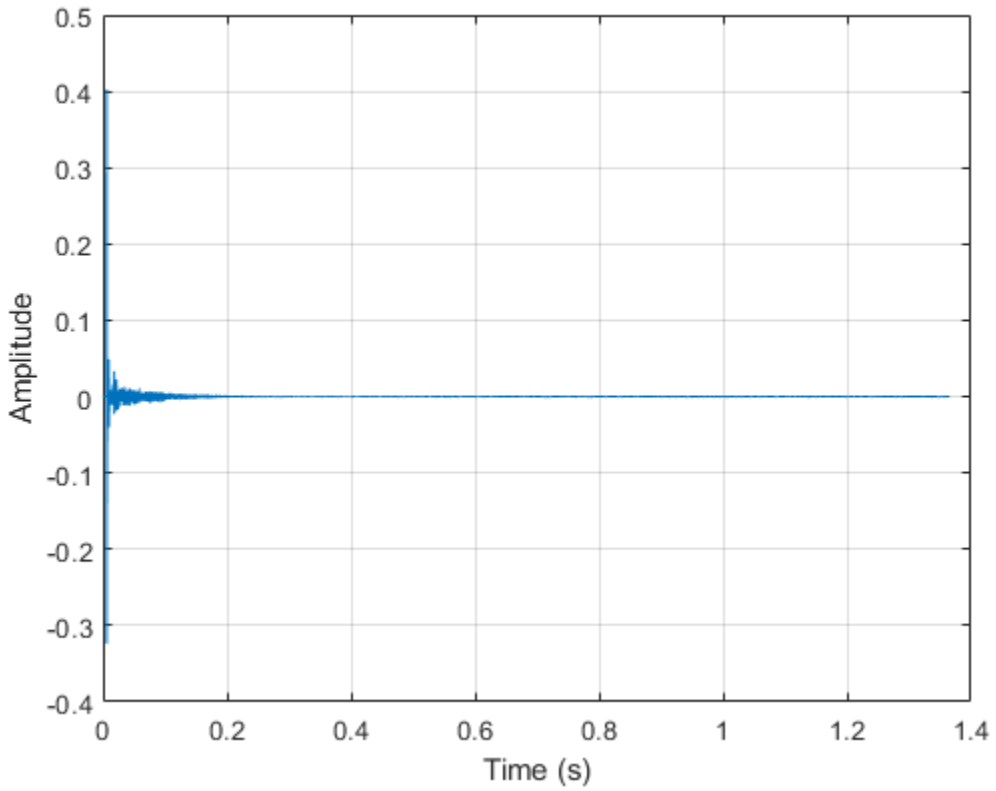
An acoustic path can be modelled using a room impulse response. You can model reverberation by convolving an anechoic signal with a room impulse response.

Load and plot a room impulse response.

```
[rirAudio,fsR] = audioread('room_impulse_response.wav');

tAxis = (1/fsR)*(0:numel(rirAudio)-1);

figure
plot(tAxis,rirAudio)
xlabel('Time (s)')
ylabel('Amplitude')
grid on
```



Convolve the clean speech with the room impulse response to obtain reverberated speech. Align the lengths and amplitudes of the reverberated and clean speech signals.

```
revAudio = conv(cleanAudio,rirAudio);

revAudio = revAudio(1:numel(cleanAudio));
revAudio = revAudio.*(max(abs(cleanAudio))/max(abs(revAudio)));
```

Listen to the reverberated speech signal.

```
sound(revAudio,fs)
```

The input to the pretrained network is the log-magnitude short-time Fourier transform (STFT) of the reverberant audio. The network predicts the log-magnitude STFT of the dereverberated input. To estimate the original time-domain audio signal, you perform an inverse STFT and assume the phase of the reverberant audio.

Use the following parameters to compute the STFT.

```
params.WindowdowLength = 512;
params.Window = hamming(params.WindowdowLength,"periodic");
params.OverlapLength = round(0.75*params.WindowdowLength);
params.FFTLength = params.WindowdowLength;
```

Use `stft` to compute the one-sided log-magnitude STFT. Use single precision when computing features to better utilize memory usage and to speed up the training. Even though the one-sided STFT yields 257 frequency bins, consider only 256 bins and ignore the highest frequency bin.

```
revAudio = single(revAudio);
audioSTFT = stft(revAudio,'Window',params.Window,'OverlapLength',params.OverlapLength, ...
                 'FFTLength',params.FFTLength,'FrequencyRange','onesided');
Eps = realmin('single');
reverbFeats = log(abs(audioSTFT(1:end-1,:)) + Eps);
```

Extract the phase of the STFT.

```
phaseOriginal = angle(audioSTFT(1:end-1,:));
```

Each input will have dimensions 256-by-256 (frequency bins by time steps). Split the log-magnitude STFT into segments of 256 time-steps.

```
params.NumSegments = 256;
params.NumFeatures = 256;
totalFrames = size(reverbFeats,2);
chunks = ceil(totalFrames/params.NumSegments);
reverbSTFTSegments = mat2cell(reverbFeats,params.NumFeatures, ...
    [params.NumSegments*ones(1,chunks - 1),(totalFrames - (chunks-1)*params.NumSegments)]);
reverbSTFTSegments{chunks} = reverbFeats(:,end-params.NumSegments + 1:end);
```

Scale the segmented features to the range [-1,1]. Retain the minimum and maximum values used to scale for reconstructing the dereverberated signal.

```
minVals = num2cell(cellfun(@(x)min(x,[],'all'),reverbSTFTSegments));
maxVals = num2cell(cellfun(@(x)max(x,[],'all'),reverbSTFTSegments));

featNorm = cellfun(@(feat,minFeat,maxFeat)2.*(feat - minFeat)./(maxFeat - minFeat) - 1, ...
    reverbSTFTSegments,minVals,maxVals,'UniformOutput',false);
```

Reshape the features so that chunks are along the fourth dimension.

```
featNorm = reshape(cell2mat(featNorm),params.NumFeatures,params.NumSegments,1,chunks);
```

Predict the log-magnitude spectra of the reverberated speech signal using the pretrained network.

```
predictedSTFT4D = predict(dereverbNet,featNorm);
```

Reshape to 3-dimensions and scale the predicted STFTs to the original range using the saved minimum-maximum pairs.

```
predictedSTFT = squeeze(mat2cell(predictedSTFT4D,params.NumFeatures,params.NumSegments,1,ones(1,c
featDeNorm = cellfun(@(feat,minFeat,maxFeat) (feat + 1).*(maxFeat-minFeat)./2 + minFeat, ...
    predictedSTFT,minVals,maxVals,'UniformOutput',false);
```

Reverse the log-scaling.

```
predictedSTFT = cellfun(@exp,featDeNorm,'UniformOutput',false);
```

Concatenate the predicted 256-by-256 magnitude STFT segments to obtain the magnitude spectrogram of original length.

```
predictedSTFTAll = predictedSTFT(1:chunks - 1);
predictedSTFTAll = cat(2,predictedSTFTAll{:});
predictedSTFTAll(:,totalFrames - params.NumSegments + 1:totalFrames) = predictedSTFT{chunks};
```

Before taking the inverse STFT, append zeros to the predicted log-magnitude spectrum and the phase in lieu of the highest frequency bin which was excluded when preparing input features.

```
nCount = size(predictedSTFTAll,3);
predictedSTFTAll = cat(1,predictedSTFTAll,zeros(1,totalFrames,nCount));
phase = cat(1,phaseOriginal,zeros(1,totalFrames,nCount));
```

Use the inverse STFT function to reconstruct the dereverberated time-domain speech signal using the predicted log-magnitude STFT and the phase of reverberant speech signal.

```
oneSidedSTFT = predictedSTFTAll.*exp(1j*phase);
dereverbedAudio = istft(oneSidedSTFT, ...
    'Window',params.Window,'OverlapLength',params.OverlapLength, ...
    'FFTLength',params.FFTLength,'ConjugateSymmetric',true, ...
    'FrequencyRange','onesided');

dereverbedAudio = dereverbedAudio./max(abs([dereverbedAudio;revAudio]));
dereverbedAudio = [dereverbedAudio;zeros(length(revAudio) - numel(dereverbedAudio), 1)];
```

Listen to the dereverberated audio signal.

```
sound(dereverbedAudio,fs)
```

Plot the clean, reverberant, and dereverberated speech signals.

```
t = (1/fs)*(0:numel(cleanAudio)-1);

figure

subplot(3,1,1)
plot(t,cleanAudio)
xlabel('Time (s)')
grid on
subtitle('Clean Speech Signal')

Download the Dataset

This example uses the Reverberant Speech Database [2] on page 14-0 and the corresponding Clean Speech Database [3] on page 14-0 to train the network.

Download the clean speech data set.

```
url1 = 'https://datashare.is.ed.ac.uk/bitstream/handle/10283/2791/clean_trainset_28spk_wav.zip';
url2 = 'https://datashare.is.ed.ac.uk/bitstream/handle/10283/2791/clean_testset_wav.zip';
```

```
downloadFolder = tempdir;
cleanDataFolder = fullfile(downloadFolder,'DS_10283_2791');

if ~exist(cleanDataFolder,'dir')
    disp('Downloading data set (6 GB) ...')
    unzip(url1,cleanDataFolder)
    unzip(url2,cleanDataFolder)
end
```

Download the reverberated speech dataset.

```
url3 = 'https://datashare.is.ed.ac.uk/bitstream/handle/10283/2031/reverb_trainset_28spk_wav.zip'
url4 = 'https://datashare.is.ed.ac.uk/bitstream/handle/10283/2031/reverb_testset_wav.zip';
downloadFolder = tempdir;
reverbDataFolder = fullfile(downloadFolder,'DS_10283_2031');

if ~exist(reverbDataFolder,'dir')
    disp('Downloading data set (6 GB) ...')
    unzip(url3,reverbDataFolder)
    unzip(url4,reverbDataFolder)
end
```

Data Preprocessing and Feature Extraction

Once the data is downloaded, preprocess the downloaded data and extract features before training the DNN model:

1. Synthetically generate reverberant data using the `reverberator` object
2. Split each speech signal into small segments of 2.072s duration
3. Discard segments which contain significant silent regions
4. Extract log-magnitude STFTs as predictor and target features
5. Scale and reshape features

First, create two `audioDatastore` objects that point to the clean and reverberant speech datasets.

```
adsCleanTrain = audioDatastore(fullfile(cleanDataFolder,'clean_trainset_28spk_wav'),'IncludeSubf
adsReverbTrain = audioDatastore(fullfile(reverbDataFolder,'reverb_trainset_28spk_wav'),'IncludeSu
```

Synthetic Reverberant Speech Data Generation

The amount of reverberation in the original data is relatively small. You will augment the reverberant speech data with significant reverberation effects using the `reverberator` object.

Create an `audioDatastore` that points to the clean speech dataset allocated for synthetic reverberant data generation.

```
adsSyntheticCleanTrain = subset(adsCleanTrain,10e3+1:length(adsCleanTrain.Files));
adsCleanTrain = subset(adsCleanTrain,1:10e3);
adsReverbTrain = subset(adsReverbTrain,1:10e3);
```

Resample from 48 kHz to 16 kHz.

```
adsSyntheticCleanTrain = transform(adsSyntheticCleanTrain,@(x)resample(x,16e3,48e3));
adsCleanTrain = transform(adsCleanTrain,@(x)resample(x,16e3,48e3));
adsReverbTrain = transform(adsReverbTrain,@(x)resample(x,16e3,48e3));
```

Combine the two audio datastores, maintaining the correspondence between the clean and reverberant speech samples.

```
adsCombinedTrain = combine(adsCleanTrain,adsReverbTrain);
```

The applyReverb on page 14-0 function creates a `reverberator` object, updates the pre delay, decay factor, and wet-dry mix parameters as specified, and then applies reverberation. Use `audioDataAugmenter` to create synthetically generated reverberant data.

```
augmenter = audioDataAugmenter('AugmentationMode','independent','NumAugmentations', 1,'ApplyAddNo
    'ApplyTimeStretch',0,'ApplyPitchShift',0,'ApplyVolumeControl',0,'ApplyTimeShift',0);
algorithmHandle = @(y,preDelay,decayFactor,wetDryMix,samplingRate) ...
    applyReverb(y,preDelay,decayFactor,wetDryMix,samplingRate);

addAugmentationMethod(augmenter,'Reverb',algorithmHandle, ...
    'AugmentationParameter',{'PreDelay','DecayFactor','WetDryMix','SamplingRate'}, ...
    'ParameterRange',{[0.15,0.25],[0.2,0.5],[0.3,0.45],[16000,16000]})

augmenter.ReverbProbability = 1;
disp(augmenter)
```

```
  audioDataAugmenter with properties:

              AugmentationMode: 'independent'
    AugmentationParameterSource: 'random'
              NumAugmentations: 1
              ApplyTimeStretch: 0
               ApplyPitchShift: 0
            ApplyVolumeControl: 0
                ApplyAddNoise: 0
               ApplyTimeShift: 0
                  ApplyReverb: 1
                PreDelayRange: [0.1500 0.2500]
              DecayFactorRange: [0.2000 0.5000]
                WetDryMixRange: [0.3000 0.4500]
             SamplingRateRange: [16000 16000]
```

Create a new `audioDatastore` corresponding to synthetically generated reverberant data by calling `transform` to apply data augmentation.

```
adsSyntheticReverbTrain = transform(adsSyntheticCleanTrain,@(y)deal(augment(augmenter,y,16e3).Au
```

Combine the two audio datastores.

```
adsSyntheticCombinedTrain = combine(adsSyntheticCleanTrain,adsSyntheticReverbTrain);
```

Next, based on the dimensions of the input features to the network, segment the audio into chunks of 2.072 s duration with an overlap of 50%.

Having too many silent segments can adversely affect the DNN model training. Remove the segments which are mostly silent (more than 50% of the duration) and exclude those from the model training. Do not completely remove silence because the model will not be robust to silent regions and slight reverberation effects could be identified as silence. `detectSpeech` can identify the start and end points of silent regions. After these two steps, the feature extraction process can be carried out as explained in the first section. helperFeatureExtract on page 14-0 implements these steps.

Define the feature extraction parameters. By setting `reduceDataSet` to true, you choose a small subset of the datasets to perform the subsequent steps.

```
reduceDataSet = true;
params.fs = 16000;
params.WindowdowLength = 512;
params.Window = hamming(params.WindowdowLength,"periodic");
params.OverlapLength = round(0.75*params.WindowdowLength);
params.FFTLength = params.WindowdowLength;
samplesPerMs = params.fs/1000;
params.samplesPerImage = (24+256*8)*samplesPerMs;
params.shiftImage = params.samplesPerImage/2;
params.NumSegments = 256;
params.NumFeatures = 256
```

```
params = struct with fields:
    WindowdowLength: 512
             Window: [512×1 double]
      OverlapLength: 384
          FFTLength: 512
        NumSegments: 256
        NumFeatures: 256
                 fs: 16000
    samplesPerImage: 33152
         shiftImage: 16576
```

To speed up processing, distribute the preprocessing and feature extraction task across multiple workers using `parfor`.

Determine the number of partitions for the dataset. If you do not have Parallel Computing Toolbox™, use a single partition.

```
if ~isempty(ver('parallel'))
    pool = gcp;
    numPar = numpartitions(adsCombinedTrain,pool);
else
    numPar = 1;
end
```

```
Starting parallel pool (parpool) using the 'local' profile ...
Connected to the parallel pool (number of workers: 6).
```

For each partition, read from the datastore, preprocess the audio signal, and then extract the features.

```
if reduceDataSet
    adsCombinedTrain = shuffle(adsCombinedTrain); %#ok
    adsCombinedTrain = subset(adsCombinedTrain,1:200);

    adsSyntheticCombinedTrain = shuffle(adsSyntheticCombinedTrain);
    adsSyntheticCombinedTrain = subset(adsSyntheticCombinedTrain,1:200);
end

allCleanFeatures = cell(1,numPar);
allReverbFeatures = cell(1,numPar);

parfor iPartition = 1:numPar
    combinedPartition = partition(adsCombinedTrain,numPar,iPartition);
    combinedSyntheticPartition = partition(adsSyntheticCombinedTrain,numPar,iPartition);
```

```
    cPartitionSize = numel(combinedPartition.UnderlyingDatastores{1}.UnderlyingDatastores{1}.File
    cSyntheticPartitionSize = numel(combinedSyntheticPartition.UnderlyingDatastores{1}.Underlying
    partitionSize = cPartitionSize + cSyntheticPartitionSize;

    cleanFeaturesPartition = cell(1,partitionSize);
    reverbFeaturesPartition = cell(1,partitionSize);

    for idx = 1:partitionSize
        if idx <= cPartitionSize
            audios = read(combinedPartition);
        else
            audios = read(combinedSyntheticPartition);
        end
        cleanAudio = single(audios(:,1));
        reverbAudio = single(audios(:,2));
        [featuresClean,featuresReverb] = helperFeatureExtract(cleanAudio,reverbAudio,false,params
        cleanFeaturesPartition{idx} = featuresClean;
        reverbFeaturesPartition{idx} = featuresReverb;
    end
    allCleanFeatures{iPartition} = cat(2,cleanFeaturesPartition{:});
    allReverbFeatures{iPartition} = cat(2,reverbFeaturesPartition{:});
end

allCleanFeatures = cat(2,allCleanFeatures{:});
allReverbFeatures = cat(2,allReverbFeatures{:});
```

Normalize the extracted features to the range [-1,1] and then reshape as explained in the first section, using the featureNormalizeAndReshape on page 14-0 function.

```
trainClean = featureNormalizeAndReshape(allCleanFeatures);
trainReverb = featureNormalizeAndReshape(allReverbFeatures);
```

Now that you have extracted the log-magnitude STFT features from the training datasets, follow the same procedure to extract features from the validation datasets. For reconstruction purposes, retain the phase of the reverberant speech samples of the validation dataset. In addition, retain the audio data for both the clean and reverberant speech samples in the validation set to use in the evaluation process (next section).

```
adsCleanVal = audioDatastore(fullfile(cleanDataFolder,'clean_testset_wav'),'IncludeSubfolders',t
adsReverbVal = audioDatastore(fullfile(reverbDataFolder,'reverb_testset_wav'),'IncludeSubfolders
```

Resample from 48 kHz to 16 kHz.

```
adsCleanVal = transform(adsCleanVal,@(x)resample(x,16e3,48e3));
adsReverbVal = transform(adsReverbVal,@(x)resample(x,16e3,48e3));

adsCombinedVal = combine(adsCleanVal,adsReverbVal);

if reduceDataSet
    adsCombinedVal = shuffle(adsCombinedVal);%#ok
    adsCombinedVal = subset(adsCombinedVal,1:50);
end

allValCleanFeatures = cell(1,numPar);
allValReverbFeatures = cell(1,numPar);
allValReverbPhase = cell(1,numPar);
allValCleanAudios = cell(1,numPar);
```

```
allValReverbAudios = cell(1,numPar);

parfor iPartition = 1:numPar
    combinedPartition = partition(adsCombinedVal,numPar,iPartition);

    partitionSize = numel(combinedPartition.UnderlyingDatastores{1}.UnderlyingDatastores{1}.Files

    cleanFeaturesPartition = cell(1,partitionSize);
    reverbFeaturesPartition = cell(1,partitionSize);
    reverbPhasePartition = cell(1,partitionSize);
    cleanAudiosPartition = cell(1,partitionSize);
    reverbAudiosPartition = cell(1,partitionSize);

    for idx = 1:partitionSize
        audios = read(combinedPartition);

        cleanAudio = single(audios(:,1));
        reverbAudio = single(audios(:,2));

        [a,b,c,d,e] = helperFeatureExtract(cleanAudio,reverbAudio,true,params);

        cleanFeaturesPartition{idx} = a;
        reverbFeaturesPartition{idx} = b;
        reverbPhasePartition{idx} = c;
        cleanAudiosPartition{idx} = d;
        reverbAudiosPartition{idx} = e;
    end
    allValCleanFeatures{iPartition} = cat(2,cleanFeaturesPartition{:});
    allValReverbFeatures{iPartition} = cat(2,reverbFeaturesPartition{:});
    allValReverbPhase{iPartition} = cat(2,reverbPhasePartition{:});
    allValCleanAudios{iPartition} = cat(2,cleanAudiosPartition{:});
    allValReverbAudios{iPartition} = cat(2,reverbAudiosPartition{:});
end

allValCleanFeatures = cat(2,allValCleanFeatures{:});
allValReverbFeatures = cat(2,allValReverbFeatures{:});
allValReverbPhase = cat(2,allValReverbPhase{:});
allValCleanAudios = cat(2,allValCleanAudios{:});
allValReverbAudios = cat(2,allValReverbAudios{:});

valClean = featureNormalizeAndReshape(allValCleanFeatures);
```

Retain the minimum and maximum values of each feature of the reverberant validation set. You will use these values in the reconstruction process.

```
[valReverb,valMinMaxPairs] = featureNormalizeAndReshape(allValReverbFeatures);
```

Define Neural Network Architecture

A fully convolutional network architecture named **U-Net** was adapted for this speech dereverberation task as proposed in [1] on page 14-0 . "U-Net" is an encoder-decoder network with skip connections. In the U-Net model, each layer downsamples its input (stride of 2) until a bottleneck layer is reached (encoding path). In subsequent layers, the input is upsampled by each layer until the output is returned to the original shape (decoding path). To minimize the loss of low-level information during the downsampling process, connections are made between the mirrored layers by directly concatenating outputs of corresponding layers (*skip connections*).

Define the network architecture and return the layer graph with connections.

```
params.WindowdowLength = 512;
params.FFTLength = params.WindowdowLength;
params.NumFeatures = params.FFTLength/2;
params.NumSegments = 256;

filterH = 6;
filterW = 6;
numChannels = 1;
nFilters = [64,128,256,512,512,512,512,512];

inputLayer = imageInputLayer([params.NumFeatures,params.NumSegments,numChannels], ...
    'Normalization','none','Name','input');
layers = inputLayer;

% U-Net squeezing path
layers = [layers;
    convolution2dLayer([filterH,filterW],nFilters(1),'Stride',2,'Padding','same','Name',"conv"+s
    leakyReluLayer(0.2,'Name',"leaky-relu"+string(1))];

for i = 2:8
    layers =  [layers;
        convolution2dLayer([filterH,filterW],nFilters(i),'Stride',2,'Padding','same','Name',"conv
        batchNormalizationLayer('Name',"batchnorm"+string(i))];%#ok
    if i ~= 8
        layers = [layers;leakyReluLayer(0.2,'Name',"leaky-relu"+string(i))];%#ok
    else
        layers = [layers;reluLayer('Name',"relu"+string(i))];%#ok
    end
end

% U-Net expanding path
for i = 7:-1:0
    nChannels = numChannels;
    if i > 0
        nChannels = nFilters(i);
    end
    layers = [layers;
        transposedConv2dLayer([filterH,filterW],nChannels,'Stride',2,'Cropping','same','Name',"de
    if i > 0
        layers = [layers; batchNormalizationLayer('Name',"de-batchnorm" +string(i))];%#ok
    end
    if i > 4
        layers = [layers;dropoutLayer(0.5,'Name',"de-dropout"+string(i))];%#ok
    end
    if i > 0
        layers = [layers;
            reluLayer('Name',"de-relu"+string(i));
            concatenationLayer(3,2,'Name',"concat"+string(i))];%#ok
    else
        layers = [layers;tanhLayer('Name',"de-tanh"+string(i))];%#ok
    end
end

layers = [layers;regressionLayer('Name','output')];

unetLayerGraph = layerGraph(layers);

% Define skip-connections
```

```
for i = 1:7
    unetLayerGraph = connectLayers(unetLayerGraph,'leaky-relu'+string(i),'concat'+string(i)+'/in2');
end
```

Use `analyzeNetwork` to view the model architecture. This is a good way to visualize the connections between layers.

```
analyzeNetwork(unetLayerGraph);
```

Train the Network

You will use the mean squared error (MSE) between the log-magnitude spectra of the dereverberated speech sample (output of the model) and the corresponding clean speech sample (target) as the loss function. Use the `adam` optimizer and a mini-batch size of 128 for the training. Allow the model to train for a maximum of 50 epochs. If the validation loss doesn't improve for 5 consecutive epochs, terminate the training process. Reduce the learning rate by a factor of 10 every 15 epochs.

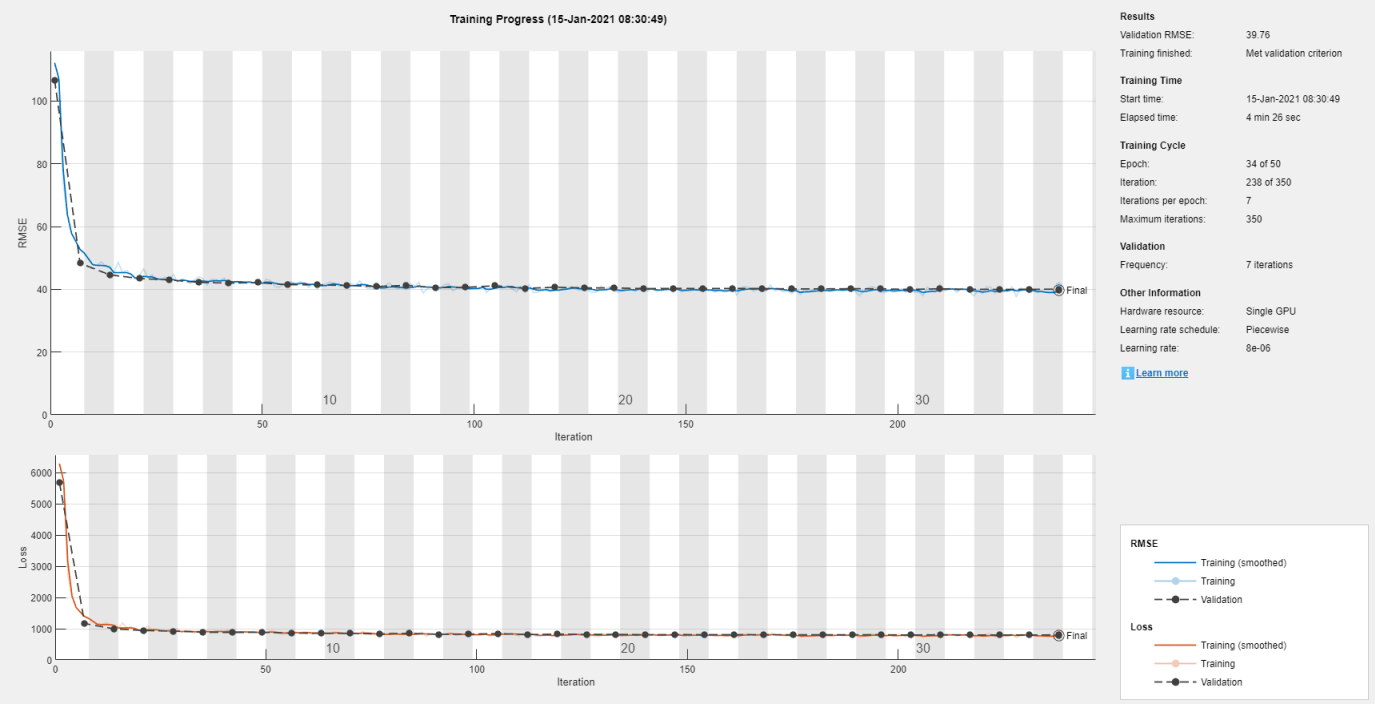
Define the training options as below. Change the execution environment and whether to perform background dispatching depending on your hardware availability and whether you have access to Parallel Computing Toolbox™.

```
initialLearnRate = 8e-4;
miniBatchSize = 64;

options = trainingOptions("adam", ...
        "MaxEpochs", 50, ...
        "InitialLearnRate",initialLearnRate, ...
        "MiniBatchSize",miniBatchSize, ...
        "Shuffle","every-epoch", ...
        "Plots","training-progress", ...
        "Verbose",false, ...
        "ValidationFrequency",max(1,floor(size(trainReverb,4)/miniBatchSize)), ...
        "ValidationPatience",5, ...
        "LearnRateSchedule","piecewise", ...
        "LearnRateDropFactor",0.1, ...
        "LearnRateDropPeriod",15, ...
        "ExecutionEnvironment","gpu", ...
        "DispatchInBackground",true, ...
        "ValidationData",{valReverb,valClean});
```

Train the network.

```
dereverbNet = trainNetwork(trainReverb,trainClean,unetLayerGraph,options);
```



Evaluate Network Performance

Prediction and Reconstruction

Predict the log-magnitude spectra of the validation set.

```
predictedSTFT4D = predict(dereverbNet,valReverb);
```

Use the helperReconstructPredictedAudios on page 14-0 function to reconstruct the predicted speech. This function performs actions outlined in the first section.

```
params.WindowdowLength = 512;
params.Window = hamming(params.WindowdowLength,"periodic");
params.OverlapLength = round(0.75*params.WindowdowLength);
params.FFTLength = params.WindowdowLength;
params.fs = 16000;

dereverbedAudioAll = helperReconstructPredictedAudios(predictedSTFT4D,valMinMaxPairs,allValReverb
```

Visualize the log-magnitude STFTs of the clean, reverberant, and corresponding dereverberated speech signals.

```
figure('Position',[100,100,1024,1200])

subplot(3,1,1)
imagesc(squeeze(allValCleanFeatures{1}))
set(gca,'Ydir','normal')

Evaluation Metrics

You will use a subset of objective measures used in [1] on page 14-0 to evaluate the performance of the network. These metrics are computed on the time-domain signals.

- Cepstrum distance (CD) - Provides an estimate of the log spectral distance between two spectra (predicted and clean). Smaller values indicate better quality.
- Log likelihood ratio (LLR) - Linear predictive coding (LPC) based objective measurement. Smaller values indicate better quality.

Compute these measurements for the reverberant speech and the dereverberated speech signals.

```
[summaryMeasuresReconstructed,allMeasuresReconstructed] = calculateObjectiveMeasures(dereverbedAu
[summaryMeasuresReverb,allMeasuresReverb] = calculateObjectiveMeasures(allValReverbAudios,allVal
disp(summaryMeasuresReconstructed)
```

```
       avgCdMean: 3.8386
     avgCdMedian: 3.3671
      avgLlrMean: 0.9152
    avgLlrMedian: 0.8096
```

```
disp(summaryMeasuresReverb)
```

```
       avgCdMean: 4.2591
     avgCdMedian: 3.6336

Supporting Functions

Apply Reverberation

```
function yOut = applyReverb(y,preDelay,decayFactor,wetDryMix,fs)
% This function generates reverberant speech data using the reverberator
% object
%
% inputs:
% y                                 - clean speech sample
% preDelay, decayFactor, wetDryMix - reverberation parameters
% fs                                - sampling rate of y
%
% outputs:
% yOut - corresponding reveberated speech sample

    revObj = reverberator('SampleRate',fs, ...
        'DecayFactor',decayFactor, ...
        'WetDryMix',wetDryMix, ...
        'PreDelay',preDelay);
    yOut = revObj(y);
    yOut = yOut(1:length(y),1);
end
```

Extract Features Batch

```
function [featuresClean,featuresReverb,phaseReverb,cleanAudios,reverbAudios] ...
    = helperFeatureExtract(cleanAudio,reverbAudio,isVal,params)
% This function performs the preprocessing and features extraction task on
% the audio files used for dereverberation model training and testing.
%
% inputs:
% cleanAudio  - the clean audio file (reference)
% reverbAudio - corresponding reverberant speech file
% isVal       - Boolean flag indicating if it is the validation set
% params      - a structure containing feature extraction parameters
%
% outputs:
% featuresClean  - log-magnitude STFT features of clean audio
% featuresReverb - log-magnitude STFT features of reverberant audio
% phaseReverb    - phase of STFT of reverberant audio
% cleanAudios    - 2.072s-segments of clean audio file used for feature extraction
% reverbAudios   - 2.072s-segments of corresponding reverberant audio

    assert(length(cleanAudio) == length(reverbAudio));
    nSegments = floor((length(reverbAudio) - (params.samplesPerImage - params.shiftImage))/params
```

```

    lpcCoeffs = real(lpcX');
end
```

Speaker Recognition Using x-vectors

Speaker recognition answers the question "Who is speaking?". Speaker recognition is usually divided into two tasks: *speaker identification* and *speaker verification*. In speaker identification, a speaker is recognized by comparing their speech to a closed set of templates. In speaker verification, a speaker is recognized by comparing the likelihood that the speech belongs to a particular speaker against a predetermined threshold. Traditional machine learning methods perform well at these tasks in ideal conditions. For examples of speaker identification using traditional machine learning methods, see “Speaker Identification Using Pitch and MFCC” (Audio Toolbox) and “Speaker Verification Using i-Vectors” (Audio Toolbox). Audio Toolbox™ provides `ivectorSystem` (Audio Toolbox) which encapsulates the ability to train an i-vector system, enroll speakers or other audio labels, evaluate the system for a decision threshold, and identify or verify speakers or other audio labels.

In adverse conditions, the deep learning approach of x-vectors has been shown to achieve state-of-the-art results for many scenarios and applications [1] on page 14-0 . The x-vector system is an evolution of i-vectors originally developed for the task of speaker verification.

In this example, you develop an x-vector system. First, you train a time-delay neural network (TDNN) to perform speaker identification. Then you train the traditional backends for an x-vector-based speaker verification system: an LDA projection matrix and a PLDA model. You then perform speaker verification using the TDNN and the backend dimensionality reduction and scoring. The x-vector system backend, or classifier, is the same as developed for i-vector systems. For details on the backend, see “Speaker Verification Using i-Vectors” (Audio Toolbox) and `ivectorSystem` (Audio Toolbox).

In Speaker Diarization Using x-vectors, you use the x-vector system trained in this example to perform speaker diarization. Speaker diarization answers the question, "Who spoke when?".

Throughout this example, you will find live controls on tunable parameters. Changing the controls does not rerun the example. If you change a control, you must rerun the example.

Data Set Management

This example uses the Pitch Tracking Database from Graz University of Technology (PTDB-TUG) [2] on page 14-0 . The data set consists of 20 English native speakers reading 2342 phonetically rich sentences from the TIMIT corpus. Download and extract the data set. Depending on your system, downloading and extracting the data set can take approximately 1.5 hours.

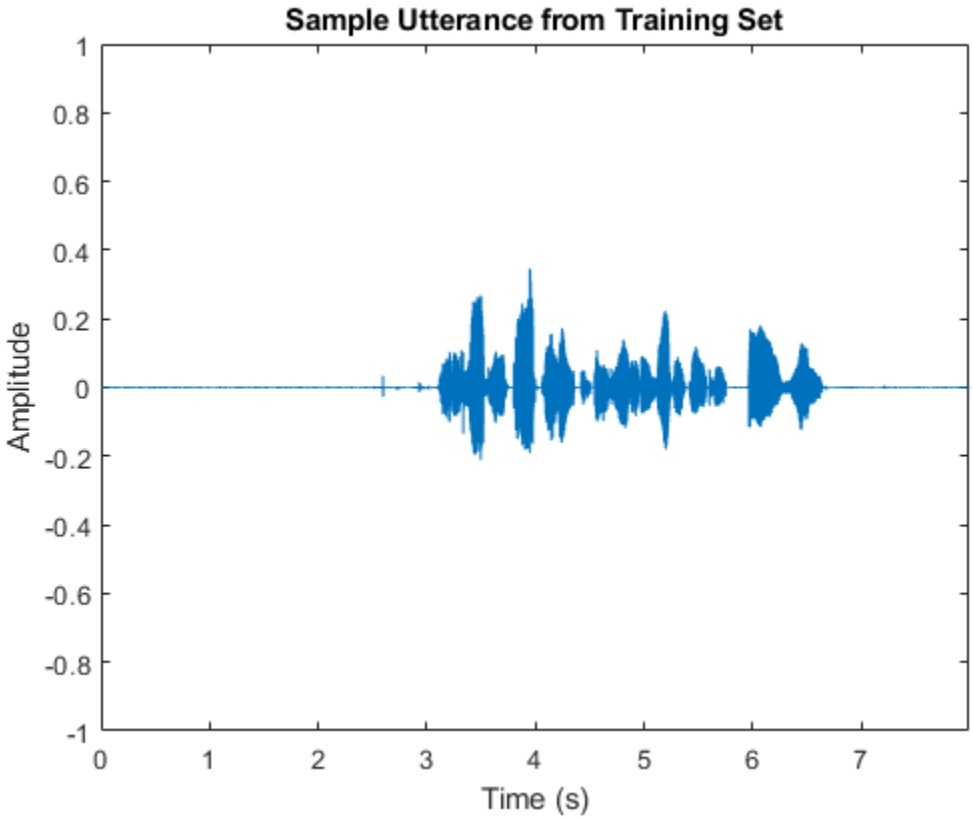
```
url = 'https://www2.spsc.tugraz.at/databases/PTDB-TUG/SPEECH_DATA_ZIPPED.zip';
downloadFolder = tempdir;
datasetFolder = fullfile(downloadFolder,'PTDB-TUG');
if ~exist(datasetFolder,'dir')
    disp('Downloading PTDB-TUG (3.9 G) ...')
    unzip(url,datasetFolder)
end
```

Create an `audioDatastore` (Audio Toolbox) object that points to the data set. The data set was originally intended for use in pitch-tracking training and evaluation, and includes laryngograph readings and baseline pitch decisions. Use only the original audio recordings.

```
ads = audioDatastore([fullfile(datasetFolder,"SPEECH DATA","FEMALE","MIC"),fullfile(datasetFolde
                      'IncludeSubfolders',true, ...
                      'FileExtensions','.wav');
fileNames = ads.Files;
```

Read an audio file from the training data set, listen to it, and then plot it.

```
[audioIn,audioInfo] = read(ads);
fs = audioInfo.SampleRate;
t = (0:size(audioIn,1)-1)/fs;
sound(audioIn,fs)
plot(t,audioIn)
xlabel('Time (s)')
ylabel('Amplitude')
axis([0 t(end) -1 1])
title('Sample Utterance from Training Set')
```



The file names contain the speaker IDs. Decode the file names to set the labels on the `audioDatastore` object.

```
speakerIDs = extractBetween(fileNames,'mic_','_');
ads.Labels = categorical(speakerIDs);
```

Separate the `audioDatastore` object into five sets:

- `adsTrain` - Contains training set for the TDNN and backend classifier.
- `adsValidation` - Contains validation set to evaluate TDNN training progress.
- `adsTest` - Contains test set to evaluate the TDNN performance for speaker identification.
- `adsEnroll` - Contains enrollment set to evaluate the detection error tradeoff of the x-vector system for speaker verification.

- `adsDET` - Contains evaluation set used to determine the detection error tradeoff of the x-vector system for speaker verification.

```
developmentLabels = categorical(["M01","M02","M03","M04","M06","M07","M08","M09","F01","F02","F0
evaluationLabels = categorical(["M05","M010","F05","F010"]);
adsTrain = subset(ads,ismember(ads.Labels,developmentLabels));
[adsTrain,adsValidation,adsTest] = splitEachLabel(adsTrain,0.8,0.1,0.1);
adsEvaluate = subset(ads,ismember(ads.Labels,evaluationLabels));
[adsEnroll,adsDET] = splitEachLabel(adsEvaluate,3);
```

Display the label distributions of the resulting `audioDatastore` objects.

```
countEachLabel(adsTrain)
```

```

You can reduce the training and detection error trade-off datasets used in this example to speed up the runtime at the cost of performance. In general, reducing the data set is a good practice for development and debugging.

```
speedUpExample = false;
if speedUpExample
    adsTrain = splitEachLabel(adsTrain,20);
    adsDET = splitEachLabel(adsDET,20);
end
```

Feature Extraction

Create an `audioFeatureExtractor` (Audio Toolbox) object to extract 30 MFCCs from 30 ms Hann windows with a 10 ms hop. The sample rate of the data set is 48 kHz, but you will downsample the data set to 16 kHz. Design the `audioFeatureExtractor` assuming the desired sample rate, 16 kHz.

```
desiredFs = 16e3;

windowDuration = 0.03 ;
hopDuration = 0.005 ;
windowSamples = round(windowDuration*desiredFs);
hopSamples = round(hopDuration*desiredFs);
overlapSamples = windowSamples - hopSamples;
numCoeffs = 30 ;
afe = audioFeatureExtractor( ...
    'SampleRate',desiredFs, ...
    'Window',hann(windowSamples,'periodic'), ...
    'OverlapLength',overlapSamples, ...
    ...
    'mfcc',true, ...
    'pitch',false, ...
    'spectralEntropy',false, ...
    'spectralFlux',false);
setExtractorParams(afe,'mfcc','NumCoeffs',numCoeffs)
```

Downsample the audio data to 16 kHz and extract features from the train and validation data sets. Use the training data set to determine the mean and standard deviation of the features to perform feature standardization. The supporting function, xVectorPreprocessBatch on page 14-0 , uses your default parallel pool if you have Parallel Computing Toolbox™.

```
adsTrain = transform(adsTrain,@(x)resample(x,desiredFs,fs));
[features,YTrain] = xVectorPreprocessBatch(adsTrain,afe);
```

```
Starting parallel pool (parpool) using the 'local' profile ...
Connected to the parallel pool (number of workers: 6).
```

```
featuresMAT = cat(1,features{:});
numFeatures = size(featuresMAT,2);
factors = struct('Mean',mean(featuresMAT,1),'STD',std(featuresMAT,1));

XTrain = cellfun(@(x)(x-factors.Mean)./factors.STD,features,'UniformOutput',false);
XTrain = cellfun(@(x)x-mean(x(:)),XTrain,'UniformOutput',false);

adsValidation = transform(adsValidation,@(x)resample(x,desiredFs,fs));
[XValidation,YValidation] = xVectorPreprocessBatch(adsTrain,afe,'Factors',factors);

classes = unique(YTrain);
numClasses = numel(classes);
```

x-vector Feature Extraction Model

In this example, you implement the x-vector feature extractor model [1] on page 14-0 using the functional programming paradigm provided by Deep Learning Toolbox™. This paradigm enables complete control of the design of your deep learning model. For a tutorial on functional programming in Deep Learning Toolbox, see “Define Model Gradients Function for Custom Training Loop” on page

18-231. The supporting function, `xvecModel`, is placed in your current folder when you open this example. Display the contents of the `xvecModel` function.

```

Initialize structs that contain the parameters and state of the TDNN model using the supporting function, initializexVecModelLayers on page 14-0 . [1] on page 14-0 specifies the number of filters between most layers, including the embedding layer, as 512. Because the training set in this example is small, use a representation size of 128.

```
numFilters = 128;
[parameters,state] = initializexVecModelLayers(numFeatures,numFilters,numClasses)

parameters = struct with fields:
         conv1: [1×1 struct]
    batchnorm1: [1×1 struct]
         conv2: [1×1 struct]
    batchnorm2: [1×1 struct]
         conv3: [1×1 struct]
    batchnorm3: [1×1 struct]
         conv4: [1×1 struct]
    batchnorm4: [1×1 struct]
         conv5: [1×1 struct]
    batchnorm5: [1×1 struct]
           fc7: [1×1 struct]
    batchnorm7: [1×1 struct]
           fc8: [1×1 struct]
    batchnorm8: [1×1 struct]
           fc9: [1×1 struct]

state = struct with fields:
    batchnorm1: [1×1 struct]
```

```
    batchnorm2: [1×1 struct]
    batchnorm3: [1×1 struct]
    batchnorm4: [1×1 struct]
    batchnorm5: [1×1 struct]
    batchnorm7: [1×1 struct]
    batchnorm8: [1×1 struct]
```

The table summarizes the architecture of the network described in [1] on page 14-0 and implemented in this example. T is the total number of frames (feature vectors over time) in an audio signal. N is the number of classes (speakers) in the training set.

Layer	Description	Layer Context	Total Context	Input-by-Output
1	**1-d convolutional** batch normalization ReLu activation	$[t-2, t+2]$	5	$(5 \times numFeatures) - by - numFilters$
2	**1-d convolutional** batch normalization ReLu activation	$\{t-2, t, t+2\}$	9	$(3 \times numFilters) - by - numFilters$
3	**1-d convolutional** batch normalization ReLu activation	$\{t-3, t, t+3\}$	15	$(3 \times numFilters) - by - numFilters$
4	**1-d convolutional** batch normalization ReLu activation	$\{t\}$	15	$numFilters - by - numFilters$
5	**1-d convolutional** batch normalization ReLu activation	$\{t\}$	15	$numFilters - by - 1500$
6	**statistics pooling**	$[0, T)$	T	$(1500 \times \mathrm{T}) - by - 3000$
7	**fully-connected** batch normalization ReLu activation	$\{0\}$	T	$3000 - by - numFilters$
8	**fully-connected** batch normalization ReLu activation	$\{0\}$	T	$numFilters - by - numFilters$
9	**fully-connected** softmax	$\{0\}$	T	$numFilters - by - N$

Train Model

Use `arrayDatastore` and `minibatchqueue` to create a mini-batch queue for the training data. If you have access to a compute GPU, set `ExecutionEnvironment` to `gpu`. Otherwise, set `ExecutionEnvironment` to `cpu`.

```
ExecutionEnvironment = gpu;

dsXTrain = arrayDatastore(XTrain,'OutputType','same');
dsYTrain = arrayDatastore(YTrain','OutputType','cell');

dsTrain = combine(dsXTrain,dsYTrain);
```

```
miniBatchSize =  128 ;
numOutputs = 2;
mbq = minibatchqueue(dsTrain,numOutputs, ...
    'MiniBatchSize',miniBatchSize, ...
    'MiniBatchFormat',{'SCB','CB'}, ...
    'MiniBatchFcn',@preprocessMiniBatch, ...
    'OutputEnvironment',ExecutionEnvironment);
```

Set the number of training epochs, the initial learn rate, the learn rate drop period, the learn rate drop factor, and the validations per epoch.

```
numEpochs =  6 ;

learnRate =  0.001 ;
gradDecay = 0.5;
sqGradDecay = 0.999;
trailingAvg = [];
trailingAvgSq = [];

LearnRateDropPeriod =  2 ;
LearnRateDropFactor =  0.1 ;

ValidationsPerEpoch =  2 ;

iterationsPerEpoch = floor(numel(XTrain)/miniBatchSize);
iterationsPerValidation = round(iterationsPerEpoch/ValidationsPerEpoch);
```

If performing validation while training, preprocess the validation set for faster in-the-loop performance.

```
if ValidationsPerEpoch ~= 0
    [XValidation,YValidation] = preprocessMiniBatch(XValidation,{YValidation});
    XValidation = dlarray(XValidation,'SCB');
    if strcmp(ExecutionEnvironment,'gpu')
        XValidation = gpuArray(XValidation);
    end
end
```

To display training progress, initialize the supporting object `progressPlotter`. The supporting object, `progressPlotter`, is placed in your current folder when you open this example.

Run the training loop.

```
pp = progressPlotter(categories(classes));

iteration = 0;
for epoch = 1:numEpochs

    % Shuffle mini-batch queue
    shuffle(mbq)

    while hasdata(mbq)
```

```
            % Update iteration counter
            iteration = iteration + 1;

            % Get mini-batch from mini-batch queue
            [dlX,Y] = next(mbq);

            % Evaluate the model gradients, state, and loss using dlfeval and the modelGradients fun
            [gradients,state,loss,predictions] = dlfeval(@modelGradients,dlX,Y,parameters,state);

            % Update the network parameters using the Adam optimizer
            [parameters,trailingAvg,trailingAvgSq] = adamupdate(parameters,gradients, ...
                trailingAvg,trailingAvgSq,iteration,learnRate,gradDecay,sqGradDecay,eps('single'));

            % Update the training progress plot
            updateTrainingProgress(pp,'Epoch',epoch,'Iteration',iteration,'LearnRate',learnRate,'Pre

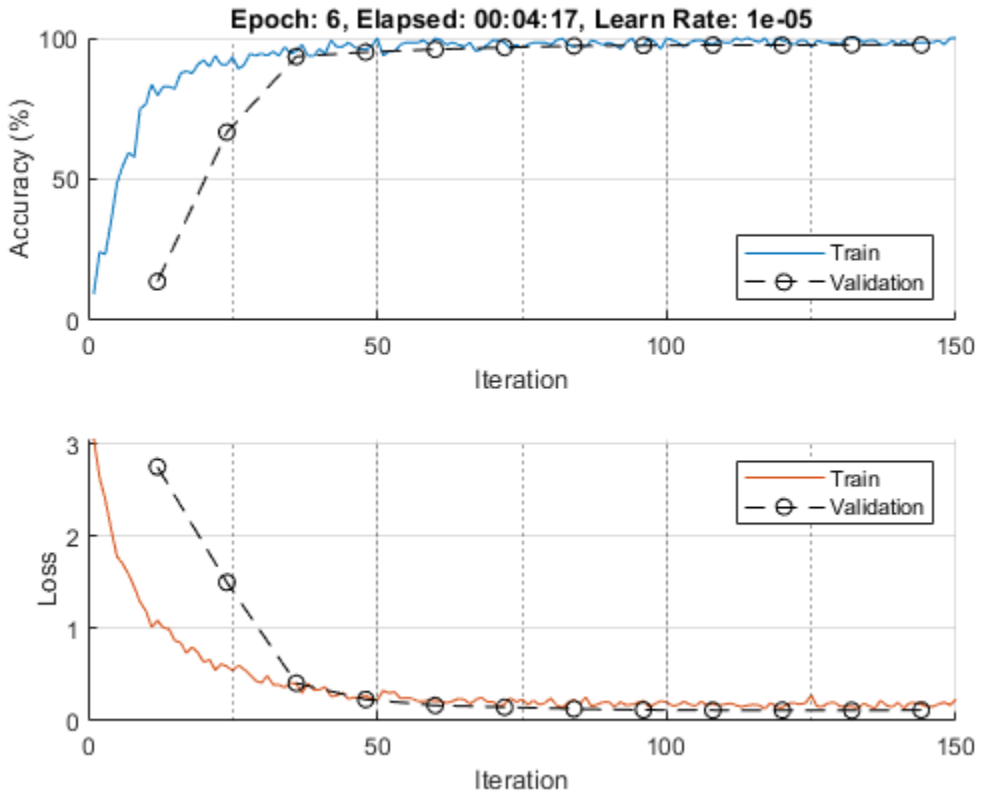
            % Update the validation plot
            if ~rem(iteration,iterationsPerValidation)

                % Pass validation data through x-vector model
                predictions = xvecModel(XValidation,parameters,state,'DoTraining',false);

                % Update plot
                updateValidation(pp,'Iteration',iteration,'Predictions',predictions,'Targets',YValida
            end
        end

        % Update learn rate
        if rem(epoch,LearnRateDropPeriod)==0
            learnRate = learnRate*LearnRateDropFactor;
        end

    end
```



Evaluate TDNN Model

Evaluate the TDNN speaker recognition accuracy using the held-out test set. For each file in the test set:

1. Resample the audio to 16 kHz
2. Extract features using the `xVectorPreprocess` on page 14-0 supporting function. Features are returned in cell arrays, where the number of elements in a cell array is equal to the number of individual speech segments.
3. To get the predicted speaker label, pass each segment through the model.
4. If more than one speech segment was present in the audio signal, average the predictions.
5. Use `onehotdecode` to convert the prediction to a label.

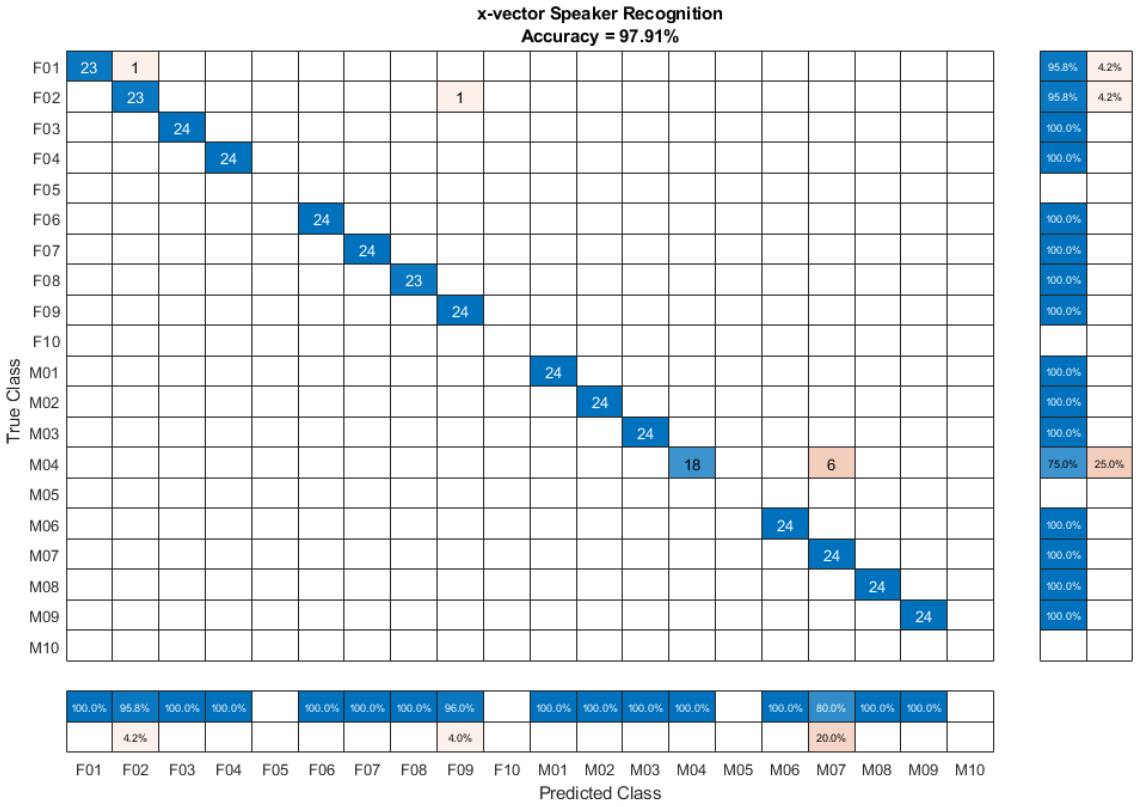
Use `confusionchart` to evaluate the system performance.

```
predictedLabels = classes;
predictedLabels(:) = [];

for sample = 1:numel(adsTest.Files)
    [audioIn,xInfo] = read(adsTest);
    audioIn = resample(audioIn,desiredFs,fs);
    f = xVectorPreprocess(audioIn,afe,'Factors',factors,'MinimumDuration',0);
    predictions = zeros(numel(classes),numel(f));
    for segment = 1:numel(f)
        dlX = dlarray(f{segment},'SCB');
```

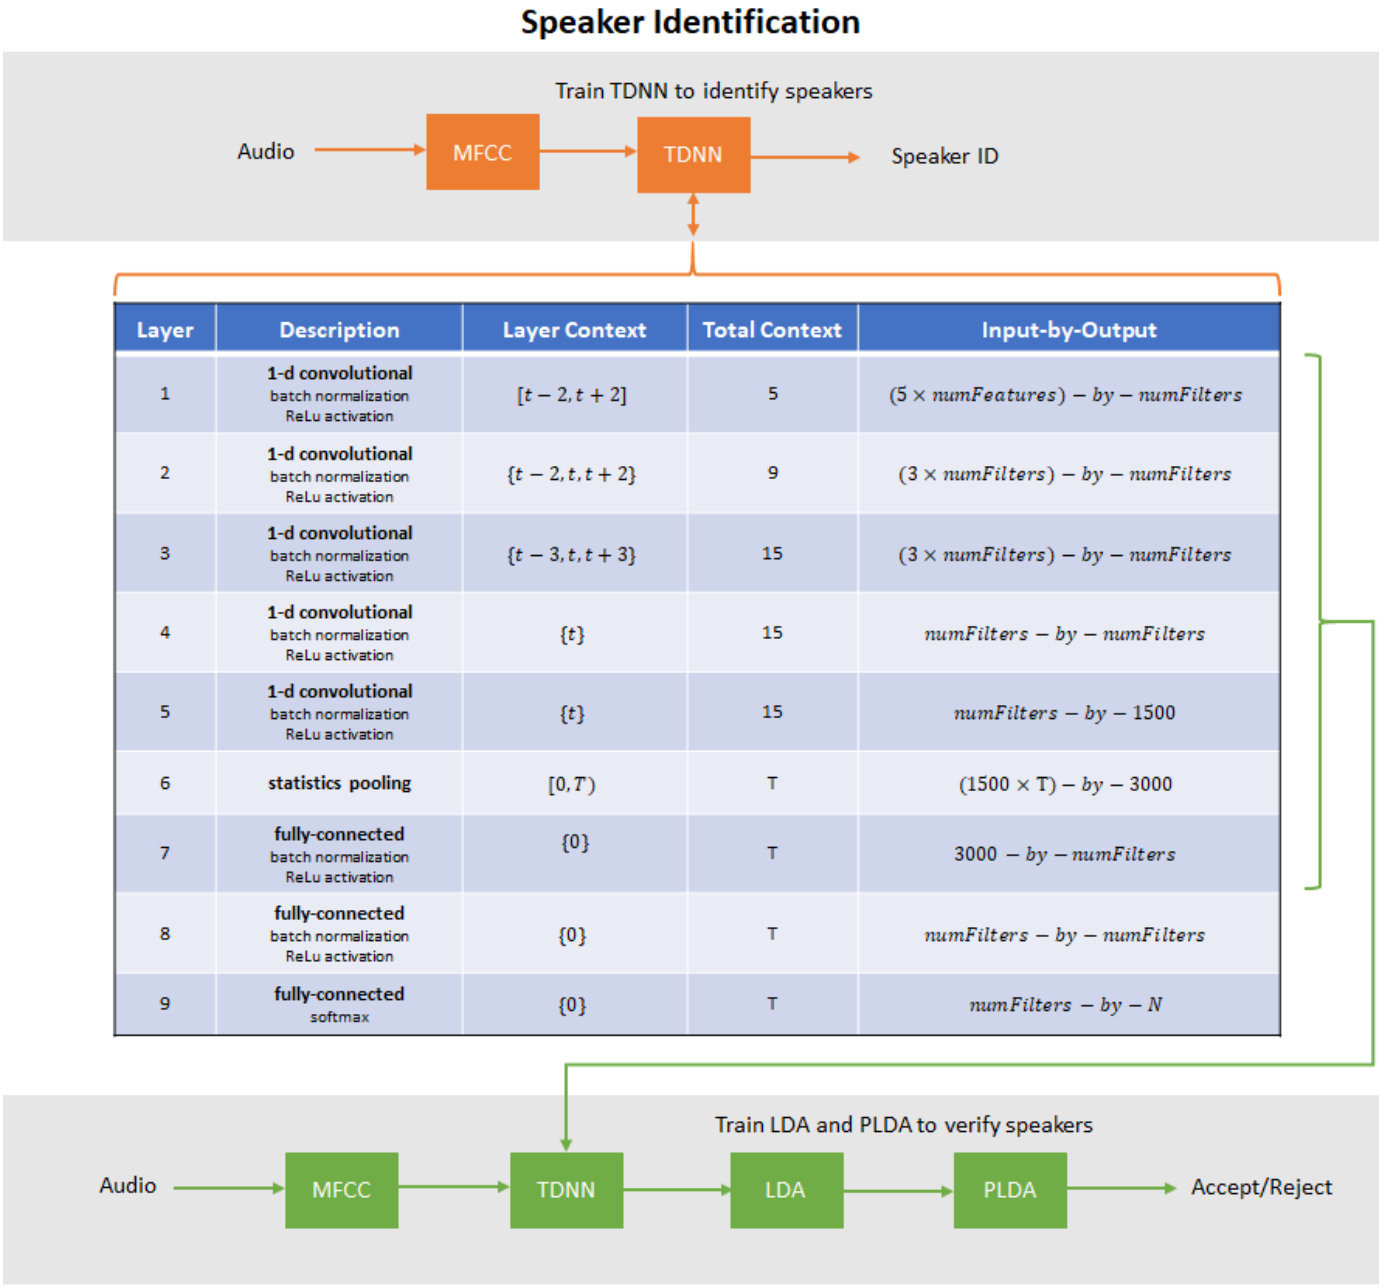
```
        predictions(:,segment) = extractdata(xvecModel(dlX,parameters,state,'DoTraining',false));
    end
    predictedLabels(sample) = onehotdecode(mean(predictions,2),categories(classes),1);
end
trueLabels = adsTest.Labels;
accuracy = mean(trueLabels==predictedLabels');

figure('Units','normalized','Position',[0.2 0.2 0.6 0.6]);
confusionchart(trueLabels,predictedLabels', ...
    'ColumnSummary','column-normalized', ...
    'RowSummary','row-normalized', ...
    'Title',sprintf('x-vector Speaker Recognition\nAccuracy = %0.2f%%',accuracy*100))
```



Train x-vector System Backend

In the x-vector system for speaker verification, the TDNN you just trained is used to output an embedding layer. The output from the embedding layer (layer 7 in this example, after batch normalization and before activation) are the 'x-vectors' in an x-vector system.



Layer	Description	Layer Context	Total Context	Input-by-Output
1	**1-d convolutional** batch normalization ReLu activation	$[t-2, t+2]$	5	$(5 \times numFeatures) - by - numFilters$
2	**1-d convolutional** batch normalization ReLu activation	$\{t-2, t, t+2\}$	9	$(3 \times numFilters) - by - numFilters$
3	**1-d convolutional** batch normalization ReLu activation	$\{t-3, t, t+3\}$	15	$(3 \times numFilters) - by - numFilters$
4	**1-d convolutional** batch normalization ReLu activation	$\{t\}$	15	$numFilters - by - numFilters$
5	**1-d convolutional** batch normalization ReLu activation	$\{t\}$	15	$numFilters - by - 1500$
6	**statistics pooling**	$[0, T)$	T	$(1500 \times T) - by - 3000$
7	**fully-connected** batch normalization ReLu activation	$\{0\}$	T	$3000 - by - numFilters$
8	**fully-connected** batch normalization ReLu activation	$\{0\}$	T	$numFilters - by - numFilters$
9	**fully-connected** softmax	$\{0\}$	T	$numFilters - by - N$

The backend (or classifier) of an x-vector system is the same as the backend of an i-vector system. For details on the algorithms, see `ivectorSystem` (Audio Toolbox) and “Speaker Verification Using i-Vectors” (Audio Toolbox).

Extract x-vectors from the train set. The supporting function, `xvecModel`, has the optional name-value pair `'OutputLayer'`. Set `'OutputLayer'` to 7 to return the output of the seventh layer. In [1] on page 14-0 , the output from either layer 7 or layer 8 are suggested as possible embedding layers.

```
xvecs = zeros(numFilters,numel(YTrain));
for sample = 1:size(YTrain,2)
```

```
    dlX = dlarray(XTrain{sample},'SCB');

    embedding = xvecModel(dlX,parameters,state,'DoTraining',false,'OutputLayer',7);
    xvecs(:,sample) = extractdata(embedding);
end
```

Create a linear discriminant analysis (LDA) projection matrix to reduce the dimensionality of the x-vectors to 32. LDA attempts to minimize the intra-class variance and maximize the variance between speakers.

```
numEigenvectors = 32;
projMat = helperTrainProjectionMatrix(xvecs,YTrain,numEigenvectors);
```

Apply the LDA projection matrix to the x-vectors.

```
xvecs = projMat*xvecs;
```

Train a G-PLDA model to perform scoring.

```
numIterations = 3;
numDimensions = 32;
plda = helperTrainPLDA(xvecs,YTrain,numIterations,numDimensions);
```

Evaluate x-vector System

Speaker verification systems verify that a speaker is who they purport to be. Before a speaker can be verified, they must be enrolled in the system. Enrollment in the system means that the system has a template x-vector representation of the speaker.

Enroll Speakers

Extract x-vectors from the held-out data set, `adsEnroll`. Set the minimum duration of an audio segment to the equivalent of 15 features hops (the minimum number required to calculate x-vectors).

```
minDur = (numel(afe.Window)+14*(numel(afe.Window)-afe.OverlapLength)+1)/desiredFs;

xvecs = zeros(numEigenvectors,numel(adsEnroll.Files));
reset(adsEnroll)
for sample = 1:numel(adsEnroll.Files)
    [audioIn,xInfo] = read(adsEnroll);
    audioIn = resample(audioIn,desiredFs,fs);
    f = xVectorPreprocess(audioIn,afe,'Factors',factors,'MinimumDuration',minDur);
    embeddings = zeros(numFilters,numel(f));
    for segment = 1:numel(f)
        dlX = dlarray(f{segment},'SCB');

        embeddings(:,segment) = extractdata(xvecModel(dlX,parameters,state,'DoTraining',false,'Ou
    end
    xvecs(:,sample) = mean(projMat*embeddings,2);
end
```

Create template x-vectors for each speaker by averaging the x-vectors of individual speakers across enrollment files.

```
labels = adsEnroll.Labels;
uniqueLabels = unique(labels);
```

```
atable = cell2table(cell(0,2),'VariableNames',{'xvector','NumSamples'});
for ii = 1:numel(uniqueLabels)
    idx = uniqueLabels(ii)==labels;
    wLocalMean = mean(xvecs(:,idx),2);
    localTable = table({wLocalMean},(sum(idx)), ...
        'VariableNames',{'xvector','NumSamples'}, ...
        'RowNames',string(uniqueLabels(ii)));
    atable = [atable;localTable]; %#ok<AGROW>
end
enrolledLabels = atable
```

```
enrolledLabels=2×2 table
              xvector       NumSamples
            ____________    __________

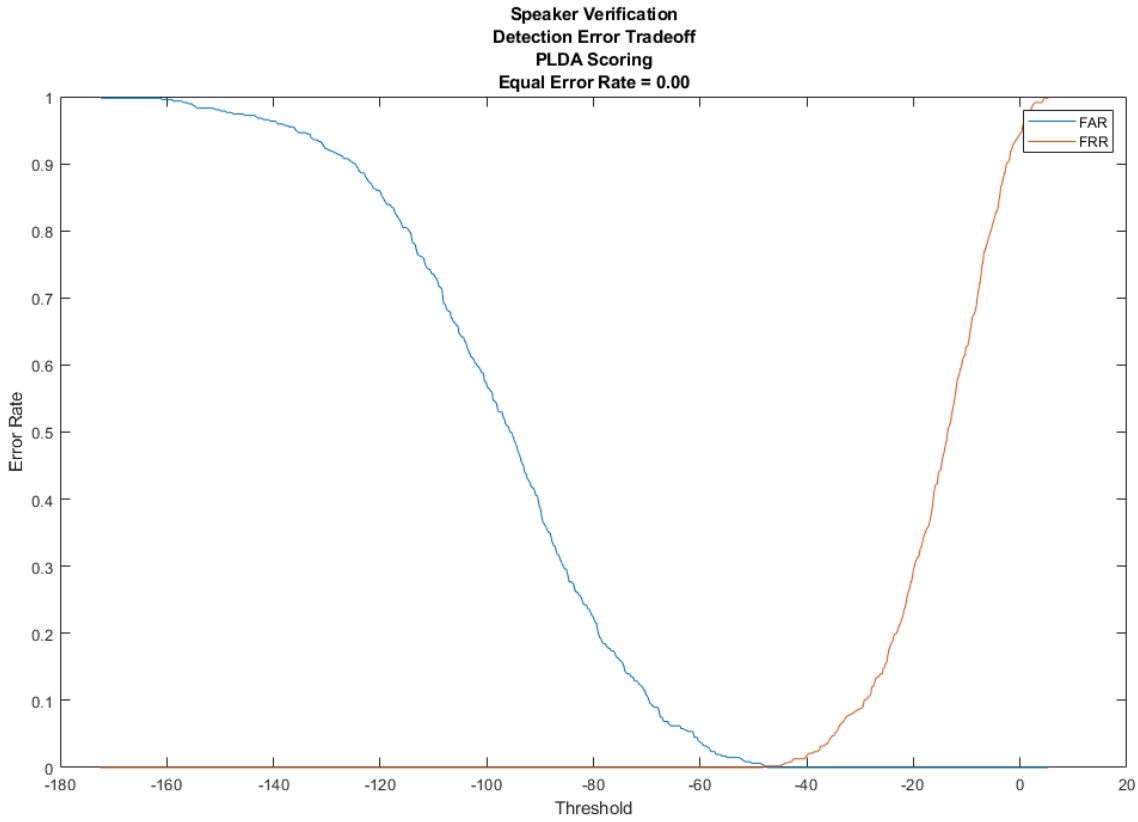
    F05     {32×1 double}        3
    M05     {32×1 double}        3
```

Speaker verification systems require you to set a threshold that balances the probability of a false acceptance (FA) and the probability of a false rejection (FR), according to the requirements of your application. To determine the threshold that meets your FA/FR requirements, evaluate the detection error tradeoff of the system.

```
xvecs = zeros(numEigenvectors,numel(adsDET.Files));
reset(adsDET)
for sample = 1:numel(adsDET.Files)
    [audioIn,xInfo] = read(adsDET);
    audioIn = resample(audioIn,desiredFs,fs);
    f = xVectorPreprocess(audioIn,afe,'Factors',factors,'MinimumDuration',minDur);
    embeddings = zeros(numFilters,numel(f));
    for segment = 1:numel(f)
        dlX = dlarray(f{segment},'SCB');
        embeddings(:,segment) = extractdata(xvecModel(dlX,parameters,state,'DoTraining',false,'Ou
    end
    xvecs(:,sample) = mean(projMat*embeddings,2);
end
labels = adsDET.Labels;
detTable = helperDetectionErrorTradeoff(xvecs,labels,enrolledLabels,plda);
```

Plot the results of the detection error tradeoff evaluation for both PLDA scoring and cosine similarity scoring (CSS).

```
plot(detTable.PLDA.Threshold,detTable.PLDA.FAR, ...
    detTable.PLDA.Threshold,detTable.PLDA.FRR)
eer = helperEqualErrorRate(detTable.PLDA);
title(sprintf('Speaker Verification\nDetection Error Tradeoff\nPLDA Scoring\nEqual Error Rate = %
xlabel('Threshold')
ylabel('Error Rate')
legend({'FAR','FRR'})
```



```
plot(detTable.CSS.Threshold,detTable.CSS.FAR, ...
    detTable.CSS.Threshold,detTable.CSS.FRR)
eer = helperEqualErrorRate(detTable.CSS);
title(sprintf('Speaker Verification\nDetection Error Tradeoff\nCosine Similarity Scoring\nEqual
xlabel('Threshold')
ylabel('Error Rate')
legend({'FAR','FRR'})
```

state.batchnorm8.TrainedMean      = zeros(numOut8,1,'single');
state.batchnorm8.TrainedVariance = ones(numOut8,1,'single');

% Initialize Layer 9 (Fully Connected)
numIn9                            = numOut8;
numOut9                           = numClasses;

parameters.fc9.Weights            = initializeGlorot([numOut9,numIn9],numOut9,numIn9);
parameters.fc9.Bias               = dlarray(zeros([numOut9,1],'single'));
end
```

Initialize Weights Using Glorot Initialization

```
function weights = initializeGlorot(sz,numOut,numIn)
% This function is only for use in this example. It may be changed or
% removed in a future release.
Z = 2*rand(sz,'single') - 1;
bound = sqrt(6 / (numIn + numOut));
weights = bound*Z;
```

```
weights = dlarray(weights);
end
```

Calculate Model Gradients and Updated State

```
function [gradients,state,loss,Y] = modelGradients(X,target,parameters,state)
% This function is only for use in this example. It may be changed or
% removed in a future release.
[Y,state] = xvecModel(X,parameters,state,'DoTraining',true);
loss = crossentropy(Y,target);
gradients = dlgradient(loss,parameters);
end
```

Preprocess Mini-Batch

```
function [sequences,labels] = preprocessMiniBatch(sequences,labels)
% This function is only for use in this example. It may be changed or
% removed in a future release.
lengths = cellfun(@(x)size(x,1),sequences);
minLength = min(lengths);
sequences = cellfun(@(x)randomTruncate(x,1,minLength),sequences,'UniformOutput',false);
sequences = cat(3,sequences{:});

labels = cat(2,labels{:});
labels = onehotencode(labels,1);
labels(isnan(labels)) = 0;
end
```

Randomly Truncate Audio Signals to Specified Length

```
function y = randomTruncate(x,dim,minLength)
% This function is only for use in this example. It may be changed or
% removed in a future release.
N = size(x,dim);
if N > minLength
    start = randperm(N-minLength,1);
    if dim==1
        y = x(start:start+minLength-1,:);
    elseif dim ==2
        y = x(:,start:start+minLength-1);
    end
else
    y = x;
end
end
```

Feature Extraction and Normalization - Datastore

```
function [features,labels] = xVectorPreprocessBatch(ads,afe,nvargs)
% This function is only for use in this example. It may be changed or
% removed in a future release.
    arguments

Speaker Diarization Using x-vectors

Speaker diarization is the process of partitioning an audio signal into segments according to speaker identity. It answers the question "who spoke when" without prior knowledge of the speakers and, depending on the application, without prior knowledge of the number of speakers.

Speaker diarization has many applications, including: enhancing speech transcription by structuring text according to active speaker, video captioning, content retrieval (*what did Jane say?*) and speaker counting (*how many speakers were present in the meeting?*).

In this example, you perform speaker diarization using a pretrained x-vector system [1] on page 14-0 to characterize regions of audio and agglomerative hierarchical clustering (AHC) to group similar regions of audio [2] on page 14-0 . To see how the x-vector system was defined and trained, see Speaker Recognition Using x-vectors.

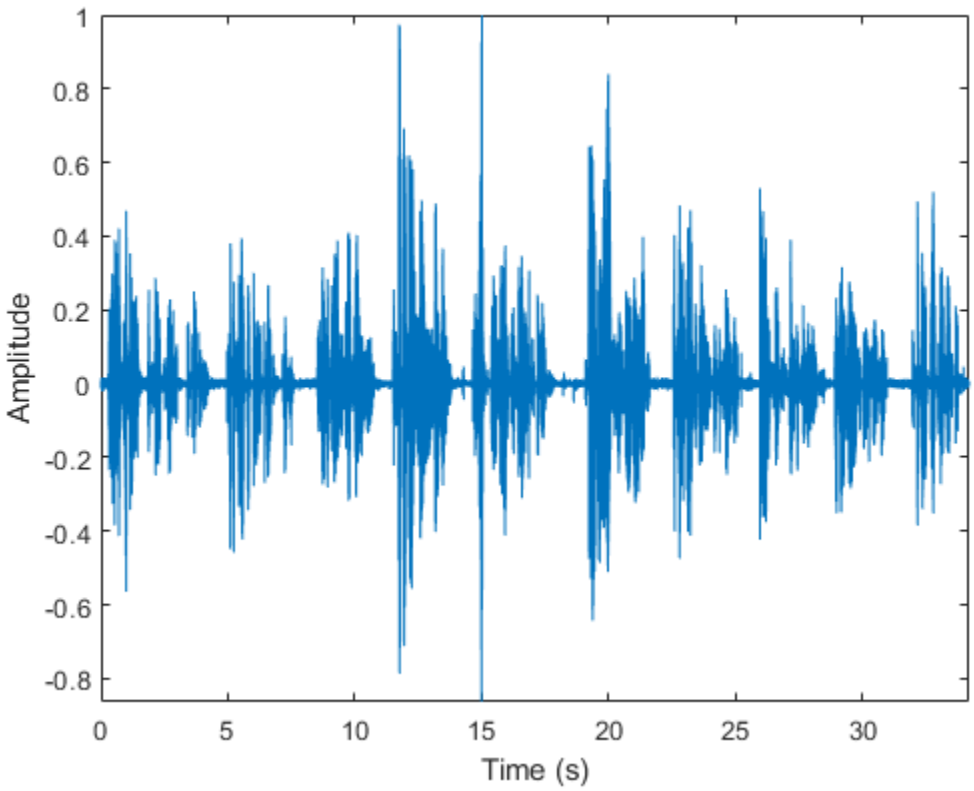
Load Audio Signal

Load an audio signal and a table containing ground truth annotations. The signal consists of five speakers. Listen to the audio signal and plot its time-domain waveform.

```
[audioIn,fs] = audioread('exampleconversation.flac');
load('exampleconversationlabels.mat')
audioIn = audioIn./max(abs(audioIn));
sound(audioIn,fs)

t = (0:size(audioIn,1)-1)/fs;

figure(1)
plot(t,audioIn)
xlabel('Time (s)')
ylabel('Amplitude')
axis tight
```



Extract x-vectors

In this example, you used a pretrained x-vector system. The x-vector system is a lightweight version of the original x-vector system described in [1] on page 14-0 . To see how the x-vector system was defined and trained, see Speaker Recognition Using x-vectors.

Load Pretrained x-Vector System

Load the lightweight pretrained x-vector system. The x-vector system consists of:

- `afe` - an `audioFeatureExtractor` (Audio Toolbox) object to extract mel frequency cepstral coefficients (MFCCs).
- `factors` - a struct containing the mean and standard deviation of MFCCs determined from a representative data set. These factors are used to standardize the MFCCs.
- `extractor` - a struct containing the parameters and state of the neural network trained to extract x-vectors. The `xvecModel` function performs the actual x-vector extraction. The `xvecModel` function is placed in your current folder when you open this example.
- `classifier` - a struct containing a trained projection matrix to reduce the dimensionality of x-vectors and a trained PLDA model for scoring x-vectors.

```
load('xvectorSystem.mat')
```

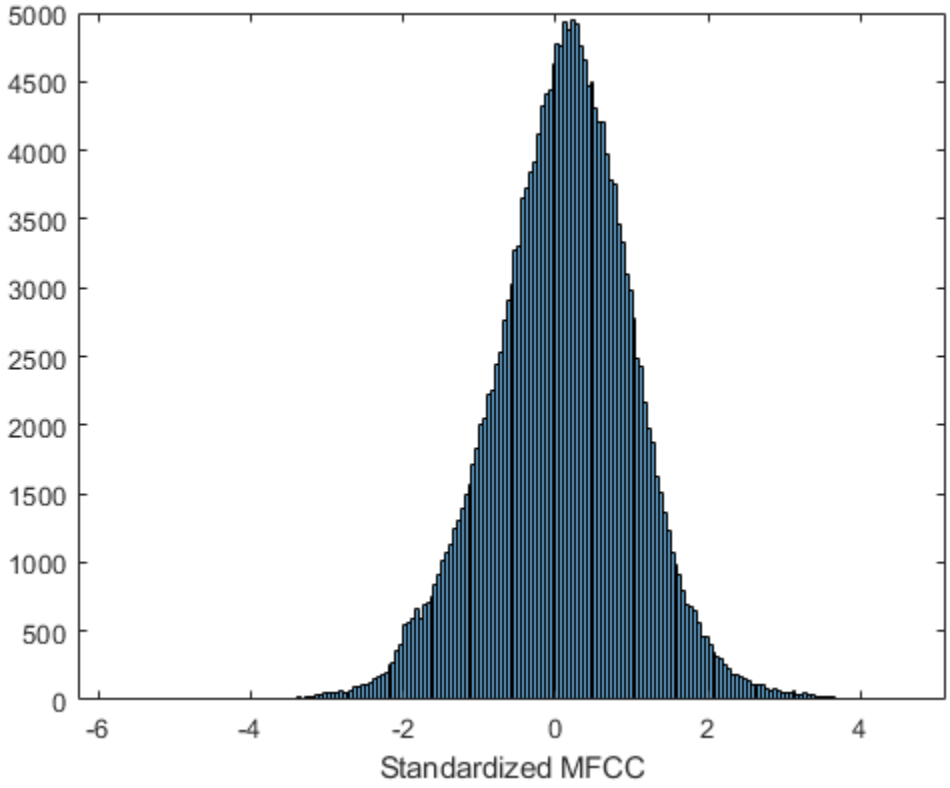
Extract Standardized Acoustic Features

Extract standardized MFCC features from the audio data. View the feature distributions to confirm that the standardization factors learned from a separate data set approximately standardize the

features derived in this example. A standard distribution has a mean of zero and a standard deviation of 1.

```
features = single((extract(afe,audioIn)-factors.Mean)./factors.STD);

figure(2)
histogram(features)
xlabel('Standardized MFCC')
```



Extract x-Vectors

Each acoustic feature vector represents approximately 0.01 seconds of audio data. Group the features into approximately 2 second segments with 0.1 second hops between segments.

```
featureVectorHopDur = (numel(afe.Window) - afe.OverlapLength)/afe.SampleRate;

segmentDur = 2 ;
segmentHopDur = 0.1 ;

segmentLength = round(segmentDur/featureVectorHopDur);
segmentHop = round(segmentHopDur/featureVectorHopDur);

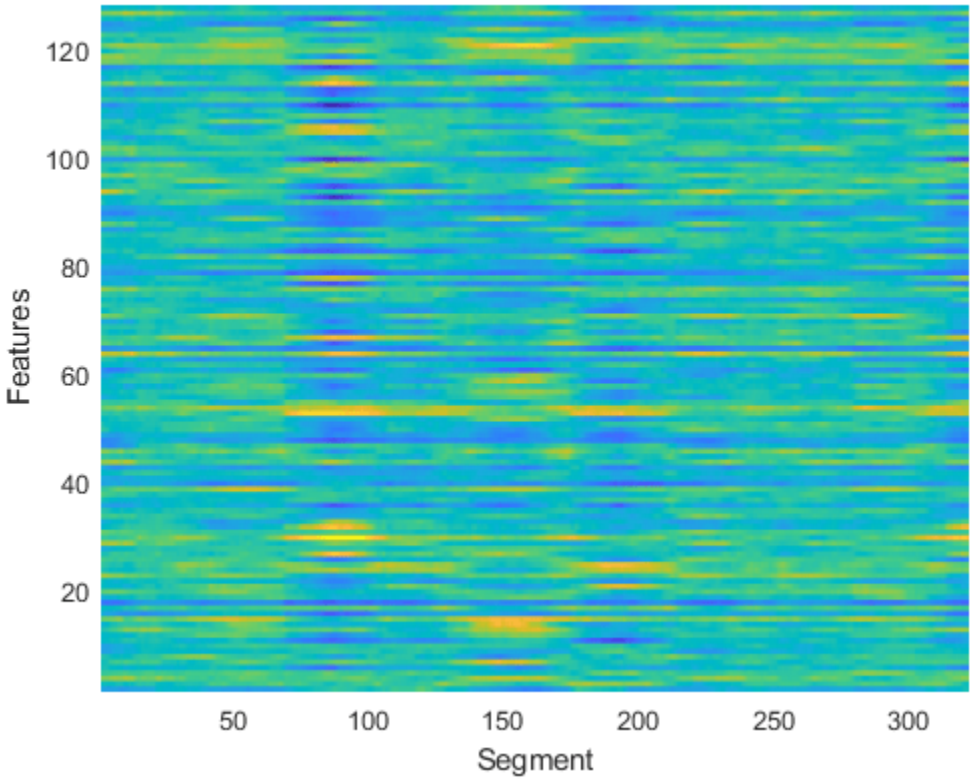
idx = 1:segmentLength;
featuresSegmented = [];
while idx(end) < size(features,1)
    featuresSegmented = cat(3,featuresSegmented,features(idx,:));
```

```
    idx = idx + segmentHop;
end
```

Extract x-vectors from each segment. x-vectors correspond to the output from the 7th layer in the x-vector model trained in Speaker Recognition Using x-vectors. The 7th layer is the first segment-level layer after statistics are calculated for the time-dilated frame-level layers. Visualize the x-vectors over time.

```
outputLayer = 7;
xvecs = zeros(numel(extractor.Parameters.("fc"+outputLayer).Bias),size(featuresSegmented,3));
for sample = 1:size(featuresSegmented,3)
    dlX = dlarray(featuresSegmented(:,:,sample),'SCB');
    xvecs(:,sample) = extractdata(xvecModel(dlX,extractor.Parameters,extractor.State,'DoTraining
end

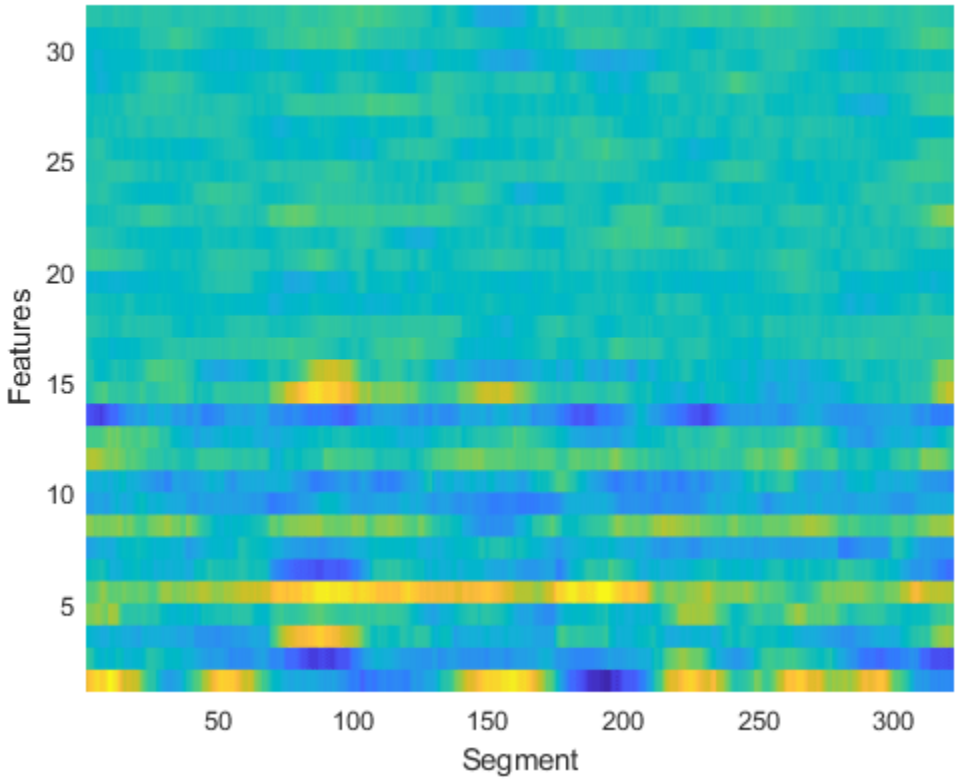
figure(3)
surf(xvecs','EdgeColor','none')
view([90,-90])
axis([1 size(xvecs,1) 1 size(xvecs,2)])
xlabel('Features')
ylabel('Segment')
```



Apply the pretrained linear discriminant analysis (LDA) projection matrix to reduce the dimensionality of the x-vectors and then visualize the x-vectors over time.

```
x = classifier.projMat*xvecs;
```

```
figure(4)
surf(x','EdgeColor','none')
view([90,-90])
axis([1 size(x,1) 1 size(x,2)])
xlabel('Features')
ylabel('Segment')
```



Cluster x-vectors

An x-vector system learns to extract compact representations (x-vectors) of speakers. Cluster the x-vectors to group similar regions of audio using either agglomerative hierarchical clustering (`clusterdata` (Statistics and Machine Learning Toolbox)) or k-means clustering (`kmeans` (Statistics and Machine Learning Toolbox)). [2] on page 14-0 suggests using agglomerative heirarchical clustering with PLDA scoring as the distance measurement. K-means clustering using a cosine similarity score is also commonly used. Assume prior knowledge of the the number of speakers in the audio. Set the maximum clusters to the number of known speakers + 1 so that the background is clustered independently.

```
knownNumberOfSpeakers = numel(unique(groundTruth.Label));
maxclusters = knownNumberOfSpeakers + 1;

clusterMethod = 'agglomerative - PL...';
switch clusterMethod
    case 'agglomerative - PLDA scoring'
        T = clusterdata(x','Criterion','distance','distance',@(a,b)helperPLDAScorer(a,b,classifie
    case 'agglomerative - CSS scoring'
        T = clusterdata(x','Criterion','distance','distance','cosine','linkage','average','maxclu
```

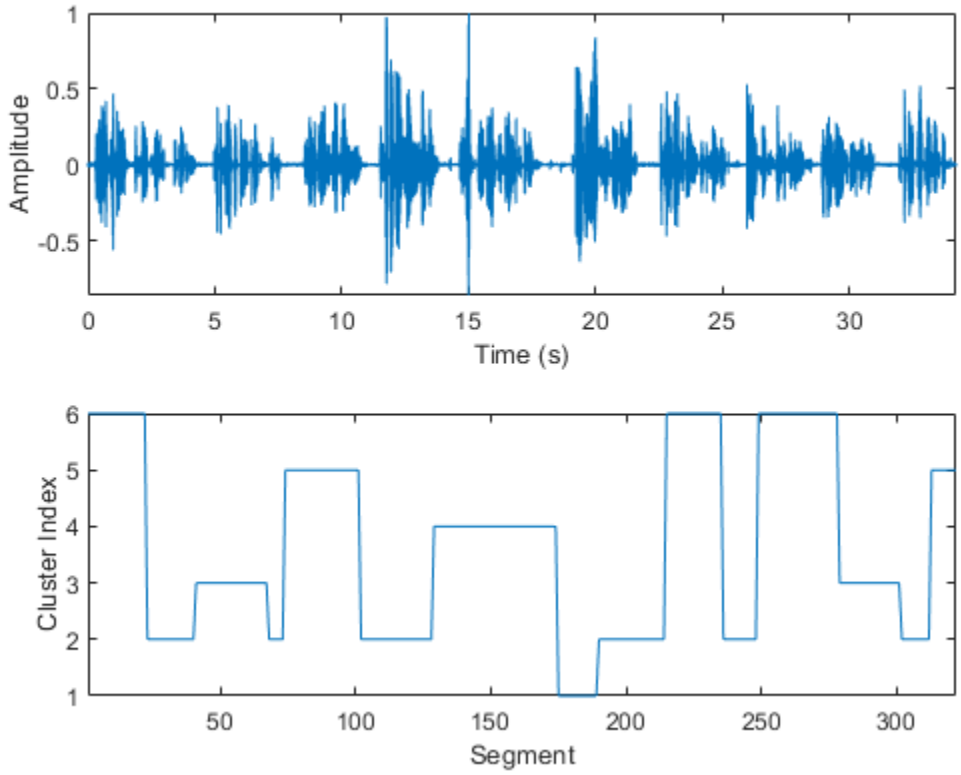
```
    case 'kmeans - CSS scoring'
        T = kmeans(x',maxclusters,'Distance','cosine');
end
```

Plot the cluster decisions over time.

```
figure(5)
tiledlayout(2,1)

nexttile
plot(t,audioIn)
axis tight
ylabel('Amplitude')
xlabel('Time (s)')

nexttile
plot(T)
axis tight
ylabel('Cluster Index')
xlabel('Segment')
```



To isolate segments of speech corresponding to clusters, map the segments back to audio samples. Plot the results.

```
mask = zeros(size(audioIn,1),1);
start = round((segmentDur/2)*fs);

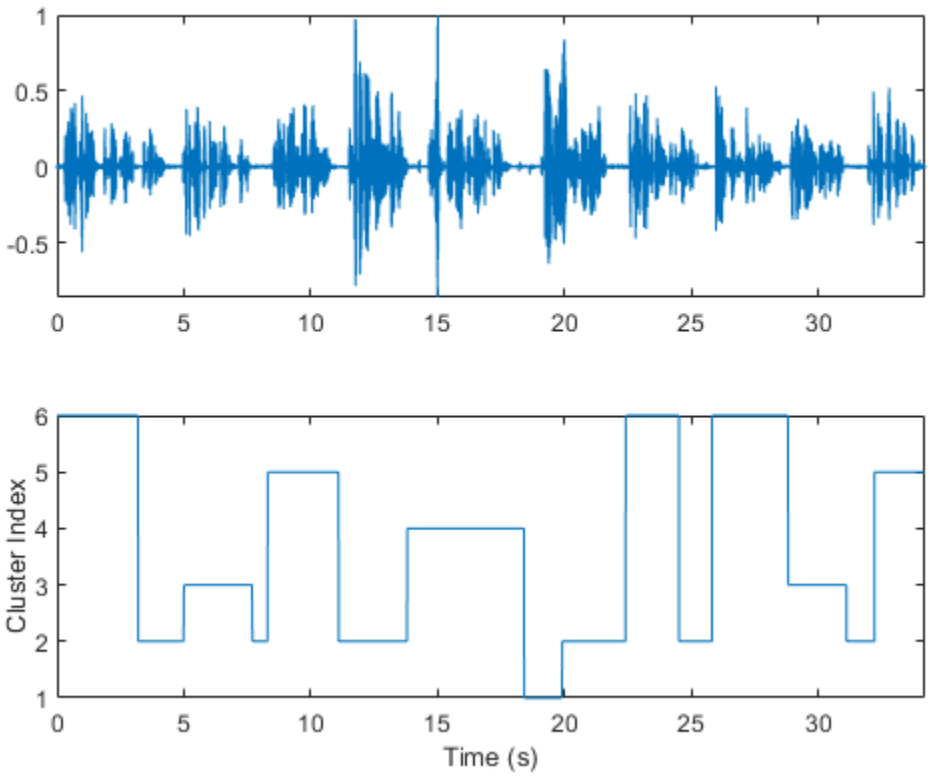
segmentHopSamples = round(segmentHopDur*fs);
```

```
mask(1:start) = T(1);
start = start + 1;
for ii = 1:numel(T)
    finish = start + segmentHopSamples;
    mask(start:start + segmentHopSamples) = T(ii);
    start = finish + 1;
end
mask(finish:end) = T(end);

figure(6)
tiledlayout(2,1)

nexttile
plot(t,audioIn)
axis tight

nexttile
plot(t,mask)
ylabel('Cluster Index')
axis tight
xlabel('Time (s)')
```

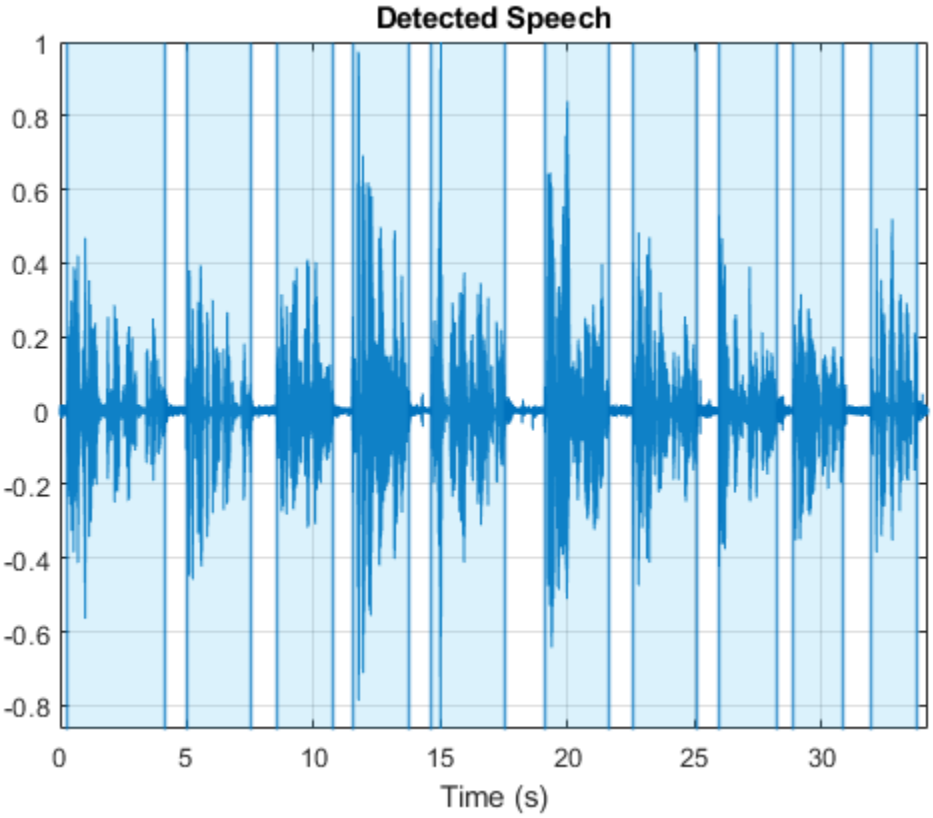


Use `detectSpeech` (Audio Toolbox) to determine speech regions. Use `sigroi2binmask` (Signal Processing Toolbox) to convert speech regions to a binary voice activity detection (VAD) mask. Call `detectSpeech` a second time without any arguments to plot the detected speech regions.

```
mergeDuration = 0.5;
VADidx = detectSpeech(audioIn,fs,'MergeDistance',fs*mergeDuration);

VADmask = sigroi2binmask(VADidx,numel(audioIn));

figure(7)
detectSpeech(audioIn,fs,'MergeDistance',fs*mergeDuration)
```



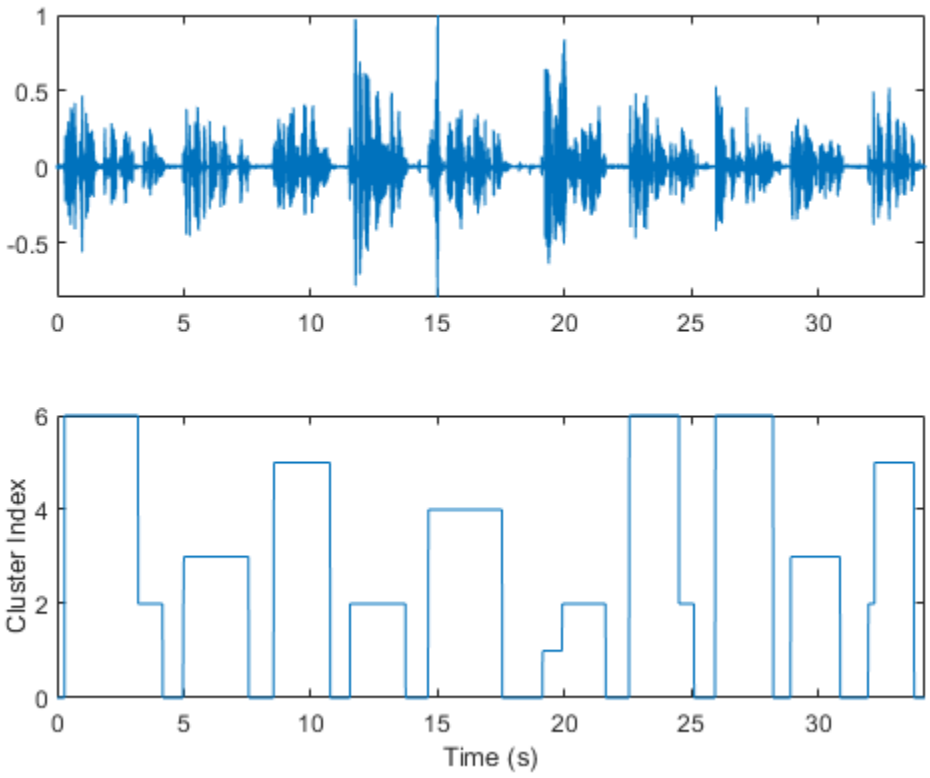
Apply the VAD mask to the speaker mask and plot the results. A cluster index of 0 indicates a region of no speech.

```
mask = mask.*VADmask;

figure(8)
tiledlayout(2,1)

nexttile
plot(t,audioIn)
axis tight

nexttile
plot(t,mask)
ylabel('Cluster Index')
axis tight
xlabel('Time (s)')
```



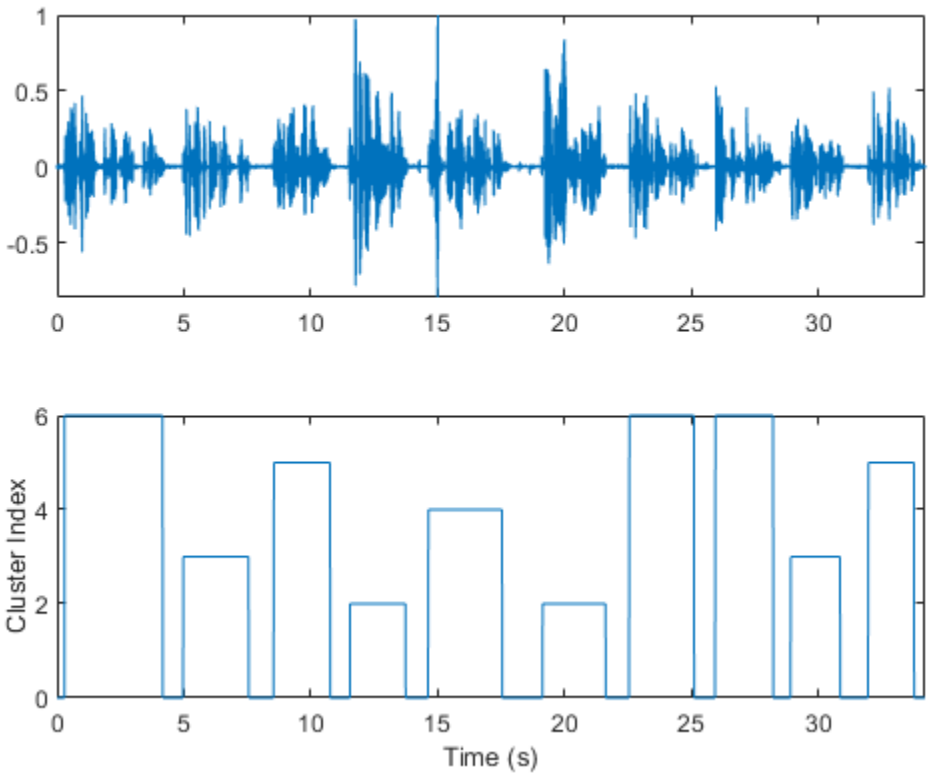
In this example, you assume each detected speech region belongs to a single speaker. If more than two labels are present in a speech region, merge them to the most frequently occuring label.

```
maskLabels = zeros(size(VADidx,1),1);
for ii = 1:size(VADidx,1)
    maskLabels(ii) = mode(mask(VADidx(ii,1):VADidx(ii,2)),'all');
    mask(VADidx(ii,1):VADidx(ii,2)) = maskLabels(ii);
end

figure(9)
tiledlayout(2,1)

nexttile
plot(t,audioIn)
axis tight

nexttile
plot(t,mask)
ylabel('Cluster Index')
axis tight
xlabel('Time (s)')
```



Count the number of remaining speaker clusters.

```
uniqueSpeakerClusters = unique(maskLabels);
numSpeakers = numel(uniqueSpeakerClusters)
```

```
numSpeakers = 5
```

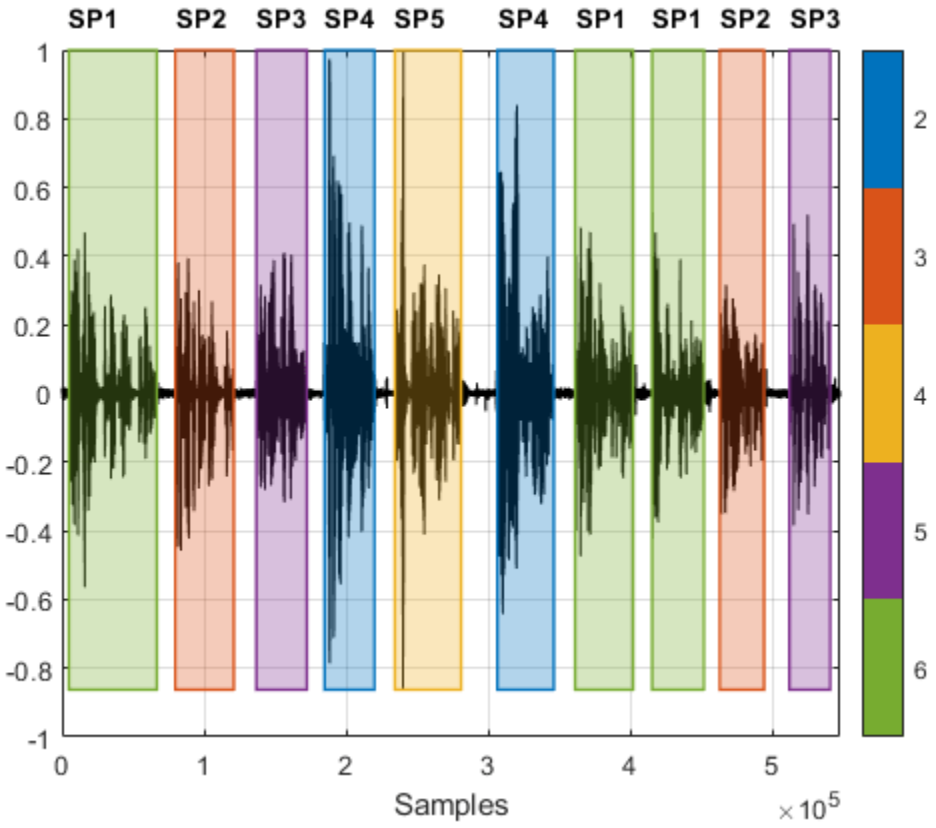
Visualize Diarization Results

Create a `signalMask` (Signal Processing Toolbox) object and then plot the speaker clusters. Label the plot with the ground truth labels. The cluster labels are color coded with a key on the right of the plot. The true labels are printed above the plot.

```
msk = signalMask(table(VADidx,categorical(maskLabels)));

figure(10)
plotsigroi(msk,audioIn,true)
axis([0 numel(audioIn) -1 1])

trueLabel = groundTruth.Label;
for ii = 1:numel(trueLabel)
    text(VADidx(ii,1),1.1,trueLabel(ii),'FontWeight','bold')
end
```



Choose a cluster to inspect and then use `binmask` (Signal Processing Toolbox) to isolate the speaker. Plot the isolated speech signal and listen to the speaker cluster.

```
speakerToInspect = 2;
cutOutSilenceFromAudio = true;

bmsk = binmask(msk,numel(audioIn));

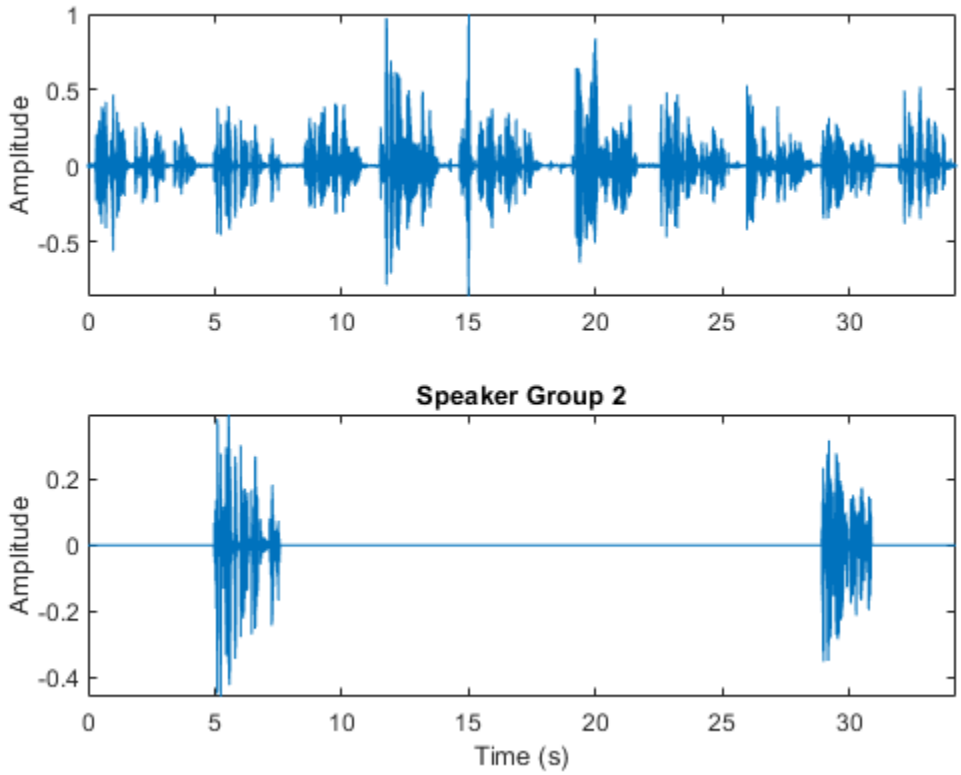
audioToPlay = audioIn;
if cutOutSilenceFromAudio
    audioToPlay(~bmsk(:,speakerToInspect)) = [];
end
sound(audioToPlay,fs)

figure(11)
tiledlayout(2,1)

nexttile
plot(t,audioIn)
axis tight
ylabel('Amplitude')

nexttile
plot(t,audioIn.*bmsk(:,speakerToInspect))
axis tight
xlabel('Time (s)')
```

```
ylabel('Amplitude')
title("Speaker Group "+speakerToInspect)
```



Diarization System Evaluation

The common metric for speaker diarization systems is the diarization error rate (DER). The DER is the sum of the miss rate (classifying speech as non-speech), the false alarm rate (classifying non-speech as speech) and the speaker error rate (confusing one speaker's speech for another).

In this simple example, the miss rate and false alarm rate are trivial problems. You evaluate the speaker error rate only.

Map each true speaker to the corresponding best-fitting speaker cluster. To determine the speaker error rate, count the number of mismatches between the true speakers and the best-fitting speaker clusters, and then divide by the number of true speaker regions.

```
uniqueLabels = unique(trueLabel);
guessLabels = maskLabels;
uniqueGuessLabels = unique(guessLabels);

totalNumErrors = 0;
for ii = 1:numel(uniqueLabels)
    isSpeaker = uniqueLabels(ii)==trueLabel;
    minNumErrors = inf;

    for jj = 1:numel(uniqueGuessLabels)
        groupCandidate = uniqueGuessLabels(jj) == guessLabels;
```

```
        numErrors = nnz(isSpeaker-groupCandidate);
        if numErrors < minNumErrors
            minNumErrors = numErrors;
            bestCandidate = jj;
        end
        minNumErrors = min(minNumErrors,numErrors);
    end
    uniqueGuessLabels(bestCandidate) = [];
    totalNumErrors = totalNumErrors + minNumErrors;
end
SpeakerErrorRate = totalNumErrors/numel(trueLabel)
```

```
SpeakerErrorRate = 0
```

Train Spoken Digit Recognition Network Using Out-of-Memory Audio Data

This example trains a spoken digit recognition network on out-of-memory audio data using a transformed datastore. In this example, you apply a random pitch shift to audio data used to train a convolutional neural network (CNN). For each training iteration, the audio data is augmented using the audioDataAugmenter object and then features are extracted using the audioFeatureExtractor object. The workflow in this example applies to any random data augmentation used in a training loop. The workflow also applies when the underlying audio data set or training features do not fit in memory.

Data

Download the Free Spoken Digit Data Set (FSDD). FSDD consists of 2000 recordings of four speakers saying the numbers 0 through 9 in English.

```
url = 'https://ssd.mathworks.com/supportfiles/audio/FSDD.zip';

downloadFolder = tempdir;
datasetFolder = fullfile(downloadFolder,'FSDD');

if ~exist(datasetFolder,'dir')
    disp('Downloading FSDD...')
    unzip(url,downloadFolder)
end
```

Create an `audioDatastore` that points to the dataset.

```
pathToRecordingsFolder = fullfile(datasetFolder,'recordings');
location = pathToRecordingsFolder;
ads = audioDatastore(location);
```

The helper function, `helperGenerateLabels`, creates a categorical array of labels from the FSDD files. The source code for `helpergenLabels` is listed in the appendix. Display the classes and the number of examples in each class.

```
ads.Labels = helpergenLabels(ads);
```

```
Starting parallel pool (parpool) using the 'local' profile ...
Connected to the parallel pool (number of workers: 8).
```

```
summary(ads.Labels)
```

```
     0      200
     1      200
     2      200
     3      200
     4      200
     5      200
     6      200
     7      200
     8      200
     9      200
```

Split the FSDD into training and test sets. Allocate 80% of the data to the training set and retain 20% for the test set. You use the training set to train the model and the test set to validate the trained model.

```
rng default
ads = shuffle(ads);
[adsTrain,adsTest] = splitEachLabel(ads,0.8);
countEachLabel(adsTrain)
```

```
ans=10×2 table
    Label    Count
    _____    _____

      0       160
      1       160
      2       160
      3       160
      4       160
      5       160
      6       160
      7       160
      8       160
      9       160
```

```
countEachLabel(adsTest)
```

```
ans=10×2 table
    Label    Count
    _____    _____

      0       40
      1       40
      2       40
      3       40
      4       40
      5       40
      6       40
      7       40
      8       40
      9       40
```

Reduce Training Dataset

To train the network with the entire dataset and achieve the highest possible accuracy, set `reduceDataset` to false. To run this example quickly, set `reduceDataset` to true.

```
reduceDataset = false;
if reduceDataset == "true"
    adsTrain = splitEachLabel(adsTrain,2);
    adsTest = splitEachLabel(adsTest,2);
end
```

Transformed Training Datastore

Data Augmentation

Augment the training data by applying pitch shifting with an `audioDataAugmenter` object.

Create an `audioDataAugmenter`. The augmenter applies pitch shifting on an input audio signal with a 0.5 probability. The augmenter selects a random pitch shifting value in the range [-12 12] semitones.

```
augmenter = audioDataAugmenter('PitchShiftProbability',.5, ...
                               'SemitoneShiftRange',[-12 12], ...
                               'TimeShiftProbability',0, ...
                               'VolumeControlProbability',0, ...
                               'AddNoiseProbability',0, ...
                               'TimeShiftProbability',0);
```

Set custom pitch-shifting parameters. Use identity phase locking and preserve formants using spectral envelope estimation with 30th order cepstral analysis.

```
setAugmenterParams(augmenter,'shiftPitch','LockPhase',true,'PreserveFormants',true,'CepstralOrde
```

Create a transformed datastore that applies data augmentation to the training data.

```
fs = 8000;
adsAugTrain = transform(adsTrain,@(y)deal(augment(augmenter,y,fs).Audio{1}));
```

Mel Spectrogram Feature Extraction

The CNN accepts mel-frequency spectrograms.

Define parameters used to extract mel-frequency spectrograms. Use 220 ms windows with 10 ms hops between windows. Use a 2048-point DFT and 40 frequency bands.

```
frameDuration = 0.22;
hopDuration = 0.01;
params.segmentLength = 8192;
segmentDuration = params.segmentLength*(1/fs);
params.numHops = ceil((segmentDuration-frameDuration)/hopDuration);
params.numBands = 40;
frameLength = round(frameDuration*fs);
hopLength = round(hopDuration*fs);
fftLength = 2048;
```

Create an `audioFeatureExtractor` object to compute mel-frequency spectrograms from input audio signals.

```
afe = audioFeatureExtractor('melSpectrum',true,'SampleRate',fs);
afe.Window = hamming(frameLength,'periodic');
afe.OverlapLength = frameLength-hopLength;
afe.FFTLength = fftLength;
```

Set the parameters for the mel-frequency spectrogram.

```
setExtractorParams(afe,'melSpectrum','NumBands',params.numBands,'FrequencyRange',[50 fs/2],'Windo
```

Create a transformed datastore that computes mel-frequency spectrograms from pitch-shifted audio data. The helper function, `getSpeechSpectrogram` (see appendix), standardizes the recording length and normalizes the amplitude of the audio input. `getSpeechSpectrogram` uses the `audioFeatureExtractor` object (afe) to obtain the log-based mel-frequency spectrograms.

```
adsSpecTrain = transform(adsAugTrain, @(x)getSpeechSpectrogram(x,afe,params));
```

Training Labels

Use an `arrayDatastore` to hold the training labels.

```
labelsTrain = arrayDatastore(adsTrain.Labels);
```

Combined Training Datastore

Create a combined datastore that points to the mel-frequency spectrogram data and the corresponding labels.

```
tdsTrain = combine(adsSpecTrain,labelsTrain);
```

Validation Data

The validation dataset fits into memory and you precompute validation features using the helper function `getValidationSpeechSpectrograms` (see appendix).

```
XTest = getValidationSpeechSpectrograms(adsTest,afe,params);
```

Get the validation labels.

```
YTest = adsTest.Labels;
```

Define CNN Architecture

Construct a small CNN as an array of layers. Use convolutional and batch normalization layers, and downsample the feature maps using max pooling layers. To reduce the possibility of the network memorizing specific features of the training data, add a small amount of dropout to the input to the last fully connected layer.

```
sz = size(XTest);
specSize = sz(1:2);
imageSize = [specSize 1];

numClasses = numel(categories(YTest));

dropoutProb = 0.2;
numF = 12;
layers = [
    imageInputLayer(imageSize,'Normalization','none')

    convolution2dLayer(5,numF,'Padding','same')
    batchNormalizationLayer
    reluLayer

    maxPooling2dLayer(3,'Stride',2,'Padding','same')

    convolution2dLayer(3,2*numF,'Padding','same')
    batchNormalizationLayer
    reluLayer

    maxPooling2dLayer(3,'Stride',2,'Padding','same')

    convolution2dLayer(3,4*numF,'Padding','same')
    batchNormalizationLayer
    reluLayer
```

```
    maxPooling2dLayer(3,'Stride',2,'Padding','same')

    convolution2dLayer(3,4*numF,'Padding','same')
    batchNormalizationLayer
    reluLayer
    convolution2dLayer(3,4*numF,'Padding','same')
    batchNormalizationLayer
    reluLayer

    maxPooling2dLayer(2)

    dropoutLayer(dropoutProb)
    fullyConnectedLayer(numClasses)
    softmaxLayer
    classificationLayer('Classes',categories(YTest));
    ];
```

Set the hyperparameters to use in training the network. Use a mini-batch size of 50 and a learning rate of 1e-4. Specify 'adam' optimization. To use the parallel pool to read the transformed datastore, set `DispatchInBackground` to `true`. For more information, see `trainingOptions`.

```
miniBatchSize = 50;
options = trainingOptions('adam', ...
    'InitialLearnRate',1e-4, ...
    'MaxEpochs',30, ...
    'LearnRateSchedule',"piecewise",...
    'LearnRateDropFactor',.1,...
    'LearnRateDropPeriod',15,...
    'MiniBatchSize',miniBatchSize, ...
    'Shuffle','every-epoch', ...
    'Plots','training-progress', ...
    'Verbose',false, ...
    'ValidationData',{XTest, YTest},...
    'ValidationFrequency',ceil(numel(adsTrain.Files)/miniBatchSize),...
    'ExecutionEnvironment','gpu',...
    'DispatchInBackground', true);
```

Train the network by passing the transformed training datastore to `trainNetwork`.

```
trainedNet = trainNetwork(tdsTrain,layers,options);
```

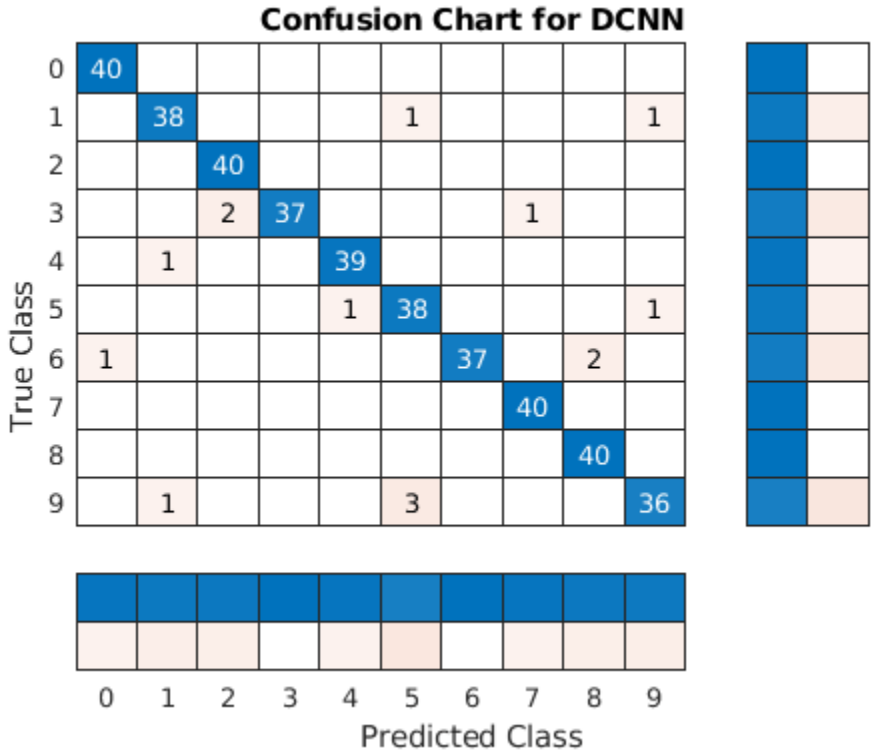
Use the trained network to predict the digit labels for the test set.

```
[Ypredicted,probs] = classify(trainedNet,XTest);
cnnAccuracy = sum(Ypredicted==YTest)/numel(YTest)*100
```

```
cnnAccuracy = 96.2500
```

Summarize the performance of the trained network on the test set with a confusion chart. Display the precision and recall for each class by using column and row summaries. The table at the bottom of the confusion chart shows the precision values. The table to the right of the confusion chart shows the recall values.

```
figure('Units','normalized','Position',[0.2 0.2 0.5 0.5]);
ccDCNN = confusionchart(YTest,Ypredicted);
ccDCNN.Title = 'Confusion Chart for DCNN';
ccDCNN.ColumnSummary = 'column-normalized';
ccDCNN.RowSummary = 'row-normalized';
```



Appendix: Helper Functions

```
function Labels = helpergenLabels(ads)
% This function is only for use in this example. It may be changed or
% removed in a future release.
files = ads.Files;
tmp = cell(numel(files),1);
expression = "[0-9]+_";
parfor nf = 1:numel(ads.Files)
    idx = regexp(files{nf},expression);
    tmp{nf} = files{nf}(idx);
end
Labels = categorical(tmp);
end

%-----------------------------------------------------------
function X = getValidationSpeechSpectrograms(ads,afe,params)
% This function is only for use in this example. It may changed or be
% removed in a future release.
%
% getValidationSpeechSpectrograms(ads,afe) computes speech spectrograms for
% the files in the datastore ads using the audioFeatureExtractor afe.

numFiles = length(ads.Files);
X = zeros([params.numBands,params.numHops,1,numFiles],'single');

for i = 1:numFiles
    x = read(ads);
    spec = getSpeechSpectrogram(x,afe,params);
    X(:,:,1,i) = spec;
```

```
end

end

%--------------------------------------------------------------------------
function X = getSpeechSpectrogram(x,afe,params)
% This function is only for use in this example. It may changed or be
% removed in a future release.
%
% getSpeechSpectrogram(x,afe) computes a speech spectrogram for the signal
% x using the audioFeatureExtractor afe.

X = zeros([params.numBands,params.numHops],'single');

x = normalizeAndResize(single(x),params);

spec = extract(afe,x).';

% If the spectrogram is less wide than numHops, then put spectrogram in
% the middle of X.
w = size(spec,2);
left = floor((params.numHops-w)/2)+1;
ind = left:left+w-1;
X(:,ind) = log10(spec + 1e-6);

end
%--------------------------------------------------------------------------
function x = normalizeAndResize(x,params)
% This function is only for use in this example. It may change or be
% removed in a future release.

L = params.segmentLength;
N = numel(x);
if N > L
    x = x(1:L);
elseif N < L
    pad = L-N;
    prepad = floor(pad/2);
    postpad = ceil(pad/2);
    x = [zeros(prepad,1) ; x ; zeros(postpad,1)];
end
x = x./max(abs(x));
end
```

Train Spoken Digit Recognition Network Using Out-of-Memory Features

This example trains a spoken digit recognition network on out-of-memory auditory spectrograms using a transformed datastore. In this example, you extract auditory spectrograms from audio using `audioDatastore` and `audioFeatureExtractor`, and you write them to disk. You then use a `signalDatastore` to access the features during training. The workflow is useful when the training features do not fit in memory. In this workflow, you only extract features once, which speeds up your workflow if you are iterating on the deep learning model design.

Data

Download the Free Spoken Digit Data Set (FSDD). FSDD consists of 2000 recordings of four speakers saying the numbers 0 through 9 in English.

```
url = 'https://ssd.mathworks.com/supportfiles/audio/FSDD.zip';

downloadFolder = tempdir;
datasetFolder = fullfile(downloadFolder,'FSDD');

if ~exist(datasetFolder,'dir')
    disp('Downloading FSDD...')
    unzip(url,downloadFolder)
end
```

Create an `audioDatastore` that points to the dataset.

```
pathToRecordingsFolder = fullfile(datasetFolder,'recordings');
location = pathToRecordingsFolder;
ads = audioDatastore(location);
```

The helper function, `helperGenerateLabels`, creates a categorical array of labels from the FSDD files. The source code for `helperGenerateLabels` is listed in the appendix. Display the classes and the number of examples in each class.

```
ads.Labels = helperGenerateLabels(ads);
```

```
Starting parallel pool (parpool) using the 'local' profile ...
Connected to the parallel pool (number of workers: 8).
```

```
summary(ads.Labels)
```

```
     0      200
     1      200
     2      200
     3      200
     4      200
     5      200
     6      200
     7      200
     8      200
     9      200
```

Split the FSDD into training and test sets. Allocate 80% of the data to the training set and retain 20% for the test set. You use the training set to train the model and the test set to validate the trained model.

```
rng default
ads = shuffle(ads);
[adsTrain,adsTest] = splitEachLabel(ads,0.8);
countEachLabel(adsTrain)
```

```
ans=10×2 table
    Label    Count
    _____    _____

      0       160
      1       160
      2       160
      3       160
      4       160
      5       160
      6       160
      7       160
      8       160
      9       160
```

```
countEachLabel(adsTest)
```

```
ans=10×2 table
    Label    Count
    _____    _____

      0       40
      1       40
      2       40
      3       40
      4       40
      5       40
      6       40
      7       40
      8       40
      9       40
```

Reduce Training Dataset

To train the network with the entire dataset and achieve the highest possible accuracy, set `reduceDataset` to false. To run this example quickly, set `reduceDataset` to true.

```
reduceDataset = false;
if reduceDataset == "true"
    adsTrain = splitEachLabel(adsTrain,2);
    adsTest = splitEachLabel(adsTest,2);
end
```

Set up Auditory Spectrogram Extraction

The CNN accepts mel-frequency spectrograms.

Define parameters used to extract mel-frequency spectrograms. Use 220 ms windows with 10 ms hops between windows. Use a 2048-point DFT and 40 frequency bands.

```
fs = 8000;
frameDuration = 0.22;
```

```
hopDuration = 0.01;
params.segmentLength = 8192;
segmentDuration = params.segmentLength*(1/fs);
params.numHops = ceil((segmentDuration-frameDuration)/hopDuration);
params.numBands = 40;
frameLength = round(frameDuration*fs);
hopLength = round(hopDuration*fs);
fftLength = 2048;
```

Create an `audioFeatureExtractor` object to compute mel-frequency spectrograms from input audio signals.

```
afe = audioFeatureExtractor('melSpectrum',true,'SampleRate',fs);
afe.Window = hamming(frameLength,'periodic');
afe.OverlapLength = frameLength-hopLength;
afe.FFTLength = fftLength;
```

Set the parameters for the mel-frequency spectrogram.

```
setExtractorParams(afe,'melSpectrum','NumBands',params.numBands,'FrequencyRange',[50 fs/2],'Windo
```

Create a transformed datastore that computes mel-frequency spectrograms from audio data. The helper function, `getSpeechSpectrogram` (see appendix), standardizes the recording length and normalizes the amplitude of the audio input. `getSpeechSpectrogram` uses the `audioFeatureExtractor` object `afe` to obtain the log-based mel-frequency spectrograms.

```
adsSpecTrain = transform(adsTrain,@(x)getSpeechSpectrogram(x,afe,params));
```

Write Auditory Spectrograms to Disk

Use `writeall` to write auditory spectrograms to disk. Set `UseParallel` to true to perform writing in parallel.

```
writeall(adsSpecTrain,pwd,'WriteFcn',@myCustomWriter,'UseParallel',true);
```

Set up Training Signal Datastore

Create a `signalDatastore` that points to the out-of-memory features. The custom read function returns a spectrogram/label pair.

```
sds = signalDatastore('recordings','ReadFcn',@myCustomRead);
```

Validation Data

The validation dataset fits into memory and you precompute validation features using the helper function `getValidationSpeechSpectrograms` (see appendix).

```
XTest = getValidationSpeechSpectrograms(adsTest,afe,params);
```

Get the validation labels.

```
YTest = adsTest.Labels;
```

Define CNN Architecture

Construct a small CNN as an array of layers. Use convolutional and batch normalization layers, and downsample the feature maps using max pooling layers. To reduce the possibility of the network memorizing specific features of the training data, add a small amount of dropout to the input to the last fully connected layer.

```
sz = size(XTest);
specSize = sz(1:2);
imageSize = [specSize 1];

numClasses = numel(categories(YTest));

dropoutProb = 0.2;
numF = 12;
layers = [
    imageInputLayer(imageSize,'Normalization','none')

    convolution2dLayer(5,numF,'Padding','same')
    batchNormalizationLayer
    reluLayer

    maxPooling2dLayer(3,'Stride',2,'Padding','same')

    convolution2dLayer(3,2*numF,'Padding','same')
    batchNormalizationLayer
    reluLayer

    maxPooling2dLayer(3,'Stride',2,'Padding','same')

    convolution2dLayer(3,4*numF,'Padding','same')
    batchNormalizationLayer
    reluLayer

    maxPooling2dLayer(3,'Stride',2,'Padding','same')

    convolution2dLayer(3,4*numF,'Padding','same')
    batchNormalizationLayer
    reluLayer
    convolution2dLayer(3,4*numF,'Padding','same')
    batchNormalizationLayer
    reluLayer

    maxPooling2dLayer(2)

    dropoutLayer(dropoutProb)
    fullyConnectedLayer(numClasses)
    softmaxLayer
    classificationLayer('Classes',categories(YTest));
    ];
```

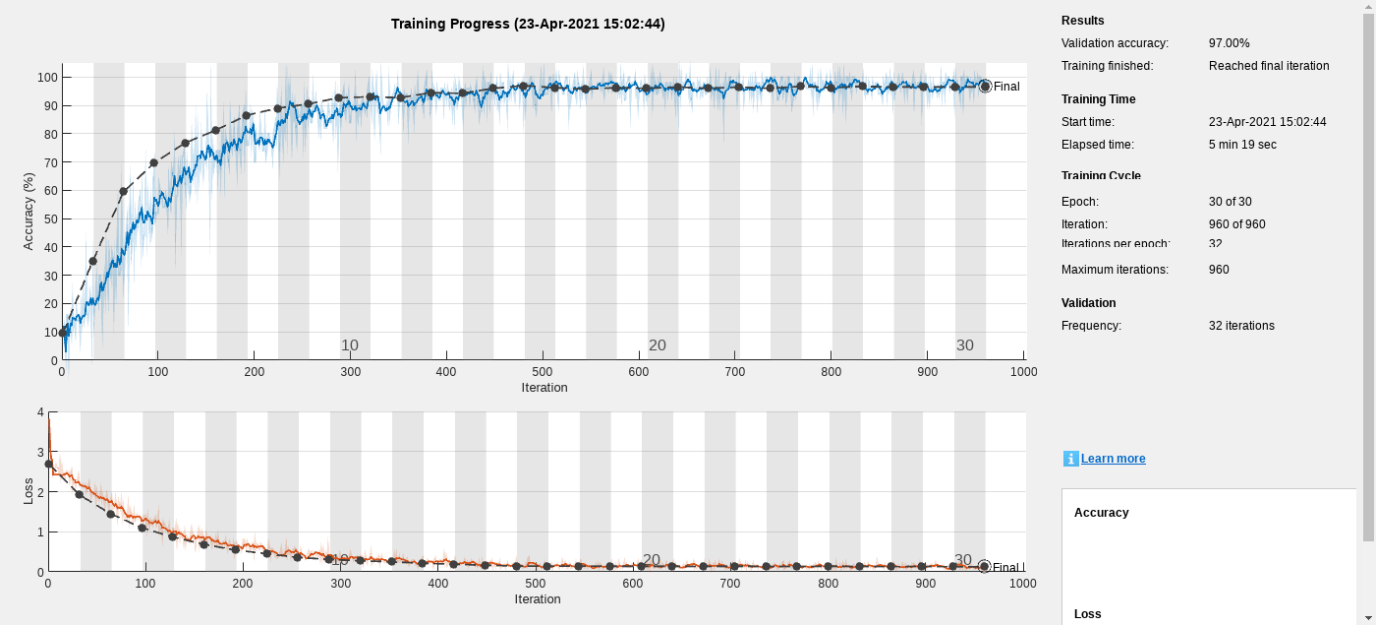
Set the hyperparameters to use in training the network. Use a mini-batch size of 50 and a learning rate of 1e-4. Specify 'adam' optimization. To use the parallel pool to read the transformed datastore, set `DispatchInBackground` to `true`. For more information, see `trainingOptions`.

```
miniBatchSize = 50;
options = trainingOptions('adam', ...
    'InitialLearnRate',1e-4, ...
    'MaxEpochs',30, ...
    'LearnRateSchedule',"piecewise",...
    'LearnRateDropFactor',.1,...
    'LearnRateDropPeriod',15,...
    'MiniBatchSize',miniBatchSize, ...
    'Shuffle','every-epoch', ...
    'Plots','training-progress', ...
```

```
    'Verbose',false, ...
    'ValidationData',{XTest, YTest},...
    'ValidationFrequency',ceil(numel(adsTrain.Files)/miniBatchSize),...
    'ExecutionEnvironment','gpu',...
    'DispatchInBackground', true);
```

Train the network by passing the training datastore to `trainNetwork`.

```
trainedNet = trainNetwork(sds,layers,options);
```



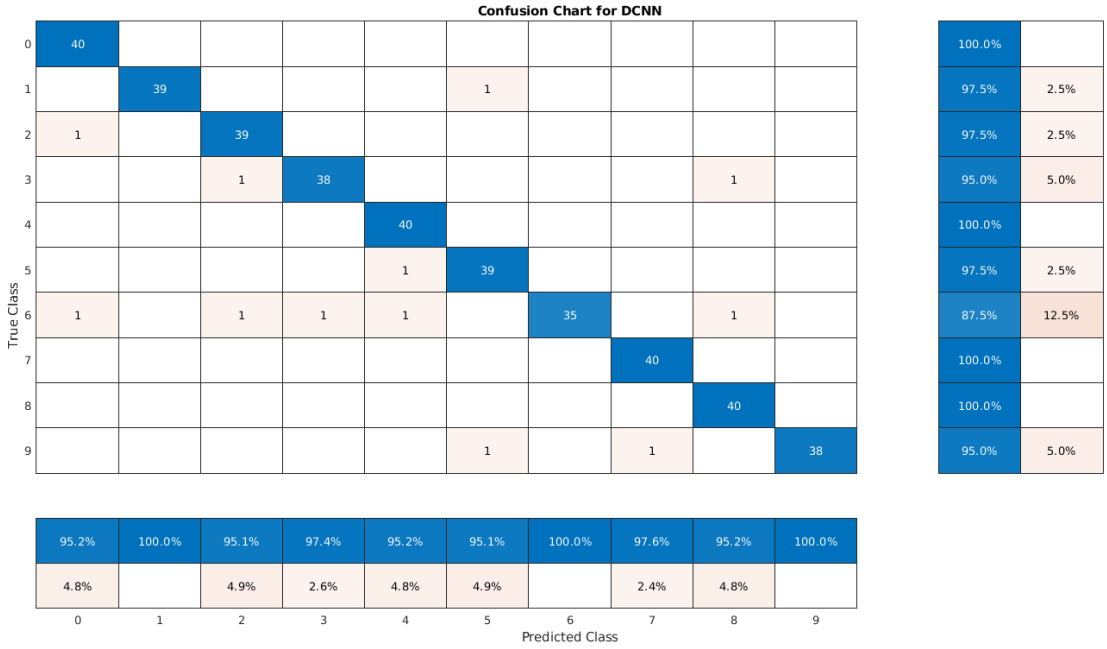
Use the trained network to predict the digit labels for the test set.

```
[Ypredicted,probs] = classify(trainedNet,XTest);
cnnAccuracy = sum(Ypredicted==YTest)/numel(YTest)*100
```

```
cnnAccuracy = 97
```

Summarize the performance of the trained network on the test set with a confusion chart. Display the precision and recall for each class by using column and row summaries. The table at the bottom of the confusion chart shows the precision values. The table to the right of the confusion chart shows the recall values.

```
figure('Units','normalized','Position',[0.2 0.2 1.5 1.5]);
ccDCNN = confusionchart(YTest,Ypredicted);
ccDCNN.Title = 'Confusion Chart for DCNN';
ccDCNN.ColumnSummary = 'column-normalized';
ccDCNN.RowSummary = 'row-normalized';
```



Appendix: Helper Functions

```
function Labels = helperGenerateLabels(ads)
% This function is only for use in this example. It may be changed or
% removed in a future release.

data = {spec,label};
```

```
info.SampleRate = 8000;
end
```

Keyword Spotting in Noise Code Generation with Intel MKL-DNN

This example demonstrates code generation for keyword spotting using a Bidirectional Long Short-Term Memory (BiLSTM) network and mel frequency cepstral coefficient (MFCC) feature extraction. MATLAB® Coder™ with Deep Learning Support enables the generation of a standalone executable (`.exe`) file. Communication between the MATLAB® (.mlx) file and the generated executable file occurs over asynchronous User Datagram Protocol (UDP). The incoming speech signal is displayed using a `timescope`. A mask is shown as a blue rectangle surrounding spotted instances of the keyword, YES. For more details on MFCC feature extraction and deep learning network training, visit "Keyword Spotting in Noise Using MFCC and LSTM Networks" (Audio Toolbox).

Example Requirements

- MATLAB® Coder Interface for Deep Learning Support Package
- Intel® Xeon® processor with support for Intel Advanced Vector Extensions 2 (Intel AVX2)
- Intel Math Kernel Library for Deep Neural Networks (MKL-DNN)
- Environment variables for Intel MKL-DNN

For supported versions of libraries and for information about setting up environment variables, see "Prerequisites for Deep Learning with MATLAB Coder" (MATLAB Coder).

Pretrained Network Keyword Spotting Using MATLAB and Streaming Audio from Microphone

The sample rate of the pretrained network is 16 kHz. Set the window length to 512 samples, with an overlap length of 384 samples, and a hop length defined as the difference between the window and overlap lengths. Define the rate at which the mask is estimated. A mask is generated once for every `numHopsPerUpdate` audio frames.

```
fs = 16e3;
windowLength = 512;
overlapLength = 384;
hopLength = windowLength - overlapLength;
numHopsPerUpdate = 16;
maskLength = hopLength*numHopsPerUpdate;
```

Create an `audioFeatureExtractor` (Audio Toolbox) object to perform MFCC feature extraction.

```
afe = audioFeatureExtractor('SampleRate',fs, ...
                            'Window',hann(windowLength,'periodic'), ...
                            'OverlapLength',overlapLength, ...
                            'mfcc',true, ...
                            'mfccDelta',true, ...
                            'mfccDeltaDelta',true);
```

Download and load the pretrained network, as well as the mean (`M`) and the standard deviation (`S`) vectors used for Feature Standardization.

```
url = 'http://ssd.mathworks.com/supportfiles/audio/KeywordSpotting.zip';
downloadNetFolder = './';
netFolder = fullfile(downloadNetFolder,'KeywordSpotting');
if ~exist(netFolder,'dir')
    disp('Downloading pretrained network and audio files (4 files - 7 MB) ...')
```

```
    unzip(url,downloadNetFolder)
end
load(fullfile(netFolder,'KWSNet.mat'),"KWSNet","M","S");
```

Call `generateMATLABFunction` (Audio Toolbox) on the `audioFeatureExtractor` (Audio Toolbox) object to create the feature extraction function. You will use this function in the processing loop.

```
generateMATLABFunction(afe,'generateKeywordFeatures','IsStreaming',true);
```

Define an Audio Device Reader (Audio Toolbox) that can read audio from your microphone. Set the frame length equal to the hop length. This enables you to compute a new set of features for every new audio frame from the microphone.

```
frameLength = hopLength;
adr = audioDeviceReader('SampleRate',fs, ...
                        'SamplesPerFrame',frameLength);
```

Create a Time Scope (DSP System Toolbox) to visualize the speech signals and estimated mask.

```
scope = timescope('SampleRate',fs, ...
                  'TimeSpanSource','property', ...
                  'TimeSpan',5, ...
                  'TimeSpanOverrunAction','Scroll', ...
                  'BufferLength',fs*5*2, ...
                  'ShowLegend',true, ...
                  'ChannelNames',{'Speech','Keyword Mask'}, ...
                  'YLimits',[-1.2 1.2], ...
                  'Title','Keyword Spotting');
```

Initialize a buffer for the audio data, a buffer for the computed features, and a buffer to plot the input audio and the output speech mask.

```
dataBuff = dsp.AsyncBuffer(windowLength);
featureBuff = dsp.AsyncBuffer(numHopsPerUpdate);
plotBuff = dsp.AsyncBuffer(numHopsPerUpdate*windowLength);
```

Perform keyword spotting on speech received from your microphone. To run the loop indefinitely, set `timeLimit` to `Inf`. To stop the simulation, close the `scope`.

```
timeLimit = 20;
show(scope);
tic
while toc < timeLimit && isVisible(scope)

    data = adr();
    write(dataBuff,data);
    write(plotBuff,data);

    frame = read(dataBuff,windowLength,overlapLength);
    features = generateKeywordFeatures(frame,fs);
    write(featureBuff,features.');

    if featureBuff.NumUnreadSamples == numHopsPerUpdate

        featureMatrix = read(featureBuff);
        featureMatrix(~isfinite(featureMatrix)) = 0;
        featureMatrix = (featureMatrix - M)./S;
```

```
        [keywordNet, v] = classifyAndUpdateState(KWSNet,featureMatrix.');

        v = double(v) - 1;
        v = repmat(v,hopLength,1);
        v = v(:);
        v = mode(v);
        predictedMask = repmat(v,numHopsPerUpdate*hopLength,1);

        data = read(plotBuff);
        scope([data,predictedMask]);

        drawnow limitrate;
    end
end

release(adr)
hide(scope)
```

The `helperKeywordSpotting` supporting function encapsulates capturing the audio, feature extraction and network prediction process demonstrated previously. To make feature extraction compatible with code generation, feature extraction is handled by the generated `generateKeywordFeatures` function. To make the network compatible with code generation, the supporting function uses the `coder.loadDeepLearningNetwork` (MATLAB Coder) (MATLAB Coder) function to load the network.

The supporting function uses a `dsp.UDPSender` (DSP System Toolbox) System object to send the input data along with the output mask predicted by the network to MATLAB. The MATLAB script uses the `dsp.UDPReceiver` (DSP System Toolbox) System object to receive the input data along with the output mask predicted by the network running in the supporting function.

Generate Executable on Desktop

Create a code generation configuration object to generate an executable. Specify the target language as C++.

```
cfg = coder.config('exe');
cfg.TargetLang = 'C++';
```

Create a configuration object for deep learning code generation with the MKL-DNN library. Attach the deep learning configuration object to the code generation configuration object.

```
dlcfg = coder.DeepLearningConfig('mkldnn');
cfg.DeepLearningConfig = dlcfg;
```

Generate the C++ main file required to produce the standalone executable.

```
cfg.GenerateExampleMain = 'GenerateCodeAndCompile';
```

Generate `helperKeywordSpotting`, a supporting function that encapsulates the audio capture, feature extraction, and network prediction processes. You get a warning in the code generation logs that you can disregard because `helperKeywordSpotting` has an infinite loop that continously looks for an audio frame from MATLAB.

```
codegen helperKeywordSpotting -config cfg -report
```

```
Warning: Function 'helperKeywordSpotting' does not terminate due to an infinite loop.
```

```
Warning in ==> helperKeywordSpotting Line: 73 Column: 1
Code generation successful (with warnings): View report
```

Prepare Dependencies and Run the Generated Executable

In this section, you generate all the required dependency files and put them into a single folder. During the build process, MATLAB Coder generates `buildInfo.mat`, a file that contains the compilation and run-time dependency information for the standalone executable.

Set the project name to `helperKeywordSpotting`.

```
projName = 'helperKeywordSpotting';
packageName = [projName,'Package'];
if ispc
    exeName = [projName,'.exe'];
else
    exeName = projName;
end
```

Load `buildinfo.mat` and use `packNGo` (MATLAB Coder) to produce a `.zip` package.

```
load(['codegen',filesep,'exe',filesep,projName,filesep,'buildInfo.mat']);
packNGo(buildInfo,'fileName',[packageName,'.zip'],'minimalHeaders',false);
```

Unzip the package and place the executable file in the unzipped directory.

```
unzip([packageName,'.zip'],packageName);
copyfile(exeName, packageName,'f');
```

To invoke a standalone executable that depends on the MKL-DNN Dynamic Link Library, append the path to the MKL-DNN library location to the environment variable `PATH`.

```
setenv('PATH',[getenv('INTEL_MKLDNN'),filesep,'lib',pathsep,getenv('PATH')]);
```

Run the generated executable.

```
if ispc
    system(['start cmd /k "title ',packageName,' && cd ',packageName,' && ',exeName]);
else
    cd(packageName);
    system(['./',exeName,' &']);
    cd ..;
end
```

Perform Keyword Spotting Using Deployed Code

Create a `dsp.UDPReceiver` (DSP System Toolbox) System object to receive speech data and the predicted speech mask from the standalone executable. Each UDP packet received from the executable consists of `maskLength` mask samples and speech samples. The maximum message length for the `dsp.UDPReceiver` (DSP System Toolbox) object is `65507` bytes. Calculate the buffer size to accommodate the maximum number of UDP packets.

```
sizeOfFloatInBytes = 4;
speechDataLength = maskLength;
numElementsPerUDPPacket = maskLength + speechDataLength;

maxUDPMessageLength = floor(65507/sizeOfFloatInBytes);
samplesPerPacket = 1 + numElementsPerUDPPacket;
```

```
numPackets = floor(maxUDPMessageLength/samplesPerPacket);
bufferSize = numPackets*samplesPerPacket*sizeOfFloatInBytes;

UDPReceive = dsp.UDPReceiver('LocalIPPort',20000, ...
    'MessageDataType','single', ...
    'MaximumMessageLength',samplesPerPacket, ...
    'ReceiveBufferSize',bufferSize);
```

To run the keyword spotting indefinitely, set `timelimit` to `Inf`. To stop the simulation, close the `scope`.

```
tic;
timelimit = 20;
show(scope);

while toc < timelimit && isVisible(scope)
    data = UDPReceive();
    if ~isempty(data)
        plotMask = data(1:maskLength);
        plotAudio = data(maskLength+1 : maskLength+speechDataLength);
        scope([plotAudio,plotMask]);
    end
    drawnow limitrate;
end

hide(scope);
```

Release the system objects and terminate the standalone executable.

```
release(UDPReceive);
release(scope);
if ispc
    system(['taskkill /F /FI "WindowTitle eq ',projName,'* " /T']);
else
    system(['killall ',exeName]);
end
```

```
SUCCESS: The process with PID 4644 (child process of PID 21188) has been terminated.

```

Evaluate Execution Time Using Alternative MEX Function Workflow

A similar workflow involves using a MEX file instead of the standalone executable. Perform MEX profiling to measure the computation time for the workflow.

Create a code generation configuration object to generate the MEX function. Specify the target language as C++.

```
cfg = coder.config('mex');
cfg.TargetLang = 'C++';
```

Create a configuration object for deep learning code generation with the MKL-DNN library. Attach the deep learning configuration object to the code generation configuration object.

```
dlcfg = coder.DeepLearningConfig('mkldnn');
cfg.DeepLearningConfig = dlcfg;
```

Call codegen to generate the MEX function for `profileKeywordSpotting`.

```
inputAudioFrame = ones(hopLength,1,'single');
codegen profileKeywordSpotting -config cfg -args {inputAudioFrame} -report
```

```
Code generation successful: View report
```

Measure the execution time of the MATLAB code.

```
x = pinknoise(hopLength,1,'single');
numPredictCalls = 100;
totalNumCalls = numPredictCalls*numHopsPerUpdate;
exeTimeStart = tic;
for call = 1:totalNumCalls
    [outputMask,inputData,plotFlag] = profileKeywordSpotting(x);
end
exeTime = toc(exeTimeStart);
fprintf('MATLAB execution time per %d ms of audio = %0.4f ms\n',int32(1000*numHopsPerUpdate*hopLe
```

```
MATLAB execution time per 128 ms of audio = 24.9238 ms
```

Measure the execution time of the MEX function.

```
exeTimeMexStart = tic;
for call = 1:totalNumCalls
    [outputMask,inputData,plotFlag] = profileKeywordSpotting_mex(x);
end
exeTimeMex = toc(exeTimeMexStart);
fprintf('MEX execution time per %d ms of audio = %0.4f ms\n',int32(1000*numHopsPerUpdate*hopLengt
```

```
MEX execution time per 128 ms of audio = 5.2710 ms
```

Compare total execution time of the standalone executable approach with the MEX function approach. This performance test is done on a machine using an NVIDIA Quadro® P620 (Version 26) GPU and an Intel Xeon W-2133 CPU running at 3.60 GHz.

```
PerformanceGain = exeTime/exeTimeMex
```

```
PerformanceGain = 4.7285
```

Keyword Spotting in Noise Code Generation on Raspberry Pi

This example demonstrates code generation for keyword spotting using a Bidirectional Long Short-Term Memory (BiLSTM) network and mel frequency cepstral coefficient (MFCC) feature extraction on Raspberry Pi™. MATLAB® Coder™ with Deep Learning Support enables the generation of a standalone executable (.elf) file on Raspberry Pi. Communication between MATLAB® (.mlx) file and the generated executable file occurs over asynchronous User Datagram Protocol (UDP). The incoming speech signal is displayed using a `timescope`. A mask is shown as a blue rectangle surrounding spotted instances of the keyword, YES. For more details on MFCC feature extraction and deep learning network training, visit “Keyword Spotting in Noise Using MFCC and LSTM Networks” (Audio Toolbox).

Example Requirements

- MATLAB® Coder Interface for Deep Learning Support Package
- ARM processor that supports the NEON extension
- ARM Compute Library version 20.02.1 (on the target ARM hardware)
- Environment variables for the compilers and libraries

For supported versions of libraries and for information about setting up environment variables, see “Prerequisites for Deep Learning with MATLAB Coder” (MATLAB Coder).

Pretrained Network Keyword Spotting Using MATLAB® and Streaming Audio from Microphone

The sample rate of the pretrained network is 16 kHz. Set the window length to 512 samples, with an overlap length of 384 samples, and a hop length defined as the difference between the window and overlap lengths. Define the rate at which the mask is estimated. A mask is generated once for every `numHopsPerUpdate` audio frames.

```
fs = 16e3;
windowLength = 512;
overlapLength = 384;
hopLength = windowLength - overlapLength;

numHopsPerUpdate = 16;
maskLength = hopLength * numHopsPerUpdate;
```

Create an `audioFeatureExtractor` (Audio Toolbox) object to perform MFCC feature extraction.

```
afe = audioFeatureExtractor('SampleRate',fs, ...
                            'Window',hann(windowLength,'periodic'), ...
                            'OverlapLength',overlapLength, ...
                            'mfcc',true, ...
                            'mfccDelta',true, ...
                            'mfccDeltaDelta',true);
```

Download and load the pretrained network, as well as the mean (`M`) and the standard deviation (`S`) vectors used for feature standardization.

```
url = 'http://ssd.mathworks.com/supportfiles/audio/KeywordSpotting.zip';
downloadNetFolder = './';
netFolder = fullfile(downloadNetFolder,'KeywordSpotting');
if ~exist(netFolder,'dir')
    disp('Downloading pretrained network and audio files (4 files - 7 MB) ...')
```

```
    unzip(url,downloadNetFolder)
end
load(fullfile(netFolder,'KWSNet.mat'),"KWSNet","M","S");
```

Call `generateMATLABFunction` (Audio Toolbox) on the `audioFeatureExtractor` (Audio Toolbox) object to create the feature extraction function.

```
generateMATLABFunction(afe,'generateKeywordFeatures','IsStreaming',true);
```

Define an Audio Device Reader (Audio Toolbox) System object™ to read audio from your microphone. Set the frame length equal to the hop length. This enables the computation of a new set of features for every new audio frame received from the microphone.

```
frameLength = hopLength;
adr = audioDeviceReader('SampleRate',fs, ...
                        'SamplesPerFrame',frameLength,'OutputDataType','single');
```

Create a Time Scope (DSP System Toolbox) to visualize the speech signals and estimated mask.

```
scope = timescope('SampleRate',fs, ...
                  'TimeSpanSource','property', ...
                  'TimeSpan',5, ...
                  'TimeSpanOverrunAction','Scroll', ...
                  'BufferLength',fs*5*2, ...
                  'ShowLegend',true, ...
                  'ChannelNames',{'Speech','Keyword Mask'}, ...
                  'YLimits',[-1.2 1.2], ...
                  'Title','Keyword Spotting');
```

Initialize a buffer for the audio data, a buffer for the computed features, and a buffer to plot the input audio and the output speech mask.

```
dataBuff = dsp.AsyncBuffer(windowLength);
featureBuff = dsp.AsyncBuffer(numHopsPerUpdate);
plotBuff = dsp.AsyncBuffer(numHopsPerUpdate*windowLength);
```

Perform keyword spotting on speech received from your microphone. To run the loop indefinitely, set `timeLimit` to `Inf`. To stop the simulation, close the `scope`.

```
show(scope);
timeLimit = 20;
tic
while toc < timeLimit && isVisible(scope)

    data = adr();
    write(dataBuff,data);
    write(plotBuff,data);

    frame = read(dataBuff,windowLength,overlapLength);
    features = generateKeywordFeatures(frame,fs);
    write(featureBuff,features.');

    if featureBuff.NumUnreadSamples == numHopsPerUpdate

        featureMatrix = read(featureBuff);
        featureMatrix(~isfinite(featureMatrix)) = 0;
        featureMatrix = (featureMatrix - M)./S;
```

```
        [keywordNet,v] = classifyAndUpdateState(KWSNet,featureMatrix.');

        v = double(v) - 1;
        v = repmat(v,hopLength,1);
        v = v(:);
        v = mode(v);
        v = repmat(v,numHopsPerUpdate * hopLength,1);

        data = read(plotBuff);
        scope([data,v]);

        drawnow limitrate;
    end
end
hide(scope)
```

The `helperKeywordSpottingRaspi` supporting function encapsulates the feature extraction and network prediction process demonstrated previously. To make feature extraction compatible with code generation, feature extraction is handled by the generated `generateKeywordFeatures` function. To make the network compatible with code generation, the supporting function uses the `coder.loadDeepLearningNetwork` (MATLAB Coder) function to load the network.

The supporting function uses a `dsp.UDPReceiver` (DSP System Toolbox) System object to receive the captured audio from MATLAB® and uses a `dsp.UDPSender` (DSP System Toolbox) System object to send the input speech signal along with the estimated mask predicted by the network to MATLAB®. Similarly, the MATLAB® live script uses the `dsp.UDPSender` (DSP System Toolbox) System object to send the captured speech signal to the executable running on Raspberry Pi and the `dsp.UDPReceiver` (DSP System Toolbox) System object to receive the speech signal and estimated mask from Raspberry Pi.

Generate Executable on Raspberry Pi

Replace the `hostIPAddress` with your machine's address. Your Raspberry Pi sends the input speech signal and estimated mask to the specified IP address.

```
hostIPAddress = coder.Constant('172.18.230.30');
```

Create a code generation configuration object to generate an executable program. Specify the target language as C++.

```
cfg = coder.config('exe');
cfg.TargetLang = 'C++';
```

Create a configuration object for deep learning code generation with the ARM compute library that is on your Raspberry Pi. Specify the architecture of the Raspberry Pi and attach the deep learning configuration object to the code generation configuration object.

```
dlcfg = coder.DeepLearningConfig('arm-compute');
dlcfg.ArmArchitecture = 'armv7';
dlcfg.ArmComputeVersion = '20.02.1';
cfg.DeepLearningConfig = dlcfg;
```

Use the Raspberry Pi Support Package function, `raspi`, to create a connection to your Raspberry Pi. In the following code, replace:

- `raspiname` with the name of your Raspberry Pi

- `pi` with your user name
- `password` with your password

```
r = raspi('raspiname','pi','password');
```

Create a `coder.hardware` (MATLAB Coder) object for Raspberry Pi and attach it to the code generation configuration object.

```
hw = coder.hardware('Raspberry Pi');
cfg.Hardware = hw;
```

Specify the build folder on the Raspberry Pi.

```
buildDir = '~/remoteBuildDir';
cfg.Hardware.BuildDir = buildDir;
```

Generate the C++ main file required to produce the standalone executable.

```
cfg.GenerateExampleMain = 'GenerateCodeAndCompile';
```

Generate C++ code for `helperKeywordSpottingRaspi` on your Raspberry Pi.

```
codegen -config cfg helperKeywordSpottingRaspi -args {hostIPAddress} -report
```

```
 Deploying code. This may take a few minutes.
Warning: Function 'helperKeywordSpottingRaspi' does not terminate due to an
infinite loop.

Warning in ==> helperKeywordSpottingRaspi Line: 78 Column: 1
Code generation successful (with warnings): View report
```

Perform Keyword Spotting Using Deployed Code

Create a command to open the `helperKeywordSpottingRaspi` application on Raspberry Pi. Use `system` to send the command to your Raspberry Pi.

```
applicationName = 'helperKeywordSpottingRaspi';

applicationDirPaths = raspi.utils.getRemoteBuildDirectory('applicationName',applicationName);
targetDirPath = applicationDirPaths{1}.directory;

exeName = strcat(applicationName,'.elf');
command = ['cd ',targetDirPath,'; ./',exeName,' &> 1 &'];

system(r,command);
```

Create a `dsp.UDPSender` (DSP System Toolbox) System object to send audio captured in MATLAB® to your Raspberry Pi. Update the `targetIPAddress` for your Raspberry Pi. Raspberry Pi receives the captured audio from the same port using the `dsp.UDPReceiver` (DSP System Toolbox) System object.

```
targetIPAddress = '172.18.240.234';
UDPSend = dsp.UDPSender('RemoteIPPort',26000,'RemoteIPAddress',targetIPAddress);
```

Create a `dsp.UDPReceiver` (DSP System Toolbox) System object to receive speech data and the predicted speech mask from your Raspberry Pi. Each UDP packet received from the Raspberry Pi consists of `maskLength` mask and speech samples. The maximum message length for the

`dsp.UDPReceiver` (DSP System Toolbox) object is `65507` bytes. Calculate the buffer size to accommodate the maximum number of UDP packets.

```
sizeOfFloatInBytes = 4;
speechDataLength = maskLength;
numElementsPerUDPPacket = maskLength + speechDataLength;
maxUDPMessageLength = floor(65507/sizeOfFloatInBytes);
numPackets = floor(maxUDPMessageLength/numElementsPerUDPPacket);
bufferSize = numPackets*numElementsPerUDPPacket*sizeOfFloatInBytes;

UDPReceive = dsp.UDPReceiver("LocalIPPort",21000, ...
    "MessageDataType","single", ...
    "MaximumMessageLength",1+numElementsPerUDPPacket, ...
    "ReceiveBufferSize",bufferSize);
```

Spot the keyword as long as time scope is open or until the time limit is reached. To stop the live detection before the time limit is reached, close the time scope.

```
tic;
show(scope);
timelimit = 20;
while toc < timelimit && isVisible(scope)
    x = adr();
    UDPSend(x);
    data = UDPReceive();
    if ~isempty(data)
        mask = data(1:maskLength);
        dataForPlot = data(maskLength + 1 : numElementsPerUDPPacket);
        scope([dataForPlot,mask]);
    end
    drawnow limitrate;
end
```

Release the system objects and terminate the standalone executable.

```
hide(scope)
release(UDPSend)
release(UDPReceive)
release(scope)
release(adr)
stopExecutable(codertarget.raspi.raspberrypi,exeName)
```

Evaluate Execution Time Using Alternative PIL Function Workflow

To evaluate execution time taken by standalone executable on Raspberry Pi, use a PIL (processor-in-loop) workflow. To perform PIL profiling, generate a PIL function for the supporting function `profileKeywordSpotting`. The `profileKeywordSpotting` is equivalent to `helperKeywordSpottingRaspi`, except that the former returns the speech and predicted speech mask while the latter sends the same parameters using UDP. The time taken by the UDP calls is less than 1 ms, which is relatively small compared to the overall execution time.

Create a code generation configuration object to generate the PIL function.

```
cfg = coder.config('lib','ecoder',true);
cfg.VerificationMode = 'PIL';
```

Set the ARM compute library and architecture.

```
dlcfg = coder.DeepLearningConfig('arm-compute');
cfg.DeepLearningConfig = dlcfg ;
cfg.DeepLearningConfig.ArmArchitecture = 'armv7';
cfg.DeepLearningConfig.ArmComputeVersion = '20.02.1';
```

Set up the connection with your target hardware.

```
if (~exist('r','var'))
  r = raspi('raspiname','pi','password');
end
hw = coder.hardware('Raspberry Pi');
cfg.Hardware = hw;
```

Set the build directory and target language.

```
buildDir = '~/remoteBuildDir';
cfg.Hardware.BuildDir = buildDir;
cfg.TargetLang = 'C++';
```

Enable profiling and generate the PIL code. A MEX file named `profileKeywordSpotting_pil` is generated in your current folder.

```
cfg.CodeExecutionProfiling = true;
codegen -config cfg profileKeywordSpotting -args {pinknoise(hopLength,1,'single')} -report
```

```
 Deploying code. This may take a few minutes.
### Connectivity configuration for function 'profileKeywordSpotting': 'Raspberry Pi'
Location of the generated elf : /home/pi/remoteBuildDir/MATLAB_ws/R2021a/E/sandbox/sporwal/Examp
Code generation successful: View report
```

Evaluate Raspberry Pi Execution Time

Call the generated PIL function multiple times to get the average execution time.

```
numPredictCalls = 10;
totalCalls = numHopsPerUpdate * numPredictCalls;

x = pinknoise(hopLength,1,'single');
for k = 1:totalCalls
    [maskReceived,inputSignal,plotFlag] = profileKeywordSpotting_pil(x);
end
```

```
### Starting application: 'codegen\lib\profileKeywordSpotting\pil\profileKeywordSpotting.elf'
    To terminate execution: clear profileKeywordSpotting_pil
### Launching application profileKeywordSpotting.elf...
    Execution profiling data is available for viewing. Open Simulation Data Inspector.
    Execution profiling report available after termination.
```

Terminate the PIL execution.

```
clear profileKeywordSpotting_pil
```

```
### Host application produced the following standard output (stdout) and standard error (stderr)

    Execution profiling report: report(getCoderExecutionProfile('profileKeywordSpotting'))
```

Generate an execution profile report to evaluate execution time.

```
executionProfile = getCoderExecutionProfile('profileKeywordSpotting');
report(executionProfile, ...
```

```
        'Units','Seconds', ...
        'ScaleFactor','1e-03', ...
        'NumericFormat','%0.4f')

ans =
'E:\sandbox\sporwal\Examples\ExampleManager\sporwal.Bdoc21a.j1572571\deeplearning_shared-ex18742
```

Code Execution Profiling Report

Code Execution Profiling Report for profileKeywordSpotting

The code execution profiling report provides metrics based on data collected from a SIL or PIL execution. Execution times are calculated from data recorded by instrumentation probes added to the SIL or PIL test harness or inside the code generated for each component. See Code Execution Profiling for more information.

1. Summary

Total time	278.7215
Unit of time	ms
Command	report(executionProfile, 'Units', 'seconds', 'ScaleFactor', '0.001', 'NumericFormat', '%0.4f');
Timer frequency (ticks per second)	1e+09
Profiling data created	28-Oct-2020 18:52:30

2. Profiled Sections of Code

Section	Maximum Execution Time in ms	Average Execution Time in ms	Maximum Self Time in ms	Average Self Time in ms	Calls	
profileKeywordSpotting_initialize	0.0868	0.0868	0.0868	0.0868	1	
profileKeywordSpotting	26.9524	1.7414	26.9524	1.7414	160	
profileKeywordSpotting_terminate	0.0029	0.0029	0.0029	0.0029	1	

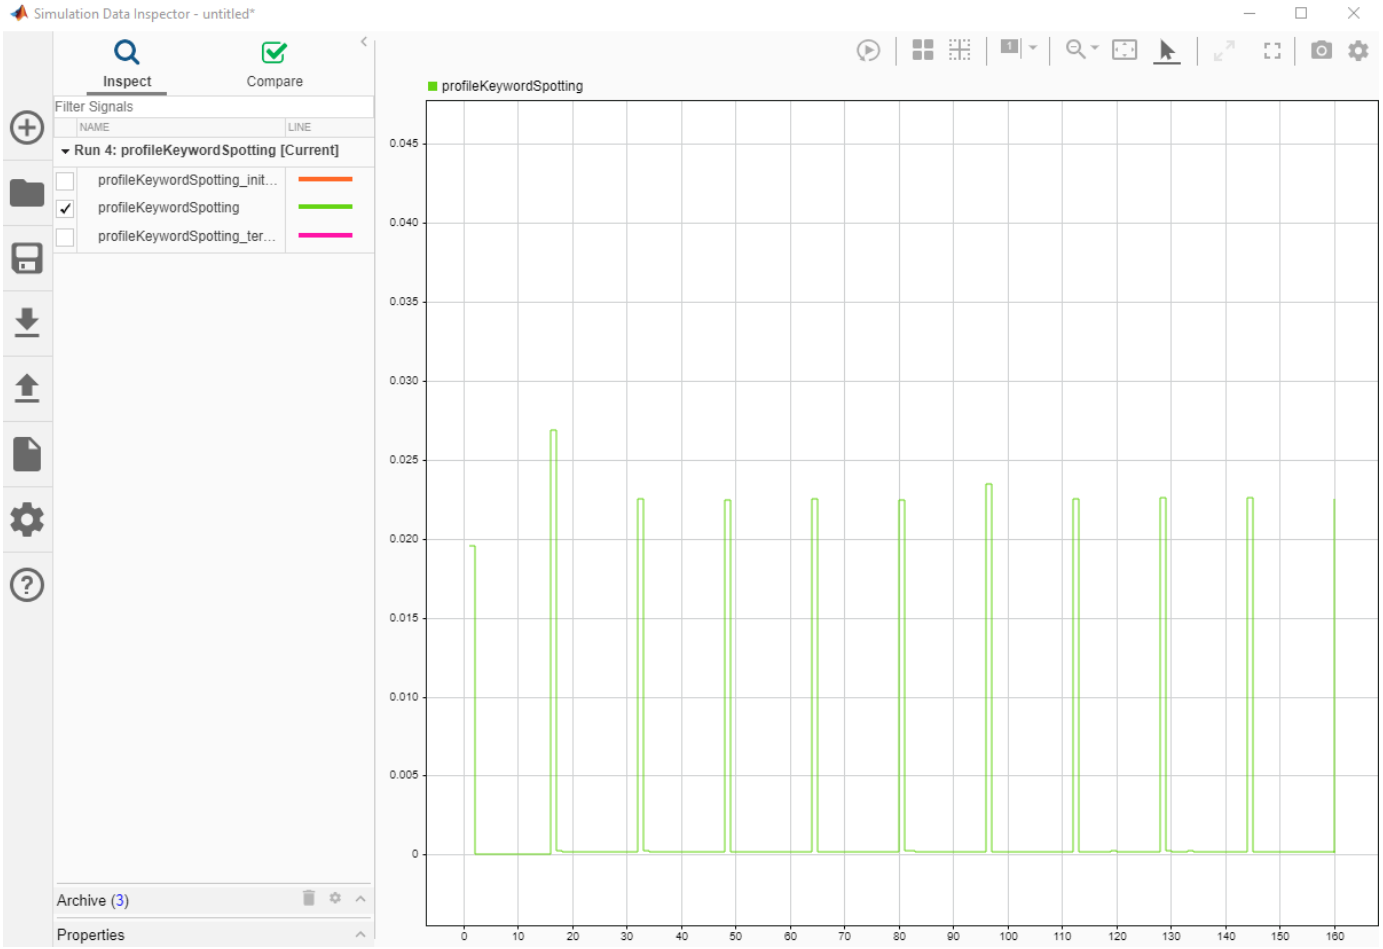
3. Definitions

Execution Time: Time between start and end of code section.

Self Time: Execution time, excluding time in child sections.

OK Help

Plot the Execution Time of each frame from the generated report.



Processing of the first frame took ~20 ms due to initialization overhead costs. The spikes in the time graph at every 16th frame (`numHopsPerUpdate`) correspond to the computationally intensive predict function called every 16th frame. The maximum execution time is ~30 ms, which is below the 128 ms budget for real-time streaming. The performance is measuerd on Raspberry Pi 4 Model B Rev 1.1.

Speech Command Recognition Code Generation on Raspberry Pi

This example shows how to deploy feature extraction and a convolutional neural network (CNN) for speech command recognition to Raspberry Pi™. To generate the feature extraction and network code, you use MATLAB Coder, MATLAB Support Package for Raspberry Pi Hardware, and the ARM® Compute Library. In this example, the generated code is an executable on your Raspberry Pi, which is called by a MATLAB script that displays the predicted speech command along with the signal and auditory spectrogram. Interaction between the MATLAB script and the executable on your Raspberry Pi is handled using the user datagram protocol (UDP). For details about audio preprocessing and network training, see “Speech Command Recognition Using Deep Learning” (Audio Toolbox).

Prerequisites

- ARM processor that supports the NEON extension
- ARM Compute Library version 19.05 (on the target ARM hardware)
- Environment variables for the compilers and libraries

For supported versions of libraries and for information about setting up environment variables, see “Prerequisites for Deep Learning with MATLAB Coder” (MATLAB Coder).

Streaming Demonstration in MATLAB

Use the same parameters for the feature extraction pipeline and classification as developed in “Speech Command Recognition Using Deep Learning” (Audio Toolbox).

Define the same sample rate the network was trained on (16 kHz). Define the classification rate and the number of audio samples input per frame. The feature input to the network is a Bark spectrogram that corresponds to 1 second of audio data. The Bark spectrogram is calculated for 25 ms windows with 10 ms hops. Calculate the number of individual spectrums in each spectrogram.

```
fs = 16000;
classificationRate = 20;
samplesPerCapture = fs/classificationRate;

segmentDuration = 1;
segmentSamples = round(segmentDuration*fs);

frameDuration = 0.025;
frameSamples = round(frameDuration*fs);

hopDuration = 0.010;
hopSamples = round(hopDuration*fs);

numSpectrumPerSpectrogram = floor((segmentSamples-frameSamples)/hopSamples) + 1;
```

Create an `audioFeatureExtractor` (Audio Toolbox) object to extract 50-band Bark spectrograms without window normalization. Calculate the number of elements in each spectrogram.

```
afe = audioFeatureExtractor( ...
    'SampleRate',fs, ...
    'FFTLength',512, ...
    'Window',hann(frameSamples,'periodic'), ...
    'OverlapLength',frameSamples - hopSamples, ...
```

```
    'barkSpectrum',true);

numBands = 50;
setExtractorParams(afe,'barkSpectrum','NumBands',numBands,'WindowNormalization',false);

numElementsPerSpectrogram = numSpectrumPerSpectrogram*numBands;
```

Load the pretrained CNN and labels.

```
load('commandNet.mat')
labels = trainedNet.Layers(end).Classes;
NumLabels = numel(labels);
BackGroundIdx = find(labels == 'background');
```

Define buffers and decision thresholds to post process network predictions.

```
probBuffer = single(zeros([NumLabels,classificationRate/2]));
YBuffer = single(NumLabels * ones(1, classificationRate/2));

countThreshold = ceil(classificationRate*0.2);
probThreshold = single(0.7);
```

Create an `audioDeviceReader` (Audio Toolbox) object to read audio from your device. Create a `dsp.AsyncBuffer` (DSP System Toolbox) object to buffer the audio into chunks.

```
adr = audioDeviceReader('SampleRate',fs,'SamplesPerFrame',samplesPerCapture,'OutputDataType','si
audioBuffer = dsp.AsyncBuffer(fs);
```

Create a `dsp.MatrixViewer` (DSP System Toolbox) object and a `timescope` (DSP System Toolbox) object to display the results.

```
matrixViewer = dsp.MatrixViewer("ColorBarLabel","Power per band (dB/Band)",...
    "XLabel","Frames",...
    "YLabel","Bark Bands", ...
    "Position",[400 100 600 250], ...
    "ColorLimits",[-4 2.6445], ...
    "AxisOrigin","Lower left corner", ...
    "Name","Speech Command Recognition using Deep Learning");

timeScope = timescope("SampleRate",fs, ...
    "YLimits",[-1 1], ...
    "Position",[400 380 600 250], ...
    "Name","Speech Command Recognition Using Deep Learning", ...
    "TimeSpanSource","Property", ...
    "TimeSpan",1, ...
    "BufferLength",fs, ...
    "YLabel","Amplitude", ...
    "ShowGrid",true);
```

Show the time scope and matrix viewer. Detect commands as long as both the time scope and matrix viewer are open or until the time limit is reached. To stop the live detection before the time limit is reached, close the time scope window or matrix viewer window.

```
show(timeScope)
show(matrixViewer)

timeLimit = 10;
```

```
tic
while isVisible(timeScope) && isVisible(matrixViewer) && toc < timeLimit
    % Capture audio
    x = adr();
    write(audioBuffer,x);
    y = read(audioBuffer,fs,fs-samplesPerCapture);

    % Compute auditory features
    features = extract(afe,y);
    auditoryFeatures = log10(features + 1e-6);

    % Perform prediction
    probs = predict(trainedNet, auditoryFeatures);
    [~, YPredicted] = max(probs);

    % Perform statistical post processing
    YBuffer = [YBuffer(2:end),YPredicted];
    probBuffer = [probBuffer(:,2:end),probs(:)];

    [YModeIdx, count] = mode(YBuffer);
    maxProb = max(probBuffer(YModeIdx,:));

    if YModeIdx == single(BackGroundIdx) || single(count) < countThreshold || maxProb < probThres
        speechCommandIdx = BackGroundIdx;
    else
        speechCommandIdx = YModeIdx;
    end

    % Update plots
    matrixViewer(auditoryFeatures');
    timeScope(x);

    if (speechCommandIdx == BackGroundIdx)
        timeScope.Title = ' ';
    else
        timeScope.Title = char(labels(speechCommandIdx));
    end
    drawnow limitrate
end
```

Hide the scopes.

```
hide(matrixViewer)
hide(timeScope)
```

Prepare MATLAB Code for Deployment

To create a function to perform feature extraction compatible with code generation, call `generateMATLABFunction` (Audio Toolbox) on the `audioFeatureExtractor` object. The `generateMATLABFunction` object function creates a standalone function that performs equivalent feature extraction and is compatible with code generation.

```
generateMATLABFunction(afe,'extractSpeechFeatures')
```

The `HelperSpeechCommandRecognitionRasPi` supporting function encapsulates the feature extraction and network prediction process demonstrated previously. So that the feature extraction is compatible with code generation, feature extraction is handled by the generated `extractSpeechFeatures` function. So that the network is compatible with code generation, the

supporting function uses the `coder.loadDeepLearningNetwork` (MATLAB Coder) function to load the network. The supporting function uses a `dsp.UDPReceiver` (DSP System Toolbox) system object to send the auditory spectrogram and the index corresponding to the predicted speech command from Raspberry Pi to MATLAB. The supporting function uses the `dsp.UDPReceiver` (DSP System Toolbox) system object to receive the audio captured by your microphone in MATLAB.

Generate Executable on Raspberry Pi

Replace the `hostIPAddress` with your machine's address. Your Raspberry Pi sends auditory spectrograms and the predicted speech command to this IP address.

```
hostIPAddress = coder.Constant('172.18.230.30');
```

Create a code generation configuration object to generate an executable program. Specify the target language as C++.

```
cfg = coder.config('exe');
cfg.TargetLang = 'C++';
```

Create a configuration object for deep learning code generation with the ARM compute library that is on your Raspberry Pi. Specify the architecture of the Raspberry Pi and attach the deep learning configuration object to the code generation configuration object.

```
dlcfg = coder.DeepLearningConfig('arm-compute');
dlcfg.ArmArchitecture = 'armv7';
dlcfg.ArmComputeVersion = '19.05';
cfg.DeepLearningConfig = dlcfg;
```

Use the Raspberry Pi Support Package function, `raspi`, to create a connection to your Raspberry Pi. In the following code, replace:

- `raspiname` with the name of your Raspberry Pi
- pi with your user name
- `password` with your password

```
r = raspi('raspiname','pi','password');
```

Create a `coder.hardware` (MATLAB Coder) object for Raspberry Pi and attach it to the code generation configuration object.

```
hw = coder.hardware('Raspberry Pi');
cfg.Hardware = hw;
```

Specify the build folder on the Raspberry Pi.

```
buildDir = '~/remoteBuildDir';
cfg.Hardware.BuildDir = buildDir;
```

Use an auto generated C++ main file for the generation of a standalone executable.

```
cfg.GenerateExampleMain = 'GenerateCodeAndCompile';
```

Call `codegen` (MATLAB Coder) to generate C++ code and the executable on your Raspberry Pi. By default, the Raspberry Pi application name is the same as the MATLAB function.

```
codegen -config cfg HelperSpeechCommandRecognitionRasPi -args {hostIPAddress} -report -v
```

```
 Deploying code. This may take a few minutes.

```

Initialize Application on Raspberry Pi

Create a command to open the `HelperSpeechCommandRasPi application on Raspberry Pi`. Use `system` to send the command to your Raspberry Pi.

```
applicationName = 'HelperSpeechCommandRecognitionRasPi';

applicationDirPaths = raspi.utils.getRemoteBuildDirectory('applicationName',applicationName);
targetDirPath = applicationDirPaths{1}.directory;

exeName = strcat(applicationName,'.elf');
command = ['cd ' targetDirPath '; ./' exeName ' &> 1 &'];

system(r,command);
```

Create a `dsp.UDPReceiver` (DSP System Toolbox) system object to send audio captured in MATLAB to your Raspberry Pi. Update the `targetIPAddress` for your Raspberry Pi. Raspberry Pi receives the captured audio from the same port using the `dsp.UDPReceiver` (DSP System Toolbox) system object.

```
targetIPAddress = '172.18.228.24';
UDPSend = dsp.UDPSender('RemoteIPPort',26000,'RemoteIPAddress',targetIPAddress);
```

Create a `dsp.UDPReceiver` (DSP System Toolbox) system object to receive auditory features and the predicted speech command index from your Raspberry Pi. Each UDP packet received from the Raspberry Pi consists of auditory features in column-major order followed by the predicted speech command index. The maximum message length for the `dsp.UDPReceiver` object is 65507 bytes. Calculate the buffer size to accommodate the maximum number of UDP packets.

```
sizeOfFloatInBytes = 4;
maxUDPMessageLength = floor(65507/sizeOfFloatInBytes);
samplesPerPacket = 1 + numElementsPerSpectrogram;
numPackets = floor(maxUDPMessageLength/samplesPerPacket);
bufferSize = numPackets*samplesPerPacket*sizeOfFloatInBytes;

UDPReceive = dsp.UDPReceiver("LocalIPPort",21000, ...
    "MessageDataType","single", ...
    "MaximumMessageLength",samplesPerPacket, ...
    "ReceiveBufferSize",bufferSize);
```

Reduce initialization overhead by sending a frame of zeros to the executable running on your Raspberry Pi.

```
UDPSend(zeros(samplesPerCapture,1,"single"));
```

Perform Speech Command Recognition Using Deployed Code

Detect commands as long as both the time scope and matrix viewer are open or until the time limit is reached. To stop the live detection before the time limit is reached, close the time scope or matrix viewer window.

```
show(timeScope)
show(matrixViewer)

timeLimit = 20;

tic
while isVisible(timeScope) && isVisible(matrixViewer) && toc < timeLimit
    % Capture audio and send that to RasPi
    x = adr();
    UDPSend(x);

    % Receive data packet from RasPi
    udpRec = UDPReceive();

    if ~isempty(udpRec)
        % Extract predicted index, the last sample of received UDP packet
        speechCommandIdx = udpRec(end);

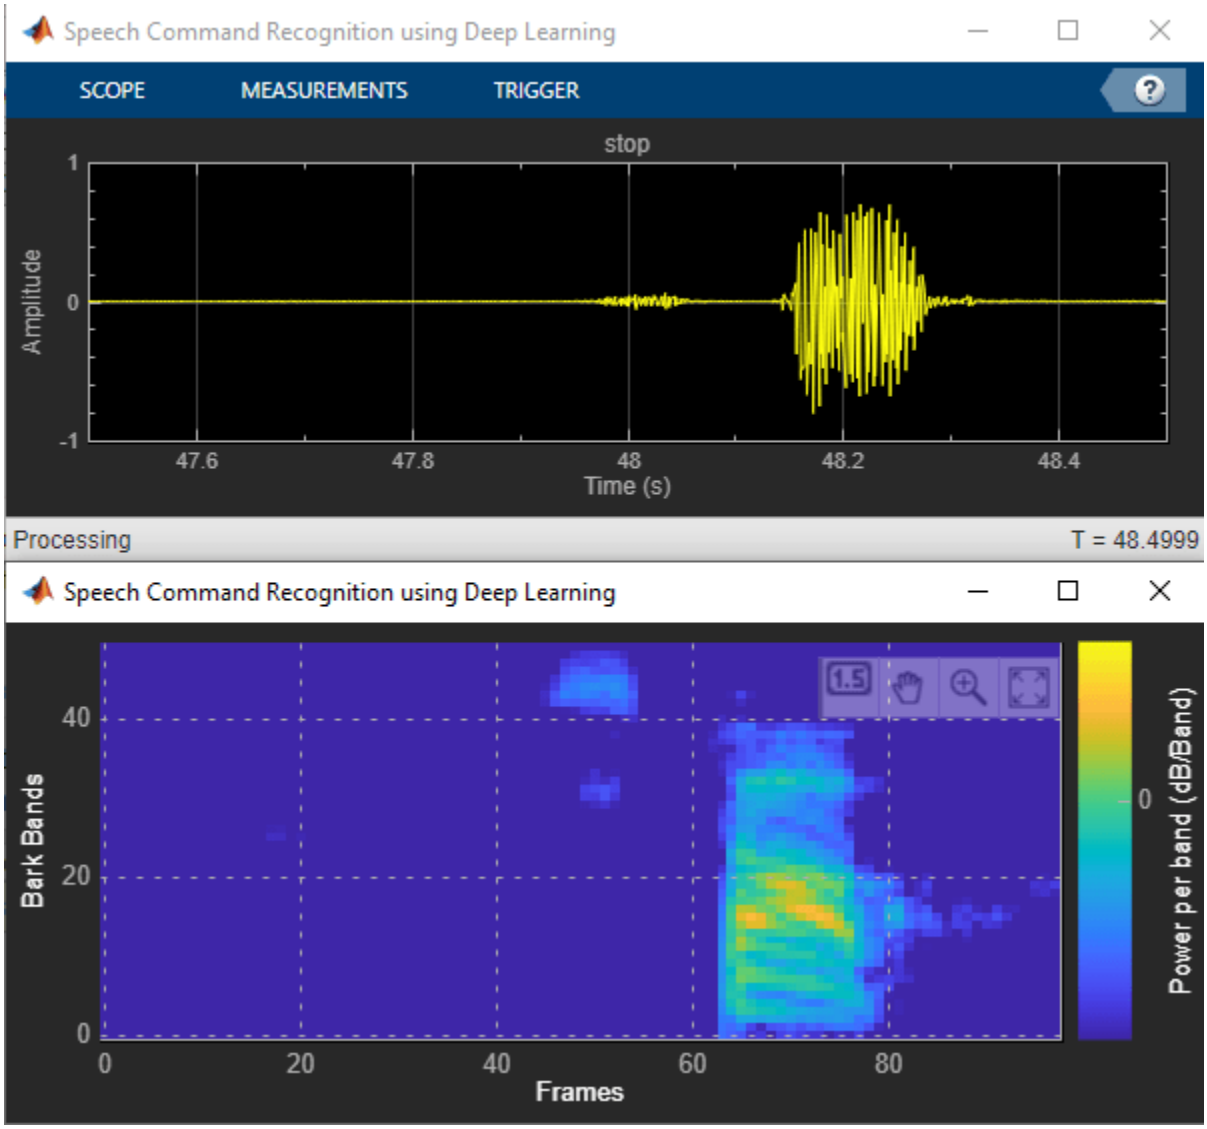
        % Extract auditory spectrogram
        spec = reshape(udpRec(1:numElementsPerSpectrogram), [numBands, numSpectrumPerSpectrogram]

        % Display time domain signal and auditory spectrogram
        timeScope(x)
        matrixViewer(spec)

        if speechCommandIdx == BackGroundIdx
            timeScope.Title = ' ';
        else
            timeScope.Title = char(labels(speechCommandIdx));
        end

        drawnow limitrate
    end
end

hide(matrixViewer)
hide(timeScope)
```



To stop the executable on your Raspberry Pi, use `stopExecutable`. Release the UDP objects.

```
stopExecutable(codertarget.raspi.raspberrypi,exeName)

release(UDPSend)
release(UDPReceive)
```

Profile Using PIL Workflow

You can measure the execution time taken on the Raspberry Pi using a PIL (processor-in-loop) workflow. The `ProfileSpeechCommandRecognitionRaspi` supporting function is the equivalent of the HelperSpeechCommandRecognitionRaspi function, except that the former returns the speech command index and auditory spectrogram while the latter sends the same parameters using UDP. The time taken by the UDP calls is less than 1 ms, which is relatively small compared to the overall execution time.

Create a PIL configuration object.

```
cfg = coder.config('lib','ecoder',true);
cfg.VerificationMode = 'PIL';
```

Set the ARM compute library and architecture.

```
dlcfg = coder.DeepLearningConfig('arm-compute');
cfg.DeepLearningConfig = dlcfg ;
cfg.DeepLearningConfig.ArmArchitecture = 'armv7';
cfg.DeepLearningConfig.ArmComputeVersion = '19.05';
```

Set up the connection with your target hardware.

```
if (~exist('r','var'))
  r = raspi('raspiname','pi','password');
end
hw = coder.hardware('Raspberry Pi');
cfg.Hardware = hw;
```

Set the build directory and target language.

```
buildDir = '~/remoteBuildDir';
cfg.Hardware.BuildDir = buildDir;
cfg.TargetLang = 'C++';
```

Enable profiling and then generate the PIL code. A MEX file named `ProfileSpeechCommandRecognition_pil` is generated in your current folder.

```
cfg.CodeExecutionProfiling = true;
codegen -config cfg ProfileSpeechCommandRecognitionRaspi -args {rand(samplesPerCapture, 1, 'sing
```

```

```

Evaluate Raspberry Pi Execution Time

Call the generated PIL function multiple times to get the average execution time.

```
testDur = 50e-3;
numCalls = 100;

for k = 1:numCalls
    x = pinknoise(fs*testDur,'single');
```

```
    [speechCommandIdx, auditoryFeatures] = ProfileSpeechCommandRecognitionRaspi_pil(x);
end

### Starting application: 'codegen\lib\ProfileSpeechCommandRecognitionRaspi\pil\ProfileSpeechComm
    To terminate execution: clear ProfileSpeechCommandRecognitionRaspi_pil
### Launching application ProfileSpeechCommandRecognitionRaspi.elf...
    Execution profiling data is available for viewing. Open Simulation Data Inspector.
    Execution profiling report available after termination.
```

Terminate the PIL execution.

```
clear ProfileSpeechCommandRecognitionRaspi_pil

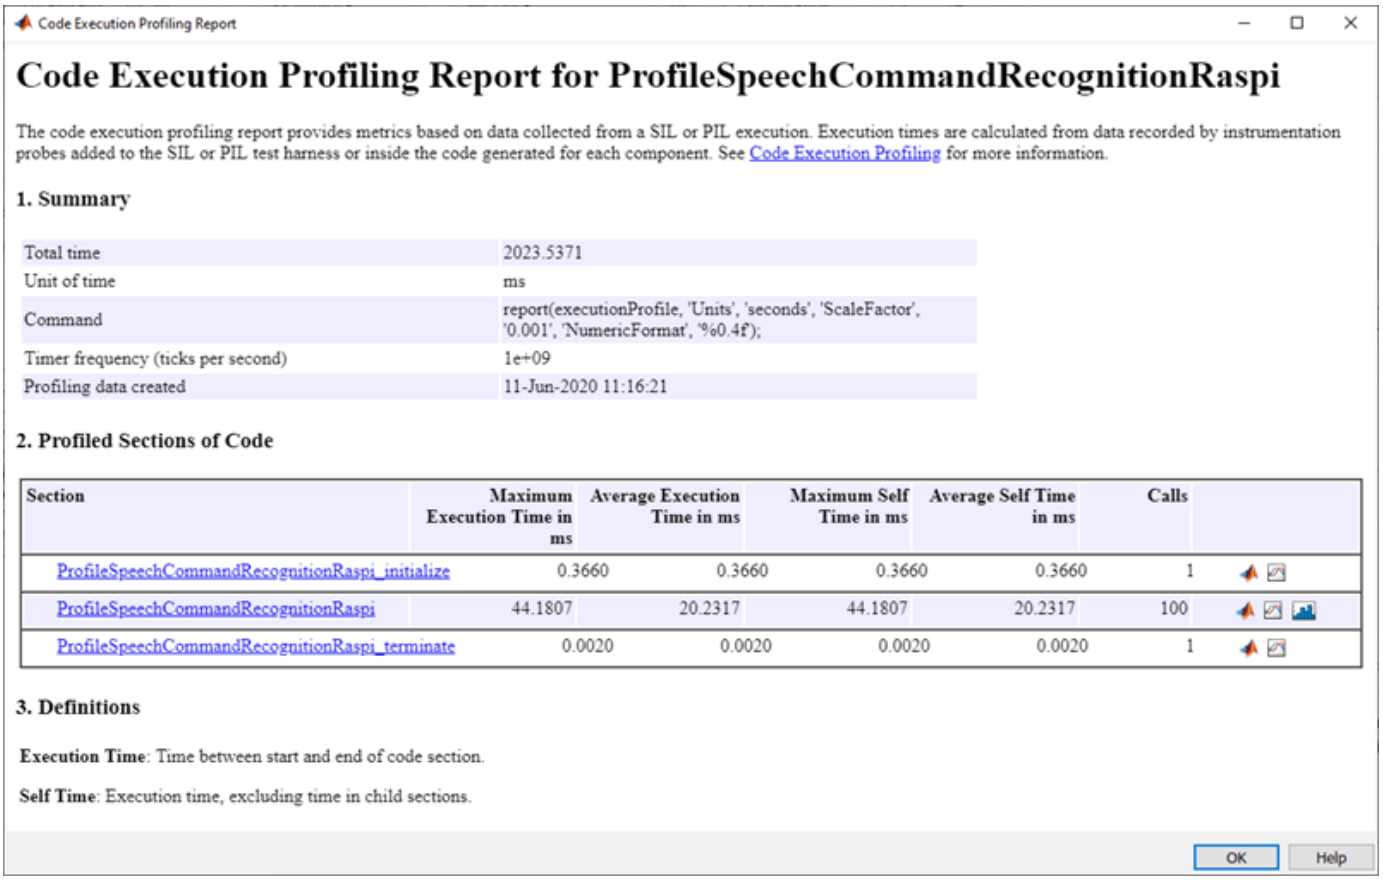
### Host application produced the following standard output (stdout) and standard error (stderr)

    Execution profiling report: report(getCoderExecutionProfile('ProfileSpeechCommandRecognitionR
```

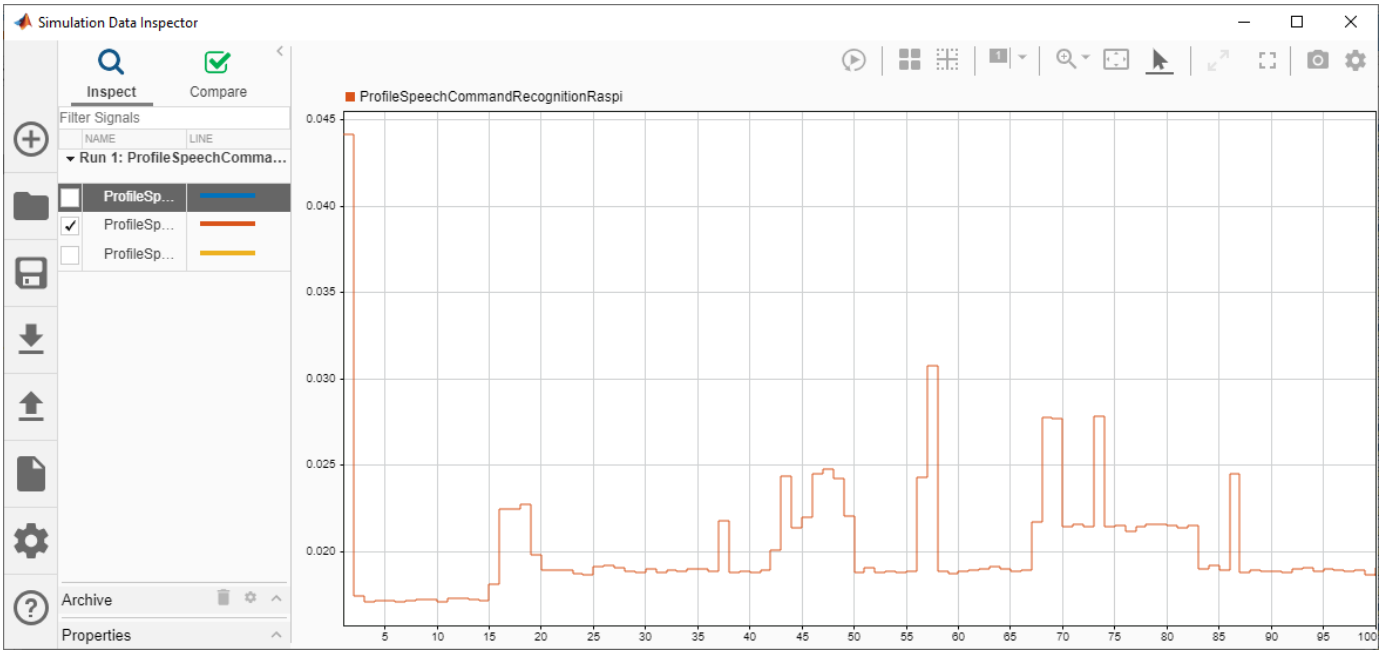
Generate an execution profile report to evaluate execution time.

```
executionProfile = getCoderExecutionProfile('ProfileSpeechCommandRecognitionRaspi');
report(executionProfile, ...
       'Units','Seconds', ...
       'ScaleFactor','1e-03', ...
       'NumericFormat','%0.4f')

ans =
'C:\ExampleMatlab\ExampleManager\sporwal.Bdoc21b.j1648568\deeplearning_shared-ex00376115\codegen\
```



The maximum execution time taken by the `ProfileSpeechCommandRecognitionRaspi` function is nearly twice the average execution time. You can notice that the execution time is maximum for the first call of the PIL function and it is due to the initialization happening in the first call. The average execution time is approximately 20 ms, which is below the 50 ms budget (audio capture time). The performance is measured on Raspberry Pi 4 Model B Rev 1.1.



Speech Command Recognition Code Generation with Intel MKL-DNN

This example shows how to deploy feature extraction and a convolutional neural network (CNN) for speech command recognition on Intel® processors. To generate the feature extraction and network code, you use MATLAB Coder and the Intel Math Kernel Library for Deep Neural Networks (MKL-DNN). In this example, the generated code is a MATLAB executable (MEX) function, which is called by a MATLAB script that displays the predicted speech command along with the time domain signal and auditory spectrogram. For details about audio preprocessing and network training, see “Speech Command Recognition Using Deep Learning” (Audio Toolbox).

Prerequisites

- The MATLAB Coder Interface for Deep Learning Support Package
- Xeon processor with support for Intel Advanced Vector Extensions 2 (Intel AVX2)
- Intel Math Kernel Library for Deep Neural Networks (MKL-DNN)
- Environment variables for Intel MKL-DNN

For supported versions of libraries and for information about setting up environment variables, see “Prerequisites for Deep Learning with MATLAB Coder” (MATLAB Coder).

Streaming Demonstration in MATLAB

Use the same parameters for the feature extraction pipeline and classification as developed in “Speech Command Recognition Using Deep Learning” (Audio Toolbox).

Define the same sample rate the network was trained on (16 kHz). Define the classification rate and the number of audio samples input per frame. The feature input to the network is a Bark spectrogram that corresponds to 1 second of audio data. The Bark spectrogram is calculated for 25 ms windows with 10 ms hops.

```
fs = 16000;
classificationRate = 20;
samplesPerCapture = fs/classificationRate;

segmentDuration = 1;
segmentSamples = round(segmentDuration*fs);

frameDuration = 0.025;
frameSamples = round(frameDuration*fs);

hopDuration = 0.010;
hopSamples = round(hopDuration*fs);
```

Create an `audioFeatureExtractor` (Audio Toolbox) object to extract 50-band Bark spectrograms without window normalization.

```
afe = audioFeatureExtractor( ...
    'SampleRate',fs, ...
    'FFTLength',512, ...
    'Window',hann(frameSamples,'periodic'), ...
    'OverlapLength',frameSamples - hopSamples, ...
    'barkSpectrum',true);
```

```
numBands = 50;
setExtractorParams(afe,'barkSpectrum','NumBands',numBands,'WindowNormalization',false);
```

Load the pretrained convolutional neural network and labels.

```
load('commandNet.mat')
labels = trainedNet.Layers(end).Classes;
numLabels = numel(labels);
backgroundIdx = find(labels == 'background');
```

Define buffers and decision thresholds to post process network predictions.

```
probBuffer = single(zeros([numLabels,classificationRate/2]));
YBuffer = single(numLabels * ones(1, classificationRate/2));

countThreshold = ceil(classificationRate*0.2);
probThreshold = single(0.7);
```

Create an `audioDeviceReader` (Audio Toolbox) object to read audio from your device. Create a `dsp.AsyncBuffer` (DSP System Toolbox) object to buffer the audio into chunks.

```
adr = audioDeviceReader('SampleRate',fs,'SamplesPerFrame',samplesPerCapture,'OutputDataType','si
audioBuffer = dsp.AsyncBuffer(fs);
```

Create a `dsp.MatrixViewer` (DSP System Toolbox) object and a `timescope` (DSP System Toolbox) object to display the results.

```
matrixViewer = dsp.MatrixViewer("ColorBarLabel","Power per band (dB/Band)", ...
    "XLabel","Frames", ...
    "YLabel","Bark Bands", ...
    "Position",[400 100 600 250], ...
    "ColorLimits",[-4 2.6445], ...
    "AxisOrigin",'Lower left corner', ...
    "Name","Speech Command Recognition Using Deep Learning");

timeScope = timescope('SampleRate', fs, ...
    'YLimits',[-1 1], 'Position', [400 380 600 250], ...
    'Name','Speech Command Recognition Using Deep Learning', ...
    'TimeSpanSource','Property', ...
    'TimeSpan',1, ...
    'BufferLength',fs);

timeScope.YLabel = 'Amplitude';
timeScope.ShowGrid = true;
```

Show the time scope and matrix viewer. Detect commands as long as both the time scope and matrix viewer are open or until the time limit is reached. To stop the live detection before the time limit is reached, close the time scope window or matrix viewer window.

```
show(timeScope)
show(matrixViewer)
timeLimit = 10;

tic
while isVisible(timeScope) && isVisible(matrixViewer) && toc < timeLimit
    %% Capture Audio
    x = adr();
    write(audioBuffer,x);
```

```
    y = read(audioBuffer,fs,fs-samplesPerCapture);

    % Compute auditory features
    features = extract(afe,y);
    auditory_features = log10(features + 1e-6);

    % Transpose to get the auditory spectrum
    auditorySpectrum = auditory_features';

    % Perform prediction
    probs = predict(trainedNet, auditory_features);
    [~, YPredicted] = max(probs);

    % Perform statistical post processing
    YBuffer = [YBuffer(2:end),YPredicted];
    probBuffer = [probBuffer(:,2:end),probs(:)];

    [YMode_idx, count] = mode(YBuffer);
    count = single(count);
    maxProb = max(probBuffer(YMode_idx,:));

    if (YMode_idx == single(backgroundIdx) || count < countThreshold || maxProb < probThreshold)
        speechCommandIdx = backgroundIdx;
    else
        speechCommandIdx = YMode_idx;
    end

    % Update plots
    matrixViewer(auditorySpectrum);
    timeScope(x);

    if (speechCommandIdx == backgroundIdx)
        timeScope.Title = ' ';
    else
        timeScope.Title = char(labels(speechCommandIdx));
    end
    drawnow
end
```

Hide the scopes.

```
hide(matrixViewer)
hide(timeScope)
```

Prepare MATLAB Code for Deployment

To create a function to perform feature extraction compatible with code generation, call `generateMATLABFunction` (Audio Toolbox) on the `audioFeatureExtractor` object. The `generateMATLABFunction` object function creates a standalone function that performs equivalent feature extraction and is compatible with code generation.

```
generateMATLABFunction(afe,'extractSpeechFeatures')
```

The HelperSpeechCommandRecognition supporting function encapsulates the feature extraction and network prediction process demonstrated previously. So that the feature extraction is compatible with code generation, feature extraction is handled by the generated `extractSpeechFeatures` function. So that the network is compatible with code generation, the supporting function uses the `coder.loadDeepLearningNetwork` (MATLAB Coder) function to load the network.

Use the HelperSpeechCommandRecognition function to perform live detection of speech commands.

```
show(timeScope)
show(matrixViewer)
timeLimit = 10;

tic
while isVisible(timeScope) && isVisible(matrixViewer) && toc < timeLimit
    x = adr();

    [speechCommandIdx, auditorySpectrum] = HelperSpeechCommandRecognition(x);

    matrixViewer(auditorySpectrum);
    timeScope(x);

    if (speechCommandIdx == backgroundIdx)
        timeScope.Title = ' ';
    else
        timeScope.Title = char(labels(speechCommandIdx));
    end
    drawnow
end
```

Hide the scopes.

```
hide(timeScope)
hide(matrixViewer)
```

Generate MATLAB Executable

Create a code generation configuration object for generation of an executable program. Specify the target language as C++.

```
cfg = coder.config('mex');
cfg.TargetLang = 'C++';
```

Create a configuration object for deep learning code generation with the MKL-DNN library. Attach the configuration object to the code generation configuration object.

```
dlcfg = coder.DeepLearningConfig('mkldnn');
cfg.DeepLearningConfig = dlcfg;
```

Call `codegen` (MATLAB Coder) to generate C++ code for the `HelperSpeechCommandRecognition` function. Specify the configuration object and prototype arguments. A MEX file named `HelperSpeechCommandRecognition_mex` is generated to your current folder.

```
codegen HelperSpeechCommandRecognition -config cfg -args {rand(samplesPerCapture, 1, 'single')} -
```

```

```

Evaluate MEX Execution Time

Use `tic` and `toc` to compare the execution time to run the simulation completely in MATLAB with the execution time of the MEX function.

Measure the performance of the simulation code.

```
testDur = 50e-3;
x = pinknoise(fs*testDur,'single');
numLoops = 100;
tic
for k = 1:numLoops
    [speechCommandIdx, auditory_features] = HelperSpeechCommandRecognition(x);
end
```

```
exeTime = toc;
fprintf('SIM execution time per 50 ms of audio = %0.4f ms\n',(exeTime/numLoops)*1000);
```

```
SIM execution time per 50 ms of audio = 6.8212 ms
```

Measure the performance of the MEX code.

```
tic
for k = 1:numLoops
    [speechCommandIdx, auditory_features] = HelperSpeechCommandRecognition_mex(x);
end
exeTimeMex = toc;
fprintf('MEX execution time per 50 ms of audio = %0.4f ms\n',(exeTimeMex/numLoops)*1000);
```

```
MEX execution time per 50 ms of audio = 1.3347 ms
```

Evaluate the performance gained from using the MEX function. This performance test is performed on a machine using NVIDIA Quadro P620 (Version 26) GPU and Intel(R) Xeon(R) W-2133 CPU running at 3.60 GHz.

```
PerformanceGain = exeTime/exeTimeMex
```

```
PerformanceGain = 5.1107
```

Train Generative Adversarial Network (GAN) for Sound Synthesis

This example shows how to train and use a generative adversarial network (GAN) to generate sounds.

Introduction

In generative adversarial networks, a generator and a discriminator compete against each other to improve the generation quality.

GANs have generated significant interest in the field of audio and speech processing. Applications include text-to-speech synthesis, voice conversion, and speech enhancement.

This example trains a GAN for unsupervised synthesis of audio waveforms. The GAN in this example generates drumbeat sounds. The same approach can be followed to generate other types of sound, including speech.

Synthesize Audio with Pre-Trained GAN

Before you train a GAN from scratch, you will use a pretrained GAN generator to synthesize drum beats.

Download the pretrained generator.

```
matFileName = 'drumGeneratorWeights.mat';
if ~exist(matFileName,'file')
    websave(matFileName,'https://www.mathworks.com/supportfiles/audio/GanAudioSynthesis/drumGene
end
```

The function `synthesizeDrumBeat` calls a pretrained network to synthesize a drumbeat sampled at 16 kHz. The `synthesizeDrumBeat` function is included at the end of this example.

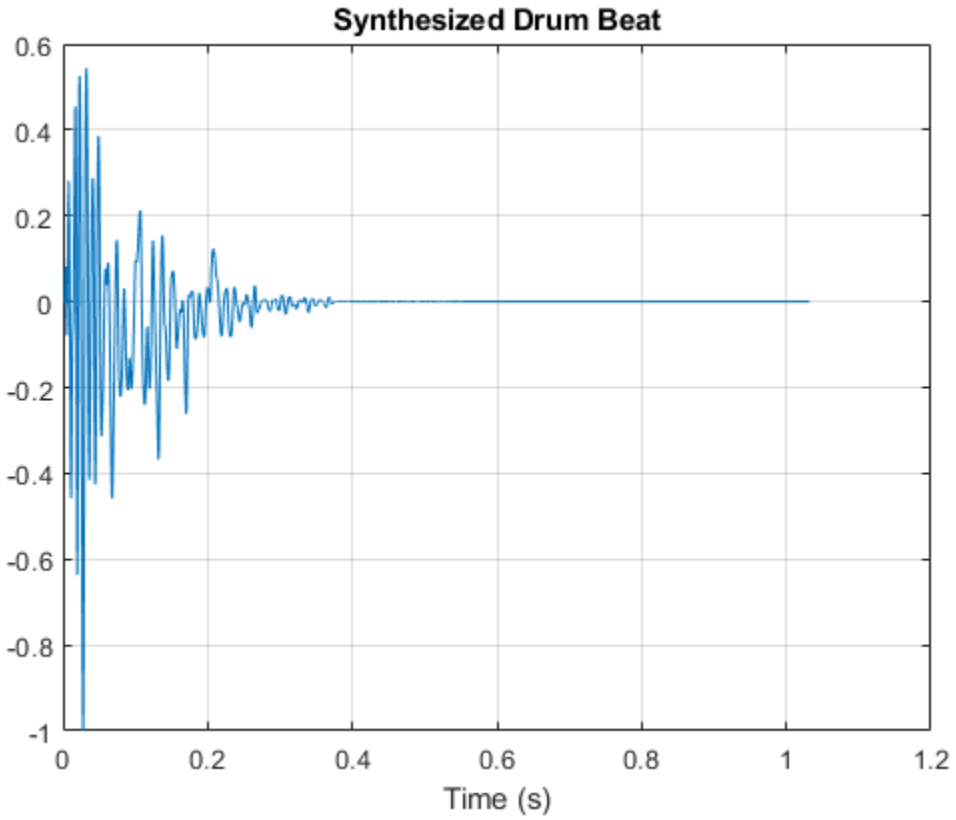
Synthesize a drumbeat and listen to it.

```
drum = synthesizeDrumBeat;

fs = 16e3;
sound(drum,fs)
```

Plot the synthesized drumbeat.

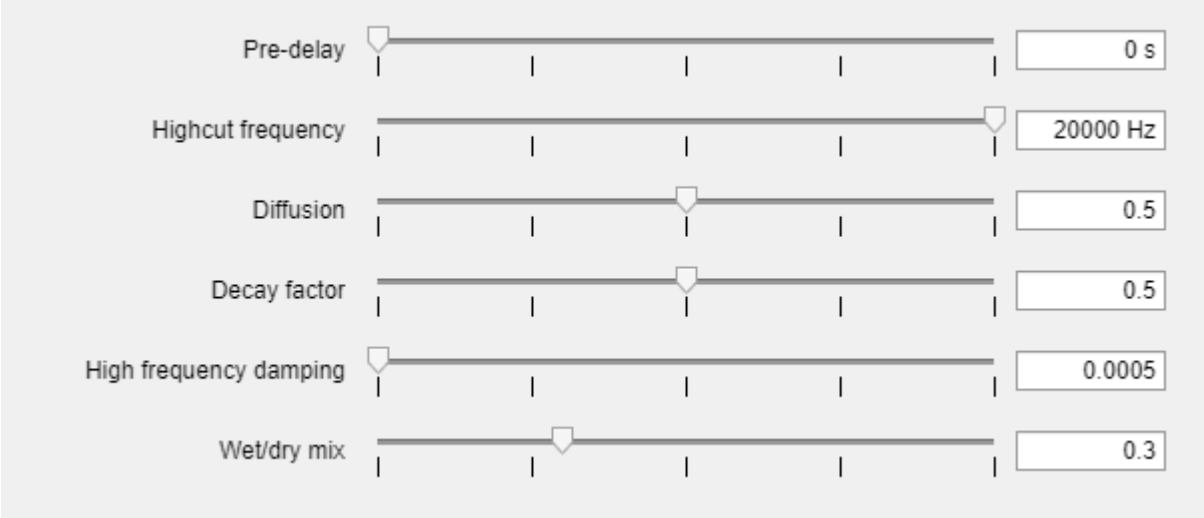
```
t = (0:length(drum)-1)/fs;
plot(t,drum)
grid on
xlabel('Time (s)')
title('Synthesized Drum Beat')
```



You can use the drumbeat synthesizer with other audio effects to create more complex applications. For example, you can apply reverberation to the synthesized drum beats.

Create a `reverberator` (Audio Toolbox) object and open its parameter tuner UI. This UI enables you to tune the `reverberator` parameters as the simulation runs.

```
reverb = reverberator('SampleRate',fs);
parameterTuner(reverb);
```

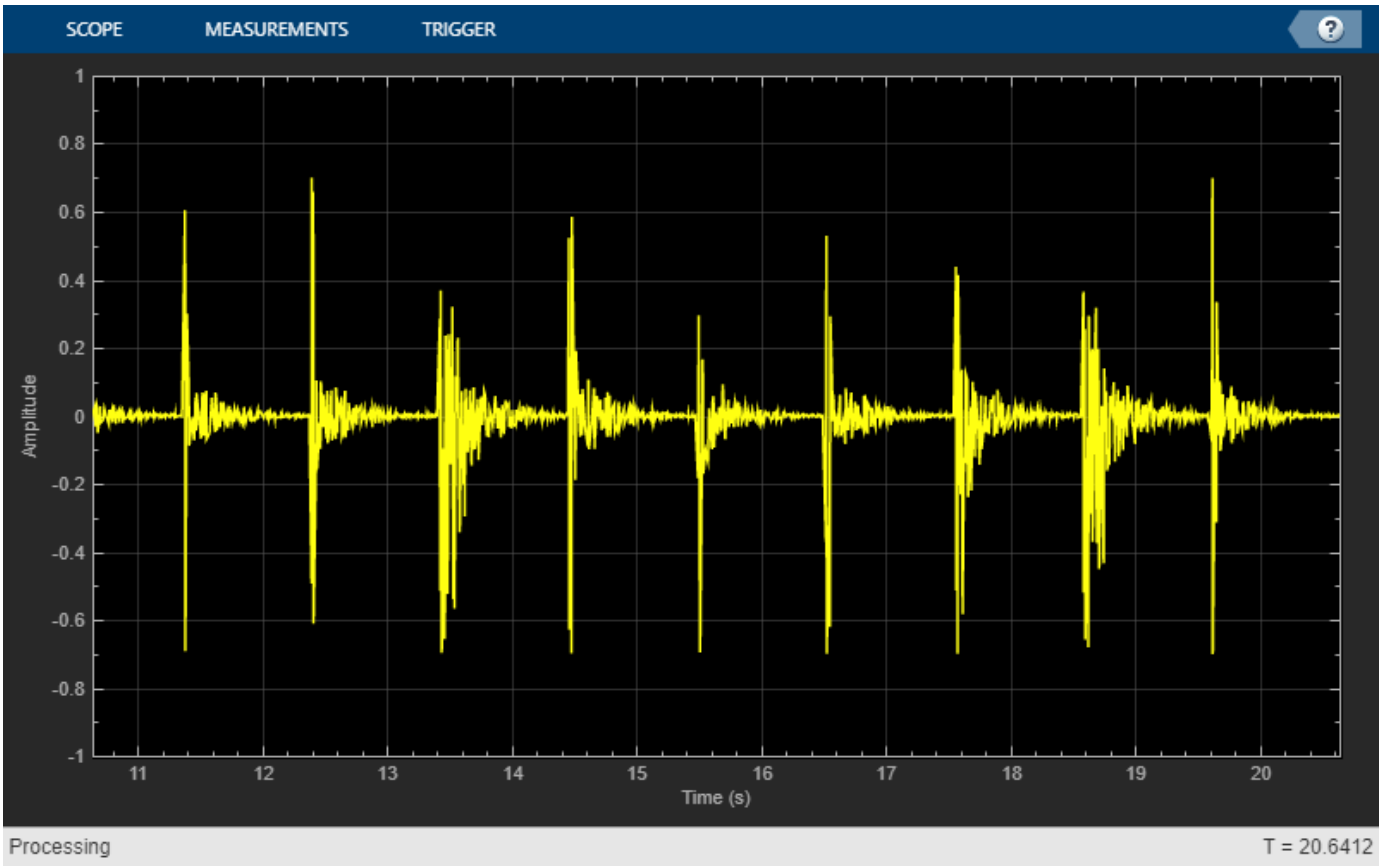


Create a time scope object to visualize the drum beats.

```
ts = timescope('SampleRate',fs, ...
    'TimeSpanSource','Property', ...
    'TimeSpanOverrunAction','Scroll', ...
    'TimeSpan',10, ...
    'BufferLength',10*256*64, ...
    'ShowGrid',true, ...
    'YLimits',[-1 1]);
```

In a loop, synthesize the drum beats and apply reverberation. Use the parameter tuner UI to tune reverberation. If you want to run the simulation for a longer time, increase the value of the `loopCount` parameter.

```
loopCount = 20;
for ii = 1:loopCount
    drum = synthesizeDrumBeat;
    drum = reverb(drum);
    ts(drum(:,1));
    soundsc(drum,fs)
    pause(0.5)
end
```



Train the GAN

Now that you have seen the pretrained drumbeat generator in action, you can investigate the training process in detail.

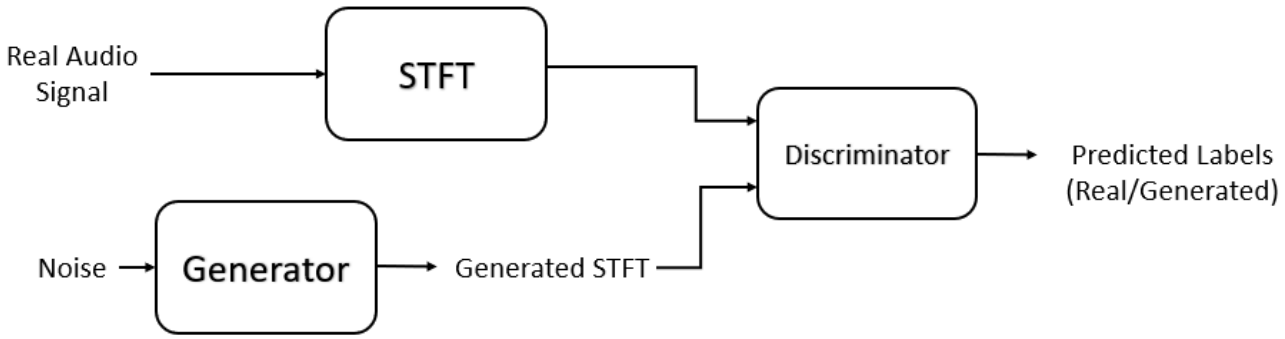
A GAN is a type of deep learning network that generates data with characteristics similar to the training data.

A GAN consists of two networks that train together, a *generator* and a *discriminator*:

- Generator - Given a vector or random values as input, this network generates data with the same structure as the training data. It is the generator's job to fool the discriminator.
- Discriminator - Given batches of data containing observations from both the training data and the generated data, this network attempts to classify the observations as real or generated.

To maximize the performance of the generator, maximize the loss of the discriminator when given generated data. That is, the objective of the generator is to generate data that the discriminator classifies as real. To maximize the performance of the discriminator, minimize the loss of the discriminator when given batches of both real and generated data. Ideally, these strategies result in a generator that generates convincingly realistic data and a discriminator that has learned strong feature representations that are characteristic of the training data.

In this example, you train the generator to create fake time-frequency short-time Fourier transform (STFT) representations of drum beats. You train the discriminator to identify real STFTs. You create the real STFTs by computing the STFT of short recordings of real drum beats.



Load Training Data

Train a GAN using the Drum Sound Effects dataset [1]. Download and extract the dataset.

```
url = 'http://deepyeti.ucsd.edu/cdonahue/wavegan/data/drums.tar.gz';
downloadFolder = tempdir;
filename = fullfile(downloadFolder,'drums_dataset.tgz');

drumsFolder = fullfile(downloadFolder,'drums');
if ~exist(drumsFolder,'dir')
    disp('Downloading Drum Sound Effects Dataset (218 MB)...')
    websave(filename,url);
    untar(filename,downloadFolder)
end
```

Create an `audioDatastore` (Audio Toolbox) object that points to the drums dataset.

```
ads = audioDatastore(drumsFolder,'IncludeSubfolders',true);
```

Define Generator Network

Define a network that generates STFTs from 1-by-1-by-100 arrays of random values. Create a network that upscales 1-by-1-by-100 arrays to 128-by-128-by-1 arrays using a fully connected layer followed by a reshape layer and a series of transposed convolution layers with ReLU layers.

This figure shows the dimensions of the signal as it travels through the generator. The generator architecture is defined in Table 4 of [1].

The generator network is defined in `modelGenerator`, which is included at the end of this example.

Define Discriminator Network

Define a network that classifies real and generated 128-by-128 STFTs.

Create a network that takes 128-by-128 images and outputs a scalar prediction score using a series of convolution layers with leaky ReLU layers followed by a fully connected layer.

This figure shows the dimensions of the signal as it travels through the discriminator. The discriminator architecture is defined in Table 5 of [1].

The discriminator network is defined in `modelDiscriminator`, which is included at the end of this example.

Generate Real Drumbeat Training Data

Generate STFT data from the drumbeat signals in the datastore.

Define the STFT parameters.

```
fftLength = 256;
win = hann(fftLength,'periodic');
overlapLength = 128;
```

To speed up processing, distribute the feature extraction across multiple workers using `parfor`.

First, determine the number of partitions for the dataset. If you do not have Parallel Computing Toolbox™, use a single partition.

```
if ~isempty(ver('parallel'))
    pool = gcp;
    numPar = numpartitions(ads,pool);
else
    numPar = 1;
end
```

For each partition, read from the datastore and compute the STFT.

```
parfor ii = 1:numPar

    subds = partition(ads,numPar,ii);
    STrain = zeros(fftLength/2+1,128,1,numel(subds.Files));

    for idx = 1:numel(subds.Files)

        x = read(subds);

        if length(x) > fftLength*64
            % Lengthen the signal if it is too short
            x = x(1:fftLength*64);
        end

        % Convert from double-precision to single-precision
        x = single(x);

        % Scale the signal
        x = x ./ max(abs(x));

        % Zero-pad to ensure stft returns 128 windows.
        x = [x ; zeros(overlapLength,1,'like',x)];

        S0 = stft(x,'Window',win,'OverlapLength',overlapLength,'Centered',false);

        % Convert from two-sided to one-sided.
        S = S0(1:129,:);
        S = abs(S);
        STrain(:,:,:,idx) = S;
    end
    STrainC{ii} = STrain;
end
```

Convert the output to a four-dimensional array with STFTs along the fourth dimension.

```
STrain = cat(4,STrainC{:});
```

Convert the data to the log scale to better align with human perception.

```
STrain = log(STrain + 1e-6);
```

Normalize training data to have zero mean and unit standard deviation.

Compute the STFT mean and standard deviation of each frequency bin.

```
SMean = mean(STrain,[2 3 4]);
SStd = std(STrain,1,[2 3 4]);
```

Normalize each frequency bin.

```
STrain = (STrain-SMean)./SStd;
```

The computed STFTs have unbounded values. Following the approach in [1], make the data bounded by clipping the spectra to 3 standard deviations and rescaling to [-1 1].

```
STrain = STrain/3;
Y = reshape(STrain,numel(STrain),1);
Y(Y<-1) = -1;
Y(Y>1) = 1;
STrain = reshape(Y,size(STrain));
```

Discard the last frequency bin to force the number of STFT bins to a power of two (which works well with convolutional layers).

```
STrain = STrain(1:end-1,:,:,:);
```

Permute the dimensions in preparation for feeding to the discriminator.

```
STrain = permute(STrain,[2 1 3 4]);
```

Specify Training Options

Train with a mini-batch size of 64 for 1000 epochs.

```
maxEpochs = 1000;
miniBatchSize = 64;
```

Compute the number of iterations required to consume the data.

```
numIterationsPerEpoch = floor(size(STrain,4)/miniBatchSize);
```

Specify the options for Adam optimization. Set the learn rate of the generator and discriminator to `0.0002`. For both networks, use a gradient decay factor of 0.5 and a squared gradient decay factor of 0.999.

```
learnRateGenerator = 0.0002;
learnRateDiscriminator = 0.0002;
gradientDecayFactor = 0.5;
squaredGradientDecayFactor = 0.999;
```

Train on a GPU if one is available. Using a GPU requires Parallel Computing Toolbox™.

```
executionEnvironment = "auto";
```

Initialize the generator and discriminator weights. The `initializeGeneratorWeights` and `initializeDiscriminatorWeights` functions return random weights obtained using Glorot uniform initialization. The functions are included at the end of this example.

```
generatorParameters = initializeGeneratorWeights;
discriminatorParameters = initializeDiscriminatorWeights;
```

Train Model

Train the model using a custom training loop. Loop over the training data and update the network parameters at each iteration.

For each epoch, shuffle the training data and loop over mini-batches of data.

For each mini-batch:

- Generate a `dlarray` object containing an array of random values for the generator network.
- For GPU training, convert the data to a `gpuArray` (Parallel Computing Toolbox) object.
- Evaluate the model gradients using `dlfeval` and the helper functions, `modelDiscriminatorGradients` and `modelGeneratorGradients`.
- Update the network parameters using the `adamupdate` function.

Initialize the parameters for Adam.

```
trailingAvgGenerator = [];
trailingAvgSqGenerator = [];
trailingAvgDiscriminator = [];
trailingAvgSqDiscriminator = [];
```

You can set `saveCheckpoints` to `true` to save the updated weights and states to a MAT file every ten epochs. You can then use this MAT file to resume training if it is interrupted. For the purpose of this example, set `saveCheckpoints` to `false`.

```
saveCheckpoints = false;
```

Specify the length of the generator input.

```
numLatentInputs = 100;
```

Train the GAN. This can take multiple hours to run.

```
iteration = 0;

for epoch = 1:maxEpochs

    % Shuffle the data.
    idx = randperm(size(STrain,4));
    STrain = STrain(:,:,:,idx);

    % Loop over mini-batches.
    for index = 1:numIterationsPerEpoch

        iteration = iteration + 1;

        % Read mini-batch of data.
```

```
            dlX = STrain(:,:,:,(index-1)*miniBatchSize+1:index*miniBatchSize);
            dlX = dlarray(dlX,'SSCB');

            % Generate latent inputs for the generator network.
            Z = 2 * ( rand(1,1,numLatentInputs,miniBatchSize,'single') - 0.5 ) ;
            dlZ = dlarray(Z);

            % If training on a GPU, then convert data to gpuArray.
            if (executionEnvironment == "auto" && canUseGPU) || executionEnvironment == "gpu"
                dlZ = gpuArray(dlZ);
                dlX = gpuArray(dlX);
            end

            % Evaluate the discriminator gradients using dlfeval and the
            % |modelDiscriminatorGradients| helper function.
            gradientsDiscriminator = ...
                dlfeval(@modelDiscriminatorGradients,discriminatorParameters,generatorParameters,dlX

            % Update the discriminator network parameters.
            [discriminatorParameters,trailingAvgDiscriminator,trailingAvgSqDiscriminator] = ...
                adamupdate(discriminatorParameters,gradientsDiscriminator, ...
                trailingAvgDiscriminator,trailingAvgSqDiscriminator,iteration, ...
                learnRateDiscriminator,gradientDecayFactor,squaredGradientDecayFactor);

            % Generate latent inputs for the generator network.
            Z = 2 * ( rand(1,1,numLatentInputs,miniBatchSize,'single') - 0.5 ) ;
            dlZ = dlarray(Z);

            % If training on a GPU, then convert data to gpuArray.
            if (executionEnvironment == "auto" && canUseGPU) || executionEnvironment == "gpu"
                dlZ = gpuArray(dlZ);
            end

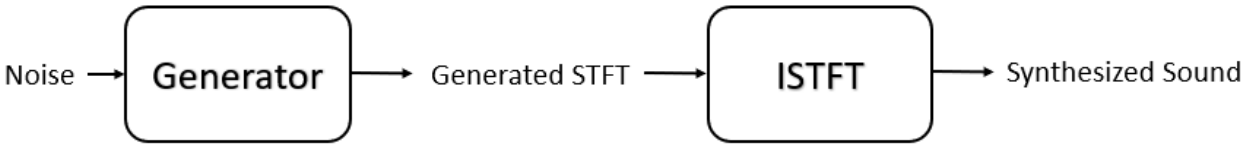
            % Evaluate the generator gradients using dlfeval and the
            % |modelGeneratorGradients| helper function.
            gradientsGenerator  = ...
                dlfeval(@modelGeneratorGradients,discriminatorParameters,generatorParameters,dlZ);

            % Update the generator network parameters.
            [generatorParameters,trailingAvgGenerator,trailingAvgSqGenerator] = ...
                adamupdate(generatorParameters,gradientsGenerator, ...
                trailingAvgGenerator,trailingAvgSqGenerator,iteration, ...
                learnRateGenerator,gradientDecayFactor,squaredGradientDecayFactor);
        end

        % Every 10 iterations, save a training snapshot to a MAT file.
        if saveCheckpoints && mod(epoch,10)==0
            fprintf('Epoch %d out of %d complete\n',epoch,maxEpochs);
            % Save checkpoint in case training is interrupted.
            save('audioganncheckpoint.mat',...
                'generatorParameters','discriminatorParameters',...
                'trailingAvgDiscriminator','trailingAvgSqDiscriminator',...
                'trailingAvgGenerator','trailingAvgSqGenerator','iteration');
        end
    end
```

Synthesize Sounds

Now that you have trained the network, you can investigate the synthesis process in more detail.



The trained drumbeat generator synthesizes short-time Fourier transform (STFT) matrices from input arrays of random values. An inverse STFT (ISTFT) operation converts the time-frequency STFT to a synthesized time-domain audio signal.

Load the weights of a pretrained generator. These weights were obtained by running the training highlighted in the previous section for 1000 epochs.

```
load(matFileName,'generatorParameters','SMean','SStd');
```

The generator takes 1-by-1-by-100 vectors of random values as an input. Generate a sample input vector.

```
numLatentInputs = 100;
dlZ = dlarray(2 * ( rand(1,1,numLatentInputs,1,'single') - 0.5 ));
```

Pass the random vector to the generator to create an STFT image. `generatorParameters` is a structure containing the weights of the pretrained generator.

```
dlXGenerated = modelGenerator(dlZ,generatorParameters);
```

Convert the STFT `dlarray` to a single-precision matrix.

```
S = dlXGenerated.extractdata;
```

Transpose the STFT to align its dimensions with the `istft` function.

```
S = S.';
```

The STFT is a 128-by-128 matrix, where the first dimension represents 128 frequency bins linearly spaced from 0 to 8 kHz. The generator was trained to generate a one-sided STFT from an FFT length of 256, with the last bin omitted. Reintroduce that bin by inserting a row of zeros into the STFT.

```
S = [S ; zeros(1,128)];
```

Revert the normalization and scaling steps used when you generated the STFTs for training.

```
S = S * 3;
S = (S.*SStd) + SMean;
```

Convert the STFT from the log domain to the linear domain.

```
S = exp(S);
```

Convert the STFT from one-sided to two-sided.

```
S = [S; S(end-1:-1:2,:)];
```

Pad with zeros to remove window edge-effects.

```
S = [zeros(256,100) S zeros(256,100)];
```

The STFT matrix does not contain any phase information. Use a fast version of the Griffin-Lim algorithm with 20 iterations to estimate the signal phase and produce audio samples.

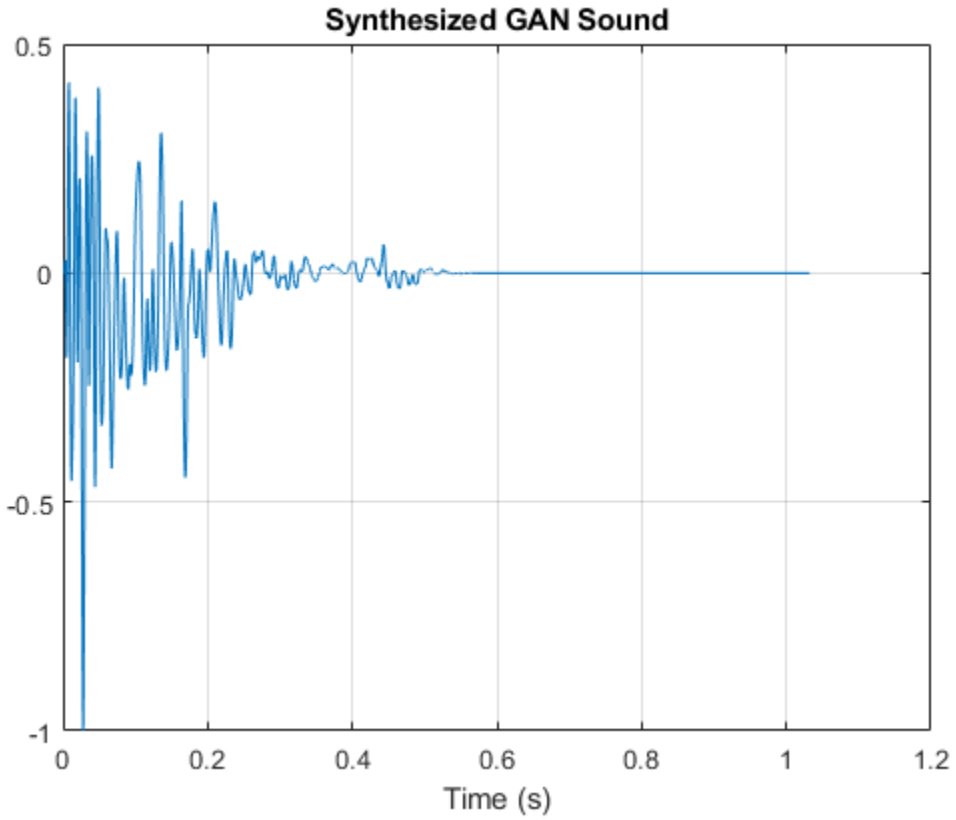
```
myAudio = stftmag2sig(S,256, ...
    'FrequencyRange','twosided', ...
    'Window',hann(256,'periodic'), ...
    'OverlapLength',128, ...
    'MaxIterations',20, ...
    'Method','fgla');
myAudio = myAudio./max(abs(myAudio),[],'all');
myAudio = myAudio(128*100:end-128*100);
```

Listen to the synthesized drumbeat.

```
sound(myAudio,fs)
```

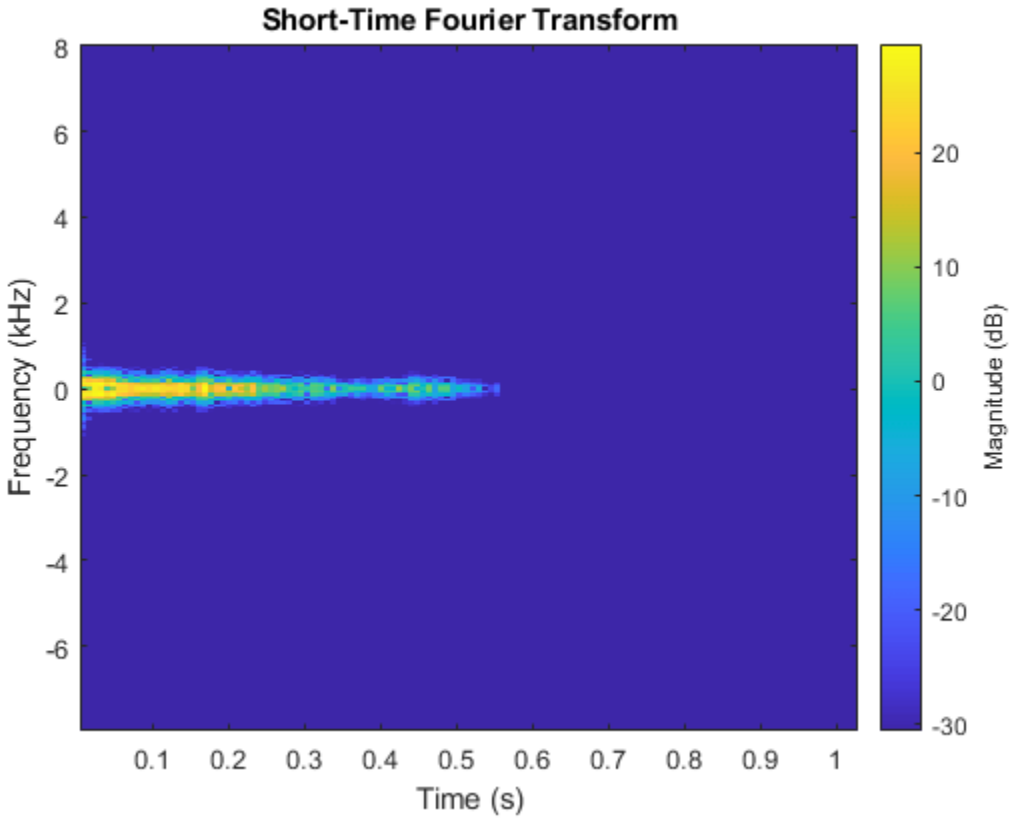
Plot the synthesized drumbeat.

```
t = (0:length(myAudio)-1)/fs;
plot(t,myAudio)
grid on
xlabel('Time (s)')
title('Synthesized GAN Sound')
```



Plot the STFT of the synthesized drumbeat.

```
figure
stft(myAudio,fs,'Window',hann(256,'periodic'),'OverlapLength',128);
```



Model Generator Function

The `modelGenerator` function upscales 1-by-1-by-100 arrays (dlX) to 128-by-128-by-1 arrays (dlY). `parameters` is a structure holding the weights of the generator layers. The generator architecture is defined in Table 4 of [1].

```
function dlY = modelGenerator(dlX,parameters)

dlY = fullyconnect(dlX,parameters.FC.Weights,parameters.FC.Bias,'Dataformat','SSCB');

dlY = reshape(dlY,[1024 4 4 size(dlY,2)]);
dlY = permute(dlY,[3 2 1 4]);
dlY = relu(dlY);

dlY = dltranspconv(dlY,parameters.Conv1.Weights,parameters.Conv1.Bias,'Stride' ,2 ,'Cropping','sa
dlY = relu(dlY);

dlY = dltranspconv(dlY,parameters.Conv2.Weights,parameters.Conv2.Bias,'Stride' ,2 ,'Cropping','sa
dlY = relu(dlY);

dlY = dltranspconv(dlY,parameters.Conv3.Weights,parameters.Conv3.Bias,'Stride' ,2 ,'Cropping','sa
dlY = relu(dlY);
```

```
dlY = dltranspconv(dlY,parameters.Conv4.Weights,parameters.Conv4.Bias,'Stride' ,2 ,'Cropping','sa
dlY = relu(dlY);

dlY = dltranspconv(dlY,parameters.Conv5.Weights,parameters.Conv5.Bias,'Stride' ,2 ,'Cropping','sa
dlY = tanh(dlY);
end
```

Model Discriminator Function

The `modelDiscriminator` function takes 128-by-128 images and outputs a scalar prediction score. The discriminator architecture is defined in Table 5 of [1].

```
function dlY = modelDiscriminator(dlX,parameters)

dlY = dlconv(dlX,parameters.Conv1.Weights,parameters.Conv1.Bias,'Stride' ,2 ,'Padding','same');
dlY = leakyrelu(dlY,0.2);

dlY = dlconv(dlY,parameters.Conv2.Weights,parameters.Conv2.Bias,'Stride' ,2 ,'Padding','same');
dlY = leakyrelu(dlY,0.2);

dlY = dlconv(dlY,parameters.Conv3.Weights,parameters.Conv3.Bias,'Stride' ,2 ,'Padding','same');
dlY = leakyrelu(dlY,0.2);

dlY = dlconv(dlY,parameters.Conv4.Weights,parameters.Conv4.Bias,'Stride' ,2 ,'Padding','same');
dlY = leakyrelu(dlY,0.2);

dlY = dlconv(dlY,parameters.Conv5.Weights,parameters.Conv5.Bias,'Stride' ,2 ,'Padding','same');
dlY = leakyrelu(dlY,0.2);

dlY = stripdims(dlY);
dlY = permute(dlY,[3 2 1 4]);
dlY = reshape(dlY,4*4*64*16,numel(dlY)/(4*4*64*16));

weights = parameters.FC.Weights;
bias = parameters.FC.Bias;
dlY = fullyconnect(dlY,weights,bias,'Dataformat','CB');

end
```

Model Discriminator Gradients Function

The `modelDiscriminatorGradients` functions takes as input the generator and discriminator parameters `generatorParameters` and `discriminatorParameters`, a mini-batch of input data `dlX`, and an array of random values `dlZ`, and returns the gradients of the discriminator loss with respect to the learnable parameters in the networks.

```
function gradientsDiscriminator = modelDiscriminatorGradients(discriminatorParameters , generator

% Calculate the predictions for real data with the discriminator network.
dlYPred = modelDiscriminator(dlX,discriminatorParameters);

% Calculate the predictions for generated data with the discriminator network.
dlXGenerated     = modelGenerator(dlZ,generatorParameters);
dlYPredGenerated = modelDiscriminator(dlarray(dlXGenerated,'SSCB'),discriminatorParameters);

% Calculate the GAN loss
lossDiscriminator = ganDiscriminatorLoss(dlYPred,dlYPredGenerated);
```

```
% For each network, calculate the gradients with respect to the loss.
gradientsDiscriminator = dlgradient(lossDiscriminator,discriminatorParameters);

end
```

Model Generator Gradients Function

The `modelGeneratorGradients` function takes as input the discriminator and generator learnable parameters and an array of random values `dlZ`, and returns the gradients of the generator loss with respect to the learnable parameters in the networks.

```
function gradientsGenerator = modelGeneratorGradients(discriminatorParameters, generatorParamete

% Calculate the predictions for generated data with the discriminator network.
dlXGenerated = modelGenerator(dlZ,generatorParameters);
dlYPredGenerated = modelDiscriminator(dlarray(dlXGenerated,'SSCB'),discriminatorParameters);

% Calculate the GAN loss
lossGenerator = ganGeneratorLoss(dlYPredGenerated);

% For each network, calculate the gradients with respect to the loss.
gradientsGenerator = dlgradient(lossGenerator, generatorParameters);

end
```

Discriminator Loss Function

The objective of the discriminator is to not be fooled by the generator. To maximize the probability that the discriminator successfully discriminates between the real and generated images, minimize the discriminator loss function. The loss function for the generator follows the DCGAN approach highlighted in [1].

```
function  lossDiscriminator = ganDiscriminatorLoss(dlYPred,dlYPredGenerated)

fake = dlarray(zeros(1,size(dlYPred,2)));
real = dlarray(ones(1,size(dlYPred,2)));

D_loss = mean(sigmoid_cross_entropy_with_logits(dlYPredGenerated,fake));
D_loss = D_loss + mean(sigmoid_cross_entropy_with_logits(dlYPred,real));
lossDiscriminator  = D_loss / 2;
end
```

Generator Loss Function

The objective of the generator is to generate data that the discriminator classifies as "real". To maximize the probability that images from the generator are classified as real by the discriminator, minimize the generator loss function. The loss function for the generator follows the deep convolutional generative adverarial network (DCGAN) approach highlighted in [1].

```
function lossGenerator = ganGeneratorLoss(dlYPredGenerated)
real = dlarray(ones(1,size(dlYPredGenerated,2)));
lossGenerator = mean(sigmoid_cross_entropy_with_logits(dlYPredGenerated,real));
end
```

Discriminator Weights Initializer

`initializeDiscriminatorWeights` initializes discriminator weights using the Glorot algorithm.

```
function discriminatorParameters = initializeDiscriminatorWeights

filterSize = [5 5];
dim = 64;

% Conv2D
weights = iGlorotInitialize([filterSize(1) filterSize(2) 1 dim]);
bias = zeros(1,1,dim,'single');
discriminatorParameters.Conv1.Weights = dlarray(weights);
discriminatorParameters.Conv1.Bias = dlarray(bias);

% Conv2D
weights = iGlorotInitialize([filterSize(1) filterSize(2) dim 2*dim]);
bias = zeros(1,1,2*dim,'single');
discriminatorParameters.Conv2.Weights = dlarray(weights);
discriminatorParameters.Conv2.Bias = dlarray(bias);

% Conv2D
weights = iGlorotInitialize([filterSize(1) filterSize(2) 2*dim 4*dim]);
bias = zeros(1,1,4*dim,'single');
discriminatorParameters.Conv3.Weights = dlarray(weights);
discriminatorParameters.Conv3.Bias = dlarray(bias);

% Conv2D
weights = iGlorotInitialize([filterSize(1) filterSize(2) 4*dim 8*dim]);
bias = zeros(1,1,8*dim,'single');
discriminatorParameters.Conv4.Weights = dlarray(weights);
discriminatorParameters.Conv4.Bias = dlarray(bias);

% Conv2D
weights = iGlorotInitialize([filterSize(1) filterSize(2) 8*dim 16*dim]);
bias = zeros(1,1,16*dim,'single');
discriminatorParameters.Conv5.Weights = dlarray(weights);
discriminatorParameters.Conv5.Bias = dlarray(bias);

% fully connected
weights = iGlorotInitialize([1,4 * 4 * dim * 16]);
bias = zeros(1,1,'single');
discriminatorParameters.FC.Weights = dlarray(weights);
discriminatorParameters.FC.Bias = dlarray(bias);
end
```

Generator Weights Initializer

`initializeGeneratorWeights` initializes generator weights using the Glorot algorithm.

```
function generatorParameters = initializeGeneratorWeights

dim = 64;

% Dense 1
weights = iGlorotInitialize([dim*256,100]);
bias = zeros(dim*256,1,'single');
generatorParameters.FC.Weights = dlarray(weights);
generatorParameters.FC.Bias = dlarray(bias);

filterSize = [5 5];
```

```
% Trans Conv2D
weights = iGlorotInitialize([filterSize(1) filterSize(2) 8*dim 16*dim]);
bias = zeros(1,1,dim*8,'single');
generatorParameters.Conv1.Weights = dlarray(weights);
generatorParameters.Conv1.Bias = dlarray(bias);

% Trans Conv2D
weights = iGlorotInitialize([filterSize(1) filterSize(2) 4*dim 8*dim]);
bias = zeros(1,1,dim*4,'single');
generatorParameters.Conv2.Weights = dlarray(weights);
generatorParameters.Conv2.Bias = dlarray(bias);

% Trans Conv2D
weights = iGlorotInitialize([filterSize(1) filterSize(2) 2*dim 4*dim]);
bias = zeros(1,1,dim*2,'single');
generatorParameters.Conv3.Weights = dlarray(weights);
generatorParameters.Conv3.Bias = dlarray(bias);

% Trans Conv2D

bias = zeros(1,1,dim,'single');
generatorParameters.Conv4.Weights = dlarray(weights);
generatorParameters.Conv4.Bias = dlarray(bias);

% Trans Conv2D
weights = iGlorotInitialize([filterSize(1) filterSize(2) 1 dim]);
bias = zeros(1,1,1,'single');
generatorParameters.Conv5.Weights = dlarray(weights);
generatorParameters.Conv5.Bias = dlarray(bias);
end
```

Synthesize Drumbeat

`synthesizeDrumBeat` uses a pretrained network to synthesize drum beats.

```
function y = synthesizeDrumBeat

persistent pGeneratorParameters pMean pSTD
if isempty(pGeneratorParameters)
    % If the MAT file does not exist, download it
    filename = 'drumGeneratorWeights.mat';
    load(filename,'SMean','SStd','generatorParameters');
    pMean = SMean;
    pSTD  = SStd;
    pGeneratorParameters = generatorParameters;
end

% Generate random vector
dlZ = dlarray(2 * ( rand(1,1,100,1,'single') - 0.5 ));

% Generate spectrograms
dlXGenerated = modelGenerator(dlZ,pGeneratorParameters);

% Convert from dlarray to single
S = dlXGenerated.extractdata;

S = S.';
% Zero-pad to remove edge effects
```

```
S = [S ; zeros(1,128)];

% Reverse steps from training
S = S * 3;
S = (S.*pSTD) + pMean;
S = exp(S);

% Make it two-sided
S = [S ; S(end-1:-1:2,:)];
% Pad with zeros at end and start
S = [zeros(256,100) S zeros(256,100)];

% Reconstruct the signal using a fast Griffin-Lim algorithm.
myAudio = stftmag2sig(gather(S),256, ...
    'FrequencyRange','twosided', ...
    'Window',hann(256,'periodic'), ...
    'OverlapLength',128, ...
    'MaxIterations',20, ...
    'Method','fgla');
myAudio = myAudio./max(abs(myAudio),[],'all');
y = myAudio(128*100:end-128*100);
end
```

Utility Functions

```
function out = sigmoid_cross_entropy_with_logits(x,z)
out = max(x, 0) - x .* z + log(1 + exp(-abs(x)));
end

function w = iGlorotInitialize(sz)
if numel(sz) == 2
    numInputs = sz(2);
    numOutputs = sz(1);
else
    numInputs = prod(sz(1:3));
    numOutputs = prod(sz([1 2 4]));
end
multiplier = sqrt(2 / (numInputs + numOutputs));
w = multiplier * sqrt(3) * (2 * rand(sz,'single') - 1);
end
```

Sequential Feature Selection for Audio Features

This example shows a typical workflow for feature selection applied to the task of spoken digit recognition.

In sequential feature selection, you train a network on a given feature set and then incrementally add or remove features until the highest accuracy is reached [1] on page 14-0 . In this example, you apply sequential forward selection to the task of spoken digit recognition using the Free Spoken Digit Dataset [2] on page 14-0 .

Streaming Spoken Digit Recognition

To motivate the example, begin by loading a pretrained network, the `audioFeatureExtractor` (Audio Toolbox) object used to train the network, and normalization factors for the features.

```
load('network_Audio_SequentialFeatureSelection.mat','bestNet','afe','normalizers');
```

Create an `audioDeviceReader` (Audio Toolbox) to read audio from a microphone. Create three `dsp.AsyncBuffer` (DSP System Toolbox) objects: one to buffer audio read from your microphone, one to buffer short-term energy of the input audio for speech detection, and one to buffer predictions.

```
fs = afe.SampleRate;

deviceReader = audioDeviceReader('SampleRate',fs,'SamplesPerFrame',256);

audioBuffer = dsp.AsyncBuffer(fs*3);
steBuffer = dsp.AsyncBuffer(1000);
predictionBuffer = dsp.AsyncBuffer(5);
```

Create a plot to display the streaming audio, the probability the network outputs during inference, and the prediction.

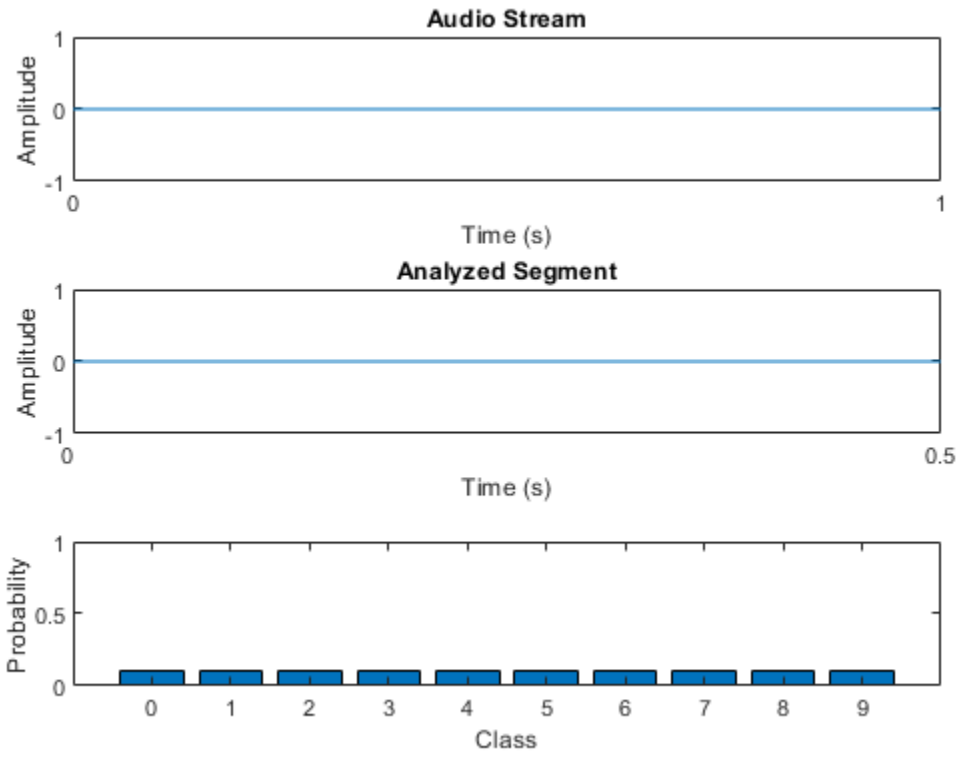
```
fig = figure;

streamAxes = subplot(3,1,1);
streamPlot = plot(zeros(fs,1));
ylabel('Amplitude')
xlabel('Time (s)')
title('Audio Stream')
streamAxes.XTick = [0,fs];
streamAxes.XTickLabel = [0,1];
streamAxes.YLim = [-1,1];

analyzedAxes = subplot(3,1,2);
analyzedPlot = plot(zeros(fs/2,1));
title('Analyzed Segment')
ylabel('Amplitude')
xlabel('Time (s)')
set(gca,'XTickLabel',[])
analyzedAxes.XTick = [0,fs/2];
analyzedAxes.XTickLabel = [0,0.5];
analyzedAxes.YLim = [-1,1];

probabilityAxes = subplot(3,1,3);
probabilityPlot = bar(0:9,0.1*ones(1,10));
axis([-1,10,0,1])
```

```
ylabel('Probability')
xlabel('Class')
```



Perform streaming digit recognition (digits 0 through 9) for 20 seconds. While the loop runs, speak one of the digits and test its accuracy.

First, define a short-term energy threshold under which to assume a signal contains no speech.

```
steThreshold = 0.015;
idxVec = 1:fs;
tic
while toc < 20

    % Read in a frame of audio from your device.
    audioIn = deviceReader();

    % Write the audio into a the buffer.
    write(audioBuffer,audioIn);

    % While 200 ms of data is unused, continue this loop.
    while audioBuffer.NumUnreadSamples > 0.2*fs

        % Read 1 second from the audio buffer. Of that 1 second, 800 ms
        % is rereading old data and 200 ms is new data.
        audioToAnalyze = read(audioBuffer,fs,0.8*fs);

        % Update the figure to plot the current audio data.
        streamPlot.YData = audioToAnalyze;
```

```
ste = mean(abs(audioToAnalyze));
write(steBuffer,ste);
if steBuffer.NumUnreadSamples > 5
    abc = sort(peek(steBuffer));
    steThreshold = abc(round(0.4*numel(abc)));
end
if ste > steThreshold

    % Use the detectSpeeech function to determine if a region of speech
    % is present.
    idx = detectSpeech(audioToAnalyze,fs);

    % If a region of speech is present, perform the following.
    if ~isempty(idx)
        % Zero out all parts of the signal except the speech
        % region, and trim to 0.5 seconds.
        audioToAnalyze = HelperTrimOrPad(audioToAnalyze(idx(1,1):idx(1,2)),fs/2);

        % Normalize the audio.
        audioToAnalyze = audioToAnalyze/max(abs(audioToAnalyze));

        % Update the analyzed segment plot
        analyzedPlot.YData = audioToAnalyze;

        % Extract the features and transpose them so that time is
        % across columns.
        features = (extract(afe,audioToAnalyze))';

        % Normalize the features.
        features = (features - normalizers.Mean) ./ normalizers.StandardDeviation;

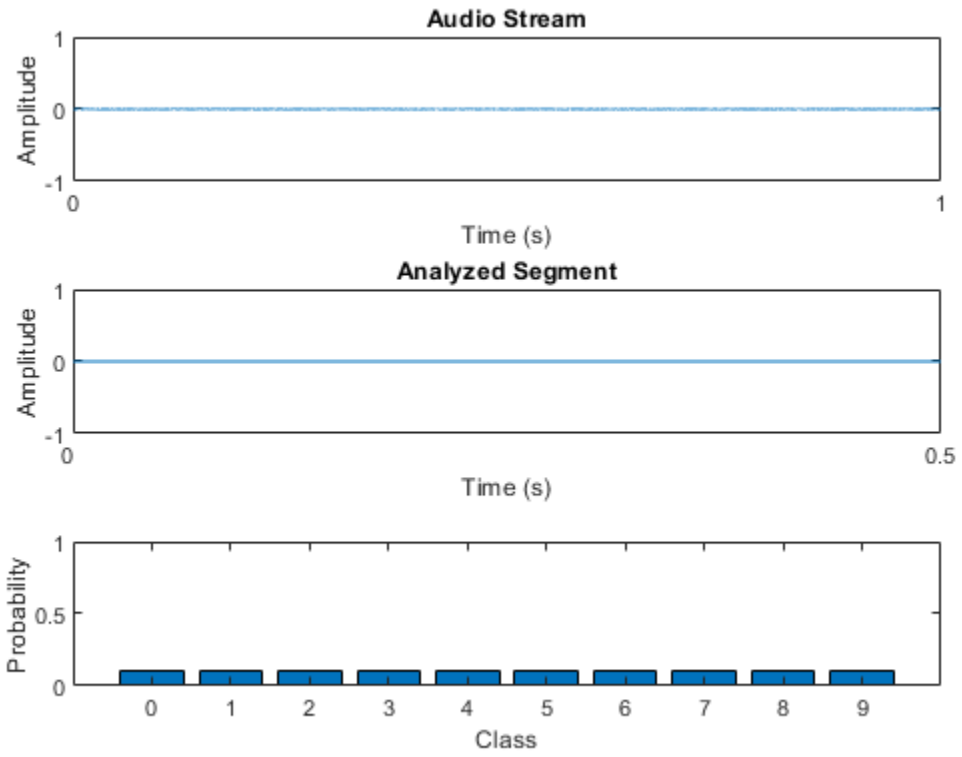
        % Call classify to determine the probabilities and the
        % winning label.
        features(isnan(features)) = 0;
        [label,probs] = classify(bestNet,features);

        % Update the plot with the probabilities and the winning
        % label.
        probabilityPlot.YData = probs;
        write(predictionBuffer,probs);

        if predictionBuffer.NumUnreadSamples == predictionBuffer.Capacity
            lastTen = peek(predictionBuffer);
            [~,decision] = max(mean(lastTen.*hann(size(lastTen,1)),1));
            probabilityAxes.Title.String = num2str(decision-1);
        end
    end
else
    % If the signal energy is below the threshold, assume no speech
    % detected.
     probabilityAxes.Title.String = '';
     probabilityPlot.YData = 0.1*ones(10,1);
     analyzedPlot.YData = zeros(fs/2,1);
     reset(predictionBuffer)
end

drawnow limitrate
```

```
    end
end
```



The remainder of the example illustrates how the network used in the streaming detection was trained and how the features fed into the network were chosen.

Create Train and Validation Data Sets

Download the Free Spoken Digit Dataset (FSDD) [2] on page 14-0 . FSDD consists of short audio files with spoken digits (0-9).

```
url = "https://zenodo.org/record/1342401/files/Jakobovski/free-spoken-digit-dataset-v1.0.8.zip";
downloadFolder = tempdir;
datasetFolder = fullfile(downloadFolder,'FSDD');

if ~exist(datasetFolder,'dir')
    fprintf('Downloading Free Spoken Digit Dataset ...\n')
    unzip(url,datasetFolder)
end
```

Create an `audioDatastore` (Audio Toolbox) to point to the recordings. Get the sample rate of the data set.

```
ads = audioDatastore(datasetFolder,'IncludeSubfolders',true);
[~,adsInfo] = read(ads);
fs = adsInfo.SampleRate;
```

The first element of the file names is the digit spoken in the file. Get the first element of the file names, convert them to categorical, and then set the `Labels` property of the `audioDatastore`.

```
[~,filenames] = cellfun(@(x)fileparts(x),ads.Files,'UniformOutput',false);
ads.Labels = categorical(string(cellfun(@(x)x(1),filenames)));
```

To split the datastore into a development set and a validation set, use `splitEachLabel` (Audio Toolbox). Allocate 80% of the data for development and the remaining 20% for validation.

```
[adsTrain,adsValidation] = splitEachLabel(ads,0.8);
```

Set Up Audio Feature Extractor

Create an `audioFeatureExtractor` (Audio Toolbox) object to extract audio features over 30 ms windows with an update rate of 10 ms. Set all features you would like to test in this example to `true`.

```
win = hamming(round(0.03*fs),"periodic");
overlapLength = round(0.02*fs);

afe = audioFeatureExtractor( ...
    'Window',       win, ...
    'OverlapLength',overlapLength, ...
    'SampleRate',   fs, ...
    ...
    'linearSpectrum',      false, ...
    'melSpectrum',         false, ...
    'barkSpectrum',        false, ...
    'erbSpectrum',         false, ...
    ...
    'mfcc',                true, ...
    'mfccDelta',           true, ...
    'mfccDeltaDelta',      true, ...
    'gtcc',                true, ...
    'gtccDelta',           true, ...
    'gtccDeltaDelta',      true, ...
    ...
    'spectralCentroid',    true, ...
    'spectralCrest',       true, ...
    'spectralDecrease',    true, ...
    'spectralEntropy',     true, ...
    'spectralFlatness',    true, ...
    'spectralFlux',        true, ...
    'spectralKurtosis',    true, ...
    'spectralRolloffPoint',true, ...
    'spectralSkewness',    true, ...
    'spectralSlope',       true, ...
    'spectralSpread',      true, ...
    ...
    'pitch',               false, ...
    'harmonicRatio',       false);
```

Define Layers and Training Options

Define the “List of Deep Learning Layers” on page 1-21 and `trainingOptions` used in this example. The first layer, `sequenceInputLayer`, is just a placeholder. Depending on which features you test during sequential feature selection, the first layer is replaced with a `sequenceInputLayer` of the appropriate size.

```
numUnits = 100 ;
layers = [ ...
    sequenceInputLayer(1)
    bilstmLayer(numUnits,"OutputMode","last")
    fullyConnectedLayer(numel(categories(adsTrain.Labels)))
    softmaxLayer
    classificationLayer];

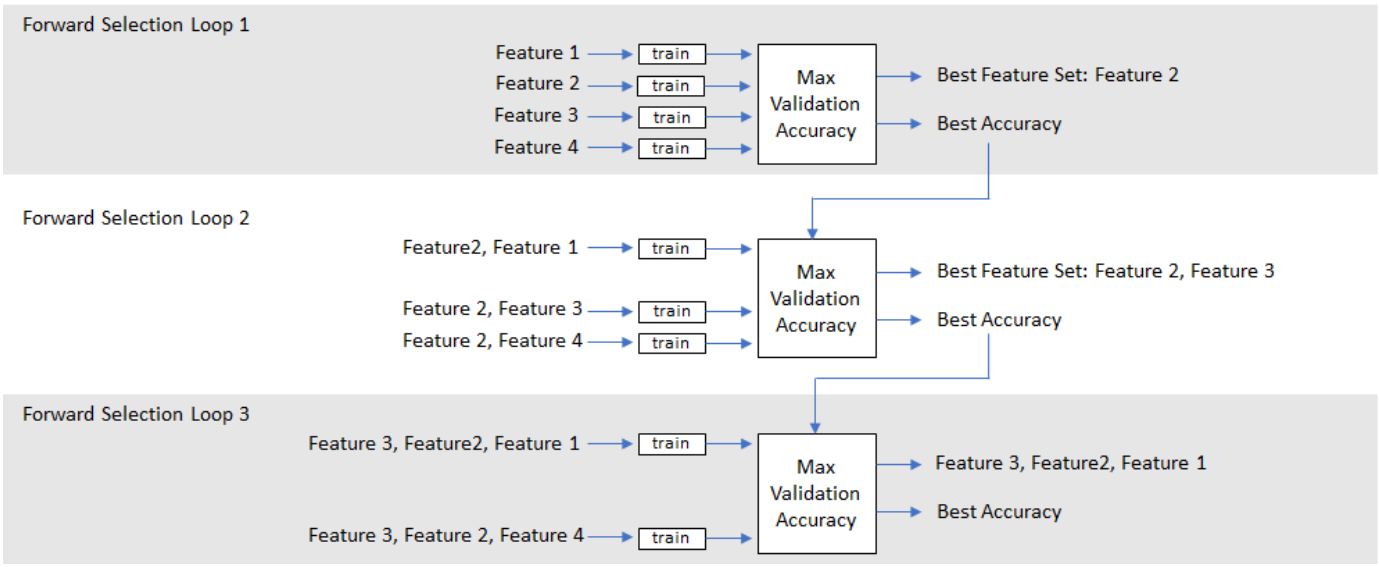
options = trainingOptions("adam", ...
    "LearnRateSchedule","piecewise", ...
    "Shuffle","every-epoch", ...
    "Verbose",false, ...
    "MaxEpochs",20);
```

Sequential Feature Selection

In the basic form of sequential feature selection, you train a network on a given feature set and then incrementally add or remove features until the accuracy no longer improves [1] on page 14-0 .

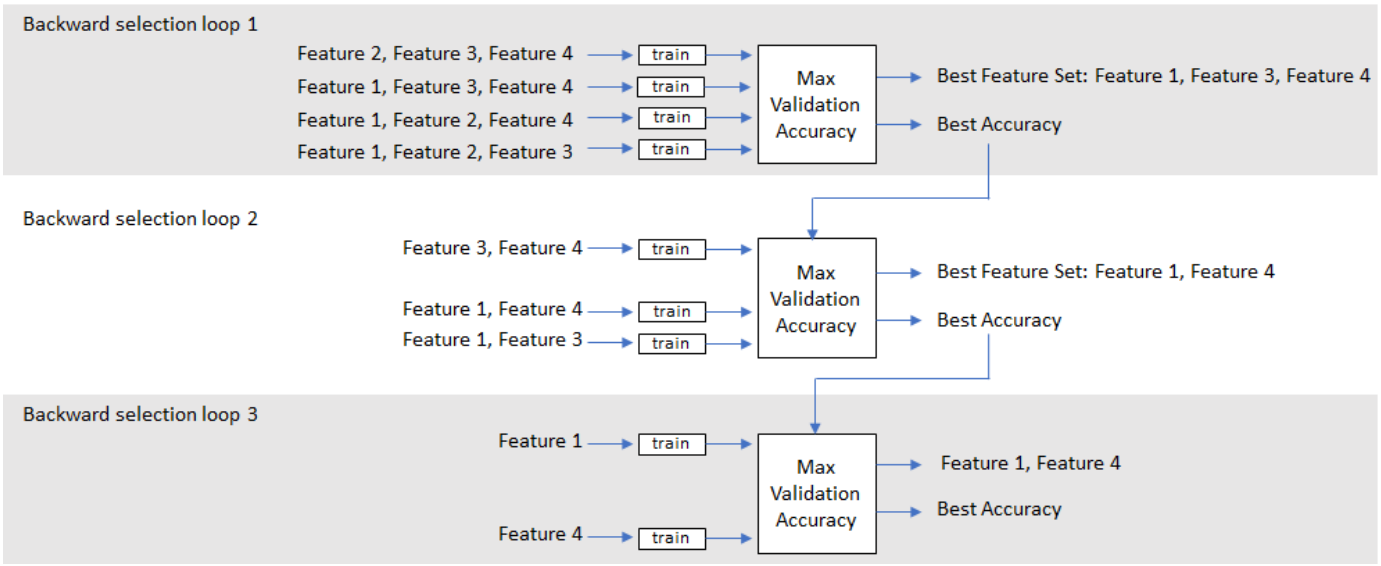
Forward Selection

Consider a simple case of forward selection on a set of four features. In the first forward selection loop, each of the four features are tested independently by training a network and comparing their validation accuracy. The feature that resulted in the highest validation accuracy is noted. In the second forward selection loop, the best feature from the first loop is combined with each of the remaining features. Now each pair of features is used for training. If the accuracy in the second loop did not improve over the accuracy in the first loop, the selection process ends. Otherwise, a new best feature set is selected. The forward selection loop continues until the accuracy no longer improves.



Backward Selection

In backward feature selection, you begin by training on a feature set that consists of all features and test whether or not accuracy improves as you remove features.



Run Sequential Feature Selection

The helper functions (HelperSFS on page 14-0 , HelperTrainAndValidateNetwork on page 14-0 , and HelperTrimOrPad on page 14-0) implement forward or backward sequential feature selection. Specify the training datastore, validation datastore, audio feature extractor, network layers, network options, and direction. As a general rule, choose forward if you anticipate a small feature set or backward if you anticipate a large feature set.

```
direction = forward;
[logbook,bestFeatures,bestNet,normalizers] = HelperSFS(adsTrain,adsValidation,afe,layers,options,
```

```
Starting parallel pool (parpool) using the 'local' profile ...
Connected to the parallel pool (number of workers: 6).
```

The `logbook` output from `HelperFeatureExtractor` is a table containing all feature configurations tested and the corresponding validation accuracy.

```
logbook
```

```
logbook=48×2 table
                Features                    Accuracy
    ____________________________________    ________

    "mfcc, gtcc"                             97.333
    "mfcc, mfccDelta, gtcc"                      97
    "mfcc, gtcc, spectralEntropy"                97
    "mfcc, gtcc, spectralFlatness"               97
    "mfcc, gtcc, spectralFlux"                   97
    "mfcc, gtcc, spectralSpread"                 97
    "gtcc"                                   96.667
    "gtcc, spectralCentroid"                 96.667
    "gtcc, spectralFlux"                     96.667
    "mfcc, gtcc, spectralRolloffPoint"       96.667
    "mfcc, gtcc, spectralSkewness"           96.667
    "gtcc, spectralEntropy"                  96.333
    "mfcc, gtcc, gtccDeltaDelta"             96.333
```

```
    "mfcc, gtcc, spectralKurtosis"         96.333
    "mfccDelta, gtcc"                          96
    "gtcc, gtccDelta"                          96
      ⋮
```

The `bestFeatures` output from `HelperSFS` contains a struct with the optimal features set to `true`.

```
bestFeatures
```

```
bestFeatures = struct with fields:
                    mfcc: 1
                mfccDelta: 0
           mfccDeltaDelta: 0
                    gtcc: 1
                gtccDelta: 0
           gtccDeltaDelta: 0
          spectralCentroid: 0
             spectralCrest: 0
          spectralDecrease: 0
           spectralEntropy: 0
          spectralFlatness: 0
              spectralFlux: 0
          spectralKurtosis: 0
      spectralRolloffPoint: 0
          spectralSkewness: 0
             spectralSlope: 0
           spectralSpread: 0
```

You can set your `audioFeatureExtractor` using the struct.

```
set(afe,bestFeatures)
afe
```

```
afe =
  audioFeatureExtractor with properties:

   Properties
                     Window: [240×1 double]
              OverlapLength: 160
                 SampleRate: 8000
                  FFTLength: []
    SpectralDescriptorInput: 'linearSpectrum'

   Enabled Features
     mfcc, gtcc

   Disabled Features
     linearSpectrum, melSpectrum, barkSpectrum, erbSpectrum, mfccDelta, mfccDeltaDelta
     gtccDelta, gtccDeltaDelta, spectralCentroid, spectralCrest, spectralDecrease, spectralEntrop
     spectralFlatness, spectralFlux, spectralKurtosis, spectralRolloffPoint, spectralSkewness, sp
     spectralSpread, pitch, harmonicRatio

   To extract a feature, set the corresponding property to true.
   For example, obj.mfcc = true, adds mfcc to the list of enabled features.
```

`HelperSFS` also outputs the best performing network and the normalization factors that correspond to the chosen features. To save the network, configured `audioFeatureExtractor`, and normalization factors, uncomment this line:

```
% save('network_Audio_SequentialFeatureSelection.mat','bestNet','afe','normalizers')
```

Conclusion

This example illustrates a workflow for sequential feature selection for a Recurrent Neural Network (LSTM or BiLSTM). It could easily be adapted for CNN and RNN-CNN workflows.

Supporting Functions

HelperTrainAndValidateNetwork

```
function [trueLabels,predictedLabels,net,normalizers] = HelperTrainAndValidateNetwork(adsTrain,ad
% Train and validate a network.
%

Acoustic Scene Recognition Using Late Fusion

This example shows how to create a multi-model late fusion system for acoustic scene recognition. The example trains a convolutional neural network (CNN) using mel spectrograms and an ensemble classifier using wavelet scattering. The example uses the TUT dataset for training and evaluation [1].

Introduction

Acoustic scene classification (ASC) is the task of classifying environments from the sounds they produce. ASC is a generic classification problem that is foundational for context awareness in devices, robots, and many other applications [1]. Early attempts at ASC used mel-frequency cepstral coefficients (`mfcc` (Audio Toolbox)) and Gaussian mixture models (GMMs) to describe their statistical distribution. Other popular features used for ASC include zero crossing rate, spectral centroid (`spectralCentroid` (Audio Toolbox)), spectral rolloff (`spectralRolloffPoint` (Audio Toolbox)), spectral flux (`spectralFlux` (Audio Toolbox)), and linear prediction coefficients (`lpc` (Signal Processing Toolbox)) [5]. Hidden Markov models (HMMs) were trained to describe the temporal evolution of the GMMs. More recently, the best performing systems have used deep learning, usually CNNs, and a fusion of multiple models. The most popular feature for top-ranked systems in the DCASE 2017 contest was the mel spectrogram (`melSpectrogram` (Audio Toolbox)). The top-ranked systems in the challenge used late fusion and data augmentation to help their systems generalize.

To illustrate a simple approach that produces reasonable results, this example trains a CNN using mel spectrograms and an ensemble classifier using wavelet scattering. The CNN and ensemble classifier produce roughly equivalent overall accuracy, but perform better at distinguishing different acoustic scenes. To increase overall accuracy, you merge the CNN and ensemble classifier results using late fusion.

Load Acoustic Scene Recognition Data Set

To run the example, you must first download the data set [1]. The full data set is approximately 15.5 GB. Depending on your machine and internet connection, downloading the data can take about 4 hours.

```
downloadFolder = tempdir;
datasetFolder = fullfile(downloadFolder,'TUT-acoustic-scenes-2017');

if ~exist(datasetFolder,'dir')
    disp('Downloading TUT-acoustic-scenes-2017 (15.5 GB)...')
    HelperDownload_TUT_acoustic_scenes_2017(datasetFolder);
end
```

Read in the development set metadata as a table. Name the table variables `FileName`, `AcousticScene`, and `SpecificLocation`.

```
metadata_train = readtable(fullfile(datasetFolder,'TUT-acoustic-scenes-2017-development','meta.tx
    'Delimiter',{'\t'}, ...
    'ReadVariableNames',false);
metadata_train.Properties.VariableNames = {'FileName','AcousticScene','SpecificLocation'};
head(metadata_train)
```

```
ans =

    {'audio/231.wav' }      {'beach'}          {'b174'}
    {'audio/768.wav' }      {'beach'}          {'b174'}
```

Note that the specific recording locations in the test set do not intersect with the specific recording locations in the development set. This makes it easier to validate that the trained models can generalize to real-world scenarios.

```
sharedRecordingLocations = intersect(metadata_test.SpecificLocation,metadata_train.SpecificLocati
fprintf('Number of specific recording locations in both train and test sets = %d\n',numel(sharedR
```

```
Number of specific recording locations in both train and test sets = 0
```

The first variable of the metadata tables contains the file names. Concatenate the file names with the file paths.

```
train_filePaths = fullfile(datasetFolder,'TUT-acoustic-scenes-2017-development',metadata_train.Fi

test_filePaths = fullfile(datasetFolder,'TUT-acoustic-scenes-2017-evaluation',metadata_test.FileN
```

Create audio datastores for the train and test sets. Set the `Labels` property of the `audioDatastore` (Audio Toolbox) to the acoustic scene. Call `countEachLabel` (Audio Toolbox) to verify an even distribution of labels in both the train and test sets.

```
adsTrain = audioDatastore(train_filePaths, ...
    'Labels',categorical(metadata_train.AcousticScene), ...
```

```
    'IncludeSubfolders',true);
display(countEachLabel(adsTrain))

adsTest = audioDatastore(test_filePaths, ...
    'Labels',categorical(metadata_test.AcousticScene), ...
    'IncludeSubfolders',true);
display(countEachLabel(adsTest))
```

```

```

You can reduce the data set used in this example to speed up the run time at the cost of performance. In general, reducing the data set is a good practice for development and debugging. Set `reduceDataset` to `true` to reduce the data set.

```
reduceDataset = false;
if reduceDataset
    adsTrain = splitEachLabel(adsTrain,20);
```

```
    adsTest = splitEachLabel(adsTest,10);
end
```

Call `read` (Audio Toolbox) to get the data and sample rate of a file from the train set. Audio in the database has consistent sample rate and duration. Normalize the audio and listen to it. Display the corresponding label.

```
[data,adsInfo] = read(adsTrain);
data = data./max(data,[],'all');

fs = adsInfo.SampleRate;
sound(data,fs)

fprintf('Acoustic scene = %s\n',adsTrain.Labels(1))
```

```
Acoustic scene = beach
```

Call `reset` (Audio Toolbox) to return the datastore to its initial condition.

```
reset(adsTrain)
```

Feature Extraction for CNN

Each audio clip in the dataset consists of 10 seconds of stereo (left-right) audio. The feature extraction pipeline and the CNN architecture in this example are based on [3]. Hyperparameters for the feature extraction, the CNN architecture, and the training options were modified from the original paper using a systematic hyperparameter optimization workflow.

First, convert the audio to mid-side encoding. [3] suggests that mid-side encoded data provides better spatial information that the CNN can use to identify moving sources (such as a train moving across an acoustic scene).

```
dataMidSide = [sum(data,2),data(:,1)-data(:,2)];
```

Divide the signal into one-second segments with overlap. The final system uses a probability-weighted average on the one-second segments to predict the scene for each 10-second audio clip in the test set. Dividing the audio clips into one-second segments makes the network easier to train and helps prevent overfitting to specific acoustic events in the training set. The overlap helps to ensure all combinations of features relative to one another are captured by the training data. It also provides the system with additional data that can be mixed uniquely during augmentation.

```
segmentLength = 1;
segmentOverlap = 0.5;

[dataBufferedMid,~] = buffer(dataMidSide(:,1),round(segmentLength*fs),round(segmentOverlap*fs),'
[dataBufferedSide,~] = buffer(dataMidSide(:,2),round(segmentLength*fs),round(segmentOverlap*fs),
dataBuffered = zeros(size(dataBufferedMid,1),size(dataBufferedMid,2)+size(dataBufferedSide,2));
dataBuffered(:,1:2:end) = dataBufferedMid;
dataBuffered(:,2:2:end) = dataBufferedSide;
```

Use `melSpectrogram` (Audio Toolbox) to transform the data into a compact frequency-domain representation. Define parameters for the mel spectrogram as suggested by [3].

```
windowLength = 2048;
samplesPerHop = 1024;
samplesOverlap = windowLength - samplesPerHop;
```

```
fftLength = 2*windowLength;
numBands = 128;
```

`melSpectrogram` operates along channels independently. To optimize processing time, call `melSpectrogram` with the entire buffered signal.

```
spec = melSpectrogram(dataBuffered,fs, ...
    'Window',hamming(windowLength,'periodic'), ...
    'OverlapLength',samplesOverlap, ...
    'FFTLength',fftLength, ...
    'NumBands',numBands);
```

Convert the mel spectrogram into the logarithmic scale.

```
spec = log10(spec+eps);
```

Reshape the array to dimensions (Number of bands)-by-(Number of hops)-by-(Number of channels)-by-(Number of segments). When you feed an image into a neural network, the first two dimensions are the height and width of the image, the third dimension is the channels, and the fourth dimension separates the individual images.

```
X = reshape(spec,size(spec,1),size(spec,2),size(data,2),[]);
```

Call `melSpectrogram` without output arguments to plot the mel spectrogram of the mid channel for the first six of the one-second increments.

```
for channel = 1:2:11
    figure
    melSpectrogram(dataBuffered(:,channel),fs, ...
        'Window',hamming(windowLength,'periodic'), ...
        'OverlapLength',samplesOverlap, ...
        'FFTLength',fftLength, ...
        'NumBands',numBands);
    title(sprintf('Segment %d',ceil(channel/2)))
end
```

The helper function `HelperSegmentedMelSpectrograms` performs the feature extraction steps outlined above.

To speed up processing, extract mel spectrograms of all audio files in the datastores using `tall` arrays. Unlike in-memory arrays, tall arrays remain unevaluated until you request that the calculations be performed using the `gather` function. This deferred evaluation enables you to work quickly with large data sets. When you eventually request the output using `gather`, MATLAB combines the queued calculations where possible and takes the minimum number of passes through the data. If you have Parallel Computing Toolbox™, you can use tall arrays in your local MATLAB session, or on a local parallel pool. You can also run tall array calculations on a cluster if you have MATLAB® Parallel Server™ installed.

If you do not have Parallel Computing Toolbox™, the code in this example still runs.

```
pp = parpool('IdleTimeout',inf);

train_set_tall = tall(adsTrain);
xTrain = cellfun(@(x)HelperSegmentedMelSpectrograms(x,fs, ...
    'SegmentLength',segmentLength, ...
    'SegmentOverlap',segmentOverlap, ...
    'WindowLength',windowLength, ...
    'HopLength',samplesPerHop, ...
    'NumBands',numBands, ...
    'FFTLength',fftLength), ...
    train_set_tall, ...
    'UniformOutput',false);
xTrain = gather(xTrain);
```

```
xTrain = cat(4,xTrain{:});

test_set_tall = tall(adsTest);
xTest = cellfun(@(x)HelperSegmentedMelSpectrograms(x,fs, ...
    'SegmentLength',segmentLength, ...
    'SegmentOverlap',segmentOverlap, ...
    'WindowLength',windowLength, ...
    'HopLength',samplesPerHop, ...
    'NumBands',numBands, ...
    'FFTLength',fftLength), ...
    test_set_tall, ...
    'UniformOutput',false);
xTest = gather(xTest);
xTest = cat(4,xTest{:});
```

```
Starting parallel pool (parpool) using the 'local' profile ...
Connected to the parallel pool (number of workers: 6).

Evaluation completed in 3 min 45 sec
Evaluating tall expression using the Parallel Pool 'local':
- Pass 1 of 1: Completed in 1 min 22 sec
Evaluation completed in 1 min 22 sec
```

Replicate the labels of the training set so that they are in one-to-one correspondence with the segments.

```
numSegmentsPer10seconds = size(dataBuffered,2)/2;
yTrain = repmat(adsTrain.Labels,1,numSegmentsPer10seconds)';
yTrain = yTrain(:);
```

Data Augmentation for CNN

The DCASE 2017 dataset contains a relatively small number of acoustic recordings for the task, and the development set and evaluation set were recorded at different specific locations. As a result, it is easy to overfit to the data during training. One popular method to reduce overfitting is *mixup*. In mixup, you augment your dataset by mixing the features of two different classes. When you mix the features, you mix the labels in equal proportion. That is:

$$\tilde{\mathrm{x}} = \lambda \mathrm{x}_i + (1-\lambda)\,\mathrm{x}_j$$
$$\tilde{y} = \lambda y_i + (1-\lambda)\,y_j$$

Mixup was reformulated by [2] as labels drawn from a probability distribution instead of mixed labels. The implementation of mixup in this example is a simplified version of mixup: each spectrogram is mixed with a spectrogram of a different label with lambda set to 0.5. The original and mixed datasets are combined for training.

```
xTrainExtra = xTrain;
yTrainExtra = yTrain;
lambda = 0.5;
for i = 1:size(xTrain,4)

    % Find all available spectrograms with different labels.
    availableSpectrograms = find(yTrain~=yTrain(i));

    % Randomly choose one of the available spectrograms with a different label.
    numAvailableSpectrograms = numel(availableSpectrograms);
```

```
    idx = randi([1,numAvailableSpectrograms]);

    % Mix.
    xTrainExtra(:,:,:,i) = lambda*xTrain(:,:,:,i) + (1-lambda)*xTrain(:,:,:,availableSpectrograms

    % Specify the label as randomly set by lambda.
    if rand > lambda
        yTrainExtra(i) = yTrain(availableSpectrograms(idx));
    end
end
xTrain = cat(4,xTrain,xTrainExtra);
yTrain = [yTrain;yTrainExtra];
```

Call `summary` to display the distribution of labels for the augmented training set.

```
summary(yTrain)
```

```

Define and Train CNN

Define the CNN architecture. This architecture is based on [1] and modified through trial and error. See “List of Deep Learning Layers” on page 1-21 to learn more about deep learning layers available in MATLAB®.

```
imgSize = [size(xTrain,1),size(xTrain,2),size(xTrain,3)];
numF = 32;
layers = [ ...
    imageInputLayer(imgSize)

    batchNormalizationLayer

    convolution2dLayer(3,numF,'Padding','same')
    batchNormalizationLayer
    reluLayer
    convolution2dLayer(3,numF,'Padding','same')
    batchNormalizationLayer
    reluLayer

    maxPooling2dLayer(3,'Stride',2,'Padding','same')

    convolution2dLayer(3,2*numF,'Padding','same')
    batchNormalizationLayer
    reluLayer
```

```
    convolution2dLayer(3,2*numF,'Padding','same')
    batchNormalizationLayer
    reluLayer

    maxPooling2dLayer(3,'Stride',2,'Padding','same')

    convolution2dLayer(3,4*numF,'Padding','same')
    batchNormalizationLayer
    reluLayer
    convolution2dLayer(3,4*numF,'Padding','same')
    batchNormalizationLayer
    reluLayer

    maxPooling2dLayer(3,'Stride',2,'Padding','same')

    convolution2dLayer(3,8*numF,'Padding','same')
    batchNormalizationLayer
    reluLayer
    convolution2dLayer(3,8*numF,'Padding','same')
    batchNormalizationLayer
    reluLayer

    globalAveragePooling2dLayer

    dropoutLayer(0.5)

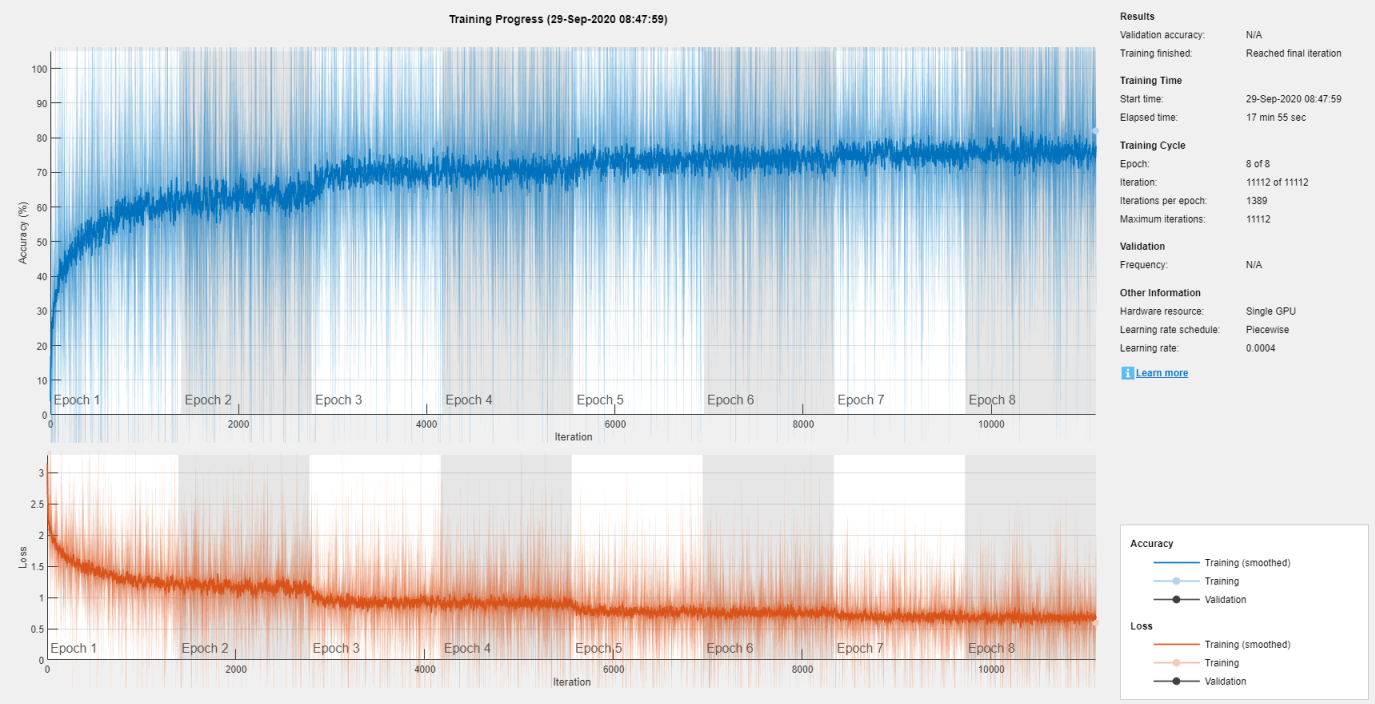
    fullyConnectedLayer(15)
    softmaxLayer
    classificationLayer];
```

Define `trainingOptions` for the CNN. These options are based on [3] and modified through a systematic hyperparameter optimization workflow.

```
miniBatchSize = 128;
tuneme = 128;
lr = 0.05*miniBatchSize/tuneme;
options = trainingOptions('sgdm', ...
    'InitialLearnRate',lr, ...
    'MiniBatchSize',miniBatchSize, ...
    'Momentum',0.9, ...
    'L2Regularization',0.005, ...
    'MaxEpochs',8, ...
    'Shuffle','every-epoch', ...
    'Plots','training-progress', ...
    'Verbose',false, ...
    'LearnRateSchedule','piecewise', ...
    'LearnRateDropPeriod',2, ...
    'LearnRateDropFactor',0.2);
```

Call `trainNetwork` to train the network.

```
trainedNet = trainNetwork(xTrain,yTrain,layers,options);
```



Evaluate CNN

Call `predict` to predict responses from the trained network using the held-out test set.

```
cnnResponsesPerSegment = predict(trainedNet,xTest);
```

Average the responses over each 10-second audio clip.

```
classes = trainedNet.Layers(end).Classes;
numFiles = numel(adsTest.Files);

counter = 1;
cnnResponses = zeros(numFiles,numel(classes));
for channel = 1:numFiles
    cnnResponses(channel,:) = sum(cnnResponsesPerSegment(counter:counter+numSegmentsPer10seconds
    counter = counter + numSegmentsPer10seconds;
end
```

For each 10-second audio clip, choose the maximum of the predictions, then map it to the corresponding predicted location.

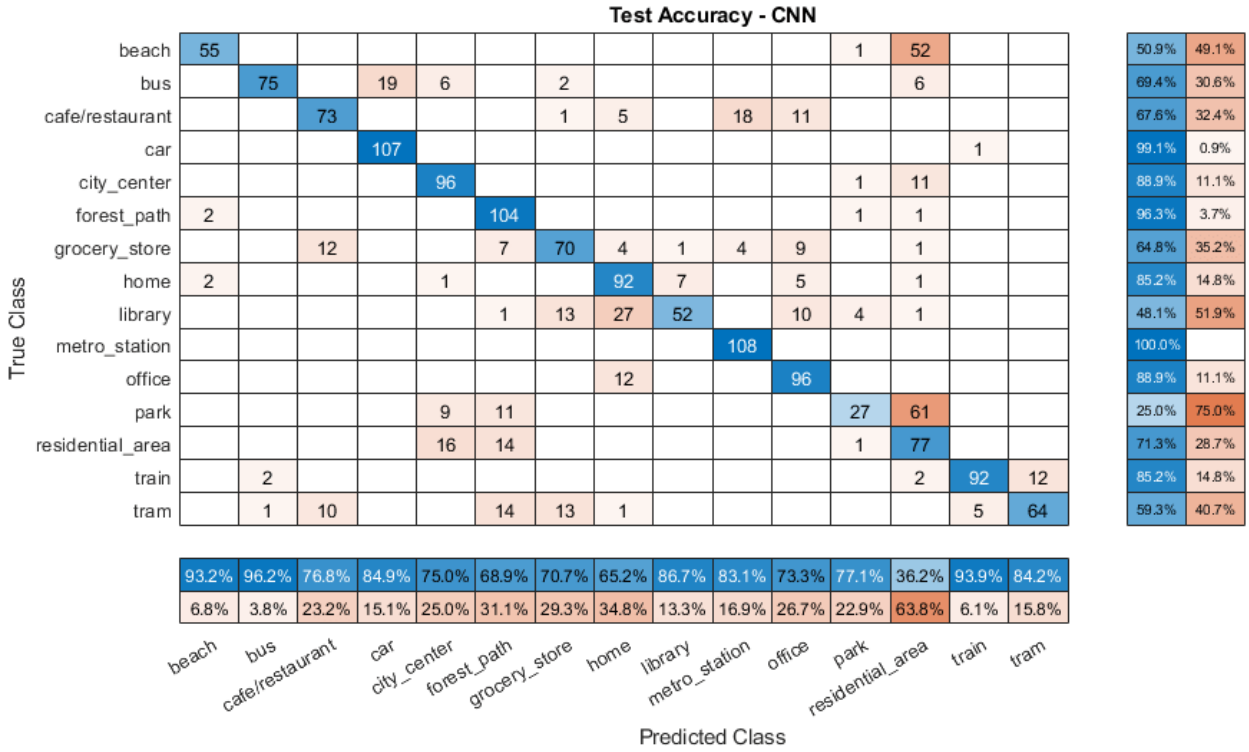
```
[~,classIdx] = max(cnnResponses,[],2);
cnnPredictedLabels = classes(classIdx);
```

Call `confusionchart` to visualize the accuracy on the test set. Return the average accuracy to the Command Window.

```
figure('Units','normalized','Position',[0.2 0.2 0.5 0.5])
cm = confusionchart(adsTest.Labels,cnnPredictedLabels,'title','Test Accuracy - CNN');
cm.ColumnSummary = 'column-normalized';
cm.RowSummary = 'row-normalized';

fprintf('Average accuracy of CNN = %0.2f\n',mean(adsTest.Labels==cnnPredictedLabels)*100)
```

```
Average accuracy of CNN = 73.33
```



Feature Extraction for Ensemble Classifier

Wavelet scattering has been shown in [4] to provide a good representation of acoustic scenes. Define a `waveletScattering` (Wavelet Toolbox) object. The invariance scale and quality factors were determined through trial and error.

```
sf = waveletScattering('SignalLength',size(data,1), ...
                       'SamplingFrequency',fs, ...
                       'InvarianceScale',0.75, ...
                       'QualityFactors',[4 1]);
```

Convert the audio signal to mono, and then call `featureMatrix` (Wavelet Toolbox) to return the scattering coefficients for the scattering decomposition framework, `sf`.

```
dataMono = mean(data,2);
scatteringCoeffients = featureMatrix(sf,dataMono,'Transform','log');
```

Average the scattering coefficients over the 10-second audio clip.

```
featureVector = mean(scatteringCoeffients,2);
fprintf('Number of wavelet features per 10-second clip = %d\n',numel(featureVector))
```

```
Number of wavelet features per 10-second clip = 290
```

The helper function `HelperWaveletFeatureVector` performs the above steps. Use a `tall` array with `cellfun` and `HelperWaveletFeatureVector` to parallelize the feature extraction. Extract wavelet feature vectors for the train and test sets.

```
scatteringTrain = cellfun(@(x)HelperWaveletFeatureVector(x,sf),train_set_tall,'UniformOutput',fa
xTrain = gather(scatteringTrain);
xTrain = cell2mat(xTrain')';

scatteringTest = cellfun(@(x)HelperWaveletFeatureVector(x,sf),test_set_tall,'UniformOutput',false
xTest = gather(scatteringTest);
xTest = cell2mat(xTest')';
```

```
Evaluating tall expression using the Parallel Pool 'local':
- Pass 1 of 1: Completed in 25 min 15 sec
Evaluation completed in 25 min 15 sec
Evaluating tall expression using the Parallel Pool 'local':
- Pass 1 of 1: Completed in 8 min 2 sec
Evaluation completed in 8 min 2 sec
```

Define and Train Ensemble Classifier

Use `fitcensemble` to create a trained classification ensemble model (`ClassificationEnsemble`).

```
subspaceDimension = min(150,size(xTrain,2) - 1);
numLearningCycles = 30;
classificationEnsemble = fitcensemble(xTrain,adsTrain.Labels, ...
    'Method','Subspace', ...
    'NumLearningCycles',numLearningCycles, ...
    'Learners','discriminant', ...
    'NPredToSample',subspaceDimension, ...
    'ClassNames',removecats(unique(adsTrain.Labels)));
```

Evaluate Ensemble Classifier

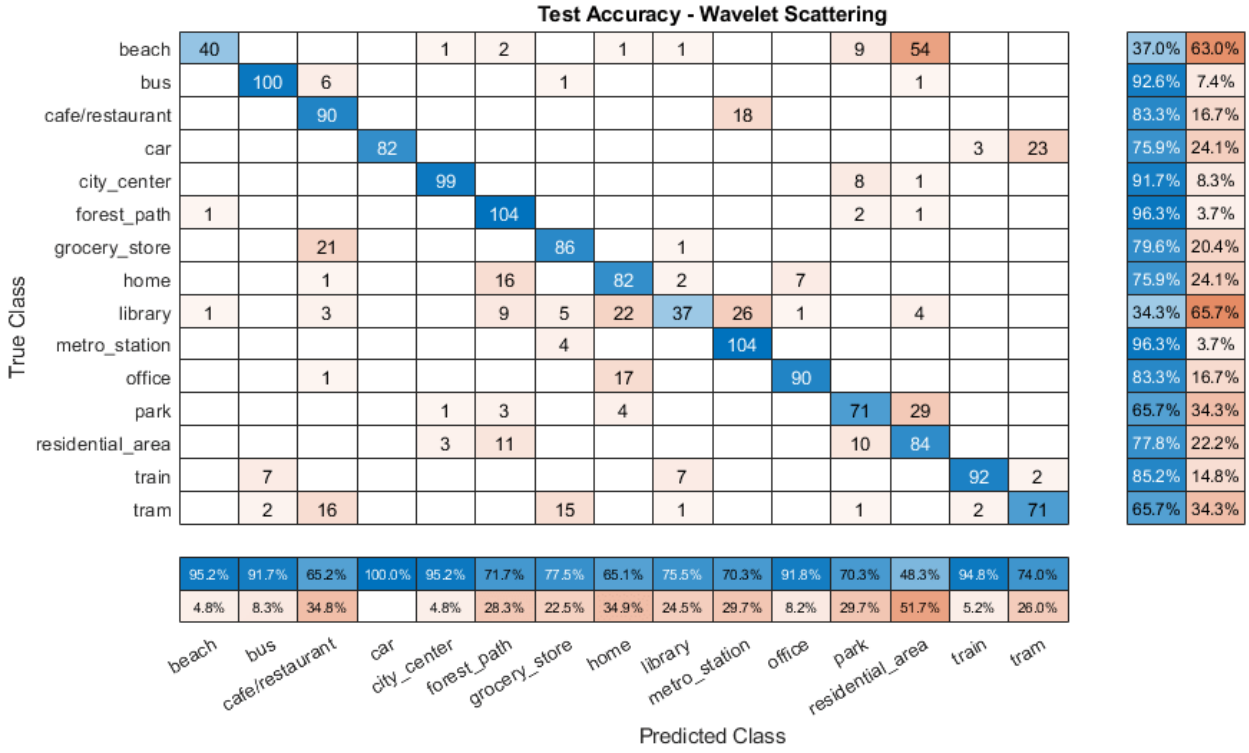
For each 10-second audio clip, call `predict` to return the labels and the weights, then map it to the corresponding predicted location. Call `confusionchart` to visualize the accuracy on the test set. Print the average.

```
[waveletPredictedLabels,waveletResponses] = predict(classificationEnsemble,xTest);

figure('Units','normalized','Position',[0.2 0.2 0.5 0.5])
cm = confusionchart(adsTest.Labels,waveletPredictedLabels,'title','Test Accuracy - Wavelet Scatte
cm.ColumnSummary = 'column-normalized';
cm.RowSummary = 'row-normalized';

fprintf('Average accuracy of classifier = %0.2f\n',mean(adsTest.Labels==waveletPredictedLabels)*1
```

```
Average accuracy of classifier = 76.05
```



Apply Late Fusion

For each 10-second clip, calling predict on the wavelet classifier and the CNN returns a vector indicating the relative confidence in their decision. Multiply the `waveletResponses` with the `cnnResponses` to create a late fusion system.

```
fused = waveletResponses .* cnnResponses;
[~,classIdx] = max(fused,[],2);

predictedLabels = classes(classIdx);
```

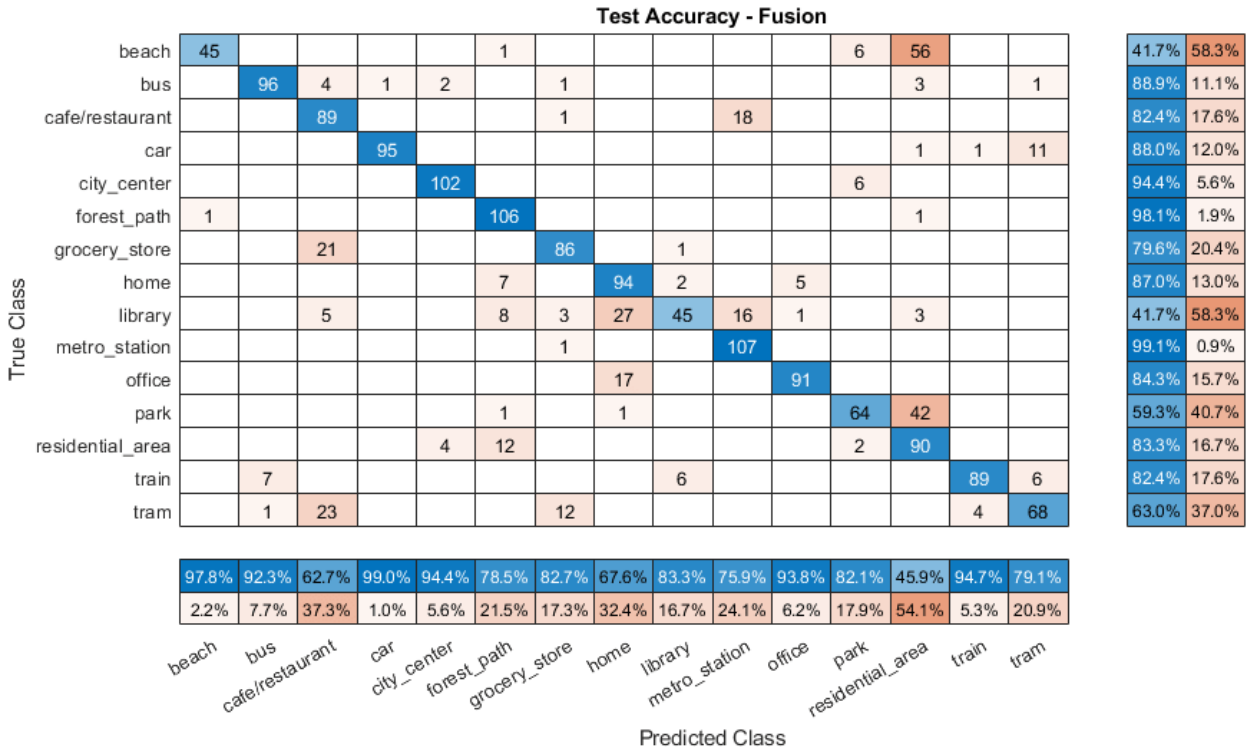
Evaluate Late Fusion

Call `confusionchart` to visualize the fused classification accuracy. Print the average accuracy to the Command Window.

```
figure('Units','normalized','Position',[0.2 0.2 0.5 0.5])
cm = confusionchart(adsTest.Labels,predictedLabels,'title','Test Accuracy - Fusion');
cm.ColumnSummary = 'column-normalized';
cm.RowSummary = 'row-normalized';

fprintf('Average accuracy of fused models = %0.2f\n',mean(adsTest.Labels==predictedLabels)*100)
```

```
Average accuracy of fused models = 78.21
```



Close the parallel pool.

```
delete(pp)
```

```
Parallel pool using the 'local' profile is shutting down.
```

Keyword Spotting in Noise Using MFCC and LSTM Networks

This example shows how to identify a keyword in noisy speech using a deep learning network. In particular, the example uses a Bidirectional Long Short-Term Memory (BiLSTM) network and mel frequency cepstral coefficients (MFCC).

Introduction

Keyword spotting (KWS) is an essential component of voice-assist technologies, where the user speaks a predefined keyword to wake-up a system before speaking a complete command or query to the device.

This example trains a KWS deep network with feature sequences of mel-frequency cepstral coefficients (MFCC). The example also demonstrates how network accuracy in a noisy environment can be improved using data augmentation.

This example uses long short-term memory (LSTM) networks, which are a type of recurrent neural network (RNN) well-suited to study sequence and time-series data. An LSTM network can learn long-term dependencies between time steps of a sequence. An LSTM layer (`lstmLayer`) can look at the time sequence in the forward direction, while a bidirectional LSTM layer (`bilstmLayer`) can look at the time sequence in both forward and backward directions. This example uses a bidirectional LSTM layer.

The example uses the google Speech Commands Dataset to train the deep learning model. To run the example, you must first download the data set. If you do not want to download the data set or train the network, then you can download and use a pretrained network by opening this example in MATLAB® and running lines 3-10 of the example.

Spot Keyword with Pretrained Network

Before going into the training process in detail, you will download and use a pretrained keyword spotting network to identify a keyword.

In this example, the keyword to spot is **YES**.

Read a test signal where the keyword is uttered.

```
[audioIn, fs] = audioread('keywordTestSignal.wav');
sound(audioIn,fs)
```

Download and load the pretrained network, the mean (M) and standard deviation (S) vectors used for feature normalization, as well as 2 audio files used for validating the network later in the example.

```
url = 'http://ssd.mathworks.com/supportfiles/audio/KeywordSpotting.zip';
downloadNetFolder = tempdir;
netFolder = fullfile(downloadNetFolder,'KeywordSpotting');
if ~exist(netFolder,'dir')
    disp('Downloading pretrained network and audio files (4 files - 7 MB) ...')
    unzip(url,downloadNetFolder)
end
load(fullfile(netFolder,'KWSNet.mat'));
```

Create an `audioFeatureExtractor` (Audio Toolbox) object to perform feature extraction.

```
WindowLength = 512;
OverlapLength = 384;
```

```
afe = audioFeatureExtractor('SampleRate',fs, ...
                            'Window',hann(WindowLength,'periodic'), ...
                            'OverlapLength',OverlapLength, ...
                            'mfcc',true, ...
                            'mfccDelta', true, ...
                            'mfccDeltaDelta',true);
```

Extract features from the test signal and normalize them.

```
features = extract(afe,audioIn);

features = (features - M)./S;
```

Compute the keyword spotting binary mask. A mask value of one corresponds to a segment where the keyword was spotted.

```
mask = classify(KWSNet,features.');
```

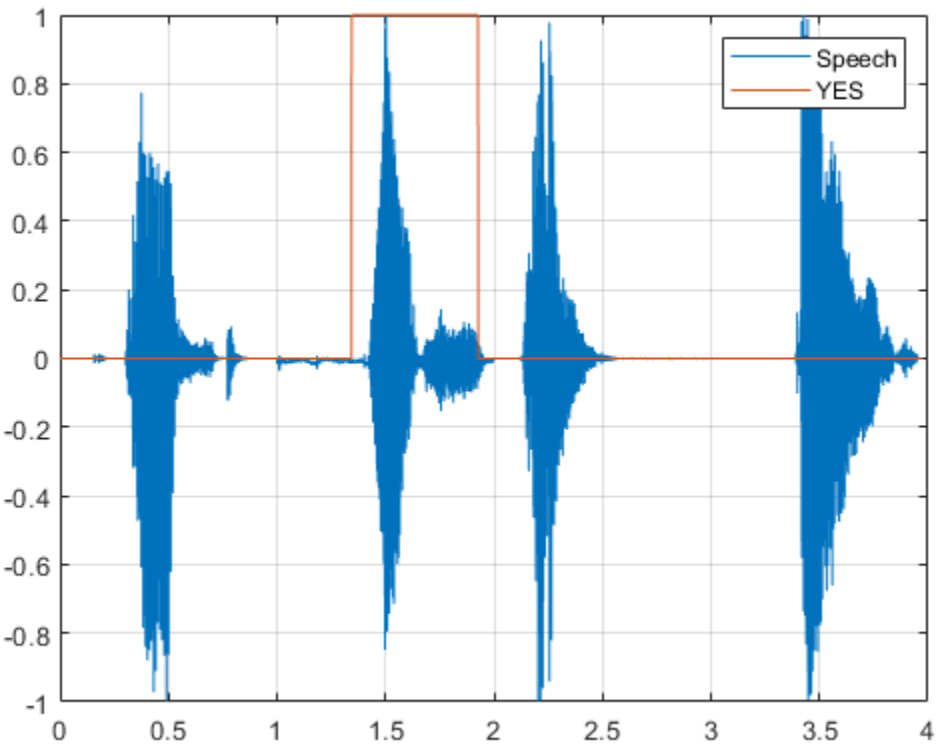
Each sample in the mask corresponds to 128 samples from the speech signal (`WindowLength - OverlapLength`).

Expand the mask to the length of the signal.

```
mask = repmat(mask, WindowLength-OverlapLength, 1);
mask = double(mask) - 1;
mask = mask(:);
```

Plot the test signal and the mask.

```
figure
audioIn = audioIn(1:length(mask));
t = (0:length(audioIn)-1)/fs;
plot(t, audioIn)
grid on
hold on
plot(t, mask)
legend('Speech', 'YES')
```



Listen to the spotted keyword.

```
sound(audioIn(mask==1),fs)
```

Detect Commands Using Streaming Audio from Microphone

Test your pre-trained command detection network on streaming audio from your microphone. Try saying random words, including the keyword (**YES**).

Call `generateMATLABFunction` (Audio Toolbox) on the `audioFeatureExtractor` object to create the feature extraction function. You will use this function in the processing loop.

```
generateMATLABFunction(afe,'generateKeywordFeatures','IsStreaming',true);
```

Define an audio device reader that can read audio from your microphone. Set the frame length to the hop length. This enables you to compute a new set of features for every new audio frame from the microphone.

```
HopLength = WindowLength - OverlapLength;
FrameLength = HopLength;
adr = audioDeviceReader('SampleRate',fs, ...
                        'SamplesPerFrame',FrameLength);
```

Create a scope for visualizing the speech signal and the estimated mask.

```
scope = timescope('SampleRate',fs, ...
                  'TimeSpanSource','property', ...
                  'TimeSpan',5, ...
```

```
                'TimeSpanOverrunAction','Scroll', ...
                'BufferLength',fs*5*2, ...
                'ShowLegend',true, ...
                'ChannelNames',{'Speech','Keyword Mask'}, ...
                'YLimits',[-1.2 1.2], ...
                'Title','Keyword Spotting');
```

Define the rate at which you estimate the mask. You will generate a mask once every `NumHopsPerUpdate` audio frames.

```
NumHopsPerUpdate = 16;
```

Initialize a buffer for the audio.

```
dataBuff = dsp.AsyncBuffer(WindowLength);
```

Initialize a buffer for the computed features.

```
featureBuff = dsp.AsyncBuffer(NumHopsPerUpdate);
```

Initialize a buffer to manage plotting the audio and the mask.

```
plotBuff = dsp.AsyncBuffer(NumHopsPerUpdate*WindowLength);
```

To run the loop indefinitely, set timeLimit to `Inf`. To stop the simulation, close the scope.

```
timeLimit = 20;

tic
while toc < timeLimit

    data = adr();
    write(dataBuff, data);
    write(plotBuff, data);

    frame = read(dataBuff,WindowLength,OverlapLength);
    features = generateKeywordFeatures(frame,fs);
    write(featureBuff,features.');

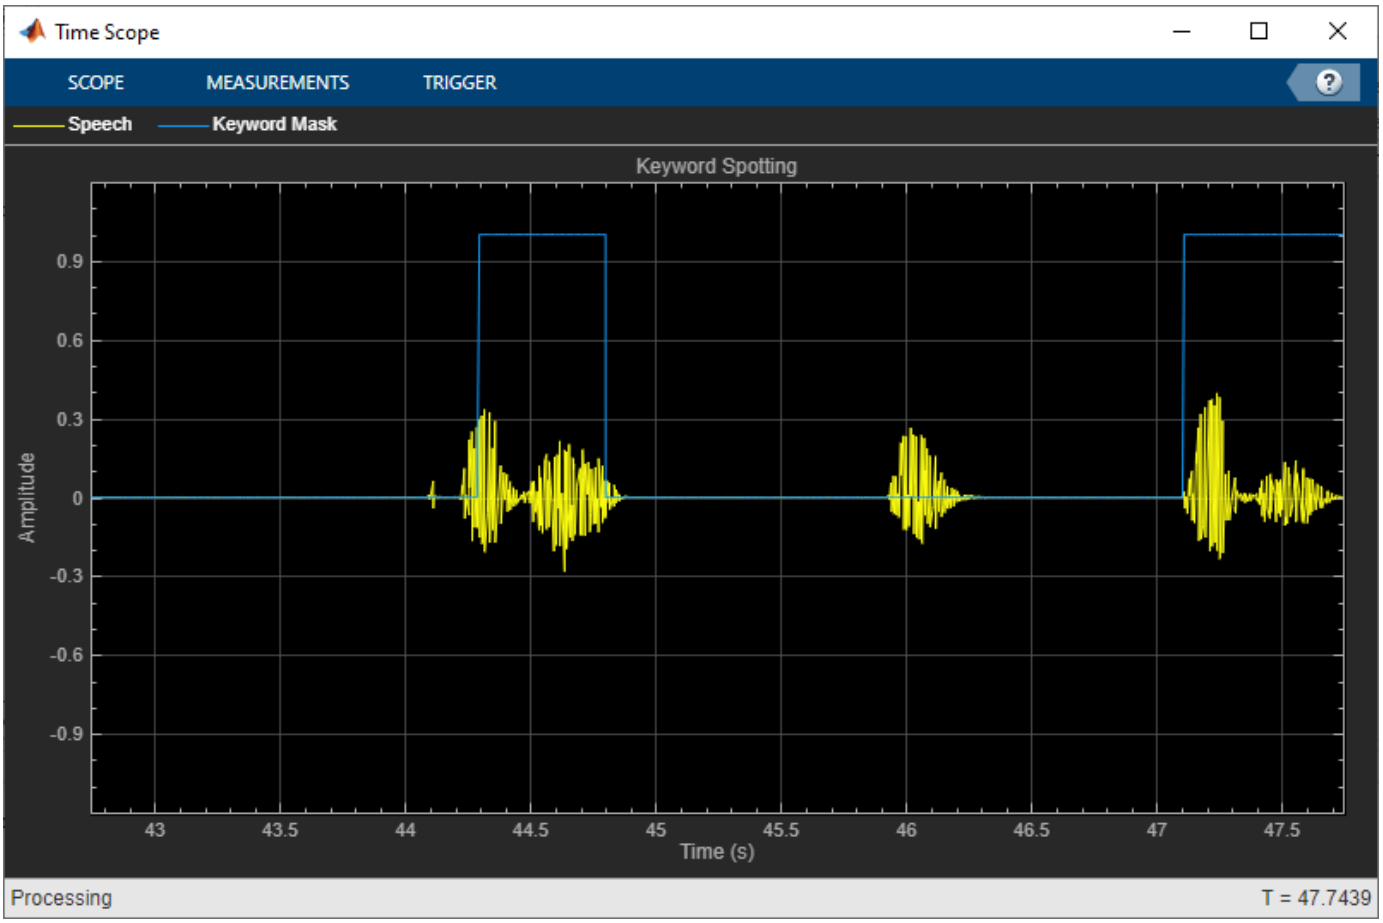
    if featureBuff.NumUnreadSamples == NumHopsPerUpdate
        featureMatrix = read(featureBuff);
        featureMatrix(~isfinite(featureMatrix)) = 0;
        featureMatrix = (featureMatrix - M)./S;

        [keywordNet, v] = classifyAndUpdateState(KWSNet,featureMatrix.');
        v = double(v) - 1;
        v = repmat(v, HopLength, 1);
        v = v(:);
        v = mode(v);
        v = repmat(v, NumHopsPerUpdate * HopLength,1);

        data = read(plotBuff);
        scope([data, v]);

        if ~isVisible(scope)
            break;
        end
    end
```

```
    end
    hide(scope)
```



In the rest of the example, you will learn how to train the keyword spotting network.

Training Process Summary

The training process goes through the following steps:

1. Inspect a "gold standard" keyword spotting baseline on a validation signal.
2. Create training utterances from a noise-free dataset.
3. Train a keyword spotting LSTM network using MFCC sequences extracted from those utterances.
4. Check the network accuracy by comparing the validation baseline to the output of the network when applied to the validation signal.
5. Check the network accuracy for a validation signal corrupted by noise.
6. Augment the training dataset by injecting noise to the speech data using `audioDataAugmenter` (Audio Toolbox).
7. Retrain the network with the augmented dataset.
8. Verify that the retrained network now yields higher accuracy when applied to the noisy validation signal.

Inspect the Validation Signal

You use a sample speech signal to validate the KWS network. The validation signal consists 34 seconds of speech with the keyword **YES** appearing intermittently.

Load the validation signal.

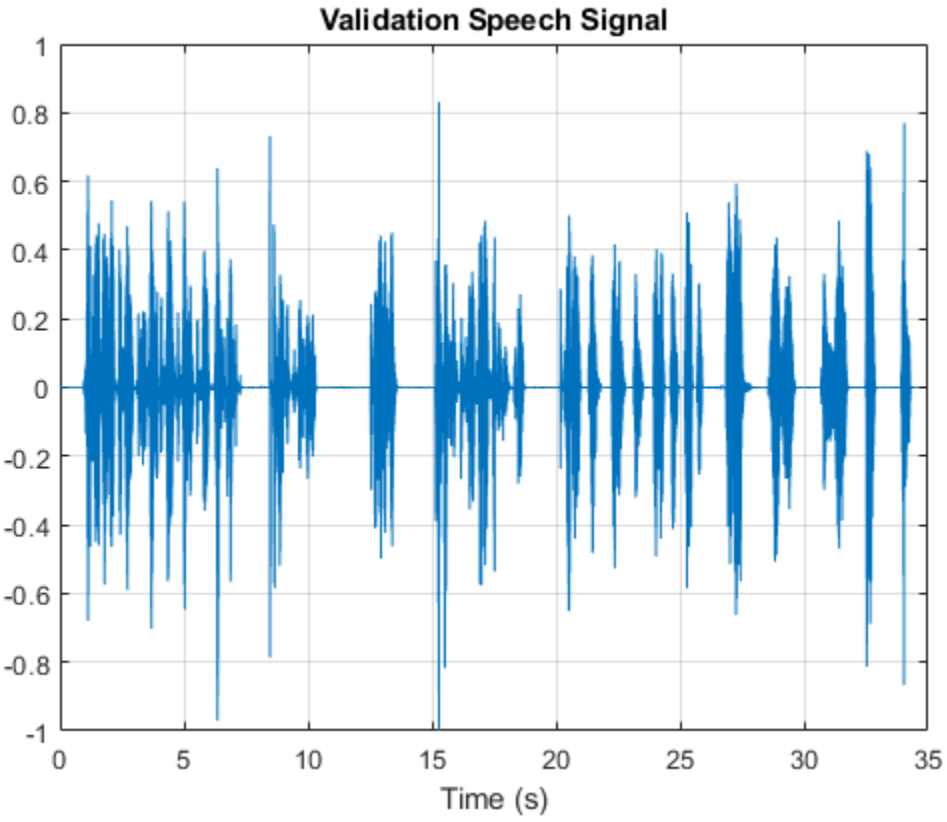
```
[audioIn,fs] = audioread(fullfile(netFolder,'KeywordSpeech-16-16-mono-34secs.flac'));
```

Listen to the signal.

```
sound(audioIn,fs)
```

Visualize the signal.

```
figure
t = (1/fs) * (0:length(audioIn)-1);
plot(t,audioIn);
grid on
xlabel('Time (s)')
title('Validation Speech Signal')
```



Inspect the KWS Baseline

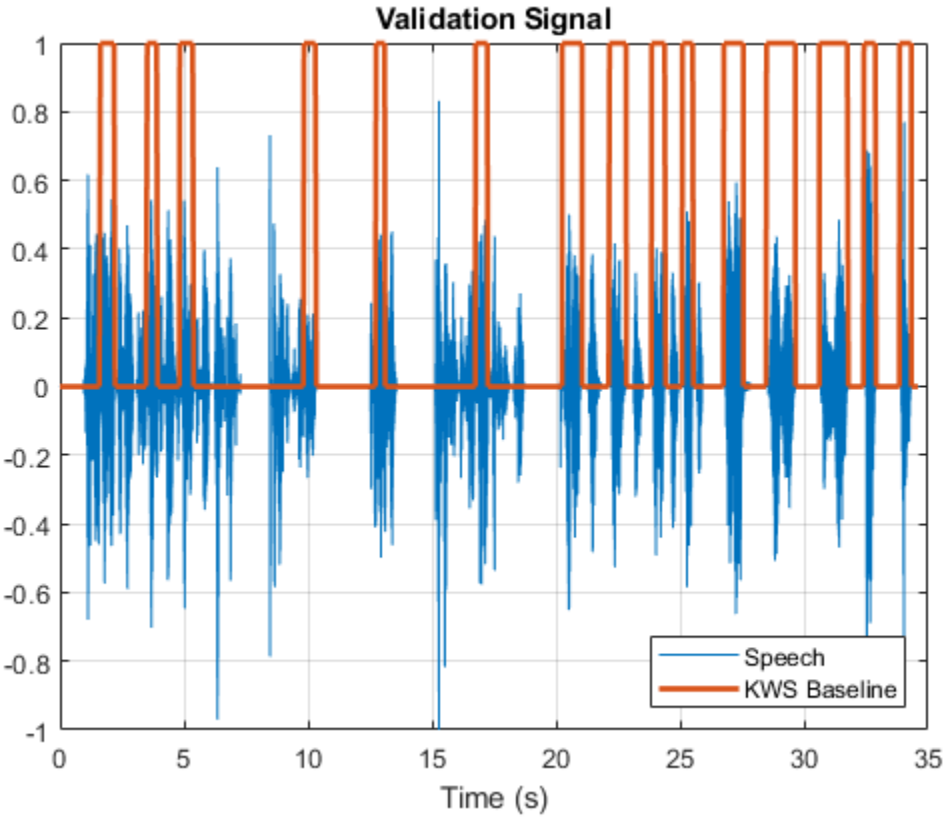
Load the KWS baseline. This baseline was obtained using `speech2text`: “Create Keyword Spotting Mask Using Audio Labeler” (Audio Toolbox).

```
load('KWSBaseline.mat','KWSBaseline')
```

The baseline is a logical vector of the same length as the validation audio signal. Segments in `audioIn` where the keyword is uttered are set to one in `KWSBaseline`.

Visualize the speech signal along with the KWS baseline.

```
fig = figure;
plot(t,[audioIn,KWSBaseline'])
grid on
xlabel('Time (s)')
legend('Speech','KWS Baseline','Location','southeast')
l = findall(fig,'type','line');
l(1).LineWidth = 2;
title("Validation Signal")
```



Listen to the speech segments identified as keywords.

```
sound(audioIn(KWSBaseline),fs)
```

The objective of the network that you train is to output a KWS mask of zeros and ones like this baseline.

Load Speech Commands Data Set

Download and extract the Google Speech Commands Dataset [1] on page 14-0 .

```
url = 'https://ssd.mathworks.com/supportfiles/audio/google_speech.zip';

downloadFolder = tempdir;
```

```
datasetFolder = fullfile(downloadFolder,'google_speech');

if ~exist(datasetFolder,'dir')
    disp('Downloading Google speech commands data set (1.5 GB)...')
    unzip(url,datasetFolder)
end
```

Create an `audioDatastore` (Audio Toolbox) that points to the data set.

```
ads = audioDatastore(datasetFolder,'LabelSource','foldername','Includesubfolders',true);
ads = shuffle(ads);
```

The dataset contains background noise files that are not used in this example. Use `subset` (Audio Toolbox) to create a new datastore that does not have the background noise files.

```
isBackNoise = ismember(ads.Labels,"background");
ads = subset(ads,~isBackNoise);
```

The dataset has approximately 65,000 one-second long utterances of 30 short words (including the keyword YES). Get a breakdown of the word distribution in the datastore.

```
countEachLabel(ads)
```

```
ans=30×2 table
    Label     Count
    ______    _____

    bed       1713
    bird      1731
    cat       1733
    dog       1746
    down      2359
    eight     2352
    five      2357
    four      2372
    go        2372
    happy     1742
    house     1750
    left      2353
    marvin    1746
    nine      2364
    no        2375
    off       2357
      ⋮
```

Split `ads` into two datastores: The first datastore contains files corresponding to the keyword. The second datastore contains all the other words.

```
keyword = 'yes';
isKeyword = ismember(ads.Labels,keyword);
ads_keyword = subset(ads,isKeyword);
ads_other = subset(ads,~isKeyword);
```

To train the network with the entire dataset and achieve the highest possible accuracy, set `reduceDataset` to `false`. To run this example quickly, set `reduceDataset` to `true`.

```
reduceDataset = false;
if reduceDataset
```

```
    % Reduce the dataset by a factor of 20
    ads_keyword = splitEachLabel(ads_keyword,round(numel(ads_keyword.Files)  / 20));
    numUniqueLabels = numel(unique(ads_other.Labels));
    ads_other = splitEachLabel(ads_other,round(numel(ads_other.Files) / numUniqueLabels / 20));
end
```

Get a breakdown of the word distribution in each datastore. Shuffle the `ads_other` datastore so that consecutive reads return different words.

```
countEachLabel(ads_keyword)
```

```
ans=1×2 table
    Label    Count
    _____    _____

     yes     2377
```

```
countEachLabel(ads_other)
```

```
ans=29×2 table
    Label     Count
    ______    _____

    bed       1713
    bird      1731
    cat       1733
    dog       1746
    down      2359
    eight     2352
    five      2357
    four      2372
    go        2372
    happy     1742
    house     1750
    left      2353
    marvin    1746
    nine      2364
    no        2375
    off       2357
      ⋮
```

```
ads_other = shuffle(ads_other);
```

Create Training Sentences and Labels

The training datastores contain one-second speech signals where one word is uttered. You will create more complex training speech utterances that contain a mixture of the keyword along with other words.

Here is an example of a constructed utterance. Read one keyword from the keyword datastore and normalize it to have a maximum value of one.

```
yes = read(ads_keyword);
yes = yes / max(abs(yes));
```

The signal has non-speech portions (silence, background noise, etc.) that do not contain useful speech information. This example removes silence using `detectSpeech` (Audio Toolbox).

Get the start and end indices of the useful portion of the signal.

```
speechIndices = detectSpeech(yes,fs);
```

Randomly select the number of words to use in the synthesized training sentence. Use a maximum of 10 words.

```
numWords = randi([0 10]);
```

Randomly pick the location at which the keyword occurs.

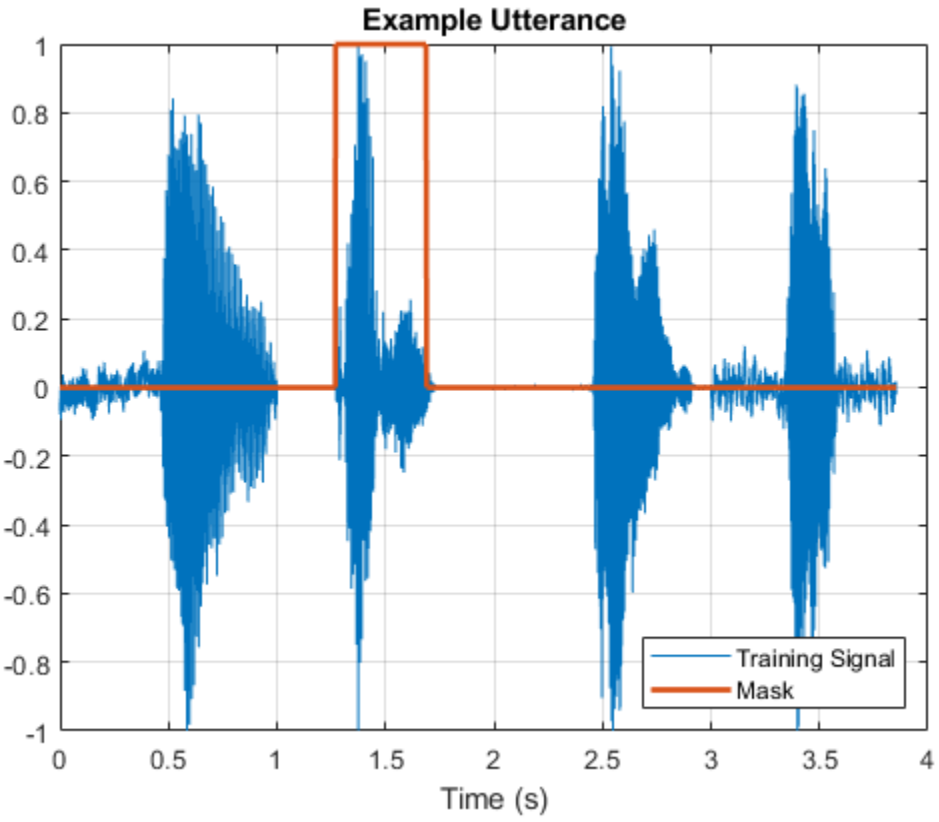
```
keywordLocation = randi([1 numWords+1]);
```

Read the desired number of non-keyword utterances, and construct the training sentence and mask.

```
sentence = [];
mask = [];
for index = 1:numWords+1
    if index == keywordLocation
        sentence = [sentence;yes]; %#ok
        newMask = zeros(size(yes));
        newMask(speechIndices(1,1):speechIndices(1,2)) = 1;
        mask = [mask;newMask]; %#ok
    else
        other = read(ads_other);
        other = other ./ max(abs(other));
        sentence = [sentence;other]; %#ok
        mask = [mask;zeros(size(other))]; %#ok
    end
end
```

Plot the training sentence along with the mask.

```
figure
t = (1/fs) * (0:length(sentence)-1);
fig = figure;
plot(t,[sentence,mask])
grid on
xlabel('Time (s)')
legend('Training Signal','Mask','Location','southeast')
l = findall(fig,'type','line');
l(1).LineWidth = 2;
title("Example Utterance")
```



Listen to the training sentence.

```
sound(sentence,fs)
```

Extract Features

This example trains a deep learning network using 39 MFCC coefficients (13 MFCC, 13 delta and 13 delta-delta coefficients).

Define parameters required for MFCC extraction.

```
WindowLength = 512;
OverlapLength = 384;
```

Create an audioFeatureExtractor object to perform the feature extraction.

```
afe = audioFeatureExtractor('SampleRate',fs, ...
                            'Window',hann(WindowLength,'periodic'), ...
                            'OverlapLength',OverlapLength, ...
                            'mfcc',true, ...
                            'mfccDelta',true, ...
                            'mfccDeltaDelta',true);
```

Extract the features.

```
featureMatrix = extract(afe,sentence);
size(featureMatrix)
```

```
ans = 1×2

   478    39
```

Note that you compute MFCC by sliding a window through the input, so the feature matrix is shorter than the input speech signal. Each row in `featureMatrix` corresponds to 128 samples from the speech signal (`WindowLength - OverlapLength`).

Compute a mask of the same length as `featureMatrix`.

```
HopLength = WindowLength - OverlapLength;
range = HopLength * (1:size(featureMatrix,1)) + HopLength;
featureMask = zeros(size(range));
for index = 1:numel(range)
    featureMask(index) = mode(mask( (index-1)*HopLength+1:(index-1)*HopLength+WindowLength ));
end
```

Extract Features from Training Dataset

Sentence synthesis and feature extraction for the whole training dataset can be quite time-consuming. To speed up processing, if you have Parallel Computing Toolbox™, partition the training datastore, and process each partition on a separate worker.

Select a number of datastore partitions.

```
numPartitions = 6;
```

Initialize cell arrays for the feature matrices and masks.

```
TrainingFeatures = {};
TrainingMasks= {};
```

Perform sentence synthesis, feature extraction, and mask creation using `parfor`.

```
emptyCategories = categorical([1 0]);
emptyCategories(:) = [];

tic
parfor ii = 1:numPartitions

    subads_keyword = partition(ads_keyword,numPartitions,ii);
    subads_other = partition(ads_other,numPartitions,ii);

    count = 1;
    localFeatures = cell(length(subads_keyword.Files),1);
    localMasks = cell(length(subads_keyword.Files),1);

    while hasdata(subads_keyword)

        % Create a training sentence
        [sentence,mask] = HelperSynthesizeSentence(subads_keyword,subads_other,fs,WindowLength);

        % Compute mfcc features
        featureMatrix = extract(afe, sentence);
        featureMatrix(~isfinite(featureMatrix)) = 0;

        % Create mask
```

```
        hopLength = WindowLength - OverlapLength;
        range = (hopLength) * (1:size(featureMatrix,1)) + hopLength;
        featureMask = zeros(size(range));
        for index = 1:numel(range)
            featureMask(index) = mode(mask( (index-1)*hopLength+1:(index-1)*hopLength+WindowLengt
        end

        localFeatures{count} = featureMatrix;
        localMasks{count} = [emptyCategories,categorical(featureMask)];

        count = count + 1;
    end

    TrainingFeatures = [TrainingFeatures;localFeatures];
    TrainingMasks = [TrainingMasks;localMasks];
end
fprintf('Training feature extraction took %f seconds.\n',toc)
```

```
Training feature extraction took 33.656404 seconds.
```

It is good practice to normalize all features to have zero mean and unity standard deviation. Compute the mean and standard deviation for each coefficient and use them to normalize the data.

```
sampleFeature = TrainingFeatures{1};
numFeatures = size(sampleFeature,2);
featuresMatrix = cat(1,TrainingFeatures{:});
if reduceDataset
    load(fullfile(netFolder,'keywordNetNoAugmentation.mat'),'keywordNetNoAugmentation','M','S');
else
    M = mean(featuresMatrix);
    S = std(featuresMatrix);
end
for index = 1:length(TrainingFeatures)
    f = TrainingFeatures{index};
    f = (f - M) ./ S;
    TrainingFeatures{index} = f.'; %#ok
end
```

Extract Validation Features

Extract MFCC features from the validation signal.

```
featureMatrix = extract(afe, audioIn);
featureMatrix(~isfinite(featureMatrix)) = 0;
```

Normalize the validation features.

```
FeaturesValidationClean = (featureMatrix - M)./S;
range = HopLength * (1:size(FeaturesValidationClean,1)) + HopLength;
```

Construct the validation KWS mask.

```
featureMask = zeros(size(range));
for index = 1:numel(range)
    featureMask(index) = mode(KWSBaseline( (index-1)*HopLength+1:(index-1)*HopLength+WindowLengt
end
BaselineV = categorical(featureMask);
```

Define the LSTM Network Architecture

LSTM networks can learn long-term dependencies between time steps of sequence data. This example uses the bidirectional LSTM layer `bilstmLayer` to look at the sequence in both forward and backward directions.

Specify the input size to be sequences of size `numFeatures`. Specify two hidden bidirectional LSTM layers with an output size of 150 and output a sequence. This command instructs the bidirectional LSTM layer to map the input time series into 150 features that are passed to the next layer. Specify two classes by including a fully connected layer of size 2, followed by a softmax layer and a classification layer.

```
layers = [ ...
    sequenceInputLayer(numFeatures)
    bilstmLayer(150,"OutputMode","sequence")
    bilstmLayer(150,"OutputMode","sequence")
    fullyConnectedLayer(2)
    softmaxLayer
    classificationLayer
    ];
```

Define Training Options

Specify the training options for the classifier. Set `MaxEpochs` to 10 so that the network makes 10 passes through the training data. Set `MiniBatchSize` to `64` so that the network looks at 64 training signals at a time. Set `Plots` to `"training-progress"` to generate plots that show the training progress as the number of iterations increases. Set `Verbose` to `false` to disable printing the table output that corresponds to the data shown in the plot. Set `Shuffle` to `"every-epoch"` to shuffle the training sequence at the beginning of each epoch. Set `LearnRateSchedule` to `"piecewise"` to decrease the learning rate by a specified factor (0.1) every time a certain number of epochs (5) has passed. Set `ValidationData` to the validation predictors and targets.

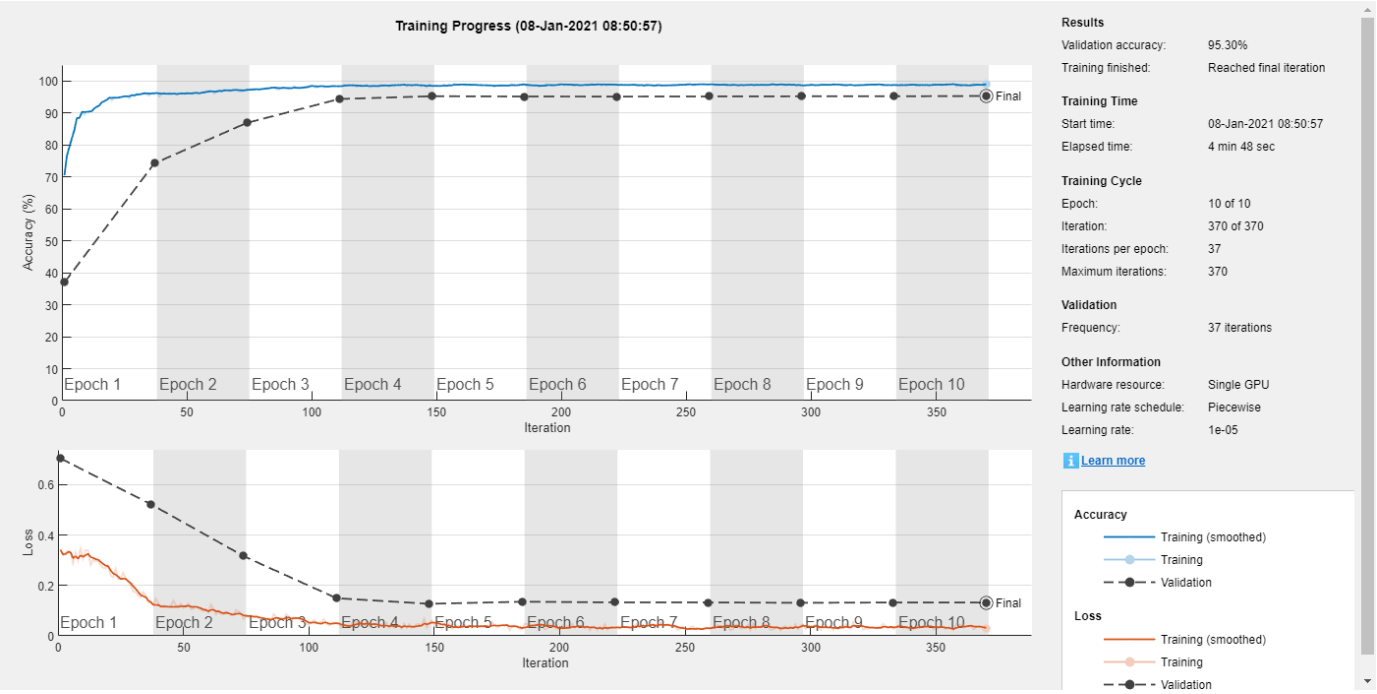
This example uses the adaptive moment estimation (ADAM) solver. ADAM performs better with recurrent neural networks (RNNs) like LSTMs than the default stochastic gradient descent with momentum (SGDM) solver.

```
maxEpochs = 10;
miniBatchSize = 64;
options = trainingOptions("adam", ...
    "InitialLearnRate",1e-4, ...
    "MaxEpochs",maxEpochs, ...
    "MiniBatchSize",miniBatchSize, ...
    "Shuffle","every-epoch", ...
    "Verbose",false, ...
    "ValidationFrequency",floor(numel(TrainingFeatures)/miniBatchSize), ...
    "ValidationData",{FeaturesValidationClean.',BaselineV}, ...
    "Plots","training-progress", ...
    "LearnRateSchedule","piecewise", ...
    "LearnRateDropFactor",0.1, ...
    "LearnRateDropPeriod",5);
```

Train the LSTM Network

Train the LSTM network with the specified training options and layer architecture using `trainNetwork`. Because the training set is large, the training process can take several minutes.

```
[keywordNetNoAugmentation,netInfo] = trainNetwork(TrainingFeatures,TrainingMasks,layers,options)
```



```
if reduceDataset
    load(fullfile(netFolder,'keywordNetNoAugmentation.mat'),'keywordNetNoAugmentation','M','S');
end
```

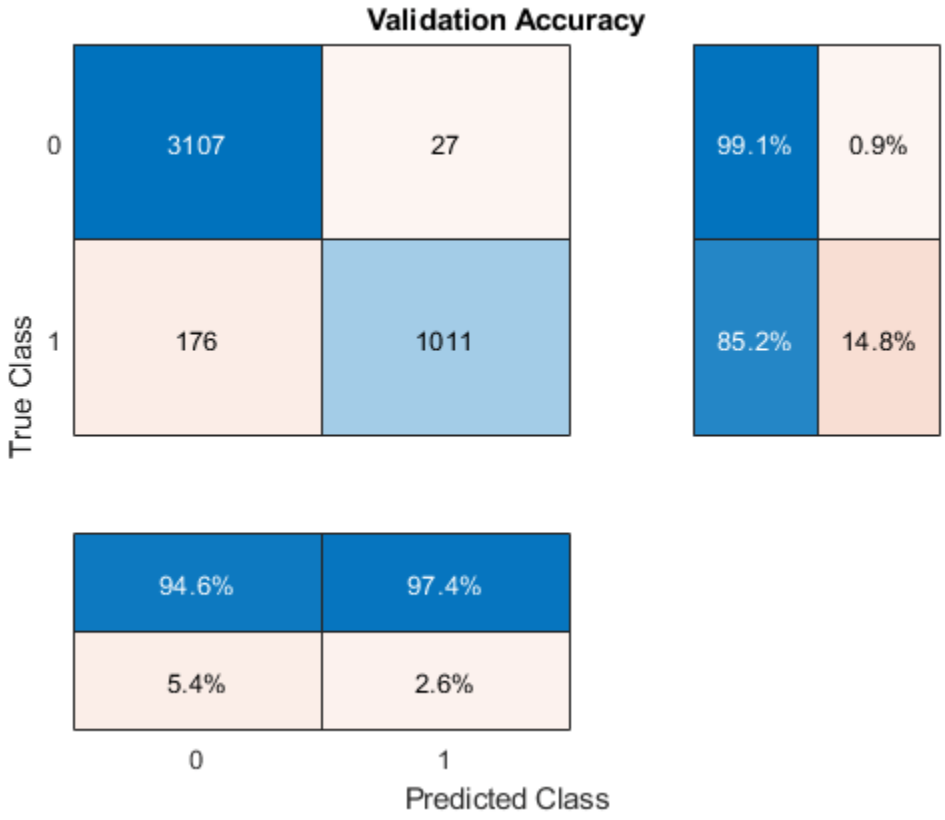
Check Network Accuracy for Noise-Free Validation Signal

Estimate the KWS mask for the validation signal using the trained network.

```
v = classify(keywordNetNoAugmentation,FeaturesValidationClean.');
```

Calculate and plot the validation confusion matrix from the vectors of actual and estimated labels.

```
figure
cm = confusionchart(BaselineV,v,"title","Validation Accuracy");
cm.ColumnSummary = "column-normalized";
cm.RowSummary = "row-normalized";
```



Convert the network output from categorical to double.

```
v = double(v) - 1;
v = repmat(v,HopLength,1);
v = v(:);
```

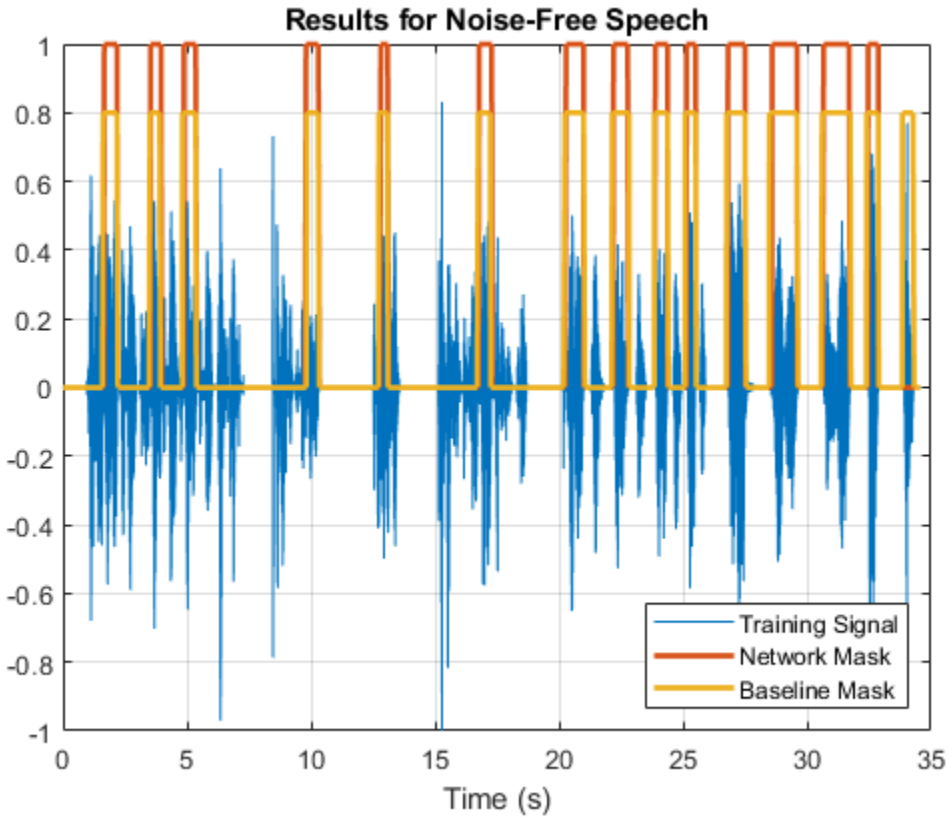
Listen to the keyword areas identified by the network.

```
sound(audioIn(logical(v)),fs)
```

Visualize the estimated and expected KWS masks.

```
baseline = double(BaselineV) - 1;
baseline = repmat(baseline,HopLength,1);
baseline = baseline(:);

t = (1/fs) * (0:length(v)-1);
fig = figure;
plot(t,[audioIn(1:length(v)),v,0.8*baseline])
grid on
xlabel('Time (s)')
legend('Training Signal','Network Mask','Baseline Mask','Location','southeast')
l = findall(fig,'type','line');
l(1).LineWidth = 2;
l(2).LineWidth = 2;
title('Results for Noise-Free Speech')
```



Check Network Accuracy for a Noisy Validation Signal

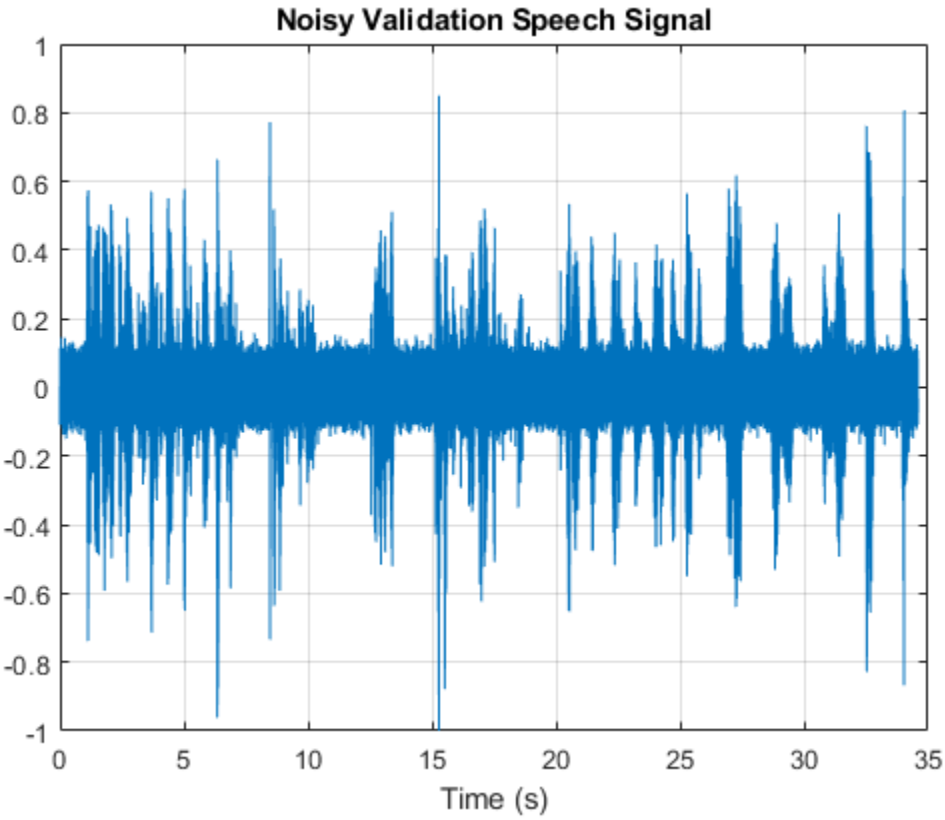
You will now check the network accuracy for a noisy speech signal. The noisy signal was obtained by corrupting the clean validation signal by additive white Gaussian noise.

Load the noisy signal.

```
[audioInNoisy,fs] = audioread(fullfile(netFolder,'NoisyKeywordSpeech-16-16-mono-34secs.flac'));
sound(audioInNoisy,fs)
```

Visualize the signal.

```
figure
t = (1/fs) * (0:length(audioInNoisy)-1);
plot(t,audioInNoisy)
grid on
xlabel('Time (s)')
title('Noisy Validation Speech Signal')
```



Extract the feature matrix from the noisy signal.

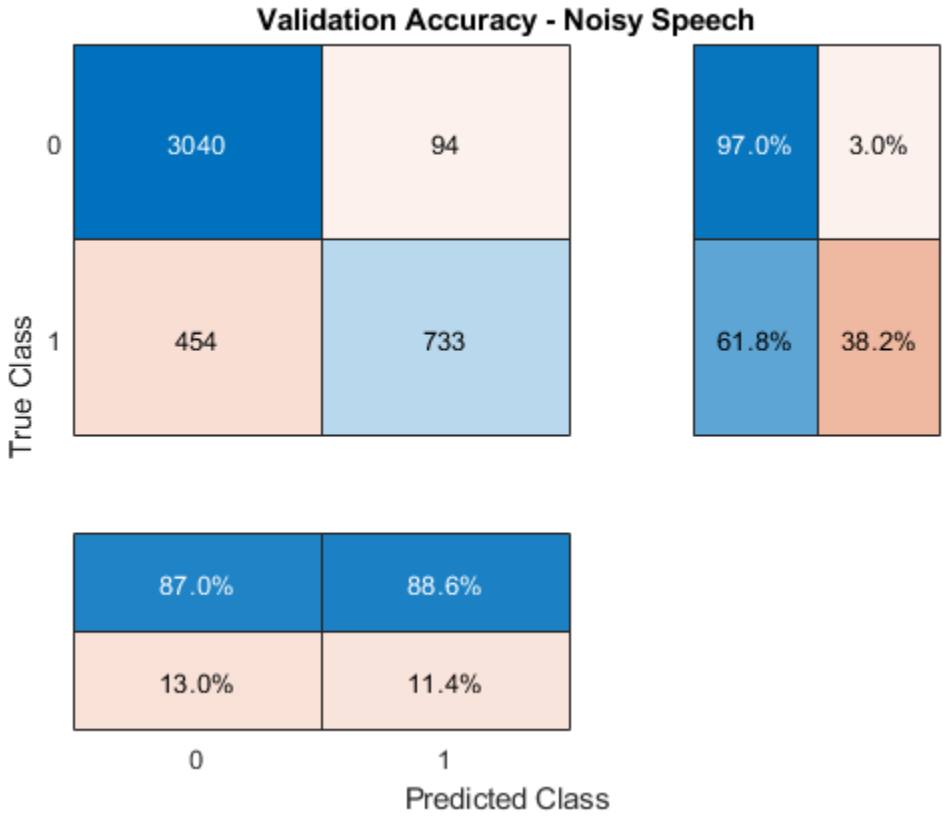
```
featureMatrixV = extract(afe, audioInNoisy);
featureMatrixV(~isfinite(featureMatrixV)) = 0;
FeaturesValidationNoisy = (featureMatrixV - M)./S;
```

Pass the feature matrix to the network.

```
v = classify(keywordNetNoAugmentation,FeaturesValidationNoisy.');
```

Compare the network output to the baseline. Note that the accuracy is lower than the one you got for a clean signal.

```
figure
cm = confusionchart(BaselineV,v,"title","Validation Accuracy - Noisy Speech");
cm.ColumnSummary = "column-normalized";
cm.RowSummary = "row-normalized";
```



Convert the network output from categorical to double.

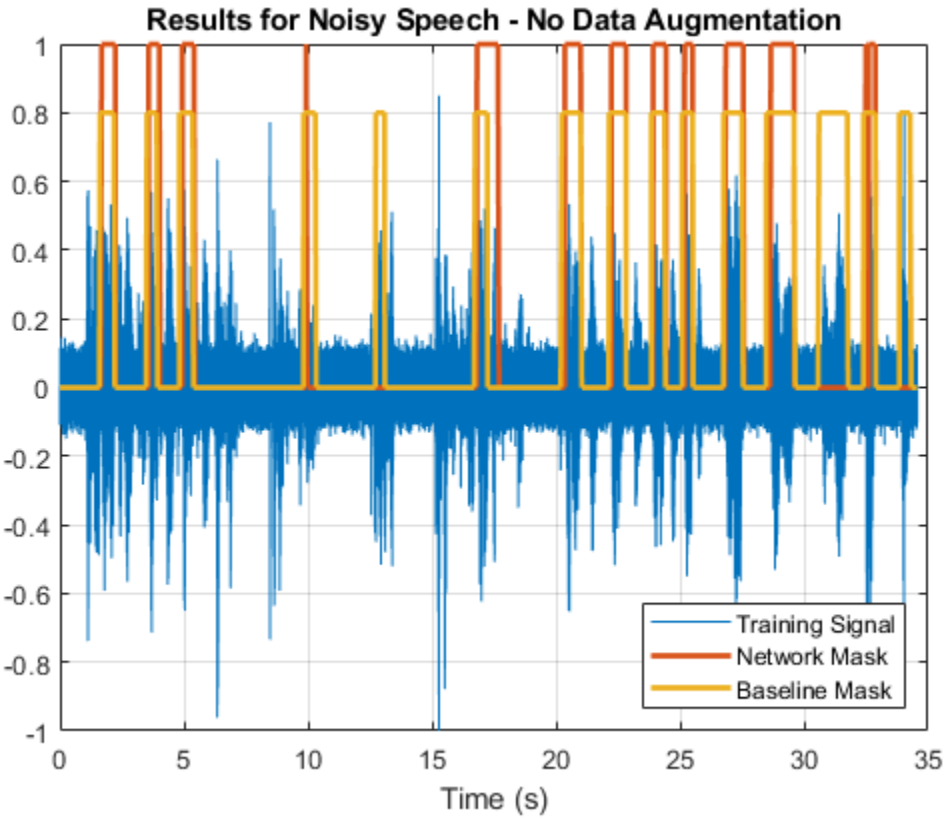
```
v = double(v) - 1;
v = repmat(v,HopLength,1);
v = v(:);
```

Listen to the keyword areas identified by the network.

```
sound(audioIn(logical(v)),fs)
```

Visualize the estimated and baseline masks.

```
t = (1/fs)*(0:length(v)-1);
fig = figure;
plot(t,[audioInNoisy(1:length(v)),v,0.8*baseline])
grid on
xlabel('Time (s)')
legend('Training Signal','Network Mask','Baseline Mask','Location','southeast')
l = findall(fig,'type','line');
l(1).LineWidth = 2;
l(2).LineWidth = 2;
title('Results for Noisy Speech - No Data Augmentation')
```



Perform Data Augmentation

The trained network did not perform well on a noisy signal because the trained dataset contained only noise-free sentences. You will rectify this by augmenting your dataset to include noisy sentences.

Use `audioDataAugmenter` (Audio Toolbox) to augment your dataset.

```
ada = audioDataAugmenter('TimeStretchProbability',0, ...
                         'PitchShiftProbability',0, ...
                         'VolumeControlProbability',0, ...
                         'TimeShiftProbability',0, ...
                         'SNRRange',[-1, 1], ...
                         'AddNoiseProbability',0.85);
```

With these settings, the `audioDataAugmenter` object corrupts an input audio signal with white Gaussian noise with a probability of 85%. The SNR is randomly selected from the range [-1 1] (in dB). There is a 15% probability that the augmenter does not modify your input signal.

As an example, pass an audio signal to the augmenter.

```
reset(ads_keyword)
x = read(ads_keyword);
data = augment(ada,x,fs)
```

```
data=1×2 table
        Audio          AugmentationInfo
    _______________    _______________
```

```
    {16000×1 double}      [1×1 struct]
```

Inspect the `AugmentationInfo` variable in `data` to verify how the signal was modified.

```
data.AugmentationInfo
```

```
ans = struct with fields:
    SNR: 0.3410
```

Reset the datastores.

```
reset(ads_keyword)
reset(ads_other)
```

Initialize the feature and mask cells.

```
TrainingFeatures = {};
TrainingMasks = {};
```

Perform feature extraction again. Each signal is corrupted by noise with a probability of 85%, so your augmented dataset has approximately 85% noisy data and 15% noise-free data.

```
tic
parfor ii = 1:numPartitions

    subads_keyword = partition(ads_keyword,numPartitions,ii);
    subads_other = partition(ads_other,numPartitions,ii);

    count = 1;
    localFeatures = cell(length(subads_keyword.Files),1);
    localMasks = cell(length(subads_keyword.Files),1);

    while hasdata(subads_keyword)

        [sentence,mask] = HelperSynthesizeSentence(subads_keyword,subads_other,fs,WindowLength);

        % Corrupt with noise
        augmentedData = augment(ada,sentence,fs);
        sentence = augmentedData.Audio{1};

        % Compute mfcc features
        featureMatrix = extract(afe, sentence);
        featureMatrix(~isfinite(featureMatrix)) = 0;

        hopLength = WindowLength - OverlapLength;
        range = hopLength * (1:size(featureMatrix,1)) + hopLength;
        featureMask = zeros(size(range));
        for index = 1:numel(range)
            featureMask(index) = mode(mask( (index-1)*hopLength+1:(index-1)*hopLength+WindowLeng
        end

        localFeatures{count} = featureMatrix;
        localMasks{count} = [emptyCategories,categorical(featureMask)];

        count = count + 1;
    end
```

```
    TrainingFeatures = [TrainingFeatures;localFeatures];
    TrainingMasks = [TrainingMasks;localMasks];
end
fprintf('Training feature extraction took %f seconds.\n',toc)
```

```
Training feature extraction took 36.090923 seconds.
```

Compute the mean and standard deviation for each coefficient; use them to normalize the data.

```
sampleFeature = TrainingFeatures{1};
numFeatures = size(sampleFeature,2);
featuresMatrix = cat(1,TrainingFeatures{:});
if reduceDataset
    load(fullfile(netFolder,'KWSNet.mat'),'KWSNet','M','S');
else
    M = mean(featuresMatrix);
    S = std(featuresMatrix);
end
for index = 1:length(TrainingFeatures)
    f = TrainingFeatures{index};
    f = (f - M) ./ S;
    TrainingFeatures{index} = f.'; %#ok
end
```

Normalize the validation features with the new mean and standard deviation values.

```
FeaturesValidationNoisy = (featureMatrixV - M)./S;
```

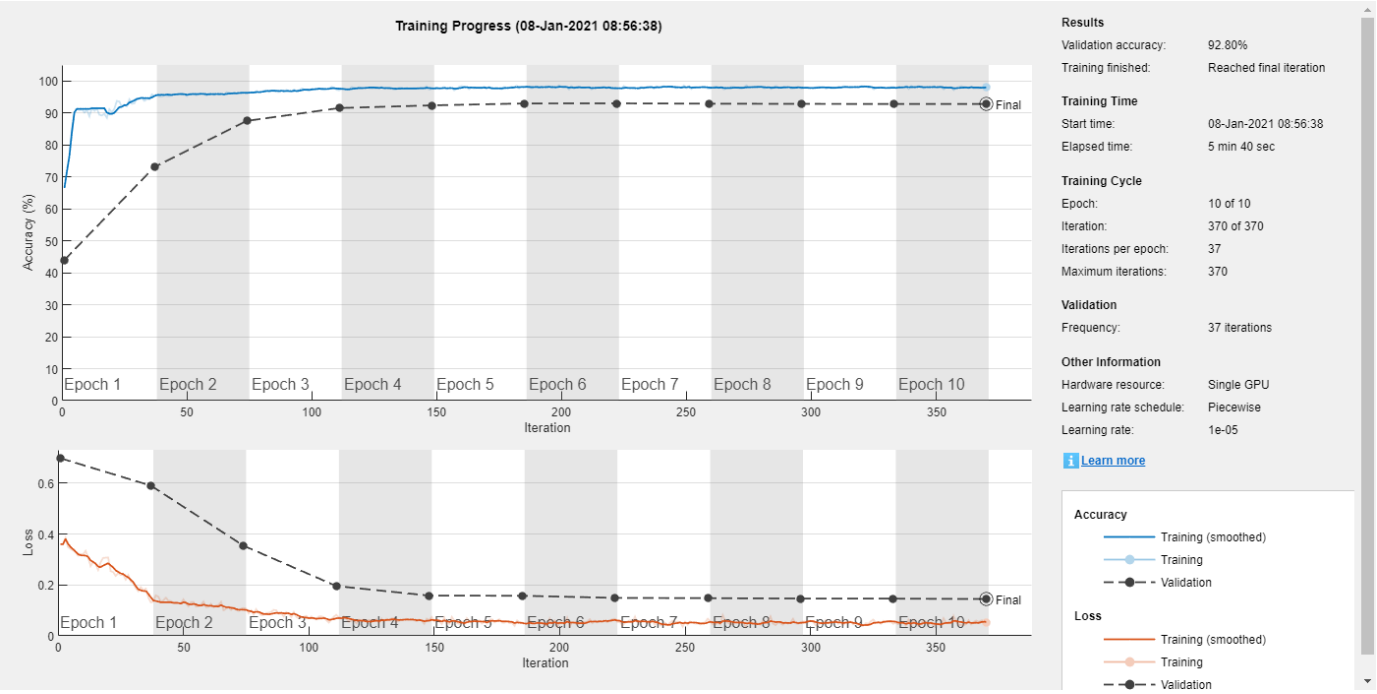
Retrain Network with Augmented Dataset

Recreate the training options. Use the noisy baseline features and mask for validation.

```
options = trainingOptions("adam", ...
    "InitialLearnRate",1e-4, ...
    "MaxEpochs",maxEpochs, ...
    "MiniBatchSize",miniBatchSize, ...
    "Shuffle","every-epoch", ...
    "Verbose",false, ...
    "ValidationFrequency",floor(numel(TrainingFeatures)/miniBatchSize), ...
    "ValidationData",{FeaturesValidationNoisy.',BaselineV}, ...
    "Plots","training-progress", ...
    "LearnRateSchedule","piecewise", ...
    "LearnRateDropFactor",0.1, ...
    "LearnRateDropPeriod",5);
```

Train the network.

```
[KWSNet,netInfo] = trainNetwork(TrainingFeatures,TrainingMasks,layers,options);
```



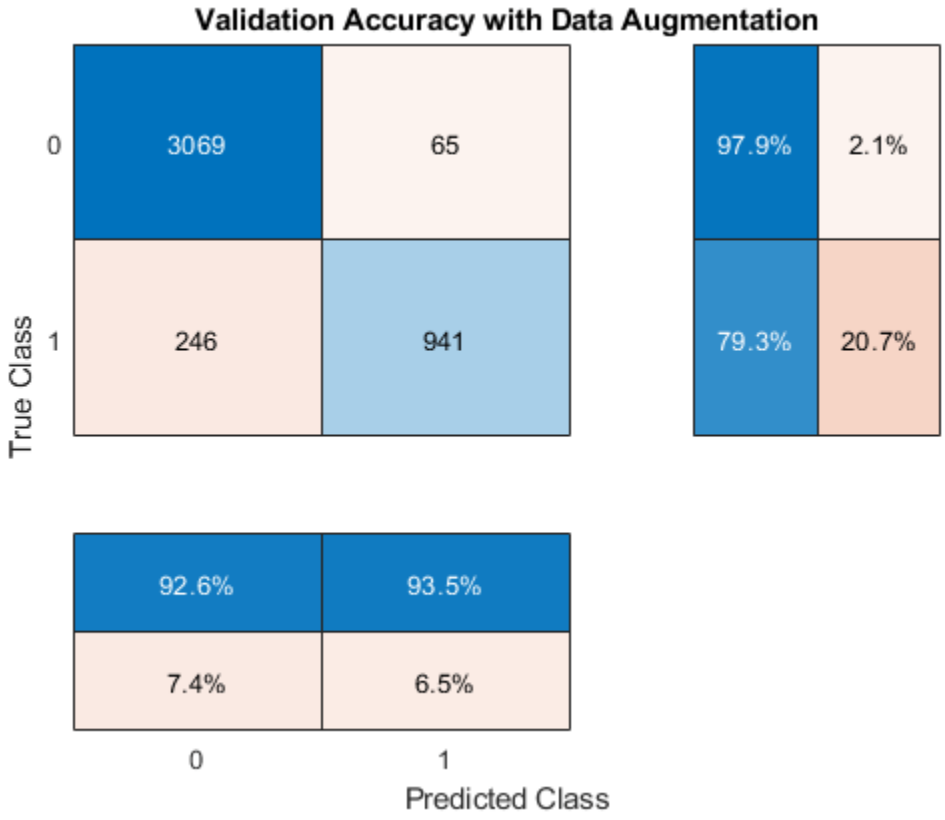
```
if reduceDataset
    load(fullfile(netFolder,'KWSNet.mat'));
end
```

Verify the network accuracy on the validation signal.

```
v = classify(KWSNet,FeaturesValidationNoisy.');
```

Compare the estimated and expected KWS masks.

```
figure
cm = confusionchart(BaselineV,v,"title","Validation Accuracy with Data Augmentation");
cm.ColumnSummary = "column-normalized";
cm.RowSummary = "row-normalized";
```



Listen to the identified keyword regions.

```
v = double(v) - 1;
v = repmat(v,HopLength,1);
v = v(:);

sound(audioIn(logical(v)),fs)
```

Visualize the estimated and expected masks.

```
fig = figure;
plot(t,[audioInNoisy(1:length(v)),v,0.8*baseline])
grid on
xlabel('Time (s)')
legend('Training Signal','Network Mask','Baseline Mask','Location','southeast')
l = findall(fig,'type','line');
l(1).LineWidth = 2;
l(2).LineWidth = 2;
title('Results for Noisy Speech - With Data Augmentation')
```

Speech Emotion Recognition

This example illustrates a simple speech emotion recognition (SER) system using a BiLSTM network. You begin by downloading the data set and then testing the trained network on individual files. The network was trained on a small German-language database [1] on page 14-0 .

The example walks you through training the network, which includes downloading, augmenting, and training the dataset. Finally, you perform leave-one-speaker-out (LOSO) 10-fold cross validation to evaluate the network architecture.

The features used in this example were chosen using sequential feature selection, similar to the method described in “Sequential Feature Selection for Audio Features” (Audio Toolbox).

Download Data Set

Download the Berlin Database of Emotional Speech [1] on page 14-0 . The database contains 535 utterances spoken by 10 actors intended to convey one of the following emotions: anger, boredom, disgust, anxiety/fear, happiness, sadness, or neutral. The emotions are text independent.

```
url = "http://emodb.bilderbar.info/download/download.zip";
downloadFolder = tempdir;
datasetFolder = fullfile(downloadFolder,"Emo-DB");

if ~exist(datasetFolder,'dir')
    disp('Downloading Emo-DB (40.5 MB) ...')
    unzip(url,datasetFolder)
end
```

Create an `audioDatastore` (Audio Toolbox) that points to the audio files.

```
ads = audioDatastore(fullfile(datasetFolder,"wav"));
```

The file names are codes indicating the speaker ID, text spoken, emotion, and version. The website contains a key for interpreting the code and additional information about the speakers such as gender and age. Create a table with the variables `Speaker` and `Emotion`. Decode the file names into the table.

```
filepaths = ads.Files;
emotionCodes = cellfun(@(x)x(end-5),filepaths,'UniformOutput',false);
emotions = replace(emotionCodes,{'W','L','E','A','F','T','N'}, ...
    {'Anger','Boredom','Disgust','Anxiety/Fear','Happiness','Sadness','Neutral'});

speakerCodes = cellfun(@(x)x(end-10:end-9),filepaths,'UniformOutput',false);
labelTable = cell2table([speakerCodes,emotions],'VariableNames',{'Speaker','Emotion'});
labelTable.Emotion = categorical(labelTable.Emotion);
labelTable.Speaker = categorical(labelTable.Speaker);
summary(labelTable)
```

```
Variables:

    Speaker: 535×1 categorical

        Values:

            03       49
            08       58
            09       43
```

```
            10       38
            11       55
            12       35
            13       61
            14       69
            15       56
            16       71

    Emotion: 535×1 categorical

        Values:

            Anger             127
            Anxiety/Fear       69
            Boredom            81
            Disgust            46
            Happiness          71
            Neutral            79
            Sadness            62
```

`labelTable` is in the same order as the files in `audioDatastore`. Set the `Labels` property of the `audioDatastore` to the `labelTable`.

```
ads.Labels = labelTable;
```

Perform Speech Emotion Recognition

Download and load the pretrained network, the `audioFeatureExtractor` (Audio Toolbox) object used to train the network, and normalization factors for the features. This network was trained using all speakers in the data set except speaker `03`.

```
url = 'http://ssd.mathworks.com/supportfiles/audio/SpeechEmotionRecognition.zip';
    downloadNetFolder = tempdir;
    netFolder = fullfile(downloadNetFolder,'SpeechEmotionRecognition');
    if ~exist(netFolder,'dir')
        disp('Downloading pretrained network (1 file - 1.5 MB) ...')
        unzip(url,downloadNetFolder)
    end
load(fullfile(netFolder,'network_Audio_SER.mat'));
```

The sample rate set on the `audioFeatureExtractor` corresponds to the sample rate of the data set.

```
fs = afe.SampleRate;
```

Select a speaker and emotion, then subset the datastore to only include the chosen speaker and emotion. Read from the datastore and listen to the file.

```
speaker = 03 - male, 31 ;
emotion = Disgust ;

adsSubset = subset(ads,ads.Labels.Speaker==speaker & ads.Labels.Emotion == emotion);

audio = read(adsSubset);
sound(audio,fs)
```

Use the `audioFeatureExtractor` object to extract the features and then transpose them so that time is along rows. Normalize the features and then convert them to 20-element sequences with 10-element overlap, which corresponds to approximately 600 ms windows with 300 ms overlap. Use the supporting function, HelperFeatureVector2Sequence on page 14-0 , to convert the array of feature vectors to sequences.

```
features = (extract(afe,audio))';

featuresNormalized = (features - normalizers.Mean)./normalizers.StandardDeviation;

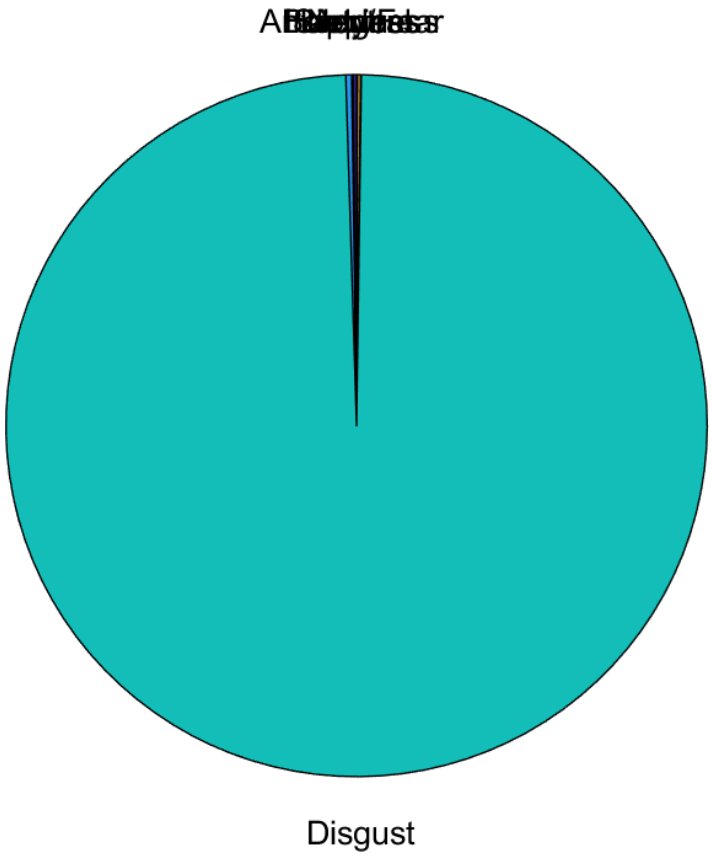
numOverlap = 10 ;
featureSequences = HelperFeatureVector2Sequence(featuresNormalized,20,numOverlap);
```

Feed the feature sequences into the network for prediction. Compute the mean prediction and plot the probability distribution of the chosen emotions as a pie chart. You can try different speakers, emotions, sequence overlap, and prediction average to test the network's performance. To get a realistic approximation of the network's performance, use speaker `03`, which the network was not trained on.

```
YPred = double(predict(net,featureSequences));

average = mode;
switch average
    case 'mean'
        probs = mean(YPred,1);
    case 'median'
        probs = median(YPred,1);
    case 'mode'
        probs = mode(YPred,1);
end

pie(probs./sum(probs),string(net.Layers(end).Classes))
```



The remainder of the example illustrates how the network was trained and validated.

Train Network

The 10-fold cross validation accuracy of a first attempt at training was about 60% because of insufficient training data. A model trained on the insufficient data overfits some folds and underfits others. To improve overall fit, increase the size of the dataset using `audioDataAugmenter` (Audio Toolbox). 50 augmentations per file was chosen empirically as a good tradeoff between processing time and accuracy improvement. You can decrease the number of augmentations to speed up the example.

Create an `audioDataAugmenter` object. Set the probability of applying pitch shifting to `0.5` and use the default range. Set the probability of applying time shifting to `1` and use a range of `[-0.3,0.3]` seconds. Set the probability of adding noise to `1` and specify the SNR range as `[-20,40]` dB.

```
numAugmentations = 50;
augmenter = audioDataAugmenter('NumAugmentations',numAugmentations, ...
    'TimeStretchProbability',0, ...
    'VolumeControlProbability',0, ...
```

```
    ...
    'PitchShiftProbability',0.5, ...
    ...
    'TimeShiftProbability',1, ...
    'TimeShiftRange',[-0.3,0.3], ...
    ...
    'AddNoiseProbability',1, ...
    'SNRRange', [-20,40]);
```

Create a new folder in your current folder to hold the augmented data set.

```
currentDir = pwd;
writeDirectory = fullfile(currentDir,'augmentedData');
mkdir(writeDirectory)
```

For each file in the audio datastore:

1. Create 50 augmentations.
2. Normalize the audio to have a max absolute value of 1.
3. Write the augmented audio data as a WAV file. Append `_augK` to each of the file names, where *K* is the augmentation number. To speed up processing, use `parfor` and partition the datastore.

This method of augmenting the database is time consuming (approximately 1 hour) and space consuming (approximately 26 GB). However, when iterating on choosing a network architecture or feature extraction pipeline, this upfront cost is generally advantageous.

```
N = numel(ads.Files)*numAugmentations;
myWaitBar = HelperPoolWaitbar(N,"Augmenting Dataset...");

reset(ads)

numPartitions = 18;

tic
parfor ii = 1:numPartitions
    adsPart = partition(ads,numPartitions,ii);
    while hasdata(adsPart)
        [x,adsInfo] = read(adsPart);
        data = augment(augmenter,x,fs);

        [~,fn] = fileparts(adsInfo.FileName);
        for i = 1:size(data,1)
            augmentedAudio = data.Audio{i};
            augmentedAudio = augmentedAudio/max(abs(augmentedAudio),[],'all');
            augNum = num2str(i);
            if numel(augNum)==1
                iString = ['0',augNum];
            else
                iString = augNum;
            end
            audiowrite(fullfile(writeDirectory,sprintf('%s_aug%s.wav',fn,iString)),augmentedAudio
            increment(myWaitBar)
        end
    end
end
```

```
Starting parallel pool (parpool) using the 'local' profile ...
Connected to the parallel pool (number of workers: 6).
```

```
delete(myWaitBar)
fprintf('Augmentation complete (%0.2f minutes).\n',toc/60)
```

```
Augmentation complete (6.28 minutes).
```

Create an audio datastore that points to the augmented data set. Replicate the rows of the label table of the original datastore `NumAugmentations` times to determine the labels of the augmented datastore.

```
adsAug = audioDatastore(writeDirectory);
adsAug.Labels = repelem(ads.Labels,augmenter.NumAugmentations,1);
```

Create an `audioFeatureExtractor` (Audio Toolbox) object. Set `Window` to a periodic 30 ms Hamming window, `OverlapLength` to `0`, and `SampleRate` to the sample rate of the database. Set `gtcc`, `gtccDelta`, `mfccDelta`, and `spectralCrest` to `true` to extract them. Set `SpectralDescriptorInput` to `melSpectrum` so that the `spectralCrest` is calculated for the mel spectrum.

```
win = hamming(round(0.03*fs),"periodic");
overlapLength = 0;

afe = audioFeatureExtractor( ...
    'Window',win, ...
    'OverlapLength',overlapLength, ...
    'SampleRate',fs, ...
    ...
    'gtcc',true, ...
    'gtccDelta',true, ...
    'mfccDelta',true, ...
    ...
    'SpectralDescriptorInput','melSpectrum', ...
    'spectralCrest',true);
```

Train for Deployment

When you train for deployment, use all available speakers in the data set. Set the training datastore to the augmented datastore.

```
adsTrain = adsAug;
```

Convert the training audio datastore to a tall array. If you have Parallel Computing Toolbox™, the extraction is automatically parallelized. If you do not have Parallel Computing Toolbox™, the code continues to run.

```
tallTrain = tall(adsTrain);
```

Extract the training features and reorient the features so that time is along rows to be compatible with `sequenceInputLayer`.

```
featuresTallTrain = cellfun(@(x)extract(afe,x),tallTrain,"UniformOutput",false);
featuresTallTrain = cellfun(@(x)x',featuresTallTrain,"UniformOutput",false);
featuresTrain = gather(featuresTallTrain);
```

```
Evaluating tall expression using the Parallel Pool 'local':
- Pass 1 of 1: Completed in 1 min 7 sec
Evaluation completed in 1 min 7 sec
```

Use the training set to determine the mean and standard deviation of each feature.

```
allFeatures = cat(2,featuresTrain{:});
M = mean(allFeatures,2,'omitnan');
S = std(allFeatures,0,2,'omitnan');

featuresTrain = cellfun(@(x)(x-M)./S,featuresTrain,'UniformOutput',false);
```

Buffer the feature vectors into sequences so that each sequence consists of 20 feature vectors with overlaps of 10 feature vectors.

```
featureVectorsPerSequence = 20;
featureVectorOverlap = 10;
[sequencesTrain,sequencePerFileTrain] = HelperFeatureVector2Sequence(featuresTrain,featureVectors
```

Replicate the labels of the training and validation sets so that they are in one-to-one correspondence with the sequences. Not all speakers have utterances for all emotions. Create an empty `categorical` array that contains all the emotional categories and append it to the validation labels so that the categorical array contains all emotions.

```
labelsTrain = repelem(adsTrain.Labels.Emotion,[sequencePerFileTrain{:}]);

emptyEmotions = ads.Labels.Emotion;
emptyEmotions(:) = [];
```

Define a BiLSTM network using `bilstmLayer`. Place a `dropoutLayer` before and after the `bilstmLayer` to help prevent overfitting.

```
dropoutProb1 = 0.3;
numUnits = 200;
dropoutProb2 = 0.6;
layers = [ ...
    sequenceInputLayer(size(sequencesTrain{1},1))
    dropoutLayer(dropoutProb1)
    bilstmLayer(numUnits,"OutputMode","last")
    dropoutLayer(dropoutProb2)
    fullyConnectedLayer(numel(categories(emptyEmotions)))
    softmaxLayer
    classificationLayer];
```

Define training options using `trainingOptions`.

```
miniBatchSize = 512;
initialLearnRate = 0.005;
learnRateDropPeriod = 2;
maxEpochs = 3;
options = trainingOptions("adam", ...
    "MiniBatchSize",miniBatchSize, ...
    "InitialLearnRate",initialLearnRate, ...
    "LearnRateDropPeriod",learnRateDropPeriod, ...
    "LearnRateSchedule","piecewise", ...
    "MaxEpochs",maxEpochs, ...
    "Shuffle","every-epoch", ...
    "Verbose",false, ...
    "Plots","Training-Progress");
```

Train the network using `trainNetwork`.

```
net = trainNetwork(sequencesTrain,labelsTrain,layers,options);
```

To save the network, configured `audioFeatureExtractor`, and normalization factors, set `saveSERSystem` to `true`.

```
saveSERSystem = false;
if saveSERSystem
    normalizers.Mean = M;
    normalizers.StandardDeviation = S;
    save('network_Audio_SER.mat','net','afe','normalizers')
end
```

Training for System Validation

To provide an accurate assessment of the model you created in this example, train and validate using leave-one-speaker-out (LOSO) k-fold cross validation. In this method, you train using $k - 1$ speakers and then validate on the left-out speaker. You repeat this procedure k times. The final validation accuracy is the average of the k folds.

Create a variable that contains the speaker IDs. Determine the number of folds: 1 for each speaker. The database contains utterances from 10 unique speakers. Use `summary` to display the speaker IDs (left column) and the number of utterances they contribute to the database (right column).

```
speaker = ads.Labels.Speaker;
numFolds = numel(speaker);
summary(speaker)
```

```
     03      49
     08      58
     09      43
     10      38
     11      55
     12      35
     13      61
     14      69
     15      56
     16      71
```

The helper function HelperTrainAndValidateNetwork on page 14-0 performs the steps outlined above for all 10 folds and returns the true and predicted labels for each fold. Call `HelperTrainAndValidateNetwork` with the `audioDatastore`, the augmented `audioDatastore`, and the `audioFeatureExtractor`.

```
[labelsTrue,labelsPred] = HelperTrainAndValidateNetwork(ads,adsAug,afe);
```

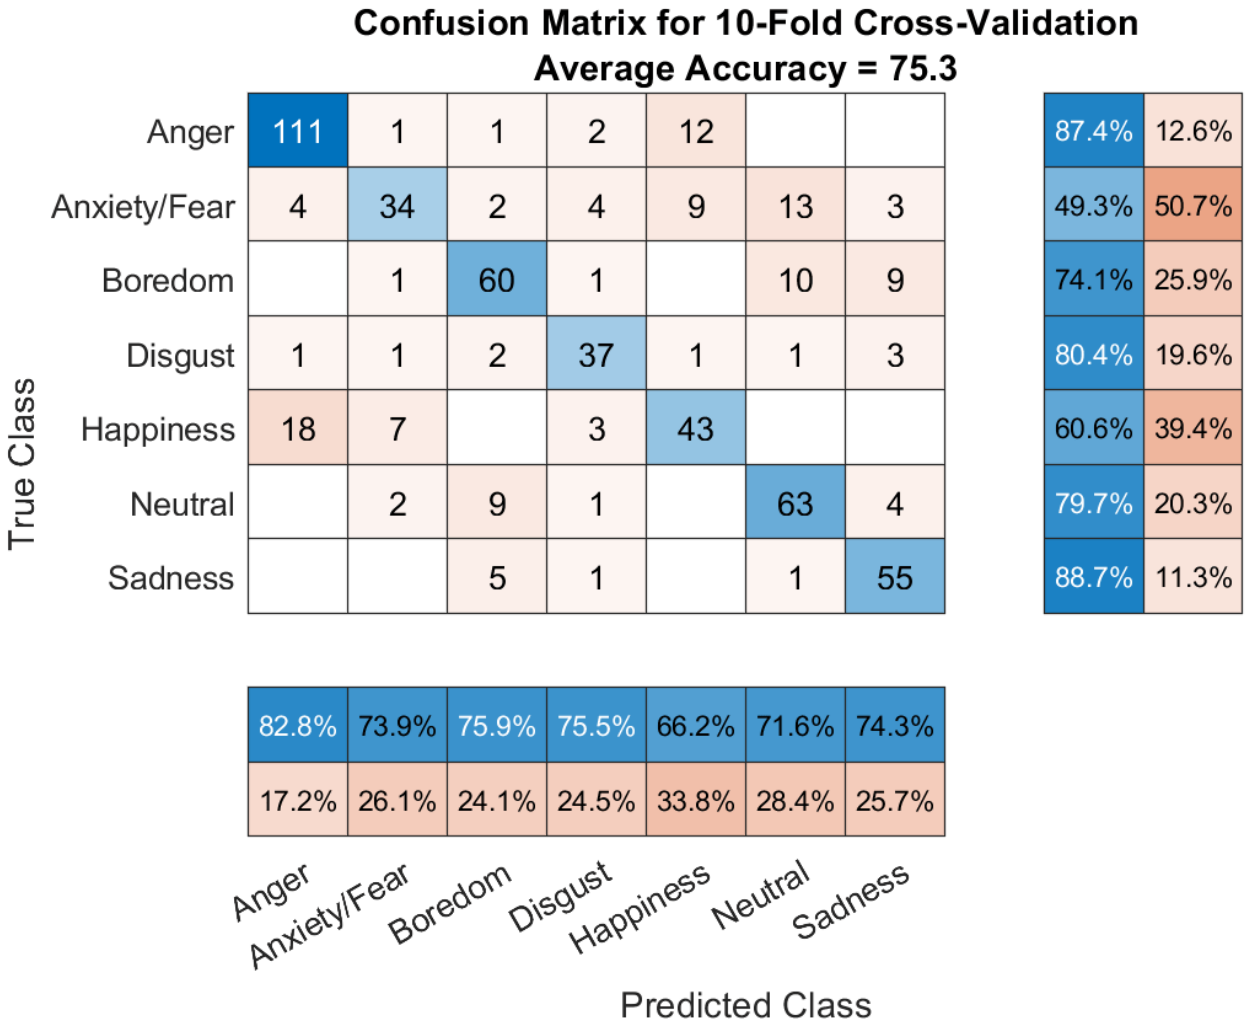
Print the accuracy per fold and plot the 10-fold confusion chart.

```
for ii = 1:numel(labelsTrue)
    foldAcc = mean(labelsTrue{ii}==labelsPred{ii})*100;
    fprintf('Fold %1.0f, Accuracy = %0.1f\n',ii,foldAcc);
end
```

```
Fold 1, Accuracy = 73.5
Fold 2, Accuracy = 77.6
Fold 3, Accuracy = 74.4
Fold 4, Accuracy = 68.4
Fold 5, Accuracy = 76.4
Fold 6, Accuracy = 80.0
Fold 7, Accuracy = 73.8
```

```
Fold 8, Accuracy = 87.0
Fold 9, Accuracy = 69.6
Fold 10, Accuracy = 70.4
```

```
labelsTrueMat = cat(1,labelsTrue{:});
labelsPredMat = cat(1,labelsPred{:});
figure
cm = confusionchart(labelsTrueMat,labelsPredMat);
valAccuracy = mean(labelsTrueMat==labelsPredMat)*100;
cm.Title = sprintf('Confusion Matrix for 10-Fold Cross-Validation\nAverage Accuracy = %0.1f',valA
sortClasses(cm,categories(emptyEmotions))
cm.ColumnSummary = 'column-normalized';
cm.RowSummary = 'row-normalized';
```



Supporting Functions

Convert Array of Feature Vectors to Sequences

```
function [sequences,sequencePerFile] = HelperFeatureVector2Sequence(features,featureVectorsPerSe
    % Copyright 2019 MathWorks, Inc.
```

```
    if featureVectorsPerSequence <= featureVectorOverlap
        error('The number of overlapping feature vectors must be less than the number of feature
    end

    if ~iscell(features)
        features = {features};
    end
    hopLength = featureVectorsPerSequence - featureVectorOverlap;
    idx1 = 1;
    sequences = {};
    sequencePerFile = cell(numel(features),1);
    for ii = 1:numel(features)
        sequencePerFile{ii} = floor((size(features{ii},2) - featureVectorsPerSequence)/hopLength)
        idx2 = 1;
        for j = 1:sequencePerFile{ii}
            sequences{idx1,1} = features{ii}(:,idx2:idx2 + featureVectorsPerSequence - 1); %#ok<A
            idx1 = idx1 + 1;
            idx2 = idx2 + hopLength;
        end
    end
end
```

Train and Validate Network

Spoken Digit Recognition with Wavelet Scattering and Deep Learning

This example shows how to classify spoken digits using both machine and deep learning techniques. In the example, you perform classification using wavelet time scattering with a support vector machine (SVM) and with a long short-term memory (LSTM) network. You also apply Bayesian optimization to determine suitable hyperparameters to improve the accuracy of the LSTM network. In addition, the example illustrates an approach using a deep convolutional neural network (CNN) and mel-frequency spectrograms.

Data

Clone or download the Free Spoken Digit Dataset (FSDD), available at https://github.com/Jakobovski/free-spoken-digit-dataset. FSDD is an open data set, which means that it can grow over time. This example uses the version committed on January 29, 2019, which consists of 2000 recordings in English of the digits 0 through 9 obtained from four speakers. In this version, two of the speakers are native speakers of American English, one speaker is a nonnative speaker of English with a Belgian French accent, and one speaker is a nonnative speaker of English with a German accent. The data is sampled at 8000 Hz.

Use `audioDatastore` to manage data access and ensure the random division of the recordings into training and test sets. Set the `location` property to the location of the FSDD recordings folder on your computer, for example:

```
pathToRecordingsFolder = fullfile(tempdir,'free-spoken-digit-dataset-master','recordings');
location = pathToRecordingsFolder;
```

Point `audioDatastore` to that location.

```
ads = audioDatastore(location);
```

The helper function `helpergenLabels` creates a categorical array of labels from the FSDD files. The source code for `helpergenLabels` is listed in the appendix. List the classes and the number of examples in each class.

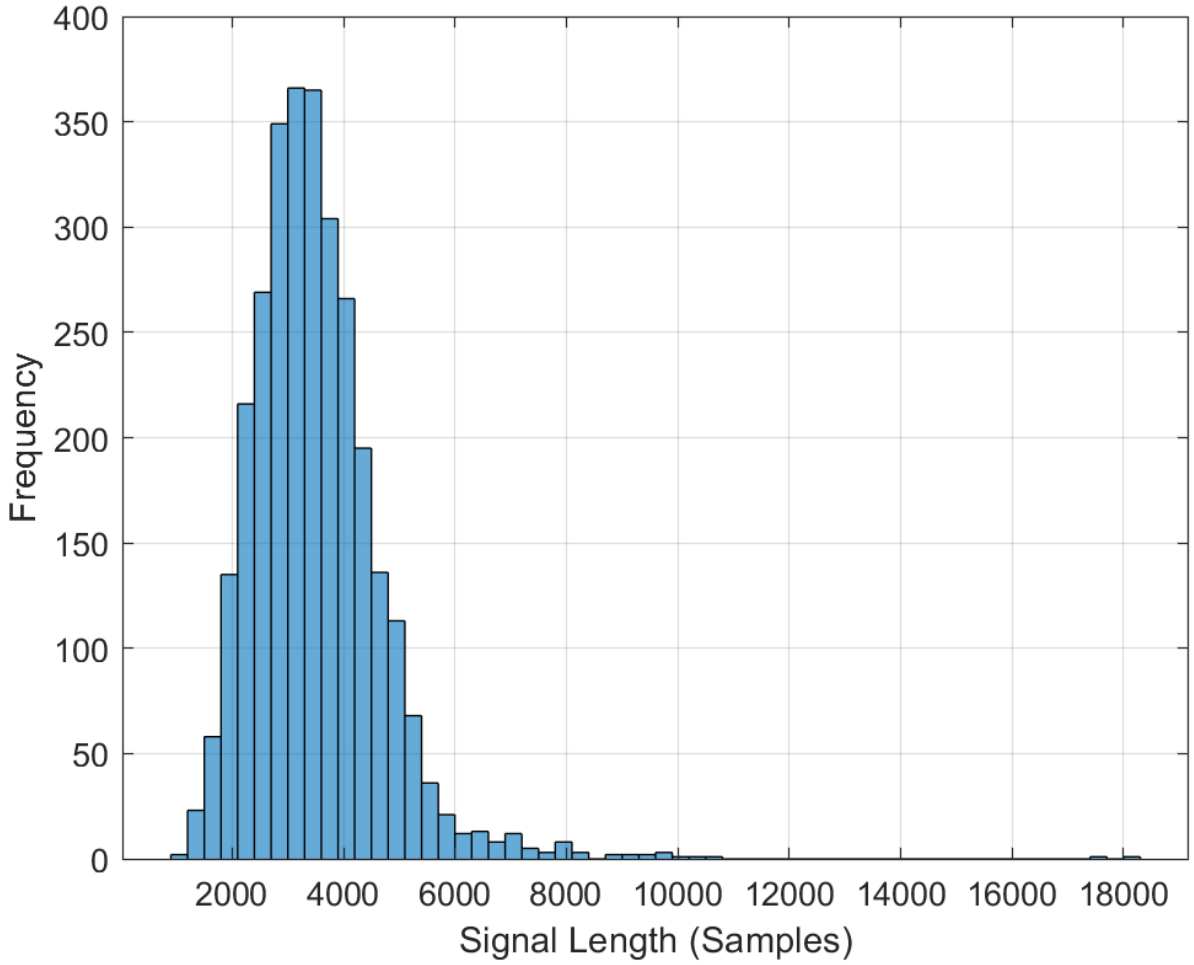
```
ads.Labels = helpergenLabels(ads);
summary(ads.Labels)
```

```
     0      300
     1      300
     2      300
     3      300
     4      300
     5      300
     6      300
     7      300
     8      300
     9      300
```

The FSDD data set consists of 10 balanced classes with 200 recordings each. The recordings in the FSDD are not of equal duration. The FSDD is not prohibitively large, so read through the FSDD files and construct a histogram of the signal lengths.

```
LenSig = zeros(numel(ads.Files),1);
nr = 1;
```

```
while hasdata(ads)
    digit = read(ads);
    LenSig(nr) = numel(digit);
    nr = nr+1;
end
reset(ads)
histogram(LenSig)
grid on
xlabel('Signal Length (Samples)')
ylabel('Frequency')
```



The histogram shows that the distribution of recording lengths is positively skewed. For classification, this example uses a common signal length of 8192 samples, a conservative value that ensures that truncating longer recordings does not cut off speech content. If the signal is greater than 8192 samples (1.024 seconds) in length, the recording is truncated to 8192 samples. If the signal is less than 8192 samples in length, the signal is prepadded and postpadded symmetrically with zeros out to a length of 8192 samples.

Wavelet Time Scattering

Use `waveletScattering` (Wavelet Toolbox) to create a wavelet time scattering framework using an invariant scale of 0.22 seconds. In this example, you create feature vectors by averaging the scattering transform over all time samples. To have a sufficient number of scattering coefficients per time window to average, set `OversamplingFactor` to 2 to produce a four-fold increase in the number of scattering coefficients for each path with respect to the critically downsampled value.

```
sf = waveletScattering('SignalLength',8192,'InvarianceScale',0.22,...
    'SamplingFrequency',8000,'OversamplingFactor',2);
```

Split the FSDD into training and test sets. Allocate 80% of the data to the training set and retain 20% for the test set. The training data is for training the classifier based on the scattering transform. The test data is for validating the model.

```
rng default;
ads = shuffle(ads);
[adsTrain,adsTest] = splitEachLabel(ads,0.8);
countEachLabel(adsTrain)
```

```
ans=10×2 table
    Label    Count
    _____    _____

      0       240
      1       240
      2       240
      3       240
      4       240
      5       240
      6       240
      7       240
      8       240
      9       240
```

```
countEachLabel(adsTest)
```

```
ans=10×2 table
    Label    Count
    _____    _____

      0       60
      1       60
      2       60
      3       60
      4       60
      5       60
      6       60
      7       60
      8       60
      9       60
```

The helper function `helperReadSPData` truncates or pads the data to a length of 8192 and normalizes each recording by its maximum value. The source code for `helperReadSPData` is listed in the appendix. Create an 8192-by-1600 matrix where each column is a spoken-digit recording.

```
Xtrain = [];
scatds_Train = transform(adsTrain,@(x)helperReadSPData(x));
while hasdata(scatds_Train)
    smat = read(scatds_Train);
    Xtrain = cat(2,Xtrain,smat);

end
```

Repeat the process for the test set. The resulting matrix is 8192-by-400.

```
Xtest = [];
scatds_Test = transform(adsTest,@(x)helperReadSPData(x));
while hasdata(scatds_Test)
    smat = read(scatds_Test);
    Xtest = cat(2,Xtest,smat);

end
```

Apply the wavelet scattering transform to the training and test sets.

```
Strain = sf.featureMatrix(Xtrain);
Stest = sf.featureMatrix(Xtest);
```

Obtain the mean scattering features for the training and test sets. Exclude the zeroth-order scattering coefficients.

```
TrainFeatures = Strain(2:end,:,:);
TrainFeatures = squeeze(mean(TrainFeatures,2))';
TestFeatures = Stest(2:end,:,:);
TestFeatures = squeeze(mean(TestFeatures,2))';
```

SVM Classifier

Now that the data has been reduced to a feature vector for each recording, the next step is to use these features for classifying the recordings. Create an SVM learner template with a quadratic polynomial kernel. Fit the SVM to the training data.

```
template = templateSVM(...
    'KernelFunction', 'polynomial', ...
    'PolynomialOrder', 2, ...
    'KernelScale', 'auto', ...
    'BoxConstraint', 1, ...
    'Standardize', true);
classificationSVM = fitcecoc(...
    TrainFeatures, ...
    adsTrain.Labels, ...
    'Learners', template, ...
    'Coding', 'onevsone', ...
    'ClassNames', categorical({'0'; '1'; '2'; '3'; '4'; '5'; '6'; '7'; '8'; '9'}));
```

Use k-fold cross-validation to predict the generalization accuracy of the model based on the training data. Split the training set into five groups.

```
partitionedModel = crossval(classificationSVM, 'KFold', 5);
[validationPredictions, validationScores] = kfoldPredict(partitionedModel);
validationAccuracy = (1 - kfoldLoss(partitionedModel, 'LossFun', 'ClassifError'))*100
```

```
validationAccuracy = 97.4167
```

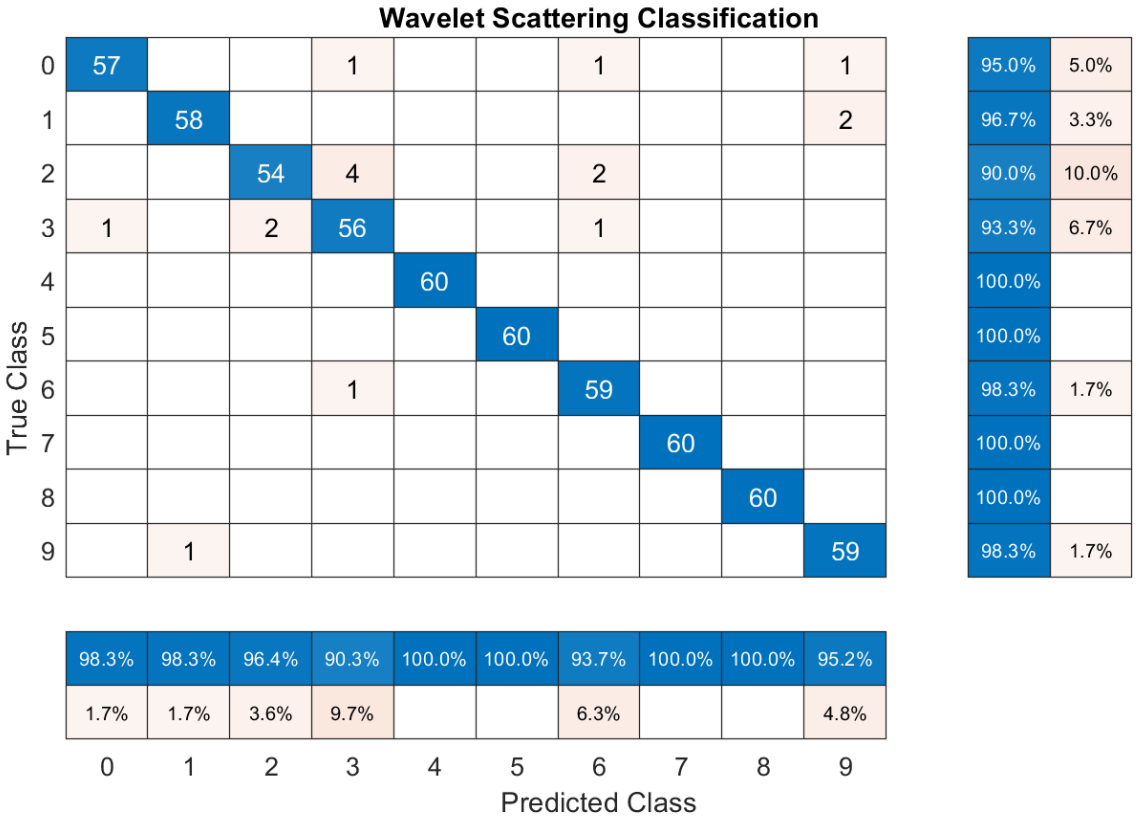
The estimated generalization accuracy is approximately 97%. Use the trained SVM to predict the spoken-digit classes in the test set.

```
predLabels = predict(classificationSVM,TestFeatures);
testAccuracy = sum(predLabels==adsTest.Labels)/numel(predLabels)*100
```

```
testAccuracy = 97.1667
```

Summarize the performance of the model on the test set with a confusion chart. Display the precision and recall for each class by using column and row summaries. The table at the bottom of the confusion chart shows the precision values for each class. The table to the right of the confusion chart shows the recall values.

```
figure('Units','normalized','Position',[0.2 0.2 0.5 0.5]);
ccscat = confusionchart(adsTest.Labels,predLabels);
ccscat.Title = 'Wavelet Scattering Classification';
ccscat.ColumnSummary = 'column-normalized';
ccscat.RowSummary = 'row-normalized';
```



The scattering transform coupled with a SVM classifier classifies the spoken digits in the test set with an accuracy of 98% (or an error rate of 2%).

Long Short-Term Memory (LSTM) Networks

An LSTM network is a type of recurrent neural network (RNN). RNNs are neural networks that are specialized for working with sequential or temporal data such as speech data. Because the wavelet

scattering coefficients are sequences, they can be used as inputs to an LSTM. By using scattering features as opposed to the raw data, you can reduce the variability that your network needs to learn.

Modify the training and testing scattering features to be used with the LSTM network. Exclude the zeroth-order scattering coefficients and convert the features to cell arrays.

```
TrainFeatures = Strain(2:end,:,:);
TrainFeatures = squeeze(num2cell(TrainFeatures,[1 2]));
TestFeatures = Stest(2:end,:,:);
TestFeatures = squeeze(num2cell(TestFeatures, [1 2]));
```

Construct a simple LSTM network with 512 hidden layers.

```
[inputSize, ~] = size(TrainFeatures{1});
YTrain = adsTrain.Labels;

numHiddenUnits = 512;
numClasses = numel(unique(YTrain));

layers = [ ...
    sequenceInputLayer(inputSize)
    lstmLayer(numHiddenUnits,'OutputMode','last')
    fullyConnectedLayer(numClasses)
    softmaxLayer
    classificationLayer];
```

Set the hyperparameters. Use Adam optimization and a mini-batch size of 50. Set the maximum number of epochs to 300. Use a learning rate of 1e-4. You can turn off the training progress plot if you do not want to track the progress using plots. The training uses a GPU by default if one is available. Otherwise, it uses a CPU. For more information, see `trainingOptions`.

```
maxEpochs = 300;
miniBatchSize = 50;

options = trainingOptions('adam', ...
    'InitialLearnRate',0.0001,...
    'MaxEpochs',maxEpochs, ...
    'MiniBatchSize',miniBatchSize, ...
    'SequenceLength','shortest', ...
    'Shuffle','every-epoch',...
    'Verbose', false, ...
    'Plots','training-progress');
```

Train the network.

```
net = trainNetwork(TrainFeatures,YTrain,layers,options);

predLabels = classify(net,TestFeatures);
testAccuracy = sum(predLabels==adsTest.Labels)/numel(predLabels)*100
```

```
testAccuracy = 96.3333
```

Bayesian Optimization

Determining suitable hyperparameter settings is often one of the most difficult parts of training a deep network. To mitigate this, you can use Bayesian optimization. In this example, you optimize the number of hidden layers and the initial learning rate by using Bayesian techniques. Create a new

directory to store the MAT-files containing information about hyperparameter settings and the network along with the corresponding error rates.

```
YTrain = adsTrain.Labels;
YTest = adsTest.Labels;

if ~exist("results/",'dir')
    mkdir results
end
```

Initialize the variables to be optimized and their value ranges. Because the number of hidden layers must be an integer, set `'type'` to `'integer'`.

```
optVars = [
    optimizableVariable('InitialLearnRate',[1e-5, 1e-1],'Transform','log')
    optimizableVariable('NumHiddenUnits',[10, 1000],'Type','integer')
    ];
```

Bayesian optimization is computationally intensive and can take several hours to finish. For the purposes of this example, set `optimizeCondition` to `false` to download and use predetermined optimized hyperparameter settings. If you set `optimizeCondition` to `true`, the objective function `helperBayesOptLSTM` is minimized using Bayesian optimization. The objective function, listed in the appendix, is the error rate of the network given specific hyperparameter settings. The loaded settings are for the objective function minimum of 0.02 (2% error rate).

```
ObjFcn = helperBayesOptLSTM(TrainFeatures,YTrain,TestFeatures,YTest);

optimizeCondition = false;
if optimizeCondition
    BayesObject = bayesopt(ObjFcn,optVars,...
            'MaxObjectiveEvaluations',15,...
            'IsObjectiveDeterministic',false,...
            'UseParallel',true);
else
    url = 'http://ssd.mathworks.com/supportfiles/audio/SpokenDigitRecognition.zip';
    downloadNetFolder = tempdir;
    netFolder = fullfile(downloadNetFolder,'SpokenDigitRecognition');
    if ~exist(netFolder,'dir')
        disp('Downloading pretrained network (1 file - 12 MB) ...')
        unzip(url,downloadNetFolder)
    end
    load(fullfile(netFolder,'0.02.mat'));
end
```

```
Downloading pretrained network (1 file - 12 MB) ...
```

If you perform Bayesian optimization, figures similar to the following are generated to track the objective function values with the corresponding hyperparameter values and the number of iterations. You can increase the number of Bayesian optimization iterations to ensure that the global minimum of the objective function is reached.

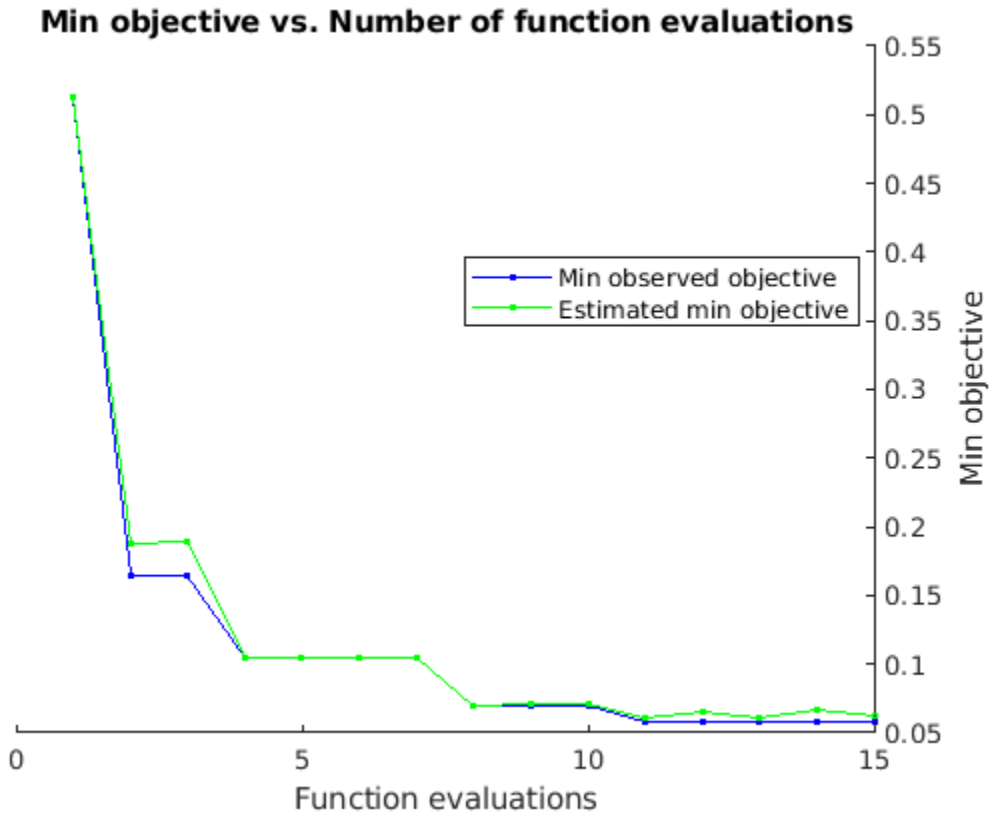
InitialLearnRate



Use the optimized values for the number of hidden units and initial learning rate and retrain the network.

```
numHiddenUnits = 768;
numClasses = numel(unique(YTrain));

layers = [ ...
    sequenceInputLayer(inputSize)
    lstmLayer(numHiddenUnits,'OutputMode','last')
    fullyConnectedLayer(numClasses)
    softmaxLayer
    classificationLayer];

maxEpochs = 300;
miniBatchSize = 50;

options = trainingOptions('adam', ...
    'InitialLearnRate',2.198827960269379e-04,...
    'MaxEpochs',maxEpochs, ...
    'MiniBatchSize',miniBatchSize, ...
    'SequenceLength','shortest', ...
    'Shuffle','every-epoch',...
    'Verbose', false, ...
    'Plots','training-progress');

net = trainNetwork(TrainFeatures,YTrain,layers,options);
```

```
predLabels = classify(net,TestFeatures);
testAccuracy = sum(predLabels==adsTest.Labels)/numel(predLabels)*100

testAccuracy = 97.5000
```

As the plot shows, using Bayesian optimization yields an LSTM with a higher accuracy.

Deep Convolutional Network Using Mel-Frequency Spectrograms

As another approach to the task of spoken digit recognition, use a deep convolutional neural network (DCNN) based on mel-frequency spectrograms to classify the FSDD data set. Use the same signal truncation/padding procedure as in the scattering transform. Similarly, normalize each recording by dividing each signal sample by the maximum absolute value. For consistency, use the same training and test sets as for the scattering transform.

Set the parameters for the mel-frequency spectrograms. Use the same window, or frame, duration as in the scattering transform, 0.22 seconds. Set the hop between windows to 10 ms. Use 40 frequency bands.

```
segmentDuration = 8192*(1/8000);
frameDuration = 0.22;
hopDuration = 0.01;
numBands = 40;
```

Reset the training and test datastores.

```
reset(adsTrain);
reset(adsTest);
```

The helper function `helperspeechSpectrograms`, defined at the end of this example, uses `melSpectrogram` to obtain the mel-frequency spectrogram after standardizing the recording length and normalizing the amplitude. Use the logarithm of the mel-frequency spectrograms as the inputs to the DCNN. To avoid taking the logarithm of zero, add a small epsilon to each element.

```
epsil = 1e-6;
XTrain = helperspeechSpectrograms(adsTrain,segmentDuration,frameDuration,hopDuration,numBands);

Computing speech spectrograms...
Processed 500 files out of 2400
Processed 1000 files out of 2400
Processed 1500 files out of 2400
Processed 2000 files out of 2400
...done

XTrain = log10(XTrain + epsil);

XTest = helperspeechSpectrograms(adsTest,segmentDuration,frameDuration,hopDuration,numBands);

Computing speech spectrograms...
Processed 500 files out of 600
...done

XTest = log10(XTest + epsil);

YTrain = adsTrain.Labels;
YTest = adsTest.Labels;
```

Define DCNN Architecture

Construct a small DCNN as an array of layers. Use convolutional and batch normalization layers, and downsample the feature maps using max pooling layers. To reduce the possibility of the network memorizing specific features of the training data, add a small amount of dropout to the input to the last fully connected layer.

```
sz = size(XTrain);
specSize = sz(1:2);
imageSize = [specSize 1];

numClasses = numel(categories(YTrain));

dropoutProb = 0.2;
numF = 12;
layers = [
    imageInputLayer(imageSize)

    convolution2dLayer(5,numF,'Padding','same')
    batchNormalizationLayer
    reluLayer

    maxPooling2dLayer(3,'Stride',2,'Padding','same')

    convolution2dLayer(3,2*numF,'Padding','same')
    batchNormalizationLayer
    reluLayer

    maxPooling2dLayer(3,'Stride',2,'Padding','same')

    convolution2dLayer(3,4*numF,'Padding','same')
    batchNormalizationLayer
    reluLayer

    maxPooling2dLayer(3,'Stride',2,'Padding','same')

    convolution2dLayer(3,4*numF,'Padding','same')
    batchNormalizationLayer
    reluLayer
    convolution2dLayer(3,4*numF,'Padding','same')
    batchNormalizationLayer
    reluLayer

    maxPooling2dLayer(2)

    dropoutLayer(dropoutProb)
    fullyConnectedLayer(numClasses)
    softmaxLayer
    classificationLayer('Classes',categories(YTrain));
    ];
```

Set the hyperparameters to use in training the network. Use a mini-batch size of 50 and a learning rate of 1e-4. Specify Adam optimization. Because the amount of data in this example is relatively small, set the execution environment to `'cpu'` for reproducibility. You can also train the network on an available GPU by setting the execution environment to either `'gpu'` or `'auto'`. For more information, see `trainingOptions`.

```
miniBatchSize = 50;
options = trainingOptions('adam', ...
    'InitialLearnRate',1e-4, ...
    'MaxEpochs',30, ...
    'MiniBatchSize',miniBatchSize, ...
    'Shuffle','every-epoch', ...
    'Plots','training-progress', ...
    'Verbose',false, ...
    'ExecutionEnvironment','cpu');
```

Train the network.

```
trainedNet = trainNetwork(XTrain,YTrain,layers,options);
```

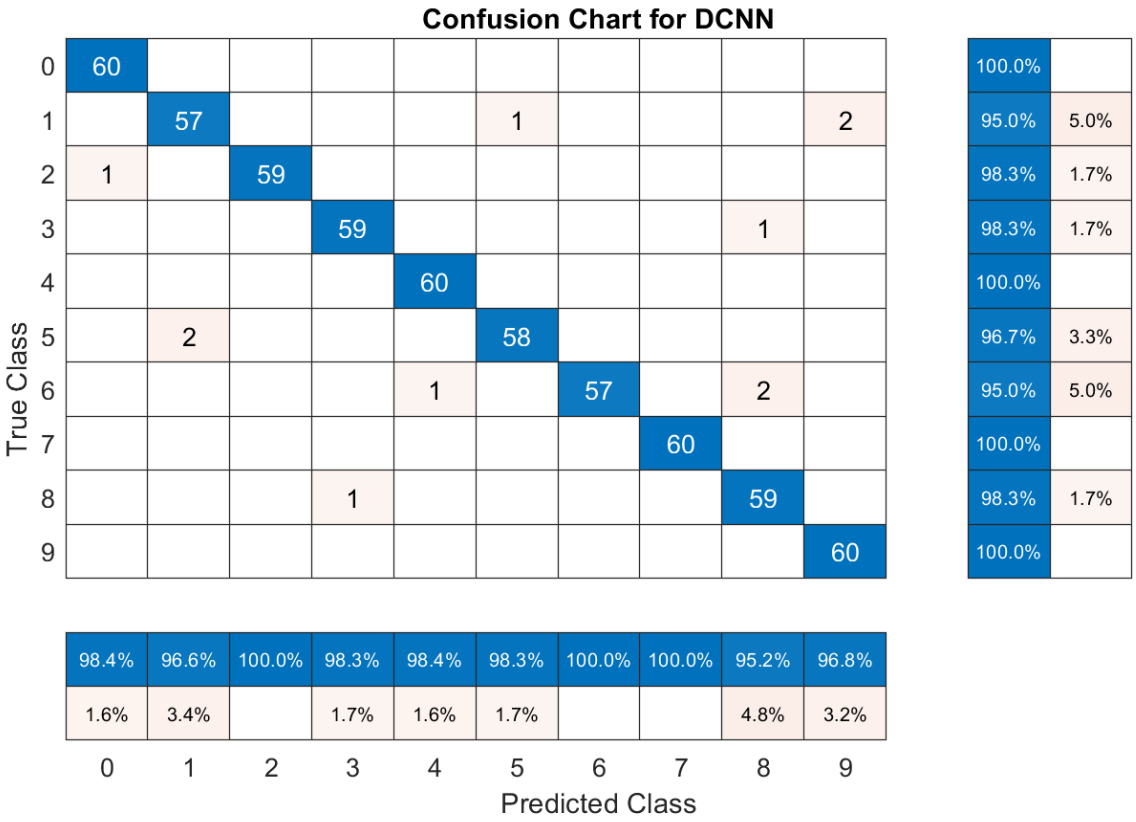
Use the trained network to predict the digit labels for the test set.

```
[Ypredicted,probs] = classify(trainedNet,XTest,'ExecutionEnvironment','CPU');
cnnAccuracy = sum(Ypredicted==YTest)/numel(YTest)*100
```

```
cnnAccuracy = 98.1667
```

Summarize the performance of the trained network on the test set with a confusion chart. Display the precision and recall for each class by using column and row summaries. The table at the bottom of the confusion chart shows the precision values. The table to the right of the confusion chart shows the recall values.

```
figure('Units','normalized','Position',[0.2 0.2 0.5 0.5]);
ccDCNN = confusionchart(YTest,Ypredicted);
ccDCNN.Title = 'Confusion Chart for DCNN';
ccDCNN.ColumnSummary = 'column-normalized';
ccDCNN.RowSummary = 'row-normalized';
```



The DCNN using mel-frequency spectrograms as inputs classifies the spoken digits in the test set with an accuracy rate of approximately 98% as well.

Summary

This example shows how to use different machine and deep learning approaches for classifying spoken digits in the FSDD. The example illustrated wavelet scattering paired with both an SVM and a LSTM. Bayesian techniques were used to optimize LSTM hyperparameters. Finally, the example shows how to use a CNN with mel-frequency spectrograms.

The goal of the example is to demonstrate how to use MathWorks® tools to approach the problem in fundamentally different but complementary ways. All workflows use `audioDatastore` to manage flow of data from disk and ensure proper randomization.

All approaches used in this example performed equally well on the test set. This example is not intended as a direct comparison between the various approaches. For example, you can also use Bayesian optimization for hyperparameter selection in the CNN. An additional strategy that is useful in deep learning with small training sets like this version of the FSDD is to use data augmentation. How manipulations affect class is not always known, so data augmentation is not always feasible. However, for speech, established data augmentation strategies are available through `audioDataAugmenter`.

In the case of wavelet time scattering, there are also a number of modifications you can try. For example, you can change the invariant scale of the transform, vary the number of wavelet filters per filter bank, and try different classifiers.

Appendix: Helper Functions

```

Cocktail Party Source Separation Using Deep Learning Networks

This example shows how to isolate a speech signal using a deep learning network.

Introduction

The cocktail party effect refers to the ability of the brain to focus on a single speaker while filtering out other voices and background noise. Humans perform very well at the cocktail party problem. This example shows how to use a deep learning network to separate individual speakers from a speech mix where one male and one female are speaking simultaneously.

Download Required Files

Before going into the example in detail, you will download a pre-trained network and 4 audio files.

```
url = 'http://ssd.mathworks.com/supportfiles/audio/CocktailPartySourceSeparation.zip';

downloadNetFolder = tempdir;
netFolder = fullfile(downloadNetFolder,'CocktailPartySourceSeparation');

if ~exist(netFolder,'dir')
    disp('Downloading pretrained network and audio files (5 files - 24.5 MB) ...')
    unzip(url,downloadNetFolder)
end
```

Problem Summary

Load audio files containing male and female speech sampled at 4 kHz. Listen to the audio files individually for reference.

```
[mSpeech,Fs] = audioread(fullfile(netFolder,"MaleSpeech-16-4-mono-20secs.wav"));
sound(mSpeech,Fs)

[fSpeech] = audioread(fullfile(netFolder,"FemaleSpeech-16-4-mono-20secs.wav"));
sound(fSpeech,Fs)
```

Combine the two speech sources. Ensure the sources have equal power in the mix. Normalize the mix so that its max amplitude is one.

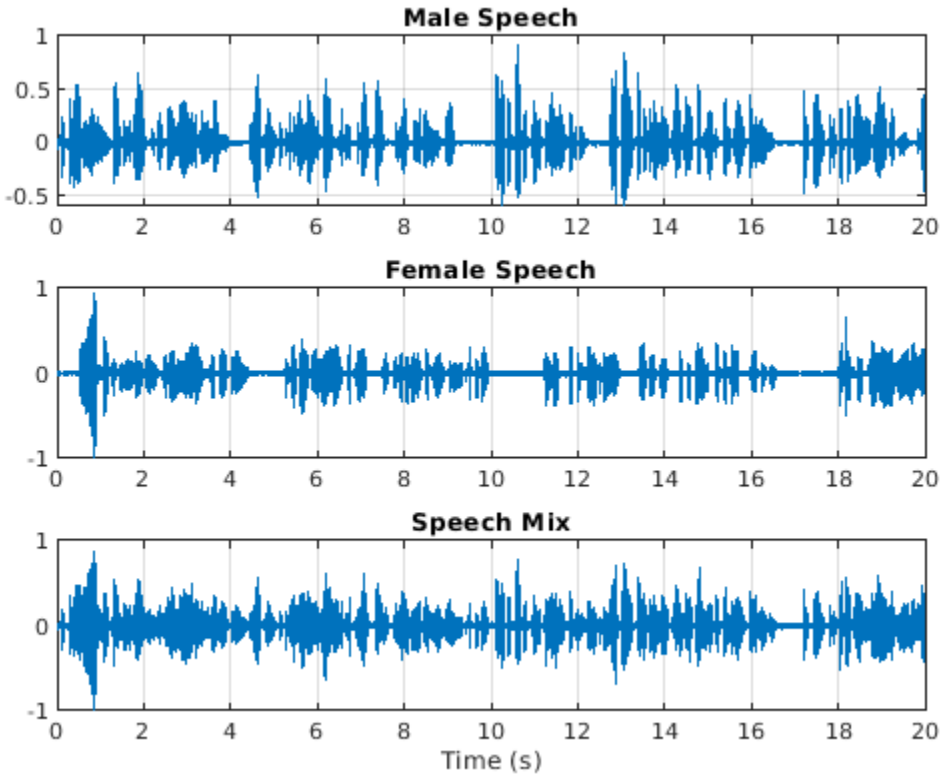
```
mSpeech = mSpeech/norm(mSpeech);
fSpeech = fSpeech/norm(fSpeech);
ampAdj  = max(abs([mSpeech;fSpeech]));
mSpeech = mSpeech/ampAdj;
fSpeech = fSpeech/ampAdj;
mix     = mSpeech + fSpeech;
mix     = mix ./ max(abs(mix));
```

Visualize the original and mix signals. Listen to the mixed speech signal. This example shows a source separation scheme that extracts the male and female sources from the speech mix.

```
t = (0:numel(mix)-1)*(1/Fs);

figure(1)
subplot(3,1,1)
plot(t,mSpeech)
title("Male Speech")
```

```
grid on
subplot(3,1,2)
plot(t,fSpeech)
title("Female Speech")
grid on
subplot(3,1,3)
plot(t,mix)
title("Speech Mix")
xlabel("Time (s)")
grid on
```



Listen to the mix audio.

```
sound(mix,Fs)
```

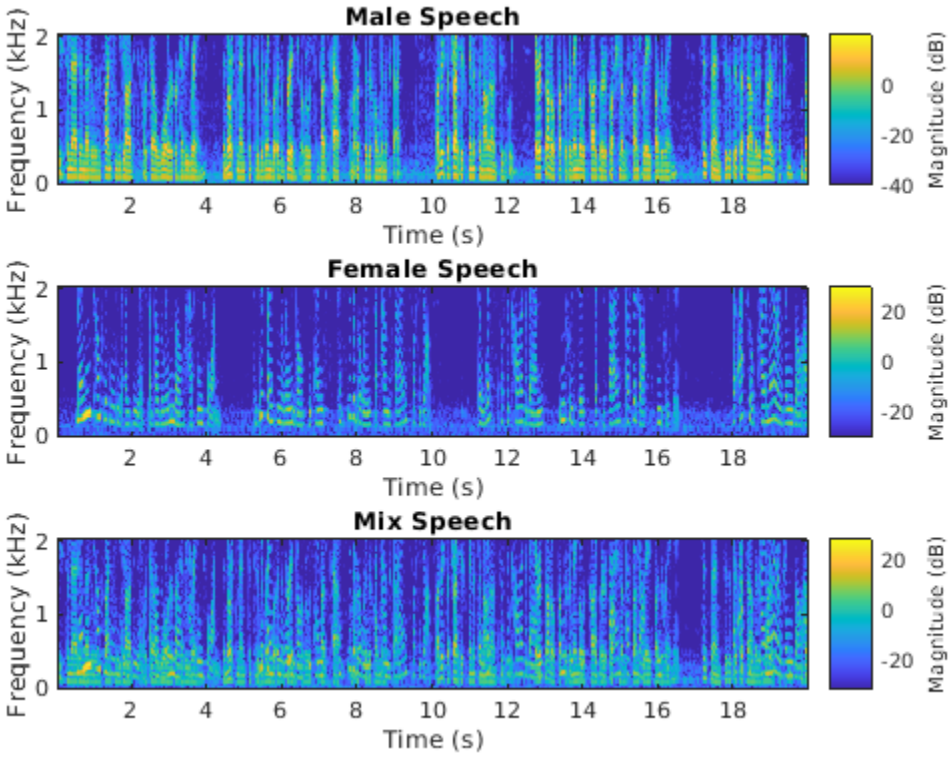
Time-Frequency Representation

Use `stft` to visualize the time-frequency (TF) representation of the male, female, and mix speech signals. Use a Hann window of length 128, an FFT length of 128, and an overlap length of 96.

```
WindowLength  = 128;
FFTLength     = 128;
OverlapLength = 96;
win           = hann(WindowLength,"periodic");

figure(2)
subplot(3,1,1)
stft(mSpeech, Fs, 'Window', win,'OverlapLength',OverlapLength,...
```

```
     'FFTLength', FFTLength, 'FrequencyRange', 'onesided');
title("Male Speech")
subplot(3,1,2)
stft(fSpeech, Fs, 'Window', win, 'OverlapLength', OverlapLength,...
     'FFTLength', FFTLength, 'FrequencyRange', 'onesided');
title("Female Speech")
subplot(3,1,3)
stft(mix, Fs, 'Window', win, 'OverlapLength', OverlapLength,...
    'FFTLength', FFTLength, 'FrequencyRange', 'onesided');
title("Mix Speech")
```



Source Separation Using Ideal Time-Frequency Masks

The application of a TF mask has been shown to be an effective method for separating desired audio signals from competing sounds. A TF mask is a matrix of the same size as the underlying STFT. The mask is multiplied element-by-element with the underlying STFT to isolate the desired source. The TF mask can be binary or soft.

Source Separation Using Ideal Binary Masks

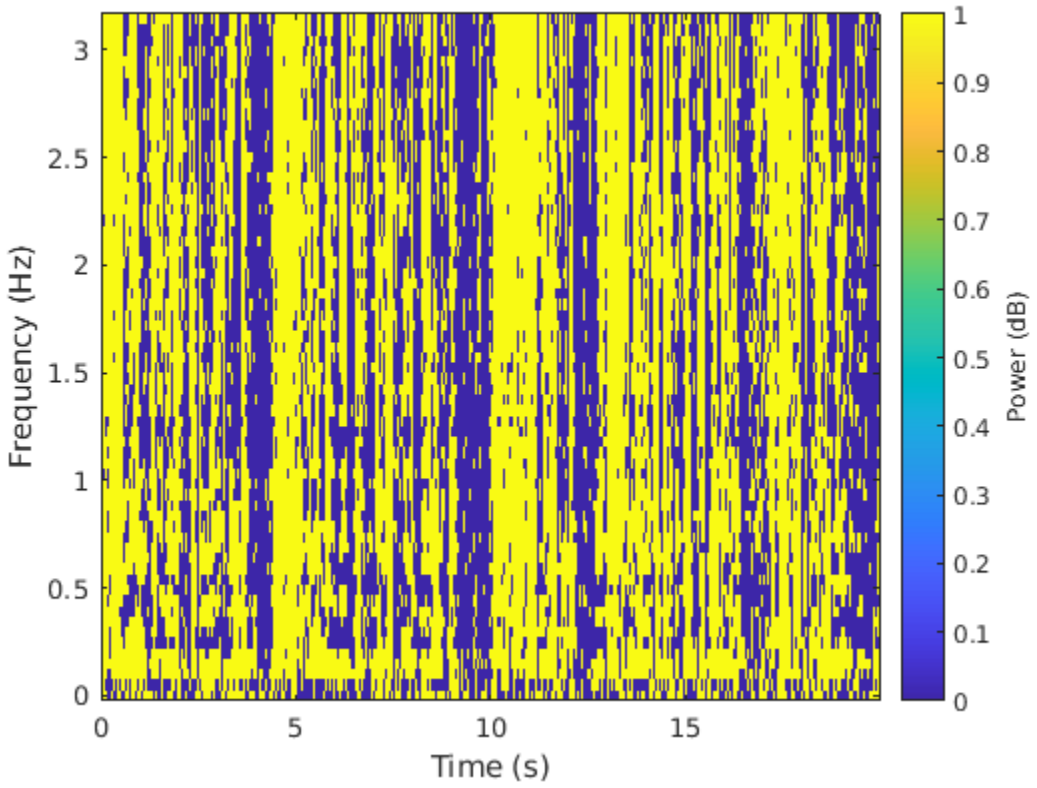
In an ideal binary mask, the mask cell values are either 0 or 1. If the power of the desired source is greater than the combined power of other sources at a particular TF cell, then that cell is set to 1. Otherwise, the cell is set to 0.

Compute the ideal binary mask for the male speaker and then visualize it.

```
P_M        = stft(mSpeech, 'Window', win, 'OverlapLength', OverlapLength,...
                  'FFTLength', FFTLength, 'FrequencyRange', 'onesided');
```

```
P_F        = stft(fSpeech, 'Window', win, 'OverlapLength', OverlapLength,...
                  'FFTLength', FFTLength, 'FrequencyRange', 'onesided');
[P_mix,F]  = stft(mix, 'Window', win, 'OverlapLength', OverlapLength,...
                   'FFTLength', FFTLength, 'FrequencyRange', 'onesided');
binaryMask = abs(P_M) >= abs(P_F);

figure(3)
plotMask(binaryMask, WindowLength - OverlapLength, F, Fs)
```



Estimate the male speech STFT by multiplying the mix STFT by the male speaker's binary mask. Estimate the female speech STFT by multiplying the mix STFT by the inverse of the male speaker's binary mask.

```
P_M_Hard = P_mix .* binaryMask;
P_F_Hard = P_mix .* (1-binaryMask);
```

Estimate the male and female audio signals using the inverse short-time FFT (ISTFT). Visualize the estimated and original signals. Listen to the estimated male and female speech signals.

```
mSpeech_Hard = istft(P_M_Hard , 'Window', win, 'OverlapLength', OverlapLength,...
                     'FFTLength', FFTLength, 'FrequencyRange', 'onesided');
fSpeech_Hard = istft(P_F_Hard , 'Window', win, 'OverlapLength', OverlapLength,...
                     'FFTLength', FFTLength, 'FrequencyRange', 'onesided');
figure(4)
subplot(2,2,1)
plot(t,mSpeech)
axis([t(1) t(end) -1 1])
title("Original Male Speech")
```

```

xlabel("Time (s)")
grid on
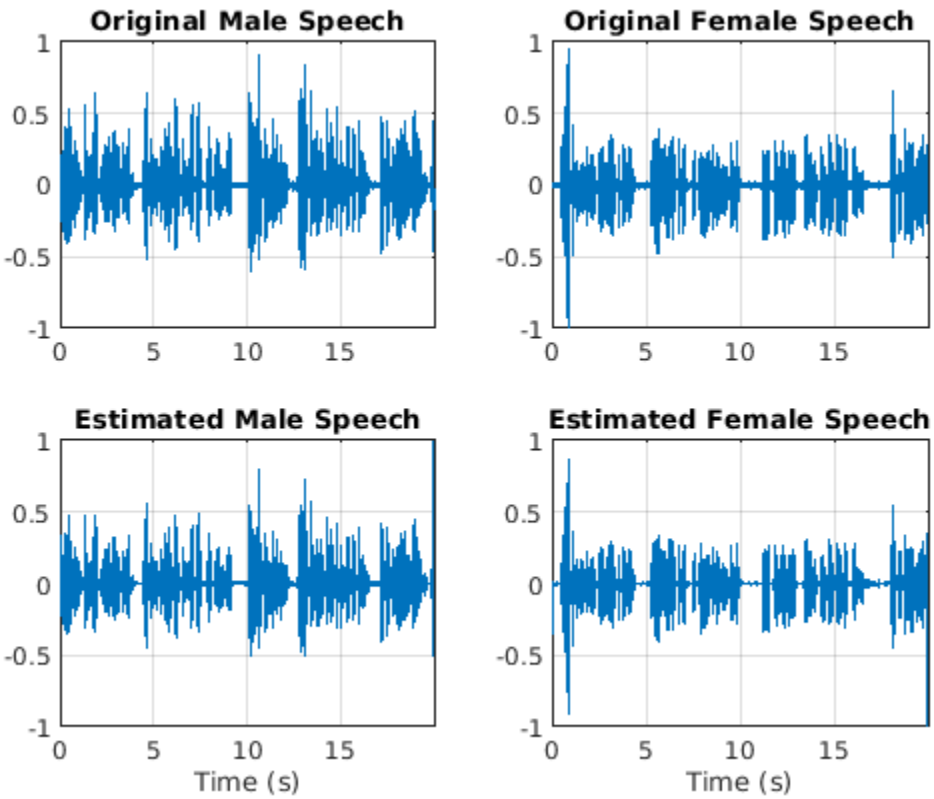
```



```
sound(mSpeech_Hard,Fs)

sound(fSpeech_Hard,Fs)
```

Source Separation Using Ideal Soft Masks

In a soft mask, the TF mask cell value is equal to the ratio of the desired source power to the total mix power. TF cells have values in the range [0,1].

Compute the soft mask for the male speaker. Estimate the STFT of the male speaker by multiplying the mix STFT by the male speaker's soft mask. Estimate the STFT of the female speaker by multiplying the mix STFT by the female speaker's soft mask.

Estimate the male and female audio signals using the ISTFT.

```
softMask = abs(P_M) ./ (abs(P_F) + abs(P_M) + eps);

P_M_Soft = P_mix .* softMask;
P_F_Soft = P_mix .* (1-softMask);

mSpeech_Soft = istft(P_M_Soft, 'Window', win, 'OverlapLength', OverlapLength,...
                     'FFTLength', FFTLength, 'FrequencyRange', 'onesided');
fSpeech_Soft = istft(P_F_Soft, 'Window', win, 'OverlapLength', OverlapLength,...
                     'FFTLength', FFTLength, 'FrequencyRange', 'onesided');
```

Visualize the estimated and original signals. Listen to the estimated male and female speech signals. Note that the results are very good because the mask is created with full knowledge of the separated male and female signals.

```
figure(5)
subplot(2,2,1)
plot(t,mSpeech)
axis([t(1) t(end) -1 1])
title("Original Male Speech")
grid on

xlabel("Time (s)")
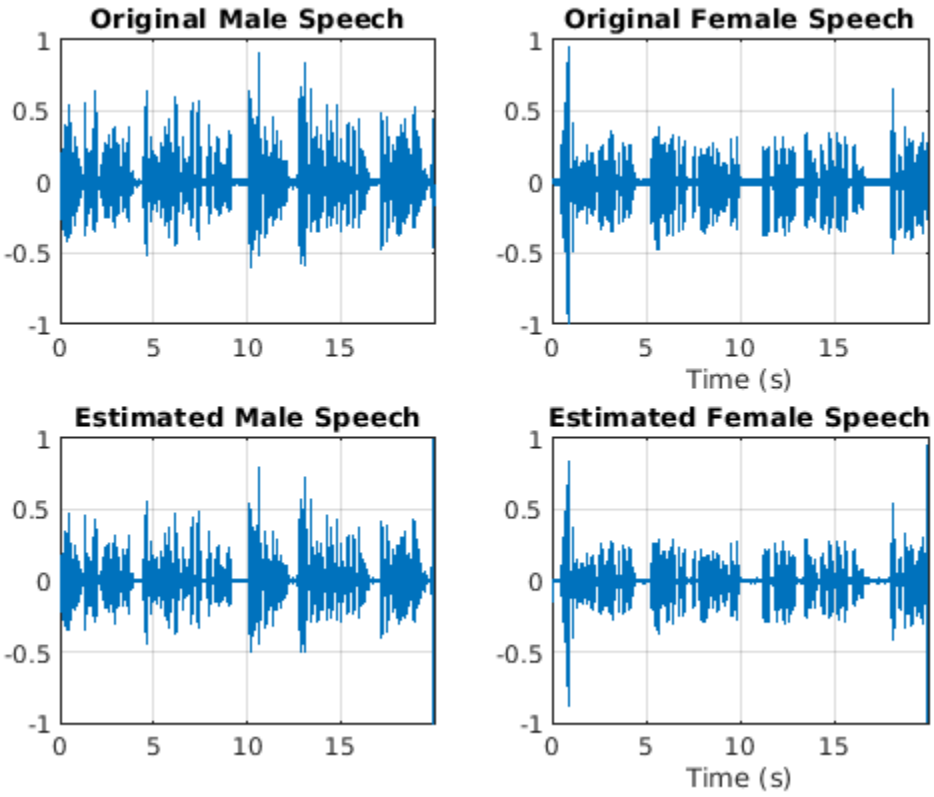
title("Estimated Female Speech")
grid on
```



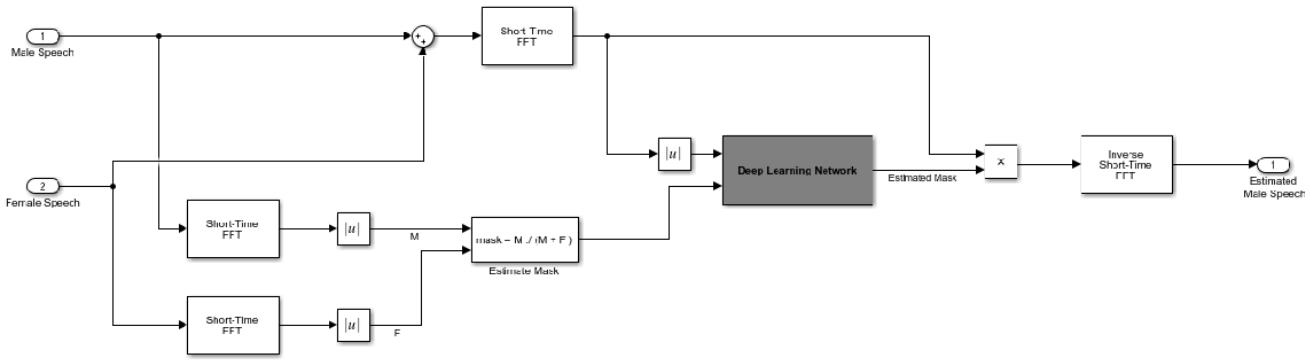
```
sound(mSpeech_Soft,Fs)
```

```
sound(fSpeech_Soft,Fs)
```

Mask Estimation Using Deep Learning

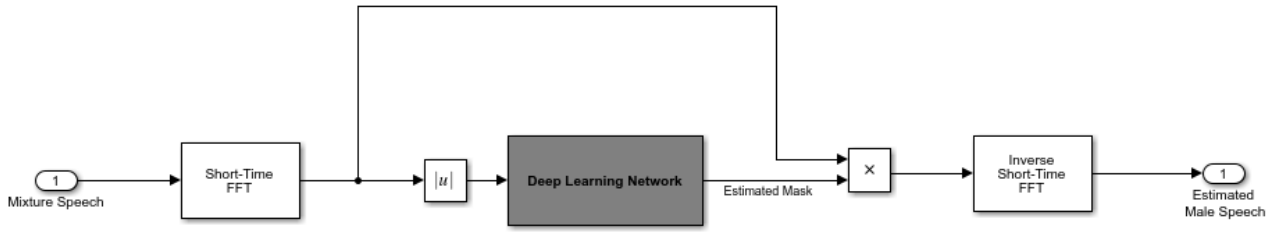
The goal of the deep learning network in this example is to estimate the ideal soft mask described above. The network estimates the mask corresponding to the male speaker. The female speaker mask is derived directly from the male mask.

The basic deep learning training scheme is shown below. The predictor is the magnitude spectra of the mixed (male + female) audio. The target is the ideal soft masks corresponding to the male speaker. The regression network uses the predictor input to minimize the mean square error between its output and the input target. At the output, the audio STFT is converted back to the time domain using the output magnitude spectrum and the phase of the mix signal.



You transform the audio to the frequency domain using the Short-Time Fourier transform (STFT), with a window length of 128 samples, an overlap of 127, and a Hann window. You reduce the size of the spectral vector to 65 by dropping the frequency samples corresponding to negative frequencies (because the time-domain speech signal is real, this does not lead to any information loss). The predictor input consists of 20 consecutive STFT vectors. The output is a 65-by-20 soft mask.

You use the trained network to estimate the male speech. The input to the trained network is the mixture (male + female) speech audio.



STFT Targets and Predictors

This section illustrates how to generate the target and predictor signals from the training dataset.

Read in training signals consisting of around 400 seconds of speech from male and female speakers, respectively, sampled at 4 kHz. The low sample rate is used to speed up training. Trim the training signals so that they are the same length.

```
maleTrainingAudioFile   = "MaleSpeech-16-4-mono-405secs.wav";
femaleTrainingAudioFile = "FemaleSpeech-16-4-mono-405secs.wav";

maleSpeechTrain   = audioread(fullfile(netFolder,maleTrainingAudioFile));
femaleSpeechTrain = audioread(fullfile(netFolder,femaleTrainingAudioFile));

L = min(length(maleSpeechTrain),length(femaleSpeechTrain));
maleSpeechTrain   = maleSpeechTrain(1:L);
femaleSpeechTrain = femaleSpeechTrain(1:L);
```

Read in validation signals consisting of around 20 seconds of speech from male and female speakers, respectively, sampled at 4 kHz. Trim the validation signals so that they are the same length

```
maleValidationAudioFile   = "MaleSpeech-16-4-mono-20secs.wav";
femaleValidationAudioFile = "FemaleSpeech-16-4-mono-20secs.wav";

maleSpeechValidate   = audioread(fullfile(netFolder,maleValidationAudioFile));
femaleSpeechValidate = audioread(fullfile(netFolder,femaleValidationAudioFile));

L = min(length(maleSpeechValidate),length(femaleSpeechValidate));
maleSpeechValidate   = maleSpeechValidate(1:L);
femaleSpeechValidate = femaleSpeechValidate(1:L);
```

Scale the training signals to the same power. Scale the validation signals to the same power.

```
maleSpeechTrain   = maleSpeechTrain/norm(maleSpeechTrain);
femaleSpeechTrain = femaleSpeechTrain/norm(femaleSpeechTrain);
ampAdj            = max(abs([maleSpeechTrain;femaleSpeechTrain]));
maleSpeechTrain   = maleSpeechTrain/ampAdj;
femaleSpeechTrain = femaleSpeechTrain/ampAdj;

maleSpeechValidate   = maleSpeechValidate/norm(maleSpeechValidate);
femaleSpeechValidate = femaleSpeechValidate/norm(femaleSpeechValidate);
ampAdj               = max(abs([maleSpeechValidate;femaleSpeechValidate]));
maleSpeechValidate   = maleSpeechValidate/ampAdj;
femaleSpeechValidate = femaleSpeechValidate/ampAdj;
```

Create the training and validation "cocktail party" mixes.

```
mixTrain = maleSpeechTrain + femaleSpeechTrain;
mixTrain = mixTrain / max(mixTrain);

mixValidate = maleSpeechValidate + femaleSpeechValidate;
mixValidate = mixValidate / max(mixValidate);
```

Generate training STFTs.

```
WindowLength  = 128;
FFTLength     = 128;
OverlapLength = 128-1;
Fs            = 4000;
win           = hann(WindowLength,"periodic");

P_mix0 = stft(mixTrain, 'Window', win, 'OverlapLength', OverlapLength,...
              'FFTLength', FFTLength, 'FrequencyRange', 'onesided');
P_M    = abs(stft(maleSpeechTrain, 'Window', win, 'OverlapLength', OverlapLength,...
              'FFTLength', FFTLength, 'FrequencyRange', 'onesided'));
P_F    = abs(stft(femaleSpeechTrain, 'Window', win, 'OverlapLength', OverlapLength,...
              'FFTLength', FFTLength, 'FrequencyRange', 'onesided'));
```

Take the log of the mix STFT. Normalize the values by their mean and standard deviation.

```
P_mix = log(abs(P_mix0) + eps);
MP    = mean(P_mix(:));
SP    = std(P_mix(:));
P_mix = (P_mix - MP) / SP;
```

Generate validation STFTs. Take the log of the mix STFT. Normalize the values by their mean and standard deviation.

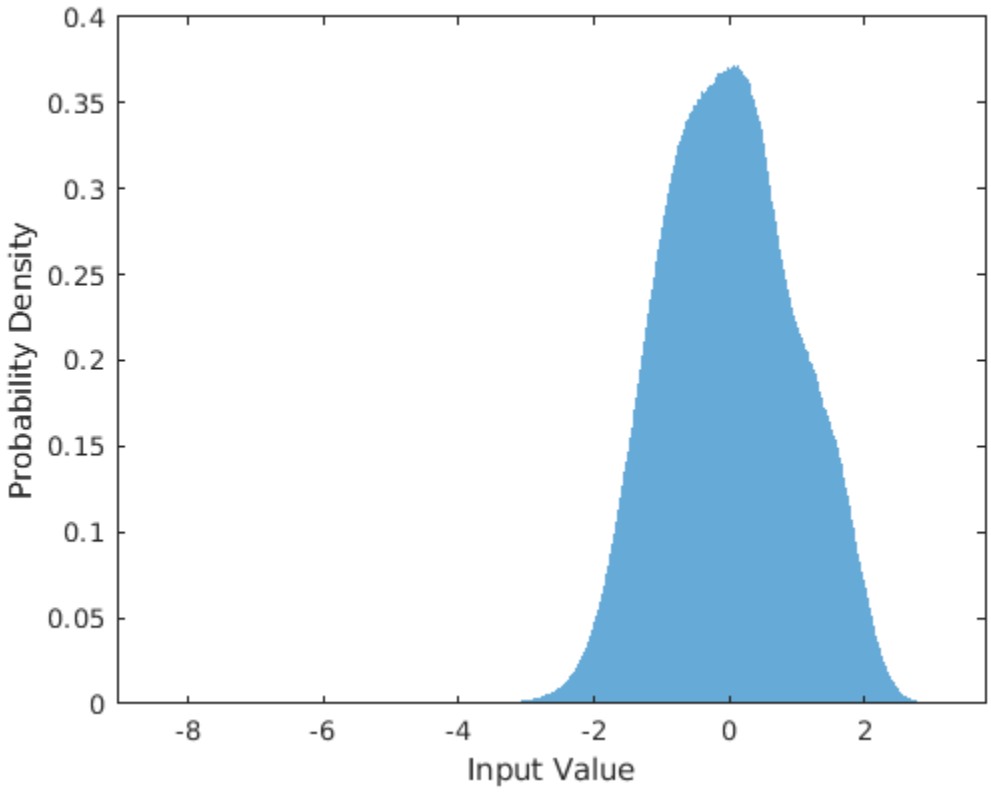
```
P_Val_mix0 = stft(mixValidate, 'Window', win, 'OverlapLength', OverlapLength,...
                  'FFTLength', FFTLength, 'FrequencyRange', 'onesided');
```

```
P_Val_M    = abs(stft(maleSpeechValidate, 'Window', win, 'OverlapLength', OverlapLength,...
                 'FFTLength', FFTLength, 'FrequencyRange', 'onesided'));
P_Val_F    = abs(stft(femaleSpeechValidate, 'Window', win, 'OverlapLength', OverlapLength,...
                 'FFTLength', FFTLength, 'FrequencyRange', 'onesided'));

P_Val_mix = log(abs(P_Val_mix0) + eps);
MP        = mean(P_Val_mix(:));
SP        = std(P_Val_mix(:));
P_Val_mix = (P_Val_mix - MP) / SP;
```

Training neural networks is easiest when the inputs to the network have a reasonably smooth distribution and are normalized. To check that the data distribution is smooth, plot a histogram of the STFT values of the training data.

```
figure(6)
histogram(P_mix,"EdgeColor","none","Normalization","pdf")
xlabel("Input Value")
ylabel("Probability Density")
```



Compute the training soft mask. Use this mask as the target signal while training the network.

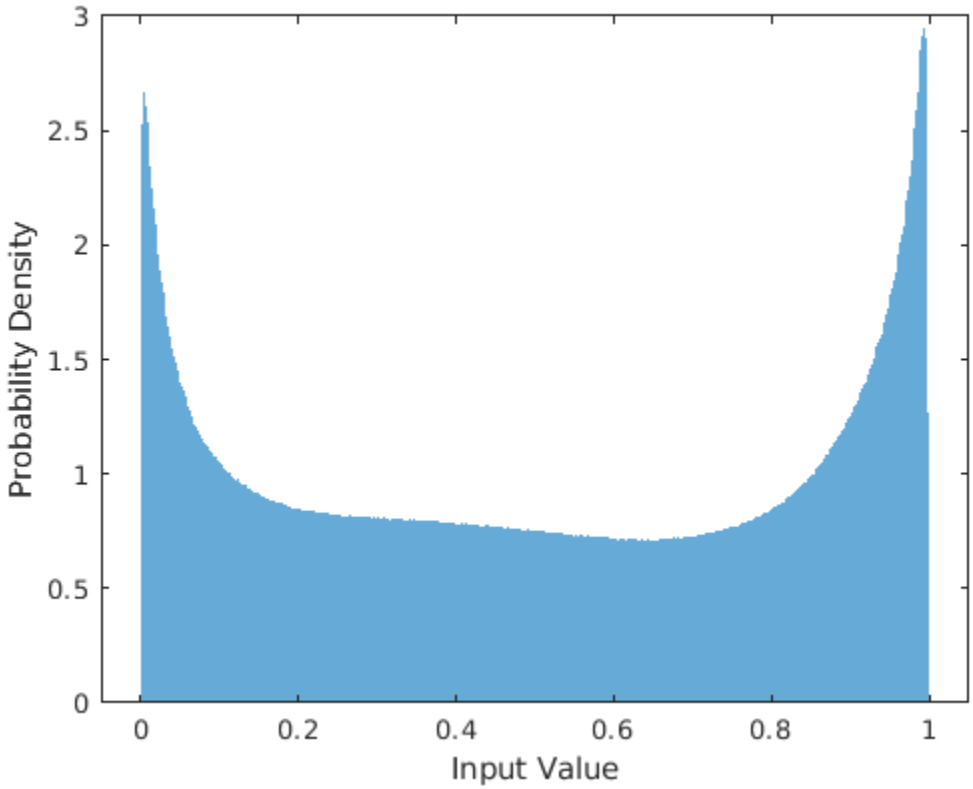
```
maskTrain = P_M ./ (P_M + P_F + eps);
```

Compute the validation soft mask. Use this mask to evaluate the mask emitted by the trained network.

```
maskValidate = P_Val_M ./ (P_Val_M + P_Val_F + eps);
```

To check that the target data distribution is smooth, plot a histogram of the mask values of the training data.

```
figure(7)
histogram(maskTrain,"EdgeColor","none","Normalization","pdf")
xlabel("Input Value")
ylabel("Probability Density")
```



Create chunks of size (65, 20) from the predictor and target signals. In order to get more training samples, use an overlap of 10 segments between consecutive chunks.

```
seqLen        = 20;
seqOverlap    = 10;
mixSequences  = zeros(1 + FFTLength/2,seqLen,1,0);
maskSequences = zeros(1 + FFTLength/2,seqLen,1,0);

loc = 1;
while loc < size(P_mix,2) - seqLen
    mixSequences(:,:,:,end+1)  = P_mix(:,loc:loc+seqLen-1); %#ok
    maskSequences(:,:,:,end+1) = maskTrain(:,loc:loc+seqLen-1); %#ok
    loc                        = loc + seqOverlap;
end
```

Create chunks of size (65,20) from the validation predictor and target signals.

```
mixValSequences  = zeros(1 + FFTLength/2,seqLen,1,0);
maskValSequences = zeros(1 + FFTLength/2,seqLen,1,0);
seqOverlap       = seqLen;
```

```
loc = 1;
while loc < size(P_Val_mix,2) - seqLen
    mixValSequences(:,:,:,end+1)  = P_Val_mix(:,loc:loc+seqLen-1); %#ok
    maskValSequences(:,:,:,end+1) = maskValidate(:,loc:loc+seqLen-1); %#ok
    loc                           = loc + seqOverlap;
end
```

Reshape the training and validation signals.

```
mixSequencesT  = reshape(mixSequences,    [1 1 (1 + FFTLength/2) * seqLen size(mixSequences,4)]);
mixSequencesV  = reshape(mixValSequences, [1 1 (1 + FFTLength/2) * seqLen size(mixValSequences,4
maskSequencesT = reshape(maskSequences,   [1 1 (1 + FFTLength/2) * seqLen size(maskSequences,4)]
maskSequencesV = reshape(maskValSequences,[1 1 (1 + FFTLength/2) * seqLen size(maskValSequences,4
```

Define Deep Learning Network

Define the layers of the network. Specify the input size to be images of size 1-by-1-by-1300. Define two hidden fully connected layers, each with 1300 neurons. Follow each hidden fully connected layer with a sigmoid layer. The batch normalization layers normalize the means and standard deviations of the outputs. Add a fully connected layer with 1300 neurons, followed by a regression layer.

```
numNodes = (1 + FFTLength/2) * seqLen;

layers = [ ...

    imageInputLayer([1 1 (1 + FFTLength/2)*seqLen],"Normalization","None")

    fullyConnectedLayer(numNodes)
    BiasedSigmoidLayer(6)
    batchNormalizationLayer
    dropoutLayer(0.1)

    fullyConnectedLayer(numNodes)
    BiasedSigmoidLayer(6)
    batchNormalizationLayer
    dropoutLayer(0.1)

    fullyConnectedLayer(numNodes)
    BiasedSigmoidLayer(0)

    regressionLayer

    ];
```

Specify the training options for the network. Set `MaxEpochs` to `3` so that the network makes three passes through the training data. Set `MiniBatchSize` to `64` so that the network looks at `64` training signals at a time. Set `Plots` to `training-progress` to generate plots that show the training progress as the number of iterations increases. Set `Verbose` to `false` to disable printing the table output that corresponds to the data shown in the plot into the command line window. Set `Shuffle` to `every-epoch` to shuffle the training sequences at the beginning of each epoch. Set `LearnRateSchedule` to `piecewise` to decrease the learning rate by a specified factor (0.1) every time a certain number of epochs (1) has passed. Set `ValidationData` to the validation predictors and targets. Set `ValidationFrequency` such that the validation mean square error is computed once per epoch. This example uses the adaptive moment estimation (ADAM) solver.

```
maxEpochs     = 3;
miniBatchSize = 64;
```

```
options = trainingOptions("adam", ...
    "MaxEpochs",maxEpochs, ...
    "MiniBatchSize",miniBatchSize, ...
    "SequenceLength","longest", ...
    "Shuffle","every-epoch",...
    "Verbose",0, ...
    "Plots","training-progress",...
    "ValidationFrequency",floor(size(mixSequencesT,4)/miniBatchSize),...
    "ValidationData",{mixSequencesV,maskSequencesV},...
    "LearnRateSchedule","piecewise",...
    "LearnRateDropFactor",0.9, ...
    "LearnRateDropPeriod",1);
```

Train Deep Learning Network

Train the network with the specified training options and layer architecture using `trainNetwork`. Because the training set is large, the training process can take several minutes. To load a pre-trained network, set `doTraining` to `false`.

```
doTraining = true;
if doTraining
    CocktailPartyNet = trainNetwork(mixSequencesT,maskSequencesT,layers,options);
else
    s = load("CocktailPartyNet.mat");
    CocktailPartyNet = s.CocktailPartyNet;
end
```

Pass the validation predictors to the network. The output is the estimated mask. Reshape the estimated mask.

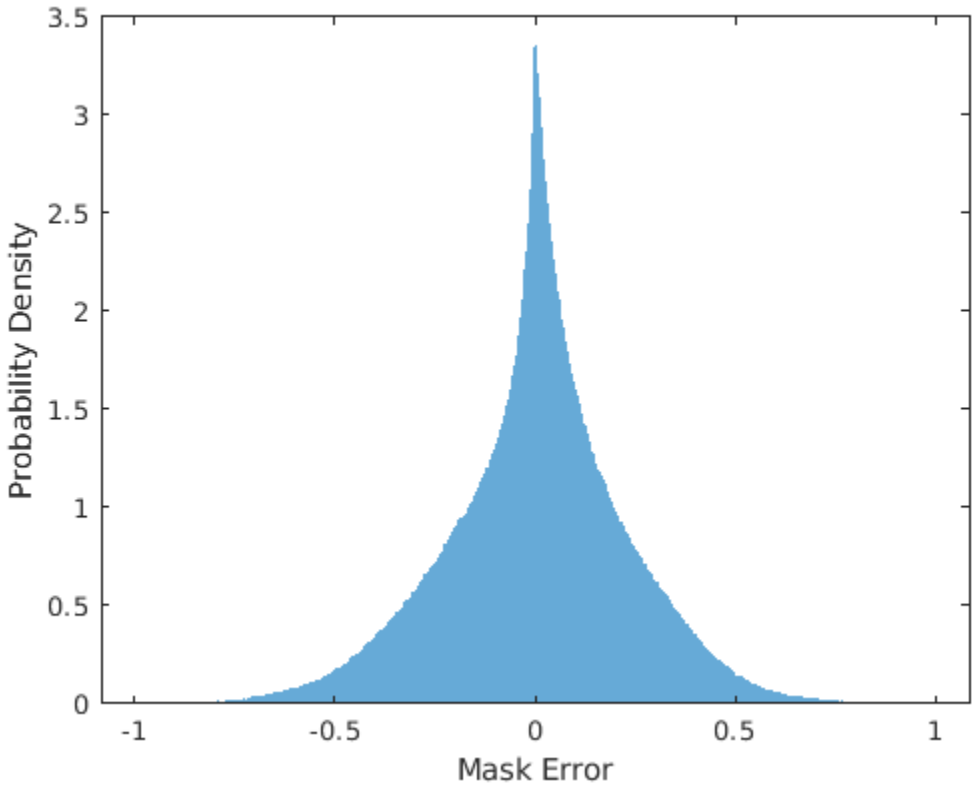
```
estimatedMasks0 = predict(CocktailPartyNet,mixSequencesV);

estimatedMasks0 = estimatedMasks0.';
estimatedMasks0 = reshape(estimatedMasks0,1 + FFTLength/2,numel(estimatedMasks0)/(1 + FFTLength/2
```

Evaluate Deep Learning Network

Plot a histogram of the error between the actual and expected mask.

```
figure(8)
histogram(maskValSequences(:) - estimatedMasks0(:),"EdgeColor","none","Normalization","pdf")
xlabel("Mask Error")
ylabel("Probability Density")
```



Evaluate Soft Mask Estimation

Estimate male and female soft masks. Estimate male and female binary masks by thresholding the soft masks.

```
SoftMaleMask   = estimatedMasks0;
SoftFemaleMask = 1 - SoftMaleMask;
```

Shorten the mix STFT to match the size of the estimated mask.

```
P_Val_mix0 = P_Val_mix0(:,1:size(SoftMaleMask,2));
```

Multiply the mix STFT by the male soft mask to get the estimated male speech STFT.

```
P_Male = P_Val_mix0 .* SoftMaleMask;
```

Use the ISTFT to get the estimated male audio signal. Scale the audio.

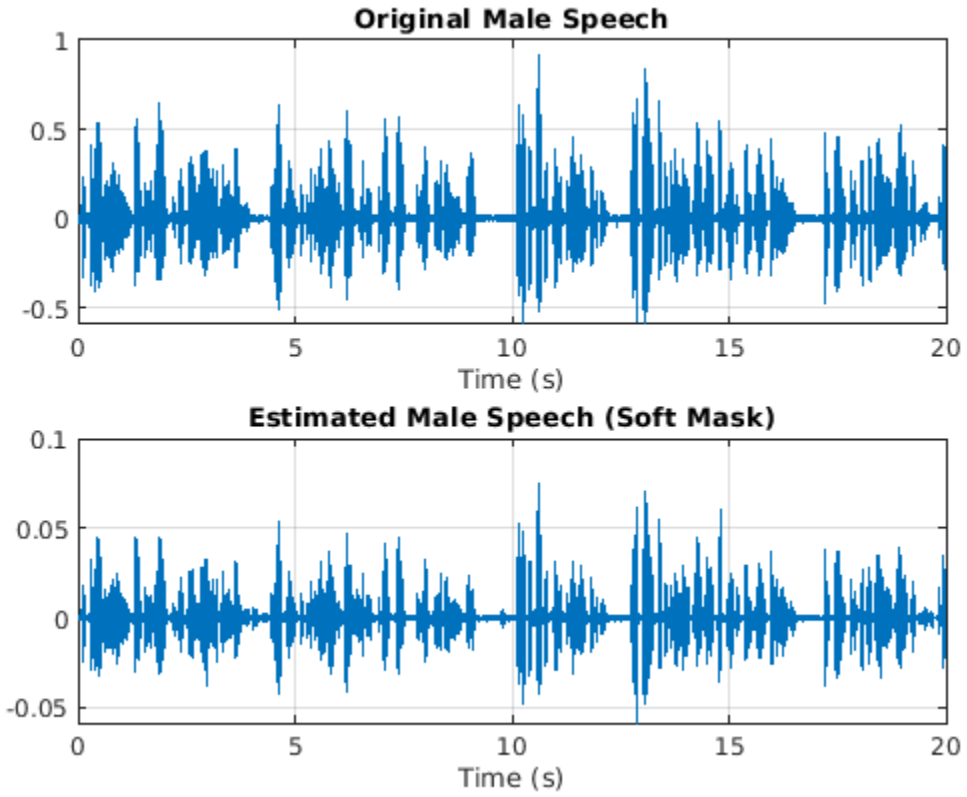
```
maleSpeech_est_soft = istft(P_Male, 'Window', win, 'OverlapLength', OverlapLength,...
                            'FFTLength', FFTLength, 'ConjugateSymmetric', true,...
                            'FrequencyRange', 'onesided');
maleSpeech_est_soft = maleSpeech_est_soft / max(abs(maleSpeech_est_soft));
```

Visualize the estimated and original male speech signals. Listen to the estimated soft mask male speech.

```
range = (numel(win):numel(maleSpeech_est_soft)-numel(win));
t     = range * (1/Fs);
```

```
figure(9)
subplot(2,1,1)
plot(t,maleSpeechValidate(range))
title("Original Male Speech")
xlabel("Time (s)")
grid on

subplot(2,1,2)
plot(t,maleSpeech_est_soft(range))
xlabel("Time (s)")
title("Estimated Male Speech (Soft Mask)")
grid on
```



```
sound(maleSpeech_est_soft(range),Fs)
```

Multiply the mix STFT by the female soft mask to get the estimated female speech STFT. Use the ISTFT to get the estimated male audio signal. Scale the audio.

```
P_Female = P_Val_mix0 .* SoftFemaleMask;

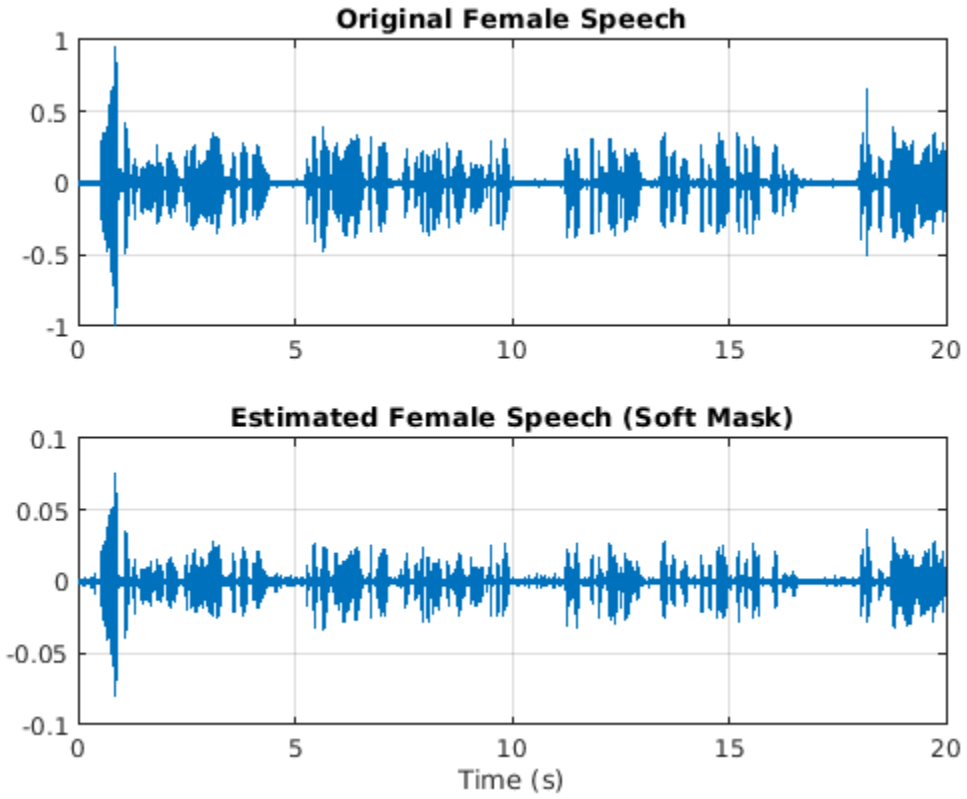
femaleSpeech_est_soft = istft(P_Female, 'Window', win, 'OverlapLength', OverlapLength,...
                              'FFTLength',FFTLength, 'ConjugateSymmetric',true,...
                              'FrequencyRange', 'onesided');
femaleSpeech_est_soft = femaleSpeech_est_soft / max(femaleSpeech_est_soft);
```

Visualize the estimated and original female signals. Listen to the estimated female speech.

```
range = (numel(win):numel(maleSpeech_est_soft) - numel(win));
t     = range * (1/Fs);

figure(10)
subplot(2,1,1)
plot(t,femaleSpeechValidate(range))
title("Original Female Speech")
grid on

subplot(2,1,2)
plot(t,femaleSpeech_est_soft(range))
xlabel("Time (s)")
title("Estimated Female Speech (Soft Mask)")
grid on
```



```
sound(femaleSpeech_est_soft(range),Fs)
```

Evaluate Binary Mask Estimation

Estimate male and female binary masks by thresholding the soft masks.

```
HardMaleMask   = SoftMaleMask >= 0.5;
HardFemaleMask = SoftMaleMask < 0.5;
```

Multiply the mix STFT by the male binary mask to get the estimated male speech STFT. Use the ISTFT to get the estimated male audio signal. Scale the audio.

```
P_Male = P_Val_mix0 .* HardMaleMask;

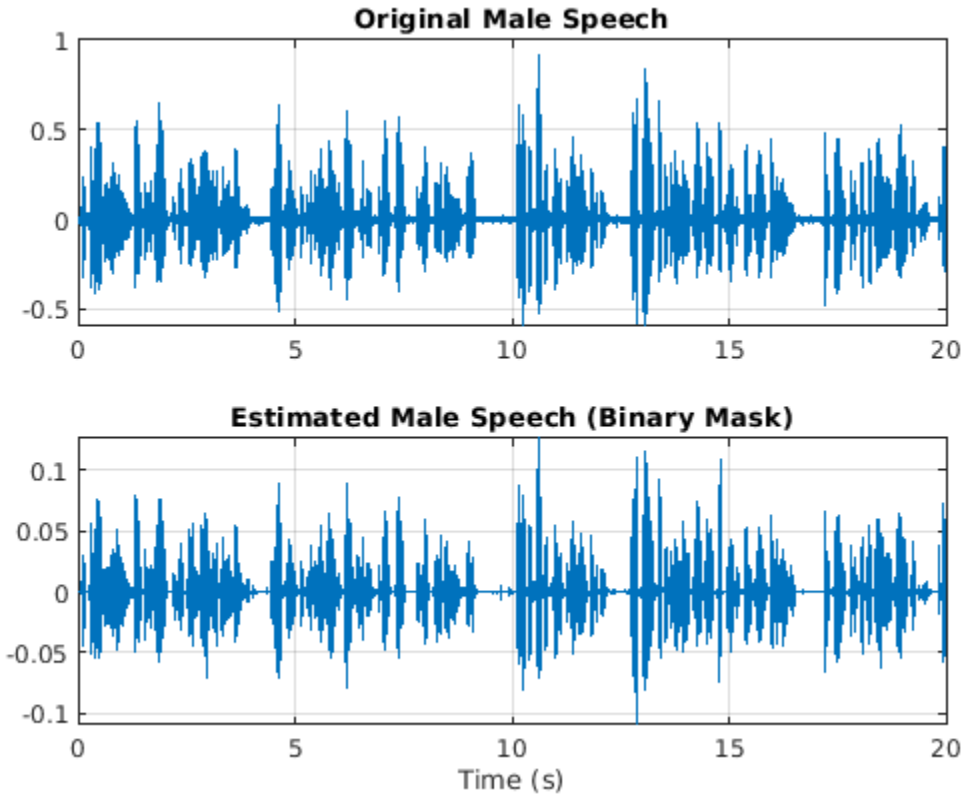
maleSpeech_est_hard = istft(P_Male, 'Window', win, 'OverlapLength', OverlapLength,...
                            'FFTLength', FFTLength, 'ConjugateSymmetric', true,...
                            'FrequencyRange', 'onesided');
maleSpeech_est_hard = maleSpeech_est_hard / max(maleSpeech_est_hard);
```

Visualize the estimated and original male speech signals. Listen to the estimated binary mask male speech.

```
range = (numel(win):numel(maleSpeech_est_soft)-numel(win));
t = range * (1/Fs);

figure(11)
subplot(2,1,1)
plot(t,maleSpeechValidate(range))
title("Original Male Speech")
grid on

subplot(2,1,2)
plot(t,maleSpeech_est_hard(range))
xlabel("Time (s)")
title("Estimated Male Speech (Binary Mask)")
grid on
```



```
sound(maleSpeech_est_hard(range),Fs)
```

Multiply the mix STFT by the female binary mask to get the estimated male speech STFT. Use the ISTFT to get the estimated male audio signal. Scale the audio.

```
P_Female = P_Val_mix0 .* HardFemaleMask;

femaleSpeech_est_hard = istft(P_Female, 'Window', win, 'OverlapLength', OverlapLength,...
                              'FFTLength', FFTLength, 'ConjugateSymmetric', true,...
                              'FrequencyRange', 'onesided');
femaleSpeech_est_hard = femaleSpeech_est_hard / max(femaleSpeech_est_hard);
```

Visualize the estimated and original female speech signals. Listen to the estimated female speech.

```
range = (numel(win):numel(maleSpeech_est_soft)-numel(win));
t = range * (1/Fs);

figure(12)
subplot(2,1,1)
plot(t,femaleSpeechValidate(range))
title("Original Female Speech")
grid on

Voice Activity Detection in Noise Using Deep Learning

This example shows how to detect regions of speech in a low signal-to-noise environment using deep learning. The example uses the Speech Commands Dataset to train a Bidirectional Long Short-Term Memory (BiLSTM) network to detect voice activity.

Introduction

Voice activity detection is an essential component of many audio systems, such as automatic speech recognition and speaker recognition. Voice activity detection can be especially challenging in low signal-to-noise (SNR) situations, where speech is obstructed by noise.

This example uses long short-term memory (LSTM) networks, which are a type of recurrent neural network (RNN) well-suited to study sequence and time-series data. An LSTM network can learn long-term dependencies between time steps of a sequence. An LSTM layer (`lstmLayer`) can look at the time sequence in the forward direction, while a bidirectional LSTM layer (`bilstmLayer`) can look at the time sequence in both forward and backward directions. This example uses a bidirectional LSTM layer.

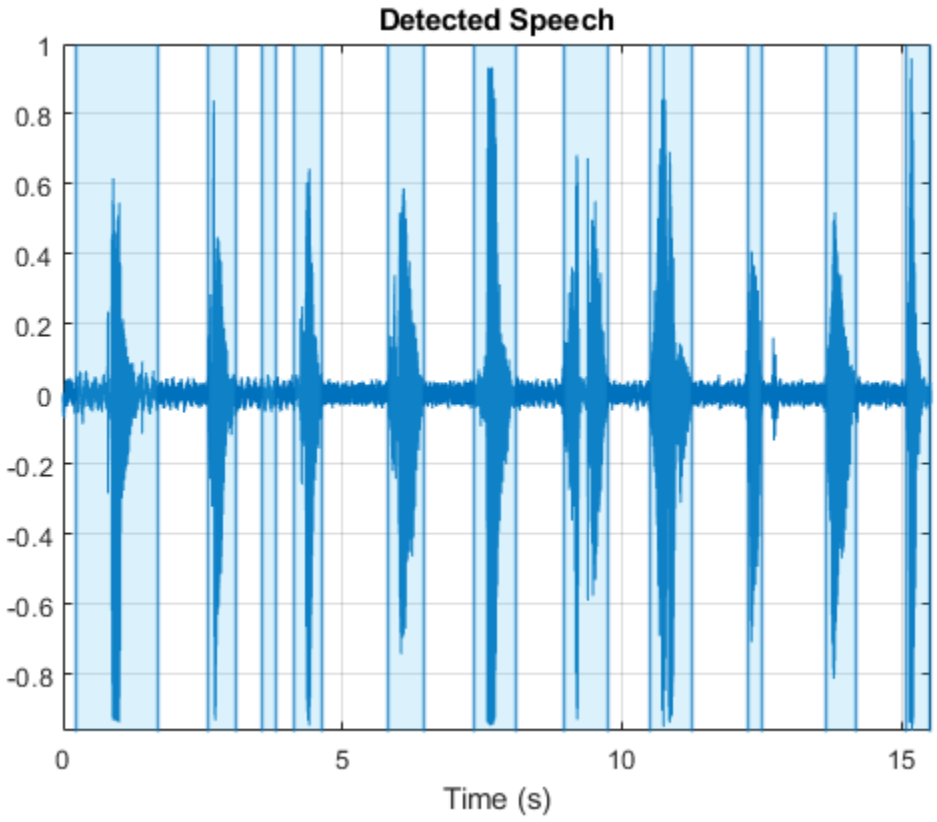
This example trains a voice activity detection bidirectional LSTM network with feature sequences of spectral characteristics and a harmonic ratio metric.

In high SNR scenarios, traditional speech detection algorithms perform adequately. Read in an audio file that consists of words spoken with pauses between. Resample the audio to 16 kHz. Listen to the audio.

```
fs = 16e3;
[speech,fileFs] = audioread('Counting-16-44p1-mono-15secs.wav');
speech = resample(speech,fs,fileFs);
speech = speech/max(abs(speech));
sound(speech,fs)
```

Use the `detectSpeech` (Audio Toolbox) function to locate regions of speech. The `detectSpeech` function correctly identifies all regions of speech.

```
win = hamming(50e-3 * fs,'periodic');
detectSpeech(speech,fs,'Window',win)
```



Corrupt the audio signal with washing machine noise at a -20 dB SNR. Listen to the corrupted audio.

```
[noise,fileFs] = audioread('WashingMachine-16-8-mono-200secs.mp3');
noise = resample(noise,fs,fileFs);

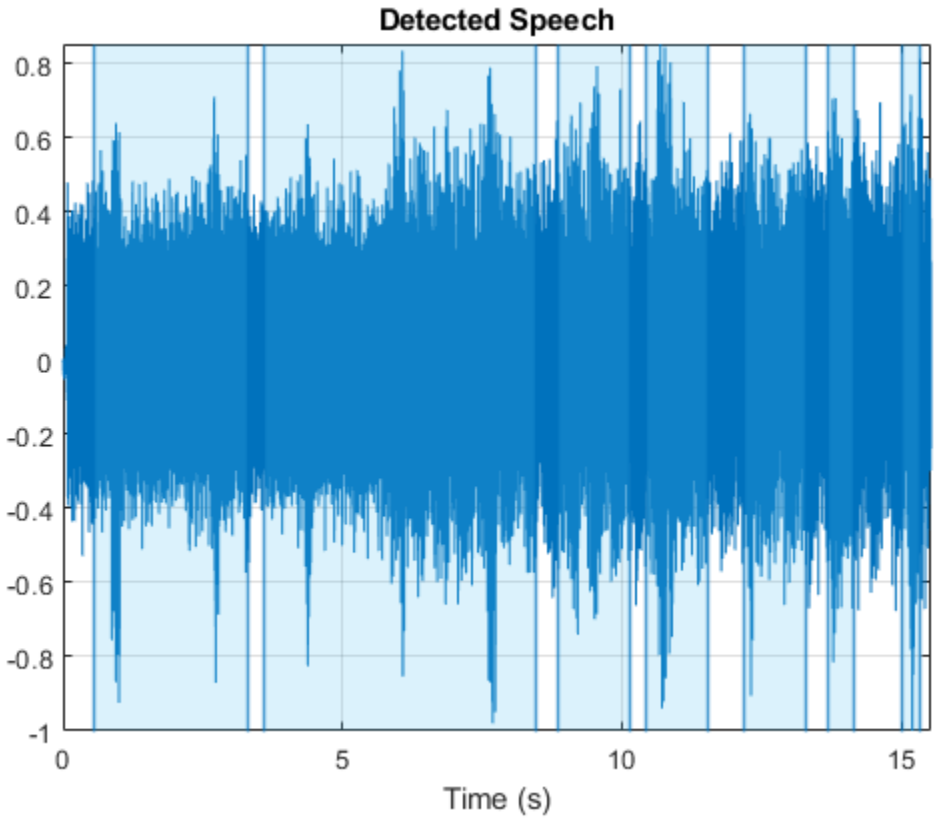
SNR = -20;
noiseGain = 10^(-SNR/20) * norm(speech) / norm(noise);

noisySpeech = speech + noiseGain*noise(1:numel(speech));
noisySpeech = noisySpeech./max(abs(noisySpeech));

sound(noisySpeech,fs)
```

Call `detectSpeech` on the noisy audio signal. The function fails to detect the speech regions given the very low SNR.

```
detectSpeech(noisySpeech,fs,'Window',win)
```



Download and load a pretrained network and a configured `audioFeatureExtractor` (Audio Toolbox) object. The network was trained to detect speech in a low SNR environments given features output from the `audioFeatureExtractor` object.

```
url = 'http://ssd.mathworks.com/supportfiles/audio/VoiceActivityDetection.zip';
    downloadNetFolder = tempdir;
    netFolder = fullfile(downloadNetFolder,'VoiceActivityDetection');
    if ~exist(netFolder,'dir')
        disp('Downloading pretrained network (1 file - 8 MB) ...')
        unzip(url,downloadNetFolder)
    end
load(fullfile(netFolder,'voiceActivityDetectionExample.mat'));

speechDetectNet
```

```
speechDetectNet =
  SeriesNetwork with properties:

         Layers: [6×1 nnet.cnn.layer.Layer]
     InputNames: {'sequenceinput'}
    OutputNames: {'classoutput'}
```

```
afe
```

```
afe =
  audioFeatureExtractor with properties:
```

```
  Properties
                    Window: [256×1 double]
              OverlapLength: 128
                 SampleRate: 16000
                  FFTLength: []
   SpectralDescriptorInput: 'linearSpectrum'

  Enabled Features
    spectralCentroid, spectralCrest, spectralEntropy, spectralFlux, spectralKurtosis, spectralRo
    spectralSkewness, spectralSlope, harmonicRatio

  Disabled Features
    linearSpectrum, melSpectrum, barkSpectrum, erbSpectrum, mfcc, mfccDelta
    mfccDeltaDelta, gtcc, gtccDelta, gtccDeltaDelta, spectralDecrease, spectralFlatness
    spectralSpread, pitch

  To extract a feature, set the corresponding property to true.
  For example, obj.mfcc = true, adds mfcc to the list of enabled features.
```

Extract features from the speech data and then normalize them. Orient the features so that time is across columns.

```
features = extract(afe,noisySpeech);
features = (features - mean(features,1)) ./ std(features,[],1);
features = features';
```

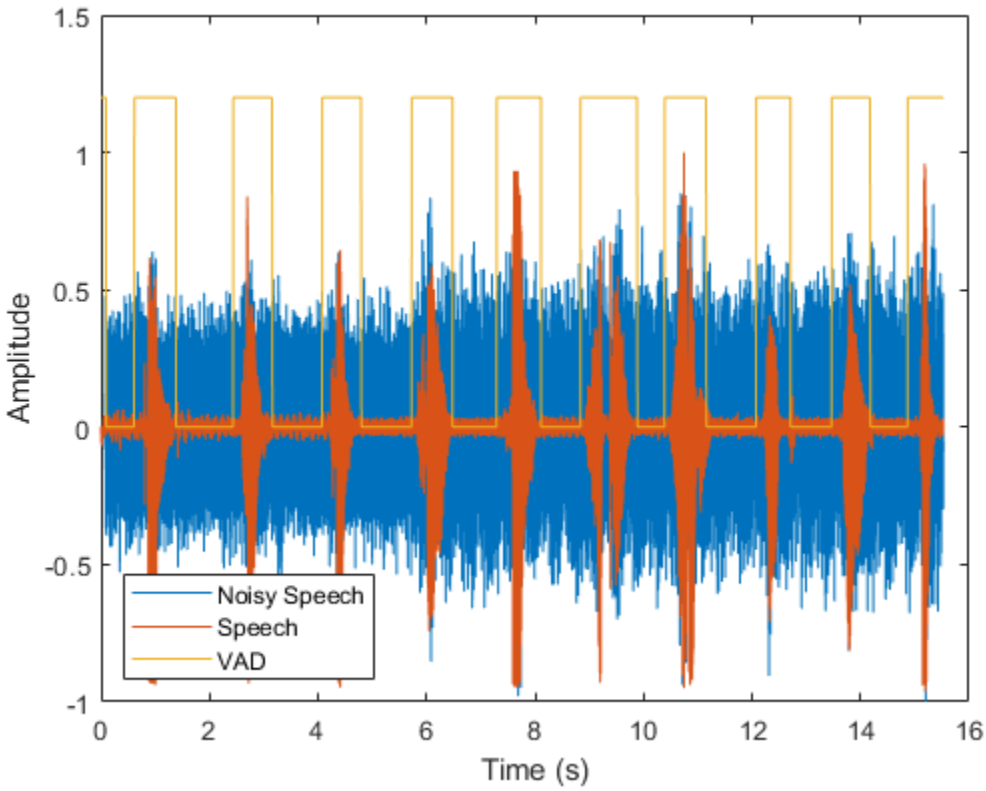
Pass the features through the speech detection network to classify each feature vector as belonging to a frame of speech or not.

```
decisionsCategorical = classify(speechDetectNet,features);
```

Each decision corresponds to an analysis window analyzed by the `audioFeatureExtractor`. Replicate the decisions so that they are in one-to-one correspondence with the audio samples. Plot the speech, the noisy speech, and the VAD decisions.

```
decisionsWindow = 1.2*(double(decisionsCategorical)-1);
decisionsSample = [repelem(decisionsWindow(1),numel(afe.Window)), ...
                   repelem(decisionsWindow(2:end),numel(afe.Window)-afe.OverlapLength)];

t = (0:numel(decisionsSample)-1)/afe.SampleRate;
plot(t,noisySpeech(1:numel(t)), ...
     t,speech(1:numel(t)), ...
     t,decisionsSample);
xlabel('Time (s)')
ylabel('Amplitude')
legend('Noisy Speech','Speech','VAD','Location','southwest')
```



You can also use the trained VAD network in a streaming context. To simulate a streaming environment, first save the speech and noise signals as WAV files. To simulate streaming input, you will read frames from the files and mix them at a desired SNR.

```
audiowrite('Speech.wav',speech,fs)
audiowrite('Noise.wav',noise,fs)
```

To apply the VAD network to streaming audio, you have to trade off between delay and accuracy. Define parameters for the streaming voice activity detection in noise demonstration. You can set the duration of the test, the sequence length fed into the network, the sequence hop length, and the SNR to test. Generally, increasing the sequence length increases the accuracy but also increases the lag. You can also choose the signal output to your device as the original signal or the noisy signal.

```
testDuration = 20 ;

sequenceLength = 400 ;

sequenceHop = 20 ;

SNR = -20 ;
noiseGain = 10^(-SNR/20) * norm(speech) / norm(noise);

signalToListenTo = "noisy" ;
```

Call the streaming demo helper function to observe the performance of the VAD network on streaming audio. The parameters you set using the live controls do not interrupt the streaming example. After the streaming demo is complete, you can modify parameters of the demonstration, then run the streaming demo again. You can find the code for the streaming demo in the Supporting Functions on page 14-0 .

```
helperStreamingDemo(speechDetectNet,afe, ...
                    'Speech.wav','Noise.wav', ...
                    testDuration,sequenceLength,sequenceHop,signalToListenTo,noiseGain);
```

The remainder of the example walks through training and evaluating the VAD network.

Train and Evaluate VAD Network

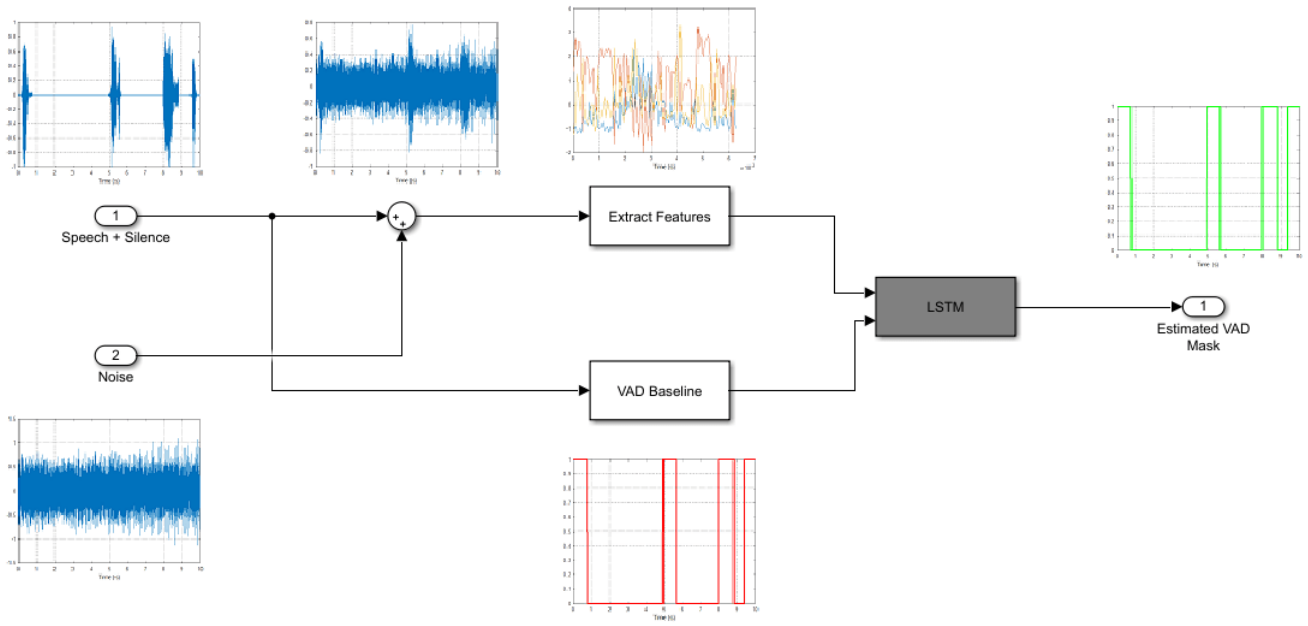
Training:

1. Create an `audioDatastore` (Audio Toolbox) that points to the audio speech files used to train the LSTM network.
2. Create a training signal consisting of speech segments separated by segments of silence of varying durations.
3. Corrupt the speech-plus-silence signal with washing machine noise (SNR = -10 dB).
4. Extract feature sequences consisting of spectral characteristics and harmonic ratio from the noisy signal.
5. Train the LSTM network using the feature sequences to identify regions of voice activity.

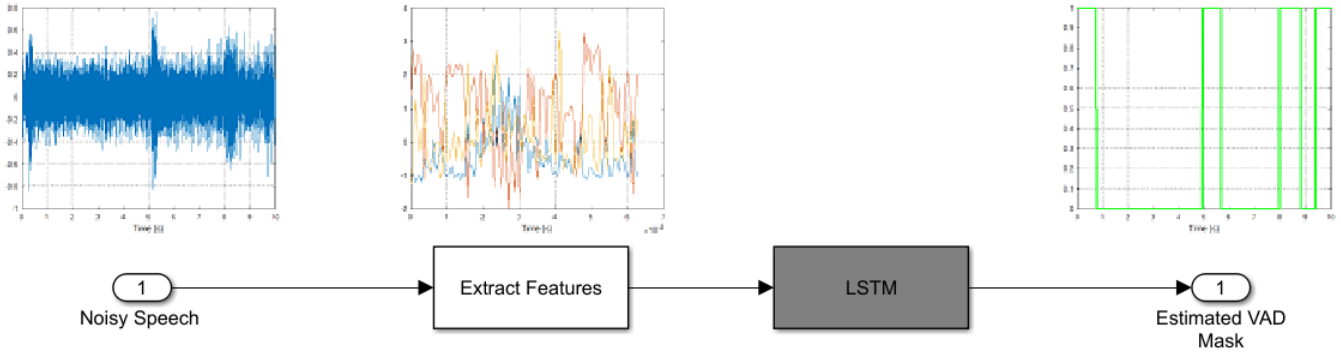
Prediction:

1. Create an `audioDatastore` of speech files used to test the trained network, and create a test signal consisting of speech separated by segments of silence.
2. Corrupt the test signal with washing machine noise (SNR = -10 dB).
3. Extract feature sequences from the noisy test signal.
4. Identify regions of voice activity by passing the test features through the trained network.
5. Compare the network's accuracy to the voice activity baseline from the signal-plus-silence test signal.

Here is a sketch of the training process.



Here is a sketch of the prediction process. You use the trained network to make predictions.



Load Speech Commands Data Set

Download and extract the Google Speech Commands Dataset [1] on page 14-0 .

```
url = 'https://ssd.mathworks.com/supportfiles/audio/google_speech.zip';

downloadFolder = tempdir;
datasetFolder = fullfile(downloadFolder,'google_speech');

if ~exist(datasetFolder,'dir')
    disp('Downloading Google speech commands data set (1.9 GB)...')
    unzip(url,downloadFolder)
end
```

```
Downloading Google speech commands data set (1.9 GB)...
```

Create an `audioDatastore` (Audio Toolbox) that points to the training data set.

```
adsTrain = audioDatastore(fullfile(datasetFolder, 'train'), "Includesubfolders",true);
```

Create an `audioDatastore` (Audio Toolbox) that points to the validation data set.

```
adsValidation = audioDatastore(fullfile(datasetFolder, 'validation'), "Includesubfolders",true);
```

Create Speech-Plus-Silence Training Signal

Read the contents of an audio file using `read` (Audio Toolbox). Get the sample rate from the `adsInfo` struct.

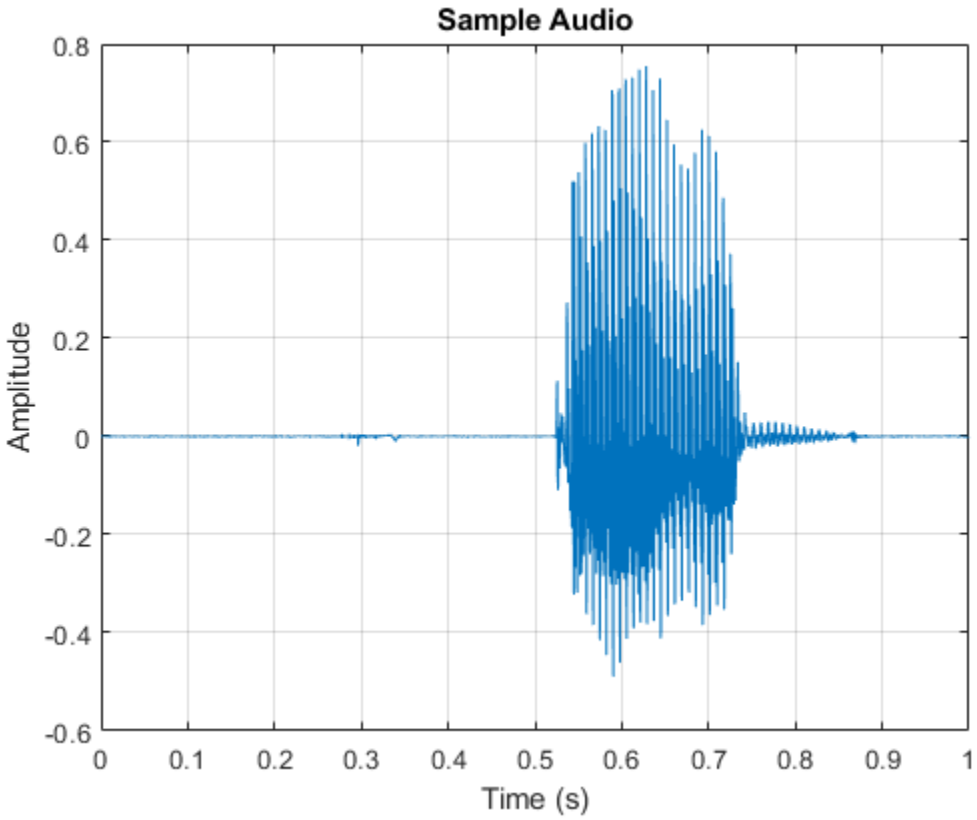
```
[data,adsInfo] = read(adsTrain);
Fs = adsInfo.SampleRate;
```

Listen to the audio signal using the sound command.

```
sound(data,Fs)
```

Plot the audio signal.

```
timeVector = (1/Fs) * (0:numel(data)-1);
plot(timeVector,data)
ylabel("Amplitude")
xlabel("Time (s)")
title("Sample Audio")
grid on
```

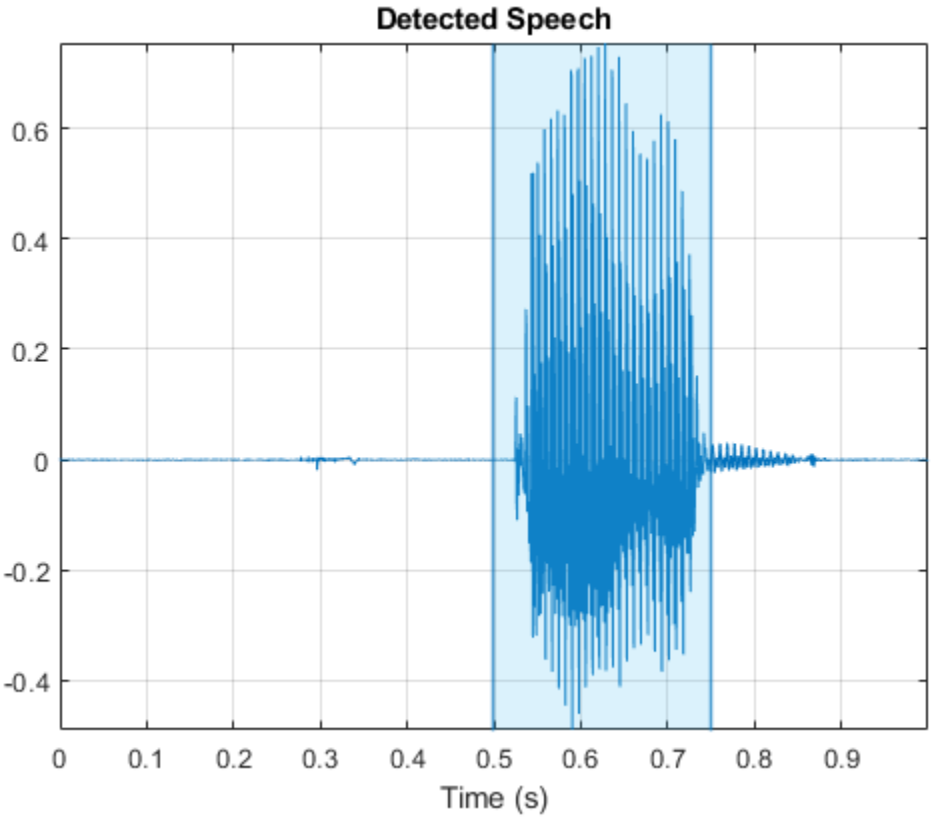


The signal has non-speech portions (silence, background noise, etc) that do not contain useful speech information. This example removes silence using the `detectSpeech` (Audio Toolbox) function.

Extract the useful portion of data. Define a 50 ms periodic Hamming window for analysis. Call `detectSpeech` with no output arguments to plot the detected speech regions. Call `detectSpeech` again to return the indices of the detected speech. Isolate the detected speech regions and then use the `sound` command to listen to the audio.

```
win = hamming(50e-3 * Fs,'periodic');

detectSpeech(data,Fs,'Window',win);
```



```
speechIndices = detectSpeech(data,Fs,'Window',win);

sound(data(speechIndices(1,1):speechIndices(1,2)),Fs)
```

The `detectSpeech` function returns indices that tightly surround the detected speech region. It was determined empirically that, for this example, extending the indices of the detected speech by five frames on either side increased the final model's performance. Extend the speech indices by five frames and then listen to the speech.

```
speechIndices(1,1) = max(speechIndices(1,1) - 5*numel(win),1);
speechIndices(1,2) = min(speechIndices(1,2) + 5*numel(win),numel(data));

sound(data(speechIndices(1,1):speechIndices(1,2)),Fs)
```

Reset the training datastore and shuffle the order of files in the datastores.

```
reset(adsTrain)
adsTrain = shuffle(adsTrain);
adsValidation = shuffle(adsValidation);
```

The `detectSpeech` function calculates statistics-based thresholds to determine the speech regions. You can skip the threshold calculation and speed up the `detectSpeech` function by specifying the thresholds directly. To determine thresholds for a data set, call `detectSpeech` on a sampling of files and get the thresholds it calculates. Take the mean of the thresholds.

```
TM = [];
for index1 = 1:500
     data = read(adsTrain);
     [~,T] = detectSpeech(data,Fs,'Window',win);
     TM = [TM;T];
end

T = mean(TM);

reset(adsTrain)
```

Create a 1000-second training signal by combining multiple speech files from the training data set. Use `detectSpeech` to remove unwanted portions of each file. Insert a random period of silence between speech segments.

Preallocate the training signal.

```
duration = 2000*Fs;
audioTraining = zeros(duration,1);
```

Preallocate the voice activity training mask. Values of 1 in the mask correspond to samples located in areas with voice activity. Values of 0 correspond to areas with no voice activity.

```
maskTraining = zeros(duration,1);
```

Specify a maximum silence segment duration of 2 seconds.

```
maxSilenceSegment = 2;
```

Construct the training signal by calling `read` on the datastore in a loop.

```
numSamples = 1;

while numSamples < duration
    data = read(adsTrain);
    data = data ./ max(abs(data)); % Normalize amplitude

    % Determine regions of speech
    idx = detectSpeech(data,Fs,'Window',win,'Thresholds',T);

    % If a region of speech is detected
    if ~isempty(idx)

        % Extend the indices by five frames
        idx(1,1) = max(1,idx(1,1) - 5*numel(win));
        idx(1,2) = min(length(data),idx(1,2) + 5*numel(win));

        % Isolate the speech
        data = data(idx(1,1):idx(1,2));
```

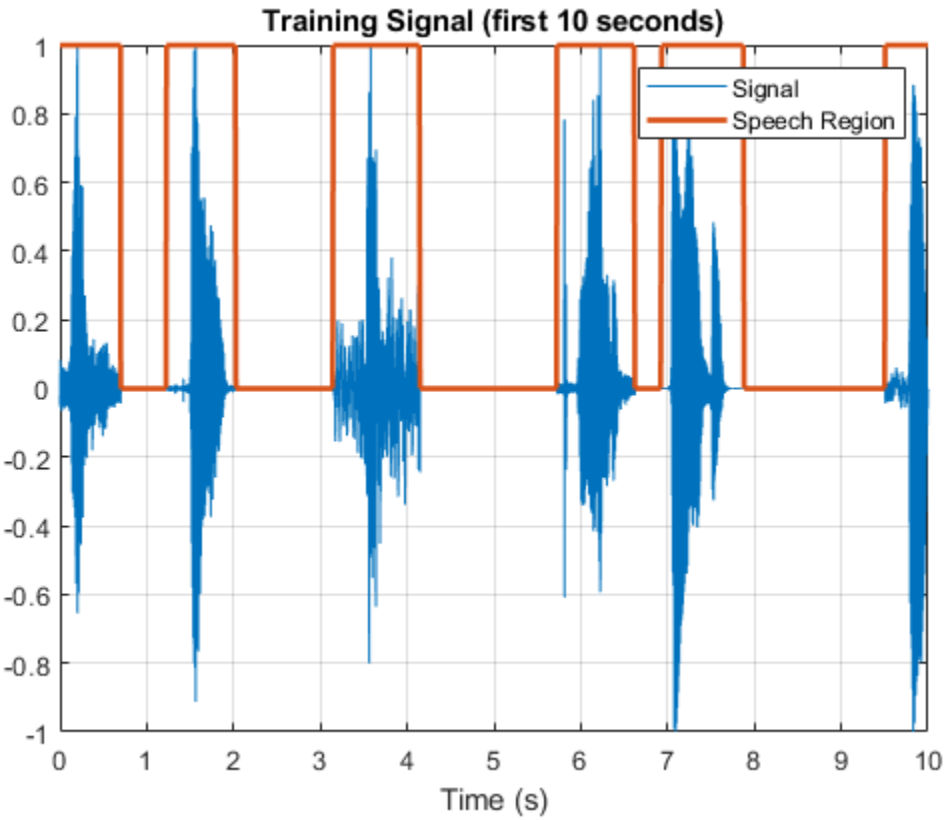
```
            % Write speech segment to training signal
            audioTraining(numSamples:numSamples+numel(data)-1) = data;

            % Set VAD baseline
            maskTraining(numSamples:numSamples+numel(data)-1) = true;

            % Random silence period
            numSilenceSamples = randi(maxSilenceSegment*Fs,1,1);
            numSamples = numSamples + numel(data) + numSilenceSamples;
        end
    end
```

Visualize a 10-second portion of the training signal. Plot the baseline voice activity mask.

```
figure
range = 1:10*Fs;
plot((1/Fs)*(range-1),audioTraining(range));
hold on
plot((1/Fs)*(range-1),maskTraining(range));
grid on
lines = findall(gcf,"Type","Line");
lines(1).LineWidth = 2;
xlabel("Time (s)")
legend("Signal","Speech Region")
title("Training Signal (first 10 seconds)");
```



Listen to the first 10 seconds of the training signal.

```
sound(audioTraining(range),Fs);
```

Add Noise to the Training Signal

Corrupt the training signal with washing machine noise by adding washing machine noise to the speech signal such that the signal-to-noise ratio is -10 dB.

Read 8 kHz noise and convert it to 16 kHz.

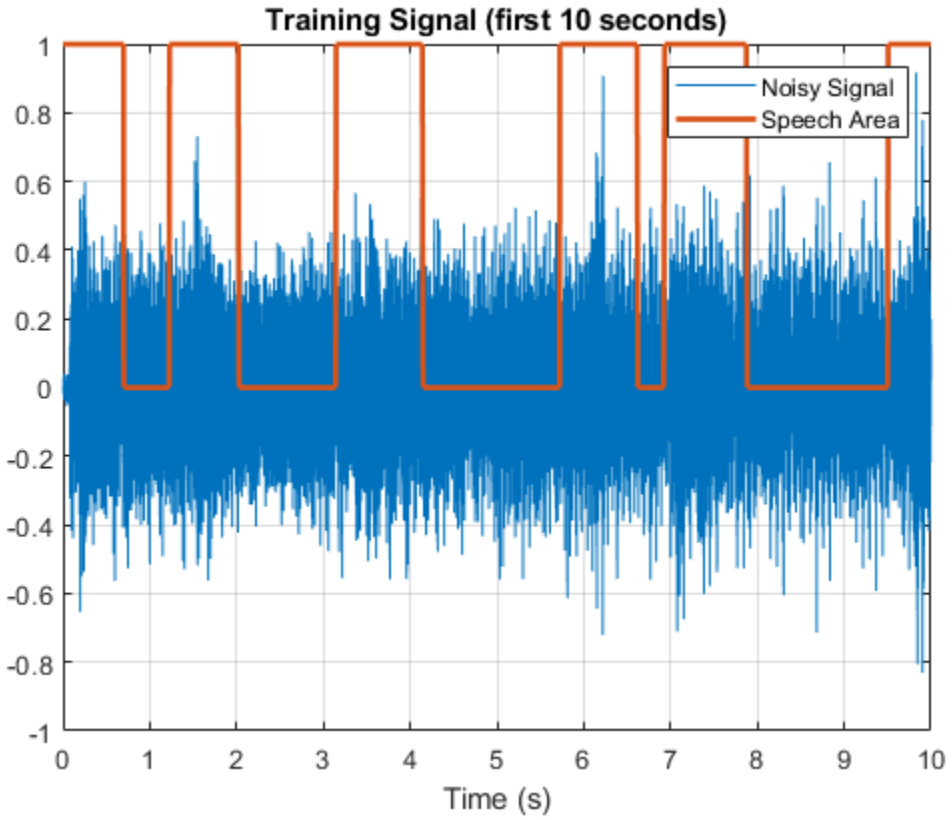
```
noise = audioread("WashingMachine-16-8-mono-1000secs.mp3");
noise = resample(noise,2,1);
```

Corrupt training signal with noise.

```
audioTraining = audioTraining(1:numel(noise));
SNR = -10;
noise = 10^(-SNR/20) * noise * norm(audioTraining) / norm(noise);
audioTrainingNoisy = audioTraining + noise;
audioTrainingNoisy = audioTrainingNoisy / max(abs(audioTrainingNoisy));
```

Visualize a 10-second portion of the noisy training signal. Plot the baseline voice activity mask.

```
figure
plot((1/Fs)*(range-1),audioTrainingNoisy(range));
hold on
plot((1/Fs)*(range-1),maskTraining(range));
grid on
lines = findall(gcf,"Type","Line");
lines(1).LineWidth = 2;
xlabel("Time (s)")
legend("Noisy Signal","Speech Area")
title("Training Signal (first 10 seconds)");
```



Listen to the first 10 seconds of the noisy training signal.

```
sound(audioTrainingNoisy(range),Fs)
```

Note that you obtained the baseline voice activity mask using the noiseless speech-plus-silence signal. Verify that using `detectSpeech` on the noise-corrupted signal does not yield good results.

```
speechIndices = detectSpeech(audioTrainingNoisy,Fs,'Window',win);

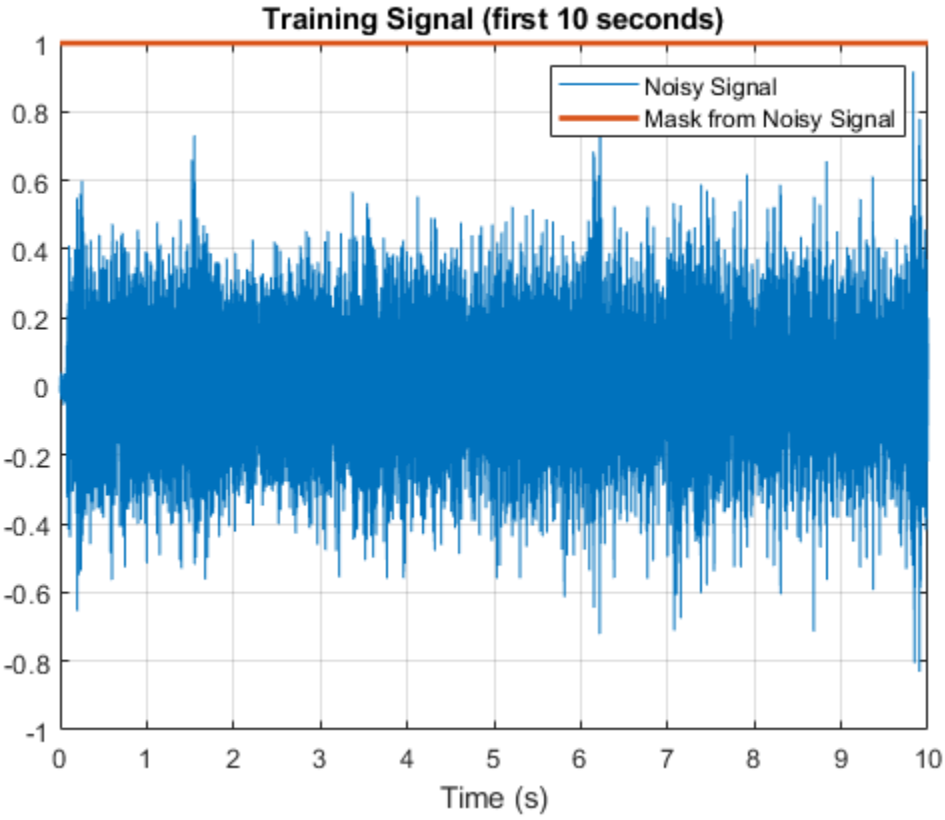
speechIndices(:,1) = max(1,speechIndices(:,1) - 5*numel(win));
speechIndices(:,2) = min(numel(audioTrainingNoisy),speechIndices(:,2) + 5*numel(win));

noisyMask = zeros(size(audioTrainingNoisy));
for ii = 1:size(speechIndices)
    noisyMask(speechIndices(ii,1):speechIndices(ii,2)) = 1;
end
```

Visualize a 10-second portion of the noisy training signal. Plot the voice activity mask obtained by analyzing the noisy signal.

```
figure
plot((1/Fs)*(range-1),audioTrainingNoisy(range));
hold on
plot((1/Fs)*(range-1),noisyMask(range));
grid on
lines = findall(gcf,"Type","Line");
lines(1).LineWidth = 2;
xlabel("Time (s)")
```

```
legend("Noisy Signal","Mask from Noisy Signal")
title("Training Signal (first 10 seconds)");
```



Create Speech-Plus-Silence Validation Signal

Create a 200-second noisy speech signal to validate the trained network. Use the validation datastore. Note that the validation and training datastores have different speakers.

Preallocate the validation signal and the validation mask. You will use this mask to assess the accuracy of the trained network.

```
duration = 200*Fs;
audioValidation = zeros(duration,1);
maskValidation = zeros(duration,1);
```

Construct the validation signal by calling `read` on the datastore in a loop.

```
numSamples = 1;
while numSamples < duration
    data = read(adsValidation);
    data = data ./ max(abs(data)); % Normalize amplitude

    % Determine regions of speech
    idx = detectSpeech(data,Fs,'Window',win,'Thresholds',T);

    % If a region of speech is detected
    if ~isempty(idx)
```

```
            % Extend the indices by five frames
            idx(1,1) = max(1,idx(1,1) - 5*numel(win));
            idx(1,2) = min(length(data),idx(1,2) + 5*numel(win));

            % Isolate the speech
            data = data(idx(1,1):idx(1,2));

            % Write speech segment to training signal
            audioValidation(numSamples:numSamples+numel(data)-1) = data;

            % Set VAD Baseline
            maskValidation(numSamples:numSamples+numel(data)-1) = true;

            % Random silence period
            numSilenceSamples = randi(maxSilenceSegment*Fs,1,1);
            numSamples = numSamples + numel(data) + numSilenceSamples;
        end
    end
```

Corrupt the validation signal with washing machine noise by adding washing machine noise to the speech signal such that the signal-to-noise ratio is -10 dB. Use a different noise file for the validation signal than you did for the training signal.

```
noise = audioread("WashingMachine-16-8-mono-200secs.mp3");
noise = resample(noise,2,1);
noise = noise(1:duration);
audioValidation = audioValidation(1:numel(noise));

noise = 10^(-SNR/20) * noise * norm(audioValidation) / norm(noise);
audioValidationNoisy = audioValidation + noise;
audioValidationNoisy = audioValidationNoisy / max(abs(audioValidationNoisy));
```

Extract Training Features

This example trains the LSTM network using the following features:

1. `spectralCentroid` (Audio Toolbox)
2. `spectralCrest` (Audio Toolbox)
3. `spectralEntropy` (Audio Toolbox)
4. `spectralFlux` (Audio Toolbox)
5. `spectralKurtosis` (Audio Toolbox)
6. `spectralRolloffPoint` (Audio Toolbox)
7. `spectralSkewness` (Audio Toolbox)
8. `spectralSlope` (Audio Toolbox)
9. `harmonicRatio` (Audio Toolbox)

This example uses `audioFeatureExtractor` (Audio Toolbox) to create an optimal feature extraction pipeline for the feature set. Create an `audioFeatureExtractor` object to extract the feature set. Use a 256-point Hann window with 50% overlap.

```
afe = audioFeatureExtractor('SampleRate',Fs, ...
    'Window',hann(256,"Periodic"), ...
    'OverlapLength',128, ...
    ...
```

```
    'spectralCentroid',true, ...
    'spectralCrest',true, ...
    'spectralEntropy',true, ...
    'spectralFlux',true, ...
    'spectralKurtosis',true, ...
    'spectralRolloffPoint',true, ...
    'spectralSkewness',true, ...
    'spectralSlope',true, ...
    'harmonicRatio',true);

featuresTraining = extract(afe,audioTrainingNoisy);
```

Display the dimensions of the features matrix. The first dimension corresponds to the number of windows the signal was broken into (it depends on the window length and the overlap length). The second dimension is the number of features used in this example.

```
[numWindows,numFeatures] = size(featuresTraining)
```

```
numWindows = 125009
```

```
numFeatures = 9
```

In classification applications, it is a good practice to normalize all features to have zero mean and unity standard deviation.

Compute the mean and standard deviation for each coefficient, and use them to normalize the data.

```
M = mean(featuresTraining,1);
S = std(featuresTraining,[],1);
featuresTraining = (featuresTraining - M) ./ S;
```

Extract the features from the validation signal using the same process.

```
featuresValidation = extract(afe,audioValidationNoisy);
featuresValidation = (featuresValidation - mean(featuresValidation,1)) ./ std(featuresValidation
```

Each feature corresponds to 128 samples of data (the hop length). For each hop, set the expected voice/no voice value to the mode of the baseline mask values corresponding to those 128 samples. Convert the voice/no voice mask to categorical.

```
windowLength = numel(afe.Window);
hopLength = windowLength - afe.OverlapLength;
range = (hopLength) * (1:size(featuresTraining,1)) + hopLength;
maskMode = zeros(size(range));
for index = 1:numel(range)
    maskMode(index) = mode(maskTraining( (index-1)*hopLength+1:(index-1)*hopLength+windowLength
end
maskTraining = maskMode.';

maskTrainingCat = categorical(maskTraining);
```

Do the same for the validation mask.

```
range = (hopLength) * (1:size(featuresValidation,1)) + hopLength;
maskMode = zeros(size(range));
for index = 1:numel(range)
    maskMode(index) = mode(maskValidation( (index-1)*hopLength+1:(index-1)*hopLength+windowLengt
end
```

```
maskValidation = maskMode.';

maskValidationCat = categorical(maskValidation);
```

Split the training features and the mask into sequences of length 800, with 75% overlap between consecutive sequences.

```
sequenceLength = 800;
sequenceOverlap = round(0.75*sequenceLength);

trainFeatureCell = helperFeatureVector2Sequence(featuresTraining',sequenceLength,sequenceOverlap)
trainLabelCell = helperFeatureVector2Sequence(maskTrainingCat',sequenceLength,sequenceOverlap);
```

Define the LSTM Network Architecture

LSTM networks can learn long-term dependencies between time steps of sequence data. This example uses the bidirectional LSTM layer `bilstmLayer` to look at the sequence in both forward and backward directions.

Specify the input size to be sequences of length `9` (the number of features). Specify a hidden bidirectional LSTM layer with an output size of 200 and output a sequence. This command instructs the bidirectional LSTM layer to map the input time series into 200 features that are passed to the next layer. Then, specify a bidirectional LSTM layer with an output size of 200 and output the last element of the sequence. This command instructs the bidirectional LSTM layer to map its input into 200 features and then prepares the output for the fully connected layer. Finally, specify two classes by including a fully connected layer of size `2`, followed by a softmax layer and a classification layer.

```
layers = [ ...
    sequenceInputLayer( size(featuresValidation,2) )
    bilstmLayer(200,"OutputMode","sequence")
    bilstmLayer(200,"OutputMode","sequence")
    fullyConnectedLayer(2)
    softmaxLayer
    classificationLayer
    ];
```

Next, specify the training options for the classifier. Set `MaxEpochs` to `20` so that the network makes 20 passes through the training data. Set `MiniBatchSize` to `64` so that the network looks at 64 training signals at a time. Set `Plots` to `"training-progress"` to generate plots that show the training progress as the number of iterations increases. Set `Verbose` to `false` to disable printing the table output that corresponds to the data shown in the plot. Set `Shuffle` to `"every-epoch"` to shuffle the training sequence at the beginning of each epoch. Set `LearnRateSchedule` to `"piecewise"` to decrease the learning rate by a specified factor (0.1) every time a certain number of epochs (10) has passed. Set `ValidationData` to the validation predictors and targets.

This example uses the adaptive moment estimation (ADAM) solver. ADAM performs better with recurrent neural networks (RNNs) like LSTMs than the default stochastic gradient descent with momentum (SGDM) solver.

```
maxEpochs = 20;
miniBatchSize = 64;
options = trainingOptions("adam", ...
    "MaxEpochs",maxEpochs, ...
    "MiniBatchSize",miniBatchSize, ...
    "Shuffle","every-epoch", ...
    "Verbose",0, ...
```

```
    "SequenceLength",sequenceLength, ...
    "ValidationFrequency",floor(numel(trainFeatureCell)/miniBatchSize), ...
    "ValidationData",{featuresValidation.',maskValidationCat.'}, ...
    "Plots","training-progress", ...
    "LearnRateSchedule","piecewise", ...
    "LearnRateDropFactor",0.1, ...
    "LearnRateDropPeriod",5);
```

Train the LSTM Network

Train the LSTM network with the specified training options and layer architecture using `trainNetwork`. Because the training set is large, the training process can take several minutes.

```
doTraining = true;
if doTraining
   [speechDetectNet,netInfo] = trainNetwork(trainFeatureCell,trainLabelCell,layers,options);
    fprintf("Validation accuracy: %f percent.\n", netInfo.FinalValidationAccuracy);
else
    load speechDetectNet
end
```

```
Validation accuracy: 91.320312 percent.
```

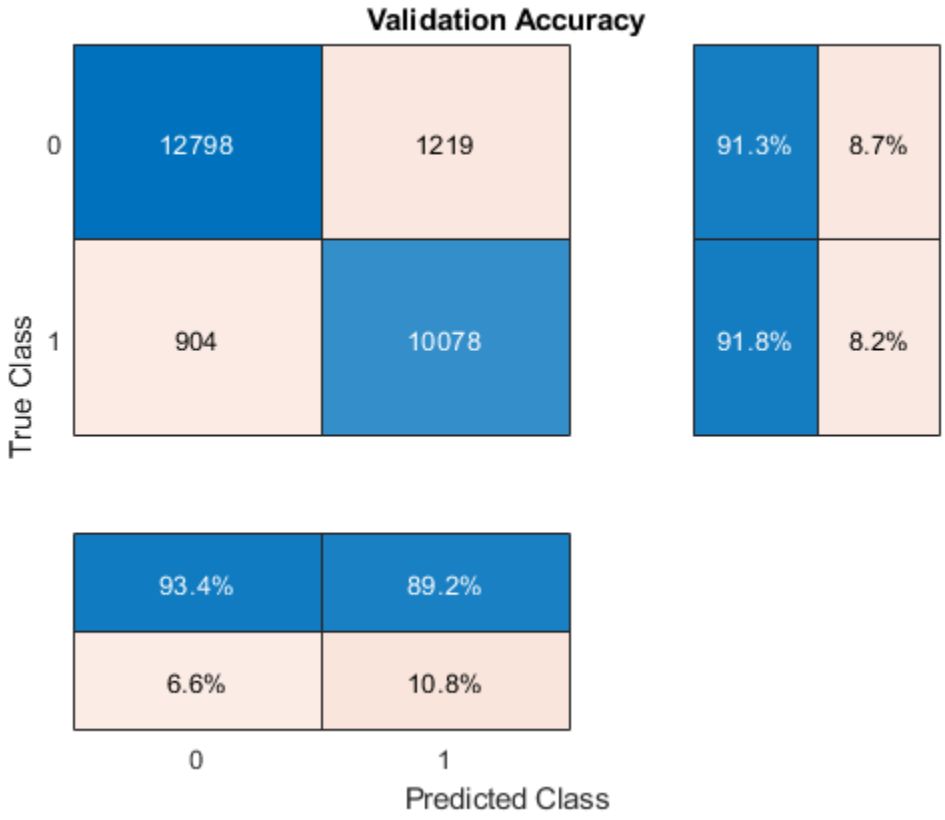
Use Trained Network to Detect Voice Activity

Estimate voice activity in the validation signal using the trained network. Convert the estimated VAD mask from categorical to double.

```
EstimatedVADMask = classify(speechDetectNet,featuresValidation.');
EstimatedVADMask = double(EstimatedVADMask);
EstimatedVADMask = EstimatedVADMask.' - 1;
```

Calculate and plot the validation confusion matrix from the vectors of actual and estimated labels.

```
figure
cm = confusionchart(maskValidation,EstimatedVADMask,"title","Validation Accuracy");
cm.ColumnSummary = "column-normalized";
cm.RowSummary = "row-normalized";
```



If you changed parameters of your network or feature extraction pipeline, consider resaving the MAT file with the new network and `audioFeatureExtractor` object.

```
resaveNetwork = false;
if resaveNetwork
     save('Audio_VoiceActivityDetectionExample.mat','speechDetectNet','afe');
end
```

Supporting Functions

Convert Feature Vectors to Sequences

```
function [sequences,sequencePerFile] = helperFeatureVector2Sequence(features,featureVectorsPerSe
    if featureVectorsPerSequence <= featureVectorOverlap
        error('The number of overlapping feature vectors must be less than the number of feature
    end

    if ~iscell(features)
        features = {features};
    end
    hopLength = featureVectorsPerSequence - featureVectorOverlap;
    idx1 = 1;
    sequences = {};
    sequencePerFile = cell(numel(features),1);
    for ii = 1:numel(features)
        sequencePerFile{ii} = floor((size(features{ii},2) - featureVectorsPerSequence)/hopLength
        idx2 = 1;
```

```
        for j = 1:sequencePerFile{ii}
            sequences{idx1,1} = features{ii}(:,idx2:idx2 + featureVectorsPerSequence - 1); %#ok<A
            idx1 = idx1 + 1;
            idx2 = idx2 + hopLength;
        end
    end
end
```

Streaming Demo

```
function helperStreamingDemo(speechDetectNet,afe,cleanSpeech,noise,testDuration,sequenceLength,se
```

Create `dsp.AudioFileReader` (DSP System Toolbox) objects to read from the speech and noise files frame by frame.

```
speechReader = dsp.AudioFileReader(cleanSpeech,'PlayCount',inf);
noiseReader = dsp.AudioFileReader(noise,'PlayCount',inf);
fs = speechReader.SampleRate;
```

Create a `dsp.MovingStandardDeviation` (DSP System Toolbox) object and a `dsp.MovingAverage` (DSP System Toolbox) object. You will use these to determine the standard deviation and mean of the audio features for normalization. The statistics should improve over time.

```
movSTD = dsp.MovingStandardDeviation('Method','Exponential weighting','ForgettingFactor',1);
movMean = dsp.MovingAverage('Method','Exponential weighting','ForgettingFactor',1);
```

Create three `dsp.AsyncBuffer` (DSP System Toolbox) objects. One to buffer the input audio, one to buffer the extracted features, and one to buffer the output buffer. The output buffer is only necessary for visualizing the decisions in real time.

```
audioInBuffer = dsp.AsyncBuffer;
featureBuffer = dsp.AsyncBuffer;
audioOutBuffer = dsp.AsyncBuffer;
```

For the audio buffers, you will buffer both the original clean speech signal, and the noisy signal. You will play back only the specified `signalToListenTo`. Convert the `signalToListenTo` variable to the channel you want to listen to.

```
channelToListenTo = 1;
if strcmp(signalToListenTo,"clean")
    channelToListenTo = 2;
end
```

Create a time scope to visualize the original speech signal, the noisy signal that the network is applied to, and the decision output from the network.

```
scope = timescope('SampleRate',fs, ...
    'TimeSpanSource','property', ...
    'TimeSpan',3, ...
    'BufferLength',fs*3*3, ...
    'YLimits',[-1 1], ...
    'TimeSpanOverrunAction','Scroll', ...
    'ShowGrid',true, ...
    'NumInputPorts',3, ...
    'LayoutDimensions',[3,1], ...
    'Title','Noisy Speech');
scope.ActiveDisplay = 2;
scope.Title = 'Clean Speech (Original)';
```

```
scope.YLimits = [-1 1];
scope.ActiveDisplay = 3;
scope.Title = 'Detected Speech';
scope.YLimits = [-1 1];
```

Create an `audioDeviceWriter` (Audio Toolbox) object to play either the original or noisy audio from your speakers.

```
deviceWriter = audioDeviceWriter('SampleRate',fs);
```

Initialize variables used in the loop.

```
windowLength = numel(afe.Window);
hopLength = windowLength - afe.OverlapLength;
myMax = 0;
audioBufferInitialized = false;
featureBufferInitialized = false;
```

Run the streaming demonstration.

```
tic
while toc < testDuration

    % Read a frame of the speech signal and a frame of the noise signal
    speechIn = speechReader();
    noiseIn = noiseReader();

    % Mix the speech and noise at the specified SNR
    noisyAudio = speechIn + noiseGain*noiseIn;

    % Update a running max for normalization
    myMax = max(myMax,max(abs(noisyAudio)));

    % Write the noisy audio and speech to buffers
    write(audioInBuffer,[noisyAudio,speechIn]);

    % If enough samples are buffered,
    % mark the audio buffer as initialized and push the read pointer
    % for the audio buffer up a window length.
    if audioInBuffer.NumUnreadSamples >= windowLength && ~audioBufferInitialized
        audioBufferInitialized = true;
        read(audioInBuffer,windowLength);
    end

    % If enough samples are in the audio buffer to calculate a feature
    % vector, read the samples, normalize them, extract the feature vectors, and write
    % the latest feature vector to the features buffer.
    while (audioInBuffer.NumUnreadSamples >= hopLength) && audioBufferInitialized
        x = read(audioInBuffer,windowLength + hopLength,windowLength);
        write(audioOutBuffer,x(end-hopLength+1:end,:));
        noisyAudio = x(:,1);
        noisyAudio = noisyAudio/myMax;
        features = extract(afe,noisyAudio);
        write(featureBuffer,features(2,:));
    end

    % If enough feature vectors are buffered, mark the feature buffer
    % as initialized and push the read pointer for the feature buffer
```

```
            % and the audio output buffer (so that they are in sync).
            if featureBuffer.NumUnreadSamples >= (sequenceLength + sequenceHop) && ~featureBufferIni
                featureBufferInitialized = true;
                read(featureBuffer,sequenceLength - sequenceHop);
                read(audioOutBuffer,(sequenceLength - sequenceHop)*windowLength);
            end

            while featureBuffer.NumUnreadSamples >= sequenceHop && featureBufferInitialized
                features = read(featureBuffer,sequenceLength,sequenceLength - sequenceHop);
                features(isnan(features)) = 0;

                % Use only the new features to update the
                % standard deviation and mean. Normalize the features.
                localSTD = movSTD(features(end-sequenceHop+1:end,:));
                localMean = movMean(features(end-sequenceHop+1:end,:));
                features = (features - localMean(end,:)) ./ localSTD(end,:);

                decision = classify(speechDetectNet,features');
                decision = decision(end-sequenceHop+1:end);
                decision = double(decision)' - 1;
                decision = repelem(decision,hopLength);

                audioHop = read(audioOutBuffer,sequenceHop*hopLength);

                % Listen to the speech or speech+noise
                deviceWriter(audioHop(:,channelToListenTo));

                % Visualize the speech+noise, the original speech, and the
                % voice activity detection.
                scope(audioHop(:,1),audioHop(:,2),audioHop(:,1).*decision)
            end
        end
        release(deviceWriter)
        release(audioInBuffer)
        release(audioOutBuffer)
        release(featureBuffer)
        release(movSTD)
        release(movMean)
        release(scope)
    end
```

Denoise Speech Using Deep Learning Networks

This example shows how to denoise speech signals using deep learning networks. The example compares two types of networks applied to the same task: fully connected, and convolutional.

Introduction

The aim of speech denoising is to remove noise from speech signals while enhancing the quality and intelligibility of speech. This example showcases the removal of washing machine noise from speech signals using deep learning networks. The example compares two types of networks applied to the same task: fully connected, and convolutional.

Problem Summary

Consider the following speech signal sampled at 8 kHz.

```
[cleanAudio,fs] = audioread("SpeechDFT-16-8-mono-5secs.wav");
sound(cleanAudio,fs)
```

Add washing machine noise to the speech signal. Set the noise power such that the signal-to-noise ratio (SNR) is zero dB.

```
noise = audioread("WashingMachine-16-8-mono-1000secs.mp3");

% Extract a noise segment from a random location in the noise file
ind = randi(numel(noise) - numel(cleanAudio) + 1, 1, 1);
noiseSegment = noise(ind:ind + numel(cleanAudio) - 1);

speechPower = sum(cleanAudio.^2);
noisePower = sum(noiseSegment.^2);
noisyAudio = cleanAudio + sqrt(speechPower/noisePower) * noiseSegment;
```

Listen to the noisy speech signal.

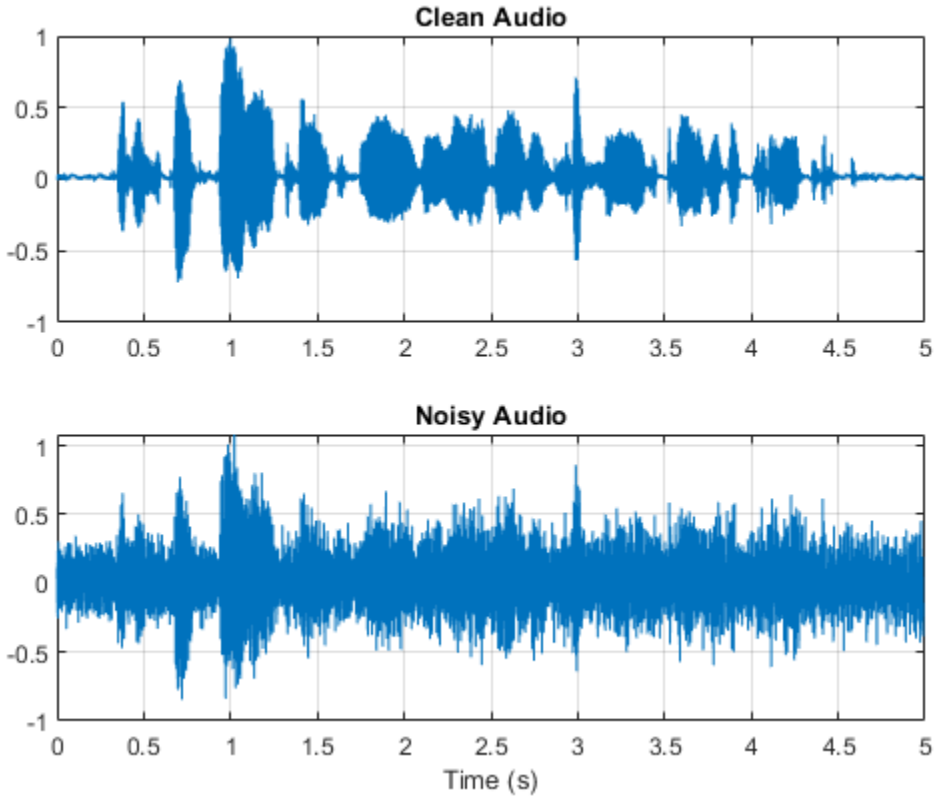
```
sound(noisyAudio,fs)
```

Visualize the original and noisy signals.

```
t = (1/fs) * (0:numel(cleanAudio)-1);

subplot(2,1,1)
plot(t,cleanAudio)
title("Clean Audio")
grid on

subplot(2,1,2)
plot(t,noisyAudio)
title("Noisy Audio")
xlabel("Time (s)")
grid on
```



The objective of speech denoising is to remove the washing machine noise from the speech signal while minimizing undesired artifacts in the output speech.

Examine the Dataset

This example uses a subset of the Mozilla Common Voice dataset [1 on page 14-0] to train and test the deep learning networks. The data set contains 48 kHz recordings of subjects speaking short sentences. Download the data set and unzip the downloaded file.

```
url = 'http://ssd.mathworks.com/supportfiles/audio/commonvoice.zip';
downloadFolder = tempdir;
dataFolder = fullfile(downloadFolder,'commonvoice');

if ~exist(dataFolder,'dir')
    disp('Downloading data set (956 MB) ...')
    unzip(url,downloadFolder)
end
```

Use `audioDatastore` to create a datastore for the training set. To speed up the runtime of the example at the cost of performance, set `reduceDataset` to `true`.

```
adsTrain = audioDatastore(fullfile(dataFolder,'train'),'IncludeSubfolders',true);

reduceDataset = true;
if reduceDataset
    adsTrain = shuffle(adsTrain);
```

```
    adsTrain = subset(adsTrain,1:1000);
end
```

Use `read` to get the contents of the first file in the datastore.

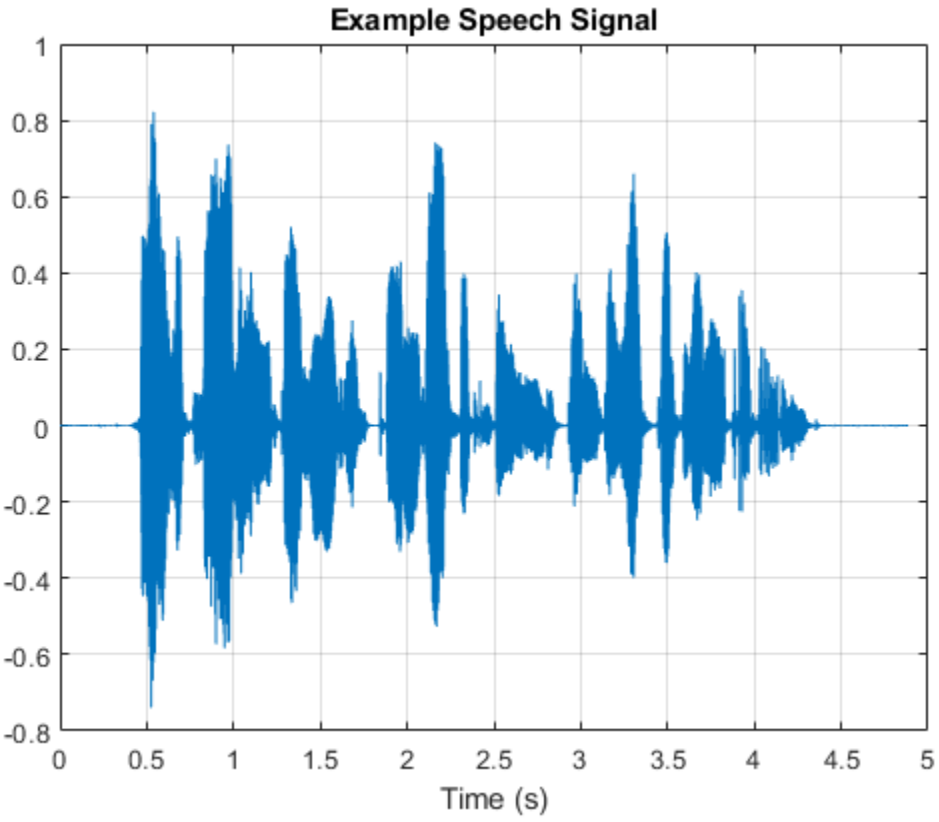
```
[audio,adsTrainInfo] = read(adsTrain);
```

Listen to the speech signal.

```
sound(audio,adsTrainInfo.SampleRate)
```

Plot the speech signal.

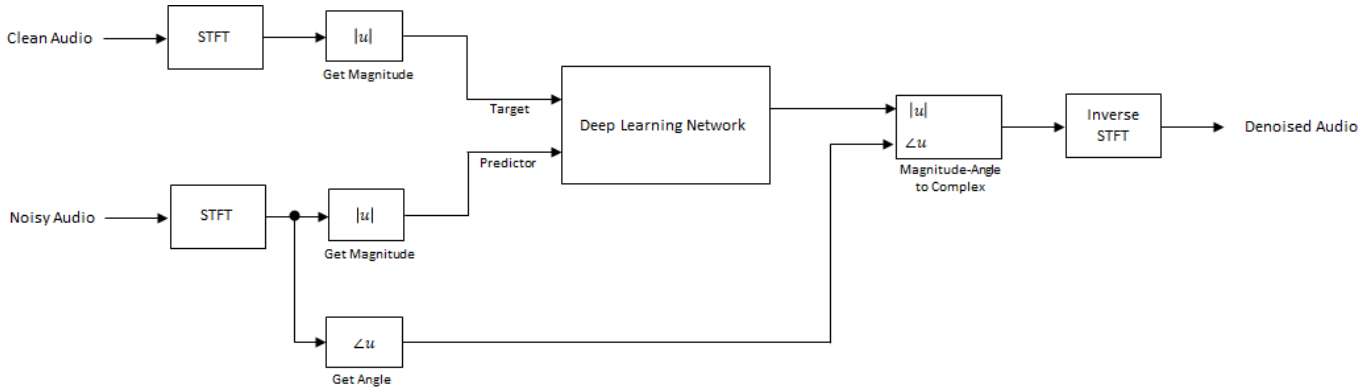
```
figure
t = (1/adsTrainInfo.SampleRate) * (0:numel(audio)-1);
plot(t,audio)
title("Example Speech Signal")
xlabel("Time (s)")
grid on
```



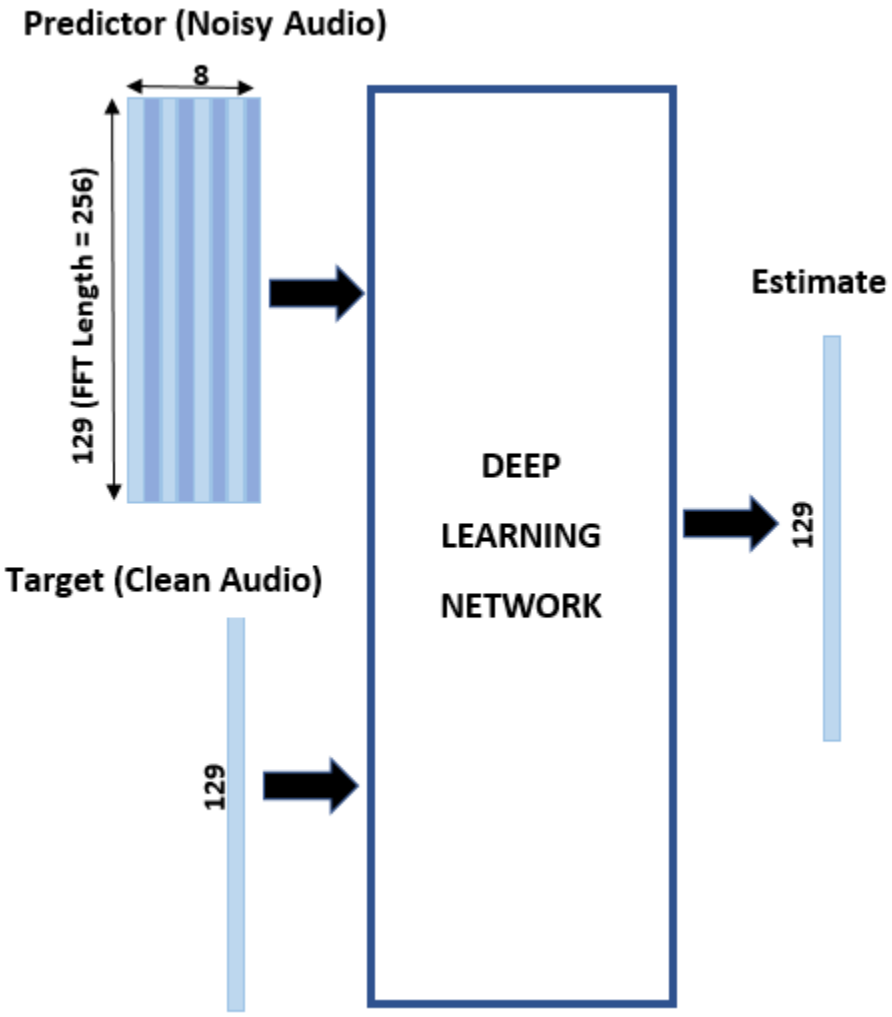
Deep Learning System Overview

The basic deep learning training scheme is shown below. Note that, since speech generally falls below 4 kHz, you first downsample the clean and noisy audio signals to 8 kHz to reduce the computational load of the network. The predictor and target network signals are the magnitude spectra of the noisy and clean audio signals, respectively. The network's output is the magnitude spectrum of the denoised signal. The regression network uses the predictor input to minimize the mean square error between its output and the input target. The denoised audio is converted back to

the time domain using the output magnitude spectrum and the phase of the noisy signal [2 on page 14-0].



You transform the audio to the frequency domain using the Short-Time Fourier transform (STFT), with a window length of 256 samples, an overlap of 75%, and a Hamming window. You reduce the size of the spectral vector to 129 by dropping the frequency samples corresponding to negative frequencies (because the time-domain speech signal is real, this does not lead to any information loss). The predictor input consists of 8 consecutive noisy STFT vectors, so that each STFT output estimate is computed based on the current noisy STFT and the 7 previous noisy STFT vectors.



STFT Targets and Predictors

This section illustrates how to generate the target and predictor signals from one training file.

First, define system parameters:

```
windowLength = 256;
win = hamming(windowLength,"periodic");
overlap = round(0.75 * windowLength);
ffTLength = windowLength;
inputFs = 48e3;
fs = 8e3;
numFeatures = ffTLength/2 + 1;
numSegments = 8;
```

Create a `dsp.SampleRateConverter` (DSP System Toolbox) object to convert the 48 kHz audio to 8 kHz.

```
src = dsp.SampleRateConverter("InputSampleRate",inputFs, ...
                              "OutputSampleRate",fs, ...
                              "Bandwidth",7920);
```

Use `read` to get the contents of an audio file from the datastore.

```
audio = read(adsTrain);
```

Make sure the audio length is a multiple of the sample rate converter decimation factor.

```
decimationFactor = inputFs/fs;
L = floor(numel(audio)/decimationFactor);
audio = audio(1:decimationFactor*L);
```

Convert the audio signal to 8 kHz.

```
audio = src(audio);
reset(src)
```

Create a random noise segment from the washing machine noise vector.

```
randind = randi(numel(noise) - numel(audio),[1 1]);
noiseSegment = noise(randind : randind + numel(audio) - 1);
```

Add noise to the speech signal such that the SNR is 0 dB.

```
noisePower = sum(noiseSegment.^2);
cleanPower = sum(audio.^2);
noiseSegment = noiseSegment .* sqrt(cleanPower/noisePower);
noisyAudio = audio + noiseSegment;
```

Use `stft` (Signal Processing Toolbox) to generate magnitude STFT vectors from the original and noisy audio signals.

```
cleanSTFT = stft(audio,'Window',win,'OverlapLength',overlap,'FFTLength',ffTLength);
cleanSTFT = abs(cleanSTFT(numFeatures-1:end,:));
noisySTFT = stft(noisyAudio,'Window',win,'OverlapLength',overlap,'FFTLength',ffTLength);
noisySTFT = abs(noisySTFT(numFeatures-1:end,:));
```

Generate the 8-segment training predictor signals from the noisy STFT. The overlap between consecutive predictors is 7 segments.

```
noisySTFT = [noisySTFT(:,1:numSegments - 1), noisySTFT];
stftSegments = zeros(numFeatures, numSegments , size(noisySTFT,2) - numSegments + 1);
for index = 1:size(noisySTFT,2) - numSegments + 1
    stftSegments(:,:,index) = (noisySTFT(:,index:index + numSegments - 1));
end
```

Set the targets and predictors. The last dimension of both variables corresponds to the number of distinct predictor/target pairs generated by the audio file. Each predictor is 129-by-8, and each target is 129-by-1.

```
targets = cleanSTFT;
size(targets)
```

```
ans = 1×2

   129   544
```

```
predictors = stftSegments;
size(predictors)
```

```
ans = 1×3

   129     8   544
```

Extract Features Using Tall Arrays

To speed up processing, extract feature sequences from the speech segments of all audio files in the datastore using tall arrays. Unlike in-memory arrays, tall arrays typically remain unevaluated until you call the `gather` function. This deferred evaluation enables you to work quickly with large data sets. When you eventually request output using `gather`, MATLAB combines the queued calculations where possible and takes the minimum number of passes through the data. If you have Parallel Computing Toolbox™, you can use tall arrays in your local MATLAB session, or on a local parallel pool. You can also run tall array calculations on a cluster if you have MATLAB® Parallel Server™ installed.

First, convert the datastore to a tall array.

```
reset(adsTrain)
T = tall(adsTrain)
```

```
Starting parallel pool (parpool) using the 'local' profile ...
Connected to the parallel pool (number of workers: 6).

T =

  M×1 tall cell array

    {234480×1 double}
    {210288×1 double}
    {282864×1 double}
    {292080×1 double}
    {410736×1 double}
    {303600×1 double}
    {326640×1 double}
    {233328×1 double}
        :        :
        :        :
```

The display indicates that the number of rows (corresponding to the number of files in the datastore), M, is not yet known. M is a placeholder until the calculation completes.

Extract the target and predictor magnitude STFT from the tall table. This action creates new tall array variables to use in subsequent calculations. The function `HelperGenerateSpeechDenoisingFeatures` performs the steps already highlighted in the STFT Targets and Predictors on page 14-0 section. The `cellfun` command applies `HelperGenerateSpeechDenoisingFeatures` to the contents of each audio file in the datastore.

```
[targets,predictors] = cellfun(@(x)HelperGenerateSpeechDenoisingFeatures(x,noise,src),T,"Uniform(
```

Use `gather` to evaluate the targets and predictors.

```
[targets,predictors] = gather(targets,predictors);
```

```
Evaluating tall expression using the Parallel Pool 'local':
- Pass 1 of 1: Completed in 42 sec
Evaluation completed in 1 min 36 sec
```

It is good practice to normalize all features to zero mean and unity standard deviation.

Compute the mean and standard deviation of the predictors and targets, respectively, and use them to normalize the data.

```
predictors = cat(3,predictors{:});
noisyMean = mean(predictors(:));
noisyStd = std(predictors(:));
predictors(:) = (predictors(:) - noisyMean)/noisyStd;

targets = cat(2,targets{:});
cleanMean = mean(targets(:));
cleanStd = std(targets(:));
targets(:) = (targets(:) - cleanMean)/cleanStd;
```

Reshape predictors and targets to the dimensions expected by the deep learning networks.

```
predictors = reshape(predictors,size(predictors,1),size(predictors,2),1,size(predictors,3));
targets = reshape(targets,1,1,size(targets,1),size(targets,2));
```

You will use 1% of the data for validation during training. Validation is useful to detect scenarios where the network is overfitting the training data.

Randomly split the data into training and validation sets.

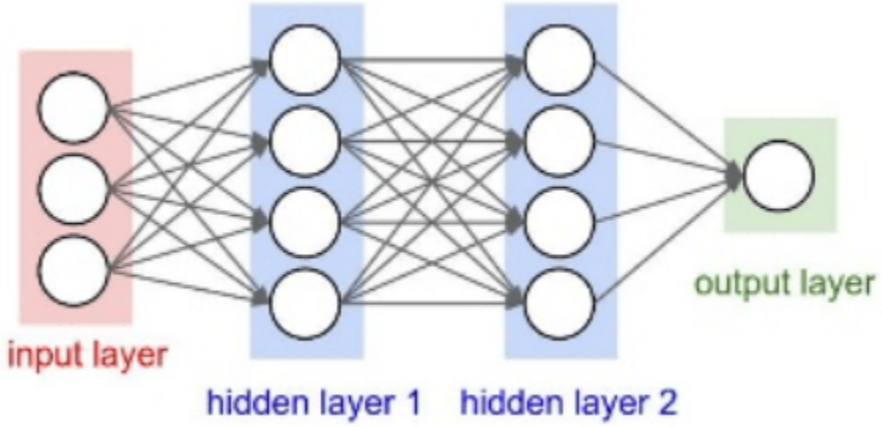
```
inds = randperm(size(predictors,4));
L = round(0.99 * size(predictors,4));

trainPredictors = predictors(:,:,:,inds(1:L));
trainTargets = targets(:,:,:,inds(1:L));

validatePredictors = predictors(:,:,:,inds(L+1:end));
validateTargets = targets(:,:,:,inds(L+1:end));
```

Speech Denoising with Fully Connected Layers

You first consider a denoising network comprised of fully connected layers. Each neuron in a fully connected layer is connected to all activations from the previous layer. A fully connected layer multiplies the input by a weight matrix and then adds a bias vector. The dimensions of the weight matrix and bias vector are determined by the number of neurons in the layer and the number of activations from the previous layer.



Define the layers of the network. Specify the input size to be images of size `NumFeatures`-by-`NumSegments` (129-by-8 in this example). Define two hidden fully connected layers, each with 1024 neurons. Since purely linear systems, follow each hidden fully connected layer with a Rectified Linear Unit (ReLU) layer. The batch normalization layers normalize the means and standard deviations of the outputs. Add a fully connected layer with 129 neurons, followed by a regression layer.

```
layers = [
    imageInputLayer([numFeatures,numSegments])
    fullyConnectedLayer(1024)
    batchNormalizationLayer
    reluLayer
    fullyConnectedLayer(1024)
    batchNormalizationLayer
    reluLayer
    fullyConnectedLayer(numFeatures)
    regressionLayer
    ];
```

Next, specify the training options for the network. Set `MaxEpochs` to `3` so that the network makes 3 passes through the training data. Set `MiniBatchSize` of `128` so that the network looks at 128 training signals at a time. Specify `Plots` as `"training-progress"` to generate plots that show the training progress as the number of iterations increases. Set `Verbose` to `false` to disable printing the table output that corresponds to the data shown in the plot into the command line window. Specify `Shuffle` as `"every-epoch"` to shuffle the training sequences at the beginning of each epoch. Specify `LearnRateSchedule` to `"piecewise"` to decrease the learning rate by a specified factor (0.9) every time a certain number of epochs (1) has passed. Set `ValidationData` to the validation predictors and targets. Set `ValidationFrequency` such that the validation mean square error is computed once per epoch. This example uses the adaptive moment estimation (Adam) solver.

```
miniBatchSize = 128;
options = trainingOptions("adam", ...
    "MaxEpochs",3, ...
    "InitialLearnRate",1e-5,...
    "MiniBatchSize",miniBatchSize, ...
    "Shuffle","every-epoch", ...
    "Plots","training-progress", ...
    "Verbose",false, ...
    "ValidationFrequency",floor(size(trainPredictors,4)/miniBatchSize), ...
    "LearnRateSchedule","piecewise", ...
    "LearnRateDropFactor",0.9, ...
    "LearnRateDropPeriod",1, ...
    "ValidationData",{validatePredictors,validateTargets});
```

Train the network with the specified training options and layer architecture using `trainNetwork`. Because the training set is large, the training process can take several minutes. To download and load a pre-trained network instead of training a network from scratch, set `doTraining` to `false`.

```
doTraining = true;
if doTraining
    denoiseNetFullyConnected = trainNetwork(trainPredictors,trainTargets,layers,options);
else
    url = 'http://ssd.mathworks.com/supportfiles/audio/SpeechDenoising.zip';
    downloadNetFolder = tempdir;
    netFolder = fullfile(downloadNetFolder,'SpeechDenoising');
    if ~exist(netFolder,'dir')
        disp('Downloading pretrained network (1 file - 8 MB) ...')
```

```
        unzip(url,downloadNetFolder)
    end
    s = load(fullfile(netFolder,"denoisenet.mat"));
    denoiseNetFullyConnected = s.denoiseNetFullyConnected;
    cleanMean = s.cleanMean;
    cleanStd = s.cleanStd;
    noisyMean = s.noisyMean;
    noisyStd = s.noisyStd;
end
```

Count the number of weights in the fully connected layers of the network.

```
numWeights = 0;
for index = 1:numel(denoiseNetFullyConnected.Layers)
    if isa(denoiseNetFullyConnected.Layers(index),"nnet.cnn.layer.FullyConnectedLayer")
        numWeights = numWeights + numel(denoiseNetFullyConnected.Layers(index).Weights);
    end
end
fprintf("The number of weights is %d.\n",numWeights);
```

```
The number of weights is 2237440.
```

Speech Denoising with Convolutional Layers

Consider a network that uses convolutional layers instead of fully connected layers [3 on page 14-0]. A 2-D convolutional layer applies sliding filters to the input. The layer convolves the input by moving the filters along the input vertically and horizontally and computing the dot product of the weights and the input, and then adding a bias term. Convolutional layers typically consist of fewer parameters than fully connected layers.

Define the layers of the fully convolutional network described in [3 on page 14-0], comprising 16 convolutional layers. The first 15 convolutional layers are groups of 3 layers, repeated 5 times, with filter widths of 9, 5, and 9, and number of filters of 18, 30 and 8, respectively. The last convolutional layer has a filter width of 129 and 1 filter. In this network, convolutions are performed in only one direction (along the frequency dimension), and the filter width along the time dimension is set to 1 for all layers except the first one. Similar to the fully connected network, convolutional layers are followed by ReLu and batch normalization layers.

```
layers = [imageInputLayer([numFeatures,numSegments])
          convolution2dLayer([9 8],18,"Stride",[1 100],"Padding","same")
          batchNormalizationLayer
          reluLayer

          repmat( ...
          [convolution2dLayer([5 1],30,"Stride",[1 100],"Padding","same")
          batchNormalizationLayer
          reluLayer
          convolution2dLayer([9 1],8,"Stride",[1 100],"Padding","same")
          batchNormalizationLayer
          reluLayer
          convolution2dLayer([9 1],18,"Stride",[1 100],"Padding","same")
          batchNormalizationLayer
          reluLayer],4,1)

          convolution2dLayer([5 1],30,"Stride",[1 100],"Padding","same")
          batchNormalizationLayer
          reluLayer
```

```
    convolution2dLayer([9 1],8,"Stride",[1 100],"Padding","same")
    batchNormalizationLayer
    reluLayer

    convolution2dLayer([129 1],1,"Stride",[1 100],"Padding","same")

    regressionLayer
    ];
```

The training options are identical to the options for the fully connected network, except that the dimensions of the validation target signals are permuted to be consistent with the dimensions expected by the regression layer.

```
options = trainingOptions("adam", ...
    "MaxEpochs",3, ...
    "InitialLearnRate",1e-5, ...
    "MiniBatchSize",miniBatchSize, ...
    "Shuffle","every-epoch", ...
    "Plots","training-progress", ...
    "Verbose",false, ...
    "ValidationFrequency",floor(size(trainPredictors,4)/miniBatchSize), ...
    "LearnRateSchedule","piecewise", ...
    "LearnRateDropFactor",0.9, ...
    "LearnRateDropPeriod",1, ...
    "ValidationData",{validatePredictors,permute(validateTargets,[3 1 2 4])});
```

Train the network with the specified training options and layer architecture using `trainNetwork`. Because the training set is large, the training process can take several minutes. To download and load a pre-trained network instead of training a network from scratch, set `doTraining` to `false`.

```
doTraining = true;
if doTraining
    denoiseNetFullyConvolutional = trainNetwork(trainPredictors,permute(trainTargets,[3 1 2 4]),
else
    url = 'http://ssd.mathworks.com/supportfiles/audio/SpeechDenoising.zip';
    downloadNetFolder = tempdir;
    netFolder = fullfile(downloadNetFolder,'SpeechDenoising');
    if ~exist(netFolder,'dir')
        disp('Downloading pretrained network (1 file - 8 MB) ...')
        unzip(url,downloadNetFolder)
    end
    s = load(fullfile(netFolder,"denoisenet.mat"));
    denoiseNetFullyConvolutional = s.denoiseNetFullyConvolutional;
    cleanMean = s.cleanMean;
    cleanStd = s.cleanStd;
    noisyMean = s.noisyMean;
    noisyStd = s.noisyStd;
end
```

Count the number of weights in the fully connected layers of the network.

```
numWeights = 0;
for index = 1:numel(denoiseNetFullyConvolutional.Layers)
    if isa(denoiseNetFullyConvolutional.Layers(index),"nnet.cnn.layer.Convolution2DLayer")
        numWeights = numWeights + numel(denoiseNetFullyConvolutional.Layers(index).Weights);
    end
end
fprintf("The number of weights in convolutional layers is %d\n",numWeights);
```

```
The number of weights in convolutional layers is 31812
```

Test the Denoising Networks

Read in the test data set.

```
adsTest = audioDatastore(fullfile(dataFolder,'test'),'IncludeSubfolders',true);
```

Read the contents of a file from the datastore.

```
[cleanAudio,adsTestInfo] = read(adsTest);
```

Make sure the audio length is a multiple of the sample rate converter decimation factor.

```
L = floor(numel(cleanAudio)/decimationFactor);
cleanAudio = cleanAudio(1:decimationFactor*L);
```

Convert the audio signal to 8 kHz.

```
cleanAudio = src(cleanAudio);
reset(src)
```

In this testing stage, you corrupt speech with washing machine noise not used in the training stage.

```
noise = audioread("WashingMachine-16-8-mono-200secs.mp3");
```

Create a random noise segment from the washing machine noise vector.

```
randind = randi(numel(noise) - numel(cleanAudio), [1 1]);
noiseSegment = noise(randind : randind + numel(cleanAudio) - 1);
```

Add noise to the speech signal such that the SNR is 0 dB.

```
noisePower = sum(noiseSegment.^2);
cleanPower = sum(cleanAudio.^2);
noiseSegment = noiseSegment .* sqrt(cleanPower/noisePower);
noisyAudio = cleanAudio + noiseSegment;
```

Use `stft` to generate magnitude STFT vectors from the noisy audio signals.

```
noisySTFT = stft(noisyAudio,'Window',win,'OverlapLength',overlap,'FFTLength',ffTLength);
noisyPhase = angle(noisySTFT(numFeatures-1:end,:));
noisySTFT = abs(noisySTFT(numFeatures-1:end,:));
```

Generate the 8-segment training predictor signals from the noisy STFT. The overlap between consecutive predictors is 7 segments.

```
noisySTFT = [noisySTFT(:,1:numSegments-1) noisySTFT];
predictors = zeros( numFeatures, numSegments , size(noisySTFT,2) - numSegments + 1);
for index = 1:(size(noisySTFT,2) - numSegments + 1)
    predictors(:,:,index) = noisySTFT(:,index:index + numSegments - 1);
end
```

Normalize the predictors by the mean and standard deviation computed in the training stage.

```
predictors(:) = (predictors(:) - noisyMean) / noisyStd;
```

Compute the denoised magnitude STFT by using `predict` with the two trained networks.

```
predictors = reshape(predictors, [numFeatures,numSegments,1,size(predictors,3)]);
STFTFullyConnected = predict(denoiseNetFullyConnected, predictors);
STFTFullyConvolutional = predict(denoiseNetFullyConvolutional, predictors);
```

Scale the outputs by the mean and standard deviation used in the training stage.

```
STFTFullyConnected(:) = cleanStd * STFTFullyConnected(:) + cleanMean;
STFTFullyConvolutional(:) = cleanStd * STFTFullyConvolutional(:) + cleanMean;
```

Convert the one-sided STFT to a centered STFT.

```
STFTFullyConnected = STFTFullyConnected.' .* exp(1j*noisyPhase);
STFTFullyConnected = [conj(STFTFullyConnected(end-1:-1:2,:)); STFTFullyConnected];
STFTFullyConvolutional = squeeze(STFTFullyConvolutional) .* exp(1j*noisyPhase);
STFTFullyConvolutional = [conj(STFTFullyConvolutional(end-1:-1:2,:)) ; STFTFullyConvolutional];
```

Compute the denoised speech signals. `istft` performs the inverse STFT. Use the phase of the noisy STFT vectors to reconstruct the time-domain signal.

```
denoisedAudioFullyConnected = istft(STFTFullyConnected,  ...
                                    'Window',win,'OverlapLength',overlap, ...
                                    'FFTLength',ffTLength,'ConjugateSymmetric',true);

denoisedAudioFullyConvolutional = istft(STFTFullyConvolutional,  ...
                                        'Window',win,'OverlapLength',overlap, ...
                                        'FFTLength',ffTLength,'ConjugateSymmetric',true);
```

Plot the clean, noisy and denoised audio signals.

```
t = (1/fs) * (0:numel(denoisedAudioFullyConnected)-1);

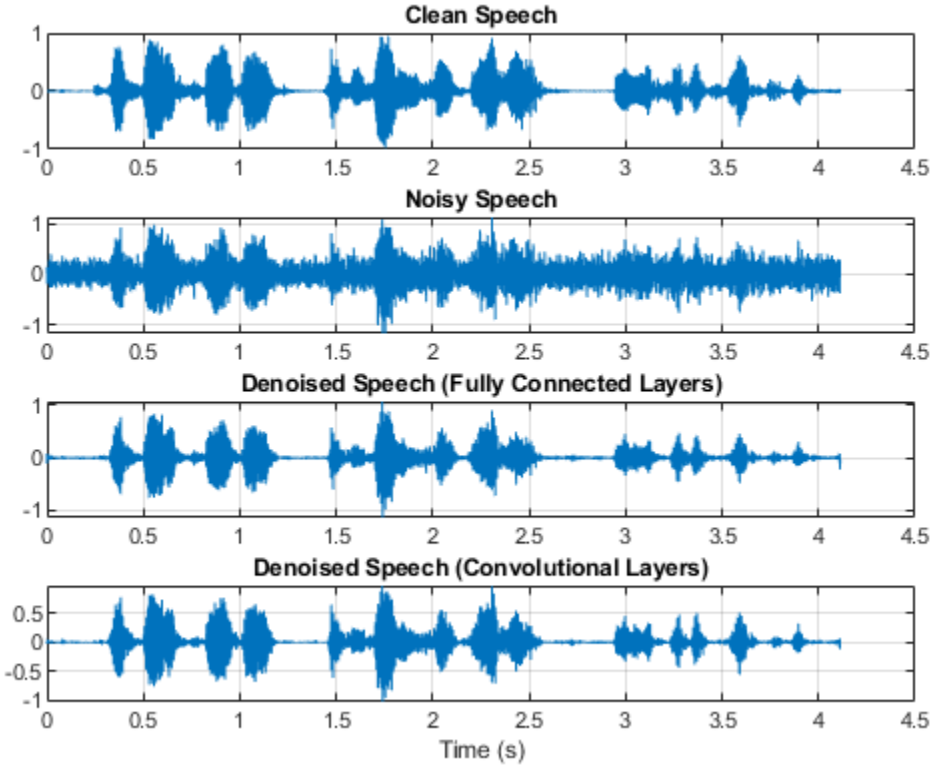
figure

subplot(4,1,1)
plot(t,cleanAudio(1:numel(denoisedAudioFullyConnected)))
title("Clean Speech")
grid on

subplot(4,1,2)
plot(t,noisyAudio(1:numel(denoisedAudioFullyConnected)))
title("Noisy Speech")
grid on

subplot(4,1,3)
plot(t,denoisedAudioFullyConnected)
title("Denoised Speech (Fully Connected Layers)")
grid on

subplot(4,1,4)
plot(t,denoisedAudioFullyConvolutional)
title("Denoised Speech (Convolutional Layers)")
grid on
xlabel("Time (s)")
```



Plot the clean, noisy, and denoised spectrograms.

```
h = figure;

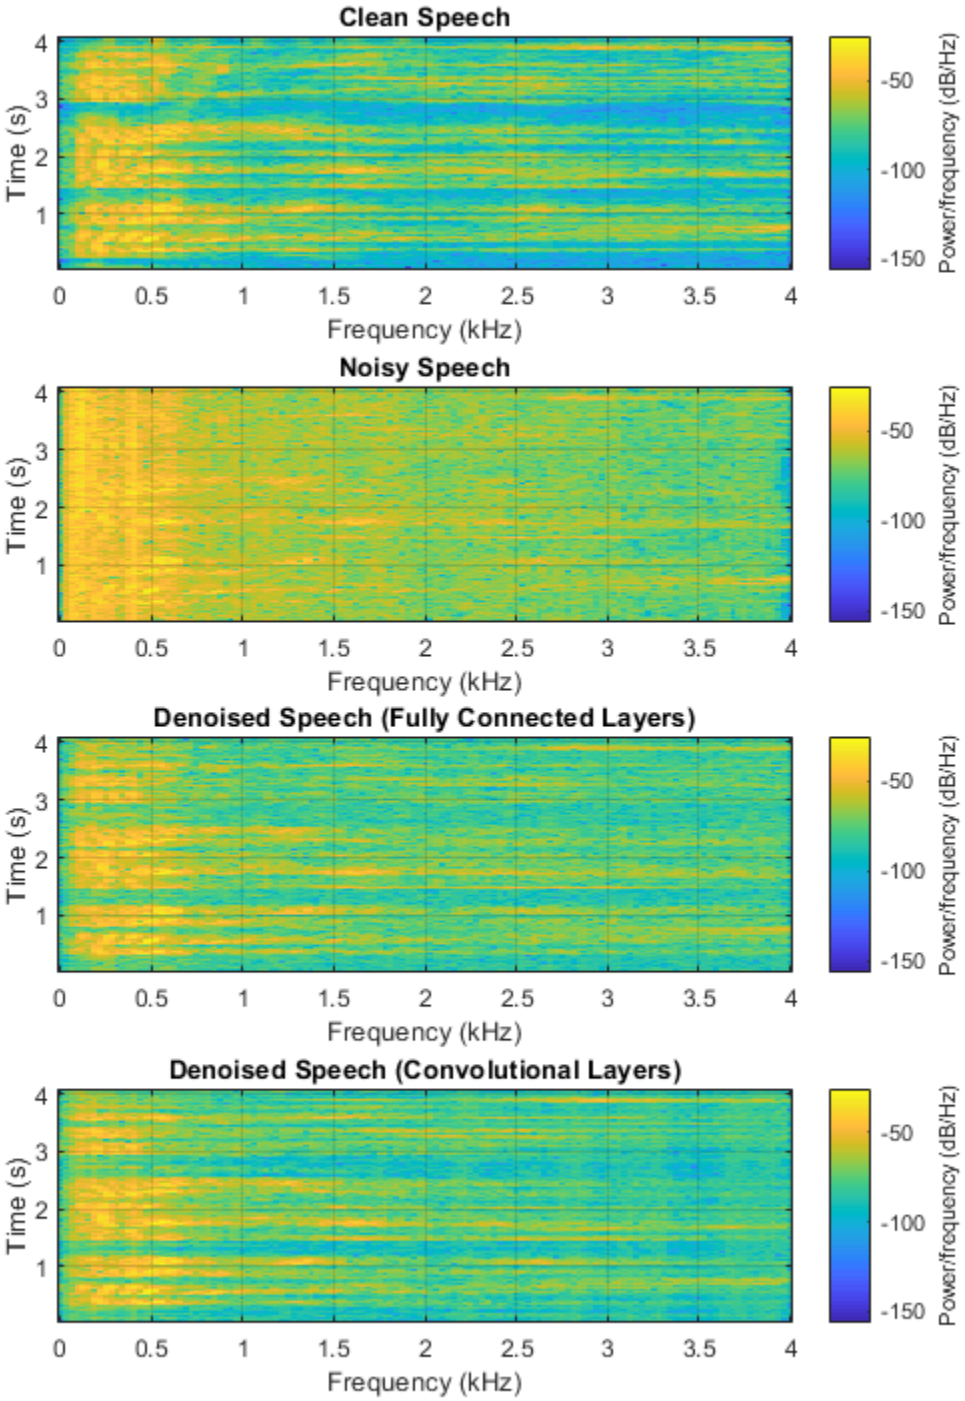
subplot(4,1,1)
spectrogram(cleanAudio,win,overlap,ffTLength,fs);
title("Clean Speech")
grid on

subplot(4,1,2)
spectrogram(noisyAudio,win,overlap,ffTLength,fs);
title("Noisy Speech")
grid on

subplot(4,1,3)
spectrogram(denoisedAudioFullyConnected,win,overlap,ffTLength,fs);
title("Denoised Speech (Fully Connected Layers)")
grid on

subplot(4,1,4)
spectrogram(denoisedAudioFullyConvolutional,win,overlap,ffTLength,fs);
title("Denoised Speech (Convolutional Layers)")
grid on

p = get(h,'Position');
set(h,'Position',[p(1) 65 p(3) 800]);
```



Listen to the noisy speech.

```
sound(noisyAudio,fs)
```

Listen to the denoised speech from the network with fully connected layers.

```
sound(denoisedAudioFullyConnected,fs)
```

Listen to the denoised speech from the network with convolutional layers.

```
sound(denoisedAudioFullyConvolutional,fs)
```

Listen to clean speech.

```
sound(cleanAudio,fs)
```

You can test more files from the datastore by calling `testDenoisingNets`. The function produces the time-domain and frequency-domain plots highlighted above, and also returns the clean, noisy, and denoised audio signals.

```
[cleanAudio,noisyAudio,denoisedAudioFullyConnected,denoisedAudioFullyConvolutional] = testDenois
```

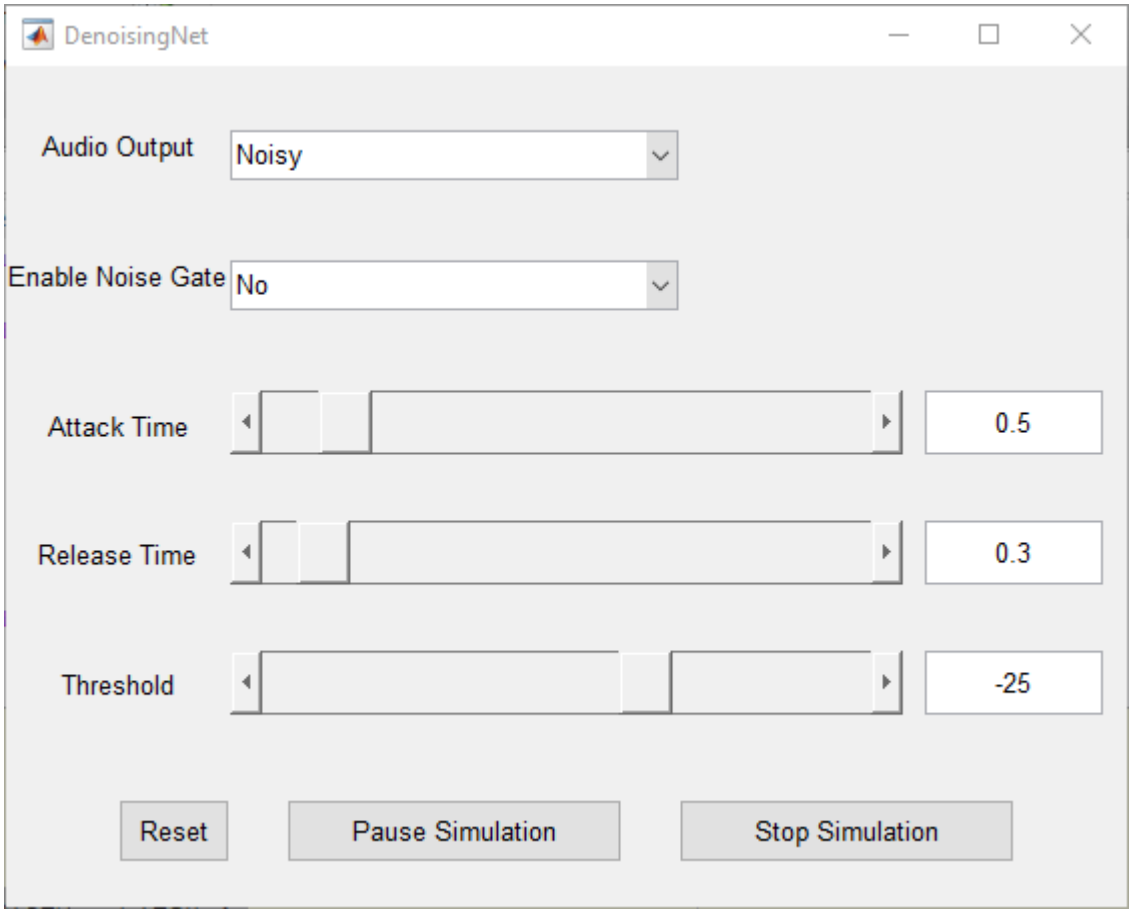
Real-Time Application

The procedure in the previous section passes the entire spectrum of the noisy signal to `predict`. This is not suitable for real-time applications where low latency is a requirement.

Run `speechDenoisingRealtimeApp` for an example of how to simulate a streaming, real-time version of the denoising network. The app uses the network with fully connected layers. The audio frame length is equal to the STFT hop size, which is 0.25 * 256 = 64 samples.

`speechDenoisingRealtimeApp` launches a User Interface (UI) designed to interact with the simulation. The UI enables you to tune parameters and the results are reflected in the simulation instantly. You can also enable/disable a noise gate that operates on the denoised output to further reduce the noise, as well as tune the attack time, release time, and threshold of the noise gate. You can listen to the noisy, clean or denoised audio from the UI.



The scope plots the clean, noisy and denoised signals, as well as the gain of the noise gate.

More About

- “Deep Learning in MATLAB” on page 1-2

Accelerate Audio Deep Learning Using GPU-Based Feature Extraction

In this example, you leverage GPUs for feature extraction and augmentation to decrease the time required to train a deep learning model. The model you train is a convolutional neural network (CNN) for acoustic fault recognition.

Audio Toolbox™ includes `gpuArray` (Parallel Computing Toolbox) support for most feature extractors, including popular ones such as `melSpectrogram` (Audio Toolbox) and `mfcc` (Audio Toolbox). For an overview of GPU support, see “Code Generation and GPU Support” (Audio Toolbox).

Load Training Data

Download and unzip the air compressor data set [1] on page 14-0 . This data set consists of recordings from air compressors in a healthy state or one of seven faulty states.

```
url = 'https://www.mathworks.com/supportfiles/audio/AirCompressorDataset/AirCompressorDataset.zip
downloadFolder = fullfile(tempdir,'AirCompressorDataset');
datasetLocation = tempdir;

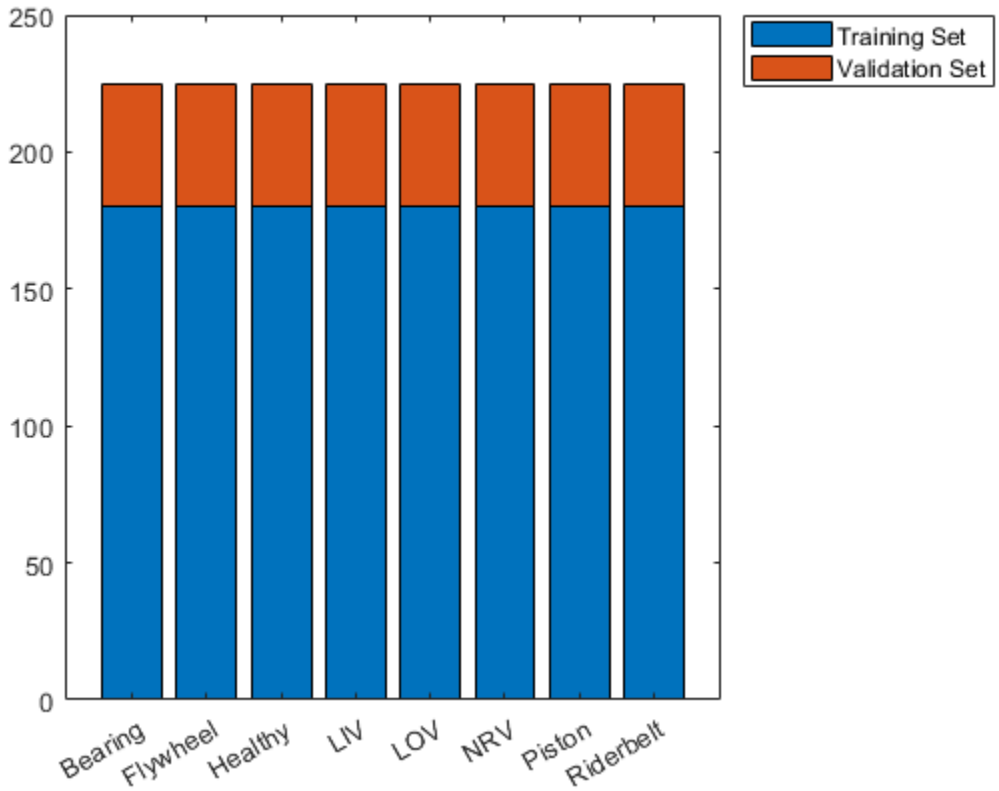
if ~isfolder(fullfile(datasetLocation,'AirCompressorDataset'))
    loc = websave(downloadFolder,url);
    unzip(loc,fullfile(datasetLocation,'AirCompressorDataset'))
end
```

Create an `audioDatastore` (Audio Toolbox) object to manage the data and split it into training and validation sets.

```
ads = audioDatastore(downloadFolder,'IncludeSubfolders',true,'LabelSource','foldernames');
rng default
[adsTrain,adsValidation] = splitEachLabel(ads,0.8);
```

Visualize the number of files in the training and validation sets.

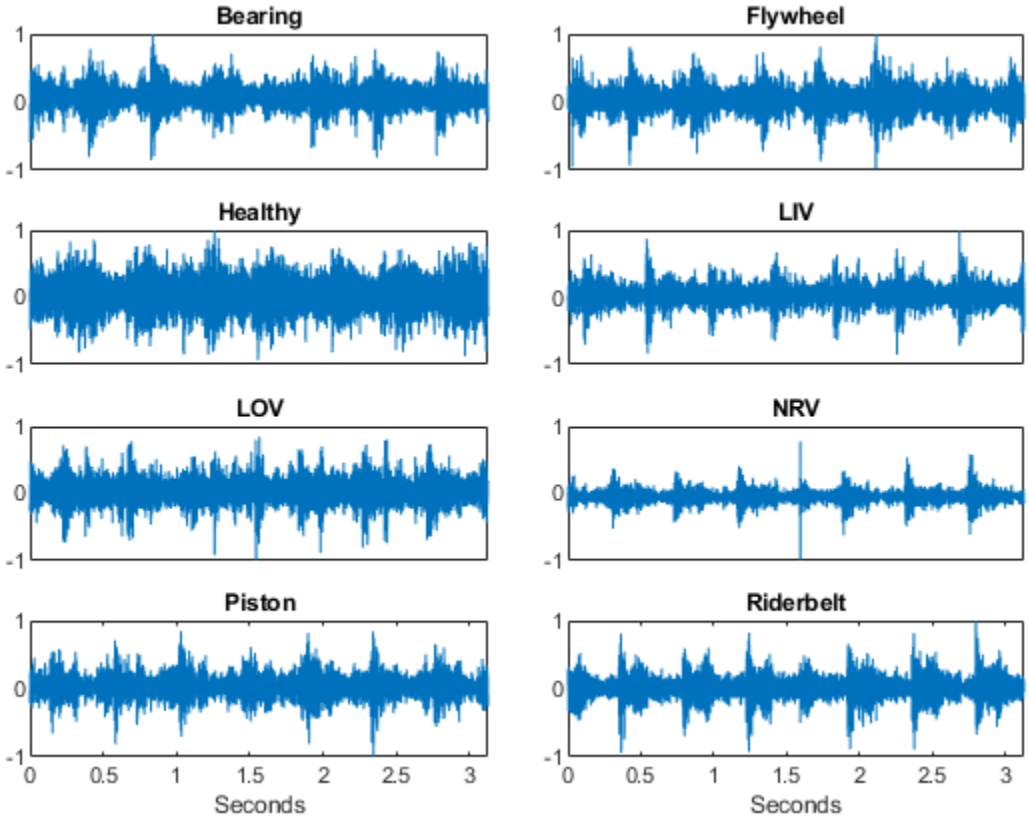
```
uniqueLabels = unique(adsTrain.Labels);
tblTrain = countEachLabel(adsTrain);
tblValidation = countEachLabel(adsValidation);
H = bar(uniqueLabels,[tblTrain.Count, tblValidation.Count],'stacked');
legend(H,["Training Set","Validation Set"],'Location','NorthEastOutside')
```



Select random examples from the training set for plotting. Each recording has 50,000 samples sampled at 16 kHz.

```
t = (0:5e4-1)/16e3;
tiledlayout(4,2,'TileSpacing','compact','Padding','compact')
for n = 1:numel(uniqueLabels)
    idx = find(adsTrain.Labels==uniqueLabels(n));
    [x,fs] = audioread(adsTrain.Files{idx(randperm(numel(idx),1))});

    nexttile
    plotHandle = plot(t,x);
    if n == 7 || n == 8
        xlabel('Seconds');
    else
        set(gca,'xtick',[])
    end
    title(string(uniqueLabels(n)));
end
```



Preprocess Data on CPU and GPU

In this example, you perform feature extraction and data augmentation while training the network. In this section, you define the feature extraction and augmentation pipeline and compare the speed of the pipeline executed on a CPU against the speed of the pipeline executed on a GPU. The output of this pipeline is the input to the CNN you train.

Create an `audioFeatureExtractor` (Audio Toolbox) object to extract mel spectrums using 200 ms mel windows with a 5 ms hop. The output from `extract` is a `numHops`-by-128-by-1 array.

```
afe = audioFeatureExtractor('SampleRate',fs, ...
    'FFTLength',4096, ...
    'Window',hann(round(fs*0.2),'periodic'), ...
    'OverlapLength',round(fs*0.195), ...
    'melSpectrum',true);
setExtractorParams(afe,"melSpectrum",'NumBands',128);

featureVector = extract(afe,x);
[numHops,numFeatures,numChannels] = size(featureVector)
```

```
numHops = 586
```

```
numFeatures = 128
```

```
numChannels = 1
```

Deep learning methods are data-hungry, and the training dataset in this example is relatively small. Use the mixup [2] on page 14-0 augmentation technique to effectively enlarge the training set. In

mixup, you merge the features extracted from two audio signals as a weighted sum. The two signals have different labels, and the label assigned to the merged feature matrix is probabilistically assigned based on the mixing coefficient. The mixup augmentation is implemented in the supporting object, `Mixup` on page 14-0 .

Create the pipeline to perform the following steps:

1. Extract the log-mel spectrogram.
2. Apply mixup to the feature matrices. The `Mixup` supporting object outputs a cell array containing the features and the label.

Create two versions of the pipeline for comparison: one that executes the pipeline on your CPU, and one that converts the raw audio signal to a `gpuArray` so that the pipeline is executed on your GPU.

```
offset = eps;

adsTrainCPU = transform(adsTrain,@(x)log10(extract(afe,x)+offset));
mixerCPU = Mixup(adsTrainCPU);
adsTrainCPU = transform(adsTrainCPU,@(x,info)mix(mixerCPU,x,info),'IncludeInfo',true);

adsTrainGPU = transform(adsTrain,@gpuArray);
adsTrainGPU = transform(adsTrainGPU,@(x)log10(extract(afe,x)+offset));
mixerGPU = Mixup(adsTrainGPU);
adsTrainGPU = transform(adsTrainGPU,@(x,info)mix(mixerGPU,x,info),'IncludeInfo',true);
```

For the validation set, apply the feature extraction pipeline but not the augmentation. Because you are not applying mixup, create a combined datastore to output a cell array containing the features and the label. Again, create one validation pipeline that executes on your GPU and one validation pipeline that executes on your CPU.

```
adsValidationGPU = transform(adsValidation,@gpuArray);
adsValidationGPU = transform(adsValidationGPU,@(x){log10(extract(afe,x)+offset)});
adsValidationGPU = combine(adsValidationGPU,arrayDatastore(adsValidation.Labels));

adsValidationCPU = transform(adsValidation,@(x){log10(extract(afe,x)+offset)});
adsValidationCPU = combine(adsValidationCPU,arrayDatastore(adsValidation.Labels));
```

Compare the time it takes for the CPU and a single GPU to extract features and perform data augmentation.

```
tic
for ii = 1:numel(adsTrain.Files)
    x = read(adsTrainCPU);
end
cpuPipeline = toc;
reset(adsTrainCPU)

tic
for ii = 1:numel(adsTrain.Files)
    x = read(adsTrainGPU);
end
wait(gpuDevice) % Ensure all calculations are completed
gpuPipeline = toc;
reset(adsTrainGPU)

fprintf(['Read, extract, and augment train set (CPU): %0.2f seconds\n' ...
    'Read, extract, and augment train set (GPU): %0.2f seconds\n' ...
```

```
    'Speedup (CPU time)/(GPU time): %0.3f\n\n'], ...
    cpuPipeline,gpuPipeline,cpuPipeline/gpuPipeline)
```

```
Read, extract, and augment train set (CPU): 110.80 seconds
Read, extract, and augment train set (GPU): 34.65 seconds
Speedup (CPU time)/(GPU time): 3.198
```

Reading from the datastore contributes a significant amount of the overall time to the pipeline. A comparison of just extraction and augmentation shows an even greater speedup. Compare just feature extraction on the GPU versus on the CPU.

```
x = read(ads);

extract(afe,x); % Incur initialization cost outside timing loop
tic
for ii = 1:numel(adsTrain.Files)
    features = log10(extract(afe,x)+offset);
end
cpuFeatureExtraction = toc;

x = gpuArray(x); % Incur initialization cost outside timing loop
extract(afe,x);
tic
for ii = 1:numel(adsTrain.Files)
    features = log10(extract(afe,x)+offset);
end
wait(gpuDevice) % Ensure all calculations are completed
gpuFeatureExtraction = toc;

fprintf(['Extract features from train set (CPU): %0.2f seconds\n' ...
    'Extract features from train set (GPU): %0.2f seconds\n' ...
    'Speedup (CPU time)/(GPU time): %0.3f\n\n'], ...
    cpuFeatureExtraction,gpuFeatureExtraction,cpuFeatureExtraction/gpuFeatureExtraction)
```

```
Extract features from train set (CPU): 50.57 seconds
Extract features from train set (GPU): 4.48 seconds
Speedup (CPU time)/(GPU time): 11.299
```

Define Network

Define a convolutional neural network that takes the augmented mel spectrogram as input. This network applies a single convolutional layer consisting of 48 filters with 3-by-3 kernels, followed by a batch normalization layer and a ReLU activation layer. The time dimension is then collapsed using a max pooling layer. Finally, the output of the pooling layer is reduced using a fully connected layer followed by softmax and classification layers. See “List of Deep Learning Layers” on page 1-21 for more information.

```
numClasses = numel(categories(adsTrain.Labels));
imageSize = [numHops,afe.FeatureVectorLength];

layers = [
    imageInputLayer(imageSize,'Normalization','none')

    convolution2dLayer(3,48,'Padding','same')
    batchNormalizationLayer
    reluLayer

    maxPooling2dLayer([numHops,1])
```

```
    fullyConnectedLayer(numClasses)
    softmaxLayer
    classificationLayer('Classes',categories(adsTrain.Labels));
    ];
```

To define the training options, use `trainingOptions`. Set the `ExecutionEnvironment` to `multi-gpu` to leverage multiple GPUs, if available. Otherwise, you can set `ExecutionEnvironment` to `gpu`. The computer used in this example has access to four Titan V GPU devices. In this example, the network training always leverages GPUs.

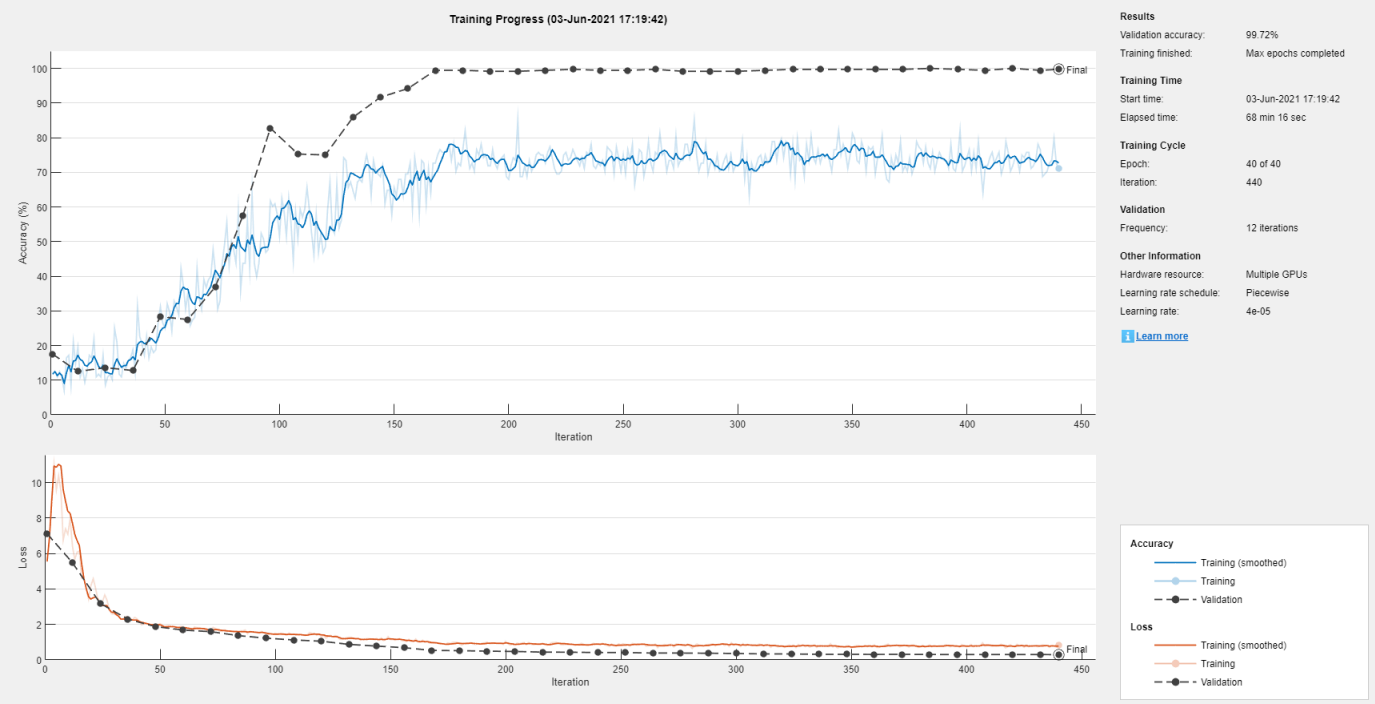
```
miniBatchSize = 128;
options = trainingOptions('adam', ...
    'Shuffle','every-epoch', ...
    'MaxEpochs',40, ...
    'LearnRateSchedule',"piecewise", ...
    'LearnRateDropPeriod',15, ...
    'LearnRateDropFactor',0.2, ...
    'MiniBatchSize',miniBatchSize, ...
    'Plots','training-progress', ...
    'Verbose',false, ...
    'ValidationData',adsValidationCPU, ...
    'ValidationFrequency',ceil(numel(adsTrain.Files)/miniBatchSize), ...
    'ExecutionEnvironment','multi-gpu');
```

Train Network

Train Network Using CPU-Based Preprocessing

Call `trainNetwork` to train the network using your CPU for the feature extraction pipeline. The execution environment for the network training is your GPU(s).

```
tic
net = trainNetwork(adsTrainCPU,layers,options);
```

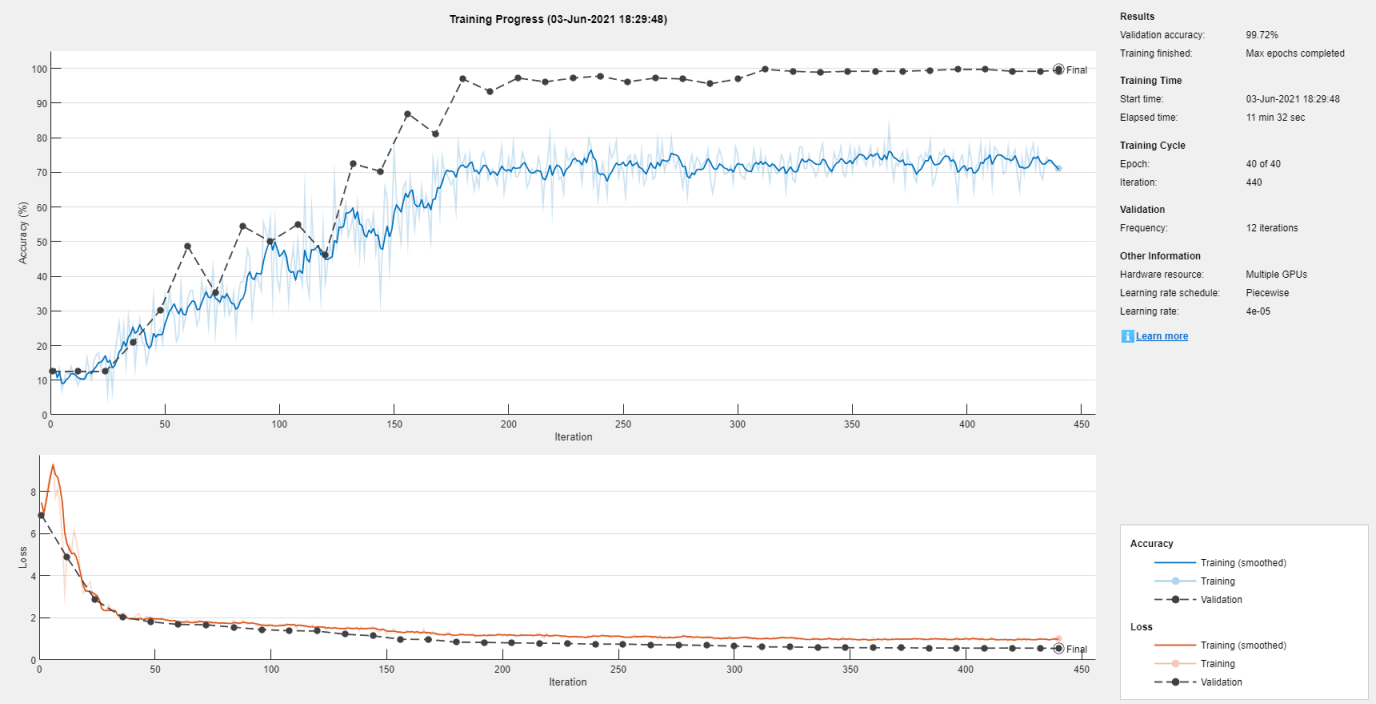


```
cpuTrainTime = toc;
```

Train Network Using GPU-Based Preprocessing

Replace the validation data in the training options with the GPU-based pipeline. Train the network using your GPU(s) for the feature extraction pipeline. The execution environment for the network training is your GPU(s).

```
options.ValidationData = adsValidationGPU;
tic
net = trainNetwork(adsTrainGPU,layers,options);
```



```
gpuTrainTime = toc;
```

Compare CPU- and GPU-based Preprocessing

Print the timing results for training using a CPU for feature extraction and augmentation, and training using GPU(s) for feature extraction and augmentation.

```
fprintf(['Training time (CPU): %0.2f seconds\n' ...
    'Training time (GPU): %0.2f seconds\n' ...
    'Speedup (CPU time)/(GPU time): %0.3f\n\n'], ...
    cpuTrainTime,gpuTrainTime,cpuTrainTime/gpuTrainTime)
```

```
Training time (CPU): 4242.82 seconds
Training time (GPU): 731.77 seconds
Speedup (CPU time)/(GPU time): 5.798
```

Compare CPU and GPU Inference Performance

Compare the time it takes to perform prediction on a single 3-second clip when feature extraction is performed on the GPU versus the CPU. In both cases, the network prediction happens on your GPU.

```
signalToClassify = read(ads);

gpuFeatureExtraction = gputimeit(@()predict(net,log10(extract(afe,gpuArray(signalToClassify))+of
cpuFeatureExtraction = gputimeit(@()predict(net,log10(extract(afe,(signalToClassify))+offset)));

fprintf(['Prediction time for 3 s of data (feature extraction on CPU): %0.2f ms\n' ...
    'Prediction time for 3 s of data (feature extraction on GPU): %0.2f ms\n' ...
    'Speedup (CPU time)/(GPU time): %0.3f\n\n'], ...
    cpuFeatureExtraction*1e3,gpuFeatureExtraction*1e3,cpuFeatureExtraction/gpuFeatureExtraction)
```

```
Prediction time for 3 s of data (feature extraction on CPU): 41.62 ms
Prediction time for 3 s of data (feature extraction on GPU): 7.71 ms
Speedup (CPU time)/(GPU time): 5.397
```

Compare the time it takes to perform prediction on a set of 3-second clips when feature extraction is performed on the GPU(s) versus the CPU. In both cases, the network prediction happens on your GPU(s).

```
adsValidationGPU = transform(adsValidation,@(x)gpuArray(x));
adsValidationGPU = transform(adsValidationGPU,@(x){log10(extract(afe,x)+offset)});
adsValidationCPU = transform(adsValidation,@(x){log10(extract(afe,x)+offset)});

gpuFeatureExtraction = gputimeit(@()predict(net,adsValidationGPU,'ExecutionEnvironment','multi-g
cpuFeatureExtraction = gputimeit(@()predict(net,adsValidationCPU,'ExecutionEnvironment','multi-g

fprintf(['Prediction time for validation set (feature extraction on CPU): %0.2f s\n' ...
    'Prediction time for validation set (feature extraction on GPU): %0.2f s\n' ...
    'Speedup (CPU time)/(GPU time): %0.3f\n\n'], ...
    cpuFeatureExtraction,gpuFeatureExtraction,cpuFeatureExtraction/gpuFeatureExtraction)
```

```
Prediction time for validation set (feature extraction on CPU): 34.11 s
Prediction time for validation set (feature extraction on GPU): 5.53 s
Speedup (CPU time)/(GPU time): 6.173
```

Conclusion

It is well known that you can decrease the time it takes to train a network by leveraging GPU devices. This enables you to more quickly iterate and develop your final system. In many training setups, you can achieve additional performance gains by leveraging GPU devices for feature extraction and data augmentation. This example shows a significant decrease in the overall time it takes to train a CNN when leveraging GPU devices for feature extraction and data augmentation. Additionally, leveraging GPU devices for feature extraction at inference time, for both single-observations and data sets, achieves significant performance gains.

Supporting Functions

Mixup

The supporting object, `Mixup`, is placed in your current folder when you open this example.

```
type Mixup
```

Acoustics-Based Machine Fault Recognition

In this example, you develop a deep learning model to detect faults in an air compressor using acoustic measurements. After developing the model, you package the system so that you can recognize faults based on streaming input data.

Data Preparation

Download and unzip the air compressor data set [1] on page 14-0 . This data set consists of recordings from air compressors in a healthy state or one of seven faulty states.

```
loc = matlab.internal.examples.downloadSupportFile('audio','AirCompressorDataset/AirCompressorDa
unzip(loc,pwd)
```

Create an `audioDatastore` (Audio Toolbox) object to manage the data and split it into training and validation sets. Call `countEachLabel` (Audio Toolbox) to inspect the distribution of labels in the train and validation sets.

```
ads = audioDatastore(pwd,'IncludeSubfolders',true,'LabelSource','foldernames');

[adsTrain,adsValidation] = splitEachLabel(ads,0.9,0.1);

countEachLabel(adsTrain)
```

```
ans=8×2 table
      Label      Count
    _________    _____

    Bearing       203
    Flywheel      203
    Healthy       203
    LIV           203
    LOV           203
    NRV           203
    Piston        203
    Riderbelt     203
```

```
countEachLabel(adsValidation)
```

```
ans=8×2 table
      Label      Count
    _________    _____

    Bearing       22
    Flywheel      22
    Healthy       22
    LIV           22
    LOV           22
    NRV           22
    Piston        22
    Riderbelt     22
```

```
adsTrain = shuffle(adsTrain);
adsValidation = shuffle(adsValidation);
```

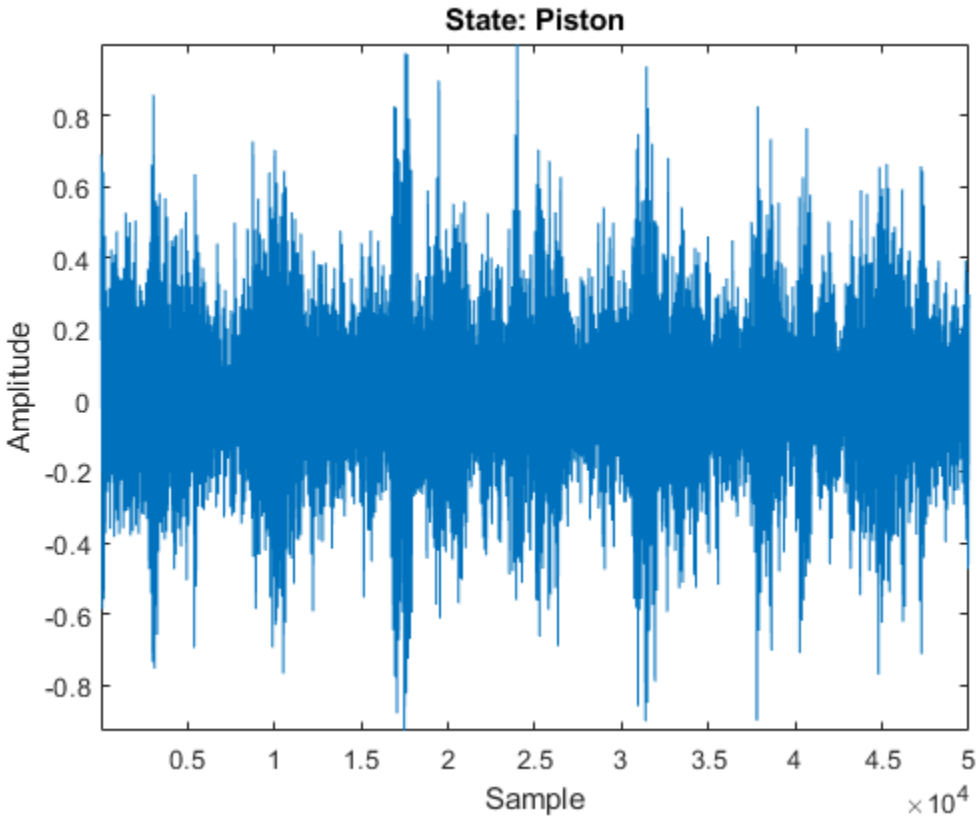
You can reduce the training data set used in this example to speed up the runtime at the cost of performance. In general, reducing the data set is a good practice for development and debugging.

```
reduceDataset = false;
if reduceDataset
    adsTrain = splitEachLabel(adsTrain,20);
end
```

The data consists of time-series recordings of acoustics from faulty or healthy air compressors. As such, there are strong relationships between samples in time. Listen to a recording and plot the waveform.

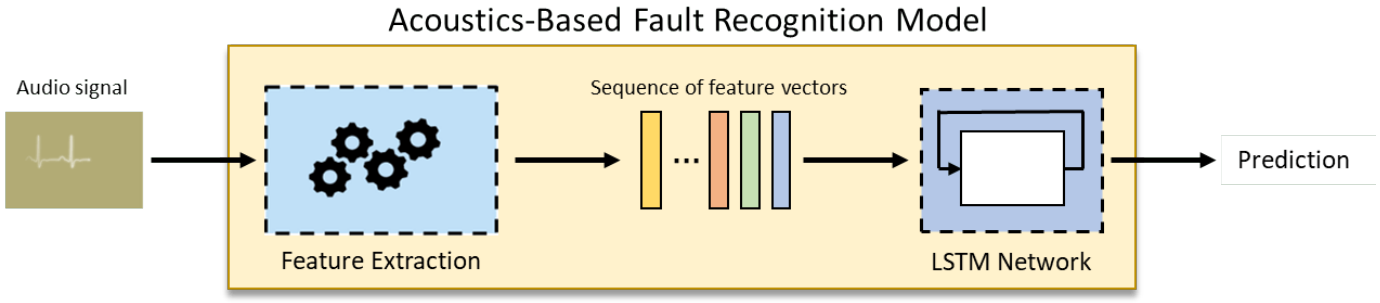
```
[sampleData,sampleDataInfo] = read(adsTrain);
fs = sampleDataInfo.SampleRate;

soundsc(sampleData,fs)
plot(sampleData)
xlabel("Sample")
ylabel("Amplitude")
title("State: " + string(sampleDataInfo.Label))
axis tight
```



Because the samples are related in time, you can use a recurrent neural network (RNN) to model the data. A long short-term memory (LSTM) network is a popular choice of RNN because it is designed to avoid vanishing and exploding gradients. Before you can train the network, it's important to prepare

the data adequately. Often, it is best to transform or extract features from 1-dimensional signal data in order to provide a richer set of features for the model to learn from.



Feature Engineering

The next step is to extract a set of acoustic features used as inputs to the network. Audio Toolbox™ enables you to extract spectral descriptors that are commonly used as inputs in machine learning tasks. You can extract the features using individual functions, or you can use `audioFeatureExtractor` (Audio Toolbox) to simplify the workflow and do it all at once.

```
trainFeatures = cell(1,numel(adsTrain.Files));
windowLength = 512;
overlapLength = 0;

aFE = audioFeatureExtractor('SampleRate',fs, ...
    'Window',hamming(windowLength,'periodic'),...
    'OverlapLength',overlapLength,...
    'spectralCentroid',true, ...
    'spectralCrest',true, ...
    'spectralDecrease',true, ...
    'spectralEntropy',true, ...
    'spectralFlatness',true, ...
    'spectralFlux',false, ...
    'spectralKurtosis',true, ...
    'spectralRolloffPoint',true, ...
    'spectralSkewness',true, ...
    'spectralSlope',true, ...
    'spectralSpread',true);

reset(adsTrain)
tic
for index = 1:numel(adsTrain.Files)
    data = read(adsTrain);
    trainFeatures{index} = (extract(aFE,data))';
end
fprintf('Feature extraction of training set took %f seconds.\n',toc);
```

```
Feature extraction of training set took 13.648354 seconds.
```

Data Augmentation

The training set contains a relatively small number of acoustic recordings for training a deep learning model. A popular method to enlarge the dataset is to use mixup. In mixup, you augment your dataset by mixing the features and labels from two different class instances. Mixup was reformulated by [2] on page 14-0 as labels drawn from a probability distribution instead of mixed labels. The supporting function, mixup on page 14-0 , takes the training features, associated labels, and the number of mixes per observation and then outputs the mixes and associated labels.

```
trainLabels = adsTrain.Labels;

numMixesPerInstance = 2 ;
tic
[augData,augLabels] = mixup(trainFeatures,trainLabels,numMixesPerInstance);

trainLabels = cat(1,trainLabels,augLabels);
trainFeatures = cat(2,trainFeatures,augData);
fprintf('Feature augmentation of train set took %f seconds.\n',toc);
```

```
Feature augmentation of train set took 0.250037 seconds.
```

Generate Validation Features

Repeat the feature extraction for the validation features.

```
validationFeatures = cell(1,numel(adsValidation.Files));

reset(adsValidation)
tic
for index = 1:numel(adsValidation.Files)
    data = read(adsValidation);
    validationFeatures{index} = (extract(aFE,data))';
end
fprintf('Feature extraction of validation set took %f seconds.\n',toc);
```

```
Feature extraction of validation set took 1.388853 seconds.
```

Train Model

Next, you define and train a network. To skip training the network, set `downloadPretrainedSystem` to `true`, then continue to the next section on page 14-0 .

```
downloadPretrainedSystem = false ;
if downloadPretrainedSystem
    loc = matlab.internal.examples.downloadSupportFile('audio','AcousticsBasedMachineFaultRecogn
    unzip(loc,pwd)
    addpath(fullfile(pwd,'AcousticsBasedMachineFaultRecognition'))
end
```

Define Network

An LSTM layer learns long-term dependencies between time steps of time series or sequence data. The first `lstmLayer` has 100 hidden units and outputs sequence data. Then a dropout layer is used to reduce overfitting. The second `lstmLayer` outputs the last step of the time sequence.

```
numHiddenUnits = 100 ;
dropProb = 0.2 ;
```

```
layers = [ ...
    sequenceInputLayer(aFE.FeatureVectorLength,'Normalization','zscore')
    lstmLayer(numHiddenUnits,"OutputMode","sequence")
    dropoutLayer(dropProb)
    lstmLayer(numHiddenUnits,"OutputMode","last")
    fullyConnectedLayer(numel(unique(adsTrain.Labels)))
    softmaxLayer
    classificationLayer];
```

Define Network Hyperparameters

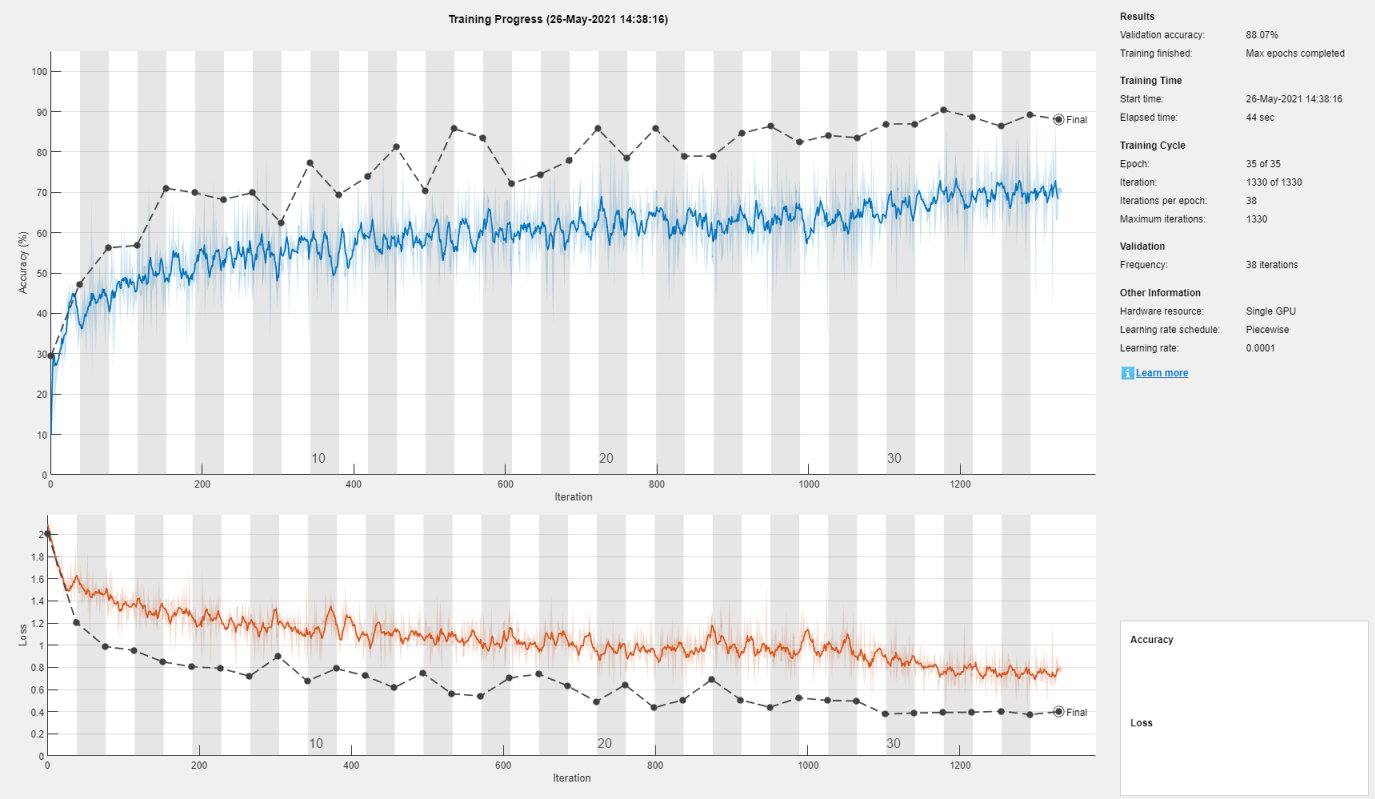
To define hyperparameters for the network, use `trainingOptions`.

```
miniBatchSize = 128 ;
validationFrequency = floor(numel(trainFeatures)/miniBatchSize);
options = trainingOptions("adam", ...
    "MiniBatchSize",miniBatchSize, ...
    "MaxEpochs",35, ...
    "Plots","training-progress", ...
    "Verbose",false, ...
    "Shuffle","every-epoch", ...
    "LearnRateSchedule","piecewise", ...
    "LearnRateDropPeriod",30, ...
    "LearnRateDropFactor",0.1, ...
    "ValidationData",{validationFeatures,adsValidation.Labels}, ...
    "ValidationFrequency",validationFrequency);
```

Train Network

To train the network, use `trainNetwork`.

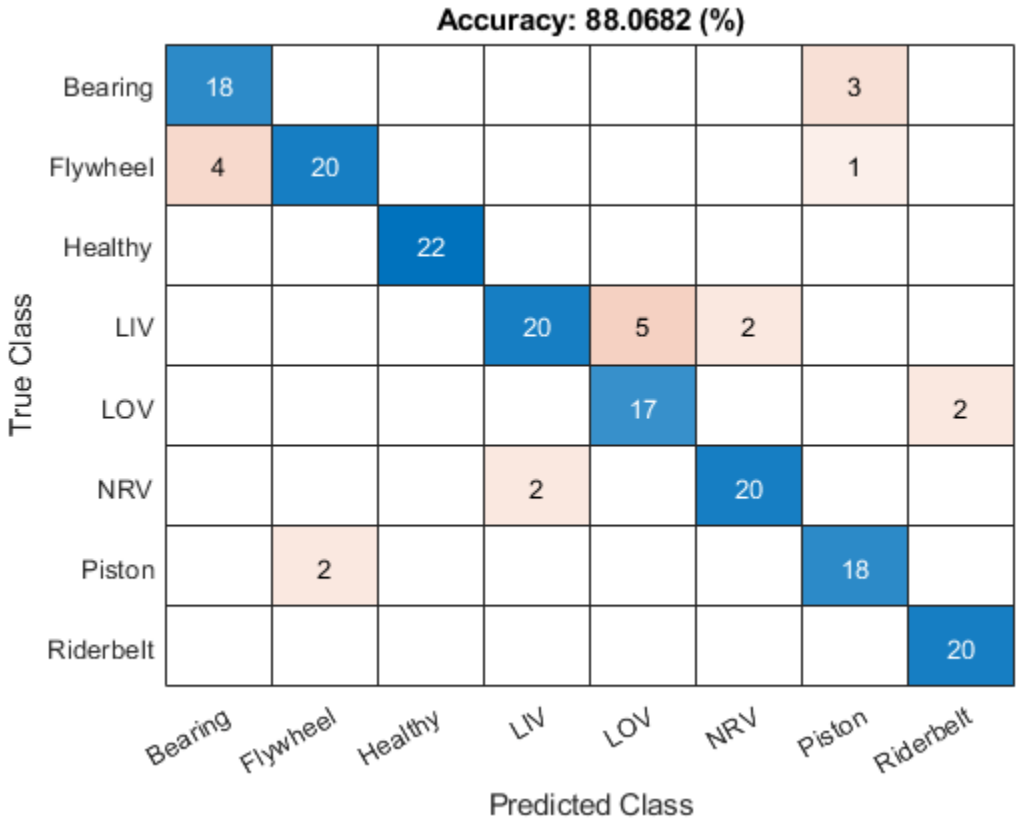
```
airCompNet = trainNetwork(trainFeatures,trainLabels,layers,options);
```



Evaluate Network

View the confusion chart for the validation data.

```
validationResults = classify(airCompNet,validationFeatures);
cm = confusionchart(validationResults,adsValidation.Labels);
accuracy = mean(validationResults == adsValidation.Labels)*100;
cm.title("Accuracy: " + accuracy + " (%)")
```



Model Streaming Detection

Create Functions to Process Data in a Streaming Loop

Once you have a trained network with satisfactory performance, you can apply the network to test data in a streaming fashion.

There are many additional considerations to take into account to make the system work in a real-world embedded system.

For example,

- The rate or interval at which classification can be performed with accurate results
- The size of the network in terms of generated code (program memory) and weights (data memory)
- The efficiency of the network in terms of computation speed

In MATLAB, you can mimic how the network is deployed and used in hardware on a real embedded system and begin to answer these important questions.

Create MATLAB Function Compatible with C/C++ Code Generation

Once you train your deep learning model, you will deploy it to an embedded target. That means you also need to deploy the code used to perform the feature extraction. Use the `generateMATLABFunction` method of `audioFeatureExtractor` to generate a MATLAB function compatible with C/C++ code generation. Specify `IsStreaming` as `true` so that the generated function is optimized for stream processing.

```
filename = fullfile(pwd,"extractAudioFeatures");
generateMATLABFunction(aFE,filename,'IsStreaming',true);
```

Combine Streaming Feature Extraction and Classification

Save the trained network as a MAT file.

```
save('AirCompressorFaultRecognitionModel.mat','airCompNet')
```

Create a function that combines the feature extraction and deep learning classification.

```
type recognizeAirCompressorFault.m
```

```
function scores = recognizeAirCompressorFault(audioIn,rs)
% This is a streaming classifier function

persistent airCompNet

if isempty(airCompNet)
    airCompNet = coder.loadDeepLearningNetwork('AirCompressorFaultRecognitionModel.mat');
end
if rs
    airCompNet = resetState(airCompNet);
end

% Extract features using function
features = extractAudioFeatures(audioIn);

% Classify
[airCompNet,scores] = predictAndUpdateState(airCompNet,features);

end
```

Test Streaming Loop

Next, you test the streaming classifier in MATLAB. Stream audio one frame at a time to represent a system as it would be deployed in a real-time embedded system. This enables you to measure and visualize the timing and accuracy of the streaming implementation.

Stream in several audio files and plot the output classification results for each frame of data. At a time interval equal to the length of each file, evaluate the output of the classifier.

```
reset(adsValidation)

N = 10;
labels = categories(ads.Labels);
numLabels = numel(labels);

% Create a dsp.AsyncBuffer to read audio in a streaming fashion
audioSource = dsp.AsyncBuffer;

% Create a dsp.AsyncBuffer to accumulate scores
scoreBuffer = dsp.AsyncBuffer;

% Create a dsp.AsyncBuffer to record execution time.
timingBuffer = dsp.AsyncBuffer;

% Pre-allocate array to store results
```

```
streamingResults = categorical(zeros(N,1));

% Loop over files
for fileIdx = 1:N

    % Read one audio file and put it in the source buffer
    [data,dataInfo] = read(adsValidation);
    write(audioSource,data);

    % Inner loop over frames
    rs = true;
    while audioSource.NumUnreadSamples >= windowLength

        % Get a frame of audio data
        x = read(audioSource,windowLength);

        % Apply streaming classifier function
        tic
        score = recognizeAirCompressorFault(x,rs);
        write(timingBuffer,toc);

        % Store score for analysis
        write(scoreBuffer,score);

        rs = false;
    end
    reset(audioSource)

    % Store class result for that file
    scores = read(scoreBuffer);
    [~,result] = max(scores(end,:),[],2);
    streamingResults(fileIdx) = categorical(labels(result));

    % Plot scores to compare over time
    figure
    plot(scores) %#ok<*NASGU>
    legend(string(airCompNet.Layers(end).Classes),'Location','northwest')
    xlabel("Time Step")
    ylabel("Score")
    str = sprintf('Known label = %s\nPredicted label = %s',string(dataInfo.Label),string(streami
    title(str)
end

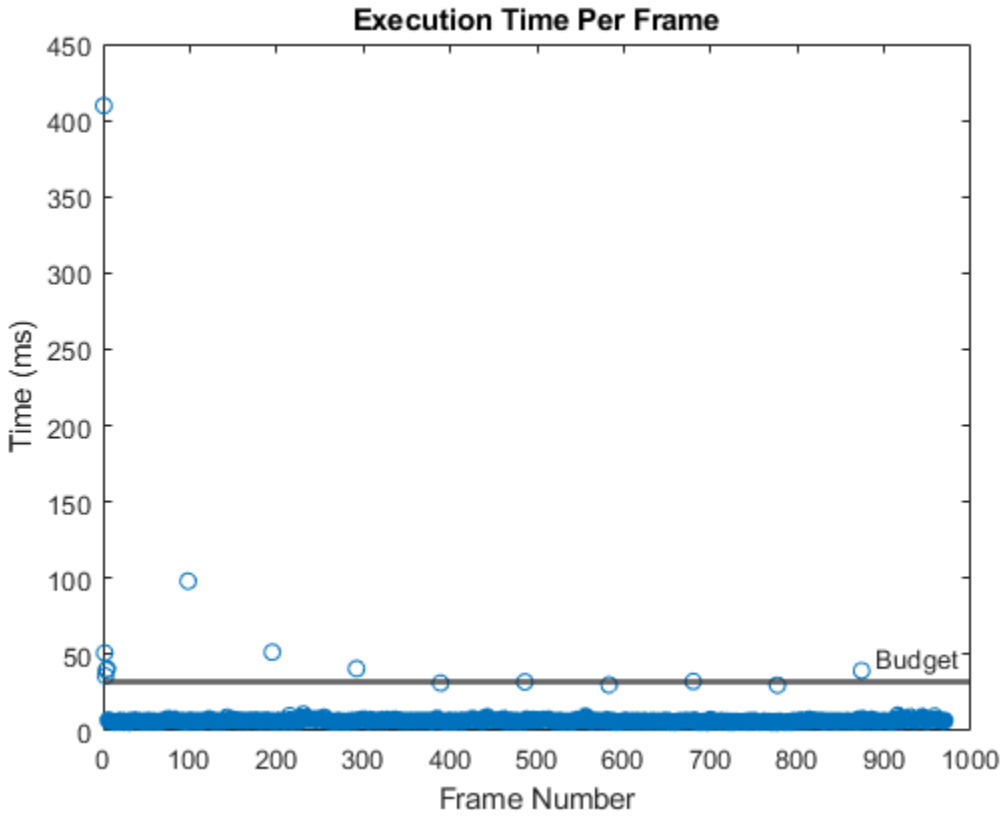
Compare the test results for the streaming version of the classifier and the non-streaming.

```
testError = mean(validationResults(1:N) ~= streamingResults);
disp("Error between streaming classifier and non-streaming: " + testError*100 + " (%)")
```

```
Error between streaming classifier and non-streaming: 0 (%)
```

Analyze the execution time. The execution time when state is reset is often above the 32 ms budget. However, in a real, deployed system, that initialization time will only be incurred once. The execution time of the main loop is around 10 ms, which is well below the 32 ms budget for real-time performance.

```
executionTime = read(timingBuffer)*1000;
budget = (windowLength/aFE.SampleRate)*1000;
plot(executionTime,'o')
title('Execution Time Per Frame')
xlabel('Frame Number')
ylabel('Time (ms)')
yline(budget,'',{'Budget'},'LineWidth',2)
```



Supporting Functions

```
function [augData,augLabels] = mixup(data,labels,numMixesPerInstance)
augData = cell(1,numel(data)*numMixesPerInstance);
augLabels = repelem(labels,numMixesPerInstance);

kk = 1;
for ii = 1:numel(data)
    for jj = 1:numMixesPerInstance
        lambda = max(min((randn./10)+0.5,1),0);

        % Find all available data with different labels.
        availableData = find(labels~=labels(ii));

        % Randomly choose one of the available data with a different label.
        numAvailableData = numel(availableData);
        idx = randi([1,numAvailableData]);

        % Mix.
        augData{kk} = lambda*data{ii} + (1-lambda)*data{availableData(idx)};

        % Specify the label as randomly set by lambda.
        if lambda < rand
            augLabels(kk) = labels(availableData(idx));
        else
            augLabels(kk) = labels(ii);
        end
```

```
            kk = kk + 1;
        end
    end

    end
```

Acoustics-Based Machine Fault Recognition Code Generation with Intel MKL-DNN

This example demonstrates code generation for “Acoustics-Based Machine Fault Recognition” (Audio Toolbox) using a long short-term memory (LSTM) network and spectral descriptors. This example uses MATLAB® Coder™ with deep learning support to generate a MEX (MATLAB executable) function that leverages performance of Intel® MKL-DNN library. The input data consists of acoustics time-series recordings from faulty or healthy air compressors and the output is the state of the mechanical machine predicted by the LSTM network. For details on audio preprocessing and network training, see “Acoustics-Based Machine Fault Recognition” (Audio Toolbox).

Example Requirements

- The MATLAB Coder Interface f or Deep Learning Libraries Support Package
- Intel processor with support for Intel Advanced Vector Extensions 2 (Intel AVX2)
- Intel Deep Neural Networks Library (MKL-DNN)
- Environment variables for Intel MKL-DNN

For supported versions of libraries and for information about setting up environment variables, see “Prerequisites for Deep Learning with MATLAB Coder” (MATLAB Coder)

Prepare Input Dataset

Specify a sample rate `fs` of 16 kHz and a `windowLength` of 512 samples, as defined in “Acoustics-Based Machine Fault Recognition” (Audio Toolbox). Set `numFrames` to `100`.

```
fs = 16000;
windowLength = 512;
numFrames = 100;
```

To run the Example on a test signal, generate a pink noise signal. To test the performance of the system on a real dataset, download the air compressor dataset [1] on page 14-0 .

```
downloadDataset = false

if ~downloadDataset
    pinkNoiseSignal = pinknoise(windowLength*numFrames);
else
    % Download AirCompressorDataset.zip
    component = 'audio';
    filename = 'AirCompressorDataset/AirCompressorDataset.zip';
    localfile = matlab.internal.examples.downloadSupportFile(component,filename);

    % Unzip the downloaded zip file to the downloadFolder
    downloadFolder = fileparts(localfile);
    if ~exist(fullfile(downloadFolder,'AirCompressorDataset'),'dir')
        unzip(localfile, downloadFolder)
    end

    % Create an audioDatastore object dataStore, to manage, the data.
    dataStore = audioDatastore(downloadFolder,'IncludeSubfolders',true,'LabelSource','foldernames

    % Use countEachLabel to get the number of samples of each category in the dataset.
```

```
    countEachLabel(dataStore)
end
```

Recognize Machine Fault in MATLAB

To run the streaming classifier in MATLAB, download and unzip the system developed in "Acoustics-Based Machine Fault Recognition" (Audio Toolbox).

```
component = 'audio';
filename = 'AcousticsBasedMachineFaultRecognition/AcousticsBasedMachineFaultRecognition.zip';
localfile = matlab.internal.examples.downloadSupportFile(component,filename);

downloadFolder = fullfile(fileparts(localfile),'system');
if ~exist(downloadFolder,'dir')
    unzip(localfile,downloadFolder)
end
```

To access the `recognizeAirCompressorFault` function of the system, add `downloadFolder` to the search path.

```
addpath(downloadFolder)
```

Create a `dsp.AsyncBuffer` (DSP System Toolbox) object to read audio in a streaming fashion and a `dsp.AsyncBuffer` (DSP System Toolbox) object to accumulate scores.

```
audioSource = dsp.AsyncBuffer;
scoreBuffer = dsp.AsyncBuffer;
```

Load the pretrained network and extract labels from the network.

```
airCompNet = coder.loadDeepLearningNetwork('AirCompressorFaultRecognitionModel.mat');
labels = string(airCompNet.Layers(end).Classes);
```

Initialize `signalToBeTested` to `pinkNoiseSignal` or select a signal from the drop-down list to test the file of your choice from the dataset.

```
if ~downloadDataset
    signalToBeTested = pinkNoiseSignal;
else
    [allFiles,~] = splitEachLabel(dataStore,1);
    allData = readall(allFiles);
    signalToBeTested = NRV ;
    signalToBeTested = cell2mat(signalToBeTested);
end
```

Stream one audio frame at a time to represent the system as it would be deployed in a real-time embedded system. Use `recognizeAirCompressorFault` developed in "Acoustics-Based Machine Fault Recognition" (Audio Toolbox) to compute audio features and perform deep learning classification.

```
write(audioSource,signalToBeTested);
resetNetworkState = true;

while audioSource.NumUnreadSamples >= windowLength

    % Get a frame of audio data
    x = read(audioSource,windowLength);
```

```
    % Apply streaming classifier function
    score = recognizeAirCompressorFault(x,resetNetworkState);

    % Store score for analysis
    write(scoreBuffer,score);

    resetNetworkState = false;
end
```

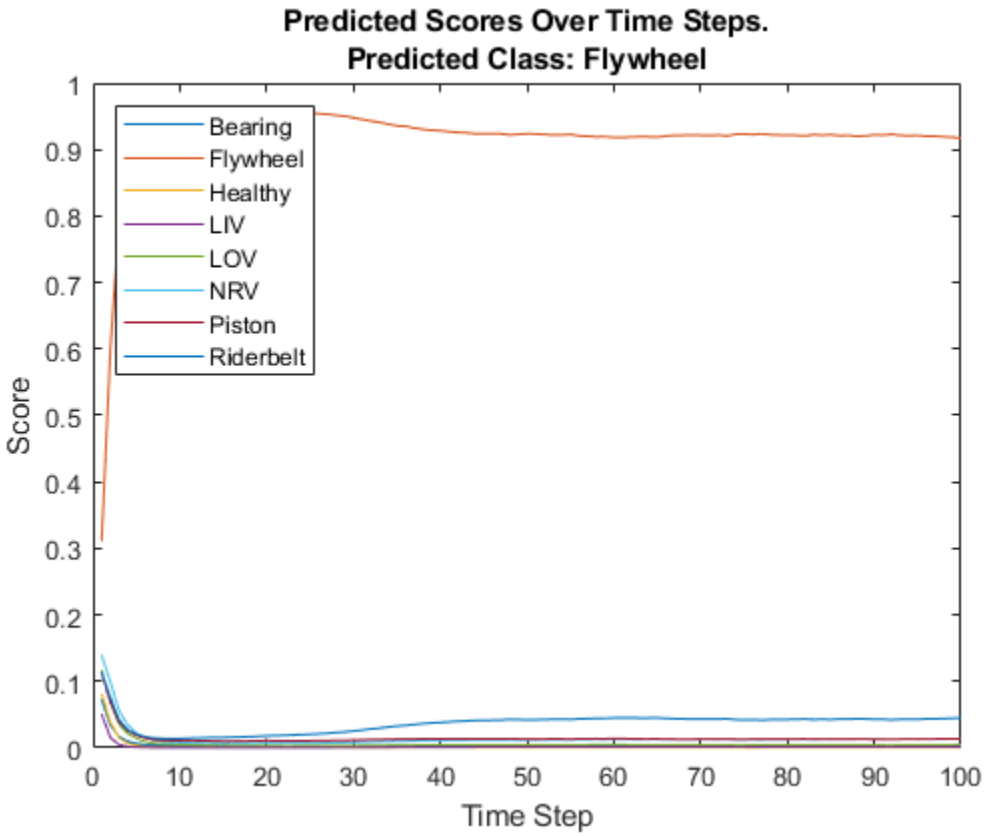
Compute the recognized fault from scores and display it.

```
scores = read(scoreBuffer);
[~,labelIndex] = max(scores(end,:),[],2);
detectedFault = labels(labelIndex)
```

```
detectedFault =
"Flywheel"
```

Plot the scores of each label for each frame.

```
plot(scores)
legend("" + labels,'Location','northwest')
xlabel("Time Step")
ylabel("Score")
str = sprintf("Predicted Scores Over Time Steps.\nPredicted Class: %s",detectedFault);
title(str)
```



Generate MATLAB Executable

Create a code generation configuration object to generate an executable. Specify the target language as C++.

```
cfg = coder.config('mex');
cfg.TargetLang = 'C++';
```

Create a configuration object for deep learning code generation with the MKL-DNN library. Attach the deep learning configuration object to the code generation configuration object.

```
dlcfg = coder.DeepLearningConfig('mkldnn');
cfg.DeepLearningConfig = dlcfg;
```

Create an audio data frame of length `windowLength`.

```
audioFrame = ones(windowLength,1);
```

Call the `codegen` (MATLAB Coder) function from MATLAB Coder to generate C++ code for the `recognizeAirCompressorFault` function. Specify the configuration object and prototype arguments. A MEX-file named `recognizeAirCompressorFault_mex` is generated to your current folder.

```
codegen -config cfg recognizeAirCompressorFault -args {audioFrame,resetNetworkState} -report
```

```
Code generation successful: View report
```

Perform Machine Fault Recognition Using MATLAB Executable

Initialize `signalToBeTested` to `pinkNoiseSignal` or select a signal from the drop-down list to test the file of your choice from the dataset.

```
if ~downloadDataset
    signalToBeTested = pinkNoiseSignal;
else
    [allFiles,~] = splitEachLabel(dataStore,1);
    allData = readall(allFiles);
    signalToBeTested = Riderbelt ;
    signalToBeTested = cell2mat(signalToBeTested);
end
```

Stream one audio frame at a time to represent the system as it would be deployed in a real-time embedded system. Use generated `recognizeAirCompressorFault_mex` to compute audio features and perform deep learning classification.

```
write(audioSource,signalToBeTested);
resetNetworkState = true;

while audioSource.NumUnreadSamples >= windowLength

    % Get a frame of audio data
    x = read(audioSource,windowLength);

    % Apply streaming classifier function
    score = recognizeAirCompressorFault_mex(x,resetNetworkState);

    % Store score for analysis
```

```
    write(scoreBuffer,score);

    resetNetworkState = false;
end
```

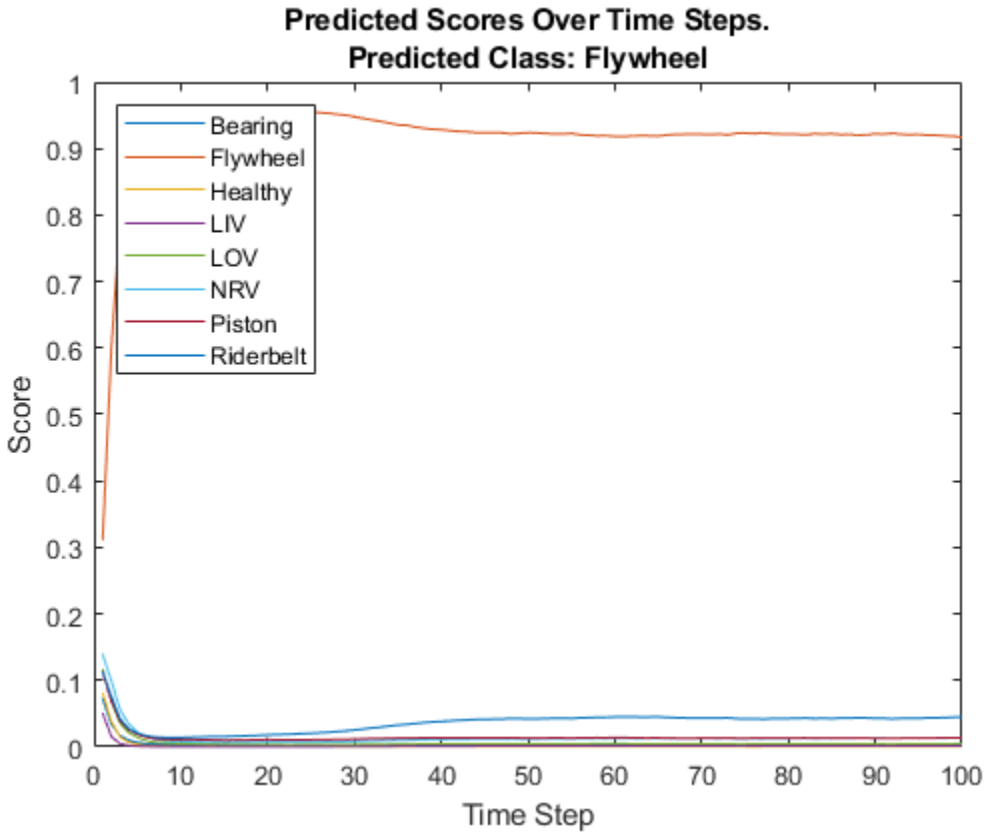
Compute the recognized fault from scores and display it.

```
scores = read(scoreBuffer);
[~,labelIndex] = max(scores(end,:),[],2);
detectedFault = labels(labelIndex)
```

```
detectedFault =
"Flywheel"
```

Plot the scores of each label for each frame.

```
plot(scores)
legend("" + labels,'Location','northwest')
xlabel("Time Step")
ylabel("Score")
str = sprintf("Predicted Scores Over Time Steps.\nPredicted Class: %s",detectedFault);
title(str)
```



Evaluate Execution Time of Alternative MEX Function Workflow

Use `tic` and `toc` to measure the execution time of MATLAB function `recognizeAirCompressorFault` and MATLAB executable (MEX) `recognizeAirCompressorFault_mex`.

Create a `dsp.AsyncBuffer` (DSP System Toolbox) object to record execution time.

```
timingBufferMATLAB = dsp.AsyncBuffer;
timingBufferMEX = dsp.AsyncBuffer;
```

Use same recording that you chose in previous section as input to `recognizeAirCompressorFault` function and its MEX equivalent `recognizeAirCompressorFault_mex`.

```
write(audioSource,signalToBeTested);
```

Measure the execution time of the MATLAB code.

```
resetNetworkState = true;
while audioSource.NumUnreadSamples >= windowLength

    % Get a frame of audio data
    x = read(audioSource,windowLength);

    % Apply streaming classifier function
    tic
    scoreMATLAB = recognizeAirCompressorFault(x,resetNetworkState);
    write(timingBufferMATLAB,toc);

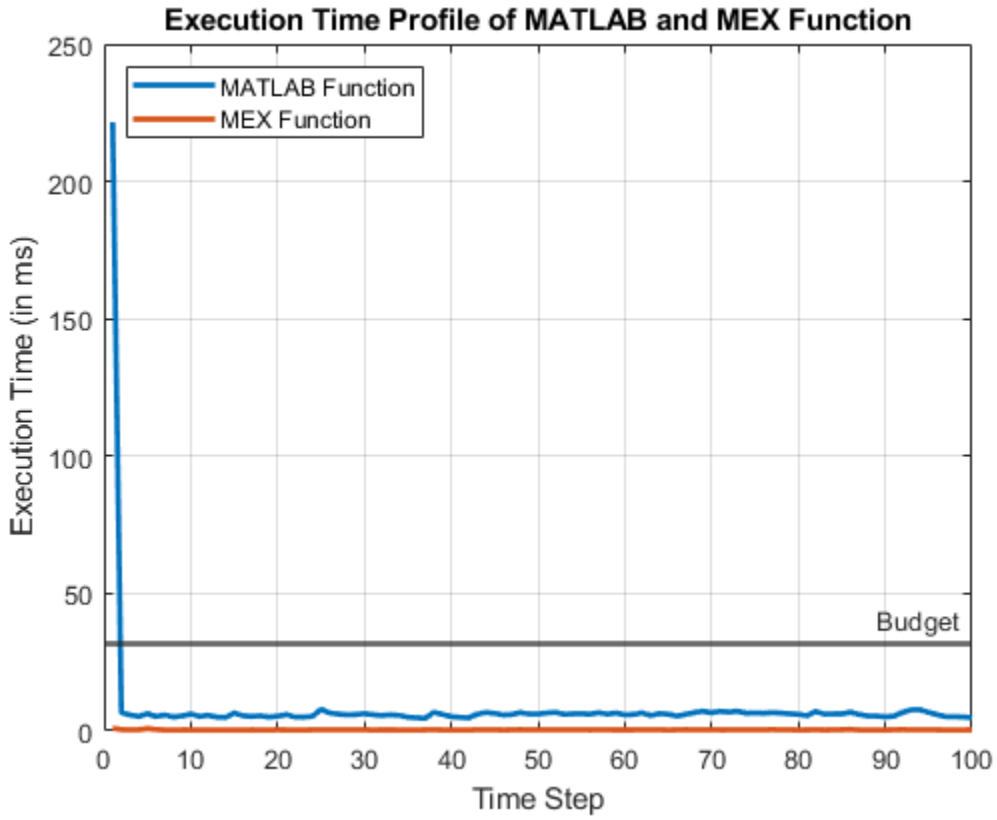
    % Apply streaming classifier MEX function
    tic
    scoreMEX = recognizeAirCompressorFault_mex(x,resetNetworkState);
    write(timingBufferMEX,toc);

    resetNetworkState = false;

end
```

Plot the execution time for each frame and analyze the profile. The first call of `recognizeAirCompressorFault_mex` consumes around four times of the budget as it includes loading of network and resetting of the states. However, in a real, deployed system, that initialization time is only incurred once. The execution time of the MATLAB function is around 10 ms and that of MEX function is ~1 ms, which is well below the 32 ms budget for real-time performance.

```
budget = (windowLength/fs)*1000;
timingMATLAB = read(timingBufferMATLAB)*1000;
timingMEX = read(timingBufferMEX)*1000;
frameNumber = 1:numel(timingMATLAB);
perfGain = timingMATLAB./timingMEX;
plot(frameNumber,timingMATLAB,frameNumber,timingMEX,'LineWidth',2)
grid on
yline(budget,'',{'Budget'},'LineWidth',2)
legend('MATLAB Function','MEX Function','Location','northwest')
xlabel("Time Step")
ylabel("Execution Time (in ms)")
title("Execution Time Profile of MATLAB and MEX Function")
```



Compute the performance gain of MEX over MATLAB function excluding the first call. This performance test is done on a machine using an NVIDIA Quadro P620 (Version 26) GPU and an Intel® Xeon® W-2133 CPU running at 3.60 GHz.

```
PerformanceGain = sum(timingMATLAB(2:end))/sum(timingMEX(2:end))
```

```
PerformanceGain = 15.5501
```

This example ends here. For deploying machine fault recognition on Raspberry Pi, see “Acoustics-Based Machine Fault Recognition Code Generation on Raspberry Pi” (Audio Toolbox).

Acoustics-Based Machine Fault Recognition Code Generation on Raspberry Pi

This example demonstrates code generation for “Acoustics-Based Machine Fault Recognition” (Audio Toolbox) using a long short-term memory (LSTM) network and spectral descriptors. This example uses MATLAB® Coder™, MATLAB Coder Interface for Deep Learning Libraries, MATLAB Support Package for Raspberry Pi Hardware to generate a standalone executable (`.elf`) file on a Raspberry Pi™ that leverages performance of the Arm Compute Library. The input data consists of acoustics time-series recordings from faulty or healthy air compressors and the output is the state of the mechanical machine predicted by the LSTM network. This standalone executable on Raspberry Pi runs the streaming classifier on the input data received from MATLAB and sends the computed scores for each label to MATLAB. Interaction between MATLAB script and the executable on your Raspberry Pi is handled using the user datagram protocol (UDP). For more details on audio preprocessing and network training, see “Acoustics-Based Machine Fault Recognition” (Audio Toolbox).

Example Requirements

- The MATLAB Coder Interface for Deep Learning Libraries Support Package
- ARM processor that supports the NEON extension
- ARM Compute Library version 20.02.1 (on the target ARM hardware)
- Environment variables for the compilers and libraries

For supported versions of libraries and for information about setting up environment variables, see “Prerequisites for Deep Learning with MATLAB Coder” (MATLAB Coder)

Prepare Input Dataset

Specify a sample rate `fs` of 16 kHz and a `windowLength` of 512 samples, as defined in “Acoustics-Based Machine Fault Recognition” (Audio Toolbox). Set `numFrames` to `100`.

```
fs = 16000;
windowLength = 512;
numFrames = 100;
```

To run the Example on a test signal, generate a pink noise signal. To test the performance of the system on a real dataset, download the air compressor dataset [1] on page 14-0 .

```
downloadDataset = false

if ~downloadDataset
    pinkNoiseSignal = pinknoise(windowLength*numFrames);
else
    % Download AirCompressorDataset.zip
    component = 'audio';
    filename = 'AirCompressorDataset/AirCompressorDataset.zip';
    localfile = matlab.internal.examples.downloadSupportFile(component,filename);

    % Unzip the downloaded zip file to the downloadFolder
    downloadFolder = fileparts(localfile);
    if ~exist(fullfile(downloadFolder,'AirCompressorDataset'),'dir')
        unzip(localfile, downloadFolder)
    end
```

```
    % Create an audioDatastore object dataStore, to manage, the data.
    dataStore = audioDatastore(downloadFolder,'IncludeSubfolders',true,'LabelSource','foldernames

    % Use countEachLabel to get the number of samples of each category in the dataset.
    countEachLabel(dataStore)
end
```

Recognize Machine Fault in MATLAB

To run the streaming classifier in MATLAB, download and unzip the system developed in "Acoustics-Based Machine Fault Recognition" (Audio Toolbox).

```
component = 'audio';
filename = 'AcousticsBasedMachineFaultRecognition/AcousticsBasedMachineFaultRecognition.zip';
localfile = matlab.internal.examples.downloadSupportFile(component,filename);

downloadFolder = fullfile(fileparts(localfile),'system');
if ~exist(downloadFolder,'dir')
    unzip(localfile,downloadFolder)
end
```

To access the `recognizeAirCompressorFault` function of the system, add `downloadFolder` to the search path.

```
addpath(downloadFolder)
```

Create a `dsp.AsyncBuffer` (DSP System Toolbox) object to read audio in a streaming fashion and a `dsp.AsyncBuffer` (DSP System Toolbox) object to accumulate scores.

```
audioSource = dsp.AsyncBuffer;
scoreBuffer = dsp.AsyncBuffer;
```

Load the pretrained network and extract labels from the network.

```
airCompNet = coder.loadDeepLearningNetwork('AirCompressorFaultRecognitionModel.mat');
labels = string(airCompNet.Layers(end).Classes);
```

Initialize `signalToBeTested` to `pinkNoiseSignal` or select a signal from the drop-down list to test the file of your choice from the dataset.

```
if ~downloadDataset
    signalToBeTested = pinkNoiseSignal;
else
    [allFiles,~] = splitEachLabel(dataStore,1);
    allData = readall(allFiles);
    signalToBeTested = Bearing ;
    signalToBeTested = cell2mat(signalToBeTested);
end
```

Stream one audio frame at a time to represent the system as it would be deployed in a real-time embedded system. Use `recognizeAirCompressorFault` developed in "Acoustics-Based Machine Fault Recognition" (Audio Toolbox) to compute audio features and perform deep learning classification.

```
write(audioSource,signalToBeTested);
resetNetworkState = true;
```

```
while audioSource.NumUnreadSamples >= windowLength

    % Get a frame of audio data
    x = read(audioSource,windowLength);

    % Apply streaming classifier function
    score = recognizeAirCompressorFault(x,resetNetworkState);

    % Store score for analysis
    write(scoreBuffer,score);

    resetNetworkState = false;
end
```

Compute the recognized fault from scores and display it.

```
scores = read(scoreBuffer);
[~,labelIndex] = max(scores(end,:),[],2);
detectedFault = labels(labelIndex)
```

```
detectedFault =
"Flywheel"
```

Plot the scores of each label for each frame.

```
plot(scores)
legend("" + labels,'Location','northwest')
xlabel("Time Step")
ylabel("Score")
str = sprintf("Predicted Scores Over Time Steps.\nPredicted Class: %s",detectedFault);
title(str)
```

Reset the asynchronous buffer `audioSource`.

```
reset(audioSource)
```

Prepare MATLAB Code For Deployment

This example uses the `dsp.UDPSender` (DSP System Toolbox) System object to send the audio frame to the executable running on Raspberry Pi and the `dsp.UDPReceiver` (DSP System Toolbox) System object to receive the score vector from the Raspberry Pi. Create a `dsp.UDPSender` (DSP System Toolbox) system object to send audio captured in MATLAB to your Raspberry Pi. Set the `targetIPAddress` to the IP address of your Raspberry Pi. Set the `RemoteIPPort` to `25000`. Raspberry Pi receives the input audio frame from the same port using the `dsp.UDPReceiver` (DSP System Toolbox) system object.

```
targetIPAddress = '172.31.164.247';
UDPSend = dsp.UDPSender('RemoteIPPort',25000,'RemoteIPAddress',targetIPAddress);
```

Create a `dsp.UDPReceiver` (DSP System Toolbox) system object to receive predicted scores from your Raspberry Pi. Each UDP packet received from the Raspberry Pi is a vector of scores and each vector element is a score for a state of the air compressor. The maximum message length for the `dsp.UDPReceiver` (DSP System Toolbox) object is 65507 bytes. Calculate the buffer size to accommodate the maximum number of UDP packets.

```
sizeOfDoubleInBytes = 8;
numScores = 8;
maxUDPMessageLength = floor(65507/sizeOfDoubleInBytes);
numPackets = floor(maxUDPMessageLength/numScores);
```

```
bufferSize = numPackets*numScores*sizeOfDoubleInBytes;

UDPReceive = dsp.UDPReceiver("LocalIPPort",21000, ...
    "MessageDataType","single", ...
    "MaximumMessageLength",numScores, ...
    "ReceiveBufferSize",bufferSize);
```

Create a supporting function, `recognizeAirCompressorFaultRaspi`, that receives an audio frame using `dsp.UDPReceiver` (DSP System Toolbox) and applies the streaming classifier and sends the predicted score vector to MATLAB using `dsp.UDPSender` (DSP System Toolbox).

```
type recognizeAirCompressorFaultRaspi
```

```
function recognizeAirCompressorFaultRaspi(hostIPAddress)
% This function receives acoustic input using dsp.UDPReceiver and runs a
% streaming classifier by calling recognizeAirCompressorFault, developed in
% the Acoustics-Based Machine Fault Recognition - MATLAB Example.
% Computed scores are sent to MATLAB using dsp.UDPSender.
%#codegen

%   Copyright 2021 The MathWorks, Inc.

frameLength = 512;

% Configure UDP Sender System Object
UDPSend = dsp.UDPSender('RemoteIPPort',21000,'RemoteIPAddress',hostIPAddress);

% Configure UDP Receiver system object
sizeOfDoubleInBytes = 8;
maxUDPMessageLength = floor(65507/sizeOfDoubleInBytes);
numPackets = floor(maxUDPMessageLength/frameLength);
bufferSize = numPackets*frameLength*sizeOfDoubleInBytes;
UDPReceiveRaspi = dsp.UDPReceiver('LocalIPPort',25000, ...
    'MaximumMessageLength',frameLength, ...
    'ReceiveBufferSize',bufferSize, ...
    'MessageDataType','double');

% Reset network state for first call
resetNetworkState = true;

while true
    % Receive audio frame of size frameLength x 1
    x = UDPReceiveRaspi();

    if(~isempty(x))

        x = x(1:frameLength,1);

        % Apply streaming classifier function
        scores = recognizeAirCompressorFault(x,resetNetworkState);

        %Send output to the host machine
        UDPSend(scores);

        resetNetworkState = false;
    end
end
```

Generate Executable on Raspberry Pi

Replace the `hostIPAddress` with your machine's address. Your Raspberry Pi sends the predicted scores to the IP address you specify.

```
hostIPAddress = coder.Constant('172.18.230.30');
```

Create a code generation configuration object to generate an executable program. Specify the target language as C++.

```
cfg = coder.config('exe');
cfg.TargetLang = 'C++';
```

Create a configuration object for deep learning code generation with the ARM compute library that is on your Raspberry Pi. Specify the architecture of the Raspberry Pi and attach the deep learning configuration object to the code generation configuration object.

```
dlcfg = coder.DeepLearningConfig('arm-compute');
dlcfg.ArmArchitecture = 'armv7';
dlcfg.ArmComputeVersion = '20.02.1';
cfg.DeepLearningConfig = dlcfg;
```

Use the Raspberry Pi Support Package function `raspi` to create a connection to your Raspberry Pi. In the next block of code, replace:

- `raspiname` with the name of your Raspberry Pi
- `pi` with your user name
- `password` with your password

```
if (~exist('r','var'))
  r = raspi('raspiname','pi','password');
end
```

Create a `coder.hardware` (MATLAB Coder) object for Raspberry Pi and attach it to the code generation configuration object.

```
hw = coder.hardware('Raspberry Pi');
cfg.Hardware = hw;
```

Specify the build folder on the Raspberry Pi.

```
buildDir = '~/remoteBuildDir';
cfg.Hardware.BuildDir = buildDir;
```

Use an autogenerated C++ main file to generate a standalone executable.

```
cfg.GenerateExampleMain = 'GenerateCodeAndCompile';
```

Call the `codegen` (MATLAB Coder) function from MATLAB Coder to generate C++ code and the executable on your Raspberry Pi. By default, the Raspberry Pi executable has the same name as the MATLAB function. You get a warning in the code generation logs `that` you can disregard because `recognizeAirCompressorFaultRaspi` has an infinite loop that looks for an audio frame from MATLAB.

```
codegen -config cfg recognizeAirCompressorFaultRaspi -args {hostIPAddress} -report
```

```
 Deploying code. This may take a few minutes.
Warning: Function 'recognizeAirCompressorFaultRaspi' does not terminate due to an infinite loop.
```

```
Warning in ==> recognizeAirCompressorFaultRaspi Line: 1 Column: 1
Code generation successful (with warnings): View report
```

Perform Machine Fault Recognition Using Deployed Code

Create a command to open the `recognizeAirCompressorFaultRaspi` application on a Raspberry Pi. Use `system` to send the command to your Raspberry Pi.

```
applicationName = 'recognizeAirCompressorFaultRaspi';

applicationDirPaths = raspi.utils.getRemoteBuildDirectory('applicationName',applicationName);
targetDirPath = applicationDirPaths{1}.directory;

exeName = strcat(applicationName,'.elf');
command = ['cd ',targetDirPath,'; ./',exeName,' &> 1 &'];

system(r,command);
```

Initialize `signalToBeTested` to `pinkNoiseSignal` or select a signal from the drop-down list to test the file of your choice from the dataset.

```
if ~downloadDataset
    signalToBeTested = pinkNoiseSignal;
else
    [allFiles,~] = splitEachLabel(dataStore,1);
    allData = readall(allFiles);
    signalToBeTested = Bearing ;
    signalToBeTested = cell2mat(signalToBeTested);
end
```

Stream one audio frame at a time to represent a system as it would be deployed in a real-time embedded system. Use the generated MEX file `recognizeAirCompressorFault_mex` to compute audio features and perform deep learning classification.

```
write(audioSource,signalToBeTested);

while audioSource.NumUnreadSamples >= windowLength
    x = read(audioSource,windowLength);
    UDPSend(x);
    score = UDPReceive();
    if ~isempty(score)
        write(scoreBuffer,score');

```

Terminate the standalone executable running on Raspberry Pi.

```
stopExecutable(codertarget.raspi.raspberrypi,exeName)
```

Evaluate Execution Time Using Alternative PIL Function Workflow

To evaluate execution time taken by standalone executable on Raspberry Pi, use a PIL (processor-in-loop) workflow. To perform PIL profiling, generate a PIL function for the supporting function `recognizeAirCompressorFault`.

Create a code generation configuration object to generate the PIL function.

```
cfg = coder.config('lib','ecoder',true);
cfg.VerificationMode = 'PIL';
```

Set the ARM compute library and architecture.

```
dlcfg = coder.DeepLearningConfig('arm-compute');
cfg.DeepLearningConfig = dlcfg ;
cfg.DeepLearningConfig.ArmArchitecture = 'armv7';
cfg.DeepLearningConfig.ArmComputeVersion = '20.02.1';
```

Set up the connection with your target hardware.

```
if (~exist('r','var'))
  r = raspi('raspiname','pi','password');
end
hw = coder.hardware('Raspberry Pi');
cfg.Hardware = hw;
```

Set the build directory and target language.

```
buildDir = '~/remoteBuildDir';
cfg.Hardware.BuildDir = buildDir;
cfg.TargetLang = 'C++';
```

Enable profiling and generate the PIL code. A MEX file named `recognizeAirCompressorFault_pil` is generated in your current folder.

```
cfg.CodeExecutionProfiling = true;
audioFrame = ones(windowLength,1);
resetNetworkStateFlag = true;
codegen -config cfg recognizeAirCompressorFault -args {audioFrame,resetNetworkStateFlag}
```

```
 Deploying code. This may take a few minutes.
### Connectivity configuration for function 'recognizeAirCompressorFault': 'Raspberry Pi'
Location of the generated elf : /home/pi/remoteBuildDir/MATLAB_ws/R2021b/S/MATLAB/Examples/Examp
Code generation successful.
```

Call the generated PIL function 50 times to get the average execution time.

```
totalCalls = 50;

for k = 1:totalCalls
    x = pinknoise(windowLength,1);
    score = recognizeAirCompressorFault_pil(x,resetNetworkStateFlag);
    resetNetworkStateFlag = false;
end
```

```

Code Execution Profiling Report for recognizeAirCompressorFault
The code execution profiling report provides metrics based on data collected from a SIL or PIL execution. Execution times are calculated from data recorded by instrumentation probes added to the SIL or PIL test harness or inside the code generated for each component. See Code Execution Profiling for more information.

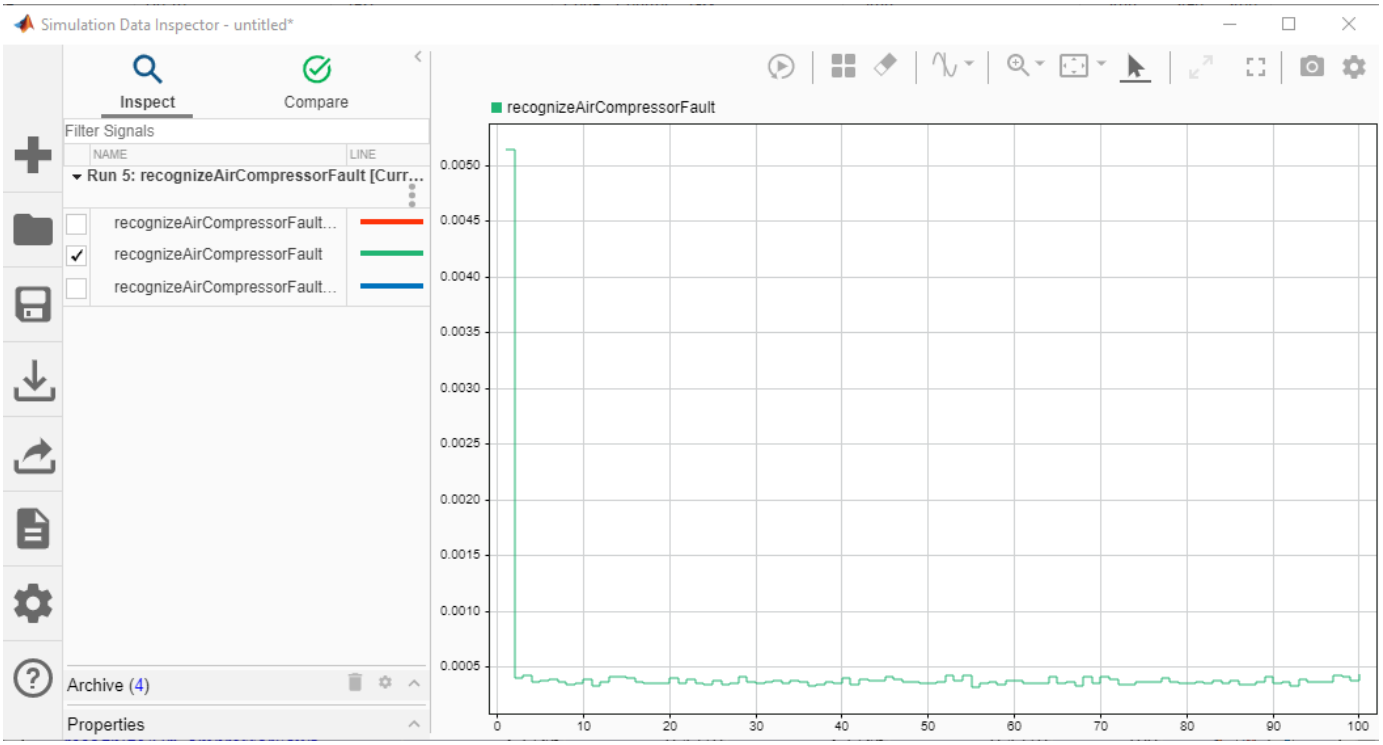
Help



The average execution time of `recognizeAirCompressorFault_pil` function is `0.423` `ms`, which is well below the `32` `ms` budget for real-time performance. The first call of `recognizeAirCompressorFault_pil` consumes around `12` times of the average execution time as it includes loading of network and resetting of the states. However, in a real, deployed system, that initialization time is incurred only once. This example ends here. For deploying machine fault recognition on desktops, see “Acoustics-Based Machine Fault Recognition Code Generation with Intel MKL-DNN” (Audio Toolbox).

End-to-End Deep Speech Separation

This example showcases an end-to-end deep learning network for speaker-independent speech separation.

Introduction

Speech separation is a challenging and critical speech processing task. A number of speech separation methods based on deep learning have been proposed recently, most of which rely on time-frequency transformations of the time-domain audio mixture (See “Cocktail Party Source Separation Using Deep Learning Networks” (Audio Toolbox) for an implementation of such a deep learning system).

Solutions based on time-frequency methods suffer from two main drawbacks:

- The conversion of the time-frequency representations back to the time domain requires phase estimation, which introduces errors and leads to imperfect reconstruction.
- Relatively long windows are required to yield high resolution frequency representations, which leads to high computational complexity and unacceptable latency for real-time scenarios.

In this example, you explore a deep learning speech separation network (based on [1]) which acts directly on the audio signal and bypasses the issues arising from time-frequency transformations.

Separate Speech using the Pretrained Network

Download the Pretrained Network

Before training the deep learning network from scratch, you will use a pretrained version of the network to separate two speakers from an example mixture signal.

First, download the pretrained network and example audio files.

```
url = 'http://ssd.mathworks.com/supportfiles/audio/speechSeparation.zip';
downloadNetFolder = tempdir;
netFolder = fullfile(downloadNetFolder,'speechSeparation');

if ~exist(netFolder,'dir')
    disp('Downloading pretrained network and audio files ...')
    unzip(url,downloadNetFolder)
end
```

Prepare Test Signal

Load two audio signals corresponding to two different speakers. Both signals are sampled at 8 kHz.

```
Fs = 8000;
s1 = audioread(fullfile(netFolder,'speaker1.wav'));
s2 = audioread(fullfile(netFolder,'speaker2.wav'));
```

Normalize the signals.

```
s1 = s1/max(abs(s1));
s2 = s2/max(abs(s2));
```

Listen to a few seconds of each signal.

```
T = 5;
sound(s1(1:T*Fs))
pause(T)

sound(s2(1:T*Fs))
pause(T)
```

Combine the two signals into a mixture signal.

```
mix = s1+s2;
mix = mix/max(abs(mix));
```

Listen to the first few seconds of the mixture signal.

```
sound(mix(1:T*Fs))
pause(T)
```

Separate Speakers

Load the parameters of the pretrained speech separation network.

```
load(fullfile(netFolder,'paramsBest.mat'),'learnables','states')
```

Separate the two speakers in the mixture signals by calling the `separateSpeakers` function.

```
[z1,z2] = separateSpeakers(mix,learnables,states,false);
```

Listen to the first few seconds of the first estimated speech signal.

```
sound(z1(1:T*Fs))
pause(T)
```

Listen to the second estimated signal.

```
sound(z2(1:T*Fs))
pause(T)
```

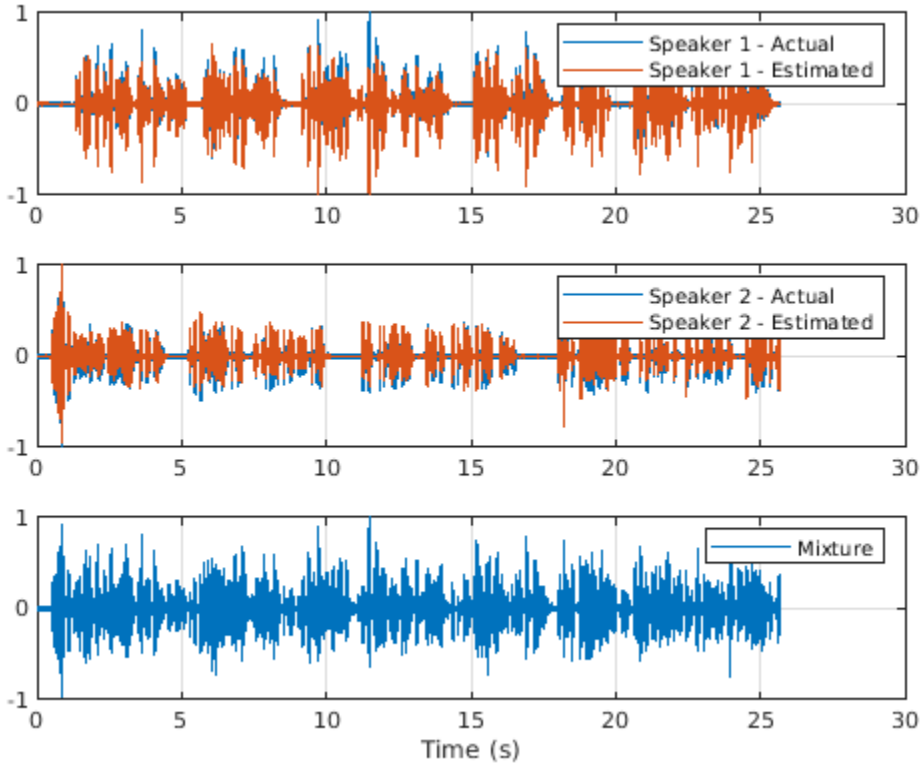
To illustrate the effect of speech separation, plot the estimated and original separated signals along with the mixture signal.

```
s1 = s1(1:length(z1));
s2 = s2(1:length(z2));
mix = mix(1:length(s1));

t  = (0:length(s1)-1)/Fs;

figure;
subplot(311)
plot(t,s1)
hold on
plot(t,z1)
grid on
legend('Speaker 1 - Actual','Speaker 1 - Estimated')
subplot(312)
plot(t,s2)
hold on
plot(t,z2)
grid on
legend('Speaker 2 - Actual','Speaker 2 - Estimated')
```

```
subplot(313)
plot(t,mix)
grid on
legend('Mixture')
xlabel('Time (s)')
```



Compare to a Time-Frequency Transformation Deep Learning Network

Next, you compare the performance of the network to the network developed in the “Cocktail Party Source Separation Using Deep Learning Networks” (Audio Toolbox) example. This speech separation network is based on traditional time-frequency representations of the audio mixture (using the short-time Fourier transform, STFT, and the inverse short-time Fourier transform, ISTFT).

Download the pretrained network.

```
url = 'http://ssd.mathworks.com/supportfiles/audio/CocktailPartySourceSeparation.zip';

downloadNetFolder = tempdir;
cocktailNetFolder = fullfile(downloadNetFolder,'CocktailPartySourceSeparation');

if ~exist(cocktailNetFolder,'dir')
    disp('Downloading pretrained network and audio files (5 files - 24.5 MB) ...')
    unzip(url,downloadNetFolder)
end
```

The function `separateSpeakersTimeFrequency` encapsulates the steps required to separate speech using this network. The function performs the following steps:

- Compute the magnitude STFT of the input time-domain mixture.
- Compute a soft time-frequency mask by passing the STFT to the network.
- Compute the STFT of the separated signals by multiplying the mixture STFT by the mask.
- Reconstruct the time-domain separated signals using ISTFT. The phase of the mixture STFT is used.

Refer to the “Cocktail Party Source Separation Using Deep Learning Networks” (Audio Toolbox) example for more details about this network.

Separate the two speakers.

```
[y1,y2] = separateSpeakersTimeFrequency(mix,cocktailNetFolder);
```

Listen to the first separated signal.

```
sound(y1(1:Fs*T))
pause(T)
```

Listen to the second separated signal.

```
sound(y2(1:Fs*T))
pause(T)
```

Evaluate Network Performance using SI-SNR

You will compare the two networks using the scale-invariant source-to-noise ratio (SI-SNR) objective measure [1].

Compute the SISNR for the first speaker with the end-to-end network.

First, normalize the actual and estimated signals.

```
s10 = s1 - mean(s1);
z10 = z1 - mean(z1);
```

Compute the "signal" component of the SNR.

```
t = sum(s10.*z10) .* z10 ./ (sum(z10.^2)+eps);
```

Compute the "noise" component of the SNR.

```
n = s1 - t;
```

Now compute the SI-SNR (in dB).

```
v1 = 20*log((sqrt(sum(t.^2))+eps)./sqrt((sum(n.^2))+eps))/log(10);
fprintf('End-to-end network - Speaker 1 SISNR: %f dB\n',v1)
```

```
End-to-end network - Speaker 1 SISNR: 14.316869 dB
```

The SI-SNR computation steps are encapsulated in the function `SISNR`. Use the function to compute the SI-SNR of the second speaker with the end-to-end network.

```
v2 = SISNR(z2,s2);
fprintf('End-to-end network - Speaker 2 SISNR: %f dB\n',v2)
```

```
End-to-end network - Speaker 2 SISNR: 13.706421 dB
```

Next, compute the SI-SNR for each speaker for the STFT-based network.

```
w1 = SISNR(y1,s1(1:length(y1)));
w2 = SISNR(y2,s2(1:length(y2)));
fprintf('STFT network - Speaker 1 SISNR: %f dB\n',w1)
```

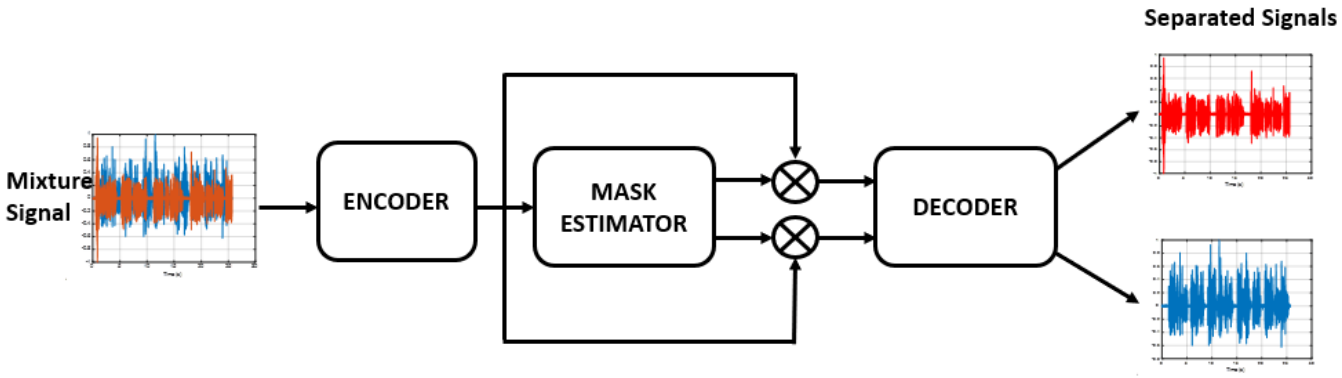
```
STFT network - Speaker 1 SISNR: 7.003789 dB
```

```
fprintf('STFT network - Speaker 2 SISNR: %f dB\n',w2)
```

```
STFT network - Speaker 2 SISNR: 7.382209 dB
```

Training the Speech Separation Network

Examine the Network Architecture



The network is based on [1] and consists of three stages: Encoding, mask estimation or separation, and decoding.

- The encoder transforms the time-domain input mixture signals into an intermediate representation using convolutional layers.
- The mask estimator computes one mask per speaker. The intermediate representation of each speaker is obtained by multiplying the encoder's output by its respective mask. The mask estimator is comprised of 32 blocks of convolutional and normalization layers with skip connections between blocks.
- The decoder transforms the intermediate representations to time-domain separated speech signals using transposed convolutional layers.

The operation of the network is encapsulated in `separateSpeakers`.

Optionally Reduce the Dataset Size

To train the network with the entire dataset and achieve the highest possible accuracy, set `reduceDataset` to false. To run this example quickly, set `reduceDataset` to true. This will run the rest of the example on only a handful of files.

```
reduceDataset = true;
```

Download the Training Dataset

You use a subset of the LibriSpeech Dataset [2] to train the network. The LibriSpeech Dataset is a large corpus of read English speech sampled at 16 kHz. The data is derived from audiobooks read from the LibriVox project.

Download the LibriSpeech dataset. If `reduceDataset` is true, this steo is skipped.

```
downloadDatasetFolder = tempdir;
datasetFolder = fullfile(downloadDatasetFolder,"LibriSpeech","train-clean-360");
if ~reduceDataset
    filename = "train-clean-360.tar.gz";
    url = "http://www.openSLR.org/resources/12/" + filename;
    if ~isfolder(datasetFolder)
        gunzip(url,downloadDatasetFolder);
        unzippedFile = fullfile(downloadDatasetFolder,filename);
        untar(unzippedFile{1}(1:end-3),downloadDatasetFolder);
    end
end
```

Preprocess the Dataset

The LibriSpeech dataset is comprised of a large number of audio files with a single speaker. It does not contain mixture signals where 2 or more persons are speaking simultaneously.

You will process the original dataset to create a new dataset that is suitable for training the speech separation network.

The steps for creating the training dataset are encapsulated in `createTrainingDataset`. The function creates mixture signals comprised of utterances of two random speakers. The function returns three audio datastores:

- `mixDatastore` points to mixture files (where two speakers are talking simultaneously).
- `speaker1Datastore` points to files containing the isolated speech of the first speaker in the mixture.
- `speaker2Datastore` points to files containing the isolated speech of the second speaker in the mixture.

```
miniBatchSize = 4;
[mixDatastore,speaker1Datastore,speaker2Datastore] = createTrainingDataset(netFolder,datasetFolde
```

Combine the datastores. This ensures that the files stay in the correct order when you shuffle them at the start of each new epoch in the training loop.

```
ds = combine(mixDatastore,speaker1Datastore,speaker2Datastore);
```

Create a minibatch queue from the datastore.

```
mqueue = minibatchqueue(ds,'MiniBatchSize',miniBatchSize,'OutputEnvironment','cpu','OutputAsDlar
```

Specify Training Options

Define training parameters.

Train for 10 epochs.

```
if reduceDataset
    numEpochs = 1;
```

```
else
    numEpochs = 10; %#ok
end
```

Specify the options for Adam optimization. Set the initial learning rate to 1e-3. Use a gradient decay factor of 0.9 and a squared gradient decay factor of 0.999.

```
learnRate = 1e-3;
averageGrad = [];
averageSqGrad = [];

gradDecay = 0.9;
sqGradDecay = 0.999;
```

Train on a GPU if one is available. Using a GPU requires Parallel Computing Toolbox™.

```
executionEnvironment = "auto"; % Change to "gpu" to train on a GPU.

duration = 4 * 8000;
```

Set Up Validation Data

You will use the test signal you previously employed to test the pretrained network to compute a validation SI-SNR periodically during training.

If a GPU is available, move the validation signal to the GPU.

```
mix = dlarray(mix,'SCB');
if (executionEnvironment == "auto" && canUseGPU) || executionEnvironment == "gpu"
    mix = gpuArray(mix);
end
```

Define the number of iterations between validation SI-SNR computations.

```
numIterPerValidation = 50;
```

Define a vector to hold the validation SI-SNR from each iteration.

```
valSNR = [];
```

Define a variable to hold the best validation SI-SNR.

```
bestSNR = -Inf;
```

Define a variable to hold the epoch in which the best validation score occurred.

```
bestEpoch = 1;
```

Initialize Network

Initialize the network parameters. `learnables` is a structure containing the learnable parameters from the network layers. `states` is a structure containing the states from the normalization layers.

```
[learnables,states] = initializeNetworkParams;
```

Train the Network

Execute the training loop. This can take many hours to run.

Note that there is no a priori way to associate the estimated output speaker signals with the expected speaker signals. This is resolved by using Utterance-level permutation invariant training (uPIT) [1]. The loss is based on computing the SI-SNR. uPIT minimizes the loss over all permutations between outputs and targets. It is defined in the function `uPIT`.

The validation SI-SNR is computed periodically. If the SI-SNR is the best value to-date, the network parameters are saved to `params.mat`.

```
iteration = 0;

% Loop over epochs.
for jj =1:numEpochs

    % Shuffle the data
    shuffle(mqueue);

    while hasdata(mqueue)

        % Compute validation loss/SNR periodically
        if mod(iteration,numIterPerValidation)==0

            [z1,z2] = separateSpeakers(mix, learnables,states,false);

            l = uPIT(z1,s1,z2,s2);
            valSNR(end+1) = l; %#ok

            if l > bestSNR
                bestSNR = l;
                bestEpoch = jj;
                filename = 'params.mat';
                save(filename,'learnables','states');
            end
        end

        iteration = iteration + 1;

        % Get a new batch of training data
        [x1Batch,x2Batch,mixBatch] = next(mqueue);
        x1Batch = reshape(x1Batch,[duration 1 miniBatchSize]);
        x2Batch = reshape(x2Batch,[duration 1 miniBatchSize]);
        mixBatch = reshape(mixBatch,[duration 1 miniBatchSize]);

        x1Batch = dlarray(x1Batch,'SCB');
        x2Batch = dlarray(x2Batch,'SCB');
        mixBatch = dlarray(mixBatch,'SCB');

        if (executionEnvironment == "auto" && canUseGPU) || executionEnvironment == "gpu"
            x1Batch = gpuArray(x1Batch);
            x2Batch = gpuArray(x2Batch);
            mixBatch = gpuArray(mixBatch);
        end

        % Evaluate the model gradients and loss using dlfeval and the modelGradients function.
        [gradients,states] = dlfeval( @modelGradients,mixBatch,x1Batch,x2Batch,learnables,states

        % Update the network parameters using the ADAM optimizer.
        [learnables,averageGrad,averageSqGrad] = adamupdate(learnables,gradients,averageGrad,aver
```

```
    end

    % Reduce the learning rate if the validation accuracy did not improve
    % during the epoch
    if bestEpoch ~= jj
        learnRate = learnRate/2;
    end
end
```

Plot the validation SNR values.

```
if ~reduceDataset
    valIterNum = 0:length(valSNR)-1;
    figure
    semilogx(numIterPerValidation*(valIterNum-1),valSNR,'b*-')
    grid on
    xlabel('Iteration #')
    ylabel('Validation SINR (dB)')
    valFig.Visible = 'on';
end
```

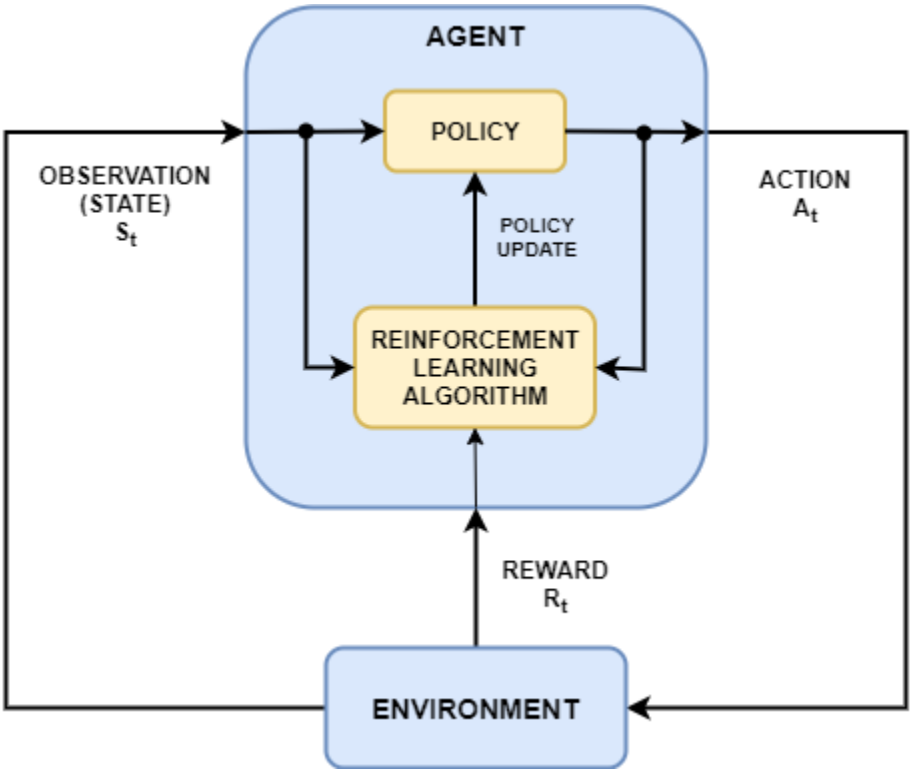
Reinforcement Learning Examples

Reinforcement Learning Using Deep Neural Networks

Reinforcement learning is a goal-directed computational approach where a computer learns to perform a task by interacting with an unknown dynamic environment. This learning approach enables the computer to make a series of decisions to maximize the cumulative reward for the task without human intervention and without being explicitly programmed to achieve the task. The following diagram shows a general representation of a reinforcement learning scenario.



The goal of reinforcement learning is to train the *policy* of an *agent* to complete a task within an unknown *environment*. The agent receives *observations* and a *reward* from the environment and sends *actions* to the environment. The reward is a measure of how successful an action is with respect to completing the task goal.

To create and train reinforcement learning agents, you can use Reinforcement Learning Toolbox™ software. Typically, agent policies are implemented using deep neural networks, which you can create using Deep Learning Toolbox software.

Reinforcement learning is useful for many control and planning applications. The following examples show how to train reinforcement learning agents for robotics and automated driving tasks.

- “Train DDPG Agent to Control Flying Robot” on page 15-45
- “Train Biped Robot to Walk Using Reinforcement Learning Agents” on page 15-51
- “Train DDPG Agent for Adaptive Cruise Control” on page 15-70
- “Train DDPG Agent for Path-Following Control” on page 15-87
- “Train PPO Agent for Automatic Parking Valet” on page 15-95

Reinforcement Learning Workflow

The general workflow for training an agent using reinforcement learning includes the following steps.

1. **Formulate problem** — Define the task for the agent to learn, including how the agent interacts with the environment and any primary and secondary goals the agent must achieve.
2. **Create environment** — Define the environment within which the agent operates, including the interface between agent and environment and the environment dynamic model.
3. **Define reward** — Specify the reward signal that the agent uses to measure its performance against the task goals and how to calculate this signal from the environment.
4. **Create agent** — Create the agent, which includes defining a policy representation and configuring the agent learning algorithm.
5. **Train agent** — Train the agent policy representation using the defined environment, reward, and agent learning algorithm.
6. **Validate agent** — Evaluate the performance of the trained agent by simulating the agent and environment together.
7. **Deploy policy** — Deploy the trained policy representation using, for example, generated GPU code.

Training an agent using reinforcement learning is an iterative process. Decisions and results in later stages can require you to return to an earlier stage in the learning workflow. For example, if the training process does not converge to an optimal policy within a reasonable amount of time, you might have to update any of the following before retraining the agent:

- Training settings
- Learning algorithm configuration
- Policy representation
- Reward signal definition
- Action and observation signals
- Environment dynamics

Reinforcement Learning Environments

In a reinforcement learning scenario, where you train an agent to complete a task, the environment models the dynamics with which the agent interacts. The environment:

1. Receives actions from the agent.

2 Outputs observations in response to the actions.

3 Generates a reward measuring how well the action contributes to achieving the task.

Creating an environment model includes defining the following:

- Action and observation signals that the agent uses to interact with the environment.
- Reward signal that the agent uses to measure its success. For more information, see “Define Reward Signals” (Reinforcement Learning Toolbox).
- Environment dynamic behavior.

You can create an environment in either MATLAB or Simulink. For more information, see “Create MATLAB Reinforcement Learning Environments” (Reinforcement Learning Toolbox) and “Create Simulink Reinforcement Learning Environments” (Reinforcement Learning Toolbox).

Reinforcement Learning Agents

A reinforcement learning agent contains two components: a *policy* and a *learning algorithm*.

- The policy is a mapping that selects actions based on observations from the environment. Typically, the policy is a function approximator with tunable parameters, such as a deep neural network.
- The learning algorithm continuously updates the policy parameters based on the actions, observations, and reward. The goal of the learning algorithm is to find an optimal policy that maximizes the cumulative reward received during the task.

Agents are distinguished by their learning algorithms and policy representations. Agents can operate in discrete action spaces, continuous action spaces, or both. In a discrete action space, the agent selects actions from a finite set of possible actions. In a continuous action space, the agent selects an action from a continuous range of possible action values. Reinforcement Learning Toolbox software supports the following types of agents.

Agent	Action Space
“Q-Learning Agents” (Reinforcement Learning Toolbox)	Discrete
“Deep Q-Network Agents” (Reinforcement Learning Toolbox)	Discrete
“SARSA Agents” (Reinforcement Learning Toolbox)	Discrete
“Policy Gradient Agents” (Reinforcement Learning Toolbox)	Discrete or continuous
“Actor-Critic Agents” (Reinforcement Learning Toolbox)	Discrete or continuous
“Proximal Policy Optimization Agents” (Reinforcement Learning Toolbox)	Discrete or continuous
“Deep Deterministic Policy Gradient Agents” (Reinforcement Learning Toolbox)	Continuous
“Twin-Delayed Deep Deterministic Policy Gradient Agents” (Reinforcement Learning Toolbox)	Continuous

Agent	Action Space
“Soft Actor-Critic Agents” (Reinforcement Learning Toolbox)	Continuous

For more information, see “Reinforcement Learning Agents” (Reinforcement Learning Toolbox).

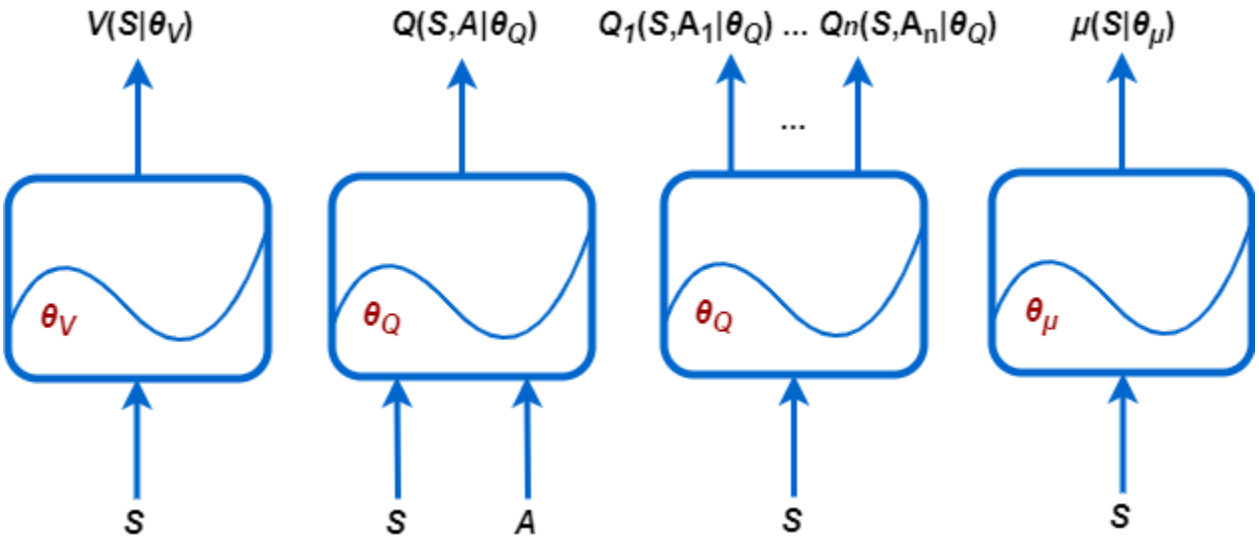
Create Deep Neural Network Policies and Value Functions

Depending on the type of agent you use, its policy and learning algorithm require one or more policy and value function representations, which you can implement using deep neural networks.

Reinforcement Learning Toolbox supports the following types of value function and policy representations.

- $V(S|\theta_V)$ — Critics that estimate the expected cumulative long-term reward (value function) based on a given observation S.
- $Q(S,A|\theta_Q)$ — Critics that estimate the value function for a given discrete action A and a given observation S.
- $Q_i(S,A_i|\theta_Q)$ — Multi-output critics that estimate the value function for all possible discrete actions A_i and a given observation S.
- $\mu(S|\theta_\mu)$ — Actors that select an action based on a given observation S. Actors can select actions using either deterministic or stochastic methods.

During training, the agent updates the parameters of these representations (θ_V, θ_Q, and θ_μ).



You can create most Reinforcement Learning Toolbox agents with default policy and value function representations. The agents define the input and output layers of these deep neural networks based on the action and observation specifications from the environment.

Alternatively, you can create actor and critic representations for your agent using Deep Learning Toolbox functionality, such as the **Deep Network Designer** app. In this case, ensure that the input and output dimensions of the actor and critic representations match the corresponding action and observation specifications of the environment. For an example that creates a critic representation

using **Deep Network Designer**, see “Create Agent Using Deep Network Designer and Train Using Image Observations” on page 15-24.

Deep neural networks consist of a series of interconnected layers. For a full list of available layers, see “List of Deep Learning Layers” on page 1-21.

All agents, except Q-learning and SARSA agents, support recurrent neural networks (RNNs). These networks have an input `sequenceInputLayer` and at least one layer that has hidden state information, such as an `lstmLayer`. These networks can be especially useful when the environment has states that are not in the observation vector.

For more information on creating agents and their associated value function and policy representations, see the corresponding agent pages in the previous table.

Reinforcement Learning Toolbox software provides additional layers that you can use when creating deep neural network representations.

Layer	Description
`scalingLayer`	Applies a linear scale and bias to an input array. This layer is useful for scaling and shifting the outputs of nonlinear layers, such as `tanhLayer` and `sigmoidLayer`.
`quadraticLayer`	Creates a vector of quadratic monomials constructed from the elements of the input array. This layer is useful when you need an output that is some quadratic function of its inputs, such as for an LQR controller.
`softplusLayer`	Implements the softplus activation $Y = \log(1 + e^X)$, which ensures that the output is always positive. This is a smoothed version of the rectified linear unit (ReLU).

For more information on creating policy and value function representations, see “Create Policy and Value Function Representations” (Reinforcement Learning Toolbox).

You can also import pretrained deep neural networks or deep neural network layer architectures using the Deep Learning Toolbox network import functionality. For more information, see “Import Policy and Value Function Representations” (Reinforcement Learning Toolbox).

Train Reinforcement Learning Agents

Once you create an environment and reinforcement learning agent, you can train the agent in the environment using the `train` function. To configure your training, use an `rlTrainingOptions` object. For more information, see “Train Reinforcement Learning Agents” (Reinforcement Learning Toolbox)

If you have Parallel Computing Toolbox software, you can accelerate training and simulation by using multicore processors or GPUs. For more information, see “Train Agents Using Parallel Computing and GPUs” (Reinforcement Learning Toolbox).

Deploy Trained Policies

Once you train a reinforcement learning agent, you can generate code to deploy the optimal policy. You can generate:

- CUDA® code using GPU Coder™
- C/C++ code using MATLAB Coder™

To create a policy evaluation function that selects an action based on a given observation, use the `generatePolicyFunction` command. This command generates a MATLAB script, which contains the policy evaluation function, and a MAT-file, which contains the optimal policy data.

You can generate code to deploy this policy function using GPU Coder or MATLAB Coder.

For more information, see “Deploy Trained Reinforcement Learning Policies” (Reinforcement Learning Toolbox).

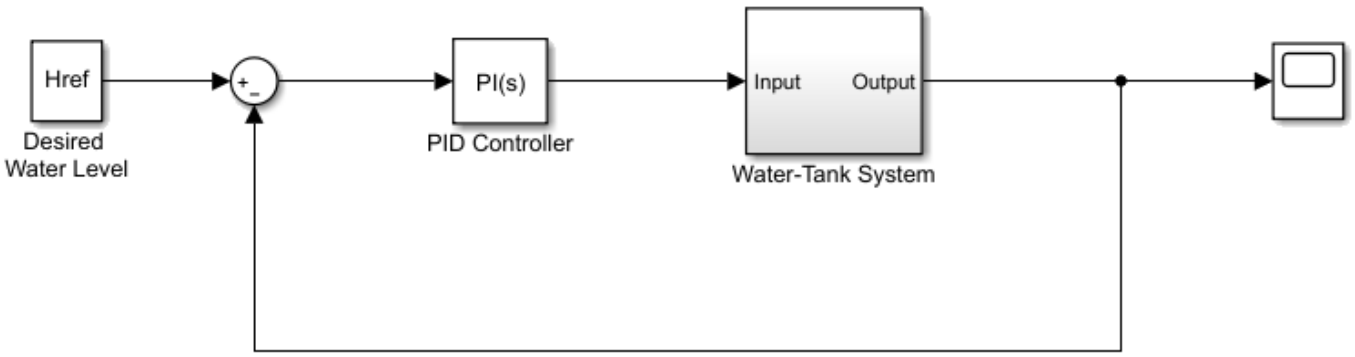
Create Simulink Environment and Train Agent

This example shows how to convert the PI controller in the `watertank` Simulink® model to a reinforcement learning deep deterministic policy gradient (DDPG) agent. For an example that trains a DDPG agent in MATLAB®, see “Train DDPG Agent to Control Double Integrator System” (Reinforcement Learning Toolbox).

Water Tank Model

The original model for this example is the water tank model. The goal is to control the level of the water in the tank. For more information about the water tank model, see “watertank Simulink Model” (Simulink Control Design).

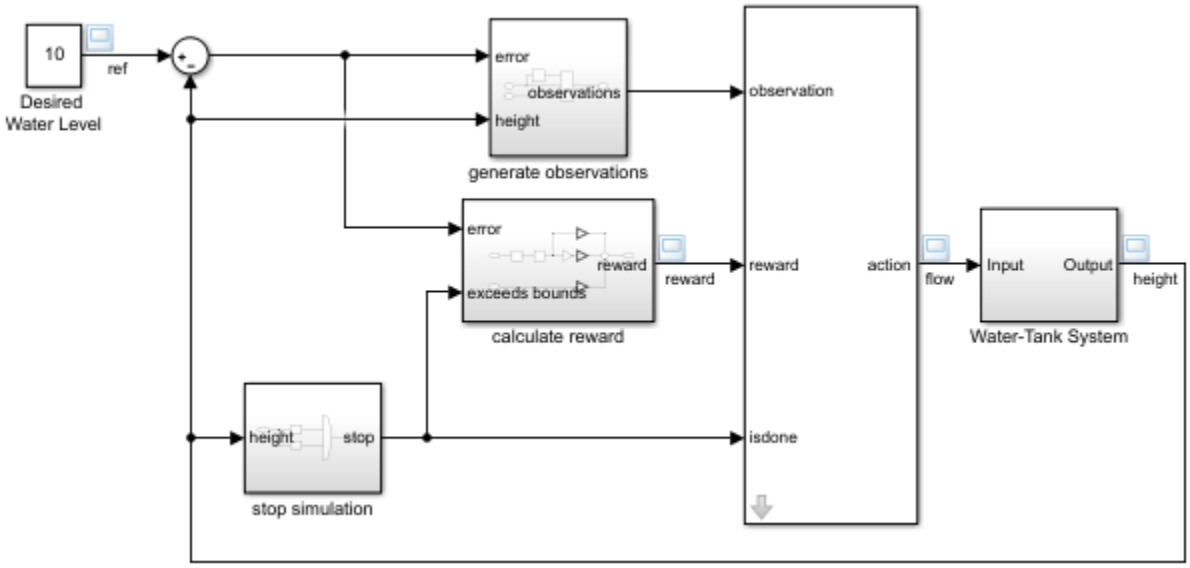


Modify the original model by making the following changes:

1. Delete the PID Controller.
2. Insert the RL Agent block.
3. Connect the observation vector $[\int e\,\mathrm{dt}\ \ e\ \ h]^T$, where h is the height of the tank, $e = r - h$, and r is the reference height.
4. Set up the reward reward $= 10(|e| < 0.1) - 1(|e| \geq 0.1) - 100(h \leq 0 \,||\, h \geq 20)$.
5. Configure the termination signal such that the simulation stops if $h \leq 0$ or $h \geq 20$.

The resulting model is `rlwatertank.slx`. For more information on this model and the changes, see “Create Simulink Reinforcement Learning Environments” (Reinforcement Learning Toolbox).

```
open_system('rlwatertank')
```



Create Environment Interface

Creating an environment model includes defining the following:

- Action and observation signals that the agent uses to interact with the environment. For more information, see `rlNumericSpec` (Reinforcement Learning Toolbox) and `rlFiniteSetSpec` (Reinforcement Learning Toolbox).
- Reward signal that the agent uses to measure its success. For more information, see “Define Reward Signals” (Reinforcement Learning Toolbox).

Define the observation specification `obsInfo` and action specification `actInfo`.

```
obsInfo = rlNumericSpec([3 1],...
    'LowerLimit',[-inf -inf 0  ]',...
    'UpperLimit',[ inf  inf inf]');
obsInfo.Name = 'observations';
obsInfo.Description = 'integrated error, error, and measured height';
numObservations = obsInfo.Dimension(1);

actInfo = rlNumericSpec([1 1]);
actInfo.Name = 'flow';
numActions = actInfo.Dimension(1);
```

Build the environment interface object.

```
env = rlSimulinkEnv('rlwatertank','rlwatertank/RL Agent',...
    obsInfo,actInfo);
```

Set a custom reset function that randomizes the reference values for the model.

```
env.ResetFcn = @(in)localResetFcn(in);
```

Specify the simulation time `Tf` and the agent sample time `Ts` in seconds.

```
Ts = 1.0;
Tf = 200;
```

Fix the random generator seed for reproducibility.

```
rng(0)
```

Create DDPG Agent

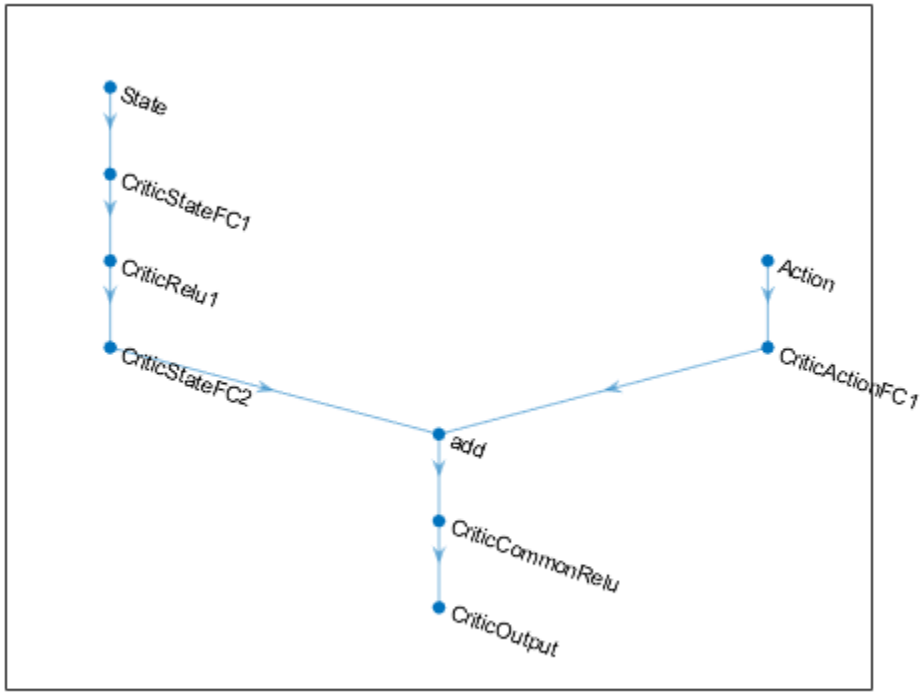
Given observations and actions, a DDPG agent approximates the long-term reward using a critic value function representation. To create the critic, first create a deep neural network with two inputs, the observation and action, and one output. For more information on creating a deep neural network value function representation, see “Create Policy and Value Function Representations” (Reinforcement Learning Toolbox).

```
statePath = [
    featureInputLayer(numObservations,'Normalization','none','Name','State')
    fullyConnectedLayer(50,'Name','CriticStateFC1')
    reluLayer('Name','CriticRelu1')
    fullyConnectedLayer(25,'Name','CriticStateFC2')];
actionPath = [
    featureInputLayer(numActions,'Normalization','none','Name','Action')
    fullyConnectedLayer(25,'Name','CriticActionFC1')];
commonPath = [
    additionLayer(2,'Name','add')
    reluLayer('Name','CriticCommonRelu')
    fullyConnectedLayer(1,'Name','CriticOutput')];

criticNetwork = layerGraph();
criticNetwork = addLayers(criticNetwork,statePath);
criticNetwork = addLayers(criticNetwork,actionPath);
criticNetwork = addLayers(criticNetwork,commonPath);
criticNetwork = connectLayers(criticNetwork,'CriticStateFC2','add/in1');
criticNetwork = connectLayers(criticNetwork,'CriticActionFC1','add/in2');
```

View the critic network configuration.

```
figure
plot(criticNetwork)
```



Specify options for the critic representation using `rlRepresentationOptions` (Reinforcement Learning Toolbox).

```
criticOpts = rlRepresentationOptions('LearnRate',1e-03,'GradientThreshold',1);
```

Create the critic representation using the specified deep neural network and options. You must also specify the action and observation specifications for the critic, which you obtain from the environment interface. For more information, see `rlQValueRepresentation` (Reinforcement Learning Toolbox).

```
critic = rlQValueRepresentation(criticNetwork,obsInfo,actInfo,'Observation',{'State'},'Action',{
```

Given observations, a DDPG agent decides which action to take using an actor representation. To create the actor, first create a deep neural network with one input, the observation, and one output, the action.

Construct the actor in a similar manner to the critic. For more information, see `rlDeterministicActorRepresentation` (Reinforcement Learning Toolbox).

```
actorNetwork = [
    featureInputLayer(numObservations,'Normalization','none','Name','State')
    fullyConnectedLayer(3, 'Name','actorFC')
    tanhLayer('Name','actorTanh')
    fullyConnectedLayer(numActions,'Name','Action')
    ];

actorOptions = rlRepresentationOptions('LearnRate',1e-04,'GradientThreshold',1);
```

```
actor = rlDeterministicActorRepresentation(actorNetwork,obsInfo,actInfo,'Observation',{'State'},
```

To create the DDPG agent, first specify the DDPG agent options using `rlDDPGAgentOptions` (Reinforcement Learning Toolbox).

```
agentOpts = rlDDPGAgentOptions(...
    'SampleTime',Ts,...
    'TargetSmoothFactor',1e-3,...
    'DiscountFactor',1.0, ...
    'MiniBatchSize',64, ...
    'ExperienceBufferLength',1e6);
agentOpts.NoiseOptions.Variance = 0.3;
agentOpts.NoiseOptions.VarianceDecayRate = 1e-5;
```

Then, create the DDPG agent using the specified actor representation, critic representation, and agent options. For more information, see `rlDDPGAgent` (Reinforcement Learning Toolbox).

```
agent = rlDDPGAgent(actor,critic,agentOpts);
```

Train Agent

To train the agent, first specify the training options. For this example, use the following options:

- Run each training for at most `5000` episodes. Specify that each episode lasts for at most `ceil(Tf/Ts)` (that is `200`) time steps.
- Display the training progress in the Episode Manager dialog box (set the `Plots` option) and disable the command line display (set the `Verbose` option to `false`).
- Stop training when the agent receives an average cumulative reward greater than `800` over `20` consecutive episodes. At this point, the agent can control the level of water in the tank.

For more information, see `rlTrainingOptions` (Reinforcement Learning Toolbox).

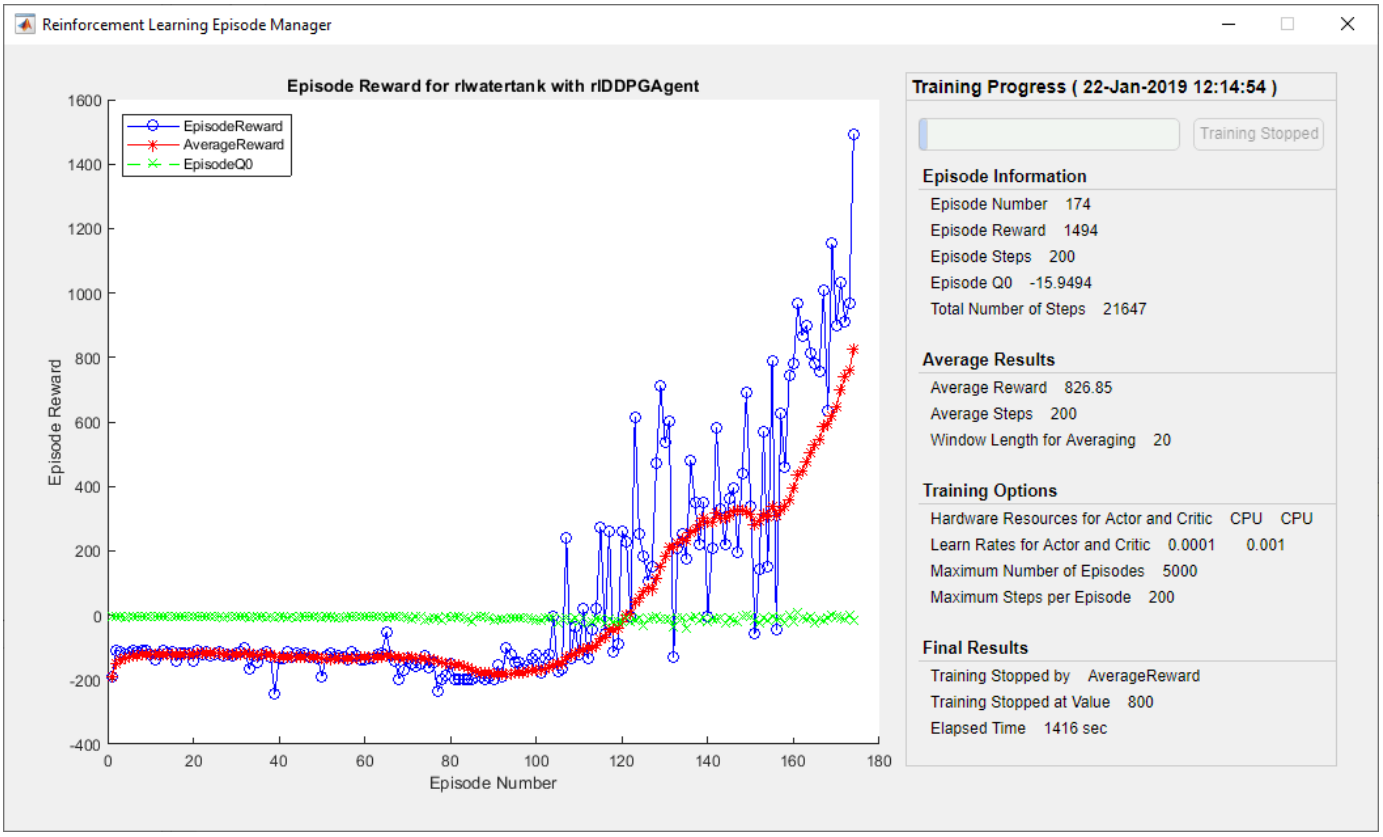
```
maxepisodes = 5000;
maxsteps = ceil(Tf/Ts);
trainOpts = rlTrainingOptions(...
    'MaxEpisodes',maxepisodes, ...
    'MaxStepsPerEpisode',maxsteps, ...
    'ScoreAveragingWindowLength',20, ...
    'Verbose',false, ...
    'Plots','training-progress',...
    'StopTrainingCriteria','AverageReward',...
    'StopTrainingValue',800);
```

Train the agent using the `train` (Reinforcement Learning Toolbox) function. Training is a computationally intensive process that takes several minutes to complete. To save time while running this example, load a pretrained agent by setting `doTraining` to `false`. To train the agent yourself, set `doTraining` to `true`.

```
doTraining = false;

if doTraining
    % Train the agent.
    trainingStats = train(agent,env,trainOpts);
else
    % Load the pretrained agent for the example.
```

```
    load('WaterTankDDPG.mat','agent')
end
```



Validate Trained Agent

Validate the learned agent against the model by simulation.

```
simOpts = rlSimulationOptions('MaxSteps',maxsteps,'StopOnError','on');
experiences = sim(env,agent,simOpts);
```

Train DDPG Agent to Swing Up and Balance Pendulum with Image Observation

This example shows how to train a deep deterministic policy gradient (DDPG) agent to swing up and balance a pendulum with an image observation modeled in MATLAB®.

For more information on DDPG agents, see “Deep Deterministic Policy Gradient Agents” (Reinforcement Learning Toolbox).

Simple Pendulum with Image MATLAB Environment

The reinforcement learning environment for this example is a simple frictionless pendulum that initially hangs in a downward position. The training goal is to make the pendulum stand upright without falling over using minimal control effort.

For this environment:

- The upward balanced pendulum position is `0` radians, and the downward hanging position is `pi` radians.
- The torque action signal from the agent to the environment is from –2 to 2 N·m.
- The observations from the environment are an image indicating the location of the pendulum mass and the pendulum angular velocity.
- The reward r_t, provided at every time step, is

$$r_t = -\left(\theta_t^2 + 0.1\dot{\theta}_t^2 + 0.001u_{t-1}^2\right)$$

Here:

- θ_t is the angle of displacement from the upright position.
- $\dot{\theta}_t$ is the derivative of the displacement angle.
- u_{t-1} is the control effort from the previous time step.

For more information on this model, see “Load Predefined Control System Environments” (Reinforcement Learning Toolbox).

Create Environment Interface

Create a predefined environment interface for the pendulum.

```
env = rlPredefinedEnv('SimplePendulumWithImage-Continuous')
```

```
env =
  SimplePendlumWithImageContinuousAction with properties:

            Mass: 1
       RodLength: 1
      RodInertia: 0
         Gravity: 9.8100
    DampingRatio: 0
   MaximumTorque: 2
              Ts: 0.0500
           State: [2x1 double]
```

```
    Q: [2x2 double]
    R: 1.0000e-03
```

The interface has a continuous action space where the agent can apply a torque between –2 to 2 N·m.

Obtain the observation and action specification from the environment interface.

```
obsInfo = getObservationInfo(env);
actInfo = getActionInfo(env);
```

Fix the random generator seed for reproducibility.

```
rng(0)
```

Create DDPG Agent

A DDPG agent approximates the long-term reward, given observations and actions, using a critic value function representation. To create the critic, first create a deep convolutional neural network (CNN) with three inputs (the image, angular velocity, and action) and one output. For more information on creating representations, see “Create Policy and Value Function Representations” (Reinforcement Learning Toolbox).

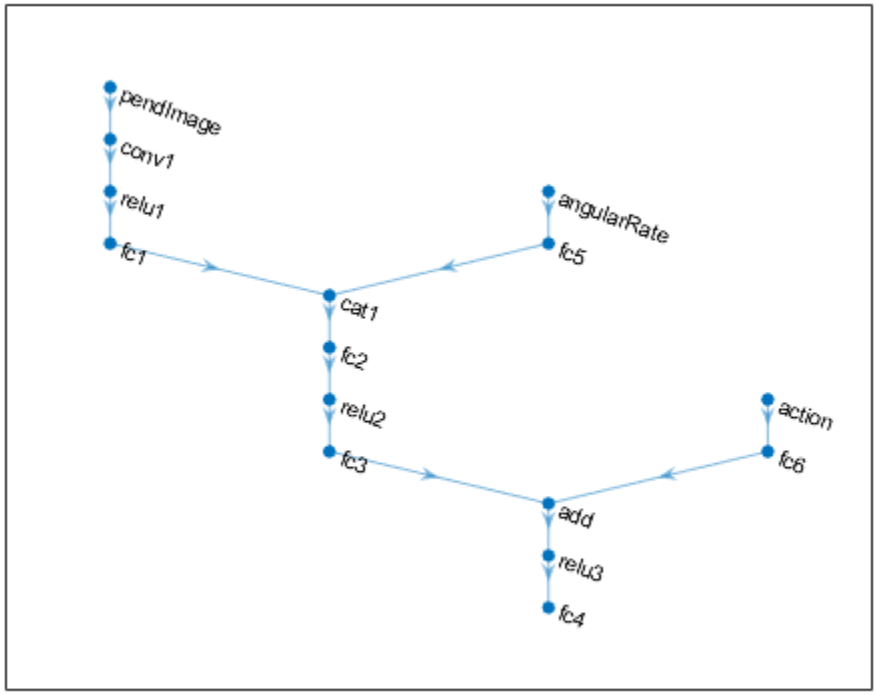
```
hiddenLayerSize1 = 400;
hiddenLayerSize2 = 300;

imgPath = [
    imageInputLayer(obsInfo(1).Dimension,'Normalization','none','Name',obsInfo(1).Name)
    convolution2dLayer(10,2,'Name','conv1','Stride',5,'Padding',0)
    reluLayer('Name','relu1')
    fullyConnectedLayer(2,'Name','fc1')
    concatenationLayer(3,2,'Name','cat1')
    fullyConnectedLayer(hiddenLayerSize1,'Name','fc2')
    reluLayer('Name','relu2')
    fullyConnectedLayer(hiddenLayerSize2,'Name','fc3')
    additionLayer(2,'Name','add')
    reluLayer('Name','relu3')
    fullyConnectedLayer(1,'Name','fc4')
    ];
dthetaPath = [
    imageInputLayer(obsInfo(2).Dimension,'Normalization','none','Name',obsInfo(2).Name)
    fullyConnectedLayer(1,'Name','fc5','BiasLearnRateFactor',0,'Bias',0)
    ];
actPath =[
    imageInputLayer(actInfo(1).Dimension,'Normalization','none','Name','action')
    fullyConnectedLayer(hiddenLayerSize2,'Name','fc6','BiasLearnRateFactor',0,'Bias',zeros(hidde
    ];

criticNetwork = layerGraph(imgPath);
criticNetwork = addLayers(criticNetwork,dthetaPath);
criticNetwork = addLayers(criticNetwork,actPath);
criticNetwork = connectLayers(criticNetwork,'fc5','cat1/in2');
criticNetwork = connectLayers(criticNetwork,'fc6','add/in2');
```

View the critic network configuration.

```
figure
plot(criticNetwork)
```



Specify options for the critic representation using `rlRepresentationOptions` (Reinforcement Learning Toolbox).

```
criticOptions = rlRepresentationOptions('LearnRate',1e-03,'GradientThreshold',1);
```

Uncomment the following line to use the GPU to accelerate training of the critic CNN. For more information on supported GPUs, see “GPU Support by Release” (Parallel Computing Toolbox).

```
% criticOptions.UseDevice = 'gpu';
```

Create the critic representation using the specified neural network and options. You must also specify the action and observation info for the critic, which you obtain from the environment interface. For more information, see `rlQValueRepresentation` (Reinforcement Learning Toolbox).

```
critic = rlQValueRepresentation(criticNetwork,obsInfo,actInfo,...
    'Observation',{'pendImage','angularRate'},'Action',{'action'},criticOptions);
```

A DDPG agent decides which action to take given observations using an actor representation. To create the actor, first create a deep convolutional neural network (CNN) with two inputs (the image and angular velocity) and one output (the action).

Construct the actor in a similar manner to the critic.

```
imgPath = [
    imageInputLayer(obsInfo(1).Dimension,'Normalization','none','Name',obsInfo(1).Name)
    convolution2dLayer(10,2,'Name','conv1','Stride',5,'Padding',0)
    reluLayer('Name','relu1')
```

```
    fullyConnectedLayer(2,'Name','fc1')
    concatenationLayer(3,2,'Name','cat1')
    fullyConnectedLayer(hiddenLayerSize1,'Name','fc2')
    reluLayer('Name','relu2')
    fullyConnectedLayer(hiddenLayerSize2,'Name','fc3')
    reluLayer('Name','relu3')
    fullyConnectedLayer(1,'Name','fc4')
    tanhLayer('Name','tanh1')
    scalingLayer('Name','scale1','Scale',max(actInfo.UpperLimit))
    ];
dthetaPath = [
    imageInputLayer(obsInfo(2).Dimension,'Normalization','none','Name',obsInfo(2).Name)
    fullyConnectedLayer(1,'Name','fc5','BiasLearnRateFactor',0,'Bias',0)
    ];

actorNetwork = layerGraph(imgPath);
actorNetwork = addLayers(actorNetwork,dthetaPath);
actorNetwork = connectLayers(actorNetwork,'fc5','cat1/in2');

actorOptions = rlRepresentationOptions('LearnRate',1e-04,'GradientThreshold',1);
```

Uncomment the following line to use the GPU to accelerate training of the actor CNN.

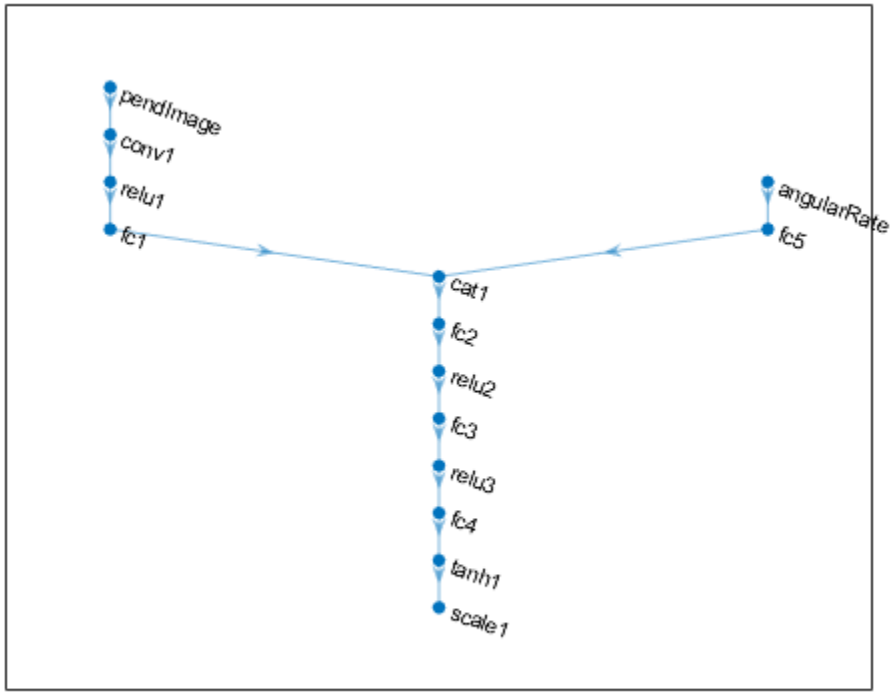
```
% actorOptions.UseDevice = 'gpu';
```

Create the actor representation using the specified neural network and options. For more information, see `rlDeterministicActorRepresentation` (Reinforcement Learning Toolbox).

```
actor = rlDeterministicActorRepresentation(actorNetwork,obsInfo,actInfo,'Observation',{'pendImage
```

View the actor network configuration.

```
figure
plot(actorNetwork)
```



To create the DDPG agent, first specify the DDPG agent options using `rlDDPGAgentOptions` (Reinforcement Learning Toolbox).

```
agentOptions = rlDDPGAgentOptions(...
    'SampleTime',env.Ts,...
    'TargetSmoothFactor',1e-3,...
    'ExperienceBufferLength',1e6,...
    'DiscountFactor',0.99,...
    'MiniBatchSize',128);
agentOptions.NoiseOptions.Variance = 0.6;
agentOptions.NoiseOptions.VarianceDecayRate = 1e-6;
```

Then create the agent using the specified actor representation, critic representation, and agent options. For more information, see `rlDDPGAgent` (Reinforcement Learning Toolbox).

```
agent = rlDDPGAgent(actor,critic,agentOptions);
```

Train Agent

To train the agent, first specify the training options. For this example, use the following options.

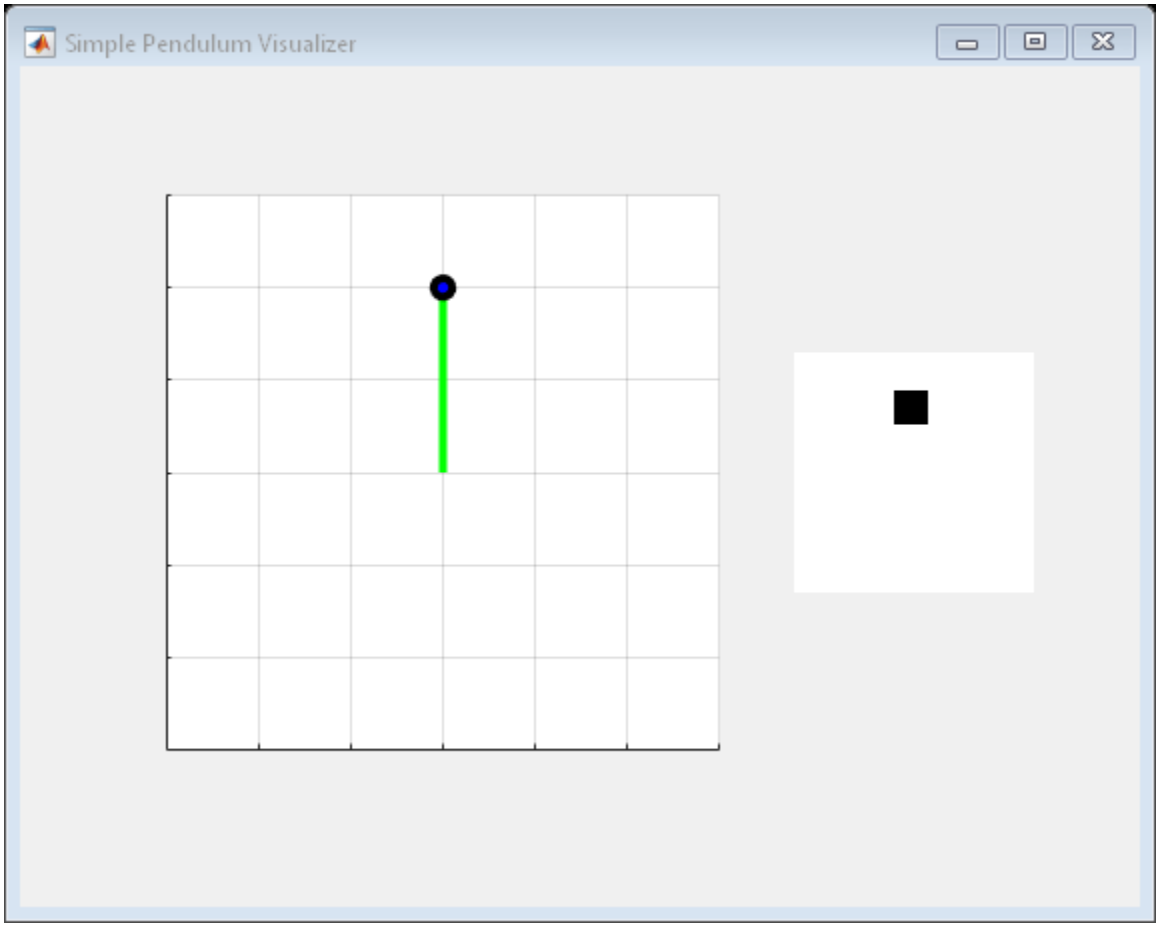
- Run each training for at most 5000 episodes, with each episode lasting at most 400 time steps.
- Display the training progress in the Episode Manager dialog box (set the `Plots` option).
- Stop training when the agent receives a moving average cumulative reward greater than -740 over ten consecutive episodes. At this point, the agent can quickly balance the pendulum in the upright position using minimal control effort.

For more information, see `rlTrainingOptions` (Reinforcement Learning Toolbox).

```
maxepisodes = 5000;
maxsteps = 400;
trainingOptions = rlTrainingOptions(...
    'MaxEpisodes',maxepisodes,...
    'MaxStepsPerEpisode',maxsteps,...
    'Plots','training-progress',...
    'StopTrainingCriteria','AverageReward',...
    'StopTrainingValue',-740);
```

You can visualize the pendulum by using the `plot` function during training or simulation.

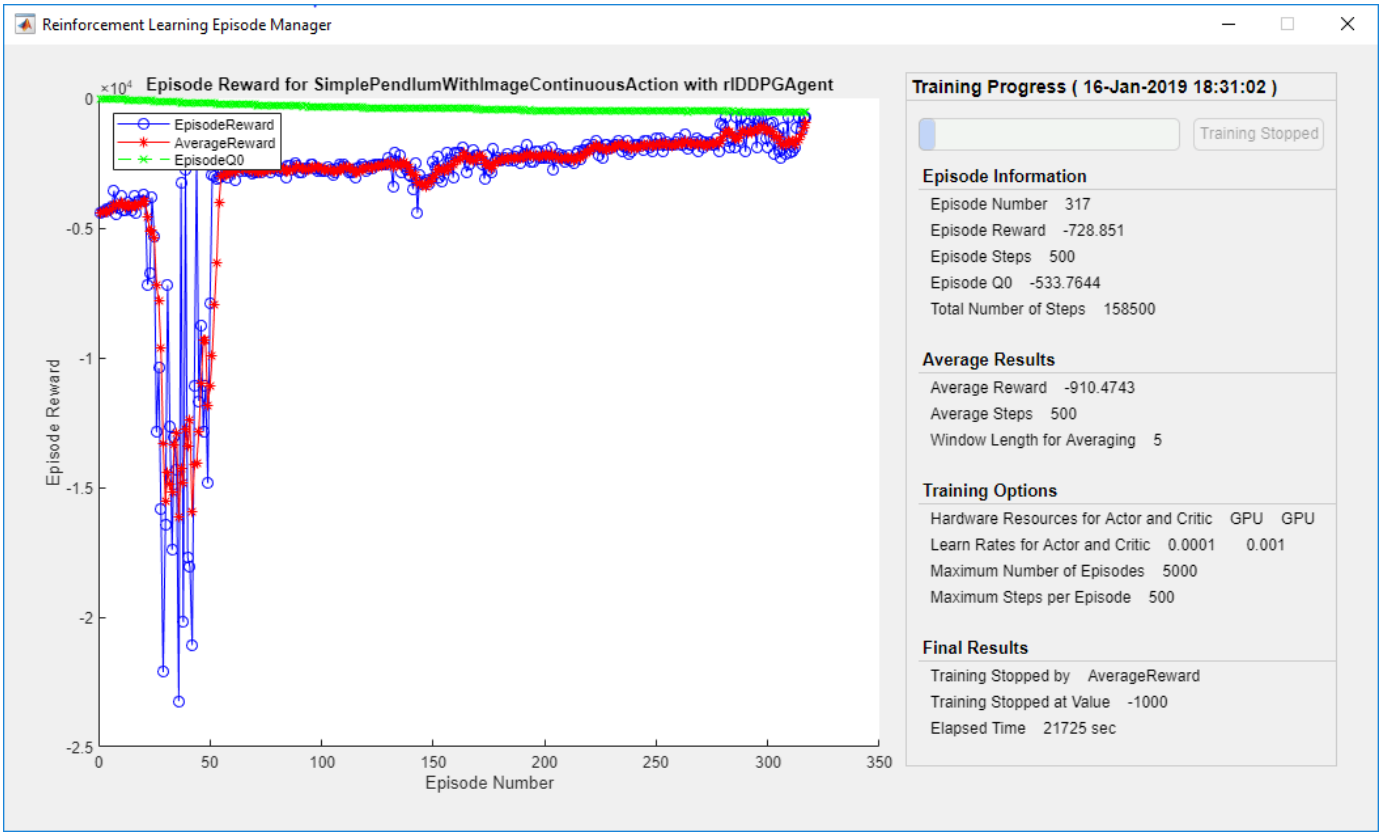
```
plot(env)
```



Train the agent using the `train` (Reinforcement Learning Toolbox) function. Training this agent is a computationally intensive process that takes several hours to complete. To save time while running this example, load a pretrained agent by setting `doTraining` to `false`. To train the agent yourself, set `doTraining` to `true`.

```
doTraining = false;
if doTraining
    % Train the agent.
    trainingStats = train(agent,env,trainingOptions);
else
```

```
    % Load pretrained agent for the example.
    load('SimplePendulumWithImageDDPG.mat','agent')
end
```



Simulate DDPG Agent

To validate the performance of the trained agent, simulate it within the pendulum environment. For more information on agent simulation, see `rlSimulationOptions` (Reinforcement Learning Toolbox) and `sim` (Reinforcement Learning Toolbox).

```
simOptions = rlSimulationOptions('MaxSteps',500);
experience = sim(env,agent,simOptions);
```

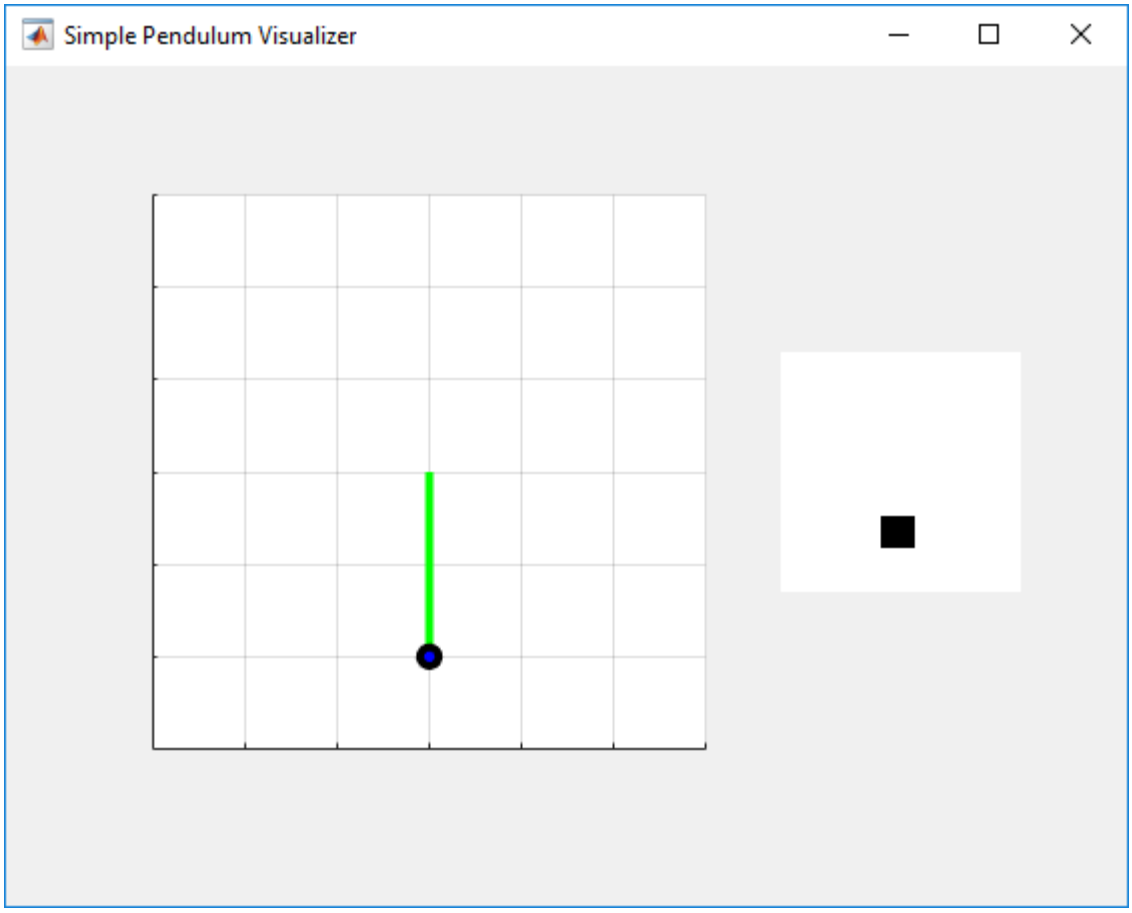
Create Agent Using Deep Network Designer and Train Using Image Observations

This example shows how to create a deep Q-learning network (DQN) agent that can swing up and balance a pendulum modeled in MATLAB®. In this example, you create the DQN agent using Deep Network Designer. For more information on DQN agents, see “Deep Q-Network Agents” (Reinforcement Learning Toolbox).

Pendulum Swing-Up with Image MATLAB Environment

The reinforcement learning environment for this example is a simple frictionless pendulum that initially hangs in a downward position. The training goal is to make the pendulum stand upright without falling over using minimal control effort.



For this environment:

- The upward balanced pendulum position is `0` radians, and the downward hanging position is `pi` radians.
- The torque action signal from the agent to the environment is from –2 to 2 N·m.
- The observations from the environment are the simplified grayscale image of the pendulum and the pendulum angle derivative.

- The reward r_t, provided at every time step, is

$$r_t = -\left(\theta_t^2 + 0.1\dot{\theta}_t^2 + 0.001u_{t-1}^2\right)$$

Here:

- θ_t is the angle of displacement from the upright position.
- $\dot{\theta}_t$ is the derivative of the displacement angle.
- u_{t-1} is the control effort from the previous time step.

For more information on this model, see “Train DDPG Agent to Swing Up and Balance Pendulum with Image Observation” (Reinforcement Learning Toolbox).

Create Environment Interface

Create a predefined environment interface for the pendulum.

```
env = rlPredefinedEnv('SimplePendulumWithImage-Discrete');
```

The interface has two observations. The first observation, named `"pendImage"`, is a 50-by-50 grayscale image.

```
obsInfo = getObservationInfo(env);
obsInfo(1)
```

```
ans =
  rlNumericSpec with properties:

     LowerLimit: 0
     UpperLimit: 1
           Name: "pendImage"
    Description: [0x0 string]
      Dimension: [50 50]
       DataType: "double"
```

The second observation, named `"angularRate"`, is the angular velocity of the pendulum.

```
obsInfo(2)
```

```
ans =
  rlNumericSpec with properties:

     LowerLimit: -Inf
     UpperLimit: Inf
           Name: "angularRate"
    Description: [0x0 string]
      Dimension: [1 1]
       DataType: "double"
```

The interface has a discrete action space where the agent can apply one of five possible torque values to the pendulum: –2, –1, 0, 1, or 2 N·m.

```
actInfo = getActionInfo(env)
```

```
actInfo =
  rlFiniteSetSpec with properties:

       Elements: [-2 -1 0 1 2]
           Name: "torque"
    Description: [0x0 string]
      Dimension: [1 1]
       DataType: "double"
```

Fix the random generator seed for reproducibility.

```
rng(0)
```

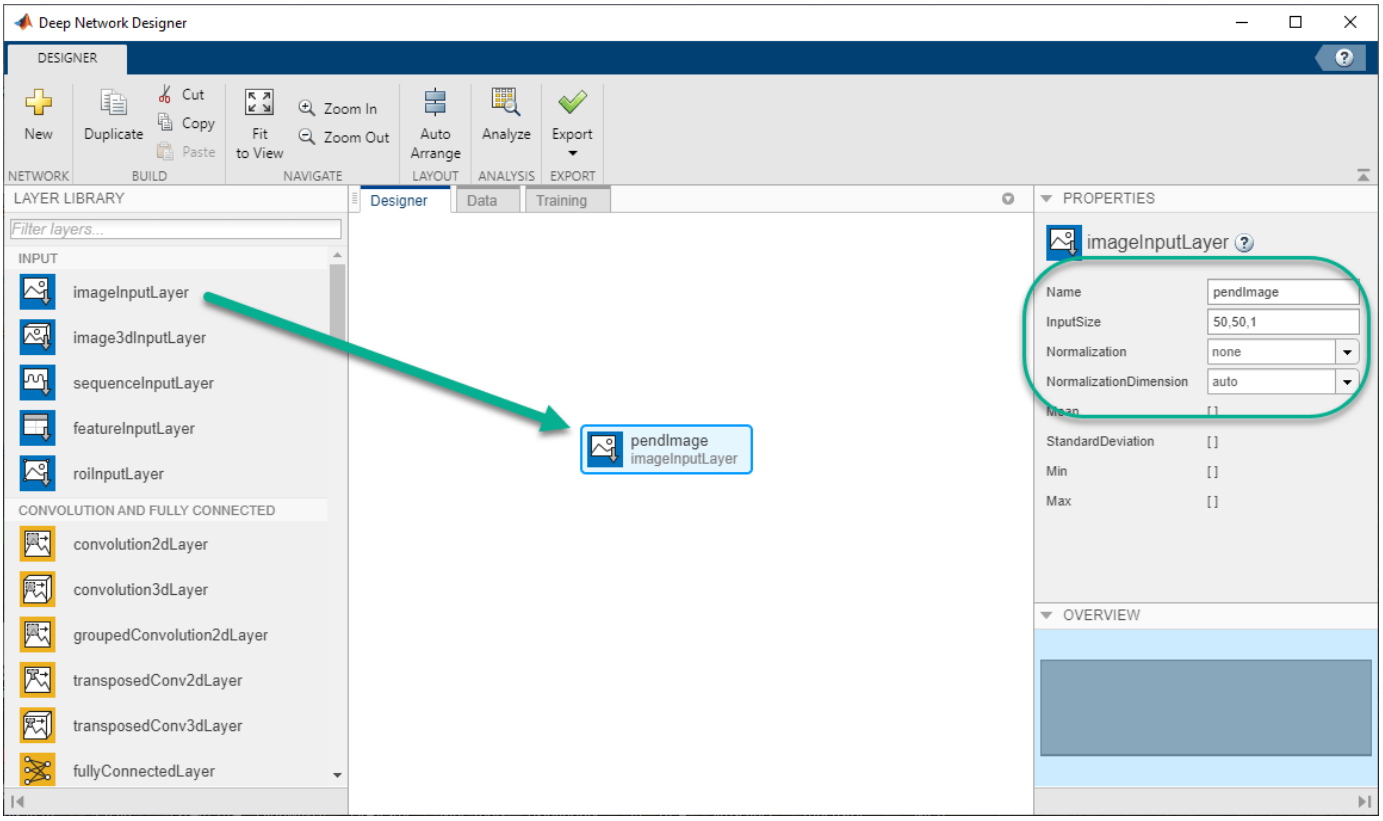
Construct Critic Network Using Deep Network Designer

A DQN agent approximates the long-term reward, given observations and actions, using a critic value function representation. For this environment, the critic is a deep neural network with three inputs (two observations and one action), and one output. For more information on creating a deep neural network value function representation, see “Create Policy and Value Function Representations” (Reinforcement Learning Toolbox).

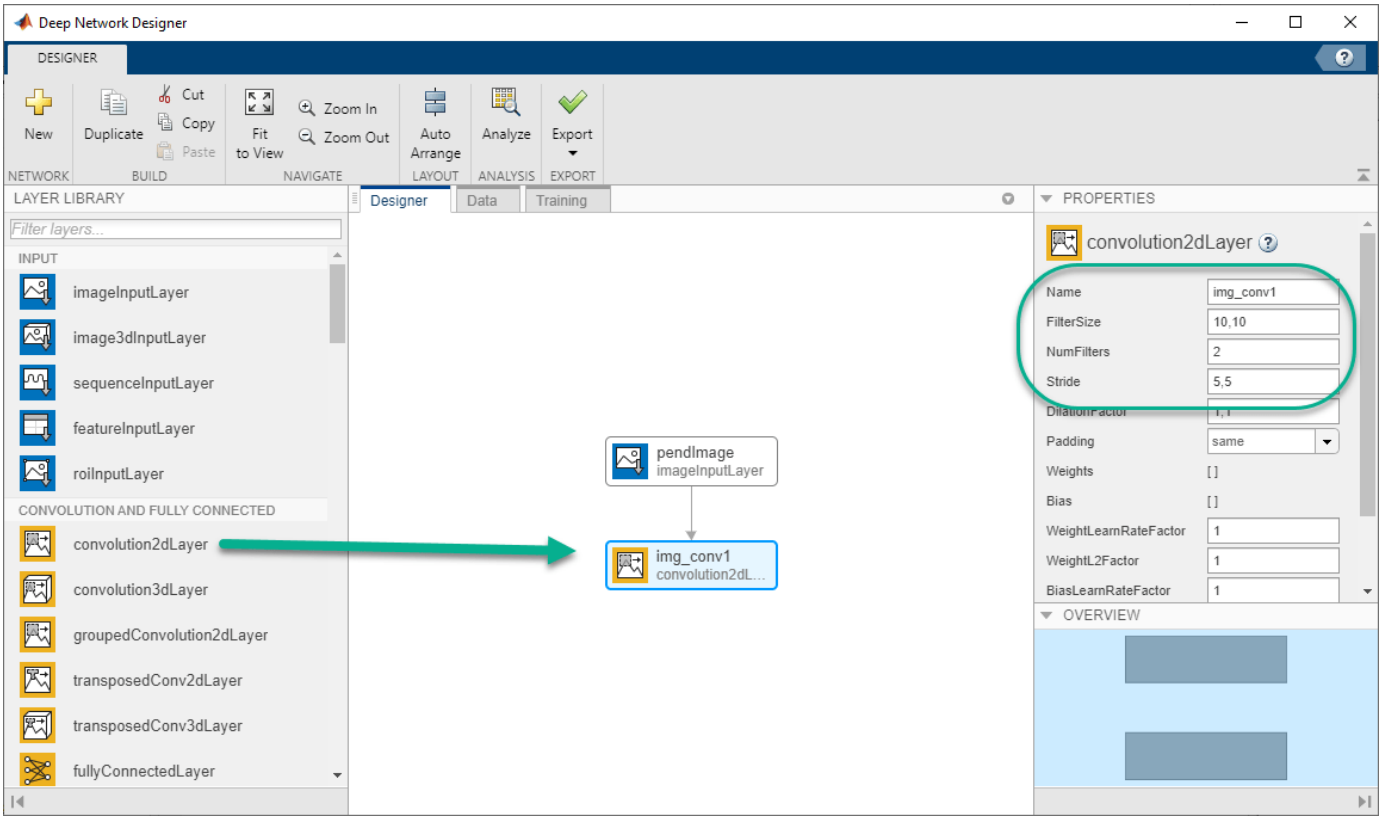
You can construct the critic network interactively by using the Deep Network Designer app. To do so, you first create separate input paths for each observation and action. These paths learn lower-level features from their respective inputs. You then create a common output path that combines the outputs from the input paths.

Create Image Observation Path

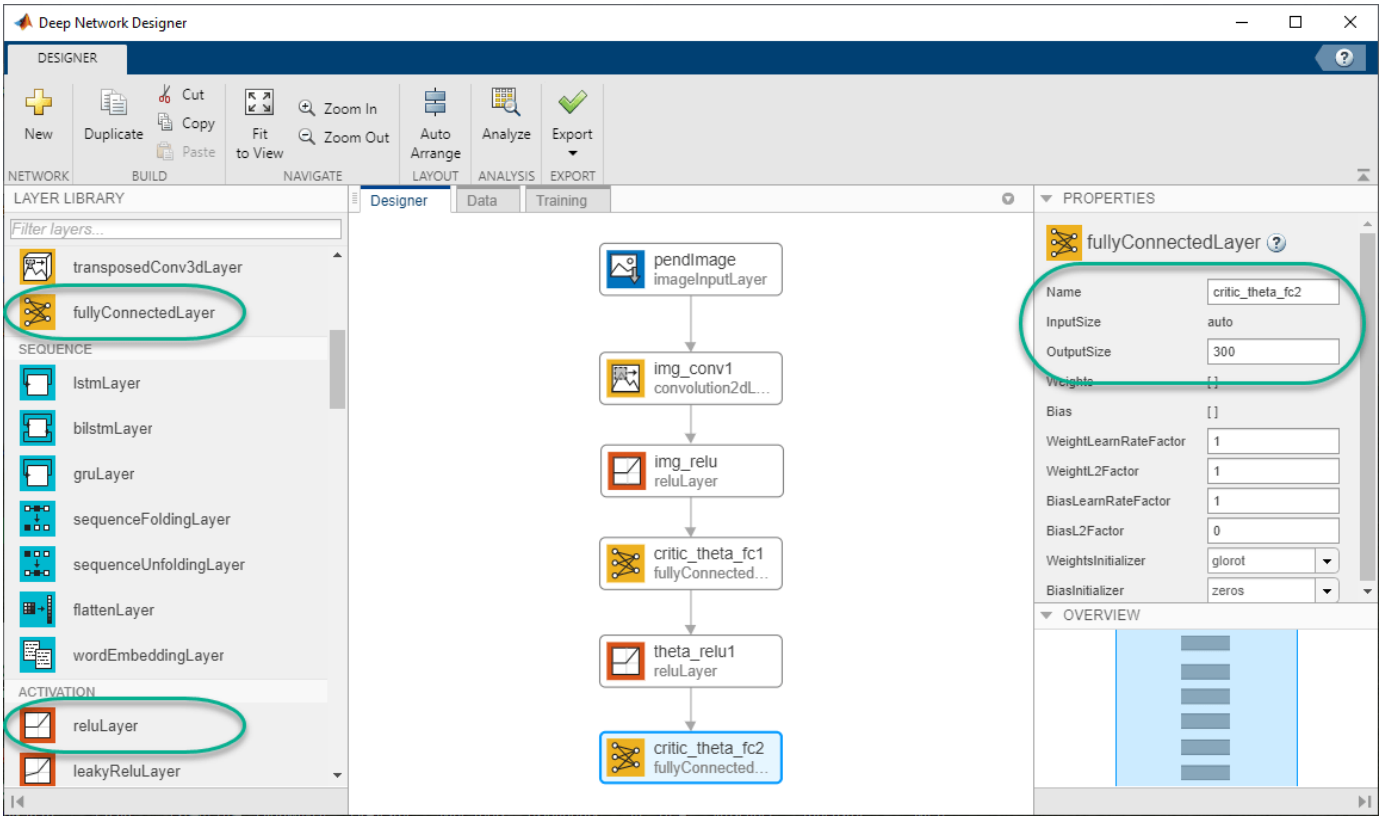
To create the image observation path, first drag an `imageInputLayer` from the **Layer Library** pane to the canvas. Set the layer **InputSize** to `50,50,1` for the image observation, and set **Normalization** to `none`.



Second, drag a `convolution2DLayer` to the canvas and connect the input of this layer to the output of the `imageInputLayer`. Create a convolution layer with `2` filters (**NumFilters** property) that have a height and width of `10` (**FilterSize** property), and use a stride of `5` in the horizontal and vertical directions (**Stride** property).



Finally, complete the image path network with two sets of `reLULayer` and `fullyConnectedLayer` layers. The output sizes of the first and second `fullyConnectedLayer` layers are 400 and 300, respectively.



Create All Input Paths and Output Path

Construct the other input paths and output path in a similar manner. For this example, use the following options.

Angular velocity path (scalar input):

- `imageInputLayer` — Set **InputSize** to `1,1` and **Normalization** to `none`.
- `fullyConnectedLayer` — Set **OutputSize** to `400`.
- `reLULayer`
- `fullyConnectedLayer` — Set **OutputSize** to `300`.

Action path (scalar input):

- `imageInputLayer` — Set **InputSize** to `1,1` and **Normalization** to `none`.
- `fullyConnectedLayer` — Set **OutputSize** to `300`.

Output path:

- `additionLayer` — Connect the output of all input paths to the input of this layer.
- `reLULayer`
- `fullyConnectedLayer` — Set **OutputSize** to `1` for the scalar value function.

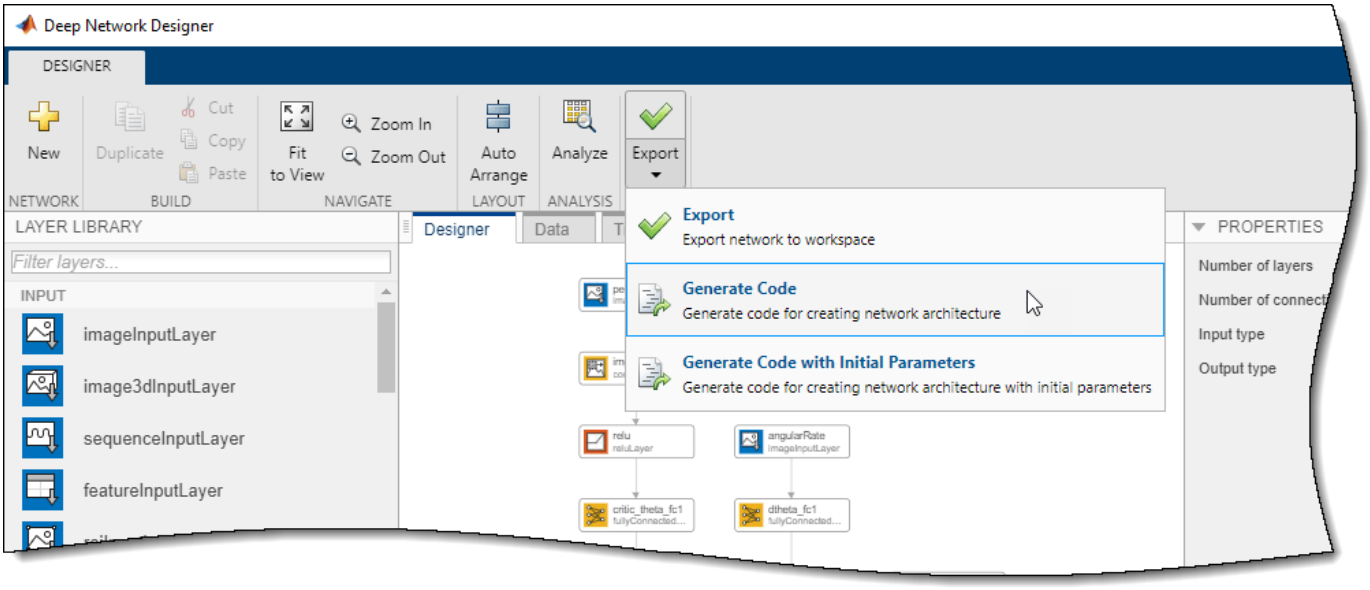
Export Network from Deep Network Designer

To export the network to the MATLAB workspace, in **Deep Network Designer**, click **Export**. **Deep Network Designer** exports the network as a new variable containing the network layers. You can create the critic representation using this layer network variable.

Alternatively, to generate equivalent MATLAB code for the network, click **Export > Generate Code**.



The generated code is as follows.

```
lgraph = layerGraph();

tempLayers = [
    imageInputLayer([1 1 1],"Name","angularRate","Normalization","none")
    fullyConnectedLayer(400,"Name","dtheta_fc1")
    reluLayer("Name","dtheta_relu1")
    fullyConnectedLayer(300,"Name","dtheta_fc2")];
lgraph = addLayers(lgraph,tempLayers);

tempLayers = [
    imageInputLayer([1 1 1],"Name","torque","Normalization","none")
    fullyConnectedLayer(300,"Name","torque_fc1")];
lgraph = addLayers(lgraph,tempLayers);

tempLayers = [
    imageInputLayer([50 50 1],"Name","pendImage","Normalization","none")
    convolution2dLayer([10 10],2,"Name","img_conv1","Padding","same","Stride",[5 5])
    reluLayer("Name","relu_1")
    fullyConnectedLayer(400,"Name","critic_theta_fc1")
    reluLayer("Name","theta_relu1")
    fullyConnectedLayer(300,"Name","critic_theta_fc2")];
lgraph = addLayers(lgraph,tempLayers);

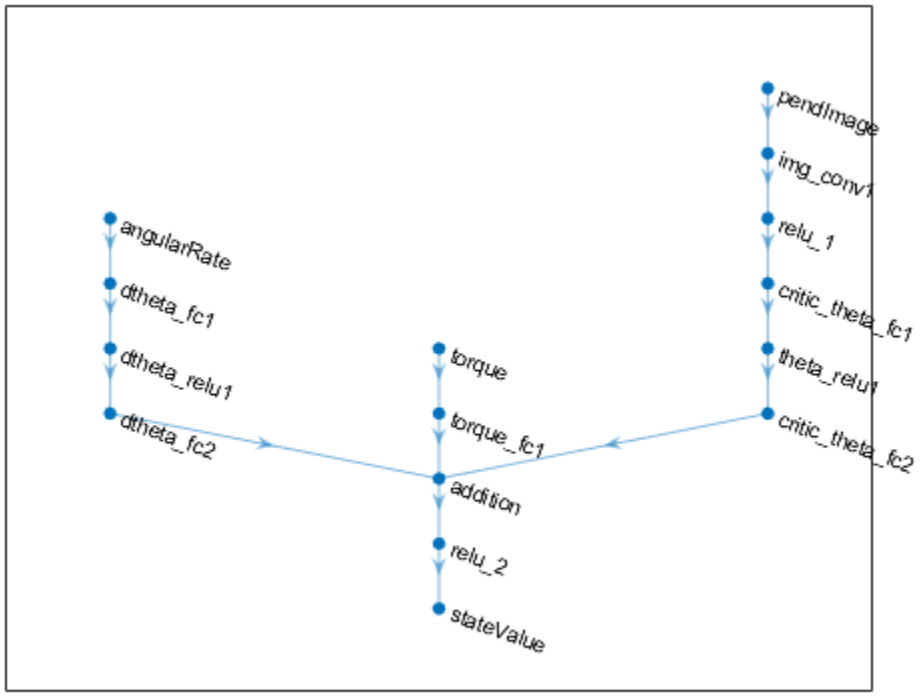
tempLayers = [
    additionLayer(3,"Name","addition")
    reluLayer("Name","relu_2")
```

```
    fullyConnectedLayer(1,"Name","stateValue")];
lgraph = addLayers(lgraph,tempLayers);

lgraph = connectLayers(lgraph,"torque_fc1","addition/in3");
lgraph = connectLayers(lgraph,"critic_theta_fc2","addition/in1");
lgraph = connectLayers(lgraph,"dtheta_fc2","addition/in2");
```

View the critic network configuration.

```
figure
plot(lgraph)
```



Specify options for the critic representation using `rlRepresentationOptions` (Reinforcement Learning Toolbox).

```
criticOpts = rlRepresentationOptions('LearnRate',1e-03,'GradientThreshold',1);
```

Create the critic representation using the specified deep neural network `lgraph` and options. You must also specify the action and observation info for the critic, which you obtain from the environment interface. For more information, see `rlQValueRepresentation` (Reinforcement Learning Toolbox).

```
critic = rlQValueRepresentation(lgraph,obsInfo,actInfo,...
    'Observation',{'pendImage','angularRate'},'Action',{'torque'},criticOpts);
```

To create the DQN agent, first specify the DQN agent options using `rlDQNAgentOptions` (Reinforcement Learning Toolbox).

```
agentOpts = rlDQNAgentOptions(...
    'UseDoubleDQN',false,...
    'TargetUpdateMethod',"smoothing",...
    'TargetSmoothFactor',1e-3,...
    'ExperienceBufferLength',1e6,...
    'DiscountFactor',0.99,...
    'SampleTime',env.Ts,...
    'MiniBatchSize',64);
agentOpts.EpsilonGreedyExploration.EpsilonDecay = 1e-5;
```

Then, create the DQN agent using the specified critic representation and agent options. For more information, see `rlDQNAgent` (Reinforcement Learning Toolbox).

```
agent = rlDQNAgent(critic,agentOpts);
```

Train Agent

To train the agent, first specify the training options. For this example, use the following options.

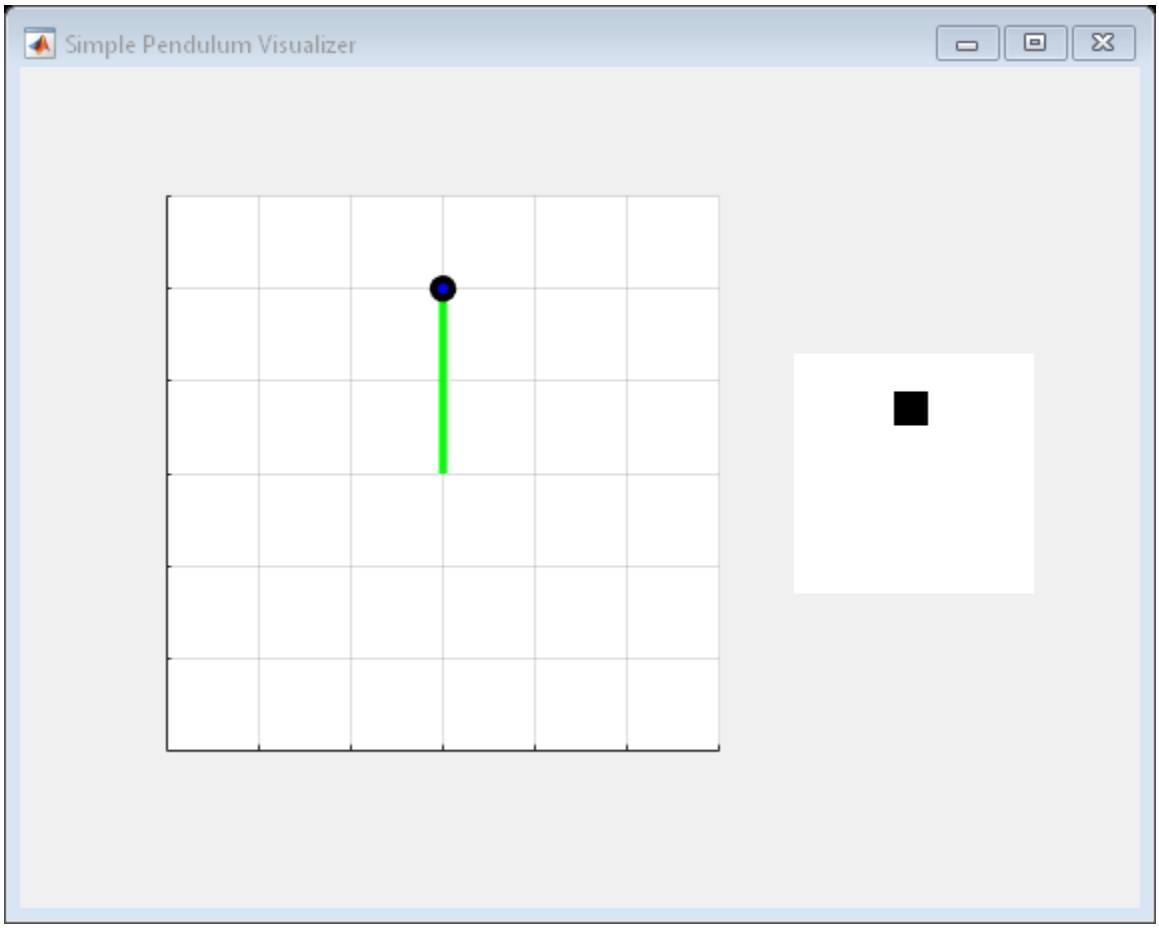
- Run each training for at most 5000 episodes, with each episode lasting at most 500 time steps.
- Display the training progress in the Episode Manager dialog box (set the `Plots` option) and disable the command line display (set the `Verbose` option to `false`).
- Stop training when the agent receives an average cumulative reward greater than –1000 over the default window length of five consecutive episodes. At this point, the agent can quickly balance the pendulum in the upright position using minimal control effort.

For more information, see `rlTrainingOptions` (Reinforcement Learning Toolbox).

```
trainOpts = rlTrainingOptions(...
    'MaxEpisodes',5000,...
    'MaxStepsPerEpisode',500,...
    'Verbose',false,...
    'Plots','training-progress',...
    'StopTrainingCriteria','AverageReward',...
    'StopTrainingValue',-1000);
```

You can visualize the pendulum system during training or simulation by using the `plot` function.

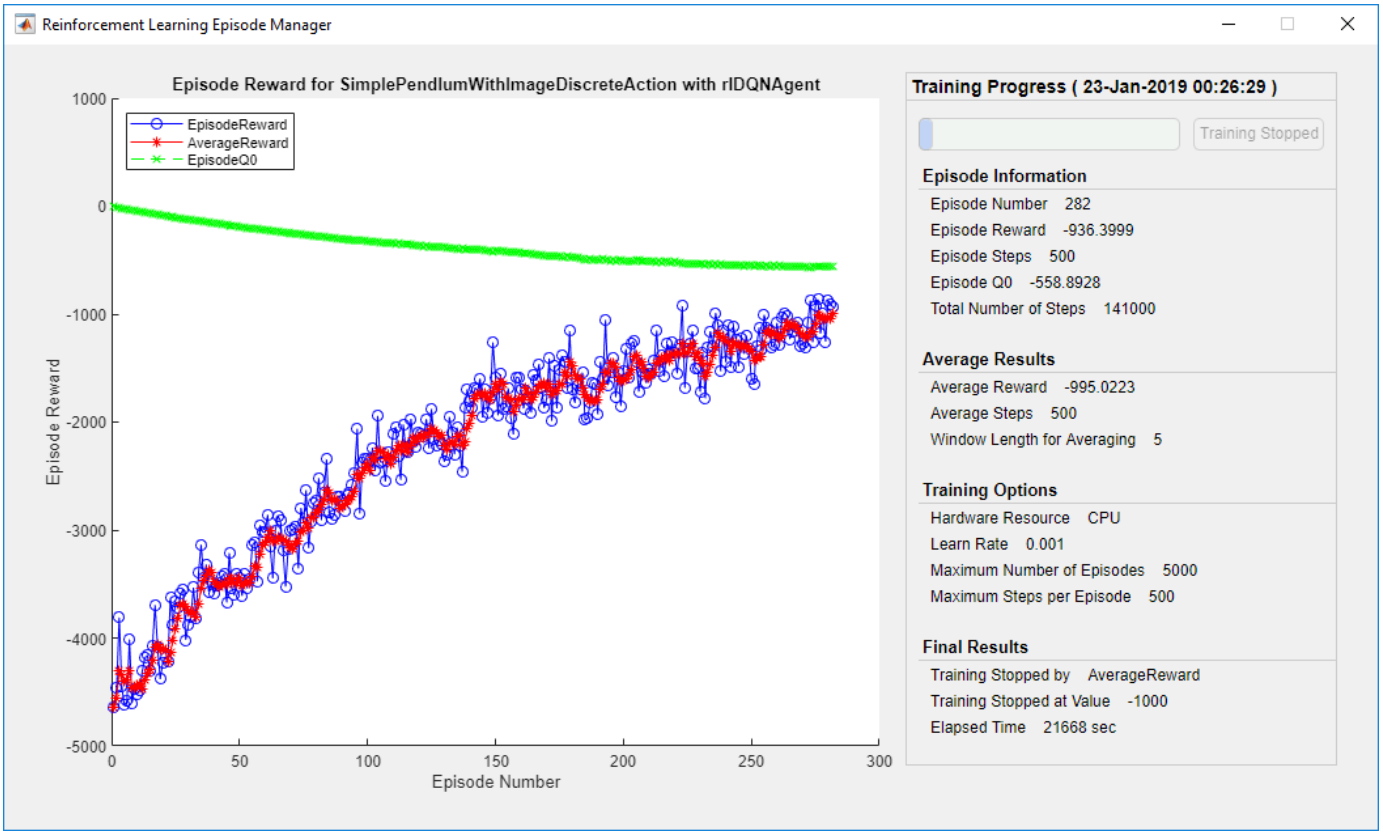
```
plot(env)
```



Train the agent using the `train` (Reinforcement Learning Toolbox) function. This is a computationally intensive process that takes several hours to complete. To save time while running this example, load a pretrained agent by setting `doTraining` to `false`. To train the agent yourself, set `doTraining` to `true`.

```
doTraining = false;

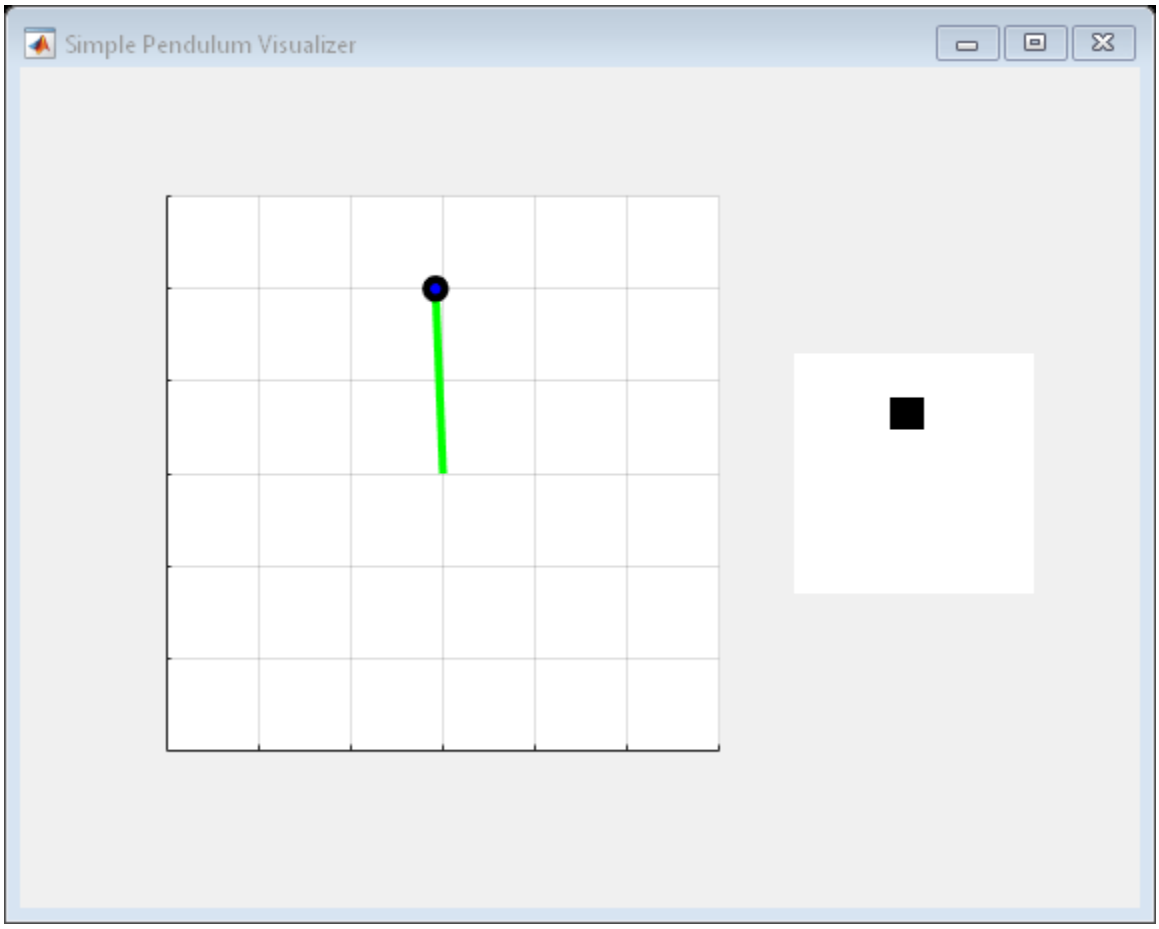
if doTraining
    % Train the agent.
    trainingStats = train(agent,env,trainOpts);
else
    % Load pretrained agent for the example.
    load('MATLABPendImageDQN.mat','agent');
end
```



Simulate DQN Agent

To validate the performance of the trained agent, simulate it within the pendulum environment. For more information on agent simulation, see `rlSimulationOptions` (Reinforcement Learning Toolbox) and `sim` (Reinforcement Learning Toolbox).

```
simOptions = rlSimulationOptions('MaxSteps',500);
experience = sim(env,agent,simOptions);
```



```
totalReward = sum(experience.Reward)
```

```
totalReward = -888.9802
```

- “Train DQN Agent to Swing Up and Balance Pendulum” (Reinforcement Learning Toolbox)

Imitate MPC Controller for Lane Keeping Assist

This example shows how to train, validate, and test a deep neural network that imitates the behavior of a model predictive controller for an automotive lane keeping assist system. In the example, you also compare the behavior of the deep neural network with that of the original controller.

Model predictive control (MPC) solves a constrained quadratic-programming (QP) optimization problem in real time based on the current state of the plant. Because MPC solves its optimization problem in an open-loop fashion, you can potentially replace the controller with a deep neural network. Evaluating a deep neural network is more computationally efficient than solving a QP problem in real time.

If the training of the network sufficiently traverses the state-space for the application, you can create a reasonable approximation of the controller behavior. You can then deploy the network for your control application. You can also use the network as a warm starting point for training the actor network of a reinforcement learning agent. For an example, see “Train DDPG Agent with Pretrained Actor Network” (Reinforcement Learning Toolbox).

Design MPC Controller

Design an MPC controller for lane keeping assist. To do so, first create a dynamic model for the vehicle.

```
[sys,Vx] = createModelForMPCImLKA;
```

Create and design the MPC controller object `mpcobj`. Also, create an `mpcstate` object for setting the initial controller state. For details on the controller design, type `edit createMPCobjImLKA`.

```
[mpcobj,initialState] = createMPCobjImLKA(sys);
```

For more information on designing model predictive controllers for lane keeping assist applications, see “Lane Keeping Assist System Using Model Predictive Control” (Model Predictive Control Toolbox) and “Lane Keeping Assist with Lane Detection” (Model Predictive Control Toolbox).

Prepare Input Data

Load the input data from `InputDataFileImLKA.mat`. The columns of the data set follow:

1. Lateral velocity V_y
2. Yaw angle rate r
3. Lateral deviation e_1
4. Relative yaw angle e_2
5. Previous steering angle (control variable) u
6. Measured disturbance (road yaw rate: longitudinal velocity * curvature (ρ))
7. Cost function value
8. MPC iterations
9. Steering angle computed by MPC controller: u*

The data in `InputDataFileImLKA.mat` was created by computing the MPC control action for randomly generated states, previous control actions, and measured disturbances. To generate your own training data, use the `collectDataImLKA` function.

Load the input data.

```
dataStruct = load('InputDataFileImLKA.mat');
data = dataStruct.Data;
```

Divide the input data into training, validation, and testing data. First, determine the number of validation data rows based on a given percentage.

```
totalRows = size(data,1);
validationSplitPercent = 0.1;
numValidationDataRows = floor(validationSplitPercent*totalRows);
```

Determine the number of test data rows based on a given percentage.

```
testSplitPercent = 0.05;
numTestDataRows = floor(testSplitPercent*totalRows);
```

Randomly extract validation and testing data from the input data set. To do so, first randomly extract enough rows for both data sets.

```
randomIdx = randperm(totalRows,numValidationDataRows + numTestDataRows);
randomData = data(randomIdx,:);
```

Divide the random data into validation and testing data.

```
validationData = randomData(1:numValidationDataRows,:);
testData = randomData(numValidationDataRows + 1:end,:);
```

Extract the remaining rows as training data.

```
trainDataIdx = setdiff(1:totalRows,randomIdx);
trainData = data(trainDataIdx,:);
```

Randomize the training data.

```
numTrainDataRows = size(trainData,1);
shuffleIdx = randperm(numTrainDataRows);
shuffledTrainData = trainData(shuffleIdx,:);
```

Reshape the training and validation data into 4-D matrices for use with `trainNetwork`.

```
numObservations = 6;
numActions = 1;

trainInput = shuffledTrainData(:,1:6);
trainOutput = shuffledTrainData(:,9);

validationInput = validationData(:,1:6);
validationOutput = validationData(:,9);
validationCellArray = {validationInput,validationOutput};
```

Reshape the testing data for use with `predict`.

```
testDataInput = testData(:,1:6);
testDataOutput = testData(:,9);
```

Create Deep Neural Network

The deep neural network architecture uses the following layers.

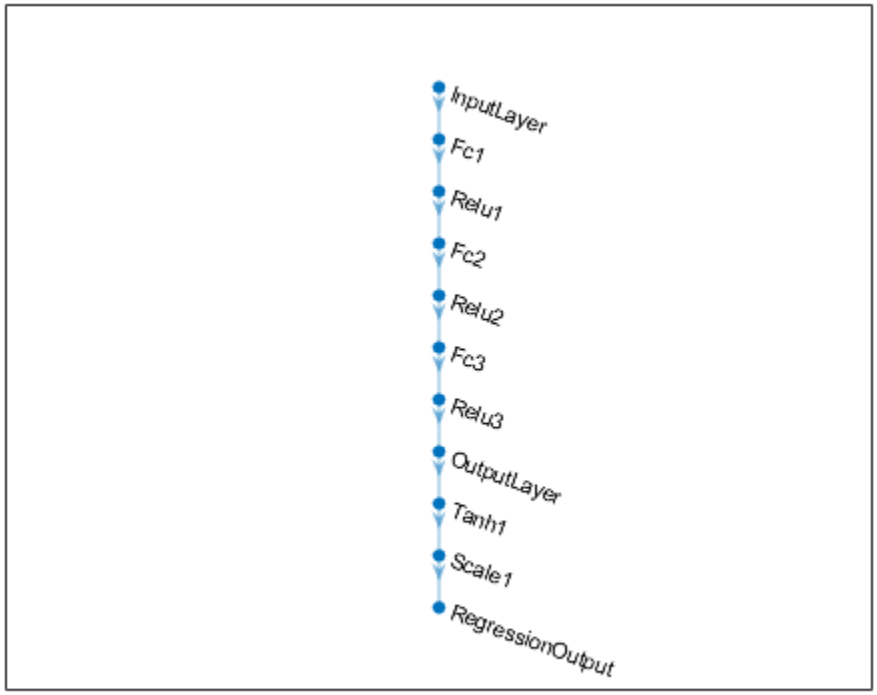
- `imageInputLayer` is the input layer of the neural network.
- `fullyConnectedLayer` multiplies the input by a weight matrix and then adds a bias vector.
- `reluLayer` is the activation function of the neural network.
- `tanhLayer` constrains the value to the range to [-1,1].
- `scalingLayer` scales the value to the range to [-1.04,1.04], implies that the steering angle is constrained to be [-60,60] degrees.
- `regressionLayer` defines the loss function of the neural network.

Create the deep neural network that will imitate the MPC controller after training.

```
imitateMPCNetwork = [
    featureInputLayer(numObservations,'Normalization','none','Name','InputLayer')
    fullyConnectedLayer(45,'Name','Fc1')
    reluLayer('Name','Relu1')
    fullyConnectedLayer(45,'Name','Fc2')
    reluLayer('Name','Relu2')
    fullyConnectedLayer(45,'Name','Fc3')
    reluLayer('Name','Relu3')
    fullyConnectedLayer(numActions,'Name','OutputLayer')
    tanhLayer('Name','Tanh1')
    scalingLayer('Name','Scale1','Scale',1.04)
    regressionLayer('Name','RegressionOutput')
];
```

Plot the network.

```
plot(layerGraph(imitateMPCNetwork))
```



Train Deep Neural Network

Specify training options.

```
options = trainingOptions('adam', ...
    'Verbose',false, ...
    'Plots','training-progress', ...
    'Shuffle','every-epoch', ...
    'MaxEpochs', 30, ...
    'MiniBatchSize',512, ...
    'ValidationData',validationCellArray, ...
    'InitialLearnRate',1e-3, ...
    'GradientThresholdMethod','absolute-value', ...
    'ExecutionEnvironment','cpu', ...
    'GradientThreshold',10, ...
    'Epsilon',1e-8);
```

Train the deep neural network. To view detailed training information in the Command Window, set the `'Verbose'` training option to `true`.

```
imitateMPCNetObj = trainNetwork(trainInput,trainOutput,imitateMPCNetwork,options);
```

Training of the deep neural network stops after the final iteration.

The training and validation loss are nearly the same for each mini-batch, which indicates that the trained network does not overfit.

Test Trained Network

Check that the trained deep neural network returns steering angles similar to the MPC controller control actions given the test input data. Compute the network output using the `predict` function.

```
predictedTestDataOutput = predict(imitateMPCNetObj,testDataInput);
```

Calculate the root mean squared error (RMSE) between the network output and the testing data.

```
testRMSE = sqrt(mean((testDataOutput - predictedTestDataOutput).^2));
fprintf('Test Data RMSE = %d\n', testRMSE);
```

```
Test Data RMSE = 3.578066e-02
```

The small RMSE value indicates that the network outputs closely reproduce the MPC controller outputs.

Compare Trained Network with MPC Controller

To compare the performance of the MPC controller and the trained deep neural network, run closed-loop simulations using the vehicle plant model.

Generate random initial conditions for the vehicle that are not part of the original input data set, with values selected from the following ranges:

1. Lateral velocity V_y — Range (-2,2) *m/s*
2. Yaw angle rate r — Range (-60,60) *deg/s*
3. Lateral deviation e_1 — Range (-1,1) *m*
4. Relative yaw angle e_2 — Range (-45,45) *deg*
5. Last steering angle (control variable) u — Range (-60,60) *deg*
6. Measured disturbance (road yaw rate, defined as longitudinal velocity * curvature (ρ)) — Range (-0.01,0.01) with a minimum road radius of 100 *m*

```
rng(5e7)
[x0,u0,rho] = generateRandomDataImLKA(data);
```

Set the initial plant state and control action in the `mpcstate` object.

```
initialState.Plant = x0;
initialState.LastMove = u0;
```

Extract the sample time from the MPC controller. Also, set the number of simulation steps.

```
Ts = mpcobj.Ts;
Tsteps = 30;
```

Obtain the `A` and `B` state-space matrices for the vehicle model.

```
A = sys.A;
B = sys.B;
```

Initialize the state and input trajectories for the MPC controller simulation.

```
xHistoryMPC = repmat(x0',Tsteps+1,1);
uHistoryMPC = repmat(u0',Tsteps,1);
```

Run a closed-loop simulation of the MPC controller and the plant using the `mpcmove` function.

```
for k = 1:Tsteps
    % Obtain plant output measurements, which correspond to the plant outputs.
    xk = xHistoryMPC(k,:)';
    % Compute the next cotnrol action using the MPC controller.
    uk = mpcmove(mpcobj,initialState,xk,zeros(1,4),Vx*rho);
    % Store the control action.
    uHistoryMPC(k,:) = uk;
    % Update the state using the control action.
    xHistoryMPC(k+1,:) = (A*xk + B*[uk;Vx*rho])';
end
```

Initialize the state and input trajectories for the deep neural network simulation.

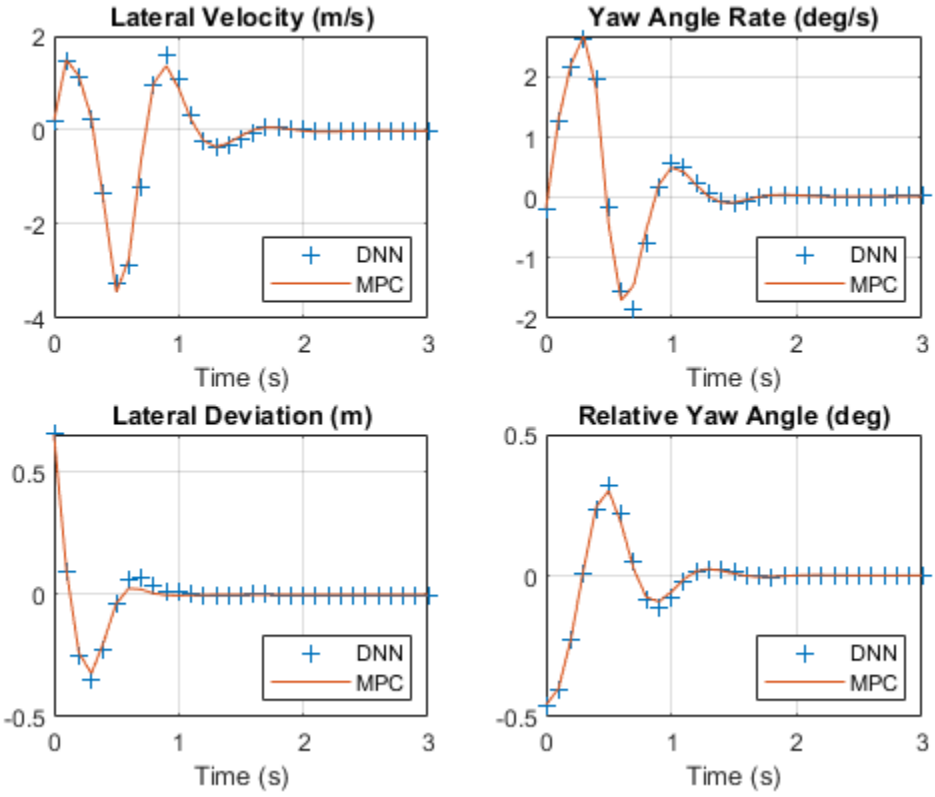
```
xHistoryDNN = repmat(x0',Tsteps+1,1);
uHistoryDNN = repmat(u0',Tsteps,1);
lastMV = u0;
```

Run a closed-loop simulation of the trained network and the plant. The `neuralnetLKAmove` function computes the deep neural network output using the `predict` function.

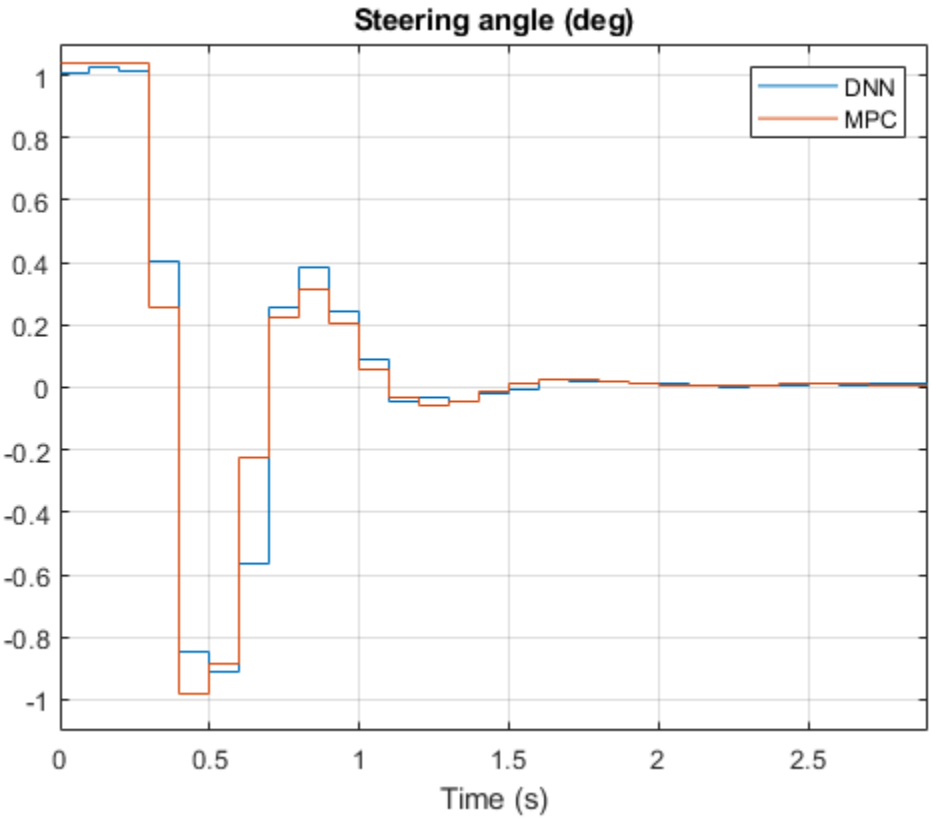
```
for k = 1:Tsteps
    % Obtain plant output measurements, which correspond to the plant outputs.
    xk = xHistoryDNN(k,:)';
    % Predict the next move using the trained deep neural network.
    uk = neuralnetLKAmove(imitateMPCNetObj,xk,lastMV,rho);
    % Store the control action and update the last MV for the next step.
    uHistoryDNN(k,:) = uk;
    lastMV = uk;
    % Update the state using the control action.
    xHistoryDNN(k+1,:) = (A*xk + B*[uk;Vx*rho])';
end
```

Plot the results, and compare the MPC controller and trained deep neural network (DNN) trajectories.

```
plotValidationResultsImLKA(Ts,xHistoryDNN,uHistoryDNN,xHistoryMPC,uHistoryMPC);
```



Lateral Velocity (m/s)
Yaw Angle Rate (deg/s)
Lateral Deviation (m)
Relative Yaw Angle (deg)
DNN
MPC
Time (s)



The deep neural network successfully imitates the behavior of the MPC controller. The vehicle state and control action trajectories for the controller and the deep neural network closely align.

Train DDPG Agent to Control Flying Robot

This example shows how to train a deep deterministic policy gradient (DDPG) agent to generate trajectories for a flying robot modeled in Simulink®. For more information on DDPG agents, see "Deep Deterministic Policy Gradient Agents" (Reinforcement Learning Toolbox).

Flying Robot Model

The reinforcement learning environment for this example is a flying robot with its initial condition randomized around a ring of radius 15 m. The orientation of the robot is also randomized. The robot has two thrusters mounted on the side of the body that are used to propel and steer the robot. The training goal is to drive the robot from its initial condition to the origin facing east.

Open the model.

```
mdl = 'rlFlyingRobotEnv';
open_system(mdl)
```

Set the initial model state variables.

```
theta0 = 0;
x0 = -15;
y0 = 0;
```

Define the sample time `Ts` and the simulation duration `Tf`.

```
Ts = 0.4;
Tf = 30;
```

For this model:

- The goal orientation is `0` rad (robot facing east).
- The thrust from each actuator is bounded from `-1` to `1` N
- The observations from the environment are the position, orientation (sine and cosine of orientation), velocity, and angular velocity of the robot.
- The reward r_t provided at every time step is

$$r_1 = 10\left(\left(x_t^2 + y_t^2 + \theta_t^2\right) < 0.5\right)$$

$$r_2 = -100(|x_t| \geq 20 \,||\, |y_t| \geq 20)$$

$$r_3 = -\left(0.2(R_{t-1} + L_{t-1})^2 + 0.3(R_{t-1} - L_{t-1})^2 + 0.03x_t^2 + 0.03y_t^2 + 0.02\theta_t^2\right)$$

$$r_t = r_1 + r_2 + r_3$$

where:

- x_t is the position of the robot along the x-axis.
- y_t is the position of the robot along the y-axis.
- θ_t is the orientation of the robot.
- L_{t-1} is the control effort from the left thruster.

- R_{t-1} is the control effort from the right thruster.
- r_1 is the reward when the robot is close to the goal.
- r_2 is the penalty when the robot drives beyond `20` m in either the x or y direction. The simulation is terminated when $r_2 < 0$.
- r_3 is a QR penalty that penalizes distance from the goal and control effort.

Create Integrated Model

To train an agent for the `FlyingRobotEnv` model, use the `createIntegratedEnv` function to automatically generate an integrated model with the RL Agent block that is ready for training.

```
integratedMdl = 'IntegratedFlyingRobot';
[~,agentBlk,observationInfo,actionInfo] = createIntegratedEnv(mdl,integratedMdl);
```

Actions and Observations

Before creating the environment object, specify names for the observation and action specifications, and bound the thrust actions between `-1` and `1`.

The observation signals for this environment are observation = $\left[x\ y\ \dot{x}\ \dot{y}\ \sin(\theta)\ \cos(\theta)\ \dot{\theta}\right]^T$.

```
numObs = prod(observationInfo.Dimension);
observationInfo.Name = 'observations';
```

The action signals for this environment are action = $\left[T_R\ T_L\right]^T$.

```
numAct = prod(actionInfo.Dimension);
actionInfo.LowerLimit = -ones(numAct,1);
actionInfo.UpperLimit =  ones(numAct,1);
actionInfo.Name = 'thrusts';
```

Create Environment Interface

Create an environment interface for the flying robot using the integrated model.

```
env = rlSimulinkEnv(integratedMdl,agentBlk,observationInfo,actionInfo);
```

Reset Function

Create a custom reset function that randomizes the initial position of the robot along a ring of radius `15` m and the initial orientation. For details on the reset function, see `flyingRobotResetFcn`.

```
env.ResetFcn = @(in) flyingRobotResetFcn(in);
```

Fix the random generator seed for reproducibility.

```
rng(0)
```

Create DDPG agent

A DDPG agent approximates the long-term reward given observations and actions by using a critic value function representation. To create the critic, first create a deep neural network with two inputs (the observation and action) and one output. For more information on creating a neural network value function representation, see “Create Policy and Value Function Representations” (Reinforcement Learning Toolbox).

```
% Specify the number of outputs for the hidden layers.
hiddenLayerSize = 100;

observationPath = [
    featureInputLayer(numObs,'Normalization','none','Name','observation')
    fullyConnectedLayer(hiddenLayerSize,'Name','fc1')
    reluLayer('Name','relu1')
    fullyConnectedLayer(hiddenLayerSize,'Name','fc2')
    additionLayer(2,'Name','add')
    reluLayer('Name','relu2')
    fullyConnectedLayer(hiddenLayerSize,'Name','fc3')
    reluLayer('Name','relu3')
    fullyConnectedLayer(1,'Name','fc4')];
actionPath = [
    featureInputLayer(numAct,'Normalization','none','Name','action')
    fullyConnectedLayer(hiddenLayerSize,'Name','fc5')];

% Create the layer graph.
criticNetwork = layerGraph(observationPath);
criticNetwork = addLayers(criticNetwork,actionPath);

% Connect actionPath to observationPath.
criticNetwork = connectLayers(criticNetwork,'fc5','add/in2');
```

Specify options for the critic using `rlRepresentationOptions` (Reinforcement Learning Toolbox).

```
criticOptions = rlRepresentationOptions('LearnRate',1e-03,'GradientThreshold',1);
```

Create the critic representation using the specified neural network and options. You must also specify the action and observation specification for the critic. For more information, see `rlQValueRepresentation` (Reinforcement Learning Toolbox).

```
critic = rlQValueRepresentation(criticNetwork,observationInfo,actionInfo,...
    'Observation',{'observation'},'Action',{'action'},criticOptions);
```

A DDPG agent decides which action to take given observations by using an actor representation. To create the actor, first create a deep neural network with one input (the observation) and one output (the action).

Construct the actor similarly to the critic. For more information, see `rlDeterministicActorRepresentation` (Reinforcement Learning Toolbox).

```
actorNetwork = [
    featureInputLayer(numObs,'Normalization','none','Name','observation')
    fullyConnectedLayer(hiddenLayerSize,'Name','fc1')
    reluLayer('Name','relu1')
    fullyConnectedLayer(hiddenLayerSize,'Name','fc2')
    reluLayer('Name','relu2')
    fullyConnectedLayer(hiddenLayerSize,'Name','fc3')
    reluLayer('Name','relu3')
    fullyConnectedLayer(numAct,'Name','fc4')
    tanhLayer('Name','tanh1')];

actorOptions = rlRepresentationOptions('LearnRate',1e-04,'GradientThreshold',1);

actor = rlDeterministicActorRepresentation(actorNetwork,observationInfo,actionInfo,...
    'Observation',{'observation'},'Action',{'tanh1'},actorOptions);
```

To create the DDPG agent, first specify the DDPG agent options using `rlDDPGAgentOptions` (Reinforcement Learning Toolbox).

```
agentOptions = rlDDPGAgentOptions(...
    'SampleTime',Ts,...
    'TargetSmoothFactor',1e-3,...
    'ExperienceBufferLength',1e6 ,...
    'DiscountFactor',0.99,...
    'MiniBatchSize',256);
agentOptions.NoiseOptions.Variance = 1e-1;
agentOptions.NoiseOptions.VarianceDecayRate = 1e-6;
```

Then, create the agent using the specified actor representation, critic representation, and agent options. For more information, see `rlDDPGAgent` (Reinforcement Learning Toolbox).

```
agent = rlDDPGAgent(actor,critic,agentOptions);
```

Train Agent

To train the agent, first specify the training options. For this example, use the following options:

- Run each training for at most `20000` episodes, with each episode lasting at most `ceil(Tf/Ts)` time steps.
- Display the training progress in the Episode Manager dialog box (set the `Plots` option) and disable the command line display (set the `Verbose` option to `false`).
- Stop training when the agent receives an average cumulative reward greater than `415` over 10 consecutive episodes. At this point, the agent can drive the flying robot to the goal position.
- Save a copy of the agent for each episode where the cumulative reward is greater than `415`.

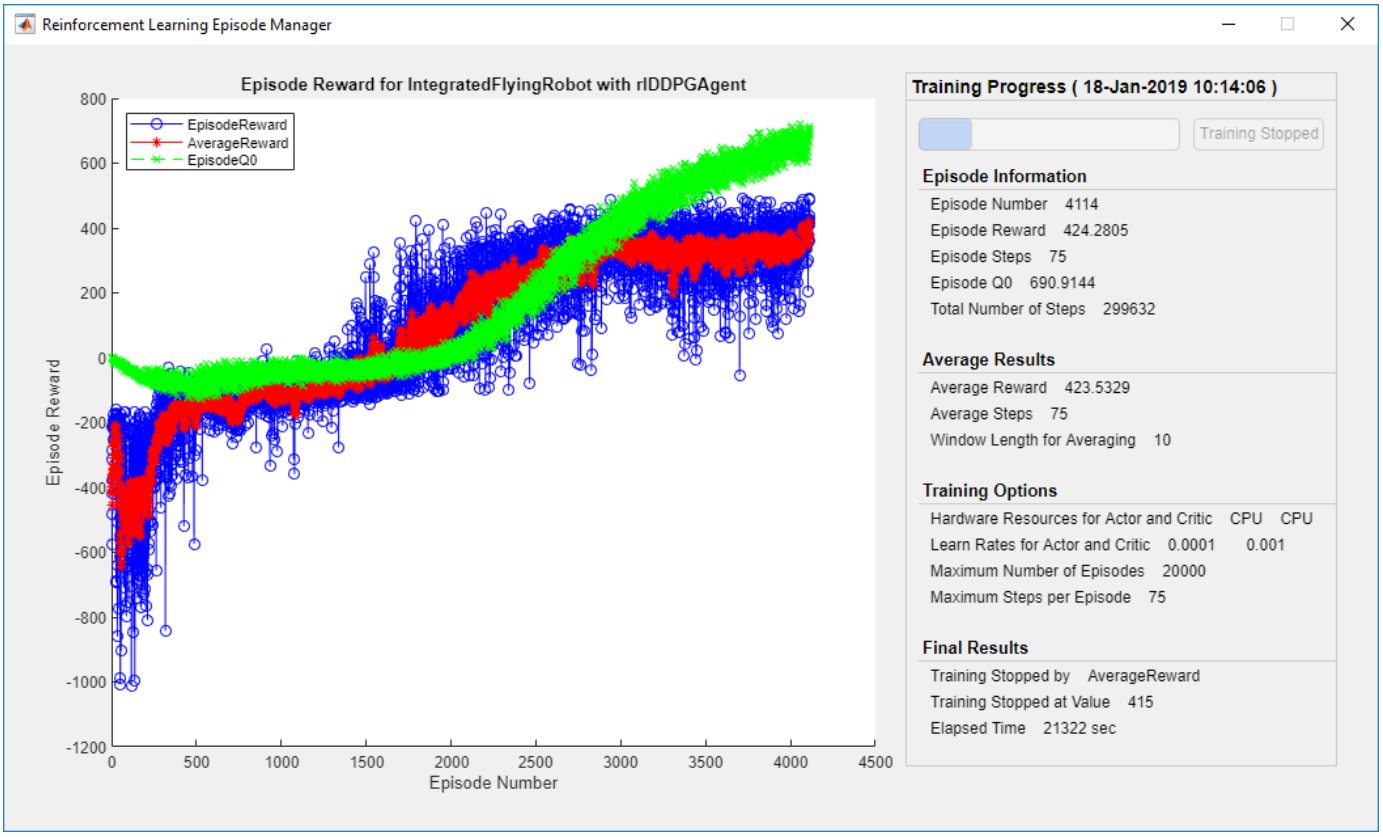
For more information, see `rlTrainingOptions` (Reinforcement Learning Toolbox).

```
maxepisodes = 20000;
maxsteps = ceil(Tf/Ts);
trainingOptions = rlTrainingOptions(...
    'MaxEpisodes',maxepisodes,...
    'MaxStepsPerEpisode',maxsteps,...
    'StopOnError',"on",...
    'Verbose',false,...
    'Plots',"training-progress",...
    'StopTrainingCriteria',"AverageReward",...
    'StopTrainingValue',415,...
    'ScoreAveragingWindowLength',10,...
    'SaveAgentCriteria',"EpisodeReward",...
    'SaveAgentValue',415);
```

Train the agent using the `train` (Reinforcement Learning Toolbox) function. Training is a computationally intensive process that takes several hours to complete. To save time while running this example, load a pretrained agent by setting `doTraining` to `false`. To train the agent yourself, set `doTraining` to `true`.

```
doTraining = false;
if doTraining
    % Train the agent.
    trainingStats = train(agent,env,trainingOptions);
else
    % Load the pretrained agent for the example.
```

```
    load('FlyingRobotDDPG.mat','agent')
end
```



Simulate DDPG Agent

To validate the performance of the trained agent, simulate the agent within the environment. For more information on agent simulation, see `rlSimulationOptions` (Reinforcement Learning Toolbox) and `sim` (Reinforcement Learning Toolbox).

```
simOptions = rlSimulationOptions('MaxSteps',maxsteps);
experience = sim(env,agent,simOptions);
```

- “Train Reinforcement Learning Agents” (Reinforcement Learning Toolbox)

Train Biped Robot to Walk Using Reinforcement Learning Agents

This example shows how to train a biped robot to walk using both a deep deterministic policy gradient (DDPG) agent and a twin-delayed deep deterministic policy gradient (TD3) agent. In the example, you also compare the performance of these trained agents. The robot in this example is modeled in Simscape™ Multibody™.

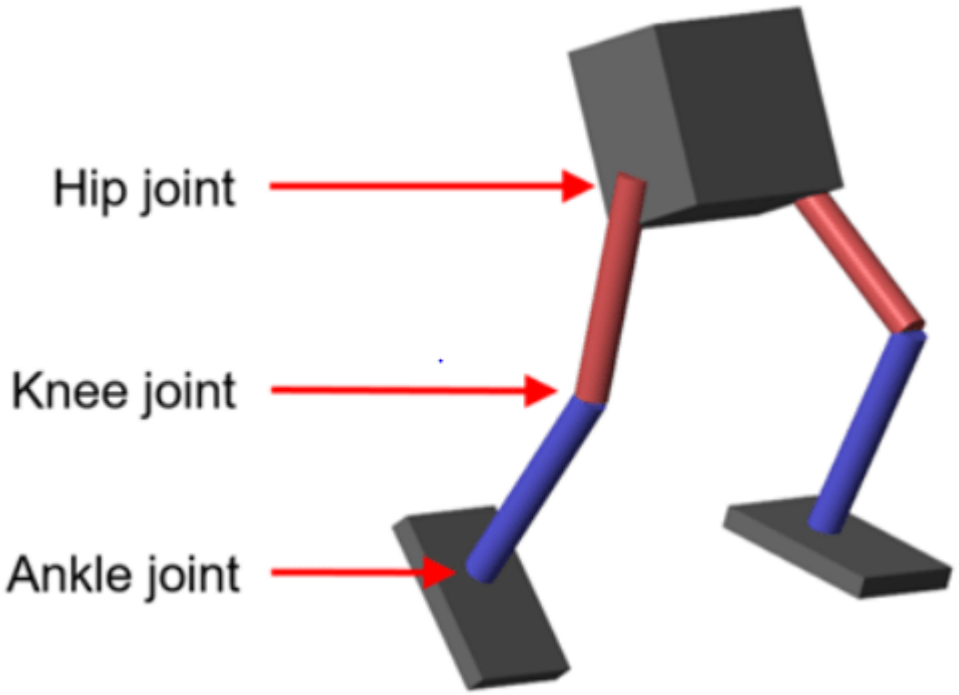
For more information on these agents, see “Deep Deterministic Policy Gradient Agents” (Reinforcement Learning Toolbox) and “Twin-Delayed Deep Deterministic Policy Gradient Agents” (Reinforcement Learning Toolbox).

For the purpose of comparison in this example, this example trains both agents on the biped robot environment with the same model parameters. The example also configures the agents to have the following settings in common.

- Initial condition strategy of the biped robot
- Network structure of actor and critic, inspired by [1]
- Options for actor and critic representations
- Training options (sample time, discount factor, mini-batch size, experience buffer length, exploration noise)

Biped Robot Model

The reinforcement learning environment for this example is a biped robot. The training goal is to make the robot walk in a straight line using minimal control effort.

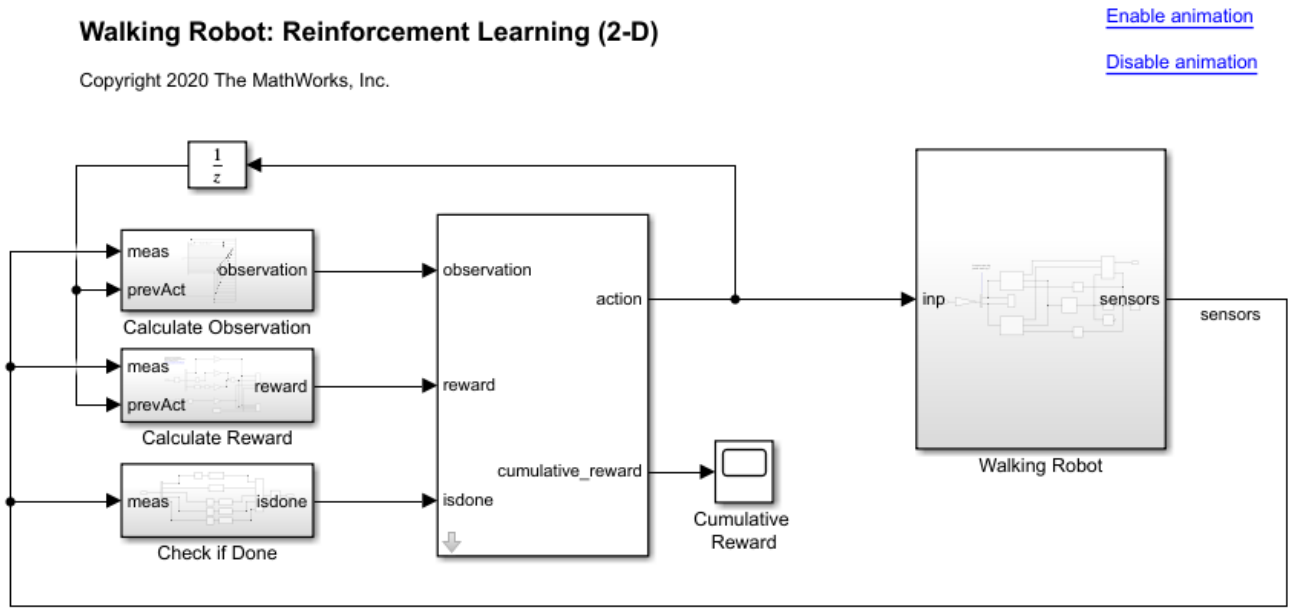


Load the parameters of the model into the MATLAB® workspace.

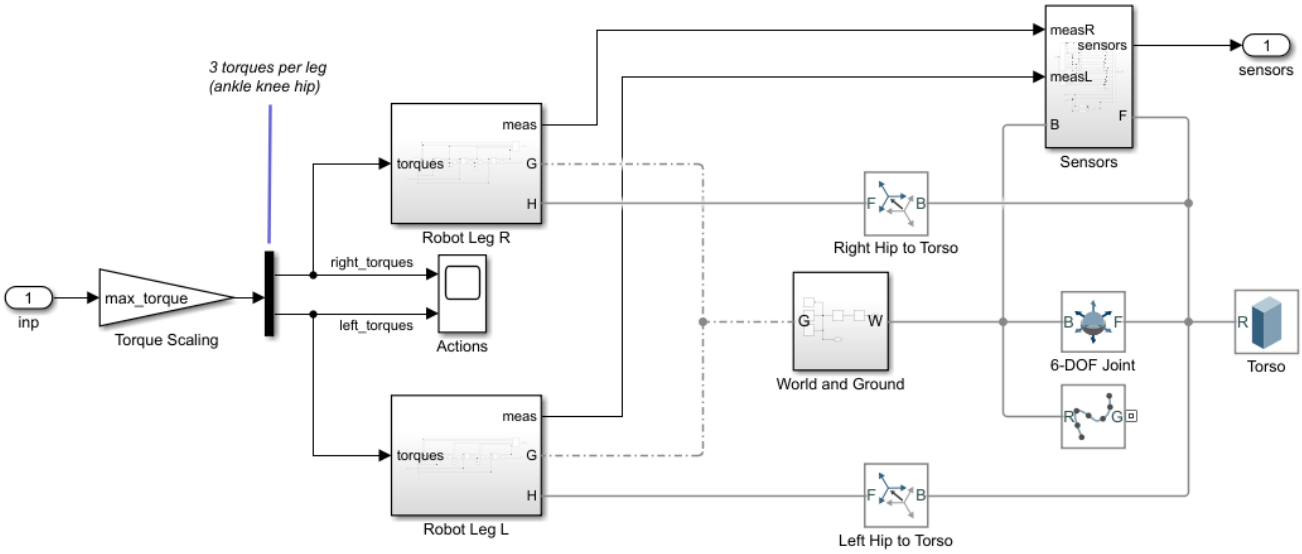
```
robotParametersRL
```

Open the Simulink model.

```
mdl = 'rlWalkingBipedRobot';
open_system(mdl)
```



The robot is modeled using Simscape Multibody.



For this model:

- In the neutral 0 rad position, both of the legs are straight and the ankles are flat.
- The foot contact is modeled using the Spatial Contact Force (Simscape Multibody) block.
- The agent can control 3 individual joints (ankle, knee, and hip) on both legs of the robot by applying torque signals from -3 to 3 N·m. The actual computed action signals are normalized between -1 and 1.

The environment provides the following 29 observations to the agent.

- Y (lateral) and Z (vertical) translations of the torso center of mass. The translation in the Z direction is normalized to a similar range as the other observations.
- X (forward), Y (lateral), and Z (vertical) translation velocities.
- Yaw, pitch, and roll angles of the torso.
- Yaw, pitch, and roll angular velocities of the torso.
- Angular positions and velocities of the three joints (ankle, knee, hip) on both legs.
- Action values from the previous time step.

The episode terminates if either of the following conditions occur.

- The robot torso center of mass is less than 0.1 m in the Z direction (the robot falls) or more than 1 m in the either Y direction (the robot moves too far to the side).
- The absolute value of either the roll, pitch, or yaw is greater than 0.7854 rad.

The following reward function r_t, which is provided at every time step is inspired by [2].

$$\boldsymbol{r_t} = v_x - 3y^2 - 50\hat{z}^2 + 25\frac{\mathrm{Ts}}{\mathrm{Tf}} - 0.02\sum_i {u_{t-1}^i}^2$$

Here:

- v_x is the translation velocity in the X direction (forward toward goal) of the robot.
- y is the lateral translation displacement of the robot from the target straight line trajectory.
- $\hat{z}$ is the normalized vertical translation displacement of the robot center of mass.
- u_{t-1}^i is the torque from joint i from the previous time step.
- Ts is the sample time of the environment.
- Tf is the final simulation time of the environment.

This reward function encourages the agent to move forward by providing a positive reward for positive forward velocity. It also encourages the agent to avoid episode termination by providing a constant reward ($25\frac{\mathrm{Ts}}{\mathrm{Tf}}$) at every time step. The other terms in the reward function are penalties for substantial changes in lateral and vertical translations, and for the use of excess control effort.

Create Environment Interface

Create the observation specification.

```
numObs = 29;
obsInfo = rlNumericSpec([numObs 1]);
obsInfo.Name = 'observations';
```

Create the action specification.

```
numAct = 6;
actInfo = rlNumericSpec([numAct 1],'LowerLimit',-1,'UpperLimit',1);
actInfo.Name = 'foot_torque';
```

Create the environment interface for the walking robot model.

```
blk = [mdl,'/RL Agent'];
env = rlSimulinkEnv(mdl,blk,obsInfo,actInfo);
env.ResetFcn = @(in) walkerResetFcn(in,upper_leg_length/100,lower_leg_length/100,h/100);
```

Select and Create Agent for Training

This example provides the option to train the robot either using either a DDPG or TD3 agent. To simulate the robot with the agent of your choice, set the `AgentSelection` flag accordingly.

```
AgentSelection = 'TD3';
switch AgentSelection
    case 'DDPG'
        agent = createDDPGAgent(numObs,obsInfo,numAct,actInfo,Ts);
    case 'TD3'
        agent = createTD3Agent(numObs,obsInfo,numAct,actInfo,Ts);
    otherwise
        disp('Enter DDPG or TD3 for AgentSelection')
end
```

The `createDDPGAgent` and `createTD3Agent` helper functions perform the following actions.

- Create actor and critic networks.
- Specify options for actor and critic representations.
- Create actor and critic representations using created networks and specified options.
- Configure agent specific options.
- Create agent.

DDPG Agent

A DDPG agent approximates the long-term reward given observations and actions using a critic value function representation. A DDPG agent decides which action to take given observations by using an actor representation. The actor and critic networks for this example are inspired by [1].

For details on the creating the DDPG agent, see the `createDDPGAgent` helper function. For information on configuring DDPG agent options, see `rlDDPGAgentOptions` (Reinforcement Learning Toolbox).

For more information on creating a deep neural network value function representation, see “Create Policy and Value Function Representations” (Reinforcement Learning Toolbox). For an example that creates neural networks for DDPG agents, see “Train DDPG Agent to Control Double Integrator System” (Reinforcement Learning Toolbox).

TD3 Agent

A TD3 agent approximates the long-term reward given observations and actions using two critic value function representations. A TD3 agent decides which action to take given observations using an actor representation. The structure of the actor and critic networks used for this agent are the same as the ones used for DDPG agent.

A DDPG agent can overestimate the Q value. Since the agent uses the Q value to update its policy (actor), the resultant policy can be suboptimal and accumulating training errors can lead to divergent behavior. The TD3 algorithm is an extension of DDPG with improvements that make it more robust by preventing overestimation of Q values [3].

- Two critic networks — TD3 agents learn two critic networks independently and use the minimum value function estimate to update the actor (policy). Doing so prevents accumulation of error in subsequent steps and overestimation of Q values.
- Addition of target policy noise — Adding clipped noise to value functions smooths out Q function values over similar actions. Doing so prevents learning an incorrect sharp peak of noisy value estimate.
- Delayed policy and target updates — For a TD3 agent, delaying the actor network update allows more time for the Q function to reduce error (get closer to the required target) before updating the policy. Doing so prevents variance in value estimates and results in a higher quality policy update.

For details on the creating the TD3 agent, see the `createTD3Agent` helper function. For information on configuring TD3 agent options, see `rlTD3AgentOptions` (Reinforcement Learning Toolbox).

Specify Training Options and Train Agent

For this example, the training options for the DDPG and TD3 agents are the same.

- Run each training session for 2000 episodes with each episode lasting at most `maxSteps` time steps.
- Display the training progress in the Episode Manager dialog box (set the `Plots` option) and disable the command line display (set the `Verbose` option).
- Terminate the training only when it reaches the maximum number of episodes (`maxEpisodes`). Doing so allows the comparison of the learning curves for multiple agents over the entire training session.

For more information and additional options, see `rlTrainingOptions` (Reinforcement Learning Toolbox).

```
maxEpisodes = 2000;
maxSteps = floor(Tf/Ts);
trainOpts = rlTrainingOptions(...
    'MaxEpisodes',maxEpisodes,...
    'MaxStepsPerEpisode',maxSteps,...
    'ScoreAveragingWindowLength',250,...
    'Verbose',false,...
    'Plots','training-progress',...
    'StopTrainingCriteria','EpisodeCount',...
    'StopTrainingValue',maxEpisodes,...
    'SaveAgentCriteria','EpisodeCount',...
    'SaveAgentValue',maxEpisodes);
```

To train the agent in parallel, specify the following training options. Training in parallel requires Parallel Computing Toolbox™. If you do not have Parallel Computing Toolbox software installed, set `UseParallel` to `false`.

- Set the `UseParallel` option to `true`.
- Train the agent in parallel asynchronously.

- After every 32 steps, have each worker send experiences to the parallel pool client (the MATLAB® process which starts the training). DDPG and TD3 agents require workers to send experiences to the client.

```
trainOpts.UseParallel = true;
trainOpts.ParallelizationOptions.Mode = 'async';
trainOpts.ParallelizationOptions.StepsUntilDataIsSent = 32;
trainOpts.ParallelizationOptions.DataToSendFromWorkers = 'Experiences';
```

Train the agent using the `train` (Reinforcement Learning Toolbox) function. This process is computationally intensive and takes several hours to complete for each agent. To save time while running this example, load a pretrained agent by setting `doTraining` to `false`. To train the agent yourself, set `doTraining` to `true`. Due to randomness in the parallel training, you can expect different training results from the plots that follow. The pretrained agents were trained in parallel using four workers.

```
doTraining = false;
if doTraining
    % Train the agent.
    trainingStats = train(agent,env,trainOpts);
else
    % Load a pretrained agent for the selected agent type.
    if strcmp(AgentSelection,'DDPG')
       load('rlWalkingBipedRobotDDPG.mat','agent')
    else
       load('rlWalkingBipedRobotTD3.mat','agent')
    end
end
```

For the preceding example training curves, the average time per training step for the DDPG and TD3 agents are 0.11 and 0.12 seconds, respectively. The TD3 agent takes more training time per step because it updates two critic networks compared to the single critic used for DDPG.

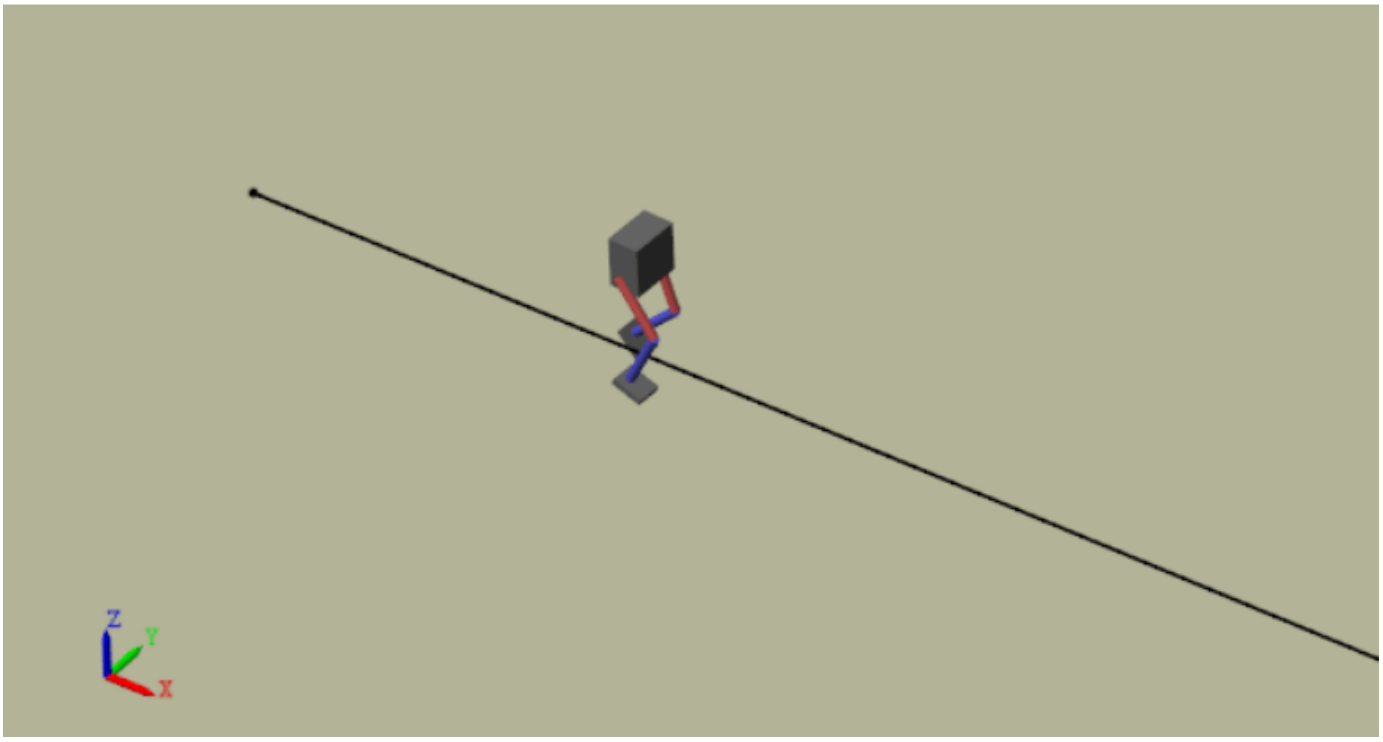
Simulate Trained Agents

Fix the random generator seed for reproducibility.

```
rng(0)
```

To validate the performance of the trained agent, simulate it within the biped robot environment. For more information on agent simulation, see `rlSimulationOptions` (Reinforcement Learning Toolbox) and `sim` (Reinforcement Learning Toolbox).

```
simOptions = rlSimulationOptions('MaxSteps',maxSteps);
experience = sim(env,agent,simOptions);
```



Compare Agent Performance

For the following agent comparison, each agent was trained five times using a different random seed each time. Due to the random exploration noise and the randomness in the parallel training, the learning curve for each run is different. Since the training of agents for multiple runs takes several days to complete, this comparison uses pretrained agents.

For the DDPG and TD3 agents, plot the average and standard deviation of the episode reward (top plot) and the episode Q0 value (bottom plot). The episode Q0 value is the critic estimate of the discounted long-term reward at the start of each episode given the initial observation of the environment. For a well-designed critic, the episode Q0 value approaches the true discounted long-term reward.

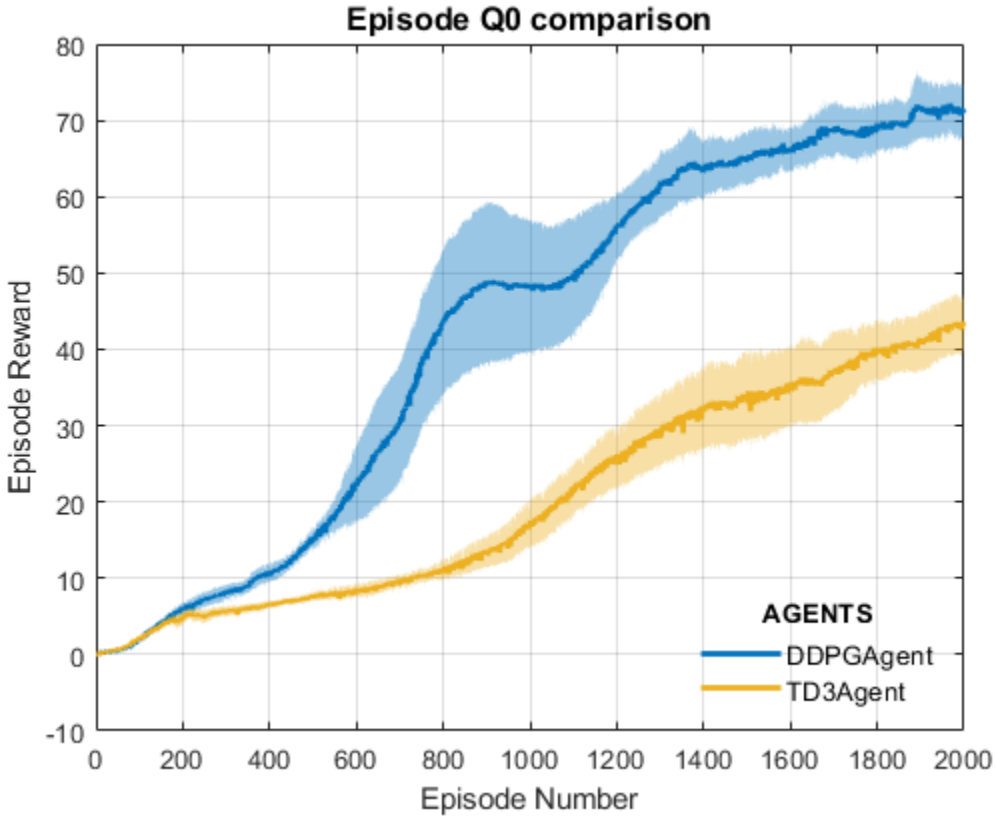
AGENTS
DDPGAgent
TD3Agent



Based on the Learning curve comparison plot:

- The DDPG agent appears to pick up learning faster (around episode number 600 on average) but hits a local minimum. TD3 starts slower but eventually achieves higher rewards than DDPG as it avoids overestimation of Q values.
- The TD3 agent shows a steady improvement in its learning curve, which suggests improved stability when compared to the DDPG agent.

Based on the Episode Q0 comparison plot:

- For the TD3 agent, the critic estimate of the discounted long-term reward (for 2000 episodes) is lower compared to the DDPG agent. This difference is because the TD3 algorithm takes a conservative approach in updating its targets by using a minimum of two Q functions. This behavior is further enhanced because of delayed updates to the targets.
- Although the TD3 estimate for these 2000 episodes is low, the TD3 agent shows a steady increase in the episode Q0 values, unlike the DDPG agent.

In this example, the training was stopped at 2000 episodes. For a larger training period, the TD3 agent with its steady increase in estimates shows the potential to converge to the true discounted long-term reward.

For another example on how to train a humanoid robot to walk using a DDPG agent, see “Train Humanoid Walker” (Simscape Multibody). For an example on how to train a quadruped robot to walk using a DDPG agent, see “Quadruped Robot Locomotion Using DDPG Agent” (Reinforcement Learning Toolbox).

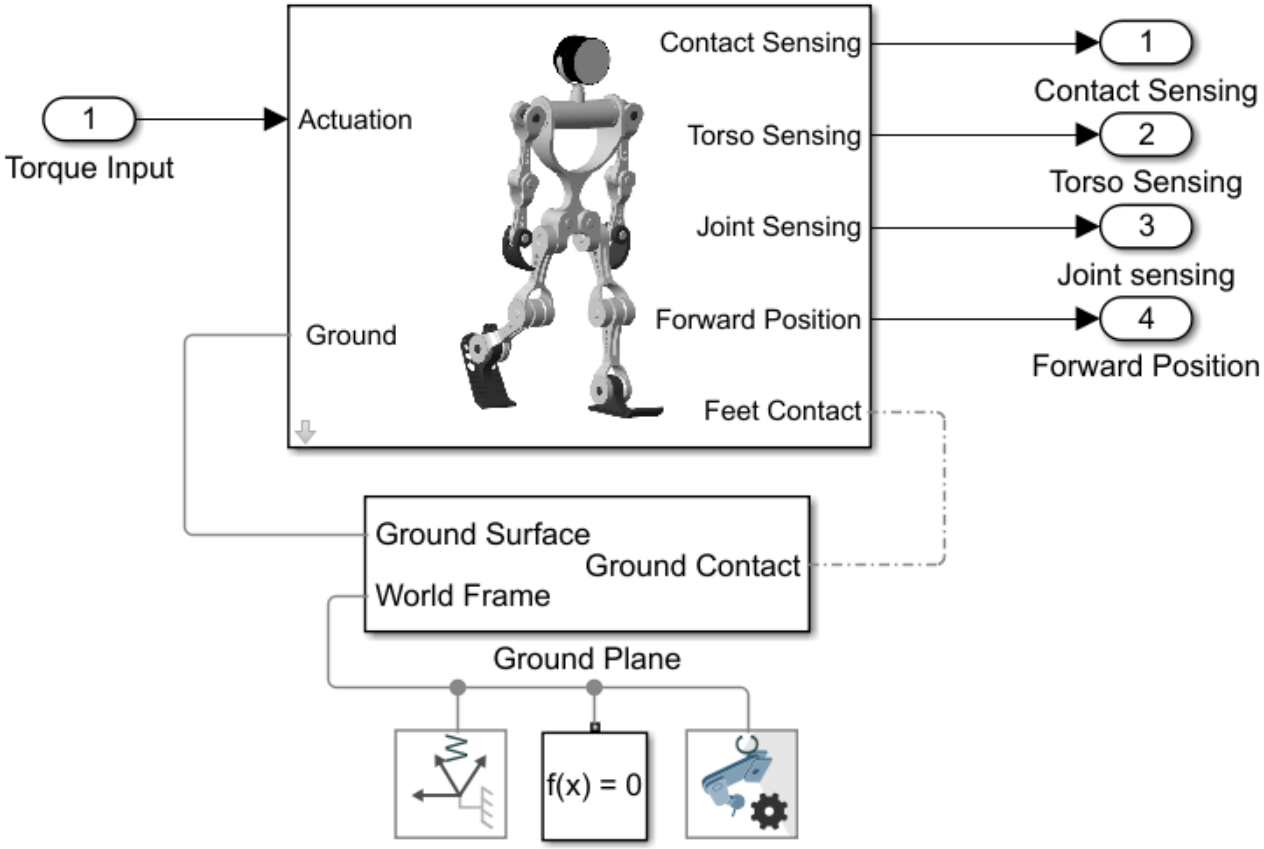
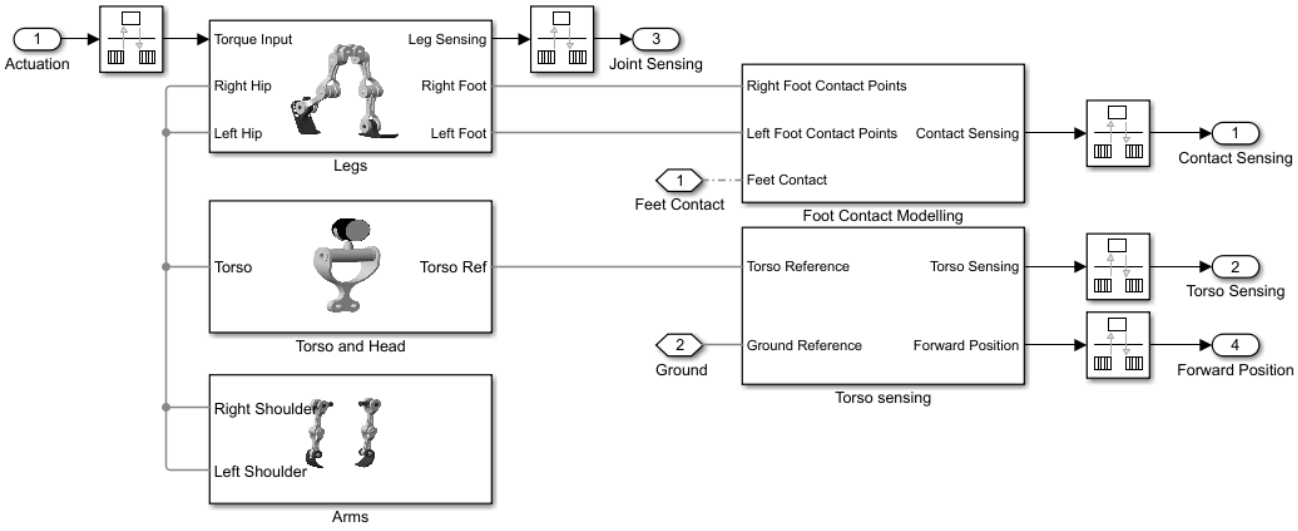
Train Humanoid Walker

This example shows how to model a humanoid robot using “Simscape Multibody”™ and train it using either a genetic algorithm (which requires a “Global Optimization Toolbox” license) or reinforcement learning (which requires “Deep Learning Toolbox”™ and “Reinforcement Learning Toolbox”™ licenses).

Humanoid Walker Model

This example is based on a humanoid robot model. You can open the model by entering `sm_import_humanoid_urdf` in the MATLAB® command prompt. Each leg of the robot has torque-actuated revolute joints in the frontal hip, knee, and ankle. Each arm has two passive revolute joints in the frontal and sagittal shoulder. During the simulation, the model senses the contact forces, position and orientation of the torso, joint states, and forward position. The figure shows the Simscape Multibody model on different levels.





Contact Modeling

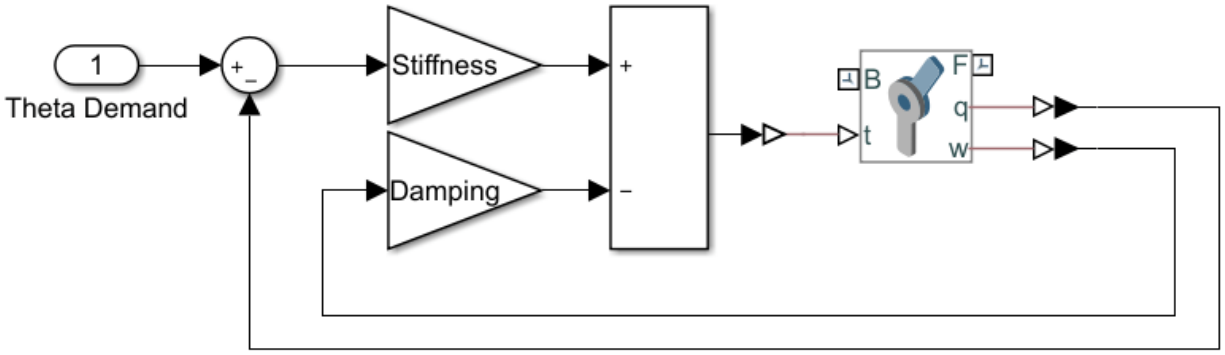
The model uses Spatial Contact Force (Simscape Multibody) blocks to simulate the contact between the feet and ground. To simplify the contact and speed up the simulation, red spheres are used to represent the bottoms of the robotic feet. For more details, see “Use Contact Proxies to Simulate Contact” (Simscape Multibody).

Joint Controller

The model uses a stiffness-based feedback controller to control each joint [1]. Model the joints as first-order systems with an associated stiffness (K) and damping (B), which you can set to make the joint behavior critically damped. The torque is applied when the setpoint θ_0 differs from the current joint position θ:

$T = B\dot{\theta} + K(\theta_0 - \theta)$.

You can vary the spring set-point θ_0 to elicit a feedback response to move the joint. The figure shows the Simulink model of the controller.



Humanoid Walker Training

The goal of this example is to train a humanoid robot to walk, and you can use various methods to train the robot. The example shows the genetic algorithm and reinforcement learning methods.

The Walking Objective Function

This example uses an objective function to evaluate different walking styles. The model gives a reward (r_t) at each timestep:

$$r_t = w_1 v_y + w_2 t_s - w_3 p - w_4 \Delta z - w_5 \Delta x$$

Here:

- v_y — Forward velocity (rewarded)
- p — Power consumption (penalized)
- Δz — Vertical displacement (penalized)
- Δx — Lateral displacement (penalized)
- $w_{1,\ldots,5}$: Weights, which represent the relative importance of each term in the reward function

Additionally, not falling over is rewarded.

Consequently, the total reward (R) for a walking trial is:

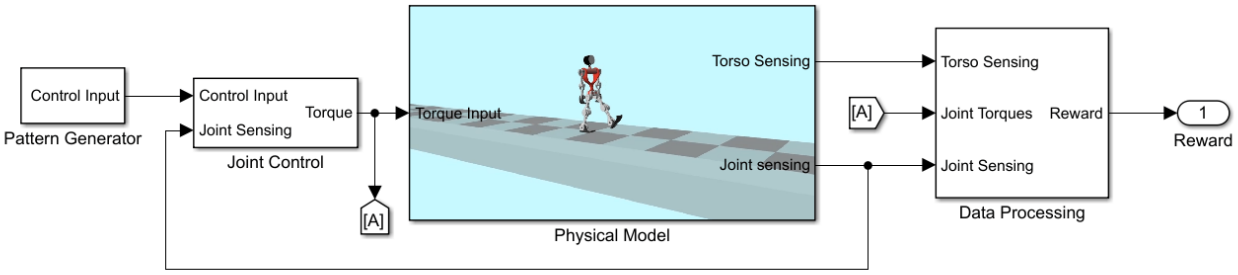
$$R = \sum_{t=0}^{T} r_t$$

Here T is the time at which the simulation terminates. You can change the reward weights in the `sm_humanoid_walker_rl_parameters` script. The simulation terminates when the simulation time is reached or the robot falls. Falling is defined as:

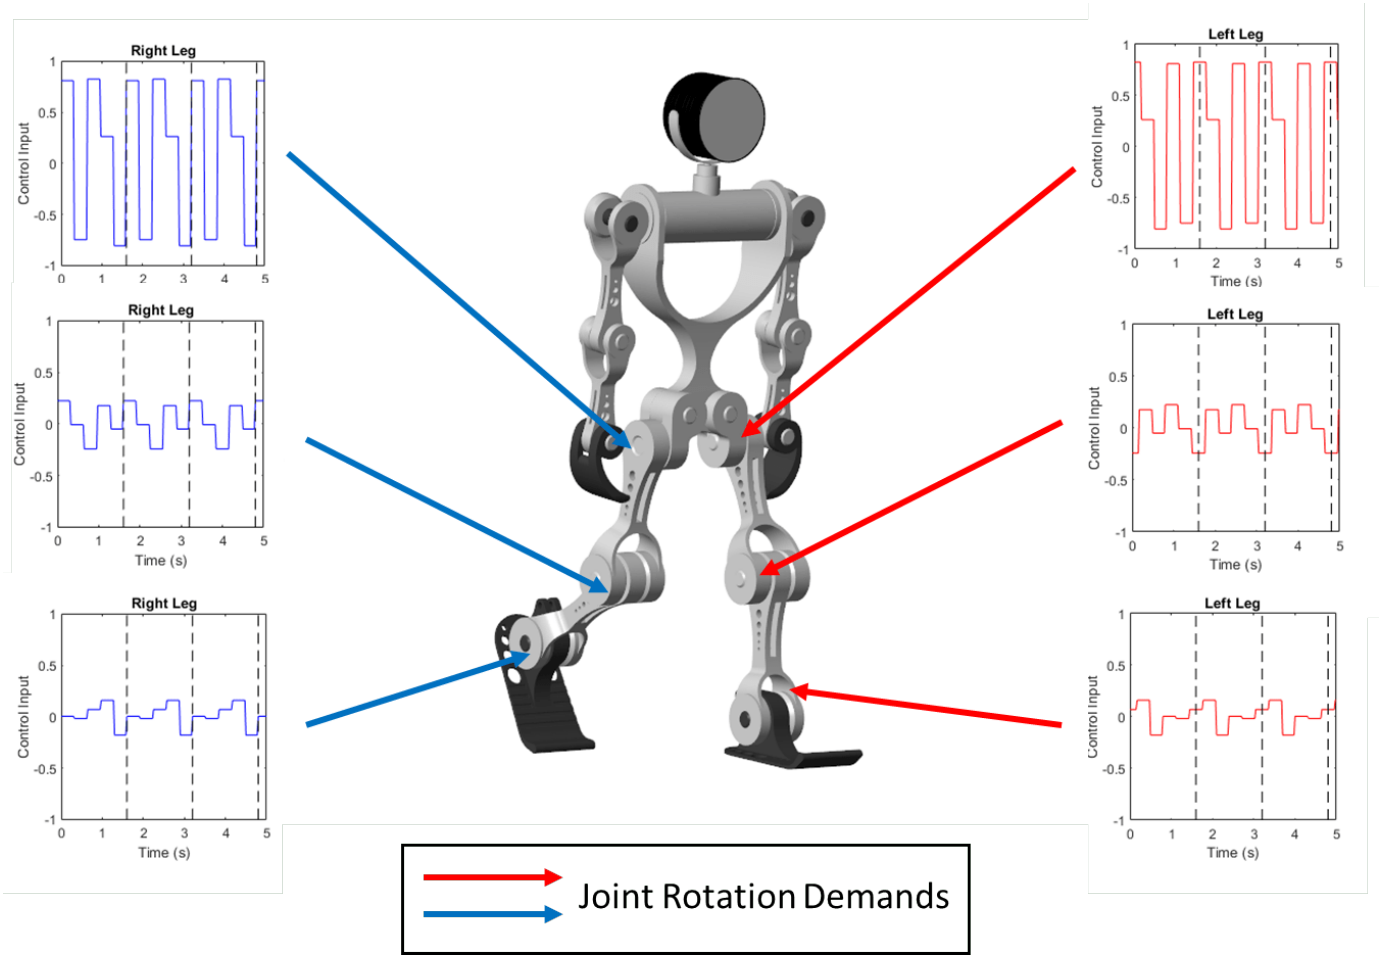
- The robot drops below 0.5 m.
- The robot moves laterally by more than 1 m.
- The robot torso rotates by more than 30 degrees.

Train with Genetic Algorithm

To optimize the walking of the robot, you can use a genetic algorithm. A genetic algorithm solves optimization problems based on a natural selection process that mimics biological evolution. Genetic algorithms are especially suited to problems when the objective function is discontinuous, nondifferentiable, stochastic, or highly nonlinear. For more information, see `ga` (Global Optimization Toolbox).



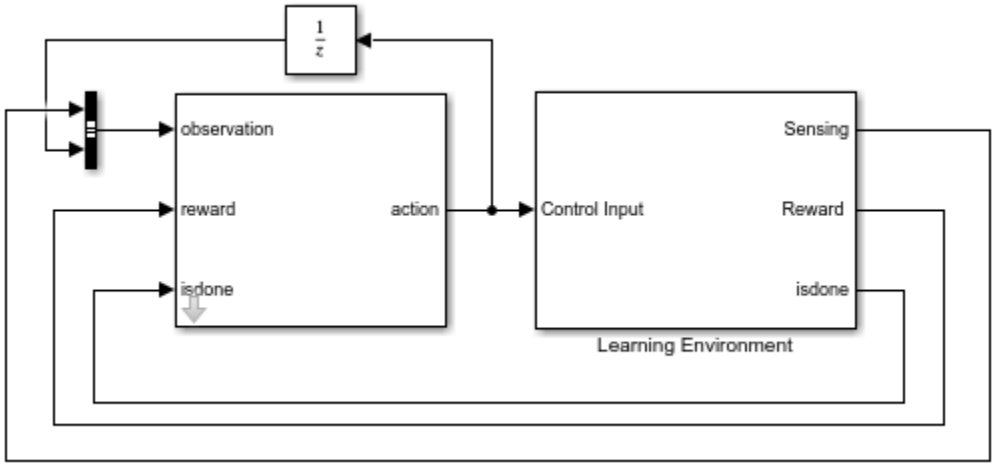
The model sets the angular demand for each joint to a repeating pattern that is analogous to the central pattern generators seen in nature [2]. The repeating pattern yields an open-loop controller. The periodicity of the signals is the gait period, which is the time taken to complete one full step. During each gait period, the signal switches between different angular demand values. Ideally, the humanoid robot walks symmetrically, and the control pattern for each joint in the right leg is transmitted to the corresponding joint in the left leg, with a delay of half a gait period. The pattern generator aims to determine the optimal control pattern for each joint and to maximize the walking objective function.



To train the robot with a genetic algorithm, open the `sm_humanoid_walker_ga_train` script. By default, this example uses a pretrained humanoid walker. To train the humanoid walker, set `trainWalker` to `true`.

Train with Reinforcement Learning

Alternatively, you can also train the robot using a deep deterministic policy gradient (DDPG) reinforcement learning agent. A DDPG agent is an actor-critic reinforcement learning agent that computes an optimal policy that maximizes the long-term reward. DDPG agents can be used in systems with continuous actions and states. For details about DDPG agents, see `rlDDPGAgent` (Reinforcement Learning Toolbox).



To train the robot with reinforcement learning, open the `sm_humanoid_walker_rl_train` script. By default, this example uses a pretrained humanoid walker. To train the humanoid walker, set `trainWalker` to `true`.

Train DDPG Agent for Adaptive Cruise Control

This example shows how to train a deep deterministic policy gradient (DDPG) agent for adaptive cruise control (ACC) in Simulink®. For more information on DDPG agents, see “Deep Deterministic Policy Gradient Agents” (Reinforcement Learning Toolbox).

Simulink Model

The reinforcement learning environment for this example is the simple longitudinal dynamics for an ego car and lead car. The training goal is to make the ego car travel at a set velocity while maintaining a safe distance from lead car by controlling longitudinal acceleration and braking. This example uses the same vehicle model as the “Adaptive Cruise Control System Using Model Predictive Control” (Model Predictive Control Toolbox) example.

Specify the initial position and velocity for the two vehicles.

```
x0_lead = 50;   % initial position for lead car (m)
v0_lead = 25;   % initial velocity for lead car (m/s)
x0_ego = 10;    % initial position for ego car (m)
v0_ego = 20;    % initial velocity for ego car (m/s)
```

Specify standstill default spacing (m), time gap (s) and driver-set velocity (m/s).

```
D_default = 10;
t_gap = 1.4;
v_set = 30;
```

To simulate the physical limitations of the vehicle dynamics, constraint the acceleration to the range `[-3,2]` m/s^2.

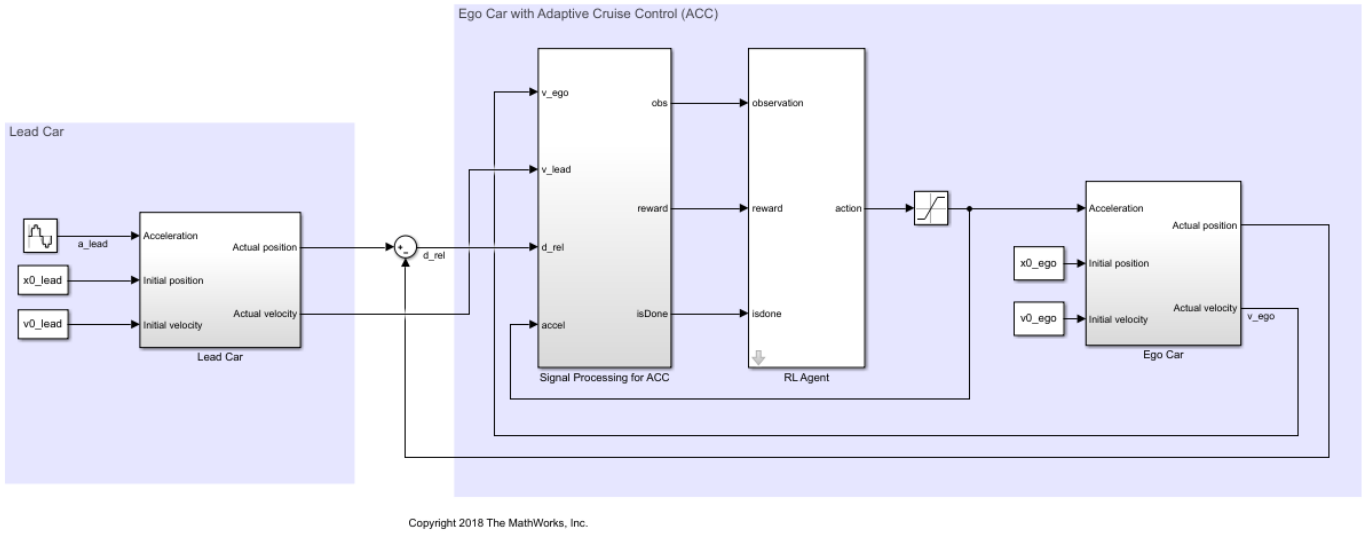
```
amin_ego = -3;
amax_ego = 2;
```

Define the sample time `Ts` and simulation duration `Tf` in seconds.

```
Ts = 0.1;
Tf = 60;
```

Open the model.

```
mdl = 'rlACCMdl';
open_system(mdl)
agentblk = [mdl '/RL Agent'];
```



For this model:

- The acceleration action signal from the agent to the environment is from –3 to 2 m/s^2.
- The reference velocity for the ego car V_{ref} is defined as follows. If the relative distance is less than the safe distance, the ego car tracks the minimum of the lead car velocity and driver-set velocity. In this manner, the ego car maintains some distance from the lead car. If the relative distance is greater than the safe distance, the ego car tracks the driver-set velocity. In this example, the safe distance is defined as a linear function of the ego car longitudinal velocity V; that is, $t_{gap}*V + D_{default}$. The safe distance determines the reference tracking velocity for the ego car.
- The observations from the environment are the velocity error $e = V_{ref} - V_{ego}$, its integral $\int e$, and the ego car longitudinal velocity V.
- The simulation is terminated when longitudinal velocity of the ego car is less than 0, or the relative distance between the lead car and ego car becomes less than 0.
- The reward r_t, provided at every time step t, is

$$r_t = -(0.1e_t^2 + u_{t-1}^2) + M_t$$

where u_{t-1} is the control input from the previous time step. The logical value $M_t = 1$ if velocity error $e_t^2 <= 0.25$; otherwise, $M_t = 0$.

Create Environment Interface

Create a reinforcement learning environment interface for the model.

Create the observation specification.

```
observationInfo = rlNumericSpec([3 1],'LowerLimit',-inf*ones(3,1),'UpperLimit',inf*ones(3,1));
observationInfo.Name = 'observations';
observationInfo.Description = 'information on velocity error and ego velocity';
```

Create the action specification.

```
actionInfo = rlNumericSpec([1 1],'LowerLimit',-3,'UpperLimit',2);
actionInfo.Name = 'acceleration';
```

Create the environment interface.

```
env = rlSimulinkEnv(mdl,agentblk,observationInfo,actionInfo);
```

To define the initial condition for the position of the lead car, specify an environment reset function using an anonymous function handle. The reset function `localResetFcn`, which is defined at the end of the example, randomizes the initial position of the lead car.

```
env.ResetFcn = @(in)localResetFcn(in);
```

Fix the random generator seed for reproducibility.

```
rng('default')
```

Create DDPG agent

A DDPG agent approximates the long-term reward given observations and actions using a critic value function representation. To create the critic, first create a deep neural network with two inputs, the state and action, and one output. For more information on creating a neural network value function representation, see “Create Policy and Value Function Representations” (Reinforcement Learning Toolbox).

```
L = 48; % number of neurons
statePath = [
    featureInputLayer(3,'Normalization','none','Name','observation')
    fullyConnectedLayer(L,'Name','fc1')
    reluLayer('Name','relu1')
    fullyConnectedLayer(L,'Name','fc2')
    additionLayer(2,'Name','add')
    reluLayer('Name','relu2')
    fullyConnectedLayer(L,'Name','fc3')
    reluLayer('Name','relu3')
    fullyConnectedLayer(1,'Name','fc4')];

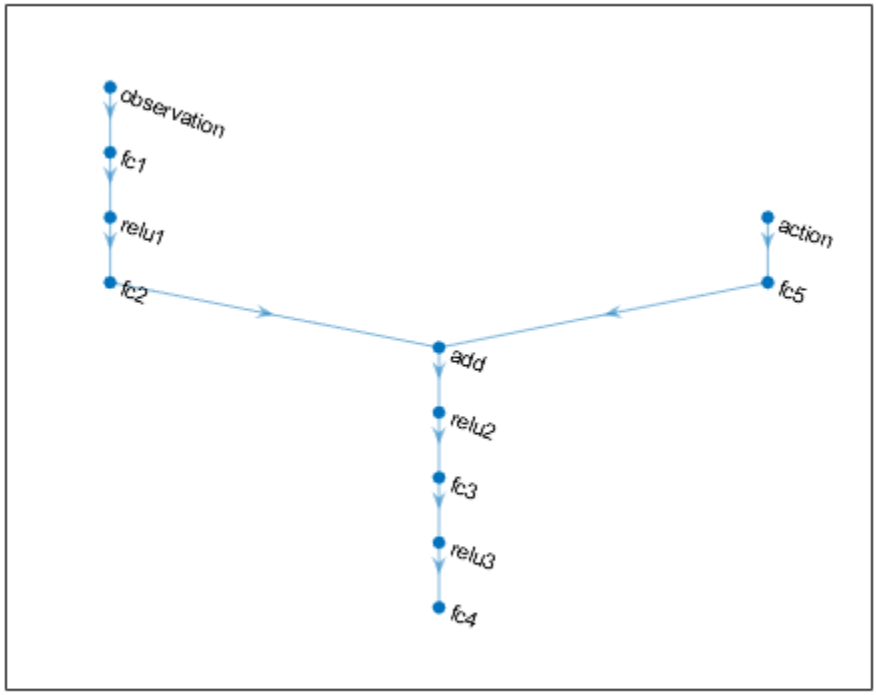
actionPath = [
    featureInputLayer(1,'Normalization','none','Name','action')
    fullyConnectedLayer(L, 'Name', 'fc5')];

criticNetwork = layerGraph(statePath);
criticNetwork = addLayers(criticNetwork, actionPath);

criticNetwork = connectLayers(criticNetwork,'fc5','add/in2');
```

View the critic network configuration.

```
plot(criticNetwork)
```



Specify options for the critic representation using `rlRepresentationOptions` (Reinforcement Learning Toolbox).

```
criticOptions = rlRepresentationOptions('LearnRate',1e-3,'GradientThreshold',1,'L2RegularizationF
```

Create the critic representation using the specified neural network and options. You must also specify the action and observation info for the critic, which you obtain from the environment interface. For more information, see `rlQValueRepresentation` (Reinforcement Learning Toolbox).

```
critic = rlQValueRepresentation(criticNetwork,observationInfo,actionInfo,...
    'Observation',{'observation'},'Action',{'action'},criticOptions);
```

A DDPG agent decides which action to take given observations by using an actor representation. To create the actor, first create a deep neural network with one input, the observation, and one output, the action.

Construct the actor similarly to the critic. For more information, see `rlDeterministicActorRepresentation` (Reinforcement Learning Toolbox).

```
actorNetwork = [
    featureInputLayer(3,'Normalization','none','Name','observation')
    fullyConnectedLayer(L,'Name','fc1')
    reluLayer('Name','relu1')
    fullyConnectedLayer(L,'Name','fc2')
    reluLayer('Name','relu2')
    fullyConnectedLayer(L,'Name','fc3')
    reluLayer('Name','relu3')
```

```
    fullyConnectedLayer(1,'Name','fc4')
    tanhLayer('Name','tanh1')
    scalingLayer('Name','ActorScaling1','Scale',2.5,'Bias',-0.5)];

actorOptions = rlRepresentationOptions('LearnRate',1e-4,'GradientThreshold',1,'L2RegularizationFa
actor = rlDeterministicActorRepresentation(actorNetwork,observationInfo,actionInfo,...
    'Observation',{'observation'},'Action',{'ActorScaling1'},actorOptions);
```

To create the DDPG agent, first specify the DDPG agent options using `rlDDPGAgentOptions` (Reinforcement Learning Toolbox).

```
agentOptions = rlDDPGAgentOptions(...
    'SampleTime',Ts,...
    'TargetSmoothFactor',1e-3,...
    'ExperienceBufferLength',1e6,...
    'DiscountFactor',0.99,...
    'MiniBatchSize',64);
agentOptions.NoiseOptions.Variance = 0.6;
agentOptions.NoiseOptions.VarianceDecayRate = 1e-5;
```

Then, create the DDPG agent using the specified actor representation, critic representation, and agent options. For more information, see `rlDDPGAgent` (Reinforcement Learning Toolbox).

```
agent = rlDDPGAgent(actor,critic,agentOptions);
```

Train Agent

To train the agent, first specify the training options. For this example, use the following options:

- Run each training episode for at most `5000` episodes, with each episode lasting at most 600 time steps.
- Display the training progress in the Episode Manager dialog box.
- Stop training when the agent receives an episode reward greater than 260.

For more information, see `rlTrainingOptions` (Reinforcement Learning Toolbox).

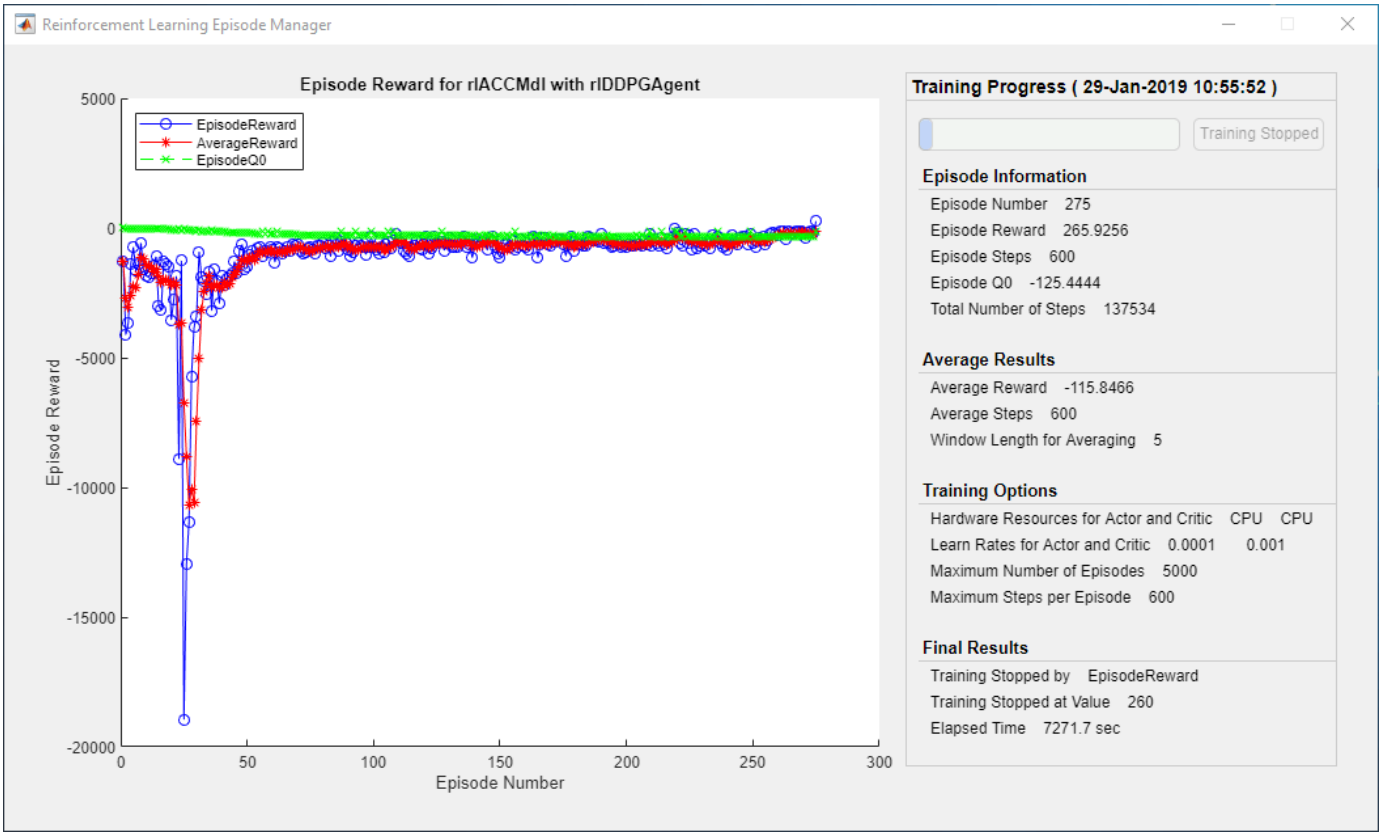
```
maxepisodes = 5000;
maxsteps = ceil(Tf/Ts);
trainingOpts = rlTrainingOptions(...
    'MaxEpisodes',maxepisodes,...
    'MaxStepsPerEpisode',maxsteps,...
    'Verbose',false,...
    'Plots','training-progress',...
    'StopTrainingCriteria','EpisodeReward',...
    'StopTrainingValue',260);
```

Train the agent using the `train` (Reinforcement Learning Toolbox) function. Training is a computationally intensive process that takes several minutes to complete. To save time while running this example, load a pretrained agent by setting `doTraining` to `false`. To train the agent yourself, set `doTraining` to `true`.

```
doTraining = false;

if doTraining
    % Train the agent.
    trainingStats = train(agent,env,trainingOpts);
else
```

```
    % Load a pretrained agent for the example.
    load('SimulinkACCDDPG.mat','agent')
end
```



Simulate DDPG Agent

To validate the performance of the trained agent, simulate the agent within the Simulink environment by uncommenting the following commands. For more information on agent simulation, see `rlSimulationOptions` (Reinforcement Learning Toolbox) and `sim` (Reinforcement Learning Toolbox).

```
% simOptions = rlSimulationOptions('MaxSteps',maxsteps);
% experience = sim(env,agent,simOptions);
```

To demonstrate the trained agent using deterministic initial conditions, simulate the model in Simulink.

```
x0_lead = 80;
sim(mdl)
```

The following plots show the simulation results when lead car is 70 (m) ahead of the ego car.

- In the first 28 seconds, the relative distance is greater than the safe distance (bottom plot), so the ego car tracks set velocity (middle plot). To speed up and reach the set velocity, acceleration is positive (top plot).
- From 28 to 60 seconds, the relative distance is less than the safe distance (bottom plot), so the ego car tracks the minimum of the lead velocity and set velocity. From 28 to 36 seconds, the lead

velocity is less than the set velocity (middle plot). To slow down and track the lead car velocity, acceleration is negative (top plot). From 36 to 60 seconds, the ego car adjusts its acceleration to track the reference velocity closely (middle plot). Within this time interval, the ego car tracks the set velocity from 43 to 52 seconds and tracks lead velocity from 36 to 43 seconds and 52 to 60 seconds.

Train DQN Agent for Lane Keeping Assist Using Parallel Computing

This example shows how to train a deep Q-learning network (DQN) agent for lane keeping assist (LKA) in Simulink® using parallel training. For an example that shows how to train the agent without using parallel training, see “Train DQN Agent for Lane Keeping Assist” (Reinforcement Learning Toolbox).

For more information on DQN agents, see “Deep Q-Network Agents” (Reinforcement Learning Toolbox). For an example that trains a DQN agent in MATLAB®, see “Train DQN Agent to Balance Cart-Pole System” (Reinforcement Learning Toolbox).

DQN Parallel Training Overview

In a DQN agent, each worker generates new experiences from its copy of the agent and the environment. After every **N** steps, the worker sends experiences to the client agent (the agent associated with the MATLAB® process which starts the training). The client agent updates its parameters as follows.

- For asynchronous training, the client agent learns from received experiences without waiting for all workers to send experiences, and sends the updated parameters back to the worker that provided the experiences. Then, the worker continues to generate experiences from its environment using the updated parameters.
- For synchronous training, the client agent waits to receive experiences from all of the workers and learns from these experiences. The client then sends updated parameters to all the workers at the same time. Then, all workers continue to generate experiences using the updated parameters.

For more information about synchronous versus asynchronous parallelization, see “Train Agents Using Parallel Computing and GPUs” (Reinforcement Learning Toolbox).

Simulink Model for Ego Car

The reinforcement learning environment for this example is a simple bicycle model for ego vehicle dynamics. The training goal is to keep the ego vehicle traveling along the centerline of the lanes by adjusting the front steering angle. This example uses the same vehicle model as “Train DQN Agent for Lane Keeping Assist” (Reinforcement Learning Toolbox).

```
m = 1575;   % total vehicle mass (kg)
Iz = 2875;  % yaw moment of inertia (mNs^2)
lf = 1.2;   % longitudinal distance from center of gravity to front tires (m)
lr = 1.6;   % longitudinal distance from center of gravity to rear tires (m)
Cf = 19000; % cornering stiffness of front tires (N/rad)
Cr = 33000; % cornering stiffness of rear tires (N/rad)
Vx = 15;    % longitudinal velocity (m/s)
```

Define the sample time `Ts` and simulation duration `T` in seconds.

```
Ts = 0.1;
T = 15;
```

The output of the LKA system is the front steering angle of the ego car. To simulate the physical steering limits of the ego car, constrain the steering angle to the range `[–0.5,0.5]` rad.

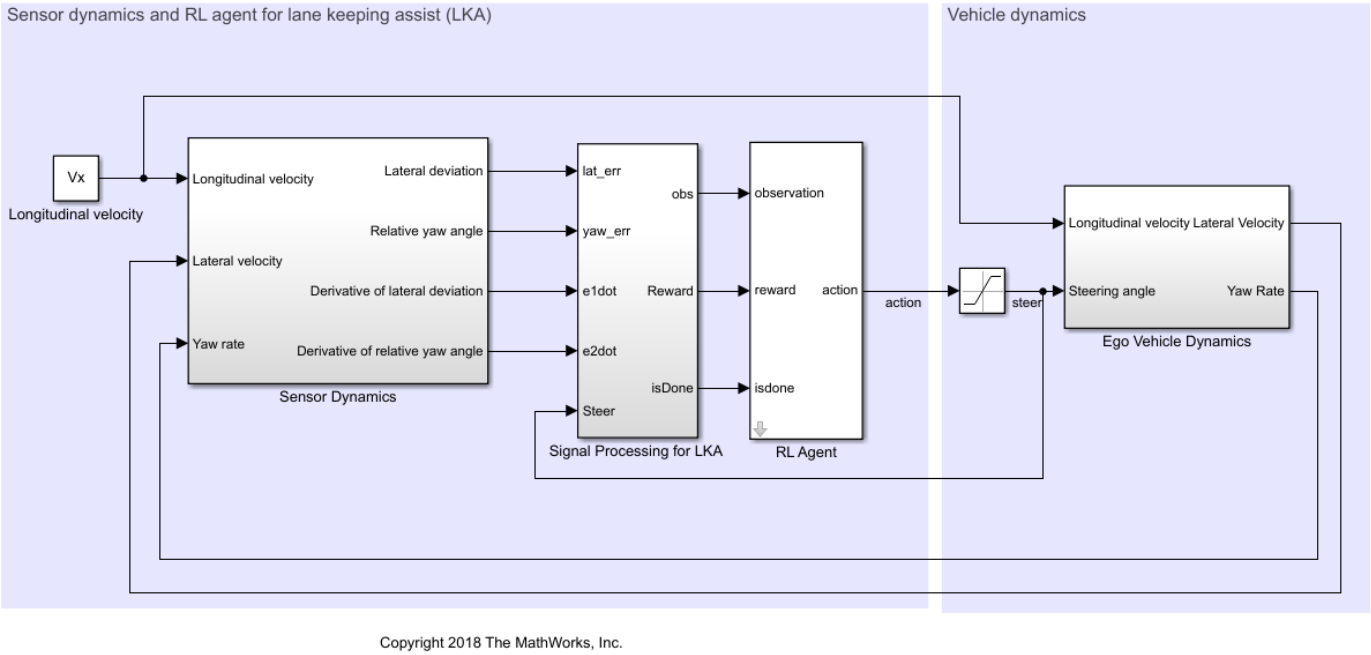
```
u_min = -0.5;
u_max = 0.5;
```

The curvature of the road is defined by a constant 0.001 (m^{-1}). The initial value for the lateral deviation is `0.2` m and the initial value for the relative yaw angle is `–0.1` rad.

```
rho = 0.001;
e1_initial = 0.2;
e2_initial = -0.1;
```

Open the model.

```
mdl = 'rlLKAMdl';
open_system(mdl)
agentblk = [mdl '/RL Agent'];
```



For this model:

- The steering-angle action signal from the agent to the environment is from –15 degrees to 15 degrees.
- The observations from the environment are the lateral deviation e_1, relative yaw angle e_2, their derivatives $\dot{e}_1$ and $\dot{e}_2$, and their integrals $\int e_1$ and $\int e_2$.
- The simulation is terminated when the lateral deviation $|e_1| > 1$.
- The reward r_t, provided at every time step t, is

$$r_t = -(10e_1^2 + 5e_2^2 + 2u^2 + 5\dot{e}_1^2 + 5\dot{e}_2^2)$$

where u is the control input from the previous time step $t - 1$.

Create Environment Interface

Create a reinforcement learning environment interface for the ego vehicle.

Define the observation information.

```
observationInfo = rlNumericSpec([6 1],'LowerLimit',-inf*ones(6,1),'UpperLimit',inf*ones(6,1));
observationInfo.Name = 'observations';
observationInfo.Description = 'information on lateral deviation and relative yaw angle';
```

Define the action information.

```
actionInfo = rlFiniteSetSpec((-15:15)*pi/180);
actionInfo.Name = 'steering';
```

Create the environment interface.

```
env = rlSimulinkEnv(mdl,agentblk,observationInfo,actionInfo);
```

The interface has a discrete action space where the agent can apply one of 31 possible steering angles from –15 degrees to 15 degrees. The observation is the six-dimensional vector containing lateral deviation, relative yaw angle, as well as their derivatives and integrals with respect to time.

To define the initial condition for the lateral deviation and relative yaw angle, specify an environment reset function using an anonymous function handle. `localResetFcn`, which is defined at the end of this example, randomizes the initial lateral deviation and relative yaw angle.

```
env.ResetFcn = @(in)localResetFcn(in);
```

Fix the random generator seed for reproducibility.

```
rng(0)
```

Create DQN Agent

DQN agents can use multi-output Q-value critic approximators, which are generally more efficient. A multi-output approximator has observations as inputs and state-action values as outputs. Each output element represents the expected cumulative long-term reward for taking the corresponding discrete action from the state indicated by the observation inputs.

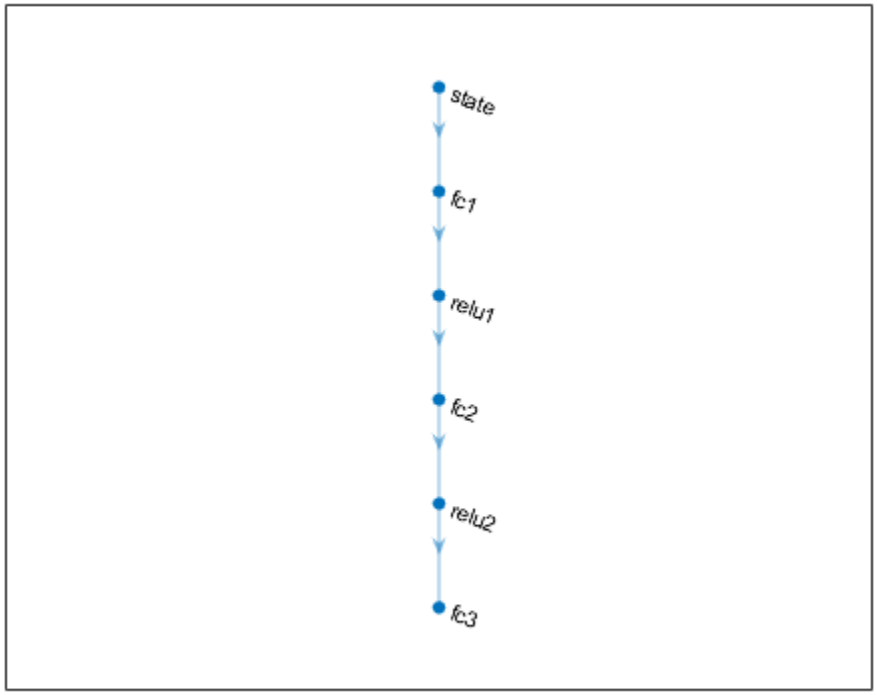
To create the critic, first create a deep neural network with one input (the six-dimensional observed state) and one output vector with 31 elements (evenly spaced steering angles from -15 to 15 degrees). For more information on creating a deep neural network value function representation, see “Create Policy and Value Function Representations” (Reinforcement Learning Toolbox).

```
nI = observationInfo.Dimension(1);  % number of inputs (6)
nL = 120;                           % number of neurons
nO = numel(actionInfo.Elements);    % number of outputs (31)

dnn = [
    featureInputLayer(nI,'Normalization','none','Name','state')
    fullyConnectedLayer(nL,'Name','fc1')
    reluLayer('Name','relu1')
    fullyConnectedLayer(nL,'Name','fc2')
    reluLayer('Name','relu2')
    fullyConnectedLayer(nO,'Name','fc3')];
```

View the network configuration.

```
figure
plot(layerGraph(dnn))
```



Specify options for the critic representation using `rlRepresentationOptions` (Reinforcement Learning Toolbox).

```
criticOptions = rlRepresentationOptions('LearnRate',1e-4,'GradientThreshold',1,'L2RegularizationF
```

Create the critic representation using the specified deep neural network and options. You must also specify the action and observation info for the critic, which you obtain from the environment interface. For more information, see `rlQValueRepresentation` (Reinforcement Learning Toolbox).

```
critic = rlQValueRepresentation(dnn,observationInfo,actionInfo,'Observation',{'state'},criticOpti
```

To create the DQN agent, first specify the DQN agent options using `rlDQNAgentOptions` (Reinforcement Learning Toolbox).

```
agentOpts = rlDQNAgentOptions(...
    'SampleTime',Ts,...
    'UseDoubleDQN',true,...
    'TargetSmoothFactor',1e-3,...
    'DiscountFactor',0.99,...
    'ExperienceBufferLength',1e6,...
    'MiniBatchSize',256);

agentOpts.EpsilonGreedyExploration.EpsilonDecay = 1e-4;
```

Then create the DQN agent using the specified critic representation and agent options. For more information, see `rlDQNAgent` (Reinforcement Learning Toolbox).

```
agent = rlDQNAgent(critic,agentOpts);
```

Training Options

To train the agent, first specify the training options. For this example, use the following options.

- Run each training for at most `10000` episodes, with each episode lasting at most `ceil(T/Ts)` time steps.
- Display the training progress in the Episode Manager dialog box only (set the `Plots` and `Verbose` options accordingly).
- Stop training when the episode reward reaches `-1`.
- Save a copy of the agent for each episode where the cumulative reward is greater than 100.

For more information, see `rlTrainingOptions` (Reinforcement Learning Toolbox).

```
maxepisodes = 10000;
maxsteps = ceil(T/Ts);
trainOpts = rlTrainingOptions(...
    'MaxEpisodes',maxepisodes, ...
    'MaxStepsPerEpisode',maxsteps, ...
    'Verbose',false,...
    'Plots','training-progress',...
    'StopTrainingCriteria','EpisodeReward',...
    'StopTrainingValue', -1,...
    'SaveAgentCriteria','EpisodeReward',...
    'SaveAgentValue',100);
```

Parallel Training Options

To train the agent in parallel, specify the following training options.

- Set the `UseParallel` option to `true`.
- Train agent in parallel asynchronously by setting the `ParallelizationOptions.Mode` option to `"async"`.
- After every 30 steps, each worker sends experiences to the client.
- DQN agent requires workers to send "`experiences`" to the client.

```
trainOpts.UseParallel = true;
trainOpts.ParallelizationOptions.Mode = "async";
trainOpts.ParallelizationOptions.DataToSendFromWorkers = "experiences";
trainOpts.ParallelizationOptions.StepsUntilDataIsSent = 32;
```

For more information, see `rlTrainingOptions` (Reinforcement Learning Toolbox).

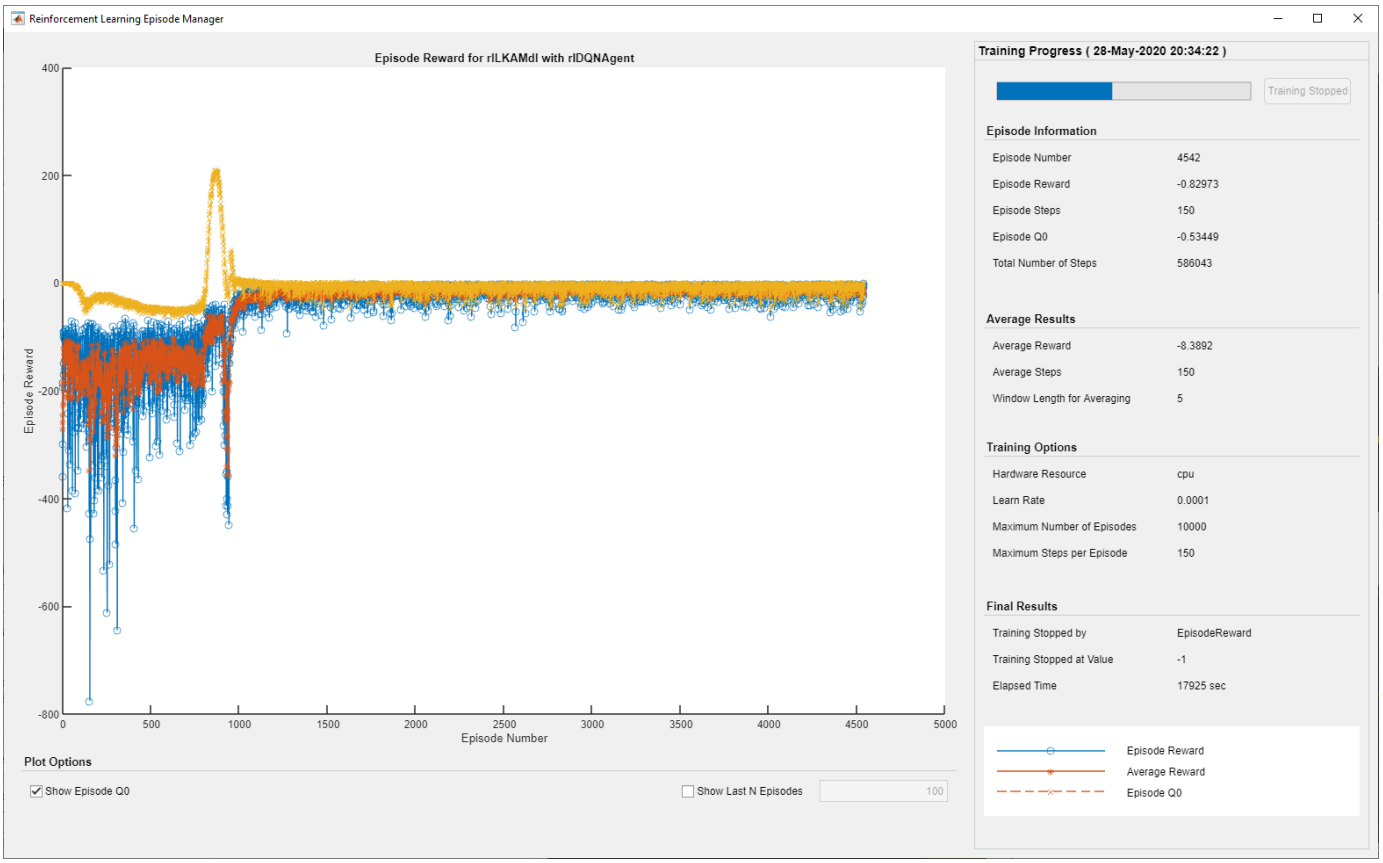
Train Agent

Train the agent using the `train` (Reinforcement Learning Toolbox) function. Training the agent is a computationally intensive process that takes several minutes to complete. To save time while running this example, load a pretrained agent by setting `doTraining` to `false`. To train the agent yourself, set `doTraining` to `true`. Due to randomness of the parallel training, you can expect different training results from the plot below. The plot shows the result of training with four workers.

```
doTraining = false;

if doTraining
    % Train the agent.
    trainingStats = train(agent,env,trainOpts);
```

```
else
    % Load pretrained agent for the example.
    load('SimulinkLKADQNParallel.mat','agent')
end
```



Simulate DQN Agent

To validate the performance of the trained agent, uncomment the following two lines and simulate the agent within the environment. For more information on agent simulation, see `rlSimulationOptions` (Reinforcement Learning Toolbox) and `sim` (Reinforcement Learning Toolbox).

```
% simOptions = rlSimulationOptions('MaxSteps',maxsteps);
% experience = sim(env,agent,simOptions);
```

To demonstrate the trained agent using deterministic initial conditions, simulate the model in Simulink.

```
e1_initial = -0.4;
e2_initial = 0.2;
sim(mdl)
```

As shown below, the lateral error (middle plot) and relative yaw angle (bottom plot) are both driven to zero. The vehicle starts from off centerline (–0.4 m) and nonzero yaw angle error (0.2 rad). The LKA enables the ego car to travel along the centerline after 2.5 seconds. The steering angle (top plot) shows that the controller reaches steady state after 2 seconds.

Train DDPG Agent for Path-Following Control

This example shows how to train a deep deterministic policy gradient (DDPG) agent for path-following control (PFC) in Simulink®. For more information on DDPG agents, see “Deep Deterministic Policy Gradient Agents” (Reinforcement Learning Toolbox).

Simulink Model

The reinforcement learning environment for this example is a simple bicycle model for the ego car and a simple longitudinal model for the lead car. The training goal is to make the ego car travel at a set velocity while maintaining a safe distance from lead car by controlling longitudinal acceleration and braking, and also while keeping the ego car travelling along the centerline of its lane by controlling the front steering angle. For more information on PFC, see Path Following Control System (Model Predictive Control Toolbox). The ego car dynamics are specified by the following parameters.

```
m = 1600;   % total vehicle mass (kg)
Iz = 2875;  % yaw moment of inertia (mNs^2)
lf = 1.4;   % longitudinal distance from center of gravity to front tires (m)
lr = 1.6;   % longitudinal distance from center of gravity to rear tires (m)
Cf = 19000; % cornering stiffness of front tires (N/rad)
Cr = 33000; % cornering stiffness of rear tires (N/rad)
tau = 0.5;  % longitudinal time constant
```

Specify the initial position and velocity for the two vehicles.

```
x0_lead = 50;   % initial position for lead car (m)
v0_lead = 24;   % initial velocity for lead car (m/s)
x0_ego = 10;    % initial position for ego car (m)
v0_ego = 18;    % initial velocity for ego car (m/s)
```

Specify the standstill default spacing (m), time gap (s), and driver-set velocity (m/s).

```
D_default = 10;
t_gap = 1.4;
v_set = 28;
```

To simulate the physical limitations of the vehicle dynamics, constrain the acceleration to the range `[-3,2]` (m/s^2), and steering angle is constrained to be `[-0.5,0.5]` (rad).

```
amin_ego = -3;
amax_ego = 2;
umin_ego = -0.5;
umax_ego = 0.5;
```

The curvature of the road is defined by a constant 0.001 (m^{-1}). The initial value for lateral deviation is 0.2 m and the initial value for the relative yaw angle is –0.1 rad.

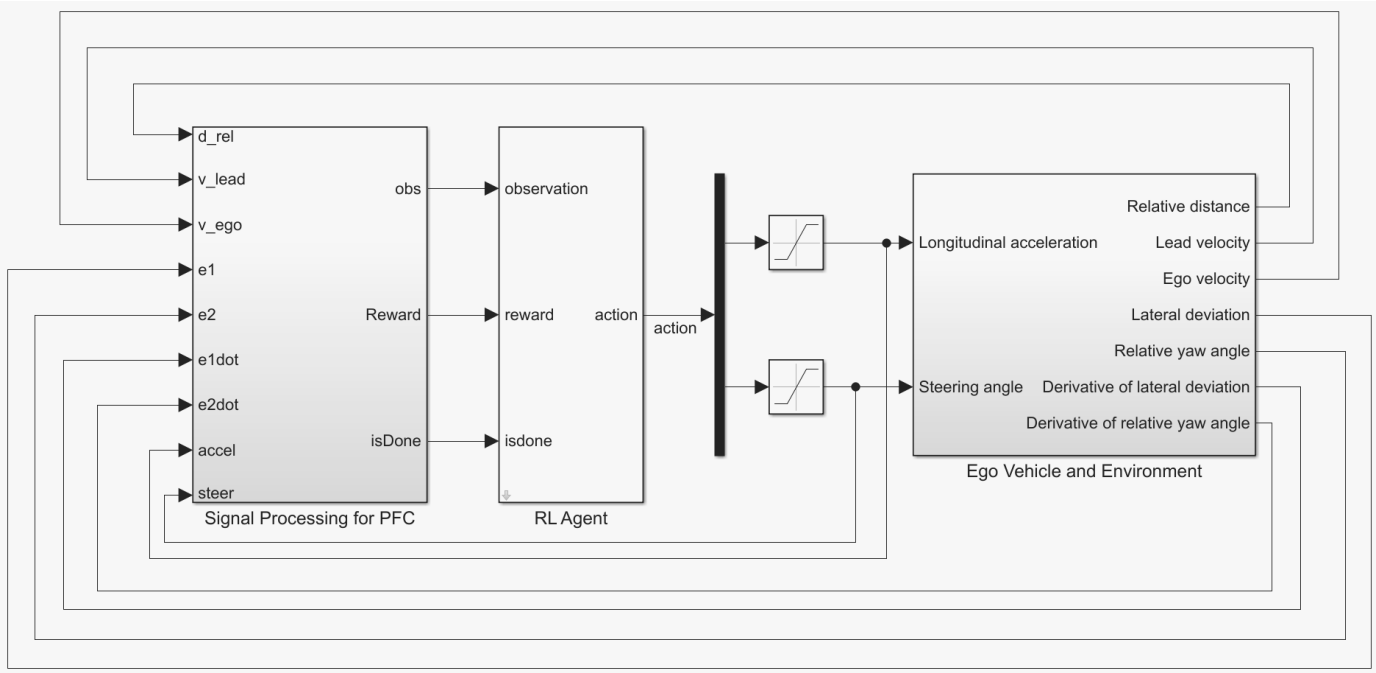
```
rho = 0.001;
e1_initial = 0.2;
e2_initial = -0.1;
```

Define the sample time `Ts` and simulation duration `Tf` in seconds.

```
Ts = 0.1;
Tf = 60;
```

Open the model.

```
mdl = 'rlPFCMdl';
open_system(mdl)
agentblk = [mdl '/RL Agent'];
```



For this model:

- The action signal consists of acceleration and steering angle actions. The acceleration action signal takes value between –3 and 2 (m/s^2). The steering action signal takes a value between –15 degrees (–0.2618 rad) and 15 degrees (0.2618 rad).
- The reference velocity for the ego car V_{ref} is defined as follows. If the relative distance is less than the safe distance, the ego car tracks the minimum of the lead car velocity and driver-set velocity. In this manner, the ego car maintains some distance from the lead car. If the relative distance is greater than the safe distance, the ego car tracks the driver-set velocity. In this example, the safe distance is defined as a linear function of the ego car longitudinal velocity V, that is, $t_{gap} * V + D_{default}$. The safe distance determines the tracking velocity for the ego car.
- The observations from the environment contain the longitudinal measurements: the velocity error $e_V = V_{ref} - V_{ego}$, its integral $\int e$, and the ego car longitudinal velocity V. In addition, the observations contain the lateral measurements: the lateral deviation e_1, relative yaw angle e_2, their derivatives $\dot{e}_1$ and $\dot{e}_2$, and their integrals $\int e_1$ and $\int e_2$.
- The simulation terminates when the lateral deviation $|e_1| > 1$, when the longitudinal velocity $V_{ego} < 0.5$, or when the relative distance between the lead car and ego car $D_{rel} < 0$.
- The reward r_t, provided at every time step t, is

$$r_t = -(100e_1^2 + 500u_{t-1}^2 + 10e_V^2 + 100a_{t-1}^2) \times 1e^{-3} - 10F_t + 2H_t + M_t$$

where u_{t-1} is the steering input from the previous time step $t-1$, a_{t-1} is the acceleration input from the previous time step. The three logical values are as follows.

- F_t = 1if simulation is terminated, otherwise $F_t = 0$
- $H_t = 1$ if lateral error $e_1^2 < 0.01$, otherwise $H_t = 0$
- $M_t = 1$ if velocity error $e_V^2 < 1$, otherwise $M_t = 0$

The three logical terms in the reward encourage the agent to make both lateral error and velocity error small, and in the meantime, penalize the agent if the simulation is terminated early.

Create Environment Interface

Create an environment interface for the Simulink model.

Create the observation specification.

```
observationInfo = rlNumericSpec([9 1],'LowerLimit',-inf*ones(9,1),'UpperLimit',inf*ones(9,1));
observationInfo.Name = 'observations';
```

Create the action specification.

```
actionInfo = rlNumericSpec([2 1],'LowerLimit',[-3;-0.2618],'UpperLimit',[2;0.2618]);
actionInfo.Name = 'accel;steer';
```

Create the environment interface.

```
env = rlSimulinkEnv(mdl,agentblk,observationInfo,actionInfo);
```

To define the initial conditions, specify an environment reset function using an anonymous function handle. The reset function `localResetFcn`, which is defined at the end of the example, randomizes the initial position of the lead car, the lateral deviation, and the relative yaw angle.

```
env.ResetFcn = @(in)localResetFcn(in);
```

Fix the random generator seed for reproducibility.

```
rng(0)
```

Create DDPG Agent

A DDPG agent approximates the long-term reward given observations and actions by using a critic value function representation. To create the critic, first create a deep neural network with two inputs, the state and action, and one output. For more information on creating a deep neural network value function representation, see “Create Policy and Value Function Representations” (Reinforcement Learning Toolbox).

```
L = 100; % number of neurons
statePath = [
    featureInputLayer(9,'Normalization','none','Name','observation')
    fullyConnectedLayer(L,'Name','fc1')
    reluLayer('Name','relu1')
    fullyConnectedLayer(L,'Name','fc2')
    additionLayer(2,'Name','add')
    reluLayer('Name','relu2')
    fullyConnectedLayer(L,'Name','fc3')
    reluLayer('Name','relu3')
    fullyConnectedLayer(1,'Name','fc4')];

actionPath = [
```

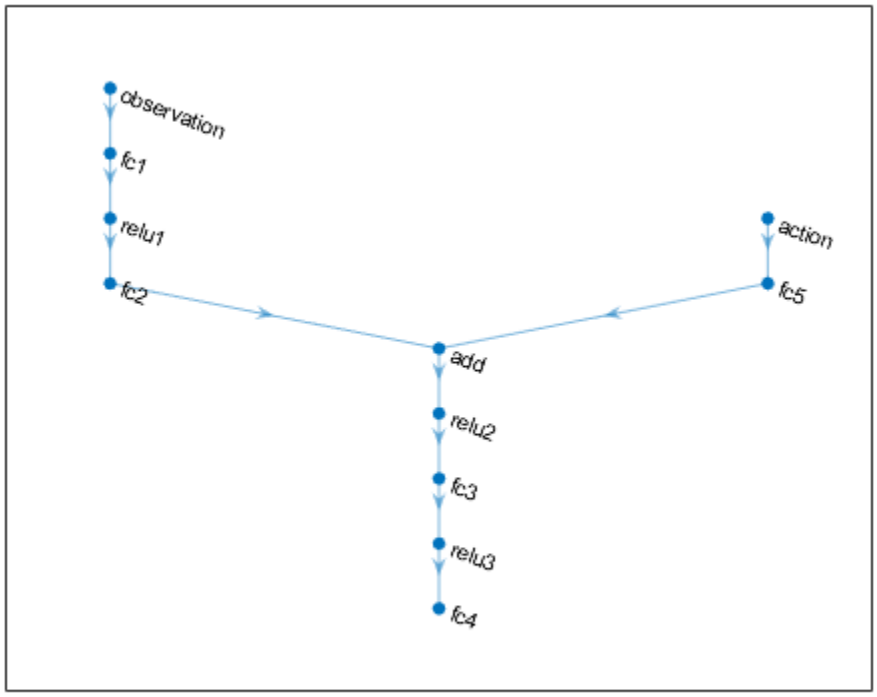
```
    featureInputLayer(2,'Normalization','none','Name','action')
    fullyConnectedLayer(L,'Name','fc5')];

criticNetwork = layerGraph(statePath);
criticNetwork = addLayers(criticNetwork,actionPath);

criticNetwork = connectLayers(criticNetwork,'fc5','add/in2');
```

View the critic network configuration.

```
figure
plot(criticNetwork)
```



Specify options for the critic representation using `rlRepresentationOptions` (Reinforcement Learning Toolbox).

```
criticOptions = rlRepresentationOptions('LearnRate',1e-3,'GradientThreshold',1,'L2RegularizationF
```

Create the critic representation using the specified deep neural network and options. You must also specify the action and observation info for the critic, which you obtain from the environment interface. For more information, see `rlQValueRepresentation` (Reinforcement Learning Toolbox).

```
critic = rlQValueRepresentation(criticNetwork,observationInfo,actionInfo,...
    'Observation',{'observation'},'Action',{'action'},criticOptions);
```

A DDPG agent decides which action to take given observations by using an actor representation. To create the actor, first create a deep neural network with one input, the observation, and one output, the action.

Construct the actor similarly to the critic. For more information, see `rlDeterministicActorRepresentation` (Reinforcement Learning Toolbox).

```
actorNetwork = [
    featureInputLayer(9,'Normalization','none','Name','observation')
    fullyConnectedLayer(L,'Name','fc1')
    reluLayer('Name','relu1')
    fullyConnectedLayer(L,'Name','fc2')
    reluLayer('Name','relu2')
    fullyConnectedLayer(L,'Name','fc3')
    reluLayer('Name','relu3')
    fullyConnectedLayer(2,'Name','fc4')
    tanhLayer('Name','tanh1')
    scalingLayer('Name','ActorScaling1','Scale',[2.5;0.2618],'Bias',[-0.5;0])];
actorOptions = rlRepresentationOptions('LearnRate',1e-4,'GradientThreshold',1,'L2RegularizationFa
actor = rlDeterministicActorRepresentation(actorNetwork,observationInfo,actionInfo,...
    'Observation',{'observation'},'Action',{'ActorScaling1'},actorOptions);
```

To create the DDPG agent, first specify the DDPG agent options using `rlDDPGAgentOptions` (Reinforcement Learning Toolbox).

```
agentOptions = rlDDPGAgentOptions(...
    'SampleTime',Ts,...
    'TargetSmoothFactor',1e-3,...
    'ExperienceBufferLength',1e6,...
    'DiscountFactor',0.99,...
    'MiniBatchSize',64);
agentOptions.NoiseOptions.Variance = [0.6;0.1];
agentOptions.NoiseOptions.VarianceDecayRate = 1e-5;
```

Then, create the DDPG agent using the specified actor representation, critic representation, and agent options. For more information, see `rlDDPGAgent` (Reinforcement Learning Toolbox).

```
agent = rlDDPGAgent(actor,critic,agentOptions);
```

Train Agent

To train the agent, first specify the training options. For this example, use the following options:

- Run each training episode for at most `10000` episodes, with each episode lasting at most `maxsteps` time steps.
- Display the training progress in the Episode Manager dialog box (set the `Verbose` and `Plots` options).
- Stop training when the agent receives an cumulative episode reward greater than `1700`.

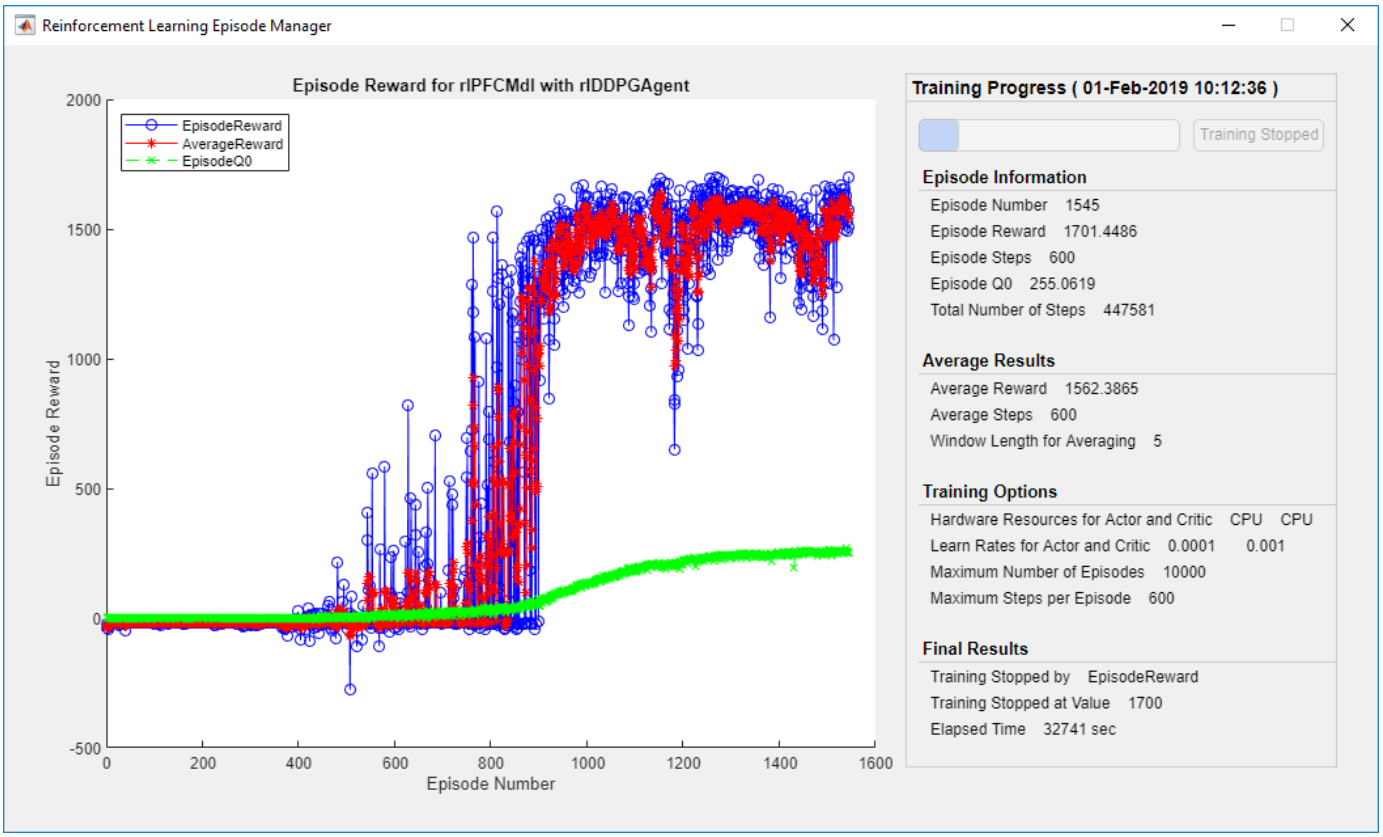
For more information, see `rlTrainingOptions` (Reinforcement Learning Toolbox).

```
maxepisodes = 1e4;
maxsteps = ceil(Tf/Ts);
trainingOpts = rlTrainingOptions(...
    'MaxEpisodes',maxepisodes,...
    'MaxStepsPerEpisode',maxsteps,...
    'Verbose',false,...
    'Plots','training-progress',...
    'StopTrainingCriteria','EpisodeReward',...
    'StopTrainingValue',1700);
```

Train the agent using the `train` (Reinforcement Learning Toolbox) function. Training is a computationally intensive process that takes several minutes to complete. To save time while running this example, load a pretrained agent by setting `doTraining` to `false`. To train the agent yourself, set `doTraining` to `true`.

```
doTraining = false;

if doTraining
    % Train the agent.
    trainingStats = train(agent,env,trainingOpts);
else
    % Load a pretrained agent for the example.
    load('SimulinkPFCDDPG.mat','agent')
end
```



Simulate DDPG Agent

To validate the performance of the trained agent, simulate the agent within the Simulink environment by uncommenting the following commands. For more information on agent simulation, see `rlSimulationOptions` (Reinforcement Learning Toolbox) and `sim` (Reinforcement Learning Toolbox).

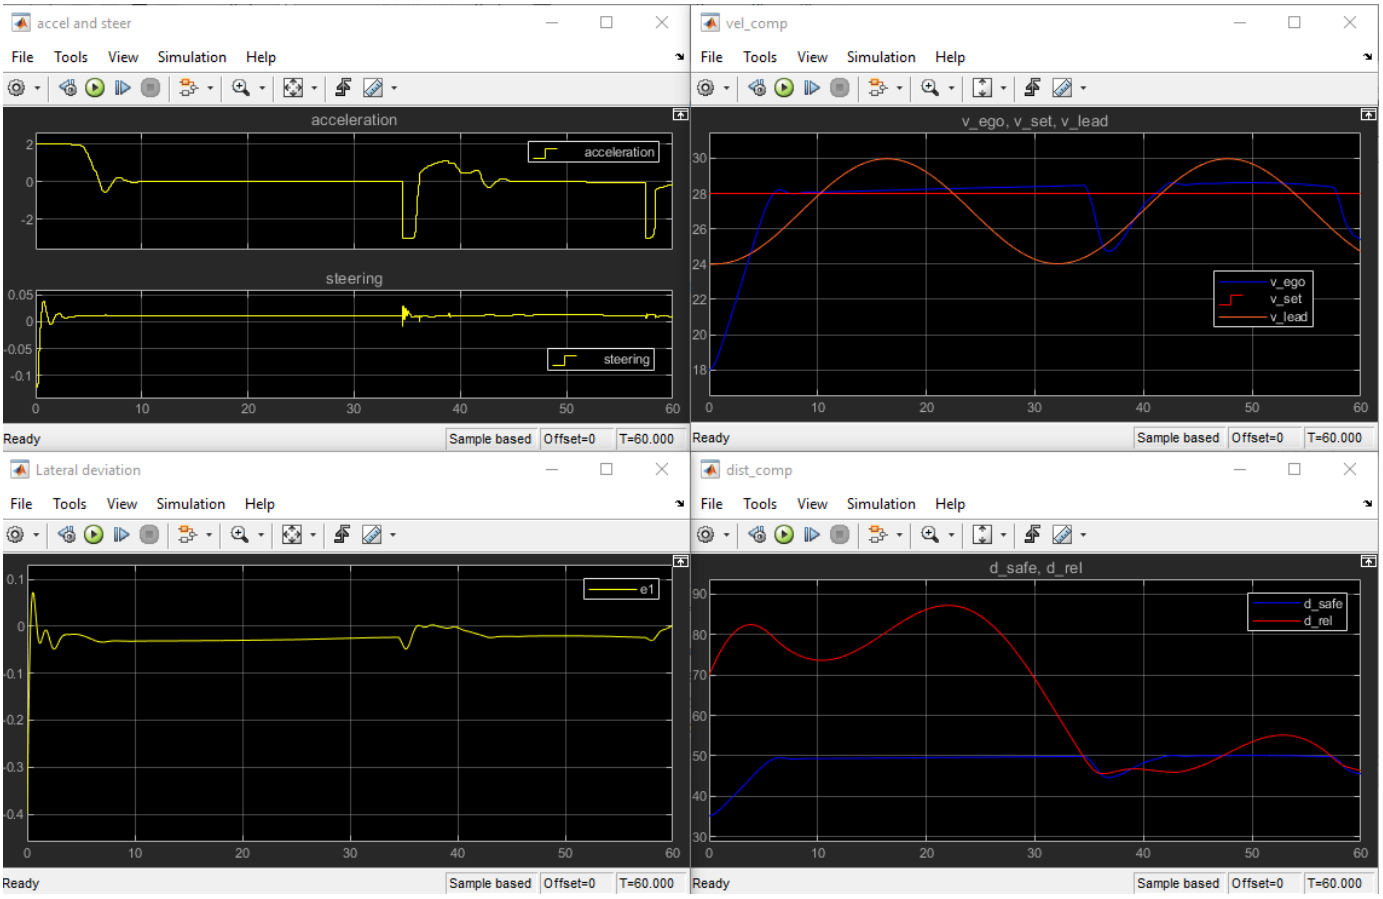
```
% simOptions = rlSimulationOptions('MaxSteps',maxsteps);
% experience = sim(env,agent,simOptions);
```

To demonstrate the trained agent using deterministic initial conditions, simulate the model in Simulink.

```
e1_initial = -0.4;
e2_initial = 0.1;
x0_lead = 80;
sim(mdl)
```

The following plots show the simulation results when the lead car is 70 (m) ahead of the ego car.

- In the first 35 seconds, the relative distance is greater than the safe distance (bottom-right plot), so the ego car tracks the set velocity (top-right plot). To speed up and reach the set velocity, the acceleration is mostly nonnegative (top-left plot).
- From 35 to 42 seconds, the relative distance is mostly less than the safe distance (bottom-right plot), so the ego car tracks the minimum of the lead velocity and set velocity. Because the lead velocity is less than the set velocity (top-right plot), to track the lead velocity, the acceleration becomes nonzero (top-left plot).
- From 42 to 58 seconds, the ego car tracks the set velocity (top-right plot) and the acceleration remains zero (top-left plot).
- From 58 to 60 seconds, the relative distance becomes less than the safe distance (bottom-right plot), so the ego car slows down and tracks the lead velocity.
- The bottom-left plot shows the lateral deviation. As shown in the plot, the lateral deviation is greatly decreased within 1 second. The lateral deviation remains less than 0.05 m.



Close the Simulink model.

```
bdclose(mdl)
```

Reset Function

```
function in = localResetFcn(in)
in = setVariable(in,'x0_lead',40+randi(60,1,1));    % random value for initial position of lead c
in = setVariable(in,'e1_initial', 0.5*(-1+2*rand)); % random value for lateral deviation
in = setVariable(in,'e2_initial', 0.1*(-1+2*rand)); % random value for relative yaw angle
end
```

Train PPO Agent for Automatic Parking Valet

This example demonstrates the design of a hybrid controller for an automatic search and parking task. The hybrid controller uses model predictive control (MPC) to follow a reference path in a parking lot and a trained reinforcement learning (RL) agent to perform the parking maneuver.

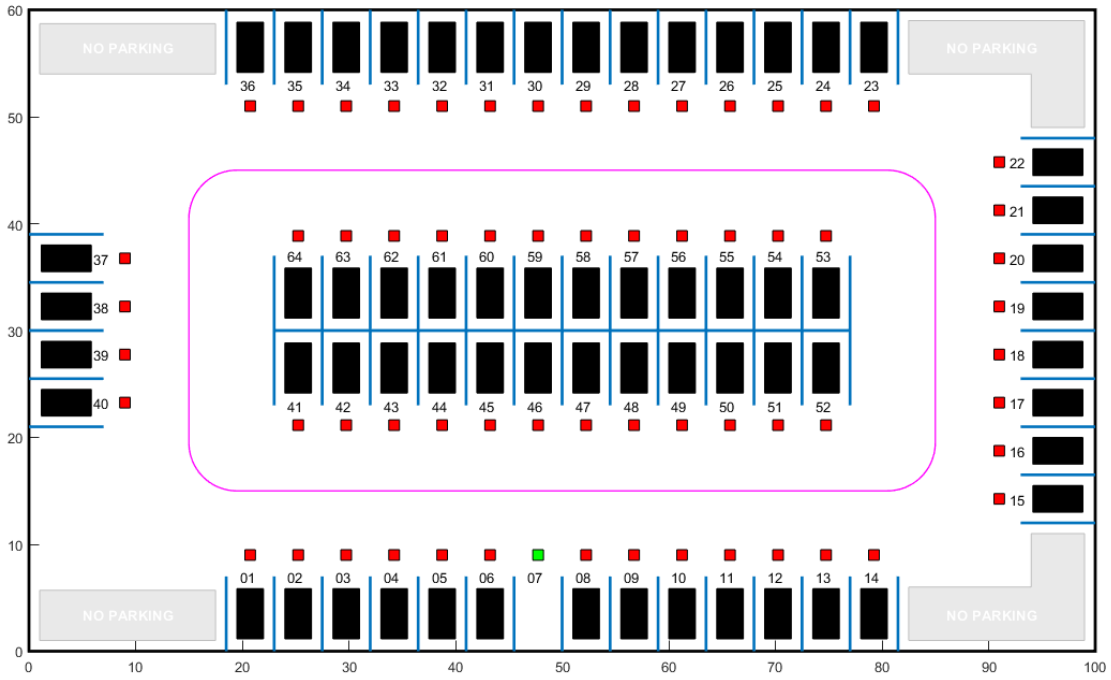
The automatic parking algorithm in this example executes a series of maneuvers while simultaneously sensing and avoiding obstacles in tight spaces. It switches between an adaptive MPC controller and an RL agent to complete the parking maneuver. The MPC controller moves the vehicle at a constant speed along a reference path while an algorithm searches for an empty parking spot. When a spot is found, the RL Agent takes over and executes a pretrained parking maneuver. Prior knowledge of the environment (the parking lot) including the locations of the empty spots and parked vehicles is available to the controllers.

Parking Lot

The parking lot is represented by the `ParkingLot` class, which stores information about the ego vehicle, empty parking spots, and static obstacles (parked cars). Each parking spot has a unique index number and an indicator light that is either green (free) or red (occupied). Parked vehicles are represented in black.

Create a `ParkingLot` object with a free spot at location 7.

```
freeSpotIdx = 7;
map = ParkingLot(freeSpotIdx);
```



Specify an initial pose (X_0, Y_0, θ_0) for the ego vehicle. The target pose is determined based on the first available free spot as the vehicle navigates the parking lot.

```
egoInitialPose = [20, 15, 0];
```

Compute the target pose for the vehicle using the `createTargetPose` function. The target pose corresponds to the location in `freeSpotIdx`.

```
egoTargetPose = createTargetPose(map,freeSpotIdx)
```

```
egoTargetPose = 1×3

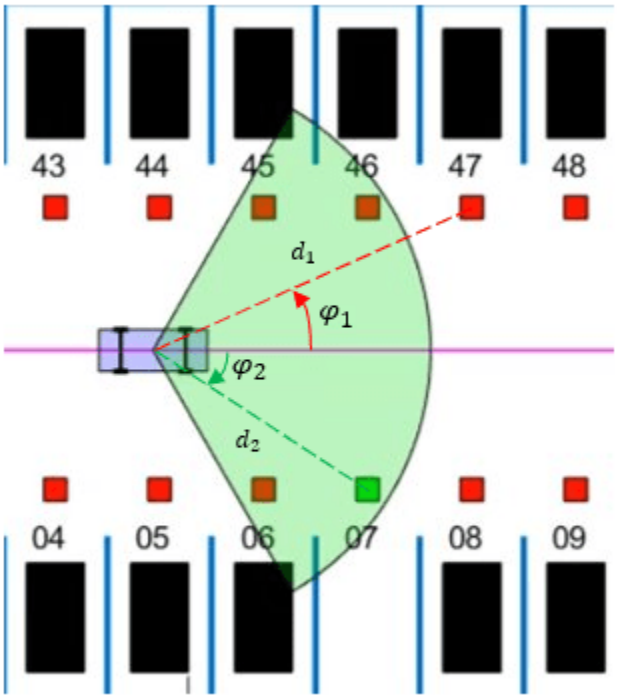
   47.7500    4.9000   -1.5708
```

Sensor Modules

The parking algorithm uses camera and lidar sensors to gather information from the environment.

Camera

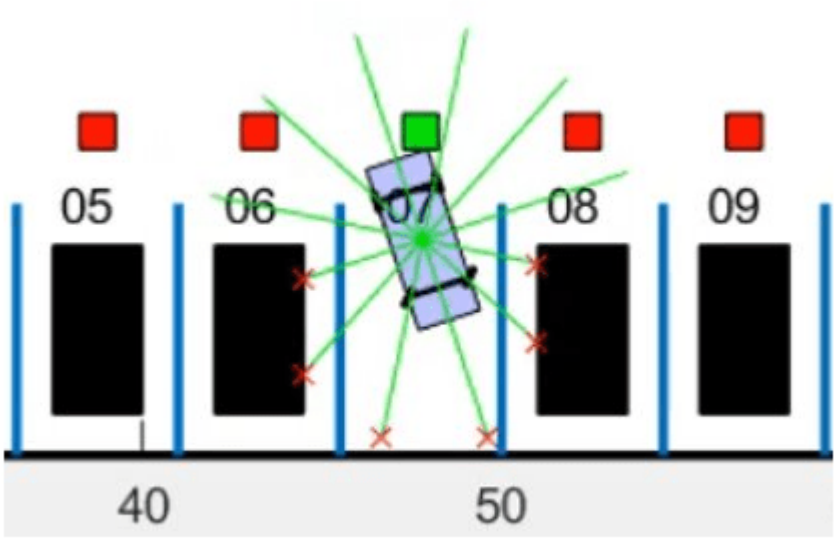
The field of view of a camera mounted on the ego vehicle is represented by the area shaded in green in the following figure. The camera has a field of view φ bounded by ±60 degrees and a maximum measurement depth $d_{\max}$ of 10 m.



As the ego vehicle moves forward, the camera module senses the parking spots that fall within the field of view and determines whether a spot is free or occupied. For simplicity, this action is implemented using geometrical relationships between the spot locations and the current vehicle pose. A parking spot is within the camera range if $d_i \le d_{\max}$ and $\varphi_{\min} \le \varphi_i \le \varphi_{\max}$, where d_i is the distance to the parking spot and φ_i is the angle to the parking spot.

Lidar

The reinforcement learning agent uses lidar sensor readings to determine the proximity of the ego vehicle to other vehicles in the environment. The lidar sensor in this example is also modeled using geometrical relationships. Lidar distances are measured along 12 line segments that radially emerge from the center of the ego vehicle. When a lidar line intersects an obstacle, it returns the distance of the obstacle from the vehicle. The maximum measurable lidar distance along any line segment is 6 m.



Auto Parking Valet Model

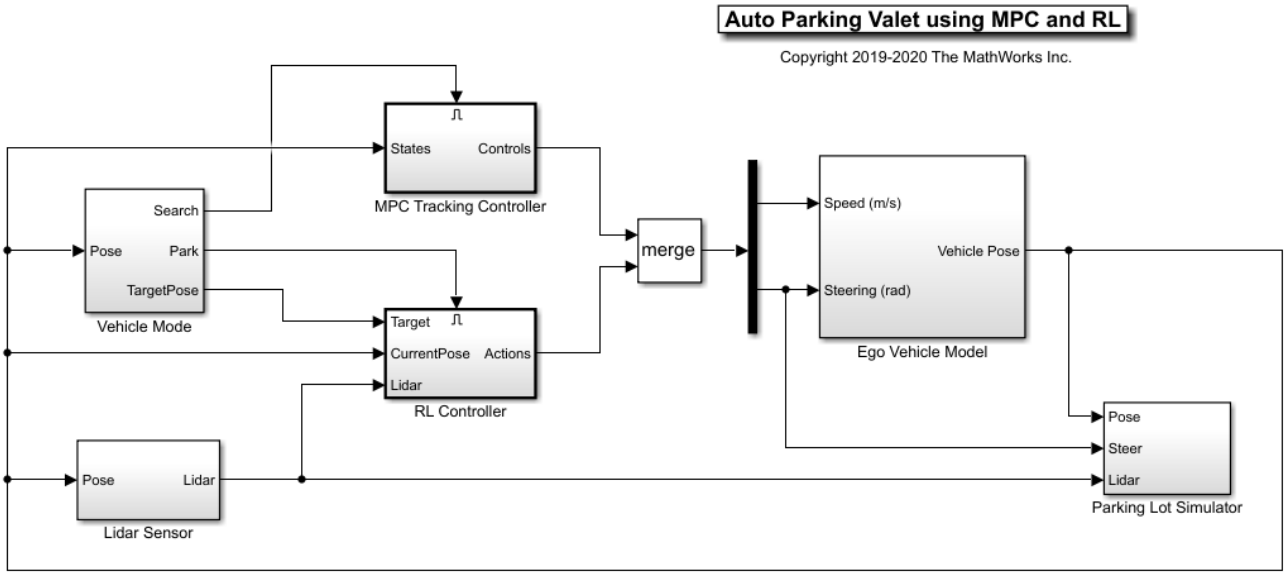
The parking valet model, including the controllers, ego vehicle, sensors, and parking lot, is implemented in Simulink®.

Load the auto parking valet parameters.

```
autoParkingValetParams
```

Open the Simulink model.

```
mdl = 'rlAutoParkingValet';
open_system(mdl)
```



The ego vehicle dynamics in this model are represented by a single-track bicycle model with two inputs: vehicle speed v (m/s) and steering angle δ (radians). The MPC and RL controllers are placed within Enabled Subsystem blocks that are activated by signals representing whether the vehicle has to search for an empty spot or execute a parking maneuver. The enable signals are determined by the Camera algorithm within the Vehicle Mode subsystem. Initially, the vehicle is in *search* mode and the MPC controller tracks the reference path. When a free spot is found, *park* mode is activated and the RL agent executes the parking maneuver.

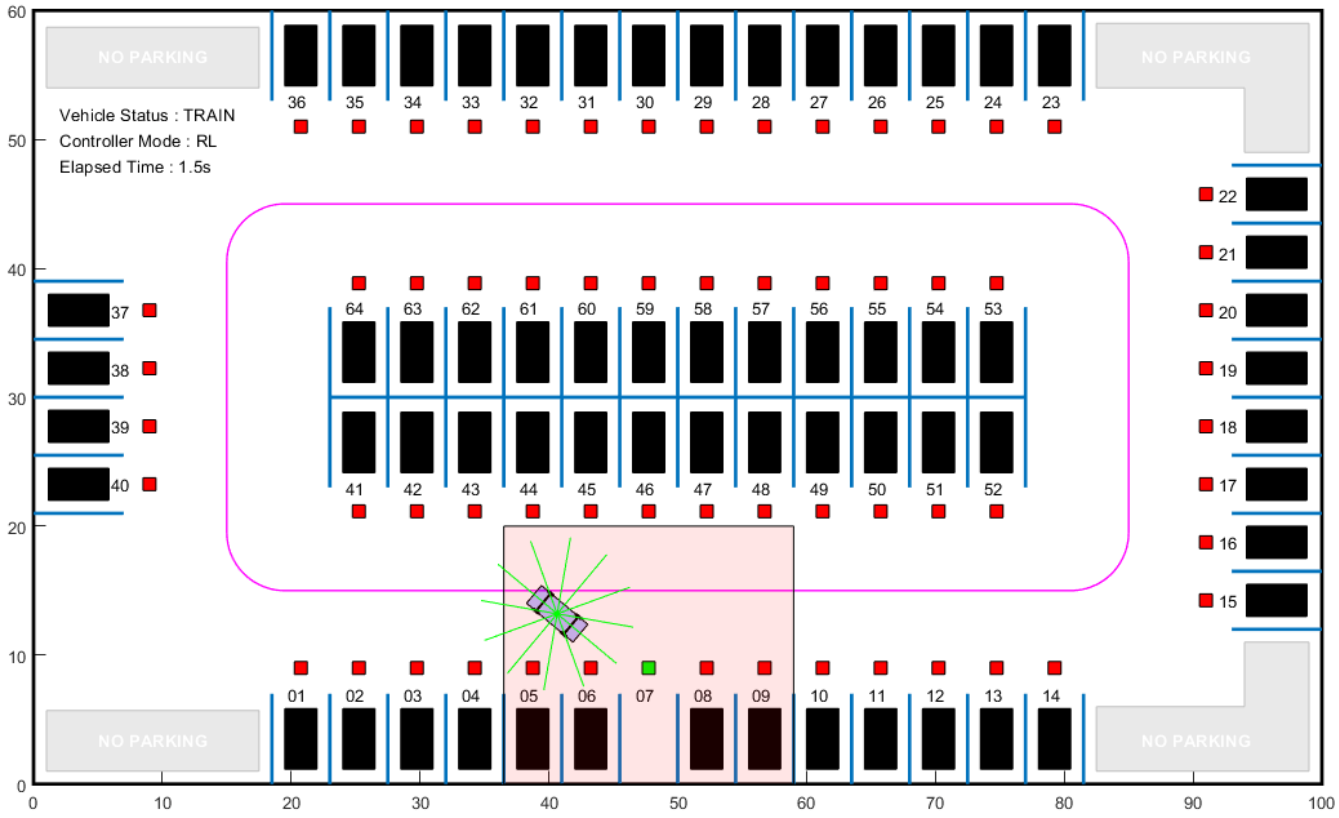
Adaptive Model Predictive Controller

Create the adaptive MPC controller object for reference trajectory tracking using the `createMPCForParking` script. For more information on adaptive MPC, see “Adaptive MPC” (Model Predictive Control Toolbox).

```
createMPCForParking
```

Reinforcement Learning Environment

The environment for training the RL agent is the region shaded in red in the following figure. Due to symmetry in the parking lot, training within this region is sufficient for the policy to adjust to other regions after applying appropriate coordinate transformations to the observations. Using this smaller training region significantly reduces training time compared to training over the entire parking lot.



For this environment:

- The training region is a 22.5 m x 20 m space with the target spot at its horizontal center.
- The observations are the position errors X_e and Y_e of the ego vehicle with respect to the target pose, the sine and cosine of the true heading angle θ, and the lidar sensor readings.
- The vehicle speed during parking is a constant 2 m/s.
- The action signals are discrete steering angles that range between +/- 45 degrees in steps of 15 degrees.
- The vehicle is considered parked if the errors with respect to target pose are within specified tolerances of +/- 0.75 m (position) and +/-10 degrees (orientation).
- The episode terminates if the ego vehicle goes out of the bounds of the training region, collides with an obstacle, or parks successfully.
- The reward r_t provided at time t, is:

$$r_t = 2e^{-\left(0.05{X_e}^2 + 0.04{Y_e}^2\right)} + 0.5e^{-40{\theta_e}^2} - 0.05\delta^2 + 100f_t - 50g_t$$

Here, X_e, Y_e, and θ_e are the position and heading angle errors of the ego vehicle from the target pose, and δ is the steering angle. f_t (0 or 1) indicates whether the vehicle has parked and g_t (0 or 1) indicates if the vehicle has collided with an obstacle at time t.

The coordinate transformations on vehicle pose (X, Y, θ) observations for different parking spot locations are as follows:

- 1-14: no transformation
- 15-22: $\bar{X} = Y, \bar{Y} = -X, \bar{\theta} = \theta - \pi/2$
- 23-36: $\bar{X} = 100 - X, \bar{Y} = 60 - Y, \bar{\theta} = \theta - \pi$
- 37-40: $\bar{X} = 60 - Y, \bar{Y} = X, \bar{\theta} = \theta - 3\pi/2$
- 41-52: $\bar{X} = 100 - X, \bar{Y} = 30 - Y, \bar{\theta} = \theta + \pi$
- 53-64: $\bar{X} = X, \bar{Y} = Y - 28, \bar{\theta} = \theta$

Create the observation and action specifications for the environment.

```
numObservations = 16;
observationInfo = rlNumericSpec([numObservations 1]);
observationInfo.Name = 'observations';

steerMax = pi/4;
discreteSteerAngles = -steerMax : deg2rad(15) : steerMax;
actionInfo = rlFiniteSetSpec(num2cell(discreteSteerAngles));
actionInfo.Name = 'actions';
numActions = numel(actionInfo.Elements);
```

Create the Simulink environment interface, specifying the path to the RL Agent block.

```
blk = [mdl '/RL Controller/RL Agent'];
env = rlSimulinkEnv(mdl,blk,observationInfo,actionInfo);
```

Specify a reset function for training. The `autoParkingValetResetFcn` function resets the initial pose of the ego vehicle to random values at the start of each episode.

```
env.ResetFcn = @autoParkingValetResetFcn;
```

For more information on creating Simulink environments, see `rlSimulinkEnv` (Reinforcement Learning Toolbox).

Create Agent

The RL agent in this example is a proximal policy optimization (PPO) agent with a discrete action space. PPO agents rely on actor and critic representations to learn the optimal policy. The agent maintains deep neural network-based function approximators for the actor and critic. To learn more about PPO agents, see “Proximal Policy Optimization Agents” (Reinforcement Learning Toolbox).

Set the random seed generator for reproducibility.

```
rng(0)
```

To create the critic representations, first create a deep neural network with 16 inputs and one output. The output of the critic network is the state value function for a particular observation.

```
criticNetwork = [
    featureInputLayer(numObservations,'Normalization','none','Name','observations')
    fullyConnectedLayer(128,'Name','fc1')
    reluLayer('Name','relu1')
    fullyConnectedLayer(128,'Name','fc2')
    reluLayer('Name','relu2')
    fullyConnectedLayer(128,'Name','fc3')
    reluLayer('Name','relu3')
    fullyConnectedLayer(1,'Name','fc4')];
```

Create the critic for the PPO agent. For more information, see `rlValueRepresentation` (Reinforcement Learning Toolbox) and `rlRepresentationOptions` (Reinforcement Learning Toolbox).

```
criticOptions = rlRepresentationOptions('LearnRate',1e-3,'GradientThreshold',1);
critic = rlValueRepresentation(criticNetwork,observationInfo,...
    'Observation',{'observations'},criticOptions);
```

The outputs of the actor networks are the probabilities of taking each possible steering action when the vehicle is in a certain state. Create the actor deep neural network.

```
actorNetwork = [
    featureInputLayer(numObservations,'Normalization','none','Name','observations')
    fullyConnectedLayer(128,'Name','fc1')
    reluLayer('Name','relu1')
    fullyConnectedLayer(128,'Name','fc2')
    reluLayer('Name','relu2')
    fullyConnectedLayer(numActions, 'Name', 'out')
    softmaxLayer('Name','actionProb')];
```

Create a stochastic actor representation for the PPO agent. For more information, see `rlStochasticActorRepresentation` (Reinforcement Learning Toolbox).

```
actorOptions = rlRepresentationOptions('LearnRate',2e-4,'GradientThreshold',1);
actor = rlStochasticActorRepresentation(actorNetwork,observationInfo,actionInfo,...
    'Observation',{'observations'},actorOptions);
```

Specify the agent options and create the PPO agent. For more information on PPO agent options, see `rlPPOAgentOptions` (Reinforcement Learning Toolbox).

```
agentOpts = rlPPOAgentOptions(...
    'SampleTime',Ts,...
    'ExperienceHorizon',200,...
    'ClipFactor',0.2,...
    'EntropyLossWeight',0.01,...
    'MiniBatchSize',64,...
    'NumEpoch',3,...
    'AdvantageEstimateMethod',"gae",...
    'GAEFactor',0.95,...
    'DiscountFactor',0.998);
agent = rlPPOAgent(actor,critic,agentOpts);
```

During training, the agent collects experiences until it reaches experience horizon of 200 steps or the episode terminates and then trains from mini-batches of 64 experiences for three epochs. An objective function clip factor of 0.2 improves training stability and a discount factor value of 0.998 encourages long term rewards. Variance in critic the output is reduced by the generalized advantage estimate method with a GAE factor of 0.95.

Train Agent

For this example, you train the agent for a maximum of 10000 episodes, with each episode lasting a maximum of 200 time steps. The training terminates when the maximum number of episodes is reached or the average reward over 100 episodes exceeds 100.

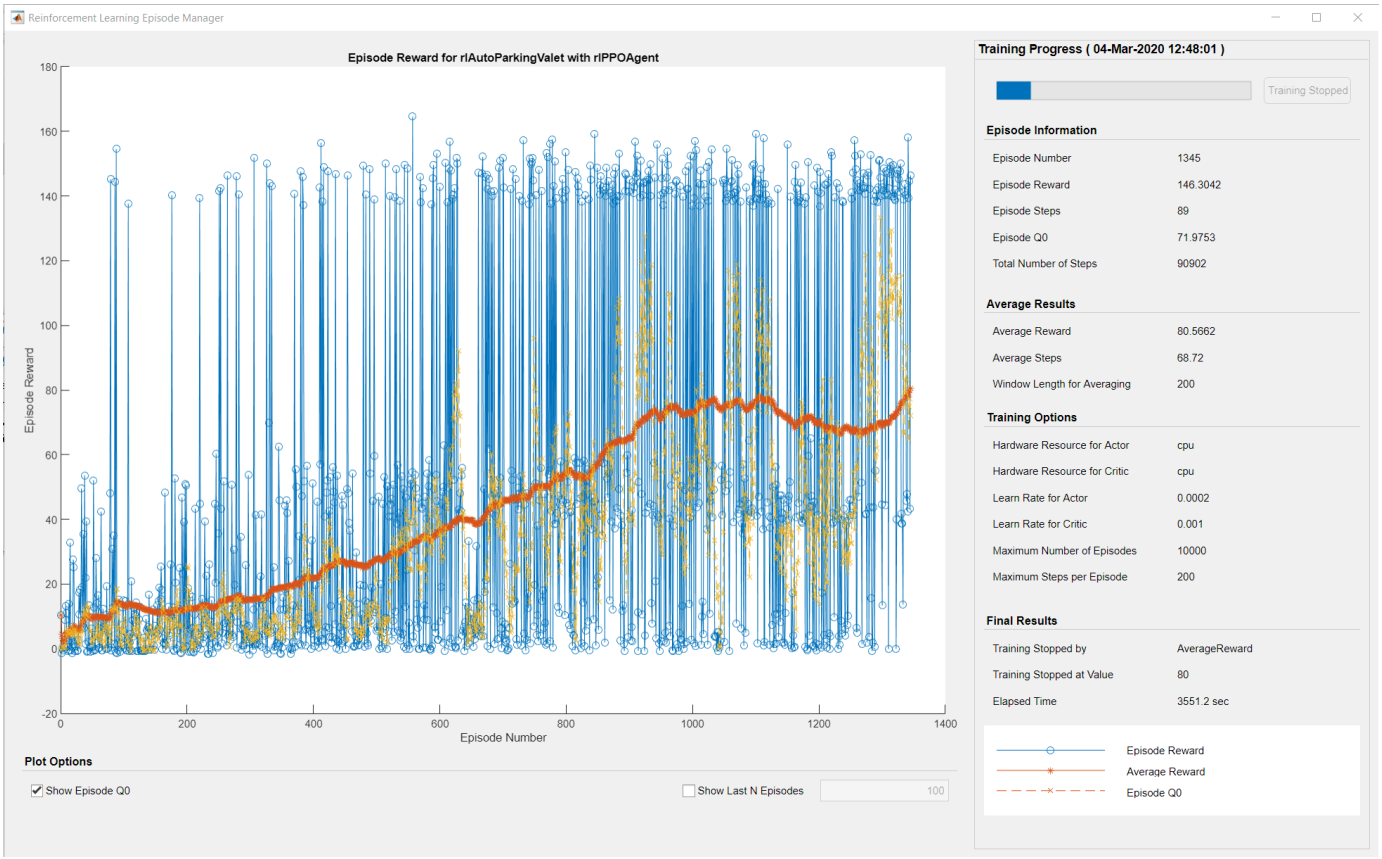
Specify the options for training using an `rlTrainingOptions` object.

```
trainOpts = rlTrainingOptions(...
    'MaxEpisodes',10000,...
```

```
    'MaxStepsPerEpisode',200,...
    'ScoreAveragingWindowLength',200,...
    'Plots','training-progress',...
    'StopTrainingCriteria','AverageReward',...
    'StopTrainingValue',80);
```

Train the agent using the `train` (Reinforcement Learning Toolbox) function. Training this agent is a computationally intensive process that takes several minutes to complete. To save time while running this example, load a pretrained agent by setting `doTraining` to `false`. To train the agent yourself, set `doTraining` to `true`.

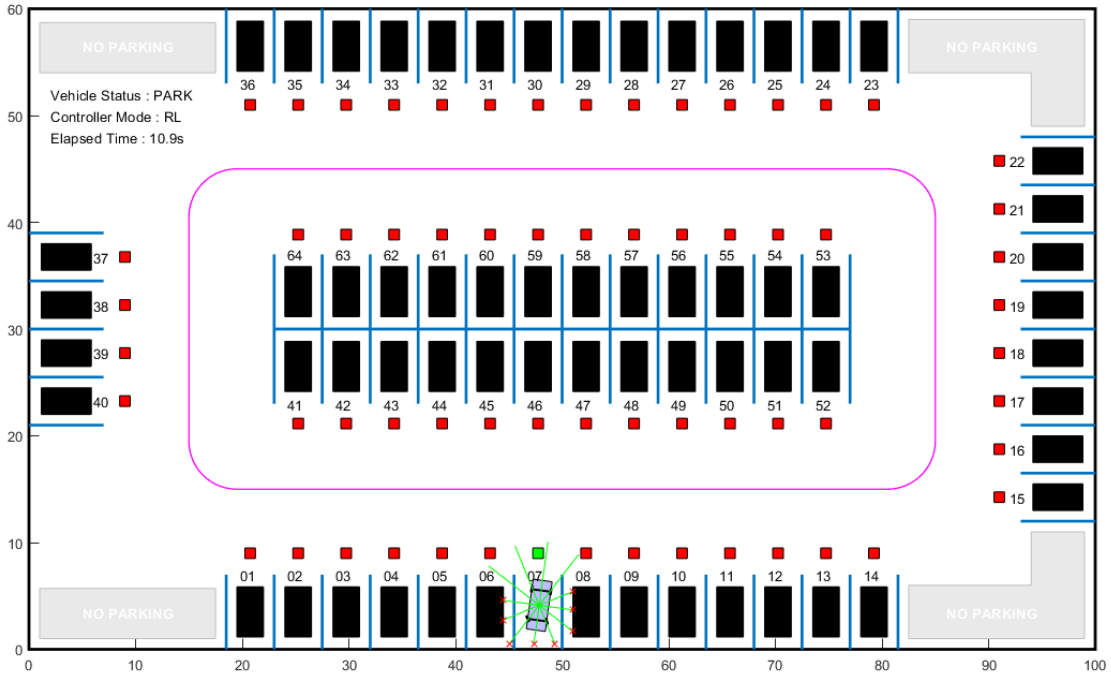
```
doTraining = false;
if doTraining
    trainingStats = train(agent,env,trainOpts);
else
    load('rlAutoParkingValetAgent.mat','agent');
end
```



Simulate Agent

Simulate the model to park the vehicle in the free parking spot. To simulate the vehicle parking in different locations, change the free spot location in the following code.

```
freeSpotIdx = 7;  % free spot location
sim(mdl);
```



The vehicle reaches the target pose within the specified error tolerances of +/- 0.75 m (position) and +/-10 degrees (orientation).

To view the ego vehicle position and orientation, open the Ego Vehicle Pose scope.

Predictive Maintenance Examples

Chemical Process Fault Detection Using Deep Learning

This example shows how to use simulation data to train a neural network that can detect faults in a chemical process. The network detects the faults in the simulated process with high accuracy. The typical workflow is as follows:

1. Preprocess the data
2. Design the layer architecture
3. Train the network
4. Perform validation
5. Test the network

Download Data Set

This example uses MATLAB-formatted files converted by MathWorks® from the Tennessee Eastman Process (TEP) simulation data [1] on page 16-0 . These files are available at the MathWorks support files site. See the disclaimer.

The data set consists of four components — fault-free training, fault-free testing, faulty training, and faulty testing. Download each file separately.

```
url = 'https://www.mathworks.com/supportfiles/predmaint/chemical-process-fault-detection-data/fau
websave('faultytesting.mat',url);
url = 'https://www.mathworks.com/supportfiles/predmaint/chemical-process-fault-detection-data/fau
websave('faultytraining.mat',url);
url = 'https://www.mathworks.com/supportfiles/predmaint/chemical-process-fault-detection-data/fau
websave('faultfreetesting.mat',url);
url = 'https://www.mathworks.com/supportfiles/predmaint/chemical-process-fault-detection-data/fau
websave('faultfreetraining.mat',url);
```

Load the downloaded files into the MATLAB® workspace.

```
load('faultfreetesting.mat');
load('faultfreetraining.mat');
load('faultytesting.mat');
load('faultytraining.mat');
```

Each component contains data from simulations that were run for every permutation of two parameters:

- Fault Number — For faulty data sets, an integer value from 1 to 20 that represents a different simulated fault. For fault-free data sets, a value of 0.
- Simulation run — For all data sets, integer values from 1 to 500, where each value represents a unique random generator state for the simulation.

The length of each simulation was dependent on the data set. All simulations were sampled every three minutes.

- Training data sets contain 500 time samples from 25 hours of simulation.
- Testing data sets contain 960 time samples from 48 hours of simulation.

Each data frame has the following variables in its columns:

- Column 1 (`faultNumber`) indicates the fault type, which varies from 0 through 20. A fault number 0 means fault-free while fault numbers 1 to 20 represent different fault types in the TEP.
- Column 2 (`simulationRun`) indicates the number of times the TEP simulation ran to obtain complete data. In the training and test data sets, the number of runs varies from 1 to 500 for all fault numbers. Every `simulationRun` value represents a different random generator state for the simulation.
- Column 3 (`sample`) indicates the number of times TEP variables were recorded per simulation. The number varies from 1 to 500 for the training data sets and from 1 to 960 for the testing data sets. The TEP variables (columns 4 to 55) were sampled every 3 minutes for a duration of 25 hours and 48 hours for the training and testing data sets respectively.
- Columns 4–44 (`xmeas_1` through `xmeas_41`) contain the measured variables of the TEP.
- Columns 45–55 (`xmv_1` through `xmv_11`) contain the manipulated variables of the TEP.

Examine subsections of two of the files.

```

Clean Data

Remove data entries with the fault numbers 3, 9, and 15 in both the training and testing data sets. These fault numbers are not recognizable, and the associated simulation results are erroneous.

```
faultytesting(faultytesting.faultNumber == 3,:) = [];
faultytesting(faultytesting.faultNumber == 9,:) = [];
faultytesting(faultytesting.faultNumber == 15,:) = [];

faultytraining(faultytraining.faultNumber == 3,:) = [];
faultytraining(faultytraining.faultNumber == 9,:) = [];
faultytraining(faultytraining.faultNumber == 15,:) = [];
```

Divide Data

Divide the training data into training and validation data by reserving 20 percent of the training data for validation. Using a validation data set enables you to evaluate the model fit on the training data

set while you tune the model hyperparameters. Data splitting is commonly used to prevent the network from overfitting and underfitting.

Get the total number of rows in both faulty and fault-free training data sets.

```
H1 = height(faultfreetraining);
H2 = height(faultytraining);
```

The simulation run is the number of times the TEP process was repeated with a particular fault type. Get the maximum simulation run from the training data set as well as from the testing data set.

```
msTrain = max(faultfreetraining.simulationRun);
msTest = max(faultytesting.simulationRun);
```

Calculate the maximum simulation run for the validation data.

```
rTrain = 0.80;
msVal = ceil(msTrain*(1 - rTrain));
msTrain = msTrain*rTrain;
```

Get the maximum number of samples or time steps (that is, the maximum number of times that data was recorded during a TEP simulation).

```
sampleTrain = max(faultfreetraining.sample);
sampleTest = max(faultfreetesting.sample);
```

Get the division point (row number) in the fault-free and faulty training data sets to create validation data sets from the training data sets.

```
rowLim1 = ceil(rTrain*H1);
rowLim2 = ceil(rTrain*H2);

trainingData = [faultfreetraining{1:rowLim1,:}; faultytraining{1:rowLim2,:}];
validationData = [faultfreetraining{rowLim1 + 1:end,:}; faultytraining{rowLim2 + 1:end,:}];
testingData = [faultfreetesting{:,:}; faultytesting{:,:}];
```

Network Design and Preprocessing

The final data set (consisting of training, validation, and testing data) contains 52 signals with 500 uniform time steps. Hence, the signal, or sequence, needs to be classified to its correct fault number which makes it a problem of sequence classification.

- Long short-term memory (LSTM) networks are suited to the classification of sequence data.
- LSTM networks are good for time-series data as they tend to remember the uniqueness of past signals in order to classify new signals
- An LSTM network enables you to input sequence data into a network and make predictions based on the individual time steps of the sequence data. For more information on LSTM networks, see “Long Short-Term Memory Networks” on page 1-75.
- To train the network to classify sequences using the `trainNetwork` function, you must first preprocess the data. The data must be in cell arrays, where each element of the cell array is a matrix representing a set of 52 signals in a single simulation. Each matrix in the cell array is the set of signals for a particular simulation of TEP and can either be faulty or fault-free. Each set of signals points to a specific fault class ranging from 0 through 20.

As was described previously in the Data Set section, the data contains 52 variables whose values are recorded over a certain amount of time in a simulation. The `sample` variable represents the number

of times these 52 variables are recorded in one simulation run. The maximum value of the `sample` variable is 500 in the training data set and 960 in the testing data set. Thus, for each simulation, there is a set of 52 signals of length 500 or 960. Each set of signals belongs to a particular simulation run of the TEP and points to a particular fault type in the range 0 – 20.

The training and test datasets both contain 500 simulations for each fault type. Twenty percent (from training) is kept for validation which leaves the training data set with 400 simulations per fault type and validation data with 100 simulations per fault type. Use the helper function `helperPreprocess` to create sets of signals, where each set is a double matrix in a single element of the cell array that represents a single TEP simulation. Hence, the sizes of the final training, validation, and testing data sets are as follows:

- Size of `Xtrain`: (Total number of simulations) X (Total number of fault types) = 400 X 18 = 7200
- Size of `XVal`: (Total number of simulations) X (Total number of fault types) = 100 X 18 = 1800
- Size of `Xtest`: (Total number of simulations) X (Total number of fault types) = 500 X 18 = 9000

In the data set, the first 500 simulations are of `0` fault type (fault-free) and the order of the subsequent faulty simulations is known. This knowledge enables the creation of true responses for the training, validation, and testing data sets.

```
Xtrain = helperPreprocess(trainingData,sampleTrain);
Ytrain = categorical([zeros(msTrain,1);repmat([1,2,4:8,10:14,16:20],1,msTrain)']);

XVal = helperPreprocess(validationData,sampleTrain);
YVal = categorical([zeros(msVal,1);repmat([1,2,4:8,10:14,16:20],1,msVal)']);

Xtest = helperPreprocess(testingData,sampleTest);
Ytest = categorical([zeros(msTest,1);repmat([1,2,4:8,10:14,16:20],1,msTest)']);
```

Normalize Data Sets

Normalization is a technique that scales the numeric values in a data set to a common scale without distorting differences in the range of values. This technique ensures that a variable with a larger value does not dominate other variables in the training. It also converts the numeric values in a higher range to a smaller range (usually –1 to 1) without losing any important information required for training.

Compute the mean and the standard deviation for 52 signals using data from all simulations in the training data set.

```
tMean = mean(trainingData(:,4:end))';
tSigma = std(trainingData(:,4:end))';
```

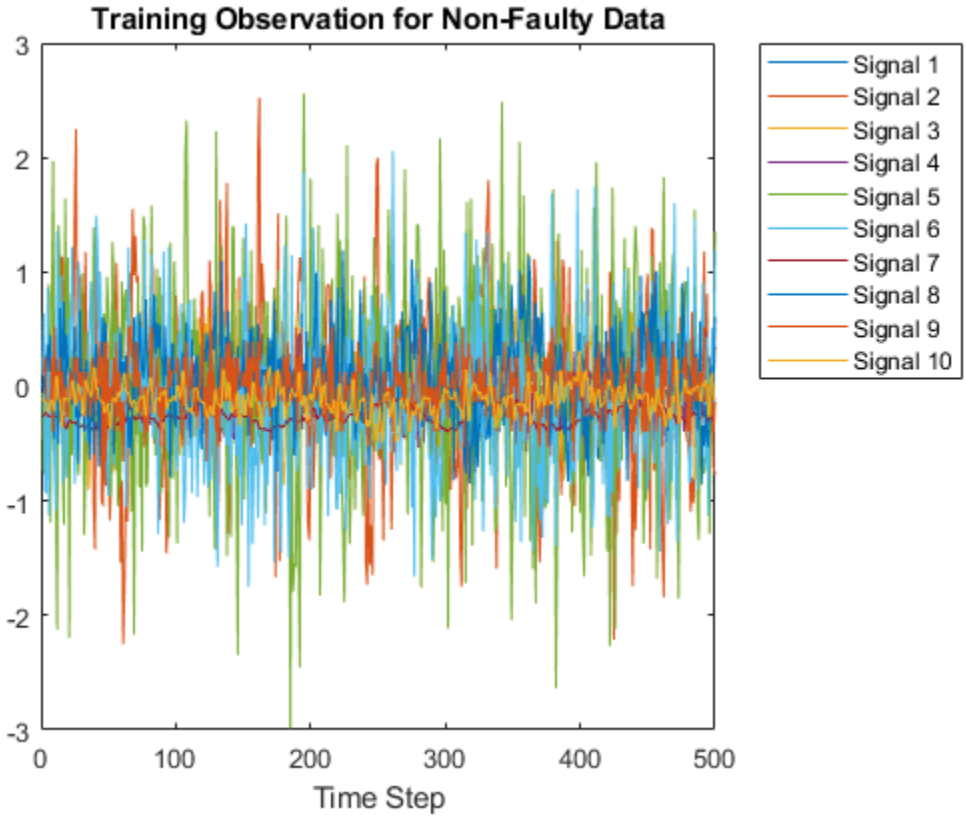
Use the helper function `helperNormalize` to apply normalization to each cell in the three data sets based on the mean and standard deviation of the training data.

```
Xtrain = helperNormalize(Xtrain, tMean, tSigma);
XVal = helperNormalize(XVal, tMean, tSigma);
Xtest = helperNormalize(Xtest, tMean, tSigma);
```

Visualize Data

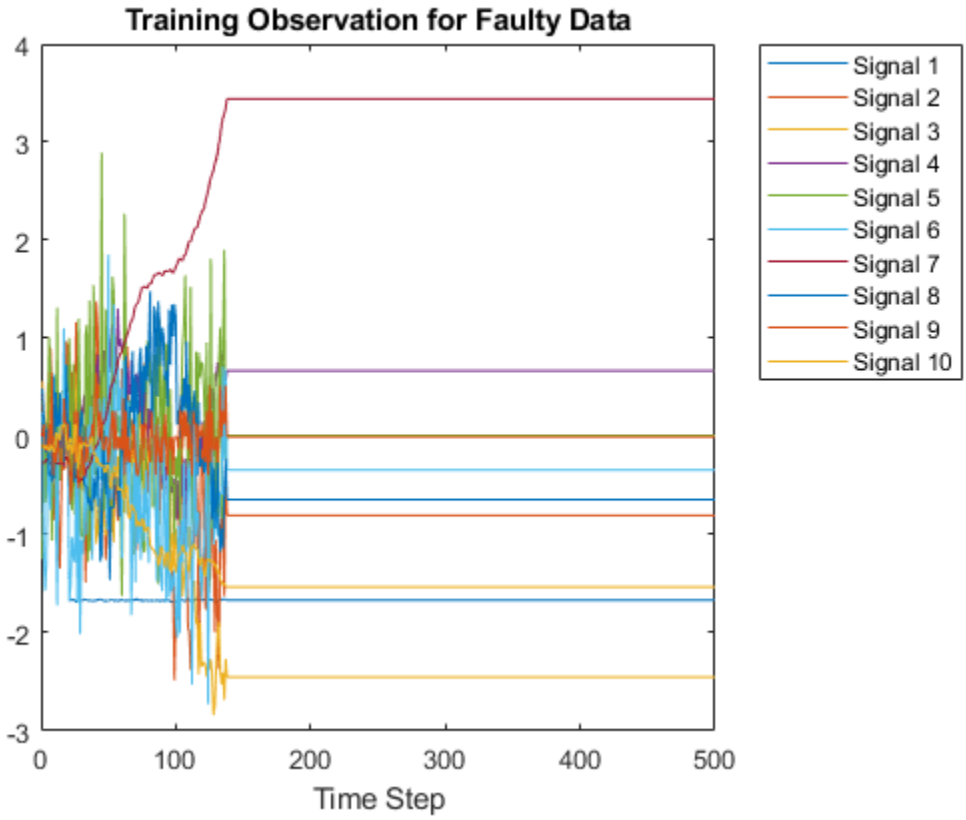
The `Xtrain` data set contains 400 fault-free simulations followed by 6800 faulty simulations.Visualize the fault-free and faulty data. First, create a plot of the fault-free data. For the purposes of this example, plot and label only 10 signals in the `Xtrain` data set to create an easy-to-read figure.

```
figure;
splot = 10;
plot(Xtrain{1}(1:10,:)');
xlabel("Time Step");
title("Training Observation for Non-Faulty Data");
legend("Signal " + string(1:splot),'Location','northeastoutside');
```



Now, compare the fault-free plot to a faulty plot by plotting any of the cell array elements after 400.

```
figure;
plot(Xtrain{1000}(1:10,:)');
xlabel("Time Step");
title("Training Observation for Faulty Data");
legend("Signal " + string(1:splot),'Location','northeastoutside');
```



Layer Architecture and Training Options

LSTM layers are a good choice for sequence classification as LSTM layers tend to remember only the important aspects of the input sequence.

- Specify the input layer `sequenceInputLayer` to be of the same size as the number of input signals (52).
- Specify 3 LSTM hidden layers with 52, 40, and 25 units. This specification is inspired by the experiment performed in [2] on page 16-0 . For more information on using LSTM networks for sequence classification, see “Sequence Classification Using Deep Learning” on page 4-2.
- Add 3 dropout layers in between the LSTM layers to prevent over-fitting. A dropout layer randomly sets input elements of the next layer to zero with a given probability so that the network does not become sensitive to a small set of neurons in the layer
- Finally, for classification, include a fully connected layer of the same size as the number of output classes (18). After the fully connected layer, include a softmax layer that assigns decimal probabilities (prediction possibility) to each class in a multi-class problem and a classification layer to output the final fault type based on output from the softmax layer.

```
numSignals = 52;
numHiddenUnits2 = 52;
numHiddenUnits3 = 40;
numHiddenUnits4 = 25;
numClasses = 18;

layers = [ ...
```

```
    sequenceInputLayer(numSignals)
    lstmLayer(numHiddenUnits2,'OutputMode','sequence')
    dropoutLayer(0.2)
    lstmLayer(numHiddenUnits3,'OutputMode','sequence')
    dropoutLayer(0.2)
    lstmLayer(numHiddenUnits4,'OutputMode','last')
    dropoutLayer(0.2)
    fullyConnectedLayer(numClasses)
    softmaxLayer
    classificationLayer];
```

Set the training options that `trainNetwork` uses.

Maintain the default value of name-value pair `'ExecutionEnvironment'` as `'auto'`. With this setting, the software chooses the execution environment automatically. By default, `trainNetwork` uses a GPU if one is available, otherwise, it uses a CPU. Training on a GPU requires Parallel Computing Toolbox™ and a supported GPU device. For information on supported devices, see “GPU Support by Release” (Parallel Computing Toolbox). Because this example uses a large amount of data, using GPU speeds up training time considerably.

Setting the name-value argument pair `'Shuffle'` to `'every-epoch'` avoids discarding the same data every epoch.

For more information on training options for deep learning, see `trainingOptions`.

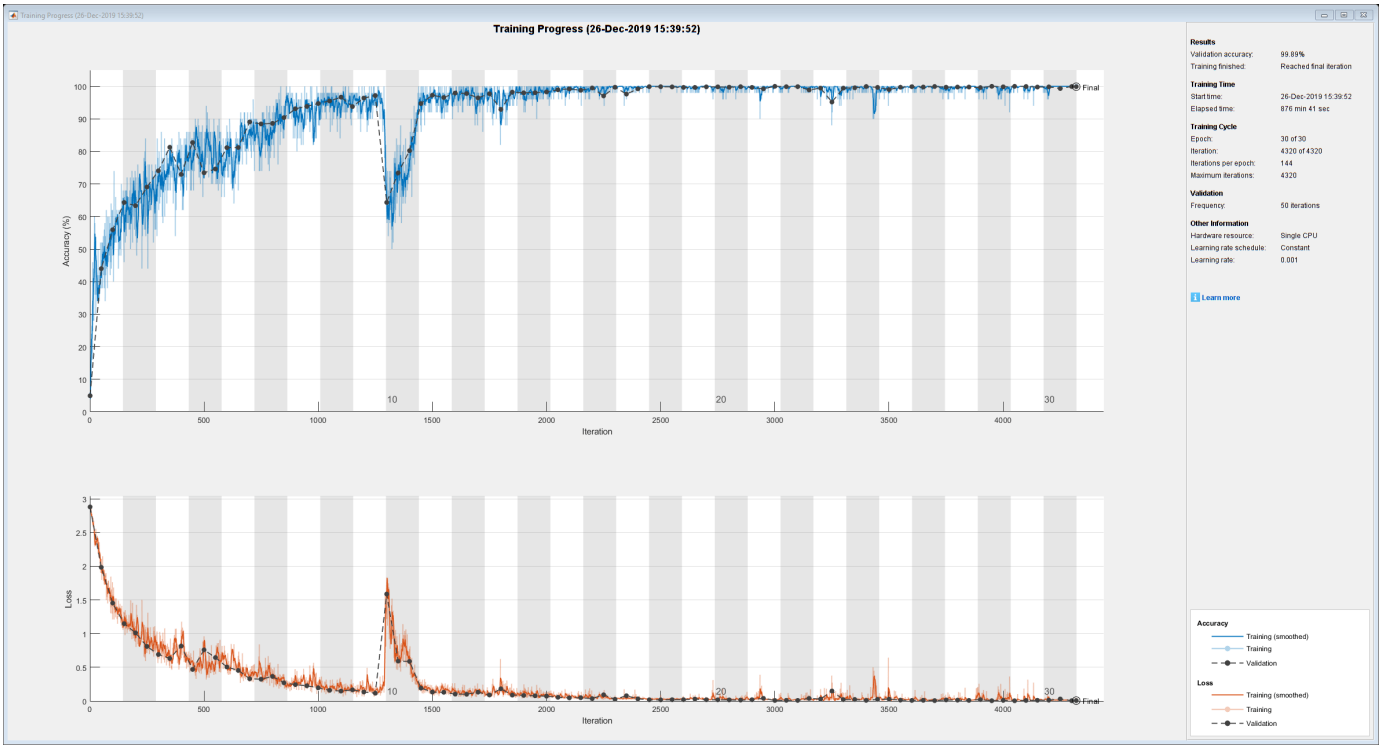
```
maxEpochs = 30;
miniBatchSize = 50;

options = trainingOptions('adam', ...
    'ExecutionEnvironment','auto', ...
    'GradientThreshold',1, ...
    'MaxEpochs',maxEpochs, ...
    'MiniBatchSize', miniBatchSize,...
    'Shuffle','every-epoch', ...
    'Verbose',0, ...
    'Plots','training-progress',...
    'ValidationData',{XVal,YVal});
```

Train Network

Train the LSTM network using `trainNetwork`.

```
net = trainNetwork(Xtrain,Ytrain,layers,options);
```



The training progress figure displays a plot of the network accuracy. To the right of the figure, view information on the training time and settings.

Testing Network

Run the trained network on the test set and predict the fault type in the signals.

```
Ypred = classify(net,Xtest,...
    'MiniBatchSize', miniBatchSize,...
    'ExecutionEnvironment','auto');
```

Calculate the accuracy. The accuracy is the number of true labels in the test data that match the classifications from `classify` divided by the number of images in the test data.

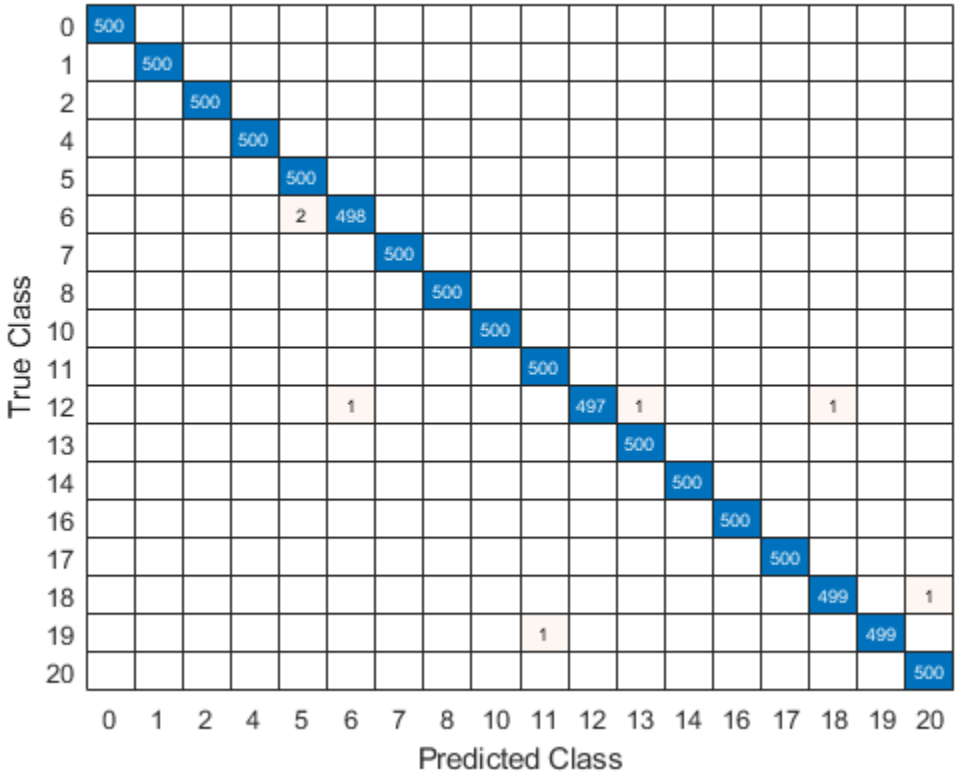
```
acc = sum(Ypred == Ytest)./numel(Ypred)
```

```
acc = 0.9992
```

High accuracy indicates that the neural network is successfully able to identify the fault type of unseen signals with minimal errors. Hence, the higher the accuracy, the better the network.

Plot a confusion matrix using true class labels of the test signals to determine how well the network identifies each fault.

```
confusionchart(Ytest,Ypred);
```



Using a confusion matrix, you can assess the effectiveness of a classification network. the confusion matrix has numerical values in the main diagonal and zeros elsewhere. The trained network in this example is effective and classifies more than 99% of signals correctly.

Helper Functions

`helperPreprocess`

The helper function `helperPreprocess` uses the maximum sample number to preprocess the data. The sample number indicates the signal length, which is consistent across the data set. A for-loop goes over the data set with a signal length filter to form sets of 52 signals. Each set is an element of a cell array. Each cell array represents a single simulation.

```
function processed = helperPreprocess(mydata,limit)
    H = size(mydata);
    processed = {};
    for ind = 1:limit:H
```

```
        x = mydata(ind:(ind+(limit-1)),4:end);
        processed = [processed; x'];
    end
end
```

`helperNormalize`

The helper function `helperNormalize` uses the data, mean, and standard deviation to normalize the data.

```
function data = helperNormalize(data,m,s)
    for ind = 1:size(data)
        data{ind} = (data{ind} - m)./s;
    end
end
```

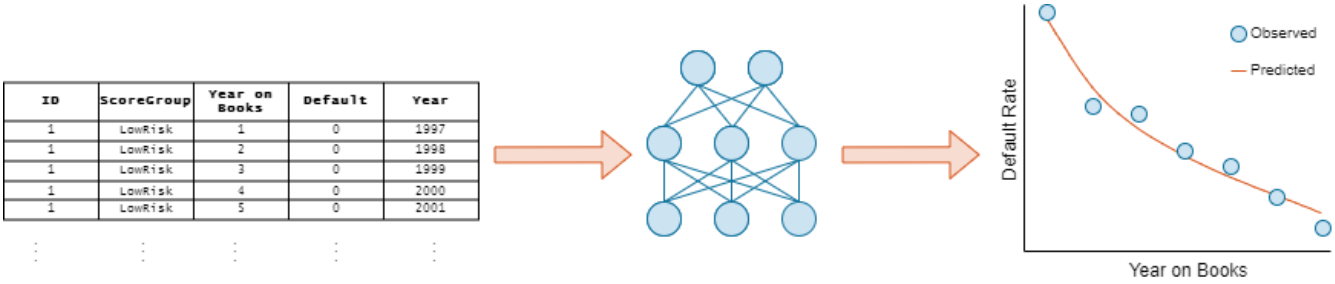
Computational Finance Examples

Compare Deep Learning Networks for Credit Default Prediction

This example shows how to create, train, and compare three deep learning networks for predicting credit default probability.

The panel data set of consumer loans enables you to identify and predict default rate patterns. You can train a neural network using the panel data to predict the default rate from year on books and risk level.

This example requires Deep Learning Toolbox™ and Risk Management Toolbox™.



In this example, you create and train three models for credit default prediction:

- Logistic regression network (also known as a single-layer perceptron)
- Multilayer perceptron (MLP)
- Residual network (ResNet)

You can express each of these models as a neural network of varying complexity and depth.

Load Credit Default Data

Load the retail credit panel data set. This data includes the following variables:

- `ID` — Loan identifier.
- `ScoreGroup` — Credit score at the beginning of the loan, discretized into three groups: `High Risk`, `Medium Risk`, and `Low Risk`.
- `YOB` — Years on books.
- `Default` — Default indicator. A value of `1` for `Default` means that the loan defaulted in the corresponding calendar year.
- `Year` — Calendar year.

```
filename = fullfile(toolboxdir('risk'),'riskdata','RetailCreditPanelData.mat');
tbl = load(filename).data;
```

Encode Categorical Variables

To train a deep learning network, you must first encode the categorical `ScoreGroup` variable to one-hot encoded vectors.

View the order of the `ScoreGroup` categories.

```
categories(tbl.ScoreGroup)'
```

```
ans = 1×3 cell
    {'High Risk'}    {'Medium Risk'}    {'Low Risk'}
```

Convert the categorical `ScoreGroup` variable to one-hot encoded vectors using the `onehotencode` function.

```
riskGroup = onehotencode(tbl.ScoreGroup,2);
```

Add the one-hot vectors to the table.

```
tbl.HighRisk = riskGroup(:,1);
tbl.MediumRisk = riskGroup(:,2);
tbl.LowRisk = riskGroup(:,3);
```

Remove the original `ScoreGroup` variable from the table using `removevars`.

```
tbl = removevars(tbl,{'ScoreGroup'});
```

Because you want to predict the `Default` variable response, move the `Default` variable to the end of the table.

```
tbl = movevars(tbl,'Default','After','LowRisk');
```

View the first few rows of the table. Notice that the `ScoreGroup` variable has been split into multiple columns, with the categorical values as the variable names.

```
head(tbl)
```

```
ans=8×7 table
    ID    YOB    Year    HighRisk    MediumRisk    LowRisk    Default
    __    ___    ____    ________    __________    _______    _______

    1      1     1997       0            0           1          0
    1      2     1998       0            0           1          0
    1      3     1999       0            0           1          0
    1      4     2000       0            0           1          0
    1      5     2001       0            0           1          0
    1      6     2002       0            0           1          0
    1      7     2003       0            0           1          0
    1      8     2004       0            0           1          0
```

Split Data

Partition the data set into training, validation, and test partitions using the unique loan ID numbers. Set aside 60% of the data for training, 20% for validation, and 20% for testing.

Find the unique loan IDs.

```
idx = unique(tbl.ID);
numObservations = length(idx);
```

Determine the number of observations for each partition.

```
numObservationsTrain = floor(0.6*numObservations);
numObservationsValidation = floor(0.2*numObservations);
numObservationsTest = numObservations - numObservationsTrain - numObservationsValidation;
```

Create an array of random indices corresponding to the observations and partition it using the partition sizes.

```
rng('default')
idxShuffle = idx(randperm(numObservations));

idxTrain = idxShuffle(1:numObservationsTrain);
idxValidation = idxShuffle(numObservationsTrain+1:numObservationsTrain+numObservationsValidation)
idxTest = idxShuffle(numObservationsTrain+numObservationsValidation+1:end);
```

Find the table entries corresponding to the data set partitions.

```
idxTrainTbl = ismember(tbl.ID,idxTrain);
idxValidationTbl = ismember(tbl.ID,idxValidation);
idxTestTbl = ismember(tbl.ID,idxTest);
```

Keep the variables of interest for the task (`YOB`, `HighRisk`, `MediumRisk`, `LowRisk`, and `Default`) and remove all other variables from the table.

```
tbl = removevars(tbl,{'ID','Year'});
head(tbl)
```

```
ans=8×5 table
    YOB    HighRisk    MediumRisk    LowRisk    Default
    ___    ________    __________    _______    _______

     1         0            0           1          0
     2         0            0           1          0
     3         0            0           1          0
     4         0            0           1          0
     5         0            0           1          0
     6         0            0           1          0
     7         0            0           1          0
     8         0            0           1          0
```

Partition the table of data into training, validation, and testing partitions using the indices.

```
tblTrain = tbl(idxTrainTbl,:);
tblValidation = tbl(idxValidationTbl,:);
tblTest = tbl(idxTestTbl,:);
```

Define Network Architectures

You can use different deep learning architectures for the task of predicting credit default probabilities. Smaller networks are quick to train, but deeper networks can learn more abstract features. Choosing a neural network architecture requires balancing computation time against accuracy. In this example, you define three network architectures, with varying levels of complexity.

Logistic Regression Network

The first network is a simple neural network containing four layers.

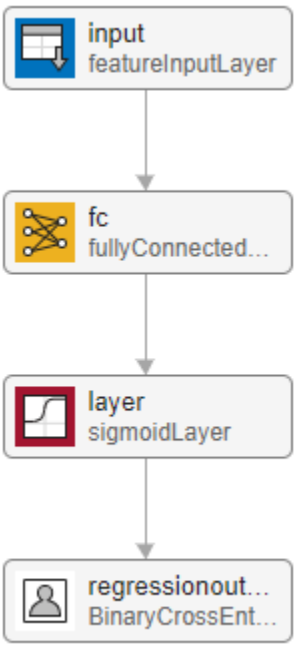
Start with a feature input layer, which passes tabular data (credit panel data) to the network. In this example, there are four input features: `YOB`, `HighRisk`, `MediumRisk`, and `LowRisk`. Configure the input layer to normalize the data using z-score normalization. Normalizing the data is important for tasks where the scale and range of the input variables is very different.

Next, use a fully connected layer with a single output followed by a sigmoid layer. For the final layer, use a custom binary cross-entropy loss layer. This layer is attached to this example as a supporting file.

```
logisticLayers = [
    featureInputLayer(4,'Normalization','zscore')
    fullyConnectedLayer(1)
    sigmoidLayer
    BinaryCrossEntropyLossLayer('output')];
```

This network is called a *single-layer perceptron*. You can visualize the network using Deep Network Designer or the `analyzeNetwork` function.

```
deepNetworkDesigner(logisticLayers)
```



You can easily show that the single-layer perceptron neural network is equivalent to logistic regression. Let $\mathbf{x}_i$ be a 1-by-4 vector containing the features for observation i. With input $\mathbf{x}_i$, the output of the fully connected layer is

$$\mathbf{W}\mathbf{x}_i + b = W_1 x_{i,1} + W_2 x_{i,2} + W_3 x_{i,3} + W_4 x_{i,4} + b.$$

The output of the fully connected layer provides the input for the sigmoid layer. The sigmoid layer then outputs

$$S(\mathbf{W}\mathbf{x}_i + b) = \frac{1}{1 + \exp\{-(W_1 x_{i,1} + W_2 x_{i,2} + W_3 x_{i,3} + W_4 x_{i,4} + b)\}}.$$

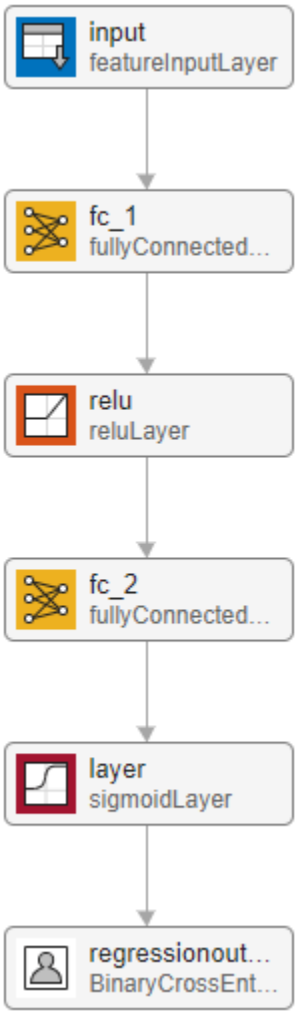
The output of the sigmoid layer is equivalent to the logistic regression model. The final layer of the neural network is a binary cross-entropy loss layer. Minimizing the binary cross-entropy loss is equivalent to maximizing the likelihood in a logistic regression model.

Multilayer Perceptron

The next network has a similar architecture to the logistic regression model, but has an additional fully connected layer with an output size of 100, followed by a ReLU nonlinear activation function. This type of network is called a *multilayer perceptron* due to the addition of another hidden layer and a nonlinear activation function. Whereas the single-layer perceptron can learn only linear functions, the multilayer perceptron can learn complex, nonlinear relationships between the input and output data.

```
mlpLayers = [
    featureInputLayer(4,'Normalization','zscore')
    fullyConnectedLayer(100)
    reluLayer
    fullyConnectedLayer(1)
    sigmoidLayer
    BinaryCrossEntropyLossLayer('output')];

deepNetworkDesigner(mlpLayers)
```



Residual Network

For the final network, create a residual network (ResNet) [1] on page 17-0 from multiple stacks of fully connected layers and ReLU activations. Originally developed for image classification, ResNets have proven successful across many domains. Because a ResNet has many more parameters than multilayer perceptrons or logistic networks, they take longer to train.

```
residualLayers = [
    featureInputLayer(4,'Normalization','zscore','Name','input')

    fullyConnectedLayer(16,'Name','fc1')
    batchNormalizationLayer('Name','bn1')
    reluLayer('Name','relu1')

    fullyConnectedLayer(32,'Name','resblock1-fc1')
    batchNormalizationLayer('Name','resblock1-bn1')
    reluLayer('Name','resblock1-relu1')

    fullyConnectedLayer(32,'Name','resblock1-fc2')
    additionLayer(2,'Name','resblock1-add')
    batchNormalizationLayer('Name','resblock1-bn2')
    reluLayer('Name','resblock1-relu2')

    fullyConnectedLayer(64,'Name','resblock2-fc1')
    batchNormalizationLayer('Name','resblock2-bn1')
    reluLayer('Name','resblock2-relu1')

    fullyConnectedLayer(64,'Name','resblock2-fc2')
    additionLayer(2,'Name','resblock2-add')
    batchNormalizationLayer('Name','resblock2-bn2')
    reluLayer('Name','resblock2-relu2')

    fullyConnectedLayer(1,'Name','fc2')
    sigmoidLayer('Name','sigmoid')
    BinaryCrossEntropyLossLayer('output')];

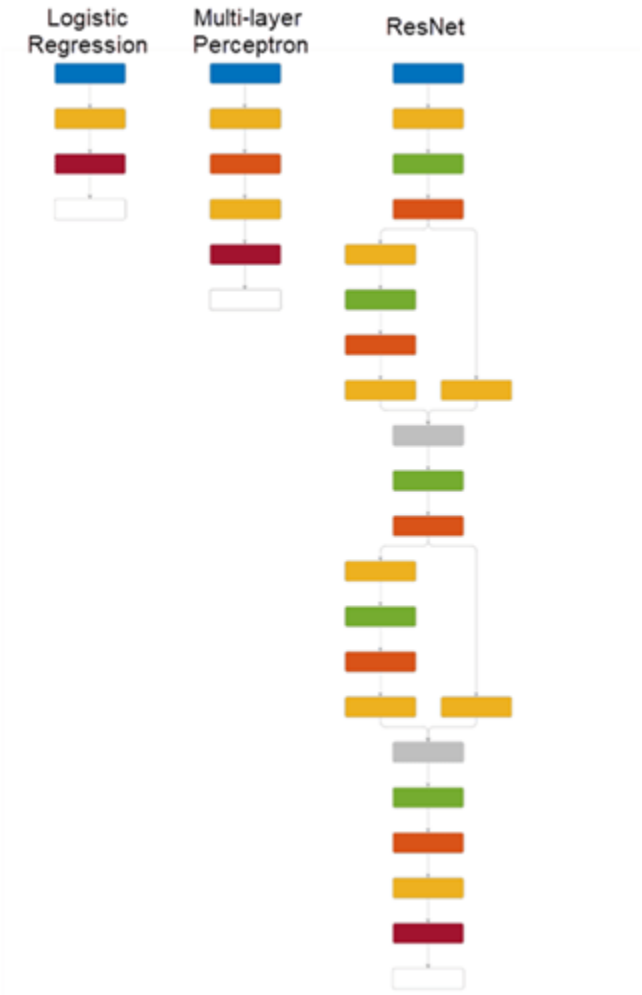
residualLayers = layerGraph(residualLayers);
residualLayers = addLayers(residualLayers,fullyConnectedLayer(32,'Name','resblock1-fc-shortcut'));
residualLayers = addLayers(residualLayers,fullyConnectedLayer(64,'Name','resblock2-fc-shortcut'));

residualLayers = connectLayers(residualLayers,'relu1','resblock1-fc-shortcut');
residualLayers = connectLayers(residualLayers,'resblock1-fc-shortcut','resblock1-add/in2');
residualLayers = connectLayers(residualLayers,'resblock1-relu2','resblock2-fc-shortcut');
residualLayers = connectLayers(residualLayers,'resblock2-fc-shortcut','resblock2-add/in2');

deepNetworkDesigner(residualLayers)
```

Network Depth

The *depth* of a network is an important concept in deep learning and is defined as the largest number of sequential convolutional or fully connected layers (represented by yellow blocks in the following diagram) on a path from the input layer to the output layer. The deeper a network is, the more complex features it can learn. In this example, the logistic network has a depth of 1, the multilayer perceptron has a depth of 2, and the residual network has a depth of 6.



Specify Training Options

Specify the training options.

- Train using the Adam optimizer.
- Set the initial learning rate to 0.001.
- Set the mini-batch size to 512.
- Turn on the training progress plot and turn off the command window output.
- Shuffle the data at the beginning of each epoch.
- Monitor the network accuracy during training by specifying validation data and using it to validate the network every 1000 iterations.

```
options = trainingOptions('adam', ...
    'InitialLearnRate',0.001, ...
    'MiniBatchSize',512, ...
    'Plots','training-progress', ...
    'Verbose',false, ...
    'Shuffle','every-epoch', ...
    'ValidationData',tblValidation, ...
    'ValidationFrequency',1000);
```

The loss landscape of the logistic regression network is convex, therefore, it does not need to train for as many epochs. For the logistic regression and multilayer perceptron models, train for 15 epochs. For the more complex residual network, train for 50 epochs.

```
logisticOptions = options;
logisticOptions.MaxEpochs = 15;

mlpOptions = options;
mlpOptions.MaxEpochs = 15;

residualOptions = options;
residualOptions.MaxEpochs = 50;
```

The three networks have different architectures, so they require different sets of training options to achieve optimal performance. You can perform optimization programmatically or interactively using Experiment Manager. For an example showing how to perform a hyperparameter sweep of the training options, see “Create a Deep Learning Experiment for Classification” on page 6-2.

Train Network

Train the networks using the architectures defined, the training data, and the training options. By default, `trainNetwork` uses a GPU if one is available; otherwise, it uses a CPU. Training on a GPU requires Parallel Computing Toolbox™ and a supported GPU device. For information on supported devices, see “GPU Support by Release” (Parallel Computing Toolbox). You can also specify the execution environment by using the `ExecutionEnvironment` name-value argument of `trainingOptions`.

To avoid waiting for training, load pretrained networks by setting the `doTrain` flag to `false`. To train the networks using `trainNetwork`, set the `doTrain` flag to `true`.

Training times using a NVIDIA® GeForce® RTX 2080 Ti are:

- Logistic network — Approximately 4 minutes
- Multilayer perceptron — Approximately 5 minutes
- Residual network — Approximately 35 minutes

```
doTrain = false;

if doTrain
    logisticNet = trainNetwork(tblTrain,'Default',logisticLayers,logisticOptions);
    mlpNet = trainNetwork(tblTrain,'Default',mlpLayers,mlpOptions);
    residualNet = trainNetwork(tblTrain,'Default',residualLayers,residualOptions);
else
    load logisticTrainedNetwork
    load mlpTrainedNetwork
    load residualTrainedNetwork
end
```

Test Network

Predict the default probability of the test data using the trained networks.

```
tblTest.logisticPred = predict(logisticNet,tblTest(:,1:end-1));
tblTest.mlpPred = predict(mlpNet,tblTest(:,1:end-1));
tblTest.residualPred = predict(residualNet,tblTest(:,1:end-1));
```

Default Rates by Year on Books

To assess the performance of the network, use the `groupsummary` function to group the true default rates and corresponding predictions by years on books (represented by the `YOB` variable) and calculate the mean value.

```
summaryYOB = groupsummary(tblTest,'YOB','mean',{'Default','logisticPred','mlpPred','residualPred
head(summaryYOB)
```

```
ans=8×6 table
    YOB    GroupCount    mean_Default    mean_logisticPred    mean_mlpPred    mean_residualPred
    ___    __________    ____________    _________________    ____________    _________________

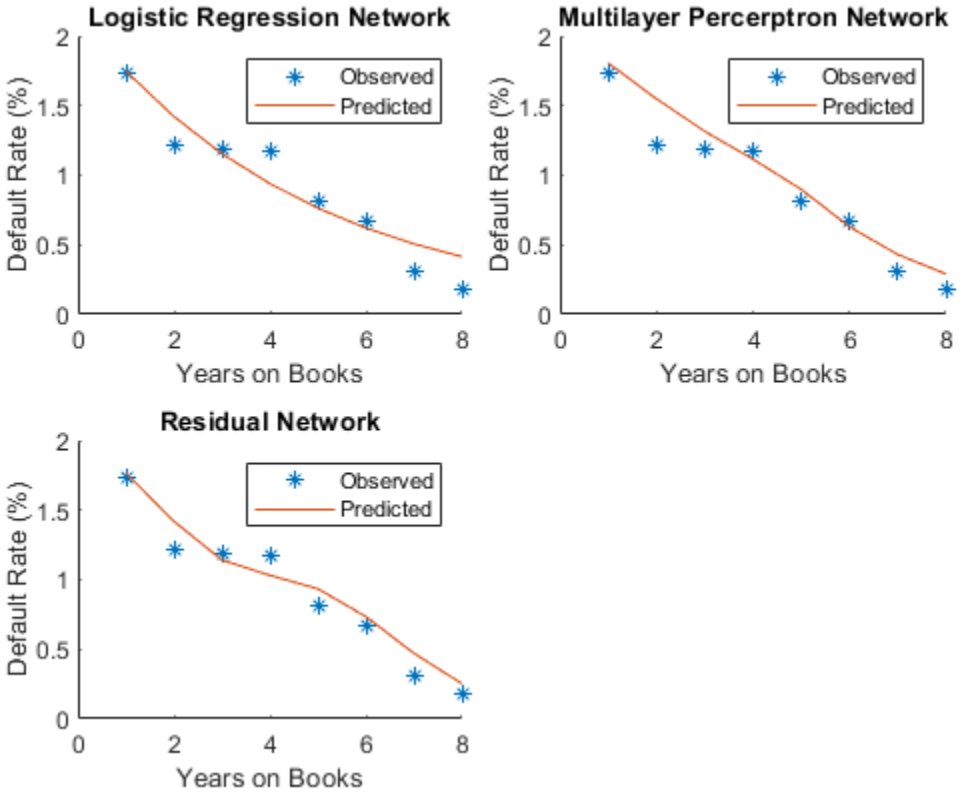
     1       19364         0.017352           0.017471          0.018056           0.017663
     2       18917         0.012158           0.014209          0.015486           0.014192
     3       18526         0.011875           0.011538          0.013154           0.011409
     4       18232         0.011683          0.0093902          0.011151           0.010311
     5       17925        0.0082008           0.007626         0.0089826          0.0093438
     6       17727        0.0066565          0.0062047         0.0062967          0.0073401
     7       12294        0.0030909          0.0050643         0.0042998          0.0047071
     8        6361        0.0017293          0.0041463         0.0029052          0.0025272
```

Plot the true average default rate against the average predictions by years on books.

```
networks = ["Logistic Regression Network","Multilayer Percerptron Network","Residual Network"];

figure
tiledlayout('flow','TileSpacing','compact')

for i = 1:3
    nexttile
    scatter(summaryYOB.YOB,summaryYOB.mean_Default*100,'*');
    hold on
    plot(summaryYOB.YOB,summaryYOB{:,i+3}*100);
    hold off
    title(networks(i))
    xlabel('Years on Books')
    ylabel('Default Rate (%)')
    legend('Observed','Predicted')
end
```



All three networks show a clear downward trend, with default rates going down as the number of years on books increases. Years three and four are an exception to the downward trend. Overall, the three models predict the default rates well, and even the simpler logistic regression model predicts the general trend. The residual network captures a more complex, nonlinear relationship compared to the logistic model, which can fit only a linear relationship.

Default Rates by Score Groups

Use the credit score group as a grouping variable to compute the observed and predicted default rate for each score group.

Decode `ScoreGroup` back into the categorical score groups.

```
ScoreGroup = onehotdecode(tblTest{:,2:4},{'HighRisk','MediumRisk','LowRisk'},2);
tblTest.ScoreGroup = ScoreGroup;
tblTest = removevars(tblTest,{'HighRisk','MediumRisk','LowRisk'});

riskGroups = categories(tblTest.ScoreGroup);
```

Use the `groupsummary` function to group the true default rate and the predictions by `YOB` and `ScoreGroup`, and return the mean for each group.

```
numYOB = height(summaryYOB);
numRiskGroups = height(riskGroups);

summaryYOBScore = groupsummary(tblTest,{'ScoreGroup','YOB'},'mean',{'Default','logisticPred','ml
head(summaryYOBScore)
```

```
ans=8×7 table
    ScoreGroup    YOB    GroupCount    mean_Default    mean_logisticPred    mean_mlpPred    mean
    __________    ___    __________    ____________    _________________    ____________    ____

     HighRisk      1        6424          0.029577           0.028404          0.031563
     HighRisk      2        6180          0.020065            0.02325          0.026649
     HighRisk      3        5949          0.019163           0.019013          0.022484
     HighRisk      4        5806          0.020668           0.015535          0.018957
     HighRisk      5        5634           0.01349           0.012686           0.01577
     HighRisk      6        5531          0.013379           0.010354          0.010799
     HighRisk      7        3862         0.0051787          0.0084466         0.0071398
     HighRisk      8        2027         0.0034534          0.0068881         0.0047145
```

Plot the true average default rate against the predicted rate by years on books and risk group.

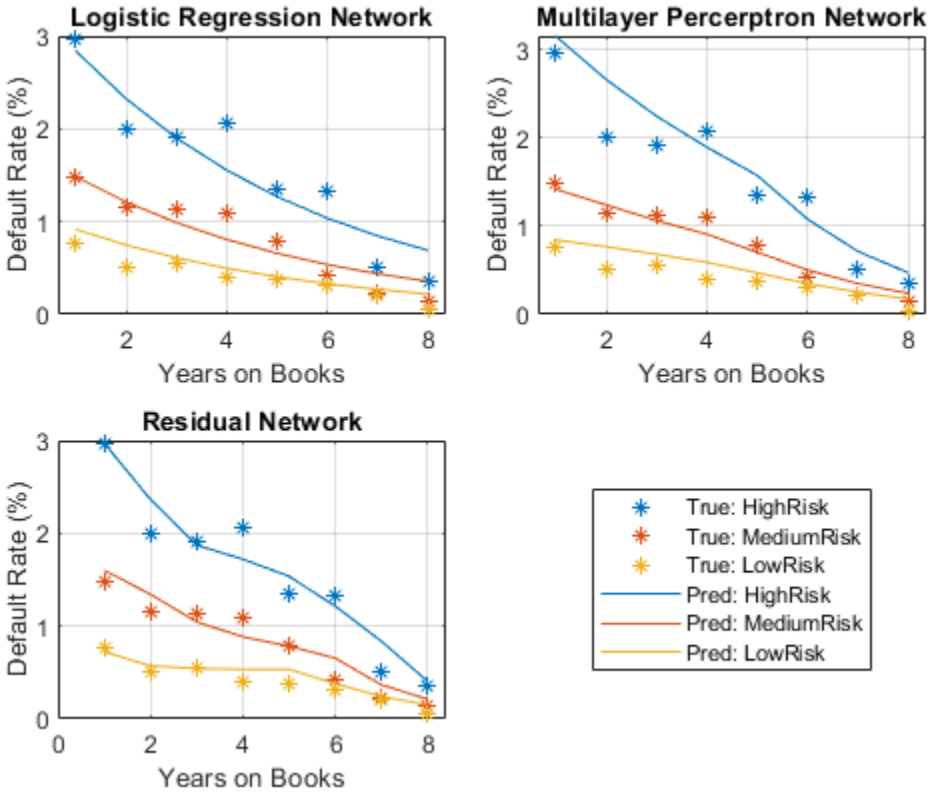
```
figure
t = tiledlayout('flow','TileSpacing','compact');
color = lines(3);

YOB = summaryYOBScore.YOB;
default = summaryYOBScore.mean_Default*100;
group = summaryYOBScore.ScoreGroup;

for i = 1:3
    pred = summaryYOBScore{:,i+4}*100;
    meanScore = reshape(pred,numYOB,numRiskGroups);

    nexttile
    hs = gscatter(YOB,default,group,color,'*',6,false);
    hold on
    colororder(color)
    plot(meanScore)
    hold off
    title(networks(i))
    xlabel('Years on Books')
    ylabel('Default Rate (%)')
    grid on
end

labels = ["True: " + riskGroups; "Pred: " + riskGroups];
lgd = legend(labels);
lgd.Layout.Tile = 4;
```



The plot shows that all score groups behave similarly as time progresses, with a general downward trend. Across the high risk group, year four does not follow the downward trend. In the medium risk group, years three and four appear flat. Finally, in the low risk group, year three shows an increase. These irregular trends are difficult to discern with the simpler logistic regression model.

For an example showing how to use the locally-interpretable model-agnostic explanations (LIME) and Shapley values interpretability techniques to understand the predictions of a residual network for credit default prediction, see “Interpret and Stress-Test Deep Learning Networks for Probability of Default” (Risk Management Toolbox).

Interpret and Stress-Test Deep Learning Networks for Probability of Default

This example shows how to train a credit risk for probability of default (PD) prediction using a deep neural network. The example also shows how to use the locally interpretable model-agnostic explanations (LIME) and Shapley values interpretability techniques to understand the predictions of the model. In addition, the example analyzes model predictions for out-of-sample values and performs a stress-testing analysis.

The “Stress Testing of Consumer Credit Default Probabilities Using Panel Data” (Risk Management Toolbox) example presents a similar workflow but uses a logistic model. The “Modeling Probabilities of Default with Cox Proportional Hazards” (Risk Management Toolbox) example uses a Cox regression, or Cox proportional hazards model. However, interpretability techniques are not discussed in either of these examples because the models are simpler and interpretable. The “Compare Deep Learning Networks for Credit Default Prediction” on page 17-2 example focuses on alternative network designs and fits simpler models without the macroeconomic variables.

While you can use these alternative, simpler models successfully to model credit risk, this example introduces explainability tools for exploring complex-modeling techniques in credit applications. To visualize and interpret the model predictions, you use Deep Learning Toolbox™ and the `lime` (Statistics and Machine Learning Toolbox) and `shapley` (Statistics and Machine Learning Toolbox) functions. To run this example, you:

1. Load and prepare credit data, reformat predictors, and split the data into training, validation, and testing sets.
2. Define a network architecture, select training options, and train the network. (A saved version of the trained network `residualTrainedNetworkMacro` is available for convenience.)
3. Apply the LIME and Shapley interpretability techniques on observations of interest (or "query points") to determine if the importance of predictors in the model is as expected.
4. Explore extreme predictor out-of-sample values to investigate the behavior of the model for new, extreme data.
5. Use the model to perform a stress-testing analysis of the predicted PD values.

Load Credit Default Data

Load the retail credit panel data set including its macroeconomic variables. The main data set (`data`) contains the following variables:

- `ID`: Loan identifier
- `ScoreGroup`: Credit score at the beginning of the loan, discretized into three groups, `High Risk`, `Medium Risk`, and `Low Risk`
- `YOB`: Years on books
- `Default`: Default indicator; the response variable
- `Year`: Calendar year

The small data set (`dataMacro`) contains macroeconomic data for the corresponding calendar years:

- `Year`: Calendar year
- `GDP`: Gross domestic product growth (year over year)

- `Market`: Market return (year over year)

The variables `YOB`, `Year`, `GDP`, and `Market` are observed at the end of the corresponding calendar year. The score group is a discretization of the original credit score when the loan started. A value of `1` for `Default` means that the loan defaulted in the corresponding calendar year.

The third data set (`dataMacroStress`) contains baseline, adverse, and severely adverse scenarios for the macroeconomic variables. This table is for the stress-testing analysis.

This example uses simulated data, but the same approach has been successfully applied to real data sets.

```
load RetailCreditPanelData.mat
data = join(data,dataMacro);
head(data)
```

```
ans=8×7 table
    ID    ScoreGroup    YOB    Default    Year     GDP     Market

```

Encode Categorical Variables

To train a deep learning network, you must first encode the categorical `ScoreGroup` variable to one-hot encoded vectors.

View the order of the `ScoreGroup` categories.

```
categories(data.ScoreGroup)'
```

```
ans = 1×3 cell
    {'High Risk'}    {'Medium Risk'}    {'Low Risk'}
```

ans = 1×3 cell

{'High Risk'} {'Medium Risk'} {'Low Risk'}

One-hot encode the `ScoreGroup` variable.

```
riskGroup = onehotencode(data.ScoreGroup,2);
```

Add the one-hot vectors to the table.

```
data.HighRisk = riskGroup(:,1);
data.MediumRisk = riskGroup(:,2);
data.LowRisk = riskGroup(:,3);
```

Remove the original `ScoreGroup` variable from the table using `removevars`.

```
data = removevars(data,{'ScoreGroup'});
```

Move the `Default` variable to the end of the table, as this variable is the response you want to predict.

```
data = movevars(data,'Default','After','LowRisk');
```

View the first few rows of the table. The `ScoreGroup` variable is split into multiple columns with the categorical values as the variable names.

```
head(data)
```

```
ans=8×9 table
    ID    YOB    Year     GDP     Market    HighRisk    MediumRisk    LowRisk    Default
    __    ___    ____    _____    ______    ________    __________    _______    _______

    1      1     1997     2.72      7.61       0            0           1          0
    1      2     1998     3.57     26.24       0            0           1          0
    1      3     1999     2.86      18.1       0            0           1          0
    1      4     2000     2.43      3.19       0            0           1          0
    1      5     2001     1.26    -10.51       0            0           1          0
    1      6     2002    -0.59    -22.95       0            0           1          0
    1      7     2003     0.63      2.78       0            0           1          0
    1      8     2004     1.85      9.48       0            0           1          0
```

Split Data

Partition the data set into training, validation, and test partitions using the unique loan ID numbers. Set aside 60% of the data for training, 20% for validation, and 20% for testing.

Find the unique loan IDs.

```
idx = unique(data.ID);
numObservations = length(idx);
```

Determine the number of observations for each partition.

```
numObservationsTrain = floor(0.6*numObservations);
numObservationsValidation = floor(0.2*numObservations);
numObservationsTest = numObservations - numObservationsTrain - numObservationsValidation;
```

Create an array of random indices corresponding to the observations and partition it using the partition sizes.

```
rng('default'); % for reproducibility
idxShuffle = idx(randperm(numObservations));

idxTrain = idxShuffle(1:numObservationsTrain);
idxValidation = idxShuffle(numObservationsTrain+1:numObservationsTrain+numObservationsValidation)
idxTest = idxShuffle(numObservationsTrain+numObservationsValidation+1:end);
```

Find the table entries corresponding to the data set partitions.

```
idxTrainTbl = ismember(data.ID,idxTrain);
idxValidationTbl = ismember(data.ID,idxValidation);
idxTestTbl = ismember(data.ID,idxTest);
```

Keep the variables of interest for the task (`YOB`, `Default`, and `ScoreGroup`) and remove all other variables from the table.

```
data = removevars(data,{'ID','Year'});
head(data)
```

```
ans=8×7 table
    YOB     GDP     Market    HighRisk    MediumRisk    LowRisk    Default
    ___    _____    ______    ________    __________    _______    _______

     1      2.72      7.61        0            0            1          0
     2      3.57     26.24        0            0            1          0
     3      2.86      18.1        0            0            1          0
     4      2.43      3.19        0            0            1          0
     5      1.26    -10.51        0            0            1          0
     6     -0.59    -22.95        0            0            1          0
     7      0.63      2.78        0            0            1          0
     8      1.85      9.48        0            0            1          0
```

Partition the table of data into training, validation, and testing partitions using the indices.

```
tblTrain = data(idxTrainTbl,:);
tblValidation = data(idxValidationTbl,:);
tblTest = data(idxTestTbl,:);
```

Define Network Architecture

You can use different deep learning architectures for the task of predicting credit default probabilities. Smaller networks are quick to train, but deeper networks can learn more abstract features. Choosing a neural network architecture requires balancing computation time against accuracy. This example uses a residual architecture. For an example of other networks, see the “Compare Deep Learning Networks for Credit Default Prediction” on page 17-2 example.

Create a residual architecture (ResNet) from multiple stacks of fully connected layers and ReLU activations. ResNet architectures are state of the art in deep learning applications and popular in deep learning literature. Originally developed for image classification, ResNets have proven successful across many domains [1 on page 17-0].

```
residualLayers = [
    featureInputLayer(6, 'Normalization', 'zscore', 'Name', 'input')
    fullyConnectedLayer(16, 'Name', 'fc1','WeightsInitializer','he')
    batchNormalizationLayer('Name', 'bn1')
    reluLayer('Name','relu1')
    fullyConnectedLayer(32, 'Name', 'resblock1-fc1','WeightsInitializer','he')
    batchNormalizationLayer('Name', 'resblock1-bn1')
    reluLayer('Name', 'resblock1-relu1')
    fullyConnectedLayer(32, 'Name', 'resblock1-fc2','WeightsInitializer','he')
    additionLayer(2, 'Name', 'resblock1-add')
    batchNormalizationLayer('Name', 'resblock1-bn2')
    reluLayer('Name', 'resblock1-relu2')
    fullyConnectedLayer(64, 'Name', 'resblock2-fc1','WeightsInitializer','he')
    batchNormalizationLayer('Name', 'resblock2-bn1')
    reluLayer('Name', 'resblock2-relu1')
    fullyConnectedLayer(64, 'Name', 'resblock2-fc2','WeightsInitializer','he')
    additionLayer(2, 'Name', 'resblock2-add')
    batchNormalizationLayer('Name', 'resblock2-bn2')
    reluLayer('Name', 'resblock2-relu2')
```

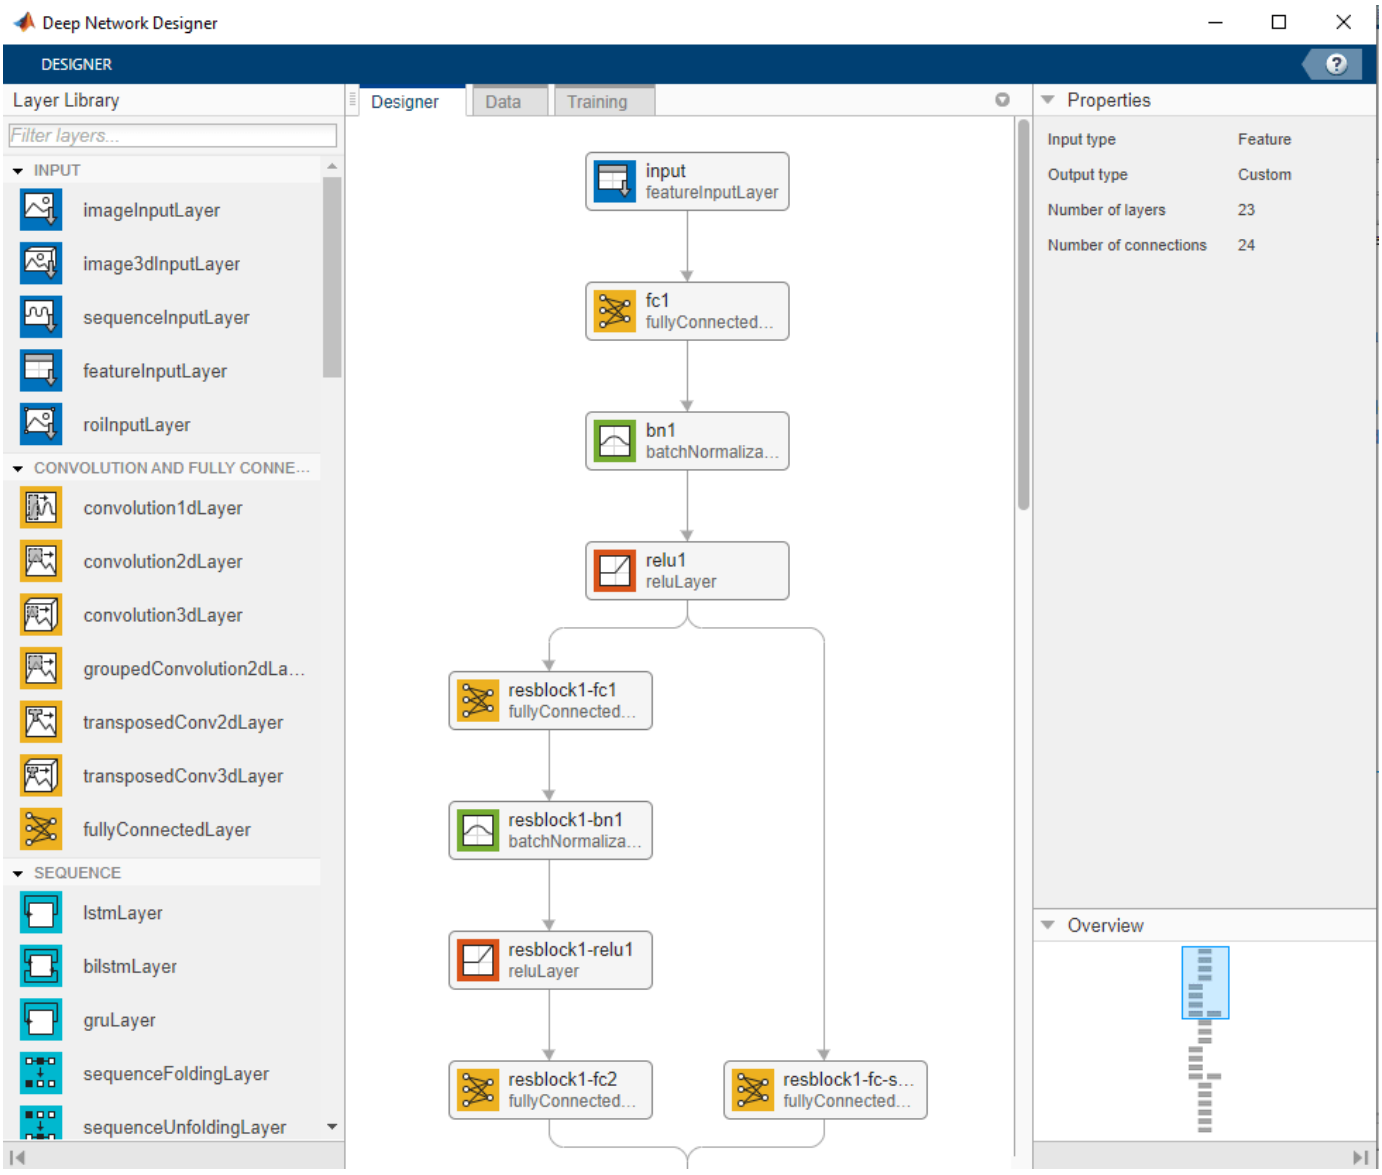
```
    fullyConnectedLayer(1, 'Name', 'fc2','WeightsInitializer','he')
    sigmoidLayer('Name', 'sigmoid')
    BinaryCrossEntropyLossLayer('output')];

residualLayers = layerGraph(residualLayers);
residualLayers = addLayers(residualLayers,fullyConnectedLayer(32, 'Name', 'resblock1-fc-shortcut
residualLayers = addLayers(residualLayers,fullyConnectedLayer(64, 'Name', 'resblock2-fc-shortcut

residualLayers = connectLayers(residualLayers, 'relu1', 'resblock1-fc-shortcut');
residualLayers = connectLayers(residualLayers, 'resblock1-fc-shortcut', 'resblock1-add/in2');
residualLayers = connectLayers(residualLayers, 'resblock1-relu2', 'resblock2-fc-shortcut');
residualLayers = connectLayers(residualLayers, 'resblock2-fc-shortcut', 'resblock2-add/in2');
```

You can visualize the network using Deep Network Designer or the `analyzeNetwork` function.

```
deepNetworkDesigner(residualLayers)
```



Specify Training Options

In this example, train each network with these training options:

- Train using the Adam optimizer.
- Set the initial learning rate to `0.001`.
- Set the mini-batch size to `512`.
- Train for `75` epochs.
- Turn on the training progress plot and turn off the command window output.
- Shuffle the data at the beginning of each epoch.
- Monitor the network accuracy during training by specifying validation data and using it to validate the network every 1000 iterations.

```
options = trainingOptions('adam', ...
    'InitialLearnRate',0.001, ...
    'MiniBatchSize',512, ...
    'MaxEpochs',75, ...
    'Plots','training-progress', ...
    'Verbose',false, ...
    'Shuffle','every-epoch', ...
    'ValidationData',tblValidation, ...
    'ValidationFrequency',1000);
```

The “Compare Deep Learning Networks for Credit Default Prediction” on page 17-2 example fits the same type of network, but it excludes the macroeconomic predictors. In that example, if you increase the number of epochs from `50` to `75`, you can improve accuracy without overfitting concerns.

You can perform optimization programmatically or interactively using Experiment Manager. For an example showing how to perform a hyperparameter sweep of the training options, see “Create a Deep Learning Experiment for Classification” on page 6-2.

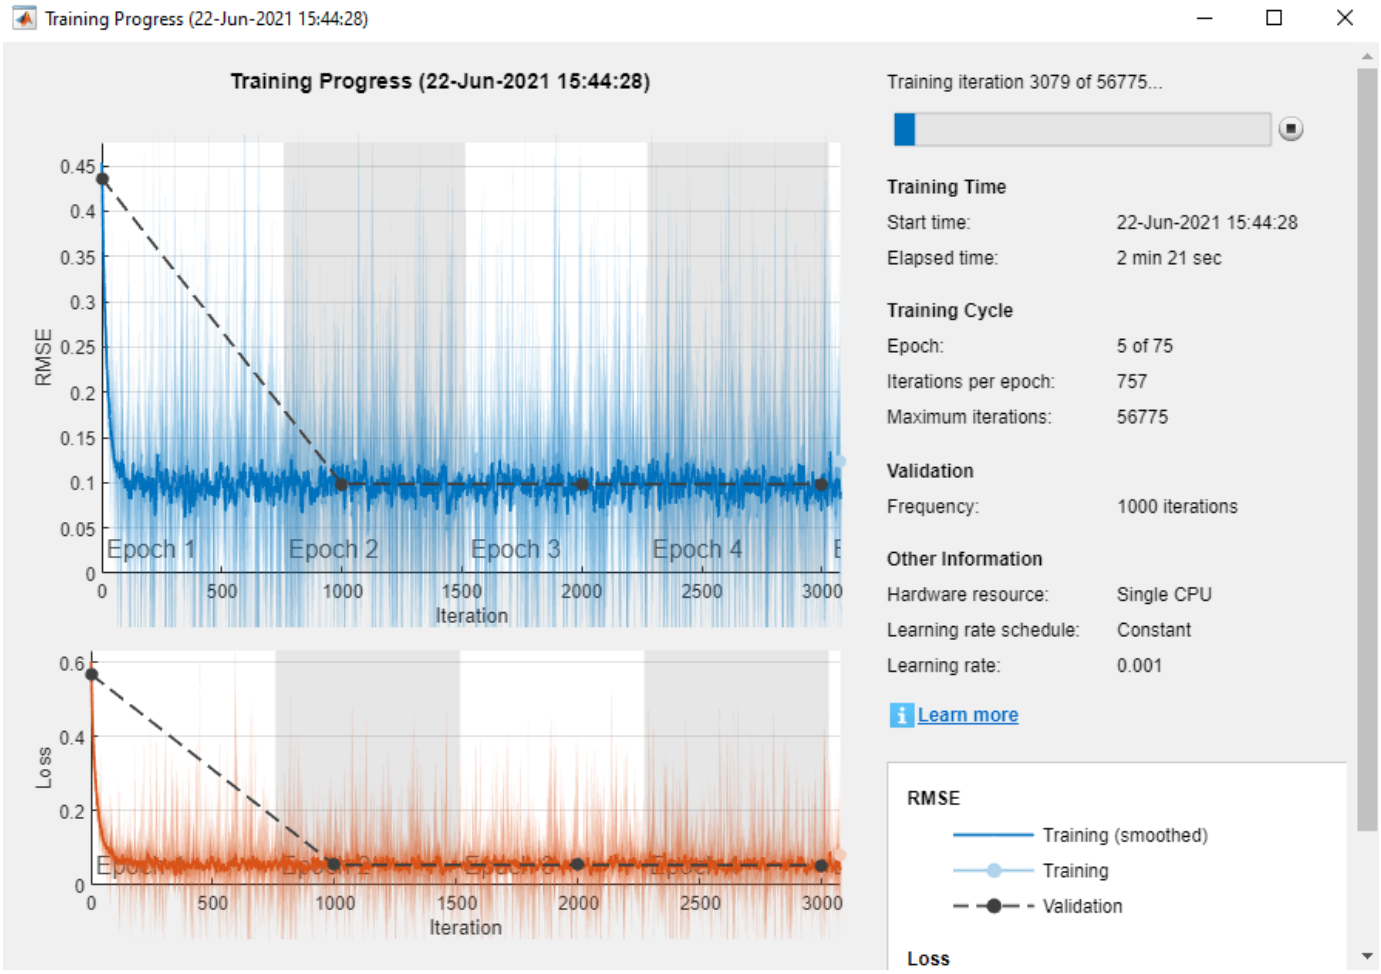
Train Network

Train the network using the architecture that yoy defined, the training data, and the training options. By default, `analyzeNetwork` uses a GPU if one is available; otherwise, it uses a CPU. Training on a GPU requires Parallel Computing Toolbox™ and a supported GPU device. For information on supported devices, see “GPU Support by Release” (Parallel Computing Toolbox). You can also specify the execution environment by using the `'ExecutionEnvironment'` name-value argument of `trainingOptions`.

To avoid waiting for the training, load pretrained networks by setting the `doTrain` flag to `false`. To train the networks using `analyzeNetwork`, set the `doTrain` flag to `true`. The Training Progress window displays progress. The training time using an NVIDIA® GeForce® RTX 2080 is about 35 minutes for 75 epochs.

```
doTrain = false;

if doTrain
    residualNetMacro = trainNetwork(tblTrain,'Default',residualLayers,options);
else
    load residualTrainedNetworkMacro.mat
end
```



Test Network

Use the `predict` function to predict the default probability of the test data using the trained networks.

```
tblTest.residualPred = predict(residualNetMacro,tblTest(:,1:end-1));
```

Plot Default Rates by Year on Books

To assess the performance of the network, use the `groupsummary` function to group the true default rates and corresponding predictions by years on the books (represented by the `YOB` variable) and calculate the mean value.

```
summaryYOB = groupsummary(tblTest,'YOB','mean',{'Default','residualPred'});
head(summaryYOB)
```

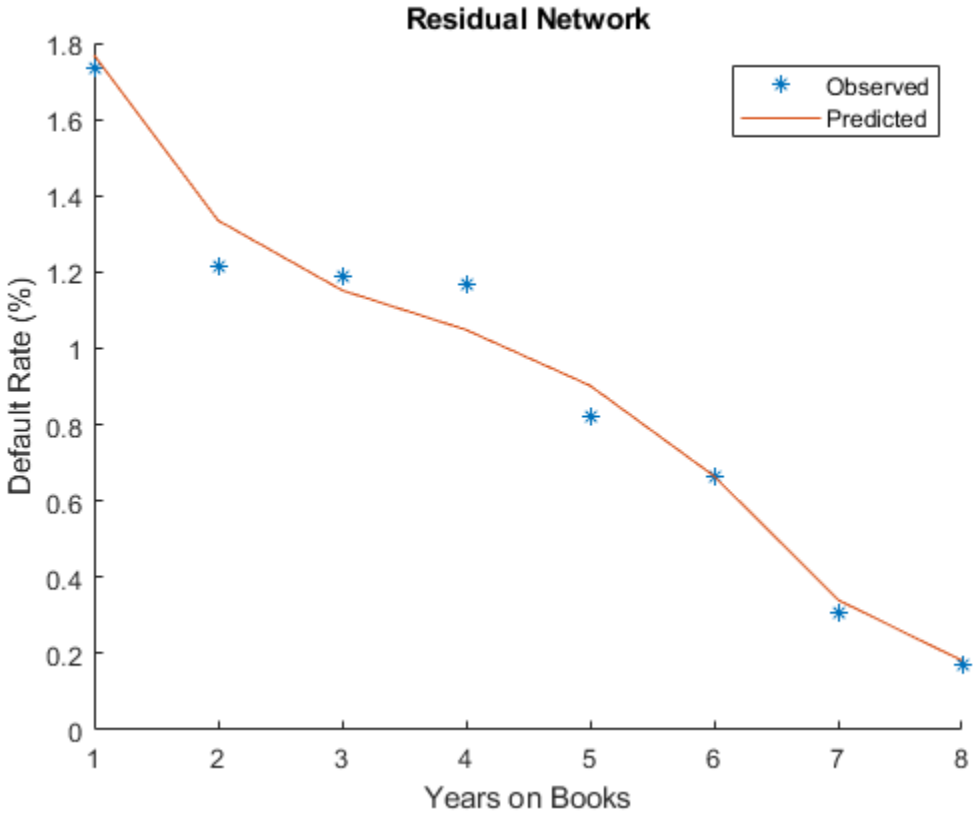
```
ans=8×4 table
    YOB    GroupCount    mean_Default    mean_residualPred
    ___    __________    ____________    _________________

     1       19364         0.017352          0.017688
     2       18917         0.012158          0.013354
     3       18526         0.011875          0.011522
```

```
    4       18232         0.011683          0.010485
    5       17925        0.0082008         0.0090247
    6       17727        0.0066565         0.0066525
    7       12294        0.0030909         0.0034051
    8        6361        0.0017293         0.0018151
```

Plot the true average default rate against the average predictions by `YOB`.

```
figure
scatter(summaryYOB.YOB,summaryYOB.mean_Default*100,'*');
hold on
plot(summaryYOB.YOB,summaryYOB.mean_residualPred*100);
hold off
title('Residual Network')
xlabel('Years on Books')
ylabel('Default Rate (%)')
legend('Observed','Predicted')
```



The plot shows a good fit on the test data. The model seems to capture the overall trend as the age of the loan (`YOB` value) increases, as well as changes in the steepness of the trend.

The rest of this example shows some ways to better understand the model. First, it reviews standard explainability techniques that you can apply to this model, specifically, the `lime` (Statistics and Machine Learning Toolbox) and `shapley` (Statistics and Machine Learning Toolbox) functions. Then, it explores the behavior of the model in new (out-of-sample) data values. Finally, the example uses the model to predict PD values under stressed macroeconomic conditions, also known as stress testing.

Explain Model with LIME and Shapley

The local interpretable model-agnostic explanations (LIME) method and the Shapley method both aim to explain the behavior of the model at a particular observation of interest or "query point." More specifically, these techniques help you to understand the importance of each variable in the prediction made for a particular observation. For more information, see `lime` (Statistics and Machine Learning Toolbox) and `shapley` (Statistics and Machine Learning Toolbox).

For illustration purposes, choose two observations from the data to better interpret the model predictions. The response values (last column) are not needed.

The first observation is a seasoned, low-risk loan. In other words, it has an initial score of `LowRisk` and eight years on the books.

```
obs1 = data(8,1:end-1);
disp(obs1)
```

YOB	GDP	Market	HighRisk	MediumRisk	LowRisk
8	1.85	9.48	0	0	1

The second observation is a new, high-risk loan. That is, the score is `HighRisk` and it is in its first year on the books.

```
obs2 = data(88,1:end-1);
disp(obs2)
```

YOB	GDP	Market	HighRisk	MediumRisk	LowRisk
1	2.72	7.61	1	0	0

Both `lime` (Statistics and Machine Learning Toolbox) and `shapley` (Statistics and Machine Learning Toolbox) require a reference data set with predictor values. This reference data can be the training data itself, or any other reference data where the model can be evaluated to explore the behavior of the model. More data points allow the explainability methods to understand the behavior of the model in more regions. However, a large data set can also slow down the computations, especially for `shapley` (Statistics and Machine Learning Toolbox). For illustration purposes, use the first 1000 rows from the training data set. The response values (last column) are not needed.

```
predictorData = data(1:1000,1:end-1);
```

`lime` (Statistics and Machine Learning Toolbox) and `shapley` (Statistics and Machine Learning Toolbox) also require a function handle to the `predict` function. Treat `predict` like a black-box model and call it multiple times to make predictions on data and gather information on the behavior of the model.

```
blackboxFcn = @(x)predict(residualNetMacro,x);
```

Create `lime` Object

Create a `lime` (Statistics and Machine Learning Toolbox) object by passing the black-box function handle and the selected predictor data.

Randomly generated synthetic data underlying `lime` (Statistics and Machine Learning Toolbox) can affect the importance. The report may change depending on the synthetic data generated. It can also

change due to optional arguments, such as the `'KernelWidth'` parameter that controls the area around the observation of interest ("query point") while you fit the local model.

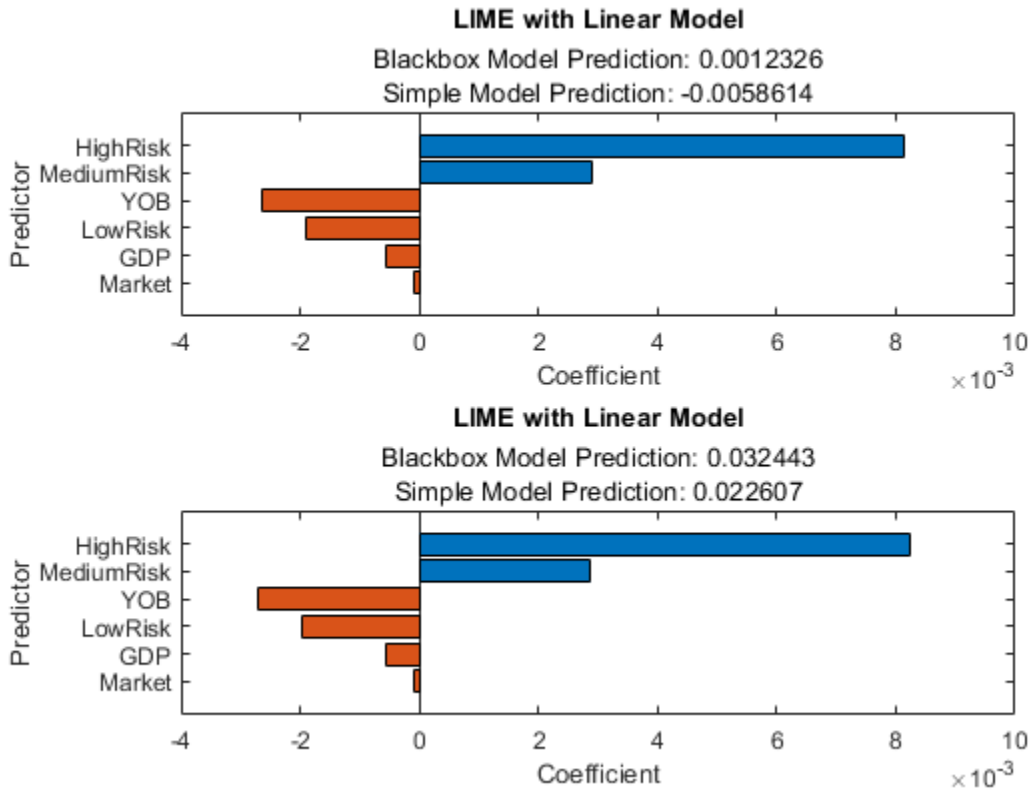
```
explainerLIME = lime(blackboxFcn,predictorData,'Type','regression');
```

Choose a number of important predictors of interest and fit a local model around the selected observations. For illustration purposes, the model contains all of the predictors.

```
numImportantPredictors = 6;
explainerObs1 = fit(explainerLIME,obs1,numImportantPredictors);
explainerObs2 = fit(explainerLIME,obs2,numImportantPredictors);
```

Plot the importance for each predictor.

```
figure
subplot(2,1,1)
plot(explainerObs1);
subplot(2,1,2)
plot(explainerObs2);
```



The `lime` (Statistics and Machine Learning Toolbox) results are quite similar for both observations. The information in the plots show that the most important variables are the `High Risk` and `Medium Risk` variables. `High Risk` and `Medium Risk` contribute positively to higher probabilities of default. On the other hand, `YOB`, `LowRisk`, `GDP`, and `Market` have a negative contribution to the default probability. The `Market` variable does not seem to contribute as much as the other variables. The values in the plots are coefficients of a simple model fitted around the point of interest, so the values can be interpreted as sensitivities of the PD to the different predictors, and these results seem to

align with expectations. For example, PD predictions decrease as the `YOB` value (age of the loan) increases, consistent with the downward trend observed in the model fit plot in the Test Network on page 17-0 section.

Create `shapley` Object

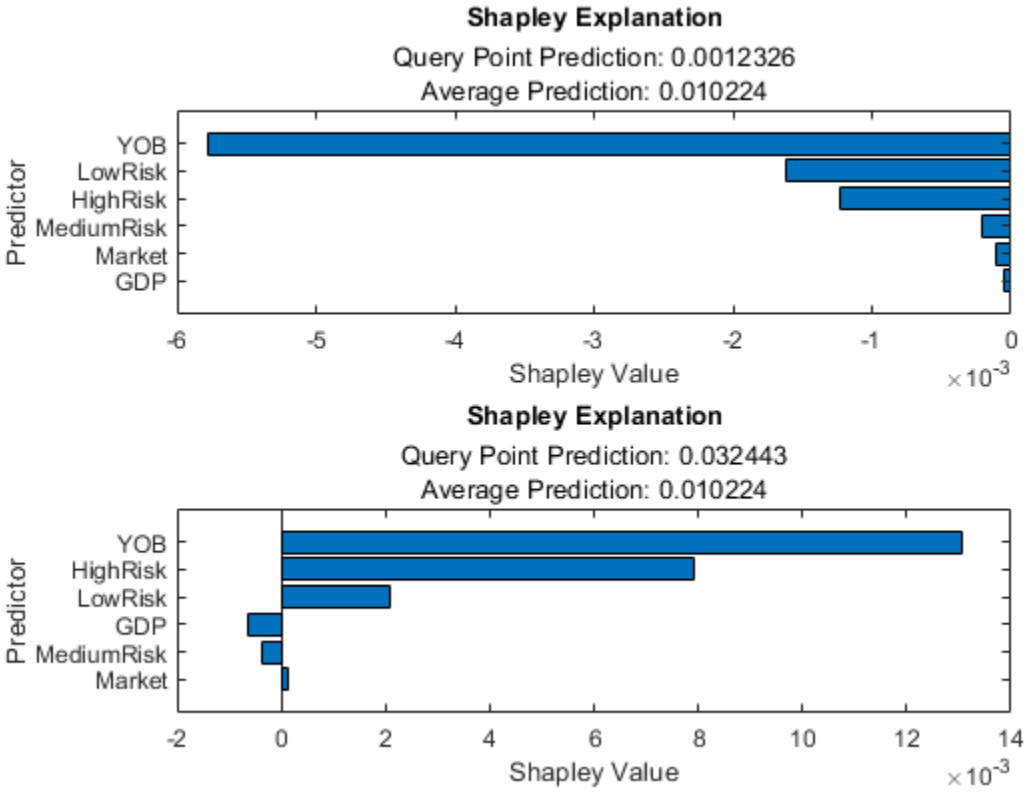
The steps for creating a `shapley` (Statistics and Machine Learning Toolbox) object are the same as for `lime` (Statistics and Machine Learning Toolbox). Create a `shapley` (Statistics and Machine Learning Toolbox) object by passing the black-box function handle and the predictor data selected previously.

The `shapley` (Statistics and Machine Learning Toolbox) analysis can also be affected by randomly generated data, and it requires different methods to control the simulations required for the analysis. For illustration purposes, create the `shapley` (Statistics and Machine Learning Toolbox) object with default settings.

```
explainerShapley = shapley(blackboxFcn,predictorData);
```

Find and plot the importance of predictors for each query point. `shapley` (Statistics and Machine Learning Toolbox) is more computationally intensive than `lime` (Statistics and Machine Learning Toolbox). As the number of rows in the predictor data increases, the computational time for the `shapley` (Statistics and Machine Learning Toolbox) results increases. For large data sets, using parallel computing is recommended (see the `'UseParallel'` option in `shapley` (Statistics and Machine Learning Toolbox)).

```
explainerShapleyObs1 = fit(explainerShapley, obs1);
explainerShapleyObs2 = fit(explainerShapley, obs2);
figure;
subplot(2,1,1)
plot(explainerShapleyObs1)
subplot(2,1,2)
plot(explainerShapleyObs2)
```



In this case, the results look different for the two observations. The `shapley` (Statistics and Machine Learning Toolbox) results explain the deviations from the average PD prediction. For the first observation, which is a very low risk observation, the predicted value is well below the average PD Therefore, all `shapley` (Statistics and Machine Learning Toolbox) values are negative, with `YOB` being the most important variable in this case, followed by `LowRisk`. For the second observation, which is a very high risk observation, most `shapley` (Statistics and Machine Learning Toolbox) values are positive, with `YOB` and `HighRisk` as the main contributors to a predicted PD well above average.

Explore Out-of-Sample Model Predictions

Splitting the original data set into training, validation, and testing helps prevent overfitting. However, the validation and test data sets share similar characteristics with the training data, for example, the range of values for `YOB`, or the observed values for the macroeconomic variables.

```
rangeYOB = [min(data.YOB) max(data.YOB)]
```

```
rangeYOB = 1×2

     1     8
```

```
rangeGDP = [min(data.GDP) max(data.GDP)]
```

```
rangeGDP = 1×2

   -0.5900    3.5700
```

```
rangeMarket = [min(data.Market) max(data.Market)]
```

```
rangeMarket = 1×2

  -22.9500   26.2400
```

You can explore the behavior of the out-of-sample (OOS) model in two different ways. First, you can predict for age values (`YOB` variable) larger than the maximum age value observed in the data. You can predict `YOB` values up to `15`. Second, you can predict for economic conditions not observed in the data either. This example uses two extremely severe macroeconomic situations, where both the `GDP` and `Market` values are very negative and outside the range of values in the data.

Start by setting up a baseline scenario where the last macroeconomic data in the sample is used as reference. The `YOB` values go out of sample for all scenarios.

```
dataBaseline = table;
dataBaseline.YOB = repmat((1:15)',3,1);
dataBaseline.GDP = zeros(size(dataBaseline.YOB));
dataBaseline.Market = zeros(size(dataBaseline.YOB));
dataBaseline.HighRisk = zeros(size(dataBaseline.YOB));
dataBaseline.MediumRisk = zeros(size(dataBaseline.YOB));
dataBaseline.LowRisk = zeros(size(dataBaseline.YOB));

dataBaseline.GDP(:) = data.GDP(8);
dataBaseline.Market(:) = data.Market(8);
dataBaseline.HighRisk(1:15) = 1;
dataBaseline.MediumRisk(16:30) = 1;
dataBaseline.LowRisk(31:45) = 1;

disp(head(dataBaseline))
```

YOB	GDP	Market	HighRisk	MediumRisk	LowRisk
1	1.85	9.48	1	0	0
2	1.85	9.48	1	0	0
3	1.85	9.48	1	0	0
4	1.85	9.48	1	0	0
5	1.85	9.48	1	0	0
6	1.85	9.48	1	0	0
7	1.85	9.48	1	0	0
8	1.85	9.48	1	0	0

Create two new extreme scenarios that include out-of-sample values not only for `YOB`, but also for the macroeconomic variables. This example uses pessimistic scenarios, but you could repeat the analysis for optimistic situations to explore the behavior of the model in either kind of extreme situation.

```
dataExtremeS1 = dataBaseline;
dataExtremeS1.GDP(:) = -1;
dataExtremeS1.Market(:) = -25;
dataExtremeS2 = dataBaseline;
dataExtremeS2.GDP(:) = -2;
dataExtremeS2.Market(:) = -40;
```

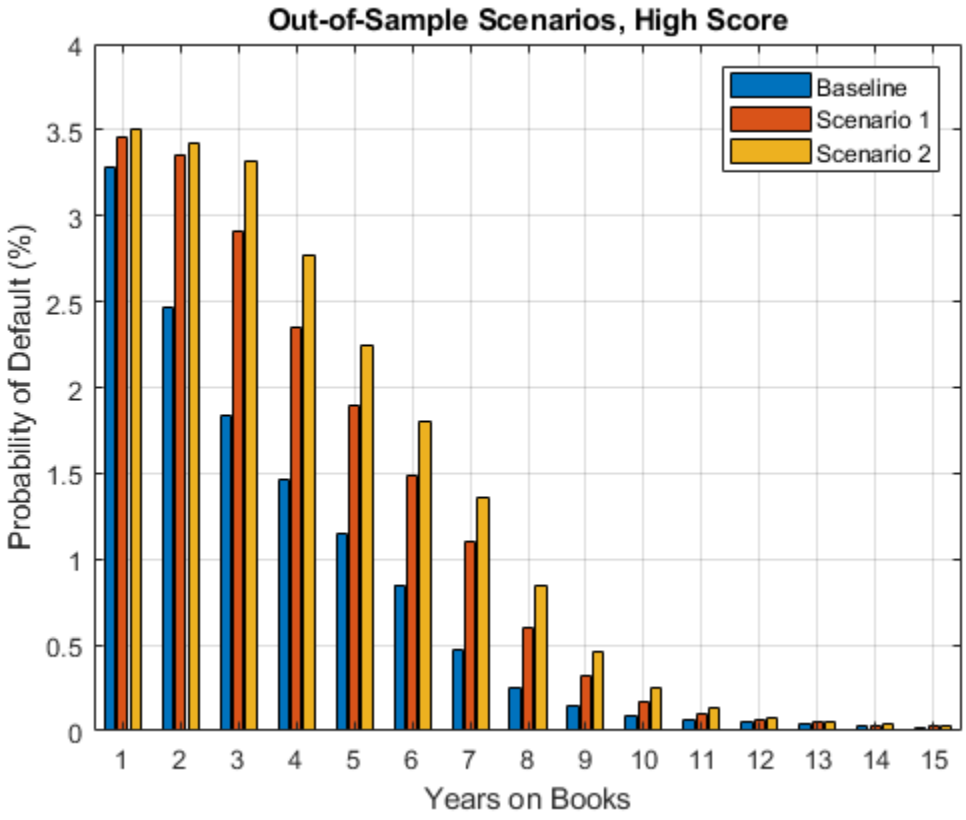
Predict PD values for all scenarios using `predict`.

```
dataBaseline.PD = predict(residualNetMacro,dataBaseline);
dataExtremeS1.PD = predict(residualNetMacro,dataExtremeS1);
dataExtremeS2.PD = predict(residualNetMacro,dataExtremeS2);
```

Visualize the results for a selected score. For convenience, the average of the PD values over the three scores is visualized as a summary.

```
ScoreSelected = High;
switch ScoreSelected
   case 'High'
      ScoreInd = dataBaseline.HighRisk==1;
      PredPDYOB = [dataBaseline.PD(ScoreInd) dataExtremeS1.PD(ScoreInd) dataExtremeS2.PD(ScoreInd
   case 'Medium'
      ScoreInd = dataBaseline.MediumRisk==1;
      PredPDYOB = [dataBaseline.PD(ScoreInd) dataExtremeS1.PD(ScoreInd) dataExtremeS2.PD(ScoreInd
   case 'Low'
      ScoreInd = dataBaseline.LowRisk==1;
      PredPDYOB = [dataBaseline.PD(ScoreInd) dataExtremeS1.PD(ScoreInd) dataExtremeS2.PD(ScoreInd
   case 'Average'
      PredPDYOBBase = groupsummary(dataBaseline,'YOB','mean','PD');
      PredPDYOBS1 = groupsummary(dataExtremeS1,'YOB','mean','PD');
      PredPDYOBS2 = groupsummary(dataExtremeS2,'YOB','mean','PD');
      PredPDYOB = [PredPDYOBBase.mean_PD PredPDYOBS1.mean_PD PredPDYOBS2.mean_PD];
end

figure;
bar(PredPDYOB*100);
xlabel('Years on Books')
ylabel('Probability of Default (%)')
legend('Baseline','Scenario 1','Scenario 2')
title(strcat("Out-of-Sample Scenarios, ",ScoreSelected," Score"))
grid on
```



The overall results are in line with expectations, since the PD values decrease as the `YOB` value increases, and worse economic conditions result in higher PD values. However, the relative increase of the predicted PD values shows an interesting result. For `Low` and `Medium` scores, there is a significant increase for the first year on books (`YOB = 1`). In contrast, for `High` scores, the relative increase from baseline, to the first extreme scenario, then to the second extreme case, is small. This result suggests an implicit upper limit in the predicted values in the structure of the model. The extreme scenarios in this exercise seem unlikely to occur, however, for extreme but plausible scenarios, this behavior would require investigation with stress testing.

Stress-Test Predicted Probabilities of Default (PD)

Because the model includes macroeconomic variables, it can be used to perform a stress-testing analysis (see for example [2 on page 17-0], [3 on page 17-0] on page 17-0 , [4 on page 17-0]). The steps are similar to the previous section except that the scenarios are plausible scenarios set periodically at an institution level, or set by regulators to be used by all institutions.

The `dataMacroStress` data set contains three scenarios for the stress testing of the model, namely, baseline, adverse, and severely adverse scenarios. The adverse and severe scenarios are relative to the baseline scenario, and the macroeconomic conditions are are plausible given the baseline. These scenarios fall within the range of values observed in the data used for training and validation. The stress testing of the PD values for given macroeconomic scenarios is conceptually different from the exercise in the previous section, where the focus is on exploring the behavior of the model on out-of-sample data, regardless of how plausible those extreme scenarios are from an economic point of view.

Following the prior steps, you generate PD predictions for each score level and each scenario.

```
dataBaselineStress = dataBaseline(:,1:end-1);
dataAdverse = dataBaselineStress;
dataSevere = dataBaselineStress;

dataBaselineStress.GDP(:) = dataMacroStress{'Baseline','GDP'};
dataBaselineStress.Market(:) = dataMacroStress{'Baseline','Market'};

dataAdverse.GDP(:) = dataMacroStress{'Adverse','GDP'};
dataAdverse.Market(:) = dataMacroStress{'Adverse','Market'};

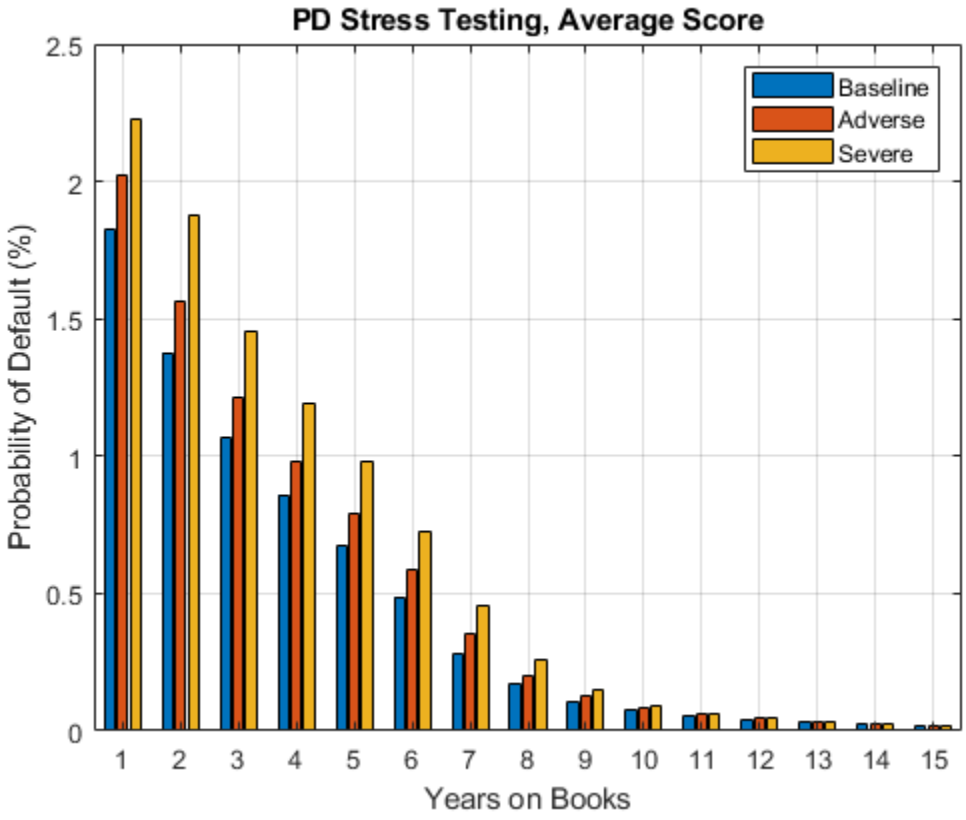
dataSevere.GDP(:) = dataMacroStress{'Severe','GDP'};
dataSevere.Market(:) = dataMacroStress{'Severe','Market'};
```

Use the `predict` function to predict PD values for all scenarios. Visualize the results for a selected score.

```
dataBaselineStress.PD = predict(residualNetMacro,dataBaselineStress);
dataAdverse.PD = predict(residualNetMacro,dataAdverse);
dataSevere.PD = predict(residualNetMacro,dataSevere);

ScoreSelected = Average;
switch ScoreSelected
   case 'High'
      ScoreInd = dataBaselineStress.HighRisk==1;
      PredPDYOBStress = [dataBaselineStress.PD(ScoreInd) dataAdverse.PD(ScoreInd) dataSevere.PD(S
   case 'Medium'
      ScoreInd = dataBaselineStress.MediumRisk==1;
      PredPDYOBStress = [dataBaselineStress.PD(ScoreInd) dataAdverse.PD(ScoreInd) dataSevere.PD(S
   case 'Low'
      ScoreInd = dataBaselineStress.LowRisk==1;
      PredPDYOBStress = [dataBaselineStress.PD(ScoreInd) dataAdverse.PD(ScoreInd) dataSevere.PD(S
   case 'Average'
      PredPDYOBBaseStress = groupsummary(dataBaselineStress,'YOB','mean','PD');
      PredPDYOBAdverse = groupsummary(dataAdverse,'YOB','mean','PD');
      PredPDYOBSevere = groupsummary(dataSevere,'YOB','mean','PD');
      PredPDYOBStress = [PredPDYOBBaseStress.mean_PD PredPDYOBAdverse.mean_PD PredPDYOBSevere.mea
end

figure;
bar(PredPDYOBStress*100);
xlabel('Years on Books')
ylabel('Probability of Default (%)')
legend('Baseline','Adverse','Severe')
title(strcat("PD Stress Testing, ",ScoreSelected," Score"))
grid on
```



The overall results are in line with expectations. As in the Explore Out-of-Sample Model Predictions on page 17-0 section, the predictions for the `High` score in the first year on books (`YOB = 1`) needs to be reviewed, since the relative increase in the predicted PD from one scenario to the next seems smaller than for other scores and loan ages. All other predictions show a reasonable pattern that are consistent with expectations.

Hedging an Option Using Reinforcement Learning Toolbox

This example shows how to learn an optimal option hedging policy and outperform the traditional BSM approach using Reinforcement Learning Toolbox™ .

Option Modeling Using Black-Scholes-Merton Model

The Black-Scholes-Merton (BSM) model, which earned its creators a Nobel Prize in Economics in 1997, provides a modeling framework for pricing and analyzing financial derivatives or options. Options are financial instruments that derive their value from a particular underlying asset. The concept of *dynamic hedging* is fundamental to the BSM model. Dynamic hedging is the idea that, by continuously buying and selling shares in the relevant underlying asset, you can hedge the risk of the derivative instrument such that the risk is zero. This "risk-neutral" pricing framework is used to derive pricing formulae for many different financial instruments.

The simplest financial derivative is a European call option, which provides the buyer with the right, but not the obligation, to buy the underlying asset at a previously specified value (strike price) at a previously specified time (maturity).

You can use a BSM model to price a European call option. The BSM model makes the following simplifying assumptions:

- The behavior of the underlying asset is defined by geometric Brownian motion (GBM).
- There are no transaction costs.
- Volatility is constant.

The BSM dynamic hedging strategy is also called "delta-hedging," after the quantity *Delta*, which is the sensitivity of the option with respect to the underlying asset. In an environment that meets the previously stated BSM assumptions, using a delta-hedging strategy is an optimal approach to hedging an option. However, it is well-known that in an environment with transaction costs, the use of the BSM model leads to an inefficient hedging strategy. The goal of this example is to use Reinforcement Learning Toolbox™ to learn a strategy that outperforms the BSM hedging strategy, in the presence of transaction costs.

The goal of reinforcement learning (RL) is to train an agent to complete a task within an unknown environment. The agent receives observations and a reward from the environment and sends actions to the environment. The reward is a measure of how successful an action is with respect to completing the task goal.

The agent contains two components: a policy and a learning algorithm.

- The policy is a mapping that selects actions based on the observations from the environment. Typically, the policy is a function approximator with tunable parameters, such as a deep neural network.
- The learning algorithm continuously updates the policy parameters based on the actions, observations, and reward. The goal of the learning algorithm is to find an optimal policy that maximizes the cumulative reward received during the task.

In other words, reinforcement learning involves an agent learning the optimal behavior through repeated trial-and-error interactions with the environment without human involvement. For more information on reinforcement learning, see “What Is Reinforcement Learning?” (Reinforcement Learning Toolbox).

Cao [2 on page 17-0] describes the setup for reinforcement learning as:

- S_i is the state at time i.
- A_i is the action taken at i.
- R_{i+1} is the resulting reward at time $i + 1$.

The aim of reinforcement learning is to maximize expected future rewards. In this financial application of reinforcement learning, maximizing expected rewards is learning a delta-hedging strategy as an optimal approach to hedging a European call option.

This example follows the framework outlined in Cao [2 on page 17-0]. Specifically, an accounting profit and loss (P&L) formulation from that paper is used to set up the reinforcement learning problem and a deep deterministic policy gradient (DDPG) agent is used. This example does not exactly reproduce the approach from [2 on page 17-0] because Cao *et. al.* recommend a Q-learning approach with two separate Q-functions (one for the hedging cost and one for the expected square of the hedging cost), but this example uses instead a simplified reward function.

Define Training Parameters

Next, specify an at-the-money option with three months to maturity is hedged. For simplicity, both the interest rate and dividend yield are set to `0`.

```
% Option parameters
Strike = 100;
Maturity = 21*3/250;

% Asset parameters
SpotPrice = 100;
ExpVol = .2;
ExpReturn = .05;

% Simulation parameters
rfRate = 0;
dT = 1/250;
nSteps = Maturity/dT;
nTrials = 5000;

% Transacation cost and cost function parameters
c = 1.5;
kappa = .01;
InitPosition = 0;

% Set the random generator seed for reproducibility.
rng(3)
```

Define Environment

In this section, the action and observation parameters, `actInfo` and `obsInfo`. The agent action is the current `hedge` value which can range between `0` and `1`. There are three variables in the agent observation:

- Moneyness (ratio of the spot price to the strike price)
- Time to maturity
- Position or amount of the underlying asset that is held

```
ObservationInfo             = rlNumericSpec([3 1],'LowerLimit',0,'UpperLimit',[10 Maturity 1]');
ObservationInfo.Name        = 'Hedging State';
ObservationInfo.Description = ['Moneyness', 'TimeToMaturity','Position'];

ActionInfo = rlNumericSpec([1 1],'LowerLimit',0,'UpperLimit',1);
ActionInfo.Name = 'Hedge';
```

Define Reward

From Cao [2 on page 17-0], the accounting P&L formulation and rewards (negative costs) are

$R_{i+1} = V_{i+1} - V_i + H_{i+1}(S_{i+1} - S_i) - \kappa|S_{i+1}(H_{i+1} - H_i)|$

where

R_i: Reward

V_i: Value of option

S_i: Spot price of underlying asset

H_i: Holding

κ: Transaction costs

A final reward at the last time step liquidates the hedge that is $\kappa|S_n(H_n)|$.

In this implementation, the reward (R_i) is penalized by the square of the reward multiplied by a constant to punish large swings in the value of the hedged position:

$R_{i+1} = R_{i+1} - c(R_{i+1})^2$

The reward is defined in `stepFcn` which is called at each step of the simulation.

```
env = rlFunctionEnv(ObservationInfo,ActionInfo, ...
    @(Hedge, LoggedSignals) stepFcn(Hedge,LoggedSignals,rfRate,ExpVol,dT,Strike,ExpReturn,c,kappa
    @() resetFcn(SpotPrice/Strike,Maturity,InitPosition));

obsInfo = getObservationInfo(env);
actInfo = getActionInfo(env);
```

Create Environment Interface for RL Agent

Create the DDPG agent using `rlDDPGAgent` (Reinforcement Learning Toolbox). While it is possible to create custom actor and critic networks, this example uses the default networks.

```
initOpts = rlAgentInitializationOptions('NumHiddenUnit',64);

agent = rlDDPGAgent(obsInfo,actInfo,initOpts);

critic = getCritic(agent);
critic.Options.LearnRate = 1e-4;
% critic.Options.UseDevice = "gpu";
agent  = setCritic(agent,critic);

actor = getActor(agent);
```

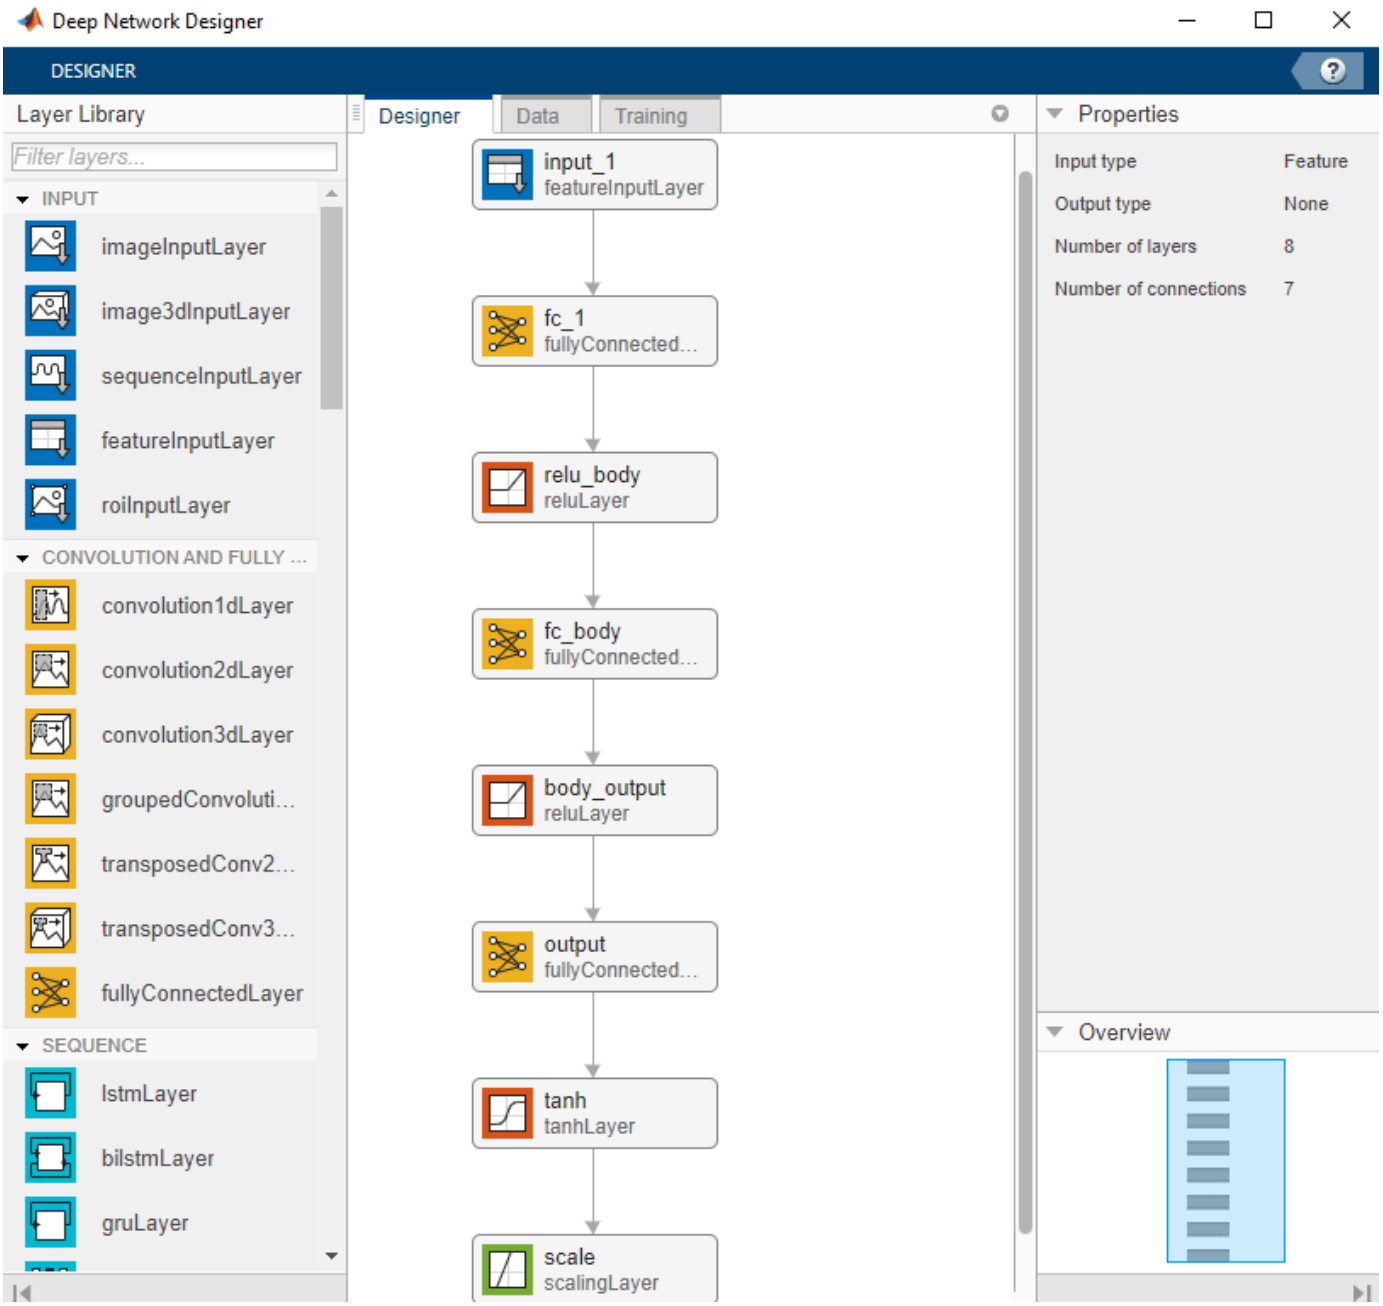
```
actor.Options.LearnRate = 1e-4;
% actor.Options.UseDevice = "gpu";
agent  = setActor(agent,actor);

agent.AgentOptions.DiscountFactor = .9995;
agent.AgentOptions.TargetSmoothFactor = 5e-4;
```

Visualize Actor and Critic Networks

Visualize the actor and critic networks using the Deep Network Designer.

```
deepNetworkDesigner(layerGraph(getModel(actor)))
```



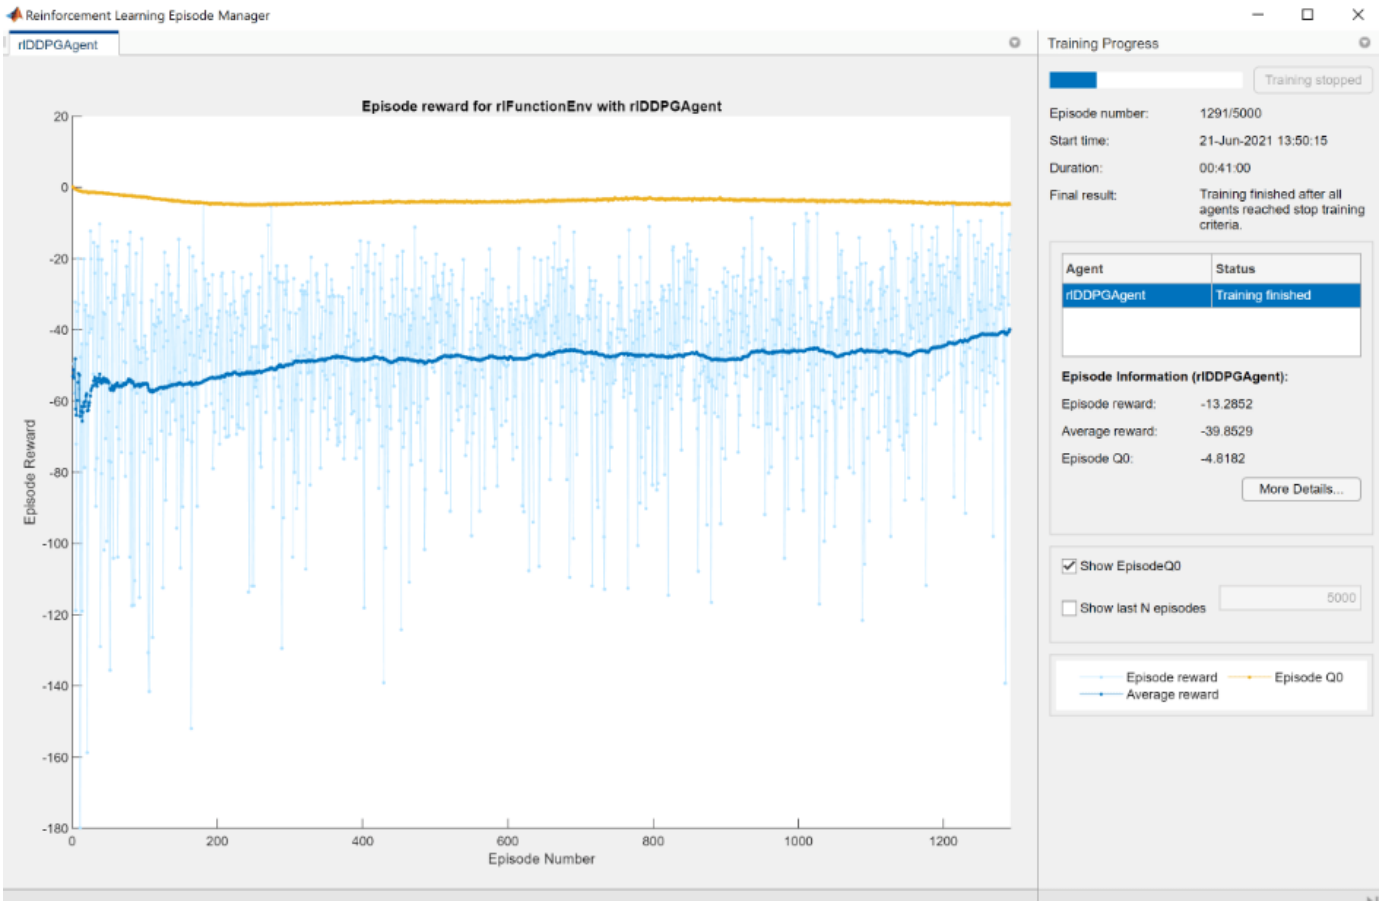
Train Agent

Train the agent using the `train` (Reinforcement Learning Toolbox) function.

```
trainOpts = rlTrainingOptions( ...
    'MaxEpisodes', nTrials, ...
    'MaxStepsPerEpisode',nSteps, ...
    'Verbose', false, ...
    'ScoreAveragingWindowLength',200,...
    'StopTrainingCriteria',"AverageReward", ...
    'StopTrainingValue',-40, ...
    'StopOnError',"on", ...
    "UseParallel",false);

doTraining = false;
if doTraining
    % Train the agent.
    trainingStats = train(agent,env,trainOpts);
else
    % Load the pretrained agent for the example.
    load('DeepHedgingDDPG.mat','agent')
end
```

To avoid waiting for the training, load pretrained networks by setting the `doTraining` flag to `false`. If you set `doTraining` to `true`, the Reinforcement Learning Episode Manager displays the training progress.



Validate Agent

Use the Financial Toolbox™ functions `blsdelta` (Financial Toolbox) and `blsprice` (Financial Toolbox) for a coventional approach to caculate the price as a European call option. When comparing the conventional approach to the RL approach, the results are similar to the findings of Cao [2 on page 17-0] in Exhibit 4. This example demonstrates that the RL approach significantly reduces hedging costs.

```
% Simulation parameters
nTrials = 1000;

policy_BSM = @(mR,TTM,Pos) blsdelta(mR,1,rfRate,max(TTM,eps),ExpVol);
policy_RL = @(mR,TTM,Pos) arrayfun(@(mR,TTM,Pos) cell2mat(getAction(agent,[mR TTM Pos])),mR,TTM,

OptionPrice = blsprice(SpotPrice,Strike,rfRate,Maturity,ExpVol);

Costs_BSM = computeCosts(policy_BSM,nTrials,nSteps,SpotPrice,Strike,Maturity,rfRate,ExpVol,InitPo
Costs_RL = computeCosts(policy_RL,nTrials,nSteps,SpotPrice,Strike,Maturity,rfRate,ExpVol,InitPosi

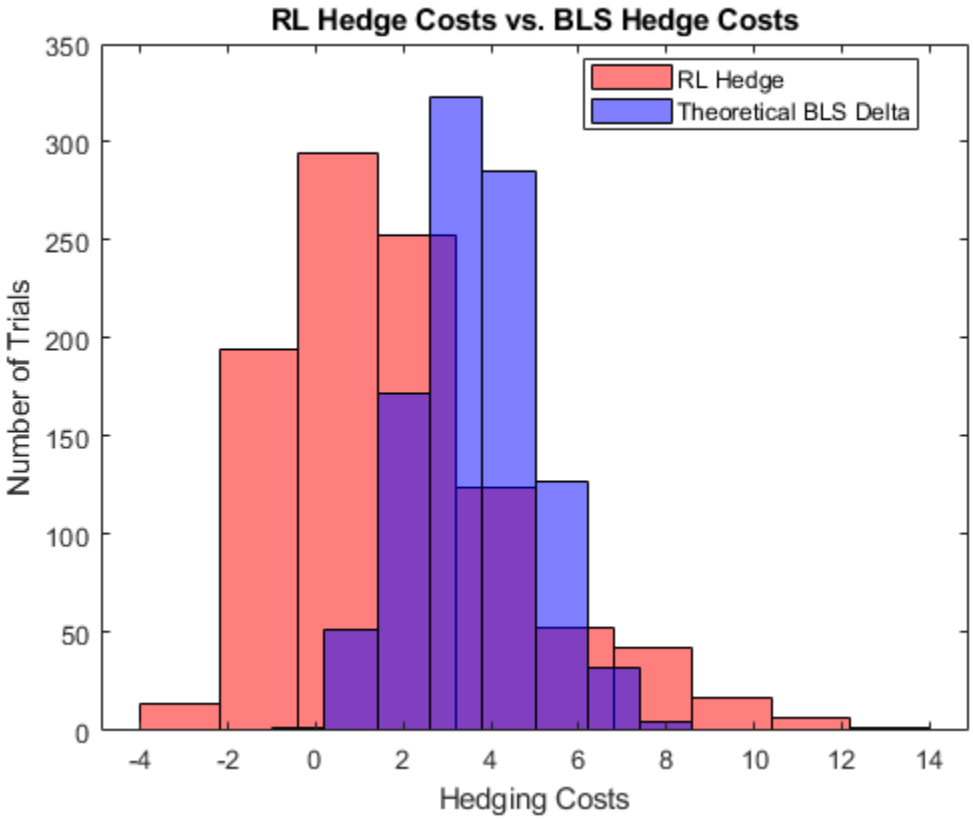
HedgeComp = table(100*[-mean(Costs_BSM) std(Costs_BSM)]'/OptionPrice, ...
    100*[-mean(Costs_RL) std(Costs_RL)]'/OptionPrice, ...
    'RowNames',["Average Hedge Cost (% of Option Price)","STD Hedge Cost (% of Option Price)"],
    'VariableNames',["BSM","RL"]);
disp(HedgeComp)
```

```
                                          BSM        RL
                                        _______    _______

    Average Hedge Cost (% of Option Price)    91.259    47.022
    STD Hedge Cost (% of Option Price)        35.712    68.119
```

The following histogram shows the range of different hedging costs for both approaches. The RL approach performs better, but with a larger variance than the BSM approach. The RL appraoch in this example would likely benefit from the two Q-function approach that Cao [2 on page 17-0] discusses and implements.

```
figure
numBins = 10;
histogram(-Costs_RL,numBins,'FaceColor','r','FaceAlpha',.5)
hold on
histogram(-Costs_BSM,numBins,'FaceColor','b','FaceAlpha',.5)
xlabel('Hedging Costs')
ylabel('Number of Trials')
title('RL Hedge Costs vs. BLS Hedge Costs')
legend('RL Hedge','Theoretical BLS Delta','location','best')
```



A plot of the hedge Ratio with respect to moneyness shows the differences between the BSM and RL approaches. As discussed in Cao [2 on page 17-0], in the presence of transaction costs, the agent learns that "when delta hedging would require shares to be purchased, it tends to be optimal for a trader to be underhedged relative to delta. Similarly, when delta hedging would require shares to be sold, it tends to be optimal for a trader to be over-hedged relative to delta."

```
policy_RL_mR = @(mR,TTM,Pos) cell2mat(getAction(agent,[mR TTM Pos]));
mRange = (.8:.01:1.2)';

figure
t_plot = 2/12;
plot(mRange,blsdelta(mRange,1,rfRate,t_plot,ExpVol),'b')
hold on
plot(mRange,arrayfun(@(mR) policy_RL_mR(mR,t_plot,blsdelta(mR,1,rfRate,t_plot,ExpVol)),mRange),'
plot(mRange,arrayfun(@(mR) policy_RL_mR(mR,t_plot,blsdelta(mR+.1,1,rfRate,t_plot,ExpVol)),mRange
plot(mRange,arrayfun(@(mR) policy_RL_mR(mR,t_plot,blsdelta(mR-.1,1,rfRate,t_plot,ExpVol)),mRange
legend('Theoretical BLS Delta','RL Hedge -- ATM','RL Hedge -- Selling','RL Hedge -- Buying', ...
    'location','best')
xlabel('Moneyness')
ylabel('Hedge Ratio')
title('RL Hedge vs. BLS Delta for TTM of 2/12')
```

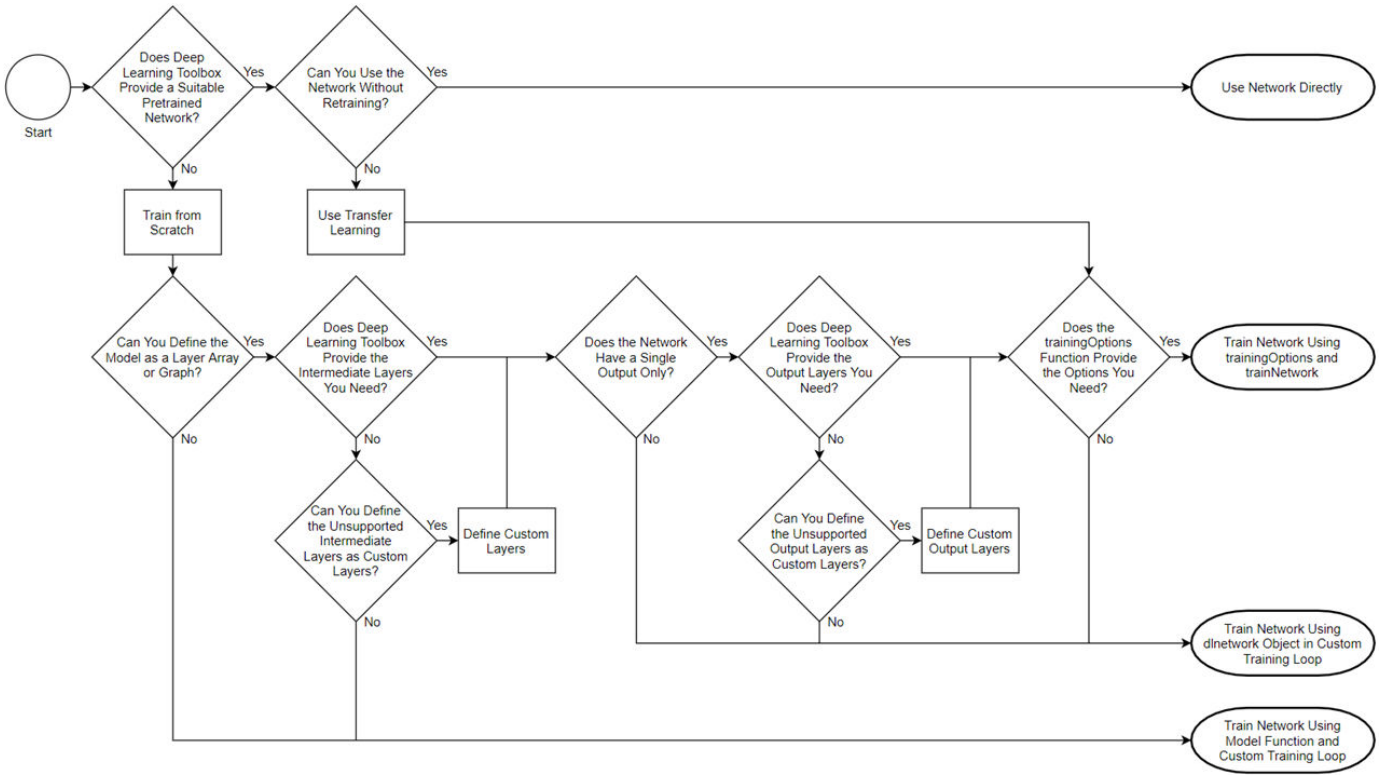
Import, Export, and Customization

Train Deep Learning Model in MATLAB

You can train and customize a deep learning model in various ways—for example, you can retrain a pretrained model with new data (transfer learning), train a network from scratch, or define a deep learning model as a function and use a custom training loop. Use this flow chart to choose the training method that is best suited for your task.



Tip For information on computer vision workflows, including for object detection, see “Computer Vision Using Deep Learning”. For information on importing networks and network architectures from TensorFlow-Keras, Caffe, and the ONNX (Open Neural Network Exchange) model format, see “Deep Learning Import and Export”.

Training Methods

This table provides information about the different training methods.

Method	More Information
Use network directly	If a pretrained network already performs the task you require, then you do not need to retrain the network. Instead, you can make predictions with the network directly by using the `classify` and `predict` functions. For an example, see “Classify Image Using GoogLeNet” on page 3-23.
Train network using `trainingOptions` and `trainNetwork`	If you have a network specified as a layer array or layer graph, and the `trainingOptions` function provides all the options you need, then you can train the network using the `trainNetwork` function. For an example showing how to retrain a network (transfer learning), see “Train Deep Learning Network to Classify New Images” on page 3-6. For an example showing how to train a network from scratch, see “Create Simple Deep Learning Network for Classification” on page 3-47.
Train network using `dlnetwork` object and custom training loop	For most tasks, you can control the training algorithm details using the `trainingOptions` and `trainNetwork` functions. If the `trainingOptions` function does not provide the options you need for your task (for example, a custom learning rate schedule), then you can define your own custom training loop using a `dlnetwork` object. A `dlnetwork` object allows you to train a network specified as a layer graph using automatic differentiation. For loss functions that cannot be specified using an output layer, you can specify the loss in a custom training loop. For an example showing how to train a network with a custom learning rate schedule, see “Train Network Using Custom Training Loop” on page 18-225. To learn, more see “Define Custom Training Loops, Loss Functions, and Networks” on page 18-209.

Method	More Information
Train network using model function and custom training loop	For networks that cannot be created using layer graphs, you can define a custom network as a function. For an example showing how to train a deep learning model defined as a function, see “Train Network Using Model Function” on page 18-259. If you can create parts of the network using a layer graph, then you can define those parts as layer graphs and the unsupported parts using model functions.

Decisions

This table provides more information on each decision in the flow chart.

Decision	More Information
Does Deep Learning Toolbox provide a suitable pretrained network?	For most tasks, you can use or retrain a pretrained network such as `googlenet`. For a list of pretrained deep learning networks in MATLAB, see “Pretrained Deep Neural Networks” on page 1-8. You can use pretrained networks directly with new data, or you can retrain them with new data for different tasks using transfer learning.
Can you use the network without retraining?	If a pretrained network already performs the task you need, then you can use the network directly without retraining. For example, you can use the `googlenet` network to classify images in 1000 classes. To make predictions with the network directly, use the `classify` and `predict` functions. For an example, see “Classify Image Using GoogLeNet” on page 3-23. If you need to retrain the network—for example, to classify a different set of classes—then you can retrain the network using transfer learning.

Decision	More Information
Can you define the model as a layer array or graph?	You can specify most deep learning models as a layer array or layer graph. In other words, you can define the model as a collection of layers with layer outputs connected to other layer inputs. Some network architectures cannot be defined as a layer graph. For example, Siamese networks require weight sharing and cannot be defined as a layer graph. For these networks, you must define the model as a function. For an example, see “Train Network Using Model Function” on page 18-259.
Does the network have a single output only?	For networks with multiple outputs, you must train the network using a custom training loop. For an example, see “Train Network with Multiple Outputs” on page 3-61.
Does Deep Learning Toolbox provide the intermediate layers you need?	Deep Learning Toolbox provides many different layers for deep learning tasks. For a list of layers, see “List of Deep Learning Layers” on page 1-21. If Deep Learning Toolbox provides the intermediate layers (layers in the middle of the network) that you need, then you can define the network as a layer array or layer graph using these layers. Otherwise, try defining any unsupported layers as custom layers. For more information, see “Define Custom Deep Learning Layers” on page 18-9.
Can you define the unsupported intermediate layers as custom layers?	If Deep Learning Toolbox does not provide the layer you need, then you can try defining a custom deep learning layer. For more information, see “Define Custom Deep Learning Layers” on page 18-9. If you can define custom layers for any unsupported layers, then you can include these custom layers in a layer array or layer graph. Otherwise, specify the deep learning model using a function and train the model using a custom training loop. For an example, see “Train Network Using Model Function” on page 18-259.

Decision	More Information
Does Deep Learning Toolbox provide the output layers you need?	Output layers specify the loss function used for training. Deep Learning Toolbox provides different output layers for deep learning tasks. For example, `classificationLayer` and `regressionLayer`. For a list of output layers, see the "Output Layers" on page 1-28 section in the page "List of Deep Learning Layers" on page 1-21. If Deep Learning Toolbox provides the output layers that you need, then you can define a layer graph using these layers. Otherwise, try defining any unsupported output layers as a custom layer. For more information, see "Define Custom Deep Learning Layers" on page 18-9.
Can you define the unsupported output layers as custom layers?	If Deep Learning Toolbox does not provide the output layer you need, then you can try defining a custom output layer. For more information, see "Define Custom Deep Learning Layers" on page 18-9. If you can define a custom output layer for any unsupported output layers, then you can include these custom layers in a layer array or layer graph. Otherwise, train the model using a `dlnetwork` object and a custom training loop, and specify a custom loss function. For an example, see "Train Network Using Custom Training Loop" on page 18-225.
Does the `trainingOptions` function provide the options you need?	The `trainingOptions` function provides many options for customizing a the training process. If the `trainingOptions` function provides all the options you need for training, then you can train the deep learning network using the `trainNetwork` function. For an example, see "Create Simple Deep Learning Network for Classification" on page 3-47. If the `trainingOptions` function does not provide the training option you need, for example, a custom learning rate schedule, then you can define a custom training loop using a `dlnetwork` object. For an example, see "Train Network Using Custom Training Loop" on page 18-225.

Define Custom Deep Learning Layers

Tip This topic explains how to define custom deep learning layers for your problems. For a list of built-in layers in Deep Learning Toolbox, see “List of Deep Learning Layers” on page 1-21.

You can define your own custom deep learning layers for your task. You can specify a custom loss function using a custom output layer and define custom layers with or without learnable and state parameters. After defining a custom layer, you can check that the layer is valid, GPU compatible, and outputs correctly defined gradients.

This topic explains the architecture of deep learning layers and how to define custom layers to use for your tasks.

Type	Description
Intermediate layer	Define a custom deep learning layer and specify optional learnable parameters and state parameters. For more information, see “Define Custom Deep Learning Intermediate Layers” on page 18-16. For an example showing how to define a custom layer with learnable parameters, see “Define Custom Deep Learning Layer with Learnable Parameters” on page 18-35. For an example showing how to define a custom layer with multiple inputs, see “Define Custom Deep Learning Layer with Multiple Inputs” on page 18-48.
Classification output layer	Define a custom classification output layer and specify a loss function. For more information, see “Define Custom Deep Learning Output Layers” on page 18-29. For an example showing how to define a custom classification output layer and specify a loss function, see “Define Custom Classification Output Layer” on page 18-91.
Regression output layer	Define a custom regression output layer and specify a loss function. For more information, see “Define Custom Deep Learning Output Layers” on page 18-29. For an example showing how to define a custom regression output layer and specify a loss function, see “Define Custom Regression Output Layer” on page 18-99.

Layer Templates

You can use the following templates to define new layers.

Intermediate Layer Template

This template outlines the structure of an intermediate layer. For more information, see “Define Custom Deep Learning Intermediate Layers” on page 18-16.

For an example showing how to define a layer with learnable parameters, see “Define Custom Deep Learning Layer with Learnable Parameters” on page 18-35.

```
classdef myLayer < nnet.layer.Layer % & nnet.layer.Formattable (Optional)

    properties
        % (Optional) Layer properties.

        % Declare layer properties here.
    end

    properties (Learnable)
        % (Optional) Layer learnable parameters.

        % Declare learnable parameters here.
    end

    properties (State)
        % (Optional) Layer state parameters.

        % Declare state parameters here.
    end

    properties (Learnable, State)
        % (Optional) Nested dlnetwork objects with both learnable
        % parameters and state.

        % Declare nested networks with learnable and state parameters here.
    end

    methods
        function layer = myLayer()
            % (Optional) Create a myLayer.
            % This function must have the same name as the class.

            % Define layer constructor function here.
        end

        function [Z,state] = predict(layer,X)
            % Forward input data through the layer at prediction time and
            % output the result and updated state.
            %
            % Inputs:
            %         layer - Layer to forward propagate through
            %         X     - Input data
            % Outputs:
            %         Z     - Output of layer forward function
            %         state - (Optional) Updated layer state.
            %
            %  - For layers with multiple inputs, replace X with X1,...,XN,
            %    where N is the number of inputs.
            %  - For layers with multiple outputs, replace Z with
            %    Z1,...,ZM, where M is the number of outputs.
            %  - For layers with multiple state parameters, replace state
            %    with state1,...,stateK, where K is the number of state
            %    parameters.

            % Define layer predict function here.
        end
```

```
        function [Z,state,memory] = forward(layer,X)
            % (Optional) Forward input data through the layer at training
            % time and output the result, updated state, and a memory
            % value.
            %
            % Inputs:
            %         layer - Layer to forward propagate through
            %         X     - Layer input data
            % Outputs:
            %         Z      - Output of layer forward function
            %         state  - (Optional) Updated layer state
            %         memory - (Optional) Memory value for custom backward
            %                  function
            %
            %  - For layers with multiple inputs, replace X with X1,...,XN,
            %    where N is the number of inputs.
            %  - For layers with multiple outputs, replace Z with
            %    Z1,...,ZM, where M is the number of outputs.
            %  - For layers with multiple state parameters, replace state
            %    with state1,...,stateK, where K is the number of state
            %    parameters.

            % Define layer forward function here.
        end

        function layer = resetState(layer)
            % (Optional) Reset layer state.

            % Define reset state function here.
        end

        function [dLdX,dLdW,dLdSin] = backward(layer,X,Z,dLdZ,dLdSout,memory)
            % (Optional) Backward propagate the derivative of the loss
            % function through the layer.
            %
            % Inputs:
            %         layer   - Layer to backward propagate through
            %         X       - Layer input data
            %         Z       - Layer output data
            %         dLdZ    - Derivative of loss with respect to layer
            %                   output
            %         dLdSout - (Optional) Derivative of loss with respect
            %                   to state output
            %         memory  - Memory value from forward function
            % Outputs:
            %         dLdX   - Derivative of loss with respect to layer input
            %         dLdW   - (Optional) Derivative of loss with respect to
            %                  learnable parameter
            %         dLdSin - (Optional) Derivative of loss with respect to
            %                  state input
            %
            %  - For layers with state parameters, the backward syntax must
            %    include both dLdSout and dLdSin, or neither.
            %  - For layers with multiple inputs, replace X and dLdX with
            %    X1,...,XN and dLdX1,...,dLdXN, respectively, where N is
            %    the number of inputs.
            %  - For layers with multiple outputs, replace Z and dlZ with
            %    Z1,...,ZM and dLdZ,...,dLdZM, respectively, where M is the
            %    number of outputs.
            %  - For layers with multiple learnable parameters, replace
            %    dLdW with dLdW1,...,dLdWP, where P is the number of
            %    learnable parameters.
            %  - For layers with multiple state parameters, replace dLdSin
            %    and dLdSout with dLdSin1,...,dLdSinK and
            %    dLdSout1,...dldSoutK, respectively, where K is the number
            %    of state parameters.

            % Define layer backward function here.
        end
    end
end
```

Classification Output Layer Template

This template outlines the structure of a classification output layer with a loss function. For more information, see “Define Custom Deep Learning Output Layers” on page 18-29.

For an example showing how to define a classification output layer and specify a loss function, see “Define Custom Classification Output Layer” on page 18-91.

```
classdef myClassificationLayer < nnet.layer.ClassificationLayer

    properties
        % (Optional) Layer properties.

        % Layer properties go here.
    end

    methods
        function layer = myClassificationLayer()
            % (Optional) Create a myClassificationLayer.

            % Layer constructor function goes here.
        end

        function loss = forwardLoss(layer, Y, T)
            % Return the loss between the predictions Y and the training
            % targets T.
            %
            % Inputs:
            %         layer - Output layer
            %         Y     – Predictions made by network
            %         T     – Training targets
            %
            % Output:
            %         loss  - Loss between Y and T

            % Layer forward loss function goes here.
        end

        function dLdY = backwardLoss(layer, Y, T)
            % (Optional) Backward propagate the derivative of the loss
            % function.
            %
            % Inputs:
            %         layer - Output layer
            %         Y     – Predictions made by network
            %         T     – Training targets
            %
            % Output:
            %         dLdY  - Derivative of the loss with respect to the
            %                 predictions Y

            % Layer backward loss function goes here.
        end
    end
end
```

Regression Output Layer Template

This template outlines the structure of a regression output layer with a loss function. For an example showing how to define a regression output layer and specify a loss function, see “Define Custom Regression Output Layer” on page 18-99.

```
classdef myRegressionLayer < nnet.layer.RegressionLayer

    properties
        % (Optional) Layer properties.

        % Layer properties go here.
    end
```

```
    methods
        function layer = myRegressionLayer()
            % (Optional) Create a myRegressionLayer.

            % Layer constructor function goes here.
        end

        function loss = forwardLoss(layer, Y, T)
            % Return the loss between the predictions Y and the training
            % targets T.
            %
            % Inputs:
            %         layer - Output layer
            %         Y     – Predictions made by network
            %         T     – Training targets
            %
            % Output:
            %         loss  - Loss between Y and T

            % Layer forward loss function goes here.
        end

        function dLdY = backwardLoss(layer, Y, T)
            % (Optional) Backward propagate the derivative of the loss
            % function.
            %
            % Inputs:
            %         layer - Output layer
            %         Y     – Predictions made by network
            %         T     – Training targets
            %
            % Output:
            %         dLdY  - Derivative of the loss with respect to the
            %                 predictions Y

            % Layer backward loss function goes here.
        end
    end
end
```

Intermediate Layer Architecture

During training, the software iteratively performs forward and backward passes through the network.

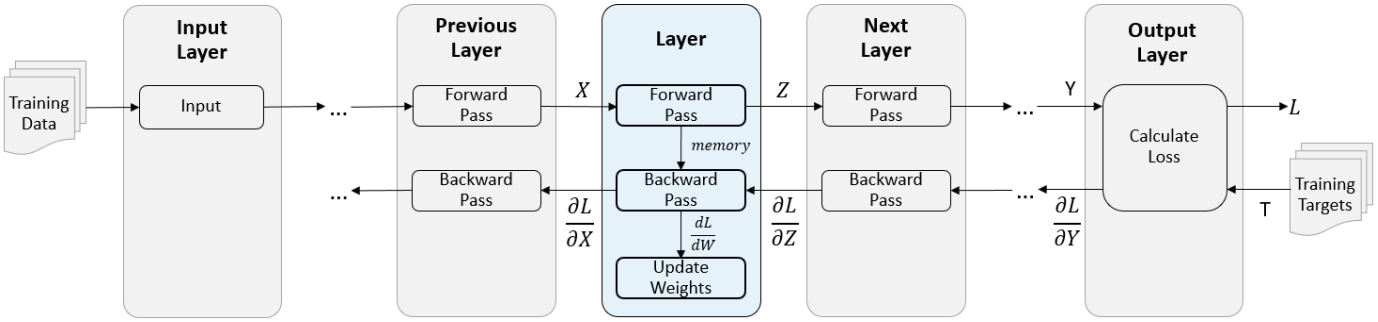
When making a forward pass through the network, each layer takes the outputs of the previous layers, applies a function, and then outputs (forward propagates) the results to the next layers. Stateful layers, such as LSTM layers, also update the layer state.

Layers can have multiple inputs or outputs. For example, a layer can take $X_1, \ldots, X_N$ from multiple previous layers and forward propagate the outputs $Z_1, \ldots, Z_M$ to subsequent layers.

At the end of a forward pass of the network, the output layer calculates the loss L between the predictions Y and the targets T.

During the backward pass of a network, each layer takes the derivatives of the loss with respect to the outputs of the layer, computes the derivatives of the loss L with respect to the inputs, and then backward propagates the results. If the layer has learnable parameters, then the layer also computes the derivatives of the layer weights (learnable parameters). The layer uses the derivatives of the weights to update the learnable parameters.

The following figure describes the flow of data through a deep neural network and highlights the data flow through a layer with a single input X, a single output Z, and a learnable parameter W.

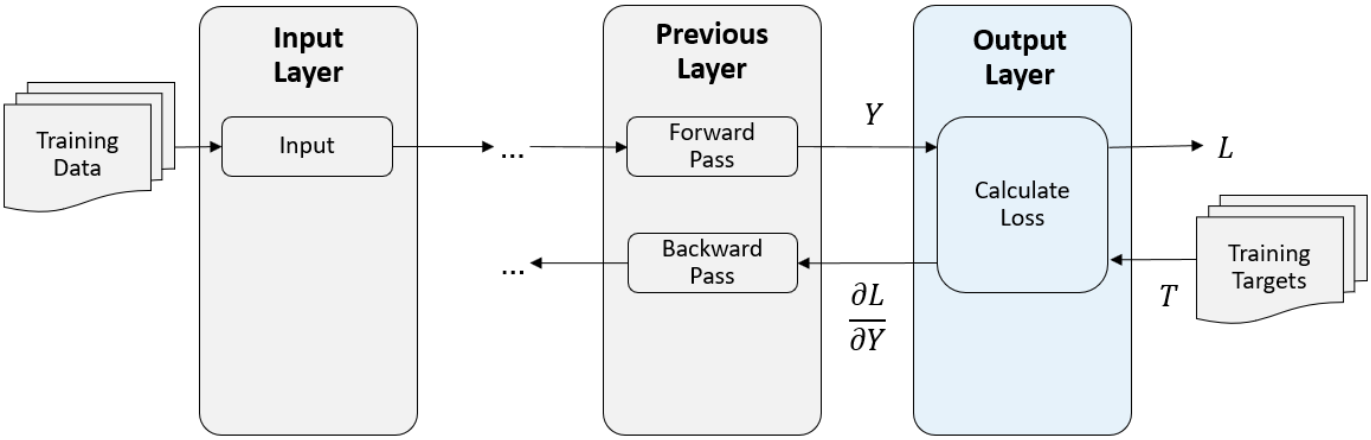


For more information about custom intermediate layers, see “Define Custom Deep Learning Intermediate Layers” on page 18-16.

Output Layer Architecture

At the end of a forward pass at training time, an output layer takes the outputs Y of the previous layer (the network predictions) and calculates the loss L between these predictions and the training targets. The output layer computes the derivatives of the loss L with respect to the predictions Y and outputs (backward propagates) results to the previous layer.

The following figure describes the flow of data through a neural network and an output layer.



For more information, see “Define Custom Deep Learning Output Layers” on page 18-29.

Check Validity of Custom Layer

If you create a custom deep learning layer, then you can use the `checkLayer` function to check that the layer is valid. The function checks layers for validity, GPU compatibility, correctly defined gradients, and code generation compatibility. To check that a layer is valid, run the following command:

```
checkLayer(layer,validInputSize)
```

where `layer` is an instance of the layer, `validInputSize` is a vector or cell array specifying the valid input sizes to the layer. To check with multiple observations, use the `ObservationDimension` option. To check for code generation compatibility, set the `CheckCodegenCompatibility` option to

1 (true). For large input sizes, the gradient checks take longer to run. To speed up the tests, specify a smaller valid input size.

For more information, see “Check Custom Layer Validity” on page 18-154.

Define Custom Deep Learning Intermediate Layers

Tip This topic explains how to define custom deep learning layers for your problems. For a list of built-in layers in Deep Learning Toolbox, see “List of Deep Learning Layers” on page 1-21.

To learn how to define custom output layers, see “Define Custom Deep Learning Output Layers” on page 18-29.

If Deep Learning Toolbox does not provide the layer that you require for your task, then you can define your own custom layer using this topic as a guide. After defining the custom layer, you can automatically check that the layer is valid, GPU compatible, and outputs correctly defined gradients.

Intermediate Layer Architecture

During training, the software iteratively performs forward and backward passes through the network.

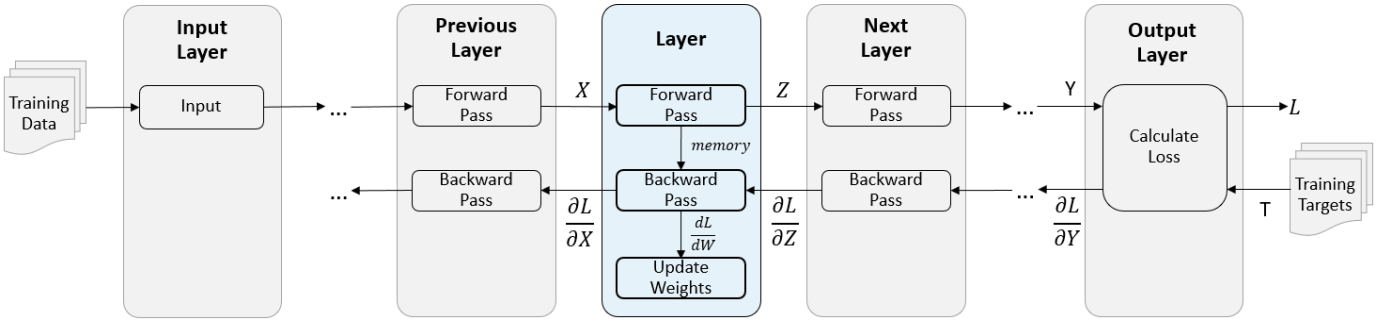
When making a forward pass through the network, each layer takes the outputs of the previous layers, applies a function, and then outputs (forward propagates) the results to the next layers. Stateful layers, such as LSTM layers, also update the layer state.

Layers can have multiple inputs or outputs. For example, a layer can take $X_1, \ldots, X_N$ from multiple previous layers and forward propagate the outputs $Z_1, \ldots, Z_M$ to subsequent layers.

At the end of a forward pass of the network, the output layer calculates the loss L between the predictions Y and the targets T.

During the backward pass of a network, each layer takes the derivatives of the loss with respect to the outputs of the layer, computes the derivatives of the loss L with respect to the inputs, and then backward propagates the results. If the layer has learnable parameters, then the layer also computes the derivatives of the layer weights (learnable parameters). The layer uses the derivatives of the weights to update the learnable parameters.

The following figure describes the flow of data through a deep neural network and highlights the data flow through a layer with a single input X, a single output Z, and a learnable parameter W.



Intermediate Layer Template

To define a custom intermediate layer, use this class definition template. This template outlines the structure of an intermediate layer class definition. It outlines:

- The optional `properties` blocks for the layer properties, learnable parameters, and state parameters. For more information, see “Intermediate Layer Properties” on page 18-19.
- The layer constructor function.
- The `predict` function and the optional `forward` function. For more information, see “Forward Functions” on page 18-21.
- The optional `resetState` function for layers with state properties. For more information, see “Reset State Function” on page 18-24.
- The optional `backward` function. For more information, see “Backward Function” on page 18-24.

```
classdef myLayer < nnet.layer.Layer % & nnet.layer.Formattable (Optional)

    properties
        % (Optional) Layer properties.

        % Declare layer properties here.
    end

    properties (Learnable)
        % (Optional) Layer learnable parameters.

        % Declare learnable parameters here.
    end

    properties (State)
        % (Optional) Layer state parameters.

        % Declare state parameters here.
    end

    properties (Learnable, State)
        % (Optional) Nested dlnetwork objects with both learnable
        % parameters and state.

        % Declare nested networks with learnable and state parameters here.
    end

    methods
        function layer = myLayer()
            % (Optional) Create a myLayer.
            % This function must have the same name as the class.

            % Define layer constructor function here.
        end

        function [Z,state] = predict(layer,X)
            % Forward input data through the layer at prediction time and
            % output the result and updated state.
            %
            % Inputs:
            %         layer - Layer to forward propagate through
            %         X     - Input data
            % Outputs:
            %         Z     - Output of layer forward function
            %         state - (Optional) Updated layer state.
            %
            %  - For layers with multiple inputs, replace X with X1,...,XN,
            %    where N is the number of inputs.
            %  - For layers with multiple outputs, replace Z with
            %    Z1,...,ZM, where M is the number of outputs.
            %  - For layers with multiple state parameters, replace state
            %    with state1,...,stateK, where K is the number of state
            %    parameters.

            % Define layer predict function here.
        end

        function [Z,state,memory] = forward(layer,X)
```

```
            % (Optional) Forward input data through the layer at training
            % time and output the result, updated state, and a memory
            % value.
            %
            % Inputs:
            %         layer - Layer to forward propagate through
            %         X     - Layer input data
            % Outputs:
            %         Z      - Output of layer forward function
            %         state  - (Optional) Updated layer state
            %         memory - (Optional) Memory value for custom backward
            %                  function
            %
            %  - For layers with multiple inputs, replace X with X1,...,XN,
            %    where N is the number of inputs.
            %  - For layers with multiple outputs, replace Z with
            %    Z1,...,ZM, where M is the number of outputs.
            %  - For layers with multiple state parameters, replace state
            %    with state1,...,stateK, where K is the number of state
            %    parameters.

            % Define layer forward function here.
        end

        function layer = resetState(layer)
            % (Optional) Reset layer state.

            % Define reset state function here.
        end

        function [dLdX,dLdW,dLdSin] = backward(layer,X,Z,dLdZ,dLdSout,memory)
            % (Optional) Backward propagate the derivative of the loss
            % function through the layer.
            %
            % Inputs:
            %         layer   - Layer to backward propagate through
            %         X       - Layer input data
            %         Z       - Layer output data
            %         dLdZ    - Derivative of loss with respect to layer
            %                   output
            %         dLdSout - (Optional) Derivative of loss with respect
            %                   to state output
            %         memory  - Memory value from forward function
            % Outputs:
            %         dLdX   - Derivative of loss with respect to layer input
            %         dLdW   - (Optional) Derivative of loss with respect to
            %                  learnable parameter
            %         dLdSin - (Optional) Derivative of loss with respect to
            %                  state input
            %
            %  - For layers with state parameters, the backward syntax must
            %    include both dLdSout and dLdSin, or neither.
            %  - For layers with multiple inputs, replace X and dLdX with
            %    X1,...,XN and dLdX1,...,dLdXN, respectively, where N is
            %    the number of inputs.
            %  - For layers with multiple outputs, replace Z and dlZ with
            %    Z1,...,ZM and dLdZ,...,dLdZM, respectively, where M is the
            %    number of outputs.
            %  - For layers with multiple learnable parameters, replace
            %    dLdW with dLdW1,...,dLdWP, where P is the number of
            %    learnable parameters.
            %  - For layers with multiple state parameters, replace dLdSin
            %    and dLdSout with dLdSin1,...,dLdSinK and
            %    dLdSout1,...dldSoutK, respectively, where K is the number
            %    of state parameters.

            % Define layer backward function here.
        end
    end
end
```

Formatted Inputs and Outputs

Using `dlarray` objects makes working with high dimensional data easier by allowing you to label the dimensions. For example, you can label which dimensions correspond to spatial, time, channel, and batch dimensions using the `"S"`, `"T"`, `"C"`, and `"B"` labels, respectively. For unspecified and other dimensions, use the `"U"` label. For `dlarray` object functions that operate over particular dimensions, you can specify the dimension labels by formatting the `dlarray` object directly, or by using the `DataFormat` option.

Using formatted `dlarray` objects in custom layers also allows you to define layers where the inputs and outputs have different formats, such as layers that permute, add, or remove dimensions. For example, you can define a layer that takes as input a mini-batch of images with format `"SSCB"` (spatial, spatial, channel, batch) and output a mini-batch of sequences with format `"CBT"` (channel, batch, time). Using formatted `dlarray` objects also allows you to define layers that can operate on data with different input formats, for example, layers that support inputs with formats `"SSCB"` (spatial, spatial, channel, batch) and `"CBT"` (channel, batch, time).

If you do not specify a backward function, then the layer functions, by default, receive *unformatted* `dlarray` objects as input. To specify that the layer receives *formatted* `dlarray` objects as input and also outputs formatted `dlarray` objects, also inherit from the `nnet.layer.Formattable` class when defining the custom layer.

For an example showing how to define a custom layer with formatted inputs, see “Define Custom Deep Learning Layer with Formatted Inputs” on page 18-61.

Intermediate Layer Properties

Declare the layer properties in the `properties` section of the class definition.

By default, custom intermediate layers have these properties. Do not declare these properties in the `properties` section.

Property	Description
`Name`	Layer name, specified as a character vector or a string scalar. For `Layer` array input, the `trainNetwork`, `assembleNetwork`, `layerGraph`, and `dlnetwork` functions automatically assign names to layers with `Name` set to `''`.
`Description`	One-line description of the layer, specified as a string scalar or a character vector. This description appears when the layer is displayed in a `Layer` array. If you do not specify a layer description, then the software displays the layer class name.
`Type`	Type of the layer, specified as a character vector or a string scalar. The value of `Type` appears when the layer is displayed in a `Layer` array. If you do not specify a layer type, then the software displays the layer class name.

Property	Description
`NumInputs`	Number of inputs of the layer, specified as a positive integer. If you do not specify this value, then the software automatically sets `NumInputs` to the number of names in `InputNames`. The default value is 1.
`InputNames`	Input names of the layer, specified as a cell array of character vectors. If you do not specify this value and `NumInputs` is greater than 1, then the software automatically sets `InputNames` to `{'in1',...,'inN'}`, where `N` is equal to `NumInputs`. The default value is `{'in'}`.
`NumOutputs`	Number of outputs of the layer, specified as a positive integer. If you do not specify this value, then the software automatically sets `NumOutputs` to the number of names in `OutputNames`. The default value is 1.
`OutputNames`	Output names of the layer, specified as a cell array of character vectors. If you do not specify this value and `NumOutputs` is greater than 1, then the software automatically sets `OutputNames` to `{'out1',...,'outM'}`, where `M` is equal to `NumOutputs`. The default value is `{'out'}`.

If the layer has no other properties, then you can omit the `properties` section.

Tip If you are creating a layer with multiple inputs, then you must set either the `NumInputs` or `InputNames` properties in the layer constructor. If you are creating a layer with multiple outputs, then you must set either the `NumOutputs` or `OutputNames` properties in the layer constructor. For an example, see “Define Custom Deep Learning Layer with Multiple Inputs” on page 18-48.

Learnable Parameters

Declare the layer learnable parameters in the `properties (Learnable)` section of the class definition. You can specify numeric arrays or `dlnetwork` objects as learnable parameters. If the `dlnetwork` object has both learnable and state parameters (for example, a `dlnetwork` object that contains an LSTM layer), then you must specify it in the `properties (Learnable, State)` section. If the layer has no learnable parameters, then you can omit the `properties` sections with the `Learnable` attribute.

Optionally, you can specify the learning rate factor and the L2 factor of the learnable parameters. By default, each learnable parameter has its learning rate factor and L2 factor set to `1`. For both built-in and custom layers, you can set and get the learn rate factors and L2 regularization factors using the following functions.

Function	Description
`setLearnRateFactor`	Set the learn rate factor of a learnable parameter.

Function	Description
`setL2Factor`	Set the L2 regularization factor of a learnable parameter.
`getLearnRateFactor`	Get the learn rate factor of a learnable parameter.
`getL2Factor`	Get the L2 regularization factor of a learnable parameter.

To specify the learning rate factor and the L2 factor of a learnable parameter, use the syntaxes `layer = setLearnRateFactor(layer,parameterName,value)` and `layer = setL2Factor(layer,parameterName,value)`, respectively.

To get the value of the learning rate factor and the L2 factor of a learnable parameter, use the syntaxes `getLearnRateFactor(layer,parameterName)` and `getL2Factor(layer,parameterName)` respectively.

For example, this syntax sets the learn rate factor of the learnable parameter with the name `"Alpha"` to `0.1`.

```
layer = setLearnRateFactor(layer,"Alpha",0.1);
```

State Parameters

For stateful layers, such as recurrent layers, declare the layer state parameters in the `properties (State)` section of the class definition. For `dlnetwork` objects that have both learnable and state parameters (for example, a `dlnetwork` object that contains an LSTM layer), then you must specify it in the `properties (Learnable, State)` section. If the layer has no state parameters, then you can omit the `properties` sections with the `State` attribute.

If the layer has state parameters, then the forward functions must also return the updated layer state. For more information, see “Forward Functions” on page 18-21.

To specify a custom reset state function, include a function with syntax `layer = resetState(layer)` in the class definition. For more information, see “Reset State Function” on page 18-24.

Forward Functions

Some layers behave differently during training and during prediction. For example, a dropout layer performs dropout only during training and has no effect during prediction. A layer uses one of two functions to perform a forward pass: `predict` or `forward`. If the forward pass is at prediction time, then the layer uses the `predict` function. If the forward pass is at training time, then the layer uses the `forward` function. If you do not require two different functions for prediction time and training time, then you can omit the `forward` function. In this case, the layer uses `predict` at training time.

If the layer has state parameters, then the forward functions must also return the updated layer state parameters as numeric arrays.

If you define both a custom `forward` function and a custom `backward` function, then the forward function must return a `memory` output.

The `predict` function syntax depends on the type of layer.

- `Z = predict(layer,X)` forwards the input data `X` through the layer and outputs the result `Z`, where `layer` has a single input, a single output.
- `[Z,state] = predict(layer,X)` also outputs the updated state parameter `state`, where `layer` has a single state parameter.

You can adjust the syntaxes for layers with multiple inputs, multiple outputs, or multiple state parameters:

- For layers with multiple inputs, replace `X` with `X1,...,XN`, where `N` is the number of inputs. The `NumInputs` property must match `N`.
- For layers with multiple outputs, replace `Z` with `Z1,...,ZM`, where `M` is the number of outputs. The `NumOutputs` property must match `M`.
- For layers with multiple state parameters, replace `state` with `state1,...,stateK`, where `K` is the number of state parameters.

Tip If the number of inputs to the layer can vary, then use `varargin` instead of `X1,…,XN`. In this case, `varargin` is a cell array of the inputs, where `varargin{i}` corresponds to `Xi`.

If the number of outputs can vary, then use `varargout` instead of `Z1,…,ZN`. In this case, `varargout` is a cell array of the outputs, where `varargout{j}` corresponds to `Zj`.

Tip If the custom layer has a `dlnetwork` object for a learnable parameter, then in the `predict` function of the custom layer, use the `predict` function for the `dlnetwork`. Using the `dlnetwork` object `predict` function ensures that the software uses the correct layer operations for prediction.

The `forward` function syntax depends on the type of layer:

- `Z = forward(layer,X)` forwards the input data `X` through the layer and outputs the result `Z`, where `layer` has a single input, a single output.
- `[Z,state] = forward(layer,X)` also outputs the updated state parameter `state`, where `layer` has a single state parameter.
- `[__,memory] = forward(layer,X)` also returns a memory value for a custom `backward` function using any of the previous syntaxes. If the layer has both a custom `forward` function and a custom `backward` function, then the forward function must return a memory value.

You can adjust the syntaxes for layers with multiple inputs, multiple outputs, or multiple state parameters:

- For layers with multiple inputs, replace `X` with `X1,...,XN`, where `N` is the number of inputs. The `NumInputs` property must match `N`.
- For layers with multiple outputs, replace `Z` with `Z1,...,ZM`, where `M` is the number of outputs. The `NumOutputs` property must match `M`.
- For layers with multiple state parameters, replace `state` with `state1,...,stateK`, where `K` is the number of state parameters.

Tip If the number of inputs to the layer can vary, then use `varargin` instead of `X1,…,XN`. In this case, `varargin` is a cell array of the inputs, where `varargin{i}` corresponds to `Xi`.

If the number of outputs can vary, then use `varargout` instead of `Z1,…,ZN`. In this case, `varargout` is a cell array of the outputs, where `varargout{j}` corresponds to `Zj`.

Tip If the custom layer has a `dlnetwork` object for a learnable parameter, then in the `forward` function of the custom layer, use the `forward` function of the `dlnetwork` object. Using the `dlnetwork` object `forward` function ensures that the software uses the correct layer operations for training.

The dimensions of the inputs depend on the type of data and the output of the connected layers:

Layer Input	Input Size	Observation Dimension
Feature vectors	*c*-by-*N*, where *c* corresponds to the number of channels and *N* is the number of observations.	2
2-D images	*h*-by-*w*-by-*c*-by-*N*, where *h*, *w*, and *c* correspond to the height, width, and number of channels of the images, respectively, and *N* is the number of observations.	4
3-D images	*h*-by-*w*-by-*d*-by-*c*-by-*N*, where *h*, *w*, *d*, and *c* correspond to the height, width, depth, and number of channels of the 3-D images, respectively, and *N* is the number of observations.	5
Vector sequences	*c*-by-*N*-by-*S*, where *c* is the number of features of the sequences, *N* is the number of observations, and *S* is the sequence length.	2
2-D image sequences	*h*-by-*w*-by-*c*-by-*N*-by-*S*, where *h*, *w*, and *c* correspond to the height, width, and number of channels of the images, respectively, *N* is the number of observations, and *S* is the sequence length.	4
3-D image sequences	*h*-by-*w*-by-*d*-by-*c*-by-*N*-by-*S*, where *h*, *w*, *d*, and *c* correspond to the height, width, depth, and number of channels of the 3-D images, respectively, *N* is the number of observations, and *S* is the sequence length.	5

For layers that output sequences, the layers can output sequences of any length or output data with no time dimension. Note that when training a network that outputs sequences using the `trainNetwork` function, the lengths of the input and output sequences must match.

The outputs of the custom layer forward functions must not be complex. If the `predict` or `forward` functions of your custom layer involve complex numbers, convert all outputs to real values before returning them. Using complex numbers in the `predict` or `forward` functions of your custom layer can lead to complex learnable parameters. If you are using automatic differentiation (in other words, you are not writing a backward function for your custom layer) then convert all learnable parameters to real values at the beginning of the function computation. Doing so ensures that the outputs of automatically generated backward functions are not complex.

Reset State Function

When `DAGNetwork` or `SeriesNetwork` objects contain layers with state parameters, you can make predictions and update the layer states using the `predictAndUpdateState` and `classifyAndUpdateState` functions. You can reset the network state using the `resetState` function.

The `resetState` function for `DAGNetwork`, `SeriesNetwork`, and `dlnetwork` objects, by default, has no effect on custom layers with state parameters. To define the layer behavior for the `resetState` function for network objects, define the optional layer `resetState` function in the layer definition that resets the state parameters.

The `resetState` function must have the syntax `layer = resetState(layer)`, where the returned layer has the state properties reset.

Backward Function

The layer backward function computes the derivatives of the loss with respect to the input data and then outputs (backward propagates) results to the previous layer. If the layer has learnable parameters (for example, layer weights), then `backward` also computes the derivatives of the learnable parameters. When using the `trainNetwork` function, the layer automatically updates the learnable parameters using these derivatives during the backward pass.

Defining the backward function is optional. If you do not specify a backward function, and the layer forward functions support `dlarray` objects, then the software automatically determines the backward function using automatic differentiation. For a list of functions that support `dlarray` objects, see “List of Functions with dlarray Support” on page 18-423. Define a custom backward function when you want to:

- Use a specific algorithm to compute the derivatives.
- Use operations in the forward functions that do not support `dlarray` objects.

Custom layers with learnable `dlnetwork` objects do not support custom backward functions.

To define a custom backward function, create a function named `backward`.

The `backward` function syntax depends on the type of layer.

- `dLdX = backward(layer,X,Z,dLdZ,memory)` returns the derivatives `dLdX` of the loss with respect to the layer input, where `layer` has a single input and a single output. `Z` corresponds to the forward function output and `dLdZ` corresponds to the derivative of the loss with respect to `Z`. The function input `memory` corresponds to the memory output of the forward function.
- `[dLdX,dLdW] = backward(layer,X,Z,dLdZ,memory)` also returns the derivative `dLdW` of the loss with respect to the learnable parameter, where `layer` has a single learnable parameter.

- `[dLdX,dLdSin] = backward(layer,X,Z,dLdZ,dLdSout,memory)` also returns the derivative `dLdSin` of the loss with respect to the state input using any of the previous syntaxes, where `layer` has a single state parameter and `dLdSout` corresponds to the derivative of the loss with respect to the layer state output.
- `[dLdX,dLdW,dLdSin] = backward(layer,X,Z,dLdZ,dLdSout,memory)` also returns the derivative `dLdW` of the loss with respect to the learnable parameter and returns the derivative `dLdSin` of the loss with respect to the layer state input using any of the previous syntaxes, where `layer` has a single state parameter and single learnable parameter.

You can adjust the syntaxes for layers with multiple inputs, multiple outputs, multiple learnable parameters, or multiple state parameters:

- For layers with multiple inputs, replace `X` and `dLdX` with `X1,...,XN` and `dLdX1,...,dLdXN`, respectively, where `N` is the number of inputs.
- For layers with multiple outputs, replace `Z` and `dLdZ` with `Z1,...,ZM` and `dLdZ1,...,dLdZM`, respectively, where `M` is the number of outputs.
- For layers with multiple learnable parameters, replace `dLdW` with `dLdW1,...,dLdWP`, where `P` is the number of learnable parameters.
- For layers with multiple state parameters, replace `dLdSin` and `dLdSout` with `dLdSin1,...,dLdSinK` and `dLdSout1,...,dLdSoutK`, respectively, where `K` is the number of state parameters.

To reduce memory usage by preventing unused variables being saved between the forward and backward pass, replace the corresponding input arguments with `~`.

Tip If the number of inputs to `backward` can vary, then use `varargin` instead of the input arguments after `layer`. In this case, `varargin` is a cell array of the inputs, where the first `N` elements correspond to the `N` layer inputs, the next `M` elements correspond to the `M` layer outputs, the next `M` elements correspond to the derivatives of the loss with respect to the `M` layer outputs, the next `K` elements correspond to the `K` derivatives of the loss with respect to the `K` states outputs, and the last element corresponds to `memory`.

If the number of outputs can vary, then use `varargout` instead of the output arguments. In this case, `varargout` is a cell array of the outputs, where the first `N` elements correspond to the `N` the derivatives of the loss with respect to the `N` layer inputs, the next `P` elements correspond to the derivatives of the loss with respect to the `P` learnable parameters, and the next `K` elements correspond to the derivatives of the loss with respect to the `K` state inputs.

The values of `X` and `Z` are the same as in the forward functions. The dimensions of `dLdZ` are the same as the dimensions of `Z`.

The dimensions and data type of `dLdX` are the same as the dimensions and data type of `X`. The dimensions and data types of `dLdW` are the same as the dimensions and data types of `W`.

To calculate the derivatives of the loss, you can use the chain rule:

$$\frac{\partial L}{\partial X^{(i)}} = \sum_j \frac{\partial L}{\partial Z_j}\frac{\partial Z_j}{\partial X^{(i)}}$$

$$\frac{\partial L}{\partial W_i} = \sum_j \frac{\partial L}{\partial Z_j}\frac{\partial Z_j}{\partial W_i}$$

When using the `trainNetwork` function, the layer automatically updates the learnable parameters using the derivatives `dLdW` during the backward pass.

For an example showing how to define a custom backward function, see “Specify Custom Layer Backward Function” on page 18-107.

The outputs of the custom layer backward function must not be complex. If your backward function involves complex numbers, then convert all outputs of the backward function to real values before returning them.

GPU Compatibility

If the layer forward functions fully support `dlarray` objects, then the layer is GPU compatible. Otherwise, to be GPU compatible, the layer functions must support inputs and return outputs of type `gpuArray`.

Many MATLAB built-in functions support `gpuArray` and `dlarray` input arguments. For a list of functions that support `dlarray` objects, see “List of Functions with dlarray Support” on page 18-423. For a list of functions that execute on a GPU, see “Run MATLAB Functions on a GPU” (Parallel Computing Toolbox). To use a GPU for deep learning, you must also have a supported GPU device. For information on supported devices, see “GPU Support by Release” (Parallel Computing Toolbox). For more information on working with GPUs in MATLAB, see “GPU Computing in MATLAB” (Parallel Computing Toolbox).

Code Generation Compatibility

To create a custom layer that supports code generation:

- The layer must specify the pragma `%#codegen` in the layer definition.
- The inputs of `predict` must be:
  - Consistent in dimension. Each input must have the same number of dimensions.
  - Consistent in batch size. Each input must have the same batch size.
- The outputs of `predict` must be consistent in dimension and batch size with the layer inputs.
- Nonscalar properties must have type single, double, or character array.
- Scalar properties must have type numeric, logical, or string.

Code generation supports intermediate layers with 2-D image or feature input only. Code generation does not support layers with state properties (properties with attribute `State`).

For an example showing how to create a custom layer that supports code generation, see “Define Custom Deep Learning Layer for Code Generation” on page 18-142.

Network Composition

To create a custom layer that itself defines a layer graph, you can declare a `dlnetwork` object as a learnable parameter in the `properties (Learnable)` section of the layer definition. This method is known as *network composition*. You can use network composition to:

- Create a single custom layer that represents a block of learnable layers, for example, a residual block.
- Create a network with control flow, for example, a network with a section that can dynamically change depending on the input data.

- Create a network with loops, for example, a network with sections that feed the output back into itself.

For nested networks that have both learnable and state parameters, for example, networks with batch normalization or LSTM layers, declare the network in the `properties (Learnable, State)` section of the layer definition.

GPU Compatibility

If the layer forward functions fully support `dlarray` objects, then the layer is GPU compatible. Otherwise, to be GPU compatible, the layer functions must support inputs and return outputs of type `gpuArray`.

Many MATLAB built-in functions support `gpuArray` and `dlarray` input arguments. For a list of functions that support `dlarray` objects, see “List of Functions with dlarray Support” on page 18-423. For a list of functions that execute on a GPU, see “Run MATLAB Functions on a GPU” (Parallel Computing Toolbox). To use a GPU for deep learning, you must also have a supported GPU device. For information on supported devices, see “GPU Support by Release” (Parallel Computing Toolbox). For more information on working with GPUs in MATLAB, see “GPU Computing in MATLAB” (Parallel Computing Toolbox).

Check Validity of Layer

If you create a custom deep learning layer, then you can use the `checkLayer` function to check that the layer is valid. The function checks layers for validity, GPU compatibility, correctly defined gradients, and code generation compatibility. To check that a layer is valid, run the following command:

```
checkLayer(layer,validInputSize)
```

where `layer` is an instance of the layer, `validInputSize` is a vector or cell array specifying the valid input sizes to the layer. To check with multiple observations, use the `ObservationDimension` option. To check for code generation compatibility, set the `CheckCodegenCompatibility` option to `1` (true). For large input sizes, the gradient checks take longer to run. To speed up the tests, specify a smaller valid input size.

For more information, see “Check Custom Layer Validity” on page 18-154.

Check Validity of Custom Layer Using checkLayer

Check the layer validity of the custom layer `preluLayer`.

The custom layer `preluLayer`, attached to this is example as a supporting file, applies the PReLU operation to the input data. To access this layer, open this example as a live script.

Create an instance of the layer and check its validity using `checkLayer`. Specify the valid input size to be the size of a single observation of typical input to the layer. The layer expects 4-D array inputs, where the first three dimensions correspond to the height, width, and number of channels of the previous layer output, and the fourth dimension corresponds to the observations.

Specify the typical size of the input of an observation and set the `ObservationDimension` option to 4.

```
layer = preluLayer(20);
validInputSize = [24 24 20];
checkLayer(layer,validInputSize,ObservationDimension=4)

Skipping GPU tests. No compatible GPU device found.

Skipping code generation compatibility tests. To check validity of the layer for code generation

Running nnet.checklayer.TestLayerWithoutBackward
.......... ........
Done nnet.checklayer.TestLayerWithoutBackward
__________

Test Summary:
     18 Passed, 0 Failed, 0 Incomplete, 10 Skipped.
     Time elapsed: 0.21297 seconds.
```

Here, the function does not detect any issues with the layer.

Define Custom Deep Learning Output Layers

Tip This topic explains how to define custom deep learning output layers for your problems. For a list of built-in layers in Deep Learning Toolbox, see “List of Deep Learning Layers” on page 1-21.

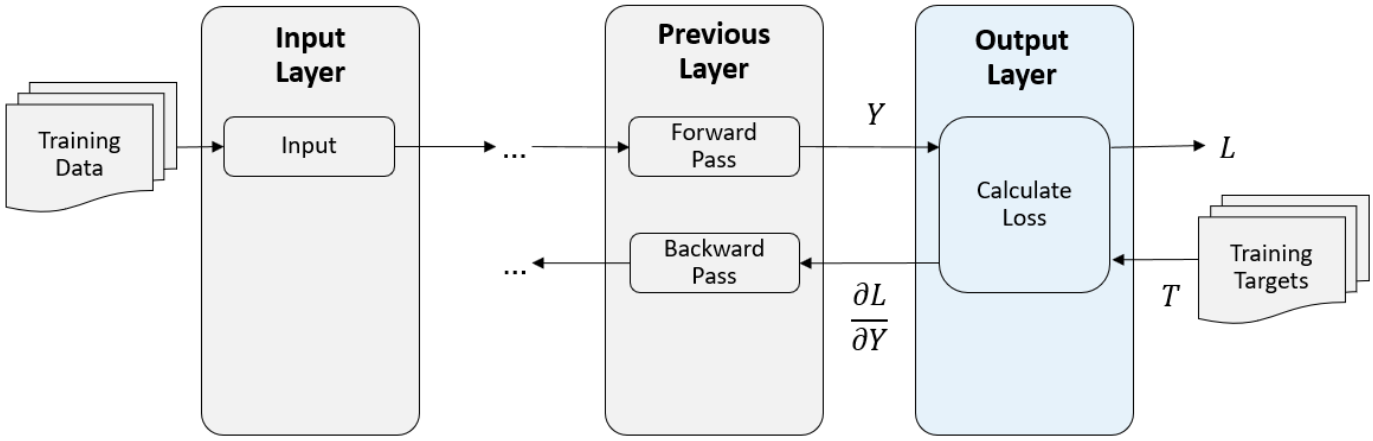
To learn how to define custom intermediate layers, see “Define Custom Deep Learning Intermediate Layers” on page 18-16.

If Deep Learning Toolbox does not provide the output layer that you require for your task, then you can define your own custom layer using this topic as a guide. After defining the custom layer, you can automatically check that the layer is valid, GPU compatible, and outputs correctly defined gradients.

Output Layer Architecture

At the end of a forward pass at training time, an output layer takes the predictions (network outputs) Y of the previous layer and calculates the loss L between these predictions and the training targets. The output layer computes the derivatives of the loss L with respect to the predictions Y and outputs (backward propagates) results to the previous layer.

The following figure describes the flow of data through a convolutional neural network and an output layer.



Output Layer Templates

To define a custom intermediate layer, use one of these class definition templates. The templates outline the structure of an output layer class definition. They outline:

- The optional `properties` blocks for the layer properties. For more information, see “Output Layer Properties” on page 18-31.
- The layer constructor function.
- The `forwardLoss` function. For more information, see “Forward Loss Function” on page 18-32.
- The optional `backwardLoss` function. For more information, see “Backward Loss Function” on page 18-32.

Classification Output Layer Template

This template outlines the structure of a classification output layer with a loss function. For an example showing how to define a classification output layer and specify a loss function, see “Define Custom Classification Output Layer” on page 18-91.

```
classdef myClassificationLayer < nnet.layer.ClassificationLayer

    properties
        % (Optional) Layer properties.

        % Layer properties go here.
    end

    methods
        function layer = myClassificationLayer()
            % (Optional) Create a myClassificationLayer.

            % Layer constructor function goes here.
        end

        function loss = forwardLoss(layer, Y, T)
            % Return the loss between the predictions Y and the training
            % targets T.
            %
            % Inputs:
            %         layer - Output layer
            %         Y     – Predictions made by network
            %         T     – Training targets
            %
            % Output:
            %         loss  - Loss between Y and T

            % Layer forward loss function goes here.
        end

        function dLdY = backwardLoss(layer, Y, T)
            % (Optional) Backward propagate the derivative of the loss
            % function.
            %
            % Inputs:
            %         layer - Output layer
            %         Y     – Predictions made by network
            %         T     – Training targets
            %
            % Output:
            %         dLdY  - Derivative of the loss with respect to the
            %                 predictions Y

            % Layer backward loss function goes here.
        end
    end
end
```

Regression Output Layer Template

This template outlines the structure of a regression output layer with a loss function. For an example showing how to define a regression output layer and specify a loss function, see “Define Custom Regression Output Layer” on page 18-99.

```
classdef myRegressionLayer < nnet.layer.RegressionLayer

    properties
        % (Optional) Layer properties.

        % Layer properties go here.
    end

    methods
        function layer = myRegressionLayer()
            % (Optional) Create a myRegressionLayer.
```

```
            % Layer constructor function goes here.
        end

        function loss = forwardLoss(layer, Y, T)
            % Return the loss between the predictions Y and the training
            % targets T.
            %
            % Inputs:
            %         layer - Output layer
            %         Y     – Predictions made by network
            %         T     – Training targets
            %
            % Output:
            %         loss  - Loss between Y and T

            % Layer forward loss function goes here.
        end

        function dLdY = backwardLoss(layer, Y, T)
            % (Optional) Backward propagate the derivative of the loss
            % function.
            %
            % Inputs:
            %         layer - Output layer
            %         Y     – Predictions made by network
            %         T     – Training targets
            %
            % Output:
            %         dLdY  - Derivative of the loss with respect to the
            %                 predictions Y

            % Layer backward loss function goes here.
        end
    end
end
```

Output Layer Properties

Declare the layer properties in the `properties` section of the class definition.

By default, custom output layers have the following properties:

- `Name` – Layer name, specified as a character vector or a string scalar. For `Layer` array input, the `trainNetwork`, `assembleNetwork`, `layerGraph`, and `dlnetwork` functions automatically assign names to layers with `Name` set to `''`.
- `Description` – One-line description of the layer, specified as a character vector or a string scalar. This description appears when the layer is displayed in a `Layer` array. If you do not specify a layer description, then the software displays `"Classification Output"` or `"Regression Output"`.
- `Type` – Type of the layer, specified as a character vector or a string scalar. The value of `Type` appears when the layer is displayed in a `Layer` array. If you do not specify a layer type, then the software displays the layer class name.

Custom classification layers also have the following property:

- `Classes` – Classes of the output layer, specified as a categorical vector, string array, cell array of character vectors, or `'auto'`. If `Classes` is `'auto'`, then the software automatically sets the classes at training time. If you specify the string array or cell array of character vectors `str`, then the software sets the classes of the output layer to `categorical(str,str)`.

Custom regression layers also have the following property:

- `ResponseNames` – Names of the responses, specified a cell array of character vectors or a string array. At training time, the software automatically sets the response names according to the training data. The default is `{}`.

If the layer has no other properties, then you can omit the `properties` section.

Forward Loss Function

The output layer computes the loss `L` between predictions and targets using the forward loss function and computes the derivatives of the loss with respect to the predictions using the backward loss function.

The syntax for `forwardLoss` is `loss = forwardLoss(layer,Y,T)`. The input `Y` corresponds to the predictions made by the network. These predictions are the output of the previous layer. The input `T` corresponds to the training targets. The output `loss` is the loss between `Y` and `T` according to the specified loss function. The output `loss` must be scalar.

Backward Loss Function

If the layer forward loss function supports `dlarray` objects, then the software automatically determines the backward loss function. For a list of functions that support `dlarray` objects, see “List of Functions with dlarray Support” on page 18-423. Alternatively, to define a custom backward loss function, create a function named `backwardLoss`. For an example showing how to define a custom backward loss function, see “Specify Custom Output Layer Backward Loss Function” on page 18-113.

The syntax for `backwardLoss` is `dLdY = backwardLoss(layer,Y,T)`. The input `Y` contains the predictions made by the network and `T` contains the training targets. The output `dLdY` is the derivative of the loss with respect to the predictions `Y`. The output `dLdY` must be the same size as the layer input `Y`.

For classification problems, the dimensions of `T` depend on the type of problem.

Classification Task	Input Size	Observation Dimension
2-D image classification	1-by-1-by-*K*-by-*N*, where *K* is the number of classes and *N* is the number of observations.	4
3-D image classification	1-by-1-by-1-by-*K*-by-*N*, where *K* is the number of classes and *N* is the number of observations.	5
Sequence-to-label classification	*K*-by-*N*, where *K* is the number of classes and *N* is the number of observations.	2
Sequence-to-sequence classification	*K*-by-*N*-by-*S*, where *K* is the number of classes, *N* is the number of observations, and *S* is the sequence length.	2

The size of `Y` depends on the output of the previous layer. To ensure that `Y` is the same size as `T`, you must include a layer that outputs the correct size before the output layer. For example, to ensure that `Y` is a 4-D array of prediction scores for *K* classes, you can include a fully connected layer of size *K* followed by a softmax layer before the output layer.

For regression problems, the dimensions of `T` also depend on the type of problem.

Regression Task	Input Size	Observation Dimension
2-D image regression	1-by-1-by-*R*-by-*N*, where *R* is the number of responses and *N* is the number of observations.	4
2-D Image-to-image regression	*h*-by-*w*-by-*c*-by-`N`, where *h*, *w*, and *c* are the height, width, and number of channels of the output respectively, and *N* is the number of observations.	4
3-D image regression	1-by-1-by-1-by-*R*-by-*N*, where *R* is the number of responses and *N* is the number of observations.	5
3-D Image-to-image regression	*h*-by-*w*-by-*d*-by-*c*-by-`N`, where *h*, *w*, *d*, and *c* are the height, width, depth, and number of channels of the output respectively, and *N* is the number of observations.	5
Sequence-to-one regression	*R*-by-*N*, where *R* is the number of responses and *N* is the number of observations.	2
Sequence-to-sequence regression	*R*-by-*N*-by-*S*, where *R* is the number of responses, *N* is the number of observations, and *S* is the sequence length.	2

For example, if the network defines an image regression network with one response and has mini-batches of size 50, then `T` is a 4-D array of size 1-by-1-by-1-by-50.

The size of `Y` depends on the output of the previous layer. To ensure that `Y` is the same size as `T`, you must include a layer that outputs the correct size before the output layer. For example, for image regression with *R* responses, to ensure that `Y` is a 4-D array of the correct size, you can include a fully connected layer of size *R* before the output layer.

The `forwardLoss` and `backwardLoss` functions have the following output arguments.

Function	Output Argument	Description
`forwardLoss`	`loss`	Calculated loss between the predictions `Y` and the true target `T`.
`backwardLoss`	`dLdY`	Derivative of the loss with respect to the predictions `Y`.

The `backwardLoss` must output `dLdY` with the size expected by the previous layer and `dLdY` to be the same size as `Y`.

GPU Compatibility

If the layer forward functions fully support `dlarray` objects, then the layer is GPU compatible. Otherwise, to be GPU compatible, the layer functions must support inputs and return outputs of type `gpuArray`.

Many MATLAB built-in functions support `gpuArray` and `dlarray` input arguments. For a list of functions that support `dlarray` objects, see “List of Functions with dlarray Support” on page 18-423. For a list of functions that execute on a GPU, see “Run MATLAB Functions on a GPU” (Parallel Computing Toolbox). To use a GPU for deep learning, you must also have a supported GPU device. For information on supported devices, see “GPU Support by Release” (Parallel Computing Toolbox). For more information on working with GPUs in MATLAB, see “GPU Computing in MATLAB” (Parallel Computing Toolbox).

Check Validity of Layer

If you create a custom deep learning layer, then you can use the `checkLayer` function to check that the layer is valid. The function checks layers for validity, GPU compatibility, correctly defined gradients, and code generation compatibility. To check that a layer is valid, run the following command:

```
checkLayer(layer,validInputSize)
```

where `layer` is an instance of the layer, `validInputSize` is a vector or cell array specifying the valid input sizes to the layer. To check with multiple observations, use the `ObservationDimension` option. To check for code generation compatibility, set the `CheckCodegenCompatibility` option to `1` (true). For large input sizes, the gradient checks take longer to run. To speed up the tests, specify a smaller valid input size.

For more information, see “Check Custom Layer Validity” on page 18-154.

Define Custom Deep Learning Layer with Learnable Parameters

If Deep Learning Toolbox does not provide the layer you require for your task, then you can define your own custom layer using this example as a guide. For a list of built-in layers, see “List of Deep Learning Layers” on page 1-21.

To define a custom deep learning layer, you can use the template provided in this example, which takes you through the following steps:

1. Name the layer — Give the layer a name so that you can use it in MATLAB.
2. Declare the layer properties — Specify the properties of the layer including learnable parameters and state parameters.
3. Create a constructor function (optional) — Specify how to construct the layer and initialize its properties. If you do not specify a constructor function, then at creation, the software initializes the `Name`, `Description`, and `Type` properties with `[]` and sets the number of layer inputs and outputs to 1.
4. Create forward functions — Specify how data passes forward through the layer (forward propagation) at prediction time and at training time.
5. Create reset state function (optional) — Specify how to reset state parameters.
6. Create a backward function (optional) — Specify the derivatives of the loss with respect to the input data and the learnable parameters (backward propagation). If you do not specify a backward function, then the forward functions must support `dlarray` objects.

When defining the layer functions, you can use `dlarray` objects. Using `dlarray` objects makes working with high dimensional data easier by allowing you to label the dimensions. For example, you can label which dimensions correspond to spatial, time, channel, and batch dimensions using the `"S"`, `"T"`, `"C"`, and `"B"` labels, respectively. For unspecified and other dimensions, use the `"U"` label. For `dlarray` object functions that operate over particular dimensions, you can specify the dimension labels by formatting the `dlarray` object directly, or by using the `DataFormat` option.

Using formatted `dlarray` objects in custom layers also allows you to define layers where the inputs and outputs have different formats, such as layers that permute, add, or remove dimensions. For example, you can define a layer that takes as input a mini-batch of images with format `"SSCB"` (spatial, spatial, channel, batch) and output a mini-batch of sequences with format `"CBT"` (channel, batch, time). Using formatted `dlarray` objects also allows you to define layers that can operate on data with different input formats, for example, layers that support inputs with formats `"SSCB"` (spatial, spatial, channel, batch) and `"CBT"` (channel, batch, time).

`dlarray` objects also enable support for automatic differentiation. This means that if your forward functions fully support `dlarray` objects, then defining the backward function is optional.

To enable support for using formatted `dlarray` objects in custom layer forward functions, also inherit from the `nnet.layer.Formattable` class when defining the custom layer. For an example, see “Define Custom Deep Learning Layer with Formatted Inputs” on page 18-61.

This example shows how to create a PReLU layer, which is a layer with a learnable parameter and use it in a convolutional neural network. A PReLU layer performs a threshold operation, where for each channel, any input value less than zero is multiplied by a scalar learned at training time.[1] For values less than zero, a PReLU layer applies scaling coefficients α_i to each channel of the input. These coefficients form a learnable parameter, which the layer learns during training.

This figure from [1] compares the ReLU and PReLU layer functions.

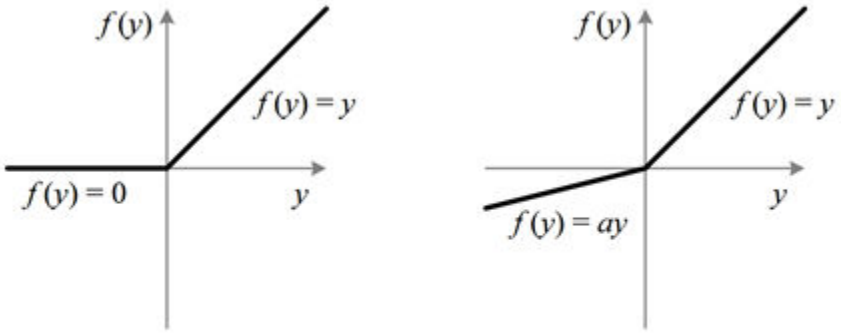

Figure 1. ReLU vs. PReLU. For PReLU, the coefficient of the negative part is not constant and is adaptively learned.

Intermediate Layer Template

Copy the intermediate layer template into a new file in MATLAB. This template outlines the structure of an intermediate layer class definition. It outlines:

- The optional `properties` blocks for the layer properties, learnable parameters, and state parameters.
- The layer constructor function.
- The `predict` function and the optional `forward` function.
- The optional `resetState` function for layers with state properties.
- The optional `backward` function.

```
classdef myLayer < nnet.layer.Layer % & nnet.layer.Formattable (Optional)

    properties
        % (Optional) Layer properties.

        % Declare layer properties here.
    end

        % (Optional) Layer learnable parameters.

        % Declare learnable parameters here.
    end

    properties (State)
        % (Optional) Layer state parameters.

        % Declare state parameters here.
    end

    properties (Learnable, State)
        % (Optional) Nested dlnetwork objects with both learnable
        % parameters and state.

        % Declare nested networks with learnable and state parameters here.
    end

    methods
        function layer = myLayer()
```

```
    % (Optional) Create a myLayer.
    % This function must have the same name as the class.

    % Define layer constructor function here.
end

function [Z,state] = predict(layer,X)
    % Forward input data through the layer at prediction time and
    % output the result and updated state.
    %
    % Inputs:
    %         layer - Layer to forward propagate through
    %         X     - Input data
    % Outputs:
    %         Z     - Output of layer forward function
    %         state - (Optional) Updated layer state.
    %
    %  - For layers with multiple inputs, replace X with X1,...,XN,
    %    where N is the number of inputs.
    %  - For layers with multiple outputs, replace Z with
    %    Z1,...,ZM, where M is the number of outputs.
    %  - For layers with multiple state parameters, replace state
    %    with state1,...,stateK, where K is the number of state
    %    parameters.

    % Define layer predict function here.
end

function [Z,state,memory] = forward(layer,X)
    % (Optional) Forward input data through the layer at training
    % time and output the result, updated state, and a memory
    % value.
    %
    % Inputs:
    %         layer - Layer to forward propagate through
    %         X     - Layer input data
    % Outputs:
    %         Z      - Output of layer forward function
    %         state  - (Optional) Updated layer state
    %         memory - (Optional) Memory value for custom backward
    %                  function
    %
    %  - For layers with multiple inputs, replace X with X1,...,XN,
    %    where N is the number of inputs.
    %  - For layers with multiple outputs, replace Z with
    %    Z1,...,ZM, where M is the number of outputs.
    %  - For layers with multiple state parameters, replace state
    %    with state1,...,stateK, where K is the number of state
    %    parameters.

    % Define layer forward function here.
end

function layer = resetState(layer)
    % (Optional) Reset layer state.

    % Define reset state function here.
end

function [dLdX,dLdW,dLdSin] = backward(layer,X,Z,dLdZ,dLdSout,memory)
    % (Optional) Backward propagate the derivative of the loss
    % function through the layer.
    %
    % Inputs:
    %         layer   - Layer to backward propagate through
    %         X       - Layer input data
    %         Z       - Layer output data
    %         dLdZ    - Derivative of loss with respect to layer
    %                   output
    %         dLdSout - (Optional) Derivative of loss with respect
    %                   to state output
    %         memory  - Memory value from forward function
```

```
            % Outputs:
            %         dLdX   - Derivative of loss with respect to layer input
            %         dLdW   - (Optional) Derivative of loss with respect to
            %                  learnable parameter
            %         dLdSin - (Optional) Derivative of loss with respect to
            %                  state input
            %
            %  - For layers with state parameters, the backward syntax must
            %    include both dLdSout and dLdSin, or neither.
            %  - For layers with multiple inputs, replace X and dLdX with
            %    X1,...,XN and dLdX1,...,dLdXN, respectively, where N is
            %    the number of inputs.
            %  - For layers with multiple outputs, replace Z and dlZ with
            %    Z1,...,ZM and dLdZ,...,dLdZM, respectively, where M is the
            %    number of outputs.
            %  - For layers with multiple learnable parameters, replace
            %    dLdW with dLdW1,...,dLdWP, where P is the number of
            %    learnable parameters.
            %  - For layers with multiple state parameters, replace dLdSin
            %    and dLdSout with dLdSin1,...,dLdSinK and
            %    dLdSout1,...dldSoutK, respectively, where K is the number
            %    of state parameters.

            % Define layer backward function here.
        end
    end
end
```

Name Layer and Specify Superclasses

First, give the layer a name. In the first line of the class file, replace the existing name `myLayer` with `preluLayer`.

```
classdef preluLayer < nnet.layer.Layer % & nnet.layer.Formattable (Optional)
    ...
end
```

If you do not specify a backward function, then the layer functions, by default, receive *unformatted* `dlarray` objects as input. To specify that the layer receives *formatted* `dlarray` objects as input and also outputs formatted `dlarray` objects, also inherit from the `nnet.layer.Formattable` class when defining the custom layer.

The layer does not require formattable inputs, so remove the optional `nnet.layer.Formattable` superclass.

```
classdef preluLayer < nnet.layer.Layer
    ...
end
```

Next, rename the `myLayer` constructor function (the first function in the `methods` section) so that it has the same name as the layer.

```
    methods
        function layer = preluLayer()
            ...
        end

        ...
     end
```

Save the Layer

Save the layer class file in a new file named `preluLayer.m`. The file name must match the layer name. To use the layer, you must save the file in the current folder or in a folder on the MATLAB path.

Declare Properties and Learnable Parameters

Declare the layer properties in the `properties` section and declare learnable parameters by listing them in the `properties (Learnable)` section.

By default, custom intermediate layers have these properties. Do not declare these properties in the `properties` section.

Property	Description
`Name`	Layer name, specified as a character vector or a string scalar. For `Layer` array input, the `trainNetwork`, `assembleNetwork`, `layerGraph`, and `dlnetwork` functions automatically assign names to layers with `Name` set to `''`.
`Description`	One-line description of the layer, specified as a string scalar or a character vector. This description appears when the layer is displayed in a `Layer` array. If you do not specify a layer description, then the software displays the layer class name.
`Type`	Type of the layer, specified as a character vector or a string scalar. The value of `Type` appears when the layer is displayed in a `Layer` array. If you do not specify a layer type, then the software displays the layer class name.
`NumInputs`	Number of inputs of the layer, specified as a positive integer. If you do not specify this value, then the software automatically sets `NumInputs` to the number of names in `InputNames`. The default value is 1.
`InputNames`	Input names of the layer, specified as a cell array of character vectors. If you do not specify this value and `NumInputs` is greater than 1, then the software automatically sets `InputNames` to `{'in1',...,'inN'}`, where `N` is equal to `NumInputs`. The default value is `{'in'}`.
`NumOutputs`	Number of outputs of the layer, specified as a positive integer. If you do not specify this value, then the software automatically sets `NumOutputs` to the number of names in `OutputNames`. The default value is 1.

Property	Description
`OutputNames`	Output names of the layer, specified as a cell array of character vectors. If you do not specify this value and `NumOutputs` is greater than 1, then the software automatically sets `OutputNames` to `{'out1',...,'outM'}`, where `M` is equal to `NumOutputs`. The default value is `{'out'}`.

If the layer has no other properties, then you can omit the `properties` section.

Tip If you are creating a layer with multiple inputs, then you must set either the `NumInputs` or `InputNames` properties in the layer constructor. If you are creating a layer with multiple outputs, then you must set either the `NumOutputs` or `OutputNames` properties in the layer constructor. For an example, see “Define Custom Deep Learning Layer with Multiple Inputs” on page 18-48.

A PReLU layer does not require any additional properties, so you can remove the `properties` section.

A PReLU layer has only one learnable parameter, the scaling coefficient a. Declare this learnable parameter in the `properties (Learnable)` section and call the parameter `Alpha`.

```
properties (Learnable)
    % Layer learnable parameters

    % Scaling coefficient
    Alpha
end
```

Create Constructor Function

Create the function that constructs the layer and initializes the layer properties. Specify any variables required to create the layer as inputs to the constructor function.

The PReLU layer constructor function requires one input argument (the number of channels) and one optional argument (the layer name). The number of channels specifies the size of the learnable parameter `Alpha`. Specify two input arguments named `numChannels` and `args` in the `preluLayer` function that correspond to the number of channels and optional input arguments, respectively. Add a comment to the top of the function that explains the syntax of the function.

```
function layer = preluLayer(numChannels,args)
    % layer = preluLayer(numChannels) creates a PReLU layer
    % with numChannels channels.
    %
    % layer = preluLayer(numChannels,Name=name) also specifies the
    % layer name

    ...
end
```

Initialize Layer Properties

Initialize the layer properties, including learnable parameters in the constructor function. Replace the comment `% Layer constructor function goes here` with code that initializes the layer properties.

Parse the input arguments using an `arguments` block and set the `Name` property.

```
arguments
    numChannels
    args.Name = "";
end

% Set layer name.
layer.Name = args.Name;
```

Give the layer a one-line description by setting the `Description` property of the layer. Set the description to describe the type of layer and its size.

```
% Set layer description.
layer.Description = "PReLU with " + numChannels + " channels";
```

For a PReLU layer, when the input values are negative, the layer multiplies each channel of the input by the corresponding channel of `Alpha`. Initialize the learnable parameter `Alpha` to be a random vector of size 1-by-1-by-`numChannels`. With the third dimension specified as size `numChannels`, the layer can use element-wise multiplication of the input in the forward function. `Alpha` is a property of the layer object, so you must assign the vector to `layer.Alpha`.

```
% Initialize scaling coefficient.
layer.Alpha = rand([1 1 numChannels]);
```

View the completed constructor function.

```
function layer = preluLayer(numChannels,args)
    % layer = preluLayer(numChannels) creates a PReLU layer
    % with numChannels channels.
    %
    % layer = preluLayer(numChannels,Name=name) also specifies the
    % layer name.

    arguments
        numChannels
        args.Name = "";
    end

    % Set layer name.
    layer.Name = name;

    % Set layer description.
    layer.Description = "PReLU with " + numChannels + " channels";

    % Initialize scaling coefficient.
    layer.Alpha = rand([1 1 numChannels]);
end
```

With this constructor function, the command `preluLayer(3,Name="prelu")` creates a PReLU layer with three channels and the name `"prelu"`.

Create Forward Functions

Create the layer forward functions to use at prediction time and training time.

Create a function named `predict` that propagates the data forward through the layer at *prediction time* and outputs the result.

The `predict` function syntax depends on the type of layer.

- `Z = predict(layer,X)` forwards the input data `X` through the layer and outputs the result `Z`, where `layer` has a single input, a single output.

- `[Z,state] = predict(layer,X)` also outputs the updated state parameter `state`, where `layer` has a single state parameter.

You can adjust the syntaxes for layers with multiple inputs, multiple outputs, or multiple state parameters:

- For layers with multiple inputs, replace `X` with `X1,...,XN`, where `N` is the number of inputs. The `NumInputs` property must match `N`.
- For layers with multiple outputs, replace `Z` with `Z1,...,ZM`, where `M` is the number of outputs. The `NumOutputs` property must match `M`.
- For layers with multiple state parameters, replace `state` with `state1,...,stateK`, where `K` is the number of state parameters.

Tip If the number of inputs to the layer can vary, then use `varargin` instead of `X1,…,XN`. In this case, `varargin` is a cell array of the inputs, where `varargin{i}` corresponds to `Xi`.

If the number of outputs can vary, then use `varargout` instead of `Z1,…,ZN`. In this case, `varargout` is a cell array of the outputs, where `varargout{j}` corresponds to `Zj`.

Tip If the custom layer has a `dlnetwork` object for a learnable parameter, then in the `predict` function of the custom layer, use the `predict` function for the `dlnetwork`. Using the `dlnetwork` object `predict` function ensures that the software uses the correct layer operations for prediction.

Because a PReLU layer has only one input and one output, the syntax for `predict` for a PReLU layer is `Z = predict(layer,X)`.

By default, the layer uses `predict` as the forward function at training time. To use a different forward function at training time, or retain a value required for a custom backward function, you must also create a function named `forward`.

The dimensions of the inputs depend on the type of data and the output of the connected layers:

Layer Input	Input Size	Observation Dimension
Feature vectors	*c*-by-*N*, where *c* corresponds to the number of channels and *N* is the number of observations.	2
2-D images	*h*-by-*w*-by-*c*-by-*N*, where *h*, *w*, and *c* correspond to the height, width, and number of channels of the images, respectively, and *N* is the number of observations.	4
3-D images	*h*-by-*w*-by-*d*-by-*c*-by-*N*, where *h*, *w*, *d*, and *c* correspond to the height, width, depth, and number of channels of the 3-D images, respectively, and *N* is the number of observations.	5

Layer Input	Input Size	Observation Dimension
Vector sequences	*c*-by-*N*-by-*S*, where *c* is the number of features of the sequences, *N* is the number of observations, and *S* is the sequence length.	2
2-D image sequences	*h*-by-*w*-by-*c*-by-*N*-by-*S*, where *h*, *w*, and *c* correspond to the height, width, and number of channels of the images, respectively, *N* is the number of observations, and *S* is the sequence length.	4
3-D image sequences	*h*-by-*w*-by-*d*-by-*c*-by-*N*-by-*S*, where *h*, *w*, *d*, and *c* correspond to the height, width, depth, and number of channels of the 3-D images, respectively, *N* is the number of observations, and *S* is the sequence length.	5

For layers that output sequences, the layers can output sequences of any length or output data with no time dimension. Note that when training a network that outputs sequences using the `trainNetwork` function, the lengths of the input and output sequences must match.

The `forward` function propagates the data forward through the layer at *training time* and also outputs a memory value.

The `forward` function syntax depends on the type of layer:

- `Z = forward(layer,X)` forwards the input data `X` through the layer and outputs the result `Z`, where `layer` has a single input, a single output.
- `[Z,state] = forward(layer,X)` also outputs the updated state parameter `state`, where `layer` has a single state parameter.
- `[__,memory] = forward(layer,X)` also returns a memory value for a custom `backward` function using any of the previous syntaxes. If the layer has both a custom `forward` function and a custom `backward` function, then the forward function must return a memory value.

You can adjust the syntaxes for layers with multiple inputs, multiple outputs, or multiple state parameters:

- For layers with multiple inputs, replace `X` with `X1,...,XN`, where `N` is the number of inputs. The `NumInputs` property must match `N`.
- For layers with multiple outputs, replace `Z` with `Z1,...,ZM`, where `M` is the number of outputs. The `NumOutputs` property must match `M`.
- For layers with multiple state parameters, replace `state` with `state1,...,stateK`, where `K` is the number of state parameters.

Tip If the number of inputs to the layer can vary, then use `varargin` instead of `X1,…,XN`. In this case, `varargin` is a cell array of the inputs, where `varargin{i}` corresponds to `Xi`.

If the number of outputs can vary, then use `varargout` instead of `Z1,…,ZN`. In this case, `varargout` is a cell array of the outputs, where `varargout{j}` corresponds to `Zj`.

Tip If the custom layer has a `dlnetwork` object for a learnable parameter, then in the `forward` function of the custom layer, use the `forward` function of the `dlnetwork` object. Using the `dlnetwork` object `forward` function ensures that the software uses the correct layer operations for training.

The PReLU operation is given by

$$f(x_i) = \begin{cases} x_i & \text{if } x_i > 0 \\ \alpha_i x_i & \text{if } x_i \le 0 \end{cases}$$

where x_i is the input of the nonlinear activation f on channel i, and α_i is the coefficient controlling the slope of the negative part. The subscript i in α_i indicates that the nonlinear activation can vary on different channels.

Implement this operation in `predict`. In `predict`, the input `X` corresponds to x in the equation. The output `Z` corresponds to $f(x_i)$. The PReLU layer does not require memory or a different forward function for training, so you can remove the `forward` function from the class file. Add a comment to the top of the function that explains the syntaxes of the function.

Tip If you preallocate arrays using functions such as `zeros`, then you must ensure that the data types of these arrays are consistent with the layer function inputs. To create an array of zeros of the same data type as another array, use the `"like"` option of `zeros`. For example, to initialize an array of zeros of size `sz` with the same data type as the array `X`, use `Z = zeros(sz,"like",X)`.

```
function Z = predict(layer, X)
    % Z = predict(layer, X) forwards the input data X through the
    % layer and outputs the result Z.

    Z = max(X,0) + layer.Alpha .* min(0,X);
end
```

Because the `predict` function only uses functions that support `dlarray` objects, defining the `backward` function is optional. For a list of functions that support `dlarray` objects, see “List of Functions with dlarray Support” on page 18-423.

Completed Layer

View the completed layer class file.

```
classdef preluLayer < nnet.layer.Layer
    % Example custom PReLU layer.

    properties (Learnable)
        % Layer learnable parameters

        % Scaling coefficient
        Alpha
    end
```

```
    methods
        function layer = preluLayer(numChannels,args)
            % layer = preluLayer(numChannels) creates a PReLU layer
            % with numChannels channels.
            %
            % layer = preluLayer(numChannels,Name=name) also specifies the
            % layer name.

            arguments
                numChannels
                args.Name = "";
            end

            % Set layer name.
            layer.Name = name;

            % Set layer description.
            layer.Description = "PReLU with " + numChannels + " channels";

            % Initialize scaling coefficient.
            layer.Alpha = rand([1 1 numChannels]);
        end

        function Z = predict(layer, X)
            % Z = predict(layer, X) forwards the input data X through the
            % layer and outputs the result Z.

            Z = max(X,0) + layer.Alpha .* min(0,X);
        end
    end
end
```

GPU Compatibility

If the layer forward functions fully support `dlarray` objects, then the layer is GPU compatible. Otherwise, to be GPU compatible, the layer functions must support inputs and return outputs of type `gpuArray`.

Many MATLAB built-in functions support `gpuArray` and `dlarray` input arguments. For a list of functions that support `dlarray` objects, see “List of Functions with dlarray Support” on page 18-423. For a list of functions that execute on a GPU, see “Run MATLAB Functions on a GPU” (Parallel Computing Toolbox). To use a GPU for deep learning, you must also have a supported GPU device. For information on supported devices, see “GPU Support by Release” (Parallel Computing Toolbox). For more information on working with GPUs in MATLAB, see “GPU Computing in MATLAB” (Parallel Computing Toolbox).

In this example, the MATLAB functions used in `predict` all support `dlarray` objects, so the layer is GPU compatible.

Check Validity of Custom Layer Using checkLayer

Check the layer validity of the custom layer `preluLayer`.

The custom layer `preluLayer`, attached to this is example as a supporting file, applies the PReLU operation to the input data. To access this layer, open this example as a live script.

Create an instance of the layer and check its validity using `checkLayer`. Specify the valid input size to be the size of a single observation of typical input to the layer. The layer expects 4-D array inputs, where the first three dimensions correspond to the height, width, and number of channels of the previous layer output, and the fourth dimension corresponds to the observations.

Specify the typical size of the input of an observation and set the `ObservationDimension` option to 4.

```
layer = preluLayer(20);
validInputSize = [24 24 20];
checkLayer(layer,validInputSize,ObservationDimension=4)
```

```
Skipping GPU tests. No compatible GPU device found.

Skipping code generation compatibility tests. To check validity of the layer for code generation

Running nnet.checklayer.TestLayerWithoutBackward
.......... ........
Done nnet.checklayer.TestLayerWithoutBackward
__________

Test Summary:
     18 Passed, 0 Failed, 0 Incomplete, 10 Skipped.
     Time elapsed: 0.21297 seconds.
```

Here, the function does not detect any issues with the layer.

Include Custom Layer in Network

You can use a custom layer in the same way as any other layer in Deep Learning Toolbox. This section shows how to create and train a network for digit classification using the PReLU layer you created earlier.

Load the example training data.

```
[XTrain,YTrain] = digitTrain4DArrayData;
```

Create a layer array containing the custom layer `preluLayer`, attached to this is example as a supporting file. To access this layer, open this example as a live script.

```
layers = [
    imageInputLayer([28 28 1])
    convolution2dLayer(5,20)
    batchNormalizationLayer
    preluLayer(20)
    fullyConnectedLayer(10)
    softmaxLayer
    classificationLayer];
```

Set the training options and train the network.

```
options = trainingOptions("adam",MaxEpochs=10);
net = trainNetwork(XTrain,YTrain,layers,options);
```

```
Training on single CPU.
Initializing input data normalization.
```

```

```

Evaluate the network performance by predicting on new data and calculating the accuracy.

```
[XTest,YTest] = digitTest4DArrayData;
YPred = classify(net,XTest);
accuracy = mean(YTest==YPred)
```

```
accuracy = 0.9188
```

Define Custom Deep Learning Layer with Multiple Inputs

If Deep Learning Toolbox does not provide the layer you require for your classification or regression problem, then you can define your own custom layer using this example as a guide. For a list of built-in layers, see “List of Deep Learning Layers” on page 1-21.

To define a custom deep learning layer, you can use the template provided in this example, which takes you through the following steps:

1. Name the layer — Give the layer a name so that you can use it in MATLAB.
2. Declare the layer properties — Specify the properties of the layer including learnable parameters and state parameters.
3. Create a constructor function (optional) — Specify how to construct the layer and initialize its properties. If you do not specify a constructor function, then at creation, the software initializes the `Name`, `Description`, and `Type` properties with `[]` and sets the number of layer inputs and outputs to 1.
4. Create forward functions — Specify how data passes forward through the layer (forward propagation) at prediction time and at training time.
5. Create reset state function (optional) — Specify how to reset state parameters.
6. Create a backward function (optional) — Specify the derivatives of the loss with respect to the input data and the learnable parameters (backward propagation). If you do not specify a backward function, then the forward functions must support `dlarray` objects.

This example shows how to create a weighted addition layer, which is a layer with multiple inputs and learnable parameter, and use it in a convolutional neural network. A weighted addition layer scales and adds inputs from multiple neural network layers element-wise.

Intermediate Layer Template

Copy the intermediate layer template into a new file in MATLAB. This template outlines the structure of an intermediate layer class definition. It outlines:

- The optional `properties` blocks for the layer properties, learnable parameters, and state parameters.
- The layer constructor function.
- The `predict` function and the optional `forward` function.
- The optional `resetState` function for layers with state properties.
- The optional `backward` function.

```
classdef myLayer < nnet.layer.Layer % & nnet.layer.Formattable (Optional)

    properties
        % (Optional) Layer properties.

        % Declare layer properties here.
    end

    properties (Learnable)
        % (Optional) Layer learnable parameters.

        % Declare learnable parameters here.
    end
```

```
properties (State)
    % (Optional) Layer state parameters.

    % Declare state parameters here.
end

properties (Learnable, State)
    % (Optional) Nested dlnetwork objects with both learnable
    % parameters and state.

    % Declare nested networks with learnable and state parameters here.
end

methods
    function layer = myLayer()
        % (Optional) Create a myLayer.
        % This function must have the same name as the class.

        % Define layer constructor function here.
    end

    function [Z,state] = predict(layer,X)
        % Forward input data through the layer at prediction time and
        % output the result and updated state.
        %
        % Inputs:
        %         layer - Layer to forward propagate through
        %         X     - Input data
        % Outputs:
        %         Z     - Output of layer forward function
        %         state - (Optional) Updated layer state.
        %
        %  - For layers with multiple inputs, replace X with X1,...,XN,
        %    where N is the number of inputs.
        %  - For layers with multiple outputs, replace Z with
        %    Z1,...,ZM, where M is the number of outputs.
        %  - For layers with multiple state parameters, replace state
        %    with state1,...,stateK, where K is the number of state
        %    parameters.

        % Define layer predict function here.
    end

    function [Z,state,memory] = forward(layer,X)
        % (Optional) Forward input data through the layer at training
        % time and output the result, updated state, and a memory
        % value.
        %
        % Inputs:
        %         layer - Layer to forward propagate through
        %         X     - Layer input data
        % Outputs:
        %         Z      - Output of layer forward function
        %         state  - (Optional) Updated layer state
        %         memory - (Optional) Memory value for custom backward
        %                  function
        %
        %  - For layers with multiple inputs, replace X with X1,...,XN,
        %    where N is the number of inputs.
        %  - For layers with multiple outputs, replace Z with
        %    Z1,...,ZM, where M is the number of outputs.
        %  - For layers with multiple state parameters, replace state
        %    with state1,...,stateK, where K is the number of state
        %    parameters.

        % Define layer forward function here.
    end

    function layer = resetState(layer)
        % (Optional) Reset layer state.

        % Define reset state function here.
```

```
        end

        function [dLdX,dLdW,dLdSin] = backward(layer,X,Z,dLdZ,dLdSout,memory)
            % (Optional) Backward propagate the derivative of the loss
            % function through the layer.
            %
            % Inputs:
            %         layer   - Layer to backward propagate through
            %         X       - Layer input data
            %         Z       - Layer output data
            %         dLdZ    - Derivative of loss with respect to layer
            %                   output
            %         dLdSout - (Optional) Derivative of loss with respect
            %                   to state output
            %         memory  - Memory value from forward function
            % Outputs:
            %         dLdX   - Derivative of loss with respect to layer input
            %         dLdW   - (Optional) Derivative of loss with respect to
            %                  learnable parameter
            %         dLdSin - (Optional) Derivative of loss with respect to
            %                  state input
            %
            %  - For layers with state parameters, the backward syntax must
            %    include both dLdSout and dLdSin, or neither.
            %  - For layers with multiple inputs, replace X and dLdX with
            %    X1,...,XN and dLdX1,...,dLdXN, respectively, where N is
            %    the number of inputs.
            %  - For layers with multiple outputs, replace Z and dlZ with
            %    Z1,...,ZM and dLdZ,...,dLdZM, respectively, where M is the
            %    number of outputs.
            %  - For layers with multiple learnable parameters, replace
            %    dLdW with dLdW1,...,dLdWP, where P is the number of
            %    learnable parameters.
            %  - For layers with multiple state parameters, replace dLdSin
            %    and dLdSout with dLdSin1,...,dLdSinK and
            %    dLdSout1,...dldSoutK, respectively, where K is the number
            %    of state parameters.

            % Define layer backward function here.
        end
    end
end
```

Name Layer and Specify Superclasses

First, give the layer a name. In the first line of the class file, replace the existing name `myLayer` with `weightedAdditionLayer`.

```
classdef weightedAdditionLayer < nnet.layer.Layer % & nnet.layer.Formattable (Optional)
    ...
end
```

If you do not specify a backward function, then the layer functions, by default, receive *unformatted* `dlarray` objects as input. To specify that the layer receives *formatted* `dlarray` objects as input and also outputs formatted `dlarray` objects, also inherit from the `nnet.layer.Formattable` class when defining the custom layer.

The layer does not require formattable inputs, so remove the optional `nnet.layer.Formattable` superclass.

```
classdef weightedAdditionLayer < nnet.layer.Layer
    ...
end
```

Next, rename the `myLayer` constructor function (the first function in the `methods` section) so that it has the same name as the layer.

```
    methods
        function layer = weightedAdditionLayer()
            ...
        end

        ...
     end
```

Save the Layer

Save the layer class file in a new file named `weightedAdditionLayer.m`. The file name must match the layer name. To use the layer, you must save the file in the current folder or in a folder on the MATLAB path.

Declare Properties and Learnable Parameters

Declare the layer properties in the `properties` section and declare learnable parameters by listing them in the `properties (Learnable)` section.

By default, custom intermediate layers have these properties. Do not declare these properties in the `properties` section.

Property	Description
`Name`	Layer name, specified as a character vector or a string scalar. For `Layer` array input, the `trainNetwork`, `assembleNetwork`, `layerGraph`, and `dlnetwork` functions automatically assign names to layers with `Name` set to `''`.
`Description`	One-line description of the layer, specified as a string scalar or a character vector. This description appears when the layer is displayed in a `Layer` array. If you do not specify a layer description, then the software displays the layer class name.
`Type`	Type of the layer, specified as a character vector or a string scalar. The value of `Type` appears when the layer is displayed in a `Layer` array. If you do not specify a layer type, then the software displays the layer class name.
`NumInputs`	Number of inputs of the layer, specified as a positive integer. If you do not specify this value, then the software automatically sets `NumInputs` to the number of names in `InputNames`. The default value is 1.

Property	Description
`InputNames`	Input names of the layer, specified as a cell array of character vectors. If you do not specify this value and `NumInputs` is greater than 1, then the software automatically sets `InputNames` to `{'in1',...,'inN'}`, where `N` is equal to `NumInputs`. The default value is `{'in'}`.
`NumOutputs`	Number of outputs of the layer, specified as a positive integer. If you do not specify this value, then the software automatically sets `NumOutputs` to the number of names in `OutputNames`. The default value is 1.
`OutputNames`	Output names of the layer, specified as a cell array of character vectors. If you do not specify this value and `NumOutputs` is greater than 1, then the software automatically sets `OutputNames` to `{'out1',...,'outM'}`, where `M` is equal to `NumOutputs`. The default value is `{'out'}`.

If the layer has no other properties, then you can omit the `properties` section.

Tip If you are creating a layer with multiple inputs, then you must set either the `NumInputs` or `InputNames` properties in the layer constructor. If you are creating a layer with multiple outputs, then you must set either the `NumOutputs` or `OutputNames` properties in the layer constructor.

A weighted addition layer does not require any additional properties, so you can remove the `properties` section.

A weighted addition layer has only one learnable parameter, the weights. Declare this learnable parameter in the `properties (Learnable)` section and call the parameter `Weights`.

```
properties (Learnable)
    % Layer learnable parameters

    % Scaling coefficients
    Weights
end
```

Create Constructor Function

Create the function that constructs the layer and initializes the layer properties. Specify any variables required to create the layer as inputs to the constructor function.

The weighted addition layer constructor function requires two inputs: the number of inputs to the layer and the layer name. This number of inputs to the layer specifies the size of the learnable parameter `Weights`. Specify two input arguments named `numInputs` and `name` in the `weightedAdditionLayer` function. Add a comment to the top of the function that explains the syntax of the function.

```
function layer = weightedAdditionLayer(numInputs,name)
    % layer = weightedAdditionLayer(numInputs,name) creates a
    % weighted addition layer and specifies the number of inputs
    % and the layer name.

    ...
end
```

Initialize Layer Properties

Initialize the layer properties, including learnable parameters, in the constructor function. Replace the comment `% Layer constructor function goes here` with code that initializes the layer properties.

Set the `NumInputs` property to the input argument `numInputs`.

```
% Set number of inputs.
layer.NumInputs = numInputs;
```

Set the `Name` property to the input argument `name`.

```
% Set layer name.
layer.Name = name;
```

Give the layer a one-line description by setting the `Description` property of the layer. Set the description to describe the type of layer and its size.

```
% Set layer description.
layer.Description = "Weighted addition of " + numInputs + ...
    " inputs";
```

A weighted addition layer multiplies each layer input by the corresponding coefficient in `Weights` and adds the resulting values together. Initialize the learnable parameter `Weights` to be a random vector of size 1-by-`numInputs`. `Weights` is a property of the layer object, so you must assign the vector to `layer.Weights`.

```
% Initialize layer weights
layer.Weights = rand(1,numInputs);
```

View the completed constructor function.

```
function layer = weightedAdditionLayer(numInputs,name)
    % layer = weightedAdditionLayer(numInputs,name) creates a
    % weighted addition layer and specifies the number of inputs
    % and the layer name.

    % Set number of inputs.
    layer.NumInputs = numInputs;

    % Set layer name.
    layer.Name = name;

    % Set layer description.
    layer.Description = "Weighted addition of " + numInputs +  ...
        " inputs";

    % Initialize layer weights.
```

```
            layer.Weights = rand(1,numInputs);
        end
```

With this constructor function, the command `weightedAdditionLayer(3,'add')` creates a weighted addition layer with three inputs and the name `'add'`.

Create Forward Functions

Create the layer forward functions to use at prediction time and training time.

Create a function named `predict` that propagates the data forward through the layer at *prediction time* and outputs the result.

The `predict` function syntax depends on the type of layer.

- `Z = predict(layer,X)` forwards the input data `X` through the layer and outputs the result `Z`, where `layer` has a single input, a single output.
- `[Z,state] = predict(layer,X)` also outputs the updated state parameter `state`, where `layer` has a single state parameter.

You can adjust the syntaxes for layers with multiple inputs, multiple outputs, or multiple state parameters:

- For layers with multiple inputs, replace `X` with `X1,...,XN`, where `N` is the number of inputs. The `NumInputs` property must match `N`.
- For layers with multiple outputs, replace `Z` with `Z1,...,ZM`, where `M` is the number of outputs. The `NumOutputs` property must match `M`.
- For layers with multiple state parameters, replace `state` with `state1,...,stateK`, where `K` is the number of state parameters.

Tip If the number of inputs to the layer can vary, then use `varargin` instead of `X1,…,XN`. In this case, `varargin` is a cell array of the inputs, where `varargin{i}` corresponds to `Xi`.

If the number of outputs can vary, then use `varargout` instead of `Z1,…,ZN`. In this case, `varargout` is a cell array of the outputs, where `varargout{j}` corresponds to `Zj`.

Tip If the custom layer has a `dlnetwork` object for a learnable parameter, then in the `predict` function of the custom layer, use the `predict` function for the `dlnetwork`. Using the `dlnetwork` object `predict` function ensures that the software uses the correct layer operations for prediction.

Because a weighted addition layer has only one output and a variable number of inputs, the syntax for `predict` for a weighted addition layer is `Z = predict(layer,varargin)`, where `varargin{i}` corresponds to `Xi` for positive integers `i` less than or equal to `NumInputs`.

By default, the layer uses `predict` as the forward function at training time. To use a different forward function at training time, or retain a value required for the backward function, you must also create a function named `forward`.

The dimensions of the inputs depend on the type of data and the output of the connected layers:

Layer Input	Input Size	Observation Dimension
Feature vectors	*c*-by-*N*, where *c* corresponds to the number of channels and *N* is the number of observations.	2
2-D images	*h*-by-*w*-by-*c*-by-*N*, where *h*, *w*, and *c* correspond to the height, width, and number of channels of the images, respectively, and *N* is the number of observations.	4
3-D images	*h*-by-*w*-by-*d*-by-*c*-by-*N*, where *h*, *w*, *d*, and *c* correspond to the height, width, depth, and number of channels of the 3-D images, respectively, and *N* is the number of observations.	5
Vector sequences	*c*-by-*N*-by-*S*, where *c* is the number of features of the sequences, *N* is the number of observations, and *S* is the sequence length.	2
2-D image sequences	*h*-by-*w*-by-*c*-by-*N*-by-*S*, where *h*, *w*, and *c* correspond to the height, width, and number of channels of the images, respectively, *N* is the number of observations, and *S* is the sequence length.	4
3-D image sequences	*h*-by-*w*-by-*d*-by-*c*-by-*N*-by-*S*, where *h*, *w*, *d*, and *c* correspond to the height, width, depth, and number of channels of the 3-D images, respectively, *N* is the number of observations, and *S* is the sequence length.	5

For layers that output sequences, the layers can output sequences of any length or output data with no time dimension. Note that when training a network that outputs sequences using the `trainNetwork` function, the lengths of the input and output sequences must match.

The `forward` function propagates the data forward through the layer at *training time* and also outputs a memory value.

The `forward` function syntax depends on the type of layer:

- `Z = forward(layer,X)` forwards the input data `X` through the layer and outputs the result `Z`, where `layer` has a single input, a single output.
- `[Z,state] = forward(layer,X)` also outputs the updated state parameter `state`, where `layer` has a single state parameter.

- `[__,memory] = forward(layer,X)` also returns a memory value for a custom `backward` function using any of the previous syntaxes. If the layer has both a custom `forward` function and a custom `backward` function, then the forward function must return a memory value.

You can adjust the syntaxes for layers with multiple inputs, multiple outputs, or multiple state parameters:

- For layers with multiple inputs, replace `X` with `X1,...,XN`, where `N` is the number of inputs. The `NumInputs` property must match `N`.
- For layers with multiple outputs, replace `Z` with `Z1,...,ZM`, where `M` is the number of outputs. The `NumOutputs` property must match `M`.
- For layers with multiple state parameters, replace `state` with `state1,...,stateK`, where `K` is the number of state parameters.

Tip If the number of inputs to the layer can vary, then use `varargin` instead of `X1,…,XN`. In this case, `varargin` is a cell array of the inputs, where `varargin{i}` corresponds to `Xi`.

If the number of outputs can vary, then use `varargout` instead of `Z1,…,ZN`. In this case, `varargout` is a cell array of the outputs, where `varargout{j}` corresponds to `Zj`.

Tip If the custom layer has a `dlnetwork` object for a learnable parameter, then in the `forward` function of the custom layer, use the `forward` function of the `dlnetwork` object. Using the `dlnetwork` object `forward` function ensures that the software uses the correct layer operations for training.

The forward function of a weighted addition layer is

$$f(X^{(1)},...,X^{(n)}) = \sum_{i=1}^{n} W_i X^{(i)}$$

where $X^{(1)}, ..., X^{(n)}$ correspond to the layer inputs and $W_1,...,W_n$ are the layer weights.

Implement the forward function in `predict`. In `predict`, the output `Z` corresponds to $f(X^{(1)},...,X^{(n)})$. The weighted addition layer does not require memory or a different forward function for training, so you can remove the `forward` function from the class file. Add a comment to the top of the function that explains the syntaxes of the function.

Tip If you preallocate arrays using functions such as `zeros`, then you must ensure that the data types of these arrays are consistent with the layer function inputs. To create an array of zeros of the same data type as another array, use the `"like"` option of `zeros`. For example, to initialize an array of zeros of size `sz` with the same data type as the array `X`, use `Z = zeros(sz,"like",X)`.

```
function Z = predict(layer, varargin)
    % Z = predict(layer, X1, ..., Xn) forwards the input data X1,
    % ..., Xn through the layer and outputs the result Z.

    X = varargin;
    W = layer.Weights;
```

```
            % Initialize output
            X1 = X{1};
            sz = size(X1);
            Z = zeros(sz,'like',X1);

            % Weighted addition
            for i = 1:layer.NumInputs
                Z = Z + W(i)*X{i};
            end
        end
```

Because the `predict` function only uses functions that support `dlarray` objects, defining the `backward` function is optional. For a list of functions that support `dlarray` objects, see “List of Functions with dlarray Support” on page 18-423.

Completed Layer

View the completed layer class file.

```
classdef weightedAdditionLayer < nnet.layer.Layer
    % Example custom weighted addition layer.

    properties (Learnable)
        % Layer learnable parameters

        % Scaling coefficients
        Weights
    end

    methods
        function layer = weightedAdditionLayer(numInputs,name)
            % layer = weightedAdditionLayer(numInputs,name) creates a
            % weighted addition layer and specifies the number of inputs
            % and the layer name.

            % Set number of inputs.
            layer.NumInputs = numInputs;

            % Set layer name.
            layer.Name = name;

            % Set layer description.
            layer.Description = "Weighted addition of " + numInputs +  ...
                " inputs";

            % Initialize layer weights.
            layer.Weights = rand(1,numInputs);
        end

        function Z = predict(layer, varargin)
            % Z = predict(layer, X1, ..., Xn) forwards the input data X1,
            % ..., Xn through the layer and outputs the result Z.

            X = varargin;
            W = layer.Weights;

            % Initialize output
```

```
            X1 = X{1};
            sz = size(X1);
            Z = zeros(sz,'like',X1);

            % Weighted addition
            for i = 1:layer.NumInputs
                Z = Z + W(i)*X{i};
            end
        end
    end
end
```

GPU Compatibility

If the layer forward functions fully support `dlarray` objects, then the layer is GPU compatible. Otherwise, to be GPU compatible, the layer functions must support inputs and return outputs of type `gpuArray`.

Many MATLAB built-in functions support `gpuArray` and `dlarray` input arguments. For a list of functions that support `dlarray` objects, see “List of Functions with dlarray Support” on page 18-423. For a list of functions that execute on a GPU, see “Run MATLAB Functions on a GPU” (Parallel Computing Toolbox). To use a GPU for deep learning, you must also have a supported GPU device. For information on supported devices, see “GPU Support by Release” (Parallel Computing Toolbox). For more information on working with GPUs in MATLAB, see “GPU Computing in MATLAB” (Parallel Computing Toolbox).

In this example, the MATLAB functions used in `predict` all support `dlarray` objects, so the layer is GPU compatible.

Check Validity of Layer with Multiple Inputs

Check the layer validity of the custom layer `weightedAdditionLayer`.

Define a custom weighted addition layer. To create this layer, save the file `weightedAdditionLayer.m` in the current folder.

Create an instance of the layer and check its validity using `checkLayer`. Specify the valid input sizes to be the typical sizes of a single observation for each input to the layer. The layer expects 4-D array inputs, where the first three dimensions correspond to the height, width, and number of channels of the previous layer output, and the fourth dimension corresponds to the observations.

Specify the typical size of the input of an observation and set `'ObservationDimension'` to 4.

```
layer = weightedAdditionLayer(2,'add');
validInputSize = {[24 24 20],[24 24 20]};
checkLayer(layer,validInputSize,'ObservationDimension',4)
```

```

     Time elapsed: 0.55735 seconds.
```

Here, the function does not detect any issues with the layer.

Use Custom Weighted Addition Layer in Network

You can use a custom layer in the same way as any other layer in Deep Learning Toolbox. This section shows how to create and train a network for digit classification using the weighted addition layer you created earlier.

Load the example training data.

```
[XTrain,YTrain] = digitTrain4DArrayData;
```

Define a custom weighted addition layer. To create this layer, save the file `weightedAdditionLayer.m` in the current folder.

Create a layer graph including the custom layer `weightedAdditionLayer`.

```
layers = [
    imageInputLayer([28 28 1],'Name','in')
    convolution2dLayer(5,20,'Name','conv1')
    reluLayer('Name','relu1')
    convolution2dLayer(3,20,'Padding',1,'Name','conv2')
    reluLayer('Name','relu2')
    convolution2dLayer(3,20,'Padding',1,'Name','conv3')
    reluLayer('Name','relu3')
    weightedAdditionLayer(2,'add')
    fullyConnectedLayer(10,'Name','fc')
    softmaxLayer('Name','softmax')
    classificationLayer('Name','classoutput')];

lgraph = layerGraph(layers);
lgraph = connectLayers(lgraph, 'relu1', 'add/in2');
```

Set the training options and train the network.

```
options = trainingOptions('adam','MaxEpochs',10);
net = trainNetwork(XTrain,YTrain,lgraph,options);
```

```
Training on single CPU.
Initializing input data normalization.

Define Custom Deep Learning Layer with Formatted Inputs

If Deep Learning Toolbox does not provide the layer you require for your task, then you can define your own custom layer using this example as a guide. For a list of built-in layers, see “List of Deep Learning Layers” on page 1-21.

To define a custom deep learning layer, you can use the template provided in this example, which takes you through the following steps:

1. Name the layer — Give the layer a name so that you can use it in MATLAB.
2. Declare the layer properties — Specify the properties of the layer including learnable parameters and state parameters.
3. Create a constructor function (optional) — Specify how to construct the layer and initialize its properties. If you do not specify a constructor function, then at creation, the software initializes the `Name`, `Description`, and `Type` properties with `[]` and sets the number of layer inputs and outputs to 1.
4. Create forward functions — Specify how data passes forward through the layer (forward propagation) at prediction time and at training time.
5. Create reset state function (optional) — Specify how to reset state parameters.
6. Create a backward function (optional) — Specify the derivatives of the loss with respect to the input data and the learnable parameters (backward propagation). If you do not specify a backward function, then the forward functions must support `dlarray` objects.

When defining the layer functions, you can use `dlarray` objects. Using `dlarray` objects makes working with high dimensional data easier by allowing you to label the dimensions. For example, you can label which dimensions correspond to spatial, time, channel, and batch dimensions using the `"S"`, `"T"`, `"C"`, and `"B"` labels, respectively. For unspecified and other dimensions, use the `"U"` label. For `dlarray` object functions that operate over particular dimensions, you can specify the dimension labels by formatting the `dlarray` object directly, or by using the `DataFormat` option.

Using formatted `dlarray` objects in custom layers also allows you to define layers where the inputs and outputs have different formats, such as layers that permute, add, or remove dimensions. For example, you can define a layer that takes as input a mini-batch of images with format `"SSCB"` (spatial, spatial, channel, batch) and output a mini-batch of sequences with format `"CBT"` (channel, batch, time). Using formatted `dlarray` objects also allows you to define layers that can operate on data with different input formats, for example, layers that support inputs with formats `"SSCB"` (spatial, spatial, channel, batch) and `"CBT"` (channel, batch, time).

`dlarray` objects also enable support for automatic differentiation. This means that if your forward functions fully support `dlarray` objects, then defining the backward function is optional.

This example shows how to create a *project and reshape* layer, which is a layer commonly used in generative adversarial networks (GANs) that takes an array of noise with format `"CB"` (channel, batch) and projects and reshapes it to a mini-batch of images with format `"SSCB"` (spatial, spatial, channel, batch) using fully connected, reshape, and relabel operations.

Intermediate Layer Template

Copy the intermediate layer template into a new file in MATLAB. This template outlines the structure of an intermediate layer class definition. It outlines:

- The optional `properties` blocks for the layer properties, learnable parameters, and state parameters.
- The layer constructor function.
- The `predict` function and the optional `forward` function.
- The optional `resetState` function for layers with state properties.
- The optional `backward` function.

```
classdef myLayer < nnet.layer.Layer % & nnet.layer.Formattable (Optional)

    properties
        % (Optional) Layer properties.

        % Declare layer properties here.
    end

    properties (Learnable)
        % (Optional) Layer learnable parameters.

        % Declare learnable parameters here.
    end

    properties (State)
        % (Optional) Layer state parameters.

        % Declare state parameters here.
    end

    properties (Learnable, State)
        % (Optional) Nested dlnetwork objects with both learnable
        % parameters and state.

        % Declare nested networks with learnable and state parameters here.
    end

    methods
        function layer = myLayer()
            % (Optional) Create a myLayer.
            % This function must have the same name as the class.

            % Define layer constructor function here.
        end

        function [Z,state] = predict(layer,X)
            % Forward input data through the layer at prediction time and
            % output the result and updated state.
            %
            % Inputs:
            %         layer - Layer to forward propagate through
            %         X     - Input data
            % Outputs:
            %         Z     - Output of layer forward function
            %         state - (Optional) Updated layer state.
            %
            %  - For layers with multiple inputs, replace X with X1,...,XN,
            %    where N is the number of inputs.
            %  - For layers with multiple outputs, replace Z with
            %    Z1,...,ZM, where M is the number of outputs.
            %  - For layers with multiple state parameters, replace state
            %    with state1,...,stateK, where K is the number of state
            %    parameters.

            % Define layer predict function here.
        end

        function [Z,state,memory] = forward(layer,X)
            % (Optional) Forward input data through the layer at training
            % time and output the result, updated state, and a memory
            % value.
```

```
            %
            % Inputs:
            %         layer - Layer to forward propagate through
            %         X     - Layer input data
            % Outputs:
            %         Z      - Output of layer forward function
            %         state  - (Optional) Updated layer state
            %         memory - (Optional) Memory value for custom backward
            %                  function
            %
            %  - For layers with multiple inputs, replace X with X1,...,XN,
            %    where N is the number of inputs.
            %  - For layers with multiple outputs, replace Z with
            %    Z1,...,ZM, where M is the number of outputs.
            %  - For layers with multiple state parameters, replace state
            %    with state1,...,stateK, where K is the number of state
            %    parameters.

            % Define layer forward function here.
        end

        function layer = resetState(layer)
            % (Optional) Reset layer state.

            % Define reset state function here.
        end

        function [dLdX,dLdW,dLdSin] = backward(layer,X,Z,dLdZ,dLdSout,memory)
            % (Optional) Backward propagate the derivative of the loss
            % function through the layer.
            %
            % Inputs:
            %         layer   - Layer to backward propagate through
            %         X       - Layer input data
            %         Z       - Layer output data
            %         dLdZ    - Derivative of loss with respect to layer
            %                   output
            %         dLdSout - (Optional) Derivative of loss with respect
            %                   to state output
            %         memory  - Memory value from forward function
            % Outputs:
            %         dLdX   - Derivative of loss with respect to layer input
            %         dLdW   - (Optional) Derivative of loss with respect to
            %                  learnable parameter
            %         dLdSin - (Optional) Derivative of loss with respect to
            %                  state input
            %
            %  - For layers with state parameters, the backward syntax must
            %    include both dLdSout and dLdSin, or neither.
            %  - For layers with multiple inputs, replace X and dLdX with
            %    X1,...,XN and dLdX1,...,dLdXN, respectively, where N is
            %    the number of inputs.
            %  - For layers with multiple outputs, replace Z and dlZ with
            %    Z1,...,ZM and dLdZ,...,dLdZM, respectively, where M is the
            %    number of outputs.
            %  - For layers with multiple learnable parameters, replace
            %    dLdW with dLdW1,...,dLdWP, where P is the number of
            %    learnable parameters.
            %  - For layers with multiple state parameters, replace dLdSin
            %    and dLdSout with dLdSin1,...,dLdSinK and
            %    dLdSout1,...dldSoutK, respectively, where K is the number
            %    of state parameters.

            % Define layer backward function here.
        end
    end
end
```

Name Layer and Specify Superclasses

First, give the layer a name. In the first line of the class file, replace the existing name `myLayer` with `projectAndReshapeLayer`.

```
classdef projectAndRehapeLayer < nnet.layer.Layer % & nnet.layer.Formattable (Optional)
    ...
end
```

If you do not specify a backward function, then the layer functions, by default, receive *unformatted* `dlarray` objects as input. To specify that the layer receives *formatted* `dlarray` objects as input and also outputs formatted `dlarray` objects, also inherit from the `nnet.layer.Formattable` class when defining the custom layer.

Because a project and reshape layer outputs data with different dimensions as the input data, that is, it outputs data with added spatial dimensions, the layer must also inherit from `nnet.layer.Formattable`. This enables the layer to receive and output formatted `dlarray` objects.

Next, specify to inherit from both the `nnet.layer.Layer` and `nnet.layer.Formattable` superclasses.

```
classdef projectAndRehapeLayer < nnet.layer.Layer & nnet.layer.Formattable
    ...
end
```

Next, rename the `myLayer` constructor function (the first function in the `methods` section) so that it has the same name as the layer.

```
    methods
        function layer = projectAndReshapeLayer()
            ...
        end

        ...
     end
```

Save the Layer

Save the layer class file in a new file named `projectAndReshapeLayer.m`. The file name must match the layer name. To use the layer, you must save the file in the current folder or in a folder on the MATLAB path.

Declare Properties and Learnable Parameters

Declare the layer properties in the `properties` section and declare learnable parameters by listing them in the `properties (Learnable)` section.

By default, custom intermediate layers have these properties. Do not declare these properties in the `properties` section.

Property	Description
`Name`	Layer name, specified as a character vector or a string scalar. For `Layer` array input, the `trainNetwork`, `assembleNetwork`, `layerGraph`, and `dlnetwork` functions automatically assign names to layers with `Name` set to `''`.
`Description`	One-line description of the layer, specified as a string scalar or a character vector. This description appears when the layer is displayed in a `Layer` array. If you do not specify a layer description, then the software displays the layer class name.
`Type`	Type of the layer, specified as a character vector or a string scalar. The value of `Type` appears when the layer is displayed in a `Layer` array. If you do not specify a layer type, then the software displays the layer class name.
`NumInputs`	Number of inputs of the layer, specified as a positive integer. If you do not specify this value, then the software automatically sets `NumInputs` to the number of names in `InputNames`. The default value is 1.
`InputNames`	Input names of the layer, specified as a cell array of character vectors. If you do not specify this value and `NumInputs` is greater than 1, then the software automatically sets `InputNames` to `{'in1',...,'inN'}`, where `N` is equal to `NumInputs`. The default value is `{'in'}`.
`NumOutputs`	Number of outputs of the layer, specified as a positive integer. If you do not specify this value, then the software automatically sets `NumOutputs` to the number of names in `OutputNames`. The default value is 1.
`OutputNames`	Output names of the layer, specified as a cell array of character vectors. If you do not specify this value and `NumOutputs` is greater than 1, then the software automatically sets `OutputNames` to `{'out1',...,'outM'}`, where `M` is equal to `NumOutputs`. The default value is `{'out'}`.

If the layer has no other properties, then you can omit the `properties` section.

Tip If you are creating a layer with multiple inputs, then you must set either the `NumInputs` or `InputNames` properties in the layer constructor. If you are creating a layer with multiple outputs,

then you must set either the `NumOutputs` or `OutputNames` properties in the layer constructor. For an example, see “Define Custom Deep Learning Layer with Multiple Inputs” on page 18-48.

A project and reshape layer requires an additional property that holds the layer output size. Specify a single property with name `OutputSize` in the `properties` section.

```
properties
    % Output size
    OutputSize
end
```

A project and reshape layer has two learnable parameters: the weights and the biases of the fully connect operation. Declare these learnable parameter in the `properties (Learnable)` section and call the parameters `Weights` and `Bias`, respectively.

```
properties (Learnable)
% Layer learnable parameters
    Weights
    Bias
end
```

Create Constructor Function

Create the function that constructs the layer and initializes the layer properties. Specify any variables required to create the layer as inputs to the constructor function.

The project and reshape layer constructor function requires two input arguments:

- Layer output size
- Number of channels
- Layer name (optional, with default name `''`)

In the constructor function `projectAndReshapeLayer`, specify the two required input arguments named `outputSize` and `numChannels`, and the optional arguments as name-value pairs with the name `NameValueArgs`. Add a comment to the top of the function that explains the syntax of the function.

```
function layer = projectAndReshapeLayer(outputSize,numChannels,NameValueArgs)
    % layer = projectAndReshapeLayer(outputSize,numChannels)
    % creates a projectAndReshapeLayer object that projects and
    % reshapes the input to the specified output size using and
    % specifies the number of input channels.
    %
    % layer = projectAndReshapeLayer(outputSize,numChannels,'Name',name)
    % also specifies the layer name.

    ...
end
```

Parse Input Arguments

Parse the input arguments using an `arguments` block. List the arguments in the same order as the function syntax and specify the default values. Then, extract the values from the `NameValueArgs` input.

```
    % Parse input arguments.
    arguments
        outputSize
        numChannels
```

```
    NameValueArgs.Name = ''
end

name = NameValueArgs.Name;
```

Initialize Layer Properties

Initialize the layer properties, including learnable parameters in the constructor function. Replace the comment `% Layer constructor function goes here` with code that initializes the layer properties.

Set the `Name` property to the input argument `name`.

```
% Set layer name.
layer.Name = name;
```

Give the layer a one-line description by setting the `Description` property of the layer. Set the description to describe the type of layer and its size.

```
% Set layer description.
layer.Description = "Project and reshape layer with output size " + join(string(outpu
```

Specify the type of the layer by setting the `Type` property. The value of `Type` appears when the layer is displayed in a `Layer` array.

```
% Set layer type.
layer.Type = "Project and Reshape";
```

Set the layer property `OutputSize` to the specified input value.

```
% Set output size.
layer.OutputSize = outputSize;
```

A project and reshape layer applies a fully connect operation to project the input to batch of images. Initialize the weights using the Glorot initializer and initialize the bias with an array of zeros. The functions `initializeGlorot` and `initializeZeros` are attached to the example "Train Generative Adversarial Network (GAN)" on page 3-76 as supporting files. To access these functions, open this example as a live script. For more information about initializing learnable parameters for deep learning operations, see "Initialize Learnable Parameters for Model Function" on page 18-292.

```
% Initialize fully connect weights and bias.
sz = [prod(outputSize) numChannels];
numOut = prod(outputSize);
numIn = numChannels;
layer.Weights = initializeGlorot(sz,numOut,numIn);
layer.Bias = initializeZeros([prod(outputSize) 1]);
```

View the completed constructor function.

```
function layer = projectAndReshapeLayer(outputSize,numChannels,NameValueArgs)
    % layer = projectAndReshapeLayer(outputSize,numChannels)
    % creates a projectAndReshapeLayer object that projects and
    % reshapes the input to the specified output size using and
    % specifies the number of input channels.
    %
    % layer = projectAndReshapeLayer(outputSize,numChannels,'Name',name)
    % also specifies the layer name.

    % Parse input arguments.
```

```
        arguments
            outputSize
            numChannels
            NameValueArgs.Name = '';
        end

        name = NameValueArgs.Name;

        % Set layer name.
        layer.Name = name;

        % Set layer description.
        layer.Description = "Project and reshape layer with output size " + join(string(outpu

        % Set layer type.
        layer.Type = "Project and Reshape";

        % Set output size.
        layer.OutputSize = outputSize;

        % Initialize fully connect weights and bias.
        sz = [prod(outputSize) numChannels];
        numOut = prod(outputSize);
        numIn = numChannels;
        layer.Weights = initializeGlorot(sz,numOut,numIn);
        layer.Bias = initializeZeros([prod(outputSize) 1]);
    end
```

With this constructor function, the command `projectAndReshapeLayer([4 4 512],100,'Name','proj');` creates a project and reshape layer with name `'proj'` that projects the input arrays with size 100 to a batch of 512 4-by-4 images.

Create Forward Functions

Create the layer forward functions to use at prediction time and training time.

Create a function named `predict` that propagates the data forward through the layer at *prediction time* and outputs the result.

The `predict` function syntax depends on the type of layer.

- `Z = predict(layer,X)` forwards the input data `X` through the layer and outputs the result `Z`, where `layer` has a single input, a single output.
- `[Z,state] = predict(layer,X)` also outputs the updated state parameter `state`, where `layer` has a single state parameter.

You can adjust the syntaxes for layers with multiple inputs, multiple outputs, or multiple state parameters:

- For layers with multiple inputs, replace `X` with `X1,...,XN`, where `N` is the number of inputs. The `NumInputs` property must match `N`.
- For layers with multiple outputs, replace `Z` with `Z1,...,ZM`, where `M` is the number of outputs. The `NumOutputs` property must match `M`.
- For layers with multiple state parameters, replace `state` with `state1,...,stateK`, where `K` is the number of state parameters.

Tip If the number of inputs to the layer can vary, then use `varargin` instead of `X1,…,XN`. In this case, `varargin` is a cell array of the inputs, where `varargin{i}` corresponds to `Xi`.

If the number of outputs can vary, then use `varargout` instead of `Z1,…,ZN`. In this case, `varargout` is a cell array of the outputs, where `varargout{j}` corresponds to `Zj`.

Tip If the custom layer has a `dlnetwork` object for a learnable parameter, then in the `predict` function of the custom layer, use the `predict` function for the `dlnetwork`. Using the `dlnetwork` object `predict` function ensures that the software uses the correct layer operations for prediction.

Because a project and reshape layer has only one input and one output, the syntax for `predict` for a project and reshape layer is `Z = predict(layer,X)`.

By default, the layer uses `predict` as the forward function at training time. To use a different forward function at training time, or retain a value required for a custom backward function, you must also create a function named `forward`.

The dimensions of the inputs depend on the type of data and the output of the connected layers:

Layer Input	Input Size	Observation Dimension
Feature vectors	*c*-by-*N*, where *c* corresponds to the number of channels and *N* is the number of observations.	2
2-D images	*h*-by-*w*-by-*c*-by-*N*, where *h*, *w*, and *c* correspond to the height, width, and number of channels of the images, respectively, and *N* is the number of observations.	4
3-D images	*h*-by-*w*-by-*d*-by-*c*-by-*N*, where *h*, *w*, *d*, and *c* correspond to the height, width, depth, and number of channels of the 3-D images, respectively, and *N* is the number of observations.	5
Vector sequences	*c*-by-*N*-by-*S*, where *c* is the number of features of the sequences, *N* is the number of observations, and *S* is the sequence length.	2
2-D image sequences	*h*-by-*w*-by-*c*-by-*N*-by-*S*, where *h*, *w*, and *c* correspond to the height, width, and number of channels of the images, respectively, *N* is the number of observations, and *S* is the sequence length.	4

Layer Input	Input Size	Observation Dimension
3-D image sequences	*h*-by-*w*-by-*d*-by-*c*-by-*N*-by-*S*, where *h*, *w*, *d*, and *c* correspond to the height, width, depth, and number of channels of the 3-D images, respectively, *N* is the number of observations, and *S* is the sequence length.	5

For layers that output sequences, the layers can output sequences of any length or output data with no time dimension. Note that when training a network that outputs sequences using the `trainNetwork` function, the lengths of the input and output sequences must match.

Because the custom layer inherits from the `nnet.layer.Formattable` class, the layer receives formatted `dlarray` objects with labels corresponding to the output of the previous layer.

The `forward` function propagates the data forward through the layer at *training time* and also outputs a memory value.

The `forward` function syntax depends on the type of layer:

- `Z = forward(layer,X)` forwards the input data `X` through the layer and outputs the result `Z`, where `layer` has a single input, a single output.
- `[Z,state] = forward(layer,X)` also outputs the updated state parameter `state`, where `layer` has a single state parameter.
- `[__,memory] = forward(layer,X)` also returns a memory value for a custom `backward` function using any of the previous syntaxes. If the layer has both a custom `forward` function and a custom `backward` function, then the forward function must return a memory value.

You can adjust the syntaxes for layers with multiple inputs, multiple outputs, or multiple state parameters:

- For layers with multiple inputs, replace `X` with `X1,...,XN`, where `N` is the number of inputs. The `NumInputs` property must match `N`.
- For layers with multiple outputs, replace `Z` with `Z1,...,ZM`, where `M` is the number of outputs. The `NumOutputs` property must match `M`.
- For layers with multiple state parameters, replace `state` with `state1,...,stateK`, where `K` is the number of state parameters.

Tip If the number of inputs to the layer can vary, then use `varargin` instead of `X1,…,XN`. In this case, `varargin` is a cell array of the inputs, where `varargin{i}` corresponds to `Xi`.

If the number of outputs can vary, then use `varargout` instead of `Z1,…,ZN`. In this case, `varargout` is a cell array of the outputs, where `varargout{j}` corresponds to `Zj`.

Tip If the custom layer has a `dlnetwork` object for a learnable parameter, then in the `forward` function of the custom layer, use the `forward` function of the `dlnetwork` object. Using the `dlnetwork` object `forward` function ensures that the software uses the correct layer operations for training.

The project and reshape operation consists of a three operations:

- Apply a fully connect operations with the learnable weights and biases.
- Reshape the output to the specified output size.
- Relabel the dimensions so that the output has format `'SSCB'` (spatial, spatial, channel, batch)

Implement this operation in the `predict` function. The project and reshape layer does not require memory or a different forward function for training, so you can remove the `forward` function from the class file. Add a comment to the top of the function that explains the syntaxes of the function.

```
function Z = predict(layer, X)
    % Forward input data through the layer at prediction time and
    % output the result.
    %
    % Inputs:
    %         layer - Layer to forward propagate through
    %         X     - Input data, specified as a formatted dlarray
    %                 with a 'C' and optionally a 'B' dimension.
    % Outputs:
    %         Z     - Output of layer forward function returned as
    %                 a formatted dlarray with format 'SSCB'.

    % Fully connect.
    weights = layer.Weights;
    bias = layer.Bias;
    X = fullyconnect(X,weights,bias);

    % Reshape.
    outputSize = layer.OutputSize;
    Z = reshape(X, outputSize(1), outputSize(2), outputSize(3), []);

    % Relabel.
    Z = dlarray(Z,'SSCB');
end
```

Tip If you preallocate arrays using functions such as `zeros`, then you must ensure that the data types of these arrays are consistent with the layer function inputs. To create an array of zeros of the same data type as another array, use the `"like"` option of `zeros`. For example, to initialize an array of zeros of size `sz` with the same data type as the array `X`, use `Z = zeros(sz,"like",X)`.

Because the `predict` function only uses functions that support `dlarray` objects, defining the `backward` function is optional. For a list of functions that support `dlarray` objects, see “List of Functions with dlarray Support” on page 18-423.

Completed Layer

View the completed layer class file.

```
classdef projectAndReshapeLayer < nnet.layer.Layer & nnet.layer.Formattable
    % Example project and reshape layer.

    properties
        % Output size
        OutputSize
```

```
end

properties (Learnable)
% Layer learnable parameters
    Weights
    Bias
end

methods
    function layer = projectAndReshapeLayer(outputSize,numChannels,NameValueArgs)
        % layer = projectAndReshapeLayer(outputSize,numChannels)
        % creates a projectAndReshapeLayer object that projects and
        % reshapes the input to the specified output size using and
        % specifies the number of input channels.
        %
        % layer = projectAndReshapeLayer(outputSize,numChannels,'Name',name)
        % also specifies the layer name.

        % Parse input arguments.
        arguments
            outputSize
            numChannels
            NameValueArgs.Name = '';
        end

        name = NameValueArgs.Name;

        % Set layer name.
        layer.Name = name;

        % Set layer description.
        layer.Description = "Project and reshape layer with output size " + join(string(outpu

        % Set layer type.
        layer.Type = "Project and Reshape";

        % Set output size.
        layer.OutputSize = outputSize;

        % Initialize fully connect weights and bias.
        sz = [prod(outputSize) numChannels];
        numOut = prod(outputSize);
        numIn = numChannels;
        layer.Weights = initializeGlorot(sz,numOut,numIn);
        layer.Bias = initializeZeros([prod(outputSize) 1]);
    end

    function Z = predict(layer, X)
        % Forward input data through the layer at prediction time and
        % output the result.
        %
        % Inputs:
        %         layer - Layer to forward propagate through
        %         X     - Input data, specified as a formatted dlarray
        %                 with a 'C' and optionally a 'B' dimension.
        % Outputs:
        %         Z     - Output of layer forward function returned as
        %                 a formatted dlarray with format 'SSCB'.
```

```
            % Fully connect.
            weights = layer.Weights;
            bias = layer.Bias;
            X = fullyconnect(X,weights,bias);

            % Reshape.
            outputSize = layer.OutputSize;
            Z = reshape(X, outputSize(1), outputSize(2), outputSize(3), []);

            % Relabel.
            Z = dlarray(Z,'SSCB');
        end
    end
end
```

GPU Compatibility

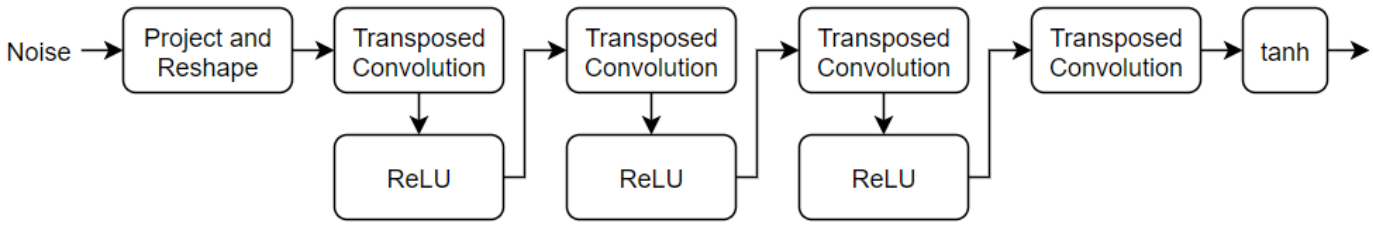
If the layer forward functions fully support `dlarray` objects, then the layer is GPU compatible. Otherwise, to be GPU compatible, the layer functions must support inputs and return outputs of type `gpuArray`.

Many MATLAB built-in functions support `gpuArray` and `dlarray` input arguments. For a list of functions that support `dlarray` objects, see “List of Functions with dlarray Support” on page 18-423. For a list of functions that execute on a GPU, see “Run MATLAB Functions on a GPU” (Parallel Computing Toolbox). To use a GPU for deep learning, you must also have a supported GPU device. For information on supported devices, see “GPU Support by Release” (Parallel Computing Toolbox). For more information on working with GPUs in MATLAB, see “GPU Computing in MATLAB” (Parallel Computing Toolbox).

In this example, the MATLAB functions used in `predict` all support `dlarray` objects, so the layer is GPU compatible.

Include Custom Layer in Network

Define the following generator network architecture for a GAN, which generates images from 1-by-1-by-100 arrays of random values:



This network:

- Converts the random vectors of size 100 to 7-by-7-by-128 arrays using a *project and reshape* layer.
- Upscales the resulting arrays to 64-by-64-by-3 arrays using a series of transposed convolution layers and ReLU layers.

Define this network architecture as a layer graph and specify the following network properties.

- For the transposed convolution layers, specify 5-by-5 filters with a decreasing number of filters for each layer, a stride of 2, and cropping of the output on each edge.
- For the final transposed convolution layer, specify three 5-by-5 filters corresponding to the three RGB channels of the generated images, and the output size of the previous layer.
- At the end of the network, include a tanh layer.

To project and reshape the noise input, use the custom layer `projectAndReshapeLayer.`

```
filterSize = 5;
numFilters = 64;
numLatentInputs = 100;

projectionSize = [4 4 512];

layersG = [
    featureInputLayer(numLatentInputs,'Normalization','none','Name','in')
    projectAndReshapeLayer(projectionSize,numLatentInputs,'Name','proj');
    transposedConv2dLayer(filterSize,4*numFilters,'Name','tconv1')
    reluLayer('Name','relu1')
    transposedConv2dLayer(filterSize,2*numFilters,'Stride',2,'Cropping','same','Name','tconv2')
    reluLayer('Name','relu2')
    transposedConv2dLayer(filterSize,numFilters,'Stride',2,'Cropping','same','Name','tconv3')
    reluLayer('Name','relu3')
    transposedConv2dLayer(filterSize,3,'Stride',2,'Cropping','same','Name','tconv4')
    tanhLayer('Name','tanh')];

lgraphG = layerGraph(layersG);
```

To train the network with a custom training loop and enable automatic differentiation, convert the layer graph to a `dlnetwork` object.

```
dlnetG = dlnetwork(lgraphG);
```

Define Custom Recurrent Deep Learning Layer

If Deep Learning Toolbox does not provide the layer you require for your task, then you can define your own custom layer using this example as a guide. For a list of built-in layers, see “List of Deep Learning Layers” on page 1-21.

To define a custom deep learning layer, you can use the template provided in this example, which takes you through the following steps:

1. Name the layer — Give the layer a name so that you can use it in MATLAB.
2. Declare the layer properties — Specify the properties of the layer including learnable parameters and state parameters.
3. Create a constructor function (optional) — Specify how to construct the layer and initialize its properties. If you do not specify a constructor function, then at creation, the software initializes the `Name`, `Description`, and `Type` properties with `[]` and sets the number of layer inputs and outputs to 1.
4. Create forward functions — Specify how data passes forward through the layer (forward propagation) at prediction time and at training time.
5. Create reset state function (optional) — Specify how to reset state parameters.
6. Create a backward function (optional) — Specify the derivatives of the loss with respect to the input data and the learnable parameters (backward propagation). If you do not specify a backward function, then the forward functions must support `dlarray` objects.

When defining the layer functions, you can use `dlarray` objects. Using `dlarray` objects makes working with high dimensional data easier by allowing you to label the dimensions. For example, you can label which dimensions correspond to spatial, time, channel, and batch dimensions using the `"S"`, `"T"`, `"C"`, and `"B"` labels, respectively. For unspecified and other dimensions, use the `"U"` label. For `dlarray` object functions that operate over particular dimensions, you can specify the dimension labels by formatting the `dlarray` object directly, or by using the `DataFormat` option.

Using formatted `dlarray` objects in custom layers also allows you to define layers where the inputs and outputs have different formats, such as layers that permute, add, or remove dimensions. For example, you can define a layer that takes as input a mini-batch of images with format `"SSCB"` (spatial, spatial, channel, batch) and output a mini-batch of sequences with format `"CBT"` (channel, batch, time). Using formatted `dlarray` objects also allows you to define layers that can operate on data with different input formats, for example, layers that support inputs with formats `"SSCB"` (spatial, spatial, channel, batch) and `"CBT"` (channel, batch, time).

`dlarray` objects also enable support for automatic differentiation. This means that if your forward functions fully support `dlarray` objects, then defining the backward function is optional.

To enable support for using formatted `dlarray` objects in custom layer forward functions, also inherit from the `nnet.layer.Formattable` class when defining the custom layer. For an example, see “Define Custom Deep Learning Layer with Formatted Inputs” on page 18-61.

This example shows how to define a peephole LSTM layer [1], which is a recurrent layer with learnable parameters, and use it in a neural network. A peephole LSTM layer is a variant of an LSTM layer, where the gate calculations use the layer cell state.

Intermediate Layer Template

Copy the intermediate layer template into a new file in MATLAB. This template outlines the structure of an intermediate layer class definition. It outlines:

- The optional `properties` blocks for the layer properties, learnable parameters, and state parameters.
- The layer constructor function.
- The `predict` function and the optional `forward` function.
- The optional `resetState` function for layers with state properties.
- The optional `backward` function.

```
classdef myLayer < nnet.layer.Layer % & nnet.layer.Formattable (Optional)

    properties
        % (Optional) Layer properties.

        % Declare layer properties here.
    end

    properties (Learnable)
        % (Optional) Layer learnable parameters.

        % Declare learnable parameters here.
    end

    properties (State)
        % (Optional) Layer state parameters.

        % Declare state parameters here.
    end

    properties (Learnable, State)
        % (Optional) Nested dlnetwork objects with both learnable
        % parameters and state.

        % Declare nested networks with learnable and state parameters here.
    end

    methods
        function layer = myLayer()
            % (Optional) Create a myLayer.
            % This function must have the same name as the class.

            % Define layer constructor function here.
        end

        function [Z,state] = predict(layer,X)
            % Forward input data through the layer at prediction time and
            % output the result and updated state.
            %
            % Inputs:
            %         layer - Layer to forward propagate through
            %         X     - Input data
            % Outputs:
            %         Z     - Output of layer forward function
            %         state - (Optional) Updated layer state.
            %
            %  - For layers with multiple inputs, replace X with X1,...,XN,
            %    where N is the number of inputs.
            %  - For layers with multiple outputs, replace Z with
            %    Z1,...,ZM, where M is the number of outputs.
            %  - For layers with multiple state parameters, replace state
            %    with state1,...,stateK, where K is the number of state
            %    parameters.
```

```
    % Define layer predict function here.
end

function [Z,state,memory] = forward(layer,X)
    % (Optional) Forward input data through the layer at training
    % time and output the result, updated state, and a memory
    % value.
    %
    % Inputs:
    %         layer - Layer to forward propagate through
    %         X     - Layer input data
    % Outputs:
    %         Z      - Output of layer forward function
    %         state  - (Optional) Updated layer state
    %         memory - (Optional) Memory value for custom backward
    %                  function
    %
    %  - For layers with multiple inputs, replace X with X1,...,XN,
    %    where N is the number of inputs.
    %  - For layers with multiple outputs, replace Z with
    %    Z1,...,ZM, where M is the number of outputs.
    %  - For layers with multiple state parameters, replace state
    %    with state1,...,stateK, where K is the number of state
    %    parameters.

    % Define layer forward function here.
end

function layer = resetState(layer)
    % (Optional) Reset layer state.

    % Define reset state function here.
end

function [dLdX,dLdW,dLdSin] = backward(layer,X,Z,dLdZ,dLdSout,memory)
    % (Optional) Backward propagate the derivative of the loss
    % function through the layer.
    %
    % Inputs:
    %         layer   - Layer to backward propagate through
    %         X       - Layer input data
    %         Z       - Layer output data
    %         dLdZ    - Derivative of loss with respect to layer
    %                   output
    %         dLdSout - (Optional) Derivative of loss with respect
    %                   to state output
    %         memory  - Memory value from forward function
    % Outputs:
    %         dLdX   - Derivative of loss with respect to layer input
    %         dLdW   - (Optional) Derivative of loss with respect to
    %                  learnable parameter
    %         dLdSin - (Optional) Derivative of loss with respect to
    %                  state input
    %
    %  - For layers with state parameters, the backward syntax must
    %    include both dLdSout and dLdSin, or neither.
    %  - For layers with multiple inputs, replace X and dLdX with
    %    X1,...,XN and dLdX1,...,dLdXN, respectively, where N is
    %    the number of inputs.
    %  - For layers with multiple outputs, replace Z and dlZ with
    %    Z1,...,ZM and dLdZ,...,dLdZM, respectively, where M is the
    %    number of outputs.
    %  - For layers with multiple learnable parameters, replace
    %    dLdW with dLdW1,...,dLdWP, where P is the number of
    %    learnable parameters.
    %  - For layers with multiple state parameters, replace dLdSin
    %    and dLdSout with dLdSin1,...,dLdSinK and
    %    dLdSout1,...dldSoutK, respectively, where K is the number
    %    of state parameters.

    % Define layer backward function here.
end
```

```
    end
end
```

Name the Layer

First, give the layer a name. In the first line of the class file, replace the existing name `myLayer` with `peepholeLSTMLayer`. To allow the layer to output different data formats, for example data with format `"CBT"` (channel, batch, time) for sequence output and format `"CB"` (channel, batch) for single time step or feature output, also include the `nnet.layer.Formattable` mixin.

```
classdef peepholeLSTMLayer < nnet.layer.Layer & nnet.layer.Formattable
    ...
end
```

Next, rename the `myLayer` constructor function (the first function in the `methods` section) so that it has the same name as the layer.

```
    methods
        function layer = peepholeLSTMLayer()
            ...
        end

        ...
     end
```

Save the Layer

Save the layer class file in a new file named `peepholeLSTMLayer.m`. The file name must match the layer name. To use the layer, you must save the file in the current folder or in a folder on the MATLAB path.

Declare Properties, State, and Learnable Parameters

Declare the layer properties in the `properties` section, the layer states in the `properties (State)` section, and the learnable parameters in the `properties (Learnable)` section.

By default, custom intermediate layers have these properties. Do not declare these properties in the `properties` section.

Property	Description
`Name`	Layer name, specified as a character vector or a string scalar. For `Layer` array input, the `trainNetwork`, `assembleNetwork`, `layerGraph`, and `dlnetwork` functions automatically assign names to layers with `Name` set to `''`.
`Description`	One-line description of the layer, specified as a string scalar or a character vector. This description appears when the layer is displayed in a `Layer` array. If you do not specify a layer description, then the software displays the layer class name.

Property	Description
`Type`	Type of the layer, specified as a character vector or a string scalar. The value of `Type` appears when the layer is displayed in a `Layer` array. If you do not specify a layer type, then the software displays the layer class name.
`NumInputs`	Number of inputs of the layer, specified as a positive integer. If you do not specify this value, then the software automatically sets `NumInputs` to the number of names in `InputNames`. The default value is 1.
`InputNames`	Input names of the layer, specified as a cell array of character vectors. If you do not specify this value and `NumInputs` is greater than 1, then the software automatically sets `InputNames` to `{'in1',...,'inN'}`, where `N` is equal to `NumInputs`. The default value is `{'in'}`.
`NumOutputs`	Number of outputs of the layer, specified as a positive integer. If you do not specify this value, then the software automatically sets `NumOutputs` to the number of names in `OutputNames`. The default value is 1.
`OutputNames`	Output names of the layer, specified as a cell array of character vectors. If you do not specify this value and `NumOutputs` is greater than 1, then the software automatically sets `OutputNames` to `{'out1',...,'outM'}`, where `M` is equal to `NumOutputs`. The default value is `{'out'}`.

If the layer has no other properties, then you can omit the `properties` section.

Tip If you are creating a layer with multiple inputs, then you must set either the `NumInputs` or `InputNames` properties in the layer constructor. If you are creating a layer with multiple outputs, then you must set either the `NumOutputs` or `OutputNames` properties in the layer constructor. For an example, see “Define Custom Deep Learning Layer with Multiple Inputs” on page 18-48.

Declare the following layer properties in the `properties` section:

- `NumHiddenUnits` — Number of hidden units in peephole LSTM operation.
- `OutputMode` — Flag indicating whether layer returns a sequence or a single time step.

```
properties
    % Layer properties.

    NumHiddenUnits
    OutputMode
end
```

A peephole LSTM layer has four learnable parameters: the input weights, the recurrent weights, the peephole weights, and the bias. Declare these learnable parameters in the `properties (Learnable)` section with names `InputWeights`, `RecurrentWeights`, `PeepholeWeights`, and `Bias`, respectively.

```
properties (Learnable)
    % Layer learnable parameters.

    InputWeights
    RecurrentWeights
    PeepholeWeights
    Bias
end
```

A peephole LSTM layer has two state parameters: the hidden state and the cell state. Declare these state parameters in the `properties (State)` section with names `HiddenState` and `CellState`, respectively.

```
properties (State)
    % Layer state parameters.

    HiddenState
    CellState
end
```

Create Constructor Function

Create the function that constructs the layer and initializes the layer properties. Specify any variables required to create the layer as inputs to the constructor function.

The peephole LSTM layer constructor function requires two input arguments (the number of hidden units and the number of input channels) and two optional arguments (the layer name and output mode). Specify two input arguments named `numHiddenUnits` and `inputSize` in the `peepholeLSTMLayer` function that correspond to the number of hidden units and the number of input channels, respectively. Specify the optional input arguments as a single argument with name `args`. Add a comment to the top of the function that explains the syntaxes of the function.

```
function layer = peepholeLSTMLayer(numHiddenUnits,inputSize,args)
    %PEEPHOLELSTMLAYER Peephole LSTM Layer
    %   layer = peepholeLSTMLayer(numHiddenUnits,inputSize)
    %   creates a peephole LSTM layer with the specified number of
    %   hidden units and input channels.
    %
    %   layer = peepholeLSTMLayer(numHiddenUnits,inputSize,Name=Value)
    %   creates a peephole LSTM layer and specifies additional
    %   options using one or more name-value arguments:
    %
    %      Name       - Name for the layer, specified as a string.
    %                   The default is "".
    %
    %      OutputMode - Output mode, specified as one of the
    %                   following:
    %                      "sequence" - Output the entire sequence
    %                                   of data.
    %
    %                      "last"     - Output the last time step
    %                                   of the data.
    %                   The default is "sequence".

    ...
end
```

Initialize Layer Properties

Initialize the layer properties, including the learnable and state parameters in the constructor function. Replace the comment `% Layer constructor function goes here` with code that initializes the layer properties.

Parse the input arguments using an `arguments` block and set the `Name` and output properties.

```
arguments
    numHiddenUnits
    inputSize
    args.Name = "";
    args.OutputMode = "sequence"
end

layer.NumHiddenUnits = numHiddenUnits;
layer.Name = args.Name;
layer.OutputMode = args.OutputMode;
```

Give the layer a one-line description by setting the `Description` property of the layer. Set the description to describe the type of layer and its size.

```
% Set layer description.
layer.Description = "Peephole LSTM with " + numHiddenUnits + " hidden units";
```

Initialize the learnable parameters. Initialize the input weights using Glorot initialization. Initialize the recurrent weights using orthogonal initialization. Initialize the bias using unit-forget-gate normalization. This code uses the helper functions `initializeGlorot`, `initializeOrthogonal`, and `initializeUnitForgetGate`. To access these functions, open the example as a live script. For more information about initializing weights, see “Initialize Learnable Parameters for Model Function” on page 18-292.

Note that the recurrent weights of a peephole LSTM layer and standard LSTM layers have different sizes. A peephole LSTM layer does not require recurrent weights for the cell candidate calculation, so the recurrent weights is a `3*NumHiddenUnits`-by-`NumHiddenUnits` array.

```
% Initialize weights and bias.
sz = [4*numHiddenUnits inputSize];
numOut = 4*numHiddenUnits;
numIn = inputSize;
layer.InputWeights = initializeGlorot(sz,numOut,numIn);

sz = [4*numHiddenUnits numHiddenUnits];
layer.RecurrentWeights = initializeOrthogonal(sz);

sz = [3*numHiddenUnits 1];
numOut = 3*numHiddenUnits;
numIn = 1;
layer.PeepholeWeights = initializeGlorot(sz,numOut,numIn);

layer.Bias = initializeUnitForgetGate(numHiddenUnits);
```

Initialize the layer state parameters. For convenience, use the `resetState` function defined in the section.

```
% Initialize layer states.
layer = resetState(layer);
```

View the completed constructor function.

```
function layer = peepholeLSTMLayer(numHiddenUnits,inputSize,args)
    %PEEPHOLELSTMLAYER Peephole LSTM Layer
    %   layer = peepholeLSTMLayer(numHiddenUnits,inputSize)
```

```
            %   creates a peephole LSTM layer with the specified number of
            %   hidden units and input channels.
            %
            %   layer = peepholeLSTMLayer(numHiddenUnits,inputSize,Name=Value)
            %   creates a peephole LSTM layer and specifies additional
            %   options using one or more name-value arguments:
            %
            %      Name       - Name for the layer, specified as a string.
            %                   The default is "".
            %
            %      OutputMode - Output mode, specified as one of the
            %                   following:
            %                      "sequence" - Output the entire sequence
            %                                   of data.
            %
            %                      "last"     - Output the last time step
            %                                   of the data.
            %                   The default is "sequence".

            % Parse input arguments.
            arguments
                numHiddenUnits
                inputSize
                args.Name = "";
                args.OutputMode = "sequence";
            end

            layer.NumHiddenUnits = numHiddenUnits;
            layer.Name = args.Name;
            layer.OutputMode = args.OutputMode;

            % Set layer description.
            layer.Description = "Peephole LSTM with " + numHiddenUnits + " hidden units";

            % Initialize weights and bias.
            sz = [4*numHiddenUnits inputSize];
            numOut = 4*numHiddenUnits;
            numIn = inputSize;
            layer.InputWeights = initializeGlorot(sz,numOut,numIn);

            sz = [4*numHiddenUnits numHiddenUnits];
            layer.RecurrentWeights = initializeOrthogonal(sz);

            sz = [3*numHiddenUnits 1];
            numOut = 3*numHiddenUnits;
            numIn = 1;
            layer.PeepholeWeights = initializeGlorot(sz,numOut,numIn);

            layer.Bias = initializeUnitForgetGate(numHiddenUnits);

            % Initialize layer states.
            layer = resetState(layer);
        end
```

With this constructor function, the command `peepholeLSTMLayer(200,12,OutputMode="last",Name="peephole")` creates a peephole

LSTM layer with 200 hidden units, an input size of 12, and name `"peephole"`, and outputs the last time step of the peephole LSTM operation.

Create Predict Function

Create the layer forward functions to use at prediction time and training time.

Create a function named `predict` that propagates the data forward through the layer at *prediction time* and outputs the result.

The `predict` function syntax depends on the type of layer.

- `Z = predict(layer,X)` forwards the input data `X` through the layer and outputs the result `Z`, where `layer` has a single input, a single output.
- `[Z,state] = predict(layer,X)` also outputs the updated state parameter `state`, where `layer` has a single state parameter.

You can adjust the syntaxes for layers with multiple inputs, multiple outputs, or multiple state parameters:

- For layers with multiple inputs, replace `X` with `X1,...,XN`, where `N` is the number of inputs. The `NumInputs` property must match `N`.
- For layers with multiple outputs, replace `Z` with `Z1,...,ZM`, where `M` is the number of outputs. The `NumOutputs` property must match `M`.
- For layers with multiple state parameters, replace `state` with `state1,...,stateK`, where `K` is the number of state parameters.

Tip If the number of inputs to the layer can vary, then use `varargin` instead of `X1,…,XN`. In this case, `varargin` is a cell array of the inputs, where `varargin{i}` corresponds to `Xi`.

If the number of outputs can vary, then use `varargout` instead of `Z1,…,ZN`. In this case, `varargout` is a cell array of the outputs, where `varargout{j}` corresponds to `Zj`.

Tip If the custom layer has a `dlnetwork` object for a learnable parameter, then in the `predict` function of the custom layer, use the `predict` function for the `dlnetwork`. Using the `dlnetwork` object `predict` function ensures that the software uses the correct layer operations for prediction.

Because a peephole LSTM layer has only one input, one output, and two state parameters, the syntax for `predict` for a peephole LSTM layer is `[Z,hiddenState,cellState] = predict(layer,X)`.

By default, the layer uses `predict` as the forward function at training time. To use a different forward function at training time, or retain a value required for a custom backward function, you must also create a function named `forward`.

Because the layer inherits from `nnet.layer.Formattable`, the layer inputs are formatted `dlarray` objects and the `predict` function must also output data as formatted `dlarray` objects.

The hidden state at time step t is given by

$$\mathbf{h}_t = \tanh(\mathbf{c}_t) \odot \mathbf{o}_t,$$

where ⊙ denotes the Hadamard product (element-wise multiplication of vectors).

The cell state at time step t is given by

$$\mathbf{c}_t = \mathbf{g}_t \odot \mathbf{i}_t + \mathbf{c}_{t-1} \odot \mathbf{f}_t .$$

The following formulas describe the components at time step t.

Component	Formula
Input gate	$i_t = \sigma_g(W_i\mathbf{x}_t + R_i\mathbf{h}_{t-1} + \mathbf{p}_i \odot \mathbf{c}_{t-1} + \mathbf{b}_i)$
Forget gate	$f_t = \sigma_g\left(W_f\mathbf{x}_t + R_f\mathbf{h}_{t-1} + \mathbf{p}_f \odot \mathbf{c}_{t-1} + \mathbf{b}_f\right)$
Cell candidate	$g_t = \sigma_c\left(W_g\mathbf{x}_t + R_h\mathbf{h}_{t-1} + b_g\right)$
Output gate	$o_t = \sigma_g(W_o\mathbf{x}_t + R_o\mathbf{h}_{t-1} + \mathbf{p}_o \odot \mathbf{c}_t + \mathbf{b}_o)$

Note that the output gate calculation requires the updated cell state $\mathbf{c}_t$.

In these calculations, σ_g and σ_c denote the gate and state activation functions. For peephole LSTM layers, use the sigmoid and hyperbolic tangent functions as the gate and state activation functions, respectively.

Implement this operation in the `predict` function. Because the layer does not require a different forward function for training and memory value for a custom backward function, you can remove the `forward` function from the class file. Add a comment to the top of the function that explains the syntaxes of the function.

Tip If you preallocate arrays using functions such as `zeros`, then you must ensure that the data types of these arrays are consistent with the layer function inputs. To create an array of zeros of the same data type as another array, use the `"like"` option of `zeros`. For example, to initialize an array of zeros of size `sz` with the same data type as the array `X`, use `Z = zeros(sz,"like",X)`.

```
function [Z,cellState,hiddenState] = predict(layer,X)
    %PREDICT Peephole LSTM predict function
    %   [Z,hiddenState,cellState] = predict(layer,X) forward
    %   propagates the data X through the layer and returns the
    %   layer output Z and the updated hidden and cell states. X
    %   is a dlarray with format "CBT" and Z is a dlarray with
    %   format "CB" or "CBT", depending on the layer OutputMode
    %   property.

    % Initialize sequence output.
    numHiddenUnits = layer.NumHiddenUnits;
    miniBatchSize = size(X,finddim(X,"B"));
    numTimeSteps = size(X,finddim(X,"T"));

    if layer.OutputMode == "sequence"
        Z = zeros(numHiddenUnits,miniBatchSize,numTimeSteps,"like",X);
        Z = dlarray(Z,"CBT");
    end

    % Calculate WX + b.
    X = stripdims(X);
    WX = pagemtimes(layer.InputWeights,X) + layer.Bias;

    % Indices of concatenated weight arrays.
    idx1 = 1:numHiddenUnits;
    idx2 = 1+numHiddenUnits:2*numHiddenUnits;
    idx3 = 1+2*numHiddenUnits:3*numHiddenUnits;
    idx4 = 1+3*numHiddenUnits:4*numHiddenUnits;

    % Initial states.
```

```
        hiddenState = layer.HiddenState;
        cellState = layer.CellState;

        % Loop over time steps.
        for t = 1:numTimeSteps
            % Calculate R*h_{t-1}.
            Rht = layer.RecurrentWeights * hiddenState;

            % Calculate p*c_{t-1}.
            pict = layer.PeepholeWeights(idx1) .* cellState;
            pfct = layer.PeepholeWeights(idx2) .* cellState;

            % Gate calculations.
            it = sigmoid(WX(idx1,:,t) + Rht(idx1,:) + pict);
            ft = sigmoid(WX(idx2,:,t) + Rht(idx2,:) + pfct);
            gt = tanh(WX(idx3,:,t) + Rht(idx3,:));

            % Calculate ot using updated cell state.
            cellState = gt .* it + cellState .* ft;
            poct = layer.PeepholeWeights(idx3) .* cellState;
            ot = sigmoid(WX(idx4,:,t) + Rht(idx4,:) + poct);

            % Update hidden state.
            hiddenState = tanh(cellState) .* ot;

            % Update sequence output.
            if layer.OutputMode == "sequence"
                Z(:,:,t) = hiddenState;
            end
        end

        % Last time step output.
        if layer.OutputMode == "last"
            Z = dlarray(hiddenState,"CB");
        end
    end
```

Because the `predict` function only uses functions that support `dlarray` objects, defining the `backward` function is optional. For a list of functions that support `dlarray` objects, see “List of Functions with dlarray Support” on page 18-423.

Create Reset State Function

When `DAGNetwork` or `SeriesNetwork` objects contain layers with state parameters, you can make predictions and update the layer states using the `predictAndUpdateState` and `classifyAndUpdateState` functions. You can reset the network state using the `resetState` function.

The `resetState` function for `DAGNetwork`, `SeriesNetwork`, and `dlnetwork` objects, by default, has no effect on custom layers with state parameters. To define the layer behavior for the `resetState` function for network objects, define the optional layer `resetState` function in the layer definition that resets the state parameters.

The `resetState` function must have the syntax `layer = resetState(layer)`, where the returned layer has the state properties reset.

Create a function named `resetState` that resets the layer state parameters to vectors of zeros.

```
    function layer = resetState(layer)
        %RESETSTATE Reset layer state
        % layer = resetState(layer) resets the state properties of the
        % layer.

        numHiddenUnits = layer.NumHiddenUnits;
        layer.HiddenState = zeros(numHiddenUnits,1);
        layer.CellState = zeros(numHiddenUnits,1);
    end
```

Completed Layer

View the completed layer class file.

```
classdef peepholeLSTMLayer < nnet.layer.Layer & nnet.layer.Formattable
    %PEEPHOLELSTMLAYER Peephole LSTM Layer

    properties
        % Layer properties.

        NumHiddenUnits

                ft = sigmoid(WX(idx2,:,t) + Rht(idx2,:) + pfct);
                gt = tanh(WX(idx3,:,t) + Rht(idx3,:));

                % Calculate ot using updated cell state.
                cellState = gt .* it + cellState .* ft;
                poct = layer.PeepholeWeights(idx3) .* cellState;
                ot = sigmoid(WX(idx4,:,t) + Rht(idx4,:) + poct);

                % Update hidden state.
                hiddenState = tanh(cellState) .* ot;

                % Update sequence output.
                if layer.OutputMode == "sequence"
                    Z(:,:,t) = hiddenState;
                end
            end

            % Last time step output.
            if layer.OutputMode == "last"
                Z = dlarray(hiddenState,"CB");
            end
        end

        function layer = resetState(layer)
            %RESETSTATE Reset layer state
            % layer = resetState(layer) resets the state properties of the
            % layer.

            numHiddenUnits = layer.NumHiddenUnits;
            layer.HiddenState = zeros(numHiddenUnits,1);
            layer.CellState = zeros(numHiddenUnits,1);
        end
    end
end
```

GPU Compatibility

If the layer forward functions fully support `dlarray` objects, then the layer is GPU compatible. Otherwise, to be GPU compatible, the layer functions must support inputs and return outputs of type `gpuArray`.

Many MATLAB built-in functions support `gpuArray` and `dlarray` input arguments. For a list of functions that support `dlarray` objects, see “List of Functions with dlarray Support” on page 18-423. For a list of functions that execute on a GPU, see “Run MATLAB Functions on a GPU” (Parallel Computing Toolbox). To use a GPU for deep learning, you must also have a supported GPU device. For information on supported devices, see “GPU Support by Release” (Parallel Computing Toolbox). For more information on working with GPUs in MATLAB, see “GPU Computing in MATLAB” (Parallel Computing Toolbox).

In this example, the MATLAB functions used in `predict` all support `dlarray` objects, so the layer is GPU compatible.

Include Custom Layer in Network

You can use a custom layer in the same way as any other layer in Deep Learning Toolbox. This section shows how to create and train a network for sequence classification using the peephole LSTM layer you created earlier.

Load the example training data.

```
[XTrain,TTrain] = japaneseVowelsTrainData;
```

Define the network architecture. Create a layer array containing a peephole LSTM layer.

```
inputSize = 12;
numHiddenUnits = 100;
numClasses = 9;

layers = [
    sequenceInputLayer(inputSize)
    peepholeLSTMLayer(numHiddenUnits,inputSize,OutputMode="last")
    fullyConnectedLayer(numClasses)
    softmaxLayer
    classificationLayer];
```

Specify the training options and train the network. Train with a mini-batch size of 27 and left-pad the data.

```
options = trainingOptions("adam",MiniBatchSize=27,SequencePaddingDirection="left");
net = trainNetwork(XTrain,TTrain,layers,options);
```

```
Training on single CPU.
|=========================================================================================|
|  Epoch  |  Iteration  |  Time Elapsed  |  Mini-batch  |  Mini-batch  |  Base Learning  |
|         |             |   (hh:mm:ss)   |   Accuracy   |     Loss     |      Rate       |
|=========================================================================================|
|       1 |           1 |       00:00:01 |        3.70% |       2.2060 |          0.0010 |
|       5 |          50 |       00:00:19 |       92.59% |       0.5917 |          0.0010 |
|      10 |         100 |       00:00:37 |       92.59% |       0.2182 |          0.0010 |
|      15 |         150 |       00:00:54 |      100.00% |       0.0588 |          0.0010 |
|      20 |         200 |       00:01:16 |       96.30% |       0.0843 |          0.0010 |
|      25 |         250 |       00:01:37 |      100.00% |       0.0331 |          0.0010 |
|      30 |         300 |       00:01:58 |      100.00% |       0.0130 |          0.0010 |
|=========================================================================================|
Training finished: Max epochs completed.
```

Evaluate the network performance by predicting on new data and calculating the accuracy.

```
[XTest,TTest] = japaneseVowelsTestData;
YTest = classify(net,XTest,MiniBatchSize=27);
accuracy = mean(YTest==TTest)
```

```
accuracy = 0.8757
```

Define Custom Classification Output Layer

Tip To construct a classification output layer with cross entropy loss for k mutually exclusive classes, use `classificationLayer`. If you want to use a different loss function for your classification problems, then you can define a custom classification output layer using this example as a guide.

This example shows how to define a custom classification output layer with the sum of squares error (SSE) loss and use it in a convolutional neural network.

To define a custom classification output layer, you can use the template provided in this example, which takes you through the following steps:

1. Name the layer – Give the layer a name so it can be used in MATLAB.
2. Declare the layer properties – Specify the properties of the layer.
3. Create a constructor function (optional) – Specify how to construct the layer and initialize its properties. If you do not specify a constructor function, then the software initializes the properties with `''` at creation.
4. Create a forward loss function – Specify the loss between the predictions and the training targets.
5. Create a backward loss function (optional) – Specify the derivative of the loss with respect to the predictions. If you do not specify a backward loss function, then the forward loss function must support `dlarray` objects.

A classification SSE layer computes the sum of squares error loss for classification problems. SSE is an error measure between two continuous random variables. For predictions Y and training targets T, the SSE loss between Y and T is given by

$$L = \frac{1}{N}\sum_{n=1}^{N}\sum_{i=1}^{K}(Y_{ni} - T_{ni})^2,$$

where N is the number of observations and K is the number of classes.

Classification Output Layer Template

Copy the classification output layer template into a new file in MATLAB. This template outlines the structure of a classification output layer and includes the functions that define the layer behavior.

```
classdef myClassificationLayer < nnet.layer.ClassificationLayer

    properties
        % (Optional) Layer properties.

        % Layer properties go here.
    end

    methods
        function layer = myClassificationLayer()
            % (Optional) Create a myClassificationLayer.

            % Layer constructor function goes here.
        end
```

```
        function loss = forwardLoss(layer, Y, T)
            % Return the loss between the predictions Y and the training
            % targets T.
            %
            % Inputs:
            %         layer - Output layer
            %         Y     – Predictions made by network
            %         T     – Training targets
            %
            % Output:
            %         loss  - Loss between Y and T

            % Layer forward loss function goes here.
        end

        function dLdY = backwardLoss(layer, Y, T)
            % (Optional) Backward propagate the derivative of the loss
            % function.
            %
            % Inputs:
            %         layer - Output layer
            %         Y     – Predictions made by network
            %         T     – Training targets
            %
            % Output:
            %         dLdY  - Derivative of the loss with respect to the
            %                 predictions Y

            % Layer backward loss function goes here.
        end
    end
end
```

Name the Layer

First, give the layer a name. In the first line of the class file, replace the existing name `myClassificationLayer` with `sseClassificationLayer`.

```
classdef sseClassificationLayer < nnet.layer.ClassificationLayer
    ...
end
```

Next, rename the `myClassificationLayer` constructor function (the first function in the `methods` section) so that it has the same name as the layer.

```
    methods
        function layer = sseClassificationLayer()
            ...
        end

        ...
     end
```

Save the Layer

Save the layer class file in a new file named `sseClassificationLayer.m`. The file name must match the layer name. To use the layer, you must save the file in the current folder or in a folder on the MATLAB path.

Declare Layer Properties

Declare the layer properties in the `properties` section.

By default, custom output layers have the following properties:

- `Name` – Layer name, specified as a character vector or a string scalar. For `Layer` array input, the `trainNetwork`, `assembleNetwork`, `layerGraph`, and `dlnetwork` functions automatically assign names to layers with `Name` set to `''`.
- `Description` – One-line description of the layer, specified as a character vector or a string scalar. This description appears when the layer is displayed in a `Layer` array. If you do not specify a layer description, then the software displays `"Classification Output"` or `"Regression Output"`.
- `Type` – Type of the layer, specified as a character vector or a string scalar. The value of `Type` appears when the layer is displayed in a `Layer` array. If you do not specify a layer type, then the software displays the layer class name.

Custom classification layers also have the following property:

- `Classes` – Classes of the output layer, specified as a categorical vector, string array, cell array of character vectors, or `'auto'`. If `Classes` is `'auto'`, then the software automatically sets the classes at training time. If you specify the string array or cell array of character vectors `str`, then the software sets the classes of the output layer to `categorical(str,str)`.

Custom regression layers also have the following property:

- `ResponseNames` – Names of the responses, specified a cell array of character vectors or a string array. At training time, the software automatically sets the response names according to the training data. The default is `{}`.

If the layer has no other properties, then you can omit the `properties` section.

In this example, the layer does not require any additional properties, so you can remove the `properties` section.

Create Constructor Function

Create the function that constructs the layer and initializes the layer properties. Specify any variables required to create the layer as inputs to the constructor function.

Specify the input argument `name` to assign to the `Name` property at creation. Add a comment to the top of the function that explains the syntax of the function.

```
function layer = sseClassificationLayer(name)
    % layer = sseClassificationLayer(name) creates a sum of squares
    % error classification layer and specifies the layer name.

    ...
end
```

Initialize Layer Properties

Replace the comment `% Layer constructor function goes here` with code that initializes the layer properties.

Give the layer a one-line description by setting the `Description` property of the layer. Set the `Name` property to the input argument `name`.

```
function layer = sseClassificationLayer(name)
    % layer = sseClassificationLayer(name) creates a sum of squares
```

```
        % error classification layer and specifies the layer name.

        % Set layer name.
        layer.Name = name;

        % Set layer description.
        layer.Description = 'Sum of squares error';
    end
```

Create Forward Loss Function

Create a function named `forwardLoss` that returns the SSE loss between the predictions made by the network and the training targets. The syntax for `forwardLoss` is `loss = forwardLoss(layer, Y, T)`, where `Y` is the output of the previous layer and `T` represents the training targets.

For classification problems, the dimensions of `T` depend on the type of problem.

Classification Task	Input Size	Observation Dimension
2-D image classification	1-by-1-by-*K*-by-*N*, where *K* is the number of classes and *N* is the number of observations.	4
3-D image classification	1-by-1-by-1-by-*K*-by-*N*, where *K* is the number of classes and *N* is the number of observations.	5
Sequence-to-label classification	*K*-by-*N*, where *K* is the number of classes and *N* is the number of observations.	2
Sequence-to-sequence classification	*K*-by-*N*-by-*S*, where *K* is the number of classes, *N* is the number of observations, and *S* is the sequence length.	2

The size of `Y` depends on the output of the previous layer. To ensure that `Y` is the same size as `T`, you must include a layer that outputs the correct size before the output layer. For example, to ensure that `Y` is a 4-D array of prediction scores for *K* classes, you can include a fully connected layer of size *K* followed by a softmax layer before the output layer.

A classification SSE layer computes the sum of squares error loss for classification problems. SSE is an error measure between two continuous random variables. For predictions *Y* and training targets *T*, the SSE loss between *Y* and *T* is given by

$$L = \frac{1}{N}\sum_{n=1}^{N}\sum_{i=1}^{K}(Y_{ni} - T_{ni})^2,$$

where *N* is the number of observations and *K* is the number of classes.

The inputs `Y` and `T` correspond to *Y* and *T* in the equation, respectively. The output `loss` corresponds to *L*. Add a comment to the top of the function that explains the syntaxes of the function.

```
        function loss = forwardLoss(layer, Y, T)
            % loss = forwardLoss(layer, Y, T) returns the SSE loss between
            % the predictions Y and the training targets T.

            % Calculate sum of squares.
            sumSquares = sum((Y-T).^2);

            % Take mean over mini-batch.
            N = size(Y,4);
            loss = sum(sumSquares)/N;
        end
```

Because the `forwardLoss` function only uses functions that support `dlarray` objects, defining the `backwardLoss` function is optional. For a list of functions that support `dlarray` objects, see “List of Functions with dlarray Support” on page 18-423.

Completed Layer

View the completed classification output layer class file.

```
classdef sseClassificationLayer < nnet.layer.ClassificationLayer
    % Example custom classification layer with sum of squares error loss.

    methods
        function layer = sseClassificationLayer(name)
            % layer = sseClassificationLayer(name) creates a sum of squares
            % error classification layer and specifies the layer name.

            % Set layer name.
            layer.Name = name;

            % Set layer description.
            layer.Description = 'Sum of squares error';
        end

        function loss = forwardLoss(layer, Y, T)
            % loss = forwardLoss(layer, Y, T) returns the SSE loss between
            % the predictions Y and the training targets T.

            % Calculate sum of squares.
            sumSquares = sum((Y-T).^2);

            % Take mean over mini-batch.
            N = size(Y,4);
            loss = sum(sumSquares)/N;
        end
    end
end
```

GPU Compatibility

If the layer forward functions fully support `dlarray` objects, then the layer is GPU compatible. Otherwise, to be GPU compatible, the layer functions must support inputs and return outputs of type `gpuArray`.

Many MATLAB built-in functions support `gpuArray` and `dlarray` input arguments. For a list of functions that support `dlarray` objects, see “List of Functions with dlarray Support” on page 18-423.

For a list of functions that execute on a GPU, see “Run MATLAB Functions on a GPU” (Parallel Computing Toolbox). To use a GPU for deep learning, you must also have a supported GPU device. For information on supported devices, see “GPU Support by Release” (Parallel Computing Toolbox). For more information on working with GPUs in MATLAB, see “GPU Computing in MATLAB” (Parallel Computing Toolbox).

The MATLAB functions used in `forwardLoss` all support `dlarray` objects, so the layer is GPU compatible.

Check Output Layer Validity

Check the layer validity of the custom classification output layer `sseClassificationLayer`.

Define a custom sum-of-squares error classification layer. To create this layer, save the file `sseClassificationLayer.m` in the current folder. Create an instance of the layer.

```
layer = sseClassificationLayer('sse');
```

Check the layer is valid using `checkLayer`. Specify the valid input size to be the size of a single observation of typical input to the layer. The layer expects a 1-by-1-by-*K*-by-*N* array inputs, where *K* is the number of classes, and *N* is the number of observations in the mini-batch.

```
validInputSize = [1 1 10];
checkLayer(layer,validInputSize,'ObservationDimension',4);
```

```
Skipping GPU tests. No compatible GPU device found.

Skipping code generation compatibility tests. To check validity of the layer for code generation

Running nnet.checklayer.TestOutputLayerWithoutBackward
........
Done nnet.checklayer.TestOutputLayerWithoutBackward
__________

Test Summary:
     8 Passed, 0 Failed, 0 Incomplete, 2 Skipped.
     Time elapsed: 0.6486 seconds.
```

The test summary reports the number of passed, failed, incomplete, and skipped tests.

Include Custom Classification Output Layer in Network

You can use a custom output layer in the same way as any other output layer in Deep Learning Toolbox. This section shows how to create and train a network for classification using the custom classification output layer that you created earlier.

Load the example training data.

```
[XTrain,YTrain] = digitTrain4DArrayData;
```

Define a custom sum-of-squares error classification layer. To create this layer, save the file `sseClassificationLayer.m` in the current folder. Create an instance of the layer. Create a layer array including the custom classification output layer `sseClassificationLayer`.

```
layers = [
    imageInputLayer([28 28 1])
    convolution2dLayer(5,20)
    batchNormalizationLayer
    reluLayer
    fullyConnectedLayer(10)
    softmaxLayer
    sseClassificationLayer('sse')]

layers =
  7x1 Layer array with layers:

     1   ''      Image Input             28x28x1 images with 'zerocenter' normalization
     2   ''      Convolution             20 5x5 convolutions with stride [1  1] and padding [0  0
     3   ''      Batch Normalization     Batch normalization
     4   ''      ReLU                    ReLU
     5   ''      Fully Connected         10 fully connected layer
     6   ''      Softmax                 softmax
     7   'sse'   Classification Output   Sum of squares error
```

Set the training options and train the network.

```
options = trainingOptions('sgdm');
net = trainNetwork(XTrain,YTrain,layers,options);

Training on single CPU.
Initializing input data normalization.

Define Custom Regression Output Layer

Tip To create a regression output layer with mean squared error loss, use `regressionLayer`. If you want to use a different loss function for your regression problems, then you can define a custom regression output layer using this example as a guide.

This example shows how to create a custom regression output layer with the mean absolute error (MAE) loss.

To define a custom regression output layer, you can use the template provided in this example, which takes you through the following steps:

1. Name the layer – Give the layer a name so it can be used in MATLAB.
2. Declare the layer properties – Specify the properties of the layer.
3. Create a constructor function (optional) – Specify how to construct the layer and initialize its properties. If you do not specify a constructor function, then the software initializes the properties with `''` at creation.
4. Create a forward loss function – Specify the loss between the predictions and the training targets.
5. Create a backward loss function (optional) – Specify the derivative of the loss with respect to the predictions. If you do not specify a backward loss function, then the forward loss function must support `dlarray` objects.

A regression MAE layer computes the mean absolute error loss for regression problems. MAE loss is an error measure between two continuous random variables. For predictions Y and training targets T, the MAE loss between Y and T is given by

$$L = \frac{1}{N}\sum_{n=1}^{N}\left(\frac{1}{R}\sum_{i=1}^{R}|Y_{ni} - T_{ni}|\right),$$

where N is the number of observations and R is the number of responses.

Regression Output Layer Template

Copy the regression output layer template into a new file in MATLAB. This template outlines the structure of a regression output layer and includes the functions that define the layer behavior.

```
classdef myRegressionLayer < nnet.layer.RegressionLayer

    properties
        % (Optional) Layer properties.

        % Layer properties go here.
    end

    methods
        function layer = myRegressionLayer()
            % (Optional) Create a myRegressionLayer.

            % Layer constructor function goes here.
        end

        function loss = forwardLoss(layer, Y, T)
            % Return the loss between the predictions Y and the training
```

```
            % targets T.
            %
            % Inputs:
            %         layer - Output layer
            %         Y     – Predictions made by network
            %         T     – Training targets
            %
            % Output:
            %         loss  - Loss between Y and T

            % Layer forward loss function goes here.
        end

        function dLdY = backwardLoss(layer, Y, T)
            % (Optional) Backward propagate the derivative of the loss
            % function.
            %
            % Inputs:
            %         layer - Output layer
            %         Y     – Predictions made by network
            %         T     – Training targets
            %
            % Output:
            %         dLdY  - Derivative of the loss with respect to the
            %                 predictions Y

            % Layer backward loss function goes here.
        end
    end
end
```

Name the Layer

First, give the layer a name. In the first line of the class file, replace the existing name `myRegressionLayer` with `maeRegressionLayer`.

```
classdef maeRegressionLayer < nnet.layer.RegressionLayer
    ...
end
```

Next, rename the `myRegressionLayer` constructor function (the first function in the `methods` section) so that it has the same name as the layer.

```
    methods
        function layer = maeRegressionLayer()
            ...
        end

        ...
     end
```

Save the Layer

Save the layer class file in a new file named `maeRegressionLayer.m`. The file name must match the layer name. To use the layer, you must save the file in the current folder or in a folder on the MATLAB path.

Declare Layer Properties

Declare the layer properties in the `properties` section.

By default, custom output layers have the following properties:

- `Name` – Layer name, specified as a character vector or a string scalar. For `Layer` array input, the `trainNetwork`, `assembleNetwork`, `layerGraph`, and `dlnetwork` functions automatically assign names to layers with `Name` set to `''`.
- `Description` – One-line description of the layer, specified as a character vector or a string scalar. This description appears when the layer is displayed in a `Layer` array. If you do not specify a layer description, then the software displays `"Classification Output"` or `"Regression Output"`.
- `Type` – Type of the layer, specified as a character vector or a string scalar. The value of `Type` appears when the layer is displayed in a `Layer` array. If you do not specify a layer type, then the software displays the layer class name.

Custom classification layers also have the following property:

- `Classes` – Classes of the output layer, specified as a categorical vector, string array, cell array of character vectors, or `'auto'`. If `Classes` is `'auto'`, then the software automatically sets the classes at training time. If you specify the string array or cell array of character vectors `str`, then the software sets the classes of the output layer to `categorical(str,str)`.

Custom regression layers also have the following property:

- `ResponseNames` – Names of the responses, specified a cell array of character vectors or a string array. At training time, the software automatically sets the response names according to the training data. The default is `{}`.

If the layer has no other properties, then you can omit the `properties` section.

The layer does not require any additional properties, so you can remove the `properties` section.

Create Constructor Function

Create the function that constructs the layer and initializes the layer properties. Specify any variables required to create the layer as inputs to the constructor function.

To initialize the `Name` property at creation, specify the input argument `name`. Add a comment to the top of the function that explains the syntax of the function.

```
function layer = maeRegressionLayer(name)
    % layer = maeRegressionLayer(name) creates a
    % mean-absolute-error regression layer and specifies the layer
    % name.

    ...
end
```

Initialize Layer Properties

Replace the comment `% Layer constructor function goes here` with code that initializes the layer properties.

Give the layer a one-line description by setting the `Description` property of the layer. Set the `Name` property to the input argument `name`. Set the description to describe the type of layer and its size.

```
function layer = maeRegressionLayer(name)
    % layer = maeRegressionLayer(name) creates a
    % mean-absolute-error regression layer and specifies the layer
    % name.

    % Set layer name.
```

```
        layer.Name = name;

        % Set layer description.
        layer.Description = 'Mean absolute error';
    end
```

Create Forward Loss Function

Create a function named `forwardLoss` that returns the MAE loss between the predictions made by the network and the training targets. The syntax for `forwardLoss` is `loss = forwardLoss(layer, Y, T)`, where `Y` is the output of the previous layer and `T` contains the training targets.

For regression problems, the dimensions of `T` also depend on the type of problem.

Regression Task	Input Size	Observation Dimension
2-D image regression	1-by-1-by-*R*-by-*N*, where *R* is the number of responses and *N* is the number of observations.	4
2-D Image-to-image regression	*h*-by-*w*-by-*c*-by-`N`, where *h*, *w*, and *c* are the height, width, and number of channels of the output respectively, and *N* is the number of observations.	4
3-D image regression	1-by-1-by-1-by-*R*-by-*N*, where *R* is the number of responses and *N* is the number of observations.	5
3-D Image-to-image regression	*h*-by-*w*-by-*d*-by-*c*-by-`N`, where *h*, *w*, *d*, and *c* are the height, width, depth, and number of channels of the output respectively, and *N* is the number of observations.	5
Sequence-to-one regression	*R*-by-*N*, where *R* is the number of responses and *N* is the number of observations.	2
Sequence-to-sequence regression	*R*-by-*N*-by-*S*, where *R* is the number of responses, *N* is the number of observations, and *S* is the sequence length.	2

For example, if the network defines an image regression network with one response and has mini-batches of size 50, then `T` is a 4-D array of size 1-by-1-by-1-by-50.

The size of `Y` depends on the output of the previous layer. To ensure that `Y` is the same size as `T`, you must include a layer that outputs the correct size before the output layer. For example, for image regression with *R* responses, to ensure that `Y` is a 4-D array of the correct size, you can include a fully connected layer of size *R* before the output layer.

A regression MAE layer computes the mean absolute error loss for regression problems. MAE loss is an error measure between two continuous random variables. For predictions Y and training targets T, the MAE loss between Y and T is given by

$$L = \frac{1}{N}\sum_{n=1}^{N}\left(\frac{1}{R}\sum_{i=1}^{R}|Y_{ni} - T_{ni}|\right),$$

where N is the number of observations and R is the number of responses.

The inputs `Y` and `T` correspond to Y and T in the equation, respectively. The output `loss` corresponds to L. To ensure that `loss` is scalar, output the mean loss over the mini-batch. Add a comment to the top of the function that explains the syntaxes of the function.

```
function loss = forwardLoss(layer, Y, T)
    % loss = forwardLoss(layer, Y, T) returns the MAE loss between
    % the predictions Y and the training targets T.

    % Calculate MAE.
    R = size(Y,3);
    meanAbsoluteError = sum(abs(Y-T),3)/R;

    % Take mean over mini-batch.
    N = size(Y,4);
    loss = sum(meanAbsoluteError)/N;
end
```

Because the `forwardLoss` function only uses functions that support `dlarray` objects, defining the `backwardLoss` function is optional. For a list of functions that support `dlarray` objects, see “List of Functions with dlarray Support” on page 18-423.

Completed Layer

View the completed regression output layer class file.

```
classdef maeRegressionLayer < nnet.layer.RegressionLayer
    % Example custom regression layer with mean-absolute-error loss.

    methods
        function layer = maeRegressionLayer(name)
            % layer = maeRegressionLayer(name) creates a
            % mean-absolute-error regression layer and specifies the layer
            % name.

            % Set layer name.
            layer.Name = name;

            % Set layer description.
            layer.Description = 'Mean absolute error';
        end

        function loss = forwardLoss(layer, Y, T)
            % loss = forwardLoss(layer, Y, T) returns the MAE loss between
            % the predictions Y and the training targets T.
```

```
            % Calculate MAE.
            R = size(Y,3);
            meanAbsoluteError = sum(abs(Y-T),3)/R;

            % Take mean over mini-batch.
            N = size(Y,4);
            loss = sum(meanAbsoluteError)/N;
        end
    end
end
```

GPU Compatibility

If the layer forward functions fully support `dlarray` objects, then the layer is GPU compatible. Otherwise, to be GPU compatible, the layer functions must support inputs and return outputs of type `gpuArray`.

Many MATLAB built-in functions support `gpuArray` and `dlarray` input arguments. For a list of functions that support `dlarray` objects, see “List of Functions with dlarray Support” on page 18-423. For a list of functions that execute on a GPU, see “Run MATLAB Functions on a GPU” (Parallel Computing Toolbox). To use a GPU for deep learning, you must also have a supported GPU device. For information on supported devices, see “GPU Support by Release” (Parallel Computing Toolbox). For more information on working with GPUs in MATLAB, see “GPU Computing in MATLAB” (Parallel Computing Toolbox).

The MATLAB functions used in `forwardLoss` in `maeRegressionLayer` all support `dlarray` objects, so the layer is GPU compatible.

Check Output Layer Validity

Check the layer validity of the custom classification output layer `maeRegressionLayer`.

Define a custom mean absolute error regression layer. To create this layer, save the file `maeRegressionLayer.m` in the current folder. Create an instance of the layer.

```
layer = maeRegressionLayer('mae');
```

Check the layer is valid using `checkLayer`. Specify the valid input size to be the size of a single observation of typical input to the layer. The layer expects a 1-by-1-by-R-by-*N* array inputs, where R is the number of responses, and *N* is the number of observations in the mini-batch.

```
validInputSize = [1 1 10];
checkLayer(layer,validInputSize,'ObservationDimension',4);
```

```
Skipping GPU tests. No compatible GPU device found.

Skipping code generation compatibility tests. To check validity of the layer for code generation

Running nnet.checklayer.TestOutputLayerWithoutBackward
........
Done nnet.checklayer.TestOutputLayerWithoutBackward
__________

Test Summary:
     8 Passed, 0 Failed, 0 Incomplete, 2 Skipped.
     Time elapsed: 0.14109 seconds.
```

The test summary reports the number of passed, failed, incomplete, and skipped tests.

Include Custom Regression Output Layer in Network

You can use a custom output layer in the same way as any other output layer in Deep Learning Toolbox. This section shows how to create and train a network for regression using the custom output layer you created earlier.

The example constructs a convolutional neural network architecture, trains a network, and uses the trained network to predict angles of rotated, handwritten digits. These predictions are useful for optical character recognition.

Load the example training data.

```
[XTrain,~,YTrain] = digitTrain4DArrayData;
```

Create a layer array including the regression output layer `maeRegressionLayer`.

```
layers = [
    imageInputLayer([28 28 1])
    convolution2dLayer(5,20)
    batchNormalizationLayer
    reluLayer
    fullyConnectedLayer(1)
    maeRegressionLayer('mae')]
```

```
layers =
  6x1 Layer array with layers:

     1   ''      Image Input           28x28x1 images with 'zerocenter' normalization
     2   ''      Convolution           20 5x5 convolutions with stride [1  1] and padding [0  0
     3   ''      Batch Normalization   Batch normalization
     4   ''      ReLU                  ReLU
     5   ''      Fully Connected       1 fully connected layer
     6   'mae'   Regression Output     Mean absolute error
```

Set the training options and train the network.

```
options = trainingOptions('sgdm');
net = trainNetwork(XTrain,YTrain,layers,options);
```

```
Training on single CPU.

Specify Custom Layer Backward Function

If Deep Learning Toolbox does not provide the layer you require for your classification or regression problem, then you can define your own custom layer. For a list of built-in layers, see “List of Deep Learning Layers” on page 1-21.

The example “Define Custom Deep Learning Layer with Learnable Parameters” on page 18-35 shows how to create a custom PreLU layer and goes through the following steps:

1. Name the layer — Give the layer a name so that you can use it in MATLAB.
2. Declare the layer properties — Specify the properties of the layer including learnable parameters and state parameters.
3. Create a constructor function (optional) — Specify how to construct the layer and initialize its properties. If you do not specify a constructor function, then at creation, the software initializes the `Name`, `Description`, and `Type` properties with `[]` and sets the number of layer inputs and outputs to 1.
4. Create forward functions — Specify how data passes forward through the layer (forward propagation) at prediction time and at training time.
5. Create reset state function (optional) — Specify how to reset state parameters.
6. Create a backward function (optional) — Specify the derivatives of the loss with respect to the input data and the learnable parameters (backward propagation). If you do not specify a backward function, then the forward functions must support `dlarray` objects.

If the forward function only uses functions that support `dlarray` objects, then creating a backward function is optional. In this case, the software determines the derivatives automatically using automatic differentiation. For a list of functions that support `dlarray` objects, see “List of Functions with dlarray Support” on page 18-423. If you want to use functions that do not support `dlarray` objects, or want to use a specific algorithm for the backward function, then you can define a custom backward function using this example as a guide.

Create Custom Layer

The example “Define Custom Deep Learning Layer with Learnable Parameters” on page 18-35 shows how to create a PReLU layer. A PReLU layer performs a threshold operation, where for each channel, any input value less than zero is multiplied by a scalar learned at training time.[1] For values less than zero, a PReLU layer applies scaling coefficients α_i to each channel of the input. These coefficients form a learnable parameter, which the layer learns during training.

The PReLU operation is given by

$$f(x_i) = \begin{cases} x_i & \text{if } x_i > 0 \\ \alpha_i x_i & \text{if } x_i \le 0 \end{cases}$$

where x_i is the input of the nonlinear activation f on channel i, and α_i is the coefficient controlling the slope of the negative part. The subscript i in α_i indicates that the nonlinear activation can vary on different channels.

View the layer created in the example “Define Custom Deep Learning Layer with Learnable Parameters” on page 18-35. This layer does not have a `backward` function.

```
classdef preluLayer < nnet.layer.Layer
    % Example custom PReLU layer.

    properties (Learnable)
        % Layer learnable parameters

        % Scaling coefficient
        Alpha
    end

    methods
        function layer = preluLayer(numChannels,args)
            % layer = preluLayer(numChannels) creates a PReLU layer
            % with numChannels channels.
            %
            % layer = preluLayer(numChannels,Name=name) also specifies the
            % layer name.

            arguments
                numChannels
                args.Name = "";
            end

            % Set layer name.
            layer.Name = name;

            % Set layer description.
            layer.Description = "PReLU with " + numChannels + " channels";

            % Initialize scaling coefficient.
            layer.Alpha = rand([1 1 numChannels]);
        end

        function Z = predict(layer, X)
            % Z = predict(layer, X) forwards the input data X through the
            % layer and outputs the result Z.

            Z = max(X,0) + layer.Alpha .* min(0,X);
        end
    end
end
```

Note If the layer has a custom backward function, then you can still inherit from `nnet.layer.Formattable`.

Create Backward Function

Implement the `backward` function that returns the derivatives of the loss with respect to the input data and the learnable parameters.

The `backward` function syntax depends on the type of layer.

- `dLdX = backward(layer,X,Z,dLdZ,memory)` returns the derivatives `dLdX` of the loss with respect to the layer input, where `layer` has a single input and a single output. `Z` corresponds to

the forward function output and `dLdZ` corresponds to the derivative of the loss with respect to `Z`. The function input `memory` corresponds to the memory output of the forward function.

- `[dLdX,dLdW] = backward(layer,X,Z,dLdZ,memory)` also returns the derivative `dLdW` of the loss with respect to the learnable parameter, where `layer` has a single learnable parameter.
- `[dLdX,dLdSin] = backward(layer,X,Z,dLdZ,dLdSout,memory)` also returns the derivative `dLdSin` of the loss with respect to the state input using any of the previous syntaxes, where `layer` has a single state parameter and `dLdSout` corresponds to the derivative of the loss with respect to the layer state output.
- `[dLdX,dLdW,dLdSin] = backward(layer,X,Z,dLdZ,dLdSout,memory)` also returns the derivative `dLdW` of the loss with respect to the learnable parameter and returns the derivative `dLdSin` of the loss with respect to the layer state input using any of the previous syntaxes, where `layer` has a single state parameter and single learnable parameter.

You can adjust the syntaxes for layers with multiple inputs, multiple outputs, multiple learnable parameters, or multiple state parameters:

- For layers with multiple inputs, replace `X` and `dLdX` with `X1,...,XN` and `dLdX1,...,dLdXN`, respectively, where `N` is the number of inputs.
- For layers with multiple outputs, replace `Z` and `dLdZ` with `Z1,...,ZM` and `dLdZ1,...,dLdZM`, respectively, where `M` is the number of outputs.
- For layers with multiple learnable parameters, replace `dLdW` with `dLdW1,...,dLdWP`, where `P` is the number of learnable parameters.
- For layers with multiple state parameters, replace `dLdSin` and `dLdSout` with `dLdSin1,...,dLdSinK` and `dLdSout1,...,dLdSoutK`, respectively, where `K` is the number of state parameters.

To reduce memory usage by preventing unused variables being saved between the forward and backward pass, replace the corresponding input arguments with `~`.

Tip If the number of inputs to `backward` can vary, then use `varargin` instead of the input arguments after `layer`. In this case, `varargin` is a cell array of the inputs, where the first `N` elements correspond to the `N` layer inputs, the next `M` elements correspond to the `M` layer outputs, the next `M` elements correspond to the derivatives of the loss with respect to the `M` layer outputs, the next `K` elements correspond to the `K` derivatives of the loss with respect to the `K` states outputs, and the last element corresponds to `memory`.

If the number of outputs can vary, then use `varargout` instead of the output arguments. In this case, `varargout` is a cell array of the outputs, where the first `N` elements correspond to the `N` the derivatives of the loss with respect to the `N` layer inputs, the next `P` elements correspond to the derivatives of the loss with respect to the `P` learnable parameters, and the next `K` elements correspond to the derivatives of the loss with respect to the `K` state inputs.

Note `dlnetwork` objects do not support custom layers that require a memory value in a custom backward function. To use a custom layer with a custom backward function in a `dlnetwork` object, the `memory` input of the `backward` function definition must be `~`.

Because a PReLU layer has only one input, one output, one learnable parameter, and does not require the outputs of the layer forward function or a memory value, the syntax for `backward` for a PReLU layer is `[dLdX,dLdAlpha] = backward(layer,X,~,dLdZ,~)`. The dimensions of `X` are the same

as in the forward function. The dimensions of `dLdZ` are the same as the dimensions of the output `Z` of the forward function. The dimensions and data type of `dLdX` are the same as the dimensions and data type of `X`. The dimension and data type of `dLdAlpha` is the same as the dimension and data type of the learnable parameter `Alpha`.

During the backward pass, the layer automatically updates the learnable parameters using the corresponding derivatives.

To include a custom layer in a network, the layer forward functions must accept the outputs of the previous layer and forward propagate arrays with the size expected by the next layer. Similarly, when `backward` is specified, the `backward` function must accept inputs with the same size as the corresponding output of the forward function and backward propagate derivatives with the same size.

The derivative of the loss with respect to the input data is

$$\frac{\partial L}{\partial x_i} = \frac{\partial L}{\partial f(x_i)} \frac{\partial f(x_i)}{\partial x_i}$$

where $\partial L / \partial f(x_i)$ is the gradient propagated from the next layer, and the derivative of the activation is

$$\frac{\partial f(x_i)}{\partial x_i} = \begin{cases} 1 & \text{if } x_i \geq 0 \\ \alpha_i & \text{if } x_i < 0 \end{cases}.$$

The derivative of the loss with respect to the learnable parameters is

$$\frac{\partial L}{\partial \alpha_i} = \sum_j \frac{\partial L}{\partial f(x_{ij})} \frac{\partial f(x_{ij})}{\partial \alpha_i}$$

where i indexes the channels, j indexes the elements over height, width, and observations, and the gradient of the activation is

$$\frac{\partial f(x_i)}{\partial \alpha_i} = \begin{cases} 0 & \text{if } x_i \geq 0 \\ x_i & \text{if } x_i < 0 \end{cases}.$$

Create the backward function that returns these derivatives.

```
function [dLdX, dLdAlpha] = backward(layer, X, ~, dLdZ, ~)
    % [dLdX, dLdAlpha] = backward(layer, X, ~, dLdZ, ~)
    % backward propagates the derivative of the loss function
    % through the layer.
    % Inputs:
    %         layer    - Layer to backward propagate through
    %         X        - Input data
    %         dLdZ     - Gradient propagated from the deeper layer
    % Outputs:
    %         dLdX     - Derivative of the loss with respect to the
    %                    input data
    %         dLdAlpha - Derivative of the loss with respect to the
    %                    learnable parameter Alpha
