If a table or timetable is passed into this function using the AssetReturns argument and the GetAssetList flag is true, the column names from the table or timetable are used as asset names in obj.AssetList.

If a matrix is passed and the GetAssetList flag is true, default asset names are created based on the AbstractPortfolio property defaultforAssetList, which is 'Asset'.

If the GetAssetList flag is false, no action occurs, which is the default behavior.

Data Types: logical

**Output Arguments****obj — Updated portfolio object**

object for portfolio

Updated portfolio object, returned as a PortfolioCVaR or PortfolioMAD object. For more information on creating a portfolio object, see

- PortfolioCVaR
- PortfolioMAD

**Tips**

You can also use dot notation to simulate multivariate normal asset return scenarios from data for a PortfolioCVaR or PortfolioMAD object.

```
obj = obj.simulateNormalScenariosByData(AssetReturns, NumScenarios, Name, Value);
```

**See Also**

## simulateNormalScenariosByMoments

Simulate multivariate normal asset return scenarios from mean and covariance of asset returns

### Syntax

```
obj = simulateNormalScenariosByMoments(obj,AssetMean,AssetCovar,NumScenarios)
obj = simulateNormalScenariosByMoments(obj,AssetMean,AssetCovarNumScenarios,
NumAssets)
```

### Description

`obj = simulateNormalScenariosByMoments(obj,AssetMean,AssetCovar,NumScenarios)` simulates multivariate normal asset return scenarios from mean and covariance of asset returns for `PortfolioCVaR` or `PortfolioMAD` objects. For details on the workflows, see “PortfolioCVaR Object Workflow” on page 5-15, and “PortfolioMAD Object Workflow” on page 6-15.

`obj = simulateNormalScenariosByMoments(obj,AssetMean,AssetCovarNumScenarios, NumAssets)` simulates multivariate normal asset return scenarios from mean and covariance of asset returns for `PortfolioCVaR` or `PortfolioMAD` objects using the optional input `NumScenarios`.

---

**Note** This function overwrites existing scenarios associated with `PortfolioCVaR` or `PortfolioMAD` objects, and also, possibly, `NumScenarios`.

If you want to use the function multiple times and you want to simulate identical scenarios each time the function is called, precede each function call with `rng(seed)` using a specified integer seed.

---

### Examples

#### Simulate Multivariate Normal Asset Return Scenarios from Moments for a PortfolioCVaR Object

Given `PortfolioCVaR` object `p`, use the `simulateNormalScenariosByMoments` function to simulate multivariate normal asset return scenarios from moments.

```
m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
      0.00408 0.0289 0.0204 0.0119;
      0.00192 0.0204 0.0576 0.0336;
      0 0.0119 0.0336 0.1225 ];
m = m/12;
C = C/12;

AssetScenarios = mvnrnd(m, C, 20000);

p = PortfolioCVaR;
p = setScenarios(p, AssetScenarios);
p = setDefaultConstraints(p);
p = setProbabilityLevel(p, 0.95);
```

```

AssetMean = [.5]
AssetMean = 0.5000
AssetCovar = [.5]
AssetCovar = 0.5000
NumScenarios = 100
NumScenarios = 100

p = simulateNormalScenariosByMoments(p, AssetMean, AssetCovar, NumScenarios)
p =
  PortfolioCVaR with properties:

### Simulate Multivariate Normal Asset Return Scenarios from Moments for a PortfolioMAD Object

Given PortfolioMAD object `p`, use the `simulateNormalScenariosByMoments` function to simulate multivariate normal asset return scenarios from moments.

```
m = [ 0.05; 0.1; 0.12; 0.18 ];
C = [ 0.0064 0.00408 0.00192 0;
      0.00408 0.0289 0.0204 0.0119;
      0.00192 0.0204 0.0576 0.0336;
      0 0.0119 0.0336 0.1225 ];
m = m/12;
C = C/12;

AssetScenarios = mvnrnd(m, C, 20000);

p = PortfolioMAD;
p = setScenarios(p, AssetScenarios);
p = setDefaultConstraints(p);

AssetMean = [.5]
AssetMean = 0.5000

AssetCovar = [.5]
AssetCovar = 0.5000

NumScenarios = 100
NumScenarios = 100

p = simulateNormalScenariosByMoments(p, AssetMean, AssetCovar, NumScenarios)

p =
PortfolioMAD with properties:

    BuyCost: []
    SellCost: []
RiskFreeRate: []
    Turnover: []
    BuyTurnover: []
    SellTurnover: []
    NumScenarios: 100
        Name: []
    NumAssets: 4
    AssetList: []

    UpperGroup: []
        GroupA: []
        GroupB: []
    LowerRatio: []
    UpperRatio: []
    MinNumAssets: []
```

```

MaxNumAssets: []
BoundType: [4x1 categorical]

```

## Input Arguments

### **obj** — Object for portfolio

object

Object for portfolio, specified using a `PortfolioCVaR` or `PortfolioMAD` object.

For more information on creating a `PortfolioCVaR` or `PortfolioMAD` object, see

- `PortfolioCVaR`
- `PortfolioMAD`

Data Types: object

### **AssetMean** — Mean of asset returns

vector

Mean of asset returns, specified as a vector.

---

**Note** If `AssetMean` is a scalar and the number of assets is known, scalar expansion occurs. If the number of assets cannot be determined, this function assumes that `NumAssets = 1`.

---

Data Types: double

### **AssetCovar** — Covariance of asset returns

symmetric positive semidefinite matrix

Covariance of asset returns, specified as a symmetric positive semidefinite matrix.

---

### **Note**

- If `AssetCovar` is a scalar and the number of assets is known, a diagonal matrix is formed with the scalar value along the diagonals. If it is not possible to determine the number of assets, this method assumes that `NumAssets = 1`.
  - If `AssetCovar` is a vector, a diagonal matrix is formed with the vector along the diagonal.
  - If `AssetCovar` is not a symmetric positive semidefinite matrix, use `nearcorr` to create a positive semidefinite matrix for a correlation matrix.
- 

Data Types: double

### **NumScenarios** — Number of scenarios to simulate

positive integer

Number of scenarios to simulate, specified as a positive integer.

Data Types: double

**NumAssets — Number of assets**

scalar

Number of assets, specified as a scalar.

Data Types: double

**Output Arguments****obj — Updated portfolio object**

object for portfolio

Updated portfolio object, returned as a `PortfolioCVaR` or `PortfolioMAD` object. For more information on creating a portfolio object, see

- `PortfolioCVaR`
- `PortfolioMAD`

**Tips**

You can also use dot notation to simulate multivariate normal asset return scenarios from a mean and covariance of asset returns for a `PortfolioCVaR` or `PortfolioMAD` object.

```
obj = obj.simulateNormalScenariosByMoments(AssetMean, AssetCovar, NumScenarios, NumAssets);
```

# setfield

Set content of specific field

---

**Note** `setfield` is not recommended. Use `timetable` instead. For more information, see “Convert Financial Time Series Objects `fints` to Timetables”.

---

## Syntax

```
newfts = setfield(tsoobj,field,V)
```

```
newfts = setfield(tsoobj,field,{dates},V)
```

## Description

`setfield` treats the contents of fields in a time series object (`tsoobj`) as fields in a structure.

`newfts = setfield(tsoobj,field,V)` sets the contents of the specified field to the value `V`. This is equivalent to the syntax `S.field = V`.

`newfts = setfield(tsoobj,field,{dates},V)` sets the contents of the specified field for the specified dates. `dates` can be individual cells of date character vectors or a cell of a date character vector's range using the `::` operator, for example, `'03/01/99::03/31/99'`. Dates can contain time-of-day information.

## Examples

**Example 1.** Set the closing value for all days to 3890.

```
load dji30short
format bank
myfts1 = setfield(myfts1, 'Close', 3890)
```

```
Warning: FINTS will be removed in a future release. Use TIMETABLE instead.
> In fints/setfield (line 84)
Warning: FINTS will be removed in a future release. Use TIMETABLE instead.
> In fints/display (line 66)
```

```
myfts1 =
    desc: DJI30MAR94.dat
    freq: Daily (1)

    'dates: (20)'    'Open: (20)'    'High: (20)'    'Low: (20)'    'Close: (20)'
    '04-Mar-1994'   [ 3830.90]     [ 3868.04]     [ 3800.50]     [ 3890.00]
    '07-Mar-1994'   [ 3851.72]     [ 3882.40]     [ 3824.71]     [ 3890.00]
    '08-Mar-1994'   [ 3858.48]     [ 3881.55]     [ 3822.45]     [ 3890.00]
    '09-Mar-1994'   [ 3853.97]     [ 3874.52]     [ 3817.95]     [ 3890.00]
    '10-Mar-1994'   [ 3852.57]     [ 3865.51]     [ 3801.63]     [ 3890.00]
    '11-Mar-1994'   [ 3832.58]     [ 3872.83]     [ 3806.69]     [ 3890.00]

    '15-Mar-1994'   [ 3863.41]     [ 3888.46]     [ 3826.85]     [ 3890.00]
    '16-Mar-1994'   [ 3851.03]     [ 3879.53]     [ 3819.94]     [ 3890.00]
    '17-Mar-1994'   [ 3853.62]     [ 3891.34]     [ 3821.66]     [ 3890.00]
    '18-Mar-1994'   [ 3865.42]     [ 3911.78]     [ 3838.65]     [ 3890.00]
    '21-Mar-1994'   [ 3878.38]     [ 3898.25]     [ 3838.65]     [ 3890.00]
    '22-Mar-1994'   [ 3865.71]     [ 3896.23]     [ 3840.66]     [ 3890.00]
    '23-Mar-1994'   [ 3868.88]     [ 3901.41]     [ 3839.80]     [ 3890.00]
    '24-Mar-1994'   [ 3849.88]     [ 3865.42]     [ 3792.58]     [ 3890.00]
```

```
'25-Mar-1994' [ 3827.13] [ 3826.85] [ 3774.73] [ 3890.00]
'28-Mar-1994' [ 3776.46] [ 3793.45] [ 3719.74] [ 3890.00]
'29-Mar-1994' [ 3757.17] [ 3771.86] [ 3689.23] [ 3890.00]
'30-Mar-1994' [ 3688.36] [ 3718.88] [ 3612.36] [ 3890.00]
'31-Mar-1994' [ 3639.71] [ 3673.10] [ 3544.12] [ 3890.00]
```

**Example 2.** Set values for specific times on specific days.

First create a financial time series containing time-of-day data.

```
dates = ['01-Jan-2001'; '01-Jan-2001'; '02-Jan-2001'; ...
         '02-Jan-2001'; '03-Jan-2001'; '03-Jan-2001'];
times = ['11:00'; '12:00'; '11:00'; '12:00'; '11:00'; '12:00'];
dates_times = cellstr([dates, repmat(' ', size(dates,1),1), ...
                       times]);
myfts = fints(dates_times, [(1:4)'; nan; 6], {'Data1'}, 1, ...
             'My FINTS')
```

Warning: FINTS will be removed in a future release. Use TIMETABLE instead.

> In fints (line 165)

Warning: FINTS will be removed in a future release. Use TIMETABLE instead.

> In fints/display (line 66)

myfts =

```
desc: My FINTS
freq: Daily (1)
```

```
'dates: (6)'      'times: (6)'      'Data1: (6)'
'01-Jan-2001'    '11:00'          [          1]
'    "    '      '12:00'          [          2]
'02-Jan-2001'    '11:00'          [          3]
'    "    '      '12:00'          [          4]
'03-Jan-2001'    '11:00'          [         NaN]
'    "    '      '12:00'          [          6]
```

Now use `setfield` to replace the data in `myfts` with new data starting at 12:00 on January 1, 2001 and ending at 11:00 on January 3, 2001.

```
S = setfield(myfts, 'Data1', ...
             {'01-Jan-2001 12:00:03-Jan-2001 11:00'}, (102:105)')
```

Warning: FINTS will be removed in a future release. Use TIMETABLE instead.

> In fints/setfield (line 84)

Warning: FINTS will be removed in a future release. Use TIMETABLE instead.

> In fints/display (line 66)

S =

```
desc: My FINTS
freq: Daily (1)
```

```
'dates: (6)'      'times: (6)'      'Data1: (6)'
'01-Jan-2001'    '11:00'          [          1.00]
'    "    '      '12:00'          [         102.00]
'02-Jan-2001'    '11:00'          [         103.00]
'    "    '      '12:00'          [         104.00]
'03-Jan-2001'    '11:00'          [         105.00]
'    "    '      '12:00'          [           6.00]
```

## sharpe

Compute Sharpe ratio for one or more assets

### Syntax

```
sharpe(Asset)
sharpe(Asset,Cash)
Ratio = sharpe(Asset,Cash)
```

### Description

`sharpe(Asset)` computes Sharpe ratio for each asset.

`sharpe(Asset,Cash)` computes Sharpe ratio for each asset including the optional argument `Cash`.

`Ratio = sharpe(Asset,Cash)` computes Sharpe ratio for each asset including the optional argument `Cash`.

### Examples

#### Compute Sharpe Ratio

This example shows how to compute the Sharpe ratio using the mean return of a cash asset as the return for the riskless asset.

Given asset return data and the riskless asset return, the Sharpe ratio is calculated:

```
load FundMarketCash
Returns = tick2ret(TestData);
Riskless = mean>Returns(:,3))

Riskless = 0.0017

Sharpe = sharpe>Returns, Riskless)

Sharpe = 1×3
    0.0886    0.0315    0
```

The Sharpe ratio of the example fund is significantly higher than the Sharpe ratio of the market. As is demonstrated with `portalpha`, this translates into a strong risk-adjusted return. Since the `Cash` asset is the same as `Riskless`, it makes sense that its Sharpe ratio is `0`. The Sharpe ratio is calculated with the mean of cash returns. The Sharpe ratio can also be calculated with the cash return series as input for the riskless asset.

```
Sharpe = sharpe>Returns, Returns(:,3))

Sharpe = 1×3
```

0.0886    0.0315    0

When using the `Portfolio` object, you can use the `estimateMaxSharpeRatio` function to estimate an efficient portfolio that maximizes the Sharpe ratio. For more information, see “Efficient Portfolio That Maximizes Sharpe Ratio” on page 4-106.

## Input Arguments

### Asset — Asset returns

matrix

Asset returns, specified as a `NUMSAMPLES` × `NUMSERIES` matrix with `NUMSAMPLES` observations of asset returns for `NUMSERIES` asset return series.

Data Types: `double`

### Cash — Riskless asset

0 (default) | numeric | vector

(Optional) Riskless asset, specified as either a scalar return for a riskless asset or a vector of asset returns to be a proxy for a “riskless” asset. In either case, the periodicity must be the same as the periodicity of `Asset`. For example, if `Asset` is monthly data, then `Cash` must be monthly returns. If no value is supplied, the default value for `Cash` returns is 0.

Data Types: `double`

## Output Arguments

### Ratio — Sharpe ratios

vector

Sharpe ratios, returned as a 1-by-`NUMSERIES` row vector of Sharpe ratios for each series in `Asset`. Any series in `Asset` with standard deviation of returns equal to 0 has a NaN value for its Sharpe ratio.

---

**Note** If `Cash` is a vector, `Asset` and `Cash` need not have the same number of returns but must have the same periodicity of returns. The classic Sharpe ratio assumes that `Cash` is riskless. In reality, a short-term cash rate is not necessarily riskless. NaN values in the data are ignored.

**Introduced in R2006b**

# size

Number of dates and data series

---

**Note** `size` is not recommended. Use `timetable` instead. For more information, see “Convert Financial Time Series Objects `fints` to Timetables”.

---

## Syntax

```
szfts = size(tsoobj,dim)
```

```
[numRows,numCols] = size(tsoobj)
```

## Arguments

|                     |                                                                                                                                                                                              |
|---------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>tsoobj</code> | Financial time series object.                                                                                                                                                                |
| <code>dim</code>    | (Optional) A scalar that specifies the following dimension:<br><br><code>dim = 1</code> returns number of dates (rows).<br><br><code>dim = 2</code> returns number of data series (columns). |

## Description

`szfts = size(tsoobj)` returns the number of dates (rows) and the number of data series (columns) in the financial time series object `tsoobj`. The result is returned in the vector `szfts`, whose first element is the number of dates and second is the number of data series.

`szfts = size(tsoobj,dim)` specifies the dimension you want to extract.

`numRows` returns a scalar representing the number of dates (rows).

`numCols` returns a scalar representing the number of data series (columns).

|------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| input            | Financial time series object or a row-oriented matrix. In a row-oriented matrix, each row represents an individual set of observations.                                                                                                                                                                                                                                                                                                              |
| 'b', 'g', or 'e' | Smoothing method (essentially the type of filter used). Can be Exponential (e), Gaussian (g), or Box (b). Default = b.                                                                                                                                                                                                                                                                                                                               |
| wsize            | Window size (scalar). Default = 5.                                                                                                                                                                                                                                                                                                                                                                                                                   |
| stdev            | Scalar that represents the standard deviation of the Gaussian window. Default = 0.65.                                                                                                                                                                                                                                                                                                                                                                |
| n                | For Exponential method, specifies window size or exponential factor, depending upon value. <ul style="list-style-type: none"> <li>• <math>n &gt; 1</math> (window size) or period length</li> <li>• <math>n &lt; 1</math> and <math>&gt; 0</math> (exponential factor: alpha)</li> <li>• <math>n = 1</math> (either window size or alpha)</li> </ul> If n is not supplied, the defaults are <code>wsize = 5</code> and <code>alpha = 0.3333</code> . |

### Description

`smoothts` smooths the input data using the specified method.

`output = smoothts(input)` smooths the input data using the default Box method with window size, `wsize`, of 5.

`output = smoothts(input, 'b', wsize)` smooths the input data using the Box (simple, linear) method. `wsize` specifies the width of the box to be used.

`output = smoothts(input, 'g', wsize, stdev)` smooths the input data using the Gaussian window method.

`output = smoothts(input, 'e', n)` smooths the input data using the Exponential method. `n` can represent the window size (period length) or alpha. If  $n > 1$ , `n` represents the window size. If  $0 < n < 1$ , `n` represents alpha, where

$$\alpha = \frac{2}{wsize + 1}.$$

If `input` is a financial time series object, `output` is a financial time series object identical to `input` except for contents. If `input` is a row-oriented matrix, `output` is a row-oriented matrix of the same length.

## sortfts

Sort financial time series

---

**Note** `sortfts` is not recommended. Use `timetable` instead. For more information, see “Convert Financial Time Series Objects `fints` to Timetables”.

---

### Syntax

```
sfts = sortfts(tsoobj)
sfts = sortfts(tsoobj, flag)
sfts = sortfts(tsoobj, seriesnames, flag)
[sfts, sidx] = sortfts(...)
```

### Arguments

|                          |                                                                                                                                      |
|--------------------------|--------------------------------------------------------------------------------------------------------------------------------------|
| <code>tsoobj</code>      | Financial time series object.                                                                                                        |
| <code>flag</code>        | (Optional) Sort order:<br><br><code>flag = 1</code> ; increasing order (default)<br><br><code>flag = -1</code> ; decreasing order    |
| <code>seriesnames</code> | (Optional) Character vector containing a data series name or cell array of character vectors containing a list of data series names. |

### Description

`sfts = sortfts(tsoobj)` sorts the financial time series object `tsoobj` in increasing order based only upon the `'dates'` vector if `tsoobj` does not contain time-of-day information. If the object includes time-of-day information, the sort is based upon a combination of the `'dates'` and `'times'` vectors. The `'times'` vector cannot be sorted individually.

`sfts = sortfts(tsoobj, flag)` sets the order of the sort. `flag = 1`: increasing date and time order. `flag = -1`: decreasing date and time order.

`sfts = sortfts(tsoobj, seriesnames, flag)` sorts the financial time series object `tsoobj` based upon the data series name(s) `seriesnames`. The `seriesnames` argument can be a single character vector containing a data series name or a cell array of character vectors containing a list of data series names. If the optional `flag` is set to `-1`, the sort is in decreasing order.

`[sfts, sidx] = sortfts(...)` also returns the index of the original object `tsoobj` sorted based on `'dates'` or specified data series name(s).

## spctkd

Slow stochastics

---

**Note** `spctkd` is not recommended. Use `stochosc` instead.

---

### Syntax

```
[spctk,spctd] = spctkd(fastpctk,fastpctd)
[spctk,spctd] = spctkd([fastpctk fastpctd])
[spctk,spctd] = spctkd(fastpctk,fastpctd,dperiods,dmmethod)
[spctk,spctd] = spctkd([fastpctk fastpctd], dperiods, dmmethod)
skdts = spctkd(tsobj)
skdts = spctkd(tsobj,dperiods,dmmethod)
skdts = spctkd(tsobj,dperiods,dmmethod,'ParameterName',ParameterValue, ...)
```

### Arguments

|                       |                                                                   |
|-----------------------|-------------------------------------------------------------------|
| <code>fastpctk</code> | Fast stochastic F%K (vector).                                     |
| <code>fastpctd</code> | Fast stochastic F%D (vector).                                     |
| <code>dperiods</code> | (Optional) %D periods. Default = 3.                               |
| <code>dmmethod</code> | (Optional) %D moving average method. Default = 'e' (exponential). |
| <code>tsobj</code>    | Financial time series object.                                     |

### Description

`[spctk,spctd] = spctkd(fastpctk,fastpctd)` calculates the slow stochastics S%K and S%D. `spctk` and `spctd` are column vectors representing the respective slow stochastics. The inputs must be single column-oriented vectors containing the fast stochastics F%K and F%D.

`[spctk,spctd] = spctkd([fastpctk fastpctd])` accepts a two-column matrix as input. The first column contains the fast stochastic F%K values, and the second contains the fast stochastic F%D values.

`[spctk,spctd] = spctkd(fastpctk,fastpctd,dperiods,dmmethod)` calculates the slow stochastics, S%K and S%D, using the value of `dperiods` to set the number of periods and `dmmethod` to indicate the moving average method. The inputs `fastpctk` and `fastpctd` must contain the fast stochastics, F%K and F%D, in column orientation. `spctk` and `spctd` are column vectors representing the respective slow stochastics.

Valid moving average methods for %D are exponential ('e'), triangular ('t'), and modified ('m'). See `tsmovav` for explanations of these methods.

`[spctk,spctd] = spctkd([fastpctk fastpctd],dperiods,dmamethod)` accepts a two-column matrix rather than two separate vectors. The first column contains the F%K values, and the second contains the F%D values.

`skdts = spctkd(tsoobj)` calculates the slow stochastics, S%K and S%D. `tsoobj` must contain the fast stochastics, F%K and F%D, in data series named `PercentK` and `PercentD`. The `skdts` output is a financial time series object with the same dates as `tsoobj`. Within `tsoobj` the two series `SlowPctK` and `SlowPctD` represent the respective slow stochastics.

`skdts = spctkd(tsoobj,dperiods,dmamethod)` lets you specify the length and the method of the moving average used to calculate S%D values.

`skdts = spctkd(tsoobj,dperiods,dmamethod,'ParameterName',ParameterValue, ...)` accepts parameter name/parameter value pairs as input. These pairs specify the name(s) for the required data series if it is different from the expected default name(s). Valid parameter names are

- `KName`: F%K series name
- `DName`: F%D series name

Parameter values are the character vectors that represent the valid parameter names.

## Examples

### Calculate the Slow Stochastics

This example shows how to calculate the slow stochastics for Disney stock and plot the results.

```
load disney.mat
```

```
Warning: FINTS is not recommended. Use TIMETABLE instead. For more information, see <a href="mat
```

```
dis_FastStoch = fpctkd(dis);
```

```
Warning: FINTS is not recommended. Use TIMETABLE instead. For more information, see <a href="mat
```

```
dis_SlowStoch = spctkd(dis_FastStoch);
```

```
Warning: FINTS is not recommended. Use TIMETABLE instead. For more information, see <a href="mat
```

```
plot(dis_SlowStoch)
```

```
Warning: FINTS is not recommended. Use TIMETABLE instead. For more information, see <a href="mat
```

```
title('Slow Stochastics for Disney')
```

## std

Standard deviation

---

**Note** `std` is not recommended. Use `timetable` instead. For more information, see “Convert Financial Time Series Objects `fints` to Timetables”.

---

### Syntax

```
tsstd = std(tsobj)
```

```
tsstd = std(tsobj,flag)
```

### Arguments

|                    |                                                                                                                                                                            |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>tsobj</code> | Financial time series object.                                                                                                                                              |
| <code>flag</code>  | (Optional) Normalization factor:<br><code>flag = 1</code> normalizes by <code>n</code> (number of observations).<br><code>flag = 0</code> normalizes by <code>n-1</code> . |

### Description

`tsstd = std(tsobj)` computes the standard deviation of each data series in the financial time series object `tsobj` and returns the results in `tsstd`. The `tsstd` output is a structure with field `name(s)` identical to the data series `name(s)`.

`tsstd = std(tsobj,flag)` normalizes the data as indicated by `flag`.

# stochosc

Stochastic oscillator

---

**Note** Using a `fints` object for the `Data` argument of `stochosc` is not recommended. Use a matrix, `timetable`, or `table` instead for financial time series. For more information, see “Convert Financial Time Series Objects `fints` to `Timetables`”.

---

## Syntax

```
percentKnD = stochosc(Data)
percentKnD = stochosc( ___, Name, Value)
```

## Description

`percentKnD = stochosc(Data)` calculates the stochastic oscillator.

`percentKnD = stochosc( ___, Name, Value)` adds optional name-value pair arguments.

## Input Arguments

### Data — Data with high, low, open, close information

matrix | table | timetable

Data with high, low, open, close information, specified as a matrix, table, or timetable. For matrix input, `Data` is an M-by-3 matrix of high, low, and closing prices stored in the corresponding columns, respectively. Timetables and tables with M rows must contain variables named 'High', 'Low', and 'Close' (case insensitive).

Data Types: double | table | timetable

### Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `percentKnD = stochosc(TMW, 'NumPeriodsD', 10, 'NumPeriodsK', 3, 'Type', 'exponential')`

### NumPeriodsK — Period difference for PercentK

10 (default) | positive integer

Period difference for `PercentK`, specified as the comma-separated pair consisting of 'NumPeriodsK' and a scalar positive integer.

Data Types: double

### NumPeriodsD — Length of moving average in periods for PercentD

3 (default) | positive integer

Length of moving average in periods for PercentD, specified as the comma-separated pair consisting of 'NumPeriodsD' and a scalar positive integer.

Data Types: double

### Type — Moving average method for PercentD calculation

'e' (exponential) (default) | character vector with values 'exponential' or 'triangular'

Moving average method for PercentD calculation, specified as the comma-separated pair consisting of 'Type' and a character vector with a value of:

- 'exponential' - Exponential moving average is a weighted moving average. Exponential moving averages reduce the lag by applying more weight to recent prices. For example, a 10 period exponential moving average weights the most recent price by 18.18%.
- 'triangular' - Triangular moving average is a double-smoothing of the data. The first simple moving average is calculated and then a second simple moving average is calculated on the first moving average with the same window size.

Data Types: char

## Output Arguments

### percentKnD — PercentK and PercentD

matrix | table | timetable

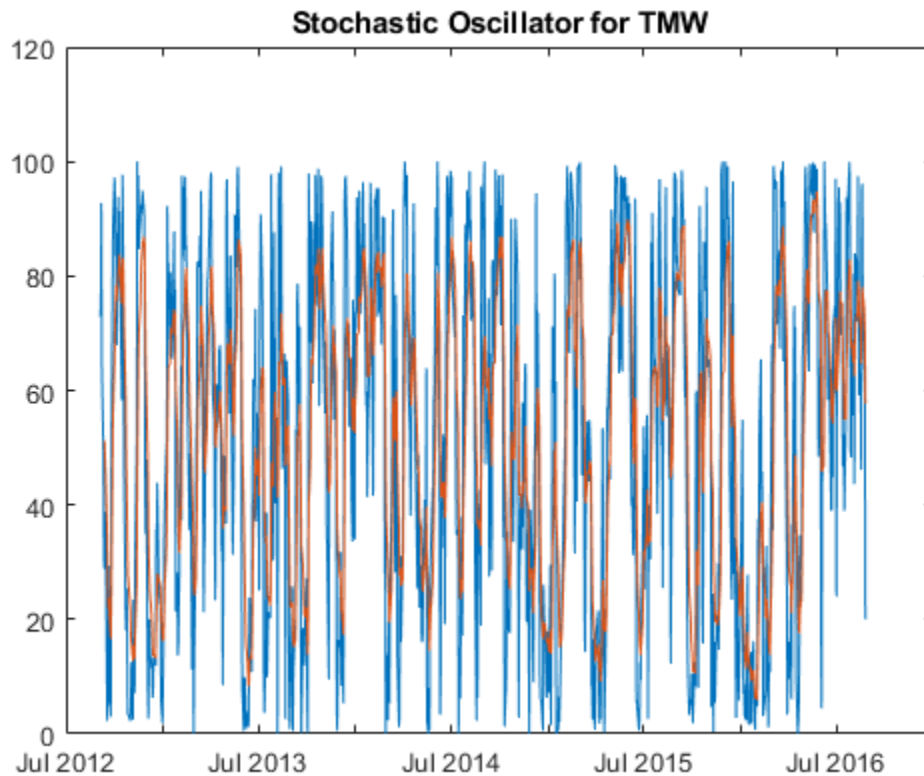

PercentK and PercentD, returned with the same number of rows (M) and type (matrix, table, or timetable) as the input Data.

## Examples

### Calculate the Stochastic Oscillator for a Stock

Load the file `SimulatedStock.mat`, which provides a timetable (TMW) for financial data for TMW stock.

```
load SimulatedStock.mat
oscillator = stochosc(TMW,'NumPeriodsD',7,'NumPeriodsK',10,'Type','exponential');
plot(oscillator.Time,oscillator.FastPercentK,oscillator.Time,oscillator.FastPercentD)
title('Stochastic Oscillator for TMW')
```

## More About

### Stochastic Oscillator

The stochastic oscillator calculates the Fast PercentK (F%K), Fast PercentD (F%D), Slow PercentK (S%K), and Slow PercentD (S%D) from the series of high, low, and closing stock prices.

By default, the stochastic oscillator is based on 10-period difference for PercentK and a 3-period exponential moving average for PercentD.

# subsasgn

Content assignment

---

**Note** `subsasgn` is not recommended. Use `timetable` instead. For more information, see “Convert Financial Time Series Objects `fints` to Timetables”.

---

## Syntax

```
subsasgn
```

## Description

`subsasgn` assigns content to a component within a financial time series object. `subsasgn` supports integer indexing or date character vector indexing into the time series object with values assigned to the designated components. *Serial date numbers cannot be used as indices.* To use date character vector indexing, enclose the date character vector(s) in a pair of single quotation marks ' '.

You can use integer indexing on the object as in any other MATLAB matrix. It will return the appropriate entry(ies) from the object.

You must specify the component to which you want to assign values. An assigned value must be either a scalar or a column vector.

## Examples

Given a time series `myfts` with a default data series name of `series1`,

```
myfts.series1('07/01/98::07/03/98') = [1 2 3]';
```

assigns the values 1, 2, and 3 corresponding to the first three days of July, 1998.

```
myfts('07/01/98::07/05/98')
```

```
Warning: FINTS will be removed in a future release. Use TIMETABLE instead.
> In fints/subsref (line 106)
```

```
ans =
```

```
desc: Data Assignment
freq: Daily (1)

'dates: (5)'   'series1: (5)'
'01-Jul-1998' [         1]
'02-Jul-1998' [         2]
'03-Jul-1998' [         3]
'04-Jul-1998' [    4561.2]
'05-Jul-1998' [    5612.3]
```

When the financial time series object contains a time-of-day specification, you can assign data to a specific time on a specific day. For example, create a financial time series object called `timeday` containing both dates and times:

```

dates = ['01-Jan-2001'; '01-Jan-2001'; '02-Jan-2001'; ...
'02-Jan-2001'; '03-Jan-2001'; '03-Jan-2001'];
times = ['11:00'; '12:00'; '11:00'; '12:00'; '11:00'; '12:00'];
dates_times = cellstr([dates, repmat(' ', size(dates,1),1), ...
times]);
timeday = fints(dates_times, (1:6)', {'Data1'}, 1, 'My first FINTS')

```

```

Warning: FINTS will be removed in a future release. Use TIMETABLE instead.
> In fints (line 165)
Warning: FINTS will be removed in a future release. Use TIMETABLE instead.
> In fints/display (line 66)

```

```
timeday =
```

```

desc: My first FINTS
freq: Daily (1)

```

| 'dates: (6)'  | 'times: (6)' | 'Data1: (6)' |
|---------------|--------------|--------------|
| '01-Jan-2001' | '11:00'      | [ 1]         |
| ' "           | '12:00'      | [ 2]         |
| '02-Jan-2001' | '11:00'      | [ 3]         |
| ' "           | '12:00'      | [ 4]         |
| '03-Jan-2001' | '11:00'      | [ 5]         |
| ' "           | '12:00'      | [ 6]         |

Use integer indexing to assign the value 999 to the first item in the object.

```
timeday(1) = 999
```

```

Warning: FINTS will be removed in a future release. Use TIMETABLE instead.
> In fints/subsasgn (line 118)
Warning: FINTS will be removed in a future release. Use TIMETABLE instead.
> In fints/display (line 66)

```

```
timeday =
```

```

desc: My first FINTS
freq: Daily (1)

```

| 'dates: (6)'  | 'times: (6)' | 'Data1: (6)' |
|---------------|--------------|--------------|
| '01-Jan-2001' | '11:00'      | [ 999]       |
| ' "           | '12:00'      | [ 2]         |
| '02-Jan-2001' | '11:00'      | [ 3]         |
| ' "           | '12:00'      | [ 4]         |
| '03-Jan-2001' | '11:00'      | [ 5]         |
| ' "           | '12:00'      | [ 6]         |

For value assignment using date character vectors, enclose the character vector in single quotation marks. If a date has multiple times, designating only the date and assigning a value results in every element of that date taking on the assigned value. For example, to assign the value 0.5 to all times-of-day on January 1, 2001, enter

```
timedata('01-Jan-2001') = 0.5
```

The result is

```

Warning: FINTS will be removed in a future release. Use TIMETABLE instead.
> In fints/size (line 28)
In help (line 53)

```

```

timedata =

  '    "    '    '12:00'         [ 4]
  '03-Jan-2001' '11:00'         [ 5]
  '    "    '    '12:00'         [ 6]

```

To access the individual components of the financial time series object, use the structure syntax. For example, to assign a range of data to all the data items in the series `Data1`, you can use

```
timedata.Data1 = (0: .1 : .5)'
```

```

Warning: FINTS will be removed in a future release. Use TIMETABLE instead.
> In fints/size (line 28)
   In help (line 53)

```

```

timedata =

  desc: My first FINTS
  freq: Daily (1)

  'dates: (6)'   'times: (6)'   'Data1: (6)'
  '01-Jan-2001' '11:00'         [ 0]
  '    "    '    '12:00'         [ 0.1000]
  '02-Jan-2001' '11:00'         [ 0.2000]
  '    "    '    '12:00'         [ 0.3000]
  '03-Jan-2001' '11:00'         [ 0.4000]
  '    "    '    '12:00'         [ 0.5000]

```

“Financial Time Series Operations” on page 13-6

**Introduced before R2006a**

## subref

Subscripted reference

---

**Note** `subref` is not recommended. Use `timetable` instead. For more information, see “Convert Financial Time Series Objects `fints` to Timetables”.

---

### Syntax

`subref`

### Description

`subref` implements indexing for a financial time series object. Integer indexing or date (and time) character vector indexing is allowed. *Serial date numbers cannot be used as indices.*

To use date character vector indexing, enclose the date character vector(s) in a pair of single quotation marks ' '.

You can use integer indexing on the object as in any other MATLAB matrix. It returns the appropriate entry(ies) from the object.

Additionally, `subref` lets you access the individual components of the object using the structure syntax.

### Examples

Create a time series named `myfts`:

```
myfts = fints((datenum('07/01/98'):datenum('07/01/98')+4)',...
[1234.56; 2345.61; 3456.12; 4561.23; 5612.34], [], 'Daily',...
'Data Reference')
```

Warning: FINTS will be removed in a future release. Use TIMETABLE instead.

> In `fints` (line 165)

Warning: FINTS will be removed in a future release. Use TIMETABLE instead.

> In `fints/display` (line 66)

```
myfts =
```

```
desc: Data Reference
freq: Daily (1)
```

```
'dates: (5)'      'series1: (5)'
'01-Jul-1998'    [ 1.2346e+03]
'02-Jul-1998'    [ 2.3456e+03]
'03-Jul-1998'    [ 3.4561e+03]
'04-Jul-1998'    [ 4.5612e+03]
'05-Jul-1998'    [ 5.6123e+03]
```

Extract the data for the single day July 1, 1998:

```
myfts('07/01/98')
```

```
Warning: FINTS will be removed in a future release. Use TIMETABLE instead.
> In fints/subsref (line 106)
Warning: FINTS will be removed in a future release. Use TIMETABLE instead.
> In fints/display (line 66)
```

```
ans =
```

```
desc: Data Reference
freq: Daily (1)

'dates: (1)'    'series1: (1)'
'01-Jul-1998'  [ 1.2346e+03]
```

Now, extract the data for the range of dates July 1, 1998, through July 5, 1998:

```
myfts('07/01/98::07/03/98')
```

```
Warning: FINTS will be removed in a future release. Use TIMETABLE instead.
> In fints/subsref (line 106)
Warning: FINTS will be removed in a future release. Use TIMETABLE instead.
> In fints/display (line 66)
```

```
ans =
```

```
desc: Data Reference
freq: Daily (1)

'dates: (3)'    'series1: (3)'
'01-Jul-1998'  [ 1.2346e+03]
'02-Jul-1998'  [ 2.3456e+03]
'03-Jul-1998'  [ 3.4561e+03]
```

You can use the MATLAB structure syntax to access the individual components of a financial time series object. To get the description field of `myfts`, enter

```
myfts.desc
```

at the command line, which returns

```
Warning: FINTS will be removed in a future release. Use TIMETABLE instead.
> In fints/subsref (line 106)
```

```
ans =
```

```
'Data Reference'
```

Similarly

```
myfts.series1
```

returns

```
Warning: FINTS will be removed in a future release. Use TIMETABLE instead.
> In fints/subsref (line 106)
Warning: FINTS will be removed in a future release. Use TIMETABLE instead.
> In fints/display (line 66)
```

```
ans =
```

```

desc: Data Reference
freq: Daily (1)

'dates: (5)'      'series1: (5)'
'01-Jul-1998'    [ 1.2346e+03]
'02-Jul-1998'    [ 2.3456e+03]
'03-Jul-1998'    [ 3.4561e+03]
'04-Jul-1998'    [ 4.5612e+03]
'05-Jul-1998'    [ 5.6123e+03]

```

The syntax for integer indexing is the same as for any other MATLAB matrix. Create a new financial time series object containing both dates and times:

```

dates = ['01-Jan-2001'; '01-Jan-2001'; '02-Jan-2001'; ...
         '02-Jan-2001'; '03-Jan-2001'; '03-Jan-2001'];
times = ['11:00'; '12:00'; '11:00'; '12:00'; '11:00'; '12:00'];
dates_times = cellstr([dates, repmat(' ', size(dates,1),1), ...
                      times]);
anewfts = fints(dates_times, (1:6), {'Data1'}, 1, 'Another FinTs')

```

```

Warning: FINTS will be removed in a future release. Use TIMETABLE instead.
> In fints (line 165)
Warning: FINTS will be removed in a future release. Use TIMETABLE instead.
> In fints/display (line 66)

```

```
anewfts =
```

```

desc: Another FinTs
freq: Daily (1)

'dates: (6)'      'times: (6)'      'Data1: (6)'
'01-Jan-2001'    '11:00'          [ 1]
'    "    '    '12:00'          [ 2]
'02-Jan-2001'    '11:00'          [ 3]
'    "    '    '12:00'          [ 4]
'03-Jan-2001'    '11:00'          [ 5]
'    "    '    '12:00'          [ 6]

```

Use integer indexing to extract the second and third data items from the object.

```
anewfts(2:3)
```

```

Warning: FINTS will be removed in a future release. Use TIMETABLE instead.
> In fints/subsref (line 106)
Warning: FINTS will be removed in a future release. Use TIMETABLE instead.
> In fints/display (line 66)

```

```
ans =
```

```

desc: Another FinTs
freq: Daily (1)

'dates: (2)'      'times: (2)'      'Data1: (2)'
'01-Jan-2001'    '12:00'          [ 2]
'02-Jan-2001'    '11:00'          [ 3]

```

For date character vector, enclose the indexing character vector in a pair of single quotation marks.

If there is one date with multiple times, indexing with only the date returns all the times for that specific date:

```
anewfts('01-Jan-2001')
```

```
Warning: FINTS will be removed in a future release. Use TIMETABLE instead.
> In fints/subsref (line 106)
Warning: FINTS will be removed in a future release. Use TIMETABLE instead.
> In fints/display (line 66)
```

```
ans =
```

```
desc: Another FinTs
freq: Daily (1)
```

```
'dates: (2)'    'times: (2)'    'Data1: (2)'
'01-Jan-2001'  '11:00'        [          1]
'    "    '    '12:00'        [          2]
```

To specify one specific date and time, index with that date and time:

```
anewfts('01-Jan-2001 12:00')
```

```
Warning: FINTS will be removed in a future release. Use TIMETABLE instead.
> In fints/subsref (line 106)
Warning: FINTS will be removed in a future release. Use TIMETABLE instead.
> In fints/display (line 66)
```

```
ans =
```

```
desc: Another FinTs
freq: Daily (1)
```

```
'dates: (1)'    'times: (1)'    'Data1: (1)'
'01-Jan-2001'  '12:00'        [          2]
```

To specify a range of dates and times, use the double colon (: :) operator:

```
anewfts('01-Jan-2001 12:00::03-Jan-2001 11:00')
```

```
Warning: FINTS will be removed in a future release. Use TIMETABLE instead.
> In fints/subsref (line 106)
Warning: FINTS will be removed in a future release. Use TIMETABLE instead.
> In fints/display (line 66)
```

```
ans =
```

```
desc: Another FinTs
freq: Daily (1)
```

```
'dates: (4)'    'times: (4)'    'Data1: (4)'
'01-Jan-2001'  '12:00'        [          2]
'02-Jan-2001'  '11:00'        [          3]
'    "    '    '12:00'        [          4]
'03-Jan-2001'  '11:00'        [          5]
```

To request all the dates, times, and data, use the :: operator without specifying any specific date or time:

```
anewfts('::')
```

```
Warning: FINTS will be removed in a future release. Use TIMETABLE instead.
> In fints/subsref (line 106)
```

Warning: FINTS will be removed in a future release. Use TIMETABLE instead.  
> In fints/display (line 66)

ans =

```
desc: Another FinTs  
freq: Daily (1)
```

```
'dates: (6)'    'times: (6)'    'Data1: (6)'  
'01-Jan-2001'  '11:00'         [          1]  
'    "    '    '12:00'         [          2]  
'02-Jan-2001'  '11:00'         [          3]  
'    "    '    '12:00'         [          4]  
'03-Jan-2001'  '11:00'         [          5]  
'    "    '    '12:00'         [          6]
```

# targetreturn

Portfolio weight accuracy

## Syntax

```
return = targetreturn(Universe,Window,Offset,Weights)
```

## Arguments

|          |                                                                                                                                                                                                                                                                                                   |
|----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Universe | Number of observations (NUMOBS) by number of assets plus one (NASSETS + 1) array containing total return data for a group of securities. Each row represents an observation. Column 1 contains MATLAB serial date numbers. The remaining columns contain the total return data for each security. |
| Window   | Number of data periods used to calculate frontier.                                                                                                                                                                                                                                                |
| Offset   | Increment in number of periods at which each frontier is generated.                                                                                                                                                                                                                               |
| Weights  | Number of assets (NASSETS) by number of curves (NCURVES) matrix of asset allocation weights needed to obtain the target rate of return.                                                                                                                                                           |

## Description

`return = targetreturn(Universe,Window,Offset,Weights)` computes target return values for each window of data and given portfolio weights. These values should match the input target return used with `selectreturn`.

## taxedrr

After-tax rate of return

### Syntax

```
Return = taxedrr(PreTaxReturn, TaxRate)
```

### Description

Return = taxedrr(PreTaxReturn, TaxRate) calculates the after-tax rate of return.

### Examples

#### Calculate the After-Tax Rate of Return

This example shows how to calculate the after-tax rate of return, given an investment that has a 12% nominal rate of return and is taxed at a 30% rate.

```
Return = taxedrr(0.12, 0.30)
```

```
Return = 0.0840
```

### Input Arguments

#### PreTaxReturn — Normal rate of return

decimal

Normal rate of return, specified as a decimal.

Data Types: double

#### TaxRate — Tax rate

decimal

Tax rate, specified as a decimal.

Data Types: double

### Output Arguments

#### Return — After-tax rate of return

decimal

After-tax rate of return, returned as a decimal.

## tbilldisc2yield

Convert Treasury bill discount to equivalent yield

### Syntax

```
[BEyield,MMYield] = tbilldisc2yield(Discount,Settle,Maturity)
```

### Description

[BEyield,MMYield] = tbilldisc2yield(Discount,Settle,Maturity) converts the discount rate on Treasury bills into their respective money-market or bond-equivalent yields.

### Examples

#### Convert the Discount Rate on Treasury Bills

This example shows how to convert the discount rate on Treasury bills into their respective money-market or bond-equivalent yields, given a Treasury bill with the following characteristics.

```
Discount = 0.0497;  
Settle = '01-Oct-02';  
Maturity = '31-Mar-03';
```

```
[BEyield MMYield] = tbilldisc2yield(Discount, Settle, Maturity)
```

```
BEyield = 0.0517
```

```
MMYield = 0.0510
```

#### Convert the Discount Rate on Treasury Bills Using datetime Inputs

This example shows how to use `datetime` inputs to convert the discount rate on Treasury bills into their respective money-market or bond-equivalent yields, given a Treasury bill with the following characteristics.

```
Discount = 0.0497;  
Settle = datetime('01-Oct-02','Locale','en_US');  
Maturity = datetime('31-Mar-03','Locale','en_US');  
[BEyield MMYield] = tbilldisc2yield(Discount, Settle, Maturity)
```

```
BEyield = 0.0517
```

```
MMYield = 0.0510
```

## Input Arguments

### Discount — Discount rate of Treasury bills

decimal

Discount rate of the Treasury bills, specified as a scalar or a NTBILLS-by-1 vector of decimal values. The discount rate basis is actual/360.

Data Types: double

### Settle — Settlement date of Treasury bill

serial date number | date character vector | datetime

Settlement date of the Treasury bill, specified as a scalar or a NTBILLS-by-1 vector of serial date numbers, date character vectors, or datetime arrays. **Settle** must be earlier than **Maturity**.

Data Types: double | char | datetime

### Maturity — Maturity date of Treasury bill

serial date number | date character vector | datetime

Maturity date of the Treasury bill, specified as a scalar or a NTBILLS-by-1 vector of serial date numbers, date character vectors, or datetime arrays.

Data Types: double | char | datetime

## Output Arguments

### BEYield — Bond equivalent yields of Treasury bills

numeric

Bond equivalent yields of the Treasury bills, returned as a NTBILLS-by-1 vector. The bond-equivalent yield basis is actual/365.

### MMYield — Money-market yields of Treasury bills

numeric

Money-market yields of the Treasury bills, returned as a NTBILLS-by-1 vector. The money-market yield basis is actual/360.

# tbillprice

Price Treasury bill

## Syntax

```
Price = tbillprice(Rate,Settle,Maturity)
Price = tbillprice( ____,Type)
```

## Description

Price = tbillprice(Rate,Settle,Maturity) computes the price of a Treasury bill given a yield or discount rate.

Price = tbillprice( \_\_\_\_,Type) adds an optional argument for Type.

## Examples

### Compute the Price of a Treasury Bill Using the Bond-Equivalent Yield

Given a Treasury bill with the following characteristics, compute the price of the Treasury bill using the bond-equivalent yield (Type = 2) as input.

```
Rate = 0.045;
Settle = '01-Oct-02';
Maturity = '31-Mar-03';
```

```
Type = 2;
```

```
Price = tbillprice(Rate, Settle, Maturity, Type)
```

```
Price = 97.8172
```

### Price a Portfolio of Treasury Bills

Use tbillprice to price a portfolio of Treasury bills.

```
Rate = [0.045; 0.046];
Settle = {'02-Jan-02'; '01-Mar-02'};
Maturity = {'30-June-02'; '30-June-02'};
Type = [2 3];
```

```
Price = tbillprice(Rate, Settle, Maturity, Type)
```

```
Price = 2×1
```

```
97.8408
98.4539
```

### Price a Portfolio of Treasury Bills Using datetime Input

Use `tbillprice` to price a portfolio of Treasury bills using `datetime` input.

```
Rate = [0.045; 0.046];  
Type = [2 3];
```

```
Settle = datetime({'2002-01-02'; '2002-03-01'}, 'InputFormat', 'yyyy-MM-dd', 'Locale', 'en_US');  
Maturity = datetime({'2002-06-30'; '2002-06-30'}, 'InputFormat', 'yyyy-MM-dd', 'Locale', 'en_US');  
Price = tbillprice(Rate, Settle, Maturity, Type)
```

```
Price = 2×1  
  
    97.8408  
    98.4539
```

## Input Arguments

### Rate — Bond-equivalent yield, money-market yield, or discount rate

decimal

Bond-equivalent yield, money-market yield, or discount rate (defined by the input `Type`), specified as a scalar or a `NTBILLS`-by-1 vector of decimal values.

Data Types: `double`

### Settle — Settlement date of Treasury bill

serial date number | date character vector | `datetime`

Settlement date of the Treasury bill, specified as a scalar or a `NTBILLS`-by-1 vector of serial date numbers, date character vectors, or `datetime` arrays.

Data Types: `double` | `char` | `datetime`

### Maturity — Maturity date of Treasury bill

serial date number | date character vector | `datetime`

Maturity date of the Treasury bill, specified as a scalar or a `NTBILLS`-by-1 vector of serial date numbers, date character vectors, or `datetime` arrays.

Data Types: `double` | `char` | `datetime`

### Type — (Optional) Rate type

2 (default) | numeric with values 1 = money market, 2 = bond-equivalent, 3 = discount rate

Rate type (determines how to interpret values entered in `Rate`), specified as a numeric value of 1, 2, or 3 using a scalar or a `NTBILLS`-by-1 vector.

---

**Note** The bond-equivalent yield basis is `actual/365`. The money-market yield basis is `actual/360`. The discount rate basis is `actual/360`.

---

Data Types: double

## Output Arguments

### Price — Treasury bill price for every \$100 face

numeric

Treasury bill prices for every \$100 face, returned as a NTBILLS-by-1 vector.

## tbillrepo

Break-even discount of repurchase agreement

### Syntax

```
TBEDiscount = tbillrepo(RepoRate,InitialDiscount,PurchaseDate,SaleDate,
Maturity)
```

### Description

TBEDiscount = tbillrepo(RepoRate,InitialDiscount,PurchaseDate,SaleDate, Maturity) computes the true break-even discount of a repurchase agreement.

### Examples

#### Compute the True Break-Even Discount

This example shows how to compute the true break-even discount of a Treasury bill repurchase agreement.

```
RepoRate = [0.045; 0.0475];
InitialDiscount = 0.0475;
PurchaseDate = '3-Jan-2002';
SaleDate = '3-Feb-2002';
Maturity = '3-Apr-2002';
```

```
TBEDiscount = tbillrepo(RepoRate, InitialDiscount,...
PurchaseDate, SaleDate, Maturity)
```

```
TBEDiscount = 2×1
```

```
0.0491
0.0478
```

#### Compute the True Break-Even Discount Using datetime Inputs

This example shows how to use datetime inputs to compute the true break-even discount of a Treasury bill repurchase agreement.

```
RepoRate = [0.045; 0.0475];
InitialDiscount = 0.0475;
PurchaseDate = datetime('3-Jan-2002','Locale','en_US');
SaleDate = datetime('3-Feb-2002','Locale','en_US');
Maturity = datetime('3-Apr-2002','Locale','en_US');
TBEDiscount = tbillrepo(RepoRate, InitialDiscount,...
PurchaseDate, SaleDate, Maturity)
```

```
TBEDiscount = 2×1
```

```
0.0491
```

```
0.0478
```

## Input Arguments

### **RepoRate — Annualized, 360-day based repurchase rate**

decimal

Annualized, 360-day based repurchase rate, specified as a scalar of a NTBILLS-by-1 vector of decimal values.

Data Types: double

### **InitialDiscount — Discount on Treasury bill on day of purchase**

decimal

Discount on the Treasury bill on the day of purchase, specified as a scalar of a NTBILLS-by-1 vector of decimal values.

Data Types: double

### **PurchaseDate — Date Treasury bill is purchased**

serial date number | date character vector | datetime

Date the Treasury bill is purchased, specified as a scalar or a NTBILLS-by-1 vector of serial date numbers, date character vectors, or datetime arrays.

Data Types: double | char | datetime

### **SaleDate — Date Treasury bill repurchase term is due**

serial date number | date character vector | datetime

Date the Treasury bill repurchase term is due, specified as a scalar or a NTBILLS-by-1 vector of serial date numbers, date character vectors, or datetime arrays.

Data Types: double | char | datetime

### **Maturity — Maturity date of Treasury bill**

serial date number | date character vector | datetime

Maturity date of the Treasury bill, specified as a scalar or a NTBILLS-by-1 vector of serial date numbers, date character vectors, or datetime arrays.

Data Types: double | char | datetime

## Output Arguments

### **TBEDiscount — True break-even discount of repurchase agreement**

numeric

True break-even discount of a repurchase agreement, returned as a scalar or NTBILLS-by-1 vector.

# tbillval01

Value of one basis point

## Syntax

```
[Val01Disc,Val01MMY,Val01BEY] = tbillval01(Settle,Maturity)
```

## Description

[Val01Disc,Val01MMY,Val01BEY] = tbillval01(Settle,Maturity) calculates the value of one basis point of \$100 Treasury bill face value on the discount rate, money-market yield, or bond-equivalent yield.

## Examples

### Compute the Value of One Basis Point

This example shows how to compute the value of one basis point, given a Treasury bill with the following settle and maturity dates.

```
Settle = '01-Mar-03';  
Maturity = '30-June-03';  
[Val01Disc, Val01MMY, Val01BEY] = tbillval01(Settle, Maturity)
```

```
Val01Disc = 0.0034
```

```
Val01MMY = 0.0034
```

```
Val01BEY = 0.0033
```

### Compute the Value of One Basis Point Using datetime Inputs

This example shows how to use `datetime` inputs to compute the value of one basis point, given a Treasury bill with the following settle and maturity dates.

```
Settle = datetime(2003,3,1);  
Maturity = datetime(2003,6,30);  
[Val01Disc, Val01MMY, Val01BEY] = tbillval01(Settle, Maturity)
```

```
Val01Disc = 0.0034
```

```
Val01MMY = 0.0034
```

```
Val01BEY = 0.0033
```

## Input Arguments

### Settle — Settlement date of Treasury bill

serial date number | date character vector | datetime

Settlement date of the Treasury bill, specified as a scalar or a NTBILLS-by-1 vector of serial date numbers, date character vectors, or datetime arrays. **Settle** must be earlier than **Maturity**.

Data Types: double | char | datetime

### Maturity — Maturity date of Treasury bill

serial date number | date character vector | datetime

Maturity date of the Treasury bill, specified as a scalar or a NTBILLS-by-1 vector of serial date numbers, date character vectors, or datetime arrays.

Data Types: double | char | datetime

## Output Arguments

### Val01Disc — Value of one basis point of discount rate for every \$100 face

numeric

Value of one basis point of discount rate for every \$100 face, returned as a NTBILLS-by-1 vector.

### Val01MMY — Value of one basis point of money-market yield for every \$100 face

numeric

Value of one basis point of money-market yield for every \$100 face, returned as a NTBILLS-by-1 vector.

### Val01BEY — Value of one basis point of bond-equivalent yield for every \$100 face

numeric

Value of one basis point of bond-equivalent yield for every \$100 face, returned as a NTBILLS-by-1 vector.

## tbillyield

Yield on Treasury bill

### Syntax

```
[MMYield,BEYield,Discount] = tbillyield(Price,Settle,Maturity)
```

### Description

[MMYield,BEYield,Discount] = tbillyield(Price,Settle,Maturity) computes the yield of US Treasury bills given Price, Settle, and Maturity.

### Examples

#### Compute the Yield of U.S. Treasury Bills

This example shows how to compute the yield of U.S. Treasury bills, given a Treasury bill with the following characteristics.

```
Price = 98.75;  
Settle = '01-Oct-02';  
Maturity = '31-Mar-03';
```

```
[MMYield, BEYield, Discount] = tbillyield(Price, Settle,...  
Maturity)
```

```
MMYield = 0.0252
```

```
BEYield = 0.0255
```

```
Discount = 0.0249
```

#### Compute the Yield of U.S. Treasury Bills Using datetime Inputs

This example shows how to use datetime inputs to compute the yield of U.S. Treasury bills, given a Treasury bill with the following characteristics.

```
Price = 98.75;  
Settle = datetime('01-Oct-2002','Locale','en_US');  
Maturity = datetime('31-Mar-2003','Locale','en_US');  
[MMYield, BEYield, Discount] = tbillyield(Price, Settle,Maturity)
```

```
MMYield = 0.0252
```

```
BEYield = 0.0255
```

```
Discount = 0.0249
```

## Input Arguments

### Price — Price of Treasury bills for every \$100 face value

numeric

Price of Treasury bills for every \$100 face value, specified as a scalar or a NTBILLS-by-1 vector of decimal values.

Data Types: double

### Settle — Settlement date of Treasury bill

serial date number | date character vector | datetime

Settlement date of the Treasury bill, specified as a scalar or a NTBILLS-by-1 vector of serial date numbers, date character vectors, or datetime arrays. **Settle** must be earlier than **Maturity**.

Data Types: double | char | datetime

### Maturity — Maturity date of Treasury bill

serial date number | date character vector | datetime

Maturity date of the Treasury bill, specified as a scalar or a NTBILLS-by-1 vector of serial date numbers, date character vectors, or datetime arrays.

Data Types: double | char | datetime

## Output Arguments

### MMYield — Money-market yields of Treasury bills

numeric

Money-market yields of the Treasury bills, returned as a NTBILLS-by-1 vector.

### BEYield — Bond equivalent yields of Treasury bills

numeric

Bond equivalent yields of the Treasury bills, returned as a NTBILLS-by-1 vector.

### Discount — Discount rates of Treasury bills

numeric

Discount rates of the Treasury bills, returned as a NTBILLS-by-1 vector.

# tbillyield2disc

Convert Treasury bill yield to equivalent discount

## Syntax

```
Discount = tbillyield2disc(Yield,Settle,Maturity)
Discount = tbillyield2disc( ____,Type)
```

## Description

`Discount = tbillyield2disc(Yield,Settle,Maturity)` converts the yield on some Treasury bills into their respective discount rates.

`Discount = tbillyield2disc( ____,Type)` adds an optional argument for Type.

## Examples

### Compute the Discount Rate on a Money-Market Basis

Given a Treasury bill with these characteristics, compute the discount rate.

```
Yield = 0.0497;
Settle = '01-Oct-02';
Maturity = '31-Mar-03';

Discount = tbillyield2disc(Yield,Settle,Maturity)

Discount = 0.0485
```

### Compute the Discount Rate on a Money-Market Basis Using datetime Inputs

Given a Treasury bill with these characteristics, compute the discount rate using datetime inputs.

```
Yield = 0.0497;
Settle = datetime('01-Oct-2002','Locale','en_US');
Maturity = datetime('31-Mar-2003','Locale','en_US');

Discount = tbillyield2disc(Yield,Settle,Maturity)

Discount = 0.0485
```

## Input Arguments

### Yield — Yield of Treasury bills

decimal

Yield of Treasury bills, specified as a scalar of a `NTBILLS`-by-1 vector of decimal values.

Data Types: double

### **Settle — Settlement date of Treasury bill**

serial date number | date character vector | datetime

Settlement date of the Treasury bill, specified as a scalar or a NTBILLS-by-1 vector of serial date numbers, date character vectors, or datetime arrays.

Data Types: double | char | datetime

### **Maturity — Maturity date of Treasury bill**

serial date number | date character vector | datetime

Maturity date of the Treasury bill, specified as a scalar or a NTBILLS-by-1 vector of serial date numbers, date character vectors, or datetime arrays.

Data Types: double | char | datetime

### **Type — Yield type**

1 (default) | numeric with values 1 = money market, 2 = bond-equivalent

(Optional) Yield type (determines how to interpret values entered in `Yield`), specified as a numeric value of 1 or 2 using a scalar or a NTBILLS-by-1 vector.

---

**Note** The bond-equivalent yield basis is actual/365. The money-market yield basis is actual/360.

---

Data Types: double

## **Output Arguments**

### **Discount — Discount rates of Treasury bills**

numeric

Discount rates of the Treasury bills, returned as a NTBILLS-by-1 vector.

## **References**

## tbl2bond

Treasury bond parameters given Treasury bill parameters

### Syntax

```
[TBondMatrix,Settle] = tbl2bond(TBillMatrix)
```

### Description

[TBondMatrix,Settle] = `tbl2bond`(TBillMatrix) restates US Treasury bill market parameters in US Treasury bond form as zero-coupon bonds. This function makes Treasury bills directly comparable to Treasury bonds and notes.

### Examples

#### Restate U.S. Treasury Bill in U.S. Treasury Bond Form

This example shows how to restate U.S. Treasury bill market parameters in U.S. Treasury bond form, given published Treasury bill market parameters for December 22, 1997.

```
TBill = [datenum('jan 02 1998') 10 0.0526 0.0522 0.0530
         datenum('feb 05 1998') 44 0.0537 0.0533 0.0544
         datenum('mar 05 1998') 72 0.0529 0.0527 0.0540];
```

```
TBond = tbl2bond(TBill)
```

```
TBond = 3×5
105 ×
```

```
    0    7.2976    0.0010    0.0010    0.0000
    0    7.2979    0.0010    0.0010    0.0000
    0    7.2982    0.0010    0.0010    0.0000
```

#### Restate U.S. Treasury Bill in U.S. Treasury Bond Form Using datetime Input

This example shows how to use `datetime` input to restate U.S. Treasury bill market parameters in U.S. Treasury bond form, given published Treasury bill market parameters for December 22, 1997.

```
TBill = [datenum('jan 02 1998') 10 0.0526 0.0522 0.0530
         datenum('feb 05 1998') 44 0.0537 0.0533 0.0544
         datenum('mar 05 1998') 72 0.0529 0.0527 0.0540];
```

```
dates = datetime(TBill(:,1), 'ConvertFrom', 'datenum', 'Locale', 'en_US');
data = TBill(:,2:end);
t=[table(dates) array2table(data)];
[TBond, Settle] = tbl2bond(t)
```

TBond=3x5 table

| CouponRate | Maturity    | Bid    | Asked  | AskYield |
|------------|-------------|--------|--------|----------|
| 0          | 02-Jan-1998 | 99.854 | 99.855 | 0.053    |
| 0          | 05-Feb-1998 | 99.344 | 99.349 | 0.0544   |
| 0          | 05-Mar-1998 | 98.942 | 98.946 | 0.054    |

Settle = 3x1 datetime  
 22-Dec-1997  
 22-Dec-1997  
 22-Dec-1997

## Input Arguments

### TBillMatrix — Treasury bill parameters

table | matrix

Treasury bill parameters, specified as a 5-column table or a N-by-5 matrix of bond information where the table columns or matrix columns contains:

- **Maturity** (Required) Maturity date of Treasury bills, specified as a serial date number when using a matrix. Use `datenum` to convert date character vectors to serial date numbers. If the input `TBillMatrix` is a table, the `Maturity` dates can be serial date numbers, date character vectors, or datetime arrays.
- **DaysMaturity** (Required) Days to maturity, specified as an integer. Days to maturity are quoted on a skip-day basis; the actual number of days from settlement to maturity is `DaysMaturity + 1`.
- **Bid** (Required) Bid bank-discount rate (the percentage discount from face value at which the bill could be bought, annualized on a simple-interest basis), specified as a decimal fraction.
- **Asked** (Required) Asked bank-discount rate, specified as a decimal fraction.
- **AskYield** (Required) Asked yield (the bond-equivalent yield from holding the bill to maturity, annualized on a simple-interest basis and assuming a 365-day year), specified as a decimal fraction.

Data Types: double | table

## Output Arguments

### TBondMatrix — Treasury bond parameters

table | matrix

Treasury bond parameters, returned as a table or matrix depending on the `TBillMatrix` input.

When `TBillMatrix` is a table, `TBondMatrix` is also a table, and the variable type for the `Maturity` dates in `TBondMatrix` (column 1) matches the variable type for `Maturity` in `TBillMatrix`. For example, if `Maturity` dates are datetime arrays in `TBillMatrix`, they will also be datetime arrays in `TBondMatrix`.

When `TBillMatrix` input is a N-by-5 matrix, then each row describes a Treasury bond.

The parameters or columns returned for `TBondMatrix` are:

- `CouponRate` (Column 1) Coupon rate, which is always 0 since the Treasury bills are, by definition, a zero coupon instrument.
- `Maturity` (Column 2) Maturity date for each bond in the portfolio as a serial date number. The format of the dates matches the format used for `Maturity` in `TBillMatrix` (serial date number, date character vector, or datetime array).
- `Bid` (Column 3) Bid price based on \$100 face value.
- `Asked` (Column 4) Asked price based on \$100 face value.
- `AskYield` (Column 5) Asked yield to maturity: the effective return from holding the bond to maturity, annualized on a compound-interest basis.

### **Settle — Settlement dates implied by maturity dates and number of days to maturity quote**

serial date number | datetime

Settlement dates implied by the maturity dates and the number of days to maturity quote, returned as a N-by-5 vector containing serial date numbers, by default. `Settle` is returned as a datetime array only if the input `TBillMatrix` is a table containing datetime arrays for `Maturity` in the first column.

# thirdwednesday

Find third Wednesday of month

## Syntax

```
[BeginDates,EndDates] = thirdwednesday(Month,Year)
[BeginDates,EndDates] = thirdwednesday( ____,outputType)
```

## Description

[BeginDates,EndDates] = thirdwednesday(Month,Year) computes the beginning and end period date for a LIBOR contract (third Wednesdays of delivery months).

[BeginDates,EndDates] = thirdwednesday( \_\_\_\_,outputType), using optional input arguments, computes the beginning and end period date for a LIBOR contract (third Wednesdays of delivery months).

The type of the outputs depends on the input outputType. If this variable is 'datenum', BeginDates and EndDates are serial date numbers. If outputType is 'datetime', then BeginDates and EndDates are datetime arrays. By default, outputType is set to 'datenum'.

## Examples

### Determine the Third Wednesday for Given Months and Years

Find the third Wednesday dates for swaps commencing in the month of October in the years 2002, 2003, and 2004.

```
Months = [10; 10; 10];
Year = [2002; 2003; 2004];
[BeginDates, EndDates] = thirdwednesday(Months, Year);
datestr(BeginDates)
```

```
ans = 3x11 char array
    '16-Oct-2002'
    '15-Oct-2003'
    '20-Oct-2004'
```

```
datestr(EndDates)
```

```
ans = 3x11 char array
    '16-Jan-2003'
    '15-Jan-2004'
    '20-Jan-2005'
```

Find the third Wednesday dates for swaps commencing in the month of October in the years 2002, 2003, and 2004 using an outputType of 'datetime'.

```
Months = [10; 10; 10];  
Year = [2002; 2003; 2004];  
[BeginDates, EndDates] = thirdwednesday(Months, Year, 'datetime')
```

```
BeginDates = 3x1 datetime  
    16-Oct-2002  
    15-Oct-2003  
    20-Oct-2004
```

```
EndDates = 3x1 datetime  
    16-Jan-2003  
    15-Jan-2004  
    20-Jan-2005
```

## Input Arguments

### **Month — Month of delivery for Eurodollar futures**

integer from 1 through 12 | vector of integers from 1 through 12

Month of delivery for Eurodollar futures, specified as an N-by-1 vector of integers from 1 through 12.

Duplicate dates are returned when identical months and years are supplied.

Data Types: `single` | `double`

### **Year — Delivery year for Eurodollar futures/Libor contracts corresponding to Month**

four-digit nonnegative integer | vector of four-digit nonnegative integers

Delivery year for Eurodollar futures/Libor contracts corresponding to `Month`, specified as an N-by-1 vector of four-digit nonnegative integers.

Duplicate dates are returned when identical months and years are supplied.

Data Types: `single` | `double`

### **outputType — Output date format**

'datenum' (default) | character vector with values 'datenum' or 'datetime'

Output date format, specified as a character vector with values 'datenum' or 'datetime'. If `outputType` is 'datenum', then `BeginDates` and `EndDates` are serial date numbers. However, if `outputType` is 'datetime', then `BeginDates` and `EndDates` are datetime arrays.

Data Types: `char`

## Output Arguments

### **BeginDates — Third Wednesday of given month and year**

serial date number | date character vector

Third Wednesday of given month and year, returned as serial date numbers or date character vectors, or datetime arrays. This is also the beginning of the 3-month period contract.

The type of the outputs depends on the input `outputType`. If this variable is `'datenum'`, `BeginDates` and `EndDates` are serial date numbers. If `outputType` is `'datetime'`, `thenBeginDates` and `EndDates` are datetime arrays. By default, `outputType` is set to `'datenum'`.

### **EndDates — End of three-month period contract for given month and year**

serial date number | date character vector

End of three-month period contract for given month and year, returned as serial date numbers or date character vectors, or datetime arrays.

The type of the outputs depends on the input `outputType`. If this variable is `'datenum'`, `BeginDates` and `EndDates` are serial date numbers. If `outputType` is `'datetime'`, `thenBeginDates` and `EndDates` are datetime arrays. By default, `outputType` is set to `'datenum'`.

## thirtytwo2dec

Thirty-second quotation to decimal

### Syntax

```
OutNumber = thirtytwo2dec(InNumber,InFraction)
```

### Description

`OutNumber = thirtytwo2dec(InNumber,InFraction)` changes the price quotation for a bond or bond future from a fraction with a denominator of 32 to a decimal.

### Examples

#### Change the Price Quotation for a Bond or Bond Future From a Fraction

This example shows how to change the price quotation for a bond or bond future from a fraction with a denominator of 32 to a decimal, given two bonds that are quoted as 101-25 and 102-31.

```
InNumber = [101; 102];  
InFraction = [25; 31];
```

```
OutNumber = thirtytwo2dec(InNumber, InFraction)
```

```
OutNumber = 2×1
```

```
101.7812  
102.9688
```

### Input Arguments

#### **InNumber** — Input number

integer

Input number, specified as a scalar or an N-by-1 vector of integers representing price without the fractional components.

Data Types: double

#### **InFraction** — Fractional portions of each element in InNumber

numeric decimal fraction

Fractional portions of each element in `InNumber`, specified as a scalar or an N-by-1 vector of numeric decimal fractions.

Data Types: double

## **Output Arguments**

**OutNumber** — **Output number that represents sum of InNumber and InFraction**  
decimal

Output number that represents sum of InNumber and InFraction, returned as a decimal.

## **See Also**

dec2thirtytwo

**Introduced before R2006a**

## tick2ret

Convert price series to return series

### Syntax

```
[Returns,Intervals] = tick2ret(Data)
[Returns,Intervals] = tick2ret( ___,Name,Value)
```

### Description

[Returns,Intervals] = tick2ret(Data) computes asset returns for NUMOBS price observations of NASSETS assets.

[Returns,Intervals] = tick2ret( \_\_\_,Name,Value) adds optional name-value pair arguments.

### Examples

#### Convert Price Series to Return Series

Load the file `SimulatedStock.mat`, which provides a timetable (TMW) for financial data for TMW stock. Then convert a price series to a return series, given the first 10 periodic returns of TMW.

```
load SimulatedStock.mat
```

```
TMW_Close = TMW(1:10,'Close');
[Returns,Intervals] = tick2ret(TMW_Close)
```

```
Returns=9x1 timetable

```

## Convert Price Series to Return Series Using datetime Input

Use `datetime` input to convert a price series to a return series, given periodic returns of two stocks observed in the first, second, third, and fourth quarters.

```
TickSeries = [100 80
110 90
115 88
110 91];
```

```
TickTimes = datetime({'1/1/2015','1/7/2015','1/16/2015','1/28/2015'},'InputFormat','MM/dd/yyyy')
[Returns,Intervals] = tick2ret(TickSeries,'TickTimes',TickTimes)
```

```
Returns = 3x2
```

```

```

```
144:00:00
216:00:00
288:00:00
```

## Input Arguments

### Data — Data for asset prices

matrix | table | timetable

Data for asset prices, specified as a `NUMOBS` `NASSETS` matrix, `table`, or `timetable`. Prices across a given row are assumed to occur at the same time for all columns, and each column is a price series of an individual asset.

Data Types: `double` | `table` | `timetable`

### Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `[Returns,Intervals] = tick2ret(TickSeries,'TickTimes',TickTimes)`

### TickTimes — Observation times associated with prices

sequential observation times from 1,2,...`NUMOBS` assumed for all assets (default) | vector

Observation times associated with prices, specified as the comma-separated pair consisting of `'TickTimes'` and a `NUMOBS` element column vector of monotonically increasing observation times

associated with the prices in `Data`. Times are taken either as serial date numbers (day units), date strings, datetime arrays, or as decimal numbers in arbitrary units (for example, yearly).

---

**Note** If the input `Data` type is a timetable, the row times information in the timetable overwrites the `TickTimes` input.

---

Data Types: `double` | `datetime` | `string`

### Method — Method to convert asset prices to returns

'Simple' (default) | character vector with value of 'Simple' or 'Continuous' | string with value of "Simple" or "Continuous"

Method to convert asset prices to returns, specified as the comma-separated pair consisting of 'Method' and a string or character vector indicating the method to convert asset prices to returns.

If the method is 'Simple', then simple periodic returns at time  $t$  are computed as:

$$\text{Returns}(t) = \text{Data}(t)/\text{Data}(t-1) - 1.$$

If the method is 'Continuous', the continuous returns are computed as:

$$\text{Returns}(t) = \log(\text{Data}(t)/\text{Data}(t-1)).$$

Data Types: `char` | `string`

## Output Arguments

### Returns — Time series array of asset returns

`matrix` | `table` | `timetable`

Time series array of asset returns, returned as a `NUMOBS - 1`-by-`NASSETS` array of asset returns with the same type (`matrix`, `table`, or `timetable`) as the input `Data`. The first row contains the oldest returns and the last row contains the most recent. Returns across a given row are assumed to occur at the same time for all columns, and each column is a return series of an individual asset.

### Intervals — Interval times between successive prices

`vector`

Interval times between successive prices, returned as a `NUMOBS - 1` length column vector where  $\text{Intervals}(t) = \text{TickTimes}(t) - \text{TickTimes}(t - 1)$ .

## Extended Capabilities

### Tall Arrays

Calculate with arrays that have more rows than fit in memory.

This function supports input `Data` that is specified as a tall column vector, a tall table, or a tall timetable. For more information, see `tall` and "Tall Arrays".

## tick2ret (fts)

Convert price series to return series for time series object

---

**Note** `tick2ret (fts)` is not recommended. Use `tick2ret` instead.

---

### Syntax

```
returnFts = tick2ret(priceFts)
```

```
returnFts = tick2ret(priceFts, 'PARAM1', VALUE1, 'PARAM2', VALUE2', ...)
```

### Arguments

|                       |                                                                                                                                                                                                                                                                                                                                                                                      |
|-----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>priceFts</code> | Financial time series object of prices.                                                                                                                                                                                                                                                                                                                                              |
| <code>'PARAM1'</code> | (Optional) <i>Method</i> is a character vector indicating the method to convert asset returns to prices. The value must be defined as 'Simple' (default) or 'Continuous'. If <i>Method</i> is 'Simple', <code>tick2ret</code> uses simple periodic returns. If <i>Method</i> is 'Continuous', the function uses continuously compounded returns. Case is ignored for <i>Method</i> . |

### Description

`returnFts = tick2ret(priceFts, 'PARAM1', VALUE1, 'PARAM2', VALUE2', ...)` generates a financial time series object of returns.

---

**Note** The *i*'th return is quoted for the period `PriceSeries(i)` to `PriceSeries(i+1)` and is not normalized by the time increment between successive price observations.

---

If *Method* is unspecified or 'Simple', the prices are

$$\text{ReturnSeries}(i) = \text{PriceSeries}(i+1)/\text{PriceSeries}(i) - 1$$

If *Method* is 'Continuous', the prices are

$$\text{ReturnSeries}(i) = \log[\text{PriceSeries}(i+1)/\text{PriceSeries}(i)]$$

### Examples

#### Convert Price Series to Return Series for a `fints` Object

Compute the return series from the following price series:

```
PriceSeries = [100.0000  100.0000
110.0000  112.0000
```

```
115.5000 116.4800
109.7250 122.3040]
```

```
PriceSeries = 4x2
```

```
100.0000 100.0000
110.0000 112.0000
115.5000 116.4800
109.7250 122.3040
```

Use the following dates:

```
Dates = {'18-Dec-2000'
'18-Jun-2001'
'17-Sep-2001'
'18-Dec-2001'}
```

```
Dates = 4x1 cell
{'18-Dec-2000'}
{'18-Jun-2001'}
{'17-Sep-2001'}
{'18-Dec-2001'}
```

The fints object is:

```
p = fints(Dates, PriceSeries)
```

Warning: FINTS is not recommended. Use TIMETABLE instead. For more information, see [mat](#)

```
p =
```

```
desc: (none)
freq: Unknown (0)
```

```
{'dates: (4)'} {'series1: (4)'} {'series2: (4)'}
{'18-Dec-2000'} {[ 100]} {[ 100]}
{'18-Jun-2001'} {[ 110]} {[ 112]}
{'17-Sep-2001'} {[ 115.5000]} {[ 116.4800]}
{'18-Dec-2001'} {[ 109.7250]} {[ 122.3040]}
```

returnFts is computed as:

```
tick2ret(p)
```

Warning: FINTS is not recommended. Use TIMETABLE instead. For more information, see [mat](#)

```
ans =
```

```
desc: (none)
freq: Unknown (0)
```

```
{'dates: (3)'} {'series1: (3)'} {'series2: (3)'}
{'18-Jun-2001'} {[ 0.1000]} {[ 0.1200]}
{'17-Sep-2001'} {[ 0.0500]} {[ 0.0400]}
{'18-Dec-2001'} {[ -0.0500]} {[ 0.0500]}
```

Note that for  $n$  dates in the original time series, there are  $(n-1)$  dates returned for `returnFts` from `tick2ret`. The formula for the date output dates is described as: `RetDate(i) = PriceDate (i+1)`.

# time2date

Dates from time and frequency

## Syntax

```
Dates = time2date(Settle,TFactors)
Dates = time2date( ____,Compounding,Basis,EndMonthRule)
```

## Description

Dates = time2date(Settle,TFactors) computes Dates corresponding to compounded rate quotes between Settle and TFactors. time2date is the inverse of date2time.

Dates = time2date( \_\_\_\_,Compounding,Basis,EndMonthRule) computes Dates corresponding to compounded rate quotes between Settle and TFactors using optional input arguments for Compounding, Basis, and EndMonthRule. time2date is the inverse of date2time.

## Examples

### Calculate Dates Using time2date

Show that date2time and time2date are the inverse of each other. First compute the time factors using date2time.

```
Settle = '1-Sep-2002';
Dates = datenum(['31-Aug-2005'; '28-Feb-2006'; '15-Jun-2006';
                '31-Dec-2006']);
Compounding = 2;
Basis = 0;
EndMonthRule = 1;
TFactors = date2time(Settle, Dates, Compounding, Basis,...
EndMonthRule)
```

```
TFactors = 4×1
```

```
5.9945
6.9945
7.5738
8.6576
```

Now use the calculated TFactors in time2date and compare the calculated dates with the original set.

```
Dates_calc = time2date(Settle, TFactors, Compounding, Basis,...
EndMonthRule)
```

```
Dates_calc = 4×1
```

```
732555
732736
```

```
732843
733042
```

```
datestr(Dates_calc)
```

```
ans = 4x11 char array
'31-Aug-2005'
'28-Feb-2006'
'15-Jun-2006'
'31-Dec-2006'
```

Show time2date support for datetime input for Settle.

```
Settle = '1-Sep-2002';
Dates = datenum(['31-Aug-2005'; '28-Feb-2006'; '15-Jun-2006';
'31-Dec-2006']);
Compounding = 2;
Basis = 0;
EndMonthRule = 1;
TFactors = date2time(Settle, Dates, Compounding, Basis,...
EndMonthRule);
Dates_calc = time2date(datetime(Settle,'Locale','en_US'), TFactors,...
Compounding, Basis, EndMonthRule)

Dates_calc = 4x1 datetime
31-Aug-2005
28-Feb-2006
15-Jun-2006
31-Dec-2006
```

## Input Arguments

### Settle — Settlement date

serial date number | date character vector | datetime object

Settlement date, specified as a serial date number, date character vector, or datetime array.

Data Types: double | char | datetime

### TFactors — Time factors

vector

Time factors, corresponding to the compounding value, specified as a vector. TFactors must be equal to or greater than zero.

Data Types: double

### Compounding — Rate at which input zero rates are compounded when annualized

2 (Semiannual compounding) (default) | scalar with numeric values of 0, 1, 2, 3, 4, 5, 6, 12, 365, -1

Rate at which input zero rates are compounded when annualized, specified as a scalar with numeric values of: 0, 1, 2, 3, 4, 5, 6, 12, 365, or -1. Allowed values are defined as:

- 0 — Simple interest (no compounding)
- 1 — Annual compounding
- 2 — Semiannual compounding (default)
- 3 — Compounding three times per year
- 4 — Quarterly compounding
- 6 — Bimonthly compounding
- 12 — Monthly compounding
- 365 — Daily compounding
- -1 — Continuous compounding

The optional **Compounding** argument determines the formula for the discount factors (**Disc**):

- **Compounding** = 1, 2, 3, 4, 6, 12
  - $\text{Disc} = (1 + Z/F)^{-T}$ , where  $F$  is the compounding frequency,  $Z$  is the zero rate, and  $T$  is the time in periodic units, for example,  $T = F$  is one year.
- **Compounding** = 365
  - $\text{Disc} = (1 + Z/F)^{-T}$ , where  $F$  is the number of days in the basis year and  $T$  is a number of days elapsed computed by basis.
- **Compounding** = -1
  - $\text{Disc} = \exp(-T*Z)$ , where  $T$  is time in years.

### **Basis — Day-count basis**

0 (actual/actual) (default) | numeric with value 0 through 13 | vector of numerics with values 0 through 13

Day-count basis, specified as an integer with a value of 0 through 13 or a N-by-1 vector of integers with values 0 through 13.

- 0 = actual/actual (default)
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (BMA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-19.

Data Types: `single` | `double`

### **EndMonthRule — End-of-month rule flag for month having 30 or fewer days**

1 (in effect) (default) | nonnegative integer [0, 1]

End-of-month rule flag for month having 30 or fewer days, specified as scalar nonnegative integer [0, 1] or a using a N-by-1 vector of values. This rule applies only when `Maturity` is an end-of-month date for a month having 30 or fewer days.

- 0 = Ignore rule, meaning that a payment date is always the same numerical day of the month.
- 1 = Set rule on, meaning that a payment date is always the last actual day of the month.

Data Types: `logical`

## **Output Arguments**

### **Dates — Dates corresponding to compounded rate quotes between `Settle` and `TFactors`**

serial date number | datetime array

Dates corresponding to compounded rate quotes between `Settle` and `TFactors`, returned as a scalar or a N-by-1 vector using serial date numbers or datetime arrays.

Data Types: `double` | `datetime`

## **See Also**

`cftimes` | `date2time` | `datetime` | `cfamounts`

# times

Financial time series multiplication

---

**Note** `times` is not recommended. Use `timetable` instead. For more information, see “Convert Financial Time Series Objects `fints` to Timetables”.

---

## Syntax

```
newfts = tsubj_1 .* tsubj_2
```

```
newfts = tsubj .* array
```

```
newfts = array .* tsubj
```

## Arguments

|                               |                                                                                                                                                                                         |
|-------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>tsubj_1, tsubj_2</code> | Pair of financial time series objects.                                                                                                                                                  |
| <code>array</code>            | A scalar value or array with the number of rows equal to the number of dates in <code>tsubj</code> and the number of columns equal to the number of data series in <code>tsubj</code> . |

## Description

The `times` method multiplies element by element the components of one financial time series object by the components of the other. You can also multiply the entire object by an array.

If an object is to be multiplied by another object, both objects must have the same dates and data series names, although the order need not be the same. The order of the data series, when an object is multiplied by another object, follows the order of the first object.

`newfts = tsubj_1 .* tsubj_2` multiplies financial time series objects element by element.

`newfts = tsubj .* array` multiplies a financial time series object element by element by an array.

`newfts = array .* tsubj` and `newfts = array / tsubj` multiplies an array element by element by a financial time series object.

For financial time series objects, the `times` operation is identical to the `mtimes` operation.

## tmfactor

Time factors of arbitrary dates

### Syntax

```
TMFactors = tmfactor(Settle,Maturity)
```

### Description

`TMFactors = tmfactor(Settle,Maturity)` determines the time factors from a vector of Settlement dates to a vector of Maturity dates.

### Examples

#### Find Time Factors of Settle and Maturity Dates

Find the TFactors for Settle and Maturity dates.

```
TFactors = tmfactor('1-Jan-2015','1-Jan-2016')
```

```
TFactors = 2
```

Find the TFactors for Settle and Maturity dates using a datetimes.

```
TFactors = tmfactor(datetime('1-Jan-2015','Locale','en_US'),datetime('1-Jan-2016','Locale','en_US'))
```

```
TFactors = 2
```

### Input Arguments

#### Settle — Settlement date

serial date number | date character vector | datetime

Settlement date, specified as a cell array of date character vectors, a vector of serial date numbers, or a datetime array.

---

**Note** Settle must be earlier than Maturity.

---

Data Types: double | char | datetime

#### Maturity — Maturity date

serial date number | date character vector | datetime

Maturity date, specified as a cell array of date character vectors, a vector of serial date numbers, or a datetime array.

Data Types: double | char | datetime

## Output Arguments

**TMFactors** — Time factors from a vector of Settle dates to a vector of Maturity dates

scalar numeric

Time factors from a vector of Settle dates to a vector of Maturity dates, returned as a scalar numeric.

# toannual

Convert to annual

---

**Note** `toannual` is not recommended. Use `convert2annual` instead.

---

## Syntax

```
newfts = toannual(oldfts)
```

```
newfts = toannual(oldfts, 'ParameterName', ParameterValue, ...)
```

## Arguments

|                     |                               |
|---------------------|-------------------------------|
| <code>oldfts</code> | Financial time series object. |
|---------------------|-------------------------------|

## Description

`newfts = toannual(oldfts)` converts a financial time series of any frequency to one of an annual frequency. The default end-of-year is the last business day of the December. `toannual` uses `holidays.m` to determine valid trading days.

---

**Note** If `oldfts` contains time-of-day information, `newfts` displays the time-of-day as '00:00' for those days that did not previously exist in `oldfts`.

Empty (`[]`) passed as inputs for parameter pair values for `toannual` triggers the use of the defaults.

---

`newfts = toannual(oldfts, 'ParameterName', ParameterValue, ...)` accepts parameter name/parameter value pairs as input, as specified in the following table.

| Parameter Name          | Parameter Value      | Description                                                                                                                                                                  |
|-------------------------|----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>CalcMethod</code> | <code>CumSum</code>  | Returns the cumulative sum of the values within each year. Data for missing dates are given the value 0.                                                                     |
| <code>CalcMethod</code> | <code>Exact</code>   | Returns the exact value at the end-of-year date. No data manipulation occurs.                                                                                                |
| <code>CalcMethod</code> | <code>Nearest</code> | (Default) Returns the values located at the end-of-year dates. If there is missing data, <code>Nearest</code> returns the nearest data point preceding the end-of-year date. |
| <code>CalcMethod</code> | <code>SimpAvg</code> | Returns an averaged annual value that only takes into account dates with data (non- <code>NaN</code> ) within each year.                                                     |

| Parameter Name                                                                                                                    | Parameter Value | Description                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|-----------------------------------------------------------------------------------------------------------------------------------|-----------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| CalcMethod                                                                                                                        | v21x            | This mode is compatible with previous versions of this function (Version 2.1.x and earlier). It returns an averaged end-of-year value using a previous toannual algorithm. This algorithm takes into account all dates and data. For dates that do not contain any data, the data is assumed to be 0.                                                                                                                                                    |
| <b>Note</b> If you set CalcMethod to v21x, settings for all the following parameter name/parameter value pairs are not supported. |                 |                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| BusDays                                                                                                                           | 0               | Returns a financial time series that ranges from (or between) the first date to the last date in oldfts (includes NYSE nonbusiness days and holidays).                                                                                                                                                                                                                                                                                                   |
| BusDays                                                                                                                           | 1               | (Default) Generates a monthly financial time series that ranges from the first date to the last date in oldfts (excludes NYSE nonbusiness days and holidays and weekends based on AltHolidays and Weekend). If an end-of-month date falls on a nonbusiness day or NYSE holiday, returns the last business day of the month.<br><br>NYSE market closures, holidays, and weekends are observed if AltHolidays and Weekend are not supplied or empty ( []). |
| DateFilter                                                                                                                        | Absolute        | (Default) Returns all annual dates between the start and end dates of oldfts. Some dates may be disregarded if BusDays = 1.<br><br><b>Note</b> The default is to create a time series with every date at the specified periodicity, which is with DateFilter = Absolute. If you use DateFilter = Relative, the endpoint effects do not apply since only your data defines which dates appear in the output time series object.                           |
| DateFilter                                                                                                                        | Relative        | Returns only the annual dates that exist in oldfts. Some dates may be disregarded if BusDays = 1.                                                                                                                                                                                                                                                                                                                                                        |
| ED                                                                                                                                | 0               | Annual period ends on the last day or last business day of the month.                                                                                                                                                                                                                                                                                                                                                                                    |
| ED                                                                                                                                | 1 - 31          | Specifies a particular annual day. Months that do not contain the specified day return the last day (or last business day) of the month (for example, ED = 31 does not exist for February.)                                                                                                                                                                                                                                                              |
| EM                                                                                                                                | 1 - 12          | (Default) The annual period ends on the last day (or last business day) of the specified month. All subsequent annual dates are calculated from this month. Default annual month is December (12).                                                                                                                                                                                                                                                       |

| Parameter Name | Parameter Value | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|----------------|-----------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| EndPtTol       | [Begin, End]    | Denotes the minimum number of days that constitute an odd annual period at the endpoints of the time series (before the first-time series date and after the last end-of-year date).<br><br>Begin and End must be -1 or any positive integer greater than or equal to 0.<br><br>A single value input for 'EndPtTol' is the same as specifying that single value for Begin and End.<br><br>-1 Exclude odd annual period dates and data from calculations.<br><br>0 (Default) Include odd annual period dates and data in calculations.<br><br>n Number of days (any positive integer) that constitute an odd annual period. If there are insufficient days for a complete year, the endpoint data is ignored. |

The following diagram is a general depiction of the factors involved in the determination of endpoints for this function.

|             |       |                                                                                                                                                                                                                                          |
|-------------|-------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| TimeSpec    | First | Returns only the observation that occurs at the first (earliest) time for a specific date.                                                                                                                                               |
| TimeSpec    | Last  | (Default) Returns only the observation that occurs at the last (latest) time for a specific date.                                                                                                                                        |
| AltHolidays |       | Vector of dates specifying an alternate set of market closure dates.                                                                                                                                                                     |
| AltHolidays | -1    | Excludes all holidays.                                                                                                                                                                                                                   |
| Weekend     |       | Vector of length 7 containing 0's and 1's. The value 1 indicates a weekend day. The first element of this vector corresponds to Sunday. For example, when Saturday and Sunday are weekend days (default) then Weekend = [1 0 0 0 0 0 1]. |

## Examples

## Transform Time Series Object from Weekly to Annual Values

This example shows how to transform a time series object from weekly to annual values.

Load the data from the file `predict_ret_data.mat` and use the `fints` function to create a time series object with a weekly frequency.

```
load predict_ret_data.mat
x0 = fints(expdates, expdata, {'Metric'}, 'w', 'Index')
```

Warning: FINTS is not recommended. Use TIMETABLE instead. For more information, see ["mat"](#)

x0 =

```
desc: Index
freq: Weekly (2)

“Data Transformation and Frequency Conversion” on page 13-11

**Introduced before R2006a**

# todayly

Convert to daily

---

**Note** todayly is not recommended. Use convert2daily instead.

---

## Syntax

```
newfts = todayly(oldfts)
```

```
newfts = todayly(oldfts,'ParameterName',ParameterValue, ...)
```

## Arguments

|        |                              |
|--------|------------------------------|
| oldfts | Financial time series object |
|--------|------------------------------|

## Description

`newfts = todayly(oldfts)` converts a financial time series of any frequency to a daily frequency. `todayly` uses `holidays.m` to determine valid trading days.

---

**Note** If `oldfts` contains time-of-day information, `newfts` displays the time-of-day as '00:00' for those days that did not previously exist in `oldfts`.

Empty ([ ]) passed as inputs for parameter pair values for `todayly` trigger the use of the defaults.

---

`newfts = todayly(oldfts,'ParameterName',ParameterValue, ...)` accepts parameter name/parameter value pairs as input, as specified in the following table.

| Parameter Name                                                                                                                                               | Parameter Value | Description                                                                                                                                                                |
|--------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| CalcMethod                                                                                                                                                   | Exact           | Returns the value at specific dates/times. No data manipulation occurs.                                                                                                    |
| CalcMethod                                                                                                                                                   | v21x            | This mode is compatible with previous versions of this function (Version 2.1.x and earlier). It returns a five-day business week that starts on Monday and ends on Friday. |
| <b>Note</b> If you set <code>CalcMethod</code> to <code>v21x</code> , settings for all the following parameter name/parameter value pairs are not supported. |                 |                                                                                                                                                                            |
| BusDays                                                                                                                                                      | 0               | Generates a financial time series that ranges from (or between) the first date to the last date in <code>oldfts</code> (includes NYSE nonbusiness days and holidays).      |

| Parameter Name | Parameter Value | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|----------------|-----------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| BusDays        | 1               | (Default) Generates a daily financial time series that ranges from the first date to the last date in <code>oldfts</code> (excludes NYSE nonbusiness days and holidays and weekends based on <code>AltHolidays</code> and <code>Weekend</code> ).                                                                                                                                                                                                                                                                                                                                                                                                                  |
| DateFilter     | Absolute        | <p>NYSE market closures, holidays, and weekends are observed if <code>AltHolidays</code> and <code>Weekend</code> are not supplied or empty (<code>[]</code>).</p> <p>(Default) Displays all daily dates between the start and end dates of <code>oldfts</code>. Some dates may be disregarded if <code>BusDays = 1</code>.</p> <hr/> <p><b>Note</b> The default is to create a time series with every date at the specified periodicity, which is with <code>DateFilter = Absolute</code>. If you use <code>DateFilter = Relative</code>, the endpoint effects do not apply since only your data defines which dates appear in the output time series object.</p> |
| DateFilter     | Relative        | Displays only dates that exist in <code>oldfts</code> . Some dates may be disregarded if <code>BusDays = 1</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| TimeSpec       | First           | Returns only the observation that occurs at the first (earliest) time for a specific date.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| TimeSpec       | Last            | (Default) Returns only the observation that occurs at the last (latest) time for a specific date.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| AltHolidays    |                 | Vector of dates specifying an alternate set of market closure dates.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| AltHolidays    | -1              | Excludes all holidays.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| Weekend        |                 | Vector of length 7 containing 0's and 1's. The value 1 indicates a weekend day. The first element of this vector corresponds to Sunday. For example, when Saturday and Sunday are weekend days (default) then <code>Weekend = [1 0 0 0 0 0 1]</code> .                                                                                                                                                                                                                                                                                                                                                                                                             |

## Examples

### Transform Time Series Object from Weekly to Daily Values

Load the data from the file `predict_ret_data.mat` and use the `fints` function to create a time series object with a weekly frequency.

```
load predict_ret_data.mat
x0 = fints(expdates, expdata, {'Metric'}, 'w', 'Index')
```

Warning: FINTS is not recommended. Use TIMETABLE instead. For more information, see [mat](#)

```
x0 =
```

```
    desc: Index
```

freq: Weekly (2)

```

## Introduced before R2006a

# today

Current date

## Syntax

```
Date = today
Date = today(outputType)
```

## Description

`Date = today` returns the current date as a serial date number.

`Date = today(outputType)` returns the current date using an optional `outputType`. The type of output is determined by an optional `outputType` variable input.

## Examples

### Return the Current Date

Use `today` to return the current date with the default serial date number.

```
Date = today
Date = 738400
```

Use the optional argument `outputType` to return a datetime array.

```
Date = today('datetime')
Date = datetime
      01-Sep-2021
```

## Input Arguments

### `outputType` — Type of output

'datenum' (default) | character vector with values 'datetime' or 'datenum'

Type of output, specified as a character vector with values 'datetime' or 'datenum'.

If `outputType` is 'datenum', then `Date` is a serial date number. If `outputType` is 'datetime', then `Date` is a datetime array. By default, `outputType` is 'datenum'.

Data Types: char

## Output Arguments

### `Date` — Current date

serial date number or datetime array

Current date, returned as a serial date number or datetime array, depending on the optional input argument `outputType`.

# todecimal

Fractional to decimal conversion

## Syntax

```
usddec = todecimal(quote,fracpart)
```

## Description

`usddec = todecimal(quote,fracpart)` returns the decimal equivalent, `usddec`, of a security whose price is normally quoted as a whole number and a fraction (`quote`). `fracpart` indicates the fractional base (denominator) with which the security is normally quoted (default = 32).

## Examples

In the *Wall Street Journal*, bond prices are quoted in fractional form based on a denominator of 32. For example, if you see the quoted price is 100:05 it means 100 5/32. To find the equivalent decimal value, enter

```
usddec = todecimal(100.05)
```

```
usddec =  
100.1563
```

```
usddec = todecimal(97.04, 16)
```

```
usddec =  
97.2500
```

---

**Note** The convention of using . (period) as a substitute for : (colon) in the input is adopted from Excel software.

## tomonthly

Convert to monthly

---

**Note** `tomonthly` is not recommended. Use `convert2monthly` instead.

---

### Syntax

```
newfts = tomonthly(oldfts)
```

```
newfts = tomonthly(oldfts, 'ParameterName', ParameterValue, ...)
```

### Arguments

|                     |                               |
|---------------------|-------------------------------|
| <code>oldfts</code> | Financial time series object. |
|---------------------|-------------------------------|

### Description

`newfts = tomonthly(oldfts)` converts a financial time series of any frequency to a monthly frequency. The default end-of-month day is the last business day of the month. `tomonthly` uses `holidays.m` to determine valid trading days.

---

**Note** If `oldfts` contains time-of-day information, `newfts` displays the time-of-day as `00:00` for those days that did not previously exist in `oldfts`.

Empty (`[]`) passed as inputs for parameter pair values for `tomonthly` triggers the use of the defaults.

---

`newfts = tomonthly(oldfts, 'ParameterName', ParameterValue, ...)` accepts parameter name/parameter value pairs as input, as specified in the following table.

| Parameter Name | Parameter Value | Description                                                                                                                                                        |
|----------------|-----------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| CalcMethod     | CumSum          | Returns the cumulative sum of the values within each month. Data for missing dates are given the value 0.                                                          |
|                | Exact           | Returns the exact value at the end-of-month date. No data manipulation occurs.                                                                                     |
|                | Nearest         | (Default) Returns the values located at the end-of-month date. If there is missing data, 'Nearest' returns the nearest data point preceding the end-of-month date. |
|                | SimpAvg         | Returns an averaged monthly value that only takes into account dates with data (non-NaN) within each month.                                                        |

| Parameter Name                                                                                                                    | Parameter Value | Description                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|-----------------------------------------------------------------------------------------------------------------------------------|-----------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                                                                                                                   | v21x            | This mode is compatible with previous versions of this function (Version 2.1.x and earlier). It returns an averaged end-of-month value using a previous tomonthly algorithm. This algorithm takes into account all dates and data. For dates that do not contain any data, the data is assumed to be 0.                                                                                                                                                  |
| <b>Note</b> If you set CalcMethod to v21x, settings for all the following parameter name/parameter value pairs are not supported. |                 |                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| BusDays                                                                                                                           | 0               | Generates a monthly financial time series that ranges from the first date to the last date in oldfts (includes NYSE nonbusiness days and holidays).                                                                                                                                                                                                                                                                                                      |
|                                                                                                                                   | 1               | (Default) Generates a monthly financial time series that ranges from the first date to the last date in oldfts (excludes NYSE nonbusiness days and holidays and weekends based on AltHolidays and Weekend). If an end-of-month date falls on a nonbusiness day or NYSE holiday, returns the last business day of the month.<br><br>NYSE market closures, holidays, and weekends are observed if AltHolidays and Weekend are not supplied or empty ( []). |
| DateFilter                                                                                                                        | Absolute        | (Default) Returns all monthly dates between the start and end dates of oldfts. Some dates may be disregarded if BusDays = 1.<br><br><b>Note</b> The default is to create a time series with every date at the specified periodicity, which is with DateFilter = Absolute. If you use DateFilter = Relative, the endpoint effects do not apply since only your data defines which dates appear in the output time series object.                          |
|                                                                                                                                   | Relative        | Returns only monthly dates that exist in oldfts. Some dates may be disregarded if BusDays = 1.                                                                                                                                                                                                                                                                                                                                                           |
| ED                                                                                                                                | 0               | (Default) The end-of-month date is the last day (or last business day) of the month.                                                                                                                                                                                                                                                                                                                                                                     |
|                                                                                                                                   | 1 - 31          | Returns values on the specified end-of-month day. Months that do not contain the specified end-of-month day return the last day of the month instead (for example, ED = 31 does not exist for February).<br><br>If end-of-month falls on a NYSE non-business day or holiday, the previous business day is returned if BusDays = 1.                                                                                                                       |

| Parameter Name | Parameter Value | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|----------------|-----------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| EndPtTol       | [Begin, End]    | <p>Denotes the minimum number of days that constitute an odd month at the end points of the time series (before the first whole period and after the last whole period).</p> <p>Begin and End must be -1 or any positive integer greater than or equal to 0.</p> <p>A single value input for EndPtTol is the same as specifying that single value for Begin and End.</p> <p>-1 Do not include odd month dates and data in calculations.</p> <p>0 (Default) Include all odd month dates and data in calculations.</p> <p>n Number of days that constitute an odd month. If the minimum number of days is not met, the odd month dates and data are ignored.</p> |

The following diagram is a general depiction of the factors involved in the determination of end points for this function.

|             |       |                                                                                                                                                                                                                                          |
|-------------|-------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| TimeSpec    | First | Returns only the observation that occurs at the first (earliest) time for a specific date.                                                                                                                                               |
|             | Last  | (Default) Returns only the observation that occurs at the last (latest) time for a specific date.                                                                                                                                        |
| AltHolidays |       | Vector of dates specifying an alternate set of market closure dates.                                                                                                                                                                     |
|             | -1    | Excludes all holidays.                                                                                                                                                                                                                   |
| Weekend     |       | Vector of length 7 containing 0's and 1's. The value 1 indicates a weekend day. The first element of this vector corresponds to Sunday. For example, when Saturday and Sunday are weekend days (default) then Weekend = [1 0 0 0 0 0 1]. |

## Examples

## Transform Time Series Object from Weekly to Monthly Values

This example shows how to transform a time series object from weekly to monthly values.

Load the data from the file `predict_ret_data.mat` and use the `fints` function to create a time series object with a weekly frequency.

```
load predict_ret_data.mat
x0 = fints(expdates, expdata, {'Metric'}, 'w', 'Index')
```

Warning: FINTS is not recommended. Use TIMETABLE instead. For more information, see [mat](#)

```
x0 =
```

```
desc: Index
freq: Weekly (2)

“Data Transformation and Frequency Conversion” on page 13-11

## Introduced before R2006a

# toquarterly

Convert to quarterly

---

**Note** toquarterly is not recommended. Use convert2quarterly instead.

---

## Syntax

```
newfts = toquarterly(oldfts)
```

```
newfts = toquarterly(oldfts, 'ParameterName', ParameterValue, ...)
```

## Arguments

|        |                              |
|--------|------------------------------|
| oldfts | Financial time series object |
|--------|------------------------------|

## Description

`newfts = toquarterly(oldfts)` converts a financial time series of any frequency to a quarterly frequency. The default quarterly days are the last business day of March, June, September, and December. `toquarterly` uses `holidays.m` to determine valid trading days.

---

**Note** If `oldfts` contains time-of-day information, `newfts` displays the time-of-day as `00:00` for those days that did not previously exist in `oldfts`.

Empty (`[]`) passed as inputs for parameter pair values for `toquarterly` triggers the use of the defaults.

---

`newfts = toquarterly(oldfts, 'ParameterName', ParameterValue, ...)` accepts parameter name/parameter value pairs as input, as specified in the following table.

| Parameter Name | Parameter Value | Description                                                                                                                                                                 |
|----------------|-----------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| CalcMethod     | CumSum          | Returns the cumulative sum of the values between each quarter. Data for missing dates are given the value 0.                                                                |
|                | Exact           | Returns the exact value at the end-of-quarter date. No data manipulation occurs.                                                                                            |
|                | Nearest         | (Default) Returns the values located at the end-of-quarter date. If there is missing data, <b>Nearest</b> returns the nearest data point preceding the end-of-quarter date. |
|                | SimpAvg         | Returns an averaged quarterly value that only takes into account dates with data (non-NaN) within each quarter.                                                             |

| Parameter Name                                                                                                                                               | Parameter Value | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|--------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                                                                                                                                              | v21x            | This mode is compatible with previous versions of this function (Version 2.1.x and earlier). It returns an averaged end-of-quarter value using a previous <code>toquarterly</code> algorithm. This algorithm takes into account all dates and data. For dates that do not contain any data, the data is assumed to be 0.                                                                                                                                                                                              |
| <b>Note</b> If you set <code>CalcMethod</code> to <code>v21x</code> , settings for all the following parameter name/parameter value pairs are not supported. |                 |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| BusDays                                                                                                                                                      | 0               | Generates a financial time series that ranges from (or between) the first date to the last date in <code>oldfts</code> (includes NYSE nonbusiness days and holidays).                                                                                                                                                                                                                                                                                                                                                 |
|                                                                                                                                                              | 1               | (Default) Generates a financial time series that ranges from the first date to the last date in <code>oldfts</code> (excludes NYSE nonbusiness days and holidays and weekends based on <code>AltHolidays</code> and <code>Weekend</code> ). If an end-of-quarter date falls on a nonbusiness day or NYSE holiday, returns the last business day of the quarter.<br><br>NYSE market closures, holidays, and weekends are observed if <code>AltHolidays</code> and <code>Weekend</code> are not supplied or empty ({}). |
| DateFilter                                                                                                                                                   | Absolute        | (Default) Returns all quarterly dates between the start and end dates of <code>oldfts</code> . Some dates may be disregarded if <code>BusDays = 1</code> .                                                                                                                                                                                                                                                                                                                                                            |
|                                                                                                                                                              | Relative        | <b>Note</b> The default is to create a time series with every date at the specified periodicity, which is with <code>DateFilter = Absolute</code> . If you use <code>DateFilter = Relative</code> , the endpoint effects do not apply since only your data defines which dates appear in the output time series object.                                                                                                                                                                                               |
| ED                                                                                                                                                           | 0               | (Default) The end-of-quarter date is the last day (or last business day) of the quarter.                                                                                                                                                                                                                                                                                                                                                                                                                              |
|                                                                                                                                                              | 1 - 31          | Specifies a particular end-of-quarter day. Months that do not contain the specified end-of-quarter day return the last day of the quarter instead (for example, <code>ED = 31</code> does not exist for February).                                                                                                                                                                                                                                                                                                    |
| EM                                                                                                                                                           | 1 - 12          | Last month of the first quarter. All subsequent quarterly dates are based on this month. The default end-of-first-quarter month is March (3).                                                                                                                                                                                                                                                                                                                                                                         |

| Parameter Name | Parameter Value | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|----------------|-----------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| EndPtTol       | [Begin, End]    | <p>Denotes the minimum number of days that constitute an odd quarter at the endpoints of the time series (before the first whole period and after the last whole period).</p> <p>Begin and End must be -1 or any positive integer greater than or equal to 0.</p> <p>A single value input for EndPtTol is the same as specifying that single value for Begin and End.</p> <p>-1 Do not include odd quarter dates and data in calculations.</p> <p>0 (Default) Include all odd quarter dates and data in calculations.</p> <p>n Number of days (any positive integer) that constitute an odd quarter. If there are insufficient days for a complete quarter, the odd quarter dates and data are ignored.</p> |

The following diagram is a general depiction of the factors involved in the determination of endpoints for this function.

|             |       |                                                                                                                                                                                                                                          |
|-------------|-------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| TimeSpec    | First | Returns only the observation that occurs at the first (earliest) time for a specific date.                                                                                                                                               |
|             | Last  | (Default) Returns only the observation that occurs at the last (latest) time for a specific date.                                                                                                                                        |
| AltHolidays |       | Vector of dates specifying an alternate set of market closure dates.                                                                                                                                                                     |
|             | -1    | Excludes all holidays.                                                                                                                                                                                                                   |
| Weekend     |       | Vector of length 7 containing 0's and 1's. The value 1 indicates a weekend day. The first element of this vector corresponds to Sunday. For example, when Saturday and Sunday are weekend days (default) then Weekend = [1 0 0 0 0 0 1]. |

## Examples

### Transform Time Series Object from Weekly to Quarterly Values

This example shows how to transform a time series object from weekly to quarterly values.

Load the data from the file `predict_ret_data.mat` and use the `fints` function to create a time series object with a weekly frequency.

```
load predict_ret_data.mat

### Transform Time Series Object from Weekly to Quarterly Values Including NYSE Nonbusiness Days and Holidays

Load the data from the file `predict_ret_data.mat` and use the `fints` function to create a time series object with a weekly frequency.

```

load predict_ret_data.mat
x0 = fints(expdates, expdata, {'Metric'}, 'w', 'Index')

```

Warning: FINTS is not recommended. Use `TIMETABLE` instead. For more information, see [mat](#)

## toquoted

Decimal to fractional conversion

### Syntax

```
quote = toquoted(usddec,fracpart)
```

### Description

`quote = toquoted(usddec,fracpart)` returns the fractional equivalent, `quote`, of the decimal figure, `usddec`, based on the fractional base (denominator), `fracpart`. The fractional bases are the ones used for quoting equity prices in the United States (denominator 2, 4, 8, 16, or 32). If `fracpart` is not entered, the denominator 32 is assumed.

### Examples

A United States equity price in decimal form is 101.625. To convert this to fractional form in eighths of a dollar:

```
quote = toquoted(101.625, 8)
```

```
quote =  
    101.05
```

The answer is interpreted as 101 5/8.

---

**Note** The convention of using . (period) as a substitute for : (colon) in the output is adopted from Excel software.

# tosemi

Convert to semiannual

---

**Note** `tosemi` is not recommended. Use `convert2semiannual` instead.

---

## Syntax

```
newfts = tosemi(oldfts)
```

```
newfts = tosemi(oldfts,'ParameterName',ParameterValue, ...)
```

## Arguments

|                     |                               |
|---------------------|-------------------------------|
| <code>oldfts</code> | Financial time series object. |
|---------------------|-------------------------------|

## Description

`newfts = tosemi(oldfts)` converts a financial time series of any frequency to a semiannual frequency. The default semiannual days are the last business day of June and December. `tosemi` uses `holidays.m` to determine valid trading days.

---

**Note** If `oldfts` contains time-of-day information, `newfts` displays the time-of-day as `00:00` for those days that did not previously exist in `oldfts`.

---

Empty (`[]`) passed as inputs for parameter pair values for `tosemi` triggers the use of the defaults.

---

`newfts = tosemi(oldfts,'ParameterName',ParameterValue, ...)` accepts parameter name/parameter value pairs as input, as specified in the following table.

| Parameter Name | Parameter Value | Description                                                                                                                                                                     |
|----------------|-----------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| CalcMethod     | CumSum          | Returns the cumulative sum of the values within each semiannual period. Data for missing dates are given the value 0.                                                           |
|                | Exact           | Returns the exact value at the end-of-period date. No data manipulation occurs.                                                                                                 |
|                | Nearest         | (Default) Returns the values located at the end-of-period date. If there is missing data, <code>Nearest</code> returns the nearest data point preceding the end-of-period date. |
|                | SimpAvg         | Returns an averaged semiannual value that only takes into account dates with data (non- <code>NaN</code> ) within each semiannual period.                                       |

| Parameter Name                                                                                                                    | Parameter Value | Description                                                                                                                                                                                                                                                                                                             |
|-----------------------------------------------------------------------------------------------------------------------------------|-----------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                                                                                                                   | v21x            | This mode is compatible with previous versions of this function (Version 2.1.x and earlier). It returns an averaged end-of-period value using a previous tosemi algorithm. This algorithm takes into account all dates and data. For dates that do not contain any data, the data is assumed to be 0.                   |
| <b>Note</b> If you set CalcMethod to v21x, settings for all the following parameter name/parameter value pairs are not supported. |                 |                                                                                                                                                                                                                                                                                                                         |
| BusDays                                                                                                                           | 0               | Generates a financial time series that ranges from (or between) the first date to the last date in oldfts (includes NYSE nonbusiness days and holidays).                                                                                                                                                                |
|                                                                                                                                   | 1               | (Default) Generates a financial time series that ranges from the first date to the last date in oldfts (excludes NYSE nonbusiness days and holidays and weekends based on AltHolidays and Weekend). If an end-of-quarter date falls on a nonbusiness day or NYSE holiday, returns the last business day of the quarter. |
| DateFilter                                                                                                                        | Absolute        | NYSE market closures, holidays, and weekends are observed if AltHolidays and Weekend are not supplied or empty ( []).<br>(Default) Returns all semiannual dates between the start and end dates of oldfts. Some dates may be disregarded if BusDays = 1.                                                                |
|                                                                                                                                   | Relative        | <b>Note</b> The default is to create a time series with every date at the specified periodicity, which is with DateFilter = Absolute. If you use DateFilter = Relative, the endpoint effects do not apply since only your data defines which dates appear in the output time series object.                             |
| ED                                                                                                                                | 0               | Returns only semiannual dates that exist in oldfts. Some dates may be disregarded if BusDays = 1.<br>(Default) The end-of-period date is the last day (or last business day) of the semiannual period.                                                                                                                  |
|                                                                                                                                   | 1 - 31          | Specifies a particular end-of-period day. Months that do not contain the specified end-of-period day return the last day of the semiannual period instead (for example, ED = 31 does not exist for February).                                                                                                           |
| EM                                                                                                                                | 1 - 12          | End month of the first semiannual period. All subsequent period dates are based on this month. The default end-of-period months are June (6) and December (12).                                                                                                                                                         |

| Parameter Name | Parameter Value | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|----------------|-----------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| EndPtTol       | [Begin, End]    | <p>Denotes the minimum number of days that constitute an odd semiannual period at the endpoints of the time series (before the first whole period and after the last whole period).</p> <p>Begin and End must be -1 or any positive integer greater than or equal to 0.</p> <p>A single value input for EndPtTol is the same as specifying that single value for Begin and End.</p> <p>-1 Do not include odd period dates and data in calculations.</p> <p>0 (Default) Include all odd period dates and data in calculations.</p> <p>n Number of days (any positive integer) that constitute an odd period. If there are insufficient days for a complete semiannual period, the odd period dates and data are ignored.</p> |

The following diagram is a general depiction of the factors involved in the determination of endpoints for this function.

|             |       |                                                                                                                                                                                                                                          |
|-------------|-------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| TimeSpec    | First | Returns only the observation that occurs at the first (earliest) time for a specific date.                                                                                                                                               |
|             | Last  | (Default) Returns only the observation that occurs at the last (latest) time for a specific date.                                                                                                                                        |
| AltHolidays |       | Vector of dates specifying an alternate set of market closure dates.                                                                                                                                                                     |
|             | -1    | Excludes all holidays.                                                                                                                                                                                                                   |
| Weekend     |       | Vector of length 7 containing 0's and 1's. The value 1 indicates a weekend day. The first element of this vector corresponds to Sunday. For example, when Saturday and Sunday are weekend days (default) then Weekend = [1 0 0 0 0 0 1]. |

## Examples

## Transform Time Series Object from Weekly to Semiannual Values

This example shows how to transform a time series object from weekly to semiannual values.

Load the data from the file `predict_ret_data.mat` and then use the `fints` function to create a time series object with a weekly frequency.

```
load predict_ret_data.mat
x0 = fints(expdates, expdata, {'Metric'}, 'w', 'Index')
```

Warning: FINTS is not recommended. Use TIMETABLE instead. For more information, see [mat](#)

```
x0 =
```

```
desc: Index
freq: Weekly (2)
```

```
{'dates: (53)'} {'Metric: (53)'}
{'01-Jan-1999'} {[ 97.8872]}
{'08-Jan-1999'} {[ 97.0847]}
{'15-Jan-1999'} {[ 109.6312]}
{'22-Jan-1999'} {[ 105.5743]}
{'29-Jan-1999'} {[ 108.4028]}
{'05-Feb-1999'} {[ 134.4882]}
{'12-Feb-1999'} {[ 117.5581]}

## Introduced before R2006a

## convert2daily

Aggregate timetable data to daily periodicity

### Syntax

```
TT2 = convert2daily(TT1)
TT2 = convert2daily(TT1,Name,Value)
```

### Description

`TT2 = convert2daily(TT1)` aggregates data (for example, high-frequency and intra-day data) to a daily periodicity.

`TT2 = convert2daily(TT1,Name,Value)` uses additional options specified by one or more name-value arguments.

### Examples

#### Aggregate Prices and Logarithmic Returns to Daily Periodicity

Apply separate aggregation methods to related variables in a `timetable` while maintaining consistency between aggregated results for a daily periodicity.

Load a timetable (TT) of simulated stock price data and corresponding logarithmic returns. The data stored in TT is recorded at various times throughout the day on New York Stock Exchange (NYSE) business days from January 1, 2018, to December 31, 2020. The timetable TT also includes NYSE business calendar awareness. If your timetable does not account for nonbusiness days (weekends, holidays, and market closures), add business calendar awareness by using `addBusinessCalendar` first.

```
load('SimulatedStock.mat','TT');
head(TT)
```

```
ans=8x2 timetable
           Time      Price      Log_Return
           _____  _____  _____
02-Jan-2018 11:52:11  100.71    0.0070749
02-Jan-2018 13:23:09  103.11    0.023551
02-Jan-2018 14:45:30  100.24   -0.028229
02-Jan-2018 15:30:48  101.37    0.01121
03-Jan-2018 10:02:21  101.81    0.0043311
03-Jan-2018 11:22:37  100.17   -0.01624
03-Jan-2018 14:45:20   99.66   -0.0051043
03-Jan-2018 14:55:39  100.12    0.0046051
```

Aggregate prices and logarithmic returns to a daily periodicity. To maintain consistency between prices and returns, for any given trading day, aggregate the prices by reporting the last recorded

price by using "lastvalue" and aggregate the returns by summing all logarithmic returns by using "sum".

```
tt = convert2daily(TT, 'Aggregation', ["lastvalue" "sum"]);
head(tt)
```

```
ans=8x2 timetable
      Time      Price      Log_Return
      -----
02-Jan-2018  101.37      0.013607
03-Jan-2018  100.12     -0.012408
04-Jan-2018  106.76      0.064214
05-Jan-2018  112.78      0.054856
08-Jan-2018  119.07      0.054273
09-Jan-2018  119.46      0.00327
10-Jan-2018  124.44      0.040842
11-Jan-2018  125.63      0.0095174
```

To verify consistency, examine the input and output timetables for January 2 and 3, 2018.

```
TT(1:8,:) % Input data for 02-Jan-2018 and 03-Jan-2018
```

```
ans=8x2 timetable
      Time      Price      Log_Return
      -----
02-Jan-2018 11:52:11  100.71      0.0070749
02-Jan-2018 13:23:09  103.11      0.023551
02-Jan-2018 14:45:30  100.24     -0.028229
02-Jan-2018 15:30:48  101.37      0.01121
03-Jan-2018 10:02:21  101.81      0.0043311
03-Jan-2018 11:22:37  100.17     -0.01624
03-Jan-2018 14:45:20   99.66     -0.0051043
03-Jan-2018 14:55:39  100.12      0.0046051
```

```
tt(1:2,:) % Return aggregated results
```

```
ans=2x2 timetable
      Time      Price      Log_Return
      -----
02-Jan-2018  101.37      0.013607
03-Jan-2018  100.12     -0.012408
```

For each business day in TT, notice that the output aggregated price is the last price of the day and that the aggregated return is the sum of all logarithmic returns. Also, the aggregated returns are consistent with aggregated prices.

For example, the aggregated return for January 3, 2018, is  $-0.012408$ , which is the logarithmic return associated with the last prices recorded on January 2 and 3, 2018 (that is,  $-0.012408 = \log(100.12) - \log(101.37)$ ).

The dates of the aggregated results are whole dates that indicate the dates for which aggregated results are reported.

## Input Arguments

### TT1 — Data to aggregate to daily periodicity

timetable

Data to aggregate to a daily periodicity, specified as a timetable.

Each variable can be a numeric vector (univariate series) or numeric matrix (multivariate series).

---

#### Note

- NaNs indicate missing values.
  - Timestamps must be in ascending or descending order.
- 

By default, all days are business days. If your timetable does not account for nonbusiness days (weekends, holidays, and market closures), add business calendar awareness by using `addBusinessCalendar` first. For example, the following command adds business calendar logic to include only NYSE business days.

```
TT = addBusinessCalendar(TT);
```

Data Types: timetable

#### Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1, ..., NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Example: `TT2 = convert2daily(TT1, 'Aggregation', ["lastvalue" "sum"])`

#### Aggregation — Intra-day aggregation method for data in TT1

"lastvalue" (default) | "sum" | "prod" | "mean" | "min" | "max" | "firstvalue" | character vector | function handle | string vector | cell vector of character vectors or function handles

Intra-day aggregation method for TT1 defining how data is aggregated over business days, specified as one of the following methods, a string vector of methods, or a length `numVariables` cell vector of methods, where `numVariables` is the number of variables in TT1.

- "sum" — Sum the values in each year or day.
- "mean" — Calculate the mean of the values in each year or day.
- "prod" — Calculate the product of the values in each year or day.
- "min" — Calculate the minimum of the values in each year or day.
- "max" — Calculate the maximum of the values in each year or day.
- "firstvalue" — Use the first value in each year or day.
- "lastvalue" — Use the last value in each year or day.
- @customfcn — A custom aggregation method that accepts a timetable and returns a numeric scalar (for univariate series) or row vector (for multivariate series). The function must accept empty inputs `[]`.

If you specify a single method, `convert2daily` applies the specified method to all time series in `TT1`. If you specify a string vector or cell vector aggregation, `convert2daily` applies `aggregation(j)` to `TT1(:,j)`; `convert2daily` applies each aggregation method one at a time (for more details, see `retime`). For example, consider a daily timetable representing `TT1` with three variables.

| Time                 | AAA    | BBB    | CCC    |        |
|----------------------|--------|--------|--------|--------|
| 01-Jan-2018 09:45:47 | 100.00 | 200.00 | 300.00 | 400.00 |
| 01-Jan-2018 12:48:09 | 100.03 | 200.06 | 300.09 | 400.12 |
| 02-Jan-2018 10:27:32 | 100.07 | 200.14 | 300.21 | 400.28 |
| 02-Jan-2018 12:46:09 | 100.08 | 200.16 | 300.24 | 400.32 |
| 02-Jan-2018 14:14:13 | 100.25 | 200.50 | 300.75 | 401.00 |
| 02-Jan-2018 15:52:31 | 100.19 | 200.38 | 300.57 | 400.76 |
| 03-Jan-2018 09:47:11 | 100.54 | 201.08 | 301.62 | 402.16 |
| 03-Jan-2018 11:24:23 | 100.59 | 201.18 | 301.77 | 402.36 |
| 03-Jan-2018 14:41:17 | 101.40 | 202.80 | 304.20 | 405.60 |
| 03-Jan-2018 16:00:00 | 101.94 | 203.88 | 305.82 | 407.76 |
| 04-Jan-2018 09:55:51 | 102.53 | 205.06 | 307.59 | 410.12 |
| 04-Jan-2018 10:07:12 | 103.35 | 206.70 | 310.05 | 413.40 |
| 04-Jan-2018 14:26:23 | 103.40 | 206.80 | 310.20 | 413.60 |
| 05-Jan-2018 13:13:12 | 103.91 | 207.82 | 311.73 | 415.64 |
| 05-Jan-2018 14:57:53 | 103.89 | 207.78 | 311.67 | 415.56 |

The corresponding default daily results representing `TT2` (where the `'lastvalue'` is reported for each day) are as follows.

| Time        | AAA    | BBB    | CCC    |        |
|-------------|--------|--------|--------|--------|
| 01-Jan-2018 | 100.03 | 200.06 | 300.09 | 400.12 |
| 02-Jan-2018 | 100.19 | 200.38 | 300.57 | 400.76 |
| 03-Jan-2018 | 101.94 | 203.88 | 305.82 | 407.76 |
| 04-Jan-2018 | 103.40 | 206.80 | 310.20 | 413.60 |
| 05-Jan-2018 | 103.89 | 207.78 | 311.67 | 415.56 |

All methods omit missing data (NaNs) in direct aggregation calculations on each variable. However, for situations in which missing values appear in the first row of `TT1`, missing values can also appear in the aggregated results `TT2`. To address missing data, write and specify a custom aggregation method (function handle) that supports missing data.

Data Types: `char` | `string` | `cell` | `function_handle`

## Output Arguments

### TT2 — Daily data

timetable

Daily data, returned as a timetable. The time arrangement of `TT1` and `TT2` are the same.

If a variable of `TT1` has no records for a business day within the sampling time span, `convert2daily` returns a NaN for that variable and business day in `TT2`.

The first date in `TT2` is the first business date on or after the first date in `TT1`. The last date in `TT2` is the last business date on or before the last date in `TT1`.

# convert2weekly

Aggregate timetable data to weekly periodicity

## Syntax

```
TT2 = convert2weekly(TT1)
TT2 = convert2weekly( ___, Name, Value)
```

## Description

TT2 = convert2weekly(TT1) aggregates data (for example, data recorded daily) to a weekly periodicity.

TT2 = convert2weekly( \_\_\_, Name, Value) uses additional options specified by one or more name-value arguments.

## Examples

### Aggregate Timetable Daily Data to Weekly Periodicity

Apply separate aggregation methods to related variables in a `timetable` while maintaining consistency between aggregated results when converting from a daily to a weekly periodicity. You can use `convert2weekly` to aggregate both intra-daily data and aggregated daily data. These methods result in equivalent weekly aggregates.

Load a timetable (TT) of simulated stock price data and corresponding logarithmic returns. The data stored in TT is recorded at various times throughout the day on New York Stock Exchange (NYSE) business days from January 1, 2018, to December 31, 2020. The timetable TT also includes NYSE business calendar awareness. If your timetable does not account for nonbusiness days (weekends, holidays, and market closures), add business calendar awareness by using `addBusinessCalendar` first.

```
load('SimulatedStock.mat', 'TT');
head(TT)
```

```
ans=8x2 timetable
      Time      Price      Log_Return
-----
02-Jan-2018 11:52:11  100.71  0.0070749
02-Jan-2018 13:23:09  103.11  0.023551
02-Jan-2018 14:45:30  100.24 -0.028229
02-Jan-2018 15:30:48  101.37  0.01121
03-Jan-2018 10:02:21  101.81  0.0043311
03-Jan-2018 11:22:37  100.17 -0.01624
03-Jan-2018 14:45:20   99.66 -0.0051043
03-Jan-2018 14:55:39  100.12  0.0046051
```

Use `convert2daily` to aggregate intra-daily prices and returns to daily periodicity. To maintain consistency between prices and returns, for any given trading day, aggregate prices by reporting the

last recorded price with "lastvalue" and aggregate returns by summing all logarithmic returns with "sum".

```
TT1 = convert2daily(TT, 'Aggregation', ["lastvalue" "sum"]);
head(TT1)
```

```
ans=8x2 timetable
      Time      Price      Log_Return
      -----
02-Jan-2018    101.37     0.013607
03-Jan-2018    100.12    -0.012408
04-Jan-2018    106.76     0.064214
05-Jan-2018    112.78     0.054856
08-Jan-2018    119.07     0.054273
09-Jan-2018    119.46     0.00327
10-Jan-2018    124.44     0.040842
11-Jan-2018    125.63     0.0095174
```

Use `convert2weekly` to aggregate the data to a weekly periodicity and compare the results of two different aggregation approaches. The first approach computes weekly results by aggregating the daily aggregates and the second approach computes weekly results by directly aggregating the original intra-daily data.

```
tt1 = convert2weekly(TT1, 'Aggregation', ["lastvalue" "sum"]); % Daily to weekly
tt2 = convert2weekly(TT, 'Aggregation', ["lastvalue" "sum"]); % Intra-daily to weekly
```

```
head(tt1)
```

```

19-Jan-2018    117.67    -0.067842
26-Jan-2018    118.8     0.0095573
02-Feb-2018    120.85     0.017109
09-Feb-2018    123.68     0.023147
16-Feb-2018    124.33     0.0052417
23-Feb-2018    127.09     0.021956
```

Notice that the results of the two approaches are the same and that `convert2weekly` reports on Fridays by default. For weeks in which Friday is not an NYSE trading day, the function reports results on the previous business day. In addition, you can use the `convert2weekly` optional name-value pair argument `'EndOfWeekDay'` to specify a different day of the week that ends business weeks.

## Input Arguments

### TT1 — Data to aggregate to weekly periodicity

`timetable`

Data to aggregate to a weekly periodicity, specified as a timetable.

Each variable can be a numeric vector (univariate series) or numeric matrix (multivariate series).

---

#### Note

- NaNs indicate missing values.
  - Timestamps must be in ascending or descending order.
- 

By default, all days are business days. If your timetable does not account for nonbusiness days (weekends, holidays, and market closures), add business calendar awareness by using `addBusinessCalendar` first. For example, the following command adds business calendar logic to include only NYSE business days.

```
TT = addBusinessCalendar(TT);
```

Data Types: `timetable`

### Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1, ..., NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Example: `TT2 = convert2weekly(TT1, 'Aggregation', ["lastvalue" "sum"])`

### Aggregation — Aggregation method for TT1 data for intra-week or inter-day aggregation

`"lastvalue"` (default) | `"sum"` | `"prod"` | `"mean"` | `"min"` | `"max"` | `"firstvalue"` | character vector | function handle | string vector | cell vector of character vectors or function handles

Aggregation method for `TT1` defining how data is aggregated over business days in an intra-week or inter-day periodicity, specified as one of the following methods, a string vector of methods, or a length `numVariables` cell vector of methods, where `numVariables` is the number of variables in `TT1`.

- `"sum"` — Sum the values in each year or day.
- `"mean"` — Calculate the mean of the values in each year or day.
- `"prod"` — Calculate the product of the values in each year or day.
- `"min"` — Calculate the minimum of the values in each year or day.
- `"max"` — Calculate the maximum of the values in each year or day.

- "firstvalue" — Use the first value in each year or day.
- "lastvalue" — Use the last value in each year or day.
- @customfcn — A custom aggregation method that accepts a table variable and returns a numeric scalar (for univariate series) or row vector (for multivariate series). The function must accept empty inputs [].

If you specify a single method, `convert2weekly` applies the specified method to all time series in `TT1`. If you specify a string vector or cell vector `aggregation`, `convert2weekly` applies `aggregation(j)` to `TT1(:,j)`; `convert2weekly` applies each aggregation method one at a time (for more details, see `retime`). For example, consider a daily timetable representing `TT1` with three variables.

| Time        | AAA    | BBB    | CCC    |        |
|-------------|--------|--------|--------|--------|
| 01-Jan-2018 | 100.00 | 200.00 | 300.00 | 400.00 |
| 02-Jan-2018 | 100.03 | 200.06 | 300.09 | 400.12 |
| 03-Jan-2018 | 100.07 | 200.14 | 300.21 | 400.28 |
| 04-Jan-2018 | 100.08 | 200.16 | 300.24 | 400.32 |
| 05-Jan-2018 | 100.25 | 200.50 | 300.75 | 401.00 |
| 06-Jan-2018 | 100.19 | 200.38 | 300.57 | 400.76 |
| 07-Jan-2018 | 100.54 | 201.08 | 301.62 | 402.16 |
| 08-Jan-2018 | 100.59 | 201.18 | 301.77 | 402.36 |
| 09-Jan-2018 | 101.40 | 202.80 | 304.20 | 405.60 |
| 10-Jan-2018 | 101.94 | 203.88 | 305.82 | 407.76 |
| 11-Jan-2018 | 102.53 | 205.06 | 307.59 | 410.12 |
| 12-Jan-2018 | 103.35 | 206.70 | 310.05 | 413.40 |
| 13-Jan-2018 | 103.40 | 206.80 | 310.20 | 413.60 |
| 14-Jan-2018 | 103.91 | 207.82 | 311.73 | 415.64 |
| 15-Jan-2018 | 103.89 | 207.78 | 311.67 | 415.56 |
| 16-Jan-2018 | 104.44 | 208.88 | 313.32 | 417.76 |
| 17-Jan-2018 | 104.44 | 208.88 | 313.32 | 417.76 |
| 18-Jan-2018 | 104.04 | 208.08 | 312.12 | 416.16 |
| 19-Jan-2018 | 104.94 | 209.88 | 314.82 | 419.76 |

The corresponding default weekly results representing `TT2` (in which all days are business days and the 'lastvalue' is reported on Fridays) are as follows.

| Time        | AAA    | BBB    | CCC    |        |
|-------------|--------|--------|--------|--------|
| 05-Jan-2018 | 100.25 | 200.50 | 300.75 | 401.00 |
| 12-Jan-2018 | 103.35 | 206.70 | 310.05 | 413.40 |
| 19-Jan-2018 | 104.94 | 209.88 | 314.82 | 419.76 |

The default 'lastvalue' returns the latest observed in a given week for all variables in `TT1`.

All methods omit missing data (NaNs) in direct aggregation calculations on each variable. However, for situations in which missing values appear in the first row of `TT1`, missing values can also appear in the aggregated results `TT2`. To address missing data, write and specify a custom aggregation method (function handle) that supports missing data.

Data Types: char | string | cell | function\_handle

#### Daily — Intra-day aggregation method for `TT1`

"lastvalue" (default) | "sum" | "prod" | "mean" | "min" | "max" | "firstvalue" | character vector | function handle | string vector | cell vector of character vectors or function handles

Intra-day aggregation method for TT1, specified as an aggregation method, a string vector of methods, or a length numVariables cell vector of methods. For more details on supported methods and behaviors, see the 'Aggregation' name-value argument.

Data Types: char | string | cell | function\_handle

### EndOfWeekDay — Day of week that ends business weeks

"Friday" (weeks end on Friday) (default) | scalar integer with value 1 through 7 | "Sunday" | "Monday" | "Tuesday" | "Wednesday" | "Thursday" | "Friday" | "Saturday" | character vector

Day of the week that ends business weeks, specified as a value in the table.

| Value            | Day Ending Each Week |
|------------------|----------------------|
| "Sunday" or 1    | Sunday               |
| "Monday" or 2    | Monday               |
| "Tuesday" or 3   | Tuesday              |
| "Wednesday" or 4 | Wednesday            |
| "Thursday" or 5  | Thursday             |
| "Friday" or 6    | Friday               |
| "Saturday" or 7  | Saturday             |

If the specified end-of-week day in a given week is not a business day, the preceding business day ends that week.

Data Types: double | char | string

## Output Arguments

### TT2 — Weekly data

timetable

Weekly data, returned as a timetable. The time arrangement of TT1 and TT2 are the same.

If a variable of TT1 has no business-day records during an annual period within the sampling time span, convert2weekly returns a NaN for that variable and annual period in TT2.

If the first week (week1) of TT1 contains at least one business day, the first date in TT2 is the last business date of week1. Otherwise, the first date in TT2 is the next end-of-week business date of TT1.

If the last week (weekT) of TT1 contains at least one business day, the last date in TT2 is the last business date of weekT. Otherwise, the last date in TT2 is the previous end-of-week business date of TT1.

# convert2monthly

Aggregate timetable data to monthly periodicity

## Syntax

```
TT2 = convert2monthly(TT1)
TT2 = convert2monthly(TT1,Name,Value)
```

## Description

TT2 = convert2monthly(TT1) aggregates data (for example, data recorded daily or weekly) to monthly periodicity.

TT2 = convert2monthly(TT1,Name,Value) uses additional options specified by one or more name-value arguments.

## Examples

### Aggregate Timetable Data to Monthly Periodicity

Apply separate aggregation methods to related variables in a `timetable` while maintaining consistency between aggregated results when converting to a monthly periodicity. You can use `convert2monthly` to aggregate both intra-daily data and aggregated daily data. These methods result in equivalent monthly aggregates. Lastly, you can aggregate results on a specific day of each month (for example, the 15th), rather than the default end of the month.

Load a timetable (TT) of simulated stock price data and corresponding logarithmic returns. The data stored in TT is recorded at various times throughout the day on New York Stock Exchange (NYSE) business days from January 1, 2018, to December 31, 2020. The timetable TT also includes NYSE business calendar awareness. If your timetable does not account for nonbusiness days (weekends, holidays, and market closures), add business calendar awareness by using `addBusinessCalendar` first.

```
load('SimulatedStock.mat','TT');
head(TT)
```

```
ans=8x2 timetable
      Time      Price      Log_Return
-----
02-Jan-2018 11:52:11  100.71  0.0070749
02-Jan-2018 13:23:09  103.11  0.023551
02-Jan-2018 14:45:30  100.24 -0.028229
02-Jan-2018 15:30:48  101.37  0.01121
03-Jan-2018 10:02:21  101.81  0.0043311
03-Jan-2018 11:22:37  100.17 -0.01624
03-Jan-2018 14:45:20   99.66 -0.0051043
03-Jan-2018 14:55:39  100.12  0.0046051
```

First aggregate intra-daily prices and returns to daily periodicity. To maintain consistency between prices and returns, for any given trading day aggregate prices by reporting the last recorded price using "lastvalue" and aggregate returns by summing all logarithmic returns using "sum".

```
TT1 = convert2daily(TT, 'Aggregation', ["lastvalue" "sum"]);
head(TT1)
```

```
ans=8x2 timetable
      Time      Price      Log_Return
      -----
02-Jan-2018  101.37      0.013607
03-Jan-2018  100.12     -0.012408
04-Jan-2018  106.76      0.064214
05-Jan-2018  112.78      0.054856
08-Jan-2018  119.07      0.054273
09-Jan-2018  119.46       0.00327
10-Jan-2018  124.44      0.040842
11-Jan-2018  125.63      0.0095174
```

Use `convert2monthly` to aggregate the data to a monthly periodicity and compare the results of two different approaches. The first approach computes monthly results by aggregating the daily aggregates and the second approach computes monthly results by directly aggregating the original intra-daily data. Note that although `convert2monthly` reports results on the last business day of each month by default, you can report monthly results on the 15th of each month by using the optional name-value pair argument 'EndOfMonthDay'.

```
tt1 = convert2monthly(TT1, 'Aggregation', ["lastvalue" "sum"], 'EndOfMonthDay', 15); % Daily to monthly
tt2 = convert2monthly(TT, 'Aggregation', ["lastvalue" "sum"], 'EndOfMonthDay', 15); % Intra-daily to monthly
```

```
head(tt1)
```

```
ans=8x2 timetable
      Time      Price      Log_Return
      -----
12-Jan-2018  125.93      0.23056
15-Feb-2018  120.55     -0.043662
15-Mar-2018  113.49     -0.06035
13-Apr-2018  112.07     -0.012591
15-May-2018  110.47     -0.01438
15-Jun-2018   99.06     -0.10902
13-Jul-2018   95.74     -0.03409
15-Aug-2018   99.94      0.042934
```

```
head(tt2)
```

```
ans=8x2 timetable
      Time      Price      Log_Return
      -----
12-Jan-2018  125.93      0.23056
15-Feb-2018  120.55     -0.043662
15-Mar-2018  113.49     -0.06035
13-Apr-2018  112.07     -0.012591
15-May-2018  110.47     -0.01438
```

```

15-Jun-2018    99.06    -0.10902
13-Jul-2018    95.74    -0.03409
15-Aug-2018    99.94     0.042934

```

Notice that the results of the two approaches are the same. For months in which the 15th is not an NYSE trading day, the function reports results on the previous business day.

### Use Custom Aggregation Method to Convert Timetable Daily Data to Monthly Periodicity

You can apply custom aggregation methods using function handles. Specify a function handle to aggregate related variables in a `timetable` while maintaining consistency between aggregated results when converting from a daily to a monthly periodicity.

Load a timetable (TT) of simulated stock price data and corresponding logarithmic returns. The data stored in TT is recorded at various times throughout the day on New York Stock Exchange (NYSE) business days from January 1, 2018, to December 31, 2020. The timetable TT also includes NYSE business calendar awareness. If your timetable does not account for nonbusiness days (weekends, holidays, and market closures), add business calendar awareness by using `addBusinessCalendar` first.

```

load('SimulatedStock.mat','TT')
head(TT)

```

```

ans=8x2 timetable
      Time          Price    Log_Return

```

```
03-Jan-2018 14:55:39    100.12    0.0046051    0.0046157
```

Create a function to aggregate simple returns and compute the monthly aggregates. To maintain consistency between prices and returns, for any given month, aggregate prices by reporting the last recorded price by using "lastvalue" and report logarithmic returns by summing all intervening logarithmic returns by using "sum".

Notice that the aggregation function for simple returns operates along the first (row) dimension and omits missing data (NaNs). For more information on custom aggregation functions, see `timetable` and `retime`. When aggregation methods are a mix of supported methods and user-supplied functions, the 'Aggregation' name-value pair argument must be specified as a cell vector of methods enclosed in curly braces.

```
f = @(x)(prod(1 + x,1,'omitnan') - 1);    % Aggregate simple returns
tt = convert2monthly(TT,'Aggregation',{ 'lastvalue' 'sum' f});
head(tt)
```

```
ans=8x3 timetable

```

## Input Arguments

### TT1 — Data to aggregate to monthly periodicity

timetable

Data to aggregate to a monthly periodicity, specified as a timetable.

Each variable can be a numeric vector (univariate series) or numeric matrix (multivariate series).

---

### Note

- NaNs indicate missing values.
  - Timestamps must be in ascending or descending order.
- 

By default, all days are business days. If your timetable does not account for nonbusiness days (weekends, holidays, and market closures), add business calendar awareness by using `addBusinessCalendar` first. For example, the following command adds business calendar logic to include only NYSE business days.

```
TT = addBusinessCalendar(TT);
```

Data Types: timetable

### Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1, ..., NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Example: `TT2 = convert2monthly(TT1, 'Aggregation', ["lastvalue" "sum"])`

### Aggregation — Aggregation method for TT1

"lastvalue" (default) | "sum" | "prod" | "mean" | "min" | "max" | "firstvalue" | character vector | function handle | string vector | cell vector of character vectors or function handles

Aggregation method for `TT1` defining how to aggregate data over business days in an intra-month or inter-day periodicity, specified as one of the following methods, a string vector of methods, or a length `numVariables` cell vector of methods, where `numVariables` is the number of variables in `TT1`.

- "sum" — Sum the values in each year or day.
- "mean" — Calculate the mean of the values in each year or day.
- "prod" — Calculate the product of the values in each year or day.
- "min" — Calculate the minimum of the values in each year or day.
- "max" — Calculate the maximum of the values in each year or day.
- "firstvalue" — Use the first value in each year or day.
- "lastvalue" — Use the last value in each year or day.
- @customfcn — A custom aggregation method that accepts a table variable and returns a numeric scalar (for univariate series) or row vector (for multivariate series). The function must accept empty inputs `[]`.

If you specify a single method, `convert2monthly` applies the specified method to all time series in `TT1`. If you specify a string vector or cell vector aggregation, `convert2monthly` applies `aggregation(j)` to `TT1(:,j)`; `convert2monthly` applies each aggregation method one at a time (for more details, see `retime`). For example, consider a daily timetable representing `TT1` with three variables.

| Time        | AAA    | BBB    | CCC    |        |
|-------------|--------|--------|--------|--------|
| 01-Jan-2018 | 100.00 | 200.00 | 300.00 | 400.00 |
| 02-Jan-2018 | 100.03 | 200.06 | 300.09 | 400.12 |
| 03-Jan-2018 | 100.07 | 200.14 | 300.21 | 400.28 |
| .           | .      | .      | .      | .      |
| .           | .      | .      | .      | .      |
| .           | .      | .      | .      | .      |
| 31-Jan-2018 | 114.65 | 229.3  | 343.95 | 458.60 |

| 28-Feb-2018 | 129.19 | 258.38 | 387.57 | 516.76 |
| .           | .      | .      | .      | .      |
| .           | .      | .      | .      | .      |
| .           | .      | .      | .      | .      |
| 31-Mar-2018 | 162.93 | 325.86 | 488.79 | 651.72 |
| .           | .      | .      | .      | .      |

|             |        |        |        |        |
|-------------|--------|--------|--------|--------|
| .           | .      | .      | .      | .      |
| .           | .      | .      | .      | .      |
| 30-Apr-2018 | 171.72 | 343.44 | 515.16 | 686.88 |
| .           | .      | .      | .      | .      |
| .           | .      | .      | .      | .      |
| 31-May-2018 | 201.24 | 402.48 | 603.72 | 804.96 |
| .           | .      | .      | .      | .      |
| .           | .      | .      | .      | .      |
| 30-Jun-2018 | 223.22 | 446.44 | 669.66 | 892.88 |

The corresponding default monthly results representing TT2 (in which all days are business days and the 'lastvalue' is reported on the last business day of each month) are as follows.

| Time        | AAA    | BBB    | CCC    |        |
|-------------|--------|--------|--------|--------|
| 31-Jan-2018 | 114.65 | 229.30 | 343.95 | 458.60 |
| 28-Feb-2018 | 129.19 | 258.38 | 387.57 | 516.76 |
| 31-Mar-2018 | 162.93 | 325.86 | 488.79 | 651.72 |
| 30-Apr-2018 | 171.72 | 343.44 | 515.16 | 686.88 |
| 31-May-2018 | 201.24 | 402.48 | 603.72 | 804.96 |
| 30-Jun-2018 | 223.22 | 446.44 | 669.66 | 892.88 |

All methods omit missing data (NaNs) in direct aggregation calculations on each variable. However, for situations in which missing values appear in the first row of TT1, missing values can also appear in the aggregated results TT2. To address missing data, write and specify a custom aggregation method (function handle) that supports missing data.

Data Types: char | string | cell | function\_handle

### Daily — Intra-day aggregation method for TT1

"lastvalue" (default) | "sum" | "prod" | "mean" | "min" | "max" | "firstvalue" | character vector | function handle | string vector | cell vector of character vectors or function handles

Intra-day aggregation method for TT1, specified as an aggregation method, a string vector of methods, or a length numVariables cell vector of methods. For more details on supported methods and behaviors, see the 'Aggregation' name-value argument.

Data Types: char | string | cell | function\_handle

### EndOfMonthDay — Day of the month that ends months

last business day of month (default) | integer with value 1 to 31

Day of the month that ends months, specified as a scalar integer with value 1 to 31. For months with fewer days than EndOfMonthDay, convert2monthly reports aggregation results on the last business day of the month.

Data Types: double

## Output Arguments

### TT2 — Monthly data

timetable

Monthly data, returned as a timetable. The time arrangement of TT1 and TT2 are the same.

If a variable of TT1 has no business-day records during a month within the sampling time span, `convert2monthly` returns a NaN for that variable and month in TT2.

If the first month (`month1`) of TT1 contains at least one business day, the first date in TT2 is the last business date of `month1`. Otherwise, the first date in TT2 is the next end-of-month business date of TT1.

If the last month (`monthT`) of TT1 contains at least one business day, the last date in TT2 is the last business date of `monthT`. Otherwise, the last date in TT2 is the previous end-of-month business date of TT1.

## convert2quarterly

Aggregate timetable data to quarterly periodicity

### Syntax

```
TT2 = convertquarterly(TT1)
TT2 = convert2quarterly(TT1,Name,Value)
```

### Description

TT2 = convertquarterly(TT1) aggregates data (for example, data recorded daily or weekly) to a quarterly periodicity.

TT2 = convert2quarterly(TT1,Name,Value) uses additional options specified by one or more name-value arguments.

### Examples

#### Aggregate Timetable Data to Quarterly Periodicity

Apply separate aggregation methods to related variables in a `timetable` while maintaining consistency between aggregated results when converting to a quarterly periodicity. You can use `convert2quarterly` to aggregate both intra-daily data and aggregated monthly data. These methods result in equivalent quarterly aggregates.

Load a timetable (TT) of simulated stock price data and corresponding logarithmic returns. The data stored in TT is recorded at various times throughout the day on New York Stock Exchange (NYSE) business days from January 1, 2018, to December 31, 2020. The timetable TT also includes NYSE business calendar awareness. If your timetable does not account for nonbusiness days (weekends, holidays, and market closures), add business calendar awareness by using `addBusinessCalendar` first.

```
load('SimulatedStock.mat','TT');
head(TT)
```

```
ans=8x2 timetable
      Time      Price      Log_Return
-----
02-Jan-2018 11:52:11  100.71  0.0070749
02-Jan-2018 13:23:09  103.11  0.023551
02-Jan-2018 14:45:30  100.24 -0.028229
02-Jan-2018 15:30:48  101.37  0.01121
03-Jan-2018 10:02:21  101.81  0.0043311
03-Jan-2018 11:22:37  100.17 -0.01624
03-Jan-2018 14:45:20   99.66 -0.0051043
03-Jan-2018 14:55:39  100.12  0.0046051
```

Use `convert2monthly` to aggregate intra-daily prices and returns to a monthly periodicity. To maintain consistency between prices and returns for any given month, aggregate prices by reporting

the last recorded price using "lastvalue" and aggregate returns by summing all logarithmic returns using "sum".

```
TT1 = convert2monthly(TT, 'Aggregation', ["lastvalue" "sum"]);
head(TT1)
```

```
ans=8x2 timetable
      Time      Price      Log_Return
      -----
31-Jan-2018    122.96      0.20669
28-Feb-2018    121.92     -0.008494
29-Mar-2018     108.9      -0.11294
30-Apr-2018    110.38      0.013499
31-May-2018     99.02     -0.10861
29-Jun-2018     96.24     -0.028477
31-Jul-2018     97.15      0.0094111
31-Aug-2018    101.51      0.043901
```

Use `convert2quarterly` to aggregate the data to a quarterly periodicity and compare the results of two different approaches. The first approach computes quarterly results by aggregating the monthly aggregates and the second approach computes quarterly results by directly aggregating the original intra-daily data. Note that `convert2quarterly` reports results on the last business day of each quarter.

```
tt1 = convert2quarterly(TT1, 'Aggregation', ["lastvalue" "sum"]); % Monthly to quarterly
tt2 = convert2quarterly(TT, 'Aggregation', ["lastvalue" "sum"]); % Intra-daily to quarterly
```

```
head(tt1)
```

```
ans=8x2 timetable
      Time      Price      Log_Return
      -----
29-Mar-2018     108.9      0.08526
29-Jun-2018     96.24     -0.12358
28-Sep-2018    111.37      0.14601
31-Dec-2018     92.72     -0.18327
29-Mar-2019     78.7      -0.16394
28-Jun-2019    110.54      0.33973
30-Sep-2019    180.13      0.4883
31-Dec-2019    163.65     -0.095949
```

```
head(tt2)
```

```
ans=8x2 timetable
      Time      Price      Log_Return
      -----
29-Mar-2018     108.9      0.08526
29-Jun-2018     96.24     -0.12358
28-Sep-2018    111.37      0.14601
31-Dec-2018     92.72     -0.18327
29-Mar-2019     78.7      -0.16394
28-Jun-2019    110.54      0.33973
30-Sep-2019    180.13      0.4883
```

```
31-Dec-2019    163.65    -0.095949
```

The results of the two approaches are the same because each quarter contains exactly three calendar months.

## Input Arguments

### TT1 — Data to aggregate to quarterly periodicity

timetable

Data to aggregate to a quarterly periodicity, specified as a timetable.

Each variable can be a numeric vector (univariate series) or numeric matrix (multivariate series).

---

#### Note

- NaNs indicate missing values.
  - Timestamps must be in ascending or descending order.
- 

By default, all days are business days. If your timetable does not account for nonbusiness days (weekends, holidays, and market closures), add business calendar awareness by using `addBusinessCalendar` first. For example, the following command adds business calendar logic to include only NYSE business days.

```
TT = addBusinessCalendar(TT);
```

Data Types: timetable

### Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1, ..., NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Example: `TT2 = convert2quarterly(TT1, 'Aggregation', ["lastvalue" "sum"])`

### Aggregation — Aggregation method for TT1 data for intra-quarter or inter-day aggregation

"lastvalue" (default) | "sum" | "prod" | "mean" | "min" | "max" | "firstvalue" | character vector | function handle | string vector | cell vector of character vectors or function handles

Aggregation method for TT1 data defining how to aggregate data over business days in an intra-quarter or inter-day periodicity, specified as one of the following methods, a string vector of methods, or a length `numVariables` cell vector of methods, where `numVariables` is the number of variables in TT1.

- "sum" — Sum the values in each year or day.
- "mean" — Calculate the mean of the values in each year or day.
- "prod" — Calculate the product of the values in each year or day.
- "min" — Calculate the minimum of the values in each year or day.

- "max" — Calculate the maximum of the values in each year or day.
- "firstvalue" — Use the first value in each year or day.
- "lastvalue" — Use the last value in each year or day.
- @customfcn — A custom aggregation method that accepts a table variable and returns a numeric scalar (for univariate series) or row vector (for multivariate series). The function must accept empty inputs [].

If you specify a single method, `convert2quarterly` applies the specified method to all time series in `TT1`. If you specify a string vector or cell vector `aggregation`, `convert2quarterly` applies `aggregation(j)` to `TT1(:,j)`; `convert2quarterly` applies each aggregation method one at a time (for more details, see `retime`). For example, consider a daily timetable representing `TT1` with three variables.

| Time        | AAA    | BBB    | CCC    |        |
|-------------|--------|--------|--------|--------|
| 01-Jan-2018 | 100.00 | 200.00 | 300.00 | 400.00 |
| 02-Jan-2018 | 100.03 | 200.06 | 300.09 | 400.12 |
| 03-Jan-2018 | 100.07 | 200.14 | 300.21 | 400.28 |
| .           | .      | .      | .      | .      |
| .           | .      | .      | .      | .      |
| 31-Mar-2018 | 162.93 | 325.86 | 488.79 | 651.72 |
| .           | .      | .      | .      | .      |
| .           | .      | .      | .      | .      |
| 30-Jun-2018 | 223.22 | 446.44 | 669.66 | 892.88 |
| .           | .      | .      | .      | .      |
| .           | .      | .      | .      | .      |
| 30-Sep-2018 | 232.17 | 464.34 | 696.51 | 928.68 |
| .           | .      | .      | .      | .      |
| .           | .      | .      | .      | .      |
| 31-Dec-2018 | 243.17 | 486.34 | 729.51 | 972.68 |

The corresponding default quarterly results representing `TT2` (in which all days are business days and the 'lastvalue' is reported on the last business day of each quarter) are as follows.

| Time        | AAA    | BBB    | CCC    |        |
|-------------|--------|--------|--------|--------|
| 31-Mar-2018 | 162.93 | 325.86 | 488.79 | 651.72 |
| 30-Jun-2018 | 223.22 | 446.44 | 669.66 | 892.88 |
| 30-Sep-2018 | 232.17 | 464.34 | 696.51 | 928.68 |
| 31-Dec-2018 | 243.17 | 486.34 | 729.51 | 972.68 |

All methods omit missing data (NaNs) in direct aggregation calculations on each variable. However, for situations in which missing values appear in the first row of `TT1`, missing values can also appear in the aggregated results `TT2`. To address missing data, write and specify a custom aggregation method (function handle) that supports missing data.

Data Types: char | string | cell | function\_handle

#### Daily — Intra-day aggregation method for `TT1`

"lastvalue" (default) | "sum" | "prod" | "mean" | "min" | "max" | "firstvalue" | character vector | function handle | string vector | cell vector of character vectors or function handles

Intra-day aggregation method for TT1, specified as an aggregation method, a string vector of methods, or a length `numVariables` cell vector of methods. For more details on supported methods and behaviors, see the 'Aggregation' name-value argument.

Data Types: `char` | `string` | `cell` | `function_handle`

## Output Arguments

### TT2 — Quarterly data

`timetable`

Quarterly data, returned as a timetable. The time arrangement of TT1 and TT2 are the same.

`convert2quarterly` reports quarterly aggregation results on the last business day of March, June, September, and December.

If a variable of TT1 has no business-day records during an quarter within the sampling time span, `convert2quarterly` returns a NaN for that variable and quarter in TT2.

If the first quarter (Q1) of TT1 contains at least one business day, the first date in TT2 is the last business date of Q1. Otherwise, the first date in TT2 is the next end-of-quarter business date of TT1.

If the last quarter (QT) of TT1 contains at least one business day, the last date in TT2 is the last business date of QT. Otherwise, the last date in TT2 is the previous end-of-quarter business date of TT1.

# convert2semiannual

Aggregate timetable data to semiannual periodicity

## Syntax

```
TT2 = convert2semiannual(TT1)
TT2 = convert2semiannual(TT1,Name,Value)
```

## Description

`TT2 = convert2semiannual(TT1)` aggregates data (for example, data recorded daily or weekly) to a semiannual periodicity.

`TT2 = convert2semiannual(TT1,Name,Value)` uses additional options specified by one or more name-value arguments.

## Examples

### Aggregate Timetable Data to Semiannual Periodicity

Apply separate aggregation methods to related variables in a `timetable` while maintaining consistency between aggregated results when converting to a semiannual periodicity. You can use `convert2semiannual` to aggregate both intra-daily data and aggregated quarterly data. These methods result in equivalent semiannual aggregates.

Load a timetable (TT) of simulated stock price data and corresponding logarithmic returns. The data stored in TT is recorded at various times throughout the day on New York Stock Exchange (NYSE) business days from January 1, 2018 to December 31, 2020. The timetable TT also includes NYSE business calendar awareness. If your timetable does not account for nonbusiness days (weekends, holidays, and market closures), add business calendar awareness by using `addBusinessCalendar` first.

```

03-Jan-2018 14:55:39  100.12  0.0046051
```

Use `convert2quarterly` to aggregate intra-daily prices and returns to a quarterly periodicity. To maintain consistency between prices and returns, for any given quarter, aggregate prices by

reporting the last recorded price using "lastvalue" and aggregate returns by summing all logarithmic returns using "sum".

```
TT1 = convert2quarterly(TT, 'Aggregation', ["lastvalue" "sum"])
```

```
TT1=12×2 timetable
```

| Time        | Price  | Log_Return |
|-------------|--------|------------|
| 29-Mar-2018 | 108.9  | 0.08526    |
| 29-Jun-2018 | 96.24  | -0.12358   |
| 28-Sep-2018 | 111.37 | 0.14601    |
| 31-Dec-2018 | 92.72  | -0.18327   |
| 29-Mar-2019 | 78.7   | -0.16394   |
| 28-Jun-2019 | 110.54 | 0.33973    |
| 30-Sep-2019 | 180.13 | 0.4883     |
| 31-Dec-2019 | 163.65 | -0.095949  |
| 31-Mar-2020 | 177.46 | 0.081015   |
| 30-Jun-2020 | 168.96 | -0.049083  |
| 30-Sep-2020 | 260.77 | 0.43398    |
| 31-Dec-2020 | 274.75 | 0.052223   |

Use `convert2semiannual` to aggregate the data to a semiannual periodicity and compare the results of two different approaches. The first approach computes semiannual results by aggregating the quarterly aggregates and the second approach computes semiannual results by directly aggregating the original intra-daily data. Note that `convert2semiannual` reports results on the last business day of June and December.

```
tt1 = convert2semiannual(TT1, 'Aggregation', ["lastvalue" "sum"]) % Quarterly to semiannual
```

```
tt1=6×2 timetable
```

| Time        | Price  | Log_Return |
|-------------|--------|------------|
| 29-Jun-2018 | 96.24  | -0.038325  |
| 31-Dec-2018 | 92.72  | -0.037261  |
| 28-Jun-2019 | 110.54 | 0.17579    |
| 31-Dec-2019 | 163.65 | 0.39235    |
| 30-Jun-2020 | 168.96 | 0.031932   |
| 31-Dec-2020 | 274.75 | 0.4862     |

```
tt2 = convert2semiannual(TT , 'Aggregation', ["lastvalue" "sum"]) % Intra-daily to semiannual
```

```
tt2=6×2 timetable
```

| Time        | Price  | Log_Return |
|-------------|--------|------------|
| 29-Jun-2018 | 96.24  | -0.038325  |
| 31-Dec-2018 | 92.72  | -0.037261  |
| 28-Jun-2019 | 110.54 | 0.17579    |
| 31-Dec-2019 | 163.65 | 0.39235    |
| 30-Jun-2020 | 168.96 | 0.031932   |
| 31-Dec-2020 | 274.75 | 0.4862     |

The results of the two approaches are the same because each semiannual period contains exactly two calendar quarters.

## Input Arguments

### TT1 — Data to aggregate to semiannual periodicity

timetable

Data to aggregate to a semiannual periodicity, specified as a timetable.

Each variable can be a numeric vector (univariate series) or numeric matrix (multivariate series).

---

#### Note

- NaNs indicate missing values.
  - Timestamps must be in ascending or descending order.
- 

By default, all days are business days. If your timetable does not account for nonbusiness days (weekends, holidays, and market closures), add business calendar awareness by using `addBusinessCalendar` first. For example, the following command adds business calendar logic to include only NYSE business days.

```
TT = addBusinessCalendar(TT);
```

Data Types: timetable

### Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1, . . . , NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Example: `TT2 = convert2semiannual(TT1, 'Aggregation', ["lastvalue" "sum"])`

### Aggregation — Aggregation method for semiannual period to semiannual periodicity (inter-day aggregation)

"lastvalue" (default) | "sum" | "prod" | "mean" | "min" | "max" | "firstvalue" | character vector | function handle | string vector | cell vector of character vectors or function handles

Aggregation method for TT1 defining how data is aggregated over business days in a semiannual period to semiannual periodicity aggregation, specified as one of the following methods, a string vector of methods, or a length `numVariables` cell vector of methods, where `numVariables` is the number of variables in TT1.

- "sum" — Sum the values in each year or day.
- "mean" — Calculate the mean of the values in each year or day.
- "prod" — Calculate the product of the values in each year or day.
- "min" — Calculate the minimum of the values in each year or day.
- "max" — Calculate the maximum of the values in each year or day.
- "firstvalue" — Use the first value in each year or day.
- "lastvalue" — Use the last value in each year or day.

- `@customfcn` — A custom aggregation method that accepts a table variable and returns a numeric scalar (for univariate series) or row vector (for multivariate series). The function must accept empty inputs `[]`.

If you specify a single method, `convert2semiannual` applies the specified method to all time series in `TT1`. If you specify a string vector or cell vector aggregation, `convert2semiannual` applies `aggregation(j)` to `TT1(:,j)`; `convert2semiannual` applies each aggregation method one at a time (for more details, see `retime`). For example, consider a daily timetable representing `TT1` with three variables.

| Time        | AAA    | BBB    | CCC    |         |
|-------------|--------|--------|--------|---------|
| 01-Jan-2018 | 100.00 | 200.00 | 300.00 | 400.00  |
| 02-Jan-2018 | 100.02 | 200.04 | 300.06 | 400.08  |
| 03-Jan-2018 | 99.96  | 199.92 | 299.88 | 399.84  |
| .           | .      | .      | .      | .       |
| .           | .      | .      | .      | .       |
| .           | .      | .      | .      | .       |
| 28-Jun-2018 | 69.63  | 139.26 | 208.89 | 278.52  |
| 29-Jun-2018 | 70.15  | 140.3  | 210.45 | 280.60  |
| 30-Jun-2018 | 75.77  | 151.54 | 227.31 | 303.08  |
| 01-Jul-2018 | 75.68  | 151.36 | 227.04 | 302.72  |
| 02-Jul-2018 | 71.34  | 142.68 | 214.02 | 285.36  |
| 03-Jul-2018 | 69.25  | 138.50 | 207.75 | 277.00  |
| .           | .      | .      | .      | .       |
| .           | .      | .      | .      | .       |
| .           | .      | .      | .      | .       |
| 29-Dec-2018 | 249.16 | 498.32 | 747.48 | 996.64  |
| 30-Dec-2018 | 250.21 | 500.42 | 750.63 | 1000.84 |
| 31-Dec-2018 | 256.75 | 513.50 | 770.25 | 1027.00 |

The corresponding default semiannual results representing `TT2` (in which all days are business days and the `'lastvalue'` is reported on the last business day of each semiannual period) are as follows.

| Time        | AAA    | BBB    | CCC    |         |
|-------------|--------|--------|--------|---------|
| 30-Jun-2018 | 75.77  | 151.54 | 227.31 | 303.08  |
| 31-Dec-2018 | 256.75 | 513.50 | 770.25 | 1027.00 |

All methods omit missing data (NaNs) in direct aggregation calculations on each variable. However, for situations in which missing values appear in the first row of `TT1`, missing values can also appear in the aggregated results `TT2`. To address missing data, write and specify a custom aggregation method (function handle) that supports missing data.

Data Types: `char` | `string` | `cell` | `function_handle`

#### Daily — Intra-day aggregation method for `TT1`

`"lastvalue"` (default) | `"sum"` | `"prod"` | `"mean"` | `"min"` | `"max"` | `"firstvalue"` | character vector | function handle | string vector | cell vector of character vectors or function handles

Intra-day aggregation method for `TT1`, specified as an aggregation method, a string vector of methods, or a length `numVariables` cell vector of methods. For more details on supported methods and behaviors, see the `'Aggregation'` name-value argument.

Data Types: `char` | `string` | `cell` | `function_handle`

## Output Arguments

### TT2 — Semiannual data

timetable

Semiannual data, returned as a timetable. `convert2semiannual` reports semiannual aggregation results on the last business day of June and December. The function returns NaNs for variables in TT2 for semiannual periods when no data is recorded on any business days for those variables in TT1. If TT1 is in ascending order, so too is TT2, and if TT1 is in descending order, so too is TT2.

The first date in TT2 is the last business date of the semiannual period in which the first date in TT1 occurs, provided TT1 has business dates in that semiannual period, otherwise the first date in TT2 is the next end-of-semiannual-period business date.

The last date in TT2 is the last business date of the semiannual period in which the last date in TT1 occurs, provided TT1 has business dates in that semiannual period, otherwise the last date in TT2 is the previous end-of-semiannual-period business date.

## convert2annual

Aggregate timetable data to annual periodicity

### Syntax

```
TT2 = convert2annual(TT1)
TT2 = convert2annual(TT1,Name,Value)
```

### Description

`TT2 = convert2annual(TT1)` aggregates data (for example, recorded daily or weekly data) to annual periodicity.

`TT2 = convert2annual(TT1,Name,Value)` uses additional options specified by one or more name-value arguments.

### Examples

#### Aggregate Timetable Data to Annual Periodicity

Apply separate aggregation methods to related variables in a `timetable` while maintaining consistency between aggregated results when converting to an annual periodicity. You can use `convert2annual` to aggregate both intra-daily data and aggregated monthly data. These methods result in equivalent annual aggregates.

Load a timetable (TT) of simulated stock price data and corresponding logarithmic returns. The data stored in TT is recorded at various times throughout the day on New York Stock Exchange (NYSE) business days from January 1, 2018, to December 31, 2020. The timetable TT also includes NYSE business calendar awareness. If your timetable does not account for nonbusiness days (weekends, holidays, and market closures), add business calendar awareness by using `addBusinessCalendar` first.

```
load('SimulatedStock.mat','TT');
head(TT)
```

```
ans=8x2 timetable
      Time      Price      Log_Return
-----
02-Jan-2018 11:52:11  100.71  0.0070749
02-Jan-2018 13:23:09  103.11  0.023551
02-Jan-2018 14:45:30  100.24 -0.028229
02-Jan-2018 15:30:48  101.37  0.01121
03-Jan-2018 10:02:21  101.81  0.0043311
03-Jan-2018 11:22:37  100.17 -0.01624
03-Jan-2018 14:45:20   99.66 -0.0051043
03-Jan-2018 14:55:39  100.12  0.0046051
```

First, aggregate intra-daily prices and returns to a monthly periodicity. To maintain consistency between prices and returns, for any given month aggregate prices by reporting the last recorded price using "lastvalue" and aggregate returns by summing all logarithmic returns using "sum".

```
TT1 = convert2monthly(TT, 'Aggregation', ["lastvalue" "sum"]);
head(TT1)
```

```
ans=8x2 timetable
      Time      Price      Log_Return
      -----
31-Jan-2018    122.96      0.20669
28-Feb-2018    121.92     -0.008494
29-Mar-2018     108.9     -0.11294
30-Apr-2018    110.38      0.013499
31-May-2018     99.02     -0.10861
29-Jun-2018     96.24     -0.028477
31-Jul-2018     97.15      0.0094111
31-Aug-2018    101.51      0.043901
```

Use `convert2annual` to aggregate the data to an annual periodicity and compare the results of the two different aggregation approaches. The first approach computes annual results by aggregating the monthly aggregates and the second approach computes annual results by directly aggregating the original intra-daily data. Notice that by default, `convert2annual` reports results on the last business day of December. To change the month that ends annual periods, use the 'EndOfYearMonth' name-value pair argument for `convert2annual`.

```
tt1 = convert2annual(TT1, 'Aggregation', ["lastvalue" "sum"]) % Monthly to annual
```

```
tt1=3x2 timetable
      Time      Price      Log_Return
      -----
31-Dec-2018     92.72     -0.075586
31-Dec-2019    163.65      0.56815
31-Dec-2020    274.75      0.51813
```

```
tt2 = convert2annual(TT, 'Aggregation', ["lastvalue" "sum"]) % Intra-daily to semiannual
```

```
tt2=3x2 timetable
      Time      Price      Log_Return
      -----
31-Dec-2018     92.72     -0.075586
31-Dec-2019    163.65      0.56815
31-Dec-2020    274.75      0.51813
```

The results of the two approaches are the same because each annual period contains exactly 12 calendar months.

## Input Arguments

### TT1 — Data to aggregate to annual periodicity

timetable

Data to aggregate to an annual periodicity, specified as a timetable.

Each variable can be a numeric vector (univariate series) or numeric matrix (multivariate series).

---

### Note

- NaNs indicate missing values.
  - Timestamps must be in ascending or descending order.
- 

By default, all days are business days. If your timetable does not account for nonbusiness days (weekends, holidays, and market closures), add business calendar awareness by using `addBusinessCalendar` first. For example, the following command adds business calendar logic to include only NYSE business days.

```
TT = addBusinessCalendar(TT);
```

Data Types: `timetable`

### Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1, ..., NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Example: `TT2 = convert2annual(TT1, 'Aggregation', ["lastvalue" "sum"])`

### Aggregation — Aggregation method for TT1

"lastvalue" (default) | "sum" | "prod" | "mean" | "min" | "max" | "firstvalue" | character vector | function handle | string vector | cell vector of character vectors or function handles

Aggregation method for `TT1` defining how to aggregate data over business days in a year to an annual periodicity, specified as one of the following methods, a string vector of methods, or a length `numVariables` cell vector of methods, where `numVariables` is the number of variables in `TT1`.

- "sum" — Sum the values in each year or day.
- "mean" — Calculate the mean of the values in each year or day.
- "prod" — Calculate the product of the values in each year or day.
- "min" — Calculate the minimum of the values in each year or day.
- "max" — Calculate the maximum of the values in each year or day.
- "firstvalue" — Use the first value in each year or day.
- "lastvalue" — Use the last value in each year or day.
- `@customfcn` — A custom aggregation method that accepts a table variable and returns a numeric scalar (for univariate series) or row vector (for multivariate series). The function must accept empty inputs `[]`.

If you specify a single method, `convert2annual` applies the specified method to all time series in `TT1`. If you specify a string vector or cell vector aggregation, `convert2annual` applies `aggregation(j)` to `TT1(:,j)`; `convert2annual` applies each aggregation method one at a time (for more details, see `retime`). For example, consider an input daily timetable with three variables.

| Time        | AAA    | BBB    | CCC    |         |
|-------------|--------|--------|--------|---------|
| 01-Jan-2018 | 100.00 | 200.00 | 300.00 | 400.00  |
| 02-Jan-2018 | 100.03 | 200.06 | 300.09 | 400.12  |
| 03-Jan-2018 | 100.07 | 200.14 | 300.21 | 400.28  |
| .           | .      | .      | .      | .       |
| .           | .      | .      | .      | .       |
| 29-Dec-2018 | 249.16 | 498.32 | 747.48 | 996.64  |
| 30-Dec-2018 | 250.21 | 500.42 | 750.63 | 1000.84 |
| 31-Dec-2018 | 256.75 | 513.50 | 770.25 | 1027.00 |

By default, `convert2annual` applies the aggregation method "lastvalue", which reports for each variable the values of the last business day of each year. The aggregated annual results are as follows:

```
TT2 = convert2annual(TT1)
```

```
TT2 =
```

```
1×3 timetable
```

| Time        | AAA    | BBB    | CCC    |         |
|-------------|--------|--------|--------|---------|
| 31-Dec-2018 | 256.75 | 513.50 | 770.25 | 1027.00 |

All methods omit missing data (NaNs) in direct aggregation calculations on each variable. However, for situations in which missing values appear in the first row of `TT1`, missing values can also appear in the aggregated results `TT2`. To address missing data, write and specify a custom aggregation method (function handle) that supports missing data.

Data Types: char | string | cell | function\_handle

#### Daily — Intra-day aggregation method for TT1

"lastvalue" (default) | "sum" | "prod" | "mean" | "min" | "max" | "firstvalue" | character vector | function handle | string vector | cell vector of character vectors or function handles

Intra-day aggregation method for `TT1`, specified as an aggregation method, a string vector of methods, or a length `numVariables` cell vector of methods. For more details on supported methods and behaviors, see the 'Aggregation' name-value argument.

Data Types: char | string | cell | function\_handle

#### EndOfYearMonth — Month that ends annual periods

"December" (weeks end on Friday) (default) | integer with value 1 to 12 | "January" | "February" | "March" | "April" | "May" | "June" | "July" | "August" | "September" | "October" | "November" | "December" | character vector

Month that ends annual periods, specified as a value in this table.

| Value           | Month Ending Each Year |
|-----------------|------------------------|
| "January" or 1  | January                |
| "February" or 2 | February               |
| "March" or 3    | March                  |
| "April" or 4    | April                  |

| Value            | Month Ending Each Year |
|------------------|------------------------|
| "May" or 5       | May                    |
| "June" or 6      | June                   |
| "July" or 7      | July                   |
| "August" or 8    | August                 |
| "September" or 9 | September              |
| "October" or 10  | October                |
| "November" or 11 | November               |
| "December" or 12 | December               |

Data Types: double | char | string

## Output Arguments

### TT2 — Annual data

timetable

Annual data, returned as a timetable. The time arrangement of TT1 and TT2 are the same.

If a variable of TT1 has no business-day records during an annual period within the sampling time span, `convert2annual` returns a NaN for that variable and annual period in TT2.

If the first annual period (`year1`) of TT1 contains at least one business day, the first date in TT2 is the last business date of `year1`. Otherwise, the first date in TT2 is the next end-of-year-period business date of TT1.

If the last annual period (`yearT`) of TT1 contains at least one business day, the last date in TT2 is the last business date of `yearT`. Otherwise, the last date in TT2 is the previous end-of-year-period business date of TT1.

“Retime and Synchronize Timetable Variables Using Different Methods”

**Introduced in R2021a**

# totalreturnprice

Total return price time series

## Syntax

Return = totalreturnprice(Price,Action,Dividend)

## Description

Return = totalreturnprice(Price,Action,Dividend) generates a total return price time series given price data, action or split data, and dividend data. All input data is unadjusted.

## Examples

### Compute Return Using datetime Input for Price and Action

Compute Return returned as a table using datetime input in tables for Price and Action.

```
act = [732313, 2; 732314 ,2];
div = [732313, 0.0800; 732314, 0.0800];
prc = [732313, 12; 732314, 13];

prcTableDateTime=table(datetime(prc(:,1),'ConvertFrom','datenum'),prc(:,2));
acttableString=table(datestr(act(:,1)),act(:,2));
divTableNum = array2table(div);
Return = totalreturnprice(prcTableDateTime,acttableString,divTableNum)
```

Return=2×2 table

| Date        | Return |
|-------------|--------|
| 01-Jan-2005 | 1      |
| 02-Jan-2005 | 1.0833 |

## Input Arguments

### Price — Price of security

matrix | table

Price of security, specified as a table or an NUMOBS-by-2 matrix. If Price is a table, the dates can either be serial date numbers, date character vectors, or datetime arrays. If Price is an NUMOBS-by-2 matrix of price data, column 1 contains MATLAB serial date numbers and column 2 contains price values.

Data Types: double | table

### Action — Action or split data

matrix | table

Action or split data, specified as a table or an NUMOBS-by-2 matrix. If Action is a table, the dates can either be serial date numbers, date character vectors, or datetime arrays. If Action is an NUMOBS-by-2 matrix of price data, column 1 contains MATLAB serial date numbers and column 2 contains split ratios.

Data Types: double | table

### **Dividend — Dividend payouts**

matrix | table

Dividend payouts, specified as a table or an NUMOBS-by-2 matrix. If Dividend is a table, the dates can either be serial date numbers, date character vectors, or datetime arrays. If Dividend is a NUMOBS-by-2 matrix of price data, column 1 contains MATLAB serial date numbers and column 2 contains dividend payouts.

Data Types: double | table

## **Output Arguments**

### **Return — Total return price time series**

matrix | table

Total return price time series, returned as a NUMOBS-by-2 matrix (if all inputs are matrices) or table (if any inputs are tables) of price data, where column 1 is dates and column 2 is total return price values. Dates in column 1 are in datetime format if any inputs specify dates in datetime format. Dates in column 1 are in date character vector format if no inputs specify dates in datetime format, but any of them use date character vector format. Otherwise, dates in column 1 are specified as serial date numbers.

# tweekly

Convert to weekly

---

**Note** `tweekly` is not recommended. Use `convert2weekly` instead.

---

## Syntax

```
newfts = tweekly(oldfts)
```

```
newfts = tweekly(oldfts, 'ParameterName', ParameterValue, ...)
```

## Arguments

|                     |                               |
|---------------------|-------------------------------|
| <code>oldfts</code> | Financial time series object. |
|---------------------|-------------------------------|

## Description

`newfts = tweekly(oldfts)` converts a financial time series of any frequency to a weekly frequency. The default weekly days are Fridays or the last business day of the week. `tweekly` uses `holidays.m` to determine valid trading days.

---

**Note** If `oldfts` contains time-of-day information, `newfts` displays the time-of-day as `00:00` for those days that did not previously exist in `oldfts`.

Empty (`[]`) passed as inputs for parameter pair values for `tweekly` triggers the use of the defaults.

---

`newfts = tweekly(oldfts, 'ParameterName', ParameterValue, ...)` accepts parameter name/parameter value pairs as input, as specified in the following table.

| Parameter Name | Parameter Value | Description                                                                                                                                                                  |
|----------------|-----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| CalcMethod     | CumSum          | Returns the cumulative sum of the values within each week. Data for missing dates are given the value 0.                                                                     |
|                | Exact           | Returns the exact value at the end-of-week dates. No data manipulation occurs.                                                                                               |
|                | Nearest         | (Default) Returns the values located at the end-of-week dates. If there is missing data, <code>Nearest</code> returns the nearest data point preceding the end-of-week date. |
|                | SimpAvg         | Returns an averaged weekly value that only takes into account dates with data (non- <code>NaN</code> ) within each week.                                                     |

| Parameter Name                                                                                                                                                                                                                                                                                                          | Parameter Value | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                                                                                                                                                                                                                                                                                                         | v21x            | This mode is compatible with previous versions of this function (Version 2.1.x and earlier). It returns an averaged end-of-weekly value using a previous <code>toquarterly</code> algorithm. This algorithm takes into account all dates and data. For dates that do not contain any data, the data is assumed to be 0.                                                                                                                                                                                                |
| <b>Note</b> If you set <code>CalcMethod</code> to v21x, settings for all the following parameter name/parameter value pairs are not supported.                                                                                                                                                                          |                 |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| BusDays                                                                                                                                                                                                                                                                                                                 | 0               | Generates a financial time series that ranges from (or between) the first date to the last date in <code>oldfts</code> (includes NYSE nonbusiness days and holidays).                                                                                                                                                                                                                                                                                                                                                  |
|                                                                                                                                                                                                                                                                                                                         | 1               | (Default) Generates a financial time series that ranges from the first date to the last date in <code>oldfts</code> (excludes NYSE nonbusiness days and holidays and weekends based on <code>AltHolidays</code> and <code>Weekend</code> ). If an end-of-quarter date falls on a nonbusiness day or NYSE holiday, returns the last business day of the quarter.<br><br>NYSE market closures, holidays, and weekends are observed if <code>AltHolidays</code> and <code>Weekend</code> are not supplied or empty ( []). |
| DateFilter                                                                                                                                                                                                                                                                                                              | Absolute        | (Default) Returns all weekly dates between the start and end dates of <code>oldfts</code> . Some dates may be disregarded if <code>BusDays = 1</code> .                                                                                                                                                                                                                                                                                                                                                                |
|                                                                                                                                                                                                                                                                                                                         | Relative        | Returns only end-of-week dates that exist in <code>oldfts</code> . Some dates may be disregarded if <code>BusDays = 1</code> .                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>Note</b> The default is to create a time series with every date at the specified periodicity, which is with <code>DateFilter = Absolute</code> . If you use <code>DateFilter = Relative</code> , the endpoint effects do not apply since only your data defines which dates appear in the output time series object. |                 |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

| Parameter Name                                                                                                                   | Parameter Value | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

| Parameter Name | Parameter Value | Description                                                                                                                                                                                                                              |
|----------------|-----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                | -1              | Excludes all holidays.                                                                                                                                                                                                                   |
| Weekend        |                 | Vector of length 7 containing 0's and 1's. The value 1 indicates a weekend day. The first element of this vector corresponds to Sunday. For example, when Saturday and Sunday are weekend days (default) then Weekend = [1 0 0 0 0 0 1]. |

## Examples

### Transform Time Series Object from Quarterly to Weekly Values

This example shows how to transform a time series object from quarterly to weekly values.

Load the data from the file `predict_ret_data.mat` and use the `fints` function to create a time series object with a quarterly frequency.

```
load predict_ret_data.mat
x0 = fints(expdates, expdata, {'Metric'}, 'q', 'Index')
```

Warning: FINTS is not recommended. Use TIMETABLE instead. For more information, see [mat](#)

```
x0 =
```

```

## tr2bonds

Term-structure parameters given Treasury bond parameters

### Syntax

```
[Bonds,Prices,Yields] = tr2bonds(TreasuryMatrix,Settle)
[Bonds,Prices,Yields] = tr2bonds( ___,Settle)
```

### Description

[Bonds,Prices,Yields] = tr2bonds(TreasuryMatrix,Settle) returns term-structure parameters (Bonds, Prices, and Yields) sorted by ascending maturity date, given Treasury bond parameters. The formats of the output matrix and vectors meet requirements for input to the zbtprice and zbtyield zero-curve bootstrapping functions.

[Bonds,Prices,Yields] = tr2bonds( \_\_\_,Settle) adds an optional argument for Settle.

### Examples

#### Return Term-Structure Parameters Given Treasury Bond Parameters

This example shows how to return term-structure parameters (bond information, prices, and yields) sorted by ascending maturity date, given Treasury bond market parameters for December 22, 1997.

```
Matrix =[0.0650 datenum('15-apr-1999') 101.03125 101.09375 0.0564
         0.05125 datenum('17-dec-1998') 99.4375 99.5 0.0563
         0.0625 datenum('30-jul-1998') 100.3125 100.375 0.0560
         0.06125 datenum('26-mar-1998') 100.09375 100.15625 0.0546];
```

```
[Bonds, Prices, Yields] = tr2bonds(Matrix)
```

```
Bonds = 4×6
105 ×
```

```
    7.2984    0.0000    0.0010    0.0000    0    0.0000
    7.2997    0.0000    0.0010    0.0000    0    0.0000
    7.3011    0.0000    0.0010    0.0000    0    0.0000
    7.3022    0.0000    0.0010    0.0000    0    0.0000

### Return Term-Structure Parameters Given Treasury Bond Parameters Using `datetime` Input

This example shows how to use `datetime` input to return term-structure parameters (bond information, prices, and yields) sorted by ascending maturity date, given Treasury bond market parameters for December 22, 1997.

```

Matrix =[0.0650 datetime('15-apr-1999') 101.03125 101.09375 0.0564
         0.05125 datetime('17-dec-1998') 99.4375 99.5 0.0563
         0.0625 datetime('30-jul-1998') 100.3125 100.375 0.0560
         0.06125 datetime('26-mar-1998') 100.09375 100.15625 0.0546];

```

```

t=array2table(Matrix);
t.Matrix2=datetime(t{:,2},'ConvertFrom','datetime','Locale','en_US');
[Bonds, Prices, Yields] = tr2bonds(t,datetime('1-Jan-1997','Locale','en_US'))

```

Bonds=4×6 table

## Input Arguments

### TreasuryMatrix — Treasury bond parameters

table | matrix

Treasury bond parameters, specified as a 5-column table or a NumBonds-by-5 matrix of bond information where the table columns or matrix columns contains:

- **CouponRate** (Required) Coupon rate of the Treasury bond, specified as a decimal indicating the coupon rates for each bond in the portfolio.
- **Maturity** (Required) Maturity date of the Treasury bond, specified as a serial date number when using a matrix. Use `datenum` to convert date character vectors to serial date numbers. If the input `TreasuryMatrix` is a table, the **Maturity** dates can be serial date numbers, date character vectors, or datetime arrays.
- **Bid** (Required) Bid prices, specified using an integer-decimal form for each bond in the portfolio.
- **Asked** (Required) Asked prices, specified using an integer-decimal form for each bond in the portfolio.
- **AskYield** (Required) Quoted ask yield, specified using a decimal form for each bond in the portfolio.

Data Types: `double` | `table`

### **Settle — Settlement date of Treasury bond**

`serial date number` | `date character vector` | `datetime`

(Optional) Settlement date of the Treasury bond, specified as a scalar or a NINST-by-1 vector of serial date numbers, date character vectors, or datetime arrays. The **Settle** date must be before the **Maturity** date.

Data Types: `double` | `char` | `datetime`

## **Output Arguments**

### **Bonds — Coupon bond information**

`numeric`

Coupon bond information, returned as a table or matrix depending on the `TreasuryMatrix` input.

When `TreasuryMatrix` is a table, **Bonds** is also a table, and the variable type for the **Maturity** dates in **Bonds** (column 1) matches the variable type for **Maturity** in `TreasuryMatrix`.

When `TreasuryMatrix` input is a n-by-5 matrix, then each row describes a bond.

The parameters or columns returned for **Bonds** are:

- **Maturity** (Column 1) Maturity date for each bond in the portfolio as a serial date number. The format of the dates matches the format used for **Maturity** in `TreasuryMatrix` (serial date number, date character vector, or datetime array).
- **CouponRate** (Column 2) Coupon rate for each bond in the portfolio in decimal form.
- **Face** (Column 3, Optional) Face or par value for each bond in the portfolio. The default is 100.
- **Period** (Column 4, Optional) Number of coupon payments per year for each bond in the portfolio with allowed values: 1, 2, 3, 4, 6, and 12. The default is 2, unless you are dealing with zero coupons, then **Period** is 0 instead of 2.
- **Basis** (Column 5, Optional) Day-count basis for each bond in the portfolio with possible values:
  - 0 = actual/actual (default)
  - 1 = 30/360 (SIA)
  - 2 = actual/360

- 3 = actual/365
  - 4 = 30/360 (BMA)
  - 5 = 30/360 (ISDA)
  - 6 = 30/360 (European)
  - 7 = actual/365 (Japanese)
  - 8 = actual/actual (ICMA)
  - 9 = actual/360 (ICMA)
  - 10 = actual/365 (ICMA)
  - 11 = 30/360E (ICMA)
  - 12 = actual/365 (ISDA)
  - 13 = BUS/252
  - For more information, see “Basis” on page 2-19.
- `EndMonthRule` (Column 6, Optional) End-of-month rule flag for each bond in the portfolio. This rule applies only when `Maturity` is an end-of-month date for a month having 30 or fewer days. 0 = ignore rule, meaning that a bond's coupon payment date is always the same numerical day of the month. 1 = set rule on, meaning that a bond's coupon payment date is always the last actual day of the month. The default is 1.

### Prices — Bond prices

numeric

Bond prices, returned as a column vector containing the price of each bond in `Bonds`, respectively. The number of rows ( $n$ ) matches the number of rows in `Bonds`.

### Yields — Bond yields

numeric

Bond yields, returned as a column vector containing the yield to maturity of each bond in `Bonds`, respectively. The number of rows ( $n$ ) matches the number of rows in `Bonds`.

If the optional input argument `Settle` is used, `Yields` is computed as a semiannual yield to maturity. If the input `Settle` is not used, the quoted input yields are used.

# transprob

Estimate transition probabilities from credit ratings data

## Syntax

```
[transMat,sampleTotals,idTotals] = transprob(data)
[transMat,sampleTotals,idTotals] = transprob( ___,Name,Value)
```

## Description

[transMat,sampleTotals,idTotals] = transprob(data) constructs a transition matrix from historical data of credit ratings.

[transMat,sampleTotals,idTotals] = transprob( \_\_\_,Name,Value) adds optional name-value pair arguments.

## Examples

### Construct a Transition Matrix From a Table of Historical Data of Credit Ratings

Using the historical credit rating table as input data from Data\_TransProb.mat display the first ten rows and compute the transition matrix:

```
load Data_TransProb
data(1:10,:)
```

```
ans=10x3 table
      ID          Date          Rating
      ---          -
      {'00010283'} {'10-Nov-1984'} {'CCC'}
      {'00010283'} {'12-May-1986'} {'B'  }
      {'00010283'} {'29-Jun-1988'} {'CCC'}
      {'00010283'} {'12-Dec-1991'} {'D'  }
      {'00013326'} {'09-Feb-1985'} {'A'  }
      {'00013326'} {'24-Feb-1994'} {'AA' }
      {'00013326'} {'10-Nov-2000'} {'BBB'}
      {'00014413'} {'23-Dec-1982'} {'B'  }
      {'00014413'} {'20-Apr-1988'} {'BB' }
      {'00014413'} {'16-Jan-1998'} {'B'  }
```

```
% Estimate transition probabilities with default settings
transMat = transprob(data)
```

```
transMat = 8x8

    93.1170    5.8428    0.8232    0.1763    0.0376    0.0012    0.0001    0.0017

```

Using the historical credit rating table input data from `Data_TransProb.mat`, compute the transition matrix using the cohort algorithm:

```

%Estimate transition probabilities with 'cohort' algorithm
transMatCoh = transprob(data,'algorithm','cohort')

```

```
transMatCoh = 8x8
```

```

93.1345    5.9335    0.7456    0.1553    0.0311    0         0         0
1.7359    92.9198    4.5446    0.6046    0.1560    0         0         0.0390

0.0221    0.1105    0.6851    6.2320    88.3757    3.6464    0.2873    0.6409
0         0         0.0761    0.7230    7.9909    86.1872    2.7397    2.2831
0         0         0         0.3094    1.8561    4.5630    80.8971    12.3743
0         0         0         0         0         0         0         100.0000

```

Using the historical credit rating data with ratings investment grade ('IG'), speculative grade ('SG'), and default ('D'), from `Data_TransProb.mat` display the first ten rows and compute the transition matrix:

```
dataIGSG(1:10,:)
```

```
ans=10x3 table
```

| ID           | Date            | Rating |
|--------------|-----------------|--------|
| {'00011253'} | {'04-Apr-1983'} | {'IG'} |
| {'00012751'} | {'17-Feb-1985'} | {'SG'} |
| {'00012751'} | {'19-May-1986'} | {'D' } |
| {'00014690'} | {'17-Jan-1983'} | {'IG'} |
| {'00012144'} | {'21-Nov-1984'} | {'IG'} |
| {'00012144'} | {'25-Mar-1992'} | {'SG'} |
| {'00012144'} | {'07-May-1994'} | {'IG'} |
| {'00012144'} | {'23-Jan-2000'} | {'SG'} |
| {'00012144'} | {'20-Aug-2001'} | {'IG'} |
| {'00012937'} | {'07-Feb-1984'} | {'IG'} |

```
transMatIGSG = transprob(dataIGSG,'labels',{'IG','SG','D'})
```

```
transMatIGSG = 3x3
```

```

98.6719    1.2020    0.1261
3.5781    93.3318    3.0901
0         0         100.0000

```

Using the historical credit rating data with numeric ratings for investment grade (1), speculative grade (2), and default (3), from `Data_TransProb.mat` display the first ten rows and compute the transition matrix:

```
dataIGSGnum(1:10,:)
```

```
ans=10x3 table
      ID          Date          Rating
  _____  _____  _____
 {'00011253'} {'04-Apr-1983'}      1
 {'00012751'} {'17-Feb-1985'}      2
 {'00012751'} {'19-May-1986'}      3

 {'00012144'} {'20-Aug-2001'}      1
 {'00012937'} {'07-Feb-1984'}      1
```

```
transMatIGSGnum = transprob(dataIGSGnum,'labels',{1,2,3})
```

```
transMatIGSGnum = 3x3
```

```
98.6719    1.2020    0.1261
 3.5781    93.3318    3.0901
 0          0    100.0000
```

### Create a Transition Matrix Using a Cell Array for Historical Data of Credit Ratings

Using a MATLAB® table containing the historical credit rating cell array input data (dataCellFormat) from Data\_TransProb.mat, estimate the transition probabilities with default settings.

```
load Data_TransProb
transMat = transprob(dataCellFormat)
```

```
transMat = 8x8
```

```
93.1170    5.8428    0.8232    0.1763    0.0376    0.0012    0.0001    0.0017
 1.6166    93.1518    4.3632    0.6602    0.1626    0.0055    0.0004    0.0396
 0.1237    2.9003    92.2197    4.0756    0.5365    0.0661    0.0028    0.0753
 0.0236    0.2312    5.0059    90.1846    3.7979    0.4733    0.0642    0.2193
 0.0216    0.1134    0.6357    5.7960    88.9866    3.4497    0.2919    0.7050
 0.0010    0.0062    0.1081    0.8697    7.3366    86.7215    2.5169    2.4399
 0.0002    0.0011    0.0120    0.2582    1.4294    4.2898    81.2927    12.7167
 0          0          0          0          0          0          0    100.0000
```

Using the historical credit rating cell array input data (dataCellFormat), compute the transition matrix using the cohort algorithm:

```
%Estimate transition probabilities with 'cohort' algorithm
transMatCoh = transprob(dataCellFormat,'algorithm','cohort')
```

```
transMatCoh = 8x8
```

```

93.1345    5.9335    0.7456    0.1553    0.0311    0    0    0
1.7359    92.9198    4.5446    0.6046    0.1560    0    0    0.0390
0.1268    2.9716    91.9913    4.3124    0.4711    0.0544    0    0.0725
0.0210    0.3785    5.0683    89.7792    4.0379    0.4627    0.0421    0.2103
0.0221    0.1105    0.6851    6.2320    88.3757    3.6464    0.2873    0.6409
0    0    0.0761    0.7230    7.9909    86.1872    2.7397    2.2831
0    0    0    0.3094    1.8561    4.5630    80.8971    12.3743
0    0    0    0    0    0    0    100.0000

```

### Visualize Transitions Data for `transprob`

This example shows how to visualize credit rating transitions that are used as an input to the `transprob` function. The example also describes how the `transprob` function treats rating transitions when the company data starts after the start date of the analysis, or when the end date of the analysis is after the last transition observed.

#### Sample Data

Set up fictitious sample data for illustration purposes.

```

data = {'ABC', '17-Feb-2015', 'AA';
        'ABC', '6-Jul-2017', 'A';
        'LMN', '12-Aug-2014', 'B';
        'LMN', '9-Nov-2015', 'CCC';
        'LMN', '7-Sep-2016', 'D';
        'XYZ', '14-May-2013', 'BB';
        'XYZ', '21-Jun-2016', 'BBB'};
data = cell2table(data, 'VariableNames', {'ID', 'Date', 'Rating'});
disp(data)

```

| ID      | Date            | Rating  |
|---------|-----------------|---------|
| {'ABC'} | {'17-Feb-2015'} | {'AA' } |
| {'ABC'} | {'6-Jul-2017' } | {'A' }  |
| {'LMN'} | {'12-Aug-2014'} | {'B' }  |
| {'LMN'} | {'9-Nov-2015' } | {'CCC'} |
| {'LMN'} | {'7-Sep-2016' } | {'D' }  |
| {'XYZ'} | {'14-May-2013'} | {'BB' } |
| {'XYZ'} | {'21-Jun-2016'} | {'BBB'} |

The `transprob` function understands that this panel-data format indicates the dates when a new rating is assigned to a given company. `transprob` assumes that such ratings remain unchanged, unless a subsequent row explicitly indicates a rating change. For example, for company 'ABC', `transprob` understands that the 'A' rating is unchanged for any date after '6-Jul-2017' (indefinitely).

#### Compute Transition Matrix and Transition Counts

The `transprob` function returns a transition probability matrix as the primary output. There are also optional outputs that contain additional information for how many transitions occurred. For more information, see `transprob` for information on the optional outputs for both the 'cohort' and the 'duration' methods.

For illustration purposes, this example allows you to pick the `StartYear` (limited to 2014 or 2015 for this example) and the `EndYear` (2016 or 2017). This example also uses the `hDisplayTransitions` helper function (see the Local Functions on page 19-0 section) to format the transitions information for ease of reading.

```
StartYear = 2014 ;
EndYear = 2017 ;
startDate = datetime(StartYear,12,31,'Locale','en_US');
endDate = datetime(EndYear,12,31,'Locale','en_US');
RatingLabels = ["AAA","AA","A","BBB","BB","B","CCC","D"];

[tm,st,it] = transprob(data,'startDate',startDate,'endDate',endDate,'algorithm','cohort','labels
```

The transition probabilities of the `TransMat` output indicate the probability of migrating between ratings. The probabilities are expressed in %, that is, they are multiplied by 100.

```
hDisplayTransitions(tm,RatingLabels,"Transition Matrix")
```

Transition Matrix

|     | AAA | AA | A   | BBB | BB | B | CCC | D   |
|-----|-----|----|-----|-----|----|---|-----|-----|
| AAA | 100 | 0  | 0   | 0   | 0  | 0 | 0   | 0   |
| AA  | 0   | 50 | 50  | 0   | 0  | 0 | 0   | 0   |
| A   | 0   | 0  | 100 | 0   | 0  | 0 | 0   | 0   |
| BBB | 0   | 0  | 0   | 100 | 0  | 0 | 0   | 0   |
| BB  | 0   | 0  | 0   | 50  | 50 | 0 | 0   | 0   |
| B   | 0   | 0  | 0   | 0   | 0  | 0 | 100 | 0   |
| CCC | 0   | 0  | 0   | 0   | 0  | 0 | 0   | 100 |
| D   | 0   | 0  | 0   | 0   | 0  | 0 | 0   | 100 |

The transition counts are stored in the `sampleTotals` optional output and indicate how many transitions occurred between ratings for the entire sample (that is, all companies).

```
hDisplayTransitions(st.totalsMat,RatingLabels,"Transition counts, all companies")
```

Transition counts, all companies

|     | AAA | AA | A | BBB | BB | B | CCC | D |
|-----|-----|----|---|-----|----|---|-----|---|
| AAA | 0   | 0  | 0 | 0   | 0  | 0 | 0   | 0 |
| AA  | 0   | 1  | 1 | 0   | 0  | 0 | 0   | 0 |
| A   | 0   | 0  | 0 | 0   | 0  | 0 | 0   | 0 |
| BBB | 0   | 0  | 0 | 1   | 0  | 0 | 0   | 0 |
| BB  | 0   | 0  | 0 | 1   | 1  | 0 | 0   | 0 |
| B   | 0   | 0  | 0 | 0   | 0  | 0 | 1   | 0 |
| CCC | 0   | 0  | 0 | 0   | 0  | 0 | 0   | 1 |
| D   | 0   | 0  | 0 | 0   | 0  | 0 | 0   | 1 |

The third output of `transprob` is `idTotals` that contains information about transitions at an ID level, company by company (in the same order that the companies appear in the input data).

Select a company to display the transition counts and a corresponding visualization of the transitions. The `hPlotTransitions` helper function (see the Local Functions on page 19-0 section) shows the transitions history for a company.

```

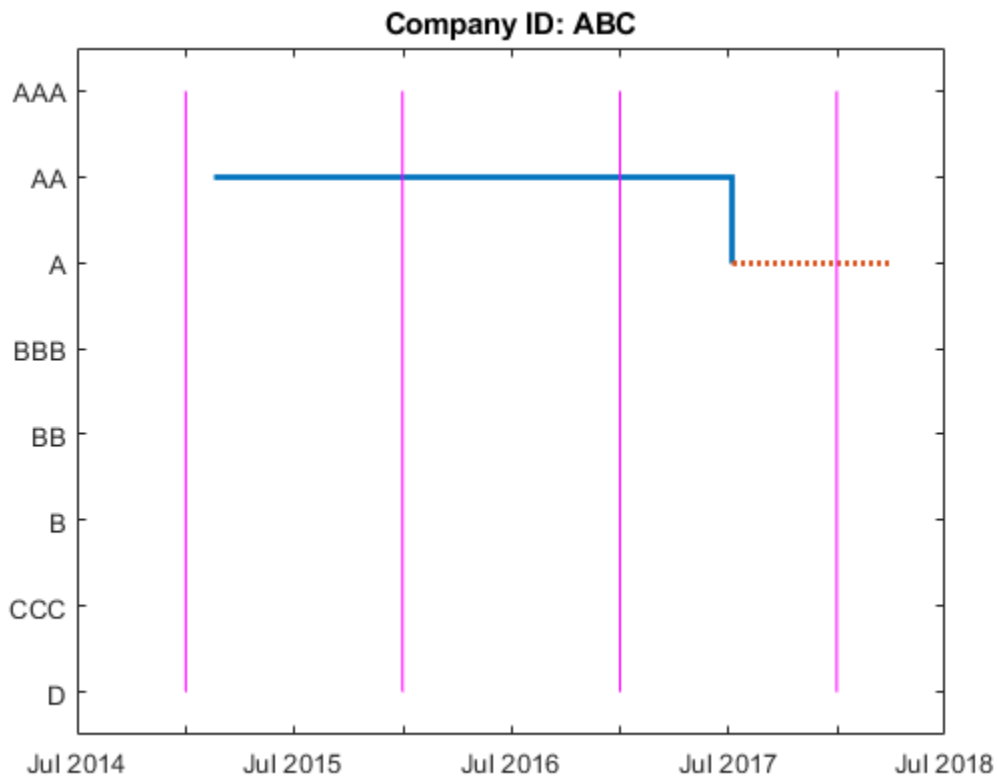

CompanyID = ;
UniqueIDs = unique(data.ID, 'stable');
[~, CompanyIndex] = ismember(CompanyID, UniqueIDs);
hDisplayTransitions(it(CompanyIndex).totalsMat, RatingLabels, strcat("Transition counts, company ID: ", CompanyID));

```

Transition counts, company ID: ABC

|     | AAA | AA | A | BBB | BB | B | CCC | D |
|-----|-----|----|---|-----|----|---|-----|---|
| AAA | 0   | 0  | 0 | 0   | 0  | 0 | 0   | 0 |
| AA  | 0   | 1  | 1 | 0   | 0  | 0 | 0   | 0 |
| A   | 0   | 0  | 0 | 0   | 0  | 0 | 0   | 0 |
| BBB | 0   | 0  | 0 | 0   | 0  | 0 | 0   | 0 |
| BB  | 0   | 0  | 0 | 0   | 0  | 0 | 0   | 0 |
| B   | 0   | 0  | 0 | 0   | 0  | 0 | 0   | 0 |
| CCC | 0   | 0  | 0 | 0   | 0  | 0 | 0   | 0 |
| D   | 0   | 0  | 0 | 0   | 0  | 0 | 0   | 0 |

```
hPlotTransitions(CompanyID, startDate, endDate, data, RatingLabels)
```

To understand how `transprob` handles data when the first observed date is after the start date of the analysis, or whose last observed date occurs before the end date of the analysis, consider the following example. For company 'ABC' suppose that the analysis has a start date of 31-Dec-2014 and end date of 31-Dec-2017. There are only two transitions reported for this company for that analysis time window. The first observation for 'ABC' happened on 17-Feb-2015. So the 31-Dec-2015 snapshot is the first time the company is observed. By 31-Dec-2016, the company

remained in the original 'AA' rating. By 31-Dec-2017, a downgrade to 'A' is recorded. Consistent with this, the transition counts show one transition from 'AA' to 'AA' (from the end of 2015 to the end of 2016), and one transition from 'AA' to 'A' (from the end of 2016 to the end of 2017). The plot shows the last rating as a dotted red line to emphasize that the last rating in the data is extrapolated indefinitely into the future. There is no extrapolation into the past; the company's history is ignored until a company rating is known for an entire transition period (31-Dec-2015 through 31-Dec-2016 in the case of 'ABC').

### Compute Transition Matrix Containing NR (Not Rated) Rating

Consider a different sample data containing only a single company 'DEF'. The data contains transitions of company 'DEF' from 'A' to 'NR' rating and a subsequent transition from 'NR' to 'BBB'.

```
dataNR = {'DEF', '17-Mar-2011', 'A';
          'DEF', '24-Mar-2014', 'NR';
          'DEF', '26-Sep-2016', 'BBB'};
dataNR = cell2table(dataNR, 'VariableNames', {'ID', 'Date', 'Rating'});
disp(dataNR)
```

| ID      | Date            | Rating  |
|---------|-----------------|---------|
| {'DEF'} | {'17-Mar-2011'} | {'A' }  |
| {'DEF'} | {'24-Mar-2014'} | {'NR' } |
| {'DEF'} | {'26-Sep-2016'} | {'BBB'} |

transprob treats 'NR' as another rating. The transition matrix below shows the estimated probability of transitioning into and out of 'NR'.

```
StartYearNR = 2010;
EndYearNR = 2018;
startDateNR = datetime(StartYearNR,12,31, 'Locale', 'en_US');
endDateNR = datetime(EndYearNR,12,31, 'Locale', 'en_US');
CompanyID_NR = "DEF";
```

```
RatingLabelsNR = ["AAA", "AA", "A", "BBB", "BB", "B", "CCC", "D", "NR"];
```

```
[tmNR,~,itNR] = transprob(dataNR, 'startDate', startDateNR, 'endDate', endDateNR, 'algorithm', 'cohort');
hDisplayTransitions(tmNR, RatingLabelsNR, "Transition Matrix")
```

Transition Matrix

|     | AAA | AA  | A      | BBB | BB  | B   | CCC | D   | NR     |
|-----|-----|-----|--------|-----|-----|-----|-----|-----|--------|
| AAA | 100 | 0   | 0      | 0   | 0   | 0   | 0   | 0   | 0      |
| AA  | 0   | 100 | 0      | 0   | 0   | 0   | 0   | 0   | 0      |
| A   | 0   | 0   | 66.667 | 0   | 0   | 0   | 0   | 0   | 33.333 |
| BBB | 0   | 0   | 0      | 100 | 0   | 0   | 0   | 0   | 0      |
| BB  | 0   | 0   | 0      | 0   | 100 | 0   | 0   | 0   | 0      |
| B   | 0   | 0   | 0      | 0   | 0   | 100 | 0   | 0   | 0      |
| CCC | 0   | 0   | 0      | 0   | 0   | 0   | 100 | 0   | 0      |
| D   | 0   | 0   | 0      | 0   | 0   | 0   | 0   | 100 | 0      |
| NR  | 0   | 0   | 0      | 50  | 0   | 0   | 0   | 0   | 50     |

Display the transition counts and corresponding visualization of the transitions.

```
hDisplayTransitions(itNR.totalsMat,RatingLabelsNR, strcat("Transition counts, company ID: ",CompanyIDNR))
```

```
Transition counts, company ID: DEF
```

|     | AAA | AA | A | BBB | BB | B | CCC | D | NR |
|-----|-----|----|---|-----|----|---|-----|---|----|
| AAA | 0   | 0  | 0 | 0   | 0  | 0 | 0   | 0 | 0  |
| AA  | 0   | 0  | 0 | 0   | 0  | 0 | 0   | 0 | 0  |
| A   | 0   | 0  | 2 | 0   | 0  | 0 | 0   | 0 | 1  |
| BBB | 0   | 0  | 0 | 2   | 0  | 0 | 0   | 0 | 0  |
| BB  | 0   | 0  | 0 | 0   | 0  | 0 | 0   | 0 | 0  |
| B   | 0   | 0  | 0 | 0   | 0  | 0 | 0   | 0 | 0  |
| CCC | 0   | 0  | 0 | 0   | 0  | 0 | 0   | 0 | 0  |
| D   | 0   | 0  | 0 | 0   | 0  | 0 | 0   | 0 | 0  |
| NR  | 0   | 0  | 0 | 1   | 0  | 0 | 0   | 0 | 1  |

```
hPlotTransitions(CompanyID_NR,startDateNR,endDateNR,dataNR,RatingLabelsNR)
```

To remove the 'NR' from the transition matrix, use the 'excludeLabels' name-value input argument in `transprob`. The list of labels to exclude may or may not be specified in the name-value pair argument `labels`. For example, both `RatingLabels` and `RatingLabelsNR` generate the same output from `transprob`.

```
[tmNR,stNR,itNR] = transprob(dataNR,'startDate',startDateNR,'endDate',endDateNR,'algorithm','coh...')
hDisplayTransitions(tmNR,RatingLabels,"Transition Matrix")
```

## Transition Matrix

|     | AAA | AA  | A   | BBB | BB  | B   | CCC | D   |
|-----|-----|-----|-----|-----|-----|-----|-----|-----|
|     | —   | —   | —   | —   | —   | —   | —   | —   |
| AAA | 100 | 0   | 0   | 0   | 0   | 0   | 0   | 0   |
| AA  | 0   | 100 | 0   | 0   | 0   | 0   | 0   | 0   |
| A   | 0   | 0   | 100 | 0   | 0   | 0   | 0   | 0   |
| BBB | 0   | 0   | 0   | 100 | 0   | 0   | 0   | 0   |
| BB  | 0   | 0   | 0   | 0   | 100 | 0   | 0   | 0   |
| B   | 0   | 0   | 0   | 0   | 0   | 100 | 0   | 0   |
| CCC | 0   | 0   | 0   | 0   | 0   | 0   | 100 | 0   |
| D   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 100 |

Display the transition counts and corresponding visualization of the transitions.

```
hDisplayTransitions(itNR.totalsMat,RatingLabels, strcat("Transition counts, company ID: ", CompanyID))
```

Transition counts, company ID: DEF

|     | AAA | AA | A | BBB | BB | B | CCC | D |
|-----|-----|----|---|-----|----|---|-----|---|
|     | —   | —  | — | —   | —  | — | —   | — |
| AAA | 0   | 0  | 0 | 0   | 0  | 0 | 0   | 0 |
| AA  | 0   | 0  | 0 | 0   | 0  | 0 | 0   | 0 |
| A   | 0   | 0  | 2 | 0   | 0  | 0 | 0   | 0 |
| BBB | 0   | 0  | 0 | 2   | 0  | 0 | 0   | 0 |
| BB  | 0   | 0  | 0 | 0   | 0  | 0 | 0   | 0 |
| B   | 0   | 0  | 0 | 0   | 0  | 0 | 0   | 0 |
| CCC | 0   | 0  | 0 | 0   | 0  | 0 | 0   | 0 |
| D   | 0   | 0  | 0 | 0   | 0  | 0 | 0   | 0 |

```
hPlotTransitions(CompanyID_NR, startDateNR, endDateNR, dataNR, RatingLabels)
```

Consistent with the previous plot, the transition counts still show two transitions from 'A' to 'A' (from the end of 2012 to the end of 2014), and two transitions from 'BBB' to 'BBB' (from the end of 2017 to the end of 2019).

However, different from the previous plot, specifying 'NR' using the 'excludeLabels' name-value input argument of `transprob` removes any transitions into and out of the 'NR' rating.

### Local Functions

```
function hDisplayTransitions(TransitionsData,RatingLabels,Title)
```

```
% Helper function to format transition information outputs
```

```
TransitionsAsTable = array2table(TransitionsData,...
    'VariableNames',RatingLabels,'RowNames',RatingLabels);
```

```
fprintf('\n%s\n\n',Title)
disp(TransitionsAsTable)
```

```
end
```

```
function hPlotTransitions(CompanyID,startDate,endDate,data,RatingLabels)
```

```
% Helper function to visualize transitions between ratings
```

```
Ind = string(data.ID)==CompanyID;
DatesOriginal = datetime(data.Date(Ind),'Locale','en_US');
RatingsOriginal = categorical(data.Rating(Ind),flipud(RatingLabels(:)),flipud(RatingLabels(:))
```

```

stairs(DatesOriginal,RatingsOriginal,'LineWidth',2)
hold on;

% Indicate rating extrapolated into the future (arbitrarily select 91
% days after endDate as the last date on the plot)
endDateExtrap = endDate+91;
if endDateExtrap>DatesOriginal(end)
    DatesExtrap = [DatesOriginal(end); endDateExtrap];
    RatingsExtrap = [RatingsOriginal(end); RatingsOriginal(end)];
    stairs(DatesExtrap,RatingsExtrap,'LineWidth',2,'LineStyle',':')
end
hold off;

% Add lines to indicate the snapshot dates
% transprob uses 1 as the default for 'snapsPerYear', hardcoded here for simplicity
% The call to cfdates generates the exact same snapshot dates that transprob uses
snapsPerYear = 1;
snapDates = cfdates(startDate-1,endDate,snapsPerYear)';
yLimits = ylim;
for ii=1:length(snapDates)
    line([snapDates(ii) snapDates(ii)],yLimits,'Color','m')
end
title(strcat("Company ID: ",CompanyID))
end

```

## Input Arguments

### data — Credit migration data

table | cell array of character vectors | preprocessed data structure

Using `transprob` to estimate transition probabilities given credit ratings historical data (that is, credit migration data), the data input can be one of the following:

- An `nRecords-by-3` MATLAB table containing the historical credit ratings data of the form:

| ID         | Date          | Rating |
|------------|---------------|--------|
| '00010283' | '10-Nov-1984' | 'CCC'  |
| '00010283' | '12-May-1986' | 'B'    |
| '00010283' | '29-Jun-1988' | 'CCC'  |
| '00010283' | '12-Dec-1991' | 'D'    |
| '00013326' | '09-Feb-1985' | 'A'    |
| '00013326' | '24-Feb-1994' | 'AA'   |
| '00013326' | '10-Nov-2000' | 'BBB'  |
| '00014413' | '23-Dec-1982' | 'B'    |

where each row contains an ID (column 1), a date (column 2), and a credit rating (column 3). Column 3 is the rating assigned to the corresponding ID on the corresponding date. All information corresponding to the same ID must be stored in contiguous rows. Sorting this information by date is not required, but recommended for efficiency. When using a MATLAB table input, the names of the columns are irrelevant, but the ID, date and rating information are assumed to be in the first, second, and third columns, respectively. Also, when using a table input, the first and third columns can be categorical arrays, and the second can be a datetime array. The following summarizes the supported data types for table input:

| Data Input Type | ID (1st Column)                                                                                                                     | Date (2nd Column)                                                                                                                | Rating (3rd Column)                                                                                                                 |
|-----------------|-------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------|
| Table           | <ul style="list-style-type: none"> <li>Numeric array</li> <li>Cell array of character vectors</li> <li>Categorical array</li> </ul> | <ul style="list-style-type: none"> <li>Numeric array</li> <li>Cell array of character vectors</li> <li>Datetime array</li> </ul> | <ul style="list-style-type: none"> <li>Numeric array</li> <li>Cell array of character vectors</li> <li>Categorical array</li> </ul> |

- An `nRecords-by-3` cell array of character vectors containing the historical credit ratings data of the form:

```
'00010283' '10-Nov-1984' 'CCC'
'00010283' '12-May-1986' 'B'
'00010283' '29-Jun-1988' 'CCC'
'00010283' '12-Dec-1991' 'D'
'00013326' '09-Feb-1985' 'A'
'00013326' '24-Feb-1994' 'AA'
'00013326' '10-Nov-2000' 'BBB'
'00014413' '23-Dec-1982' 'B'
```

where each row contains an ID (column 1), a date (column 2), and a credit rating (column 3). Column 3 is the rating assigned to the corresponding ID on the corresponding date. All information corresponding to the same ID must be stored in contiguous rows. Sorting this information by date is not required, but recommended for efficiency. IDs, dates, and ratings are stored in character vector format, but they can also be entered in numeric format. The following summarizes the supported data types for cell array input:

| Data Input Type | ID (1st Column)                                                                                       | Date (2nd Column)                                                                                     | Rating (3rd Column)                                                                                   |
|-----------------|-------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------|
| Cell            | <ul style="list-style-type: none"> <li>Numeric elements</li> <li>Character vector elements</li> </ul> | <ul style="list-style-type: none"> <li>Numeric elements</li> <li>Character vector elements</li> </ul> | <ul style="list-style-type: none"> <li>Numeric elements</li> <li>Character vector elements</li> </ul> |

- A preprocessed data structure obtained using `transprobprep`. This data structure contains the fields `'idStart'`, `'numericDates'`, `'numericRatings'`, and `'ratingsLabels'`.

Data Types: `table` | `cell` | `struct`

### Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `transMat = transprob(data, 'algorithm', 'cohort')`

#### **algorithm** — Estimation algorithm

`'duration'` (default) | character vector with values are `'duration'` or `'cohort'`

Estimation algorithm, specified as the comma-separated pair consisting of `'algorithm'` and a character vector with a value of `'duration'` or `'cohort'`.

Data Types: `char`

#### **endDate** — End date of the estimation time window

latest date in `data` (default) | character vector | serial date number | datetime

End date of the estimation time window, specified as the comma-separated pair consisting of 'endDate' and a date character vector, serial date number, or datetime object. The endDate cannot be a date before the startDate.

Data Types: char | double | datetime

### Labels — Credit-rating scale

{'AAA', 'AA', 'A', 'BBB', 'BB', 'B', 'CCC', 'D'} (default) | cell array of character vectors

Credit-rating scale, specified as the comma-separated pair consisting of 'labels' and a nRatings-by-1, or 1-by-nRatings cell array of character vectors.

labels must be consistent with the ratings labels used in the third column of data. Use a cell array of numbers for numeric ratings, and a cell array for character vectors for categorical ratings.

---

**Note** When the input argument data is a preprocessed data structure obtained from a previous call to transprobbprep, this optional input for 'labels' is unused because the labels in the 'ratingsLabels' field of transprobbprep take priority.

---

Data Types: cell

### snapsPerYear — Number of credit-rating snapshots per year

1 (default) | numeric values are 1, 2, 3, 4, 6, or 12

Number of credit-rating snapshots per year to be considered for the estimation, specified as the comma-separated pair consisting of 'snapsPerYear' and a numeric value of 1, 2, 3, 4, 6, or 12.

---

**Note** This parameter is only used with the 'cohort' algorithm.

---

Data Types: double

### startDate — Start date of the estimation time window

earliest date in data (default) | character vector | serial date number | datetime

Start date of the estimation time window, specified as the comma-separated pair consisting of 'startDate' and a date character vector, serial date number, or datetime object.

Data Types: char | double | datetime

### transInterval — Length of the transition interval in years

1 (one year transition probability) (default) | numeric

Length of the transition interval, in years, specified as the comma-separated pair consisting of 'transInterval' and a numeric value.

Data Types: double

### excludeLabels — Label that is excluded from the transition probability computation

' ' (do not exclude any label) (default) | numeric | character vector | string

Label that is excluded from the transition probability computation, specified as the comma-separated pair consisting of 'excludeLabels' and a character vector, string, or numerical rating.

If multiple labels are to be excluded, 'excludeLabels' must be a cell array containing all of the labels for exclusion. The type of the labels given in 'excludeLabels' must be consistent with the data type specified in the labels input.

The list of labels to exclude may or may not be specified in labels.

Data Types: double | char | string

## Output Arguments

### transMat — Matrix of transition probabilities in percent

matrix

Matrix of transition probabilities in percent, returned as a nRatings-by-nRatings transition matrix.

### sampleTotals — Structure with sample totals

structure

Structure with sample totals, returned with fields:

- totalsVec — A vector of size 1-by-nRatings.
- totalsMat — A matrix of size nRatings-by-nRatings.
- algorithm — A character vector with values 'duration' or 'cohort'.

For the 'duration' algorithm, totalsMat(*i,j*) contains the total transitions observed out of rating *i* into rating *j* (all the diagonal elements are zero). The total time spent on rating *i* is stored in totalsVec(*i*). For example, if there are three rating categories, Investment Grade (IG), Speculative Grade (SG), and Default (D), and the following information:

|                  |         |         |         |
|------------------|---------|---------|---------|
| Total time spent | IG      | SG      | D       |
| in rating:       | 4859.09 | 1503.36 | 1162.05 |

|                |    |     |    |    |
|----------------|----|-----|----|----|
| Transitions    |    | IG  | SG | D  |
| out of (row)   | IG | 0   | 89 | 7  |
| into (column): | SG | 202 | 0  | 32 |
|                | D  | 0   | 0  | 0  |

Then

```
totals.totalsVec = [4859.09 1503.36 1162.05]
totals.totalsMat = [ 0 89 7
                  202 0 32
                  0 0 0]
totals.algorithm = 'duration'
```

For the 'cohort' algorithm, totalsMat(*i,j*) contains the total transitions observed from rating *i* to rating *j*, and totalsVec(*i*) is the initial count in rating *i*. For example, given the following information:

|               |      |      |      |
|---------------|------|------|------|
| Initial count | IG   | SG   | D    |
| in rating:    | 4808 | 1572 | 1145 |

|              |    |      |      |      |
|--------------|----|------|------|------|
| Transitions  |    | IG   | SG   | D    |
| from (row)   | IG | 4721 | 80   | 7    |
| to (column): | SG | 193  | 1347 | 32   |
|              | D  | 0    | 0    | 1145 |

Then

```
totals.totalsVec = [4808  1572  1145]
totals.totalsMat = [4721   80    7
                  193  1347   32
                   0    0  1145]
totals.algorithm = 'cohort'
```

### **idTotals — IDs totals**

struct array

IDs totals, returned as a struct array of size  $nIDs$ -by-1, where  $nIDs$  is the number of distinct IDs in column 1 of `data` when this is a table or cell array or, equivalently, equal to the length of the `idStart` field minus 1 when `data` is a preprocessed data structure from `transprobprep`. For each ID in the sample, `idTotals` contains one structure with the following fields:

- `totalsVec` — A sparse vector of size 1-by- $nRatings$ .
- `totalsMat` — A sparse matrix of size  $nRatings$ -by- $nRatings$ .
- `algorithm` — A character vector with values 'duration' or 'cohort'.

These fields contain the same information described for the output `sampleTotals`, but at an ID level. For example, for 'duration', `idTotals(k).totalsVec` contains the total time that the  $k$ -th company spent on each rating.

## **More About**

### **Cohort Estimation**

The cohort algorithm estimates the transition probabilities based on a sequence of snapshots of credit ratings at regularly spaced points in time.

If the credit rating of a company changes twice between two snapshot dates, the intermediate rating is overlooked and only the initial and final ratings influence the estimates.

### **Duration Estimation**

Unlike the cohort method, the duration algorithm estimates the transition probabilities based on the full credit ratings history, looking at the exact dates on which the credit rating migrations occur.

There is no concept of snapshots in this method, and all credit rating migrations influence the estimates, even when a company's rating changes twice within a short time.

## **Algorithms**

### **Cohort Estimation**

The algorithm first determines a sequence  $t_0, \dots, t_K$  of snapshot dates. The elapsed time, in years, between two consecutive snapshot dates  $t_{k-1}$  and  $t_k$  is equal to  $1 / ns$ , where  $ns$  is the number of snapshots per year. These  $K + 1$  dates determine  $K$  transition periods.

The algorithm computes  $N_i^n$ , the number of transition periods in which obligor  $n$  starts at rating  $i$ . These are added up over all obligors to get  $N_i$ , the number of obligors in the sample that start a period at rating  $i$ . The number periods in which obligor  $n$  starts at rating  $i$  and ends at rating  $j$ , or

migrates from  $i$  to  $j$ , denoted by  $N_{ij}^n$ , is also computed. These are also added up to get  $N_{ij}$ , the total number of migrations from  $i$  to  $j$  in the sample.

The estimate of the transition probability from  $i$  to  $j$  in one period, denoted by  $P_{ij}$ , is

$$P_{ij} = \frac{N_{ij}}{N_i}$$

These probabilities are arranged in a one-period transition matrix  $P_0$ , where the  $ij$  entry in  $P_0$  is  $P_{ij}$ .

If the number of snapshots per year  $ns$  is 4 (quarterly snapshots), the probabilities in  $P_0$  are 3-month (or 0.25-year) transition probabilities. You may, however, be interested in 1-year or 2-year transition probabilities. The latter time interval is called the transition interval,  $\Delta t$ , and it is used to convert  $P_0$  into the final transition matrix,  $P$ , according to the formula:

$$P = P_0^{ns * \Delta t}$$

For example, if  $ns = 4$  and  $\Delta t = 2$ ,  $P$  contains the two-year transition probabilities estimated from quarterly snapshots.

---

**Note** For the cohort algorithm, optional output arguments `idTotals` and `sampleTotals` from `transprob` contain the following information:

- `idTotals(n).totalsVec = (N_i^n) \forall i`
- `idTotals(n).totalsMat = (N_{i,j}^n) \forall ij`
- `idTotals(n).algorithm = 'cohort'`
- `sampleTotals.totalsVec = (N_i) \forall i`
- `sampleTotals.totalsMat = (N_{i,j}) \forall ij`
- `sampleTotals.algorithm = 'cohort'`

For efficiency, the vectors and matrices in `idTotals` are stored as sparse arrays.

---

When ratings must be excluded (see the `excludeLabels` name-value input argument), all transitions involving the excluded ratings are removed from the sample. For example, if the 'NR' rating must be excluded, any transitions into 'NR' and out of 'NR' are excluded from the sample. The total counts for all other ratings are adjusted accordingly. For more information, see "Visualize Transitions Data for `transprob`" on page 8-111.

### Duration Estimation

The algorithm computes  $T_i^n$ , the total time that obligor  $n$  spends in rating  $i$  within the estimation time window. These quantities are added up over all obligors to get  $T_i$ , the total time spent in rating  $i$ , collectively, by all obligors in the sample. The algorithm also computes  $T_{ij}^n$ , the number times that obligor  $n$  migrates from rating  $i$  to rating  $j$ , with  $i$  not equal to  $j$ , within the estimation time window. And it also adds them up to get  $T_{ij}$ , the total number of migrations, by all obligors in the sample, from the rating  $i$  to  $j$ , with  $i$  not equal to  $j$ .

To estimate the transition probabilities, the duration algorithm first computes a generator matrix  $\Lambda$ . Each off-diagonal entry of this matrix is an estimate of the transition rate out of rating  $i$  into rating  $j$ , and is

$$\lambda_{ij} = \frac{T_{ij}}{T_i}, i \neq j$$

The diagonal entries are computed as:

$$\lambda_{ii} = - \sum_{j \neq i} \lambda_{ij}$$

With the generator matrix and the transition interval  $\Delta t$  (e.g.,  $\Delta t = 2$  corresponds to two-year transition probabilities), the transition matrix is obtained as  $P = \exp(\Delta t \Lambda)$ , where *exp* denotes matrix exponentiation (`expm` in MATLAB).

---

**Note** For the duration algorithm, optional output arguments `idTotals` and `sampleTotals` from `transprob` contain the following information:

- `idTotals(n).totalsVec = (T_i^n) \forall i`
- `idTotals(n).totalsMat = (T_{i,j}^n) \forall ij`
- `idTotals(n).algorithm = 'duration'`
- `sampleTotals.totalsVec = (T_i) \forall i`
- `sampleTotals.totalsMat = (T_{i,j}) \forall ij`
- `sampleTotals.algorithm = 'duration'`

For efficiency, the vectors and matrices in `idTotals` are stored as sparse arrays.

---

When ratings must be excluded (see the `excludeLabels` name-value input argument), all transitions involving the exclude ratings are removed from the sample. For example, if the 'NR' rating must be excluded, any transitions into 'NR' and out of 'NR' are excluded from the sample. The total time spent in 'NR' (or any other excluded rating) is also removed.

# transprobytotals

Estimate transition probabilities using totals structure input

## Syntax

```
[transMat, sampleTotals] = transprobytotals(totals)
[transMat, sampleTotals] = transprobytotals( ___, Name, Value)
```

## Description

[transMat, sampleTotals] = transprobytotals(totals) estimates transition probabilities using a totals structure input. transprobytotals is useful for removing outlier information, obtaining bootstrapped confidence intervals, or computing transition probability estimates for different periodicity parameters (1-year transitions, 2-year transitions, and so on) efficiently.

[transMat, sampleTotals] = transprobytotals( \_\_\_, Name, Value) adds optional name-value pair arguments.

## Examples

### Estimate Transition Probabilities Using a totals Structure Input

Use historical credit rating input data from Data\_TransProb.mat and transprob to generate input for transprobytotals:

```
load Data_TransProb
```

```
% Call TRANSPROB with three output arguments
```

```
[transMat, sampleTotals, idTotals] = transprob(data);
transMat
```

```
transMat = 8×8
```

```

93.1170    5.8428    0.8232    0.1763    0.0376    0.0012    0.0001    0.0017

12.6875   23.1184   31.7177   38.8282   44.7266

```

## Input Arguments

### **totals** — Total transitions observed

structure | struct array

Total transitions observed, specified as a structure, or a struct array of length `nTotals`, with fields:

- `totalsVec` — A sparse vector of size 1-by-`nRatings1`.
- `totalsMat` — A sparse matrix of size `nRatings1`-by-`nRatings2` with `nRatings1` ≤ `nRatings2`.
- `algorithm` — A character vector with values 'duration' or 'cohort'.

For the 'duration' algorithm, `totalsMat(i,j)` contains the total transitions observed out of rating *i* into rating *j* (all the diagonal elements are 0). The total time spent on rating *i* is stored in `totalsVec(i)`. For example, you have three rating categories, Investment Grade (IG), Speculative Grade (SG), and Default (D), and the following information:

```

Total time spent   IG      SG      D
in rating:        4859.09  1503.36  1162.05

```

```

Transitions
out of (row)      IG      SG      D
into (column):   SG    202     0    32
                  D     0     0     0

```

Then:

```
totals.totalsVec = [4859.09 1503.36 1162.05]
totals.totalsMat = [ 0 89 7
                   202 0 32
                   0 0 0]
totals.algorithm = 'duration'
```

For the 'cohort' algorithm, `totalsMat(i,j)` contains the total transitions observed from rating  $i$  to rating  $j$ , and `totalsVec(i)` is the initial count in rating  $i$ . For example, given the following information:

|               |    |      |      |      |
|---------------|----|------|------|------|
| Initial count |    | IG   | SG   | D    |
| in rating:    |    | 4808 | 1572 | 1145 |
| Transitions   |    | IG   | SG   | D    |
| from (row)    | IG | 4721 | 80   | 7    |
| to (column):  | SG | 193  | 1347 | 32   |
|               | D  | 0    | 0    | 1145 |

Then:

```
totals.totalsVec = [4808 1572 1145]
totals.totalsMat = [4721 80 7
                   193 1347 32
                   0 0 1145]
totals.algorithm = 'cohort'
```

Common totals structures are the optional output arguments from `transprob`:

- `sampleTotals` — A single structure summarizing the totals information for the whole dataset.
- `idTotals` — A struct array with the totals information at the ID level.

Data Types: `struct` | `structure`

### Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `transMat = transprobytotals(Totals1, 'transInterval', 5)`

### snapsPerYear — Number of credit-rating snapshots per year

1 (default) | numeric values are 1, 2, 3, 4, 6, or 12

Number of credit-rating snapshots per year to be considered for the estimation, specified as the comma-separated pair consisting of 'snapsPerYear' and a numeric value of 1, 2, 3, 4, 6, or 12.

---

**Note** This parameter is only used with the 'cohort' algorithm.

---

Data Types: `double`

### transInterval — Length of the transition interval in years

1 (one year transition probability) (default) | numeric

Length of the transition interval, in years, specified as the comma-separated pair consisting of 'transInterval' and a numeric value.

Data Types: `double`

## Output Arguments

### **transMat** — Matrix of transition probabilities in percent

`matrix`

Matrix of transition probabilities in percent, returned as a `nRatings1`-by-`nRatings2` transition matrix.

### **sampleTotals** — Structure with sample totals

`structure`

Structure with sample totals, returned with fields:

- `totalsVec` — A vector of size `1`-by-`nRatings1`.
- `totalsMat` — A matrix of size `nRatings1`-by-`nRatings2` with `nRatings1` ≤ `nRatings2`.
- `algorithm` — A character vector with values `'duration'` or `'cohort'`.

If `totals` is a struct array, `sampleTotals` contains the aggregated information. That is, `sampleTotals.totalsVec` is the sum of `totals(k).totalsVec` over all `k`, and similarly for `totalsMat`. When `totals` is itself a single structure, `sampleTotals` and `totals` are the same.

## More About

### Cohort Estimation

The cohort algorithm estimates the transition probabilities based on a sequence of snapshots of credit ratings at regularly spaced points in time.

If the credit rating of a company changes twice between two snapshot dates, the intermediate rating is overlooked and only the initial and final ratings influence the estimates.

### Duration Estimation

Unlike the cohort method, the duration algorithm estimates the transition probabilities based on the full credit ratings history, looking at the exact dates on which the credit rating migrations occur.

There is no concept of snapshots in this method, and all credit rating migrations influence the estimates, even when a company's rating changes twice within a short time.

## transprobfromthresholds

Convert from credit quality thresholds to transition probabilities

### Syntax

```
trans = transprobfromthresholds(thresh)
```

### Description

`trans = transprobfromthresholds(thresh)` transforms credit quality thresholds into transition probabilities

### Examples

#### Transform Credit Quality Thresholds Into Transition Probabilities

Use historical credit rating input data from `Data_TransProb.mat`, estimate transition probabilities with default settings.

```
load Data_TransProb
```

```
% Estimate transition probabilities with default settings
```

```
transMat = transprob(data)
```

```
transMat = 8x8
```

```

```

## Input Arguments

### thresh — Credit quality thresholds

matrix

Credit quality thresholds, specified as a M-by-N matrix of credit quality thresholds.

In each row, the first element must be `Inf` and the entries must satisfy the following monotonicity condition:

$$\text{thresh}(i,j) \geq \text{thresh}(i,j+1), \text{ for } 1 \leq j < N$$

The M-by-N input `thresh` and the M-by-N output `trans` are related as follows. The thresholds `thresh(i,j)` are critical values of a standard normal distribution  $z$ , such that:

$$\text{trans}(i,N) = P[z < \text{thresh}(i,N)],$$

$$\text{trans}(i,j) = P[z < \text{thresh}(i,j)] - P[z < \text{thresh}(i,j+1)], \text{ for } 1 \leq j < N$$

Any given row in the output matrix `trans` determines a probability distribution over a discrete set of  $N$  ratings 'R1', ..., 'RN', so that for any row  $i$  `trans(i,j)` is the probability of migrating into 'Rj'. `trans` can be a standard transition matrix, with  $M \leq N$ , in which case row  $i$  contains the transition probabilities for issuers with rating 'Ri'. But `trans` does not have to be a standard transition matrix. `trans` can contain individual transition probabilities for a set of M-specific issuers, with  $M > N$ .

For example, suppose that there are only  $N=3$  ratings, 'High', 'Low', and 'Default', with these credit quality thresholds:

|      | High | Low     | Default |
|------|------|---------|---------|
| High | Inf  | -2.0814 | -3.1214 |
| Low  | Inf  | 2.4044  | -1.7530 |

The matrix of transition probabilities is then:

|      | High  | Low   | Default |
|------|-------|-------|---------|
| High | 98.13 | 1.78  | 0.09    |
| Low  | 0.81  | 95.21 | 3.98    |

This means the probability of default for 'High' is equivalent to drawing a standard normal random number smaller than  $-3.1214$ , or 0.09%. The probability that a 'High' ends up the period with a

rating of 'Low' or lower is equivalent to drawing a standard normal random number smaller than  $-2.0814$ , or 1.87%. From here, the probability of ending with a 'Low' rating is:

$$P[z < -2.0814] - P[z < -3.1214] = 1.87\% - 0.09\% = 1.78\%$$

And the probability of ending with a 'High' rating is:

$$100\% - 1.87\% = 98.13\%$$

where 100% is the same as:

$$P[z < \text{Inf}]$$

Data Types: double

## Output Arguments

**trans** — Matrix of transition probabilities in percent  
matrix

Matrix of transition probabilities in percent, returned as a M-by-N matrix.

# transprobrouptotals

Aggregate credit ratings information into fewer rating categories

## Syntax

```
totalsGrouped = transprobrouptotals(totals,groupingEdges)
```

## Description

`totalsGrouped = transprobrouptotals(totals,groupingEdges)` aggregates the credit ratings information stored in the `totals` input into fewer ratings categories, which are defined by the `groupingEdges` argument.

## Examples

### Aggregate the Credit Ratings Information Stored in the totals Input

Use historical credit rating input data from `Data_TransProb.mat`. Load input data from file `Data_TransProb.mat`.

```
load Data_TransProb
```

```
% Call TRANSPROB with two output arguments
[transMat, sampleTotals] = transprob(data);
transMat
```

```
transMat = 8×8
```

```

```

## Input Arguments

### **totals** — Total transitions observed

structure | struct array

Total transitions observed, specified as a structure, or a struct array of length nTotals, with fields:

- **totalsVec** — A sparse vector of size 1-by-nRatings1.
- **totalsMat** — A sparse matrix of size nRatings1-by-nRatings2 with nRatings1 ≤ nRatings2.
- **algorithm** — A character vector with values 'duration' or 'cohort'.

For the 'duration' algorithm, **totalsMat**(*i,j*) contains the total transitions observed out of rating *i* into rating *j* (all the diagonal elements are 0). The total time spent on rating *i* is stored in **totalsVec**(*i*). For example, you have three rating categories, Investment Grade (IG), Speculative Grade (SG), and Default (D), and the following information:

|                  |         |         |         |
|------------------|---------|---------|---------|
| Total time spent | IG      | SG      | D       |
| in rating:       | 4859.09 | 1503.36 | 1162.05 |

|                |    |     |    |
|----------------|----|-----|----|
| Transitions    | IG | SG  | D  |
| out of (row)   | IG | 0   | 89 |
| into (column): | SG | 202 | 0  |
|                | D  | 0   | 0  |

Then:

```
totals.totalsVec = [4859.09 1503.36 1162.05]
totals.totalsMat = [ 0 89 7
                   202 0 32
                   0 0 0]
totals.algorithm = 'duration'
```

For the 'cohort' algorithm, **totalsMat**(*i,j*) contains the total transitions observed from rating *i* to rating *j*, and **totalsVec**(*i*) is the initial count in rating *i*. For example, given the following information:

```

Initial count      IG      SG      D
in rating:        4808    1572    1145

Transitions        IG      SG      D
from (row)  IG  4721     80     7
to (column): SG   193    1347    32
                D     0       0    1145

```

Then:

```

totals.totalsVec = [4808    1572    1145]
totals.totalsMat = [4721     80     7
                   193    1347    32
                   0       0    1145]
totals.algorithm = 'cohort'

```

Common totals structures are the optional output arguments from `transprob`:

- `sampleTotals` — A single structure summarizing the totals information for the whole dataset.
- `idTotals` — A struct array with the totals information at the ID level.

Data Types: `struct` | `structure`

### **groupingEdges** — Indicator for grouping credit ratings into categories

numeric array

Indicator for grouping credit ratings into categories, specified as a numeric array.

This table illustrates how to group a list of whole ratings into investment grade (IG) and speculative grade (SG) categories. Eight ratings are in the original list. Ratings 1 to 4 are IG, ratings 5 to 7 are SG, and rating 8 is a category of its own. In this example, the array of grouping edges is `[4 7 8]`.

```

Original ratings: 'AAA' 'AA'  'A'  'BBB' | 'BB' 'B'  'CCC' | 'D'
Relative ordering: (1)  (2)  (3)  (4)  | (5) (6)  (7)  | (8)
Grouped ratings:           'IG'          |           'SG'          | 'D'
Grouping edges:           (4)  |           (7)  | (8)

```

In general, if `groupingEdges` has  $K$  elements  $\text{edge1} < \text{edge2} < \dots < \text{edgeK}$ , ratings 1 to  $\text{edge1}$  (inclusive) are grouped in the first category, ratings  $\text{edge1}+1$  to  $\text{edge2}$  in the second category, and so forth.

Regarding the last element,  $\text{edgeK}$ :

- If  $n\text{Ratings1}$  equals  $n\text{Ratings2}$ , then  $\text{edgeK}$  must equal  $n\text{Ratings1}$ . This leads to  $K$  groups, and  $n\text{RatingsGrouped1} = n\text{RatingsGrouped2} = K$ .
- If  $n\text{Ratings1} < n\text{Ratings2}$ , then either:
  - $\text{edgeK}$  equals  $n\text{Ratings1}$ , in which case ratings  $\text{edgeK}+1, \dots, n\text{Ratings2}$  are treated as categories of their own. This results in  $K+(n\text{Ratings2}-\text{edgeK})$  groups, with  $n\text{RatingsGrouped1} = K$  and  $n\text{RatingsGrouped2} = K + (n\text{Ratings2} - \text{edgeK})$ ; or
  - $\text{edgeK}$  equals  $n\text{Ratings2}$ , in which case there must be a  $j$ th edge element,  $\text{edgej}$ , such that  $\text{edgej}$  equals  $n\text{Ratings1}$ . This leads to  $K$  groups, and  $n\text{RatingsGrouped1} = j$  and  $n\text{RatingsGrouped2} = K$ .

Data Types: `double`

## Output Arguments

### **totalsGrouped — Aggregated information by categories**

structure | struct array

Aggregated information by categories, returned as a structure, or a struct array of length `nTotals`, with fields:

- `totalsVec` — A vector of size 1-by-`nRatingsGrouped1`.
- `totalsMat` — A matrix of size `nRatingsGrouped1`-by-`nRatingsGrouped2`.
- `algorithm` — A character vector, 'duration' or 'cohort'.

`nRatingsGrouped1` and `nRatingsGrouped2` are defined in the description of `groupingEdges`. Each structure contains aggregated information by categories, based on the information provided in the corresponding structure in `totals`, according to the grouping of ratings defined by `groupingEdges` and consistent with the `algorithm` choice.

Following the examples in the description of the `totals` input, suppose IG and SG are grouped into a single ND (Not-Defaulted) category, using the edges[2 3]. For the 'cohort' algorithm, the output is:

```
totalsGrouped.totalsVec = [6380  1145]
totalsGrouped.totalsMat = [6341   39
                          0   1145]
totalsGrouped.algorithm = 'cohort'
```

and for the 'duration' algorithm:

```
totalsGrouped.totalsVec = [6362.45  1162.05]
totalsGrouped.totalsMat = [0  39
                          0  0]
totalsGrouped.algorithm = 'duration'
```

## More About

### **Cohort Estimation**

The cohort algorithm estimates the transition probabilities based on a sequence of snapshots of credit ratings at regularly spaced points in time.

If the credit rating of a company changes twice between two snapshot dates, the intermediate rating is overlooked and only the initial and final ratings influence the estimates. For more information, see the Algorithms section of `transprob`.

### **Duration Estimation**

Unlike the cohort algorithm, the duration algorithm estimates the transition probabilities based on the full credit ratings history, looking at the exact dates on which the credit rating migrations occur.

There is no concept of snapshots in this method, and all credit rating migrations influence the estimates, even when a company's rating changes twice within a short time. For more information, see the Algorithms section of `transprob`.

## transprobprep

Preprocess credit ratings data to estimate transition probabilities

### Syntax

```
[prepData] = transprobprep(data)
[prepData] = transprobprep( ___,Name,Value)
```

### Description

[prepData] = transprobprep(data) preprocesses credit ratings historical data (that is, credit migration data) for the subsequent estimation of transition probabilities.

[prepData] = transprobprep( \_\_\_,Name,Value) adds optional name-value pair arguments.

### Examples

#### Aggregate the Credit Ratings Information Stored in the totals Input

Load input data from the file `Data_TransProb.mat` and display the first ten rows. In this example, the inputs are provided in character vector format.

```
load Data_TransProb
```

```
% Preprocess credit ratings data.
prepData = transprobprep(data)
```

```
prepData = struct with fields:
    idStart: [1506x1 double]
    numericDates: [4315x1 double]
    numericRatings: [4315x1 double]
    ratingsLabels: {'AAA' 'AA' 'A' 'BBB' 'BB' 'B' 'CCC' 'D'}
```

Estimate transition probabilities with the default settings.

```
transMat = transprob(prepData)
```

```
transMat = 8×8
```

```

## Input Arguments

### data — Historical data for credit ratings

table | cell array of character vectors

Historical input data for credit ratings, specified as one of the following:

- A MATLAB table of size nRecords-by-3 containing the credit ratings. Each row contains an ID (column 1), a date (column 2), and a credit rating (column 3). The assigned credit rating corresponds to the associated ID on the associated date. All information corresponding to the same ID must be stored in contiguous rows. Sorting this information by date is not required, but recommended for efficiency. When using a MATLAB table input, the names of the columns are irrelevant, but the ID, date and rating information are assumed to be in the first, second, and third columns, respectively. Also, when using a table input, the first and third columns can be categorical arrays, and the second can be a datetime array. Here is an example with all the information in table format:

| ID         | Date          | Rating |
|------------|---------------|--------|
| '00010283' | '10-Nov-1984' | 'CCC'  |
| '00010283' | '12-May-1986' | 'B'    |
| '00010283' | '29-Jun-1988' | 'CCC'  |
| '00010283' | '12-Dec-1991' | 'D'    |
| '00013326' | '09-Feb-1985' | 'A'    |
| '00013326' | '24-Feb-1994' | 'AA'   |

The following summarizes the supported data types for table input:

| Data Input Type | ID (1st Column)                                                                                                                     | Date (2nd Column)                                                                                                                | Rating (3rd Column)                                                                                                                 |
|-----------------|-------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------|
| Table           | <ul style="list-style-type: none"> <li>Numeric array</li> <li>Cell array of character vectors</li> <li>Categorical array</li> </ul> | <ul style="list-style-type: none"> <li>Numeric array</li> <li>Cell array of character vectors</li> <li>Datetime array</li> </ul> | <ul style="list-style-type: none"> <li>Numeric array</li> <li>Cell array of character vectors</li> <li>Categorical array</li> </ul> |

- A cell array of size nRecords-by-3 containing the credit ratings. Each row contains an ID (column 1), a date (column 2), and a credit rating (column 3). The assigned credit rating corresponds to the associated ID on the associated date. All information corresponding to the same ID must be stored in contiguous rows. Sorting this information by date is not required but is recommended. IDs, dates, and ratings are stored in character vector format, but they can also be entered in numeric format. Here is an example with all the information in character vector format:

```
'00010283' '10-Nov-1984' 'CCC'
'00010283' '12-May-1986' 'B'
'00010283' '29-Jun-1988' 'CCC'
'00010283' '12-Dec-1991' 'D'
'00013326' '09-Feb-1985' 'A'
'00013326' '24-Feb-1994' 'AA'
```

The following summarizes the supported data types for cell array input:

| Data Input Type | ID (1st Column)                                                                                       | Date (2nd Column)                                                                                     | Rating (3rd Column)                                                                                   |
|-----------------|-------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------|
| Cell            | <ul style="list-style-type: none"> <li>Numeric elements</li> <li>Character vector elements</li> </ul> | <ul style="list-style-type: none"> <li>Numeric elements</li> <li>Character vector elements</li> </ul> | <ul style="list-style-type: none"> <li>Numeric elements</li> <li>Character vector elements</li> </ul> |

Data Types: `table` | `cell`

### Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1`, `Value1`, ..., `NameN`, `ValueN`.

Example: `prepData = transprobbprep(data, 'labels', {'AAA', 'AA', 'A', 'BBB', 'BB', 'B', 'CCC', 'F'})`

### Labels — Credit-rating scale

`{'AAA', 'AA', 'A', 'BBB', 'BB', 'B', 'CCC', 'D'}` (default) | cell array of character vectors

Credit-rating scale, specified as the comma-separated pair consisting of `'labels'` and a `nRatings`-by-1, or 1-by-`nRatings` cell array of character vectors.

`labels` must be consistent with the ratings labels used in the third column of `data`. Use a cell array of numbers for numeric ratings, and a cell array for character vectors for categorical ratings.

Data Types: `cell`

## Output Arguments

### `prepData` — Summary where credit ratings information corresponding to each company starts and ends

structure

Summary where the credit ratings information corresponding to each company starts and ends, returned as a structure with the following fields:

- `idStart` — Array of size  $(nIDs+1)$ -by-1, where `nIDs` is the number of distinct IDs in column 1 of `data`. This array summarizes where the credit ratings information corresponding to each company starts and ends. The dates and ratings corresponding to company `j` in `data` are stored from row `idStart(j)` to row `idStart(j+1)-1` of `numericDates` and `numericRatings`.
- `numericDates` — Array of size `nRecords`-by-1, containing the dates in column 2 of `data`, in numeric format.
- `numericRatings` — Array of size `nRecords`-by-1, containing the ratings in column 3 of `data`, mapped into numeric format.

- `ratingsLabels` — Cell array of size `1-by-nRatings`, containing the credit rating scale.

## transprobtothresholds

Convert from transition probabilities to credit quality thresholds

### Syntax

```
thresh = transprobtothresholds(trans)
```

### Description

`thresh = transprobtothresholds(trans)` transforms transition probabilities into credit quality thresholds.

### Examples

#### Transform Transition Probabilities Into Credit Quality Thresholds

Use historical credit rating input data from `Data_TransProb.mat`. Load input data from file `Data_TransProb.mat`.

```
load Data_TransProb
```

```
% Estimate transition probabilities with default settings
transMat = transprob(data)
```

```
transMat = 8x8
```

```

```

## Input Arguments

### trans — Transition probabilities in percent

matrix

Transition probabilities in percent, specified as a M-by-N matrix. Entries cannot be negative and cannot exceed 100, and all rows must add up to 100.

Any given row in the M-by-N input matrix `trans` determines a probability distribution over a discrete set of N ratings. If the ratings are 'R1', . . . , 'RN', then for any row *i* `trans(i,j)` is the probability of migrating into 'Rj'. If `trans` is a standard transition matrix, then  $M \leq N$  and row *i* contains the transition probabilities for issuers with rating 'Ri'. But `trans` does not have to be a standard transition matrix. `trans` can contain individual transition probabilities for a set of M-specific issuers, with  $M > N$ .

The credit quality thresholds `thresh(i,j)` are critical values of a standard normal distribution *z*, such that:

$$\text{trans}(i,N) = P[z < \text{thresh}(i,N)],$$

$$\text{trans}(i,j) = P[z < \text{thresh}(i,j)] - P[z < \text{thresh}(i,j+1)], \text{ for } 1 \leq j < N$$

This implies that `thresh(i,1) = Inf`, for all *i*. For example, suppose that there are only  $N=3$  ratings, 'High', 'Low', and 'Default', with the following transition probabilities:

|      | High  | Low   | Default |
|------|-------|-------|---------|
| High | 98.13 | 1.78  | 0.09    |
| Low  | 0.81  | 95.21 | 3.98    |

The matrix of credit quality thresholds is:

|      | High | Low     | Default |
|------|------|---------|---------|
| High | Inf  | -2.0814 | -3.1214 |
| Low  | Inf  | 2.4044  | -1.7530 |

This means the probability of default for 'High' is equivalent to drawing a standard normal random number smaller than  $-3.1214$ , or 0.09%. The probability that a 'High' ends up the period with a rating of 'Low' or lower is equivalent to drawing a standard normal random number smaller than  $-2.0814$ , or 1.87%. From here, the probability of ending with a 'Low' rating is:

$$P[z < -2.0814] - P[z < -3.1214] = 1.87\% - 0.09\% = 1.78\%$$

And the probability of ending with a 'High' rating is:

$$100\% - 1.87\% = 98.13\%$$

where 100% is the same as:

$$P[z < \text{Inf}]$$

Data Types: double

## Output Arguments

### thresh — Credit quality thresholds

matrix

Credit quality thresholds, returned as a M-by-N matrix.

# tsaccel

Acceleration between times

---

**Note** Using a `fints` object for the `Data` argument of `tsaccel` is not recommended. Use a vector, matrix, `timetable`, or `table` instead for financial time series. For more information, see “Convert Financial Time Series Objects `fints` to `Timetables`”.

---

## Syntax

```
acceleration = tsaccel(Data)
acceleration = tsaccel( ___,Name,Value)
```

## Description

`acceleration = tsaccel(Data)` calculates the acceleration of a data series with time distance of  $n$  periods.

$n$  periods.

`acceleration = tsaccel( ___,Name,Value)` adds optional name-value pair arguments.

## Examples

### Calculate the Acceleration of a Data Series for a Stock

Load the file `SimulatedStock.mat`, which provides a timetable (TMW) for financial data for TMW stock.

```
load SimulatedStock.mat
TMW.Volume = []; % remove VOLUME field
acceleration = tsaccel(TMW);
plot(acceleration.Time,acceleration.Variables)
legend('OPEN','HIGH','LOW','CLOSE')
title('Acceleration for TMW')
```

## Input Arguments

### Data — Data with high, low, open, close information

vector | matrix | table | timetable

Data with high, low, open, close information, specified as a vector, matrix, table, or timetable. For vector input, `Data` is a column vector of high, low, open, and closing prices stored in the corresponding columns. For matrix input, `Data` is an M-by-N column-oriented matrix of high, low, open, and closing prices stored in the corresponding columns. Timetables and tables with M rows must contain variables named 'High', 'Low', 'Open', and 'Close' (case insensitive).

Data Types: double | table | timetable

### Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `acceleration = tsaccel(TMW, 'NumPeriods', 10, 'Datatype', 1)`

### NumPeriods — Period difference for acceleration

12 (default) | positive integer

Period difference for acceleration, specified as the comma-separated pair consisting of 'NumPeriods' and a scalar positive integer.

Data Types: double

### **Datatype — Indicates if Data contains the data itself or the momentum of the data**

0 (Data contains the data itself) (default) | integer with values 0 or 1

Indicates if Data contains the data itself or the momentum of the data, specified as the comma-separated pair consisting of 'Datatype' and a scalar integer with a value of:

- 0 - Data contains the data itself.
- 1 - Data contains the momentum of the data.

Data Types: double

## **Output Arguments**

### **acceleration — Acceleration series**

vector | matrix | table | timetable

Acceleration series, returned with the same number of rows (M) and columns (N) and the same type (vector, matrix, table, or timetable) as the input Data.

## **More About**

### **Acceleration**

Acceleration is defined as the difference of two momentum series separated by  $n$  periods.

Acceleration is the difference of the current momentum with the momentum  $n$  periods ago. By default, acceleration is based on 12-period difference.

## tsmom

Momentum between times

---

**Note** Using a `fints` object for the `Data` argument of `tsmom` is not recommended. Use a vector, matrix, `timetable`, or `table` instead for financial time series. For more information, see “Convert Financial Time Series Objects `fints` to `Timetables`”.

---

### Syntax

```
momentum = tsmom(Data)
momentum = tsmom( ___,Name,Value)
```

### Description

`momentum = tsmom(Data)` calculates the momentum of a data series with time distance of  $n$  periods.

`momentum = tsmom( ___,Name,Value)` adds optional name-value pair arguments.

### Examples

#### Calculate the Momentum for a Data Series for a Stock

Load the file `SimulatedStock.mat`, which provides a `timetable` (TMW) for financial data for TMW stock.

```
load SimulatedStock.mat
TMW.Volume = []; % remove VOLUME field
momentum = tsmom(TMW);
plot(momentum.Time,momentum.Variables)
legend('OPEN','HIGH','LOW','CLOSE')
title('Acceleration for TMW')
```

## Input Arguments

### Data — Data with high, low, open, close information

vector | matrix | table | timetable

Data with high, low, open, close information, specified as a vector, matrix, table, or timetable. For vector input, `Data` is a column vector. For matrix input, `Data` is an M-by-N column oriented matrix. Timetables and tables with M rows can contain variables named 'High', 'Low', 'Open', and 'Close' (case insensitive).

Data Types: double | table | timetable

### Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `momentum = tsmom(TMW, 'NumPeriods', 15)`

### NumPeriods — Period difference for momentum

12 (default) | positive integer

Period difference for momentum, specified as the comma-separated pair consisting of 'NumPeriods' and a scalar positive integer.

Data Types: double

## Output Arguments

### **momentum** — Momentum series

matrix | table | timetable

Momentum series, returned with the same number of rows (M) and the same type (matrix, table, or timetable) as the input Data.

## More About

### **Momentum Series**

Momentum series is the difference of the current data with the data  $n$  periods ago. By default, momentum is based on 12-period difference.

# tsmovavg

Moving average

---

**Note** `tsmovavg` is not recommended. Use `timetable` instead. For more information, see “Convert Financial Time Series Objects `fints` to Timetables”.

---

## Syntax

```
output = tsmovavg(tsobj, 's', lag)
output = tsmovavg(vector, 's', lag, dim)

output = tsmovavg(tsobj, 'e', timeperiod)
output = tsmovavg(vector, 'e', timeperiod, dim)

output = tsmovavg(tsobj, 't', numperiod)
output = tsmovavg(vector, 't', numperiod, dim)

output = tsmovavg(tsobj, 'w', weights)
output = tsmovavg(vector, 'w', weights, dim)

output = tsmovavg(tsobj, 'm', numperiod)
output = tsmovavg(vector, 'm', numperiod, dim)
```

## Description

`tsmovavg` calculates the simple, exponential, triangular, weighted, and modified moving average of a vector or `fints` object of data. For information on working with financial time series (`fints` objects) data, see “Working with Financial Time Series Objects” on page 13-2.

`output = tsmovavg(tsobj, 's', lag)` returns the simple moving average by for financial time series object, `tsobj`. `lag` indicates the number of previous data points used with the current data point when calculating the moving average.

`output = tsmovavg(vector, 's', lag, dim)` returns the simple moving average for a vector. `lag` indicates the number of previous data points used with the current data point when calculating the moving average.

`output = tsmovavg(tsobj, 'e', timeperiod)` returns the exponential weighted moving average for financial time series object, `tsobj`. The exponential moving average is a weighted moving average, where `timeperiod` specifies the time period. Exponential moving averages reduce the lag by applying more weight to recent prices. For example, a 10-period exponential moving average weights the most recent price by 18.18%.  $\text{Exponential Percentage} = 2 / (\text{TIMEPER} + 1)$  or  $2 / (\text{WINDOW\_SIZE} + 1)$ .

`output = tsmovavg(vector, 'e', timeperiod, dim)` returns the exponential weighted moving average for a vector. The exponential moving average is a weighted moving average, where `timeperiod` specifies the time period. Exponential moving averages reduce the lag by applying more weight to recent prices. For example, a 10-period exponential moving average weights the most recent price by 18.18%.  $(2 / (\text{timeperiod} + 1))$ .

`output = tsmovavg(tsobj, 't', numperiod)` returns the triangular moving average for financial time series object, `tsobj`. The triangular moving average double-smooths the data. `tsmovavg` calculates the first simple moving average with window width of `ceil(numperiod + 1)/2`. Then it calculates a second simple moving average on the first moving average with the same window size.

`output = tsmovavg(vector, 't', numperiod, dim)` returns the triangular moving average for a vector. The triangular moving average double-smooths the data. `tsmovavg` calculates the first simple moving average with window width of `ceil(numperiod + 1)/2`. Then it calculates a second simple moving average on the first moving average with the same window size.

`output = tsmovavg(tsobj, 'w', weights)` returns the weighted moving average for the financial time series object, `tsobj`, by supplying weights for each element in the moving window. The length of the weight vector determines the size of the window. If larger weight factors are used for more recent prices and smaller factors for previous prices, the trend is more responsive to recent changes.

`output = tsmovavg(vector, 'w', weights, dim)` returns the weighted moving average for the vector by supplying weights for each element in the moving window. The length of the weight vector determines the size of the window. If larger weight factors are used for more recent prices and smaller factors for previous prices, the trend is more responsive to recent changes.

`output = tsmovavg(tsobj, 'm', numperiod)` returns the modified moving average for the financial time series object, `tsobj`. The modified moving average is similar to the simple moving average. Consider the argument `numperiod` to be the lag of the simple moving average. The first modified moving average is calculated like a simple moving average. Subsequent values are calculated by adding the new price and subtracting the last average from the resulting sum.

`output = tsmovavg(vector, 'm', numperiod, dim)` returns the modified moving average for the vector. The modified moving average is similar to the simple moving average. Consider the argument `numperiod` to be the lag of the simple moving average. The first modified moving average is calculated like a simple moving average. Subsequent values are calculated by adding the new price and subtracting the last average from the resulting sum.

## Examples

### Compute Five Forms of Moving Averages Using a Financial Time Series Object

Load the financial time series object, `dis` for Disney stock and look at the weekly data for this time series.

```
load disney.mat
weekly = toweekly(dis);
```

Warning: FINTS is not recommended. Use `convert2weekly` instead.

```
dates = (weekly.dates);
price = fts2mat(weekly.CLOSE);
```

Warning: FINTS is not recommended. Use `TIMETABLE` instead. For more information, see [mat](#)

Set the `|lag|` input argument for the window size for the moving average.

```
window_size = 12;
```

Calculate the simple moving average.

```
simple = tsmovavg(price, 's', window_size, 1);
```

Warning: TSMOVAVG will be removed in a future release. Use MOVAVG instead.

Calculate the exponential weighted moving average moving average.

```
exp = tsmovavg(price, 'e', window_size, 1);
```

Warning: TSMOVAVG will be removed in a future release. Use MOVAVG instead.

Calculate the triangular moving average moving average.

```
tri = tsmovavg(price, 't', window_size, 1);
```

Warning: TSMOVAVG will be removed in a future release. Use MOVAVG instead.

Calculate the weighted moving average moving average.

```
semi_gaussian = [0.026 0.045 0.071 0.1 0.12 0.138];
semi_gaussian = [semi_gaussian fliplr(semi_gaussian)];
weighted = tsmovavg(price, 'w', semi_gaussian, 1);
```

Warning: TSMOVAVG will be removed in a future release. Use MOVAVG instead.

Calculate the modified moving average moving average.

```
modif = tsmovavg(price, 'm', window_size, 1);
```

Warning: TSMOVAVG will be removed in a future release. Use MOVAVG instead.

Plot the results for the five moving average calculations for Disney stock.

```
plot(dates, price, ...
     dates, simple, ...
     dates, exp, ...
     dates, tri, ...
     dates, weighted, ...
     dates, modif)
datetick
legend('Stock Price', 'Simple', 'Exponential', 'Triangular', 'Weighted', ...
      'Modified', 'Location', 'NorthWest')
title('Disney Weekly Price & Moving Averages')
```

## Input Arguments

### **tsobj** — Financial time series object

object

Financial time series object specified using a time series object created using `fints`.

### **'s'** — Indicator for simple moving average

character vector

`lag` is the parameter indicating the number of previous data points to be used in conjunction with the current data point when calculating the simple moving average.

### **lag** — Number of previous data points

nonnegative integer

Number of previous data points specified as a nonnegative integer. `lag` indicates the window size or number of periods of the moving average.

### **vector** — Set of observations

vector or matrix

Set of observations specified as a vector or matrix.

**dim — dimension to operate along**

positive integer with value 1 or 2

Dimension to operate along, specified as a positive integer with a value of 1 or 2. `dim` is an optional input argument, and if it is not included as an input, the default value 2 is assumed. The default of `dim = 2` indicates a row-oriented matrix, where each row is a variable and each column is an observation.

If `dim = 1`, the input is assumed to be a column vector or column-oriented matrix, where each column is a variable and each row an observation.

**'e' — Indicator for exponential moving average**

character vector

Exponential moving average is a weighted moving average, where `timeperiod` is the time period of the exponential moving average. Exponential moving averages reduce the lag by applying more weight to recent prices. For example, a 10 period exponential moving average weights the most recent price by 18.18%.

Exponential Percentage =  $2 / (\text{TIMEPER} + 1)$  or  $2 / (\text{WINDOW\_SIZE} + 1)$

**timeperiod — Length of time period**

nonnegative integer

Length of time period specified as a nonnegative integer.

**'t' — Indicator for triangular moving average**

character vector

Triangular moving average is a double-smoothing of the data. The first simple moving average is calculated with a window width of  $\text{ceil}(\text{numperiod} + 1) / 2$ . Then a second simple moving average is calculated on the first moving average with the same window size.

**'m' — Indicator for modified moving average**

character vector

The modified moving average is similar to the simple moving average. Consider the argument `numperiod` to be the lag of the simple moving average. The first modified moving average is calculated like a simple moving average. Subsequent values are calculated by adding the new price and subtracting the last average from the resulting sum.

**numperiod — Number of periods considered**

nonnegative integer

Number of periods considered specified as a nonnegative integer.

**'w' — Indicator for weighted moving average**

character vector

A weighted moving average is calculated with a weight vector, `weights`. The length of the weight vector determines the size of the window. If larger weight factors are used for more recent prices and smaller factors for previous prices, the trend is more responsive to recent changes.

**weights — Weights for each element in the moving window**

vector of weights

Weights for each element in the window specified as a vector of weights.

## Output Arguments

### **output** — Moving average calculation

vector or matrix

Moving average calculation returned as a vector or matrix. The output returned from `tsmovavg` is identical in format to the input.

# typprice

Typical price

---

**Note** Using a `fints` object for the `Data` argument of `typprice` is not recommended. Use a matrix, `timetable`, or `table` instead for financial time series. For more information, see “Convert Financial Time Series Objects `fints` to Timetables”.

---

## Syntax

```
TypicalPrice = typprice(Data)
```

## Description

`TypicalPrice = typprice(Data)` calculates the typical prices from the series of high, low, and closing prices. The typical price is the average of the high, low, and closing prices for each period.

## Examples

### Calculate the Typical Price for a Data Series for a Stock

Load the file `SimulatedStock.mat`, which provides a timetable (TMW) for financial data for TMW stock.

```
load SimulatedStock.mat
TypicalPrice = typprice(TMW);
plot(TypicalPrice.Time, TypicalPrice.TypicalPrice)
title('Typical Price for TMW')
```

## Input Arguments

### Data — Data for high, low, and closing prices

matrix | table | timetable

Data for high, low, and closing prices, specified as a matrix, table, or timetable. For matrix input, **Data** is an M-by-3 matrix of high, low, and closing prices stored in the corresponding columns. Timetables and tables with M rows must contain variables named 'High', 'Low', and 'Close' (case insensitive).

Data Types: double | table | timetable

## Output Arguments

### TypicalPrice — Typical price series

matrix | table | timetable

Typical price series, returned with the same number of rows (M) and the same type (matrix, table, or timetable) as the input **Data**.

## References

## uicalendar

Graphical calendar

### Syntax

```
uicalendar(Name,Value)
```

### Description

`uicalendar(Name,Value)` supports a customizable graphical calendar that interfaces with one or more `uicontrol`. `uicalendar` populates one or more `uicontrol` with user-selected dates.

---

**Note** As an alternative to `uicalendar`, you can use `uidatepicker`.

---

### Examples

#### Use `uicalendar` with an `uicontrol`

Create an `uicontrol`:

```
textH1 = uicontrol('style', 'edit', 'position', [10 10 100 20])  
textH1 =
```

```
    UIControl with properties:
```

```
        Style: 'edit'  
        String: ''  
    BackgroundColor: [0.9400 0.9400 0.9400]  
        Callback: ''  
        Value: 0  
        Position: [10 10 100 20]  
        Units: 'pixels'
```

Call `UICalendar`:

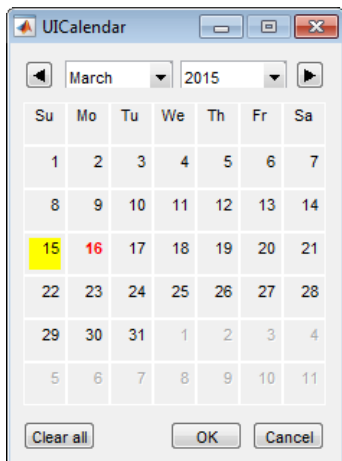

```
uicalendar('DestinationUI', {textH1, 'string'})
```

Select a date and click OK.

Alternatively, you can use datetime arrays for `InitDate` and `Holiday`.

```
uicalendar('InitDate',datetime('15-Mar-2015','Locale','en_US'),'Holiday',datetime('16-Mar-2015','Locale','en_US'))
```

Select a date and click OK. For more information on using `uicalendar` with an application, see “Example of Using UICalendar with an Application” on page 16-4.

## Input Arguments

### Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `uicalendar('InitDate',datetime('15-Mar-2015','Locale','en_US'),'Holiday',datetime('16-Mar-2015','Locale','en_US'))`

### BusDays — Flag to indicate nonbusiness days

0 (Standard calendar without nonbusiness day indicators) (default) | numeric values of 0 or 1

Flag to indicate nonbusiness days, specified using numeric values of 0 or 1. The values are:

- 0 — (Default) Standard calendar without nonbusiness day indicators.
- 1 — Marks NYSE nonbusiness days in red.

Data Types: logical

### **BusDaySelect — Flag to indicate whether business and nonbusiness days**

1 (Allows selections of business and nonbusiness days) (default) | numeric values of 0 or 1

Flag to indicate whether business and nonbusiness days, specified using numeric values of 0 or 1. The values are:

- 0 — Only allow selection of business days. Nonbusiness days are determined from the following parameters:
  - 'BusDays'
  - 'Holiday'
  - 'Weekend'
- 1 — (Default) Allows selections of business and nonbusiness days.

Data Types: logical

### **DateBoxColor — Color of date squares**

[date R G B]

Color of date squares, specified using [date R G B], where [R G B] is the color.

Data Types: double

### **DateStrColor — Color of numeric date number in the date square**

[date R G B]

Color of numeric date number in the date square, specified using [date R G B], where [R G B] is the color.

Data Types: double

### **DestinationUI — Destination object's handles**

'string' (default UI property populated with dates) (default) | values are H or {H, {Prop}}

Destination object's handles, specified with values H or {H, {Prop}}. The values are:

- H — Scalar or vector of the destination object's handles. The default UI property that is populated with the dates is a character vector.
- {H, {Prop}} — Cell array of handles and the destination object's UI properties. H must be a scalar or vector and Prop must be a single property character vector or a cell array of property character vectors.

Data Types: char | cell

### **Holiday — Holiday dates in calendar**

serial date numbers | datetime arrays

Holiday dates in calendar, specified using a scalar or vector of serial date numbers or datetime arrays. The corresponding date character vector of the holiday appears Red.

Data Types: `double` | `datetime`

### **InitDate — Initial start date when calendar is initialized**

TODAY (default) | serial date number | datetime array | date character vector

Initial start date when calendar is initialized, specified with date values using a serial date number, datetime array, or date character vector. The values are:

- **Datenum** — Numeric or datetime array date value specifying the initial start date when the calendar is initialized. The default date is TODAY.
- **Datestr** — Date character vector value specifying the initial start date when the calendar is initialized. **Datestr** must include a Year, Month, and Day (for example, 01-Jan-2006).

Data Types: `double` | `char` | `datetime`

### **InputDateFormat — Format of initial start date**

character vector

Format of initial start date (**InitDate**), specified using a character vector. **Seedatestr** for date format values.

Data Types: `double` | `datetime`

### **OutputDateFormat — Format of output date**

character vector

Format of output date, specified using a character vector. **Seedatestr** for date format values.

Data Types: `double` | `datetime`

### **OutputDateStyle — Style for output date**

0 (default) | numeric value of 0, 1, 2, or 3

Style for output date, specified using a value of 0, 1, 2, or 3. The values are:

- **0** — (Default) Returns a single date character vector or a cell array (row) of date character vectors. For example, {'01-Jan-2001', '02-Jan-2001', ...'}.
- **1** — Returns a single date character vector or a cell (column) array of date character vectors. For example, {'01-Jan-2001'; '02-Jan-2001'; ...'}.
- **2** — Returns a character vector representation of a row vector of datenums. For example, '[732758, 732759, 732760, 732761]'.
- **3** — Returns a character vector representation of a column vector of datenums. For example, '[732758; 732759; 732760; 732761]'.

Data Types: `double`

### **SelectionType — Flag for date selection**

1 (default) | numeric value of 0 or 1

Flag for date selection, specified with using a value of 0 or 1. The values are:

- 0 — Allows multiple date selections.
- 1 — (Default) Allows only a single date selection.

Data Types: `logical`

### **Weekend — Define weekend days**

1 (default) | numeric values of 1 through 7

Define weekend days, specified using a value of 1 through 7. Weekend days are marked in red. `DayOfWeek` can be a vector containing the following numeric values:

- 1 — Sunday
- 2 — Monday
- 3 — Tuesday
- 4 — Wednesday
- 5 — Thursday
- 6 — Friday
- 7 — Saturday

Also this value can be a vector of length 7 containing 0's and 1's. The value 1 indicates a weekend day. The first element of this vector corresponds to Sunday. For example, when Saturday and Sunday are weekend days then `WEEKEND = [1 0 0 0 0 0 1]`.

Data Types: `double`

### **WindowStyle — Window figure properties**

`Normal` (default) | character vector with value of `Normal` or `Modal`

Window figure properties, specified with using a character vector with a value of `Normal` or `Modal`. The values are:

- `Normal` — (Default) Standard figure properties.
- `Modal` — Modal figures remain stacked above all normal figures and the MATLAB Command Window.

Data Types: `char`

## var

Variance

---

**Note** `var` is not recommended. Use `timetable` instead. For more information, see “Convert Financial Time Series Objects `fints` to Timetables”.

---

### Syntax

```
y = var(X)
y = var(X,1)
y = var(X,W)
y = var(X,W,DIM)
```

### Arguments

|     |                                              |
|-----|----------------------------------------------|
| X   | Financial time series object.                |
| W   | Weight vector used in calculating variance.  |
| DIM | Dimension of X used in calculating variance. |

### Description

`var` supports financial time series objects based on the MATLAB `var` function. See `var`.

`y = var(X)`, if `X` is a financial time series object and returns the variance of each series.

`var` normalizes `y` by  $N - 1$  if  $N > 1$ , where  $N$  is the sample size. This is an unbiased estimator of the variance of the population from which `X` is drawn, as long as `X` consists of independent, identically distributed samples. For  $N = 1$ , `y` is normalized by  $N$ .

`y = var(X,1)` normalizes by  $N$  and produces the second moment of the sample about its mean. `var(X, 0)` is the same as `var(X)`.

`y = var(X,W)` computes the variance using the weight vector `W`. The length of `W` must equal the length of the dimension over which `var` operates, and its elements must be nonnegative. `var` normalizes `W` to sum to 1. Use a value of 0 for `W` to use the default normalization by  $N - 1$ , or use a value of 1 to use  $N$ .

`y = var(X,W,DIM)` takes the variance along the dimension `DIM` of `X`.

### Examples

The variance is the square of the standard deviation. Consider if

```
f = fints((today:today+1)', [4 -2 1; 9 5 7])
```

```
Warning: FINTS will be removed in a future release. Use TIMETABLE instead.  
> In fints (line 165)  
Warning: FINTS will be removed in a future release. Use TIMETABLE instead.  
> In fints/display (line 66)
```

```
f =
```

```
  desc: (none)  
  freq: Unknown (0)
```

```
  'dates: (2)'   'series1: (2)'   'series2: (2)'   'series3: (2)'  
'02-Oct-2017'  [          4]   [          -2]   [          1]  
'03-Oct-2017'  [          9]   [          5]   [          7]
```

```
then
```

```
var(f, 0, 1)
```

```
is
```

```
Warning: FINTS will be removed in a future release. Use TIMETABLE instead.  
> In fints/var (line 49)  
[12.5 24.5 18.0]
```

```
and
```

```
var(f, 0, 2)
```

```
is
```

```
Warning: FINTS will be removed in a future release. Use TIMETABLE instead.  
> In fints/var (line 49)  
[9.0; 4.0]
```

# vertcat

Concatenate financial time series objects vertically

---

**Note** `vertcat` is not recommended. Use `timetable` instead. For more information, see “Convert Financial Time Series Objects `fints` to Timetables”.

---

## Syntax

```
vertcat
```

## Description

`vertcat` implements vertical concatenation of financial time series objects. `vertcat` essentially adds data points to a time series object. Objects to be vertically concatenated must not have any duplicate dates and/or times or any overlapping dates and/or times. The description fields are concatenated as well. They are separated by `||`.

## Examples

Create two financial time series objects with daily frequencies:

```
myfts = fints((today:today+4)', (1:5)', 'DataSeries', 'd')
yourfts = fints((today+5:today+9)', (11:15)', 'DataSeries', 'd')
```

```
Warning: FINTS will be removed in a future release. Use TIMETABLE instead.
> In fints (line 165)
```

```
Warning: FINTS will be removed in a future release. Use TIMETABLE instead.
> In fints/display (line 66)
```

```
myfts =
```

```
desc: (none)
freq: Daily (1)

'dates: (5)'      'DataSeries: (5)'
'02-Oct-2017'    [          1]
'03-Oct-2017'    [          2]
'04-Oct-2017'    [          3]
'05-Oct-2017'    [          4]
'06-Oct-2017'    [          5]
```

```
Warning: FINTS will be removed in a future release. Use TIMETABLE instead.
> In fints (line 165)
```

```
Warning: FINTS will be removed in a future release. Use TIMETABLE instead.
> In fints/display (line 66)
```

```
yourfts =
```

```
desc: (none)
freq: Daily (1)
```

```

'dates: (5)'      'DataSeries: (5)'
'07-Oct-2017'   [          11]
'08-Oct-2017'   [          12]
'09-Oct-2017'   [          13]
'10-Oct-2017'   [          14]
'11-Oct-2017'   [          15]

```

Use `vertcat` to concatenate them vertically:

```
newfts1 = [myfts; yourfts]
```

```
Warning: FINTS will be removed in a future release. Use TIMETABLE instead.
> In fints/vertcat (line 35)
```

```
Warning: FINTS will be removed in a future release. Use TIMETABLE instead.
> In fints/display (line 66)
```

```
newfts1 =
```

```

desc:  ||
freq:  Daily (1)

'dates: (10)'      'DataSeries: (10)'
'11-Dec-2001'     [          1]
'12-Dec-2001'     [          2]
'13-Dec-2001'     [          3]
'14-Dec-2001'     [          4]
'15-Dec-2001'     [          5]
'16-Dec-2001'     [         11]
'17-Dec-2001'     [         12]
'18-Dec-2001'     [         13]
'19-Dec-2001'     [         14]
'20-Dec-2001'     [         15]

```

Create two financial time series objects with different frequencies:

```
myfts = fints((today:today+4)', (1:5)', 'DataSeries', 'd');
hisfts = fints((today+5:7:today+34)', (11:15)', 'DataSeries', ...
'w')
```

```
Warning: FINTS will be removed in a future release. Use TIMETABLE instead.
> In fints (line 165)
```

```
Warning: FINTS will be removed in a future release. Use TIMETABLE instead.
> In fints (line 165)
```

```
Warning: FINTS will be removed in a future release. Use TIMETABLE instead.
> In fints/display (line 66)
```

```
hisfts =
```

```

desc: (none)
freq: Weekly (2)

'dates: (5)'      'DataSeries: (5)'
'07-Oct-2017'     [          11]
'14-Oct-2017'     [          12]
'21-Oct-2017'     [          13]
'28-Oct-2017'     [          14]
'04-Nov-2017'     [          15]

```

Concatenate these two objects vertically:

```
newfts2 = [myfts; hisfts]
```

```
Warning: FINTS will be removed in a future release. Use TIMETABLE instead.
> In fints/vertcat (line 35)
Warning: FINTS will be removed in a future release. Use TIMETABLE instead.
> In fints/display (line 66)
```

```
newfts2 =
```

```
desc:  ||
freq:  Unknown (0)

'dates: (10)'    'DataSeries: (10)'
'11-Dec-2001'   [          1]
'12-Dec-2001'   [          2]
'13-Dec-2001'   [          3]
'14-Dec-2001'   [          4]
'15-Dec-2001'   [          5]
'16-Dec-2001'   [         11]
'23-Dec-2001'   [         12]
'30-Dec-2001'   [         13]
'06-Jan-2002'   [         14]
'13-Jan-2002'   [         15]
```

If all frequency indicators are the same, the new object has the same frequency indicator. However, if one of the concatenated objects has a different `freq` from the other(s), the frequency of the resulting object is set to `Unknown (0)`. In these examples, `newfts1` has `Daily` frequency, while `newfts2` has `Unknown (0)` frequency.

## volarea

Price and volume chart

---

**Note** `volarea` is updated to accept data input as a matrix, `timetable`, or `table`.

The syntax for `volarea` has changed. Previously, when using table input, the first column of dates could be serial date numbers, date character vectors, or datetime arrays, and you were required to have specific number of columns.

When using table input, the new syntax for `volarea` supports:

- No need for time information. If you want to pass in date information, use `timetable` input.
  - No requirement of specific number of columns. However, you must provide valid column names. `volarea` must contain a column named 'price' (case insensitive).
- 

### Syntax

```
volarea(Data)
h = volarea(ax,Data)
```

### Description

`volarea(Data)` plots a chart from a series of price and traded volume of a security.

`h = volarea(ax,Data)` adds an optional argument for `ax`.

### Examples

#### Plot Asset Date, Price, and Volume on a Single Axis for a Stock

Load the file `SimulatedStock.mat`, which provides a `timetable` (TMW) for financial data for TMW stock. This example shows how to plot asset date, price, and volume on a single axis, given asset TMW containing asset price and volume in most recent 21 days. Note that the variable name of asset price is be renamed to 'Price' (case insensitive).

```
load SimulatedStock.mat;
TMW.Properties.VariableNames{'Close'} = 'Price';
volarea(TMW(end-20:end,:))
title('Price and Volume Chart for TMW')
```

## Input Arguments

### Data — Data for prices and traded volume

matrix | table | timetable

Data for prices and traded volume, specified as a matrix, table, or timetable. For matrix input, Data is an M-by-2 matrix of prices and traded volume. Timetables and tables with M rows must contain variables named 'Price' and 'Volume' (case insensitive).

Data Types: double | table | timetable

### ax — Valid axis object

current axes (ax = gca) (default) | axes object

(Optional) Valid axis object, specified as an axes object. The volarea plot is created in the axes specified by ax instead of in the current axes (ax = gca). The option ax can precede any of the input argument combinations.

Data Types: object

## Output Arguments

### h — Graphic handle of the figure

handle object

Graphic handle of the figure, returned as a handle object.

# volroc

Volume rate of change

---

**Note** Using a `fints` object for the `Data` argument of `volroc` is not recommended. Use a vector, `timetable`, or `table` instead for financial time series. For more information, see “Convert Financial Time Series Objects `fints` to Timetables”.

---

## Syntax

```
volumeChangeRate = volroc(Data)
volumeChangeRate = volroc( ___,Name,Value)
```

## Description

`volumeChangeRate = volroc(Data)` calculates the volume rate-of-change from a data series of volume traded. The volume rate-of-change is calculated between the current volume and the volume  $n$  periods ago. By default, the Volume rate of change is based on a 12-period difference.

`volumeChangeRate = volroc( ___,Name,Value)` adds optional name-value pair arguments.

## Examples

### Calculate the Volume Rate of Change for a Data Series for a Stock

Load the file `SimulatedStock.mat`, which provides a timetable (TMW) for financial data for TMW stock.

```
load SimulatedStock.mat
volumeChangeRate = volroc(TMW);
plot(volumeChangeRate.Time,volumeChangeRate.VolumeChangeRate)
title('Volume Rate of Change for TMW')
```

## Input Arguments

### Data — Data for volume traded

vector | table | timetable

Data for volume traded, specified as a vector, table, or timetable. For vector input, `Data` is an M-by-1 column vector of volume traded. Timetables and tables with M rows must contain a variable named 'Volume' (case insensitive).

Data Types: double | table | timetable

### Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1`, `Value1`, ..., `NameN`, `ValueN`.

Example: `volumeChangeRate = volroc(TMW, 'NumPeriods', 18)`

### NumPeriods — Period difference for volumeChangeRate

12 (default) | positive integer

Period difference for `volumeChangeRate`, specified as the comma-separated pair consisting of 'NumPeriods' and a scalar positive integer.

Data Types: double

## Output Arguments

### **volumeChangeRate — Volume rate of change series**

vector | table | timetable

Volume rate of change series, returned with the same number of rows (M) and the same type (vector, table, or timetable) as the input Data.

## References

[1] Achelis, S. B. *Technical Analysis from A to Z*. Second Edition. McGraw-Hill, 1995, pp. 310-311.

## Topics

“Using Timetables in Finance” on page 12-7

“Convert Financial Time Series Objects fints to Timetables” on page 12-2

**Introduced before R2006a**

## wclose

Weighted close

---

**Note** Using a `fints` object for the `tobj` argument is not recommended. Use a matrix, `timetable`, or `table` instead for financial time series.

Use `fts2timetable` to convert a `fints` object to a `timetable` object.

---

### Syntax

`WeightedClose = wclose(Data)`

### Description

`WeightedClose = wclose(Data)` calculates the weighted closing prices from the series of high, low, and closing prices. The weighted closing price is the average of twice the closing price plus the high and low prices.

### Examples

#### Calculate the Weighted Closing Prices for a Data Series for a Stock

Load the file `SimulatedStock.mat`, which provides a timetable (TMW) for financial data for TMW stock.

```
load SimulatedStock.mat
WeightedClose = wclose(TMW);
plot(WeightedClose.Time,WeightedClose.WeightedClose)
title('Weighted Closing Prices for TMW')
```

## Input Arguments

### Data — Data for high, low, and closing prices

matrix | table | timetable

Data for high, low, and closing prices, specified as a matrix, table, or timetable. For matrix input, **Data** is an M-by-3 matrix of high, low, and closing prices stored in the corresponding columns. Timetables and tables with M rows must contain variables named 'High', 'Low', and 'Close' (case insensitive).

Data Types: double | table | timetable

## Output Arguments

### WeightedClose — Weighted closing price series

matrix | table | timetable

Weighted closing price series, returned with the same number of rows (M) and the same type (matrix, table, or timetable) as the input **Data**.

# weeknum

Week in year

## Syntax

```
[N] = weeknum(D)
[N] = weeknum( ____, W, E)
```

## Description

[N] = weeknum(D) returns the week in year. The weeknum function considers the week containing January 1 to be the first week of the year.

[N] = weeknum( \_\_\_\_, W, E) returns the week in year using the optional input arguments for W and E. The weeknum function considers the week containing January 1 to be the first week of the year.

## Examples

### Determine the Week of the Year

Determine the week of the year using a serial date number.

```
N = weeknum(728647)
```

```
N = 52
```

Determine the week of the year using a character vector.

```
N = weeknum('19-Dec-1994')
```

```
N = 52
```

Determine the week of the year using a datetime array.

```
N = weeknum(datetime('19-Dec-1994','Locale','en_US'))
```

```
N = 52
```

The first week of the year must have at least four days in it. For example, January 8, 2004 was a Thursday. The European standard is used because the first week of the year is the first week longer than three days.

```
weeknum('08-jan-2004',1,1)
```

```
ans = 1
```

You can also use weeknum with datenum.

```
weeknum(datenum('01-Jan-2004'):datenum('08-Jan-2004'))
```

```
ans = 1×8
```

```
1 1 1 2 2 2 2 2
```

The default start day of the week is Sunday. Every day after, and including the first Sunday of the year (04-Jan-2004), returns 2 denoting the second week. In this case, the first of week of the year started before January 1, 2004. You can also use `weeknum` with `datenum` and specify a `D` value of 5 to indicate that the weeks start on Thursday.

```
weeknum(datenum('01-Jan-2004'):datenum('08-Jan-2004'),5)
```

```
ans = 1×8
```

```
1 1 1 1 1 1 1 2
```

The first week of the year that has four or more days, based on the specified start day, is considered week one (even if this is not the first week in the calendar). Any day falling in (or before) this week is given a week number of 1.

## Input Arguments

### D — Date to determine week in year

serial date number | data character vector | datetime array

Date to determine week in year, specified as a serial date number, date character vector, or datetime array.

Serial date numbers can be a matrix. Date character vectors can be specified as a one-dimensional cell array of character vectors. All the date character vectors must have the same format.

Use the function `datestr` to convert serial date numbers to formatted date character vectors.

Data Types: `single` | `double` | `char` | `datetime`

### W — Day a week begins

1 (default) | integer with value 1 through 7 | vector of integers with values 1 through 7

Day a week begins, specified as an integer or a vector of integers from 1 through 7.

- 1 — Sunday (default)
- 2 — Monday
- 3 — Tuesday
- 4 — Wednesday
- 5 — Thursday
- 6 — Friday
- 7 — Saturday

The `weeknum` function considers the week containing January 1 to be the first week of the year.

Data Types: `single` | `double`

### E — Flag indicates if week of year display is European standard

0 (default) | numeric with values 1 or 0

Flag indicates if week of year display is European standard, specified as 1 (to use the European standard) or 0 (not to use the European standard).

The European standard considers first week of year to be first week longer than three days, offset by the given week's start day.

Data Types: `logical`

## Output Arguments

### **N** — Week number of the year, given D

`numeric` | `column vector`

Week number of the year, given D, returned as a numeric value, given D, a serial date number, date character vector, or datetime array. If D is a one-dimensional cell array of character vectors, then `weeknum` returns a column vector of *M* week numbers, where *M* is the number of character vectors in D.

If the optional input arguments *W* and *E* are defined, the week of the year is in the European standard.

## weights2holdings

Portfolio values and weights into holdings

### Syntax

Holdings = weights2holdings(Values,Weights,Prices)

### Arguments

|         |                                                                                                                                                                                                               |
|---------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Values  | Scalar or number of portfolios (NPORTS) vector containing portfolio values.                                                                                                                                   |
| Weights | NPORTS by number of assets (NASSETS) matrix with portfolio weights. The weights sum to the value of a Budget constraint, which is usually 1. (See holdings2weights for information about budget constraints.) |
| Prices  | NASSETS vector of prices.                                                                                                                                                                                     |

### Description

Holdings = weights2holdings(Values,Weights,Prices) converts portfolio values and weights into portfolio holdings.

Holdings is a NPORTS-by-NASSETS matrix containing the holdings of NPORTS portfolios that contain NASSETS assets.

---

**Note** This function does not create round-lot positions. Holdings are floating-point values.

---

# willad

Williams Accumulation/Distribution line

---

**Note** Using a `fints` object for the `Data` argument of `willad` is not recommended. Use a matrix, `timetable`, or `table` instead for financial time series. For more information, see “Convert Financial Time Series Objects `fints` to Timetables”.

---

## Syntax

```
WADLine = willad(Data)
```

## Description

`WADLine = willad(Data)` calculates the Williams Accumulation/Distribution line from the series of high, low, and closing prices.

## Examples

### Calculate the Williams Accumulation/Distribution Line for a Data Series for a Stock

Load the file `SimulatedStock.mat`, which provides a timetable (`TMW`) for financial data for `TMW` stock.

```
load SimulatedStock.mat
WADLine = willad(TMW);
plot(WADLine.Time,WADLine.WillAD)
title('Williams A/D Line for TMW')
```

## Input Arguments

### Data — Data for high, low, and closing prices

matrix | table | timetable

Data for high, low, and closing prices, specified as a matrix, table, or timetable. For matrix input, **Data** is an M-by-3 matrix of high, low, and closing prices stored in the corresponding columns. Timetables and tables with M rows must contain variables named 'High', 'Low', and 'Close' (case insensitive).

Data Types: double | table | timetable

## Output Arguments

### WADLine — Williams Accumulation/Distribution line

matrix | table | timetable

Williams Accumulation/Distribution line, returned with the same number of rows (M) and the same type (matrix, table, or timetable) as the input **Data**.

## References

## willpctr

Williams %R

---

**Note** Using a `fints` object for the `Data` argument of `willpctr` is not recommended. Use a matrix, `timetable`, or `table` instead for financial time series. For more information, see “Convert Financial Time Series Objects `fints` to Timetables”.

---

### Syntax

```
PercentR = willpctr(Data)
PercentR = willpctr( ____,Name,Value)
```

### Description

`PercentR = willpctr(Data)` calculates the Williams PercentR (%R) values for a data series of with high, low, and closing prices.

`PercentR = willpctr( ____,Name,Value)` adds optional name-value pair arguments.

### Examples

#### Calculate the Williams %R for a Data Series for a Stock

Load the file `SimulatedStock.mat`, which provides a timetable (TMW) for financial data for TMW stock.

```
load SimulatedStock.mat
PercentR = willpctr(TMW);
plot(PercentR.Time,PercentR.WillPercentR)
title('Williams %R for TMW')
```

## Input Arguments

### Data — Data with high, low, and close information

matrix | table | timetable

Data with high, low, open, close information, specified as a matrix, table, or timetable. For matrix input, `Data` is an `M`-by-3 with high, low, and closing prices stored in the corresponding columns. Timetables and tables with `M` rows must contain variables named `'High'`, `'Low'`, and `'Close'` (case insensitive).

Data Types: double | table | timetable

### Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `PercentR = willpctr(TMW, 'NumPeriods', 15)`

### NumPeriods — Moving window for Williams PercentR

14 (default) | positive integer

Moving window for Williams PercentR, specified as the comma-separated pair consisting of `'NumPeriods'` and a scalar positive integer.

Data Types: double

## Output Arguments

### PercentR — Williams PercentR series

matrix | table | timetable

Williams PercentR series, returned with the same number of rows (**M**) and the same type (matrix, table, or timetable) as the input **Data**.

## More About

### Williams %R

Williams %R shows the current closing price in relation to the high and low of the past *n* days.

By default, Williams %R values are based on 14 periods.

# wrkdydif

Number of working days between dates

## Syntax

```
Days = wrkdydif(StartDate,EndDate,Holidays)
```

## Description

`Days = wrkdydif(StartDate,EndDate,Holidays)` returns the number of working days between dates `StartDate` and `EndDate` inclusive. `Holidays` is the number of holidays between the given dates, an integer.

## Examples

### Determine the Number of Working Days Between a StartDate and EndDate

Determine `Days` using date character vectors for `StartDate` and `EndDate`.

```
Days = wrkdydif('9/1/2000', '9/11/2000', 1)
```

```
Days = 6
```

Determine `Days` using serial date numbers for `StartDate` and `EndDate`.

```
Days = wrkdydif(730730, 730740, 1)
```

```
Days = 6
```

Determine `Days` using a datetime array for `EndDate`.

```
Days = wrkdydif('9/1/2000', datetime('11-Sep-2000','Locale','en_US'), 1)
```

```
Days = 6
```

## Input Arguments

### StartDate — Start date

serial date number | date character vector | datetime object

Start date, specified as an N-by-1 or 1-by-N vector using serial date numbers, date character vectors, or datetime arrays.

Data Types: double | char | datetime

### EndDate — End date

serial date number | date character vector | datetime object

End date, specified as an N-by-1 or 1-by-N vector using serial date numbers, date character vectors, or datetime arrays.

Data Types: double | char | datetime

**Holidays — Holidays between StartDate and EndDate**

vector of integers

Holidays between the StartDate and EndDate, specified as an N-by-1 or 1-by-N vector of integers.

Data Types: single | double

**Output Arguments****Days — Number of working days between dates StartDate and EndDate inclusive**

integer

Number of working days between dates StartDate and EndDate inclusive, returned an N-by-1 or 1-by-N vector of integers.

# x2mdate

Excel serial date number to MATLAB serial date number or datetime format

## Syntax

```
MATLABDate = x2mdate(ExcelDateNumber,Convention)
MATLABDate = x2mdate( ____,outputType)
```

## Description

`MATLABDate = x2mdate(ExcelDateNumber,Convention)` converts Excel serial date numbers to MATLAB serial date numbers or datetime format.

MATLAB date numbers start with 1 = January 1, 0000 A.D., hence there is a difference of 693960 relative to the 1900 date system, or 695422 relative to the 1904 date system. This function is useful with Spreadsheet Link software.

`MATLABDate = x2mdate( ____,outputType)` converts Excel serial date numbers to MATLAB serial date numbers or datetime format using an optional input argument for `outputType`.

The type of output is determined by an optional `outputType` input. If `outputType` is 'datenum', then `MATLABDate` is a serial date number. If `outputType` is 'datetime', then `MATLABDate` is a datetime array. By default, `outputType` is 'datenum'.

## Examples

### Convert Excel Serial Date Numbers to MATLAB Dates

Given Excel® date numbers in the 1904 system, convert them to MATLAB® serial date numbers, and then to date character vectors.

```
ExDates = [35423 35788 36153];
MATLABDate = x2mdate(ExDates, 1)

MATLABDate = 1×3

    730845    731210    731575
```

```
datestr(MATLABDate)
```

```
ans = 3×11 char array
    '25-Dec-2000'
    '25-Dec-2001'
    '25-Dec-2002'
```

Alternatively, use the optional input `outputType` to specify 'datetime' to return datetime format.

```
ExDates = [35423 35788 36153];
MATLABDate = x2mdate(ExDates, 1,'datetime')
```

```
MATLABDate = 1x3 datetime
    25-Dec-2000    25-Dec-2001    25-Dec-2002
```

## Input Arguments

### ExcelDateNumber — Excel serial date number

serial date number

Excel serial date number, specified as a scalar or vector of Excel serial date numbers.

Data Types: `double`

### Convention — Flag for Excel date system

0 (Excel 1900 date system is in effect) (default) | numeric with value 0 or 1

Flag for Excel date system, specified as a scalar or vector as a numeric with a value 0 or 1. `Convention` must be either a scalar or else must be the same size as `ExcelDateNumber`.

When `Convention = 0` (default), the Excel 1900 date system is in effect. When `Convention = 1`, the Excel 1904 date system is used.

In the Excel 1900 date system, the Excel serial date number 1 corresponds to January 1, 1900 A.D. In the Excel 1904 date system, date number 0 is January 1, 1904 A.D.

Due to a software limitation in Excel software, the year 1900 is considered a leap year. As a result, all `DATEVALUE`'s reported by Excel software between Jan. 1, 1900 and Feb. 28, 1900 (inclusive) differs from the values reported by 1. For example:

- In Excel software, Jan. 1, 1900 = 1
- In MATLAB, Jan. 1, 1900 - 693960 (for 1900 date system) = 2

```
datenum('Jan 1, 1900') - 693960
```

```
ans =
```

```
2
```

Data Types: `logical`

### outputType — Output date format

'datenum' (default) | character vector with values 'datenum' or 'datetime'

Output date format, specified as a character vector with values 'datenum' or 'datetime'. The output `MATLABDate` is in serial date format if 'datenum' is specified or datetime format if 'datetime' is specified. By default the output is in serial date format.

Data Types: `char`

## Output Arguments

### MATLABDate — MATLAB date

serial date numbers | datetime format

MATLAB date, returned as serial date numbers or datetime format.

The type of output is determined by an optional `outputType` input argument. If `outputType` is `'datenum'`, then `MATLABDate` is a serial date number. If `outputType` is `'datetime'`, then `MATLABDate` is a datetime array. By default, `outputType` is `'datenum'`.

**See Also**

`datenum` | `datestr` | `m2xdate` | `datetime`

**Topics**

“Handle and Convert Dates” on page 2-2

**Introduced before R2006a**

## xirr

Internal rate of return for nonperiodic cash flow

### Syntax

```
Return = xirr(CashFlow,CashFlowDates)
Return = xirr( ____,Guess,MaxIterations,Basis)
```

### Description

`Return = xirr(CashFlow,CashFlowDates)` returns the internal rate of return for a schedule of nonperiodic cash flows.

`Return = xirr( ____,Guess,MaxIterations,Basis)` adds optional arguments.

### Examples

#### Find Internal Rate of Return for Nonperiodic Cash Flow

Find the internal rate of return for an investment of \$10,000 that returns the following nonperiodic cash flow. The original investment is the first cash flow and is a negative number.

Cash Flow Dates

-10000 12-Jan-2007

2500 14-Feb-2008

2000 03-Mar-2008

3000 14-Jun-2008

4000 01-Dec-2008

Calculate the internal rate of return for this nonperiodic cash flow:

```
CashFlow = [-10000, 2500, 2000, 3000, 4000];
```

```
CashFlowDates = ['01/12/2007'  
                '02/14/2008'  
                '03/03/2008'  
                '06/14/2008'  
                '12/01/2008'];
```

```
Return = xirr(CashFlow, CashFlowDates)
```

```
Return = 0.1006
```

Alternatively, you can use datetime input to calculate the internal rate of return for this nonperiodic cash flow:

```
CashFlow = [-10000, 2500, 2000, 3000, 4000];
```

```
CashFlowDates = ['01/12/2007'
```

```

        '02/14/2008'
        '03/03/2008'
        '06/14/2008'
        '12/01/2008'];
CashFlowDates = datetime(CashFlowDates,'Locale','en_US');
Return = xirr(CashFlow, CashFlowDates)

Return = 0.1006

```

## Input Arguments

### CashFlow — Cash flow

vector | matrix

Cash flow, specified as a vector or matrix. The first entry is the initial investment. If `CashFlow` is a matrix, each column represents a separate stream of cash flows whose internal rate of return is calculated. The first cash flow of each stream is the initial investment, usually entered as a negative number.

Data Types: double

### CashFlowDates — Cash flow dates

serial date number | date character vector | datetime

Cash flow dates, specified as a vector or matrix of serial date numbers, cell array of date character vectors, or datetime arrays. The size of the input date numbers for `CashFlowDates` must be the same size as `CashFlow`. Each column of `CashFlowDates` represents the dates of the corresponding column of `CashFlow`.

Data Types: double | char | datetime | cell

### Guess — Initial estimate of the internal rate of return

0.1 (10%) (default) | numeric

(Optional) Initial estimate of the internal rate of return, specified as a scalar or vector. If `Guess` is a scalar, then it is applied to all streams, and if `Guess` is a vector, then it is the same length as the number of streams.

Data Types: double

### MaxIterations — Number of iterations used by Newton's method to solve the internal rate of return

50 (default) | positive integer

(Optional) Number of iterations used by Newton's method to solve the internal rate of return, specified as a scalar or vector of positive integers. If `MaxIterations` is a scalar, then it is applied to all streams, and if `MaxIterations` is a vector, then it is the same length as the number of streams.

Data Types: double

### Basis — Day-count basis

0 (actual/actual) (default) | positive integers of the set [1...13] | vector of positive integers of the set [1...13]

(Optional) Day-count basis, specified as a positive integer using scalar or a N-by-1 vector. If `Basis` is a scalar, then it is applied to all streams, and if `Basis` is a vector, then it is the same length as the number of streams.

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-19.

Data Types: `double`

## Output Arguments

### Return — Annualized internal rate of return of each cash flow stream

`numeric`

Annualized internal rate of return of each cash flow stream, returned as a vector. A NaN indicates that a solution was not found.

# year

Year of date

## Syntax

```
Year = year(Date)
Year = year( ____, F)
```

## Description

`Year = year(Date)` returns the year of date given a serial date number or a date character vector.

`Year = year( ____, F)` returns the year of date given a serial date number or a date character vector, `Date`, using format defined by the optional input `F`. `Date` can be a character array where each row corresponds to one date character vector, or a one-dimensional cell array of character vectors. All the character vectors in `Date` must have the same format `F`. `F` must designate a supported date format symbol. For more information on supported date formats, see `datestr`.

## Examples

### Determine the Year of the Date for Various Dates

Find the year for `Date` using a serial date number.

```
Year = year(731798.776)
Year = 2003
```

Find the year for `Date` using a date character vector format.

```
Year = year('05-Aug-2003')
Year = 2003
```

Use the optional `F` argument to designate a country-specific date format for a given `Date`.

```
Year = year('1999/05/09', 'yyyy/dd/mm')
Year = 1999
```

## Input Arguments

### Date — Date to determine year

serial date number | date character vector | cell array of date character vectors

Date to determine year, specified as a serial date number or date character vector.

`Date` can be an array of date character vectors, where each row corresponds to one date character vector, or a one-dimensional cell array of character vectors. All the character vectors in `Date` must

have the same format `F`. `F` must designate a supported date format symbol. For more information on supported date formats, see `datestr`

Data Types: `single` | `double` | `char` | `cell`

### **F — Date format symbol**

character vector designating date format

Date format symbol, specified as a character vector to designate the date format symbol for input argument `Date`. For more information on supported date character vector formats, see `datestr`. Note, formats with 'Q' are not accepted.

Data Types: `char`

## **Output Arguments**

### **Year — Numeric representation of the year**

nonnegative integer

Numeric representation of the year, returned as a nonnegative integer.

## **See Also**

`datevec` | `day` | `month` | `yeardays`

# yeardays

Number of days in year

## Syntax

```
Days = yeardays(Year)
Days = yeardays( ____,Basis)
```

## Description

Days = yeardays(Year) returns the number of days in the given Year.

Days = yeardays( \_\_\_\_,Basis) returns the number of days in the given Year, based on the optional argument Basis for day-count.

## Examples

### Determine the Number of Days in a Given Year

Find the number of days in a given Year.

```
Days = yeardays(2000)
```

```
Days = 366
```

Find the number of days in a given Year using the optional argument Basis.

```
Days = yeardays(2000, 1)
```

```
Days = 360
```

## Input Arguments

### Year — Year to determine days

4 digit integer

Data Types: single | double

### Basis — Day-count basis

0 (actual/actual) (default) | vector of integers with values 0,1,2,3,4,5,6,7,8,9,10,11,12,13

Day-count basis, specified as a vector of integers with values 0,1,2,3,4,5,6,7,8,9,10,11,12,13.

- 0 = actual/actual (default)
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365

- 4 = 30/360 (BMA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-19.

Data Types: `single` | `double`

## Output Arguments

### Days — Number of days in given Year

`nonnegative integer`

Number of days in given Year, returned as a nonnegative integer.

### See Also

`days360` | `days365` | `daysact` | `year` | `yearfrac`

### Topics

“Handle and Convert Dates” on page 2-2

**Introduced before R2006a**

# yearfrac

Fraction of year between dates

## Syntax

YearFraction = yearfrac(StartDate,EndDate,Basis)

## Description

YearFraction = yearfrac(StartDate,EndDate,Basis) returns a fraction, in years, based on the number of days between dates StartDate and EndDate using the given day-count Basis.

The number of days in a year (365 or 366) is equal to the number of days in the calendar year after the StartDate. If EndDate is earlier than StartDate, YearFraction is negative.

All specified arguments must be number of instruments (NUMINST-by-1) or (1-by-NUMINST) conforming vectors or scalar arguments.

## Examples

### Compute yearfrac When the Calendar Year After the StartDate is Not a Leap Year

Given a Basis of 0 and a Basis of 1, compute yearfrac.

Define the StartDate and EndDate using a Basis of 0.

```
YearFraction = yearfrac('14 mar 01', '14 sep 01', 0)
```

```
YearFraction = 0.5041
```

Define the StartDate and EndDate using a Basis of 1.

```
YearFraction = yearfrac('14 mar 01', '14 sep 01', 1)
```

```
YearFraction = 0.5000
```

### Compute yearfrac When the Calendar Year After the StartDate is a Leap Year

Given a Basis of 0, compute yearfrac when the calendar after StartDate is in a leap year.

Define the StartDate and EndDate using a Basis of 0.

```
yearFraction = yearfrac('14 mar 03', '14 sep 03', 0)
```

```
yearFraction = 0.5027
```

There are 184 days between March 14 and September 14, and the calendar year after the StartDate is a leap year, so yearfrac returns  $184/366 = 0.5027$ .

### Compute the Fraction of a Year Using an actual/actual Basis

To get the fraction of a year between '31-Jul-2015' and '30-Sep-2015' using the actual/actual basis:

```
yearfrac('31-Jul-2015', '30-Sep-2015', 0)*2
```

```
ans = 0.3333
```

For the actual/actual basis, the fraction of a year is calculated as:

(Actual Days between Start Date and End Date)/(Actual Days between Start Date and exactly one year after Start Date)

There are 61 days between 31-Jul-2015 and 30-Sep-2015. Since the next year is a leap year, there are 366 days between 31-Jul-2015 and 31-Jul-2016. So, there is 61/366 which is exactly 1/6. So given this, exactly 2/6 is the expected result for the fraction of the six-month period.

### Compute yearfrac When the Date Range Spans a Leap Year

Use a Basis of 12 to compute yearfrac when parts of the date range are in leap year and in a non-leap year. The output YearFraction is a fraction, in years, based on the number of days between the StartDate and EndDate.

```
YearFraction = yearfrac('1-Jan-2016', '30-Jan-2017', 12)
```

```
YearFraction = 1.0795
```

### Compute yearfrac When Specifying datetime Arrays

Given a Basis of 9, compute yearfrac when the StartDate and EndDate are specified using datetime arrays.

```
yearfrac(datetime('1-Jan-2000', 'Locale', 'en_US'), '1/1/2001', 9)
```

```
ans = 1.0167
```

## Input Arguments

### StartDate — Start date

serial date number | date character vector | datetime object

Start date, specified as an N-by-1 or 1-by-N vector using serial date numbers, date character vectors, or datetime arrays.

Data Types: double | char | datetime

### EndDate — End date

serial date number | date character vector | datetime object

End date, specified as an N-by-1 or 1-by-N vector using serial date numbers, date character vectors, or datetime arrays.

Data Types: `double` | `char` | `datetime`

### **Basis — Day-count basis for each set of dates**

0 (actual/actual) (default) | vector of numerics with values 0 through 13

Day-count basis for each set of dates, specified as an N-by-1 or 1-by-N vector of integers with values of 0 through 13.

- 0 = actual/actual (default)
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (BMA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-19.

Data Types: `single` | `double`

## **Output Arguments**

### **YearFraction — Real numbers identifying interval, in years, between StartDate and EndDate**

vector

Real numbers identifying the interval, in years, between StartDate and EndDate, returned an N-by-1 or 1-by-N vector.

## **More About**

### **Difference Between yearfrac and date2time**

The difference between `yearfrac` and `date2time` is that `date2time` counts full periods as a whole integer, even if the number of actual days in the periods are different. `yearfrac` does not count full periods.

For example,

```
yearfrac('1/1/2000', '1/1/2001', 9)
```

```
ans =
```

```
1.0167
```

yearfrac for Basis 9 (ACT/360 ICMA) calculates  $366/360 = 1.0167$ . So, even if the dates have the same month and date, with a difference of 1 in the year, the returned value may not be exactly 1. On the other hand, date2time calculates one full year period:

```
date2time('1/1/2000', '1/1/2001', 1, 9)
```

```
ans =
```

```
1
```

# ylddisc

Yield of discounted security

## Syntax

```
Yield = ylddisc(Settle,Maturity,Face,Price)
Yield = ylddisc( ____,Basis)
```

## Description

Yield = ylddisc(Settle,Maturity,Face,Price) returns the yield of a discounted security.

Yield = ylddisc( \_\_\_\_,Basis) adds optional an argument for Basis.

## Examples

### Find the Yield of a Discounted Security

This example shows how to find the yield of the following discounted security.

```
Settle = '10/14/2000';
Maturity = '03/17/2001';
Face = 100;
Price = 96.28;
Basis = 2;
```

```
Yield = ylddisc(Settle, Maturity, Face, Price, Basis)
```

```
Yield = 0.0903
```

### Find the Yield of a Discounted Security Using datetime Inputs

This example shows how to use datetime inputs to find the yield of the following discounted security.

```
Settle = '10/14/2000';
Maturity = '03/17/2001';
Face = 100;
Price = 96.28;
Basis = 2;
```

```
Settle = datetime(Settle,'Locale','en_US');
Maturity = datetime(Maturity,'Locale','en_US');
```

```
Yield = ylddisc(Settle, Maturity, Face, Price, Basis)
```

```
Yield = 0.0903
```

## Input Arguments

### **Settle — Settlement date of security**

serial date number | date character vector | datetime

Settlement date of the security, specified as serial date numbers, date character vectors, or datetime arrays. The `Settle` date must be before the `Maturity` date.

Data Types: `double` | `char` | `datetime`

### **Maturity — Maturity date of security**

serial date number | date character vector | datetime

Maturity date of the security, specified as serial date numbers, date character vectors, or datetime arrays.

Data Types: `double` | `char` | `datetime`

### **Face — Redemption value of security**

numeric

Redemption value (par value) of the security, specified as a numeric value.

Data Types: `double`

### **Price — Discount price of security**

numeric

Discount price of the security, specified as a numeric value.

Data Types: `double`

### **Basis — (Optional) Day-count basis**

0 (actual/actual) (default) | integers of the set [0 . . . 13] | vector of integers of the set [0 . . . 13]

Day-count basis for the security, specified using the following values:

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-19.

Data Types: double

## Output Arguments

### **Yield — Yield of discounted security**

numeric

Yield of discounted security, returned as a numeric value.

## yldmat

Yield with interest at maturity

### Syntax

```
Yield = yldmat(Settle,Maturity,Issue,Face,Price,CouponRate)
Yield = yldmat( ____,Basis)
```

### Description

`Yield = yldmat(Settle,Maturity,Issue,Face,Price,CouponRate)` returns the yield of a security paying interest at maturity.

`Yield = yldmat( ____,Basis)` adds an optional argument for Basis.

### Examples

#### Find the Yield of a Security Paying Interest at Maturity

This example shows how to find the yield of a security paying interest at maturity for the following.

```
Settle = '02/07/2000';
Maturity = '04/13/2000';
Issue = '10/11/1999';
Face = 100;
Price = 99.98;
CouponRate = 0.0608;
Basis = 1;
```

```
Yield = yldmat(Settle, Maturity, Issue, Face, Price, ...
CouponRate, Basis)
```

```
Yield = 0.0607
```

#### Find the Yield of a Security Paying Interest at Maturity Using datetime Inputs

This example shows how to use `datetime` inputs find the yield of a security paying interest at maturity for the following:

```
Settle = '7-Feb-2000';
Maturity = '13-Apr-2000';
Issue = '11-Oct-1999';
Face = 100;
Price = 99.98;
CouponRate = 0.0608;
Basis = 1;
```

```
Settle = datetime(Settle,'Locale','en_US');
```

```

Maturity = datetime(Maturity, 'Locale', 'en_US');
Issue = datetime(Issue, 'Locale', 'en_US');

Yield = yldmat(Settle, Maturity, Issue, Face, Price, ...
CouponRate, Basis)

Yield = 0.0607

```

## Input Arguments

### **Settle** — Settlement date of security

serial date number | date character vector | datetime

Settlement date of the security, specified as serial date numbers, date character vectors, or datetime arrays. The **Settle** date must be before the **Maturity** date.

Data Types: double | char | datetime

### **Maturity** — Maturity date of security

serial date number | date character vector | datetime

Maturity date of the security, specified as serial date numbers, date character vectors, or datetime arrays.

Data Types: double | char | datetime

### **Issue** — Issue date of security

serial date number | date character vector | datetime

Issue date of the security, specified as serial date numbers, date character vectors, or datetime arrays.

Data Types: double | char | datetime

### **Face** — Redemption value of security

numeric

Redemption value (par value) of the security, specified as a numeric value.

Data Types: double

### **Price** — Price of security

numeric

Price of the security, specified as a numeric value.

Data Types: double

### **CouponRate** — Coupon rate of security

decimal fraction

Coupon rate of the security, specified as a decimal fraction.

Data Types: double

### **Basis** — Day-count basis

0 (actual/actual) (default) | integers of the set [0...13] | vector of integers of the set [0...13]

(Optional) Day-count basis for the security, specified using the following values:

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-19.

Data Types: `double`

## Output Arguments

**Yield** — Yield of a security paying interest at maturity

`numeric`

Yield of a security paying interest at maturity, returned as a numeric value.

## References

# yldtbill

Yield of Treasury bill

## Syntax

```
Yield = yldtbill(Settle,Maturity,Face,Price)
```

## Description

`Yield = yldtbill(Settle,Maturity,Face,Price)` returns the yield for a Treasury bill.

## Examples

### Find the Yield for a Treasury Bill

This example shows how to return the yield for a Treasury bill, given the settlement date of a Treasury bill is February 10, 2000, the maturity date is August 6, 2000, the par value is \$1000, and the price is \$981.36.

```
Yield = yldtbill('2/10/2000', '8/6/2000', 1000, 981.36)
```

```
Yield = 0.0384
```

### Find the Yield for a Treasury Bill Using datetime Inputs

This example shows how to use `datetime` inputs to return the yield for a Treasury bill, given the settlement date of a Treasury bill is February 10, 2000, the maturity date is August 6, 2000, the par value is \$1000, and the price is \$981.36.

```
Yield = yldtbill(datetime('10-Feb-2000','Locale','en_US'), datetime('6-Aug-2000','Locale','en_US
```

```
Yield = 0.0384
```

## Input Arguments

### Settle — Settlement date of Treasury bill

serial date number | date character vector | datetime

Settlement date of the Treasury bill, specified as serial date numbers, date character vectors, or datetime arrays. The `Settle` date must be before the `Maturity` date.

Data Types: double | char | datetime

### Maturity — Maturity date of Treasury bill

serial date number | date character vector | datetime

Maturity date of the Treasury bill, specified as serial date numbers, date character vectors, or datetime arrays.

Data Types: `double` | `char` | `datetime`

### **Face — Redemption value of Treasury bill**

numeric

Redemption value (par value) of the Treasury bill, specified as a numeric value.

Data Types: `double`

### **Price — Price of Treasury bill**

numeric

Price of the Treasury bill, specified as a numeric value.

Data Types: `double`

## **Output Arguments**

### **Yield — Yield for Treasury bill**

numeric

Yield for Treasury bill, returned as a numeric value.

## zbtprice

Zero curve bootstrapping from coupon bond data given price

### Syntax

```
[ZeroRates, CurveDates] = zbtprice(Bonds, Prices, Settle)
ZeroRates, CurveDates = zbtprice( ___, OutputCompounding)
```

### Description

[ZeroRates, CurveDates] = zbtprice(Bonds, Prices, Settle) uses the bootstrap method to return a zero curve given a portfolio of coupon bonds and their prices.

A zero curve consists of the yields to maturity for a portfolio of theoretical zero-coupon bonds that are derived from the input `Bonds` portfolio. The bootstrap method that this function uses does *not* require alignment among the cash-flow dates of the bonds in the input portfolio. It uses theoretical par bond arbitrage and yield interpolation to derive all zero rates; specifically, the interest rates for cash flows are determined using linear interpolation. For best results, use a portfolio of at least 30 bonds evenly spaced across the investment horizon.

ZeroRates, CurveDates = zbtprice( \_\_\_, OutputCompounding) adds an optional argument for OutputCompounding.

### Examples

#### Compute a Zero Curve Given a Portfolio of Coupon Bonds and Their Prices

Given data and prices for 12 coupon bonds, two with the same maturity date, and given the common settlement date.

```
Bonds = [datenum('6/1/1998')    0.0475    100    2    0    0;
          datenum('7/1/2000')    0.06       100    2    0    0;
          datenum('7/1/2000')    0.09375   100    6    1    0;
          datenum('6/30/2001')   0.05125   100    1    3    1;
          datenum('4/15/2002')   0.07125   100    4    1    0;
          datenum('1/15/2000')   0.065     100    2    0    0;
          datenum('9/1/1999')    0.08      100    3    3    0;
          datenum('4/30/2001')   0.05875   100    2    0    0;
          datenum('11/15/1999')  0.07125   100    2    0    0;
          datenum('6/30/2000')   0.07      100    2    3    1;
          datenum('7/1/2001')    0.0525    100    2    3    0;
          datenum('4/30/2002')   0.07      100    2    0    0];

Prices = [99.375;
          99.875;
          105.75 ;
          96.875;
          103.625;
          101.125;
          103.125;
```

```

    99.375;
    101.0 ;

## Input Arguments

### Bonds — Coupon bond information to generate zero curve

table | matrix

Coupon bond information to generate zero curve, specified as a 6-column table or a n-by-2 to n-by-6 matrix of bond information, where the table columns or matrix columns contains:

- **Maturity** (Column 1, Required) Maturity date of the bond, as a serial date number. Use `datenum` to convert date character vectors to serial date numbers. If the input **Bonds** is a table, the **Maturity** dates can be serial date numbers, date character vectors, or datetime arrays.
- **CouponRate** (Column 2, Required) Decimal fraction indicating the coupon rate of the bond.
- **Face** (Column 3, Optional) Redemption or face value of the bond. Default = 100.
- **Period** (Column 4, Optional) Coupons per year of the bond. Allowed values are 0, 1, 2 (default), 3, 4, 6, and 12.
- **Basis** (Column 5, Optional) Day-count basis of the bond. A vector of integers.
  - 0 = actual/actual (default)
  - 1 = 30/360 (SIA)
  - 2 = actual/360
  - 3 = actual/365
  - 4 = 30/360 (BMA)
  - 5 = 30/360 (ISDA)
  - 6 = 30/360 (European)
  - 7 = actual/365 (Japanese)
  - 8 = actual/actual (ICMA)
  - 9 = actual/360 (ICMA)
  - 10 = actual/365 (ICMA)
  - 11 = 30/360E (ICMA)
  - 12 = actual/365 (ISDA)
  - 13 = BUS/252
  - For more information, see “Basis” on page 2-19.
- **EndMonthRule** (Column 6, Optional) End-of-month rule. This rule applies only when **Maturity** is an end-of-month date for a month having 30 or fewer days. 0 = ignore rule, meaning that a bond's coupon payment date is always the same numerical day of the month. 1 = set rule on (default), meaning that a bond's coupon payment date is always the last actual day of the month

:

---

### Note

- If **Bonds** is a table, the **Maturity** dates can be serial date numbers, date character vectors, or datetime arrays.
- If **Bonds** is a matrix, is an n-by-2 to n-by-6 matrix where each row describes a bond, the first two columns (**Maturity** and **CouponRate**) are required. The remainder of the columns are optional but must be added in order. All rows in **Bonds** must have the same number of columns.

Data Types: double | table

### **Prices — Clean price (price without accrued interest) of each bond in Bonds**

numeric

Clean price (price without accrued interest) of each bond in **Bonds**, specified as a N-by-1 column vector. The number of rows (*n*) must match the number of rows in **Bonds**.

Data Types: double

### **Settle — Settlement date representing time zero in derivation of zero curve**

serial date number | date character vector | datetime

Settlement date representing time zero in derivation of zero curve, specified as serial date number, date character vector, or datetime array. **Settle** represents time zero for deriving the zero curve, and it is normally the common settlement date for all the bonds.

Data Types: double | char | datetime

### **OutputCompounding — Compounding frequency of output ZeroRates**

2 (default) | numeric values: 0,1, 2, 3, 4, 6, 12, 365, -1

(Optional) Compounding frequency of output **ZeroRates**, specified using the allowed values:

- 0 — Simple interest (no compounding)
- 1 — Annual compounding
- 2 — Semiannual compounding (default)
- 3 — Compounding three times per year
- 4 — Quarterly compounding
- 6 — Bimonthly compounding
- 12 — Monthly compounding
- -1 — Continuous compounding

Data Types: double

## **Output Arguments**

### **ZeroRates — Implied zero rates for each point along the investment horizon defined by maturity date**

decimal fractions

Implied zero rates for each point along the investment horizon defined by a maturity date, returned as a  $m$ -by-1 vector of decimal fractions where  $m$  is the number of bonds of unique maturity dates. In aggregate, the rates in `ZeroRates` constitute a zero curve.

If more than one bond has the same `Maturity` date, `zbtprice` returns the mean zero rate for that `Maturity`. Any rates before the first `Maturity` are assumed to be equal to the rate at the first `Maturity`, that is, the curve is assumed to be flat before the first `Maturity`.

### **CurveDates — Maturity dates that correspond to ZeroRates**

serial date number | date character vector | datetime

Maturity dates that correspond to the `ZeroRates`, returned as a  $m$ -by-1 vector of unique maturity dates, where  $m$  is the number of bonds of different maturity dates. These dates begin with the earliest `Maturity` date and end with the latest `Maturitydate` in the `Bonds` table or matrix.

If either inputs for `Bonds` or `Settle` have datetime values, then `CurveDates` is datetimes. Otherwise `CurveDates` is serial date numbers.

# zbtyield

Zero curve bootstrapping from coupon bond data given yield

## Syntax

```
[ZeroRates, CurveDates] = zbtyield(Bonds, YieldsSettle)
ZeroRates, CurveDates = zbtyield( ____, OutputCompounding)
```

## Description

[ZeroRates, CurveDates] = zbtyield(Bonds, YieldsSettle) uses the bootstrap method to return a zero curve given a portfolio of coupon bonds and their yields.

A zero curve consists of the yields to maturity for a portfolio of theoretical zero-coupon bonds that are derived from the input `Bonds` portfolio. The bootstrap method that this function uses does *not* require alignment among the cash-flow dates of the bonds in the input portfolio. It uses theoretical par bond arbitrage and yield interpolation to derive all zero rates; specifically, the interest rates for cash flows are determined using linear interpolation. For best results, use a portfolio of at least 30 bonds evenly spaced across the investment horizon.

ZeroRates, CurveDates = zbtyield( \_\_\_\_, OutputCompounding) adds an optional argument for `OutputCompounding`.

## Examples

### Compute a Zero Curve Given a Portfolio of Coupon Bonds and Their Yields

Given data and yields to maturity for 12 coupon bonds, two with the same maturity date; and given the common settlement date.

```
Bonds = [datenum('6/1/1998') 0.0475 100 2 0 0;
         datenum('7/1/2000') 0.06 100 2 0 0;
         datenum('7/1/2000') 0.09375 100 6 1 0;
         datenum('6/30/2001') 0.05125 100 1 3 1;
         datenum('4/15/2002') 0.07125 100 4 1 0;
         datenum('1/15/2000') 0.065 100 2 0 0;
         datenum('9/1/1999') 0.08 100 3 3 0;
         datenum('4/30/2001') 0.05875 100 2 0 0;
         datenum('11/15/1999') 0.07125 100 2 0 0;
         datenum('6/30/2000') 0.07 100 2 3 1;
         datenum('7/1/2001') 0.0525 100 2 3 0;
         datenum('4/30/2002') 0.07 100 2 0 0];

Yields = [0.0616
          0.0605
          0.0687
          0.0612
          0.0615

## Input Arguments

### Bonds — Coupon bond information to generate zero curve

table | matrix

Coupon bond information to generate zero curve, specified as a 6-column table or a n-by-2 to n-by-6 matrix of bond information, where the table columns or matrix columns contains:

- **Maturity** (Column 1, Required) Maturity date of the bond, as a serial date number. Use `datenum` to convert date character vectors to serial date numbers. If the input **Bonds** is a table, the **Maturity** dates can be serial date numbers, date character vectors, or datetime arrays.
- **CouponRate** (Column 2, Required) Decimal fraction indicating the coupon rate of the bond.
- **Face** (Column 3, Optional) Redemption or face value of the bond. Default = 100.
- **Period** (Column 4, Optional) Coupons per year of the bond. Allowed values are 0, 1, 2 (default), 3, 4, 6, and 12.
- **Basis** (Column 5, Optional) Day-count basis of the bond. A vector of integers.
  - 0 = actual/actual (default)
  - 1 = 30/360 (SIA)
  - 2 = actual/360
  - 3 = actual/365
  - 4 = 30/360 (BMA)
  - 5 = 30/360 (ISDA)
  - 6 = 30/360 (European)
  - 7 = actual/365 (Japanese)
  - 8 = actual/actual (ICMA)
  - 9 = actual/360 (ICMA)
  - 10 = actual/365 (ICMA)
  - 11 = 30/360E (ICMA)
  - 12 = actual/365 (ISDA)
  - 13 = BUS/252
  - For more information, see “Basis” on page 2-19.
- **EndMonthRule** (Column 6, Optional) End-of-month rule. This rule applies only when **Maturity** is an end-of-month date for a month having 30 or fewer days. 0 = ignore rule, meaning that a bond's coupon payment date is always the same numerical day of the month. 1 = set rule on (default), meaning that a bond's coupon payment date is always the last actual day of the month

:

---

**Note**

- If **Bonds** is a table, the **Maturity** dates can be serial date numbers, date character vectors, or datetime arrays.
  - If **Bonds** is a matrix, is an n-by-2 to n-by-6 matrix where each row describes a bond, the first two columns (**Maturity** and **CouponRate**) are required. The remainder of the columns are optional but must be added in order. All rows in **Bonds** must have the same number of columns.
- 

Data Types: double | table

**Yields — Yield to maturity of each bond in Bonds**

numeric

Yield to maturity of each bond in **Bonds**, specified as a N-by-1 column vector. The number of rows (*n*) must match the number of rows in **Bonds**.

---

**Note** Yield to maturity must be compounded semiannually.

---

Data Types: double

**Settle — Settlement date representing time zero in derivation of zero curve**

serial date number | date character vector | datetime

Settlement date representing time zero in derivation of zero curve, specified as serial date number, date character vector, or datetime array. **Settle** represents time zero for deriving the zero curve, and it is normally the common settlement date for all the bonds.

Data Types: double | char | datetime

**OutputCompounding — Compounding frequency of output ZeroRates**

2 (default) | numeric values: 0,1, 2, 3, 4, 6, 12, 365, -1

(Optional) Compounding frequency of output **ZeroRates**, specified using the allowed values:

- 0 — Simple interest (no compounding)
- 1 — Annual compounding
- 2 — Semiannual compounding (default)
- 3 — Compounding three times per year
- 4 — Quarterly compounding
- 6 — Bimonthly compounding
- 12 — Monthly compounding
- -1 — Continuous compounding

Data Types: double

## Output Arguments

### **ZeroRates** — Implied zero rates for each point along the investment horizon defined by maturity date

decimal fractions

Implied zero rates for each point along the investment horizon defined by a maturity date, returned as a  $m$ -by-1 vector of decimal fractions where  $m$  is the number of bonds with unique maturity dates. In aggregate, the rates in `ZeroRates` constitute a zero curve.

If more than one bond has the same `Maturity` date, `zbtyield` returns the mean zero rate for that `Maturity`. Any rates before the first `Maturity` are assumed to be equal to the rate at the first `Maturity`, that is, the curve is assumed to be flat before the first `Maturity`.

### **CurveDates** — Maturity dates that correspond to ZeroRates

serial date number | date character vector | datetime

Maturity dates that correspond to the `ZeroRates`, returned as a  $m$ -by-1 vector of unique maturity dates, where  $m$  is the number of bonds of different maturity dates. These dates begin with the earliest `Maturity` date and end with the latest `Maturitydate` in the `Bonds` table or matrix.

If either inputs for `Bonds` or `Settle` have datetime values, then `CurveDatesCurveDates` is datetimes. Otherwise `CurveDates` is serial date numbers.

 "Fixed-Income Terminology" on page 2-18

**Introduced before R2006a**

## zero2disc

Discount curve given zero curve

---

**Note** In R2017b, the specification of optional input arguments has changed. While the previous ordered inputs syntax is still supported, it may no longer be supported in a future release. Use the optional name-value pair inputs: `Compounding` and `Basis`.

---

### Syntax

```
[DiscRates, CurveDates] = zero2disc(ZeroRates, CurveDates, Settle)
[DiscRates, CurveDates] = zero2disc( ___, Name, Value)
```

### Description

`[DiscRates, CurveDates] = zero2disc(ZeroRates, CurveDates, Settle)` returns a discount curve given a zero curve and its maturity dates. If either inputs for `ZeroRates` or `CurveDates` are a datetime array, `CurveDates` is returned as a datetime array. Otherwise, `CurveDates` is returned as a serial date number. The `DiscRates` output is the same for any of these input data types.

`[DiscRates, CurveDates] = zero2disc( ___, Name, Value)` adds optional name-value pair arguments

### Examples

#### Compute a Discount Curve Given a Zero Curve and Maturity Dates

Given a zero curve over a set of maturity dates and a settlement date.

```
ZeroRates = [0.0464
             0.0509
             0.0524
             0.0525
             0.0531
             0.0525
             0.0530
             0.0531
             0.0549
             0.0536];

CurveDates = [datenum('06-Nov-2000')
              datenum('11-Dec-2000')
              datenum('15-Jan-2001')
              datenum('05-Feb-2001')
              datenum('04-Mar-2001')
              datenum('02-Apr-2001')
              datenum('30-Apr-2001')
              datenum('25-Jun-2001')
              datenum('04-Sep-2001')
              datenum('12-Nov-2001')];
```

```
Settle = datenum('03-Nov-2000');
```

The zero curve is compounded daily on an actual/365 basis.

```
Compounding = 365;
Basis = 3;
```

Execute the function `zero2disc` which returns the discount curve `DiscRates` at the maturity dates `CurveDates`.

```
[DiscRates, CurveDates] = zero2disc(ZeroRates, CurveDates, ...
Settle, Compounding, Basis)
```

```
DiscRates = 10×1

## Input Arguments

### ZeroRates — Annualized zero rates

decimal fraction

Annualized zero rates, specified as a `NUMBONDS`-by-1 vector using decimal fractions. In aggregate, the zero rates constitute an implied zero curve for the investment horizon represented by `CurveDates`.

Data Types: `double`

### CurveDates — Maturity dates

serial date number | date character vector | datetime

Maturity dates that correspond to the input `ZeroRates`, specified as `NUMBONDS`-by-1 vector using serial date numbers, date character vectors, or datetime arrays.

Data Types: `double` | `datetime` | `char`

### Settle — Common settlement date for ZeroRates

serial date number | date character vector | datetime

Common settlement date for `ZeroRates`, specified as serial date numbers, date character vectors, or datetime arrays. `Settle` is the settlement date for the bonds from which the zero curve was bootstrapped.

Data Types: `double` | `datetime` | `char`

### Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `[DiscRates, CurveDates] = zero2disc(ZeroRates, CurveDates, Settle, 'Compounding', 4, 'Basis', 6)`

### Compounding — Rate at which input ZeroRates zero rates are compounded when annualized

2 (default) | numeric values: 0, 1, 2, 3, 4, 6, 12, 365, -1

Rate at which the input `ZeroRates` are compounded when annualized, specified as the comma-separated pair consisting of `'Compounding'` and allowed numeric values:

- 0 — Simple interest (no compounding)
- 1 — Annual compounding
- 2 — Semiannual compounding (default)
- 3 — Compounding three times per year
- 4 — Quarterly compounding
- 6 — Bimonthly compounding
- 12 — Monthly compounding
- 365 — Daily compounding
- -1 — Continuous compounding

Data Types: `double`

**Basis — Day-count basis used for annualizing input ZeroRates**

0 (default) | numeric values: 0,1, 2, 3, 4, 6, 7, 8, 9, 10, 11, 12, 13

Day-count basis used for annualizing the input `ZeroRates`, specified as the comma-separated pair consisting of 'Basis' and allowed numeric values:

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-19.

Data Types: `double`

**Output Arguments****DiscRates — Discount factors**

`decimal`

Discount factors, returned as a `NUMBONDS`-by-1 vector of decimal fractions. In aggregate, the discount factors constitute a discount curve for the investment horizon represented by `CurveDates`.

**CurveDates — Maturity dates that correspond to DiscRates**

`serial date number` | `date character vector` | `datetime`

Maturity dates that correspond to the `DiscRates`, returned as a `NUMBONDS`-by-1 vector of maturity dates that correspond to the discount factors. This vector is the same as the input vector `CurveDates`, but is sorted by ascending maturity.

If either inputs for `CurveDates` or `Settle` are a `datetime` array, `CurveDates` is returned as a `datetime` array. Otherwise, `CurveDates` is returned as a `serial date number`.

## zero2fwd

Forward curve given zero curve

---

**Note** In R2017b, the specification of optional input arguments has changed. While the previous ordered inputs syntax is still supported, it may no longer be supported in a future release. Use the new optional name-value pair inputs: `InputCompounding`, `InputBasis`, `OutputCompounding`, and `OutputBasis`.

---

### Syntax

```
[ForwardRates, CurveDates] = zero2fwd(ZeroRates, CurveDates, Settle)
[ForwardRates, CurveDates] = zero2fwd( ___, Name, Value)
```

### Description

`[ForwardRates, CurveDates] = zero2fwd(ZeroRates, CurveDates, Settle)` returns an implied forward rate curve given a zero curve and its maturity dates. If either input for `CurveDates` or `Settle` is a datetime array, `CurveDates` is returned as a datetime array. Otherwise, `CurveDates` is returned as a serial date number. `ForwardRates` is the same for any of these input data types.

`[ForwardRates, CurveDates] = zero2fwd( ___, Name, Value)` adds optional name-value pair arguments

### Examples

#### Compute an Implied Forward Rate Curve Given a Zero Curve and Maturity Dates

Given a zero curve over a set of maturity dates, a settlement date, and a compounding rate, compute the forward rate curve.

```
ZeroRates = [0.0458
             0.0502
             0.0518
             0.0519
             0.0524
             0.0519
             0.0523
             0.0525
             0.0541
             0.0529];

CurveDates = [datenum('06-Nov-2000')
              datenum('11-Dec-2000')
              datenum('15-Jan-2001')
              datenum('05-Feb-2001')
              datenum('04-Mar-2001')
              datenum('02-Apr-2001')
              datenum('30-Apr-2001')
              datenum('25-Jun-2001')]
```

```

    datenum('04-Sep-2001')
    datenum('12-Nov-2001')];

```

```

Settle = datenum('03-Nov-2000');
InputCompounding = 1;
InputBasis = 2;
OutputCompounding = 1;
OutputBasis = 2;

```

Execute the function zero2fwd to return the forward rate curve ForwardRates at the maturity dates CurveDates.

```

[ForwardRates, CurveDates] = zero2fwd(ZeroRates, CurveDates,...
Settle, 'InputCompounding',1,'InputBasis',2,'OutputCompounding',1,'OutputBasis',2)

```

```

ForwardRates = 10×1

## Input Arguments

### ZeroRates — Annualized zero rates

decimal fraction

Annualized zero rates, specified as a `NUMBONDS`-by-1 vector using decimal fractions. In aggregate, the rates constitute an implied zero curve for the investment horizon represented by `CurveDates`. The first element pertains to forward rates from the settlement date to the first curve date.

Data Types: `double`

### CurveDates — Maturity dates

serial date number | date character vector | datetime

Maturity dates, specified as a `NUMBONDS`-by-1 vector using serial date numbers, date character vectors, or datetime arrays, that correspond to the `ZeroRates`.

Data Types: `double` | `datetime` | `char`

### Settle — Common settlement date for ZeroRates

serial date number | date character vector | datetime

Common settlement date for input `ZeroRates`, specified as serial date numbers, date character vectors, or datetime arrays.

Data Types: `double` | `datetime` | `char`

### Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `[ForwardRates, CurveDates] = zero2fwd(ZeroRates, CurveDates, Settle, 'InputCompounding', 3, 'InputBasis', 5, 'OutputCompounding', 4, 'OutputBasis', 5)`

### InputCompounding — Compounding frequency of input zero rates

2 (default) | numeric values: 0, 1, 2, 3, 4, 6, 12, 365, -1

Compounding frequency of input zero rates, specified as the comma-separated pair consisting of `'InputCompounding'` and allowed values:

- 0 — Simple interest (no compounding)
- 1 — Annual compounding
- 2 — Semiannual compounding (default)
- 3 — Compounding three times per year
- 4 — Quarterly compounding
- 6 — Bimonthly compounding
- 12 — Monthly compounding
- 365 — Daily compounding
- -1 — Continuous compounding

---

**Note** If `InputCompounding` is not specified, then `InputCompounding` is assigned the value specified for `OutputCompounding`. If either `InputCompounding` or `OutputCompounding` are not specified, the default is 2 (semiannual) for both.

---

Data Types: double

**InputBasis — Day-count basis of input zero rates**

0 (default) | numeric values: 0,1, 2, 3, 4, 6, 7, 8, 9, 10, 11, 12, 13

Day count basis of input zero rates, specified as the comma-separated pair consisting of 'InputBasis' and allowed values:

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-19.

---

**Note** If `InputBasis` is not specified, then `InputBasis` is assigned the value specified for `OutputBasis`. If either `InputBasis` or `OutputBasis` are not specified, the default is 0 (actual/actual) for both.

---

Data Types: double

**OutputCompounding — Compounding frequency of output forward rates**

2 (default) | numeric values: 0,1, 2, 3, 4, 6, 12, 365, -1

Compounding frequency of output forward rates, specified as the comma-separated pair consisting of 'OutputCompounding' and allowed values:

- 0 — Simple interest (no compounding)
- 1 — Annual compounding
- 2 — Semiannual compounding (default)
- 3 — Compounding three times per year

- 4 — Quarterly compounding
- 6 — Bimonthly compounding
- 12 — Monthly compounding
- 365 — Daily compounding
- -1 — Continuous compounding

---

**Note** If `OutputCompounding` is not specified, then `OutputCompounding` is assigned the value specified for `InputCompounding`. If either `InputCompounding` or `OutputCompounding` are not specified, the default is 2 (semiannual) for both.

---

Data Types: double

### **OutputBasis — Day-count basis of output forward rates**

0 (default) | numeric values: 0, 1, 2, 3, 4, 6, 7, 8, 9, 10, 11, 12, 13

Day count basis of output forward rates, specified as the comma-separated pair consisting of 'OutputBasis' and allowed values:

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-19.

---

**Note** If `OutputBasis` is not specified, then `OutputBasis` is assigned the value specified for `InputBasis`. If either `InputBasis` or `OutputBasis` are not specified, the default is 0 (actual/actual) for both.

---

Data Types: double

## **Output Arguments**

### **ForwardRates — Forward curve for investment horizon represented by CurveDates**

numeric

Forward curve for the investment horizon represented by `CurveDates`, returned as a `NUMBONDS`-by-1 vector of decimal fractions. In aggregate, the rates in `ForwardRates` constitute a forward curve over the dates in `CurveDates`. `ForwardRates` are ordered by ascending maturity.

**CurveDates — Maturity dates that correspond to ForwardRates**

serial date number | date character vector | datetime

Maturity dates that correspond to the `ForwardRates`, returned as a `NUMBONDS`-by-1 vector of maturity dates that correspond to the `ForwardRates`.

`ForwardRates` are expressed as serial date numbers (default) or datetimes (if `CurveDates` or `Settle` are datetime arrays), representing the maturity dates for each rate in `ForwardRates`. These dates are the same dates as those associated with the input `ZeroRates`, but are ordered by ascending maturity.

**See Also**

## zero2pyld

Par yield curve given zero curve

---

**Note** In R2017b, the specification of optional input arguments has changed. While the previous ordered inputs syntax is still supported, it may no longer be supported in a future release. Use the new optional name-value pair inputs: `InputCompounding`, `InputBasis`, `OutputCompounding`, and `OutputBasis`.

---

### Syntax

```
[ParRates, CurveDates] = zero2pyld(ZeroRates, CurveDates, Settle)
[ParRates, CurveDates] = zero2pyld( ____, Name, Value)
```

### Description

`[ParRates, CurveDates] = zero2pyld(ZeroRates, CurveDates, Settle)` returns a par yield curve given a zero curve and its maturity dates. If either input for `CurveDates` or `Settle` is a datetime array, `CurveDates` is returned as a datetime array. Otherwise, `CurveDates` is returned as a serial date number. `ParRates` is the same for any of these input data types.

`[ParRates, CurveDates] = zero2pyld( ____, Name, Value)` adds optional name-value pair arguments

### Examples

#### Compute Par Yield Curve Given a Zero Curve and Maturity Dates

Given a zero curve over a set of maturity dates, a settlement date, and annual compounding for the input zero curve and monthly compounding for the output par rates, compute a par yield curve.

```
ZeroRates = [0.0457
             0.0487
             0.0506
             0.0507
             0.0505
             0.0504
             0.0506
             0.0516
             0.0539
             0.0530];
```

```
CurveDates = [datenum('06-Nov-2000')
              datenum('11-Dec-2000')
              datenum('15-Jan-2001')
              datenum('05-Feb-2001')
              datenum('04-Mar-2001')
              datenum('02-Apr-2001')
              datenum('30-Apr-2001')
              datenum('25-Jun-2001')]
```

```

        datenum('04-Sep-2001')
        datenum('12-Nov-2001')]);

Settle = datenum('03-Nov-2000');
InputCompounding = 12;
InputBasis = 2;
OutputCompounding = 1;
OutputBasis = 2;

[ParRates, CurveDates] = zero2pyld(ZeroRates, CurveDates,...
Settle, 'InputCompounding',1,'InputBasis',1,'OutputCompounding',12,'OutputBasis',1)

    0.0329
    0.0355

```

```

max(abs(OriginalZeroRates - ZeroRatesOut)) % Roundtrip error

ans = 1.4919e-16

```

## Input Arguments

### ZeroRates — Annualized zero rates

decimal fraction

Annualized zero rates, specified as a `NUMBONDS`-by-1 vector using decimal fractions. In aggregate, the rates constitute an implied zero curve for the investment horizon represented by `CurveDates`.

Data Types: `double`

### CurveDates — Maturity dates

serial date number | date character vector | datetime

Maturity dates which correspond to the input `ZeroRates`, specified as a `NUMBONDS`-by-1 vector using serial date numbers, date character vectors, or datetime arrays.

Data Types: `double` | `datetime` | `char`

### Settle — Common settlement date for ZeroRates

serial date number | date character vector | datetime

Common settlement date for input `ZeroRates`, specified as serial date numbers, date character vectors, or datetime arrays.

Data Types: `double` | `datetime` | `char`

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `[ParRates, CurveDates] = zero2pyld(ZeroRates, CurveDates, Settle, 'OutputCompounding', 3, 'OutputBasis', 5, 'InputCompounding', 4, 'InputBasis', 5)`

### OutputCompounding — Compounding frequency of output ParRates

2 (default) | numeric values: 0, 1, 2, 3, 4, 6, 12, 365, -1

Compounding frequency of output `ParRates`, specified as the comma-separated pair consisting of `'OutputCompounding'` and allowed values:

- 1 — Annual compounding
- 2 — Semiannual compounding (default)
- 3 — Compounding three times per year
- 4 — Quarterly compounding
- 6 — Bimonthly compounding
- 12 — Monthly compounding

---

## Note

- If `InputCompounding` is 1, 2, 3, 4, 6, or 12 and `OutputCompounding` is not specified, the value of `InputCompounding` is used.

- If `InputCompounding` is 0 (simple), -1 (continuous), or 365 (daily), a valid `OutputCompounding` value must also be specified.
  - If either `InputCompounding` or `OutputCompounding` are not specified, the default is 2 (semiannual) for both.
- 

Data Types: double

### **OutputBasis — Day-count basis of output ParRates**

0 (default) | numeric values: 0,1, 2, 3, 4, 6, 7, 8, 9, 10, 11, 12, 13

Day count basis of output `ParRates`, specified as the comma-separated pair consisting of '`OutputBasis`' and allowed values:

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-19.

---

**Note** If `OutputBasis` is not specified, then `OutputBasis` is assigned the value specified for `InputBasis`. If either `InputBasis` or `OutputBasis` are not specified, the default is 0 (actual/actual) for both.

---

Data Types: double

### **InputCompounding — Compounding frequency of input ZeroRates**

2 (default) | numeric values: 0,1, 2, 3, 4, 6, 12, 365, -1

Compounding frequency of input `ZeroRates`, specified as the comma-separated pair consisting of '`InputCompounding`' and allowed values:

- 0 — Simple interest (no compounding)
- 1 — Annual compounding
- 2 — Semiannual compounding (default)

- 3 — Compounding three times per year
- 4 — Quarterly compounding
- 6 — Bimonthly compounding
- 12 — Monthly compounding
- 365 — Daily compounding
- -1 — Continuous compounding

---

#### Note

- If `InputCompounding` is set to 0 (simple), -1 (continuous), or 365 (daily), the `OutputCompounding` must also be specified using a valid value.
  - If `InputCompounding` is not specified, then `InputCompounding` is assigned the value specified for `OutputCompounding`.
  - If either `InputCompounding` or `OutputCompounding` are not specified, the default is 2 (semiannual) for both.
- 

Data Types: double

#### **InputBasis — Day-count basis of input ZeroRates**

0 (default) | numeric values: 0,1, 2, 3, 4, 6, 7, 8, 9, 10, 11, 12, 13

Day count basis of the input `ZeroRates`, specified as the comma-separated pair consisting of '`InputBasis`' and allowed values:

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-19.

---

**Note** If `InputBasis` is not specified, then `InputBasis` is assigned the value specified for `OutputBasis`. If either `InputBasis` or `OutputBasis` are not specified, the default is 0 (actual/actual) for both.

---

Data Types: double

## Output Arguments

### **ParRates — Par bond coupon rates**

numeric

Par bond coupon rates, returned as a NUMBONDS-by-1 numeric vector. ParRates are ordered by ascending maturity.

### **CurveDates — Maturity dates that correspond to ParRates**

serial date number | date character vector | datetime

Maturity dates that correspond to the ParRates, returned as a NUMBONDS-by-1 vector of maturity dates that correspond to each par rate contained in ParRates.

ParRates are expressed as serial date numbers (default) or datetimes (if CurveDates or Settle are datetime arrays). CurveDates are ordered by ascending maturity.

**Introduced before R2006a**

# compact

Create compact credit scorecard

## Syntax

```
csc = compact(sc)
```

## Description

`csc = compact(sc)` converts an existing `creditscorecard` object to a `compactCreditScorecard` object (`csc`).

---

**Note** To use this function, you must have a license for Risk Management Toolbox.

---

## Examples

### Convert `creditscorecard` Object into `compactCreditScorecard` Object

Convert a `creditscorecard` object into a `compactCreditScorecard` object to use `displaypoints` (Risk Management Toolbox), `score` (Risk Management Toolbox), and `probdefault` (Risk Management Toolbox) from Risk Management Toolbox™ with the object.

First, create a `creditscorecard` object using the `CreditCardData.mat` file to load the data (using a dataset from Refaat 2011).

```
load CreditCardData.mat
sc = creditscorecard(data)

sc =
    creditscorecard with properties:
        GoodLabel: 0
        ResponseVar: 'status'
        WeightsVar: ''
        VarNames: {1x11 cell}
        NumericPredictors: {1x7 cell}
        CategoricalPredictors: {'ResStatus' 'EmpStatus' 'OtherCC'}
        BinMissingData: 0
        IDVar: ''
        PredictorVars: {1x10 cell}
        Data: [1200x11 table]
```

Before creating a `compactCreditScorecard` object, you must use `autobinning` and `fitmodel` with the `creditscorecard` object.

```
sc = autobinning(sc);
sc = fitmodel(sc);
```

1. Adding CustIncome, Deviance = 1490.8527, Chi2Stat = 32.588614, PValue = 1.1387992e-08
2. Adding TmWBank, Deviance = 1467.1415, Chi2Stat = 23.711203, PValue = 1.1192909e-06
3. Adding AMBalance, Deviance = 1455.5715, Chi2Stat = 11.569967, PValue = 0.00067025601
4. Adding EmpStatus, Deviance = 1447.3451, Chi2Stat = 8.2264038, PValue = 0.0041285257
5. Adding CustAge, Deviance = 1441.994, Chi2Stat = 5.3511754, PValue = 0.020708306
6. Adding ResStatus, Deviance = 1437.8756, Chi2Stat = 4.118404, PValue = 0.042419078
7. Adding OtherCC, Deviance = 1433.707, Chi2Stat = 4.1686018, PValue = 0.041179769

Generalized linear regression model:

```
status ~ [Linear formula with 8 terms in 7 predictors]
Distribution = Binomial
```

Estimated Coefficients:

|             | Estimate | SE       | tStat  | pValue     |
|-------------|----------|----------|--------|------------|
| (Intercept) | 0.70239  | 0.064001 | 10.975 | 5.0538e-28 |
| CustAge     | 0.60833  | 0.24932  | 2.44   | 0.014687   |
| ResStatus   | 1.377    | 0.65272  | 2.1097 | 0.034888   |
| EmpStatus   | 0.88565  | 0.293    | 3.0227 | 0.0025055  |
| CustIncome  | 0.70164  | 0.21844  | 3.2121 | 0.0013179  |
| TmWBank     | 1.1074   | 0.23271  | 4.7589 | 1.9464e-06 |
| OtherCC     | 1.0883   | 0.52912  | 2.0569 | 0.039696   |
| AMBalance   | 1.045    | 0.32214  | 3.2439 | 0.0011792  |

1200 observations, 1192 error degrees of freedom

Dispersion: 1

Chi<sup>2</sup>-statistic vs. constant model: 89.7, p-value = 1.4e-16

Convert the `creditscorecard` object into a `compactCreditScorecard` object by using the `compact` function. To use `compact`, you must have a Risk Management Toolbox™ license.

```
csc = compact(sc)
```

```
csc =
```

```
compactCreditScorecard with properties:
```

```

    Description: ''
    GoodLabel: 0
    ResponseVar: 'status'
    WeightsVar: ''
    NumericPredictors: {'CustAge' 'CustIncome' 'TmWBank' 'AMBalance'}
    CategoricalPredictors: {'ResStatus' 'EmpStatus' 'OtherCC'}
    PredictorVars: {1x7 cell}
```

You can then use `displaypoints` (Risk Management Toolbox), `score` (Risk Management Toolbox), and `probdefault` (Risk Management Toolbox) from Risk Management Toolbox™ with the `compactCreditScorecard` object.

## Input Arguments

### **sc** — Credit scorecard model

`creditscorecard` object

Credit scorecard model, specified as a `creditscorecard` object.

---

**Note** You must use a `creditscorecard` object (`sc`) for input that has been previously processed with `autobinning` and `fitmodel`, or `fitConstrainedModel`. Optionally, you can use `formatpoints` in addition to these functions.

---

## Output Arguments

### **csc** — Compact credit scorecard

`compactCreditScorecard` object

Compact credit scorecard, returned as a `compactCreditScorecard` object. You can then use `displaypoints`, `score`, and `probdefault` from the Risk Management Toolbox with this `csc` object.

## Introduced in R2019a

## score

Compute credit scores for given data

### Syntax

```
Scores = score(sc)
```

```
Scores = score(sc, data)
```

```
[Scores,Points] = score(sc)
```

```
[Scores,Points] = score(sc,data)
```

### Description

`Scores = score(sc)` computes the credit scores for the `creditscorecard` object's training data. This data can be a "training" or a "live" dataset. If the `data` input argument is not explicitly provided, the `score` function determines scores for the existing `creditscorecard` object's data.

`formatpoints` supports multiple alternatives to modify the scaling of the scores and can also be used to control the rounding of points and scores, and whether the base points are reported separately or spread across predictors. Missing data translates into NaN values for the corresponding points, and therefore for the total score. Use `formatpoints` to modify the score behavior for rows with missing data.

`Scores = score(sc, data)` computes the credit scores for the given input data. This data can be a "training" or a "live" dataset.

`formatpoints` supports multiple alternatives to modify the scaling of the scores and can also be used to control the rounding of points and scores, and whether the base points are reported separately or spread across predictors. Missing data translates into NaN values for the corresponding points, and therefore for the total score. Use `formatpoints` to modify the score behavior for rows with missing data.

`[Scores,Points] = score(sc)` computes the credit scores and points for the given data. If the `data` input argument is not explicitly provided, the `score` function determines scores for the existing `creditscorecard` object's data.

`formatpoints` supports multiple alternatives to modify the scaling of the scores and can also be used to control the rounding of points and scores, and whether the base points are reported separately or spread across predictors. Missing data translates into NaN values for the corresponding points, and therefore for the total score. Use `formatpoints` to modify the score behavior for rows with missing data.

`[Scores,Points] = score(sc,data)` computes the credit scores and points for the given input data. This data can be a "training" or a "live" dataset.

`formatpoints` supports multiple alternatives to modify the scaling of the scores and can also be used to control the rounding of points and scores, and whether the base points are reported separately or spread across predictors. Missing data translates into NaN values for the corresponding points, and therefore for the total score. Use `formatpoints` to modify the score behavior for rows with missing data.

## Examples

### Obtain Scores for Training Data

This example shows how to use `score` to obtain scores for the training data.

Create a `creditscorecard` object using the `CreditCardData.mat` file to load the data (using a dataset from Refaat 2011). Use the `'IDVar'` argument in `creditscorecard` to indicate that `'CustID'` contains ID information and should not be included as a predictor variable.

```
load CreditCardData
sc = creditscorecard(data, 'IDVar', 'CustID');
```

Perform automatic binning to bin for all predictors.

```
sc = autobinning(sc);
```

Fit a linear regression model using default parameters.

```
sc = fitmodel(sc);
```

1. Adding CustIncome, Deviance = 1490.8527, Chi2Stat = 32.588614, PValue = 1.1387992e-08
2. Adding TmWBank, Deviance = 1467.1415, Chi2Stat = 23.711203, PValue = 1.1192909e-06
3. Adding AMBalance, Deviance = 1455.5715, Chi2Stat = 11.569967, PValue = 0.00067025601
4. Adding EmpStatus, Deviance = 1447.3451, Chi2Stat = 8.2264038, PValue = 0.0041285257
5. Adding CustAge, Deviance = 1441.994, Chi2Stat = 5.3511754, PValue = 0.020708306
6. Adding ResStatus, Deviance = 1437.8756, Chi2Stat = 4.118404, PValue = 0.042419078
7. Adding OtherCC, Deviance = 1433.707, Chi2Stat = 4.1686018, PValue = 0.041179769

Generalized linear regression model:

```
status ~ [Linear formula with 8 terms in 7 predictors]
Distribution = Binomial
```

Estimated Coefficients:

|             | Estimate | SE       | tStat  | pValue     |
|-------------|----------|----------|--------|------------|
| (Intercept) | 0.70239  | 0.064001 | 10.975 | 5.0538e-28 |

Dispersion: 1

Chi<sup>2</sup>-statistic vs. constant model: 89.7, p-value = 1.4e-16

Score training data using the `score` function without an optional input for `data`. By default, it returns unscaled scores. For brevity, only the first ten scores are displayed.

```
Scores = score(sc);
disp(Scores(1:10))
```

```

1.0968
1.4646
0.7662
1.5779
1.4535
1.8944
-0.0872
0.9207
1.0399
0.8252

```

Scale scores and display both points and scores for each individual in the training data (for brevity, only the first ten rows are displayed). For other scaling methods, and other options for formatting points and scores, use the `formatpoints` function.

```

sc = formatpoints(sc, 'WorstAndBestScores', [300 850]);
[Scores,Points] = score(sc);
disp(Scores(1:10))

```

```

| 95.256  | 82.276    | 56.765    | 121.18     | 62.107  | 86.224  | 64.15     |

### Scores for Missing or Out-of-Range Data When Using the 'BinMissingData' Option

This example describes the assignment of points for missing data when the 'BinMissingData' option is set to `true`.

- Predictors that have missing data in the training set have an explicit bin for `<missing>` with corresponding points in the final scorecard. These points are computed from the Weight-of-Evidence (WOE) value for the `<missing>` bin and the logistic model coefficients. For scoring purposes, these points are assigned to missing values and to out-of-range values.

- Predictors with no missing data in the training set have no <missing> bin, therefore no WOE can be estimated from the training data. By default, the points for missing and out-of-range values are set to NaN, and this leads to a score of NaN when running score. For predictors that have no explicit <missing> bin, use the name-value argument 'Missing' in formatpoints to indicate how missing data should be treated for scoring purposes.

Create a `creditscorecard` object using the `CreditCardData.mat` file to load the `dataMissing` with missing values.

```
load CreditCardData.mat
head(dataMissing,5)
```

```
ans=5x11 table
```

| CustID | CustAge | TmAtAddress | ResStatus   | EmpStatus | CustIncome | TmWBank | OtherCC |
|--------|---------|-------------|-------------|-----------|------------|---------|---------|
| 1      | 53      | 62          | <undefined> | Unknown   | 50000      | 55      | Yes     |
| 2      | 61      | 22          | Home Owner  | Employed  | 52000      | 25      | Yes     |
| 3      | 47      | 30          | Tenant      | Employed  | 37000      | 61      | No      |
| 4      | NaN     | 75          | Home Owner  | Employed  | 53000      | 20      | Yes     |
| 5      | 68      | 56          | Home Owner  | Employed  | 53000      | 14      | Yes     |

```
fprintf('Number of rows: %d\n',height(dataMissing))
```

```
Number of rows: 1200
```

```
fprintf('Number of missing values CustAge: %d\n',sum(ismissing(dataMissing.CustAge)))
```

```
Number of missing values CustAge: 30
```

```
fprintf('Number of missing values ResStatus: %d\n',sum(ismissing(dataMissing.ResStatus)))
```

```
Number of missing values ResStatus: 40
```

Use `creditscorecard` with the name-value argument 'BinMissingData' set to true to bin the missing numeric or categorical data in a separate bin. Apply automatic binning.

```
sc = creditscorecard(dataMissing,'IDVar','CustID','BinMissingData',true);
sc = autobinning(sc);
```

```
disp(sc)
```

```
creditscorecard with properties:
```

```

    GoodLabel: 0
    ResponseVar: 'status'
    WeightsVar: ''
    VarNames: {1x11 cell}
    NumericPredictors: {1x6 cell}
    CategoricalPredictors: {'ResStatus' 'EmpStatus' 'OtherCC'}
    BinMissingData: 1
    IDVar: 'CustID'
    PredictorVars: {1x9 cell}
    Data: [1200x11 table]
```

Set a minimum value of zero for CustAge and CustIncome. With this, any negative age or income information becomes invalid or "out-of-range". For scoring purposes, out-of-range values are given the same points as missing values.

```
sc = modifybins(sc, 'CustAge', 'MinValue', 0);
sc = modifybins(sc, 'CustIncome', 'MinValue', 0);
```

Display and plot bin information for numeric data for 'CustAge' that includes missing data in a separate bin labelled <missing>.

```
[bi,cp] = bininfo(sc, 'CustAge');
disp(bi)
```

| Bin             | Good | Bad | Odds   | WOE      | InfoValue  |

Use `fitmodel` to fit a logistic regression model using Weight of Evidence (WOE) data. `fitmodel` internally transforms all the predictor variables into WOE values, using the bins found with the automatic binning process. `fitmodel` then fits a logistic regression model using a stepwise method (by default). For predictors that have missing data, there is an explicit `<missing>` bin, with a corresponding WOE value computed from the data. When using `fitmodel`, the corresponding WOE value for the `<missing>` bin is applied when performing the WOE transformation.

```
[sc,mdl] = fitmodel(sc);
```

1. Adding CustIncome, Deviance = 1490.8527, Chi2Stat = 32.588614, PValue = 1.1387992e-08

Chi^2-statistic vs. constant model: 88.5, p-value = 2.55e-16

Scale the scorecard points by the "points, odds, and points to double the odds (PDO)" method using the 'PointsOddsAndPDO' argument of `formatpoints`. Suppose that you want a score of 500 points to have odds of 2 (twice as likely to be good than to be bad) and that the odds double every 50 points (so that 550 points would have odds of 4).

Display the scorecard showing the scaled points for predictors retained in the fitting model.

```
sc = formatpoints(sc, 'PointsOddsAndPDO', [500 2 50]);
PointsInfo = displaypoints(sc)
```

```
PointsInfo=38x3 table
    Predictors      Bin      Points
    _____  _____  _____
    {'CustAge' } {' [0,33) ' } 54.062

    {'EmpStatus' } {' Unknown' } 58.807
    {'EmpStatus' } {' Employed' } 86.937
    {'EmpStatus' } {' <missing>' } NaN
    :
```

Notice that points for the <missing> bin for `CustAge` and `ResStatus` are explicitly shown (as 64.9836 and 74.1250, respectively). These points are computed from the WOE value for the <missing> bin, and the logistic model coefficients.

For predictors that have no missing data in the training set, there is no explicit <missing> bin. By default the points are set to `NaN` for missing data and they lead to a score of `NaN` when running `score`. For predictors that have no explicit <missing> bin, use the name-value argument 'Missing' in `formatpoints` to indicate how missing data should be treated for scoring purposes.

For the purpose of illustration, take a few rows from the original data as test data and introduce some missing data. Also introduce some invalid, or out-of-range values. For numeric data, values below the minimum (or above the maximum) allowed are considered invalid, such as a negative value for age (recall 'MinValue' was earlier set to 0 for `CustAge` and `CustIncome`). For categorical data, invalid values are categories not explicitly included in the scorecard, for example, a residential status not previously mapped to scorecard categories, such as "House", or a meaningless string such as "abc123".

```
tdata = dataMissing(11:18, mdl.PredictorNames); % Keep only the predictors retained in the model
% Set some missing values
tdata.CustAge(1) = NaN;
tdata.ResStatus(2) = '<undefined>';
tdata.EmpStatus(3) = '<undefined>';
tdata.CustIncome(4) = NaN;
% Set some invalid values
```

```

tdata.CustAge(5) = -100;
tdata.ResStatus(6) = 'House';
tdata.EmpStatus(7) = 'Freelancer';
tdata.CustIncome(8) = -1;
disp(tdata)

```

| CustAge | ResStatus   | EmpStatus   | CustIncome | TmWBank | OtherCC | AMBalance |
|---------|-------------|-------------|------------|---------|---------|-----------|
| NaN     | Tenant      | Unknown     | 34000      | 44      | Yes     | 119.8     |
| 48      | <undefined> | Unknown     | 44000      | 14      | Yes     | 403.62    |
| 65      | Home Owner  | <undefined> | 48000      | 6       | No      | 111.88    |
| 44      | Other       | Unknown     | NaN        | 35      | No      | 436.41    |
| -100    | Other       | Employed    | 46000      | 16      | Yes     | 162.21    |
| 33      | House       | Employed    | 36000      | 36      | Yes     | 845.02    |
| 39      | Tenant      | Freelancer  | 34000      | 40      | Yes     | 756.26    |
| 24      | Home Owner  | Employed    | -1         | 19      | Yes     | 449.61    |

Score the new data and see how points are assigned for missing CustAge and ResStatus, because we have an explicit bin with points for <missing>. However, for EmpStatus and CustIncome the score function sets the points to NaN.

```

[Scores,Points] = score(sc,tdata);

### Score a New Dataset

This example shows how to use `score` to obtain scores for a new dataset (for example, a validation or a test dataset) using the optional `'data'` input in the `score` function.

Create a `creditscorecard` object using the `CreditCardData.mat` file to load the data (using a dataset from Refaat 2011). Use the `'IDVar'` argument in `creditscorecard` to indicate that `'CustID'` contains ID information and should not be included as a predictor variable.

```
load CreditCardData
sc = creditscorecard(data, 'IDVar', 'CustID');
```

Perform automatic binning to bin for all predictors.

```
sc = autobinning(sc);
```

Fit a linear regression model using default parameters.

```
sc = fitmodel(sc);
```

1. Adding `CustIncome`, Deviance = 1490.8527, Chi2Stat = 32.588614, PValue = 1.1387992e-08
2. Adding `TmWBank`, Deviance = 1467.1415, Chi2Stat = 23.711203, PValue = 1.1192909e-06
3. Adding `AMBalance`, Deviance = 1455.5715, Chi2Stat = 11.569967, PValue = 0.00067025601
4. Adding `EmpStatus`, Deviance = 1447.3451, Chi2Stat = 8.2264038, PValue = 0.0041285257
5. Adding `CustAge`, Deviance = 1441.994, Chi2Stat = 5.3511754, PValue = 0.020708306
6. Adding `ResStatus`, Deviance = 1437.8756, Chi2Stat = 4.118404, PValue = 0.042419078

For the purpose of illustration, suppose that a few rows from the original data are our "new" data. Use the optional `data` input argument in the `score` function to obtain the scores for the `newdata`.

```
newdata = data(10:20,:);
Scores = score(sc,newdata)
```

Scores = 11×1

```

0.6553
1.2443
0.9478
0.5690
1.6192
0.4899
0.3824
0.2945
1.4401
⋮
```

## Input Arguments

### **sc** — Credit scorecard model

creditscorecard object

Credit scorecard model, specified as a `creditscorecard` object. Use `creditscorecard` to create a `creditscorecard` object.

### **data** — Dataset to be scored

table

(Optional) Dataset to be scored, specified as a MATLAB table where each row corresponds to individual observations. The `data` must contain columns for each of the predictors in the `creditscorecard` object.

## Output Arguments

### **Scores** — Scores for each observation

vector

Scores for each observation, returned as a vector.

### Points — Points per predictor for each observation

table

Points per predictor for each observation, returned as a table.

## Algorithms

The score of an individual  $i$  is given by the formula

$$\text{Score}(i) = \text{Shift} + \text{Slope} * (b_0 + b_1 * \text{WOE}_1(i) + b_2 * \text{WOE}_2(i) + \dots + b_p * \text{WOE}_p(i))$$

where  $b_j$  is the coefficient of the  $j$ -th variable in the model, and  $\text{WOE}_j(i)$  is the Weight of Evidence (WOE) value for the  $i$ -th individual corresponding to the  $j$ -th model variable. **Shift** and **Slope** are scaling constants that can be controlled with `formatpoints`.

If the data for individual  $i$  is in the  $i$ -th row of a given dataset, to compute a score, the  $\text{data}(i,j)$  is binned using existing binning maps, and converted into a corresponding Weight of Evidence value  $\text{WOE}_j(i)$ . Using the model coefficients, the unscaled score is computed as

$$s = b_0 + b_1 * \text{WOE}_1(i) + \dots + b_p * \text{WOE}_p(i).$$

For simplicity, assume in the description above that the  $j$ -th variable in the model is the  $j$ -th column in the data input, although, in general, the order of variables in a given dataset does not have to match the order of variables in the model, and the dataset could have additional variables that are not used in the model.

The formatting options can be controlled using `formatpoints`.

## Introduced in R2014b

## formatpoints

Format scorecard points and scaling

### Syntax

```
sc = formatpoints(sc,Name,Value)
```

### Description

`sc = formatpoints(sc,Name,Value)` modifies the scorecard points and scaling using optional name-value pair arguments. For example, use optional name-value pair arguments to change the scaling of the scores or the rounding of the points.

### Examples

#### Scale Points Using Points, Odds Levels, and PDO

This example shows how to use `formatpoints` to scale by providing the points, odds levels, and PDO (points to double the odds). By using `formatpoints` to scale, you can put points and scores in a desired range that is more meaningful for practical purposes. Technically, this involves a linear transformation from the unscaled to the scaled points by the `formatpoints` function.

Create a `creditscorecard` object using the `CreditCardData.mat` file to load the data (using a dataset from Refaat 2011). Use the `'IDVar'` argument in `creditscorecard` to indicate that `'CustID'` contains ID information and should not be included as a predictor variable.

```
load CreditCardData
sc = creditscorecard(data,'IDVar','CustID');
```

Perform automatic binning to bin for all predictors.

```
sc = autobinning(sc);
```

Fit a linear regression model using default parameters.

```
sc = fitmodel(sc);
```

### Report Base Points Separately

This example shows how to use `formatpoints` to separate the base points from the rest of the points assigned to each predictor variable. The `formatpoints` name-value pair argument 'BasePoints' serves this purpose.

Create a `creditscorecard` object using the `CreditCardData.mat` file to load the data (using a dataset from Refaat 2011). Use the 'IDVar' argument in `creditscorecard` to indicate that 'CustID' contains ID information and should not be included as a predictor variable.

```
load CreditCardData
sc = creditscorecard(data, 'IDVar', 'CustID');
```

Perform automatic binning to bin for all predictors.

```
sc = autobinning(sc);
```

Fit a linear regression model using default parameters.

```
sc = fitmodel(sc);
```

1. Adding CustIncome, Deviance = 1490.8527, Chi2Stat = 32.588614, PValue = 1.1387992e-08
2. Adding TmWBank, Deviance = 1467.1415, Chi2Stat = 23.711203, PValue = 1.1192909e-06

3. Adding AMBalance, Deviance = 1455.5715, Chi2Stat = 11.569967, PValue = 0.00067025601
4. Adding EmpStatus, Deviance = 1447.3451, Chi2Stat = 8.2264038, PValue = 0.0041285257
5. Adding CustAge, Deviance = 1441.994, Chi2Stat = 5.3511754, PValue = 0.020708306
6. Adding ResStatus, Deviance = 1437.8756, Chi2Stat = 4.118404, PValue = 0.042419078
7. Adding OtherCC, Deviance = 1433.707, Chi2Stat = 4.1686018, PValue = 0.041179769

Generalized linear regression model:

## Round Points

This example shows how to use `formatpoints` to round points. Rounding is usually applied after scaling, otherwise, if the points for a particular predictor are all in a small range, rounding could cause the rounded points for different bins to be the same. Also, rounding all the points may slightly change the minimum and maximum total points.

Create a `creditscorecard` object using the `CreditCardData.mat` file to load the data (using a dataset from Refaat 2011). Use the `'IDVar'` argument in `creditscorecard` to indicate that `'CustID'` contains ID information and should not be included as a predictor variable.

```
load CreditCardData
sc = creditscorecard(data, 'IDVar', 'CustID');
```

Perform automatic binning to bin for all predictors.

```
sc = autobinning(sc);
```

Fit a linear regression model using default parameters.

```
sc = fitmodel(sc);
```

1. Adding CustIncome, Deviance = 1490.8527, Chi2Stat = 32.588614, PValue = 1.1387992e-08
2. Adding TmWBank, Deviance = 1467.1415, Chi2Stat = 23.711203, PValue = 1.1192909e-06
3. Adding AMBalance, Deviance = 1455.5715, Chi2Stat = 11.569967, PValue = 0.00067025601
4. Adding EmpStatus, Deviance = 1447.3451, Chi2Stat = 8.2264038, PValue = 0.0041285257

## Rounding and Default Probabilities

This example shows that rounding scorecard points can modify the original risk ranking of a credit scorecard. You can control rounding by using `formatpoints` with the optional name-value pair argument for `'Rounding'`.

Credit scores rank customers by risk. If higher scores are given to better, less risky customers, then higher scores must correspond to lower default probabilities. When you use the name-value pair argument for `'Rounding'`, depending on the value for `'Rounding'`, the rounding behavior is:

- When `'Rounding'` is set to `'None'` (default option), no rounding is applied to points or scores, and the risk ranking is completely consistent with the calibrated model.
- When `'Rounding'` is set to `'FinalScore'`, rounding is only applied to the final scores. In this case: a) Customers with different scores (different risk) may have the same rounded score. b) Customers with the same rounded score may have different default probabilities. c) Customer with higher rounded scores will always have lower default probability than customers with lower scores.
- When `'Rounding'` is set to `'AllPoints'`, rounding is applied to all points in the scorecard (all bins, all predictors). In this case: a) Customers with different scores (different risk) may have the same rounded score, or their ranking may even be reversed (the customer with the lower original score may have a higher rounded score). b) Customers with the same rounded score may have different default probabilities. c) Customer with higher rounded scores may in some cases have *higher* default probabilities than customers with lower scores.

## Create a creditscorecard

To demonstrate the rounding behavior, first create a `creditscorecard` object.

```
load CreditCardData
sc = creditscorecard(data, 'IDVar', 'CustID', 'ResponseVar', 'status');
sc = autobinning(sc);
sc = modifybins(sc, 'CustIncome', 'CutPoints', 20000:5000:60000);
sc = fitmodel(sc);
```

1. Adding `CustIncome`, Deviance = 1487.9719, Chi2Stat = 35.469392, PValue = 2.5909009e-09
2. Adding `TmWBank`, Deviance = 1465.7998, Chi2Stat = 22.172089, PValue = 2.4927133e-06
3. Adding `AMBBalance`, Deviance = 1455.206, Chi2Stat = 10.593833, PValue = 0.0011346548
4. Adding `EmpStatus`, Deviance = 1446.3918, Chi2Stat = 8.8142314, PValue = 0.0029889009
5. Adding `CustAge`, Deviance = 1440.6825, Chi2Stat = 5.709236, PValue = 0.016875883
6. Adding `ResStatus`, Deviance = 1436.1363, Chi2Stat = 4.5462043, PValue = 0.032991806
7. Adding `OtherCC`, Deviance = 1431.9546, Chi2Stat = 4.1817827, PValue = 0.040860699

Generalized linear regression model:

```
status ~ [Linear formula with 8 terms in 7 predictors]
Distribution = Binomial
```

Estimated Coefficients:

|             | Estimate | SE       | tStat  | pValue     |
|-------------|----------|----------|--------|------------|
| (Intercept) | 0.70247  | 0.064046 | 10.968 | 5.4345e-28 |
| CustAge     | 0.60579  | 0.24405  | 2.4822 | 0.013058   |
| ResStatus   | 1.4463   | 0.65427  | 2.2105 | 0.02707    |
| EmpStatus   | 0.90501  | 0.29262  | 3.0928 | 0.0019828  |

|            |         |         |        |            |
|------------|---------|---------|--------|------------|
| CustIncome | 0.70869 | 0.20535 | 3.4512 | 0.00055815 |
| TmWBank    | 1.0839  | 0.23244 | 4.6631 | 3.1145e-06 |
| OtherCC    | 1.0906  | 0.52936 | 2.0602 | 0.039377   |
| AMBalance  | 1.0148  | 0.32273 | 3.1445 | 0.0016636  |

1200 observations, 1192 error degrees of freedom  
 Dispersion: 1  
 Chi<sup>2</sup>-statistic vs. constant model: 91.5, p-value = 6.12e-17

### Apply the 'Rounding' Options

Apply each of the three 'Rounding' options to the `creditscorecard` object.

```
sc = formatpoints(sc, 'PointsOddsAndPDO', [500 2 50]); % No Rounding
points1 = displaypoints(sc);
[S1,P1] = score(sc);
defProb1 = probdefault(sc);

sc = formatpoints(sc, 'Round', 'AllPoints'); % 'AllPoints' Rounding
points2 = displaypoints(sc);
[S2,P2] = score(sc);
defProb2 = probdefault(sc);

sc = formatpoints(sc, 'Round', 'FinalScore'); % 'FinalScore' Rounding
points3 = displaypoints(sc);
[S3,P3] = score(sc);
defProb3 = probdefault(sc);
```

### Compare the 'Rounding' Options

Visualize the default probabilities versus the scores.

```

```

The original `creditscorecard` model, without rounding, was calibrated to the data with a logistic regression. The ranking and probabilities have a statistical foundation.

Rounding, however, effectively modifies the `creditscorecard` model. When only the final score is rounded, this leads to some "ties" in rounded scores, but at least the risk ranking *across* scores is preserved (because if  $s1 \leq s2$ , then  $\text{round}(s1) \leq \text{round}(s2)$ ).

However, when you round all points, a score may gain extra points by chance. For example, in the second row in the table (row 363 of original data), the points for all predictors are rounded up by almost 0.5. The original score is 389.27. Rounding the final score makes it 389. However, rounding all points makes it 392, that is three points higher than rounding the final score.

### Scores for Missing or Out-of-Range Data

This example shows how to use `formatpoints` to score missing or out-of-range data. When data is scored, some observations can be either missing (NaN, or `undefined`) or out of range. You will need to decide whether or not points are assigned to these cases. Use the name-value pair argument `Missing` to do so.

Create a `creditscorecard` object using the `CreditCardData.mat` file to load the data (using a dataset from Refaat 2011). Use the `'IDVar'` argument in `creditscorecard` to indicate that `'CustID'` contains ID information and should not be included as a predictor variable.

```
load CreditCardData
sc = creditscorecard(data, 'IDVar', 'CustID');
```

Perform automatic binning to bin for all predictors.

```
sc = autobinning(sc);
```

Indicate that the minimum allowed value for 'CustAge' is zero. This makes any negative values for age invalid or out-of-range.

```
sc = modifybins(sc, 'CustAge', 'MinValue', 0);
```

Fit a linear regression model using default parameters.

```
sc = fitmodel(sc);
```

1. Adding CustIncome, Deviance = 1490.8527, Chi2Stat = 32.588614, PValue = 1.1387992e-08

ans = 0.4790
```

### Scores for Missing or Out-of-Range Data When Using the 'BinMissingData' Option

This example describes the assignment of points for missing data when the 'BinMissingData' option is set to `true`.

- Predictors that have missing data in the training set have an explicit bin for `<missing>` with corresponding points in the final scorecard. These points are computed from the Weight-of-Evidence (WOE) value for the `<missing>` bin and the logistic model coefficients. For scoring purposes, these points are assigned to missing values and to out-of-range values.
- Predictors with no missing data in the training set have no `<missing>` bin, therefore no WOE can be estimated from the training data. By default, the points for missing and out-of-range values are set to `NaN`, and this leads to a score of `NaN` when running `score`. For predictors that have no explicit `<missing>` bin, use the name-value argument 'Missing' in `formatpoints` to indicate how missing data should be treated for scoring purposes.

Create a `creditscorecard` object using the `CreditCardData.mat` file to load the `dataMissing` with missing values.

```
load CreditCardData.mat
head(dataMissing,5)
```

```
ans=5x11 table
    CustID  CustAge  TmAtAddress  ResStatus  EmpStatus  CustIncome  TmWBank  Other
    _____  _____  _____  _____  _____  _____  _____  _____
    1         53         62         <undefined>  Unknown    50000       55       Ye
    2         61         22         Home Owner   Employed    52000       25       Ye
    3         47         30         Tenant       Employed    37000       61       Ne
    4         NaN        75         Home Owner   Employed    53000       20       Ye
    5         68         56         Home Owner   Employed    53000       14       Ye
```

```
fprintf('Number of rows: %d\n',height(dataMissing))
Number of rows: 1200
fprintf('Number of missing values CustAge: %d\n',sum(ismissing(dataMissing.CustAge)))
Number of missing values CustAge: 30
fprintf('Number of missing values ResStatus: %d\n',sum(ismissing(dataMissing.ResStatus)))
Number of missing values ResStatus: 40
```

Use `creditscorecard` with the name-value argument `'BinMissingData'` set to `true` to bin the missing numeric or categorical data in a separate bin. Apply automatic binning.

```
sc = creditscorecard(dataMissing,'IDVar','CustID','BinMissingData',true);
sc = autobinning(sc);
```

```
disp(sc)
```

```
creditscorecard with properties:
```

```

    GoodLabel: 0
    ResponseVar: 'status'
    WeightsVar: ''
    VarNames: {1x11 cell}
    NumericPredictors: {1x6 cell}
    CategoricalPredictors: {'ResStatus' 'EmpStatus' 'OtherCC'}
    BinMissingData: 1
    IDVar: 'CustID'
    PredictorVars: {1x9 cell}
    Data: [1200x11 table]
```

Set a minimum value of zero for `CustAge` and `CustIncome`. With this, any negative age or income information becomes invalid or "out-of-range". For scoring purposes, out-of-range values are given the same points as missing values.

```
sc = modifybins(sc,'CustAge','MinValue',0);
sc = modifybins(sc,'CustIncome','MinValue',0);
```

Display and plot bin information for numeric data for `'CustAge'` that includes missing data in a separate bin labelled `<missing>`.

```
[bi,cp] = bininfo(sc,'CustAge');
disp(bi)
```

| Bin             | Good | Bad | Odds   | WOE      | InfoValue  |

| { '<missing>' } | 19   | 11  | 1.7273 | -0.15787 | 0.00063885 |
| { 'Totals' }    | 803  | 397 | 2.0227 | NaN      | 0.087112   |

```
plotbins(sc, 'CustAge')
```

Display and plot bin information for categorical data for 'ResStatus' that includes missing data in a separate bin labelled <missing>.

```
[bi,cg] = bininfo(sc, 'ResStatus');  
disp(bi)
```

| Bin             | Good | Bad | Odds   | WOE       | InfoValue  |
|-----------------|------|-----|--------|-----------|------------|
| {'Tenant' }     | 296  | 161 | 1.8385 | -0.095463 | 0.0035249  |
| {'Home Owner' } | 352  | 171 | 2.0585 | 0.017549  | 0.00013382 |
| {'Other' }      | 128  | 52  | 2.4615 | 0.19637   | 0.0055808  |
| {'<missing>' }  | 27   | 13  | 2.0769 | 0.026469  | 2.3248e-05 |
| {'Totals' }     | 803  | 397 | 2.0227 | NaN       | 0.0092627  |

```
plotbins(sc, 'ResStatus')
```

For the 'CustAge' and 'ResStatus' predictors, there is missing data (NaNs and <undefined>) in the training data, and the binning process estimates a WOE value of  $-0.15787$  and  $0.026469$  respectively for missing data in these predictors, as shown above.

For EmpStatus and CustIncome there is no explicit bin for missing values because the training data has no missing values for these predictors.

```
bi = bininfo(sc, 'EmpStatus');
disp(bi)
```

```

Use `fitmodel` to fit a logistic regression model using Weight of Evidence (WOE) data. `fitmodel` internally transforms all the predictor variables into WOE values, using the bins found with the automatic binning process. `fitmodel` then fits a logistic regression model using a stepwise method (by default). For predictors that have missing data, there is an explicit `<missing>` bin, with a corresponding WOE value computed from the data. When using `fitmodel`, the corresponding WOE value for the `<missing>` bin is applied when performing the WOE transformation.

```
[sc,mdl] = fitmodel(sc);
```

Scale the scorecard points by the "points, odds, and points to double the odds (PDO)" method using the `'PointsOddsAndPDO'` argument of `formatpoints`. Suppose that you want a score of 500 points to have odds of 2 (twice as likely to be good than to be bad) and that the odds double every 50 points (so that 550 points would have odds of 4).

Display the scorecard showing the scaled points for predictors retained in the fitting model.

```

sc = formatpoints(sc, 'PointsOddsAndPDO', [500 2 50]);
PointsInfo = displaypoints(sc)

```

PointsInfo=38x3 table

{'EmpStatus' } {'<missing>' } NaN
:

```

Notice that points for the <missing> bin for CustAge and ResStatus are explicitly shown (as 64.9836 and 74.1250, respectively). These points are computed from the WOE value for the <missing> bin, and the logistic model coefficients.

For predictors that have no missing data in the training set, there is no explicit <missing> bin. By default the points are set to NaN for missing data and they lead to a score of NaN when running score. For predictors that have no explicit <missing> bin, use the name-value argument 'Missing' in formatpoints to indicate how missing data should be treated for scoring purposes.

For the purpose of illustration, take a few rows from the original data as test data and introduce some missing data. Also introduce some invalid, or out-of-range values. For numeric data, values below the minimum (or above the maximum) allowed are considered invalid, such as a negative value for age (recall 'MinValue' was earlier set to 0 for CustAge and CustIncome). For categorical data, invalid values are categories not explicitly included in the scorecard, for example, a residential status not previously mapped to scorecard categories, such as "House", or a meaningless string such as "abc123".

```

tdata = dataMissing(11:18,mdl.PredictorNames); % Keep only the predictors retained in the model
% Set some missing values
tdata.CustAge(1) = NaN;
tdata.ResStatus(2) = '<undefined>';
tdata.EmpStatus(3) = '<undefined>';
tdata.CustIncome(4) = NaN;
% Set some invalid values
tdata.CustAge(5) = -100;
tdata.ResStatus(6) = 'House';
tdata.EmpStatus(7) = 'Freelancer';
tdata.CustIncome(8) = -1;
disp(tdata)

```

| CustAge | ResStatus   | EmpStatus   | CustIncome | TmWBank | OtherCC | AMBalance |
|---------|-------------|-------------|------------|---------|---------|-----------|
| NaN     | Tenant      | Unknown     | 34000      | 44      | Yes     | 119.8     |
| 48      | <undefined> | Unknown     | 44000      | 14      | Yes     | 403.62    |
| 65      | Home Owner  | <undefined> | 48000      | 6       | No      | 111.88    |
| 44      | Other       | Unknown     | NaN        | 35      | No      | 436.41    |
| -100    | Other       | Employed    | 46000      | 16      | Yes     | 162.21    |
| 33      | House       | Employed    | 36000      | 36      | Yes     | 845.02    |

```

39    Tenant    Freelancer    34000    40    Yes    756.26
24    Home Owner    Employed    -1    19    Yes    449.61

```

Score the new data and see how points are assigned for missing `CustAge` and `ResStatus`, because we have an explicit bin with points for `<missing>`. However, for `EmpStatus` and `CustIncome` the score function sets the points to `NaN`.

```

[Scores,Points] = score(sc,tdata);

## Input Arguments

### sc — Credit scorecard model

creditscorecard object

Credit scorecard model, specified as a `creditscorecard` object. Use `creditscorecard` to create a `creditscorecard` object.

### Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1`, `Value1`, ..., `NameN`, `ValueN`.

Example: `sc = formatpoints(sc, 'BasePoints', true, 'Round', 'AllPoints', 'WorstAndBestScores', [100, 700])`

---

**Note** `ShiftAndSlope`, `PointsOddsAndPDO`, and `WorstAndBestScores` are scaling methods and you can use only one of these name-value pair arguments at one time. The other three name-value pair arguments (`BasePoints`, `Missing`, and `Round`) are not scaling methods and can be used together or with any one of the three scaling methods.

---

### BasePoints — Indicator for separating base points

false (default) | logical scalar

Indicator for separating base points, specified as the comma-separated pair consisting of `'BasePoints'` and a logical scalar. If `true`, the scorecard explicitly separates base points. If `false`, the base points are spread across all variables in the `creditscorecard` object.

Data Types: char

### Missing — Indicator for points assigned to missing or out-of-range information when scoring

NoScore (default) | character vector with values `NoScore`, `ZeroWOE`, `MinPoints`, and `MaxPoints`

Indicator for points assigned to missing or out-of-range information when scoring, specified as the comma-separated pair consisting of `'Missing'` and a character vector with a value for `NoScore`, `ZeroWOE`, `MinPoints`, or `MaxPoints`, where:

- `NoScore` — Missing and out-of-range data do not get points assigned and points are set to `NaN`. Also, the total score is set to `NaN`.
- `ZeroWOE` — Missing or out-of-range data get assigned a zero Weight-of-Evidence (WOE) value.
- `MinPoints` — Missing or out-of-range data get the minimum possible points for that predictor. This penalizes the score if higher scores are better.

- **MaxPoints** — Missing or out-of-range data get the maximum possible points for that predictor. This penalizes the score if lower scores are better.

---

**Note** When using the `creditscorecard` name-value argument `'BinMissingData'` with a value of `true`, missing data for numeric and categorical predictors is binned in a separate bin labeled `<missing>`. The `<missing>` bin only contains missing values for a predictor and does not contain invalid or out-of-range values for a predictor.

---

Data Types: `char`

### **Round — Indicator whether to round points or scores**

`'None'` (default) | character vector with values `'AllPoints'`, `'FinalScore'`

Indicator whether to round points or scores, specified as the comma-separated pair consisting of `'Round'` and a character vector with values `'AllPoints'`, `'FinalScore'` or `'None'`, where:

- `None` — No rounding is applied.
- `AllPoints` — Apply rounding to each predictor's points before adding up the total score.
- `FinalScore` — Round the final score only (rounding is applied after all points are added up).

For more information and an example of using the `'Round'` name-value pair argument, see “Rounding and Default Probabilities” on page 19-1733.

Data Types: `char`

### **ShiftAndSlope — Indicator for shift and slope scaling parameters**

`[0,1]` (default) | numeric array with two elements `[Shift,Slope]`

Indicator for shift and slope scaling parameters for the credit scorecard, specified as the comma-separated pair consisting of `'ShiftAndSlope'` and a numeric array with two elements `[Shift, Slope]`. `Slope` cannot be zero. The `ShiftAndSlope` values are used scale the scoring model.

---

**Note** `ShiftAndSlope`, `PointsOddsAndPDO`, and `WorstAndBestScores` are scaling methods and you can use only one of these name-value pair arguments at one time. The other three name-value pair arguments (`BasePoints`, `Missing`, and `Round`) are not scaling methods and can be used together or with any one of the three scaling methods.

---

To remove a previous scaling and revert to unscaled scores, set `ShiftAndSlope` to `[0,1]`.

---

Data Types: `double`

### **PointsOddsAndPDO — Indicator for target points for given odds and double odds level**

numeric array with three elements `[Points,Odds,PDO]`

Indicator for target points (`Points`) for a given odds level (`Odds`) and the desired number of points to double the odds (`PDO`), specified as the comma-separated pair consisting of `'PointsOddsAndPDO'` and a numeric array with three elements `[Points,Odds,PDO]`. `Odds` must be a positive number. The `PointsOddsAndPDO` values are used to find scaling parameters for the scoring model.

---

**Note** The points to double the odds (`PDO`) may be positive or negative, depending on whether higher scores mean lower risk, or vice versa.

---

`ShiftAndSlope`, `PointsOddsAndPDO`, and `WorstAndBestScores` are scaling methods and you can use only one of these name-value pair arguments at one time. The other three name-value pair arguments (`BasePoints`, `Missing`, and `Round`) are not scaling methods and can be used together or with any one of the three scaling methods.

To remove a previous scaling and revert to unscaled scores, set `ShiftAndSlope` to `[0, 1]`.

---

Data Types: `double`

### **WorstAndBestScores — Indicator for worst (highest risk) and best (lowest risk) scores in scorecard**

numeric array with two elements [`WorstScore`, `BestScore`]

Indicator for worst (highest risk) and best (lowest risk) scores in the scorecard, specified as the comma-separated pair consisting of '`WorstAndBestScores`' and a numeric array with two elements [`WorstScore`, `BestScore`]. `WorstScore` and `BestScore` must be different values. These `WorstAndBestScores` values are used to find scaling parameters for the scoring model.

---

**Note** `WorstScore` means the riskiest score, and its value could be lower or higher than the 'best' score. In other words, the 'minimum' score may be the 'worst' score or the 'best' score, depending on the desired scoring scale.

`ShiftAndSlope`, `PointsOddsAndPDO`, and `WorstAndBestScores` are scaling methods and you can use only one of these name-value pair arguments at one time. The other three name-value pair arguments (`BasePoints`, `Missing`, and `Round`) are not scaling methods and can be used together or with any one of the three scaling methods.

To remove a previous scaling and revert to unscaled scores, set `ShiftAndSlope` to `[0, 1]`.

---

Data Types: `double`

## **Output Arguments**

### **sc — Credit scorecard model**

`creditscorecard` object

Credit scorecard model returned as an updated `creditscorecard` object. For more information on using the `creditscorecard` object, see `creditscorecard`.

## **Algorithms**

The score of an individual  $i$  is given by the formula

$$\text{Score}(i) = \text{Shift} + \text{Slope} * (b_0 + b_1 * \text{WOE}_1(i) + b_2 * \text{WOE}_2(i) + \dots + b_p * \text{WOE}_p(i))$$

where  $b_j$  is the coefficient of the  $j$ th variable in the model, and  $\text{WOE}_j(i)$  is the Weight of Evidence (WOE) value for the  $i$ th individual corresponding to the  $j$ th model variable. `Shift` and `Slope` are scaling constants further discussed below. The scaling constant can be controlled with `formatpoints`.

If the data for individual  $i$  is in the  $i$ -th row of a given dataset, to compute a score, the data( $i,j$ ) is binned using existing binning maps, and converted into a corresponding Weight of Evidence value  $WOE_j(i)$ . Using the model coefficients, the unscaled score is computed as

$$s = b_0 + b_1 * WOE_1(i) + \dots + b_p * WOE_p(i).$$

For simplicity, assume in the description above that the  $j$ -th variable in the model is the  $j$ -th column in the data input, although, in general, the order of variables in a given dataset does not have to match the order of variables in the model, and the dataset could have additional variables that are not used in the model.

The formatting options can be controlled using `formatpoints`. When the base points are reported separately (see the `formatpoints` parameter `BasePoints`), the base points are given by

$$\text{Base Points} = \text{Shift} + \text{Slope} * b_0,$$

and the points for the  $j$ -th predictor,  $i$ -th row are given by

$$\text{Points}_{ji} = \text{Slope} * (b_j * WOE_j(i)).$$

By default, the base points are not reported separately, in which case

$$\text{Points}_{ji} = (\text{Shift} + \text{Slope} * b_0) / p + \text{Slope} * (b_j * WOE_j(i)),$$

where  $p$  is the number of predictors in the scorecard model.

By default, no rounding is applied to the points by the score function (`Round` is `None`). If `Round` is set to `AllPoints` using `formatpoints`, then the points for individual  $i$  for variable  $j$  are given by

$$\text{points if rounding is 'AllPoints': round( Points}_{ji} )$$

and, if base points are reported separately, they are also rounded. This yields integer-valued points per predictor, hence also integer-valued scores. If `Round` is set to `FinalScore` using `formatpoints`, then the points per predictor are not rounded, and only the final score is rounded

$$\text{score if rounding is 'FinalScore': round(Score}(i)).$$

Regarding the scaling parameters, the `Shift` parameter, and the `Slope` parameter can be set directly with the `ShiftAndSlope` parameter of `formatpoints`. Alternatively, you can use the `formatpoints` parameter for `WorstAndBestScores`. In this case, the parameters `Shift` and `Slope` are found internally by solving the system

$$\begin{aligned} \text{Shift} + \text{Slope} * s_{\min} &= \text{WorstScore}, \\ \text{Shift} + \text{Slope} * s_{\max} &= \text{BestScore}, \end{aligned}$$

where `WorstScore` and `BestScore` are the first and second elements in the `formatpoints` parameter for `WorstAndBestScores` and `smin` and `smax` are the minimum and maximum possible unscaled scores:

$$\begin{aligned} s_{\min} &= b_0 + \min(b_1 * WOE_1) + \dots + \min(b_p * WOE_p), \\ s_{\max} &= b_0 + \max(b_1 * WOE_1) + \dots + \max(b_p * WOE_p). \end{aligned}$$

A third alternative to scale scores is the `PointsOddsAndPDO` parameter in `formatpoints`. In this case, assume that the unscaled score  $s$  gives the log-odds for a row, and the `Shift` and `Slope` parameters are found by solving the following system

$$\begin{aligned} \text{Points} &= \text{Shift} + \text{Slope} * \log(\text{Odds}) \\ \text{Points} + \text{PDO} &= \text{Shift} + \text{Slope} * \log(2 * \text{Odds}) \end{aligned}$$

where `Points`, `Odds`, and `PDO` ("points to double the odds") are the first, second, and third elements in the `PointsOddsAndPDO` parameter.

Whenever a given dataset has a missing or out-of-range value data ( $i_j$ ), the points for predictor  $j$ , for individual  $i$ , are set to `NaN` by default, which results in a missing score for that row (a `NaN` score). Using the `Missing` parameter for `formatpoints`, you can modify this behavior and set the corresponding Weight-of-Evidence (WOE) value to zero, or set the points to the minimum points, or the maximum points for that predictor.

## Introduced in R2014b

## displaypoints

Return points per predictor per bin

### Syntax

```
PointsInfo = displaypoints(sc)
[PointsInfo,MinScore,MaxScore] = displaypoints(sc)
[PointsInfo,MinScore,MaxScore] = displaypoints( ___,Name,Value)
```

### Description

`PointsInfo = displaypoints(sc)` returns a table of points for all bins of all predictor variables used in the `creditscorecard` object after a linear logistic regression model is fit using `fitmodel` to the Weight of Evidence data. The `PointsInfo` table displays information on the predictor name, bin labels, and the corresponding points per bin.

`[PointsInfo,MinScore,MaxScore] = displaypoints(sc)` returns a table of points for all bins of all predictor variables used in the `creditscorecard` object after a linear logistic regression model is fit (`fitmodel`) to the Weight of Evidence data. The `PointsInfo` table displays information on the predictor name, bin labels, and the corresponding points per bin and `displaypoints`. In addition, the optional `MinScore` and `MaxScore` values are returned.

`[PointsInfo,MinScore,MaxScore] = displaypoints( ___,Name,Value)` specifies options using one or more name-value pair arguments in addition to the input arguments in the previous syntax.

### Examples

#### Display Unscaled Points

This example shows how to use `displaypoints` after a model is fitted to compute the unscaled points per bin, for a given predictor in the `creditscorecard` model.

Create a `creditscorecard` object using the `CreditCardData.mat` file to load the data (using a dataset from Refaat 2011). Use the `'IDVar'` argument in the `creditscorecard` function to indicate that `'CustID'` contains ID information and should not be included as a predictor variable.

```
load CreditCardData
sc = creditscorecard(data,'IDVar','CustID');
```

Perform automatic binning to bin for all predictors.

```
sc = autobinning(sc);
```

Fit a linear regression model using default parameters.

```
sc = fitmodel(sc);
```

1. Adding `CustIncome`, Deviance = 1490.8527, Chi2Stat = 32.588614, PValue = 1.1387992e-08
2. Adding `TmWBank`, Deviance = 1467.1415, Chi2Stat = 23.711203, PValue = 1.1192909e-06

3. Adding AMBalance, Deviance = 1455.5715, Chi2Stat = 11.569967, PValue = 0.00067025601
4. Adding EmpStatus, Deviance = 1447.3451, Chi2Stat = 8.2264038, PValue = 0.0041285257
5. Adding CustAge, Deviance = 1441.994, Chi2Stat = 5.3511754, PValue = 0.020708306
6. Adding ResStatus, Deviance = 1437.8756, Chi2Stat = 4.118404, PValue = 0.042419078
7. Adding OtherCC, Deviance = 1433.707, Chi2Stat = 4.1686018, PValue = 0.041179769

Generalized linear regression model:

```
status ~ [Linear formula with 8 terms in 7 predictors]
Distribution = Binomial
```

Display unscaled points for predictors retained in the fitting model.

```
PointsInfo = displaypoints(sc)
```

PointsInfo=37x3 table

| Predictors      | Bin               | Points    |
|-----------------|-------------------|-----------|
| {'CustAge' }    | {'[-Inf,33)' }    | -0.15894  |
| {'CustAge' }    | {'[33,37)' }      | -0.14036  |
| {'CustAge' }    | {'[37,40)' }      | -0.060323 |
| {'CustAge' }    | {'[40,46)' }      | 0.046408  |
| {'CustAge' }    | {'[46,48)' }      | 0.21445   |
| {'CustAge' }    | {'[48,58)' }      | 0.23039   |
| {'CustAge' }    | {'[58,Inf]' }     | 0.479     |
| {'CustAge' }    | {'<missing>' }    | NaN       |
| {'ResStatus' }  | {'Tenant' }       | -0.031252 |
| {'ResStatus' }  | {'Home Owner' }   | 0.12696   |
| {'ResStatus' }  | {'Other' }        | 0.37641   |
| {'ResStatus' }  | {'<missing>' }    | NaN       |
| {'EmpStatus' }  | {'Unknown' }      | -0.076317 |
| {'EmpStatus' }  | {'Employed' }     | 0.31449   |
| {'EmpStatus' }  | {'<missing>' }    | NaN       |
| {'CustIncome' } | {'[-Inf,29000)' } | -0.45716  |
| :               |                   |           |

`displaypoints` always displays a '<missing>' bin for each predictor. The value of the '<missing>' bin comes from the initial `creditscorecard` object, and the '<missing>' bin is set to NaN whenever the scorecard model has no information on how to assign points to missing data.

To configure the points for the '<missing>' bin, you must use the initial `creditscorecard` object. For predictors that have missing values in the training set, the points for the '<missing>' bin are estimated from the data if the `'BinMissingData'` name-value pair argument is set to `true` using `creditscorecard`. When the `'BinMissingData'` parameter is set to `false`, or when the data contains no missing values in the training set, use the `'Missing'` name-value pair argument in `formatpoints` to indicate how to assign points to the missing data.

### Display Unscaled Points When Using Missing Data

Create a `creditscorecard` object using the `CreditCardData.mat` file to load the data with missing values.

```
load CreditCardData.mat
head(dataMissing,5)
```

```
ans=5x11 table
```

| CustID | CustAge | TmAtAddress | ResStatus   | EmpStatus | CustIncome | TmWBank | OtherCC |
|--------|---------|-------------|-------------|-----------|------------|---------|---------|
| 1      | 53      | 62          | <undefined> | Unknown   | 50000      | 55      | Yes     |
| 2      | 61      | 22          | Home Owner  | Employed  | 52000      | 25      | Yes     |
| 3      | 47      | 30          | Tenant      | Employed  | 37000      | 61      | No      |
| 4      | NaN     | 75          | Home Owner  | Employed  | 53000      | 20      | Yes     |
| 5      | 68      | 56          | Home Owner  | Employed  | 53000      | 14      | Yes     |

```
fprintf('Number of rows: %d\n',height(dataMissing))
```

```
Number of rows: 1200
```

```
fprintf('Number of missing values CustAge: %d\n',sum(ismissing(dataMissing.CustAge)))
```

```
Number of missing values CustAge: 30
```

```
fprintf('Number of missing values ResStatus: %d\n',sum(ismissing(dataMissing.ResStatus)))
```

```
Number of missing values ResStatus: 40
```

Use `creditscorecard` with the name-value argument `'BinMissingData'` set to `true` to bin the missing numeric or categorical data in a separate bin. Apply automatic binning.

```
sc = creditscorecard(dataMissing,'IDVar','CustID','BinMissingData',true);
sc = autobinning(sc);
```

```
disp(sc)
```

```
creditscorecard with properties:
```

```
    GoodLabel: 0
    ResponseVar: 'status'
    WeightsVar: ''
    VarNames: {1x11 cell}
    NumericPredictors: {1x6 cell}
    CategoricalPredictors: {'ResStatus' 'EmpStatus' 'OtherCC'}
    BinMissingData: 1
```

```
IDVar: 'CustID'
PredictorVars: {1x9 cell}
Data: [1200x11 table]
```

Display and plot bin information for numeric data for 'CustAge' that includes missing data in a separate bin labelled <missing>.

```
[bi,cp] = bininfo(sc,'CustAge');
disp(bi)
```

| Bin             | Good | Bad | Odds   | WOE      | InfoValue  |

| {'Totals' } }   | 803  | 397 | 2.0227 | NaN      | 0.087112   |

```
plotbins(sc,'CustAge')
```

Display and plot bin information for categorical data for 'ResStatus' that includes missing data in a separate bin labelled <missing>.

```
[bi,cg] = bininfo(sc, 'ResStatus');
disp(bi)
```

| Bin             | Good | Bad | Odds   | WOE       | InfoValue  |
|-----------------|------|-----|--------|-----------|------------|
| {'Tenant' }     | 296  | 161 | 1.8385 | -0.095463 | 0.0035249  |
| {'Home Owner' } | 352  | 171 | 2.0585 | 0.017549  | 0.00013382 |
| {'Other' }      | 128  | 52  | 2.4615 | 0.19637   | 0.0055808  |
| {'<missing>' }  | 27   | 13  | 2.0769 | 0.026469  | 2.3248e-05 |
| {'Totals' }     | 803  | 397 | 2.0227 | NaN       | 0.0092627  |

```
plotbins(sc, 'ResStatus')
```

For the 'CustAge' and 'ResStatus' predictors, there is missing data (NaNs and <undefined>) in the training data, and the binning process estimates a WOE value of -0.15787 and 0.026469 respectively for missing data in these predictors, as shown above.

Use `fitmodel` to fit a logistic regression model using Weight of Evidence (WOE) data. `fitmodel` internally transforms all the predictor variables into WOE values, using the bins found with the automatic binning process. `fitmodel` then fits a logistic regression model using a stepwise method (by default). For predictors that have missing data, there is an explicit <missing> bin, with a corresponding WOE value computed from the data. When using `fitmodel`, the corresponding WOE value for the <missing> bin is applied when performing the WOE transformation.

```
[sc,mdl] = fitmodel(sc);
```

1. Adding CustIncome, Deviance = 1490.8527, Chi2Stat = 32.588614, PValue = 1.1387992e-08

Dispersion: 1

Chi<sup>2</sup>-statistic vs. constant model: 88.5, p-value = 2.55e-16

Display unscaled points for predictors retained in the fitting model (to scale points use `formatpoints`).

```
PointsInfo = displaypoints(sc)
```

PointsInfo=38x3 table

| Predictors     | Bin             | Points    |
|----------------|-----------------|-----------|
| {'CustAge' }   | {'[-Inf,33)' }  | -0.14173  |
| {'CustAge' }   | {'[33,37)' }    | -0.11095  |
| {'CustAge' }   | {'[37,40)' }    | -0.059244 |
| {'CustAge' }   | {'[40,46)' }    | 0.074167  |
| {'CustAge' }   | {'[46,48)' }    | 0.1889    |
| {'CustAge' }   | {'[48,51)' }    | 0.20204   |
| {'CustAge' }   | {'[51,58)' }    | 0.22935   |
| {'CustAge' }   | {'[58,Inf]' }   | 0.45019   |
| {'CustAge' }   | {'<missing>' }  | 0.0096749 |
| {'ResStatus' } | {'Tenant' }     | -0.029778 |
| {'ResStatus' } | {'Home Owner' } | 0.12425   |
| {'ResStatus' } | {'Other' }      | 0.36796   |
| {'ResStatus' } | {'<missing>' }  | 0.1364    |
| {'EmpStatus' } | {'Unknown' }    | -0.075948 |
| {'EmpStatus' } | {'Employed' }   | 0.31401   |
| {'EmpStatus' } | {'<missing>' }  | NaN       |
| :              |                 |           |

Notice that points for the <missing> bin for `CustAge` and `ResStatus` are explicitly shown. These points are computed from the WOE value for the <missing> bin and the logistic model coefficients.

For predictors that have no missing data in the training set, there is no explicit <missing> bin, and by default the points are set to NaN for missing data, and they lead to a score of NaN when running `score`. For predictors that have no explicit <missing> bin, use the name-value argument 'Missing' in `formatpoints` to indicate how missing data should be treated for scoring purposes.

## Display Scaled Points

This example shows how to use `formatpoints` after a model is fitted to format scaled points, and then use `displaypoints` to display the scaled points per bin, for a given predictor in the `creditscorecard` model.

Points become scaled when a range is defined. Specifically, a linear transformation from the unscaled to the scaled points is necessary. This transformation is defined either by supplying a shift and slope or by specifying the worst and best scores possible. (For more information, see `formatpoints`.)

Create a `creditscorecard` object using the `CreditCardData.mat` file to load the data (using a dataset from Refaat 2011). Use the 'IDVar' argument in the `creditscorecard` function to indicate that 'CustID' contains ID information and should not be included as a predictor variable.

```
load CreditCardData
sc = creditscorecard(data, 'IDVar', 'CustID');
```

Perform automatic binning to bin for all predictors.

```
sc = autobinning(sc);
```

Fit a linear regression model using default parameters.

```
sc = fitmodel(sc);
```

1. Adding `CustIncome`, Deviance = 1490.8527, Chi2Stat = 32.588614, PValue = 1.1387992e-08
2. Adding `TmWBank`, Deviance = 1467.1415, Chi2Stat = 23.711203, PValue = 1.1192909e-06
3. Adding `AMBALANCE`, Deviance = 1455.5715, Chi2Stat = 11.569967, PValue = 0.00067025601

| AMBALANCE | 1.045  | 0.32214 | 3.2439 | 0.0011792  |

1200 observations, 1192 error degrees of freedom  
 Dispersion: 1  
 Chi<sup>2</sup>-statistic vs. constant model: 89.7, p-value = 1.4e-16

Use the `formatpoints` function to scale providing the 'Worst' and 'Best' score values. The range provided below is a common score range.

```
sc = formatpoints(sc, 'WorstAndBestScores', [300 850]);
```

Display the points information again to verify that the points are now scaled and also display the scaled minimum and maximum scores.

```
[PointsInfo, MinScore, MaxScore] = displaypoints(sc)
```

PointsInfo=37x3 table

| Predictors      | Bin                | Points |
|-----------------|--------------------|--------|
| {'CustAge' }    | {'[-Inf,33) ' }    | 46.396 |
| {'CustAge' }    | {'[33,37) ' }      | 48.727 |
| {'CustAge' }    | {'[37,40) ' }      | 58.772 |
| {'CustAge' }    | {'[40,46) ' }      | 72.167 |
| {'CustAge' }    | {'[46,48) ' }      | 93.256 |
| {'CustAge' }    | {'[48,58) ' }      | 95.256 |
| {'CustAge' }    | {'[58,Inf] ' }     | 126.46 |
| {'CustAge' }    | {'<missing>' }     | NaN    |
| {'ResStatus' }  | {'Tenant' }        | 62.421 |
| {'ResStatus' }  | {'Home Owner' }    | 82.276 |
| {'ResStatus' }  | {'Other' }         | 113.58 |
| {'ResStatus' }  | {'<missing>' }     | NaN    |
| {'EmpStatus' }  | {'Unknown' }       | 56.765 |
| {'EmpStatus' }  | {'Employed' }      | 105.81 |
| {'EmpStatus' }  | {'<missing>' }     | NaN    |
| {'CustIncome' } | {'[-Inf,29000) ' } | 8.9706 |
|                 | :                  |        |

```
MinScore = 300.0000
```

```
MaxScore = 850
```

Notice that, as expected, the values of `MinScore` and `MaxScore` correspond to the worst and best possible scores.

### Separate the Base Points From the Total Points

This example shows how to use `displaypoints` after a model is fitted to separate the base points from the rest of the points assigned to each predictor variable. The name-value pair argument `'BasePoints'` in the `formatpoints` function is a boolean that serves this purpose. By default, the base points are spread across all variables in the scorecard.

Create a `creditscorecard` object using the `CreditCardData.mat` file to load the data (using a dataset from Refaat 2011). Use the `'IDVar'` argument in the `creditscorecard` function to indicate that `'CustID'` contains ID information and should not be included as a predictor variable.

```
load CreditCardData
sc = creditscorecard(data, 'IDVar', 'CustID');
```

Perform automatic binning to bin for all predictors.

```
sc = autobinning(sc);
```

Fit a linear regression model using default parameters.

```
sc = fitmodel(sc);
```

1. Adding CustIncome, Deviance = 1490.8527, Chi2Stat = 32.588614, PValue = 1.1387992e-08

### Display Points After Modifying Bin Labels

This example shows how to use `displaypoints` after a model is fitted and the `modifybins` function is used to provide user-defined bin labels for a numeric predictor.

Create a `creditscorecard` object using the `CreditCardData.mat` file to load the data (using a dataset from Refaat 2011). Use the `'IDVar'` argument in the `creditscorecard` function to indicate that `'CustID'` contains ID information and should not be included as a predictor variable.

```

load CreditCardData
sc = creditscorecard(data, 'IDVar', 'CustID');

```

Perform automatic binning to bin for all predictors.

```
sc = autobinning(sc);
```

Fit a linear regression model using default parameters.

```
sc = fitmodel(sc);
```

1. Adding CustIncome, Deviance = 1490.8527, Chi2Stat = 32.588614, PValue = 1.1387992e-08

## Compute the Predictor Weights

This example shows how to use a credit scorecard to compute the weights of the predictors. The weights of the predictors are determined from the range of points of each predictor, divided by the total range of points for the scorecard. The points for the scorecard not only take into consideration the betas, but also implicitly the binning of the predictor values and the corresponding weights of evidence.

Create a scorecard.

```

load CreditCardData.mat
sc = creditscorecard(data, 'IDVar', 'CustID');
sc = autobinning(sc);
sc = fitmodel(sc);

```

1. Adding CustIncome, Deviance = 1490.8527, Chi2Stat = 32.588614, PValue = 1.1387992e-08
2. Adding TmWBank, Deviance = 1467.1415, Chi2Stat = 23.711203, PValue = 1.1192909e-06
3. Adding AMBalance, Deviance = 1455.5715, Chi2Stat = 11.569967, PValue = 0.00067025601
4. Adding EmpStatus, Deviance = 1447.3451, Chi2Stat = 8.2264038, PValue = 0.0041285257
5. Adding CustAge, Deviance = 1441.994, Chi2Stat = 5.3511754, PValue = 0.020708306
6. Adding ResStatus, Deviance = 1437.8756, Chi2Stat = 4.118404, PValue = 0.042419078
7. Adding OtherCC, Deviance = 1433.707, Chi2Stat = 4.1686018, PValue = 0.041179769

Generalized linear regression model:

```

status ~ [Linear formula with 8 terms in 7 predictors]
Distribution = Binomial

```

1200 observations, 1192 error degrees of freedom  
 Dispersion: 1  
 Chi<sup>2</sup>-statistic vs. constant model: 89.7, p-value = 1.4e-16

Compute scorecard points and the MinPts and MaxPts scores.

```
sc = formatpoints(sc, 'PointsOddsAndPDO', [500 2 50]);
[PointsTable, MinPts, MaxPts] = displaypoints(sc);
PtsRange = MaxPts - MinPts;
disp(PointsTable(1:10, :));
```

| Predictors     | Bin             | Points |
|----------------|-----------------|--------|
| {'CustAge' }   | {'[-Inf, 33)' } | 52.821 |
| {'CustAge' }   | {'[33, 37)' }   | 54.161 |
| {'CustAge' }   | {'[37, 40)' }   | 59.934 |
| {'CustAge' }   | {'[40, 46)' }   | 67.633 |
| {'CustAge' }   | {'[46, 48)' }   | 79.755 |
| {'CustAge' }   | {'[48, 58)' }   | 80.905 |
| {'CustAge' }   | {'[58, Inf)' }  | 98.838 |
| {'CustAge' }   | {'<missing>' }  | NaN    |
| {'ResStatus' } | {'Tenant' }     | 62.031 |
| {'ResStatus' } | {'Home Owner' } | 73.444 |

```
fprintf('Min points: %g, Max points: %g\n', MinPts, MaxPts);
```

Min points: 355.505, Max points: 671.64

Compute the predictor weights.

```
Predictor = unique(PointsTable.Predictors, 'stable');
NumPred = length(Predictor);
Weight = zeros(NumPred, 1);
for ii=1:NumPred
    Ind = cellfun(@(x) strcmpi(Predictor{ii}, x), PointsTable.Predictors);
    MaxPtsPred = max(PointsTable.Points(Ind));
    MinPtsPred = min(PointsTable.Points(Ind));
    Weight(ii) = 100*(MaxPtsPred - MinPtsPred)/PtsRange;
end

PredictorWeights = table(Predictor, Weight);
PredictorWeights(end+1, :) = PredictorWeights(end, :);
PredictorWeights.Predictor{end} = 'Total';
PredictorWeights.Weight(end) = sum(Weight);
disp(PredictorWeights)
```

| Predictor | Weight |
|-----------|--------|
|-----------|--------|

```

{'CustAge'   }    14.556
{'ResStatus' }     9.302
{'EmpStatus' }    8.9174
{'CustIncome'}   20.401
{'TmWBank'   }    25.884
{'OtherCC'   }     7.9885
{'AMBalance' }    12.951
{'Total'    }     100

```

The weights are defined as the range of points for the predictor divided by the range of points for the scorecard.

### Display Points for creditcorecard Object That Contains Missing Data

To create a `creditscorecard` object using the `CreditCardData.mat` file, load the data (using a dataset from Refaat 2011). Using the `dataMissing` dataset, set the `'BinMissingData'` indicator to `true`.

```

load CreditCardData.mat
sc = creditscorecard(dataMissing, 'BinMissingData', true);

```

Use autobin角度 with the `creditscorecard` object.

```

sc = autobin角度(sc);

```

The binning map or rules for categorical data are summarized in a "category grouping" table, returned as an optional output. By default, each category is placed in a separate bin. Here is the information for the predictor `ResStatus`.

```

[bi, cg] = bininfo(sc, 'ResStatus')

```

```

bi=5x6 table
      Bin          Good    Bad    Odds      WOE      InfoValue
-----
{'Tenant'   }    296    161    1.8385   -0.095463    0.0035249
{'Home Owner'}  352    171    2.0585    0.017549    0.00013382
{'Other'    }    128     52    2.4615     0.19637     0.0055808
{'<missing>' }     27     13    2.0769    0.026469    2.3248e-05
{'Totals'   }    803    397    2.0227         NaN     0.0092627

```

```

cg=3x2 table
      Category      BinNumber
-----
{'Tenant'   }          1
{'Home Owner'}         2
{'Other'    }          3

```

To group categories `'Tenant'` and `'Other'`, modify the category grouping table `cg`, so the bin number for `'Other'` is the same as the bin number for `'Tenant'`. Then use `modifybins` to update the `creditscorecard` object.

```
cg.BinNumber(3) = 2;
sc = modifybins(sc, 'ResStatus', 'Catg', cg);
```

Display the updated bin information using `bininfo`. Note that the bin labels has been updated and that the bin membership information is contained in the category grouping `cg`.

```
[bi,cg] = bininfo(sc, 'ResStatus')
```

```
bi=4x6 table
      Bin          Good    Bad    Odds      WOE      InfoValue

{'Other'     }          2
```

Use `formatpoints` with the 'Missing' name-value pair argument to indicate that missing data is assigned 'maxpoints'.

```
sc = formatpoints(sc, 'BasePoints', true, 'Missing', 'maxpoints', 'WorstAndBest', [300 800]);
```

Use `fitmodel` to fit the model.

```
sc = fitmodel(sc, 'VariableSelection', 'fullmodel', 'Display', 'Off');
```

Then use `displaypoints` (Risk Management Toolbox) with the `creditscorecard` object to return a table of points for all bins of all predictor variables used in the `compactCreditScorecard` object. By setting the `displaypoints` (Risk Management Toolbox) name-value pair argument for 'ShowCategoricalMembers' to true, all the members contained in each individual group are displayed.

```
[PointsInfo,MinScore,MaxScore] = displaypoints(sc, 'ShowCategoricalMembers', true)
```

```
PointsInfo=51x3 table
      Predictors      Bin      Points

```
MaxScore = 800.0000
```

## Input Arguments

### sc — Credit scorecard model

creditscorecard object

Credit scorecard model, specified as a `creditscorecard` object. Use `creditscorecard` to create a `creditscorecard` object.

### Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `[PointsInfo,MinScore,MaxScore] = displaypoints(sc, 'ShowCategoricalMembers', true)`

### ShowCategoricalMembers — Indicator for how to display bins labels of categories that were grouped together

false (default) | true or false

Indicator for how to display bins labels of categories that were grouped together, specified as the comma-separated pair consisting of `'ShowCategoricalMembers'` and a logical scalar with a value of true or false.

By default, when `'ShowCategoricalMembers'` is false, bin labels are displayed as `Group1`, `Group2`, ..., `Groupn`, or if the bin labels were modified in `creditscorecard`, then the user-defined bin label names are displayed.

If `'ShowCategoricalMembers'` is true, all the members contained in each individual group are displayed.

Data Types: logical

## Output Arguments

### PointsInfo — One row per bin, per predictor, with the corresponding points

table

One row per bin, per predictor, with the corresponding points, returned as a table. For example:

| Predictors  | Bin         | Points        |
|-------------|-------------|---------------|
| Predictor_1 | Bin_11      | Points_11     |
| Predictor_1 | Bin_12      | Points_12     |
| Predictor_1 | Bin_13      | Points_13     |
|             | ...         | ...           |
| Predictor_1 | '<missing>' | NaN (Default) |
| Predictor_2 | Bin_21      | Points_21     |
| Predictor_2 | Bin_22      | Points_22     |
| Predictor_2 | Bin_23      | Points_23     |
|             | ...         | ...           |
| Predictor_2 | '<missing>' | NaN (Default) |
| Predictor_j | Bin_ji      | Points_ji     |
|             | ...         | ...           |
| Predictor_j | '<missing>' | NaN (Default) |

`displaypoints` always displays a '<missing>' bin for each predictor. The value of the '<missing>' bin comes from the initial `creditscorecard` object, and the '<missing>' bin is set to NaN whenever the scorecard model has no information on how to assign points to missing data.

To configure the points for the '<missing>' bin, you must use the initial `creditscorecard` object. For predictors that have missing values in the training set, the points for the '<missing>' bin are estimated from the data if the `'BinMissingData'` name-value pair argument for is set to `true` using `creditscorecard`. When the `'BinMissingData'` parameter is set to `false`, or when the data contains no missing values in the training set, use the `'Missing'` name-value pair argument in `formatpoints` to indicate how to assign points to the missing data.

Another option is to use `fillmissing` to specify replacement "fill" values for predictors with a NaN or `<undefined>` value. If you use `fillmissing`, then the `displaypoints` '<missing>' row has the same points as the bin associated with the fill value.

When base points are reported separately (see `formatpoints`), the first row of the returned `PointsInfo` table contains the base points.

### **MinScore — Minimum possible total score**

scalar

Minimum possible total score, returned as a scalar.

---

**Note** Minimum score is the lowest possible total score in the mathematical sense, independently of whether a low score means high risk or low risk.

---

### **MaxScore — Maximum possible total score**

scalar

Maximum possible total score, returned as a scalar.

---

**Note** Maximum score is the highest possible total score in the mathematical sense, independently of whether a high score means high risk or low risk.

---

## Algorithms

The points for predictor  $j$  and bin  $i$  are, by default, given by

$$\text{Points}_{ji} = (\text{Shift} + \text{Slope} * b_0) / p + \text{Slope} * (b_j * \text{WOE}_j(i))$$

where  $b_j$  is the model coefficient of predictor  $j$ ,  $p$  is the number of predictors in the model, and  $\text{WOE}_j(i)$  is the Weight of Evidence (WOE) value for the  $i$ -th bin corresponding to the  $j$ -th model predictor.  $\text{Shift}$  and  $\text{Slope}$  are scaling constants.

When the base points are reported separately (see the `formatpoints` name-value pair argument `BasePoints`), the base points are given by

$$\text{Base Points} = \text{Shift} + \text{Slope} * b_0,$$

and the points for the  $j$ -th predictor,  $i$ -th row are given by

$$\text{Points}_{ji} = \text{Slope} * (b_j * \text{WOE}_j(i)).$$

By default, the base points are not reported separately.

The minimum and maximum scores are:

$$\begin{aligned} \text{MinScore} &= \text{Shift} + \text{Slope} * b_0 + \min(\text{Slope} * b_1 * \text{WOE}_1) + \dots + \min(\text{Slope} * b_p * \text{WOE}_p), \\ \text{MaxScore} &= \text{Shift} + \text{Slope} * b_0 + \max(\text{Slope} * b_1 * \text{WOE}_1) + \dots + \max(\text{Slope} * b_p * \text{WOE}_p). \end{aligned}$$

Use `formatpoints` to control the way points are scaled, rounded, and whether the base points are reported separately. See `formatpoints` for more information on format parameters and for details and formulas on these formatting options.

## Introduced in R2014b

## fitmodel

Fit logistic regression model to Weight of Evidence (WOE) data

### Syntax

```
sc = fitmodel(sc)

[sc,mdl] = fitmodel(sc)
[sc,mdl] = fitmodel( ____,Name,Value)
```

### Description

`sc = fitmodel(sc)` fits a logistic regression model to the Weight of Evidence (WOE) data and stores the model predictor names and corresponding coefficients in the `creditscorecard` object.

`fitmodel` internally transforms all the predictor variables into WOE values, using the bins found with the automatic or manual binning process. The response variable is mapped so that "Good" is 1, and "Bad" is 0. This implies that higher (unscaled) scores correspond to better (less risky) individuals (smaller probability of default).

Alternatively, you can use `setmodel` to provide names of the predictors that you want in the logistic regression model, along with their corresponding coefficients.

`[sc,mdl] = fitmodel(sc)` fits a logistic regression model to the Weight of Evidence (WOE) data and stores the model predictor names and corresponding coefficients in the `creditscorecard` object. `fitmodel` returns an updated `creditscorecard` object and a `GeneralizedLinearModel` object containing the fitted model.

`fitmodel` internally transforms all the predictor variables into WOE values, using the bins found with the automatic or manual binning process. The response variable is mapped so that "Good" is 1, and "Bad" is 0. This implies that higher (unscaled) scores correspond to better (less risky) individuals (smaller probability of default).

Alternatively, you can use `setmodel` to provide names of the predictors that you want in the logistic regression model, along with their corresponding coefficients.

`[sc,mdl] = fitmodel( ____,Name,Value)` fits a logistic regression model to the Weight of Evidence (WOE) data using optional name-value pair arguments and stores the model predictor names and corresponding coefficients in the `creditscorecard` object. Using name-value pair arguments, you can select which Generalized Linear Model to fit the data. `fitmodel` returns an updated `creditscorecard` object and a `GeneralizedLinearModel` object containing the fitted model.

### Examples

#### Fit a Stepwise Logistic Model

Create a `creditscorecard` object using the `CreditCardData.mat` file to load the data (using a dataset from Refaat 2011).

```

load CreditCardData
sc = creditscorecard(data, 'IDVar', 'CustID')

sc =
  creditscorecard with properties:

      GoodLabel: 0
      ResponseVar: 'status'
      WeightsVar: ''
      VarNames: {1x11 cell}
      NumericPredictors: {1x6 cell}
      CategoricalPredictors: {'ResStatus' 'EmpStatus' 'OtherCC'}
      BinMissingData: 0
      IDVar: 'CustID'
      PredictorVars: {1x9 cell}
      Data: [1200x11 table]

```

Perform automatic binning.

```

sc = autobinning(sc)

sc =
  creditscorecard with properties:

      GoodLabel: 0
      ResponseVar: 'status'
      WeightsVar: ''
      VarNames: {1x11 cell}
      NumericPredictors: {1x6 cell}
      CategoricalPredictors: {'ResStatus' 'EmpStatus' 'OtherCC'}
      BinMissingData: 0
      IDVar: 'CustID'
      PredictorVars: {1x9 cell}
      Data: [1200x11 table]

```

Use `fitmodel` to fit a logistic regression model using Weight of Evidence (WOE) data. `fitmodel` internally transforms all the predictor variables into WOE values, using the bins found with the automatic binning process. `fitmodel` then fits a logistic regression model using a stepwise method (by default).

```
sc = fitmodel(sc);
```

1. Adding CustIncome, Deviance = 1490.8527, Chi2Stat = 32.588614, PValue = 1.1387992e-08

1200 observations, 1192 error degrees of freedom  
 Dispersion: 1  
 Chi<sup>2</sup>-statistic vs. constant model: 89.7, p-value = 1.4e-16

### Fit a Stepwise Logistic Model For a `creditscorecard` Object Containing Weights

Use the `CreditCardData.mat` file to load the data (`dataWeights`) that contains a column (`RowWeights`) for the weights (using a dataset from Refaat 2011).

load `CreditCardData`

Create a `creditscorecard` object using the optional name-value pair argument for `'WeightsVar'`.

```
sc = creditscorecard(dataWeights, 'IDVar', 'CustID', 'WeightsVar', 'RowWeights')
```

```
sc =
  creditscorecard with properties:

    GoodLabel: 0
    ResponseVar: 'status'
    WeightsVar: 'RowWeights'
    VarNames: {1x12 cell}
    NumericPredictors: {1x6 cell}
    CategoricalPredictors: {'ResStatus' 'EmpStatus' 'OtherCC'}
    BinMissingData: 0
    IDVar: 'CustID'
    PredictorVars: {1x9 cell}
    Data: [1200x12 table]
```

Perform automatic binning.

```
sc = autobinning(sc)
```

```
sc =
  creditscorecard with properties:

    GoodLabel: 0
    ResponseVar: 'status'
    WeightsVar: 'RowWeights'
    VarNames: {1x12 cell}
    NumericPredictors: {1x6 cell}
    CategoricalPredictors: {'ResStatus' 'EmpStatus' 'OtherCC'}
    BinMissingData: 0
```

```
IDVar: 'CustID'
PredictorVars: {1x9 cell}
Data: [1200x12 table]
```

Use `fitmodel` to fit a logistic regression model using Weight of Evidence (WOE) data. `fitmodel` internally transforms all the predictor variables into WOE values, using the bins found with the automatic binning process. `fitmodel` then fits a logistic regression model using a stepwise method (by default). When the optional name-value pair argument `'WeightsVar'` is used to specify observation (sample) weights, the `mdl` output uses the weighted counts with `stepwiseglm` and `fitglm`.

```
[sc,mdl] = fitmodel(sc);
```

1. Adding CustIncome, Deviance = 764.3187, Chi2Stat = 15.81927, PValue = 6.968927e-05
2. Adding TmWBank, Deviance = 751.0215, Chi2Stat = 13.29726, PValue = 0.0002657942
3. Adding AMBalance, Deviance = 743.7581, Chi2Stat = 7.263384, PValue = 0.007037455

Generalized linear regression model:

```
logit(status) ~ 1 + CustIncome + TmWBank + AMBalance
Distribution = Binomial
```

Estimated Coefficients:

|             | Estimate | SE       | tStat  | pValue     |
|-------------|----------|----------|--------|------------|
| (Intercept) | 0.70642  | 0.088702 | 7.964  | 1.6653e-15 |
| CustIncome  | 1.0268   | 0.25758  | 3.9862 | 6.7132e-05 |
| TmWBank     | 1.0973   | 0.31294  | 3.5063 | 0.0004543  |
| AMBalance   | 1.0039   | 0.37576  | 2.6717 | 0.0075464  |

1200 observations, 1196 error degrees of freedom

Dispersion: 1

Chi<sup>2</sup>-statistic vs. constant model: 36.4, p-value = 6.22e-08

## Fit a Logistic Model with All Predictors

Create a `creditscorecard` object using the `CreditCardData.mat` file to load the data (using a dataset from Refaat 2011).

```
load CreditCardData
```

```
sc = creditscorecard(data, 'IDVar', 'CustID')
```

```
sc =
```

```
creditscorecard with properties:
```

```
    GoodLabel: 0
    ResponseVar: 'status'
    WeightsVar: ''
    VarNames: {1x11 cell}
    NumericPredictors: {1x6 cell}
    CategoricalPredictors: {'ResStatus' 'EmpStatus' 'OtherCC'}
    BinMissingData: 0
    IDVar: 'CustID'
```

```
PredictorVars: {1x9 cell}
Data: [1200x11 table]
```

Perform automatic binning.

```
sc = autobinning(sc, 'Algorithm', 'EqualFrequency')
```

```
sc =
creditscorecard with properties:

    GoodLabel: 0
    ResponseVar: 'status'
    WeightsVar: ''
    VarNames: {1x11 cell}
    NumericPredictors: {1x6 cell}
    CategoricalPredictors: {'ResStatus' 'EmpStatus' 'OtherCC'}
    BinMissingData: 0
    IDVar: 'CustID'
    PredictorVars: {1x9 cell}
    Data: [1200x11 table]
```

Use `fitmodel` to fit a logistic regression model using Weight of Evidence (WOE) data. `fitmodel` internally transforms all the predictor variables into WOE values, using the bins found with the automatic binning process. Set the `VariableSelection` name-value pair argument to `FullModel` to specify that all predictors must be included in the fitted logistic regression model.

```
sc = fitmodel(sc, 'VariableSelection', 'FullModel');
```

```
Generalized linear regression model:
status ~ [Linear formula with 10 terms in 9 predictors]
Distribution = Binomial
```

Estimated Coefficients:

|             | Estimate | SE       | tStat   | pValue    |
|-------------|----------|----------|---------|-----------|
| (Intercept) | 0.70262  | 0.063862 | 11.002  | 3.734e-28 |
| CustAge     | 0.57683  | 0.27064  | 2.1313  | 0.033062  |
| TmAtAddress | 1.0653   | 0.55233  | 1.9287  | 0.053762  |
| ResStatus   | 1.4189   | 0.65162  | 2.1775  | 0.029441  |
| EmpStatus   | 0.89916  | 0.29217  | 3.0776  | 0.002087  |
| CustIncome  | 0.77506  | 0.21942  | 3.5323  | 0.0004119 |
| TmWBank     | 1.0826   | 0.26583  | 4.0727  | 4.648e-05 |
| OtherCC     | 1.1354   | 0.52827  | 2.1493  | 0.031612  |
| AMBalance   | 0.99315  | 0.32642  | 3.0425  | 0.0023459 |
| UtilRate    | 0.16723  | 0.55745  | 0.29999 | 0.76419   |

1200 observations, 1190 error degrees of freedom

Dispersion: 1

Chi<sup>2</sup>-statistic vs. constant model: 85.6, p-value = 1.25e-14

## Fit a Stepwise Logistic Model When Using Missing Data

Create a `creditscorecard` object using the `CreditCardData.mat` file to load the `dataMissing` with missing values.

```
load CreditCardData.mat
head(dataMissing,5)
```

```
ans=5x11 table
```

| CustID | CustAge | TmAtAddress | ResStatus   | EmpStatus | CustIncome | TmWBank | OtherCC |
|--------|---------|-------------|-------------|-----------|------------|---------|---------|
| 1      | 53      | 62          | <undefined> | Unknown   | 50000      | 55      | Yes     |
| 2      | 61      | 22          | Home Owner  | Employed  | 52000      | 25      | Yes     |
| 3      | 47      | 30          | Tenant      | Employed  | 37000      | 61      | No      |
| 4      | NaN     | 75          | Home Owner  | Employed  | 53000      | 20      | Yes     |
| 5      | 68      | 56          | Home Owner  | Employed  | 53000      | 14      | Yes     |

```
fprintf('Number of rows: %d\n',height(dataMissing))
```

```
Number of rows: 1200
```

```
fprintf('Number of missing values CustAge: %d\n',sum(ismissing(dataMissing.CustAge)))
```

```
Number of missing values CustAge: 30
```

```
fprintf('Number of missing values ResStatus: %d\n',sum(ismissing(dataMissing.ResStatus)))
```

```
Number of missing values ResStatus: 40
```

Use `creditscorecard` with the name-value argument `'BinMissingData'` set to `true` to bin the missing numeric or categorical data in a separate bin.

```
sc = creditscorecard(dataMissing,'IDVar','CustID','BinMissingData',true);
sc = autobinning(sc);
disp(sc)
```

```
creditscorecard with properties:
```

```

    GoodLabel: 0
    ResponseVar: 'status'
    WeightsVar: ''
    VarNames: {1x11 cell}
    NumericPredictors: {'CustAge' 'TmAtAddress' 'CustIncome' 'TmWBank' 'AMBalance' 'Utili...}
    CategoricalPredictors: {'ResStatus' 'EmpStatus' 'OtherCC'}
    BinMissingData: 1
    IDVar: 'CustID'
    PredictorVars: {1x9 cell}
    Data: [1200x11 table]
```

Display and plot bin information for numeric data for `'CustAge'` that includes missing data in a separate bin labelled `<missing>`.

```
[bi,cp] = bininfo(sc,'CustAge');
disp(bi)
```

| Bin | Good | Bad | Odds | WOE | InfoValue |
|-----|------|-----|------|-----|-----------|
|-----|------|-----|------|-----|-----------|

|                 |     |     |        |          |            |
|-----------------|-----|-----|--------|----------|------------|
| {'[-Inf,33)'} } | 69  | 52  | 1.3269 | -0.42156 | 0.018993   |
| {'[33,37)'} }   | 63  | 45  | 1.4    | -0.36795 | 0.012839   |
| {'[37,40)'} }   | 72  | 47  | 1.5319 | -0.2779  | 0.0079824  |

```
plotbins(sc, 'ResStatus')
```

Use `fitmodel` to fit a logistic regression model using Weight of Evidence (WOE) data. `fitmodel` internally transforms all the predictor variables into WOE values, using the bins found with the automatic binning process. `fitmodel` then fits a logistic regression model using a stepwise method (by default). For predictors that have missing data, there is an explicit `<missing>` bin, with a corresponding WOE value computed from the data. When using `fitmodel`, the corresponding WOE value for the `<missing>` bin is applied when performing the WOE transformation. For example, a missing value for customer age (`CustAge`) is replaced with `-0.15787` which is the WOE value for the `<missing>` bin for the `CustAge` predictor. However, when `'BinMissingData'` is false, a missing value for `CustAge` remains as missing (NaN) when applying the WOE transformation.

```
[sc,mdl] = fitmodel(sc);
```

1. Adding `CustIncome`, Deviance = 1490.8527, Chi2Stat = 32.588614, PValue = 1.1387992e-08

## Input Arguments

### sc — Credit scorecard model

creditscorecard object

Credit scorecard model, specified as a `creditscorecard` object. Use `creditscorecard` to create a `creditscorecard` object.

### Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `[sc, mdl] = fitmodel(sc, 'VariableSelection', 'FullModel')`

### PredictorVars — Predictor variables for fitting creditscorecard object

all predictors in the `creditscorecard` object (default) | cell array of character vectors

Predictor variables for fitting the `creditscorecard` object, specified as the comma-separated pair consisting of `'PredictorVars'` and a cell array of character vectors. When provided, the `creditscorecard` object property `PredictorsVars` is updated. Note that the order of predictors in the original dataset is enforced, regardless of the order in which `'PredictorVars'` is provided. When not provided, the predictors used to create the `creditscorecard` object (by using `creditscorecard`) are used.

Data Types: `cell`

### VariableSelection — Variable selection method to fit logistic regression model

`'Stepwise'` (default) | character vector with values `'Stepwise'`, `'FullModel'`

The variable selection method to fit the logistic regression model, specified as the comma-separated pair consisting of `'VariableSelection'` and a character vector with values `'Stepwise'` or `'FullModel'`:

- **Stepwise** — Uses a stepwise selection method which calls the Statistics and Machine Learning Toolbox function `stepwiseglm`. Only variables in `PredictorVars` can potentially become part of the model and uses the `StartingModel` name-value pair argument to select the starting model.

- **FullModel** — Fits a model with all predictor variables in the `PredictorVars` name-value pair argument and calls `fitglm`.

---

**Note** Only variables in the `PredictorVars` property of the `creditscorecard` object can potentially become part of the logistic regression model and only linear terms are included in this model with no interactions or any other higher-order terms.

---

The response variable is mapped so that “Good” is 1 and “Bad” is 0.

---

Data Types: char

### **StartingModel — Initial model for Stepwise variable selection**

'Constant' (default) | character vector with values 'Constant', 'Linear'

Initial model for the Stepwise variable selection method, specified as the comma-separated pair consisting of 'StartingModel' and a character vector with values 'Constant' or 'Linear'. This option determines the initial model (constant or linear) that the Statistics and Machine Learning Toolbox function `stepwiseglm` starts with.

- **Constant** — Starts the stepwise method with an empty (constant only) model.
- **Linear** — Starts the stepwise method from a full (all predictors in) model.

---

**Note** `StartingModel` is used only for the Stepwise option of `VariableSelection` and has no effect for the `FullModel` option of `VariableSelection`.

---

Data Types: char

### **Display — Indicator to display model information at command line**

'On' (default) | character vector with values 'On', 'Off'

Indicator to display model information at command line, specified as the comma-separated pair consisting of 'Display' and a character vector with value 'On' or 'Off'.

Data Types: char

## **Output Arguments**

### **sc — Credit scorecard model**

`creditscorecard` object

Credit scorecard model, returned as an updated `creditscorecard` object. The `creditscorecard` object contains information about the model predictors and coefficients used to fit the WOE data. For more information on using the `creditscorecard` object, see `creditscorecard`.

### **mdl — Fitted logistic model**

`GeneralizedLinearModel` object

Fitted logistic model, returned as an object of type `GeneralizedLinearModel` containing the fitted model. For more information on a `GeneralizedLinearModel` object, see `GeneralizedLinearModel`.

---

**Note** When creating the `creditscorecard` object with `creditscorecard`, if the optional name-value pair argument `WeightsVar` was used to specify observation (sample) weights, then `mdl` uses the weighted counts with `stepwiseglm` and `fitglm`.

---

## More About

### Using `fitmodel` with Weights

When observation weights are provided in the credit scorecard data, the weights are used to calibrate the model coefficients.

The underlying Statistics and Machine Learning Toolbox functionality for `stepwiseglm` and `fitglm` supports observation weights. The weights also affect the logistic model through the WOE values. The WOE transformation is applied to all predictors before fitting the logistic model. The observation weights directly impact the WOE values. For more information, see “Using `bininfo` with Weights” on page 19-1866 and “Credit Scorecard Modeling Using Observation Weights” on page 8-54.

Therefore, the credit scorecard points and final score depend on the observation weights through both the logistic model coefficients and the WOE values.

### Models

A logistic regression model is used in the `creditscorecard` object.

For the model, the probability of being “Bad” is defined as:  $\text{ProbBad} = \exp(-s) / (1 + \exp(-s))$ .

### Introduced in R2014b

# fitConstrainedModel

Fit logistic regression model to Weight of Evidence (WOE) data subject to constraints on model coefficients

## Syntax

```
[sc,mdl] = fitConstrainedModel(sc)
```

```
[sc,mdl] = fitConstrainedModel( ___,Name,Value)
```

## Description

`[sc,mdl] = fitConstrainedModel(sc)` fits a logistic regression model to the Weight of Evidence (WOE) data subject to equality, inequality, or bound constraints on the model coefficients. `fitConstrainedModel` stores the model predictor names and corresponding coefficients in an updated `creditscorecard` object `sc` and returns the `GeneralizedLinearModel` object `mdl` which contains the fitted model.

`[sc,mdl] = fitConstrainedModel( ___,Name,Value)` specifies options using one or more name-value pair arguments in addition to the input arguments in the previous syntax.

## Examples

### Credit Scorecards with Constrained Logistic Regression Coefficients

To compute scores for a `creditscorecard` object with constraints for equality, inequality, or bounds on the coefficients of the logistic regression model, use `fitConstrainedModel`. Unlike `fitmodel`, `fitConstrainedModel` solves for both the unconstrained and constrained problem. The current solver used to minimize an objective function for `fitConstrainedModel` is `fmincon`, from the Optimization Toolbox™.

This example has three main sections. First, `fitConstrainedModel` is used to solve for the coefficients in the unconstrained model. Then, `fitConstrainedModel` demonstrates how to use several types of constraints. Finally, `fitConstrainedModel` uses bootstrapping for the significance analysis to determine which predictors to reject from the model.

#### Create the `creditscorecard` Object and Bin data

```
load CreditCardData.mat
sc = creditscorecard(data, 'IDVar', 'CustID');
sc = autobinning(sc);
```

#### Unconstrained Model Using `fitConstrainedModel`

Solve for the unconstrained coefficients using `fitConstrainedModel` with default values for the input parameters. `fitConstrainedModel` uses the internal optimization solver `fmincon` from the Optimization Toolbox™. If you do not set any constraints, `fmincon` treats the model as an unconstrained optimization problem. The default parameters for the `LowerBound` and `UpperBound` are `-Inf` and `+Inf`, respectively. For the equality and inequality constraints, the default is an empty numeric array.

```
[sc1,mdl1] = fitConstrainedModel(sc);
coeff1 = mdl1.Coefficients.Estimate;
disp(mdl1.Coefficients);
```

|             | Estimate  |
|-------------|-----------|
| (Intercept) | 0.70246   |
| CustAge     | 0.6057    |
| TmAtAddress | 1.0381    |
| ResStatus   | 1.3794    |
| EmpStatus   | 0.89648   |
| CustIncome  | 0.70179   |
| TmWBank     | 1.1132    |
| OtherCC     | 1.0598    |
| AMBalance   | 1.0572    |
| UtilRate    | -0.047597 |

Unlike `fitmodel` which gives  $p$ -values, when using `fitConstrainedModel`, you must use bootstrapping to find out which predictors are rejected from the model, when subject to constraints. This is illustrated in the "Significance Bootstrapping" section.

### Using `fitmodel` to Compare the Results and Calibrate the Model

`fitmodel` fits a logistic regression model to the Weight-of-Evidence (WOE) data and there are no constraints. You can compare the results from the "Unconstrained Model Using `fitConstrainedModel`" section with those of `fitmodel` to verify that the model is well calibrated.

Now, solve the unconstrained problem by using `fitmodel`. Note that `fitmodel` and `fitConstrainedModel` use different solvers. While `fitConstrainedModel` uses `fmincon`, `fitmodel` uses `stepwiseglm` by default. To include all predictors from the start, set the 'VariableSelection' name-value pair argument of `fitmodel` to 'fullmodel'.

```
[sc2,mdl2] = fitmodel(sc,'VariableSelection','fullmodel','Display','off');
coeff2 = mdl2.Coefficients.Estimate;
disp(mdl2.Coefficients);
```

|             | Estimate  | SE       | tStat     | pValue     |
|-------------|-----------|----------|-----------|------------|
| (Intercept) | 0.70246   | 0.064039 | 10.969    | 5.3719e-28 |
| CustAge     | 0.6057    | 0.24934  | 2.4292    | 0.015131   |
| TmAtAddress | 1.0381    | 0.94042  | 1.1039    | 0.26963    |
| ResStatus   | 1.3794    | 0.6526   | 2.1137    | 0.034538   |
| EmpStatus   | 0.89648   | 0.29339  | 3.0556    | 0.0022458  |
| CustIncome  | 0.70179   | 0.21866  | 3.2095    | 0.0013295  |
| TmWBank     | 1.1132    | 0.23346  | 4.7683    | 1.8579e-06 |
| OtherCC     | 1.0598    | 0.53005  | 1.9994    | 0.045568   |
| AMBalance   | 1.0572    | 0.36601  | 2.8884    | 0.0038718  |
| UtilRate    | -0.047597 | 0.61133  | -0.077858 | 0.93794    |

```
figure
plot(coeff1,'*')
hold on
plot(coeff2,'s')
xticklabels(mdl1.Coefficients.Properties.RowNames)
ylabel('Model Coefficients')
title('Unconstrained Model Coefficients')
```

```
legend({'Calculated by fitConstrainedModel with defaults', 'Calculated by fimodel'}, 'Location', 'bottomright', 'grid on')
```

As both the tables and the plot show, the model coefficients match. You can be confident that this implementation of `fitConstrainedModel` is well calibrated.

### Constrained Model

In the constrained model approach, you solve for the values of the coefficients  $b_i$  of the logistic model, subject to constraints. The supported constraints are bound, equality, or inequality. The coefficients maximize the likelihood-of-default function defined, for observation  $i$ , as:

$$L_i = p(\text{Default}_i)^{y_i} \times (1 - p(\text{Default}_i))^{1 - y_i}$$

where:

- $p(\text{Default}_i) = \frac{1}{1 + e^{-b\mathbf{x}_i}}$
- $\mathbf{b} = [b_1 \ b_2 \ \dots \ b_K]$  is an unknown model coefficient
- $\mathbf{x}_i = [x_{i1} \ x_{i2} \ \dots \ x_{iK}]$  is the predictor values at observation  $i$
- $y_i$  is the response value; a value of 1 represents default and a value of 0 represents non-default

This formula is for non-weighted data. When observation  $i$  has weight  $w_i$ , it means that there are  $w_i$  as many observations  $i$ . Therefore, the probability that default occurs at observation  $i$  is the product of the probabilities of default:

$$p_i = p(\text{Default}_i)^{y_i} * p(\text{Default}_i)^{y_i} * \dots * p(\text{Default}_i)^{y_i} = p(\text{Default}_i)^{w_i * y_i}$$

Likewise, the probability of non-default for weighted observation  $i$  is:

$$\hat{p}_i = p(\sim\text{Default}_i)^{1 - y_i} * p(\sim\text{Default}_i)^{1 - y_i} * \dots * p(\sim\text{Default}_i)^{1 - y_i} = (1 - p(\text{Default}_i))^{w_i * (1 - y_i)}$$

For weighted data, if there is default at a given observation  $i$  whose weight is  $w_i$ , it is as if there was a  $w_i$  count of that one observation, and all of them either all default, or all non-default.  $w_i$  may or may not be an integer.

Therefore, for the weighted data, the likelihood-of-default function for observation  $i$  in the first equation becomes

$$L_i = p(\text{Default}_i)^{w_i * y_i} \times (1 - p(\text{Default}_i))^{w_i * (1 - y_i)}$$

By assumption, all defaults are independent events, so the objective function is

$$L = L_1 \times L_2 \times \dots \times L_N$$

or, in more convenient logarithmic terms:

$$\log(L) = \sum_{i=1}^N w_i * [y_i \log(p(\text{Default}_i)) + (1 - y_i) \log(1 - p(\text{Default}_i))]$$

### Apply Constraints on the Coefficients

After calibrating the unconstrained model as described in the "Unconstrained Model Using fitConstrainedModel" section, you can solve for the model coefficients subject to constraints. You can choose lower and upper bounds such that  $0 \leq b_i \leq 1, \forall i = 1 \dots K$ , except for the intercept. Also, since the customer age and customer income are somewhat correlated, you can also use additional constraints on their coefficients, for example,  $|b_{CusAge} - b_{CustIncome}| < 0.1$ . The coefficients corresponding to the predictors 'CustAge' and 'CustIncome' in this example are  $b_2$  and  $b_6$ , respectively.

```
K = length(sc.PredictorVars);
lb = [-Inf;zeros(K,1)];
ub = [Inf;ones(K,1)];
AIneq = [0 -1 0 0 0 1 0 0 0 0;0 -1 0 0 0 -1 0 0 0 0];
bIneq = [0.05;0.05];
Options = optimoptions('fmincon','SpecifyObjectiveGradient',true,'Display','off');
[sc3,mdl] = fitConstrainedModel(sc,'AInequality',AIneq,'bInequality',bIneq,...
    'LowerBound',lb,'UpperBound',ub,'Options',Options);
```

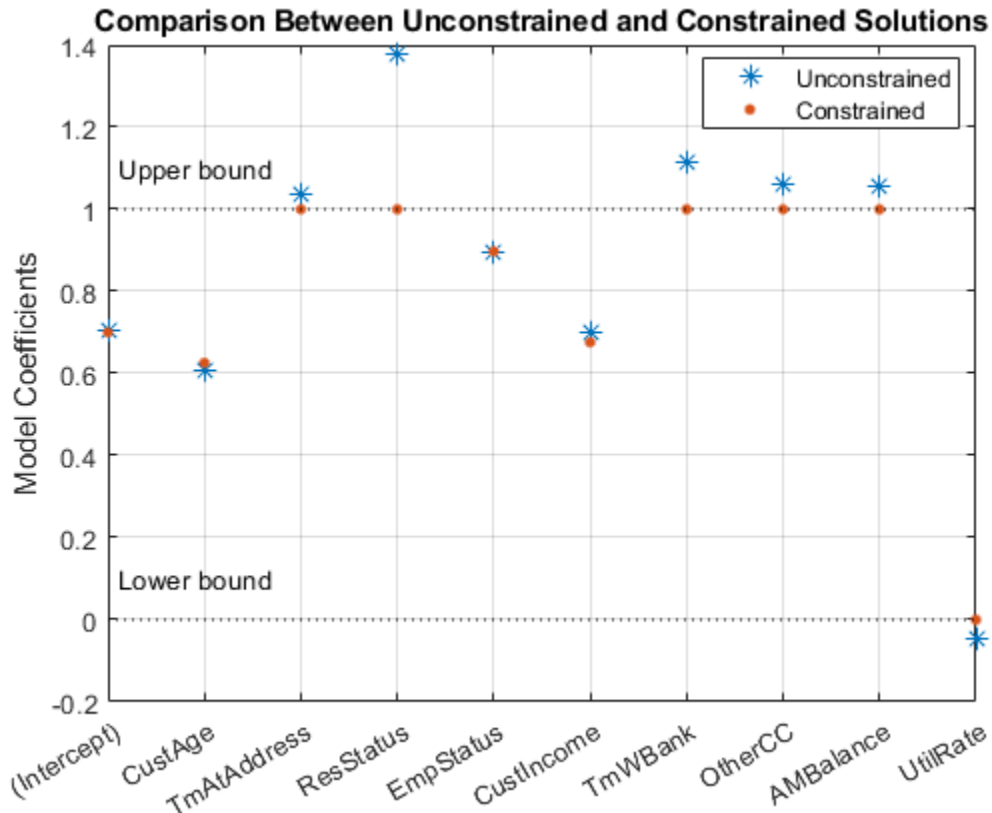

```
figure
plot(coeff1,'*','MarkerSize',8)
hold on
plot(mdl.Coefficients.Estimate,','MarkerSize',12)
line(xlim,[0 0],'color','k','linestyle',':')
```

```

line(xlim,[1 1], 'color', 'k', 'linestyle', ':')
text(1.1, 0.1, 'Lower bound')
text(1.1, 1.1, 'Upper bound')
grid on

xticklabels mdl.Coefficients.Properties.RowNames)
ylabel('Model Coefficients')
title('Comparison Between Unconstrained and Constrained Solutions')
legend({'Unconstrained', 'Constrained'}, 'Location', 'best')

```

### Significance Bootstrapping

For the unconstrained problem, standard formulas are available for computing  $p$ -values, which you use to evaluate which coefficients are significant and which are to be rejected. However, for the constrained problem, standard formulas are not available, and the derivation of formulas for significance analysis is complicated. A practical alternative is to perform significance analysis through *bootstrapping*.

In the bootstrapping approach, when using `fitConstrainedModel`, you set the name-value argument `'Bootstrap'` to `true` and chose a value for the name-value argument `'BootstrapIter'`. Bootstrapping means that  $N$  iter samples (with replacement) from the original observations are selected. In each iteration, `fitConstrainedModel` solves for the same constrained problem as the "Constrained Model" section. `fitConstrainedModel` obtains several values (solutions) for each coefficient  $b_i$  and you can plot these as a boxplot or histogram. Using the boxplot or histogram, you can examine the median values to evaluate whether the coefficients are away from zero and how much the coefficients deviate from their means.

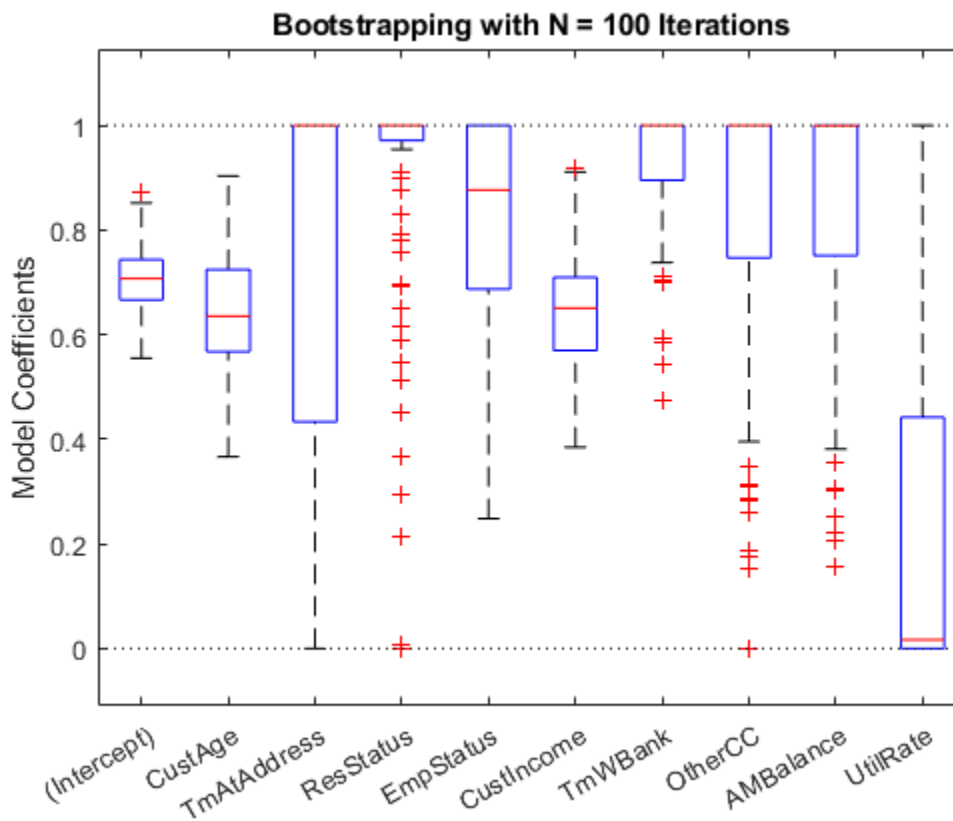

```

lb = [-Inf;zeros(K,1)];
ub = [Inf;ones(K,1)];
AIneq = [0 -1 0 0 0 1 0 0 0 0;0 1 0 0 0 -1 0 0 0 0];
bIneq = [0.05;0.05];
c0 = zeros(K,1);
NIter = 100;
Options = optimoptions('fmincon','SpecifyObjectiveGradient',true,'Display','off');
rng('default')

[sc,mdl] = fitConstrainedModel(sc,'AInequality',AIneq,'bInequality',bIneq,...
    'LowerBound',lb,'UpperBound',ub,'Bootstrap',true,'BootstrapIter',NIter,'Options',Options);

figure
boxplot(mdl.Bootstrap.Matrix,mdl.Coefficients.Properties.RowNames)
hold on
line(xlim,[0 0],'color','k','linestyle',':')
line(xlim,[1 1],'color','k','linestyle',':')
title('Bootstrapping with N = 100 Iterations')
ylabel('Model Coefficients')

```

The solid red lines in the boxplot indicate that the median values and the bottom and top edges are for the 25<sup>th</sup> and 75<sup>th</sup> percentiles. The "whiskers" are the minimum and maximum values, not including outliers. The dotted lines represent the lower and upper bound constraints on the coefficients. In this example, the coefficients cannot be negative, by construction.

To help decide which predictors to keep in the model, assess the proportion of times each coefficient is zero.

```

Tol = 1e-6;
figure
bar(100*sum mdl.Bootstrap.Matrix<= Tol)/NIter)
ylabel('% of Zeros')
title('Percentage of Zeros Over Bootstrap Iterations')
xticklabels mdl.Coefficients.Properties.RowNames)
grid on

```

Based on the plot, you can reject 'UtilRate' since it has the highest number of zero values. You can also decide to reject 'TmAtAddress' since it shows a peak, albeit small.

### Set the Corresponding Coefficients to Zero

To set the corresponding coefficients to zero, set their upper bound to zero and solve the model again using the original data set.

```

ub(3) = 0;
ub(end) = 0;
[sc,mdl] = fitConstrainedModel(sc,'AInequality',AIneq,'bInequality',bIneq,'LowerBound',lb,'UpperBound',ub);
Ind = (abs(mdl.Coefficients.Estimate) <= Tol);
ModelCoeff = mdl.Coefficients.Estimate(~Ind);
ModelPreds = mdl.Coefficients.Properties.RowNames(~Ind)';

figure
hold on
plot(ModelCoeff, '.', 'MarkerSize', 12)
ylim([0.2 1.2])
ylabel('Model Coefficients')

```

```
xticklabels(ModelPreds)
title('Selected Model Coefficients After Bootstrapping')
grid on
```

### Set Constrained Coefficients Back Into the creditscorecard

Now that you have solved for the constrained coefficients, use `setmodel` to set the model's coefficients and predictors. Then you can compute the (unscaled) points.

```
ModelPreds = ModelPreds(2:end);
sc = setmodel(sc,ModelPreds,ModelCoeff);
p = displaypoints(sc);
```

```
disp(p)
```

| Predictors     | Bin               | Points    |

Using the unscaled points, you can follow the remainder of the “Credit Scorecard Modeling Workflow” on page 8-51 to compute scores and probabilities of default and to validate the model.

## Input Arguments

### sc — Credit scorecard model

creditscorecard object

Credit scorecard model, specified as a `creditscorecard` object. Use `creditscorecard` to create a `creditscorecard` object.

### Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `[sc,mdl] = fitConstrainedModel(sc,'LowerBound',2,'UpperBound',100)`

### PredictorVars — Predictor variables for fitting creditscorecard object

all predictors in the `creditscorecard` object (default) | cell array of character vectors

Predictor variables for fitting the `creditscorecard` object, specified as the comma-separated pair consisting of `'PredictorVars'` and a cell array of character vectors. If you provide predictor variables, then the function updates the `creditscorecard` object property `PredictorVars`. The order of predictors in the original dataset is enforced, regardless of the order in which `'PredictorVars'` is provided. When not provided, the predictors used to create the `creditscorecard` object (by using `creditscorecard`) are used.

Data Types: cell

**LowerBound — Lower bound**

-Inf (default) | scalar | vector

Lower bound, specified as the comma-separated pair consisting of 'LowerBound' and a scalar or a real vector of length  $N+1$ , where  $N$  is the number of model coefficients in the `creditscorecard` object.

Data Types: double

**UpperBound — Upper bound**

Inf (default) | scalar | vector

Upper bound, specified as the comma-separated pair consisting of 'UpperBound' and a scalar or a real vector of length  $N+1$ , where  $N$  is the number of model coefficients in the `creditscorecard` object.

Data Types: double

**AInequality — Matrix of linear inequality constraints**

[] (default) | matrix

Matrix of linear inequality constraints, specified as the comma-separated pair consisting of 'AInequality' and a real  $M$ -by- $N+1$  matrix, where  $M$  is the number of constraints and  $N$  is the number of model coefficients in the `creditscorecard` object.

Data Types: double

**bInequality — Vector of linear inequality constraints**

[] (default) | vector

Vector of linear inequality constraints, specified as the comma-separated pair consisting of 'bInequality' and a real  $M$ -by-1 vector, where  $M$  is the number of constraints.

Data Types: double

**AEquality — Matrix of linear equality constraints**

[] (default) | matrix

Matrix of linear equality constraints, specified as the comma-separated pair consisting of 'AEquality' and a real  $M$ -by- $N+1$  matrix, where  $M$  is the number of constraints and  $N$  is the number of model coefficients in the `creditscorecard` object.

Data Types: double

**bEquality — Vector of linear equality constraints**

[] (default) | vector

Vector of linear equality constraints, specified as the comma-separated pair consisting of 'bEquality' and a real  $M$ -by-1 vector, where  $M$  is the number of constraints.

Data Types: double

**Bootstrap — Indicator that bootstrapping defines the solution accuracy**

false (default) | logical with a value of true or false

Indicator that bootstrapping defines the solution accuracy, specified as the comma-separated pair consisting of 'Bootstrap' and a logical with a value of true or false.

Data Types: logical

### **BootstrapIter — Number of bootstrapping iterations**

100 (default) | positive integer

Number of bootstrapping iterations, specified as the comma-separated pair consisting of 'BootstrapIter' and a positive integer.

Data Types: double

### **Options — optimoptions object**

optimoptions('fmincon','SpecifiedObjectiveGradient',true,'Display','off') (default) | object

optimoptions object, specified as the comma-separated pair consisting of 'Options' and an optimoptions object. You can create the object by using optimoptions from Optimization Toolbox.

Data Types: object

## **Output Arguments**

### **sc — Credit scorecard model**

creditscorecard object

Credit scorecard model, returned as an updated creditscorecard object. The creditscorecard object contains information about the model predictors and coefficients that fit the WOE data. For more information on using the creditscorecard object, see creditscorecard.

### **mdl — Fitted logistic model**

GeneralizedLinearModel object

Fitted logistic model, returned as a GeneralizedLinearModel object containing the fitted model. For more information on a GeneralizedLinearModel object, see GeneralizedLinearModel.

---

**Note** If you specify the optional `WeightsVar` argument when creating a `creditscorecard` object, then `mdl` uses the weighted counts with `stepwiseglm` and `fitglm`.

---

The `mdl` structure has the following fields:

- `Coefficients` is a table in which the `RowNames` property contains the names of the model coefficients and has a single column, 'Estimate', containing the solution.
- `Bootstrap` exists when 'Bootstrap' is set to true, and has two fields:
  - `CI` contains the 95% confidence interval for the solution.
  - `Matrix` an `NIter`-by-`N` matrix of coefficients, where `NIter` is the number of bootstrap iterations and `N` is the number of model coefficients.
- `Solver` has three fields:
  - `Options` additional information on the algorithm and solution.

- `ExitFlag` contains an integer that codes the reason why the solver stopped. For more information, see `fmincon`.
- `Output` is a structure with additional information on the optimization process.

## More About

### Model Coefficients

When you use `fitConstrainedModel` to solve for the model coefficients, the function solves for the same number of parameters as predictor variables you specify, plus one additional coefficient for the intercept.

The first coefficient corresponds to the intercept. If you provide predictor variables using the `'PredictorVars'` optional input argument, then `fitConstrainedModel` updates the `creditscorecard` object property `PredictorsVars`. The order of predictors in the original dataset is enforced, regardless of the order in which `'PredictorVars'` is provided. When not provided, the predictors used to create the `creditscorecard` object (by using `creditscorecard`) are used.

### Calibration

The constrained model is first calibrated such that, when unconstrained, the solution is identical, within a certain tolerance, to the solution given by `fitmodel`, with the `'fullmodel'` choice for the name-value argument `'VariableSelection'`.

As an exercise, you can test the calibration by leaving all name-value parameters of `fitConstrainedModel` to their default values. The solutions are identical to within a  $10^{-6}$  to  $10^{-5}$  tolerance.

### Calibration with Weights and Missing Data

If the credit scorecard data contains observation weights, the `fitConstrainedModel` function uses the weights to calibrate the model coefficients.

For credit scorecard data with no missing data and no weights, the likelihood function for observation  $i$  is

$$L_i = p^{\text{Default}_i} \times \left( \frac{1}{1 + e^{-bx_i}} \right)$$

where  $p(\text{Default}_i) = \frac{1}{1 + e^{-bx_i}}$

where:

- $b = [b_1 \ b_2 \dots \ b_K]$  is for unknown model coefficients
- $x_i = [x_{i1} \ x_{i2} \dots \ x_{iK}]$  is the predictor values at observation  $i$
- $y_i$  is the response value of 1 (the default) or a value of 0.

When observation  $i$  has weight  $w_i$ , it means that there are  $w_i$  observations. Because of the independence of defaults between observations, the probability that there is default at observation  $i$  is the product of the probabilities of default

$$p_i = p^{\text{Default}_i} * p^{\text{Default}_i} * \dots * p^{\text{Default}_i} = p^{\text{Default}_i}$$

$w_i$  times

Likewise, the probability of non-default for weighted observation  $i$  is

$$\hat{p}_i = p(\sim) * p(\sim) * \dots * p(\sim) = (1 - p(\text{Default}_i))^{w_i \text{ times}}$$

For weighted data, if there is default at a given observation  $i$  whose weight is  $w_i$ , it is as if there was  $w_i$  defaults of that one observation, and all of them either all default, or all non-default.  $w_i$  may or may not be an integer. Therefore, the likelihood function for observation  $i$  becomes

$$L_i = p(\text{Default}_i)^{w_i * y_i} \times (1 - p(\text{Default}_i))^{w_i * (1 - y_i)}$$

Likewise, for data with missing observations (NaN, <undefined>, or “Missing”), the model is calibrated by comparing the unconstrained case with results given by `fitglm`. Where the data contains missing observations, the WOE input matrix has NaN values. The NaN values do not pose any issue for `fitglm` (unconstrained), or `fmincon` (constrained). The only edge case is if all observations of a given predictor are missing, in which case, that predictor is discarded from the model.

### Bootstrapping

Bootstrapping is a method for estimating the accuracy of the solution obtained after iterating the objective function `NIter` times.

When 'Bootstrap' is set to `true`, the `fitConstrainedModel` function performs sampling with replacement of the WOE values and is passed to the objective function. At the end of the iterative process, the solutions are stored in a `NIter-by-N+1` matrix, where `N` is the number of model coefficients.

The 95% confidence interval (CI) returned in the output structure `mdl.Bootstrap` contains the values of the coefficients at the 25th and 97.5th percentiles.

### Models

A logistic regression model is used in the `creditscorecard` object.

For the model, the probability of being “Bad” is given by  $\text{ProbBad} = \exp(-s) / (1 + \exp(-s))$ .

# setmodel

Set model predictors and coefficients

## Syntax

```
sc = setmodel(sc,ModelPredictors,ModelCoefficients)
```

## Description

`sc = setmodel(sc,ModelPredictors,ModelCoefficients)` sets the predictors and coefficients of a linear logistic regression model fitted outside the `creditscorecard` object and returns an updated `creditscorecard` object. The predictors and coefficients are used for the computation of scorecard points. Use `setmodel` in lieu of `fitmodel`, which fits a linear logistic regression model, because `setmodel` offers increased flexibility. For example, when a model fitted with `fitmodel` needs to be modified, you can use `setmodel`. For more information, see “Workflows for Using `setmodel`” on page 19-1802.

---

**Note** When using `setmodel`, the following assumptions apply:

- The model coefficients correspond to a linear logistic regression model (where only linear terms are included in the model and there are no interactions or any other higher-order terms).
  - The model was previously fitted using Weight of Evidence (WOE) data with the response mapped so that ‘Good’ is 1 and ‘Bad’ is 0.
- 

## Examples

### Modify a GLM Model Fitted with `fitmodel`

This example shows how to use `setmodel` to make modifications to a logistic regression model initially fitted using the `fitmodel` function, and then set the new logistic regression model predictors and coefficients back into the `creditscorecard` object.

Create a `creditscorecard` object using the `CreditCardData.mat` file to load the data (using a dataset from Refaat 2011).

```
load CreditCardData
sc = creditscorecard(data, 'IDVar', 'CustID')

sc =
  creditscorecard with properties:

      GoodLabel: 0
      ResponseVar: 'status'
      WeightsVar: ''
      VarNames: {1x11 cell}
      NumericPredictors: {1x6 cell}
      CategoricalPredictors: {'ResStatus' 'EmpStatus' 'OtherCC'}
```

```

BinMissingData: 0
  IDVar: 'CustID'
  PredictorVars: {1x9 cell}
  Data: [1200x11 table]

```

Perform automatic binning.

```
sc = autobinning(sc);
```

The standard workflow is to use the `fitmodel` function to fit a logistic regression model using a stepwise method. However, `fitmodel` only supports limited options regarding the stepwise procedure. You can use the optional `mdl` output argument from `fitmodel` to get a copy of the fitted `GeneralizedLinearModel` object, to later modify.

```
[sc,mdl] = fitmodel(sc);
```

Suppose you want to include, or "force," the predictor 'UtilRate' in the logistic regression model, even though the stepwise method did not include it in the fitted model. You can add 'UtilRate' to the logistic regression model using the `GeneralizedLinearModel` object `mdl` directly.

```
mdl = mdl.addTerms('UtilRate')
```

```
mdl =
```

Generalized linear regression model:

```

status ~ [Linear formula with 9 terms in 8 predictors]
Distribution = Binomial

```

Chi<sup>2</sup>-statistic vs. constant model: 89.7, p-value = 5.26e-16

Use `setmodel` to update the model predictors and model coefficients in the `creditscorecard` object. The `ModelPredictors` input argument does not explicitly include a string for the intercept. However, the `ModelCoefficients` input argument does have the intercept information as its first element.

```
ModelPredictors = mdl.PredictorNames
```

```
ModelPredictors = 8x1 cell
```

```
    {'CustAge'   }
    {'ResStatus'}

### Fit a Logistic Regression Model Outside of the `creditscorecard` Object

This example shows how to use `setmodel` to fit a logistic regression model directly, without using the `fitmodel` function, and then set the new model predictors and coefficients back into the `creditscorecard` object. This approach gives more flexibility regarding options to control the stepwise procedure. This example fits a logistic regression model with a nondefault value for the `'PEnter'` parameter, the criterion to admit a new predictor in the logistic regression model during the stepwise procedure.

Create a `creditscorecard` object using the `CreditCardData.mat` file to load the data (using a dataset from Refaat 2011). Use the `'IDVar'` argument to indicate that `'CustID'` contains ID information and should not be included as a predictor variable.

```

load CreditCardData
sc = creditscorecard(data, 'IDVar', 'CustID')

sc =
creditscorecard with properties:

    GoodLabel: 0
    ResponseVar: 'status'
    WeightsVar: ''
    VarNames: {1x11 cell}
    NumericPredictors: {1x6 cell}
    CategoricalPredictors: {'ResStatus' 'EmpStatus' 'OtherCC'}
    BinMissingData: 0
    IDVar: 'CustID'
    PredictorVars: {1x9 cell}
    Data: [1200x11 table]

```

Perform automatic binning.

```
sc = autobinning(sc);
```

The logistic regression model needs to be fit with Weight of Evidence (WOE) data. The WOE transformation is a special case of binning, since the data first needs to be binned, and then the binned information is mapped to the corresponding WOE values. This transformation is done using the `bindata` function. `bindata` has an argument that prepares the data for the model fitting step. By setting the `bindata` name-value pair argument for `'OutputType'` to `WOEModelInput`:

- All predictors are converted to WOE values.
- The output contains only predictors and response (no `'IDVar'` or any unused variables).
- Predictors with infinite or undefined (NaN) WOE values are discarded.
- The response values are mapped so that "Good" is 1 and "Bad" is 0 (this implies that higher unscaled scores correspond to better, less risky customers).

```
bd = bindata(sc, 'OutputType', 'WOEModelInput');
```

For example, the first ten rows in the original data for the variables `'CustAge'`, `'ResStatus'`, `'CustIncome'`, and `'status'` (response variable) look like this:

```
data(1:10, {'CustAge' 'ResStatus' 'CustIncome' 'status'})
```

```
ans=10x4 table
```

| CustAge | ResStatus  | CustIncome | status |
|---------|------------|------------|--------|
| 53      | Tenant     | 50000      | 0      |
| 61      | Home Owner | 52000      | 0      |
| 47      | Tenant     | 37000      | 0      |
| 50      | Home Owner | 53000      | 0      |
| 68      | Home Owner | 53000      | 0      |
| 65      | Home Owner | 48000      | 0      |
| 34      | Home Owner | 32000      | 1      |
| 50      | Other      | 51000      | 0      |
| 50      | Tenant     | 52000      | 1      |
| 49      | Home Owner | 53000      | 1      |

Here is how the same ten rows look after calling `bindata` with the name-value pair argument `'OutputType'` set to `WOEModelInput`:

```
bd(1:10, {'CustAge' 'ResStatus' 'CustIncome' 'status'})
```

```
ans=10x4 table
```

| CustAge  | ResStatus | CustIncome | status |

Fit a logistic linear regression model using a stepwise method with the Statistics and Machine Learning Toolbox™ function `stepwiseglm`, but use a nondefault value for the 'PEnter' and 'PRemove' optional arguments. The predictors 'ResStatus' and 'OtherCC' would normally be included in the logistic linear regression model using default options for the stepwise procedure.

```
mdl = stepwiseglm(bd,'constant','Distribution','binomial',...
'Upper','linear','PEnter',0.025,'PRemove',0.05)
```

1. Adding CustIncome, Deviance = 1490.8527, Chi2Stat = 32.588614, PValue = 1.1387992e-08
2. Adding TmWBank, Deviance = 1467.1415, Chi2Stat = 23.711203, PValue = 1.1192909e-06
3. Adding AMBalance, Deviance = 1455.5715, Chi2Stat = 11.569967, PValue = 0.00067025601
4. Adding EmpStatus, Deviance = 1447.3451, Chi2Stat = 8.2264038, PValue = 0.0041285257
5. Adding CustAge, Deviance = 1441.994, Chi2Stat = 5.3511754, PValue = 0.020708306

```
mdl =
```

```
Generalized linear regression model:
```

```
logit(status) ~ 1 + CustAge + EmpStatus + CustIncome + TmWBank + AMBalance
Distribution = Binomial
```

```
Estimated Coefficients:
```

## Input Arguments

### **sc** — Credit scorecard model

creditscorecard object

Credit scorecard model, specified as a `creditscorecard` object. Use `creditscorecard` to create a `creditscorecard` object.

### **ModelPredictors** — Predictor names included in fitted model

cell array of character vectors with predictor values

```
{'PredictorName1','PredictorName2',...}
```

Predictor names included in the fitted model, specified as a cell array of character vectors as `{'PredictorName1','PredictorName2',...}`. The predictor names must match predictor variable names in the `creditscorecard` object.

---

**Note** Do not include a character vector for the constant term in `ModelPredictors`, `setmodel` internally handles the '(Intercept)' term based on the number of model coefficients (see `ModelCoefficients`).

---

Data Types: `cell`

### **ModelCoefficients** — Model coefficients corresponding to model predictors

numeric array with values `[coeff1,coeff2,..]`

Model coefficients corresponding to the model predictors, specified as a numeric array of model coefficients, `[coeff1,coeff2,..]`. If  $N$  is the number of predictor names provided in `ModelPredictors`, the size of `ModelCoefficients` can be  $N$  or  $N+1$ . If `ModelCoefficients` has  $N+1$  elements, then the first coefficient is used as the '(Intercept)' of the fitted model. Otherwise, the '(Intercept)' is set to 0.

Data Types: `double`

## **Output Arguments**

### **sc** — Credit scorecard model

`creditscorecard` object

Credit scorecard model, returned as an updated `creditscorecard` object. The `creditscorecard` object contains information about the model predictors and coefficients of the fitted model. For more information on using the `creditscorecard` object, see `creditscorecard`.

## **More About**

### **Workflows for Using `setmodel`**

When using `setmodel`, there are two possible workflows to set the final model predictors and model coefficients into a `creditscorecard` object.

The first workflow is:

- Use `fitmodel` to get the optional output argument `mdl`. This is a `GeneralizedLinearModel` object and you can add and remove terms, or modify the parameters of the stepwise procedure. Only linear terms can be in the model (no interactions or any other higher-order terms).
- Once the `GeneralizedLinearModel` object is satisfactory, set the final model predictors and model coefficients into the `creditscorecard` object using the `setmodel` input arguments for `ModelPredictors` and `ModelCoefficients`.

An alternate workflow is:

- Obtain the Weight of Evidence (WOE) data using `bindata`. Use the '`WOEModelInput`' option for the '`OutputType`' name-value pair argument in `bindata` to ensure that:
  - The predictors data is transformed to WOE.
  - Only predictors whose bins have finite WOE values are included.
  - The response variable is placed in the last column.
  - The response variable is mapped ("Good" is 1 and "Bad" is 0).
- Use the data from the previous step to fit a linear logistic regression model (only linear terms in the model, no interactions, or any other higher-order terms). See, for example, `stepwiseglm`.
- Once the `GeneralizedLinearModel` object is satisfactory, set the final model predictors and model coefficients into the `creditscorecard` object using the `setmodel` input arguments for `ModelPredictors` and `ModelCoefficients`.

## Introduced in R2014b

## bindata

Binned predictor variables

### Syntax

```
bdata = bindata(sc)
bdata = bindata(sc,data)
bdata = bindata(sc,Name,Value)
```

### Description

`bdata = bindata(sc)` binned predictor variables returned as a table. This is a table of the same size as the data input, but only the predictors specified in the `creditscorecard` object's `PredictorVars` property are binned and the remaining ones are unchanged.

`bdata = bindata(sc,data)` returns a table of binned predictor variables. `bindata` returns a table of the same size as the `creditscorecard` data, but only the predictors specified in the `creditscorecard` object's `PredictorVars` property are binned and the remaining ones are unchanged.

`bdata = bindata(sc,Name,Value)` binned predictor variables returned as a table using optional name-value pair arguments. This is a table of the same size as the data input, but only the predictors specified in the `creditscorecard` object's `PredictorVars` property are binned and the remaining ones are unchanged.

### Examples

#### Bin `creditscorecard` Data as Bin Numbers, Categories, or WOE Values

This example shows how to use the `bindata` function to simply bin or discretize data.

Suppose bin ranges of

- '0 to 30'
- '31 to 50'
- '51 and up'

are determined for the age variable (via manual or automatic binning). If a data point with age 41 is given, binning this data point means placing it in the bin for 41 years old, which is the second bin, or the '31 to 50' bin. Binning is then the mapping from the original data, into discrete groups or bins. In this example, you can say that a 41-year old is mapped into bin number 2, or that it is binned into the '31 to 50' category. If you know the Weight of Evidence (WOE) value for each of the three bins, you could also replace the data point 41 with the WOE value corresponding to the second bin. `bindata` supports the three binning formats just mentioned:

- Bin number (where the `'OutputType'` name-value pair argument is set to `'BinNumber'`); this is the default option, and in this case, 41 is mapped to bin 2.

- Categorical (where the 'OutputType' name-value pair argument is set to 'Categorical'); in this case, 41 is mapped to the '31 to 50' bin.
- WOE value (where the 'OutputType' name-value pair argument is set to 'WOE'); in this case, 41 is mapped to the WOE value of bin number 2.

Create a `creditscorecard` object using the `CreditCardData.mat` file to load the data (using a dataset from Refaat 2011). Use the 'IDVar' argument to indicate that 'CustID' contains ID information and should not be included as a predictor variable.

```
load CreditCardData
sc = creditscorecard(data, 'IDVar', 'CustID')

sc =
    creditscorecard with properties:

        GoodLabel: 0
        ResponseVar: 'status'
        WeightsVar: ''
        VarNames: {1x11 cell}
        NumericPredictors: {1x6 cell}
        CategoricalPredictors: {'ResStatus' 'EmpStatus' 'OtherCC'}
        BinMissingData: 0
        IDVar: 'CustID'
        PredictorVars: {1x9 cell}
        Data: [1200x11 table]
```

Perform automatic binning.

```
sc = autobinning(sc);
```

Show the bin information for 'CustAge'.

```
bininfo(sc, 'CustAge')

ans=8x6 table

### Bin Additional "Test" Data

This example shows how to use the `bindata` function's optional input for the data to bin. If not provided, `bindata` bins the `creditscorecard` training data. However, if a different dataset needs to be binned, for example, some "test" data, this can be passed into `bindata` as an optional input.

Create a `creditscorecard` object using the `CreditCardData.mat` file to load the data (using a dataset from Refaat 2011). Use the `'IDVar'` argument to indicate that `'CustID'` contains ID information and should not be included as a predictor variable.

```
load CreditCardData
sc = creditscorecard(data, 'IDVar', 'CustID')

sc =
  creditscorecard with properties:

    GoodLabel: 0
    ResponseVar: 'status'
    WeightsVar: ''
    VarNames: {1x11 cell}
    NumericPredictors: {1x6 cell}
    CategoricalPredictors: {'ResStatus' 'EmpStatus' 'OtherCC'}
    BinMissingData: 0
    IDVar: 'CustID'
    PredictorVars: {1x9 cell}
    Data: [1200x11 table]
```

Perform automatic binning.

```
sc = autobinning(sc);
```

Show the bin information for 'CustAge'.

```
bininfo(sc, 'CustAge')
```

```
ans=8x6 table
      Bin          Good    Bad    Odds      WOE      InfoValue
      ---          ---    ---    ---      ---      ---
      {' [-Inf,33) ' }    70    53    1.3208   -0.42622   0.019746
      {' [33,37) '   }    64    47    1.3617   -0.39568   0.015308
      {' [37,40) '   }    73    47    1.5532   -0.26411   0.0072573
      {' [40,46) '   }   174    94    1.8511   -0.088658   0.001781
      {' [46,48) '   }    61    25     2.44    0.18758   0.0024372
      {' [48,58) '   }   263   105    2.5048    0.21378   0.013476
      {' [58,Inf] '  }    98    26    3.7692    0.62245    0.0352
      {' Totals '    }   803   397    2.0227      NaN    0.095205
```

For the purpose of illustration, take a few rows from the original data as "test" data and display the first 10 age values in the test data.

```
tdata = data(101:110, :);
tdata(1:10, 'CustAge')
```

```
ans=10x1 table
      CustAge
      ---

```

```
34
59
64
61
28
65
55
37
49
51
```

Convert the test data to WOE values. To do this, set the `bindata` name-value pair argument for 'OutputType' to 'WOE', passing the test data (`tdata`) as an optional input.

```
bdata = bindata(sc, tdata, 'OutputType', 'WOE')
```

```

### Bin Additional "Test" Data When Using the 'BinMissingData' Option

Create a `creditscorecard` object using the `CreditCardData.mat` file to load the data with missing values. The variables `CustAge` and `ResStatus` have missing values.

```
load CreditCardData.mat
head(dataMissing,5)
```

```
ans=5x11 table
```

```

CustID    CustAge    TmAtAddress    ResStatus    EmpStatus    CustIncome    TmWBank    Oth
-----
 1         53         62            <undefined>    Unknown      50000         55         Ye
 2         61         22            Home Owner     Employed      52000         25         Ye
 3         47         30            Tenant         Employed      37000         61         No
 4         NaN        75            Home Owner     Employed      53000         20         Ye
 5         68         56            Home Owner     Employed      53000         14         Ye

```

Use `creditscorecard` with the name-value argument `'BinMissingData'` set to `true` to bin the missing numeric or categorical data in a separate bin. Apply automatic binning.

```
sc = creditscorecard(dataMissing, 'IDVar', 'CustID', 'BinMissingData', true);
sc = autobinning(sc);
```

```
disp(sc)
```

```
creditscorecard with properties:
```

```

    GoodLabel: 0
    ResponseVar: 'status'
    WeightsVar: ''
    VarNames: {1x11 cell}
    NumericPredictors: {1x6 cell}
    CategoricalPredictors: {'ResStatus' 'EmpStatus' 'OtherCC'}
    BinMissingData: 1
    IDVar: 'CustID'
    PredictorVars: {1x9 cell}
    Data: [1200x11 table]

```

Display and plot bin information for numeric data for 'CustAge' that includes missing data in a separate bin labelled <missing>.

```

[bi,cp] = bininfo(sc,'CustAge');
disp(bi)

```

| Bin             | Good | Bad | Odds   | WOE      | InfoValue  |
|-----------------|------|-----|--------|----------|------------|
| {'[-Inf,33)'} } | 69   | 52  | 1.3269 | -0.42156 | 0.018993   |
| {'[33,37)'} }   | 63   | 45  | 1.4    | -0.36795 | 0.012839   |

| {'[51,58)'} }   | 157  | 62  | 2.5323 | 0.22469  | 0.0088407  |
| {'[58,Inf]'} }  | 93   | 25  | 3.72   | 0.60931  | 0.032198   |
| {'<missing>'} } | 19   | 11  | 1.7273 | -0.15787 | 0.00063885 |
| {'Totals' }     | 803  | 397 | 2.0227 | NaN      | 0.087112   |

```

plotbins(sc,'CustAge')

```

Display and plot bin information for categorical data for 'ResStatus' that includes missing data in a separate bin labelled <missing>.

```
[bi,cg] = bininfo(sc, 'ResStatus');
disp(bi)
```

| Bin             | Good | Bad | Odds   | WOE       | InfoValue  |
|-----------------|------|-----|--------|-----------|------------|
| {'Tenant' }     | 296  | 161 | 1.8385 | -0.095463 | 0.0035249  |
| {'Home Owner' } | 352  | 171 | 2.0585 | 0.017549  | 0.00013382 |
| {'Other' }      | 128  | 52  | 2.4615 | 0.19637   | 0.0055808  |
| {'<missing>' }  | 27   | 13  | 2.0769 | 0.026469  | 2.3248e-05 |
| {'Totals' }     | 803  | 397 | 2.0227 | NaN       | 0.0092627  |

```
plotbins(sc, 'ResStatus')
```

For the 'CustAge' and 'ResStatus' predictors, there is missing data (NaNs and <undefined>) in the training data, and the binning process estimates a WOE value of -0.15787 and 0.026469 respectively for missing data in these predictors, as shown above.

For the purpose of illustration, take a few rows from the original data as test data and introduce some missing data.

```
tdata = dataMissing(11:14,:);
tdata.CustAge(1) = NaN;
tdata.TmAtAddress(2) = NaN;
tdata.ResStatus(3) = '<undefined>';
tdata.EmpStatus(4) = '<undefined>';
disp(tdata)
```

| CustID | CustAge | TmAtAddress | ResStatus   | EmpStatus   | CustIncome | TmWBank | 0 |
|--------|---------|-------------|-------------|-------------|------------|---------|---|
| 11     | NaN     | 24          | Tenant      | Unknown     | 34000      | 44      |   |
| 12     | 48      | NaN         | Other       | Unknown     | 44000      | 14      |   |
| 13     | 65      | 63          | <undefined> | Unknown     | 48000      | 6       |   |
| 14     | 44      | 75          | Other       | <undefined> | 41000      | 35      |   |

Convert the test data to WOE values. To do this, set the bindata name-value pair argument for 'OutputType' to 'WOE', passing the test data tdata as an optional input.

```
bdata = bindata(sc,tdata,'OutputType','WOE');
disp(bdata)
```

| CustID | CustAge  | TmAtAddress | ResStatus | EmpStatus | CustIncome | TmWBank  | Other     |
|--------|----------|-------------|-----------|-----------|------------|----------|-----------|
| 11     | -0.15787 | 0.02263     | -0.095463 | -0.19947  | -0.06843   | -0.12109 | 0.095463  |
| 12     | 0.17713  | NaN         | 0.19637   | -0.19947  | 0.20579    | -0.13107 | 0.095463  |
| 13     | 0.60931  | 0.02263     | 0.026469  | -0.19947  | 0.47972    | -0.25547 | -0.095463 |
| 14     | -0.04556 | 0.02263     | 0.19637   | NaN       | -0.011271  | -0.12109 | -0.095463 |

For the 'CustAge' and 'ResStatus' predictors, because there is missing data in the training data, the missing values in the test data get mapped to the WOE value estimated for the <missing> bin. Therefore, a missing value for 'CustAge' is replaced with -0.15787, and a missing value for 'ResStatus' is replaced with 0.026469.

For 'TmAtAddress' and 'EmpStatus', the training data has no missing values, therefore there is no bin for missing data, and there is no way to estimate a WOE value for missing data. Therefore, for these predictors, the WOE transformation leaves missing values as missing (that is, sets a WOE value of NaN).

These rules apply when 'OutputType' is set to 'WOE' or 'WOEModelInput'. The rationale is that if a data-based WOE value exists for missing data, it should be used for the WOE transformation and for subsequent steps (for example, fitting a logistic model or scoring).

On the other hand, when 'OutputType' is set to 'BinNumber' or 'Categorical', bindata leaves missing values as missing, since this allows you to subsequently treat the missing data as you see fit.

For example, when 'OutputType' is set to 'BinNumber', missing values are set to NaN:

```
bdata = bindata(sc,tdata,'OutputType','BinNumber');
disp(bdata)
```

| CustID | CustAge | TmAtAddress | ResStatus | EmpStatus | CustIncome | TmWBank | Other |
|--------|---------|-------------|-----------|-----------|------------|---------|-------|
| 11     | NaN     | 2           | 1         | 1         | 3          | 3       | 2     |
| 12     | 6       | NaN         | 3         | 1         | 6          | 2       | 2     |
| 13     | 8       | 2           | NaN       | 1         | 7          | 1       | 1     |
| 14     | 4       | 2           | 3         | NaN       | 5          | 3       | 1     |

And when 'OutputType' is set to 'Categorical', missing values are set to '<undefined>':

```
bdata = bindata(sc,tdata,'OutputType','Categorical');
disp(bdata)
```

| CustID | CustAge     | TmAtAddress | ResStatus   | EmpStatus   | CustIncome    | TmWBank   | Other     |
|--------|-------------|-------------|-------------|-------------|---------------|-----------|-----------|
| 11     | <undefined> | [23,83)     | Tenant      | Unknown     | [33000,35000) | [23,45)   | [23,45)   |
| 12     | [48,51)     | <undefined> | Other       | Unknown     | [42000,47000) | [12,23)   | [12,23)   |
| 13     | [58,Inf]    | [23,83)     | <undefined> | Unknown     | [47000,Inf]   | [-Inf,45) | [-Inf,45) |
| 14     | [40,46)     | [23,83)     | Other       | <undefined> | [40000,42000) | [23,45)   | [23,45)   |

### Apply a Weight of Evidence (WOE) Transformation to Data

bindata supports the following types of WOE transformation:

- When the 'OutputType' name-value argument is set to 'WOE', `bindata` simply applies the WOE transformation to all predictors and keeps the rest of the variables in the original data in place and unchanged.
- When the 'OutputType' name-value pair argument is set to 'WOEModelInput', `bindata` returns a table that can be used directly as an input for fitting a logistic regression model for the scorecard. In this case, `bindata`:
  - Applies WOE transformation to all predictors.
  - Returns predictor variables, but no IDVar or unused variables are included in the output.
  - Includes the mapped response variable as the last column.
  - The `fitmodel` function calls `bindata` internally using the 'WOEModelInput' option to fit the logistic regression model for the `creditscorecard` model.

Create a `creditscorecard` object using the `CreditCardData.mat` file to load the data (using a dataset from Refaat 2011). Use the 'IDVar' argument to indicate that 'CustID' contains ID information and should not be included as a predictor variable.

```
load CreditCardData
sc = creditscorecard(data, 'IDVar', 'CustID')

sc =
    creditscorecard with properties:

        GoodLabel: 0
        ResponseVar: 'status'
        WeightsVar: ''
        VarNames: {1x11 cell}
        NumericPredictors: {1x6 cell}
        CategoricalPredictors: {'ResStatus' 'EmpStatus' 'OtherCC'}
        BinMissingData: 0
        IDVar: 'CustID'
        PredictorVars: {1x9 cell}
        Data: [1200x11 table]
```

Perform automatic binning.

```
sc = autobinning(sc);
```

Show the bin information for 'CustAge'.

```
bininfo(sc, 'CustAge')
```

```
ans=8x6 table
      Bin      Good      Bad      Odds      WOE      InfoValue
      _____  _____  _____  _____  _____  _____
    {'[-Inf,33)'}      70       53      1.3208     -0.42622     0.019746
    {'[33,37)'}       64       47      1.3617     -0.39568     0.015308
    {'[37,40)'}       73       47      1.5532     -0.26411     0.0072573
    {'[40,46)'}      174       94      1.8511     -0.088658     0.001781
    {'[46,48)'}       61       25       2.44      0.18758     0.0024372
    {'[48,58)'}      263      105      2.5048      0.21378     0.013476
    {'[58,Inf]'}       98       26      3.7692      0.62245      0.0352
    {'Totals'}       803      397      2.0227           NaN     0.095205
```

These are the first 10 age values in the original data, used to create the `creditscorecard` object.

```
data(1:10, 'CustAge')
```

```
ans=10×1 table
```

```

0.62245
-0.39568
0.21378
0.21378
0.21378

```

The size of the original data and the size of `bdata` output are the same because `bindata` leaves unused variables (such as `'IDVar'`) unchanged and in place.

```
whos data bdata
```

| Name  | Size    | Bytes  | Class | Attributes |
|-------|---------|--------|-------|------------|
| bdata | 1200x11 | 108987 | table |            |
| data  | 1200x11 | 84603  | table |            |

The response values are the same in the original data and in the binned data because, by default, `bindata` does not modify response values.

```
disp([data.status(1:10) bdata.status(1:10)])
```

```

0      0
0      0
0      0
0      0
0      0
0      0
1      1
0      0
1      1
1      1

```

When fitting a logistic regression model with WOE data, set the `'OutputType'` name-value pair argument to `'WOEModelInput'`.

```
bdata = bindata(sc, 'OutputType', 'WOEModelInput');
```

The binned predictor data is the same as when the `'OutputType'` name-value pair argument is set to `'WOE'`.

```
bdata(1:10, 'CustAge')
```

```
ans=10x1 table
    CustAge
```

```

0.62245
0.62245
-0.39568
0.21378
0.21378
0.21378

```

However, the size of the original data and the size of `bdata` output are different. This is because `bindata` removes unused variables (such as `'IDVar'`).

```
whos data bdata
```

| Name  | Size    | Bytes | Class | Attributes |
|-------|---------|-------|-------|------------|
| bdata | 1200x10 | 99167 | table |            |
| data  | 1200x11 | 84603 | table |            |

The response values are also modified in this case and are mapped so that "Good" is 1 and "Bad" is 0.

```
disp([data.status(1:10) bdata.status(1:10)])
```

```

0     1
0     1
0     1

1     0

```

## Input Arguments

### **sc** — Credit scorecard model

creditscorecard object

Credit scorecard model, specified as a `creditscorecard` object. Use `creditscorecard` to create a `creditscorecard` object.

### **data** — Data to bin given the rules set in creditscorecard object

table

Data to bin given the rules set in the `creditscorecard` object, specified using a table. By default, `data` is set to the `creditscorecard` object's raw data.

Before creating a `creditscorecard` object, perform a data preparation task to have an appropriately structured data as input to a `creditscorecard` object.

Data Types: `table`

### **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `bdata = bindata(sc, 'OutputType', 'WOE', 'ResponseFormat', 'Mapped')`

### **OutputType** — Output format

'BinNumber' (default) | character vector with values 'BinNumber', 'Categorical', 'WOE'

Output format, specified as the comma-separated pair consisting of `'OutputType'` and a character vector with the following values:

- `BinNumber` — Returns the bin numbers corresponding to each observation.
- `Categorical` — Returns the bin label corresponding to each observation.
- `WOE` — Returns the Weight of Evidence (WOE) corresponding to each observation.
- `WOEModelInput` — Use this option when fitting a model. This option:
  - Returns the Weight of Evidence (WOE) corresponding to each observation.
  - Returns predictor variables, but no `IDVar` or unused variables are included in the output.
  - Discards any predictors whose bins have `Inf` or `NaN` WOE values.
  - Includes the mapped response variable as the last column.

---

**Note** When the `bindata` name-value pair argument `'OutputType'` is set to `'WOEModelInput'`, the `bdata` output only contains the columns corresponding to predictors whose bins do not have `Inf` or `NaN` Weight of Evidence (WOE) values, and `bdata` includes the mapped response as the last column.

Missing data (if any) are included in the `bdata` output as missing data as well, and do not influence the rules to discard predictors when `'OutputType'` is set to `'WOEModelInput'`.

---

Data Types: `char`

### ResponseFormat — Response values format

`'RawData'` (default) | character vector with values `'RawData'`, `'Mapped'`

Response values format, specified as the comma-separated pair consisting of `'ResponseFormat'` and a character vector with the following values:

- `RawData` — The response variable is copied unchanged into the `bdata` output.
- `Mapped` — The response values are modified (if necessary) so that "Good" is mapped to 1, and "Bad" is mapped to 0.

Data Types: `char`

## Output Arguments

### `bdata` — Binned predictor variables

table

Binned predictor variables, returned as a table. This is a table of the same size (see exception in the following Note) as the data input, but only the predictors specified in the `creditscorecard` object's `PredictorVars` property are binned and the remaining ones are unchanged.

---

**Note** When the `bindata` name-value pair argument `'OutputType'` is set to `'WOEModelInput'`, the `bdata` output only contains the columns corresponding to predictors whose bins do not have `Inf` or `NaN` Weight of Evidence (WOE) values, and `bdata` includes the mapped response as the last column.

Missing data (if any) are included in the `bdata` output as missing data as well, and do not influence the rules to discard predictors when `'OutputType'` is set to `'WOEModelInput'`.

---

## plotbins

Plot histogram counts for predictor variables

### Syntax

```
plotbins(sc,PredictorName)
hFigure = plotbins(sc,PredictorName)
hFigure = plotbins( ___,Name,Value)
```

### Description

`plotbins(sc,PredictorName)` plots histogram counts for given predictor variables. When a predictor's bins are modified using `modifybins` or `autobinning`, rerun `plotbins` to update the figure to reflect the change.

`hFigure = plotbins(sc,PredictorName)` returns a handle to the figure. `plotbins` plots histogram counts for given predictor variables. When a predictor's bins are modified using `modifybins` or `autobinning`, rerun `plotbins` to update the figure to reflect the change.

`hFigure = plotbins( ___,Name,Value)` returns a handle to the figure. `plotbins` plots histogram counts for given predictor variables using optional name-value pair arguments. When a predictor's bins are modified using `modifybins` or `autobinning`, rerun `plotbins` to update the figure to reflect the change.

### Examples

#### Plot a Histogram for Bin Information

Create a `creditscorecard` object using the `CreditCardData.mat` file to load the data (using a dataset from Refaat 2011).

```
load CreditCardData
sc = creditscorecard(data);
```

Perform automatic binning for the `PredictorName` input argument for `CustIncome` using the defaults for the algorithm `Monotone`.

```
sc = autobinning(sc, 'CustIncome')
```

```
sc =
  creditscorecard with properties:

    GoodLabel: 0
    ResponseVar: 'status'
    WeightsVar: ''
    VarNames: {1x11 cell}
    NumericPredictors: {1x7 cell}
    CategoricalPredictors: {'ResStatus' 'EmpStatus' 'OtherCC'}
    BinMissingData: 0
    IDVar: ''
```

```
PredictorVars: {1x10 cell}
Data: [1200x11 table]
```

Use `bininfo` to display the autobinned data.

```
[bi, cp] = bininfo(sc, 'CustIncome')
```

```
bi=8x6 table
      Bin          Good    Bad    Odds      WOE      InfoValue
-----
{'[-Inf,29000)'}    53     58    0.91379   -0.79457    0.06364
{'[29000,33000)'}    74     49    1.5102   -0.29217    0.0091366
{'[33000,35000)'}    68     36    1.8889   -0.06843    0.00041042
{'[35000,40000)'}   193     98    1.9694  -0.026696    0.00017359
{'[40000,42000)'}    68     34         2  -0.011271    1.0819e-05
{'[42000,47000)'}   164     66    2.4848    0.20579    0.0078175
{'[47000,Inf]'}     183     56    3.2679    0.47972    0.041657
{'Totals'}          803    397    2.0227         NaN    0.12285
```

```
cp = 6x1
```

```
29000
33000
35000
40000
42000
47000
```

Manually remove the second cut point (the boundary between the second and third bins) to merge bins two and three. Use the `modifybins` function to update the scorecard and then display updated bin information.

```
cp(2) = [];
sc = modifybins(sc, 'CustIncome', 'CutPoints', cp);
bi = bininfo(sc, 'CustIncome')
```

```
bi=7x6 table
      Bin          Good    Bad    Odds      WOE      InfoValue
-----
{'[-Inf,29000)'}    53     58    0.91379   -0.79457    0.06364
{'[29000,35000)'}   142     85    1.6706   -0.19124    0.0071274
{'[35000,40000)'}   193     98    1.9694  -0.026696    0.00017359
{'[40000,42000)'}    68     34         2  -0.011271    1.0819e-05
{'[42000,47000)'}   164     66    2.4848    0.20579    0.0078175
{'[47000,Inf]'}     183     56    3.2679    0.47972    0.041657
{'Totals'}          803    397    2.0227         NaN    0.12043
```

Plot the histogram count for updated bin information for the PredictorName called `CustIncome`.

```
plotbins(sc, 'CustIncome')
```

### Plot a Histogram for Bin Information Using Name-Value Pair Arguments

Create a `creditscorecard` object using the `CreditCardData.mat` file to load the data (using a dataset from Refaat 2011).

```
load CreditCardData
sc = creditscorecard(data);
```

Perform automatic binning for the `PredictorName` input argument for `CustIncome` using the defaults for the algorithm `Monotone`.

```
sc = autobinning(sc, 'CustIncome')
```

```
sc =
  creditscorecard with properties:
    GoodLabel: 0
    ResponseVar: 'status'
    WeightsVar: ''
    VarNames: {1x11 cell}
    NumericPredictors: {1x7 cell}
    CategoricalPredictors: {'ResStatus' 'EmpStatus' 'OtherCC'}
    BinMissingData: 0
    IDVar: ''
    PredictorVars: {1x10 cell}
```

Data: [1200x11 table]

Use `bininfo` to display the autobinned data.

```
[bi, cp] = bininfo(sc, 'CustIncome')
```

bi=8x6 table

| Bin                 | Good | Bad | Odds    | WOE       | InfoValue  |
|---------------------|------|-----|---------|-----------|------------|
| {'[-Inf,29000)'} }  | 53   | 58  | 0.91379 | -0.79457  | 0.06364    |
| {'[29000,33000)'} } | 74   | 49  | 1.5102  | -0.29217  | 0.0091366  |
| {'[33000,35000)'} } | 68   | 36  | 1.8889  | -0.06843  | 0.00041042 |
| {'[35000,40000)'} } | 193  | 98  | 1.9694  | -0.026696 | 0.00017359 |
| {'[40000,42000)'} } | 68   | 34  | 2       | -0.011271 | 1.0819e-05 |
| {'[42000,47000)'} } | 164  | 66  | 2.4848  | 0.20579   | 0.0078175  |
| {'[47000,Inf]'} }   | 183  | 56  | 3.2679  | 0.47972   | 0.041657   |
| {'Totals' }         | 803  | 397 | 2.0227  | NaN       | 0.12285    |

cp = 6x1

```
29000
33000
35000
40000
42000
47000
```

Plot the bin information for `CustIncome` without the Weight of Evidence (WOE) line and without a legend by setting the `'WOE'` and `'Legend'` name-value arguments to `'Off'`. Also, set the `'BinText'` name-value pair argument to `'PercentRows'` to show as text over the plot bars for the proportion of "Good" and "Bad" within each bin, that is, the probability of "Good" and "Bad" within each bin.

```
plotbins(sc, 'CustIncome', 'WOE', 'Off', 'Legend', 'Off', 'BinText', 'PercentRows')
```

### Plot Bin Information When Using Missing Data

Create a `creditscorecard` object using the `CreditCardData.mat` file to load the data with missing values.

```
load CreditCardData.mat
head(dataMissing,5)
```

ans=5×11 table

|   | CustID | CustAge | TmAtAddress | ResStatus   | EmpStatus | CustIncome | TmWBank | Other |
|---|--------|---------|-------------|-------------|-----------|------------|---------|-------|
| 1 |        | 53      | 62          | <undefined> | Unknown   | 50000      | 55      | Ye    |
| 2 |        | 61      | 22          | Home Owner  | Employed  | 52000      | 25      | Ye    |
| 3 |        | 47      | 30          | Tenant      | Employed  | 37000      | 61      | Ne    |
| 4 |        | NaN     | 75          | Home Owner  | Employed  | 53000      | 20      | Ye    |
| 5 |        | 68      | 56          | Home Owner  | Employed  | 53000      | 14      | Ye    |

```
fprintf('Number of rows: %d\n',height(dataMissing))
```

Number of rows: 1200

```
fprintf('Number of missing values CustAge: %d\n',sum(ismissing(dataMissing.CustAge)))
```

Number of missing values CustAge: 30

```
fprintf('Number of missing values ResStatus: %d\n',sum(ismissing(dataMissing.ResStatus)))
```

Number of missing values ResStatus: 40

Use `creditscorecard` with the name-value argument `'BinMissingData'` set to `true` to bin the missing numeric or categorical data in a separate bin.

```
sc = creditscorecard(dataMissing,'IDVar','CustID','BinMissingData',true);
sc = autobinning(sc);
```

```
disp(sc)
```

creditscorecard with properties:

```

    GoodLabel: 0
    ResponseVar: 'status'
    WeightsVar: ''
    VarNames: {1x11 cell}
    NumericPredictors: {1x6 cell}
    CategoricalPredictors: {'ResStatus' 'EmpStatus' 'OtherCC'}
    BinMissingData: 1
    IDVar: 'CustID'
    PredictorVars: {1x9 cell}
    Data: [1200x11 table]
```

Display and plot bin information for numeric data for `'CustAge'` that includes missing data in a separate bin labelled `<missing>`.

```
[bi,cp] = bininfo(sc,'CustAge');
disp(bi)
```

| Bin             | Good | Bad | Odds   | WOE      | InfoValue  |
|-----------------|------|-----|--------|----------|------------|
| {'[-Inf,33)'} } | 69   | 52  | 1.3269 | -0.42156 | 0.018993   |
| {'[33,37)'} }   | 63   | 45  | 1.4    | -0.36795 | 0.012839   |
| {'[37,40)'} }   | 72   | 47  | 1.5319 | -0.2779  | 0.0079824  |
| {'[40,46)'} }   | 172  | 89  | 1.9326 | -0.04556 | 0.0004549  |
| {'[46,48)'} }   | 59   | 25  | 2.36   | 0.15424  | 0.0016199  |
| {'[48,51)'} }   | 99   | 41  | 2.4146 | 0.17713  | 0.0035449  |
| {'[51,58)'} }   | 157  | 62  | 2.5323 | 0.22469  | 0.0088407  |
| {'[58,Inf]'} }  | 93   | 25  | 3.72   | 0.60931  | 0.032198   |
| {'<missing>'} } | 19   | 11  | 1.7273 | -0.15787 | 0.00063885 |
| {'Totals' }     | 803  | 397 | 2.0227 | NaN      | 0.087112   |

```
plotbins(sc,'CustAge')
```

Display and plot bin information for categorical data for 'ResStatus' that includes missing data in a separate bin labelled <missing>.

```
[bi,cg] = bininfo(sc, 'ResStatus');
disp(bi)
```

| Bin             | Good | Bad | Odds   | WOE       | InfoValue  |

| {'<missing>' }  | 27   | 13  | 2.0769 | 0.026469  | 2.3248e-05 |
| {'Totals' }     | 803  | 397 | 2.0227 | NaN       | 0.0092627  |

```
plotbins(sc, 'ResStatus')
```

## Input Arguments

### sc — Credit scorecard model

creditscorecard object

Credit scorecard model, specified as a `creditscorecard` object. Use `creditscorecard` to create a `creditscorecard` object.

### PredictorName — Name of one or more predictors to plot

character vector with predictor name | cell array of character vectors with predictor names

Name of one or more predictors to plot, specified using a character vector or cell array of character vectors containing one or more names of the predictors.

Data Types: `char` | `cell`

### Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1`, `Value1`, ..., `NameN`, `ValueN`.

Example: `plotbins(sc,PredictorName,'BinText','Count','WOE','On')`

**BinText — Information to display on top of plotted bin counts**

'None' (default) | character vector with values 'None', 'Count', 'PercentRows', 'PercentCols', 'PercentTotal'

Information to display on top of plotted bin counts, specified as the comma-separated pair consisting of 'BinText' and a character vector with values:

- **None** — No text is displayed on top of the bins.
- **Count** — For each bin, displays the count for “Good” and “Bad.”
- **PercentRows** — For each bin, displays the count for “Good” and “Bad” as a percentage of the number of observations in the bin.
- **PercentCols** — For each bin, displays the count for “Good” and “Bad” as a percentage of the total “Good” and total “Bad” in the entire sample.
- **PercentTotal** — For each bin, displays the count for “Good” and “Bad” as a percentage of the total number of observations in the entire sample.

Data Types: char

**WOE — Indicator for Weight of Evidence (WOE)**

'On' (default) | character vector with values 'On', 'Off'

Indicator for Weight of Evidence (WOE) line, specified as the comma-separated pair consisting of 'WOE' and a character vector with values On or Off. When set to On, the WOE line is plotted on top of the histogram.

Data Types: char

**Legend — Indicator for legend on plot**

'On' (default) | character vector with values 'On', 'Off'

Indicator for legend on the plot, specified as the comma-separated pair consisting of 'Legend' and a character vector with values On or Off.

Data Types: char

**Output Arguments****hFigure — Figure handle for histogram plot for predictor variables**

figure object

Figure handle for histogram plot for predictor variables, returned as figure object or array of figure objects if more than one PredictorName is specified as an input.

## modifybins

Modify predictor's bins

### Syntax

```
sc = modifybins(sc, PredictorName, Name, Value)
```

### Description

`sc = modifybins(sc, PredictorName, Name, Value)` manually modifies predictor bins for numeric predictors or categorical predictors using optional name-value pair arguments. For numeric predictors, minimum value, maximum value, and cut points can be specified. For categorical predictors, category groupings can be specified. Bin labels can be specified for both types of predictors.

### Examples

#### Modify Predictor Bins for Numeric Data

Create a `creditscorecard` object using the `CreditCardData.mat` file to load the data (using a dataset from Refaat 2011).

```
load CreditCardData
sc = creditscorecard(data);
```

The predictor `CustIncome` is numeric. By default, each value of a predictor is placed in a separate bin.

```
bi = bininfo(sc, 'CustIncome')
```

```
bi=46x6 table
      Bin      Good      Bad      Odds      WOE      InfoValue

```

:

Use `modifybins` to set a minimum value of 0, and cut points every 10000, from 20000 to 60000. Display updated bin information, including cut points.

```
sc = modifybins(sc, 'CustIncome', 'MinValue', 0, 'CutPoints', 20000:10000:60000);
[bi, cp] = bininfo(sc, 'CustIncome')
```

bi=7x6 table

| Bin                 | Good | Bad | Odds    | WOE       | InfoValue |
|---------------------|------|-----|---------|-----------|-----------|
| { '[0,20000)' }     | 3    | 5   | 0.6     | -1.2152   | 0.010765  |
| { '[20000,30000)' } | 61   | 63  | 0.96825 | -0.73668  | 0.060942  |
| { '[30000,40000)' } | 324  | 173 | 1.8728  | -0.076967 | 0.0024846 |
| { '[40000,50000)' } | 304  | 123 | 2.4715  | 0.20042   | 0.013781  |
| { '[50000,60000)' } | 103  | 32  | 3.2188  | 0.46457   | 0.022144  |
| { '[60000,Inf]' }   | 8    | 1   | 8       | 1.375     | 0.010235  |
| { 'Totals' }        | 803  | 397 | 2.0227  | NaN       | 0.12035   |

cp = 5x1

```
20000
30000
40000
50000
60000
```

The first and last bins contain very few points. To merge the first bin into the second one, remove the first cut point. Similarly, to merge the last bin into the second-to-last one, remove the last cut point. Then use `modifybins` to update the scorecard, and display updated bin information.

```
cp(1)=[];
cp(end)=[];
sc = modifybins(sc, 'CustIncome', 'CutPoints', cp);
bi = bininfo(sc, 'CustIncome')
```

bi=5x6 table

| { '[40000,50000)' } | 304  | 123 | 2.4715  | 0.20042   | 0.013781  |
| { '[50000,Inf]' }   | 111  | 33  | 3.3636  | 0.5086    | 0.028028  |
| { 'Totals' }        | 803  | 397 | 2.0227  | NaN       | 0.11436   |

### Modify Predictor Bins for Categorical Data

Create a `creditscorecard` object using the `CreditCardData.mat` file to load the data (using a dataset from Refaat 2011).

```
load CreditCardData
sc = creditscorecard(data);
```

The binning map or rules for categorical data are summarized in a "category grouping" table, returned as an optional output. By default, each category is placed in a separate bin. Here is the information for the predictor ResStatus.

```
[bi,cg] = bininfo(sc, 'ResStatus')
```

```
bi=4x6 table
      Bin          Good    Bad    Odds      WOE      InfoValue
-----
{'Home Owner'}  365    177    2.0621    0.019329    0.0001682
{'Tenant'      }  307    167    1.8383   -0.095564    0.0036638
{'Other'       }  131     53    2.4717     0.20049    0.0059418
{'Totals'     }  803    397    2.0227         NaN    0.0097738
```

```
cg=3x2 table
      Category      BinNumber
-----
{'Home Owner'}    1
{'Tenant'        }    2
{'Other'         }    3
```

To group categories 'Tenant' and 'Other', modify the category grouping table cg, so the bin number for 'Other' is the same as the bin number for 'Tenant'. Then use `modifybins` to update the scorecard.

```
cg.BinNumber(3) = 2;
sc = modifybins(sc, 'ResStatus', 'CatGrouping', cg);
```

Display the updated bin information. Note that the bin labels has been updated and that the bin membership information is contained in the category grouping cg.

```
[bi,cg] = bininfo(sc, 'ResStatus')
```

```
bi=3x6 table
      Bin          Good    Bad    Odds      WOE      InfoValue
-----
{'Group1'}      365    177    2.0621    0.019329    0.0001682
{'Group2'}      438    220    1.9909   -0.015827    0.00013772
{'Totals'}      803    397    2.0227         NaN    0.00030592
```

```
cg=3x2 table
      Category      BinNumber
-----
{'Home Owner'}    1
{'Tenant'        }    2
{'Other'         }    2
```

## Merge Bins for Numerical and Categorical Predictors

Create a `creditscorecard` object (using a dataset from Refaat 2011).

```
load CreditCardData
sc = creditscorecard(data, 'IDVar', 'CustID', 'GoodLabel', 0);
```

For the numerical predictor `CustAge`, use the `modifybins` function to set the following cut points:

```
cp = [25 37 49 65];
sc = modifybins(sc, 'CustAge', 'CutPoints', cp, 'MinValue', 0, 'MaxValue', 75);
bininfo(sc, 'CustAge')
```

```
ans=6x6 table
      Bin      Good      Bad      Odds      WOE      InfoValue
-----
{'[0,25)'}      9       8      1.125    -0.58664    0.0052464
{'[25,37)'}    125      92      1.3587   -0.39789    0.030268
{'[37,49)'}    340     183      1.8579  -0.084959   0.0031898
{'[49,65)'}    298     108      2.7593    0.31054    0.030765
{'[65,75]'}     31       6      5.1667    0.93781    0.022031
{'Totals' }    803     397      2.0227     NaN         0.0915
```

Use the `modifybins` function to merge the 2nd and 3rd bins.

```
sc = modifybins(sc, 'CustAge', 'CutPoints', cp([1 3 4]));
bininfo(sc, 'CustAge')
```

```
ans=5x6 table
      Bin      Good      Bad      Odds      WOE      InfoValue
-----
{'[0,25)'}      9       8      1.125    -0.58664    0.0052464
{'[25,49)'}    465     275      1.6909   -0.17915    0.020355
{'[49,65)'}    298     108      2.7593    0.31054    0.030765
{'[65,75]'}     31       6      5.1667    0.93781    0.022031
{'Totals' }    803     397      2.0227     NaN         0.078397
```

Display bin information for the categorical predictor `ResStatus`.

```
[bi,cg] = bininfo(sc, 'ResStatus');
disp(bi)
```

```
      Bin      Good      Bad      Odds      WOE      InfoValue
-----
{'Home Owner'}  365     177      2.0621    0.019329   0.0001682
{'Tenant' }    307     167      1.8383   -0.095564   0.0036638
{'Other' }     131      53      2.4717    0.20049    0.0059418
{'Totals' }    803     397      2.0227     NaN         0.0097738
```

Use the `modifybins` function to merge categories 2 and 3.

```
cg.BinNumber(3) = 2;
sc = modifybins(sc, 'ResStatus', 'CatGrouping', cg);
bininfo(sc, 'ResStatus')
```

```
ans=3x6 table
      Bin      Good      Bad      Odds      WOE      InfoValue
-----
{'Group1'}    365     177     2.0621     0.019329     0.0001682
{'Group2'}    438     220     1.9909    -0.015827     0.00013772
{'Totals'}    803     397     2.0227           NaN     0.00030592
```

### Split Bins for Numerical and Categorical Predictors

Create a creditcard object (using a dataset from Refaat 2011).

```
load CreditCardData
sc = creditcard(data, 'IDVar', 'CustID', 'GoodLabel', 0)

sc =
  creditcard with properties:
      GoodLabel: 0
      ResponseVar: 'status'
      WeightsVar: ''
      VarNames: {1x11 cell}
      NumericPredictors: {1x6 cell}
      CategoricalPredictors: {'ResStatus' 'EmpStatus' 'OtherCC'}
      BinMissingData: 0
      IDVar: 'CustID'
      PredictorVars: {1x9 cell}
      Data: [1200x11 table]
```

For the numerical predictor `TmAtAddress`, use the `modifybins` function to set the following cut points:

```
cp = [30 80 120];
sc = modifybins(sc, 'TmAtAddress', 'CutPoints', cp, 'MinValue', 0, 'MaxValue', 210);
bininfo(sc, 'TmAtAddress')
```

```
ans=5x6 table
      Bin      Good      Bad      Odds      WOE      InfoValue
-----
{'[0,30)'}    }    330     154     2.1429     0.057722     0.0013305
{'[30,80)'}    }    379     201     1.8856    -0.070187     0.0024086
{'[80,120)'}   }     78      36     2.1667     0.068771     0.00044396
{'[120,210]'}  }     16       6     2.6667     0.27641      0.0013301
{'Totals'}     }    803     397     2.0227           NaN     0.0055131
```

Use the `modifybins` function to split the 2nd bin.

```
sc = modifybins(sc, 'TmAtAddress', 'CutPoints', [cp(1) 50 cp(2:end)]);
bininfo(sc, 'TmAtAddress')
```

ans=6x6 table

| Bin             | Good | Bad | Odds   | WOE       | InfoValue  |
|-----------------|------|-----|--------|-----------|------------|
| { '[0,30)' }    | 330  | 154 | 2.1429 | 0.057722  | 0.0013305  |
| { '[30,50)' }   | 211  | 104 | 2.0288 | 0.0030488 | 2.4387e-06 |
| { '[50,80)' }   | 168  | 97  | 1.732  | -0.15517  | 0.005449   |
| { '[80,120)' }  | 78   | 36  | 2.1667 | 0.068771  | 0.00044396 |
| { '[120,210]' } | 16   | 6   | 2.6667 | 0.27641   | 0.0013301  |
| { 'Totals' }    | 803  | 397 | 2.0227 | NaN       | 0.0085559  |

Display bin information for the categorical predictor ResStatus.

```
[bi,cg] = bininfo(sc, 'ResStatus')
```

bi=4x6 table

| Bin              | Good | Bad | Odds   | WOE       | InfoValue |
|------------------|------|-----|--------|-----------|-----------|
| { 'Home Owner' } | 365  | 177 | 2.0621 | 0.019329  | 0.0001682 |
| { 'Tenant' }     | 307  | 167 | 1.8383 | -0.095564 | 0.0036638 |
| { 'Other' }      | 131  | 53  | 2.4717 | 0.20049   | 0.0059418 |
| { 'Totals' }     | 803  | 397 | 2.0227 | NaN       | 0.0097738 |

cg=3x2 table

| Category         | BinNumber |
|------------------|-----------|
| { 'Home Owner' } | 1         |
| { 'Tenant' }     | 2         |
| { 'Other' }      | 3         |

Use the modifybins function to merge categories 2 and 3.

```
cg.BinNumber(3) = 2;
sc = modifybins(sc, 'ResStatus', 'CatGrouping', cg);
bininfo(sc, 'ResStatus')
```

ans=3x6 table

| Bin          | Good | Bad | Odds   | WOE       | InfoValue  |
|--------------|------|-----|--------|-----------|------------|
| { 'Group1' } | 365  | 177 | 2.0621 | 0.019329  | 0.0001682  |
| { 'Group2' } | 438  | 220 | 1.9909 | -0.015827 | 0.00013772 |
| { 'Totals' } | 803  | 397 | 2.0227 | NaN       | 0.00030592 |

Use the modifybins function to split bin 2 and put Other under bin 3.

```
cg.BinNumber(3) = 3;
sc = modifybins(sc, 'ResStatus', 'CatGrouping', cg);
[bi,cg] = bininfo(sc, 'ResStatus')
```

```

bi=4x6 table
      Bin          Good    Bad    Odds      WOE      InfoValue
-----
{'Home Owner'}    365    177    2.0621    0.019329    0.0001682
{'Tenant'        }    307    167    1.8383   -0.095564    0.0036638
{'Other'         }    131     53    2.4717     0.20049    0.0059418
{'Totals'        }    803    397    2.0227         NaN    0.0097738

```

```

cg=3x2 table
      Category      BinNumber
-----
{'Home Owner'}    1
{'Tenant'        }    2
{'Other'         }    3

```

### Modify Bin Labels

Create a `creditscorecard` object using the `CreditCardData.mat` file to load the data (using a dataset from Refaat 2011).

```

load CreditCardData
sc = creditscorecard(data);

```

Use `modifybins` to reset the minimum value and create three bins for the predictor `CustIncome` and display updated bin information.

```

sc = modifybins(sc, 'CustIncome', 'MinValue', 0, 'CutPoints', [30000 50000]);
bi = bininfo(sc, 'CustIncome')

```

```

bi=4x6 table
      Bin          Good    Bad    Odds      WOE      InfoValue
-----
{'[0,30000)'     }    64     68    0.94118   -0.76504    0.070065
{'[30000,50000)' }    628    296    2.1216    0.047762    0.0017421
{'[50000,Inf)'   }    111     33    3.3636     0.5086     0.028028
{'Totals'        }    803    397    2.0227         NaN    0.099836

```

Modify the bin labels and display updated bin information.

```

NewLabels = {'Up to 30k', '30k to 50k', '50k and more'};
sc = modifybins(sc, 'CustIncome', 'BinLabels', NewLabels);
bi = bininfo(sc, 'CustIncome')

```

```

bi=4x6 table
      Bin          Good    Bad    Odds      WOE      InfoValue
-----
{'Up to 30k'     }    64     68    0.94118   -0.76504    0.070065
{'30k to 50k'   }    628    296    2.1216    0.047762    0.0017421
{'50k and more' }    111     33    3.3636     0.5086     0.028028

```

```
{'Totals' } 803 397 2.0227 NaN 0.099836
```

Bin labels should be the last bin-modification step. As in this example, user-defined bin labels often contain information about the cut points, minimum, or maximum values for numeric data, or information about category groupings for categorical data. To prevent situations where user-defined labels and cut points are inconsistent (and labels are misleading), the `creditscorecard` object overrides user-defined labels every time the bins are modified using `modifybins`.

To illustrate `modifybins` overriding user-defined labels every time the bins are modified, reset the first cut point to 31000 and display updated bin information. Note that the bin labels are reset to their default format and accurately reflect the change in the cut points.

```
sc = modifybins(sc, 'CustIncome', 'CutPoints', [31000 50000]);
bi = bininfo(sc, 'CustIncome')
```

bi=4x6 table

| Bin                 | Good | Bad | Odds    | WOE      | InfoValue |
|---------------------|------|-----|---------|----------|-----------|
| {'[0,31000)'} }     | 82   | 84  | 0.97619 | -0.72852 | 0.079751  |
| {'[31000,50000)'} } | 610  | 280 | 2.1786  | 0.074251 | 0.0040364 |
| {'[50000,Inf]'} }   | 111  | 33  | 3.3636  | 0.5086   | 0.028028  |
| {'Totals' }         | 803  | 397 | 2.0227  | NaN      | 0.11182   |

### Modify Bin Information When Using Missing Data

Create a `creditscorecard` object using the `CreditCardData.mat` file to load the `dataMissing` with missing values.

```
load CreditCardData.mat
head(dataMissing,5)
```

ans=5x11 table

| CustID | CustAge | TmAtAddress | ResStatus   | EmpStatus | CustIncome | TmWBank | Other |
|--------|---------|-------------|-------------|-----------|------------|---------|-------|
| 1      | 53      | 62          | <undefined> | Unknown   | 50000      | 55      | Ye    |
| 2      | 61      | 22          | Home Owner  | Employed  | 52000      | 25      | Ye    |
| 3      | 47      | 30          | Tenant      | Employed  | 37000      | 61      | Ne    |
| 4      | NaN     | 75          | Home Owner  | Employed  | 53000      | 20      | Ye    |
| 5      | 68      | 56          | Home Owner  | Employed  | 53000      | 14      | Ye    |

```
fprintf('Number of rows: %d\n',height(dataMissing))
Number of rows: 1200
fprintf('Number of missing values CustAge: %d\n',sum(ismissing(dataMissing.CustAge)))
Number of missing values CustAge: 30
fprintf('Number of missing values ResStatus: %d\n',sum(ismissing(dataMissing.ResStatus)))
```

Number of missing values ResStatus: 40

Use `creditscorecard` with the name-value argument `'BinMissingData'` set to `true` to bin the missing data in a separate bin.

```
sc = creditscorecard(dataMissing, 'IDVar', 'CustID', 'BinMissingData', true);
sc = autobinining(sc);
```

```
disp(sc)
```

```
creditscorecard with properties:
```

```

    GoodLabel: 0
    ResponseVar: 'status'
    WeightsVar: ''
    VarNames: {1x11 cell}
    NumericPredictors: {1x6 cell}
    CategoricalPredictors: {'ResStatus' 'EmpStatus' 'OtherCC'}
    BinMissingData: 1
    IDVar: 'CustID'
    PredictorVars: {1x9 cell}
    Data: [1200x11 table]
```

Display bin information for numeric data for `'CustAge'` that includes missing data in a separate bin labelled `<missing>`.

```
[bi,cp] = bininfo(sc, 'CustAge');
disp(bi)
```

| Bin             | Good | Bad | Odds   | WOE      | InfoValue  |
|-----------------|------|-----|--------|----------|------------|
| {'[-Inf,33)'} } | 69   | 52  | 1.3269 | -0.42156 | 0.018993   |
| {'[33,37)'} }   | 63   | 45  | 1.4    | -0.36795 | 0.012839   |
| {'[37,40)'} }   | 72   | 47  | 1.5319 | -0.2779  | 0.0079824  |
| {'[40,46)'} }   | 172  | 89  | 1.9326 | -0.04556 | 0.0004549  |
| {'[46,48)'} }   | 59   | 25  | 2.36   | 0.15424  | 0.0016199  |
| {'[48,51)'} }   | 99   | 41  | 2.4146 | 0.17713  | 0.0035449  |
| {'[51,58)'} }   | 157  | 62  | 2.5323 | 0.22469  | 0.0088407  |
| {'[58,Inf]'} }  | 93   | 25  | 3.72   | 0.60931  | 0.032198   |
| {'<missing>'} } | 19   | 11  | 1.7273 | -0.15787 | 0.00063885 |
| {'Totals' }     | 803  | 397 | 2.0227 | NaN      | 0.087112   |

```
plotbins(sc, 'CustAge')
```

For the numeric predictor CustAge, remove cut points 48 and 51 and then use modifybins to define a 'MinValue' of 0 to manually change the binning and notice that this does not affect the data in the <missing> bin and the <missing> bin remains at the end.

```
cp(cp==48) = [];
cp(cp==51) = [];
sc = modifybins(sc, 'CustAge', 'CutPoints', cp, 'MinValue', 0);
bi = bininfo(sc, 'CustAge');
disp(bi)
```

| Bin             | Good | Bad | Odds   | WOE      | InfoValue  |
|-----------------|------|-----|--------|----------|------------|
| { '[0,33)' }    | 69   | 52  | 1.3269 | -0.42156 | 0.018993   |
| { '[33,37)' }   | 63   | 45  | 1.4    | -0.36795 | 0.012839   |
| { '[37,40)' }   | 72   | 47  | 1.5319 | -0.2779  | 0.0079824  |
| { '[40,46)' }   | 172  | 89  | 1.9326 | -0.04556 | 0.0004549  |
| { '[46,58)' }   | 315  | 128 | 2.4609 | 0.19612  | 0.013701   |
| { '[58,Inf]' }  | 93   | 25  | 3.72   | 0.60931  | 0.032198   |
| { '<missing>' } | 19   | 11  | 1.7273 | -0.15787 | 0.00063885 |
| { 'Totals' }    | 803  | 397 | 2.0227 | NaN      | 0.086808   |

```
plotbins(sc, 'CustAge')
```

Display bin information for categorical data for 'ResStatus' that includes missing data in a separate bin labelled <missing>.

```
[bi,cg] = bininfo(sc, 'ResStatus');
disp(bi)
```

| Bin             | Good | Bad | Odds   | WOE       | InfoValue  |
|-----------------|------|-----|--------|-----------|------------|
| {'Tenant' }     | 296  | 161 | 1.8385 | -0.095463 | 0.0035249  |
| {'Home Owner' } | 352  | 171 | 2.0585 | 0.017549  | 0.00013382 |
| {'Other' }      | 128  | 52  | 2.4615 | 0.19637   | 0.0055808  |
| {'<missing>' }  | 27   | 13  | 2.0769 | 0.026469  | 2.3248e-05 |
| {'Totals' }     | 803  | 397 | 2.0227 | NaN       | 0.0092627  |

```
plotbins(sc, 'ResStatus')
```

For the categorical predictor ResStatus, use modifybins to manually merge 'HomeOwner' and 'Other' into a single group by assigning the same bin number to these categories. Notice that this does not affect the data in the <missing> bin and the <missing> bin remains at the end.

```
cg.BinNumber(3) = 2;
sc = modifybins(sc, 'ResStatus', 'CatGrouping', cg);
[bi, cg] = bininfo(sc, 'ResStatus');
disp(bi)
```

| Bin            | Good | Bad | Odds   | WOE       | InfoValue  |
|----------------|------|-----|--------|-----------|------------|
| {'Group1' }    | 296  | 161 | 1.8385 | -0.095463 | 0.0035249  |
| {'Group2' }    | 480  | 223 | 2.1525 | 0.062196  | 0.0022419  |
| {'<missing>' } | 27   | 13  | 2.0769 | 0.026469  | 2.3248e-05 |
| {'Totals' }    | 803  | 397 | 2.0227 | NaN       | 0.00579    |

```
disp(cg)
```

| Category        | BinNumber |
|-----------------|-----------|
| {'Tenant' }     | 1         |
| {'Home Owner' } | 2         |
| {'Other' }      | 2         |

## Input Arguments

### **sc — Credit scorecard model**

creditscorecard object

Credit scorecard model, specified as a `creditscorecard` object. Use `creditscorecard` to create a `creditscorecard` object.

### **PredictorName — Name of predictor**

character vector

Name of predictor, specified as a character vector containing the name of the predictor. `PredictorName` is case-sensitive.

Data Types: `char`

### **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `sc = modifybins(sc, PredictorName, 'MinValue', 10, 'CutPoints', [23, 44, 66, 88])`

### **MinValue — Minimum acceptable value (numeric predictors only)**

-Inf (default) | numeric

Minimum acceptable value, specified as the comma-separated pair consisting of `'MinValue'` and a numeric value (for numeric predictors only). Values below this number are considered out of range.

Data Types: `double`

### **MaxValue — Maximum acceptable value (numeric predictors only)**

Inf (default) | numeric

Maximum acceptable value, specified as the comma-separated pair consisting of `'MaxValue'` and a numeric value (for numeric predictors only). Values above this number are considered out of range.

Data Types: `double`

### **CutPoints — Split points between bins**

each observed value of the predictor is placed in a separate bin (default) | nondecreasing numeric array

Split points between bins, specified as the comma-separated pair consisting of `'CutPoints'` and a nondecreasing numeric array. If there are `NumBins` bins, there are  $n = \text{NumBins} - 1$  cut points so that  $C_1, C_2, \dots, C_n$  describe the bin boundaries with the following convention:

- The first bin includes any values  $\geq \text{MinValue}$ , but  $< C_1$ .
- The second bin includes any values  $\geq C_1$ , but  $< C_2$ .
- The last bin includes any values  $\geq C_n$ , and  $\leq \text{MaxValue}$ .

---

**Note** Cut points do not include `MinValue` or `MaxValue`.

---

By default, cut points are defined so that each observed value of the predictor is placed in a separate bin. If the sorted observed values are  $V_1, \dots, V_M$ , the default cut points are  $V_2, \dots, V_M$ , which define  $M$  bins.

Data Types: double

### CatGrouping — Table with two columns named Category and BinNumber

each category is placed in a separate bin (default) | table with two columns named Category and BinNumber

Table with two columns named Category and BinNumber, specified as the comma-separated pair consisting of 'CatGrouping' and a table, where the first column contains an exhaustive list of categories for the predictor, and the second column contains the bin number to which each category belongs.

By default, each category is placed in a separate bin. If the observed categories are 'Cat1' ..., 'CatM', the default category grouping is as follows.

| Category | BinNumber |
|----------|-----------|
| 'Cat1'   | 1         |
| 'Cat2'   | 2         |
| ...      | ...       |
| 'CatM'   | $M$       |

Data Types: double

### BinLabels — Bin labels for each bin

automatically generated bin labels depending on the predictor's type (default) | cell array of character vectors

Bin labels for each bin, specified as the comma-separated pair consisting of 'BinLabels' and a cell array of character vectors with bin label names.

---

**Note** 'BinLabels' does not support a value of <missing>.

---

Bin labels are used to tag the bins in different object functions such as `bininfo`, `plotbins`, and `displaypoints`. A `creditscorecard` object automatically sets default bins whenever bins are modified. The default format for bin labels depends on the predictor's type.

The format for BinLabels is:

- Numeric data — Before any manual or automatic modification of the predictor bins, there is a bin for each observed predictor value by default. In that case, the bin labels simply show the predictor values. Once the predictor bins have been modified, there are nondefault values for `MinValue` or `MaxValue`, or nondefault cut points  $C_1, C_2, \dots, C_n$ . In that case, the bin labels are:
  - Bin 1 label: '[MinValue, C1]'
  - Bin 2 label: '[C1, C2]'
  - Last bin label: '[Cn, MaxValue]'

For example, if there are three bins, `MinValue` is 0 and `MaxValue` is 40, and cut point 1 is 20 and cut point 2 is 30, then the corresponding three bin labels are:

```
' [0,20) '  
' [20,30) '  
' [30,40] '
```

- **Categorical data** — For categorical data, before any modification of the predictor bins, there is one bin per category. In that case, the bin labels simply show the predictor categories. Once the bins have been modified, the labels are set to `'Group1'`, `'Group2'`, and so on, for bin 1, bin 2, and so on, respectively. For example, suppose that we have the following category grouping

| Category | BinNumber |
|----------|-----------|
| 'Cat1'   | 1         |
| 'Cat2'   | 2         |
| 'Cat3'   | 2         |

Bin 1 contains `'Cat1'` only and its bin label is set to `'Group1'`. Bin 2 contains `'Cat2'` and `'Cat3'` and its bin label is set to `'Group2'`.

---

**Tip** Using `BinLabels` should be the last step (if needed) in modifying bins. `BinLabels` definitions are overridden each time that the bins are modified using the `modifybins` or `autobinning` functions.

---

Data Types: `cell`

## Output Arguments

**sc** — Credit scorecard model  
`creditscorecard` object

Credit scorecard model, returned as an updated `creditscorecard` object. For more information on using the `creditscorecard` object, see `creditscorecard`.

## modifypredictor

Set properties of credit scorecard predictors

### Syntax

```
sc = modifypredictor(sc,PredictorName)
sc = modifypredictor( ___,Name,Value)
```

### Description

`sc = modifypredictor(sc,PredictorName)` sets the properties of the credit scorecard predictors.

`sc = modifypredictor( ___,Name,Value)` sets the properties of the credit scorecard predictors using optional name-value pair arguments.

### Examples

#### Modify a Predictor to Change the Predictor Type from Numeric to Categorical

Create a `creditscorecard` object using the `CreditCardData.mat` file to load the data (using a dataset from Refaat 2011). In practice, categorical data many times is represented with numeric values. To show the case where categorical data is given as numeric data, the data for the variable 'ResStatus' is intentionally converted to numeric values.

```
load CreditCardData
data.ResStatus = double(data.ResStatus);
sc = creditscorecard(data, 'IDVar', 'CustID')
```

```
sc =
  creditscorecard with properties:

    GoodLabel: 0
    ResponseVar: 'status'
    WeightsVar: ''
    VarNames: {1x11 cell}
    NumericPredictors: {1x7 cell}
    CategoricalPredictors: {'EmpStatus' 'OtherCC'}
    BinMissingData: 0
    IDVar: 'CustID'
    PredictorVars: {1x9 cell}
    Data: [1200x11 table]
```

```
[T,Stats] = predictorinfo(sc, 'ResStatus')
```

```
T=1x4 table
```

| PredictorType | LatestBinning | LatestFillMissingType | LatestFillMissing |
|---------------|---------------|-----------------------|-------------------|
|---------------|---------------|-----------------------|-------------------|

```
ResStatus      {'Numeric'}      {'Original Data'}      {'Original'}      {0x0 double}
```

```
Stats=4x1 table
      Value
-----
Min      1
Max      3
Mean     1.7017
Std      0.71833
```

Note that 'ResStatus' appears as part of the NumericPredictors property. Assume that you want 'ResStatus' to be treated as categorical data. For example, you may want to allow automatic binning algorithms to reorder the categories. Use modifypredictor to change the 'PredictorType' of the PredictorName 'ResStatus' from numeric to categorical.

```
sc = modifypredictor(sc, 'ResStatus', 'PredictorType', 'Categorical')
```

```
sc =
creditscorecard with properties:
    GoodLabel: 0
    ResponseVar: 'status'
    WeightsVar: ''
    VarNames: {1x11 cell}
    NumericPredictors: {1x6 cell}
    CategoricalPredictors: {'ResStatus' 'EmpStatus' 'OtherCC'}
    BinMissingData: 0
    IDVar: 'CustID'
    PredictorVars: {1x9 cell}
    Data: [1200x11 table]
```

```
[T,Stats] = predictorinfo(sc, 'ResStatus')
```

```
T=1x5 table
      PredictorType      Ordinal      LatestBinning      LatestFillMissingType      Late
-----
ResStatus      {'Categorical'}      false      {'Original Data'}      {'Original'}
```

```
Stats=3x1 table
      Count
-----
C1      542
C2      474
C3      184
```

Notice that 'ResStatus' now appears as part of the 'Categorical' predictors.

## Input Arguments

### **sc — Credit scorecard model**

creditscorecard object

Credit scorecard model, specified as a `creditscorecard` object. Use `creditscorecard` to create a `creditscorecard` object.

### **PredictorName — Predictor name**

character vector | cell array of character vectors

Predictor name, specified using a character vector or cell array of character vectors containing the names of the credit scorecard predictors. `PredictorName` is case-sensitive.

Data Types: `char` | `cell`

### **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1`, `Value1`, ..., `NameN`, `ValueN`.

Example: `sc = modifypredictor(sc, {'CustAge', 'CustIncome'}, 'PredictorType', 'Categorical', 'Ordinal', true)`

### **PredictorType — Predictor type that one or more predictors are converted to**

' ' no conversion occurs (default) | character vector with values 'Numeric', 'Categorical'

Predictor type that one or more predictors are converted to, specified as the comma-separated pair consisting of 'PredictorType' and a character vector. Possible values are:

- ' ' — No conversion occurs.
- 'Numeric' — The predictor data specified by `PredictorName` is converted to numeric.
- 'Categorical' — The predictor data specified by `PredictorName` is converted to categorical.

Data Types: `char`

### **Ordinal — Indicator for whether predictors being converted to categorical are ordinal**

false (default) | logical with values true, false

Indicator for whether predictors being converted to categorical or existing categorical predictors are treated as ordinal data, specified as the comma-separated pair consisting of 'Ordinal' and a logical with values `true` or `false`.

---

**Note** This optional input parameter is only used for predictors of type 'Categorical'.

---

Data Types: `logical`

## Output Arguments

### **sc — Credit scorecard model**

creditscorecard object

Credit scorecard model, returned as an updated `creditscorecard` object.

**See Also**

`creditscorecard` | `modifybins` | `predictorinfo` | `bininfo`

**Introduced in R2015b**

## predictorinfo

Summary of credit scorecard predictor properties

### Syntax

```
[T,Stats] = predictorinfo(sc,PredictorName)
```

### Description

[T,Stats] = predictorinfo(sc,PredictorName) returns a summary of credit scorecard predictor properties and some basic predictor statistics.

### Examples

#### Obtain Information for a Specified PredictorName

Create a `creditscorecard` object using the `CreditCardData.mat` file to load the data (using a dataset from Refaat 2011).

```
load CreditCardData
sc = creditscorecard(data, 'IDVar', 'CustID')

sc =
  creditscorecard with properties:

    GoodLabel: 0
    ResponseVar: 'status'
    WeightsVar: ''
    VarNames: {1x11 cell}
    NumericPredictors: {1x6 cell}
    CategoricalPredictors: {'ResStatus' 'EmpStatus' 'OtherCC'}
    BinMissingData: 0
    IDVar: 'CustID'
    PredictorVars: {1x9 cell}
    Data: [1200x11 table]
```

Obtain the predictor statistics for the PredictorName of CustAge.

```
[T,Stats] = predictorinfo(sc, 'CustAge')
```

T=1×4 table

|         | PredictorType | LatestBinning     | LatestFillMissingType | LatestFillMissingV |
|---------|---------------|-------------------|-----------------------|--------------------|
| CustAge | {'Numeric'}   | {'Original Data'} | {'Original'}          | {0×0 double}       |

Stats=4×1 table

Value

```

Min      21
Max      74
Mean     45.174
Std      9.8302

```

Obtain the predictor statistics for the PredictorName of ResStatus.

```
[T,Stats] = predictorinfo(sc, 'ResStatus')
```

T=1×5 table

|           | PredictorType   | Ordinal | LatestBinning     | LatestFillMissingType | LatestFillMissingValue |
|-----------|-----------------|---------|-------------------|-----------------------|------------------------|
| ResStatus | {'Categorical'} | false   | {'Original Data'} | {'Original'}          | {}                     |

Stats=3×1 table

|            | Count |
|------------|-------|
| Home Owner | 542   |
| Tenant     | 474   |
| Other      | 184   |

### Obtain Information for a Specified PredictorName After Using fillmissing

Create a `creditscorecard` object using the `CreditCardData.mat` file to load the data (using a dataset from Refaat 2011).

```

load CreditCardData
sc = creditscorecard(dataMissing, 'BinMissingData', true, 'IDVar', 'CustID');
sc = autobinning(sc);

```

Use `fillmissing` to replace missing values for the `CustAge` predictor with a value of 38.

```
sc = fillmissing(sc, 'CustAge', 'constant', 38);
```

Obtain the predictor statistics for the PredictorName of CustAge.

```
[T,Stats] = predictorinfo(sc, 'CustAge')
```

T=1×4 table

|         | PredictorType | LatestBinning            | LatestFillMissingType | LatestFillMissingValue |
|---------|---------------|--------------------------|-----------------------|------------------------|
| CustAge | {'Numeric'}   | {'Automatic / Monotone'} | {'Constant'}          | {38}                   |

Stats=4×1 table

|     | Value |
|-----|-------|
| Min | 21    |
| Max | 74    |

```
Mean    44.932
Std     9.7436
```

Use `fillmissing` to replace missing values for the `ResStatus` predictor with a mode value.

```
sc = fillmissing(sc, 'ResStatus', 'mode');
```

Obtain the predictor statistics for the `PredictorName` of `ResStatus`.

```
[T,Stats] = predictorinfo(sc, 'ResStatus')
```

`T=1×5 table`

|           | PredictorType   | Ordinal | LatestBinning            | LatestFillMissingType |
|-----------|-----------------|---------|--------------------------|-----------------------|
| ResStatus | {'Categorical'} | false   | {'Automatic / Monotone'} | {'Mode'}              |

`Stats=3×1 table`

|            | Count |
|------------|-------|
| Tenant     | 457   |
| Home Owner | 563   |
| Other      | 180   |

## Input Arguments

### **sc** — Credit scorecard model

creditscorecard object

Credit scorecard model, specified as a `creditscorecard` object. Use `creditscorecard` to create a `creditscorecard` object.

### **PredictorName** — Predictor name

character vector

Predictor name, specified using a character vector containing the names of the credit scorecard predictor of interest. `PredictorName` is case-sensitive.

Data Types: `char`

## Output Arguments

### **T** — Summary information for specified predictor

table

Summary information for specified predictor, returned as table with the following columns:

- `'PredictorType'` — `'Numeric'` or `'Categorical'`.
- `'Ordinal'` — For categorical predictors, a boolean indicating whether it is ordinal.
- `'LatestBinning'` — Character vector indicating the last applied algorithm for the input argument `PredictorName`. The values are:

- 'Original Data' — When no binning is applied to the predictor.
- 'Automatic / BinningName' — Where 'BinningName' is one of the following: Monotone, Equal Width, or Equal Frequency.
- 'Manual' — After each call of `modifybins`, where either 'CutPoints', 'CatGrouping', 'MinValue', or 'MaxValue' are modified.
- 'LatestFillMissingType' — If `fillmissing` has been applied to the predictor, the value of the `Statistics` argument for `fillmissing` is displayed. If the predictor does not have any missing data, then the fill type is 'Original'.
- 'LatestFillMissingValue' — If `fillmissing` has been applied to the predictor, the fill value is displayed. If the predictor does not have any missing data, then the fill value is [ ].

The predictor's name is used as a row name in the table that is returned.

### Stats — Summary statistics for the input PredictorName

table

Summary statistics for the input `PredictorName`, returned as a table. The corresponding value is stored in the 'Value' column.

The table's row names indicate the relevant statistics for numeric predictors:

- 'Min' — Minimum value in the sample.
- 'Max' — Maximum value in the sample.
- 'Mean' — Mean value in the sample.
- 'Std' — Standard deviation of the sample.

---

**Note** For data types other than 'double' or 'single', numeric precision may be lost for the standard deviation. Data types other than 'double' or 'single' are cast as 'double' before computing the standard deviation.

---

For categorical predictors, the row names contain the names of the categories, with corresponding total count in the 'Count' column.

**Introduced in R2015b**

## bininfo

Return predictor's bin information

### Syntax

```
bi = bininfo(sc,PredictorName)
```

```
bi = bininfo( ___,Name,Value)
```

```
[bi,bm] = bininfo(sc,PredictorName,Name,Value)
```

```
[bi,bm,mv] = bininfo(sc,PredictorName,Name,Value)
```

### Description

`bi = bininfo(sc,PredictorName)` returns information at bin level, such as frequencies of "Good," "Bad," and bin statistics for the predictor specified in `PredictorName`.

`bi = bininfo( ___,Name,Value)` adds optional name-value arguments.

`[bi,bm] = bininfo(sc,PredictorName,Name,Value)` adds optional name-value arguments. `bininfo` also optionally returns the binning map (`bm`) or bin rules in the form of a vector of cut points for numeric predictors, or a table of category groupings for categorical predictors.

`[bi,bm,mv] = bininfo(sc,PredictorName,Name,Value)` returns information at bin level, such as frequencies of "Good," "Bad," and bin statistics for the predictor specified in `PredictorName` using optional name-value pair arguments. `bininfo` optionally returns the binning map or bin rules in the form of a vector of cut points for numeric predictors, or a table of category groupings for categorical predictors. In addition, optional name-value pair arguments `mv` returns a numeric array containing the minimum and maximum values, as set (or defined) by the user. The `mv` output argument is set to an empty array for categorical predictors.

### Examples

#### Display Bin Information Using Default Options

Create a `creditscorecard` object using the `CreditCardData.mat` file to load the data (using a dataset from Refaat 2011).

```
load CreditCardData
sc = creditscorecard(data);
```

Display bin information for the categorical predictor `ResStatus`.

```
bi = bininfo(sc,'ResStatus')
```

```
bi=4x6 table
      Bin          Good    Bad    Odds      WOE      InfoValue
      _____  _____  _____  _____  _____  _____
      {'Home Owner'}  365    177    2.0621    0.019329    0.0001682
```

```

{'Tenant'    }    307    167    1.8383    -0.095564    0.0036638
{'Other'     }    131     53    2.4717     0.20049    0.0059418
{'Totals'    }    803    397    2.0227         NaN    0.0097738

```

## Display Bin Information For a creditcard Object Containing Weights

Use the `CreditCardData.mat` file to load the data (`dataWeights`) that contains a column (`RowWeights`) for the weights (using a dataset from Refaat 2011).

load `CreditCardData`

Create a `creditcard` object using the optional name-value pair argument for `'WeightsVar'`.

```
sc = creditcard(dataWeights, 'WeightsVar', 'RowWeights')
```

```

sc =
    creditcard with properties:

        GoodLabel: 0
        ResponseVar: 'status'
        WeightsVar: 'RowWeights'
        VarNames: {1x12 cell}
        NumericPredictors: {1x7 cell}
        CategoricalPredictors: {'ResStatus' 'EmpStatus' 'OtherCC'}
        BinMissingData: 0
        IDVar: ''
        PredictorVars: {1x10 cell}
        Data: [1200x12 table]

```

Display bin information for the numerical predictor `'CustIncome'`. When the optional name-value pair argument `'WeightsVar'` is used to specify observation (sample) weights, the `bi` table contains weighted counts.

```
bi = bininfo(sc, 'CustIncome');
bi(1:10,:)
```

```
ans=10x6 table

```

### Display Bin Information Using Name-Value Arguments

Create a `creditscorecard` object using the `CreditCardData.mat` file to load the data (using a dataset from Refaat 2011).

```
load CreditCardData
sc = creditscorecard(data);
```

Display customized bin information for the categorical predictor `ResStatus`, keeping only the `WOE` column. The Weight-of-Evidence (WOE) is defined bin by bin, but there is no concept of "total WOE", therefore the last element in the `'Totals'` row is set to `NaN`.

```
bi = bininfo(sc, 'ResStatus', 'Statistics', 'WOE');
disp(bi)
```

| Bin             | Good | Bad | WOE       |
|-----------------|------|-----|-----------|
| {'Home Owner' } | 365  | 177 | 0.019329  |
| {'Tenant' }     | 307  | 167 | -0.095564 |
| {'Other' }      | 131  | 53  | 0.20049   |
| {'Totals' }     | 803  | 397 | NaN       |

Display customized bin information for the categorical predictor `ResStatus`, keeping only the `Odds` and `WOE` columns, without the `Totals` row.

```
bi = bininfo(sc, 'ResStatus', 'Statistics', {'Odds', 'WOE'}, 'Totals', 'Off');
disp(bi)
```

| Bin             | Good | Bad | Odds   | WOE       |
|-----------------|------|-----|--------|-----------|
| {'Home Owner' } | 365  | 177 | 2.0621 | 0.019329  |
| {'Tenant' }     | 307  | 167 | 1.8383 | -0.095564 |
| {'Other' }      | 131  | 53  | 2.4717 | 0.20049   |

Display information value, entropy, Gini, and chi square statistics. For more information on these statistics, see "Statistics for a Credit Scorecard" on page 19-1864.

For information value, entropy and Gini, the value reported at a bin level is the contribution of the bin to the total value. The total information value, entropy, and Gini measures are in the `'Totals'` row.

For chi square, if there are  $N$  bins, the first  $N-1$  values in the `'Chi2'` column report pairwise chi square statistics for contiguous bins. For example, this pairwise measure is also used by the `'Merge'` algorithm in `autobinning` to determine if two contiguous bins should be merged. In this example, the first value in the `'Chi2'` column (1.0331) is the chi square statistic of bins 1 and 2 (`'Home Owner'` and `'Tenant'`), and the second value in the column (2.5103) is the chi square statistic of bins 2 and 3 (`'Tenant'` and `'Other'`). There are no more pairwise chi square values to compute in this example, so the third element of the `'Chi2'` column is set to `NaN`. The chi square value reported in the `'Totals'` row is the chi square statistic computed over all bins.

```
bi = bininfo(sc, 'ResStatus', 'Statistics', {'InfoValue', 'Entropy', 'Gini', 'Chi2'});
disp(bi)
```

| Bin | Good | Bad | InfoValue | Entropy | Gini | Chi2 |
|-----|------|-----|-----------|---------|------|------|
|-----|------|-----|-----------|---------|------|------|

```

{'Home Owner'} 365 177 0.0001682 0.91138 0.43984 1.0331
{'Tenant' }    307 167 0.0036638 0.93612 0.45638 2.5103
{'Other' }     131 53 0.0059418 0.86618 0.41015 NaN
{'Totals' }    803 397 0.0097738 0.91422 0.44182 2.5549

```

## Display Bin Information and Binning Map for Categorical Data

Create a `creditscorecard` object using the `CreditCardData.mat` file to load the data (using a dataset from Refaat 2011).

```
load CreditCardData
sc = creditscorecard(data);
```

The binning map or rules for categorical data are summarized in a "category grouping" table, returned as an optional output. By default, each category is placed in a separate bin. Here is the information for the predictor `ResStatus`.

```
[bi,cg] = bininfo(sc, 'ResStatus')
```

```
bi=4x6 table
      Bin      Good      Bad      Odds      WOE      InfoValue
-----
{'Home Owner'} 365      177      2.0621      0.019329      0.0001682
{'Tenant' }    307      167      1.8383     -0.095564      0.0036638
{'Other' }     131      53      2.4717      0.20049       0.0059418
{'Totals' }    803      397      2.0227           NaN       0.0097738
```

```
cg=3x2 table
      Category      BinNumber
-----
{'Home Owner'}      1
{'Tenant' }         2
{'Other' }          3
```

To group categories `Tenant` and `Other`, modify the category grouping table `cg` so that the bin number for `Other` is the same as the bin number for `Tenant`. Then use the `modifybins` function to update the scorecard.

```
cg.BinNumber(3) = 2;
sc = modifybins(sc, 'ResStatus', 'CatGrouping', cg);
```

Display the updated bin information. The bin labels have been updated and that the bin membership information is contained in the category grouping `cg`.

```
[bi,cg] = bininfo(sc, 'ResStatus')
```

```
bi=3x6 table
      Bin      Good      Bad      Odds      WOE      InfoValue
-----
{'Group1'} 365      177      2.0621      0.019329      0.0001682
{'Group2'} 438      220      1.9909     -0.015827      0.00013772
```

```
{'Totals'}      803      397      2.0227      NaN      0.00030592
```

```
cg=3x2 table
      Category      BinNumber
-----
{'Home Owner'}      1
{'Tenant' }          2
{'Other' }           2
```

### Display Bin Information and Binning Map for Numeric Data

Create a `creditscorecard` object using the `CreditCardData.mat` file to load the data (using a dataset from Refaat 2011).

```
load CreditCardData
sc = creditscorecard(data);
```

The predictor `CustIncome` is numeric. By default, each value of the predictor is placed in a separate bin.

```
bi = bininfo(sc, 'CustIncome')
```

```
bi=46x6 table
      Bin      Good      Bad      Odds      WOE      InfoValue
-----
{'18000'}      2       3      0.66667     -1.1099     0.0056227
{'19000'}      1       2       0.5         -1.3976     0.0053002
{'20000'}      4       2       2         -0.011271    6.3641e-07
{'21000'}      6       3       2         -0.011271    9.5462e-07
{'22000'}      4       2       2         -0.011271    6.3641e-07
{'23000'}      4       4       1         -0.70442     0.0035885
{'24000'}      5       5       1         -0.70442     0.0044856
{'25000'}      4       9      0.44444     -1.5153     0.026805
{'26000'}      4      11      0.36364     -1.716      0.038999
{'27000'}      6       6       1         -0.70442     0.0053827
{'28000'}     13      11      1.1818     -0.53736    0.0061896
{'29000'}     11      10       1.1         -0.60911    0.0069988
{'30000'}     18      16      1.125      -0.58664     0.010493
{'31000'}     24       8       3         0.39419     0.0038382
{'32000'}     21      15       1.4         -0.36795     0.0042797
{'33000'}     35      19      1.8421     -0.093509    0.00039951
      ⋮
```

Reduce the number of bins using the `autobinning` function (the `modifybins` function can also be used).

```
sc = autobinning(sc, 'CustIncome');
```

Display the updated bin information. The binning map or rules for numeric data are summarized as "cut points," returned as an optional output (`cp`).

```
[bi,cp] = bininfo(sc, 'CustIncome')
```

```
bi=8x6 table
```

| Bin                 | Good | Bad | Odds    | WOE       | InfoValue  |
|---------------------|------|-----|---------|-----------|------------|
| {'[-Inf,29000)'} }  | 53   | 58  | 0.91379 | -0.79457  | 0.06364    |
| {'[29000,33000)'} } | 74   | 49  | 1.5102  | -0.29217  | 0.0091366  |
| {'[33000,35000)'} } | 68   | 36  | 1.8889  | -0.06843  | 0.00041042 |
| {'[35000,40000)'} } | 193  | 98  | 1.9694  | -0.026696 | 0.00017359 |
| {'[40000,42000)'} } | 68   | 34  | 2       | -0.011271 | 1.0819e-05 |
| {'[42000,47000)'} } | 164  | 66  | 2.4848  | 0.20579   | 0.0078175  |
| {'[47000,Inf]'} }   | 183  | 56  | 3.2679  | 0.47972   | 0.041657   |
| {'Totals' }         | 803  | 397 | 2.0227  | NaN       | 0.12285    |

```
cp = 6x1
```

```
29000
33000
35000
40000
42000
47000
```

Manually remove the second cut point (the boundary between the second and third bins) to merge bins two and three. Use the `modifybins` function to update the scorecard.

```
cp(2) = [];
sc = modifybins(sc, 'CustIncome', 'CutPoints', cp, 'MinValue', 0);
```

Display the updated bin information.

```
[bi,cp,mv] = bininfo(sc, 'CustIncome')
```

```
bi=7x6 table
```

| Bin                 | Good | Bad | Odds    | WOE       | InfoValue  |
|---------------------|------|-----|---------|-----------|------------|
| {'[0,29000)'} }     | 53   | 58  | 0.91379 | -0.79457  | 0.06364    |
| {'[29000,35000)'} } | 142  | 85  | 1.6706  | -0.19124  | 0.0071274  |
| {'[35000,40000)'} } | 193  | 98  | 1.9694  | -0.026696 | 0.00017359 |
| {'[40000,42000)'} } | 68   | 34  | 2       | -0.011271 | 1.0819e-05 |
| {'[42000,47000)'} } | 164  | 66  | 2.4848  | 0.20579   | 0.0078175  |
| {'[47000,Inf]'} }   | 183  | 56  | 3.2679  | 0.47972   | 0.041657   |
| {'Totals' }         | 803  | 397 | 2.0227  | NaN       | 0.12043    |

```
cp = 5x1
```

```
29000
35000
40000
42000
47000
```

```
mv = 1x2
```

```
0 Inf
```

Note, it is recommended to avoid having bins with frequencies of zero because they lead to infinite or undefined (NaN) statistics. Use the `modifybins` or `autobinning` functions to modify bins.

### Display Bin Information for Missing Data

Create a `creditscorecard` object using the `CreditCardData.mat` file to load the `dataMissing` with missing values.

```
load CreditCardData.mat
head(dataMissing,5)
```

```
ans=5x11 table
```

| CustID | CustAge | TmAtAddress | ResStatus   | EmpStatus | CustIncome | TmWBank | OtherCC |
|--------|---------|-------------|-------------|-----------|------------|---------|---------|
| 1      | 53      | 62          | <undefined> | Unknown   | 50000      | 55      | Yes     |
| 2      | 61      | 22          | Home Owner  | Employed  | 52000      | 25      | Yes     |
| 3      | 47      | 30          | Tenant      | Employed  | 37000      | 61      | No      |
| 4      | NaN     | 75          | Home Owner  | Employed  | 53000      | 20      | Yes     |
| 5      | 68      | 56          | Home Owner  | Employed  | 53000      | 14      | Yes     |

```
fprintf('Number of rows: %d\n',height(dataMissing))
```

```
Number of rows: 1200
```

```
fprintf('Number of missing values CustAge: %d\n',sum(ismissing(dataMissing.CustAge)))
```

```
Number of missing values CustAge: 30
```

```
fprintf('Number of missing values ResStatus: %d\n',sum(ismissing(dataMissing.ResStatus)))
```

```
Number of missing values ResStatus: 40
```

Use `creditscorecard` with the name-value argument `'BinMissingData'` set to `true` to bin the missing data in a separate bin.

```
sc = creditscorecard(dataMissing,'IDVar','CustID','BinMissingData',true);
sc = autobinning(sc);
```

```
disp(sc)
```

```
creditscorecard with properties:
```

```

    GoodLabel: 0
    ResponseVar: 'status'
    WeightsVar: ''
    VarNames: {1x11 cell}
    NumericPredictors: {1x6 cell}
    CategoricalPredictors: {'ResStatus' 'EmpStatus' 'OtherCC'}
    BinMissingData: 1
    IDVar: 'CustID'
```

```
PredictorVars: {1x9 cell}
Data: [1200x11 table]
```

Display bin information for numeric data for 'CustAge' that includes missing data in a separate bin labelled <missing>.

```
bi = bininfo(sc, 'CustAge');
disp(bi)
```

| Bin             | Good | Bad | Odds   | WOE      | InfoValue  |
|-----------------|------|-----|--------|----------|------------|
| {'[-Inf,33)'} } | 69   | 52  | 1.3269 | -0.42156 | 0.018993   |
| {'[33,37)'} }   | 63   | 45  | 1.4    | -0.36795 | 0.012839   |
| {'[37,40)'} }   | 72   | 47  | 1.5319 | -0.2779  | 0.0079824  |
| {'[40,46)'} }   | 172  | 89  | 1.9326 | -0.04556 | 0.0004549  |
| {'[46,48)'} }   | 59   | 25  | 2.36   | 0.15424  | 0.0016199  |
| {'[48,51)'} }   | 99   | 41  | 2.4146 | 0.17713  | 0.0035449  |
| {'[51,58)'} }   | 157  | 62  | 2.5323 | 0.22469  | 0.0088407  |
| {'[58,Inf]'} }  | 93   | 25  | 3.72   | 0.60931  | 0.032198   |
| {'<missing>'} } | 19   | 11  | 1.7273 | -0.15787 | 0.00063885 |
| {'Totals' }     | 803  | 397 | 2.0227 | NaN      | 0.087112   |

```
plotbins(sc, 'CustAge')
```

Display bin information for categorical data for 'ResStatus' that includes missing data in a separate bin labelled <missing>.

```
[bi,cg] = bininfo(sc, 'ResStatus');
disp(bi)
```

| Bin             | Good | Bad | Odds   | WOE       | InfoValue  |
|-----------------|------|-----|--------|-----------|------------|
| {'Tenant' }     | 296  | 161 | 1.8385 | -0.095463 | 0.0035249  |
| {'Home Owner' } | 352  | 171 | 2.0585 | 0.017549  | 0.00013382 |
| {'Other' }      | 128  | 52  | 2.4615 | 0.19637   | 0.0055808  |
| {'<missing>' }  | 27   | 13  | 2.0769 | 0.026469  | 2.3248e-05 |
| {'Totals' }     | 803  | 397 | 2.0227 | NaN       | 0.0092627  |

```
disp(cg)
```

| Category        | BinNumber |
|-----------------|-----------|
| {'Tenant' }     | 1         |
| {'Home Owner' } | 2         |
| {'Other' }      | 3         |

Note that the category grouping table does not include <missing> because this is a reserved bin and users cannot interact directly with the <missing> bin.

```
plotbins(sc, 'ResStatus')
```

## Input Arguments

### sc — Credit scorecard model

creditscorecard object

Credit scorecard model, specified as a `creditscorecard` object. Use `creditscorecard` to create a `creditscorecard` object.

### PredictorName — Predictor name

character vector

Predictor name, specified using a character vector containing the name of the predictor. `PredictorName` is case-sensitive.

Data Types: char

### Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1`, `Value1`, ..., `NameN`, `ValueN`.

Example: `bi = bininfo(sc, PredictorName, 'Statistics', 'WOE', 'Totals', 'On')`

### Statistics — List of statistics to include for bin information

{'Odds', 'WOE', 'InfoValue'} (default) | character vector with values 'Odds', 'WOE', 'InfoValue', 'Entropy', 'Gini', 'Chi2' | cell array of character vectors with values 'Odds', 'WOE', 'InfoValue', 'Entropy', 'Gini', 'Chi2'

List of statistics to include in the bin information, specified as the comma-separated pair consisting of 'Statistics' and a character vector or a cell array of character vectors. For more information, see "Statistics for a Credit Scorecard" on page 19-1864. Possible values are:

- 'Odds' — Odds information is the ratio of "Goods" over "Bads."
- 'WOE' — Weight of Evidence. The WOE Statistic measures the deviation between the distribution of "Goods" and "Bads."
- 'InfoValue' — Information value. Closely tied to the WOE, it is a statistic used to determine how strong a predictor is to use in the fitting model. It measures how strong the deviation is between the distributions of "Goods" and "Bads." However, bins with only "Good" or only "Bad" observations do lead to an infinite Information Value. Consider modifying the bins in those cases by using `modifybins` or `autobinning`.
- 'Entropy' — Entropy is a measure of unpredictability contained in the bins. The more the number of "Goods" and "Bads" differ within the bins, the lower the entropy.
- 'Gini' — Measure of statistical dispersion or inequality within a sample of data.
- 'Chi2' — Measure of statistical difference and independence between groups.

---

**Note** Avoid having bins with frequencies of zero because they lead to infinite or undefined (NaN) statistics. Use `modifybins` or `autobinning` to modify bins.

---

Data Types: char | cell

**Totals — Indicator to include row of totals at bottom information table**

'On' (default) | character vector with values 'On', 'Off'

Indicator to include a row of totals at the bottom of the information table, specified as the comma-separated pair consisting of 'Totals' and a character vector with values On or Off.

Data Types: char

**Output Arguments****bi — Bin information**

table

Bin information, returned as a table. The bin information table contains one row per bin and a row of totals. The columns contain bin descriptions, frequencies of “Good” and “Bad,” and bin statistics. Avoid having bins with frequencies of zero because they lead to infinite or undefined (NaN) statistics. Use `modifybins` or `autobinning` to modify bins.

---

**Note** When creating the `creditscorecard` object with `creditscorecard`, if the optional name-value pair argument `WeightsVar` was used to specify observation (sample) weights, then the `bi` table contains weighted counts.

---

**bm — Binning map or rules**

vector of cut points for numeric predictors | table of category groupings for categorical predictors

Binning map or rules, returned as a vector of cut points for numeric predictors, or a table of category groupings for categorical predictors. For more information, see `modifybins`.

**mv — Binning minimum and maximum values**

numeric array

Binning minimum and maximum values (as set or defined by the user), returned as a numeric array. The `mv` output argument is set to an empty array for categorical predictors.

**More About****Statistics for a Credit Scorecard**

Weight of Evidence (WOE) is a measure of the difference of the distribution of “Goods” and “Bads” within a bin.

Suppose the predictor's data takes on  $M$  possible values  $b_1, \dots, b_M$ . For binned data,  $M$  is a small number. The response takes on two values, “Good” and “Bad.” The frequency table of the data is given by:

|     | Good | Bad | Total |
|-----|------|-----|-------|
| b1: | n11  | n12 | n1    |
| b2: | n21  | n22 | n2    |
| bM: | nM1  | nM2 | nM    |

|        | Good  | Bad  | Total  |
|--------|-------|------|--------|
| Total: | nGood | nBad | nTotal |

The Weight of Evidence (WOE) is defined for each data value  $b_i$  as

$$\text{WOE}(i) = \log((n_{i1}/n_{\text{Good}})/(n_{i2}/n_{\text{Bad}})).$$

If you define

$$p_{\text{Good}}(i) = n_{i1}/n_{\text{Good}}, \quad p_{\text{Bad}}(i) = n_{i2}/n_{\text{Bad}}$$

then  $p_{\text{Good}}(i)$  is the proportion of “Good” observations that take on the value  $b_i$ , and similarly for  $p_{\text{Bad}}(i)$ . In other words,  $p_{\text{Good}}(i)$  gives the distribution of good observations over the  $M$  observed values of the predictor, and similarly for  $p_{\text{Bad}}(i)$ . With this, an equivalent formula for the WOE is

$$\text{WOE}(i) = \log(p_{\text{Good}}(i)/p_{\text{Bad}}(i)).$$

Using the same frequency table, the odds for row  $i$  are defined as

$$\text{Odds}(i) = n_{i1} / n_{i2},$$

and the odds for the sample are defined as

$$\text{Odds}_{\text{Total}} = n_{\text{Good}} / n_{\text{Bad}}.$$

For each row  $i$ , you can also compute its contribution to the total Information Value, given by

$$\text{InfoValue}(i) = (p_{\text{Good}}(i) - p_{\text{Bad}}(i)) * \text{WOE}(i),$$

and the total Information Value is simply the sum of all the  $\text{InfoValue}(i)$  terms. (A nansum is returned to discard contributions from rows with no observations at all.)

Likewise, for each row  $i$ , we can compute its contribution to the total Entropy, given by

$$\text{Entropy}(i) = -1/\log(2)*(n_{i1}/n_i*\log(n_{i1}/n_i)+n_{i2}/n_i*\log(n_{i2}/n_i)),$$

and the total Entropy is simply the weighted sum of the row entropies,

$$\text{Entropy} = \sum(n_i/n_{\text{Total}} * \text{Entropy}(i)), \quad i = 1..M.$$

Chi2 is computed pairwise for each pair of bins and measures the statistical difference between two groups when splitting or merging bins and is defined as:

$$\text{Chi2} = \sum(\sum((A_{ij} - E_{ij})^2/E_{ij}, j=1..k), i=m,m+1).$$

For more information on splitting and merging bins, see Split on page 19-1888 and Merge on page 19-1891.

Gini ratio is a measure of the parent node, that is, of the given bins/categories prior to splitting or merging. The Gini ratio is defined as:

$$\text{Gr} = 1 - G_{\text{hat}}/G_p$$

$G_{\text{hat}}$  is the weighted Gini measure for the current split or merge:

$$G_{\text{hat}} = \sum((n_j/N) * G_j, j=1..m).$$

For more information on splitting and merging bins, see Split on page 19-1888 and Merge on page 19-1891.

### Using bininfo with Weights

When observation weights are defined using the optional `WeightsVar` argument when creating a `creditscorecard` object, instead of counting the rows that are good or bad in each bin, the `bininfo` function accumulates the weight of the rows that are good or bad in each bin.

The “frequencies” reported are no longer the basic “count” of rows, but the “cumulative weight” of the rows that are good or bad and fall in a particular bin. Once these “weighted frequencies” are known, all other relevant statistics (`Good`, `Bad`, `Odds`, `WOE`, and `InfoValue`) are computed with the usual formulas. For more information, see “Credit Scorecard Modeling Using Observation Weights” on page 8-54.

### Introduced in R2014b

# autobinning

Perform automatic binning of given predictors

## Syntax

```
sc = autobinning(sc)
sc = autobinning(sc,PredictorNames)
sc = autobinning( ____,Name,Value)
```

## Description

`sc = autobinning(sc)` performs automatic binning of all predictors.

Automatic binning finds binning maps or rules to bin numeric data and to group categories of categorical data. The binning rules are stored in the `creditscorecard` object. To apply the binning rules to the `creditscorecard` object data, or to a new dataset, use `bindata`.

`sc = autobinning(sc,PredictorNames)` performs automatic binning of the predictors given in `PredictorNames`.

Automatic binning finds binning maps or rules to bin numeric data and to group categories of categorical data. The binning rules are stored in the `creditscorecard` object. To apply the binning rules to the `creditscorecard` object data, or to a new dataset, use `bindata`.

`sc = autobinning( ____,Name,Value)` performs automatic binning of the predictors given in `PredictorNames` using optional name-value pair arguments. See the name-value argument `Algorithm` for a description of the supported binning algorithms.

Automatic binning finds binning maps or rules to bin numeric data and to group categories of categorical data. The binning rules are stored in the `creditscorecard` object. To apply the binning rules to the `creditscorecard` object data, or to a new dataset, use `bindata`.

## Examples

### Perform Automatic Binning Using the Defaults

Create a `creditscorecard` object using the `CreditCardData.mat` file to load the data (using a dataset from Refaat 2011).

```
load CreditCardData
sc = creditscorecard(data, 'IDVar', 'CustID');
```

Perform automatic binning using the default options. By default, `autobinning` bins all predictors and uses the `Monotone` algorithm.

```
sc = autobinning(sc);
```

Use `bininfo` to display the binned data for the predictor `CustAge`.

```
bi = bininfo(sc, 'CustAge')
```

```
bi=8x6 table
```

| Bin             | Good | Bad | Odds   | WOE       | InfoValue |
|-----------------|------|-----|--------|-----------|-----------|
| {'[-Inf,33)'} } | 70   | 53  | 1.3208 | -0.42622  | 0.019746  |
| {'[33,37)'} }   | 64   | 47  | 1.3617 | -0.39568  | 0.015308  |
| {'[37,40)'} }   | 73   | 47  | 1.5532 | -0.26411  | 0.0072573 |
| {'[40,46)'} }   | 174  | 94  | 1.8511 | -0.088658 | 0.001781  |
| {'[46,48)'} }   | 61   | 25  | 2.44   | 0.18758   | 0.0024372 |
| {'[48,58)'} }   | 263  | 105 | 2.5048 | 0.21378   | 0.013476  |
| {'[58,Inf]'} }  | 98   | 26  | 3.7692 | 0.62245   | 0.0352    |
| {'Totals' }     | 803  | 397 | 2.0227 | NaN       | 0.095205  |

Use `plotbins` to display the histogram and WOE curve for the predictor `CustAge`.

```
plotbins(sc, 'CustAge')
```

### Perform Automatic Binning with a Named Predictor Using the Defaults

Create a `creditscorecard` object using the `CreditCardData.mat` file to load the data (using a dataset from Refaat 2011).

```
load CreditCardData
sc = creditscorecard(data);
```

Perform automatic binning for the predictor `CustIncome` using the default options. By default, `autobinning` uses the Monotone algorithm.

```
sc = autobinning(sc, 'CustIncome');
```

Use `bininfo` to display the binned data.

```
bi = bininfo(sc, 'CustIncome')
```

```
bi=8x6 table
```

| Bin                  | Good | Bad | Odds    | WOE       | InfoValue  |
|----------------------|------|-----|---------|-----------|------------|
| {' [-Inf,29000) ' }  | 53   | 58  | 0.91379 | -0.79457  | 0.06364    |
| {' [29000,33000) ' } | 74   | 49  | 1.5102  | -0.29217  | 0.0091366  |
| {' [33000,35000) ' } | 68   | 36  | 1.8889  | -0.06843  | 0.00041042 |
| {' [35000,40000) ' } | 193  | 98  | 1.9694  | -0.026696 | 0.00017359 |
| {' [40000,42000) ' } | 68   | 34  | 2       | -0.011271 | 1.0819e-05 |
| {' [42000,47000) ' } | 164  | 66  | 2.4848  | 0.20579   | 0.0078175  |
| {' [47000,Inf] ' }   | 183  | 56  | 3.2679  | 0.47972   | 0.041657   |
| {' Totals ' }        | 803  | 397 | 2.0227  | NaN       | 0.12285    |

### Perform Automatic Binning Using Two Name-Value Pair Arguments

Create a `creditscorecard` object using the `CreditCardData.mat` file to load the data (using a dataset from Refaat 2011).

```
load CreditCardData
sc = creditscorecard(data);
```

Perform automatic binning for the predictor `CustIncome` using the Monotone algorithm with the initial number of bins set to 20. This example explicitly sets both the `Algorithm` and the `AlgorithmOptions` name-value arguments.

```
AlgoOptions = {'InitialNumBins',20};
sc = autobinning(sc, 'CustIncome', 'Algorithm', 'Monotone', 'AlgorithmOptions', ...
    AlgoOptions);
```

Use `bininfo` to display the binned data. Here, the cut points, which delimit the bins, are also displayed.

```
[bi,cp] = bininfo(sc, 'CustIncome')
```

```
bi=11x6 table
```

| Bin                  | Good | Bad | Odds    | WOE       | InfoValue  |
|----------------------|------|-----|---------|-----------|------------|
| {' [-Inf,19000) ' }  | 2    | 3   | 0.66667 | -1.1099   | 0.0056227  |
| {' [19000,29000) ' } | 51   | 55  | 0.92727 | -0.77993  | 0.058516   |
| {' [29000,31000) ' } | 29   | 26  | 1.1154  | -0.59522  | 0.017486   |
| {' [31000,34000) ' } | 80   | 42  | 1.9048  | -0.060061 | 0.0003704  |
| {' [34000,35000) ' } | 33   | 17  | 1.9412  | -0.041124 | 7.095e-05  |
| {' [35000,40000) ' } | 193  | 98  | 1.9694  | -0.026696 | 0.00017359 |
| {' [40000,42000) ' } | 68   | 34  | 2       | -0.011271 | 1.0819e-05 |
| {' [42000,43000) ' } | 39   | 16  | 2.4375  | 0.18655   | 0.001542   |

```

{'[43000,47000)'} 125    50    2.5    0.21187    0.0062972
{'[47000,Inf]'}  183    56    3.2679  0.47972    0.041657
{'Totals'}       803   397    2.0227    NaN        0.13175

```

```
cp = 9×1
```

```

19000
29000

34000
35000
40000
42000
43000
47000

```

### Perform Automatic Binning Using Multiple Name-Value Pair Arguments

This example shows how to use the autobinning default Monotone algorithm and the `AlgorithmOptions` name-value pair arguments associated with the Monotone algorithm. The `AlgorithmOptions` for the Monotone algorithm are three name-value pair parameters: 'InitialNumBins', 'Trend', and 'SortCategories'. 'InitialNumBins' and 'Trend' are applicable for numeric predictors and 'Trend' and 'SortCategories' are applicable for categorical predictors.

Create a `creditscorecard` object using the `CreditCardData.mat` file to load the data (using a dataset from Refaat 2011).

```
load CreditCardData
sc = creditscorecard(data, 'IDVar', 'CustID');
```

Perform automatic binning for the numeric predictor `CustIncome` using the Monotone algorithm with 20 bins. This example explicitly sets both the `Algorithm` argument and the `AlgorithmOptions` name-value arguments for 'InitialNumBins' and 'Trend'.

```
AlgoOptions = {'InitialNumBins',20,'Trend','Increasing'};

sc = autobinning(sc,'CustIncome','Algorithm','Monotone',...
    'AlgorithmOptions',AlgoOptions);
```

Use `bininfo` to display the binned data.

```
bi = bininfo(sc,'CustIncome')
```

```
bi=11×6 table
      Bin          Good    Bad    Odds      WOE      InfoValue
-----
{'[-Inf,19000)'}    2     3  0.66667  -1.1099  0.0056227
{'[19000,29000)'}  51    55  0.92727  -0.77993  0.058516
{'[29000,31000)'}  29    26  1.1154   -0.59522  0.017486

## Perform Automatic Binning for Multiple Predictors

Create a `creditscorecard` object using the `CreditCardData.mat` file to load the data (using a dataset from Refaat 2011).

```
load CreditCardData
sc = creditscorecard(data, 'IDVar', 'CustID');
```

Perform automatic binning for the predictor `CustIncome` and `CustAge` using the default Monotone algorithm with `AlgorithmOptions` for `InitialNumBins` and `Trend`.

```
AlgoOptions = {'InitialNumBins',20,'Trend','Increasing'};
sc = autobinning(sc,{'CustAge','CustIncome'},'Algorithm','Monotone',...
    'AlgorithmOptions',AlgoOptions);
```

Use `bininfo` to display the binned data.

```
bi1 = bininfo(sc, 'CustIncome')
```

```
bi1=11x6 table
      Bin          Good    Bad    Odds      WOE      InfoValue
-----
{ '[-Inf,19000)' }      2      3    0.66667   -1.1099   0.0056227

```

### Perform Automatic Binning for a Categorical Predictor Using the Defaults

Create a `creditscorecard` object using the `CreditCardData.mat` file to load the data (using a dataset from Refaat 2011).

```
load CreditCardData
sc = creditscorecard(data);
```

Perform automatic binning for the predictor that is a categorical predictor called `ResStatus` using the default options. By default, `autobinning` uses the Monotone algorithm.

```
sc = autobinning(sc, 'ResStatus');
```

Use `bininfo` to display the binned data.

```
bi = bininfo(sc, 'ResStatus')
```

```
bi=4x6 table
      Bin          Good    Bad    Odds      WOE      InfoValue
-----
{ 'Tenant'   }    307    167    1.8383  -0.095564  0.0036638
{ 'Home Owner' }    365    177    2.0621   0.019329  0.0001682
{ 'Other'    }    131     53    2.4717   0.20049   0.0059418
{ 'Totals'   }    803    397    2.0227      NaN   0.0097738
```

### Perform Automatic Binning for a Categorical Predictor Using Name-Value Pair Arguments

This example shows how to modify the data (for this example only) to illustrate binning categorical predictors using the Monotone algorithm.

Create a `creditscorecard` object using the `CreditCardData.mat` file to load the data (using a dataset from Refaat 2011).

```
load CreditCardData
```

Add two new categories and updating the response variable.

```
newdata = data;
rng('default'); %for reproducibility
Predictor = 'ResStatus';
Status     = newdata.status;
NumObs     = length(newdata.(Predictor));
Ind1 = randi(NumObs,100,1);
Ind2 = randi(NumObs,100,1);
newdata.(Predictor)(Ind1) = 'Subtenant';
newdata.(Predictor)(Ind2) = 'Coowner';
```

```
Status(Ind1) = randi(2,100,1)-1;
Status(Ind2) = randi(2,100,1)-1;
```

```
newdata.status = Status;
```

Update the `creditscorecard` object using the `newdata` and plot the bins for a later comparison.

```
scnew = creditscorecard(newdata, 'IDVar', 'CustID');
[bi, cg] = bininfo(scnew, Predictor)
```

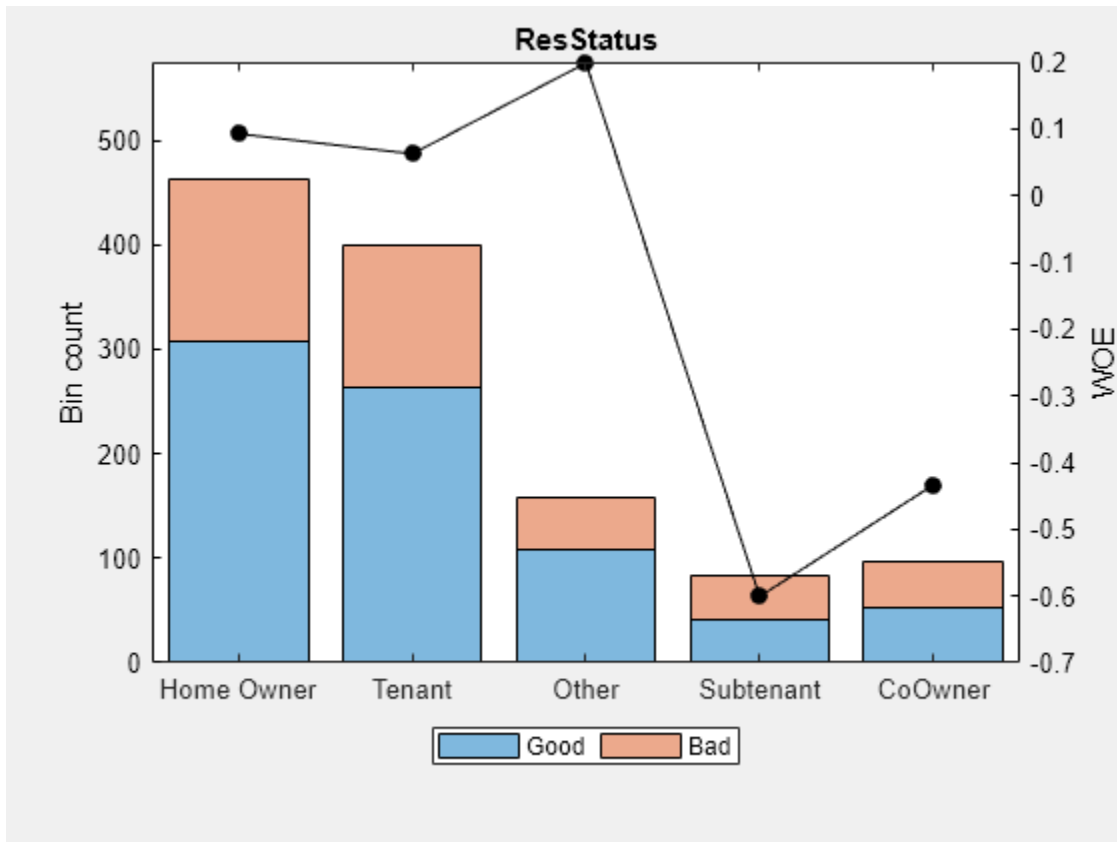

`bi=6x6 table`

| Bin             | Good | Bad | Odds   | WOE      | InfoValue |
|-----------------|------|-----|--------|----------|-----------|
| {'Home Owner' } | 308  | 154 | 2      | 0.092373 | 0.0032392 |
| {'Tenant' }     | 264  | 136 | 1.9412 | 0.06252  | 0.0012907 |
| {'Other' }      | 109  | 49  | 2.2245 | 0.19875  | 0.0050386 |
| {'Subtenant' }  | 42   | 42  | 1      | -0.60077 | 0.026813  |
| {'CoOwner' }    | 52   | 44  | 1.1818 | -0.43372 | 0.015802  |
| {'Totals' }     | 775  | 425 | 1.8235 | NaN      | 0.052183  |

`cg=5x2 table`

| Category        | BinNumber |
|-----------------|-----------|
| {'Home Owner' } | 1         |
| {'Tenant' }     | 2         |
| {'Other' }      | 3         |
| {'Subtenant' }  | 4         |
| {'CoOwner' }    | 5         |

```
plotbins(scnew, Predictor)
```

Perform automatic binning for the categorical Predictor using the default Monotone algorithm with the AlgorithmOptions name-value pair arguments for 'SortCategories' and 'Trend'.

```
AlgoOptions = {'SortCategories','Goods','Trend','Increasing'};
```

```
scnew = autobinning(scnew,Predictor,'Algorithm','Monotone',...  
    'AlgorithmOptions',AlgoOptions);
```

Use bininfo to display the bin information. The second output parameter 'cg' captures the bin membership, which is the bin number that each group belongs to.

```
[bi,cg] = bininfo(scnew,Predictor)
```

bi=4x6 table

| Bin        | Good | Bad | Odds   | WOE      | InfoValue |
|------------|------|-----|--------|----------|-----------|
| {'Group1'} | 42   | 42  | 1      | -0.60077 | 0.026813  |
| {'Group2'} | 52   | 44  | 1.1818 | -0.43372 | 0.015802  |
| {'Group3'} | 681  | 339 | 2.0088 | 0.096788 | 0.0078459 |
| {'Totals'} | 775  | 425 | 1.8235 | NaN      | 0.05046   |

cg=5x2 table

| Category       | BinNumber |
|----------------|-----------|
| {'Subtenant' } | 1         |

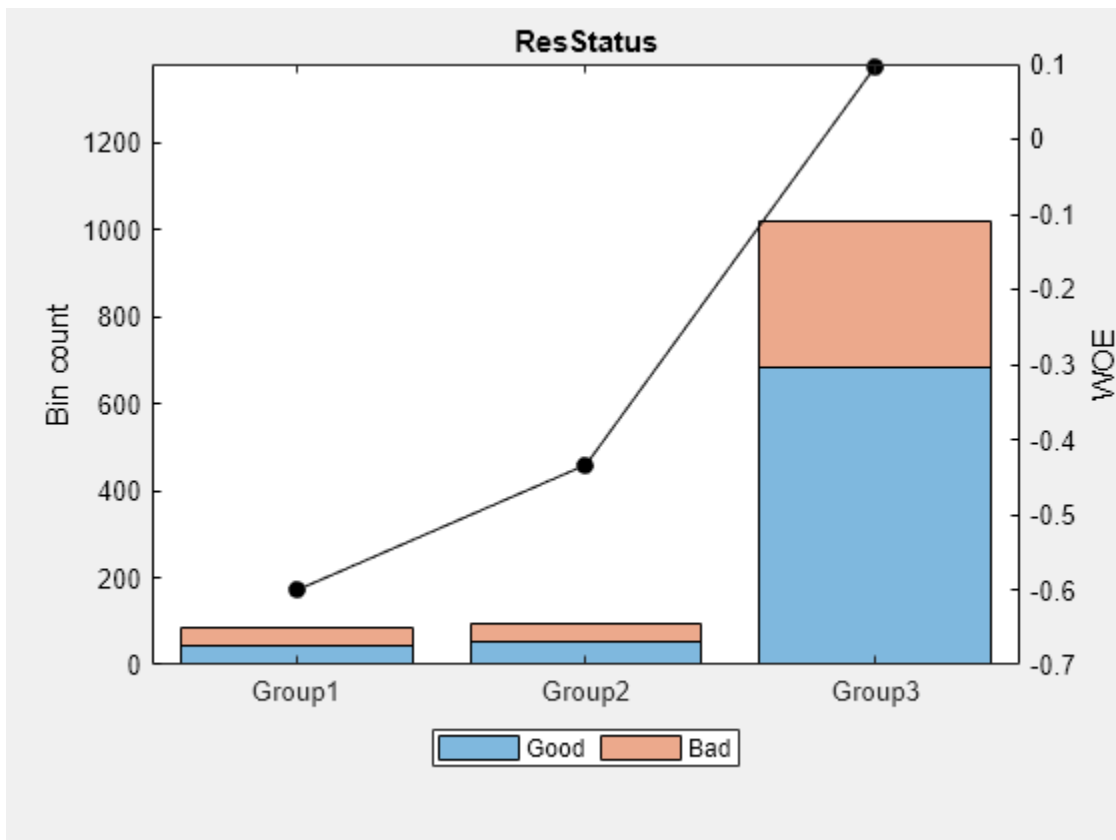

```

{'CoOwner' } 2
{'Other' } 3
{'Tenant' } 3
{'Home Owner' } 3

```

Plot bins and compare with the histogram plotted pre-binning.

```
plotbins(scnew, Predictor)
```

### Perform Automatic Binning When Using Missing Data

Create a `creditscorecard` object using the `CreditCardData.mat` file to load the dataMissing with missing values.

```
load CreditCardData.mat
head(dataMissing,5)
```

ans=5×11 table

| CustID | CustAge | TmAtAddress | ResStatus   | EmpStatus | CustIncome | TmWBank | Other |
|--------|---------|-------------|-------------|-----------|------------|---------|-------|
| 1      | 53      | 62          | <undefined> | Unknown   | 50000      | 55      | Ye    |
| 2      | 61      | 22          | Home Owner  | Employed  | 52000      | 25      | Ye    |
| 3      | 47      | 30          | Tenant      | Employed  | 37000      | 61      | No    |

|   |     |    |            |          |       |    |
|---|-----|----|------------|----------|-------|----|
| 4 | NaN | 75 | Home Owner | Employed | 53000 | 20 |
| 5 | 68  | 56 | Home Owner | Employed | 53000 | 14 |

```
fprintf('Number of rows: %d\n',height(dataMissing))
```

```
Number of rows: 1200
```

```
fprintf('Number of missing values CustAge: %d\n',sum(ismissing(dataMissing.CustAge)))
```

```
Number of missing values CustAge: 30
```

```
fprintf('Number of missing values ResStatus: %d\n',sum(ismissing(dataMissing.ResStatus)))
```

```
Number of missing values ResStatus: 40
```

Use `creditscorecard` with the name-value argument `'BinMissingData'` set to `true` to bin the missing numeric and categorical data in a separate bin.

```
sc = creditscorecard(dataMissing,'BinMissingData',true);
disp(sc)
```

```
creditscorecard with properties:
```

```

    GoodLabel: 0
    ResponseVar: 'status'
    WeightsVar: ''
    VarNames: {1x11 cell}
    NumericPredictors: {1x7 cell}
    CategoricalPredictors: {'ResStatus' 'EmpStatus' 'OtherCC'}
    BinMissingData: 1
    IDVar: ''
    PredictorVars: {1x10 cell}
    Data: [1200x11 table]
```

Perform automatic binning using the Merge algorithm.

```
sc = autobinning(sc,'Algorithm','Merge');
```

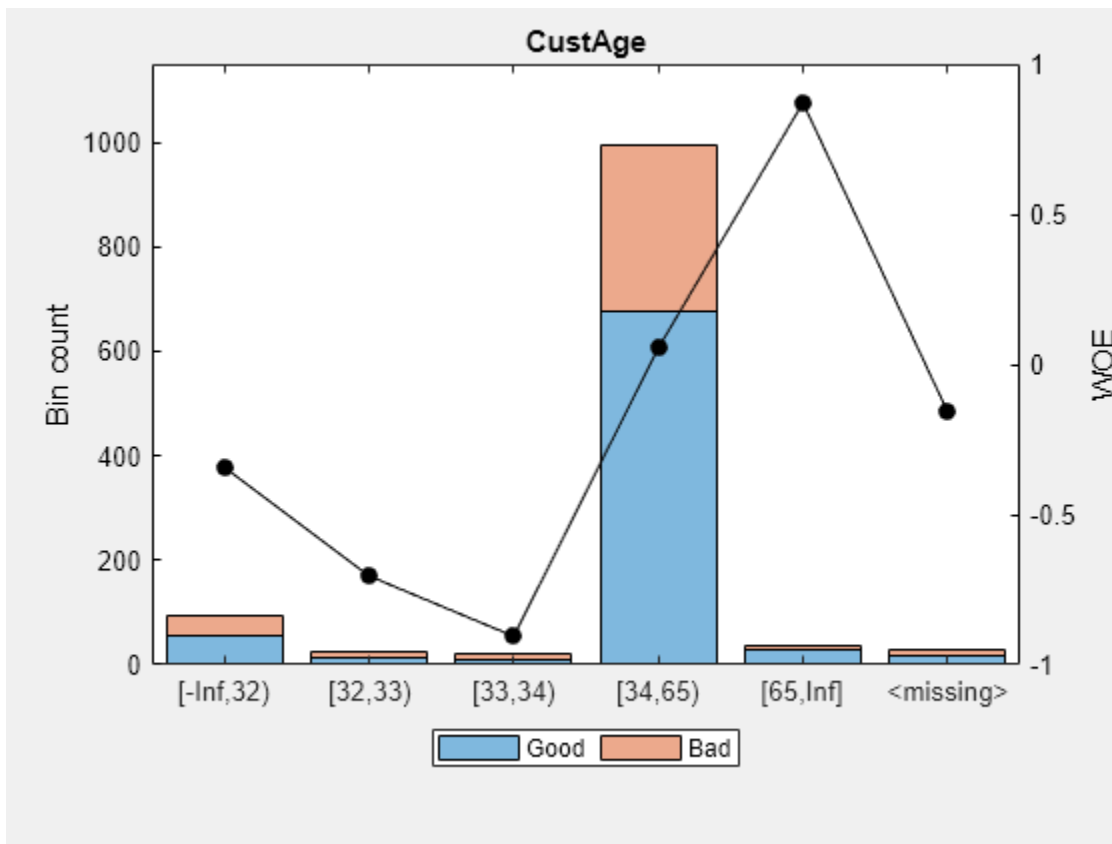

Display bin information for numeric data for `'CustAge'` that includes missing data in a separate bin labelled `<missing>` and this is the last bin. No matter what binning algorithm is used in `autobinning`, the algorithm operates on the non-missing data and the bin for the `<missing>` numeric values for a predictor is always the last bin.

```
[bi,cp] = bininfo(sc,'CustAge');
disp(bi)
```

| Bin             | Good | Bad | Odds    | WOE      | InfoValue  |
|-----------------|------|-----|---------|----------|------------|
| {'[-Inf,32)'} } | 56   | 39  | 1.4359  | -0.34263 | 0.0097643  |
| {'[32,33)'} }   | 13   | 13  | 1       | -0.70442 | 0.011663   |
| {'[33,34)'} }   | 9    | 11  | 0.81818 | -0.90509 | 0.014934   |
| {'[34,65)'} }   | 677  | 317 | 2.1356  | 0.054351 | 0.002424   |
| {'[65,Inf]'} }  | 29   | 6   | 4.8333  | 0.87112  | 0.018295   |
| {'<missing>'} } | 19   | 11  | 1.7273  | -0.15787 | 0.00063885 |
| {'Totals' } }   | 803  | 397 | 2.0227  | NaN      | 0.057718   |

```
plotbins(sc,'CustAge')
```

Display bin information for categorical data for 'ResStatus' that includes missing data in a separate bin labelled <missing> and this is the last bin. No matter what binning algorithm is used in autobinning, the algorithm operates on the non-missing data and the bin for the <missing> categorical values for a predictor is always the last bin.

```
[bi,cg] = bininfo(sc, 'ResStatus');
disp(bi)
```

| Bin            | Good | Bad | Odds   | WOE       | InfoValue  |
|----------------|------|-----|--------|-----------|------------|
| {'Group1' }    | 648  | 332 | 1.9518 | -0.035663 | 0.0010449  |
| {'Group2' }    | 128  | 52  | 2.4615 | 0.19637   | 0.0055808  |
| {'<missing>' } | 27   | 13  | 2.0769 | 0.026469  | 2.3248e-05 |
| {'Totals' }    | 803  | 397 | 2.0227 | NaN       | 0.0066489  |

```
plotbins(sc, 'ResStatus')
```

### Perform Automatic Binning Using the Split Algorithm

This example demonstrates using the 'Split' algorithm with categorical and numeric predictors. Load the `CreditCardData.mat` dataset and modify so that it contains four categories for the predictor 'ResStatus' to demonstrate how the split algorithm works.

```
load CreditCardData.mat
x = data.ResStatus;
Ind = find(x == 'Tenant');
Nx = length(Ind);
x(Ind(1:floor(Nx/3))) = 'Subletter';
data.ResStatus = x;
```

Create a `creditscorecard` and use `bininfo` to display the 'Statistics'.

```
sc = creditscorecard(data, 'IDVar', 'CustID');
[bin, cg1] = bininfo(sc, 'ResStatus', 'Statistics', {'Odds', 'WOE', 'InfoValue'});
disp(bin)
```

| Bin            | Good | Bad | Odds   | WOE      | InfoValue |
|----------------|------|-----|--------|----------|-----------|
| {'Home Owner'} | 365  | 177 | 2.0621 | 0.019329 | 0.0001682 |
| {'Tenant' }    | 204  | 112 | 1.8214 | -0.1048  | 0.0029415 |
| {'Other' }     | 131  | 53  | 2.4717 | 0.20049  | 0.0059418 |

```

{'Subletter' } 103    55    1.8727   -0.077023   0.00079103
{'Totals'    } 803    397    2.0227           NaN    0.0098426

```

```
disp(cg1)
```

```

      Category      BinNumber
-----
{'Home Owner' }          1
{'Tenant'     }          2
{'Other'      }          3
{'Subletter'  }          4

```

### Using the Split Algorithm with a Categorical Predictor

Apply presorting to the 'ResStatus' category using the default sorting by 'Odds' and specify the 'Split' algorithm.

```

sc = autobinning(sc, 'ResStatus', 'Algorithm', 'split', 'AlgorithmOptions', ...
    {'Measure', 'gini', 'SortCategories', 'odds', 'Tolerance', 1e-4});
[bi2, cg2] = bininfo(sc, 'ResStatus', 'Statistics', {'Odds', 'WOE', 'InfoValue'});
disp(bi2)

```

```

      Bin      Good      Bad      Odds      WOE      InfoValue
-----
{'Group1' } 307      167      1.8383   -0.095564   0.0036638
{'Group2' } 365      177      2.0621    0.019329   0.0001682
{'Group3' } 131       53      2.4717    0.20049    0.0059418
{'Totals' } 803      397      2.0227           NaN    0.0097738

```

```
disp(cg2)
```

```

      Category      BinNumber
-----
{'Tenant'     }          1
{'Subletter'  }          1
{'Home Owner' }          2
{'Other'      }          3

```

### Using the Split Algorithm with a Numeric Predictor

To demonstrate a split for the numeric predictor, 'TmAtAddress', first use autobinning with the default 'Monotone' algorithm.

```

sc = autobinning(sc, 'TmAtAddress');
bi3 = bininfo(sc, 'TmAtAddress', 'Statistics', {'Odds', 'WOE', 'InfoValue'});
disp(bi3)

```

```

      Bin      Good      Bad      Odds      WOE      InfoValue
-----
{'[-Inf,23)' } 239      129      1.8527   -0.087767   0.0023963
{'[23,83)'   } 480      232      2.069    0.02263    0.00030269
{'[83,Inf]'  } 84       36      2.3333    0.14288    0.00199
{'Totals'    } 803      397      2.0227           NaN    0.004689

```

Then use autobinning with the 'Split' algorithm.

```
sc = autobinining(sc, 'TmAtAddress', 'Algorithm', 'Split');
bi4 = bininfo(sc, 'TmAtAddress', 'Statistics', {'Odds', 'WOE', 'InfoValue'});
disp(bi4)
```

| Bin            | Good | Bad | Odds    | WOE       | InfoValue  |
|----------------|------|-----|---------|-----------|------------|
| {'[-Inf,4)'} } | 20   | 12  | 1.6667  | -0.19359  | 0.0010299  |
| {'[4,5)'} }    | 4    | 7   | 0.57143 | -1.264    | 0.015991   |
| {'[5,23)'} }   | 215  | 110 | 1.9545  | -0.034261 | 0.00031973 |
| {'[23,33)'} }  | 130  | 39  | 3.3333  | 0.49955   | 0.0318     |
| {'[33,Inf]'} } | 434  | 229 | 1.8952  | -0.065096 | 0.0023664  |
| {'Totals' }    | 803  | 397 | 2.0227  | NaN       | 0.051507   |

### Perform Automatic Binning Using the Merge Algorithm

Load the `CreditCardData.mat` dataset. This example demonstrates using the 'Merge' algorithm with categorical and numeric predictors.

```
load CreditCardData.mat
```

#### Using the Merge Algorithm with a Categorical Predictor

To merge a categorical predictor, create a `creditscorecard` using default sorting by 'Odds' and then use `bininfo` on the categorical predictor 'ResStatus'.

```
sc = creditscorecard(data, 'IDVar', 'CustID');
[bi1, cg1] = bininfo(sc, 'ResStatus', 'Statistics', {'Odds', 'WOE', 'InfoValue'});
disp(bi1);
```

| Bin             | Good | Bad | Odds   | WOE       | InfoValue |
|-----------------|------|-----|--------|-----------|-----------|
| {'Home Owner' } | 365  | 177 | 2.0621 | 0.019329  | 0.0001682 |
| {'Tenant' }     | 307  | 167 | 1.8383 | -0.095564 | 0.0036638 |
| {'Other' }      | 131  | 53  | 2.4717 | 0.20049   | 0.0059418 |
| {'Totals' }     | 803  | 397 | 2.0227 | NaN       | 0.0097738 |

```
disp(cg1);
```

| Category        | BinNumber |
|-----------------|-----------|
| {'Home Owner' } | 1         |
| {'Tenant' }     | 2         |
| {'Other' }      | 3         |

Use `autobinining` and specify the 'Merge' algorithm.

```
sc = autobinining(sc, 'ResStatus', 'Algorithm', 'Merge');
[bi2, cg2] = bininfo(sc, 'ResStatus', 'Statistics', {'Odds', 'WOE', 'InfoValue'});
disp(bi2)
```

| Bin         | Good | Bad | Odds   | WOE       | InfoValue |
|-------------|------|-----|--------|-----------|-----------|
| {'Group1' } | 672  | 344 | 1.9535 | -0.034802 | 0.0010314 |

```

{'Group2'}    131    53    2.4717    0.20049    0.0059418
{'Totals'}    803   397    2.0227         NaN    0.0069732

```

```
disp(cg2)
```

```

      Category      BinNumber
-----
{'Tenant'   }          1
{'Home Owner'}        1
{'Other'    }          2

```

### Using the Merge Algorithm with a Numeric Predictor

To demonstrate a merge for the numeric predictor, 'TmAtAddress', first use autobinning with the default 'Monotone' algorithm.

```

sc = autobinning(sc, 'TmAtAddress');
bi3 = bininfo(sc, 'TmAtAddress', 'Statistics', {'Odds', 'WOE', 'InfoValue'});
disp(bi3)

```

```

      Bin      Good      Bad      Odds      WOE      InfoValue
-----
{'[-Inf,23)'}  239     129     1.8527    -0.087767    0.0023963
{'[23,83)'}    480     232     2.069     0.02263     0.00030269
{'[83,Inf]'}   84      36     2.3333     0.14288     0.00199
{'Totals'}    803     397     2.0227         NaN     0.004689

```

Then use autobinning with the 'Merge' algorithm.

```

sc = autobinning(sc, 'TmAtAddress', 'Algorithm', 'Merge');
bi4 = bininfo(sc, 'TmAtAddress', 'Statistics', {'Odds', 'WOE', 'InfoValue'});
disp(bi4)

```

```

      Bin      Good      Bad      Odds      WOE      InfoValue
-----
{'[-Inf,28)'}  303     152     1.9934    -0.014566    8.0646e-05
{'[28,30)'}    27      2      13.5      1.8983      0.054264
{'[30,98)'}    428     216     1.9815    -0.020574    0.00022794
{'[98,106)'}   11     13     0.84615   -0.87147     0.016599
{'[106,Inf]'}  34     14     2.4286     0.18288     0.0012942
{'Totals'}    803     397     2.0227         NaN     0.072466

```

## Input Arguments

### sc — Credit scorecard model

creditscorecard object

Credit scorecard model, specified as a creditscorecard object. Use `creditscorecard` to create a creditscorecard object.

### PredictorNames — Predictor or predictors names to automatically bin

character vector | cell array of character vectors

Predictor or predictors names to automatically bin, specified as a character vector or a cell array of character vectors containing the name of the predictor or predictors. PredictorNames are case-

sensitive and when no `PredictorNames` are defined, all predictors in the `PredictorVars` property of the `creditscorecard` object are binned.

Data Types: `char` | `cell`

### Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `sc = autobinning(sc, 'Algorithm', 'EqualFrequency')`

### Algorithm — Algorithm selection

'Monotone' (default) | character vector with values 'Monotone', 'Split', 'Merge', 'EqualFrequency', 'EqualWidth'

Algorithm selection, specified as the comma-separated pair consisting of 'Algorithm' and a character vector indicating which algorithm to use. The same algorithm is used for all predictors in `PredictorNames`. Possible values are:

- 'Monotone' — (default) Monotone Adjacent Pooling Algorithm (MAPA), also known as Maximum Likelihood Monotone Coarse Classifier (MLMCC). Supervised optimal binning algorithm that aims to find bins with a monotone Weight-Of-Evidence (WOE) trend. This algorithm assumes that only neighboring attributes can be grouped. Thus, for categorical predictors, categories are sorted before applying the algorithm (see 'SortCategories' option for `AlgorithmOptions`). For more information, see “Monotone” on page 19-1886.
- 'Split' — Supervised binning algorithm, where a measure is used to split the data into bins. The measures supported by 'Split' are `gini`, `chi2`, `infovalue`, and `entropy`. The resulting split must be such that the gain in the information function is maximized. For more information on these measures, see `AlgorithmOptions` and “Split” on page 19-1888.
- 'Merge' — Supervised automatic binning algorithm, where a measure is used to merge bins into buckets. The measures supported by 'Merge' are `chi2`, `gini`, `infovalue`, and `entropy`. The resulting merging must be such that any pair of adjacent bins is statistically different from each other, according to the chosen measure. For more information on these measures, see `AlgorithmOptions` and “Merge” on page 19-1891.
- 'EqualFrequency' — Unsupervised algorithm that divides the data into a predetermined number of bins that contain approximately the same number of observations. This algorithm is also known as “equal height” or “equal depth.” For categorical predictors, categories are sorted before applying the algorithm (see 'SortCategories' option for `AlgorithmOptions`). For more information, see “Equal Frequency” on page 19-1893.
- 'EqualWidth' — Unsupervised algorithm that divides the range of values in the domain of the predictor variable into a predetermined number of bins of “equal width.” For numeric data, the width is measured as the distance between bin edges. For categorical data, width is measured as the number of categories within a bin. For categorical predictors, categories are sorted before applying the algorithm (see 'SortCategories' option for `AlgorithmOptions`). For more information, see “Equal Width” on page 19-1894.

Data Types: `char`

### AlgorithmOptions — Algorithm options for selected Algorithm

{'InitialNumBins', 10, 'Trend', 'Auto', 'SortCategories', 'Odds'} for Monotone (default) | cell array with {'OptionName', *OptionValue*} for Algorithm options

Algorithm options for the selected Algorithm, specified as the comma-separated pair consisting of 'AlgorithmOptions' and a cell array. Possible values are:

- For Monotone algorithm:
  - {'InitialNumBins', *n*} — Initial number (*n*) of bins (default is 10). 'InitialNumBins' must be an integer > 2. Used for numeric predictors only.
  - {'Trend', 'TrendOption'} — Determines whether the Weight-Of-Evidence (WOE) monotonic trend is expected to be increasing or decreasing. The values for 'TrendOption' are:
    - 'Auto' — (Default) Automatically determines if the WOE trend is increasing or decreasing.
    - 'Increasing' — Look for an increasing WOE trend.
    - 'Decreasing' — Look for a decreasing WOE trend.

The value of the optional input parameter 'Trend' does not necessarily reflect that of the resulting WOE curve. The parameter 'Trend' tells the algorithm to “look for” an increasing or decreasing trend, but the outcome may not show the desired trend. For example, the algorithm cannot find a decreasing trend when the data actually has an increasing WOE trend. For more information on the 'Trend' option, see “Monotone” on page 19-1886.

- {'SortCategories', 'SortOption'} — Used for categorical predictors only. Used to determine how the predictor categories are sorted as a preprocessing step before applying the algorithm. The values of 'SortOption' are:
  - 'Odds' — (default) The categories are sorted by order of increasing values of odds, defined as the ratio of “Good” to “Bad” observations, for the given category.
  - 'Goods' — The categories are sorted by order of increasing values of “Good.”
  - 'Bads' — The categories are sorted by order of increasing values of “Bad.”
  - 'Totals' — The categories are sorted by order of increasing values of total number of observations (“Good” plus “Bad”).
  - 'None' — No sorting is applied. The existing order of the categories is unchanged before applying the algorithm. (The existing order of the categories can be seen in the category grouping optional output from bininfo.)

For more information, see Sort Categories on page 19-1894

- For Split algorithm:
  - {'InitialNumBins', *n*} — Specifies an integer that determines the number ( $n > 0$ ) of bins that the predictor is initially binned into before splitting. Valid for numeric predictors only. Default is 50.
  - {'Measure', *MeasureName*} — Specifies the measure where '*MeasureName*' is one of the following: 'Gini' (default), 'Chi2', 'InfoValue', or 'Entropy'.
  - {'MinBad', *n*} — Specifies the minimum number *n* ( $n \geq 0$ ) of Bads per bin. The default value is 1, to avoid pure bins.
  - {'MaxBad', *n*} — Specifies the maximum number *n* ( $n \geq 0$ ) of Bads per bin. The default value is Inf.
  - {'MinGood', *n*} — Specifies the minimum number *n* ( $n \geq 0$ ) of Goods per bin. The default value is 1, to avoid pure bins.
  - {'MaxGood', *n*} — Specifies the maximum number *n* ( $n \geq 0$ ) of Goods per bin. The default value is Inf.

- `{'MinCount',  $n$ }` — Specifies the minimum number  $n$  ( $n \geq 0$ ) of observations per bin. The default value is 1, to avoid empty bins.
- `{'MaxCount',  $n$ }` — Specifies the maximum number  $n$  ( $n \geq 0$ ) of observations per bin. The default value is `Inf`.
- `{'MaxNumBins',  $n$ }` — Specifies the maximum number  $n$  ( $n \geq 2$ ) of bins resulting from the splitting. The default value is 5.
- `{'Tolerance',  $Tol$ }` — Specifies the minimum gain ( $>0$ ) in the information function, during the iteration scheme, to select the cut-point that maximizes the gain. The default is  $1e-4$ .
- `{'Significance',  $n$ }` — Significance level threshold for the chi-square statistic, above which splitting happens. Values are in the interval  $[0, 1]$ . Default is 0.9 (90% significance level).
- `{'SortCategories', 'SortOption'}` — Used for categorical predictors only. Used to determine how the predictor categories are sorted as a preprocessing step before applying the algorithm. The values of 'SortOption' are:
  - 'Goods' — The categories are sorted by order of increasing values of "Good."
  - 'Bads' — The categories are sorted by order of increasing values of "Bad."
  - 'Odds' — (default) The categories are sorted by order of increasing values of odds, defined as the ratio of "Good" to "Bad" observations, for the given category.
  - 'Totals' — The categories are sorted by order of increasing values of total number of observations ("Good" plus "Bad").
  - 'None' — No sorting is applied. The existing order of the categories is unchanged before applying the algorithm. (The existing order of the categories can be seen in the category grouping optional output from `bininfo`.)

For more information, see Sort Categories on page 19-1894

- For Merge algorithm:
  - `{'InitialNumBins',  $n$ }` — Specifies an integer that determines the number ( $n > 0$ ) of bins that the predictor is initially binned into before merging. Valid for numeric predictors only. Default is 50.
  - `{'Measure',  $MeasureName$ }` — Specifies the measure where ' $MeasureName$ ' is one of the following: 'Chi2' (default), 'Gini', 'InfoValue', or 'Entropy'.
  - `{'MinNumBins',  $n$ }` — Specifies the minimum number  $n$  ( $n \geq 2$ ) of bins that result from merging. The default value is 2.
  - `{'MaxNumBins',  $n$ }` — Specifies the maximum number  $n$  ( $n \geq 2$ ) of bins that result from merging. The default value is 5.
  - `{'Tolerance',  $n$ }` — Specifies the minimum threshold below which merging happens for the information value and entropy statistics. Valid values are in the interval  $(0, 1)$ . Default is  $1e-3$ .
  - `{'Significance',  $n$ }` — Significance level threshold for the chi-square statistic, below which merging happens. Values are in the interval  $[0, 1]$ . Default is 0.9 (90% significance level).
  - `{'SortCategories', 'SortOption'}` — Used for categorical predictors only. Used to determine how the predictor categories are sorted as a preprocessing step before applying the algorithm. The values of 'SortOption' are:
    - 'Goods' — The categories are sorted by order of increasing values of "Good."
    - 'Bads' — The categories are sorted by order of increasing values of "Bad."

- 'Odds' — (default) The categories are sorted by order of increasing values of odds, defined as the ratio of “Good” to “Bad” observations, for the given category.
- 'Totals' — The categories are sorted by order of increasing values of total number of observations (“Good” plus “Bad”).
- 'None' — No sorting is applied. The existing order of the categories is unchanged before applying the algorithm. (The existing order of the categories can be seen in the category grouping optional output from `bininfo`.)

For more information, see Sort Categories on page 19-1894

- For EqualFrequency algorithm:
  - {'NumBins',  $n$ } — Specifies the desired number ( $n$ ) of bins. The default is {'NumBins', 5} and the number of bins must be a positive number.
  - {'SortCategories', 'SortOption'} — Used for categorical predictors only. Used to determine how the predictor categories are sorted as a preprocessing step before applying the algorithm. The values of 'SortOption' are:
    - 'Odds' — (default) The categories are sorted by order of increasing values of odds, defined as the ratio of “Good” to “Bad” observations, for the given category.
    - 'Goods' — The categories are sorted by order of increasing values of “Good.”
    - 'Bads' — The categories are sorted by order of increasing values of “Bad.”
    - 'Totals' — The categories are sorted by order of increasing values of total number of observations (“Good” plus “Bad”).
    - 'None' — No sorting is applied. The existing order of the categories is unchanged before applying the algorithm. (The existing order of the categories can be seen in the category grouping optional output from `bininfo`.)

For more information, see Sort Categories on page 19-1894

- For EqualWidth algorithm:
  - {'NumBins',  $n$ } — Specifies the desired number ( $n$ ) of bins. The default is {'NumBins', 5} and the number of bins must be a positive number.
  - {'SortCategories', 'SortOption'} — Used for categorical predictors only. Used to determine how the predictor categories are sorted as a preprocessing step before applying the algorithm. The values of 'SortOption' are:
    - 'Odds' — (default) The categories are sorted by order of increasing values of odds, defined as the ratio of “Good” to “Bad” observations, for the given category.
    - 'Goods' — The categories are sorted by order of increasing values of “Good.”
    - 'Bads' — The categories are sorted by order of increasing values of “Bad.”
    - 'Totals' — The categories are sorted by order of increasing values of total number of observations (“Good” plus “Bad”).
    - 'None' — No sorting is applied. The existing order of the categories is unchanged before applying the algorithm. (The existing order of the categories can be seen in the category grouping optional output from `bininfo`.)

For more information, see Sort Categories on page 19-1894

```
Example: sc =
autobinning(sc, 'CustAge', 'Algorithm', 'Monotone', 'AlgorithmOptions',
{'Trend', 'Increasing'})
```

Data Types: cell

### **Display** — Indicator to display information on status of the binning process at command line

'Off' (default) | character vector with values 'On', 'Off'

Indicator to display the information on status of the binning process at command line, specified as the comma-separated pair consisting of 'Display' and a character vector with a value of 'On' or 'Off'.

Data Types: char

## **Output Arguments**

### **sc** — Credit scorecard model

creditscorecard object

Credit scorecard model, returned as an updated `creditscorecard` object containing the automatically determined binning maps or rules (cut points or category groupings) for one or more predictors. For more information on using the `creditscorecard` object, see `creditscorecard`.

---

**Note** If you have previously used the `modifybins` function to manually modify bins, these changes are lost when running `autobinning` because all the data is automatically binned based on internal `autobinning` rules.

---

## **More About**

### **Monotone**

The 'Monotone' algorithm is an implementation of the Monotone Adjacent Pooling Algorithm (MAPA), also known as Maximum Likelihood Monotone Coarse Classifier (MLMCC); see Anderson or Thomas in the "References" on page 19-1895.

### **Preprocessing**

During the preprocessing phase, preprocessing of numeric predictors consists in applying equal frequency binning, with the number of bins determined by the 'InitialNumBins' parameter (the default is 10 bins). The preprocessing of categorical predictors consists in sorting the categories according to the 'SortCategories' criterion (the default is to sort by odds in increasing order). Sorting is not applied to ordinal predictors. See the "Sort Categories" on page 19-1894 definition or the description of `AlgorithmOptions` option for 'SortCategories' for more information.

### **Main Algorithm**

The following example illustrates how the 'Monotone' algorithm arrives at cut points for numeric data.

| Bin                      | Good | Bad | Iteration1 | Iteration2 | Iteration3 | Iteration4 |
|--------------------------|------|-----|------------|------------|------------|------------|
| ' [-<br>Inf, 33000)<br>' | 127  | 107 | 0.543      |            |            |            |
| ' [33000, 38<br>000) '   | 194  | 90  | 0.620      | 0.683      |            |            |
| ' [38000, 42<br>000) '   | 135  | 78  | 0.624      | 0.662      |            |            |
| ' [42000, 47<br>000) '   | 164  | 66  | 0.645      | 0.678      | 0.713      |            |
| ' [47000, In<br>f] '     | 183  | 56  | 0.669      | 0.700      | 0.740      | 0.766      |

Initially, the numeric data is preprocessed with an equal frequency binning. In this example, for simplicity, only the five initial bins are used. The first column indicates the equal frequency bin ranges, and the second and third columns have the “Good” and “Bad” counts per bin. (The number of observations is 1,200, so a perfect equal frequency binning would result in five bins with 240 observations each. In this case, the observations per bin do not match 240 exactly. This is a common situation when the data has repeated values.)

Monotone finds break points based on the cumulative proportion of “Good” observations. In the 'Iteration1' column, the first value (0.543) is the number of “Good” observations in the first bin (127), divided by the total number of observations in the bin (127+107). The second value (0.620) is the number of “Good” observations in bins 1 and 2, divided by the total number of observations in bins 1 and 2. And so forth. The first cut point is set where the minimum of this cumulative ratio is found, which is in the first bin in this example. This is the end of iteration 1.

Starting from the second bin (the first bin after the location of the minimum value in the previous iteration), cumulative proportions of “Good” observations are computed again. The second cut point is set where the minimum of this cumulative ratio is found. In this case, it happens to be in bin number 3, therefore bins 2 and 3 are merged.

The algorithm proceeds the same way for two more iterations. In this particular example, in the end it only merges bins 2 and 3. The final binning has four bins with cut points at 33,000, 42,000, and 47,000.

For categorical data, the only difference is that the preprocessing step consists in reordering the categories. Consider the following categorical data:

| Bin          | Good | Bad | Odds  |
|--------------|------|-----|-------|
| 'Home Owner' | 365  | 177 | 2.062 |
| 'Tenant'     | 307  | 167 | 1.838 |
| 'Other'      | 131  | 53  | 2.474 |

The preprocessing step, by default, sorts the categories by 'Odds'. (See the “Sort Categories” on page 19-1894 definition or the description of `AlgorithmOptions` option for 'SortCategories' for more information.) Then, it applies the same steps described above, shown in the following table:

| Bin          | Good | Bad | Odds  | Iteration1 | Iteration2 | Iteration3 |
|--------------|------|-----|-------|------------|------------|------------|
| 'Tenant'     | 307  | 167 | 1.838 | 0.648      |            |            |
| 'Home Owner' | 365  | 177 | 2.062 | 0.661      | 0.673      |            |
| 'Other'      | 131  | 53  | 2.472 | 0.669      | 0.683      | 0.712      |

In this case, the Monotone algorithm would not merge any categories. The only difference, compared with the data before the application of the algorithm, is that the categories are now sorted by 'Odds'.

In both the numeric and categorical examples above, the implicit 'Trend' choice is 'Increasing'. (See the description of `AlgorithmOptions` option for the 'Monotone' 'Trend' option.) If you set the trend to 'Decreasing', the algorithm looks for the maximum (instead of the minimum) cumulative ratios to determine the cut points. In that case, at iteration 1, the maximum would be in the last bin, which would imply that all bins should be merged into a single bin. Binning into a single bin is a total loss of information and has no practical use. Therefore, when the chosen trend leads to a single bin, the Monotone implementation rejects it, and the algorithm returns the bins found after the preprocessing step. This state is the initial equal frequency binning for numeric data and the sorted categories for categorical data. The implementation of the Monotone algorithm by default uses a heuristic to identify the trend ('Auto' option for 'Trend').

## Split

Split is a supervised automatic binning algorithm, where a measure is used to split the data into buckets. The supported measures are `gini`, `chi2`, `infovalue`, and `entropy`.

Internally, the split algorithm proceeds as follows:

- 1 All categories are merged into a single bin.
- 2 At the first iteration, all potential cutpoint indices are tested to see which one results in the maximum increase in the information function (Gini, InfoValue, Entropy, or Chi2). That cutpoint is then selected, and the bin is split.
- 3 The same procedure is reiterated for the next sub-bins.
- 4 The algorithm stops when the maximum number of bins is reached or when the splitting does not result in any additional change in the information change function.

The following table for a categorical predictor summarizes the values of the change function at each iteration. In this example, 'Gini' is the measure of choice, such that the goal is to see a decrease of the Gini measure at each iteration.

| Iteration<br>0 Bin<br>Number | Member       | Gini | Iteration<br>1 Bin<br>Number | Member       | Gini    | Iteration<br>2 Bin<br>Number | Member       | Gini    |
|------------------------------|--------------|------|------------------------------|--------------|---------|------------------------------|--------------|---------|
| 1                            | 'Tenant'     |      | 1                            | 'Tenant'     |         | 1                            | 'Tenant'     | 0.45638 |
| 1                            | 'Subletter'  |      | 1                            | 'Subletter'  | 0.44789 | 1                            | 'Subletter'  |         |
| 1                            | 'Home Owner' |      | 1                            | 'Home Owner' |         | 2                            | 'Home Owner' | 0.43984 |
| 1                            | 'Other'      |      | 2                            | 'Other'      | 0.41015 | 3                            | 'Other'      | 0.41015 |

| Iteration<br>0 Bin<br>Number | Member | Gini     | Iteration<br>1 Bin<br>Number | Member | Gini     | Iteration<br>2 Bin<br>Number | Member | Gini     |
|------------------------------|--------|----------|------------------------------|--------|----------|------------------------------|--------|----------|
| Total Gini                   |        | 0.442765 |                              |        | 0.442102 |                              |        | 0.441822 |
| Relative<br>Change           |        | 0        |                              |        | 0.001498 |                              |        | 0.002128 |

The relative change at iteration  $i$  is with respect to the Gini measure of the entire bins at iteration  $i-1$ . The final result corresponds to that from the last iteration which, in this example, is iteration 2.

The following table for a numeric predictor summarizes the values of the change function at each iteration. In this example, 'Gini' is the measure of choice, such that the goal is to see a decrease of the Gini measure at each iteration. Since most numeric predictors in datasets contain many bins, there is a preprocessing step where the data is pre-binned into 50 equal-frequency bins. This makes the pool of valid cutpoints to choose from for splitting smaller and more manageable.

| Iteration<br>0 Bin<br>Number | Member | Gini     | Iteration<br>1 Bin<br>Number | Gini     | Iteration<br>2 Bin<br>Number | Gini     | Iteration<br>3 Bin<br>Number | Gini     |
|------------------------------|--------|----------|------------------------------|----------|------------------------------|----------|------------------------------|----------|
| 1                            | '21'   |          | ' [-<br>Inf, 47]<br>'        | 0.473897 | ' [-<br>Inf, 47]<br>'        | 0.473897 | ' [-<br>Inf, 35]<br>'        | 0.494941 |
| 1                            | '22'   |          | ' [47, In<br>f] '            | 0.385238 | ' [47, 61<br>] '             | 0.407072 | ' [35,<br>47] '              | 0.463201 |
| 1                            | '23'   |          |                              |          | ' [61, In<br>f] '            | 0.208795 | ' [47,<br>61] '              | 0.407072 |
| 1                            | '74'   |          |                              | 0        |                              |          | ' [61, In<br>f] '            | 0.208795 |
| Total Gini                   |        | 0.442765 |                              | 0.435035 |                              | 0.432048 |                              | 0.430511 |
| Relative<br>Change           |        | 0        |                              | 0.01746  |                              | 0.006867 |                              | 0.0356   |

The resulting split must be such that the information function (content) increases. As such, the best split is the one that results in the maximum information gain. The information functions supported are:

- Gini: Each split results in an increase in the Gini Ratio, defined as:

$$G_r = 1 - G_{\text{hat}}/G_p$$

$G_p$  is the Gini measure of the parent node, that is, of the given bins/categories prior to splitting.  
 $G_{\text{hat}}$  is the weighted Gini measure for the current split:

$$G_{\text{hat}} = \text{Sum}((n_j/N) * \text{Gini}(j), j=1..m)$$

where

$n_j$  is the total number of observations in the  $j$ th bin.

$N$  is the total number of observations in the dataset.

$m$  is the number of splits for the given variable.

$Gini(j)$  is the Gini measure for the  $j$ th bin.

The Gini measure for the split/node  $j$  is:

$$Gini(j) = 1 - (G_j^2 + B_j^2) / (n_j)^2$$

where  $G_j, B_j$  = Number of Goods and Bads for bin  $j$ .

- **InfoValue:** The information value for each split results in an increase in the total information. The split that is retained is the one which results in the maximum gain, within the acceptable gain tolerance. The Information Value (IV) for a given observation  $j$  is defined as:

$$IV = \sum (pG_i - pB_i) * \log(pG_i/pB_i), i=1..n$$

where

$pG_i$  is the distribution of Goods at observation  $i$ , that is  $Goods(i)/Total\_Goods$ .

$pB_i$  is the distribution of Bads at observation  $i$ , that is  $Bads(i)/Total\_Bads$ .

$n$  is the total number of bins.

- **Entropy:** Each split results in a decrease in entropy variance defined as:

$$E = -\sum(n_i * E_i, i=1..n)$$

where

$n_i$  is the total count for bin  $i$ , that is  $(n_i = G_i + B_i)$ .

$E_i$  is the entropy for row (or bin)  $i$ , defined as:

$$E_i = -\sum(G_i * \log_2(G_i/n_i) + B_i * \log_2(B_i/n_i)) / N, i=1..n$$

- **Chi2:** Chi2 is computed pairwise for each pair of bins and measures the statistical difference between two groups. Splitting is selected at a point (cutpoint or category indexing) where the maximum Chi2 value is:

$$Chi2 = \sum(\sum((A_{ij} - E_{ij})^2 / E_{ij}, j=1..k), i=m, m+1)$$

where

$m$  takes values from 1 ...  $n-1$ , where  $n$  is the number of bins.

$k$  is the number of classes. Here  $k = 2$  for the (Goods, Bads).

$A_{ij}$  is the number of observations in bin  $i$ ,  $j$ th class.

$E_{ij}$  is the expected frequency of  $A_{ij}$ , which is equal to  $(R_i * C_j) / N$ .

$R_i$  is the number of observations in bin  $i$ , which is equal to  $\sum(A_{ij}, j=1..k)$ .

$C_j$  is the number of observations in the  $j$ th class, which is equal to  $\sum(A_{ij}, I = m, m+1)$ .

$N$  is the total number of observations, which is equal to  $\sum(C_j, j=1..k)$ .

The Chi2 measure for the entire sample (as opposed to the pairwise Chi2 measure for adjacent bins) is:

$$\text{Chi2} = \text{sum}(\text{sum}((A_{ij} - E_{ij})^2/E_{ij}, j=1..k), i=1..n)$$

## Merge

Merge is a supervised automatic binning algorithm, where a measure is used to merge bins into buckets. The supported measures are chi2, gini, infovalue, and entropy.

Internally, the merge algorithm proceeds as follows:

- 1 All categories are initially in separate bins.
- 2 The user selected information function (Chi2, Gini, InfoValue or Entropy) is computed for any pair of adjacent bins.
- 3 At each iteration, the pair with the smallest information change measured by the selected information function is merged.
- 4 The merging continues until either:
  - a All pairwise information values are greater than the threshold set by the significance level or the relative change is smaller than the tolerance.
  - b If at the end, the number of bins is still greater than the MaxNumBins allowed, merging is forced until there are at most MaxNumBins bins. Similarly, merging stops when there are only MinNumBins bins.
- 5 For categorical, original bins/categories are pre-sorted according to the sorting of choice set by the user. For numeric data, the data is preprocessed to get InitialNumBins bins of equal frequency before the merging algorithm starts.

The following table for a categorical predictor summarizes the values of the change function at each iteration. In this example, 'Chi2' is the measure of choice. The default sorting by Odds is applied as a preprocessing step. The Chi2 value reported below at row  $i$  is for bins  $i$  and  $i+1$ . The significance level is 0.9 (90%), so that the inverse Chi2 value is 2.705543. This is the threshold below which adjacent pairs of bins are merged. The minimum number of bins is 2.

| Iteration<br>0 Bin<br>Number | Member          | Chi2     | Iteration<br>1 Bin<br>Number | Member          | Chi2     | Iteration<br>2 Bin<br>Number | Member          | Chi2     |
|------------------------------|-----------------|----------|------------------------------|-----------------|----------|------------------------------|-----------------|----------|
| 1                            | 'Tenant'        | 1.007613 | 1                            | 'Tenant'        | 0.795920 | 1                            | 'Tenant'        |          |
| 2                            | 'Subletter'     | 0.257347 | 2                            | 'Subletter'     |          | 1                            | 'Subletter'     |          |
| 3                            | 'Home<br>Owner' | 1.566330 | 2                            | 'Home<br>Owner' | 1.522914 | 1                            | 'Home<br>Owner' | 1.797395 |
| 4                            | 'Other'         |          | 3                            | 'Other'         |          | 2                            | 'Other'         |          |
| Total Chi2                   |                 | 2.573943 |                              |                 | 2.317717 |                              |                 | 1.797395 |

The following table for a numeric predictor summarizes the values of the change function at each iteration. In this example, 'Chi2' is the measure of choice.

| Iteration 0 Bin Number | Chi2     | Iteration 1 Bins | Chi2    |     | Final Iteration Bins | Chi2   |
|------------------------|----------|------------------|---------|-----|----------------------|--------|
| '[- Inf,22]'           | 0.11814  | '[- Inf,22]'     | 0.11814 |     | '[- Inf,33]'         | 8.4876 |
| '[22,23]'              | 1.6464   | '[22,23]'        | 1.6464  |     | '[33, 48]'           | 7.9369 |
| ...                    |          | ...              |         |     | '[48,64]'            | 9.956  |
| '[58,59]'              | 0.311578 | '[58,59]'        | 0.27489 |     | '[64,65]'            | 9.6988 |
| '[59,60]'              | 0.068978 | '[59,61]'        | 1.8403  |     | '[65,Inf]'           | NaN    |
| '[60,61]'              | 1.8709   | '[61,62]'        | 5.7946  | ... |                      |        |
| '[61,62]'              | 5.7946   | ...              |         |     |                      |        |
| ...                    |          | '[69,70]'        | 6.4271  |     |                      |        |
| '[69,70]'              | 6.4271   | '[70,Inf]'       | NaN     |     |                      |        |
| '[70,Inf]'             | NaN      |                  |         |     |                      |        |
|                        |          |                  |         |     |                      |        |
| <i>Total Chi2</i>      | 67.467   |                  | 67.399  |     |                      | 23.198 |

The resulting merging must be such that any pair of adjacent bins is statistically different from each other, according to the chosen measure. The measures supported for Merge are:

- Chi2: Chi2 is computed pairwise for each pair of bins and measures the statistical difference between two groups. Merging is selected at a point (cutpoint or category indexing) where the maximum Chi2 value is:

$$\text{Chi2} = \text{sum}(\text{sum}((A_{ij} - E_{ij})^2/E_{ij}, j=1..k), i=m,m+1)$$

where

m takes values from 1 ... n-1, and n is the number of bins.

k is the number of classes. Here k = 2 for the (Goods, Bads).

$A_{ij}$  is the number of observations in bin i, jth class.

$E_{ij}$  is the expected frequency of  $A_{ij}$ , which is equal to  $(R_i * C_j) / N$ .

$R_i$  is the number of observations in bin i, which is equal to  $\text{sum}(A_{ij}, j=1..k)$ .

$C_j$  is the number of observations in the jth class, which is equal to  $\text{sum}(A_{ij}, I = m,m+1)$ .

N is the total number of observations, which is equal to  $\text{sum}(C_j, j=1..k)$ .

The Chi2 measure for the entire sample (as opposed to the pairwise Chi2 measure for adjacent bins) is:

$$\text{Chi2} = \text{sum}(\text{sum}((A_{ij} - E_{ij})^2/E_{ij}, j=1..k), i=1..n)$$

- Gini: Each merge results in a decrease in the Gini Ratio, defined as:

$$G_r = 1 - G_{\text{hat}}/G_p$$

$G_p$  is the Gini measure of the parent node, that is, of the given bins/categories prior to merging.  
 $G_{\hat{}}$  is the weighted Gini measure for the current merge:

$$G_{\hat{}} = \text{Sum}((n_j/N) * \text{Gini}(j), j=1..m)$$

where

$n_j$  is the total number of observations in the  $j$ th bin.

$N$  is the total number of observations in the dataset.

$m$  is the number of merges for the given variable.

$\text{Gini}(j)$  is the Gini measure for the  $j$ th bin.

The Gini measure for the merge/node  $j$  is:

$$\text{Gini}(j) = 1 - (G_j^2 + B_j^2) / (n_j)^2$$

where  $G_j, B_j$  = Number of Goods and Bads for bin  $j$ .

- **InfoValue:** The information value for each merge will result in a decrease in the total information. The merge that is retained is the one which results in the minimum gain, within the acceptable gain tolerance. The Information Value (IV) for a given observation  $j$  is defined as:

$$IV = \text{sum}((pG_i - pB_i) * \log(pG_i/pB_i), i=1..n)$$

where

$pG_i$  is the distribution of Goods at observation  $i$ , that is  $\text{Goods}(i)/\text{Total\_Goods}$ .

$pB_i$  is the distribution of Bads at observation  $i$ , that is  $\text{Bads}(i)/\text{Total\_Bads}$ .

$n$  is the total number of bins.

- **Entropy:** Each merge results in an increase in entropy variance defined as:

$$E = -\text{sum}(n_i * E_i, i=1..n)$$

where

$n_i$  is the total count for bin  $i$ , that is  $(n_i = G_i + B_i)$ .

$E_i$  is the entropy for row (or bin)  $i$ , defined as:

$$E_i = -\text{sum}(G_i * \log_2(G_i/n_i) + B_i * \log_2(B_i/n_i)) / N, \\ i=1..n$$

---

**Note** When using the Merge algorithm, if there are pure bins (bins that have either zero count of Goods or zero count of Bads), the statistics such as Information Value and Entropy have non-finite values. To account for this, a frequency shift of .5 is applied for computing various statistics whenever the algorithm finds pure bins.

---

## Equal Frequency

Unsupervised algorithm that divides the data into a predetermined number of bins that contain approximately the same number of observations.

EqualFrequency is defined as:

Let  $v[1], v[2], \dots, v[N]$  be the sorted list of different values or categories observed in the data. Let  $f[i]$  be the frequency of  $v[i]$ . Let  $F[k] = f[1] + \dots + f[k]$  be the cumulative sum of frequencies up to the  $k$ th sorted value. Then  $F[N]$  is the same as the total number of observations.

Define  $\text{AvgFreq} = F[N] / \text{NumBins}$ , which is the ideal average frequency per bin after binning. The  $n$ th cut point index is the index  $k$  such that the distance  $\text{abs}(F[k] - n * \text{AvgFreq})$  is minimized.

This rule attempts to match the cumulative frequency up to the  $n$ th bin. If a single value contains too many observations, equal frequency bins are not possible, and the above rule yields less than  $\text{NumBins}$  total bins. In that case, the algorithm determines  $\text{NumBins}$  bins by breaking up bins, in the order in which the bins were constructed.

The preprocessing of categorical predictors consists in sorting the categories according to the 'SortCategories' criterion (the default is to sort by odds in increasing order). Sorting is not applied to ordinal predictors. See the "Sort Categories" on page 19-1894 definition or the description of AlgorithmOptions option for 'SortCategories' for more information.

### Equal Width

Unsupervised algorithm that divides the range of values in the domain of the predictor variable into a predetermined number of bins of "equal width." For numeric data, the width is measured as the distance between bin edges. For categorical data, width is measured as the number of categories within a bin.

The EqualWidth option is defined as:

For numeric data, if `MinValue` and `MaxValue` are the minimum and maximum data values, then

$$\text{Width} = (\text{MaxValue} - \text{MinValue}) / \text{NumBins}$$

and the `CutPoints` are set to `MinValue + Width`, `MinValue + 2*Width`, ... `MaxValue - Width`. If a `MinValue` or `MaxValue` have not been specified using the `modifybins` function, the EqualWidth option sets `MinValue` and `MaxValue` to the minimum and maximum values observed in the data.

For categorical data, if there are  $\text{NumCats}$  numbers of original categories, then

$$\text{Width} = \text{NumCats} / \text{NumBins},$$

and set cut point indices to the rounded values of  $\text{Width}$ ,  $2 * \text{Width}$ , ...,  $\text{NumCats} - \text{Width}$ , plus 1.

The preprocessing of categorical predictors consists in sorting the categories according to the 'SortCategories' criterion (the default is to sort by odds in increasing order). Sorting is not applied to ordinal predictors. See the "Sort Categories" on page 19-1894 definition or the description of AlgorithmOptions option for 'SortCategories' for more information.

### Sort Categories

As a preprocessing step for categorical data, 'Monotone', 'EqualFrequency', and 'EqualWidth' support the 'SortCategories' input. This serves the purpose of reordering the categories before applying the main algorithm. The default sorting criterion is to sort by 'Odds'. For example, suppose that the data originally looks like this:

| Bin          | Good | Bad | Odds  |
|--------------|------|-----|-------|
| 'Home Owner' | 365  | 177 | 2.062 |
| 'Tenant'     | 307  | 167 | 1.838 |
| 'Other'      | 131  | 53  | 2.472 |

After the preprocessing step, the rows would be sorted by 'Odds' and the table looks like this:

| Bin          | Good | Bad | Odds  |
|--------------|------|-----|-------|
| 'Tenant'     | 307  | 167 | 1.838 |
| 'Home Owner' | 365  | 177 | 2.062 |
| 'Other'      | 131  | 53  | 2.472 |

The three algorithms only merge adjacent bins, so the initial order of the categories makes a difference for the final binning. The 'None' option for 'SortCategories' would leave the original table unchanged. For a description of the sorting criteria supported, see the description of the AlgorithmOptions option for 'SortCategories'.

Upon the construction of a scorecard, the initial order of the categories, before any algorithm or any binning modifications are applied, is the order shown in the first output of `bininfo`. If the bins have been modified (either manually with `modifybins` or automatically with `autobinning`), use the optional output (cg, 'category grouping') from `bininfo` to get the current order of the categories.

The 'SortCategories' option has no effect on categorical predictors for which the 'Ordinal' parameter is set to true (see the 'Ordinal' input parameter in MATLAB categorical arrays for `categorical`). Ordinal data has a natural order, which is honored in the preprocessing step of the algorithms by leaving the order of the categories unchanged. Only categorical predictors whose 'Ordinal' parameter is false (default option) are subject to reordering of categories according to the 'SortCategories' criterion.

### Using autobinning with Weights

When observation weights are defined using the optional `WeightsVar` argument when creating a `creditscorecard` object, instead of counting the rows that are good or bad in each bin, the `autobinning` function accumulates the weight of the rows that are good or bad in each bin.

The "frequencies" reported are no longer the basic "count" of rows, but the "cumulative weight" of the rows that are good or bad and fall in a particular bin. Once these "weighted frequencies" are known, all other relevant statistics (Good, Bad, Odds, WOE, and InfoValue) are computed with the usual formulas. For more information, see "Credit Scorecard Modeling Using Observation Weights" on page 8-54.

### **Introduced in R2014b**

# probdefault

Likelihood of default for given data set

## Syntax

```
pd = probdefault(sc)
pd = probdefault(sc,data)
```

## Description

`pd = probdefault(sc)` computes the probability of default for `sc`, the data used to build the `creditscorecard` object.

`pd = probdefault(sc,data)` computes the probability of default for a given data set specified using the optional argument `data`.

By default, the data used to build the `creditscorecard` object are used. You can also supply input data, to which the same computation of probability of default is applied.

## Examples

### Compute Probability for Default Using Credit ScoreCard Data

Create a `creditscorecard` object using the `CreditCardData.mat` file to load the data (using a dataset from Refaat 2011).

```
load CreditCardData
sc = creditscorecard(data, 'IDVar', 'CustID')

sc =
  creditscorecard with properties:

      GoodLabel: 0
      ResponseVar: 'status'
      WeightsVar: ''
      VarNames: {1x11 cell}
      NumericPredictors: {1x6 cell}
      CategoricalPredictors: {'ResStatus' 'EmpStatus' 'OtherCC'}
      BinMissingData: 0
      IDVar: 'CustID'
      PredictorVars: {1x9 cell}
      Data: [1200x11 table]
```

Perform automatic binning using the default options. By default, autobinning uses the Monotone algorithm.

```
sc = autobinning(sc);
```

Fit the model.

```
sc = fitmodel(sc);
```

1. Adding CustIncome, Deviance = 1490.8527, Chi2Stat = 32.588614, PValue = 1.1387992e-08
2. Adding TmWBank, Deviance = 1467.1415, Chi2Stat = 23.711203, PValue = 1.1192909e-06
3. Adding AMBalance, Deviance = 1455.5715, Chi2Stat = 11.569967, PValue = 0.00067025601

```

## Compute Probability for Default Using Credit ScoreCard Data When Using the 'BinMissingData' Option

This example describes both the assignment of points for missing data when the 'BinMissingData' option is set to `true`, and the corresponding computation of probabilities of default.

- Predictors that have missing data in the training set have an explicit bin for `<missing>` with corresponding points in the final scorecard. These points are computed from the Weight-of-Evidence (WOE) value for the `<missing>` bin and the logistic model coefficients. For scoring purposes, these points are assigned to missing values and to out-of-range values, and the final score is mapped to a probability of default when using `probdefault`.
- Predictors with no missing data in the training set have no `<missing>` bin, therefore no WOE can be estimated from the training data. By default, the points for missing and out-of-range values are set to `NaN`, and this leads to a score of `NaN` when running `score`. For predictors that have no explicit `<missing>` bin, use the name-value argument 'Missing' in `formatpoints` to indicate how missing data should be treated for scoring purposes. The final score is then mapped to a probability of default when using `probdefault`.

Create a `creditscorecard` object using the `CreditCardData.mat` file to load the `dataMissing` with missing values.

```
load CreditCardData.mat
head(dataMissing,5)
```

```
ans=5x11 table
```

|   | CustID | CustAge | TmAtAddress | ResStatus   | EmpStatus | CustIncome | TmWBank | OtherCC |
|---|--------|---------|-------------|-------------|-----------|------------|---------|---------|
| 1 |        | 53      | 62          | <undefined> | Unknown   | 50000      | 55      | Yes     |
| 2 |        | 61      | 22          | Home Owner  | Employed  | 52000      | 25      | Yes     |
| 3 |        | 47      | 30          | Tenant      | Employed  | 37000      | 61      | No      |
| 4 |        | NaN     | 75          | Home Owner  | Employed  | 53000      | 20      | Yes     |
| 5 |        | 68      | 56          | Home Owner  | Employed  | 53000      | 14      | Yes     |

Use `creditscorecard` with the name-value argument 'BinMissingData' set to `true` to bin the missing numeric or categorical data in a separate bin. Apply automatic binning.

```
sc = creditscorecard(dataMissing,'IDVar','CustID','BinMissingData',true);
sc = autobinning(sc);
```

```
disp(sc)
```

```
creditscorecard with properties:
```

```

    GoodLabel: 0
    ResponseVar: 'status'
    WeightsVar: ''
    VarNames: {1x11 cell}
    NumericPredictors: {1x6 cell}
    CategoricalPredictors: {'ResStatus' 'EmpStatus' 'OtherCC'}
    BinMissingData: 1
    IDVar: 'CustID'
    PredictorVars: {1x9 cell}
    Data: [1200x11 table]
```

Set a minimum value of 0 for `CustAge` and `CustIncome`. With this, any negative age or income information becomes invalid or "out-of-range". For scoring and probability of default computations, out-of-range values are given the same points as missing values.

```
sc = modifybins(sc, 'CustAge', 'MinValue', 0);
sc = modifybins(sc, 'CustIncome', 'MinValue', 0);
```

Display bin information for numeric data for '`CustAge`' that includes missing data in a separate bin labelled `<missing>`.

```
bi = bininfo(sc, 'CustAge');
disp(bi)
```

| Bin             | Good | Bad | Odds   | WOE      | InfoValue  |
|-----------------|------|-----|--------|----------|------------|

| { '[46,48)' }   | 59   | 25  | 2.36   | 0.15424  | 0.0016199  |
| { '[48,51)' }   | 99   | 41  | 2.4146 | 0.17713  | 0.0035449  |
| { '[51,58)' }   | 157  | 62  | 2.5323 | 0.22469  | 0.0088407  |
| { '[58,Inf]' }  | 93   | 25  | 3.72   | 0.60931  | 0.032198   |
| { '<missing>' } | 19   | 11  | 1.7273 | -0.15787 | 0.00063885 |
| { 'Totals' }    | 803  | 397 | 2.0227 | NaN      | 0.087112   |

Display bin information for categorical data for '`ResStatus`' that includes missing data in a separate bin labelled `<missing>`.

```
bi = bininfo(sc, 'ResStatus');
disp(bi)
```

| Bin              | Good | Bad | Odds   | WOE       | InfoValue  |
|------------------|------|-----|--------|-----------|------------|
| { 'Tenant' }     | 296  | 161 | 1.8385 | -0.095463 | 0.0035249  |
| { 'Home Owner' } | 352  | 171 | 2.0585 | 0.017549  | 0.00013382 |
| { 'Other' }      | 128  | 52  | 2.4615 | 0.19637   | 0.0055808  |
| { '<missing>' }  | 27   | 13  | 2.0769 | 0.026469  | 2.3248e-05 |
| { 'Totals' }     | 803  | 397 | 2.0227 | NaN       | 0.0092627  |

For the '`CustAge`' and '`ResStatus`' predictors, there is missing data (NaNs and `<undefined>`) in the training data, and the binning process estimates a WOE value of -0.15787 and 0.026469 respectively for missing data in these predictors, as shown above.

For `EmpStatus` and `CustIncome` there is no explicit bin for missing values because the training data has no missing values for these predictors.

```
bi = bininfo(sc, 'EmpStatus');
disp(bi)
```

Use `fitmodel` to fit a logistic regression model using Weight of Evidence (WOE) data. `fitmodel` internally transforms all the predictor variables into WOE values, using the bins found with the automatic binning process. `fitmodel` then fits a logistic regression model using a stepwise method (by default). For predictors that have missing data, there is an explicit `<missing>` bin, with a corresponding WOE value computed from the data. When using `fitmodel`, the corresponding WOE value for the `<missing>` bin is applied when performing the WOE transformation.

```
[sc,mdl] = fitmodel(sc);
```

Scale the scorecard points by the "points, odds, and points to double the odds (PDO)" method using the `'PointsOddsAndPDO'` argument of `formatpoints`. Suppose that you want a score of 500 points to have odds of 2 (twice as likely to be good than to be bad) and that the odds double every 50 points (so that 550 points would have odds of 4).

Display the scorecard showing the scaled points for predictors retained in the fitting model.

```
sc = formatpoints(sc, 'PointsOddsAndPDO', [500 2 50]);
PointsInfo = displaypoints(sc)
```

```
PointsInfo=38x3 table

    {'EmpStatus'}    {'<missing>' }    NaN
    :
```

Notice that points for the <missing> bin for CustAge and ResStatus are explicitly shown (as 64.9836 and 74.1250, respectively). These points are computed from the WOE value for the <missing> bin and the logistic model coefficients.

For predictors that have no missing data in the training set, there is no explicit <missing> bin. By default the points are set to NaN for missing data, and they lead to a score of NaN when running `score`. For predictors that have no explicit <missing> bin, use the name-value argument 'Missing' in `formatpoints` to indicate how missing data should be treated for scoring purposes.

For the purpose of illustration, take a few rows from the original data as test data and introduce some missing data. Also introduce some invalid, or out-of-range, values. For numeric data, values below the minimum (or above the maximum) allowed are considered invalid, such as a negative value for age (recall 'MinValue' was earlier set to 0 for CustAge and CustIncome). For categorical data, invalid values are categories not explicitly included in the scorecard, for example, a residential status not previously mapped to scorecard categories, such as "House", or a meaningless string such as "abc123".

```
tdata = dataMissing(11:18, mdl.PredictorNames); % Keep only the predictors retained in the model
% Set some missing values
tdata.CustAge(1) = NaN;
tdata.ResStatus(2) = '<undefined>';
tdata.EmpStatus(3) = '<undefined>';
tdata.CustIncome(4) = NaN;
% Set some invalid values
tdata.CustAge(5) = -100;
tdata.ResStatus(6) = 'House';
tdata.EmpStatus(7) = 'Freelancer';
tdata.CustIncome(8) = -1;
disp(tdata)
```

| CustAge | ResStatus   | EmpStatus   | CustIncome | TmWBank | OtherCC | AMBalance |
|---------|-------------|-------------|------------|---------|---------|-----------|
| NaN     | Tenant      | Unknown     | 34000      | 44      | Yes     | 119.8     |
| 48      | <undefined> | Unknown     | 44000      | 14      | Yes     | 403.62    |
| 65      | Home Owner  | <undefined> | 48000      | 6       | No      | 111.88    |
| 44      | Other       | Unknown     | NaN        | 35      | No      | 436.41    |
| -100    | Other       | Employed    | 46000      | 16      | Yes     | 162.21    |
| 33      | House       | Employed    | 36000      | 36      | Yes     | 845.02    |
| 39      | Tenant      | Freelancer  | 34000      | 40      | Yes     | 756.26    |
| 24      | Home Owner  | Employed    | -1         | 19      | Yes     | 449.61    |

Score the new data and see how points are assigned for missing `CustAge` and `ResStatus`, because we have an explicit bin with points for `<missing>`. However, for `EmpStatus` and `CustIncome` the score function sets the points to `NaN`. The corresponding probabilities of default are also set to `NaN`.

Use the name-value argument `'Missing'` in `formatpoints` to choose how to assign points to missing values for predictors that do not have an explicit `<missing>` bin. In this example, use the `'MinPoints'` option for the `'Missing'` argument. The minimum points for `EmpStatus` in the scorecard displayed above are 58.8072, and for `CustIncome` the minimum points are 29.3753. All rows now have a score and a corresponding probability of default.

```
sc = formatpoints(sc, 'Missing', 'MinPoints');
[Scores,Points] = score(sc,tdata);
disp(Scores)

## Input Arguments

### **sc** — Credit scorecard model

creditscorecard object

Credit scorecard model, specified as a `creditscorecard` object. To create this object, use `creditscorecard`.

### **data** — Dataset to apply probability of default rules

table

(Optional) Dataset to apply probability of default rules, specified as a MATLAB table, where each row corresponds to individual observations. The data must contain columns for each of the predictors in the `creditscorecard` object.

Data Types: table

## Output Arguments

### pd — Probability of default

array

Probability of default, returned as a NumObs-by-1 numerical array of default probabilities.

## More About

### Default Probability

After the unscaled scores are computed (see “Algorithms for Computing and Scaling Scores” on page 19-1721), the probability of the points being “Good” is represented by the following formula:

$$\text{ProbGood} = 1. / (1 + \exp(-\text{UnscaledScores}))$$

Thus, the probability of default is

$$\text{pd} = 1 - \text{ProbGood}$$

### Introduced in R2015a

## validatemodel

Validate quality of credit scorecard model

### Syntax

```
Stats = validatemodel(sc)
Stats = validatemodel(sc,data)
[Stats,T] = validatemodel(sc,Name,Value)
[Stats,T,hf] = validatemodel(sc,Name,Value)
```

### Description

`Stats = validatemodel(sc)` validates the quality of the `creditscorecard` model.

By default, the data used to build the `creditscorecard` object is used. You can also supply input data to which the validation is applied.

`Stats = validatemodel(sc,data)` validates the quality of the `creditscorecard` model for a given data set specified using the optional argument `data`.

`[Stats,T] = validatemodel(sc,Name,Value)` validates the quality of the `creditscorecard` model using the optional name-value pair arguments, and returns `Stats` and `T` outputs.

`[Stats,T,hf] = validatemodel(sc,Name,Value)` validates the quality of the `creditscorecard` model using the optional name-value pair arguments, and returns the figure handle `hf` to the CAP, ROC, and KS plots.

### Examples

#### Validate a Credit Scorecard Model

Create a `creditscorecard` object using the `CreditCardData.mat` file to load the data (using a dataset from Refaat 2011).

```
load CreditCardData
sc = creditscorecard(data, 'IDVar','CustID')

sc =
  creditscorecard with properties:

      GoodLabel: 0
      ResponseVar: 'status'
      WeightsVar: ''
      VarNames: {1x11 cell}
      NumericPredictors: {1x6 cell}
      CategoricalPredictors: {'ResStatus' 'EmpStatus' 'OtherCC'}
      BinMissingData: 0
      IDVar: 'CustID'
      PredictorVars: {1x9 cell}
      Data: [1200x11 table]
```

Perform automatic binning using the default options. By default, autobinning uses the Monotone algorithm.

```
sc = autobinning(sc);
```

Fit the model.

```
sc = fitmodel(sc);
```

1. Adding CustIncome, Deviance = 1490.8527, Chi2Stat = 32.588614, PValue = 1.1387992e-08
2. Adding TmWBank, Deviance = 1467.1415, Chi2Stat = 23.711203, PValue = 1.1192909e-06

### Validate a Credit Score Card Model With Weights

Use the `CreditCardData.mat` file to load the data (`dataWeights`) that contains a column (`RowWeights`) for the weights (using a dataset from Refaat 2011).

```
load CreditCardData
```

Create a `creditscorecard` object using the optional name-value pair argument for `'WeightsVar'`.

```
sc = creditscorecard(dataWeights, 'IDVar', 'CustID', 'WeightsVar', 'RowWeights')
```

```
sc =
creditscorecard with properties:
    GoodLabel: 0
    ResponseVar: 'status'
    WeightsVar: 'RowWeights'
    VarNames: {1x12 cell}
    NumericPredictors: {1x6 cell}
    CategoricalPredictors: {'ResStatus' 'EmpStatus' 'OtherCC'}
    BinMissingData: 0
    IDVar: 'CustID'
    PredictorVars: {1x9 cell}
    Data: [1200x12 table]
```

Perform automatic binning.

```
sc = autobinning(sc)
```

```
sc =
creditscorecard with properties:
    GoodLabel: 0
    ResponseVar: 'status'
    WeightsVar: 'RowWeights'
    VarNames: {1x12 cell}
    NumericPredictors: {1x6 cell}
    CategoricalPredictors: {'ResStatus' 'EmpStatus' 'OtherCC'}
    BinMissingData: 0
    IDVar: 'CustID'
    PredictorVars: {1x9 cell}
    Data: [1200x12 table]
```

Fit the model.

```
sc = fitmodel(sc);
```

1. Adding `CustIncome`, Deviance = 764.3187, Chi2Stat = 15.81927, PValue = 6.968927e-05
2. Adding `TmWBank`, Deviance = 751.0215, Chi2Stat = 13.29726, PValue = 0.0002657942
3. Adding `AMBBalance`, Deviance = 743.7581, Chi2Stat = 7.263384, PValue = 0.007037455

Generalized linear regression model:

```
logit(status) ~ 1 + CustIncome + TmWBank + AMBalance  
Distribution = Binomial
```

Estimated Coefficients:

|             | Estimate | SE       | tStat  | pValue     |
|-------------|----------|----------|--------|------------|
| (Intercept) | 0.70642  | 0.088702 | 7.964  | 1.6653e-15 |
| CustIncome  | 1.0268   | 0.25758  | 3.9862 | 6.7132e-05 |
| TmWBank     | 1.0973   | 0.31294  | 3.5063 | 0.0004543  |
| AMBalance   | 1.0039   | 0.37576  | 2.6717 | 0.0075464  |

1200 observations, 1196 error degrees of freedom

Dispersion: 1

Chi<sup>2</sup>-statistic vs. constant model: 36.4, p-value = 6.22e-08

Format the unscaled points.

```
sc = formatpoints(sc, 'PointsOddsAndPDO', [500,2,50]);
```

Score the data.

```
scores = score(sc);
```

Validate the credit scorecard model by generating the CAP, ROC, and KS plots. When the optional name-value pair argument 'WeightsVar' is used to specify observation (sample) weights, the T table uses statistics, sums, and cumulative sums that are weighted counts.

```
[Stats,T] = validatemodel(sc, 'Plot', {'CAP', 'ROC', 'KS'});
```

### Validate a Credit Score Card Model When Using the 'BinMissingData' Option

This example describes both the assignment of points for missing data when the 'BinMissingData' option is set to `true`, and the corresponding computation of model validation statistics.

- Predictors that have missing data in the training set have an explicit bin for `<missing>` with corresponding points in the final scorecard. These points are computed from the Weight-of-Evidence (WOE) value for the `<missing>` bin and the logistic model coefficients. For scoring purposes, these points are assigned to missing values and to out-of-range values, and the final score is used to compute model validation statistics with `validateModel`.
- Predictors with no missing data in the training set have no `<missing>` bin, therefore no WOE can be estimated from the training data. By default, the points for missing and out-of-range values are set to `NaN`, and this leads to a score of `NaN` when running `score`. For predictors that have no explicit `<missing>` bin, use the name-value argument 'Missing' in `formatPoints` to indicate how missing data should be treated for scoring purposes. The final score is used to compute model validation statistics with `validateModel`.

Create a `creditscorecard` object using the `CreditCardData.mat` file to load the `dataMissing` with missing values.

```
load CreditCardData.mat
head(dataMissing,5)
```

ans=5×11 table

|   | CustID | CustAge | TmAtAddress | ResStatus   | EmpStatus | CustIncome | TmWBank | OtherCC |
|---|--------|---------|-------------|-------------|-----------|------------|---------|---------|
| 1 |        | 53      | 62          | <undefined> | Unknown   | 50000      | 55      | Yes     |
| 2 |        | 61      | 22          | Home Owner  | Employed  | 52000      | 25      | Yes     |
| 3 |        | 47      | 30          | Tenant      | Employed  | 37000      | 61      | No      |
| 4 |        | NaN     | 75          | Home Owner  | Employed  | 53000      | 20      | Yes     |
| 5 |        | 68      | 56          | Home Owner  | Employed  | 53000      | 14      | Yes     |

Use `creditscorecard` with the name-value argument 'BinMissingData' set to `true` to bin the missing numeric or categorical data in a separate bin. Apply automatic binning.

```
sc = creditscorecard(dataMissing, 'IDVar', 'CustID', 'BinMissingData', true);
sc = autobinning(sc);
```

```
disp(sc)
```

```
creditscorecard with properties:
```

```
    GoodLabel: 0
    ResponseVar: 'status'
    WeightsVar: ''
    VarNames: {1x11 cell}
    NumericPredictors: {1x6 cell}
    CategoricalPredictors: {'ResStatus' 'EmpStatus' 'OtherCC'}
    BinMissingData: 1
```

```
IDVar: 'CustID'
PredictorVars: {1x9 cell}
Data: [1200x11 table]
```

Set a minimum value of zero for CustAge and CustIncome. With this, any negative age or income information becomes invalid or "out-of-range". For scoring and probability of default computations, out-of-range values are given the same points as missing values.

```
sc = modifybins(sc, 'CustAge', 'MinValue', 0);
sc = modifybins(sc, 'CustIncome', 'MinValue', 0);
```

Display bin information for numeric data for 'CustAge' that includes missing data in a separate bin labelled <missing>.

```
bi = bininfo(sc, 'CustAge');
disp(bi)
```

| Bin             | Good | Bad | Odds   | WOE      | InfoValue  |
|-----------------|------|-----|--------|----------|------------|
| { '[0,33)' }    | 69   | 52  | 1.3269 | -0.42156 | 0.018993   |
| { '[33,37)' }   | 63   | 45  | 1.4    | -0.36795 | 0.012839   |

| { '[40,46)' }   | 172  | 89  | 1.9326 | -0.04556 | 0.0004549  |
| { '[46,48)' }   | 59   | 25  | 2.36   | 0.15424  | 0.0016199  |
| { '[48,51)' }   | 99   | 41  | 2.4146 | 0.17713  | 0.0035449  |
| { '[51,58)' }   | 157  | 62  | 2.5323 | 0.22469  | 0.0088407  |
| { '[58,Inf]' }  | 93   | 25  | 3.72   | 0.60931  | 0.032198   |
| { '<missing>' } | 19   | 11  | 1.7273 | -0.15787 | 0.00063885 |
| { 'Totals' }    | 803  | 397 | 2.0227 | NaN      | 0.087112   |

Display bin information for categorical data for 'ResStatus' that includes missing data in a separate bin labelled <missing>.

```
bi = bininfo(sc, 'ResStatus');
disp(bi)
```

| Bin              | Good | Bad | Odds   | WOE       | InfoValue  |
|------------------|------|-----|--------|-----------|------------|
| { 'Tenant' }     | 296  | 161 | 1.8385 | -0.095463 | 0.0035249  |
| { 'Home Owner' } | 352  | 171 | 2.0585 | 0.017549  | 0.00013382 |
| { 'Other' }      | 128  | 52  | 2.4615 | 0.19637   | 0.0055808  |
| { '<missing>' }  | 27   | 13  | 2.0769 | 0.026469  | 2.3248e-05 |
| { 'Totals' }     | 803  | 397 | 2.0227 | NaN       | 0.0092627  |

For the 'CustAge' and 'ResStatus' predictors, there is missing data (NaNs and <undefined>) in the training data, and the binning process estimates a WOE value of -0.15787 and 0.026469 respectively for missing data in these predictors, as shown above.

For EmpStatus and CustIncome there is no explicit bin for missing values, because the training data has no missing values for these predictors.

```
bi = bininfo(sc, 'EmpStatus');
disp(bi)
```

| Bin | Good | Bad | Odds | WOE | InfoValue |
|-----|------|-----|------|-----|-----------|
|-----|------|-----|------|-----|-----------|

```

{'Unknown' } 396 239 1.6569 -0.19947 0.021715
{'Employed'} 407 158 2.5759 0.2418 0.026323
{'Totals' } 803 397 2.0227 NaN 0.048038

```

```

bi = bininfo(sc, 'CustIncome');
disp(bi)

```

| Bin                 | Good | Bad | Odds    | WOE       | InfoValue  |

Use `fitmodel` to fit a logistic regression model using Weight of Evidence (WOE) data. `fitmodel` internally transforms all the predictor variables into WOE values, using the bins found with the automatic binning process. `fitmodel` then fits a logistic regression model using a stepwise method (by default). For predictors that have missing data, there is an explicit `<missing>` bin, with a corresponding WOE value computed from the data. When using `fitmodel`, the corresponding WOE value for the `<missing>` bin is applied when performing the WOE transformation.

```
[sc,mdl] = fitmodel(sc);
```

Scale the scorecard points by the "points, odds, and points to double the odds (PDO)" method using the 'PointsOddsAndPDO' argument of formatpoints. Suppose that you want a score of 500 points to have odds of 2 (twice as likely to be good than to be bad) and that the odds double every 50 points (so that 550 points would have odds of 4).

Display the scorecard showing the scaled points for predictors retained in the fitting model.

```
sc = formatpoints(sc, 'PointsOddsAndPDO', [500 2 50]);
PointsInfo = displaypoints(sc)
```

| { 'ResStatus' } | { 'Tenant' }     | 62.138 |
| { 'ResStatus' } | { 'Home Owner' } | 73.248 |
| { 'ResStatus' } | { 'Other' }      | 90.828 |
| { 'ResStatus' } | { '<missing>' }  | 74.125 |
| { 'EmpStatus' } | { 'Unknown' }    | 58.807 |
| { 'EmpStatus' } | { 'Employed' }   | 86.937 |
| { 'EmpStatus' } | { '<missing>' }  | NaN    |
|                 | :                |        |

Notice that points for the <missing> bin for CustAge and ResStatus are explicitly shown (as 64.9836 and 74.1250, respectively). These points are computed from the WOE value for the <missing> bin, and the logistic model coefficients.

For predictors that have no missing data in the training set, there is no explicit <missing> bin. By default the points are set to NaN for missing data, and they lead to a score of NaN when running score. For predictors that have no explicit <missing> bin, use the name-value argument 'Missing' in formatpoints to indicate how missing data should be treated for scoring purposes.

For the purpose of illustration, take a few rows from the original data as test data and introduce some missing data. Also introduce some invalid, or out-of-range, values. For numeric data, values below the minimum (or above the maximum) allowed are considered invalid, such as a negative value for age (recall 'MinValue' was earlier set to 0 for CustAge and CustIncome). For categorical data, invalid values are categories not explicitly included in the scorecard, for example, a residential status not previously mapped to scorecard categories, such as "House", or a meaningless string such as "abc123".

This is a very small validation data set, only used to illustrate the scoring of rows with missing and out-of-range values, and its relationship with model validation.

```
tdata = dataMissing(11:18,mdl.PredictorNames); % Keep only the predictors retained in the model
tdata.status = dataMissing.status(11:18); % Copy the response variable value, needed for validation
% Set some missing values
tdata.CustAge(1) = NaN;
```

```

tdata.ResStatus(2) = '<undefined>';
tdata.EmpStatus(3) = '<undefined>';
tdata.CustIncome(4) = NaN;
% Set some invalid values
tdata.CustAge(5) = -100;
tdata.ResStatus(6) = 'House';
tdata.EmpStatus(7) = 'Freelancer';
tdata.CustIncome(8) = -1;
disp(tdata)

```

| CustAge | ResStatus   | EmpStatus   | CustIncome | TmWBank | OtherCC | AMBalance | st |
|---------|-------------|-------------|------------|---------|---------|-----------|----|
| NaN     | Tenant      | Unknown     | 34000      | 44      | Yes     | 119.8     | :  |
| 48      | <undefined> | Unknown     | 44000      | 14      | Yes     | 403.62    | 0  |
| 65      | Home Owner  | <undefined> | 48000      | 6       | No      | 111.88    | 0  |
| 44      | Other       | Unknown     | NaN        | 35      | No      | 436.41    | 0  |
| -100    | Other       | Employed    | 46000      | 16      | Yes     | 162.21    | 0  |
| 33      | House       | Employed    | 36000      | 36      | Yes     | 845.02    | 0  |
| 39      | Tenant      | Freelancer  | 34000      | 40      | Yes     | 756.26    | :  |
| 24      | Home Owner  | Employed    | -1         | 19      | Yes     | 449.61    | 0  |

Score the new data and see how points are assigned for missing `CustAge` and `ResStatus`, because we have an explicit bin with points for `<missing>`. However, for `EmpStatus` and `CustIncome` the score function sets the points to `NaN`.

The validation results are unreliable, the scores with `NaN` values are kept (see the validation table `ValTable` below), but it is unclear what impact these `NaN` values have in the validation statistics (`ValStats`). This is a very small validation data set, but `NaN` scores could still influence the validation results on a larger data set.

| 551.79 | 0.19605     | 2        | 6         | 0         | 0          | 1           |

Use the name-value argument 'Missing' in formatpoints to choose how to assign points to missing values for predictors that do not have an explicit <missing> bin. In this example, use the 'MinPoints' option for the 'Missing' argument. The minimum points for EmpStatus in the scorecard displayed above are 58.8072 and for CustIncome the minimum points are 29.3753.

The validation results are no longer influenced by NaN values, since all rows now have a score.

```
sc = formatpoints(sc, 'Missing', 'MinPoints');
[Scores,Points] = score(sc,tdata);

## Input Arguments

### sc — Credit scorecard model

creditscorecard object

Credit scorecard model, specified as a `creditscorecard` object. To create this object, use `creditscorecard`.

### data — Validation data

table

(Optional) Validation data, specified as a MATLAB table, where each table row corresponds to individual observations. The `data` must contain columns for each of the predictors in the credit scorecard model. The columns of data can be any one of the following data types:

- Numeric
- Logical
- Cell array of character vectors
- Character array
- Categorical
- String
- String array

In addition, the table must contain a binary response variable.

---

**Note** When observation weights are defined using the optional `WeightsVar` name-value pair argument when creating a `creditscorecard` object, the weights stored in the `WeightsVar` column are used when validating the model on the training data. If a different validation data set is provided using the optional `data` input, observation weights for the validation data must be included in a

column whose name matches `WeightsVar`, otherwise unit weights are used for the validation data. For more information, see “Using `validatemodel` with `Weights`” on page 19-1926.

---

Data Types: `table`

### Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, . . . , NameN, ValueN`.

Example: `sc = validatemodel(sc,data,'AnalysisLevel','Deciles','Plot','CAP')`

### AnalysisLevel — Type of analysis level

'Scores' (default) | character vector with values 'Deciles', 'Scores'

Type of analysis level, specified as the comma-separated pair consisting of 'AnalysisLevel' and a character vector with one of the following values:

- 'Scores' — Returns the statistics (`Stats`) at the observation level. Scores are sorted from riskiest to safest, and duplicates are removed.
- 'Deciles' — Returns the statistics (`Stats`) at decile level. Scores are sorted from riskiest to safest and binned with their corresponding statistics into 10 deciles (10%, 20%, ..., 100%).

Data Types: `char`

### Plot — Type of plot

'None' (default) | character vector with values 'None', 'CAP', 'ROC', 'KS' | cell array of character vectors with values 'None', 'CAP', 'ROC', 'KS'

Type of plot, specified as the comma-separated pair consisting of 'Plot' and a character vector with one of the following values:

- 'None' — No plot is displayed.
- 'CAP' — Cumulative Accuracy Profile. Plots the fraction of borrowers up to score “s” versus the fraction of defaulters up to score “s” ('PctObs' versus 'Sensitivity' columns of T optional output argument). For more details, see “Cumulative Accuracy Profile (CAP)” on page 19-1925.
- 'ROC' — Receiver Operating Characteristic. Plots the fraction of non-defaulters up to score “s” versus the fraction of defaulters up to score “s” ('FalseAlarm' versus 'Sensitivity' columns of T optional output argument). For more details, see “Receiver Operating Characteristic (ROC)” on page 19-1925.
- 'KS' — Kolmogorov-Smirnov. Plots each score “s” versus the fraction of defaulters up to score “s,” and also versus the fraction of non-defaulters up to score “s” ('Scores' versus both 'Sensitivity' and 'FalseAlarm' columns of the optional output argument T). For more details, see “Kolmogorov-Smirnov statistic (KS)” on page 19-1925.

---

**Tip** For the Kolmogorov-Smirnov statistic option, you can enter 'KS' or 'K-S'.

---

Data Types: `char` | `cell`

## Output Arguments

### Stats — Validation measures

table

Validation measures, returned as a 4-by-2 table. The first column, 'Measure', contains the names of the following measures:

- Accuracy ratio (AR)
- Area under the ROC curve (AUROC)
- The KS statistic
- KS score

The second column, 'Value', contains the values corresponding to these measures.

### T — Validation statistics data

array

Validation statistics data, returned as an N-by-9 table of validation statistics data, sorted, by score, from riskiest to safest. When `AnalysisLevel` is set to 'Deciles', N is equal to 10. Otherwise, N is equal to the total number of unique scores, that is, scores without duplicates.

The table T contains the following nine columns, in this order:

- 'Scores' — Scores sorted from riskiest to safest. The data in this row corresponds to all observations up to, and including the score in this row.
- 'ProbDefault' — Probability of default for observations in this row. For deciles, the average probability of default for all observations in the given decile is reported.
- 'TrueBads' — Cumulative number of "bads" up to, and including, the corresponding score.
- 'FalseBads' — Cumulative number of "goods" up to, and including, the corresponding score.
- 'TrueGoods' — Cumulative number of "goods" above the corresponding score.
- 'FalseGoods' — Cumulative number of "bads" above the corresponding score.
- 'Sensitivity' — Fraction of defaulters (or the cumulative number of "bads" divided by total number of "bads"). This is the distribution of "bads" up to and including the corresponding score.
- 'FalseAlarm' — Fraction of non-defaulters (or the cumulative number of "goods" divided by total number of "goods"). This is the distribution of "goods" up to and including the corresponding score.
- 'PctObs' — Fraction of borrowers, or the cumulative number of observations, divided by total number of observations up to and including the corresponding score.

---

**Note** When creating the `creditscorecard` object with `creditscorecard`, if the optional name-value pair argument `WeightsVar` was used to specify observation (sample) weights, then the T table uses statistics, sums, and cumulative sums that are weighted counts.

---

### hf — Handle to the plotted measures

figure handle

Figure handle to plotted measures, returned as a figure handle or array of handles. When `Plot` is set to 'None', hf is an empty array.

## More About

### Cumulative Accuracy Profile (CAP)

CAP is generally a concave curve and is also known as the Gini curve, Power curve, or Lorenz curve.

The scores of given observations are sorted from riskiest to safest. For a given fraction  $M$  (0% to 100%) of the total borrowers, the height of the CAP curve is the fraction of defaulters whose scores are less than or equal to the maximum score of the fraction  $M$ , also known as "Sensitivity."

The area under the CAP curve, known as the AUCAP, is then compared to that of the perfect or "ideal" model, leading to the definition of a summary index known as the accuracy ratio ( $AR$ ) or the Gini coefficient:

$$AR = \frac{A_R}{A_P}$$

where  $A_R$  is the area between the CAP curve and the diagonal, and  $A_P$  is the area between the perfect model and the diagonal. This represents a "random" model, where scores are assigned randomly and therefore the proportion of defaulters and non-defaulters is independent of the score. The perfect model is the model for which all defaulters are assigned the lowest scores, and therefore, perfectly discriminates between defaulters and nondefaulters. Thus, the closer to unity  $AR$  is, the better the scoring model.

### Receiver Operating Characteristic (ROC)

To find the receiver operating characteristic (ROC) curve, the proportion of defaulters up to a given score "s," or "Sensitivity," is computed.

This proportion is known as the true positive rate (TPR). Additionally, the proportion of nondefaulters up to score "s," or "False Alarm Rate," is also computed. This proportion is also known as the false positive rate (FPR). The ROC curve is the plot of the "Sensitivity" vs. the "False Alarm Rate." Computing the ROC curve is similar to computing the equivalent of a confusion matrix at each score level.

Similar to the CAP, the ROC has a summary statistic known as the area under the ROC curve (AUROC). The closer to unity, the better the scoring model. The accuracy ratio ( $AR$ ) is related to the area under the curve by the following formula:

$$AR = 2(AUROC) - 1$$

### Kolmogorov-Smirnov statistic (KS)

The Kolmogorov-Smirnov (KS) plot, also known as the fish-eye graph, is a common statistic used to measure the predictive power of scorecards.

The KS plot shows the distribution of defaulters and the distribution of non-defaulters on the same plot. For the distribution of defaulters, each score "s" is plotted versus the proportion of defaulters up to "s," or "Sensitivity." For the distribution of non-defaulters, each score "s" is plotted versus the proportion of non-defaulters up to "s," or "False Alarm." The statistic of interest is called the KS statistic and is the maximum difference between these two distributions ("Sensitivity" minus "False Alarm"). The score at which this maximum is attained is also of interest.

### Using `validatemodel` with Weights

Model validation statistics incorporate observation weights when these are provided by the user.

Without weights, the validation statistics are based on how many good and bad observations fall below a particular score. On the other hand, when observation weights are provided, the weight (not the count) is accumulated for the good and the bad observations that fall below a particular score.

When observation weights are defined using the optional `WeightsVar` name-value pair argument when creating a `creditscorecard` object, the weights stored in the `WeightsVar` column are used when validating the model on the training data. When a different validation data set is provided using the optional `data` input, observation weights for the validation data must be included in a column whose name matches `WeightsVar`, otherwise unit weights are used for the validation data set.

Not only the validation statistics, but also the credit scorecard scores themselves depend on the observation weights of the training data. For more information, see “Using `fitmodel` with Weights” on page 19-1780 and “Credit Scorecard Modeling Using Observation Weights” on page 8-54.

### Introduced in R2015a

## fillmissing

Replace missing values for credit scorecard predictors

### Syntax

```
sc = fillmissing(sc,PredictorNames,Statistics)
sc = fillmissing( ___,ConstantValue)
```

### Description

`sc = fillmissing(sc,PredictorNames,Statistics)` replaces missing values of the predictor `PredictorNames` with values defined by `Statistics` and returns an updated credit scorecard object (`sc`). Standard missing data is defined as follows:

- NaN for numeric arrays
- <undefined> for categorical arrays

---

**Note** If you run `fillmissing` after binning a predictor, the existing cutpoints and bin edges are preserved and the "Good" and "Bad" counts from the <missing> bin are added to the corresponding bin.

---

`sc = fillmissing( ___,ConstantValue)` uses arguments from the previous syntax and a value for a `ConstantValue` to replace missing values.

### Examples

#### Fill Missing Data in a creditscorecard Object

This example shows how to use `fillmissing` to replace missing values in the `CustAge` and `ResStatus` predictors with user-defined values. For additional information on alternative approaches for "treating" missing data, see "Credit Scorecard Modeling with Missing Values" on page 8-56.

Load the credit scorecard data and use `dataMissing` for the training data.

```
load CreditCardData.mat
disp(head(dataMissing));
```

When a validation data set has missing values and you use `fillmissing` with the training dataset, the missing values in the validation data set are assigned the same points as the corresponding bins containing the filled values.

As the table shows, the '`<missing>`' bin for the `CustAge` predictor is assigned the same points as the '`[40,46)`' bin because the missing data is filled with the median value 45.

The points assigned to the '`<missing>`' bin for the `EmpStatus` predictor are `NaN` because `fillmissing` is not used for that predictor. The assigned points are decided by the default '`NoScore`' for the '`Missing`' name-value pair argument in `formatpoints`.

Create a test validation data set (`tdata`) and add missing values.

```

tdata = data(1:10,:);
tdata.CustAge(1) = NaN;
tdata.ResStatus(2) = '<undefined>';
[scr,pts] = score(sc,tdata)

```

```
scr = 10×1

## Handling of Missing Values in Validation Data Sets

This example shows different possibilities for handling missing data in validation data.

When scoring data from a validation data set, you have several options. If you choose to do nothing, the points assigned to the missing data are NaN, which comes from the default 'NoScore' for the 'Missing' name-value pair argument in `formatpoints`.

If you want to score missing values of all the predictors with one consistent metric, you can use the options 'ZeroWOE', 'MinPoints', or 'MaxPoints' for the 'Missing' name-value pair argument in `formatpoints`.

```

load CreditCardData.mat
sc = creditscorecard(data);
predictorinfo(sc, 'CustAge')

```

```
ans=1x4 table
```

|         | PredictorType | LatestBinning     | LatestFillMissingType | LatestFillMissingValue |
|---------|---------------|-------------------|-----------------------|------------------------|
| CustAge | {'Numeric'}   | {'Original Data'} | {'Original'}          | {0x0 double}           |

```
predictorinfo(sc, 'ResStatus')
```

```
ans=1x5 table
```

|           | PredictorType   | Ordinal | LatestBinning     | LatestFillMissingType | LatestFillMissingValue |
|-----------|-----------------|---------|-------------------|-----------------------|------------------------|
| ResStatus | {'Categorical'} | false   | {'Original Data'} | {'Original'}          | {0x0 double}           |

```

sc = autobinning(sc);
sc = fitmodel(sc, 'display', 'off');

```

```
displaypoints(sc)
```

```
ans=37x3 table
```

| 93.256  | 62.421    | 105.81    | 76.585     | 116.05  | 42.287  | 64.15     |
| 48.727  | 82.276    | 105.81    | 121.18     | 60.719  | 86.224  | 110.96    |
| 126.46  | 82.276    | 105.81    | 121.18     | 60.719  | 86.224  | 64.15     |

## Input Arguments

### sc — Credit scorecard model

creditscorecard object

Credit scorecard model, specified as a `creditscorecard` object.

### PredictorNames — Name of creditscorecard predictor whose missing data is filled

character vector | string | cell array of character vectors | string array

Name of `creditscorecard` predictor to fill missing data for, specified as a scalar character vector, scalar string, cell array of character vectors, or string array.

Data Types: `char` | `string` | `cell`

### Statistics — Statistic to use to fill missing data for predictors

character vector with a value of 'mean', 'median', 'mode', 'original', or 'constant' | string with a value of "mean", "median", "mode", "original", or "constant"

Statistic to use to fill missing data for the predictors, specified as a character vector or string with one of the following values.

- 'mean' — Replace missing data with the average or mean value. The option is valid only for numeric data. The 'mean' calculates the weighted mean of the predictor by referring to the

predictor column and the `Weights` column from the `creditscorecard` object. For more information, see “Weighted Mean” on page 19-1937.

- `'median'` — Replace missing data with the median value. Valid for numeric and ordinal data. The `'median'` calculates the weighted median of the predictor by referring to the predictor column and the `Weights` column from the `creditscorecard` object. For more information, see “Weighted Median” on page 19-1938.
- `'mode'` — Replace missing data with the mode. Valid for numeric and both nominal and ordinal categorical data. The `'mode'` calculates the weighted mode of the predictor by referring to the predictor column and the `Weights` column from the `creditscorecard` object. For more information, see “Weighted Mode” on page 19-1938.
- `'original'` — Set the missing data for numeric and categorical predictors back to its original value: `NaN` if numeric, `<undefined>` or `<missing>` if categorical.
- `'constant'` — Set the missing data for numeric and categorical predictors to a constant value that you specify in the optional argument for `ConstantValue`.

Data Types: `char` | `string`

### **ConstantValue** — Value to fill missing entries in predictors specified in `PredictorNames`

[ ] (default) | numeric | character vector | string | cell array of character vectors | string array

(Optional) Value to fill missing entries in predictors specified in `PredictorNames`, specified as a numeric value, character vector, string, or cell array of character vectors.

---

**Note** You can use `ConstantValue` only if you set the `Statistics` argument to `'constant'`.

---

Data Types: `char` | `double` | `string` | `cell`

## **Output Arguments**

### **sc** — Updated `creditscorecard`

`creditscorecard` object

Updated `creditscorecard` object, returned as an object.

## **More About**

### **Weighted Mean**

The weighted mean is similar to an ordinary mean except that instead of each of the data points contributing equally to the final average, some data points contribute more than others.

The weighted mean for a nonempty finite multiset of data ( $x$ ) with corresponding nonnegative weights ( $w$ ) is

$$\bar{x} = \frac{\sum_{i=1}^n w_i x_i}{\sum_{i=1}^n w_i}$$

## Weighted Median

The weighted median is the 50% weighted percentile, where the percentage in the total weight is counted instead of the total number.

For  $n$  distinct ordered elements ( $x$ ) positive weights ( $w$ ) such that  $\sum_{i=1}^n w_i = 1$ , the weighted median is the element  $x_k$ :

$$\sum_{i=1}^{k-1} w_i \leq \frac{1}{2} \text{ and } \sum_{i=k+1}^n w_i \leq \frac{1}{2}$$

In the case where the respective weights of both elements border the midpoint of the set of weights without encapsulating it, each element defines a partition equal to  $1/2$ . These elements are referred to as the lower weighted median and upper weighted median. The weighted median is chosen based on which element keeps the partitions most equal. This median is always the weighted median with the lowest weight. In the event that the upper and lower weighted medians are equal, the lower weighted median is accepted.

## Weighted Mode

The weighted mode of a set of weighted data values is the value that appears most often.

The mode of a sample is the element that occurs most often in the collection. For example, the mode of the sample [1, 3, 6, 6, 6, 6, 7, 7, 12, 12, 17] is 6.

## Introduced in R2020a

# creditscorecard

Create `creditscorecard` object to build credit scorecard model

## Description

Build a credit scorecard model by creating a `creditscorecard` object and specify input data in a table format.

After creating a `creditscorecard` object, you can use the associated object functions to bin the data and perform logistic regression analysis to develop a credit scorecard model to guide credit decisions. This workflow shows how to develop a credit scorecard model.

- 1 Use `screenpredictors` from Risk Management Toolbox to pare down a potentially large set of predictors to a subset that is most predictive of the credit score card response variable. Use this subset of predictors when creating the `creditscorecard` object.
- 2 Create a `creditscorecard` object (see “Create `creditscorecard`” on page 19-1939 and “Properties” on page 19-1942).
- 3 Bin the data using `autobinning`.
- 4 Fit a logistic regression model using `fitmodel` or `fitConstrainedModel`.
- 5 Review and format the credit scorecard points using `displaypoints` and `formatpoints`. At this point in the workflow, if you have a license for Risk Management Toolbox, you have the option to create a `compactCreditScorecard` object (`csc`) using the `compact` function. You can then use the following functions `displaypoints`, `score`, and `probdefault` from the Risk Management Toolbox with the `csc` object.
- 6 Score the data using `score`.
- 7 Calculate the probabilities of default for the data using `probdefault`.
- 8 Validate the quality of the credit scorecard model using `validatemodel`.

For more detailed information on this workflow, see “Credit Scorecard Modeling Workflow” on page 8-51.

## Creation

### Syntax

```
sc = creditscorecard(data)
sc = creditscorecard( ___, Name, Value)
```

### Description

`sc = creditscorecard(data)` creates a `creditscorecard` object by specifying `data`. The credit scorecard model, returned as a `creditscorecard` object, contains the binning maps or rules (cut points or category groupings) for one or more predictors.

`sc = creditscorecard( ___, Name, Value)` sets Properties on page 19-1942 using name-value pairs and any of the arguments in the previous syntax. For example, `sc =`

`creditscorecard(data, 'GoodLabel', 0, 'IDVar', 'CustID', 'ResponseVar', 'status', 'PredictorVars', {'CustAge', 'CustIncome'}, 'WeightsVar', 'RowWeights', 'BinMissingData', true)`. You can specify multiple name-value pairs.

---

**Note** To use observation (sample) weights in the credit scorecard workflow, when creating a `creditscorecard` object, you must use the optional name-value pair `WeightsVar` to define which column in the `data` contains the weights.

---

## Input Arguments

### **data** — Data for `creditscorecard` object

table

Data for the `creditscorecard` object, specified as a MATLAB table, where each column of data can be any one of the following data types:

- Numeric
- Logical
- Cell array of character vectors
- Character array
- Categorical
- String

In addition, the table must contain a binary response variable. Before creating a `creditscorecard` object, perform a data preparation task to have appropriately structured data as input to a `creditscorecard` object. The `data` input sets the `Data` on page 19-0 property.

Data Types: table

### **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `sc =`

```
creditscorecard(data, 'GoodLabel', 0, 'IDVar', 'CustAge', 'ResponseVar', 'status', 'PredictorVars', {'CustID', 'CustIncome'}, 'WeightsVar', 'RowWeights', 'BinMissingData', true)
```

### **GoodLabel** — Indicator for which of two possible values in response variable correspond to “Good” observations

set to the response value with the highest count (default) | character vector | numeric scalar | logical

Indicator for which of the two possible values in the response variable correspond to “Good” observations, specified as the comma-separated pair consisting of `'GoodLabel'` and a numeric scalar, logical, or character vector. The `GoodLabel` name-value pair argument sets the `GoodLabel` on page 19-0 property.

When specifying `GoodLabel`, follow these guidelines.

| If Response Variable is...      | GoodLabel Must be... |
|---------------------------------|----------------------|
| numeric                         | numeric              |
| logical                         | logical or numeric   |
| cell array of character vectors | character vector     |
| character array                 | character vector     |
| categorical                     | character vector     |

If not specified, `GoodLabel` is set to the response value with the highest count. However, if the optional `WeightsVar` argument is provided when creating the `creditscorecard` object, then counts are replaced with weighted frequencies. For more information, see “Credit Scorecard Modeling Using Observation Weights” on page 8-54.

`GoodLabel` can only be set when creating the `creditscorecard` object. This parameter cannot be set using dot notation.

Data Types: `char` | `double`

### **IDVar — Variable name used as ID or tag for observations**

empty character vector `''` (default) | character vector

Variable name used as ID or tag for the observations, specified as the comma-separated pair consisting of `'IDVar'` and a character vector. The `IDVar` data could be an ordinal number (for example, 1,2,3...), a Social Security number. This is provided as a convenience to remove this column from the predictor variables. `IDVar` is case-sensitive. The `IDVar` name-value pair argument sets the `IDVar` on page 19-0 `property`.

You can set this optional parameter using the `creditscorecard` function or by using dot notation at the command line, as follows.

Example: `sc.IDVar = 'CustID'`

Data Types: `char`

### **ResponseVar — Response variable name for “Good” or “Bad” indicator**

last column of the data input (default) | character vector

Response variable name for the “Good” or “Bad” indicator, specified as the comma-separated pair consisting of `'ResponseVar'` and a character vector. The response variable data must be binary. The `ResponseVar` name-value pair argument sets the `ResponseVar` on page 19-0 `property`.

If not specified, `ResponseVar` is set to the last column of the data input. `ResponseVar` can only be set when creating the `creditscorecard` object using the `creditscorecard` function. `ResponseVar` is case-sensitive.

Data Types: `char`

### **WeightsVar — Weights variable name**

empty character vector `''` (default) | character vector

Weights variable name, specified as the comma-separated pair consisting of `'WeightsVar'` and a character vector to indicate which column name in the `data` table contains the row weights. `WeightsVar` is case-sensitive. The `WeightsVar` name-value pair argument sets the `WeightsVar` on page 19-0 `property`, and this property can only be set at the creation of a `creditscorecard`

object. If the name-value pair argument `WeightsVar` is not specified when creating a `creditscorecard` object, then observation weights are set to unit weights by default.

The `WeightsVar` values are used in the credit scorecard workflow by `autobinning`, `bininfo`, `fitmodel`, and `validatemodel`. For more information, see “Credit Scorecard Modeling Using Observation Weights” on page 8-54.

Data Types: `char`

**BinMissingData** — Indicates if missing data is removed or displayed in a separate bin  
`false` (missing data removed) (default) | logical with value `true` or `false`

Indicates if missing data is removed or displayed in a separate bin, specified as the comma-separated pair consisting of 'BinMissingdata' and a logical scalar with a value of `true` or `false`. If `BinMissingData` is `true`, the missing data for a predictor is displayed in a separate bin labeled `<missing>`.

Data Types: `logical`

## Properties

**Data** — Data used to create the `creditscorecard` object  
`table`

Data used to create the `creditscorecard` object, specified as a table when creating a `creditscorecard` object. In the Data property, categorical predictors are stored as categorical arrays.

Example: `sc.Data(1:10, :)`

Data Types: `table`

**IDVar** — Name of the variable used as ID or tag for the observations  
empty character vector `''` (default) | character vector

Name of the variable used as ID or tag for the observations, specified as a character vector. This property can be set as an optional parameter when creating a `creditscorecard` object or by using dot notation at the command line. `IDVar` is case-sensitive.

Example: `sc.IDVar = 'CustID'`

Data Types: `char`

**VarNames** — All variable names from the data input  
`VarNames` come directly from data input to `creditscorecard` object (default)

This property is read-only.

`VarNames` is a cell array of character vectors containing the names of all variables in the data. The `VarNames` come directly from the data input to the `creditscorecard` object. `VarNames` is case-sensitive.

Data Types: `cell`

**ResponseVar** — Name of the response variable, “Good” or “Bad” indicator  
last column of the data input (default) | character vector

Name of the response variable, “Good” or “Bad” indicator, specified as a character vector. The response variable data must be binary. If not specified, `ResponseVar` is set to the last column of the data input. This property can only be set with an optional parameter when creating a `creditscorecard` object. `ResponseVar` is case-sensitive.

Data Types: `char`

### **WeightsVar — Name of the variable used as ID or tag for weights**

empty character vector `''` (default) | character vector

Name of the variable used as ID or tag to indicate which column name in the `data` table contains the row weights, specified as a character vector. This property can be set as an optional parameter (`WeightsVar`) when creating a `creditscorecard` object. `WeightsVar` is case-sensitive.

Data Types: `char`

### **GoodLabel — Indicator for which of the two possible values in the response variable correspond to “Good” observations**

set to the response value with the highest count (default) | character vector | numeric scalar | logical

Indicator for which of the two possible values in the response variable correspond to “Good” observations. When specifying `GoodLabel`, follow these guidelines:

| If Response Variable is...      | GoodLabel must be: |
|---------------------------------|--------------------|
| numeric                         | numeric            |
| logical                         | logical or numeric |
| cell array of character vectors | character vector   |
| character array                 | character vector   |
| categorical                     | character vector   |

If not specified, `GoodLabel` is set to the response value with the highest count. This property can only be set with an optional parameter when creating a `creditscorecard` object. This property cannot be set using dot notation.

Data Types: `char` | `double`

### **PredictorVars — Predictor variable names**

set difference between `VarNames` and `{IDVar,ResponseVar}` (default) | cell array of character vectors containing names

Predictor variable names, specified using a cell array of character vectors containing names. By default, when you create a `creditscorecard` object, all variables are predictors except for `IDVar` and `ResponseVar`. This property can be modified using a name-value pair argument for the `fitmodel` function or by using dot notation. `PredictorVars` is case-sensitive and the predictor variable name cannot be the same as the `IDVar` or `ResponseVar`.

Example: `sc.PredictorVars = {'CustID', 'CustIncome'}`

Data Types: `cell`

### **NumericPredictors — Name of numeric predictors**

empty character vector `''` (default) | character vector

Name of numeric predictors, specified as a character vector. This property cannot be set by using dot notation at the command line. It can only be modified using the `modifypredictor` function.

Data Types: char

### CategoricalPredictors — Name of categorical predictors

empty character vector '' (default) | character vector

Name of categorical predictors, specified as a character vector. This property cannot be set by using dot notation at the command line. It can only be modified using the `modifypredictor` function.

Data Types: char

### BinMissingData — Indicates if missing data is removed or displayed in a separate bin

false (missing data removed) (default) | logical with value true or false

Indicates if missing data is removed or displayed in a separate bin, specified as the comma-separated pair consisting of 'BinMissingdata' and a logical scalar with a value of true or false. If `BinMissingData` is true, the missing data for a predictor is displayed in a separate bin labeled `<missing>`. For more information on working with missing data, see “Credit Scorecard Modeling with Missing Values” on page 8-56.

Data Types: logical

| creditscorecard Property | Set/Modify Property from Command Line Using creditscorecard Function  | Modify Property Using Dot Notation | Property Not User-Defined and Value Is Defined Internally  |
|--------------------------|-----------------------------------------------------------------------|------------------------------------|------------------------------------------------------------|
| Data                     | No                                                                    | No                                 | Yes, copy of data input                                    |
| IDVar                    | Yes                                                                   | Yes                                | No, but the user specifies this                            |
| VarNames                 | No                                                                    | No                                 | Yes                                                        |
| ResponseVar              | Yes                                                                   | No                                 | If not specified, set to last column of data input         |
| WeightsVar               | No                                                                    | No                                 | Yes                                                        |
| GoodLabel                | Yes                                                                   | No                                 | If not specified, set to response value with highest count |
| PredictorVars            | Yes (also modifiable using <code>fitmodel</code> function)            | Yes                                | Yes, but the user can modify this                          |
| NumericPredictors        | No (can only be modified using <code>modifypredictor</code> function) | No                                 | Yes, but the user can modify this                          |
| CategoricalPredictors    | No (can only be modified using <code>modifypredictor</code> function) | No                                 | Yes, but the user can modify this                          |

| creditscorecard Property | Set/Modify Property from Command Line Using creditscorecard Function | Modify Property Using Dot Notation | Property Not User-Defined and Value Is Defined Internally |
|--------------------------|----------------------------------------------------------------------|------------------------------------|-----------------------------------------------------------|
| BinMissingData           | Yes                                                                  | No                                 | False by default, but the user can modify this            |

## Object Functions

|                     |                                                                                                             |
|---------------------|-------------------------------------------------------------------------------------------------------------|
| autobinning         | Perform automatic binning of given predictors                                                               |
| bininfo             | Return predictor's bin information                                                                          |
| predictorinfo       | Summary of credit scorecard predictor properties                                                            |
| modifypredictor     | Set properties of credit scorecard predictors                                                               |
| fillmissing         | Replace missing values for credit scorecard predictors                                                      |
| modifybins          | Modify predictor's bins                                                                                     |
| bindata             | Binned predictor variables                                                                                  |
| plotbins            | Plot histogram counts for predictor variables                                                               |
| fitmodel            | Fit logistic regression model to Weight of Evidence (WOE) data                                              |
| fitConstrainedModel | Fit logistic regression model to Weight of Evidence (WOE) data subject to constraints on model coefficients |
| setmodel            | Set model predictors and coefficients                                                                       |
| displaypoints       | Return points per predictor per bin                                                                         |
| formatpoints        | Format scorecard points and scaling                                                                         |
| score               | Compute credit scores for given data                                                                        |
| probdefault         | Likelihood of default for given data set                                                                    |
| validatemodel       | Validate quality of credit scorecard model                                                                  |
| compact             | Create compact credit scorecard                                                                             |

## Examples

### Create a creditscorecard Object

Create a `creditscorecard` object using the `CreditCardData.mat` file to load the data (using a dataset from Refaat 2011).

```
load CreditCardData
sc = creditscorecard(data)

sc =
  creditscorecard with properties:

      GoodLabel: 0
      ResponseVar: 'status'
      WeightsVar: ''
      VarNames: {1x11 cell}
      NumericPredictors: {1x7 cell}
      CategoricalPredictors: {'ResStatus' 'EmpStatus' 'OtherCC'}
      BinMissingData: 0
      IDVar: ''
      PredictorVars: {1x10 cell}
      Data: [1200x11 table]
```

### Create a `creditscorecard` Object Containing Weights

Use the `CreditCardData.mat` file to load the data (`dataWeights`) that contains a column (`RowWeights`) for the weights (using a dataset from Refaat 2011).

```
load CreditCardData
```

Create a `creditscorecard` object using the optional name-value pair argument for `'WeightsVar'`.

```
sc = creditscorecard(dataWeights, 'WeightsVar', 'RowWeights')
```

```
sc =
  creditscorecard with properties:
      GoodLabel: 0
      ResponseVar: 'status'
      WeightsVar: 'RowWeights'
      VarNames: {1x12 cell}
      NumericPredictors: {1x7 cell}
      CategoricalPredictors: {'ResStatus' 'EmpStatus' 'OtherCC'}
      BinMissingData: 0
      IDVar: ''
      PredictorVars: {1x10 cell}
      Data: [1200x12 table]
```

### Display `creditscorecard` Object Properties

Create a `creditscorecard` object using the `CreditCardData.mat` file to load the data (using a dataset from Refaat 2011).

```
load CreditCardData
```

```
sc = creditscorecard(data)
```

```
sc =
  creditscorecard with properties:
      GoodLabel: 0
      ResponseVar: 'status'
      WeightsVar: ''
      VarNames: {1x11 cell}
      NumericPredictors: {1x7 cell}
      CategoricalPredictors: {'ResStatus' 'EmpStatus' 'OtherCC'}
      BinMissingData: 0
      IDVar: ''
      PredictorVars: {1x10 cell}
      Data: [1200x11 table]
```

To display the `creditscorecard` object properties, use dot notation.

```
sc.PredictorVars
```

```
ans = 1x10 cell
Columns 1 through 4
    {'CustID'}    {'CustAge'}    {'TmAtAddress'}    {'ResStatus'}
Columns 5 through 8
    {'EmpStatus'}    {'CustIncome'}    {'TmWBank'}    {'OtherCC'}
Columns 9 through 10
    {'AMBalance'}    {'UtilRate'}
```

### sc.VarNames

```
ans = 1x11 cell
Columns 1 through 4
    {'CustID'}    {'CustAge'}    {'TmAtAddress'}    {'ResStatus'}
Columns 5 through 8
    {'EmpStatus'}    {'CustIncome'}    {'TmWBank'}    {'OtherCC'}
Columns 9 through 11
    {'AMBalance'}    {'UtilRate'}    {'status'}
```

## Change a Property Value for a creditscorecard Object

Create a `creditscorecard` object using the `CreditCardData.mat` file to load the data (using a dataset from Refaat 2011).

```
load CreditCardData
sc = creditscorecard(data)
```

```
sc =
creditscorecard with properties:
    GoodLabel: 0
    ResponseVar: 'status'
    WeightsVar: ''
    VarNames: {1x11 cell}
    NumericPredictors: {1x7 cell}
    CategoricalPredictors: {'ResStatus' 'EmpStatus' 'OtherCC'}
    BinMissingData: 0
    IDVar: ''
    PredictorVars: {1x10 cell}
    Data: [1200x11 table]
```

Since the `IDVar` property has public access, you can change its value at the command line.

```
sc.IDVar = 'CustID'
```

```

sc =
  creditscorecard with properties:

        GoodLabel: 0
        ResponseVar: 'status'
        WeightsVar: ''
        VarNames: {1x11 cell}
        NumericPredictors: {1x6 cell}
        CategoricalPredictors: {'ResStatus' 'EmpStatus' 'OtherCC'}
        BinMissingData: 0
        IDVar: 'CustID'
        PredictorVars: {1x9 cell}
        Data: [1200x11 table]

```

### Create a creditscorecard Object

Create a `creditscorecard` object using the `CreditCardData.mat` file to load the data (using a dataset from Refaat 2011).

```

load CreditCardData
sc = creditscorecard(data)

```

```

sc =
  creditscorecard with properties:

        GoodLabel: 0
        ResponseVar: 'status'
        WeightsVar: ''
        VarNames: {1x11 cell}
        NumericPredictors: {1x7 cell}
        CategoricalPredictors: {'ResStatus' 'EmpStatus' 'OtherCC'}
        BinMissingData: 0
        IDVar: ''
        PredictorVars: {1x10 cell}
        Data: [1200x11 table]

```

In this example, the default values for the properties `ResponseVar`, `PredictorVars` and `GoodLabel` are assigned when this object is created. By default, the property `ResponseVar` is set to the variable name that is in the last column of the input data ('`status`' in this example). The property `PredictorVars` contains the names of all the variables that are in `VarNames`, but excludes `IDVar` and `ResponseVar`. Also, by default in the previous example, `GoodLabel` is set to 0, since it is the value in the response variable (`ResponseVar`) with the highest count.

Display the `creditscorecard` object properties using dot notation.

```

sc.PredictorVars

ans = 1x10 cell
      Columns 1 through 4

      {'CustID'}      {'CustAge'}      {'TmAtAddress'}      {'ResStatus'}

      Columns 5 through 8

```

```

    {'EmpStatus'}    {'CustIncome'}    {'TmWBank'}    {'OtherCC'}
Columns 9 through 10
    {'AMBalance'}    {'UtilRate'}

```

### sc.VarNames

```

ans = 1x11 cell
Columns 1 through 4
    {'CustID'}    {'CustAge'}    {'TmAtAddress'}    {'ResStatus'}
Columns 5 through 8
    {'EmpStatus'}    {'CustIncome'}    {'TmWBank'}    {'OtherCC'}
Columns 9 through 11
    {'AMBalance'}    {'UtilRate'}    {'status'}

```

Since `IDVar` and `PredictorVars` have public access, you can change their values at the command line.

```
sc.IDVar = 'CustID'
```

```

sc =
creditscorecard with properties:
    GoodLabel: 0
    ResponseVar: 'status'
    WeightsVar: ''
    VarNames: {1x11 cell}
    NumericPredictors: {1x6 cell}
    CategoricalPredictors: {'ResStatus' 'EmpStatus' 'OtherCC'}
    BinMissingData: 0
    IDVar: 'CustID'
    PredictorVars: {1x9 cell}
    Data: [1200x11 table]

```

```
sc.PredictorVars = {'CustIncome', 'ResStatus', 'AMBalance'}
```

```

sc =
creditscorecard with properties:
    GoodLabel: 0
    ResponseVar: 'status'
    WeightsVar: ''
    VarNames: {1x11 cell}
    NumericPredictors: {'CustIncome' 'AMBalance'}
    CategoricalPredictors: {'ResStatus'}
    BinMissingData: 0
    IDVar: 'CustID'
    PredictorVars: {'ResStatus' 'CustIncome' 'AMBalance'}

```

```
Data: [1200x11 table]
```

```
disp(sc)
```

```
creditscorecard with properties:
```

```

    GoodLabel: 0
    ResponseVar: 'status'
    WeightsVar: ''
    VarNames: {1x11 cell}
    NumericPredictors: {'CustIncome' 'AMBalance'}
    CategoricalPredictors: {'ResStatus'}
    BinMissingData: 0
    IDVar: 'CustID'
    PredictorVars: {'ResStatus' 'CustIncome' 'AMBalance'}
    Data: [1200x11 table]

```

### Create a `creditscorecard` Object and Set `GoodLabel` and `ResponseVar`

Create a `creditscorecard` object using the `CreditCardData.mat` file to load the data (using a dataset from Refaat 2011). Then use name-value pair arguments for `creditscorecard` to define `GoodLabel` and `ResponseVar`.

```
load CreditCardData
sc = creditscorecard(data, 'IDVar', 'CustID', 'GoodLabel', 0, 'ResponseVar', 'status')
```

```
sc =
```

```
creditscorecard with properties:
```

```

    GoodLabel: 0
    ResponseVar: 'status'
    WeightsVar: ''
    VarNames: {1x11 cell}
    NumericPredictors: {1x6 cell}
    CategoricalPredictors: {'ResStatus' 'EmpStatus' 'OtherCC'}
    BinMissingData: 0
    IDVar: 'CustID'
    PredictorVars: {1x9 cell}
    Data: [1200x11 table]

```

`GoodLabel` and `ResponseVar` can only be set (enforced) when creating a `creditscorecard` object using `creditscorecard`.

### Create a `creditscorecard` Object and Set the `'BinMissingData'` Property

Create a `creditscorecard` object using the `CreditCardData.mat` file to load the `dataMissing` with missing values.

```
load CreditCardData
head(dataMissing,5)
```

```
ans=5x11 table
```

| CustID | CustAge | TmAtAddress | ResStatus   | EmpStatus | CustIncome | TmWBank | Other |
|--------|---------|-------------|-------------|-----------|------------|---------|-------|
| 1      | 53      | 62          | <undefined> | Unknown   | 50000      | 55      | Ye    |
| 2      | 61      | 22          | Home Owner  | Employed  | 52000      | 25      | Ye    |
| 3      | 47      | 30          | Tenant      | Employed  | 37000      | 61      | N     |
| 4      | NaN     | 75          | Home Owner  | Employed  | 53000      | 20      | Ye    |
| 5      | 68      | 56          | Home Owner  | Employed  | 53000      | 14      | Ye    |

```
fprintf('Number of rows: %d\n',height(dataMissing))
```

```
Number of rows: 1200
```

```
fprintf('Number of missing values CustAge: %d\n',sum(ismissing(dataMissing.CustAge)))
```

```
Number of missing values CustAge: 30
```

```
fprintf('Number of missing values ResStatus: %d\n',sum(ismissing(dataMissing.ResStatus)))
```

```
Number of missing values ResStatus: 40
```

Use `creditscorecard` with the name-value argument `'BinMissingData'` set to `true` to bin the missing data in a separate bin.

```
sc = creditscorecard(dataMissing,'IDVar','CustID','BinMissingData',true);
sc = autobinning(sc);
disp(sc)
```

```
creditscorecard with properties:
```

```

    GoodLabel: 0
    ResponseVar: 'status'
    WeightsVar: ''
    VarNames: {1x11 cell}
    NumericPredictors: {1x6 cell}
    CategoricalPredictors: {'ResStatus' 'EmpStatus' 'OtherCC'}
    BinMissingData: 1
    IDVar: 'CustID'
    PredictorVars: {1x9 cell}
    Data: [1200x11 table]
```

Display bin information for numeric data for `'CustAge'` that includes missing data in a separate bin labelled `<missing>`.

```
bi = bininfo(sc,'CustAge');
disp(bi)
```

| Bin             | Good | Bad | Odds   | WOE      | InfoValue |
|-----------------|------|-----|--------|----------|-----------|
| {'[-Inf,33)'} } | 69   | 52  | 1.3269 | -0.42156 | 0.018993  |
| {'[33,37)'} }   | 63   | 45  | 1.4    | -0.36795 | 0.012839  |
| {'[37,40)'} }   | 72   | 47  | 1.5319 | -0.2779  | 0.0079824 |
| {'[40,46)'} }   | 172  | 89  | 1.9326 | -0.04556 | 0.0004549 |
| {'[46,48)'} }   | 59   | 25  | 2.36   | 0.15424  | 0.0016199 |
| {'[48,51)'} }   | 99   | 41  | 2.4146 | 0.17713  | 0.0035449 |
| {'[51,58)'} }   | 157  | 62  | 2.5323 | 0.22469  | 0.0088407 |

```
{ '[58,Inf]' }      93      25      3.72      0.60931      0.032198
{' <missing>' }     19      11      1.7273     -0.15787     0.00063885
{' Totals' }       803     397     2.0227      NaN          0.087112
```

plotbins(sc, 'CustAge')

Display bin information for categorical data for 'ResStatus' that includes missing data in a separate bin labelled <missing>.

```
bi = bininfo(sc, 'ResStatus');
disp(bi)
```

| Bin              | Good | Bad | Odds   | WOE       | InfoValue  |

# addBusinessCalendar

Add business calendar awareness to timetables

## Syntax

```
TT = addBusinessCalendar(TT)
TT = addBusinessCalendar( ____,Name,Value)
```

## Description

TT = addBusinessCalendar(TT) adds business calendar awareness to an input timetable TT by setting a custom property for the output timetable TT.

TT = addBusinessCalendar( \_\_\_\_,Name,Value) specifies options using one or more optional name-value pair arguments in addition to the input arguments in the previous syntax. For example, TT = addBusinessCalendar(TT, 'Holidays', H) specifies a list of holidays specified as a datetime vector that replaces the default holidays found in holidays.m. You can specify more than one name-value pair argument.

## Examples

### Add Business Calendar for Calculating Period-Over-Period Rolling Returns

This example shows how to add a business calendar when you calculate period-over-period (PoP) rolling differences for 5 years of simulated daily prices. For each date in timetable TT, the difference represents the PoP difference of the corresponding price compared to the price one period earlier.

Use holidays to indicate the holidays in holidays.m for the simulation period.

```
H = holidays(datetime(2014,1,1),datetime(2018,12,31));
```

Simulate daily prices for three assets.

```
t = (datetime(2014,1,1):caldays:datetime(2018,12,31))';
rng(200, 'twister')
Price = 100 + 0.1*(0:numel(t) - 1)'.*cumsum(randn(numel(t),1)/100);
Price = round(Price*100)/100;
Price2 = round(Price*94)/100;
Price3 = round(Price*88)/100;
```

```
TT = timetable(Price,Price2,Price3,'RowTimes',t);
head(TT,15)
```

```
ans=15x3 timetable
      Time      Price      Price2      Price3
  _____  _____  _____  _____
01-Jan-2014      100         94         88
02-Jan-2014      100         94         88
03-Jan-2014      100         94         88
```

|             |        |       |       |
|-------------|--------|-------|-------|
| 04-Jan-2014 | 100    | 94    | 88    |
| 05-Jan-2014 | 100.01 | 94.01 | 88.01 |
| 06-Jan-2014 | 100.01 | 94.01 | 88.01 |
| 07-Jan-2014 | 100.02 | 94.02 | 88.02 |
| 08-Jan-2014 | 100.02 | 94.02 | 88.02 |
| 09-Jan-2014 | 100.04 | 94.04 | 88.04 |
| 10-Jan-2014 | 100.06 | 94.06 | 88.05 |
| 11-Jan-2014 | 100.08 | 94.08 | 88.07 |
| 12-Jan-2014 | 100.11 | 94.1  | 88.1  |
| 13-Jan-2014 | 100.11 | 94.1  | 88.1  |
| 14-Jan-2014 | 100.12 | 94.11 | 88.11 |
| 15-Jan-2014 | 100.12 | 94.11 | 88.11 |

Use `addBusinessCalendar` to indicate the holidays for the simulation period in the timetable `TT`.

```
TT = addBusinessCalendar(TT, 'Holidays', H);
```

Use `rollingreturns` with the 'Method' name-value pair argument set to 'difference' to compute the differences, that is, the period-over-period changes.

```
deltas = rollingreturns(TT, 'Period', calweeks(1), 'Method', 'difference');
head(deltas, 15)
```

```
ans=15x3 timetable
      Time      Price_Difference_1w      Price2_Difference_1w      Price3_Difference_1w

14-Jan-2014      0.1      0.09      0.09
15-Jan-2014      0.1      0.09      0.09
```

## Input Arguments

### **TT** — Input timetable to update with business calendar awareness

timetable

Input timetable to update with business calendar awareness, specified as a timetable.

Data Types: timetable

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, . . . , NameN, ValueN`.

Example: `TT = addBusinessCalendar(TT, 'Holidays', H)`

## Holidays — Alternate holidays and market closure dates

New York Stock Exchange (NYSE) holidays and market closures in `holidays.m` (default) | vector of datetimes

Alternate holidays and market closure dates, specified as the comma-separated pair consisting of `'Holidays'` and a vector of datetimes. The dates in `Holidays` must be whole dates, without any `HH:MM:SS` components. No business is conducted on the dates in `Holidays`. For more information, see `holidays` and `isbusday`.

You can generate alternate holiday schedules by using the `createholidays` function. To do so, perform the following steps:

- 1 Generate a new `holidays` function using `createholidays`.
- 2 Call the new `holidays` function to get the list of holidays.
- 3 Pass the alternate holidays to `addBusinessCalendar` using the `'Holidays'` name-value pair argument.

Data Types: `char` | `double`

## Weekends — Alternate weekend days on which no business is conducted

`[1 0 0 0 0 0 1]` which is equivalent to `["Sunday" "Saturday"]` (default) | logical vector with 7 elements | string vector with the value `["Sunday" "Saturday"]`

Alternate weekend days on which no business is conducted, specified as the comma-separated pair consisting of `'Weekends'` and a logical vector with seven elements in which true (1) indicates a weekend day and false (0) indicates a weekday. The elements of `'Weekends'` are encoded as Sunday, Monday, Tuesday, Wednesday, Thursday, Friday, and Saturday. You can also specify `'Weekends'` as a string vector whose elements explicitly list the weekend days. If business is conducted seven days per week, then specify `'Weekends'` as `[0 0 0 0 0 0 0]`.

Data Types: `logical`

## Output Arguments

### TT — Updated timetable TT with added business calendar awareness by a custom property timetable

Updated timetable TT with added business calendar awareness by a custom property `BusinessCalendar`, returned as a `timetable`.

The custom property `BusinessCalendar` contains a data structure that contains a field `IsBusinessDay` that stores a callable function (F). The function F accepts a datetime matrix (D) and returns a logical indicator matrix (I) of the same size: `I = F(D)`. True (1) elements of I indicate that the corresponding element of D occurs on a business day; false (0) elements of I indicate otherwise. Access the callable function F by using `F = TT.Properties.CustomProperties.BusinessCalendar.IsBusinessDay`.

**Introduced in R2020b**

# rollingreturns

Period-over-period rolling returns or differences from prices

## Syntax

```
returns = rollingreturns(TT)
returns = rollingreturns( ____,Name,Value)
```

## Description

`returns = rollingreturns(TT)` calculates period-over-period (PoP) returns or differences from corresponding prices. For each date in timetable `TT`, the return represents the PoP return of the corresponding price compared to the price one `Period` earlier.

`returns = rollingreturns( ____,Name,Value)` specifies options using one or more optional name-value pair arguments in addition to the input arguments in the previous syntax.

## Examples

### Year-over-Year Returns from Daily Prices with Business Calendar Awareness

This example shows how to compute year-over-year rolling returns for five years of simulated daily prices and also includes business calendar awareness.

Simulate five years of daily prices and store the result in the timetable `TT`. Then, use `isbusday` to retain only data for New York Stock Exchange (NYSE) business dates.

```
rng(200,'twister')
time = (datetime(2014,1,1):caldays:datetime(2018,12,31))';
price = 100 + 0.1*(0:numel(time) - 1)'.*cumsum(randn(numel(time),1)/100);
price = round(price*100)/100; % Round prices to the nearest penny
TT = timetable(price,'RowTimes',time,'VariableNames',{'Prices'});
TT = TT(isbusday(TT.Properties.RowTimes),:); % Retain only NYSE business days
head(TT,10)
```

ans=10×1 timetable

| Time        | Prices |
|-------------|--------|
| 02-Jan-2014 | 100    |
| 03-Jan-2014 | 100    |
| 06-Jan-2014 | 100.01 |
| 07-Jan-2014 | 100.02 |
| 08-Jan-2014 | 100.02 |
| 09-Jan-2014 | 100.04 |
| 10-Jan-2014 | 100.06 |
| 13-Jan-2014 | 100.11 |
| 14-Jan-2014 | 100.12 |
| 15-Jan-2014 | 100.12 |

Use `addBusinessCalendar` to add NYSE business calendar awareness. The business calendar logic determines if the date of the previous period is a business date, and if it is not, then the most recent business day preceding that date is found. For example, since 21-May-2016 is a Saturday and 22-May-2016 is a Sunday, year-over-year prices for Monday 22-May-2017 are compared to Friday 20-May-2016.

```
TT = addBusinessCalendar(TT); % Add NYSE business calendar
```

Compute the year-over-year returns and display the last few prices and corresponding returns.

```
returns = rollingreturns(TT, 'Period', calyears);
tail([TT returns])
```

```
ans=8x2 timetable
      Time      Prices      Prices_Return_ly
      -----

21-Dec-2018    217.66      0.18648
24-Dec-2018    221.42      0.20882
26-Dec-2018    224.81      0.21473
27-Dec-2018    222.17      0.19897
28-Dec-2018    224.63      0.19142
31-Dec-2018    224.37      0.19206
```

### Year-over-Year Returns from Monthly Prices with End-of-Month Dates

Economic data is often reported on the last day of each month or quarter. So end-of-month ambiguities can arise when computing period-over-period returns for periods that exceed the periodicity at which data is reported.

Simulate five years of daily prices and store the result in the timetable `TT`.

```
rng(200, 'twister')
time = (datetime(2014,1,1):caldays:datetime(2018,12,31))';
price = 100 + 0.1*(0:numel(time) - 1)'.*cumsum(randn(numel(time),1)/100);
price = round(price*100)/100; % Round prices to the nearest penny
TT = timetable(price, 'RowTimes', time, 'VariableNames', {'Prices'});
head(TT,10)
```

```
ans=10x1 timetable
      Time      Prices
      -----
01-Jan-2014      100
02-Jan-2014      100
03-Jan-2014      100
04-Jan-2014      100
05-Jan-2014    100.01
06-Jan-2014    100.01
07-Jan-2014    100.02
08-Jan-2014    100.02
09-Jan-2014    100.04
```

```
10-Jan-2014    100.06
```

Create a new timetable by sampling TT on the last day of each month to mimic monthly reporting.

```
monthEndDates = dateshift(TT.Time(1):calmonths:TT.Time(end),'end','month');
TT = TT(monthEndDates,:); % Sample TT at end-of-month dates
head(TT,10)
```

```
ans=10x1 timetable
      Time      Prices
-----
31-Jan-2014    100.47
28-Feb-2014    100.93
31-Mar-2014      102
30-Apr-2014    102.28
31-May-2014    103.22
30-Jun-2014    103.92
31-Jul-2014     102.2
31-Aug-2014    104.79
30-Sep-2014    103.11
31-Oct-2014    105.29
```

Display a subset of the dates and compare a direct calculation of the dates in previous months to those shifted to the end of the month in which the previous period occurs.

```
dates = timerange(datetime(2016,2,29),datetime(2017,2,28),'month');
[TT.Time(dates) (TT.Time(dates) - calyears) dateshift(TT.Time(dates) - calyears,'end','month')]
```

```
ans = 13x3 datetime
29-Feb-2016    28-Feb-2015    28-Feb-2015
31-Mar-2016    31-Mar-2015    31-Mar-2015
30-Apr-2016    30-Apr-2015    30-Apr-2015
31-May-2016    31-May-2015    31-May-2015
30-Jun-2016    30-Jun-2015    30-Jun-2015
31-Jul-2016    31-Jul-2015    31-Jul-2015
31-Aug-2016    31-Aug-2015    31-Aug-2015
30-Sep-2016    30-Sep-2015    30-Sep-2015
31-Oct-2016    31-Oct-2015    31-Oct-2015
30-Nov-2016    30-Nov-2015    30-Nov-2015
31-Dec-2016    31-Dec-2015    31-Dec-2015
31-Jan-2017    31-Jan-2016    31-Jan-2016
28-Feb-2017    28-Feb-2016    29-Feb-2016
```

Examine these results and notice that the dates in the second and third columns of the last row differ. Specifically, when the current date in the first column is 28-Feb-2017 the dates in the second and third columns differ because 2016 is a leap year. More generally, the dates differ whenever the month of the previous period has more days than the current month for which returns are computed. In this example, end-of-months dates present the following ambiguity. When the current date of interest is 28-Feb-2017, should subtracting one calendar year produce 28-Feb-2016 or 29-Feb-2016?

The correct answer depends on the application, and both approaches are valid use cases. This problem is exacerbated, for example, when working with end-of-monthly price data and computing month-over-month returns. To address the end-of-month ambiguity, the `rollingreturns` function supports an `EndOfMonth` flag.

```
returns = rollingreturns(TT, 'Period', calyears, 'EndOfMonth', true);
```

The `EndOfMonth` flag ensures that the `rollingreturns` function uses the correct end-of-month date of each calendar month. In this example, the return on 28-Feb-2017 is correctly computed from the price reported 29-Feb-2016 rather than 28-Feb-2016.

```
[TT(dates,:) returns(dates,:)]
```

```
ans=13x2 timetable

28-Feb-2017    136.36      0.0056789
```

## Input Arguments

### TT — Input timetable of prices

timetable

Input timetable of prices, specified as a `timetable`. The timetable `TT` must satisfy the following conditions:

- All observations in `TT` must be associated with whole dates specified as datetimes with no HH:MM:SS time component (no time-of-day component).
- `TT` dates must be sorted in ascending order.
- `TT` must have no duplicate dates.
- Each variable in `TT` must contain either a single numeric vector or a numeric matrix of prices. For example, suppose `TT` contains three variables of daily prices.

| Time        | Price1 | Price2 | Prices |        |
|-------------|--------|--------|--------|--------|
| 24-Dec-2018 | 221.42 | 442.84 | 221.42 | 442.84 |
| 25-Dec-2018 | 220.62 | 441.24 | 220.62 | 441.24 |
| 26-Dec-2018 | 224.81 | 449.62 | 224.81 | 449.62 |
| 27-Dec-2018 | 222.17 | 444.34 | 222.17 | 444.34 |
| 28-Dec-2018 | 224.63 | 449.26 | 224.63 | 449.26 |
| 29-Dec-2018 | 225.36 | 450.72 | 225.36 | 450.72 |
| 30-Dec-2018 | 226.73 | 453.46 | 226.73 | 453.46 |
| 31-Dec-2018 | 224.37 | 448.74 | 224.37 | 448.74 |

The corresponding daily returns are formatted as three returns for the three price variables.

| Time        | Price1_Return | Price2_Return | Prices_Return |           |
|-------------|---------------|---------------|---------------|-----------|
| 24-Dec-2018 | NaN           | NaN           | NaN           | NaN       |
| 25-Dec-2018 | -0.003613     | -0.003613     | -0.003613     | -0.003613 |
| 26-Dec-2018 | 0.018992      | 0.018992      | 0.018992      | 0.018992  |
| 27-Dec-2018 | -0.011743     | -0.011743     | -0.011743     | -0.011743 |
| 28-Dec-2018 | 0.011073      | 0.011073      | 0.011073      | 0.011073  |
| 29-Dec-2018 | 0.003249      | 0.003249      | 0.003249      | 0.003249  |
| 30-Dec-2018 | 0.006079      | 0.006079      | 0.006079      | 0.006079  |
| 31-Dec-2018 | -0.010409     | -0.010409     | -0.010409     | -0.010409 |

---

**Note** To include business-calendar-awareness and account for nonbusiness days (for example, weekends, holidays, market closures), you must first use the `addBusinessCalendar` function to populate a custom property for the input `TT`. For example, to add business calendar logic to include only NYSE business days, you can use `TT = addBusinessCalendar(TT)`.

---

Data Types: `timetable`

### Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `returns = rollingreturns(TT, 'Period', calweeks(1), 'EndOfMonth', true, 'Method', 'continuous')`

### Period — Period to compute period-over-period returns

`TT.Properties.TimeStep` (default) | scalar calendar duration

Period to compute period-over-period returns, specified as the comma-separated pair consisting of `'EndMonthRule'` and a scalar calendar duration (for example, `caldays`, `calweeks`, or `calmonths`).

The default is the time step defined in `TT` (`TT.Properties.TimeStep`), but only when `TT.Properties.TimeStep` is not `NaN`. If `TT.Properties.TimeStep` is `NaN`, then `Period` is required.

Data Types: `double`

### EndOfMonth — End-of-month flag indicates whether prices at current date are compared to last date of month for previous Period

`false` (default) | value of `true` or `false`

End-of-month flag indicates whether the prices at the current date are compared to last date of month for the previous `Period`, specified as the comma-separated pair consisting of `'EndOfMonth'` and a scalar logical value of `true` or `false`.

- If you set `EndOfMonth` to `true` (logical 1), meaning that the current prices are compared to end-of-month prices of the previous `Period`.
- If you set `EndOfMonth` to `false` (logical 0), meaning that the current prices are compared to prices recorded on the actual date of the previous `Period`.

---

**Note** The `EndOfMonth` flag is intended to address end-of-month date calculations when computing the dates of a previous `Period` one or more months in the past.

For example, suppose you have monthly prices reported at the end of each month and want to compute year-over-year returns (that is, `Period = calyears(1)`). When the current date of interest is `28-Feb-2017`, setting `EndOfMonth = true` (logical 1) ensures that returns computed for `28-Feb-2017` compare the prices on `28-Feb-2017` to those on `29-Feb-2016` rather than `28-Feb-2016`.

Similarly, suppose you have monthly prices reported at the end of each month and want to compute month-over-month returns (that is, `Period = calmonths(1)`). When the current date of interest is `30-Apr-2020`, setting `EndOfMonth = true` (logical 1) ensures that returns computed for `30-Apr-2020` compare the prices on `30-Apr-2020` to those on `31-Mar-2020` rather than `30-Mar-2020`.

---

Data Types: `logical`

### Method — Method for computing returns from prices

'simple' (default) | character vector with value 'simple', 'continuous', or 'difference'

Method for computing returns from prices, specified as the comma-separated pair consisting of 'Method' and a scalar character vector.

- 'simple' — Compute simple (proportional) returns:  $R(t) = P(t)/P(t\text{-period}) - 1$ .
- 'continuous' — Compute continuous (logarithmic) returns:  $R(t) = \log(P(t)/P(t\text{-period}))$ .
- 'difference' — Compute differences (period-over-period changes):  $R(t) = P(t) - P(t\text{-period})$

Data Types: `char`

## Output Arguments

### returns — Period-over-period decimal returns or differences

timetable

Period-over-period decimal returns or differences, returned as a timetable of the same size and format as the input argument `TT`. The returns or differences in row  $t$  are associated with the  $t$ th date in `TT` and represent the return or difference of the  $t$ th price  $P(t)$  relative to the price in the previous period  $P(t\text{-period})$ . If the date in the previous period is not found in `TT`, then the result is `NaN` to indicate a missing value.

Variable names in the output append `_Return` or `_Difference` to the variable names in `TT` for returns and differences, respectively, followed by the period used in the period-over-period results. For example, if `TT` has a variable named `ABC` and week-over-week returns are computed for a `Period` of `calweeks(1)`, the corresponding output variable is named `ABC_Returns_1w`.

`rollingreturns` is an aggregation function in which the frequency at which prices are recorded must equal or exceed that at which returns or differences are computed. For example, daily prices can be used to compute daily, weekly, or monthly returns, but computing daily returns from weekly or monthly prices generally makes no sense.

## Algorithms

Period-over-period results are computed for every date in TT as follows:

- 1 For each date  $t$  in TT, the date  $t$ -period is computed.
  - If date  $t$ -period is a business date, then this date is the date "one period ago"
  - If date  $t$ -period is not a business date, then each calendar day preceding  $t$ -period is examined repeatedly until a business date is found, at which point this date is the date "one period ago," or the preceding date occurs prior to the first date in TT, at which point no previous business date exists in TT.
- 2 If the date "one period ago" is found in TT, then the corresponding price  $P(t\text{-period})$  is recorded and the return  $R(t)$  is computed. However, if the date "one period ago" is not found in TT, then the previous price  $P(t\text{-period})$  is assumed missing (that is, an implicit NaN), and the return  $R(t) = \text{NaN}$ .
- 3 The previous steps are repeated until the date  $t$ -period precedes the first date found in TT, at which point the algorithm terminates.

## simByTransition

Simulate Bates sample paths with transition density

### Syntax

```
[Paths,Times] = simByTransition(MDL,NPeriods)
[Paths,Times] = simByTransition( ____,Name,Value)
```

### Description

[Paths,Times] = simByTransition(MDL,NPeriods) simulates NTrials of Bates bivariate models driven by two Brownian motion sources of risk and one compound Poisson process representing the arrivals of important events over NPeriods consecutive observation periods. simByTransition approximates continuous-time stochastic processes by the transition density.

[Paths,Times] = simByTransition( \_\_\_\_,Name,Value) specifies options using one or more name-value pair arguments in addition to the input arguments in the previous syntax.

### Examples

#### Use simByTransition with bates Object

Simulate Bates sample paths with transition density.

Define the parameters for the bates object.

```
AssetPrice = 80;
Return = 0.03;
JumpMean = 0.02;
JumpVol = 0.08;
JumpFreq = 0.1;
V0 = 0.04;
Level = 0.05;
Speed = 1.0;
Volatility = 0.2;
Rho = -0.7;
StartState = [AssetPrice;V0];
Correlation = [1 Rho;Rho 1];
```

Create a bates object.

```
batesObj = bates(Return, Speed, Level, Volatility,...
                JumpFreq, JumpMean, JumpVol, 'startstate', StartState,...
                'correlation', Correlation)
```

```
batesObj =
  Class BATES: Bates Bivariate Stochastic Volatility
  -----
  Dimensions: State = 2, Brownian = 2
  -----
  StartTime: 0
```

```

StartState: 2x1 double array
Correlation: 2x2 double array
  Drift: drift rate function F(t,X(t))
  Diffusion: diffusion rate function G(t,X(t))
Simulation: simulation method/function simByEuler
  Return: 0.03
  Speed: 1
  Level: 0.05
Volatility: 0.2
  JumpFreq: 0.1
  JumpMean: 0.02
  JumpVol: 0.08

```

Define the simulation parameters.

```

nPeriods = 5; % Simulate sample paths over the next five years
Paths = simByTransition(batesObj,nPeriods);
Paths

```

```

Paths = 6x2

```

```

80.0000    0.0400

49.9649    0.0638
58.9553    0.0467

```

## Input Arguments

### MDL — Stochastic differential equation model

bates object

Stochastic differential equation model, specified as a bates object. For more information on creating a bates object, see bates.

Data Types: object

### NPeriods — Number of simulation periods

positive scalar integer

Number of simulation periods, specified as a positive scalar integer. The value of NPeriods determines the number of rows of the simulated output series.

Data Types: double

### Name-Value Pair Arguments

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1, Value1, ..., NameN, ValueN.

Example: [Paths,Times] = simByTransition(Bates,NPeriods,'DeltaTimes',dt)

### NTrials — Simulated trials (sample paths)

1 (single path of correlated state variables) (default) | positive integer

Simulated trials (sample paths) of `NPeriods` observations each, specified as the comma-separated pair consisting of `'NTrials'` and a positive scalar integer.

Data Types: `double`

### **DeltaTimes — Positive time increments between observations**

1 (default) | `scalar` | `column vector`

Positive time increments between observations, specified as the comma-separated pair consisting of `'DeltaTimes'` and a scalar or `NPeriods-by-1` column vector.

`DeltaTime` represents the familiar  $dt$  found in stochastic differential equations, and determines the times at which the simulated paths of the output state variables are reported.

Data Types: `double`

### **NSteps — Number of intermediate time steps**

1 (indicating no intermediate evaluation) (default) | `positive integer`

Number of intermediate time steps within each time increment  $dt$  (defined as `DeltaTimes`), specified as the comma-separated pair consisting of `'NSteps'` and a positive scalar integer.

The `simByTransition` function partitions each time increment  $dt$  into `NSteps` subintervals of length  $dt/NSteps$ , and refines the simulation by evaluating the simulated state vector at `NSteps - 1` intermediate points. Although `simByTransition` does not report the output state vector at these intermediate points, the refinement improves accuracy by enabling the simulation to more closely approximate the underlying continuous-time process.

Data Types: `double`

### **StorePaths — Flag for storage and return method**

`True` (default) | `logical with values True or False`

Flag for storage and return method that indicates how the output array `Paths` is stored and returned, specified as the comma-separated pair consisting of `'StorePaths'` and a scalar logical flag with a value of `True` or `False`.

- If `StorePaths` is `True` (the default value) or is unspecified, then `simByTransition` returns `Paths` as a three-dimensional time series array.
- If `StorePaths` is `False` (logical 0), then `simByTransition` returns the `Paths` output array as an empty matrix.

Data Types: `logical`

### **Processes — Sequence of end-of-period processes or state vector adjustments**

`simByTransition` makes no adjustments and performs no processing (default) | `function` | `cell array of functions`

Sequence of end-of-period processes or state vector adjustments, specified as the comma-separated pair consisting of `'Processes'` and a function or cell array of functions of the form

$$X_t = P(t, X_t)$$

`simByTransition` applies processing functions at the end of each observation period. The processing functions accept the current observation time  $t$  and the current state vector  $X_t$ , and return a state vector that might adjust the input state.

If you specify more than one processing function, `simByTransition` invokes the functions in the order in which they appear in the cell array.

Data Types: `cell` | `function`

## Output Arguments

### Paths — Simulated paths of correlated state variables

array

Simulated paths of correlated state variables, returned as an  $(N\text{Periods} + 1)$ -by- $N\text{Vars}$ -by- $N\text{Trials}$  three-dimensional time series array.

For a given trial, each row of `Paths` is the transpose of the state vector  $X_t$  at time  $t$ . When the input flag `StorePaths = False`, `simByTransition` returns `Paths` as an empty matrix.

### Times — Observation times associated with the simulated paths

column vector

Observation times associated with the simulated paths, returned as an  $(N\text{Periods} + 1)$ -by-1 column vector. Each element of `Times` is associated with the corresponding row of `Paths`.

## More About

### Transition Density Simulation

The CIR SDE has no solution such that  $r(t) = f(r(0), \dots)$ .

In other words, the equation is not explicitly solvable. However, the transition density for the process is known.

The exact simulation for the distribution of  $r(t_1), \dots, r(t_n)$  is that of the process at times  $t_1, \dots, t_n$  for the same value of  $r(0)$ . The transition density for this process is known and is expressed as

$$r(t) = \frac{\sigma^2(1 - e^{-\alpha(t-u)})}{4\alpha} \chi_d^2 \left( \frac{4\alpha e^{-\alpha(t-u)}}{\sigma^2(1 - e^{-\alpha(t-u)})} r(u) \right), t > u$$

where

$$d \equiv \frac{4b\alpha}{\sigma^2}$$

### Bates Model

Bates models are bivariate composite models.

Each Bates model consists of two coupled univariate models:

- A geometric Brownian motion (gbm) model with a stochastic volatility function and jumps.

$$dX_{1t} = B(t)X_{1t}dt + \sqrt{X_{2t}}X_{1t}dW_{1t} + Y(t)X_{1t}dN_t$$

This model usually corresponds to a price process whose volatility (variance rate) is governed by the second univariate model.

- A Cox-Ingersoll-Ross (cir) square root diffusion model.

$$dX_{2t} = S(t)[L(t) - X_{2t}]dt + V(t)\sqrt{X_{2t}}dW_{2t}$$

This model describes the evolution of the variance rate of the coupled Bates price process.

**Introduced in R2020b**

# simByTransition

Simulate Heston sample paths with transition density

## Syntax

```
[Paths,Times] = simByTransition(MDL,NPeriods)
[Paths,Times] = simByTransition( ____,Name,Value)
```

## Description

[Paths,Times] = simByTransition(MDL,NPeriods) simulates NTrials sample paths of Heston bivariate models driven by two Brownian motion sources of risk. simByTransition approximates continuous-time stochastic processes by the transition density.

[Paths,Times] = simByTransition( \_\_\_\_,Name,Value) specifies options using one or more name-value pair arguments in addition to the input arguments in the previous syntax.

## Examples

### Use simByTransition with heston Object

Simulate Heston sample paths with transition density.

Define the parameters for the heston object.

```
Return = 0.03;
Level = 0.05;
Speed = 1.0;
Volatility = 0.2;

AssetPrice = 80;
V0 = 0.04;
Rho = -0.7;
StartState = [AssetPrice;V0];
Correlation = [1 Rho;Rho 1];
```

Create a heston object.

```
hestonObj = heston(Return,Speed,Level,Volatility,'startstate',StartState,'correlation',Correlation)
```

```
hestonObj =
  Class HESTON: Heston Bivariate Stochastic Volatility
  -----
  Dimensions: State = 2, Brownian = 2
  -----
  StartTime: 0
  StartState: 2x1 double array
  Correlation: 2x2 double array
  Drift: drift rate function F(t,X(t))
  Diffusion: diffusion rate function G(t,X(t))
  Simulation: simulation method/function simByEuler
```

```

Return: 0.03
Speed: 1
Level: 0.05
Volatility: 0.2

```

Define the simulation parameters.

```

nPeriods = 5; % Simulate sample paths over the next five years
Paths = simByTransition(hestonObj,nPeriods);
Paths

```

```

Paths = 6x2

```

```

80.0000 0.0400
92.9915 0.0343
108.6211 0.0737
52.9617 0.1012
46.9805 0.1243
54.3704 0.0571

```

## Input Arguments

### MDL — Stochastic differential equation model

heston object

Stochastic differential equation model, specified as a heston object. For more information on creating a heston object, see `heston`.

Data Types: object

### NPeriods — Number of simulation periods

positive scalar integer

Number of simulation periods, specified as a positive scalar integer. The value of `NPeriods` determines the number of rows of the simulated output series.

Data Types: double

### Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `[Paths,Times] = simByTransition(Heston,NPeriods,'DeltaTimes',dt)`

### NTrials — Simulated trials (sample paths)

1 (single path of correlated state variables) (default) | positive integer

Simulated trials (sample paths) of `NPeriods` observations each, specified as the comma-separated pair consisting of `'NTrials'` and a positive scalar integer.

Data Types: double

### DeltaTimes — Positive time increments between observations

1 (default) | scalar | column vector

Positive time increments between observations, specified as the comma-separated pair consisting of 'DeltaTimes' and a scalar or NPeriods-by-1 column vector.

DeltaTime represents the familiar  $dt$  found in stochastic differential equations, and determines the times at which the simulated paths of the output state variables are reported.

Data Types: double

### **NSteps — Number of intermediate time steps**

1 (indicating no intermediate evaluation) (default) | positive integer

Number of intermediate time steps within each time increment  $dt$  (defined as DeltaTimes), specified as the comma-separated pair consisting of 'NSteps' and a positive scalar integer.

The simByTransition function partitions each time increment  $dt$  into NSteps subintervals of length  $dt/NSteps$ , and refines the simulation by evaluating the simulated state vector at NSteps - 1 intermediate points. Although simByTransition does not report the output state vector at these intermediate points, the refinement improves accuracy by enabling the simulation to more closely approximate the underlying continuous-time process.

Data Types: double

### **StorePaths — Flag for storage and return method**

True (default) | logical with True or False

Flag for storage and return method that indicates how the output array Paths is stored and returned, specified as the comma-separated pair consisting of 'StorePaths' and a scalar logical flag with a value of True or False.

- If StorePaths is True (the default value) or is unspecified, then simByTransition returns Paths as a three-dimensional time series array.
- If StorePaths is False (logical 0), then simByTransition returns the Paths output array as an empty matrix.

Data Types: logical

### **Processes — Sequence of end-of-period processes or state vector adjustments**

simByTransition makes no adjustments and performs no processing (default) | function | cell array of functions

Sequence of end-of-period processes or state vector adjustments, specified as the comma-separated pair consisting of 'Processes' and a function or cell array of functions of the form

$$X_t = P(t, X_t)$$

simByTransition applies processing functions at the end of each observation period. The processing functions accept the current observation time  $t$  and the current state vector  $X_t$ , and return a state vector that might adjust the input state.

If you specify more than one processing function, simByTransition invokes the functions in the order in which they appear in the cell array.

Data Types: cell | function

## Output Arguments

### Paths — Simulated paths of correlated state variables

array

Simulated paths of correlated state variables, returned as an  $(N\text{Periods} + 1)$ -by- $N\text{Vars}$ -by- $N\text{Trials}$  three-dimensional time series array.

For a given trial, each row of `Paths` is the transpose of the state vector  $X_t$  at time  $t$ . When the input flag `StorePaths = False`, `simByTransition` returns `Paths` as an empty matrix.

### Times — Observation times associated with simulated paths

column vector

Observation times associated with the simulated paths, returned as an  $(N\text{Periods} + 1)$ -by-1 column vector. Each element of `Times` is associated with the corresponding row of `Paths`.

## More About

### Transition Density Simulation

The CIR SDE has no solution such that  $r(t) = f(r(0), \dots)$ .

In other words, the equation is not explicitly solvable. However, the transition density for the process is known.

The exact simulation for the distribution of  $r(t_1), \dots, r(t_n)$  is that of the process at times  $t_1, \dots, t_n$  for the same value of  $r(0)$ . The transition density for this process is known and is expressed as

$$r(t) = \frac{\sigma^2(1 - e^{-\alpha(t-u)})}{4\alpha} \chi_d^2 \left( \frac{4\alpha e^{-\alpha(t-u)}}{\sigma^2(1 - e^{-\alpha(t-u)})} r(u) \right), t > u$$

where

$$d \equiv \frac{4b\alpha}{\sigma^2}$$

### Heston Model

Heston models are bivariate composite models.

Each Heston model consists of two coupled univariate models:

- A geometric Brownian motion (`gbm`) model with a stochastic volatility function.

$$dX_{1t} = B(t)X_{1t}dt + \sqrt{X_{2t}}X_{1t}dW_{1t}$$

This model usually corresponds to a price process whose volatility (variance rate) is governed by the second univariate model.

- A Cox-Ingersoll-Ross (`cir`) square root diffusion model.

$$dX_{2t} = S(t)[L(t) - X_{2t}]dt + V(t)\sqrt{X_{2t}}dW_{2t}$$

This model describes the evolution of the variance rate of the coupled GBM price process.

---

### Bond Pricing and Yields

The pricing and yield formulas for fixed-income securities come from:

- [1] Golub, B.W. and L.M. Tilman. *Risk Management: Approaches for Fixed Income Markets*. Wiley, 2000.
- [2] Martellini, L., P. Priaulet, and S. Priaulet. *Fixed Income Securities*. Wiley, 2003.
- [3] Mayle, Jan. *Standard Securities Calculation Methods*. New York: Securities Industry Association, Inc. Vol. 1, 3rd ed., 1993, ISBN 1-882936-01-9. Vol. 2, 1994, ISBN 1-882936-02-7.
- [4] Tuckman, B. *Fixed Income Securities: Tools for Today's Markets*. Wiley, 2002.

In many cases these formulas compute the price of a security given yield, dates, rates, and other data. These formulas are nonlinear, however; so when solving for an independent variable within a formula, Financial Toolbox software uses Newton's method. See any elementary numerical methods textbook for the mathematics underlying Newton's method.

### Term Structure of Interest Rates

The formulas and methodology for term structure functions come from:

- [5] Fabozzi, Frank J. "The Structure of Interest Rates." Ch. 6 in Fabozzi, Frank J. and T. Dossa Fabozzi, eds. *The Handbook of Fixed Income Securities*. 4th ed. New York, Irwin Professional Publishing, 1995, ISBN 0-7863-0001-9.
- [6] McEnally, Richard W. and James V. Jordan. "The Term Structure of Interest Rates." Ch. 37 in Fabozzi and Fabozzi, *ibid*.
- [7] Das, Satyajit. "Calculating Zero Coupon Rates." *Swap and Derivative Financing*. Appendix to Ch. 8, pp. 219-225, New York, Irwin Professional Publishing., 1994, ISBN 1-55738-542-4.

## Derivatives Pricing and Yields

The pricing and yield formulas for derivative securities come from:

[8] Chriss, Neil A. *Black-Scholes and Beyond: Option Pricing Models*. Chicago, Irwin Professional Publishing, 1997, ISBN 0-7863-1025-1.

[9] Cox, J., S. Ross, and M. Rubenstein. "Option Pricing: A Simplified Approach." *Journal of Financial Economics*. Vol. 7, Sept. 1979, pp. 229-263.

[10] Hull, John C. *Options, Futures, and Other Derivatives*. 5th edition, Prentice Hall, 2003, ISBN 0-13-009056-5.

## Portfolio Analysis

The Markowitz model is used for portfolio analysis computations. For a discussion of this model see Chapter 7 of:

[11] Bodie, Zvi, Alex Kane, and Alan J. Marcus. *Investments*. 2nd. Edition. Burr Ridge, IL, Irwin Professional Publishing, 1993, ISBN 0-256-08342-8.

## Investment Performance Metrics

The risk and ratio formulas for investment performance metrics come from:

[12] Daniel Bernoulli. "Exposition of a New Theory on the Measurement of Risk." *Econometrica*. Vol. 22, No 1, January 1954, pp. 23-36 (English translation of "Specimen Theoriae Novae de Mensura Sortis." *Commentarii Academiae Scientiarum Imperialis Petropolitanae*. Tomus V, 1738, pp. 175-192).
