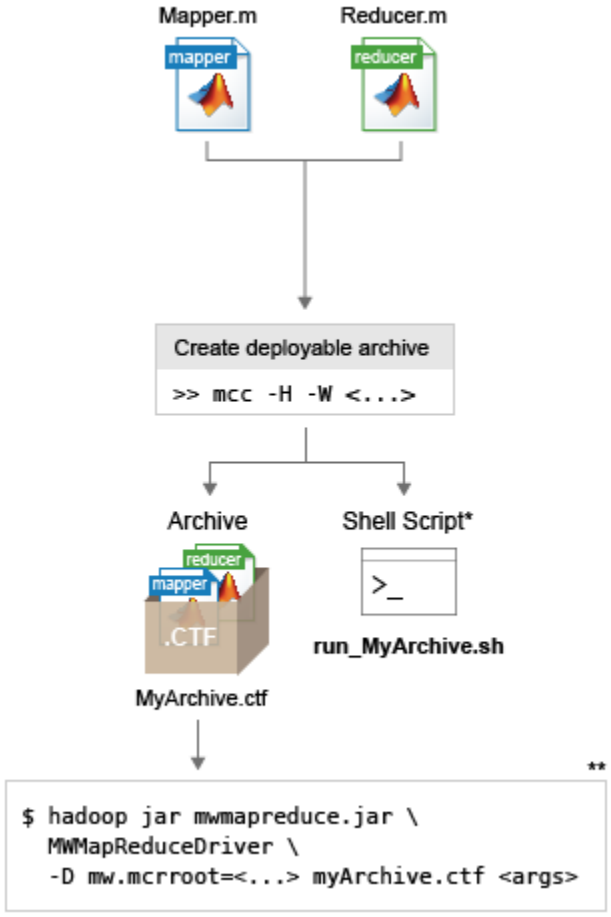
# Workflow to Incorporate MATLAB Map and Reduce Functions into a Hadoop Job



* You can use automatically generated shell scripts to execute applications from the terminal.

** Commands are not exact. For complete commands, see the auto-generated shell scripts.

1. Write mapper and reducer functions in MATLAB.
2. Create a MAT-file that contains a datastore that describes the structure of the data and the names of the variables to analyze. The datastore in the MAT-file can be created from a test data set that is representative of the actual data set.
3. Create a text file that contains Hadoop settings such as the name of the mapper, reducer, and the type of data being analyzed. This file is automatically created if you are using the **Hadoop Compiler** app.
4. Use the **Hadoop Compiler** app or the `mcc` command to package the components into a deployable archive. Both options generate a deployable archive (.ctf file) that can be incorporated into a Hadoop mapreduce job.

5 Incorporate the deployable archive into a Hadoop mapreduce job using the `hadoop` command and syntax.

**Execution Signature**

```
A  $ hadoop \
B    jar \
C    /<MATLAB_Runtime_Location>/v91/toolbox/mlhadoop/jar/a2.2.0/mwmapreduce.jar \
D    com.mathworks.hadoop.MWMapReduceDriver \
E    -D mw.mcrroot=<MATLAB_Runtime_Location> \
F    MapRedDeployableArchive.ctf \
G    <inputFolderOnHDFS> \
H    <outputFolderOnHDFS>
```

*Key*

| Letter | Description |
|---|---|
| A | Hadoop command |
| B | JAR option |
| C | The standard name of the JAR file. All applications have the same JAR: `mwmapreduce.jar`.The path to the JAR is also fixed relative to the MATLAB Runtime location. |
| D | The standard name of the driver. All applications have the same driver name: `MWMapReduceDriver` |
| E | A generic option specifying the MATLAB Runtime location as a key-value pair. |
| F | Deployable archive (`.ctf` file) generated by the **Hadoop Compiler** app or `mcc` is passed as a payload argument to the job. |
| G | Location of input files on HDFS™. |
| H | Location on HDFS where output can be written. |

To simplify the inclusion of the deployable archive (`.ctf` file) into a Hadoop mapreduce job, both the **Hadoop Compiler** app and the `mcc` command generate a shell script alongside the deployable archive. The shell script has the following naming convention: `run_<deployableArchiveName>.sh`

To run the deployable archive using the shell script, use the following syntax:

```
$./run_myDeployableArchive.sh\
<MATLAB_Runtime_Location>\
[hadoop_specific_properites] \
<inputFolderOnHDFS>\
<outputFolderOnHDFS>
```

# Example Using the Hadoop Compiler App Workflow

**Supported Platform:** Linux® only.

This example shows you how to use the **Hadoop Compiler** app to create a deployable archive consisting of MATLAB map and reduce functions and then pass the deployable archive as a payload argument to a job submitted to a Hadoop cluster.

**Goal:** Calculate the maximum arrival delay of an airline from the given dataset.

| | |
|---|---|
| **Dataset:** | `airlinesmall.csv` |
| **Description:** | Airline departure and arrival information from 1987-2008. |
| **Location:** | `/usr/local/MATLAB/R2021b/toolbox/matlab/demos` |

## Prerequisites

1. Start this example by creating a new work folder that is visible to the MATLAB search path.
2. Before starting MATLAB, at a terminal, set the environment variable `HADOOP_PREFIX` to point to the Hadoop installation folder. For example:

| Shell | Command |
|---|---|
| *csh / tcsh* | `% setenv HADOOP_PREFIX /usr/lib/hadoop` |
| *bash* | `$ export HADOOP_PREFIX=/usr/lib/hadoop` |

**Note** This example uses `/usr/lib/hadoop` as directory where Hadoop is installed. Your Hadoop installation directory maybe different.

If you forget setting the `HADOOP_PREFIX` environment variable prior to starting MATLAB, set it up using the MATLAB function `setenv` at the MATLAB command prompt as soon as you start MATLAB. For example:

```
setenv('HADOOP_PREFIX','/usr/lib/hadoop')
```

3. Install the MATLAB Runtime in a folder that is accessible by every worker node in the Hadoop cluster. This example uses `/usr/local/MATLAB/MATLAB_Runtime/v911` as the location of the MATLAB Runtime folder.

   If you don’t have the MATLAB Runtime, you can download it from the website at: `https://www.mathworks.com/products/compiler/mcr`.

**Note** For information about MATLAB Runtime version numbers corresponding MATLAB releases, see this list.

4. Copy the map function `maxArrivalDelayMapper.m` from `/usr/local/MATLAB/R2021b/toolbox/matlab/demos` folder to the work folder.

**maxArrivalDelayMapper.m**

```
function maxArrivalDelayMapper (data, info, intermKVStore)
partMax = max(data.ArrDelay);
add(intermKVStore,'PartialMaxArrivalDelay',partMax);
```

For more information, see “Write a Map Function”.

5 Copy the reduce function `maxArrivalDelayReducer.m` from *`matlabroot`*`/toolbox/matlab/demos` folder to the work folder.

**maxArrivalDelayReducer.m**

```
function maxArrivalDelayReducer(intermKey, intermValIter, outKVStore)
maxVal = -inf;
while hasnext(intermValIter)
   maxVal = max(getnext(intermValIter), maxVal);
end
add(outKVStore,'MaxArrivalDelay',maxVal);
```

For more information, see “Write a Reduce Function”.

6 Create the directory `/user/<`*`username`*`>/datasets` on HDFS and copy the file `airlinesmall.csv` to that directory. Here <*`username`*> refers to your user name in HDFS.

```
$ ./hadoop fs -copyFromLocal airlinesmall.csv hdfs://host:54310/user/<username>/datasets
```

## Procedure

1 Start MATLAB and verify that the `HADOOP_PREFIX` environment variable has been set. At the command prompt, type:

```
>> getenv('HADOOP_PREFIX')
```

If `ans` is empty, review the **Prerequisites** section above to see how you can set the `HADOOP_PREFIX` environment variable.

2 Create a `datastore` to the file `airlinesmall.csv` and save it to a `.mat` file. This `datastore` object is meant to capture the structure of your actual dataset on HDFS.

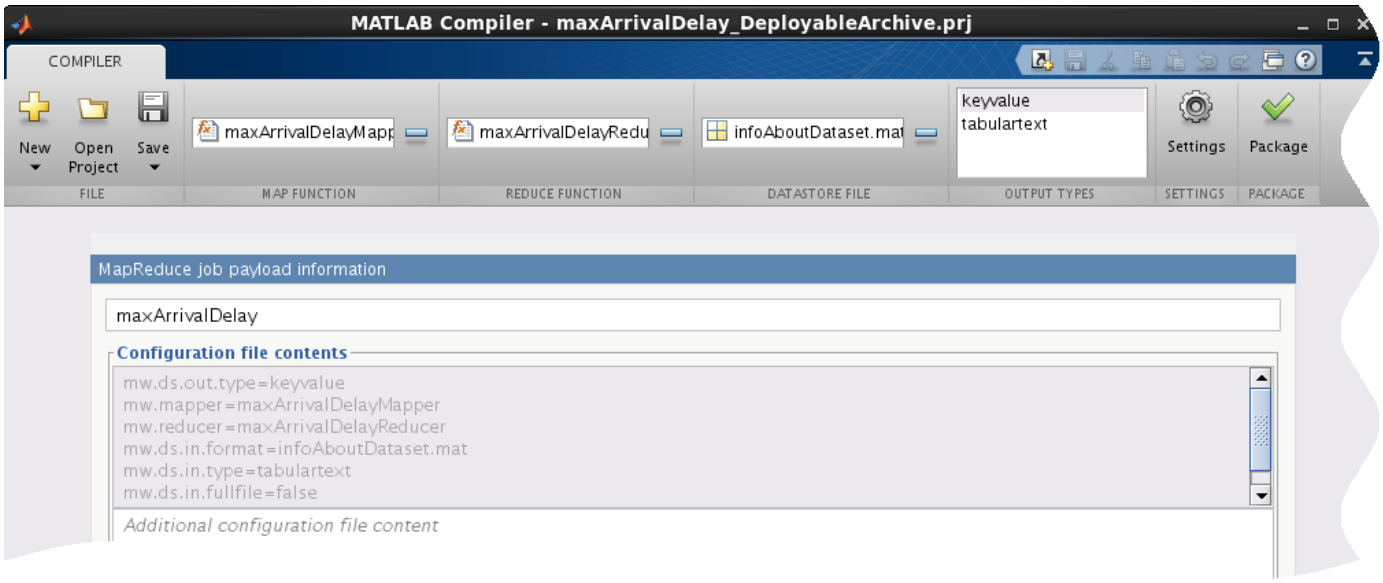
```
ds = datastore('airlinesmall.csv','TreatAsMissing','NA',...
     'SelectedVariableNames','ArrDelay','ReadSize',1000);

save('infoAboutDataset.mat','ds')
```

In most cases, you will start off by working on a small sample dataset residing on a local machine that is representative of the actual dataset on the cluster. This sample dataset has the same structure and variables as the actual dataset on the cluster. By creating a `datastore` object to the dataset residing on your local machine you are taking a snapshot of that structure. By having access to this `datastore` object, a Hadoop job executing on the cluster will know how to access and process the actual dataset residing on HDFS.

**Note** In this example, the sample dataset (local) and the actual dataset on HDFS are the same.

3 Launch the **Hadoop Compiler** app through the MATLAB command line (`>> hadoopCompiler`) or through the apps gallery.



4. In the **Map Function** section of the toolstrip, click the plus button to add mapper file `maxArrivalDelayMapper.m`.
5. In the **Reduce Function** section of the toolstrip, click the plus button to add reducer file `maxArrivalDelayReducer.m`.
6. In the **Datastore File** section, click the plus button to add the `.mat` file `infoAboutDataset.mat` containing the `datastore` object.
7. In the **Output Types** section, select `keyvalue` as output type. Selecting `keyvalue` as your output type means your results can only be read within MATLAB. If you want your results to be accessible outside of MATLAB, select output type as `tabulartext`.
8. Rename the **MapReduce job payload information** to `maxArrivalDelay`.
9. Click **Package** to build a deployable archive.

   The **Hadoop Compiler** app creates a log file `PackagingLog.txt` and two folders `for_redistribution` and `for_testing`.

| for_redistribution | for_testing |
|---|---|
| readme.txt | readme.txt |
| maxArrivalDelay.ctf | maxArrivalDelay.ctf |
| run_maxArrivalDelay.sh | run_maxArrivalDelay.sh |
| | mccExcludedFiles.log |
| | requiredMCRProducts.txt |

   You can use the log file `PackagingLog.txt` to see the exact `mcc` syntax used to package the deployable archive.
10. From a Linux shell navigate to the `for_redistribution` folder.
11. **a** Incorporate the deployable archive containing MATLAB map and reduce functions into a Hadoop mapreduce job from a Linux shell using the following command:

```
$ hadoop \
jar /usr/local/MATLAB/MATLAB_Runtime/v911/toolbox/mlhadoop/jar/a2.2.0/mwmapreduce.jar \
com.mathworks.hadoop.MWMapReduceDriver \
-D mw.mcrroot=/usr/local/MATLAB/MATLAB_Runtime/v911 \
maxArrivalDelay.ctf \
```

```
hdfs://host:54310/user/<username>/datasets/airlinesmall.csv \
hdfs://host:54310/user/<username>/results
```

**b** Alternately, you can incorporate the deployable archive containing MATLAB map and reduce functions into a Hadoop mapreduce job using the shell script generated by the **Hadoop Compiler** app. At the Linux shell type the following command:

```
$ ./run_maxArrivalDelay.sh \
/usr/local/MATLAB/MATLAB_Runtime/v911 \
-D mw.mcrroot=/usr/local/MATLAB/MATLAB_Runtime/v911 \
hdfs://host:54310/user/username/datasets/airlinesmall.csv \
hdfs://host:54310/user/<username>/results
```

**12** To examine the results, switch to the MATLAB desktop and create a `datastore` to the results on HDFS. You can then view the results using the `read` method.

```
d = datastore('hdfs:///user/<username>/results/part*');
read(d)
```

```
ans =

            Key             Value
    ____________________    ______

    'MaxArrivalDelay'       [1014]
```

Other examples of map and reduce functions are available at `toolbox/matlab/demos` folder. You can use other examples to prototype similar deployable archives to run on a Hadoop cluster. For more information, see “Build Effective Algorithms with MapReduce”.

# Example on Incorporating MATLAB Map and Reduce Functions into a Hadoop Job

**Supported Platform:** Linux only.

This example shows you how to use the `mcc` command to create a deployable archive consisting of MATLAB map and reduce functions and then pass the deployable archive as a payload argument to a job submitted to a Hadoop cluster.

**Goal:** Calculate the maximum arrival delay of an airline from the given dataset.

| | |
|---|---|
| **Dataset:** | `airlinesmall.csv` |
| **Description:** | Airline departure and arrival information from 1987-2008. |
| **Location:** | `/usr/local/MATLAB/R2021b/toolbox/matlab/demos` |

**Note** When compared to the **Hadoop Compiler** app workflow, this workflow requires the explicit creation of a Hadoop settings file. Follow the example for details.

### Prerequisites

1. Start this example by creating a new work folder that is visible to the MATLAB search path.
2. Before starting MATLAB, at a terminal, set the environment variable `HADOOP_PREFIX` to point to the Hadoop installation folder. For example:

| Shell | Command |
|---|---|
| *csh / tcsh* | `% setenv HADOOP_PREFIX /usr/lib/hadoop` |
| *bash* | `$ export HADOOP_PREFIX=/usr/lib/hadoop` |

**Note** This example uses `/usr/lib/hadoop` as directory where Hadoop is installed. Your Hadoop installation directory maybe different.

If you forget setting the `HADOOP_PREFIX` environment variable prior to starting MATLAB, set it up using the MATLAB function `setenv` at the MATLAB command prompt as soon as you start MATLAB. For example:

```
setenv('HADOOP_PREFIX','/usr/lib/hadoop')
```

3. Install the MATLAB Runtime in a folder that is accessible by every worker node in the Hadoop cluster. This example uses `/usr/local/MATLAB/MATLAB_Runtime/v911` as the location of the MATLAB Runtime folder.

   If you don’t have the MATLAB Runtime, you can download it from the website at: `https://www.mathworks.com/products/compiler/mcr`.

**Note** For information about MATLAB Runtime version numbers corresponding MATLAB releases, see this list.

4 Copy the map function `maxArrivalDelayMapper.m` from `/usr/local/MATLAB/R2021b/toolbox/matlab/demos` folder to the work folder.

**maxArrivalDelayMapper.m**

```
function maxArrivalDelayMapper (data, info, intermKVStore)
partMax = max(data.ArrDelay);
add(intermKVStore,'PartialMaxArrivalDelay',partMax);
```

For more information, see “Write a Map Function”.

5 Copy the reduce function `maxArrivalDelayReducer.m` from *`matlabroot`*`/toolbox/matlab/demos` folder to the work folder.

**maxArrivalDelayReducer.m**

```
function maxArrivalDelayReducer(intermKey, intermValIter, outKVStore)
maxVal = -inf;
while hasnext(intermValIter)
   maxVal = max(getnext(intermValIter), maxVal);
end
add(outKVStore,'MaxArrivalDelay',maxVal);
```

For more information, see “Write a Reduce Function”.

6 Create the directory `/user/<`*`username`*`>/datasets` on HDFS and copy the file `airlinesmall.csv` to that directory. Here *<username>* refers to your user name in HDFS.

```
$ ./hadoop fs -copyFromLocal airlinesmall.csv hdfs://host:54310/user/<username>/datasets
```

**Procedure**

1 Start MATLAB and verify that the `HADOOP_PREFIX` environment variable has been set. At the command prompt, type:

```
>> getenv('HADOOP_PREFIX')
```

If `ans` is empty, review the **Prerequisites** section above to see how you can set the `HADOOP_PREFIX` environment variable.

2 Create a `datastore` to the file `airlinesmall.csv` and save it to a `.mat` file. This `datastore` object is meant to capture the structure of your actual dataset on HDFS.

```
ds = datastore('airlinesmall.csv','TreatAsMissing','NA',...
     'SelectedVariableNames','ArrDelay','ReadSize',1000);

save('infoAboutDataset.mat','ds')
```

In most cases, you will start off by working on a small sample dataset residing on a local machine that is representative of the actual dataset on the cluster. This sample dataset has the same structure and variables as the actual dataset on the cluster. By creating a `datastore` object to the dataset residing on your local machine you are taking a snapshot of that structure. By having access to this `datastore` object, a Hadoop job executing on the cluster will know how to access and process the actual dataset residing on HDFS.

**Note** In this example, the sample dataset (local) and the actual dataset on HDFS are the same.

3. Create a configuration file (`config.txt`) that specifies the input type of the data, the format of the data specified by the `datastore` created in the previous step, the output type of the data, the name of map function, and the name of reduce function.

```
mw.ds.in.type = tabulartext
mw.ds.in.format = infoAboutDataset.mat
mw.ds.out.type = keyvalue
mw.mapper = maxArrivalDelayMapper
mw.reducer = maxArrivalDelayReducer
```

For more information, see “Configuration File for Creating Deployable Archive Using the mcc Command” on page 3-2.

4. Use the `mcc` command with the `-m` flag to create a deployable archive. The `-m` flag creates a standard executable that can be run from a command line. However, the `mcc` command cannot package the results in an installer. The command must be entered as a single line.

```
mcc -H -W 'hadoop:maxArrivalDelay,CONFIG:config.txt'
  maxArrivalDelayMapper.m maxArrivalDelayReducer.m
   -a infoAboutDataset.mat
```

For more information, see `mcc`.

MATLAB Compiler creates a shell script `run_maxarrivaldelay.sh`, a deployable archive `airlinesmall.ctf`, and a log file `mccExcludedfiles.log`.

5. **a** Incorporate the deployable archive containing MATLAB map and reduce functions into a Hadoop mapreduce job from a Linux shell using the following command:

```
$ hadoop \
jar /usr/local/MATLAB/MATLAB_Runtime/v911/toolbox/mlhadoop/jar/a2.2.0/mwmapreduce.jar \
com.mathworks.hadoop.MWMapReduceDriver \
-D mw.mcrroot=/usr/local/MATLAB/MATLAB_Runtime/v911 \
maxArrivalDelay.ctf \
hdfs://host:54310/user/<username>/datasets/airlinesmall.csv \
hdfs://host:54310/user/<username>/results
```

   **b** Alternately, you can incorporate the deployable archive containing MATLAB map and reduce functions into a Hadoop mapreduce job using the shell script generated by the **Hadoop Compiler** app. At the Linux shell type the following command:

```
$ ./run_maxArrivalDelay.sh \
/usr/local/MATLAB/MATLAB_Runtime/v911 \
-D mw.mcrroot=/usr/local/MATLAB/MATLAB_Runtime/v911 \
hdfs://host:54310/user/username/datasets/airlinesmall.csv \
hdfs://host:54310/user/<username>/results
```

6. To examine the results, switch to the MATLAB desktop and create a `datastore` to the results on HDFS. You can then view the results using the `read` method.

```
d = datastore('hdfs:///user/<username>/results/part*');
read(d)

ans =

          Key            Value
    ___________________    _____

    'MaxArrivalDelay'    [1014]
```

Other examples of `map` and `reduce` functions are available at `toolbox/matlab/demos` folder. You can use other examples to prototype similar deployable archives that run against Hadoop. For more information, see “Build Effective Algorithms with MapReduce”.

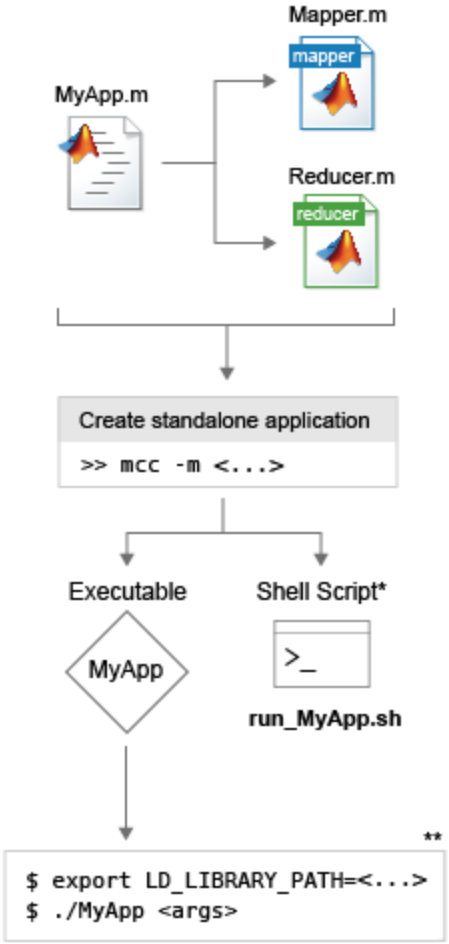
- “Example on Running a Standalone MATLAB MapReduce Application” on page 2-4

# Workflow to Run Compiled Standalone Applications Against a Hadoop Cluster



* You can use automatically generated shell scripts to execute applications from the terminal.

** Commands are not exact. For complete commands, see the auto-generated shell scripts.

1. Write mapper and reducer functions in MATLAB.
2. Write a MATLAB application script or function that calls the mapper and reducer functions. While writing applications it is preferable to structure them as MATLAB functions over scripts since functions accept inputs. End users can make use of this and pass inputs such as the location of the data to the application.
3. Use the **Application Compiler** app or the `mcc` command to package your application as a standalone application. Both options generate an executable and a shell script to run the executable.
4. Run the shell scripts at the terminal. Specify the location of MATLAB Runtime and any inputs the application takes.

**Execution Signature**

```
$./run_myStandaloneApp.sh \
  <MATLAB_Runtime_Location> \
  <inputFolderOnHDFS> \
  <outputFolderOnHDFS>
```

- “Example on Running a Standalone MATLAB MapReduce Application” on page 2-4

# Example on Running a Standalone MATLAB MapReduce Application

**Supported Platform:** Linux only.

This example shows you how to create a standalone MATLAB MapReduce application using the `mcc` command and run it against a Hadoop cluster.

**Goal:** Calculate the maximum arrival delay of an airline from the given dataset.

| | |
|---|---|
| **Dataset:** | `airlinesmall.csv` |
| **Description:** | Airline departure and arrival information from 1987-2008. |
| **Location:** | `/usr/local/MATLAB/R2021b/toolbox/matlab/demos` |

## Prerequisites

1. Start this example by creating a new work folder that is visible to the MATLAB search path.
2. Before starting MATLAB, at a terminal, set the environment variable `HADOOP_PREFIX` to point to the Hadoop installation folder. For example:

| Shell | Command |
|---|---|
| *csh / tcsh* | `% setenv HADOOP_PREFIX /usr/lib/hadoop` |
| *bash* | `$ export HADOOP_PREFIX=/usr/lib/hadoop` |

**Note** This example uses `/usr/lib/hadoop` as directory where Hadoop is installed. Your Hadoop installation directory maybe different.

If you forget setting the `HADOOP_PREFIX` environment variable prior to starting MATLAB, set it up using the MATLAB function `setenv` at the MATLAB command prompt as soon as you start MATLAB. For example:

```
setenv('HADOOP_PREFIX','/usr/lib/hadoop')
```

3. Install the MATLAB Runtime in a folder that is accessible by every worker node in the Hadoop cluster. This example uses `/usr/local/MATLAB/MATLAB_Runtime/v911` as the location of the MATLAB Runtime folder.

   If you don’t have the MATLAB Runtime, you can download it from the website at: `https://www.mathworks.com/products/compiler/mcr`.

**Note** For information about MATLAB Runtime version numbers corresponding MATLAB releases, see this list.

4. Copy the map function `maxArrivalDelayMapper.m` from `/usr/local/MATLAB/R2021b/toolbox/matlab/demos` folder to the work folder.

**maxArrivalDelayMapper.m**

```
function maxArrivalDelayMapper (data, info, intermKVStore)
partMax = max(data.ArrDelay);
add(intermKVStore,'PartialMaxArrivalDelay',partMax);
```

For more information, see “Write a Map Function”.

5 Copy the reduce function `maxArrivalDelayReducer.m` from *`matlabroot`*`/toolbox/matlab/demos` folder to the work folder.

**maxArrivalDelayReducer.m**

```
function maxArrivalDelayReducer(intermKey, intermValIter, outKVStore)
maxVal = -inf;
while hasnext(intermValIter)
   maxVal = max(getnext(intermValIter), maxVal);
end
add(outKVStore,'MaxArrivalDelay',maxVal);
```

For more information, see “Write a Reduce Function”.

6 Create the directory `/user/<`*`username`*`>/datasets` on HDFS and copy the file `airlinesmall.csv` to that directory. Here *<username>* refers to your user name in HDFS.

```
$ ./hadoop fs -copyFromLocal airlinesmall.csv hdfs://host:54310/user/<username>/datasets
```

## Procedure

1 Start MATLAB and verify that the `HADOOP_PREFIX` environment variable has been set. At the command prompt, type:

```
>> getenv('HADOOP_PREFIX')
```

If `ans` is empty, review the **Prerequisites** section above to see how you can set the `HADOOP_PREFIX` environment variable.

2 Create a new MATLAB script with the name `depMapRedStandAlone.m`. You will add the code listed in the steps listed below to this script file.

3 Create a `datastore` that points to the airline data in Hadoop Distributed File System (HDFS) .

```
ds = datastore('hdfs:///user/username/datasets/airlinesmall.csv',...
'TreatAsMissing','NA',...
'SelectedVariableNames',{'UniqueCarrier','ArrDelay'});
```

For more information, see “Work with Remote Data”.

4 Configure the application for deployment against Hadoop with default settings.

```
config = matlab.mapreduce.DeployHadoopMapReducer;
```

The class `matlab.mapreduce.DeployHadoopMapReducer` can be used to configure a standalone application based on the Hadoop environment where it is going to be deployed.

For example, if you want to specify the location of the MATLAB Runtime on each of the worker nodes on the cluster, include a line of code similar to this:

```
config = matlab.mapreduce.DeployHadoopMapReducer('MCRRoot','/opt/MATLAB/MATLAB_Runtime/v911')
```

In this scenario, we assume that the MATLAB Runtime is installed in a non-default location such as `/opt/MATLAB/MATLAB_Runtime` on the worker nodes.

For information on specifying additional cluster specific properties, see `matlab.mapreduce.DeployHadoopMapReducer`.

---

**Note** Specifying a MATLAB Runtime location as part of the class `matlab.mapreduce.DeployHadoopMapReducer` will override any MATLAB Runtime location specified during the execution of the standalone application.

---

5 Define the execution environment using the `mapreducer`.

```
mr = mapreducer(config);
```

6 Apply the `mapreduce` function.

```
result = mapreduce(...
    ds,...
    @maxArrivalDelayMapper,@maxArrivalDelayReducer,...
    mr,...
    'OutputType','Binary', ...
    'OutputFolder','hdfs:///user/<username>/results/myresults');
```

---

**Note** An HDFS directory such as `.../myresults` can be written to only once. If you plan on running your standalone application multiple times against the Hadoop cluster, make sure you delete the `.../myresults` directory on HDFS prior to each execution. Another option is to change the name of the `.../myresults` directory in the MATLAB code and recompile the application.

---

7 Read the result from the resulting datastore.

```
myAppResult = readall(result)
```

8 Use the `mcc` command with the `-m` flag to create a standalone application.

```
mcc -m depMapRedStandAlone.m
```

The `-m` flag creates a standard executable that can be run from a command line. However, the `mcc` command cannot package the results in an installer.

9 Run the standalone application from a Linux shell using the following command:

```
$ ./run_depMapRedStandAlone.sh /usr/local/MATLAB/MATLAB_Runtime/v911
```

`/usr/local/MATLAB/MATLAB_Runtime/v911` is an argument indicating the location of the MATLAB Runtime.

Prior to executing the above command, verify that the `HADOOP_PREFIX` environment variable is set in the Terminal by typing:

```
$ echo $HADOOP_PREFIX
```

If `echo` comes up empty, see the **Prerequisites** section above to see how you can set the `HADOOP_PREFIX` environment variable.

Your application will fail to execute if the `HADOOP_PREFIX` environment variable is not set.

10 You will see the following output:

```
myAppResult =
```

```
        Key             Value
    ________________    _______

    'MaxArrivalDelay'    [1014]
```

Other examples of `map` and `reduce` functions are available at `toolbox/matlab/demos` folder. You can use other examples to prototype similar standalone applications that run against Hadoop. For more information, see “Build Effective Algorithms with MapReduce”.

Complete code for the standalone application `depMapRedStandAlone` can be found here:

**depMapRedStandAlone.m**

```
%% Create datastore
ds = datastore(...
    'hdfs:///user/username/datasets/airlinesmall.csv',...
    'TreatAsMissing','NA',...
    'SelectedVariableNames',{'UniqueCarrier','ArrDelay'});

%% Configure application for deployment against Hadoop with default settings
config = matlab.mapreduce.DeployHadoopMapReducer;

%% Define the execution environment
mr = mapreducer(config);

%% Apply the mapreduce function
result = mapreduce(...
    ds,...
    @maxArrivalDelayMapper,@maxArrivalDelayReducer,...
    mr,...
    'OutputType','Binary', ...
    'OutputFolder','hdfs:///user/username/results/myresults');

%% Read the result from the resulting datastore
myAppResult = readall(result)
```

# Hadoop Configuration

# Configuration File for Creating Deployable Archive Using the mcc Command

When creating a deployable archive using the `mcc` command, you must create a text file containing the following information:

| Parameter Type | Description |
|---|---|
| `mw.ds.out.type` | Output type of data from Hadoop mapreduce job<br><br>The options are:<br><br>• `keyvalue`<br>• `tabulartext` |
| `mw.mapper` | Name of MATLAB map function |
| `mw.reducer` | Name of MATLAB reduce function |
| `mw.ds.in.format` | Name of MAT-file containing a `datastore` object representing the format of the data to be processed.<br><br>In most cases, you will start off by working on a small sample dataset residing on a local machine that is representative of the actual dataset on the cluster. This sample dataset has the same structure and variables as the actual dataset on the cluster. By creating a datastore object to the dataset residing on your local machine you are taking a snapshot of that structure. By having access to this datastore object, a Hadoop job executing on the cluster will know how to access and process the actual dataset residing on HDFS. |
| `mw.ds.in.type` | Input type of data to Hadoop mapreduce job<br><br>The options are:<br><br>• `keyvalue`<br>• `tabulartext` |
| `mw.ds.in.fullfile` | Default value is `false` |

## Sample Configuration File

**`config.txt`**

```
mw.ds.out.type = keyvalue
mw.mapper = maxArrivalDelayMapper
mw.reducer = maxArrivalDelayReducer
mw.ds.in.format = infoAboutDataset.mat
mw.ds.in.type = tabulartext
```

# Functions

# deploytool

Open a list of application deployment apps

## Syntax

```
deploytool
deploytool project_name
```

## Description

`deploytool` opens a list of application deployment apps.

`deploytool project_name` opens the appropriate deployment app with the project preloaded.

## Examples

### Open a List of Application Deployment Apps

Open the list of apps.

```
deploytool
```

## Input Arguments

**`project_name` — name of the project to be opened**
character array or string

Name of the project to be opened by the appropriate deployment app, specified as a character array or string. The project must be on the current path.

## Compatibility Considerations

**`-build` and `-package` options will be removed**
*Not recommended starting in R2020a*

The `-build` and `-package` options will be removed. To build applications, use one of the `compiler.build` family of functions or the `mcc` command; and to package and create an installer, use the `compiler.package.installer` function.

### Introduced in R2006b

# mcc

Compile MATLAB functions for deployment

## Syntax

```
mcc options mfilename1 mfilename2...mfilenameN

mcc -m options mfilename
mcc -e options mfilename

mcc -W 'excel:addin_name,className,version=version_number' -T link:lib
options mfilename1 mfilename2...mfilenameN

mcc -H -W hadoop:archiveName,CONFIG:configFile mfilename

mcc -m options mfilename
```

## Description

#### General Usage

`mcc options mfilename1 mfilename2...mfilenameN` compiles the functions as specified by the options. The options used depend on the intended results of the compilation.

For information on compiling:

- C/C++ shared libraries, .NET assemblies, Java® packages, or Python® packages, see `mcc` for MATLAB Compiler SDK™
- MATLAB Production Server™ deployable archives or Excel® add-ins for MATLAB Production Server, see `mcc` for MATLAB Compiler SDK

#### Standalone Application

`mcc -m options mfilename` compiles the function into a standalone application.

This is equivalent to `mcc -W main -T link:exe`.

`mcc -e options mfilename` compiles the function into a standalone application that does not open a Windows® command prompt on execution. The `-e` option works only on Windows operating systems.

This syntax is equivalent to `-W WinMain -T link:exe`.

#### Excel Add-In

`mcc -W 'excel:addin_name,className,version=version_number' -T link:lib options mfilename1 mfilename2...mfilenameN` creates a Microsoft® Excel add-in from the specified files.

- *`addin_name`* — Specifies the name of the add-in.

- *`className`* — Specifies the name of the class to be created. If you do not specify the class name, `mcc` uses the *`addin_name`* as the default. If specified, *`className`* needs to be different from *`mfilename`*.
- *`version_number`* — Specifies the version number of the add-in file as *`major.minor.bug.build`* in the file system. You are not required to specify a version number. If you do not specify a version number, `mcc` sets the version number to `1.0.0.0` by default.
  - *`major`* — Specifies the major version number. If you do not specify a number, `mcc` sets *`major`* to `0`.
  - *`minor`* — Specifies the minor version number. If you do not specify a number, `mcc` sets *`minor`* to `0`.
  - *`bug`*— Specifies the bug fix maintenance release number. If you do not specify a number, `mcc` sets *`bug`* to `0`.
  - *`build`*— Specifies the build number. If you do not specify a number, `mcc` sets *`build`* to `0`.

**Note** Excel add-ins can be created only in MATLAB running on Windows.

**Note** Remove the single quotes around `'excel:addin_name,className,version'` when executing the `mcc` command from a DOS prompt.

#### MapReduce Applications on Hadoop

`mcc -H -W hadoop:`*`archiveName`*`,CONFIG:`*`configFile`* `mfilename` generates a deployable archive from `mfilename` that can be run as a job by Hadoop.

- *`archiveName`* — Specifies the name of the generated archive.
- *`configFile`* — Specifies the path to the configuration file for creating a deployable archive. For more information, see “Configuration File for Creating Deployable Archive Using the mcc Command” on page 3-2.

**Tip** You can issue the `mcc` command either at the MATLAB command prompt or the Windows or Linux system command-line.

#### Simulink Simulations (Requires Simulink Compiler)

`mcc -m options mfilename` compiles a MATLAB application containing a Simulink® simulation into a standalone application. For more information, see “Create and Deploy a Script with Simulink Compiler” (Simulink Compiler).

## Examples

### Create a standalone application

```
mcc -m magic.m
```

### Create a standalone application that does not open the Command shell (Windows only)

```
mcc -e magic.m
```

#### Create a standalone application with a system-level file version number (Windows only)

Create a standalone application in Windows with version number `3.4.1.5`.

```
mcc -W 'main:mymagic,version=3.4.1.5' -T link:exe mymagic.m
```

#### Create an Excel add-in

```
mcc -W 'excel:myAddin,myClass,1.0' -T link:lib magic.m
```

#### Create an Excel add-in with a system-level file version number (Windows only)

Create an Excel add-in in Windows with version number `5.2.1.7`.

```
mcc -W 'excel:myAddin,myClass,version=5.2.1.7' -T link:lib -b mymagic.m
```

#### Create an Excel add-in for MATLAB Production Server

```
mcc -W 'mpsxl:myDeployableArchvie,myExcelClass,version=1.0' -T link:lib mymagic.m
```

#### Create a Standalone Application for a Simulink Simulation (Requires Simulink Compiler)

To create a standalone application for a Simulink simulation:

Create a Simulink model using Simulink. This example uses the model `sldemo_suspn_3dof` that ships with Simulink.

Create a MATLAB application that uses APIs from Simulink Compiler to simulate the model. For more information, see “Deploy Simulations with Tunable Parameters” (Simulink Compiler).

```
function deployParameterTuning(outputFile, mbVariable)

    if ischar(mbVariable) || isstring(mbVariable)
        mbVariable = str2double(mbVariable);
    end

    if isnan(mbVariable) || ~isa(mbVariable, 'double') || ~isscalar(mbVariable)
        disp('mb must be a double scalar or a string or char that can be converted to a double scalar');
    end

    in = Simulink.SimulationInput('sldemo_suspn_3dof');
    in = in.setVariable('Mb', mbVariable);
    in = simulink.compiler.configureForDeployment(in);
    out = sim(in);

    save(outputFile, 'out');

end
```

Use `mcc` to create a standalone application from the MATLAB application.

```
mcc -m deployParameterTuning.m
```

## Input Arguments

### `mfilename` — File to be compiled

file name

File to be compiled, specified as a character vector or string scalar.

### `mfilename1 mfilename2...mfilenameN` — Files to be compiled

list of file names

One or more files to be compiled, specified as a space-separated list of file names.

**`options` — Options for customizing the output**
-a | -b | -B | -c | -C | -d | -f | -g | -G | -I | -K | -m | -M | -n | -N | -o | -p | -r | -R | -s | -S | -T | -u | -U | -v | -w | -W | -X | -Y | -Z

Options for customizing the output, specified as a list of character vectors or string scalars.

- **`-a`**

  Add files to the deployable archive using `-a path` to specify the files to be added. Multiple `-a` options are permitted.

  If a file name is specified with `-a`, the compiler looks for these files on the MATLAB path, so specifying the full path name is optional. These files are not passed to `mbuild`, so you can include files such as data files.

  If a folder name is specified with the `-a` option, the entire contents of that folder are added recursively to the deployable archive. For example,

  ```
  mcc -m hello.m -a ./testdir
  ```

  specifies that all files in `testdir`, as well as all files in its subfolders, are added to the deployable archive. The folder subtree in `testdir` is preserved in the deployable archive.

  If the filename includes a wildcard pattern, only the files in the folder that match the pattern are added to the deployable archive and subfolders of the given path are not processed recursively. For example,

  ```
  mcc -m hello.m -a ./testdir/*
  ```

  specifies that all files in `./testdir` are added to the deployable archive and subfolders under `./testdir` are not processed recursively.

  ```
  mcc -m hello.m -a ./testdir/*.m
  ```

  specifies that all files with the extension `.m` under `./testdir` are added to the deployable archive and subfolders of `./testdir` are not processed recursively.

  **Note** * is the only supported wildcard.

  When you add files to the archive using `-a` that do not appear on the MATLAB path at the time of compilation, a path entry is added to the application's run-time path so that they appear on the path when the deployed code executes.

  When you use the `-a` option to specify a full path to a resource, the basic path is preserved, with some modifications, but relative to a subdirectory of the runtime cache directory, not to the user's local folder. The cache directory is created from the deployable archive the first time the application is executed. You can use the `isdeployed` function to determine whether the application is being run in deployed mode, and adjust the path accordingly. The `-a` option also creates a `.auth` file for authorization purposes.

**Caution** If you use the `-a` flag to include a file that is not on the MATLAB path, the folder containing the file is added to the MATLAB dependency analysis path. As a result, other files from that folder might be included in the compiled application.

**Note** If you use the `-a` flag to include custom Java classes, standalone applications work without any need to change the `classpath` as long as the Java class is not a member of a package. The same applies for JAR files. However, if the class being added is a member of a package, the MATLAB code needs to make an appropriate call to `javaaddpath` to update the `classpath` with the parent folder of the package.

- **`-b`**

  Generate a Visual Basic® file (`.bas`) containing the Microsoft Excel Formula Function interface to the COM object generated by MATLAB Compiler. When imported into the workbook Visual Basic code, this code allows the MATLAB function to be seen as a cell formula function.

- **`-B`**

  Replace the file on the `mcc` command line with the contents of the specified file. Use

  ```
  -B filename[:<a1>,<a2>,...,<an>]
  ```

  The bundle `filename` should contain only `mcc` command-line options and corresponding arguments and/or other file names. The file might contain other `-B` options. A bundle can include replacement parameters for compiler options that accept names and version numbers. See “Using Bundles to Build MATLAB Code” (MATLAB Compiler SDK).

- **`-c`**

  When used in conjunction with the `-l` option, suppresses compiling and linking of the generated C wrapper code. The `-c` option cannot be used independently of the `-l` option.

- **`-C`**

  Do not embed the deployable archive in binaries.

  **Note** The `-C` flag is ignored for Java libraries.

- **`-d`**

  Place output in a specified folder. Use

  ```
  -d outFolder
  ```

  to direct the generated files to *`outFolder`*. The specified folder must already exist.

- **`-e`**

  Use `-e` in place of the `-m` option to generate a standalone Windows application that does not open a Windows command prompt on execution. `-e` is equivalent to `-W WinMain -T link:exe`.

  This option works only on Windows operating systems.

- **`-f`**

  Override the default options file with the specified options file. It specifically applies to the C/C++ shared libraries, COM, and Excel targets. Use

```
-f filename
```

to specify `filename` as the options file when calling `mbuild`. This option lets you use different ANSI compilers for different invocations of the compiler. This option is a direct pass-through to `mbuild`.

- **`-g, -G`**

  Include debugging symbol information for the C/C++ code generated by MATLAB Compiler SDK. It also causes `mbuild` to pass appropriate debugging flags to the system C/C++ compiler. The debug option lets you backtrace up to the point where you can identify if the failure occurred in the initialization of MATLAB Runtime, the function call, or the termination routine. This option does not let you debug your MATLAB files with a C/C++ debugger.

- **`-I`**

  Add a new folder path to the list of included folders. Each `-I` option appends the folder to the end of the list of paths to search. For example,

  ```
  -I <directory1> -I <directory2>
  ```

  sets up the search path so that `directory1` is searched first for MATLAB files, followed by `directory2`. This option is important for standalone compilation where the MATLAB path is not available.

  If used in conjunction with the `-N` option, the `-I` option adds the folder to the compilation path in the same position where it appeared in the MATLAB path rather than at the head of the path.

- **`-K`**

  Direct `mcc` to not delete output files if the compilation ends prematurely due to error.

  The default behavior of `mcc` is to dispose of any partial output if the command fails to execute successfully.

- **`-m`**

  Direct `mcc` to generate a standalone application.

- **`-M`**

  Define compile-time options. Use

  ```
  -M string
  ```

  to pass `string` directly to `mbuild`. This option provides a useful mechanism for defining compile-time options, for example, `-M "-Dmacro=value"`.

  **Note** Multiple `-M` options do not accumulate; only the rightmost `-M` option is used.

  To pass options such as `/bigobj`, delineate the string according to your platform.

| Platform | Syntax |
|---|---|
| MATLAB | `-M 'COMPFLAGS=$COMPFLAGS /bigobj'` |
| Windows command prompt | `-M COMPFLAGS="$COMPFLAGS /bigobj"` |

| Platform | Syntax |
|---|---|
| Linux and macOS command line | `-M CFLAGS='$CFLAGS /bigobj'` |

- **`-n`**

  The `-n` option automatically identifies numeric command line inputs and treats them as MATLAB doubles.

- **`-N`**

  Passing `-N` clears the path of all folders except the following core folders (this list is subject to change over time):

  - *`matlabroot`*`\toolbox\matlab`
  - *`matlabroot`*`\toolbox\local`
  - *`matlabroot`*`\toolbox\compiler`
  - *`matlabroot`*`\toolbox\shared\bigdata`

  Passing `-N` also retains all subfolders in this list that appear on the MATLAB path at compile time. Including `-N` on the command line lets you replace folders from the original path, while retaining the relative ordering of the included folders. All subfolders of the included folders that appear on the original path are also included. In addition, the `-N` option retains all folders that you included on the path that are not under *`matlabroot`*`\toolbox`.

  When using the –N option, use the –I option to force inclusion of a folder, which is placed at the head of the compilation path. Use the –p option to conditionally include folders and their subfolders; if they are present in the MATLAB path, they appear in the compilation path in the same order.

- **`-o`**

  Specify the name of the final executable (standalone applications only). Use

  ```
  -o outputfile
  ```

  to name the final executable output of MATLAB Compiler. A suitable platform-dependent extension is added to the specified name (for example, `.exe` for Windows standalone applications).

- **`-p`**

  Use in conjunction with the option `-N` to add specific folders and subfolders under *`matlabroot`*`\toolbox` to the compilation MATLAB path. The files are added in the same order in which they appear in the MATLAB path. Use the syntax

  ```
  -N -p directory
  ```

  where `directory` is the folder to be included. If `directory` is not an absolute path, it is assumed to be under the current working folder.

  - If a folder is included with `-p` that is on the original MATLAB path, the folder and all its subfolders that appear on the original path are added to the compilation path in the same order.
  - If a folder is included with `-p` that is not on the original MATLAB path, that folder is ignored. (You can use `-I` to force its inclusion.)

- **`-r`**

  Embed resource icon in binary. The syntax is as follows:

  `-r 'path/to/my_icon.ico'`

- **`-R`**

  Provide MATLAB Runtime options that are passed to the application at initialization time.

  **Note** This option is relevant only when building standalone applications or Excel add-ins using MATLAB Compiler.

  The syntax is as follows:

  `-R option`

  | Option | Description | Target |
  |---|---|---|
  | `'-logfile, filename '` | Specify a log file name. The file is created in the application folder at runtime. Option must be in single quotes. Use double quotes when executing the command from a Windows Command Prompt. | MATLAB Compiler |
  | `-nodisplay` | Suppress the MATLAB `nodisplay` run-time warning. | MATLAB Compiler |
  | `-nojvm` | Do not use the Java Virtual Machine (JVM). | MATLAB Compiler |
  | `-startmsg` | Customizable user message displayed at initialization time. | MATLAB Compiler Standalone Applications |
  | `-completemsg` | Customizable user message displayed when initialization is complete. | MATLAB Compiler Standalone Applications |
  | `-singleCompThread` | Limit MATLAB to a single computational thread. | MATLAB Compiler |

  **Caution** When running on macOS, if you use `-nodisplay` as one of the options included in `mclInitializeApplication`, then the call to `mclInitializeApplication` must occur before calling `mclRunMain`.

  **Note** If you specify the `-R` option for libraries created from MATLAB Compiler SDK, `mcc` still compiles and generates the results, but the `-R` option doesn't apply to these libraries and does not do anything.

- **`-s`**

  Obfuscate folder structures and file names in the deployable archive (`.ctf` file) from the end user. Optionally encrypt additional file types.

The `-s` option directs `mcc` to place user code and data contained in `.m`, `.p`, v7.3 `.mat`, and MEX files into a user package within the CTF. During runtime, MATLAB code and data is decrypted and loaded directly from the user package rather than extracted to the file system. MEX files are temporarily extracted from the user package before being loaded.

To manually include additional file types in the user package, add each file type in a separate extension tag to the file *`matlabroot`*`/toolbox/compiler/advanced_package_supported_files.xml`.

The following is not supported:

- `ver` function
- Out-of-process MATLAB Runtime ( C++ shared library for MATLAB Data Array)
- Out-of-process MEX file execution (`mexhost`, `feval`, `matlab.mex.MexHost`)

- **`-S`**

The standard behavior for the MATLAB Runtime is that every instance of a class gets its own MATLAB Runtime context. The context includes a global MATLAB workspace for variables, such as the path and a base workspace for each function in the class. If multiple instances of a class are created, each instance gets an independent context. This ensures that changes made to the global or base workspace in one instance of the class does not affect other instances of the same class.

In a singleton MATLAB Runtime, all instances of a class share the context. If multiple instances of a class are created, they use the context created by the first instance which saves startup time and some resources. However, any changes made to the global workspace or the base workspace by one instance impacts all class instances. For example, if `instance1` creates a global variable `A` in a singleton MATLAB Runtime, then `instance2` can use variable `A`.

Singleton MATLAB Runtime is only supported by the following products on these specific targets:

| Target supported by Singleton MATLAB Runtime | Create a Singleton MATLAB Runtime by.... |
|---|---|
| Excel add-in | Default behavior for target is singleton MATLAB Runtime. You do not need to perform other steps. |
| .NET assembly | Default behavior for target is singleton MATLAB Runtime. You do not need to perform other steps. |
| COM component<br>Java package | • Using the Library Compiler app, click **Settings** and add `-S` to the **Additional parameters passed to MCC** field.<br>• Using `mcc`, pass the `-S` flag. |

- **`-T`**

Specify the output target phase and type.

Use the syntax `-T` *`target`* to define the output type.

| Target | Description |
|---|---|
| `compile:exe` | Generate a C/C++ wrapper file, and compile C/C++ files to an object form suitable for linking into a standalone application. |

| Target | Description |
|---|---|
| `compile:lib` | Generate a C/C++ wrapper file, and compile C/C++ files to an object form suitable for linking into a shared library or DLL. |
| `link:exe` | Same as `compile:exe` and also link object files into a standalone application. |
| `link:lib` | Same as `compile:lib` and also link object files into a shared library or DLL. |

- **`-u`**

  Register COM component for the current user only on the development machine. The argument applies only to the generic COM component and Microsoft Excel add-in targets.

- **`-U`**

  Build deployable archive (`.ctf` file) for MATLAB Production Server.

- **`-v`**

  Display the compilation steps, including:

  - MATLAB Compiler version number
  - The source file names as they are processed
  - The names of the generated output files as they are created
  - The invocation of `mbuild`

  The `-v` option passes the `-v` option to `mbuild` and displays information about `mbuild`.

- **`-w`**

  Display warning messages. Use the syntax

  ```
  -w option [:<msg>]
  ```

  to control the display of warnings.

| Syntax | Description |
|---|---|
| `-w list` | List the compile-time warnings that have abbreviated identifiers, together with their status. |
| `-w enable` | Enable all compile-time warnings. |
| `-w disable[:<string>]` | Disable specific compile-time warnings associated with `<string>`. Omit the optional `<string>` to apply the `disable` action to all compile-time warnings. |
| `-w enable[:<string>]` | Enable specific compile-time warnings associated with `<string>`. Omit the optional `<string>` to apply the `enable` action to all compile-time warnings. |
| `-w error[:<string>]` | Treat specific compile-time and runtime warnings associated with `<string>` as an error. Omit the optional `<string>` to apply the `error` action to all compile-time and runtime warnings. |

| Syntax | Description |
|---|---|
| `-w off[:<string>]` | Turn off warnings for specific error messages defined by `<string>`. Omit the optional `<string>` to apply the `off` action to all runtime warnings. |
| `-w on[:<string>]` | Turn on runtime warnings associated with `<string>`. Omit the optional `<string>` to apply the `on` action to all runtime warnings. This option is enabled by default. |

You can also turn warnings on or off in your MATLAB code.

For example, to turn off warnings for deployed applications (specified using `isdeployed`) in `startup.m`, you write:

```
if isdeployed
    warning off
end
```

To turn on warnings for deployed applications, you write:

```
if isdeployed
    warning on
end
```

You can also specify multiple `-w` options.

For example, if you want to disable all warnings except `repeated_file`, you write:

```
-w disable -w enable:repeated_file
```

When you specify multiple `-w` options, they are processed from left to right.

- **`-W`**

  Control the generation of function wrappers. Use the syntax

  `-W type`

  to control the generation of function wrappers for a collection of MATLAB files generated by the compiler. You provide a list of functions, and the compiler generates the wrapper functions and any appropriate global variable definitions.

| Target | Syntax |
|---|---|
| Standalone Application | `-W 'main:appName,version=version'` |
| Standalone Application (no Windows console) | `-W 'WinMain:appName,version=version'` |
| Excel Add-In | `-W 'excel:addinName,className,version=version'` |
| Hadoop MapReduce Application | `-W 'hadoop:archiveName,CONFIG:configFile'` |
| Spark Application | `-W 'spark:appName,version'` |

**Note** Replace single quotes with double when executing the command from a Windows Command Prompt.

- `-X`

  Use `-X` to ignore data files read by common MATLAB file I/O functions during dependency analysis. For more information, see “Dependency Analysis Using MATLAB Compiler”. For examples on how to use the `-X` option, see `%#exclude`.

- **`-Y`**

  Use

  ```
  -Y license.lic
  ```

  to override the default license file with the specified argument.

  **Note** The `-Y` flag works only with the command-line mode.

  ```
  >>!mcc -m foo.m -Y license.lic
  ```

- **`-Z`**

  Use

  `-Z option`

  to specify the method of adding support packages to the deployable archive.

| Syntax | Description |
|---|---|
| `-Z 'autodetect'` | The dependency analysis process detects and includes the required support packages automatically. This is the default behavior of mcc. |
| `-Z 'none'` | No support packages are included. Using this option can cause runtime errors. |
| `-Z packagename` | Only the specified support package is included. To specify multiple support packages, use multiple `-Z` inputs. |

**Note** To list installed support packages or those used by a specific file, see `compiler.codetools.deployableSupportPackages`.

## Tips

- On Windows, you can generate a system-level file version number for your target file by appending `version=version_number` to the target generating `mcc` syntax. For an example, see “Create a standalone application with a system-level file version number (Windows only)”.

  *`version_number`* — Specifies the version of the target file as *`major.minor.bug.build`* in the file system. You are not required to specify a version number. If you do not specify a version number, `mcc` sets the version number, by default, to `1.0.0.0`.

- *major* — Specifies the major version number. If you do not specify a version number, mcc sets *major* to 1.
- *minor* — Specifies the minor version number. If you do not specify a version number, mcc sets *minor* to 0.
- *bug* — Specifies the bug fix maintenance release number. If you do not specify a version number, mcc sets *bug* to 0.
- *build* — Specifies build number. If you do not specify a version number, mcc sets *build* to 0.

This functionality is supported for standalone applications and Excel add-ins in MATLAB Compiler. For supported targets in MATLAB Compiler SDK, see the **Tips** section in mcc.

**Introduced before R2006a**

# matlab.mapreduce.DeployHadoopMapReducer class

**Package:** `matlab.mapreduce`

Configure a MapReduce application for deployment against Hadoop

## Description

A `DeployHadoopMapReducer` object represents executing MapReduce on a Hadoop cluster with MATLAB Runtime.

## Construction

`config = matlab.mapreduce.DeployHadoopMapReducer` creates a `matlab.mapreduce.DeployHadoopMapReducer` object that specifies the default properties for Hadoop execution.

Use the resulting object as input to the `mapreducer` function to specify the configuration properties for Hadoop execution. For deploying a standalone application, pass the `matlab.mapreduce.DeployHadoopMapReducer` object as input to `mapreduce`.

`config = matlab.mapreduce.DeployHadoopMapReducer(Name,Value)` creates a `matlab.mapreduce.DeployHadoopMapReducer` object with properties specified by one or more name-value pair arguments.

#### Input Arguments

##### Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

**`HadoopInstallFolder` — Path to Hadoop installation**
character vector | string scalar

Path to Hadoop installation, specified as the comma-separated pair consisting of the `HadoopInstallFolder` and a character vector or a string scalar.

The default value of Hadoop install folder is specified by the environment variables in the order of precedence of `MATLAB_HADOOP_INSTALL`, `HADOOP_PREFIX`, and `HADOOP_HOME`.

**`HadoopConfigurationFile` — Path to Hadoop application configuration files**
character vector | string scalar

Path to Hadoop application configuration files, specified as the comma-separated pair consisting of the `HadoopConfigurationFile` and a character vector or a string scalar.

**`MCRRoot` — MATLAB Runtime installation folder for Hadoop cluster**
character vector | string scalar

MATLAB Runtime installation folder for Hadoop cluster, specified as the comma-separated pair consisting of the `MCRRoot` and a character vector or a string scalar.

MCRRoot specifies the MATLAB Runtime installation folder used by Hadoop when executing `mapreduce` tasks in Hadoop.

Example: `'MCRRoot','/hd-shared/hadoop-2.2.0/MCR/v84'`

**`HadoopProperties` — Job or application-specific Hadoop configuration properties**
containers.Map

A `containers.Map` object of name-value pairs that specify Hadoop configuration properties for a specific job or application. Name-value pairs must be specified as character vectors.

The properties specified in the `containers.Map` object are passed as a [GENERIC_OPTION] consisting of name-value pairs signaled by a `-D` flag to the `hadoop` shell command.

**Example:**

```
setenv('HADOOP_PREFIX', '/usr/lib/hadoop') % replace with your Hadoop install location
name = {'mapreduce.map.maxattempts','mapreduce.job.reduces'};
value = {'2','1'};
prop = containers.Map(name,value);
obj = matlab.mapreduce.DeployHadoopMapReducer('HadoopProperties', prop)
```

## Examples

### Create a Deploy Hadoop MapReducer object

Create and use a `matlab.mapreduce.DeployHadoopMapReducer` object to deploy into a standalone application, and deploy against Hadoop.

```
config = matlab.mapreduce.DeployHadoopMapReducer('MCRRoot',...
    '/hd-shared/hadoop-2.2.0/MCR/v84');
mr = mapreducer(config);
```

### Topics

“Example on Running a Standalone MATLAB MapReduce Application” on page 2-4

# hadoopCompiler

(Not recommended) Package MATLAB Compiler programs for deployment against Hadoop clusters as MapReduce programs

**Note** The `hadoopCompiler` function will be removed in a future release. To create standalone MATLAB® MapReduce applications, or deployable archives from MATLAB map and reduce functions, use the `mcc` command. For details, see "Compatibility Considerations".

## Syntax

```
hadoopCompiler
hadoopCompiler project_name
```

## Description

`hadoopCompiler` opens the **Hadoop Compiler** app.

`hadoopCompiler project_name` opens **Hadoop Compiler** app with the project preloaded.

## Examples

### Create a New Hadoop Compiler Project

Open the Hadoop compiler app to create a new project.

```
hadoopCompiler
```

## Input Arguments

### `project_name` — name of the project to be compiled

character array or string

Name of previously saved MATLAB Compiler project to be compiled, specified as a character array or string. The project must be on the current path.

## Compatibility Considerations

### `hadoopCompiler` will be removed

*Not recommended starting in R2020a*

`hadoopCompiler` will be removed. To create standalone MATLAB MapReduce applications or deployable archives from MATLAB map and reduce functions use the `mcc` command.

**Introduced in R2014b**

# mapreducer

Define deployed execution for mapreduce

## Syntax

```
mapreducer(config)
mr = mapreducer(config)
```

## Description

Use this function with MATLAB Compiler to specify information about the execution environment for standalone applications that execute against Hadoop.

`mapreducer(config)` specifies execution environment. When deploying a standalone application against Hadoop, `config` is an object of `matlab.mapreduce.DeployHadoopMapReducer` class.

`mr = mapreducer(config)` returns a MapReducer object to specify the execution environment. You can define MapReducer objects, allowing you to swap execution environments by passing one as an input argument to `mapreduce`.

## Examples

### Create a mapreducer object in deployed mode

```
mr = mapreducer(...
    matlab.mapreduce.DeployHadoopMapReducer('MCRRoot',...
    '/hd-shared/hadoop-2.2.0/MCR/v84'))
```

## Input Arguments

### `config` — `mapreducer` object for running in deployed environment

`matlab.mapreduce.DeployHadoopMapReducer` object

`mapreducer` object for running in deployed environment, specified as a `matlab.mapreduce.DeployHadoopMapReducer` object.

Example: `config = mapreducer(matlab.mapreduce.DeployHadoopMapReducer('MCRRoot','/hd-shared/hadoop-2.2.0/MCR/v84'))`

## Output Arguments

### `mr` — Execution environment for `mapreduce`

`mapreducer` object

Execution environment for `mapreduce`, returned as a `mapreducer` object.

## Tips

- `mapreducer` and `mapreducer(0)` enables different configurations based on the products you have. In MATLAB, the `mapreduce` function automatically runs using a `SerialMapReducer`. For more information, see `mapreducer`.

  If you have Parallel Computing Toolbox™, see the function reference page for `mapreducer` for additional information.

# Apps

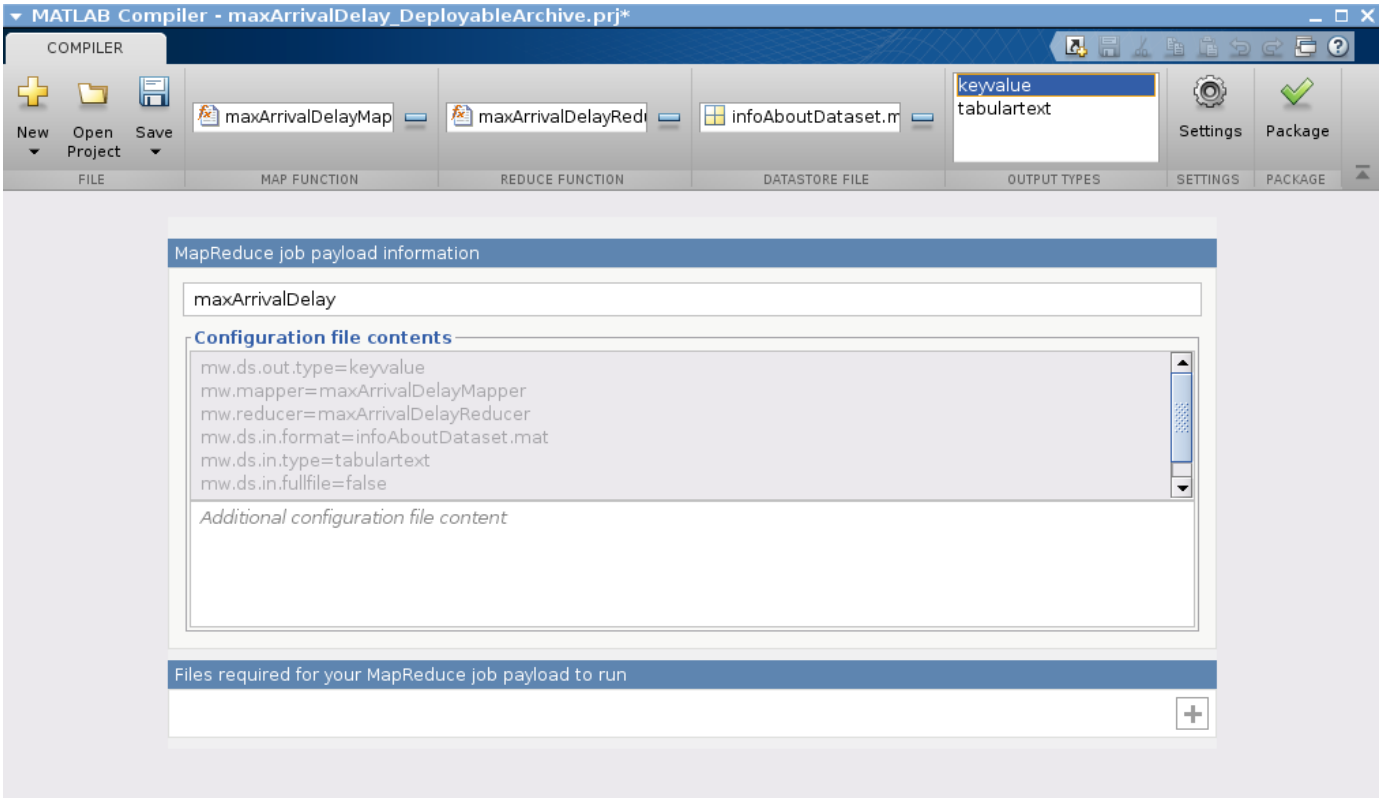
# Hadoop Compiler

Package MATLAB programs for deployment to Hadoop clusters as MapReduce programs

**Note** The **Hadoop Compiler** app will be removed in a future release. To create standalone MATLAB® MapReduce applications, or deployable archives from MATLAB map and reduce functions, use the `mcc` command. For details, see “Compatibility Considerations”.

## Description

The **Hadoop Compiler** app packages MATLAB map and reduce functions into a deployable archive. You can incorporate the archive into a Hadoop mapreduce job by passing it as a payload argument to job submitted to a Hadoop cluster.



## Open the Hadoop Compiler App

- MATLAB Toolstrip: On the **Apps** tab, under **Application Deployment**, click the app icon.
- MATLAB command prompt: Enter `hadoopCompiler`.

# Parameters

**`map function` — mapper file**
character vector

Function for the mapper, specified as a character vector.

**`reduce function` — reducer file**
character vector

Function for the reducer, specified as a character vector.

**`datastore file` — file containing a datastore representing the data to be processed**
character vector

A file containing a datastore representing the data to be processed, specified as a character vector.

In most cases, you will start off by working on a small sample dataset residing on a local machine that is representative of the actual dataset on the cluster. This sample dataset has the same structure and variables as the actual dataset on the cluster. By creating a datastore object to the dataset residing on your local machine you are taking a snapshot of that structure. By having access to this datastore object, a Hadoop job executing on the cluster will know how to access and process the actual dataset residing on HDFS.

**`output types` — format of output**
keyvalue (default) | tabulartext

Format of output from Hadoop mapreduce job, specified as a keyvalue or tabular text.

**`additional configuration file content` — additional parameters configuring how Hadoop executes the job**
character vector

Additional parameters to configure how Hadoop executes the job, specified as a character vector. For more information, see “Configuration File for Creating Deployable Archive Using the mcc Command” on page 3-2.

**`files required for your MapReduce job payload to run` — files that must be included with generated artifacts**
list of files

Files that must be included with generated artifacts, specified as a list of files.

#### Settings

**`Additional parameters passed to MCC` — flags controlling the behavior of the compiler**
character vector

Flags controlling the behavior of the compiler, specified as a character vector.

**`testing files` — folder where files for testing are stored**
character vector

Folder where files for testing are stored, specified as a character vector.

**`packaged files` — folder where generated artifacts are stored**
character vector

Folder where generated artifacts are stored, specified as a character vector.

## Compatibility Considerations

**Hadoop Compiler will be removed**
*Not recommended starting in R2020a*

**Hadoop Compiler** app will be removed in a future release. To create standalone MATLAB MapReduce applications, or deployable archives from MATLAB map and reduce functions, use the `mcc` command.
