- 4 In the list of variables, click `t>1`. The report highlights the instances of the variable `t` that are inside of the `if` statement. These instances of `t` are scalar double.
- 5 Click `t>2`. The code generation report highlights the instances of `t` that are outside of the `if` statement. These instances of `t` are variable-size column vectors with an upper bound of 25.

### Limitations of Variable Reuse

The following variables cannot be renamed in generated code:

- Persistent variables.
- Global variables.
- Variables passed to C code using `coder.ref`, `coder.rref`, `coder.wref`.
- Variables whose size is set using `coder.varsize`.
- The index variable of a `for`-loop when it is used inside the loop body.
- The block outputs of a MATLAB Function block in a Simulink model.
- Chart-owned variables of a MATLAB function in a Stateflow chart.

## Supported Variable Types

You can use the following data types for C/C++ code generation from MATLAB:

| Type                          | Description                                                     |
|-------------------------------|-----------------------------------------------------------------|
| char                          | Character array                                                 |
| complex                       | Complex data. Cast function takes real and imaginary components |
| double                        | Double-precision floating point                                 |
| int8, int16, int32, int64     | Signed integer                                                  |
| logical                       | Boolean true or false                                           |
| single                        | Single-precision floating point                                 |
| struct                        | Structure                                                       |
| uint8, uint16, uint32, uint64 | Unsigned integer                                                |
| Fixed-point                   | Fixed-point data types                                          |

## Edit and Represent Coder Type Objects and Properties

Passing an object to `coder.typeof` or passing a class name as a string scalar to `coder.newtype` creates an object that represents the type of object for code generation.

The coder type object displays a succinct description of the object properties while excluding internal state values. Nonconstant properties display their type and size, while constant properties display only their values.

To create a coder type object, pass a compatible object to `coder.typeof`. For example:

```
t = categorical({'r','g','b'});
tType = coder.typeof(t)
```

The representation of variable `t` is stored in coder type object `tType`.

```
tType =
 matlab.coder.type.CategoricalType
 1x3 categorical
 Categories : 3x1 homogeneous cell
 Ordinal : 1x1 logical
 Protected : 1x1 logical
```

### Object Properties

You can edit the properties of coder type objects. You can assign scalar values to the object properties. Values are implicitly converted to the corresponding coder type values when they are assigned to coder type object properties. The code generator implicitly converts constants assigned to coder type object properties to `coder.Constant` values. You can resize objects themselves

#### Resize Objects by Using `coder.resize`

You can resize most objects by using `coder.resize`. You can resize objects, its properties and create arrays within the properties.

For example, for a `timetable` coder object, you can resize the object:

```
t = timetable((1:5)',(11:15)', 'SampleRate',1);
tType = coder.typeof(t);
tType = coder.resize(tType, [10 2],[1 0])
```

This code resizes the `timetable` to a `:10x2` object.

```
tType =
 matlab.coder.type.RegularTimetableType
 :10x2 timetable
 Data : 1x2 homogeneous cell
 Description : 1x0 char
 UserData : 0x0 double
 DimensionNames : {'Time'} {'Variables'}
 VariableNames : {'Var1'} {'Var2'}
VariableDescriptions : 1x2 homogeneous cell
 VariableUnits : 1x2 homogeneous cell
 VariableContinuity : 1x2 matlab.internal.coder.tabular.Continuity
```

```
StartTime : 1x1 matlab.coder.type.DurationType
SampleRate : 1x1 double
TimeStep : 1x1 matlab.coder.type.DurationType
```

The constant properties of `tType` display their values. The nonconstant properties display only their type and size.

---

**Note** Not all types representing MATLAB classes are compatible with `coder.resize`.

---

### Resize Objects by Editing Object Properties

You can resize the objects by editing the properties themselves. For a `duration` coder type object `x`, edit the `Size` property to change the size as needed.

```
x = coder.typeof(duration((1:3),0,0));
x.Size = [10 10]
```

This code changes the size of the coder type object.

```
x =
 matlab.coder.type.DurationType
 10x10 duration
 Format : 1x8 char
```

You can also make the coder type object variable-size by setting the `VarDims` flag:

```
x.VarDims(2) = true
```

The second dimension of the coder type object is upper-bounded at 10.

```
x =
 matlab.coder.type.DurationType
 10x:10 duration
 Format : 1x8 char
```

### Legacy Representation of Coder Type Objects

In R2021a, calling `coder.typeof` no longer returns a `coder.ClassType` object. If your workflow requires the legacy representation of coder type objects, use the `getCoderType` function on the variable that has the new representation of your class or object. For example, to get the legacy representation of a `datetime` variable, use the variable that has the new representation `tt` to call the `getCoderType` function:

```
t = datetime;
tt = coder.typeof(t);
ttLegacy = tt.getCoderType()
```

In the Coder Type Editor, the code generator includes the function `getCoderType` for coder type objects. Use this function to return the legacy representation of coder types. See, “Create and Edit Input Types by Using the Coder Type Editor” (MATLAB Coder)

Certain MATLAB data types provide customized type representations for MATLAB code generation. In other cases, the type is represented using `coder.ClassType`.

## Data Definition for Code Generation

To generate efficient standalone code, you must define the following types and classes of data differently than you normally would when running your code in MATLAB.

| Data             | What Is Different                                                                                                                                                                                                                                                                                                                                                                                                | More Information                                           |
|------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------|
| Arrays           | Maximum number of elements is restricted                                                                                                                                                                                                                                                                                                                                                                         | "Array Size Restrictions for Code Generation" on page 53-7 |

## Code Generation for Complex Data

### In this section...

“Restrictions When Defining Complex Variables” on page 53-3

“Code Generation for Complex Data with Zero-Valued Imaginary Parts” on page 53-3

“Results of Expressions That Have Complex Operands” on page 53-5

“Results of Complex Multiplication with Nonfinite Values” on page 53-5

### Restrictions When Defining Complex Variables

For code generation, you must set the complexity of variables at the time of assignment. Assign a complex constant to the variable or use the `complex` function. For example:

```
x = 5 + 6i; % x is a complex number by assignment.
y = complex(5,6); % y is the complex number 5 + 6i.
```

After assignment, you cannot change the complexity of a variable. Code generation for the following function fails because `x(k) = 3 + 4i` changes the complexity of `x`.

```
function x = test1()
x = zeros(3,3); % x is real
for k = 1:numel(x)
 x(k) = 3 + 4i;
end
end
```

To resolve this issue, assign a complex constant to `x`.

```
function x = test1()
x = zeros(3,3)+ 0i; %x is complex
for k = 1:numel(x)
 x(k) = 3 + 4i;
end
end
```

### Code Generation for Complex Data with Zero-Valued Imaginary Parts

For code generation, complex data that has all zero-valued imaginary parts remains complex. This data does not become real. This behavior has the following implications:

- In some cases, results from functions that sort complex data by absolute value can differ from the MATLAB results. See “Functions That Sort Complex Values by Absolute Value” on page 53-3.
- For functions that require that complex inputs are sorted by absolute value, complex inputs with zero-valued imaginary parts must be sorted by absolute value. These functions include `ismember`, `union`, `intersect`, `setdiff`, and `setxor`.

#### Functions That Sort Complex Values by Absolute Value

Functions that sort complex values by absolute value include `sort`, `issorted`, `sortrows`, `median`, `min`, and `max`. These functions sort complex numbers by absolute value even when the imaginary parts are zero. In general, sorting the absolute values produces a different result than sorting the real parts. Therefore, when inputs to these functions are complex with zero-valued imaginary parts in

generated code, but real in MATLAB, the generated code can produce different results than MATLAB. In the following examples, the input to `sort` is real in MATLAB, but complex with zero-valued imaginary parts in the generated code:

- **You Pass Real Inputs to a Function Generated for Complex Inputs**

- 1 Write this function:

```
function myout = mysort(A)
myout = sort(A);
end
```

- 2 Call `mysort` in MATLAB.

```
A = -2:2;
mysort(A)

ans =
```

```
 -2 -1 0 1 2
```

- 3 Generate a MEX function for complex inputs.

```
A = -2:2;
codegen mysort -args {complex(A)} -report
```

- 4 Call the MEX Function with real inputs.

```
mysort_mex(A)

ans =
```

```
 0 1 -1 2 -2
```

You generated the MEX function for complex inputs, therefore, it treats the real inputs as complex numbers with zero-valued imaginary parts. It sorts the numbers by the absolute values of the complex numbers. Because the imaginary parts are zero, the MEX function returns the results to the MATLAB workspace as real numbers.

- **Input to `sort` Is Output from a Function That Returns Complex in Generated Code**

- 1 Write this function:

```
function y = myfun(A)
x = eig(A);
y = sort(x, 'descend');
```

The output from `eig` is the input to `sort`. In generated code, `eig` returns a complex result. Therefore, in the generated code, `x` is complex.

- 2 Call `myfun` in MATLAB.

```
A = [2 3 5;0 5 5;6 7 4];
myfun(A)

ans =
```

```
 12.5777
 2.0000
 -3.5777
```

The result of `eig` is real. Therefore, the inputs to `sort` are real.

- 3 Generate a MEX function for complex inputs.

```
codegen myfun -args {complex(A)}
```

- 4 Call the MEX function.

```
myfun_mex(A)

ans =

 12.5777
 -3.5777
 2.0000
```

In the MEX function, `eig` returns a complex result. Therefore, the inputs to `sort` are complex. The MEX function sorts the inputs in descending order of the absolute values.

## Results of Expressions That Have Complex Operands

In general, expressions that contain one or more complex operands produce a complex result in generated code, even if the value of the result is zero. Consider the following line of code:

```
z = x + y;
```

Suppose that at run time,  $x$  has the value  $2 + 3i$  and  $y$  has the value  $2 - 3i$ . In MATLAB, this code produces the real result  $z = 4$ . During code generation, the types for  $x$  and  $y$  are known, but their values are not known. Because either or both operands in this expression are complex,  $z$  is defined as a complex variable requiring storage for a real and an imaginary part.  $z$  equals the complex result  $4 + 0i$  in generated code, not  $4$ , as in MATLAB code.

Exceptions to this behavior are:

- Functions that take complex arguments but produce real results return real values.

```
y = real(x); % y is the real part of the complex number x.
y = imag(x); % y is the real-valued imaginary part of x.
y = isreal(x); % y is false (0) for a complex number x.
```

- Functions that take real arguments but produce complex results return complex values.

```
z = complex(x,y); % z is a complex number for a real x and y.
```

## Results of Complex Multiplication with Nonfinite Values

When an operand of a complex multiplication contains a nonfinite value, the generated code might produce a different result than the result that MATLAB produces. The difference is due to the way that code generation defines complex multiplication. For code generation:

- Multiplication of a complex value by a complex value  $(a + bi)(c + di)$  is defined as  $(ac - bd) + (ad + bc)i$ . The complete calculation is performed, even when a real or an imaginary part is zero.
- Multiplication of a real value by a complex value  $c(a + bi)$  is defined as  $ca + cbi$ .

## Encoding of Characters in Code Generation

MATLAB represents characters in 16-bit Unicode. The code generator represents characters in an 8-bit codeset that the locale setting determines. Differences in character encoding between MATLAB and code generation have these consequences:

- Code generation of characters with numeric values greater than 255 produces an error.
- For some characters in the range 128–255, it might not be possible to represent the character in the codeset of the locale setting or to convert the character to an equivalent 16-bit Unicode character. Passing characters in this range between MATLAB and generated code can result in errors or different answers.
- For code generation, some toolbox functions accept only 7-bit ASCII characters.
- Casting a character that is not in the 7-bit ASCII codeset to a numeric type, such as double, can produce a different result in the generated code than in MATLAB. As a best practice, for code generation, avoid performing arithmetic with characters.

- “Locale Setting Concepts for Internationalization”

## Array Size Restrictions for Code Generation

For code generation, the maximum number of elements of an array is constrained by the code generator and the target hardware.

For fixed-size arrays and variable-size arrays that use static memory allocation, the maximum number of elements is the smaller of:

- `intmax('int32')`.
- The largest integer that fits in the C `int` data type on the target hardware.

For variable-size arrays that use dynamic memory allocation, the maximum number of elements is the smaller of:

- `intmax('int32')`.
- The largest power of 2 that fits in the C `int` data type on the target hardware.

These restrictions apply even on a 64-bit platform.

For a fixed-size array, if the number of elements exceeds the maximum, the code generator reports an error at compile time. For a variable-size array, if the number of elements exceeds the maximum during simulation, the software reports an error. Generated standalone code cannot report array size violations.

### See Also

## Code Generation for Constants in Structures and Arrays

The code generator does not recognize constant structure fields or array elements in the following cases:

### Fields or elements are assigned inside control constructs

In the following code, the code generator recognizes that the structure fields `s.a` and `s.b` are constants.

```
function y = mystruct()
s.a = 3;
s.b = 5;
y = zeros(s.a,s.b);
```

If any structure field is assigned inside a control construct, the code generator does not recognize the constant fields. This limitation also applies to arrays with constant elements. Consider the following code:

```
function y = mystruct(x)
s.a = 3;
if x > 1
 s.b = 4;
else
 s.b = 5;
end
y = zeros(s.a,s.b);
```

The code generator does not recognize that `s.a` and `s.b` are constant. If variable-sizing is enabled, `y` is treated as a variable-size array. If variable-sizing is disabled, the code generator reports an error.

### Constants are assigned to array elements using non-scalar indexing

In the following code, the code generator recognizes that `a(1)` is constant.

```
function y = myarray()
a = zeros(1,3);
a(1) = 20;
y = coder.const(a(1));
```

In the following code, because `a(1)` is assigned using non-scalar indexing, the code generator does not recognize that `a(1)` is constant.

```
function y = myarray()
a = zeros(1,3);
a(1:2) = 20;
y = coder.const(a(1));
```

### A function returns a structure or array that has constant and nonconstant elements

For an output structure that has both constant and nonconstant fields, the code generator does not recognize the constant fields. This limitation also applies to arrays that have constant and nonconstant elements. Consider the following code:

```
function y = mystruct_out(x)
s = create_structure(x);
y = coder.const(s.a);
```

```
function s = create_structure(x)
s.a = 10;
s.b = x;
```

Because `create_structure` returns a structure `s` that has one constant field and one nonconstant field, the code generator does not recognize that `s.a` is constant. The `coder.const` call fails because `s.a` is not constant.

## Code Generation for Strings

Code generation supports 1-by-1 MATLAB string arrays. Code generation does not support string arrays that have more than one element.

A 1-by-1 string array, called a string scalar, contains one piece of text, represented as a 1-by-n character vector. An example of a string scalar is "Hello, world". For more information about strings, see "Text in String and Character Arrays".

### Limitations

For string scalars, code generation does not support:

- Global variables
- Indexing with curly braces {}
- Missing values
- Their use as Simulink signals, parameters, or data store memory

For code generation, limitations that apply to classes apply to strings. See "MATLAB Classes Definition for Code Generation" on page 62-2.

### Differences Between Generated Code and MATLAB Code

- Converting a string that contains multiple unary operators to double can produce different results between MATLAB and the generated code. Consider this function:

```
function out = foo(op)
out = double(op + 1);
end
```

For an input value "--", the function converts the string "--1" to double. In MATLAB, the answer is NaN. In the generated code, the answer is 1.

- Double conversion for a string with misplaced commas (commas that are not used as thousands separators) can produce different results from MATLAB.

## Code Generation for Sparse Matrices

Sparse matrices provide efficient storage in memory for arrays with many zero elements. Sparse matrices can provide improved performance and reduced memory usage for generated code. Computation time on sparse matrices scales only with the number of operations on nonzero elements.

Functions for creating and manipulating sparse matrices are listed in “Sparse Matrices”. To check if a function is supported for code generation, see the function reference page. Code generation does not support sparse matrix inputs for all functions.

### Code Generation Guidelines

Initialize matrices by using sparse constructors to maximize your code efficiency. For example, to construct a 3-by-3 identity matrix, use `speye(3,3)` rather than `sparse(eye(3,3))`.

Indexed assignment into sparse matrices incurs an overhead compared to indexed assignment into full matrices. For example:

```
S = speye(10);
S(7,7) = 42;
```

As in MATLAB, sparse matrices are stored in compressed sparse column format. When you insert a new nonzero element into a sparse matrix, all subsequent nonzero elements must be shifted downward, column by column. These extra manipulations can slow performance.

### Code Generation Limitations

Code generation does not support sparse matrices for Simulink signals, parameters, or data store memory. Simulation state save and restore is not supported.

To generate code that uses sparse matrices, dynamic memory allocation must be enabled. To store the changing number of nonzero elements, and their values, sparse matrices use variable-size arrays in the generated code. To change dynamic memory allocation settings, see “Control Memory Allocation for Variable-Size Arrays in a MATLAB Function Block” on page 45-80. Because sparse matrices use variable-size arrays for dynamic memory allocation, limitations on “Variable-Size Data” also apply to sparse matrices.

You cannot assign sparse data to data that is not sparse. The generated code uses distinct data type representations for sparse and full matrices. To convert to and from sparse data, use the explicit `sparse` and `full` conversion functions.

You cannot define a sparse matrix with competing size specifications. The code generator fixes the size of the sparse matrix when it produces the corresponding data type definition in C/C++. As an example, the function `foo` causes an error in code generation:

```
function y = foo(n)
%#codegen
if n > 0
 y = sparse(3,2);
else
 y = sparse(4,3);
end
```

Logical indexing into sparse matrices is not supported for code generation. For example, this syntax causes an error:

```
S = magic(3);
S(S > 7) = 42;
```

For sparse matrices, you cannot delete array elements by assigning empty arrays:

```
S(:,2) = [];
```

## Specify Array Layout in Functions and Classes

You can specialize individual MATLAB functions for row-major layout or column-major layout by inserting `coder.rowMajor` or `coder.columnMajor` calls into the function body. Using these function specializations, you can combine row-major data and column-major data in your generated code. You can also specialize classes for one specific array layout. Function and class specializations allow you to:

- Incrementally modify your code for row-major layout or column-major layout.
- Define array layout boundaries for applications that require different layouts in different components.
- Structure the inheritance of array layout between many different functions and classes.

For MATLAB Coder entry-point (top-level) functions, all inputs and outputs must use the same array layout. In the generated C/C++ code, the entry-point function interface accepts and returns data with the same array layout as the function array layout specification.

---

**Note** By default, code generation uses column-major array layout.

---

### Specify Array Layout in a Function

For an example of a specialized function, consider `addMatrixRM`:

```
function [S] = addMatrixRM(A,B)
%#codegen
S = zeros(size(A));
coder.rowMajor; % specify row-major code
for row = 1:size(A,1)
 for col = 1:size(A,2)
 S(row,col) = A(row,col) + B(row,col);
 end
end
```

For MATLAB Coder, you can generate code for `addMatrixRM` by using the `codegen` command.

```
codegen addMatrixRM -args {ones(20,10),ones(20,10)} -config:lib -launchreport
```

Because of the `coder.rowMajor` call, the code generator produces code that uses data stored in row-major layout.

Other functions called from a row-major function or column-major function inherit the same array layout. If a called function has its own distinct `coder.rowMajor` or `coder.columnMajor` call, the local call takes precedence.

You can mix column-major and row-major functions in the same code. The code generator inserts transpose or conversion operations when passing data between row-major and column-major functions. These conversion operations ensure that array elements are stored as required by functions with different array layout specifications. For example, the inputs to a column-major function, called from a row-major function, are converted to column-major layout before being passed to the column-major function.

## Query Array Layout of a Function

To query the array layout of a function at compile time, use `coder.isRowMajor` or `coder.isColumnMajor`. This query can be useful for specializing your generated code when it involves row-major and column-major functions. For example, consider this function:

```
function [S] = addMatrixRouted(A,B)
 if coder.isRowMajor
 %execute this code if row-major
 S = addMatrixRM(A,B);
 elseif coder.isColumnMajor
 %execute this code if column-major
 S = addMatrix_OptimizedForColumnMajor(A,B);
 end
```

This function behaves differently depending on whether it is row-major or column-major. When `addMatrixRouted` is row-major, it calls the `addMatrixRM` function, which has efficient memory access for row-major data. When the function is column-major, it calls a version of the `addMatrixRM` function optimized for column-major data.

For example, consider this function definition. The algorithm iterates through the columns in the outer loop and the rows in the inner loop, in contrast to the `addMatrixRM` function.

```
function [S] = addMatrix_OptimizedForColumnMajor(A,B)
 %#codegen
 S = zeros(size(A));
 for col = 1:size(A,2)
 for row = 1:size(A,1)
 S(row,col) = A(row,col) + B(row,col);
 end
 end
```

Code generation for this function yields:

```
...
/* column-major layout */
for (col = 0; col < 10; col++) {
 for (row = 0; row < 20; row++) {
 S[row + 20 * col] = A[row + 20 * col] + B[row + 20 * col];
 }
}
...
```

The generated code has a stride length of only one element. Due to the specializing queries, the generated code for `addMatrixRouted` provides efficient memory access for either choice of array layout.

## Specify Array Layout in a Class

You can specify array layout for a class so that object property variables are stored with a specific array layout. To specify the array layout, place a `coder.rowMajor` or `coder.columnMajor` call in the class constructor. If you assign an object with a specified array layout to the property of another object, the array layout of the assigned object takes precedence.

Consider the row-major class `rowMats` as an example. This class contains matrix properties and a method that consists of an element-wise addition algorithm. The algorithm in the method performs

more efficiently for data stored in row-major layout. By specifying `coder.rowMajor` in the class constructor, the generated code uses row-major layout for the property data.

```
classdef rowMats
 properties (Access = public)
 A;
 B;
 C;
 end
 methods
 function obj = rowMats(A,B)
 coder.rowMajor;
 if nargin == 0
 obj.A = 0;
 obj.B = 0;
 obj.C = 0;
 else
 obj.A = A;
 obj.B = B;
 obj.C = zeros(size(A));
 end
 end
 function obj = add(obj)
 for row = 1:size(obj.A,1)
 for col = 1:size(obj.A,2)
 obj.C(row,col) = obj.A(row,col) + obj.B(row,col);
 end
 end
 end
 end
end
```

Use the class in a simple function `doMath`. The inputs and outputs of the entry-point function must all use the same array layout.

```
function [out] = doMath(in1,in2)
 %#codegen
 out = zeros(size(in1));
 myMats = rowMats(in1,in2);
 myMats = myMats.add;
 out = myMats.C;
end
```

For MATLAB Coder, you can generate code by entering:

```
A = rand(20,10);
B = rand(20,10);
cfg = coder.config('lib');
codegen -config cfg doMath -args {A,B} -launchreport
```

With default settings, the code generator assumes that the entry-point function inputs and outputs use column-major layout, because you do not specify row-major layout for the function `doMath`. Therefore, before calling the class constructor, the generated code converts `in1` and `in2` to row-major layout. Similarly, it converts the `doMath` function output back to column-major layout.

When designing a class for a specific array layout, consider:

- If you do not specify the array layout in a class constructor, objects inherit their array layout from the function that calls the class constructor, or from code generation configuration settings.
- You cannot specify the array layout in a nonstatic method by using `coder.rowMajor` or `coder.columnMajor`. Methods use the same array layout as the receiving object. Methods do not inherit the array layout of the function that calls them. For static methods, which are used similarly to ordinary functions, you can specify the array layout in the method.
- If you specify the array layout of a superclass, the subclass inherits this array layout specification. You cannot specify conflicting array layouts between superclasses and subclasses.

## Code Design for Row-Major Array Layout

Outside of code generation, MATLAB uses column-major layout by default. Array layout specifications do not affect self-contained MATLAB code. To test the efficiency of your generated code or your MATLAB Function block, create separate versions with row-major layout and column-major layout. Then, compare their performance.

You can design your MATLAB code to avoid potential inefficiencies related to array layout. Inefficiencies can be caused by:

- Conversions between row-major layout and column-major layout.
- One-dimensional or linear indexing of row-major data.
- Reshaping or rearrangement of row-major data.

Array layout conversions are necessary when you mix row-major and column-major specifications in the same code or model, or when you use linear indexing on data that is stored in row-major. When you simulate a model or generate code for a model that uses column-major, and that contains a MATLAB Function block that uses row-major, then the software converts input data to row-major and output data back to column-major as needed, and vice versa.

Inefficiencies can be caused by functions or algorithms that are less optimized for a given choice of array layout. If a function or algorithm is more efficient for a different layout, you can enforce that layout by embedding it in another function with a `coder.rowMajor` or `coder.columnMajor` call.

### Linear Indexing Uses Column-Major Array Layout

The code generator follows MATLAB column-major semantics for linear indexing. For more information on linear indexing in MATLAB, see “Array Indexing”.

To use linear indexing on row-major data, the code generator must first recalculate the data representation in column-major layout. This additional processing can slow performance. To improve code efficiency, avoid using linear indexing on row-major data, or use column-major layout for code that uses linear indexing.

For example, consider the function `sumShiftedProducts`, which accepts a matrix as an input and outputs a scalar value. The function uses linear indexing on the input matrix to sum up the product of each matrix element with an adjacent element. The output value of this operation depends on the order in which the input elements are stored.

```
function mySum = sumShiftedProducts(A)
%#codegen
mySum = 0;
% create linear vector of A elements
B = A(:);
% multiply B by B with elements shifted by one, and take sum
mySum = sum(B.*circshift(B,1));
end
```

For MATLAB Coder, to generate code that uses row-major layout, enter:

```
codegen -config:mex sumShiftedProducts -args {ones(2,3)} -launchreport -rowmajor
```

For an example input, consider the matrix:

```
D = reshape(1:6,3,2)'
```

which yields:

```
D =
 1 2 3
 4 5 6
```

If you pass this matrix as input to the generated code, the elements of A are stored in the order:

```
 1 2 3 4 5 6
```

In contrast, because the vector B is obtained by linear indexing, it is stored in the order:

```
 1 4 2 5 3 6
```

The code generator must insert a reshaping operation to rearrange the data from row-major layout for A to column-major layout for B. This additional operation reduces the efficiency of the function for row-major layout. The inefficiency increases with the size of the array. Because linear indexing always uses column-major layout, the generated code for `sumShiftedProducts` produces the same output result whether generated with row-major layout or column-major layout.

In general, functions that compute indices or subscripts also use linear indexing, and produce results corresponding to data stored in column-major layout. These functions include:

- `ind2sub`
- `sub2ind`
- `colon`

## Code Generation for Variable-Size Arrays

For code generation, an array dimension is fixed-size or variable-size. If the code generator can determine the size of the dimension and that the size of the dimension does not change, then the dimension is fixed-size. When all dimensions of an array are fixed-size, the array is a fixed-size array. In the following example, *Z* is a fixed-size array.

```
function Z = myfcn()
Z = zeros(1,4);
end
```

The size of the first dimension is 1 and the size of the second dimension is 4.

If the code generator cannot determine the size of a dimension or the code generator determines that the size changes, then the dimension is variable-size. When at least one of its dimensions is variable-size, an array is a variable-size array.

A variable-size dimension is either bounded or unbounded. A bounded dimension has a fixed upper size. An unbounded dimension does not have a fixed upper size.

In the following example, the second dimension of *Z* is bounded, variable-size. It has an upper bound of 16.

```
function s = myfcn(n)
if (n > 0)
 Z = zeros(1,4);
else
 Z = zeros(1,16);
end
s = length(Z);
```

In the following example, if the value of *n* is unknown at compile time, then the second dimension of *Z* is unbounded.

```
function s = myfcn(n)
Z = rand(1,n);
s = sum(Z);
end
```

You can define variable-size arrays by:

- Using constructors, such as `zeros`, with a nonconstant dimension
- Assigning multiple, constant sizes to the same variable before using it
- Declaring all instances of a variable to be variable-size by using `coder.varsize`

For more information, see “Define Variable-Size Data for Code Generation” on page 54-7.

You can control whether variable-size arrays are allowed for code generation. See “Enabling and Disabling Support for Variable-Size Arrays” on page 54-3.

## Memory Allocation for Variable-Size Arrays

For fixed-size arrays and variable-size arrays whose size is less than a threshold, the code generator allocates memory statically on the stack. For unbounded, variable-size arrays and variable-size arrays

whose size is greater than or equal to a threshold, the code generator allocates memory dynamically on the heap.

For a MATLAB Function block, you cannot use dynamic memory allocation for:

- Input and output signals. Variable-size input and output signals must have an upper bound.
- Parameters or global variables. Parameters and global variables must be fixed-size.
- Fields of bus arrays. Bus arrays cannot have variable-size fields.

You can control whether dynamic memory allocation is allowed or when it is used for code generation. See “Control Memory Allocation for Variable-Size Arrays in a MATLAB Function Block” on page 45-80.

The code generator represents dynamically allocated data as a structure type called `emxArray`. The code generator generates utility functions that create and interact with `emxArrays`. If you use Embedded Coder, you can customize the generated identifiers for the `emxArray` types and utility functions. See “Identifier Format Control” (Embedded Coder).

## Enabling and Disabling Support for Variable-Size Arrays

By default, for MATLAB Function blocks, support for variable-size arrays is enabled. To disable this support:

- 1 In the MATLAB Function Block Editor, select **Edit Data**.
- 2 Clear the **Support variable-size arrays** check box.

## Variable-Size Arrays in a MATLAB Function Report

You can tell whether an array is fixed-size or variable-size by looking at the **Size** column of the **Variables** tab in a MATLAB Function Report.

| Name | Type   | Size   | Class  |
|------|--------|--------|--------|
| y    | Output | 1 × 1  | double |
| n    | Input  | 1 × 1  | double |
| x    | Local  | 1 × :? | double |

A colon (:) indicates that a dimension is variable-size. A question mark (?) indicates that the size is unbounded. For example, a size of 1-by-:? indicates that the size of the first dimension is fixed-size 1 and the size of the second dimension is unbounded, variable-size. *Italic* indicates that your code specifies that an array is variable-size, but the code generator determined that it does not change size.

| ALL MESSAGES (0) |        | VARIABLES |        |
|------------------|--------|-----------|--------|
| Name             | Type   | Size      | Class  |
| y                | Output | 1 × 2     | double |
| n                | Input  | 1 × 1     | double |
| Z                | Local  | 1 × 4     | double |

- “Define Variable-Size Data for Code Generation” on page 54-7
- “Use Dynamic Memory Allocation for Variable-Size Arrays in a MATLAB Function Block” on page 45-82

## Specify Upper Bounds for Variable-Size Arrays

Specify upper bounds for an array when:

- Dynamic memory allocation is disabled.

If dynamic memory allocation is disabled, you must specify upper bounds for all arrays.

- You do not want the code generator to use dynamic memory allocation for the array.

Specify upper bounds that result in an array size (in bytes) that is less than the dynamic memory allocation threshold.

## Specify Upper Bounds for MATLAB Function Block Inputs and Outputs

See “Declare Variable-Size Inputs and Outputs” on page 45-73.

## Specify Upper Bounds for Local Variables

When using static allocation, the code generator uses a sophisticated analysis to calculate the upper bounds of local data. However, when the analysis fails to detect an upper bound or calculates an upper bound that is not precise enough for your application, you must specify upper bounds explicitly for local variables.

### Constrain the Value of Variables That Specify the Dimensions of Variable-Size Arrays

To constrain the value of variables that specify the dimensions of variable-size arrays, use the `assert` function with relational operators. For example:

```
function y = dim_need_bound(n) %#codegen
assert (n <= 5);
L = ones(n,n);
M = zeros(n,n);
M = [L; M];
y = M;
```

This `assert` statement constrains input `n` to a maximum size of 5. `L` is variable-size with upper bounds of 5 in each dimension. `M` is variable-size with an upper bound of 10 in the first dimension and 5 in the second dimension.

### Specify the Upper Bounds for All Instances of a Local Variable

To specify the upper bounds for all instances of a local variable in a function, use the `coder.varsize` function. For example:

```
function Y = example_bounds1(u) %#codegen
Y = [1 2 3 4 5];
coder.varsize('Y',[1 10]);
if (u > 0)
 Y = [Y Y+u];
else
 Y = [Y Y*u];
end
```

The second argument of `coder. varsize` specifies the upper bound for each instance of the variable specified in the first argument. In this example, the argument `[1 10]` indicates that for every instance of `Y`:

- The first dimension is fixed at size 1.
- The second dimension can grow to an upper bound of 10.

### **See Also**

`coder. varsize`

### **More About**

- “Code Generation for Variable-Size Arrays” on page 54-2
- “Define Variable-Size Data for Code Generation” on page 54-7

## Define Variable-Size Data for Code Generation

For code generation, before using variables in operations or returning them as outputs, you must assign them a specific class, size, and complexity. Generally, after the initial assignment, you cannot reassign variable properties. Therefore, after assigning a fixed size to a variable or structure field, attempts to grow the variable or structure field might cause a compilation error. In these cases, you must explicitly define the data as variable-size by using one of these methods.

| Method                                                                                                                                                       | See                                                                        |
|--------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------|
| Assign the data from a variable-size matrix constructor such as: <ul style="list-style-type: none"> <li>• ones</li> <li>• zeros</li> <li>• repmat</li> </ul> | “Use a Matrix Constructor with Nonconstant Dimensions” on page 54-7        |
| Assign multiple, constant sizes to the same variable before using (reading) the variable.                                                                    | “Assign Multiple Sizes to the Same Variable” on page 54-7                  |
| Define all instances of a variable to be variable-size.                                                                                                      | “Define Variable-Size Data Explicitly by Using coder.varsize” on page 54-8 |

### Use a Matrix Constructor with Nonconstant Dimensions

You can define a variable-size matrix by using a constructor with nonconstant dimensions. For example:

```
function s = var_by_assign(u) %#codegen
y = ones(3,u);
s = numel(y);
```

If you are not using dynamic memory allocation, you must also add an `assert` statement to provide upper bounds for the dimensions. For example:

```
function s = var_by_assign(u) %#codegen
assert (u < 20);
y = ones(3,u);
s = numel(y);
```

### Assign Multiple Sizes to the Same Variable

Before you use (read) a variable in your code, you can make it variable-size by assigning multiple, constant sizes to it. When the code generator uses static allocation on the stack, it infers the upper bounds from the largest size specified for each dimension. When you assign the same size to a given dimension across all assignments, the code generator assumes that the dimension is fixed at that size. The assignments can specify different shapes and sizes.

When the code generator uses dynamic memory allocation, it does not check for upper bounds. It assumes that the variable-size data is unbounded.

#### Inferring Upper Bounds from Multiple Definitions with Different Shapes

```
function s = var_by_multiassign(u) %#codegen
if (u > 0)
```

```
 y = ones(3,4,5);
else
 y = zeros(3,1);
end
s = numel(y);
```

When the code generator uses static allocation, it infers that `y` is a matrix with three dimensions:

- The first dimension is fixed at size 3
- The second dimension is variable-size with an upper bound of 4
- The third dimension is variable-size with an upper bound of 5

When the code generator uses dynamic allocation, it analyzes the dimensions of `y` differently:

- The first dimension is fixed at size 3.
- The second and third dimensions are unbounded.

## Define Variable-Size Data Explicitly by Using `coder.versize`

To explicitly define variable-size data, use the function `coder.versize`. Optionally, you can also specify which dimensions vary along with their upper bounds. For example:

- Define `B` as a variable-size 2-dimensional array, where each dimension has an upper bound of 64.

```
coder.versize('B', [64 64]);
```

- Define `B` as a variable-size array:

```
coder.versize('B');
```

When you supply only the first argument, `coder.versize` assumes that all dimensions of `B` can vary and that the upper bound is `size(B)`.

If a MATLAB Function block input or output signal is variable-size, in the Ports and Data Manager, you must specify that the signal is variable-size. You must also provide the upper bounds. You do not have to use `coder.versize` with the corresponding input or output variable inside the MATLAB Function block. However, if you specify upper bounds with `coder.versize`, they must match the upper bounds in the Ports and Data Manager.

### Specify Which Dimensions Vary

You can use the function `coder.versize` to specify which dimensions vary. For example, the following statement defines `B` as an array whose first dimension is fixed at 2, but whose second dimension can grow to a size of 16:

```
coder.versize('B',[2, 16],[0 1])
```

.

The third argument specifies which dimensions vary. This argument must be a logical vector or a double vector containing only zeros and ones. Dimensions that correspond to zeros or `false` have fixed size. Dimensions that correspond to ones or `true` vary in size. `coder.versize` usually treats dimensions of size 1 as fixed. See “Define Variable-Size Matrices with Singleton Dimensions” on page 54-9.

For an input or output signal, if you specify the upper bounds with `coder. varsize` inside the MATLAB Function block, they must match the upper bounds in the Ports and Data Manager.

### Allow a Variable to Grow After Defining Fixed Dimensions

Function `var_by_if` defines matrix `Y` with fixed 2-by-2 dimensions before the first use (where the statement `Y = Y + u` reads from `Y`). However, `coder. varsize` defines `Y` as a variable-size matrix, allowing it to change size based on decision logic in the `else` clause:

```
function Y = var_by_if(u) %#codegen
if (u > 0)
 Y = zeros(2,2);
 coder. varsize('Y');
 if (u < 10)
 Y = Y + u;
 end
else
 Y = zeros(5,5);
end
```

Without `coder. varsize`, the code generator infers `Y` to be a fixed-size, 2-by-2 matrix. It generates a size mismatch error.

### Define Variable-Size Matrices with Singleton Dimensions

A singleton dimension is a dimension for which `size(A, dim) = 1`. Singleton dimensions are fixed in size when:

- You specify a dimension with an upper bound of 1 in `coder. varsize` expressions.

For example, in this function, `Y` behaves like a vector with one variable-size dimension:

```
function Y = dim_singleton(u) %#codegen
Y = [1 2];
coder. varsize('Y', [1 10]);
if (u > 0)
 Y = [Y 3];
else
 Y = [Y u];
end
```

- You initialize variable-size data with singleton dimensions by using matrix constructor expressions or matrix functions.

For example, in this function, `X` and `Y` behave like vectors where only their second dimensions are variable-size.

```
function [X,Y] = dim_singleton_vects(u) %#codegen
Y = ones(1,3);
X = [1 4];
coder. varsize('Y','X');
if (u > 0)
 Y = [Y u];
else
 X = [X u];
end
```

You can override this behavior by using `coder. varsize` to specify explicitly that singleton dimensions vary. For example:

```
function Y = dim_singleton_vary(u) %#codegen
Y = [1 2];
coder. varsize('Y', [1 10], [1 1]);
if (u > 0)
 Y = [Y Y+u];
else
 Y = [Y Y*u];
end
```

In this example, the third argument of `coder. varsize` is a vector of ones, indicating that each dimension of `Y` varies in size.

### Define Variable-Size Structure Fields

To define structure fields as variable-size arrays, use a colon (`:`) as the index expression. The colon (`:`) indicates that all elements of the array are variable-size. For example:

```
function y=struct_example() %#codegen

d = struct('values', zeros(1,0), 'color', 0);
data = repmat(d, [3 3]);
coder. varsize('data(:).values');

for i = 1:numel(data)
 data(i).color = rand-0.5;
 data(i).values = 1:i;
end

y = 0;
for i = 1:numel(data)
 if data(i).color > 0
 y = y + sum(data(i).values);
 end
end
```

The expression `coder. varsize('data(:).values')` defines the field `values` inside each element of matrix `data` to be variable-size.

Here are other examples:

- `coder. varsize('data.A(:).B')`

In this example, `data` is a scalar variable that contains matrix `A`. Each element of matrix `A` contains a variable-size field `B`.

- `coder. varsize('data(:).A(:).B')`

This expression defines field `B` inside each element of matrix `A` inside each element of matrix `data` to be variable-size.

## Diagnose and Fix Variable-Size Data Errors

### Diagnosing and Fixing Size Mismatch Errors

#### Issue: Assigning Variable-Size Matrices to Fixed-Size Matrices

You cannot assign variable-size matrices to fixed-size matrices in generated code. Consider this example:

```
function Y = example_mismatch1(n) %#codegen
assert(n < 10);
B = ones(n,n);
A = magic(3);
A(1) = mean(A(:));
if (n == 3)
 A = B;
end
Y = A;
```

Compiling this function produces this error:

```
??? Dimension 1 is fixed on the left-hand side
but varies on the right ...
```

There are several ways to fix this error:

- Allow matrix A to grow by adding the `coder. varsize` construct:

```
function Y = example_mismatch1_fix1(n) %#codegen
coder. varsize('A');
assert(n < 10);
B = ones(n,n);
A = magic(3);
A(1) = mean(A(:));
if (n == 3)
 A = B;
end
Y = A;
```

- Explicitly restrict the size of matrix B to 3-by-3 by modifying the `assert` statement:

```
function Y = example_mismatch1_fix2(n) %#codegen
coder. varsize('A');
assert(n == 3)
B = ones(n,n);
A = magic(3);
A(1) = mean(A(:));
if (n == 3)
 A = B;
end
Y = A;
```

- Use explicit indexing to make B the same size as A:

```
function Y = example_mismatch1_fix3(n) %#codegen
assert(n < 10);
B = ones(n,n);
A = magic(3);
```

```
A(1) = mean(A(:));
if (n == 3)
 A = B(1:3, 1:3);
end
Y = A;
```

### Issue: Empty Matrix Reshaped to Match Variable-Size Specification

If you assign an empty matrix `[]` to variable-size data, MATLAB might silently reshape the data in generated code to match a `coder. varsize` specification. For example:

```
function Y = test(u) %#codegen
Y = [];
coder. varsize('Y', [1 10]);
if u < 0
 Y = [Y u];
end
```

In this example, `coder. varsize` defines `Y` as a column vector of up to 10 elements, so its first dimension is fixed at size 1. The statement `Y = []` designates the first dimension of `Y` as 0, creating a mismatch. The right hand side of the assignment is an empty matrix and the left hand side is a variable-size vector. In this case, MATLAB reshapes the empty matrix `Y = []` in generated code to `Y = zeros(1,0)` so it matches the `coder. varsize` specification.

### Issue: Assigning Implicitly Expanded Outputs to Fixed-Size Variable

If you assign the implicitly expanded output of a binary operation or function to a variable of different size, the code generator might produce an error. For example:

```
function out = test(n) %#codegen
x = ones(n,1);
if mod(n,2) == 1
 y = ones(n,n);
 x = y + x;
end
out = out + x(2);
end
```

In this example, `x` is an unbounded vector. Due to implicit expansion, the plus operation on `x` and `y` results in an unbounded matrix (Inf-by-Inf). Assigning an unbounded matrix to `x`, which is an unbounded vector, results in an error.

If you want to use the implicitly expanded output, assign the output to a new variable with the same size as the output.

If you want `x` to retain its size and not apply implicit expansion in the generated code, use `coder. sameSizeBinaryOp` to apply the operation. You can also call `coder. noImplicitExpansionInFunction` in your function body to disable implicit expansion in the code generated for that function.

Implicit expansion automatically expands the operands to apply binary operations on arrays of compatible sizes. See “Generate Code With Implicit Expansion Enabled” (MATLAB Coder), “Optimize Implicit Expansion in Generated Code” (MATLAB Coder), and “Compatible Array Sizes for Basic Operations”.

## Diagnosing and Fixing Errors in Detecting Upper Bounds

### Issue: Using Nonconstant Dimensions in a Matrix Constructor

You can define variable-size data by assigning a variable to a matrix with nonconstant dimensions. For example:

```
function y = dims_vary(u) %#codegen
if (u > 0)
 y = ones(3,u);
else
 y = zeros(3,1);
end
```

However, compiling this function generates an error because you did not specify an upper bound for `u`.

To fix the problem, add an `assert` statement before the first use of `u`:

```
function y = dims_vary_fix(u) %#codegen
assert (u < 20);
if (u > 0)
 y = ones(3,u);
else
 y = zeros(3,1);
end
```

## Incompatibilities with MATLAB in Variable-Size Support for Code Generation

### Incompatibility with MATLAB for Scalar Expansion

Scalar expansion is a method of converting scalar data to match the dimensions of vector or matrix data. If one operand is a scalar and the other is not, scalar expansion applies the scalar to every element of the other operand.

During code generation, scalar expansion rules apply except when operating on two variable-size expressions. In this case, both operands must be the same size. The generated code does not perform scalar expansion even if one of the variable-size expressions turns out to be scalar at run time. Therefore, when run-time error checks are enabled, a run-time error can occur.

Consider this function:

```
function y = scalar_exp_test_err1(u) %#codegen
y = ones(3);
switch u
 case 0
 z = 0;
 case 1
 z = 1;
 otherwise
 z = zeros(3);
end
y(:) = z;
```

When you generate code for this function, the code generator determines that `z` is variable size with an upper bound of 3.

| SUMMARY |        | ALL MESSAGES (0) |        | BUILD LOGS |  | CODE INSIGHTS (1) |  | VARIABLES |  |
|---------|--------|------------------|--------|------------|--|-------------------|--|-----------|--|
| Name    | Type   | Size             | Class  |            |  |                   |  |           |  |
| y       | Output | 3 × 3            | double |            |  |                   |  |           |  |
| u       | Input  | 1 × 1            | double |            |  |                   |  |           |  |
| z       | Local  | :3 × :3          | double |            |  |                   |  |           |  |

If you run the MEX function with `u` equal to 0 or 1, the generated code does not perform scalar expansion, even though `z` is scalar at run time. Therefore, when run-time error checks are enabled, a run-time error can occur.

```
scalar_exp_test_err1_mex(0)
Subscripted assignment dimension mismatch: [9] ~= [1].

Error in scalar_exp_test_err1 (line 11)
y(:) = z;
```

To avoid this issue, use indexing to force `z` to be a scalar value.

```
function y = scalar_exp_test_err1(u) %#codegen
y = ones(3);
switch u
 case 0
 z = 0;
 case 1
 z = 1;
 otherwise
 z = zeros(3);
end
y(:) = z(1);
```

## Incompatibility with MATLAB in Determining Size of Variable-Size N-D Arrays

For variable-size N-D arrays, the `size` function can return a different result in generated code than in MATLAB. In generated code, `size(A)` returns a fixed-length output because it does not drop trailing singleton dimensions of variable-size N-D arrays. By contrast, `size(A)` in MATLAB returns a variable-length output because it drops trailing singleton dimensions.

For example, if the shape of array `A` is `:?x:?x:?` and `size(A,3)==1`, `size(A)` returns:

- Three-element vector in generated code
- Two-element vector in MATLAB code

### Workarounds

If your application requires generated code to return the same size of variable-size N-D arrays as MATLAB code, consider one of these workarounds:

- Use the two-argument form of `size`.

For example, `size(A,n)` returns the same answer in generated code and MATLAB code.

- Rewrite `size(A)`:

```
B = size(A);
X = B(1:ndims(A));
```

This version returns `X` with a variable-length output. However, you cannot pass a variable-size `X` to matrix constructors such as `zeros` that require a fixed-size argument.

## Incompatibility with MATLAB in Determining Size of Empty Arrays

The size of an empty array in generated code might be different from its size in MATLAB source code. The size might be  $1 \times 0$  or  $0 \times 1$  in generated code, but  $0 \times 0$  in MATLAB. Therefore, you should not write code that relies on the specific size of empty matrices.

For example, consider the following code:

```
function y = foo(n) %#codegen
x = [];
i = 0;
while (i < 10)
 x = [5 x];
 i = i + 1;
end
if n > 0
 x = [];
end
y = size(x);
end
```

Concatenation requires its operands to match on the size of the dimension that is not being concatenated. In the preceding concatenation, the scalar value has size  $1 \times 1$  and  $x$  has size  $0 \times 0$ . To support this use case, the code generator determines the size for  $x$  as  $[1 \times ?]$ . Because there is another assignment  $x = []$  after the concatenation, the size of  $x$  in the generated code is  $1 \times 0$  instead of  $0 \times 0$ .

This behavior persists while determining the size of empty character vectors which are denoted as `''`. For example, consider the following code:

```
function out = string_size
out = size('');
end
```

Here, the value of `out` might be  $1 \times 0$  or  $0 \times 1$  in generated code, but  $0 \times 0$  in MATLAB.

For incompatibilities with MATLAB in determining the size of an empty array that results from deleting elements of an array, see “Size of Empty Array That Results from Deleting Elements of an Array” on page 49-13.

### Workaround

If your application checks whether a matrix is empty, use one of these workarounds:

- Rewrite your code to use the `isempty` function instead of the `size` function.
- Instead of using `x=[]` to create empty arrays, create empty arrays of a specific size using `zeros`. For example:

```
function y = test_empty(n) %#codegen
x = zeros(1,0);
i=0;
while (i < 10)
 x = [5 x];
 i = i + 1;
end
if n > 0
```

```

 x = zeros(1,0);
 end
 y=size(x);
end

```

## Incompatibility with MATLAB in Determining Class of Empty Arrays

The class of an empty array in generated code can be different from its class in MATLAB source code. Therefore, do not write code that relies on the class of empty matrices.

For example, consider the following code:

```

function y = fun(n)
x = [];
if n > 1
 x = ['a' x];
end
y=class(x);
end

```

`fun(0)` returns `double` in MATLAB, but `char` in the generated code. When the statement `n > 1` is false, MATLAB does not execute `x = ['a' x]`. The class of `x` is `double`, the class of the empty array. However, the code generator considers all execution paths. It determines that based on the statement `x = ['a' x]`, the class of `x` is `char`.

### Workaround

Instead of using `x=[]` to create an empty array, create an empty array of a specific class. For example, use `blanks(0)` to create an empty array of characters.

```

function y = fun(n)
x = blanks(0);
if n > 1
 x = ['a' x];
end
y=class(x);
end

```

## Incompatibility with MATLAB in Matrix-Matrix Indexing

In matrix-matrix indexing, you use one matrix to index into another matrix. In MATLAB, the general rule for matrix-matrix indexing is that the size and orientation of the result match the size and orientation of the index matrix. For example, if `A` and `B` are matrices, `size(A(B))` equals `size(B)`. When `A` and `B` are vectors, MATLAB applies a special rule. The special vector-vector indexing rule is that the orientation of the result is the orientation of the data matrix. For example, if `A` is 1-by-5 and `B` is 3-by-1, then `A(B)` is 1-by-3.

The code generator applies the same matrix-matrix indexing rules as MATLAB. If `A` and `B` are variable-size matrices, to apply the matrix-matrix indexing rules, the code generator assumes that the `size(A(B))` equals `size(B)`. If, at run time, `A` and `B` become vectors and have different orientations, then the assumption is incorrect. Therefore, when run-time error checks are enabled, an error can occur.

To avoid this issue, force your data to be a vector by using the colon operator for indexing. For example, suppose that your code intentionally toggles between vectors and regular matrices at run time. You can do an explicit check for vector-vector indexing.

```

...
if isvector(A) && isvector(B)
 C = A(:);
 D = C(B(:));
else
 D = A(B);
end
...

```

The indexing in the first branch specifies that `C` and `B(:)` are compile-time vectors. Therefore, the code generator applies the indexing rule for indexing one vector with another vector. The orientation of the result is the orientation of the data vector, `C`.

## Incompatibility with MATLAB in Vector-Vector Indexing

In MATLAB, the special rule for vector-vector indexing is that the orientation of the result is the orientation of the data vector. For example, if `A` is 1-by-5 and `B` is 3-by-1, then `A(B)` is 1-by-3. If, however, the data vector `A` is a scalar, then the orientation of `A(B)` is the orientation of the index vector `B`.

The code generator applies the same vector-vector indexing rules as MATLAB. If `A` and `B` are variable-size vectors, to apply the indexing rules, the code generator assumes that the orientation of `B` matches the orientation of `A`. At run time, if `A` is scalar and the orientation of `A` and `B` do not match, then the assumption is incorrect. Therefore, when run-time error checks are enabled, a run-time error can occur.

To avoid this issue, make the orientations of the vectors match. Alternatively, index single elements by specifying the row and column. For example, `A(row, column)`.

## Incompatibility with MATLAB in Matrix Indexing Operations for Code Generation

The following limitation applies to matrix indexing operations for code generation:

- Initialization of the following style:

```

for i = 1:10
 M(i) = 5;
end

```

In this case, the size of `M` changes as the loop is executed. Code generation does not support increasing the size of an array over time.

For code generation, preallocate `M`.

```

M = zeros(1,10);
for i = 1:10
 M(i) = 5;
end

```

The following limitation applies to matrix indexing operations for code generation when dynamic memory allocation is disabled:

- $M(i:j)$  where  $i$  and  $j$  change in a loop

During code generation, memory is not dynamically allocated for the size of the expressions that change as the program executes. To implement this behavior, use `for`-loops as shown:

```
...
M = ones(10,10);
for i=1:10
 for j = i:10
 M(i,j) = 2*M(i,j);
 end
end
...
```

---

**Note** The matrix  $M$  must be defined before entering the loop.

---

## Incompatibility with MATLAB in Concatenating Variable-Size Matrices

For code generation, when you concatenate variable-size arrays, the dimensions that are not being concatenated must match exactly.

## Differences When Curly-Brace Indexing of Variable-Size Cell Array Inside Concatenation Returns No Elements

Suppose that:

- $c$  is a variable-size cell array.
- You access the contents of  $c$  by using curly braces. For example,  $c\{2:4\}$ .
- You include the results in concatenation. For example,  $[a \ c\{2:4\} \ b]$ .
- $c\{I\}$  returns no elements. Either  $c$  is empty or the indexing inside the curly braces produces an empty result.

For these conditions, MATLAB omits  $c\{I\}$  from the concatenation. For example,  $[a \ c\{I\} \ b]$  becomes  $[a \ b]$ . The code generator treats  $c\{I\}$  as the empty array  $[c\{I\}]$ . The concatenation becomes  $[\dots [c\{i\}] \dots]$ . This concatenation then omits the array  $[c\{I\}]$ . So that the properties of  $[c\{I\}]$  are compatible with the concatenation  $[\dots [c\{i\}] \dots]$ , the code generator assigns the class, size, and complexity of  $[c\{I\}]$  according to these rules:

- The class and complexity are the same as the base type of the cell array.
- The size of the second dimension is always 0.
- For the rest of the dimensions, the size of  $N_i$  depends on whether the corresponding dimension in the base type is fixed or variable size.
  - If the corresponding dimension in the base type is variable size, the dimension has size 0 in the result.
  - If the corresponding dimension in the base type is fixed size, the dimension has that size in the result.

Suppose that `c` has a base type with class `int8` and size `10x7x8x?`. In the generated code, the class of `[c{I}]` is `int8`. The size of `[c{I}]` is `0x0x8x0`. The second dimension is 0. The first and last dimensions are 0 because those dimensions are variable size in the base type. The third dimension is 8 because the size of the third dimension of the base type is a fixed size 8.

Inside concatenation, if curly-brace indexing of a variable-size cell array returns no elements, the generated code can have the following differences from MATLAB:

- The class of `[...c{i}...]` in the generated code can differ from the class in MATLAB.

When `c{I}` returns no elements, MATLAB removes `c{I}` from the concatenation. Therefore, `c{I}` does not affect the class of the result. MATLAB determines the class of the result based on the classes of the remaining arrays, according to a precedence of classes. See “Valid Combinations of Unlike Classes”. In the generated code, the class of `[c{I}]` affects the class of the result of the overall concatenation `[...[c{I}]...]` because the code generator treats `c{I}` as `[c{I}]`. The previously described rules determine the class of `[c{I}]`.

- In the generated code, the size of `[c{I}]` can differ from the size in MATLAB.

In MATLAB, the concatenation `[c{I}]` is a `0x0` double. In the generated code, the previously described rules determine the size of `[c{I}]`.

## Variable-Sizing Restrictions for Code Generation of Toolbox Functions

### In this section...

“Common Restrictions” on page 54-22

“Toolbox Functions with Restrictions for Variable-Size Data” on page 54-22

### Common Restrictions

The following common restrictions apply to multiple toolbox functions, but only for code generation. To determine which of these restrictions apply to specific library functions, see the table in “Toolbox Functions with Restrictions for Variable-Size Data” on page 54-22.

#### Variable-length vector restriction

Inputs to the library function must be variable-length vectors or fixed-size vectors. A variable-length vector is a variable-size array that has the shape  $1 \times n$  or  $n \times 1$  (one dimension is variable sized and the other is fixed at size 1). Other shapes are not permitted, even if they are vectors at run time.

#### Automatic dimension restriction

This restriction applies to functions that take the working dimension (the dimension along which to operate) as input. In MATLAB and in code generation, if you do not supply the working dimension, the function selects it. In MATLAB, the function selects the first dimension whose size does not equal 1. For code generation, the function selects the first dimension that has a variable size or that has a fixed size that does not equal 1. If the working dimension has a variable size and it becomes 1 at run time, then the working dimension is different from the working dimension in MATLAB. Therefore, when run-time error checks are enabled, an error can occur.

For example, suppose that  $X$  is a variable-size matrix with dimensions  $1 \times 3 \times 5$ . In the generated code, `sum(X)` behaves like `sum(X,2)`. In MATLAB, `sum(X)` behaves like `sum(X,2)` unless `size(X,2)` is 1. In MATLAB, when `size(X,2)` is 1, `sum(X)` behaves like `sum(X,3)`.

To avoid this issue, specify the intended working dimension explicitly as a constant value. For example, `sum(X,2)`.

#### Array-to-vector restriction

The function issues an error when a variable-size array that is not a variable-length vector assumes the shape of a vector at run time. To avoid the issue, specify the input explicitly as a variable-length vector instead of a variable-size array.

#### Array-to-scalar restriction

The function issues an error if a variable-size array assumes a scalar value at run time. To avoid this issue, specify scalars as fixed size.

### Toolbox Functions with Restrictions for Variable-Size Data

The following table list functions that have code generation restrictions for variable-size data. For additional restrictions for these functions, and restrictions for all functions and objects supported for

code generation, see “Functions and Objects Supported for C/C++ Code Generation” (MATLAB Coder).

| Function | Restrictions for Variable-Size Data                                                                                                                                                                                                                                                                                                                                                                       |
|----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

| mtimes   | <p>Consider the multiplication <math>A*B</math>. If the code generator is aware that <math>A</math> is scalar and <math>B</math> is a matrix, the code generator produces code for scalar-matrix multiplication. However, if the code generator is aware that <math>A</math> and <math>B</math> are variable-size matrices, it produces code for a general matrix multiplication. At run time, if <math>A</math> turns out to be scalar, the generated code does not change its behavior. Therefore, when run-time error checks are enabled, a size mismatch error can occur.</p> |

## Generate Code With Implicit Expansion Enabled

Implicit expansion refers to the automatic size change of compatible operands to apply element-wise operations. Two dimensions have compatible sizes if, for every dimension, the dimension sizes of the arrays are either the same or one of them is singleton. See “Compatible Array Sizes for Basic Operations”.

Implicit expansion in the generated code is enabled by default. Code generated with implicit expansion enabled might differ from code generated with implicit expansion disabled in these ways:

- Output size
- Additional code generation
- Performance variation

For variable-size dynamic arrays, the generated code exhibits these changes to accomplish implicit expansion at run-time.

For fixed-size and constant arrays, because the values and sizes of the operands are known at compile time, the code generated to calculate the implicitly expanded output does not require additional code generation or cause performance variations.

To control implicit expansion in the generated code, see “Optimize Implicit Expansion in Generated Code” (MATLAB Coder).

### Output Size

Implicit expansion automatically expands the operands to apply element-wise operations. For example, consider these input types of compatible size:

```
a_type = coder.typeof(1,[2 1]);
b_type = coder.typeof(1,[2 inf]);
```

A binary operation on these two operands with implicit expansion enabled automatically expands the second dimension of `a_type` to result in an output size of 2-by-Inf. With implicit expansion disabled, the second dimension of `a_type` is not automatically expanded, and the output size is 2-by-1.

For existing workflows created with implicit expansion disabled in the generated code, generating code for the same MATLAB code with implicit expansion enabled might generate size mismatch errors or change the size of outputs from binary operations and functions. To troubleshoot size mismatch errors, see “Diagnose and Fix Variable-Size Data Errors” (MATLAB Coder).

### Additional Code Generation

Implicit expansion enables the operands to be automatically expanded if the operand sizes are compatible. To perform this size change, the generated code introduces code that allows the operands to be expanded.

For example, consider the following code snippet. The function `vector_sum` finds the sum of two arrays.

```
function out = vector_sum(a,b)
out = a + b;
end
```

Consider the variable-size dynamic array defined here:

```
c_type = coder.typeof(1,[1 Inf]);
```

Generate code for `vector_sum` by using this command:

```
codegen vector_sum -args {c_type, c_type} -config:lib -report
```

The generated code for this function with and without implicit expansion is listed in this table.

| Generated Code With Implicit Expansion Disabled                                                                                                                                                                                                                                                                                                                                                                        | Generated Code With Implicit Expansion Enabled                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <pre>void vector_sum(const emxArray_real_T *a, const emxArray_real_T *b, emxArray_real_T *out) {     int i;     int loop_ub;     i = out-&gt;size[0] * out-&gt;size[1];     out-&gt;size[0] = 1;     out-&gt;size[1] = b-&gt;size[1];     emxEnsureCapacity_real_T(out, i);     loop_ub = b-&gt;size[1];     for (i = 0; i &lt; loop_ub; i++) {         out-&gt;data[i] = b-&gt;data[i] + a-&gt;data[i];     } }</pre> | <pre>static void plus(const emxArray_real_T *a, const emxArray_real_T *b, emxArray_real_T *out) {     int i;     ....     if (a-&gt;size[1] == 1) {         out-&gt;size[1] = b-&gt;size[1];     } else {         out-&gt;size[1] = a-&gt;size[1];     }     ....     if (a-&gt;size[1] == 1) {         loop_ub = b-&gt;size[1];     }     else {         loop_ub = a-&gt;size[1];     }     for (i = 0; i &lt; loop_ub; i++) {         out-&gt;data[i] = b-&gt;data[i * stride_0_1] + a-&gt;data[i];     } }  void vector_sum(const emxArray_real_T *a, const emxArray_real_T *b, emxArray_real_T *out) {     int i;     int loop_ub;     if (b-&gt;size[1] == a-&gt;size[1]) {         i = out-&gt;size[0] * out-&gt;size[1];         out-&gt;size[0] = 1;         out-&gt;size[1] = b-&gt;size[1];         emxEnsureCapacity_real_T(out, i);         loop_ub = b-&gt;size[1];         for (i = 0; i &lt; loop_ub; i++) {             out-&gt;data[i] = b-&gt;data[i] + a-&gt;data[i];         }     } else {         plus(out, b, a);     } }</pre> |

With implicit expansion enabled, the code generator creates a supporting function, in this case `plus`, to carry out the size change and to calculate the output.

In most cases, the supporting function carrying out implicit expansion is named after the binary operation it is assisting. In the previous example, if the expression `out = a + b` is changed to `out = a - b`, the name of the supporting function changes to `minus`.

Some supporting functions might also be named as `expand_op`, where `op` refers to the binary operation. In the previous example, if the expression `out = a + b` is replaced with `out = max(a, b)`, the name of the supporting function in the generated code changes to `expand_max`.

If multiple operations in an expression require implicit expansion, the generated code includes a supporting function that is named `binary_expand_op`. The supporting functions change the size of the operand and apply the binary operations.

If you want to apply specific binary operations and functions without implicit expansion, use `coder.sameSizeBinaryOp`. The code generated to apply this function does not include additional code to expand the operands. The output of this function does not expand the operands in MATLAB. This function does not support scalar expansion. Operands must be of the same size.

If you want to disable implicit expansion inside a function for all binary operations within that function in the generated code, call `coder.noImplicitExpansionInFunction` in the required function. Implicit expansion in MATLAB code is still enabled.

## Performance Variation

Code generated with implicit expansion enabled might perform differently than when implicit expansion is disabled. Depending on the input to the generated code that uses implicit expansion, the code might take longer to evaluate the output.

If the generated code does not match the performance requirements of your workflow due to implicit expansion, generate code for your project by turning off implicit expansion for specific binary operations, specific function bodies, or for your whole project. See “Optimize Implicit Expansion in Generated Code” (MATLAB Coder).

---

**Note** Before disabling implicit expansion, ensure that the external code does not use implicit expansion. Disabling implicit expansion for an entire project might cause errors when generating code if your project includes MATLAB code from external sources.

## Optimize Implicit Expansion in Generated Code

Implicit expansion in the generated code is enabled by default. The code generator introduces modifications in the generated code to perform implicit expansion. The changes in the generated code might result in additional code to expand the operands. The expansion of the operands might affect the performance of the generated code. See “Generate Code With Implicit Expansion Enabled” (MATLAB Coder).

Implicit expansion might change the size of the outputs from the supported operators and functions causing size and type mismatch errors in your workflow.

For fine-grained control of where implicit expansion is enabled in the generated code, use the following functions in your MATLAB code:

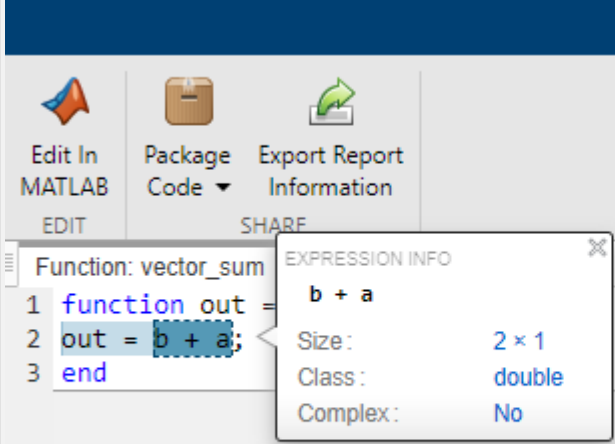

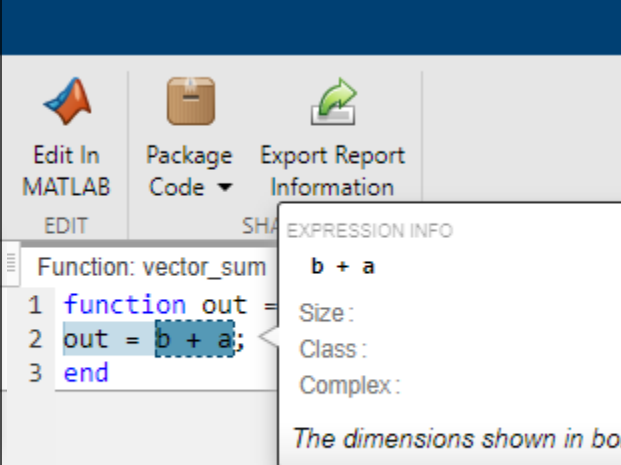

- `coder.noImplicitExpansionInFunction`
- `coder.sameSizeBinaryOp`

For example, consider this code snippet. The function `vector_sum` finds the sum of two arrays of compatible sizes.

```
function out = vector_sum(a,b)
out = b + a;
end
```

The types of operands `a` and `b` are defined as:

```
a_type = coder.typeof(1,[2 1]) %size: 2x1
b_type = coder.typeof(1,[2 Inf]) %size: 2x:inf
```

| Without Implicit Expansion                                                                                | With Implicit Expansion                                                                                 |
|-----------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------|
| Without implicit expansion, the size of the <code>out</code> variable is calculated as <code>2x1</code> . | With implicit expansion, the size of the variable <code>out</code> is calculated as <code>2x:?</code> . |
|                        |                     |

These code snippets outline the changes in the generated code for the function `vector_sum`, while implicit expansion is disabled and enabled. To generate the code, the types of operands `a` and `b` are defined as:

```
a_type = coder.typeof(1,[1 Inf]) %size: 1x:inf
b_type = coder.typeof(1,[1 Inf]) %size: 1x:inf
```

| Generated Code With Implicit Expansion Disabled                                                                                                                                                                                                                                                                                                                                                    | Generated Code With Implicit Expansion Enabled                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <pre>void vector_sum(const emxArray_real_T *a, const emxArray_real_T *out) {     int i;     int loop_ub;     i = out-&gt;size[0] * out-&gt;size[1];     out-&gt;size[0] = 1;     out-&gt;size[1] = b-&gt;size[1];     emxEnsureCapacity_real_T(out, i);     loop_ub = b-&gt;size[1];     for (i = 0; i &lt; loop_ub; i++) {         out-&gt;data[i] = b-&gt;data[i] + a-&gt;data[i];     } }</pre> | <pre>static void plus(const emxArray_real_T *out, const emxArray_real_T *a) {     int i;     ....     if (a-&gt;size[1] == 1) {         out-&gt;size[1] = b-&gt;size[1];     } else {         out-&gt;size[1] = a-&gt;size[1];     }     ....     if (a-&gt;size[1] == 1) {         loop_ub = b-&gt;size[1];     } else {         loop_ub = a-&gt;size[1];     }     for (i = 0; i &lt; loop_ub; i++) {         out-&gt;data[i] = b-&gt;data[i * stride_0_1] + a-&gt;data[i];     } }  void vector_sum(const emxArray_real_T *a, const emxArray_real_T *out) {     int i;     int loop_ub;     if (b-&gt;size[1] == a-&gt;size[1]) {         i = out-&gt;size[0] * out-&gt;size[1];         out-&gt;size[0] = 1;         out-&gt;size[1] = b-&gt;size[1];         emxEnsureCapacity_real_T(out, i);         loop_ub = b-&gt;size[1];         for (i = 0; i &lt; loop_ub; i++) {             out-&gt;data[i] = b-&gt;data[i] + a-&gt;data[i];         }     } else {         plus(out, b, a);     } }</pre> |

## Disable Implicit Expansion in Specified Function by Using `coder.noImplicitExpansionInFunction`

If you require implicit expansion in your project but not in specific functions, disable implicit expansion for the generated code of that function by calling `coder.noImplicitExpansionInFunction` within the function.

For example, the code generated for `vector_sum` does not apply implicit expansion.

| MATLAB Code                                                                                                                                                                                                                          | Generated Code with <code>coder.sameSizeBinaryOp</code>                                                                                                                                                                                                                                                                                                                                          |
|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <pre>function out = vector_sum(a,b) out = coder.sameSizeBinaryOp(@plus, a, b); end  a = coder.typeof(1,[1 Inf]) %size: 1x:inf b = coder.typeof(1,[1 Inf]) %size: 1x:inf codegen vector_sum -launchreport -args {a,b} configLib</pre> | <pre>void vector_sum(const mxArray_real_T *a, const mxArray_real_T *out) {     int i;     int loop_ub;     i = out-&gt;size[0] * out-&gt;size[1];     out-&gt;size[0] = 1;     out-&gt;size[1] = a-&gt;size[1];     emxEnsureCapacity_real_T(out, i);     loop_ub = a-&gt;size[1];     for (i = 0; i &lt; loop_ub; i++) {         out-&gt;data[i] = a-&gt;data[i] + b-&gt;data[i];     } }</pre> |

**Note** `coder.noImplicitExpansionInFunction` does not disable implicit expansion in your MATLAB code. It disables implicit expansion only in the generated code.

## Disable Implicit Expansion for Specific Binary Operation by Using `coder.sameSizeBinaryOp`

Use the function `coder.sameSizeBinaryOp` to perform an error check to ensure that the operands are the same size and prevent the code generator from generating implicitly expanded code for that function.

For example, this code snippet applies the plus operation by using `coder.sameSizeBinaryOp` without implicit expansion.

| MATLAB Code                                                                                                                                                                                                                                   | Generated Code                                                                                                                                                                                                                                                                                                                                                                                   |
|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <pre>function out = vector_sum(a,b) coder.noImplicitExpansionInFunction(); out = a + b; end  a = coder.typeof(1,[1 Inf]) %size: 1x:inf b = coder.typeof(1,[1 Inf]) %size: 1x:inf codegen vector_sum -launchreport -args {a,b} configLib</pre> | <pre>void vector_sum(const mxArray_real_T *a, const mxArray_real_T *out) {     int i;     int loop_ub;     i = out-&gt;size[0] * out-&gt;size[1];     out-&gt;size[0] = 1;     out-&gt;size[1] = a-&gt;size[1];     emxEnsureCapacity_real_T(out, i);     loop_ub = a-&gt;size[1];     for (i = 0; i &lt; loop_ub; i++) {         out-&gt;data[i] = a-&gt;data[i] + b-&gt;data[i];     } }</pre> |

`coder.sameSizeBinaryOp` does not support scalar expansion. Operands given to `coder.sameSizeBinaryOp` must be of the same size.

## Disable Implicit Expansion in your Project

If you do not require implicit expansion in your generated code or do not want the modifications to affect your generated code, turn it off by setting the `EnableImplicitExpansion` flag in your `coder.config` object to `false`. This flag is set to `true` by default.

Disable implicit expansion in your Simulink model by setting the model-wide parameter **Enable Implicit Expansion in MATLAB blocks** to `false`. Alternatively, use this command:

```
set_param(gcm, 'EnableImplicitExpansion', false);
```

---

**Note** Before turning off implicit expansion, ensure that the external code does not use implicit expansion. Disabling implicit expansion for an entire project might cause errors when generating code if your project includes MATLAB code from external sources.

## Structure Definition for Code Generation

To generate efficient standalone code for structures, you must define and use structures differently than you normally would when running your code in the MATLAB environment:

| <b>What's Different</b>                                             | <b>More Information</b>                                         |
|---------------------------------------------------------------------|-----------------------------------------------------------------|

## Structure Operations Allowed for Code Generation

To generate efficient standalone code for MATLAB structures, you are restricted to the following operations:

- Index structure fields using dot notation
- Define primary function inputs as structures
- Pass structures to local functions

## Define Scalar Structures for Code Generation

### In this section...

“Restrictions When Defining Scalar Structures by Assignment” on page 55-4

“Adding Fields in Consistent Order on Each Control Flow Path” on page 55-4

“Restriction on Adding New Fields After First Use” on page 55-4

### Restrictions When Defining Scalar Structures by Assignment

When you define a scalar structure by assigning a variable to a preexisting structure, you do not need to define the variable before the assignment. However, if you already defined that variable, it must have the same class, size, and complexity as the structure you assign to it. In the following example, `p` is defined as a structure that has the same properties as the predefined structure `S`:

```
...
S = struct('a', 0, 'b', 1, 'c', 2);
p = S;
...
```

### Adding Fields in Consistent Order on Each Control Flow Path

When you create a structure, you must add fields in the same order on each control flow path. For example, the following code generates a compiler error because it adds the fields of structure `x` in a different order in each `if` statement clause:

```
function y = fcn(u) %#codegen
if u > 0
 x.a = 10;
 x.b = 20;
else
 x.b = 30; % Generates an error (on variable x)
 x.a = 40;
end
y = x.a + x.b;
```

In this example, the assignment to `x.a` comes before `x.b` in the first `if` statement clause, but the assignments appear in reverse order in the `else` clause. Here is the corrected code:

```
function y = fcn(u) %#codegen
if u > 0
 x.a = 10;
 x.b = 20;
else
 x.a = 40;
 x.b = 30;
end
y = x.a + x.b;
```

### Restriction on Adding New Fields After First Use

You cannot add fields to a structure after you perform the following operations on the structure:

- Reading from the structure
- Indexing into the structure array
- Passing the structure to a function

For example, consider this code:

```
...
x.c = 10; % Defines structure and creates field c
y = x; % Reads from structure
x.d = 20; % Generates an error
...
```

In this example, the attempt to add a new field `d` after reading from structure `x` generates an error.

This restriction extends across the structure hierarchy. For example, you cannot add a field to a structure after operating on one of its fields or nested structures, as in this example:

```
function y = fcn(u) %#codegen

x.c = 10;
y = x.c;
x.d = 20; % Generates an error
```

In this example, the attempt to add a new field `d` to structure `x` after reading from the structure's field `c` generates an error.

## Define Arrays of Structures for Code Generation

### In this section...

“Ensuring Consistency of Fields” on page 55-6

“Using repmat to Define an Array of Structures with Consistent Field Properties” on page 55-6

“Defining an Array of Structures by Using struct” on page 55-6

“Defining an Array of Structures Using Concatenation” on page 55-7

### Ensuring Consistency of Fields

For code generation, when you create an array of MATLAB structures, corresponding fields in the array elements must have the same size, type, and complexity.

Once you have created the array of structures, you can make the structure fields variable-size by using `coder.varsize`. See “Declare Variable-Size Structure Fields” (MATLAB Coder).

### Using repmat to Define an Array of Structures with Consistent Field Properties

You can create an array of structures from a scalar structure by using the MATLAB `repmat` function, which replicates and tiles an existing scalar structure:

- 1 Create a scalar structure, as described in “Define Scalar Structures for Code Generation” on page 55-4.
- 2 Call `repmat`, passing the scalar structure and the dimensions of the array.
- 3 Assign values to each structure using standard array indexing and structure dot notation.

For example, the following code creates `X`, a 1-by-3 array of scalar structures. Each element of the array is defined by the structure `s`, which has two fields, `a` and `b`:

```
...
s.a = 0;
s.b = 0;
X = repmat(s,1,3);
X(1).a = 1;
X(2).a = 2;
X(3).a = 3;
X(1).b = 4;
X(2).b = 5;
X(3).b = 6;
...
```

### Defining an Array of Structures by Using struct

To create an array of structures using the `struct` function, specify the field value arguments as cell arrays. Each cell array element is the value of the field in the corresponding structure array element. For code generation, corresponding fields in the structures must have the same type. Therefore, the elements in a cell array of field values must have the same type.

For example, the following code creates a 1-by-3 structure array. For each structure in the array of structures, a has type `double` and b has type `char`.

```
s = struct('a', {1 2 3}, 'b', {'a' 'b' 'c'});
```

## Defining an Array of Structures Using Concatenation

To create a small array of structures, you can use the concatenation operator, square brackets ( `[ ]` ), to join one or more structures into an array. See “Creating, Concatenating, and Expanding Matrices”. For code generation, the structures that you concatenate must have the same size, class, and complexity.

For example, the following code uses concatenation and a local function to create the elements of a 1-by-3 structure array:

```
...
W = [sab(1,2) sab(2,3) sab(4,5)];

function s = sab(a,b)
 s.a = a;
 s.b = b;
...
```

## Index Substructures and Fields

Use these guidelines when indexing substructures and fields for code generation:

### Reference substructure field values individually using dot notation

For example, the following MATLAB code uses dot notation to index fields and substructures:

```

...
substruct1.a1 = 15.2;
substruct1.a2 = int8([1 2;3 4]);

mystruct = struct('ele1',20.5,'ele2',single(100),
 'ele3',substruct1);

substruct2 = mystruct;
substruct2.ele3.a2 = 2*(substruct1.a2);
...

```

The generated code indexes elements of the structures in this example by resolving symbols as follows:

| Dot Notation            | Symbol Resolution                                                                                |
|-------------------------|--------------------------------------------------------------------------------------------------|
| substruct1.a1           | Field a1 of local structure substruct1                                                           |
| substruct2.ele3.a1      | Value of field a1 of field ele3, a substructure of local structure substruct2                    |
| substruct2.ele3.a2(1,1) | Value in row 1, column 1 of field a2 of field ele3, a substructure of local structure substruct2 |

### Reference field values individually in structure arrays

To reference the value of a field in a structure array, you must index into the array to the structure of interest and then reference that structure's field individually using dot notation, as in this example:

```

...
y = X(1).a % Extracts the value of field a
 % of the first structure in array X
...

```

To reference all the values of a particular field for each structure in an array, use this notation in a for loop, as in this example:

```

...
s.a = 0;
s.b = 0;
X = repmat(s,1,5);
for i = 1:5
 X(i).a = i;
 X(i).b = i+1;
end
...

```

This example uses the `repmat` function to define an array of structures, each with two fields `a` and `b` as defined by `s`. See “Define Arrays of Structures for Code Generation” on page 55-6 for more information.

**Do not reference fields dynamically**

You cannot reference fields in a structure by using dynamic names, which express the field as a variable expression that MATLAB evaluates at run time (see “Generate Field Names from Variables”).

## Assign Values to Structures and Fields

When assigning values to a structure, substructure, or field for code generation, use these guidelines:

### Field properties must be consistent across structure-to-structure assignments

| If:                                                                                | Then:                                                                                    |
|------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------|
| Assigning one structure to another structure.                                      | Define each structure with the same number, type, and size of fields.                    |
| Assigning one structure to a substructure of a different structure and vice versa. | Define the structure with the same number, type, and size of fields as the substructure. |
| Assigning an element of one structure to an element of another structure.          | The elements must have the same type and size.                                           |

### For structures with constant fields, do not assign field values inside control flow constructs

In the following code, the code generator recognizes that the structure fields `s.a` and `s.b` are constants.

```
function y = mystruct()
s.a = 3;
s.b = 5;
y = zeros(s.a,s.b);
```

If a field of a structure is assigned inside a control flow construct, the code generator does not recognize that `s.a` and `s.b` are constant. Consider the following code:

```
function y = mystruct(x)
s.a = 3;
if x > 1
 s.b = 4;
else
 s.b = 5;
end
y = zeros(s.a,s.b);
```

If variable-sizing is enabled, `y` is treated as a variable-size array. If variable-sizing is disabled, `y`, the code generator reports an error.

### Do not assign mxArray to structures

You cannot assign `mxArrays` to structure elements; convert `mxArrays` to known types before code generation (see “Working with `mxArrays`” on page 65-11).

### Do not assign handle classes or sparse arrays to global structure variables

Global structure variables cannot contain handle objects or sparse arrays.

## Pass Large Structures as Input Parameters

If you generate a MEX function for a MATLAB function that takes a large structure as an input parameter, for example, a structure containing fields that are matrices, the MEX function might fail to load. This load failure occurs because, when you generate a MEX function from a MATLAB function that has input parameters, the code generator allocates memory for these input parameters on the stack. To avoid this issue, pass the structure by reference to the MATLAB function. For example, if the original function signature is:

```
y = foo(a, S)
```

where S is the structure input, rewrite the function to:

```
[y, S] = foo(a, S)
```

# Code Generation for Cell Arrays

- “Control Whether a Cell Array Is Variable-Size” on page 56-4
- “Cell Array Limitations for Code Generation” on page 56-6

## Code Generation for Cell Arrays

When you generate code from MATLAB code that contains cell arrays, the code generator classifies the cell arrays as homogeneous or heterogeneous. This classification determines how a cell array is represented in the generated code. It also determines how you can use the cell array in MATLAB code from which you generate code.

When you use cell arrays in MATLAB code that is intended for code generation, you must adhere to certain restrictions. See “Cell Array Limitations for Code Generation” on page 56-6.

### Homogeneous vs. Heterogeneous Cell Arrays

A homogeneous cell array has these characteristics:

- The cell array is represented as an array in the generated code.
- All elements have the same properties. The type associated with the cell array specifies the properties of all elements rather than the properties of individual elements.
- The cell array can be variable-size.
- You can index into the cell array with an index whose value is determined at run time.

A heterogeneous cell array has these characteristics:

- The cell array is represented as a structure in the generated code. Each element is represented as a field of the structure.
- The elements can have different properties. The type associated with the cell array specifies the properties of each element individually.
- The cell array cannot be variable-size.
- You must index into the cell array with a constant index or with `for`-loops that have constant bounds.

The code generator uses heuristics to determine the classification of a cell array as homogeneous or heterogeneous. It considers the properties (class, size, complexity) of the elements and other factors, such as how you use the cell array in your program. Depending on how you use a cell array, the code generator can classify a cell array as homogeneous in one case and heterogeneous in another case. For example, consider the cell array `{1 [2 3]}`. The code generator can classify this cell array as a heterogeneous 1-by-2 cell array. The first element is double scalar. The second element is a 1-by-2 array of doubles. However, if you index into this cell array with an index whose value is determined at run time, the code generator classifies it as a homogeneous cell array. The elements are variable-size arrays of doubles with an upper bound of 2.

### Controlling Whether a Cell Array Is Homogeneous or Heterogeneous

For cell arrays with certain characteristics, you cannot control the classification as homogeneous or heterogeneous:

- If the elements have different classes, the cell array must be heterogeneous.
- If the cell array is variable-size, it must be homogeneous.
- If you index into the cell array with an index whose value is determined at run time, the cell array must be homogeneous.

For other cell arrays, you can control the classification as homogeneous or heterogeneous.

- If the cell array elements have the same class, you can force a cell array to be homogeneous by using `coder. varsize`. See “Control Whether a Cell Array Is Variable-Size” on page 56-4.

## Cell Arrays in Reports

To see whether a cell array is homogeneous or heterogeneous, view the variable in the MATLAB Function report.

For a homogeneous cell array, the report has one entry that specifies the properties of all elements. The notation `{:}` indicates that all elements of the cell array have the same properties.

| ALL MESSAGES (0) |        | VARIABLES |        |
|------------------|--------|-----------|--------|
| Name             | Type   | Size      | Class  |
| z                | Output | 1 × 1     | double |
| ▲ c              | Local  | 1 × 3     | cell   |
| {:}              |        | 1 × 1     | double |

For a heterogeneous cell array, the report has an entry for each element. For example, for a heterogeneous cell array `c` with two elements, the entry for `c{1}` shows the properties for the first element. The entry for `c{2}` shows the properties for the second element.

| ALL MESSAGES (0) |        | VARIABLES |        |
|------------------|--------|-----------|--------|
| Name             | Type   | Size      | Class  |
| z                | Output | 1 × 1     | double |
| ▲ c              | Local  | 1 × 2     | cell   |
| {1}              |        | 1 × 1     | double |
| {2}              |        | 1 × 1     | char   |

## Control Whether a Cell Array Is Variable-Size

The code generator classifies a variable-size cell array as homogeneous. The cell array elements must have the same class. In the generated code, the cell array is represented as an array.

To make a cell array variable-size:

- Create the cell array by using the `cell` function. For example:

```
function z = mycell(n, j)
 %#codegen
 assert (n < 100);
 x = cell(1,n);
 for i = 1:n
 x{i} = i;
 end
 z = x{j};
end
```

For code generation, when you create a variable-size cell array by using `cell`, you must adhere to certain restrictions. See “Definition of Variable-Size Cell Array by Using `cell`” on page 56-7.

- Grow the cell array. For example:

```
function z = mycell(n)
 %#codegen
 c = {1 2 3};
 if n > 3
 c = {1 2 3 4};
 end
 z = c{n};
end
```

- Force the cell array to be variable-size by using `coder. varsize`. Consider this code:

```
function y = mycellfun()
 %#codegen
 c = {1 2 3};
 coder. varsize('c', [1 10]);
 y = c{1};
end
```

Without `coder. varsize`, `c` is fixed-size with dimensions 1-by-3. With `coder. varsize`, `c` is variable-size with an upper bound of 10.

Sometimes, using `coder. varsize` changes the classification of a cell array from heterogeneous to homogeneous. Consider this code:

```
function y = mycell()
 %#codegen
 c = {1 [2 3]};
 y = c{2};
end
```

The code generator classifies `c` as heterogeneous because the elements have different sizes. `c` is fixed-size with dimensions 1-by-2. If you use `coder. varsize` with `c`, it becomes homogeneous. For example:

```
function y = mycell()
%#codegen
c = {1 [2 3]};
coder.varsize('c', [1 10], [0 1]);
y = c{2};
end
```

c becomes a variable-size homogeneous cell array with dimensions 1-by-:10.

To force c to be homogeneous, but not variable-size, specify that none of the dimensions vary. For example:

```
function y = mycell()
%#codegen
c = {1 [2 3]};
coder.varsize('c', [1 2], [0 0]);
y = c{2};
end
```

## Cell Array Limitations for Code Generation

When you use cell arrays in MATLAB code that is intended for code generation, you must adhere to these restrictions:

- “Cell Array Element Assignment” on page 56-6
- “Variable-Size Cell Arrays” on page 56-7
- “Definition of Variable-Size Cell Array by Using `cell`” on page 56-7
- “Cell Array Indexing” on page 56-10
- “Growing a Cell Array by Using `{end + 1}`” on page 56-11
- “Cell Array Contents” on page 56-12
- “Passing Cell Arrays to External C/C++ Functions” on page 56-12
- “Use in MATLAB Function Block” on page 56-12

### Cell Array Element Assignment

You must assign a cell array element on all execution paths before you use it. For example:

```
function z = foo(n)
%#codegen
c = cell(1,3);
if n < 1
 c{2} = 1;

else
 c{2} = n;
end
z = c{2};
end
```

The code generator considers passing a cell array to a function or returning it from a function as a use of all elements of the cell array. Therefore, before you pass a cell array to a function or return it from a function, you must assign all of its elements. For example, the following code is not allowed because it does not assign a value to `c{2}` and `c` is a function output.

```
function c = foo()
%#codegen
c = cell(1,3);
c{1} = 1;
c{3} = 3;
end
```

The assignment of values to elements must be consistent on all execution paths. The following code is not allowed because `y{2}` is double on one execution path and char on the other execution path.

```
function y = foo(n)
y = cell(1,3)
if n > 1;
 y{1} = 1
 y{2} = 2;
 y{3} = 3;
else
 y{1} = 10;
```

```

 y{2} = 'a';
 y{3} = 30;
end

```

## Variable-Size Cell Arrays

- `coder.versize` is not supported for heterogeneous cell arrays.
- If you use the `cell` function to define a fixed-size cell array, you cannot use `coder.versize` to specify that the cell array has a variable size. For example, this code causes a code generation error because `x = cell(1,3)` makes `x` a fixed-size, 1-by-3 cell array.

```

...
x = cell(1,3);
coder.versize('x',[1 5])
...

```

You can use `coder.versize` with a cell array that you define by using curly braces. For example:

```

...
x = {1 2 3};
coder.versize('x',[1 5])
...

```

- To create a variable-size cell array by using the `cell` function, use this code pattern:

```

function mycell(n)
 %#codegen
 x = cell(1,n);
 for i = 1:n
 x{i} = i;
 end
end

```

See “Definition of Variable-Size Cell Array by Using `cell`” on page 56-7.

To specify upper bounds for the cell array, use `coder.versize`.

```

function mycell(n)
 %#codegen
 x = cell(1,n);
 for i = 1:n
 x{i} = i;
 end
 coder.versize('x',[1,20]);
end

```

## Definition of Variable-Size Cell Array by Using `cell`

For code generation, before you use a cell array element, you must assign a value to it. When you use `cell` to create a variable-size cell array, for example, `cell(1,n)`, MATLAB assigns an empty matrix to each element. However, for code generation, the elements are unassigned. For code generation, after you use `cell` to create a variable-size cell array, you must assign all elements of the cell array before any use of the cell array. For example:

```

function z = mycell(n, j)
 %#codegen

```

```

assert(n < 100);
x = cell(1,n);
for i = 1:n
 x{i} = i;
end
z = x{j};
end

```

The code generator analyzes your code to determine whether all elements are assigned before the first use of the cell array. If the code generator detects that some elements are not assigned, code generation fails with an error message. For example, modify the upper bound of the for-loop to j.

```

function z = mycell(n, j)
%#codegen
assert(n < 100);
x = cell(1,n);
for i = 1:j %<- Modified here
 x{i} = i;
end
z = x{j};
end

```

With this modification and with inputs j less than n, the function does not assign values to all of the cell array elements. Code generation produces the error:

```

Unable to determine that every element of 'x{:}' is assigned
before this line.

```

Sometimes, even though your code assigns all elements of the cell array, the code generator reports this message because the analysis does not detect that all elements are assigned. See “Unable to Determine That Every Element of Cell Array Is Assigned” on page 67-8.

To avoid this error, follow these guidelines:

- When you use `cell` to define a variable-size cell array, write code that follows this pattern:

```

function z = mycell(n, j)
%#codegen
assert(n < 100);
x = cell(1,n);
for i = 1:n
 x{i} = i;
end
z = x{j};
end

```

Here is the pattern for a multidimensional cell array:

```

function z = mycell(m,n,p)
%#codegen
assert(m < 100);
assert(n < 100);
assert(p < 100);
x = cell(m,n,p);
for i = 1:m
 for j =1:n
 for k = 1:p
 x{i,j,k} = i+j+k;
 end
 end
end

```

```

 end
 end
end
z = x{m,n,p};
end

```

- Increment or decrement the loop counter by 1.
- Define the cell array within one loop or one set of nested loops. For example, this code is not allowed:

```

function z = mycell(n, j)
assert(n < 50);
assert(j < 50);
x = cell(1,n);
for i = 1:5
 x{i} = 5;
end
for i = 6:n
 x{i} = 5;
end
z = x{j};
end

```

- Use the same variables for the cell dimensions and loop initial and end values. For example, code generation fails for the following code because the cell creation uses `n` and the loop end value uses `m`:

```

function z = mycell(n, j)
assert(n < 50);
assert(j < 50);
x = cell(1,n);
m = n;
for i = 1:m
 x{i} = 2;
end
z = x{j};
end

```

Rewrite the code to use `n` for the cell creation and the loop end value:

```

function z = mycell(n, j)
assert(n < 50);
assert(j < 50);
x = cell(1,n);
for i = 1:n
 x{i} = 2;
end
z = x{j};
end

```

- Create the cell array with this pattern:

```
x = cell(1,n)
```

Do not assign the cell array to a field of a structure or a property of an object. For example, this code is not allowed:

```

myobj.prop = cell(1,n)
for i = 1:n

```

```
...
end
```

Do not use the `cell` function inside the cell array constructor `{}`. For example, this code is not allowed:

```
x = {cell(1,n)};
```

- The cell array creation and the loop that assigns values to the cell array elements must be together in a unique execution path. For example, the following code is not allowed.

```
function z = mycell(n)
assert(n < 100);
if n > 3
 c = cell(1,n);
else
 c = cell(n,1);
end
for i = 1:n
 c{i} = i;
end
z = c{n};
end
```

To fix this code, move the assignment loop inside the code block that creates the cell array.

```
function z = cellerr(n)
assert(n < 100);
if n > 3
 c = cell(1,n);
 for i = 1:n
 c{i} = i;
 end
else
 c = cell(n,1);
 for i = 1:n
 c{i} = i;
 end
end
z = c{n};
end
```

## Cell Array Indexing

- You cannot index cell arrays by using smooth parentheses `()`. Consider indexing cell arrays by using curly braces `{}` to access the contents of the cell.
- You must index into heterogeneous cell arrays by using constant indices or by using `for`-loops with constant bounds.

For example, the following code is not allowed.

```
x = {1, 'mytext'};
disp(x{randi});
```

You can index into a heterogeneous cell array in a `for`-loop with constant bounds because the code generator unrolls the loop. Unrolling creates a separate copy of the loop body for each loop iteration, which makes the index in each loop iteration constant. However, if the `for`-loop has a

large body or it has many iterations, the unrolling can increase compile time and generate inefficient code.

If A and B are constant, the following code shows indexing into a heterogeneous cell array in a for-loop with constant bounds.

```
x = {1, 'mytext'};
for i = A:B
 disp(x{i});
end
```

## Growing a Cell Array by Using {end + 1}

To grow a cell array X, you can use X{end + 1}. For example:

```
...
X = {1 2};
X{end + 1} = 'a';
...
```

When you use {end + 1} to grow a cell array, follow these restrictions:

- In a MATLAB Function block, do not use {end + 1} in a for-loop.
- Use only {end + 1}. Do not use {end + 2}, {end + 3}, and so on.
- Use {end + 1} with vectors only. For example, the following code is not allowed because X is a matrix, not a vector:

```
...
X = {1 2; 3 4};
X{end + 1} = 5;
```

- Use {end + 1} only with a variable. In the following code, {end + 1} does not cause {1 2 3} to grow. In this case, the code generator treats {end + 1} as an out-of-bounds index into X{2}.

```
...
X = {'a' { 1 2 3 }};
X{2}{end + 1} = 4;
```

- When {end + 1} grows a cell array in a loop, the cell array must be variable-size. Therefore, the cell array must be homogeneous on page 56-2.

This code is allowed because X is homogeneous.

```
...
X = {1 2};
for i=1:n
 X{end + 1} = 3;
end
...
```

This code is not allowed because X is heterogeneous.

```
...
X = {1 'a' 2 'b'};
```

```
for i=1:n
 X{end + 1} = 3;
end
...
```

## Cell Array Contents

Cell arrays cannot contain `mxarrays`. In a cell array, you cannot store a value that an extrinsic function returns.

## Passing Cell Arrays to External C/C++ Functions

You cannot pass a cell array to `coder.ceval`. If a variable is an input argument to `coder.ceval`, define the variable as an array or structure instead of as a cell array.

## Use in MATLAB Function Block

You cannot use cell arrays for Simulink signals, parameters, or data store memory.

# Code Generation for Categorical Arrays

---

## Code Generation for Categorical Arrays

### In this section...

“Define Categorical Arrays for Code Generation” on page 57-2

“Allowed Operations on Categorical Arrays” on page 57-2

“MATLAB Toolbox Functions That Support Categorical Arrays” on page 57-3

Categorical arrays store data with values from a finite set of discrete categories. You can specify an order for the categories, but it is not required. A categorical array provides efficient storage and manipulation of nonnumeric data, while also maintaining meaningful names for the values.

When you use categorical arrays with code generation, adhere to these restrictions:

### Define Categorical Arrays for Code Generation

For code generation, use the `categorical` function to create categorical arrays. For example, suppose the input argument to your MATLAB function is a numeric array of arbitrary size whose elements have values of either 1, 2, or 3. You can convert these values to the categories `small`, `medium`, and `large` and turn the input array into a categorical array, as shown in this code.

```
function c = foo(x) %#codegen
 c = categorical(x,1:3,{'small','medium','large'});
end
```

### Allowed Operations on Categorical Arrays

For code generation, you are restricted to the operations on categorical arrays listed in this table.

| Operation                             | Example                                                                                                                                               | Notes                                                                                                                                                                                                                                                                |
|---------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| assignment operator: =                | <pre>c = categorical(1:3,1:3,{'small','medium','large'}); c(1) = 'large';  c = categorical(1:3,1:3,{'small','medium','large'}); c(1) = 'large';</pre> | <p>Code generation does not support using the assignment operator = to:</p> <ul style="list-style-type: none"> <li>Delete an element.</li> <li>Expand the size of a categorical array.</li> <li>Add a new category, even when the array is not protected.</li> </ul> |
| relational operators: < > <= >= == ~= | <pre>c = categorical(1:3,'Ordinal',true); tf = c(1) &lt; c(2);  c = categorical(1:3,'Ordinal',true); tf = c(1) &lt; c(2);</pre>                       | Code generation supports all relational operators.                                                                                                                                                                                                                   |
| cast to numeric type                  | <pre>c = categorical(1:3); double(c(1));  c = categorical(1:3); double(c(1));</pre>                                                                   | Code generation supports casting categorical arrays to arrays of double- or single-precision floating-point numbers, or to integers.                                                                                                                                 |

| Operation          | Example                                                                                                                                                                                                                                                                           | Notes                                                                                                                                                                                                                                                     |

## MATLAB Toolbox Functions That Support Categorical Arrays

For code generation, you can use categorical arrays with these MATLAB toolbox functions:

- `addcats`
- `cat`
- `categorical`
- `categories`
- `cellstr`
- `countcats`
- `ctranspose`
- `double`
- `eq`
- `ge`
- `gt`
- `histcounts`
- `horzcat`
- `int8`
- `int16`
- `int32`

- `int64`
- `intersect`
- `iscategory`
- `iscolumn`
- `isempty`
- `isequal`
- `isequaln`
- `ismatrix`
- `ismember`
- `isordinal`
- `isprotected`
- `isrow`
- `isscalar`
- `issorted`
- `issortedrows`
- `isundefined`
- `isvector`
- `le`
- `length`
- `lt`
- `max`
- `mergecats`
- `min`
- `ndims`
- `ne`
- `numel`
- `permute`
- `removecats`
- `renamecats`
- `reordercats`
- `reshape`
- `setcats`
- `setdiff`
- `setxor`
- `single`
- `size`
- `sort`
- `sortrows`
- `transpose`

- `uint8`
- `uint16`
- `uint32`
- `uint64`
- `union`
- `unique`
- `vertcat`

## **See Also**

### **More About**

- “Categorical Array Limitations for Code Generation” on page 57-8

## Define Categorical Array Inputs

### Define Categorical Array Inputs at the Command Line

Use one of these procedures:

- “Provide an Example Categorical Array Input” on page 57-6
- “Provide a Categorical Array Type” on page 57-6
- “Provide a Constant Categorical Array Input” on page 57-6

Alternatively, if you have a test file that calls your entry-point function with example inputs, you can determine the input types by using `coder.getArgTypes`.

#### Provide an Example Categorical Array Input

##### Provide a Categorical Array Type

To provide a type for a categorical array to :

- 1 Define a categorical array. For example:

```
C = categorical({'r','g','b'});
```

- 2 Create a type from C.

```
t = coder.typeof(C);
```

##### Provide a Constant Categorical Array Input

To specify that a categorical array input is constant, use `coder.Constant` with the `-args` option:

## Representation of Categorical Arrays

A coder type object for a categorical array describes the object and its properties. Use `coder.typeof` or pass `categorical` as a string scalar to `coder.newtype`.

The coder type object displays a succinct description of the object properties while excluding internal state values. Nonconstant properties display their type and size, while constant properties display only their values. For example:

```
t = categorical({'r','g','b'});
tType = coder.typeof(t)
```

The representation of variable `t` is stored in coder type object `tType`.

```
tType =
```

```
matlab.coder.type.CategoricalType
 1x3 categorical
 Categories : 3x1 homogeneous cell
 Ordinal : 1x1 logical
 Protected : 1x1 logical
```

If your workflow requires the legacy representation of coder type objects, use the `getCoderType` function on the variable that has the new representation of your class or object. See “Legacy Representation of Coder Type Objects” (MATLAB Coder).

### Resize Object Properties by Using `coder.resize`

You can resize most objects by using `coder.resize`. You can resize objects, its properties and create arrays within the properties.

For a categorical coder object, you can resize the object properties:

```
t = categorical({'r','g','b'});
tType = coder.typeof(t);
tType.Categories = coder.resize(tType.Categories, [3 1],[1 0])
```

This code resizes the `Categories` property to be upper-bounded at 3 for the first dimension.

```
tType =
 matlab.coder.type.CategoricalType
 1x3 categorical
 Categories : :3x1 homogeneous cell
 Ordinal : 1x1 logical
 Protected : 1x1 logical
```

You can also resize the object by using `coder.resize`. See “Edit and Represent Coder Type Objects and Properties” (MATLAB Coder).

## Categorical Array Limitations for Code Generation

When you create categorical arrays in MATLAB code that you intend for code generation, you must specify the categories and elements of each categorical array by using the `categorical` function. See “Categorical Arrays”.

For categorical arrays, code generation does not support the following inputs and operations:

- Arrays of MATLAB objects.
- Sparse matrices.
- Duplicate category names when you specify them using the `categoryNames` input argument of the `categorical` function.
- Growth by assignment. For example, assigning a value beyond the end of an array produces an error.

```
function c = foo() %#codegen
 c = categorical(1:3,1:3,{'small','medium','large'});
 c(4) = 'medium';
end
```

- Adding a category. For example, specifying a new category by using the `=` operator produces an error, even when the categorical array is unprotected.

```
function c = foo() %#codegen
 c = categorical(1:3,1:3,{'small','medium','large'});
 c(1) = 'extra-large';
end
```

- Deleting an element. For example, assigning an empty array to an element produces an error.

```
function c = foo() %#codegen
 c = categorical(1:3,1:3,{'small','medium','large'});
 c(1) = [];
end
```

- Converting categorical values to text by using the `char` or `string` functions. To convert elements of a categorical array to text, use the `cellstr` function.

Limitations that apply to classes also apply to categorical arrays. For more information, see “MATLAB Classes Definition for Code Generation” (MATLAB Coder).

## Code Generation for Datetime Arrays

### In this section...

“Define Datetime Arrays for Code Generation” on page 58-2  
 “Allowed Operations on Datetime Arrays” on page 58-2  
 “MATLAB Toolbox Functions That Support Datetime Arrays” on page 58-3

The values in a `datetime` array represent points in time using the proleptic ISO calendar.

When you use `datetime` arrays with code generation, adhere to these restrictions.

### Define Datetime Arrays for Code Generation

For code generation, use the `datetime` function to create `datetime` arrays. For example, suppose the input arguments to your MATLAB function are numeric arrays whose values indicate the year, month, day, hour, minute, and second components for a point in time. You can create a `datetime` array from these input arrays.

```
function d = foo(y,mo,d,h,mi,s) %#codegen
 d = datetime(y,mo,d,h,mi,s);
end
```

### Allowed Operations on Datetime Arrays

For code generation, you are restricted to the operations on `datetime` arrays listed in this table.

| Operation                             | Example                                                                                                                                                                                   | Notes                                                                                                                                                                                                       |
|---------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Assignment operator: =                | <pre>d = datetime(2019,1:12,1,12,0,0); d(1) = datetime(2019,1,31);  d = datetime(2019,1:12,1,12,0,0); d(1) = datetime(2019,1,31);</pre>                                                   | <p>Code generation does not support using the assignment operator = to:</p> <ul style="list-style-type: none"> <li>Delete an element.</li> <li>Expand the size of a <code>datetime</code> array.</li> </ul> |
| Relational operators: < > <= >= == ~= | <pre>d = datetime(2019,1:12,1,12,0,0); tf = d(1) &lt; d(2);  d = datetime(2019,1:12,1,12,0,0); tf = d(1) &lt; d(2);</pre>                                                                 | Code generation supports relational operators.                                                                                                                                                              |
| Indexing operation                    | <pre>d = datetime(2019,1:12,1,12,0,0); idx = [1 2]; d(idx); idx = logical([1 1 0]); d(idx);  d = datetime(2019,1:12,1,12,0,0); idx = [1 2]; d(idx); idx = logical([1 1 0]); d(idx);</pre> | Code generation supports indexing by position, linear indexing, and logical indexing.                                                                                                                       |

| Operation     | Example                                                                                                                                                                         | Notes                                                      |
|---------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------|
| Concatenation | <pre>d1 = datetime(2019,1:6,1,12,0,0); d2 = datetime(2019,7:12,1,12,0,0); d = [d1 d2];  d1 = datetime(2019,1:6,1,12,0,0); d2 = datetime(2019,7:12,1,12,0,0); d = [d1 d2];</pre> | Code generation supports concatenation of datetime arrays. |

## MATLAB Toolbox Functions That Support Datetime Arrays

For code generation, you can use datetime arrays with these MATLAB toolbox functions:

- cat
- colon
- ctranspose
- datetime
- datevec
- diff
- eq
- ge
- gt
- hms
- horzcat
- hour
- interp1
- intersect
- iscolumn
- isempty
- isequal
- isequaln
- isfinite
- isinf
- ismatrix
- ismember
- isnat
- isreal
- isrow
- isscalar
- issorted
- issortedrows
- isvector
- le

- `length`
- `linspace`
- `lt`
- `max`
- `mean`
- `min`
- `minus`
- `minute`
- `NaT`
- `ndims`
- `ne`
- `numel`
- `permute`
- `plus`
- `posixtime`
- `repmat`
- `reshape`
- `setdiff`
- `setxor`
- `size`
- `sort`
- `sortrows`
- `topkrows`
- `transpose`
- `union`
- `unique`
- `vertcat`
- `ymd`

## **See Also**

### **More About**

- “Datetime Array Limitations for Code Generation” on page 58-7

## Define Datetime Array Inputs

### Define Datetime Array Inputs at the Command Line

Use one of these procedures:

- “Provide an Example Datetime Array Input” on page 58-5
- “Provide a Datetime Array Type” on page 58-5
- “Provide a Constant Datetime Array Input” on page 58-5

Alternatively, if you have a test file that calls your entry-point function with example inputs, you can determine the input types by using `coder.getArgTypes`.

#### Provide an Example Datetime Array Input

##### Provide a Datetime Array Type

To provide a type for a datetime array to :

- 1 Define a `datetime` array. For example:
 

```
D = datetime(2019,1:12,1,12,0,0);
```
- 2 Create a type from D.
 

```
t = coder.typeof(D);
```

##### Provide a Constant Datetime Array Input

To specify that a datetime array input is constant, use `coder.Constant` with the `-args` option:

### Representation of Datetime Arrays

A coder type object for a datetime array describes the object and its properties. Use `coder.typeof` or pass `datetime` as a string scalar to `coder.newtype`.

The coder type object displays a succinct description of the object properties while excluding internal state values. Nonconstant properties display their type and size, while constant properties display only their values. For example:

```
t = datetime(2019,1:12,1,12,0,0);
tType = coder.typeof(t)
```

The representation of variable `t` is stored in coder type object `tType`.

```
tType =
 matlab.coder.type.DatetimeType
 1x12 datetime
 Format : 1x0 char
 TimeZone : 1x0 char
```

If your workflow requires the legacy representation of coder type objects, use the `getCoderType` function on the variable that has the new representation of your class or object. See “Legacy Representation of Coder Type Objects” (MATLAB Coder).

### Resize Object Properties by Using `coder.resize`

You can resize most objects by using `coder.resize`. You can resize objects, its properties and create arrays within the properties.

For a `datetime` coder object, you can resize the object properties:

```
t = datetime(2019,1:12,1,12,0,0);
tType = coder.typeof(t)
tType.Format = coder.resize(tType.Format, [1 12])
```

This code resizes the `Format` property to be a 1x12 char property.

```
tType =
 matlab.coder.type.DatetimeType
 1x12 datetime
 Format : 1x12 char
 TimeZone : 1x0 char
```

You can also resize the object by using `coder.resize`. See “Edit and Represent Coder Type Objects and Properties” (MATLAB Coder).

### More About

- “Code Generation for Datetime Arrays” on page 58-2
- “Datetime Array Limitations for Code Generation” on page 58-7

## Datetime Array Limitations for Code Generation

When you create `datetime` arrays in MATLAB code that you intend for code generation, you must specify the values by using the `datetime` function. See “Dates and Time”.

For `datetime` arrays, code generation does not support the following inputs and operations:

- Text inputs. For example, specifying a character vector as the input argument produces an error.

```
function d = foo() %#codegen
 d = datetime('2019-12-01');
end
```

- The 'Format' name-value pair argument. You cannot specify the display format by using the `datetime` function, or by setting the `Format` property of a `datetime` array. To use a specific display format, create a `datetime` array in MATLAB, then pass it as an input argument to a function that is intended for code generation.
- The 'TimeZone' name-value pair argument and the `TimeZone` property. When you use `datetime` arrays in code that is intended for code generation, they must be unzoned.
- Setting time component properties. For example, setting the `Hour` property in the following code produces an error:

```
d = datetime;
d.Hour = 2;
```

- Growth by assignment. For example, assigning a value beyond the end of an array produces an error.

```
function d = foo() %#codegen
 d = datetime(2019,1:12,1,12,0,0);
 d(13) = datetime(2020,1,1,12,0,0);
end
```

- Deleting an element. For example, assigning an empty array to an element produces an error.

```
function d = foo() %#codegen
 d = datetime(2019,1:12,1,12,0,0);
 d(1) = [];
end
```

- Converting `datetime` values to text by using the `char`, `cellstr`, or `string` functions.

Limitations that apply to classes also apply to `datetime` arrays. For more information, see “MATLAB Classes Definition for Code Generation” (MATLAB Coder).

# Code Generation for Duration Arrays

---

- “Code Generation for Duration Arrays” on page 59-2
- “Define Duration Array Inputs” on page 59-6
- “Duration Array Limitations for Code Generation” on page 59-8

## Code Generation for Duration Arrays

### In this section...

“Define Duration Arrays for Code Generation” on page 59-2

“Allowed Operations on Duration Arrays” on page 59-2

“MATLAB Toolbox Functions That Support Duration Arrays” on page 59-3

The values in a duration array represent elapsed times in units of fixed length, such as hours, minutes, and seconds. You can create elapsed times in terms of fixed-length (24-hour) days and fixed-length (365.2425-day) years.

You can add, subtract, sort, compare, concatenate, and plot duration arrays.

When you use duration arrays with code generation, adhere to these restrictions.

### Define Duration Arrays for Code Generation

For code generation, use the `duration` function to create duration arrays. For example, suppose the input arguments to your MATLAB function are three numeric arrays of arbitrary size whose elements specify lengths of time as hours, minutes, and seconds. You can create a duration array from these three input arrays.

```
function d = foo(h,m,s) %#codegen
 d = duration(h,m,s);
end
```

You can use the `years`, `days`, `hours`, `minutes`, `seconds`, and `milliseconds` functions to create duration arrays in units of years, days, hours, minutes, or seconds. For example, you can create an array of hours from an input numeric array.

```
function d = foo(h) %#codegen
 d = hours(h);
end
```

### Allowed Operations on Duration Arrays

For code generation, you are restricted to the operations on duration arrays listed in this table.

| Operation                             | Example                                                                                             | Notes                                                                                                                                                                                          |

## **More About**

- “Duration Array Limitations for Code Generation” on page 59-8

## Define Duration Array Inputs

### Define Duration Array Inputs at the Command Line

Use one of these procedures:

- “Provide an Example Duration Array Input” on page 59-6
- “Provide a Duration Array Type” on page 59-6
- “Provide a Constant Duration Array Input” on page 59-6

Alternatively, if you have a test file that calls your entry-point function with example inputs, you can determine the input types by using `coder.getArgTypes`.

#### Provide an Example Duration Array Input

##### Provide a Duration Array Type

To provide a type for a duration array to :

- 1 Define a duration array. For example:

```
D = duration(1:3,0,0);
```

- 2 Create a type from D.

```
t = coder.typeof(D);
```

##### Provide a Constant Duration Array Input

To specify that a duration array input is constant, use `coder.Constant` with the `-args` option:

## Representation of Duration Arrays

A coder type object for a duration array describes the object and its properties. Use `coder.typeof` or pass `duration` as a string scalar to `coder.newtype`.

The coder type object displays a succinct description of the object properties while excluding internal state values. Nonconstant properties display their type and size, while constant properties display only their values. For example:

```
tType = coder.newtype('duration')
```

A representation of an empty duration variable is stored in coder type object `tType`.

```
tType =
matlab.coder.type.DurationType
 1x1 duration
 Format : 1x8 char
```

If your workflow requires the legacy representation of coder type objects, use the `getCoderType` function on the variable that has the new representation of your class or object. See “Legacy Representation of Coder Type Objects” (MATLAB Coder).

## Resize duration Properties by Editing Object Properties

You can resize most objects by editing the object properties. You can resize duration objects, its properties and create arrays within the properties.

For a duration coder object, you can resize the object properties:

```
t = duration((1:3),0,0);
tType = coder.typeof(t)
tType.Format = 'DD/MM/YYYY'
```

This code resizes the Format property to be a 1x10 char property.

```
tType =
 matlab.coder.type.DurationType
 1x3 duration
 Format : 1x10 char
```

You can also resize the object by using `coder.resize`. See “Edit and Represent Coder Type Objects and Properties” (MATLAB Coder).

## More About

- “Code Generation for Duration Arrays” on page 59-2
- “Duration Array Limitations for Code Generation” on page 59-8

## Duration Array Limitations for Code Generation

When you create duration arrays in MATLAB code that you intend for code generation, you must specify the durations by using the `duration`, `years`, `days`, `hours`, `minutes`, `seconds`, or `milliseconds` functions. See “Dates and Time”.

For duration arrays, code generation does not support the following inputs and operations:

- Text inputs. For example, specifying a character vector as the input argument produces an error.

```
function d = foo() %#codegen
 d = duration('01:30:00');
end
```

- Growth by assignment. For example, assigning a value beyond the end of an array produces an error.

```
function d = foo() %#codegen
 d = duration(1:3,0,0);
 d(4) = hours(4);
end
```

- Deleting an element. For example, assigning an empty array to an element produces an error.

```
function d = foo() %#codegen
 d = duration(1:3,0,0);
 d(1) = [];
end
```

- Converting duration values to text by using the `char`, `cellstr`, or `string` functions.

Limitations that apply to classes also apply to duration arrays. For more information, see “MATLAB Classes Definition for Code Generation” (MATLAB Coder).

# Code Generation for Tables

---

- “Code Generation for Tables” on page 60-2
- “Define Table Inputs” on page 60-5
- “Table Limitations for Code Generation” on page 60-7

## Code Generation for Tables

### In this section...

“Define Tables for Code Generation” on page 60-2

“Allowed Operations on Tables” on page 60-2

“MATLAB Toolbox Functions That Support Tables” on page 60-3

The `table` data type is a data type suitable for column-oriented or tabular data that is often stored as columns in a text file or in a spreadsheet. Tables consist of rows and column-oriented variables. Each variable in a table can have a different data type and a different size with one restriction: each variable must have the same number of rows. For more information, see “Tables”.

When you use tables with code generation, adhere to these restrictions.

### Define Tables for Code Generation

For code generation, use the `table` function. For example, suppose the input arguments to your MATLAB function are three arrays that have the same number of rows and a cell array that has variable names. You can create a table that contains these arrays as table variables.

```
function T = foo(A,B,C,vnames) %#codegen
 T = table(A,B,C,'VariableNames',vnames);
end
```

You can use the `array2table`, `cell2table`, and `struct2table` functions to convert arrays, cell arrays, and structures to tables. For example, you can convert an input cell array to a table.

```
function T = foo(C,vnames) %#codegen
 T = cell2table(C,'VariableNames',vnames);
end
```

For code generation, you must supply table variable names when you create a table. Table variable names do not have to be valid MATLAB identifiers. The names must be composed of ASCII characters, but can include any ASCII characters (such as commas, dashes, and space characters).

### Allowed Operations on Tables

For code generation, you are restricted to the operations on tables listed below.

| Operation              | Example                                                                                                               | Notes                                                                                                                                                                                       |
|------------------------|-----------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| assignment operator: = | <pre>T = table(A,B,C,'VariableNames',vnames); T(:,1) = D;  T = table(A,B,C,'VariableNames',vnames); T(:,1) = D;</pre> | <p>Code generation does not support using the assignment operator = to:</p> <ul style="list-style-type: none"> <li>Delete a variable or a row.</li> <li>Add a variable or a row.</li> </ul> |

| Operation          | Example                                                                                                                                                                                                           | Notes                                                                                                                                                                                                                                                                                                                                                                                  |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| indexing operation | <pre>T = table(A,B,C,'VariableNames',vnames); T(1:5,1:3);  T = table(A,B,C,'VariableNames',vnames); T(1:5,1:3);</pre>                                                                                             | <p>Code generation supports indexing by position, variable or row name, and logical indexing.</p> <p>Code generation supports:</p> <ul style="list-style-type: none"> <li>• Table indexing with smooth parentheses, ().</li> <li>• Content indexing with curly braces, {}.</li> <li>• Dot notation to access a table variable.</li> </ul>                                              |
| concatenation      | <pre>T1 = table(A,B,C,'VariableNames',vnames); T2 = table(D,E,F,'VariableNames',vnames); T = [T1 ; T2];  T1 = table(A,B,C,'VariableNames',vnames); T2 = table(D,E,F,'VariableNames',vnames); T = [T1 ; T2];</pre> | <p>Code generation supports table concatenation:</p> <ul style="list-style-type: none"> <li>• For vertical concatenation, tables must have variables that have the same names in the same order.</li> <li>• For horizontal concatenation, tables must have the same number of rows. If the tables have row names, then they must have the same row names in the same order.</li> </ul> |

## MATLAB Toolbox Functions That Support Tables

For code generation, you can use tables with these MATLAB toolbox functions:

- `addvars`
- `array2table`
- `cat`
- `cell2table`
- `convertvars`
- `height`
- `horzcat`
- `innerjoin`
- `intersect`
- `isempty`
- `ismember`
- `issortedrows`
- `join`
- `mergevars`

- `movevars`
- `ndims`
- `numel`
- `outerjoin`
- `removevars`
- `renamevars`
- `rows2vars`
- `setdiff`
- `setxor`
- `size`
- `sortrows`
- `splitvars`
- `stack`
- `struct2table`
- `table`
- `table2array`
- `table2cell`
- `table2struct`
- `union`
- `unique`
- `unstack`
- `varfun`
- `vertcat`
- `width`

## **See Also**

### **More About**

- “Table Limitations for Code Generation” on page 60-7

## Define Table Inputs

### Define Table Inputs at the Command Line

Use one of these procedures:

- “Provide an Example Table Input” on page 60-5
- “Provide a Table Type” on page 60-5
- “Provide a Constant Table Input” on page 60-5

Alternatively, if you have a test file that calls your entry-point function with example inputs, you can determine the input types by using `coder.getArgTypes`.

### Provide an Example Table Input

#### Provide a Table Type

To provide a type for a table to :

- 1 Define a table. For example:

```
T = table(A,B,C, 'VariableNames', vnames);
```

- 2 Create a type from T.

```
t = coder.typeof(T);
```

#### Provide a Constant Table Input

To specify that a table input is constant, use `coder.Constant` with the `-args` option:

## Representation of Tables

A coder type object for a table describes the object and its properties. Use `coder.typeof` or pass `table` as a string scalar to `coder.newtype`.

The coder type object displays a succinct description of the object properties while excluding internal state values. Nonconstant properties display their type and size, while constant properties display only their values. For example:

```
A = [1 2 3]';
B = [4 5 6]';
C = [7 8 9]';
t = table(A,B,C);
tType = coder.typeof(t)
```

The representation of variable `t` is stored in coder type object `tType`.

```
tType =
```

```
matlab.coder.type.TableType
 3x3 table
 Data : 1x3 homogeneous cell
 Description : 1x0 char
 UserData : 0x0 double
```

```

 DimensionNames : {'Row'} {'Variables'}
 VariableNames : {'A'} {'B'} {'C'}
 VariableDescriptions : 1x3 homogeneous cell
 VariableUnits : 1x3 homogeneous cell
 VariableContinuity : 1x3 matlab.internal.coder.tabular.Continuity
 RowNames : 0x0 homogeneous cell

```

If your workflow requires the legacy representation of coder type objects, use the `getCoderType` function on the variable that has the new representation of your class or object. See “Legacy Representation of Coder Type Objects” (MATLAB Coder).

### Resize Object Properties by Using `coder.resize`

You can resize most objects by using `coder.resize`. You can resize objects, its properties and create arrays within the properties.

For a table coder object, you can resize the object properties:

```

A = [1 2 3]';
B = [4 5 6]';
C = [7 8 9]';
t = table(A,B,C);
tType = coder.typeof(t)
tType.Description = coder.resize(tType.Description,[1 12],[0 1])

```

This code resizes the `Description` property to be a `1x:12 char` property which has an upper bound of 12.

```

tType =
 matlab.coder.type.TableType
 3x3 table
 Data : 1x3 homogeneous cell
 Description : 1x:12 char
 UserData : 0x0 double
 DimensionNames : {'Row'} {'Variables'}
 VariableNames : {'A'} {'B'} {'C'}
 VariableDescriptions : 1x3 homogeneous cell
 VariableUnits : 1x3 homogeneous cell
 VariableContinuity : 1x3 matlab.internal.coder.tabular.Continuity
 RowNames : 0x0 homogeneous cell

```

You can also resize the object by using `coder.resize`. See “Edit and Represent Coder Type Objects and Properties” (MATLAB Coder).

### More About

- “Code Generation for Tables” on page 60-2
- “Table Limitations for Code Generation” on page 60-7

## Table Limitations for Code Generation

If you create tables, modify them, or use table functions in MATLAB code that you intend for code generation, then code generation has limitations described in the next sections. Limitations that apply to classes also apply to tables. For more information on class limitations, see “MATLAB Classes Definition for Code Generation” (MATLAB Coder).

### Creating Tables Limitations

If your MATLAB code creates tables, then code generation has these limitations.

| Inputs for Table Creation                 | Limitations                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

## Modifying Tables Limitations

If your MATLAB code modifies data in a table or its properties, then code generation has these limitations.

| Table Operation or Property                                               | Limitations                                                                                                                                                                                                                                                                                                                                                |

## Using Table Functions Limitations

If your MATLAB code uses the functions listed in the table, then code generation has these limitations.

| Function                                                                                    | Limitations                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

## Code Generation for Timetables

### In this section...

“Define Timetables for Code Generation” on page 61-2

“Allowed Operations on Timetables” on page 61-2

“MATLAB Toolbox Functions That Support Timetables” on page 61-3

The `timetable` data type is a data type suitable for tabular data with time-stamped rows. Like tables, timetables consist of rows and column-oriented variables. Each variable in a timetable can have a different data type and a different size with one restriction: each variable must have the same number of rows.

The *row times* of a timetable are time values that label the rows. You can index into a timetable by row time and variable. To index into a timetable, use smooth parentheses ( ) to return a subtable or curly braces { } to extract the contents. You can refer to variables and to the vector of row times by their names. For more information, see “Timetables”.

When you use timetables with code generation, adhere to these restrictions.

### Define Timetables for Code Generation

For code generation, use the `timetable` function. For example, suppose the input arguments to your MATLAB function are three arrays that have the same number of rows (A, B, and C), a `datetime` or `duration` vector containing row times (D), and a cell array that has variable names (vnames). You can create a timetable that contains these arrays as timetable variables.

```
function TT = foo(A,B,C,D,vnames) %#codegen
 TT = table(A,B,C,'RowTimes',D,'VariableNames',vnames);
end
```

To convert arrays and tables to timetables, use the `array2timetable` and `table2timetable` functions. For example, you can convert an input M-by-N matrix to a timetable, where each column of the matrix becomes a variable in the timetable. Assign row times by using a `duration` vector.

```
function TT = foo(A,D,vnames) %#codegen
 TT = array2timetable(A,'RowTimes',D,'VariableNames',vnames);
end
```

For code generation, you must supply timetable variable names when you create a timetable. Timetable variable names do not have to be valid MATLAB identifiers. The names must be composed of ASCII characters, but can include any ASCII characters (such as commas, dashes, and space characters).

The row times can have either the `datetime` or `duration` data type.

### Allowed Operations on Timetables

For code generation, you are restricted to the operations on timetables listed in this table.

| Operation              | Example                                                                                                                                                                                                                                                                                             | Notes                                                                                                                                                                                                                                                                                                                                                                                                                            |

## MATLAB Toolbox Functions That Support Timetables

For code generation, you can use timetables with these MATLAB toolbox functions:

- addvars
- array2timetable
- cat
- convertvars
- height
- horzcat
- innerjoin

- intersect
- isempty
- ismember
- isregular
- issorted
- issortedrows
- join
- mergevars
- movevars
- ndims
- numel
- outerjoin
- removevars
- renamevars
- rows2vars
- retime
- setdiff
- setxor
- size
- sortrows
- splitvars
- stack
- synchronize
- table2timetable
- timerange
- timetable
- timetable2table
- union
- unique
- unstack
- varfun
- vertcat
- width
- withtol

## Define Timetable Inputs

### Define Timetable Inputs at the Command Line

Use one of these procedures:

- “Provide an Example Timetable Input” on page 61-5
- “Provide a Timetable Type” on page 61-5
- “Provide a Constant Timetable Input” on page 61-5

Alternatively, if you have a test file that calls your entry-point function with example inputs, you can determine the input types by using `coder.getArgTypes`.

### Provide an Example Timetable Input

#### Provide a Timetable Type

To provide a type for a timetable to :

- 1 Define a timetable. For example:

```
TT = timetable(A,B,C, 'RowTimes',D, 'VariableNames',vnames);
```

- 2 Create a type from T.

```
t = coder.typeof(TT);
```

#### Provide a Constant Timetable Input

To specify that a timetable input is constant, use `coder.Constant` with the `-args` option:

## Representation of Timetables

A coder type object for a timetable describes the object and its properties. Use `coder.typeof` or pass `timetable` as a string scalar to `coder.newtype`.

The coder type object displays a succinct description of the object properties while excluding internal state values. Nonconstant properties display their type and size, while constant properties display only their values. For example:

```
t = timetable((1:5)',(11:15)', 'SampleRate',1);
tType = coder.typeof(t)
```

The representation of variable `t` is stored in coder type object `tType`.

```
tType =
```

```
matlab.coder.type.RegularTimetableType
 5x2 timetable
 Data : 1x2 homogeneous cell
 Description : 1x0 char
 UserData : 0x0 double
 DimensionNames : {'Time'} {'Variables'}
 VariableNames : {'Var1'} {'Var2'}
 VariableDescriptions : 1x2 homogeneous cell
```

```

VariableUnits : 1x2 homogeneous cell
VariableContinuity : 1x2 matlab.internal.coder.tabular.Continuity
StartTime : 1x1 matlab.coder.type.DurationType
SampleRate : 1x1 double
TimeStep : 1x1 matlab.coder.type.DurationType

```

Define a regular `timetable` by specifying the `SampleRate` or `TimeStep`. You can also define an irregular `timetable` by specifying the `RowTimes`. For example:

```

t1 = timetable((1:3), 'RowTimes', seconds(1:3));
t1Type = coder.typeof(t)

```

The representation of irregular table `t1` is stored in coder type object `t1Type`.

```

t1Type =
matlab.coder.type.TimetableType
 3x1 timetable
 Data : 1x1 homogeneous cell
 Description : 1x0 char
 UserData : 0x0 double
 DimensionNames : {'Time'} {'Variables'}
 VariableNames : {'Var1'}
VariableDescriptions : 1x1 homogeneous cell
VariableUnits : 1x1 homogeneous cell
VariableContinuity : 1x1 matlab.internal.coder.tabular.Continuity
RowTimes : 3x1 matlab.coder.type.DurationType

```

If your workflow requires the legacy representation of coder type objects, use the `getCoderType` function on the variable that has the new representation of your class or object. See “Legacy Representation of Coder Type Objects” (MATLAB Coder).

### Resize Object Properties by Using `coder.resize`

You can resize most objects by using `coder.resize`. You can resize objects, its properties and create arrays within the properties.

For a `timetable` coder object, you can resize the object properties:

```

t = timetable((1:5)', (11:15)', 'SampleRate', 1);
tType = coder.typeof(t);
tType.UserData = coder.resize(tType.UserData, [10 1], [1 0])

```

This code resizes the `UserData` property to be a `:10x1` double property. The first dimension is upper-bound at 10.

```

tType =
matlab.coder.type.RegularTimetableType
 5x2 timetable
 Data : 1x2 homogeneous cell
 Description : 1x0 char
 UserData : :10x1 double
 DimensionNames : {'Time'} {'Variables'}
 VariableNames : {'Var1'} {'Var2'}
VariableDescriptions : 1x2 homogeneous cell
VariableUnits : 1x2 homogeneous cell
VariableContinuity : 1x2 matlab.internal.coder.tabular.Continuity

```

```
StartTime : 1x1 matlab.coder.type.DurationType
SampleRate : 1x1 double
TimeStep : 1x1 matlab.coder.type.DurationType
```

You can also resize the object by using `coder.resize`. See “Edit and Represent Coder Type Objects and Properties” (MATLAB Coder).

## Timetable Limitations for Code Generation

If you create timetables, modify them, or use timetable functions in MATLAB code that you intend for code generation, then code generation has limitations described in the next sections. Limitations that apply to classes also apply to timetables. For more information on class limitations, see “MATLAB Classes Definition for Code Generation” (MATLAB Coder).

### Creating Timetables Limitations

If your MATLAB code creates timetables, then code generation has these limitations.

| Inputs for Timetable Creation       | Limitations                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

## Modifying Timetables Limitations

If your MATLAB code modifies data in a timetable, its row times, or its properties, then code generation has these limitations.

| Timetable Operation or Property                       | Limitations                                                                                                                                                                                                                                                                                                                        |

## Using Timetable Functions Limitations

If your MATLAB code uses the functions listed in the table, then code generation has these limitations.

| Function                 | Limitations                                                                                                                                                                                                                                                                   |
|--------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>addvars</code>     | <ul style="list-style-type: none"> <li>You cannot specify name-value arguments using <code>Name=Value</code> syntax.</li> </ul>                                                                                                                                               |
| <code>convertvars</code> | <ul style="list-style-type: none"> <li>Function handles are not supported.</li> <li>The second and third input arguments (<code>vars</code> and <code>dataType</code>) must be constant.</li> <li>You cannot specify <code>dataType</code> as <code>'char'</code>.</li> </ul> |

| Function                                | Limitations                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

## MATLAB Classes Definition for Code Generation

To generate efficient standalone code for MATLAB classes, you must use classes differently than when running your code in the MATLAB environment.

| What's Different                                                                         | More Information                                                                                                                                                                                                    |

### Language Limitations

Although code generation support is provided for common features of classes such as properties and methods, there are a number of advanced features which are not supported, such as:

- Events
- Listeners
- Arrays of objects
- Recursive data structures
  - Linked lists
  - Trees
  - Graphs
- Nested functions in constructors
- Overloadable operators `subsref`, `subsassign`, and `subsindex`

In MATLAB, classes can define their own versions of the `subsref`, `subsassign`, and `subsindex` methods. Code generation does not support classes that have their own definitions of these methods.

- The empty method

In MATLAB, classes have a built-in static method, `empty`, which creates an empty array of the class. Code generation does not support this method.

- The following MATLAB handle class methods:
  - `addlistener`
  - `eq`
  - `findobj`
  - `findpro`
- The `AbortSet` property attribute

## Code Generation Features Not Compatible with Classes

- You can generate code for entry-point MATLAB functions that use classes, but you cannot generate code directly for a MATLAB class.

For example, if `ClassNameA` is a class definition, you cannot generate code by executing:

```
codegen ClassNameA
```

- A handle class object cannot be an entry-point function input or output.
- A value class object can be an entry-point function input or output. However, if a value class object contains a handle class object, then the value class object cannot be an entry-point function input or output. A handle class object cannot be an entry-point function input or output.
- Code generation does not support global variables that are handle classes.
- You cannot use classes for Simulink signals, parameters, or data store memory.
- Code generation does not support assigning an object of a value class into a nontunable property. For example, `obj.prop=v;` is invalid when `prop` is a nontunable property and `v` is an object based on a value class.
- You cannot use `coder.extrinsic` to declare a class or method as extrinsic.
- You cannot pass a MATLAB class to `coder.ceval`. You can pass class properties to `coder.ceval`.
- If a property has a get method, a set method, or validators, or is a System object property with certain attributes, then you cannot pass the property by reference to an external function. See “Passing By Reference Not Supported for Some Properties” on page 62-20.
- If you use classes in code in the MATLAB Function block, you cannot use the debugger to view class information.
- If an object has duplicate property names and the code generator tries to constant-fold the object, code generation can fail. The code generator constant-folds an object when it is used with `coder.const`, or when it is an input to or output from a constant-folded extrinsic function.

Duplicate property names occur in an object of a subclass in these situations:

- The subclass has a property with the same name as a property of the superclass.
- The subclass derives from multiple superclasses that use the same name for a property.

For information about when MATLAB allows duplicate property names, see “Subclassing Multiple Classes”.

## Defining Class Properties for Code Generation

For code generation, you must define class properties differently than you do when running your code in the MATLAB environment:

- A property validation error ends a simulation with an error message. To test property validation, it is a best practice to run a simulation over the full range of input values. C/C++ code generated by Simulink Coder does not detect or report property validation errors.
- After defining a property, do not assign it an incompatible type. Do not use a property before attempting to grow it.

When you define class properties for code generation, consider the same factors that you take into account when defining variables. In the MATLAB language, variables can change their class, size, or complexity dynamically at run time so you can use the same variable to hold a value of varying class, size, or complexity. C and C++ use static typing. Before using variables, to determine their type, the code generator requires a complete assignment to each variable. Similarly, before using properties, you must explicitly define their class, size, and complexity.

- Initial values:
  - If the property does not have an explicit initial value, the code generator assumes that it is undefined at the beginning of the constructor. The code generator does not assign an empty matrix as the default.
  - If the property does not have an initial value and the code generator cannot determine that the property is assigned prior to first use, the software generates a compilation error.
  - For System objects, if a nontunable property is a structure, you must completely assign the structure. You cannot do partial assignment using subscripting.

For example, for a nontunable property, you can use the following assignment:

```
mySystemObject.nonTunableProperty=struct('fieldA','a','fieldB','b');
```

You cannot use the following partial assignments:

```
mySystemObject.nonTunableProperty.fieldA = 'a';
mySystemObject.nonTunableProperty.fieldB = 'b';
```

- `coder. varsize` is not supported for class properties.
- If the initial value of a property is an object, then the property must be constant. To make a property constant, declare the `Constant` attribute in the property block. For example:

```
classdef MyClass
 properties (Constant)
 p1 = MyClass2;
 end
end
```

- MATLAB computes class initial values at class loading time before code generation. If you use persistent variables in MATLAB class property initialization, the value of the persistent variable computed when the class loads belongs to MATLAB; it is not the value used at code generation time. If you use `coder.target` in MATLAB class property initialization, `coder.target('MATLAB')` returns `true (1)`.
- Variable-size properties:
  - Code generation supports upper-bounded and unbounded variable-size properties for both value and handle classes.

- To generate unbounded variable-size class properties, enable dynamic memory allocation.
- To make a variable-size class property, make two sequential assignments of a class property, one to a scalar and the next to an array.

```
classdef varSizeProp1 < handle
 properties
 prop
 varProp
 end
end

function extFunc(n)
 obj = varSizeProp1;
 % Assign a scalar value to the property.
 obj.prop = 1;
 obj.varProp = 1;
 % Assign an array to the same property to make it variable-sized.
 obj.prop = 1:98;
 obj.varProp = 1:n;
end
```

In the preceding code, the first assignment to `prop` and `varProp` is scalar, and their second assignment is to an array with the same base type. The size of `prop` has an upper bound of 98, making it an upper-bounded, variable-size property.

If `n` is unknown at compile time, `obj.varProp` is an unbounded variable-size property. If it is known, it is an upper-bounded, variable-size class property.

- If the class property is initialized with a variable-size array, the property is variable-size.

```
classdef varSizeProp2
 properties
 prop
 end
 methods
 function obj = varSizeProp2(inVar)
 % Assign incoming value to local variable
 locVar = inVar;

 % Declare the local variable to be a variable-sized column
 % vector with no size limit
 coder.varsize('locVar',[inf 1],[1 0]);

 % Assign value
 obj.prop = locVar;
 end
 end
end
```

In the preceding code, `inVar` is passed to the class constructor and stored in `locVar`. `locVar` is modified to be variable-size by `coder.varsize` and assigned to the class property `obj.prop`, which makes the property variable-size.

- If the input to the function call `varSizeProp2` is variable-size, `coder.varsize` is not required.

```
function z = constructCall(n)
 z = varSizeProp2(1:n);
end
```

- If the value of `n` is unknown at compile-time and has no specified bounds, `z.prop` is an unbounded variable-size class property.
- If the value of `n` is unknown at compile-time and has specified bounds, `z.prop` is an upper-bounded variable-size class property.
- If a property is constant and its value is an object, you cannot change the value of a property of that object. For example, suppose that:

- `obj` is an object of `myClass1`.
- `myClass1` has a constant property `p1` that is an object of `myClass2`.
- `myClass2` has a property `p2`.

Code generation does not support the following code:

```
obj.p1.p2 = 1;
```

## **Inheritance from Built-In MATLAB Classes Not Supported**

You cannot generate code for classes that inherit from built-in MATLAB classes. For example, you cannot generate code for the following class:

```
classdef myclass < double
```

An exception to this rule is the MATLAB enumeration class. You can generate code for enumeration classes that inherit from built-in MATLAB classes. See “Code Generation for Enumerations” (MATLAB Coder).

## Classes That Support Code Generation

You can generate code for MATLAB value and handle classes and user-defined System objects. Your class can have multiple methods and properties and can inherit from multiple classes.

| <b>To generate code for:</b>                         | <b>Example:</b>                                                            |
|------------------------------------------------------|----------------------------------------------------------------------------|
| Value classes                                        | "Generate Code for MATLAB Value Classes" on page 62-8                      |
| Handle classes including user-defined System objects | "Generate Code for MATLAB Handle Classes and System Objects" on page 62-12 |

For more information, see:

- "Role of Classes in MATLAB"
- "MATLAB Classes Definition for Code Generation" on page 62-2

## Generate Code for MATLAB Value Classes

This example shows how to generate code for a MATLAB value class and then view the generated code in the code generation report.

- 1 In a writable folder, create a MATLAB value class, Shape. Save the code as Shape.m.

```

classdef Shape
% SHAPE Create a shape at coordinates
% centerX and centerY
 properties
 centerX;
 centerY;
 end
 properties (Dependent = true)
 area;
 end
 methods
 function out = get.area(obj)
 out = obj.getarea();
 end
 function obj = Shape(centerX,centerY)
 obj.centerX = centerX;
 obj.centerY = centerY;
 end
 end
end
methods(Abstract = true)
 getarea(obj);
end
methods(Static)
 function d = distanceBetweenShapes(shape1,shape2)
 xDist = abs(shape1.centerX - shape2.centerX);
 yDist = abs(shape1.centerY - shape2.centerY);
 d = sqrt(xDist^2 + yDist^2);
 end
end
end
end

```

- 2 In the same folder, create a class, Square, that is a subclass of Shape. Save the code as Square.m.

```

classdef Square < Shape
% Create a Square at coordinates center X and center Y
% with sides of length of side
 properties
 side;
 end
 methods
 function obj = Square(side,centerX,centerY)
 obj@Shape(centerX,centerY);
 obj.side = side;
 end
 function Area = getarea(obj)
 Area = obj.side^2;
 end
 end
end
end
end

```

- 3 In the same folder, create a class, Rhombus, that is a subclass of Shape. Save the code as Rhombus.m.

```
classdef Rhombus < Shape
 properties
 diag1;
 diag2;
 end
 methods
 function obj = Rhombus(diag1,diag2,centerX,centerY)
 obj@Shape(centerX,centerY);
 obj.diag1 = diag1;
 obj.diag2 = diag2;
 end
 function Area = getarea(obj)
 Area = 0.5*obj.diag1*obj.diag2;
 end
 end
end
```

- 4 Write a function that uses this class.

```
function [TotalArea, Distance] = use_shape
 %#codegen
 s = Square(2,1,2);
 r = Rhombus(3,4,7,10);
 TotalArea = s.area + r.area;
 Distance = Shape.distanceBetweenShapes(s,r);
```

- 5 Generate a static library for use\_shape and generate a code generation report.

```
codegen -config:lib -report use_shape
```

codegen generates a C static library with the default name, use\_shape, and supporting files in the default folder, codegen/lib/use\_shape.

- 6 Click the **View report** link.

- 7 To see the Rhombus class definition, on the **MATLAB Source** pane, under Rhombus.m, click Rhombus. The Rhombus class constructor is highlighted.

- 8 Click the **Variables** tab. You see that the variable obj is an object of the Rhombus class. To see its properties, expand obj.

The screenshot shows the MATLAB IDE interface. The top toolbar includes 'Back', 'Forward', 'Go To', 'Trace Code', 'Edit In MATLAB', and 'Package Code'. The 'MATLAB SOURCE' pane on the left shows a 'Function List' and a 'Call Tree'. The 'Call Tree' view shows the following structure:

- use\_shape.m
  - fx use\_shape
    - Rhombus.m
      - fx Rhombus
        - fx getarea
          - Shape.m
            - Shape
              - fx distanceBetweenShapes
                - Square.m
                  - fx Square
                    - fx getarea

The main code pane shows the Rhombus class definition:

```

1 classdef Rhombus < Shape
2 properties
3 diag1;
4 diag2;
5 end
6 methods
7 function obj = Rhombus(diag1,diag2,centerX,centerY)
8 obj@Shape(centerX,centerY);
9 obj.diag1 = diag1;
10 obj.diag2 = diag2;
11 end
12 function Area = getarea(obj)
13 Area = 0.5*obj.diag1*obj.diag2;
14 end
15 end
16 end

```

The bottom pane shows a table with columns: SUMMARY, ALL MESSAGES (0), BUILD LOGS, CODE INSIGHTS (1), and VARIABLES. The 'CODE INSIGHTS (1)' section shows a table of variables:

| Name    | Type   | Size  | Class   |
|---------|--------|-------|---------|
| obj     | Output | 1 × 1 | Rhombus |
| centerX |        | 1 × 1 | double  |
| centerY |        | 1 × 1 | double  |
| diag1   |        | 1 × 1 | double  |
| diag2   |        | 1 × 1 | double  |
| diag1   | Input  | 1 × 1 | double  |
| diag2   | Input  | 1 × 1 | double  |
| centerX | Input  | 1 × 1 | double  |
| centerY | Input  | 1 × 1 | double  |

9 In the **MATLAB Source** pane, click **Call Tree**.

The **Call Tree** view shows that `use_shape` calls the Rhombus constructor and that the Rhombus constructor calls the Shape constructor.

The close-up shows the 'MATLAB SOURCE' pane with the 'Call Tree' view selected. The tree structure is as follows:

- fx use\_shape
  - fx Square/Square
  - fx Rhombus/Rhombus
    - fx Shape/Shape
  - fx Shape/get.area
  - fx Shape/get.area
  - fx Shape/distanceBetweenShapes

10 In the code pane, in the Rhombus class constructor, move your pointer to this line:

```
obj@Shape(centerX,centerY)
```

The Rhombus class constructor calls the Shape method of the base Shape class. To view the Shape class definition, in `obj@Shape`, double-click Shape.

```
Shape.m
1 classdef Shape
2 % SHAPE Create a shape at coordinates
3 % centerX and centerY
4 properties
5 centerX;
6 centerY;
7 end
8 properties (Dependent = true)
9 area;
10 end
11 methods
12 function out = get.area(obj)
13 out = obj.getarea();
14 end
15 function obj = Shape(centerX,centerY)
16 obj.centerX = centerX;
17 obj.centerY = centerY;
18 end
19 end
20 methods(Abstract = true)
21 getarea(obj);
22 end
23 methods(Static)
24 function d = distanceBetweenShapes(shape1, shape2)
25 xDist = abs(shape1.centerX - shape2.centerX);
26 yDist = abs(shape1.centerY - shape2.centerY);
27 d = sqrt(xDist^2 + yDist^2);
28 end
29 end
30 end
31
32
```

## Generate Code for MATLAB Handle Classes and System Objects

This example shows how to generate code for a user-defined System object and then view the generated code in the code generation report.

- 1 In a writable folder, create a System object, `AddOne`, which subclasses from `matlab.System`. Save the code as `AddOne.m`.

```
classdef AddOne < matlab.System
% ADDONE Compute an output value that increments the input by one

 methods (Access=protected)
 % stepImpl method is called by the step method
 function y = stepImpl(~,x)
 y = x+1;
 end
 end
end
```

- 2 Write a function that uses this System object.

```
function y = testAddOne(x)
%#codegen
 p = AddOne();
 y = p.step(x);
end
```

- 3 Generate a MEX function for this code.

```
codegen -report testAddOne -args {0}
```

The `-report` option instructs `codegen` to generate a code generation report, even if no errors or warnings occur. The `-args` option specifies that the `testAddOne` function takes one scalar double input.

- 4 Click the **View report** link.
- 5 In the **MATLAB Source** pane, click `testAddOne`. To see information about the variables in `testAddOne`, click the **Variables** tab.

The screenshot shows the MATLAB IDE interface. The top bar includes navigation and editing tools. The left pane is divided into 'MATLAB SOURCE' and 'GENERATED CODE'. The 'MATLAB SOURCE' pane shows a function list with 'testAddOne.m' selected. The main editor displays the code for 'testAddOne.m':

```

1 function y = test
2 %#codegen
3 p = AddOne();
4 y = p.step(x);
5 end

```

A tooltip for the variable 'p' is visible, showing its properties:

- Variable Name: p
- Size: 1 x 1
- Class: AddOne

The 'GENERATED CODE' pane shows source and interface files. At the bottom, a table provides a summary of variables:

| Name | Type   | Size  | Class  |
|------|--------|-------|--------|
| y    | Output | 1 x 1 | double |
| x    | Input  | 1 x 1 | double |
| p    | Local  | 1 x 1 | AddOne |

6 To view the class definition for addOne, in the **MATLAB Source** pane, click AddOne.

### More About

- “Code Generation for Handle Class Destructors” on page 62-15

## Code Generation for Handle Class Destructors

You can generate code for MATLAB code that uses `delete` methods (destructors) for handle classes. To perform clean-up operations, such as closing a previously opened file before an object is destroyed, use a `delete` method. The generated code calls the `delete` method at the end of an object's lifetime, even if execution is interrupted by a run-time error. When System objects are destroyed, `delete` calls the `release` method, which in turn calls the user-defined `releaseImpl`. For more information on when to define a `delete` method in a MATLAB code, see "Handle Class Destructor".

### Guidelines and Restrictions

When you write the MATLAB code, adhere to these guidelines and restrictions:

- Code generation does not support recursive calls of the `delete` method. Do not create an object of a certain class inside the `delete` method for the same class. This usage might cause a recursive call of `delete` and result in an error message.
- The generated code always calls the `delete` method, when an object goes out of scope. Code generation does not support explicit calls of the `delete` method.
- Initialize all properties of `MyClass` that the `delete` method of `MyClass` uses either in the constructor or as the default property value. If `delete` tries to access a property that has not been initialized in one of these two ways, the code generator produces an error message.
- Suppose a property `prop1` of `MyClass1` is itself an object (an instance of another class `MyClass2`). Initialize all properties of `MyClass2` that the `delete` method of `MyClass1` uses. Perform this initialization either in the constructor of `MyClass2` or as the default property value. If `delete` tries to access a property of `MyClass2` that has not been initialized in one of these two ways, the code generator produces an error message. For example, define the two classes `MyClass1` and `MyClass2`:

```
classdef MyClass1 < handle
 properties
 prop1
 end
 methods
 function h = MyClass1(index)
 h.prop1 = index;
 end
 function delete(h)
 fprintf('h.prop1.prop2 is: %1.0f\n',h.prop1.prop2);
 end
 end
end

classdef MyClass2 < handle
 properties
 prop2
 end
end
```

Suppose you try to generate code for this function:

```
function MyFunction
obj2 = MyClass2;
```

```
obj1 = MyClass1(obj2); % Assign obj1.prop1 to the input (obj2)
end
```

The code generator produces an error message because you have not initialized the property `obj2.prop2` that the `delete` method displays.

## Behavioral Differences of Objects in Generated Code and in MATLAB

The behavior of objects in the generated code can be different from their behavior in MATLAB in these situations:

- The order of destruction of several independent objects might be different in MATLAB than in the generated code.
- The lifetime of objects in the generated code can be different from their lifetime in MATLAB. MATLAB calls the `delete` method when an object can no longer be reached from any live variable. The generated code calls the `delete` method when an object goes out of scope. In some situations, this difference causes `delete` to be called later on in the generated code than in MATLAB. For example, define the class:

```
classdef MyClass < handle
 methods
 function delete(h)
 global g
 % Destructor displays current value of global variable g
 fprintf('The global variable is: %1.0f\n',g);
 end
 end
end
```

Run the function:

```
function MyFunction
 global g
 g = 1;
 obj = MyClass;
 obj = MyClass;
 % MATLAB destroys the first object here
 g = 2;
 % MATLAB destroys the second object here
 % Generated code destroys both objects here
end
```

The first object can no longer be reached from any live variable after the second instance of `obj = MyClass` in `MyFunction`. MATLAB calls the `delete` method for the first object after the second instance of `obj = MyClass` in `MyFunction` and for the second object at the end of the function. The output is:

```
The global variable is: 1
The global variable is: 2
```

In the generated code, both `delete` method calls happen at the end of the function when the two objects go out of scope. Running `MyFunction_mex` results in a different output:

```
The global variable is: 2
The global variable is: 2
```

- In MATLAB, persistent objects are automatically destroyed when they cannot be reached from any live variable. In the generated code, you have to call the `terminate` function explicitly to destroy the persistent objects.
- The generated code does not destroy partially constructed objects. If a handle object is not fully constructed at run time, the generated code produces an error message but does not call the `delete` method for that object. For a System object, if there is a run-time error in `setupImpl`, the generated code does not call `releaseImpl` for that object.

MATLAB does call the `delete` method to destroy a partially constructed object.

- “System Objects in MATLAB Code Generation” on page 62-24

## Class Does Not Have Property

If a MATLAB class has a method, `mymethod`, that returns a handle class with a property, `myprop`, you cannot generate code for the following type of assignment:

```
obj.mymethod().myprop=...
```

For example, consider the following classes:

```
classdef MyClass < handle
 properties
 myprop
 end
 methods
 function this = MyClass
 this.myprop = MyClass2;
 end
 function y = mymethod(this)
 y = this.myprop;
 end
 end
end

classdef MyClass2 < handle
 properties
 aa
 end
end
```

You cannot generate code for function `foo`.

```
function foo

h = MyClass;

h.mymethod().aa = 12;
```

In this function, `h.mymethod()` returns a handle object of type `MyClass2`. In MATLAB, the assignment `h.mymethod().aa = 12;` changes the property of that object. Code generation does not support this assignment.

### Solution

Rewrite the code to return the object and then assign a value to a property of the object.

```
function foo

h = MyClass;

b=h.mymethod();
b.aa=12;
```

## **More About**

- “MATLAB Classes Definition for Code Generation” on page 62-2

## Passing By Reference Not Supported for Some Properties

The code generator does not support passing a property by reference to an external function for these types of properties:

- A property with a get method or a set method.
- A property that uses validation functions.
- A System object property with an attribute, such as `Logical` or `PositiveInteger`, that constrains or modifies the property value.

Instead of passing a property by reference, save the property value in a temporary variable. Then, pass the temporary variable by reference to the external function. After the external function call, assign the temporary variable to the property. For example:

```
tmp = myObj.prop;
coder.ceval('myFcn', coder.ref(tmp));
myObj.prop = tmp;
```

The assignment after the `coder.ceval` call validates or modifies the property value according to the property access methods, validation functions, or attributes.

### More About

- “MATLAB Classes Definition for Code Generation” on page 62-2

## Handle Object Limitations for Code Generation

The code generator statically determines the lifetime of a handle object. When you use handle objects, this static analysis has certain restrictions.

With static analysis the generated code can reuse memory rather than rely on a dynamic memory management scheme, such as reference counting or garbage collection. The code generator can avoid dynamic memory allocation and run-time automatic memory management. These generated code characteristics are important for some safety-critical and real-time applications.

For limitations, see:

- “A Variable Outside a Loop Cannot Refer to a Handle Object Allocated Inside a Loop” on page 62-21
- “A Handle Object That a Persistent Variable Refers To Must Be a Singleton Object” on page 62-22

The code generator analyzes whether all variables are defined prior to use. Undefined variables or data types cause an error during code generation. In certain circumstances, the code generator cannot determine if references to handle objects are defined. See “References to Handle Objects Can Appear Undefined” on page 62-23.

### A Variable Outside a Loop Cannot Refer to a Handle Object Allocated Inside a Loop

Consider the handle class `mycls` and the function `usehandle1`.

```
classdef mycls < handle
 properties
 prop
 end

 methods
 function obj = mycls(x)
 obj.prop = x;
 end
 end
end

function y = usehandle1
 p = mycls(0); % Instance of mycls with prop value 10 created

 for i = 1:10
 p = mycls(i); % Handle object allocated inside loop
 end

 y = p.prop; % Handle object referenced outside loop
end
```

If you try to generate code for the `usehandle1` function, the code generator produces an error. The error occurs because:

- A handle object is allocated inside the `for` loop. The variable `p.prop` refers to this handle object.
- Outside the loop, the variable `x` refers to the property `prop` handle object.

## A Handle Object That a Persistent Variable Refers To Must Be a Singleton Object

If a persistent variable refers to a handle object, the code generator allows only one instance of the object during the program's lifetime. The object must be a singleton object. To create a singleton handle object, enclose statements that create the object in the `if isempty()` guard for the persistent variable.

For example, consider the class `mycls` and the function `usehandle2`. The code generator reports an error for `usehandle2` because `p.prop` refers to the `mycls` object that the statement `inner = mycls` creates. This statement creates a `mycls` object for each invocation of `usehandle2`.

```
classdef mycls < handle
 properties
 prop
 end
end

function usehandle2(x)
 assert(isa(x, 'double'));
 persistent p;
 inner = mycls;
 inner.prop = x;
 if isempty(p)
 p = mycls;
 p.prop = inner;
 end
end
```

If you move the statements `inner = mycls` and `inner.prop = x` inside the `if isempty()` guard, code generation succeeds. The statement `inner = mycls` executes only once during the program's lifetime.

```
function usehandle2(x)
 assert(isa(x, 'double'));
 persistent p;
 if isempty(p)
 inner = mycls;
 inner.prop = x;
 p = mycls;
 p.prop = inner;
 end
end
```

Consider the function `usehandle3`. The code generator reports an error for `usehandle3` because the persistent variable `p` refers to the `mycls` object that the statement `myobj = mycls` creates. This statement creates a `mycls` object for each invocation of `usehandle3`.

```
function usehandle3(x)
 assert(isa(x, 'double'));
 myobj = mycls;
 myobj.prop = x;
 doinit(myobj);
 disp(myobj.prop);
 function doinit(obj)
 persistent p;
 if isempty(p)
 p = obj;
 end
 end
end
```

If you make `myobj` persistent and enclose the statement `myobj = mycls` inside an `if isempty()` guard, code generation succeeds. The statement `myobj = mycls` executes only once during the program's lifetime.

```
function usehandle3(x)
assert(isa(x, 'double'));
persistent myobj;
if isempty(myobj)
 myobj = mycls;
end

doinit(myobj);

function doinit(obj)
persistent p;
if isempty(p)
 p = obj;
end
```

## References to Handle Objects Can Appear Undefined

Consider the function `refHandle` that copies a handle object property to another object. The function uses a simple handle class and value class. In MATLAB, the function runs without error.

```
function [out1, out2, out3] = refHandle()
 x = myHandleClass;
 y = x;
 v = myValueClass();
 v.prop = x;
 x.prop = 42;
 out1 = x.prop;
 out2 = y.prop;
 out3 = v.prop.prop;
end

classdef myHandleClass < handle
 properties
 prop
 end
end

classdef myValueClass
 properties
 prop
 end
end
```

During code generation, an error occurs:

```
Property 'v.prop.prop' is undefined on some execution paths.
```

Three variables reference the same memory location: `x`, `y`, and `v.prop`. The code generator determines that `x.prop` and `y.prop` share the same value. The code generator cannot determine that the handle object property `v.prop.prop` shares its definition with `x.prop` and `y.prop`. To avoid the error, define `v.prop.prop` directly.

## System Objects in MATLAB Code Generation

### In this section...

“Usage Rules and Limitations for System Objects for Generating Code” on page 62-24

“System Objects in codegen” on page 62-26

“System Objects in the MATLAB Function Block” on page 62-26

“System Objects in the MATLAB System Block” on page 62-26

“System Objects and MATLAB Compiler Software” on page 62-26

You can generate C/C++ code in MATLAB from your system that contains System objects by using MATLAB Coder. You can generate efficient and compact code for deployment in desktop and embedded systems and accelerate fixed-point algorithms.

### Usage Rules and Limitations for System Objects for Generating Code

The following usage rules and limitations apply to using System objects in code generated from MATLAB.

#### Object Construction and Initialization

- If objects are stored in persistent variables, initialize System objects once by embedding the object handles in an `if` statement with a call to `isempty()`.
- Set arguments to System object constructors as compile-time constants.
- Initialize all System objects properties that `releaseImpl` uses before the end of `setupImpl`.
- You cannot initialize System objects properties with other MATLAB class objects as default values in code generation. You must initialize these properties in the constructor.

#### Inputs and Outputs

- System objects accept a maximum of 1024 inputs. A maximum of eight dimensions per input is supported.
- The data type of the inputs should not change.
- The complexity of the inputs should not change.
- If you want the size of inputs to change, verify that support for variable-size is enabled. Code generation support for variable-size data also requires that variable-size support is enabled. By default in MATLAB, support for variable-size data is enabled.
- System objects predefined in the software do not support variable-size if their data exceeds the `DynamicMemoryAllocationThreshold` value.
- Do not set System objects to become outputs from the MATLAB Function block.
- Do not use the Save and Restore Simulation State as `SimState` option for any System object in a MATLAB Function block.
- Do not pass a System object as an example input argument to a function being compiled with `codegen`.
- Do not pass a System object to functions declared as extrinsic (functions called in interpreted mode) using the `coder.extrinsic` function. System objects returned from extrinsic functions and scope System objects that automatically become extrinsic can be used as inputs to another extrinsic function. But, these functions do not generate code.

## Properties

- In MATLAB System blocks, you cannot use variable-size for discrete state properties of System objects. Private properties can be variable-size.
- Objects cannot be used as default values for properties.
- You can only assign values to nontunable properties once, including the assignment in the constructor.
- Nontunable property values must be constant.
- For fixed-point inputs, if a tunable property has dependent data type properties, you can set tunable properties only at construction time or after the object is locked.
- For `getNumInputsImpl` and `getNumOutputsImpl` methods, if you set the return argument from an object property, that object property must have the `Nontunable` attribute.

## Global Variables

- Global variables are allowed in a System object, unless you are using that System object in Simulink via the MATLAB System block. See “Generate Code for Global Data” (MATLAB Coder).

## Methods

- Code generation support is available only for these System object methods:
  - `get`
  - `getNumInputs`
  - `getNumOutputs`
  - `isDone` (for sources only)
  - `isLocked`
  - `release`
  - `reset`
  - `set` (for tunable properties)
  - `step`
- For System objects that you define, code generation support is available only for these methods:
  - `getDiscreteStateImpl`
  - `getNumInputsImpl`
  - `getNumOutputsImpl`
  - `infoImpl`
  - `isDoneImpl`
  - `isInputDirectFeedthroughImpl`
  - `outputImpl`
  - `processTunedPropertiesImpl`
  - `releaseImpl` — Code is not generated automatically for this method. To release an object, you must explicitly call the `release` method in your code.
  - `resetImpl`
  - `setupImpl`

- `stepImpl`
- `updateImpl`
- `validateInputsImpl`
- `validatePropertiesImpl`

## System Objects in codegen

You can include System objects in MATLAB code in the same way you include any other elements. You can then compile a MEX file from your MATLAB code by using the `codegen` command, which is available if you have a MATLAB Coder license. This compilation process, which involves a number of optimizations, is useful for accelerating simulations. See “Get Started with MATLAB Coder” (MATLAB Coder) and “MATLAB Classes” (MATLAB Coder) for more information.

---

**Note** Most, but not all, System objects support code generation. Refer to the particular object’s reference page for information.

---

## System Objects in the MATLAB Function Block

Using the MATLAB Function block, you can include any System object and any MATLAB language function in a Simulink model. This model can then generate embeddable code. System objects provide higher-level algorithms for code generation than do most associated blocks. For more information, see “Implementing MATLAB Functions Using Blocks” on page 45-3.

## System Objects in the MATLAB System Block

Using the MATLAB System block, you can include in a Simulink model individual System objects that you create with a class definition file. The model can then generate embeddable code. For more information, see “MATLAB System Block” on page 46-2.

## System Objects and MATLAB Compiler Software

MATLAB Compiler software supports System objects for use inside MATLAB functions. The compiler product does not support System objects for use in MATLAB scripts.

- “Generate Code That Uses Row-Major Array Layout” (MATLAB Coder)

# Work Around Language Limitation: Code Generation Does Not Support Object Arrays

## Issue

In certain situations, your MATLAB algorithm uses an array of objects that are instances of the same class. But code generation does not support object arrays. When attempting to generate code for such MATLAB code, you get this or a similar error message:

Code generation does not support object arrays.

## Possible Solutions

### Use Cell Array of Objects

Code generation supports cell arrays of objects. In your MATLAB code, represent the collection of objects by using a cell array instead of an array.

For example, suppose that your MATLAB algorithm uses the class `Square`:

```
classdef Square
 properties(Access = private)
 side
 end

 methods(Access = public)
 function obj = Square(side)
 obj.side = side;
 end

 function area = calculateArea(obj)
 area = obj.side^2;
 end
 end
end
```

The function `addAreas` constructs and uses a 1-by-3 array of `Square` objects:

```
function y = addAreas(n)
 obj = Square(0);
 collection = [obj obj obj]; % collection is an array

 for i = 1:numel(collection)
 collection(i) = Square(n + i);
 end

 y = 0;
 for i = 1:numel(collection)
 y = y + collection(i).calculateArea;
 end
end
```

Attempt to generate a MEX function for `addAreas`. Code generation fails because the local variable `collection` is an object array.

```
codegen addAreas -args 0 -report
```

??? Code generation does not support object arrays.

```
Error in ==> addAreas Line: 3 Column: 14
Code generation failed: View Error Report
```

Redefine `collection` to be a cell array instead. Modify the code to use cell array indexing to index into `collection`. Name the modified function `addAreas_new`.

```
function y = addAreas_new(n)
obj = Square(0);
collection = {obj obj obj}; % collection is a cell array

for i = 1:numel(collection)
 collection{i} = Square(n + i);
end

y = 0;
for i = 1:numel(collection)
 y = y + collection{i}.calculateArea;
end
end
```

Attempt to generate a MEX function for `addAreas_new`. Code generation succeeds and produces `addAreas_new_mex`.

```
codegen addAreas_new -args 0 -report
```

```
Code generation successful: View report
```

Verify that `addAreas_new` and `addAreas_new_mex` have the same runtime behavior.

```
disp([addAreas_new(0) addAreas_new_mex(0)])
```

```
14 14
```

### For Assignment with Nonscalar Indexing, Use Curly Braces and deal

Suppose that your original MATLAB code performs assignment to the array of objects by using nonscalar indexing. For example, you might add this line after the first `for` loop in the `addAreas` function:

```
collection(1:2) = [Square(10) Square(20)];
```

In the modified function `addAreas_new`, index into the corresponding cell array by using curly braces `{}` and perform assignment by using the `deal` function. Replace the above line by:

```
[collection{1:2}] = deal(Square(10),Square(20));
```

# Code Generation for Function Handles

---

## Function Handle Limitations for Code Generation

When you use function handles in MATLAB code intended for code generation, adhere to the following restrictions:

### Do not use the same bound variable to reference different function handles

In some cases, using the same bound variable to reference different function handles causes a compile-time error. For example, this code does not compile:

```
function y = foo(p)
x = @plus;
if p
 x = @minus;
end
y = x(1, 2);
```

### Do not pass function handles to or from `coder.ceval`

You cannot pass function handles as inputs to or outputs from `coder.ceval`. For example, suppose that `f` and `str.f` are function handles:

```
f = @sin;
str.x = pi;
str.f = f;
```

The following statements result in compilation errors:

```
coder.ceval('foo', @sin);
coder.ceval('foo', f);
coder.ceval('foo', str);
```

### Do not associate a function handle with an extrinsic function

You cannot create a function handle that references an extrinsic MATLAB function.

### Do not pass function handles to or from extrinsic functions

You cannot pass function handles to or from `feval` and other extrinsic MATLAB functions.

### Do not pass function handles to or from entry-point functions

You cannot pass function handles as inputs to or outputs from entry-point functions. For example, consider this function:

```
function x = plotFcn(fhandle, data)

assert(isa(fhandle,'function_handle') && isa(data,'double'));

plot(data, fhandle(data));
x = fhandle(data);
```

In this example, the function `plotFcn` receives a function handle and its data as inputs. `plotFcn` attempts to call the function referenced by the `fhandle` with the input `data` and plot the results. However, this code generates a compilation error. The error indicates that the function `isa` does not recognize `'function_handle'` as a class name when called inside a MATLAB function to specify properties of inputs.

**Do not try to view function handles from the debugger**

You cannot display or watch function handles from the debugger. The function handles appear as empty matrices.

**Do not use function handles for Simulink signals, parameters, or data store memory**

You can use function handles in a MATLAB Function block. You cannot use function handles for Simulink signals, parameters, or data store memory.

# Defining Functions for Code Generation

---

- “Code Generation for Variable Length Argument Lists” on page 64-2
- “Code Generation for Anonymous Functions” on page 64-3
- “Code Generation for Nested Functions” on page 64-4

## Code Generation for Variable Length Argument Lists

When you use `varargin` and `varargout` for code generation, there are these restrictions:

- You cannot use `varargin` or `varargout` in the function definition for a top-level function in a MATLAB Function block or in a Stateflow chart that uses MATLAB as the action language.
- You cannot write to `varargin`. If you want to write to input arguments, copy the values into a local variable.
- To index into `varargin` and `varargout`, use curly braces `{}`, not parentheses `()`.
- The code generator must be able to determine the value of the index into `varargin` or `varargout`.

### See Also

### More About

- “Nonconstant Index into `varargin` or `varargout` in a for-Loop” on page 67-12

## Code Generation for Anonymous Functions

You can use anonymous functions in MATLAB code intended for code generation. For example, you can generate code for the following MATLAB code that defines an anonymous function that finds the square of a number.

```
sqr = @(x) x.^2;
a = sqr(5);
```

Anonymous functions are useful for creating a function handle to pass to a MATLAB function that evaluates an expression over a range of values. For example, this MATLAB code uses an anonymous function to create the input to the `fzero` function:

```
b = 2;
c = 3.5;
x = fzero(@(x) x^3 + b*x + c,0);
```

### Anonymous Function Limitations for Code Generation

Anonymous functions have the code generation limitations of value classes and cell arrays.

You can use anonymous functions in a MATLAB Function block. You cannot use anonymous functions for Simulink signals, parameters, or data store memory.

### See Also

- “MATLAB Classes Definition for Code Generation” on page 62-2
- “Cell Array Limitations for Code Generation” on page 56-6
- “Parameterizing Functions”

## Code Generation for Nested Functions

You can generate code for MATLAB functions that contain nested functions. For example, you can generate code for the function `parent_fun`, which contains the nested function `child_fun`.

```
function parent_fun
x = 5;
child_fun

 function child_fun
 x = x + 1;
 end

end
```

### Nested Function Limitations for Code Generation

When you generate code for nested functions, you must adhere to the code generation restrictions for value classes, cell arrays, and handle classes. You must also adhere to these restrictions:

- If the parent function declares a persistent variable, it must assign the persistent variable before it calls a nested function that uses the persistent variable.
- A nested recursive function cannot refer to a variable that the parent function uses.
- If a nested function refers to a structure variable, you must define the structure by using `struct`.
- If a nested function uses a variable defined by the parent function, you cannot use `coder.varsize` with the variable in either the parent or the nested function.

# Calling Functions for Code Generation

---

- “Resolution of Function Calls for Code Generation” on page 65-2
- “Resolution of File Types on Code Generation Path” on page 65-5
- “Compilation Directive %#codegen” on page 65-7
- “Use MATLAB Engine to Execute a Function Call in Generated Code” on page 65-8
- “Code Generation for Recursive Functions” on page 65-14
- “Force Code Generator to Use Run-Time Recursion” on page 65-16
- “Avoid Duplicate Functions in Generated Code” on page 65-19

## **Resolution of Function Calls for Code Generation**

From a MATLAB function, you can call local functions, supported toolbox functions, and other MATLAB functions. MATLAB resolves function names for code generation as follows:

## Key Points About Resolving Function Calls

The diagram illustrates key points about how MATLAB resolves function calls for code generation:

- Searches two paths, the code generation path and the MATLAB path

See “Compile Path Search Order” on page 65-4.

- Attempts to compile functions unless the code generator determines that it should not compile them or you explicitly declare them to be extrinsic.

If a MATLAB function is not supported for code generation, you can declare it to be extrinsic by using the construct `coder.extrinsic`, as described in “Using the `coder.extrinsic` Construct” on page 65-9. During simulation, the code generator produces code for the call to an extrinsic function, but does not generate the internal code for the function. Therefore, simulation can run only on platforms where MATLAB software is installed. During standalone code generation, the code generator attempts to determine whether the extrinsic function affects the output of the function in which it is called — for example by returning `mxArrays` to an output variable. If the output does not change, code generation proceeds, but the extrinsic function is excluded from the generated code. Otherwise, compilation errors occur.

The code generator detects calls to many common visualization functions, such as `plot`, `disp`, and `figure`. The software treats these functions like extrinsic functions but you do not have to declare them extrinsic using the `coder.extrinsic` function.

- Resolves file type based on precedence rules described in “Resolution of File Types on Code Generation Path” on page 65-5

## Compile Path Search Order

During code generation, function calls are resolved on two paths:

### 1 Code generation path

MATLAB searches this path first during code generation. The code generation path contains the toolbox functions supported for code generation.

### 2 MATLAB path

If the function is not on the code generation path, MATLAB searches this path.

MATLAB applies the same dispatcher rules when searching each path (see “Function Precedence Order”).

## When to Use the Code Generation Path

Use the code generation path to override a MATLAB function with a customized version. A file on the code generation path shadows a file of the same name on the MATLAB path.

For more information on how to add additional folders to the code generation path, see “Paths and File Infrastructure Setup” (MATLAB Coder).

## **Resolution of File Types on Code Generation Path**

MATLAB uses the following precedence rules for code generation:

## Compilation Directive %#codegen

Add the %#codegen directive (or pragma) to your function after the function signature to indicate that you intend to generate code for the MATLAB algorithm. Adding this directive instructs the MATLAB Code Analyzer to help you diagnose and fix violations that would result in errors during code generation.

```
function y = my_fcn(x) %#codegen
```

```
.....
```

---

**Note** The %#codegen directive is not necessary for MATLAB Function blocks. Code inside a MATLAB Function block is always intended for code generation. The %#codegen directive, or the absence of it, does not change the error checking behavior.

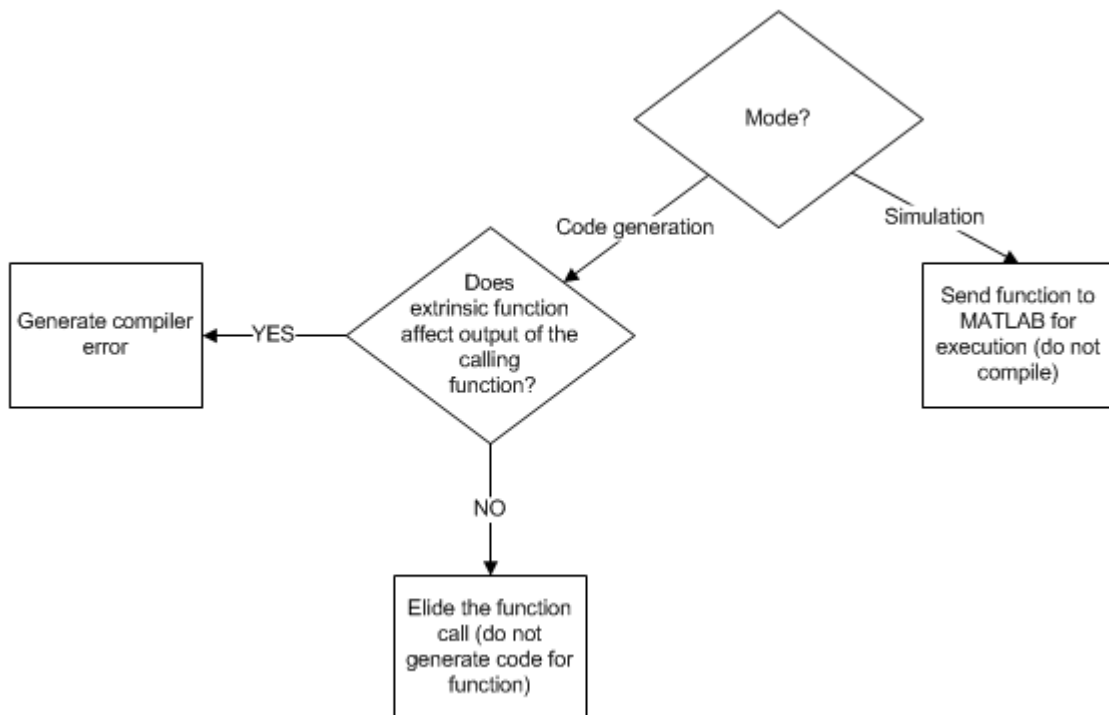

---

## Use MATLAB Engine to Execute a Function Call in Generated Code

When processing a call to a function `foo` in your MATLAB code, the code generator finds the definition of `foo` and generates code for its body. In some cases, you might want to bypass code generation and instead use the MATLAB engine to execute the call. Use `coder.extrinsic('foo')` to declare that calls to `foo` do not generate code and instead use the MATLAB engine for execution. In this context, `foo` is referred to as an extrinsic function. This functionality is available only when the MATLAB engine is available during execution. Examples of such situations include execution of MEX functions, Simulink simulations, or function calls at the time of code generation (also known as compile time).

If you generate standalone code for a function that calls `foo` and includes `coder.extrinsic('foo')`, the code generator attempts to determine whether `foo` affects the output. If `foo` does not affect the output, the code generator proceeds with code generation, but excludes `foo` from the generated code. Otherwise, the code generator produces a compilation error.

Including the `coder.extrinsic('foo')` directive inside a certain MATLAB function declares all calls to `foo` inside that MATLAB function as extrinsic. Alternatively, you might want to narrow the scope of extrinsic declaration to just one call to `foo`. See “Calling MATLAB Functions Using `feval`” (MATLAB Coder).

### When To Declare a Function as Extrinsic

These are some common situations in which you might consider declaring a MATLAB function as extrinsic:

- The function performs display or logging actions. Such functions are useful primarily during simulation and are not used in embedded systems.
- In your MEX execution or Simulink simulation, you want to use a MATLAB function that is not supported for code generation. This workflow does not apply to non-simulation targets.
- You instruct the code generator to constant fold a function call by using `coder.const`. In such situations, the function is called only during code generation when the MATLAB engine is available for executing the call.

## Using the `coder.extrinsic` Construct

To declare a function `foo` as extrinsic, include this statement in your MATLAB code.

```
coder.extrinsic('foo')
```

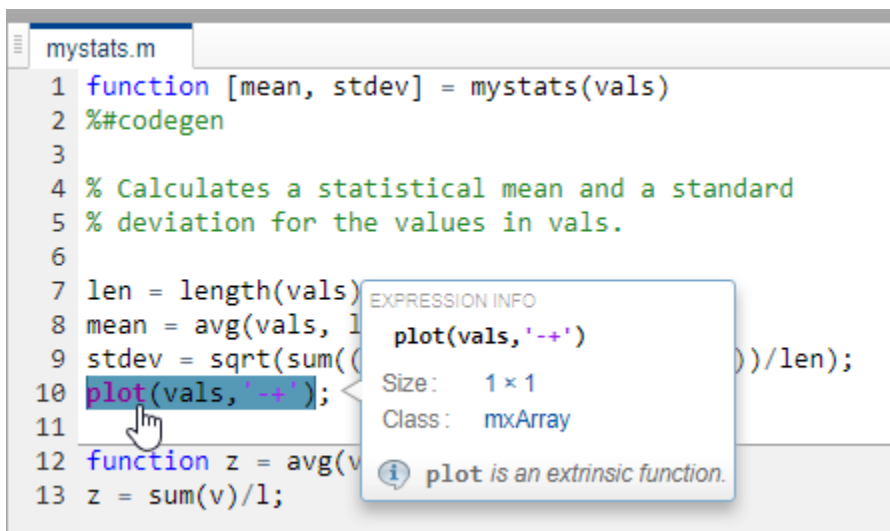

When declaring functions as extrinsic for code generation, adhere to these rules:

- Declare the function as extrinsic before you call it.
- Do not use the extrinsic declaration in conditional statements.
- Assign the return value of an extrinsic function to a known type. See “Working with mxArrays” (MATLAB Coder).

For additional information and examples, see `coder.extrinsic`.

The code generator automatically treats many common MATLAB visualization functions, such as `plot`, `disp`, and `figure`, as extrinsic. You do not have to explicitly declare them as extrinsic functions by using `coder.extrinsic`. For example, you might want to call `plot` to visualize your results in the MATLAB environment. If you generate a MEX function from a function that calls `plot`, and then run the generated MEX function, the code generator dispatches calls to the `plot` function to the MATLAB engine. If you generate a library or executable, the generated code does not contain calls to the `plot` function.

If you generate MEX or standalone C/C++ code by using MATLAB Coder, the code generation report highlights calls from your MATLAB code to extrinsic functions. By inspecting the report, you can determine which functions are supported only in the MATLAB environment.

```
mystats.m
1 function [mean, stdev] = mystats(vals)
2 %#codegen
3
4 % Calculates a statistical mean and a standard
5 % deviation for the values in vals.
6
7 len = length(vals)
8 mean = avg(vals, 1)
9 stdev = sqrt(sum((vals - mean).^2)/len);
10 plot(vals, '-+');
11
12 function z = avg(v)
13 z = sum(v)/l;
```

EXPRESSION INFO

`plot(vals, '-+')`

Size: 1 × 1

Class: mxArray

*plot is an extrinsic function.*

### Scope of Extrinsic Function Declarations

The `coder.extrinsic` construct has function scope. For example, consider the following code:

```
function y = foo %#codegen
coder.extrinsic('rat','min');
[N D] = rat(pi);
y = 0;
y = min(N, D);
```

In this example, `rat` and `min` are treated as extrinsic every time they are called in the main function `foo`. There are two ways to narrow the scope of an extrinsic declaration inside the main function:

- Declare the MATLAB function extrinsic in a local function, as in this example:

```
function y = foo %#codegen
coder.extrinsic('rat');
[N D] = rat(pi);
y = 0;
y = mymin(N, D);

function y = mymin(a,b)
coder.extrinsic('min');
y = min(a,b);
```

Here, the function `rat` is extrinsic every time it is called inside the main function `foo`, but the function `min` is extrinsic only when called inside the local function `mymin`.

- Instead of using the `coder.extrinsic` construct, call the MATLAB function using `feval`. This approach is described in the next section.

### Extrinsic Declaration for Nonstatic Methods

Suppose that you define a class `myClass` that has a nonstatic method `foo`, and then create an instance `obj` of this class. If you want to declare the method `obj.foo` as extrinsic in your MATLAB code that you intend for code generation, follow these rules:

- Write the call to `foo` as a function call. Do not write the call by using the dot notation.
- Declare `foo` to be extrinsic by using the syntax `coder.extrinsic('foo')`.

For example, define `myClass` as:

```
classdef myClass
 properties
 prop = 1
 end
 methods
 function y = foo(obj,x)
 y = obj.prop + x;
 end
 end
end
```

Here is an example MATLAB function that declares `foo` as extrinsic.

```
function y = myFunction(x) %#codegen
coder.extrinsic('foo');
obj = myClass;
```

```
y = foo(obj,x);
end
```

Nonstatic methods are also known as ordinary methods. See “Define Class Methods and Functions”.

### Additional Uses

Use the `coder.extrinsic` construct to:

- Call MATLAB functions that do not produce output during simulation, without generating unnecessary code.
- Make your code self-documenting and easier to debug. You can scan the source code for `coder.extrinsic` statements to isolate calls to MATLAB functions, which can potentially create and propagate `mxArrays`. See “Working with `mxArrays`” (MATLAB Coder).

## Calling MATLAB Functions Using `feval`

To narrow the scope of extrinsic declaration to just one function call, use the function `feval`. `feval` is automatically interpreted as an extrinsic function during code generation. Therefore, you can use `feval` to conveniently call functions that you want to execute in the MATLAB environment, rather than compile to generated code.

Consider the following example:

```
function y = foo
coder.extrinsic('rat');
[N D] = rat(pi);
y = 0;
y = feval('min',N,D);
```

Because `feval` is extrinsic, the statement `feval('min',N,D)` is evaluated by MATLAB — not compiled — which has the same result as declaring the function `min` extrinsic for just this one call. By contrast, the function `rat` is extrinsic throughout the function `foo`.

The code generator does not support the use of `feval` to call local functions or functions that are located in a private folder.

## Working with `mxArrays`

The output of an extrinsic function is an `mxArray`, also known as a MATLAB array. The only valid operations for `mxArrays` are:

- Storing an `mxArray` in a variable.
- Passing an `mxArray` to a function.
- Returning an `mxArray` from a function back to MATLAB.
- Converting an `mxArray` to a known type at run time. To perform this action, assign the `mxArray` to a variable whose type is already defined by a prior assignment. See example below.

To use an `mxArray` returned by an extrinsic function in other operations (for example, returning it from a MATLAB Function block to Simulink execution), you must first convert it to a known type.

If the input arguments of a function are `mxArrays`, the code generator automatically treats the function as extrinsic.

## Converting mxArray to Known Types

To convert an mxArray to a known type, assign the mxArray to a variable whose type is defined. At run time, the mxArray is converted to the type of the variable that it is assigned to. However, if the data in the mxArray is not consistent with the type of the variable, you get a run-time error.

For example, consider this code:

```
function y = foo %#codegen
coder.extrinsic('rat');
[N D] = rat(pi);
y = min(N,D);
```

Here, the top-level function `foo` calls the extrinsic MATLAB function `rat`, which returns two mxArrays representing the numerator `N` and denominator `D` of the rational fraction approximation of `pi`. You can pass these mxArrays to another MATLAB function — in this case, `min`. Because the inputs passed to `min` are mxArrays, the code generator automatically treats `min` as an extrinsic function. As a result, `min` returns an mxArray.

While generating a MEX function by using MATLAB Coder, you can directly assign this mxArray returned by `min` to the output `y` because the MEX function returns its output to MATLAB.

But if you put `foo` in a MATLAB Function block in a Simulink model and then update or run the model, you get this error:

```
Function output 'y' cannot be an mxArray in this context.
Consider preinitializing the output variable with a known type.
```

This error occurs because returning an mxArray back to Simulink is not supported. To fix this problem, define `y` to be the type and size of the value that you expect `min` to return — in this case, a scalar double — as follows:

```
function y = foo %#codegen
coder.extrinsic('rat');
[N D] = rat(pi);
y = 0; % Define y as a scalar of type double
y = min(N,D);
```

## Restrictions on Using Extrinsic Functions

The full MATLAB run-time environment is not supported during code generation. Therefore, the following restrictions apply when calling MATLAB functions extrinsically:

- MATLAB functions that inspect the caller, or read or write to the caller workspace do not work during code generation. Such functions include:
  - `dbstack`
  - `evalin`
  - `assignin`
  - `save`
- Functions in generated code can produce unpredictable results if your extrinsic function performs the following actions at run time:
  - Change folders

- Change the MATLAB path
- Delete or add MATLAB files
- Change warning states
- Change MATLAB preferences
- Change Simulink parameters
- The code generator does not support the use of `coder.extrinsic` to call functions that are located in a private folder.
- The code generator does not support the use of `coder.extrinsic` to call local functions.
- You can call extrinsic functions with up to 64 inputs and 64 outputs.

## Code Generation for Recursive Functions

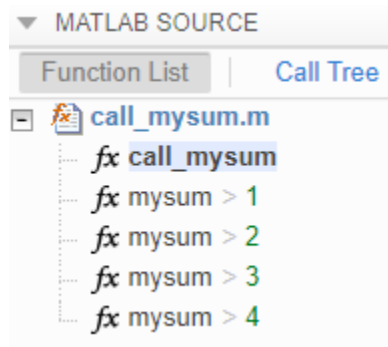

To generate code for recursive MATLAB functions, the code generator uses compile-time recursion on page 65-14 or run-time recursion on page 65-15. You can influence whether the code generator uses compile-time or run-time recursion by modifying your MATLAB code. See “Force Code Generator to Use Run-Time Recursion” on page 65-16.

You can disallow recursion on page 65-15 or disable run-time recursion on page 65-15 by modifying configuration parameters.

When you use recursive functions in MATLAB code that is intended for code generation, you must adhere to certain restrictions. See “Recursive Function Limitations for Code Generation” on page 65-15.

### Compile-Time Recursion

With compile-time recursion, the code generator creates multiple versions of a recursive function in the generated code. The inputs to each version have values or sizes that are customized for that version. These versions are known as function specializations. You can tell that the code generator used compile-time recursion by looking at the MATLAB Function report or the generated C code. Here is an example of compile-time recursion in the report.

### Run-Time Recursion

With run-time recursion, the code generator produces a recursive function in the generated code. You can tell that the code generator used run-time recursion by looking at the MATLAB Function report or the generated C code. Here is an example of run-time recursion in the report.

## Disallow Recursion

In the model configuration parameters, set **Compile-time recursion limit for MATLAB functions** to 0.

## Disable Run-Time Recursion

Some coding standards, such as MISRA®, do not allow recursion. To increase the likelihood of generating code that is compliant with MISRA C®, disable run-time recursion.

In the model configuration parameters, clear the **Enable run-time recursion for MATLAB functions** check box.

If your code requires run-time recursion and run-time recursion is disabled, you must rewrite your code so that it uses compile-time recursion or does not use recursion.

## Recursive Function Limitations for Code Generation

When you use recursion in MATLAB code that is intended for code generation, follow these restrictions:

- The top-level function in a MATLAB Function block cannot be a recursive function, but it can call a recursive function.
- Assign all outputs of a run-time recursive function before the first recursive call in the function.
- Assign all elements of cell array outputs of a run-time recursive function.
- Inputs and outputs of run-time recursive functions cannot be classes.
- The **Maximum stack size** parameter is ignored for run-time recursion.

- “Compile-time recursion limit for MATLAB functions”
- “MATLAB Function Reports” on page 45-38

## Force Code Generator to Use Run-Time Recursion

When your MATLAB code includes recursive function calls, the code generator uses compile-time or run-time recursion. With compile-time recursion on page 65-14, the code generator creates multiple versions of the recursive function in the generated code. These versions are known as function specializations. With run-time recursion on page 65-14, the code generator produces a recursive function. If compile-time recursion results in too many function specializations or if you prefer run-time recursion, you can try to force the code generator to use run-time recursion. Try one of these approaches:

- “Treat the Input to the Recursive Function as a Nonconstant” on page 65-16
- “Make the Input to the Recursive Function Variable-Size” on page 65-17
- “Assign Output Variable Before the Recursive Call” on page 65-18

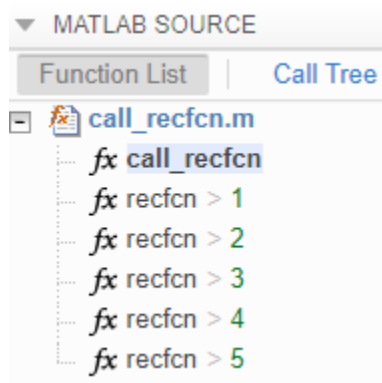

### Treat the Input to the Recursive Function as a Nonconstant

Consider this function:

```
function y = call_recfcn(n)
A = ones(1,n);
x = 5;
y = recfcn(A,x);
end

function y = recfcn(A,x)
if size(A,2) == 1 || x == 1
 y = A(1);
else
 y = A(1)+recfcn(A(2:end),x-1);
end
end
```

`call_recfcn` calls `recfcn` with the value 5 for the second argument. `recfcn` calls itself recursively until `x` is 1. For each `recfcn` call, the input argument `x` has a different value. The code generator produces five specializations of `recfcn`, one for each call. You can see the specializations in the MATLAB Function report.

To force run-time recursion, in `call_recfcn`, in the call to `recfcn`, instruct the code generator to treat the value of the input argument `x` as a nonconstant value by using `coder.ignoreConst`.

```

function y = call_recfcn(n)
A = ones(1,n);
x = coder.ignoreConst(5);
y = recfcn(A,x);
end

function y = recfcn(A,x)
if size(A,2) == 1 || x == 1
 y = A(1);
else
 y = A(1)+recfcn(A(2:end),x-1);
end
end

```

In the MATLAB Function report, you see only one specialization.

## Make the Input to the Recursive Function Variable-Size

Consider this code:

```

function z = call_mysum(A)
%#codegen
z = mysum(A);
end

function y = mysum(A)
coder.inline('never');
if size(A,2) == 1
 y = A(1);
else
 y = A(1)+mysum(A(2:end));
end
end

```

If the input to mysum is fixed-size, the code generator uses compile-time recursion. To force the code generator to use run-time conversion, make the input to mysum variable-size by using `coder.varsize`.

```

function z = call_mysum(A)
%#codegen
B = A;
coder.varsize('B');
z = mysum(B);
end

function y = mysum(A)
coder.inline('never');
if size(A,2) == 1

```

```
 y = A(1);
else
 y = A(1)+ mysum(A(2:end));
end
end
```

## Assign Output Variable Before the Recursive Call

The code generator uses compile-time recursion for this code:

```
function y = callrecursive(n)
x = 10;
y = myrecursive(x,n);
end

function y = myrecursive(x,n)
coder.inline('never')
if x > 1
 y = n + myrecursive(x-1,n-1);

else
 y = n;
end
end
```

To force the code generator to use run-time recursion, modify `myrecursive` so that the output `y` is assigned before the recursive call. Place the assignment `y = n` in the `if` block and the recursive call in the `else` block.

```
function y = callrecursive(n)
x = 10;
y = myrecursive(x,n);
end

function y = myrecursive(x,n)
coder.inline('never')
if x == 1
 y = n;
else
 y = n + myrecursive(x-1,n-1);
end
end
```

## Avoid Duplicate Functions in Generated Code

### Issue

You generate code and it contains multiple, duplicate copies of the same functions, with only slight differences, such as modifications to the function signature. For example, your generated code might contain functions called `foo` and `b_foo`. Duplicate functions can make the generated code more difficult to analyze and manage.

### Cause

Duplicate functions in the generated code are the result of function specializations. The code generator specializes functions when it detects that they differ at different call sites by:

- Number of input or output variables.
- Type of input or output variables.
- Size of input or output variables.
- Values of input variables.

In some cases, these specializations are necessary for the generated C/C++ code because C/C++ functions do not have the same flexibility as MATLAB functions. In other cases, the code generator specializes functions to optimize the generated code or because of a lack of information.

### Solution

In certain cases, you can alter your MATLAB code to avoid the generation of duplicate functions.

#### Identify Duplicate Functions by Using Code Generation Report

You can determine whether the code generator created duplicate functions by inspecting the code generation report or in Simulink, the MATLAB Function report. The report shows a list of the duplicate functions underneath the entry-point function. For example:

#### Duplicate Functions Generated for Multiple Input Sizes

If your MATLAB code calls a function multiple times and passes inputs of different sizes, the code generator can create specializations of the function for each size. To avoid this issue, use

`coder.ignoreSize` on the function input. For example, this code uses `coder.ignoreSize` to avoid creating multiple copies of the function `indexOf`:

```
function [out1, out2] = test1(in)
 a = 1:10;
 b = 2:40;
 % Without coder.ignoreSize duplicate functions are generated
 out1 = indexOf(coder.ignoreSize(a), in);
 out2 = indexOf(coder.ignoreSize(b), in);
end

function index = indexOf(array, value)
 coder.inline('never');
 for i = 1:numel(array)
 if array(i) == value
 index = i;
 return
 end
 end
 index = -1;
 return
end
```

To generate code, enter:

```
codegen test1 -config:lib -report -args {1}
```

### Duplicate Functions Generated for Different Input Values

If your MATLAB code calls a function and passes multiple different constant inputs, the code generator can create specializations of the function for each different constant. In this case, use `coder.ignoreConst` to indicate to the code generator not to treat the value as an immutable constant. For example:

```
function [out3, out4] = test2(in)
 c = ['a', 'b', 'c'];
 if in > 0
 c(2)='d';
 end
 out3 = indexOf(c, coder.ignoreConst('a'));
 out4 = indexOf(c, coder.ignoreConst('b'));
end

function index = indexOf(array, value)
 coder.inline('never');
 for i = 1:numel(array)
 if array(i) == value
 index = i;
 return
 end
 end
 index = -1;
 return
end
```

To generate code, enter:

```
codegen test2 -config:lib -report -args {1}
```

### Duplicate Functions Generated for Different Number of Outputs

If your MATLAB code calls a function and accepts a different number of outputs at different call sites, the code generator can produce specializations for each call. For example:

```
[a b] = foo();
c = foo();
```

To make each call return the same number of outputs and avoid duplicate functions, use the ~ symbol:

```
[a b] = foo();
[c, ~] = foo();
```

## Avoid Data Copies of Function Inputs in Generated Code

You can reduce the number of copies in your generated code by writing functions that use the same variable as both an input and an output. For example:

```
function A = foo(A, B) %#codegen
A = A * B;
end
```

This coding practice uses a reference parameter optimization. When a variable acts as both input and output, the generated code passes the variable by reference instead of redundantly copying the input to a temporary variable. In the preceding example, input A is passed by reference in the generated code because it also acts as an output for function foo:

```
...
/* Function Definitions */
void foo(double *A, double B)
{
 *A *= B;
}
...
```

The reference parameter optimization reduces memory usage and execution time, especially when the variable passed by reference is a large data structure. To achieve these benefits at the call site, call the function with the same variable as both input and output.

By contrast, suppose that you rewrite function foo without the optimization:

```
function y = foo2(A, B) %#codegen
y = A * B;
end
```

The generated code passes the inputs by value and returns the value of the output:

```
...
/* Function Definitions */
double foo2(double A, double B)
{
 return A * B;
}
...
```

In some cases, the output of the function cannot be a modified version of its inputs. If you do not use the inputs later in the function, you can modify your code to operate on the inputs instead of on a copy of the inputs. One method is to create additional return values for the function. For example, consider the code:

```
function y1=foo(u1) %#codegen
 x1=u1+1;
 y1=bar(x1);
end

function y2=bar(u2)
 % Since foo does not use x1 later in the function,
 % it would be optimal to do this operation in place
 x2=u2.*2;
 % The change in dimensions in the following code
```

```

 % means that it cannot be done in place
 y2=[x2,x2];
end

```

You can modify the code to eliminate redundant copies.

```

function y1=foo(u1) %#codegen
 u1=u1+1;
 [y1, u1]=bar(u1);
end

function [y2, u2]=bar(u2)
 u2=u2.*2;
 % The change in dimensions in the following code
 % still means that it cannot be done in place
 y2=[u2,u2];
end

```

The reference parameter optimization does not apply to constant inputs. If the same variable is an input and an output, and the input is constant, the code generator treats the output as a separate variable. For example, consider the function `foo`:

```

function A = foo(A, B) %#codegen
A = A * B;
end

```

Generate code in which `A` has a constant value 2.

```
codegen -config:lib foo -args {coder.Constant(2) 3} -report
```

The generated code defines the constant `A` and returns the value of the output.

```

...
#define A (2.0)
...
double foo(double B)
{
 return A * B;
}
...

```

## See Also

## Inline Code

Inlining is a technique that replaces a function call with the contents (body) of that function. Inlining eliminates the overhead of a function call, but can produce larger C/C++ code. Inlining can create opportunities for further optimization of the generated C/C++ code. The code generator uses internal heuristics to determine whether to inline functions in the generated code. You can use the `coder.inline` directive to fine-tune these heuristics for individual functions. For more information, see `coder.inline`.

### See Also

## Unroll for-Loops and parfor-Loops

When the code generator unrolls a `for`-loop or `parfor`-loop, instead of producing a loop in the generated code, it produces a copy of the loop body for each iteration. For small, tight loops, unrolling can improve performance. However, for large loops, unrolling can significantly increase code generation time and generate inefficient code.

### Force for-Loop Unrolling by Using `coder.unroll`

The code generator uses heuristics to determine when to unroll a `for`-loop. To force loop unrolling, use `coder.unroll`. This affects only the `for` loop that is immediately after `coder.unroll`. For example:

```
function z = call_myloop()
%#codegen
z = myloop(5);
end

function b = myloop(n)
b = zeros(1,n);
coder.unroll();
for i = 1:n
 b(i)=i+n;
end
end
```

Here is the generated code for the `for`-loop:

```
z[0] = 6.0;
z[1] = 7.0;
z[2] = 8.0;
z[3] = 9.0;
z[4] = 10.0;
```

To control when a `for`-loop is unrolled, use the `coder.unroll` flag argument. For example, unroll the loop only when the number of iterations is less than 10.

```
function z = call_myloop()
%#codegen
z = myloop(5);
end

function b = myloop(n)
unroll_flag = n < 10;
b = zeros(1,n);
coder.unroll(unroll_flag);
for i = 1:n
 b(i)=i+n;
end
end
```

To unroll a `for`-loop, the code generator must be able to determine the bounds of the `for`-loop. For example, code generation fails for the following code because the value of `n` is not known at code generation time.

```
function b = myloop(n)
b = zeros(1,n);
```

```
coder.unroll();
for i = 1:n
 b(i)=i+n;
end
end
```

## Generate Reusable Code

With MATLAB, you can generate reusable code in the following ways:

- Write reusable functions using standard MATLAB function file names which you can call from different locations, for example, in a Simulink model or MATLAB function library.
- Compile external functions on the MATLAB path and integrate them into generated C code for embedded targets.

See “Resolution of Function Calls for Code Generation” (MATLAB Coder).

Common applications include:

- Overriding generated library function with a custom implementation.
- Implementing a reusable library on top of standard library functions that can be used with Simulink.
- Swapping between different implementations of the same function.

## LAPACK Calls for Linear Algebra in a MATLAB Function Block

To improve the simulation speed of MATLAB Function block algorithms that call certain linear algebra functions, Simulink can call LAPACK functions. LAPACK is a software library for numerical linear algebra. If the input arrays for the linear algebra functions meet certain criteria, the simulation calls LAPACK functions in the LAPACK library that is included with MATLAB. MATLAB uses LAPACK in some linear algebra functions such as `eig` and `svd`.

If you use Simulink Coder to generate code for these algorithms, you can specify that the code generator produce LAPACK function calls. The code generator uses the LAPACKE C interface to LAPACK. If you specify that you want to generate LAPACK calls, and the input arrays for the linear algebra functions meet the criteria, the code generator produces LAPACK calls. The build process links to the LAPACK library that you specify. See “Speed Up Linear Algebra in Code Generated from a MATLAB Function Block” (Simulink Coder).

## BLAS Calls for Matrix Operations in a MATLAB Function Block

To improve the simulation speed of MATLAB Function block algorithms that call certain low-level vector and matrix functions (such as matrix multiplication), Simulink can call BLAS functions. BLAS is a software library for low-level vector and matrix computations that has several highly optimized machine-specific implementations. If the input arrays for the matrix functions meet certain criteria, the simulation calls BLAS functions in the BLAS library that is included with MATLAB.

If you use Simulink Coder to generate code for these algorithms, you can specify that the code generator produce BLAS function calls. The code generator uses the CBLAS C interface to BLAS. If you specify that you want to generate BLAS calls, and the input arrays for the matrix functions meet the criteria, the code generator produces BLAS calls. The build process links to the BLAS library that you specify. See “Speed Up Matrix Operations in Code Generated from a MATLAB Function Block” (Simulink Coder).

## **FFTW calls for fast Fourier transform functions in a MATLAB Function Block**

To execute MATLAB Function block algorithms that call MATLAB fast Fourier transform (FFT) functions (`fft`, `fft2`, `fftn`, `ifft`, `ifft2`, or `ifftn`), Simulink uses the library that MATLAB uses for FFT algorithms.

If you use Simulink Coder to generate code for these algorithms, by default, the code generator produces code for the FFT algorithms instead of producing FFT library calls. To increase the speed of fast Fourier transforms in generated code, you can specify that the code generator produce calls to a specific installed FFTW library. See “Speed Up Fast Fourier Transforms in Code Generated from a MATLAB Function Block” (Simulink Coder).

# Troubleshooting MATLAB Code in MATLAB Function Blocks

---

- “Compile-Time Recursion Limit Reached” on page 67-2
- “Output Variable Must Be Assigned Before Run-Time Recursive Call” on page 67-5
- “Unable to Determine That Every Element of Cell Array Is Assigned” on page 67-8
- “Nonconstant Index into varargin or varargout in a for-Loop” on page 67-12
- “Unknown Output Type for coder.ceval” on page 67-14

## Compile-Time Recursion Limit Reached

### Issue

You see a message such as:

```
Compile-time recursion limit reached. Size or type of
input #1 of function 'foo' may change at every call.
```

```
Compile-time recursion limit reached. Value of input #1
of function 'foo' may change at every call.
```

### Cause

With compile-time recursion, the code generator produces multiple versions of the recursive function instead of producing a recursive function in the generated code. These versions are known as function specializations. The code generator is unable to use compile-time recursion for a recursive function in your MATLAB code because the number of function specializations exceeds the limit.

### Solutions

To address the issue, try one of these solutions:

- “Force Run-Time Recursion” on page 67-2
- “Increase the Compile-Time Recursion Limit” on page 67-4

### Force Run-Time Recursion

- For this message:

```
Compile-time recursion limit reached. Value of input #1
of function 'foo' may change at every call.
```

Use this solution:

“Force Run-Time Recursion by Treating the Input Value as Nonconstant” on page 67-2.

- For this message:

```
Compile-time recursion limit reached. Size or type of
input #1 of function 'foo' may change at every call.
```

In the MATLAB Function report, look at the function specializations. If you can see that the size of an argument is changing for each function specialization, then try this solution:

“Force Run-Time Recursion by Making the Input Variable-Size” on page 67-3.

### Force Run-Time Recursion by Treating the Input Value as Nonconstant

Consider this function:

```
function y = call_recfcn(n)
A = ones(1,n);
x = 100;
```

```

y = recfcn(A,x);
end

function y = recfcn(A,x)
if size(A,2) == 1 || x == 1
 y = A(1);
else
 y = A(1)+recfcn(A(2:end),x-1);
end
end

```

The second input to `recfcn` has the constant value 100. The code generator determines that the number of recursive calls is finite and tries to produce 100 copies of `recfcn`. This number of specializations exceeds the compile-time recursion limit. To force run-time recursion, instruct the code generator to treat the second input as a nonconstant value by using `coder.ignoreConst`.

```

function y = call_recfcn(n)
A = ones(1,n);
x = coder.ignoreConst(100);
y = recfcn(A,x);
end

function y = recfcn(A,x)
if size(A,2) == 1 || x == 1
 y = A(1);
else
 y = A(1)+recfcn(A(2:end),x-1);
end
end

```

If the code generator cannot determine that the number of recursive calls is finite, it produces a run-time recursive function.

### Force Run-Time Recursion by Making the Input Variable-Size

Consider this function:

```

function z = call_mysum(A)
%#codegen
z = mysum(A);
end

function y = mysum(A)
coder.inline('never');
if size(A,2) == 1
 y = A(1);
else
 y = A(1)+mysum(A(2:end));
end
end

```

If the input to `mysum` is fixed-size, the code generator uses compile-time recursion. If `A` is large enough, the number of function specializations exceeds the compile-time limit. To cause the code generator to use run-time conversion, make the input to `mysum` variable-size by using `coder.varsize`.

```
function z = call_mysum(A)
 %#codegen
 B = A;
 coder.varsize('B');
 z = mysum(B);
end

function y = mysum(A)
 coder.inline('never');
 if size(A,2) == 1
 y = A(1);
 else
 y = A(1)+ mysum(A(2:end));
 end
end
```

## Increase the Compile-Time Recursion Limit

The default compile-time recursion limit of 50 is large enough for most recursive functions that require compile-time recursion. Usually, increasing the limit does not fix the issue. However, if you can determine the number of recursive calls and you want compile-time recursion, increase the limit. For example, consider this function:

```
function z = call_mysum()
 %#codegen
 B = 1:125;
 z = mysum(B);
end

function y = mysum(A)
 coder.inline('never');
 if size(A,2) == 1
 y = A(1);
 else
 y = A(1)+ mysum(A(2:end));
 end
end
```

You can determine that the code generator produces 125 copies of the `mysum` function. In this case, if you want compile-time recursion, increase the compile-time recursion limit to 125.

To increase the limit, increase the value of the **Compile-time recursion limit for MATLAB functions** configuration parameter.

# Output Variable Must Be Assigned Before Run-Time Recursive Call

## Issue

You see one of these messages:

All outputs must be assigned before any run-time recursive call. Output 'y' is not assigned here.

Simulink does not have enough information to determine output sizes for this block

.

## Cause

Run-time recursion produces a recursive function in the generated code. The code generator is unable to use run-time recursion for a recursive function in your MATLAB code because an output is not assigned before the first recursive call.

## Solution

Rewrite the code so that it assigns the output before the recursive call.

### Direct Recursion Example

In the following code, the statement `y = A(1)` assigns a value to the output `y`. This statement occurs after the recursive call `y = A(1)+ mysum(A(2:end))`.

```
function z = call_mysum(A)
B = A;
coder.varsize('B');
z = mysum(B);
end

function y = mysum(A)
coder.inline('never');
if size(A,2) > 1
 y = A(1)+ mysum(A(2:end));

else
 y = A(1);
end
end
```

Rewrite the code so that assignment `y = A(1)` occurs in the `if` block and the recursive call occurs in the `else` block.

```
function z = call_mysum(A)
B = A;
coder.varsize('B');
z = mysum(B);
end
```

```
function y = mysum(A)
coder.inline('never');

if size(A,2) == 1
 y = A(1);
else
 y = A(1)+ mysum(A(2:end));
end
end
```

Alternatively, before the if block, add an assignment, for example,  $y = 0$ .

```
function z = call_mysum(A)
B = A;
coder.varsize('B');
z = mysum(B);
end

function y = mysum(A)
coder.inline('never');
y = 0;
if size(A,2) > 1
 y = A(1)+ mysum(A(2:end));

else
 y = A(1);
end
end
```

### Indirect Recursion Example

In the following code, `rec1` calls `rec2` before the assignment  $y = 0$ .

```
function z = callrec(n)
z = rec1(n);
end

function y = rec1(x)
%#codegen

if x >= 0
 y = rec2(x-1)+1;
else
 y = 0;
end
end

function y = rec2(x)
y = rec1(x-1)+2;
end
```

Rewrite this code so that in `rec1`, the assignment  $y = 0$  occurs in the if block and the recursive call occurs in the else block.

```
function z = callrec(n)
z = rec1(n);
end
```

```
function y = rec1(x)
 %#codegen

 if x < 0
 y = 0;
 else
 y = rec2(x-1)+1;
 end
end

function y = rec2(x)
 y = rec1(x-1)+2;
end
```

## Unable to Determine That Every Element of Cell Array Is Assigned

### Issue

You see one of these messages:

```
Unable to determine that every element of 'y' is
assigned before this line.
```

```
Unable to determine that every element of 'y' is
assigned before exiting the function.
```

```
Unable to determine that every element of 'y' is
assigned before exiting the recursively called function.
```

### Cause

For code generation, before you use a cell array element, you must assign a value to it. When you use `cell` to create a variable-size cell array, for example, `cell(1,n)`, MATLAB assigns an empty matrix to each element. However, for code generation, the elements are unassigned. For code generation, after you use `cell` to create a variable-size cell array, you must assign all elements of the cell array before any use of the cell array.

The code generator analyzes your code to determine whether all elements are assigned before the first use of the cell array. The code generator detects that all elements are assigned when the code follows this pattern:

```
function z = CellVarSize1D(n, j)
%#codegen
assert(n < 100);
x = cell(1,n);
for i = 1:n
 x{i} = i;
end
z = x{j};
end
```

Here is the pattern for a multidimensional cell array:

```
function z = CellAssign3D(m,n,p)
%#codegen
assert(m < 100);
assert(n < 100);
assert(p < 100);
x = cell(m,n,p);
for i = 1:m
 for j = 1:n
 for k = 1:p
 x{i,j,k} = i+j+k;
 end
 end
end
z = x{m,n,p};
end
```

If the code generator detects that some elements are not assigned, code generation fails. Sometimes, even though your code assigns all elements of the cell array, code generation fails because the analysis does not detect that all elements are assigned.

Here are examples where the code generator is unable to detect that elements are assigned:

- Elements are assigned in different loops

```
...
x = cell(1,n)
for i = 1:5
 x{i} = 5;
end
for i = 6:n
 x{i} = 7;
end
...
```

- The variable that defines the loop end value is not the same as the variable that defines the cell dimension.

```
...
x = cell(1,n);
m = n;
for i = 1:m
 x{i} = 2;
end
...
```

For more information, see “Definition of Variable-Size Cell Array by Using cell” on page 56-7.

## Solution

Try one of these solutions:

- “Use recognized pattern for assigning elements” on page 67-9
- “Use repmat” on page 67-9
- “Use coder.nullcopy” on page 67-10

### Use recognized pattern for assigning elements

If possible, rewrite your code to follow this pattern:

```
...
x = cell(1,n);
for i = 1:n
 x{i} = i;
end
z = x{j};
...
```

### Use repmat

Sometimes, you can use repmat to define the variable-size cell array.

Consider this code that defines a variable-size cell array. It assigns the value 1 to odd elements and the value 2 to even elements.

```
function z = repDefine(n, j)
%#codegen
assert(n < 100);
c = cell(1,n);
for i = 1:2:n-1
 c{i} = 1;
end
for i = 2:2:n
 c{i} = 2;
end
z = c{j};
```

Code generation does not allow this code because:

- More than one loop assigns the elements.
- The loop counter does not increment by 1.

Rewrite the code to first use `cell` to create a 1-by-2 cell array whose first element is 1 and whose second element is 2. Then, use `repmat` to create a variable-size cell array whose element values alternate between 1 and 2.

```
function z = repVarSize(n, j)
%#codegen
assert(n < 100);
c = cell(1,2);
c{1} = 1;
c{2} = 2;
c1= repmat(c,1,n);
z = c1{j};
end
```

You can pass an initially empty, variable-size cell array into or out of a function by using `repmat`. Use the following pattern:

```
function x = emptyVarSizeCellArray
x = repmat({'abc'},0,0);
coder.varsize('x');
end
```

This code indicates that `x` is an empty, variable-size cell array of 1x3 characters that can be passed into or out of functions.

### Use `coder.nullcopy`

As a last resort, you can use `coder.nullcopy` to indicate that the code generator can allocate the memory for your cell array without initializing the memory. For example:

```
function z = nulcpyCell(n, j)
%#codegen
assert(n < 100);
c = cell(1,n);
c1 = coder.nullcopy(c);
for i = 1:4
 c1{i} = 1;
end
for i = 5:n
 c1{i} = 2;
```

```
end
z = cl{j};
end
```

Use `coder.nullcopy` with caution. If you access uninitialized memory, results are unpredictable.

## More About

- “Cell Array Limitations for Code Generation” on page 56-6

## Nonconstant Index into varargin or varargout in a for-Loop

### Issue

Your MATLAB code contains a for-loop that indexes into varargin or varargout. When you generate code, you see this error message:

```
Non-constant expression or empty matrix. This expression
must be constant because its value determines the size
or class of some expression.
```

### Cause

At code generation time, the code generator must be able to determine the value of an index into varargin or varargout. When varargin or varargout are indexed in a for-loop, the code generator determines the index value for each loop iteration by unrolling the loop. Loop unrolling makes a copy of the loop body for each loop iteration. In each iteration, the code generator determines the value of the index from the loop counter.

The code generator is unable to determine the value of an index into varargin or varargout when:

- The number of copies of the loop body exceeds the limit for loop unrolling.
- Heuristics fail to identify that loop unrolling is warranted for a particular for-loop. For example, consider the following function:

```
function [x,y,z] = fcn(a,b,c)
 %#codegen

 [x,y,z] = subfcn(a,b,c);

 function varargout = subfcn(varargin)
 j = 0;
 for i = 1:nargin
 j = j+1;
 varargout{j} = varargin{j};
 end
```

The heuristics do not detect the relationship between the index *j* and the loop counter *i*. Therefore, the code generator does not unroll the for-loop.

### Solution

Use one of these solutions:

- “Force Loop Unrolling” on page 67-12
- “Rewrite the Code” on page 67-13

#### Force Loop Unrolling

Force loop unrolling by using `coder.unroll`. For example:

```
function [x,y,z] = fcn(a,b,c)
 %#codegen
```

```
[x,y,z] = subfcn(a,b,c);

function varargout = subfcn(varargin)
j = 0;

coder.unroll();
for i = 1:nargin
 j = j + 1;
 varargout{j} = varargin{j};
end
```

### Rewrite the Code

Rewrite the code so that the code generator can detect the relationship between the index and the loop counter. For example:

```
function [x,y,z] = fcn(a,b,c)
%#codegen
[x,y,z] = subfcn(a,b,c);

function varargout = subfcn(varargin)
for i = 1:nargin
 varargout{i} = varargin{i};
end
```

## Unknown Output Type for coder.ceval

### Issue

You see this error message:

```
Output of 'coder.ceval' has unknown type. The enclosing
expression cannot be evaluated.
Specify the output type by assigning the output of
'coder.ceval' to a variable with a known type.
```

### Cause

This error message occurs when the code generator cannot determine the output type of a `coder.ceval` call.

### Solution

Initialize a temporary variable with the expected output type. Assign the output of `coder.ceval` to this variable.

### Example

Assume that you have a C function called `cFunctionThatReturnsDouble`. You want to generate C library code for a function `foo`. The code generator returns the error message because it cannot determine the return type of `coder.ceval`.

```
function foo
%#codegen
callFunction(coder.ceval('cFunctionThatReturnsDouble'));
end

function callFunction(~)
end
```

To fix the error, define the type of the C function output by using a temporary variable.

```
function foo
%#codegen
temp = 0;
temp = coder.ceval('cFunctionThatReturnsDouble');
callFunction(temp);
end

function callFunction(~)
end
```

You can also use `coder.opaque` to initialize the temporary variable.

### Example Using Classes

Assume that you have a class with a custom `set` method. This class uses the `set` method to ensure that the object property value falls within a certain range.

```

classdef classWithSetter
 properties
 expectedResult = []
 end
 properties(Constant)
 scalingFactor = 0.001
 end
 methods
 function obj = set.expectedResult(obj,erIn)
 if erIn >= 0 && erIn <= 100
 erIn = erIn.*obj.scalingFactor;
 obj.expectedResult = erIn;
 else
 obj.expectedResult = NaN;
 end
 end
 end
end
end
end

```

When generating C library code for the function `foo`, the code generator produces the error message. The input type into the `set` method cannot be determined.

```

function foo
 %#codegen
 obj = classWithSetter;
 obj.expectedResult = coder.ceval('cFunctionThatReturnsDouble');
end

```

To fix the error, initialize a temporary variable with a known type. For this example, use a type of scalar double.

```

function foo
 %#codegen
 obj = classWithSetter;
 temp = 0;
 temp = coder.ceval('cFunctionThatReturnsDouble');
 obj.expectedResult = temp;
end

```

## About Data Types in Simulink

### In this section...

“About Data Types” on page 68-2

“Data Typing Guidelines” on page 68-2

“Data Type Propagation” on page 68-3

### About Data Types

The term *data type* refers to the way in which a computer represents numbers or text in memory. A data type determines the amount of storage allocated to a number or letter, the method used to encode the number's value as a pattern of binary digits, and the operations available for manipulating the type. Most computers provide a choice of data types for representing numbers, each with specific advantages in the areas of precision, dynamic range, performance, and memory usage. To optimize performance, you can specify the data types of variables used in the MATLAB technical computing environment. Simulink builds on this capability by allowing you to specify the data types of Simulink signals and block parameters.

The ability to specify the data types of a model's signals and block parameters is particularly useful in real-time control applications. For example, it allows a Simulink model to specify the optimal data types to use to represent signals and block parameters in code generated from a model by automatic code-generation tools, such as the Simulink Coder product. By choosing the most appropriate data types for your model's signals and parameters, you can dramatically increase performance and decrease the size of the code generated from the model.

Simulink performs extensive checking before and during a simulation to ensure that your model is *typesafe*, that is, that code generated from the model will not overflow or underflow and thus produce incorrect results. Simulink models that use the default data type (`double`) are inherently typesafe. Thus, if you never plan to generate code from your model or use a nondefault data type in your models, you can skip the remainder of this section.

On the other hand, if you plan to generate code from your models and use nondefault data types, read the remainder of this section carefully, especially the section on data type rules (see “Data Typing Guidelines” on page 68-2). In that way, you can avoid introducing data type errors that prevent your model from running to completion or simulating at all.

### Data Typing Guidelines

Observing the following rules can help you to create models that are typesafe and, therefore, execute without error:

- Signal data types generally do not affect parameter data types, and vice versa.

A significant exception to this rule is the Constant block, whose output data type is determined by the data type of its parameter.

- If the output of a block is a function of an input and a parameter, and the input and parameter differ in type, Simulink converts the parameter to the input type before computing the output.
- In general, a block outputs the data type that appears at its inputs.

Significant exceptions include Constant blocks and Data Type Conversion blocks, whose output data types are determined by block parameters.

- Virtual blocks accept signals of any type on their inputs.

Examples of virtual blocks include Mux and Demux blocks and unconditionally executed subsystems.

- The elements of a signal array connected to a port of a nonvirtual block must be of the same data type.
- The signals connected to the input data ports of a nonvirtual block cannot differ in type.
- Control ports (for example, Enable and Trigger ports) accept any data type.
- Solver blocks accept only `double` signals.
- Connecting a non-`double` signal to a block disables zero-crossing detection for that block.

## Data Type Propagation

Whenever you start a simulation, enable display of port data types, or refresh the port data type display, Simulink performs a processing step called data type propagation. This step involves determining the types of signals whose type is not otherwise specified and checking the types of signals and input ports to ensure that they do not conflict. If type conflicts arise, an error dialog is displayed that specifies the signal and port whose data types conflict. The signal path that creates the type conflict is also highlighted.

---

**Note** You can insert typecasting (data type conversion) blocks in your model to resolve type conflicts. For more information, see [Data Type Conversion](#).

## Data Types Supported by Simulink

Simulink supports all built-in numeric MATLAB data types. The term *built-in data type* refers to data types defined by MATLAB itself as opposed to data types defined by MATLAB users. Unless otherwise specified, the term data type in the Simulink documentation refers to built-in data types.

The following table lists the built-in MATLAB data types supported by Simulink.

| Name                | Description                                                           |
|---------------------|-----------------------------------------------------------------------|
| <code>double</code> | Double-precision floating point                                       |
| <code>single</code> | Single-precision floating point                                       |
| <code>int8</code>   | Signed 8-bit integer                                                  |
| <code>uint8</code>  | Unsigned 8-bit integer                                                |
| <code>int16</code>  | Signed 16-bit integer                                                 |
| <code>uint16</code> | Unsigned 16-bit integer                                               |
| <code>int32</code>  | Signed 32-bit integer                                                 |
| <code>uint32</code> | Unsigned 32-bit integer                                               |
| <code>int64</code>  | Signed 64-bit integer                                                 |
| <code>uint64</code> | Unsigned 64-bit integer                                               |
| <code>half</code>   | Half-precision floating point (requires Fixed-Point Designer license) |
| <code>string</code> | Text                                                                  |

Some model elements do not support all data types. For more information on the data types supported by a specific block for parameter and input and output values, see the Data Type Support section of the reference page for that block.

Besides these built-in types, Simulink defines a `boolean` (`true` or `false`) type. The values `1` and `0` represent `true` and `false` respectively. For this data type, Simulink represents real, nonzero numeric values (including `Inf`) as `true` (`1`).

### Block Support for Data and Signal Types

All Simulink blocks accept signals of type `double` by default. Some blocks prefer `boolean` input and others support multiple data types on their inputs. For more information on the data types supported by a specific block for parameter and input and output values, see the reference page for that block. If the documentation for a block does not specify a data type, the block inputs or outputs only data of type `double`.

Several blocks support bus objects (`Simulink.Bus`) as data types. See “Data Types for Buses” on page 68-40.

Many Simulink blocks also support fixed-point data types. For more information about fixed-point data, see “Specify Fixed-Point Data Types” on page 68-28. For more information on the data types supported by a specific block for parameter and input and output values, in the Simulink documentation see the Data Type Support section of the reference page for that block. If the documentation for a block does not specify a data type, the block inputs or outputs only data of type `double`.

To view a table that summarizes the data types supported by the blocks in the Simulink block libraries, execute the following command at the MATLAB command line:

```
showblockdatatypetable
```

## Control Data Types of Signals

To control the data type of a signal in a Simulink model, you specify a data type for the corresponding block output.

You can also introduce a new signal of a specific data type into a model in any of the following ways:

- Load signal data of the desired type from the MATLAB workspace into your model via a root-level Inport block or a From Workspace block.
- Create a Constant block in your model and set its parameter to the desired type.
- Use a Data Type Conversion block to convert a signal to the desired data type.

Simulink blocks determine the data type of their outputs by default. Many blocks allow you to override the default type and explicitly specify an output data type, using a block parameter that is typically named **Output data type**. For example, the **Output data type** parameter appears on the **Signal Attributes** pane of the Constant block dialog box.

See the following topics for more information:

| For Information About...                                             | See...                                                       |
|----------------------------------------------------------------------|--------------------------------------------------------------|
| Valid data type values that you can specify                          | "Entering Valid Data Type Values" on page 68-6               |
| An assistant that helps you specify valid data type values           | "Specify Data Types Using Data Type Assistant" on page 68-30 |
| Specifying valid data type values for multiple blocks simultaneously | "Use the Model Data Editor for Batch Editing" on page 68-8   |

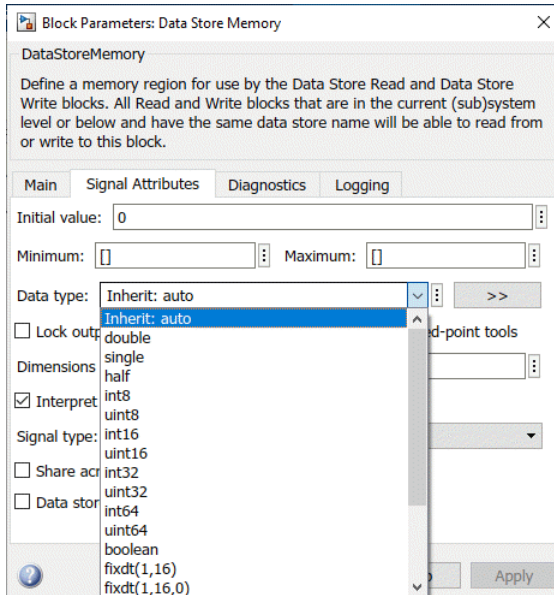

## Entering Valid Data Type Values

In general, you can specify the output data type as any of the following:

- A rule that inherits a data type (see "Data Type Inheritance Rules" on page 68-7)
- The name of a built-in data type (see "Built-In Data Types" on page 68-8)

- An expression that evaluates to a data type (see “Data Type Expressions” on page 68-8)

Valid data type values vary among blocks. You can use the pull-down menu associated with a block data type parameter to view the data types that a particular block supports. For example, the **Data type** pull-down menu on the Data Store Memory block dialog box lists the data types that it supports, as shown here.

For more information about the data types that a specific block supports, see the documentation for the block in the Simulink documentation.

### Data Type Inheritance Rules

Blocks can inherit data types from a variety of sources, including signals to which they are connected and particular block parameters. You can specify the value of a data type parameter as a rule that determines how the output signal inherits its data type. To view the inheritance rules that a block supports, use the data type pull-down menu on the block dialog box. The following table lists typical rules that you can select.

| Inheritance Rule                      | Description                                                                                                                                                                                                                     |
|---------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Inherit: Inherit via back propagation | Simulink automatically determines the output data type of the block during data type propagation (see “Data Type Propagation” on page 68-3). In this case, the block uses the data type of a downstream block or signal object. |
| Inherit: Same as input                | The block uses the data type of its sole input signal for its output signal.                                                                                                                                                    |
| Inherit: Same as first input          | The block uses the data type of its first input signal for its output signal.                                                                                                                                                   |
| Inherit: Same as second input         | The block uses the data type of its second input signal for its output signal.                                                                                                                                                  |

| Inheritance Rule                   | Description                                                                                                                                                                                                                                                                                                                                                            |
|------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Inherit: Inherit via internal rule | The block uses an internal rule to determine its output data type. The internal rule chooses a data type that optimizes numerical accuracy, performance, and generated code size, while taking into account the properties of the embedded target hardware. It is not always possible for the software to optimize efficiency and numerical accuracy at the same time. |

When you apply inherited data types to a signal, Simulink determines the specific data type of the signal only after you update the block diagram.

- To display this specific data type on the block diagram, see “Port Data Types” on page 76-53.
- To inspect this specific data type for multiple signals in a searchable, sortable table, use the Model Data Editor (on the **Modeling** tab, click **Model Data Editor**). The right side of the **Data Type** column shows the specific data type for each signal. For more information, see **Model Data Editor**.

### Built-In Data Types

You can specify the value of a data type parameter as the name of a built-in data type, for example, `single` or `boolean`. To view the built-in data types that a block supports, use the data type pull-down menu on the block dialog box. See “Data Types Supported by Simulink” on page 68-4 for a list of all built-in data types that are supported.

### Data Type Expressions

You can specify the value of a data type parameter as an expression that evaluates to a numeric data type object. Simply enter the expression in the data type field on the block dialog box. In general, enter one of the following expressions:

- **fixdt Command**

Specify the value of a data type parameter as a command that invokes the `fixdt` function. This function allows you to create a `Simulink.NumericType` object that describes a fixed-point or floating-point data type. See the documentation for the `fixdt` function for more information.

- **Data Type Object Name**

Specify the value of a data type parameter as the name of a data object that represents a data type. Simulink data objects that you instantiate from classes, such as `Simulink.NumericType` and `Simulink.AliasType`, simplify the task of making model-wide changes to output data types and allow you to use custom aliases for data types. See “Data Objects” on page 68-59 for more information about Simulink data objects.

### Use the Model Data Editor for Batch Editing

Using the **Model Data Editor**, you can assign the same data type to multiple signals simultaneously. You can use this technique to design the interface of your model by configuring data types and other attributes of multiple Inport and Outport blocks at once (see “Configure Data Interfaces” on page 22-21). You can also finely control the data types of arbitrary signals in your block algorithm.

For example, the `slexAircraftExample` model in the “Aircraft Longitudinal Flight Control” example contains numerous Gain blocks. Suppose you want to specify the output data type of the three Gain blocks at the root level of the model as `single`. You can achieve this task as follows:

- 1 In the Model Data Editor (on the **Modeling** tab, click **Model Data Editor**), inspect the **Signals** tab.
- 2 Next to the **Filter contents** box, toggle the **Filter using selection** button.
- 3 At the top level of the model, select the signal lines that represent the outputs of the three Gain blocks (labeled `Zw`, `Mw`, and `Mq`). The Model Data Editor shows three rows that correspond to the three signals.
- 4 In the Model Data Editor, select all three signals (rows). For example, you can press **Ctrl+A** or hold **Shift** while clicking the top and bottom rows in the **Source** column.
- 5 For any of the three signals, click the cell in the **Data Type** column. From the drop-down list, select `single`. The Model Data Editor applies this selection to all of the selected rows.

To convert a model to a strict single precision design, see “Validate a Floating-Point Embedded Model” on page 68-12.

## Share a Data Type Between Separate Algorithms, Data Paths, Models, and Bus Elements

In some cases, you cannot rely on data type inheritance (see “Data Type Inheritance Rules” on page 68-7) to establish equivalence between the data types of different data items (such as signal lines in parallel data paths or bus elements in a `Simulink.Bus` object). Instead, you can create a `Simulink.NumericType` or `Simulink.AliasType` object in a workspace or data dictionary.

Create a `Simulink.NumericType` object if you do not want to rename the shared data type by creating an alias. Set the `IsAlias` property to `false` (the default).

This example shows how to use a `Simulink.NumericType` object to share an output data type between two lookup table blocks in the same model.

- 1 Open the example model `sldemo_fuelsys`.

```
sldemo_fuelsys
```

The model creates `Simulink.NumericType` objects in the base workspace. One of the objects is named `s16En15`.

- 2 At the command prompt, inspect the properties of `s16En15`.

```
s16En15
s16En15 =
 NumericType with properties:
 DataTypeMode: 'Single'
 IsAlias: 0
 DataScope: 'Auto'
 HeaderFile: ''
 Description: ''
```

This object represents the built-in Simulink data type `single`.

- 3 In the model, navigate into the `fuel_rate_control/airflow_calc` subsystem.
- 4 On the **Modeling** tab, click **Model Data Editor**. In the Model Data Editor, inspect the **Signals** tab.
- 5 In the model, click the output signal of the Pumping Constant block. The Model Data Editor **Data Type** column shows that the signal data type is set to `s16En15`.
- 6 Click the output signal of the Ramp Rate Ki block. The output data type of this block is also set to `s16En15`.
- 7 Update the block diagram and, if necessary, expand the width of the **Data Type** column. The right side of the column shows that the two lookup table blocks use the data type `single`.
- 8 At the command prompt, configure `s16En15` to represent the data type `double`.

```
s16En15.DataTypeMode = 'Double';
```

- 9 Update the block diagram.

The output signals of the two lookup table blocks now use the data type `double`. Due to data type inheritance, other signals, such as `e0` and `e1`, acquire the same data type.

Alternatively, to establish data type equivalence between algorithms or data paths in the same model, you can use blocks such as Data Type Propagation and Data Type Conversion Inherited. When you use these blocks, you do not need to create and permanently store a data type object. However, you cannot use the blocks to share a data type between signals in different models unless the models are in the same model reference hierarchy.

## Reuse Custom C Data Types for Signal Data

In a model, you can create signals that conform to custom C data types, such as structures, that your existing C code defines. Use these signals to:

- Replace existing C code with a Simulink model.
- Integrate C code for simulation in Simulink (for example, by using the Legacy Code Tool).
- Prepare to generate code (Simulink Coder) that you can integrate with existing code.

Use these techniques to match your custom data types:

- For a structure type, create a `Simulink.Bus` object. Use the object as the data type for bus signals. See “Data Types for Buses” on page 68-40.
- For an enumeration, create an enumeration class and use it as the data type for signals. See “Use Enumerated Data in Simulink Models” on page 69-6.
- To match a `typedef` statement that represents an alias of a primitive, numeric data type, use a `Simulink.AliasType` object as the data type for signals. See `Simulink.AliasType`.

To create these classes and objects, you can use the function `Simulink.importExternalCTypes`.

If a MATLAB Function block or Stateflow chart in your model uses an imported enumeration or structure type, configure the model configuration parameters to include (`#include`) the type definition from your external header file. See “Control Imported Bus and Enumeration Type Definitions” on page 45-112 (for a MATLAB Function block) and “Access Custom Code Variables and Functions in Stateflow Charts” (Stateflow) and “Integrate Custom Structures in Stateflow Charts” (Stateflow) (for a chart).

## Determine Data Type of Signal That Uses Inherited Setting

When a signal uses an inherited data type setting such as `Inherit: Inherit via internal rule` (the default setting for most blocks), to determine the meaningful data type that the signal uses for simulation, update the block diagram and then use one or both of these techniques:

- In the Simulink Editor, on the **Debug** tab, select **Information Overlays** and navigate to the ports section. Select the port data type you want to display. The data types appear on the block diagram next to each signal. For more information, see “Port Data Types” on page 76-53.
- Inspect the right side of the **Data Type** column in the Model Data Editor (on the **Modeling** tab, click **Model Data Editor**). For more information, see **Model Data Editor**.

Using these techniques to inspect data types helps you to:

- Design the data type strategy for a model on a high level.
- Debug numerical issues due to quantization and overflows.
- Make a model more easily understood when sharing it.

For more information, see “Port Data Types” on page 76-53.

## Data Types Remain double Despite Changing Settings

If many of the data items (signals, parameters, and states) in your model continue to use the data type `double` after you configure block parameters such as **Output data type**, confirm that the model is not configured to override data types. See “Control Data Type Override” on page 68-26.

## Validate a Floating-Point Embedded Model

You can use data type override mode to temporarily switch the data types in your model. This capability allows you to maintain one model but simulate your model using multiple data types, and validate the numerical behavior for each type. For example, if you implement an algorithm using double-precision data types and want to check whether the algorithm is also suitable for single-precision use, you can apply a data type override to floating-point data types to replace all doubles with singles without permanently affecting any other data types in your model.

### Apply a Data Type Override to Floating-Point Data Types

To apply data type override, you must specify the data type that you want to apply and the data type that you want to replace.

You can set data type override using the following method. This example changes all floating-point data types to single.

For example:

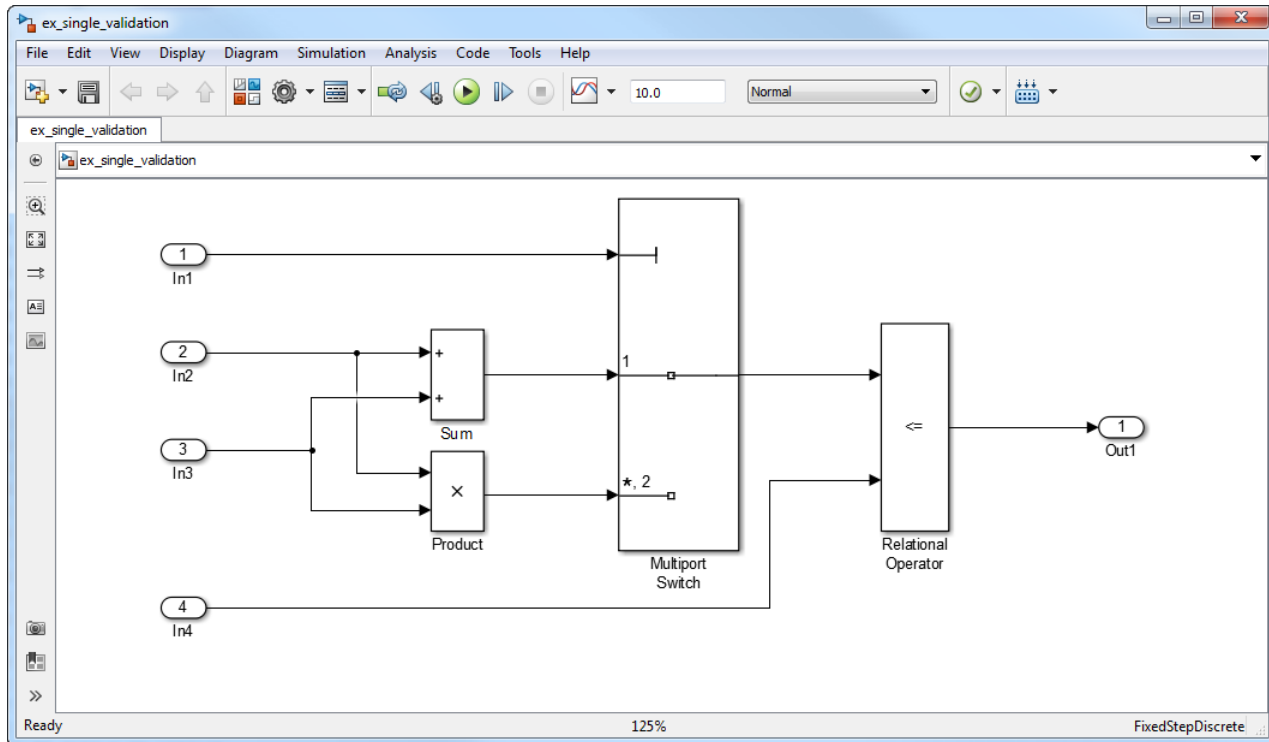

```
set_param(gcs, 'DataTypeOverride', 'Single', ...
 'DataTypeOverrideAppliesTo', 'Floating-point');
```

For more information on data type override settings, see “Control Data Type Override” on page 68-26.

### Validate a Single-Precision Model

This example uses the `ex_single_validation` model to show how you can use data type override. It proves that an algorithm, which implements double-precision data types, is also suitable for single-precision embedded use.

## About the Model

- The inputs In2 and In3 are double-precision inputs to the Sum and Product blocks.
- The outputs of the Sum and Product blocks are data inputs to the Multiport Switch block.
- The input In1 is the control input to the Multiport Switch block. The value of this control input determines which of its other inputs, the sum of In2 and In3 or the product of In2 and In3, passes to the output port. Because In1 is a control input, its data type is `int8`.
- The Relational Operator block compares the output of the Multiport Switch block to In4, and outputs a Boolean signal.

## Run the Example

### Open the Model

- 1 Open the `ex_single_validation` model. At the MATLAB command line, enter:

```
addpath(fullfile(docroot, 'toolbox', 'simulink', 'examples'))
ex_single_validation
```

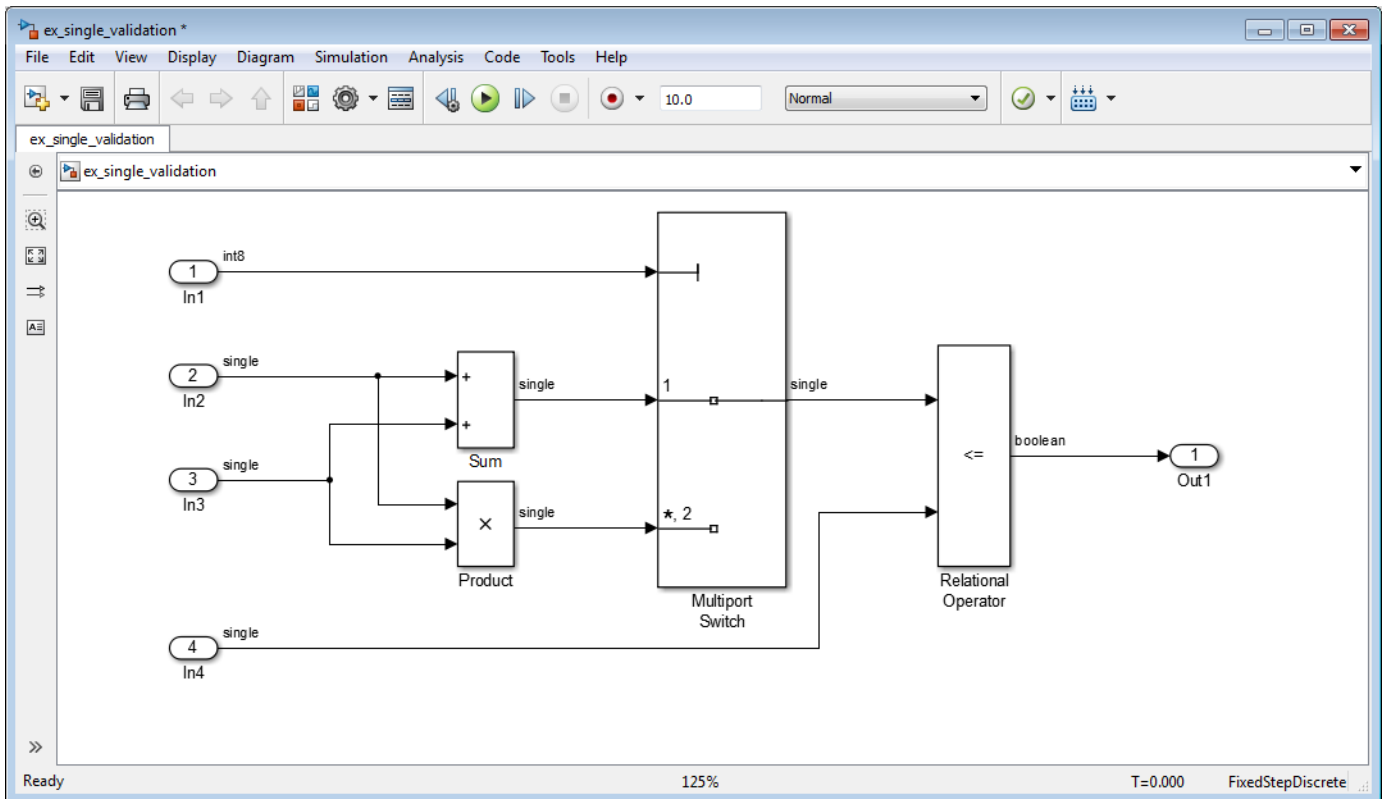

### Override Floating-Point Data Types With Singles

- 1 At the command line, override the floating-point data types in the model with singles

```
set_param(gcs, 'DataTypeOverride', 'Single', ...
'DataTypeOverrideAppliesTo', 'Floating-point');
```

- 2 In the model, on the **Modeling** tab, click **Update Model**.

The data type override replaces all the floating-point (double) data types in the model with single data types, but does not affect the integer or Boolean data types.

### Run Model Advisor Check

- 1 From the model, on the **Modeling** tab, click **Model Advisor**.
- 2 In the System Selector dialog box, click **OK**.

The Model Advisor opens.

- 3 In the Model Advisor, expand the **By Task** node and, under **Modeling Single-Precision Systems**, select the **Identify questionable operations for strict single-precision design** check.
- 4 In the right pane, click **Run This Check**.

The check passes indicating that this algorithm is suitable for single-precision use. To ensure that no double-precision data types remain in the generated code, use the Single-Precision Converter before generating code for single-precision embedded use. For more information, see “Getting Started with Single Precision Converter” (Fixed-Point Designer).

### Blocks That Support Single Precision

To identify Simulink blocks that support single precision, at the command prompt, enter `showblockdatatypetable`. In a model, to find blocks that do not support single precision, use the Model Advisor check “Identify questionable operations for strict single-precision design”.

## Fixed-Point Numbers

### In this section...

“Binary Point Interpretation” on page 68-16

“Signed Fixed-Point Numbers” on page 68-17

In digital hardware, numbers are stored in binary words. A binary word is a fixed-length sequence of binary digits (1's and 0's). The way in which hardware components or software functions interpret this sequence of 1's and 0's is described by a data type. There are several distinct differences between fixed-point data types and the built-in integer types in MATLAB®. The most notable difference, is that the built-in integer data types can only represent whole numbers, while the fixed-point data types also contain information on the position of the binary point, or the scaling of the number.

Binary numbers are represented as either fixed-point or floating-point data types. A fixed-point data type is characterized by the word size in bits, the binary point, and whether it is signed or unsigned. The position of the binary point is the means by which fixed-point values are scaled and interpreted. With Fixed-Point Designer, fixed-point data types can be integers, fractionals, or generalized fixed-point numbers. The main difference between these data types is their default binary point. For example, a binary representation of a generalized fixed-point number (either signed or unsigned) is shown below:

where

- $b_i$  is the  $i^{\text{th}}$  binary digit.
- $wl$  is the word length in bits.
- $b_{wl-1}$  is the location of the most significant, or highest, bit (MSB).
- $b_0$  is the location of the least significant, or lowest, bit (LSB).
- The binary point is shown four places to the left of the LSB. In this example, therefore, the number is said to have four fractional bits, or a fraction length of four.

### Binary Point Interpretation

The binary point is the means by which fixed-point numbers are scaled. It is usually the software that determines the binary point. When performing basic math functions such as addition or subtraction, the hardware uses the same logic circuits regardless of the value of the scale factor. In essence, the logic circuits have no knowledge of a scale factor. They are performing signed or unsigned fixed-point binary algebra as if the binary point is to the right of  $b_0$ .

Fixed-Point Designer supports the general binary point scaling  $V=Q*2^E$ .  $V$  is the real-world value,  $Q$  is the stored integer value, and  $E$  is equal to  $-\text{FractionLength}$ . In other words,  $\text{RealWorldValue} = \text{StoredInteger} * 2^{-\text{FractionLength}}$ .

$\text{FractionLength}$  defines the scaling of the stored integer value. The word length limits the values that the stored integer can take, but it does not limit the values  $\text{FractionLength}$  can take. The

software does not restrict the value of exponent  $E$  based on the word length of the stored integer  $Q$ . Because  $E$  is equal to  $-\text{FractionLength}$ , restricting the binary point to being contiguous with the fraction is unnecessary; the fraction length can be negative or greater than the word length.

For example, a word consisting of three unsigned bits is usually represented in scientific notation in one of the following ways.

$$\begin{aligned}bbb. &= bbb. \times 2^0 \\bb.b &= bbb. \times 2^{-1} \\b.bb &= bbb. \times 2^{-2} \\\.bbb &= bbb. \times 2^{-3}\end{aligned}$$

If the exponent were greater than 0 or less than -3, then the representation would involve lots of zeros.

$$\begin{aligned}bbb00000. &= bbb. \times 2^5 \\bbb00. &= bbb. \times 2^2 \\\.00bbb &= bbb. \times 2^{-5} \\\.00000bbb &= bbb. \times 2^{-8}\end{aligned}$$

These extra zeros never change to ones, however, so they don't show up in the hardware. Furthermore, unlike floating-point exponents, a fixed-point exponent never shows up in the hardware, so fixed-point exponents are not limited by a finite number of bits.

Consider a signed value with a word length of 8, a fraction length of 10, and a stored integer value of 5 (binary value 00000101). The real-world value is calculated using the formula  $\text{RealWorldValue} = \text{StoredInteger} * 2^{-\text{FractionLength}}$ . In this case,  $\text{RealWorldValue} = 5 * 2^{-10} = 0.0048828125$ . Because the fraction length is 2 bits longer than the word length, the binary value of the stored integer is  $x.xx00000101$ , where  $x$  is a placeholder for implicit zeros.  $0.0000000101$  (binary) is equivalent to  $0.0048828125$  (decimal). For an example using a `fi` object, see "Fraction Length Greater Than Word Length" (Fixed-Point Designer).

## Signed Fixed-Point Numbers

Computer hardware typically represents the negation of a binary fixed-point number in three different ways: sign/magnitude, one's complement, and two's complement. Two's complement is the preferred representation of signed fixed-point numbers and is the only representation used by Fixed-Point Designer.

Negation using two's complement consists of a bit inversion (translation into one's complement) followed by the addition of a one. For example, the two's complement of 000101 is 111011.

Whether a fixed-point value is signed or unsigned is usually not encoded explicitly within the binary word; that is, there is no sign bit. Instead, the sign information is implicitly defined within the computer architecture.

### **More About**

- “Scaling, Precision, and Range” on page 68-20

## Benefits of Using Fixed-Point Hardware

Digital hardware is becoming the primary means by which control systems and signal processing filters are implemented. Digital hardware can be classified as either off-the-shelf hardware (for example, microcontrollers, microprocessors, general-purpose processors, and digital signal processors) or custom hardware. Within these two types of hardware, there are many architecture designs. These designs range from systems with a single instruction, single data stream processing unit to systems with multiple instruction, multiple data stream processing units.

Within digital hardware, numbers are represented as either fixed-point or floating-point data types. For both of these data types, word sizes are fixed at a set number of bits. However, the dynamic range of fixed-point values is much less than floating-point values with equivalent word sizes. Therefore, in order to avoid overflow or unreasonable quantization errors, fixed-point values must be scaled. Since floating-point processors can greatly simplify the real-time implementation of a control law or digital filter, and floating-point numbers can effectively approximate real-world numbers, then why use a microcontroller or processor with fixed-point hardware support?

- **Size and Power Consumption** — The logic circuits of fixed-point hardware are much less complicated than those of floating-point hardware. This means that the fixed-point chip size is smaller with less power consumption when compared with floating-point hardware. For example, consider a portable telephone where one of the product design goals is to make it as portable (small and light) as possible. If one of today's high-end floating-point, general-purpose processors is used, a large heat sink and battery would also be needed, resulting in a costly, large, and heavy portable phone.
- **Memory Usage and Speed** — In general fixed-point calculations require less memory and less processor time to perform.
- **Cost** — Fixed-point hardware is more cost effective where price/cost is an important consideration. When digital hardware is used in a product, especially mass-produced products, fixed-point hardware costs much less than floating-point hardware and can result in significant savings.

After making the decision to use fixed-point hardware, the next step is to choose a method for implementing the dynamic system (for example, control system or digital filter). Floating-point software emulation libraries are generally ruled out because of timing or memory size constraints. Therefore, you are left with fixed-point math where binary integer values are scaled.

## Scaling, Precision, and Range

### In this section...

“Scaling” on page 68-20

“Precision” on page 68-20

“Range” on page 68-21

The dynamic range of fixed-point values is less than floating-point values with equivalent word sizes. To avoid overflow and minimize quantization errors, fixed-point numbers must be scaled.

### Scaling

With Fixed-Point Designer, you can select a fixed-point data type whose scaling is defined by its binary point, or you can select an arbitrary linear scaling that suits your needs.

#### Slope and Bias Scaling

You can represent a fixed-point number by a general slope and bias encoding scheme. The real world value of a slope bias scaled number can be represented by:

$$\text{real-world value} = (\text{slope} \times \text{integer}) + \text{bias}$$

$$\text{slope} = \text{slope adjustment factor} \times 2^{\text{fixed exponent}}$$

The slope and bias together represent the scaling of the fixed-point number. In a number with zero bias, only the slope affects the scaling. A fixed-point number that is only scaled by binary point position is equivalent to a number in slope bias representation that has a bias equal to zero and a slope adjustment factor equal to one. This is referred to as binary point-only scaling or power-of-two scaling.

#### Binary-Point-Only Scaling

Binary-point-only or power-of-two scaling involves moving the binary point within the fixed-point word. The advantage of this scaling mode is to minimize the number of processor arithmetic operations. The real world value of a binary-point only scaled number can be represented by:

$$\text{real world value} = 2^{-\text{fraction length}} \times \text{integer}$$

### Precision

The precision of a fixed-point number is the difference between successive values representable by its data type and scaling, which is equal to the value of its least significant bit. The value of the least significant bit, and therefore the precision of the number, is determined by the number of fractional bits. A fixed-point value can be represented to within half of the precision of its data type and scaling.

For example, a fixed-point representation with four bits to the right of the binary point has a precision of  $2^{-4}$  or 0.0625, which is the value of its least significant bit. Any number within the range of this data type and scaling can be represented to within  $(2^{-4})/2$  or 0.03125, which is half the precision.

#### Rounding Methods

When you represent numbers with finite precision, not every number in the available range can be represented exactly. If a number cannot be represented exactly by the specified data type and

scaling, a rounding method is used to cast the value to a representable number. Although precision is always lost in the rounding operation, the cost of the operation and the amount of bias that is introduced depends on the rounding method itself. For more information on the rounding methods available with Fixed-Point Designer, see “Rounding Methods” (Fixed-Point Designer)

## Range

Range is the span of numbers that a fixed-point data type and scaling can represent. The range of representable numbers for an unsigned two’s complement fixed-point number of word length  $w$ , scaling  $S$ , and bias  $B$  is illustrated below:

The following figure illustrates the range of representable numbers for a two’s complement signed fixed-point number:

For both signed and unsigned fixed-point numbers of any data type, the number of different bit patterns is  $2^{wl}$ .

For example, in two’s complement, negative numbers must be represented as well as zero, so the maximum value is  $2^{wl-1}-1$ . Because there is only one representation for zero, there are an unequal number of positive and negative numbers. This means there is a representation for  $-2^{wl-1}$ , but not for  $2^{wl-1}$ .

### Fixed-Point Data in Simulink

You can use the `fixdt` function in Simulink to specify a fixed-point data type. The `fixdt` function creates a `Simulink.NumericType` object.

#### Fixed-Point Data Type and Scaling Notation

Simulink data type names must be valid MATLAB identifiers with less than 128 characters. The data type name provides information about container type, number encoding, and scaling.

The following table provides a key for various symbols that appear in Simulink products to indicate the data type and scaling of a fixed-point value.

| Symbol                  | Description                                                                       | Example                                                                                            |
|-------------------------|-----------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------|
| <b>Container Type</b>   |                                                                                   |                                                                                                    |
| <code>ufix</code>       | Unsigned fixed-point data type                                                    | <code>ufix8</code> is an 8-bit unsigned fixed-point data type                                      |
| <code>sfix</code>       | Signed fixed-point data type                                                      | <code>sfix128</code> is a 128-bit signed fixed-point data type                                     |
| <code>fltu</code>       | Scaled double override of an unsigned fixed-point data type ( <code>ufix</code> ) | <code>fltu32</code> is a scaled doubles override of <code>ufix32</code>                            |
| <code>flts</code>       | Scaled double override of a signed fixed-point data type ( <code>sfix</code> )    | <code>flts64</code> is a scaled doubles override of <code>sfix64</code>                            |
| <b>Number Encoding</b>  |                                                                                   |                                                                                                    |
| <code>e</code>          | $10^{\wedge}$                                                                     | <code>125e8</code> equals $125 * (10^{\wedge}(8))$                                                 |
| <code>n</code>          | Negative                                                                          | <code>n31</code> equals -31                                                                        |
| <code>p</code>          | Decimal point                                                                     | <code>1p5</code> equals 1.5<br><code>p2</code> equals 0.2                                          |
| <b>Scaling Encoding</b> |                                                                                   |                                                                                                    |
| <code>S</code>          | Slope                                                                             | <code>ufix16_S5_B7</code> is a 16-bit unsigned fixed-point data type with Slope of 5 and Bias of 7 |
| <code>B</code>          | Bias                                                                              | <code>ufix16_S5_B7</code> is a 16-bit unsigned fixed-point data type with Slope of 5 and Bias of 7 |

| Symbol      | Description                                                                                                                                                                         | Example                                                                                                                                                                                                              |
|-------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| E           | Fixed exponent ( $2^{\wedge}$ )<br>A negative fixed exponent describes the fraction length                                                                                          | <code>sfix32_En31</code> is a 32-bit signed fixed-point data type with a fraction length of 31                                                                                                                       |
| F           | Slope adjustment factor                                                                                                                                                             | <code>ufix16_Flp5_En50</code> is a 16-bit unsigned fixed-point data type with a <code>SlopeAdjustmentFactor</code> of 1.5 and a <code>FixedExponent</code> of -50                                                    |

## Fixed-Point Data in MATLAB

To assign a fixed-point data type to a number or variable in MATLAB, use the `fi` constructor. The resulting fixed-point value is called a `fi` object. For example, the following creates `fi` objects `a` and `b` with attributes shown in the display, all of which we can specify when the variables are constructed. Note that when the `FractionLength` property is not specified, it is set automatically to "best precision" for the given word length, keeping the most-significant bits of the value. When the `WordLength` property is not specified it defaults to 16 bits.

```
a = fi(pi)
```

```
a =
```

```
3.1416015625
```

```
DataTypeMode: Fixed-point: binary point scaling
Signedness: Signed
WordLength: 16
FractionLength: 13
```

```
b = fi(0.1)
```

```
b =
```

```
0.0999984741210938
```

```
DataTypeMode: Fixed-point: binary point scaling
```

```
Signedness: Signed
WordLength: 16
FractionLength: 18
```

### **Read Fixed-Point Data from the Workspace**

Use the From Workspace block to read fixed-point data from the MATLAB workspace into a Simulink model. To do this, the data must be in structure format with a `fi` object in the `values` field. In array format, the From Workspace block only accepts real, double-precision data.

### **Write Fixed-Point Data to the Workspace**

You can write fixed-point output from a model to the MATLAB workspace via the To Workspace block in either array or structure format. Fixed-point data written by a To Workspace block to the workspace in structure format can be read back into a Simulink model in structure format by a From Workspace block.

## **Scaled Doubles**

Scaled doubles are a hybrid between floating-point and fixed-point numbers. Fixed-Point Designer stores them as doubles with the scaling, sign, and word length information retained. For example, the storage container for a fixed-point data type `sfixed16_En14` is `int16`. The storage container of the equivalent scaled doubles data type, `floats16_En14` is floating-point double. Fixed-Point Designer applies the scaling information to the stored floating-point double to obtain the real-world value. Storing the value in a double almost always eliminates overflow and precision issues.

## Share Fixed-Point Models

You can edit a model containing fixed-point blocks without having Fixed-Point Designer. However, you must have Fixed-Point Designer to:

- Update a Simulink diagram (**Ctrl+D**) containing fixed-point data types
- Run a model containing fixed-point data types
- Generate code from a model containing fixed-point data types
- Log the minimum and maximum values produced by a simulation
- Automatically scale the output of a model

If you do not have Fixed-Point Designer, you can work with a model containing Simulink blocks with fixed-point settings as follows:

- 1 `set_param(gcs, 'DataTypeOverride', 'Double', ...  
'DataTypeOverrideAppliesTo', 'AllNumericTypes', ...  
'MinMaxOverflowLogging', 'ForceOff')`
- 2 If you use `fi` objects or embedded numeric data types in your model, set the `fipref` `DataTypeOverride` property to `TrueDoubles` or `TrueSingles` (to be consistent with the model-wide data type override setting) and the `DataTypeOverrideAppliesTo` property to `All numeric types`.

For example, at the MATLAB command line, enter:

```
p = fipref('DataTypeOverride', 'TrueDoubles', ...
 'DataTypeOverrideAppliesTo', 'AllNumericTypes');
```

---

**Note** If you use `fi` objects or embedded numeric data types in your model or workspace, you might introduce fixed-point data types into your model. You can set `fipref` to prevent the checkout of a Fixed-Point Designer license.

## Control Fixed-Point Instrumentation and Data Type Override

### In this section...

“Control Instrumentation Settings” on page 68-26

“Control Data Type Override” on page 68-26

“Instrumentation Settings and Data Type Override for a Model Reference Hierarchy” on page 68-26

The conversion of a model from floating point to fixed point requires configuring fixed-point instrumentation and data type overrides. However, leaving these settings on after the conversion can lead to unexpected results. If you do not have Fixed-Point Designer, you can work with a model containing Simulink blocks with fixed-point settings by turning off fixed-point instrumentation and setting data type override to scaled doubles.

### Control Instrumentation Settings

The fixed-point instrumentation mode controls which objects log minimum, maximum, and overflow data during simulation. Instrumentation is required to collect simulation ranges using the Fixed-Point Tool. These ranges are used to propose data types for the model. When you are not actively converting your model to fixed point, disable the fixed-point instrumentation to restore the maximum simulation speed to your model.

To enable instrumentation outside of the Fixed-Point Tool, at the command line set the `MinMaxOverflowLogging` parameter to `MinMaxAndOverflow` or `OverflowOnly`.

```
set_param('MyModel', 'MinMaxOverflowLogging', 'MinMaxAndOverflow')
```

Instrumentation requires a Fixed-Point Designer license. To disable instrumentation on a model, set the parameter to `ForceOff` or `UseLocalSettings`.

```
set_param('MyModel', 'MinMaxOverflowLogging', 'UseLocalSettings')
```

### Control Data Type Override

Use data type override to simulate your model using double, single, or scaled double data types. If you do not have Fixed-Point Designer software, you can still configure data type override settings to simulate a model that specifies fixed-point data types. Using this setting, the software temporarily overrides data types with floating-point data types during simulation.

```
set_param('MyModel', 'DataTypeOverride', 'Double')
```

To observe the true behavior of your model, set the data type override parameter to `UseLocalSettings` or `Off`.

```
set_param('MyModel', 'DataTypeOverride', 'Off')
```

### Instrumentation Settings and Data Type Override for a Model Reference Hierarchy

When you simulate a model that contains referenced models, the data type override and fixed-point instrumentation settings for the top-level model do not control the settings for the referenced models.

You must specify these settings separately for the referenced model. If the settings are inconsistent, for example, if you set the top-level model data type override setting to double and the referenced model to use local settings and the referenced model uses fixed-point data types, data type propagation issues might occur.

When you change the fixed-point instrumentation and data type override settings for any instance of a referenced model, the settings change on all instances of the model and on the referenced model itself.

- “Share Fixed-Point Models” on page 68-25

## Specify Fixed-Point Data Types

Simulink allows you to create models that use fixed-point numbers to represent signals and parameter values. Use of fixed-point data can reduce the memory requirements and increase the speed of code generated from a model.

To execute a model that uses fixed-point numbers, you must have the Fixed-Point Designer product installed on your system. Specifically, you must have the product to:

- Update a Simulink diagram (**Ctrl+D**) containing fixed-point data types
- Run a model containing fixed-point data types
- Generate code from a model containing fixed-point data types
- Log the minimum and maximum values produced by a simulation
- Automatically scale the output of a model using the autoscaling tool

If the Fixed-Point Designer product is not installed on your system, you can execute a fixed-point model as a floating-point model by enabling automatic conversion of fixed-point data to floating-point data during simulation. See “Overriding Fixed-Point Specifications” on page 68-28 for details.

If you do not have the Fixed-Point Designer product installed and do not enable automatic conversion of fixed-point to floating-point data, an error occurs if you try to execute a fixed-point model.

---

**Note** You do not need the Fixed-Point Designer product to edit a model containing fixed-point blocks, or to use the Data Type Assistant to specify fixed-point data types, as described in “Specifying a Fixed-Point Data Type” on page 68-32.

Fixed-point data types that resolve to a base integer type do not require a Fixed-Point Designer license. For example, a block or signal that specifies a data type of `fixdt(1,8,0)`, which is equivalent to the `int8` built-in type will not check out a Fixed-Point Designer license.

---

## Overriding Fixed-Point Specifications

Most of the functionality in the Fixed-Point Tool is for use with Fixed-Point Designer. However, even if you do not have Fixed-Point Designer, you can configure data type override settings to simulate a model that specifies fixed-point data types. In this mode, Simulink temporarily overrides fixed-point data types with floating-point data types when simulating the model.

---

**Note** If you use `fi` (Fixed-Point Designer) objects or embedded numeric data types in your model or workspace, you might introduce fixed-point data types into your model. You can set `fipref` (Fixed-Point Designer) to prevent the checkout of a Fixed-Point Designer license.

---

To simulate a model without using Fixed-Point Designer, enter the following at the command line.

```
set_param(gcs, 'DataTypeOverride', 'Double', ...
'DataTypeOverrideAppliesTo', 'AllNumericTypes')
```

If you use `fi` objects or embedded numeric data types in your model, set the `fipref` `DataTypeOverride` property to `TrueDoubles` or `TrueSingles` (to be consistent with the model-wide data type override setting) and the `DataTypeOverrideAppliesTo` property to `All` numeric types.

For example, at the MATLAB command line, enter:

```
p = fipref('DataTypeOverride', 'TrueDoubles', ...
 'DataTypeOverrideAppliesTo', 'AllNumericTypes');
```

## Specify Data Types Using Data Type Assistant

The **Data Type Assistant** is an interactive graphical tool that simplifies the task of specifying data types for blocks and data objects. The assistant appears on block and object dialog boxes, adjacent to parameters that provide data type control, such as the **Output data type** parameter. For example, it appears on the **Signal Attributes** tab of the Block Parameters dialog box for the Constant block.

You can selectively show or hide the **Data Type Assistant** by clicking the applicable button:

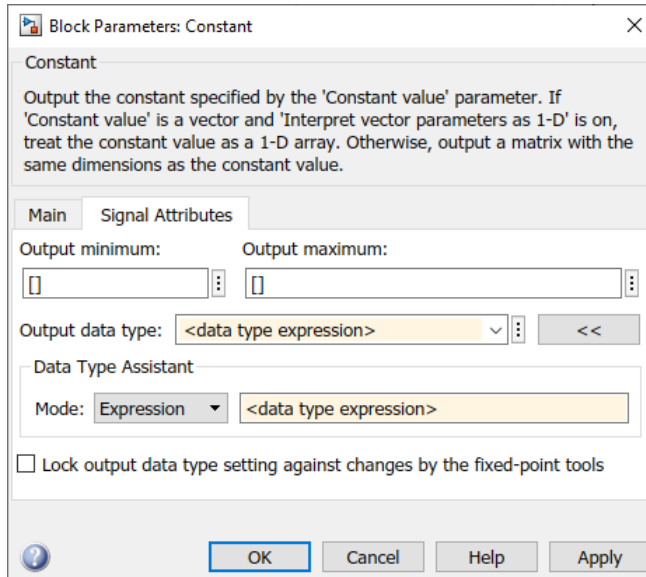

- Click the **Show data type assistant** button  to display the assistant.
- Click the **Hide data type assistant** button  to hide a visible assistant.

Use the **Data Type Assistant** to specify a data type as follows:

- 1 From the **Mode** list, select the category of data type that you want to specify. In general, these options are included.

| Mode        | Description                                             |
|-------------|---------------------------------------------------------|
| Inherit     | Inheritance rules for data types                        |
| Built in    | Built-in data types                                     |
| Fixed point | Fixed-point data types                                  |
| Enumerated  | Enumerated data types                                   |
| Bus object  | Bus object data types                                   |
| Value type  | Application-specific value types, such as wind velocity |
| Expression  | Expressions that evaluate to data types                 |

The assistant changes dynamically to display different options that correspond to the selected mode. For example, setting **Mode** to **Expression** in the Block Parameters dialog box for a Constant block updates the values in the boxes next to **Output data type** and **Mode**.

- 2 To the right of the **Mode** list, select or enter a data type.

For example, suppose you designate the variable `myDataType` as an alias for a single data type. You create an instance of the `Simulink.AliasType` class and set its `BaseType` property by entering these commands.

```
myDataType = Simulink.AliasType
myDataType.BaseType = 'single'
```

You can use this data type object to specify the output data type of a Constant block. Enter the data type alias name, `myDataType`, as the value of the expression in the assistant.

- 3 Click **OK** or **Apply** to apply your changes.

The assistant uses the data type that you specified to populate the associated data type parameter in the block or object dialog box. For example, the **Output data type** parameter of the Constant block specifies the same expression that you entered using the assistant.

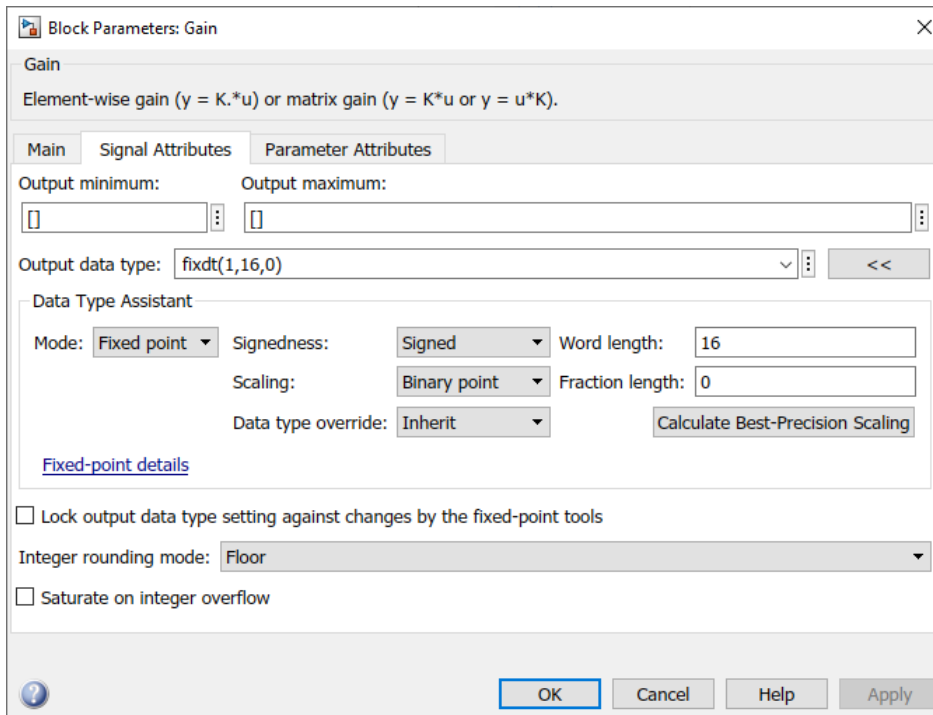

For more information about the data types that you can specify using the **Data Type Assistant**, see “Entering Valid Data Type Values” on page 68-6. For details about specifying fixed-point data types, see “Specify Fixed-Point Data Types with the Data Type Assistant” (Fixed-Point Designer).

## Specifying a Fixed-Point Data Type

When the Data Type Assistant **Mode** is **Fixed point**, the Data Type Assistant displays fields for specifying information about your fixed-point data type. For example, the next figure shows the Block Parameters dialog box for a Gain block, with the **Signal Attributes** tab selected and a fixed-point data type specified.

If the **Scaling** is Slope and bias rather than Binary point, the Data Type Assistant displays a **Slope** field and a **Bias** field rather than a **Fraction length** field:

You can use the Data Type Assistant to set these fixed-point properties:

### Signedness

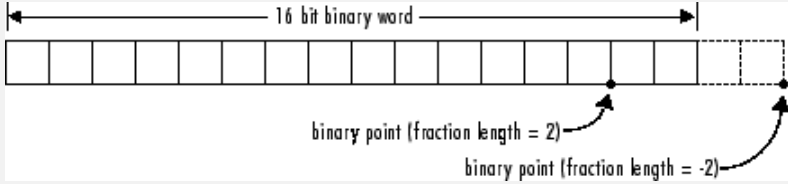

Specify whether you want the fixed-point data to be **Signed** or **Unsigned**. Signed data can represent positive and negative values, but unsigned data represents positive values only. The default setting is **Signed**.

### Word length

Specify the bit size of the word that will hold the quantized integer. Large word sizes represent large values with greater precision than small word sizes. Word length can be any integer between 0 and 128. The default bit size is 16.

## Scaling

Specify the method for scaling your fixed-point data to avoid overflow conditions and minimize quantization errors. The default method is Binary point scaling. You can select one of two scaling modes:

| Scaling Mode   | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Binary point   | <p>If you select this mode, the Data Type Assistant displays the <b>Fraction Length</b> field, which specifies the binary point location.</p> <p>Binary points can be positive or negative integers. A positive integer moves the binary point left of the rightmost bit by that amount. For example, an entry of 2 sets the binary point in front of the second bit from the right. A negative integer moves the binary point further right of the rightmost bit by that amount, as in this example:</p>  <p>The default binary point is 0.</p> |
| Slope and bias | <p>If you select this mode, the Data Type Assistant displays fields for entering the <b>Slope</b> and <b>Bias</b>.</p> <p>Slope can be any positive real number, and the default slope is 1.0. Bias can be any real number, and the default bias is 0.0. You can enter slope and bias as expressions that contain parameters you define in the MATLAB workspace.</p>                                                                                                                                                                                                                                                               |

**Note** Use binary-point scaling whenever possible to simplify the implementation of fixed-point data in generated code. Operations with fixed-point data using binary-point scaling are performed with simple bit shifts and eliminate expensive code implementations, which are required for separate slope and bias values.

For more information about fixed-point scaling, see “Scaling” (Fixed-Point Designer).

### Data type override

When the **Mode** is **Built in** or **Fixed point**, you can use the **Data type override** option to specify whether you want this data type to inherit or ignore the data type override setting specified for its context, that is, for the block, `Simulink.Signal` object or Stateflow chart in Simulink that is using the signal. The default behavior is `Inherit`.

| Data Type Override Mode | Description                                                                                                                                                                     |
|-------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Inherit (default)       | Inherits the data type override setting from its context, that is, from the block, <code>Simulink.Signal</code> object or Stateflow chart in Simulink that is using the signal. |

| Data Type Override Mode | Description                                                                                                        |
|-------------------------|--------------------------------------------------------------------------------------------------------------------|
| Off                     | Ignores the data type override setting of its context and uses the fixed-point data type specified for the signal. |

The ability to turn off data type override for an individual data type provides greater control over the data types in your model when you apply data type override. For example, you can use this option to ensure that data types meet the requirements of downstream blocks regardless of the data type override setting.

### Calculate Best-Precision Scaling

Click this button to calculate best-precision values for both **Binary point** and **Slope and bias** scaling, based on the specified minimum and maximum values. Simulink displays the scaling values in the **Fraction Length** field or the **Slope** and **Bias** fields. For more information, see “Constant Scaling for Best Precision” (Fixed-Point Designer).

### Showing Fixed-Point Details

When you specify a fixed-point data type, you can use the **Fixed-point details** subpane to see information about the fixed-point data type that is currently displayed in the Data Type Assistant. To see the subpane, click the expander next to **Fixed-point details** in the Data Type Assistant. The **Fixed-point details** subpane appears at the bottom of the Data Type Assistant:

Output minimum:  Output maximum:

Output data type:  <<

Data Type Assistant

Mode:  Signedness:  Word length:

Scaling:  Slope:

Bias:

Data type override:

[Fixed-point details](#)

Representable maximum: 32767

Output maximum:

Constant value: 90

Output minimum:

Representable minimum: -32768

Precision: 1

The rows labeled **Output minimum** and **Output maximum** show the same values that appear in the corresponding **Output minimum** and **Output maximum** fields above the Data Type Assistant. The names of these fields may differ from those shown. For example, a fixed-point block parameter would show **Parameter minimum** and **Parameter maximum**, and the corresponding **Fixed-point details** rows would be labeled accordingly. See “Specify Signal Ranges” on page 76-34 and “Specify Minimum and Maximum Values for Block Parameters” on page 37-52 for more information.

The rows labeled `Representable minimum`, `Representable maximum`, and `Precision` always appear. These rows show the minimum value, maximum value, and precision that can be represented by the fixed-point data type currently displayed in the Data Type Assistant.

The values displayed by the **Fixed-point details** subpane *do not* automatically update if you click **Calculate Best-Precision Scaling**, or change the range limits, the values that define the fixed-point data type, or anything elsewhere in the model. To update the values shown in the **Fixed-point details** subpane, click **Refresh Details**. The Data Type Assistant then updates or recalculates all values and displays the results.

Clicking **Refresh Details** does not change anything in the model, it only changes the display. Click **OK** or **Apply** to put the displayed values into effect. If the value of a field cannot be known without first compiling the model, the **Fixed-point details** subpane shows the value as `Unknown`.

If any errors occur when you click **Refresh Details**, the **Fixed-point details** subpane shows an error flag on the left of the applicable row, and a description of the error on the right. For example, the next figure shows two errors:

The screenshot shows the Data Type Assistant interface. At the top, there are input fields for 'Output minimum:' (containing 'MySymbol') and 'Output maximum:' (containing '50000'). Below these is a dropdown for 'Output data type:' set to 'fixdt(1,16,0)' with a '<<' button. The main 'Data Type Assistant' panel has the following settings:

- Mode: Fixed point
- Signedness: Signed
- Word length: 16
- Scaling: Binary point
- Fraction length: 0
- Data type override: Inherit

There is a 'Calculate Best-Precision Scaling' button. Below the settings is the 'Fixed-point details' subpane, which contains the following information:

|                        |          |                                                          |
|------------------------|----------|----------------------------------------------------------|
| Representable maximum: | 32767    |                                                          |
| ⚠ Output maximum:      | 50000    | Outside representable range by 17233 (17233 x precision) |
| ⚠ Output minimum:      | MySymbol | Cannot evaluate                                          |
| Representable minimum: | -32768   |                                                          |

At the bottom, it shows 'Precision: 1' and a 'Refresh Details' button.

The row labeled `Output minimum` shows the error `Cannot evaluate` because evaluating the expression `MySymbol`, specified in the **Output minimum** field, did not return an appropriate numeric value. When an expression does not evaluate successfully, the **Fixed-point details** subpane displays the unevaluated expression (truncating to 10 characters if necessary to save space) in place of the unavailable value.

To correct the error in this case, you would need to define `MySymbol` in an accessible workspace to provide an appropriate numeric value. After you clicked **Refresh Details**, the value of `MySymbol` would appear in place of its unevaluated text, and the error indicator and error description would disappear.

To correct the error shown for `Output maximum`, you would need to decrease **Output maximum**, increase **Word length**, or decrease **Fraction length** (or some combination of these changes) sufficiently to allow the fixed-point data type to represent the maximum value that it could have.

Other values relevant to a particular block can also appear in the **Fixed-point details** subpane. For example, on a Discrete-Time Integrator block **Signal Attributes** tab, the subpane can look like this:

|                                                              |                                 |
|--------------------------------------------------------------|---------------------------------|
| <input type="checkbox"/> <a href="#">Fixed-point details</a> |                                 |
| Representable maximum:                                       | 32767                           |
| Output maximum:                                              | <input type="text" value="[]"/> |
| Upper saturation limit:                                      | inf                             |
| Initial condition:                                           | 1 .. 4                          |
| Lower saturation limit:                                      | -inf                            |
| Output minimum:                                              | <input type="text" value="[]"/> |
| Representable minimum:                                       | -32768                          |
|                                                              |                                 |
| Precision:                                                   | 1                               |

The values displayed for **Upper saturation limit** and **Lower saturation limit** are greyed out. This appearance indicates that the corresponding parameters are not currently used by the block. The greyed-out values can be ignored.

To conserve space, **Initial condition** displays the smallest value and the largest value in the vector or matrix, using ellipsis to represent the other values. The underlying definition of the vector or matrix is unaffected.

### Lock output data type setting against changes by the fixed-point tools

Select this check box to prevent replacement of the current data type with a type that the Fixed-Point Tool or Fixed-Point Advisor chooses. For instructions on autoscaling fixed-point data, see “Scaling” (Fixed-Point Designer).

## Specify an Enumerated Data Type

You can use the **Data Type Assistant** to specify an enumerated object as a data type for a block. In the **Data Type Assistant**, set **Mode** to Enumerated and specify an enumerated object.

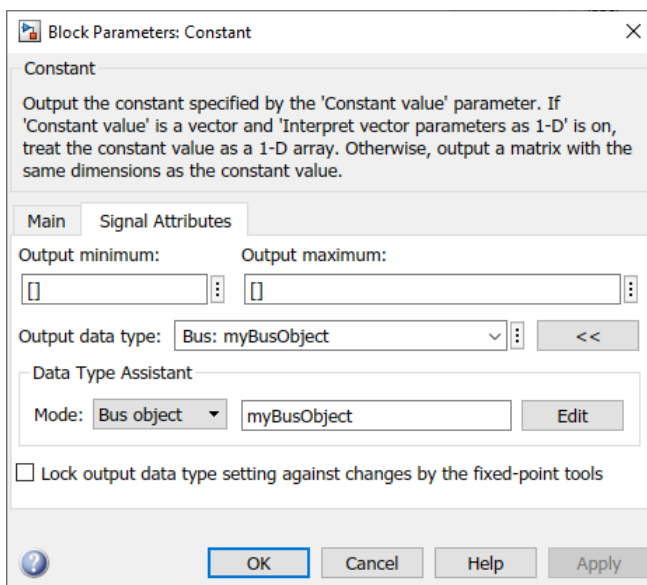

For details about enumerated data types, see “Data Types”.

## Specify a Bus Object Data Type

You can use the **Data Type Assistant** to specify a `Simulink.Bus` object as a data type for a block or data object.

- For information on blocks that support `Bus` object data types, see “Data Types for Buses” on page 68-40. You can use the Block Parameters dialog box to access the Data Type Assistant.
- For `Simulink.Signal` and `Simulink.Parameter` objects, use the **Model Explorer** to access the Data Type Assistant.
- For `Simulink.BusElement` objects, use the **Bus Editor** to access the Data Type Assistant.

In the **Data Type Assistant**, set **Mode** to `Bus` object and specify a `Bus` object.

For more information on specifying a `Bus` object data type, see “Specify Bus Properties with `Simulink.Bus` Object Data Types” on page 77-51.

## Specify a Value Type

You can use the **Data Type Assistant** to specify a `Simulink.ValueType` object as a data type for a block or `Simulink.BusElement` object.

- For information on blocks that support `ValueType` object data types, see `Simulink.ValueType`. You can use the Block Parameters dialog box to access the Data Type Assistant.
- For `Simulink.BusElement` objects, use the **Bus Editor** to access the Data Type Assistant.

In the **Data Type Assistant**, set **Mode** to `Value` type and specify a `ValueType` object.

For more information on specifying value types, see “Specify Application-Specific Signal Properties” on page 76-48.

- “Data Types for Buses” on page 68-40

## Data Types for Buses

A `Simulink.Bus` object specifies the architectural properties of a bus, as distinct from the values of the signals or messages it contains. For example, a `Bus` object can specify the number of elements in a bus, the order of those elements, whether and how elements are nested, and the data types of constituent elements; but not the values.

You can specify a `Bus` object as a data type for the following blocks:

- Bus Creator
- Constant
- Data Store Memory
- In Bus Element
- Inport
- Out Bus Element
- Outport
- Signal Specification

You can specify a `Bus` object as a data type for the following objects:

- `Simulink.BusElement`
- `Simulink.Parameter`
- `Simulink.Signal`

See “Specify a Bus Object Data Type” on page 68-38 for information about how to specify a `Bus` object as a data type for blocks and objects.

## Simulink Strings

Use strings in multiple applications when you want to pass and manipulate text. For example, when modeling a fuel control system, instead of using enumerated data to model the fuel levels, you can use strings like "LOW" or "EMPTY". Simulink strings are compatible with MATLAB strings.

Simulink strings are a built-in signal data type. They appear in the Simulink Editor as "strN" (for example, string with maximum length of  $N$  characters) or "string" for strings without maximum length (dynamic strings). String lengths can range from 1 to 32,766 characters.

Simulink string signals are inherently discrete. If your string signal has a continuous sample time, the model generates an error at compilation time.

Simulink treats string variables and expressions, such as "a" + "b", the same way it treats numeric variables. The value of a string variable can be both a character vector and a MATLAB string. String variables can exist in base, model, and mask workspaces.

String literals are specified with double quotes ("Hello") or single quotes ('Hello'). To be consistent with MATLAB strings, use double quotes. Strings appear on ports and in the Display block with double quotes.

Simulink strings support 256 characters of the ISO/IEC 8859-1 character set. These characters are the first 256 code points of Unicode. Simulink does not support the first character char(0) ("NULL") and returns an error if the string contains this character.

When a character cannot be displayed, the block stores the actual information and outputs an escape character with the associated octal value for the character. For example, the decimal value control character for BREAK PERMITTED HERE is 130. The block displays this control character as the escaped octal \02. The ASCII to String block returns as escaped octals characters in the Unicode set range 0000 to 001F and 007F-009F.

This topic describes how to use strings in Simulink, including:

- A list of available string blocks and blocks particular to string conversions
- Passing string constants into other string blocks
- Null characters in strings
- Strings with no maximum length
- Interactions with Stateflow
- Generated code
- Limitations

This topic also includes simple examples illustrating how to use string blocks. Examples in this topic enable the display of block names. To control the display of block names, on the **Format** tab, select **Auto > Hide Automatic Block Names**. For example, you can use string blocks to display and extract coordinate data and find patterns in strings.

To work with strings in your model, use this table:

| Action                                     | Block           |
|--------------------------------------------|-----------------|
| Convert a uint8 vector to a string signal. | ASCII to String |

| Action                                                                                                    | Block              |
|-----------------------------------------------------------------------------------------------------------|--------------------|
| Compose an output string signal based on the <b>Format</b> parameter and input signals.                   | Compose String     |
| Scan an input string and convert it to signals per the format specified by <b>Format</b> parameter.       | Scan String        |
| Compare two input strings.                                                                                | String Compare     |
| Concatenate input strings to form one output string.                                                      | String Concatenate |
| Output the string specified by the <b>String</b> parameter.                                               | String Constant    |
| Return the index of the first occurrence of the pattern string <b>sub</b> in the text string <b>str</b> . | String Find        |
| Output the number of characters in the input string.                                                      | String Length      |
| Convert a string signal to a uint8 vector.                                                                | String to ASCII    |
| Convert string signal to double signal.                                                                   | String to Double   |
| Convert string signal to single signal.                                                                   | String to Single   |
| Convert an input string to an enumerated signal.                                                          | String to Enum     |
| Extract a substring from a string signal.                                                                 | Substring          |
| Convert the input signal to a string signal.                                                              | To String          |

These Simulink blocks support strings.

| Block                 | Notes                                   |

## Simulink Strings and Stateflow

To use textual data to control chart behavior and manipulate text to create natural language output in Stateflow, use strings in C action language charts. Stateflow provides operators to manipulate strings. For more information, see “Manage Textual Information by Using Strings” (Stateflow).

## String Constants

To specify string constants, use the String Constant block. Do not use the Constant block, which does not accept strings. In the String Constant block, enter the string with double quotes, such as "Hello!" in the **String** parameter. It is the same as adding a numeric constant in the **Constant value** parameter of the Constant block.

## Simulink Strings and Null Characters

Simulink strings automatically deal with string termination. Do not use a null terminator at the end of a string. If Simulink detects a null character anywhere in a string, it generates an error. Simulink handles strings during simulation and code generation as follows:

- During simulation, the model simulates. You do not need to do anything else.
- During C code generation, the software adds a null terminator to the end of the string. For example, if the string buffer size is 10 and the real string value is "AB", the third character in the generated code is a null terminator.

## String Data Type

As necessary, string blocks create and use string data types, for example, when a block outputs a string type. You can create strings without specifying a maximum length of characters. We refer to strings without a maximum length of characters as dynamic strings.

To create string data types for blocks that support strings, you can:

- Use the **Output data type** or **Data type** parameter on the **Signal Attributes** tab of a Simulink block.
  - To create a string data type with no maximum length of characters, specify `string`. This action creates a dynamic string.
  - To create a string data type with maximum length of characters, such as 100, enter `stringtype(100)`. You can also use the `stringtype` function on the MATLAB command line to create a string data type.
- Use the `set_param` function with the `OutDataTypeStr` parameter, for example:

```
set_param(gcf, 'OutDataTypeStr', 'stringtype(100)')
```

This function creates a string data type object with a maximum length of 100 characters. String type lengths can range from 1 to 32,766 characters, inclusive.

For example, using the String Constant block to create a string with the **Output data type** parameter set to `stringtype(31)` creates a string data type of `str31`. 31 is the maximum number of characters the string can have.

## Strings in Bus Objects

To configure an element of a `Simulink.Bus` object to accept strings using the Bus Editor, for the **Data Type** parameter of the `Simulink.BusElement` object, enter a string type. For example, to specify a string data type whose maximum length of characters is 10, enter `stringtype(10)`. The **Mode** parameter updates accordingly. To specify a dynamic signal with a variable length, enter `string`. You can create mixed use numeric and string objects for bus elements. For more information on creating Bus and BusElement objects with the Bus Editor, see **Bus Editor**.

## Strings and Generated Code

Consider these notes for strings and generated C and C++ code.

### Differences Between Simulation and Generated C Code for the Dynamic String Data Type

Simulation of blocks that use a dynamic string data type differ from generated C code in these ways:

- Signals with `string` data type have dynamic sizes during simulation. In other words, the size of a string can vary between 0 and 32766. However, in generated C code, the coder stores strings as fixed-size `char_T` arrays. Therefore, the size of a string is limited by a fixed buffer size in

generated C code. The software truncates extra characters and inserts a null terminator at the end (for example, at the output of a String Concatenate block).

- The coder generates string invariants (parameters or signals) as C-style double-quoted strings.
- The default buffer size for a signal with string data type is 256 bytes (contains at most 255 8-bit ASCII characters). To change this buffer size, use the “Buffer size of dynamically-sized string (bytes)” (Simulink Coder) configuration parameter.
- To override a model-wide setting for an individual string signal, use `stringtype(N)` as the signal data type. Signals with this data type are allocated a buffer of  $N+1$  bytes in generated C code ( $N$  characters plus one null terminator).
- There is no difference between simulation and generated C++ code when strings are stored as `std::string` objects that have the same dynamic behavior as simulation.

### C++ Code Generation String Library

For C++ code generation, `std::string` library is available for an ERT-based target with an Embedded Coder license. For more information, see “Generate Code for String Blocks by using the Standard C++ String Library” (Embedded Coder).

## String Data Type Conversions

You cannot use the Data Type Conversion block to convert string data types to other data types and conversely. Instead, use these string conversion blocks.

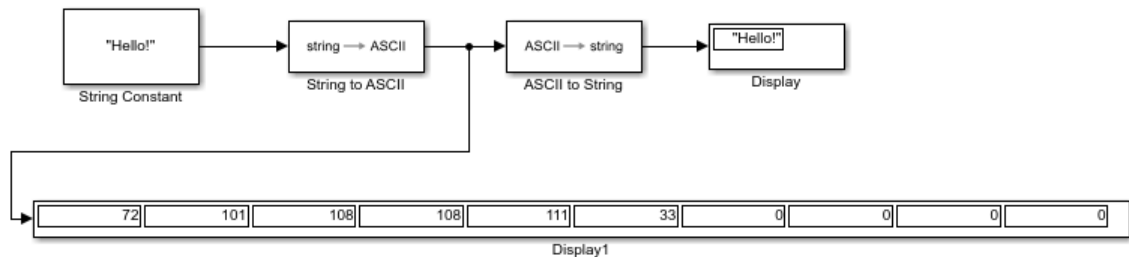

| To Convert                                                             | Block            |
|------------------------------------------------------------------------|------------------|
| String signal to uint8 vector signal while preserving ASCII characters | String to ASCII  |
| Uint8 vector signal to string signal                                   | ASCII to String  |
| String signal to numerical signal double data type                     | String to Double |
| String signal to numerical signal single data type                     | String to Single |
| String signal to enumerated signal data type                           | String to Enum   |
| Input signal to string signal                                          | To String        |

### Convert String to ASCII and Back to String

- 1 Add these blocks to a model:
  - String Constant
  - String to ASCII
  - ASCII to String
  - Two Display blocks
- 2 Connect the blocks as shown.

- 3 In the String Constant block, enter a string, such as "Hello!".
- 4 In the String to ASCII block, change the maximum string size to 10.
- 5 Simulate the model and observe the contents of the Display blocks.
  - Display1 shows Hello! converted to its ASCII equivalent. For example, 72 is the ASCII equivalent of H and 33 is the ASCII equivalent of !.
  - Display1 has filled the remaining space to the maximum string length of 10 with zeros (null characters).
  - Display shows Hello! after the ASCII to String block reconverts the ASCII code to a string.

### Convert String to Enumerated Data Type

- 1 Add these blocks to a model:
  - String Constant
  - String to Enum
  - Display
- 2 Connect the blocks as shown.

- 3 In the String Constant block, enter a string, such as "Hello!"
- 4 Create a Simulink enumeration class named `BasicStrings` and store it in the current folder with the file name `BasicStrings.m`, for example:

```
classdef BasicStrings < Simulink.IntEnumType
enumeration
```

```

Hello(0)
Red(1)
Blue(2)
end
end

```

- 5 In the String to Enum block, enter the enumeration class as Enum: `BasicStrings`.
- 6 Simulate the model and observe the contents of the Display block.

## Display and Extract Coordinate Data

This example shows how you can format and output a set of data as geographic coordinates using the Compose String and Scan String blocks. Based on the C `scanf` and `printf` functions, the Compose String and Scan String blocks are similar in concept to the `sprintf` and `sscanf` functions, with the primary exception being that those functions work with arrays, which the blocks do not. For more information on string block formatted characters, see Compose String and Scan String.

The Compose String block constructs a string from multiple string and numerical inputs combined. Use the **Format** parameter to format the output of each input, one format operator for each input. Each format operator starts with a percent sign, `%`, followed by the conversion character, for example, `%f` generates fixed point output. To supplement the string output, you can also add extra characters to the format specification to appear in the output.

- 1 Add these blocks to a model:
  - Six Constant
  - One Compose String
  - One Scan String
  - Seven Display
- 2 Change the Constant block constant values to those shown and connect the blocks.

3 In the **Format** parameter for the Compose String blocks, enter these format specifications:

```
'%g° %g' ' %f" N, %f" W'
```

- The %g and %f formatting operators convert numeric inputs to floating point values. %g is a more compact version of %f.
- The degree symbol (°), N, W, and ' are supplemental strings to display in the output string.

The Compose String block combines the output in the input order, formats each input according to its format operator, adds the extra strings, and outputs the string, formatted as directed and surrounded by double quotes (").

4 In the **Format** parameter for the Scan String block, enter these format specifications:

```
'%g° %g' ' %f" N, %f" W'
```

- The %g and %f formatting operators convert numeric inputs to floating point values. %g is a more compact version of %f.
- The degree symbol (°), N, W, and ' are supplemental strings to display in the output string.

The Scan String block reads its input, converts it according to the format specified by a conversion specification, and returns the results as scalars. The block formats each output according to its conversion specification. It ignores specified text immediately before or after a conversion specifier.

## Find Patterns in Strings

To find a pattern in a string, use the String Find block.

- 1 Add these blocks to a model:
  - Two String Constant
  - String Find
  - One Display
- 2 Connect the blocks as shown.

- 3 In the first String Constant block, enter a string, such as "Hello!Goodbye!".

Connecting this block to the **str** input port of the String Find block causes the String Find block to look for the pattern in this string.

- 4 In the second String Constant block, enter a string (or pattern) to look for in the first String Constant string, such as "Goodbye!".

Connecting this block to the **sub** input port of the block means that the String Find looks for this pattern from the **str** input.

- 5 Simulate the model and observe the contents of the Display block. For this example, the block displays 7, which is the location of the letter G.

## Extract a String

To extract a string from a source string, use the Substring block. This example uses the model described in “Find Patterns in Strings” on page 68-49.

- 1 Add a Substring block to the model.
- 2 In the Substring block, select the **Output string from 'idx' to end** parameter. Setting this parameter extracts the string from the location input at the idx port to the end of the string.
- 3 Connect the new block as shown.

- 4 Simulate the model and observe the contents of the Display block. For this example, the block displays "Goodbye! ", which is the substring extracted starting **idx** to the end of the string.

## Get Text Following a Keyword

This example shows basic string manipulation using the Simulink string blocks.

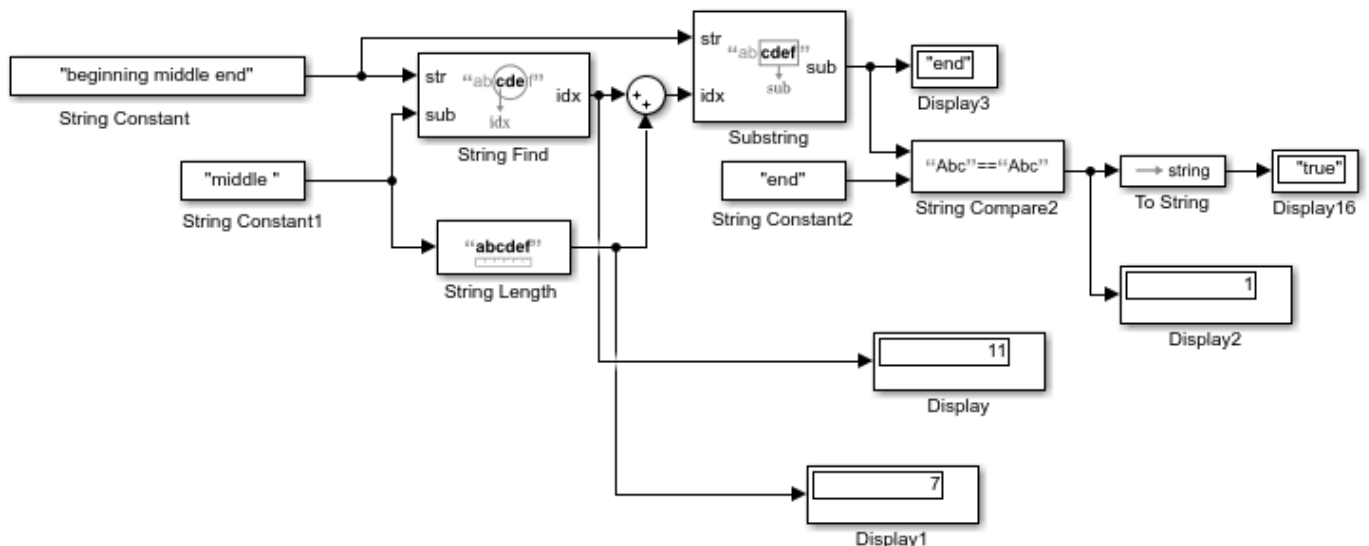

For a model that looks like the following, simulate it.

Observe that the model:

- Creates two strings, "beginning middle end" and "middle", using String Constant blocks.
- Looks for the first occurrence of "middle" (**idx**) and adds the location of the first letter (11) to the length of "middle" (7). It uses the String Find and String Length blocks.
- Extracts from "beginning middle end" the substring that starts from the end of "middle" ( $\text{idx} + \text{string length} = 18$ ), which is the string "end". It uses the Substring block.
- Compares the calculated value of "end" with the actual string "end", which returns the Boolean value "1". It uses the String Constant and String Compare blocks.
- Converts the Boolean value "1" to its string equivalent, "true". It uses the To String block.

To see the locations of the characters throughout the model, add one Display block each to the output of the String Find and String Length blocks and simulate it.

## Change Existing Models to Use Strings

In addition to using strings in new models, you can update existing models to use strings. Using strings can simplify the model and make it easier to understand.

For example, in older models, you may have used enumerated data types to represent or pass text in your model. The `sldemo_fuelsys` example enumerated constants in multiple areas to work with textual data.

In `sldemo_fuelsys/fuel_rate_control/control_logic`, the Stateflow chart uses enumerated data to indicate fuel levels.

In `sldemo_fuelsys/fuel_rate_control/airflow_calc`, to detect if the fuel is low, the model uses Enumerated Constant and Relational Operator blocks.

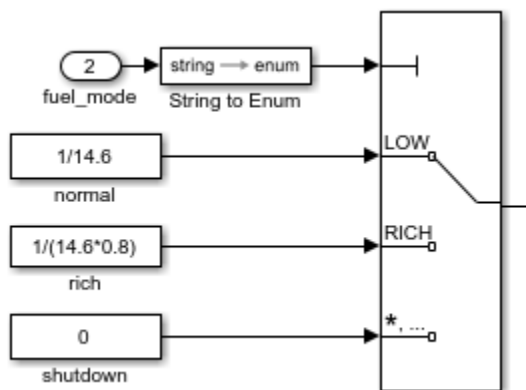

Instead, you can use the String Constant and String Compare blocks by setting:

- The String Constant **String** parameter to `LOW`.
- Using the String Compare block to detect if `LOW` is coming from another part of the model.

Instead of removing all instances of enumerated constants, you can use strings in conjunction with enumerated constants. Doing so allows you to incrementally migrate your model to use strings. In `sldemo_fuelsys/fuel_rate_control/fuel_calc/feedforward_fuel_rate`, the Multiport Switch block accepts four enumerated data inputs.

If the **fuel\_mode** port is outputting a string, you can convert that string to an enumerated data type to work with the output from the Constant blocks in this model.

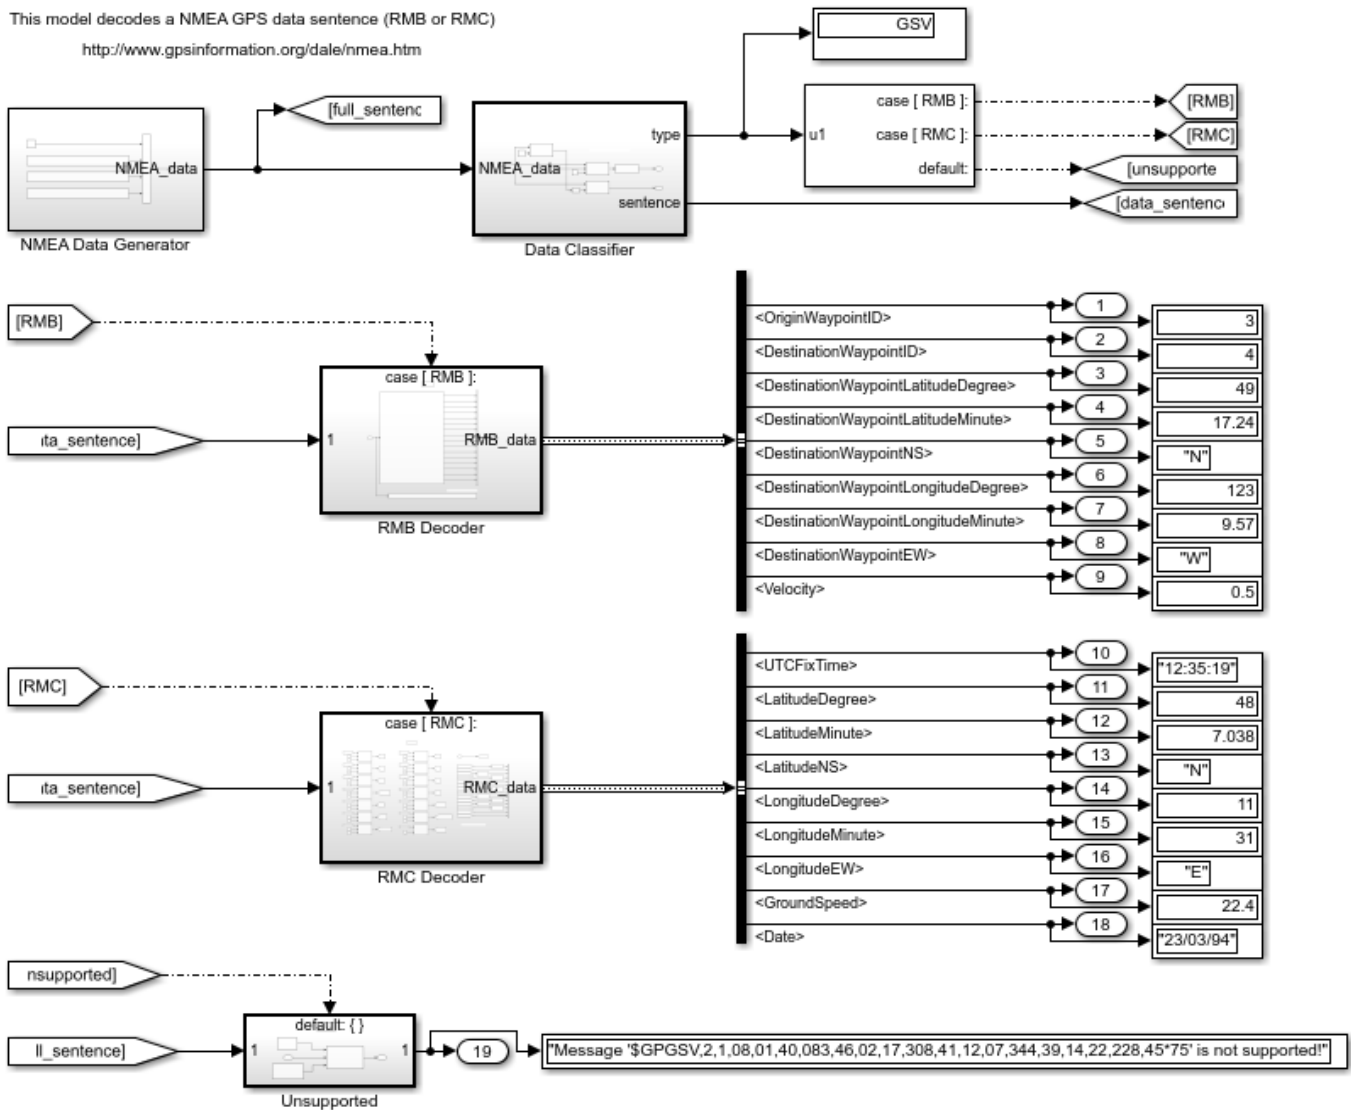

## Parse NMEA GPS Text Message

This example shows how to parse text messages in NMEA GPS format using Simulink® string blocks.

### Overview

This model shows how to use string data type and blocks provided by Simulink® to read input text messages and extract numeric and text data.

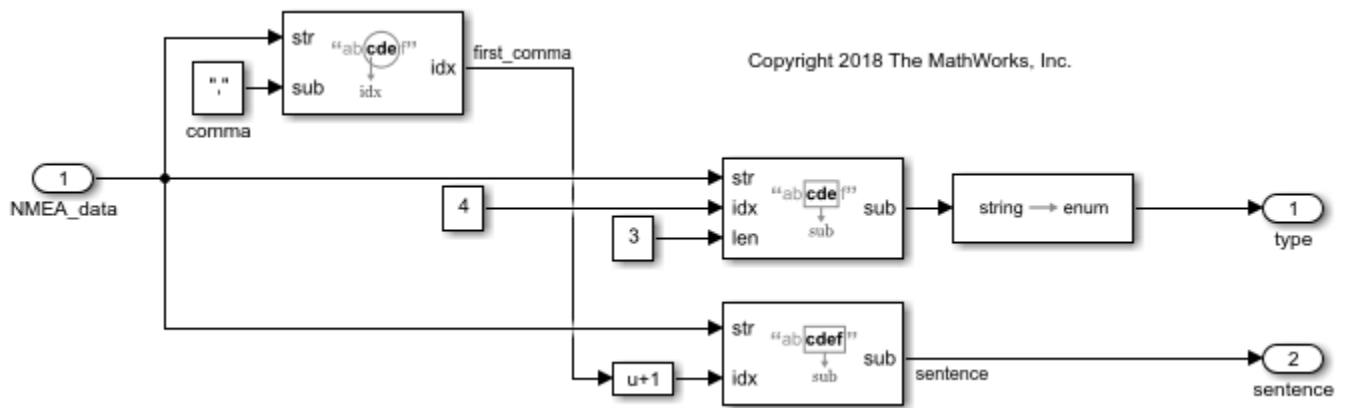

This model decodes a NMEA GPS data sentence (RMB or RMC)  
<http://www.gpsinformation.org/dale/nmea.htm>

Copyright 2018 The MathWorks, Inc.

### Read message header and convert to enumeration

Simulink® provides the String To Enum block to convert a string to the corresponding enumeration value. In this model, header string "RMB" is converted to NMEASentence.RMB.

### Parse text message using Scan String block

One way to parse a text message is to use the Scan String block. It works like sscanf function in C and MATLAB®.

Definition of NMEA GPRMB data sentence can be found at:  
<http://www.gpsinformation.org/dale/nmea.htm#RMB>

case [ RMB ];  
 Action Port

Scan String block is as powerful as sscanf function in C or MATLAB  
 It provides a flexible approach to parse input string message

**Parse text message with fixed field width**

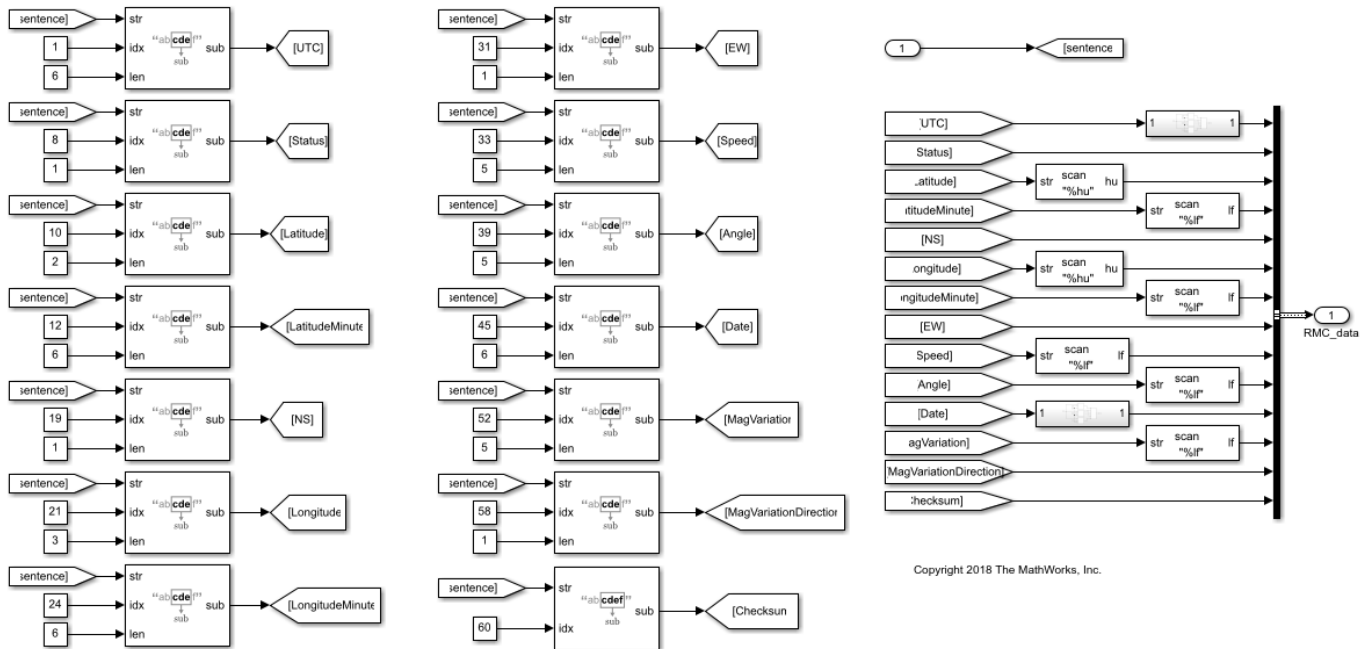

When a text message has fixed width for each data field, Simulink® provides blocks to split the string by index. After the strings have been split, each field can be handled separately.

Definition of NMEA GPRMC sentence can be found at: <http://www.gpsinformation.org/dale/nmea.htm#RMC>

case [ RMC ]  
Action Port

String messages that have fields with fixed width can be splitted by the width and each fields can be handled separately.

You can create data objects to specify values, value ranges, data types, tunability, and other characteristics of signals, states, and block parameters. You use the object names in Simulink dialog boxes to specify signal, state, and parameter characteristics. The objects exist in a workspace such as the base workspace, a model workspace, or a Simulink data dictionary. Data objects allow you to make model-wide changes to signal, state, and parameter characteristics by changing only the values of workspace objects.

You create data objects as instances of data classes. Memory structures called data class packages contain the data class definitions. The built-in package `Simulink` defines two data classes, `Simulink.Signal` and `Simulink.Parameter`, that you can use to create data objects. To store lookup table data for sharing between lookup table blocks (such as n-D Lookup Table), you can use the `Simulink.LookupTable` and `Simulink.Breakpoint` classes.

To decide whether to use data objects to configure signals, including Inport and Outport blocks, see “Store Design Attributes of Signals and States” on page 76-5.

You can customize data object properties and methods by defining subclasses of the built-in data classes. For more information about creating a data class package, see “Define Data Classes” on page 68-97.

### Data Class Naming Conventions

Simulink uses dot notation to name data classes:

*package.class*

- *package* is the name of the package that contains the class definition.
- *class* is the name of the class.

This notation allows you to create and reference identically named classes that belong to different packages. In this notation, the name of the package qualifies the name of the class.

Class and package names are case sensitive. For example, you cannot use `MYPACKAGE.MYCLASS` and `mypackage.myclass` interchangeably to refer to the same class.

## Use Data Objects in Simulink Models

To specify simulation and code generation options for signals, block parameters, and states by modifying variables in a workspace or data dictionary, use data objects. Associate the objects with signals, parameters, and states in a model diagram.

### Use Parameter Objects

You can use parameter objects, instead of numeric MATLAB variables, to specify values for block parameters. For example, to create and use a `Simulink.Parameter` object named `myParam` to specify the **Gain** parameter of a Gain block:

- 1 In the model, on the **Modeling** tab, under **Design**, click **Property Inspector**.
- 2 In the model, click the target Gain block. The Property Inspector shows the properties and parameters of the block.
- 3 Set the value of the **Gain** parameter to `myParam`.
- 4 Next to the parameter value, click the action button  and select **Create**.
- 5 In the **Create New Data** dialog box, set **Value** to `Simulink.Parameter(15.23)` and click **Create**.

The `Simulink.Parameter` object, `myParam`, appears in the base workspace. The property dialog box shows that the object stores the parameter value `15.23` in the **Value** property.

- 6 Use the property dialog box to specify other characteristics for the block parameter by adjusting the object properties. For example, to specify the minimum and maximum values the parameter can take, use the **Minimum** and **Maximum** properties.

During simulation, the **Gain** parameter now uses the value `15.23`.

To share lookup table data by using `Simulink.LookupTable` and `Simulink.Breakpoint` objects, see “Package Shared Breakpoint and Table Data for Lookup Tables” on page 37-29.

### Use Signal Objects

You can associate a signal line or block state, such as the state of a Unit Delay block, with a signal object.

#### For Signals

To use a signal object to control the characteristics of a signal in a model, create the object in a workspace by using the same name as the signal.

- 1 In the model, on the **Modeling** tab, click **Model Data Editor**.
- 2 In the Model Data Editor, select the **Signals** tab.
- 3 In the model, select the target signal. The Model Data Editor highlights the row that corresponds to the signal.
- 4 In the Model Data Editor, in the **Name** column, give the signal a name such as `mySig`.
- 5 Click the button  next to the signal name. Select **Create and Resolve**.

- 6 In the Create New Data dialog box, set **Value** to `Simulink.Signal`. Use the **Location** drop-down list to select a workspace to store the object (the default value is `Base Workspace`). Click **Create**.

The `Simulink.Signal` object `mySig` appears in the target workspace. Simulink selects the signal property **Signal name must resolve to Simulink signal object**, which forces the signal in the model to use the properties that the signal object stores. To learn how to control the way that signal names resolve to signal objects, see “Symbol Resolution” on page 68-128.

The property dialog box of the new object opens.

- 7 Use the property dialog box to specify the signal characteristics. Click **OK**.

To configure the signal programmatically:

```
% Create the signal object.
mySig = Simulink.Signal;
mySig.DataType = 'boolean';

% Get a handle to the block port that creates the
% target signal.
portHandles = get_param('myModel/myBlock','portHandles');
outportHandle = portHandles.Outport;

% Specify the programmatic port parameter 'Name'.
set_param(outportHandle,'Name','mySig')

% Set the port parameter 'MustResolveToSignalObject'.
set_param(outportHandle,'MustResolveToSignalObject','on')
```

To configure a root-level Outport block programmatically, you must use a slightly different technique:

```
% Create the signal object.
mySig = Simulink.Signal;
mySig.DataType = 'boolean';

% Specify the programmatic block parameter 'SignalName'.
set_param('myModel/myOutport','SignalName','mySig')

% Set the block parameter 'MustResolveToSignalObject'.
set_param('myModel/myOutport','MustResolveToSignalObject','on')
```

### For States

You can use a signal object to control the characteristics of a block state, such as that of the Discrete-Time Integrator block.

- 1 In the model, on the **Modeling** tab, click **Model Data Editor**.
- 2 In the Model Data Editor, select the **States** tab.
- 3 In the model, select the block that harbors the target state. The Model Data Editor highlights the row that corresponds to the state.
- 4 In the Model Data Editor, in the **Name** column, give the state a name such as `myState`.
- 5 Click the button  next to the state name. Select **Create and Resolve**.

- 6 In the Create New Data dialog box, set **Value** to `Simulink.Signal`. Use the **Location** drop-down list to select a workspace to store the object (the default value is `Base Workspace`). Click **Create**.

The `Simulink.Signal` object `myState` appears in the target workspace. Simulink selects the block parameter **State name must resolve to Simulink signal object**, which forces the state in the model to use the properties that the signal object stores. To learn how to control the way that state names resolve to signal objects, see “Symbol Resolution” on page 68-128.

The property dialog box of the new object opens.

- 7 Use the property dialog box to specify the state characteristics. Click **OK**.

To configure the state programmatically:

```
% Create the signal object.
myState = Simulink.Signal;
myState.DataType = 'int16';

% Set the state name in the block.
set_param('myModel/myBlock', 'StateName', 'myState')

% Set the port parameter 'StateMustResolveToSignalObject'.
set_param('myModel/myBlock', 'StateMustResolveToSignalObject', 'on')
```

## Data Object Properties

To control parameter and signal characteristics using data objects, you specify values for the data object properties. For example, parameter and signal data objects have a `DataType` property that determines the data type of the target block parameter or signal. Data class definitions determine the names, value types, default values, and valid value ranges of data object properties.

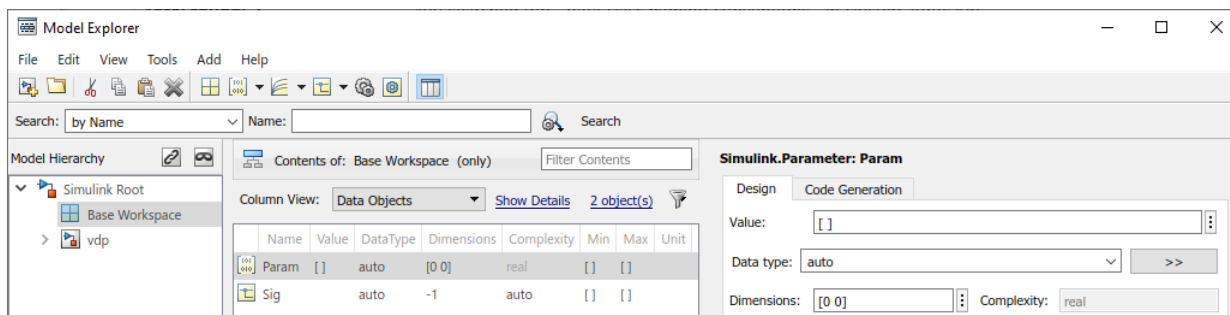

You can use either the Model Explorer or MATLAB commands to change a data object's properties.

For a list of signal object properties, see `Simulink.Signal`. For a list of parameter object properties, see `Simulink.Parameter`.

### Use the Model Explorer to Change an Object's Properties

To use the Model Explorer to change an object's properties, select the workspace that contains the object in the Model Explorer's **Model Hierarchy** pane. Then select the object in the Model Explorer's **Contents** pane.

The Model Explorer displays the object's property dialog box in its **Dialog** pane (if the pane is visible).

You can configure the Model Explorer to display some or all of the properties of an object in the **Contents** pane (see **Model Explorer**). To edit a property, click its value in the **Contents** or **Dialog** pane. The value is replaced by a control that allows you to change the value.

### Use MATLAB Commands to Change an Object's Properties

You can also use MATLAB commands to get and set data object properties. Use the following dot notation in MATLAB commands and programs to get and set a data object's properties:

```
value = obj.property;
obj.property = value;
```

where *obj* is a variable that references either the object if it is an instance of a value class or a handle to the object if the object is an instance of a handle class (see “Handle Versus Value Classes” on page 68-71), PROPERTY is the property's name, and VALUE is the property's value. For example, the following MATLAB code creates a data type alias object (i.e., an instance of Simulink.AliasType) and sets its base type to uint8:

```
gain = Simulink.AliasType;
gain.BaseType = 'uint8';
```

You can use dot notation recursively to get and set the properties of objects that are values of other object's properties, e.g.,

```
gain.CoderInfo.StorageClass = 'ExportedGlobal';
```

## Create Data Objects from Built-In Data Class Package Simulink

The built-in package Simulink defines two data object classes Simulink.Parameter and Simulink.Signal. You can create these data objects using the user interface or programmatically.

### Create Data Objects

- 1 In the Model Explorer **Model Hierarchy** pane, select a workspace to contain the data objects. For example, click Base Workspace.
- 2 On the toolbar, click the arrow next to **Add Parameter**  or **Add Signal** . From the drop-down list, select **Simulink Parameter** or **Simulink Signal**.

A parameter or signal object appears in the base workspace. The default name for new parameter objects is Param. The default name for new signal objects is Sig.

- 3 To create more objects, click **Add Parameter** or **Add Signal**.

To create Simulink.LookupTable and Simulink.Breakpoint objects, on the Model Explorer toolbar, use the  button.

### Programmatically Create Data Objects

```
% Create a Simulink.Parameter object named myParam whose value is 15.23.
myParam = Simulink.Parameter(15.23);
```

```
% Create a Simulink.Signal object named mySig.
mySig = Simulink.Signal;
```

## Convert Numeric Variable into Parameter Object

You can convert a numeric variable into a `Simulink.Parameter` object as follows.

```
/* Define numeric variable in base workspace
myVar = 5;
/* Create data object and assign variable value
myObject = Simulink.Parameter(myVar);
```

## Create Data Objects from Another Data Class Package

You can create your own package to define custom data object classes that subclass `Simulink.Parameter` and `Simulink.Signal`. You can use this technique to add your own properties and methods to data objects. If you have an Embedded Coder license, you can define storage classes and memory sections in the package. For more information about creating a data class package, see “Define Data Classes” on page 68-97.

### Create Data Objects from Another Package

Suppose that you define a data class package called `myPackage`. Before you can create data objects from the package, you must include the folder containing the package folder on your MATLAB path.

- 1 In the Model Explorer **Model Hierarchy** pane, select a workspace to contain the data objects. For example, click `Base Workspace`.
- 2 Click the arrow next to **Add Parameter**  or **Add Signal**  and select **Customize class lists**.
- 3 In the dialog box, select the check box next to the class that you want. For example, select the check boxes next to `myPackage.Parameter` and `myPackage.Signal`. Click **OK**.
- 4 Click the arrow next to **Add Parameter** or **Add Signal**. Select the class for the data object that you want to create. For example, select **myPackage Parameter** or **myPackage Signal**.

A parameter or signal object appears in the base workspace. The default name for new parameter objects is `Param`. The default name for new signal objects is `Sig`.

- 5 To create more data objects from the package `myPackage`, click **Add Parameter** or **Add Signal** again.

### Programmatically Create Data Objects from Another Package

Suppose that you define a data class package called `myPackage`. Before you can create data objects from the package, you must include the folder containing the package folder on your MATLAB path.

```
% Create a myPackage.Parameter object named
% myParam whose value is 15.23.
myParam = myPackage.Parameter(15.23);

% Create a myPackage.Signal object named mySig.
mySig = myPackage.Signal;
```

## Create Data Objects Directly from Dialog Boxes

When you open a Signal Properties dialog box, a block dialog box, or the Property Inspector (on the **Modeling** tab, under **Design**, click **Property Inspector**), you can efficiently create a signal or parameter data object in a workspace or data dictionary.

### Create Parameter Object from Block Dialog Box

- 1 In a numeric block parameter in the dialog box, specify the name that you want for the data object. For example, specify the name `myParam`.
- 2 Click the button  next to the value of the block parameter. Select **Create**.
- 3 In the **Create New Data** dialog box, specify **Value** as `Simulink.Parameter`.

Alternatively, you can specify the name of a data class that you created, such as `myPackage.Parameter`. You can also use the drop-down list to select from a list of available data object classes.

- 4 Specify **Location** as `Base Workspace` and click **Create**.

You can use the **Location** option to select a workspace to contain the new data object. If a model is linked to a data dictionary, you can choose to create a data object in the dictionary.

- 5 In the dialog box that opens, configure the data object properties. Specify a numeric value for the parameter in the **Value** box. Click **OK**.

The parameter object `myParam` appears in the base workspace.

- 6 In the block parameter dialog box, click **OK**.

### Create Signal Object from Signal Properties Dialog Box

- 1 In the **Signal name** box, specify a signal name such as `mySig`. Click **Apply**.
- 2 Click the button  next to the value of **Signal name**. Select **Create and Resolve**.
- 3 In the **Create New Data** dialog box, specify **Value** as `Simulink.Signal`.

Alternatively, you can specify the name of a data class that you created, such as `myPackage.Signal`. Also, from the drop-down list, you can select a data object class that exists on the MATLAB path.

- 4 Specify **Location** as `Base Workspace` and click **Create**.

You can use the **Location** option to select a workspace to contain the new data object. If a model is linked to a data dictionary, you can choose to create a data object in the dictionary.

- 5 In the dialog box that opens, configure the data object properties and click **OK**.

The signal object `mySig` appears in the base workspace. In the Signal Properties dialog box, the **Signal name must resolve to Simulink signal object** property is selected.

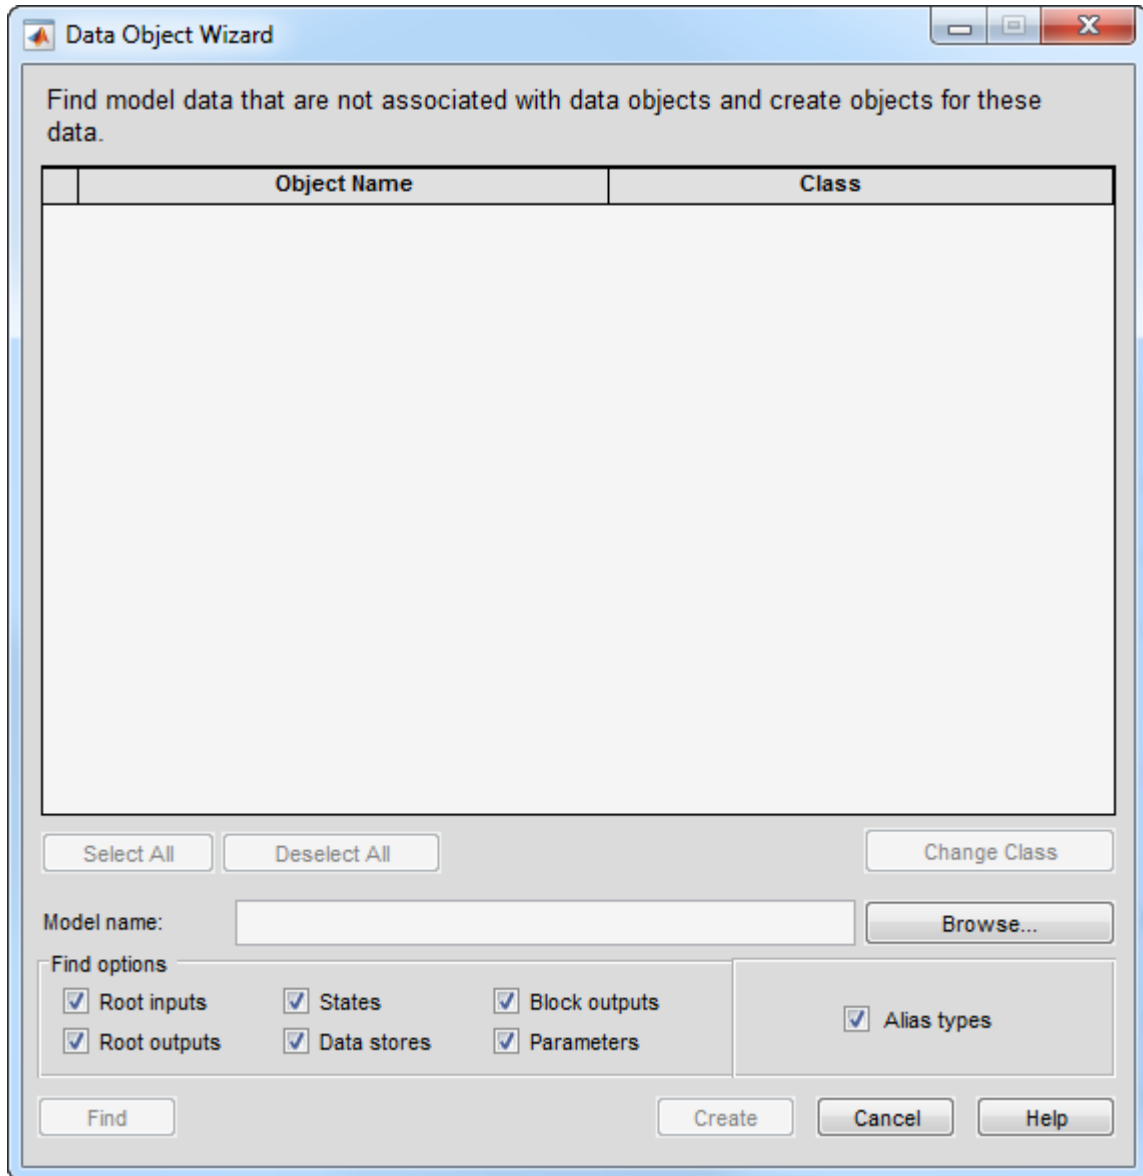

## Create Data Objects for a Model Using Data Object Wizard

To create data objects that represent signals, parameters, and states in a model, you can use the Data Object Wizard. The wizard finds data in the model that do not have corresponding data objects.

Based on specifications in the model, the wizard creates the objects and assigns these characteristics:

- Signal, parameter, or state name.
- Numeric value for parameter objects.
- Data type. For signal objects, includes alias types such as `Sumlink.AliasType` and `Simulink.NumericType`.

- 1 In the Simulink Editor, on the **Modeling** tab, under **Design**, click **Data Object Wizard**.

- 2 In the **Model name** box, enter the name of the model that you want to search.  
By default, the box contains the name of the model from which you opened the wizard.
- 3 Under **Find options**, select the check boxes next to the data object types that you want to create. The table describes the options.

| Option              | Description                                   |
|---------------------|-----------------------------------------------|
| <b>Root inputs</b>  | Named signals from root-level Inport blocks.  |
| <b>Root outputs</b> | Named signals from root-level Outport blocks. |

| Option               | Description                                                                                                                                                                                                                                                                                                                                                                                                                           |
|----------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>States</b>        | States associated with these discrete blocks:<br>Discrete Filter<br>Discrete State-Space<br>Discrete-Time Integrator<br>Discrete Transfer Fcn<br>Discrete Zero-Pole<br>Memory<br>Discrete PID Controller<br>Discrete PID Controller (2DOF)<br>Unit Delay                                                                                                                                                                              |
| <b>Data stores</b>   | Data stores. For more information about data stores, see “Local and Global Data Stores” on page 74-2 .                                                                                                                                                                                                                                                                                                                                |
| <b>Block outputs</b> | Named signals whose sources are non-root-level blocks.                                                                                                                                                                                                                                                                                                                                                                                |
| <b>Parameters</b>    | <ul style="list-style-type: none"> <li>• Numeric parameters, for example the parameters in these blocks:<br/>Constant<br/>Gain<br/>Relay</li> <li>• Stateflow data with <b>Scope</b> set to Parameter.</li> </ul>                                                                                                                                                                                                                     |
| <b>Alias types</b>   | Data type replacement names that you specify in <b>Configuration Parameters &gt; Code Generation &gt; Data Type Replacement</b> . If you have an Embedded Coder license, the Data Object Wizard creates <code>Simulink.AliasType</code> objects for these data type replacement names. For more information about data type replacement, see “Model Configuration Parameters: Code Generation Data Type Replacement” (Embedded Coder) |

**4** Click **Find**.

The data object table displays the proposed objects.

- 5 (Optional) To create objects from a data class other than the default classes, select the check box next to the objects whose class you want to change. To select all of the objects, click **Select All**. Click **Change Class**. In the dialog box that opens, select classes by using the drop-down lists next to **Parameter** and **Signal**.

If the classes that you want do not appear in the drop-down list, select **Customize class lists**. In the dialog box that opens, select the check box next to the classes that you want, and click **OK**.

To change the default parameter and signal classes that the wizard uses to propose objects:

- On the Model Explorer **Model Hierarchy** pane, select a workspace. For example, select **Base Workspace**.
- On the toolbar, click the arrow next to **Add Parameter**  or **Add Signal** .
- From the drop-down list, select the class that you want the wizard to use. For example, select **myPackage Parameter** or **myPackage Signal**.

A parameter or signal object appears in the selected workspace. The default name for new parameter objects is **Param**. The default name for new signal objects is **Sig**.

The next time that you use the Data Object Wizard, the wizard proposes objects using the parameter or signal class that you selected in Model Explorer.

- 6 Select the check box next to the proposed objects that you want to create. To select all of the proposed objects, click **Select All**.
- 7 Click **Create**.

The data objects appear in the base workspace. If the target model is linked to a data dictionary, the objects appear in the dictionary.

The wizard changes settings in your model depending on the configuration parameter **Configuration Parameters > Diagnostics > Data Validity > Signal resolution**.

- If you set the parameter to `Explicit only`, the wizard forces the corresponding signals and states in your model to resolve to the new signal objects. The wizard selects the option **Signal name must resolve to Simulink signal object** in each Signal Properties dialog box and **State name must resolve to Simulink signal object** in each block dialog box.
- If you set the parameter to `Explicit and implicit` or `Explicit and warn implicit`, the wizard does not change the setting of **Signal name must resolve to Simulink signal object** or **State name must resolve to Simulink signal object** for any signals or states.

Consider turning off implicit signal object resolution for your model by using the function `disableimplicitsignalresolution`. For more information, see “Explicit and Implicit Symbol Resolution” on page 68-130.

### Data Object Wizard Troubleshooting

- The Data Object Wizard compiles models for code generation in order to propose creation of signal objects. Because of this, the wizard cannot be used for models that are not valid for code generation.
- The Data Object Wizard does not propose creation of data objects for these entities in a model:
  - Multiple separate signals that have the same name.
  - A signal with the same name as a variable used in a block parameter.
  - A signal that lacks a single contiguous source block.
  - A signal whose source block is commented out or commented through.
  - Data items that are rendered inactive by Variant Source and Variant Sink blocks. The wizard proposes objects only for data items that are associated with active blocks.
  - Signals and states when you set the model configuration parameter **Signal resolution** to `None`.

### Create Data Objects from External Data Source Programmatically

This example shows how to create data objects based on an external data source (such as a Microsoft Excel file) by using a script.

- 1 Create a new MATLAB script file.
- 2 Place information in the file that describes the data in the external file that you want to convert to data objects. For example, the following information creates two Simulink data objects with the indicated properties. The first is for a parameter and the second is for a signal:

```
% Parameters
ParCon = Simulink.Parameter;
ParCon.CoderInfo.StorageClass = 'Custom'
ParCon.CoderInfo.CustomStorageClass = 'Const';
ParCon.Value = 3;
% Signals
SigGlb = Simulink.Signal;
SigGlb.DataType = 'int8';
```

- 3 Run the script file. The data objects appear in the MATLAB workspace.

If you want to import the target data from the external source, you can write MATLAB functions and scripts that read the information, convert the information to data objects, and load the objects into the base workspace.

You can use these functions to interact with files that are external to MATLAB:

- `xmlread`
- `xmlwrite`
- `xlsread`
- `xlswrite`
- `csvread`
- `csvwrite`
- `dlmread`
- `dlmwrite`

## Data Object Methods

Data classes define functions, called methods, for creating and manipulating the objects that they define. A class may define any of the following kinds of methods.

### Dynamic Methods

A dynamic method is a method whose identity depends on its name and the class of an object specified implicitly or explicitly as its first argument. You can use either function or dot notation to specify this object, which must be an instance of the class that defines the method or an instance of a subclass of the class that defines the method. For example, suppose class `A` defines a method called `setName` that assigns a name to an instance of `A`. Further, suppose the MATLAB workspace contains an instance of `A` assigned to the variable `obj`. Then, you can use either of the following statements to assign the name `'foo'` to `obj`:

```
obj.setName('foo');
setName(obj, 'foo');
```

A class may define a set of methods having the same name as a method defined by one of its super classes. In this case, the method defined by the subclass overrides the behavior of the method defined by the parent class. Simulink determines which method to invoke at runtime from the class of the object that you specify as its first or implicit argument. Hence, the term dynamic method.

---

**Note** Most Simulink data object methods are dynamic methods. Unless the documentation for a method specifies otherwise, you can assume that a method is a dynamic method.

---

### Static Methods

A static method is a method whose identity depends only on its name and hence cannot change at runtime. To invoke a static method, use its fully qualified name, which includes the name of the class that defines it followed by the name of the method itself. For example, `Simulink.ModelAdvisor` class defines a static method named `getModelAdvisor`. The fully qualified name of this static method is `Simulink.ModelAdvisor.getModelAdvisor`. The following example illustrates invocation of a static method.

```
ma = Simulink.ModelAdvisor.getModelAdvisor('vdp');
```

## Constructors

Every data class defines a method for creating instances of that class. The name of the method is the same as the name of the class. For example, the name of the `Simulink.Parameter` class's constructor is `Simulink.Parameter`. The constructors defined by Simulink data classes take no arguments.

The value returned by a constructor depends on whether its class is a handle class or a value class. The constructor for a handle class returns a handle to the instance that it creates if the class of the instance is a handle class; otherwise, it returns the instance itself (see “Handle Versus Value Classes” on page 68-71).

## Handle Versus Value Classes

Simulink classes, including data object classes, fall into two categories: value classes and handle classes.

### About Value Classes

The constructor for a *value* class (see “Constructors” on page 68-71) returns an instance of the class and the instance is permanently associated with the MATLAB variable to which it is initially assigned. Reassigning or passing the variable to a function causes MATLAB to create and assign or pass a copy of the original object.

For example, `Simulink.NumericType` is a value class. Executing the following statements

```
x = Simulink.NumericType;
y = x;
```

creates two instances of class `Simulink.NumericType` in the workspace, one assigned to the variable `x` and the other to `y`.

### About Handle Classes

The constructor for a *handle* class returns a handle object. The handle can be assigned to multiple variables or passed to functions without causing a copy of the original object to be created. For example, `Simulink.Parameter` class is a handle class. Executing

```
x = Simulink.Parameter;
y = x;
```

creates only one instance of `Simulink.Parameter` class in the MATLAB workspace. Variables `x` and `y` both refer to the instance via its handle.

A program can modify an instance of a handle class by modifying any variable that references it, e.g., continuing the previous example,

```
x.Description = 'input gain';
y.Description
```

```
ans =
input gain
```

Most Simulink data object classes are value classes. Exceptions include `Simulink.Signal` and `Simulink.Parameter` class.

To determine whether the value of a variable is an object (value class) or a handle to an object, see “Determine If an Object Is a Handle”.

### Copy Handle Objects

Use the copy method of a handle object to create copies of instances of that object. For example, `ConfigSet` is a handle object that represents model configuration sets. The following code creates a copy of the current model's active configuration set and attaches it to the model as an alternate configuration geared to model development.

```
activeConfig = getActiveConfigSet(gcs);
develConfig = copy(activeConfig);
develConfig.Name = 'develConfig';
attachConfigSet(gcs, develConfig);
```

### Compare Data Objects

Simulink data objects provide a method, named `isequal`, that determines whether object property values are equal. This method compares the property values of one object with those belonging to another object and returns true (1) if all of the values are the same or false (0) otherwise. For example, the following code instantiates two signal objects (A and B) and specifies values for particular properties.

```
A = Simulink.Signal;
B = Simulink.Signal;
A.DataType = 'int8';
B.DataType = 'int8';
A.InitialValue = '1.5';
B.InitialValue = '1.5';
```

Afterward, use the `isequal` method to verify that the object properties of A and B are equal.

```
result = isequal(A,B)

result =

 1
```

### Resolve Conflicts in Configuration of Signal Objects for Code Generation

If a signal is defined in the Signal Properties dialog box and a signal object of the same name is defined by using the command line or in the Model Explorer, the potential exists for ambiguity when the Simulink engine attempts to resolve the symbol representing the signal name. One way to resolve the ambiguity is to specify that a signal resolve to a `Simulink.Signal` data object. Select the **Signal name must resolve to Simulink signal object** option in the Signal Properties dialog box.

To configure the signal data, use the Code Mappings editor or code mappings API to add the signal to the model code mappings and set the storage class and storage class properties. For Simulink Coder, see “Configure Signal Data for C Code Generation” (Simulink Coder). For Embedded Coder, see “Configure Signal Data for C Code Generation” (Embedded Coder).

## Create Persistent Data Objects

To preserve data objects so that they persist when you close MATLAB, you can:

- Store the objects in a data dictionary or model workspace. To decide where to permanently store model data, see “Determine Where to Store Variables and Objects for Simulink Models” on page 68-101.
- Use the `save` command to save data objects in a MAT-file and the `load` command to restore them to the MATLAB base workspace in the same or a later session. Configure the model to load the objects from the MAT-file or a script file when the model loads.

To load data objects from a file when you load a model, write a script that creates the objects and configures their properties. Alternatively, save the objects in a MAT-file. Then use either the script or a `load` command as the `PreLoadFcn` callback routine for the model that uses the objects. Suppose that you save the data objects in a file named `data_objects.mat`, and the model to which they apply is open and active. At the command prompt, entering:

```
set_param(gcs, 'PreLoadFcn', 'load data_objects');
```

sets `load data_objects` as the model's preload function. Whenever you open the model, the data objects appear in the base workspace.

Definitions of the classes of saved objects must exist on the MATLAB path for them to be restored. If the class of a saved object acquires new properties after the object is saved, Simulink adds the new properties to the restored version of the object. If the class loses properties after the object is saved, only the properties that remain are restored.

## Simulink.Parameter Property Dialog Box

Create a `Simulink.Parameter` object to set the value of one or more block parameters in a model, such as the **Gain** parameter of a Gain block. For examples and programmatic information, see `Simulink.Parameter`.

### Value

Ideal real-world value that the object stores. Block parameters that refer to the object use the value that you specify.

You can also use MATLAB syntax to specify the value.

| Example Expression   | Description                                                                                                                                                                                                                                                                                                                            |
|----------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 15.23                | Specifies a scalar value                                                                                                                                                                                                                                                                                                               |
| [3 4; 9 8]           | Specifies a matrix                                                                                                                                                                                                                                                                                                                     |
| 3+2i                 | Specifies a complex value                                                                                                                                                                                                                                                                                                              |
| struct('A',20,'B',5) | Specifies a structure with two fields, A and B, with double-precision values 20 and 5.<br><br>Organize block parameters into structures (see “Organize Related Block Parameter Definitions in Structures” on page 37-19) or initialize the signal elements in a bus (see “Specify Initial Conditions for Bus Elements” on page 77-61). |

| Example Expression  | Description                                                                                                                                                                                                           |
|---------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| =myVar + myOtherVar | Specifies the expression myVar + myOtherVar where myVar and myOtherVar are other MATLAB variables or parameter objects. Simulink Coder preserves this mathematical relationship between the object and the variables. |

To use a `Simulink.Parameter` object to store a value of a particular numeric data type, specify the ideal value with the **Value** property and control the type with the **Data type** property.

If you set the **Value** property by using a typed expression such as `single(32.5)`, the **Data type** property changes to reflect the new type. A best practice is to use an expression that is not typed to avoid accumulating numerical error through repeated quantizations or data type saturation, especially for fixed-point data types.

When you specify an array with three or more dimensions, the **Value** property displays the array as an expression that contains a call to the `reshape` function. To edit the values in the array, modify the first argument of the `reshape` call, which contains all of the array values in a serialized vector. When you add or remove elements along a dimension, you must also correct the argument that represents the length of the modified dimension.

To more easily edit a large vector, 2-D matrix, or structure that you store in a `Simulink.Parameter` object, consider using the Variable Editor. See “Manage and Edit Workspace Variables” on page 37-14.

If you use a `Simulink.Parameter` object to set the block parameter value in a reusable referenced model, you can compile and simulate the model as a referenced model with the value for the object left empty (**Value** set to `[]`) as long as you provide an explicit value somewhere in the parent model reference hierarchy. In this case, you cannot simulate the model directly. When the value is empty, you must provide the **Data Type** and **Dimensions** for the object. Although you have specified an empty value, Simulink still synthesizes a **Value** by using one of these:

- **Max**.
- **Min**, if you have not specified **Max**.
- **1**, if you have not specified either **Min** or **Max**.

See “Parameterize Instances of a Reusable Referenced Model” on page 8-63.

### Data type

Data type of the parameter value in the **Value** property, specified as `'auto'` or a character vector. When you simulate the model or generate code, Simulink casts the value to the specified data type.

If you select `auto`, the default setting, the parameter object uses the same data type as the block parameters that use the object. See “Reduce Maintenance Effort with Data Type Inheritance” on page 37-44.

When you set the **Value** property to something other than a `double` number, the object typically sets the **Data type** property based on the value of the **Value** property. For example, when you set the **Value** property to `int8(5)`, the object sets the value of the **Data type** property to `int8`.

You can select a data type from the drop-down list or specify the name of a data type with text.

To explicitly specify a built-in data type (see “Data Types Supported by Simulink” on page 68-4), use one of these options:

- `double`
- `single`
- `half`
- `int8`
- `uint8`
- `int16`
- `uint16`
- `int32`
- `uint32`
- `boolean`

To specify a fixed-point data type, use the `fixdt` function. For example, specify `fixdt(1,16,5)`.

If you use a `Simulink.AliasType` or `Simulink.NumericType` object to create and share custom data types in your model, specify the name of the object.

To specify an enumerated data type, use the name of the type preceded by `Enum:`. For example, specify `Enum: myEnumType`.

When you store a structure or array of structures in the **Value** property of the object, the object sets the **Data type** property to `struct`. To specify a `Simulink.Bus` object as the data type, use the name of the bus object preceded by `Bus:`. For example, specify `Bus: myBusObject`.

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the **Data type** parameter. For more information, see “Specify Data Types Using Data Type Assistant” on page 68-30.

### Dimensions

Dimensions of the parameter value. When the value is empty (set to `[]`), you can configure the dimensions. Otherwise, the property is derived from the value.

When you set the **Value** property of the object, the object sets the value of the **Dimensions** property to a `double` row vector. The vector is the same vector that the `size` function returns.

If you are configuring the object as a model argument, and you intend to provide a value for the object elsewhere in the parent model reference hierarchy, you can leave the **Value** empty (set to `[]`) and set the **Dimensions** and **Data Type** explicitly. See “Parameterize Instances of a Reusable Referenced Model” on page 8-63.

To use symbolic dimensions, see “Implement Dimension Variants for Array Sizes in Generated Code” (Embedded Coder).

### Complexity

Numeric complexity of the parameter value, specified as either `'real'` or `'complex'`. For `Simulink.Parameter` objects in the model workspace, use this property to configure the complexity of a model argument. See “Parameterize Instances of a Reusable Referenced Model” on page 8-63.

For numeric values, Simulink derives the complexity from the parameter value that you specify in the **Value** property. In this case, changing the complexity results in error.

When the value is a structure or a mathematical expression, Simulink ignores the specified complexity.

### **Minimum**

Minimum value that the parameter can have. The default value is empty, which means the parameter value does not have a minimum. Specify a real double scalar.

If you store a complex number in the **Value** property, the **Minimum** property applies separately to the real and imaginary parts.

If you store a structure in the **Value** property, the object ignores the **Minimum** property. Instead, use a `Simulink.Bus` object as the data type of the parameter object and specify a minimum value for each field by using the elements of the bus object. See “Control Field Data Types and Characteristics by Creating Parameter Object” on page 37-21.

If **Value** is less than the minimum value or if the minimum value is outside the range of the object data type, Simulink generates a warning. When updating the diagram or starting a simulation, Simulink generates an error.

For more information about how Simulink uses this property, see “Specify Minimum and Maximum Values for Block Parameters” on page 37-52.

### **Maximum**

Maximum value that the parameter can have. The default value is empty, which means the parameter value does not have a maximum. Specify a real double scalar.

If you store a complex number in the **Value** property, the **Maximum** property applies separately to the real and imaginary parts.

If you store a structure in the **Value** property, the object ignores the **Maximum** property. Instead, use a `Simulink.Bus` object as the data type of the parameter object and specify a maximum value for each field by using the elements of the bus object. See “Control Field Data Types and Characteristics by Creating Parameter Object” on page 37-21.

If **Value** is greater than the maximum value or if the maximum value is outside the range of the object data type, Simulink generates a warning. When updating the diagram or starting a simulation, Simulink generates an error.

For more information about how Simulink uses this property, see “Specify Minimum and Maximum Values for Block Parameters” on page 37-52.

### **Stored Integer Minimum**

For parameter objects with a fixed-point data type, the minimum value that the parameter can have, specified as a stored integer value. The value is derived from the real-world value **Minimum**. This property is available only in the property dialog box.

### **Stored Integer Maximum**

For parameter objects with a fixed-point data type, the maximum value that the parameter can have, specified as a stored integer value. The value is derived from the real-world value **Maximum**. This property is available only in the property dialog box.

### **Unit**

Physical unit in which this value is expressed (for example, inches). To specify a unit, begin typing in the text box. As you type, the parameter displays potential unit string matches. For more information, see “Unit Specification in Simulink Models” on page 9-2.

**Storage class**

Storage class of this parameter object. Simulink code generation toolboxes use this property to allocate memory for this parameter object in the generated code.

For more information, see “C Code Generation Configuration for Model Interface Elements” (Simulink Coder) and “Choose Storage Class for Controlling Data Representation in Generated Code” (Embedded Coder).

**Identifier**

Alternative name for this parameter in the generated code.

**Alignment**

Data alignment boundary for code generation, specified in number of bytes. The starting memory address for the data allocated for the parameter is a multiple of the **Alignment** setting. The default value is -1, which specifies that the code generator determine an optimal alignment based on usage. Otherwise, specify a positive integer that is a power of 2, not exceeding 128. For more information, see “Data Alignment for Code Replacement” (Embedded Coder).

**Argument**

Specification to configure the parameter object as a model argument (see “Parameterize Instances of a Reusable Referenced Model” on page 8-63). This property appears only if the parameter object is in a model workspace.

**Description**

Custom description of this parameter object. Use this property to document the significance that the parameter object has in your algorithm.

If you have an Embedded Coder license, you can configure this description to appear in the generated code as a comment. See “Simulink data object descriptions” (Embedded Coder).

## Simulink.DualScaledParameter Property Dialog Box

Create a `Simulink.DualScaledParameter` object so that you can store two scaled values of the same physical parameter value, for example, for the **Gain** parameter of a Gain block. For examples and programmatic information, see `Simulink.DualScaledParameter`.

### Main Attributes Tab

The screenshot shows the 'Main Attributes' tab of the 'Simulink.DualScaledParameter: param' dialog box. The dialog has three tabs: 'Calibration Attributes', 'Main Attributes', and 'Code Generation'. The 'Main Attributes' tab is active. The fields are as follows:

- Value:** A text box containing `[]`.
- Data type:** A dropdown menu set to 'auto' with a '>>' button to its right.
- Dimensions:** A text box containing `[0 0]`.
- Complexity:** A dropdown menu set to 'real'.
- Minimum:** A text box containing `[]`.
- Maximum:** A text box containing `[]`.
- Unit:** An empty text box.
- Description:** A large empty text area.

At the bottom of the dialog are four buttons: 'OK', 'Cancel', 'Help', and 'Apply'.

This tab shows the properties inherited from the `Simulink.Parameter` class. For more information, see `Simulink.Parameter`.

## Calibration Attributes Tab

The screenshot shows the 'Calibration Attributes' tab of the 'Simulink.DualScaledParameter: param' dialog box. The dialog has three tabs: 'Calibration Attributes', 'Main Attributes', and 'Code Generation'. The 'Calibration Attributes' tab is active and contains the following fields:

- Calibration value:** A text box containing '[]' with a vertical ellipsis button to its right.
- Calibration minimum:** A text box containing '[]' with a vertical ellipsis button to its right.
- Calibration maximum:** A text box containing '[]' with a vertical ellipsis button to its right.
- CalToMain compute numerator:** A text box containing '[]' with a vertical ellipsis button to its right.
- CalToMain compute denominator:** A text box containing '[]' with a vertical ellipsis button to its right.
- Calibration name:** A text box containing '"' with a vertical ellipsis button to its right.
- Calibration units:** A text box containing '"' with a vertical ellipsis button to its right.

Below these fields is a section titled 'Parameter validation' which includes:

- Is configuration valid:** A dropdown menu currently showing 'true' with a vertical ellipsis button to its right.
- Diagnostic message:** A large, empty text area.

At the bottom of the dialog are four buttons: 'OK', 'Cancel', 'Help', and 'Apply'.

### Calibration value

Calibration value of the parameter. The value that you prefer to use. The default value is [] (unspecified). Specify a finite, real, double value.

Before specifying **Calibration value**, you must specify **CalToMain compute numerator** and **CalToMain compute denominator** to define the computation method. The parameter uses the computation method and the calibration value to calculate the main value that Simulink uses.

### Calibration minimum

Minimum value for the calibration parameter. The default value is [] (unspecified). Specify a finite, real, double scalar value.

Before specifying **Calibration minimum**, you must specify **CalToMain compute numerator** and **CalToMain compute denominator** to define the computation method. The parameter uses

the computation method and the calibration minimum value to calculate the minimum or maximum value that Simulink uses. A first order rational function is strictly monotonic, either increasing or decreasing. If it is increasing, setting the calibration minimum sets the main minimum value. If it is decreasing, setting the calibration minimum sets the main maximum.

If the parameter value is less than the minimum value or if the minimum value is outside the range of the parameter data type, Simulink generates a warning. In these cases, when updating the diagram or starting a simulation, Simulink generates an error.

### Calibration maximum

Maximum value for the calibration parameter. The default value is [ ] (unspecified). Specify a finite, real, double scalar value.

Before specifying **Calibration maximum**, you must specify **CalToMain compute numerator** and **CalToMain compute denominator** to define the computation method. The parameter uses the computation method and the calibration maximum value to calculate the corresponding maximum or minimum value that Simulink uses. A first order rational function is strictly monotonic, either increasing or decreasing. If it is increasing, setting the calibration maximum sets the main maximum value. If it is decreasing, setting the calibration maximum sets the main minimum.

If the parameter value is less than the minimum value or if the minimum value is outside the range of the parameter data type, Simulink generates a warning. In these cases, when updating the diagram or starting a simulation, Simulink generates an error.

### CalToMain compute numerator

Specify the numerator coefficients a and b of the first-order linear equation:

$$y = \frac{ax + b}{cx + d}$$

The default value is [ ] (unspecified). Specify finite, real, double scalar values for a and b. For example, [1 1] or, for reciprocal scaling, 1.

Once you have applied **CalToMain compute numerator**, you cannot change it.

### CalToMain compute denominator

Specify the denominator coefficients c and d of the first-order linear equation:

$$y = \frac{ax + b}{cx + d}$$

The default value is [ ] (unspecified). Specify finite, real, double scalar values for c and d. For example, [1 1].

Once you have applied **CalToMain compute denominator**, you cannot change it.

### Calibration name

Specify the name of the calibration parameter. The default value is ' '. Specify a character vector value, for example, 'T1'.

### Calibration units

Specify the measurement units for this calibration value. This field is intended for use in documenting this parameter. The default value is ' '. Specify a character vector value, for example, 'Fahrenheit'.

**Is configuration valid**

Simulink indicates whether the configuration is valid. The default value is `true`. If Simulink detects an issue with the configuration, it sets this field to `false` and provides information in the **Diagnostic message** field. You cannot set this field.

**Diagnostic message**

If you specify invalid parameter settings, Simulink displays a message in this field. Use the diagnostic information to help you fix an invalid configuration issue. You cannot set this field.

**See Also**

`Simulink.DualScaledParameter`

## Simulink.AliasType Property Dialog Box

Use a `Simulink.AliasType` object to rename data types for signal, state, and parameter data in a model. For examples and programmatic information, see `Simulink.AliasType`.

### Base type

The data type to which this alias refers. The default is `double`. To specify another data type, such as `half`, select the data type from the adjacent drop-down list of standard data types or enter the data type name in the edit field.

To specify a fixed-point data type, you can use a call to the `fixdt` function, such as `fixdt(0,16,7)`. To specify the characteristics of the type interactively, expand the Data Type Assistant and set **Mode** to `Fixed point`. For information about using the Data Type Assistant, see “Specify Data Types Using Data Type Assistant” on page 68-30.

You can, with one exception, specify a nonstandard data type, e.g., a data type defined by a `Simulink.NumericType` object, by entering the data type name in the edit field. The exception is a `Simulink.NumericType` whose `DataTypeMode` is `Fixed-point: unspecified scaling`.

---

**Note** `Fixed-point: unspecified scaling` is a partially specified type whose definition is completed by the block that uses the `Simulink.NumericType`. Forbidding its use in alias types avoids creating aliases that have different base types depending on where they are used.

---

**Data scope**

Specifies whether the data type definition is imported from, or exported to, a header file during code generation. The possible values are:

| Value          | Action                                                                                                                                                                                                                                                                                                                                                                                                      |
|----------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Auto (default) | If no value is specified for <b>Header file</b> , export the type definition to <i>model_types.h</i> , where <i>model</i> is the model name. If you have an Embedded Coder license, and you have specified a data type replacement, then export the type definition to <i>rtwtypes.h</i> . If a value is specified for <b>Header file</b> , import the data type definition from the specified header file. |
| Exported       | Export the data type definition to a header file, which can be specified in the <b>Header file</b> field. If no value is specified for <b>Header file</b> , the header file name defaults to <i>type.h</i> . <i>type</i> is the data type name.                                                                                                                                                             |
| Imported       | Import the data type definition from a header file, which can be specified in the <b>Header file</b> field. If no value is specified for <b>Header file</b> , the header file name defaults to <i>type.h</i> . <i>type</i> is the data type name.                                                                                                                                                           |

**Header file**

Name of a C header file from which a data type definition is imported, or to which a data type definition is exported, based on the value of **Data scope**. If this field is specified, the specified name is used during code generation for importing or exporting. If this field is empty, the value defaults to *type.h* if **Data scope** equals Imported or Exported, or defaults to *model\_types.h* if **Data scope** equals Auto.

By default, the generated `#include` directive uses the preprocessor delimiter " instead of < and >. To generate the directive `#include <myTypes.h>`, specify **Header file** as `<myTypes.h>`.

**Description**

Describes the usage of the data type referenced by this alias.

Simulink.AliasType

## Simulink.NumericType Property Dialog Box

Use a `Simulink.AliasType` object to set and share data types for signal, state, and parameter data in a model. For examples and programmatic information, see `Simulink.NumericType`.

### Data type mode

Data type of this numeric type. The options are listed in this table.

| Option                              | Description                                          |
|-------------------------------------|------------------------------------------------------|
| Double                              | Same as the MATLAB double type.                      |
| Single                              | Same as the MATLAB single type.                      |
| Boolean                             | Same as the MATLAB boolean type.                     |
| Fixed-point: unspecified scaling    | A fixed-point data type with unspecified scaling.    |
| Fixed-point: binary point scaling   | A fixed-point data type with binary-point scaling.   |
| Fixed-point: slope and bias scaling | A fixed-point data type with slope and bias scaling. |

Selecting a data type mode causes Simulink software to enable controls on the dialog box that apply to the mode and to disable other controls that do not apply. Selecting a fixed-point data type mode can, depending on the other dialog box options that you select, cause the model to run only on systems that have a Fixed-Point Designer option installed.

### Data type override

Data type override setting for this numeric type. The options are listed in this table.

| Option            | Description                                                                                                                                              |
|-------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------|
| Inherit (default) | Data type override setting for the context in which this numeric type is used (block, signal, Stateflow chart in Simulink) applies to this numeric type. |
| Off               | Data type override setting does not affect this numeric type.                                                                                            |

### Is alias

If you select this option for a workspace object of this type, Simulink software uses the name of the object as the data type for all objects that specify the object as its data type. Otherwise, Simulink software uses the data type mode of the data type as its name, or, if the data type mode is a fixed-point mode, Simulink software generates a name that encodes the type properties, using the encoding specified by Fixed-Point Designer.

### Data scope

Specifies whether the data type definition is imported from, or exported to, a header file during code generation. The possible values are listed in this table.

| Value          | Action                                                                                                                                                                                                                                                     |
|----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Auto (default) | If no value is specified for <b>Header file</b> , export the type definition to <i>model_types.h</i> . <i>model</i> is the model name.<br>If a value is specified for <b>Header file</b> , import the data type definition from the specified header file. |
| Exported       | Export the data type definition to a header file, which can be specified in the <b>Header file</b> field. If no value is specified for <b>Header file</b> , the header file name defaults to <i>type.h</i> . <i>type</i> is the data type name.            |
| Imported       | Import the data type definition from a header file, which can be specified in the <b>Header file</b> field. If no value is specified for <b>Header file</b> , the header file name defaults to <i>type.h</i> . <i>type</i> is the data type name.          |

### Header file

Name of a C header file from which a data type definition is imported, or to which a data type definition is exported, based on the value of **Data scope**. If this field is specified, the specified name is used during code generation for importing or exporting. If this field is empty, the value defaults to *type.h* if **Data scope** equals Imported or Exported, or defaults to *model\_types.h* if **Data scope** equals Auto.

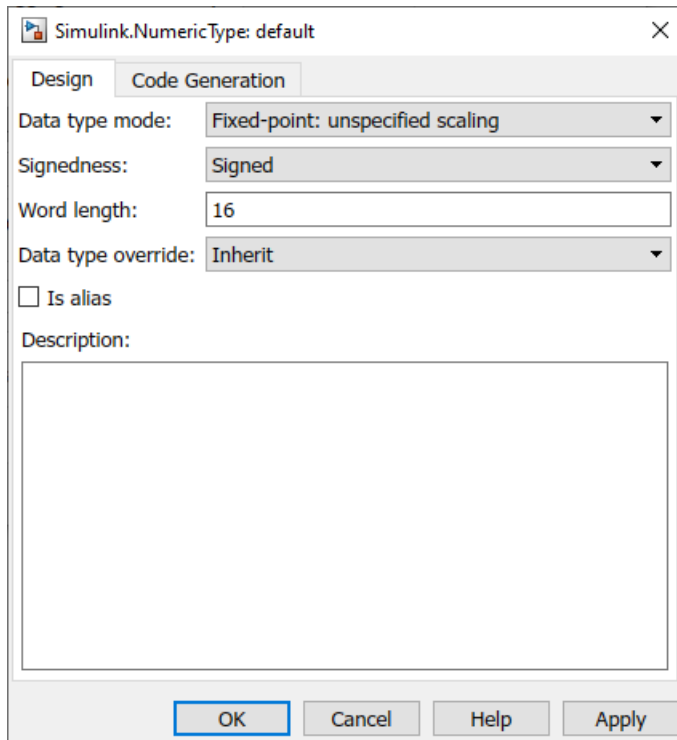

By default, the generated `#include` directive uses the preprocessor delimiter `"` instead of `<` and `>`. To generate the directive `#include <myTypes.h>`, specify **Header file** as `<myTypes.h>`.

### Description

Description of this data type. This field is intended for use in documenting this data type. Simulink software ignores it.

### Signedness

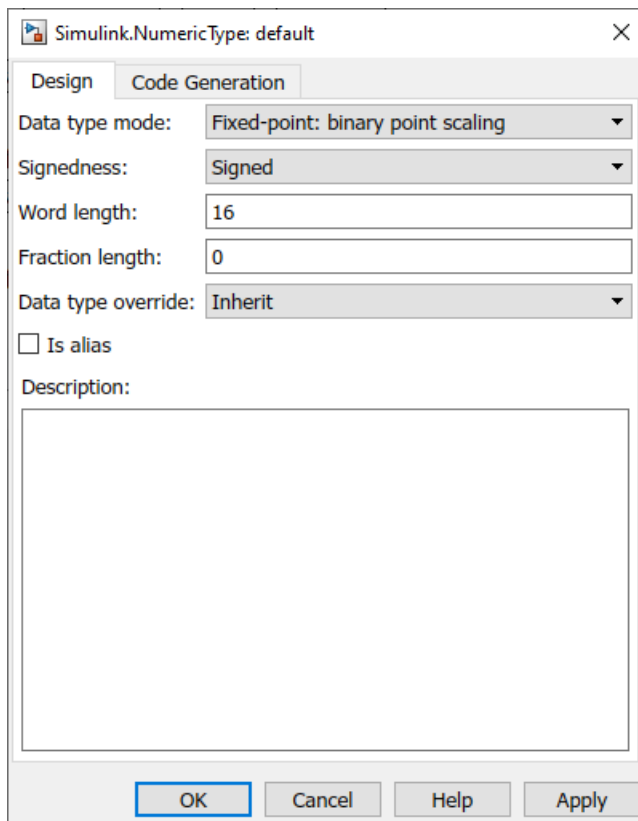

Specifies whether the data type is signed or unsigned, or inherits its signedness. Set the option to Signed, Unsigned, or Auto. This option is enabled only for fixed-point data type modes as shown.

**Word length**

Word length in bits of the fixed-point data type. This option is enabled only for fixed-point data type modes.

**Fraction length**

Number of bits to the right of the binary point. This option is enabled only if the data type mode is Fixed-point: binary point scaling.

### Slope

Slope for slope and bias scaling. This option is enabled only if the data type mode is Fixed-point: slope and bias scaling.

**Bias**

Bias for slope and bias scaling. This option is enabled only if the data type mode is Fixed-point: slope and bias scaling. See the preceding figure.

## Use Simulink.Signal Objects to Specify and Control Signal Attributes

A `Simulink.Signal` object enables you to assign or validate the attributes of a signal or discrete state, such as its data type, numeric type, dimensions, and so on. For programmatic and reference information, see `Simulink.Signal`.

### Using Signal Objects to Assign or Validate Signal Attributes

This section describes how you can use signal objects to assign or validate signal attributes. The same techniques work with discrete states also. To use a signal object to assign or validate signal attribute values:

- 1 Create a `Simulink.Signal` object that has the same name as the signal to which you want to assign attributes or whose attributes you want to validate.
  - a Open the Model Explorer.
  - b In the Model Hierarchy pane, select either the Base workspace or Model workspace node, depending on the context you want for the signal object. If you create the signal object in a model workspace, you must set the **Storage class** parameter to `Auto`.
  - c Select **Add > Simulink Signal**.
- 2 Set the properties of the object that correspond to the attributes left unspecified by the signal source, or that correspond to the attributes you want to validate. See “Property Dialog Box” on page 68-93 for details.
- 3 Enable explicit or implicit signal resolution:
  - **Explicit resolution:** In the Signal Properties dialog box for the signal, enable **Signal name must resolve to Simulink signal object**. This is the preferred technique. See “Explicit and Implicit Symbol Resolution” on page 68-130 for more information.  
  
When you use this technique, set **Configuration Parameters > Diagnostics > Data Validity > Signal resolution** to a value other than `None`. To use only explicit resolution (a best practice), set the parameter to `Explicit only`.
  - **Implicit resolution:** Set the **Configuration Parameters > Diagnostics > Data Validity > Signal resolution** option for the model to `Explicit and implicit` or `Explicit and warn implicit`. Explicit resolution is the preferred technique.
- 4 Assign the signal object to a workspace variable.
- 5 Associate the signal object with the source signal.
  - Give the signal the same name as the workspace variable that references the signal object.
  - You can use a variety of techniques to associate a signal object with a signal. For examples, see “Use Signal Objects to Initialize Signals and Discrete States” on page 76-41, “Using Signal Objects to Tune Initial Values” on page 76-43, and “Organize Parameter Data into a Structure by Using Struct Storage Class” (Embedded Coder).

### Validation

The result when a signal does not match a signal object can depend on several factors. Simulink software can validate a signal property when you update the diagram, while you run a simulation, or

both. When and how validation occurs can depend on internal rules that are subject to change, and sometimes on configuration parameter settings.

Not all signal validation compares signal source attributes with signal object properties. For example, if you specify **Minimum** and **Maximum** signal values using a signal object, the signal source must specify the same values as the signal object (or inherit the values from the object) but such validation relates only to agreement between the source and the object, not to enforcement of the minimum and maximum values during simulation.

If the value of **Configuration Parameters > Diagnostics > Data Validity > Simulation range checking** is none (the default), Simulink does not enforce any minimum and maximum signal values during simulation, even though a signal object provided or validated them. To enforce minimum and maximum signal values during simulation, set **Simulation range checking** to **warning** or **error**. See “Specify Signal Ranges” on page 76-34 and “Model Configuration Parameters: Data Validity Diagnostics” for more information.

## Multiple Signal Objects

You can associate a given *signal object* with more than one signal if the storage class of the signal object is **Auto** or **Reusable**. If the storage class is **Auto** and you clear optimizations such as **Signal storage reuse** so that the generated code allocates memory for all of the associated signals, the signals each appear as a uniquely named field of the global structure that contains signal and state data. If the storage class of the object is other than **Auto** or **Reusable**, you can associate the signal object with no more than one signal.

You can associate a given *signal* with no more than one signal object. The signal can refer to the signal object more than once, but every reference must resolve to exactly the same signal object. Referencing two different signal objects that have exactly the same properties causes a compile-time error.

A compile-time error occurs if a model associates more than one signal object with any signal. To prevent the error, decide which object you want the signal to use, then delete or reconfigure all references to any other signal objects, so that all remaining references resolve to the chosen signal object. See “Highlight Signal Sources and Destinations” on page 76-27 for a description of techniques that you can use to trace the full extent of a signal.

## Signal Specification Block: An Alternative to Simulink.Signal

You can use a Signal Specification block rather than a `Simulink.Signal` object to assign properties left unspecified by a signal source. Each technique has advantages and disadvantages:

- Using a signal object simplifies the model and allows you to change signal property values without editing the model, but does not show signal property values directly in the block diagram.
- Using a Signal Specification block displays signal property values directly in the block diagram, but complicates the model and requires editing it to change signal property values.

The following two models illustrate the respective advantages of the two ways of assigning attributes to a signal.

In the first example, the signal object named `Sig1` specifies the sample time and data type of the signal emitted by input port `In1`.

To determine the properties of the `Sig1` signal, you can view the signal object in the Model Explorer. In this model, the sample time is `-1` and the data type is `auto`.

Using a signal object to specify the sample time and data type properties of signal `Sig1` allows you to change the sample time or data type without having to edit the model. For example, you could use the Model Explorer, the MATLAB command line, or a MATLAB program to change these properties.

The second example uses a Signal Specification block to specify the sample time and data type of the signal emitted by input port `In2`. The Signal Specification block displays the data type and signal sample time properties right in the diagram, which in this case are `uint8` and `4`, respectively.

## Bus Support

### Using Bus Objects as the Data Type

`Simulink.Signal` supports nonvirtual buses as the output data type.

If you set the **Data type** of the signal object to be a bus object, then you cannot associate the signal object with a non-bus signal.

### Using Structures for the Initial Value

If you use a bus object as the data type, set **Initial value** to `0` or a MATLAB structure that matches the bus object.

The structure you specify must contain a value for every element of the bus represented by the bus object.

You can use the `Simulink.Bus.createMATLABStruct` to create a full structure that corresponds to a bus.

You can use `Simulink.Bus.createObject` to create a bus object from a MATLAB structure.

## Property Dialog Box

For examples and programmatic information about `Simulink.Signal`, see `Simulink.Signal`.

### Data type

Data type of the signal. The default entry, `auto`, specifies that Simulink should determine the data type. Use the adjacent dropdown list to specify built-in data types (for example, `uint8`) or a data type such as `'half'`. To specify a custom data type, enter a MATLAB expression that specifies the type, (for example, a base workspace variable that references a `Simulink.NumericType` object).

To specify a bus object as the data type for the signal object, use the `Bus: <object_name>` option. See "Bus Support" on page 68-92 for details about what you need to do if you specify a bus object as the data type.

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the **Data type** parameter. (See “Specify Data Types Using Data Type Assistant” on page 68-30 in *Simulink User's Guide*.)

### Complexity

Numeric type of the signal. Valid values are `auto` (determined by Simulink), `real`, or `complex`.

### Dimensions

Dimensions of this signal. Valid values are `-1` (the default) specifying any dimensions, `N` specifying a vector signal of size `N`, or `[M N]` specifying an `MxN` matrix signal.

### Dimensions mode

Dimensions mode of this signal. From the drop-down list, select

- `Auto` — Allows variable-size and fixed-size signals.
- `Fixed` — Allows only fixed-size signals. Does not allow variable-size signals.
- `Variable` — Allows only variable-size signals.

### Sample time

Rate at which the value of this signal should be computed. See “Specify Sample Time” on page 7-3 for details.

### Minimum

Minimum value that the signal should have. The default value is `[]` (unspecified). Specify a finite, real, double, scalar value.

---

**Note** If you specify a bus object as the data type for a signal, do not set the minimum value for bus data on the signal property dialog box. Simulink ignores this setting. Instead, set the minimum values for bus elements of the bus object specified as the data type. For information on the `Minimum` property of a bus element, see `Simulink.BusElement`.

---

Simulink uses this value in the following ways:

- When updating the diagram or starting a simulation, Simulink generates an error if the signal's initial value is less than the minimum value or if the minimum value is outside the range for the data type of the signal.
- When you enable the **Simulation range checking** diagnostic, Simulink alerts you during simulation if the signal value is less than the minimum value (see “Simulation range checking”).

### Maximum

Maximum value that the signal should have. The default value is `[]` (unspecified). Specify a finite, real, double, scalar value.

---

**Note** If you specify a bus object as the data type for a signal, do not set the maximum value for bus data on the signal property dialog box. Simulink ignores this setting. Instead, set the maximum values for bus elements of the bus object specified as the data type. For information on the `Maximum` property of a bus element, see `Simulink.BusElement`.

---

Simulink uses this value in the following ways:

- When updating the diagram or starting a simulation, Simulink generates an error if the initial value of the signal is greater than the maximum value or if the maximum value is outside the range of the data type of the signal.
- When you enable the **Simulation range checking** diagnostic, Simulink alerts you during simulation if the signal value is greater than the maximum value (see “Simulation range checking”).

### Stored Integer Minimum

For signal objects with a fixed-point data type, the minimum value that the signal should have, specified as a stored integer value. The value is derived from the real-world value **Minimum**. This property is available only in the property dialog box.

### Stored Integer Maximum

For signal objects with a fixed-point data type, the maximum value that the signal should have, specified as a stored integer value. The value is derived from the real-world value **Maximum**. This property is available only in the property dialog box.

### Initial value

Signal or state value before a simulation takes its first time step. You can specify any MATLAB expression, including the name of a workspace variable, that evaluates to a numeric scalar value or array.

You can use the MATLAB command prompt to provide an initial value for a signal. Even if you use a number, specify the initial value as a character vector.

```
mySigObject.InitialValue='5.3';
```

```
mySigObject.InitialValue = 'myNumericVariable';
```

To specify an initial value for a signal that uses a numeric data type other than `double`, cast the initial value to the signal data type. For example, you can specify `single(73.3)` to use 73.3 as the initial value for a signal of data type `single`.

If you use a bus object as the data type for the signal object, set **Initial value** to a character vector containing either `0` or a MATLAB structure that matches the bus object. See “Bus Support” on page 68-92 for details.

If the initial value evaluates to a MATLAB structure, then in the **Configuration Parameters** dialog box, set “Underspecified initialization detection” to `simplified`.

If necessary, Simulink converts the initial value to ensure type, complexity, and dimension consistency with the corresponding block parameter value. If you specify an invalid value or expression, an error message appears when you update the model. Also, Simulink performs range checking of the initial value. The software alerts you when the initial value of the signal lies outside a range that corresponds to its specified minimum and maximum values and data type.

**Classic initialization mode:** In this mode, initial value settings for signal objects that represent the following signals and states override the corresponding block parameter initial values if undefined (specified as `[]`):

- Output signals of conditionally executed subsystems and Merge blocks
- Block states

**Simplified initialization mode:** In this mode, initial values of signal objects associated with the following blocks are ignored. The initial values of the corresponding blocks are used instead.

- Outport blocks of conditionally executed subsystems
- Merge blocks

**Unit**

Physical unit in which the value of this signal is expressed, (for example, inches). To specify a unit, begin typing in the text box. As you type, the parameter displays potential matching units. For more information, see “Unit Specification in Simulink Models” on page 9-2.

**Storage class**

Storage class of this signal. For more information, see “C Code Generation Configuration for Model Interface Elements” (Simulink Coder) and “Organize Parameter Data into a Structure by Using Struct Storage Class” (Embedded Coder).

If you create the signal object in a model workspace, you must set the object storage class to **Auto**.

**Identifier**

Alternate name for this signal. Simulink ignores this setting. This property is used for code generation.

**Alignment**

Data alignment boundary, specified in number of bytes. The starting memory address for the data allocated for the signal will be a multiple of the **Alignment** setting. The default value is -1, which specifies that the code generator should determine an optimal alignment based on usage.

Otherwise, specify a positive integer that is a power of 2, not exceeding 128. This field is intended for use by Simulink Coder software. See “Data Alignment for Code Replacement” (Embedded Coder). Simulink software ignores this setting.

**Description**

Description of this signal. This field is intended for use in documenting this signal. This property is used by the Simulink Report Generator and for code generation.

If you have an Embedded Coder license, you can add the signal description as a comment for the variable declaration in generated code.

- Specify a storage class for the signal object other than **Auto**.
- On the **Code Generation > Comments** pane of the Model Configuration Parameters dialog box, select the model configuration parameter **Simulink data object descriptions**. For more information, see “Simulink data object descriptions” (Embedded Coder).

**See Also**

Simulink.Signal

## Define Data Classes

This example shows how to subclass Simulink data classes.

Use MATLAB class syntax to create a data class in a package. Optionally, assign properties to the data class and define storage classes.

### Use an example to define data classes

- 1 View the +SimulinkDemos data class package in the folder *matlabroot/toolbox/simulink/simdemos/dataclasses* (open).

This package contains predefined data classes.

- 2 Copy the folder to the location where you want to define your data classes.
- 3 Rename the folder +mypkg and add its parent folder to the MATLAB path.
- 4 Modify the data class definitions.

### Manually define data class

- 1 Create a package folder +mypkg and add its parent folder to the MATLAB path.
- 2 Create class folders @Parameter and @Signal inside +mypkg.

---

**Note** Simulink requires data classes to be defined inside +Package/@Class folders.

---

- 3 In the @Parameter folder, create a MATLAB file `Parameter.m` and open it for editing.
- 4 Define a data class that is a subclass of `Simulink.Parameter` using MATLAB class syntax.

```
classdef Parameter < Simulink.Parameter
end % classdef
```

To use a custom class name other than `Parameter` or `Signal`, name the class folders using the custom name. For example, to define a class `mypkg.myParameter`:

- Define the data class as a subclass of `Simulink.Parameter` or `Simulink.Signal`.

```
classdef myParameter < Simulink.Parameter
end % classdef
```

- In the class definition, name the constructor method as `myParameter` or `mySignal`.
- Name the class folder, which contains the class definition, as `@myParameter` or `@mySignal`.

### Optional: Add properties to data class

The `properties` and `end` keywords enclose a property definition block.

```
classdef Parameter < Simulink.Parameter
 properties % Unconstrained property type
 Prop1 = [];
 end

 properties(PropertyType = 'logical scalar')
 Prop2 = false;
```

```

end

properties(PropertyType = 'char')
 Prop3 = '';
end

properties(PropertyType = 'char',...
 AllowedValues = {'red'; 'green'; 'blue'})
 Prop4 = 'red';
end
end % classdef

```

If you add properties to a subclass of `Simulink.Parameter`, `Simulink.Signal`, or `Simulink.CustomStorageClassAttributes`, you can specify the following property types.

| Property Type                                       | Syntax                                                                          |
|-----------------------------------------------------|---------------------------------------------------------------------------------|
| Double number                                       | <code>properties(PropertyType = 'double scalar')</code>                         |
| int32 number                                        | <code>properties(PropertyType = 'int32 scalar')</code>                          |
| Logical number                                      | <code>properties(PropertyType = 'logical scalar')</code>                        |
| Character vector (char)                             | <code>properties(PropertyType = 'char')</code>                                  |
| Character vector with limited set of allowed values | <code>properties(PropertyType = 'char', AllowedValues = {'a', 'b', 'c'})</code> |

If you use MATLAB property validation (see “Validate Property Values”) instead of `PropertyType`, the properties are displayed as an edit field in the property dialog box of the class. If you use `PropertyType` and `AllowedValues`, then the property dialog box displays:

- A check box for logical scalar properties.
- A dropdown menu for character vectors and `AllowedValues`.

### Optional: Add initialization code to data class

You can add a constructor within your data class to perform initialization activities when the class is instantiated. The added constructor cannot require an input argument.

In this example, the constructor initializes the value of object `obj` based on an optional input argument.

```

classdef Parameter < Simulink.Parameter
 methods
 function obj = Parameter(optionalValue)
 if (nargin == 1)
 obj.Value = optionalValue;
 end
 end
 end % methods
end % classdef

```

**Optional: Define storage classes**

Use the `setupCoderInfo` method to configure the `CoderInfo` object of your class. Then, create a call to the `useLocalCustomStorageClasses` method and open the Custom Storage Class Designer.

- 1 In the constructor within your data class, call the `useLocalCustomStorageClasses` method.

```
classdef Parameter < Simulink.Parameter
 methods
 function setupCoderInfo(obj)
 useLocalCustomStorageClasses(obj, 'mypkg');

 obj.CoderInfo.StorageClass = 'Custom';
 end
 end % methods
end % classdef
```

- 2 Open the Custom Storage Class Designer for your package.

```
cscdesigner('mypkg')
```

- 3 Define storage classes.

**Optional: Define custom attributes for storage classes**

- 1 Create a MATLAB file `myCustomAttribs.m` and open it for editing. Save this file in the `+mypkg/@myCustomAttribs` folder, where `+mypkg` is the folder containing the `@Parameter` and `@Signal` folders.
- 2 Define a subclass of `Simulink.CustomStorageClassAttributes` using MATLAB class syntax. For example, consider a storage class that defines data using the original identifier but also provides an alternate name for the data in generated code.

```
classdef myCustomAttribs < Simulink.CustomStorageClassAttributes
 properties(PropertyType = 'char')
 AlternateName = '';
 end
end % classdef
```

- 3 Override the default implementation of the `isAddressable` method to determine whether the storage class is writable.

```
classdef myCustomAttribs < Simulink.CustomStorageClassAttributes
 properties(PropertyType = 'logical scalar')
 IsAlternateNameInstanceSpecific = true;
 end

 methods
 function retVal = isAddressable(hObj, hCSCDefn, hData)
 retVal = false;
 end
 end % methods
end % classdef
```

- 4 Override the default implementation of the `getInstanceSpecificProps` method.

For examples, see `CSCTypeAttributes_FlatStructure.m` in the folder `matlabroot\toolbox\simulink\simulink\dataclasses\+Simulink\@CSCTypeAttributes_FlatStructure` (open) and `CSCTypeAttributes_Unstructured.m` in the folder `matlabroot\toolbox\simulink\simulink\dataclasses\+mpt\@CSCTypeAttributes_Unstructured` (open).

---

**Note** This is an optional step. By default, all custom attributes are instance-specific and are modifiable for each data object. However, you can limit which properties are allowed to be instance-specific.

---

- 5 Override the default implementation of the `getIdentifiersForInstance` method to define identifiers for objects of the data class.

---

**Note** In its default implementation, this method queries the name or identifier of the data object and uses that identifier in generated code. By overriding this method, you can control the identifier of your data objects in generated code.

---

```
classdef myCustomAttribs < Simulink.CustomStorageClassAttributes
 properties(PropertyType = 'char')
 GetFunction = '';
 SetFunction = '';
 end

 methods
 function retVal = getIdentifiersForInstance(hCSCAttrib,...
 hCSCDefn, hData, identifier)
 retVal = struct('GetFunction',...
 hData.CoderInfo.CustomAttributes.GetFunction, ...
 'SetFunction', hData.CoderInfo.CustomAttributes.SetFunction);
 end%
 end % methods
end % classdef
```

- 6 If you are using grouped storage classes, override the default implementation of the `getIdentifiersForGroup` method to specify the identifier for the group in generated code.

For an example, see `CSCTypeAttributes_FlatStructure.m` in the folder *matlabroot* \toolbox\simulink\simulink\dataclasses\+Simulink \@CSCTypeAttributes\_FlatStructure (open).

## Determine Where to Store Variables and Objects for Simulink Models

Model data are objects and variables that you create in workspaces such as the base workspace or a data dictionary. Model data include:

- Numeric values for block parameters, such as `Simulink.Parameter` objects and MATLAB variables
- Signals, such as `Simulink.Signal` objects
- Value types defined by `Simulink.ValueType` objects
- Data types
- Model configuration sets
- Simulation input and output data

You can store, partition, and share model data in a location that is appropriate for your design. The storage locations that you choose can depend on:

- Your modeling goals.
- The model architecture (referenced models, subsystems, and other partitioning strategies) and component structure.
- The types of data that you use.

### Types of Data

- Simulation data is the set of input data that you use to drive a simulation and the set of output data that a simulation generates. For example, you can use variables to store input data that a simulation acquires through Inport blocks. A simulation can export output data through, for example, Outport blocks, To Workspace blocks, and logged signals.

You can store simulation data for your current MATLAB session in the base workspace. To permanently store this simulation data, save it in a MAT-file or script file. For more information about loading, generating, and storing simulation data, see “Comparison of Signal Loading Techniques” on page 71-21 and “Export Simulation Data” on page 73-2.

- Design data is the set of variables that you use to specify block parameters and signal characteristics in a model. For example, design data includes numeric MATLAB variables, value type objects, parameter and signal data objects, data type objects, and bus objects.

You can store design data in the base workspace, model workspaces, or the Design Data section of a data dictionary. To permanently store local design data with a model, use model workspaces. To share design data between models, use data dictionaries or the base workspace. Data dictionaries permanently store the data, and you can control the data scope to establish ownership, partition the data to ease readability and maintenance, and track changes. If you use the base workspace, to permanently store the data, you must save it in a MAT-file or script file.

- Configuration sets are sets of model configuration parameters. By default, configuration sets reside in the model file, so you do not need to store the sets separately from the model. However, you cannot share these sets with other models.

To share configuration sets between models, you must create `Simulink.ConfigSet` objects. Each object represents a standalone configuration set. You can store these objects in the base

workspace or in the Configurations section of a data dictionary. If you use data dictionaries, you can define the scope of each configuration set, compare different configuration sets, and track changes. A data dictionary inherently partitions configuration sets from other kinds of data.

## Store Data for Your Design

The table shows the techniques you can use to store, partition, and manage design data and configuration sets.

| Modeling Scenario                           | Scenario Description                                                                                                                                                                                                                                     | Storage Locations and Techniques                                                                                                                                                                                                                                                                                                                                                                     |

## Storage Locations

Choose any of these locations to store data:

- The MATLAB base workspace. Use the base workspace to store variables while you experiment with temporary models.
- A model workspace. Use a model workspace to permanently store data that is local to a model.
- A data dictionary. Use data dictionaries to permanently store global data, share data between models, and track changes made to data.

The chart shows the capabilities and advantages of each storage location.

| Capability                                 | Base Workspace | Model Workspace | Data Dictionary    |
|--------------------------------------------|----------------|-----------------|--------------------|
| Data-model linkage                         | implicit       | implicit        | ✓                  |
| Unified interface for defining data        | ✓              | ✓               | ✓                  |
| Model-data dependency                      | ✓              | ✓               | ✓                  |

| Storage and partitioning of auxiliary data |                |                 | ✓                  |
| Requirements linking                       |                |                 | ✓                  |

For information about the way that models interact with workspaces and workspace variables, see “Symbol Resolution” on page 68-128.

### **Temporary Data: Base Workspace**

Use the base workspace to temporarily store data:

- While you learn to use Simulink
- When you need to quickly create variables while experimenting with modeling techniques
- When you do not need to store the data permanently

To create variables in the base workspace, you can use the MATLAB command prompt or the Model Explorer. All open models can use the data that you create in the base workspace.

If you use variables to specify numeric block parameters in the model, you can programmatically change the parameter values during simulation by using commands at the command prompt. To programmatically change the values of parameters that you store in the model workspace or data dictionaries, you must use the function interfaces for those storage locations.

To permanently store base workspace data before you end a MATLAB session, you can save the data in a MAT-file or a script file. During a later session, you can load the data from the file. However, if you make changes to the data in the base workspace, you must save the data to the file again. Consider instead using a model workspace or data dictionary to permanently store data.

### **Local Data: Model Workspace**

Use a model workspace to store data that you use only in the associated model. This data can include:

- Constant parameters, for example, numeric variables that you use to specify block parameter values.
- Data objects, such as `Simulink.Signal` and `Simulink.Parameter` objects, that you use to control signal and parameter characteristics. However, signal objects in a model workspace can use only the `Auto` storage class. If you store an `AUTOSAR.Parameter` object in a model workspace, the code generator ignores the storage class that you specify for the object.
- `Simulink.NumericType` objects that you use to specify data types. However, you cannot use the object as a data type alias. You must set the `IsAlias` property to `false`.
- Model arguments.

You can improve model portability and establish data ownership by storing the data in the model workspace. In this case, the model file permanently stores the data.

In a model reference hierarchy, each model workspace acts as a unique namespace. Therefore, you can use the same variable name in multiple model workspaces. You can then assign a unique variable value for each model.

You can use the Model Explorer to manipulate model workspace data. Alternatively, you can use the command prompt or scripts in conjunction with the model workspace programmatic interface.

For more information about using model workspaces to store local data, see “Model Workspaces” on page 68-120.

## Global and Shared Data: Data Dictionary

A data dictionary is a standalone file that permanently stores data. Use data dictionaries instead of the base workspace to partition data, track changes, control access, and share data. If you link a model to a data dictionary, you can still use variables in the base workspace by configuring access from either the model or the dictionary.

As you can with model workspaces, you can use data dictionaries to directly associate data with a model. You can use this association to scope the data and to establish ownership.

When you use dictionaries, you can partition the data by storing it in additional referenced dictionaries. However, each entry in a dictionary must use a unique name. You must manage each dictionary as a separate file.

Use a data dictionary to store data that multiple models or system components share. This data can include:

- Numeric variables that multiple models use to specify block parameter values.
- `Simulink.AliasType` and `Simulink.NumericType` objects that you use to specify data types in multiple models at once.
- Data objects, including signal objects (such as `Simulink.Signal`) that use a storage class other than `Auto`. If you have a Simulink Coder license, these objects can represent signals and tunable parameters that appear as global variables in the generated code.
- `Simulink.ValueType` and `Simulink.Bus` objects that you use to define interfaces of model components, such as referenced models.
- `Simulink.ConfigSet` objects that you use to maintain configuration parameter uniformity across multiple models.
- Enumerated type definitions, which you store using `Simulink.data.dictionary.EnumTypeDefinition` objects.

You can use the Model Explorer to manipulate dictionary data. Alternatively, you can use the command prompt or scripts in conjunction with the data dictionary programmatic interface.

For basic information about data dictionaries, see “What Is a Data Dictionary?” on page 75-2.

## Considerations for Code Generation

If you intend to generate C code from a model (Simulink Coder), take these considerations into account.

- If you apply a storage class other than `Auto` to a signal object (such as `Simulink.Signal`) to control the appearance of a signal or block state in the generated code, you cannot store the object in a model workspace. Store the object in the base workspace or a data dictionary. For more information about storage classes for signals and states, see “C Code Generation Configuration for Model Interface Elements” (Simulink Coder).
- If you apply a storage class other than `Auto` to a parameter object (such as `Simulink.Parameter`), you can store the object in the base workspace, a model workspace, or a data dictionary. However, if you store the object in a model workspace, the code generator assumes that the containing model owns the parameter. For more information, see “Code Generation Impact of Storage Location for Parameter Objects” (Simulink Coder).

## Create, Edit, and Manage Workspace Variables

To share information such as parameter values and signal data types between separate blocks and models, you use workspace variables. For example, you can create a numeric MATLAB variable in the base workspace and use the variable to set the value of the **Gain** parameter in multiple Gain blocks simultaneously (see “Share and Reuse Block Parameter Values by Creating Variables” on page 37-9). You can create a `Simulink.Bus` object to explicitly define the structure of a bus signal.

You can store workspace variables in the base workspace, model workspaces, or data dictionaries. To decide where to store variables, see “Determine Where to Store Variables and Objects for Simulink Models” on page 68-101.

### Tools for Managing Variables

Use one or more of these techniques to create, modify, store, and migrate workspace variables:

- To share block parameter values and create `Simulink.Parameter` and `Simulink.Signal` objects (for example, in preparation for code generation), you can use the Model Data Editor. You can interact with all of the block parameters, signal lines, and block states in a model at once. You can also inspect tunable block parameters in a list that you can search, sort, and filter.

- To create a variable, in the data table, begin editing the cell that corresponds to a block parameter value (in the **Value** column) or a signal or state name (in the **Name** column). Enter the name of the variable you want to create and click the action button  in the right side of the cell.

If a block parameter value is already set to a simple numeric expression, you can create a variable for that expression. Click  in the right side of the cell that corresponds to the value, then select **Create variable**. In the Create New Data dialog box, set the name and location for the new variable, then click **Create**. The cell now displays the new variable.

- To modify variables by using the columns in the data table, click the **Show/refresh additional information** button. Then, the data table contains rows that correspond to the variables and objects that the model uses.
- To interact with one variable at a time (for example, to inspect all of the variable properties at once), open the Property Inspector (on the **Modeling** tab, under **Design**, click **Property Inspector**) and select the relevant row in the data table. The Property Inspector shows the properties of the selected variable.

For more information, see **Model Data Editor**.

- To interact with a small number of parameters, signals, or states at a time, use individual block parameter dialog boxes or the Property Inspector to create variables for sharing block parameter values and create and configure parameter and signal objects for code generation.

In the dialog box or the Property Inspector, click the action button  next to the value of a block parameter, signal name, or state name.

- To create and edit any type or class of variable or object, move variables between workspaces, and inspect all of the variables in a workspace at once, use the Model Explorer. You can also rename variables and precisely analyze the way that an entire model or an individual block uses variables. See **Model Explorer** and “Edit and Manage Workspace Variables by Using Model Explorer” on page 68-111.

## Edit Variable Value or Property From Block Parameter

This example shows how to change the value of a **Gain** parameter (Gain block) whose value is set by a numeric variable. Modify the variable, not the block parameter.

- 1 Open the model f14. The model loads variables into the base workspace.
- 2 In the model, open the Property Inspector. On the **Modeling** tab, under **Design**, click **Property Inspector**.
- 3 In the model, select the Gain block that uses the variable Mw.
- 4 In the Property Inspector, click the button  next to the value of the **Gain** parameter. Select **Open**.
- 5 In the **Data properties** dialog box, type a new value for the variable in the **Value** box and click **OK**.

## Modify Structure and Array Variables Interactively

To inspect and modify a variable whose value is a structure or array, you can launch the Variable Editor by clicking the nearby button . Choose one of these techniques:

- In the Model Explorer, select the variable in the **Contents** pane. In the Dialog pane (the right pane), the button appears.
- In the Model Data Editor (on the **Modeling** tab, click **Model Data Editor**), on the **Parameters** tab, click the **Show/refresh additional information** button. In the data table, find the row that corresponds to the variable and, in the **Value** column, begin editing the value of the variable. The button appears in the right side of the cell.
- In a block dialog box or the Property Inspector, the button appears next to the value of a block parameter that uses the variable. Click the button and use the menu options to open the property dialog box for the variable. Then, in the property dialog box, click the button again to launch the Variable Editor. You can use this technique only for parameter objects such as `Simulink.Parameter`.

## Ramifications of Modifying or Deleting a Variable

When you modify or delete a variable, the change can impact multiple blocks and models that use the variable. To assess the impact by determining where the variable is used, use the Model Explorer (see “Analyze Variable Usage in a Model” on page 68-109). However, you can analyze variable usage only for models that are open at the time of the analysis. Before you perform the analysis, open any models that you suspect use the variable.

Models and blocks use variables through name resolution (see “Symbol Resolution” on page 68-128). When you change the name of a variable without making corresponding changes to dependent blocks and models, the blocks and models generate errors. Instead, to rename a variable in the context of one or more models, see “Rename a Variable Throughout a Model” on page 68-109.

When a block or model cannot access a variable that it needs, it generates an error in the Diagnostic Viewer. In some cases, you can use buttons in the Diagnostic Viewer to fix the error (for example, by restoring a deleted variable). To increase the likelihood that you can use the Diagnostic Viewer to recover from the absence of a variable, use these techniques:

- Store variables in a data dictionary instead of the base workspace. With a data dictionary, you gain additional options for recovery. For information about data dictionaries, see “What Is a Data Dictionary?” on page 75-2.
- For every model, keep the corresponding Simulink cache file available. For example, when you share the model with someone else, share the cache file, too. When you fetch the latest model design files from a source control system, fetch the cache file from the continuous integration system or latest build folder. The cache file preserves information that Simulink Coder can use to help you recover from the absence of a variable. For more information about Simulink cache files, see “Share Simulink Cache Files for Faster Simulation” on page 8-54.

## Analyze Variable Usage in a Model

To analyze the ways in which a model uses variables, use the Model Explorer. You can:

- Determine where a variable is used in a model.
- Determine whether a model uses a variable.
- Determine which variables in a workspace are not used by a model.

For more information, see “Edit and Manage Workspace Variables by Using Model Explorer” on page 68-111.

## Rename a Variable Throughout a Model

This example shows how to rename a variable in the Model Data Editor.

- 1 Open the model f14. The model loads variables into the base workspace.
- 2 In the model, on the **Modeling** tab, click **Model Data Editor**. In the Model Data Editor, inspect the **Parameters** tab.
- 3 In the model, click the Gain block labeled Mw.

In the Model Data Editor, the **Value** column shows that the block uses the variable Mw. Suppose you want to rename this variable.

- 4 In the Model Data Editor, click the **Show/refresh additional information** button.

Now, the data table contains rows that correspond to workspace variables that the model uses.

- 5 Activate the **Change scope** button.

Now, the data table shows information about data items in subsystems.

- 6 In the **Filter contents** box, enter Mw.

The data table shows rows that correspond to the variable and to blocks that use the variable.

- 7 In the row that represents Mw, right-click and select **Rename All**.
- 8 In the **Select a system** dialog box, click the name of the model f14 to select it as the context for renaming the variable Mw.
- 9 Clear the **Search in referenced models** check box, since f14 does not reference any models, and click **OK**.

With **Search in referenced models** selected, you can rename the target variable everywhere it is used in a model reference hierarchy. However, renaming the target variable in an entire hierarchy can take more time.

The **Update diagram to include recent changes** check box is cleared by default to save time by avoiding unnecessary model diagram updates. Select the check box to incorporate recent changes you made to the model by forcing a diagram update.

- 10 In the **Rename All** dialog box, type the new name for the variable in the **New name** box and click **OK**.
- 11 Click **Show/refresh additional information** again. Because the renaming operation changed the name of the variable and the values of some block parameters, for more accurate information in the Model Data Editor, you must click **Show/refresh additional information**.

## Interact With Variables Programmatically

At the command prompt, you can create and modify variables in the base workspace by entering commands such as `myVar = 15;`. To programmatically create, modify, and store variables in a different workspace, such as a model workspace, use the programmatic interface for the target workspace. The table shows the interfaces and techniques that you can use to programmatically manage variables.

| Target Workspace | Technique or Interface                                         |
|------------------|----------------------------------------------------------------|
| Base workspace   | Enter commands at the command prompt.                          |
| Model workspace  | See <code>Simulink.ModelWorkspace</code> .                     |
| Data dictionary  | See “Store Data in Dictionary Programmatically” on page 75-38. |

To programmatically list the variables that a model uses or does not use, see `Simulink.findVars`.

To programmatically access variables for the purpose of sweeping block parameter values, consider using `Simulink.SimulationInput` objects instead of modifying the variables through the programmatic workspace interfaces. See “Optimize, Estimate, and Sweep Block Parameter Values” on page 37-38.

“Rename Variables” on page 68-115

“Compare Duplicate Workspace Variables” on page 68-116

“Export Workspace Variables” on page 68-117

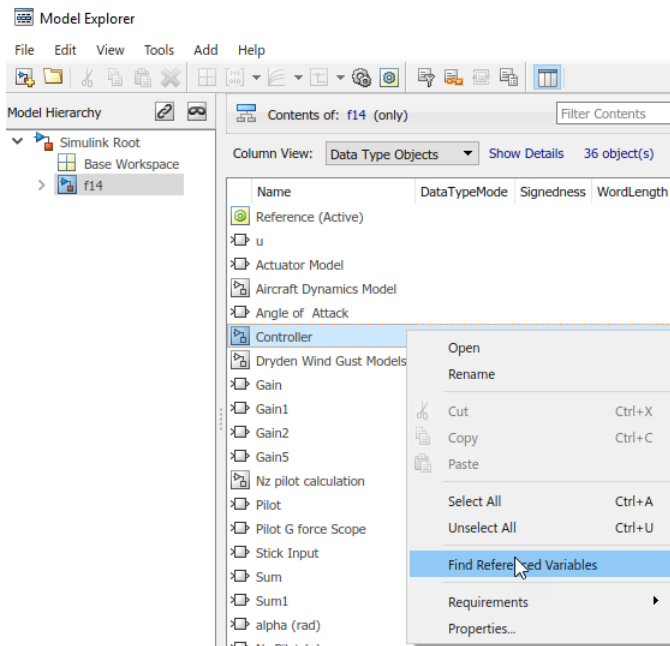

“Importing Workspace Variables” on page 68-119

To learn all of the techniques you can use to create, edit, and manage workspace variables, see “Create, Edit, and Manage Workspace Variables” on page 68-107.

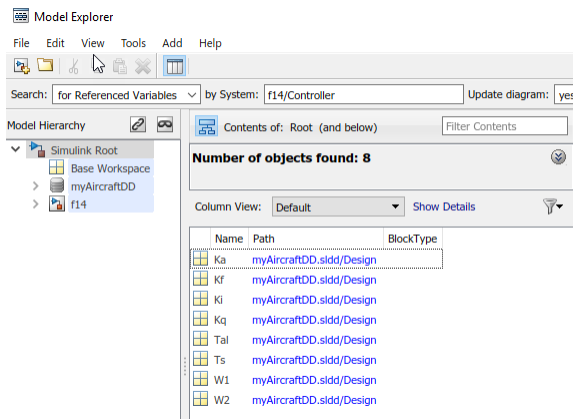

### Finding Variables That Are Used by a Model or Block

In the Model Explorer, you can get a list of variables that a model or block uses. The following approach is one way to get that list of variables:

- 1 In the **Contents** pane, right-click the block for which you want to find the variables that it uses.
- 2 Select the **Find Referenced Variables** menu item.

Model Explorer returns results similar to these:

For performance, Model Explorer uses cached information from the last compiled version of the model. If you want to recompile the model, either do so manually or, in the Model Explorer, set the **Update diagram** field to yes and repeat the search.

You can also use the following approaches to find variables that a model or block uses:

- In the Model Explorer, in the **Model Hierarchy** pane, right-click a block or model node and select the **Find Referenced Variables** menu item.
- In the Model Explorer, in the search bar, use the for Referenced Variables search type option.
- In the Simulink Editor, right-click a block, subsystem, or in the canvas and select the **Find Referenced Variables** menu item. Clicking the canvas returns results for the whole model.

The `Simulink.findVars` function provides additional options for returning information about workspace variables that is not available from the Model Explorer or Simulink Editor.

For information about limitations when finding referenced variables, see the `Simulink.findVars` documentation.

### Using the Set of Returned Variables

For a variable in the set of returned variables, you can find the blocks that use that variable (for details, see “Finding Blocks That Use a Specific Variable” on page 68-112). Also, you can export variables from the returned set of variables. For details, see “Export Workspace Variables” on page 68-117.

## Finding Blocks That Use a Specific Variable

This example shows how to use Model Explorer to get a list of blocks that use a specific workspace variable.

- 1 Open the model f14.
- 2 Open Model Explorer.
- 3 In the **Model Hierarchy** pane, select the Base Workspace node.
- 4 In the **Contents** pane, right-click the variable Mq and select **Find Where Used**.
- 5 In the **Select a system** dialog box, select f14.

- 6 Clear the **Search in referenced models** check box, since f14 does not reference any models, and click **OK**.

With **Search in referenced models** selected, you can find the target variable everywhere it is used in a model reference hierarchy. However, finding the target variable in an entire hierarchy can take more time.

The **Update diagram to include recent changes** check box is cleared by default to save time by avoiding unnecessary model diagram updates. Select the check box to incorporate recent changes you made to the model by forcing a diagram update.

- 7 Click **OK** in response to the message to update the model diagram.

Because you just opened the model, you must update the model diagram at least once before finding a variable. You could have selected **Update diagram to include recent changes** in the **Select a system** dialog box to force an initial diagram update, though you typically use that option when you make changes to the model while performing multiple searches with **Find Where Used**.

- 8 Model Explorer displays the search results:

The property columns whose values include Mq represent the block parameters that use the Mq variable. If those property columns are not already in the view, then the Model Explorer adds them to the end of the search results display.

You can also find blocks that use a specific variable by using one of these approaches:

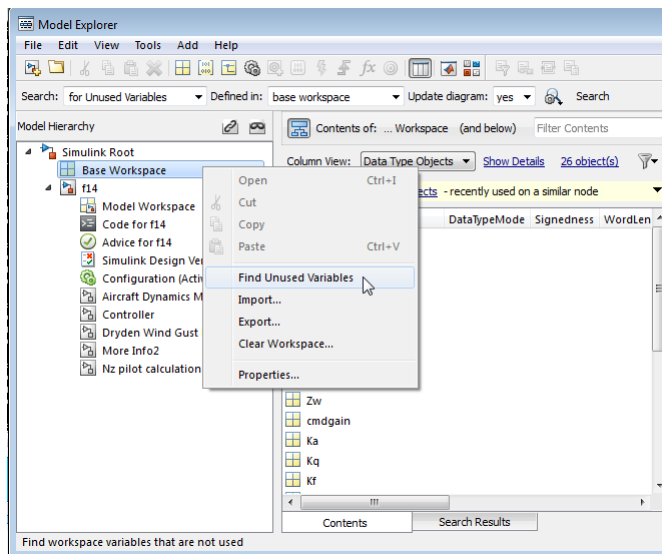

- In the search bar, select the for **Variable Usage** search type option.
- In the **Search Results** pane, right-click a variable and select the **Find Where Used** menu item.
- In the Model Data Editor, right-click a workspace variable and select the **Find Where Used** menu item.

## Finding Unused Workspace Variables

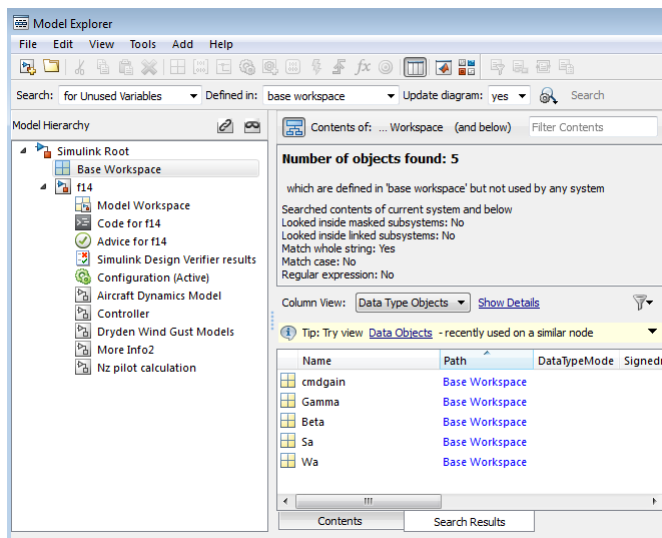

You can use the Model Explorer to get a list of variables that are defined in a workspace but not used by a model or block. One way to get that list of variables is to right-click a workspace name in the **Model Hierarchy** pane and select the **Find Unused Variables** menu item. For example:

- 1 Open the f14 model.
- 2 Open the Model Explorer.
- 3 In the search toolbar, set the **Update diagram** field to yes.

- 4 In the **Model Hierarchy** pane, right-click the Base Workspace node and select the **Find Unused Variables** menu item.

- 5 The Model Explorer displays output similar to this:

The `Simulink.findVars` function provides additional options for returning information about unused workspace variables that is not available from the Model Explorer or Simulink Editor.

## Editing Workspace Variables

In the Model Explorer, you can use the Variable Editor to edit variables from the MATLAB base workspace or model workspace. The Variable Editor is available for editing large arrays and structures.

To open the Variable Editor:

- 1 In the **Contents** pane, select the variable.
- 2 In the Dialog pane (the right pane), click the button  near the value of the variable.
- 3 In the menu, select **Open Variable Editor**.

Alternatively, to open the Variable Editor from the **Contents** pane instead of the Dialog pane, begin editing the value of the variable by clicking the appropriate cell. The button appears in the cell.

### Representation of Arrays with Three or More Dimensions

When the value of a variable or `Simulink.Parameter` object is an array with three or more dimensions, the **Value** column displays the array as an expression that contains a call to the `reshape` function.

To edit the values in the array, modify the first argument of the `reshape` call, which contains all of the array values in a serialized vector. When you add or remove elements along a dimension, you must also correct the argument that represents the length of the modified dimension.

### Rename Variables

This example shows how to use Model Explorer to rename a variable everywhere it is used by blocks in Simulink models.

- 1 Open the “Modeling an Anti-Lock Braking System” example model `sldemo_absbrake`. The model loads data to the MATLAB base workspace.
- 2 Open Model Explorer.
- 3 In the **Model Hierarchy** pane, select the base workspace.
- 4 In the **Contents** pane, right-click the base workspace variable `m` and select **Rename All**.
- 5 In the **Select a system** dialog box, click the name of the model `sldemo_absbrake` to select it as the context for renaming the variable `m`.
- 6 Clear the **Search in referenced models** check box and click **OK**. The model `sldemo_absbrake` references the model `sldemo_wheelspeed_absbrake`, but only `sldemo_absbrake` uses the variable `m`.

With **Search in referenced models** selected, you can rename the target variable everywhere it is used in a model reference hierarchy. However, renaming the target variable in an entire hierarchy can take more time.

The **Update diagram to include recent changes** check box is cleared by default to save time by avoiding unnecessary model diagram updates. Select the check box to incorporate recent changes you made to the model by forcing a diagram update.

- 7 Click **OK** in response to the message to update the model diagram.

Since you just opened the model, you must update the model diagram at least once before renaming a variable. You could have selected **Update diagram to include recent changes** in the **Select a system** dialog box to force an initial diagram update, though you typically use that option when you make changes to the model while performing multiple variable renaming operations.

- 8 In the **Rename All** dialog box, type a new name for the variable in the **New name** box and click **OK**.

You can use the hyperlinks in the **Corresponding blocks** section of the **Rename All** dialog box to view the target blocks.

---

**Note** You can rename only variables that the function `Simulink.findVars` supports.

---

For help with renaming files, use a project. See “Automatic Updates When Renaming, Deleting, or Removing Files” on page 17-10.

## Compare Duplicate Workspace Variables

You can compare duplicate variables that are stored in the same workspace or in different workspaces. For example, you can compare a variable stored in the base workspace with its duplicate, which is stored in the model workspace.

- 1 Open a model and the Model Explorer.
- 2 In the search toolbar, search for the variable that is duplicated. Select the rows with the duplicate entries. Then, right-click and select **Compare Selected**.

- 3 Review the differences in the **Comparison Viewer**.

## Export Workspace Variables

You can export (save) a set of variables listed in the Model Explorer, exporting either individual variables or all the variables in the base or model workspace.

One possible workflow is to export the set of variables returned with the **Find Referenced Variables** option or the `Simulink.findVars` function. For details, see “Finding Variables That Are Used by a Model or Block” on page 68-111.

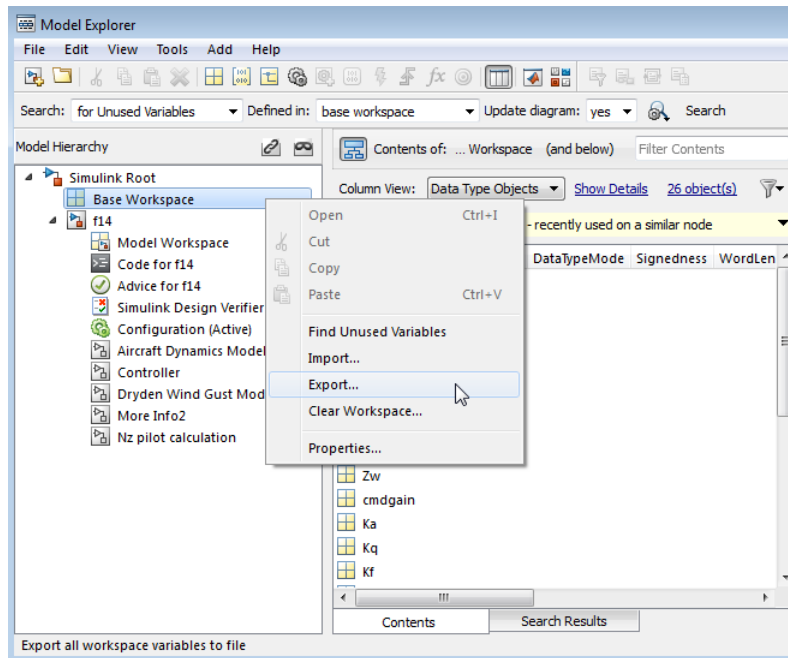

---

**Note** All the variables that you export must be from the same workspace.

---

To export all the variables in a workspace in the Model Explorer to a MATLAB code file or MAT-file:

- 1 Select the variables that you want to export.
  - a To select all the variables in a workspace, right-click the workspace node (for example, Base Workspace) and select the **Export** menu item. For example:

- b To select individual variables, in the **Contents** pane, select the variables that you want to export. Right-click one of the highlighted variables and select the **Export Selected** menu item.

If the **Contents** pane has data grouped by a property, selecting the top line in a group does not select all the variables in that group. For details about grouped data, see **Model Explorer**.

- 2 Specify whether to save the variables in a MATLAB code file or a MAT-file.

The MATLAB code file format is easier to read, is editable, and supports version control. The MAT-file format is binary, which has performance advantages.

If you specify a MATLAB code file format, the Model Explorer may create an associated MAT-file, reflecting the name of the MATLAB code file, but with an extension of `.mat` instead of `.m`.

- 3 Specify a name and location for the file.
- 4 If the file already exists, Model Explorer displays a dialog box asking you to choose one of these options:
- **Overwrite entire file**
    - Replaces all variables in the target file with the selected variables, which are stored in alphabetical order.
  - **Update variables that exist in file and append new variables to file**
    - Updates existing variables in place and appends new variables.
  - **Only update variables that exist in file**
    - Updates existing variables, but does not add any new variables, which eliminates potentially extraneous variables.

To permanently store workspace variables for a model, instead of using the base workspace, create a data dictionary. See “What Is a Data Dictionary?” on page 75-2.

## Importing Workspace Variables

You can import (load) a set of variables from a file into the base workspace or into a model workspace using the Model Explorer. When you import variables into a workspace, the Model Explorer overwrites existing variables and adds any new variables.

To import variables into a workspace:

- 1** In the **Model Hierarchy** pane, right-click the workspace into which you want to import variables.
- 2** Select the **Import** menu item.
- 3** In the Import from File dialog box, select a MATLAB code file or MAT-file for the variables that you want to import.

---

**Note** If you import a MATLAB code file, then Simulink also imports the associated MAT-file.

---

## Model Workspaces

### In this section...

“Model Workspace Differences from MATLAB Workspace” on page 68-120

“Troubleshooting Memory Issues” on page 68-120

“Manipulate Model Workspace Programmatically” on page 68-121

### Model Workspace Differences from MATLAB Workspace

Each model is provided with its own workspace for storing variable values.

The model workspace is similar to the base MATLAB workspace except that:

- Variables in a model workspace are visible only in the scope of the model.

If both the MATLAB workspace and a model workspace define a variable of the same name, and the variable does not appear in any intervening masked subsystem or model workspaces, the Simulink software uses the value of the variable in the model workspace. A model's workspace effectively provides it with its own name space, allowing you to create variables for the model without risk of conflict with other models.

- When the model is loaded, the workspace is initialized from a data source.

The data source can be a Model file, a MAT-file, a MATLAB file, or MATLAB code stored in the model file. For more information, see “Data source” on page 68-123.

- You can interactively reload and save MAT-file, MATLAB file, and MATLAB code data sources.
- To store a signal object in a model workspace, set the storage class of the object to `Auto`. Signal objects include `Simulink.Signal` and subclasses that you create.

If you specify a storage class other than `Auto`, you must store signal objects in the base workspace or a data dictionary to ensure the objects are unique within the global Simulink context and accessible to all models.

- When you store MATLAB variables and parameter objects (such as `Simulink.Parameter`) in a model workspace, some tunability limitations apply. See “Tunability Considerations and Limitations for Other Modeling Goals” on page 37-36. In addition, if you store an `AUTOSAR.Parameter` object in a model workspace, the code generator ignores the storage class that you specify for the object.

---

**Note** When resolving references to variables used in a referenced model, the variables of the referenced model are resolved as if the parent model did not exist. For example, suppose a referenced model references a variable that is defined in both the parent model's workspace and in the MATLAB workspace but not in the referenced model's workspace. In this case, the MATLAB workspace is used.

---

### Troubleshooting Memory Issues

When you use a workspace variable as a block parameter, Simulink creates a copy of the variable during the compilation phase of the simulation and stores the variable in memory. This can cause

your system to run out of memory during simulation, or in the process of generating code. Your system might run out of memory if you have:

- Large models with many parameters
- Models with parameters that have a large number of elements

This issue does not affect the amount of memory that is used to represent parameters in generated code.

## Manipulate Model Workspace Programmatically

An object of the `Simulink.ModelWorkspace` class describes a model workspace. Simulink creates an instance of this class for each model that you open during a Simulink session. The methods associated with this class can be used to accomplish a variety of tasks related to the model workspace, including:

- Listing the variables in the model workspace
- Assigning values to variables
- Evaluating expressions
- Clearing the model workspace
- Reloading the model workspace from the data source
- Saving the model workspace to a specified MAT-file or MATLAB file
- Saving the workspace to the MAT-file or MATLAB file that the workspace designates as its data source

## Specify Source for Data in Model Workspace

When you use a model workspace to contain the variables that a model uses, you can choose to store the variables in one of these sources:

- The model file, which can store static variable definitions.
- A separate MAT-file or MATLAB file. You can reload the variables from the external file into the model workspace at any time.
- Your own custom MATLAB code that creates variables. You can save the code as part of the model file, and reload the code at any time.

To specify a data source for a model workspace, in the Model Explorer, use the Model Workspace dialog box. To display the dialog box for a model workspace:

- 1 Open the Model Explorer. On the **Modeling** tab, click **Model Data Editor**.
- 2 In the **Model Hierarchy** pane, right-click the model workspace.

- 3 Select the **Properties** menu item, which opens the Model Workspace dialog box.

To use MATLAB commands to change data in a model workspace, see “Use MATLAB Commands to Change Workspace Data” on page 68-126.

## Data source

The **Data source** field in the Model Workspace dialog box includes the following data source options for a workspace:

- Model File

Specifies that the data source is the model itself.

- MAT-File

Specifies that the data source is a MAT file. Selecting this option causes additional controls to appear (see “MAT-File and MATLAB File Source Controls” on page 68-123).

- MATLAB File

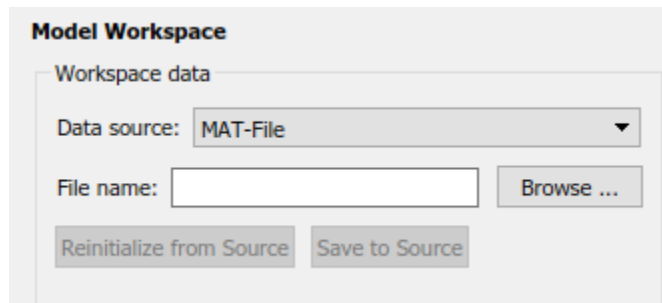

Specifies that the data source is a MATLAB file. Selecting this option causes additional controls to appear (see “MAT-File and MATLAB File Source Controls” on page 68-123).

- MATLAB Code

Specifies that the data source is MATLAB code stored in the model file. Selecting this option causes additional controls to appear (see “MATLAB Code Source Controls” on page 68-124).

## MAT-File and MATLAB File Source Controls

Selecting MAT-File or MATLAB File as the **Data source** for a workspace causes the Model Workspace dialog box to display additional controls.

### File name

Specifies the file name or path name of the MAT-file or MATLAB file that is the data source for the selected workspace. If you specify a file name, the name must reside on the MATLAB path.

### Reinitialize From Source

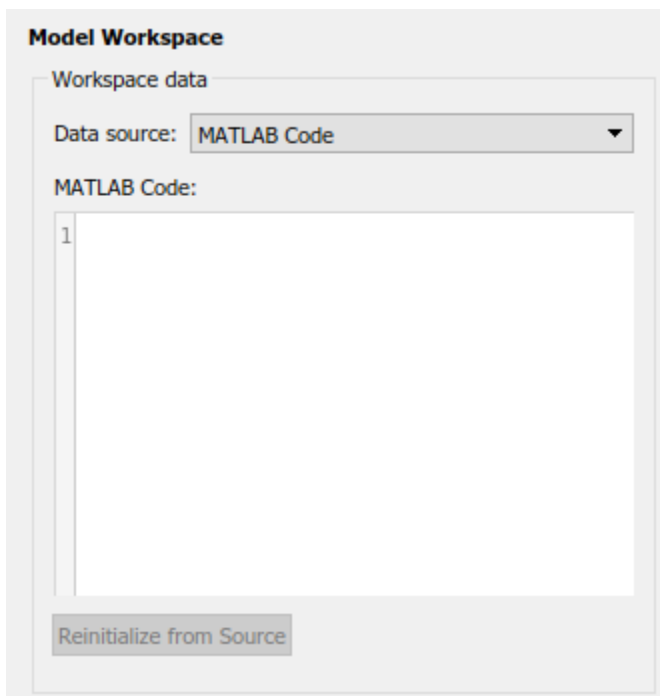

Clears the workspace and reloads the data from the MAT-file or MATLAB file specified by the **File name** field.

### Save To Source

Saves the workspace in the MAT-file or MATLAB file specified by the **File name** field.

## MATLAB Code Source Controls

Selecting MATLAB Code as the **Data source** for a workspace causes the Model Workspace dialog box to display additional controls.

### MATLAB Code

Specifies MATLAB code that initializes the selected workspace. To change the initialization code, edit this field, then select the **Reinitialize from source** button on the dialog box to clear the workspace and execute the modified code.

### Reinitialize from Source

Clears the workspace and executes the contents of the **MATLAB Code** field.

### Create Model Mask

Mask the model, which enables you to control how users of the model interact with model arguments. For more information, see “Introduction to System Mask” on page 39-47.

## See Also

### Related Examples

- “Determine Where to Store Variables and Objects for Simulink Models” on page 68-101
- “Model Workspaces” on page 68-120
- “Change Model Workspace Data” on page 68-125

## Change Model Workspace Data

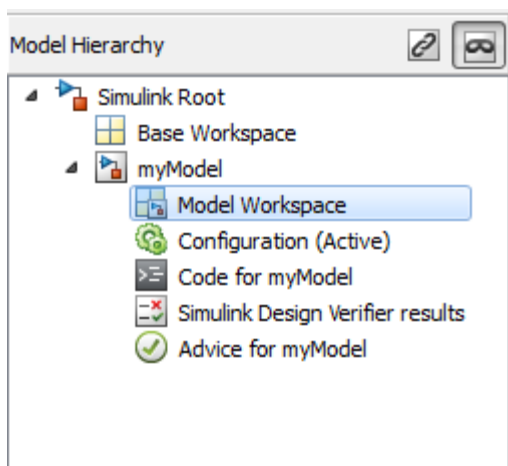

When you use a model workspace to contain the variables that a model uses, you choose a source to store the variables, such as the model file or an external MAT-file. To modify the variables at the source, you use a different procedure depending on the type of source that you selected.

### Change Workspace Data Whose Source Is the Model File

If the data source of a model workspace is the model file, you can use Model Explorer or MATLAB commands to modify the stored variables (see “Use MATLAB Commands to Change Workspace Data” on page 68-126).

For example, to create a variable in a model workspace:

- 1 Open the Model Explorer. On the **Modeling** tab, click **Model Data Editor** or press **Ctrl+H**.
- 2 In the Model Explorer **Model Hierarchy** pane, expand the node for your model, and select the model workspace.

- 3 Select **Add > MATLAB Variable**.

You can similarly use the **Add** menu or toolbar to add a `Simulink.Parameter` object to a model workspace.

To change the value of a model workspace variable:

- 1 Open the Model Explorer. On the **Modeling** tab, click **Model Explorer**.
- 2 In the Model Explorer **Model Hierarchy** pane, select the model workspace.
- 3 In the **Contents** pane, select the variable.
- 4 In the **Contents** pane or in **Dialog** pane, edit the value displayed.

To delete a model workspace variable:

- 1 Open the Model Explorer. On the **Modeling** tab, click **Model Explorer**.
- 2 In the Model Explorer **Model Hierarchy** pane, select the model workspace.
- 3 In **Contents** pane, select the variable.

- 4 Select **Edit > Delete**.

## Change Workspace Data Whose Source Is a MAT-File or MATLAB File

You can use Model Explorer or MATLAB commands to modify workspace data whose source is a MAT-file or MATLAB file.

To make the changes permanent, in the Model Workspace dialog box, use the **Save To Source** button to save the changes to the MAT-file or MATLAB file.

- 1 Open the Model Explorer. On the **Modeling** tab, click **Model Explorer**.
- 2 In the Model Explorer **Model Hierarchy** pane, right-click the workspace.
- 3 Select the **Properties** menu item.
- 4 In the Model Workspace dialog box, use the **Save To Source** button to save the changes to the MAT-file or MATLAB file.

To discard changes to the workspace, in the Model Workspace dialog box, use the **Reinitialize From Source** button.

## Changing Workspace Data Whose Source Is MATLAB Code

The safest way to change data whose source is MATLAB code is to edit and reload the source. Edit the MATLAB code and then in the Model Workspace dialog box, use **Reinitialize From Source** button to clear the workspace and re-execute the code.

To save and reload alternative versions of the workspace that result from editing the MATLAB code source or the workspace variables themselves, see “Export Workspace Variables” on page 68-117 and “Importing Workspace Variables” on page 68-119.

## Use MATLAB Commands to Change Workspace Data

To use MATLAB commands to change data in a model workspace, first get the workspace for the currently selected model:

```
hws = get_param(bdroot, 'modelworkspace');
```

This command returns a handle to a `Simulink.ModelWorkspace` object whose properties specify the source of the data used to initialize the model workspace. Edit the properties to change the data source.

Use the workspace methods to:

- List, set, and clear variables
- Evaluate expressions in the workspace
- Save and reload the workspace

For example, the following MATLAB code creates variables specifying model parameters in the model workspace, saves the parameters, modifies one of them, and then reloads the workspace to restore it to its previous state.

```
hws = get_param(bdroot, 'modelworkspace');
hws.DataSource = 'MAT-File';
```

```
hws.FileName = 'params';
hws.assignin('pitch', -10);
hws.assignin('roll', 30);
hws.assignin('yaw', -2);
hws.saveToSource;
hws.assignin('roll', 35);
hws.reload;
```

To programmatically access variables for the purpose of sweeping block parameter values, consider using `Simulink.SimulationInput` objects instead of modifying the variables through the programmatic interface of the model workspace. See “Optimize, Estimate, and Sweep Block Parameter Values” on page 37-38.

## Create Model Mask

Mask the model, which enables you to control how users of the model interact with model arguments. For more information, see “Introduction to System Mask” on page 39-47.

## Symbol Resolution

### In this section...

“Symbols” on page 68-128  
 “Symbol Resolution Process” on page 68-128  
 “Numeric Values with Symbols” on page 68-129  
 “Other Values with Symbols” on page 68-130  
 “Limit Signal Resolution” on page 68-130  
 “Explicit and Implicit Symbol Resolution” on page 68-130

### Symbols

When you create a Simulink model, you can use symbols to provide values and definitions for many types of entities in the model. Model entities that you can define with symbols include block parameters, configuration set parameters, data types, signals, signal properties, and bus architecture.

A symbol that provides a value or definition must be a legal MATLAB identifier. Such an identifier starts with an alphabetic character, followed by alphanumeric or underscore characters up to the length given by the function `namelengthmax`. You can use the function `isvarname` to determine whether a symbol is a legal MATLAB identifier.

A symbol provides a value or definition in a Simulink model by corresponding to some item that:

- Exists in an accessible workspace
- Has a name that matches the symbol
- Provides the required information

### Symbol Resolution Process

The process of finding an item that corresponds to a symbol is called *symbol resolution* or *resolving the symbol*. The matching item can provide the needed information directly, or it can itself be a symbol. A symbol must resolve to some other item that provides the information.

When the Simulink software compiles a model, it tries to resolve every symbol in the model, except symbols in MATLAB code that runs in a callback or as part of mask initialization. Depending on the particular case, the item to which a symbol resolves can be a variable, object, or function.

Simulink attempts to resolve a symbol by searching through the accessible workspaces in hierarchical order for a MATLAB variable or Simulink object whose name is the same as the symbol.

The search path is identical for every symbol. The search begins with the block that uses the symbol, or is the source of a signal that is named by the symbol, and proceeds upward. Except when simulation occurs via the `sim` command, the search order is:

- 1 Any mask workspaces, in order from the block upwards (see “Masking Fundamentals” on page 39-2).
- 2 The model workspace of the model that contains the block (see “Model Workspaces” on page 68-120).

- 3 The MATLAB base workspace (see “Create and Edit Variables”) or, if the model is linked to a data dictionary, the dictionary (see “What Is a Data Dictionary?” on page 75-2). If the data dictionary has the **Enable dictionary access to base workspace** property selected, the search treats the dictionary and the base workspace as a single namespace.

---

**Note** If the model references a configuration set that is stored in the base workspace, the search begins in the base workspace. Unlike a configuration set that is attached to the model, a configuration set that is in the base workspace does not have access to the model workspace.

The **Input** and **Initial state** parameters do not load data from a data dictionary. When a model uses a data dictionary and you disable model access to the base workspace, the **Input** and **Initial state** parameters still access data in the base workspace.

---

If Simulink finds a matching item in the course of this search, the search terminates successfully at that point, and the symbol resolves to the matching item. The result is the same as if the value of that item had appeared literally instead of the symbol that resolved to the item. An object defined at a lower level shadows any object defined at a higher level.

If no matching item exists on the search path, Simulink attempts to evaluate the symbol as a function. If the function is defined and returns an appropriate value, the symbol resolves to whatever the function returned. Otherwise, the symbol remains unresolved, and an error occurs. Evaluation as a function occurs as the final step whenever a hierarchical search terminates without having found a matching workspace variable.

If the model that contains the symbol is a referenced model, and the search reaches the model workspace but does not succeed there, the search jumps directly to the base workspace or data dictionary *without* trying to resolve the symbol in the workspace of any parent model. Thus a given symbol resolves to the same item, irrespective of whether the model that contains the symbol is a referenced model. For information about model referencing, see “Model References”.

## Numeric Values with Symbols

You can specify any block parameter that requires a numeric value by providing a literal value, a symbol, or an expression, which can contain symbols and literal values. Each symbol is resolved separately, as if none of the others existed. Different symbols in an expression can thus resolve to items on different workspaces, and to different types of item.

When a single symbol appears and resolves successfully, its value provides the value of the parameter. When an expression appears, and all symbols resolve successfully, the value of the expression provides the value of the parameter. If any symbol cannot be resolved, or resolves to a value of inappropriate type, an error occurs.

For example, suppose that the **Gain** parameter of a Gain block is given as  $\cos(a*(b+2))$ . The symbol `cos` will resolve to the MATLAB cosine function, and `a` and `b` must resolve to numeric values, which can be obtained from the same or different types of items in the same or different workspaces. If the symbols resolve to numeric values, the value returned by the cosine function becomes the value of the **Gain** parameter.

## Other Values with Symbols

Most symbols and expressions that use them provide numeric values, but the same techniques that provide numeric values can provide any type of value that is appropriate for its context.

Another common use of symbols is to name objects that provide definitions of some kind. For example, a signal name can resolve to a signal object (`Simulink.Signal`) that defines the properties of the signal, and a Bus Creator block **Data type** parameter can name a bus object (`Simulink.Bus`) that defines the properties of the bus. You can use symbols for many purposes, including:

- Define data types
- Specify input data sources
- Specify logged data destinations

For hierarchical symbol resolution, all of these different uses of symbols, whether singly or in expressions, are the same. Each symbol is resolved, if possible, independently of any others, and the result becomes available where the symbol appeared. The only difference between one symbol and another is the specific item to which the symbol resolves and the use made of that item. The only requirement is that every symbol must resolve to something that can legally appear at the location of the symbol.

## Limit Signal Resolution

Hierarchical symbol resolution traverses the complete search path by default. You can truncate the search path by using the **Permit Hierarchical Resolution** option of any subsystem. This option controls what happens if the search reaches that subsystem without resolving to a workspace variable. The **Permit Hierarchical Resolution** values are:

- All

Continue searching up the workspace hierarchy trying to resolve the symbol. This is the default value.

- None

Do not continue searching up the hierarchy.

- `ExplicitOnly`

Continue searching up the hierarchy only if the symbol specifies a block parameter value, data store memory (where no block exists), or a signal or state that explicitly requires resolution. Do not continue searching for an implicit resolution. See “Explicit and Implicit Symbol Resolution” on page 68-130 for more information.

If the search does not find a match in the workspace, and terminates because the value is `ExplicitOnly` or `None`, Simulink evaluates the symbol as a function. The search succeeds or fails depending on the result of the evaluation, as previously described.

## Explicit and Implicit Symbol Resolution

Models and some types of model entities have associated parameters that can affect symbol resolution. For example, suppose that a model includes a signal named `Amplitude`, and that a

Simulink.Signal object named Amplitude exists in an accessible workspace. If the Amplitude signal's **Signal name must resolve to Simulink signal object** option is selected, the signal resolves to the object. For more information, see **Signal Properties**.

If the option is not selected, the signal may or may not resolve to the object, depending on the value of **Configuration Parameters > Data Validity > Signal resolution**. This parameter can suppress resolution to the object even though the object exists, or it can specify that resolution occurs on the basis of the name match alone. For more information, see “Model Configuration Parameters: Data Validity Diagnostics” > “Signal resolution”.

Resolution that occurs because an option such as **Signal name must resolve to Simulink signal object** requires it is called *explicit symbol resolution*. Resolution that occurs on the basis of name match alone, without an explicit specification, is called *implicit symbol resolution*.

---

**Tip** Implicit symbol resolution can be useful for fast prototyping. However, when you are done prototyping, consider using explicit symbol resolution, because implicit resolution slows performance, complicates model validation, and can have nondeterministic effects.

## Upgrade Level-1 Data Classes

Simulink no longer supports level-1 data classes. You must upgrade data classes that you created using the level-1 data class infrastructure, which was removed in a previous release.

Run the following utility function while specifying the destination folder for the upgraded classes.

---

**Note** Property types defined in level-1 data classes that are not subclasses of `Simulink.Parameter`, `Simulink.Signal`, or `Simulink.CustomStorageClassAttributes` are not preserved during an upgrade. Only subclasses of these three classes will preserve attributes `PropertyType` and `AllowedValues`.

---

- 1 This command upgrades all your level-1 data class packages. You cannot upgrade selected data packages.

```
Simulink.data.upgradeClasses('C:\MyDataClasses')
```

Here, `C:\MyDataClasses` is the destination folder for your level-2 data classes.

---

**Note** Do not place your upgraded level-2 classes and their equivalent level-1 classes in the same folder.

---

`Simulink.data.upgradeClasses` uses the `packagedefn.mat` file in your level-1 class packages for the upgrade and creates level-2 classes in the specified destination folder. Then, `Simulink.data.upgradeClasses` adds the folder to top of the MATLAB path and saves the path.

---

**Note** If `Simulink.data.upgradeClasses` cannot save the MATLAB path because of restricted access, a warning appears. In this case, manually add the folder to the top of the MATLAB path and save the path using `savepath`.

---

- 2 You can change the location of the level-2 package folders after they have been generated. However, you will need to update your MATLAB path so that MATLAB can find these package folders.
- 3 Resave MAT-files and models that contain level-1 data objects.
- 4 Retain your level-1 classes on the MATLAB path until you have resaved all of your models and MAT-files that contain level-1 data objects. Any models or MAT-files that contain level-1 data objects will continue to load successfully while your level-1 data classes are on the MATLAB path.

---

**Note** You cannot use both level-1 and level-2 data classes at the same time. Level-2 classes need to be above the level-1 classes on the MATLAB path so that they are found by MATLAB.

## Associating User Data with Blocks

You can use the `set_param` command to associate your own data with a block. For example, the following command associates the value of the variable `mydata` with the currently selected block.

```
set_param(gcb, 'UserData', mydata)
```

The value of `mydata` can be any MATLAB data type, including arrays, structures, objects, and Simulink data objects.

Use `get_param` to retrieve the user data associated with a block.

```
get_param(gcb, 'UserData')
```

The following command saves the user data associated with a block in the model file of the model containing the block.

```
set_param(gcb, 'UserDataPersistent', 'on');
```

---

**Note** If persistent `UserData` for a block contains any Simulink data objects, the directories containing the definitions for the classes of those objects must be on the MATLAB path when you open the model containing the block.

## Supported and Unsupported Simulink Blocks

The software provides various levels of support for Simulink blocks:

- Fully supported
- Partially supported
- Not supported

If your model contains unsupported blocks, you can enable automatic stubbing. Automatic stubbing considers the interface of the unsupported blocks, but not their behavior. If any of the unsupported blocks affect the simulation outcome, however, the analysis may achieve only partial results. For details about automatic stubbing, see “Handle Incompatibilities with Automatic Stubbing” (Simulink Design Verifier).

To achieve 100% coverage, avoid using unsupported blocks in models that you analyze. Similarly, for partially supported blocks, specify only the block parameters that the software recognizes.

The following tables summarize the analysis support for Simulink blocks. Each table lists the blocks in a Simulink library and describes support information for that particular block.

### Additional Math and Discrete Library

The software supports all blocks in the Additional Math and Discrete library.

### Commonly Used Blocks Library

The Commonly Used Blocks library includes blocks from other libraries. Those blocks are listed under their respective libraries.

### Continuous Library

| Block                           | Support Notes                   |
|---------------------------------|---------------------------------|
| Derivative                      | Not supported                   |
| Integrator                      | Not supported and not stubbable |
| Integrator Limited              | Not supported and not stubbable |
| PID Controller                  | Not supported                   |
| PID Controller (2DOF)           | Not supported                   |
| Second-Order Integrator         | Not supported and not stubbable |
| Second-Order Integrator Limited | Not supported and not stubbable |
| State-Space                     | Not supported and not stubbable |
| Transfer Fcn                    | Not supported and not stubbable |
| Transport Delay                 | Not supported                   |
| Variable Time Delay             | Not supported                   |
| Variable Transport Delay        | Not supported                   |
| Zero-Pole                       | Not supported and not stubbable |

### Discontinuities Library

The software supports all blocks in the Discontinuities library.

### Discrete Library

| Block                          | Support Notes |
|--------------------------------|---------------|
| Delay                          | Supported     |
| Difference                     | Supported     |
| Discrete Derivative            | Supported     |
| Discrete Filter                | Supported     |
| Discrete FIR Filter            | Supported     |
| Discrete PID Controller        | Supported     |
| Discrete PID Controller (2DOF) | Supported     |
| Discrete State-Space           | Not supported |
| Discrete Transfer Fcn          | Supported     |
| Discrete Zero-Pole             | Not supported |
| Discrete-Time Integrator       | Supported     |
| Memory                         | Supported     |
| Tapped Delay                   | Supported     |
| Transfer Fcn First Order       | Supported     |
| Transfer Fcn Lead or Lag       | Supported     |
| Transfer Fcn Real Zero         | Supported     |
| Unit Delay                     | Supported     |
| Zero-Order Hold                | Supported     |

### Logic and Bit Operations Library

The software supports all blocks in the Logic and Bit Operations library.

### Lookup Tables Library

| Block                         | Support Notes                                                                                                                                                                                                                                                                                                                                                                                           |
|-------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Cosine                        | Supported                                                                                                                                                                                                                                                                                                                                                                                               |
| Direct Lookup Table (n-D)     | Supported                                                                                                                                                                                                                                                                                                                                                                                               |
| Interpolation Using Prelookup | Not supported when: <ul style="list-style-type: none"> <li>• The <b>Interpolation method</b> parameter is <b>Linear</b> and the <b>Number of table dimensions</b> parameter is greater than 4.</li> </ul> or <ul style="list-style-type: none"> <li>• The <b>Interpolation method</b> parameter is <b>Linear</b> and the <b>Number of sub-table selection dimensions</b> parameter is not 0.</li> </ul> |

| Block                | Support Notes                                                                                                                                                                                                                                                                                                                                                       |

## Support Limitations for Stateflow Software Features

Simulink Design Verifier does not support the following Stateflow software features. Avoid using these unsupported features in models that you analyze.

### In this section...

“ml Namespace Operator, ml Function, ml Expressions” on page 68-147

“C or C++ Operators” on page 68-147

“Machine-Parented Data” on page 68-150

“Textual Functions with Literal String Arguments” on page 68-150

### ml Namespace Operator, ml Function, ml Expressions

The software does not support calls to MATLAB functions or access to MATLAB workspace variables, which the Stateflow software allows. See “Access MATLAB Functions and Workspace Data in C Charts” (Stateflow).

### C or C++ Operators

The software does not support the `sizeof` operator, which the Stateflow software allows.

### C Math Functions

The software supports calls to the following C math functions:

- `abs`
- `ceil`
- `fabs`
- `floor`
- `fmod`
- `labs`
- `ldexp`
- `pow` (only for integer exponents)

The software does not support calls to other C math functions, which the Stateflow software allows. If automatic stubbing is enabled, which it is by default, the software eliminates these unsupported functions during the analysis.

For information about C math functions in Stateflow, see “Call C Library Functions in C Charts” (Stateflow).

---

**Note** For details about automatic stubbing, see “Handle Incompatibilities with Automatic Stubbing” (Simulink Design Verifier).

---

## Atomic Subcharts That Call Exported Graphical Functions Outside a Subchart

The software does not support atomic subcharts that call exported graphical functions, which the Stateflow software allows.

---

**Note** For information about exported functions, see “Export Stateflow Functions for Reuse” (Stateflow).

---

## Atomic Subchart Input and Output Mapping

If an input or output in an atomic subchart maps to chart-level data of a different scope, the software does not support the chart that contains that atomic subchart.

For an atomic subchart input, this incompatibility applies when the input maps to chart-level data of output, local, or parameter scope. For an atomic subchart output, this incompatibility applies when the output maps to chart-level data of local scope.

## Recursion and Cyclic Behavior

The software does not support recursive functions, which occur when a function calls itself directly or indirectly through another function call. Stateflow software allows you to implement recursion using graphical functions.

In addition, the software does not support recursion that the Stateflow software allows you to implement using a combination of event broadcasts and function calls.

---

**Note** For information about avoiding recursion in Stateflow charts, see “Avoid Unwanted Recursion in a Chart” (Stateflow).

---

Stateflow software also allows you to create *cyclic behavior*, where a sequence of steps is repeated indefinitely. If your model has a chart with cyclic behavior, the software cannot analyze it.

---

**Note** For information about cyclic behavior in Stateflow charts, see “Cyclic Behavior” (Stateflow).

---

However, you can modify a chart with cyclic behavior so that it is compatible, as in the following example.

The following chart creates cyclic behavior. State A calls state A1, which broadcasts a `Clear` event to state B, which calls state B2, which broadcasts a `Set` event back to state A, causing the cyclic behavior.

If you change the send function calls to use directed event broadcasts so that the Set and Clear events are broadcast directly to the states B1 and A1, respectively, the cyclic behavior disappears and the software can analyze the model.

**Note** For information about the benefits of directed event broadcasts, see “Broadcast Local Events to Synchronize Parallel States” (Stateflow).

## Custom C/C++ Code

If your model consists of custom C/C++ code, Simulink Design Verifier supports analysis based on these settings:

- If you enable import custom code and custom code analysis options, the software supports custom C/C++ code for analysis. For more information, see “Import custom code” and “Enable custom code analysis”.
- If you enable import custom code option and the custom code analysis option is set to `Off`, the model is compatible for analysis, but calls to the custom code are stubbed during analysis.
- If the import custom code option is set to `Off`, the custom code is not supported and the model is incompatible for analysis.

## **Machine-Parented Data**

The software does not support machine-parented data (i.e., defined at the level of the Stateflow machine), which the Stateflow software allows.

For more information, see “Best Practices for Using Data in Charts” (Stateflow).

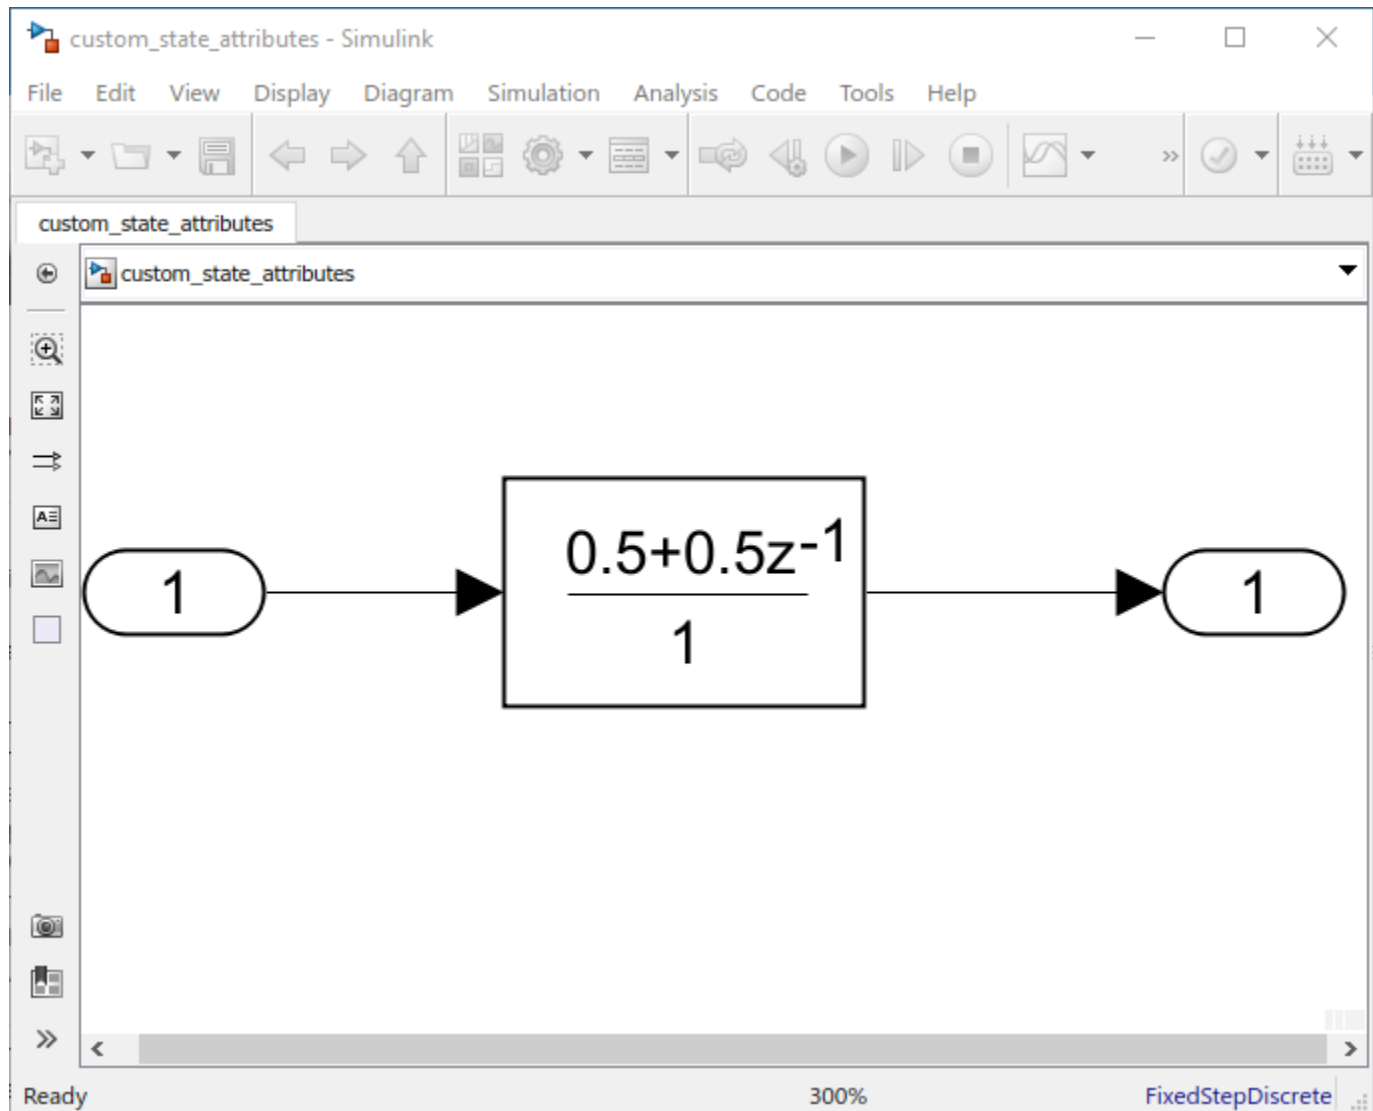

## **Textual Functions with Literal String Arguments**

The software does not support literal string arguments to textual functions in a Stateflow chart.

## Custom State Attributes in Discrete FIR Filter block

This example shows how to customize the state attributes of the Discrete FIR Filter block using the **Model Data Editor**. The Model Data Editor enables you to inspect and edit data items in a list that you can sort, group, and filter.

Consider a simple model that contains the Discrete FIR Filter block.

Using the Code Mappings editor or code mappings API, you can configure the state of the Discrete FIR Filter to appear in the generated code as a separate global variable. This is done by declaring the storage class of the state as `ExportedGlobal`. For details on how the generated code stores internal states, see “How Generated Code Stores Internal Signal, State, and Parameter Data” (Simulink Coder). For more details on storage classes and how to apply them to the states, see “C Code Generation Configuration for Model Interface Elements” (Simulink Coder).

## Open Model Data Editor

Open the Model Data Editor. On the **Modeling** tab, click **Model Data Editor**.

Under the **States** tab, enter the **Name** as myState. In the coder app, set the **Storage Class** to **ExportedGlobal**. You can alternatively select the **Resolve** check box, which requires the state name to resolve to a Simulink signal object.

The screenshot shows the Simulink Model Data Editor for a model named 'custom\_state\_attributes'. The main workspace displays a block diagram of a discrete FIR filter. The filter consists of an input port labeled '1', followed by a discrete transfer function block with the numerator  $0.5 + 0.5z^{-1}$  and denominator  $1$ , and finally an output port labeled '1'.

The Model Data Editor window is open at the bottom, showing the 'States' tab. The table below lists the state configuration for the 'Discrete FIR Filter' block.

| Source              | Name    | Resolve                  | Storage Class  | Header File | Definition File | Get Function | Set Function | Struct |
|---------------------|---------|--------------------------|----------------|-------------|-----------------|--------------|--------------|--------|
| Discrete FIR Filter | myState | <input type="checkbox"/> | ExportedGlobal | —           | —               | —            | —            | —      |

The status bar at the bottom of the window shows 'Ready', '300%' zoom, and 'FixedStepDiscrete'.

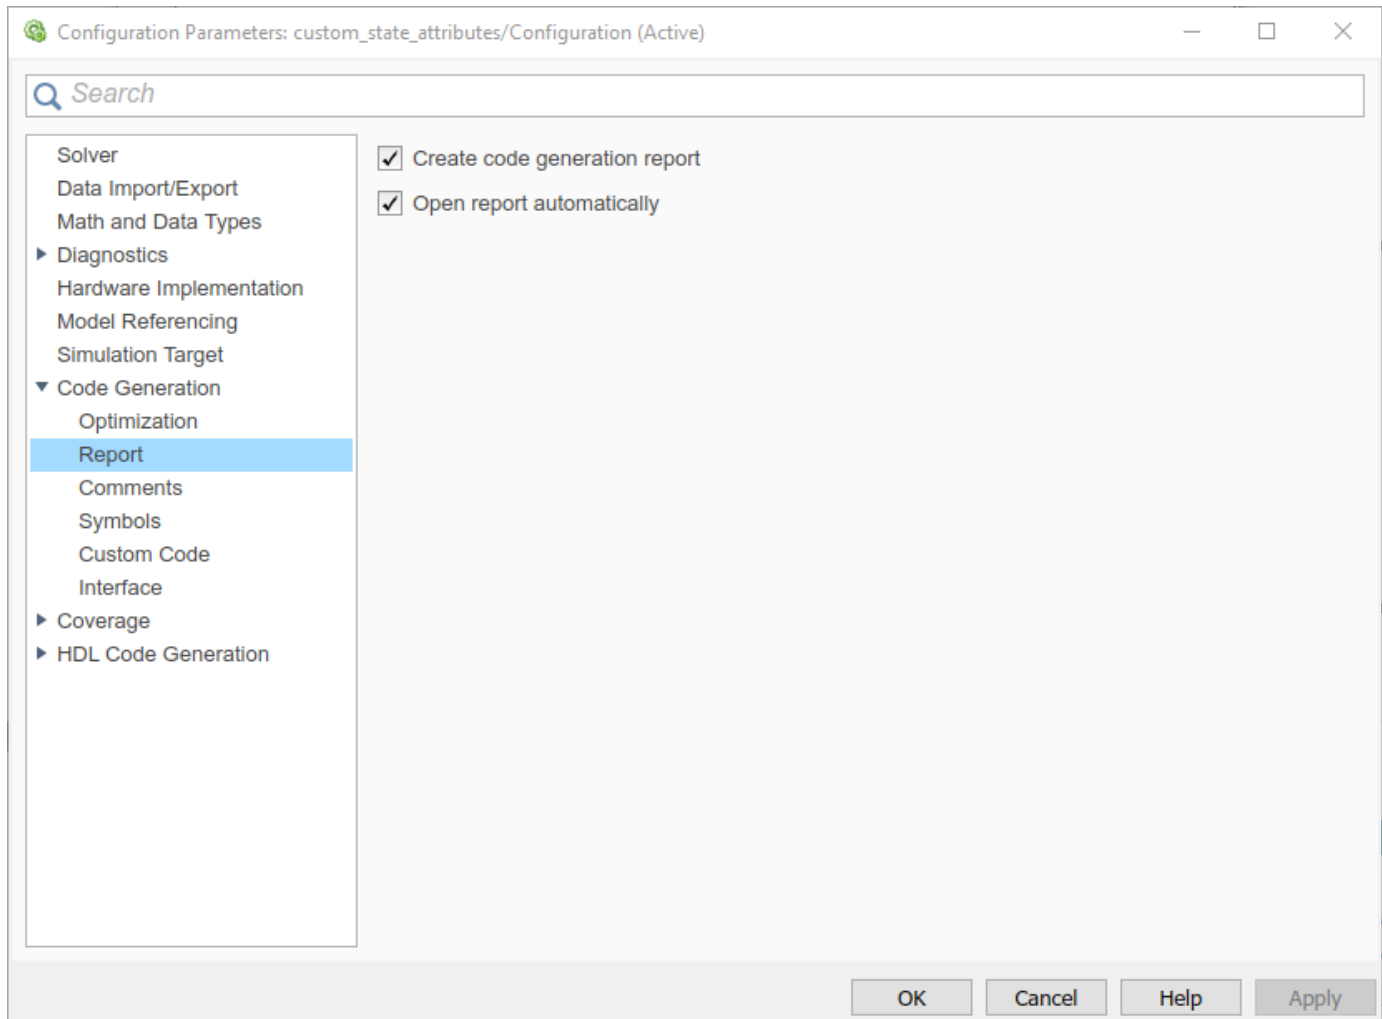

## Build the Model and Inspect the Generated Code

This example configures the model to generate code only. Open the Configuration Parameters by clicking the configuration button  in the Simulink editor. In the **Code Generation** pane, select **Generate code only**. Click **Apply**.

In the **Report** pane, select **Create code generation report** and **Open report automatically**. Click **Apply**. These settings create a report and automatically open the report in a web browser.

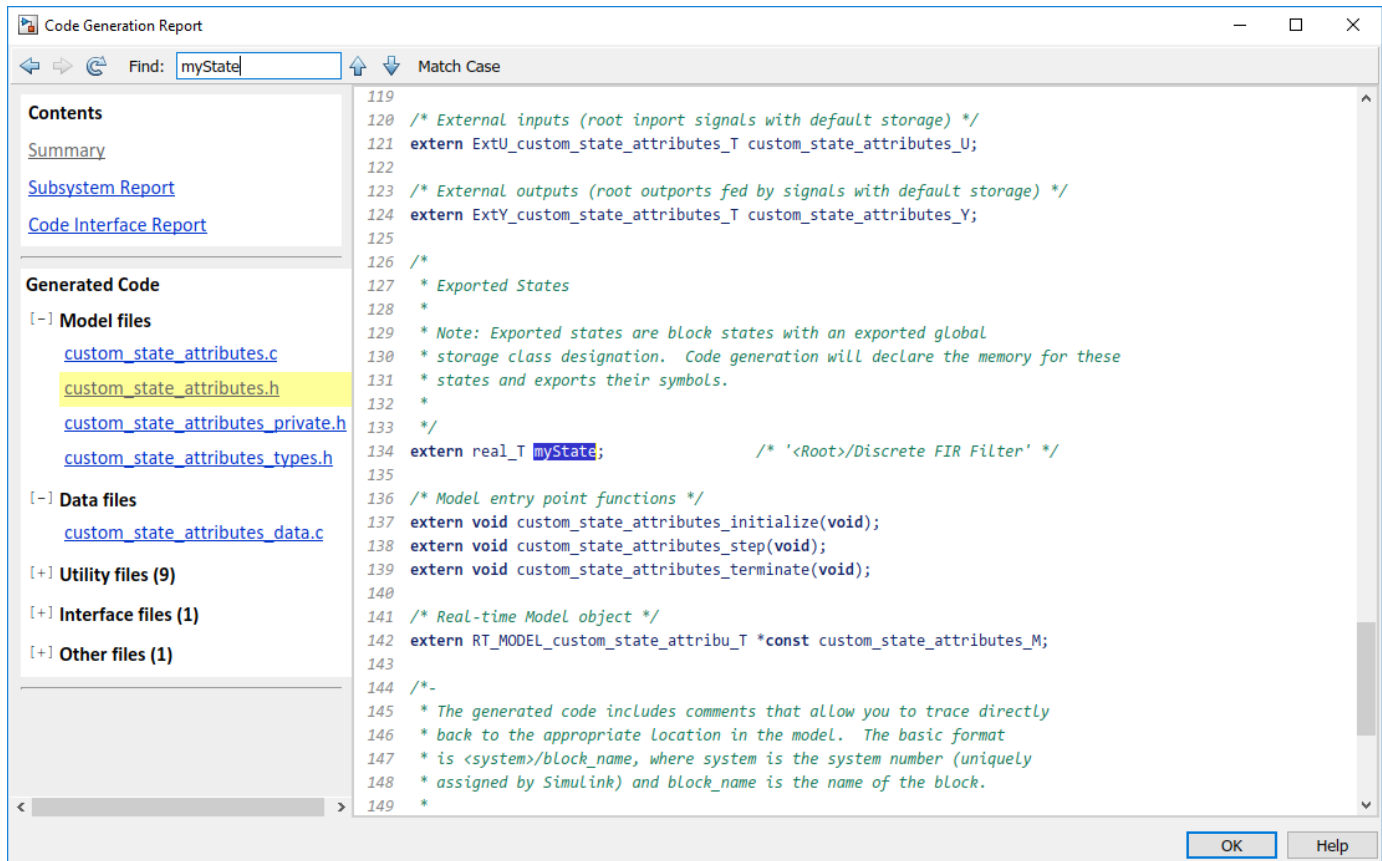

To initiate the build, click the build model button  in the Simulink editor or press **Ctrl+B**. The build process writes the code generation report files to the `html` subfolder of the build folder. Next, the build process automatically opens a MATLAB web browser window and displays the code generation report. Using this report, you can view and analyze the generated code. For more information on the generated report, see “Reports for Code Generation” (Simulink Coder).

The screenshot shows the 'Code Generation Report' window for the model 'custom\_state\_attributes'. The window is divided into several sections:

- Contents:** A list of report sections including Summary (highlighted), Subsystem Report, and Code Interface Report.
- Generated Code:** A list of files generated for the model, categorized into Model files, Data files, Utility files (9), Interface files (1), and Other files (1).
- Model Information:** A table showing details about the model's generation, including Author (rdukkipa), Last Modified By (rdukkipa), Model Version (1.5), and Tasking Mode (SingleTasking).
- Code Information:** A table showing details about the code generation process, including System Target File (grt.tlc), Hardware Device Type (Intel->x86-64 (Windows64)), Simulink Coder Version (8.14 (R2018a) 21-Dec-2017), Timestamp of Generated (Fri Jan 12 10:02:53 2018), Source Code, Location of Generated Source (H:\Documents\MATLAB\custom\_state\_attributes\custom\_state\_attributes\_grt\_rtw\Code), Type of Build (Model), and Objectives Specified (Unspecified).

The 'Objectives Specified' field is highlighted in orange, indicating it is a warning or error. The 'OK' and 'Help' buttons are visible at the bottom right of the window.

In the `custom_state_attributes.h` file, you can see that the filter state is declared as an external variable since the storage class is `ExportedGlobal`.

If you change the storage class and rebuild the model, you can see the generated code reflect the change. With the ability to customize the state attributes, you can streamline and customize how the state appears in the generated code.

# Enumerations and Modeling

---

- “Simulink Enumerations” on page 69-2
- “Use Enumerated Data in Simulink Models” on page 69-6

## Simulink Enumerations

*Enumerated data* is data that is restricted to a finite set of values. An *enumerated data type* is a MATLAB class that defines a set of *enumerated values*. Each enumerated value consists of an *enumerated name* and an *underlying integer* which the software uses internally and in generated code.

Before you begin to use enumerations in a modeling context, you should understand information provided in “Enumerations”.

To define an enumeration for use in Simulink models, choose one of these techniques:

- Use the function `Simulink.defineIntEnumType`. The enumeration exists for the duration of your MATLAB session.
- Create a permanent enumeration class by subclassing one of these built-in classes:
  - Many of the built-in integer data types such as `int8` and `uint16`
  - `Simulink.IntEnumType`
- Use the function `Simulink.importExternalCTypes` to create a Simulink representation of an enumerated data type (enum) that your external C code defines.

Use this technique to help you:

- Replace existing C code with a Simulink model.
- Integrate existing C code for simulation in Simulink (for example, by using the Legacy Code Tool).
- Generate C code (Simulink Coder) that you can compile with existing C code into a single application.

For more information, see “Define Simulink Enumerations” on page 69-6.

The following examples show how to use enumerations in Simulink and Stateflow.

| Example                                                   | Shows How To Use...                                                       |
|-----------------------------------------------------------|---------------------------------------------------------------------------|
| “Data Typing in Simulink”                                 | Data types in Simulink, including enumerated data types                   |
| “Model Media Player by Using Enumerated Data” (Stateflow) | Enumerated data types in a Simulink model that contains a Stateflow chart |

### Simulink Constructs that Support Enumerations

- “Overview” on page 69-3
- “Block Support” on page 69-3
- “Class Support” on page 69-4
- “Logging Enumerated Data” on page 69-4
- “Importing Enumerated Data” on page 69-4

## Overview

In general, all Simulink tools and constructs support enumerated types for which the support makes sense given the purpose of enumerated types: to represent program states and to control program logic. The Simulink Editor, Simulink Debugger, Port Value Displays, referenced models, subsystems, masks, buses, data logging, and most other Simulink capabilities support enumerated types without imposing any special requirements.

Enumerated types are not intended for mathematical computation, so no block that computes a numeric output (as distinct from passing a numeric input through to the output) supports enumerated types. Thus an enumerated type is not considered to be a numeric type, even though an enumerated value has an underlying integer. See “Enumerated Values in Computation” on page 69-17 for more information.

Most capabilities that do not support enumerated types obviously could not support them. Therefore, the Simulink documentation usually mentions enumerated type nonsupport only where necessary to prevent a misconception or describe an exception. See “Simulink Enumeration Limitations” on page 69-4 for information about certain constructs that could support enumerated types but do not.

## Block Support

The following Simulink blocks support enumerated types:

- Constant (but Enumerated Constant is preferable)
- Data Type Conversion
- Data Type Conversion Inherited
- Data Type Duplicate
- Display
- MATLAB Function
- Enumerated Constant
- Floating Scope
- From File
- From Workspace
- In Bus Element
- Inport
- Interval Test
- Interval Test Dynamic
- Multiport Switch
- Out Bus Element
- Outport
- Probe (input only)
- Relational Operator
- Relay (output only)
- Repeating Sequence Stair
- Scope

- Signal Specification
- Switch
- Switch Case
- To File
- To Workspace

All members of the following categories of Simulink blocks support enumerated types:

- Bus-capable blocks (see “Bus-Capable Blocks” on page 77-39)
- Pass-through blocks:
  - With state, like the Data Store Memory and Unit Delay blocks.
  - Without state, like the Mux block.

Many Simulink blocks in addition to those named above support enumerated types, but they either belong to one of the categories listed above, or are rarely used with enumerated types. The Data Type Support section of each block reference page describes all data types that the block supports.

### **Class Support**

The following Simulink classes support enumerated types:

- `Simulink.ValueType`
- `Simulink.Signal`
- `Simulink.Parameter`
- `Simulink.AliasType`
- `Simulink.BusElement`

### **Logging Enumerated Data**

Top-level model output ports, To Workspace blocks, and Scope blocks can all export enumerated values. Signal and State logging work with enumerated data in the same way as with any other data. All logging formats are supported. The From File block does not support enumerated data. Use the From Workspace block instead, combined with some technique for transferring data between a file and a workspace. See “Save Run-Time Data from Simulation” for more information.

### **Importing Enumerated Data**

Top-level model input ports and From Workspace blocks can output enumerated signals during simulation. Data must be provided in a `Structure`, `Structure with Time`, or `TimeSeries` object. No interpolation occurs for enumerated values between the specified simulation times. From File blocks produce only data of type `double`, so they do not support enumerated types. See “Load Signal Data for Simulation” for more information.

### **Simulink Enumeration Limitations**

- “Enumerations and Scopes” on page 69-5
- “Enumerated Types for Switch Blocks” on page 69-5
- “Nonsupport of Enumerations” on page 69-5

## Enumerations and Scopes

When a Scope block displays an enumerated signal, the vertical axis displays the names of the enumerated values only if the scope was open during simulation. If you open the Scope block for the first time before any simulation has occurred, or between simulations, the block displays only numeric values. When simulation begins, enumerated names replace the numeric values, and thereafter appear whenever the Scope block is opened.

When a Floating Scope block displays multiple signals, the names of enumerated values appear on the Y axis only if all signals are of the same enumerated type. If the Floating Scope block displays more than one type of enumerated signal, or any numeric signal, no names appear, and any enumerated values are represented by their underlying integers.

## Enumerated Types for Switch Blocks

The control input of a Switch block can be of any data type supported by Simulink. However, the `u2 ~ = 0` mode is not supported for enumerations. If the control input has an enumeration, choose one of the following methods to specify the criteria for passing the first input:

- Select `u2 >= Threshold` or `u2 > Threshold` and specify a threshold value of the same enumerated type as the control input.
- Use a Relational Operator block to do the comparison and then feed the Boolean result of this comparison into the control port of the Switch block.

## Nonsupport of Enumerations

The following limitations exist when using enumerated data types with Simulink:

- Packages cannot contain enumeration class definitions.
- The If Action block does not support enumerations.
- Generated code does not support logging enumerated data.
- Custom Stateflow targets do not support enumerated types.

## Use Enumerated Data in Simulink Models

### In this section...

“Define Simulink Enumerations” on page 69-6  
 “Simulate with Enumerations” on page 69-11  
 “Specify Enumerations as Data Types” on page 69-13  
 “Get Information About Enumerated Data Types” on page 69-13  
 “Enumeration Value Display” on page 69-14  
 “Instantiate Enumerations” on page 69-15  
 “Enumerated Values in Computation” on page 69-17

*Enumerated data* is data that is restricted to a finite set of values. An *enumerated data type* is a MATLAB class that defines a set of *enumerated values*. Each enumerated value consists of an *enumerated name* and an *underlying integer* which the software uses internally and in generated code.

For basic conceptual information about enumerations in Simulink, see “Simulink Enumerations” on page 69-2.

For information about generating code with enumerations, see “Use Enumerated Data in Generated Code” (Simulink Coder).

### Define Simulink Enumerations

To define an enumerated data type that you can use in Simulink models, use one of these methods:

- Define an enumeration class using a `classdef` block in a MATLAB file.
- Use the function `Simulink.defineIntEnumType`. You do not need a script file to define the type. For more information, see the function reference page.
- Use the function `Simulink.importExternalCTypes` to create a Simulink representation of an enumerated data type (enum) that your external C code defines.

#### Workflow to Define a Simulink Enumeration Class

- 1 Create a class definition on page 69-6.
- 2 Optionally, customize the enumeration on page 69-7.
- 3 Optionally, save the enumeration in a MATLAB file on page 69-9.
- 4 Optionally, permanently store the enumeration definition in a Simulink data dictionary. See “Permanently Store Enumerated Type Definition” on page 69-11.

#### Create Simulink Enumeration Class

To create a Simulink enumeration class, in the class definition:

- Define the class as a subclass of `Simulink.IntEnumType`. You can also base an enumerated type on one of these built-in integer data types: `int8`, `uint8`, `int16`, `uint16`, and `int32`.
- Add an enumeration block that specifies enumeration values with underlying integer values.

Consider the following example:

```

classdef BasicColors < Simulink.IntEnumType
 enumeration
 Red(0)
 Yellow(1)
 Blue(2)
 end
end

```

The first line defines an integer-based enumeration that is derived from built-in class `Simulink.IntEnumType`. The enumeration is integer-based because `IntEnumType` is derived from `int32`.

The enumeration section specifies three enumerated values.

| Enumerated Value | Enumerated Name | Underlying Integer |
|------------------|-----------------|--------------------|
| Red(0)           | Red             | 0                  |
| Yellow(1)        | Yellow          | 1                  |
| Blue(2)          | Blue            | 2                  |

When defining an enumeration class for use in the Simulink environment, consider the following:

- The name of the enumeration class must be unique among data type names and base workspace variable names, and is case-sensitive.
- Underlying integer values in the enumeration section need not be unique within the class and across types.
- Often, the underlying integers of a set of enumerated values are consecutive and monotonically increasing, but they need not be either consecutive or ordered.
- For simulation, an underlying integer can be any `int32` value. Use the MATLAB functions `intmin` and `intmax` to get the limits.
- For code generation, every underlying integer value must be representable as an integer on the target hardware, which may impose different limits. See “Configure a System Target File” (Simulink Coder) for more information.

For more information on superclasses, see “Convert to Superclass Value”. For information on how enumeration classes are handled when there is more than one name for an underlying value, see “How to Alias Enumeration Names”.

## Customize Simulink Enumeration

### About Simulink Enumeration Customizations

You can customize a Simulink enumeration by implementing specific static methods in the class definition. If you define these methods using the appropriate syntax, you can change the behavior of the class during simulation and in generated code.

The table shows the methods you can implement to customize an enumeration.

| Static Method           | Purpose                                                                                                                                                                                                           | Default Value Without Implementing Method            | Custom Return Value                                                                                                         | Usage Context                  |
|-------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------|--------------------------------|
| getDefaultValue         | Specifies the default enumeration member for the class.                                                                                                                                                           | First member specified in the enumeration definition | A character vector containing the name of an enumeration member in the class (see “Instantiate Enumerations” on page 69-15) | Simulation and code generation |
| getDescription          | Specifies a description of the enumeration class.                                                                                                                                                                 | ' '                                                  | A character vector containing the description of the type                                                                   | Code generation                |
| getHeaderFile           | Specifies the name of a header file. The method <code>getDataScope</code> determines the significance of the file.                                                                                                | ' '                                                  | A character vector containing the name of the header file that defines the enumerated type                                  | Code generation                |
| getDataScope            | Specifies whether generated code exports or imports the definition of the enumerated data type. Use the method <code>getHeaderFile</code> to specify the generated or included header file that defines the type. | 'Auto'                                               | One of: 'Auto', 'Exported', or 'Imported'                                                                                   | Code generation                |
| addClassNameToEnumNames | Specifies whether to prefix the class name in generated code.                                                                                                                                                     | false                                                | true or false                                                                                                               | Code generation                |

For more examples of these methods as they apply to code generation, see “Customize Enumerated Data Type” (Simulink Coder).

### Specify a Default Enumerated Value

Simulink and related generated code use an enumeration's default value for ground-value initialization of enumerated data when you provide no other initial value. For example, an enumerated signal inside a conditionally executed subsystem that has not yet executed has the enumeration's default value. Generated code uses an enumeration's default value if a safe cast fails, as described in “Type Casting for Enumerations” (Simulink Coder).

Unless you specify otherwise, the default value for an enumeration is the first value in the enumeration class definition. To specify a different default value, add your own `getDefaultValue` method to the `methods` section. The following code shows a shell for the `getDefaultValue` method:

```
function retVal = getDefaultValue()
 % GETDEFAULTVALUE Specifies the default enumeration member.
 % Return a valid member of this enumeration class to specify the default.
 % If you do not define this method, Simulink uses the first member.
 retVal = ThisClass.EnumName;
end
```

To customize this method, provide a value for *ThisClass.EnumName* that specifies the desired default.

- *ThisClass* must be the name of the class within which the method exists.
- *EnumName* must be the name of an enumerated value defined in that class.

For example:

```
classdef BasicColors < Simulink.IntEnumType
 enumeration
 Red(0)
 Yellow(1)
 Blue(2)
 end
 methods (Static)
 function retVal = getDefaultValue()
 retVal = BasicColors.Blue;
 end
 end
end
```

This example defines the default as `BasicColors.Blue`. If this method does not appear, the default value would be `BasicColors.Red`, because that is the first value listed in the enumerated class definition.

The seemingly redundant specification of *ThisClass* inside the definition of that same class is necessary because `getDefaultValue` returns an instance of the default enumerated value, not just the name of the value. The method, therefore, needs a complete specification of what to instantiate. See “Instantiate Enumerations” on page 69-15 for more information.

### Save Enumeration in a MATLAB File

You can define an enumeration within a MATLAB file.

- The name of the definition file must match the name of the enumeration exactly, including case. For example, the definition of enumeration `BasicColors` must reside in a file named `BasicColors.m`. Otherwise, MATLAB will not find the definition.
- You must define each class definition in a separate file.
- Save each definition file on the MATLAB search path. MATLAB searches the path to find a definition when necessary.

To add a file or folder to the MATLAB search path, type `addpath pathname` at the MATLAB command prompt. For more information, see “What Is the MATLAB Search Path?”, `addpath`, and `savepath`.

- You do not need to execute an enumeration class definition to use the enumeration. The only requirement, as indicated in the preceding bullet, is that the definition file be on the MATLAB search path.

### Change and Reload Enumeration Classes

You can change the definition of an enumeration by editing and saving the file that contains the definition. You do not need to inform MATLAB that a class definition has changed. MATLAB automatically reads the modified definition when you save the file. However, the class definition changes do not take full effect if any class instances (enumerated values) exist that reflect the previous class definition. Such instances might exist in the base workspace or might be cached.

The following table explains options for removing instances of an enumeration from the base workspace and cache.

| If In Base Workspace...                                                                                                                                                                                              | If In Cache...                                                                                                                                                                                                                                                            |
|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Do one of the following: <ul style="list-style-type: none"> <li>• Locate and delete specific obsolete instances.</li> <li>• Delete everything from the workspace by using the <code>clear</code> command.</li> </ul> | <ul style="list-style-type: none"> <li>• Delete obsolete instances by closing all models that you updated or simulated while the previous class definition was in effect.</li> <li>• Clear functions and close models that are caching instances of the class.</li> </ul> |

Similarly, if you defined an enumeration class by using `Simulink.defineIntEnumType`, you can redefine that class, using the same function, even if instances exist. However, you cannot change `StorageType` for the class while instances exist.

For more information about applying enumeration changes, see “Automatic Updates for Modified Classes”.

### Import Enumerations Defined Externally to MATLAB

If you have enumerations defined externally to MATLAB that you want to import for use within the Simulink environment, you can do so programmatically with calls to one of these functions:

- `Simulink.defineIntEnumType` — Defines an enumeration that you can use in MATLAB as if it is defined by a class definition file. In addition to specifying the enumeration class name and values, each function call can specify:
  - Character vector that describes the enumeration class.
  - Which of the enumeration values is the default.

For code generation, you can specify:

- Header file in which the enumeration is defined for generated code.
- Whether the code generator applies the class name as a prefix to enumeration members — for example, `BasicColors_Red` or `Red`.

As an example, consider the following class definition:

```
classdef BasicColors < Simulink.IntEnumType
 enumeration
 Red(0)
 Yellow(1)
 Blue(2)
 end
 methods (Static = true)
 function retVal = getDescription()
 retVal = 'Basic colors...';
 end
 function retVal = getDefaultValue()
 retVal = BasicColors.Blue;
 end
 function retVal = getHeaderFile()
 retVal = 'mybasiccolors.h';
 end
 function retVal = addClassNameToEnumNames()
```

```

 retVal = true;
 end
end
end

```

The following function call defines the same class for use in MATLAB:

```

Simulink.defineIntEnumType('BasicColors', ...
 {'Red', 'Yellow', 'Blue'}, [0;1;2],...
 'Description', 'Basic colors', ...
 'DefaultValue', 'Blue', ...
 'HeaderFile', 'mybasiccolors.h', ...
 'DataScope', 'Imported', ...
 'AddClassNameToEnumNames', true);

```

- `Simulink.importExternalCTypes` — Creates Simulink representations of enumerated data types (enum) that your existing C code defines.

If a MATLAB Function block in your model uses the enumerated type, configure the model configuration parameters to include (`#include`) the type definition from your external header file. See “Control Imported Bus and Enumeration Type Definitions” on page 45-112.

### Permanently Store Enumerated Type Definition

Whether you define an enumeration by using a class file or by using the function `Simulink.defineIntEnumType`, you can permanently store the enumeration definition in a Simulink data dictionary. Models that are linked to the dictionary can use the enumeration. For more information, see “Enumerations in Data Dictionary” on page 75-12.

## Simulate with Enumerations

Consider the following enumeration class definition — `BasicColors` with enumerated values Red, Yellow, and Blue, with Blue as the default value:

```

classdef BasicColors < Simulink.IntEnumType
 enumeration
 Red(0)
 Yellow(1)
 Blue(2)
 end
 methods (Static)
 function retVal = getDefaultValue()
 retVal = BasicColors.Blue;
 end
 end
end
end

```

Once this class definition is known to MATLAB, you can use the enumeration in Simulink and Stateflow models. Information specific to enumerations in Stateflow appears in “Enumerated Data” (Stateflow). The following Simulink model uses the enumeration defined above:

The output of the model looks like this:

The Data Type Conversion block OrigToInt specifies an **Output data type** of int32 and **Integer rounding mode: Floor**, so the block converts the Sine Wave block output, which appears in the top graph of the Scope display, to a cycle of integers: 1, 2, 1, 0, 1, 2, 1. The Data Type Conversion block IntToColor uses these values to select colors from the enumerated type BasicColors by referencing their underlying integers.

The result is a cycle of colors: Yellow, Blue, Yellow, Red, Yellow, Blue, Yellow, as shown in the middle graph. The Enumerated Constant block EnumConst outputs Yellow, which appears in the second graph as a straight line. The Relational Operator block compares the constant Yellow to each value in the cycle of colors. It outputs 1 (true) when Yellow is less than the current color, and 0 (false) otherwise, as shown in the third graph.

The sort order used by the comparison is the numeric order of the underlying integers of the compared values, *not* the lexical order in which the enumerated values appear in the enumerated class definition. In this example the two orders are the same, but they need not be. See “Specify Enumerations as Data Types” on page 69-13 and “Enumerated Values in Computation” on page 69-17 for more information.

## Specify Enumerations as Data Types

Once you define an enumeration, you can use it much like any other data type. Because an enumeration is a class rather than an instance, you must use the prefix `?` or `Enum:` when specifying the enumeration as a data type. You must use the prefix `?` in the MATLAB Command Window. However, you can use either prefix in a Simulink model. `Enum:` has the same effect as the `?` prefix, but `Enum:` is preferred because it is more self-explanatory in the context of a graphical user interface.

Depending on the context, type `Enum:` followed by the name of an enumeration, or select `Enum:` `<class name>` from a menu (for example, for the **Output data type** block parameter) , and replace `<class name>`.

To use the Data Type Assistant, set the **Mode** to **Enumerated**, then enter the name of the enumeration. For example, in the previous model, the Data Type Conversion block `IntToColor`, which outputs a signal of type `BasicColors`, has the following output signal specification:

You cannot set a minimum or maximum value for a signal defined as an enumeration, because the concepts of minimum and maximum are not relevant to the purpose of enumerations. If you change the minimum or maximum for a signal of an enumeration from the default value of `[]`, an error occurs when you update the model. See “Enumerated Values in Computation” on page 69-17 for more information.

## Get Information About Enumerated Data Types

The functions `enumeration` and `Simulink.data.getEnumTypeInfo` return information about enumerated data types.

### Get Information About Enumeration Members

Use the function `enumeration` to:

- Return an array that contains all enumeration values for an enumeration class in the MATLAB Command Window
- Get the enumeration values programmatically
- Provide the values to a Simulink block parameter that accepts an array or vector of enumerated values, such as the **Case conditions** parameter of the Switch Case block

### Get Information About Enumerated Class

Use the function `Simulink.data.getEnumTypeInfo` to return information about an enumeration class, such as:

- The default enumeration member
- The name of the header file that defines the type in generated code
- The data type used in generated code to store the integer values underlying the enumeration members

### Enumeration Value Display

Wherever possible, Simulink displays enumeration values by name, not by the underlying integer value. However, the underlying integers can affect value display in Scope and Floating Scope blocks.

| Block...       | Affect on Value Display..                                                                                                                                                                                                                                             |
|----------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Scope          | When displaying an enumerated signal, the names of the enumerated values appear as labels on the Y axis. The names appear in the order given by their underlying integers, with the lowest value at the bottom.                                                       |
| Floating Scope | When displaying signals that are of the same enumeration, names appear on the Y axis as they would for a Scope block. If the Floating Scope block displays mixed data types, no names appear, and any enumerated values are represented by their underlying integers. |

### Enumerated Values with Non-Unique Integers

More than one value in an enumeration can have the same underlying integer value, as described in “Specify Enumerations as Data Types” on page 69-13. When this occurs, the value on an axis of Scope block output or in Display block output always is the first value listed in the enumerated class definition that has the shared underlying integer. For example:

Although the Enumerated Constant block outputs `True`, both `On` and `True` have the same underlying integer, and `On` is defined first in the class definition enumeration section. Therefore, the Display block shows `On`. Similarly, a Scope axis would show only `On`, never `True`, no matter which of the two values is input to the Scope block.

## Instantiate Enumerations

Before you can use an enumeration, you must instantiate it. You can instantiate an enumeration in MATLAB, in a Simulink model, or in a Stateflow chart. The syntax is the same in all contexts.

### Instantiating Enumerations in MATLAB

To instantiate an enumeration in MATLAB, enter `ClassName.EnumName` in the MATLAB Command Window. The instance is created in the base workspace. For example, if `BasicColors` is defined as in “Create Simulink Enumeration Class” on page 69-6, you can type:

```
bcy = BasicColors.Yellow
```

```
bcy =
```

```
 Yellow
```

Tab completion works for enumerations. For example, if you enter:

```
bcy = BasicColors.<tab>
```

MATLAB displays the elements and methods of `BasicColors` in alphabetical order:

```

addClassNameToEnumNames
Blue
getDefaultValue
getDescription
getHeaderFile
getStorageType
Red
Yellow

```

Double-click an element or method to insert it at the position where you pressed <tab>. See “Code Suggestions and Completions” for more information.

### Casting Enumerations in MATLAB

In MATLAB, you can cast directly from an integer to an enumerated value:

```
bcb = BasicColors(2)
```

```
bcb =
 Blue
```

You can also cast from an enumerated value to its underlying integer:

```
>> bci = int32(bcb)
```

```
bci =
 2
```

In either case, MATLAB returns the result of the cast in a 1x1 array of the relevant data type.

Although casting is possible, use of enumeration values is not robust in cases where enumeration values and the integer equivalents defined for an enumeration class might change.

### Instantiating Enumerations in Simulink (or Stateflow)

To instantiate an enumeration in a Simulink model, you can enter *ClassName.EnumName* as a value in a dialog box. For example, consider the following model:

The Enumerated Constant block EnumConst, which outputs the enumerated value Yellow, defines that value as follows:

You can enter any valid MATLAB expression that evaluates to an enumerated value, including arrays and workspace variables. For example, you could enter `BasicColors(1)`, or if you had previously executed `bcy = BasicColors.Yellow` in the MATLAB Command Window, you could enter `bcy`. As another example, you could enter an array, such as `[BasicColors.Red, BasicColors.Yellow, BasicColors.Blue]`.

You can use a Constant block to output enumerated values. However, that block displays parameters that do not apply to enumerated types, such as **Output Minimum** and **Output Maximum**.

If you create a `Simulink.Parameter` object as an enumeration, you must specify the **Value** parameter as an enumeration member and the **Data type** with the `Enum:` or `?` prefix, as explained in “Specify Enumerations as Data Types” on page 69-13.

You *cannot* specify the integer value of an enumeration member for the **Value** parameter. See “Enumerated Values in Computation” on page 69-17 for more information. Thus, the following fails even though the integer value for `BasicColors.Yellow` is 1.

The same syntax and considerations apply in Stateflow. See “Enumerated Data” (Stateflow) for more information.

## Enumerated Values in Computation

By design, Simulink prevents enumerated values from being used as numeric values in mathematical computation, even though an enumerated class is a subclass of the MATLAB `int32` class. Thus, an enumerated type does not function as a numeric type despite the existence of its underlying integers. For example, you cannot input an enumerated signal directly to a Gain block.

You can use a Data Type Conversion block to convert in either direction between an integer type and an enumerated type, or between two enumerated types. That is, you can use a Data Type Conversion block to convert an enumerated signal to an integer signal (consisting of the underlying integers of

the enumerated signal values) and input the resulting integer signal to a Gain block. See “Casting Enumerated Signals” on page 69-18 for more information.

Enumerated types in Simulink are intended to represent program states and control program logic in blocks like the Relational Operator block and the Switch block. When a Simulink block compares enumerated values, the values compared must be of the same enumerated type. The block compares enumerated values based on their underlying integers, not their order in the enumerated class definition.

When a block like the Switch block or Multiport Switch block selects among multiple data signals, and any data signal is of an enumerated type, all the data signals must be of that same enumerated type. When a block inputs both control and data signals, as Switch and Multiport Switch do, the control signal type need not match the data signal type.

### Casting Enumerated Signals

You can use a Data Type Conversion block to cast an enumerated signal to a signal of any numeric type, provided that the underlying integers of all enumerated values input to the block are within the range of the numeric type. Otherwise, an error occurs during simulation.

Similarly, you can use a Data Type Conversion block to cast a signal of any integer type to an enumerated signal, provided that every value input to the Data Type Conversion block is the underlying integer of some value in the enumerated type. Otherwise, an error occurs during simulation.

You cannot use a Data Type Conversion block to cast a numeric signal of any non-integer data type to an enumerated type. For example, the model used in “Simulate with Enumerations” on page 69-11 needed two Data Conversion blocks to convert a sine wave to enumerated values.

The first block casts double to int32, and the second block casts int32 to BasicColors. You cannot cast a complex signal to an enumerated type regardless of the data types of its real and imaginary parts.

### Casting Enumerated Block Parameters

You cannot cast a block parameter of any numeric data type to an enumerated data type. For example, suppose that an Enumerated Constant block specifies a **Value** of 2 and an **Output data type** of Enum: BasicColors:

An error occurs because the specifications implicitly cast a `double` value to an enumerated type. The error occurs even though the numeric value corresponds arithmetically to one of the enumerated values in the enumerated type.

You cannot cast a block parameter of an enumeration to any other data type. For example, suppose that a Constant block specifies a **Constant value** of `BasicColors.Blue` and an **Output data type** of `int32`.

An error occurs because the specifications implicitly cast an enumerated value to a numeric type. The error occurs even though the enumerated value's underlying integer is a valid `int32`.

## Create and Edit Signal Data

### In this section...

“Differences Between the Root Inport Mapper Signal Editor and Other Signal Editors” on page 70-3

“Table Editing Data Support” on page 70-3

“Mouse, Keyboard, and Touchscreen Shortcuts” on page 70-3

“Change Signal Names and Hierarchy Orders” on page 70-4

“Create Signals with the Same Properties” on page 70-7

“Add and Edit Multidimensional Signals” on page 70-9

“Work with Data in Signals” on page 70-12

“Draw a Ramp Using Snap to Grid for Accuracy” on page 70-13

“Save and Send Changes to the Root Inport Mapper Tool” on page 70-15

Use the Signal Editor to create and edit input signals that you can organize for multiple simulations. You can then save the signal data to a MAT-file for simulation or to map to root-level ports. By default, Signal Editor creates signal data in `timeseries` format. You can access the Signal Editor in the following ways:

- `signalEditor` function — Signal Editor starts from the command line.
- From the Root Inport Mapper on page 72-7 — To create a MAT-file for your new signal data, select **Signals > New MAT-File**. To link in an existing signal data file from an existing scenario and edit the signals in that file, use the **Signals > Edit MAT-File**.
- From the Signal Editor block

Signal Editor works only with MAT-files.

You can manipulate signals in these ways:

- Create and edit multiple signals in multiple data sets. By default, Signal Editor creates `timeseries` format data.
- Use signal notations to create more complicated signals using MATLAB expressions. You can use the **Author and Insert** dialog box or manually enter simple MATLAB expressions in the tabular area.
- Use existing scenarios to get existing data sets for which you can edit and create signals.
- Create and edit multidimensional signals.
- Edit signals imported as registered custom file types. For more information, see “Import Custom File Type” on page 70-35.

While editing signal data:

- Use tabular editing or MATLAB to modify signal data.
- Use mouse or multi-touch editing to graphically modify signal data.
- Modify signal properties such as name, interpolation, and unit properties.
- Drag and drop signals to change signal hierarchies for buses and data sets.
- Use signal notations and variables to replace signal data.

Alternatively, you can import data from external sources and edit them in Signal Editor. For more information, see “Link in Signal Data from Signal Builder Block and Simulink Design Verifier Environment” on page 70-16.

To graphically create and edit signal data, see “Create Freehand Signal Data Using Mouse or Multi-Touch Gestures” on page 70-32.

## Differences Between the Root Inport Mapper Signal Editor and Other Signal Editors

Generally, the Signal Editor user interface is the same regardless of how you access it. Here are the differences in the Root Inport Mapper Signal Editor:

- FILE section **Save and Sync** and **SAVE** commands save and synchronize to the Root Inport Mapper.
- **Insert** section **Scenario** command always has the option, **Scenario from Model**.

If you start the function with a model name, the `signalEditor` function Signal Editor user interface shows the option **Scenario from Model** in the **Insert** section.

## Table Editing Data Support

The Signal Editor user interface supports all signal data types that Simulink supports and that are editable.

## Mouse, Keyboard, and Touchscreen Shortcuts

Edit actions:

Zoom actions:

| Type of Zoom or Pan                                                                                                                                                  | Button to Click                                                                     |
|----------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------|
| Zoom in along the T and Y axes.                                                                                                                                      |    |
| Zoom in along the time axis. After selecting the icon, on the graph, drag the mouse to select an area to enlarge.                                                    |    |
| Zoom in along the data value axis. After selecting the icon, on the graph, drag the mouse to select an area to enlarge.                                              |    |
| Zoom only in x while zooming in xy.                                                                                                                                  | Zoom in xy while pressing <b>Ctrl</b>                                               |
| Zoom only in y while zooming in xy.                                                                                                                                  | Zoom in xy while pressing <b>Shift</b>                                              |
| Zoom out from the graph.                                                                                                                                             |    |
| Fit the plot to the graph. After selecting the icon, click the graph to enlarge the plot to fill the graph.                                                          |    |
| Pan the graph up, down, left, or right. Select the icon. On the graph, hold the left mouse button and move the mouse to the area of the graph that you want to view. |  |

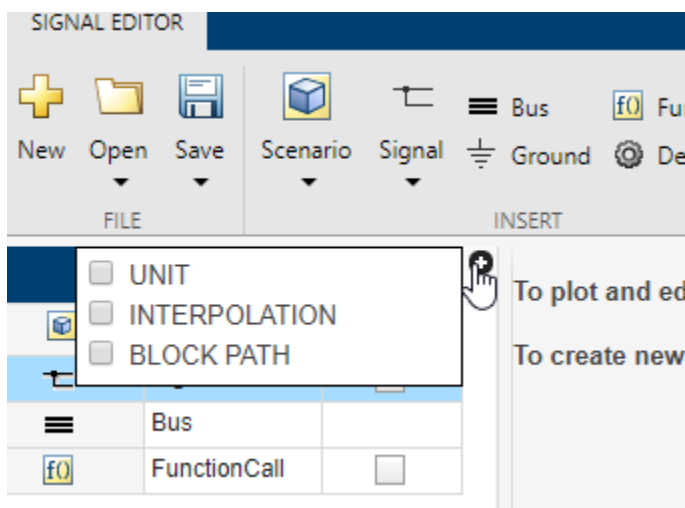

## Change Signal Names and Hierarchy Orders

In the **Scenarios and Signals** section, you can change signal names and hierarchy order, create duplicates of signals, and delete signals. Simulink ignores leading and trailing spaces in signal names.

- To change a signal name, double-click the name and change it.

- To change the unit or interpolation of a signal, click the plus sign and click the **Unit** or **Interpolation** check boxes.

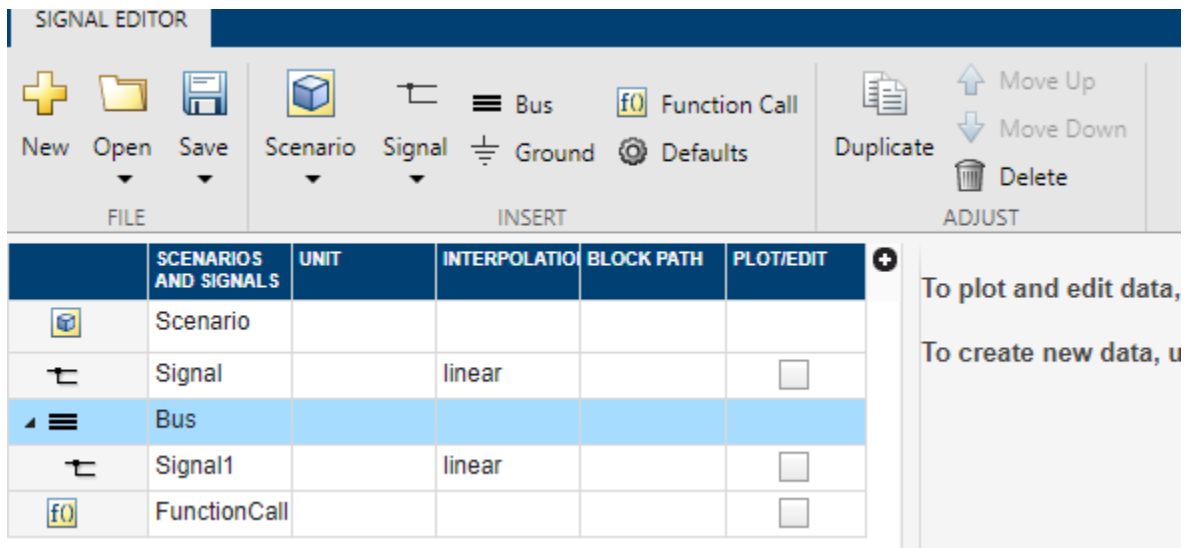

The pane updates with **Unit** and **Interpolation** columns.

- In the **Unit** column, enter an appropriate unit expression. For a suggested list of unit expressions, see allowed units.
- In the **Interpolation** column, from the drop-down list, select `linear` or `zero order hold`.

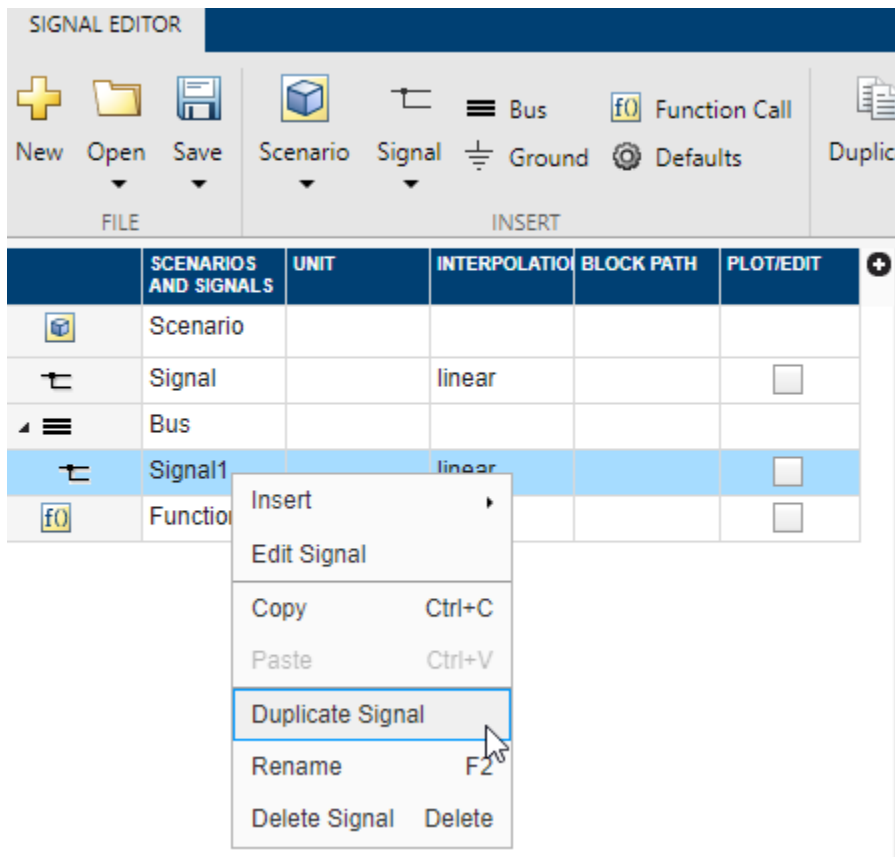

**Note** Interpolation affects only the plotting of signals in the Signal Editor user interface.

- To change the order of a signal in the hierarchy, drag and drop it. For example, you can drag and drop signals into a bus.

Alternatively, use the **Move Up** and **Move Down** buttons in the **Adjust** section.

- To copy a signal and paste it under the original, right-click it and select **Duplicate Signal**.

Alternatively, use the **Duplicate** button in the **Adjust** section. You can also adjust the default properties of the signal you duplicate. For more information, see “Create Signals with the Same Properties” on page 70-7.

- To copy a signal and paste it elsewhere in hierarchy, select **Copy** and then **Paste**.

## Create Signals with the Same Properties

To create signals of the same predefined type, use the **Duplicate** button in the **Adjust** section. To change the predefined signal type, click the **Defaults** icon, . A **Default Properties for Insertion** dialog box displays.

- **Data type** — From the drop-down list, select the signal data type.

**Enumeration** — When you select the Enum data type, this parameter displays. Enter the class name of your enumeration.

If you define an enumeration class that contains the same integer value multiple times, for example:

```
classdef(Enumeration) hEnumColors_duplicateValues < Simulink.IntEnumType
 enumeration
 Red(118)
 Yellow(-14)
 Blue(90)
 Green(87)
 White(-14)
 Black(198)
 Brown(90)
 Pink(118)
 Purple(90)
 end
 methods (Static = true)
 function retVal = getDefaultValue()
 retVal = hEnumColors_duplicateValues.Blue;
 end
 end
end
```

The Signal Editor treats the first enumeration value (Red (118)) as the canonical value and equates all subsequent instances of the same underlying integer 118 to the enumerated name Red. In other words, Pink equals Red.

- **Interpolation** — From the drop-down list, select `linear` or `zero order hold`.
- **Unit** — Enter an appropriate unit expression. For a suggested list of unit expressions, see Allowed Units.
- **Dimensions** — Enter the number of dimensions for the signal.
- **Signal type** — From the list, select `real` or `complex`.
- Variable type — From the drop-down list, select `Timeseries` (default), `Timetable`, `Logged timeseries`, `Logged timetable`.

Logged timeseries and logged timetables objects are `Simulink.SimulationData.Signal` objects whose `Value` property is of data type `timeseries` or `timetable`.

- **Bus object** — From the drop-down list, select the bus object for which to define the dimensions. If you leave the **Bus object** parameter at the default `<object name>`, Signal Editor adds empty buses.
- **Dimensions** — Enter the number of dimensions for the bus object.

## Add and Edit Multidimensional Signals

To add multidimensional signals, use either of these options:

- Change the **Dimensions** property in the Default Properties for Insertion dialog box, and then use **Insert > Blank Signal** to insert a new blank signal. For a multidimensional blank signal, enter a dimension greater than 1.
- Enter multidimensional signal data in the Author and Insert dialog box **Data** parameter, such as `[(1:10)' (1:10)']`.

When you click the **Plot/Edit** check box for the signal, the tabular area displays the signal with columns for each dimension. You can edit the data individually in the tabular area, or click the replace button  to replace the signal with a MATLAB expression. Use the Author and Replace Signal Data dialog box as though you are inserting a new expression with the Author and Insert dialog box. For more information, see “Create Signals with MATLAB Expressions and Variables” on page 70-25.

---

**Tip** When replacing a signal, the signal dimension and complexity of the new signal must be the same as the signal being replaced.

---

For example, to create signal data with two columns and time from 1 to 10:

- 1 In the Signal Editor, select **Signal > Author Signal**.
- 2 Enter signal data with two columns and time from 1 to 10:
  - **Time** — `[1:10]`
  - **Data** — `[(1:10)' (1:10)']`

**Author and Insert** ×

To specify times and data values for the signals, type MATLAB expressions or existing workspace variables.

Time:

Data:

Data type:  ▼

Number of samples:

Data type:

Dimensions:

- 3 Click **Insert Signal**.

The hierarchy updates with the new signal data.

- 4 Expand the new signal and click the **Plot/Edit** check boxes for the new signal data. Observe the associated plots and the tabular data for the signal.

**Tip** If the data does not plot as expected, use the **Fit to window** button in the **Zoom & Pan** section. For multidimensional signals, also make sure that you have the right plot selected for the column data you are editing.

- 5 You can edit the data directly in the table.

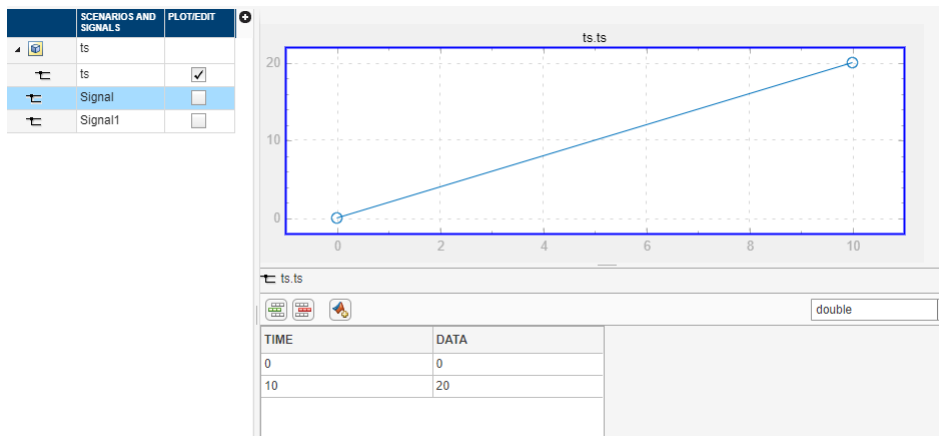

Or you can replace data completely with a new expression by clicking the **Replace** button and entering a new time range and data in the Author and Replace Signal Data dialog box.

## Work with Data in Signals

This example describes how to add and delete data to the signals in the linked scenario. To create a model and data to work with, see “Add Signals to Scenarios” on page 70-18.

- 1 In the Signal Editor, in the **Scenarios and Signals** section, click the plot check box for the signal *ts*.

2 Add some data to the signal  $ts$ .

- a Click the add row icon  and add some signals. To add a signal row between other signals, click the signal before and click the add row icon.
- b When done, click **Apply**. Clicking **Apply** updates the plot.

- 3 Remove the time 20 line from the signal. Select 20 and click .
- 4 Alternatively, if you want to replace all the signal data for  $ts$  with a signal defined with signal notations, click the replace button  and use the Author and Replace Signal Data dialog box to define new data.

## Draw a Ramp Using Snap to Grid for Accuracy

This example describes how to create a ramp signal by selecting some points in the canvas.

- 1 In the Signal Editor tab, select **Signal > Draw Signal**.
- 2 To line up the signal data values along horizontal and vertical lines, select **Snap X to Grid** and **Snap Y to Grid**.

Move and zoom also honor snap to grid settings.

- 3 In the canvas, add three points:
  - Two points horizontal to each other
  - One point set to the right at an angle to the other signals
- 4 In the Signal Properties section, in **Name**, change the signal name to **Ramp** and press **Enter**.

- 5 To add the signal to the Signal Editor, in the **Insert** section, click .
- 6 To return to the main Signal Editor window and check that the signal has been added, click .
- 7 To observe the drawn signal data In Signal Editor, click the **Plot/Edit** check box for the Ramp signal name in the hierarchy.

## Save and Send Changes to the Root Inport Mapper Tool

When you are done adding and modifying signals and scenarios, use the **Save and Sync** button to save the changes to a MAT-file. The Signal Editor also sends the data to the Root Inport Mapper Tool:

- If the Root Inport Mapper tool has the scenario loaded, the Root Inport Mapper tool updates with the new data.
- If the Root Inport Mapper tool has the scenarios mapped and your changes affect the mapping, the Root Inport Mapper tool unmaps the scenario.

## Use Scenarios and Insert Signals in Signal Editor

### Use Scenarios to Group and Organize Inputs

Signal Editor uses scenarios to group and organize sets of inputs to be saved to a MAT-file for a single simulation. To create signal data using existing data sets from existing scenarios, or create an empty scenario into which to add signals, use the Signal Editor **Scenario** menu.

| Action                                                      | Option                                                                                                                                                                                                                                                                                                                                                        |
|-------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| To create a scenario from the root inports of a model       | Select <b>Scenario &gt; Scenario from Model</b> . (Available only when accessing Signal Editor from the Root Inport Mapper.)<br><br>You can also use the <code>signaleditor</code> function with a model argument.<br><br><b>Note</b> When using this option, the resulting scenario contains signals with the data types and dimensions of the inport ports. |
| To create an empty scenario and create signals from scratch | Select <b>Scenario &gt; Blank Scenario</b> .                                                                                                                                                                                                                                                                                                                  |
| To import scenarios from MATLAB workspace                   | Select <b>Scenario &gt; From Workspace</b> .                                                                                                                                                                                                                                                                                                                  |

After you have your scenario:

- To begin inserting signals, use the other options in the **Insert** section. For more information, see “Create Signals and Signal Data” on page 70-21.
- To change the signal order in the hierarchy or change the name of a signal, see “Change Signal Names and Hierarchy Orders” on page 70-4.

### Link in Signal Data from Signal Builder Block and Simulink Design Verifier Environment

You can use **Signals > Edit MAT-File** to link in MAT-file data from these sources for editing.

- Signal Builder blocks.
- Simulink Design Verifier.

### Link in Data from Signal Builder

You can link in and edit data exported from the Signal Builder block in a MAT-file or MATLAB. Use one of these methods to export the data:

- Signal Builder block **File > Export Data > To MAT-file** option, then link in the MAT-file.
- `signalbuilder get` function with data sets, then perform either of these steps:
  - Import the data sets in the workspace and save to a MAT-file
  - Save the data sets in the workspace to a MAT-file and import the MAT-file

For more information on exporting from a Signal Builder block, see “Exporting Signal Group Data” on page 76-86.

### Link in Test Vectors from Simulink Design Verifier Environment

You can link in and edit Simulink Design Verifier test vectors. This workflow requires a Simulink Design Verifier license.

Before linking in, use the Simulink Design Verifier `sldvsimdata` function to convert a Simulink Design Verifier test structure to a set of `Simulink.SimulationData.Dataset` objects. This file contains a test vector structure `sldvData`. Save the output to a MAT-file and then import that file into Signal Editor.

## Insert Signals

To insert signals into scenarios, select the scenario, then click a signal type from the **Insert** section.

- **Signal**

Use the **Signal** split button to specify how you want to define the signal data:

- **Blank Signal** — Add signal data directly into a table (see “Work with Basic Signal Data” on page 70-21).
- **Author Signal** — Author signal data using signal notations and variables (“Create Signals with MATLAB Expressions and Variables” on page 70-25).
- **Bus**
- **Ground**
- **Function Call**

If you need a function-call signal for a root inport with explicit periodic sample time, insert a ground signal instead. Simulink then executes the function-call automatically.

The new signals appear in the **Scenarios and Signals** section.

You can also insert multiple signals of the same type. For more information, see “Create Signals with the Same Properties” on page 70-7.

To change the signal order in the hierarchy or change the name of a signal, see “Change Signal Names and Hierarchy Orders” on page 70-4.

To edit the properties of a signal:

- For tabular editing, see “Work with Basic Signal Data with a Tabular Editor” on page 70-21.
- To replace the signal data or edit the signal notation using MATLAB expressions, see “Replace Signal Data with MATLAB Expressions” on page 70-29.

## Add Signals to Scenarios

This example describes how to create a scenario to be linked to from the Root Inport Mapper tool. You can then start the Signal Editor to manipulate and add signals to this scenario.

- 1 In the MATLAB Command Window, create some data by typing:

```
ts = timeseries([0;20],[0;10]);
```

- 2 In Simulink Editor, create a model that contains three Inport blocks, three Gain blocks, a Mux block, and a Scope block. Connect these blocks as shown:

- 3 Set the gain for the Gain blocks to 5, 10, and 15, respectively.

- 4 Click one of the Inport blocks, then click the **Connect Input** button.

The Root Inport Mapper tool displays.

- 5 In Root Inport Mapper **Link** section, select **From Workspace**.
- 6 In the From Workspace window, enter a name to store the MAT-file, then click **OK**.
- 7 In the **Scenario** section of the Signal Editor, click **Signals > Edit MAT-File**.
- 8 In the Edit Signal File window, select the new MAT-file and click **OK**.

The Signal Editor displays.

- 9 Add a signal, *Signal*, to the scenario. Right-click the scenario and select **Insert > Blank Signal**.

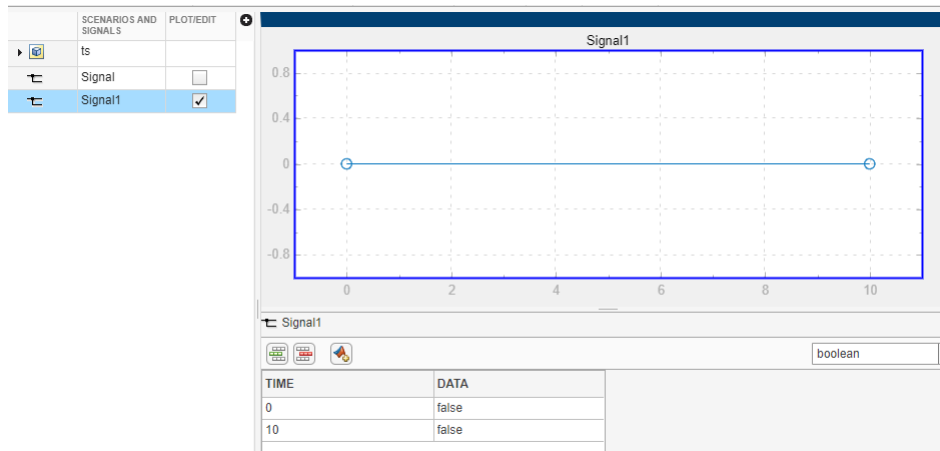

This action adds *Signal* with these default properties.

Alternatively, insert signals by clicking a signal type from the **Insert** section or using the **Signal** split button to author a signal using signal notations.

- 10 Change the default properties of signals you want to add. In the **Insert** section, select **Defaults**. In the Default Properties for Insertion dialog box, change the data type to `boolean`, then right-click the scenario and select **Insert > Blank Signal**.

This action adds *Signal1* with the data type boolean.

- 11 To check that the data type is boolean, click the plot check box for *Signal1*.

## More About

- “Create and Edit Signal Data” on page 70-2
- “Work with Basic Signal Data” on page 70-21
- “Create Signals with MATLAB Expressions and Variables” on page 70-25
- “Create Freehand Signal Data Using Mouse or Multi-Touch Gestures” on page 70-32

## Work with Basic Signal Data

### Create Signals and Signal Data

In the **Signal Editor** tab, create signal data either from existing model data (scenarios) or start with an empty scenario. By default, Signal Editor creates data in `timeseries` format. To a scenario, add signals and data by:

- Adding signal data directly into a table (“Work with Basic Signal Data” on page 70-21).
- Authoring signal data using signal notations and variables (“Create Signals with MATLAB Expressions and Variables” on page 70-25).
- Drawing signal points and lines (“Create Freehand Signal Data Using Mouse or Multi-Touch Gestures” on page 70-32)

After inserting the signal, view, plot, and edit the data by clicking the **Plot/Edit** check box. The plot opens in the **Edit** tab.

If the data does not plot as expected, use the **Fit to window** button in the **Zoom & Pan** section. For multidimensional signals, also make sure that you have the right plot selected for the column data you are editing.

Explore the plots using the **Measure** and **Zoom & Pan** sections on the toolbar.

- In the **Measure** section, use the **Data Cursors** button to display one or two cursors for the plot. These cursors display the T and Y values of a data point in the plot. To view a data point, click a point on the plot line.
- In the **Zoom & Pan** section, select how you want to zoom and pan the signal plots. Zooming is only for the selected axis.

### Work with Basic Signal Data with a Tabular Editor

To add and edit basic signal data, select a signal and click the associated **Plot/Edit** check box. The **Edit** tab opens with a plot of the signal. Each data point in the signal is demarcated with a circle (marker), which you can toggle off and on through the context menu **Show > Toggle Markers** option. Under the signal plot is a tabular editor.

- To insert or delete a data row for a signal, use  or , respectively.
- To change the data type for signal data, select the type from the drop-down.

- To change the time or data for each signal, edit the associated column of the data row, then click anywhere in the canvas to update the plot of the signal. You may need to click **Fit to View** in the toolstrip to adjust the plot axes.

**Note** If the data is fixed-point data, hovering over the data in the table displays a summary of the data

- Ideal Value — Requested value.
  - Fixed-Point Value — Value resulting from casting the ideal value as a fixed-point value.
  - Absolute Error — Absolute error of value.
  - Relative Error — Difference between cast value and the original value.
  - Additional error information, such as whether the error is an overflow or underflow.
- To change the size of the plot or tabular area, move the separator up and down.

- To evaluate MATLAB expressions in table cells, type them in a table cell:
  - The expression must be a valid MATLAB syntax.
  - The result of the syntax must be a scalar value.
  - The result of the syntax must be a valid value based on the signal properties such as data type and complexity.

Expressions can access variables in the base workspace. If an expression does not satisfy these guidelines, Simulink reverts the cell entry to the original value.

- To create multidimensional signals, use one of these methods. For more information, see “Add and Edit Multidimensional Signals” on page 70-9.
  - In the Default Properties for Insertion dialog box, enter a dimension greater than 1 in the **Dimensions** parameter.
  - In the Author and Insert dialog box, enter a MATLAB expression that creates multidimensional signals in the **Data** parameter

Instead of using the tabular editor to define signal data, you can use MATLAB expressions.

## **See Also**

Signal Editor | `signalEditor`

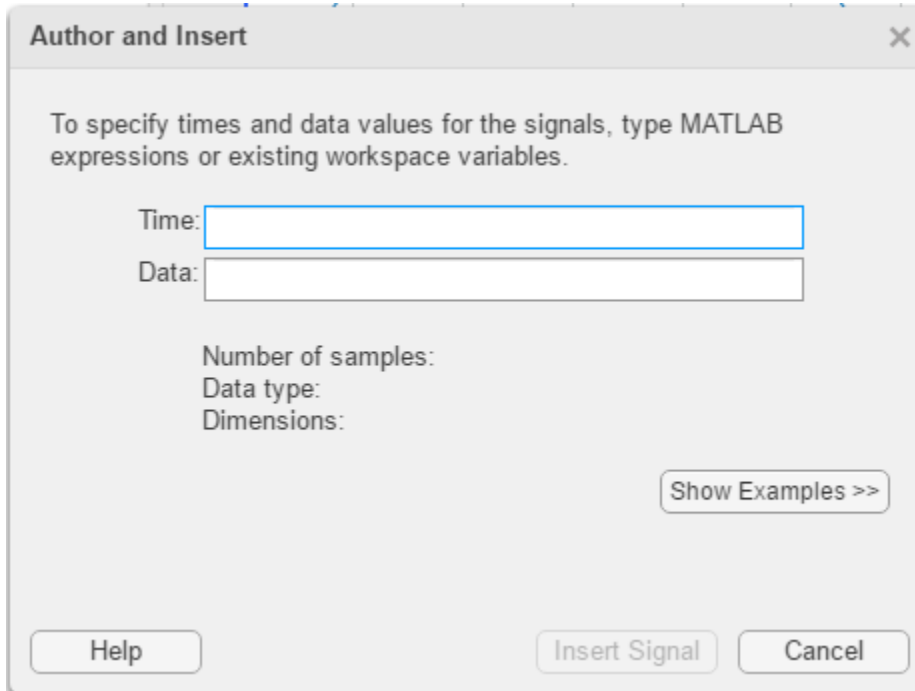

## **More About**

- “Create and Edit Signal Data” on page 70-2
- “Use Scenarios and Insert Signals in Signal Editor” on page 70-16
- “Create Signals with MATLAB Expressions and Variables” on page 70-25
- “Create Freehand Signal Data Using Mouse or Multi-Touch Gestures” on page 70-32

## Create Signals with MATLAB Expressions and Variables

To add signals using MATLAB expressions and variables, select the Signal Editor **Signal > Author Signal** option.

Author and Insert

To specify times and data values for the signals, type MATLAB expressions or existing workspace variables.

Time:

Data:

Number of samples:  
Data type:  
Dimensions:

Show Examples >>

Help Insert Signal Cancel

- **Time** — Enter the range of time for the data.
- **Data** — Enter the MATLAB expression for the signal.
- **Data type** — Select or enter the signal data type.
  - double
  - single
  - int8
  - uint8
  - int16
  - uint16
  - int32
  - uint32
  - boolean
  - fixdt(1,16)
  - fixdt(1,16,0)
  - fixdt(1,16,2<sup>0</sup>,0)
  - string
  - Enum: <class name>

If you enter your time and data and then select a fixed-point data type, the Signal Editor displays a fixed-point proposed data type for your data.

- To help you select a fixed-point data type, click the **Show Histogram** button

( **Show Histogram**). Clicking this button displays a plot of the signal data using the selected fixed-point data type. The graph displays:

| Column               | Information                                              |
|----------------------|----------------------------------------------------------|
| Values               | The negative, positive, and zero signal values.          |
| Potential Overflows  | Bins the signal values that may overflow.                |
| In-Range             | Bins the signal values that are within acceptable range. |
| Potential Underflows | Bins the signal values that may underflow.               |

To see the difference that a data type may have on the histogram, select:

- User Specified
- Binary Scaling
- Slope & Bias Scaling

For more information, see “Histogram Plot of Signal” (Fixed-Point Designer).

- To apply the proposed fixed-point data type to your data, click the **Use proposed data type** button ().

When you click **Insert Signal**, the interface evaluates the signal, updates the signal information in the dialog box, and adds the signal to the **Scenarios and Signals** section. In addition, the number of samples, signal data type, and signal dimension also appear.

To see example **Time** and **Data** entries, click the **Show Examples** button. To experiment with the signals from these example signal notations, click the **Apply Example** button for the associated example. You can also modify the examples before inserting.

For example, to create a sine wave, click the **Apply Example** button next to that example and click the **Insert Signal** button. Observe that dialog box displays the number of samples, signal data type, and signal dimensions.

**Author and Insert** ✕

To specify times and data values for the signals, type MATLAB expressions or existing workspace variables.

Time:

Data:

Data type:  ▼

Number of samples: 101  
Data type: double  
Dimensions: 1

[Hide Examples <<](#)

**Examples**

To create a vector, enter values:

Time:

Data:

To create a 2-D column vector, enter a range of values for each column:

Time:

Data:

Create a sine wave:

Time:

Data:

To reference MATLAB workspace variables, enter the variable names in the 'Time' and 'Data' fields.

To view the signal, cancel the Author and Insert dialog box, navigate to the **Scenarios and Signals** section, and click the **Plot/Edit** button for the new signal. If a signal has real and imaginary parts, both parts display in one plot. The tabular editor also reflects the signal data.

Explore the plots using the plot context menus **Align** and **Zoom & Pan**.

If the data does not plot as expected, use the **Fit to view** button in the **Zoom & Pan** section. For multidimensional signals, also make sure that you have the right plot selected for the column data you are editing.

- In the **Measure** section, use the **Data Cursors** button to display one or two cursors for the plot. These cursors display the T and Y values of a data point in the plot. To view a data point, click a point on the plot line.
- In the **Zoom & Pan** section, select how you want to zoom and pan the signal plots. Zooming is only for the selected axis.

| Type of Zoom or Pan                                                                                                     | Button to Click |
|-------------------------------------------------------------------------------------------------------------------------|-----------------|
| Zoom in along the T and Y axes.                                                                                         |                 |
| Zoom in along the time axis. After selecting the icon, on the graph, drag the mouse to select an area to enlarge.       |                 |
| Zoom in along the data value axis. After selecting the icon, on the graph, drag the mouse to select an area to enlarge. |                 |
| Zoom out from the graph.                                                                                                |                 |

| Type of Zoom or Pan                                                                                                                                                  | Button to Click                                                                   |
|----------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------|
| Fit the plot to the graph. After selecting the icon, click the graph to enlarge the plot to fill the graph.                                                          |  |
| Pan the graph up, down, left, or right. Select the icon. On the graph, hold the left mouse button and move the mouse to the area of the graph that you want to view. |  |

**Tip** To produce signals with linearly spaced values for time, use the `linspace` function, for example:

- **Time** — `linspace(0,10,101)`
- **Data** — `[0:0.1:10]`

To edit signal data without using MATLAB expressions, see “Work with Basic Signal Data” on page 70-21.

## Replace Signal Data with MATLAB Expressions

You can replace signal data using MATLAB expressions at any time, regardless of how you created the original signal data. To replace signal data, select that signal in the **Scenarios and Signals**

section, and then click the replace button (). Use the Author and Replace Signal Data dialog box as if you were inserting a new expression with the Author and Insert dialog box. For more information, see “Create Signals with MATLAB Expressions and Variables” on page 70-25.

---

**Note** You cannot change data types to or from a fixed-point data type.

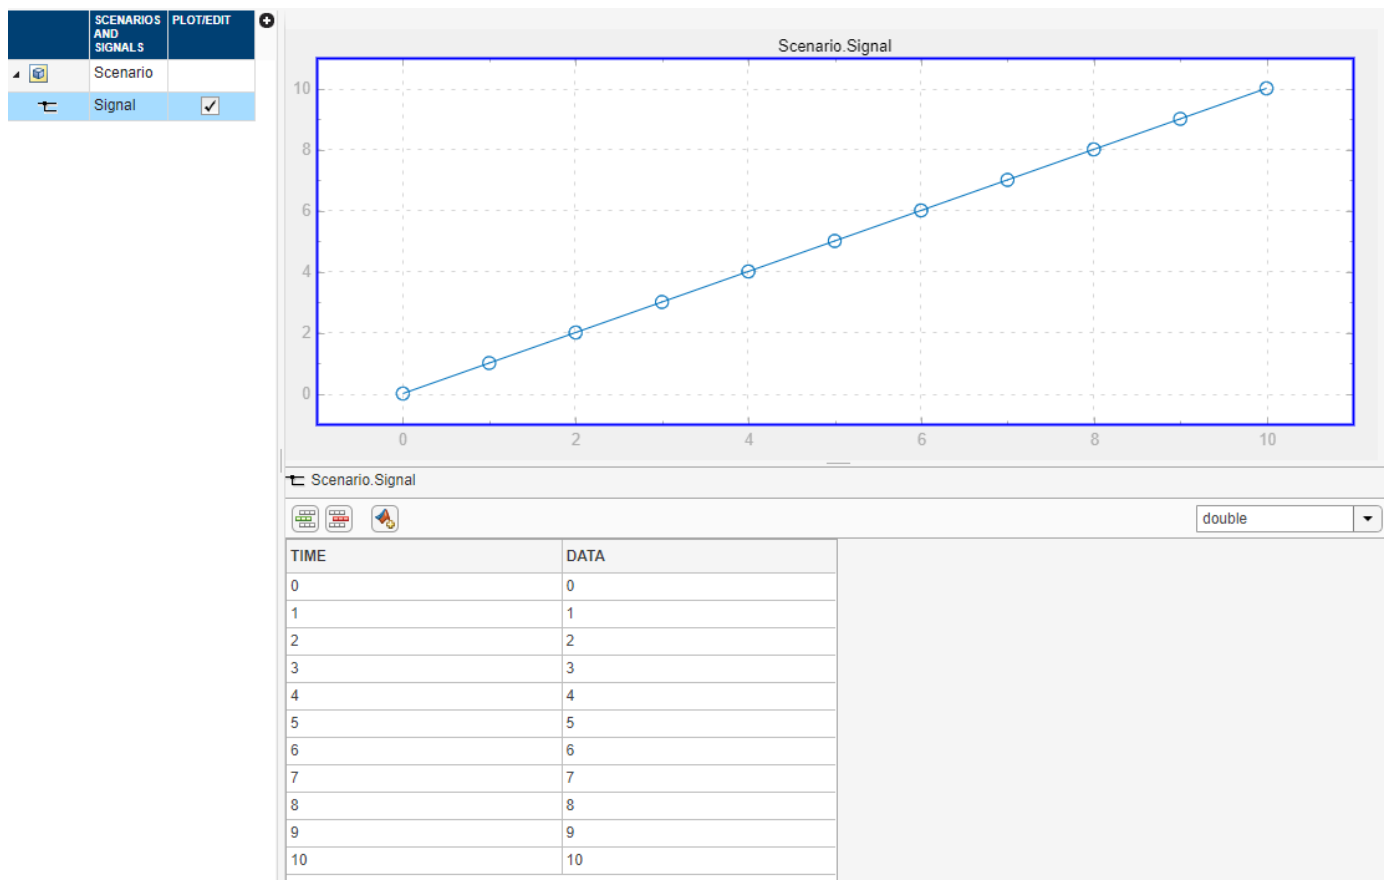

---

**Tip** When replacing a signal, the signal dimension and complexity of the new signal must be the same as the signal being replaced.

---

**Tip** To produce signals with linearly spaced values for time, use the `linspace` function. For example, using:

- **Time** — `linspace(0,10,11)`
- **Data** — `[0:10]`

Signal Editor | `signalEditor`

## More About

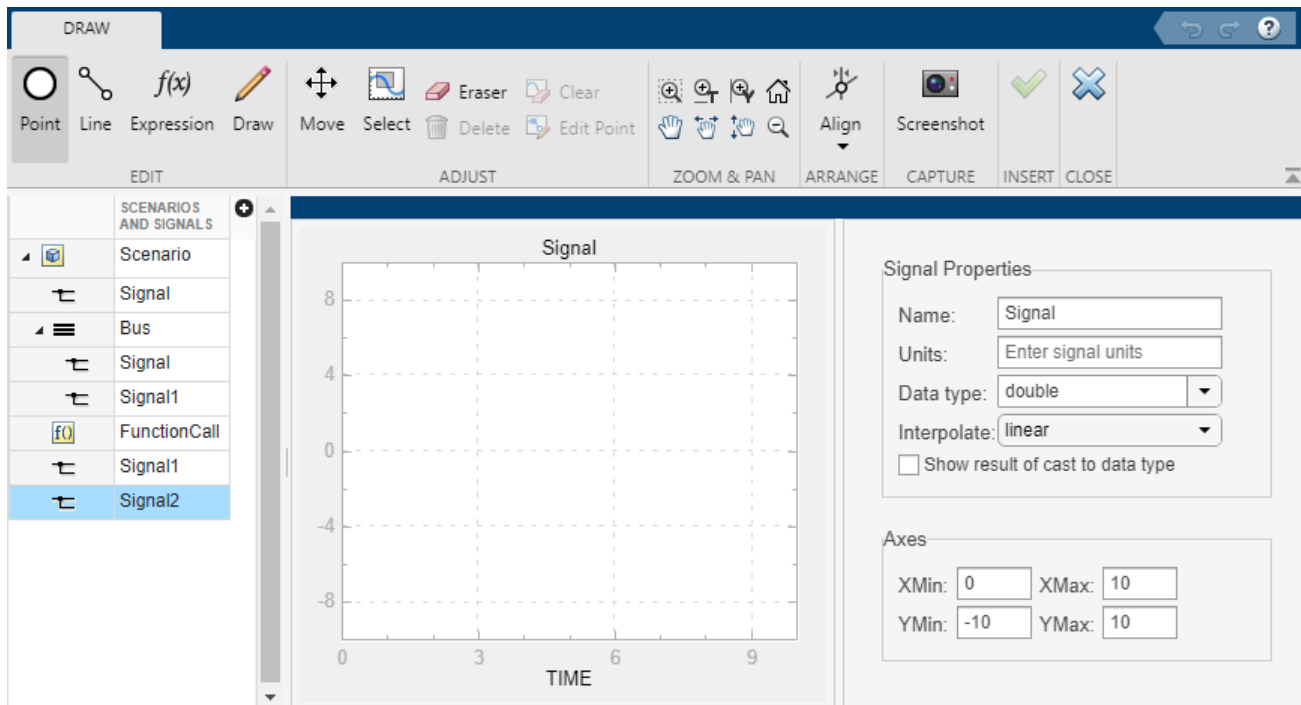

- “Create and Edit Signal Data” on page 70-2
- “Use Scenarios and Insert Signals in Signal Editor” on page 70-16
- “Work with Basic Signal Data” on page 70-21

- “Create Freehand Signal Data Using Mouse or Multi-Touch Gestures” on page 70-32

## Create Freehand Signal Data Using Mouse or Multi-Touch Gestures

Freehand signal data is data that you add graphically. Signal Editor allows you to add freehand signal data using a mouse or touchscreen (if available and supported). While using a touchscreen, use common multi-touch gestures such as tap, pan, pinch, and double-tap (select all). By default, freehand signal data is in timeseries format.

To add freehand signal data, in the **Signal Editor** tab, select **Signal > Draw Signal** option. A **Draw** tab opens.

You can draw your own signal lines or points, use MATLAB expression to enter data, move signal lines or points across the canvas, take an image of the lines of the canvas, and add the data to the Signal Editor.

To create signal data, in the **Edit** section:

- Insert a single data point by clicking **Point** and then clicking in the graph area. If you add additional points, the tool connects the points.
- Insert a signal line by clicking **Line** and then clicking in the graph area. To extend the line, click on the endpoints of the line and draw the extension.

---

**Tip** When you insert signals or signal lines, the canvas adds a shaded area bound by the leftmost and rightmost endpoints. While in **Insert Line** mode, you cannot add more points within this shaded area. You add additional line points outside the shaded area.

---

- Draw a signal freehand by clicking **Draw**.

- Draw a signal using MATLAB expressions by clicking **Expression** ( $f(x)$ , Ctrl+E). Enter time and data values that create signal points that are scalars or vectors whose number of points match the time points.

To select or move signal data, in the **Signal** section:

- Select a point or line by clicking **Select** and then selecting the point or area to be selected.
- Move a point or line by clicking **Move**.

To edit or remove the signal data, in the **Edit** section:

- Change the data of a point by clicking **Edit Point**. In the Edit Point dialog box, enter the new **Time** and **Data** values. These values must be scalar.

To work with the canvas, use the tools in the **Align**, **Show**, and **Zoom** sections.

- Snap the canvas graph to various grids using the tools in the **Align** section. Snapping to grid helps you better control data accuracy while drawing signals. For example, consider snapping to the x-grid to uniformly sample signal values or snapping to the y-grid to control the amplitude of a ramp signal.
- Toggle the display of data points, grid lines, and data markers in the canvas, explore the commands in the **Align** and **Show** sections. To zoom in and out of the canvas, see **Zoom & Pan**. These actions are touchscreen supported with the pan and pinch gestures. For more information, see “Create Signals and Signal Data” on page 70-21.

To work with signal properties, use the parameters in the **Signal Properties** section. For example, to see the changed values of your signal as you change data types in the **Data type** parameter, select the **Show result of cast to data type**. The original line is blue, the changed values are represented by the black line. This graphic illustrates a signal line with negative double values recast as uint8.

To capture an image of the signal data, in the **Capture** section, click **Screenshot** (). In the Save a screenshot dialog box, specify a name and graphic type for the file.

When you are done drawing the signal, in the **Insert** section:

- 1** To add the signal to the Signal Editor, click **Insert signal** ().
- 2** To return to the main Signal Editor window and check that the signal has been added, click **Close draw tab** (). Signal Editor discards any noninserted signal data.
- 3** To observe the drawn signal data In Signal Editor, click the signal name in the hierarchy.

For an example of how to add a freehand ramp signal, see “Draw a Ramp Using Snap to Grid for Accuracy” on page 70-13.

- “Use Scenarios and Insert Signals in Signal Editor” on page 70-16
- “Work with Basic Signal Data” on page 70-21
- “Create Signals with MATLAB Expressions and Variables” on page 70-25

## Import Custom File Type

To edit signals that are in your own custom data format or a non-MAT-file, use the **Open > Import** option on the **Signal Editor** tab. Custom file types:

- Are external to MATLAB or Simulink, such as Microsoft Excel or JSON format files.
- Contain signal data whose format does not conform to those listed in “Forms of Input Data” on page 71-37.

Simulink provides these file types.

- `Simulink.io.SignalBuilderSpreadsheet` — Signal Builder file type
- `Simulink.io.BaseWorkspace` — Base workspace file type
- `Simulink.io.MatFile` — MAT-file file type
- `Simulink.io.ModelWorkspace` — Model workspace file type
- Example file types
  - `Simulink.io.MySignalMatFile`
  - `Simulink.io.CreateSignals`

Simulink Test provides the `sltest.io.SimulinkTestSpreadsheet` file type.

To import custom file types that you develop in-house, you can create and register your own custom file type reader. For information, see “Create Custom File Type for Import to Signal Editor” on page 70-37. Afterwards, use this workflow to import custom file types into Signal Editor.

---

**Note** Before starting, check that nobody is editing the custom file type class file. Editing the custom file type class file while trying to import it as a reader causes unexpected behavior.

---

- 1** Check that your custom file types have been registered in Simulink. In the **Signal Editor** tab, select **Open > Import**. The **Export** dialog box displays.
- 2** Click **Browse**.
- 3** From the list of custom MAT-files, select the one that contains your signals, such as `custompath/newFile.mat`.

All registered file types appear in the Supported File Types table.

- 4 Select the signals you want to see in Signal Editor and click **OK**. To search for a signal name, enter it in **Name**.
- 5 In the **Signal Editor** tab, observe that the signals are now in the hierarchy. You can edit these signals as you would any signal.

## See Also

Signal Editor | `signalEditor`

## More About

- “Create Custom File Type for Import to Signal Editor” on page 70-37
- “Export Signals to Custom Registered File Types” on page 70-40

## Create Custom File Type for Import to Signal Editor

By default, Simulink supports signals in the forms listed in “Forms of Input Data” on page 71-37. To import file types containing signals that are not of the supported format, create and register your own custom file type reader. Simulink supports custom file type readers written with `Simulink.io.FileType`.

Simulink provides these file types.

- `Simulink.io.SignalBuilderSpreadsheet` — Signal Builder file type
- `Simulink.io.BaseWorkspace` — Base workspace file type
- `Simulink.io.MatFile` — MAT-file file type
- `Simulink.io.ModelWorkspace` — Model workspace file type
- Example file types
  - `Simulink.io.MySignalMatFile`
  - `Simulink.io.CreateSignals`

Simulink Test provides the `sltest.io.SimulinkTestSpreadsheet` file type.

Creating a file reader requires you to be familiar with object-oriented programming. It is intended for an advanced audience.

- 1 To contain your package folders, create a folder and add that folder path to the MATLAB path.
- 2 To that folder, add the custom file that contains your signals, such as `mySignals.mat`.

In that folder, create a `+Simulink` folder, and inside that folder, create a `+io` folder.

- 3 Create a class that inherits from the `Simulink.io.FileType`.

```
classdef MyFileType < Simulink.io.FileType
```

- 4 Save this class to *yourfolder*/`+Simulink`/`+io`.

- 5 To register and interact with Signal Editor, implement these static methods:

- `Simulink.io.FileType.isFileSupported`
- `Simulink.io.FileType.getFileTypeDescription`

- 6 Implement these public methods:

- `validateFileNameImpl`
- `whosImpl`

At run time, call `whosImpl` via `whos` when you run the `Simulink.io.FileType` object. `whos` has the same syntax as `whosImpl`.

- 7 Check if your class is registered. In the **Signal Editor** tab, select **Open > Import**, and in the **Import** dialog box window, click **Browse**.

The custom file that contains your signals, such as *custompath*/`mySignals.mat`, appears in the file browser.

- 8 Select the custom file that contains your custom signals.
- 9 Return to the class file and implement these additional public methods:

- `loadAVariableImpl`
- `loadImpl`

At run-time, call `loadImpl` via `load` when you run the `Simulink.io.FileType` object. `load` has the same syntax as `loadImpl`.

- 10** To import the custom signals, use the `import` method.

`dataOnFile = import(reader)`, where `reader` is the file type object for the reader, specified as a `Simulink.io.FileType` object. The output, `dataOnFile`, is a structure with the fields `structure.Data`, which is a cell array of signals, and `structure.Name`, which is a cell array of the corresponding signal names. For example, `dataOnFile.Data` is the cell array of signals and `dataOnFile.Name` contains the corresponding signal names.

- 11** Return to the Signal Editor **Open > Import** and try to import again.

After you successfully import your custom signals, you can manipulate them in Signal Editor. When done, and if you have implemented the `exportImpl` method, you can export the results by calling the `export` method for your reader at run time. Alternatively, you can use the export dialog from “Export Signals to Custom Registered File Types” on page 70-40.

For example implementations, see:

- `open('Simulink.io.CreateSignals')` — Implementation of how to create signals
- `open('Simulink.io.MySignalMatFile')` — Implementation of how to register custom file types to import into Simulink.

## Define New FileType Object for Use in Simulink

A `FileType` object is a component you can use to create readers for signals that exist in formats not currently supported in Simulink. Write the reader in MATLAB and use the Signal Editor **Open > Import** option to register the reader and import the custom format file.

---

**Note** Before importing, check that all editors for the custom file type class file are closed. Editing the custom file type class file while trying to import it as a reader causes unexpected behavior.

---

## Define FileType Object

- 1** Create a `FileType` object for use in Simulink. This example creates a reader for signals with a custom format.
- 2** Create a class definition text file to define your `FileType` object.
- 3** On the first line of the class definition file, specify the name of your `FileType` and subclass from `Simulink.io.FileType`. The `Simulink.io.FileType` base class enables you to use all the basic `FileType` object methods.
- 4** For your class:
  - a** Add the appropriate basic `FileType` object methods to register and interact with Signal Editor.
  - b** Validate the signal formats.
  - c** Determine the contents of the signal file.

- d** Load variables from the signal file.
- e** Import the signals.

See the reference pages for each method and the full class definition file below for the implementation of each of these methods. To see the full class definition for a custom signal reader, run: `open('Simulink.io.MySignalMatFile')`.

## See Also

`Simulink.io.FileType` | `Simulink.io.SignalBuilderSpreadsheet` | `exportImpl` | `getFileTypeInfo` | `Simulink.io.FileType.isFileSupported` | `loadImpl` | `loadAVariableImpl` | `validateFileNameImpl` | `whosImpl`

## More About

- “Import Custom File Type” on page 70-35
- “Export Signals to Custom Registered File Types” on page 70-40
- “Forms of Input Data” on page 71-37

## Export Signals to Custom Registered File Types

To export signals from Signal Editor to your own custom file types, on the **Signal Editor** tab, select **Save > Export**. Custom file types:

- Are external to MATLAB or Simulink, such as Microsoft Excel or JSON format files.
- Contain signal data whose format does not conform to those listed in “Forms of Input Data” on page 71-37.
- When exporting a `Simulink.io.SignalBuilderSpreadsheet` file type, it must contain a dataset represented with `Simulink.SimulationData.Dataset` objects that contain `timeseries` data with vector data.

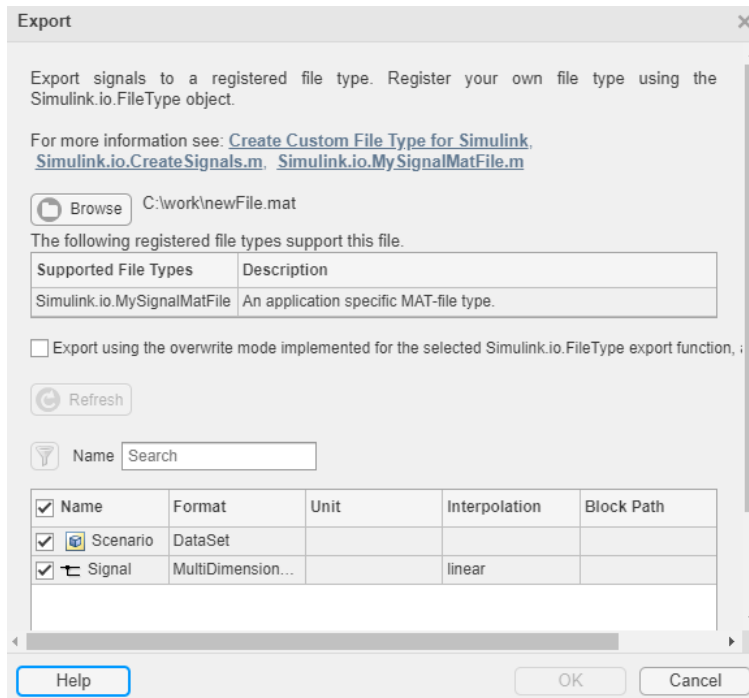

Simulink provides these file types.

- `Simulink.io.SignalBuilderSpreadsheet` — Signal Builder file type
- Example file types
  - `Simulink.io.MySignalMatFile`
  - `Simulink.io.CreateSignals`

- 1 In Signal Editor, create signals to export to your custom file type.
  - a Click **Scenario > Blank Scenario**.
  - b Click **Signal > Author Signal**.
  - c Click **Show Examples**. Select **Apply Example** for the 2-D column vector.
- 2 Check that your custom file types have been registered in Simulink. In the **Signal Editor** tab, select **Save > Export**. The **Export** dialog box displays.
- 3 Click **Browse**.
- 4 From the list of custom MAT-files, select the one that contains your signals, such as `custompath/newFile.mat`.

All registered file types appear in the Supported File Types table.

The signals in your custom file type appear in the file browser.

- 5 Select the signals you want to export from Signal Editor, then click **OK**.

## Provide Signal Data for Simulation

### In this section...

“Identify Model Signal Data Requirements” on page 71-2  
“Signal Data Storage for Loading” on page 71-2  
“Load Input Signal Data” on page 71-5  
“Log Output Signal Data” on page 71-6

A Simulink model performs algorithms on input signal data and produces output signals. The model defines what input data to use at the start of simulation and what output to capture at the end of simulation. As you create and simulate your model, you:

- 1 “Identify Model Signal Data Requirements” on page 71-2
- 2 “Load Input Signal Data” on page 71-5
- 3 “Log Output Signal Data” on page 71-6

As you create, debug, and test a model, you can use different sets of input signal data for simulation. You can use logged simulation data as input to another simulation.

### Identify Model Signal Data Requirements

To use system-generated signal data, use source blocks such as a Sine Wave block. Source blocks do not require the use of a variable or external data source. If you cannot configure source blocks to meet your modeling requirements, then supply the signal data.

As you determine your signal data requirements, identify the:

- Blocks (including subsystems and Model blocks) that you need to provide data for — Design interfaces for blocks and for model components, including data types of signals.
- Range characteristics of signals, such as sample time, dimensions, and data type.
- Storage location for data for each input signal — Determine where to store signal data: in workspace variables, a MAT-file, or an external data file such as an Microsoft Excel spreadsheet.

Create a list of equation variables and constant coefficients, and then determine the coefficient values from published sources or by performing experiments on the system.

For information about storage locations for signal data, see “Signal Data Storage for Loading” on page 71-2.

### Signal Data Storage for Loading

- “MATLAB Workspace for Signal Data” on page 71-3
- “Source and Signal Editor Blocks for Signal Data” on page 71-4
- “MAT-Files for Signal Data” on page 71-4
- “Spreadsheets for Signal Data” on page 71-4

Store signal data for loading into a model in these locations:

- MATLAB (base) workspace, or function workspace
- Model workspace
- Function workspace
- Masking workspace
- Blocks
- MAT-files
- Spreadsheets

The MATLAB (base) workspace is the most common workspace to use for loading signal data.

### **MATLAB Workspace for Signal Data**

Consider using the MATLAB (base) workspace when you want to:

- Use a small amount of signal data for iterative simulations.
- Use signal data logged during one simulation as input for another simulation.
- Have multiple models use the same signal data.

### **Create Signal Data in the MATLAB Workspace**

- At the MATLAB command line or editor, create the signal data.
- Use the `xlsread` function to read data from an Excel spreadsheet into the MATLAB workspace.
- Use the `csvread` function to read data from a CSV spreadsheet into the MATLAB workspace.
- Use a model callback to load signal data.
- Use one of these Simulink logging techniques:
  - Signal logging
  - To Workspace block
  - Scope block
  - The **Configuration Parameters > Data Import/Export** pane, the **Output, States, or Final states** parameters.
  - Data store
  - The `sim` command configured to log simulation data

### **Load Signal Data from the MATLAB Workspace**

To load signal data from a workspace, use one of these techniques:

- Add a From Workspace block.
- Use a root-level input port.
  - Specify workspace variables in the **Configuration Parameters > Data Import/Export > Input** parameter.
  - Use the Root Inport Mapper tool to specify the data for the **Input** parameter.

### **Source and Signal Editor Blocks for Signal Data**

Source blocks, such as the Sine Wave block, generate signals that you can use as inputs to other blocks. Source blocks do not store signal data. Source blocks can be useful for initial prototyping of a model when the generated signal data serves your modeling requirements.

To define scenarios to use as inputs to a model, you can use the Signal Editor block. The Signal Editor block stores the scenario definitions.

Consider using a source block to:

- Avoid having to create the data manually.
- Reduce memory consumption — source blocks do not store signal data.
- Graphically represent in the model the kind of signal data.

Consider using a Signal Editor block to:

- Create and import scenarios for use in testing.

You can use scenarios with Simulink and with these products:

- Simulink Test
- Simulink Coverage
- Simulink Design Verifier
- Switch between scenarios quickly.

### **MAT-Files for Signal Data**

Consider storing signal data in a MAT-file to:

- Load a large amount of signal data efficiently.
- Reuse the same signal data in different models.
- Reduce memory requirements for the model.
- Use different sets of signal data with the same model, with minimal model updates.

#### **Store Signal Data in a MAT-File**

To create a MAT-file to store signal data to import, you can use:

- A To File block
- The Signal Editor user interface
- MATLAB to create signal data that you store in a MAT-file

#### **Load Signal Data from a MAT-File**

To load signal data from a MAT-file into a model, you can use a From File block.

### **Spreadsheets for Signal Data**

Consider using an Excel or CSV spreadsheet to:

- Use an existing spreadsheet that already has the necessary signal data or that you can update easily to contain the signal data.

- Load a large amount of signal data efficiently.
- Reduce memory requirements for the model.
- Use different sets of signal data with the same model, with minimal model updates.
- Share the signal data with other people who do not have Simulink installed.

### Store Signal Data in a Spreadsheet

Use one of these approaches:

- Create the signal data directly in the spreadsheet.
- Export MATLAB signal data to an Excel or CSV spreadsheet using the `xlswrite` or `csvwrite` function.

### Load Signal Data from a Spreadsheet

Use the From Spreadsheet.

The From Spreadsheet block loads Microsoft Excel on all platforms. This block loads CSV spreadsheets only on Microsoft Windows platforms.

The From Spreadsheet block incrementally loads the data directly from the spreadsheet, to reduce memory consumption.

## Load Input Signal Data

You can use various sources for input signal data for simulating a model. You can:

- Use existing data from a file, such as a spreadsheet.
- Write a MATLAB script to define variables for the signal data. For example, you can create `Dataset` format data that you can use with all the signal loading techniques.
- Use data logged from a previous simulation.

You can use several different approaches to load data into a model, including:

- Root-level input ports — Import signal data from a workspace, using the **Input** configuration parameter to import it to a root-level input port of a `Inport`, `Enable`, or `Trigger` block. You can specify the input data directly in the **Input** parameter. To import multiple signals to root-level input ports, consider using the Root Inport Mapping tool on page 72-2. That tool updates the **Input** parameter based on the signal data that you import and map to root-level input ports.
- Source blocks — Add a source block, such Sine Wave block, to generate signals to input to another block.
- From File block — Read data from a MAT-file, outputting the data as a signal.
- From Spreadsheet block — Read data from Microsoft Excel spreadsheets or CSV spreadsheets, outputting the data as one or more signals.

To determine the approach to meet the input signal data requirements of your model, see “Comparison of Signal Loading Techniques” on page 71-21.

## Log Output Signal Data

You can save signal values to the MATLAB workspace or to a MAT-file during simulation for later retrieval and postprocessing. Saving simulation data is also known as logging or exporting simulation data.

To determine which approach to use for logging signal data, see “Export Simulation Data” on page 73-2.

Saving simulation data in `Dataset` format simplifies postprocessing by providing a common format for the results of various logging techniques. Using `Dataset` format stores the data as MATLAB `timeseriesobjects`, which you can process with MATLAB. Simulink provides tools for converting data logged in other formats to `Dataset` format.

For more information about logging output signal data, see “Save Run-Time Data from Simulation”.

## Load Big Data for Simulations

### In this section...

“Stream Individual Signals Using SimulationDatastore Objects” on page 71-7

“Stream an Entire Dataset Using a DatasetRef Object” on page 71-8

“Load Individual Signals from a DatasetRef Object” on page 71-9

Simulating models with many time steps and signals can use and create data that is too large to fit into working memory on your computer. When your simulation input data does not fit into memory, you can choose one of several strategies to use that data as simulation input with root-level Inport blocks. These strategies work for loading data stored in Dataset format in a Version 7.3 MAT-file, including data logged from another simulation.

- 1 When individual input signals are too large to fit into memory, you can use a `matlab.io.datastore.SimulationDatastore` object to access the signal data. The data from the `SimulationDatastore` object loads into the simulation incrementally in chunks that fit into memory.
- 2 When your simulation inputs are specified by a `Simulink.SimulationData.Dataset` object in a file that is too large to load into memory, you can stream the entire contents of the `Dataset` object into your model using a `Simulink.SimulationData.DatasetRef` object.
- 3 When the signals fit into memory and are stored in a file that is too large to load into memory, you can load individual signals from the file into memory using a `Simulink.SimulationData.DatasetRef` object.

---

**Note** When you want to use data logged in one simulation as input for another, you can also stream data into the model using a `matlab.io.datastore.sd datastore` object. The `sd datastore` object references data in the Simulation Data Inspector repository on disk, so you do not have to save the logged data to a file. Consider using a `sd datastore` object as simulation input for iterative workflows.

---

All big data loading strategies are for the special case when your data does not fit into memory and can require extra steps. These examples use data that fits fully into memory to illustrate the steps required for big data loading. When your simulation inputs fit into memory, consider using other loading techniques.

### Stream Individual Signals Using SimulationDatastore Objects

When individual signals in your input data are too large to fit into memory, you can create `matlab.io.datastore.SimulationDatastore` objects for those signals and stream them into your model. To create a `SimulationDatastore` object for a signal you want to stream into your model, first create a `Simulink.SimulationData.DatasetRef` object to reference the `Dataset` object that contains your signal of interest. For example, create a `DatasetRef` for logged data from a simulation of the `slexAircraftExample` model.

```
loglogout_DSR = Simulink.SimulationData.DatasetRef('aircraftData.mat', 'loglogout');
```

You can create a `SimulationDatastore` object for your desired signal by indexing into the `DatasetRef` object with curly braces or using the `getAsDatastore` method for the `DatasetRef`

object. In both cases, the `SimulationDatastore` object exists in the `Values` property of the returned `Simulink.SimulationData.Signal` object.

When you know the index of the signal within the `Dataset` object, you can index into the `DatasetRef` object with curly braces to create a `SimulationDatastore` for your signal.

```
alphaRad_ds = logout_DSR{4}

alphaRad_ds =
 Simulink.SimulationData.Signal
 Package: Simulink.SimulationData

 Properties:
 Name: 'alpha, rad'
 PropagatedName: ''
 BlockPath: [1x1 Simulink.SimulationData.BlockPath]
 PortType: 'outport'
 PortIndex: 4
 Values: [1x1 matlab.io.datastore.SimulationDatastore]
```

Methods, Superclasses

To create a `SimulationDatastore` object for a signal using the signal index, name, or block path, use the `getAsDatastore` method. For example, create a `SimulationDatastore` object for the `Stick` signal.

```
stick_ds = logout_DSR.getAsDatastore('Stick')

stick_ds =
 Simulink.SimulationData.Signal
 Package: Simulink.SimulationData

 Properties:
 Name: 'Stick'
 PropagatedName: ''
 BlockPath: [1x1 Simulink.SimulationData.BlockPath]
 PortType: 'outport'
 PortIndex: 1
 Values: [1x1 matlab.io.datastore.SimulationDatastore]
```

Methods, Superclasses

Because the `Values` properties of the `stick_ds` and `alphaRad_ds` `Simulink.SimulationData.Signal` objects are `SimulationDatastores`, the signal data streams into your model. You can include a `SimulationDatastore` backed `Signal` object as an element in a `Dataset` object or as an item in the Input parameter comma-separated list.

## Stream an Entire Dataset Using a DatasetRef Object

When your simulation inputs are specified in a `Dataset` in a file that is too large to load into memory, you can create a `Simulink.SimulationData.DatasetRef` object to stream your simulation inputs into your model. When you specify a `DatasetRef` object for the Input parameter on the Data Import/Export pane, all the signals in the `Dataset` object used to create the `DatasetRef` stream into your

model. Use one of the other big data loading techniques to load or stream individual signals from a `Dataset` object.

When the file where your simulation input `Dataset` is stored contains other `Datasets` and data, you can use the `Simulink.SimulationData.DatasetRef.getDatasetVariableNames` function to view a list of the `Dataset` objects contained in the file. Previewing the variable names in the `Dataset` object is particularly useful when the file contents do not fit into memory.

```
datasetNames = Simulink.SimulationData.DatasetRef.getDatasetVariableNames('aircraftData.mat')

datasetNames = 1x3 cell
 {'logout'} {'xout'} {'yout'}
```

Create a `DatasetRef` object for `logout`.

```
logout_DSR = Simulink.SimulationData.DatasetRef('aircraftData.mat', 'logout');
```

You can load `logout_DSR` using the `Input` parameter the same way you would load a `Simulink.SimulationData.Dataset` object. Each signal in the `Dataset` object used to create the `DatasetRef` streams into the model in chunks that fit into memory.

## Load Individual Signals from a DatasetRef Object

When your simulation input signals individually fit into memory and are stored in a `Dataset` object in a file that does not fit into memory, use a `Simulink.SimulationData.DatasetRef` object to load each signal of interest into memory. Then, you can load the signals as simulation inputs for your model.

First, create the `DatasetRef` object to reference the `Dataset` object in the file that contains the signals you want to load. For example, create a `DatasetRef` object for data logged to file from a simulation of the `slexAircraftExample` model.

```
logout_DSR = Simulink.SimulationData.DatasetRef('aircraftData.mat', 'logout');
```

You can use the `get` or `getElement` methods to load individual signals into memory with the `DatasetRef` object. Both methods load the specified element into memory, using the same syntax. You can specify the signal you want to load into memory using its index within the `Dataset` object or its name. If you don't know the name of the signal you want to load, use the `getElementNames` method to see the names of the elements in the `Dataset` object referenced by the `DatasetRef` object.

```
elNames = logout_DSR.getElementNames
```

```
elNames = 15x1 cell
 {0x0 char }
 {0x0 char }
 {0x0 char }
 {'alpha, rad'}
 {'q, rad/sec'}
 {0x0 char }
 {'qGust'}
 {'wGust'}
 {0x0 char }
 {0x0 char }
```

```
{0x0 char }
{'Stick' }
{0x0 char }
{0x0 char }
{0x0 char }
```

Load the `qGust` signal into memory using its name.

```
qGust = logout_DSR.getElement('qGust')
```

```
qGust =
 Simulink.SimulationData.Signal
 Package: Simulink.SimulationData

 Properties:
 Name: 'qGust'
 PropagatedName: ''
 BlockPath: [1x1 Simulink.SimulationData.BlockPath]
 PortType: 'outport'
 PortIndex: 2
 Values: [1x1 timeseries]
```

Methods, Superclasses

You can add the `qGust` signal to a `Dataset` object of simulation input signals to load to the root-level Inport blocks in your model, or you can specify `qGust` as an item in the `Input` parameter comma-separated list.

- “Analyze Big Data from a Simulation” on page 73-37

## Stream Data from a MAT-File as Input for a Parallel Simulation

This example shows how to use `Simulink.SimulationData.DatasetRef` objects and the `parsim` function to stream input data from a version 7.3 MAT-file for parallel simulations. Consider following the steps outlined in this example when the inputs for your simulation are too large to load into memory. For example, you can use data logged to persistent storage from one set of parallel simulations as input for another.

This example uses `parsim` to run multiple simulations of a model, with each simulation using unique input data. The model is based on the `sldemo_suspn_3dof` model, modified to use Inport blocks as the source for inputs instead of the Signal Editor block. The model simulates the response of a suspension system to different road conditions. The MAT-file used in this example contains multiple `Simulink.SimulationData.Dataset` objects representing various road conditions. The example uses `DatasetRef` objects to stream the contents of an entire referenced `Dataset` object as simulation input.

You can also stream data for individual signals into parallel simulations run with `parsim` using `matlab.io.datastore.SimulationDatastore` objects. For details on creating `SimulationDatastore` objects, see “Stream Individual Signals Using SimulationDatastore Objects” on page 71-7.

### Load Model and Access Input Data

Load the `ex_sldemo_suspn_3dof_parsim_stream` model. The model receives input data through two Inport blocks, and each `Dataset` object used as simulation input contains two elements: one for each Inport.

```
mdl = 'ex_sldemo_suspn_3dof_parsim_stream';
open_system(mdl)
```

You can use the `Simulink.SimulationData.DatasetRef.getDatasetVariableNames` function to evaluate the contents of the MAT-file containing the input data without loading the data into memory. The function returns a cell array that contains elements for the name of each `Simulink.SimulationData.Dataset` variable the file contains. Use the function to access the variable names and determine the number of test cases in the file.

```
varNames = Simulink.SimulationData.DatasetRef.getDatasetVariableNames('suspn_3dof_test_cases.mat');
numTestCases = numel(varNames);
```

You can stream the test case data into the model using `Simulink.SimulationData.DatasetRef` objects. The `DatasetRef` object references a variable in the file used to create it and loads the variable data incrementally. Create a `DatasetRef` object for each `Simulink.SimulationData.Dataset` object in the test cases file.

```
for idx1 = 1:numTestCases
 inputData(idx1) = Simulink.SimulationData.DatasetRef('suspn_3dof_test_cases.mat', ...
 varNames{idx1});
end
```

### Configure and Run Parallel Simulations

To use the set of test case inputs as input for a set of parallel simulations, create an array of `Simulink.SimulationInput` objects that you can pass to the `parsim` function. Use the `setExternalInput` function to specify a `Simulink.SimulationData.DatasetRef` object corresponding to a test case as data to stream as simulation input.

```

in(1:numTestCases) = Simulink.SimulationInput mdl);

for idx2 = 1:numTestCases
 in(idx2) = setExternalInput(in(idx2),inputData(idx2));
end

```

Use the `parsim` function to run a simulation for each test case. When you have the Parallel Computing Toolbox™, the `parsim` function runs simulations in parallel. Without the Parallel Computing Toolbox, the `parsim` function runs the simulations in serial.

The `parsim` function creates a worker pool based on the Parallel Computing Toolbox configuration. By default, `parsim` uses a local pool. If you use remote workers, you can use the `AttachedFiles` name-value pair to send the MAT-file containing the test case input data to each worker. When you specify the `AttachedFiles` name-value pair, `parsim` sends a copy of the file to each worker, which can take some time for large files. For streaming input data from a large file, local workers may be faster because the workers have access to the file without creating and sending copies. When you use remote workers, consider storing the MAT-file in a location that all remote workers can access and creating `DatasetRef` objects that reference that copy of the file.

```
out = parsim(in);
```

```

```

### View Simulation Results

You can access the simulation results programmatically when the simulations finish. Create a plot showing the vertical displacement for the vehicle for all the road profile test cases.

```

if isempty(out(1).ErrorMessage)
 legend_labels = cell(1,numTestCases);

```

```

for i = 1:numTestCases
 if isempty(out(i).ErrorMessage)
 simOut = out(i);
 ts = simOut.logout.get('vertical_disp').Values;
 ts.plot;
 legend_labels{i} = ['Run ' num2str(i)];
 end
 hold all
end
title('Response of a 3-DoF Suspension Model')
xlabel('Time (s)');
ylabel('Vehicle vertical displacement (m)');
legend(legend_labels,'Location','NorthEastOutside');
end

```

You can also view `parsim` simulation results using the Simulation Manager. To view results in the Simulation Manager, use the `ShowSimulationManager` name-value pair for `parsim`. With the Simulation Manager, you can monitor the progress of the runs, view simulation data, and show the `parsim` results in the Simulation Data Inspector.

### Close Parallel Workers

When you have finished running parallel simulations, you can close the worker pool.

```
delete(gcf('nocreate'));
```

## Overview of Signal Loading Techniques

### In this section...

“Source Blocks” on page 71-15  
 “Root-Level Input Ports” on page 71-16  
 “From File Block” on page 71-17  
 “From Spreadsheet Block” on page 71-18  
 “From Workspace Block” on page 71-19  
 “Signal Editor Block” on page 71-19

Simulink provides several techniques for importing signal data into a model. Each of the signal data loading techniques uses blocks to represent signal data sources visually.

For additional details about which technique to use to meet specific modeling requirements, see “Comparison of Techniques” on page 71-22.

### Source Blocks

You can add a source block, such as a Sine Wave block, to generate signals to input to another block. To specify how to generate the signal, use the Block Parameters dialog box. For example, in the Sine Wave Block Parameters dialog box, you can specify the `sim` function to use and time-based or sample-based data.

The output data types of source blocks vary. For example, a Sine Wave block outputs a vector of real doubles.

For an example of using a source block, see “Build and Edit a Model Interactively” on page 1-9.

### Recommended Uses

- Do initial prototyping in a model, when the generated signal data serves your modeling requirements

- Avoid creating the data manually.
- Reduce memory consumption. Source blocks do not store signal data.
- Make the kind of signal data visually clear in the model.

### Limitations

Source blocks generate signals based on a predefined algorithm. To use actual data from an external source or to test a model without having to modify the model, use a different signal loading technique.

## Root-Level Input Ports

You can import signal data from a workspace and apply it to a root-level input port using one of these blocks:

- Enable
- Inport
- Trigger block that has an edge-based (rising, falling, or either) trigger type

The root-level input ports load external inputs from the MATLAB (base), model, or mask workspace. These blocks import data from the workspace based on the value of the **Configuration Parameters** > **Data Import/Export** > **Input** parameter or a `sim` command argument. For an example, see “Load Data to Model a Continuous Plant” on page 71-30.

To import many signals to root-level input ports, consider using the Root Inport Mapper tool. This tool updates the **Input** configuration parameter based on the signal data that you import and map to root-level input ports. For an example, see “Map Data Using Root Inport Mapper Tool” on page 72-2.

### Recommended Uses

Use root input ports to:

- Import many signals to many blocks
- Test your model as a referenced model in a wider context with signals from the workspace, without modifying your model

For importing signal data to meet most modeling requirements and to maintain model flexibility, root-level inport mapping is a convenient technique. Root-level inport mapping:

- Displays signal data for you to inspect without loading all the signal data into MATLAB memory
- Provides memory-efficient signal viewing

## Requirements

To ensure that the Simulink variable solver executes at the times that you specify in the imported data, set the **Configuration Parameters** >

**Data Import/Export** > **Additional parameters** >

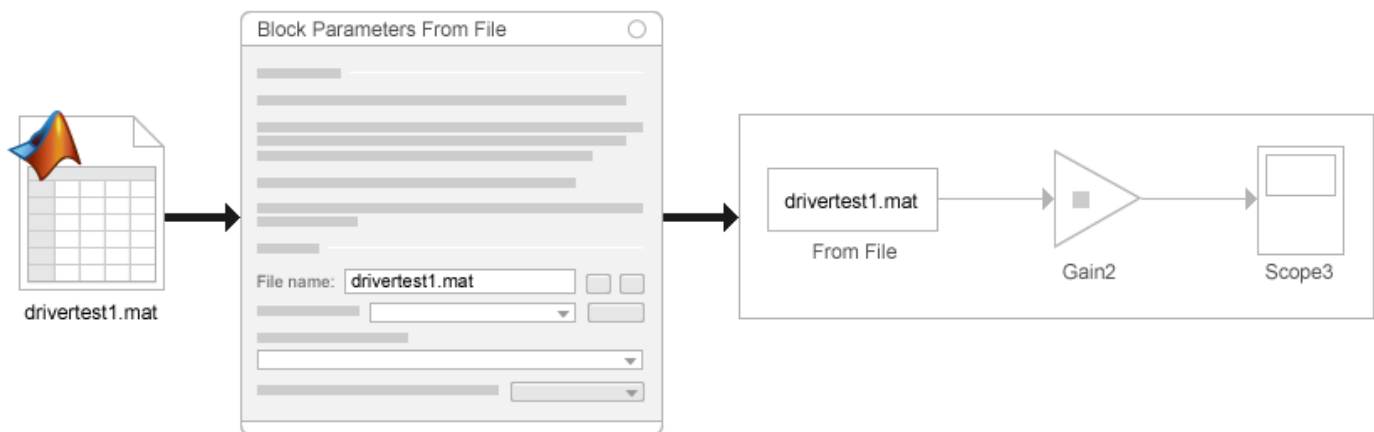

**Output options** parameter to Produce additional output.

## Limitations

- You cannot use input ports to import buses in external modes. To import bus data in rapid accelerator mode, use Dataset format.
- The Root Inport Mapper tool supported map modes depend on the data type of a signal. For details, see “Choose a Base Workspace and MAT-File Format” on page 72-10.

## From File Block

A From File block reads data from a MAT-file and outputs the data as a signal.

For an example, see “From File Block Loading Timeseries Data”.

## Recommended Uses

Consider using a From File block for loading:

- Large amounts of data. For a Version 7.3 MAT-file, the From File block loads data incrementally from the MAT-file during simulation.

---

**Tip** To convert a Version 7.0 file to Version 7.3 (for example, my\_data\_file.mat that contains the variable var), at the MATLAB command line, enter:

```
load('my_data_file.mat')
save('my_data_file.mat', 'var', '-v7.3')
```

- 
- Data that was exported to a To File block. The From File block reads data written by a To File block without any you modifying the data or making other special provisions.
  - Data stored in a MAT-file that is separate from the model file.

## Limitations

- For *Version 7.0* or earlier MAT-file, the From File block reads only array-format data.
- Version 7.3 and Version 7.0 or earlier MAT-files handle multiple variables differently.
- The From File block supports loading input data for a nonvirtual bus stored as a structure of timeseries objects.
- For array data, the From File block reads only double signal data.
- Code generation that involves building ERT or GRT targets, or using SIL or PIL simulation modes, has some special considerations. See “Code Generation”.

## From Spreadsheet Block

The From Spreadsheet block reads data from Microsoft Excel spreadsheets (all platforms) or CSV spreadsheets (Microsoft Windows platform with Microsoft Office only) and outputs the data as one or more signals.

## Recommended Uses

Use the From Spreadsheet block for loading:

- Large Microsoft Excel or CSV spreadsheets. The From Spreadsheet block incrementally reads data from the spreadsheet during simulation, rather than loading the data into Simulink memory.
- Spreadsheets that you expect to modify. The From Spreadsheet block handles changes to worksheet values automatically, because it loads data directly from the spreadsheet.

## Limitations

- You cannot import bus data.
- The From Spreadsheet file has requirements for the spreadsheet data. Organize Excel spreadsheet data using the format described in “Supported Microsoft Excel File Formats” on page 72-12.
- Linux and Mac platforms do not support using a From Spreadsheet block to import data from a CSV spreadsheet.

## From Workspace Block

The From Workspace block reads signal data from a workspace and outputs the data as a signal. In the Block Parameters dialog box, in the **Data** parameter, enter a MATLAB expression that specifies the workspace data.

For an example of how to use a From Workspace block, see “Use From Workspace Block for Test Case” on page 71-34.

### Recommended Uses

Use the From Workspace block for loading:

- A small set of signal data to perform local, temporary testing
- Data from the MATLAB (base), model, mask, or function workspace
- Variable-size signals
- Data that you saved using a To Workspace block in MATLAB `timeseries` format, without manual changes to the data
- Data saved in a previous simulation by a To Workspace block in either `Timeseries` or `Structure with Time` format for use in a later simulation

### Limitations

The data expressions that you specify must evaluate to one of these types of data:

- A `timeseries` or `timetable` object
- A structure of `timeseries` or `timetable` objects
- A structure, with or without time
- A two-dimensional matrix

## Signal Editor Block

Using a Signal Editor block, you can create interchangeable scenarios to use in a model.

For examples of how to use a Signal Editor block, see:

- “Load Data for an Input Test Case” on page 71-33
- “Parallel Simulations Using Parsim: Parameter Sweep in Normal Mode”

### **Recommended Uses**

Use the Signal Editor block to create and load scenarios to use in testing.

These products integrate the Signal Editor block into their workflows:

- Simulink Test
- Simulink Coverage
- Simulink Design Verifier

### **Limitations**

- Function-calls
- Array of buses
- Buses while using rapid accelerator mode
- `timetable` objects
- Ground signals

The Signal Editor block supports dynamic strings. It does not support strings with maximum length. In addition, strings in the Signal Editor block cannot output:

- Non-scalar MATLAB strings.
- String data that contains missing values.
- String data that contains non-ASCII characters.

## Comparison of Signal Loading Techniques

### In this section...

“Techniques” on page 71-21

“Impact of Loading Techniques on Block Diagrams” on page 71-21

“Comparison of Techniques” on page 71-22

## Techniques

Simulink provides several techniques for importing signal data into a model. Each signal data loading technique uses a block to represent signal data sources visually. You can use a:

- Source on page 71-15 block, such as the Sine Wave block, to generate signal data as input to another block
- Root-level input port on page 71-16 (Inport, Enable, or Trigger block). Loading signal data to root-level input ports, either manually or by using the Root Inport Mapper tool. “Root-level input ports” refers to both approaches and “Root Inport Mapper tool” refers specifically to using that tool.
- From File on page 71-17 block
- From Spreadsheet on page 71-18 block
- From Workspace on page 71-19 block
- Signal Editor block

## Impact of Loading Techniques on Block Diagrams

To test reusable systems, it is helpful to separate signal data loading from the block diagram. Loading root-level input ports provides a good framework for testing complex systems on an ongoing basis. Using the Root Inport Mapper tool allows you to visualize the signal data that is loaded.

To perform temporary testing on standalone models, adding data loading blocks can be simpler and make the source of the signal data visible from within the block diagram.

To avoid adding data loading blocks to a model, load the signal data to root-level input ports. You can change the data to use by changing the **Configuration Parameters > Data Import/Export > Input** parameter. You do not need to add or change blocks, or reset block parameters. You can use the Root Inport Mapper tool to update the **Input** parameter so that it reflects the mapping of signal data to the appropriate ports.

### Test Harness Models

You can use a test harness model with different test cases to load:

- Different signal data to a port
- Signal data to different ports

The Signal Editor block is useful in test harness models to simplify loading data to multiple input ports.

Alternatively, you can use the Root Inport Mapper tool to create scenarios that you can use instead of creating separate test harness models. Creating separate test harness models can be simpler than

setting up root inport mapping. However, you then need to manage the separate test harness models. For an example of using root inport mapping instead of a test harness, see “Converting Harness-Driven Models to Use Harness-Free External Inputs” on page 72-22

## Comparison of Techniques

Each technique addresses many of these modeling considerations:

- “Purpose of Importing Signal Data” on page 71-22

- “Handling of Loaded Data” on page 71-25
- “Simulation Mode” on page 71-26

### Purpose of Importing Signal Data

The model development phase you are in and your goals for loading signal data can influence the signal loading technique that you choose.

| Modeling Goal                                                            | Supported Techniques                                                         |
|--------------------------------------------------------------------------|------------------------------------------------------------------------------|
| Perform local, temporary testing by importing a small set of signal data | All<br>Root-level input ports for reusable systems.                          |
| Test a model that you want to use as a referenced model                  | Root-level input ports.                                                      |
| Verify a model by using multiple test cases                              | Root Inport Mapper tool, using exported signal data.<br>Signal Editor block. |
| Represent a continuous plant                                             | All<br>Root-level input ports work well for this goal.                       |
| Test a discrete algorithm                                                | All<br>Root-level input ports work well for this goal.                       |

## Model Development Phase

| Modeling Requirement                         | Suggested Signal Loading Technique                                                                                                                              |
|----------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Initial prototyping                          | When signals generated by source blocks meet your requirements, use Source blocks on page 71-15.<br><br>From File, From Spreadsheet, and From Workspace blocks. |
| System testing, sharing, and code generation | Root-level input port on page 71-16.<br><br>You can use the Root Inport Mapper tool to create and map signal data to load<br><br>Signal Editor block            |

For many models, loading signal data to a root Inport block is an effective approach. The Root Inport Mapping tool on page 72-2 provides a convenient way to load data for several signals to root inports.

## Signal Data

The amount, source, and kind of the signal data can influence the signal loading technique that you choose.

| Signal Data                                 | Supported Techniques                                                                                                                                                                                                                              |
|---------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Large data set                              | From File and From Spreadsheet blocks work well for large data sets, because they incrementally load the data.<br><br>You can log simulation data to persistent storage and then incrementally load data from a file to root-level Inport blocks. |
| Data exported by using a To File block      | From File block.                                                                                                                                                                                                                                  |
| Data exported by using a To Workspace block | From Workspace block.                                                                                                                                                                                                                             |
| Excel or CSV spreadsheet                    | From Spreadsheet block, which can import Microsoft Excel (all platforms) or CSV (Microsoft Windows platform with Microsoft Office only) spreadsheet data directly into Simulink.                                                                  |
| Variable-size signals                       | From Workspace block.                                                                                                                                                                                                                             |

## Data Format or Type

Each of the signal loading techniques supports a wide range of data formats for signal data (such as array or Dataset). A few signal loading techniques have some limitations for specific formats.

**Note** Some of the Root Inport Mapper tool map modes do not support all the data types that you can use with the tool. For details, see “Choose a Base Workspace and MAT-File Format” on page 72-10.

| Data Format or Type             | Supported Techniques                                                                                                                                              |
|---------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Array                           | All.                                                                                                                                                              |

| Structure without time          | Root-level Inport block<br>From Workspace block<br>Signal Editor block                                                                                            |
| timeseries                      | All.                                                                                                                                                              |
| timetable                       | Root-level Inport block<br>From Workspace block<br>Signal Editor block                                                                                            |
| Simulink.SimulationData.Dataset | Root-level Inport blocks<br>Signal Editor block                                                                                                                   |
| Enumeration                     | All.                                                                                                                                                              |
| Fixed-point                     | From Workspace block supports loading <code>fi</code> objects created using Fixed-Point Designer.<br>From File block has a word length limit of 32 or fewer bits. |
| Function-call                   | Root-level input ports (select the <b>Output function call</b> parameter).                                                                                        |

### Bus Support

You can use any of the signal loading techniques to load input data for a bus. However, for some kinds of bus data, you need to use a specific technique.

| Type of Bus or Bus Element   | Supported Techniques                                                                                                                                                                            |
|------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Virtual and nonvirtual buses | All techniques support both types of buses.<br>The Signal Editor block supports only non-virtual buses.<br>The Signal Editor block does not support loading bus data in rapid accelerator mode. |
| Partial bus specification    | Root-level Inport block<br>From Workspace block<br>From File block<br>Signal Editor block                                                                                                       |

| Type of Bus or Bus Element | Supported Techniques                            |
|----------------------------|-------------------------------------------------|
| Array of buses signals     | Root-level Inport block<br>From Workspace block |

### Time Points

The kind of time points in signal data impacts the signal loading technique that you choose.

| Time Points for Signal Data    | Supported Techniques                                                     |
|--------------------------------|--------------------------------------------------------------------------|
| Single time point              | All.                                                                     |
| Continuous                     | All.                                                                     |
| Discrete                       | All.                                                                     |
| Repeated sequence without time | Structure data by using root-level input ports and From Workspace block. |

### Location for Data Storage

Whether you want to store the signal data with the model or separate from the model impacts the signal loading technique that you choose.

| Location                                   | Supported Techniques                                                                                                                                                   |
|--------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

### Signal Data Inspection

The Root Inport Mapper tool, From File block, and Signal Editor block each provide an interface for plotting and inspecting the signal data to load.

### Handling of Loaded Data

How Simulink processes the signal data as it loads it into a model impacts the signal loading technique that you choose.

| Data Loading Handling    | Supported Techniques                                                                                                                                                                                                    |

| Extrapolation            | From File, From Spreadsheet, and Signal Editor blocks. For information about From Workspace extrapolation, see “Form output after final data value by”.                                                                 |
| Zero-crossing detection  | All except root-level input ports.                                                                                                                                                                                      |
| Fast restart             | All techniques.                                                                                                                                                                                                         |

### Simulation Mode

All signal loading techniques support all simulation modes except for SIL or PIL. Some techniques have limitations for specific simulation modes.

| Simulation Modes       | Supported Techniques                                                                      |
|------------------------|-------------------------------------------------------------------------------------------|
| Normal and accelerator | All                                                                                       |
| Rapid accelerator      | All                                                                                       |

## Load Data Logged In Another Simulation

### In this section...

“Load Logged Data” on page 71-28

“Configure Logging to Meet Loading Requirements” on page 71-29

A common source of signal data to load into a model is data that you log from a simulation. You can use the signal data captured from a simulation as roundtrip input to:

- Simulate the same model again from a known starting point.
- Test simulation results.
- Simulate another model starting with the captured signal values from a model. For example, you can log signal data when you simulate a model. Then load the signal data from that simulation as inputs to a second model that you want to reference from the first model.

You can capture the signal data from a simulation in a workspace or in a file. Use one of these techniques to capture signal data from a simulation:

- Signal logging
- To Workspace block
- To File block
- Scope block
- In the **Configuration Parameters > Data Import/Export** pane, the **Output, States, or Final states** parameters
- Data store
- The `sim` command configured to log simulation data

For an example of using simulation data for roundtrip signal data loading, see “Load Data to Model a Continuous Plant” on page 71-30.

### Load Logged Data

Here is a workflow for using signal logging data for standalone simulation of a referenced model. You can use a similar approach for other data logged in `Dataset` format.

- 1 Use the default signal logging output variable, `logsout`, or specify a variable using the **Configuration Parameters > Data Import/Export > Signal logging** edit box.
- 2 Simulate the parent model.

The signal logging output is a `Simulink.SimulationData.Dataset` object.

- 3 Use the `Simulink.SimulationData.Dataset.getElement` method to access the logged data. The logging data for individual signals is stored in `Simulink.SimulationData.Signal` objects.
- 4 For the referenced model that you want to simulate standalone, use the `Simulink.SimulationData.Signal.getElement` method to specify signal elements for the **Configuration Parameters > Data Import/Export > Input** parameter.

For example:

## 5 Simulate the referenced model.

For an example of loading signal logging data for a model that uses model referencing, see the open the `sldemo_mdhref_bus` model. After you open the model, double-click the blue block labeled **Interface Specification** and see the sections called:

- Logging Model Reference Signals
- Loading Data

Also, the “Load Data to Model a Continuous Plant” on page 71-30 example illustrates loading signal logging data.

To import signal logging data for array of buses signals, see “Import Array of Buses Data” on page 71-50.

## Configure Logging to Meet Loading Requirements

Different logging techniques support different data formats. Most logging techniques support the Dataset format, which provides a consistent data format for logged signal data. You can use the `Simulink.SimulationData.Dataset` constructor to convert other data formats to Dataset format.

To log only the data that you require, use the **Configuration Parameters > Data Import/Export > Logging intervals** parameter to specify start and stop time intervals.

## Load Data to Model a Continuous Plant

A continuous plant model uses signal data that is smooth and uninterrupted in time. There is signal data for each time value. A continuous plant model uses a continuous solver (any solver other than an explicit discrete solver). The solver can be fixed-step or variable. The model includes blocks from the Continuous library in Simulink, such as an Integrator block.

To load data to represent a continuous plant, consider using either a root-level input port or a From Workspace block. Using a From Workspace block can be useful when loading data to a port buried deep within a model.

For the signal data:

- Specify a time vector and signal values extracted from a continuous plant. For example, extract from data that you acquire experimentally or from the results of a previous simulation.
- Use any of the data formats listed in “Specify Input Data” on page 71-36. Here are recommended formats for the following imported data sources:
  - Another simulation — Dataset
  - An equation — MATLAB time expression
  - Experimental data — MATLAB timeseries, structure with time, a structure without time, or a data array

For structure data, see “Specify Time Data” on page 71-41.

## Use Simulation Data to Model a Continuous Plant

This example illustrates how to use logged data from the simulation of one model in the simulation of a second model. For more information, see “Load Data Logged In Another Simulation” on page 71-28.

When using data from a simulation that uses a variable-step solver for simulation in another model, the second simulation must read the data at the same time steps as the first simulation.

- 1 Open the `ex_data_import_continuous` model.

This model uses the `ode15s` solver and produces continuous signals.

- 2 To use the output of this model as input to the simulation of another model, log the signal that you want to use. In the Simulink Editor, select that signal, and click **Log Signals**.

---

**Note** To enable signal logging, select the **Configuration Parameters > Data Import/Export > Signal logging** parameter. This model has **Signal logging** enabled.

---

- 3 Simulate the model.

Simulating the model saves the logged signal to the workspace in the `Simulink.SimulationData.Dataset` object, `logout`.

Use the `Simulink.SimulationData.Dataset.getElement` method to access the logged data. The logged data for an individual signal is stored in a `Simulink.SimulationData.Signal` object. The Dataset object created by this model contains one logged signal: `StepResponse`.

- 4 Open the second model, `ex_data_import_continuous_second`.

You can configure this second model to simulate using the logged data from the first model. In this example, the second model uses a root-level Inport block to load the logged data as input for the simulation. The Inport block has the **Interpolate data** option selected.

- 5 In the second model, select the **Configuration Parameters > Data Import/Export > Input** parameter.

Use the `Simulink.SimulationData.Signal.getElement` method to specify the `StepResponse` signal element:

- 6 Specify that for the second model, the Simulink solver runs at the time steps specified in the saved data (u). In the Data Import/Export pane, set the **Output options** parameter to **Produce additional output** and the **Output times** parameter to:

```
logouts.getElement('StepResponse').Values.Time
```

- 7 Simulate the second model.

---

**Note** Simulink does not feed minor time step data through root input ports. For details about minor time steps, see “Types of Sample Time” on page 7-13.

---

### More About

- “Overview of Signal Loading Techniques” on page 71-15

## Load Data to Test a Discrete Algorithm

Discrete signals are signals that you define using evenly spaced time values. One signal value is read at each time step, using the sample time of the source block.

Use a structure that has an empty time vector, which results in the model using the sample time of the source block. Using this approach avoids possible mismatches between the vector and the Simulink time steps. The double-precision rounding used by computers and the values expected by Simulink can differ.

Suppose that you want to import signal data for this simple model.

- 1 In the Block Parameters dialog box for the Inport block:
  - Set the sample time.
  - Clear the **Interpolate data** parameter.
- 2 For the data that you want to import, specify a structure variable that does *not* include a time vector. For example, for the variable called `import_var`:

```

import_var.time = [];
import_var.signals.values = [0; 1; 5; 8; 10];
import_var.signals.dimension = 1;

```

The input for the first time step is read from the first element of an input port value array. The value is 0. The value for the second time step is read from the second element of the value array (1), and so on.

For details about how to specify the signal value and dimension data, see “Loading Data Structures to Root-Level Inputs” on page 71-40.

- 3 Select the **Configuration Parameters > Data Import/Export > Input** parameter and specify `import_var` for the data to import.

If you are using a From Workspace block to import data, use a similar approach. In addition, set the **Form output after final data value by** parameter to a value other than `Extrapolation`.

## Load Data for an Input Test Case

### In this section...

- “Guidelines for Importing a Test Case” on page 71-33
- “Example of Test Case Data” on page 71-33
- “Use From Workspace Block for Test Case” on page 71-34
- “Use Signal Editor Block for Test Case” on page 71-35

For most input test cases, you try to minimize the number of time points. The signal data you load includes samples with ramps and discontinuities.

### Guidelines for Importing a Test Case

Typically when importing a test case data, you want to minimize the number of time points. The test data focuses on discontinuities in the signal data.

- Create a signal that has ramps and steps. In other words, the signal has one or more discontinuities.
- Create the signal using the fewest points possible.
- Have the Simulink solver execute at the specified discontinuities.

To import this signal in Simulink, use a From Workspace, From File, or Signal Editor block, all of which support zero-crossing detection.

You can load data of these types:

- A `Simulink.SimulationData.Dataset`
- Array
- `Simulink.SimulationData.Signal`
- Structure
- A structure array containing data for all input ports (not supported by Signal Editor block)
- Empty matrix — Use an empty matrix for ports for which you want to use ground values, without having to create data values
- Time expression (not supported by Signal Editor block)

Specify a time vector and signal values, but specify only the time steps at points where the shape of the output jumps. For details about specifying a time vector, see “Specify Time Data” on page 71-41.

Use any of the input data formats described in “Forms of Input Data” on page 71-37, except for MATLAB time expressions.

### Example of Test Case Data

The following is an example of test case data:

The following two examples use this test case data.

## Use From Workspace Block for Test Case

- 1 Open the model `ex_data_import_test_case_from_workspace`.

- 2 Enable zero-crossing detection. In the From Workspace block dialog box, select **Enable zero-crossing detection**. Zero-crossing detection allows you to capture discontinuities accurately.
- 3 Create a signal structure for the test case. At each discontinuity, enter a duplicate entry in the time vector, which generates a zero crossing and forces the variable-step solver to take a time step at this exact time. For details, see “Load Data Using the From Workspace Block” on page 71-66.

Define the `var` structure representing the test case:

```

var.time = [0 1 1 5 5 8 8 10];
var.signals.values = [0 0 2 2 2 3 3 3]';
var.signals.dimensions = 1;

```

- 4 To import the test case structure, in the From Workspace block dialog box, in the **Data** parameter, specify `var`.
- 5 Simulate the model. The Scope block reflects the test case data.

## Use Signal Editor Block for Test Case

Instead of using a From Workspace block, you can use a Signal Editor block to either:

- Create a signal interactively
  - Import a signal from a MAT-file
- 1 Create a model with Signal Editor, Gain, and Scope blocks.

- 2 Create a structure and save it in a MAT-file:

```
scenario = Simulink.SimulationData.Dataset;
time = [0 1 1 5 5 8 8 10];
data = [0 0 2 2 2 3 3 3]';
scenario{1} = timeseries(data,time);
scenario{1}.Name = 'var';
save var.mat scenario
```

- 3 Open the Signal Editor dialog box by double-clicking the Signal Editor block.
- 4 In the File name parameter, enter `var.mat`.
- 5 In the **Active scenario** parameter, select `scenario`. Click **OK**.

The Scope block display reflects the test case data from the MAT-file.

- “Overview of Signal Loading Techniques” on page 71-15

## Load Data to Root-Level Input Ports

### In this section...

“Specify Input Data” on page 71-36  
 “Forms of Input Data” on page 71-37  
 “Time Values for the Input Parameter” on page 71-38  
 “Data Loading” on page 71-38  
 “Loading Dataset Data to Root-Level Inputs” on page 71-38  
 “Loading MATLAB Timeseries Data to Root-Level Inputs” on page 71-39  
 “Loading MATLAB Timetable Data to Root-Level Inputs” on page 71-40  
 “Loading Data Structures to Root-Level Inputs” on page 71-40  
 “Loading Data Arrays to Root-Level Inputs” on page 71-43  
 “Loading MATLAB Time Expressions to Root Inports” on page 71-45

You can load data from a workspace to a root-level inport modeled using one of these blocks:

- Inport block
- Enable block
- Trigger block that has an edge-based (rising, falling, or either) trigger type

These blocks import data from the workspace based on the value of the **Configuration Parameters > Data Import/Export > Input** parameter.

**Tip** To import many signals to root-level input ports, consider using the Root Inport Mapper tool. For more information, see “Map Root Inport Signal Data” on page 72-7.

You can also import data from a workspace using a From Workspace block. For details, see the From Workspace documentation and “Load Data for an Input Test Case” on page 71-33.

### Specify Input Data

You can specify input data manually, using the **Input** configuration parameter. To load many signals to root-level input ports, consider using the Root Inport Mapping tool, which automatically specifies in the **Input** parameter the data you map using the tool. For details, see “Map Data Using Root Inport Mapper Tool” on page 72-2.

- 1 Select the **Configuration Parameters > Data Import/Export > Input** parameter.

**Note** The use of the **Input** configuration parameter is independent of the setting for the **Format** configuration parameter for saving logged data.

- 2 Enter an external input specification in the adjacent edit box and click **Apply**. For a list of the forms of data you can specify, see “Forms of Input Data” on page 71-37.

In the **Input** box, specify the signal input using one of these approaches:

- Create data at run-time for each simulation time step using the input  $u = UT(\tau)$  for either a MATLAB function (expressed as a string) or MATLAB expression.
- Specify the data directly, using one of the input data forms described in “Forms of Input Data” on page 71-37.

### Comma-Separated List

If you specify `Dataset` data, specify only one `Dataset` object for the **Input** parameter. Do not include it in a comma-separated list.

Each variable or expression must evaluate to an appropriate object that corresponds to a specific root-level input port in the model. Each variable or expression in the list must evaluate to the appropriate object that corresponds to one of the root-level input ports of the model. The first item corresponds to the first root-level input port, the second to the second root-level input port, and so on. The dimensions for each data sample must match the dimensions of the data specified in the input block parameter.

For an Enable or Trigger block, the signal driving the enable or trigger port must be the last item in the comma-separated list. If you have both an enable and a trigger port, then specify:

- The enable port as the next-to-last item in the list
- The trigger port as the last item

Use an empty matrix to specify ground values for a port. For example, to load data for input ports `in1` and `in3`, and to use ground values for port `in2`, enter the following in the **Input** parameter:

```
in1, [], in3
```

### Forms of Input Data

You can provide input data with the following formats:

- `Simulink.SimulationData.Dataset` — Collection of logged data in MATLAB timeseries format. For more information, see “Loading Dataset Data to Root-Level Inputs” on page 71-38.
- MATLAB timeseries — For more information, see:
  - “Loading MATLAB Timeseries Data to Root-Level Inputs” on page 71-39
  - “Load Bus Data to Root-Level Input Ports” on page 71-47
- `Simulink.SimulationData.DatasetRef` — For more information, see “Load Big Data for Simulations” on page 71-7
- MATLAB timetable — For more information, see “Loading MATLAB Timetable Data to Root-Level Inputs” on page 71-40.
- Array — See “Loading Data Arrays to Root-Level Inputs” on page 71-43.
- `Simulink.SimulationData.Signal` — For more information, see “Load Data Logged In Another Simulation” on page 71-28.
- `matlab.io.datastore.SimulationDatastore` - For more information, see “Work with Big Data for Simulations” on page 73-31.
- `matlab.io.datastore.sd datastore`
- Structure — To simplify the specification of external input data, you can load data for a subset of root-level input port blocks. This approach avoids having to create data structures for the ports for

which you want to use ground values. For information about ground values, see “Initialize Signals and Discrete States” on page 76-40. For more information about loading structure data, see “Loading Data Structures to Root-Level Inputs” on page 71-40.

- Structure array containing data for all input ports.
- Empty matrix — Use an empty matrix for ports for which you want to use ground values, without having to create data values.
- Time expression — For more information, see “Loading MATLAB Time Expressions to Root Inports” on page 71-45.

---

**Note** When you specify timetable data to load, the timetable must contain data for only one signal.

---

For information about importing bus data, see “Load Bus Data to Root-Level Input Ports” on page 71-47.

## Time Values for the Input Parameter

Time values that you specify in the **Input** parameter do not control the times the solver uses. Solvers have their own logic for propagating time and might require input data at an arbitrary time value. The **Interpolate** parameter setting for the root-level input block (for example, the root-level Inport block) specifies how to handle output at time steps for which no corresponding workspace data exists.

The time values specified in the **Input** parameter cannot be sparse or include NAN or Inf values.

## Data Loading

If you select the **Interpolate data** option for the corresponding Inport, Enable, or Trigger block, Simulink linearly interpolates or extrapolates input values as necessary.

Simulink resolves symbols used in the external input specification as described in “Symbol Resolution” on page 68-128. The `sim` command provides some data import capabilities that are available only for programmatic simulation.

If you use a `Simulink.SimulationData.Dataset` object that includes a `matlab.io.datastore.SimulationDatastore` object as an element, then the data stored in persistent storage is streamed in from a file. For more information, see “Load Big Data for Simulations” on page 71-7.

## Loading Dataset Data to Root-Level Inputs

You can use a Dataset object as a value for the **Configuration Parameters > Data Import/Export > Input** parameter. Specify only one Dataset object and do not include it in a comma-separated list. The number of elements in the Dataset must match the number of root-level input ports.

### Dataset Elements

A Dataset object can include elements with different data types.

For individual non-bus signal data, you can specify these types of data for Dataset elements:

- `timeseries`
- `timetable`
- `matlab.io.datastore.SimulationDatastore`
- double vectors or structure of double data
- a `Simulink.SimulationData.Signal`, `Simulink.SimulationData.State`, or `Simulink.SimulationData.DataStoreMemory` object
- An array that meets one of these requirements:
  - An array with time in the first column and the remaining columns each corresponding to an input port. See “Loading Data Arrays to Root-Level Inputs” on page 71-43.
  - An  $n \times 1$  array for a root inport that drives a function-call subsystem.
- Structure — See “Loading Data Structures to Root-Level Inputs” on page 71-40.

For bus signals, use a structure with a data element for each leaf signal, using one of these formats:

- A MATLAB `timeseries` object
- A MATLAB `timetable` object
- A `matlab.io.datastore.SimulationDatastore` object
- An empty matrix
- Another structure, with data elements for each signal that are consistent with these requirements for a structure for bus data

---

**Note** When you specify `timetable` data to load, the `timetable` can contain data for only one signal.

---

### Create a Dataset Object for Inport Blocks

To generate a `Simulink.SimulationData.Dataset` object from the root-level Inport blocks in a model, you can use the `createInputDataset` function. Signals in the generated dataset have the properties of the Inport blocks and the corresponding ground values at model start and stop times. You can create `timeseries` and `timetable` objects for the time and values for signals for loading. The other signals use ground values. Each `timetable` object must contain data for only one signal.

You can load into a root-level input port data specified by a MATLAB `timeseries` object that resides in a workspace.

---

**Note** This documentation about importing MATLAB `timeseries` data includes examples of root Inport blocks. Unless specifically noted otherwise, the examples are applicable to root-level Enable, Trigger, and From Workspace blocks.

---

## Loading MATLAB Timeseries Data to Root-Level Inputs

### Time Dimension

When you create a MATLAB `timeseries` object to import data to Simulink, the time dimension (number of time samples) depends on the dimension and the type of signal data.

| Signal Data Dimension or Type                    | Time Dimension Alignment | Example of timeseries Constructor                                                                                                     |
|--------------------------------------------------|--------------------------|---------------------------------------------------------------------------------------------------------------------------------------|

### Enum Data

If you specify an enum in timetable data, clear the **Interpolate data** parameter for the corresponding Inport block.

## Loading MATLAB Timetable Data to Root-Level Inputs

In general, you can load MATLAB timetable data the same way you load MATLAB timeseries data. Each timetable must contain data for only one signal.

## Loading Data Structures to Root-Level Inputs

### Data Structures

You can load to a root-level input port data from the workspace in the form of a structure, whose name you specify in the **Configuration Parameters > Data Import/Export > Input** parameter. For information about defining MATLAB structures, see “Structure Arrays”.

You can specify structures for the model as a whole or on a per-port basis. For information about specifying per-port structures for the **Input** parameter, see “Structures for All Ports or for Each Port” on page 71-41.

The structure always includes a signals substructure, which contains a values field and a dimensions field. Depending on the modeling task that you want to perform, the structure can also include a time field. The form of a structure that you use depends on the type of signals for which you are importing data:

- Discrete signals (the signal is defined at evenly spaced values of time) — Use a structure that has an empty time vector. Specify a **signals** field, which contains an array of substructures, each of which corresponds to a model input port.
- Continuous signals (the signal is defined for all values of time) — The approach that you use depends on whether the data represents a smooth curve (continuous) or a curve that has

discontinuities (jumps) over its range (discrete). Specify a `signals` field, which contains an array of substructures, each of which corresponds to a model input port. You can specify a `time` field, which contains a time vector. See “Specify Time Data” on page 71-41.

For examples of importing data for discrete and continuous signals, see:

- “Load Data to Test a Discrete Algorithm” on page 71-32
- “Load Data to Model a Continuous Plant” on page 71-30
- “Load Data for an Input Test Case” on page 71-33

### Structures for All Ports or for Each Port

You can specify one structure to provide input to all root-level input ports in a model, or you can specify a separate structure for each port.

The per-port structure format consists of a separate structure-with-time or structure-without-time for each port. The input data structure for each has only one `signals` field. To specify this option, enter the names of the structures in the **Input** text field as a comma-separated list, `in1, in2, ..., inN`. The value `in1` is the data for first input port in the model, `in2` for the second input port, and so on.

To specify one structure for all ports:

- The `values` field must contain an array of inputs for the corresponding input port. If you specify a time vector, each input must correspond to a time value specified in the `time` field.

If the inputs for a port are scalar or vector values, the `values` field must be an `M-by-N` array. If you specify a time vector, `M` must be the number of time points specified by the `time` field and `N` is the length of each vector value.

If the inputs for a port are matrices (2-D arrays), the `values` field must be an `M-by-N-by-T` array. `M` and `N` are the dimensions of each matrix input and `T` is the number of time points. For example, suppose that you want to input 51 time samples of a 4-by-5 matrix signal into one of the input ports in your model. Then, the corresponding `dimensions` field of the workspace structure must equal `[4 5]` and the `values` array must have the dimensions 4-by-5-by-51.

- The `dimensions` field specifies the dimensions of the input. If each input is a scalar or vector (1-D array) value, the `dimensions` field must be a scalar value specifying the length of the vector (1 for a scalar). If each input is a matrix (2-D array), the `dimensions` field must be a two-element vector whose:
  - First element specifies the number of rows in the matrix
  - Second element specifies the number of columns

---

**Note** Set the **Port dimensions** parameter of the Inport or the Trigger block to be the same value as the `dimensions` field of the corresponding input structure. If the values differ, you get an error message when you try to simulate the model.

---

### Specify Time Data

You can specify a time vector of doubles as part of the data structure to import. For example, specify a time vector when importing signal data to represent a continuous plant or to create a test case. To test a discrete algorithm, use a structure with an empty time vector. This table provides additional recommendations for specifying time values, based on the kind of signal data you want to load.

| Signal Data                                         | Time Data Recommendation                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|-----------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Inport or Trigger block with a discrete sample time | Do not specify a time vector. Simulink loads one signal value at each time step.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| Evenly spaced discrete signals                      | <p>Use an expression in this form:</p> <pre>timeVector = startTime + sampleTime*(0:numSteps-1)';</pre> <p>Use the colon operator to count in increments of 1 from zero to the desired number of time steps minus one, for the first point, 0. Then, scale the resulting vector by the desired sample time so the increments between elements in the vector is now equal to the sample time. The vector is transposed because most data formats supported for loading require a column time vector. To create a time vector with a start time other than zero, add the desired start time to the vector.</p> <p>For example, use this code to create an evenly-spaced time vector that starts at 1, includes 101 time points, and has a sample time of 0.2.</p> <pre>T1 = 1 + 0.2*(0:100)'</pre> <hr/> <p><b>Note</b> Do not use an expression in this form:</p> <pre>timeVector = [startTime:timeStep:endTime]'</pre> <p>For example, do not use:</p> <pre>T2 = [0:0.2:10]'</pre> <p>The time vector T2 is not equal to the time vector T1 because of double-precision rounding. The double-precision rounding in a time vector like T2 can lead to differences between the input time vector and the time steps calculated by the solver, leading to unexpected simulation results.</p> |
| Unevenly spaced values                              | <p>Use any valid MATLAB array expression; for example, [1:5 5:10] or (1 6 10 15).</p> <p>The From Workspace, From File, and Signal Editor blocks support zero-crossing detection. If the root-level input port is connected to one of those blocks, you can specify a zero-crossing time by using a duplicate time entry.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

**Examples of Specifying Signal and Time Data**

In the first example, consider the following model that has a single input port:

- 1 Create an input structure for loading 11 time samples of a two-element signal vector of type `int8` into the model:

```
N = 10
Ts = 0.1
a.time = Ts*[0:N]';
c1 = int8([0:1:10]');
c2 = int8([0:10:100]');
a.signals(1).values = [c1 c2];
a.signals(1).dimensions = 2;
```

- 2 In the **Configuration Parameters** > **Data Import/Export** > **Input** parameter edit box, specify the variable `a`.
- 3 In the Inport block dialog box, in the **Signal Attributes** tab, set **Port dimensions** to 2 and **Data type** to `int8`.

As another example, consider a model that has two inputs.

Suppose that you want to input a sine wave into the first port and a cosine wave into the second port. Define a structure, `a`, as follows, in the MATLAB workspace:

```
a.time = 0.1*[0:1]';
a.signals(1).values = sin(a.time);
a.signals(1).dimensions = 1;
a.signals(2).values = cos(a.time);
a.signals(2).dimensions = 1;
```

Enter the structure name (`a`) in the **Configuration Parameters** > **Data Import/Export** > **Input** parameter edit box.

---

**Note** In this model you do not need to specify the dimension and data type, because the default values are 1 and `double`.

---

## Loading Data Arrays to Root-Level Inputs

You can load to a root-level input port data from the workspace in the form of a data array, which you specify in the **Configuration Parameters** > **Data Import/Export** > **Input** parameter.

This import format consists of a real (noncomplex) matrix of data type `double`. The first column of the matrix must be a vector of times in ascending order. The remaining columns specify input values.

- Each column represents the input for a different Inport or Trigger block signal (in sequential order).
- Each row is the input value for the corresponding time point.

For a Trigger block, the signal that drives the trigger port must be the last data item.

The total number of columns of the input matrix must equal  $n + 1$ , where  $n$  is the total number of signals entering the model input ports.

### Specify the Input Expression

The default input expression for a model is `[t, u]` and the default input format is `Array`. If you define `t` and `u` in the MATLAB workspace, simply select the **Configuration Parameters > Data Import/Export > Input** parameter to input data from the model workspace.

Suppose that you have a model with two Inport blocks:

- The In1 block accepts two signals (the block has the **Port dimensions** parameter set to 2).
- The In2 block accepts one signal (the block uses the default value for the **Port dimensions** parameter).

You define `t` and `u` in the MATLAB workspace:

```
numSteps = 9;
timeStep = 0.1;
t = (timeStep*(0:numSteps))';
u = [sin(t), cos(t), 4*cos(t)];
```

When the simulation runs, the signal data `sin(t)` and `cos(t)` are assigned to In1 and the signal data `4*cos(t)` is assigned to In2. Signal data is input for 100 time points.

---

**Note** The array input format allows you to load only real (noncomplex) scalar or vector data of type `double`. Use the structure format to input complex data, matrix (2-D) data, and data types other than `double`.

---

### Arrays for Input Ports Driving Function-Call Subsystems

You can use an array to drive a Function-Call Subsystem through a root-level input port. You can use an array or an array that is an element of a `Dataset` object. The array must be an  $n \times 1$  array. For the root-level Inport block, select the **Output function call** parameter.

For example, this `Dataset` object has an array element `x`:

```
ds = Simulink.SimulationData.Dataset;
x = [1 3 7 8]';
ds = ds.addElement(x, 'theElementName');
```

This model uses the `ds` data set in the **Configuration Parameters > Data Import/Export > Input** parameter.

When you simulate the model, the time values of the logged signal data in the Function-Call Subsystem show that the Function-Call Subsystem was triggered only for the times specified in an array stored in `ds`.

```
>> logouts{1}.Values.Time
```

```
ans =
```

```
1
3
7
8
```

## Loading MATLAB Time Expressions to Root Inports

### Specify the Input Expression

You can use a MATLAB time expression to load data from a workspace into a root-level input port. To use a time expression, enter the expression as a string (enclosed in single quotes) in the **Input** field of the **Data Import/Export** pane. The time expression can be any MATLAB expression that evaluates to a row vector equal in length to the number of signals entering the input ports of the model. Suppose that a model has one vector Inport that accepts two signals. Also, suppose that `timefcn` is a user-defined function that returns a row vector two elements long. Here are valid input time expressions for such a model:

```
'[3*sin(t), cos(2*t)]'
```

```
'4*timefcn(w*t)+7'
```

The expression is evaluated at each step of the simulation, applying the resulting values to the input ports of the model. Simulink defines the variable `t` when it runs the simulation. Also, you can omit the time variable in expressions for functions of one variable. For example, the expression `sin` is interpreted as `sin(t)`.

- “Loading Data Arrays to Root-Level Inputs” on page 71-43

## Load Bus Data to Root-Level Input Ports

### In this section...

“Imported Bus Data Requirements” on page 71-47

“Import Bus Data to a Top-Level Inport” on page 71-48

“Get Information About Bus Objects” on page 71-50

“Create Structures of Timeseries Objects from Buses” on page 71-50

“Import Array of Buses Data” on page 71-50

You can import bus data to top-level input ports by manually specifying the data in the **Input** configuration parameter or by using the Root Inport Mapper tool. For information about importing bus data using the Root Inport Mapper tool, see “Import Bus Data” on page 72-15.

### Imported Bus Data Requirements

You can import bus (virtual, nonvirtual, or array of buses) data to a top-level input port defined by a bus object (see `Simulink.Bus`). In the top-level Inport block, set **Data type** to **Bus** and specify the name of a bus object. To specify data values for bus signals, use a structure of:

- MATLAB `timeseries` objects
- MATLAB `timetable` objects
- A combination of `timeseries` and `timetable` objects

Bus elements for which you do not include a field in the structure use ground values. You can use an empty matrix to specify to use ground values.

---

**Note** When you specify `timetable` data to load, the `timetable` must contain data for only one signal.

---

The structure of `timeseries` or `timetable` (or both) objects must match the bus elements in terms of:

- Hierarchy
- Name of the structure field, which must match the bus element name. (The name property of the `timeseries` object does not need to match the bus element name.)
- Data type
- Dimensions
- Complexity

The order of the structure fields does not have to match the order of the bus elements.

You can include the structure as an element of a `Dataset` object. You can use a structure in a comma-separated list. You can specify an empty matrix in a comma-separated list. The empty matrix uses the ground values for the bus signal.

For example, to load data for input ports `in1` and `in3`, and to use ground values for port `in2`, enter the following in the **Input** parameter:

```
in1, [], in3
```

### Initialize Bus Signals

You can initialize bus signals, including using partial specification of initialization data. For details, see “Specify Initial Conditions for Bus Elements” on page 77-61.

For details about importing array of bus data to a root Inport block, see “Import Array of Buses Data” on page 71-50.

### Limitations for Importing Bus Data to Top-Level Inputs

The signal data that you can use the Root Inport Mapper tool to import and map to a top-level Inport block can include bus data. You cannot use that tool to map bus signals to a top-level Enable or Trigger block.

You cannot use input ports to import buses in external modes. To import bus data in rapid accelerator mode, use `Dataset` format.

### Import Bus Data to a Top-Level Inport

This model has two Inport blocks connected to Scope blocks. The data type of the In1 block is inherited (nonbus data) and the data type of the In2 block is defined by the bus object `BusObject`. The model has a callback that loads `BusObject` and its sub-bus `BusObject1`.

The `BusObject` bus object has two elements:

- `c`
- `s1`, which is a nested bus that has two elements:
  - `a`
  - `b`

- 1 Open the .
- 2 Create a MATLAB `timeseries` object for `In1`, for which you want to import nonbus data.

For example:

```
t1 = (1:10)';
d1 = sin(t1);
in1 = timeseries(d1,t1);
```

- 3 Create an input structure, which can consist of MATLAB timeseries objects or MATLAB timetable objects, or a combination of those types of objects. Create one timeseries or timetable object for each leaf bus element for which you do not want to use ground values. This example uses ground values for the b bus element, so it does not need a timeseries or timetable object for that element.

```
t2 = (1:5)';
d2 = cos(t2);
in2.c = timeseries(d1,t1);
in2.sl.a = timetable(seconds(t2),d2);
```

The MATLAB timeseries objects that you create must match the corresponding bus elements, as described in “Imported Bus Data Requirements” on page 71-47.

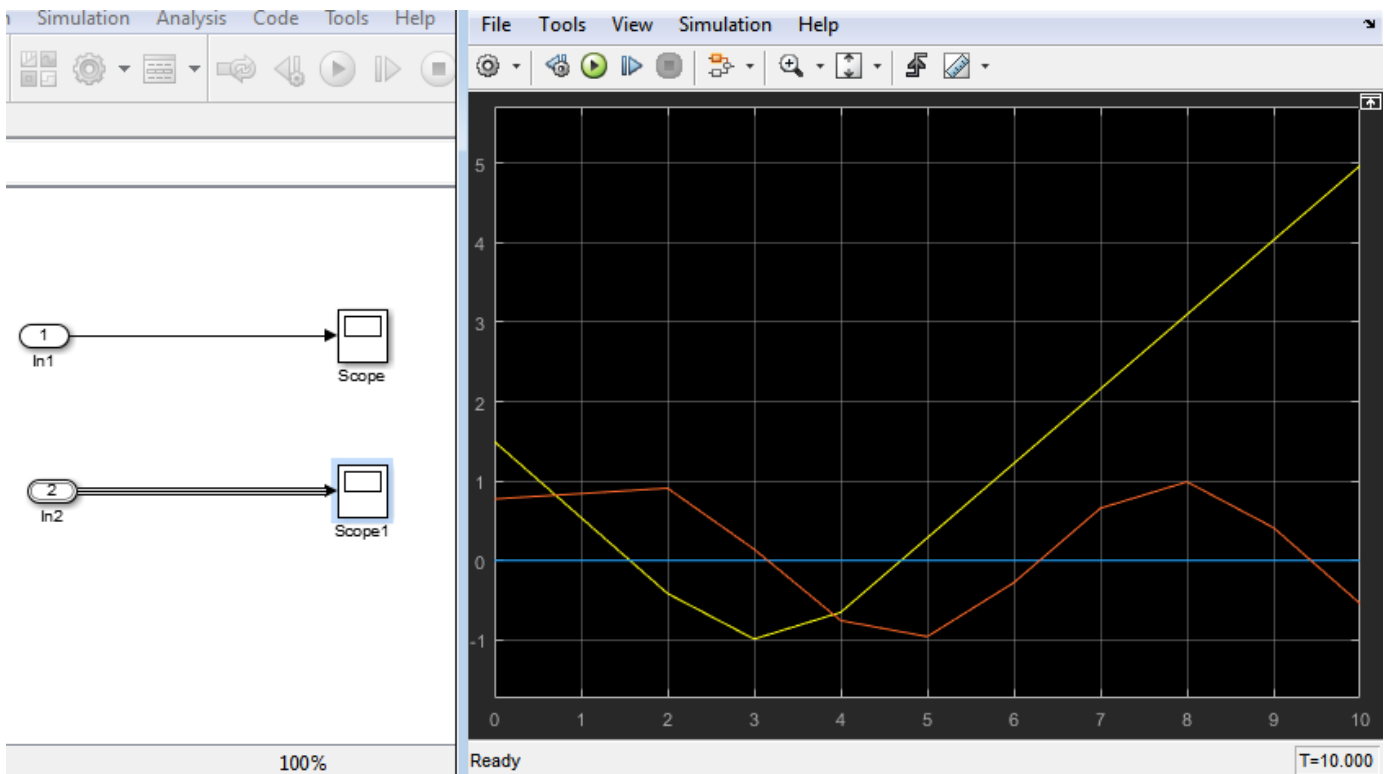

- 4 Create a Dataset object and add in1 and in2 to the data set.

```
ds = Simulink.SimulationData.Dataset;
ds = ds.addElement(in1, 'in1_signal');
ds = ds.addElement(in2, 'in2_signal');
```

- 5 In the **Configuration Parameters > Data Import/Export > Input** parameter edit box, enter the Dataset object ds.

- 6 Simulate the model. The Scope block connected to In2 shows the imported bus data.

## Get Information About Bus Objects

To determine the number of MATLAB timeseries objects and data type, complexity, and dimensions needed for creating a structure of timeseries objects from a bus, use these methods:

- `Simulink.Bus.getNumLeafBusElements`
- `Simulink.Bus.getLeafBusElements`

For example, for the bus object `BusObject`:

```
num_el = BusObject.getNumLeafBusElements
```

```
num_el =
```

```
 3
```

```
el_list = BusObject.getLeafBusElements
```

```
el_list =
```

```
 3x1 BusElement array with properties:
```

```
 Min
 Max
 DimensionsMode
 SampleTime
 Description
 Units
 Name
 DataType
 Complexity
 Dimensions
```

```
el_list(1).Dimensions
```

```
ans =
```

```
 1
```

## Create Structures of Timeseries Objects from Buses

If you have timeseries objects defined, you can use them to create a structure of timeseries objects based on a bus object. Use the `Simulink.SimulationData.createStructOfTimeseries` function. For example, if you have defined timeseries objects `ts1`, `ts2`, and `ts3`, and you have a bus object `MyBusObject`, you can use this command to create a structure of timeseries objects:

```
input = Simulink.SimulationData.createStructOfTimeseries(...
 'MyBusObject',{ts1,ts2,ts3});
```

The number of timeseries objects in the cell array must match the number of leaf elements in the bus object. The data type, dimensions, and complexity of each timeseries object must match those attributes of the corresponding bus object leaf node.

## Import Array of Buses Data

To import (load) array of buses data using a root Inport block, use an array of structures of MATLAB timeseries objects.

---

**Note** You cannot use an Enable, Trigger, From Workspace, or From File block to import data for an array of buses.

---

### Full Specification of Data

You can use logged data for an array of buses signal from a previous simulation as roundtrip input to a root-level Inport in a subsequent simulation run. The logged data is a full specification of data for the Inport block.

If you construct an array of structures of MATLAB `timeseries` objects to specify fully the data to import:

- Specify the structure fields in the same order as the signals in the bus signals.
- Do not include more fields in the structure than there are signals in the bus.

For leaf fields, match exactly the data type, dimensions, and complexity of the corresponding signal in the bus.

### Partial Specification of Data

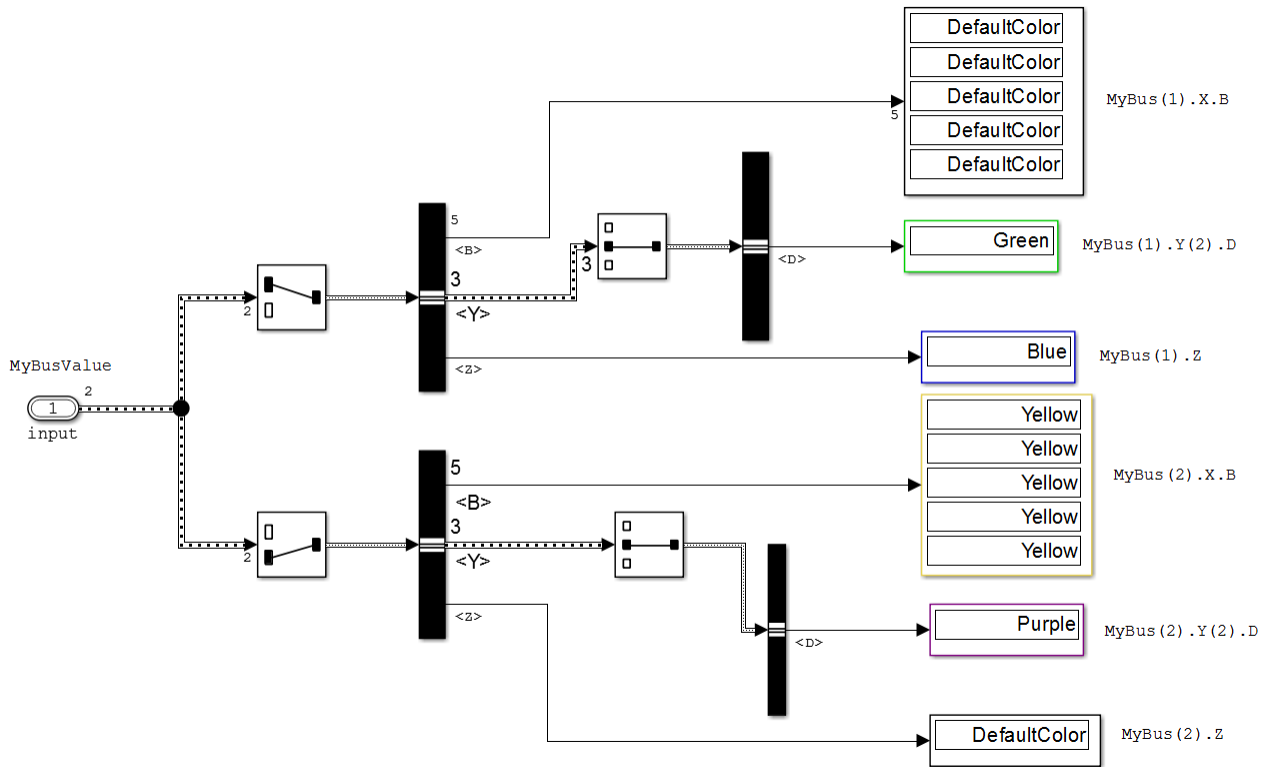

To specify partial data for array of buses, create a MATLAB array of structures with MATLAB `timeseries` objects at the leaf nodes.

The structure that you create to specify partial data must be consistent with these rules:

- You can omit fields, including leaf nodes and subbranches. You can also omit dimensions. If you do not specify a field, Simulink uses the ground value for that field.
- For nested bus nodes, make the dimension of each field equal to, or smaller than, the dimension for the corresponding node of the array of buses.

This example shows how you can specify partial data to be imported using a root Inport block whose data type is defined as bus object `MyBus`. You can open the model (`ex_partial_loading_aob_model`) and the MATLAB code that defines the data to import (`ex_partial_loading_aob_data.m`).

When you simulate `ex_partial_loading_aob_model`, you see:

The input Inport block uses the MyBus bus object as its data type.

The MyBus array of buses includes MyBus (1) and MyBus (2). The port dimension is set to 2 to reflect the two buses in the array of buses, and **Output as nonvirtual bus** is enabled.

Here are the elements of the array of buses, which includes MyBus (1) and MyBus (2). The color highlighting shows the nodes of the array of buses for which data is being imported.

Here is MATLAB code that defines the data to import. The color that highlights the code matches the color of the corresponding node in the array of buses. To view the code used in this model, open the MATLAB code file `ex_partial_loading_aob_data.m`.

```

7 %% Create timeseries data for leaf signals
8 N = 10; Ts = 1;
9 Time = ((0:N)*Ts)';
10 [m, n] = size(Time);
11
12 ZData = repmat(ex_partial_loading_aob_basicColors.Blue,m,n);
13 BData = repmat(ex_partial_loading_aob_basicColors.Yellow,m,5);
14 D1Data = repmat(ex_partial_loading_aob_basicColors.Green,m,n);
15 D2Data = repmat(ex_partial_loading_aob_basicColors.Purple,m,n);
16
17 % Create individual timeseries objects to represent Z, B, D1 and D2
18 ZT = timeseries(ZData, Time, 'Name', 'Z');
19 BT = timeseries(BData, Time, 'Name', 'B');
20 D1T = timeseries(D1Data, Time, 'Name', 'D1');
21 D2T = timeseries(D2Data, Time, 'Name', 'D2');
22
23 %% Construct MyBusValue(1)
24
25 % Y(2).D
26 Y(2) = struct('D',D1T);
27
28 % Set X.B to empty to allow the second element to support specification for
29 % this field
30 X = struct('B', []);
31
32 % MyBusValue(1)
33 MyBusValue(1) = struct('Z',ZT,'Y',Y,'X',X);
34 clear X Y;
35
36 %% Construct MyBusValue(2)
37
38 % Specify timeseries for MyBusValue(2).X.B
39 MyBusValue(2).X.B = BT;
40
41 % Specify timeseries for MyBusValue(2).Y(2).D
42 MyBusValue(2).Y(2).D = D2T;
43

```

In the code that defines the import data:

- The `timeseries` object `MyBusValue` specifies the data for the highlighted nodes.
- The `timeseries` object `BT` for `MyBus(2)`, because `BT` is a leaf node, it must match exactly the dimensions, data type, and complexity of the corresponding bus element.

- The structure specifies data for  $Y(2)$ . You can skip the first and last nested buses of  $Y$  (that is,  $Y(1)$  and  $Y(3)$ ).

This example specifies data for  $Y(2)$ ; you can skip the first and last nested buses of  $Y$  (that is,  $Y(1)$  and  $Y(3)$ ).

After you define the `MyBusValue` variable for the import data, set the **Configuration Parameters** > **Data Import/Export** > **Input** parameter to `MyBusValue`.

## Load Input Data for a Bus Using In Bus Element Blocks

You can use In Bus Element blocks to load external input data for a bus. Using In Bus Element blocks allows flexibility in the design and implementation of external interfaces for buses. You can use an In Bus Element block to load data for an element of a bus or to load data for an entire bus. You can also use multiple In Bus Element blocks to select the same bus element.

This example shows how to use In Bus Element blocks to load input data for bus elements. To load data for an entire bus using the In Bus Element block, you must specify the data type for the In Bus Element block using a `Simulink.Bus` object.

### Open and Inspect the Model

Open the `ex_load_inbuselement` model.

```
open_system('ex_load_inbuselement.slx')
```

One or more In Bus Element blocks can define a port in a model. The `ex_load_inbuselement` model has one port, `InBus`, defined by three In Bus Element blocks. The label for each In Bus Element block indicates the bus element the block selects. The `InBus` port corresponds to a bus containing a nested bus, `a`, with signals `x` and `y`, and an individual signal, `b`.

Use the **Input** parameter on the **Data Import/Export** pane to specify workspace data to load as simulation input for the port in the model. The **Input** parameter for the `ex_load_inbuselement` model loads the variable `struct1`, which maps to the port according to the **Port Number** defined in the In Bus Element block dialog box.

### Create Input Data

Ports that load bus data accept structures composed of individual `timeseries`, `timetable`, and `matlab.io.datastore.SimulationDatastore` objects. The hierarchy of the structure must

match the hierarchy of the bus. Ports that use In Bus Element blocks to select bus elements allow partial specification and overspecification of data.

This example creates the structure using three `timeseries` signals that correspond to a sine wave, a line, and a constant.

```
time = linspace(0,10,11);
sineData = sin(time);
constData = 3*ones(11,1);
lineData = linspace(0,10,11);
```

```
tsSine = timeseries(sineData,time);
tsConst = timeseries(constData,time);
tsLine = timeseries(lineData,time);
```

Construct the structure, `struct1`, to provide the input data for the port in the model. The structure field names must match the bus element names.

```
struct1.a.x = tsConst;
struct1.a.y = tsLine;
struct1.b = tsSine;
```

### Fully Specify Input Data

The data created in the previous section fully specifies data for the signals selected by the In Bus Element blocks in the model. Simulate the model and observe the signals on the Dashboard Scope blocks.

### Partially Specify Input Data

When you use In Bus Element blocks to select bus elements, you can partially specify data using a structure that does not include one or more selected elements. Elements without data defined in the structure use ground signal values for simulation.

For example, edit the label for the In Bus Element block that selects element `InBus.a.y` so that the In Bus Element block selects `InBus.a.z`. The structure that maps to the InBus port does not contain a field for `z` in the nested structure, `a`. When you simulate the model, without modifying the structure, the Dashboard Scope shows ground for `InBus.a.z`.

Change the In Bus Element port block that selects `InBus.a.z` back to select `InBus.a.y`.

### Overspecify Input Data

When you use In Bus Element blocks to select bus elements, you can overspecify data for the port. Overspecified input data contains signals that are not selected by any of the In Bus Element blocks in the model.

For example, change the label for the In Bus Element block that selects `InBus.a.y` to select `InBus.b`. Now, none of the In Bus Element blocks selects `InBus.a.y`, while the structure still contains the data for that element.

Simulate the model and observe the signals on the Dashboard Scope blocks.

## Load Signal Data That Uses Units

Signal data logged in a previous simulation using signal logging or the To File or To Workspace block can include units information for Dataset or Timeseries logging formats.

Logging top-level model Outport block data from a previous simulation contains units information if:

- These **Data Import/Export** configuration parameter settings:
  - **Output** is enabled.
  - **Format** is Dataset.
- For the Outport blocks that you log, in the Block Parameters dialog box, you set the **Unit** parameter.

Otherwise, to include units in signal data that you load, for the Units property of the MATLAB timeseries objects that you want to load, specify a Simulink.SimulationData.Unit object.

### Loading Bus Signals That Have Units

When you input a bus signal to a root-level Inport or Outport block, or you use a From File or From Workspace block, the output data type of the block must be a bus object. When you load the data from these blocks, the units in loaded data must match the units specified for the bus elements in the bus object. If the units for the loaded data do not match the units for a bus element in the bus object, Simulink uses the units specified in the bus object.

## Load Data Using the From File Block

This example shows how to load simulation input data from a MAT file using the From File block, including how to create and format the input data. You can programmatically create the data you load, load data logged from another simulation, or load real-world data collected from sensors or in a lab. You can use the code from each format section as a template to understand how to format your own simulation input data.

### Examine the Model

This example uses a simple model. Two From File blocks load data from two different MAT files to create signals that are connected to two Outport blocks. One From File block loads data for a scalar signal, and only the **File name** parameter for that block is changed from the default value. The other From File block is configured to load data for a bus. Two Dashboard Scope blocks display the output signals created by each From File block. The model also contains three Callback Button blocks you can use to generate the files with the input data using each format supported by the From File block.

#### Load Input Data for a Signal

#### Load Input Data for a Bus

The model uses the PreLoadFcn callback to:

- Create and save `timeseries` data in the file `inputData.mat`.
- Create and save input data for the bus in the file `busData.mat`.
- Create the `Simulink.Bus` object that defines the output data type for the From File block that loads data for a bus.

Use the Callback Button blocks to create data in the desired format prior to simulating the model. To create the data, click to select the Callback Button block and click again to run the code. You can view the code for each Callback Button block in the block dialog or Property Inspector.

### Create Time and Signal Data

The From File block supports loading data stored in `timeseries` objects and data stored in an array. Data you load using the From File block must contain a time value to correspond to each sample value. This example creates and loads ten seconds of data that represents a sine wave.

First, create a time vector. When you load data using the From File block, the data type for the time values must be `double`, and the time values must increase monotonically.

```
sampleTime = 0.01;
numSteps = 1001;
time = sampleTime*(0:numSteps-1);
```

Use the expression in this example to create an evenly spaced time vector for an input signal, especially when modeling discrete input signals. MATLAB® supports several other methods for creating an evenly spaced time vector, but other methods can introduce double-precision rounding errors in the time data, which can lead to unexpected simulation results.

Now, create the signal data using the `sin` function. The sample values you load using the From File block must not contain `NaN`, `Inf`, or `-Inf` values.

```
data = sin(2*pi/3*time);
```

### Load `timeseries` Data

Simulink® loading and logging both commonly use `timeseries` objects to pass time series data into and out of simulations. The From File block supports loading a variety of input data when you save the data in the MAT file as a `timeseries` object. The signal values you load can be:

- A built-in numeric data type other than `half`, `int64`, and `uint64`; a fixed-point data type with up to a 32-bit word length; or an enumerated data type.
- Real or complex.
- Scalar, vector, or multidimensional.

When you load data in a `timeseries` object using the From File block, you must save the `timeseries` data in a Version 7.3 MAT file. The To File block saves data to a Version 7.3 MAT file. When you load data from a file created using a To File block, you do not need to convert the version of the file.

The code for the Callback Button block labeled Create file with `timeseries` data to load:

- 1 Creates the time and signal data as row vectors.
- 2 Transposes the row vectors to column vectors, as required to create a `timeseries` object with scalar data values.
- 3 Creates a `timeseries` object to contain the data.
- 4 Saves the `timeseries` object in a Version 7.3 MAT file.

```
sampleTime = 0.01;
numSteps = 1001;
time = sampleTime*[0:(numSteps-1)];
```

```
data = sin(2*pi/3*time);
time = time';
data = data';
inputData = timeseries(data,time);
save("inputData.mat","inputData","-v7.3");
```

To load the `timeseries` data, you can run the code to create the `inputData.mat` file using the MATLAB Command Window or select then click the `Create file with timeseries data to load` Callback Button block. Then, simulate the model and view the loaded data on the Dashboard Scope block.

### Load Array Data

You can use the From File block to load scalar or vector signal data formatted as an array, where the first row contains time data and subsequent rows contain the sample values. When you load array data using the From File block, the sample values must be real and double. The From File block can load array data from any MAT file versions.

The code for the Callback Button block labeled `Create file with array data to load` creates the time and signal data, concatenates the row vectors into an array, and saves the array to a Version 7 MAT file.

```
sampleTime = 0.01;
numSteps = 1001;
time = sampleTime*[0:(numSteps-1)];
data = sin(2*pi/3*time);
inputData = [time;data];
save("inputData.mat","inputData")
```

To load the array data, you can run the code to create the `inputData.mat` file using the MATLAB Command Window or select then click the `Create file with array data to load` Callback Button block. Then, simulate the model and view the loaded data on the Dashboard Scope block.

### Load Bus Data

The From File block supports loading a structure that contains `timeseries` objects as input data for a bus. Each `timeseries` object in the structure can contain any kind of data supported when loading data from a single `timeseries` object.

When you load bus data using the From File block, you must specify the **Output data type** parameter as the `Simulink.Bus` object that defines the bus. The hierarchy and field names in the structure that contains the bus data must match the hierarchy and element names of the Bus object that defines the output data type.

The From File block that loads the bus data has its **Output data type** setting configured as `Bus:SinusoidBus`. The `PreLoadFcn` callback for the model and the code for the `Create file with bus data to load` Callback Button block both define the `SinusoidBus` object.

A Bus object defines the bus hierarchy as well as properties of the elements in the bus, such as name and data type. The Bus object in this example defines the bus hierarchy, the names for the signals contained in the bus, and the data type for a nested bus. The bus, `SinusoidBus`, contains one signal, `Cosine`, and a nested bus called `SineBus`, which contains two signals, `Sine` and `BigSine`.

```
elems(1) = Simulink.BusElement;
elems(1).Name = 'Sine';
elems(2) = Simulink.BusElement;
```

```
elems(2).Name = 'BigSine';
SineBus = Simulink.Bus;
SineBus.Elements = elems;

clear elems;
elems(1) = Simulink.BusElement;
elems(1).Name = 'SineBus';
elems(1).DataType = 'Bus: SineBus';
elems(2) = Simulink.BusElement;
elems(2).Name = 'Cosine';
SinusoidBus = Simulink.Bus;
SinusoidBus.Elements = elems;
```

For more information about defining buses using `Simulink.Bus` objects, see “Specify Bus Properties with `Simulink.Bus` Object Data Types” on page 77-51.

The `Create bus data to load Callback Button` block creates a structure of `timeseries` objects with a hierarchy and field names that match the hierarchy and element names of the `SinusoidBus` object and saves the structure to a Version 7.3 MAT file.

```
sampleTime = 0.01;
numSteps = 1001;
time = sampleTime*[0:(numSteps-1)];
time = time';

data = sin(2*pi/3*time);
cosdata = cos(2*pi/3*time);
ampdata = 2*data;

busData.Cosine = timeseries(cosdata,time);
busData.SineBus.Sine = timeseries(data,time);
busData.SineBus.BigSine = timeseries(ampdata,time);

save("busData.mat","busData","-v7.3");
```

To load the bus data, you can run the code to create the `busData.mat` file using the MATLAB Command Window or select then click the `Create bus data to load Callback Button` block. Then, simulate the model and view the loaded data on the `Dashboard Scope` block.

When you load input data for a bus using the `From File` block, you do not need to provide data for every element in the bus. To partially specify input data for a bus, you can omit the corresponding field in the structure or specify its value as `[]`. When you partially specify data for a bus that includes a nested bus, you can specify the entire nested bus as `[]` and the `From File` block provides ground values for all elements of the nested bus.

## Load Data Using the From Workspace Block

This example shows how to create and format data to load from the base workspace using the From Workspace block. To load data using the From Workspace block, you must create or save the data using a format the From Workspace block supports in the base, model, or mask workspace. You could programmatically create the data you load, load data logged in another simulation, or load real-world data collected from sensors or in a lab. You can use the code from each format section as a template to understand how to format your own simulation input data.

### Examine the Model

This example uses a simple model. Two From Workspace blocks load data from the base workspace to create signals that are connected to two Outputport blocks. One From Workspace block uses default values for all block settings, and the other is configured to load data for a bus. Two Dashboard Scope blocks display the output signals created by each From Workspace block. The model also contains several Callback Button blocks you can use to generate the data in the base workspace using different formats supported by the From Workspace block.

The model uses the PreLoadFcn callback to:

- Create timeseries data stored in the variable `simin`.
- Create a structure of timeseries objects stored in the variable `busin`.
- Create the `Simulink.Bus` object that defines the output data type for the From Workspace block that loads data for a bus.

Use one of the Callback Button blocks to create data in the desired format prior to simulating the model. To create the data, click to select the Callback Button block and click again to run the code. You can view the code for each Callback Button block in the block dialog or Property Inspector.

### Create Time and Signal Data

Most data formats supported by the From Workspace block fundamentally consist of time values paired with signal values. You can use the `Structure without time` format to load only input data values with no corresponding time values, which is sometimes required for discrete simulations. (For more information, see “Load Data to Test a Discrete Algorithm” on page 71-32.) This example creates and loads ten seconds of time and signal data that represents a sine wave.

First, create a time vector. When you load data that includes time values using the From Workspace block, the data type for the time values must be `double`, and the time values must increase monotonically.

```
sampleTime = 0.01;
numSteps = 1001;
time = sampleTime*(0:numSteps-1);
time = time';
```

Use the expression in this example to create an evenly spaced time vector for an input signal, especially when modeling discrete input signals. MATLAB® supports several other methods for creating an evenly spaced time vector, but other methods can introduce double-precision rounding errors in the time data, which can lead to unexpected simulation results.

Now, create the signal data using the `sin` function.

```
data = sin(2*pi/3*time);
```

### Load timeseries Data

Simulink® loading and logging both commonly use `timeseries` objects to pass time series data into and out of simulations. The code for the Callback Button block labeled `Create timeseries data to load` creates the time and signal data, uses it to create a `timeseries` object, and assigns the `timeseries` object to the loading variable `simin`.

```
sampleTime = 0.01;
numSteps = 1001;
time = sampleTime*(0:numSteps-1);
time = time';
data = sin(2*pi/3*time);
simin = timeseries(data,time);
```

To load the `timeseries` data, you can run the code to create the `simin` loading variable in the MATLAB Command Window or select then click the `Create timeseries data to load` Callback Button block. Then, simulate the model and view the loaded data on the Dashboard Scope block.

### Load timetable Data

You can also store time series data in a MATLAB `timetable`. As the name suggests, the data is formatted as a table. When you load data using a `timetable`, the `timetable` must only contain data in one column, for a single signal.

The code for the Callback Button block labeled `Create timetable data to load` creates the time and signal data, formats the data as a `timetable`, and assigns the `timetable` to the loading

variable `simin`. To create a `timetable`, the input times must be a `datetime` or `duration` vector. This example creates the duration vector, `secs`, using the `seconds` function.

```
sampleTime = 0.01;
numSteps = 1001;
time = sampleTime*(0:numSteps-1);
time = time';
data = sin(2*pi/3*time);
secs = seconds(time);
simin = timetable(secs,data);
```

To load the `timetable` data, you can run the code to create the `simin` loading variable in the MATLAB Command Window or select then click the `Create timetable data to load Callback Button` block. Then, simulate the model and view the loaded data on the `Dashboard Scope` block.

### Load Structure Data

The `From Workspace` block supports loading data for a signal using a structure that matches the `Structure` or `Structure with time` logging formats. This example shows how to create data that matches the `Structure with time` format. The `Structure` format is the same as the `Structure with time` format, except the `Structure` format does not have a `time` field.

The structure has two top-level fields, `time` and `signals`. When you log data using the `Structure with time` format, the `signals` field may be an array of structures that each contain data for a different signal. When you load data using the `Structure with time` format, the `signals` field can only contain one structure with data for a single signal. The structure for the `signals` field contains a `values` field and must contain a `dimensions` field when the signal is not scalar.

The code for the `Callback Button` block labeled `Create structure with time data to load` creates the time and signal data and uses it to build the structure with the required fields and hierarchy. The code starts by clearing any existing variable with the name `simin` which could be an object with property names that match the names for the fields of the structure.

```
clear simin;
sampleTime = 0.01;
numSteps = 1001;
time = sampleTime*(0:numSteps-1);
time = time';
data = sin(2*pi/3*time);
simin.time = time;
simin.signals.values = data;
```

To load the structure data, you can run the code to create the `simin` loading variable in the MATLAB Command Window or select then click the `Create structure data to load Callback Button` block. Then, simulate the model and view the loaded data on the `Dashboard Scope` block.

When you load data for a multidimensional signal, add one more line of code to assign the signal dimensions to `simin.signals.dimensions`. When the signal data is scalar, set the `dimensions` field to 1, if you include it. When each signal value is a row vector, you can specify the dimensions as `[1 n]` or as `n`, where `n` is the number of elements in the row vector. When each signal value is an `M`-by-`N` matrix, specify the `dimensions` field value as `[M N]`.

When you want to load simulation input data without time data, use the `Structure` format, which does not include the `time` field and specify the desired sample rate using the **Sample time** parameter. For more information, see “Load Data to Test a Discrete Algorithm” on page 71-32.

## Load Array Data

You can use the From Workspace block to load signal data formatted as an array, where the first column of the array contains time data and subsequent columns contain the signal data. When you load data in the array format, the sample values must be scalars or vectors.

The code for the Callback Button block labeled `Create array data to load` creates the time and signal data, concatenates the two row vectors into an array, and assigns the array to the `simin` loading variable.

```
sampleTime = 0.01;
numSteps = 1001;
time = sampleTime*(0:numSteps-1);
time = time';
data = sin(2*pi/3*time);
simin = [time,data];
```

To load the array data, you can run the code to create the `simin` loading variable in the MATLAB Command Window or select then click the `Create array data to load` Callback Button block. Then, simulate the model and view the loaded data on the Dashboard Scope block.

## Load Bus Data

The From Workspace block supports loading a structure that contains `timeseries` objects or `timetables` as input data for a bus. Each `timeseries` object or `timetable` can contain any kind of data supported when loading data from a single `timeseries` object or `timetable`.

When you load input data for a bus using the From Workspace block, you must specify the **Output data type** setting as the `Simulink.Bus` object that defines the bus. The hierarchy and field names in the structure that contains the bus data must match the hierarchy and element names of the `Bus` object that defines the output data type.

The From Workspace block that loads the bus data has its **Output data type** setting configured as `Bus: SinusoidBus`. The `PreloadFcn` callback for the model and the code for the `Create bus data to load` Callback button both define the `SinusoidBus` object.

A `Bus` object defines the bus hierarchy as well as the properties of the elements in the bus, such as name and data type. The `Bus` object in this example defines the bus hierarchy, the names for the signals contained in the bus, and the data type for a nested bus. The bus, `SinusoidBus`, contains one signal, `Cosine`, and a nested bus called `SineBus`, which contains two signals, `Sine` and `BigSine`.

```
elems(1) = Simulink.BusElement;
elems(1).Name = 'Sine';
elems(2) = Simulink.BusElement;
elems(2).Name = 'BigSine';
SineBus = Simulink.Bus;
SineBus.Elements = elems;

clear elems;
elems(1) = Simulink.BusElement;
elems(1).Name = 'SineBus';
elems(1).DataType = 'Bus: SineBus';
elems(2) = Simulink.BusElement;
elems(2).Name = 'Cosine';
SinusoidBus = Simulink.Bus;
SinusoidBus.Elements = elems;
```

For more information about defining buses using `Simulink.Bus` objects, see “Specify Bus Properties with Simulink.Bus Object Data Types” on page 77-51.

The `Create bus data to load Callback Button` block creates a structure of `timeseries` objects with a hierarchy and field names that match the hierarchy and element names of the `SinusoidBus` object.

```
sampleTime = 0.01;
numSteps = 1001;
time = sampleTime*(0:numSteps-1);
time = time';

data = sin(2*pi/3*time);
cosdata = cos(2*pi/3*time);
ampdata = 2*data;

clear busin;
busin.Cosine = timeseries(cosdata,time);
busin.SineBus.Sine = timeseries(data,time);
busin.SineBus.BigSine = timeseries(ampdata,time);
```

To load the bus data, you can run the code to create the `busin` loading variable in the MATLAB Command Window or select then click the `Create bus data to load Callback Button` block. Then, simulate the model and view the loaded data on the `Dashboard Scope` block.

### Load Partially Specified Bus Data

When you load input data for a bus using the `From Workspace` block, you do not need to provide data for every bus element. To partially specify input data for a bus, you can omit the corresponding field in the structure or specify its value as `[]`.

The `Create partially specified bus data to load Callback Button` block creates a structure of `timeseries` objects with a hierarchy and field names that match the hierarchy and element names of the `SinusoidBus` object. It does not specify data for the `Cosine` bus element.

```
sampleTime = 0.01;
numSteps = 1001;
time = sampleTime*(0:numSteps-1);
time = time';

data = sin(2*pi/3*time);
ampdata = 2*data;

clear busin;
busin.Cosine = [];
busin.SineBus.Sine = timeseries(data,time);
busin.SineBus.BigSine = timeseries(ampdata,time);
```

To load the partially specified bus data, you can run the code to create the `busin` loading variable in the MATLAB Command Window or select then click the `Create partially specified bus data to load Callback Button` block. Then, simulate the model and view the loaded data on the `Dashboard Scope` block.

When you partially specify data for a bus that includes a nested bus or nested array of buses, you can specify the entire nested bus or nested array of buses as `[]` and the `From Workspace` block provides ground values for all elements of the nested bus or array of buses. You can also partially specify data for an array of buses by omitting data for one or more of the buses contained in the array of buses.

## Load Array of Buses Data

When you use the From Workspace block to load data for an array of buses, you must specify the **Output data type** parameter as the `Simulink.Bus` object that defines the buses the array of buses contains. All buses in an array of buses must be defined by the same `Simulink.Bus` object. The From Workspace block that loads data for the array of buses has its **Output data type** set to `Bus : SinusoidBus`. For details about defining the `Bus` object, see Load Bus Data.

The Create array of buses data to load Callback Button block creates an array that contains two structures of `timeseries` objects with hierarchy and field names that match the hierarchy and element names of the `SinusoidBus` object. The second structure, `bus2`, uses the same data as the first, shifted down by 1 so you can see all six signals on the Dashboard Scope block.

```
sampleTime = 0.01;
numSteps = 1001;
time = sampleTime*(0:numSteps-1);
time = time';

data = sin(2*pi/3*time);
cosdata = cos(2*pi/3*time);
ampdata = 2*data;

bus1.Cosine = timeseries(cosdata,time);
bus1.SineBus.Sine = timeseries(data,time);
bus1.SineBus.BigSine = timeseries(ampdata,time);

bus2.Cosine = timeseries((cosdata-1),time);
bus2.SineBus.Sine = timeseries((data-1),time);
bus2.SineBus.BigSine = timeseries((ampdata-1),time);

busin = [bus1,bus2];
```

To load the array of buses data, you can run the code to create the `busin` loading variable in the MATLAB Command Window or select then click the Create array of buses data to load Callback Button block. Then, simulate the model and view the loaded data on the Dashboard Scope block.

## Load State Information

### In this section...

“Import Initial States” on page 71-72

“Initialize a State” on page 71-72

“Initialize States in Referenced Models” on page 71-74

### Import Initial States

To initialize a simulation, you can use:

- Final state information (with or without `ModelOperatingPoint` object) from a previous simulation
- State information that you create in MATLAB

Use **Configuration Parameters > Data Import/Export** parameters to import initial states.

- 1 Enable the **Initial state** parameter.
- 2 In the **Initial state** edit box, enter the name of the variable for the state information that you want to use for initialization.

The initial values that the variable specifies override the initial state values that the blocks in the model specify in initial condition parameters.

You can specify `Dataset`, structure, or structure with time data.

### Initialize a State

You can initialize a specific state. This example creates an initial state structure for the x2 state of the `vdp` model. The x1 state is not initialized in the structure. Therefore, during simulation, Simulink uses the value in the Integrator block associated with the x1 state.

- 1 Open the model.
 

```
open_system('vdp');
```
- 2 Set the `SaveFormat` model argument to 'Structure'.
 

```
set_param('vdp','SaveFormat','Structure');
```
- 3 Obtain an initial state structure.
 

```
states = Simulink.BlockDiagram.getInitialState('vdp');
```
- 4 Set the initial value of the signals structure element associated with x2 to 2.
 

```
states.signals(2).values = 2;
```
- 5 Remove the signals structure element associated with x1.
 

```
states.signals(1) = [];
```
- 6 Use the `states` variable for the `vdp` model. Select the initial state configuration parameter.
 

```
set_param('vdp','LoadInitialState','on','InitialState','states');
```

- 7 Simulate the model and examine the initial values of x2 and x1.

```

sim('vdp');
states

states =

 struct with fields:

 time: 0
 signals: [1x1 struct]

states.signals

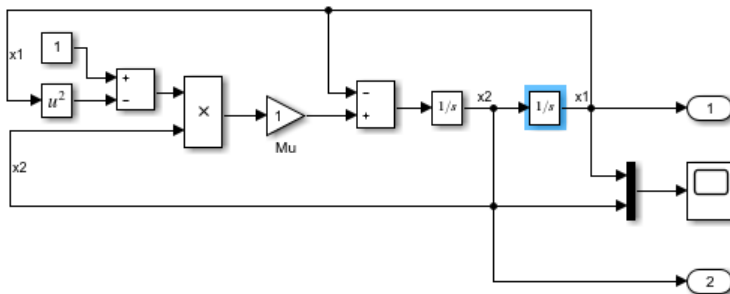

ans =

 struct with fields:

 values: 2
 dimensions: 1
 label: 'CSTATE'
 blockName: 'vdp/x2'
 stateName: ''
 inReferencedModel: 0
 sampleTime: [0 0]

```

When you simulate the model, both states have the initial value of 2. The initial value of the x2 state is assigned in the states structure, while the initial value of the x1 state is assigned in its Integrator block.

## **Initialize States in Referenced Models**

To initialize the states of a top model and the models that it references, use the structure or structure with time format or use operating point.

If the top model is in rapid accelerator mode, you cannot load discrete state data.

# Load Simulation Inputs Using the Root Inport Mapper

---

## Map Data Using Root Inport Mapper Tool

### In this section...

“The Model” on page 72-2

“Create Signal Data” on page 72-3

“Import and Visualize Workspace Signal Data” on page 72-3

“Map the Data to Inports” on page 72-4

“Save the Mapping and Data” on page 72-5

“Simulate the Model” on page 72-5

Use the Root Inport Mapper tool to import, visualize, and map signal and bus data to root-level inports.

Root-level inport mapping meets most modeling requirements and maintains model flexibility (for supported signal data, see “Create Signal Data for Root Inport Mapping” on page 72-9).

- Test your model with signals from the workspace and use your model as a referenced model in a larger context without any modification. Test signals in your model without disconnecting the inports and connecting sources to them.
- Use the Root Inport Mapper tool to update the **Input** parameter based on the signal data that you import and map to root-level inports.
- Visually inspect signal data without loading all the signal data into MATLAB memory.

To use the Root Inport Mapper tool:

- 1 Create signal data in the MATLAB workspace.
- 2 For a Simulink model, import the data from the workspace. You can visualize the data you import.
- 3 Map the data to root-level inports.
- 4 Simulate the model.
- 5 Save the Root Inport Mapper scenario.

### The Model

This model has three root-level Inport blocks. Two of the Inport blocks output scalar signals and the other Inport block outputs bus data. Open the model.

This example shows how you can use the Root Inport Mapper tool to test the model with data. This approach can be useful for performing standalone testing of a model that another model references.

## Create Signal Data

You can define the signal data as MATLAB timeseries objects.

- 1 Define the time values for the signal data.

```
sampleTime = 0.01;
endTime = 10;
numberOfSamples = endTime * 1/sampleTime +1;
timeVector = (0:numberOfSamples) * sampleTime;
```

- 2 Create the data for the two scalar signals. Naming the data variable to match the name of the corresponding signal makes it easier to map data to signals.

```
signal_1 = timeseries(sin(timeVector)*10,timeVector);
signal_2 = timeseries(rand(size(timeVector)),timeVector);
```

- 3 Create the signals for the bus.

```
busSignal.busElement_1 = timeseries(cos(timeVector)*2,timeVector);
busSignal.busElement_2 = timeseries(randn(size(timeVector)),timeVector);
```

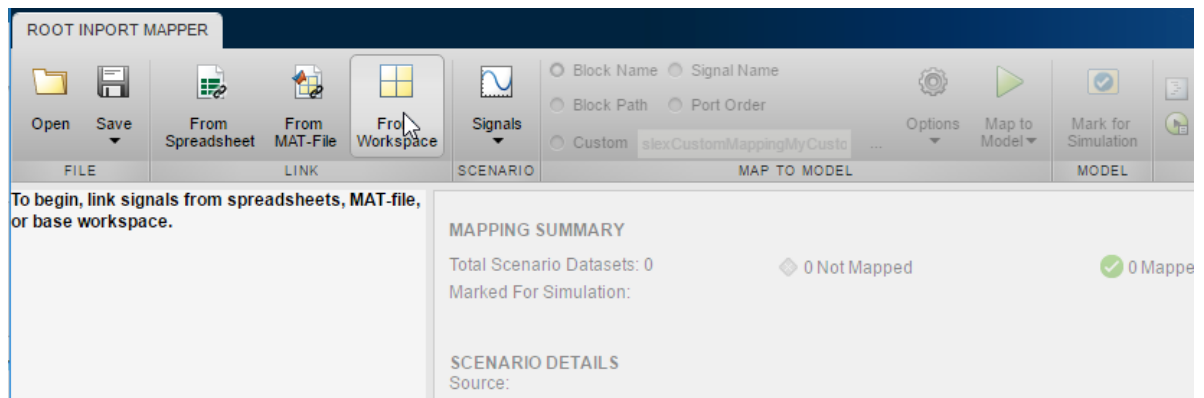

- 4 Create the bus object for the output data type of the Bus\_1 Inport block. You can create the bus object from the bus signal that you defined. Use a bus object for bus signals that cross model reference boundaries.

```
busInfo = Simulink.Bus.createObject(busSignal);
```

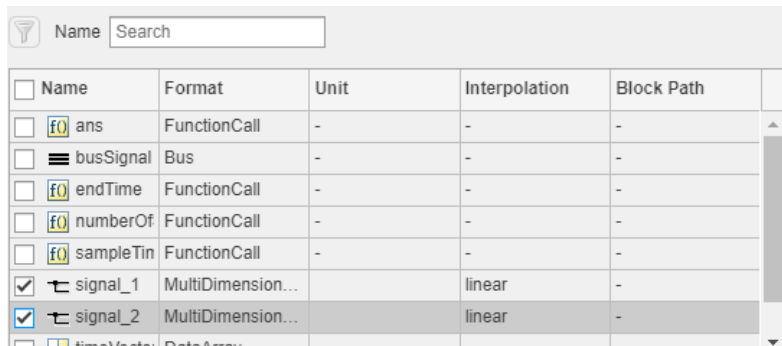

## Import and Visualize Workspace Signal Data

Import the signal data that you created from the workspace into the Root Inport Mapper tool. Then you can use the tool to visualize the imported data.

- 1 Open the Root Inport Mapper tool. Open the Block Parameters dialog box for one of the Inport blocks in the model and click **Connect Input**.
- 2 In the Root Inport Mapper tool, select the **From Workspace** button.

- 3 In the Import dialog box, specify a MAT-file to save signals to.
- 4 To clear the data variables, click the **Name** check box. Then click the check boxes for the busSignal, signal\_1, and signal\_2 signals.

Although in this example you select all the signals, you can select a subset of signals.

- 5 You can visualize signals. In the Root Inport Mapper dialog box toolbar, click **Signals > Edit MAT-File**.
- 6 In the Select Linked MAT-file window, select the MAT-file to which you saved the signals and click **OK**.

The **Signal Editor** user interface appears. You can select signals to plot. For example, to see a plot of `signal_1`, in the Navigation pane, expand the scenario data set (in this example, the top node, `ex_rootinportmappingexample`) and then expand the `signal_1` entry. Select the check box for `signal_1(1,1,:)` to plot the data.

- 7 Close the **Signal Editor** user interface by clicking the **Close** button.

## Map the Data to Imports

After you import the data, you map which data to use for specific Inport blocks.

- 1 Select the map mode, which specifies the criteria the mapping uses. In the toolbar, select the **Signal Name** option button.

The signals in this model have names, so mapping based on signal names makes it very clear which data is going to an Inport block.

- 2 You can specify options for the mapping. In the toolbar, select **Options**. Select **Update Model**, which updates the model after you do the mapping. Compiling the model verifies that signal dimensions and data types match between the data and the Inport blocks.
- 3 Map the data. In the Navigation pane, select the scenario data set. In the toolbar, click **Map to Model**. The dialog box shows the mapped data.

The screenshot shows the Root Inport Mapper tool interface. The top toolbar includes buttons for Open, Save, From Spreadsheet, From MAT-File, From Workspace, Signals, Options, Map to Model, Mark for Simulation, Generate MATLAB Script, and Run Script. The main window is divided into several panes:

- Navigation Pane:** Shows 'untitled' as the selected scenario dataset and 'Signal Name' as the selected map mode.
- MAPPING SUMMARY:**
  - Total Scenario Datasets: 1
  - Marked For Simulation: 0 Not Mapped, 1 Mapped
  - 0 Warnings, 0 Errors
- SCENARIO DETAILS:**
  - Source: untitled - untitled.mat
  - Mode: Signal Name
- Mapped Data Table:**

| STATUS | SCENARIO SIGNAL | PORT | BLOCK NAME | MAPPED SIGNAL                    |
|--------|-----------------|------|------------|----------------------------------|
| ✓      | signal_1        | 1    | Signal 1   | untitled.getElement('signal_1')  |
| ✓      | signal_2        | 2    | Input 1    | untitled.getElement('signal_2')  |
| ✓      | busSignal       | 3    | Bus_1      | untitled.getElement('busSignal') |

## Save the Mapping and Data

If you want to reuse the mapping and data that you have set up, you can save it as a scenario. In the Root Inport Mapper tool, click **Save > Save As** and save the scenario as an `.mldatx` file.

## Simulate the Model

- 1 In the Navigation pane, select the scenario data set.
- 2 In the toolbar, click **Mark for Simulation**.

The model is now set up to simulate using the workspace signal data that you mapped to root-level Inport blocks.

- 3 Simulate the model.

This model includes a Dashboard block that shows the data used during simulation for `signal_1`. The plot matches the plot you did when you visualized the data as part of the data import process.

## Map Root Inport Signal Data

### In this section...

“Open the Root Inport Mapper Tool” on page 72-7

“Command-Line Interface” on page 72-7

“Import and Mapping Workflow” on page 72-7

“Choose a Map Mode” on page 72-8

To import, visualize, and map signal and bus data to root-level input ports, use the Root Inport Mapper tool or the `getRootInportMap` function. At the top level of a model or referenced model, root-level input ports include:

- Inport blocks
- Enable blocks
- Trigger blocks

Root-level input ports import data from the MATLAB workspace based on the value of the **Configuration Parameters > Data Import/Export > Input** parameter.

Root-level inport mapping imports signal data in a way that meets most modeling requirements and maintains model flexibility. You can:

- Test your model with signals from the workspace and use your model as a referenced model in a larger context without any modification.
- Update the **Input** parameter based on the signal data you import and map to root-level inports.
- Visually inspect signal data without loading all the data into MATLAB memory.

**Tip** To determine whether another data import technique meets your specific modeling requirements (such as the amount of data or the storage location) better, see “Comparison of Signal Loading Techniques” on page 71-21.

### Open the Root Inport Mapper Tool

Use either of these approaches to open the Root Inport Mapper tool:

- In the **Configuration Parameters > Data Import/Export** pane, click **Connect Input**.
- In the block parameters dialog box for the Inport block, select **Connect Input**.

### Command-Line Interface

You can use the `getRootInportMap` to create a custom object to map signals to root-level input ports and `getSlRootInportMap` to create a custom mapping mode. For more information, see “Create and Use Custom Map Modes” on page 72-32.

### Import and Mapping Workflow

- 1 Identify and possibly create signal data to import and map on page 72-9.

- 2 Import on page 72-14 and inspect signal data on page 72-17.
- 3 Map the imported signal data on page 72-7. For example, you can map the signal data by block path or signal name.
- 4 Simulate the model using the mapped data. After associating a scenario with the model, you can generate scripts for simulation with scenarios on page 72-31 to perform batch simulations.
- 5 Optionally, save the current Root Inport Mapper scenario on page 72-34 for future reference or to share with other people.

---

**Tip** To extend the Root Inport Mapper tool map modes, you can create a custom mapping file function to map data to root-level inports.

---

## Choose a Map Mode

To specify how you want the Root Inport Mapper tool to map the signal data to a model, select from these map modes in the **MAP TO MODEL** section of the toolbar:

- Block name — Connect signal data to ports based the name of a root-level input port block.
- Block path — Connect signal data to ports based the path of a root-level input port block.
- Signal name — Connect signal data to ports based on the name of the signal on a port.
- Port order — Connect sequential port numbers to the imported data.
- Custom — Connect signal data to ports based on the definitions in a custom mapping file.

Each supported input format supports one or more mapping modes. To import MATLAB `timeseries` data, for example, you use any mapping mode. To import data array signal data, use the port order mapping mode.

## Create Signal Data for Root Inport Mapping

### In this section...

- “Choose a Source for Data to Import and Map” on page 72-9
- “Choose a Naming Convention for Signals and Buses” on page 72-9
- “Choose a Base Workspace and MAT-File Format” on page 72-10
- “Bus Signal Data for Root Inport Mapping” on page 72-11
- “Create Signal Data in a MAT-File for Root Inport Mapping” on page 72-11
- “Supported Microsoft Excel File Formats” on page 72-12

The first step for using the Root Inport Mapper tool is to know the source of signal data to import and map. You can use existing data (for example, in a Microsoft Excel spreadsheet), create data in a MAT-file, or use the Signal Editor interface to create signal data.

For a summary of the other steps involved in using the Root Inport Mapper tool, see “Import and Mapping Workflow” on page 72-7.

### Choose a Source for Data to Import and Map

You can import data from these sources.

- Base workspace — You can selectively import data from the base workspace. For more information about supported data formats, see “Choose a Base Workspace and MAT-File Format” on page 72-10.
- Data files — You can selectively import signals contained in MAT-files and Microsoft Excel files. Each time that you import the contents of the file, the contents overwrite data already loaded for the file in the Root Inport Mapper tool.

For more information, see “Choose a Base Workspace and MAT-File Format” on page 72-10 and “Supported Microsoft Excel File Formats” on page 72-12.

---

**Tip** To load input data for a simulation from a Microsoft Excel spreadsheet, consider using the From Spreadsheet block. The From Spreadsheet block incrementally loads data from the spreadsheet during simulation. If you use a From Spreadsheet block, you do not need to do anything to handle changes to sheet values.

---

You can also use the Signal Editor interface to create and edit signal data. For more information, see “Create and Edit Signal Data” on page 70-2.

### Choose a Naming Convention for Signals and Buses

When identifying signals to import, consider using a naming convention for signals and buses such that this grouping of data (scenario) is interchangeable. For example, you can have two MAT-files with the same set of variables named with the naming convention but different data values. Then, you can switch the scenarios of input data into and out of a model easily.

## Choose a Base Workspace and MAT-File Format

The Root Inport Mapper tool supports the MATLAB data types or formats described in the table for imported signal data. For each data type, you can use the mapping modes indicated in the table.

| Data Formats                                    | Block Name | Block Path | Signal Name | Port Order | Custom |
|-------------------------------------------------|------------|------------|-------------|------------|--------|
| Simulink.SimulationData.Dataset                 | ✓          | ✓          | ✓           | ✓          | ✓      |
| MATLAB timeseries                               | ✓          |            | ✓           | ✓          | ✓      |
| MATLAB timetable                                | ✓          |            | ✓           | ✓          | ✓      |
| Simulink.SimulationData.Signal                  | ✓          | ✓          | ✓           | ✓          | ✓      |
| Stateflow.SimulationData.State                  | ✓          | ✓          | ✓           | ✓          | ✓      |

| Data array                                      |            |            |             | ✓          |        |
| Array of buses                                  | ✓          |            | ✓           | ✓          | ✓      |
| Asynchronous function-call signal on page 10-76 | ✓          |            | ✓           | ✓          | ✓      |

---

**Note** If your MAT-file or base workspace contains data in a format that the Root Inport Mapper tool does not support, the tool ignores that data.

---

---

**Note** Although the Root Inport Mapper tool accepts these formats, it can only link in a `Simulink.SimulationData.Dataset` object. To convert the data in your MAT-file to a `Simulink.SimulationData.Dataset` object, in the Root Inport Mapper From dialog box, select the **Convert signals into a scenario dataset and save to MAT-file** check box. Alternatively, use the `convertToSLDataset` function to convert your data.

---

---

**Note** When you specify a `timetable` as an element in the `Dataset` or a bus, the `timetable` must contain data for only one signal.

---

### Dataset Signal Data

If data sets have nonunique element names, use the **Port Order** map mode.

### MATLAB Timeseries Signal Data

If you have MATLAB timeseries data that includes enumeration data, and the enumeration class is not on your MATLAB path, the tool ignores that timeseries data.

## Structure Signal Data

When converting structure signal data to datasets, the signals are named using the value contained in the label field of the signal field of the structure signal.

## Array Signal Data

The Root Inport Mapper tool tries to map the data array to a single input port. In this case, you can choose any of the map modes.

## Bus Signal Data for Root Inport Mapping

The signal data that you import and map to a root-level Inport block can include bus data. You cannot map bus signals to a root-level Enable or Trigger block.

- 1 In the MATLAB workspace, create or load a bus object on page 77-51 for the bus data you want to import and map.
- 2 If you create a bus object in the base workspace, save the bus object definition to a MAT-file, such as `d_myBusObj.mat`.
- 3 Create a separate MAT-file that contains the bus data you want to import for the bus object. Use one of these approaches:
  - Use an existing MAT-file that already contains a MATLAB struct or `Simulink.SimulationData.Dataset` object.
  - Create the bus in the base workspace and then save it to a MAT-file.
- 4 Set up the model to load the bus object.
  - For root-level Inport blocks that you map signals to, set the **Data type** field to Bus. Specify the name of the variable for the bus object to be used for signal mapping.
  - Load into the model the MAT-file that includes the bus objects used for mapping. For example, use a `PreLoadFcn` callback function. For details, see “Alternative Workflows to Load Mapping Data” on page 72-27.

## Create Signal Data in a MAT-File for Root Inport Mapping

You can create signal data in a MAT-file to use for root-inport mapping. For example, you can import three signals (`signal1`, `signal2`, and `signal3`) and save the signals in a MAT-file. The `Simulink.SimulationData.Signal` objects include signal names, block names, block paths, and port order index values.

You can use the `convertToSLDataset` function to convert MAT-file contents to `Simulink.SimulationData.Dataset` objects.

- 1 In MATLAB, create three `Simulink.SimulationData.Signal` objects, specifying signal names, block paths, and port order index values.

```
signal1 = Simulink.SimulationData.Signal;
signal1.Name = 'signal1';
signal1.BlockPath = Simulink.SimulationData.BlockPath('Out1');
signal1.PortType = 'inport';
signal1.PortIndex = 1;
```

```

signal2 = Simulink.SimulationData.Signal;
signal2.Name = 'signal2';
signal2.BlockPath = Simulink.SimulationData.BlockPath('Out2');
signal2.PortType = 'inport';
signal2.PortIndex = 2;

signal3 = Simulink.SimulationData.Signal;
signal3.Name = 'signal3';
signal3.BlockPath = Simulink.SimulationData.BlockPath('Out3');
signal3.PortType = 'inport';
signal3.PortIndex = 3;

```

- 2 In the MATLAB workspace, select `signal1`, `signal2`, and `signal3`. Right-click the selection, and in the context menu, click **Save as**. Save the file as `mySigData.mat`.
- 3 Open the MAT-file.

```
open mySigData.mat
```

```
ans =
```

```

signal1: [1x1 Simulink.SimulationData.Signal]
signal2: [1x1 Simulink.SimulationData.Signal]
signal3: [1x1 Simulink.SimulationData.Signal]

```

You can use the **Signal Name**, **Block Name**, **Block Path**, or **Port Order** map mode with this MAT-file. Based on your map mode, the Root Inport Mapper tool maps the signal data from the MAT-file to corresponding ports.

## Supported Microsoft Excel File Formats

You can use the Root Inport Mapper tool to import data from Excel spreadsheets. You can also use the Root Inport Mapper tool to import signal data in CSV files on a Windows system with Microsoft Office installed. The Root Inport Mapper tool does not support Excel spreadsheet charts.

- Use sheet names that follow MATLAB variable name rules. If you import from a sheet whose name does not follow these rules, the Root Inport Mapper tool uses a modified sheet name. This modified sheet name follows the MATLAB variable name rules. For example, if you have a sheet name `Group Name`, the Root Inport Mapper uses the modified name `GroupName`.
- Use the first row of a sheet to specify signal names. Either specify a signal name for every signal or do not specify any signal names. If you do not specify any signal names, the tool assigns signal names using the format `Signal#`.
- For time values, use the first column of the remaining rows. The time values must increase for each row.
- Put signal values in the remaining columns.
- During import, the Root Inport Mapper tool converts formatted numbers from Excel spreadsheets to doubles.
- The Root Inport Mapper tool does not support block path mapping mode for spreadsheets.

This example of a Microsoft Excel spreadsheet is set up for root-inport mapping.

- The sheet name is `sigData`, which is a valid MATLAB variable name.
- The first row contains the signal names `signal1`, `signal2`, and `signal3`.

- The first column has six time values that increase for each row.
- In each row with a time value, columns to the right of the first column contain signal data values for each signal.

|    | A | B       | C       | D       | E |
|----|---|---------|---------|---------|---|
| 1  |   | signal1 | signal2 | signal3 |   |
| 2  | 0 | 2       | 4       | 6       |   |
| 3  | 1 | 3       | 5       | 7       |   |
| 4  | 2 | 2       | 4       | 6       |   |
| 5  | 3 | 4       | 6       | 8       |   |
| 6  | 4 | 5       | 7       | 9       |   |
| 7  | 5 | 6       | 8       | 10      |   |
| 8  |   |         |         |         |   |
| 9  |   |         |         |         |   |
| 10 |   |         |         |         |   |

## Import Signal Data for Root Inport Mapping

### In this section...

“Import Signal Data” on page 72-14

“Import Bus Data” on page 72-15

“Import Signal Data from Other Sources” on page 72-16

“Import Data from Signal Editor” on page 72-16

“Import Test Vectors from Simulink Design Verifier Environment” on page 72-16

### Import Signal Data

Before you can import data, identify the signals that you want to import and set up the data to use with root-level inport mapping. See “Create Signal Data for Root Inport Mapping” on page 72-9. For a summary of the other steps involved in using the Root Inport Mapper tool, see “Import and Mapping Workflow” on page 72-7.

For data import purposes, the Root Inport Mapper From MAT-File and From Workspace dialog boxes provide a **Convert signals into a scenario dataset and save to MAT-file** check box, selected by default. To convert the data in your MAT-file to a `Simulink.SimulationData.Dataset` object, select this check box. Alternatively, use the `convertToSLDataset` function to convert your data.

---

**Note** The Root Inport Mapper tool uses the term link to refer to the act of importing Simulink data. The sources from which you can link your data are in the LINK section of the tool.

---

To import signal data for root-inport mapping:

- 1 Open the Root Inport Mapper tool. In the **Configuration Parameters > Data Import/Export** pane, click **Connect Input**.
- 2 In the LINK section, select the data source.
  - To browse to the MAT-file or spreadsheet file that contains the signals you want to import, select **From Spreadsheet** or **From MAT-File** and browse to the MAT-file or spreadsheet file. To return to the LINK section, click **OK**.

---

**Note** To import bus data for root inport mapping, see “Import Bus Data” on page 72-15.

---

- To display a list of base workspace variables that you can import, select **From Workspace**. Select the variables that you want to import and click **OK**.

The From dialog box displays the contents of the spreadsheet, file, or base workspace.

- 3 Select the data that you want to import, and then click **OK**.

The Root Inport Mapper tool displays the imported data.

Alternatively, you can create signal data to map using the **Signals > New MAT-File** option. For more information, see “Create and Edit Signal Data” on page 70-2.

## Import Bus Data

Use bus objects for bus data that you want to import and map to root inports or bus element ports.

Store the bus objects in a MAT-file. Use a different MAT-file that contains the bus data that you want to import for the bus object. This file can be an existing MAT-file that already contains a MATLAB `struct`. You can also create the bus in the base workspace and save it to a MAT-file. For more information, “Bus Signal Data for Root Inport Mapping” on page 72-11.

To import the bus data, in the LINK section of the Root Inport Mapper toolstrip, click **From MAT-File**. Select the MAT-file that contains the bus data and click **OK**.

## Import Signal Data from Other Sources

Use the Root Inport Mapper tool to import signals from other sources.

- To import signals from models that contain Signal Editor blocks, see “Import Data from Signal Editor” on page 72-16.
- You can import Excel spreadsheet data. The Root Inport Mapper tool imports a worksheet as a `Simulink.SimulationData.Dataset` object that contains timeseries elements.
- To import test vectors from Simulink Design Verifier, see “Import Test Vectors from Simulink Design Verifier Environment” on page 72-16.

## Import Data from Signal Editor

You can import and map data from the Signal Editor block in a MAT-file. For more information, see “Load Data with Interchangeable Scenarios Using Signal Editor Block” on page 72-37.

## Import Test Vectors from Simulink Design Verifier Environment

You can import and map Simulink Design Verifier test vectors. This workflow requires a Simulink Design Verifier license.

Before importing, use the Simulink Design Verifier `sldvsimdata` function to convert a Simulink Design Verifier test structure to a `Simulink.SimulationData.Dataset` object. This file contains a test vector structure `sldvData`. Save the output to a MAT-file and then import that file into the Root Inport Mapper tool.

## Map Signal Data to Root Input Ports

### In this section...

“Select Map Mode” on page 72-18

“Set Options for Mapping” on page 72-19

“Select Data to Map” on page 72-19

“Map Data” on page 72-20

“Understand Mapping Results” on page 72-20

“Converting Harness-Driven Models to Use Harness-Free External Inputs” on page 72-22

“Alternative Workflows to Load Mapping Data” on page 72-27

After you import data, map signal data to root input ports by selecting map modes and options and selecting data.

For a summary of the other steps involved in using the Root Inport Mapper tool, see “Import and Mapping Workflow” on page 72-7.

### Select Map Mode

To map signal data to root-level ports, use one of these map modes in the Map To Model section of the Root Inport Mapper toolstrip. The mapping mode you select from the toolstrip, such as **Block Name** or **Port Order**, is maintained between MATLAB sessions and models. You do not have to select the map mode each time you want to map signal data to root input ports.

| Goal                                                                                                                                                                                                                                                                                                                                                         | Map Mode           |
|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------|
| Assign signals to ports according to the name of the root-inport block. If the name of a signal or bus element matches the name of a root-input port block, the data is mapped to the corresponding port.                                                                                                                                                    | <b>Block Name</b>  |
| Assign signals to ports according to the block path of the root-inport port block. If the block path of a signal matches the block path of a root-inport block, the data is mapped to the corresponding port.                                                                                                                                                | <b>Block Path</b>  |
| Assign signals to ports according to the name of the signal on the port. If the signal name of a data element matches the name of a signal at a port, the signal is mapped to the corresponding port.                                                                                                                                                        | <b>Signal Name</b> |
| Assign sequential port numbers to the imported data, starting at 1. Map signals to the corresponding input ports.<br><br>If there is more data than input ports, the remaining data is mapped to enable and then trigger input ports.<br><br>If the data is not in the form of a dataset, it is processed in the order in which it appears in the data file. | <b>Port Order</b>  |

| Goal                                                                                                                                                         | Map Mode      |
|--------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------|
| Assign signals to ports according to the definitions in a custom file. To create a custom mapping mode, see “Create and Use Custom Map Modes” on page 72-32. | <b>Custom</b> |

## Set Options for Mapping

If you want to set up mapping options, in the Map To Model section on the Root Inport Mapper toolstrip, click **Options**. The option you select from the toolstrip, such as **Update Model** or **Allow Partial**, is maintained between MATLAB sessions and models. You do not have to select the option each time you want to map signal data to root inports.

To map the signals, see “Map Data” on page 72-20.

| Goal                                                                                    | Option                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|-----------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Update the model and review the data types of root-level input ports and imported data. | <b>Update Model.</b> Compare the signal data and input port parameters to the root-level port and display the results. If you do not select this option, the tool maps the imported data to the root-level input port but does not update the model.                                                                                                                                                                                                                                                                                                                                                                 |
| Use strong data typing when mapping data from spreadsheets.                             | <b>Use Strong Data Typing with Spreadsheets.</b> Clear this check box to allow the Root Inport Mapper tool to automatically convert spreadsheet input signals to the data types of the corresponding root inports. The Root Inport Mapper tool can cast the spreadsheet data to only these data types: <code>double</code> , <code>single</code> , <code>int8</code> , <code>uint8</code> , <code>int16</code> , <code>uint16</code> , <code>int32</code> , <code>uint32</code> . If you select this check box or if the root input port is not one of these data types, you may receive a data type mismatch error. |
| Import bus data that is only partially defined.                                         | <b>Allow partial.</b> Confirm that any partially specified bus data you import maps properly to root-level input ports.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| Identify unassigned root input ports and detect incomplete input data sets.             | <b>Notify of Missing Signals.</b> Show inputs with missing signals.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

## Select Data to Map

To specify a subset of scenarios to map, click the down arrow on the **Map to Model** button. You can choose different mapping modes for different scenarios.

| Goal                                                                                  | Option                 |
|---------------------------------------------------------------------------------------|------------------------|
| Map all the scenario datasets (default).                                              | <b>Map All</b>         |
| Map the datasets of the scenarios currently selected in the Scenario Dataset section. | <b>Map Selected</b>    |
| Map the disconnected datasets.                                                        | <b>Map Unconnected</b> |
| Map datasets that previously failed a mapping.                                        | <b>Map Failed</b>      |

| Goal                                          | Option            |
|-----------------------------------------------|-------------------|
| Map datasets that previously caused warnings. | <b>Map Warned</b> |

## Map Data

After you import signals or buses, you can map data.

- 1 On the Root Inport Mapper toolbar, click **Map to Model**.

The results of a signal mapping appear in the **Scenario Dataset** tab.

- 2 In the FILE section, click a data set to see the mapping results

- The **Simulation Readiness** section lists the input data and the status of the mapping.

**Note** See “Understand Mapping Results” on page 72-20.

- The mapping definition for the input data is applied to the model.

After you save and close the model, when you load input data of the same scenario to the workspace, the model uses the mapping defined for that scenario.

For an example of mapping signal data to root-level inputs, see “Converting Harness-Driven Models to Use Harness-Free External Inputs” on page 72-22.

After you save the mapping definition for a model, you can automate data loading. For more information, see “Alternative Workflows to Load Mapping Data” on page 72-27.

## Understand Mapping Results

When you complete the import and map process, the **Simulation Readiness** section displays the results in the status area. The results depend on whether you select the **Update Model** option when you set up the mapping.

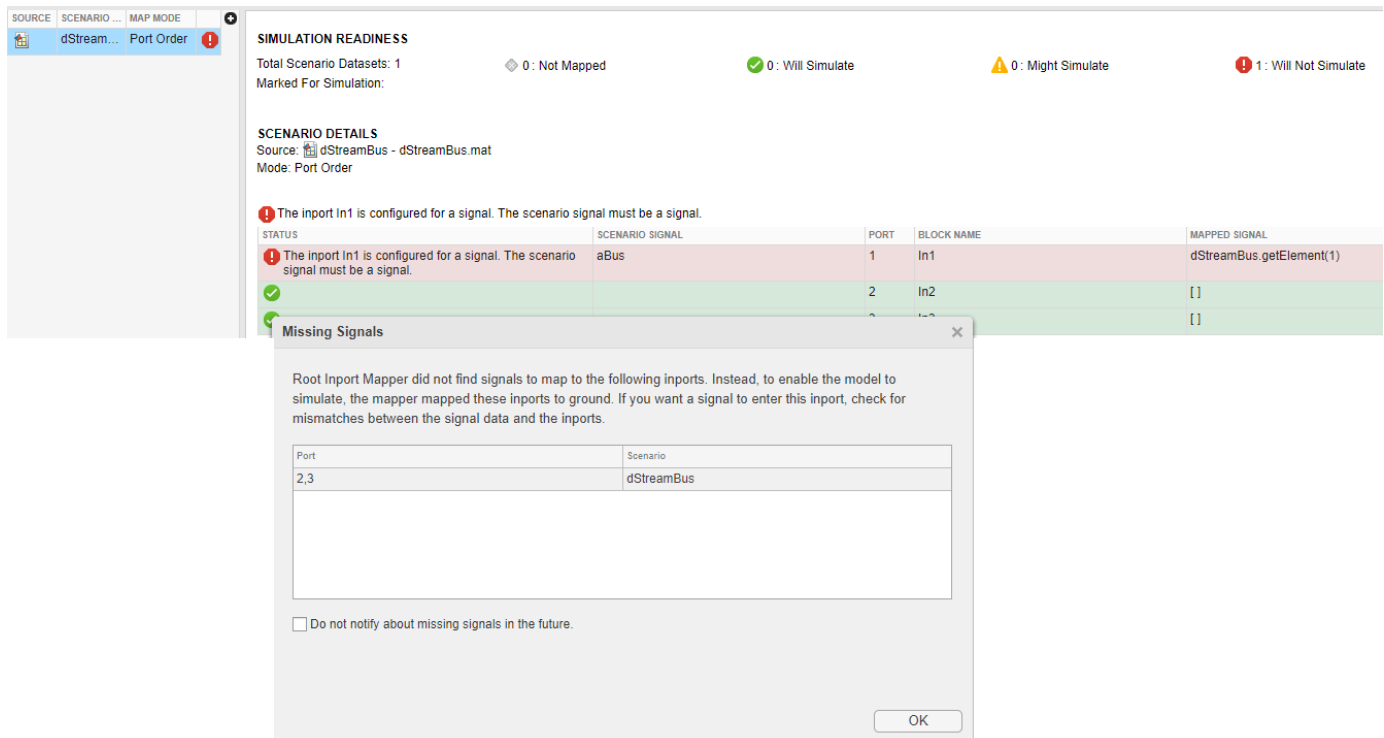

| Status | Update Model                                                                         | Continue Without Update Model                                                                   |
|--------|--------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------|
| ✔      | The properties of the mapped data and the input port are appropriate for simulation. | The data type, dimension, and signal type properties of the data and input port are compatible. |

| Status                                                                            | Update Model                                                                             | Continue Without Update Model                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|-----------------------------------------------------------------------------------|------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|  | Not applicable                                                                           | <p>Comparison of data and root-level port data type, dimension, and signal type properties cannot determine whether there is a match. If you do not update the model before mapping, the tool cannot evaluate whether all the data types match unless you explicitly specify the input port data types. Confirm that you set these block parameters correctly:</p> <p>Input block parameter <b>Data type</b> is not set to <code>Inherit:auto</code>.</p> <p>Input block parameter <b>Dimension</b> is not set to <code>-1</code>.</p> <p>Input block parameter <b>Signal type</b> cannot be <code>auto</code>.</p> |
|  | The properties of the mapped data and the input port are not appropriate for simulation. | One or more of the data types, dimensions, or signal types of the signal data are not compatible with the root-level input port.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

To enable the model to simulate, if Root Inport Mapper does not find input port signals to map, it maps these input ports to ground and displays the mapped signal as empty ([ ]).

This figure shows mapping successes, failures, and ground assignments. If there are issues, the status column displays suggested resolutions. Read through and diagnose the issues.

The screenshot shows the Root Inport Mapper interface. At the top, there are tabs for SOURCE, SCENARIO, and MAP MODE. The current scenario is 'dStreamBus - dStreamBus.mat' and the mode is 'Port Order'. The 'SIMULATION READINESS' section shows: Total Scenario Datasets: 1 (0: Not Mapped, 0: Will Simulate, 0: Might Simulate, 1: Will Not Simulate). Below this, the 'SCENARIO DETAILS' section shows the source and mode. A table lists the mapping results:

| STATUS                                                                              | SCENARIO SIGNAL | PORT | BLOCK NAME | MAPPED SIGNAL            |
|-------------------------------------------------------------------------------------|-----------------|------|------------|--------------------------|
|  | aBus            | 1    | In1        | dStreamBus.getElement(1) |
|  |                 | 2    | In2        | [ ]                      |
|  |                 | 3    | In3        | [ ]                      |

A 'Missing Signals' dialog box is open, displaying the following text: 'Root Inport Mapper did not find signals to map to the following inports. Instead, to enable the model to simulate, the mapper mapped these inports to ground. If you want a signal to enter this inport, check for mismatches between the signal data and the inports.' The dialog box contains a table with the following data:

| Port | Scenario   |
|------|------------|
| 2,3  | dStreamBus |

At the bottom of the dialog box, there is a checkbox labeled 'Do not notify about missing signals in the future.' and an 'OK' button.

Sometimes the **Simulation Readiness** section shows a warning or error, but your investigation of the elements indicates that there is no problem with mapping the data. In these cases, if you did not select the **Update Model** check box from the **Options** menu, select it and click **Map to Model** again.

In the Root Inport Mapper tool, clicking **Mark for Simulation** selects the **Input** check box in the **Data Import/Export** pane in the model Configuration Parameters dialog box. It also sets the value to the imported data variables. To apply the changes to the model configuration, in the **Data Import/Export** pane, click **OK**.

If your model uses configuration references to reference configuration sets, you cannot mark the model for simulation. To use this data to simulate the model with the Root Inport Mapper tool, use the Model Explorer to activate a configuration set first.

This graphic illustrates the application of the changes to the model configuration for the model in “Map Data” on page 72-20.

To inspect the imported data, you can:

- Connect the output to a scope, simulate the model, and observe the data.
- Log the signals and use the Simulation Data Inspector tool to observe the data.

To highlight the Inport block that is associated with the signal, select an item in the **Simulation Readiness** section. The selected Inport block is outlined with blue.

---

**Note** When the input is a bus, click the levels of the bus object to see the individual elements in the bus.

---

## Converting Harness-Driven Models to Use Harness-Free External Inputs

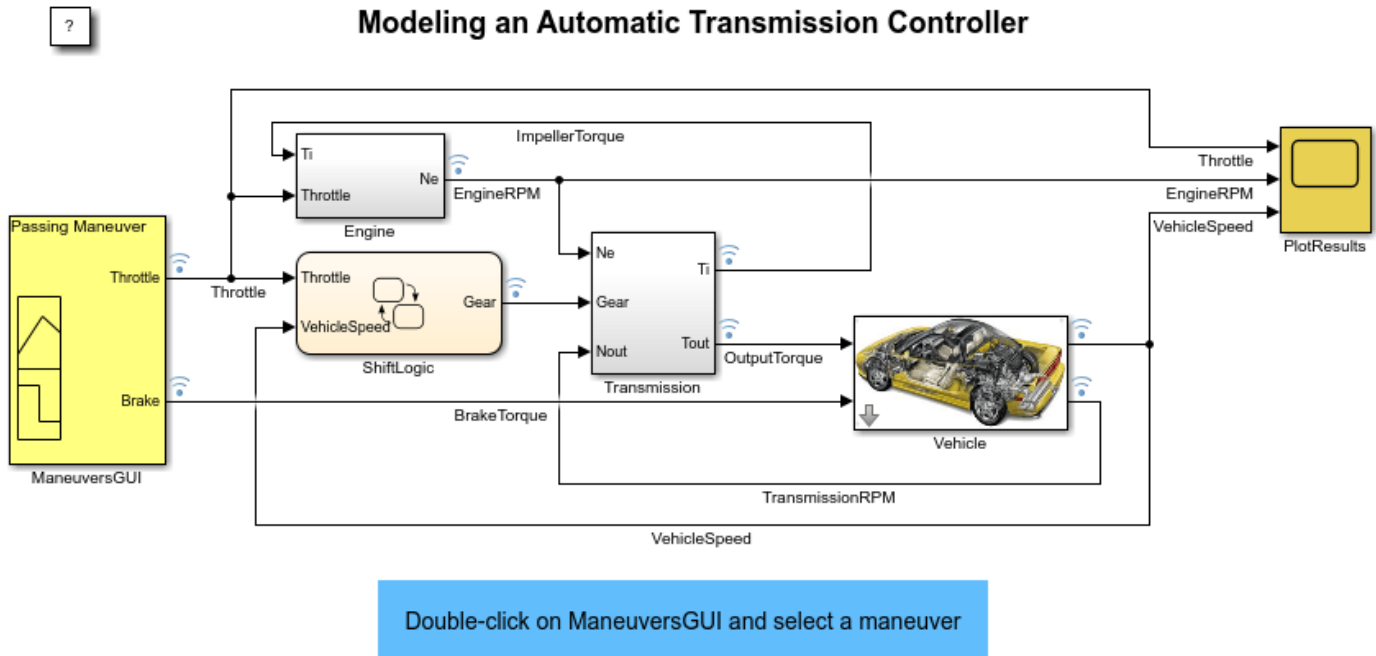

This example shows how to convert a harness model that uses a Signal Builder block as an input to a harness-free model with root inports. The example collects data from the harness model and stores it in MAT-files for the harness-free model. After storing the data, the example removes the Signal Builder block from the harness model and adds root inports to create a harness-free model. Then, the data in the MAT-files is mapped to the root inports of the model.

### Save Harness Data to MAT-Files

Before converting the model to be harness-free, collect the test cases in the harness.

For this example, you modify the model `sldemo_autotrans` from the “Modeling an Automatic Transmission Controller” example.

Open the example model.

## Exporting Signal Builder Block Groups

Export data that defines Signal Builder block signal groups to a MAT-file from the Signal Builder window. To export Signal Builder signal data, formatted as `Simulink.SimulationData.Dataset`, to a MAT-file, open the Signal Builder window and select **File > Export Data > To MAT-File**. In the dialog, enter a name for the MAT-file to contain the data and the number of the group you want to export. For this example, the file name is `slexAutotransRootInportPassingManeuver.mat` and the group number is 1 for the Passing Maneuver group.

## Remove the Signal Builder Block

Remove the Signal Builder block named `ManeuversGUI` and replace it with two inports.

- 1 Delete the Signal Builder block named `ManeuversGUI`.
- 2 From the **Simulink/Commonly Used Blocks** library, drag two inport blocks into the model.
- 3 Connect the input ports to the lines previously connected to the Signal Builder block.
- 4 Rename the inport ports. Name the input port connected to the Throttle line **Throttle**. Name the input port connected to the BrakeTorque line **Brake**.

Save the model as `slexAutotransRootInportsExample1.slx` or use the example `slexAutotransRootInportsExample.slx`.

The remaining steps of this example use the model `slexAutotransRootInportsExample.slx`. If you saved the model with a different name use your model name in the steps going forward.

## Modeling an Automatic Transmission Controller with Root Imports

Copyright 2012 - 2014 The MathWorks, Inc.

### Set Up Harness-Free Inputs

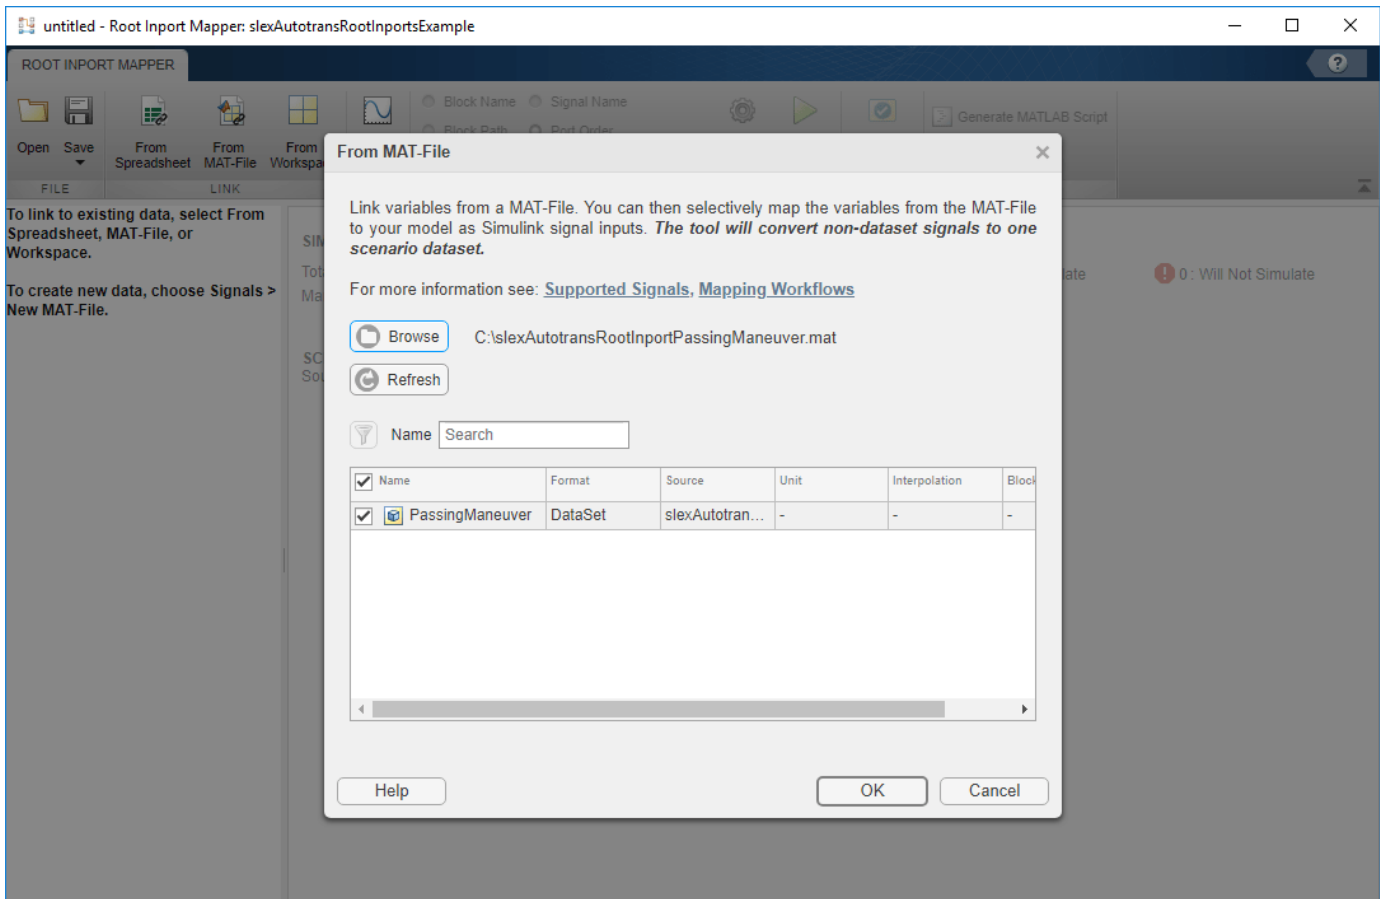

Now that the model is harness-free, set up the inputs that you already saved (See "Save Harness Data to MAT-Files").

In the Modeling tab, select Model Settings. In the Data Import/Export pane, click the **Connect Input** button.

### Map Signals to Root Inport

The Root Inport Mapper tool opens.

The example uses this tool to set up the model inputs from the MAT-file and map those inputs to an input port, based on a mapping algorithm. To select the MAT-file that contains the input data, click the **From MAT-File** button on the Root Inport Mapper toolbar. When the link dialog appears, click the Browse button. In the browser, select the MAT-file that you saved earlier.

### Select a Mapping Mode

When you select the MAT-file `slexAutotransRootInportPassingManeuver.mat` that contains the input data, determine the root input port to which to send input data. Simulink matches input data with input ports based on one of five criteria:

- **Port Order** - Maps in the order it appears in the file to the corresponding port number.
- **Block Name** - Maps by variable name to the corresponding root inport with the matching block name.
- **Signal Name** - Maps by variable name to the corresponding root inport with the matching signal name.
- **Block Path** - Maps by the BlockPath parameter to the corresponding root inport with the matching block path.
- **Custom** - Maps using a MATLAB function.

Earlier in this example, you saved input data to variables of the same name as the harness signals Throttle and Brake, and added input ports with names matching the variables. Given the set of conditions for the input data and the model input ports, the best choice for a mapping criteria is **Block Name**. Using this criteria, Simulink tries to match input data variable names to the names of the input ports. To select this option:

- 1 Click the **Block Name** radio button.

- 2 Click the **Options** button and select **Update Model**. This verifies the mapping.
- 3 Click the **Map** button.

When compiling the data, Simulink evaluates inports against the following criteria to determine compatibility issues. The status of this compatibility is reflected by the table colors green, orange, or red. Warnings and errors are flagged with diagnostic messages. If the **Options > Update Model** option is not selected, Root Inport Mapper determines the compatibility status by evaluating these block parameters and assigned signals:

- **Data Type** - Double, single, enum, ....
- **Complexity** - Real or complex
- **Dimensions** - Signal dimensions vs port dimensions

The screenshot shows the 'ROOT INPORT MAPPER' window. The 'MAPPING SUMMARY' section indicates that 1 scenario dataset is mapped, with 0 warnings and 0 errors. The 'SCENARIO DETAILS' section shows the source as 'PassingManeuver - slexAutotransRootInportPassingManeuver.mat' and the mode as 'Block Name'. A table below lists the mapped signals:

| STATUS | SCENARIO SIGNAL | PORT | BLOCK NAME | MAPPED SIGNAL                          |
|--------|-----------------|------|------------|----------------------------------------|
| ✓      | Throttle        | 1    | Throttle   | PassingManeuver.getElement('Throttle') |
| ✓      | Brake           | 2    | Brake      | PassingManeuver.getElement('Brake')    |

### Finalize the Inputs to the Model

Review the results of the mapping compatibility. Click the Scenario Dataset 'PassingManeuver' in the scenario dataset list. To prepare for simulation, click **Mark for Simulation**. This action applies the mapping variables to the Configuration Parameter **Data Import/Export > External Input** text box. If this text box has content, it is overwritten.

### Simulating the Model

With the changes applied you can now simulate the model and view the results. Run the model. To view the results of the simulation, double-click the Scope Block **PlotResults**.

## Alternative Workflows to Load Mapping Data

After you save the mapping definition to a model, you can automate data loading and simulation. Consider one of the following methods.

### Command Line or Script

To load data and simulate the model from the MATLAB command line, use commands similar to:

```
load('signaldata.mat');
simout = sim('model_name');
```

To automate testing and load different signal groups, consider using a script.

The following example code creates timeseries data and simulates a model after loading each signal group. It:

- Creates signal groups with variable names *In1*, *In2*, and *In3*, and saves these variables to MAT-files.
- Simulates a model after loading each signal group.

**Note** The variable names must match the import data variables in the **Configuration Parameters > Data Import/Export > Input** parameter.

```
% Create signal groups
fileName = 'testCase';
for k = 1 : 3
```

```

% Create the timeseries data
var1 = timeseries(rand(10,1));
var2 = timeseries(rand(10,1));
var3 = timeseries(rand(10,1));

%create a dataset
ds = Simulink.SimulationData.Dataset();
ds = ds.addElement(var1, 'var1');
ds = ds.addElement(var2, 'var2');
ds = ds.addElement(var3, 'var3');

% Save the data
save([fileName '_' num2str(k) '.mat'],'ds');
end
clear all

% After mapping and saving the model loop over signal groups and simulate
% Set the filename to append testcase # to
fileName = 'testCase';
% Loop backwards to preallocate
for k=3:-1:1
 % Load the MAT-file.
 load([fileName '_' num2str(k) '.mat']);

 % Simulate the model
 simOut{k} = sim('model_name');
end

```

### Use the PreLoadFcn Model Callback

When you are satisfied with the data and mapping, you can configure your model to load a MAT-file containing the signal group into the MATLAB workspace. Call the `load` function in the `PreLoadFcn` callback for the model.

- 1 After saving the MAT-file, on the **Modeling** tab, click the **Model Settings** drop-down and select **Model Properties**.
- 2 In the Model Properties window, select the **Callbacks** tab and then the `PreLoadFcn` node.
- 3 Enter a command to load the MAT-file containing the signal data. For example:

```
load d_signal_data.mat;
```

- 4 Click **OK** and save the model.

## Preview Signal Data

Preview input signal or bus data with the **Signal Preview** window. You can access this window from:

- `Simulink.SimulationData.DatasetRef` and `Simulink.SimulationData.Dataset` plot methods
- 1 Preview input signal or bus data with the **Signal Preview** window.
    - For `Simulink.SimulationData.Dataset` or `Simulink.SimulationData.DatasetRef` elements, use the plot method on the dataset.

If you view and inspect signal using the `Simulink.SimulationData.Dataset` or `Simulink.SimulationData.DatasetRef` plot method, the Signal Preview window contains an **Open Simulation Data Inspector** button. Click this button to plot the data using the Simulation Data Inspector.

- 2 Explore the plots using the **Measure** and **Zoom & Pan** sections on the toolbar.
  - In the **Measure** section, use the **Data Cursors** button to display one or two cursors for the plot. These cursors display the T and Y values of a data point in the plot. To view a data point, click a point on the plot line.
  - In the **Zoom & Pan** section, select how you want to zoom and pan the signal plots. Zooming is only for the selected axis.

| Type of Zoom or Pan                                                                                                     | Button to Click |
|-------------------------------------------------------------------------------------------------------------------------|-----------------|
| Zoom in along the T and Y axes.                                                                                         |                 |
| Zoom in along the time axis. After selecting the icon, on the graph, drag the mouse to select an area to enlarge.       |                 |
| Zoom in along the data value axis. After selecting the icon, on the graph, drag the mouse to select an area to enlarge. |                 |

| Type of Zoom or Pan                                                                                                                                                  | Button to Click                                                                   |
|----------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------|
| Zoom out from the graph.                                                                                                                                             |  |
| Fit the plot to the graph. After selecting the icon, click the graph to enlarge the plot to fill the graph.                                                          |  |
| Pan the graph up, down, left, or right. Select the icon. On the graph, hold the left mouse button and move the mouse to the area of the graph that you want to view. |  |

## Generate MATLAB Scripts for Simulation with Scenarios

After associating a scenario with the model, you can generate a MATLAB script to perform batch simulations. These scripts enable you to connect multiple sets of input signals to your Simulink model for interactive or batch simulation. You can run simulations multiple times and quickly generate data. This topic assumes that you have a scenario ready to run (see “Root Inport Mapping Scenarios” on page 72-34).

- 1 Associate your scenario with the model.
- 2 In the **SCRIPT** section, click **Generate MATLAB Script** and supply a script name when prompted.
- 3 To run the script, click **Run Script**.
- 4 To evaluate the results of the simulation, see the base workspace.

The resulting script uses the `Simulink.SimulationInput` object and `parsim` function.

### See Also

`Simulink.SimulationInput` | `parsim`

### More About

- “Root Inport Mapping Scenarios” on page 72-34

## Create and Use Custom Map Modes

You can create custom map modes to supplement the map modes that the Root Inport Mapper tool provides (see “Choose a Map Mode” on page 72-8).

For a summary of the other steps involved in using the Root Inport Mapper tool, see “Import and Mapping Workflow” on page 72-7.

### Create Custom Mapping File Function

If you do not want to use the map modes in the Root Inport Mapper tool, create a custom mapping file function. For example, consider creating a custom mapping file function if:

- Your signal data contains a common prefix that is not in your model.
- You want to map a signal explicitly.

When the data contains a signal name that does not match one of the block names, a custom mapping function is useful for block name mapping.

For examples, see these files in the folder *matlabroot/help/toolbox/simulink/examples* (open).

| File                            | Description                                                                                  |
|---------------------------------|----------------------------------------------------------------------------------------------|
| BlockNameIgnorePrefixMap.m      | Custom mapping file function that ignores the prefix of a signal name when importing signals |
| BlockNameIgnorePrefixData.mat   | MAT-file of signal data to be imported                                                       |
| ex_BlockNameIgnorePrefixExample | Model file into which you can import and map data                                            |

In addition, see “Using Mapping Modes with Custom-Mapped External Inputs”.

To create a custom mapping file function:

- 1 Create a MATLAB function with these input parameters:
  - Model name
  - Signal names specified as a cell array of character vectors
  - Signals specified as a cell array of signal data
- 2 In the function, call the `getRootInportMap` function to create a variable that contains the mapping object (for an example, see `BlockNameIgnorePrefixMap.m`).
- 3 Save and close the MATLAB function file.
- 4 Add the path for the new function to the MATLAB path.

To use the custom mapping file function:

- 1 Open the model that you want to import data to (for example, `ex_BlockNameIgnorePrefixExample`).
- 2 Open the Configuration Parameters dialog box for the model and select the **Data Import/Export** pane.

- 3 In the **Load from workspace** section, click **Connect Input**.
- 4 Import your signal (for example, `BlockNameIgnorePrefixData.mat`).
- 5 In the **MAP TO MODEL** section of the toolbar, click **Custom**.
- 6 In the **Custom** text box, select the MATLAB function file (for example, `BlockNameIgnorePrefixMap.m`) using the browser.

By default, this text box contains `slexcustomMappingMyCustomMap`, which is the custom function for “Attaching Input Data to External Inputs via Custom Input Mappings”.

---

**Tip** The Root Inport Mapper tool parses your custom code. Parsing reorders output alphabetically and verifies that data types are consistent.

---

- 7 Click **Options** and select the **Compile** check box.
- 8 Click **Map**.

The model is compiled and the Root Inport Mapper tool gets updated.

To understand the mapping results, see “Understand Mapping Results” on page 72-20.

- 9 Save and close the model.

After you save the mapping definition for a model, you can automate data loading. The next time that you load input data of the same signal group into the workspace, the model uses the mapping definition during simulation. For more information, see “Alternative Workflows to Load Mapping Data” on page 72-27.

### Custom Mapping Modes Similar to Simulink Modes

If your custom mapping mode is similar to a Simulink mapping mode, use the `getSlRootInportMap` function in your custom mapping file function to perform the data mapping.

For an example of a custom mapping function that uses this function, see “Using Mapping Modes with Custom-Mapped External Inputs”.

### Command-Line Interface for Input Variables

Use the `getInputString` function to supply a set of input variables to:

- The `sim` command
- A list of input variables that you can paste in the **Configuration Parameters > Data Import/Export > Input** parameter

## Root Inport Mapping Scenarios

### In this section...

- “Open Scenarios” on page 72-34
- “Save Scenarios” on page 72-35
- “Open Existing Scenarios” on page 72-35
- “Work with Multiple Scenarios” on page 72-36

Use the Root Inport Mapper tool to create scenarios, save scenarios, and load previously saved scenarios. The Root Inport Mapper tool uses scenarios to save a snapshot of the current state of the imported and mapped signals in an MLDATX file. A scenario file contains information about the:

- Location of signal files (MAT-file or Microsoft Excel files)
- Location of the model
- Map mode
- Mapping options
- Mapped state

When sharing scenario files, include the scenario file and signal files (MAT-file or Microsoft Excel). Place the signal files in the last known location (where you used the Root Inport Mapper tool most recently) or the MATLAB path.

### Open Scenarios

To open an existing scenario, click **Open**. If you are working in another scenario, the Root Inport Mapper tool displays a message.

| To...                                                                                                                   | Click...      |
|-------------------------------------------------------------------------------------------------------------------------|---------------|
| Open a new scenario. Remove the existing scenario without saving it.                                                    | <b>No</b>     |
| Cancel opening a scenario.                                                                                              | <b>Cancel</b> |
| To save the existing scenario, click <b>Yes</b> . Then click the <b>Open</b> button again to open an existing scenario. | <b>Yes</b>    |

## Save Scenarios

When the **Save** icon turns blue or when the model name in the title bar is has an asterisk (\*), you can save a scenario.

- 1 On the Root Inport Mapper toolbar, select **Save > Save As**.
- 2 In the Save As dialog box, browse to a writable folder, specify a scenario file name, and then click **Save**.
  - To save the signals and the scenario file, click **Yes**.

If a MAT-file is already associated with the scenario, the tool appends the base workspace variables to this file.

Save a scenario to an existing file (the file from which the scenario was last loaded):

- 1 On the Root Inport Mapper tool toolbar, click **Save**.
- 2 Browse to the `.mldatx` file in which to save the scenario, and then click **Save**.

If you have not saved the signals from the scenario, the tool prompts you to save the signals to a MAT-file.

| Goal                                                      | Action     |
|-----------------------------------------------------------|------------|
| Overwrite the existing <code>.mldatx</code> file.         | <b>Yes</b> |
| Exit the dialog box. The tool does not save the scenario. | <b>No</b>  |

## Open Existing Scenarios

You can open previously saved scenario files in one of the following ways:

- Double-click the previously saved scenario file (`*.mldatx`). The Root Inport Mapper tool opens and loads the model. Alternatively, right-click the file and select **Open**.
  - When loading scenario files, the tool looks for the associated model and MAT-file or Microsoft Excel file in the last known location, and then looks on the MATLAB path. If the tool cannot find the model or signal files in these two locations, an error occurs.
  - If the previously saved scenario has mapped signals, when you open the scenario, the tool applies the mapping. Also, the tool adds the signals to the base workspace so that you can simulate the model.
- Open the Root Inport Mapper tool for the model, click **Open**, and select the previously saved scenario file.

If the model is already open, the new scenario overwrites the existing scenario for the model. If there are unsaved changes in the open scenario, respond to the prompt.

| Goal                                                                            | Click      |
|---------------------------------------------------------------------------------|------------|
| Save the existing scenario and associated data before loading the new scenario. | <b>Yes</b> |

| Goal                                                                                                                    | Click |
|-------------------------------------------------------------------------------------------------------------------------|-------|
| Open the new scenario without saving the existing scenario. This option also removes the data in the existing scenario. | No    |

## Work with Multiple Scenarios

You can open and work with multiple scenario files simultaneously. Working with multiple scenario files lets you view, edit, group, and nest multiple scenario files. Use multiple scenario files to test more complex systems with interrelated components.

As you open each multiple scenario, the Root Inport Mapper tool adds its data set to the SCENARIO DATASET section. If the scenario contains only signals, convert the signals to the `Simulink.SimulationData.Dataset` format:

- 1 To convert the signals to a `Simulink.SimulationData.Dataset` format, use the `convertToSLDataset` function.
- 2 Link to the new data set. You do not need to reopen the scenario.

## Load Data with Interchangeable Scenarios

To easily exchange scenarios within models, use the Signal Editor block. This block displays, creates, edits, and switches scenarios, where scenarios contain information about groups of signals, such as:

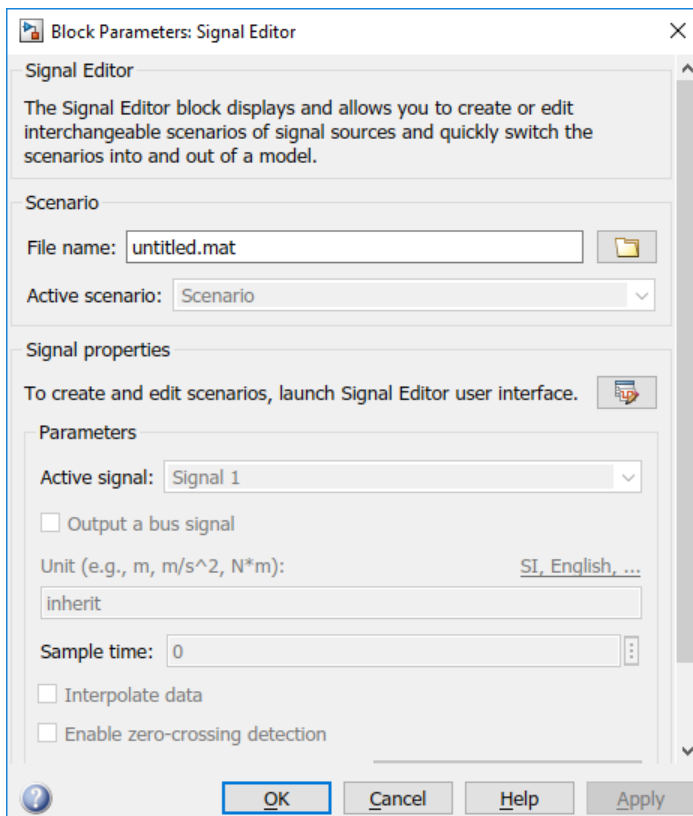

- Location of signal files (MAT-file or Microsoft Excel files)
- Location of the associated model
- Map mode
- Mapping options
- Mapped state

Use scenarios to exchange groups of signals in your model, such as when running multiple simulations or working with test harnesses.

**Tip** The Signal Editor displays, creates, and edits interchangeable scenarios and is better integrated with other Simulink capabilities such as units, signals in MAT-files, and signal edit and creation. Consider using the Signal Editor block in models where you use the Signal Builder block. The Signal Builder block is not recommended to work with signal groups. For more information on benefits of the Signal Editor block, see “Replace Signal Builder Block with Signal Editor Block” on page 72-39.

## Load Data with Interchangeable Scenarios Using Signal Editor Block

The Signal Editor block gets groups of signals (scenarios) from MAT-files.

The block has three sections.

- **Scenario** — Set up a scenario by specifying the MAT-file containing the list of scenarios and selecting the active (current) scenario.
- **Signal properties** — Use the Signal Editor user interface to examine, create, and edit scenarios and associated signals. The Signal Editor user interface organizes the signals according to the scenarios that contain them.
- **Parameters** — Select the active signal to be output and set up characteristics, such as unit, sample time, linear interpolation, and so forth, for the active signal. To change the active signal, use the drop-down list.

## Explore the Signal Editor Block

This example shows how to use the Signal Editor block with the “Parallel Simulations Using Parsim: Parameter Sweep in Normal Mode” example, which runs multiple simulations of a Monte Carlo study in parallel using Parallel Computing Toolbox. Parallel execution leverages the multiple cores of your host machine to run many simulations more quickly. If you do not have Parallel Computing Toolbox, this example runs the simulations in serial. The model simulates vehicle dynamics based on the interaction between road and suspension for different road profiles. This example stores its road profile scenarios in the `matlab\toolbox\ssldemo_suspn_3dof_sigData.mat` file.

- 1 In the `ssldemo_suspn_3dof` model, open the Signal Editor (named Road Profiles) block.

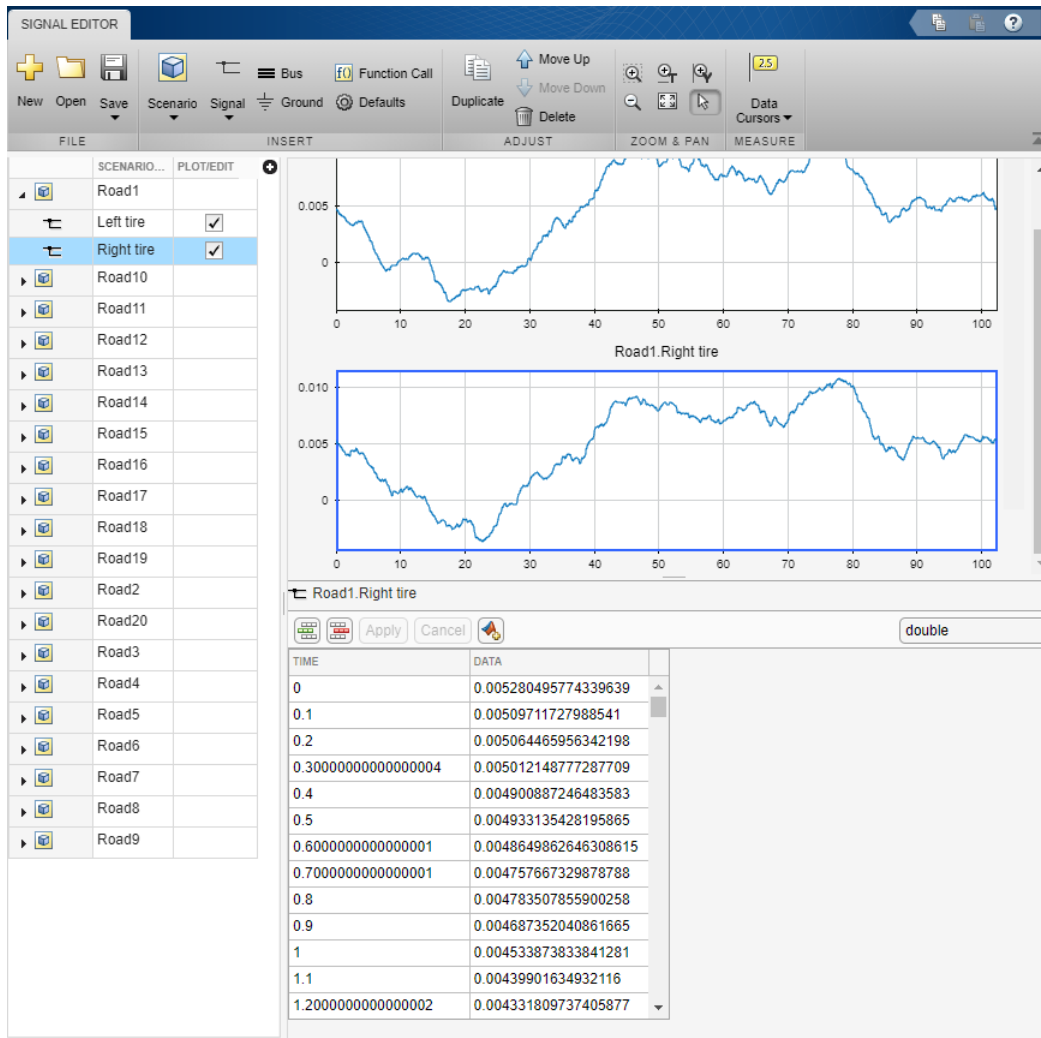

The Signal Editor block **File Name** parameter contains the MAT-file `ssldemo_suspn_3dof_sigData.mat`.

Observe that:

- **Active scenario** automatically sets to the first scenario, `Road1`. This setting means that the remainder of the block parameters apply to the signals in that scenario. To change the active scenario, select a new scenario from the list of scenarios.
- **Active signal** automatically sets to the first signal `Left_tire` in the active scenario, `Road1`. This setting means that the remainder of the settings in the **Parameter** section apply to the active signal. To change the active signal, select a new signal from the list of signals.

- 2 Explore and edit the scenarios in the MAT-file. Click .

The Signal Editor user interface displays a list of scenarios contained in the MAT-file. Explore and change the scenarios and associated signals. If you make changes, you can save them back to the MAT-file by clicking **Save**.

The output from the block is the active signal data. To simulate the model sequentially using each scenario and signal, use the `parsim` function. This function simulates dynamic systems multiple times in parallel or serial. For an example on how to use `parsim`, see “Parallel Simulations Using Parsim: Parameter Sweep in Normal Mode”.

## Replace Signal Builder Block with Signal Editor Block

The Signal Editor provides similar functionality to the Signal Builder block, but with greater flexibility. Replace the Signal Builder with the Signal Editor block. The benefits of Signal Editor block include:

- Signal data storage in a MAT-file outside the model
- Signal editing and creation
- Support for Simulink signal attributes, such as dimension and complexity
- Support for standard Simulink data types, including bus and fixed-point
- Unique signal-level data types for outputs

- Multiple rates for outputs
- Support for Simulink units
- Zero crossing on page 3-10 detection and data interpolation unique to each signal

To port signal data and properties from the Signal Builder block to Signal Editor block, use the `signalBuilderToSignalEditor` function. For the current model, this function stores to a MAT-file the signal data and properties from an existing Signal Builder block, adds a Signal Editor block to the current model, and modifies the Signal Editor block to reference the new MAT-file.

For an example see “Replace Signal Builder Block with Signal Editor Block”.

### Considerations

Converting from the Signal Builder block to the Signal Editor block is relatively straightforward using the `signalBuilderToSignalEditor` function. However, take into account these considerations:

- Internal storage format and preprocessing of data differs between the Signal Builder and Signal Editor blocks. When using the variable step solver, different simulation time steps and mismatched output occur in the two blocks. To minimize the difference between the outputs of both blocks, you can:
  - Reduce the value of **Max step size** of the variable step solver.
  - Insert more data points in the input signal of the Signal Editor block to better represent its shape.
  - Use the fixed-step solver or set the sample time for both blocks to the same discrete sample time (greater than 0). For more information on discrete sample times, see “Discrete Sample Time” on page 7-13.
- The Signal Builder block supports only doubles. To change the data type or otherwise change the signals after conversion, click the  button in the Signal Editor block to access the Signal Editor user interface.

### Get Number of Scenarios and Signals

To programmatically get the total number of scenarios and signals in the Signal Editor block, use the `get_param` `NumberOfScenarios` and `NumberOfSignals` properties. The values of these properties are character vectors. To convert these values to doubles, use the `str2double` function.

`NumberOfScenarios` and `NumberOfSignals` are read-only properties available only through `get_param`. The block dialog box does not provide these values.

## Export Simulation Data

### In this section...

“Simulation Data” on page 73-2

“Approaches for Exporting Signal Data” on page 73-2

“Enable Simulation Data Export” on page 73-4

“View Logged Data Using Simulation Data Inspector” on page 73-4

“Memory Performance” on page 73-5

Exporting (logging) simulation data provides a baseline for analyzing and debugging a model. Use standard or custom MATLAB functions to generate simulated system input signals and to graph, analyze, or otherwise postprocess the system outputs.

### Simulation Data

Simulation data can include any combination of signal, time, output, state, and data store logging data.

Exporting simulation data involves saving signal values to the MATLAB workspace or to a MAT-file during simulation for later retrieval and postprocessing. Exporting data is also known as “data logging” or “saving simulation data.”

You can have data logged in several formats:

- `Simulink.SimulationData.Dataset`
- Array
- Structure
- Structure with time
- MATLAB timeseries
- `ModelDataLogs`

---

**Note** The `ModelDataLogs` format is supported for backward compatibility. Starting in R2016a, you cannot log data in the `ModelDataLogs` format. In R2016a or later, when you open a model from an earlier release that had used `ModelDataLogs` format, the model logs data in `Dataset` format.

---

Consider converting data logged in other formats to `Dataset` format to simplify post-processing. For more information, see “Dataset Conversion for Logged Data” on page 73-12.

You can also use exported data as the input for simulating a model.

### Approaches for Exporting Signal Data

Exporting simulation data often involves exporting signal data. You can use various approaches for exporting signal data.

| Export Approach                                            | Usage                                                                                                                                                                                                                                                                                            | Documentation                                                                                                                                                                       |
|------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Connect a Scope block to a signal.                         | <p>If you use a Scope block for viewing results during simulation, consider also using the Scope block to export data.</p> <p>Save output at a sample rate other than the base sample rate.</p> <p>Scopes store data and can be memory intensive.</p>                                            | Scope                                                                                                                                                                               |
| Connect a signal to a To File block.                       | <p>Consider using a To File block for exporting large amounts of data.</p> <p>Save output at a sample rate other than the base sample rate.</p> <p>Use the MAT-file only after the simulation has completed.</p>                                                                                 | To File                                                                                                                                                                             |
| Connect a signal to a To Workspace block.                  | <p>Document in the diagram the workspace variables used to store signal data.</p> <p>Save output at a sample rate other than the base sample rate.</p>                                                                                                                                           | To Workspace                                                                                                                                                                        |
| Connect a signal to a root-level Output block.             | Consider using this approach for logging data in a top-level model, if the model already includes an Output block.                                                                                                                                                                               | Output                                                                                                                                                                              |
| Set the signal logging properties for a signal.            | <p>Use signal logging to avoid adding blocks, such as Scope, To File, and To Workspace blocks, to your model.</p> <p>Log signals based on individual signal rates.</p> <p>Data is available when simulation is paused or completed.</p> <p>Use signal logging to log array of buses signals.</p> | "Export Signal Data Using Signal Logging" on page 73-43                                                                                                                             |

## Enable Simulation Data Export

To export the states and root-level output ports of a model to the MATLAB base workspace during simulation of the model, use one of these interfaces:

- **Configuration Settings > Data Import/Export** pane (for details, see “Model Configuration Parameters: Data Import/Export”)
- `sim` command

In both approaches, specify:

- The kinds of simulation data that you want to export:
  - Signal logging
  - Time
  - Output
  - State or final state
  - Data store

Each kind of simulation data export has an associated default variable. You can specify your own variables for the exported data.

- The characteristics of the logged data, including:
  - “Data Format for Logged Simulation Data” on page 73-7
  - “Limit Data Logged” on page 73-47
  - “Samples to Export for Variable-Step Solvers” on page 73-40

## View Logged Data Using Simulation Data Inspector

To inspect exported simulation data interactively, consider using the **Simulation Data Inspector**.

The Simulation Data Inspector has some limitations on the kinds of logged data that it displays. See “View Data in the Simulation Data Inspector” on page 29-2.

## Memory Performance

### Optimization for Logged Data

When exporting simulation data in a simulation mode other than rapid accelerator, Simulink optimizes memory usage in the following situations.

- When time steps happen at regular intervals, Simulink uses compressed time representation. Simulink stores the value for the first timestamp, the length of the interval (time step), and the total number of timestamps.
- When multiple signals use identical timestamp sequences, the signals share a single stored timestamp sequence. Sharing a single stored timestamp can reduce memory use for logged data by as much as a factor of two. The difference in memory performance can be a critical performance factor, particularly when logging bus signals that have thousands of bus elements.

### Logging to Persistent Storage

You can encounter memory issues when you log many signals in a long simulation that has many time steps. Logging to persistent storage can address this kind of memory issue.

To log to persistent storage, in the **Configuration Parameters > Data Import/Export** pane, select **Log Dataset data to file** option. Specify the kinds of logging (for example, signal logging and states logging).

- For logging output and states data, set the **Format** parameter to **Dataset**.
- If you select the **Final states** parameter, clear the **Save final operating point** parameter.

Using a `Simulink.SimulationData.DatasetRef` object to access signal logging and states logging data loads data into the model workspace incrementally. Accessing data for other kinds of logging loads all the data at once.

For details, see “Log Data to Persistent Storage” on page 73-33.

## Data Format for Logged Simulation Data

### In this section...

“Data Format for Block-Based Logged Data” on page 73-7

“Data Format for Model-Based Logged Data” on page 73-7

“Signal Logging Format” on page 73-7

“Logged Data Store Format” on page 73-7

“Time, State, and Output Data Format” on page 73-7

### Data Format for Block-Based Logged Data

You can use the Scope, To File, or To Workspace blocks to export simulation data. Each of these blocks has a data format parameter.

### Data Format for Model-Based Logged Data

The data format for model-based exporting of simulation data specifies how Simulink stores the exported data.

Simulink uses different data formats, depending on the kind of data that you export. For details, see:

- “Signal Logging Format” on page 73-7
- “Logged Data Store Format” on page 73-7
- “Time, State, and Output Data Format” on page 73-7

### Signal Logging Format

Signal logging always uses `Dataset` format. You can specify whether to log data for individual signals as `timeseries` or `timetable` objects.

To control how `Dataset` elements are saved, set the **Dataset signal format** configuration parameter. The default is `timeseries`. For details, see “Dataset signal format”.

The **Dataset signal format** parameter applies to signal logging, as well as output and states data when you set the **Format** parameter to `Dataset`.

### Logged Data Store Format

When you log data store data, Simulink uses a `Simulink.SimulationData.Dataset` object.

For details, see “Accessing Data Store Logging Data” on page 74-30.

### Time, State, and Output Data Format

For exported time, states, and output data, use one of the following formats:

- “Dataset” on page 73-8 (default)

- “Array” on page 73-8
- “Structure with Time” on page 73-9
- “Structure” on page 73-10

If you select the **Configuration Parameters > Data Import/Export > Output** check box, Simulink logs fixed-point data as double. To log fixed-point data, consider using one of these approaches:

- Signal logging — For details, see “Export Signal Data Using Signal Logging” on page 73-43.
  - 1 In the Simulink Editor, select one or more signals.
  - 2 Click **Log Signals**.
- To File block
- To Workspace block — In the To Workspace Block Parameters dialog box, enable the **Log fixed-point data as a fi object** parameter.

For information about the format for logged final state data, see “State Information” on page 73-77.

### Dataset

By default, time, states, and outputs are logged using the Dataset format. The Dataset format:

- Stores logged data in `timeseries` or `timetable` objects. You can work with data saved in a `timeseries` or `timetable` object in MATLAB without a Simulink license.
- Supports logging multiple data values for a given time step, which can be required for logging data in a For Iterator Subsystem, a While Iterator Subsystem, and Stateflow.
- Does not support logging states inside a function-call subsystem or during rapid accelerator simulations.
- Does not support code generation.

Signal logging always uses the Dataset format. Logging states and output data using the Dataset format allows you to post-process simulation data without writing custom code for different types of logged data. When you log states and outputs using the Dataset format, the data also automatically streams to the Simulation Data Inspector during simulation.

### Array

If you select this Array option, Simulink saves the states and outputs of a model in a state and in an output array, respectively.

The state matrix has the name specified in the **Configuration Parameters > Data Import/Export** pane (for example, `xout`). Each row of the state matrix corresponds to a time sample of the states of a model. Each column corresponds to an element of a state. For example, suppose that your model has two continuous states, each of which is a two-element vector. Then the first two elements of each row of the state matrix contain a time sample of the first state vector. The last two elements of each row contain a time sample of the second state vector.

The model output matrix has the name specified in the **Configuration Parameters > Data Import/Export** pane (for example, `yout`). Each column corresponds to a model output port, and each row to the outputs at a specific time.

---

**Note** Use array format to save your model outputs and states only if the logged data meets *all* these conditions:

- Data is all scalars or all vectors (or all matrices for states)
- Data is all real or all complex
- Data all has the same data type
- Data includes bus signals

If your model outputs and states do not meet these conditions, use the **Structure** or **Structure with time** output formats (see “Structure with Time” on page 73-9).

---

### Structure with Time

If you select this format, Simulink saves the model states and outputs in structures that have their names specified in the **Configuration Parameters > Data Import/Export** pane. By default, the structures are `xout` for states and `yout` for output.

The structure used to save outputs has two top-level fields:

- `time`  
Contains a vector of the simulation times.
- `signals`  
Contains an array of substructures, each of which corresponds to a model output port.

Each substructure has four fields:

- `values`  
Contains the outputs for the corresponding output port.
  - If outputs are scalars or vectors — `values` field is a matrix each of whose rows represent an output at the time specified by the corresponding time vector element.
  - If the outputs are matrix (2-D) values — `values` field is a 3-D array of dimensions M-by-N-by-T. M-by-N is the dimensions of the output signal and T is the number of output samples.
  - If T = 1 — MATLAB drops the last dimension. Therefore, the `values` field is an M-by-N matrix.
- `dimensions`  
Specifies the dimensions of the output signal.
- `label`  
Specifies the label of the signal connected to the output port, S-Function block, or the type of state (continuous or discrete). The label is `DSTATE` or `CSTATE`, except for S-Function block state labels. For S-Function block state labels for discrete states, the label is the name of the state (instead of `DSTATE`).
- `blockName`  
Specifies the name of the corresponding output port or block with states.
- `inReferencedModel`  
If the `signals` field records the final state of a block that resides in the referenced model, contains a value of 1. Otherwise, the value is false (0).

The following example shows the structure-with-time format for a nonreferenced model.

```
xout.signals(1)

ans =

 values: [296206x1 double]
 dimensions: 1
 label: 'CSTATE'
 blockName: 'vdp/x1'
inReferencedModel: 0
```

The structure used to save states has a similar organization. The states structure has two top-level fields:

- `time`

The `time` field contains a vector of the simulation times.

- `signals`

The field contains an array of substructures, each of which corresponds to one of the states of the model.

Each `signals` structure has four fields: `values`, `dimensions`, `label`, and `blockName`. The `values` field contains time samples of a state of the block specified by the `blockName` field. The `label` field for built-in blocks indicates the type of state: either `CSTATE` (continuous state) or `DSTATE` (discrete state). For S-Function blocks, the label contains whatever name is assigned to the state by the S-Function block.

The time samples of a state are stored in the `values` field as a matrix of values. Each row corresponds to a time sample. Each element of a row corresponds to an element of the state. If the state is a matrix, the matrix is stored in the `values` array in column-major order. For example, suppose that the model includes a 2-by-2 matrix state and that 51 samples of the state are logged during a simulation run.

The `values` field for this state would contain a 51-by-4 matrix. Each row corresponds to a time sample of the state, and the first two elements of each row correspond to the first column of the sample. The last two elements correspond to the second column of the sample.

---

**Note** Simulink can read back simulation data saved to the MATLAB workspace in the `Structure` with `time` output format. See “Examples of Specifying Signal and Time Data” on page 71-42 for more information.

---

## Structure

This format is the same as for `Structure` with `time` output format, except that Simulink does not store simulation times in the `time` field of the saved structure.

## Dataset Conversion for Logged Data

### In this section...

“Why Convert to Dataset Format?” on page 73-12

“Results of Conversion” on page 73-12

“Dataset Conversion Limitations” on page 73-14

### Why Convert to Dataset Format?

You can use the `Simulink.SimulationData.Dataset` constructor to convert a MATLAB workspace variable that contains data that was logged in one of these formats to `Dataset` format:

- Array
- Structure
- Structure with time
- MATLAB timeseries
- `ModelDataLogs`

Converting data from other Simulink logging formats to `Dataset` format simplifies writing scripts to post-process data logged. For example, a model with multiple To Workspace blocks can use different data formats. Converting the logged data to `Dataset` format avoids the need to write special code to handle different formats.

Different simulation modes have different levels of support for data logging formats. Switching between normal and accelerator modes can require changes to the logging formats used.

The conversion to `Dataset` format also makes it easier to take advantage of features that require `Dataset` format. You can easily convert data logged in earlier releases that used a format other than `Dataset` to work well with `Dataset` data in a more recent release.

The `Dataset` format:

- Uses MATLAB `timeseries` objects to store logged data, which allows you to work with logging data in MATLAB without a Simulink license. For example, to manipulate the logged data, you can use MATLAB time-series methods such as `filter`, `detrend`, and `resample`.
- Supports logging multiple data values for a given time step, which is important for Iterator subsystem and Stateflow signal logging.

By default, the resulting `Dataset` object uses the variable name as its name. You can use a name-value pair to specify a `Dataset` name.

You can use the `concat` method to combine `Dataset` objects into one concatenated `Dataset` object.

### Results of Conversion

`Dataset` objects hold data as elements. To display the elements of a `Dataset` variable, enter the variable name at the MATLAB command prompt. The elements of `Dataset` objects are different types, depending on the data they store. For example, signal logging stores data as `Simulink.SimulationData.Signal` elements and state logging in `Dataset` format stores data as

`Simulink.SimulationData.State` elements. Each element holds data as a MATLAB time-series object. At conversion, the elements and time-series field populate as much as possible from the converted object.

| Format                            | Conversion Result Notes                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|-----------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| MATLAB time series                | <p>If you log nonbus data, during conversion, the software first adds the data as a <code>Simulink.SimulationData.Signal</code> object. It then adds that object as an element of the newly created <code>Dataset</code>.</p> <p>If you log bus data in time-series format, one time series corresponds to each element of a bus. Converting arranges the logged data as a structure with time-series objects as leaf nodes. This structure hierarchy matches the bus hierarchy. Conversion of this type of structure of time-series objects adds the whole structure to a <code>Simulink.SimulationData.Signal</code> object. It then adds that object as an element of the data set.</p> <p>Time-series objects hold relevant information such as block path and timestamps. The conversion tries to preserve this information.</p>                                                                      |
| Structure and structure with time | <p>Structure and structure with time formats do not always contain as much information as if you log in <code>Dataset</code> format. However, before converting structure and structure with time formats, the data structure must have <code>time</code> and <code>signals</code> fields.</p> <p>Conversion populates a <code>Simulink.SimulationData.Signal</code> object with the structure and adds it as an element of the data set. If other information is available, converting also adds it to the element or time-series values. For example, if the structure has a field called <code>blockName</code>, converting adds it to the block path. Otherwise, the block path is empty.</p> <p>When scope data is logged in structure format, the logged structure has a <code>PlotStyle</code> field. The software uses this field to set the interpolation in the <code>Dataset</code> object.</p> |
| Array                             | <p>Arrays contain little information. For example, there is no block path information.</p> <p>Conversion adds the array to a <code>Simulink.SimulationData.Signal</code> object and adds it as an element of the <code>Dataset</code> object. The conversion leaves unavailable information such as block path and timestamp fields as either empty or with default values.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

| Format        | Conversion Result Notes                                                                                                                                   |

| ModelDataLogs | <p>Converts data from ModelDataLogs format to Dataset format.</p> <hr/> <p><b>Note</b> The ModelDataLogs format is no longer used for signal logging.</p> |

## Dataset Conversion Limitations

- Converting logged data to Dataset format results in a Dataset object that contains all the information that the original logged data included. However, if there is no corresponding information for the other Dataset properties, the conversion uses default values for that information.
- When you convert data for a variable-size signal logged using the To Workspace block, the information in the valueDimensions field of the structure is lost in the conversion.
- When you log a bus signal in array, structure, or structure with time formats, the logged data is organized with:
  - The first column containing the data for the first signal in the bus
  - The second column containing data for the second bus signal, and so on

When you convert that data to Dataset, the Dataset preserves that organization. But if you log the bus signal in Dataset format without conversion, the conversion captures the bus data as a structure of time-series objects.

- If the logged data does not include a time vector, when you convert that data to Dataset, the conversion inserts a time vector. There is one time step for each data value. However, the simulation time steps and the Dataset time steps can vary.
- Dataset format ignores the specification of frame signals. Conversion of structure or structure with time data to Dataset reshapes the data for logged frame signals.

### Convert Workspace Data to Dataset

This example shows how to convert MATLAB time-series data to `Dataset` format. `myvdp_timeseries` is the `vdp` model with two To Workspace blocks configured for `simout` and `simout1` logging data in MATLAB timeseries format. Consider using a procedure like this one if you have models that use To Workspace blocks to log data to MATLAB timeseries format.

Use the `Simulink.SimulationData.Dataset` constructor to convert the MATLAB timeseries data to `Dataset` format and then concatenate the two data sets.

- 1 Starting with the `vdp` model, add two To Workspace blocks to the model as shown.
- 2 Set the **Save format** parameter of both blocks. Set `Timeseries`.
- 3 Save the model as `myvdp_timeseries`.
- 4 Simulate the model.

The simulation logs data using the To Workspace blocks.

- 5 Access the signal logging format, `logout`.

```
logout
```

```
logout =
```

```
Simulink.SimulationData.Dataset
Package: Simulink.SimulationData
```

```
Characteristics:
 Name: 'logout'
 Total Elements: 2
```

```
Elements:
 1: 'x1'
 2: 'x2'
```

```
-Use get or getElement to access elements by index or name.
-Use addElement or setElement to add or modify elements.
```

Methods, Superclasses

- 6 Convert the MATLAB time-series data from both To Workspace blocks to Dataset.

```
ds = Simulink.SimulationData.Dataset(simout);
ds1 = Simulink.SimulationData.Dataset(simout1);
```

*ds* is the variable name of the first To Workspace block data. *ds1* is the variable name of the second To Workspace block data.

- 7 Concatenate both datasets into *dsfinal*. Observe that the format of *dsfinal* matches that of *logout*.

```
dsfinal = ds.concat(ds1)
```

```
dsfinal =
```

```
Simulink.SimulationData.Dataset
Package: Simulink.SimulationData
```

```
Characteristics:
 Name: 'simout'
 Total Elements: 2
```

```
Elements:
 1: 'x1'
 2: 'x2'
```

```
-Use get or getElement to access elements by index or name.
-Use addElement or setElement to add or modify elements.
```

Methods, Superclasses

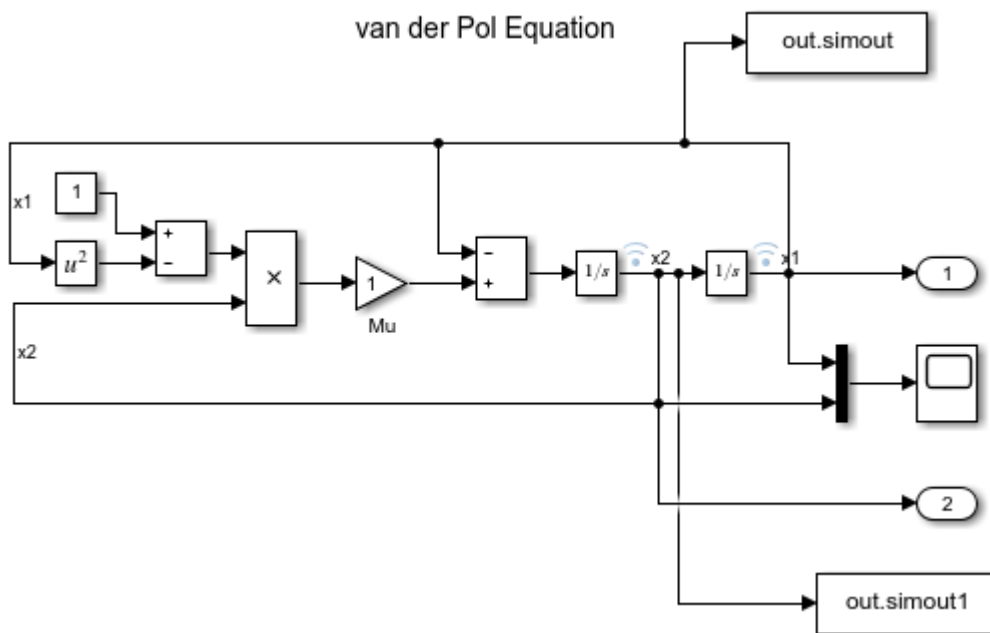

## Convert Structure Without Time to Dataset

This example shows how to convert structure without time data to Dataset format. *myvdp\_structure* is the vdp model with two To Workspace blocks configured for *simout* and *simout1* logging data in structure format, as shown.

If you have models that use To Workspace blocks to log data to structure format, consider using a procedure like this one to convert them to Dataset format.

- 1 Starting with the vdp model, add two To Workspace blocks to the model as shown.

- 2 In the **Save format** parameter of both blocks, select Structure.

- 3 Enable signal logging for the two signals going to the two To Workspace blocks to log in Ds format.
- 4 Save the model as `myvdp_structure`.
- 5 Simulate the model.

The simulation logs data using the To Workspace blocks.

- 6 Convert the structure data from both To Workspace blocks to `Dataset`.

```
ds = Simulink.SimulationData.Dataset(simout);
ds1 = Simulink.SimulationData.Dataset(simout1);
```

`simout` is the variable name of the first To Workspace block data. `simout1` is the variable name of the second To Workspace block data.

With the conversion of structure without time or an array, time starts at `t=0` and increments by 1.

- 7 Get the values of the first element in `ds`.

```
ds.get(1).Values.Time
```

```
ans =
```

```
0
1
2
3
.
.
.
61
62
63
```

- 8 Get the time values of the first element from signal logging.

```
logout.get(1).Values.Time
```

```
ans =
```

```
0
0.0001
0.0006
0.0031
.
.
.
19.2802
19.6802
20.0000
```

- 9 Observe the discrepancy in timestamps between
  - Data logged in structure without time that you convert to `Dataset` format
  - Data logged in `Dataset` format

## Programmatically Access Logged Dataset Format Data

When you use the default Dataset signal logging format, Simulink saves the logging data in a `Simulink.SimulationData.Dataset` object. For information about extracting signal data from that object, see the `Simulink.SimulationData.Dataset` reference page.

The `Simulink.SimulationData.Dataset` object contains a `Simulink.SimulationData.Signal` object for each logged signal.

For bus signals, the `Simulink.SimulationData.Signal` object contains a structure of MATLAB timeseries objects.

The `Simulink.SimulationData.Dataset` class provides two methods for accessing the signal logging data and its associated information.

| Name                                                                                                                                      | Description                                                                                  |
|-------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------|
| <code>get</code><br>You can also use the <code>getElement</code> method, which shares syntax and behavior as the <code>get</code> method. | Get element or collection of elements from the dataset, based on index, name, or block path. |
| <code>numElements</code>                                                                                                                  | Get number of elements in the dataset.                                                       |

For example of accessing signal logging data that uses the Dataset format, see `Simulink.SimulationData.Dataset`.

### Access Array of Buses Signal Logging Data

Signal logging data for an array of buses uses Dataset signal logging format.

The general approach to access data for a specific signal in an array of buses is:

- 1 Use a `Simulink.SimulationData.Dataset.get` (or `getElement`) method to access a specific signal in the logged data (by default, the `logouts` variable).
- 2 To get the values, index within the array of buses.
- 3 Index again to get data for a specific bus.

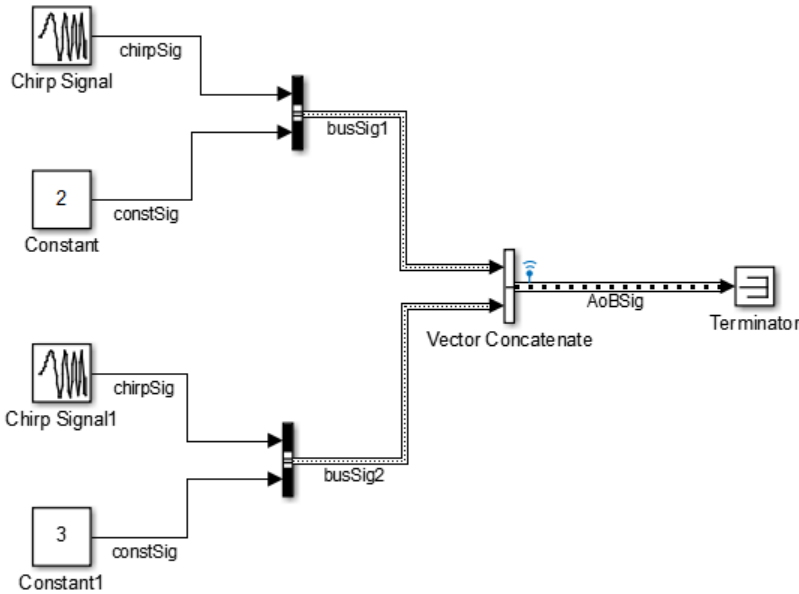

For example, to obtain the signal logging data for the `Constant6` block in the `ex_log_nested_aob` model, for the `topBus` signal that feeds the `Terminator` block:

```
logouts.getElement('topBus').Values.a(2,2).firstConst.data
```

Here are additional examples of accessing array of buses signal logging data. For another example that shows how to log array of buses data, see `sldemo_mdref_bus`.

### Simple Array of Buses

The `ex_log_simple_aob` model includes an array of buses signal `AoBSig` that combines two bus signals (`busSig1` and `busSig2`).

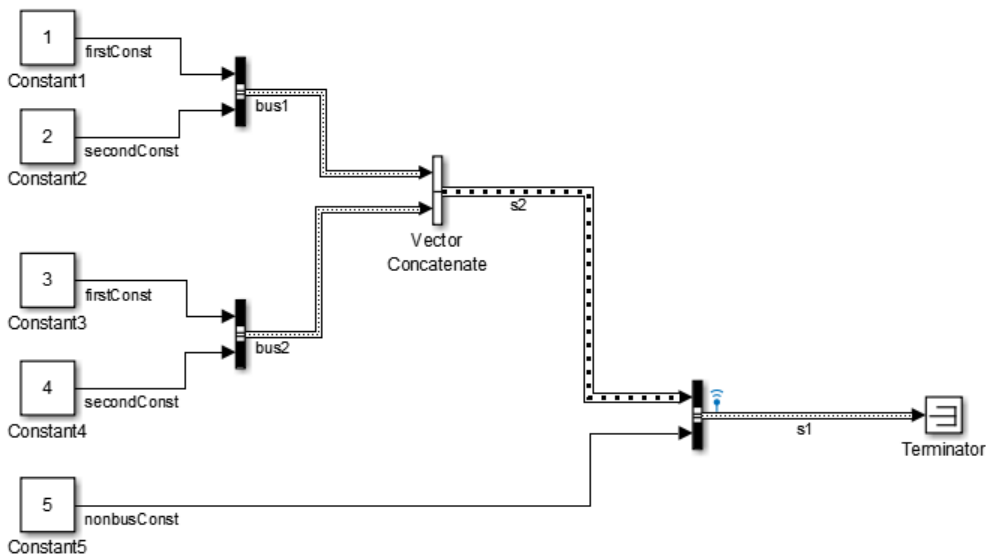

To access the signal logging data for the array of buses signal, navigate through the structure hierarchy and use an index to access a specific node. This example shows navigation to the `chirpSig` signal value in `busSig2`.

```
logout.getElement('AoBSig').Values(2).chirpSig.Data
```

```
ans=
 0
 0.9585
```

### Array of Buses in a Bus

The `ex_log_aob_in_bus` model has an array of buses (`s2`) that feeds into bus `s1`.

This example shows navigation to the Constant3 block, which is a signal in bus2.

```
logout.getElement('s1').Values.s2(2).firstConst.Data
```

```
ans=
```

```
3
3
3
3
3
3
```

### **Nested Arrays of Buses**

The `ex_log_nested_aob` model has an array of buses (`a`) that is made up of three arrays of buses: `b`, `c`, and `d`. The Matrix Concatenate block combines the nested arrays of buses into array of buses `a`.

This example shows navigation to the Constant6 block.

```
logout.getElement('topBus').Values.a(2,2).firstConst.Data
```

ans=

## Accessing Data for Signals with a Duplicate Name

For a model with multiple signals that have the same signal name, signal logging data includes a `Simulink.SimulationData.Signal` object for each signal that has a duplicate name.

To access a specific signal that has a duplicate name, use *one* of these approaches:

- To find the data for the specific signal, visually inspect the displayed output of `Simulink.SimulationData.Signal` objects.
- Use the `Simulink.SimulationData.Dataset.getElement` method, specifying the block path for the source block of the signal.
- To iterate through the signals with a duplicate signal name, create a script using the `Simulink.SimulationData.Dataset.getElement` method with an index argument.
- Use the Signal Properties dialog box to specify a different name. Consider using this approach when the signals with a duplicate name do not appear in multiple instances of a referenced model in normal mode.
  - 1 In the model, right-click the signal.
  - 2 In the context menu, select **Properties**.
  - 3 In the Signal Properties dialog box, set **Logging name** to Custom and specify a different name than the signal name.
  - 4 Simulate the model and use the `Simulink.SimulationData.Dataset.getElement` method with a name argument.

---

**Tip** Alternatively, you can use the Signal Logging Selector to access a specific signal. For details, see “Override Signal Logging Settings with Signal Logging Selector” on page 73-59.

---

## Handling Newline Characters in Signal Logging Data

To handle newline characters in logging names in signal logging data that uses Dataset format, use a `sprintf` command within a `getElement` call. For example:

```
topOut.getElement(sprintf('INCREMENT\nBUS'))
```

- “Dataset Conversion for Logged Data” on page 73-12

## Log Signal Data That Uses Units

To have logged data include the units specified for signals, use the **Dataset** or **Timeseries** logging format, which stores logging information in MATLAB **timeseries** objects.

Signal logging uses **Dataset** format. Output logging (**Configuration Parameters > Data Import/Export > Output**) uses **Dataset** as the default format. The default save format for the **To File** and **To Workspace** blocks is **Timeseries**.

If you use **Dataset** or **Timeseries** format for signal logging or for **To File** block or **To Workspace** block logging, the logged data includes units information.

To capture units information for output logging:

- 1 Set the **Format** configuration parameter to **Dataset**.
- 2 In the **Block Parameters** dialog box for **Output** blocks for which you want to capture units information, set the **Unit** parameter to match the units of the input signal.

For example, in this model the **In1** block has its **Unit** parameter set to **newton** and **In2** block uses **m** (meters). Open the model. After you simulate the model, you can see the units for the logged data.

- You can view the units in the signal logging data for **signal1** of the bus signal **b**.

```
logout.get('a').Values.signal1.DataInfo
```

```
tsdata.datametadate
Package: tsdata
```

```
Common Properties:
```

```
Units: newton (Simulink.SimulationData.Unit)
```

```
Interpolation: linear (tsdata.interpolation)
```

- You can view the units in the data logged in the **To Workspace** block.

```
simout1.signal2.DataInfo.Units
```

```
ans =
```

```
Units with properties:
```

```
Name: 'm'
```

This example model shows how to view the data logged in a **Time Scope** block. Open the model.

To use the Time Scope block to log data, in the scope select **Configuration Properties > Logging > Log data to workspace** and specify a variable (ScopeData in this example). The In3 block uses m (meters). Simulate the model and then at the MATLAB command line, enter:

```
ScopeData.get(1).Values.DataInfo.Units
```

```
ans =
```

```
Units with properties:
```

```
Name: 'm'
```

## Limit the Size of Logged Data

### In this section...

“Limit the Number of Runs Retained in the Simulation Data Inspector Archive” on page 73-26

“Specify a Minimum Disk Space Requirement or Maximum Size for Logged Data” on page 73-26

“View Data Only During Simulation” on page 73-27

“Reduce the Number of Data Points Logged from Simulation” on page 73-27

Logging simulation data can produce large amounts of data that fill up disk space. Such situations include logging many signals, logging data for long simulations, and running many simulations without deleting run data from the Simulation Data Inspector. You can choose among several options to limit the size of logged simulation data. You can:

- Limit the number of runs retained in the Simulation Data Inspector archive.
- Reduce the number of data points logged in each simulation.
- Specify a minimum disk space requirement or maximum size for logged data.
- Configure logging for only viewing data during simulation.

Depending on your requirements, you can use more than one strategy to limit the size of logged data.

### Limit the Number of Runs Retained in the Simulation Data Inspector Archive

When you run multiple simulations in a single MATLAB session, logged simulation data accumulates in the Simulation Data Inspector even if you overwrite the logging data in the MATLAB workspace. To reduce the amount of data the Simulation Data Inspector retains, you can configure a limit for the number of runs stored in the archive. When the number of runs in the archive reaches the size limit, the Simulation Data Inspector starts to delete runs from the archive on a first-in, first-out basis.

Configure the archive **Size** setting in the Simulation Data Inspector preferences. The size limit only applies to runs in the archive. For the Simulation Data Inspector to automatically limit data retention, select **Automatically archive** and specify the maximum number of runs to retain in the archive. By default, **Automatically archive** is enabled with an archive size limit of twenty runs. If you experience issues with logged data consuming too much disk space, consider adjusting the size limit for the archive in the Simulation Data Inspector preferences.

### Specify a Minimum Disk Space Requirement or Maximum Size for Logged Data

You can use preferences in the Simulation Data Inspector to directly limit the size of logged data by specifying a minimum amount of disk space to leave free or by specifying a maximum size for logged data on disk. Each setting accounts for all kinds of logged data. By default, logged data must leave at least 100 MB of free disk space with no maximum size limit. Specify the required disk space and maximum size in GB, and specify 0 to apply no disk space requirement or no maximum size limit.

When you specify a minimum disk space requirement or a maximum size for logged data, you can also specify whether to prioritize retaining data from the current simulation or data from prior simulations when approaching the limit. By default, the Simulation Data Inspector prioritizes

retaining data for the current run. As the free disk space or logged data size approaches the limit, prior runs are deleted first to free up space for data being logged in the current run. If deleting runs does not free up enough space, recording is disabled. To prioritize retaining prior data, change the **When low on disk space** setting to **Keep prior runs and stop recording**. You see a warning message when prior runs are deleted and when recording is disabled. If recording is disabled due to the size of logged data, you need to change the **Record Mode** back to **View and record data** to continue logging data, after you have freed up disk space.

## View Data Only During Simulation

In some situations, you may want to only view the data for logged signals and not save the values. For example, when using the Simulation Data Inspector to visualize data streaming from hardware, you may only want to view the data live and not record it. You can change the **Record mode** in the Simulation Data Inspector preferences to **View during simulation only** so that logged data is not saved and you can still view the data during simulation. The **Record mode** is reset to **View and record data** at the start of each MATLAB session.

When you change the **Record mode** to **View during simulation only**:

- Logged data is not available in the Simulation Data Inspector or workspace after simulation.
- You can view data using dashboard blocks, scopes, and the Simulation Data Inspector, but plots clear when you pan or zoom.
- You cannot access logged data during simulation using the Simulation Data Inspector programmatic interface.

## Reduce the Number of Data Points Logged from Simulation

Model configuration parameters and signal properties allow you to limit the number of data points logged in a simulation. Be sure to carefully consider data requirements when limiting logged data points. Limiting data can skip critical time points, and can lead to aliasing, if your effective sample rate is too low.

You can reduce the number of data points using:

- Decimation — Log every  $n$ th signal value.
- Limit data points to last — Only log the last  $n$  signal values.
- Logging intervals — Specify specific time intervals in which to log data.

For details, see “Specify Signal Values to Log” on page 73-28.

## Specify Signal Values to Log

### In this section...

“Decimation” on page 73-28

“Log Last n Signal Values” on page 73-29

“Specify Logging Intervals” on page 73-29

In some situations, you may not need to log signal values for every time step in a simulation. You can use several strategies to specify which signal data to log during simulation. Depending on your requirements, you can use more than one strategy for limiting the size of logged data. You can specify signal values to log using:

- Decimation — Log every  $n$ th signal value.
- Limit data points to last — Only log the last  $n$  signal values.
- Logging intervals — Specify specific time intervals in which to log data.

Carefully consider data requirements before you reduce the number of signal values logged in a simulation. Limiting data can skip critical time points, and decimation can cause aliasing if the effective sample rate is too low.

### Decimation

Decimation reduces the effective sample rate for logged data. To reduce the number of data points logged, specify a decimation factor greater than one. For example, a decimation of factor of 2 logs every other data point, reducing the number of logged points and effective sample rate by half. How you apply the decimation factor depends on the logged data you want to decimate.

| Logging Method     | How to Specify Decimation                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

## Log Last n Signal Values

When you only want to save or analyze the data from the end of a simulation, you can configure logging to capture only the last  $n$  signal values. How you specify the number of data points to log depends on how the data is logged.

| Logging Method            | How to Specify Decimation                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|---------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Signal logging            | <p>Use the Signal Properties dialog box or the Instrumentation Properties dialog box. Select <b>Limit data points to last</b> and specify the number of sample values to log.</p> <p>To access the Signal Properties dialog box, right-click a signal and select <b>Properties</b>.</p> <p>To access the Instrumentation Properties dialog box, right-click the logging badge for a signal and select <b>Properties</b>.</p> <p>The setting applies only to the selected signal.</p> |
| Data store logging        | <p>Use the <b>Limit data points to last</b> block parameter.</p> <p>The decimation factor applies only to that block.</p>                                                                                                                                                                                                                                                                                                                                                            |
| Output and states logging | <p>Select the <b>Limit data points to last</b> parameter in the model configuration parameters on the <b>Data Import/Export</b> pane, under <b>Additional parameters</b> and specify the number of signal values to log.</p> <p>The specified decimation factor applies for all logged outputs and states.</p>                                                                                                                                                                       |

When you only log the last simulation values, dashboard blocks and the Simulation Data Inspector do not display data during simulation.

## Specify Logging Intervals

When you only want to save and analyze data for particular time intervals, you can specify the time intervals in which to log data. Using logging intervals allows you to save specific data without changing or adding complexity to your model.

Specify logging intervals using the **Logging intervals** parameter on the model configuration parameters **Data Import/Export** pane, under **Additional parameters**. Specify the logging intervals as an  $n$ -by-2 matrix where  $n$  is the number of intervals, the number in the first column indicates the start of the logging interval, and the number in the second column indicates the end. For example, when the **Logging intervals** setting is specified as  $[2, 4; 7, 9]$ , logged data is saved between times 2 and 4 and again between times 7 and 9.

The specified logging intervals apply to:

- Time, states, and output logging.
- Signal logging.
- Data logged using the To Workspace block.
- Data logged using the To File block.
- Data logged to the workspace using the Record block.

Logging intervals do not apply to final state logging, data logged using scopes, or data logged to the Simulation Data Inspector.

When you use logging intervals, dashboard blocks only update the displayed value of a connected signal during the specified logging intervals.

## Work with Big Data for Simulations

Simulation of models with many time steps and signals can involve big data that is too large to fit into the RAM of your computer. Such situations include:

- Logging simulation data (signal logging, output port logging, and state logging)
- Loading input signal data for simulating a model
- Running multiple or parallel simulations

To work with big data for simulations, store the data to persistent storage in a MAT-file. Using big data techniques for simulations requires additional steps beyond what you do when the data is small enough to fit in workspace memory. As you develop a model, consider logging and loading simulation data without using persistent storage unless you discover that your model has big data requirements that overload memory.

### Big Data Workflow

This example is a high-level workflow for handling big data that one simulation produces and that another simulation uses as input. For more detailed information about the major workflow tasks, see:

- “Log Data to Persistent Storage” on page 73-33
- “Load Big Data for Simulations” on page 71-7
- “Analyze Big Data from a Simulation” on page 73-37

---

**Tip** This example uses a `SimulationDatastore` object for streaming data into a model. Alternatively, you can stream a `DatasetRef` object directly into a model.

---

- 1 Configure two models to log several signals.
- 2 Simulate the models, logging the data to persistent storage for each model.

```
sim(md11, 'LoggingToFile', 'on', 'LoggingFileName', 'data1.mat');
sim(md12, 'LoggingToFile', 'on', 'LoggingFileName', 'data2.mat');
```

Logging that involves big data requires saving the data to persistent storage as a v7.3 MAT-file. Only the data logged in `Dataset` format is saved to the file. Data logged in other formats, such as `Structure` with `time`, is saved in memory, in the base workspace.

The data that you log to persistent storage is streamed during the simulation in small chunks, to minimize memory requirements. The data is stored in a file that contains `Dataset` objects for each set of logged data (for example, `logout` and `xout`).

- 3 Create `DatasetRef` objects (`dsrc1` and `dsrc2`) for specific sets of logged signals. Then create `SimulationDatastore` objects (`dst1` and `dst2`) for values of elements of the `DatasetRef` objects. This example code creates a `SimulationDatastore` for the 12th element of `logout` for the first simulation. For the second simulation, the example code creates a signal with values being a `SimulationDatastore` object for the seventh element of `logout`. You can use curly braces for indexing.

```
dsrc1 = Simulink.SimulationData.DatasetRef('data1.mat', 'logout');
dsrc2 = Simulink.SimulationData.DatasetRef('data2.mat', 'logout');
```

```
dst1 = dsr1{12};
dst2 = dsr2{7};
```

- 4 Use `SimulationDatastore` objects as an external input for another simulation. To load the `SimulationDatastore` data, include it in a `Dataset` object. The datastore input is incrementally loaded from the MAT-file. The third input is a `timeseries` object, which is loaded into memory as a whole, not incrementally.

```
input = Simulink.SimulationData.Dataset;
input{1} = dst1;
input{2} = dst2;
ts = timeseries(rand(5,1),1, 'Name', 'RandomSignals');
input{3} = ts;
sim mdl3, 'ExternalInput', 'input');
```

- 5 Use MATLAB big data analysis to work with the `SimulationDatastore` objects. Create a `timetable` object by reading the values of a `SimulationDatastore` object. The `read` function reads a portion of the data. The `readall` function reads all the data.

```
tt = dst1.Values.read;
```

- 6 Set the MATLAB session as the global execution environment (`mapreducer`) for working with the tall `timetable`. Create a tall `timetable` from a `SimulationDatastore` object and read a `timetable` object with in-memory data.

```
mapreducer(0);
ttt = tall(dst1.Values);
```

---

**Tip** For another example showing how to work with big simulation data, see “Working with Big Data”.

## Log Data to Persistent Storage

### In this section...

“When to Log to Persistent Storage” on page 73-33

“Log to Persistent Storage” on page 73-34

“Enable Logging to Persistent Storage Programmatically” on page 73-34

“How Simulation Data Is Stored” on page 73-35

“Save Logged Data from Successive Simulations” on page 73-35

### When to Log to Persistent Storage

In some cases, logging simulation data can create large amounts of data that are too large for your computer to hold in working memory while also running efficiently. Such situations can include simulations that log many signals, simulations that run for a long time with many time steps, and parallel simulations. When your simulation configuration creates a large amount of data, you can log that data to persistent storage, rather than logging it to working memory.

You can store logged simulation data to persistent storage in a MAT-file. You control logging to persistent storage at the model level. You can enable and disable the feature by changing one model configuration parameter (**Log Dataset data to file**) without changing the model layout.

If you use **Dataset** format for logging, you can log each of these kinds of data to persistent storage:

- Signal logging — Uses **Dataset** format only.
- States — Defaults to **Dataset** format. You can use other formats.
- Final states — Requires that you clear the **Save final operating point** parameter
- Output — Defaults to **Dataset** format.
- Data stores — Uses **Dataset** format only.

By default, logging to persistent storage is disabled, so that logged data is stored in the MATLAB workspace. For most models, logging to the workspace is simpler because it avoids loading and saving logging files. Compared to accessing data logged to memory, accessing data logged to persistent storage requires some additional steps. For short simulations, logging to the MATLAB workspace can be faster and possibly use less memory than logging to persistent storage.

### Limitations for Logging to Persistent Storage

- Only data logged in **Dataset** format is stored in the MAT-file. Data logged in other formats is stored in the MATLAB workspace.
- To use persistent storage for logging final states data, you cannot enable the **Configuration Parameters > Data Import/Export + Save final operating point**.
- The Simulation Stepper and fast restart do not support logging to persistent storage.
- During simulation, you cannot load data from the persistent storage file directly into the model. Create objects that reference the data in the file and then load the referencing object.

### Alternative Approaches for Reducing Logging Memory Usage

When you need to simulate a model that creates a large amount of data and you do not want to log the simulation data to persistent storage, consider using one of these alternatives.

- Limit the amount of simulation data stored in the workspace.

You can limit the amount of simulation data stored in the workspace by using one or more of these techniques. For details, see “Specify Signal Values to Log” on page 73-28.

| Technique                     | Description                                                           |
|-------------------------------|-----------------------------------------------------------------------|
| Specify a decimation factor   | Skip samples when exporting data.                                     |
| Limit data points             | Limit the number of samples saved to be only the most recent samples. |
| Specify intervals for logging | Specify ranges of time steps for logging.                             |

If you limit the amount of simulation data stored in the workspace, the logged data may not contain some time steps that are critical for testing and analyzing the model.

- Use a To File block for each signal that you want to log.

Connecting a To File block to signals that you want to log stores the logged data in a MAT-file, rather than in the MATLAB workspace. However, this approach:

- Is a per-signal approach that can clutter a model with multiple To File blocks attached to individual signals.
- Creates a separate MAT-file for each To File block, instead of the single file created when you log to persistent storage.

## Log to Persistent Storage

- 1 Specify the kinds of logging to perform (for example, signal logging and output logging) and the variable names for the logging data.
- 2 In the model diagram, mark selected signals for signal logging.
- 3 Use **Dataset** format for logging the data. Data that is logged in any other format is stored in the workspace.
  - Signal logging and data store logging use **Dataset** format only. The default format for output, states, and final states logging is **Dataset**.
  - For final states logging, clear the **Save final operating point** configuration parameter.
- 4 Enable logging to persistent storage and specify an output MAT-file name.
  - Select the **Log Dataset data to file** configuration parameter.
  - Specify the MAT-file to use. Do not use a file name from one locale in a different locale.
- 5 To save the logged **Dataset** data using `timeseries` or `timetable` elements, set the **Dataset signal format** configuration parameter. The default format is `timeseries`. The `timetable` format is helpful for MATLAB combining logged data from multiple simulations. For details about the `timetable` format, see “Dataset signal format”.
- 6 Simulate the model.

## Enable Logging to Persistent Storage Programmatically

You can programmatically log to persistent storage. To enable logging to persistent storage, use the `LoggingToFile` and `LoggingFileName` name-value pairs with either the `sim` command or `set_param` command.

To enable the logging approaches that you want to use, set these parameters to 'on', as applicable:

- SignalLogging
- SaveState
- SaveFinalState
- SaveOutput
- DSMLogging

To log output, states, and final states data to persistent storage, set the SaveFormat parameter to 'Dataset'.

To log final states data to persistent storage, set the SaveOperatingPoint to 'off'.

## How Simulation Data Is Stored

Logging to persistent storage saves logged simulation data in the specified MAT-file. The data is stored as a `Simulink.SimulationData.Dataset` objects for each type of logging that uses Dataset format. The Dataset elements are stored as either `timeseries` or `timetable` objects, depending on how you set the **Dataset signal format** parameter. For details about the `timetable` format, see “Dataset signal format”.

The Dataset object name in the file is the name of the variable that you used for logging. For example, if you use the default signal logging variable `logsout`, the Dataset object in the MAT-file is `logsout`.

## Save Logged Data from Successive Simulations

The approach you use for saving data logged from successive simulations depends on whether you are performing parallel simulations.

### Without Using Parallel Simulations

Each time you simulate a model without using parallel simulation, Simulink overwrites the contents of the MAT-file unless you change the name of the file between simulations. When you use a `Simulink.SimulationData.DatasetRef` object that references data in the MAT-file to retrieve data in the file, it retrieves the most recent version of the data. To preserve data from an earlier simulation, use one of these approaches:

- Between simulations, use the **Configuration Parameters > Data Import/Export** pane to specify a different name for the MAT-file for logging.
- Between simulations, save a copy of the MAT-file. Use a different file name than the name that you specify as the MAT-file for persistent storage, or move the MAT-file.
- Programmatically specify a new file name for each simulation run.

If you run multiple simulations that overlap in time, use a unique MAT-file for each model that you log to persistent storage.

If you change the file name used for logging to persistent storage, then to access the logged data, use one of these approaches:

- Create a `Simulink.SimulationData.DatasetRef` object.

- To match the new file name, change the `Location` property of the `DatasetRef` objects.

For details about using `DatasetRef` objects to access logged data, see “Load Big Data for Simulations” on page 71-7.

### **With Parallel Simulations**

For parallel simulations, for which you specify an array of input objects, if you log to file, Simulink:

- Creates a MAT-file for each simulation
- Creates `Simulink.SimulationData.DatasetRef` objects to access output data in the MAT-file and includes those objects in the `SimulationOutput` object data
- Enables the `CaptureErrors` argument for simulation

For more information about parallel simulations, see “Running Multiple Simulations” on page 27-2.

# Analyze Big Data from a Simulation

## In this section...

“Create DatasetRef Objects to Access Logged Datasets” on page 73-37

“Use SimulationDatastore Objects to Access Signal Data” on page 73-37

“Create Timetables for MATLAB Analysis” on page 73-37

“Create Tall Timetables” on page 73-38

“Access Persistent Storage Metadata” on page 73-38

“Access Error Information” on page 73-38

To access data logged to a MAT-file for analysis in MATLAB, use references to the data in the MAT-file.

## Create DatasetRef Objects to Access Logged Datasets

When you log to a MAT-file, Simulink stores a `Simulink.SimulationData.Dataset` object in the specified MAT-file. The elements of the `Dataset` object in the file are `Dataset` objects. There is one `Dataset` object for each set of logged simulation data. For example, a file may contain a `Dataset` object that contains a `Dataset` object for logged signal data and another `Dataset` object for logged states data.

To access simulation `Dataset` format data for a set of logged simulation data, create `Simulink.SimulationData.DatasetRef` objects. You can access individual elements of the dataset using a `DatasetRef` object. For details, see “Load Individual Signals from a `DatasetRef` Object” on page 71-9.

## Use SimulationDatastore Objects to Access Signal Data

To access leaf signals in a logged `Dataset`, create a `matlab.io.datastore.SimulationDatastore` object for the signal, based on the `DatasetRef` object for the `Dataset` that contains the signal. For details, see

“Stream Individual Signals Using `SimulationDatastore` Objects” on page 71-7.

You can operate on data referenced by a `SimulationDatastore` object. For example, you can get the data in a chunk to be read into memory from the MAT-file. For an example, see `matlab.io.datastore.SimulationDatastore`.

## Create Timetables for MATLAB Analysis

When you read a `SimulationDatastore` object, using the `read` or `readall` method the output is in MATLAB `timetable` format. For details about the `timetable` format, see “`Dataset` signal format”.

You can use a `SimulationDatastore` object to create a `timetable` for the signal values and read a `timetable` object with in-memory data. For example, for `SimulationDatastore` object `dst1`:

```
tt = dst1.Values.read;
ttt = tall(dst1.Values);
```

## Create Tall Timetables

You can create a tall timetable:

```
mapreducer(0);
ttt = tall(dst1.Values);
```

## Access Persistent Storage Metadata

If you use persistent storage for several simulations, you can have multiple MAT-files. When you run multiple simulations using batch processing, you get multiple MAT-files if you specify a different persistent storage MAT-file for each simulation. For parallel simulations, Simulink produces a separate MAT-file for each simulation run. To help you identify and understand the context of the simulation data included in a MAT-file, Simulink stores metadata about logging to persistent storage.

A `Simulink.SimulationMetadata` object includes in its `ModelInfo` structure a `LoggingInfo` structure with two fields:

- `LoggingToFile` — Indicates whether logging to persistent storage is enabled ('on' or 'off')
- `LoggingFileName` — Specifies the resolved file name for the persistent storage MAT-file (if `LoggingToFile` is 'on').

The MAT-file used for persistent storage contains a `SimulationMetadata` variable that stores the same simulation metadata as the `Simulink.SimulationMetadata` object. The `SimulationMetadata` is a system-generated name, not a variable name that you specify.

To access the persistent logging storage metadata, use one of these alternatives:

- View simulation metadata by using the `SimulationOutput` object `SimulationMetadata` property.
- Use tab completion to access `SimulationMetadata` object properties such as `ModelInfo` and to access field names.
- Display simulation metadata in the Variable Editor. Click the `SimulationOutput` object and use one of these approaches:
  - Select the **Explore Simulation Metadata** check box (which displays the data in a tree structure).
  - Double-click the **SimulationMetadata** row.

## Access Error Information

You can view error message and information about the stack and causes for simulation data by using the `SimulationOutput` object `ErrorMessage` property. For parallel simulations, if you are logging to file, Simulink enables the `CaptureErrors` argument for simulation.

## Samples to Export for Variable-Step Solvers

### In this section...

“Output Options” on page 73-40  
 “Refine Output” on page 73-40  
 “Produce Additional Output” on page 73-40  
 “Produce Specified Output Only” on page 73-41

### Output Options

Use the **Output options** list under **Configuration Parameters > Data Import/Export > Additional parameters** to control how much output the simulation generates when your model uses a variable-step solver.

- Refine output (default)
- Produce additional output
- Produce specified output only

### Refine Output

The `Refine` output option provides additional output points when the simulation output does not include as many points as you would like. This parameter provides an integer number of output points between time steps. For example, a refine factor of 2 provides output midway between the time steps and at the steps. The default refine factor is 1.

Suppose that a sample simulation generates output at these times:

0, 2.5, 5, 8.5, 10

Choosing `Refine` output and specifying a refine factor of 2 generates output at these times:

0, 1.25, 2.5, 3.75, 5, 6.75, 8.5, 9.25, 10

To get smoother output more efficiently, change the refine factor instead of reducing the step size. When you change the refine factor, the solver generates additional points by evaluating a continuous extension formula at sample points. This option changes the simulation step size so that time steps coincide with the times that you specify for additional output.

The refine factor applies to variable-step solvers and is most useful when you are using `ode45`. The `ode45` solver can take large steps. However, when you graph simulation output, the output from this solver sometimes is not sufficiently smooth. In such cases, run the simulation again with a larger refine factor. A value of such as 4 for `ode45` can provide much smoother results.

---

**Note** This option helps the solver locate zero crossings, although it does not ensure that Simulink detects all zero crossings (see “Zero-Crossing Detection” on page 3-10).

---

### Produce Additional Output

Use the `Produce additional output` option to specify directly those additional times at which the solver generates output. When you select this option, the **Data Import/Export** pane displays an

**Output times** configuration parameter. In this parameter, enter a MATLAB expression that evaluates to an additional time or a vector of additional times. The solver produces hit times at the output times that you specify, in addition to the times it requires for accurate simulation.

Suppose that a sample simulation generates output at these times:

0, 2.5, 5, 8.5, 10

Choosing the `Produce additional output` option and specifying `[0:10]` generates output at these times:

0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10

and perhaps at additional times, depending on the step size chosen by the variable-step solver.

### Tips

- This option helps the solver locate zero crossings, although it does not ensure that Simulink detects all zero crossings (see “Zero-Crossing Detection” on page 3-10).
- Set the **Output times** configuration parameter to a value other than the default empty matrix (`[]`).
- For triggered subsystems and function-call subsystems, the calling function must inherit the sampling rate.

## Produce Specified Output Only

Simulink generates output at the start and stop times, in addition to the times that you specify.

Suppose that a sample simulation generates output at these times:

0, 2.5, 5, 8.5, 10

Choosing the `Produce specified output only` option and specifying `[1:9]` generates output at these times:

0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10

This option changes the simulation step size so that time steps coincide with the times that you specify for producing output. The solver can hit other time steps to accurately simulate the model. However, the output does not include these points. This option is useful when you are comparing different simulations to check that the simulations produce output at the same times.

### Tips

- This option helps the solver locate zero crossings, although it does not ensure that Simulink detects all zero crossings (see “Zero-Crossing Detection” on page 3-10).
- Set the **Output times** configuration parameter to a value other than the default empty matrix (`[]`).
- In normal, accelerator, and rapid accelerator modes, Simulink generates output at the start and stop times, as well as at the times that you specify.
- When you simulate a model in normal mode, triggered subsystems and function-call subsystems use:

- The times that you specify
- All the time steps in between the values that you specify
- The simulation start and stop times
- For triggered subsystems and function-call subsystems, the calling function must inherit the sampling rate.

# Export Signal Data Using Signal Logging

**In this section...**

“Signal Logging” on page 73-43

“Signal Logging Workflow” on page 73-43

“Signal Logging Limitations” on page 73-44

## Signal Logging

To capture signal data from a simulation, usually you can use signal logging. Mark the signals that you want to log and enable signal logging for the model. For details, see “Configure a Signal for Logging” on page 73-45 and “Enable Signal Logging for a Model” on page 73-55.

For a summary of other approaches to capture signal data, see “Export Simulation Data” on page 73-2.

## Signal Logging Workflow

To collect and use signal logging data, perform these tasks.

- 1 Mark individual signals for signal logging. See “Configure a Signal for Logging” on page 73-45.
- 2 Enable signal logging for a model. See “Enable Signal Logging for a Model” on page 73-55.
- 3 Simulate the model.
- 4 Access the signal logging data. See “View and Access Signal Logging Data” on page 73-68.

## Log Subsets of Signals

One approach for testing parts of a model as you develop it is to mark a superset of signals for logging and then override signal logging settings to select different subsets of signals for logging. You can use the Signal Logging Selector or a programmatic interface. See “Override Signal Logging Settings” on page 73-58.

Use this approach to log signals in models that use model referencing. For an example, see “Viewing Signals in Model Reference Instances”.

## Additional Signal Logging Options

With the basic signal logging workflow, you can specify additional options related to the data that signal logging collects and to how that data is displayed. You can:

- Specify a name for the signal logging data for a signal. See “Specify Signal-Level Logging Name” on page 73-46.
- Control how much data the simulation generates for a signal. See “Limit Data Logged” on page 73-47.
- Review the signal logging configuration for a model. See “View the Signal Logging Configuration” on page 73-50.
- Specify the samples for export for models with variable-step solvers. See “Samples to Export for Variable-Step Solvers” on page 73-40.

## Signal Logging Limitations

Signal logging does not support:

- Signals inside Stateflow charts for rapid accelerator simulations.
- Input signals for Function-Call subsystems, If Action subsystems, or Switch Case Action subsystems.
- Input signals for Merge blocks.
- Bus signals inside For Each subsystems.
- Signals in referenced models inside For Each subsystems when:
  - The model containing the For Each subsystem simulates in rapid accelerator mode.
  - The For Each subsystem is inside a referenced model simulated in accelerator mode.
- State port signals for Integrator and Discrete-Time Integrator blocks that show the state port.

## Configure a Signal for Logging

### In this section...

“Mark a Signal for Logging” on page 73-45  
 “Specify Signal-Level Logging Name” on page 73-46  
 “Limit Data Logged” on page 73-47  
 “Set Sample Time for a Logged Signal” on page 73-48

### Mark a Signal for Logging

Enable logging by marking a signal, using one of the following techniques:

- “Enable Logging Using Simulink Toolstrip” on page 73-45
- “Enable Logging Using Signal Properties” on page 73-45
- “Enable Logging Using the Model Data Editor” on page 73-45
- “Programmatic Interface” on page 73-46

The Simulink Editor menu options are generally the simplest way to mark signals for logging.

A signal for which you enable logging is a *logged signal*. By default, Simulink displays a logged signal indicator  for each logged signal.

#### Enable Logging Using Simulink Toolstrip

- 1 In the Simulink Editor, select one or more signals.
- 2 On the **Simulation** tab, click **Log Signals**.

#### Enable Logging Using Signal Properties

- 1 In the Simulink Editor, right-click the signal.
- 2 From the context menu, select **Properties**.
- 3 In the Signal Properties dialog box, in the **Logging and accessibility** tab, select **Log signal data**.
- 4 Click **OK**.

Alternatively, you can select the **Log Selected Signals** from the context menu that appears when you right-click the selected signal.

#### Enable Logging Using the Model Data Editor

The Model Data Editor displays a flat list of signals in your model. You can sort, group, and filter the list. Use this technique to enable logging for:

- Many signals at once.
- Signals that are not close to each other in the block diagram.
- Signals that are difficult to locate in a large model or subsystem hierarchy.

To select signals to log using the Model Data Editor:

- 1 Open the Model Data Editor. On the **Modeling** tab, click the **Model Data Editor** button.
- 2 Select the **Signals** tab in the Model Data Editor.
- 3 Select **Instrumentation** in the drop-down.
- 4 Check the boxes in the **Log Data** column for signals you would like to log.

For more information, see **Model Data Editor**.

### Programmatic Interface

To enable signal logging programmatically for selected blocks, use the output `DataLogging` property. Set this property using the `set_param` command. For example:

- 1 At the MATLAB Command Window, open a model. Type  

```
vdp
```
- 2 Get the port handles of the signal that you want to log. For example, for the Mu block output port signal.  

```
ph = get_param('vdp/Mu', 'PortHandles')
```
- 3 Enable signal logging for the desired output port signal.  

```
set_param(ph.Outport(1), 'DataLogging', 'on')
```

The logged signal indicator appears.

### Logging Referenced Model Signals

You can log any logged signal in a referenced model. Use the Signal Logging Selector to configure signal logging for a model reference hierarchy. For details, see “Models with Model Referencing: Overriding Signal Logging Settings” on page 73-61.

### Specify Signal-Level Logging Name

You can specify a signal-level logging name to the object that Simulink uses to store logging data for a signal. Specifying a signal-level logging name can be useful for signals that are unnamed or that share a duplicate name with another signal in the model hierarchy. Specifying signal-level logging names, rather than using the names that Simulink generates, can make the logged data easier to analyze.

To specify a signal-level logging name, use *one* of the following approaches:

- “Signal-Level Logging Name in the Editor” on page 73-47
- “Signal-Level Logging Name in Model Explorer” on page 73-47
- “Signal-Specific Logging Name Specified Programmatically” on page 73-47

If you do not specify a custom signal-level logging name, Simulink uses the signal name. If the signal does not have a name, the action Simulink uses a blank name.

---

**Note** The signal-level logging name is distinct from the model-level signal logging name. The model-level signal logging name is the name for the object containing all the logged signal data for the whole model. The default model-level signal logging name is `logout`. For details about the model-level signal logging name, see “Specify a Name for Signal Logging Data” on page 73-57.

---

### Signal-Level Logging Name in the Editor

- 1 In the Simulink Editor, right-click the signal.
- 2 From the context menu, select **Signal Properties**.
- 3 Specify the logging name:
  - a In the Signal Properties dialog box, select the **Logging and accessibility** tab.
  - b From the **Logging name** list, select Custom.
  - c Enter the logging name in the adjacent text field.

### Signal-Level Logging Name in Model Explorer

- 1 In the Model Explorer **Model Hierarchy** pane, select the node that contains the signal for which you want to specify a logging name.
- 2 If the **Contents** pane does not display the `LoggingName` property, add the `LoggingName` property to the current view. For details about column views, see **Model Explorer**.
- 3 Enter a logging name for one or more signals using the `LoggingName` column.

### Signal-Specific Logging Name Specified Programmatically

Enable signal logging programmatically for selected blocks with the output port `DataLogging` property. Set this property using the `set_param` command.

- 1 At the MATLAB Command Window, open a model. For example, type:
 

```
vdp
```
- 2 Get the port handles of the signal that you want to log. For example, for the Mu block output port signal:

```
ph = get_param('vdp/Mu', 'PortHandles');
```

- 3 Enable signal logging for the desired output port signal:

```
set_param(ph.Outputport(1), 'DataLogging', 'on');
```

The logged signal indicator appears.

- 4 Issue commands that use the `DataLoggingNameMode` and `DataLoggingName` parameters. For example:

```
set_param(ph.Outputport(1), 'DataLoggingNameMode', 'Custom');
set_param(ph.Outputport(1), 'DataLoggingName', 'x2_log');
```

### Limit Data Logged

You can limit the amount of data logged for a signal by:

- Specifying a decimation factor
- Limiting the number of samples saved to be only the most recent samples

You can limit data logged for a signal by using the Signal Properties dialog box, the Model Explorer, the Signal Logging Selector, or programmatically. The following sections describe the first two approaches.

### Use Signal Properties to Limit Logged Data

- 1 In the Simulink Editor, right-click the signal.
- 2 From the context menu, select **Signal Properties**.
- 3 In the Signal Properties dialog box, click the **Logging and accessibility** tab. Then select one or both of these options:
  - **Limit data points to last**
  - **Decimation**

### Use Model Explorer to Limit Data Logged

- 1 In the Model Explorer **Model Hierarchy** pane, select the node that contains the signal for which you want to limit the amount of data logged.
- 2 If the **Contents** pane does not display the `DataLoggingDecimation` property or the `DataLoggingLimitDataPoints` property, add one or both of those properties to the current view. For details about column views, see **Model Explorer**.
- 3 To specify a decimation factor, edit the `Decimation` and `DecimateData` properties. To limit the number of samples logged, edit the `LimitDataPoints` property.

## Set Sample Time for a Logged Signal

To set the sample time for a logged signal, in the Signal Properties dialog box, use the **Sample Time** option. This option:

- Separates design and testing, because you do not need to insert a Rate Transition block to have a consistent sample time for logged signals
- Reduces the amount of logged data for a continuous time signal, for which setting decimation is not relevant
- Eliminates the need to postprocess logged signal data for signals with different sample times

### Usage Notes

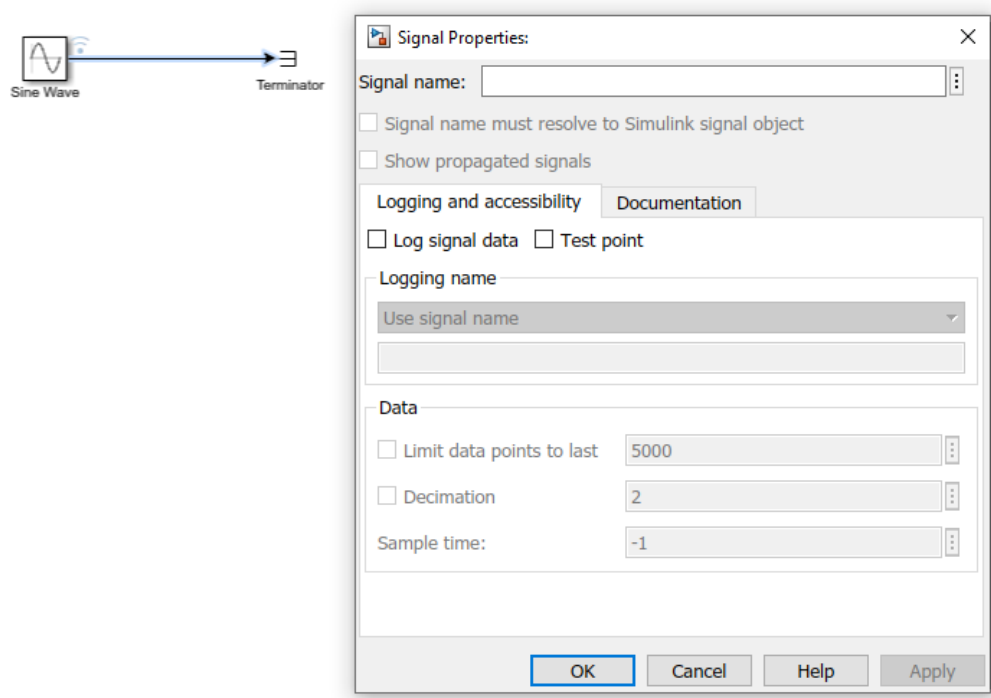

Do not specify a sample time for:

- Frame-based signals
- Conditional subsystems (for example, function-call or triggered subsystems) and conditional referenced models, which require an inherited sample time

If you simulate in SIL mode, signal logging ignores the sample times you specify for logged signals.

When you mark a signal for signal logging, Simulink inserts a hidden To Workspace block. When you specify a sample time for a logged signal, Simulink inserts a hidden Rate Transition block and a hidden To Workspace block.

Specifying a sample time for signal logging does not affect the simulation result. However, it is possible that the signal logging output for a logged signal varies depending on whether you specify a sample rate. For example, the interpolation method can differ depending on whether you specify a sample time for signal logging. Suppose that a model includes a continuous signal and the sample time is inherited (-1). The logged output for that signal shows that the interpolation method is `linear`.

```
logout.get(1).Values.DataInfo
```

```
tsdata.datametadate
 Package: tsdata
```

```
Common Properties:
 Units: ''
 Interpolation: linear (tsdata.interpolation)
```

If you change the sample time to be continuous (0), the logged output for that signal shows that the interpolation method is zoh (zero-order hold).

| Signal Logging Configuration Viewing Approach | Usage                                                                                         | Documentation                                                        |
|-----------------------------------------------|-----------------------------------------------------------------------------------------------|----------------------------------------------------------------------|
| Use MATLAB commands                           | Get the handles of the signals in the model and find the ones that have data logging enabled. | “Programmatically Find Signals Configured for Logging” on page 73-54 |

## View Signal Logging Configuration Using the Simulink Editor

By default, the Simulink Editor displays an indicator on each signal marked for logging. For example, this model logs the output signal of the Sine Wave block.

To view the signal properties, right-click the signal and select **Properties**.

Signal Properties: COUNTERBUS

Signal name:

Signal name must resolve to Simulink signal object

Show propagated signals

Logging and accessibility | Documentation

Log signal data  Test point

Logging name

Use signal name

COUNTERBUS

OK Cancel Help Apply

If you programmatically override logging for a signal, the Simulink Editor continues to display the signal logging indicator for that signal. When you simulate the model, Simulink displays a red signal logging indicator for all signals marked to be logged, reflecting any overrides. For details about configuring a signal for logging, see “Configure a Signal for Logging” on page 73-45.

A logged signal can also be a test point. See “Configure Signals as Test Points” on page 76-46 for information about test points.

To hide logging indicators, on the **Debug** tab, click to clear **Information Overlays > Log & Testpoint**.

## View Logging Configuration Using the Signal Logging Selector

In the **Simulation** tab, click **Model Settings**. Then, click **Configure Signals to Log**.

The **Contents** pane shows the signals marked for logging in the node selected in the **Model Hierarchy** pane. When no signals are marked for logging in a node, the **Contents** pane is empty. Use the arrow to the left of a hierarchical node to expand or collapse the contents of the node in the **Model Hierarchy** pane.

When a model includes referenced models, the check box in the **Model Hierarchy** pane indicates the override configuration for the model corresponding to the node.

| Check Box                           | Signal Logging Configuration                                                                                                                                                                                                                   |
|-------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <input checked="" type="checkbox"/> | For the top-level model node, logs all logged signals in the top model.<br>For a Model block node, logs all logged signals in the model reference hierarchy for that block.                                                                    |
| <input type="checkbox"/>            | For the top-level model node, disables logging for all logged signals in the top-level model.<br>For a Model block node, disables logging for all signals in the model reference hierarchy for that block.                                     |
| <input checked="" type="checkbox"/> | For the top-level model node, logs all logged signals that have the DataLogging setting enabled.<br>For a Model block node, logs all logged signals in the model reference hierarchy for that block that have the DataLogging setting enabled. |

## View Configuration of Subsystems and Linked Libraries

The following table describes default **Model Hierarchy** pane display of subsystems, masked subsystems, and linked library nodes.

| Node             | Display Default                                     |
|------------------|-----------------------------------------------------|
| Subsystem        | Displays subsystems all that include logged signals |
| Masked subsystem | Does not display masked subsystems                  |

| Node           | Display Default                                     |
|----------------|-----------------------------------------------------|
| Linked library | Displays all subsystems that include logged signals |

You can control how the **Model Hierarchy** pane displays subsystems, masked subsystems, and linked libraries. Use icons at the top of the **Model Hierarchy** pane or use the **View** menu, using the same approach as you use in the Model Explorer. For details, see **Model Explorer** and “Manage Existing Masks” on page 39-12.

- To display all subsystems, including subsystems that do not include signals marked for logging, select the  icon or **View > Show All Subsystems**. This subsystem setting also applies to masked subsystems, if you specify to display masked subsystems.
- To display masked subsystems with logged signals, use the  icon or **View > Show Masked Subsystems**
- To display linked libraries, use the  icon or **View > Show Library Links**

### Filtering Signal Logging Selector Contents

To find a specific signal or property value for a signal, use the **Filter Contents** edit box. Use the same approach as you use in the Model Explorer; for details, see **Model Explorer**.

### Highlighting a Block in a Model

To use the Model Hierarchy pane to highlight a block in model, right-click the block or signal and select **Highlight block in model**.

## View Signal Logging Configuration Using the Model Explorer

- 1 To access the logging configuration information for referenced models, open the model for which you want to view the signal logging configuration. Select the top-level model in a model reference hierarchy.
- 2 In the **Contents** pane, set **Column View** to the Signals view.

For further information, see **Model Explorer**.

## Programmatically Find Signals Configured for Logging

Use MATLAB commands to get the handles of the signals in the model and find the ones that have data logging enabled. For example:

```
mdlsignals = find_system(gcs, 'FindAll', 'on', 'LookUnderMasks', 'all', ...
 'FollowLinks', 'on', 'type', 'line', 'SegmentType', 'trunk');
ph = get_param(mdlsignals, 'SrcPortHandle')
for i=1: length(ph)
 get_param(ph{i}, 'datalogging')
end
```

## Enable Signal Logging for a Model

### In this section...

“Enable and Disable Logging at the Model Level” on page 73-55

“Specify Format for Dataset Signal Elements” on page 73-55

“Specify a Name for Signal Logging Data” on page 73-57

### Enable and Disable Logging at the Model Level

To log a signal, mark it for logging. For details, see “Configure a Signal for Logging” on page 73-45.

Enable or disable logging globally for all signals that you mark for logging in a model. By default, signal logging is enabled. Simulink logs signals if the **Configuration Parameters > Data Import/Export > Signal logging** parameter is checked. If the option is not checked, Simulink ignores the signal logging settings for individual signals.

When signals are marked for logging, the signal data logs to the workspace and to the Simulation Data Inspector. You can disable signal logging through the Configuration Parameters dialog box or programmatically.

- In the Configuration Parameters dialog box, clear the **Configuration Parameters > Data Import/Export > Signal logging** parameter check box.
- From the command line, use the `SignalLogging` parameter.

```
set_param(bdroot, 'SignalLogging', 'off')
```

### Selecting a Subset of Signals to Log

You can select a subset of signals to log for a model that has:

- Signal logging enabled
- Logged signals

For details, see “Override Signal Logging Settings” on page 73-58.

### Specify Format for Dataset Signal Elements

Logged signal data is saved in `Dataset` format (as `Simulink.SimulationData.Dataset` objects). To specify whether you want the data for individual signals in the dataset to use `MATLAB timeseries` or `timetable` elements, set the **Dataset signal format** configuration parameter. The default is `timeseries`. For details, see “Dataset signal format”.

### Migrate Scripts That Use Legacy ModelDataLogs API

For scripts that simulate a model created in a release earlier than R2016a that uses `ModelDataLogs` format for logging, update the code to log in `Dataset` format.

If you have already logged signal data in the `ModelDataLogs` format, you can use the `Simulink.ModelDataLogs.convertToDataset` function to update the `ModelDataLogs` signal logging data to use `Dataset` format. For example, to update the `older_model_dataset` from `ModelDataLogs` format to `Dataset` format:

```
new_dataset = logout.convertToDataset('older_model_data')
```

Converting a model from using `ModelDataLogs` format to using `Dataset` format can require that you modify your existing models and to code in callbacks, functions, scripts, or tests. The following table identifies possible issues to address after converting to `Dataset` format. The table provides solutions for each issue.

| Possible Issue After Conversion to Dataset Format                                                                                                               | Solution                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|-----------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Code in existing callbacks, functions, scripts, or tests that used the <code>ModelDataLogs</code> programmatic interface to access data can result in an error. | <p>Check for code that uses <code>ModelDataLogs</code> format access methods. Update that code to use <code>Dataset</code> format access methods.</p> <p>For example, suppose that existing code includes the following line:</p> <pre>logout.('Subsystem Name').X.data</pre> <p>Replace that code with a <code>Dataset</code> access method:</p> <pre>logout.getElement('X').Values.data</pre>                                                                                                                                                                                                                                              |
| Mux block signal names are lost.                                                                                                                                | The <code>Dataset</code> format treats Mux block signals as a vector. To identify signals by signal names, replace Mux blocks with Bus Creator blocks.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| Signal Viewer cannot be used for signal logging.                                                                                                                | <p>Simulink does not log signal logging data in the Signal Viewer.</p> <p>Use the signal logging output variable to view the logged data.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| The <code>unpack</code> method generates an error.                                                                                                              | <p>The <code>unpack</code> method, which is supported for <code>Simulink.ModelDataLogs</code> and <code>Simulink.SubsysDataLogs</code> objects, is <i>not</i> supported for <code>Simulink.SimulationData.Dataset</code> objects.</p> <p>For example, if the data in <code>mlog</code> has three fields: <code>x</code>, <code>y</code>, and <code>z</code>, then:</p> <p>For <code>ModelDataLogs</code> format data, the <code>mlog.unpack</code> method creates three variables in the base workspace.</p> <p>For <code>Dataset</code> format data, access methods by names. For example:</p> <pre>x = logout.getElement('X').Values</pre> |

| Possible Issue After Conversion to Dataset Format                                      | Solution                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|----------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| The ModelDataLogs and Dataset formats have different naming rules for unnamed signals. | <p>If necessary, add signal names.</p> <p>In ModelDataLogs format, for an unnamed signal coming from a block, Simulink assigns a name in this form:</p> <p>SL_BlockName+&lt;portIndex&gt;</p> <p>For example, SL_Gain1.</p> <p>In Dataset format, elements do not need a name, so Simulink leaves the signal name empty.</p> <p>For both ModelDataLogs and Dataset formats, Simulink assigns the same name to unnamed signals that come from Bus Selector blocks.</p> |
| Test points in referenced models are not logged.                                       | Consider enabling signal logging for test points in a referenced model.                                                                                                                                                                                                                                                                                                                                                                                               |
| Script uses who or whos functions.                                                     | Consider using find instead.                                                                                                                                                                                                                                                                                                                                                                                                                                          |

## Specify a Name for Signal Logging Data

You use the model-level signal logging name to access the signal logging data for a model. The default name for the signal logging data is `logout`. Specifying a model-level signal logging name can make it easier to identify the source of the logged data. For example, you could specify the signal logging name `car_logout` to identify the data as being the signal logging data for the `car` model.

To specify a different model-level signal logging name, use either of these approaches:

- In the edit box next to the **Configuration Parameters > Data Import/Export > Signal logging** parameter, enter the signal logging name.
- Use the `SignalLoggingName` parameter, specifying a signal logging name. For example:

```
set_param(bdroot, 'SignalLoggingName', 'heater_model_signals')
```

## Override Signal Logging Settings

### In this section...

“Benefits of Overriding Signal Logging Settings” on page 73-58  
 “Two Interfaces for Overriding Signal Logging Settings” on page 73-58  
 “Scope of Signal Logging Setting Overrides” on page 73-58  
 “Override Signal Logging Settings with Signal Logging Selector” on page 73-59  
 “Override Signal Logging Settings from MATLAB” on page 73-63

### Benefits of Overriding Signal Logging Settings

As you develop a model, you may want to override the signal logging settings for a specific simulation run. You can override signal logging properties without changing the model in the Simulink Editor.

To reduce memory overhead and to facilitate the analysis of simulation logging results, override signal logging properties. By overriding signal logging settings, you can avoid recompiling a model.

Overriding signal logging properties is useful when you want to:

- Focus on only a few signals by disabling logging for most of the signals marked for logging. You can mark a superset of signals for logging, and then select different subsets of them for logging.
- Exclude a few signals from the signal logging output.
- Override specific signal logging properties, such as decimation, for a signal.
- Collect only what you need when running multiple test vectors.

### Two Interfaces for Overriding Signal Logging Settings

Use either of two interfaces to override signal logging settings:

- “Override Signal Logging Settings with Signal Logging Selector” on page 73-59
- “Override Signal Logging Settings from MATLAB” on page 73-63

You can use a combination of the two interfaces. The Signal Logging Selector creates `Simulink.SimulationData.ModelLoggingInfo` objects when saving the override settings. The command-line interface has properties whose names correspond to the Signal Logging Selector interface. For example, the `Simulink.SimulationData.ModelLoggingInfo` class has a `LoggingMode` property, which corresponds to the **Logging Mode** parameter in the Signal Logging Selector.

### Scope of Signal Logging Setting Overrides

When you override signal logging settings, Simulink uses those override settings when you simulate the model.

Simulink saves in the model the signal logging override configuration that you specify. However, Simulink does not change the signal logging settings in the Signal Properties dialog box for each signal in the model.

In the Signal Logging Selector, if you override some signal logging settings, and then set the **Logging Mode** to **Log all signals as specified in model**, the logging settings defined in the model appear in the Signal Logging Selector. The override settings are greyed out, indicating that you cannot override these settings. To reactivate the override settings, set **Logging Mode** to **Override signals**. Using the Signal Logging Selector to override logging for a specific signal does not affect the signal logging indicator for that signal.

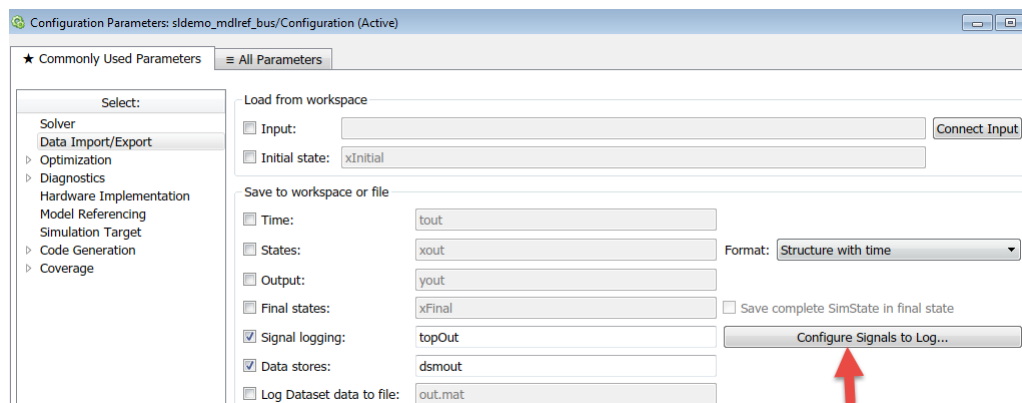

If you close and then reopen the model, the logging setting overrides that you made are in effect, if logging mode is set to override signals for that model. When the model displays the signal logging indicators, it displays the indicators for all logged signals, including logged signals that you have overridden.

**Note** Simulink rebuilds a model in the following situation:

- 1 The model contains one or more signals marked for signal logging.
- 2 You simulate the model in rapid accelerator mode.
- 3 You use the Signal Logging Selector or MATLAB command line to modify the signal logging configuration.
- 4 You simulate the model in rapid accelerator mode again.

## Override Signal Logging Settings with Signal Logging Selector

- 1 Open the Signal Logging Selector, using one of the following approaches:
  - In the **Configuration Parameters > Data Import/Export** pane, click the **Configure Signals to Log** button.

**Tip** To enable the **Configure Signals to Log** button, select the **Signal logging** configuration parameter.

- For a model that includes a Model block, you can also use the following approach:
  - a In the Simulink Editor, right-click a Model block.
  - b In the context menu, select **Log Referenced Signals**.

- 2 Set **Logging Mode** to **Override signals**.

**Note** The **Override signals** setting affects all levels of the model hierarchy. This setting can result in turning off logging for any signal throughout the hierarchy, based on existing settings. To review settings, select the appropriate node in the **Model Hierarchy** pane.

- 3 View the node containing the logged signals that you want to override. If necessary, expand nodes or configure the Model Hierarchy pane to display masked subsystems. See “View Logging Configuration Using the Signal Logging Selector” on page 73-52.
- 4 Override signal logging settings. Use one of the following approaches, depending on whether your model uses model referencing:
  - “Models Without Model Referencing: Overriding Signal Logging Settings” on page 73-60
  - “Models with Model Referencing: Overriding Signal Logging Settings” on page 73-61

**Tip** To open the **Configuration Parameters > Data Import/Export** pane from the Signal Logging Selector, use the  button.

### Models Without Model Referencing: Overriding Signal Logging Settings

If your model does not use model referencing (that is, the model does not include any Model blocks), override signal logging settings using the following procedure.

- 1 Open the Signal Logging Selector. In the **Configuration Parameters > Data Import/Export** pane, click the **Configure Signals to Log** button.
  - If necessary, select **Signal logging** to enable the **Configure Signals to Log** button.

- 2 Set **Logging Mode** to **Override signals**.
- 3 View the node containing the logged signals that you want to override. If necessary, expand nodes or configure the Model Hierarchy pane to display masked subsystems. See “View Logging Configuration Using the Signal Logging Selector” on page 73-52.

- 4 In the **Contents** pane table, select the signal whose logging settings you want to override.
- 5 Override logging settings:
  - To disable logging for a signal, clear the **DataLogging** check box for that signal.
  - To override other signal logging settings (for example, decimation), ensure that the **DataLogging** check box is selected. Then, edit values in the appropriate columns.

### Models with Model Referencing: Overriding Signal Logging Settings

If your model uses model referencing (that is, the model includes at least one Model block), override signal logging settings using one or more of these procedures:

- “Enable Logging for All Logged Signals” on page 73-61
- “Disable Logging for All Signals in Node” on page 73-61
- “Override Signal Logging for a Subset of Signals” on page 73-62
- “Override Other Signal Logging Properties” on page 73-62

#### Enable Logging for All Logged Signals

By default, Simulink logs all the logged signals in a model, including the logged signals throughout model reference hierarchies.

If logging is disabled for any logged signals in the top-level model or in the top-level Model block in a model reference hierarchy, then in the **Model Hierarchy** pane, the check box to the left of that node is:

- Solid () , if logging is disabled for some of signals.
- Empty () , if logging is disabled for all the signals.

To enable logging of all logged signals for a node:

- 1 Open the Signal Logging Selector. In the **Configuration Parameters > Data Import/Export** pane, click the **Configure Signals to Log** button.
- 2 Set **Logging Mode** to **Override signals**.
- 3 View the node containing the logged signals that you want to override. If necessary, expand nodes or configure the Model Hierarchy pane to display masked subsystems. See “View Logging Configuration Using the Signal Logging Selector” on page 73-52.
- 4 In the **Model Hierarchy** pane, select the check box to the left of the node, so that the check box has a check mark ().
  - For the top-level model, logging is enabled for all logged signals in the top-level model, but not for logged signals in model reference hierarchies.
  - For a Model block at the top of a model referencing hierarchy, logging is enabled for the whole model reference hierarchy for the selected referenced model.

#### Disable Logging for All Signals in Node

If signal logging is enabled for any signals in a model node, then in the **Model Hierarchy** pane, the check box to the left of the node is:

- Solid () , if logging is enabled for some signals.
- Checked () , if logging is enabled for all signals.

To disable logging for all logged signals in a node of a model:

- 1 Open the Signal Logging Selector. In the **Configuration Parameters > Data Import/Export** pane, click the **Configure Signals to Log** button.
- 2 Set **Logging Mode** to **Override signals**.
- 3 View the node containing the logged signals that you want to override. If necessary, expand nodes or configure the Model Hierarchy pane to display masked subsystems. See “View Logging Configuration Using the Signal Logging Selector” on page 73-52.
- 4 In the **Model Hierarchy** pane, clear the check box to the left of the node, so that the check box is empty ().
  - For the top-level model, logging is disabled for all logged signals in the top-level model, but not for logged signals in model reference hierarchies.
  - For a Model block at the top of a model referencing hierarchy, logging is disabled for the whole model reference hierarchy for the selected referenced model.

#### Override Signal Logging for a Subset of Signals

To log some, but not all, logged signals in a model node:

- 1 Open the Signal Logging Selector. In the **Configuration Parameters > Data Import/Export** pane, click the **Configure Signals to Log** button.
- 2 Set **Logging Mode** to **Override signals**.
- 3 View the node containing the logged signals that you want to override. If necessary, expand nodes or configure the Model Hierarchy pane to display masked subsystems. See “View Logging Configuration Using the Signal Logging Selector” on page 73-52.
- 4 In the **Model Hierarchy** pane, ensure that the check box for the top-level model or Model block is either solid () , if logging is disabled for some of the signals, or empty () , if logging is disabled for all the signals. Click the check box to cycle through different states.
- 5 In the **Contents** pane table, for the signals that you want to log, select the check box in the **DataLogging** column.

To enable logging for multiple signals, hold the **Shift** or **Ctrl** key and select a range of signals or individual signals. Select the check box in the **DataLogging** column of one of the highlighted signals.

#### Override Other Signal Logging Properties

In addition to overriding the setting for the **DataLogging** property for a signal, you can override other signal logging properties, such as decimation.

- 1 Open the Signal Logging Selector. In the **Configuration Parameters > Data Import/Export** pane, click the **Configure Signals to Log** button.
- 2 Set **Logging Mode** to **Override signals**.

- 3 View the node containing the logged signals that you want to override. If necessary, expand nodes or configure the Model Hierarchy pane to display masked subsystems. See “View Logging Configuration Using the Signal Logging Selector” on page 73-52.
- 4 In the **Model Hierarchy** pane, ensure that the check box for the top-level model or Model block is solid () if logging is disabled for some signals, or empty () if logging is disabled for all signals. Click the check box to cycle through different states.
- 5 In the **Contents** pane table, for the signals for which you want to override logging properties, enable logging by selecting the check box in the **DataLogging** column.

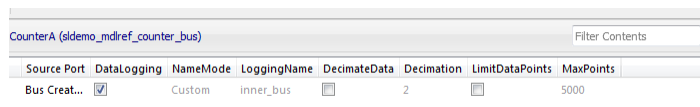

To enable logging for multiple signals, hold the **Shift** or **Ctrl** key and select a range of signals or individual signals. Select the check box in the **DataLogging** column of one of the highlighted signals.

- 6 In the **Contents** pane table, modify the settings for properties, such as **DecimateData** and **Decimation**.

## Override Signal Logging Settings from MATLAB

The MATLAB command-line interface for overriding signal logging settings includes:

- The **DataLoggingOverride** model parameter — Use to view or set signal logging override values for a model
- The following classes:
  - **Simulink.SimulationData.ModelLoggingInfo** — Specify signal logging override settings for a model. This class corresponds to the overall Signal Logging Selector interface.
  - **Simulink.SimulationData.SignalLoggingInfo** — Override settings for a specific signal. This class corresponds to a row in the logging property table in the Signal Logging Selector:

| Source Port  | DataLogging                         | NameMode | LoggingName | DecimateData             | Decimation | LimitDataPoints          | MaxPoints |
|--------------|-------------------------------------|----------|-------------|--------------------------|------------|--------------------------|-----------|
| Bus Creat... | <input checked="" type="checkbox"/> | Custom   | inner_bus   | <input type="checkbox"/> | 2          | <input type="checkbox"/> | 5000      |

- **Simulink.SimulationData.LoggingInfo** — Overrides for signal logging settings such as decimation. This class corresponds to the editable columns in a row in the logging property table in the Signal Logging Selector.

To query a model for its signal logging override status, use the **DataLoggingOverride** parameter.

To configure signal logging from the command line, use methods and properties of the three classes listed above. To apply the configuration, use **set\_param** with the **DataLoggingOverride** model parameter.

The following sections describe how to use the command-line interface to perform some common signal logging configuration tasks.

- “Create a Model Logging Information Object” on page 73-64
- “Specify Which Models to Log” on page 73-64
- “Log a Subset of Signals” on page 73-65
- “Override Other Signal Logging Properties” on page 73-66

## Create a Model Logging Information Object

To use the command-line interface for overriding signal logging settings, first create a `Simulink.SimulationData.ModelLoggingInfo` object. For example, use the following commands to create the model logging override object for the `ex_bus_logging` model and automatically add each logged signal in the model to that object:

```
open_system(docpath(fullfile(docroot, 'toolbox', 'simulink', ...
'examples', 'ex_bus_logging')));
open_system(docpath(fullfile(docroot, 'toolbox', 'simulink', ...
'examples', 'ex_mdref_counter_bus')));
mi = Simulink.SimulationData.ModelLoggingInfo.createFromModel(...
'ex_bus_logging')

mi =

ModelLoggingInfo with properties:

 Model: 'ex_bus_logging'
 LoggingMode: 'OverrideSignals'
LogAsSpecifiedByModels: {}
 Signals: [1x4 Simulink.SimulationData.SignalLoggingInfo]
```

The `LoggingMode` property is set to `OverrideSignals`, which configures the model logging override object to log only the signals specified in the `Signals` property.

To apply the model override object settings, use:

```
set_param(ex_bus_logging, 'DataLoggingOverride', mi);
```

Simulink saves the settings when you save the model.

You can control the kinds of systems from which to include logged signals. By default, the `Simulink.SimulationData.ModelLoggingInfo` object includes logged signals from:

- Libraries
- Masked subsystems
- Referenced models
- Active variants

As an alternative, you can use the `Simulink.SimulationData.ModelLoggingInfo` constructor and specify a `Simulink.SimulationData.SignalLoggingInfo` object for each signal. To ensure that you specified valid signal logging settings for a model, use the `verifySignalAndModelPaths` method with the `Simulink.SimulationData.ModelLoggingInfo` object for the model.

## Specify Which Models to Log

To specify whether to use the signal logging settings as specified in the model and all referenced models, or to override those settings, use the `LoggingMode` property of a `Simulink.SimulationData.ModelLoggingInfo` object.

You can control whether a top-level model and referenced models use override signal logging settings or use the signal logging settings specified by the model. See the `Simulink.SimulationData.ModelLoggingInfo` documentation.

This example shows how to log all signals as specified in the top model and all referenced models. The signal logging output is stored in `topOut`.

```
open_system(docpath(fullfile(docroot, 'toolbox', 'simulink', ...
'examples', 'ex_bus_logging')));
```

```

open_system(docpath(fullfile(docroot, 'toolbox', 'simulink', ...
'examples', 'ex_mdhref_counter_bus')));
mi = Simulink.SimulationData.ModelLoggingInfo...
('ex_bus_logging');
mi.LoggingMode = 'LogAllAsSpecifiedInModel'

mi =

```

ModelLoggingInfo with properties:

```

 Model: 'ex_bus_logging'
 LoggingMode: 'LogAllAsSpecifiedInModel'
 LogAsSpecifiedByModels: {}
 Signals: []

```

To apply the model override object settings, use:

```
set_param(ex_bus_logging, 'DataLoggingOverride', mi);
```

The following example shows how to log only signals in the top model:

```

open_system(docpath(fullfile(docroot, 'toolbox', 'simulink', ...
'examples', 'ex_bus_logging')));
open_system(docpath(fullfile(docroot, 'toolbox', 'simulink', ...
'examples', 'ex_mdhref_counter_bus')));
mi = Simulink.SimulationData.ModelLoggingInfo...
('ex_bus_logging');
mi.LoggingMode = 'OverrideSignals';
mi = mi.setLogAsSpecifiedInModel('ex_bus_logging', true);

```

To apply the model override object settings, use:

```
set_param(ex_bus_logging, 'DataLoggingOverride', mi);
```

Simulink saves the settings when you save the model.

### Log a Subset of Signals

For a simple model with a limited number of logged signals, you could create an empty `Simulink.SimulationData.ModelDataLogInfo` object. Then create `Simulink.SimulationData.SignalLoggingInfo` objects for each of the signals that you want to log, and assign those objects to the model logging information object.

```

open_system(docpath(fullfile(docroot, 'toolbox', 'simulink', ...
'examples', 'ex_bus_logging')));
open_system(docpath(fullfile(docroot, 'toolbox', 'simulink', ...
'examples', 'ex_mdhref_counter_bus')));
mdl = 'ex_bus_logging';
blk = 'ex_bus_logging/IncrementBusCreator';
blkPort = 1;

load_system(mdl);

ov = Simulink.SimulationData.ModelLoggingInfo(mdl);

so = Simulink.SimulationData.SignalLoggingInfo(blk, blkPort);

ov.Signals(1) = so;

```

```
% apply this object so the model
set_param mdl, 'DataLoggingOverride', ov);
```

```
% Simulate
sim mdl);
```

```
% observe that only the signal
topOut
```

To apply the model override object settings, use:

```
set_param mdl, 'DataLoggingOverride', ov);
```

Simulink saves the settings when you save the model.

For a model that uses model referencing, or that is complex, to specify a subset of logged signals to log, consider using the `findSignal` method with a `Simulink.SimulationData.ModelLoggingInfo` object. For example, to log only one signal from the referenced model instance referenced by:

```
open_system(docpath(fullfile(docroot, 'toolbox', 'simulink', ...
'examples', 'ex_bus_logging')));
open_system(docpath(fullfile(docroot, 'toolbox', 'simulink', ...
'examples', 'ex_mdref_counter_bus')));

mi = Simulink.SimulationData.ModelLoggingInfo.createFromModel(...
'ex_bus_logging');
pos = mi.findSignal({'ex_bus_logging/CounterA' ...
'ex_mdref_counter_bus/Bus Creator'}, 1)
```

```
pos =
```

```
4
```

```
for idx=1:length(mi.Signals)
mi.Signals(idx).LoggingInfo.DataLogging = (idx == pos);
end
```

To apply the model override object settings, use:

```
set_param(ex_bus_logging, 'DataLoggingOverride', mi);
```

Simulink saves the settings when you save the model.

### Override Other Signal Logging Properties

In addition to overriding the setting for the `DataLogging` property for a signal, you can override other signal logging properties, such as decimation.

Use `Simulink.SimulationData.LoggingInfo` properties to override signal logging properties. The following example shows how to set the decimation override settings.

```
open_system(docpath(fullfile(docroot, 'toolbox', 'simulink', ...
'examples', 'ex_bus_logging')));
open_system(docpath(fullfile(docroot, 'toolbox', 'simulink', ...
```

```
'examples', 'ex_mdhref_counter_bus')));
mi = Simulink.SimulationData.ModelLoggingInfo.createFromModel...
 ('ex_bus_logging');
pos = mi.findSignal({'ex_bus_logging/CounterA' ...
 'ex_mdhref_counter_bus/Bus Creator'}, 1);
mi.Signals(pos).LoggingInfo.DecimateData = true;
mi.Signals(pos).LoggingInfo.Decimation = 2;
```

To apply the model override object settings, use:

```
set_param(ex_bus_logging, 'DataLoggingOverride', mi);
```

Simulink saves the settings when you save the model.

### More About

- “Override Signal Logging Settings with Signal Logging Selector” on page 73-59

## View and Access Signal Logging Data

### In this section...

“Signal Logging Object” on page 73-68

“Access Data Programmatically” on page 73-68

“Handling Spaces and Newlines in Logged Names” on page 73-69

“Access Logged Signal Data in ModelDataLogs Format” on page 73-71

You can view logged signal data during simulation, using the Simulation Data Inspector, or for paused or stopped simulations, using other visualization interfaces. See “Decide How to Visualize Simulation Data” on page 30-2.

Alternatively, you can access signal logging data programmatically, using MATLAB commands, as described in this topic.

**Tip** If you do not see logging data for a signal that you marked in the model for signal logging, check the logging configuration. Use the Signal Logging Selector to enable logging for a signal whose logging is overridden. For details, see “View the Signal Logging Configuration” on page 73-50 and “Override Signal Logging Settings” on page 73-58.

### Signal Logging Object

Simulink saves signal logging data in a `Simulink.SimulationData.Dataset` object, which is a MATLAB workspace variable. The default name of the signal logging variable is `logsout`. You can change the variable name. For details, see “Specify a Name for Signal Logging Data” on page 73-57.

You can specify whether you want the data for individual signals in a dataset to use MATLAB `timeseries` or `timetable` elements. Set the **Dataset signal format** configuration parameter (for details, see “Dataset signal format”).

Releases earlier than R2016a also supported a `ModelDataLogs` format. For details, see “Migrate Scripts That Use Legacy ModelDataLogs API” on page 73-55.

### Access Data Programmatically

You can use the `Simulink.SimulationData.Dataset` API to access signal logging data programmatically. To access `Dataset` object elements, use indexing with curly braces. For example, you can access the first element of the `topOut` signal logging `Dataset` object using index 1. This example is based on the use of the default setting of `timeseries` for the dataset elements. For details about `timeseries` and `timetable` format data, see “Dataset signal format”.

```
open_system(docpath(fullfile(docroot,'toolbox','simulink',...
'examples','ex_bus_logging')));
open_system(docpath(fullfile(docroot,'toolbox','simulink',...
'examples','ex mdlref_counter_bus')));
sim('ex_bus_logging')
topOut
```

Simulink.SimulationData.Dataset 'topOut' with 4 elements

| Name | BlockPath |
|------|-----------|
|------|-----------|

---

```

1 [1x1 Signal] COUNTERBUS ex_bus_logging/COUNTERBUSCreator
2 [1x1 Signal] OUTPUTBUS ex_bus_logging/CounterA
3 [1x1 Signal] INCREMENTBUS ex_bus_logging/IncrementBusCreator
4 [1x1 Signal] inner_bus ..erA|ex_mdref_counter_bus/Bus Creator

```

- Use braces { } to access, modify, or add elements using index.

```
element1 = topOut{1}
```

```
element1 =
```

```

Simulink.SimulationData.Signal
Package: Simulink.SimulationData

```

```
Properties:
```

```

 Name: 'COUNTERBUS'
 PropagatedName: ''
 BlockPath: [1x1 Simulink.SimulationData.BlockPath]
 PortType: 'outport'
 PortIndex: 1
 Values: [1x1 struct]

```

```
Methods, Superclasses
```

```
element1.Values
```

```
ans =
```

```

 data: [1x1 timeseries]
 limits: [1x1 struct]

```

To search for specific elements in a `Dataset` object, use the `find` method. To return the names of the `Dataset` object elements, use the `getNames` method.

---

**Tip** To call a function on each specified MATLAB timeseries object, you can use the `Simulink.SimulationData.forEachTimeseries` function. For example, you can use this function to make it easy to resample every element of a structure of timeseries objects obtained by logging a bus signal.

---

## Handling Spaces and Newlines in Logged Names

This example shows three signals that illustrate how signal logging names:

- A signal with a name that contains a space
- A signal with a name that contains a newline
- An unnamed signal that originates on a block with a name that contains a newline

Simulate the model and then look at the signal logging results in the `logouts` variable. You can see that the names in the `Dataset` object use a space where the signal name contained a space and a newline where the name contained a newline. The unnamed signal has an empty character array as its name.

```
logouts
```

```
logouts =
```

```
Simulink.SimulationData.Dataset 'logouts' with 3 elements
```

|                | Name | BlockPath                              |
|----------------|------|----------------------------------------|
| 1 [1x1 Signal] | x y  | ex_signal_names_with_spaces/Sine Wave  |
| 2 [1x1 Signal] | a b  | ex_signal_names_with_spaces/Sine Wave1 |
| 3 [1x1 Signal] | ' '  | ex_signal_names_with_spaces/Sine Wave2 |

- Use braces `{ }` to access, modify, or add elements using index.

You can access a signal with a name that contains a space by name or by index. You just need to include the space in the name you pass to the `getElement` function. To access a signal with a name that contains a newline, use the index.

```
>> logouts{2}
```

```
ans =
```

```
Simulink.SimulationData.Signal
Package: Simulink.SimulationData
```

```
Properties:
```

```
 Name: 'a b'
 PropagatedName: ''
 BlockPath: [1x1 Simulink.SimulationData.BlockPath]
 PortType: 'output'
 PortIndex: 1
 Values: [1x1 timeseries]
```

## Access Logged Signal Data in ModelDataLogs Format

Before R2016a, you could log signals in ModelDataLogs format. Starting in R2016a, you cannot log data in the ModelDataLogs format. Signal logging uses the Dataset format.

However, you can use data that was logged in a previous release using ModelDataLogs format.

For more information, see `Simulink.ModelDataLogs`.

## Log Signals in For Each Subsystems

### In this section...

“Log Signal in Nested For Each Subsystem” on page 73-72

“Log Bus Signals in For Each Subsystem” on page 73-74

The approach you use to log data for a signal in a For Each subsystem depends on whether the signal is a:

- Nonbus signal — Log directly in a For Each subsystem
- A bus or array of buses signal — Use one of these approaches:
  - Use a Bus Selector block to select the signals you want to log and mark those signals for signal logging. This approach works well for many models.
  - Attach the signal to an Outport block and log the signal outside of the For Each subsystem. Use this approach when you want to log a whole bus signal, and that bus signal includes many bus element signals.

---

**Note** You cannot log bus signals directly in a For Each subsystem.

You cannot log a signal inside a referenced model that is inside a For Each subsystem if either of these conditions exists:

- The For Each subsystem is in a model simulating in rapid accelerator mode.
  - The For Each subsystem itself is in a model referenced by a Model block in accelerator mode.
- 

The data for each logged signal in a For Each subsystem is saved in a separate `Dataset` element as a `Simulink.SimulationData.Signal` object. The format of the logged signal data depends on how you set the **Dataset signal format** configuration parameter:

- If the setting is `timeseries`, then each signal object contains an array of MATLAB `timeseries` objects. The array keeps the data from different For Each iteration separate.
- If the setting is `timetable`, then each signal object contains a cell array of MATLAB `timetable` objects. The dimensions of this array match the number of For Each iterations. For example, if the For Each subsystem has three iterations, then the logged data has a `3x1` array of `timeseries` or `timetable` objects. For nested For Each subsystems, each layer of nesting adds another dimension to the logged data.

### Log Signal in Nested For Each Subsystem

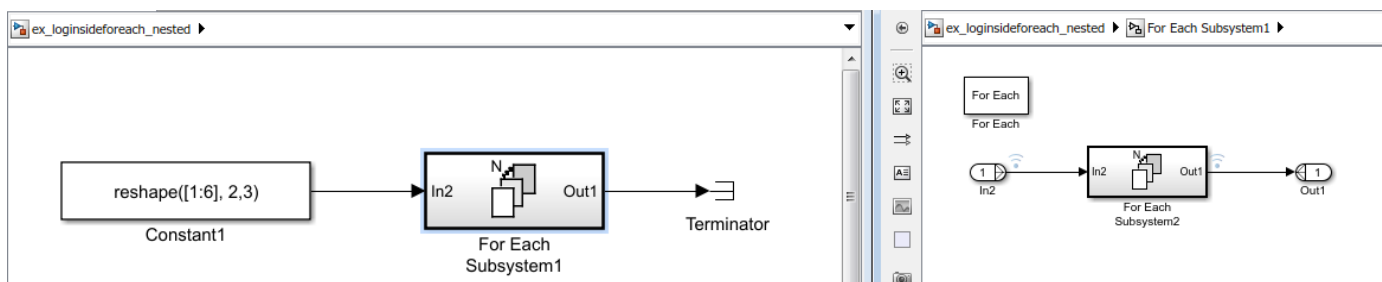

This example logs a signal in a nested For Each subsystem.

Open the `ex_loginsideforeach_nested` model.

```
open_system(docpath(fullfile(docroot,'toolbox','simulink',...
'examples','ex_loginsideforeach_nested.slx')))
```

In the Simulink Editor, open the For Each Subsystem1 block, and inside that subsystem, open the For Each Subsystem2 block.

Simulate the model and examine the signal logging data for the first iteration of the top subsystem and the third iteration of the bottom subsystem. The 2x3 timeseries results from two iterations at the first For Each level and three iterations at the second (nested) level

```
sim('ex_loginsideforeach_nested');
logout.get('nestedDelay')
```

ans =

```
Simulink.SimulationData.Signal
Package: Simulink.SimulationData
```

Properties:

struct with fields:

```
 Name: 'nestedDelay'
PropagatedName: ''
 BlockPath: [1x1 Simulink.SimulationData.BlockPath]
 PortType: 'outport'
 PortIndex: 1
 Values: [2x3 timeseries]
```

Return the values of the nestedDelay object.

```
logout.get('nestedDelay').Values(1,3)
```

timeseries

```
Common Properties:
 Name: 'nestedDelay'
 Time: [5x1 double]
 TimeInfo: [1x1 tsdata.timemetadata]
```

```
Data: [1x1x5 double]
DataInfo: [1x1 tsdata.datametadate]
```

## Log Bus Signals in For Each Subsystem

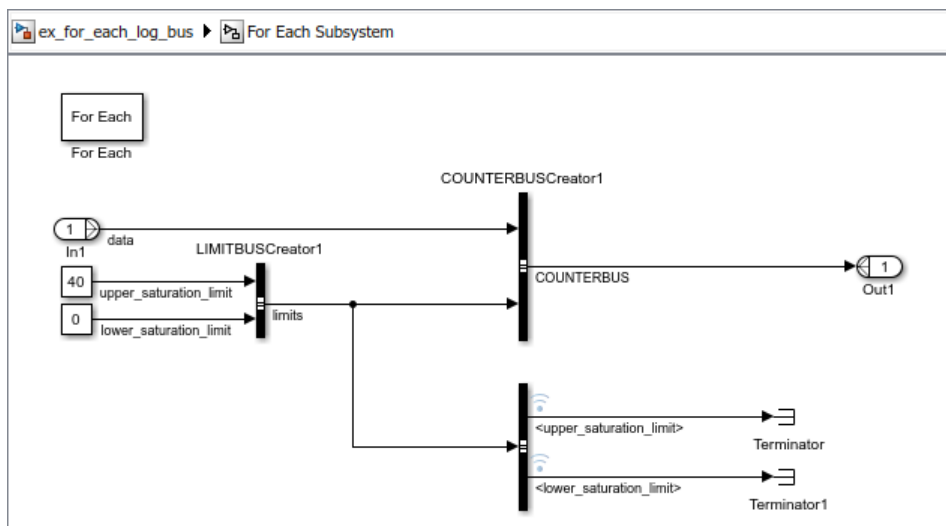

This example logs a two bus signal in a For Each subsystem. For one bus signal, you use a Bus Selector block and then log each selected signal. For the other bus signal, you use Outport blocks and log outside of the For Each subsystem.

Open the `ex_for_each_log_bus` model.

```
open_system(docpath(fullfile(docroot, 'toolbox', 'simulink', ...
'examples', 'ex_for_each_log_bus.slx')))
```

In the Simulink Editor, open the For Each Subsystem block.

To log the signals in the `limits` bus signal, the signal is branched to a Bus Selector block, and each of the bus element signals is marked for signal logging.

To log the whole `COUNTERBUS` signal, the bus signal is connected to an Outport block. The output signal from the For Each subsystem is marked for signal logging. To have the bus signal cross the subsystem boundary, the Bus Creator block that creates the `COUNTERBUS` signal has the **Output data type** parameter set to `Bus: COUNTERBUS` and **Output as nonvirtual bus** check box selected.

Simulate the model and examine the signal logging output. Focus on one of the bus element signals logged inside the For Each subsystem and on the bus signal logged outside of the For Each subsystem.

```
sim('ex_for_each_log_bus');
logshow
```

```
Simulink.SimulationData.Dataset 'logout' with 3 elements
```

|                | Name                     | BlockPath                                |
|----------------|--------------------------|------------------------------------------|
| 1 [1x1 Signal] | OutsideForEach           | ex_for_each_log_bus/For Each Subsystem   |
| 2 [1x1 Signal] | <lower_saturation_limit> | ...g_bus/For Each Subsystem/Bus Selector |
| 3 [1x1 Signal] | <upper_saturation_limit> | ...g_bus/For Each Subsystem/Bus Selector |

- Use braces { } to access, modify, or add elements using index.

Return the values of the `lower_saturation_limit` object.

```
logout{2}.Values
```

3x1 timeseries array with properties:

```
Events
Name
UserData
Data
DataInfo
Time
TimeInfo
Quality
QualityInfo
IsTimeFirst
TreatNaNasMissing
Length
```

Return the values of the `OutsideForEach` object.

```
logout{1}.Values
```

```
ans =
```

3x1 struct array with fields:

```
data
limits
```

If the Dataset signal format is `timetable`, then the output is a cell array of `timetable` objects. For example:

```
out = sim('ex_for_each_log_bus', 'DatasetSignalFormat', 'timetable');
out.logout{2}.Values
```

```
ans =
```

3x1 cell array

```
{11x1 timetable}
{11x1 timetable}
{11x1 timetable}
```

### Simulation State Information

Some blocks maintain state information that they use during simulation. For example, the state information for a Unit Delay block is the output signal value from the previous simulation step. The block uses the state information to calculate the output value for the current simulation step.

Some examples of how saved state information is used include:

- Stopping a simulation for a model and using the saved state information as input when you restart the simulation.
- Simulating one model and using the saved state information as input for the simulation of another model that builds on the results of the first model.
- Examining changes in state information throughout a simulation.

### Types of State Information

You can save these kinds of state information.

| Type of State Information                         | Description                                                                                                                                   | Configuration Parameters in Data Import/Export Pane |
|---------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------|
| States for each simulation step                   | State information of blocks (referred to as partial state data) at each time step of a simulation                                             | <b>States</b>                                       |
| Final state                                       | State information of blocks at the end of the simulation                                                                                      | <b>Final states</b>                                 |
| Final state with <code>ModelOperatingPoint</code> | Final state with a <code>ModelOperatingPoint</code> object that captures additional internal information that Simulink uses during simulation | <b>Final States and Save final operating point</b>  |

`ModelOperatingPoint` provides more complete final simulation state information than final states information by itself does. However, if the requirements and limitations of using `ModelOperatingPoint` do not meet your modeling requirements, save final state information without `ModelOperatingPoint`.

**Comparison of Operating Point and Final State Logging**

| <b>Characteristic</b>     | <b>Final State</b>                                                                                                                                                                                         | <b>Final State with Operating Point</b>                                                                                                                                                                                                                               |

| Resumed simulation        | Not supported                                                                                                                                                                                              | Supported.                                                                                                                                                                                                                                                            |
| Saved state data          | Only logged states — the continuous and discrete states of blocks — which are a subset of the complete simulation state of the model<br><br>User data, run-time parameters, or logs of the model not saved | Complete state information.<br><br>Does not save user data, run-time parameters, or logs of the model.                                                                                                                                                                |
| Block output              | User data, run-time parameters, or logs of the model not saved                                                                                                                                             | Simulink tries to save the output of a block as part of a <code>ModelOperatingPoint</code> object even if S-functions declare that no <code>ModelOperatingPoint</code> objects exist in the block. If the block output is of custom type, Simulink displays an error. |
| Readability               | Use structure with time format for best readability                                                                                                                                                        | To examine a simplified view of the data, consider using the <code>loggedStates</code> property of the <code>Simulink.op.ModelOperatingPoint</code> class.                                                                                                            |
| Restoring state data      | Can save and restore in different simulation modes. If logged state information is not sufficient, you can obtain different results in the normal mode and the accelerator mode.                           | Cannot save in normal mode and restore in accelerator mode, or conversely save in accelerator mode and restore in normal mode.                                                                                                                                        |
| Restoring multiple states | You can initialize only one out of multiple logged states in the model.                                                                                                                                    | You restore all states in the model. You cannot load a subset of states.                                                                                                                                                                                              |

| Characteristic          | Final State                                                                        | Final State with Operating Point                                                                                                                                                                                                                                                                                                                                                                             |
|-------------------------|------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Structural changes      | You can make structural changes between simulation and restoring the simulation.   | You cannot make structural changes to the model between when you save the <code>ModelOperatingPoint</code> object and when you restore the simulation using the <code>ModelOperatingPoint</code> object. For example, you cannot add or remove a block after saving the <code>ModelOperatingPoint</code> object without repeating the simulation and saving the new <code>ModelOperatingPoint</code> object. |
| Input to model function | To input to model function, use Array format with non-complex data of type double. | You cannot input the <code>ModelOperatingPoint</code> object to model function.                                                                                                                                                                                                                                                                                                                              |
| Code generation         | Supported                                                                          | Not supported.                                                                                                                                                                                                                                                                                                                                                                                               |

For both `ModelOperatingPoint` and final state logging, Simulink saves state information at one of these points:

- At the final time step
- At the execution time at which the simulation paused or stopped

For additional information about `ModelOperatingPoint`, see “Limitations of Saving and Restoring Operating Point” on page 25-47.

## Format for State Information Saved Without Operating Point

If you do not use the `ModelOperatingPoint` for saving state information, then use **Configuration Parameters > Data Import/Export > Format** to specify the data format for the saved state information.

You can set **Format** to:

- Dataset (default)
- Array
- Structure
- Structure with time

The default setting for the **Format** parameter is Dataset. The Dataset format:

- Stores logged data in `timeseries` or `timetable` objects. You can work with data saved in a `timeseries` or `timetable` object in MATLAB without a Simulink license.
- Supports logging multiple data values for a given time step, which can be required for logging data in a For Iterator Subsystem, a While Iterator Subsystem, and Stateflow.
- Does not support logging states inside a function-call subsystem or during rapid accelerator simulations.

- Does not support code generation.

Signal logging always uses the `Dataset` format. Logging states data using the `Dataset` format allows you to post-process simulation data without writing custom code for different types of logged data. When you log states using the `Dataset` format, the data also automatically streams to the Simulation Data Inspector during simulation.

The `Array` option for the **Format** parameter exists for backward compatibility with models developed in earlier releases, when Simulink supported only the `Array` format for logging state information. The order of signals within the array depends on the block sorted order, which can change from one simulation to another when you change any of the following:

- The model (even without changing the signal)
- The simulation mode
- The code generation mode

The variation in signal order can present challenges when post-processing the logged data.

The `Structure` and `Structure with time` formats are useful when using state information to initialize a model for simulation, allowing you to:

- Associate initial state values directly with the full path name to the states. This association eliminates errors that can occur if Simulink reorders the states, but the order of the initial state array does not change correspondingly.
- Assign a different data type to the initial value of each state.
- Initialize only a subset of the states.

## State Information for Referenced Models

When Simulink saves states in the structure or structure-with-time format, it adds an `inReferencedModel` subfield to the `signals` field of the structure. The value of this additional subfield is `true` (1) if the `signals` field records the final state of a block that resides in the referenced model. For example:

```
xout.signals(1)
ans =
 values: [101x1 double]
 dimensions: 1
 label: 'DSTATE'
 blockName: [1x66 char]
inReferencedModel: 1
```

If the `signals` field records a referenced model state, its `blockName` subfield contains a compound path of a top model path and a referenced model path. The top model path is the path from the model root to the Model block that references the referenced model. The referenced model path is the path from the referenced model root to the block whose state the `signals` field records. The compound path uses a `|` character to separate the top and referenced model paths. For example:

```
>> xout.signals(1).blockName
ans =
sldemo_mdref_basic/CounterA|sldemo_mdref_counter/Previous Output
```

## Save State Information

### In this section...

“Save State Information for Each Simulation Step” on page 73-82

“Save Partial Final State Information” on page 73-82

“Examine State Information Saved Without the Operating Point” on page 73-82

“Save Final State Information with Operating Point” on page 73-84

### Save State Information for Each Simulation Step

You can save state information for logged states for each simulation step during a simulation. That level of state information can be helpful for debugging.

- 1 Select the **Configuration Parameters > Data Import/Export > States** check box.
- 2 In the **States** edit box, you can specify a different variable for the state information, if you do not want to use the default `xout` variable.
- 3 Also in the **Data Import/Export** pane, set the **Format** parameter to `Dataset`, `Structure`, or `Structure with time`, unless you use array format for compatibility with a legacy model.

`Dataset` format does not support:

- Logging states information inside a function-call subsystem
- Logging states during rapid accelerator simulations
- Code generation

- 4 Click **Apply**.
- 5 Simulate the model.

### Save Partial Final State Information

To save just the logged states (the continuous and discrete states of blocks):

- 1 Select the **Configuration Parameters > Data Import/Export > Final states** check box.
- 2 In the **Final states** edit box, you can specify a different variable for the state information, if you do not want to use the default `xFinal` variable.
- 3 Clear the **Save final operating point** parameter.
- 4 Set the **Format** parameter to `Dataset`, `Structure`, or `Structure with time`.
- 5 Click **Apply**.
- 6 Simulate the model.

### Examine State Information Saved Without the Operating Point

If you enable the **Configuration Parameters > Data Import/Export > Final states** or **States** parameters, Simulink saves the state information in the format that you specify with the **Format** parameter. The default variable for **Final state** information is `xFinal`, and the variable for state information for **States** information is `xout`.

If a model has no states saved, then `xFinal` and `xout` are empty variables. To determine whether a model has states saved, use the `isempty(xout)` command.

### Final State Information in Dataset Format

For example, suppose that you saved final state information in `Dataset` format, and use the default `xFinal` variable for the saved state information.

```
xFinal
xFinal =
Simulink.SimulationData.Dataset 'xFinal' with 2 elements
```

|   |             | Name   | BlockPath |
|---|-------------|--------|-----------|
| 1 | [1x1 State] | CSTATE | vdp/x1    |
| 2 | [1x1 State] | DSTATE | vdp/x2    |

- Use braces `{ }` to access, modify, or add elements using index.

Examine the first element of the state data set.

```
xFinal{1}
ans =
Simulink.SimulationData.State
Package: Simulink.SimulationData
Properties:
 Name: 'CSTATE'
 BlockPath: [1x1 Simulink.SimulationData.BlockPath]
 Label: CSTATE
 Values: [1x1 timeseries]
```

### Final State Information in Structure with Time Format

For example, suppose that you saved final state information in a structure with time format, and use the default `xFinal` variable for the saved state information.

To find the simulation time and number of states in the `vdp` model, enter the `xFinal` variable.

```
xFinal
xFinal =
 time: 20
 signals: [1x2 struct]
```

In this case, the simulation time is 20 and there are two states. To examine the first state, use this command.

```
xFinal.signals(1)
ans =
 values: 2.0108
```

```
 dimensions: 1
 label: 'CSTATE'
 blockName: 'vdp/x1'
 stateName: ''
inReferencedModel: 0
```

The `values` and `blockName` fields of the first state structure show that the final value for the output signal of the `x1` block is 2.018.

---

**Note** If you write a script to analyze state information, use a combination of `label` and `blockName` values to identify a specific state uniquely. Do not rely on the order of the states.

---

## Save Final State Information with Operating Point

To save complete state information, save the `ModelOperatingPoint` object for a simulation.

- 1 Select the **Configuration Parameters > Data Import/Export > Final states** check box.
- 2 Also in the Data Import/Export pane, select the **Save final operating point** parameter.
- 3 In the edit box next to the **Save final operating point** parameter, enter a variable name for the `ModelOperatingPoint` object and click **Apply**.
- 4 Simulate the model.

For more information about using the operating point, see “Save and Restore Simulation Operating Point” on page 25-41.

## Log Data to the Workspace and a File Using the Record Block

When you log data using the Record block, you can log data to the workspace, to a file, or to both the workspace and a file. You can modify the recording settings for the Record block between simulations as needed. This example shows how to access data in the workspace and in a file after simulation, how to configure the Record block properties, and how to modify the data visualization in the Record block. The model for the example is simple: a Record block logs data from a Sine Wave block, a Chirp Signal block, and a Square Wave Generator block.

```
open_system('RecordWorkspaceAndFile');
```

To log data to the workspace and to the MLDATX file, simulate the model.

```
out = sim('RecordWorkspaceAndFile');
```

### Access Data Logged to the Workspace

By default, model simulations return all logged data in a single `Simulink.SimulationOutput` object using the variable `out`. Type `out` in the Command Window to see the contents of the `Simulink.SimulationOutput` object.

```
out
```

```
out =
```

```
Simulink.SimulationOutput:
 recordout: [1x1 Simulink.SimulationData.Dataset]
 tout: [51x1 double]

SimulationMetadata: [1x1 Simulink.SimulationMetadata]
ErrorMessage: [0x0 char]
```

The logged workspace data for the Record block is inside the `out` workspace variable, stored in the `Simulink.SimulationData.Dataset` object `recordout`. Type `out.recordout` in the Command Window to view the contents of the `recordout` Dataset object.

```
out.recordout
```

```
ans =
```

```
Simulink.SimulationData.Dataset 'Run 1: RecordWorkspaceAndFile' with 3 elements
```

|   |              | Name         | PropagatedName | BlockPath                     |
|---|--------------|--------------|----------------|-------------------------------|
| 1 | [1x1 Signal] | Chirp Signal | Chirp Signal   | RecordWorkspaceAndFile/Record |
| 2 | [1x1 Signal] | Sine Wave    | Sine Wave      | RecordWorkspaceAndFile/Record |
| 3 | [1x1 Signal] | Square Wave  | Square Wave    | RecordWorkspaceAndFile/Record |

- Use braces { } to access, modify, or add elements using index.

The data for each signal connected to the Record block is stored in a `Simulink.SimulationData.Signal` object. The data and time values for the signal are stored as a `timeseries` object in the **Values** property of the `Signal` object. Access the data for the Square Wave signal.

```
recorddata = out.recordout;
sqsignal = get(recorddata,3);
sqts = sqsignal.Values;
sqWaveData = sqts.Data;
```

You can also access the data by combining all the steps into a single line of code.

```
sqWaveData = get(out.recordout,3).Values.Data;
```

### Access Data Logged to a File

This example logs data to a file in the working directory. After simulating the model, you see the `recording.mldatx` file in the Current Folder pane of the MATLAB® window. You can view the data in the MLDATX file using the Simulation Data Inspector. Double-click the file or open the file using the `open` function.

```
open('recording.mldatx');
```

In the Simulation Data Inspector, you can inspect the signal data using cursors or the replay controls, and you can build custom visualizations. You can use the Simulation Data Inspector programmatic interface to access the data from the MLDATX file in the workspace or a script, and you can export the data to the workspace, a MAT file, or an Excel® file.

You can also configure the Record block to log data to a MAT file or an Excel file. To access and analyze data logged to a MAT file, you can load the data into the base workspace, or you can import the data into the Simulation Data Inspector. You can access and analyze data logged to an Excel file in Excel, by reading the data into the base workspace, or by importing the data into the Simulation Data Inspector.

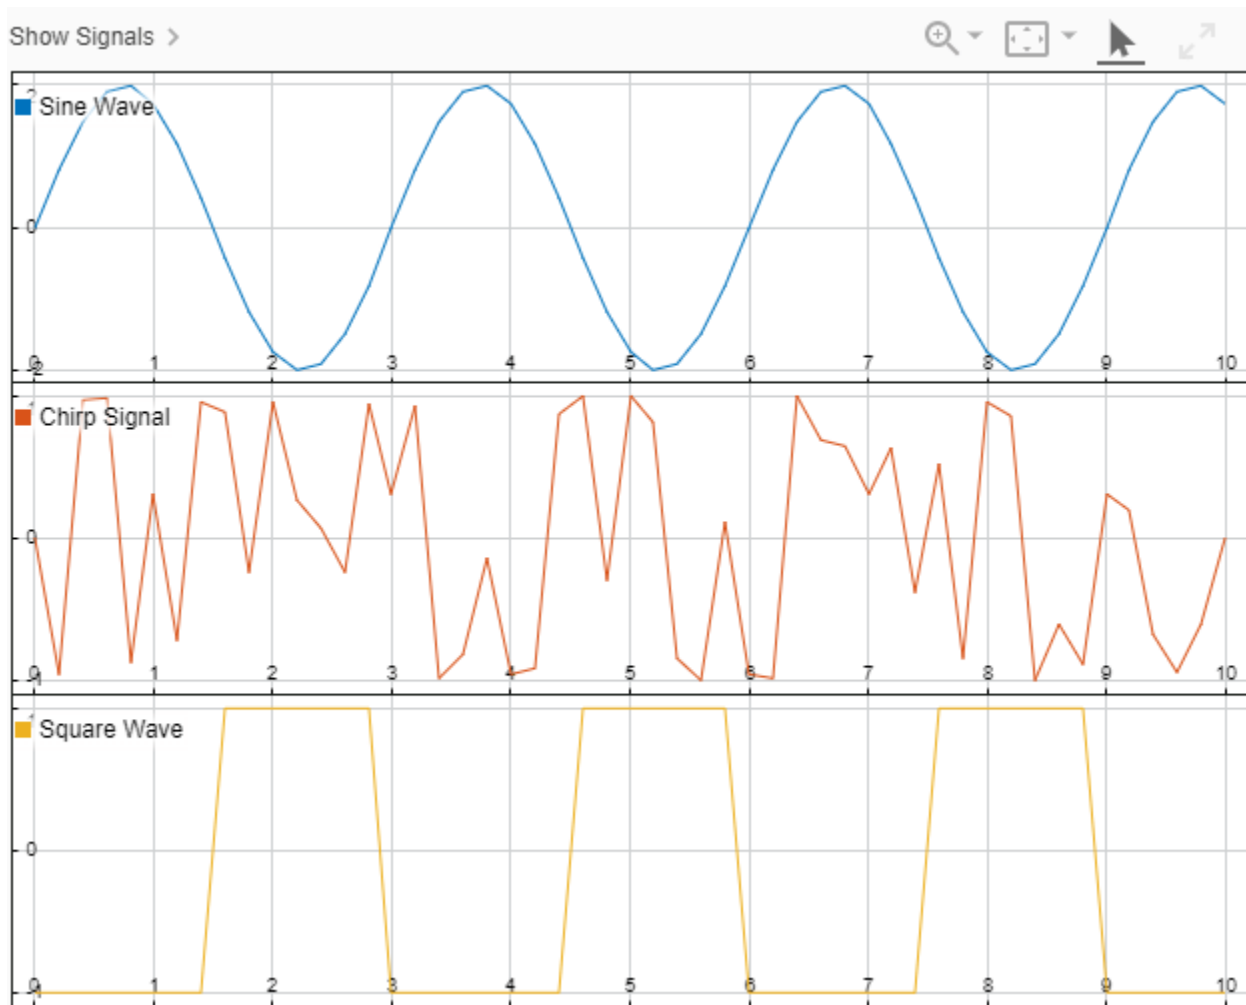

### Configure Recording Settings

View and modify the recording parameters for the Record block using the Property Inspector. To display the Property Inspector, on the **Modeling** tab, under **Design**, select **Property Inspector**. To view the parameters for the Record block in the model, select the Record block. The Record block in this example is configured to log data to the workspace using the variable `recordout` and to log data to the file `recording.mldatx`. Using the recording settings, you can disable logging to the

workspace or logging to file, and you can change the **File Type** parameter to log data to a MAT file or an Excel file and specify the location for the logged file.

### View Data Using the Record Block

The Record block also visualizes the connected signals. To view the connected signal data, double-click the Record block. By default, the Record block displays each connected signal as a sparkline.

You can change the layout and display data on other types of visualizations, including an XY plot, a map, and time plots. For example, change the visualization to a time plot. On the **Simulation** tab, under **Prepare**, select **Sparklines** and then **Time Plot**. When you change to a different visualization, plotted signals are cleared from the subplot. Next, change the layout to include three subplots. From the **Layouts** menu, select the **Column Right** option.

To plot signals in the time plots, expand the signals table by clicking **Show Signals** in the upper-left. Check the box next to the signal you want to plot on the selected subplot, outlined in blue. For example, plot the **Sine Wave** signal in the first subplot. Then, select another subplot and plot the **Chirp** signal. Select the final subplot and plot the **Square Wave** signal.

When you save the model, the updated visualization is saved in the Record block. When you simulate the model, the Record block updates the plots with data from the current simulation.

# Working with Data Stores

---

- “Data Store Basics” on page 74-2
- “Model Global Data by Creating Data Stores” on page 74-10
- “Log Data Stores” on page 74-28

## Data Store Basics

A *data store* is a repository to which you can write data, and from which you can read data, without having to connect an input or output signal directly to the data store. Data stores are accessible across model levels, so subsystems and referenced models can use data stores to share data without using I/O ports.

### When to Use a Data Store

Data stores can be useful when multiple signals at different levels of a model need the same global values, and connecting all the signals explicitly would clutter the model unacceptably or take too long to be feasible. Data stores are analogous to global variables in programs, and have similar advantages and disadvantages, such as making verification more difficult.

To share data between the instances of a reusable algorithm (for example, a subsystem in a custom library or a reusable referenced model), you can use a data store. For more information about data sharing for a reusable referenced model, see “Share Data Among Referenced Model Instances” on page 8-34.

### Data Stores and Software Verification

Data stores can have significant effects on software verification, especially in the area of data coupling and control. Models and subsystems that use only input and output ports to pass data result in clean, well-specified, and easily verifiable interfaces in the generated code.

Data stores, like any type of global data, make verification more difficult. If your development process includes software verification, consider planning for the effect of data stores early in the design process.

For more information, see RTCA DO-331, “Model-Based Development and Verification Supplement to DO-178C and DO-278A,” Section MB.6.3.3.b.

### Goto and From Blocks as a Signal Routing Alternative

In some cases, you may be able to use a simpler technique, Goto blocks and From blocks, to obtain results similar to those provided by data stores. The principal disadvantage of data Goto/From links is that they generally are not accessible across nonvirtual subsystem boundaries, while an appropriately configured data store can be accessed anywhere. See the Goto and From block reference pages for more information about Goto/From links.

## Local and Global Data Stores

You can define two types of data stores:

- A *local data store* is accessible from anywhere in the model hierarchy that is at or below the level at which you define the data store, except from referenced models. You can define a local data store graphically in a model or by creating a model workspace signal object (`Simulink.Signal`).
- A *global data store* is accessible from throughout the model hierarchy, including from referenced models. Define a global data store only in the MATLAB base workspace, using a signal object. The only type of data store that a referenced model can access is a global data store.

In general, locate a data store at the lowest level in the model that allows access to the data store by all the parts of the model that need that access. Some examples of local and global data stores appear in “Data Store Examples” on page 74-10.

For information about using referenced models, see “Model References”.

## Data Store Diagnostics

- “About Data Store Diagnostics” on page 74-3
- “Detecting Access Order Errors” on page 74-3
- “Detecting Multitasking Access Errors” on page 74-5
- “Detecting Duplicate Name Errors” on page 74-6
- “Data Store Diagnostics in the Model Advisor” on page 74-8

### About Data Store Diagnostics

Simulink provides various run-time and compile-time diagnostics that you can use to help avoid problems with data stores. Diagnostics are available in the Model Configuration Parameters dialog box and the Data Store Memory block's parameters dialog box. The Simulink Model Advisor provides support by listing cases where data store errors are more likely because diagnostics are disabled.

### Detecting Access Order Errors

- “Data Store Diagnostics and Models Referenced in Accelerator Mode” on page 74-4
- “Data Store Diagnostics and the MATLAB Function Block” on page 74-5

You can use data store run-time diagnostics to detect unintended sequences of data store reads and writes that occur during simulation. You can apply these diagnostics to all data stores, or allow each Data Store Memory block to set its own value. The diagnostics are:

- **Detect read before write**
- **Detect write after read**
- **Detect write after write**

These diagnostics appear in the **Model Configuration Parameters > Diagnostics > Data Validity > Data Store Memory block** pane, where each can have one of the following values:

- `Disable all` — Disables this diagnostic for all data stores accessed by the model.
- `Enable all as warnings` — Displays the diagnostic as a warning in the MATLAB Command Window.
- `Enable all as errors` — Halts the simulation and displays the diagnostic in an error dialog box.
- `Use local settings` — Allow each Data Store Memory block to set its own value for this diagnostic (default).

The same diagnostics also appear in each Data Store Memory block parameters dialog box **Diagnostics** tab. You can set each diagnostic to `none`, `warning`, or `error`. The value specified by an individual block takes effect only if the corresponding configuration parameter is `Use local settings`. See “Model Configuration Parameters: Data Validity Diagnostics” and the Data Store Memory documentation for more information.

The most conservative technique is to set all data store diagnostics to Enable all as errors in **Model Configuration Parameters > Diagnostics > Data Validity > Data Store Memory block**. However, this setting is not best in all cases, because it can flag intended behavior as erroneous. For example, the next figure shows a model that uses block priorities to force the Data Store Read block to execute before the Data Store Write block:

An error occurred during simulation because the data store A is read from the Data Store Read block before the Data Store Write block updates the store. If the associated delay is intended, you can suppress the error by setting the global parameter **Detect read before write** to Use local settings, then setting that parameter to none in the **Diagnostics** pane of the Data Store Memory block dialog box. If you use this technique, set the parameter to error in all other Data Store Memory blocks aside from those that are to be intentionally excluded from the diagnostic.

#### Data Store Diagnostics and Models Referenced in Accelerator Mode

For models referenced in Accelerator mode, Simulink ignores the following **Configuration Parameters > Diagnostics > Data Validity > Data Store Memory block** parameters if you set them to a value other than Disable all.

- **Detect read before write** (ReadBeforeWriteMsg)
- **Detect write after read** (WriteAfterReadMsg)
- **Detect write after write** (WriteAfterWriteMsg)

You can use the Model Advisor to identify models referenced in Accelerator mode for which Simulink ignores the configuration parameters listed above.

- 1 In the Simulink Editor, in the **Modeling** tab, click **Model Advisor**.

- 2 Select **By Task**.
- 3 Run the **Check diagnostic settings ignored during accelerated model reference simulation** check.

### Data Store Diagnostics and the MATLAB Function Block

Diagnostics might be more conservative for data store memory used by MATLAB Function blocks. For example, if you pass arrays of data store memory to MATLAB functions, optimizations such as  $A = \text{foo}(A)$  might result in MATLAB marking the entire contents of the array as read or written, even though only some elements were accessed.

### Detecting Multitasking Access Errors

Data integrity may be compromised if a data store is read from in one task and written to in another task. For example, suppose that:

- 1 A task is writing to a data store.
- 2 A second task interrupts the first task.
- 3 The second task reads from that data store.

If the first task had only partly updated the data store when the second task interrupted, the resulting data in the data store is inconsistent. For example, if the value is a vector, some of its elements may have been written in the current time step, while the rest were written in the previous step. If the value is a multi-word, it may be left in an inconsistent state that is not even partly correct.

Unless you are certain that task preemption cannot cause data integrity problems, set the compile-time diagnostic **Model Configuration Parameters > Diagnostics > Data Validity > Data Store Memory block > Multitask data store** to warning (the default) or error. This diagnostic flags any case of a data store that is read from and written to in different tasks. The next figure illustrates a problem detected by setting **Multitask data store** to error:

Since the data store A is written to in the fast task and read from in the slow task, an error is reported, with suggested remedy. This diagnostic is applicable even in the case that a data store read or write is inside of a conditional subsystem. Simulink correctly identifies the task that the block is executing within, and uses that task for the purpose of evaluating the diagnostic.

The next figure shows one solution to the problem shown above: place a rate transition block after the data store read, which previously accessed the data store at the slower rate.

With this change, the data store write can continue to occur at the faster rate. This may be important if that data store must be read at that faster rate elsewhere in the model.

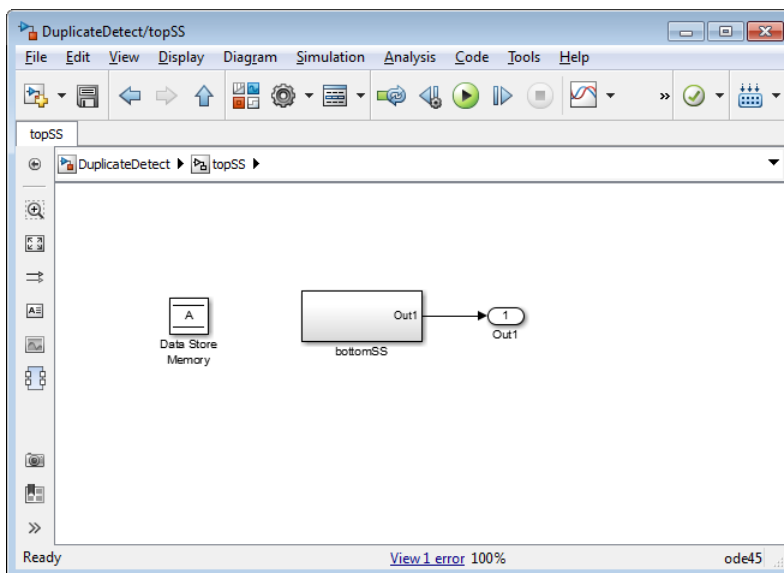

The **Multitask Data Store** diagnostic also applies to data store reads and writes in referenced models. If two different child models execute a data store's reads and writes in differing tasks, the error will be detected when Simulink compiles their common parent model.

### Detecting Duplicate Name Errors

Data store errors can occur due to duplicate uses of a data store name within a model. For instance, data store shadowing occurs when two or more data store memories in different nested scopes have the same data store name. In this situation, the data store memory referenced by a data store read or write block at a low level may not be the intended store.

To prevent errors caused by duplicate data store names, set the compile-time diagnostic **Model Configuration Parameters > Diagnostics > Data Validity > Data Store Memory block > Duplicate data store names** to warning or error. By default, the value of the diagnostic is none,

suppressing duplicate name detection. The next figure shows a problem detected by setting **Duplicate data store names** to error:

The data store read at the bottom level of a subsystem hierarchy refers to a data store named A, and two Data Store Memory blocks in the same model have that name, so an error is reported. This diagnostic guards against assuming that the data store read refers to the Data Store Memory block in the top level of the model. The read actually refers to the Data Store Memory block at the intermediate level, which is closer in scope to the Data Store Read block.

### Data Store Diagnostics in the Model Advisor

The Model Advisor provides several diagnostics that you can use with data stores. See these sections for information about Model Advisor diagnostics for data stores:

“Check Data Store Memory blocks for multitasking, strong typing, and shadowing issues”

“Check data store block sample times for modeling errors”

“Check if read/write diagnostics are enabled for data store blocks”

## Specify Initial Value for Data Store

In general, to specify an initial value for a data store, you can use the same techniques that you use for other blocks. See “Initialize Signals and Discrete States” on page 76-40.

With most blocks, you can take advantage of scalar expansion to minimize the effort of specifying an initial value for a nonscalar signal. When you specify a scalar initial value, each element in the signal uses that scalar.

However, when you set the **Dimensions** parameter to -1 in a Data Store Memory block (the default), you cannot use scalar expansion. Instead, you must specify an initial value that has the same dimensions as the stored signal. To take advantage of scalar expansion of the initial value, set the **Dimensions** parameter to a specific value such as [1 2] or [1 myDim] (for symbolic dimensions).

A *data store* is a repository to which you can write data, and from which you can read data, without having to connect an input or output signal directly to the data store. Data stores are accessible across model levels, so subsystems and referenced models can use data stores to share data without using I/O ports. To decide whether to use data stores, see “Data Store Basics” on page 74-2.

### Data Store Examples

#### Overview

The following examples illustrate techniques for defining and accessing data stores. See “Order Data Store Access” on page 74-19 for techniques that control data store access over time, such as ensuring that a given data store is always written before it is read. See “Data Store Diagnostics” on page 74-3 for techniques you can use to help detect and correct potential data store errors without needing to run any simulations.

---

**Note** In addition to the following examples, see the `sldemo_mdref_dsm` model, which shows how to use global data stores to share data among referenced models.

---

#### Local Data Store Example

The following model illustrates creation and access of a local data store, which is visible only in a model or particular subsystem.

This model uses a data store to permit subsystem A to signal that its output is invalid.

If subsystem A's output is invalid, the model uses the output of subsystem B.

**Global Data Store Example**

The following model replaces the subsystems of the previous example with functionally identical referenced models to illustrate use of a global data store to share data in a model reference hierarchy.

In this example, the top model uses a signal object in the MATLAB workspace to define the error data store. This is necessary because data stores are visible across model boundaries only if they are defined by signal objects in the MATLAB workspace or a data dictionary. The model specifies code for the `PreLoadFcn` model callback parameter that creates the signal object. This code executes before the model loads.

## Create and Apply Data Stores

**Note** To use buses and arrays of buses with data stores, perform *both* the following procedure and “Setting Up a Model to Use Data Stores with Buses and Arrays of Buses” on page 74-22.

The following is a general workflow for configuring data stores. You can perform the tasks in a different order, or separately from the rest, depending on how you use data stores.

- 1 Where applicable, plan your use of data stores to minimize their effect on software verification. For more information, see “Data Stores and Software Verification” on page 74-2.
- 2 Create data stores using the techniques described in “Data Stores with Data Store Memory Blocks” on page 74-13 or “Data Stores with Signal Objects” on page 74-16. For greater reliability, consider assigning rather than inheriting data store attributes, as described in “Specifying Data Store Memory Block Attributes” on page 74-14.
- 3 Add to the model Data Store Write and Data Store Read blocks to write to and read from the data stores, as described in “Access Data Stores with Simulink Blocks” on page 74-17.

- 4 Configure the model and the blocks that access each data store to avoid concurrency failures when reading and writing the data store, as described in “Order Data Store Access” on page 74-19.
- 5 Apply the techniques described in “Data Store Diagnostics” on page 74-3 as needed to prevent data store errors, or to diagnose them if they occur during simulation.
- 6 If you intend to generate code for your model, see “Data Stores in Generated Code” (Simulink Coder).

To create a data store, you create a Data Store Memory block or a `Simulink.Signal` object. The block or signal object represents the data store and specifies its properties. Every data store must have a unique name.

- A Data Store Memory block implements a local data store. See “Data Stores with Data Store Memory Blocks” on page 74-13.
- A `Simulink.Signal` object can act as a local or global data store. See “Data Stores with Signal Objects” on page 74-16.

Data stores implemented with Data Store Memory blocks:

- Support data store initialization
- Provide control of data store scope and options at specific levels in the model hierarchy
- Require a block to represent the data store
- Cannot be accessed within referenced models
- Cannot be in a subsystem that a For Each Subsystem block represents.

Data stores implemented with `Simulink.Signal` objects:

- Provide model-wide control of data store scope and options
- Do not require a block to represent the data store
- Can be accessed in referenced models, if the data store is global

Be careful not to equate local data stores with Data Store Memory blocks, and global data stores with `Simulink.Signal` objects. Either technique can define a local data store, and a signal object can define either a local or a global data store.

## Data Stores with Data Store Memory Blocks

- “Creating the Data Store” on page 74-13
- “Specifying Data Store Memory Block Attributes” on page 74-14

### Creating the Data Store

To use a Data Store Memory block to define a data store, drag an instance of the block into the model at the topmost level from which you want the data store to be visible. The result is a local data store, which is not accessible within referenced models.

- To define a data store that is visible at every level within a given model, except within Model blocks, drag the Data Store Memory block into the root level of the model.
- To define a data store that is visible only within a particular subsystem and the subsystems that it contains, but not within Model blocks, drag the Data Store Memory block into the subsystem.

Once you have added the Data Store Memory block, use its parameters to define the data store's properties. The **Data store name** property specifies the name of the data store that the Data Store Write and Data Store Read blocks access. See Data Store Memory documentation for details.

You can specify data store properties beyond those definable with Data Store Memory block parameters by selecting the **Data store name must resolve to Simulink signal object** option and using a signal object as the data store name. See “Specifying Attributes Using a Signal Object” on page 74-14 for details.

### Specifying Data Store Memory Block Attributes

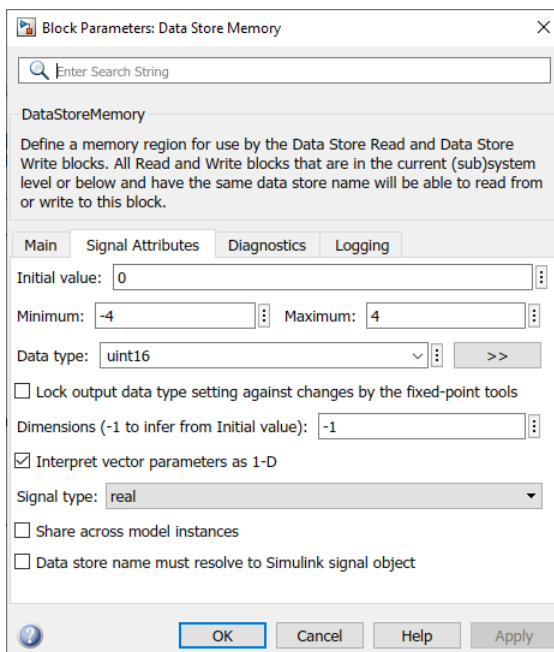

A Data Store Memory block can inherit three data attributes from its corresponding Data Store Read and Data Store Write blocks. The inheritable attributes are:

- Data type
- Complexity
- Sample time

However, allowing these attributes to be inherited can cause unexpected results that can be difficult to debug. To prevent such errors, use the Data Store Memory block dialog or a `Simulink.Signal` object to specify the attributes explicitly.

### Specifying Attributes Using Block Parameters

You can use the Data Store Memory block dialog box or the Model Data Editor **Data Stores** tab (in the **Modeling** tab, click **Model Data Editor**) to specify the data type and complexity of a data store. In the next figure, the block dialog box sets the **Data type** to `uint16` and the **Signal type** to `real`.

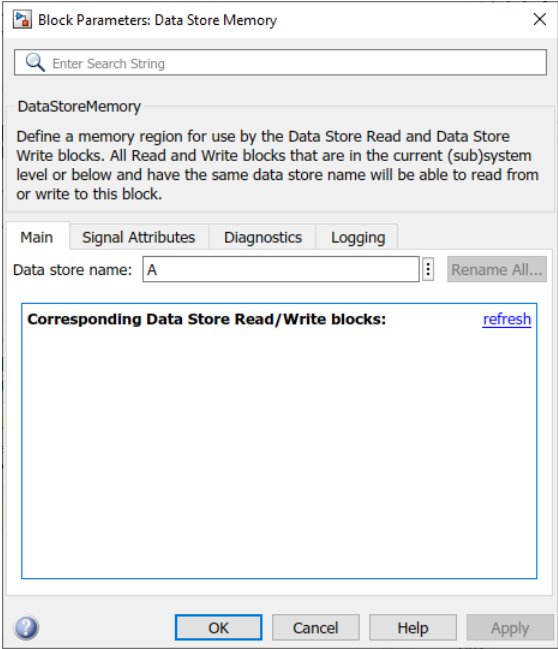

### Specifying Attributes Using a Signal Object

You can use a `Simulink.Signal` object to specify data store attributes for a Data Store Memory block.

**Tip** To establish an implicit data store, as described in “Data Stores with Signal Objects” on page 74-16, use the same general approach as when you explicitly associate a signal object with a Data Store Memory block.

The next figure shows a Data Store Memory block that specifies resolution to a Simulink.Signal object, named A. To use a signal object for the data store, set **Data store name** to the name of the signal object. For compile-time checking, open the **Signal Attributes** tab and select the **Data store name must resolve to Simulink signal object** parameter.

Alternatively, on the Model Data Editor **Data Stores** tab (on the **Modeling** tab, click **Model Data Editor**), while editing the data store name, click the nearby action button  and select **Create and Resolve**. In the Create New Data dialog box, set **Value** to Simulink.Signal.

The signal object specifies values for all three data attributes that the data store would otherwise inherit. In this example, which defines a local data store, the Simulink.Signal object A has the following inherited properties: `DataType`, `Complexity`, and `SampleTime`.

```
A =
Simulink.Signal (handle)
 CoderInfo: [1x1 Simulink.CoderInfo]
 Description: ''
 DataType: 'auto'
 Min: []
 Max: []
 Unit: ''
 Dimensions: 1
 DimensionsMode: 'auto'
 Complexity: 'auto'
 SampleTime: -1
 InitialValue: 0
```

For more information about specifying signal object attributes for local and global data stores, see “Signal Object Attributes for Data Stores” on page 74-16.

### **Use Model Data Editor to Configure Data Store Memory Blocks in a List**

Use the **Data Stores** tab in the Model Data Editor to configure the parameters of a Data Store Memory block. Use this technique to configure the data store without locating it in the model and to configure the data store together with other interface elements such as Inport and Outport blocks. The Model Data Editor also shows you information for Data Store Read and Data Store Write blocks in the same list.

To open the **Model Data Editor**, in the **Modeling** tab, click **Model Data Editor**.

## **Data Stores with Signal Objects**

- “Creating the Data Store” on page 74-16
- “Local and Global Data Stores” on page 74-16
- “Signal Object Attributes for Data Stores” on page 74-16

### **Creating the Data Store**

To use a `Simulink.Signal` object to define a data store without using a Data Store Memory block, create the signal object in a workspace that is visible to every component that needs to access the data store. The name of the associated data store is the name of the signal object. You can use this name in Data Store Read and Data Store Write blocks, just as if it were the **Data store name** of a Data Store Memory block. Simulink creates an associated data store when you use the signal object for data storage.

### **Local and Global Data Stores**

You can use a `Simulink.Signal` object to define either a local or a global data store.

- If you define the object in the MATLAB base workspace or a data dictionary, the result is a global data store, which is accessible in every model within Simulink, including all referenced models.
- If you create the object in a model workspace, the result is a local data store, which is accessible at every level in a model except any referenced models.

### **Signal Object Attributes for Data Stores**

Those data store attributes that a signal object does not define have the same default values that they do in a Data Store Memory block. The property values of a signal object used as a data store have different requirements, depending on whether the data store is local or global.

Once you have created the object, set the properties of the signal object to the values that you want the corresponding data store properties to have. For example, the following commands define a data store named `Error` in the MATLAB base workspace:

```
Error = Simulink.Signal;
Error.Description = 'Use to signal that subsystem output is invalid';
Error.DataType = 'boolean';
Error.Complexity = 'real';
Error.Dimensions = 1;
Error.SampleTime = 0.1;
```

**Attributes for Local Data Stores**

For a local data store, for each parameter listed below, you can either set the value explicitly or you can have the data store inherit the value from the Data Store Write and Data Store Read blocks.

- DataType
- Complexity
- SampleTime

To define a local data store using a Data Store Memory block, you can use a signal object for the **Data store name** parameter. For compile-time checking, in the **Signal Attributes** tab, select the **Data store must resolve to Simulink signal object** parameter. The **Data store must resolve to Simulink signal object** parameter causes Simulink to display an error and stop compilation if Simulink cannot find the signal object or if the signal object properties are inconsistent with the signal object properties.

**Attributes for Global Data Stores**

The following table describes the parameter requirements for global data stores.

| Parameter  | Global Data Store Value |
|------------|-------------------------|
| DataType   | Must be set explicitly  |
| Complexity | Must be set explicitly  |
| Dimensions | Can be set or inherited |
| SampleTime | Can be set or inherited |

**Modify Attributes of Data Store Defined by Signal Object**

You can use the Model Data Editor (in the **Modeling** tab, click **Model Data Editor**) to modify and inspect the attributes of data stores, Data Store Read, and Data Store Write blocks. On the **Data Stores** tab, to show the attributes of data stores that you define by using signal objects (such as Simulink.Signal), click the **Show/refresh additional information** button. Then, if a Data Store Read or Data Store Write block shown in the data table refers to a data store defined by a signal object, the table includes a row that corresponds to the object.

For more information, see **Model Data Editor**.

**Access Data Stores with Simulink Blocks**

- “Writing to a Data Store” on page 74-17
- “Reading from a Data Store” on page 74-18
- “Accessing a Global Data Store” on page 74-18

**Writing to a Data Store**

To set the value of a data store at each time step:

- 1 Create an instance of a Data Store Write block at the level of your model that computes the value.
- 2 Set the Data Store Write block **Data store name** parameter to the name of the data store to which you want it to write data.

- 3 Connect the output of the block that computes the value to the input of the Data Store Write block.

### Reading from a Data Store

To get the value of a data store at each time step:

- 1 Create an instance of a Data Store Read block at the level of your model that needs the value.
- 2 Set the Data Store Read block **Data store name** parameter to the name of the data store from which you want it to read.
- 3 Connect the output of the Data Store Read block to the input of the block that needs the data store value.

### Accessing a Global Data Store

When connected to a global data store (one that is defined by a signal object in the MATLAB workspace), a Data Store Read or Data Store Write block displays the word `global` above the data store name.

## Order Data Store Access

- “About Data Store Access Order” on page 74-19
- “Ordering Access Using Function Call Subsystems” on page 74-19
- “Ordering Access Using Block Priorities” on page 74-21

### About Data Store Access Order

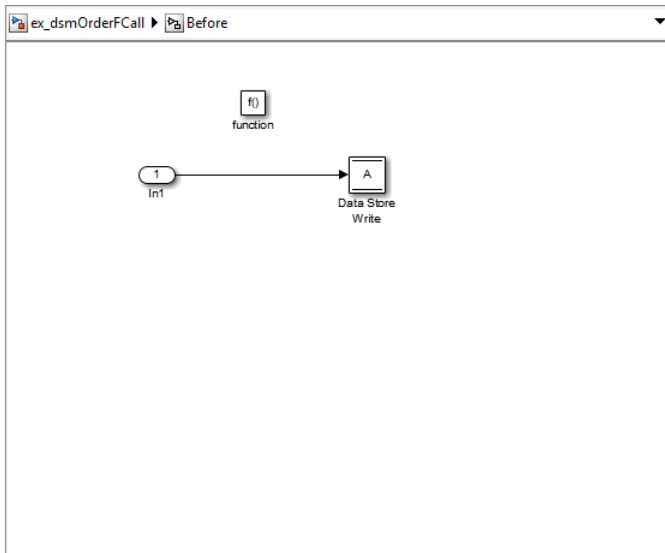

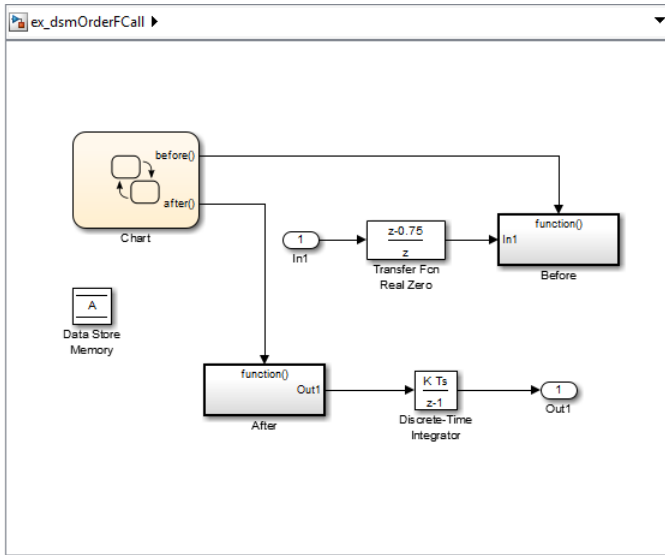

To obtain correct results from data stores, you must control the order of execution of the data store’s reads and writes. If a data store’s read occurs before its write, latency is introduced into the algorithm: the read obtains the value that was computed and stored in the previous time step, rather than the value computed and stored in the current time step.

Such latency may cause the system to behave other than as designed, and in some cases may destabilize the system. Even if these problems do not occur, an uncontrolled access order could change from one release of Simulink to the next.

This section describes several strategies for explicitly controlling the order of execution of a data store’s reads and writes. See “Data Store Diagnostics” on page 74-3 for techniques you can use to detect and correct potential data store errors without running simulations.

### Ordering Access Using Function Call Subsystems

You can use function call subsystems to control the execution order of model components that access data stores. The next figure shows this technique:

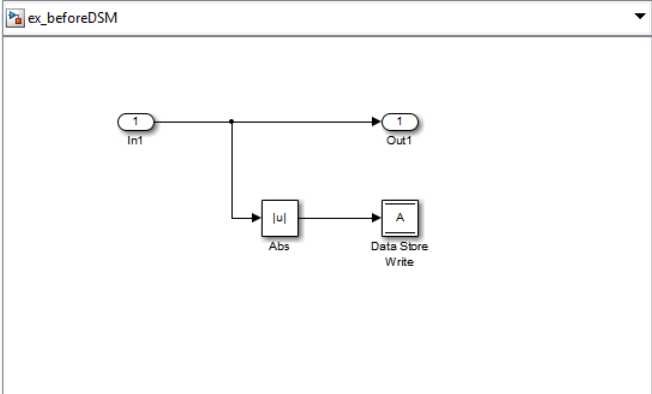

The subsystem Before contains the Data Store Write, and the Stateflow chart calls that subsystem before it calls the subsystem After, which contains the Data Store Read.

**Ordering Access Using Block Priorities**

You can embed data store reads and writes inside atomic subsystems or Model blocks whose priorities specify their relative execution order.

The Model block `beforeDSM` has a lower priority than `afterDSM`, so it is guaranteed to execute first. Since `beforeDSM` is atomic, all of its operations, including the Data Store Write, will execute prior to `afterDSM` and all of its operations, including the Data Store Read.

## Data Stores with Buses and Arrays of Buses

Benefits of using data stores with buses and arrays of buses include:

- Simplifying the model layout by associating multiple signals with a single data store
- Producing generated code that represents the data in the store data as structures that reflect the bus hierarchy
- Writing to and reading from data stores without creating data copies, which results in more efficient data access

You cannot use a bus or array of buses that contains:

- Variable-dimension signals
- Frame-based signals

### Setting Up a Model to Use Data Stores with Buses and Arrays of Buses

This procedure applies to local and global data stores, and to data stores defined with a Data Store Memory block or a `Simulink.Signal` object. Before performing the procedure, you must understand how to use data stores in a model, as described in “Create and Apply Data Stores” on page 74-12.

To use buses and arrays of buses with data stores:

- 1 Use the Bus Editor to define a bus object whose properties match the bus data that you want to write to and read from a data store. For details, see “Create and Specify `Simulink.Bus` Objects” on page 77-52.
- 2 Add a data store (using a Data Store Memory block or a `Simulink.Signal` object) for storing the bus data.
- 3 Specify the bus object as the data type of the data store. For details, see “Specify a Bus Object Data Type” on page 68-38.
- 4 If you use a MATLAB structure for the initial value of the data store, then set **Configuration Parameters > Diagnostics > Data Validity > Advanced parameters > Underspecified**

**initialization detection** to Simplified. For details, see “Specify Initial Conditions for Bus Elements” on page 77-61 and “Underspecified initialization detection”.

- 5 (Optional) Select individual bus elements to write to or read from a data store. For details, see “Accessing Specific Bus and Matrix Elements” on page 74-23.

## Accessing Specific Bus and Matrix Elements

### Selecting Specific Bus or Matrix Elements

By default, a model writes and reads all bus and matrix elements to and from a data store.

To select specific bus or matrix elements to write to or read from a data store, use the **Element Assignment** pane of the Data Store Write block and the **Element Selection** pane of the Data Store Read block . Selecting specific bus or matrix elements offers the following benefits:

- Reducing the number of blocks in the model. For example, you can eliminate a Data Store Read and Bus Selector block pair or a Data Store Write and Bus Assignment block pair for each specific bus element that you want to access).
- Faster simulation of models with large buses and arrays of buses.

### Writing Specific Elements to a Data Store

---

**Note** The following procedure describes how to use the Data Store Write block interface to write specific elements to a data store. You can also perform this task at the command line, using the `DataStoreElements` parameter to specify elements. For details, see “Specification using the command line” on page 74-26.

---

To assign specific bus or matrix elements to write to a data store:

- 1 Select the Data Store Write block and in the parameters dialog box, select the **Element Assignment** pane. For example, suppose you are using a bus with a data store named DSM:

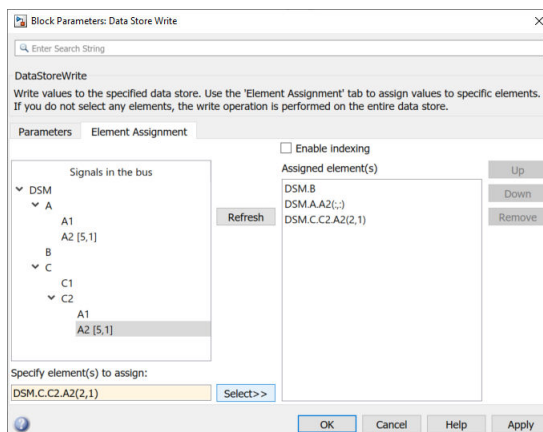

- 2 Expand all the elements in the **Signals in the bus** list.

3 Specify the elements that you want to write to the data store. For example:

- In the **Signals in the bus** list, click B. Then click **Select>>** to select the element B.
- To write all the elements of A2 (in the A nested bus), select A2 [5, 1]. Then click **Select>>**.
- To write the second element of A2 in the C2 nested bus, select the A2 [5, 1] element. In the **Specify element(s) to assign** text box, edit the text to say DSM.C.C2.A2(2, 1).

For more examples, see “Specifying Elements to Assign or Select” on page 74-25.

- 4 (Optional) Reorder the assigned elements, which changes the order of the ports of the Data Store Write block.
- To reorder an assigned element, in the **Assigned element(s)** list, select the element that you want to move, and click **Up** or **Down**.
  - To remove an assigned element, click **Remove**.
- 5 To apply the assigned elements, click **OK**.

The Data Store Write block has a port for each assigned element. The names of the selected elements that correspond to each port appear in the block icon. If you assign several signals, these additions may diminish the readability of the model. To improve readability, you can expand the size of the block or create multiple Data Store Write blocks.

### Reading Specific Elements from a Data Store

Reading specific elements from a data store involves very similar steps as described in “Writing Specific Elements to a Data Store” on page 74-23. The Data Store Read block differs slightly from the Data Store Write block. A Data Store Read block has:

- An **Element Selection** pane instead of an **Element Assignment** pane
- A **Selected element(s)** list instead of an **Assigned element(s)** list

### Specifying Elements to Assign or Select

Use MATLAB matrix element syntax to specify specific elements. For details about specifying matrices in MATLAB, see “Creating, Concatenating, and Expanding Matrices”.

---

**Note** To select matrix elements with dynamic indexing with the Data Store Read and Data Store Write blocks, select **Enable indexing** on the **Element Selection / Element Assignment** pane of the block parameters dialog. You can select only one element at a time for dynamic indexing. See Data Store Read and Data Store Write.

---

### Valid element specifications

The following table shows examples of valid syntax for specifying elements to assign or select. These examples use the A2 nested bus of the A bus, as shown in the bus hierarchy used in “Writing Specific Elements to a Data Store” on page 74-23.

| Valid Syntax               | Description                                  |
|----------------------------|----------------------------------------------|
| DSM.A.A2 (: , :)           | Selects all elements in every dimension      |
| DSM.A.A2 ([ 1, 3, 5 ] , 1) | Selects the first, third, and fifth elements |
| DSM.A.A2 ( 2 : 5 , 1)      | Selects the second through the fifth element |

### Invalid element specifications

The following table shows examples of invalid syntax for specifying elements to assign or select. These examples use the A2 nested bus of the A bus, as shown in the bus hierarchy used in “Writing Specific Elements to a Data Store” on page 74-23.

| Invalid Syntax    | Reason the Syntax Is Invalid                                                                                                                                                                                                                         |
|-------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| DSM.A.A2(:)       | You must specify a colon for each dimension. For the bus hierarchy used in these examples, you must use two colons.                                                                                                                                  |
| DSM.A.A2(2:end,1) | You cannot use the end operator.                                                                                                                                                                                                                     |
| DSM.A.A2(idx,1)   | You cannot use variables to specify indices. Consider using dynamic indexing by selecting <b>Enable indexing</b> on the <b>Element Selection / Element Assignment</b> pane of the block parameters dialog. See Data Store Read and Data Store Write. |
| DSM.A.A2(-1,1)    | The dimension -1 is not within the valid dimension bounds.                                                                                                                                                                                           |

### Specification using the command line

To set the elements to write to or read from, use the `DataStoreElements` parameter. Use a pound sign (#) to delimit multiple elements. For example, select the Data Store Write or Data Store Read block for which you want to specify elements and enter a command such as:

```
set_param(gcb, 'DataStoreElements', 'DSM.A#DSM.B#DSM.C(3,4)')
```

This specification results in the block now having three ports corresponding to the elements that you specified.

## Rename Data Stores

- “Rename Data Store Defined by Block” on page 74-26
- “Rename Data Store Defined by Signal Object” on page 74-26

### Rename Data Store Defined by Block

Rename a data store everywhere it is used by Data Store Read and Data Store Write blocks in a model.

- 1 In a Data Store Memory block dialog box, type a new name in the **Data store name** box, and click **Rename All**.
- 2 In the **Rename All** dialog box, confirm the new data store name in the **New name** field, and click **OK**.

---

**Note** You cannot use **Rename All** to rename a data store if you create a `Simulink.Signal` object in a workspace to control the code generated for the data store. Instead, you must rename the corresponding `Simulink.Signal` object using Model Explorer. For an example, see “Rename Data Store Defined by Signal Object” on page 74-26.

---

### Rename Data Store Defined by Signal Object

This example shows how to rename a data store defined by a `Simulink.Signal` object. You can use Model Explorer to rename the object everywhere it is used by Data Store Read and Data Store Write blocks in a model or in a model reference hierarchy.

- 1 Open the model `sldemo_mdhref_dsm`. The model creates a `Simulink.Signal` object `ErrorCond` in the MATLAB base workspace and uses the object as a global data store in a model reference hierarchy.
- 2 Open Model Explorer.
- 3 In the **Model Hierarchy** pane, select the base workspace.
- 4 In the **Contents** pane, right-click the data store `ErrorCond` and select **Rename All**.
- 5 In the **Select a system** dialog box, click the name of the model `sldemo_mdhref_dsm` to select it as the context for renaming the data store `ErrorCond`.
- 6 Select **Search in referenced models** since `ErrorCond` is a global data store that is used in a referenced model. Click **OK**.

The **Update diagram to include recent changes** check box is cleared by default to save time by avoiding unnecessary model diagram updates. Select the check box to incorporate recent changes you made to the model by forcing a diagram update.

- 7 Click **OK** in response to the message to update the model diagram.

Since you just opened the model, you must update the model diagram at least once before renaming a variable such as `ErrorCond`. You could have selected **Update diagram to include recent changes** in the **Select a system** dialog box to force an initial diagram update, though you typically use that option when you make changes to the model while performing multiple variable renaming operations.

- 8 In the **Rename All** dialog box, type the new name for the data store in the **New name** box and click **OK**.

## Customized Data Store Access Functions in Generated Code

Embedded Coder provides a storage class that you can use to specify customized data store access functions in generated code. See “Organize Parameter Data into a Structure by Using Struct Storage Class” (Embedded Coder) and “Access Data Through Functions with Storage Class GetSet” (Embedded Coder).

## Log Data Stores

### In this section...

“Logging Local and Global Data Store Values” on page 74-28

“Supported Data Types, Dimensions, and Complexity for Logging Data Stores” on page 74-28

“Data Store Logging Limitations” on page 74-28

“Logging Data Stores Created with a Data Store Memory Block” on page 74-29

“Logging Icon for the Data Store Memory Block” on page 74-29

“Logging Data Stores Created with a Simulink.Signal Object” on page 74-29

“Accessing Data Store Logging Data” on page 74-30

### Logging Local and Global Data Store Values

You can log the values of a local or global data store data variable for all the steps in a simulation. Two common uses of data store logging are for:

- Model debugging - view the order of all data store writes
- Confirming a model modification - use the logged data to establish a baseline for comparing results to identify the impact of a model modification

For an example of logging a global data store, see “Using Data Stores Across Multiple Models”.

### Supported Data Types, Dimensions, and Complexity for Logging Data Stores

You can log data stores that use the following data types:

- All built-in data types
- Enumerated data types
- Fixed-point data types

You can log data stores that use any dimension level or complexity.

### Data Store Logging Limitations

Limitations for using data store logging in a model are:

- To log data for a data store memory:
  - Simulate the top-level model in Normal mode.
  - For local data stores, the model containing the Data Store Memory block must be in Model Reference Normal mode.
  - Any block in a referenced model that writes to the data store memory must be executed in model reference Normal mode.
- You cannot log data stores that use custom data types, including buses.

## Logging Data Stores Created with a Data Store Memory Block

To log a local data store that you create with a Data Store Memory block:

- 1 In the model, open the Model Data Editor. In the **Modeling** tab, click **Model Data Editor**.
- 2 On the **Data Stores** tab, set the **Change view** drop-down list to Instrumentation.
- 3 In the data table, for the target data store, select the check box in the **Log Data** column.

If the target data store does not appear in the table, click the **Change scope** button to display data stores that are defined in subsystems below your current system.

- 4 Optionally, to configure additional logging characteristics such as the maximum number of data points to log, open the Property Inspector (in the **Modeling** tab, under **Design**, click **Property Inspector**). Use the Property Inspector to open the block dialog box and inspect the **Logging** tab.
- 5 Enable data store logging with the **Model Configuration Parameters > Data Import/Export > Data stores** parameter.
- 6 Simulate the model.

## Logging Icon for the Data Store Memory Block

When you enable logging for a model, and you configure a local data store for logging, the Data Store Memory block displays a blue icon. If you do not enable logging for the model, then the icon is gray.

## Logging Data Stores Created with a Simulink.Signal Object

You can create local and global data stores using a `Simulink.Signal` object. See “Data Stores with Signal Objects” on page 74-16 for details.

To log a data store that you create with a `Simulink.Signal` object:

- 1 Create a `Simulink.Signal` object in a workspace that is visible to every component that needs to access the data store, as described in “Data Stores with Signal Objects” on page 74-16.
- 2 Use the name of the `Simulink.Signal` object in the **Data store name** block parameters of the Data Store Read and Data Store Write blocks that you want to write to and read from the data store.
- 3 From the MATLAB command line, set `DataLogging` (which is a property of the `LoggingInfo` property of `Simulink.Signal`) to 1.

For example, if you use a `Simulink.Signal` object called `DataStoreSignalObject` to create a data store, use the following command:

```
DataStoreSignalObject.LoggingInfo.DataLogging = 1
```

- 4 Optionally, specify limits for the amount of data logged, using the following properties, which are properties of the `LoggingInfo` property of the `Simulink.Signal` object: `Decimation`, `LimitDataPoints`, and `MaxPoints`.

- 5 Enable data store logging with the **Model Configuration Parameters > Data Import/Export > Data stores** parameter.
- 6 Simulate the model.

## Accessing Data Store Logging Data

The following Simulink classes represent data from data store logging and provide methods for accessing that data:

| Class                                                | Description                                                                                                                                           |
|------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>Simulink.SimulationData.BlockPath</code>       | Represents a fully specified Simulink block path; use for capturing the full model reference hierarchy                                                |
| <code>Simulink.SimulationData.Dataset</code>         | Stores logged data elements and provides searching capabilities; use to group <code>Simulink.SimulationData.Element</code> objects in a single object |
| <code>Simulink.SimulationData.DataStoreMemory</code> | Stores logging information from a data store during simulation                                                                                        |

You can also convert data logged in formats other than Dataset. For more information, see “Dataset Conversion for Logged Data” on page 73-12.

### Viewing Data Store Data

To view data store logging data from the command line, view the output data set in the base workspace. The default variable for the data store logging data set is `dsmout`.

The `sldemo_mdref_dsm` model illustrates approaches for viewing data store logging data.

### Accessing Elements in the Data Store Logging Data

To find an element in the data store logging data, based on the `Name` or `BlockType` property, use the `getElement` method of `Simulink.SimulationData.Dataset`. For example:

```
dsmout.getElement('RefSignalVal')

ans =
Simulink.SimulationData.DataStoreMemory
Package: Simulink.SimulationData

Properties:
 Name: 'RefSignalVal'
 Blockpath: [1x1 Simulink.SimulationData.BlockPath]
 Scope: 'local'
 DSMWriterBlockPaths: [1x2 Simulink.SimulationData.BlockPath]
 DSMWriters: [101x1 uint32]
 Values: [101x1 timeseries]
```

To access an element by index, use the `Simulink.SimulationData.Dataset.getElement` method.

## What Is a Data Dictionary?

A data dictionary is a persistent repository of data that are relevant to your model. You can also use the base workspace to store design data that are used by your model during simulation. However, a data dictionary provides more capabilities.

The dictionary stores design data, which define parameters and signals, and include data that define the behavior of the model. The dictionary does not store simulation data, which are inputs or outputs of model simulation that enter and exit Inport and Outport blocks.

### Dictionary Capabilities

| Dictionary Capability                     | Benefit                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|-------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Dictionary as data source                 | Entries in a dictionary are persistent. You do not need to reload data during development.                                                                                                                                                                                                                                                                                                                                                  |
| Explicit data-model linkage               | You can define a data dictionary as the data source for a model. During model simulation and code generation, the model retrieves data from the data dictionary.                                                                                                                                                                                                                                                                            |
| Version handling                          | You can: <ul style="list-style-type: none"> <li>• Link a model to a data dictionary that includes model data saved in a previous version of Simulink.</li> <li>• Continue using the data dictionary of a model saved in a previous version of Simulink with versions of the model saved in later versions of Simulink.</li> <li>• Export (save) a data dictionary for use in models created with a previous version of Simulink.</li> </ul> |
| Change tracking                           | When you modify an entry, its status is updated in the dictionary and stored as metadata that can be tracked. The dictionary also tracks who made the changes and when. You can also view or revert changes.                                                                                                                                                                                                                                |
| Entry comparison                          | Compare values of entries in two dictionaries.                                                                                                                                                                                                                                                                                                                                                                                              |
| Data grouping into reference dictionaries | Partition and organize data items into reference dictionaries.                                                                                                                                                                                                                                                                                                                                                                              |
| Model-data dependency                     | Discover how entries are used in the model.                                                                                                                                                                                                                                                                                                                                                                                                 |
| Options for fixing a missing variable     | For a variable reported as undefined at compilation time: <ul style="list-style-type: none"> <li>• If the variable does not exist, create a new variable or load a file.</li> <li>• If the variable has been deleted, undo the deletion or create a new variable.</li> <li>• If the variable has been renamed, rename references to the variable or create a new variable by copying the renamed variable.</li> </ul>                       |
| Store and partition reference data        | Store and partition data that are relevant to a model, such as equipment specifications, but not used by the model during simulation.                                                                                                                                                                                                                                                                                                       |

| Dictionary Capability               | Benefit                                                                         |
|-------------------------------------|---------------------------------------------------------------------------------|
| Unified interface for defining data | Use the Model Explorer to work with design data in a dictionary.                |

| Requirements traceability linking   | Navigate from a data dictionary entry to a location in a requirements document. |

## Sections of a Dictionary

A Simulink data dictionary consists of four sections:

- **Design Data:** Contains the variables and data types that define parameters, signals, and design data that determine the behavior of the model. Design data created or imported in a dictionary are stored in this section.

This section can store only certain classes and data types. See “Valid Design Data Classes” on page 75-9 for more information.

- **Configurations:** Contains configuration sets, which are objects of the `Simulink.ConfigSet` class, that determine how the model is configured during simulation. These objects control attributes such as sample time and simulation start time.

When you store configuration sets in a data dictionary, you use configuration references to access the configuration sets. Models that are linked to a dictionary resolve configuration references to configuration sets in the dictionary. For more information about configuration references, see “Share a Configuration with Multiple Models” on page 13-10.

This section can also store variant configuration objects, which belong to the `Simulink.VariantConfigurationData` class. These objects store information about variant configurations, active and default variant settings, and definitions of the control variable associated with each configuration.

---

**Note** If you load a configuration set from the data dictionary that contains a component that is not available on your system, the parameters in the missing component are reset to their default values.

---

- **Embedded Coder Dictionary:** Contains code generation definitions for use with Embedded Coder. To inspect and modify code definitions stored in a data dictionary, use the **Embedded Coder Dictionary** not the Model Explorer.
- **Other Data:** Contains information that is relevant to your model but not used by the model during simulation. Use this section to store reference information such as data that describe physical equipment and processes that are represented by your model.

This section can store almost any built-in or custom class or data type. See “Invalid Other Data Classes” on page 75-9 for more information.

## Dictionary Usage for Models Created with Different Versions of Simulink

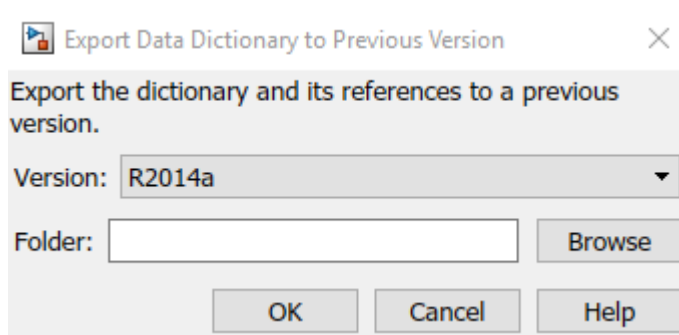

Simulink provides version handling for data dictionaries. When these events occur, Simulink synchronizes data in a dictionary for use with a model regardless of the Simulink version used to create the model:

- You link a model to a data dictionary that was saved in a previous version of Simulink- for example, you link a model that you develop in R2018b with a dictionary saved in R2018a.
- You open a model that is linked to a data dictionary and was saved in a previous version of Simulink - for example, you developed a model that uses a data dictionary in R2018a and you open that model in R2018b to continue development.

To view the Simulink version in which a data dictionary is saved, in the Current Folder browser, click the data dictionary and find the **Saved in Simulink version** field in the **Details** pane. You also have the option to export (save) a data dictionary for use with models created using a different version of Simulink. To use a data dictionary you saved in a newer Simulink version in an older Simulink version, you need to export it first.

To export a data dictionary:

- 1 In the **Current Folder** pane of the MATLAB Command Window, navigate to the location of the data dictionary.
- 2 Double-click the name of the dictionary.
- 3 In the Model Explorer, right-click the name of the data dictionary. If you have made changes to the dictionary, in the context menu, select **Save Changes**.
- 4 Right-click the name of the data dictionary. In the context menu, select **Export to Previous Version**.
- 5 In the Export Data Dictionary to Previous Version dialog box, specify the previous version of Simulink in which you want to save the model. Specify the folder into which you want Simulink to place the new version of the dictionary. The folder that you specify cannot contain dictionaries that are part of the existing dictionary hierarchy. Then, click **OK**.

- 6 Verify that the new version of the data dictionary exists in the folder that you specified.

## Manage and Edit Entries in a Dictionary

To create, modify, and view the entries in a data dictionary, use the Model Explorer. For more information, see “Create, Edit, and Manage Workspace Variables” on page 68-107 and “View and Revert Changes to Dictionary Data” on page 75-21.

To manage entries in a dictionary programmatically, see “Store Data in Dictionary Programmatically” on page 75-38.

## Dictionary Referencing

You can reference one or more dictionaries in a parent dictionary. The data in the referenced dictionaries are visible in the parent dictionary. Use this technique to meaningfully partition data, especially for model reference hierarchies. For more information, see “Partition Dictionary Data Using Referenced Dictionaries” on page 75-25 and “Partition Data for Model Reference Hierarchy Using Data Dictionaries” on page 75-27.

## Import and Export File Formats

| File Format   | Import to Dictionary | Export from Dictionary |
|---------------|----------------------|------------------------|
| MAT-file      | ✓                    | ✓                      |
| MATLAB script | ✓                    | ✓                      |

## Allow Access to Base Workspace

For information about the **Enable model access to base workspace** property and the **Enable dictionary access to base workspace** property, see “Continue to Use Shared Data in the Base Workspace” on page 75-10.

## Migrate Models to Use Simulink Data Dictionary

A Simulink data dictionary permanently stores model data including MATLAB variables, data objects, and data types. For basic information about data dictionaries, see “What Is a Data Dictionary?” on page 75-2.

### Migrate Single Model to Use Dictionary

This example shows how to link a single standalone model to a single data dictionary.

---

**Note** Simulink does not import simulation data such as Timeseries objects into the data dictionary.

---

- 1 Open the f14 model, which loads design data into the base workspace.
- 2 Save a copy of the model to your current folder. Open the copy.
- 3 In the Simulink Editor, on the **Modeling** tab, under **Design**, click **Link to Data Dictionary**.
- 4 In the **Model Properties** dialog box, click **New** to create a data dictionary.

- 5 Name the data dictionary, save it, and click **Apply**.
- 6 Click **Migrate data**.
- 7 Click **Migrate** in response to the message about copying referenced variables.
- 8 (Optional) Clear **Enable model access to base workspace**.
- 9 Click **OK**.
- 10

To open the dictionary, in the Simulink Editor, click the model data badge  in the bottom left corner, then click the **External Data** link. To inspect the contents of the dictionary, in the Model Explorer **Model Hierarchy** pane, under the **External Data** node, expand the dictionary node.

### Migrate Model Reference Hierarchy to Use Dictionary

This example shows how to link a parent model and all its referenced models to a single data dictionary.

- 1 Open the example model `sldemo_mdref_datamngt`, which references the model `sldemo_mdref_counter_datamngt`.

- 2 Save copies of the models to your current folder.
- 3 Open the top model, `sldemo_mdref_datamngt`.
- 4 In the Simulink Editor, on the **Modeling** tab, under **Design**, click **Link to Data Dictionary**.
- 5 In the **Model Properties** dialog box, click **New** to create a data dictionary.

- 6 Name the data dictionary, save it, and click **Apply**.
- 7 Click **Change all models** in response to the message about linking referenced models that do not already use a dictionary.
- 8 Click **Migrate data**.
- 9 Click **Migrate** in response to the message about copying referenced variables.
- 10 (Optional) Clear **Enable model access to base workspace**.
- 11 Click **OK**.

## Considerations before Migrating to Data Dictionary

After you link a model to a data dictionary, you can choose to migrate data from the base workspace into the dictionary. If you choose to migrate data, take these considerations into account.

### Check for Data-Loading Callbacks

You can use model callbacks such as the `PreLoadFcn` callback to load design data from a file into the base workspace when a model is loaded. For example, the following callback loads design data from the MAT file `myData.mat`.

```
load myData
```

After you migrate to a data dictionary, these callbacks will continue to load design data into the base workspace. Since the model then derives design data from the dictionary, manually remove or comment out these data-loading callbacks.

You can use the Dependency Analyzer to find data-loading callbacks. See “Analyze Model Dependencies” on page 17-40.

### Check Scripts

A new model has access to the base workspace by default, but does not lose access when it is linked to a data dictionary. Scripts must be written with the assumption that the model can have access to the base workspace, the data dictionary, or both.

If you make explicit references to the base workspace by using the handle `base` in your scripts, consider changing these references.

Consider this example. Here, the script searches the base workspace for variable `sensor` and sets the parameter `enable` depending on the value of `sensor.noiseEnable`.

```
if evalin('base','sensor.noiseEnable')
 enable = 'Enabled';
else
 enable = 'Disabled';
end
```

When you migrate to a data dictionary, replace these explicit references to `base` as follows:

```
if Simulink.data.evalInGlobal(myExampleModel,...
'sensor.noiseEnable')
 enable = 'Enabled';
else
 enable = 'Disabled';
end
```

The `Simulink.data.evalInGlobal` function evaluates an expression in the global scope of the specified model. Here, the global scope can be in a data dictionary or the base workspace, if the model is not linked to a dictionary.

### Check Tunable Parameters for Code Generation

- If your model is linked to a data dictionary, and the model does not have access to the base workspace (see “Continue to Use Shared Data in the Base Workspace” on page 75-10), Simulink ignores storage class information specified in the Model Parameter Configuration dialog box.
- If you use the Simulink interface to migrate a model to use a data dictionary, and you choose to migrate base workspace data, Simulink also migrates the storage class information of the model. If your model contains storage class information for variables in the base workspace, Simulink converts these variables into `Simulink.Parameter` objects during migration. Then, Simulink sets the storage class of these `Simulink.Parameter` objects using the storage class information from the model.
- If you migrate this model back to the base workspace, Simulink does not restore the storage class information in the model. To preserve the storage class for these variables, use the parameter objects from the data dictionary. You can also manually reset the storage class information in the model.
- If you set the `DataDictionary` property of a model from the command line, you can convert tunable variables to `Simulink.Parameter` objects using the `tunablevars2parameterobjects` function.

### Data Used by Model References

When you use model referencing to break a large system of models into smaller components and subcomponents, you can create data dictionaries to segregate the design data. Design data is the set of workspace variables that the models use to specify block parameters and signal characteristics.

The models in a model reference hierarchy typically share data. Data ownership, the number of shared variables, and the complexity of your sharing strategy can influence the way that you use dictionaries.

Duplicate data definitions can exist in a model reference hierarchy under these conditions:

- Each model in the hierarchy can see only one definition.
- Definitions must be the same across models in the hierarchy.

For more information, see “Determine Where to Store Variables and Objects for Simulink Models” on page 68-101.

### Valid Design Data Classes

You can import, store, or create MATLAB variables that use Simulink supported data types, such as `boolean` and `int32`, and structures in the **Design Data** section of a Simulink data dictionary. You can also use objects of these classes and objects of most classes that subclass these classes:

- `Simulink.AliasType`
- `Simulink.Bus`
- `Simulink.NumericType`
- `Simulink.Parameter`
- `Simulink.LookupTable`
- `Simulink.Breakpoint`
- `Simulink.Signal`
- `Simulink.ValueType`
- `Simulink.Variant`
- `Simulink.data.dictionary.EnumTypeDefinition`
- `embedded.fi`
- `embedded.fimath`
- `numlti`

In addition, you can import, store, or create configuration objects of the following classes in the **Configurations** section of a Simulink data dictionary.

- `ConfigSet`
- `Simulink.VariantConfigurationData`

### Invalid Other Data Classes

You can import, store, or create data objects of many built-in and custom classes or data types in the **Other Data** section of a Simulink data dictionary, except for the following:

- Arrays of objects created from built-in or custom classes
- Custom classes that have a property with any of these names:
  - `LastModified`
  - `LastModifiedBy`
  - `DataSource`
  - `Status`
  - `Variant`

### Migration With From Workspace Blocks

If a model contains a From Workspace block that refers to a variable in the base workspace, you can migrate the model to a data dictionary. However, the migration process takes different actions depending on the nature of the variable that the block refers to:

- If the value of the variable is not a `timeseries` object, the migration process imports the variable to the Design Data section of the data dictionary. The block can still refer to the variable.
- If the value of the variable is a `timeseries` object (which a data dictionary cannot store) or a structure with fields identical to a `timeseries` object, the migration process does not import the variable. Then, when you try to update the diagram or simulate the model, the From Workspace block cannot find the variable and issues an error. In such a case, you can configure the block to refer to the base workspace variable by using the `evalin` function. For more information, see From Workspace.

### Data Dictionary Limitations

- Simulink cannot automatically migrate variables used only by inactive variant models into a data dictionary.
- You cannot import certain kinds of design data such as meta class objects and `timeseries` objects into the Design Data section of a data dictionary.
- Simulink does not allow implicit signal resolution for a model linked to a data dictionary. To use a data dictionary, set the model configuration parameter **Signal resolution** to `Explicit only` or `None`.
- If a model reference hierarchy is already linked to a data dictionary, you can protect a referenced model that is part of the hierarchy. However, if you migrate a model reference hierarchy that includes a protected model, simulation will fail.

In other words, migrate a model to use a data dictionary before protecting it.

- Evaluation of expressions that include Simulink variables or data types that are stored in a data dictionary might not be supported.

### Continue to Use Shared Data in the Base Workspace

You can continue to store shared data in the base workspace and store model-specific data in the data dictionary by:

- Enabling access to the base workspace for the model.
- Enabling access to the base workspace from a data dictionary.

To enable access to the base workspace for a model, in the Model Properties dialog box, on the **External Data** tab, select **Enable model access to base workspace**. For a new model, this check box is selected by default. If the model is not linked to a data dictionary, this option must be selected.

You can also allow access to the base workspace from a data dictionary. For an existing dictionary, in the Model Explorer, select **Enable dictionary access to base workspace**.

When you allow base workspace access from a data dictionary, these limitations and ramifications apply:

- In general, you cannot interact with base workspace data through the dictionary.

- When you inspect the contents of the dictionary in the Model Explorer, you cannot see base workspace data. To interact with base workspace data, in the **Model Hierarchy** pane, select the **Base Workspace** node.
- With the programmatic interface of the data dictionary (see “Store Data in Dictionary Programmatically” on page 75-38), to interact with base workspace data, you can use only these functions with a `Simulink.data.dictionary.Section` object:
  - `assignin`
  - `exist`
  - `evalin`

Consider using functions such as `Simulink.data.assigninGlobal` instead. See “Transition to Using Data Dictionary” on page 75-41.

- Change-tracking features, such as the ability to view and revert changes to dictionary entries (see “View and Revert Changes to Dictionary Entries” on page 75-21), do not apply to base workspace data.
- When you export data from a dictionary (see “Import and Export Dictionary Data” on page 75-16), Simulink ignores base workspace data.
- Simulink treats the base workspace and the dictionary as a single namespace. However you can define two variables with the same name, one in the base workspace and one in the dictionary. In this case, the variables must be identical and the variable in the dictionary is used.

## Migrate Complicated Model Hierarchy with Shared Data

For examples, see “Partition Data for Model Reference Hierarchy Using Data Dictionaries” on page 75-27.

## Enumerations in Data Dictionary

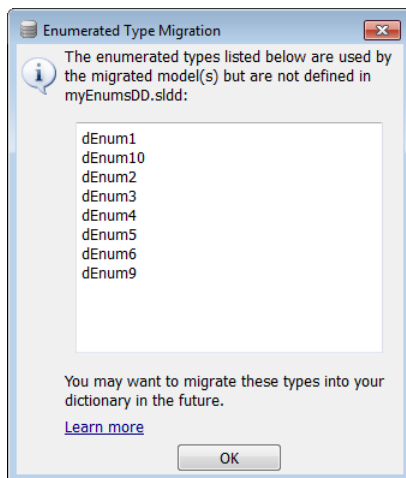

A Simulink data dictionary permanently stores model data including MATLAB variables, data objects, and data types including enumerated types. Enumeration classes defined in MATLAB by the data dictionary are owned by that dictionary and cannot be cleared by using `Simulink.clearIntEnumType`. When you close a data dictionary, the dictionary clears the enumeration classes that it owns. If an instance of an enumeration class exists when you close the dictionary, that enumeration class is not cleared and you become the owner of the class. As the owner of the class, you can then find or clear the class by using `Simulink.findIntEnumType` and `Simulink.clearIntEnumType`. For basic information about data dictionaries, see “What Is a Data Dictionary?” on page 75-2.

### Migrate Enumerated Types into Data Dictionary

This example shows how to migrate enumerated types that are used by a model into a data dictionary.

#### Import Design Data

- 1 Open a model that uses enumerated types for design data or for blocks in the model.
- 2 In the Simulink Editor, on the **Modeling** tab, under **Design**, click **Link to Data Dictionary**.
- 3 In the **Model Properties** dialog box, click **New** to create a data dictionary.
- 4 Name the data dictionary, save it, and click **Apply**.
- 5 Click **Migrate data**.
- 6 Click **Migrate** in response to the message about copying referenced variables.
- 7 Simulink reports the enumerated types that were not imported into the data dictionary.

- 8 Click **OK**.

A notification appears in the Simulink Editor, reporting that your model is now linked to the data dictionary.

#### Import Enumerated Types

Import the definitions of enumerated types only after you import all the design data that were creating using the types. When you import enumerated types to a data dictionary, Simulink disables

MATLAB files or P-files that contain the type definitions, causing variables that remain in the MATLAB base workspace to lose their definitions.

- 1 At the MATLAB command prompt, get the names of enumerated types that are used in model blocks.

```
% Find all variables and enumerated types used in model blocks
usedTypesVars = Simulink.findVars('EnumsReporting','IncludeEnumTypes',true);
% Here, EnumsReporting is the name of the model and
% usedTypesVars is an array of Simulink.VariableUsage objects

% Find indices of enumerated types that are defined by MATLAB files or P-files
enumTypesFile = strcmp({usedTypesVars.SourceType},'MATLAB file');

% Find indices of enumerated types that are defined using the function
% Simulink.defineIntEnumType
enumTypesDynamic = strcmp({usedTypesVars.SourceType},'dynamic class');

% In one array, represent indices of both kinds of enumerated types
enumTypesIndex = enumTypesFile | enumTypesDynamic;

% Use logical indexing to return the names of used enumerated types
enumTypeNames = {usedTypesVars(enumTypesIndex).Name}'

enumTypeNames =

 'dEnum1'
 'dEnum10'
 'dEnum2'
 'dEnum3'
 'dEnum4'
 'dEnum5'
 'dEnum6'
 'dEnum9'
```

- 2 Open the data dictionary, and represent it with a Simulink.data.Dictionary object.

```
ddConnection = Simulink.data.dictionary.open('myEnumsDD.sldd')

ddConnection =

 Dictionary with properties:

 DataSources: {0x1 cell}
 HasUnsavedChanges: 0
 NumberOfEntries: 3
```

- 3 Use the `importEnumTypes` method to import the enumerated types that are used by blocks in the model. The method saves changes made to the target dictionary, so before you use the method, confirm that unsaved changes are acceptable.

```
[successfulMigrations, unsuccessfulMigrations] = ...
importEnumTypes(ddConnection,enumTypeNames)

successfulMigrations =

 1x6 struct array with fields:

 className
 renamedFiles

unsuccessfulMigrations =
```

1x2 struct array with fields:

```
className
reasons
```

When enumerated types are imported, `importEnumTypes` renames the enumerated class definition file by appending `.save` to the file name. For example, if the original enumerated class definition is named `Enum1.m`, Simulink renamed the file as `Enum1.m.save`.

The structure `unsuccessfulMigrations` reports enumerated types that are not migrated. In this example, two enumerated type instances are defined in the model workspace and can be imported after closing the model. Close the model to import these enumerated types.

- 4 Open the dictionary to view the migrated enumerated types.

## Manipulate Enumerations in Data Dictionary

These examples show how to operate on existing enumerations in a data dictionary.

- “Rename Enumerated Type Definition” on page 75-14
- “Rename Enumeration Members” on page 75-15
- “Delete Enumeration Members” on page 75-15
- “Change Underlying Value of Enumeration Member” on page 75-15

### Rename Enumerated Type Definition

- 1 In the data dictionary, create a copy of the enumerated type, and rename the copy instead.
- 2 Find enumeration objects used by your model that are derived from the type with the old name.
- 3 Replace these objects with those derived from the renamed type.

- 4 Delete the type with the old name.

### Rename Enumeration Members

Use one of the following approaches.

- Select the enumeration within the dictionary, and rename one or more enumeration members.
- If your model references enumeration members, change these references to match the renamed member.

### Delete Enumeration Members

- 1 Find references in your model to an enumeration member you want to delete.
- 2 Replace these references with an alternate member.
- 3 Delete the original member from the enumeration.

### Change Underlying Value of Enumeration Member

You can change the values of enumeration members when you represent these values as MATLAB variables or by using `Value` field of `Simulink.Parameter` objects.

- 1 Find references in your model to an enumeration member whose value you want to change.
- 2 Make a note of these references.
- 3 Change the value of the enumeration member.
- 4 Manually update references to the enumeration member in your model.

## Remove Enumerated Types from Data Dictionary

If you decide that you no longer want to define an enumerated type in a dictionary, follow these steps.

- 1 Manually define the enumerated data type in MATLAB. See “Use Enumerated Data in Simulink Models” on page 69-6.
- 2 Delete instances of the enumeration class. If there is an instance of the enumeration class in existence when you delete the enumerated data type from the dictionary, the dictionary releases control of the enumeration class, but the class remains in memory as a dynamic enumeration class. You can then find or clear the class by using `Simulink.findIntEnumType` and `Simulink.clearIntEnumType`.
- 3 Delete the enumerated type from the dictionary.

## Import and Export Dictionary Data

A Simulink data dictionary permanently stores model data including MATLAB variables, data objects, and data types. For basic information about data dictionaries, see “What Is a Data Dictionary?” on page 75-2.

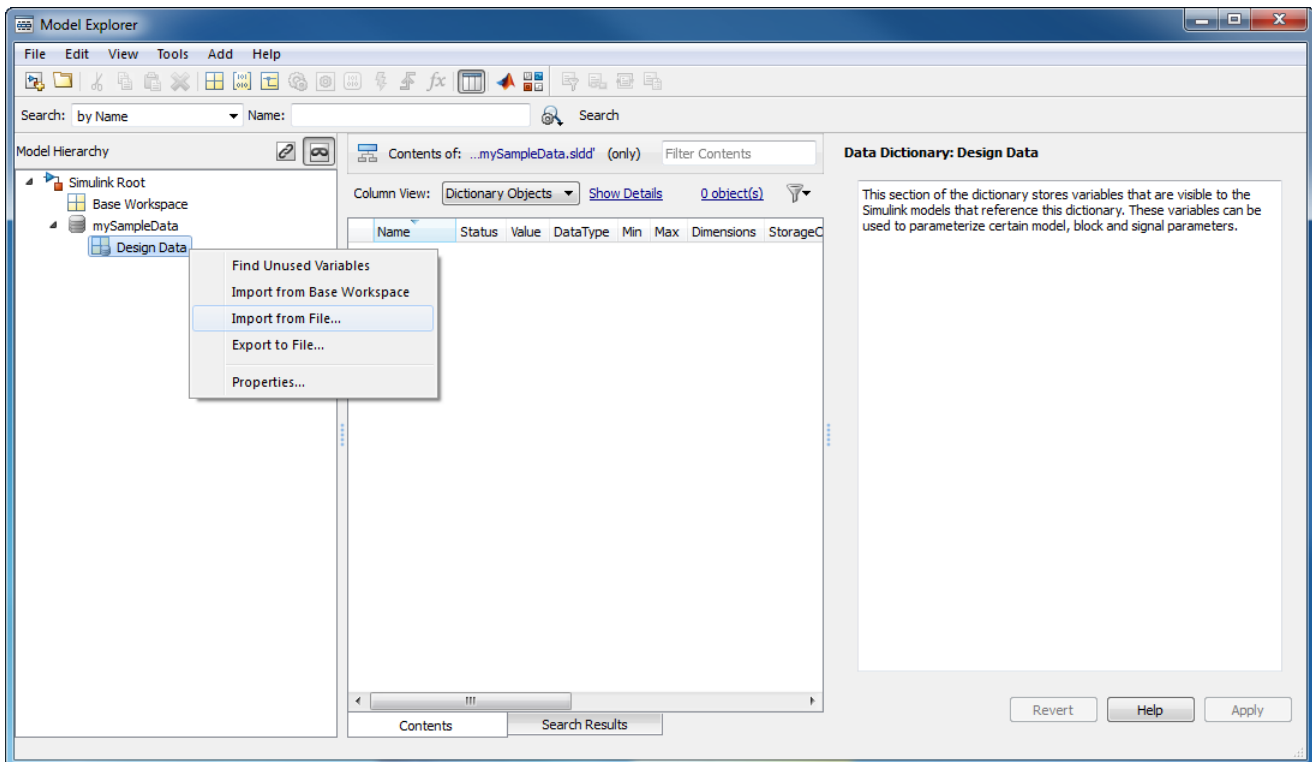

### Import Data to Dictionary from File

You can import data from a MATLAB file or MAT-file to a data dictionary using the Model Explorer window. Import variables and data objects that are used by a model during simulation to the Design Data section of a dictionary. Import variables and objects that you want to store with a model, but that are not used by the model during simulation, to the Other Data section of a dictionary.

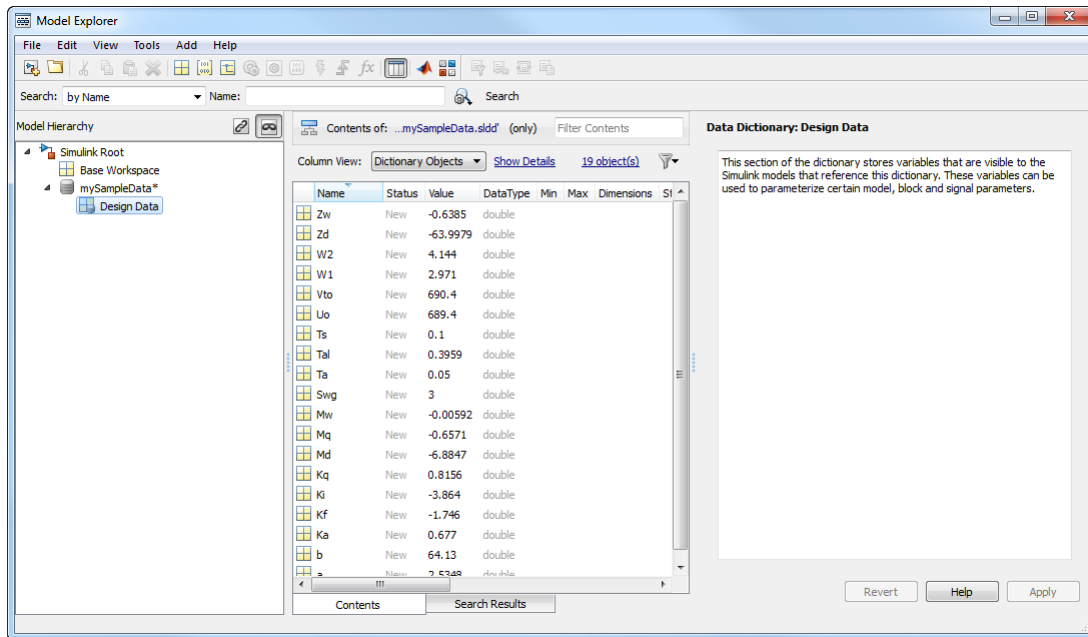

#### Import Design Data from File

This example shows how to import design data from a file into the Design Data section of a dictionary.

- 1 In the Simulink Editor, in the **Modeling** tab, click **Model Explorer** to open the Model Explorer.
- 2 Select **File > Open**. Then browse to an existing dictionary.
- 3 In the **Model Hierarchy** pane, right-click the **Design Data** section of the dictionary and select **Import from File**. Then browse to and select the MAT-file or MATLAB file that contains the data to import.

Design data from the MAT-file populate the dictionary. Data appear with **DataSource** set to the name of the dictionary.

If you import from the same MAT-file again, Simulink only imports changed or new entries into the dictionary.

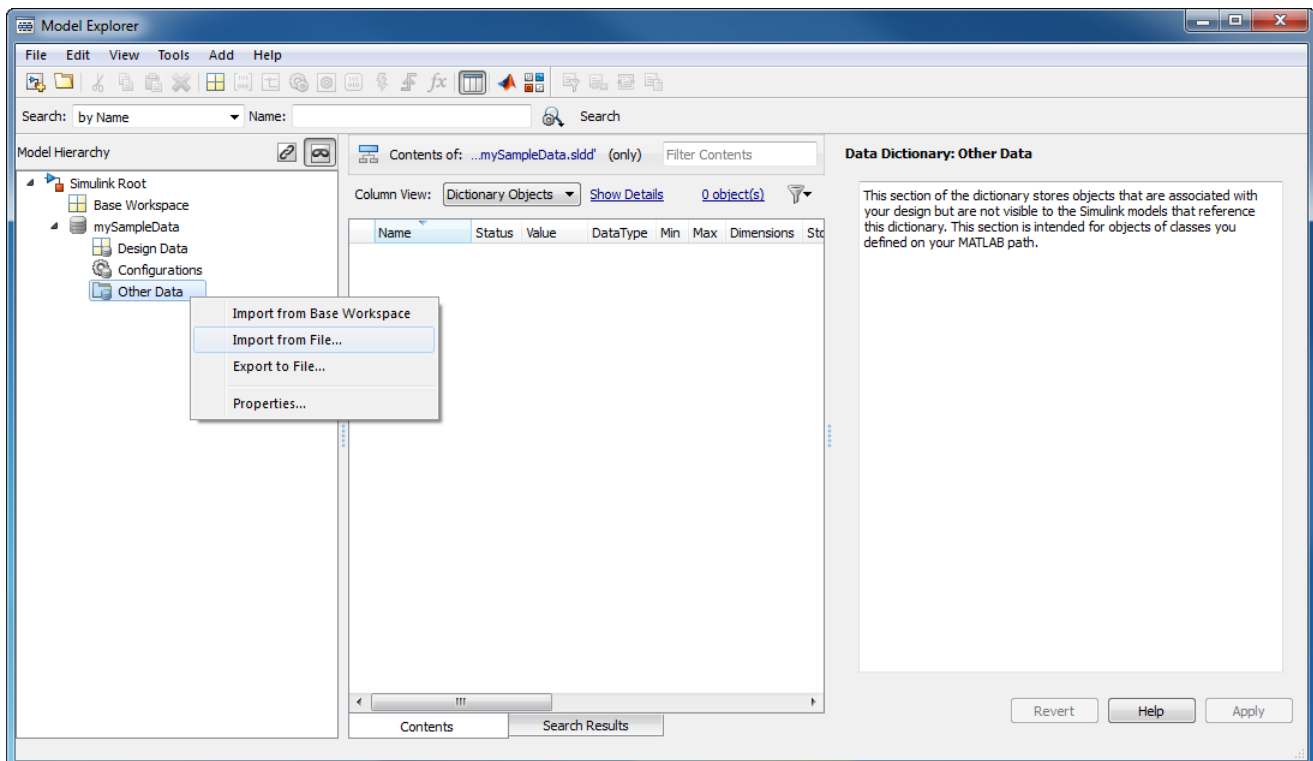

### Import Other Data from File

This example shows how to import data from a file into the Other Data section of a data dictionary. Use this section to store reference information that is not used by Simulink during simulation, such as data that describe physical equipment and processes that are represented by your model.

- 1 In the Simulink Editor, in the **Modeling** tab, click **Model Explorer** to open the Model Explorer.
- 2 Select **File > Open**. Then browse to an existing dictionary.
- 3 In the **Model Hierarchy** pane, right-click the dictionary node and select **Show Empty Sections**. Model Explorer reveals the **Other Data** and **Configurations** sections of the dictionary, even if they are empty, in addition to the **Design Data** section.

- 4 In the **Model Hierarchy** pane, right-click the **Other Data** section of the dictionary and select **Import from File**. Then browse to and select the MAT-file or MATLAB file that contains the reference data to import.

Data from the MAT-file populate the Other Data section of the dictionary. Data appear with **DataSource** set to the name of the dictionary.

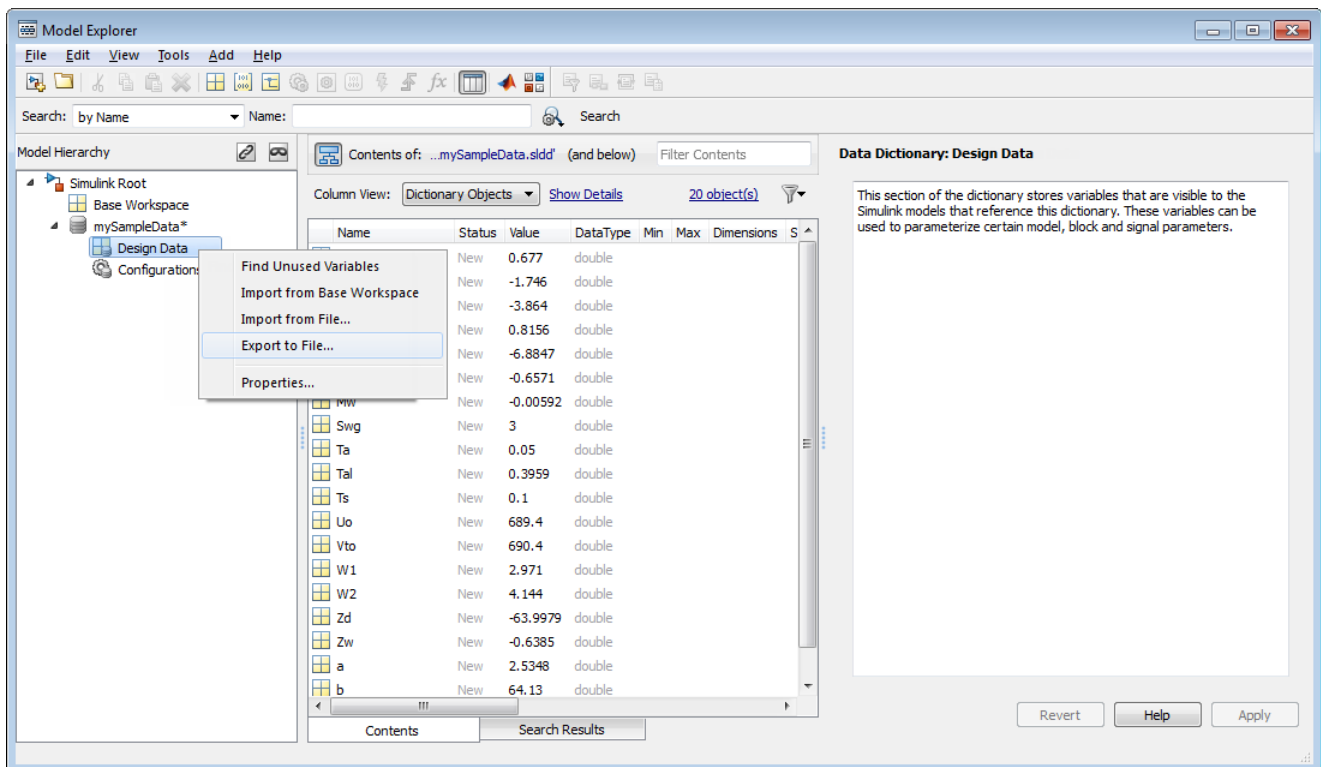

If you import from the same MAT-file again, Simulink only imports changed or new entries into the dictionary.

## Export Design Data from Dictionary

This example shows how to export model design data from a data dictionary into a MAT-file or MATLAB script.

- 1 In the Simulink Editor, in the **Modeling** tab, click **Model Explorer** to open the Model Explorer.
- 2 Open a data dictionary using **File > Open Data Dictionary**.
- 3 In the **Model Hierarchy** pane, expand the dictionary node and select **Design Data > Export to File**. Then save the design data to a MAT-file or MATLAB script.

The dictionary does not export enumerated data types (which are stored as `Simulink.data.dictionary.EnumTypeDefinition` objects). To transfer or copy an enumerated type from one dictionary to another, use the Model Explorer to cut or copy and paste the object.

- “Migrate Models to Use Simulink Data Dictionary” on page 75-6

## View and Revert Changes to Dictionary Data

A Simulink data dictionary permanently stores model data including MATLAB variables, data objects, and data types. For basic information about data dictionaries, see “What Is a Data Dictionary?” on page 75-2.

### View and Revert Changes to Dictionary Entries

This example shows how to view unsaved changes to dictionary entries, who made them, and when. You can view changes to entries in any section, including data stored in the Other Data section and configuration sets stored in the Configurations section.

- 1 Open the `sldemo_fuelsys_dd_controller` model.
- 2 Open the data dictionary linked to this model. Click the model data badge  in the bottom left corner of the model, then click the **External Data** link.
- 3 In the Model Explorer **Model Hierarchy** pane, under the **External Data** node, select the **Design Data** node for `sldemo_fuelsys_dd_controller`.
- 4 In the **Contents** pane, change `st_range` to `0.0002` and `zero_thresh` to `200`.

The **Status** column of these entries changes to **Mod**, indicating that they have been modified.

- 5 Click the heading of the **Status** column to sort the entries. Then, select the modified entries, which are indicated by the **Mod** status.

- 6 Right-click and select **Show Changes**.

The Comparison Tool appears, displaying changed entries in separate tabs. The tool highlights changed values.

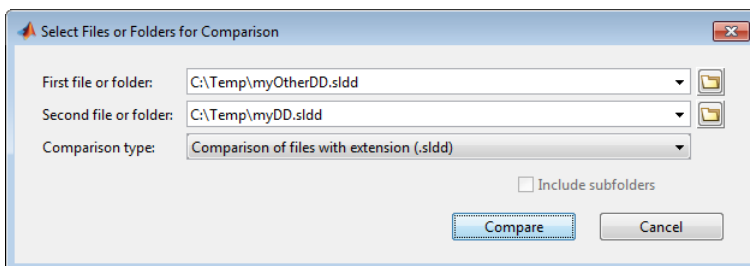

**Note** The Comparison Tool does not display changes to the data dictionary property **Enable dictionary access to base workspace**.

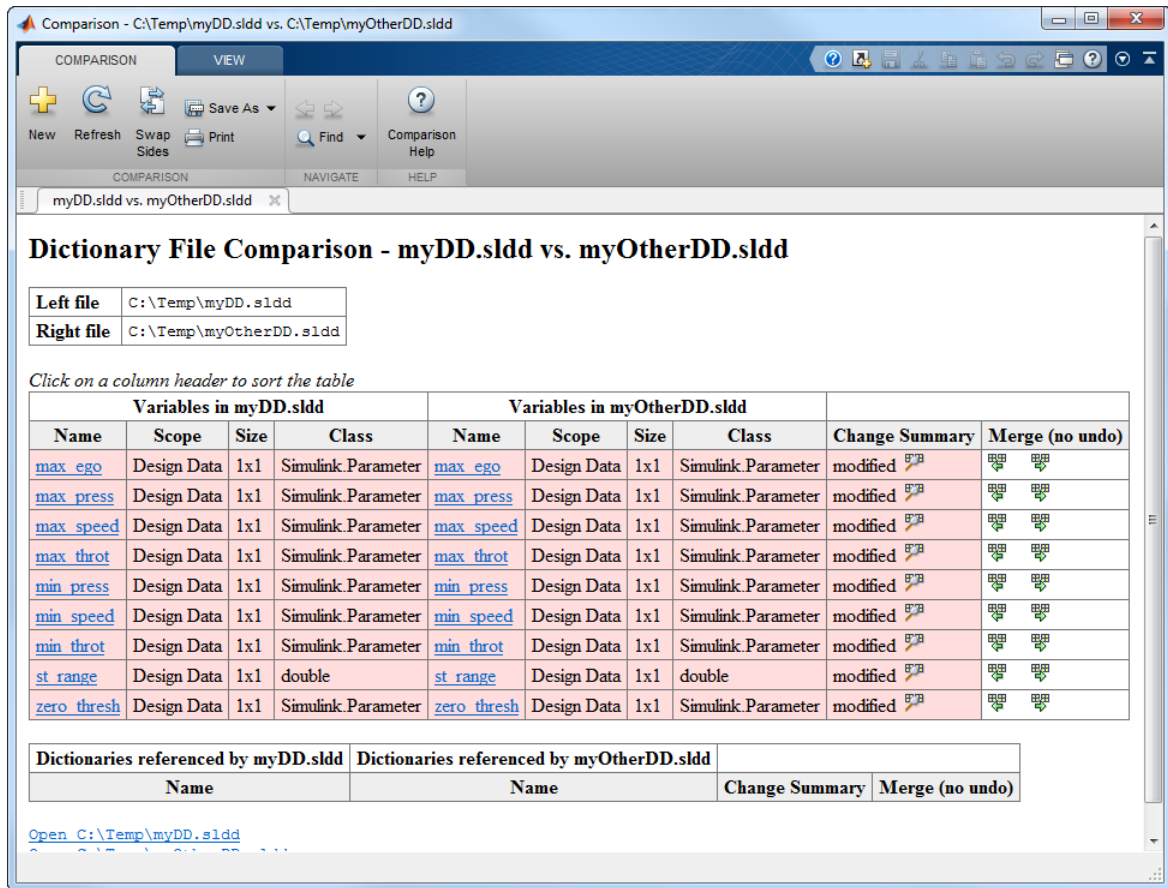

- 7 In the **Contents** pane of the Model Explorer, right-click `zero_thresh` and select **Revert to Saved**.

Simulink reverts `zero_thresh` to its value at the time of the last save action.

- 8 You can merge entries between dictionaries using the Comparison Tool. From the MATLAB desktop, on the **Home** tab, in the **File** section, click **Compare**.
- 9 Select the dictionaries to compare and merge.

- 10 In the comparison report, select the merge direction for each dictionary entry.

## View and Revert Changes to Entire Dictionary

If you store model variables in a data dictionary, you can view and manage the changes that you make while you work. You can use the Comparison Tool to see the changes made to a dictionary, which compares the modified dictionary with the most recent saved version.

When you view the changes to a dictionary, you can choose to discard changes to individual entries or dictionary references, which reverts to the last saved state. You can use this technique to recover entries that you delete in your modified version or dictionary references that you remove.

If you view changes to a dictionary that references other dictionaries, the Comparison Tool also reports changes made to the entries in the referenced dictionaries.

- 1 View the example data dictionary `sldemo_fuelsys_dd` in Model Explorer.

```
dictionary = Simulink.data.dictionary.open('sldemo_fuelsys_dd.sldd');
show(dictionary)
```

The dictionary contains entries that are defined in several referenced dictionaries, including `sldemo_fuelsys_dd_controller` and `sldemo_fuelsys_dd_plant`.

- 2 Run the script `ex_dictionary_changes`, which makes changes to `sldemo_fuelsys_dd`. Later, you can use the Comparison Tool to investigate the changes.
- 3 In the **Model Hierarchy** pane of Model Explorer, right-click the node `sldemo_fuelsys_dd` and select **Show Changes**.

The Comparison Tool displays the changes made to the dictionary.

sldemo\_fuelsys\_dd.sldd

### Show Changes in Dictionary - sldemo\_fuelsys\_dd.sldd

Click on a column header to sort the table

| Saved Entries             |             |                                   |                    | Unsaved Changes           |             |                                   |                    |                                      |                  |                                    |
|---------------------------|-------------|-----------------------------------|--------------------|---------------------------|-------------|-----------------------------------|--------------------|--------------------------------------|------------------|------------------------------------|

| <a href="#">PressVect</a> | Design Data | sldemo_fuelsys_dd_controller.sldd | Simulink.Parameter |                           |             |                                   |                    | <i>deleted</i>                       | 2013-10-22 04:05 | <a href="#">Recover from Saved</a> |
| <a href="#">min_throt</a> | Design Data | sldemo_fuelsys_dd_controller.sldd | Simulink.Parameter | <a href="#">min_throt</a> | Design Data | sldemo_fuelsys_dd_controller.sldd | Simulink.Parameter | modified ( <a href="#">compare</a> ) | 2015-03-11 09:05 | <a href="#">Revert to Saved</a>    |

| Dictionary references in sldemo_fuelsys_dd.sldd |      |                 |                                   |
|-------------------------------------------------|------|-----------------|-----------------------------------|
| Saved References                                |      | Unsaved Changes |                                   |
| Name                                            | Name | Change Summary  | Action (no undo)                  |
| sldemo_fuelsys_dd_plant.sldd                    |      | <i>removed</i>  | <a href="#">Recover Reference</a> |

- 4 In the table at the top of the report, click **compare** in the Change Summary column of the row that corresponds to the entry `min_throt`.

A new tab shows the changes made to `min_throt`. The script changed the parameter data type from `auto` to `int8` and the parameter value from 3 to 4.

- 5 Click the tab that shows the changes made to the dictionary. In the Action column of the row that corresponds to the entry `min_throt`, click **Revert to Saved**.

The entry reverts to the definition from the last saved version of the dictionary.

- 6 The remaining row in the report shows that the script deleted the entry `PressVect`, which was defined in the referenced dictionary `sldemo_fuelsys_dd_controller`. Click **Recover from Saved**, which recovers the entry in the referenced dictionary.
- 7 The table **Dictionary references in sldemo\_fuelsys\_dd.sldd** shows that the script removed the reference to the dictionary `sldemo_fuelsys_dd_plant`. In the Action column, click **Recover Reference**.

The report shows that there are no more unsaved changes to `sldemo_fuelsys_dd`.

## Partition Dictionary Data Using Referenced Dictionaries

This example shows how to partition a data dictionary into reference dictionaries that can be shared in a team. A Simulink data dictionary permanently stores model data including MATLAB variables, data objects, and data types.

### Open dictionary for partitioning

- 1 Open the Model Explorer. In the Simulink Editor, in the **Modeling** tab, click **Model Explorer**.
- 2 Select **File > Open**.

Browse and locate your dictionary.

### Create reference dictionary

Use a reference dictionary to store a subset of entries from the main dictionary.

- 1 Select **File > New > Data Dictionary**.

Name the reference dictionary and save it.

Both dictionaries appear as nodes in the **Model Hierarchy** pane.

- 2 In the **Model Hierarchy** pane, select the dictionary that serves as the parent.
- 3 In the dialog box pane, in the **Referenced Dictionaries** section, click **Add**. Browse to the location of the reference dictionary and add it as a reference.

The **Referenced Dictionaries** section displays each directly referenced data dictionary as a top level node and the indirectly referenced data dictionaries as a flat list below each top level node. To see the full dependency tree of referenced dictionaries in the Dependency Analyzer, click **View Hierarchy**.

### Move entries into reference dictionary

- 1 In the **Model Hierarchy** pane, select the **Design Data** node of the parent dictionary.
- 2 In the **Contents** pane, select the entries you want to move to the reference dictionary.
- 3 For one of the selected entries, set **DataSource** to the reference dictionary using the dropdown menu. You can also drag and drop entries between dictionaries.

To make the **DataSource** column visible, click **Show Details** in the **Contents** pane. In the text box, enter `DataSource`, and add `DataSource` to the list of displayed columns.

### Organize display of entries

- 1 Click the name of the **DataSource** column to sort the entries by the dictionaries that define them.
- 2 Right-click the name of the **DataSource** column and select **Group by This Column** to group the entries. The **Contents** pane creates a group for each dictionary that defines the entries.

## Partition Data for Model Reference Hierarchy Using Data Dictionaries

When you use model referencing to break a large system of models into smaller components and subcomponents, you can create data dictionaries to segregate the design data. Design data is the set of workspace variables that the models use to specify block parameters and signal characteristics. For basic information about data dictionaries, see “What Is a Data Dictionary?” on page 75-2.

To take this component-based approach to data management, create a shared dictionary that contains common data and a separate dictionary for each component that contains the data needed by that component.

### Create a Dictionary for Each Component

This example shows how to partition design data into dictionaries. When you finish, each component in the system has a dictionary, and dictionary references allow the components to share data.

#### Explore Example Model Hierarchy

- 1 Navigate to the folder `matlabroot/help/toolbox/simulink/examples` (open).
- 2 Copy these files to a writable folder:
  - `ProjectData_Contr.mat`
  - `ProjectData_ContrSub1.mat`
  - `ProjectData_ContrSub2.mat`
  - `ProjectData_ContrSubs.mat`
  - `ProjectData_Plant.mat`
  - `ProjectData_System.mat`
  - `ex_SystemModel`
  - `ex_PlantComp_Lvl1`
  - `ex_PlantComp_Lvl2`
  - `ex_ContrComp`
  - `ex_ContrComp_Sub1_Lvl1`
  - `ex_ContrComp_Sub1_Lvl2`
  - `ex_ContrComp_Sub2_Lvl1`
  - `ex_ContrComp_Sub2_Lvl2`
- 3 Load the MAT-files to create design data in the base workspace.
- 4 Open the example model `ex_SystemModel`. This model is at the top of a reference hierarchy that includes the other example models.
- 5 In the model, update the diagram. Each bus signal in the model uses a `Simulink.Bus` object as a data type. The objects, `SensorBus` and `CtrlBus`, are in the base workspace.

The referenced models `ex_PlantComp_Lvl1` and `ex_ContrComp` use the bus objects for root-level inputs and outputs, which means the plant and controller components share the objects.

- 6 In the base workspace, double-click the `Simulink.NumericType` object named `FloatType`. Signals, parameters, and other data items in the controller component use this shared data type.

- 7 In the Model Explorer **Model Hierarchy** pane, expand the node `ex_SystemModel`.

Click the **Configurations** node. In the **Contents** pane, the node **Reference to SimConfigSet** appears. `SimConfigSet` is a `Simulink.ConfigSet` object in the base workspace. To maintain configuration parameter uniformity for simulation, all of the models in the hierarchy refer to `SimConfigSet`.

- 8 Right-click the node **Controller (ex\_ContrComp)** and select **Open**.

- 9 In the Model Explorer **Model Hierarchy** pane, expand the new node `ex_ContrComp`. Click the **Configurations** node.

In the **Contents** pane, the node **Reference to CodeGenConfigSet** appears. `CodeGenConfigSet` is a `Simulink.ConfigSet` object in the base workspace. To maintain configuration parameter uniformity for code generation, the models in the controller component refer to `CodeGenConfigSet`. The models in the plant component do not use `CodeGenConfigSet`.

- 10 In the **Model Hierarchy** pane, select **Base Workspace**. In the **Contents** pane, right-click the variable `diff` and select **Find Where Used**. In the **Select a system** dialog box, select `ex_SystemModel` and click **OK**. If you see a message about updating the diagram, click **OK**.

In the **Contents** pane, the variable `diff` is used by Constant blocks in the models `ex_ContrComp_Sub1_Lvl1` and `ex_ContrComp_Sub1_Lvl2`, which make up the first controller subcomponent. Similarly, other models in the hierarchy share the base workspace variables `coeff`, `init`, `mu`, and `rho`.

The table shows the models that share each variable in the base workspace.

| Variable Name                 | Models Using the Variable                                                                                      | Scope of Sharing                                      |
|-------------------------------|----------------------------------------------------------------------------------------------------------------|-------------------------------------------------------|
| <code>CtrlBus</code>          | Top-level models in the plant and controller components                                                        | Shared globally by entire system                      |
| <code>SensorBus</code>        | Top-level models in the plant and controller components                                                        | Shared globally by entire system                      |
| <code>SimConfigSet</code>     | All models in the hierarchy                                                                                    | Shared globally by entire system                      |
| <code>rho</code>              | <code>ex_PlantComp_Lvl2</code> , <code>ex_ContrComp_Sub1_Lvl2</code> , and <code>ex_ContrComp_Sub2_Lvl2</code> | Shared globally by entire system                      |
| <code>mu</code>               | <code>ex_PlantComp_Lvl1</code> and <code>ex_PlantComp_Lvl2</code>                                              | Shared by models in the plant component               |
| <code>FloatType</code>        | All models in the controller component                                                                         | Shared by controller component and subcomponents      |
| <code>CodeGenConfigSet</code> | All models in the controller component                                                                         | Shared by controller component and subcomponents      |
| <code>init</code>             | <code>ex_ContrComp_Sub1_Lvl2</code> and <code>ex_ContrComp_Sub2_Lvl1</code>                                    | Shared by controller subcomponents                    |
| <code>diff</code>             | <code>ex_ContrComp_Sub1_Lvl1</code> and <code>ex_ContrComp_Sub1_Lvl2</code>                                    | Shared by models in the first controller subcomponent |

| Variable Name | Models Using the Variable                               | Scope of Sharing                                       |
|---------------|---------------------------------------------------------|--------------------------------------------------------|
| coeff         | ex_ContrComp_Sub2_Lvl1<br>and<br>ex_ContrComp_Sub2_Lvl2 | Shared by models in the second controller subcomponent |

Suppose that separate teams of developers maintain the plant component and the controller components. You can use data dictionaries to store and scope the shared design data.

### Create Shared Global Dictionary

Create a shared global data dictionary that contains the data shared globally by the entire system.

- 1 In the Model Explorer, select **File > New > Data Dictionary**.
- 2 Set the new dictionary name to `GlobalShare` and click **Save**.
- 3 In the **Model Hierarchy** pane, right-click the `GlobalShare` node and select **Show Empty Sections**.
- 4 In the **Model Hierarchy** pane, select **Base Workspace**. In the **Contents** pane, select the design data that are shared globally by the entire system: `CtrlBus`, `SensorBus`, and `rho`.
- 5 Right-click and select **Copy**.
- 6 In the **Model Hierarchy** pane, right-click the `Design Data` node under `GlobalShare` and select **Paste**.
- 7 Similarly, copy `SimConfigSet` from the **Base Workspace** and copy to the `Configurations` node under `GlobalShare`.

### Create Dictionary for Plant Component

Create a data dictionary for data shared by models in the Plant component. Add a reference from this dictionary to the shared global dictionary.

- 1 In the Model Explorer, select **File > New > Data Dictionary**.
- 2 Set the new dictionary name to `Plant` and click **Save**.
- 3 In the **Model Hierarchy** pane, select the node `Plant`. In the Dialog pane, under **Referenced Dictionaries**, click **Add**.
- 4 Double-click `GlobalShare.sldd`.
- 5 In the **Model Hierarchy** pane, right-click the node `Plant` and select **Save Changes**.

### Link Plant Component to Dictionary and Migrate Data

Link the Plant component to its component dictionary then migrate data shared by models in the Plant component from the base workspace to the dictionary.

- 1 Open the model `ex_PlantComp_Lvl1`.
- 2 In the model, update the diagram.
- 3 If the Diagnostic View displays an error for multiple inconsistent definitions of `SimConfigSet`, select **Delete others** next to the `GlobalShare` instance. This fix keeps the definition in the `GlobalShare` dictionary and removes other definitions that can be seen by the model.
- 4 In the **Modeling** tab, under **Design**, click **Link to Data Dictionary**.
- 5 In the dialog box, click **Browse**.

- 6 Double-click `Plant.sldd`.
- 7 In the **Model Properties** dialog box, click **Apply**. Click **Change all models** in response to the message about linking referenced models.
- 8 In the **Model Properties** dialog box, click **Migrate data**.
- 9 In the Migrate Data dialog box, select **Include data from referenced models** and then click **Migrate**.
- 10 (Optional) In the **Model Properties** dialog box, clear **Enable model access to base workspace**.
- 11 Remove the previous method for loading model data. In the **Model Properties** dialog box, on the **Callbacks** tab, clear the `PreLoadFcn` for the model.
- 12 Click **OK**.

### Create Dictionary for Controller Component

Create a data dictionary that contains the data shared by models in the controller component. This dictionary can also reference the shared global dictionary.

- 1 In the Model Explorer, select **File > New > Data Dictionary**.
- 2 Set the new dictionary name to `Controller` and click **Save**.
- 3 In the **Model Hierarchy** pane, select the node `Controller`. In the Dialog pane, under **Referenced Dictionaries**, click **Add**.
- 4 Double-click `GlobalShare.sldd`.
- 5 In the **Model Hierarchy** pane, right-click the node `Controller` and select **Save Changes**.

### Link Controller Component to Dictionary and Migrate Data

Link the Controller component to its component dictionary then migrate data shared by models in the Controller component from the base workspace to the dictionary.

- 1 Open the model `ex_ContrComp`.
- 2 If the Diagnostic View displays an error for multiple inconsistent definitions of `SimConfigSet`, select **Delete others** next to the `GlobalShare` instance. This fix keeps the definition in the `GlobalShare` dictionary and removes other definitions that can be seen by the model.
- 3 In the **Modeling** tab, under **Design**, click **Link to Data Dictionary**.
- 4 In the dialog box, click **Browse**.
- 5 Double-click `Controller.sldd`.
- 6 In the **Model Properties** dialog box, click **Apply**. Click **Change all models** in response to the message about linking referenced models.
- 7 In the **Model Properties** dialog box, click **Migrate data**.
- 8 In the Migrate Data dialog box, select **Include data from referenced models** and then click **Migrate**.
- 9 (Optional) In the **Model Properties** dialog box, clear **Enable model access to base workspace**.
- 10 Remove the previous method for loading model data. In the **Model Properties** dialog box, on the **Callbacks** tab, clear the `PreLoadFcn` for the model.
- 11 Click **OK**.

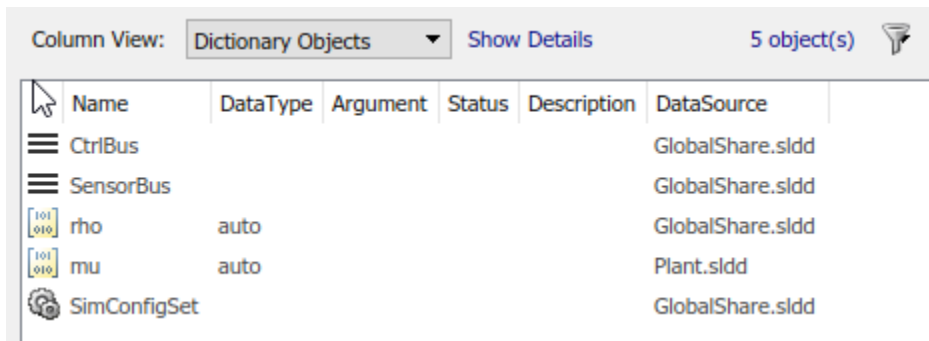

## Link System to Global Dictionary

Finally, link the top model to the global dictionary.

- 1 Open the model `ex_SystemModel`.
- 2 In the **Modeling** tab, under **Design**, click **Link to Data Dictionary**.
- 3 In the dialog box, click **Browse**.
- 4 Double-click `GlobalShare.sldd`.
- 5 In the **Model Properties** dialog box, click **OK**. Click **Change this model only** in response to the message about linking referenced models.

## Inspect Data Storage

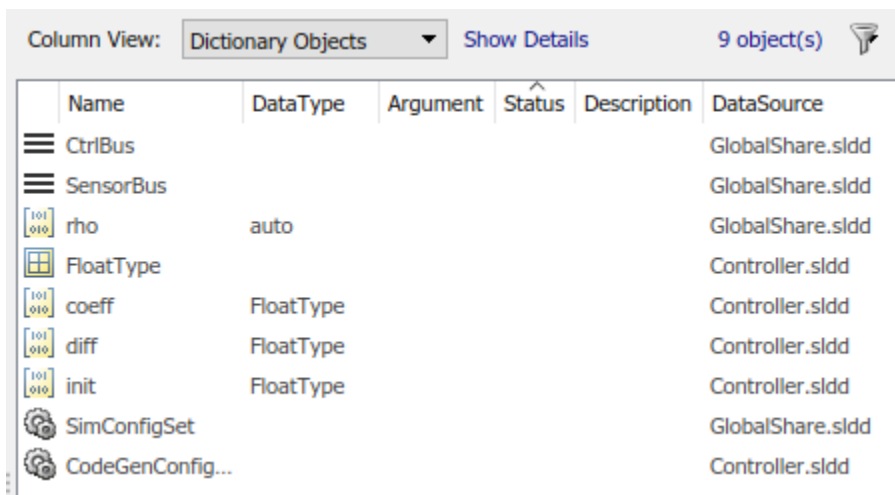

In the Model Explorer **Model Hierarchy** pane, select the dictionary node `Plant`. In the **Contents** pane, to view the contents of `Plant.sldd`, click **Show Current System and Below** . The contents of the Design Data and Configurations sections appear.

Column View: Dictionary Objects Show Details 5 object(s)

| Name         | DataType | Argument | Status | Description | DataSource       |
|--------------|----------|----------|--------|-------------|------------------|
| CtrlBus      |          |          |        |             | GlobalShare.sldd |
| SensorBus    |          |          |        |             | GlobalShare.sldd |
| rho          | auto     |          |        |             | GlobalShare.sldd |
| mu           | auto     |          |        |             | Plant.sldd       |
| SimConfigSet |          |          |        |             | GlobalShare.sldd |

Similarly, view the contents of `Controller.sldd`.

Column View: Dictionary Objects Show Details 9 object(s)

| Name             | DataType  | Argument | Status | Description | DataSource       |
|------------------|-----------|----------|--------|-------------|------------------|
| CtrlBus          |           |          |        |             | GlobalShare.sldd |
| SensorBus        |           |          |        |             | GlobalShare.sldd |
| rho              | auto      |          |        |             | GlobalShare.sldd |
| FloatType        |           |          |        |             | Controller.sldd  |
| coeff            | FloatType |          |        |             | Controller.sldd  |
| diff             | FloatType |          |        |             | Controller.sldd  |
| init             | FloatType |          |        |             | Controller.sldd  |
| SimConfigSet     |           |          |        |             | GlobalShare.sldd |
| CodeGenConfig... |           |          |        |             | Controller.sldd  |

The **DataSource** column shows the variables and objects that each dictionary stores.

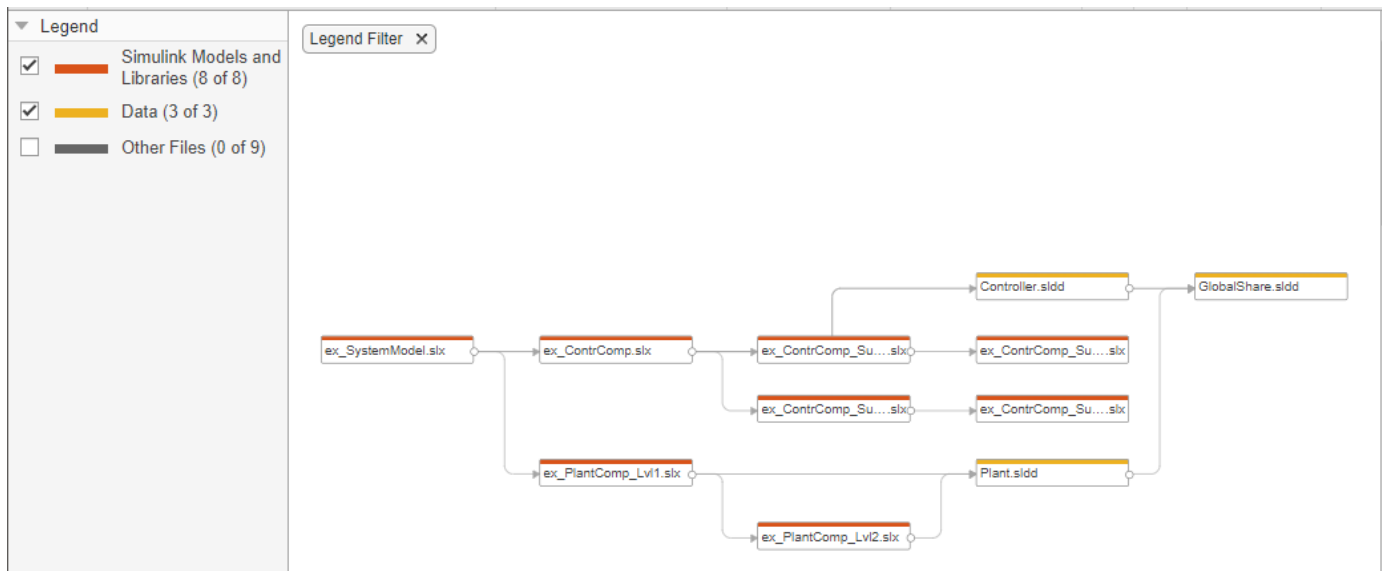

All of the globally shared variables, such as `CtrlBus` and `SensorBus`, reside in `GlobalShare.sldd`. The variable `init`, which both of the controller subcomponents share, resides in `Controller.sldd`.

If the development team assigned to the controller component must make changes to the globally shared variables, they access the `GlobalShare` dictionary file. Similarly, if the team must make changes to the variable `init`, they must access the `Controller` dictionary file.

### Inspect Dictionary Hierarchy

To view the entire dictionary and model hierarchy, perform a dependency analysis.

- 1 Open your saved model `ex_SystemModel`.
- 2 On the **Modeling** tab, in the **Design** section, click **Dependency Analyzer**.

The system model, `ex_SystemModel`, is linked to the dictionary `GlobalShare.slidd`. The plant component and the controller component are each linked to a separate dictionary. To access the shared data, the component dictionaries reference the dictionary `GlobalShare.slidd`. These dictionaries form a reference hierarchy.

### Strategies to Discover Shared Data

To learn how the models in a model reference hierarchy share data, use these techniques:

- In an open model, on the Modeling tab, select **Find > Find Ref Variables**. The Model Explorer displays the variables that the model uses, as well as the variables that referenced models use. You can then right-click a variable and select **Find Where Used** to display all of the models that use the variable. For more information, see “Edit and Manage Workspace Variables by Using Model Explorer” on page 68-111.
- At the command prompt, use the function `Simulink.findVars` to determine the variables a model uses. You can then use the function `intersect` to determine the variables two models, components, or subcomponents share.

## Link Data Dictionary to Custom Libraries

When you create a custom block library, you might define data objects — such as bus and enumeration types — to be used on block interfaces. You can make these data types available to library users by storing them in a Simulink data dictionary that is attached to the library. Library users automatically gain access to the data types contained in the dictionary when they drag a block from the library into their model.

### Author Library Blocks with Data Types Defined in Attached Data Dictionary

To define data and types for your library blocks in a data dictionary:

- 1 Create a new data dictionary or open an existing dictionary. To create a new dictionary, in the Model Explorer, select **File > New > Data Dictionary**. To open an existing dictionary, select **File > Open** and browse for your dictionary.
- 2 Add data and types, such as bus objects, to the data dictionary.

- 3 Save the data dictionary.

You can attach the data dictionary to your library by using the UI or programmatically by using the `set_param` function.

To attach the data dictionary by using the UI:

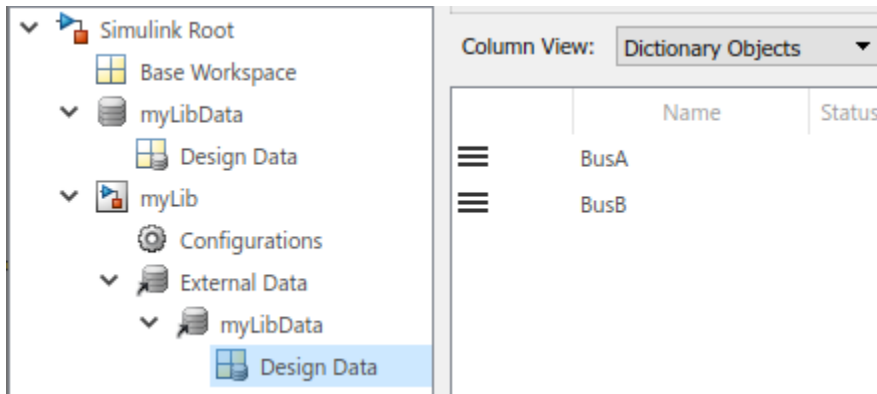

- 1 Unlock your library (see “Lock and Unlock Libraries” on page 41-6).
- 2 In the Simulink Editor, on the **Modeling** tab, click **Library Properties**.
- 3 In the Library Properties dialog box, on the **External Data** tab, click **Browse** to locate and open your data dictionary.
- 4 Click **OK** to attach the dictionary.

To attach the data dictionary by using the `set_param` function, use this command.

```
set_param('myLib', 'DataDictionary', 'myLibData.sldd');
```

After you have attached the dictionary and saved your library, the dictionary and its content appears in the Model Explorer as an external data source for the library.

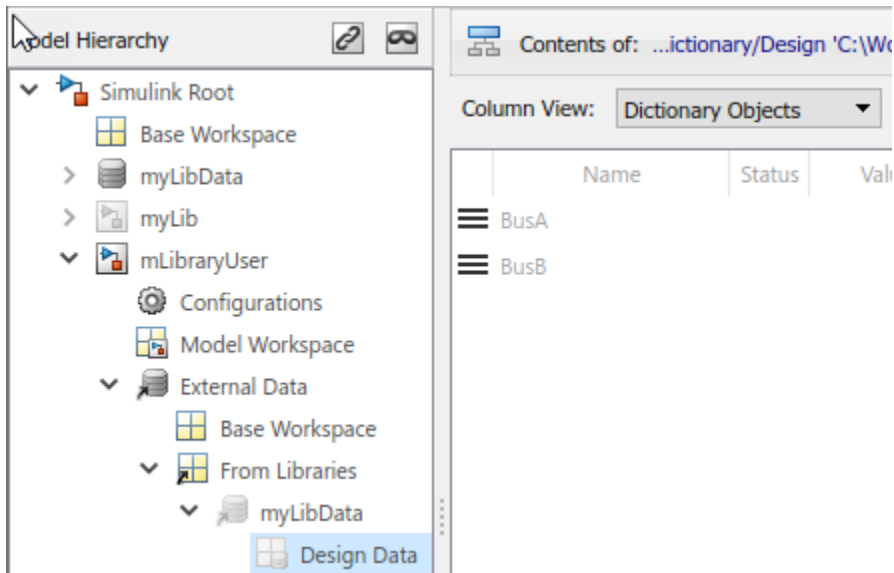

As you develop blocks for your library, you can select the types contained in the library dictionary from the **Data type** list.

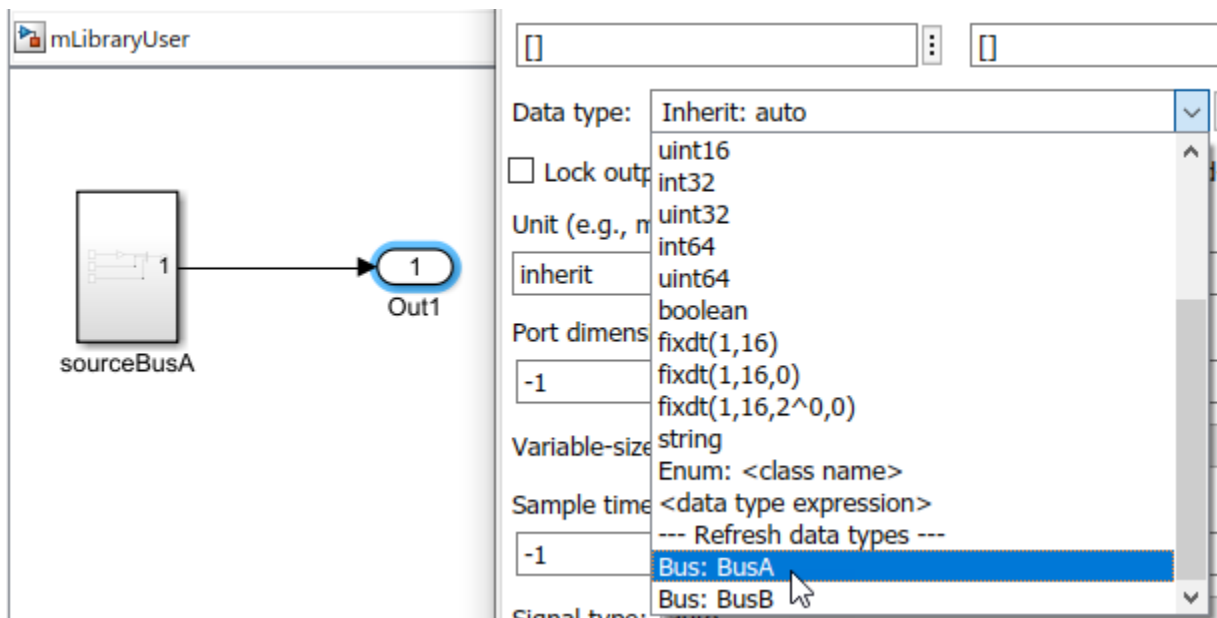

## Use Blocks From a Library with Attached Data Dictionary

When you drag a block from a library into your model, the model automatically gains access to data objects contained in the dictionary attached to that library. To see the dictionary in the Model

Explorer, in the Simulink Editor, click the model data badge  in the bottom left corner, then click **External Data**. The dictionary appears as an external data source to your model under the **From Libraries** node.

The data objects defined in the library are now available to the model for simulation and code generation without the need to bring those data objects into either the base workspace or another data dictionary.

When you update or save your model, if the model no longer contains a block from the library, the library dictionary is no longer available to your model and the dictionary is removed from the **From Libraries** node.

## Considerations When Using a Library Dictionary

There are several considerations when authoring or using a library with a linked data dictionary.

- In most cases, you will define bus or enumeration types in a library dictionary, but library authors can share any type of object with library users by adding objects to the dictionary.
- Items in the library dictionary are global in scope, and symbol resolution occurs as if the library dictionary is directly connected to the model.
- If a library link is broken, the data associated with the library is no longer available. To regain access to the data, you must manually link your model to the library dictionary. Once the link to the library dictionary is restored, access to the data is also restored.
- In a model hierarchy, a model must directly or indirectly reference a library dictionary to use the data objects that the dictionary contains.
- Simulink stores library dictionary dependency information in the user preference folder. This information is persistent across MATLAB sessions. If you have moved a library to a different folder or machine, or if you have made changes to a library hierarchy, you can use the `Simulink.LibraryDictionary.refresh` function to perform a dependency analysis and update your stored dependencies. This dependency analysis can be expensive, so call the refresh function only if you have a missing dependency. To clear the previous dependency analysis, use the `Simulink.LibraryDictionary.clear` function.
- When you drag a block from a library into your model, the model gains access to the data dictionary attached to that library. However, if the block is from a sublibrary, access is only to the data dictionary attached to that sublibrary. In this case, to provide a model with access to both library and sublibrary dictionaries when it uses the block, the library author must contain the sublibrary block in a new subsystem.
- If you store your library under the MATLAB root folder, you can attach a dictionary to the library, but a model does not have automatic access to the dictionary when you add a block from the library.
- Simulink does not support finding unused variables for a library-linked data dictionary.

- “Programmatically Partition Data Dictionary” on page 75-44
- “Make Changes to Configuration Set Stored in Dictionary” on page 75-44

A data dictionary stores Simulink model data and offers more data management features than the MATLAB base workspace or the model workspace (see “What Is a Data Dictionary?” on page 75-2). To interact with the data in a dictionary programmatically:

- 1 Create a `Simulink.data.Dictionary` object that represents the target dictionary.
- 2 Create a `Simulink.data.dictionary.Section` object that represents the target section, for example the Design Data section. Use the object to interact with the entries stored in the section and to add entries.
- 3 Optionally, create `Simulink.data.dictionary.Entry` objects that each represent an entry in the target section. Use these objects to interact with individual entries in the target section.

To programmatically access variables for the purpose of sweeping block parameter values, consider using `Simulink.SimulationInput` objects instead of modifying the variables through the programmatic interface of the data dictionary. See “Optimize, Estimate, and Sweep Block Parameter Values” on page 37-38.

To programmatically interact with the **Embedded Coder** section of a data dictionary, see “Create Code Definitions Programmatically” (Embedded Coder).

### Add Entry to Design Data Section of Data Dictionary

- 1 Represent the Design Data section of the data dictionary `myDictionary_ex_API.sldd` with a `Simulink.data.dictionary.Section` object named `dDataSectObj`.
 

```
myDictionaryObj = ...
Simulink.data.dictionary.open('myDictionary_ex_API.sldd');
dDataSectObj = getSection(myDictionaryObj, 'Design Data');
```
- 2 Add an entry to the Design Data section of `myDictionary_ex_API.sldd` an entry `myNewEntry` with value 237.

```
addEntry(dDataSectObj, 'myNewEntry', 237)
```

## Rename Data Dictionary Entry

Rename an entry in the Design Data, Configurations, or Other Data section of a data dictionary.

- 1 Represent the data dictionary entry `fuelFlow` with a `Simulink.data.dictionary.Entry` object named `fuelFlowObj`. `fuelFlow` is defined in the data dictionary `myDictionary_ex_API.sldd`.

```
myDictionaryObj = Simulink.data.dictionary.open('myDictionary_ex_API.sldd');
dDataSectObj = getSection(myDictionaryObj, 'Design Data');
fuelFlowObj = getEntry(dDataSectObj, 'fuelFlow');
```

- 2 Rename the data dictionary entry.

```
fuelFlowObj.Name = 'fuelFlowNew';
```

## Increment Value of Data Dictionary Entry

- 1 Represent the data dictionary entry `fuelFlow` with a `Simulink.data.dictionary.Entry` object named `fuelFlowObj`. `fuelFlow` is defined in the data dictionary `myDictionary_ex_API.sldd`.

```
myDictionaryObj = Simulink.data.dictionary.open('myDictionary_ex_API.sldd');
dDataSectObj = getSection(myDictionaryObj, 'Design Data');
fuelFlowObj = getEntry(dDataSectObj, 'fuelFlow');
```

- 2 Store the value of the target entry in a temporary variable. Increment the value of the temporary variable by one.

```
temp = getValue(fuelFlowObj);
temp = temp+1;
```

- 3 Set the value of the target entry by using the temporary variable.

```
setValue(fuelFlowObj, temp)
```

## Data Dictionary Management

Use `Simulink.data.Dictionary` objects to interact with entire data dictionaries.

| Goal                                                                                   | Use                                          |
|----------------------------------------------------------------------------------------|----------------------------------------------|
| Represent existing data dictionary with <code>Simulink.data.Dictionary</code> object   | <code>Simulink.data.dictionary.open</code>   |
| Create and represent data dictionary with <code>Simulink.data.Dictionary</code> object | <code>Simulink.data.dictionary.create</code> |
| Interact with data dictionary                                                          | <code>Simulink.data.Dictionary</code> class  |
| Import variables to data dictionary from MATLAB base workspace                         | <code>importFromBaseWorkspace</code> method  |
| Add reference dictionary to a data dictionary                                          | <code>addDataSource</code> method            |
| Remove reference dictionary from a data dictionary                                     | <code>removeDataSource</code> method         |

| Goal                                                                                      | Use                                                          |
|-------------------------------------------------------------------------------------------|--------------------------------------------------------------|
| Save changes to data dictionary                                                           | <code>saveChanges</code> method                              |
| Discard changes to data dictionary                                                        | <code>discardChanges</code> method                           |
| View a list of entries stored in data dictionary                                          | <code>listEntry</code> method                                |
| Import enumerated type definitions to data dictionary                                     | <code>importEnumTypes</code> method                          |
| Return file name and path of data dictionary                                              | <code>filepath</code> method                                 |
| Show data dictionary in Model Explorer window                                             | <code>show</code> method                                     |
| Hide data dictionary from Model Explorer window                                           | <code>hide</code> method                                     |
| Close connection between data dictionary and <code>Simulink.data.Dictionary</code> object | <code>close</code> method                                    |
| Identify data dictionaries that are open                                                  | <code>Simulink.data.dictionary.getOpenDictionaryPaths</code> |
| Close all connections to all open data dictionaries                                       | <code>Simulink.data.dictionary.closeAll</code>               |

## Dictionary Section Management

Data dictionaries store data as entries contained in sections, and by default all dictionaries have at least three sections named Design Data, Other Data, and Configurations. Use `Simulink.data.dictionary.Section` objects to interact with data dictionary sections.

| Goal                                                                     | Use                                                 |
|--------------------------------------------------------------------------|-----------------------------------------------------|
| Represent data dictionary section with <code>Section</code> object.      | <code>getSection</code> method                      |
| Interact with data dictionary section                                    | <code>Simulink.data.dictionary.Section</code> class |
| Import variables to data dictionary section from MAT-file or MATLAB file | <code>importFromFile</code> method                  |
| Export entries in data dictionary section to MAT-file or MATLAB file     | <code>exportToFile</code> method                    |
| Delete entry from data dictionary section                                | <code>deleteEntry</code> method                     |
| Evaluate MATLAB expression in data dictionary section                    | <code>evalin</code> method                          |
| Search for entries in data dictionary section                            | <code>find</code> method                            |
| Determine whether entry exists in data dictionary section                | <code>exist</code> method                           |

## Dictionary Entry Manipulation

A variable that is stored in a data dictionary is called an entry of the dictionary. Entries have additional properties that store status information, such as the time and date the entry was last modified. Use `Simulink.data.dictionary.Entry` objects to manipulate data dictionary entries.

| Goal                                                                 | Use                                                            |
|----------------------------------------------------------------------|----------------------------------------------------------------|
| Represent data dictionary entry with Entry object                    | <code>getEntry</code> method                                   |
| Add data dictionary entry to section and represent with Entry object | <code>addEntry</code> method                                   |
| Manipulate data dictionary entry                                     | <code>Simulink.data.dictionary.Entry</code> class              |
| Assign new value to data dictionary entry                            | <code>setValue</code> method                                   |
| Display changes made to data dictionary entry                        | <code>showChanges</code> method                                |
| Save changes made to data dictionary                                 | <code>saveChanges</code> method                                |
| Discard changes made to data dictionary entry                        | <code>discardChanges</code> method                             |
| Search in an array of data dictionary entries                        | <code>find</code> method                                       |
| Return value of data dictionary entry                                | <code>getValue</code> method                                   |
| Delete data dictionary entry                                         | <code>deleteEntry</code> method                                |
| Store enumerated type definition in dictionary                       | <code>Simulink.data.dictionary.EnumTypeDefinition</code> class |

## Transition to Using Data Dictionary

Using a data dictionary can complicate programmatic interaction with model data. If you link a model to a dictionary:

- You can no longer interact with the model data by using simple commands at the command prompt. Instead, you must use the programmatic interface of the dictionary (`Simulink.data.Dictionary`).
- When you select the dictionary property **Enable dictionary access to base workspace** (see “Continue to Use Shared Data in the Base Workspace” on page 75-10), depending on the storage location of the target data, you must use either simple commands or the programmatic interface.

To help transition from using the base workspace to using data dictionaries, consider using these functions. The functions operate on model data regardless of the storage location of the data.

| Goal                                                                                     | Use                                       |
|------------------------------------------------------------------------------------------|-------------------------------------------|
| Change value of data dictionary entry or workspace variable in context of Simulink model | <code>Simulink.data.assigninGlobal</code> |

| Goal                                                                                            | Use                                       |
|-------------------------------------------------------------------------------------------------|-------------------------------------------|
| Evaluate MATLAB expression in context of Simulink model                                         | <code>Simulink.data.evalInGlobal</code>   |
| Determine existence of data dictionary entry or workspace variable in context of Simulink model | <code>Simulink.data.existsInGlobal</code> |

## Programmatically Migrate Single Model to Use Dictionary

To change the data source of a Simulink model from the MATLAB base workspace to a new data dictionary, use this example code as a template.

```
% Define the model name and the data dictionary name
modelName = 'f14';
dictionaryName = 'myNewDictionary.slidd';

% Load the target model
load_system(modelName);

% Identify all model variables that are defined in the base workspace
varsToImport = Simulink.findVars(modelName,'SourceType','base workspace');
varNames = {varsToImport.Name};

% Create the data dictionary
dictionaryObj = Simulink.data.dictionary.create(dictionaryName);

% Import to the dictionary the model variables defined in the base
% workspace, and clear the variables from the base workspace
[importSuccess,importFailure] = importFromBaseWorkspace(dictionaryObj,...
 'varList',varNames,'clearWorkspaceVars',true);

% Link the dictionary to the model
set_param(modelName,'DataDictionary',dictionaryName);
```

---

**Note** This code does not migrate the definitions of enumerated data types that were used to define model variables. If you import model variables of enumerated data types to a data dictionary but do not migrate the enumerated type definitions, the dictionary is less portable and might not function properly if used by someone else. To migrate enumerated data type definitions to a data dictionary, see “Enumerations in Data Dictionary” on page 75-12.

---

## Import Directly From External File to Dictionary

This example shows how to use a custom MATLAB function to import data directly from an external file to a data dictionary without creating or altering variables in the base workspace.

- 1 Create a two-dimensional lookup table in one sheet of a Microsoft Excel workbook. Use the upper-left corner of the sheet to provide names for the two breakpoints and for the table. Use column B and row 2 to store the two breakpoints, and use the rest of the sheet to store the table. For example, your lookup table might look like this:

|   | A         | B         | C    | D   | E    | F   | G    | H |
|---|-----------|-----------|------|-----|------|-----|------|---|
| 1 |           | bkpt2Name |      |     |      |     |      |   |
| 2 | bkpt1Name | tableName | 0.1  | 0.2 | 0.3  | 0.4 | 0.5  |   |
| 3 |           | 0.25      | 0.35 | 0.6 | 0.85 | 1.1 | 1.35 |   |
| 4 |           | 0.5       | 0.45 | 0.7 | 0.95 | 1.2 | 1.45 |   |
| 5 |           | 0.75      | 0.55 | 0.8 | 1.05 | 1.3 | 1.55 |   |
| 6 |           | 1         | 0.65 | 0.9 | 1.15 | 1.4 | 1.65 |   |
| 7 |           | 1.25      | 0.75 | 1   | 1.25 | 1.5 | 1.75 |   |
| 8 |           |           |      |     |      |     |      |   |

Save the workbook in your current folder as `my2DLUT.xlsx`.

- Copy this custom function definition into a MATLAB file, and save the file in your current folder as `importLUTToDD.m`.

```
function importLUTToDD(workbookFile,dictionaryName)
% IMPORTLUTToDD(workbookFile,dictionaryName) imports data for a
% two-dimensional lookup table from a workbook directly into a data
% dictionary. The two-dimensional lookup table in the workbook can be
% any size but must follow a standard format.

% Read in the entire first sheet of the workbook.
[data,names,~] = xlsread(workbookFile,1,'');

% Divide the raw imported data into the breakpoints, the table, and their
% names.
% Assume breakpoint 1 is in the first column and breakpoint 2 is in the
% first row.
% Assume cells A2, B1, and B2 define the breakpoint names and table name.
bkpt1 = data(2:end,1);
bkpt2 = data(1,2:end);
table = data(2:end,2:end);
bkpt1Name = names{2,1};
bkpt2Name = names{1,2};
tableName = names{2,2};

% Prepare to import to the Design Data section of the target data
% dictionary.
myDictionaryObj = Simulink.data.dictionary.open(dictionaryName);
dDataSectObj = getSection(myDictionaryObj,'Design Data');

% Create entries in the dictionary to store the imported breakpoints and
% table. Name the entries using the breakpoint and table names imported
% from the workbook.
addEntry(dDataSectObj,bkpt1Name,bkpt1);
addEntry(dDataSectObj,bkpt2Name,bkpt2);
addEntry(dDataSectObj,tableName,table);

% Save changes to the dictionary and close it.
saveChanges(myDictionaryObj)
close(myDictionaryObj)
```

- At the MATLAB command prompt, create a data dictionary to store the lookup table data.

```
myDictionaryObj = Simulink.data.dictionary.create('myLUTDD.sldd');
```

- Call the custom function to import your lookup table to the new data dictionary.

```
importLUTToDD('my2DLUT.xlsx','myLUTDD.sldd')
```

- Open the data dictionary in Model Explorer.

```
show(myDictionaryObj)
```

Three new entries store the imported breakpoints and lookup table. These entries are ready to use in a 2-D Lookup Table block.

## Programmatically Partition Data Dictionary

To partition a data dictionary into reference dictionaries, use this example code as a template. You can use reference dictionaries to make large data dictionaries more manageable and to contain standardized data that is useful for multiple models.

```
% Define the names of a parent data dictionary and two
% reference data dictionaries
parentDDName = 'myParentDictionary.sldd';
typesDDName = 'myTypesDictionary.sldd';
paramsDDName = 'myParamsDictionary.sldd';

% Create the parent data dictionary and a
% Simulink.data.Dictionary object to represent it
parentDD = Simulink.data.dictionary.create(parentDDName);

% Create a Simulink.data.dictionary.Section object to represent
% the Design Data section of the parent dictionary
designData_parentDD = getSection(parentDD, 'Design Data');

% Import some data to the parent dictionary from the file partDD_Data_ex_API.m
importFromFile(designData_parentDD, 'partDD_Data_ex_API.m');

% Create two reference dictionaries
Simulink.data.dictionary.create(typesDDName);
Simulink.data.dictionary.create(paramsDDName);

% Create a reference dictionary hierarchy by adding reference dictionaries
% to the parent dictionary
addDataSource(parentDD, typesDDName);
addDataSource(parentDD, paramsDDName);

% Migrate all Simulink.Parameter objects from the parent data dictionary to
% a reference dictionary
paramEntries = find(designData_parentDD, '-value', '-class', 'Simulink.Parameter');
for i = 1:length(paramEntries)
 paramEntries(i).DataSource = 'myParamsDictionary.sldd';
end

% Migrate all Simulink.NumericType objects from the parent data dictionary
% to a reference dictionary
typeEntries = find(designData_parentDD, '-value', '-class', 'Simulink.NumericType');
for i = 1:length(typeEntries)
 typeEntries(i).DataSource = 'myTypesDictionary.sldd';
end

% Save all changes to the parent data dictionary
saveChanges(parentDD)
```

## Make Changes to Configuration Set Stored in Dictionary

You can store a configuration set (a `Simulink.ConfigSet` object) in the Configurations section of a dictionary. To change the setting of a configuration parameter in the set programmatically:

- 1 Create a `Simulink.data.dictionary.Entry` object that represents the configuration set (which is an entry in the dictionary). For example, suppose the name of the dictionary is `myData.sldd` and the name of the `Simulink.ConfigSet` object is `myConfigs`.

```
dictionaryObj = Simulink.data.dictionary.open('myData.sldd');
configsSectObj = getSection(dictionaryObj, 'Configurations');
entryObj = getEntry(configsSectObj, 'myConfigs');
```

- 2 Store a copy of the target `Simulink.ConfigSet` object in a temporary variable.

```
temp = getValue(entryObj);
```

- 3 In the temporary variable, modify the target configuration parameter (in this case, set **Stop time** to 20).

```
set_param(temp, 'StopTime', '20');
```

- 4 Use the temporary variable to overwrite the configuration set in the dictionary.

```
setValue(entryObj, temp);
```

- 5 Save changes made to the dictionary.

```
saveChanges(dictionaryObj)
```

 “Test Signals” on page 76-6

A *signal* is a time-varying quantity that has values at all points in time. You can specify a wide range of signal attributes, including:

- Signal name
- Data type (for example, 8-bit, 16-bit, or 32-bit integer)
- Numeric type (real or complex)
- Dimensionality (one-dimensional, two-dimensional, or multidimensional array)

In Simulink, signals are the outputs of dynamic systems represented by blocks in a Simulink diagram and by the diagram itself. The lines in a block diagram represent mathematical relationships among the signals defined by the block diagram. For example, a line connecting the output of block A to the input of block B indicates that the signal output of B depends on the signal output of A.

Simulink block diagrams represent signals with lines that have an arrowhead. The source of the signal corresponds to the block that writes to the signal during evaluation of its block methods (equations). The destinations of the signal are blocks that read the signal during the evaluation of the block methods (equations). The destination of signals in a model do not necessarily represent the order of simulation of blocks in a model. The simulation order is determined by Simulink automatically.

---

**Note** Simulink signals are mathematical, not physical, entities. The lines in a block diagram represent mathematical, not physical, relationships among blocks. Simulink signals do not travel along the lines that connect blocks in the same way that electrical signals travel along a wire. Block diagrams do not represent physical connections between blocks.

---

You can create a signal by adding a source block to your model. For example, you can create a signal that varies sinusoidally with time by adding an instance of the Sine, Cosine block from the Simulink Sources library into your model. To see a list of the blocks that create signals in a model, see “Sources”. Alternatively, you can use the “Viewers and Generators Manager” on page 28-80 to create signals in your model without using blocks.

### Signal Line Styles

A Simulink model can include many different types of signals. As you construct a block diagram, all signal types appear as a thin, solid line. After you update the diagram or start simulation, the signals appear with the specified line styles. These signal types enable you to differentiate between different signal types. From all signal types, you can only customize the nonscalar signal type. To learn more, see “Signal Types” on page 76-7.

| Signal Type                                                                                              | Line Style                                                                          |
|----------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------|
| Scalar and nonscalar                                                                                     |  |
| Nonscalar (with the <b>Wide nonscalar lines</b> option enabled—see “Wide Nonscalar Lines” on page 76-56) |  |
| Control signal                                                                                           |  |
| Virtual bus                                                                                              |  |
| Nonvirtual bus                                                                                           |  |
| Array of buses                                                                                           |  |
| Variable-size                                                                                            |  |

## Signal Properties

You may want to specify signal properties in your model to give a name or a label to your signals, prepare data for logging, or to customize your signals in a model. Use the Property Inspector, the Model Data Editor, or the Signal Properties dialog box to specify properties for:

- Signal names and labels
- Signal logging
- Simulink Coder to use to generate code
- Documentation of the signal

To access the signal properties in the Property Inspector, first display the Property Inspector. On the **Modeling** tab, under **Design**, click **Property Inspector**. When you select a signal, the properties appear in the Property Inspector.

To open the Model Data Editor, on the **Modeling** tab, click **Model Data Editor**. Then, inspect the **Signals** tab and select a signal.

To use the Signal Properties dialog box, right-click a signal and select **Properties**.

To specify signal properties programmatically, use a function such as `get_param` to create a variable that holds the handle to the block output port that creates the signal line. Then, use `set_param` to set the programmatic parameters of the port. For example:

```
p = get_param(gcf, 'PortHandles')
l = get_param(p.Outport, 'Line')
set_param(l, 'Name', 's9')
```

## Signal Names and Labels

You can name a signal interactively or programmatically in a model. The syntactic requirements for a signal name depend on how you use the name. The most common cases are:

- Do not use a less than character (<) to start a signal name.
- The signal name can resolve to a `Simulink.Signal` object. (See `Simulink.Signal`.) The signal name must then be a legal MATLAB identifier. This identifier starts with an alphabetic character, followed by alphanumeric or underscore characters up to the length given by the function `nameLengthmax`.
- The signal has a name so the signal can be identified and referenced by name in a data log. (See “Export Signal Data Using Signal Logging” on page 73-43.) Such a signal name can contain space and newline characters. These characters can improve readability but sometimes require special handling techniques, as described in “Handling Spaces and Newlines in Logged Names” on page 73-69
- The signal name exists only to clarify the diagram and has no computational significance. Such a signal name can contain anything and does not need special handling.
- The signal is an element of a bus object. Use a valid C language identifier for the signal name.
- Inputs to a Bus Creator block must have unique names. If there are duplicate names, the Bus Creator block appends (`signal#`) to all input signal names, where `#` is the input port index.

Making every signal name a legal MATLAB identifier handles a wide range of model configurations. Unexpected requirements can require changing signal names to follow a more restrictive syntax. You can use the function `isvarname` to determine whether a signal name is a legal MATLAB identifier.

Name a signal interactively by using one of these options:

- The **Property Inspector** tool
- The **Model Data Editor** tool
- The **Signal Properties** dialog box

The signal name appears below a signal, displayed as a signal label.

To name a signal programmatically, use the `get_param` and `set_param` functions on the signal. The table below summarizes how to work with signal names and labels in the Simulink Editor.

| Task                                   | Action                                                                                                                                                                                                          |
|----------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Name a signal line                     | Double-click the signal and type its name.                                                                                                                                                                      |
| Name a branch of a named signal line   | Double-click the branch.                                                                                                                                                                                        |
| Name every branch of a signal          | Right-click the signal, select <b>Properties</b> , and use the dialog box.                                                                                                                                      |
| Delete signal label and name           | Delete characters in the label or delete the name in Signal Properties dialog box.                                                                                                                              |
| Delete signal label only               | Right-click the label and select <b>Delete Label</b> .                                                                                                                                                          |
| Open signal label text box for editing | Double-click the signal line.<br><br>Click the label.<br><br>Select the signal line (not the label) and use <b>F2</b> .<br><br>On a Mac, select the signal line (not the label) and use <b>control+return</b> . |
| Move signal label                      | Drag the label to a new location on the same signal line.                                                                                                                                                       |

| Task                  | Action                                                                                                                                                        |
|-----------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Copy signal label     | <b>Ctrl+drag</b> the signal label.                                                                                                                            |
| Change the label font | Select the signal line (not the label), and then on the <b>Format</b> tab, click the <b>Font Properties</b> button arrow, then click <b>Fonts for Model</b> . |

## Signal Display Options

Displaying signal attributes in the model diagram can make the model easier to read. For example, in the Simulink Editor, on the **Debug** tab, use the **Information Overlays** menu to include in the model layout information about signal attributes, such as:

- Port data types
- Design ranges
- Signal dimensions
- Signal resolution

For details, see “Display Signal Attributes” on page 76-52.

You can also highlight a signal and its source or destination blocks. For details, see “Highlight Signal Sources and Destinations” on page 76-27.

## Store Design Attributes of Signals and States

You can use block parameters and signal properties to specify signal design attributes such as data type, minimum and maximum values, physical unit, and numeric complexity. To configure states, you can use block parameters. When you use these block parameters and signal properties, you store the specifications in the model file.

Alternatively, you can specify these attributes by using the properties of a `Simulink.Signal` or `Simulink.ValueType` object that you store in a workspace or data dictionary.

Choose which strategy to use based on your modeling goals.

| Modeling Goal                                                                                                           | Strategy                                                                                                                                                                                                                                                                                |
|-------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Improve model portability, readability, and ease of maintenance                                                         | Store signal attribute specifications in the model file. You do not need to save and manage external objects. Consider setting the model configuration parameter <b>Signal resolution</b> to <b>None</b> , which disables the use of <code>Simulink.Signal</code> objects by the model. |
| Separate signal attribute specifications from the model so that you can manage each signal independently                | Use <code>Simulink.Signal</code> objects.                                                                                                                                                                                                                                               |
| Separate signal attribute specifications from the model so that you can reuse an application-specific set of attributes | Use <code>Simulink.ValueType</code> objects.                                                                                                                                                                                                                                            |

To configure design attributes and code generation settings for signals by using a list that you can sort, group, and filter, consider using the **Model Data Editor**. For objects, you can also use the **Model Explorer**.

To determine where to permanently store a `Simulink.Signal` or `Simulink.ValueType` object, see “Determine Where to Store Variables and Objects for Simulink Models” on page 68-101.

## Test Signals

You can perform the following kinds of tests on signals:

- **Minimum and Maximum Values** — For many Simulink blocks, you can specify a range of valid values for the output signals. Simulink provides a diagnostic for detecting when blocks generate signals that exceed their specified ranges during simulation. For details, see “Specify Signal Ranges” on page 76-34.
- **Connection Validation** — Many Simulink blocks have limitations on the types of signals that they accept. Before simulating a model, Simulink checks all blocks to ensure that the blocks can accommodate the types of signals output by the ports to which the blocks connect and reports errors about incompatibilities. To detect signal compatibility errors before running a simulation, update the diagram.

The Signal Editor block displays interchangeable groups of scenarios. Use the Signal Editor to display, create, edit, and switch interchangeable scenarios.

Scenarios can help with testing a model.

## Signal Types

Multiple types of signals can connect the blocks in a model. For example, a model may contain a control signal to initiate the execution of another block and buses to simplify line routing.

The following table summarizes the types of Simulink signals.

| Name                              | Description                                                                                                                                                                                  |
|-----------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Array                             | Composite signal that provides index-based signal access.                                                                                                                                    |
| Array of Buses                    | Concatenated signal that contains nonvirtual buses.                                                                                                                                          |
| Bus                               | Composite signal that provides name-based signal access.                                                                                                                                     |
| Composite Signal                  | Signal composed of other signals. See “Composite Signals” on page 76-8.                                                                                                                      |
| Concatenated Signal               | Nonvirtual composite signal that provides index-based signal access.                                                                                                                         |
| Control Signal                    | Signal used by a block to initiate the execution of another block. For example, a signal that executes a function-call subsystem or an action subsystem. See “Control Signals” on page 76-7. |
| Matrix                            | Two-dimensional composite signal that provides index-based signal access.                                                                                                                    |
| Multidimensional ( $N$ -D) Signal | Composite signal with more than two dimensions that provides index-based signal access.                                                                                                      |
| Mux Signal                        | Virtual composite signal that provides index-based signal access. Also known as a virtual vector.                                                                                            |
| Nonscalar Signal                  | Signal with at least one dimension, such as a vector (1-D), matrix (2-D), or multidimensional array ( $N$ -D). Nonscalar signals are a type of composite signal.                             |
| Nonvirtual Signal                 | Signal that affects simulation and code generation. See “Virtual and Nonvirtual Signals” on page 76-8.                                                                                       |
| Scalar Signal                     | Signal that supports only one value at a time.                                                                                                                                               |
| Variable-Size Signal              | Signal whose size (the number of elements in a dimension), in addition to its values, can change during a model simulation.                                                                  |
| Vector                            | One-dimensional composite signal that provides index-based signal access.                                                                                                                    |
| Virtual Signal                    | Signal that represents another signal or set of signals. A virtual signal is used for graphical purposes and has no functional effect. See “Virtual and Nonvirtual Signals” on page 76-8.    |

---

**Note** Signals may also have application-specific types such as wind velocity, tire pressure, or water temperature. To assign or validate the properties of a signal based on an application-specific type, use a `Simulink.ValueType` object.

---

### Control Signals

A *control signal* is a signal used by a block to initiate the execution of another block. For example, a signal that executes a function-call or action subsystem is a control signal. When you update or simulate a block diagram, Simulink uses a dash-dot pattern to draw lines that represent the control signals.

## Composite Signals

You can group multiple signals in a composite signal, route the signal from block to block, and extract the constituent signals where needed. When you have many parallel signals, composite signals can simplify the appearance of a model and help to clarify generated code. Composite signals can be virtual or nonvirtual.

Types of composite signals include:

- Virtual buses
- Nonvirtual buses
- Mux signals
- Concatenated signals
- Arrays of buses

For more information on composite signals, see “Types of Composite Signals” on page 77-2.

## Virtual and Nonvirtual Signals

A virtual signal is a signal that graphically represents other signals or parts of other signals. Virtual signals are purely graphical entities; Simulink ignores them when simulating a model, and they do not exist in generated code. Some blocks, such as the Mux block, always generate virtual signals. Others, such as the Bus Creator block, can generate either virtual or nonvirtual signals. A signal is virtual if the block that generates it is virtual.

A nonvirtual signal is a signal that affects simulation and code generation. Some blocks, such as the Vector Concatenate block, always generate nonvirtual signals. A signal is nonvirtual if the block that generates it is nonvirtual.

For information on virtual and nonvirtual blocks, see “Nonvirtual and Virtual Blocks” on page 36-2.

## Investigate Signal Values

### In this section...

“Initialize Signal Values” on page 76-10  
 “View Signal Values” on page 76-10  
 “Display Signal Values in Model Diagrams” on page 76-11  
 “Signal Data Types” on page 76-11  
 “Complex Signals” on page 76-11  
 “Exporting Signal Data” on page 76-12

While transmitting valuable data about a model and between the blocks, signals may take different values. In this section, you learn how to initialize, display signals as well as more information on the data types and dimensions a signal can take.

### Initialize Signal Values

If a signal does not have an explicit initial value, the initial value that Simulink uses depends on the data type of the signal.

| Signal Data Type                 | Default Initial Value   |
|----------------------------------|-------------------------|
| Numeric (other than fixed-point) | Zero                    |
| Fixed-point                      | Real-world ground value |
| Boolean                          | False                   |
| Enumerated                       | Default value           |

You can specify the non-default initial values of signals for Simulink to use at the beginning of simulation.

- For any signal, you can define a signal object (`Simulink.Signal`), and use that signal object to specify an initial value for the signal.
- For some blocks, such as Outport, Data Store Memory, and Memory, you can use either a signal object or a block parameter, or both, to specify the initial value of a block state or output.

For details, see “Initialize Signals and Discrete States” on page 76-40.

### View Signal Values

You can use either blocks or the signal viewers (such as the Signal & Scope Manager) to display the values of signals during a simulation. For example, you can use either the Scope block or the Signal & Scope Manager to graph time-varying signals on an oscilloscope-like display during simulation. For general information about options for viewing signal values, see “Scope Blocks and Scope Viewer Overview” on page 28-6. For detailed information about:

- Blocks that you can use to display signals in a model, see “Sinks”
- Signal viewers, “Floating Scope and Scope Viewer Tasks” on page 28-70
- The Signal & Scope Manager, see “Viewers and Generators Manager” on page 28-80

- Test points, which are signals that Simulink guarantees to be observable when using a Floating Scope block in a model, see “Configure Signals as Test Points” on page 76-46.

## Display Signal Values in Model Diagrams

To include graphical displays of signal values in a model diagram, use one of the following approaches:

- “Display Data Tips During Simulation” on page 76-11
- “Display Signal Value After Simulation” on page 76-11

### Display Data Tips During Simulation

For many blocks, Simulink can display block output (port values) as data tips on the block diagram while a simulation is running.

- 1 In the Simulink Editor, on the **Debug** tab, select **Output Values**, go to the **Signal** tab, and toggle on the **Output Value Label > Toggle Value Displays** button.
- 2 To change display options, use the **Options** submenu.

For details, see “Display Port Values for Debugging” on page 36-18.

### Display Signal Value After Simulation

To display, below a specific signal, the signal value after simulation:

- 1 Right-click the signal.
- 2 In the context menu, select **Show Value Label of Selected Port**.

## Signal Data Types

Data type refers to the format used to represent signal values internally. By default, the data type of Simulink signals is double. You can create signals of other data types. Simulink signals support the same range of data types as MATLAB. See “About Data Types in Simulink” on page 68-2 for more information.

## Complex Signals

The values of signals can be complex numbers or real numbers. A signal whose values are complex numbers is a complex signal. Create a complex-valued signal using one of the following approaches:

- Load complex-valued signal data from the MATLAB workspace into the model via a root-level Inport block.
- Create a Constant block in your model and set its value to a complex number.
- Create real signals corresponding to the real and imaginary parts of a complex signal, then combine the parts into a complex signal, using the Real-Imag to Complex conversion block.

Manipulate complex signals via blocks that accept them. If you are not sure whether a block accepts complex signals, see the documentation for the block.

## Exporting Signal Data

You can save signal values to the MATLAB workspace during simulation, for later retrieval and postprocessing. For a summary of different approaches, see “Approaches for Exporting Signal Data” on page 73-2.

## Signal Label Propagation

### In this section...

“Blocks That Support Signal Label Propagation” on page 76-13  
 “How Simulink Propagates Signal Labels” on page 76-14  
 “Display Propagated Signal Labels” on page 76-17  
 “Special Cases of Signal Propagation” on page 76-18

You can give signals signal names and configure propagating the signal names in a Simulink model to track a signal label through one block or many blocks. For a list of supported blocks, see “Blocks That Support Signal Label Propagation” on page 76-13.

When you name a signal and enable the display of signal label propagation for output signals of allowed blocks:

- If there is a user-specified signal name that Simulink can propagate, the propagated signal label includes the name in angle brackets (for example, <sig1>).
- If there is no signal name to propagate, Simulink displays an empty set of angle brackets (<>) for the label.

Simulink does not propagate signal labels for commented out blocks.

For example, in the following model, the output signal from the Subsystem block is configured for signal label propagation. The propagated signal label (<const>) is based on the name of the upstream output signal of the Constant block (const).

For more information on how Simulink creates propagated signal labels, see “How Simulink Propagates Signal Labels” on page 76-14.

### Blocks That Support Signal Label Propagation

You can use signal label propagation with output signals for several *connection* blocks, which route signals through the model without changing the data. Connection blocks perform no signal transformation.

Also, Model blocks support signal label propagation.

The connection blocks that support signal label propagation are:

- Enable
- From
- Function-Call Split
- Goto

- Inport (subsystem only; not model input ports)
- Signal Specification
- Subsystem, Atomic Subsystem, CodeReuse Subsystem (through subsystem Inport and Outport blocks)
- Trigger

The Bus Creator and Bus Selector blocks do *not* support signal label propagation. However, if you want to view the hierarchy for any bus, use the “Display Bus Hierarchy” on page 77-35.

The Signal Properties dialog box for a signal indicates whether that signal supports signal label propagation. The **Show propagated signals** parameter is available only for blocks that support signal label propagation. For details, see “Display Propagated Signal Labels” on page 76-17.

## How Simulink Propagates Signal Labels

In general, Simulink performs signal label propagation consistently:

- For different modeling constructs (for example, non-bus and bus signals, virtual and nonvirtual buses, subsystem and model variants, model referencing, and libraries)
- In models with or without hidden blocks, which Simulink inserts in certain cases to enable simulation
- At model load, edit, update, and simulation times

For information about some special cases, see:

- “Processing for Referenced Models” on page 76-18
- “Processing for Variants and Configurable Subsystems” on page 76-19

### General Signal Label Propagation Processing

In general, when you enable signal label propagation for an output signal of a block (for example, BlockA), Simulink performs the following processing to find the source signal name to propagate:

- 1 Checks the block whose output signal connects to BlockA, and if necessary, continues checking upstream blocks, working backward from the closest block to the farthest block.
- 2 Stops when it encounters a block that either:
  - Supports signal label propagation and has a signal name
  - Does not support signal label propagation
- 3 Obtains the signal name, if any, of the output signal for the block at which Simulink stops.
- 4 Uses that signal name for the propagated signal label of any output signals of downstream blocks for which you enable signal label propagation.

For example, in the following model, suppose that you enable signal label propagation for the output signal for the Subsystem block (that is, the signal connected to the Out1 port).

Simulink checks inside the subsystem, checks upstream from the From and GoTo blocks (which support signal label propagation and do not have a name), and then checks farther upstream, to the Constant block, which does not support signal label propagation.

Simulink uses the signal name of the Constant block output signal, `const`. The propagated signal label for the Subsystem block output signal is `<const>`.

If the output signal from the Constant block did not have a signal name, then the propagated signal label would be an empty set of angle brackets (`<>`).

Suppose that in the Subsystem block you enable signal label propagation for the output signal from the In1 block, and you use the Signal Properties dialog box to specify the signal name `const-from` for the output signal of the From block, as shown below.

The propagated signal label for the Subsystem block output signal changes to `<const-from>`, because that is the first named signal that Simulink encounters in its signal label propagation processing.

In the following model, the signal label propagation for the output signal of the Subsystem block uses the signal name `bus1`, which is the name of the output bus of the Bus Creator block. The propagated signal label does not include the names of the bus element signals (a and b).

## Display Propagated Signal Labels

You can display propagated signal labels for individual signals, or display the propagated signal labels for all signals in a model. To display the labels for all signals, in the Simulink Editor, on the **Debug** tab, select **Information Overlays > Propagated Signal Labels**.

To display a propagated signal label for an individual signal:

- 1 Right-click the signal for which you want to display a propagated signal label and select **Properties**.
- 2 In the Signal Properties dialog box, select **Show propagated signals**.

The **Show propagated signals** parameter is available only for output signals from blocks that support signal label propagation.

To enable this signal property programmatically, create a handle to the signal line, and specify `signalPropagation` as 'on'. For example, you can use this code to enable or disable the property for all of the signals in a model diagram.

```
% Create an array of handles to every signal line in the diagram
signalLines = find_system(gcs, 'FindAll', 'on', 'type', 'line');

% Enable or disable the property for each signal line
for i = 1:length(signalLines)

 % set(signalLines(i), 'signalPropagation', 'off');
 set(signalLines(i), 'signalPropagation', 'on');
end
```

If a signal already has a label, then an *alternative* approach for displaying a propagated signal label is:

- 1 In the model diagram, click the signal label.
- 2 Remove the label text.
- 3 In the signal label text box, enter an angle bracket (<).
- 4 Click outside the signal label.

Simulink displays the propagated signal label.

## Special Cases of Signal Propagation

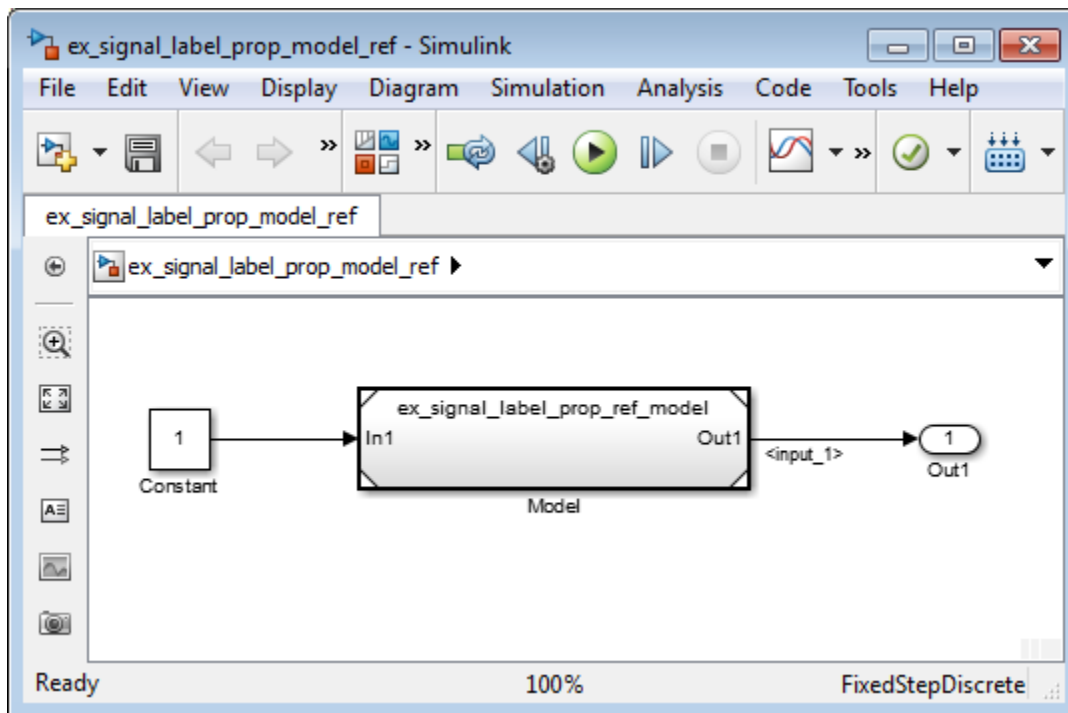

### Processing for Referenced Models

To enable signal label propagation for referenced models, in addition to the steps described in “Display Propagated Signal Labels” on page 76-17, use the default setting for the **Model Configuration Parameters > Model Referencing > Propagate all signal labels out of the model** parameter. In other words, make sure the parameter is enabled.

If you make a change inside a referenced model that affects signal label propagation, the propagated signal labels outside of the referenced model do not reflect those changes until after you update the diagram or simulate the model.

For example, the model `ex_signal_label_prop_model_ref` has a referenced model that includes an output signal from the In1 block that has a signal name of `input_1`.

If you enable signal label propagation for the signal from the Out1 port of the Model block, that signal does *not* reflect the name `input_1` until after you update the diagram or simulate the model.

### Processing for Variants and Configurable Subsystems

Simulink updates the propagated signal label (if enabled) for the output signal of the Subsystem or Model block, when *both* of these conditions occur:

- The output signals for variant models have different signal names.
- You change the active variant model or variant subsystem.

For Subsystem blocks, the signal label updates at edit time. For Model blocks, the update occurs when you update diagram or simulate the model.

## Determine Signal Dimensions

### In this section...

“Simulink Blocks that Support Multidimensional Signals” on page 76-20

“Determine the Output Dimensions of Source Blocks” on page 76-21

“Determine the Output Dimensions of Nonsource Blocks” on page 76-21

“Signal and Parameter Dimension Rules” on page 76-22

“Scalar Expansion of Inputs and Parameters” on page 76-22

Simulink blocks can output one-dimensional, two-dimensional, or multidimensional signals. The Simulink user interface and documentation generally refer to 1-D signals as *vectors* and 2-D or multidimensional signals as *matrices*. A one-element array is frequently referred to as a *scalar*. A *row vector* is a 2-D array that has one row. A *column vector* is a 2-D array that has one column.

- A one-dimensional (1-D) signal consists of a series of one-dimensional arrays output at a frequency of one array (vector) per simulation time step.
- A two-dimensional (2-D) signal consists of a series of two-dimensional arrays output at a frequency of one 2-D array (matrix) per block sample time.
- A multidimensional signal consists of a series of multidimensional (two or more dimensions) arrays output at a frequency of one array per block sample time. You can specify multidimensional arrays with any valid MATLAB multidimensional expression, such as [4 3]. See “Multidimensional Arrays” for information on multidimensional arrays.

Simulink blocks vary in the dimensionality of the signals they can accept or output. Some blocks can accept or output signals of any dimension. Some can accept or output only scalar or vector signals.

---

**Note** Simulink does not support dynamic signal dimensions during a simulation. That is, the dimension of a signal must remain constant while a simulation is executing. However, you can change the size of a signal during a simulation. See “Variable-Size Signal Basics” on page 78-2.

---

If a block can emit nonscalar signals, the dimensions of the signals that the block outputs depend on the block parameters, if the block is a source block; otherwise, the output dimensions depend on the dimensions of the block input and parameters.

To determine the dimensions that a signal ultimately uses for simulation, first update the block diagram (for example, by pressing **Ctrl+D**). Then, choose one of these techniques:

- Display the dimensions directly on the block diagram. Use this technique to trace signal dimensions along a path of blocks. In the model, on the **Debug** tab, select **Information Overlays > Signal Dimensions**).
- Inspect the dimensions in the **Model Data Editor**, which shows you information in a searchable, sortable table. In the table, the right side of each cell in the **Dimensions** column shows the true dimensions of the corresponding signal line in the model.

### Simulink Blocks that Support Multidimensional Signals

The Simulink Block Data Type Support table includes a column identifying the blocks with multi-dimension signal support.

- 1 In the MATLAB command line, enter `showblockdatatypetable`.

A separate window with the Simulink Block Data Type Support table opens.

- 2 In the Block column, locate the name of a Simulink block. Columns to the right are data types or features. An **X** in a column indicates support for that feature.

Simulink supports signals with up to 32 dimensions. Do not use signals with more than 32 dimensions.

## Determine the Output Dimensions of Source Blocks

A *source* block is a block that has no inputs. Examples of source blocks include the Constant block and the Sine Wave block. See “Sources” for a complete listing of Simulink source blocks. The output dimensions of a source block are the same as those of its output value parameters if the block **Interpret vector parameters as 1-D** parameter is off (that is, not selected in the block parameter dialog box). If the **Interpret vector parameters as 1-D** parameter is on, the output dimensions equal the output value parameter dimensions unless the parameter dimensions are N-by-1 or 1-by-N. In the latter case, the block outputs a vector signal of width N.

As an example of how the output value parameters and **Interpret vector parameters as 1-D** parameter of a source block determine the dimensionality of its output, consider the Constant block. This block outputs a constant signal equal to its **Constant value** parameter. The following table illustrates how the dimensionality of the **Constant value** parameter and the setting of the **Interpret vector parameters as 1-D** parameter determine the dimensionality of the block output.

| Constant Value | Interpret vector parameters as 1-D | Output            |
|----------------|------------------------------------|-------------------|
| scalar         | off                                | one-element array |
| scalar         | on                                 | one-element array |
| 1-by-N matrix  | off                                | 1-by-N matrix     |
| 1-by-N matrix  | on                                 | N-element vector  |
| N-by-1 matrix  | off                                | N-by-1 matrix     |
| N-by-1 matrix  | on                                 | N-element vector  |
| M-by-N matrix  | off                                | M-by-N matrix     |
| M-by-N matrix  | on                                 | M-by-N matrix     |

Simulink source blocks allow you either to specify the dimensions of the signals that they output or specify values from which Simulink infers the dimensions. You can therefore use the source blocks to introduce signals of various dimensions into your model.

## Determine the Output Dimensions of Nonsource Blocks

If a block has inputs, the dimensions of its outputs are, after scalar expansion, the same as those of its inputs. (All inputs must have the same dimensions, as discussed in “Signal and Parameter Dimension Rules” on page 76-22).

## Signal and Parameter Dimension Rules

When creating a Simulink model, you must observe the following rules regarding signal and parameter dimensions.

### Input Signal Dimension Rule

All nonscalar inputs to a block must have the same dimensions.

A block can have a mix of scalar and nonscalar inputs as long as all the nonscalar inputs have the same dimensions. Simulink expands the scalar inputs to have the same dimensions as the nonscalar inputs (see “Scalar Expansion of Inputs and Parameters” on page 76-22).

### Block Parameter Dimension Rule

In general, block parameters must have the same dimensions as the dimensions of the inputs to the block. Simulink performs some processing that provides flexibility relating to that general rule.

- A block can have scalar parameters corresponding to nonscalar inputs. In this case, Simulink expands a scalar parameter to have the same dimensions as the corresponding input (see “Scalar Expansion of Inputs and Parameters” on page 76-22).
- If an input is a vector, the corresponding parameter can be either an N-by-1 or a 1-by-N matrix. In this case, Simulink applies the N matrix elements to the corresponding elements of the input vector. This exception allows use of MATLAB row or column vectors, which are actually 1-by-N or N-by-1 matrices, respectively, to specify parameters that apply to vector inputs.

### Vector or Matrix Input Conversion Rules

Simulink converts vectors to row or column matrices and row or column matrices to vectors under the following circumstances:

- If a vector signal is connected to an input that requires a matrix, Simulink converts the vector to a one-row or one-column matrix.
- If a one-column or one-row matrix is connected to an input that requires a vector, Simulink converts the matrix to a vector.
- If the inputs to a block consist of a mixture of vectors and matrices and the matrix inputs all have one column or one row, Simulink converts the vectors to matrices having one column or one row, respectively.

---

**Note** You can configure Simulink to display a warning or error message if a vector or matrix conversion occurs during a simulation. See “Vector/matrix block input conversion” for more information.

---

## Scalar Expansion of Inputs and Parameters

*Scalar expansion* is the conversion of a scalar value into a nonscalar array. Many Simulink blocks support scalar expansion of inputs and parameters. Block-specific descriptions indicate whether Simulink applies scalar expansion to block inputs and parameters.

Scalar expansion of inputs refers to the expansion of scalar inputs to match the dimensions of other nonscalar inputs or nonscalar parameters. When the input to a block is a mix of scalar and nonscalar signals, Simulink expands the scalar inputs into nonscalar signals having the same dimensions as the

other nonscalar inputs. For example, a scalar of 4 is expanded to the vector [4 4 4] if the associated nonscalar has a dimension of 3.

Scalar expansion of parameters refers to the expansion of scalar block parameters to match the dimensions of nonscalar inputs.

| Input(s)                            | Associated Block Parameter | Scalar Expansion                                                                                                                                           |
|-------------------------------------|----------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Scalar                              | Nonscalar                  | Input expanded to match parameter dimensions.<br><br>See "Scalar Input and Nonscalar Parameter" on page 76-23.                                             |
| Nonscalar                           | Scalar                     | Scalar parameter expanded to match number of elements of input.<br><br>See "Nonscalar Input and Scalar Parameter" on page 76-23.                           |
| Combination of scalar and nonscalar | No corresponding parameter | Scalar inputs expanded to match dimensions of largest nonscalar input.<br><br>See "Scalar and Nonscalar Inputs and No Associated Parameter" on page 76-24. |

### Scalar Input and Nonscalar Parameter

In this example, the Constant block input to the Gain block is scalar. The Gain block **Gain** parameter is a nonscalar. Simulink expands the scalar input to match the dimensions of a nonscalar **Gain** parameter, as reflected in the simulation results in the Display block.

### Nonscalar Input and Scalar Parameter

In this example, the Constant block input to the Gain block is nonscalar. The Gain block **Gain** parameter is a scalar. Simulink expands the scalar parameter to match the dimensions of a nonscalar input from the Constant block, as reflected in the simulation results in the Display block.

### Scalar and Nonscalar Inputs and No Associated Parameter

In this example, the Constant1 block input to the Sum block is nonscalar, and the Constant2 block input is scalar. The Sum block has no associated parameter. Simulink expands the scalar input from Constant2 to match to the dimensions of the nonscalar Constant1 block input. The input is expanded to the vector [3 3 3].

### Get Compiled Port Dimensions

To get the dimensions of port signals, pause the simulation by using the **Step Forward** button. Select a block and use the `PortHandles` parameter. Then, use the `GetCompiledPortDimensions` parameter. For example, if you step forward in this model and select the Constant block:

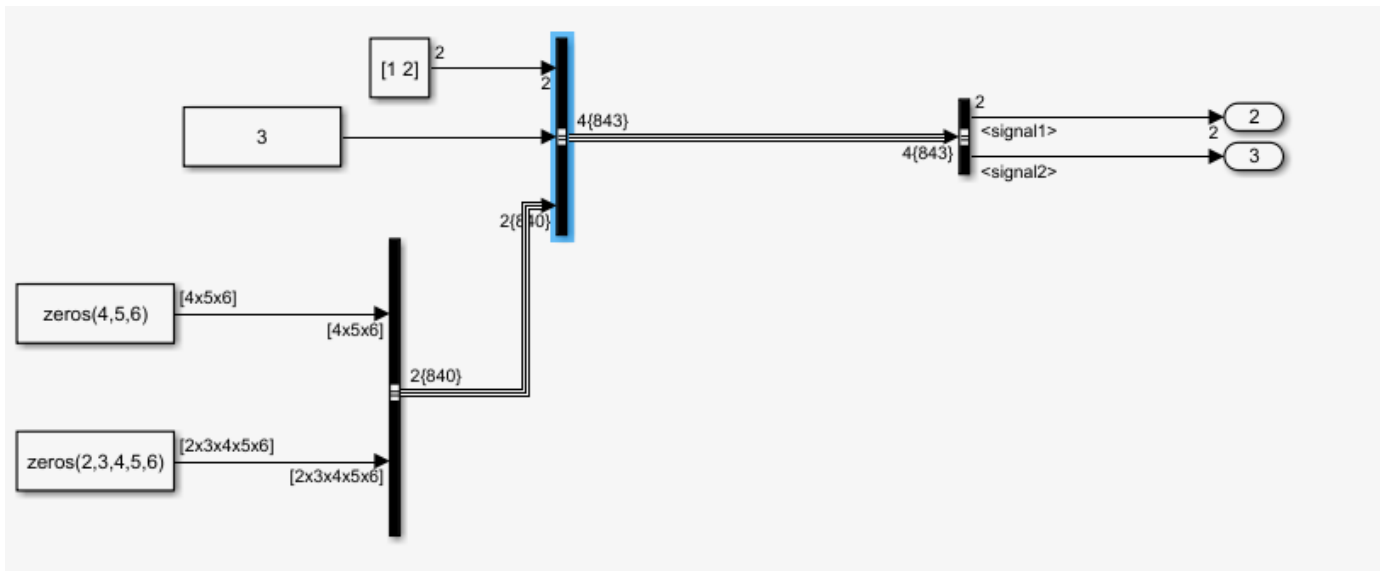

```
ph = get_param(gcb, 'PortHandles');
dim = get_param(ph.Outport, 'CompiledPortDimensions')
```

```
dim =
```

```
2 2 3
```

For nonbus ports, the result is an array in which the first element is the number of dimensions (in this case, 2), and the next two elements (corresponding to the number of dimensions) are the values of the dimensions.

For buses, the results include some extra elements. Suppose that you step forward in a model with buses, and you select the Bus Creator block that contains a nested bus:

```
ph = get_param(gcb, 'PortHandles');
dim = get_param(ph.Outport, 'CompiledPortDimensions')

dim = -2 4 1 2 1 1 3 4 5 6 5 2 3 4 5 6
```

The first element is -2, which indicates that the port corresponds to a virtual bus. The second element is the number of leaf nodes (4). The subsequent elements follow the same pattern as for nonbus signals.

- The output port of the first leaf node has one dimension (1), and the value in that dimension is 2.
- The output port of the second leaf node has one dimension (1), and the value in that dimension is 1.
- The output port of the third leaf node has three dimensions (3), and the values in those dimensions are 4 5 6.
- The output port of the fourth leaf node has five dimensions (5) and the values in those dimensions are 2 3 4 5 6.

When querying dimensions, nonvirtual buses are treated as scalars. Suppose the nested bus in the previous example were a nonvirtual bus instead of a virtual bus.

```
ph = get_param(gcb, 'PortHandles');
dim = get_param(ph.Output, 'CompiledPortDimensions')

dim = -2 3 1 2 1 1 1 1
```

The second element indicates three leaf nodes instead of four leaf nodes because the nonvirtual bus is treated as a scalar. The third leaf node corresponds to the Bus Creator block that outputs the nonvirtual bus. The output port of the third leaf node has one dimension (1), and the value in that dimension is 1.

## Highlight Signal Sources and Destinations

### In this section...

“Highlight Signal Source” on page 76-27  
 “Highlight Signal Destination” on page 76-27  
 “Choose the Path of a Trace” on page 76-28  
 “Trace a Signal To and From Subsystems” on page 76-29  
 “Show All Possible Paths of a Trace” on page 76-30  
 “Display Port Values Along a Trace” on page 76-30  
 “Remove Highlighting” on page 76-31  
 “Resolve Incomplete Highlighting to Library Blocks” on page 76-32  
 “Signal Highlighting in Variant Systems” on page 76-32  
 “Limitations” on page 76-33

You can highlight a signal and its source or destination blocks, then remove the highlighting once it has served its purpose. Signal highlighting crosses subsystem and model reference boundaries, allowing you to trace a signal across multiple subsystem levels. If a signal is composite, all source or destination blocks are highlighted. See “Types of Composite Signals” on page 77-2.

To continue the trace towards the source or destination of the signal, use the left and right arrow keys of your keyboard, respectively.

### Highlight Signal Source

To begin a trace to the source blocks of a signal, select the **Highlight Signal to Source** option from the context menu for the signal. The

badge identifies the start of the trace. This option highlights:

- All branches of the signal anywhere in the model
- All virtual blocks through which the signal passes
- The nonvirtual blocks that write the value of the signal

To continue tracing towards the source of the signal, press the **Left** arrow key.

### Highlight Signal Destination

To begin a trace to the destination blocks of a signal, select the **Highlight Signal to Destination** option from the context menu for the signal. Press the **Right** arrow key to move the trace towards the

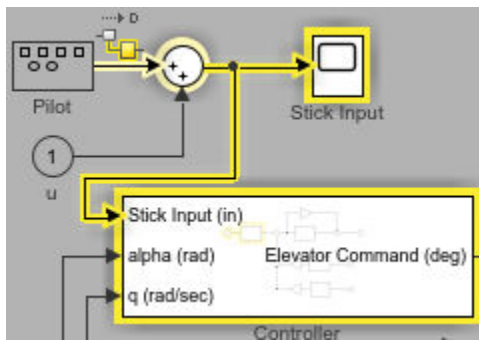

final destination. The

badge identifies the start of the trace. This option highlights:

- All branches of the signal anywhere in the model
- All virtual blocks through which the signal passes
- The nonvirtual blocks that read the value of the signal
- The signal and destination block for all blocks that are duplicates of the Inport block for the line that you select

In this example, the selected trace shows a path of the signal from the Stick Input to the Elevator Command in the Controller subsystem of the f14 model.

In the next example, selecting the signal from In2 and choosing the **Highlight Signal to Destination** option highlights the signal and destination block for In2 and In1, because In1 and In2 are duplicate Inport blocks.

## Choose the Path of a Trace

In some situations, a signal trace can take multiple viable paths in the next segment of the trace. This can be seen when a signal is combined or split through a Mux or Demux block, or if it is branched out as an input to another block. In such cases, the options are highlighted in blue and can be cycled using the **Up** and **Down** arrow keys on the keyboard. Once you have highlighted the block to which you would like to move, proceed as normal.

In the figure above, the trace to source has reached the Sum block where it can take one of three possible paths. The first option to Gain  $Zd$  is highlighted in blue.

### Trace a Signal To and From Subsystems

When the trace reaches a subsystem, it does not automatically trace in. Instead, the trace highlights the target subsystem and you are able to see a preview of the trace within the subsystem.

In this example, the selected signal trace to destination has reached the Controller subsystem of the f14 model. You can see that the contents of the subsystem are visible and the next segment of the trace is highlighted within the preview.

When the trace comes out of a subsystem, the subsystem preview also displays the path of the trace inside it. The next example shows the path of a trace through the Aircraft Dynamics Model subsystem from the input  $wGust$  to vertical velocity  $w$  output.

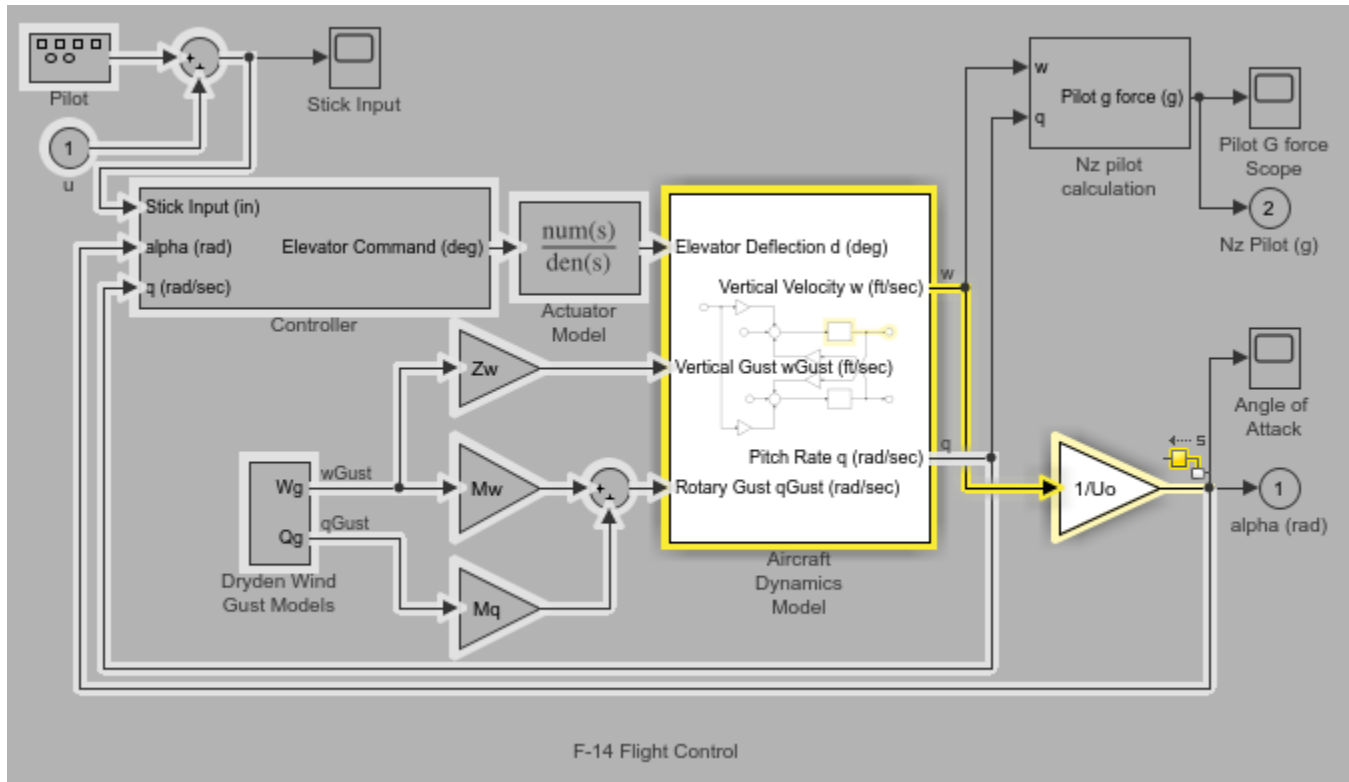

**Note** You cannot jump over a subsystem or a referenced model in your trace. You need to trace the signal path through them.

## Show All Possible Paths of a Trace

To highlight all possible paths a trace can take, press **Ctrl** key along with the **Left** (towards source) or the **Right** (towards destination) key. You can continue to trace as before.

To clear the highlighting, simultaneously press the **Ctrl** key and the arrow key in the direction opposite to the trace.

## Display Port Values Along a Trace

After you trace the path of a signal, press the **L** key to display the values of a signal at the output port of each block.

If you highlight all the possible paths of the trace as described in “Show All Possible Paths of a Trace” on page 76-30, press the **Ctrl + L** to view the signal values at all the output ports.

## Remove Highlighting

To remove all highlighting, right-click the model, and then select **Remove Highlighting**, or, on the **Signal** tab, click **Remove Trace**. You can also press **Ctrl+Shift+H** or click the  icon at the top right corner of the editor.

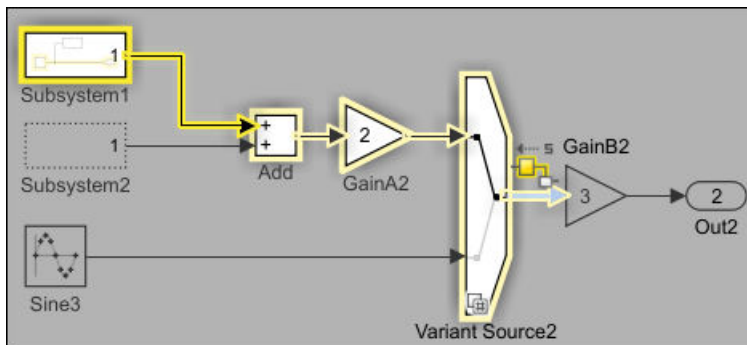

To back up a trace, press the arrow key opposite to the original intent of the trace. For example, if you would like to back up a trace to the destination of the signal, press the left arrow key. To back up a trace to the source of a signal, press the **right arrow** key.

## Resolve Incomplete Highlighting to Library Blocks

If the path from a source block or to a destination block includes an unresolved reference to a library block, the highlighting options highlight the path from or to the library block, respectively. To display the complete path, press **Ctrl+D** to update the diagram. The diagram update resolves all library references and displays the complete path to a destination block or from a source block.

## Signal Highlighting in Variant Systems

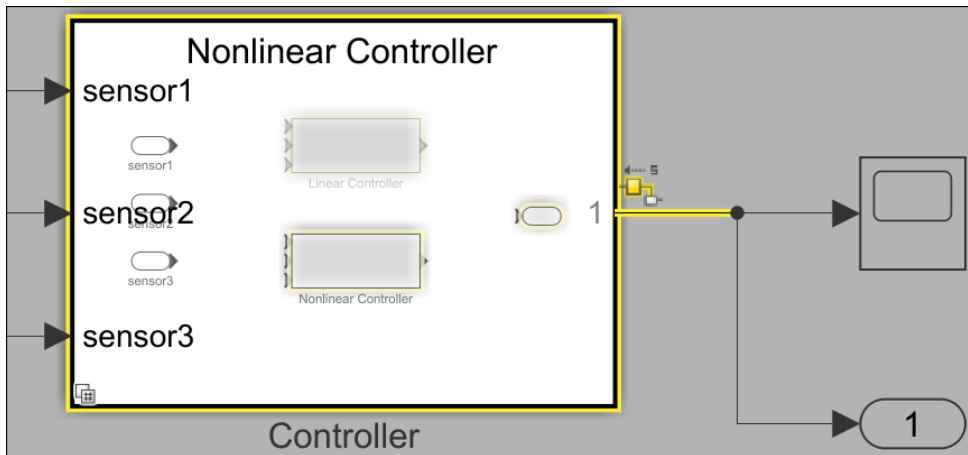

Tracing a signal that passes through inline variant blocks such as Variant Source and Variant Sink highlights the path of the active variant choice. In this example, the selected signal trace to its source shows the path of the active variant passing through the **Variant Source2** block.

For a Variant Subsystem block, the trace highlights the active choice within the subsystem by default.

If the **Variant activation time** parameter of the Variant Subsystem block is set to `code compile`, the trace highlights both the active and inactive choices within the subsystem.

## Limitations

The signal tracing tool has the following limitations in its usage:

- The signal trace does not preserve bus information when tracing into or out of a referenced model.
- Tracing past a Goto block changes the active level to that containing the matching From block. However, this does not guarantee that the matching From block is the active block if there are other valid blocks at the same level.
- Signal tracing is unsupported by certain blocks. Unsupported blocks are blocks where:
  - You cannot trace into them to highlight their contents. Examples of such blocks include but are not limited to Stateflow charts, Simscape subsystems, and function blocks,.
  - You cannot cross them and continue tracing (e.g. Simscape blocks).
- The styling of the signal does not update with modifications to the model when signal tracing is enabled.
- The operation to “Show All Possible Paths of a Trace” on page 76-30 does not traverse through referenced models in the same way as it does subsystems. Referenced models are treated as non-virtual blocks and the impact region will not highlight their contents.

## Specify Signal Ranges

### In this section...

“Blocks That Allow Signal Range Specification” on page 76-34

“Work with Signal Ranges in Blocks” on page 76-35

“Troubleshoot Signal Range Errors” on page 76-36

“Unexpected Errors or Warnings for Data with Greater Precision or Range than double” on page 76-38

Simulink blocks allow you to specify a range of valid values for their output signals. Specifying signal ranges help you to optimize data types and improve generated code.

If you have Embedded Coder, Simulink Coder can optimize the code that you generate from the model by taking into account the minimum and maximum values that you specify for signals and parameters. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values” (Embedded Coder).

### Blocks That Allow Signal Range Specification

The following blocks allow you to specify ranges for their output signals:

- Abs
- Constant
- Data Store Memory
- Data Type Conversion
- Difference
- Discrete Derivative
- Discrete-Time Integrator
- Gain
- In Bus Element
- Inport
- Interpolation Using Prelookup
- 1-D Lookup Table
- 2-D Lookup Table
- n-D Lookup Table
- Math Function
- MinMax
- Multiport Switch
- Out Bus Element
- Outport
- Product, Divide, Product of Elements
- Relay

- Repeating Sequence Interpolated
- Repeating Sequence Stair
- Saturation
- Saturation Dynamic
- Signal Specification
- Sum, Add, Subtract, Sum of Elements
- Switch

## Work with Signal Ranges in Blocks

To specify signal ranges for most blocks, use the **Output minimum** and **Output maximum** parameters of a block to specify a range of valid values for the block output signal. Exceptions include the Data Store Memory, Inport, In Bus Element, Outport, Out Bus Element, and Signal Specification blocks, for which you use their **Minimum** and **Maximum** parameters to specify a signal range. See “Blocks That Allow Signal Range Specification” on page 76-34 for a list of applicable blocks.

To access these parameters, use the Property Inspector (on the **Modeling** tab, under **Design**, click **Property Inspector**), the Model Data Editor (on the **Modeling** tab, click **Model Data Editor**), or the block dialog box.

Specify a minimum or maximum as an expression that evaluates to a scalar, real number with double data type. For example, you can use:

- A literal number such as `98.884`. Implicitly, the data type is `double`.
- A numeric workspace variable (see “Share and Reuse Block Parameter Values by Creating Variables” on page 37-9) whose data type is `double`. Use this technique to share a minimum or maximum value between multiple data items.

When you use a variable to set the `Min` or `Max` property of a `Simulink.ValueType`, `Simulink.Signal`, or `Simulink.BusElement` object, the current value of the variable is assigned to the object. The `Min` and `Max` properties of the object are not affected by future changes to the variable.

The scalar value that you specify applies to each element of a composite signal (for example, when the signal is nonscalar or a bus). For information about scalar expansion, see “Scalar Expansion of Inputs and Parameters” on page 76-22.

To leave the minimum or maximum of a signal unspecified, use an empty matrix `[]`, which is the default value.

### Specify Ranges for Modeling Constructs

If you use modeling constructs such as buses, data stores, and Stateflow charts, you can use different techniques to specify design range information. Use the information in the table.

| Description of Target Signal                                                                                                | Technique and More Information                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|-----------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Numerically complex signal                                                                                                  | When you specify an <b>Output minimum</b> or <b>Output maximum</b> for a signal that is numerically complex, the specified minimum and maximum values apply separately to the real part and to the imaginary part of the complex number. If the value of either part of the number is less than the minimum, or greater than the maximum, the complex number is outside the specified range. No range checking occurs against any combination of the real and imaginary parts, such as $(\text{sqrt}(a^2+b^2))$ .                                                                                                |
| Signal elements in a bus                                                                                                    | If you assemble the bus by using a Bus Creator block, you can specify range information on the upstream blocks that feed the Bus Creator block.<br><br>Regardless of the technique you use to assemble the bus, you can create a <code>Simulink.Bus</code> object and use it as the data type of the bus. In this case, consider specifying range information by using the <code>Min</code> and <code>Max</code> properties of the <code>Simulink.BusElement</code> objects that reside in the bus object. For more information, see “Specify Bus Properties with Simulink.Bus Object Data Types” on page 77-51. |
| Signal in a MATLAB Function block                                                                                           | Use the Ports and Data Manager to specify the <b>Minimum</b> and <b>Maximum</b> properties of the data. See “Set General Data Properties” on page 45-30.                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| Signal in a Stateflow chart                                                                                                 | Set the <b>Minimum</b> and <b>Maximum</b> properties of the corresponding Stateflow data. See “Limit Range” (Stateflow).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| Signal that you associate with an object (such as a <code>Simulink.Signal</code> or <code>Simulink.ValueType</code> object) | Set the <code>Min</code> and <code>Max</code> properties of the <code>Simulink.Signal</code> or <code>Simulink.ValueType</code> object.                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| Data store (Data Store Memory block or <code>Simulink.Signal</code> object)                                                 | For a Data Store Memory block, set the <b>Minimum</b> and <b>Maximum</b> block parameters. For a signal object, set the <code>Min</code> and <code>Max</code> properties.                                                                                                                                                                                                                                                                                                                                                                                                                                        |

## Troubleshoot Signal Range Errors

Simulink provides a diagnostic named **Simulation range checking**, which you can enable to detect when signals exceed their specified ranges during simulation. When enabled, Simulink compares the signal values that a block outputs with both the specified range (see “Work with Signal Ranges in Blocks” on page 76-35) and the block data type. That is, Simulink performs the following check:

$$\text{DataTypeMin} \leq \text{MinValue} \leq \text{VALUE} \leq \text{MaxValue} \leq \text{DataTypeMax}$$

where

- `DataTypeMin` is the minimum value representable by the block data type.
- `MinValue` is the minimum value the block should output, specified by, e.g., **Output minimum**.
- `VALUE` is the signal value that the block outputs.
- `MaxValue` is the maximum value the block should output, specified by, e.g., **Output maximum**.
- `DataTypeMax` is the maximum value representable by the block data type.

**Note** It is possible to overspecify how a block handles signals that exceed particular ranges. For example, you can specify values (other than the default values) for both signal range parameters and enable the **Saturate on integer overflow** parameter. In this case, Simulink displays a warning message that advises you to disable the **Saturate on integer overflow** parameter.

### Enable Simulation Range Checking

To enable the **Simulation range checking** diagnostic:

- 1 In your model window, on the **Modeling** tab, click **Model Settings**.

Simulink displays the Configuration Parameters dialog box.

- 2 In the **Select** tree on the left side of the Configuration Parameters dialog box, click the **Diagnostics > Data Validity** category. On the right side under **Signals**, set the **Simulation range checking** diagnostic to error or warning.

| Signals                      |               |                              |         |
|------------------------------|---------------|------------------------------|---------|
| Signal resolution:           | Explicit only | Wrap on overflow:            | warning |
| Division by singular matrix: | none          | Saturate on overflow:        | warning |
| Underspecified data types:   | none          | Inf or NaN block output:     | none    |
| Simulation range checking:   | none          | "rt" prefix for identifiers: | error   |

Detect when signals exceed specified minimum/maximum values

Parameters

- 3 Click **OK** to apply your changes and close the Configuration Parameters dialog box.

See “Simulation range checking” for more information.

### Simulate Models with Simulation Range Checking

To check for signal range errors or warnings:

- 1 Enable the **Simulation range checking** diagnostic for your model (see “Enable Simulation Range Checking” on page 76-37).
- 2 In your model window, click **Run** to simulate the model.

Simulink simulates your model and performs signal range checking. If a signal exceeds its specified range when the **Simulation range checking** diagnostic specifies error, Simulink stops the simulation and generates an error (for example, in the Diagnostic Viewer).

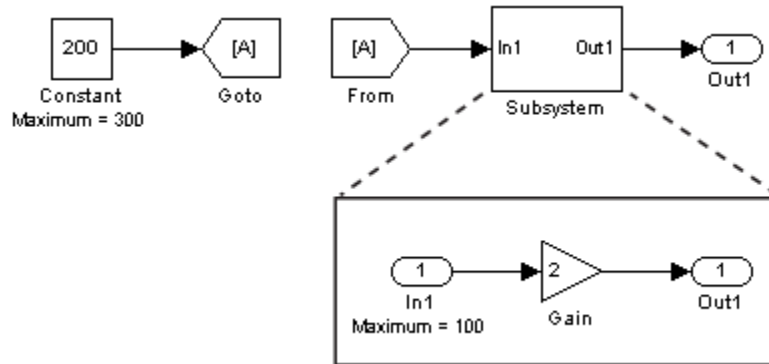

Otherwise, if a signal exceeds its specified range when the **Simulation range checking** diagnostic specifies warning, Simulink generates a warning message in the MATLAB Command Window. Each message identifies the block whose output signal exceeds its specified range, and the time step at which this violation occurs.

### Signal Range Propagation for Virtual Blocks

Some virtual blocks (see “Nonvirtual and Virtual Blocks” on page 36-2) allow you to specify ranges for their output signals, for example, the Inport and Outport blocks. When the **Simulation range checking** diagnostic is enabled for a model that contains such blocks, the signal range of the virtual

block propagates backward to the first instance of a nonvirtual block whose output signal it receives. If the nonvirtual block specifies different values for its own range, Simulink performs signal range checking with the tightest range possible. That is, Simulink checks the signal using the larger minimum value and the smaller maximum value.

For example, consider the following model:

In this model, the Constant block specifies its **Output maximum** parameter as 300, and that of the Inport block is set to 100. Suppose you enable the **Simulation range checking** diagnostic and simulate the model. The Inport block back propagates its maximum value to the nonvirtual block that precedes it, i.e., the Constant block. Simulink then uses the smaller of the two maximum values to check the signal that the Constant block outputs. Because the Constant block outputs a signal whose value (200) exceeds the tightest range, Simulink generates an error.

## Unexpected Errors or Warnings for Data with Greater Precision or Range than double

When a data item (signal or parameter) uses a data type other than `double`, before comparison, Simulink casts the data item and each design limit (minimum or maximum value that you specify) to the nondouble data type. This technique helps prevent the generation of unnecessary, misleading errors and warnings.

However, Simulink stores design limits as `double` before comparison. If the data type of the data item has higher precision than `double` (for example, a fixed-point data type with a 128-bit word length and a 126-bit fraction length) or greater range than `double`, and `double` cannot exactly represent the value of a design limit, Simulink can generate unexpected warnings and errors.

If the nondouble type has higher precision, consider rounding the design limit to the next number furthest from zero that `double` can represent. For example, suppose that a signal generates an error after you set the maximum value to `98.8847692348509014`. At the command prompt, calculate the next number furthest from zero that `double` can represent.

```
format long
98.8847692348509014 + eps(98.8847692348509014)

ans =

 98.884769234850921
```

Use the resulting number, `98.884769234850921`, to replace the maximum value.

## Initialize Signals and Discrete States

### In this section...

“Using Block Parameters to Initialize Signals and Discrete States” on page 76-40

“Use Signal Objects to Initialize Signals and Discrete States” on page 76-41

“Using Signal Objects to Tune Initial Values” on page 76-43

“Initialization Behavior Summary for Signal Objects” on page 76-43

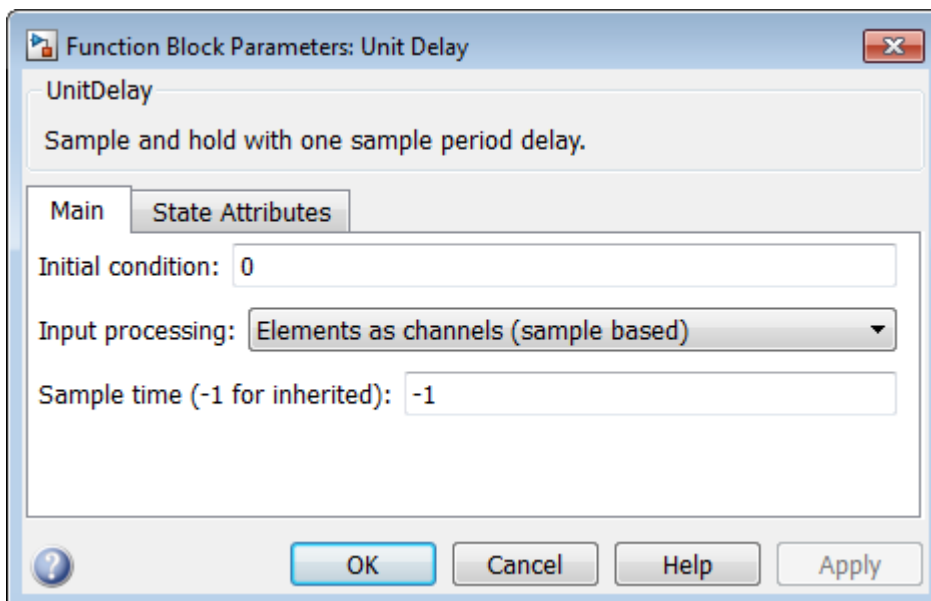

Simulink allows you to specify the initial values of signals and discrete states, i.e., the values of the signals and discrete states at the **Start time** of the simulation. You can use signal objects to specify the initial values of any signal or discrete state in a model. In addition, for some blocks, e.g., Outport, Data Store Memory, or Memory, you can use either a signal object or a block parameter or both to specify the initial value of a block state or output. In such cases, Simulink checks to ensure that the values specified by the signal object and the parameter are consistent. For information about initializing bus signals, see “Specify Initial Conditions for Bus Elements” on page 77-61

When you specify a signal object for signal or discrete state initialization, or a variable as the value of a block parameter, Simulink resolves the name that you specify to an appropriate object or variable, as described in “Symbol Resolution” on page 68-128.

A given signal can be associated with at most one signal object under any circumstances. The signal can refer to the object more than once, but every reference must resolve to exactly the same object. A different signal object that has exactly the same properties will not meet the requirement for uniqueness. A compile-time error occurs if a model associates more than one signal object with any signal. For more information, see `Simulink.Signal` and the Merge block.

### Using Block Parameters to Initialize Signals and Discrete States

For blocks that have an initial value or initial condition parameter, you can use that parameter to initialize a signal. For example, the following Block Parameters dialog box initializes the signal for a Unit Delay block with an initial condition of 0.

To access these block parameters, choose one of these techniques:

- Use the **Model Data Editor** (on the **Modeling** tab, click **Model Data Editor**) to configure multiple signals and states with a searchable, sortable table. To initialize a block state or data store, you can use the appropriate tab (**States** or **Data Stores**). To initialize a signal, state, or data store, you can use the **Parameters** tab and find the row that corresponds to the relevant block parameter.
- Use the **Property Inspector** (on the **Modeling** tab, under **Design**, click **Property Inspector**) to configure one signal or state at a time. Select the block that maintains the target state or generates the target signal and find the relevant block parameter.
- Use the block parameter dialog box. Use this technique to configure one signal or state at a time or to compare the configurations of a few signals or states side by side.

For more information about techniques to access block parameters (including the parameters that control signal and state initialization), see “Set Properties and Parameters”.

## Use Signal Objects to Initialize Signals and Discrete States

You can use signal objects that have a storage class other than 'auto' or, when you set the default storage class of the corresponding data category to `Default` (the default setting) in the Code Mapping Editor, 'Model default' to initialize:

- Discrete states with an initial condition parameter
- Signals in a model except bus signals and blocks that output constant value

To specify an initial value, use the Model Explorer or MATLAB commands to do the following:

- 1 Create the signal object.

On the Model Explorer toolbar, select **Add > Simulink Signal**. The signal object appears in the base workspace with a default name. Rename the object as `S1`. Alternatively, use this command at the command prompt:

```
S1 = Simulink.Signal;
```

The name of the signal object must be the same as the name of the signal that the object is initializing. Although not required, consider setting the **Signal name must resolve to Simulink signal object** option in the Signal Properties dialog box. This setting makes signal objects in the MATLAB workspace consistent with signals that appear in your model.

Consider using the Data Object Wizard to create signal objects. The Data Object Wizard searches a model for signals for which signal objects do not exist. You can then selectively create signal objects for multiple signals listed in the search results with a single operation. For more information about the Data Object Wizard, see “Create Data Objects for a Model Using Data Object Wizard” on page 68-65.

- 2 Set the signal object storage class to a value other than `Auto` or `Model default`. In the Model Explorer **Contents** pane, select the signal object. In the Dialog pane, set **Storage class** to `ExportedGlobal`. Alternatively, use this command at the command prompt:

```
S1.CoderInfo.StorageClass = 'ExportedGlobal';
```

- 3 Set the initial value. You can specify a MATLAB expression, including the name of a workspace variable, that evaluates to a numeric scalar value or array.

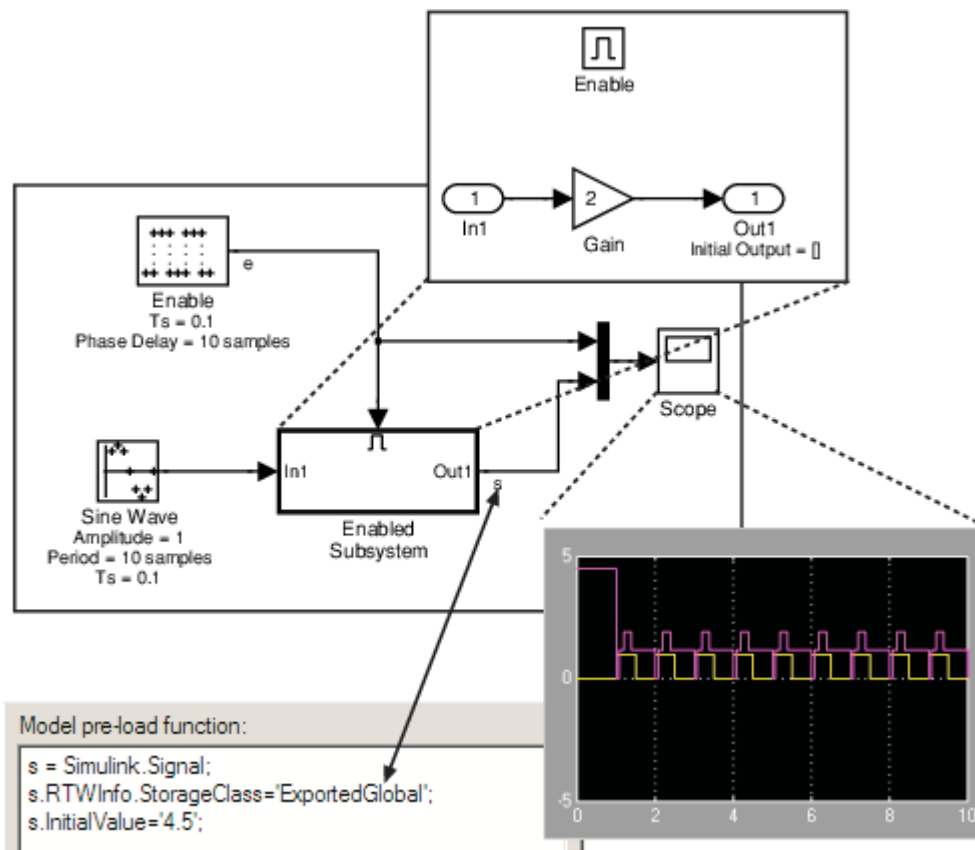

The Simulink engine converts the initial value so the type, complexity, and dimension are consistent with the corresponding block parameter value. If you specify an invalid value or expression, an error message appears when you update the model.

In the Model Explorer Dialog pane, set **Initial value** to 0.5. Alternatively, use this command at the command prompt:

```
S1.InitialValue = '0.5'
```

If you can also use a block parameter to set the initial value of the signal or state, you should set the parameter either to empty ([]) or to the same value as the initial value of the signal object. If you set the parameter value to empty, Simulink uses the value specified by the signal object to initialize the signal or state. If you set the parameter to any other value, Simulink compares the parameter value to the signal object value and displays an error if they differ.

The following example shows a signal object specifying the initial output of an enabled subsystem.

Signal *s* is initialized to 4.5. To avoid a consistency error, the initial value of the enabled subsystem Output block must be [] or 4.5.

If you need a signal object and its initial value setting to persist across Simulink sessions, see “Create Persistent Data Objects” on page 68-73.

Some initial value settings may depend on the initialization mode. For more information, see “Underspecified initialization detection”.

**Classic initialization mode:** In this mode, initial value settings for signal objects that represent the following signals and states override the corresponding block parameter initial values if undefined (specified as []):

- Output signals of conditionally executed subsystems and Merge blocks
- Block states

**Simplified initialization mode:** In this mode, initial values of signal objects associated with the output of the following blocks are ignored. The initial values of the corresponding blocks are used instead.

- Output signals of conditionally executed subsystems
- Merge blocks

## Using Signal Objects to Tune Initial Values

Simulink allows you to use signal objects as an alternative to parameter objects (see `Simulink.Parameter`) to tune the initial values of block outputs and states that can be specified via a tunable parameter. To use a signal object to tune an initial value, create a signal object with the same name as the signal or state and set the signal object initial value to an expression that includes a variable defined in the MATLAB workspace. You can then tune the initial value by changing the value of the corresponding workspace variable during the simulation.

For example, suppose you want to tune the initial value of a Memory block state named M1. To do this, you might create a signal object named M1, set its storage class to 'ExportedGlobal', set its initial value to K (`M1.InitialValue= 'K'`), where K is a workspace variable in the MATLAB workspace, and set the corresponding initial condition parameter of the Memory block to [] to avoid consistency errors. You could then change the initial value of the Memory block state any time during the simulation by changing the value of K at the MATLAB command line and updating the block diagram (e.g., by typing **Ctrl+D**).

## Initialization Behavior Summary for Signal Objects

The following model and table show different types of signals and discrete states that you can initialize and the simulation behavior that results for each.

| Signal or Discrete State | Description                                                                  | Behavior                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|--------------------------|------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| S1                       | Root input port                                                              | <ul style="list-style-type: none"> <li>Initialized to <code>S1.InitialValue</code>.</li> <li>If you use the <b>Data Import/Export</b> pane of the Configuration Parameters dialog to specify values for the root inputs, the initial value is overwritten and may differ at each time step. Otherwise, the value remains constant.</li> </ul>                                                                                                                                                                                                                                                                                                                                                           |
| X1                       | Unit Delay block — Block with a discrete state that has an initial condition | <ul style="list-style-type: none"> <li>Initialized to <code>X1.InitialValue</code>.</li> <li>Simulink checks whether <code>X1.InitialValue</code> matches the initial condition specified for the block and displays an error if a mismatch occurs.</li> <li>At first write, the output equals <code>X1.InitialValue</code> and the state equals <code>S1</code>.</li> <li>At each time step after the first write, the output equals the state and the state is updated to equal <code>S1</code>.</li> <li>If the block is inside an enabled subsystem, you can use the initial value as a reset value if the subsystem Enable block parameter <b>States when enabling</b> is set to reset.</li> </ul> |
| X2                       | Data Store Memory block                                                      | <ul style="list-style-type: none"> <li>Data type work (DWork) vector initialized to <code>X2.InitialValue</code>. ## Configure Signals as Test Points

### In this section...

“What Is a Test Point?” on page 76-46

“Displaying Test Point Indicators” on page 76-47

### What Is a Test Point?

A *test point* is a signal that Simulink guarantees to be observable when using a Floating Scope block in a model. Simulink allows you to designate any signal in a model as a test point.

Designating a signal as a test point exempts the signal from model optimizations, such as signal storage reuse (see “Signal storage reuse” (Simulink Coder)) and block reduction (see “Implement logic signals as Boolean data (vs. double)”). These optimizations render signals inaccessible and hence unobservable during simulation.

Signals designated as test points will not have algebraic loops minimized, even if **Minimize algebraic loop occurrences** is selected (for more information about algebraic loops, see “Algebraic Loop Concepts” on page 3-27).

Test points are primarily intended for use when generating code from a model with Simulink Coder. For more information about test points in the context of code generation, see “Appearance of Test Points in the Generated Code” (Simulink Coder).

Marking a signal as a test point has no impact on signal logging that uses the **Dataset** logging format. For information about logging signals, see “Export Signal Data Using Signal Logging” on page 73-43.

Use one of the following ways to designate a signal as a test point:

- Open the **Signal Properties** dialog for the signal and check **Test Point** in the **Logging and accessibility** section.
- Use the Model Data Editor for batch configuration and for signals that are difficult to locate in a large model or hierarchy of subsystems. On the **Signals** tab, set the **Change view** drop-down list to **Instrumentation** and use the **Test Point** column. For more information, see **Model Data Editor**.
- To configure Stateflow data in a chart as test points, see “Monitor Test Points in Stateflow Charts” (Stateflow).

To configure a signal as a test point programmatically:

- 1 Get handles to the ports of the block.

```
portHandles = get_param('myModel/myBlock', 'portHandles');
```

portHandles is a structure. Each field stores a handle to a block port.

- 2 Extract a handle to the output port that creates the target signal line.

```
outportHandle = portHandles.Outputport;
```

- 3 Set the port parameter TestPoint to 'on'.

```
set_param(outportHandle, 'TestPoint', 'on')
```

## Displaying Test Point Indicators

By default, Simulink displays an indicator on each signal whose **Signal Properties > Test point** option is enabled. For example, in the following model signals s2 and s3 are test points:

---

**Note** Simulink does not display an indicator on a signal that is specified as a test point by a `Simulink.Signal` object, because such a specification is external to the graphical model.

---

A signal that is a test point can also be logged. See “Export Signal Data Using Signal Logging” on page 73-43 for information about signal logging. The appearance of the indicator changes to indicate signals for which logging is also enabled.

To turn display of test point indicators on or off, in the Simulink Editor, on the **Debug** tab, select **Information Overlays > Log & Testpoint** to enable or disable the option.

## Specify Application-Specific Signal Properties

A signal in a Simulink model has properties (or attributes) such as data type, dimensions, and numeric complexity. When a signal represents a recurring type of value, such as a wind velocity, tire pressure, or water temperature, you can define the signal properties once and reuse that specification for each signal that represents the same value type.

A `Simulink.ValueType` object specifies a fundamental set of signal properties for a value type:

- Complexity
- Data type
- Description
- Dimensions
- Dimensions Mode
- Max
- Min
- Unit

The property specifications for a value type are relevant wherever the type of value appears in a model. `ValueType` objects do not include instance-specific properties, such as initial values or sample times.

## Determine Whether To Use Value Types

You can specify signal properties individually or with a predefined set of property specifications. Depending on your modeling requirement, the way you define a set of signal properties differs.

| Modeling Requirement                                                                                                                                                       | Source of Property Specifications                                                    |
|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------|
| Assign or validate the properties of signals based on a set of properties that is fundamental to the application-specific value type of the signal, such as wind velocity. | Use a <code>Simulink.ValueType</code> object.                                        |
| Assign or validate the properties of a signal based on a set of instance-specific properties, including the initial value and sample time.                                 | Use a <code>Simulink.Signal</code> object or a Signal Specification block.           |
| Assign or validate the properties of a signal that is an element of a bus.                                                                                                 | Use a <code>Simulink.BusElement</code> object in a <code>Simulink.Bus</code> object. |

A `ValueType` object can define the properties of a signal at an interface. When the ports of model components directly connect to each other, specify the same `ValueType` object for the blocks that represent those ports. If you specify different `ValueType` objects that have the same properties but different names, you receive an error. By specifying the same value type at both sides of the interface, you enforce consistency at the interface between the two components. For more information about interface design, see “Define Interfaces of Model Components” on page 22-19.

The `ValueType` object propagates through the model until it reaches a block that produces new data as output. For example, the object passes through In Bus Element and Out Bus Element blocks, but it does not pass through Sum or Gain blocks.

Information overlays display the properties specified by the `ValueType` object. Information overlays do not specify the `ValueType` object itself. Suppose your value type has units. To see the units, in the Simulink Toolstrip, on the **Debug** tab, select **Information Overlays > Units**. The units specified by the `ValueType` object appear on the signal lines.

`ValueType` objects do not appear in the generated code. The signal properties that the `ValueType` objects specify appear in the generated code.

## Create Value Types

To interactively create or edit `Simulink.ValueType` objects, use the **Model Explorer**. `ValueType` objects created with the Model Explorer are initially stored in the base workspace or data dictionary.

To create a `ValueType` object in the Model Explorer:

- 1 Open a model.
- 2 In the Simulink Toolstrip, on the **Modeling** tab, click **Model Explorer**.
- 3 In the **Model Hierarchy** pane of the Model Explorer, select the storage location for the `Simulink.ValueType` object. For example, if the model uses a data dictionary, select the data dictionary. Otherwise, select the base workspace.
- 4 In the Model Explorer toolbar, select **Add > Simulink ValueType**.
 

A new `ValueType` object appears in the **Contents** pane. The **Dialog** pane shows the properties of the new `ValueType` object.
- 5 Specify the desired property values for the value type.

To programmatically create and edit `ValueType` objects, see “Specify Signal Properties for Value Type”. `ValueType` objects created programmatically are initially stored in the base workspace.

## Specify Value Types

After you create a `ValueType` object and specify its properties, use it to specify signal properties:

- At an interface with Inport, Outport, In Bus Element, or Out Bus Element blocks
- In a model with Signal Specification blocks
- In a `Simulink.BusElement` object

To associate a block or object with a value type, set the data type of the block or object to `ValueType: <object name>` and replace `<object name>` with the `ValueType` object name.

You can specify the `ValueType` object as the data type either before or after defining the `ValueType` object. However, before you simulate the model, the `ValueType` object must be defined and loaded.

The property values specified by the `ValueType` object override the property values specified by the block, object, or signal. For example, suppose an Inport block sets **Unit** to `ft/s`. When you set the **Data type** of the Inport block to a `ValueType` object that has `m/s` as its unit, the block uses `m/s` as the unit.

During model development, you can modify signals to match `ValueType` objects or modify `ValueType` objects to match signals. If you do not want to change the `ValueType` object, you can:

- Create a `ValueType` object that matches the changes to the signal and use the new `ValueType` object for the blocks that the changed signal connects to.
- Revert the signal changes so that the signal continues to match the associated `ValueType` object.

When `ValueType` objects do not match at an interface, you can:

- Specify the same `ValueType` object at both ports.
- Remove the `ValueType` object specification from one of the ports.
- Insert a Signal Specification block between the ports. The Signal Specification block returns a mismatch warning instead of an error when it receives a different `ValueType` object than the one it specifies.

## Save Value Types

You can save `Simulink.ValueType` objects to these locations:

- Data dictionary
- Script
- Function
- MAT file

If you do not save `ValueType` objects, then when you reopen a model that uses the `ValueType` objects, you need to recreate the `ValueType` objects.

Choose where to store `ValueType` object based on your modeling requirements.

| Modeling Requirement                                 | Location                                                                                                                                                                                                                                                                            |
|------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Store data for large models and model hierarchies.   | Use a data dictionary.<br><br>When you save to a data dictionary from the base workspace, you get all the variables used by the model, not just the <code>ValueType</code> objects.<br><br>For more information, see “Migrate Models to Use Simulink Data Dictionary” on page 75-6. |
| Use MATLAB for traceability and model differencing.  | Use a script or function.<br><br>Create a script or function that programmatically defines one or more <code>ValueType</code> objects.<br><br>For more information, see “Create Scripts” and “Create Functions in Files”.                                                           |
| Save and load <code>ValueType</code> objects faster. | Use a MAT file.<br><br>To create a MAT file that contains either the specified <code>ValueType</code> objects from the base workspace or everything in the base workspace, use the <code>save</code> function.                                                                      |

To save `ValueType` objects stored in the base workspace, you can use any MATLAB technique that saves the contents of the base workspace. However, the resulting file contains everything in the base workspace, not just `ValueType` objects.

When you modify saved `ValueType` objects, you must resave them to keep the changes.

## Map Value Types to Models

Before you simulate a model, all the `ValueType` objects that the model uses must be loaded into the base workspace or a data dictionary used by the model. Mapping `ValueType` objects to models is important for automation and consistency across models.

- By identifying all of the `ValueType` objects that a model requires, you can ensure that those objects are loaded before model execution.
- By identifying all models that use a `ValueType` object, you can ensure that changes to a `ValueType` object do not cause unexpected changes in any of the models that use the `ValueType` object.

To ensure the necessary `ValueType` objects load before model execution, consider:

- **Projects** — Automatically load or run files that define `ValueType` objects by configuring the files to run when you open a project. For details, see “Project Management”.
- **Data dictionaries** — Store `ValueType` objects with variables and other objects for one or more models.

To share a `ValueType` object among models, you can link each model to a dictionary and create a common referenced dictionary to store the object. For an example, see “Partition Dictionary Data Using Referenced Dictionaries” on page 75-25.

- **Databases** — Capture mapping information in an external data source, such as a database.
- **Model callbacks** — Load or run files that define `ValueType` objects by using a model callback, such as `PreLoadFcn`. For more information, see “Model Callbacks” on page 4-53.

If a model uses only a few `ValueType` objects, consider copying the `ValueType` object code directly into the callback, instead of loading a file.

To find where a `ValueType` object is used in an open model, see “Finding Blocks That Use a Specific Variable” on page 68-112.

## Related Examples

- “Specify Signal Ranges” on page 76-34
- “Determine Signal Dimensions” on page 76-20
- “Investigate Signal Values” on page 76-10
- “Display Signal Attributes” on page 76-52

## Display Signal Attributes

### In this section...

“Ports & Signals Menu” on page 76-52  
 “Port Data Types” on page 76-53  
 “Design Ranges” on page 76-54  
 “Signal Dimensions” on page 76-54  
 “Signal to Object Resolution Indicator” on page 76-55  
 “Wide Nonscalar Lines” on page 76-56

A signal line in a model has attributes such as data type, dimensions, and numeric complexity. When you display these attributes on the block diagram, you can:

- Make the model easier to understand by others.
- Determine the value of the attribute that the signal ultimately uses for simulation (for example, when a signal uses an inherited data type).
- Plan your strategy to control these attributes along a data path (a series of connected blocks).

Additionally, to inspect and specify these attributes in a searchable, sortable table, you can use the **Model Data Editor**.

### Ports & Signals Menu

In the Simulink Editor, on the **Debug** tab, the **Information Overlays** menu offers the following options for displaying signal properties on the block diagram:

- Linearization Indicators
- Port Data Types (See “Port Data Types” on page 76-53)
- Design Ranges (See “Design Ranges” on page 76-54)
- Signal Dimensions (See “Signal Dimensions” on page 76-54)
- Storage Class
- Testpoint/Logging Indicators
- Signal Resolution Indicators (See “Signal to Object Resolution Indicator” on page 76-55)
- Viewer Indicators
- Wide Nonscalar Lines (See “Wide Nonscalar Lines” on page 76-56)

In addition, you can display sample time information. In the Simulink Editor, on the **Debug** tab, the **Information Overlays** menu provides the choices of **Colors** and **Text**. The **Colors** option allows the block diagram signal lines and blocks to be color-coded based on the sample time types and relative rates. The **Text** option provides black codes on the signal lines which indicate the type of sample time. If you select both **Colors** and **Text**, then both the colors and the annotations display. All of these options cause a Sample Time Legend to appear. The legend contains a description of the type of sample time and the sample time rate. If **Colors** is enabled, color codes also appear in the legend. The same is true if **Text** is enabled.

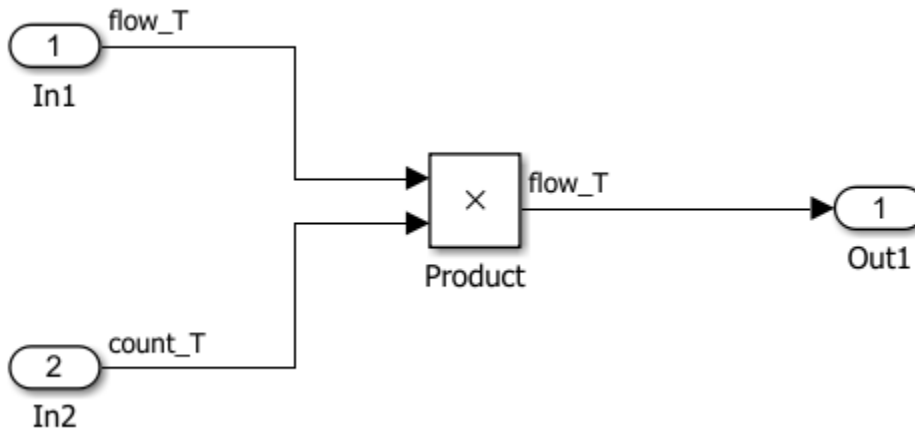

## Port Data Types

Displays the data type that each signal uses for simulation and code generation. The data type appears next to the output port that emits the signal.

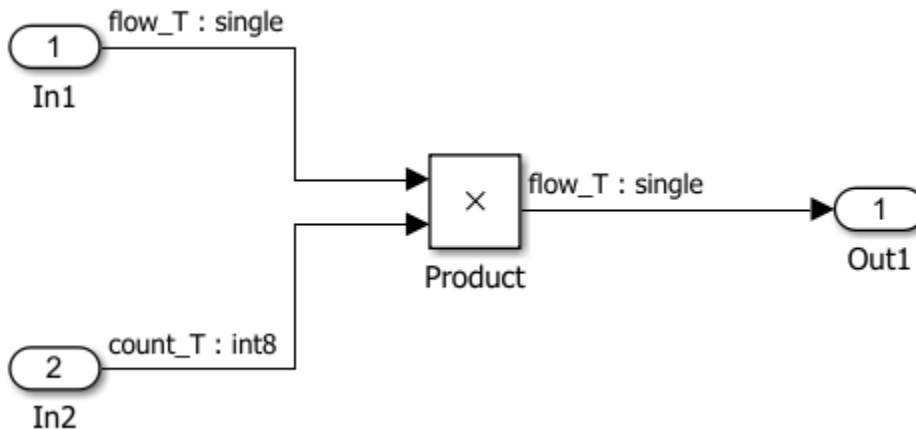

The notation (c) indicates that the signal is numerically complex (i).

If you use data type aliases (such as a `Simulink.AliasType` objects in the base workspace or a data dictionary) to set output data types in your model, by default, the diagram displays the aliases.

If you create a chain of aliases (for example, by using one `Simulink.AliasType` object as the base type of another `Simulink.AliasType` object), the diagram displays only the alias that you use to set the output data type of each signal. The diagram does not display the underlying aliases in the chain.

To display the lowest underlying base data type (such as `int8`, `single`, or `s16En14`) as well as the alias, in the **Debug** tab, open the **Information Overlays** drop-down. Under **Ports** click **Base Data Types** and **Alias Data Types**.

Alternatively, you can display the base type and not the alias by selecting **Base Data Types**.

When you use a fixed-point data type, the diagram displays the base type by using a standard notation that indicates the characteristics of the type (such as signedness and binary fraction length). To interpret this notation, see “Fixed-Point Data Type and Scaling Notation” (Fixed-Point Designer).

When you save a model with **Base Data Types** enabled, the next time you load the model, it displays the data type and complexity signal attributes.

## Design Ranges

Displays the compiled design range of a signal next to the output port that emits the signal. The ranges are computed during an update diagram.

Ranges are displayed in the format [min..max]. In the above example, the design range at the output port of the Mux block is displayed as [-10..mixed], because the two signals the Mux block combines have the same design minimum but different design maximums.

You can also use command-line parameters `CompiledPortDesignMin` and `CompiledPortDesignMax` to access the design minimum and maximum of port signals, respectively, at compile time. For more information, see “Common Block Properties”.

## Signal Dimensions

Display the dimensions of nonscalar signals next to the line that carries the signal.

The format of the display depends on whether the line represents a single signal or a bus. If the line represents a single vector signal, Simulink displays the width of the signal. If the line represents a single matrix signal, Simulink displays its dimensions as  $[N_1 \times N_2]$  where  $N_i$  is the size of the  $i$ th dimension of the signal. If the line represents a bus carrying signals of the same data type, Simulink displays  $N\{M\}$  where  $N$  is the number of signals carried by the bus and  $M$  is the total number of signal elements carried by the bus. If the bus carries signals of different data types, Simulink displays only the total number of signal elements  $\{M\}$ .

When you save a model with this option enabled, the next time you load the model, it displays signal dimensions.

## Signal to Object Resolution Indicator

The Simulink Editor by default graphically indicates signals that must resolve to signal objects. For any labeled signal whose **Signal name must resolve to signal object** property is enabled, a signal resolution icon appears to the left of the signal name. The icon looks like this:

A signal resolution icon indicates only that the **Signal name must resolve to signal object** property for a signal is enabled. The icon does not indicate whether the signal is actually resolved, and does not appear on a signal that is implicitly resolved without its **Signal name must resolve to signal object** property being enabled.

Where multiple labels exist, each label displays a signal resolution icon. No icon appears on an unlabeled branch. In the next figure, signal `x2` must resolve to a signal object, so a signal resolution icon appears to the left of the signal name in each label:

To suppress the display of signal resolution icons, in the model window, on the **Debug** tab, select **Information Overlays > Signal Resolves to Object** to disable. This option is enabled default. To restore signal resolution icons, enable **Signal Resolves to Object**. Individual signals cannot be set to show or hide signal resolution indicators independently of the setting for the whole model. For additional information, see:

- “Symbol Resolution” on page 68-128
- “Initialize Signals and Discrete States” on page 76-40
- `Simulink.Signal`

## Wide Nonscalar Lines

Draws lines that carry vector or matrix signals wider than lines that carry scalar signals.

For more information on vector and matrix signals, see “Signal Types” on page 76-7.

 “Simulation from Signal Builder Block” on page 76-89

## About Signal Groups

To display, create, and edit interchangeable groups of signal sources and quickly switch the groups into and out of a model, use the Signal Builder block. You can define any piecewise linear signal shape (waveform).

---

**Note** The Signal Builder block is not recommended to work with signal groups. Instead, use the Signal Editor block to display, create, edit, and switch interchangeable scenarios. For more information, see “Load Data with Interchangeable Scenarios” on page 72-37.

---

Use signal groups when testing a model, especially when using them in conjunction with the Simulink Assertion block and the Model Coverage Tool from the Simulink Coverage.

**Solver** pane settings in Model Configuration Parameters can affect the Signal Builder block output. See “Simulation Phases in Dynamic Systems” on page 3-2 and “Compare Solvers” on page 3-6 for a description of how solvers affect simulation.

---

**Note** The Signal Builder block adds a port for each signal you create. The block **Position** parameter limits the number of ports the Signal Builder block can have, and therefore the number of signals you can create. For more information, see the **Position** parameter at “Common Block Properties”.

---

You can also use the `signalbuilder` function to populate a Signal Builder block.

### Supported Waveforms

The Signal Builder block supports these waveforms.

## Using the Signal Builder Block with Fast Restart

After you turn on fast restart:

- In between runs, you can change data, rename signals and signal groups, and add new groups. You cannot:
  - Import signals or signal groups
  - Change signal output settings
- You can click the **Run all** button once. To reenale the **Run all** button, toggle the fast restart button on the Simulink Editor tool bar. However, **Run all** does not use fast restart.

## Editing Signal Groups

The Signal Builder window allows you to create, rename, move, then delete signal groups from the set of groups represented by a Signal Builder block.

### Creating and Deleting Signal Groups

To create a signal group:

- 1 In Signal Builder, copy an existing signal group.
- 2 Modify it to suit your needs.

To copy an existing signal group:

- 1 In Signal Builder, select the group from the list.
- 2 Select **Group > Copy**.

A new group is created.

To delete a group, select the group from the list, and select **Group > Delete**.

### Renaming Signal Groups

To rename a signal group:

- 1 In Signal Builder, select the group from the list.
- 2 Select **Group > Rename**.
- 3 Edit the existing name in the dialog box or enter a new name. Click **OK**.

### Moving Signal Groups

To reposition a group in the stack of group panes:

- 1 In Signal Builder, select the pane.
- 2 To move the group lower in the stack, select **Group > Move Down**.
- 3 To move the pane higher in the stack, select **Group > Move Up**.

## Editing Signals

Signal Builder allows you to create, cut and paste, hide, and delete signals from signal groups.

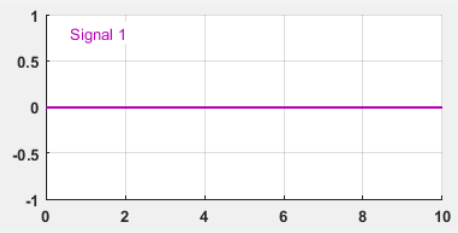

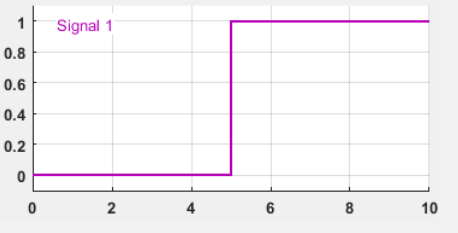

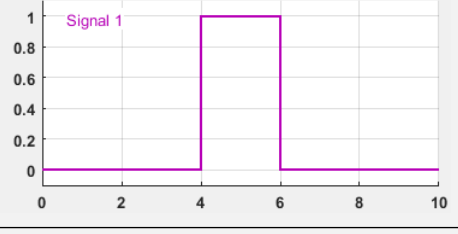

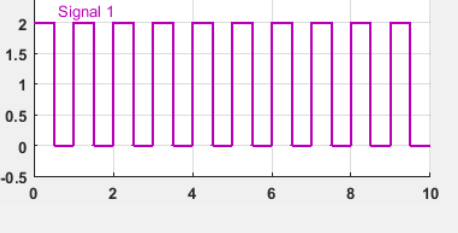

## Creating Signals

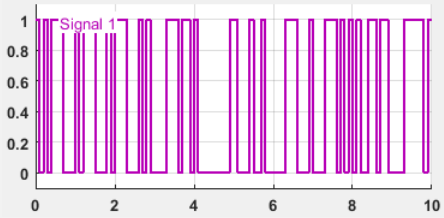

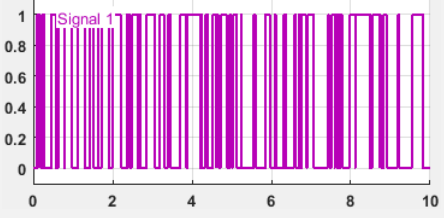

To create a signal in the currently selected signal group:

- 1 In Signal Builder, from the Active Group list, select the group you want to add the signal to.
- 2 Select **Signal > New**.

The menu lists the waveforms you can add.

| Waveform | Description       | Inputs                                                                                                                                                                                                                                                                                                                            | Output                                                                                                                                                                                                                                                                                             |
|----------|-------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Constant | Constant waveform | None                                                                                                                                                                                                                                                                                                                              |  <p>A graph showing a constant signal at 0 over a time interval from 0 to 10. The y-axis ranges from -1 to 1, and the x-axis ranges from 0 to 10. The signal is a horizontal purple line at y=0.</p>             |
| Step     | Step waveform     | None                                                                                                                                                                                                                                                                                                                              |  <p>A graph showing a step waveform. The signal is at 0 until t=5, then jumps to 1 and remains constant until t=10. The y-axis ranges from 0 to 1, and the x-axis ranges from 0 to 10.</p>                      |
| Pulse    | Pulse waveform    | None                                                                                                                                                                                                                                                                                                                              |  <p>A graph showing a pulse waveform. The signal is at 0 until t=4, jumps to 1, stays at 1 until t=6, and then returns to 0 until t=10. The y-axis ranges from 0 to 1, and the x-axis ranges from 0 to 10.</p> |

| Waveform | Description                                                                      | Inputs                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              | Output |
|----------|----------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------|
| Custom   | Custom piecewise linear waveform; custom values must fit within the display area | <ul style="list-style-type: none"> <li>• <b>Time values</b><br/>Vector of two or more time coordinates</li> <li>• <b>Y values</b><br/>Vector of two or more signal amplitudes that correspond to the values in <b>Time values</b></li> </ul> <p>The entries in either field can be any MATLAB expression that evaluates to a vector, including the results from the evaluation of a MATLAB workspace variable. The resulting vectors must be of equal length.</p> <hr/> <p><b>Note</b> Signal Builder displays a warning if you add a custom waveform with a large number of data points (100,000,000 or more).</p> |        |

- 3 Select the waveform you want to add.
- 4 Specify the inputs (in the prompt), and click **OK**.

If you select a standard waveform, Signal Builder adds a signal with that waveform to the group. If you select a custom waveform, you are prompted for **Time values** and **Y values**.

You can also use MATLAB workspace variables to create new signals.

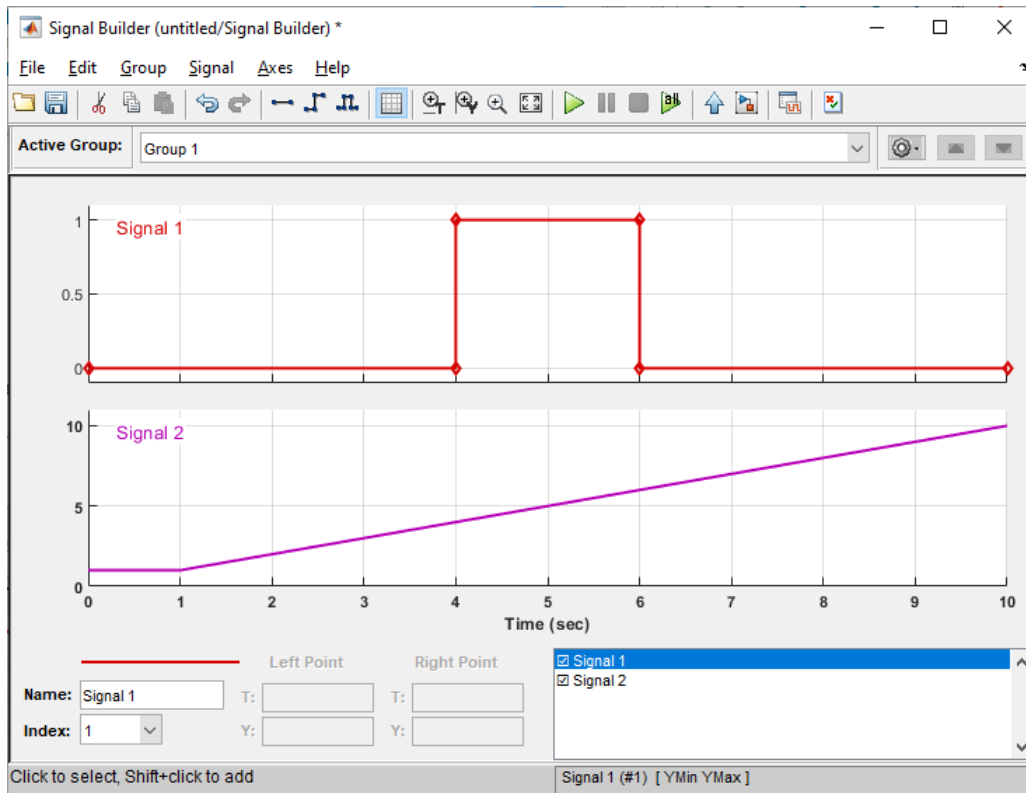

- 1 In the MATLAB Command Window, create data for two variables,  $t$  and  $y$ .

```
t = 1:10
y = 1:10
```

These vectors must be the same size.

- 2 Create a model and add a Signal Builder block.
- 3 Double-click the Signal Builder block.
- 4 Select **Signal > New > Custom**.
- 5 In the Custom Waveform window, enter  $t$  in the **Time values** field and  $y$  in the **Y values** field and then click **OK**.

The Signal Builder block window displays the new signal as Signal 2.

## Defining Signal Output

To specify the type of output to use for sending test signals:

- 1 In Signal Builder, select **Signal > Output**.
- 2 From the list, select:

- **Ports**

Default. Sends individual signals from the block. An output port named Signal *N* appears for each Signal *N*.

- **Bus**

Sends single, virtual, nonhierarchical bus of signals from the block. An output port named Bus appears.

---

### Tip

- You cannot use the **Bus** option to create a bus of nonvirtual signals.
  - The **Bus** option enables you to change your model layout without having to reroute Signal Builder block signals. Use the Bus Selector block to select the signals from this bus.
  - If you create a Signal Builder block using the Signal & Scope Manager or using the **Create & Connect Generator** option from a signal line context menu, you cannot define signal output. In these cases, the block sends individual signals.
-

### Copying and Pasting Signals

To copy a signal from one group and paste it into another group as a new signal:

- 1 In Signal Builder, select the signal you want to copy.
- 2 Select **Edit > Copy**.
- 3 Select the group you want to paste the signal into.
- 4 Select **Edit > Paste**.

To copy a signal from one axis and paste it into another axis to replace its signal:

- 1 Select the signal you want to copy.
- 2 Select **Edit > Copy**.
- 3 Select the signal on the axis that you want to update.
- 4 Select **Edit > Paste**.

### Deleting Signals

To delete a signal, in Signal Builder, select the signal and choose **Delete** or **Cut** from the **Edit** menu. Signal Builder deletes the signal from the current group. Because each signal group must contain the same number of signals, Signal Builder also deletes all signals sharing the same index in the other groups.

### Renaming a Signal

To rename a signal:

- 1 In Signal Builder, select **Signal > Rename**.

A dialog box appears with an edit field that displays the current name of the signal.

- 2 Edit or replace the current name with a new name.
- 3 Click **OK**.

You can also edit the signal name in the **Name** field in the lower-left corner of the Signal Builder window.

### Replacing a Signal

To replace a signal:

- 1 In Signal Builder, select the signal, then select **Signal > Replace with** .

A menu of waveforms appears. It includes a set of standard waveforms (**Constant**, **Step**, and so on) and a **Custom** waveform option.

- 2 Select one of the waveforms.

If you select a standard waveform, Signal Builder replaces a signal in the currently selected group with that waveform. For other waveforms, the Signal Builder displays a dialog to allow you to provide input for the requested waveform.

| Waveform    | Description           | Inputs                                                                                                                                                                                                                                                                                                                                    |

The resulting vectors must be of equal length.</p> <p><b>Note</b> Signal Builder returns a warning if you add a custom waveform with a large number of data points (100,000,000 or more). You can then cancel the action.</p> |

You can also edit the signal name in the **Name** field in the lower-left corner of the Signal Builder window.

### Changing a Signal Index

To change a signal index:

- 1 In Signal Builder, select the signal, then select **Signal > Change Index**.

A dialog box appears with a drop-down list field containing the existing index of the signal.

- 2 From the drop-down list, select another index and select **OK**. Or select an index from the **Index** list in the lower-left corner of the Signal Builder window.

### Hiding Signals

By default, the Signal Builder window displays the group waveforms in the group pane. To hide a waveform:

- 1 In Signal Builder, select the waveform, then select **Signal > Hide**.
- 2 To redisplay a hidden waveform, select the **Group** pane, then select **Signal > Show**.
- 3 Select the signal from the list. Alternatively, you can hide and redisplay a hidden waveform by double-clicking its name in the Signal Builder signal list.

### Creating Signal Group Sets Manually

This topic describes how to create signal group sets manually. If you have signal data files, such as those from test cases, consider importing this data as described in “Importing Signal Group Sets” on page 76-68.

To create an interchangeable set of signal groups:

- 1 Drag an instance of the Signal Builder block from the Simulink Sources library and drop it into your model.

By default, the block represents a single signal group containing a single signal source that outputs a square wave pulse.

- 2 Use the block signal editor to create additional signal groups, add signals to the signal groups, modify existing signals and signal groups, and select the signal group that the block outputs.

---

**Note** Each signal group must contain the same number of signals.

- 3 Connect the output of the block to your diagram.

The block displays an output port for each signal that the block can output.

You can create as many Signal Builder blocks as you like in a model, each representing a distinct set of interchangeable groups of signal sources. When a group has multiple signals, the signals might have different end times. However, Signal Builder block requires the end times of signals within a group to match. If a mismatch occurs, Signal Builder block matches the end times by holding the last value of the signal with the smaller end time.

See “Simulating with Signal Groups” on page 76-88 for information on using signal groups in a model.

## Importing Signal Group Sets

The topics in this section describe how to import signal data into the Signal Builder block. You should already have a signal data file whose contents you want to import. For example, you might have signal data from previously run test cases. See “Importing Signal Groups from Existing Data Sets” on page 76-68 for a description of the data formats that the Signal Builder block accepts. The procedures in the following topics use the file `3Grp_3Sig.xls` in the folder `matlabroot\help\toolbox\simulink\examples`.

Signal Builder accepts signals only of type double.

If you import a `Simulink.SimulationData.Dataset` data set, the block imports it as its own group.

### Importing Signal Groups from Existing Data Sets

You might have existing signal data sets that you want to enter into the Signal Builder block. The **File > Import from File** command on the Signal Builder window starts the Import File dialog box. This dialog box is modal, which means that focus cannot change to another MATLAB window while the dialog box is running. If you want to see changes in the Signal Builder window after you import data, do one of the following:

- Close the Import File dialog box.
- Set up the Import File dialog box and Signal Builder window side by side.

---

**Note** You cannot undo the results of importing a signal data file. In addition, you cannot undo the last action performed before opening the Import File dialog box. When you close the Import File dialog box, the **Undo last edit** and **Redo last edit** buttons on the Signal Builder window are grayed out. These buttons are grayed out regardless of whether you imported a data file.

---

The Import File dialog box accepts the following appropriately formatted file types:

- Microsoft Excel (`.xls`, `.xlsx`)
- Comma-separated value (CSV) text files (`.csv`)
- MAT-files (`.mat`)

---

**Tip** To import signal data from a Microsoft Excel spreadsheet, consider using the From Spreadsheet block. The From Spreadsheet block incrementally loads data from the spreadsheet during simulation.

If you use a From Spreadsheet block, you do not need to do anything to handle changes to sheet values.

You can import your data set file only if it is appropriately formatted.

For Microsoft Excel spreadsheets:

- The Signal Builder block interprets the first row as signal name. If you do not specify a signal name, the Signal Builder block assigns a default one with the format `Imported_Signal #`, where # increments with each additional unnamed signal.
- The Signal Builder block interprets the first column as time. In this column, the time values must increase.
- The Signal Builder block interprets the remaining columns as signals.
- If there are multiple sheets:
  - Each sheet must have the same number of signals (columns).
  - Each sheet must have the same set of signal names (if any).
  - Each column on each sheet must have the same number of rows.
- Signal Builder block interprets each worksheet as a signal group.

This example contains an acceptably formatted Microsoft Excel spreadsheet. It has three worksheets named Group1, Group2, and Group3, representing three signal groups.

Time must be first column

| 1  | Time | DC In | Trigger | AC In | ← Signal names (optional) |
|----|------|-------|---------|-------|---------------------------|
| 2  | 0    | 1     | 2       | 3     |                           |
| 3  | 1    | 2     | 3       | 4     |                           |
| 4  | 2    | 3     | 4       | 5     |                           |
| 5  | 3    | 4     | 5       | 6     |                           |
| 6  | 4    | 5     | 6       | 7     |                           |
| 7  | 5    | 6     | 7       | 8     |                           |
| 8  | 6    | 7     | 8       | 9     |                           |
| 9  | 7    | 8     | 9       | 10    |                           |
| 10 | 8    | 9     | 10      | 11    |                           |
| 11 | 9    | 10    | 11      | 12    |                           |
| 12 | 10   | 11    | 12      | 13    |                           |
| 13 | 11   | 12    | 13      | 14    |                           |
| 14 | 12   | 13    | 14      | 15    |                           |
| 15 | 13   | 14    | 15      | 16    |                           |
| 16 | 14   | 15    | 16      | 17    |                           |
| 17 | 15   | 16    | 17      | 18    |                           |
| 18 |      |       |         |       |                           |

Worksheets - equivalent to signal group

For CSV text files:

- Each file contains only numbers. Do not name signals in a CSV file.
- The Signal Builder block interprets the first column as time. In this column, the time values must increase.
- The Signal Builder block interprets the remaining columns as signals.
- Each column must have the same number of entries.
- The Signal Builder block interprets each file as one signal group.
- The Signal Builder block assigns a default signal name to each signal with the format `Imported_Signal #`, where `#` increments with each additional signal.

This example contains an acceptably formatted CSV file. The contents represent one signal group.

```
0,0,0,5,0
1,0,1,5,0
2,0,1,5,0
3,0,1,5,0
4,5,1,5,0
5,5,1,5,0
6,5,1,5,0
7,0,1,5,0
8,0,1,5,1
9,0,1,5,1
10,0,1,5,0
```

For MAT-files:

- The Signal Builder block supports data store logging that the `Simulink.SimulationData.Dataset` object represents and interprets this data as a single group.
- The Signal Builder block supports Simulink output saved as a structure with time.
- The Signal Builder block supports the Signal Builder data format. This format is a group of cell arrays that must be labeled.
- Signal Builder block does not support:
  - Simulink output as only a structure
  - Simulink output as only an array

---

**Note** Signal Builder returns a warning if you import a large number of data points (100,000,000 or more). You can then cancel the action.

---

This example contains an acceptably logged MATLAB workspace. Use the MATLAB workspace **Save** command to save the variables to a MAT-file. Import this file to the Signal Builder block.

### Replacing All Signal Data with Selected Data

Simulink software creates a default Signal Builder block with one signal. To replace this signal and all other signal data that the block might display:

- 1 Create a model and drag a Signal Builder block into that model.
- 2 Double-click the block.

The Signal Builder window appears with its default Signal 1.

- 3 In Signal Builder, select **File > Import from File**.

The Import File dialog box appears.

- 4 In the **File to Import** field, enter a signal data file name or click **Browse**.

The file browser appears.

- 5 If you select the file browser, navigate to and select a signal data file. Select 3Grp\_3Sig.xls.

---

**Note** If you try to import an improperly formatted data file, an error message pops up.

---

The **Select data to import** pane contains the signal data from the file. Click the expanders to display all the signals.

- 6 Select the signals you want to import. To import all the signals, click **Select All**.
- 7 From the **Select placement of data** list, select the action to take on the signal data. Select **Replace existing dataset**.

The **Confirm Selection** button is activated. Validate your signal selection before the Signal Builder block performs the specified action. If the dialog detects an error, it displays an error message.

- 8 Click the **Confirm Selection** button.
- 9 Click **Apply** to replace the existing signal data with the contents of this file.

When selecting **Replace existing dataset**, the software gives you the opportunity to save the existing contents of the Signal Builder block.

- 10 Click a button, as follows:

| To...                                                                                                                                                                                | Click...                         |
|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------|
| Save the contents of the Signal Builder block before replacing it with the new signal data.                                                                                          | <b>Yes, save as</b>              |
| <b>Note</b> This selection prompts you to save the Signal Builder block in a model name of your choice. The software saves only the Signal Builder block and no other model content. |                                  |
| Replace the contents of the Signal Builder block without saving them first.                                                                                                          | <b>No, import without saving</b> |
| Stop the replacement process.                                                                                                                                                        | <b>Cancel</b>                    |

For this example, select **No, import without saving** to replace the contents of the Signal Builder block.

- 11 The Signal Builder block updates with the new signal data. Click **OK** to close the Import File dialog box and inspect the Signal Builder block.

- 12 Click **OK**.
- 13 Inspect the updated Signal Builder window to confirm that your signal data is intact.
- 14 Close the Signal Builder window and save and close the model. For example, save the model as `signalbuilder1`.

### Appending Selected Signals to All Existing Signal Groups

You can import signals from a signal data file and append selected signals to the end of all existing signal groups. If the signal names to be appended are not unique, the software renames them by incrementing each name by 1 or higher until it is a unique signal name. For example, if the block and data file contain signals named `thermostat`, the software renames the imported signal to `thermostat1` upon appending. If you add another signal named `thermostat`, the software names that latest version `thermostat2`.

This topic uses `signalbuilder1` from the procedure in “Replacing All Signal Data with Selected Data” on page 76-70.

- 1 In the MATLAB Command Window, type `signalbuilder1`.
- 2 Double-click the Signal Builder block.

The Signal Builder window appears.

- 3 In the Signal Builder window, select **File > Import from File**.

The Import File dialog box appears.

- 4 In the **File to Import** field, enter a signal data file name or click **Browse**.

The file browser is displayed.

- 5 If you select the file browser, navigate to and select a signal data file. Select 3Grp\_3Sig.xls.

---

**Note** If you try to import an improperly formatted signal data file, an error message pops up.

---

The **Select data to import** pane contains the signal data from the file. Click the expander to display all the signals.

- 6 Select the signals you want to import. In this example, there are three groups, myGroup1, myGroupB, and myGroup\_Three. Select all the signals in myGroup1.

- 7 From the **Select placement of data** list, select the action to take on the signal data. Select Append selected signals to all groups.

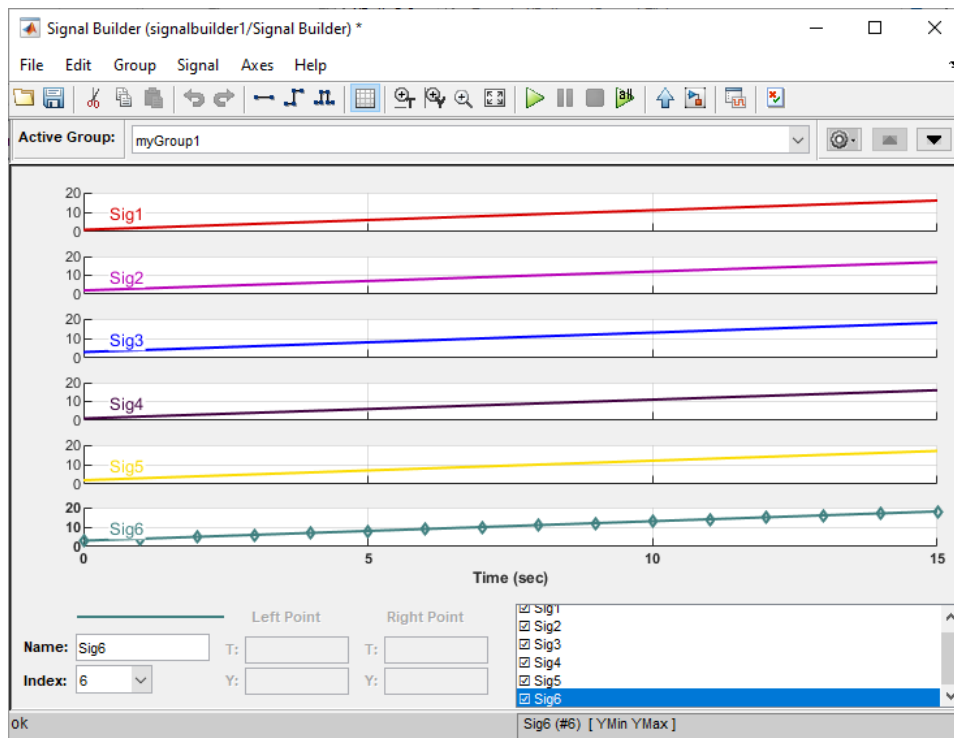

The **Confirm Selection** button is activated. Validate your signal selection before the Signal Builder block performs the specified action. If the signal data selection is not appropriate, **Confirm Selection** remains grayed out. For example, **Confirm Selection** remains grayed out if the number of signals you select is not the same as the number of signals in the Signal Builder group that you want to replace.

- 8 Click the **Confirm Selection** button.

The confirmation also enables the **OK** and **Apply** buttons.

- 9 Click **Apply** to append the selected signals to all the signal groups in the Signal Builder block.
- 10 The Signal Builder block updates with the new signal data. Click **OK** to close the Import File dialog box and inspect the Signal Builder block.

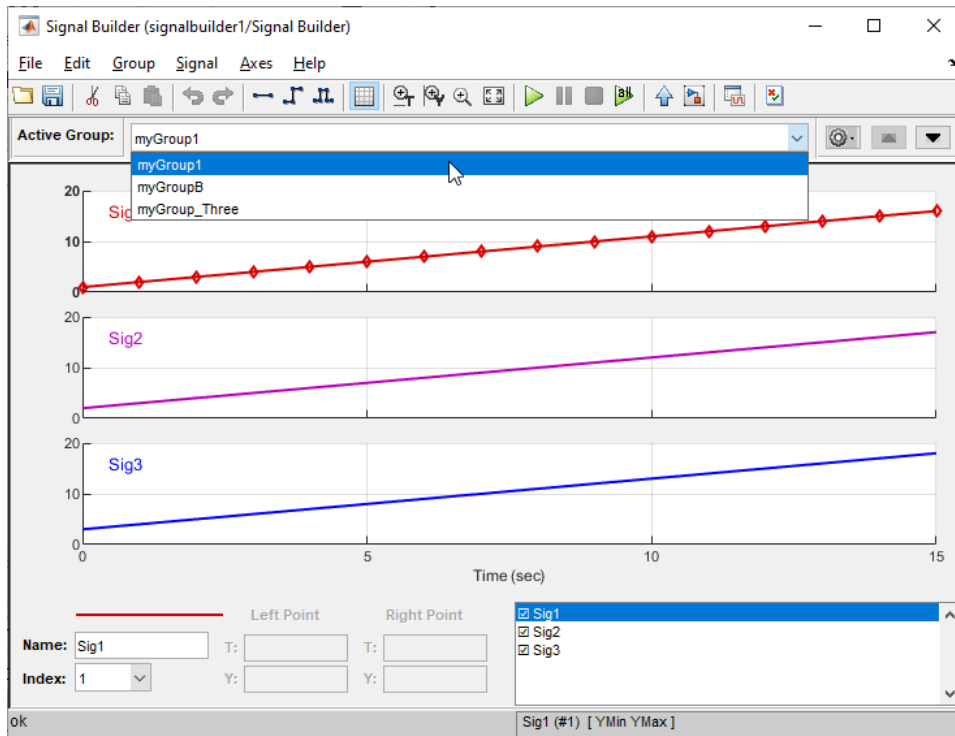

- 11 Click **OK**.
- 12 Inspect the updated Signal Builder window to confirm that your signal data is intact. Notice that the software has renamed the signals Sig1, Sig2, and Sig3 from the signal data file to Sig4, Sig5, and Sig6 in the Signal Builder block.
- 13 Close the Signal Builder window and save and close the model. For example, save the model as `signalbuilder2`.

### Appending Selected Signals to Sequential Existing Signal Groups

You can append signals, in the order in which they are selected, to the end of sequential signal groups. This statement means that you select the same number of signals as there are signal groups, and sequentially append each signal to a different group. The software renames each appended signal to the name of the last appended signal.

This topic uses `signalbuilder1` from the procedure in “Replacing All Signal Data with Selected Data” on page 76-70.

- 1 In the MATLAB Command Window, type `signalbuilder1`.
- 2 Double-click the Signal Builder block.
- 3 Note how many groups exist in the Signal Builder block. For example, this Signal Builder block has three groups, `myGroup1`, `myGroupB`, and `myGroup_Three`.

- 4 In the Signal Builder window, select **File > Import from File**.
- 5 In the **File to Import** field, enter a signal data file name or click **Browse**.
- 6 If you select the file browser, navigate to and select a signal data file. Select 3Grp\_3Sig.xls.

---

**Note** If you try to import an improperly formatted signal data file, an error message pop-up window appears.

---

The **Select data to import** pane contains the signal data from the file. Click the expander to display all the signals.

- 7 Select the signals you want to import. In this example, there are three groups, myGroup1, myGroupB, and myGroup\_Three. Select all the signals in myGroup1.

- 8 From the **Placement for Selected Data** list, select the action to take on the signal data. Select **Append selected signals to different groups (in order)**.

The **Confirm Selection** button is activated. Validate your signal selection before the Signal Builder block performs the specified action.

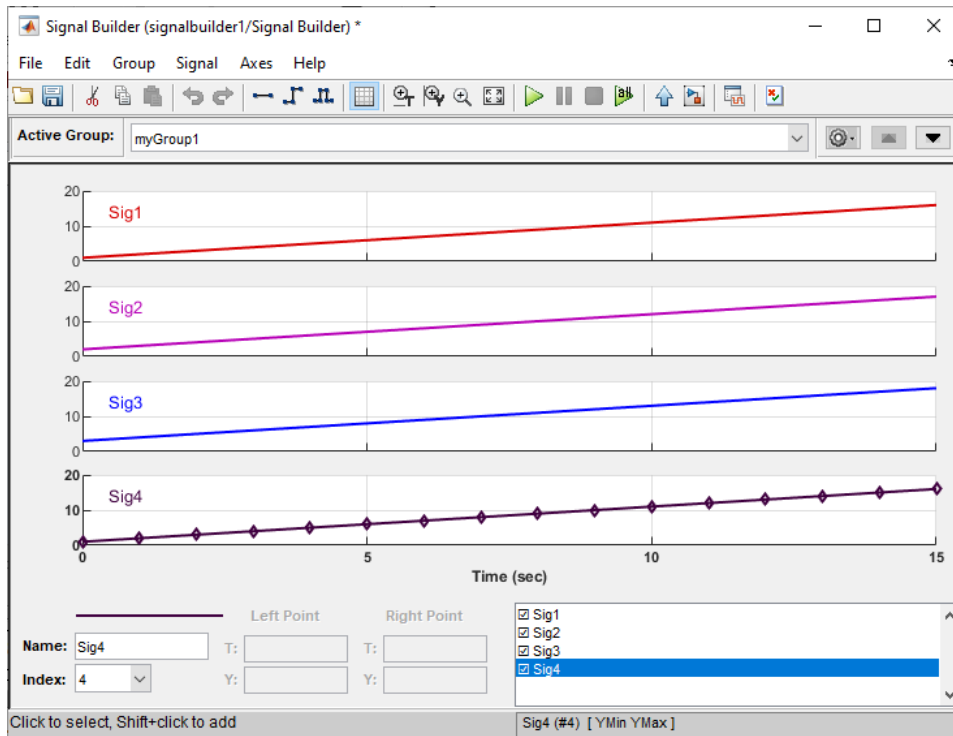

- 9 Click the **Confirm Selection** button.

The confirmation also enables the **OK** and **Apply** buttons.

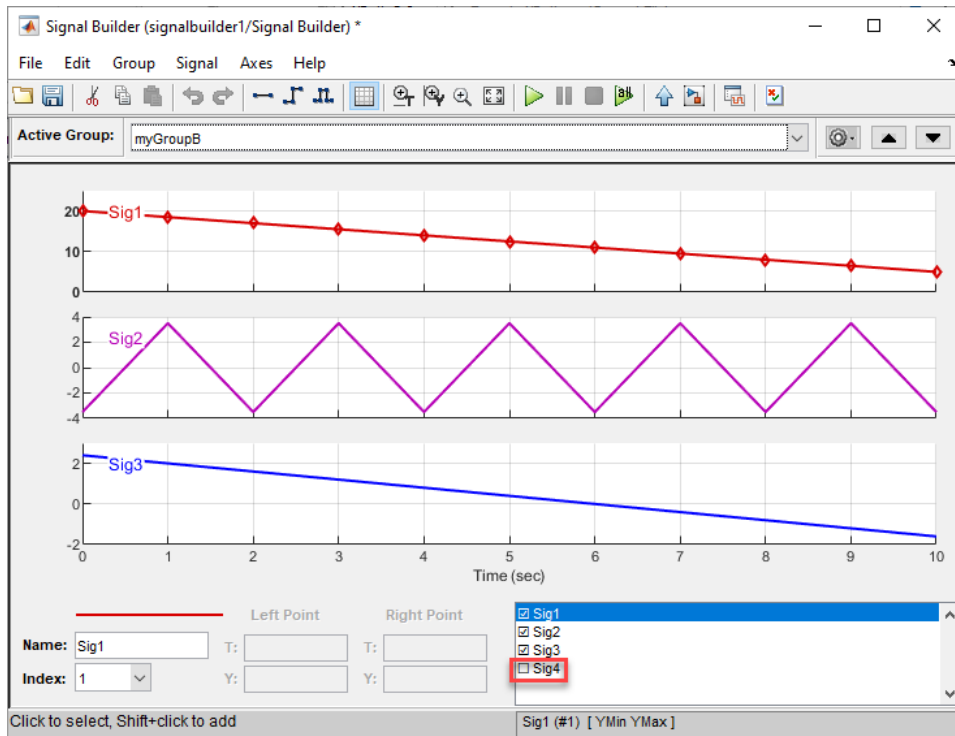

- 10** Click **Apply** to append the signals.

The Signal Builder block updates with the new signal data. Click **OK** to close the Import File dialog box and inspect the three groups of the Signal Builder block.

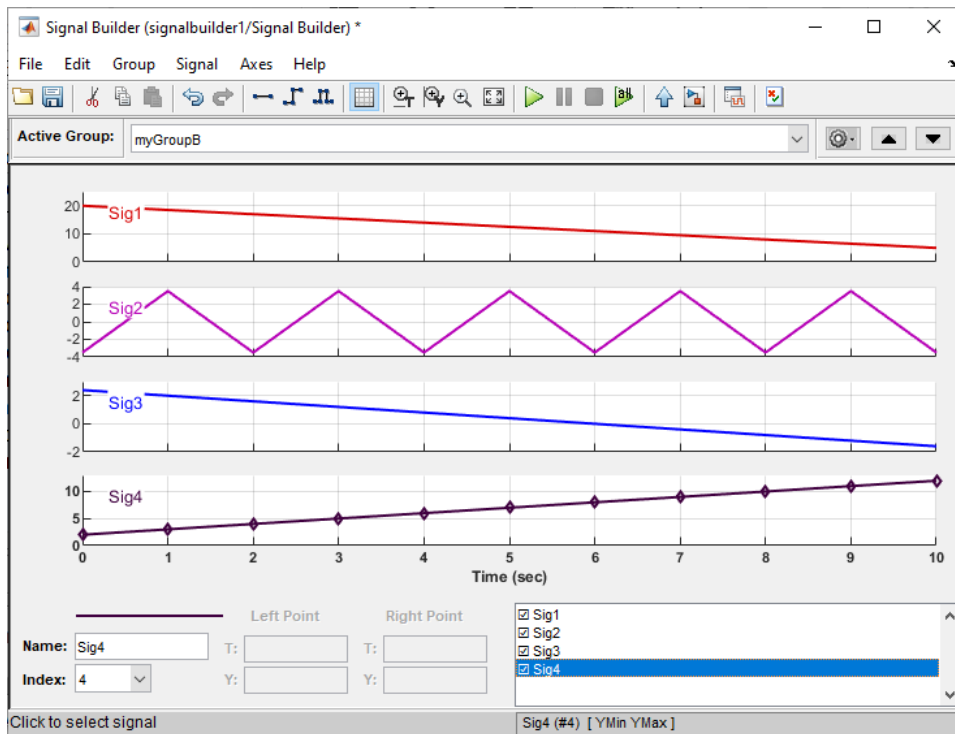

The topmost signal group, myGroup1, shows all signals by default, including the new Sig4.

- 11** Click another group name, for example, myGroupB. Notice that Sig4 exists for the group, hidden by default.

- 12 To show Sig4 on this pane, double-click Sig4 in the Selection Status area of the pane. The graph is updated to reflect Sig4.

- 13 Close the Signal Builder window and save and close the model. For example, save the model as signalbuilder3.

## Appending Signal Groups to Existing Groups

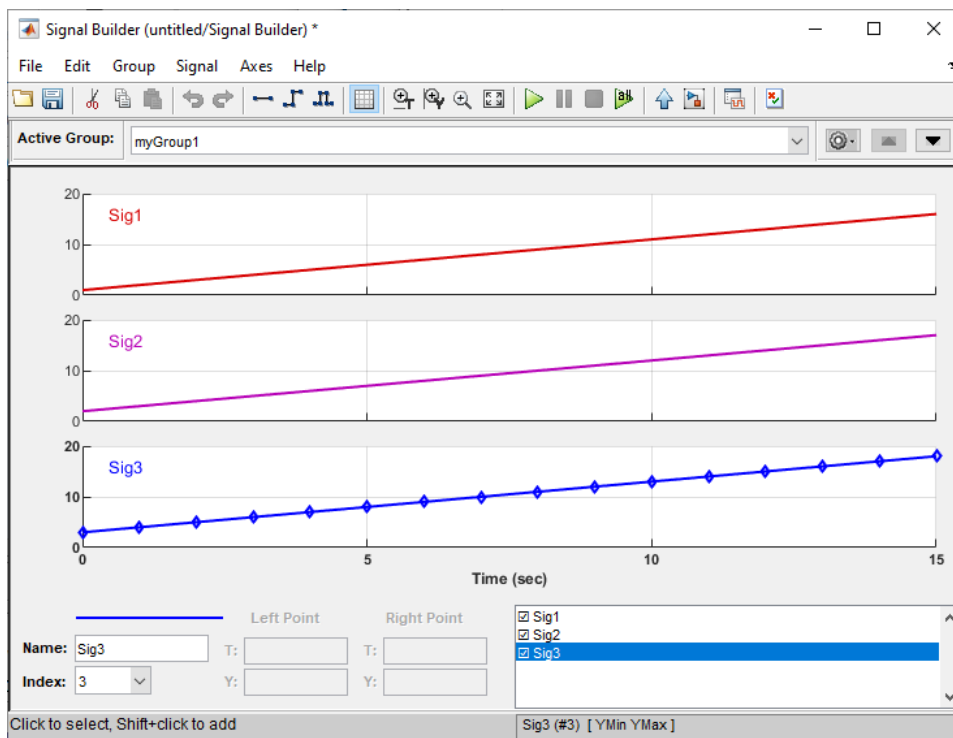

You can append one or more signal groups to the end of the list of existing signal groups. If the block already has a signal group with the same name as the one you are adding, the software increments the group name by 1 or higher until it is unique before adding it. For example, if the block and data file contain groups named MyGroup1, the software renames the imported group to MyGroup2 upon appending. If you add another group named MyGroup1, the software names that latest version MyGroup3.

This topic uses `signalbuilder1` from the procedure in “Replacing All Signal Data with Selected Data” on page 76-70.

- 1 In the MATLAB Command Window, type `signalbuilder1`.
- 2 Double-click the Signal Builder block.

The Signal Builder window appears.

- 3 Note how many groups exist in the Signal Builder block, and how many signals exist in each group. The Signal Builder block requires that all groups have the same number of signals. For example, this Signal Builder block has three groups, `myGroup1`, `myGroupB`, and `myGroup_Three`. Three signals exist in each group.

- 4 Double-click the block.
- 5 In the **File to Import** text field, enter a signal data file name or click **Browse**.
- 6 If you select the file browser, navigate to and select a signal data file. Select `3Grp_3Sig.xls`.

The **Data to Import** pane contains the signal data from the file. Click the expander to display all the signals.

- 7 Evaluate the number of signals in the groups of this data file. If the number of signals in each group equals the number of signals in the groups that exist in the block, you can append one of these groups to the block.
- 8 Select the group you want to import. In this example, there are three groups, myGroup1, myGroupB, and myGroup\_Three. Select myGroupB.

- 9 From the **Placement for Selected Data** list, select the action to take on the signal group. Select **Append groups**.

The **Confirm Selection** button is activated. Validate your signal selection before the Signal Builder block performs the specified action.

- 10 Click the **Confirm Selection** button.

The confirmation also enables the **OK** and **Apply** buttons.

- 11 Click **Apply** to append the signals.

The Signal Builder block updates with the new signal data. Click **OK** to close the Import File dialog box and inspect the groups of the Signal Builder block.

Notice the addition of the new signal group as the last pane. Because there is already a signal group named myGroupB, the software automatically increments the new signal group name by 1. Select myGroupB1.

- 12 Close the Signal Builder window and save and close the model. For example, save the model as `signalbuilder4`.

### Appending Signals with the Same Name to Existing Signal Groups

If you append a signal whose name is the same as a signal that exists in the Signal Builder block, the software increments the name of the appended signal by 1. The software repeats incrementing until the appended signal name is unique. For example:

- 1 Assume your Signal Builder block has a signal group, `myGroup1`, with the signals `Sig1`, `Sig2`, and `Sig3`.
- 2 Append a signal named `Sig1` to `myGroup1`.
- 3 Observe that the software increments `Sig1` to `Sig4` before appending it to `myGroup1`.

### Appending a Group of Signals with Different Signal Names

If you append a signal group whose signal names differ from those that exist in the Signal Builder block, the software changes the names of the existing signals to be the same as the appended signals. For example,

- 1 Assume your Signal Builder block has a signal group, `myGroup1`, with the signals `Sig1`, `Sig2`, and `Sig3`.
- 2 Append a signal group named `myGroup2` whose signal names are `SigA`, `SigB`, and `SigC`.
- 3 Observe that the software:
  - Appends `myGroup2`.
  - Renames the signals in `myGroup1` to be the same as those in `myGroup2`.

## Importing Data with Custom Formats

This topic describes how to import signal data formatted in a custom format. You should already have the signal data from a file whose contents you want to import. See “Importing Signal Groups from Existing Data Sets” on page 76-68 for a description of the data formats that the Signal Builder block accepts. If your data is not formatted using one of these data formats, use the following workflow to import the custom formatted data. This workflow uses the following files, located in the folder `matlabroot\help\toolbox\simulink\examples` (open), as examples:

- `SigBldCustomFile.xls` — Signal data Microsoft Excel file using a format that Signal Builder block does not accept, for example:

|               |         |     |     |     |     |     |     |     |     |      |      |      |      |      |      |      |      |
|---------------|---------|-----|-----|-----|-----|-----|-----|-----|-----|------|------|------|------|------|------|------|------|
| <b>Group1</b> | Time    | 0   | 1   | 2   | 3   | 4   | 5   | 6   | 7   | 8    | 9    | 10   | 11   | 12   | 13   | 14   | 15   |
|               | Signal1 | 1   | 2   | 3   | 4   | 5   | 6   | 7   | 8   | 9    | 10   | 11   | 12   | 13   | 14   | 15   | 16   |
|               | Signal2 | 1   | 2   | 3   | 4   | 5   | 6   | 7   | 8   | 9    | 10   | 11   | 12   | 13   | 14   | 15   | 16   |
|               | Signal3 | 1   | 2   | 3   | 4   | 5   | 6   | 7   | 8   | 9    | 10   | 11   | 12   | 13   | 14   | 15   | 16   |
|               | Signal4 | 1   | 2   | 3   | 4   | 5   | 6   | 7   | 8   | 9    | 10   | 11   | 12   | 13   | 14   | 15   | 16   |
| <b>Group2</b> | Signal1 | 1.6 | 2.6 | 3.6 | 4.6 | 5.6 | 6.6 | 7.6 | 8.6 | 9.6  | 10.6 | 11.6 | 12.6 | 13.6 | 14.6 | 15.6 | 16.6 |
|               | Signal2 | 1.8 | 2.8 | 3.8 | 4.8 | 5.8 | 6.8 | 7.8 | 8.8 | 9.8  | 10.8 | 11.8 | 12.8 | 13.8 | 14.8 | 15.8 | 16.8 |
|               | Signal3 | 2   | 3   | 4   | 5   | 6   | 7   | 8   | 9   | 10   | 11   | 12   | 13   | 14   | 15   | 16   | 17   |
|               | Signal4 | 2.2 | 3.2 | 4.2 | 5.2 | 6.2 | 7.2 | 8.2 | 9.2 | 10.2 | 11.2 | 12.2 | 13.2 | 14.2 | 15.2 | 16.2 | 17.2 |

- `createSignalBuilderSupportedFormat.m` — Custom MATLAB function that reads Microsoft Excel spreadsheets. This example function reformats the custom data, in a format that the Signal Builder block supports, as follows:
  - `grpNames` — Cell array that contains group name character vectors with number of rows = 1, number of columns = number of groups.

- *sigNames* — Cell array that contains signal name character vectors with number of rows = 1, columns = number of signals.
- *time* — Cell array that contains time data with number of rows = number of signals, columns = number of groups.
- *data* — Cell array that contains signal data with number of rows = number of signals, columns = number of groups.

Signal Builder has the following requirements for this custom function:

- Number of signals in each group must be the same.
- Signal names in each group must be the same.
- Number of data points in each signal must be the same.
- Each element in the *time* and *data* cell array holds a matrix of real numbers. This matrix can be [1xN] or [Nx1], where *N* is the number of data points in every signal.

- 1 Identify the format of your custom signal data, for example:

```
SigBldCustomFile.xls
```

- 2 Create a custom MATLAB function that:

- a Uses a MATLAB I/O function to read your custom formatted signal data. For example, `createSignalBuilderSupportedFormat.m`.
- b Formats the custom formatted signal data to one that the Signal Builder block accepts, for example, a MAT-file.

- 3 Use your custom MATLAB function to write your custom formatted signal data to a file that Signal Builder block accepts. For example:

```
createSignalBuilderSupportedFormat('SigBldCustomFile.xls', 'OutputData.mat')
```

- 4 Import the reformatted signal data file, `OutputData.mat`, into the Signal Builder block (see “Importing Signal Group Sets” on page 76-68).

## Editing Waveforms

Signal Builder allows you to change the shape, color, and line style and thickness of the waveforms output by a group.

### Reshaping a Waveform

Signal Builder allows you to change the waveform by selecting and dragging its line segments and points with the mouse or arrow keys or by editing the coordinates of segments or points.

### Selecting a Waveform

To select a waveform, left-click the mouse on any point on the waveform.

The Signal Builder displays the waveform points to indicate that the waveform is selected.

To deselect a waveform, left-click any point on the waveform axis that is not on the waveform itself or press the **Esc** key.

### Working with Points

You can work with points in a waveform:

- To select a point in a waveform, first select the waveform. Then, position the mouse cursor over the point. The cursor changes shape to indicate that it is over a point.

Left-click the point with the mouse. The Signal Builder draws a circle around the point to indicate your selection.

- To insert a point, select the waveform and **Shift+click** the section for the point.
- To deselect the point, press the **Esc** key.
- To delete a point, select the point and press the **Backspace** or **Delete** keys.
- To edit a point with the `signalbuilder` function, use the `signalbuilder set` function to replace the waveform. You cannot programmatically remove a point.

### Selecting Segments

To select a line segment, first select the waveform that contains it. Then, left-click the segment. The Signal Builder thickens the segment to indicate that it is selected.

To deselect the segment, press the **Esc** key.

### Moving Waveforms

To move a waveform, select it and use the arrow keys on your keyboard to move the waveform in the desired direction. Each key stroke moves the waveform to the next location on the snap grid (see “Snap Grid” on page 76-85) or by  $0.1$  inches if the snap grid is not enabled.

## Dragging Segments

To drag a line segment to a new location, position the mouse cursor over the line segment. The mouse cursor changes shape to show the direction in which you can drag the segment.

Press the left mouse button and drag the segment in the direction indicated to the desired location. You can also use the arrow keys on your keyboard to move the selected line segment.

## Dragging points

To drag a point along the signal amplitude (vertical) axis, move the mouse cursor over the point. The cursor changes shape to a circle to indicate that you can drag the point. Drag the point parallel to the y-axis to the desired location. To drag the point along the time (horizontal) axis, press the **Shift** key while dragging the point. You can also use the arrow keys on your keyboard to move the selected point.

## Snap Grid

Each waveform axis contains an invisible snap grid that facilitates precise positioning of waveform points. The origin of the snap grid coincides with the origin of the waveform axis. When you drop a point or segment that you have been dragging, the Signal Builder moves the point or the segment points to the nearest point or points on the grid, respectively. The Signal Builder **Axes** menu allows you to specify the grid horizontal (time) axis and vertical (amplitude) axis spacing independently. The finer the spacing, the more freedom you have in placing points but the harder it is to position points precisely. By default, the grid spacing is 0, which means that you can place points anywhere on the grid; i.e., the grid is effectively off. Use the **Axes** menu to select the spacing that you prefer.

## Inserting and Deleting points

To insert a point, first select the waveform. Then hold down the **Shift** key and left-click the waveform at the point where you want to insert the point. To delete a point, select the point and press the **Del** key.

## Editing Point Coordinates

To change the coordinates of a point, first select the point. The Signal Builder displays the current coordinates of the point in the **Left Point** edit fields at the bottom of the Signal Builder window. To change the amplitude of the selected point, edit or replace the value in the **Y** field with the new value and press **Enter**. The Signal Builder moves the point to its new location. Similarly edit the value in the **T** field to change the time of the selected point.

### Editing Segment Coordinates

To change the coordinates of a segment, first select the segment. The Signal Builder displays the current coordinates of the endpoints of the segment in the **Left Point** and **Right Point** edit fields at the bottom of the Signal Builder window. To change a coordinate, edit the value in its corresponding edit field and press **Enter**.

### Changing the Color of a Waveform

To change the color of a waveform, select the waveform and then select **Color** from the Signal Builder **Signal** menu. The Signal Builder displays the MATLAB color chooser. Choose a new color for the waveform. Click **OK**.

### Changing a Waveform Line Style and Thickness

The Signal Builder can display a waveform as a solid, dashed, or dotted line. It uses a solid line by default. To change the line style of a waveform, select the waveform, then select **Line Style** from the Signal Builder **Signal** menu. Select a line style from the menu.

To change the line thickness of a waveform, select the waveform, then select **Line Width** from the **Signal** menu. Edit the thickness value and click **OK**.

## Signal Builder Time Range

The Signal Builder time range determines the span of time over which its output is explicitly defined. By default, the time range runs from 0 to 10 seconds. You can change both the beginning and ending times of a block time range (see “Changing a Signal Builder Time Range” on page 76-86).

If the simulation starts before the start time of a block time range, the block extrapolates its initial output from its first two defined outputs. If the simulation runs beyond the block time range, the block by default outputs values extrapolated from the last defined signal values for the remainder of the simulation. The Signal Builder **Simulation Options** dialog box allows you to specify other final output options (see “Signal values after final time” on page 76-89 for more information).

---

**Note** When you click the **Start simulation** button on the Signal Builder block toolbar, the simulation uses the stop time of the model. The end of the time range specified in the waveform is not the stop time for the model.

---

### Changing a Signal Builder Time Range

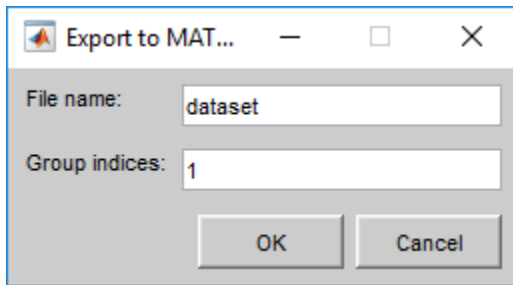

To change the time range, select **Change Time Range** from the Signal Builder **Axes** menu.

In the dialog box, edit the **Min time** and **Max time** fields as necessary to reflect the beginning and ending times of the new time range, respectively.

## Exporting Signal Group Data

You can export data that defines Signal Builder block signals groups to a MAT-file, the MATLAB Workspace, or the Signal Editor block.

To export Signal Builder signal data, formatted as `Simulink.SimulationData.Dataset`, to a MAT-file, select **File > Export Data > To MAT-file**.

- **File name** — Enter a name for the MAT-file to contain the data.
- **Group indices** — Enter one or signal group numbers for which you want to export the data, specified as a scalar or vector. Numbers must correspond to an existing group in the block.

Alternatively, you can use the `signalbuilder get` function to return one or more data sets. For example:

```
[ds1 ds2]=signalbuilder(block,'get',[group1 group2])
```

To export signal data to the MATLAB workspace, select **File > Export Data > To Workspace**.

The Signal Builder exports the data by default to a workspace variable named `channels`. To export to a differently named variable, enter the variable name in the **Variable name** field. The Signal Builder exports the data to the workspace as the value of the specified variable.

The exported data is an array of structures. The structure `xData` and `yData` fields contain the coordinate points defining signals in the currently selected signal group.

To access all the data in the signal groups of a Signal Builder block, use the `signalbuilder get` function:

```
[time, data]=signalbuilder(block,'get',signal,group)
```

For example:

```
% For time 0 to 5, create three signal groups.
block = signalbuilder([], 'create', [0 5], {[2 2] [4 4] [7 8];[0 2] [0 4] [7 10]});
% Get the signals for all three groups.
[time, data]=signalbuilder(block,'get',[1 2],[1:3])
```

```
time =
```

```
2×3 cell array
```

```
 [1×2 double] [1×2 double] [1×2 double]
 [1×2 double] [1×2 double] [1×2 double]
```

```
data =
```

```
2×3 cell array
```

```
 [1×2 double] [1×2 double] [1×2 double]
 [1×2 double] [1×2 double] [1×2 double]
```

To access signal data from the Signal Builder block and export it to the Signal Editor block, select **File > Export Data > To Signal Editor block**.

- 1 From the Signal Builder block, select **File > Export > To Signal Editor block**.

---

**Tip** Alternatively, click .

---

- 2 In the file browser, specify a file name to contain the saved signal data.

A Signal Editor block appears in the model.

- 3 To export the signal data to the Signal Editor block, double-click the block and verify the exported file name in the **File name** parameter.
- 4 To view the imported signal data in the Signal Editor user interface, click **Launch Signal Editor** ()

## Simulating with Signal Groups

You can use standard simulation commands to run models containing Signal Builder blocks or you can use the **Run** or **Run all** button in the Signal Builder window (see “Running All Signal Groups” on page 76-88).

If you want to capture inputs and outputs that the **Run all** button generates, consider using the SystemTest™ software.

### Activating a Signal Group

During a simulation, a Signal Builder block always outputs the active signal group. The active signal group is the group selected in the Signal Builder window for that block, if the dialog box is open. Otherwise, the active group is the group that was selected when the dialog box was last closed. To activate a group, open the group Signal Builder window and select the group.

### Running Different Signal Groups in Succession

The Signal Builder toolbar includes the standard Simulink buttons for running a simulation. This facilitates running several different signal groups in succession. For example, you can open the dialog box, select a group, run a simulation, select another group, run a simulation, and so on, all from the Signal Builder window.

### Running All Signal Groups

To run all the signal groups defined by a Signal Builder block, open the block dialog box and click the

 button from the Signal Builder toolbar. The **Run all** button runs a series of simulations, one for each signal group defined by the block. If you installed Simulink Coverage on your system and are using the Model Coverage Tool, the **Run all** button configures the tool to collect and save coverage data for each simulation in the MATLAB workspace and display a report of the combined coverage results at the end of the last simulation. This allows you to quickly determine how well a set of signal groups tests your model.

---

**Note** To stop a series of simulations started by the **Run all** command, enter **Ctrl+C** at the MATLAB command line.

---

## Simulation from Signal Builder Block

To control simulations from the Signal Builder block, select **File > Simulation Options**.

### Signal values after final time

The setting of this control determines the output of the Signal Builder block if a simulation runs longer than the period defined by the block.

- To output the last defined value of each signal in the currently active group for the remainder of the simulation, select **Hold final value**. For example:

- To output values extrapolated from the last defined value of each signal in the currently active group for the remainder of the simulation, select **Extrapolate**. For example:

- To output zero for the remainder of the simulation, select **Set to zero**. For example:

### Sample time

To output a continuous signal, enter 0 in the **Sample time** parameter. For example, the following display shows the output of a Signal Builder block set to output a continuous Gaussian waveform over a period of 10 seconds.

To output a discrete signal, enter the sample time of the signal in this parameter. The following example shows the output of a Signal Builder block set to emit a discrete Gaussian waveform having a 0.5 second sample time.

### **Enable zero crossing**

To have the Signal Builder block detect zero-crossing events, set **Enable zero crossing** On (default). The Signal Builder block sets the zero-crossing detection on the From Workspace block that you use to create the Signal Builder signal groups. For more information, see “Zero-Crossing Detection” on page 3-10.

## Using Composite Signals

---

## Types of Composite Signals

To reduce visual complexity in a model, you can combine signals into composite signals. The signals that a composite signal contains are called elements. Elements retain their separate identities, which let you extract them from the composite signal.

You can access composite signal elements by name or index, depending on the composite signal type.

- Name-based composite signals allow for signal hierarchy and are called buses.
- Index-based composite signals are flat, regardless of whether you create them in stages. They require that all input signals have the same data type.

When you group signals into a composite signal, you can decide whether they affect simulation and code generation.

- A virtual composite signal simplifies the visual appearance of a model by combining two or more signal lines into one line. It does not group the signals in any functional sense and, therefore, does not affect simulation or code generation. By accessing elements directly, virtual composite signals execute faster than nonvirtual composite signals in simulations and generated code.
- A nonvirtual composite signal visually and functionally groups signals, affecting both simulation and code generation.

Models can use a combination of these composite signal types.

| Composite Signal Feature   | Name-Based Access             | Index-Based Access                 |
|----------------------------|-------------------------------|------------------------------------|
| <b>Visual Grouping</b>     | "Virtual Bus" on page 77-2    | "Mux Signal" on page 77-6          |
| <b>Functional Grouping</b> | "Nonvirtual Bus" on page 77-3 | "Concatenated Signal" on page 77-5 |

You can identify composite signal types by their line style after compiling the model. When you create a line for a composite signal or open a model that contains composite signals, the composite signals have the same line style as scalar signals. To compile the model and show the composite line styles, on the **Modeling** tab, select **Update Model**.

| Composite Line Style After Compile                                                  | Composite Signal Type                                                                         |
|-------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------|
|  | Virtual bus                                                                                   |
|  | Nonvirtual bus                                                                                |
|  | Index-based composite signal when the <b>Nonscalar Signals</b> information overlay is enabled |
|  | Index-based composite signal that contains nonvirtual buses (called an array of buses)        |

### Virtual Bus

This model shows a virtual bus that contains signals a, b, and c.

Bus Creator blocks create buses within a subsystem or model. Bus Selector blocks extract specified elements of the bus.

This model shows an equivalent virtual bus passing through a subsystem boundary.

Out Bus Element blocks create a bus at a subsystem or model interface. In Bus Element blocks extract specified elements of a bus at a subsystem or model interface.

You can use virtual buses to contain bus elements that have different sample times.

To define the properties of a virtual bus, you can specify a `Simulink.Bus` object data type or specify element attributes with In Bus Element and Out Bus Element blocks.

To create a virtual bus, see “Group Signal Lines into Virtual Buses” on page 77-8.

## Nonvirtual Bus

This model shows a nonvirtual bus that contains signals a, b, and c.

Bus Creator blocks create buses within a subsystem or model. Bus Selector blocks extract specified elements of the bus.

This model shows an equivalent nonvirtual bus passing through a model reference boundary using Out Bus Element and In Bus Element blocks.

You can use nonvirtual buses to:

- Package bus data as structures in the generated C code.
- Construct an array of buses.
- Interface with external code through an S-function.
- Have bus data cross MATLAB Function block or Stateflow chart boundaries.
- Display and log buses with a Scope block.

All elements of a nonvirtual bus must use the same sample time. You can use a Rate Transition block to change the sample time of an individual signal or of all signals in a bus.

A `Simulink.Bus` object data type must define the bus you want to make nonvirtual. A bus becomes nonvirtual when you select a block parameter such as **Output as nonvirtual bus**. Selecting to make the bus nonvirtual causes simulation and code generation to apply the structure defined by the `Bus` object. When the bus is virtual, the `Bus` object only validates the properties of the bus.

The type of bus can make a significant difference in the efficiency, size, and readability of the generated code. For a bus to appear in the generated code, it must be nonvirtual. Only the elements of a virtual bus appear in the generated code.

For example, suppose a bus passes through a Unit Delay block. For simplicity, the bus contains only three elements: `a`, `b`, and `c`. This table shows the effect of a nonvirtual bus on the generated code.

| Generated Code            | Virtual Bus                                                                                                                                                                                                                                                                                                | Nonvirtual Bus                                                                                                                                                                                                                                      |
|---------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>model_types.h</i> file | Virtual buses do not require type definitions.                                                                                                                                                                                                                                                             | Bus objects appear in the generated code as structures.<br><br><pre>typedef struct {     real_T a;     real_T b;     real_T c; } BusObject;</pre>                                                                                                   |
| <i>model.h</i> file       | The generated code defines one Unit Delay block for each element of the virtual bus.<br><br><pre>typedef struct {     real_T UnitDelay_1_DSTATE; /* '<root&gt; '<root&gt;="" *="" delay'="" dw_model_t;<="" pre="" real_t="" unit="" unitdelay_2_dstate;="" unitdelay_3_dstate;="" }=""> </root&gt;></pre> | The generated code defines one Unit Delay block for the nonvirtual bus, using the BusObject structure.<br><br><pre>typedef struct {     real_T UnitDelay_DSTATE; /* '<root&gt; *="" busobject;<="" delay'="" pre="" unit="" }=""> </root&gt;></pre> |

To create a nonvirtual bus, see “Create Nonvirtual Buses” on page 77-19.

If you intend to generate code for a model that uses buses, see “Generate Efficient Code for Bus Signals” (Simulink Coder). Generating code for nonvirtual buses can result in multiple copies of some buses.

## Concatenated Signal

This model shows a concatenated signal that places the input matrices side by side.

The Matrix Concatenate block creates concatenated signals. Elements can be either vectors or matrices, depending on how you configure this block. The Selector block extracts signals based on specified indices. The extracted signals can be grouped differently than the input signals.

You can use concatenated signals in mathematical operations.

To group signals with a Vector Concatenate or Matrix Concatenate block, the signals must have the same data type. When the data type is a Bus object, the inputs must be nonvirtual buses.

Concatenated nonvirtual buses are also known as an array of buses. In an array of buses, all elements are nonvirtual buses that use the same Bus object to specify properties. An array of buses is equivalent to an array of structures in MATLAB. You can use an array of buses to model a

multichannel system. While all the channels have the same properties, each of the channels may have a different value.

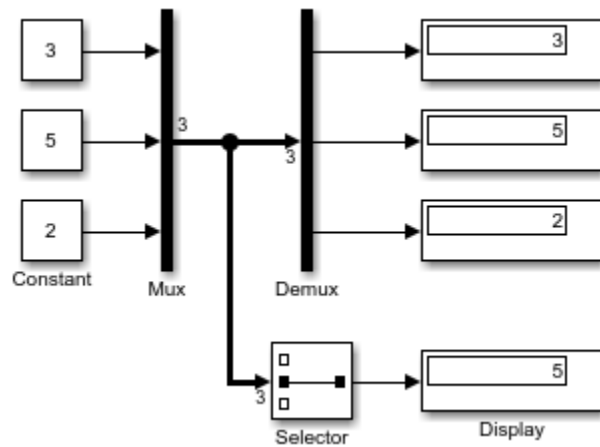

In this model, a Vector Concatenate block creates an array of buses.

For more information on arrays of buses, see “Group Nonvirtual Buses in Arrays of Buses” on page 77-68.

## Mux Signal

This model shows a mux signal that places the three input signals side by side.

The Mux block creates mux signals. The Demux block extracts all signals, which may be grouped differently than the input signals. The Selector block extracts signals based on specified indices. The extracted signals can be grouped differently than the input signals.

You can use a mux signal to perform computations on multiple vectors. You can also use a Mux block to create a vector of function calls.

Input signals for a Mux block can be any combination of scalars, vectors, and mux signals, but they must have the same data type and numeric type. The signals in the output mux signal appear in the same order as the input signals for the Mux block. You can use multiple Mux blocks to create a mux signal in stages, but the result is flat as if you used a single Mux block.

## Group Signal Lines into Virtual Buses

You can combine signals into a bus and then access the bus as a whole or select specific signals from the bus. A virtual Simulink bus is analogous to a bundle of wires held together by tie wraps. For comparison, a nonvirtual Simulink bus is analogous to a struct in C code.

Not all blocks can accept buses and some blocks implicitly convert buses to vectors. To learn which blocks support which types of buses, see “Bus-Capable Blocks” on page 77-39. To identify bus conversions, see “Manage Bus-to-Vector Conversions”.

How you create virtual buses differs based on the location of the signals that you want to group.

- “Group Signal Lines Within a Component” on page 77-8
- “Connect Multiple Output Signals to a Port” on page 77-10
- “Combine Multiple Subsystem Ports into One Port” on page 77-13

To focus on fundamental steps, these examples are simple, however, buses are most useful when you have many signals to combine.

---

**Tip** When you open a model or create a bus, the Simulink Editor does not display bus line styles. To update the line styles, you must compile the model. On the **Modeling** tab of the Simulink Toolstrip, click **Update Model** or **Run**.

---

### Group Signal Lines Within a Component

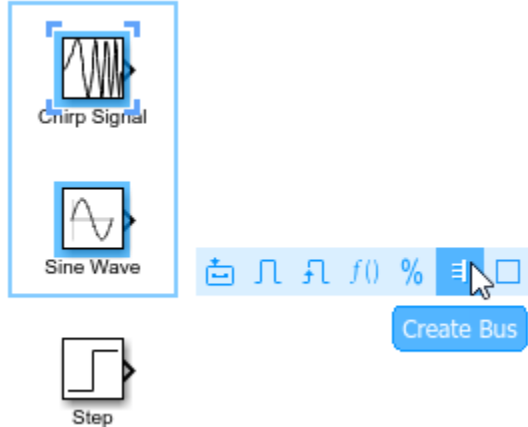

You can group signals into a virtual bus within a component by using Bus Creator blocks.

Open the example model, which contains three blocks.

Copyright 2019 The MathWorks, Inc.

To create a bus that contains the outputs from multiple blocks, drag to select the blocks. For this example, select the Chirp Signal and Sine Wave blocks. In the action bar that appears, click **Create Bus**.

Simulink adds a Bus Creator block and connects the inputs to that block. The output of the Bus Creator block is a virtual bus.

To make identifying the elements of the bus easier, label the inputs to the Bus Creator block. Label the output of the Chirp Signal block by double-clicking the line and entering `Chirp`. Similarly, label the output of the Sine Wave block `Sine`.

To create a second bus that contains the first bus and the output of the Step block, drag to select the Bus Creator and Step blocks. In the action bar that appears, click **Create Bus**. Since the Sine and Chirp signals are elements of the input bus, Simulink creates the same bus regardless of whether your selection includes the Sine Wave and Chirp Signal blocks.

Simulink adds another Bus Creator block and connects the inputs to that block. The output of the Bus Creator block is a virtual bus that contains a nested bus.

You can nest buses to any depth. If one of the inputs to a Bus Creator block is a bus, then its output is a bus hierarchy that contains at least one nested bus.

Label the output of the Step block `Step` and the output of the first Bus Creator block `NestedBus`. Optionally, arrange the blocks to improve the readability of the model.

Connect the output of the second Bus Creator block to a Scope block and label the output `TopBus`. To visually identify the buses, compile the model by clicking **Update Model** or **Run** on the **Modeling** tab of the Simulink Toolstrip. Compiling the model updates the line styles.

## Connect Multiple Output Signals to a Port

This example shows how to group the output signals of a subsystem or model into a virtual bus using Out Bus Element blocks.

Open the example model, which contains three source blocks.

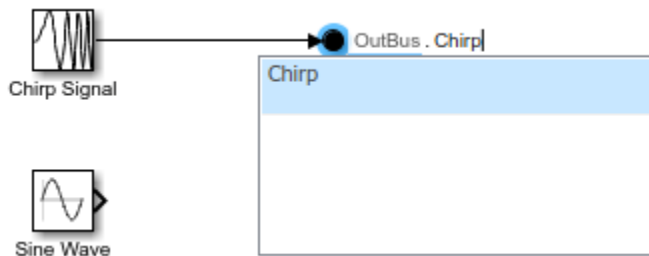

Copyright 2019-2020 The MathWorks, Inc.

Add an Out Bus Element block to the model. An Out Bus Element block is similar to a Bus Creator block connected to an Outputport block. Connect the output of the Chirp Signal block to the Out Bus Element block.

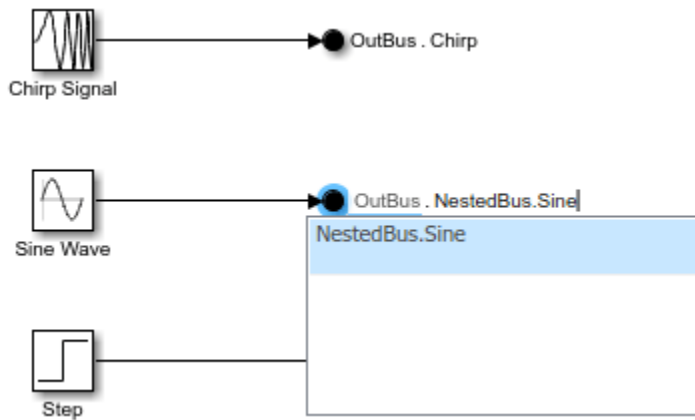

The label next to the Out Bus Element block has two parts. The first part of the label describes the bus (OutBus), and the second part of the label describes the bus element (signal1). To make identifying elements of the bus easier, rename the element by double-clicking signal1 and entering Chirp.

**Ctrl**+drag the Out Bus Element block twice to make two copies of the block. When copying the block this way, specify whether to create a new port or use the existing port. To create one output bus that contains all of the signals, choose **Use Existing Port** each time you copy the block, then connect the signals.

To create hierarchy in the output bus, use dots in the part of the label that describes the bus element. Each dot creates a new level of hierarchy. Create a nested bus named `NestedBus` by defining the bus elements as `NestedBus . Sine` and `NestedBus . Step`, respectively.

Alternatively, you can connect a bus to an Out Bus Element block. If other Out Bus Element blocks correspond to the same port, the bus is nested in the output bus. The part of the label that describes the bus element provides the name of this nested bus.

Inspect the bus hierarchy in the dialog box for the port by double-clicking any of the Out Bus Element blocks.

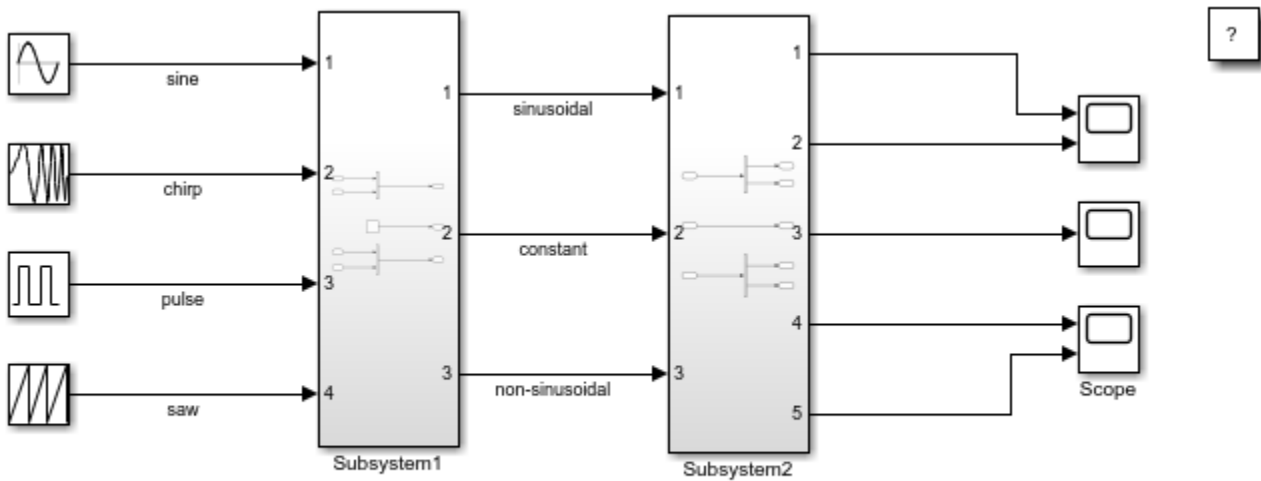

The three Out Bus Element blocks create a virtual bus at the output port of the model. To see the virtual bus, reference the model in another model or move the Out Bus Element blocks into a subsystem. The line styles update when you compile the model. To compile the model, on the **Modeling** tab of the Simulink Toolstrip, click **Update Model** or **Run**.

## Combine Multiple Subsystem Ports into One Port

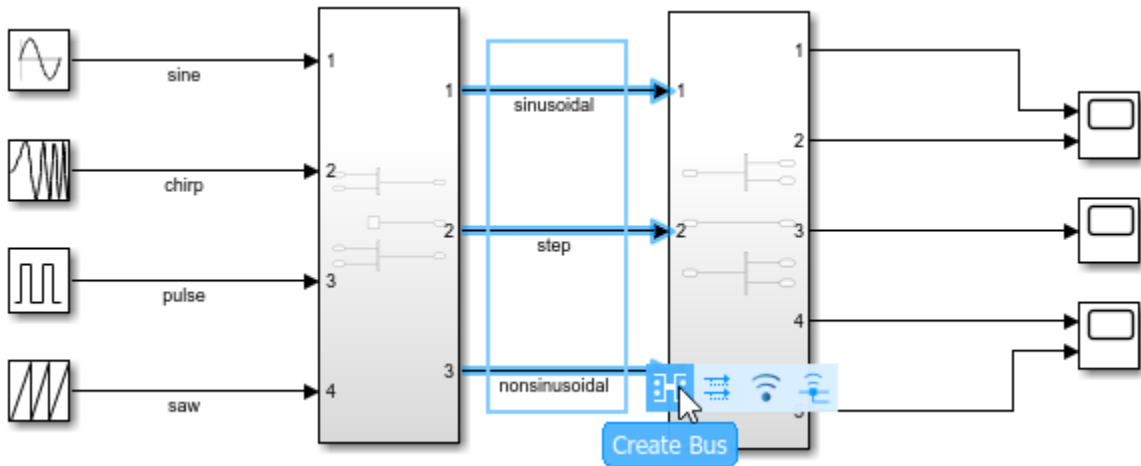

This example shows three ways to simplify a subsystem interface by converting multiple ports and their connected signals into one port and a bus. Model interfaces do not support this automated conversion.

Open the example model, which contains two subsystems with multiple input and output ports.

Copyright 2019 The MathWorks, Inc.

Drag a selection box around the signal lines between the two subsystems. From the action bar that appears, click **Create Bus**.

Simulink replaces the Inport and Outport blocks in the source and destination subsystems with In Bus Element and Out Bus Element blocks.

Drag a selection box around the signal lines between the source blocks and first subsystem. From the action bar that appears, click **Create Bus**.

Simulink adds a Bus Creator block before the first subsystem and replaces the Inport blocks in the first subsystem with In Bus Element blocks.

Drag a selection box around the signal lines between the second subsystem and Scope blocks. From the action bar that appears, click **Create Bus**.

Simulink replaces the Outport blocks in the second subsystem with Out Bus Element blocks and adds a Bus Selector block after the second subsystem.

The resulting model uses virtual buses at the subsystem interfaces.

- “Specify Bus Properties with Simulink.Bus Object Data Types” on page 77-51
- “Specify Initial Conditions for Bus Elements” on page 77-61

## Modify Bus Hierarchy

To view the hierarchy of a bus, right-click on the associated signal line and click **Signal Hierarchy** in the context menu. You can also see the signal hierarchy in the block parameter dialog box for the Bus Creator, Bus Assignment, Bus Selector, In Bus Element, and Out Bus Element blocks.

To change the hierarchy of elements in a bus, you can:

- Separate a bus into its constituent signals with a Bus Selector block, then reassemble the signals with one or more Bus Creator blocks.
- For an Out Bus Element block, edit the second part of the label, which corresponds to the bus element. Suppose you have a bus element named `signal1` and you want to move `signal1` into a nested bus named `NestedBus`. You would change the part of the label that corresponds to the bus element from `signal1` to `NestedBus.signal1`.
- In the Out Bus Element block parameter dialog box, click and drag signals to different hierarchy levels.

To change the order of elements in a bus:

- In the Bus Creator block parameter dialog box, select one signal or adjacent signals, then click the **Up** or **Down** button.
- In the Out Bus Element block parameter dialog box, click and drag signals within their existing hierarchy level.

When you change the bus hierarchy, Simulink automatically handles most of the complexities involved. For example, Simulink repairs broken selections in the Bus Selector and Bus Assignment block parameter dialog boxes due to upstream bus hierarchy changes. By default, the related **Repair bus selections** configuration parameter is set to `Warn` and `repair`. The repairs occur when you update a model.

---

**Tip** To change the value of elements in a bus, use a Bus Assignment block. For details, see “Replace Values of Bus Elements” on page 77-45.

---

## Resolve Circular Dependencies in Buses

Nesting buses can produce a loop of blocks where a bus is an element of itself. This circular definition cannot be resolved and therefore causes an error. To trace the loop, you can use the location cited in the error message.

- 1 Select a signal line associated with the location cited in the error message.
- 2 Right-click a signal and choose **Highlight Signal to Source** or **Highlight Signal to Destination**. See “Highlight Signal Sources and Destinations” on page 76-27 for more information.
- 3 Continue choosing signals and highlighting their sources and destinations until the loop becomes clear.
- 4 Restructure the model to eliminate the circular bus definition.

Because the problem is a circular definition, rather than a circular computation, the cycle cannot be broken by inserting additional blocks. For example, you cannot fix a circular definition the way that

you break an algebraic loop by inserting a Unit Delay block. You must restructure the model to eliminate the circular bus definition.

## Create Nonvirtual Buses

A nonvirtual bus is analogous to a struct in C code. Use nonvirtual buses to:

- Package bus data as structures in generated C code.
- Construct an array of buses.
- Interface with external code through an S-function.
- Have bus data cross MATLAB Function block or Stateflow chart boundaries.
- Display and log buses with a Scope block.

Nonvirtual buses require a `Simulink.Bus` object data type. To simulate a model that contains nonvirtual buses, the referenced `Bus` objects must be in the base workspace or a data dictionary used by the model. For more information, see “Specify Bus Properties with `Simulink.Bus` Object Data Types” on page 77-51.

Nonvirtual buses also require all elements of the bus to have the same sample time. For more information, see “Modify Sample Times for Nonvirtual Buses” on page 77-49.

The way to create nonvirtual buses differs based on the location of the bus and the block that creates the bus:

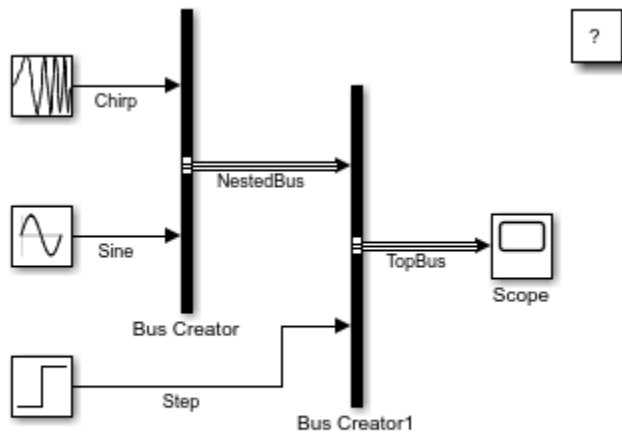

- “Create Nonvirtual Buses Within a Component” on page 77-19
- “Create Nonvirtual Buses at Interfaces” on page 77-21
- “Convert Virtual Bus to Nonvirtual Bus” on page 77-23
- “Create Nonvirtual Bus from MATLAB Structure” on page 77-24

To focus on fundamental steps, these examples are simple. However, buses are most useful when you have many signals to combine.

### Create Nonvirtual Buses Within a Component

You can use Bus Creator blocks to create nonvirtual buses within components.

Open and compile the example model, which uses Bus Creator blocks to create a hierarchy of virtual buses. To compile the model, on the **Modeling** tab of the Simulink Toolstrip, click **Update Model** or **Run**. Compiling the model updates the line styles, which you can use to visually identify buses.

Copyright 2019-2020 The MathWorks, Inc.

To create this model, see “Group Signal Lines Within a Component” on page 77-8.

The virtual buses in this model are not defined by `Simulink.Bus` objects. To change the output of the Bus Creator blocks to nonvirtual buses, you must have Bus objects that match the bus hierarchy.

To create the Bus objects that correspond to `TopBus` and `NestedBus`, use the `Simulink.Bus.createObject` function. In the MATLAB Command Window, enter:

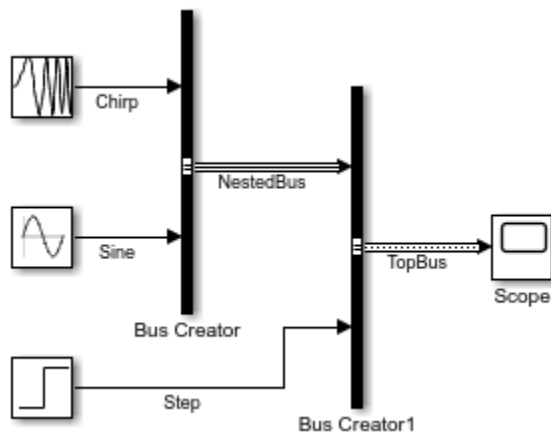

```
Simulink.Bus.createObject('NonvirtualBusCreationModel',...
 'NonvirtualBusCreationModel/Bus Creator1');
```

This function creates the Bus object that corresponds to the output bus of the specified block. If the output bus contains nested buses, the function also creates Bus objects that correspond to the nested buses. In this example, the function creates two Bus objects that are named after the corresponding buses, `TopBus` and `NestedBus`.

To view the Bus objects, open the **Bus Editor**. In the MATLAB Command Window, enter:

```
buseditor
```

Now that you have Bus objects that correspond to the nonvirtual buses you want to create, create the nonvirtual buses. In the Simulink Editor, double-click the Bus Creator block named `Bus Creator1`. In the Block Parameters dialog box, set **Output data type** to `Bus: TopBus`, select the **Output as nonvirtual bus** check box, and click **OK**. `TopBus` is now a nonvirtual bus, while `NestedBus` remains a virtual bus. To identify the nonvirtual bus by line style, compile the model.

Double-click the block named `Bus Creator`. In the Block Parameters dialog box, set **Output data type** to `Bus: NestedBus`, select the **Output as nonvirtual bus** check box, and click **OK**. `NestedBus` is now a nonvirtual bus. To update its line style, compile the model.

If you do not save the Bus objects, then you must recreate the Bus objects when you reopen the model. For information on how to save the Bus objects, see “Specify Bus Properties with Simulink.Bus Object Data Types” on page 77-51.

## Create Nonvirtual Buses at Interfaces

To create a nonvirtual bus at an interface, connect the bus elements to Out Bus Element blocks and specify that the output bus is nonvirtual.

Open the example model, which uses three Out Bus Element blocks to create a virtual bus at the output port, `OutBus`.

Copyright 2019-2020 The MathWorks, Inc.

To create this model, see “Connect Multiple Output Signals to a Port” on page 77-10.

Nonvirtual buses require a `Simulink.Bus` object data type. Create the `Bus` object data type that corresponds to the output bus.

- 1 In the Simulink Toolstrip, on the **Modeling** tab, in the **Design** gallery, select **Bus Editor**.
- 2 In the Bus Editor, create two Bus objects by clicking **Add Bus** twice.
- 3 Name the Bus objects. Select one of the Bus objects, and set **Name** to `OutBus`. Select the other Bus object, and set **Name** to `NestedBus`.
- 4 For each Bus object, create the `Simulink.BusElement` objects that correspond to the elements of the buses. Select `NestedBus`, then click **Add/Insert BusElement** twice. Name the elements `Sine` and `Step`. Select `OutBus`, then click **Add/Insert BusElement** twice. Name the elements `Chirp` and `NestedBus`.
- 5 Specify a Bus object data type for any nested buses. With the `NestedBus` `BusElement` object selected, set **Data type** to `Bus: NestedBus`, then click **Apply**.

To output a nonvirtual bus, specify the Bus object data type and bus virtuality.

- 1 Open the dialog box for the port by double-clicking one of the Out Bus Element blocks.
- 2 In the tree hierarchy of the dialog box, pause on `OutBus`, and click the pencil icon that appears next to `OutBus`.
- 3 Specify the Bus object data type. Set **Data type** to `Bus: OutBus`.
- 4 In the tree hierarchy of the dialog box, click the signal attributes that now appear next to `OutBus`.
- 5 Specify the bus virtuality. Set **Bus virtuality** to `nonvirtual`, then close the dialog box.

The output of the model is a nonvirtual bus. To see the nonvirtual bus, reference the model in another model or move the Out Bus Element blocks into a subsystem. The line styles update when you compile the model. To compile the model, on the **Modeling** tab of the Simulink Toolstrip, click **Update Model** or **Run**.

If you do not save the Bus objects, then you must recreate the Bus objects when you reopen the model. For information on how to save the Bus objects, see “Specify Bus Properties with Simulink.Bus Object Data Types” on page 77-51.

Root (top-level) Inport and Outport blocks can also create nonvirtual buses at interfaces. To specify the bus virtuality:

- For a root Inport block, on the **Signal Attributes** tab of the dialog box, select **Output as nonvirtual bus**.
- For a root Outport block, on the **Signal Attributes** tab of the dialog box, select **Output as nonvirtual bus in parent model**.

In Bus Element blocks use the **Bus virtuality** parameter to determine whether they inherit or define the bus virtuality. If the block defines the bus virtuality and the virtuality of the input bus does not match, compiling the model produces an error.

## Convert Virtual Bus to Nonvirtual Bus

You can convert a virtual bus to a nonvirtual bus anywhere within a model by using a Signal Conversion block.

Open and compile the example model, which contains a virtual bus hierarchy created by Bus Creator blocks. To compile the model, on the **Modeling** tab of the Simulink Toolstrip, click **Update Model** or **Run**. Compiling the model updates the line styles, which you can use to visually identify buses.

Copyright 2019-2020 The MathWorks, Inc.

To define the buses and support conversion to nonvirtual buses, the Bus Creator blocks specify `Simulink.Bus` object data types. To create the Bus objects in the base workspace when the model is loaded, the model uses the `PreLoadFcn` callback.

To view the callback, in the Simulink Toolstrip, on the **Modeling** tab, click **Model Settings > Model Properties**. In the Model Properties dialog box, open the **Callbacks** tab and select the **PreLoadFcn** model callback.

To convert a virtual bus to a nonvirtual bus, use a To Nonvirtual Bus block, which is a preconfigured version of the Signal Conversion block that has **Output** set to `Nonvirtual bus`.

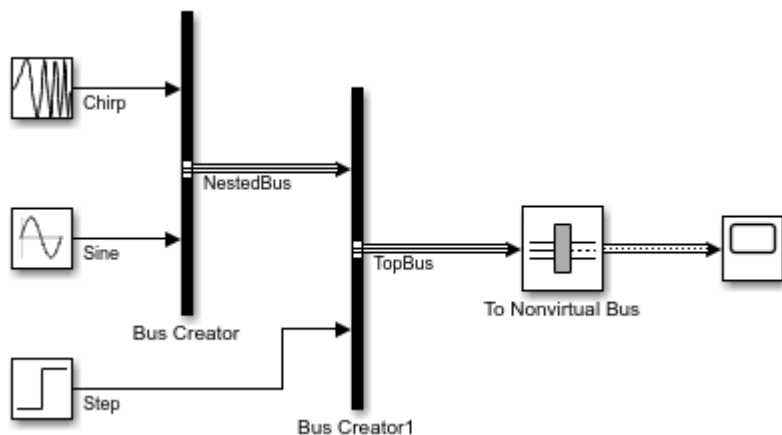

In the example model:

- 1 Add a To Nonvirtual Bus block to the model.
- 2 Drag the To Nonvirtual Bus block onto the line between the Bus Creator1 and Scope blocks. When you drag the block onto the line, the block connects to the line at both ends.

Suppose the data type of the bus you want to convert is not specified by a Bus object. You would need to perform these additional actions:

- 1 Creating the corresponding Bus objects.
- 2 Specifying the Bus object data type for the bus. For example, setting the **Data type** parameter of the To Nonvirtual Bus block to the Bus object that corresponds to the input bus.

The input to the To Nonvirtual Bus block is a virtual bus, and the output is a nonvirtual bus. To see the nonvirtual bus line style, compile the model.

## Create Nonvirtual Bus from MATLAB Structure

You can use a Constant block to compactly represent a nonvirtual bus with constant-valued elements.

On the Constant block, specify:

- A MATLAB structure for **Constant value**.
- A `Simulink.Bus` object as the **Output data type**.

Constant blocks only support MATLAB structures when the output data type is a Bus object.

For example, define a MATLAB structure named `const_param_struct` with elements named `Offset`, `Gain`, and `Threshold`.

```
const_param_struct.Offset = 197;
const_param_struct.Gain = 4.32;
const_param_struct.Threshold = 795.68;
```

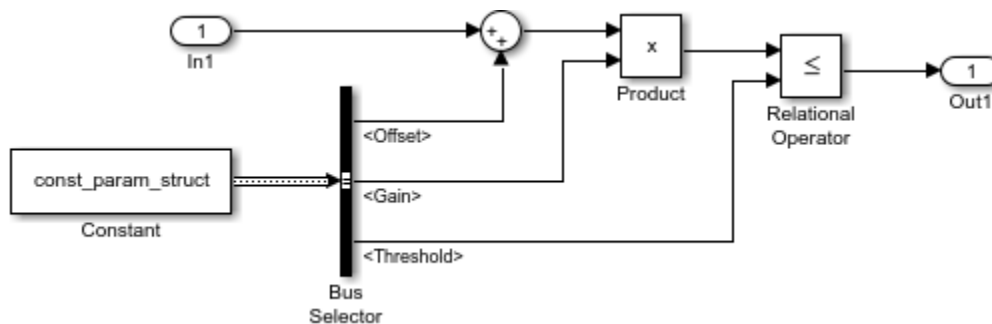

Define the corresponding Bus object data type.

```
Simulink.Bus.createObject(const_param_struct)
```

The new Bus object uses the default name `slBus1`.

Open and simulate the example model, which contains a Constant block with **Constant value** set to `const_param_struct` and **Output data type** set to Bus: `slBus1`.

```
open_system('NonvirtualBusFromStructModel')
sim('NonvirtualBusFromStructModel');
```

The output of the Constant block is a nonvirtual bus.

## Simplify Subsystem and Model Interfaces with Buses

Buses simplify subsystem and model interfaces by letting you associate multiple signals or messages with one port. They reduce line complexity and clutter in a block diagram, make it easier to change the interface incrementally, and allow access to elements closer to their point of usage.

For example, this model contains subsystems where each subsystem interface has multiple ports.

This equivalent model uses buses and has one port per subsystem interface.

For buses at interfaces, use In Bus Element and Out Bus Element blocks instead of Inport and Bus Selector blocks for inputs and Outport and Bus Creator blocks for outputs. In Bus Element and Out Bus Element blocks support multirate virtual buses and do not require Simulink.Bus objects at model interfaces, unlike Inport and Outport blocks. They also provide cleaner bus interfaces.

For example, this model uses Inport, Bus Selector, Bus Creator, and Outport blocks.

This equivalent model uses In Bus Element and Out Bus Element blocks.

At the interface you want to update, the lines and blocks must not have nondefault specifications that could cause conflicts. For example, the line between a Bus Creator block and an Outport block must not be named or marked for signal logging. Similarly, while you can specify a `Simulink.Bus` object data type for an output port, you must not specify a nondefault data type for an element of the output port, such as `TopBus1.NestedBus1`.

The following examples demonstrate how to update interfaces to use In Bus Element and Out Bus Element blocks. The example models are simple, however, buses are most useful when you have many elements to combine.

## Combine Multiple Subsystem Ports into One Port

This example shows three ways to simplify a subsystem interface by converting multiple ports and their connected signals into one port and a bus. Model interfaces do not support this automated conversion.

Open the example model, which contains two subsystems with multiple input and output ports.

Copyright 2019 The MathWorks, Inc.

Drag a selection box around the signal lines between the two subsystems. From the action bar that appears, click **Create Bus**.

Simulink replaces the Inport and Outport blocks in the source and destination subsystems with In Bus Element and Out Bus Element blocks.

Drag a selection box around the signal lines between the source blocks and first subsystem. From the action bar that appears, click **Create Bus**.

Simulink adds a Bus Creator block before the first subsystem and replaces the Inport blocks in the first subsystem with In Bus Element blocks.

Drag a selection box around the signal lines between the second subsystem and Scope blocks. From the action bar that appears, click **Create Bus**.

Simulink replaces the Outport blocks in the second subsystem with Out Bus Element blocks and adds a Bus Selector block after the second subsystem.

The resulting model uses virtual buses at the subsystem interfaces.

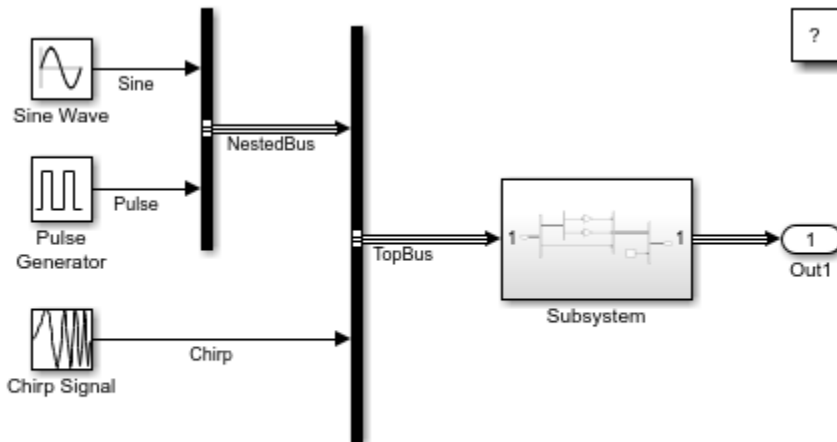

### Simplify Bus Interfaces in Subsystems and Models

This example shows how to convert a subsystem or model interface that uses Inport, Bus Selector, Bus Creator, and Outport blocks to use In Bus Element and Out Bus Element blocks.

Open the example model, which contains a subsystem that modifies an input bus hierarchy using Bus Selector and Bus Creator blocks. The subsystem uses Inport and Outport blocks for input and output.

Compile the model to update line styles, which you can use to visually identify buses. In the Simulink Toolstrip, on the **Modeling** tab, click **Update Model** or **Run**.

Copyright 2019 The MathWorks, Inc.

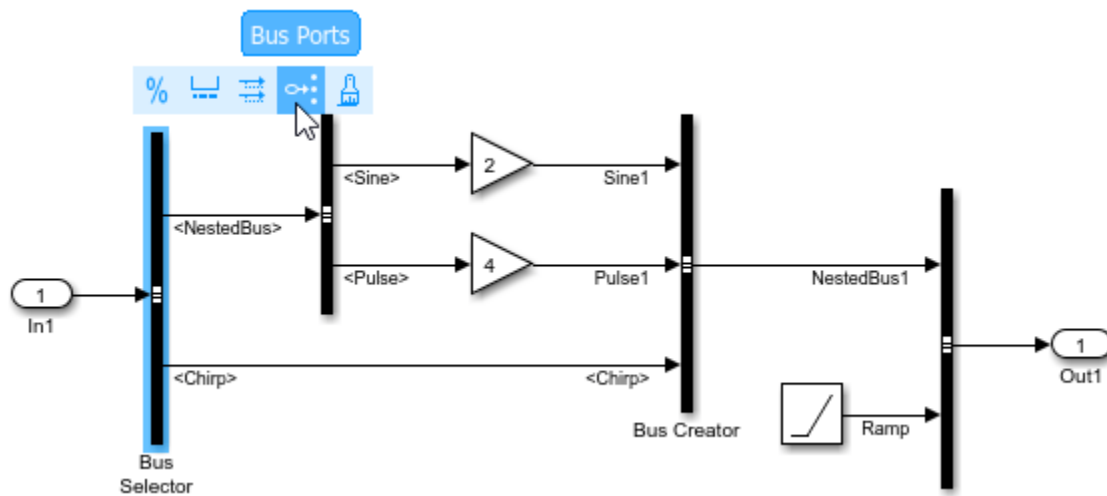

Open the subsystem.

To convert Inport and Bus Selector blocks to In Bus Element blocks:

- 1 Click a Bus Selector block that directly connects to an Inport block.
- 2 In the action bar that appears when you pause over the ellipsis, click **Bus Ports**.

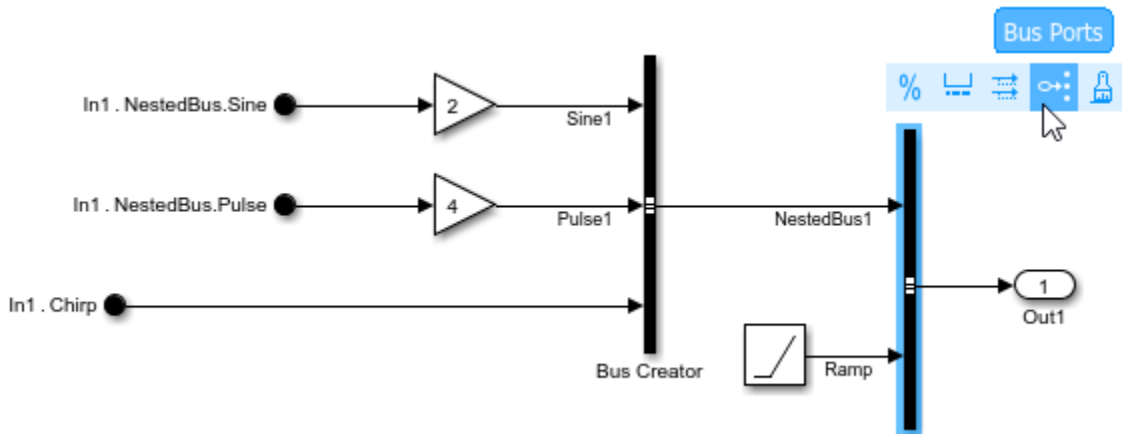

You can similarly convert an In Bus Element and Bus Selector block.

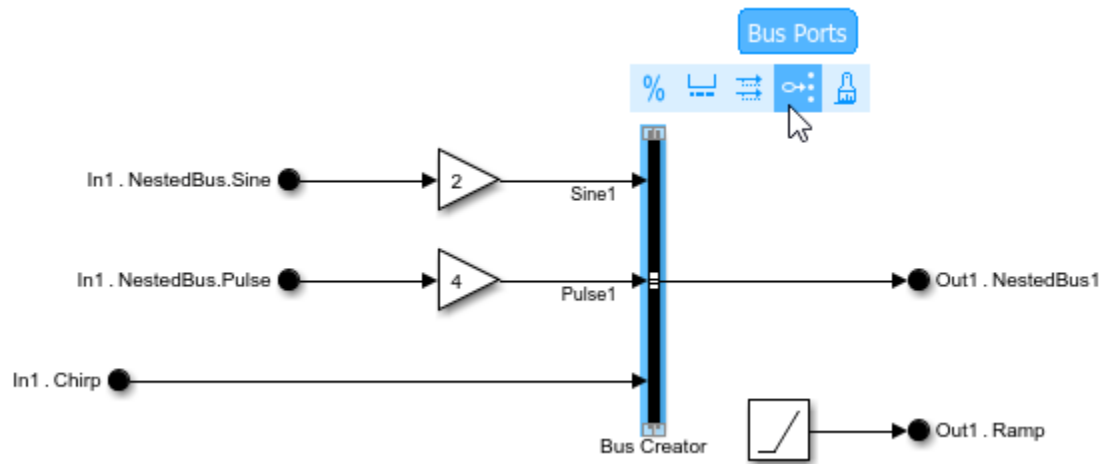

To convert Outport and Bus Creator blocks to Out Bus Element blocks:

- 1 Click a Bus Creator block that directly connects to an Outport block without branching.
- 2 In the action bar that appears when you pause over the ellipsis, click **Bus Ports**.

You can similarly convert Out Bus Element and Bus Creator blocks.

The resulting model simplifies line routing, makes it easier to incrementally change the interface, and lets you access elements closer to their point of usage.

You can change the name of a bus and its elements by double-clicking the block labels and editing them.

To easily identify elements of the same nested bus or bus port, specify block colors.

- 1 Double-click an In Bus Element or Out Bus Element block to open the dialog box for the related port.
- 2 Select an element or the top bus.
- 3 Specify the background color with the **Set color** dropdown menu.

## Use Buses at Model Interfaces

Bus input for a Model block must be consistent with the bus expected by the referenced model.

If you use a bus as an input to or an output from a referenced model:

- Only a nonvirtual bus can contain variable-size signal elements.
- For code generation, you can only configure the I/O arguments `step` method style of C++ class interface for the referenced model when using a nonvirtual bus or when using the `Default` style of C++ class interface.
- For code generation, you can only configure function prototype control for the referenced model when using a nonvirtual bus.

## Display Bus Information

You can display bus information using multiple approaches.

- To display whether a bus is virtual or nonvirtual, update or simulate the model. A virtual bus appears as three solid lines () and a nonvirtual bus appears as two solid lines on either side of a dashed line ()
- To interactively display the hierarchy of a bus, see “Display Bus Hierarchy” on page 77-35.
- To interactively display the value of bus elements at a port, see “Display Value of Bus Elements” on page 77-36.
- To programmatically display the virtuality and hierarchy of a bus, see “Programmatically Get Bus Hierarchy and Virtuality” on page 77-37.

### Display Bus Hierarchy

To interactively display bus hierarchy:

- 1 Click a signal line.
- 2 On the **Signal** tab, select **Signal Hierarchy**.

A Signal Hierarchy Viewer opens, showing the signal hierarchy for the selected signal.

For example, this Signal Hierarchy Viewer shows the signal hierarchy for a bus named `main_bus`.

Each Signal Hierarchy Viewer is associated with a specific model. If you edit a model while the associated Signal Hierarchy Viewer is open, the Signal Hierarchy Viewer reflects those updates.

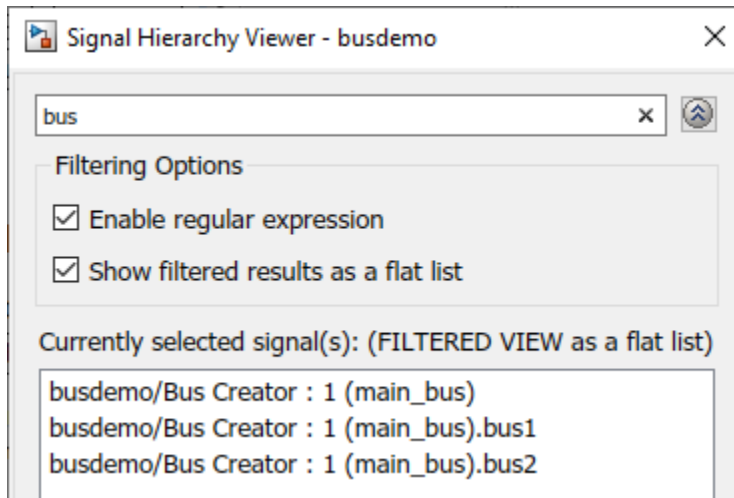

---

**Note** To produce accurate results at edit time in the Signal Hierarchy Viewer, your model must compile successfully.

---

To filter the displayed signals, click the **Options** button  on the right side of the **Filter by name** edit box.

- To use MATLAB regular expressions for filtering signal names, select **Enable regular expression**. For example, to display all signals whose names end with a lowercase r (and their immediate parents), enter r\$ in the **Filter by name** edit box. For more information, see “Regular Expressions”.
- To display a flat list of the filtered results, select **Show filtered results as a flat list**. The flat list uses dot notation to indicate the hierarchy of buses. This example shows a filtered set of nested buses.

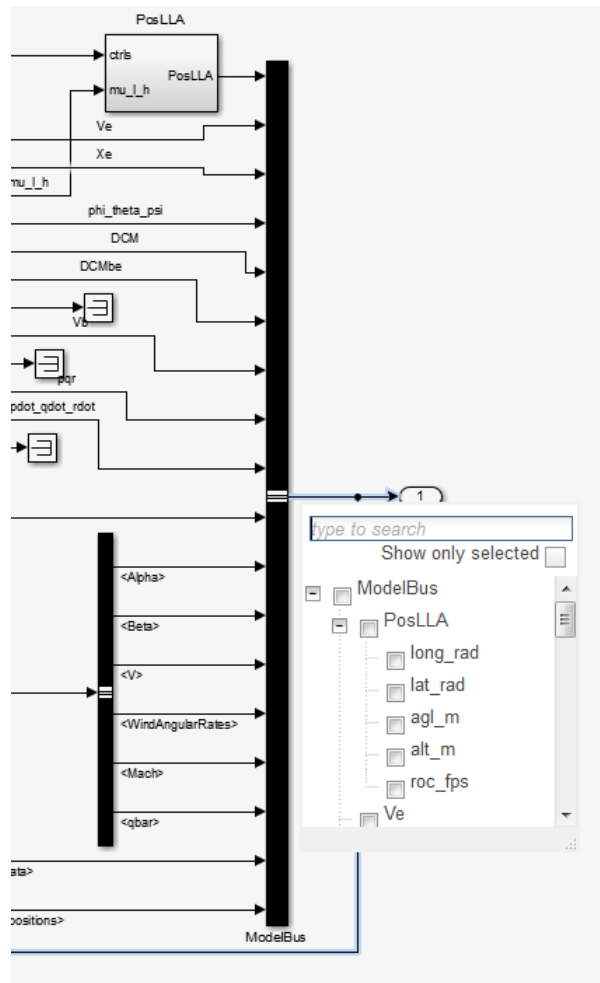

## Display Value of Bus Elements

To interactively display the values of bus elements at a port:

- 1 Click a signal line.
- 2 On the **Signal** tab, select **Output Value Label**.
- 3 Click the port value label, and select the signals you want to display.

For example, in this model, you can select which signals to display from the signals that are contained in ModelBus.

For more information, see “Display Value for a Specific Port” on page 36-21.

## Programmatically Get Bus Hierarchy and Virtuality

To programmatically get the hierarchy and virtuality of a bus in a compiled model, query these parameters with the `get_param` function:

- `'SignalHierarchy'` — If the signal is a bus, returns the name and hierarchy of the signals in the bus.
- `'CompiledBusType'` — For a model that is in the `'compile'` phase, returns information about whether the signal connected to a port is a bus and whether the signal is a virtual or nonvirtual bus. Before you query the `CompiledBusType` parameter value, use the `model` function to put the model in the `'compile'` phase.

For example, open and simulate the `busdemo` model.

```
open_system('busdemo')
sim('busdemo');
```

Obtain the handle of the port for which you want bus information.

```
ph = get_param('busdemo/Bus Creator', 'PortHandles');
```

Get the signal hierarchy at the port.

```
sh = get_param(ph.Outport, 'SignalHierarchy')
```

```
sh = struct with fields:
 SignalName: 'main_bus'
 BusObject: ''
 Children: [2x1 struct]
```

Get the compiled bus type at the port while the model is compiling.

```
busdemo([],[],[],'compile');
bt = get_param(ph.Outport, 'CompiledBusType')
```

```
bt =
'VIRTUAL_BUS'
```

Terminate compilation.

```
busdemo([],[],[],'term');
```

## Bus-Capable Blocks

Blocks that support buses or arrays of buses can accept them as input, produce them as output, store them in memory, or perform a combination of these options. Block support for buses and arrays of buses can depend on block parameter settings.

This table describes whether a block supports virtual buses, nonvirtual buses, and arrays of buses.

**Note** Buses that contain signals of enumerated data types do not pass through a block that requires a nonzero scalar initial value (such as a Unit Delay block). Use a structure value to initialize signals with enumerated types.

| Block                                                                 | Virtual Bus Support                                                                                                    | Nonvirtual Bus Support | Array of Buses Support                                                                                                                           |

## Replace Values of Bus Elements

To assign the value of an input to a bus element, you can use a Bus Assignment block. Use a Bus Assignment block to change bus element values without adding Bus Selector and Bus Creator blocks that select bus elements and reassemble them into a bus.

Connect to the Bus Assignment block ports:

- The bus to which you want to assign the values
- The lines whose values you want to assign to specified bus elements

Connect the bus to the first input port of the Bus Assignment block, and one or more lines with values to be assigned to the other ports. The Block Parameters dialog box lists the elements available for assignment in the bus. The bus can be virtual or nonvirtual. Select the elements to which you want to assign values. If you specify more than one element to assign values to, the Bus Assignment block adds ports.

The elements that you assign values to can be nonbus or bus signals. The new values must match the attributes of the elements in the original bus.

### Update a Bus Element

This simple example illustrates the mechanics of using the Bus Assignment block. In more complex models, using a Bus Assignment block simplifies updating a bus to reflect the processing that occurs in a separate component, such as a subsystem or referenced model. Here is the model after you simulate it.

Some key steps in constructing this model are:

- 1 Connect two Constant blocks to a Bus Creator block. The value of signal a is 1, and the value of signal b is 2.
- 2 Connect the Bus Creator output bus `const_bus` to the first port of a Bus Assignment block. The bus elements a and b are available to assign new values to them.
- 3 Connect the Constant block output signal c to the second port of the Bus Assignment block.
- 4 For the Bus Assignment block, in the Block Parameters dialog box **Elements in the bus** list, select the a signal and click **Select**.
- 5 Use a Bus Selector to select signals a and b from the `const_bus` bus and connect those signals to Display blocks.

- 6 Simulate the model. The Display blocks show that the value of signal `a`, which was 1 when the `const_bus` bus was created, is now 3, reflecting the assignment of the `c` signal from the `Const3` block.

## Identify Automatic Bus Conversions

To comply with composite signal requirements and limitations, Simulink may add hidden Bus to Vector and Signal Conversion blocks to your model. These additions help you avoid manually converting or refactoring your models, which can be time consuming and error prone.

### Bus-to-Vector Conversions

When a block requires a vector but receives a virtual bus, a hidden Bus to Vector block may convert the bus to a vector. Bus to Vector blocks are virtual and do not affect simulation results, code generation, or performance. However, when a bus is treated as a vector, the elements of the bus become inaccessible.

To receive warnings or errors when a bus is treated as a vector, set the **Bus signal treated as vector** configuration parameter to **warning** or **error**, respectively. These settings allow you to identify potential problems at the source, instead of at downstream blocks that expect a bus.

To correct buses used as vectors:

- In the Model Advisor for the top model, run the “Check bus signals treated as vectors” check and perform the recommended actions.
- Use the `Simulink.BlockDiagram.addBusToVector` function to add Bus To Vector blocks where Simulink would implicitly convert buses to vectors. For an example, see “Manage Bus-to-Vector Conversions”.
- Replace the related Bus Creator block with a Mux block, which creates a vector.

### Virtual and Nonvirtual Bus Conversions

When updating a diagram before simulation or code generation, Simulink might automatically convert a virtual bus to a nonvirtual bus or a nonvirtual bus to a virtual bus. For example, Simulink implicitly converts a bus when:

- A block, such as an S-Function block or a Stateflow chart, receives a virtual bus but requires a nonvirtual bus.
- A referenced model receives a nonvirtual bus, but the corresponding Inport block specifies a virtual bus.
- A root-level Outport block receives a nonvirtual bus but specifies a virtual bus.

Simulink inserts hidden Signal Conversion blocks into the model where needed. If a `Simulink.Bus` object is not specified for a virtual bus, the conversion to a nonvirtual bus fails, and you receive an error.

Unlike Bus to Vector blocks, Signal Conversion blocks do not affect the structure of the output bus.

By default, In Bus Element and Out Bus Element blocks inherit the bus virtuality from the bus. When they specify either a virtual or nonvirtual bus, they produce an error instead of automatically converting the bus virtuality.

- “Use Buses at Model Interfaces” on page 77-34

## Modify Sample Times for Nonvirtual Buses

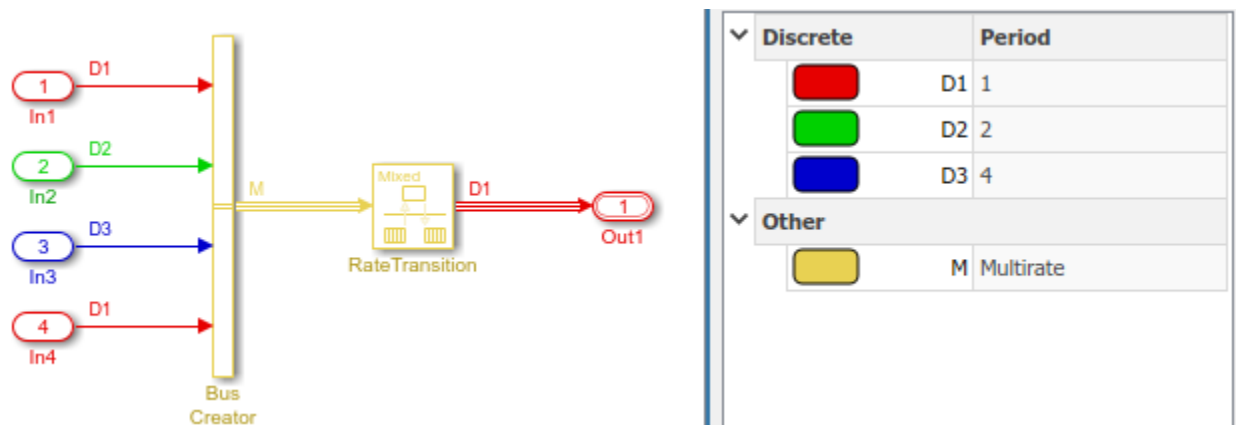

Unlike virtual buses, which can combine signals that have different sample times, all of the signals in a nonvirtual bus must have the same sample time.

To group signals with different sample times in a nonvirtual bus, make the sample times of the input signals the same by inserting Rate Transition blocks.

Suppose a model creates a nonvirtual bus using a Bus Creator block. To standardize the sample time of the input signals, the model uses three Rate Transition blocks before the Bus Creator block.

Suppose another model converts a virtual bus to a nonvirtual bus using a root-level Outport block. To standardize the sample time of the elements of the virtual bus, the model uses a single Rate Transition block before the Outport block.

Alternatively, specify the same sample time at each block that generates an element of the bus.

**Tip** To output a multirate virtual bus from a model, use Out Bus Element blocks.

## Specify Bus Properties with Simulink.Bus Object Data Types

A bus can be associated with a `Simulink.Bus` object, which specifies properties that Simulink uses to validate the bus. Bus objects are optional for virtual buses, but required for nonvirtual buses.

A Bus object specifies only the architectural properties of a bus, as distinct from the values of the signals it contains. For example, a Bus object can specify the number of elements in a bus, the order of those elements, whether and how elements are nested, and the data types of constituent signals; but not the signal values.

A Bus object is analogous to a structure definition in C: it defines the members of the bus, but does not create the bus. A Bus object is also similar to a cable connector. The connector defines all the pins and their configuration and controls what types of wires can be connected to it. Similarly, a Bus object defines the configuration and properties of the signals that the associated bus must have.

### Simulink.Bus Object Workflow

Using Bus objects in a model involves performing these tasks, in many cases iteratively.

- 1 “Determine Whether to Use Simulink.Bus Objects” on page 77-51
- 2 “Determine How to Manage Simulink.Bus Objects” on page 77-52
- 3 “Create and Specify Simulink.Bus Objects” on page 77-52
- 4 “Save Simulink.Bus Objects” on page 77-53
- 5 “Map Simulink.Bus Objects to Models” on page 77-53

### Determine Whether to Use Simulink.Bus Objects

You must use Bus objects for these modeling configurations:

- Nonvirtual buses
- Stateflow charts with bus input or output
- S-function or Legacy Code Tool interface with external code

You can associate a Bus object with multiple blocks. Some blocks require that you specify a Bus object if the block has a bus input or output. For more information, see “Bus-Capable Blocks” on page 77-39.

When a Bus object governs a signal input or output for a block, the signal must be a bus that has the properties specified by the object. Any variance causes an error.

If you use Bus Creator or In Bus Element block parameters to specify bus properties, all blocks downstream from the bus inherit the same properties.

You can use Bus Creator block parameters to define virtual buses and perform limited error checking. To perform thorough error checking on a bus, associate a Bus object with that bus. Using Bus objects to check buses for errors is important when you want to create reusable and shareable model components.

To make tracing the correspondence between the model and the generated code for a bus easier, use a nonvirtual bus. The generated code for a nonvirtual bus produces a structure. Nonvirtual buses can result in multiple copies of some buses.

## Determine How to Manage Simulink.Bus Objects

You can save Bus objects to these locations:

- Data dictionary
- Function
- MAT-file
- Database or other external files

If you do not save Bus objects, then when you reopen a model that uses the Bus objects, you need to recreate the Bus objects.

Different Bus object storage locations provide different advantages.

| Location                         | Usage Considerations                                                                                                                                                                                                                                                                                 |

| MAT-file                         | Use for faster Bus object saving and loading.                                                                                                                                                                                                                                                        |
| Database or other external files | Use for comparing bus interface information with design documents stored in an external data source.                                                                                                                                                                                                 |

## Create and Specify Simulink.Bus Objects

To create or edit Bus objects interactively, use the **Bus Editor** or **Model Explorer**. Bus objects created with these tools are initially stored in the base workspace or data dictionary. To visualize bus hierarchy and access capabilities such as import and export, use the **Bus Editor**. When you have many Bus objects or the Bus objects are stored in multiple locations, use the **Model Explorer**. The **Model Explorer** provides quick startup regardless of the number of Bus objects and allows you to easily switch between editing Bus objects in the base workspace and data dictionaries.

To create and edit Bus objects programmatically, see “Create Bus Objects Programmatically” on page 77-55. Bus objects are initially stored in either the base workspace, a data dictionary, or a function.

After you create a Bus object and specify its attributes, you can associate it with any block that needs to use the bus definition that the object provides. To associate a block with a bus, in the Block Parameters dialog box, set **Output data type** or **Data type** to Bus: <object name> and replace <object name> with the Bus object name.

You can specify the Bus object as the data type of a block either before or after defining the Bus object. However, before you simulate the model, the Bus object and the corresponding bus must have the same number of bus elements, in the same order. Also, each element in the Bus object and in the corresponding bus must have the same data type and dimensions.

During model development, you can modify buses to match Bus objects or modify Bus objects to match buses.

If you do not want to change the Bus object, you can:

- Create a Bus object that matches the changes to the bus and use the new Bus object for the blocks that the changed bus connects to.
- Revert the bus changes so that the bus continues to match the associated Bus object.

## Save Simulink.Bus Objects

To save Bus objects stored in the base workspace, you can use any MATLAB technique that saves the contents of the base workspace. However, the resulting file contains everything in the base workspace, not just Bus objects.

You can save Bus objects in a variety of locations.

| Location                         | File Creation Method                                                                                                                                                                                                                                                                                                                                                               | File Contents                                                  |
|----------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------|
| Data dictionary                  | See “Migrate Models to Use Simulink Data Dictionary” on page 75-6.                                                                                                                                                                                                                                                                                                                 | Bus objects and other base workspace variables used by a model |
| Function                         | Use the Bus Editor or <code>Simulink.Bus.save</code> function.                                                                                                                                                                                                                                                                                                                     | Bus objects                                                    |
| MAT file                         | Use the Bus Editor.                                                                                                                                                                                                                                                                                                                                                                | Bus objects                                                    |
| Database or other external files | Use the <code>Simulink.importExternalCTypes</code> function, scripts, or Database Toolbox™ functionality on C code structure ( <code>struct</code> ) definitions. In preparation for integrating existing algorithmic C code for simulation (for example, by using the Legacy Code Tool), you can package signal or parameter data in the definitions according to structure type. | Bus objects                                                    |

You can customize Bus object export by providing a custom function that writes to a location outside MATLAB. For example, exported Bus objects can be saved as records in a database. See “Customize Bus Object Import and Export” on page 77-57 for details.

When you modify saved Bus objects, you must resave them to keep the changes.

## Map Simulink.Bus Objects to Models

Before you simulate a model, all the Bus objects it uses must be loaded into the base workspace or a data dictionary used by the model. For automation and consistency across models, mapping Bus objects to models is important.

- By identifying all of the Bus objects that a model requires, you can ensure that those objects are loaded before model execution.

- By identifying all models that use a Bus object, you can ensure that changes to a Bus object do not cause unexpected changes in any of the models that use the Bus object.

To ensure the necessary Bus objects load before model execution, consider:

- Projects — Automatically load or run files that define Bus objects by configuring the files to run when you open a project. For details, see “Project Management”.
- Data dictionaries — Store Bus objects with variables and other objects for one or more models.

To share a Bus object among models, you can link each model to a dictionary and create a common referenced dictionary to store the object. For an example, see “Partition Dictionary Data Using Referenced Dictionaries” on page 75-25.

- Databases — Capture mapping information in an external data source, such as a database.

You can customize Bus object import by providing a custom function that reads from a location outside MATLAB. See “Customize Bus Object Import and Export” on page 77-57 for details.

- Model callbacks — Load or run files that define Bus objects by using a model callback, such as `PreLoadFcn`. For more information, see “Model Callbacks” on page 4-53.

If a model uses only a few Bus objects, consider copying the Bus object code directly into the callback, instead of loading a file. For an example, open model `ex_bus_tutorial_nonvirtual` and examine the callback.

To find where a Bus object is used in an open model, see “Finding Blocks That Use a Specific Variable” on page 68-112.

---

**Tip** Using a rigorous and standard naming convention is very helpful for mapping Bus object usage. For example, consider the model and data required for an actuator control function. Naming the model `Actuator` and the input and output ports `Actuator_bus_in` and `Actuator_bus_out`, respectively, makes the connection between the Bus objects and the model clear.

Note that this approach can cause issues if the output from one model is fed directly to another model. In this case, the naming mismatch results in an error.

**Bus Editor**

### Objects

`Simulink.Bus` | `Simulink.BusElement`

## Related Examples

- “Create Bus Objects Programmatically” on page 77-55
- “Customize Bus Object Import and Export” on page 77-57
- “Modify Sample Times for Nonvirtual Buses” on page 77-49

## Create Bus Objects Programmatically

You can programmatically create a `Simulink.Bus` object and its `Simulink.BusElement` objects from arrays, blocks, cell arrays, structures, or C code.

As you create Bus objects programmatically, you can store them in the MATLAB workspace or a data dictionary or save their definitions in a function. For Bus objects in the base workspace, you can programmatically save their definitions in a function using the `Simulink.Bus.save` function.

To simulate a block that uses a Bus object, that Bus object must be in the base workspace or in a data dictionary.

### Create Bus Objects from Arrays

Create a hierarchy of Bus objects using arrays. Array indexing lets you create and access multiple elements in an array. Dot notation lets you access property values.

Create two `BusElement` objects, named `Chirp` and `Sine`, in the base workspace.

```
elems(1) = Simulink.BusElement;
elems(1).Name = 'Chirp';

elems(2) = Simulink.BusElement;
elems(2).Name = 'Sine';
```

Create a `Bus` object, named `NestedBus`, that uses the elements defined in the `elems` array.

```
NestedBus = Simulink.Bus;
NestedBus.Elements = elems;
```

Create two more `BusElement` objects, named `NestedBus` and `Step`. To have `NestedBus` represent a Bus object, specify a Bus object data type.

```
clear elems

elems(1) = Simulink.BusElement;
elems(1).Name = 'NestedBus';
elems(1).DataType = 'Bus: NestedBus';

elems(2) = Simulink.BusElement;
elems(2).Name = 'Step';
```

Create the bus at the top of the bus hierarchy that uses the elements defined in the `elems` array.

```
TopBus = Simulink.Bus;
TopBus.Elements = elems;
```

You can view the created objects in the **Bus Editor**.

```
buseditor
```

### Create Bus Objects from Blocks

To programmatically create a Bus object based on a block in a model, use the `Simulink.Bus.createObject` function.

If you specify a Bus Creator block that is at the highest level of a bus hierarchy, the function creates Bus objects for all of the buses in the hierarchy, including nested buses.

## Create Bus Objects from MATLAB Data

To create a Bus object from a cell array, use the `Simulink.Bus.cellToObject` function. Each subordinate cell array represents a Bus object

To create a Bus object from a MATLAB structure, use the `Simulink.Bus.createObject` function. The structure can contain MATLAB timeseries, MATLAB timetable, and `matlab.io.datastore.SimulationDatastore` objects or be a numeric structure.

## Create Bus Objects from External C Code

You can create a Bus object that corresponds to a structure type (`struct`) that your existing C code defines. Then, in preparation for integrating existing algorithmic C code for simulation (for example, by using the Legacy Code Tool), you can use the Bus object to package signal or parameter data according to the structure type. To create the object, use the `Simulink.importExternalCTypes` function.

### Functions

`Simulink.Bus.cellToObject` | `Simulink.Bus.createObject`

### Classes

`Simulink.Bus` | `Simulink.BusElement`

## Related Examples

- “Specify Bus Properties with `Simulink.Bus` Object Data Types” on page 77-51

## Customize Bus Object Import and Export

You can use the Bus Editor to import Bus objects to the base workspace and to export Bus objects from the base workspace, as described in “Save Simulink.Bus Objects” on page 77-53. By default, the Bus Editor can save bus objects to, and import Bus objects from, a function or MAT-file. The files must be in a location that is accessible using an ordinary **Open** or **Save** dialog box.

You can write customized MATLAB functions that provide alternative import or export (or both) functionality. For example, you can write a customized function that stores the objects as records in a database, in a format that your organization uses.

After you design and implement a custom Bus object import or export function, use the Simulink Customization Manager to register the function. The registration process establishes custom import and export functions as callbacks for the Bus Editor **Import to Base Workspace** and **Export to File** commands. The callbacks replace the default capabilities of the Bus Editor. Customizing the Bus Editor import and export capabilities has no effect on other MATLAB or Simulink functions. Canceling import or export customization restores the default Bus Editor capabilities for that operation without affecting the other.

To create Bus objects from external C code, you do not need to make customizations. See “Create Bus Objects from External C Code” on page 77-56.

### Required Background Knowledge

Customizing Bus object import or export requires that you understand:

- MATLAB language and programming techniques
- Simulink Bus object syntax
- The proprietary format into which you translate Bus objects, and the techniques necessary to access the facility that stores the objects.
- Any platform-specific techniques for obtaining data from the user, such as the name of the location in which to store or access Bus objects.

### Write a Bus Object Export Function

A custom Bus object export function requires at least one argument. You can use additional arguments to handle special actions by the function. The value of the first argument is a cell array containing the names of all Bus objects that the Bus Editor has selected. You can use functions, global variables, or any other MATLAB technique, to provide values for any additional arguments. The general algorithm of a customized export function is:

- 1 Iterate over the list of object names in the first argument.
- 2 Obtain the Bus object corresponding to each name.
- 3 Translate the Bus object to the proprietary syntax.
- 4 Save the translated Bus object in the local repository.

This example shows the syntactic shell of such an export callback function is:

```
function myExportCallback(selectedBusObjects)
disp('Custom export was called!');
for idx = 1:length(selectedBusObjects)
```

```
 disp([selectedBusObjects{idx} ' was selected for export.']);
 end
```

Although this function does not export any Bus objects, it is syntactically valid and can be registered. It accepts a cell array of Bus object names, iterates over them, and prints each name. An operational export function:

- Uses each name to retrieve the corresponding Bus object from the base workspace
- Converts the object to proprietary format
- Stores the converted object

The additional logic is enterprise-specific.

## Write a Bus Object Import Function

A custom Bus object import function can take zero or more arguments to perform its task. You can use functions, global variables, or any other MATLAB technique to provide argument values. Also, the function can poll the user for information, such as a designation of where to obtain Bus object information. The general algorithm of a custom Bus object import function is:

- 1 Obtain Bus object information from the local repository.
- 2 Translate each Bus object definition to a `Simulink.Bus` object.
- 3 Save each Bus object to the MATLAB base workspace.

This example shows the syntactic shell of an import callback function is:

```
function myImportCallback
disp('Custom import was called!');
```

Although this function does not import any Bus objects, it is syntactically valid and can be registered with the Simulink Customization Manager. An operational import function:

- Gets a designation of where to obtain the Bus objects to import
- Converts each Bus object to a `Simulink.Bus` object
- Stores the object in the base workspace

The additional logic is enterprise-specific.

## Register Customizations

To customize Bus object import or export, provide a customization registration function that inputs and configures the Customization Manager whenever you start Simulink software or refresh Simulink customizations. The steps for using a customization registration function are:

- 1 Create a file named `sl_customization.m` to contain the customization registration function. Alternatively, you can use an existing customization file.
- 2 At the top of the file, create a function named `sl_customization` that takes a single argument (or use the customization function in an existing file). When the function is invoked, the value of this argument is the Customization Manager.
- 3 Configure the `sl_customization` function to set `importCallbackFcn` and `exportCallbackFcn` to be function handles that specify your customized Bus object import and export functions.

- 4 If `sl_customization.m` is a new customization file, put it anywhere on the MATLAB search path. Two frequently used locations are `matlabroot` and the current working folder. Alternatively, you can extend the search path.

Here is a simple example of a customization registration function:

```
function sl_customization(cm)
disp('My customization file was loaded.');
```

`cm.BusEditorCustomizer.importCallbackFcn = @myImportCallback;`
`cm.BusEditorCustomizer.exportCallbackFcn = @(x)myExportCallback(x);`

When Simulink starts up, it traverses the MATLAB search path looking for files named `sl_customization.m`. Simulink loads each such file that it finds (not just the first file) and executes the `sl_customization` function at its top, establishing the customizations that the function specifies.

Executing the example customization function displays a message (which an actual function probably would not). The function establishes that the Bus Editor uses a function named `myImportCallback()` to import Bus objects, and a function named `myExportCallback(x)` to export Bus objects.

The function corresponding to a handle that appears in a callback registration can be undefined when the registration occurs. However, it must be defined when the Bus Editor calls the function. The same latitude and requirement applies to any functions or global variables used to provide the values of additional arguments.

Other functions can also exist in the `sl_customization.m` file. However, the Simulink software ignores files named `sl_customization.m`, except when it starts up or refreshes customizations. Any changes to functions in the customization file are ignored until one of those events occurs. By contrast, changes to other functions on the MATLAB path take effect immediately.

For more information, see “Register Customizations with Simulink” on page 79-56.

## Change Customizations

You can change the handles established in the `sl_customization` function by:

- Changing the function to specify the changed handles
- Saving the function
- Refreshing customizations by executing `sl_refresh_customizations`

Simulink traverses the MATLAB path and reloads all `sl_customization.m` files that it finds, executing the first function in each one, just as it did on Simulink startup.

You can revert to default import or export behavior by setting in the `sl_customization` function the appropriate `BusEditorCustomizer` element to `[]` and then refreshing customizations. Alternatively, you can eliminate both customizations in one operation by executing:

```
cm.BusEditorCustomizer.clear
```

where `cm` was previously set to a customization manager object (see “Register Customizations” on page 77-58).

Changes to the import and export callback functions themselves, as distinct from changes to the handles that register them as customizations, take effect immediately, unless they are in the

`sl_customization.m` file itself. If the callback functions are in the `sl_customization.m` file, they take effect next time you refresh customizations. Keeping the callback functions in separate files usually provides more flexible and modular results.

## Specify Initial Conditions for Bus Elements

Bus initialization is a special form of signal initialization. For general information about initializing signals, see “Initialize Signals and Discrete States” on page 76-40. For details about initializing arrays of buses, see “Initialize Arrays of Buses” on page 77-75.

Bus initialization specifies the bus element values that Simulink uses for the first execution of a block that uses that bus. By default, the initial value for a bus element is the ground value (represented by 0). Bus initialization involves specifying nonzero initial conditions.

You can use bus initialization features to:

- Specify initial conditions for signals that have different data types.
- Apply a different initial condition for each element in the bus.
- Specify initial conditions for a subset of elements in a bus without specifying initial conditions for all the elements.
- Use the same initial conditions for multiple blocks, signals, or models.

### Blocks That Support Bus Initialization

You can initialize bus values that input to a block if that block meets both of these conditions:

- Has an initial value or initial condition block parameter
- Supports buses

These blocks support bus initialization:

- Data Store Memory
- IC
- Memory
- Merge
- Output (when the block is inside a conditionally executed context)
- Receive
- Rate Transition
- Unit Delay

For example, the Unit Delay block is a bus-capable block. Its Block Parameters dialog box has an **Initial conditions** parameter.

You cannot initialize a bus that has:

- Variable-size signals
- Frame-based signals

### Set Diagnostics to Support Bus Initialization

To enable bus initialization, before you start a simulation, set the “Underspecified initialization detection” configuration parameter to `simplified`.

## Create Initial Condition Structures

You can create partial or full initial condition structures to represent initial values for a bus. To create an initial condition structure, use one of these approaches:

- Define a MATLAB structure in the MATLAB base or Simulink model workspace. You can manually define the structure, or alternatively for full structures, you can use the `Simulink.Bus.createMATLABstruct` function.
- In the Block Parameters dialog box for a block that supports bus initialization, for the initial condition parameter specify an expression that evaluates to a structure.

For information about defining MATLAB structures, see “Structure Arrays”.

The field that you specify in an initial condition structure must match these data attributes of the bus element exactly:

- Name
- Dimension
- Complexity

For example, if you define a bus element to be a real [2x2] double array, then in the initial condition structure, define the value to initialize that bus element to be a real [2x2] double array.

Explicitly specify fields in the initial condition structure for every bus element that has an enumerated (enum) data type.

## Control Data Types of Structure Fields

If any of the elements of the target bus use a data type other than `double`, you can use different techniques to control the data types of the fields of initial condition structures. The technique that you choose can influence the efficiency and readability of the generated code. See “Control Data Types of Initial Condition Structure Fields” on page 77-106.

## Create Full Structures for Initialization

A full initial condition structure provides an initial value for every element of a bus. The initial condition structure mirrors the bus hierarchy and reflects the attributes of the bus elements.

Specifying full structures during code generation offers these advantages:

- Generates more readable code
- Supports a modeling style that explicitly initializes all signals

Use the `Simulink.Bus.createMATLABstruct` function to streamline the creation of a full MATLAB initial condition structure with the same hierarchy, names, and data attributes as a bus. This function fills all of the elements that you do not specify with ground values for those elements.

You can use several different kinds of input with the function, including:

- A `Simulink.Bus` object name
- An array of port handles

You can invoke the function from the Bus Editor. Select the Bus object for which you want to create a full MATLAB structure, and then select the **File > Create a MATLAB structure** menu item.

To detect when structure parameters are not consistent in shape (hierarchy and names) with the associated bus, use the Model Advisor.

- 1 On the **Modeling** tab, click **Model Advisor**.
- 2 Click **OK**.
- 3 Under **By Task > Modeling Signals and Parameters using Buses**, select **Check structure parameter usage with bus signals**.
- 4 Click the **Run This Check** button.

The Model Advisor identifies partial initial condition structures.

After you create the structure, you can edit it in the MATLAB Editor.

## Create Partial Structures for Initialization

A partial initial condition structure provides initial values for a subset of the elements of a bus. If you use a partial initial condition structure, during simulation, Simulink creates a full initial condition structure to represent all the bus elements. Simulink assigns the respective ground value to each element for which the partial initial condition structure does not explicitly assign a value.

Specifying partial structures for block parameter values can be useful during the iterative process of creating a model. Partial structures enable you to focus on a subset of signals in a bus. When you use partial structures, Simulink initializes unspecified signals implicitly.

When you define a partial initial condition structure:

- Include only fields that are in the bus.
- Omit one or more fields that are in the bus.
- Make the field in the initial condition structure correspond to the nesting level of the bus element.
- Within the same nesting level in both the structure and the bus, optionally specify the structure fields in a different order than the bus elements.

---

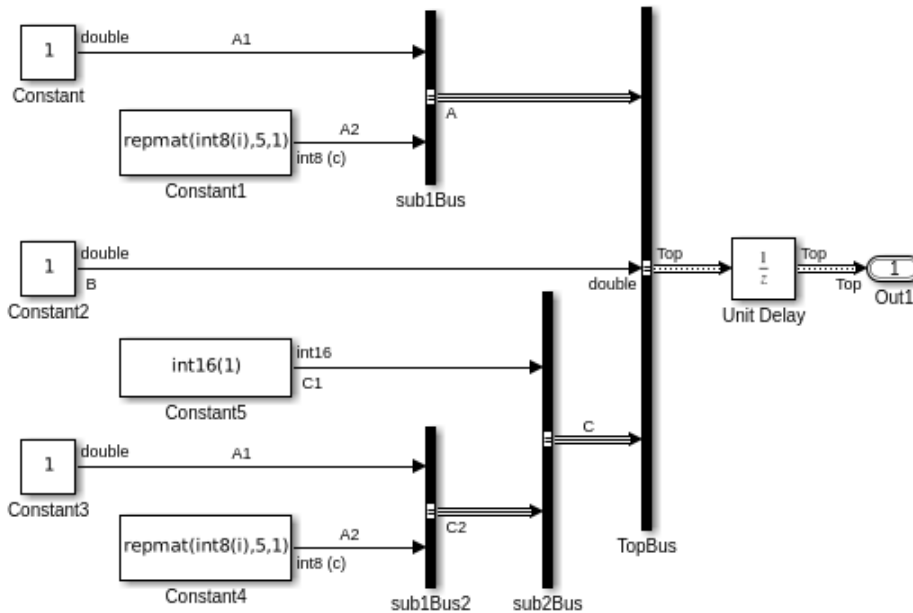

**Note** The value of an initial condition structure must lie within the design minimum and maximum range of the corresponding bus element. Simulink performs this range checking when you do an update diagram or simulate the model.

---

Suppose that you have a bus, Top, composed of three elements: A, B, and C, with these characteristics:

- A is a nested bus, with two signal elements.
- B is a single signal.
- C is a nested bus that includes bus A as a nested bus.

The `ex_bus_initial_conditions` model includes the Top bus. This is how the model appears after it has been updated.

Copyright 2004-2018 The MathWorks, Inc.

Here is a summary of the Top bus hierarchy and the data type, dimension, and complexity of the bus elements.

```

Top
 A (sub1)
 A1 (double)
 A2 (int8, 5x1, complex)
 B (double)
 C (sub2)
 C1 (int16)
 C2 (sub1)
 A1 (double)
 A2 (int8, 5x1, complex)

```

In these examples, K is an initial condition structure specified for the initial value of the Unit Delay block. The initial condition structure corresponds to the Top bus in the ex\_bus\_initial\_conditions model. Here are some valid initial condition specifications.

| Valid Syntax                                       | Description                                                                                                                                                                                         |
|----------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>K.A.A1 = 3</code>                            | Initialize the bus element Top.A.A1 using the value 3.                                                                                                                                              |
| <code>K = struct('C',struct('C1',int16(4)))</code> | The bus element Top.C.C1 is int16. The corresponding structure field explicitly specifies int16(4). Alternatively, you could specify the field value as 4 without specifying an explicit data type. |
| <code>K = struct('B',3,'A',struct('A1',4))</code>  | Bus elements Top.B and Top.A are at the same nesting level in the bus. For bus elements at the same nesting level, the order of corresponding structure fields does not matter.                     |

## Invalid Partial Initial Condition Structures

In the following examples, K is an initial condition structure specified for the initial value of the Unit Delay block. The initial condition structure corresponds to the Top bus in the `ex_bus_initial_conditions` model.

These three initial condition specifications are *not* valid:

| Invalid Syntax                       | Reason the Syntax Is Invalid                                                                                                                                                                                      |
|--------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>K.A.A2 = 3</code>              | Value dimension and complexity do not match. The bus element <code>Top.A.A2</code> is $5 \times 1$ , but <code>K.A.A2</code> is $1 \times 1$ ; <code>Top.A.A2</code> is complex, but <code>K.A.A2</code> is real. |
| <code>K.C.C2 = 3</code>              | You cannot use a scalar value to initialize initial condition substructures.                                                                                                                                      |
| <code>K = struct('B',3,'X',4)</code> | You cannot specify fields that are not in the bus ( <code>X</code> does not exist in the bus).                                                                                                                    |

## Initialize Buses Using Block Parameters

Initialize a bus by setting the initial condition parameter for a block that receives a bus as input and that supports bus initialization (see “Blocks That Support Bus Initialization” on page 77-61).

For example, the Block Parameters dialog box for the Unit Delay block has an **Initial conditions** parameter.

For a block that supports bus initialization, you can replace the default value of 0 using one of these approaches:

- “MATLAB Structure for Initialization” on page 77-66
- “MATLAB Variable for Initialization” on page 77-66
- “Simulink.Parameter Object For Initialization” on page 77-67

All three approaches require that you define an initial condition structure (see “Create Initial Condition Structures” on page 77-62). You cannot specify a nonzero scalar value or any other type of value other than 0, an initial condition structure, or `Simulink.Parameter` object to initialize a bus.

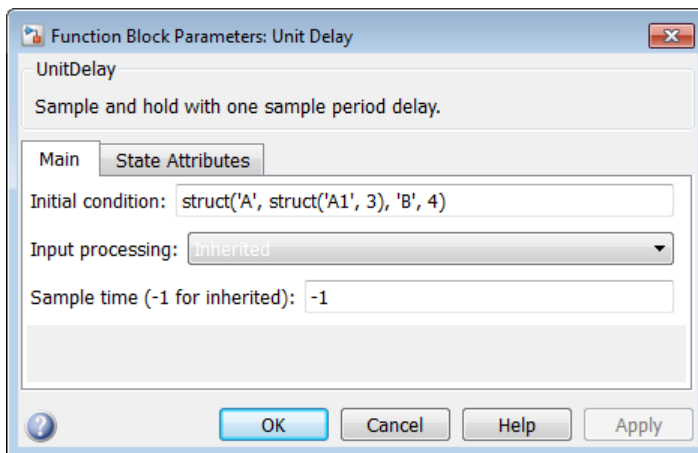

Defining an initial condition structure as a MATLAB variable, rather than specifying the initial condition structure directly in the Block Parameters dialog box offers several advantages, including:

- Reuse of the initial condition structure for multiple blocks
- Using the initial condition structure as a tunable parameter in the generated code

### MATLAB Structure for Initialization

You can initialize a bus using a MATLAB structure that explicitly defines the initial conditions for the bus.

For example, in the **Initial conditions** parameter of the Unit Delay block, you could type in a structure.

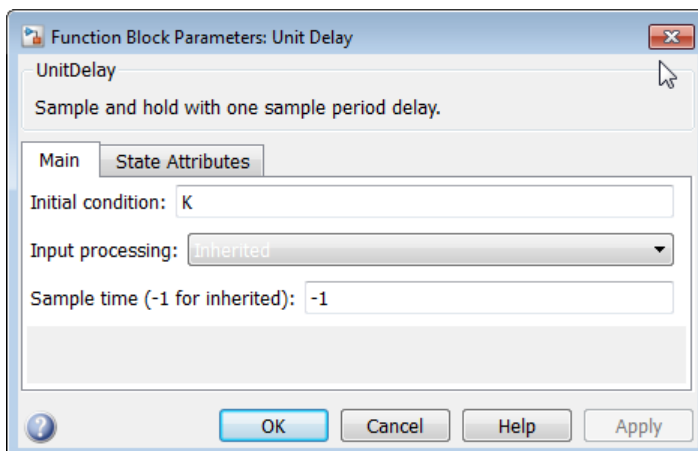

### MATLAB Variable for Initialization

You can initialize a bus using a MATLAB variable that you define as an initial condition structure with the appropriate values.

For example, you could define the following partial structure in the base workspace:

```
K = struct('A', struct('A1', 3), 'B', 4);
```

You can then specify the K structure as the **Initial conditions** parameter of the Unit Delay block:

## Simulink.Parameter Object For Initialization

You can initialize a bus using a `Simulink.Parameter` object that uses an initial condition structure for the `Value` property.

For example, you could define the partial structure `P` in the base workspace (reflecting the `ex_bus_initial_conditions` model discussed in the previous section):

```
P = Simulink.Parameter;
P.DataType = 'Bus: Top';
P.Value = Simulink.Bus.createMATLABStruct('Top');
P.Value.A.A1 = 3;
P.Value.B = 5;
```

You can then specify the `P` structure as the **Initial conditions** parameter of the Unit Delay block:

## Group Nonvirtual Buses in Arrays of Buses

An array of buses is an array whose elements are nonvirtual buses.

Use an array of buses to:

- Reduce maintenance by centralizing algorithms used for processing multiple buses.
- Streamline iterative processing of multiple buses of the same type, for example, by using a For Each subsystem with the array of buses.
- Change the number of buses being processed without having to restructure the parts of the model that use the array of buses.
- Use built-in blocks, such as the Assignment or Selector blocks, to manipulate arrays of buses just like arrays of any other type. Using an array of buses avoids the need for you to create custom S-functions to manage packing and unpacking structure signals.
- Generate code that has an array of C structures, which you can integrate with legacy C code that uses arrays of structures. This approach simplifies indexing into an array for Simulink computations, using a for loop on indexed structures.

For example, you can model a multi-channel system, such as a communications system, as an array of buses. All the channels have the same data type, and each of the channels can have a different value.

For a model that demonstrates multiple ways to use an array of buses, see “Model Arrays of Buses”.

### Requirements of Arrays of Buses

All buses combined into an array of buses must:

- Be nonvirtual
- Specify the same `Simulink.Bus` object data type (that is, the same name, hierarchies, and bus element attributes)
- Have no variable-size signals or frame-based signals

For information on creating nonvirtual buses, see “Create Nonvirtual Buses” on page 77-19.

For information on which blocks support arrays of buses, see “Bus-Capable Blocks” on page 77-39.

### Create Array of Buses from Nonvirtual Buses

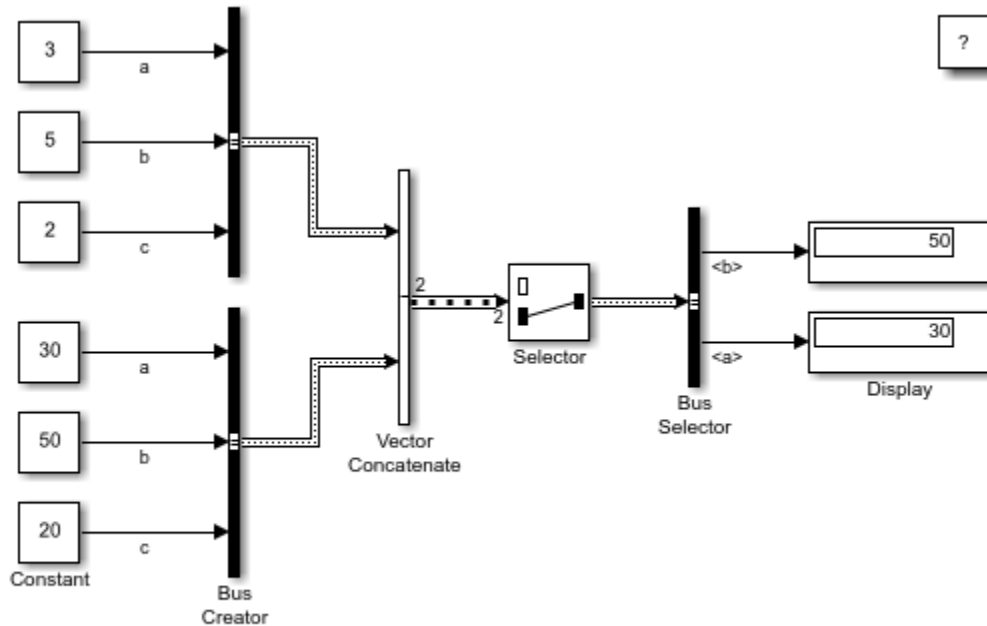

You can use a Vector Concatenate or Matrix Concatenate block to group nonvirtual buses into an array of buses. Simulink treats nonvirtual buses as scalars. Therefore, you can use either of these blocks regardless of the bus element data types.

To create an array of buses with one of these blocks:

- 1 Define one `Simulink.Bus` object data type for all of the nonvirtual buses that you want to group in the array of buses.
- 2 In the Block Parameters dialog box for the Vector Concatenate or Matrix Concatenate block, set **Number of inputs** to the number of buses you want in the array of buses. The block icon displays the number of input ports that you specify.
- 3 Connect the nonvirtual buses to the block inputs.

The block output is the array of buses.

Open and compile the example model. To compile the model, on the **Modeling** tab of the Simulink Toolstrip, click **Update Model** or **Run**. Compiling the model updates the line styles, which you can use to visually identify arrays of buses.

Copyright 2019-2020 The MathWorks, Inc.

To demonstrate how to create arrays of buses from nonvirtual buses, the model uses:

- Two Bus Creator blocks to create two nonvirtual buses that have the same Bus object data type (Bus: BusObject).
- A Vector Concatenate, Matrix Concatenate block with **Number of inputs** set to 2 to group the two nonvirtual buses in an array of buses.

To demonstrate how to select elements from the array of buses, the model uses:

- A Selector block to extract one of the buses from the array of buses based on the specified **Index** in the dialog box. Because arrays of buses are concatenated signals that provide index-based access to their elements, the Selector block uses **Index vector (dialog)** for the **Index Option**.
- A Bus Selector block to extract the elements of the nonvirtual bus using name-based access.

The **Signal Dimensions** information overlay shows that the array of buses contains two buses. To enable the **Signal Dimensions** overlay, in the Simulink Toolstrip, on the **Debug** tab, select **Information Overlays > Signal Dimensions**.

## Create Array of Buses from MATLAB Structures

You can use a Constant block to compactly represent an array of buses with constant-valued bus elements. This technique can reduce the number of lines in a model and the number of variables used by the model, especially when the model repeats an algorithm with different parameter values.

On the Constant block, specify:

- **Constant value** as an array of MATLAB structures or a `Simulink.Parameter` object that specifies an array of MATLAB structures
- **Output data type** as a `Simulink.Bus` object

Constant blocks only support MATLAB® structures when the output data type is a Bus object.

Define an array of structures named `const_struct_array`. Compose each structure of the same elements: `Offset`, `Gain`, and `Threshold`.

```
const_struct_array(1).Offset = 197;
const_struct_array(1).Gain = 4.32;
const_struct_array(1).Threshold = 795.68;
```

```
const_struct_array(2).Offset = 158;
const_struct_array(2).Gain = 3.83;
const_struct_array(2).Threshold = 1039.77;
```

To create an array of structures for a bus hierarchy with many elements, consider using the `Simulink.Bus.createMATLABStruct` function.

Define the corresponding Bus object data type.

```
Simulink.Bus.createObject(const_struct_array)
```

The new Bus object uses the default name `slBus1`.

Open and simulate the example model, which contains a Constant block with **Constant value** set to `const_struct_array` and **Output data type** set to Bus: `slBus1`.

```
open_system('ArrayOfBusesFromStructModel')
sim('ArrayOfBusesFromStructModel');
```

The output of the Constant block is an array of buses.

The For Each Subsystem block iteratively processes the constant values for each nonvirtual bus in the array. The subsystem contents display the nonvirtual bus instead of the array of buses that connects to the port.

### Related Examples

- “Types of Composite Signals” on page 77-2
- “Work with Arrays of Buses” on page 77-72
- “Convert Models to Use Arrays of Buses” on page 77-79
- “Repeat an Algorithm Using a For Each Subsystem” on page 77-81
- “Specify Initial Conditions for Bus Elements” on page 77-61
- “Access Array of Buses Signal Logging Data” on page 73-19

## Work with Arrays of Buses

Setting up a model to use an array of buses usually involves these basic tasks:

- 1 Define the array of buses (see “Create Array of Buses from Nonvirtual Buses” on page 77-68).
- 2 Add a subsystem for performing iterative processing on each element of the array of buses. For example, use a For Each Subsystem block or an Iterator block. Connect the array of buses from the Concatenate block to the iterative processing subsystem. See “Perform Iterative Processing” on page 77-72.
- 3 Model your scalar algorithm within the iterative processing subsystem (for example, a For Each subsystem).
  - a Operate on the array of buses (using Selector and Assignment blocks).
  - b Use the Bus Selector and Bus Assignment blocks to select elements from, or assign elements to, a nonvirtual bus within the subsystem.

See “Assign Values into an Array of Buses” on page 77-72 and “Select Bus Elements from Array of Buses” on page 77-74.

- 4 Optionally, import or log array of buses data. See “Import Array of Buses Data” on page 77-75 and “Log Arrays of Buses” on page 77-75

The resulting model includes these components.

### Perform Iterative Processing

You can perform iterative processing on the bus data of an array of buses using blocks such as a For Each Subsystem block, a While Iterator Subsystem block, or a For Iterator Subsystem block. You can use one of these blocks to perform the same kind of processing on:

- Each bus in the array of buses
- A selected subset of buses in the array of buses

### Assign Values into an Array of Buses

To assign a value to a signal within an array of buses, use:

- 1 A Bus Assignment block to assign a value to a bus element
- 2 An Assignment block to assign the bus to the array of buses

Use an Assignment block to assign values to specified elements in a bus array.

For example, in the `sldemo_bus_arrays` model, the Assignment block assigns the value to the first element of the array of buses.

To assign bus elements within a bus, use the Bus Assignment block. The input for the Bus Assignment block must be a bus.

### Assign into Arrays of Buses

You can use a Bus Assignment block to assign or fully replace a nested bus that is an array of buses. To assign the data for a nested bus inside an array of buses or to make a partial assignment to certain elements with the array of buses, you can use a MATLAB Function block.

For example, suppose that you have this bus structure:

| Variable | Type     | element | Modification |   |
|----------|----------|---------|--------------|---|
| A        | Parent   | 1       |              |   |
| c        | boolean  | 1       | 0            |   |
|          | children | Child   | 10           |   |
|          | a        | int32   | 5            | 0 |
|          |          | b       | single       | 1 |

The bus has a `children` element, which is a sub-bus array. This example shows how to assign to element `c` and to element `a`. The Inport and Outport blocks use the Parent Bus object. To define the assignments, this example uses a MATLAB Function block, because you cannot assign into element `a` using a Bus Assignment or Assignment block.

The MATLAB Function block uses this function code for making the assignments:

```
function y = fcn(u)
y = u;
y.c = false;
for idx = 1:length(y.children)
 y.children(idx).a = int32(zeros(5, 1));
end
```

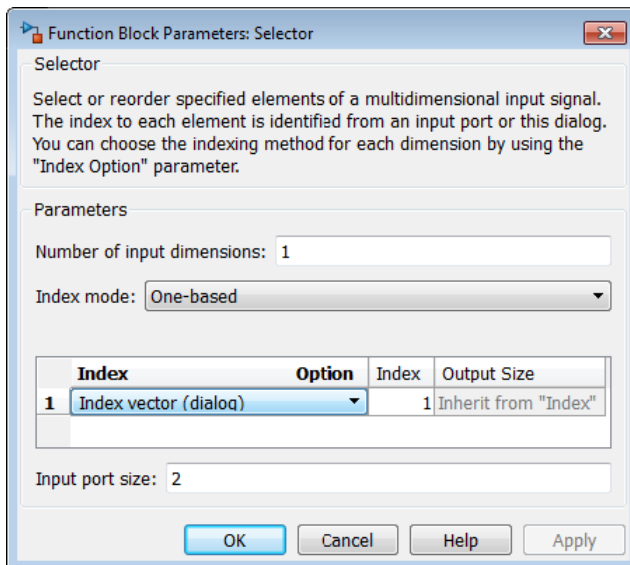

## Select Bus Elements from Array of Buses

To select a bus element from an array of buses, use a:

- 1 Selector block to select the appropriate bus within the array of buses.
- 2 Bus Selector block to select the bus element within the bus.

Use a Selector block to select elements of an array of buses. The input array of buses can have any dimension. The output bus of the Selector block is a selected or reordered set of elements from the input array of buses.

For example, the `sldemo_bus_arrays` model uses Selector blocks to select elements from the array of buses that the Assignment and For Each Subsystem blocks outputs. In this example, here is the Block Parameters dialog box for the Selector block that selects the first element:

To select bus elements within a bus, use the Bus Selector block. The input for the Bus Selector block must be a bus.

## Import Array of Buses Data

Use a root Inport block to import (load) an array of structures of MATLAB `timeseries` objects for an array of buses. You can import partial data into the array of buses.

For details, see “Import Array of Buses Data” on page 71-50.

You cannot use a From Workspace or From File block to import data for an array of buses.

## Log Arrays of Buses

To export an array of buses, mark the signal for signal logging. For more information, see “Save Run-Time Data from Simulation”.

---

**Note** Simulink does not log signals inside referenced models in rapid accelerator mode.

---

To access the signal logging data for a specific signal in an array of buses, navigate through the structure hierarchy and specify the index to the specific signal. For details, see “Access Array of Buses Signal Logging Data” on page 73-19.

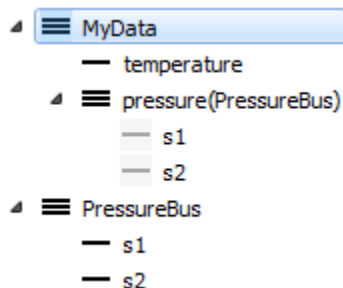

Root level bus outputs are not logged when you select the **Output** configuration parameter. Use standard signal logging instead, as described in “Export Signal Data Using Signal Logging” on page 73-43.

Do not use signal logging for bus or arrays of buses directly from within a For Each subsystem. Either use a Bus Selector block to select the bus element signals to log or add an Outport block outside of the subsystem and then log that signal. For details, see “Log Signals in For Each Subsystems” on page 73-72.

## Initialize Arrays of Buses

To specify a unique initial value for each of the individual signals in an array of buses, you can use an array of initial condition structures. Each structure in the array initializes one of the buses.

Here is an example that shows how to initialize an array of buses. Suppose that you define the bus types `MyData` and `PressureBus`.

Suppose that you set the data type of the signal element `temperature` to `int16`, and the data type of the elements `s1` and `s2` to `double`.

To specify initial conditions for an array of buses, you can create a variable whose value is an array of initial condition structures.

```
initValues(1).temperature = int16(5);
initValues(1).pressure.s1 = 9.87;
initValues(1).pressure.s2 = 8.71;

initValues(2).temperature = int16(20);
initValues(2).pressure.s1 = 10.21;
initValues(2).pressure.s2 = 9.56;

initValues(3).temperature = int16(35);
initValues(3).pressure.s1 = 8.98;
initValues(3).pressure.s2 = 9.17;
```

The variable `initValues` provides initial conditions for a signal that is an array of three buses. You can use `initValues` to specify the **Initial condition** parameter of a block such as Unit Delay.

Alternatively, you can use a single scalar structure to specify the same initial conditions for all the buses in the array.

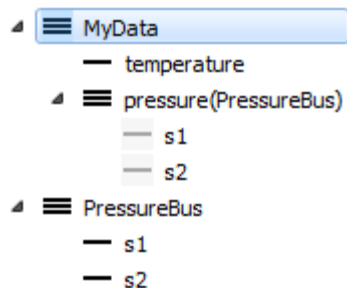

```
initStruct.temperature = int16(15);
initStruct.pressure.s1 = 10.32;
initStruct.pressure.s2 = 9.46;
```

If you specify `initStruct` in the **Initial condition** parameter of a block, each bus in the array uses the same initial value, 15, for the signal element `temperature`. Similarly, the buses use the initial value 10.32 for the element `pressure.s1` and the value 9.46 for the element `pressure.s2`.

To create an array of structures for a bus that uses a large hierarchy of signal elements, consider using the function `Simulink.Bus.createMATLABStruct`.

This example shows how to initialize a nested array of buses. Create an initial condition structure for a complicated signal hierarchy that includes nested arrays of buses.

- 1 In the Bus Editor, create the Bus objects `MyData` and `PressureBus`.

- 2 In the hierarchy pane, select the bus element `pressure`. Set the **Dimensions** property to `[1 3]`.
- 3 Create an array of four initialization structures by using the function `Simulink.Bus.createMATLABStruct`. Store the array in the variable `initStruct`. Initialize all the individual signals to the ground value, 0.

```
initStruct=Simulink.Bus.createMATLABStruct('MyData',[],[1 4]);
```

- 4 In the base workspace, double-click the variable `initStruct` to view it in the variable editor.

The four structures in the array each have the fields `temperature` and `pressure`.

- 5 To inspect a `pressure`, double-click one of the fields.

The value of each of the four `pressure` fields is an array of three substructures. Each substructure has the fields `s1` and `s2`.

- 6 To provide unique initialization values for the signals in an array of buses, you can specify the values manually using the variable editor.

Alternatively, you can write a script. For example, to access the field `s1` of the second substructure `pressure` in the third structure of `initStruct`, use this code:

```
initStruct(3).pressure(2).s1 = 15.35;
```

## Structure Parameter Requirements

To initialize an array of buses with structure parameters, you can use:

- The number `0`. In this case, all the individual signals in the array of buses use the initial value `0`.
- A scalar `struct` that represents the same hierarchy of fields and field names as the bus type. In this case, the scalar structure expands to initialize each of the individual signals in the array of buses.
- An array of structures that specifies an initial value for each of the individual signals in the array of buses.

If you use an array of structures, all the structures in the array must have the same hierarchy of fields. Each field in the hierarchy must have the same characteristics across the array:

- Field name
- Numeric data type, such as `single` or `int32`
- Complexity
- Dimensions

You cannot use partial structures.

## Code Generation

Code generation for arrays of buses produces structures with a specific format. See “Code Generation for Arrays of Buses” on page 77-111.

## Convert Models to Use Arrays of Buses

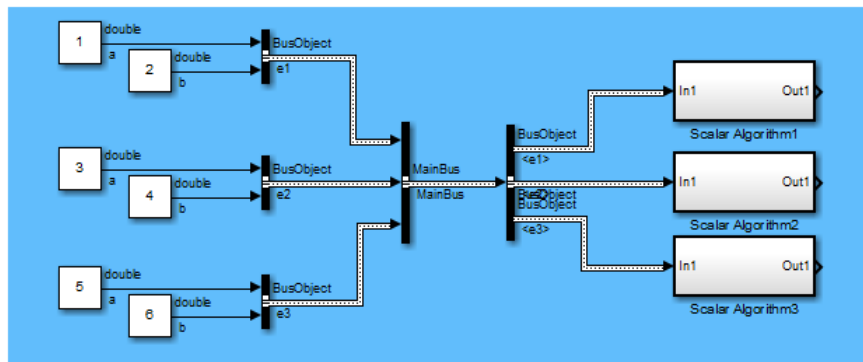

There are several reasons to convert a model to use an array of buses. For example:

- The model was developed before Simulink supported arrays of buses (introduced in R2010b), and the model contains many subsystems that perform the same kind of processing.
- The model has grown in complexity.

### General Conversion Approach

Here is a general approach for converting a model that contains buses to a model that uses an array of buses. The method that you use depends on your model. For more information, see “Group Nonvirtual Buses in Arrays of Buses” on page 77-68.

This workflow refers to a stylized example model. The example shows the original modeling pattern and a new modeling pattern that uses an array of buses.

Original modeling pattern

New modeling pattern

In the original modeling pattern:

- The target bus to be converted is named MainBus, and it has three elements, each of type BusObject.
- The ScalarAlgorithm1, ScalarAlgorithm2, and ScalarAlgorithm3 subsystems encapsulate the algorithms that operate on each of the bus elements. The subsystems all have the same content.

- A Bus Selector block picks out each element of `MainBus` to drive the subsystems.

The construction in the original modeling pattern is inefficient for two reasons:

- A copy of the subsystem that encapsulates the algorithm is made for each element of the bus that is to be processed.
- Adding another element to `MainBus` involves changing the `Bus` object definition and the Bus Selector block, and adding a subsystem. Each of these changes is a potential source of error.

To convert the original modeling pattern to use an array of buses:

- 1** Identify the target bus and associated algorithm that you want to convert. Typically, the target bus is a bus of buses, where each element bus is of the same type.
  - The bus that you convert must be a nonvirtual bus. If all elements of the target bus have the same sample time (or if the sample time is inherited), you can convert a virtual bus to a nonvirtual bus.
  - The target bus cannot have variable-dimensional and frame-based elements.
- 2** Use a Concatenate block to convert the original bus of buses to an array of buses.

In the example, the new modeling pattern uses a Vector Concatenate block to replace the Bus Creator block that creates the `MainBus` signal. The output of the Vector Concatenate block is an array of buses, where the type of the bus is `BusObject`. The new model eliminates the wrapper bus (`MainBus`).

- 3** Replace all identical copies of the algorithm subsystem with a single For Each subsystem that encapsulates the scalar algorithm. Connect the array of buses to the For Each subsystem.

The new model eliminates the Bus Selector blocks that separate out the elements of the `MainBus` signal in the original model.

- 4** Configure the For Each Subsystem block to iterate over the input array of buses and concatenate the output bus.

The scalar algorithm within the For Each subsystem cannot have continuous states. For additional limitations, see the For Each Subsystem block documentation.

## Repeat an Algorithm Using a For Each Subsystem

To repeat an algorithm, you can iterate the algorithm over signals, subsystems, and parameters that are grouped into arrays and structures. This page gives examples of how to convert an inefficiently complex repetitive algorithm into a compact form that is easier to manage.

If you repeat algorithms in a diagram by copying and pasting blocks and subsystems, maintaining the model can become difficult. Individual signal lines and subsystems can crowd the diagram, reducing readability and making simple changes difficult. Variables can also crowd workspaces, reducing model portability. A model can develop these efficiency issues as you add to the design over time.

### Explore Example Model

The model `ex_repeat_algorithm` processes and analyzes sensor data from three burners containing three sensors each, using the same algorithms for each burner in separate, identical subsystems. The model can be simplified by using For Each subsystems.

- 1 Open the example model `ex_repeat_algorithm`. The model creates about 30 variables in the base workspace.
- 2 Inspect the subsystem `Burner_1_Analysis`. This subsystem executes an algorithm by using the base workspace variables as parameters in blocks such as Constant and Discrete-Time Integrator.
- 3 Inspect the subsystems `Burner_2_Analysis` and `Burner_3_Analysis`. All three subsystems execute the same algorithm but use different workspace variables to parameterize the blocks.
- 4 Inspect the three `Analysis_Delay` subsystems. These subsystems repeat a different algorithm from the one in the `Analysis` subsystems.
- 5 Return to the top level of the model. The Memory blocks delay the input signals before they enter the `Analysis_Delay` subsystems.
- 6 Look at the **Data Import/Export** pane of the Configuration Parameters dialog box. The model uses the variables `SensorsInput` and `t` as simulation inputs.

During simulation, each of the nine columns in the matrix variable `SensorsInput` provides input data for an Inport block at the top level of the model.

### Reduce Signal Line Density with Buses

You can use buses to group related signals into a single structured signal, reducing line density and improving model readability.

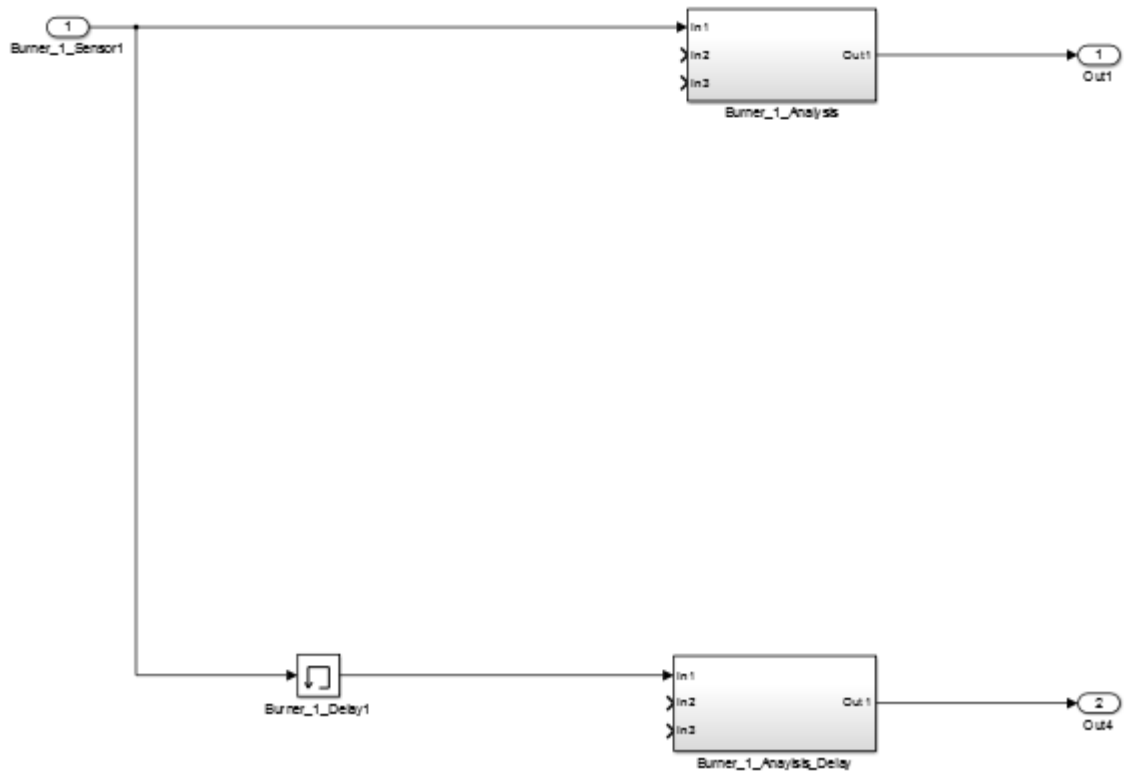

Each subsystem in the example model requires three signal inputs. You can combine each group of three signals into a single bus.

You could modify all the subsystems in the example model to use buses. However, because some of the subsystems are identical, you can delete them and later replace them with For Each Subsystem blocks.

- 1 Open the Bus Editor.  
`buseditor`
- 2 Create a bus type `SensorData` with three signal elements: `sensor1`, `sensor2`, and `sensor3`.

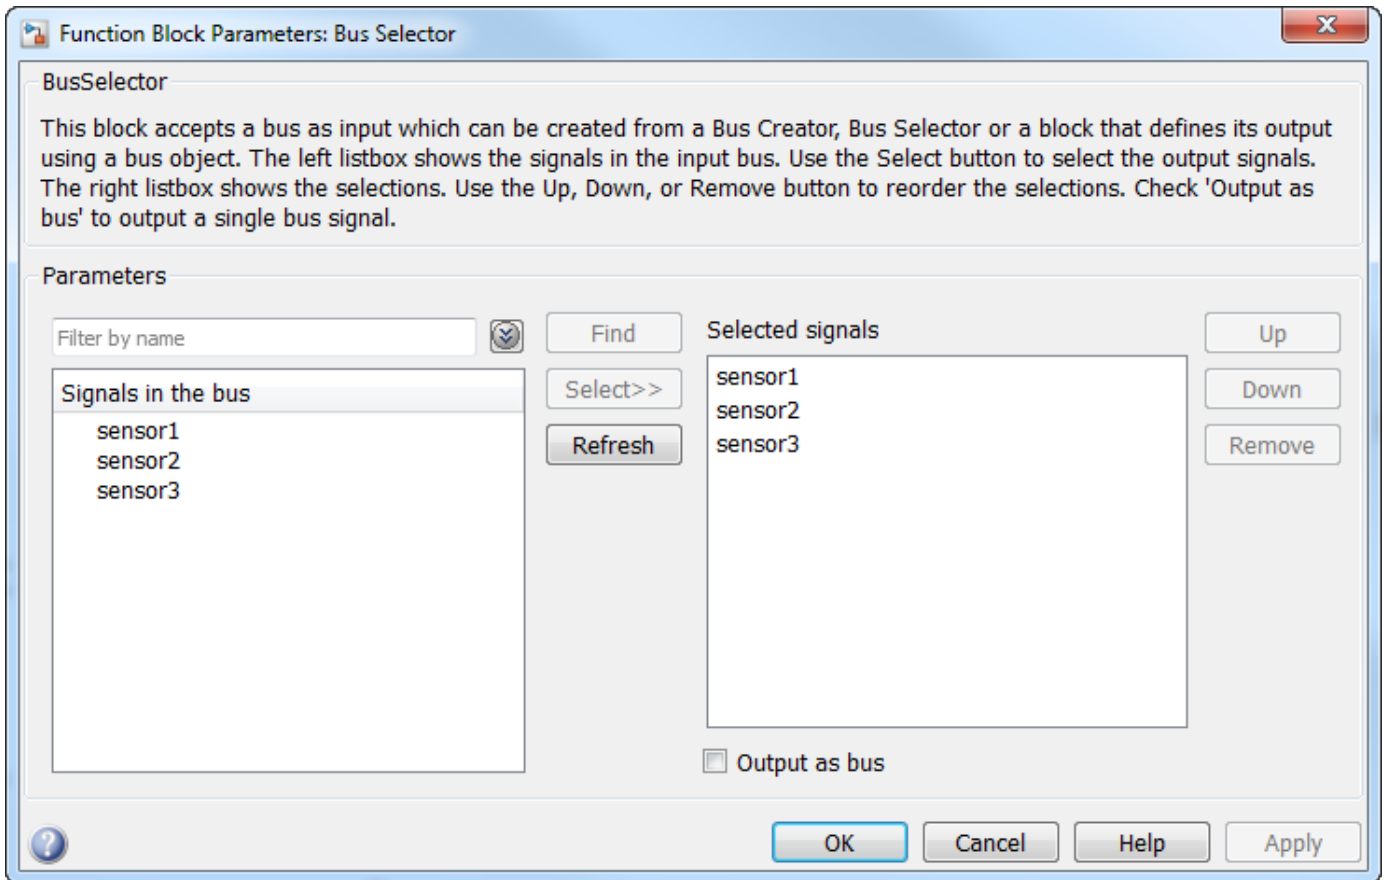

- 3 Delete the blocks as shown in the figure, leaving only the Burner\_1\_Sensor1 and Burner\_1\_Delay1 blocks as inputs to the two remaining subsystems.

- 4 On the **Signal Attributes** tab of the Burner\_1\_Sensor1 Import block dialog box, set **Data type** to Bus: SensorData.

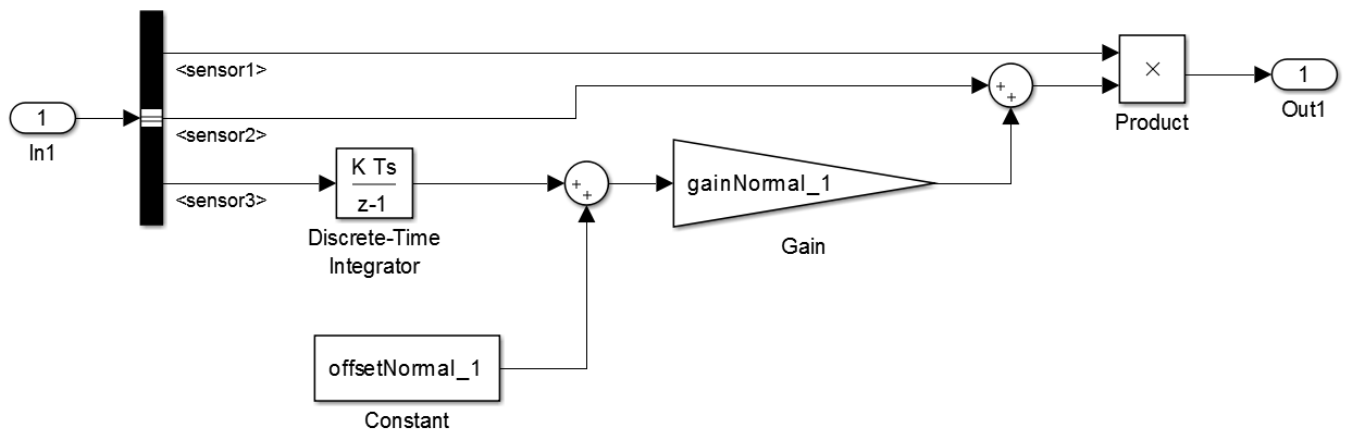

The output of the block is a bus that contains the three signal elements sensor1, sensor2, and sensor3.

- 5 Open the subsystem Burner\_1\_Analysis. Delete the signal output lines of the three Inport blocks. Delete the In2 and In3 Inport blocks.
- 6 Add a Bus Selector block to the right of the In1 Inport block. Connect the Inport block output to the Bus Selector block.
- 7 In the Bus Selector block dialog box, select the signals sensor1, sensor2, and sensor3.

The Bus Selector block extracts the three signal elements from the input bus. Other blocks in the model can use the extracted signal elements.

- 8 In the subsystem, connect the blocks as shown.

- 9 In the subsystem Burner\_1\_Analysis\_Delay, use a Bus Selector block to extract the signals in the bus. Use the same technique as you did in the subsystem Burner\_1\_Analysis.

## Repeat an Algorithm

A For Each Subsystem block partitions an input signal and sequentially executes an algorithm on each partition. For example, if the input to the subsystem is an array of six signals, you can configure the subsystem to execute the same algorithm on each of the six signals.

You can use For Each subsystems to repeat an algorithm in an iterative fashion. This approach improves model readability and makes it easy to change the repeated algorithm .

- 1 Add two For Each Subsystem blocks to the model. Name one of the subsystems Burner\_Analysis. Name the other subsystem Burner\_Analysis\_Delay.
- 2 Copy the contents of the subsystem Burner\_1\_Analysis into the subsystem Burner\_Analysis. Before you paste the blocks, delete the Inport and Outport blocks in the For Each subsystem.
- 3 In the For Each block dialog box in the Burner\_Analysis subsystem, select the check box to partition the input In1.
- 4 Copy the contents of the subsystem Burner\_1\_Analysis\_Delay into the subsystem Burner\_Analysis\_Delay.
- 5 In the For Each block dialog box in the Burner\_Analysis\_Delay subsystem, select the check box to partition the input In1.
- 6 At the top level of the model, delete the subsystems Burner\_1\_Analysis and Burner\_1\_Analysis\_Delay. Connect the new For Each Subsystem blocks in their place.
- 7 On the **Signal Attributes** tab of the Burner\_1\_Sensor1 Inport block dialog box, set **Port dimensions** to 3.

The block output is a three-element array of buses. The For Each subsystems in the model repeat an algorithm for each of the three buses in the array.

- 8 Create a Simulink.SimulationData.Dataset object that the Inport block can use to import the simulation data. You can use this code to create the object and store it in the variable SensorsInput.

```
% First, create an array of structures whose field values are
% timeseries objects

for i = 1:3 % Burner number

 % Sensor 1
 eval(['tempInput(1,' num2str(i) ').sensor1 = ' ...
 'timeseries(SensorsInput(:, ' num2str(3*(i-1)+1) '),t);'])

 % Sensor 2
 eval(['tempInput(1,' num2str(i) ').sensor2 = ' ...
 'timeseries(SensorsInput(:, ' num2str(3*(i-1)+2) '),t);'])

 % Sensor 3
 eval(['tempInput(1,' num2str(i) ').sensor3 = ' ...
 'timeseries(SensorsInput(:, ' num2str(3*(i-1)+3) '),t);'])

end

% Create the Dataset object.

SensorsInput = Simulink.SimulationData.Dataset;
SensorsInput = addElement(SensorsInput,tempInput,'element1');
```

```
clear tempInput t i
```

The code first creates a variable `tempInput` that contains an array of three structures. Each structure has three fields that correspond to the signal elements in the bus type `SensorData`, and each field stores a MATLAB `timeseries` object. Each `timeseries` object stores one of the nine columns of data from the variable `SensorsInput`, which stores the simulation input data for each of the sensors.

The code then overwrites `SensorsInput` with a new `Simulink.SimulationData.Dataset` object and adds `tempInput` as an element of the object.

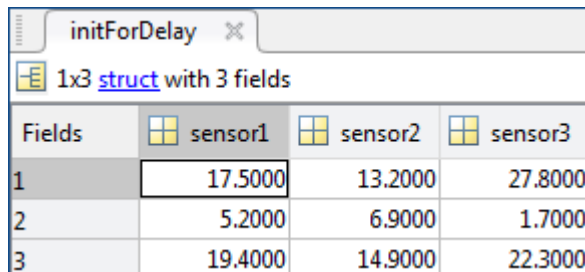

- 9 Set the **Input** configuration parameter to `SensorsInput`.

Since `SensorsInput` provides simulation input data in the form of `timeseries` objects, you do not need to specify a variable that contains time data.

- 10 Create an array of structures that initializes the remaining Memory block, and store the array in the variable `initForDelay`. Specify the structure fields with the values of the existing initialization variables such as `initDelay_1_sensor1`.

```
for i = 1:3 % Burner number
 % Sensor 1
 eval(['initForDelay(' num2str(i) ').sensor1 = ' ...
 'initDelay_' num2str(i) '_sensor1;'])
 % Sensor 2
 eval(['initForDelay(' num2str(i) ').sensor2 = ' ...
 'initDelay_' num2str(i) '_sensor2;'])
 % Sensor 3
 eval(['initForDelay(' num2str(i) ').sensor3 = ' ...
 'initDelay_' num2str(i) '_sensor3;'])
end
```

To view the contents of the new variable `initForDelay`, double-click the variable name in the base workspace. The variable contains an array of three structures that each has three fields: `sensor1`, `sensor2`, and `sensor3`.

| Fields | sensor1 | sensor2 | sensor3 |
|--------|---------|---------|---------|
| 1      | 17.5000 | 13.2000 | 27.8000 |
| 2      | 5.2000  | 6.9000  | 1.7000  |
| 3      | 19.4000 | 14.9000 | 22.3000 |

- 11 In the Memory block dialog box, set **Initial condition** to `initForDelay`.

The Memory block output is an array of buses that requires initialization. Each signal element in the array of buses acquires an initial value from the corresponding field in the array of structures.

## Organize Parameters into Arrays of Structures

The base workspace contains many variables that the example model uses for block parameters. To reduce the number of workspace variables, package them into arrays of structures, and use the individual structure fields to specify block parameters.

A For Each Subsystem block can partition an array of values that you specify as a mask parameter. Each iteration of the subsystem uses a single partition of the array to specify block parameters. If you specify the parameter as an array of structures, each iteration of the subsystem can use one of the structures in the array.

- 1 Create an array of structures that parameterizes the Burner\_Analysis For Each subsystem, and store the array in the variable `paramsNormal`. Specify the structure fields by using the values of existing parameter variables such as `gainNormal_1`, `offsetNormal_1`, and `initDelayed_1`.

```
for i = 1:3
 eval(['paramsNormal(' num2str(i) ').gain = gainNormal_' num2str(i) ';'])
 eval(['paramsNormal(' num2str(i) ').offset = offsetNormal_' num2str(i) ';'])
 eval(['paramsNormal(' num2str(i) ').init = initNormal_' num2str(i) ';'])
end
```

The variable contains an array of three structures that each has three fields: `gain`, `offset`, and `init`.

- 2 In the model, right-click the Burner\_Analysis For Each subsystem and select **Mask > Create Mask**.
- 3 On the **Parameters & Dialog** pane of the dialog box, under **Parameter**, click **Edit**. For the new mask parameter, set **Prompt** to `Parameter structure` and **Name** to `paramStruct`. Click **OK**.
- 4 In the mask for the Burner\_Analysis subsystem, set **Parameter structure** to `paramsNormal`.
- 5 Open the subsystem. In the For Each block dialog box, on the **Parameter Partition** pane, select the check box to partition the parameter `paramStruct`. Set **Partition dimension** to 2.
- 6 For the blocks in the subsystem, set these parameters.

| Block                    | Parameter Name           | Parameter Value                 |
|--------------------------|--------------------------|---------------------------------|
| Gain                     | <b>Gain</b>              | <code>paramStruct.gain</code>   |
| Discrete-Time Integrator | <b>Initial condition</b> | <code>paramStruct.init</code>   |
| Constant                 | <b>Constant value</b>    | <code>paramStruct.offset</code> |

- 7 Create an array of structures that parameterizes the Burner\_Analysis\_Delay For Each subsystem, and store the array in the variable `paramsForDelay`.

```
for i = 1:3
 eval(['paramsForDelay(' num2str(i) ').gain = gainDelayed_' num2str(i) ';'])
 eval(['paramsForDelay(' num2str(i) ').offset = offsetDelayed_' num2str(i) ';'])
 eval(['paramsForDelay(' num2str(i) ').init = initDelayed_' num2str(i) ';'])
end
```

- 8 At the top level of the model, right-click the Burner\_Analysis\_Delay For Each subsystem and select **Mask > Create Mask**.
- 9 On the **Parameters & Dialog** pane of the dialog box, under **Parameter**, click **Edit**. For the new mask parameter, set **Prompt** to `Parameter structure` and **Name** to `paramStruct`. Click **OK**.
- 10 In the mask for the For Each Subsystem block, set **Parameter structure** to `paramsForDelay`.
- 11 Open the subsystem. In the For Each block dialog box, on the **Parameter Partition** pane, select the check box to partition the parameter `paramStruct`. Set **Partition dimension** to 2.

- 12 For the blocks in the subsystem, set these parameters.

| Block                    | Parameter Name    | Parameter Value    |
|--------------------------|-------------------|--------------------|
| Gain                     | Gain              | paramStruct.gain   |
| Discrete-Time Integrator | Initial condition | paramStruct.init   |
| Constant                 | Constant value    | paramStruct.offset |

- 13 Clear the unnecessary variables from the base workspace.

```
% Clear the old parameter variables that you replaced
% with arrays of structures
clear -regexp _

% Clear the iteration variables
clear i
```

The model requires few variables in the base workspace.

## Inspect the Converted Model

To view the new signal and subsystem organization, update the diagram.

The model input is an array of three buses. The model uses two For Each subsystems to execute the two algorithms on each of the three buses in the input array.

In the base workspace, arrays of structures replace the many variables that the model used. Mathematically, the modified model behaves the same way it did when you started because the arrays of structures contain the values of all the old variables.

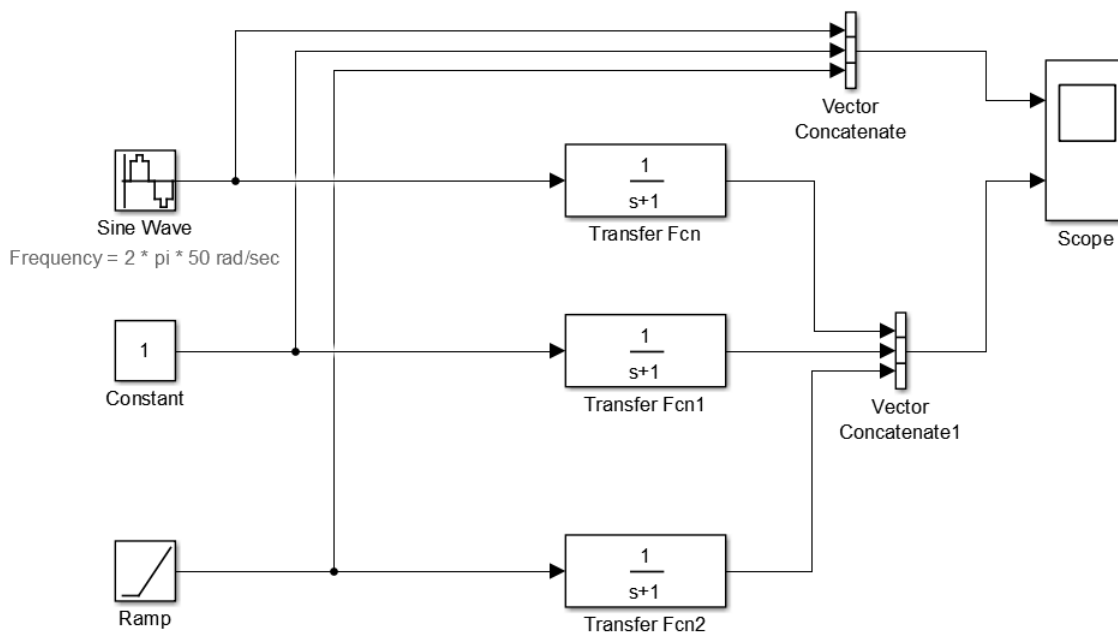

**Tip** You can log nonbus signals in a For Each subsystem. However, you cannot use signal logging for buses or arrays of buses from within a For Each subsystem. Either use a Bus Selector block to select the bus element signals that you want to log or add an Outport block outside of the subsystem and then log that signal. For details, see “Log Signals in For Each Subsystems” on page 73-72.

## Additional Examples of Working with For Each Subsystems

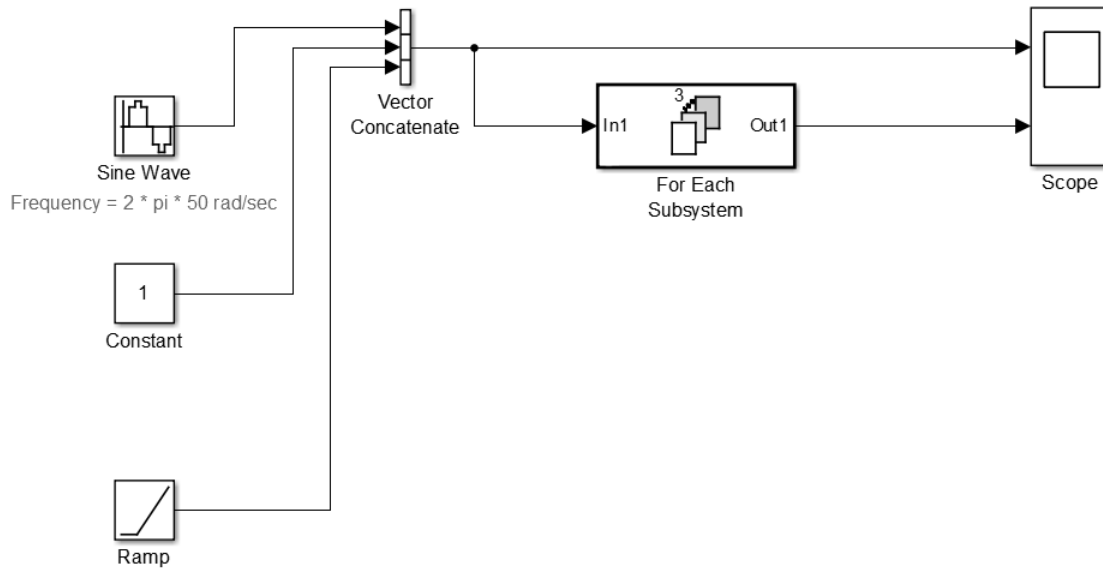

### Vectorize Algorithms Using For Each Subsystems

This example shows how to simplify modeling of vectorized algorithms. Using For Each Subsystem blocks simplifies a model where three input signals are filtered by three identical Transfer Fcn blocks. This example also shows how to add more control to the filters by changing their coefficients for each iteration of the subsystem.

This model uses identical Transfer Fcn blocks to independently process each element of the input sine wave signal. A Vector Concatenate block concatenates the resulting output signals. This repetitive process is graphically complex and difficult to maintain. Adding another element to the signal also requires significant reworking of the model.

You can simplify this model by replacing the repetitive operations with a single For Each Subsystem block.

The For Each subsystem block contains a For Each block and a model representing the algorithm of the three blocks it replaces by way of the Transfer Fcn block. The For Each block specifies how to partition the input signal vector into individual elements and how to concatenate the processed signals to form the output signal vector. Every block that has a state maintains a separate set of states for each input element processed during a given execution step.

For this example, the input signal is selected for partitioning. The **Partition Dimension** and **Partition Width** parameters on the For Each block are both set to 1 for the input.

You can scale up this approach to add more signals without having to change the model significantly. This approach is easily scalable and graphically simpler.

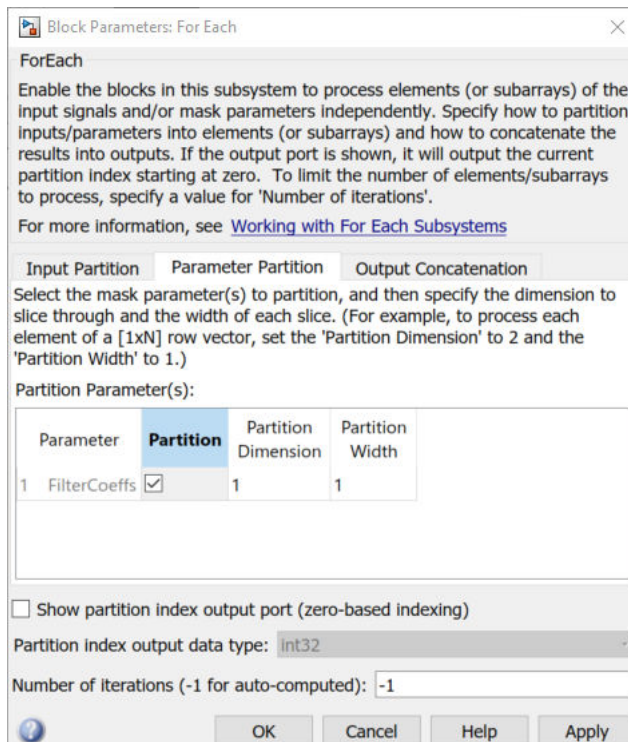

### Model Parameter Variation Without Changing Model Structure

This example shows how to model parameter variation in an algorithm. It uses the For Each Subsystem partitioning model from the above example and creates different filters for each input signal while retaining model simplicity. An array of filter coefficients is fed to the For Each subsystem block as a mask parameter marked for partitioning. In each iteration of the For Each subsystem block, a partition of the filter coefficient array is fed to the Transfer Fcn block.

- 1 Open the model `ex_ForEachSubsystem_Partitioning`. Create a mask for the For Each Subsystem block and add an editable mask parameter. Set the name to `FilterCoeffs` and the prompt to `Filter Coefficient Matrix`. For information on how to add a mask parameter, see “Create a Simple Mask” on page 39-6.

- 2 Open the For Each subsystem block. Inside the subsystem, open the For Each block dialog box.
- 3 In the **Parameter Partition** tab, select the check box next to the **FilterCoeffs** parameter to enable partitioning of this parameter. Keep the **Partition Width** and **Partition Dimension** parameters at their default value of 1.

- 4 Double-click the For Each Subsystem block and enter your filter coefficient matrix, having one row of filter coefficients for each input signal. For example, enter  $[0.0284 \ 0.2370 \ 0.4692 \ 0.2370 \ 0.0284; -0.0651 \ 0 \ 0.8698 \ 0 \ -0.0651; 0.0284 \ -0.2370 \ 0.4692 \ -0.2370 \ 0.0284]$  to implement different fourth-order filters for each input signal.
- 5 In the For Each Subsystem block, double-click the Transfer Fcn block and enter `FilterCoeffs` for the **Denominator Coefficients** parameter. This setting causes the block to get its coefficients from the mask parameter.

The For Each Subsystem block slices the input parameter into horizontal partitions of width 1, which is equivalent to one row of coefficients. The parameter of coefficients transforms from a single array

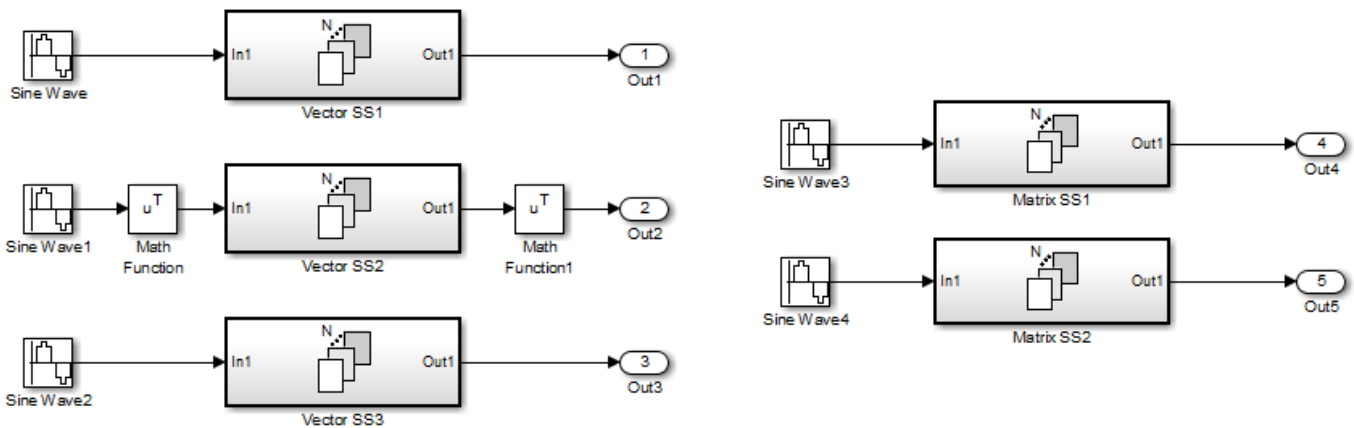

into three rows of parameters:

### Improved Code Reuse Using For Each Subsystems

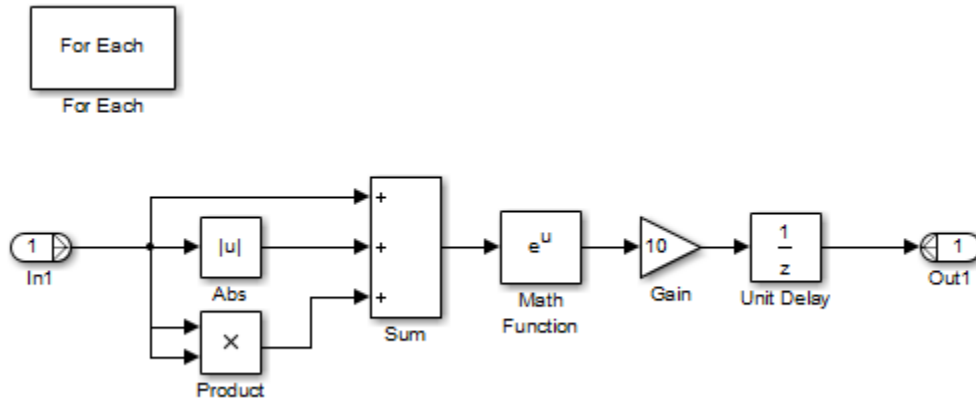

This example shows how you can improve code reuse when you have two or more identical For Each Subsystem blocks. Consider the following model, `rtwdemo_foreachreuse`.

#### Reusing Functions with Different Input Sizes

The intent is for the three subsystems — Vector SS1, Vector SS2, and Vector SS3 — to apply the same processing to each scalar element of the vector signal at their respective inputs. Because these three subsystems perform the same processing, it is desirable for them to produce a single shared Output

(and Update) function for all three subsystems in the code generated for this model. For example, the Vector SS3 subsystem contains the these blocks.

To generate a single shared function for the three subsystems, the configuration of the partitioning they perform on their input signals must be the same. For Vector SS1 and Vector SS3, this configuration is straightforward because you can set the partition dimension and width to 1. However, in order for Vector SS2 to also partition its input signal along dimension 1, you must insert a Math Function block to transpose the 1-by-8 row vector into an 8-by-1 column vector. You can then convert the output of the subsystem back to a 1-by-8 row vector using a second Math Function block set to the transpose operator.

If you press **Ctrl+B** to generate code, the resulting code uses a single output function. This function is shared by all three For Each Subsystem instances.

```

/*
 * Output and update for iterator system:
 * '<Root>/Vector SS1'
 * '<Root>/Vector SS2'
 * '<Root>/Vector SS3'
 */
void VectorProcessing(int32_T NumIters, const real_T rtu_In1[],
 real_T rty_Out1[],
 rtDW_VectorProcessing *localDW)

```

The function has an input parameter `NumIters` that indicates the number of independent scalars that each For Each Subsystem is to process. This function is called three times with the parameter `NumIters` set to 10, 8, and 7, respectively.

The remaining two subsystems in this model show how reusable code can also be generated for matrix signals that are processed using the For Each Subsystem block. Again, pressing **Ctrl+B** to generate the code provides code reuse of a single function.

## Limitations of For Each Subsystem

The For Each Subsystem block has the following limitations and workarounds.

| Limitation                                                                                                                                                                                                                                                                                                                                                                | Workaround                                                                                                                                                                                                                                                                                            |
|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <p>You cannot log bus or an array of bus signals directly in the For Each subsystem.</p>                                                                                                                                                                                                                                                                                  | <p>Use one of these approaches:</p> <ul style="list-style-type: none"> <li>• Use a Bus Selector block to select the signals you want to log and mark those signals for signal logging.</li> <li>• Attach the signal to an Outport block and log the signal outside the For Each subsystem.</li> </ul> |
| <p>You cannot log a signal inside a referenced model that is inside a For Each subsystem if either of these conditions exists:</p> <ul style="list-style-type: none"> <li>• The For Each subsystem is in a model simulating in Rapid Accelerator mode.</li> <li>• The For Each subsystem itself is in a model referenced by a Model block in Accelerator mode.</li> </ul> | <p>For the first condition, use Accelerator mode.</p> <p>For the second condition, use Normal or Rapid Accelerator mode.</p>                                                                                                                                                                          |

The For Each Subsystem block does not support these features:

- You cannot include these blocks or S-functions inside a For Each Subsystem:
  - Data Store Memory, Data Store Read, or Data Store Write blocks
  - The From Workspace block if the input is a Structure with Time that has an empty time field
  - The To Workspace and To File data saving blocks
  - Goto and From blocks that cross the subsystem boundary
  - Referenced model with simulation mode set to Normal
  - Shadow Inports
  - ERT S-functions

For a complete list of the blocks that support the For Each Subsystem, type `showblockdatatypetable` at the MATLAB command line.

- You cannot use these types of signals:
  - Signals with an external storage class inside the system

- Frame signals on subsystem input and output boundaries
- Variable-size signals
- Creation of a linearization point inside the subsystem
- Propagating the Jacobian flag for the blocks inside the subsystem. You can check this condition in MATLAB using `J.Mi.BlockAnalyticFlags.jacobian`, where `J` is the Jacobian object. To verify the correctness of the Jacobian of the For Each Subsystem block:
  - Look at the tag of the For Each Subsystem Jacobian. If it is “`not_supported`”, then the Jacobian is incorrect.
  - Move each block out of the For Each Subsystem and calculate its Jacobian. If any block is “`not_supported`” or has a warning tag, the For Each Subsystem Jacobian is incorrect.
- You cannot perform these types of code generation:
  - Generation of a Simulink Coder S-function target
  - Simulink Coder code generation under both of the following conditions:
    - A Stateflow or MATLAB Function block resides in the subsystem.
    - This block tries to access global data outside the subsystem, such as Data Store Memory blocks or `Simulink.Signal` objects of `ExportedGlobal` storage class.
  - PLC code generation
- In some cases, a model using a For Each subsystem may take longer to simulate in normal mode than it would take if the model were implemented using separate subsystems.

## Temperature Control System Communicating with Messages

This example shows how to use message communication within a distributed system where the controller manages multiple incoming messages from different senders in an iterative manner and sends messages to communicate commands to the different receivers. The example uses a model of a control system managing temperatures in two different rooms with separate thermostats. The algorithmic modeling of the components basically follows the Stateflow example “Model Bang-Bang Temperature Control System” (Stateflow), while the communication between the components is modeled using Simulink® messages and SimEvents® blocks. The referenced models Controller and Thermometer, colored in blue, are software components expected to generate standalone code, while the other components model the environment.

Copyright 2020 The MathWorks, Inc.

### Model Overview

The model contains  $N$  identical rooms with thermostats (modeled by multi-instanced model blocks), where  $N = 2$  is a Simulink parameter defined in the Simulink data dictionary file `s1ddMsg.s1dd`, which is linked to the top model and referenced models. Each room can set the setpoint temperature separately. The thermostats for the rooms are remotely controlled by a controller, using the same control algorithm for all thermostats.

The thermostats send temperature messages to the controller every  $0.2$  seconds, while the controller sends command messages to the thermostats to command heating on or off every  $1$  second. An Entity Output Switch (SimEvents) block routes the messages from the controller to one of the thermostats according to the message bus data field `deviceID`. (The bus is also defined in the data dictionary and shared across all models.) A Message Merge block routes the messages from different thermostats to the controller.

Initially, the model is configured using bus types with floating-point type fields that are defined in the data dictionary file `s1ddMsg.s1dd`. To switch from floating-point to fixed-point, change the data

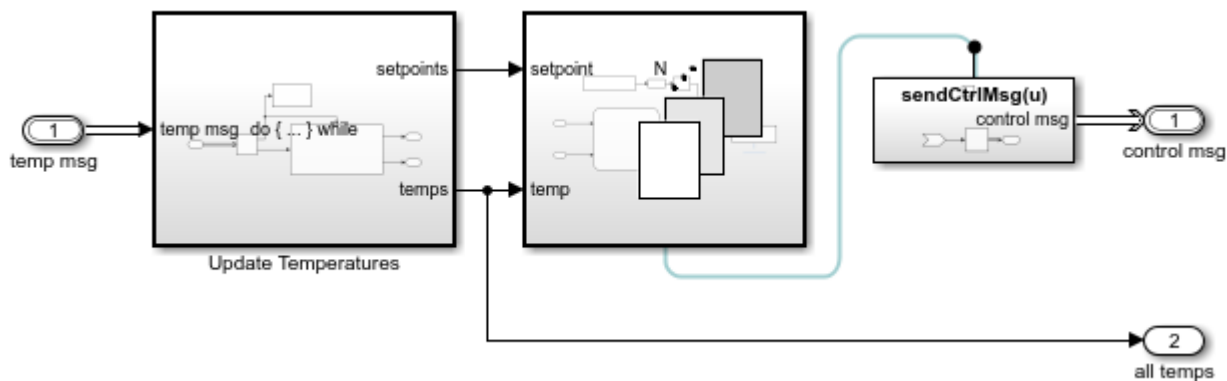

dictionary for the model from `sLddMsg.sldd` to `sLddMsgFixpt.sldd`. On the **Modeling** tab, go to **Model Settings > Model Properties > External Data**.

The model is easily scalable by changing the value of  $N$ , adding more instances of the model block, and increasing the port number of the Entity Output Switch and Message Merge blocks. Each Thermometer model inside the Room model has an ID argument, which must be set with a value that matches the output port index of the Entity Output Switch.

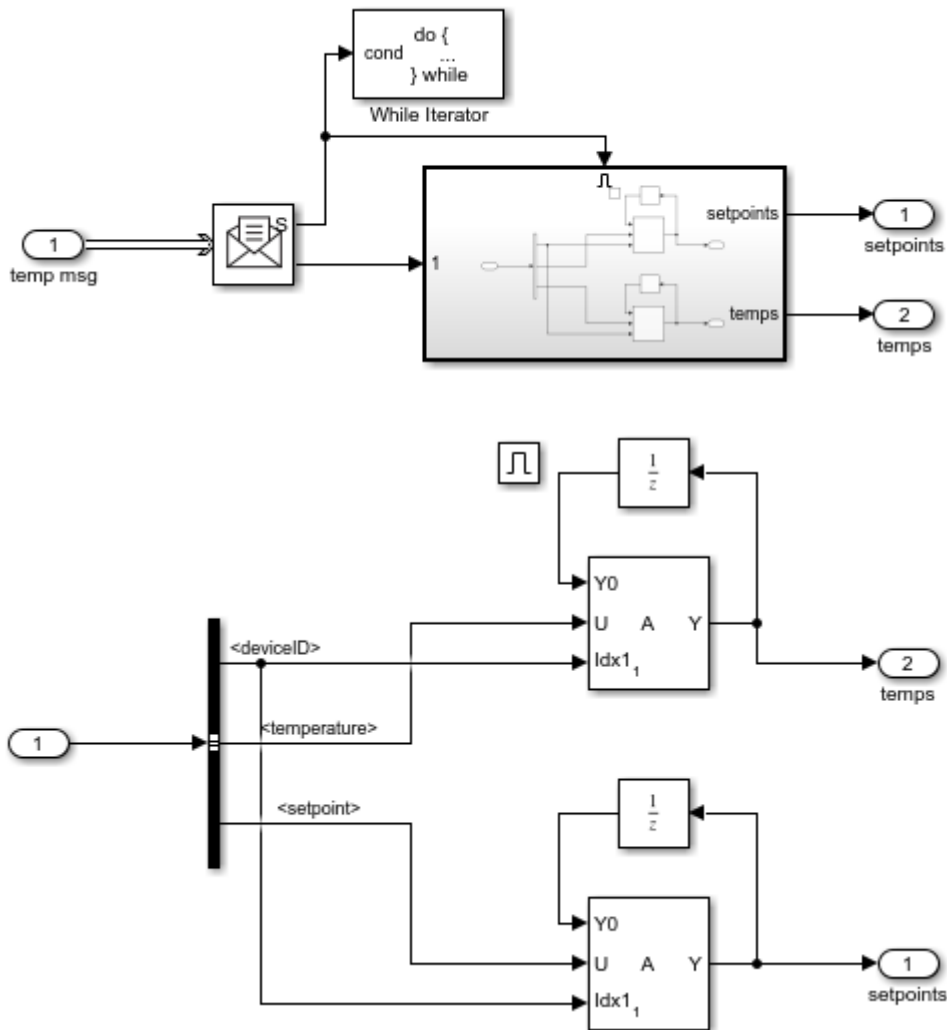

A Queue block (FIFO, overwriting type queue) in front of the controller model buffers the message, which models the queue inside the message middleware of the controller. Here, a capacity of  $N$  is good enough for the queue to overwrite the oldest messages with the new ones from each sender, assuming no message loss in transit. A capacity of  $5*N$  is needed for the worst scenario with message loss, where 5 is the sample time of the controller divided by the sample time of the thermostats. In addition, a queue in front of each thermostat with capacity 1 is automatically inserted and shows a badge icon of sandwiched "1", because a capacity-1 queue is automatically inserted if you do not intentionally place a Queue block. See "Use a Queue Block to Manage Messages" on page 11-12.

To view the sequences of messages and events, on the Simulink Toolstrip, on the **Simulation** tab, in the **Review Results** section, click **Sequence Viewer**. See Sequence Viewer.

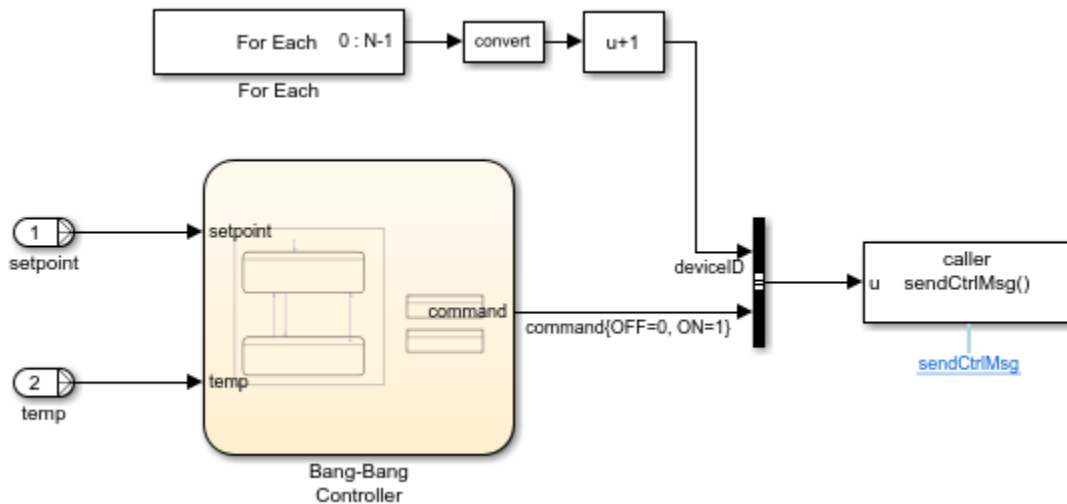

### Controller Model

In the Controller model, the Update Temperature subsystem connected with the Inport block first receives all messages containing temperature information from the rooms. The subsystem stores that information in two vectors of temperature setpoint and current temperature. Then, the For Each subsystem reads the vectors, processes the signals, and sends out the control messages via the Simulink function `sendCtrlMsg`.

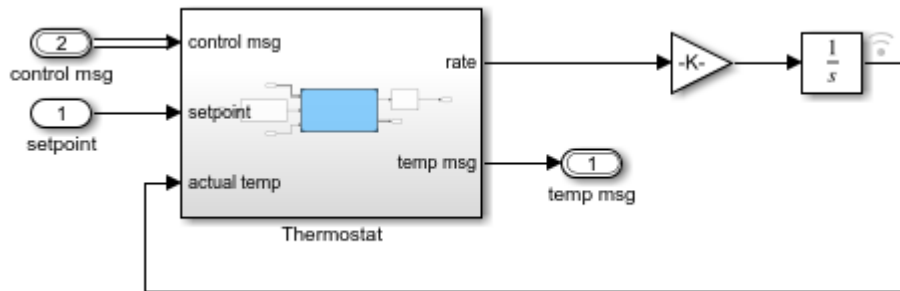

The Update Temperature subsystem is a do-while subsystem whose termination condition port is fed by the Receive block's status port, meaning it runs until cannot receive any more messages from the external queue (in the top model). The message data is of DeviceMsg bus type, which is defined in the data dictionary file, and has two fields: temperature and deviceID. Thus, when the output signal of the Receive block propagates to the enabled subsystem whose enable port is connected to the Receive block's status port, the Bus Selector block decomposes the signal into deviceID, temperature, and setpoint signals. The setpoint and temperature signals are then assigned to the respective vector elements associated with the deviceID. Finally, the vectors maintained by the Unit Delay blocks are output as signals by the enabled subsystem and Update Temperature subsystem to the For Each subsystem.

The For Each subsystem, whose block settings are shown above, is set to have N iterations, and both of its input ports are partitioned. A Stateflow chart models the Bang-Bang Controller, which resembles the one explained in “Model Bang-Bang Temperature Control System” (Stateflow). Its output port outputs a Boolean signal indicating whether or not to turn on heating. This signal is packed into a nonvirtual signal at the Bus Creator block with the deviceID (one-based) from the iteration number (zero-based). The signal is given to the Function Caller block, which calls the Simulink Function SendCtrlMsg (placed outside the For Each Subsystem) to send the message out from the model.

## Room Model

In the Room model, the Thermostat subsystem interacts with the environment. The Thermostat has two inputs, the control message and the setpoint temperature signal, and two outputs, the heating rate and the temperature message to the controller. The Gain and Integrator blocks simulate the physics of the room heating or cooling with respect to the heating rate and room size.

The Thermostat subsystem is composed of a Thermometer Sensor subsystem, a Thermometer Software model block, and a Temperature Actuator subsystem. The Thermometer Software model block periodically receives a control message from the controller and unpacks it into a Boolean command (on/off) to the Temperature Actuator subsystem, which determines the heating rate. The Thermometer Software also inputs a temperature signal from Thermometer Sensor subsystem, which detects the analog temperature, converts it to a digital signal, and sends the message back to the controller.

## Thermometer Model

In the Thermometer model, a Receive block connects with the Inport block to receive a control message from the external queue at each time step. The message data is decomposed into a command signal, which is an output, and a deviceID signal, which must match the ID argument of the model. The ID argument should be set in the model block in the top model. The Receive block's initial value is set to a MATLAB® structure with the `deviceID` field equal to the model argument ID and the `command` field taking a value of `false`. Meanwhile, the signals of digital temperature, setpoint, and deviceID are packed into a nonvirtual bus signal and sent as a message to the Outport block.

## Code Generation

For code generation and deployment, the referenced models Controller and Thermometer (colored blue) can generate standalone embedded-target C++ code and can be deployed separately on embedded devices with message middleware. For more information, see “Generate C++ Messages to Communicate Between Simulink and an Operating System or Middleware” (Embedded Coder); see also “Use Handwritten Code to Integrate C++ Messages with POSIX” (Embedded Coder).

Message root-level Inport/Outport does not support C code generation and code customization. If you need to generate C code and call into a message middleware API for sending messages, consider moving the Simulink function `sendCtrlMsg` to the top model and customizing the name properly so that the referenced model generates a customizable call site of an external function. Similarly, for the receive side, consider using a Simulink function containing a Receive block in the top model and using a Function Caller block in the referenced model to replace the Receive block.

## Multithreaded Simulation using For Each Subsystem

This example shows how to speed up execution of a model on multiple cores using a For Each subsystem in Rapid Accelerator simulation mode.

### Measure the Single-Threaded Simulation Time

In this model, a For Each subsystem accepts a numeric array input. Each element of the array serves as an upper bound in each iteration and feeds into a computationally-intensive algorithm represented by the MATLAB Function block inside the subsystem. The algorithm implemented in the MATLAB Function block computes the largest prime number within a given range using a brute force method, which is for illustrative purposes only.

```
modelName = 'slexForEachMultithreaded';
open_system(modelName);
```

By default, the multithreaded simulation support for the For Each subsystem is enabled. To opt out of multithreaded simulation, issue a `set_param` command in the MATLAB® Command Window. In a single-threaded simulation, the computations in different iterations of the For Each subsystem are executed sequentially during each time step.

```
set_param(modelName, 'MultithreadedSim', 'off');
```

Since running in Rapid Accelerator mode creates files, first create a temporary directory and move to it.

```
originalDir = pwd;
tempDir = tempname;
mkdir(tempDir);
cd(tempDir);
```

Build the Rapid Accelerator target for the model. The progress of the code generation and build process is displayed in the MATLAB Command Window. To suppress this display, wrap the command inside `evalc`.

```
evalc('Simulink.BlockDiagram.buildRapidAcceleratorTarget(modelName)');
```

This build step is optional because Simulink® automatically generates the Rapid Accelerator simulation target the first time you simulate the model. In the example, this step serves to separate the overhead in generating the Rapid Accelerator target from the actual model execution time.

Once the Rapid Accelerator target is generated, simulate the model and measure the simulation time using `tic` and `toc`.

```
tic
evalc('sim(modelName)');
toc
```

### Use Multithreaded Simulation for Speedup on Multiple Cores

To explicitly opt in to multithreading support, issue a `set_param` command in the MATLAB Command Window. In a multithreaded simulation, the computations in different iterations of the For Each subsystem are assigned to multiple cores and executed in parallel for speedup.

```
set_param(modelName, 'MultithreadedSim', 'auto');
```

Build the Rapid Accelerator target again, since the model has been reconfigured.

```
evalc('Simulink.BlockDiagram.buildRapidAcceleratorTarget(modelName)');
```

Simulate the model again and measure the multithreaded simulation time. Notice that the model simulation runs over two times faster than the single-threaded simulation on a machine with four or more cores. Remember that operating system context-switching in multithreaded simulations always results in extra overhead.

```
tic
evalc('sim(modelName)');
toc
```

### **Clean Up**

Close the model and remove the generated files.

```
bdclose(modelName);
cd(originalDir);
rmdir(tempDir, 's');
clear originalDir tempDir;
```

## Share and Reuse Bus-Routing Blocks

With custom libraries, you can share and reuse blocks that input or output buses. For a block linked to a parent library block that expects a bus input, you must provide the appropriate input bus. For example, the input bus for a Bus Selector block that is linked to a library must contain signals that have the same name as the signals that the parent library block selects.

To modify the parent library block, perform these steps. For details about modifying library links, see “Linked Blocks” on page 41-13.

- 1 Copy the parent library block to a model.
- 2 Connect a bus to the input port of the block.
- 3 Disable the link to the parent library block.
- 4 Edit the block within the context of the model.
- 5 Resolve the link to the library.
- 6 In the Link Tool, in **Push/Restore Mode**, select Push to place the edited content in the library.
- 7 Save the library.

To lock the interface of a parent library block, set its data type to a `Simulink.Bus` object.

With subsystem references, you can share and reuse a subsystem containing blocks that input or output buses and their associated signal lines. For more information, see “Subsystem Reference” on page 4-27.

## Generate Code for Nonvirtual Buses

If you have Simulink Coder, whether you use a virtual or nonvirtual bus can make a significant difference in the efficiency, size, and readability of generated code. For example, a nonvirtual bus appears as a structure in generated code, and only one copy exists of any algorithm that uses the bus. The use of a structure in the generated code can be helpful when tracing the correspondence between the model and the code. For example, here is the generated code for the COUNTERBUSCreator block in the ex\_bus\_logging model.

```

43 /* BusCreator: '<Root>/COUNTERBUSCreator' incorporates:
44 * DiscretePulseGenerator: '<Root>/Pulse Generator'
45 */
46 ex_bus_logging_B.COUNTERBUS_n.data = ((ex_bus_logging_DW.clockTickCounter < 1)
47 && (ex_bus_logging_DW.clockTickCounter >= 0));

56 /* BusCreator: '<Root>/COUNTERBUSCreator' incorporates:
57 * BusCreator: '<Root>/LIMITBUSCreator'
58 * Constant: '<Root>/Lower_saturation_limit'
59 * Constant: '<Root>/upper_saturation_limit'
60 */
61 ex_bus_logging_B.COUNTERBUS_n.limits.upper_saturation_limit = 40;
62 ex_bus_logging_B.COUNTERBUS_n.limits.lower_saturation_limit = 0;

```

A virtual bus does not appear as a structure or any other coherent unit in generated code. A separate copy of any algorithm that manipulates the bus exists for each element. In general, virtual buses do not affect the generated code.

To group signals into structures in the generated code, use nonvirtual buses. See “Organize Data into Structures in Generated Code” (Simulink Coder).

When you create a MATLAB structure to initialize a bus that contains non-double signal elements, you need to set the values of structure fields. The technique that you choose to set the values can influence the efficiency and readability of the generated code. See “Control Data Types of Initial Condition Structure Fields” on page 77-106.

When you generate code for a bus that is input to or output from a referenced model, there are some code generation limitations. See “Use Buses at Model Interfaces” on page 77-34.

Code generation for arrays of buses produces structures with a specific format. See “Code Generation for Arrays of Buses” on page 77-111.

## Control Data Types of Initial Condition Structure Fields

You can use a MATLAB structure to initialize the signal elements in a bus. See “Specify Initial Conditions for Bus Elements” on page 77-61.

If the signal elements of the target bus use numeric data types other than `double`, in general:

- To avoid manually matching the field data types with the data types of the signal elements, use untyped expressions to set the field values. As you develop and rapidly prototype a model, use this technique for convenience.
- To generate more efficient production code and to avoid floating-point storage in the code, match the data types of the structure fields with the data types of the corresponding signal elements.

The technique that you choose can influence the efficiency and readability of the generated code.

For examples and more information about tunable initial conditions in the generated code, see “Control Signal and State Initialization in the Generated Code” (Simulink Coder).

### Inline Numeric Values of Structure Fields in the Generated Code

If you set the **Default parameter behavior** configuration parameter to `Inlined`, by default, the field values of the initial condition structure appear in the generated code as inlined numbers (non-tunable). For these structures, use untyped expressions to set the field values in Simulink. The field values do not require data types because the structure is not tunable in the generated code.

However, if you later set **Default parameter behavior** to `Tunable` or apply a storage class to the structure by using a `Simulink.Parameter` object, the code can contain floating-point storage and inefficient explicit typecasts and bit shifts. To avoid these issues, consider matching the data types of the structure fields with the data types of the corresponding signal elements.

### Generate Tunable Structure Specified Directly in a Block Dialog Box

Suppose that you specify an initial condition structure directly in a block dialog box, or in a `Simulink.Signal` object, with an expression such as `struct('signal1',5,'signal2',7.2)` (instead of storing the structure in a variable or `Simulink.Parameter` object). In this case, to generate a tunable structure in the code, you set **Default parameter behavior** to `Tunable`.

Use the table to decide how to control the data types of the fields in these initial condition structures.

| Goal                  |                                                                                 | Technique                                                                                                                                                                          |
|-----------------------|---------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Use a nonvirtual bus. |                                                                                 | Use untyped expressions to set the field values.                                                                                                                                   |
| Use a virtual bus.    | Avoid manually matching the field data types with those of the signal elements. | Use untyped expressions to set the field values.                                                                                                                                   |
|                       | Generate more efficient code and avoid floating-point storage.                  | Match the structure field data types with the signal element types. Store the data type information in the <code>struct</code> by using typed expressions to set the field values. |

### Generate Tunable Structure Stored in a Variable or Parameter Object

Suppose that you store an initial condition structure in a variable or `Simulink.Parameter` object that you create in the base workspace or a data dictionary. For example, you use this technique to share the structure between multiple blocks, or to generate a tunable structure when you set **Default parameter behavior** to `Inlined`. In this case, use the table to decide how to control the data types of the fields in the initial condition structure.

| Goal                                                                                                                                                                                          | Technique                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Avoid manually matching the field data types with those of the signal elements.                                                                                                               | Use untyped expressions to set the field values. In the generated code, the structure fields use the data type <code>double</code> . The generated algorithm uses explicit typecasts to reconcile the data type mismatches.                                                                                                                                                                                                                           |
| Generate more efficient code and avoid floating-point storage.                                                                                                                                | <p>Match the structure field data types with the signal element types. Store the data type information in the structure fields or use a <code>Simulink.Bus</code> object to control the data types of the fields and the signal elements simultaneously.</p> <p>To use the Model Advisor to check your model for potentially expensive data type mismatches, see “Check structure parameter usage with bus signals”.</p>                              |
| Initialize an array of buses in a referenced model by using an array of structures. Pass the array of structures to the referenced model as the value of a model argument in the Model block. | <p>Match the structure field data types with the signal element types. Store the data type information in the structure fields or use a <code>Simulink.Bus</code> object to control the data types of the structure fields and the signal elements simultaneously.</p> <p>If you do not pass the structure to the referenced model as a model argument, follow the other guidelines for nonvirtual buses to decide how to control the data types.</p> |

### Use Untyped Expressions to Set Field Values

You can use untyped expressions to set the structure field values. The fields implicitly use the data type `double`. Set the field values to represent the ideal, real-world initialization values.

You avoid manually matching the field data types with the data types of the corresponding signal elements. However, depending on the virtuality of the bus, the method that you use to apply the

initial condition, and other factors, you can introduce floating-point storage and potentially inefficient typecasts in the generated code.

Suppose that you create a bus `myBusSig` with these signal elements. Each element uses a specific data type.

```
myBusSig
 signalElement1 (int32)
 signalElement2 (boolean)
 signalElement3 (single)
```

Create an initial condition structure `initStruct`. Use untyped expressions to specify the field values. Optionally, to enhance readability of the Boolean field `signalElement2`, use the value `false` instead of `0`.

```
initStruct.signalElement1 = 3;
initStruct.signalElement2 = false;
initStruct.signalElement3 = 17.35;
```

If you use the function `Simulink.Bus.createMATLABStruct` to create the structure, the function stores data type information in the structure fields. After you create the structure, you can optionally use untyped expressions to change the field values. See “Use `Simulink.Bus.createMATLABStruct` to Create Structure” on page 77-109.

### Store Data Type Information in Structure Fields

To store data type information in the structure fields, use typed expressions to set the field values, or use the function `Simulink.Bus.createMATLABStruct` to create the structure. Use these techniques to generate efficient code by eliminating floating-point storage and potentially inefficient explicit typecasts.

To avoid manually applying new data types to the structure fields when you change the data types of the corresponding signal elements, consider using a `Simulink.Bus` object to control the data types in the structure and the bus simultaneously.

### Use Typed Expressions to Set Field Values

Suppose that you create a bus `myBusSig` with these elements, which use specific data types.

- `signalElement1 (int32)`
- `signalElement2 (boolean)`
- `signalElement3 (single)`

Create an initial condition structure `initStruct` by using typed expressions to set the field values. Match the data types of the fields with the data types of the corresponding signal elements.

```
initStruct.signalElement1 = int32(3);
initStruct.signalElement2 = false;
initStruct.signalElement3 = single(17.35);
```

The structure fields store data type information. If you later change the data type of a signal element, manually apply the new data type to the corresponding structure field.

To match a fixed-point data type, set the field value by using a `fi` object.

### Change Field Value by Preserving Data Type Information

Suppose that you change the value of a field in an existing initial condition structure. To preserve the data type information in the field you can use subscripted assignment, with the syntax ( : ).

```
initStruct.signalElement3(:) = 16.93;
```

If you do not use subscripted assignment, you must remember to preserve the data type by using a typed expression.

```
initStruct.signalElement3 = single(16.93);
```

If you do not use either of these techniques, the field loses the data type information.

```
initStruct.signalElement3 = 16.93; % Field data type is now 'double'.
```

### Use Simulink.Bus.createMATLABStruct to Create Structure

You can use the function `Simulink.Bus.createMATLABStruct` to create a structure whose fields all have ground values, typically 0. If you configure the data types of the signal elements before using the function, for example by setting the output data types of the blocks that generate the signal elements, each field in the output structure uses the same data type as the corresponding signal element. The fields store the data type information as if you use typed expressions to set the values.

You can initialize some of the signal elements with a value other than ground by passing a partial structure to the function. When you create this partial structure, match the data type of each field with the data type of the corresponding signal element by using typed expressions. For more information and examples, see `Simulink.Bus.createMATLABStruct`.

When you later change the value of a field in the structure, choose one of these techniques to set the new value:

- Untyped expression. The field value no longer stores the data type information.
- Typed expression or subscripted assignment. The field value continues to store the data type information.

### Use Bus Object as Data Type of Initial Condition Structure

Whether you store data type information in the structure fields or use untyped expressions to set the field values, you can use a `Simulink.Bus` object as the data type of the entire initial condition structure. You can then manage the field values and data types independently.

If you use this technique, consider using untyped expressions to set the field values. Then, you do not need to match the field data types manually when you change the data types of the signal elements. To control the data types of the fields and the signal elements, use the `DataType` property of the elements in the `Bus` object.

Suppose that you use a Bus Creator block to create a bus `myBusSig` with these elements:

- `signalElement1` (`int32`)
- `signalElement2` (`boolean`)
- `signalElement3` (`single`)

- 1 Open the Bus Editor.

buseditor

- 2 Create a Bus object, `myBus`, that corresponds to the bus.

- 3 Create an initial condition structure `initStruct`. Used untyped expressions to set the field values. To enhance readability of the field `signalElement2`, use the Boolean value `false` instead of `0`.

```
initStruct.signalElement1 = 3;
initStruct.signalElement2 = false;
initStruct.signalElement3 = 17.35;
```

- 4 To represent the structure, create a `Simulink.Parameter` object.

```
initStruct = Simulink.Parameter(initStruct);
```

- 5 Use the parameter object to specify an initial condition for the bus. For example, in a Unit Delay block dialog box, set **Initial condition** to `initStruct`.

- 6 Use the Bus object to specify the data type of the parameter object.

```
initStruct.DataType = 'Bus: myBus';
```

- 7 Use the Bus object to specify the data type of the bus. For example, in the Bus Creator block dialog box, set **Output data type** to `Bus: myBus`.

During simulation and in the generated code, the structure fields and the signal elements use the data types that you specify in the Bus object. Before simulation and code generation, the parameter object casts the structure fields to the data types that you specify in the Bus object.

For basic information about Bus objects, see “Specify Bus Properties with Simulink.Bus Object Data Types” on page 77-51.

### Configure Data Types for Existing Structure

To remove data type information from all the fields of a structure, you can write a custom function that replaces the field values with double numbers. Use the example function `castStructToDb1` as a template.

To convert a structure that uses doubles to one that stores data type information, you can create a reference structure using the function `Simulink.Bus.createMATLABStruct`. You can then write a custom function to cast the field values to the data types in the reference structure. Use the example function `castStructFromDb1` as a template.

### Check for Mismatched Data Types with Model Advisor

To detect when the data types of structure fields are not consistent with associated bus elements, use the Model Advisor.

- 1 On the **Modeling** tab, click **Model Advisor**.

- 2 Click **OK**.
- 3 Under **By Task > Modeling Signals and Parameters using Buses**, select **Check structure parameter usage with bus signals**.
- 4 Click the **Run This Check** button.

## Code Generation for Arrays of Buses

When you generate code for a model that includes an array of buses, a `typedef` that represents the underlying bus type appears in the `*_types.h` file.

Code generation produces an array of C structures that you can integrate with legacy C code that uses arrays of structures. As necessary, code for bus variables (arrays) is generated in the following structures:

- Block IO
- States
- External inputs
- External outputs

Here is a simplified example of some generated code for an array of buses.

```
typedef struct {
 real_T a;
 real_T b; /* Block signals (auto storage) */
} BusObject; typedef struct {
 BusObject ForEachSubsystem_IterInp_0[2];
 } BlockIO_aob1;
```

For basic information about code generation for nonvirtual buses, which appear in the code as structures, see “Organize Data into Structures in Generated Code” (Simulink Coder).

## Inspect Generated Code for Nonvirtual Buses

This example shows how nonvirtual buses appear in the generated code for a model. The steps require a Simulink® Coder™ license.

Open and simulate the example model, which contains a nonvirtual bus.

Copyright 2019 The MathWorks, Inc.

Open the **Simulink Coder** app. On the **Apps** tab, click the arrow on the far right of the **Apps** section. Under **Code Generation**, click **Simulink Coder**.

To generate code for the model, on the **C Code** tab, click **Generate Code**.

To see the generated files, open the NonvirtualBusCodeGenModel\_grt\_rtw folder.

NonvirtualBusCodeGenModel\_types.h defines the Simulink.Bus object as a struct.

```
typedef struct {
 real_T a;
 real_T b;
 real_T c;
} BusObject;
```

NonvirtualBusCodeGenModel.h defines the Unit Delay block using the BusObject struct.

```
typedef struct {
 BusObject UnitDelay_DSTATE; /* '<Root>/Unit Delay' */
} DW_NonvirtualBusCodeGenModel_T;
```

NonvirtualBusCodeGenModel.c implements the Unit Delay block, which passes the nonvirtual bus to the Outport block.

```
NonvirtualBusCodeGenModel_Y.Out1 =
NonvirtualBusCodeGenModel_DW.UnitDelay_DSTATE;
```

## Trace Connections Using Interface Display

In the Simulink Editor, you can turn on and off the display of interfaces in a model. When you are building large, complex models, you can connect or add signal lines between blocks or buses that are at different levels. The interface view allows you to trace signals through the nested levels. This capability helps you to:

- Identify inputs and outputs.
- Trace signal lines and bus elements to sources and terminations.
- Annotate signal characteristics such as data type, dimensions, and sample time.
- View units associated with signals, where applicable.

When you build a model, transition block pairs such as Inport and Outport and From and Goto help you to simplify connections of the crossovers among many signal lines. The interface view enables you to trace the hand-off and receipt between such blocks by way of colored highlights.

### Trace Connections in a Subsystem

This example shows how to use the display of model interfaces to examine, trace, and understand the flow of signals and buses. This model propagates buses into referenced models.

- 1 Open the model `sldemo_md\ref_counter_bus`.

The `counter_bus_input` port channels the data and saturation limits of the counter to count and sets the upper and lower limit values. The `increment_bus_input` port channels a bus to change the increment and reset the counter.

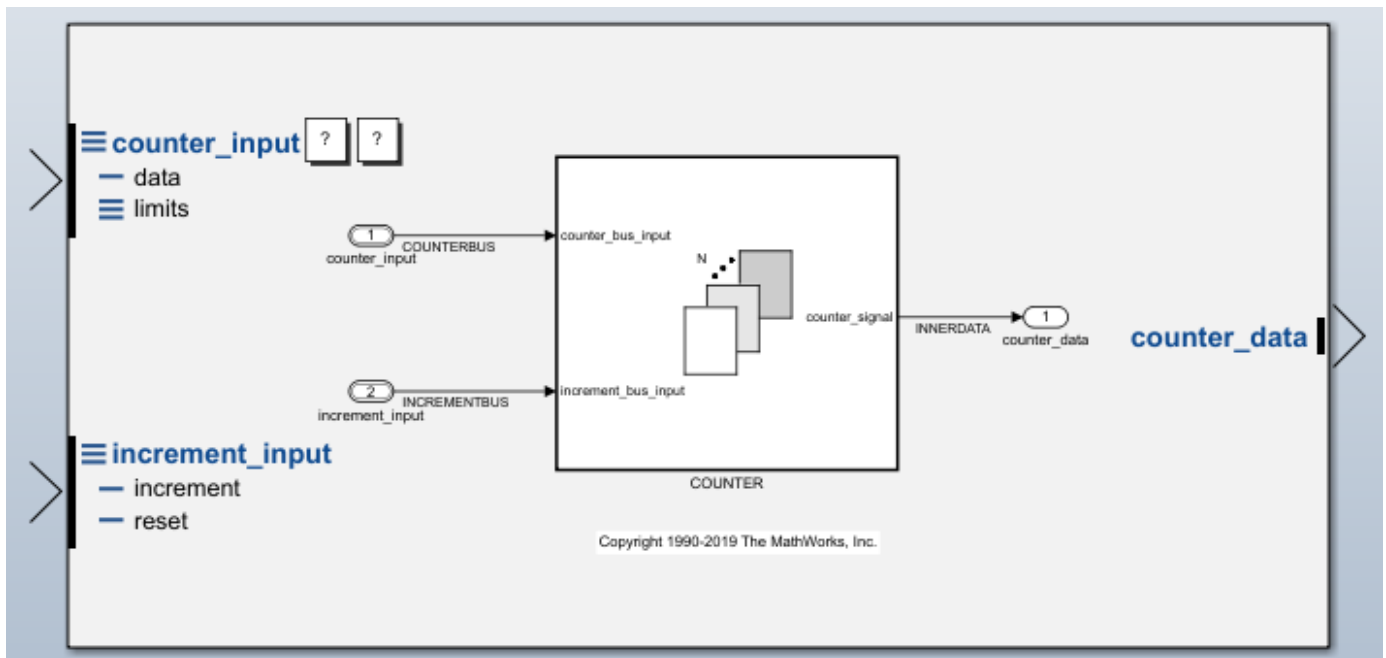

- 2 On the **Modeling** tab, under **Design**, click **Model Interface** to enable the interface view.

**Tip** Use the perspectives control in the lower-right corner of the model to toggle the display of interfaces.

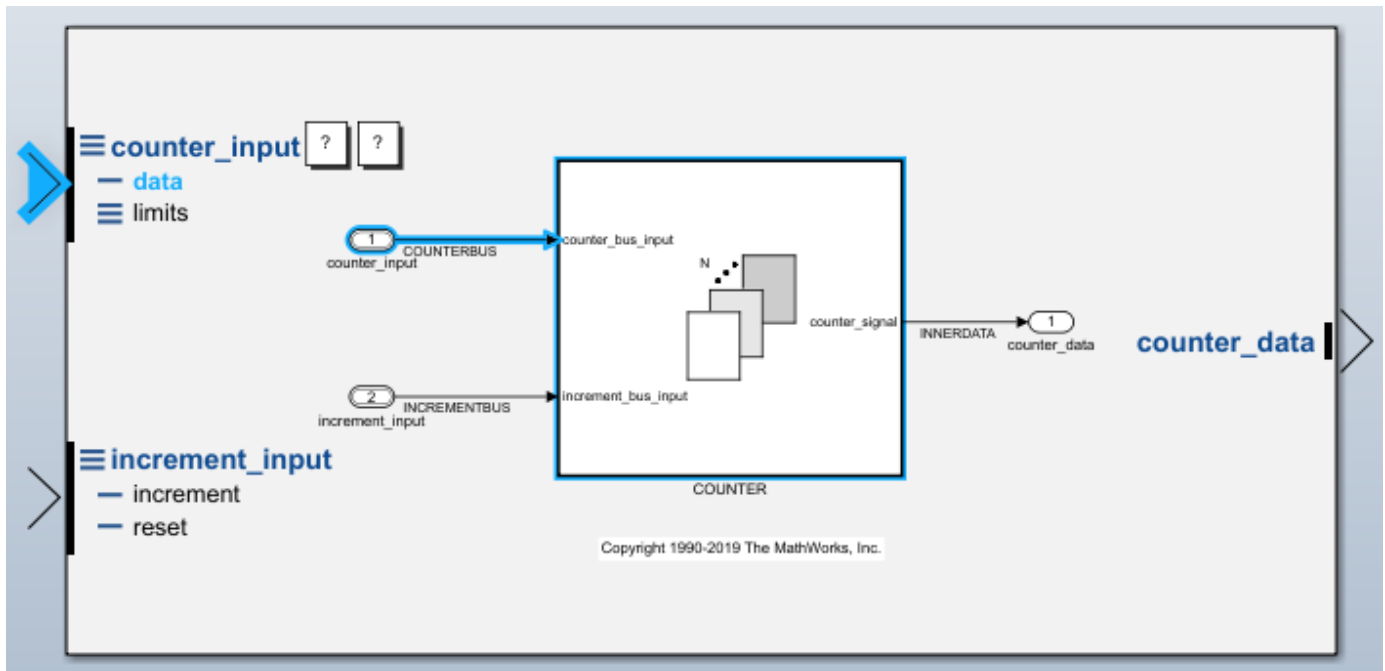

The three bars next to the `counter_input` and `increment_input` interfaces indicate the bus input signals. The single bars indicate data lines, such as counts per second, or command lines, such as reset, to start a new counting sequence. The three bars next to `limits` indicate that buses are nested inside the COUNTER subsystem.

- 3 Under `counter_input`, click data.

The path for the data appears in blue. The COUNTER subsystem is highlighted, indicating the path continues within it.

4 Double-click the COUNTER subsystem.

The continuation of the path for the data signal appears in blue.

5 On the **Modeling** tab, click **Update Model**.

---

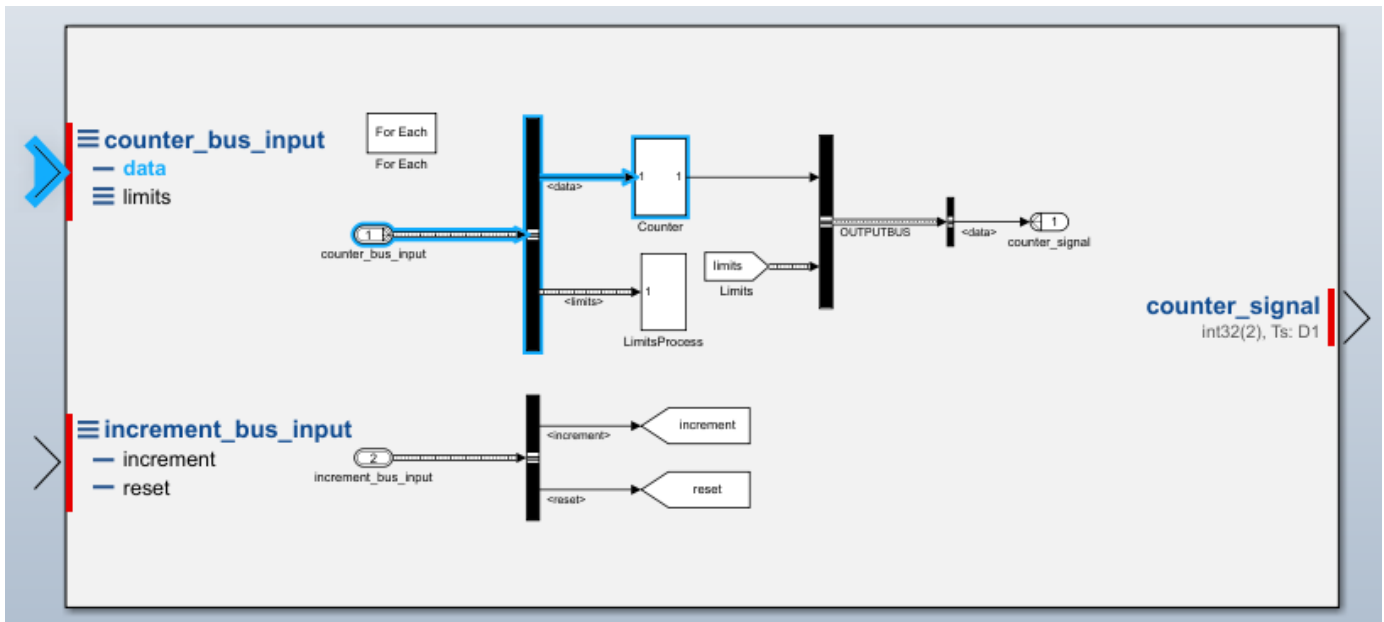

**Note** This model requires values from a parent model to simulate completely.

---

The counter\_signal interface displays these signal attributes, which help you to synchronize signals between blocks during simulation:

- Data type: int32 (signed 32-bit integer)
- Dimensions: (2) (a 1-D Simulink representation of a scalar)
- Sample time: Ts:D1 (a discrete sample time of D1, which is the highest speed)

In addition, when you update the diagram with interfaces displayed, the model displays the color code for sample time at each interface. For example, this model displays a red bar at each interface to indicate a sample time of D1.

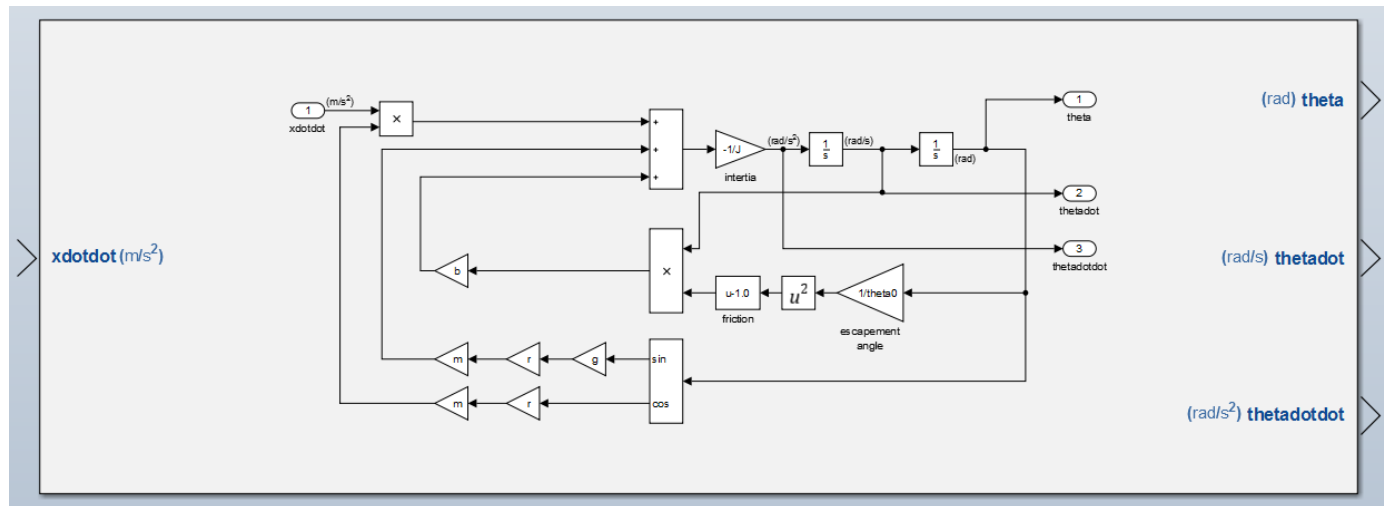

**Tip** To display a legend of the meaning of sample time colors, on the **Debug** tab, select **Information Overlays > Colors**.

- Click the `counter_signal` output interface to see the output of the bus outlined in blue, where the path ends.

- If you want to print this diagram with the interfaces displayed, in the **Simulation** tab, click **Print**.

When signals in your model have units associated with them, you see the units in the interface view. For example, in the model `sldemo_metro`, the `Metronome1` subsystem shows units for inputs and outputs of the subsystem in the interface view.

To modify the attributes of the existing interface (such as signal names, data types, and dimensions), consider using the **Model Data Editor**. On the **Modeling** tab, click **Model Data Editor**.

## Variable-Size Signal Basics

### In this section...

“How Variable-Size Signals Propagate” on page 78-2

“Determine Whether Signal Line Has Variable Size” on page 78-3

“Empty Signals” on page 78-4

“Simulink Block Support for Variable-Size Signals” on page 78-4

“Variable-Size Signal Limitations” on page 78-6

A Simulink signal can be a scalar, vector (1-D), matrix (2-D), or N-D. A Simulink variable-size signal is a signal whose size (the number of elements in a dimension), in addition to its values, can change during a model simulation. However, during a simulation, the number of dimensions cannot change. This capability allows you to model systems with varying resources, constraints, and environments.

You can create variable-size signals in your Simulink model by using:

- Switch or Multiplex blocks with different input ports having fixed-size signals with different sizes. The output is a variable-size signal.
- A selector block and the `Starting and ending indices (port)` indexing option. The index port signal can specify different subregions of the input data signal which produce an output signal of variable size as the simulation progresses.
- The S-function block with the output port configured for a variable-size signal. The output includes not only the values but also the dimension of the signal.

### How Variable-Size Signals Propagate

In the Simulink environment, variable-size signals can change their size during model execution in one of two ways:

- **At every step of model execution.**

Various blocks in the model modify the sizes of the signals during execution of the output method.

- **Only during initialization of conditionally executed subsystems.**

Size changes occur during distinct mode-switching events in subsystems such as Action, Enable, and Function-Call subsystems.

You can see the key difference by considering a Discrete 2-Tap Filter block with states.

### Discrete 2-Tap Filter

Assume that the input signal dimension to this filter changes from 4 to 1 during simulation. It is ambiguous when and how the states of the Unit Delay blocks should adapt from 4 to 1 to continue processing the input. To ensure consistency, both Unit Delay blocks must change their state behavior synchronously. To prevent ambiguity, Simulink generally disallows blocks whose number of states depends on input signal sizes in contexts where signal sizes change at any point during execution.

In contrast, consider the same Discrete 2-Tap Filter block in a Function-Call subsystem. Assume that this subsystem is using the second way to propagate variable-size signals. In this case, the size of the input signal changes from 4 to 1 only at the initialization of the subsystem. At initialization, the subsystem resets all of its states (including the states of the two Unit Delay blocks) to their initial values. Resetting the subsystem ensures no ambiguity on the assignment of states to the input signal of the filter.

“Mode-Dependent Variable-Size Signals” on page 78-13 shows how you can use the two ways of propagating variable-size signals in a complementary fashion to model complex systems.

### Determine Whether Signal Line Has Variable Size

The following example demonstrates how to use commands at the command prompt or in a script to determine whether a signal line has a variable size. In a large model or hierarchy of subsystems or referenced models, use this technique to determine whether a signal has a variable size due to an upstream block.

The example model `sldemo_varsize_basic` contains a signal `a` that is downstream of a Switch block.

- 1 Open the example model.
- 2 Select the Sum block whose output signal is labeled `a`.
- 3 Type the following at the command window to set the model to a compiled state (similar to a diagram update).

```
sldemo_varsize_basic([],[],[],'compile')
```

- 4 Get a handle to the block output port.

```
portHandles = get_param(gcf,'portHandles');
outPortHandle = portHandles.Outputport;
```

- 5 Query the programmatic parameter `CompiledPortDimensionsMode` of the output port.

```
varSize = get_param(outPortHandle,'CompiledPortDimensionsMode')
```

```
varSize =
 1
```

The value of the variable `varSize` is 1, which indicates that the signal `a` has variable size.

The value 0 indicates that a signal does not have variable size.

- 6 Terminate the model compilation.

```
sldemo_varsize_basic([],[],[],'term')
```

## Empty Signals

An empty signal is a signal with a length of 0. For example, signals with size [0], [0×3], [2×0], and [2×0×3] are all empty signals. Simulink allows empty signals with variable-size signals and supports most element-wise operations. However, Simulink does not support empty signals for blocks that modify signal dimensions. Unsupported blocks include Reshape, Permute, and Sum along a specified dimension.

## Simulink Block Support for Variable-Size Signals

The Simulink Block Data Type Support table includes a complete list of blocks that support variable-size signals.

To view the table:

- 1 Open a Simulink model.
- 2 In the MATLAB command line, enter `showblockdatatypetable`.

A separate window with the Simulink Block Data Type Support table opens.

An X in the **Variable-Size Support** column indicates support for that block.

---

**Tip** You can also view the table by entering `showblockdatatypetable` at the command prompt.

---

### Subsystem Initialization of Variable-Size Signals

The initial signal size from an Output block in a conditionally executed subsystem varies depending on the parameters you select.

If you set the **Propagate sizes of variable-size signals** parameter in the parent subsystem to **During execution**, the **Initial output** parameter for the Output block must not exceed the maximum size of the input port. If the **Initial output** parameter value is:

| Initial output parameter | Initial output signal size                                                         |
|--------------------------|------------------------------------------------------------------------------------|
| A nonscalar matrix       | The initial output signal size is the size of the <b>Initial output</b> parameter. |
| A scalar                 | The initial output signal size is a scalar.                                        |

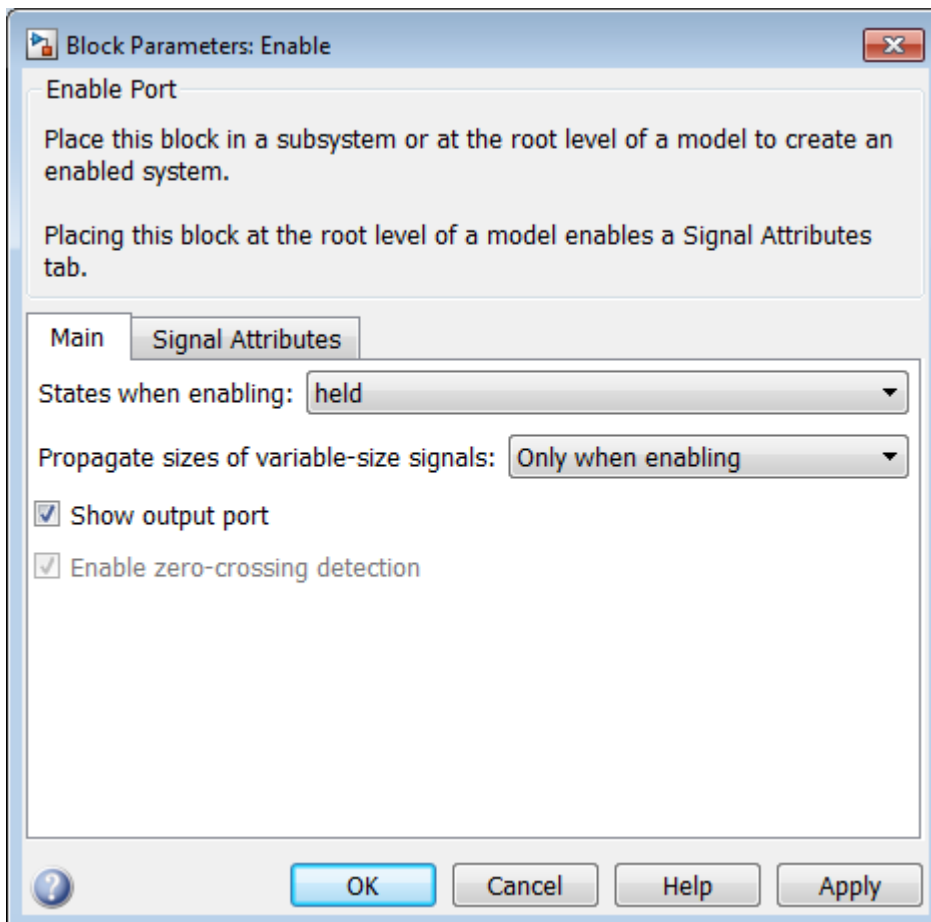

| Initial output parameter | Initial output signal size                                             |
|--------------------------|------------------------------------------------------------------------|
| The default []           | The initial output size is an empty signal (dimensions are all zeros). |

If you set the **Propagate sizes of variable-size signals** parameter in the parent subsystem to **Only when enabling**, the **Initial output** parameter for the Output block must be a scalar value.

- When size is repropagated for the input of the Output block, the initial output value is set using scalar expansion from the scalar parameter value.
- If the **Initial output** parameter is the default value [], Simulink treats the initial output as a grounded value.
- If the model does not activate the parent subsystem at start time ( $t = 0$ ), the current size of the subsystem output corresponding to the Output block is set to maximum size.
- When its parent subsystem repropagates signal sizes, the values of the subsystem variable-size output signals are also reset to their initial output parameter values.

### Conditionally Executed Subsystem Blocks

Control port blocks are in conditionally executed subsystems. You can set the **Propagate sizes of variable-size signals** parameter for these blocks to **During execution**, **Only when execution is resumed** (Action Port), and **Only when enabling** (Enable and Trigger or Function-Call).

- Action Port
- Enable
- Trigger — **Trigger type** set to function-call

### Switching Blocks

Switching blocks support variable-size signals by allowing input signals with different sizes and propagating the size of the input signal to the output signal. You can set the **Allow different data input sizes** parameter for these blocks on the Signal Attributes pane to either on or off.

- Switch
- Multiport Switch
- Manual Switch

### Variable-Size Signal Limitations

The following table describes variable-size signal limitations.

| Limitation                                                                                                                                                                                                                  | Workaround                                                                                                                                                                                                                                                                               |
|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Array format logging does not support variable-size signals.                                                                                                                                                                | Use a <b>Structure</b> , <b>Structure With Time</b> , or <b>Dataset</b> format for logging variable-size signals.                                                                                                                                                                        |
| A frame-based variable-size signal cannot change the frame length (first dimension size), but it can change the second dimension size (number of channels). Using frame-based signals requires DSP System Toolbox software. | Use the <b>Frame Conversion</b> block to convert a signal into sample-based signal.                                                                                                                                                                                                      |
| Variable-size signals must have a discrete sample time.                                                                                                                                                                     | —                                                                                                                                                                                                                                                                                        |
| Embedded Coder does not support variable-size signals with ERT S-functions, custom storage classes, function prototype control, the AUTOSAR, C++ interface, and the ERT reusable code interface.                            | —                                                                                                                                                                                                                                                                                        |
| Simulink does not support variable-size parameter or DWork vectors.                                                                                                                                                         | —                                                                                                                                                                                                                                                                                        |
| Rapid accelerator mode does not support models having root-level input ports with variable-size signals.                                                                                                                    | —                                                                                                                                                                                                                                                                                        |
| Virtual buses that you use as inputs to or outputs from a referenced model (Model block) do not support variable-size signals.                                                                                              | Configure the bus signal as nonvirtual. For more information about using buses as inputs to or outputs from a referenced model, see “Use Buses at Model Interfaces” on page 77-34. For more information about controlling bus virtuality, see “Types of Composite Signals” on page 77-2. |
| Variable-size signals are not supported for: <ul style="list-style-type: none"> <li>• Array of buses signals</li> <li>• Blocks that specify an initial condition as a MATLAB structure</li> </ul>                           | —                                                                                                                                                                                                                                                                                        |
| You cannot apply a storage class to a root-level Output block (see “C Code Generation Configuration for Model Interface Elements” (Simulink Coder)) if the signal that enters the block has a variable size.                | Apply the storage class to the signal line instead of the Output block.                                                                                                                                                                                                                  |

## Inspect Variable-Size Signals on Simulink Models

### In this section...

“Variable-Size Signal Generation and Operations” on page 78-8

“Variable-Size Signal Length Adaptation” on page 78-10

“Mode-Dependent Variable-Size Signals” on page 78-13

“S-Functions Using Variable-Size Signals” on page 78-17

### Variable-Size Signal Generation and Operations

This example model shows how to create a variable-size signal from multiple fixed-size signals and from a single data signal. It also shows some of the operations you can apply to variable-size signals.

For a complete list of blocks that support variable-size signals, see “Simulink Block Support for Variable-Size Signals” on page 78-4.

- 1 In the MATLAB Command Window, type

```
openExample('sldemo_varsize_basic')
varSize = get_param(outPortHandle,'CompiledPortDimensionsMode')
```

- 2 In the Simulink Editor, on the **Debug** tab, select **Information Overlays > Signal Dimensions**. Run a simulation or press **Ctrl-D**.

The Simulink Editor displays the signal dimensions and line styles. See “Signal Basics” on page 76-2 for an interpretation of signal line styles.

- 3 So that you can see the names of the blocks in the model, on the **Format** tab, clear **Auto > Hide Automatic Block Names**.

## Create a Variable-Size Signal from Fixed-Size Signals

One way to create a variable-size signal is to use the Switch block. The input signals to the Switch block can differ in their number of dimensions and in their size.

Output from the Switch block is a 2-D variable-size signal with a maximum size of  $3 \times 2$ . When you select the **Allow different data input sizes** parameter on the Switch block, Simulink does not expand the scalar value from the Constant1 block.

## Save Variable-Size Signal Data

You could add a To Workspace block to the output from the Switch block. Since the model already has a To Workspace block, the second To Workspace block would save data to a signal array named `simout2`. The `values` field logs the actual signal values. If logged signal data is smaller than the maximum size, values are padded with NaNs or appropriate values. To obtain these signal values, type:

```
simout2.signals.values
```

```
ans(:,:,1) =
```

```
 1 -1
 -2 2
 -3 3
```

```
ans(:,:,2) =
```

```
 1 -1
 -2 2
 -3 3
```

```
ans(:,:,3) =
```

```
 0 NaN
 NaN NaN
 NaN NaN
```

The `valueDimensions` field logs the dimensions of a variable-size signal. To obtain the dimensions, type:

```
simout2.signals.valueDimensions
```

The signal dimensions for the first three time steps are shown.

ans =

```

 3 2
 3 2
 1 1

```

### Create a Variable-Size Signal from a Single Data Signal

The data signal (Constant5) is a 3x4 matrix. The Pulse Generator represents a control signal that selects a starting and ending index value ( [1 2] or [1 3] ). The Selector block then uses the index values to select different parts of the data signal at each time step and output a variable-size signal.

### View Changes in Signal Size

The output from the Selector block is either a 2x2 or 3x3 matrix. Because the maximum dimension for a variable-size signal is the 3x4 matrix from the data signal, the logged output signals are padded with NaNs.

Use the Probe or Width blocks to inspect the current dimensions and width of a variable-size signal. In addition, you can display variable-size signals on Scope blocks and save variable-size signals to the workspace using the To Workspace block.

### Process Variable-Size Signals

The remainder of the model shows various operations that are possible with variable-size signals. Operations include using the Gain, Sum, Math Function, and Matrix Concatenate blocks. You can connect variable-size signals with the From, Goto, Bus Assignment, Bus Creator, and Bus Selector blocks.

### Variable-Size Signal Length Adaptation

This example model corresponds to a hypothetical system where the model adapts the length of a signal over time. Length adaptation is based on the value of a control signal. When the control signal falls within one of three predefined ranges, the fixed-size raw data signal changes to a variable-size data signal.

The variable-size signal connects to a processing block, where blocks that support variable-size signals operate on it. A MATLAB Function block with both input and output signals of variable size allow more flexibility than other blocks supporting variable-size signals. See “Simulink Block Support for Variable-Size Signals” on page 78-4.

To open the example model, in the MATLAB Command Window, type:

```
sldemo_varsize_dataLengthAdapt
```

So that you can see the names of the blocks, in the model, on the **Format** tab, clear **Auto > Hide Automatic Block Names**.

### Creating a Variable-Size Signal by Adapting the Length of a Data Signal

This model generates a data signal and converts the signal to a variable-size signal. The size of the signal depends on the value of a control signal. The raw data signal is a column vector with values from 1 to 9.

```
[1:9].'
```

```
ans =
 1
 2
 3
 4
 5
 6
 7
 8
 9
```

The Size Selection subsystem determines the quality of the data signal and outputs a quality value ( 1, 2, or 3). This value helps to select the length of the data signal in the Length Adaptation subsystem.

In the Length Adaptation subsystem, the Signal Size subsystem generates an index based on the quality value from the Size Selection subsystem (In2). The Data Selector block uses the starting and ending indices to adapt the length of the data signal (In1) and output a variable-size signal.

### Processing a Variable-Size Signal

The center section of the model processes the variable-size signal. The MATLAB Function block adds zeros between the data values in a way that is similar to upsampling a signal. The dimension of the signal changes from 9 to 18. The Math Function blocks show various manipulations you can do with variable-size signals.

### Visualizing a Variable-Size Signal

The right section of the model determines the signal width (size) and uses a scope to visualize the width and the processed data signal.

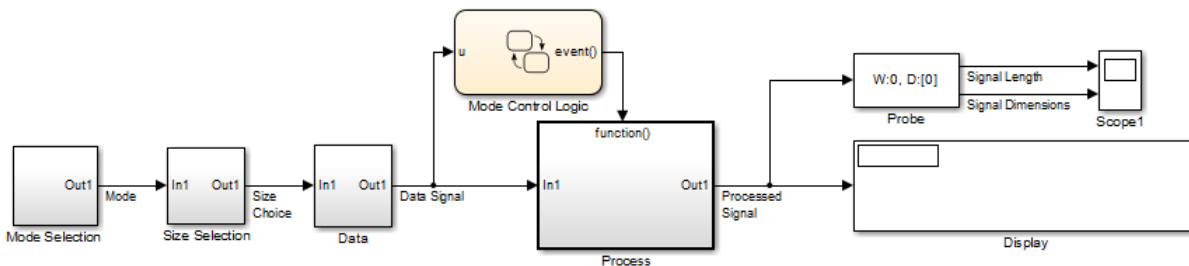

## Mode-Dependent Variable-Size Signals

This example model represents a system that has three operation modes. For each mode, the data signal to process has a different size.

The Process subsystem in this model receives a variable-size signal where the size of the signal depends on the operation mode of the system. For each mode change, the Stateflow chart, Mode Control Logic, detects when the data signal size changes. It then generates a function call to reset the blocks in the Process subsystem.

To open the model, In the MATLAB Command Window, type:

```
sldemo_varsize_multimode
```

So that you can see the names of the blocks, in the model, on the **Format** tab, clear **Auto > Hide Automatic Block Names**.

### Creating a Variable-Size Signal Based on Mode

The Mode Selection subsystem determines the mode for processing a data signal and outputs a mode value ( 1, 2, or 3). This value helps to select the length of the data signal using the Size Selection and Data subsystems.

The Size Selection subsystem creates an index value from the mode value. In this example, the index values are [1 3], [1 2], and [1 1].

The Data subsystem takes a data signal (Constant block) and selects part of the data signal dependent on the mode. The output is a variable-size signal with a matrix size of 3x3, 2x2, and 1x1.

The dimensions of the raw data signal (Constant block) is a 3x3. After connecting a To Workspace block to a signal line, you can view the signal in the MATLAB Command Window by typing:

```
simout.signals.values
```

```
ans(:,:,1) =
```

```

1 4 7
2 5 8
3 6 9
```

The variable-size signal generated from the Data subsystem is also a 3x3 matrix. For shorter signals, the matrix is padded with NaNs.

```
simout.signals.values
```

```
ans(:,:,1) =
```

```

 1 NaN NaN
 NaN NaN NaN
 NaN NaN NaN

```

```
ans(:,:,2) =
```

```

 1 4 NaN
 2 5 NaN
 NaN NaN NaN

```

```
ans(:,:,3) =
```

```

 1 4 7
 2 5 8
 3 6 9

```

### Processing a Variable-Size Signal with a Conditionally Executed Subsystem

Because the Process subsystem contains a Delay block, the subsystem resets and repropagates the signal at each time step. This model uses a Stateflow chart to detect a signal size change and reset the Process subsystem.

In the function block dialog, and from the **Propagate sizes of variable-size signals** list, choose **Only when enabling**. When the model enables this subsystem, selecting this option directs the Simulink software to propagate sizes for variable-size signals inside the conditionally executed subsystem. Signal sizes can change only when they transition from disabled to enabled. For an explanation of handling signal-size changes with blocks containing states, see “How Variable-Size Signals Propagate” on page 78-2.

The Stateflow chart determines if there is a change in the size of the signal. The function `size_detect` calculates the width of the variable-size signal at each time step, and compares the

current width to the previous width. If there is a change in signal size, the chart outputs a function-call output event that resets and repropagates the signal sizes within the Process subsystem.

### Visualizing Data

Use the Probe block to visualize signal size and signal dimension.

Since the signals are  $n \times n$  matrices, the signal dimension lines overlap in the Scope display.

You can use a Display block and the Simulink Debugger to visualize signal values at each time step.

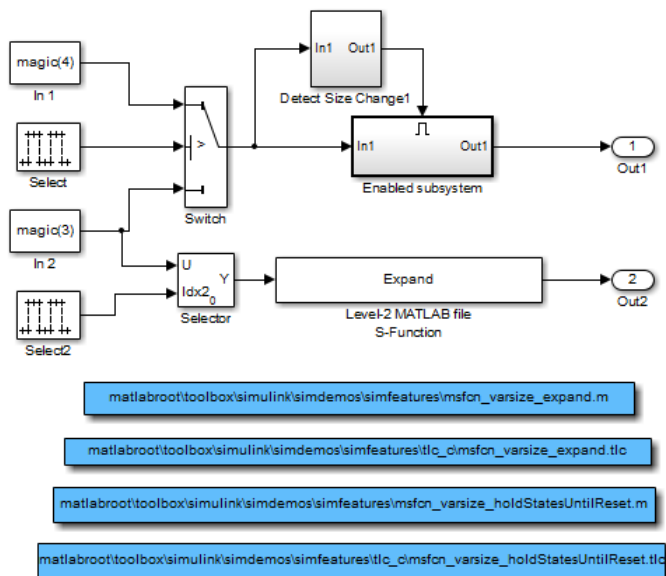

## S-Functions Using Variable-Size Signals

### Level-2 MATLAB S-Function with Variable-Size Signals

Both Level-2 MATLAB S-Functions and C S-Functions support variable-size signals when you set the **DimensionMode** for the output port to **Variable**. You also need to consider the current dimension of the input and output signals in the input and output update methods.

To open this example model, in the MATLAB Command Window, type:

```
msfcn_demo_varsize
```

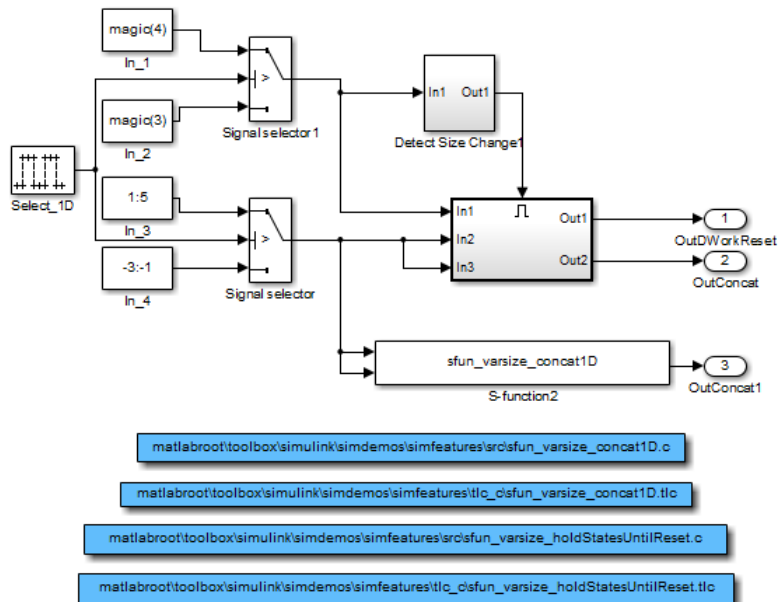

The Enabled subsystem includes a Level-2 MATLAB S-Function which shows how to implement a block that holds its states until reset. Because this block contains states and delays the input signal, the input size can change only when a reset occurs.

The Expand block is a Level-2 MATLAB S-Function that takes a scalar input and outputs a vector of length indicated by its input value. The output is by  $1:n$  where  $n$  is the input value.

### C S-Function with Variable-Size Signals

To open this example model, in the MATLAB Command Window, type:

```
sfcn_demo_varsize
```

The enabled subsystems have two S-Functions:

- `sfun_varsize_holdStatesUntilReset` is a C S-Function that has states and requires its DWorks vector to reset whenever the sizes of the input signal changes.
- `sfun_varsize_concat1D` is a C S-Function that implements the concatenation of two unoriented vectors. You can use this function within an enabled subsystem by itself.

## Access Frequently Used Features and Commands in Simulink

The Simulink quick access toolbar provides access to frequently used operations and favorite commands. This toolbar is always visible, even when you navigate between different Simulink Toolstrip tabs.

To customize the quick access toolbar, you can:

- Right-click an item in the toolstrip and select **Add to Quick Access Toolbar**. To remove a toolstrip item you have added, right-click the item and select **Remove from Quick Access Toolbar**.
- Drag items to change their position.
- Show item labels by right-clicking the item icon and selecting **Show Label**.
- Show or hide common items by clicking the **Common Controls** button  and selecting or clearing the corresponding check boxes.

To restore default settings for the quick access toolbar, use one of these options:

- Right-click an item and select **Restore Defaults**.
- Click the **Common Controls** button  and select **Restore Defaults**.

### Search for Simulink Toolstrip Actions

To search for Simulink Toolstrip actions, click the **Search Toolstrip** button . In the search box that appears, start typing the name or description of the toolstrip item, then select it from the quick action search menu.

If the **Search Toolstrip** button  is not in the quick access toolbar, click the **Common Controls** button  and select the **Search Toolstrip** check box.

Alternatively, you can open the quick action search menu by double-clicking the Simulink Editor canvas and selecting the **Actions** tab or by pressing the **Ctrl + . (period)** keyboard shortcut. For more information, see “Keyboard Shortcuts and Mouse Actions for Simulink Modeling” on page 1-57.

## Rerun Favorite Commands for Simulink

The Simulink quick access toolbar provides you with a place to access your favorite MATLAB commands. Click the **Favorites** button  to open the **Favorite Commands** gallery.

The list of favorite commands is independent of the list of favorite commands in the MATLAB quick access toolbar.

To create a favorite command:

- 1 Click **New Favorite**. The Favorite Command Editor dialog box opens.
- 2 In the **Label** box, enter a name for the favorite command.
- 3 In the **Type** box, specify whether the favorite command is a script or function. Functions run in a limited scope and receive callback information from the *cbinfo* variable.
- 4 In the **Code** box, type the statements you want the favorite command to run.
- 5 Set **Category** to an existing category from the drop-down list.
- 6 Optionally, set **Icon** to one of the options provided or a custom icon. Custom icons must be PNG files. If you rename, move, or delete a custom icon, the icon no longer appears in the icon list, and any favorite commands that used the icon revert to the default icon.
- 7 Optionally, select **Add to quick access toolbar** and **Show label on quick access toolbar**.
- 8 Click **OK**.
- 9 To run the statements in the **Code** box and ensure that they perform the desired actions, click the button for the new command. All the statements in the **Code** box of the Favorite Command Editor execute as if you ran those statements from the Command Window, although they do not appear in the Command History window.

To edit or delete a favorite command, right-click the command and choose the corresponding option.

To create a new category for your favorite commands:

- 1 Click **New Category**. The Favorite Category Editor dialog box opens.
- 2 In the **Label** box, enter a name for the category.
- 3 Click **OK**.

To reorder categories, click the **Move category to top**  and **Move category to bottom**  buttons to the right of the category names.

To edit or delete a category, right-click the category and choose the corresponding option.

To reset the Simulink **Favorite Commands** gallery, use the `slResetFavoriteCommands` function.

## Share Favorite Commands for Simulink

To export the contents of your Simulink **Favorite Commands** gallery to a file that you can share with team members, use the `slExportFavoriteCommands` function. The generated file saves the contents of the gallery, including the categories and their order.

To import favorite commands from a file, use the `slImportFavoriteCommands` function. During import, you can merge the imported content with existing content or completely overwrite the content of the gallery.

When you merge content:

- Imported content appears after existing content.
- If the category of an imported command matches an existing category, the imported command is added to the existing category.
- Commands can have the same name and properties as each other. A command will not overwrite another command.

## Create Custom Simulink Toolstrip Tabs

The Simulink Toolstrip provides a set of built-in actions to support a variety of workflows. You can customize the toolstrip by adding tabs that focus on workflows specific to you and your team. Custom tabs provide a platform for performing custom actions that you develop. You can also populate custom tabs with built-in actions from the default Simulink Toolstrip tabs.

Before you create a custom tab, consider how you want elements of the tab to appear and behave.

For an example of a prepopulated custom tab, see “Add Prepopulated Custom Tab to Simulink Toolstrip” on page 79-28.

The following sections describe how to create a custom tab that has the **Info** and **File** sections from the prepopulated custom tab example.

1. “Start Simulink” on page 79-5
2. “Create Simulink Toolstrip Component” on page 79-6
3. “Add Blank Tab to Simulink Toolstrip” on page 79-6
4. “Open JSON File to Develop Custom Tab” on page 79-7

11. “Define Pop-Up Lists” on page 79-18
- .
12. “Share Custom Tabs” on page 79-27
- .

### Start Simulink

To work with the Simulink Toolstrip, start Simulink. For example, in the MATLAB Command Window, enter:

```
start_simulink
```

## Create Simulink Toolstrip Component

A Simulink Toolstrip component contains the definition for one or more custom tabs. Before you create a custom tab, you must create the component to contain it.

Create one or more custom Simulink Toolstrip components by using the `slCreateToolstripComponent` function.

For example, create a component named `custom`.

```
slCreateToolstripComponent("custom");
```

This command creates a `resources` folder in your current folder and adds your current folder to the MATLAB path. The `resources` folder contains two folders and one JSON file.

- `icons` folder — Location of icons used by custom tab elements
- `json` folder — Location of JSON files that define custom tabs
- `sl_toolstrip_plugins.json` — JSON file that must not be edited

Each component name must be unique. If multiple components have the same name, only one of the components with that name loads. You can see the component name in the `sl_toolstrip_plugins.json` file.

---

**Tip** Use a component name that is likely to be unique from other component names. For example, name the component after the workflow it supports.

---

To load a Simulink Toolstrip component, the folder that contains the `resources` folder must be on the MATLAB path.

To get the loaded custom Simulink Toolstrip components, use the `slLoadedToolstripComponents` function.

When you want to change whether a custom Simulink Toolstrip component persists across MATLAB sessions, use the `slPersistToolstripComponent` function.

To destroy a custom Simulink Toolstrip component, use the `slDestroyToolstripComponent` function.

## Add Blank Tab to Simulink Toolstrip

Create one or more custom tabs with the `slCreateToolstripTab` function.

For example, create the tab `customTab` in the `custom` component, and title the tab `CUSTOM TAB`.

```
slCreateToolstripTab("customTab","custom",Title="CUSTOM TAB");
```

The function creates a JSON file named `customTab.json` in the `json` folder that defines the tab.

To see the custom tabs you create, open a model. For example, open the `vdp` model.

`vdp`

The Simulink Toolstrip displays a blank tab titled `CUSTOM TAB`.

## Open JSON File to Develop Custom Tab

The JSON file that defines the custom tab uses:

- Curly braces to define JSON objects
- Quotation marks to identify JSON properties and values
- Colons to specify values for JSON properties
- Commas to separate like elements, such as JSON objects or properties
- Square brackets to define JSON properties with arrays of JSON objects

To modify a JSON file, consider using a JSON editor that checks for syntax errors, helps you format the code, and lets you collapse parts of the code. For example, use Visual Studio® Code to open and edit your JSON files.

Open `customTab.json` from the `json` folder.

```
{
 "version": "R2021b",
 "entries": [
 {
 "type": "Tab",
 "id": "customTab",
 "title": "CUSTOM TAB",
 }
]
}
```

The file defines a tab as a JSON object ("type": "Tab") with the specified ID ("id": "customTab") and title ("title": "CUSTOM TAB"). You can modify the tab ID and title.

After you modify a JSON file, use the `slReloadToolstripConfig` function to reload the toolstrip configuration with your changes. In the MATLAB Command Window, enter:

```
slReloadToolstripConfig;
```

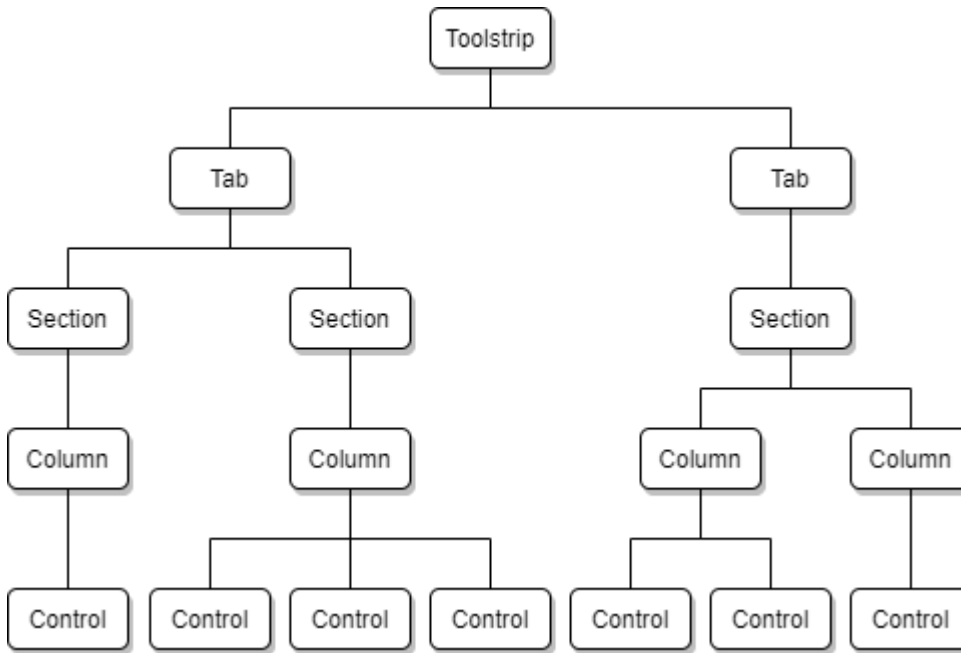

The function searches the MATLAB path for `resources` folders that contain a valid `sl_toolstrip_plugins.json` file. To temporarily modify the toolstrip configuration, add folders that contain `resources` folders to the MATLAB path or remove them from the MATLAB path before you call this function.

If the custom tab does not appear:

- Debug and correct errors in the JSON code.
- Add the folder that contains the corresponding `resources` folder to the MATLAB path.

## Define Custom Tab Layout

The Simulink Toolstrip is composed of many elements in a hierarchy. Each tab is a collection of sections. Sections contain columns. Controls, such as push buttons, populate the columns.

On a toolstrip tab, vertical lines indicate section boundaries. If a section has a title, the title appears at the bottom of the section in all uppercase letters. Columns are visible only when they contain at least one control. The size of the control depends on how many controls are in the column. Each column supports a maximum of three controls.

For example, the **Simulation** tab of the Simulink Toolstrip contains multiple sections, such as the **File** section. The **File** section contains two columns. The first column contains one control, titled **New**. The second column contains three controls, titled **Open**, **Save**, and **Print**.

To create a hierarchy in the custom tab, the tab must have a `children` property. To support controls, the tab must have a child section, and the section must have a child column.

For each tab, specify:

- `type` — Type of JSON object (Tab), specified as a string
- `id` — Unique identifier within the toolstrip component, specified as a string
- `title` — Text that appears as the tab label, specified as a string

- `children` — Sections within the tab, specified as an array of JSON objects

For each section, specify:

- `type` — Type of JSON object (`Section`), specified as a string
- `id` (optional) — Unique identifier within the tab, specified as a string
- `title` — Text that appears as the section label, specified as a string
- `children` — Columns within the section, specified as an array of JSON objects

For each column, specify:

- `type` — Type of JSON object (`Column`), specified as a string
- `id` (optional) — Unique identifier within the section, specified as a string
- `width` (optional) — Width of the column in pixels, specified as a number
- `children` — Controls within the column, specified as an array of JSON objects

For example, create the layout for the **Info** and **File** sections from the prepopulated custom tab example, and title the sections.

Update the `customTab.json` file.

```
{
 "version": "R2021b",
 "entries": [
 {
 "type": "Tab",
 "id": "customTab",
 "title": "CUSTOM TAB",
 "children": [
 {
 "type": "Section",
 "title": "Info",
 "children": [
 {
 "type": "Column",
 "children": []
 }
]
 },
 {
 "type": "Section",
 "title": "File",
 "children": [
 {
 "type": "Column",
 "children": []
 }
]
 }
]
 }
]
}
```

```

 "children": []
 },
 {
 "type": "Column",
 "children": []
 }
]
 }
]
}

```

To display the changes on the custom tab, reload the toolstrip configuration.

```
slReloadToolstripConfig;
```

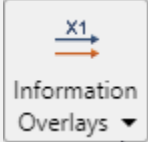

The two sections and their titles appear. The columns are not visible because they are empty.

## Choose Among Types of Controls

Different types of controls serve different goals. The default Simulink Toolstrip tabs contain a variety of controls. When a column has more than one control, the controls resize so that each control uses one third of the vertical space in the column.

Custom tabs support the subset of controls described in this table.

| Control     | Appearance                                                                                                                                                                                                                                  | Description                       | JSON Object Type |
|-------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------|------------------|
| Push button | Full size:<br><br>Library<br>Browser<br><br>Reduced size:<br> Compare | A push button performs an action. | PushButton       |

| Control          | Appearance                                                                                                                                                                                            | Description                                                                                                                                                 | JSON Object Type |
|------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------|
| Drop-down button | Full size:<br><br>Reduced size:<br> | A drop-down button displays a pop-up list.                                                                                                                  | DropDownButton   |
| Split button     | Full size:<br><br>Reduced size:<br> | A split button is a combination of a push button and a drop-down button. The push button part performs an action, and the button arrow shows a pop-up list. | SplitButton      |
| Empty control    | Same appearance as empty parts of the toolstrip                                                                                                                                                       | An empty control adds a blank space where a control would otherwise be.                                                                                     | EmptyControl     |

Add up to three controls to the `children` property of each column. The order of the controls in the JSON file determines the order in which they appear in the column.

For each control, specify:

- `type` — Type of JSON object, specified as a string.
- `id` (optional) — Unique identifier within the column, specified as a string.
- `action` (conditional) — Appearance and behavior of the control, specified as a string. Omit this property for empty controls.
- `popupName` (conditional) — Name of a pop-up list for a drop-down or split button, specified as a string. Omit this property for push buttons and empty controls.

## Get Built-In Simulink Actions

To get the name and icon for a built-in action from the Simulink Toolstrip, use the `slToolstripDeveloperMode` function.

In the MATLAB Command Window, enter this command:

```
slToolstripDeveloperMode('on')
```

```
ans =
```

```
logical
0
```

The command enables developer mode for the Simulink Toolstrip. The returned value indicates that developer mode was disabled before you entered the command.

Pause on an item in the Simulink Toolstrip and press **Ctrl**. On a Mac, press **command** (⌘) instead of **Ctrl**.

For example, pause on the **Open** button and press **Ctrl**.

```
Action: openModelAction
Icon: open

```

The names of the corresponding action and icon appear in the MATLAB Command Window.

## Specify Built-In Simulink Actions

After you get the name of a built-in Simulink action, specify it as the action for a control by using it to define the `action` property of the control.

For example, create the **Open** push button from the prepopulated custom tab example.

On the **Simulation** tab, get the built-in action for the **Open** button.

```
Action: openModelAction
Icon: open_24

```

Update the `customTab.json` file.

```
{
 "version": "R2021b",
 "entries": [
 {
 "type": "Tab",
 "id": "customTab",
 "title": "CUSTOM TAB",
 "children": [
 {
 "type": "Section",
 "title": "Info",
 "children": [
 {
 "type": "Column",
```

```
"entries": []
}
```

- 5 Define your custom actions and icons as JSON objects in the `entries` property.
- 6 Reference the custom action from a JSON object.

For each action, specify:

- `type` — Type of JSON object (`Action`), specified as a string.
- `id` — Unique identifier within the toolstrip component, specified as a string.
- `text` (optional) — Text that appears on the control as a label, specified as a string. When a control is alone in a column, its text can span two lines. Use `\n` to start a new line. When the control shares its column with other controls, a space replaces the line break.
- `description` (optional) — Text that provides additional information, specified as a string. When the action defines a control, the text appears as a tooltip when you pause on the control. When the action defines a list item for a pop-up list, the text appears underneath the title of the list item.
- `icon` (optional) — Built-in or custom icon that appears on the control, specified as a string.
- `command` — Name of a MATLAB file that executes when you click the control, specified as a string. The file must be on the MATLAB path.
- `commandType` (conditional) — Specification that the MATLAB file is a script, specified as a string. Omit this property when the MATLAB file is a function.

Use functions instead of scripts if you want to use information about the current window in which the command is being executed. For more information, see “Callback Info Object” on page 79-42.

For each icon, specify:

- `type` — Type of JSON object (`Icon`), specified as a string.
- `id` — Unique identifier within the toolstrip component, specified as a string.
- `icon16` (conditional) — 16-by-16 pixel version of a custom icon for a reduced-size control, specified as a string. The icon must be saved as a PNG file.
- `icon24` (conditional) — 24-by-24 pixel version of a custom icon for a full-size control, specified as a string. The icon must be saved as a PNG file.

For example, create the **MathWorks Website** button from the prepopulated custom tab example.

Create a script named `openMathWorksWebsite.m` that opens the MathWorks website. Make sure the script is on the MATLAB path.

```
web('https://www.mathworks.com')
```

Add 16-by-16 and 24-by-24 pixel versions of a custom icon to the icon folder in the resources directory. This example uses two PNG files that indicate their size in their file names (openMathWorksWebsite\_16.png and openMathWorksWebsite\_24.png).

Create the customTab\_actions.json file. In this file, define the custom action (openMathWorksWebsiteAction) and icon (openMathWorksWebsiteIcon).

```
{
 "version": "R2021b",
 "entries": [
 {
 "type": "Action",
 "id": "openMathWorksWebsiteAction",
 "text": "MathWorks\nWebsite",
 "description": "Open the MathWorks website",
 "icon": "openMathWorksWebsiteIcon",
 "command": "openMathWorksWebsite",
 "commandType": "Script"
 },
 {
 "type": "Icon",
 "id": "openMathWorksWebsiteIcon",
 "icon16": "openMathWorksWebsite_16.png",
 "icon24": "openMathWorksWebsite_24.png"
 }
]
}
```

In the customTab.json file, add the push button and reference the openMathWorksWebsiteAction action.

```
{
 "version": "R2021b",
 "entries": [
 {
 "type": "Tab",
 "id": "customTab",
 "title": "CUSTOM TAB",
 "children": [
 {
 "type": "Section",
 "title": "Info",
 "children": [
 {
 "type": "Column",
 "children": [
 {
 "type": "PushButton",
 "action": "openMathWorksWebsiteAction"
 }
]
 }
]
 },
 {
 "type": "Section",
 "title": "File",
 "children": [

```

```

 {
 "type": "Column",
 "children": []
 },
 {
 "type": "Column",
 "children": [
 {
 "type": "PushButton",
 "action": "openModelAction"
 }
]
 }
]
}

```

To see the custom push button, reload the toolstrip configuration.

```
slReloadToolstripConfig;
```

Using developer mode, you can get the fully qualified names of custom actions and icons on a custom tab. For more information, see `slToolstripDeveloperMode`.

```
Action: custom:openMathWorksWebsiteAction
Icon: custom:openMathWorksWebsiteIcon

```

You can also define a custom icon in a custom action, a custom action in a control, and a MATLAB command in a JSON file. For example, this push-button control uses nested JSON objects to define the custom action and icon and the command no longer references an external script.

```

{
 "type": "PushButton",
 "action": {
 "text": "MathWorks\nWebsite",
 "description": "Open the MathWorks website",
 "icon": {
 "icon16": "openMathWorksWebsite_16.png",
 "icon24": "openMathWorksWebsite_24.png"
 },
 "command": "web('https://www.mathworks.com')",
 "commandType": "Script"
 }
}

```

Nesting JSON objects and defining commands in the JSON file add complexity to the JSON file. Debugging is easier when you have fewer levels of hierarchy and use MATLAB functions or scripts to define and debug commands.

## Choose Among Pop-Up List Elements

Pop-up lists display multiple actions in a menu. You can use them to simplify the appearance of your custom tab by grouping similar actions under one control. Drop-down and split buttons support pop-up lists.

The order in which you add elements to the pop-up list determines the order in which they appear in the list. This table describes the elements you can add to a pop-up list.

| List Control               | Appearance                                                                                                                                                                                        | Description                                                                           | JSON Object Type  |
|----------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------|-------------------|
| List item                  |  Blank Model Ctrl+N                                                                                              | A list item performs an action, similar to a push button.                             | ListItem          |
| List item with pop-up list |  Project                                                                                                         | A list item with a pop-up list displays a pop-up list, similar to a drop-down button. | ListItemWithPopup |
| List header                | FROM TEMPLATE                                                                                                                                                                                     | A list header adds a titled heading to the list.                                      | ListHeader        |
| List separator             |  Architecture...<br> Project | A list separator adds a horizontal line to separate items in the list.                | ListSeparator     |

For each list item, specify:

- `type` — Type of JSON object (`ListItem` or `ListItemWithPopup`), specified as a string.
- `id` (optional) — Unique identifier within the pop-up list, specified as a string.
- `action` — Appearance and behavior of the list item, specified as a string.
- `showDescription` (optional) — Option to display the text from the `description` property of the action on the list item, specified as a Boolean (`true` or `false`). By default, the list item displays the description.
- `popupName` (conditional) — Name of another pop-up list, specified as a string. Omit this property for `ListItem` JSON objects.

For each list header, specify:

- `type` — Type of JSON object (`ListHeader`), specified as a string
- `id` (optional) — Unique identifier within the pop-up list, specified as a string
- `text` — Text to appear in the heading, specified as a string

For each list separator, specify:

- `type` — Type of JSON object (`ListSeparator`), specified as a string
- `id` (optional) — Unique identifier within the pop-up list, specified as a string

## Define Pop-Up Lists

To create pop-up lists:

- 1 Define any custom actions the pop-up lists use.
- 2 Get the built-in actions that the pop-up lists use.
- 3 In the `json` folder of the `resources` directory, create a JSON file that defines pop-up lists. For example, create a JSON file named `customTab_popups.json`.
- 4 Populate the new file with the required JSON properties: `version` and `entries`. For example:

```
{
 "version": "R2021b",
 "entries": []
}
```

- 5 Define the pop-up lists as JSON objects in the `entries` property.
- 6 Reference each pop-up list from a JSON object for a drop-down button, split button, or list item with a pop-up list.

For each pop-up list, specify:

- `type` — Type of JSON object (`PopupMenu`), specified as a string
- `id` (optional) — Unique identifier within the toolstrip component, specified as a string
- `children` — Elements within the pop-up list, specified as an array of JSON objects

For example, create the **New** drop-down button from the prepopulated custom tab example.

Get the built-in icon for the **New** button on the **Simulation** tab.

```
Action: createNewBlankModelAction
Icon: new_24

```

The built-in icon has a suffix (`_24`) to indicate the icon size. When you reference the icon for a custom action, drop this suffix.

In the `customTab_actions.json` file, add a custom action (`newPopUpAction`) that defines the icon and text for the drop-down button.

```
{
 "version": "R2021b",
 "entries": [
 {
 "type": "Action",
 "id": "newPopUpAction",
 "text": "New",
 "icon": "new"
 },
 {
 "type": "Action",
 "id": "openMathWorksWebsiteAction",
 "text": "MathWorks\nWebsite",
 "description": "Open the MathWorks website",
 "icon": "openMathWorksWebsiteIcon",
 "command": "openMathWorksWebsite",
 "commandType": "Script"
 },
 {
 "type": "Icon",
 "id": "openMathWorksWebsiteIcon",
 "icon16": "openMathWorksWebsite_16.png",
 "icon24": "openMathWorksWebsite_24.png"
 }
]
}
```

Get the built-in actions for these buttons on the **Simulation** tab:

- **New > Blank Model**
- **New > Blank Subsystem**
- **New > Project > New Project from this Model**

```
Action: createNewBlankModelAction
Icon: model_24

```

```
Action: createNewBlankReferenceableSubsystemAction
Icon: referenceableSubsystem_24

```

```
Action: createNewProjectFromModelAction
Icon: projectNewFromModel_24

```

Create the `customTab_popups.json` file. In this file, define the pop-up list (`newPopUpList`) for the button.

```
{
 "version": "R2021b",
 "entries": [
 {
 "type": "PopUpList",
 "id": "newPopUpList",
 "children": [
 {
 "type": "ListItem",
 "action": "createNewBlankModelAction"
 },
 {

```

```

 "type": "ListItem",
 "action": "createNewBlankReferenceableSubsystemAction"
 },
 {
 "type": "ListItem",
 "action": "createNewProjectFromModelAction"
 }
]
 }
}

```

In the `customTab.json` file, add the **New** drop-down button and reference the corresponding action (`newPopUpAction`) and pop-up list (`newPopUpList`).

```

{
 "version": "R2021b",
 "entries": [
 {
 "type": "Tab",
 "id": "customTab",
 "title": "CUSTOM TAB",
 "children": [
 {
 "type": "Section",
 "title": "Info",
 "children": [
 {
 "type": "Column",
 "children": [
 {
 "type": "PushButton",
 "action": "openMathWorksWebsiteAction"
 }
]
 }
]
 },
 {
 "type": "Section",
 "title": "File",
 "children": [
 {
 "type": "Column",
 "children": [
 {
 "type": "DropDownButton",
 "action": "newPopUpAction",
 "popupName": "newPopUpList"
 }
]
 }
]
 },
 {
 "type": "Column",
 "children": [
 {
 "type": "PushButton",
 "action": "openModelAction"
 }
]
 }
]
 }
]
}

```

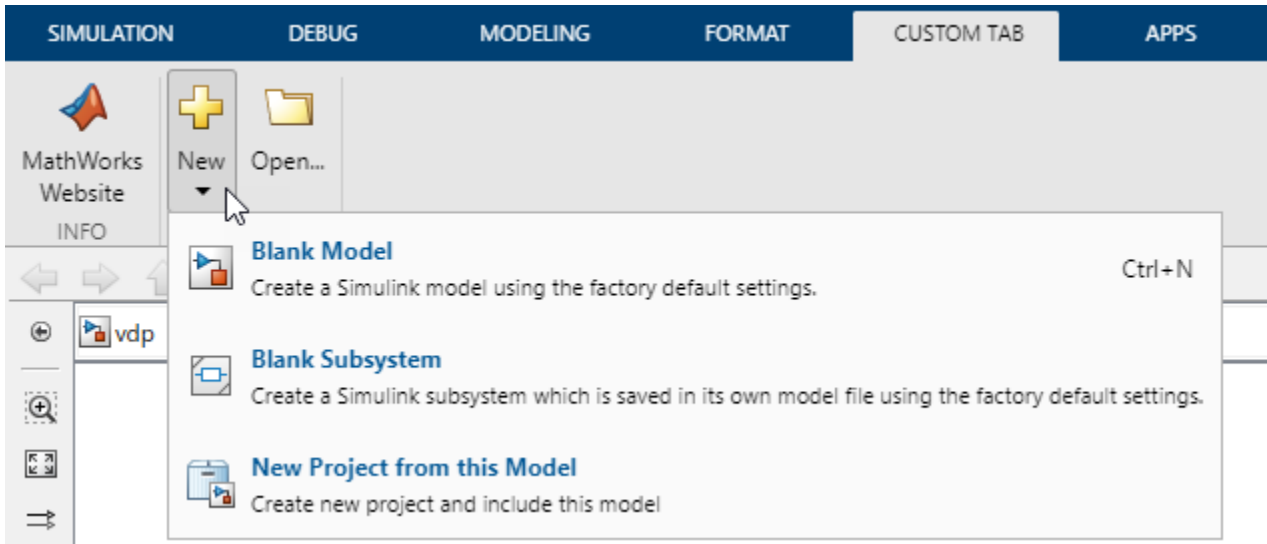

```

 }
 }
}

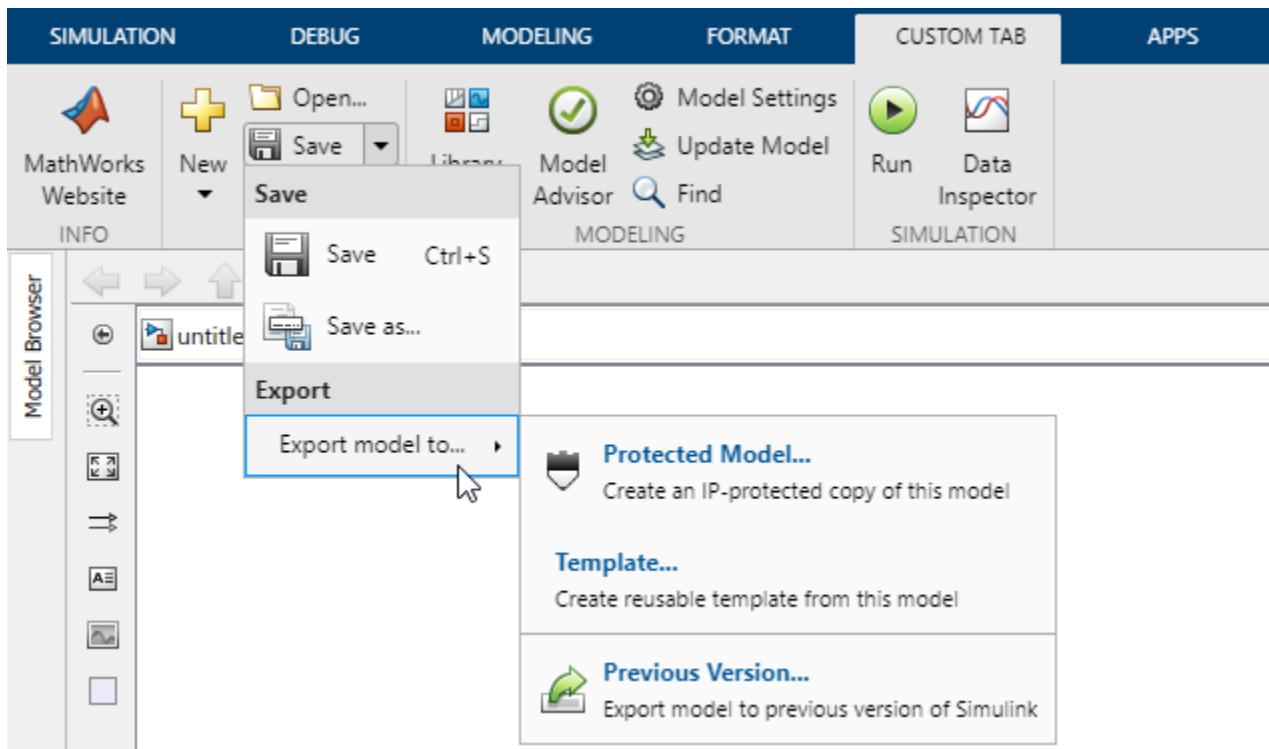

```

To see the **New** drop-down button and its pop-up list, reload the toolstrip configuration.

```
slReloadToolstripConfig;
```

For a more complicated example, create the **Save** split button from the prepopulated custom tab example.

In the `customTab_actions.json` file, add a custom action (`exportPopUpAction`) that defines the text for the list item with a pop-up list.

```
{
 "version": "R2021b",
 "entries": [
 {
 "type": "Action",
 "id": "newPopUpAction",
 "text": "New",
 "icon": "new"
 },
 {
 "type": "Action",
 "id": "exportPopUpAction",
 "text": "Export model to..."
 },
 {
 "type": "Action",
 "id": "openMathWorksWebsiteAction",
 "text": "MathWorks\nWebsite",
 "description": "Open the MathWorks website",
 "icon": "openMathWorksWebsiteIcon",
 "command": "openMathWorksWebsite",
 "commandType": "Script"
 },
 {
 "type": "Icon",
 "id": "openMathWorksWebsiteIcon",
 "icon16": "openMathWorksWebsite_16.png",
 "icon24": "openMathWorksWebsite_24.png"
 }
]
}
```

```

 }
]
}

```

Get the built-in actions for these buttons on the **Simulation** tab:

- **Save**
- **Save > Save As**
- **Save > Protected Model**
- **Save > Template**
- **Save > Previous Version**

```

Action: saveModelAction
Icon: save_24

Action: saveModelAsAction
Icon: save_as_16

Action: createProtectedModelAction
Icon: referencedModelProtect_16

Action: exportModelToTemplateAction
Icon: exportModelToTemplate_16

Action: exportModelToPreviousVersionAction
Icon: export_16

```

In the `customTab_popups.json` file, define the two additional pop-up lists:

- `savePopUpList` — Pop-up list for the **Save** split button
- `exportPopUpList` — Pop-up list for the **Export model to** list item

For the list item that has a pop-up list, reference the corresponding action (`exportPopUpAction`) and pop-up list (`exportPopUpList`).

```

{
 "version": "R2021b",
 "entries": [
 {
 "type": "PopupMenu",
 "id": "newPopUpList",
 "children": [
 {
 "type": "ListItem",
 "action": "createNewBlankModelAction"
 },
 {
 "type": "ListItem",
 "action": "createNewBlankReferenceableSubsystemAction"
 },
 {
 "type": "ListItem",
 "action": "createNewProjectFromModelAction"
 }
]
 },
 {
 "type": "PopupMenu",
 "id": "savePopUpList",
 "children": [
 {
 "type": "ListHeader",
 "text": "Save"
 }
]
 }
]
}

```

```

 },
 {
 "type": "ListItem",
 "action": "saveModelAction"
 },
 {
 "type": "ListItem",
 "action": "saveModelAsAction"
 },
 {
 "type": "ListHeader",
 "text": "Export"
 },
 {
 "type": "ListItemWithPopup",
 "action": "exportPopUpAction",
 "popupName": "exportPopUpList"
 }
]
},
{
 "type": "PopupList",
 "id": "exportPopUpList",
 "children": [
 {
 "type": "ListItem",
 "action": "createProtectedModelAction"
 },
 {
 "type": "ListItem",
 "action": "exportModelToTemplateAction"
 },
 {
 "type": "ListSeparator"
 },
 {
 "type": "ListItem",
 "action": "exportModelToPreviousVersionAction"
 }
]
}
]
}
}
}

```

In the `customTab.json` file, add the **Save** split button after the **Open** button. Reference the corresponding action (`saveModelAction`) and pop-up list (`savePopUpList`).

```

{
 "version": "R2021b",
 "entries": [
 {
 "type": "Tab",
 "id": "customTab",
 "title": "CUSTOM TAB",
 "children": [
 {
 "type": "Section",
 "title": "Info",
 "children": [
 {
 "type": "Column",
 "children": [
 {
 "type": "PushButton",
 "action": "openMathWorksWebsiteAction"
 }
]
 }
]
 }
]
 },
],
}

```

```

{
 "type": "Section",
 "title": "File",
 "children": [
 {
 "type": "Column",
 "children": [
 {
 "type": "DropDownButton",
 "action": "newPopUpAction",
 "popupName": "newPopUpList"
 }
]
 },
 {
 "type": "Column",
 "children": [
 {
 "type": "PushButton",
 "action": "openModelAction"
 },
 {
 "type": "SplitButton",
 "action": "saveModelAction",
 "popupName": "savePopUpList"
 }
]
 }
]
}

```

To see the **Save** split button and its pop-up lists, reload the toolstrip configuration.

```
slReloadToolstripConfig;
```

To vertically align the first control with the top of the column, add an empty control under the **Save** split button.

```

 }
]
 }
]
 }
]
 }
]
}
```

## Add Prepopulated Custom Tab to Simulink Toolstrip

This example provides the `resources` folder contents for a prepopulated custom tab. When you add custom tabs to the Simulink® Toolstrip, you might find modifying a prepopulated tab easier than starting with a blank tab.

A custom tab provides a single location for the actions you use most often. Use custom tabs to collect built-in actions that span multiple tabs on the default Toolstrip, such as the **Open** and **Model Advisor** buttons. While this example focuses on Simulink actions, you can also add actions from other products to your custom tab, such as the **Build** button from Simulink Coder™. If you do not have a product installed or do not have a license for a product, the built-in actions from that product appear as empty buttons on the custom tab.

Custom tabs also support custom actions. In this example, the **MathWorks Website** button uses a custom action defined by a script.

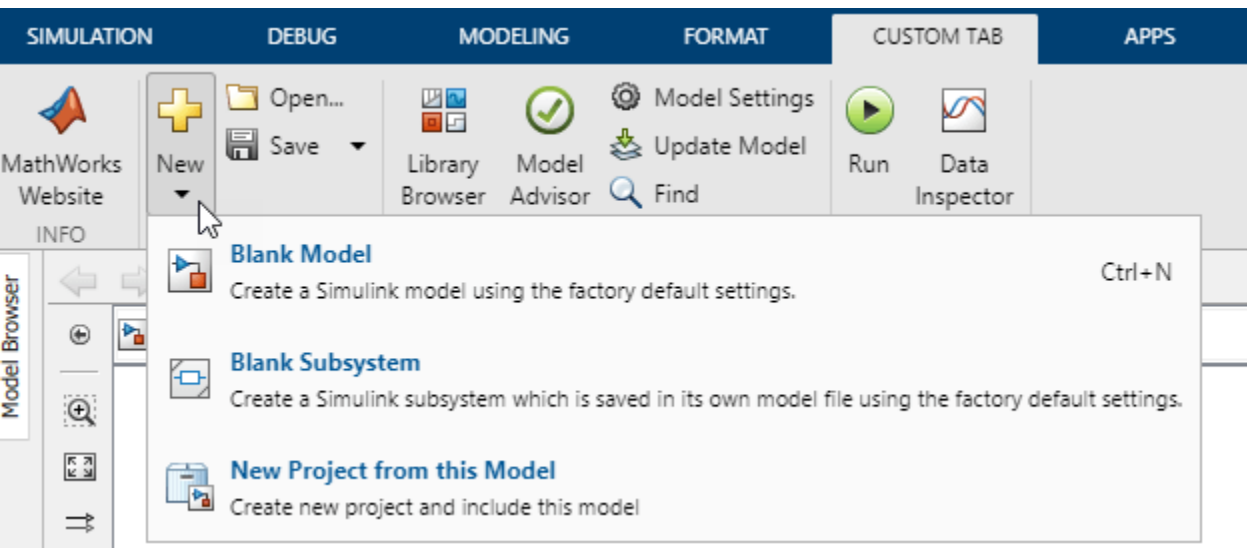

The prepopulated custom tab provides one or more examples of each type of control that custom tabs support.

- The **New** button is a *drop-down button* that expands to show additional items in a pop-up list.
- The **Open** button is a *push button* that you click to perform an action.
- The **Save** button is a *split button* that consists of a push button and drop-down button.
- An *empty control* adds space below the **Save** button.

You can distinguish a drop-down button from a split button by pausing on the button. The split button has two interactive parts separated by a line, while a drop-down button has only one part.

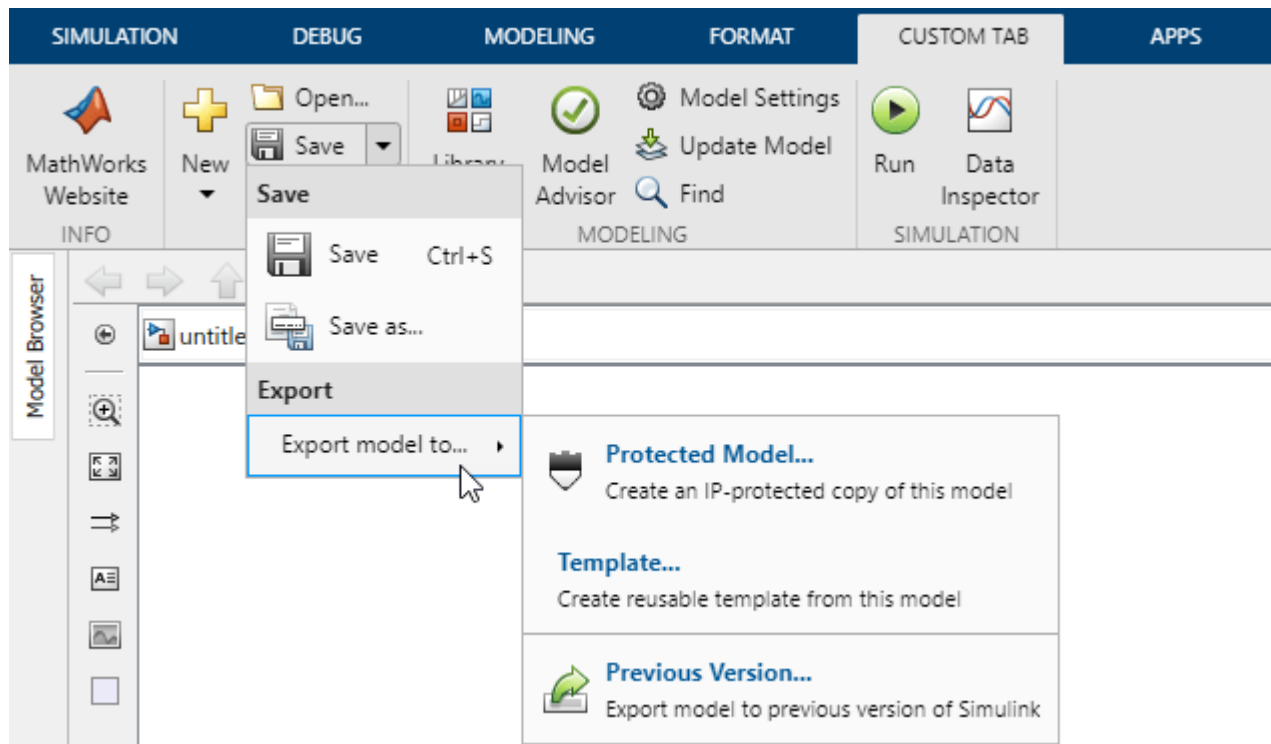

The **New** button expands to show a pop-up list with three *list items* that you click to perform an action.

The **Save** button expands to show a pop-up list with more features.

- **Save** and **Export** are *list headers* that provide headings.
- The line between **Template** and **Previous Version** is a *list separator*.
- **Export model to** is a *list item with a pop-up list* that expands to show additional items in a nested pop-up list.

## Examine Files That Define Custom Tab Appearance and Behavior

The files that define the prepopulated custom tab are in the `resourcesExample` folder. To view the custom tab in the Simulink Toolstrip, you must rename the folder from `resourcesExample` to `resources` and add its parent folder to the MATLAB path.

The `sl_toolstrip_plugins.json` file defines the Simulink Toolstrip component. Do not edit this file.

```
file0 = fullfile(pwd,"resourcesExample","sl_toolstrip_plugins.json");
type(file0)
```

```
{"entries":[{"content":{"Name":"custom"},"type":"config.ComponentData"},"packageUri":[],"version":
```

The two images in the `icons` folder of the `resourcesExample` folder provide the 16-by-16 and 24-by-24 pixel versions of a custom icon.

Three JSON files in the `json` folder of the `resourcesExample` folder define the custom tab.

- `customTab.json` — JSON file that defines the tab, layout, and controls.
- `customTab_actions.json` — Optional JSON file that defines custom actions. One of the actions references the `openMathWorksWebsite.m` script in the example folder.
- `customTab_popups.json` — Optional JSON file that defines the pop-up lists for drop-down buttons, split buttons, and list items with pop-up lists.

```
file1 = fullfile(pwd,"resourcesExample","json","customTab.json");
type(file1)
```

```
{
 "version": "R2021b",
 "entries": [
 {
 "type": "Tab",
 "id": "customTab",
 "title": "CUSTOM TAB",
 "children": [
 {
 "type": "Section",
 "title": "Info",
 "children": [
 {
 "type": "Column",
 "children": [
 {
 "type": "PushButton",
 "action": "openMathWorksWebsiteAction"
 }
]
 }
]
 }
]
 }
],
}
```

```

{
 "type": "Section",
 "title": "File",
 "children": [
 {
 "type": "Column",
 "children": [
 {
 "type": "DropDownButton",
 "action": "newPopUpAction",
 "popupName": "newPopUpList"
 }
]
 },
 {
 "type": "Column",
 "children": [
 {
 "type": "PushButton",
 "action": "openModelAction"
 },
 {
 "type": "SplitButton",
 "action": "saveModelAction",
 "popupName": "savePopUpList"
 },
 {

 }
]
 }
]
},
{
 "type": "Section",
 "title": "Modeling",
 "children": [
 {
 "type": "Column",
 "children": [
 {
 "type": "PushButton",
 "action": "showLibraryBrowserAction"
 }
]
 },
 {
 "type": "Column",
 "children": [
 {
 "type": "PushButton",
 "action": "openModelAdvisorAction"
 }
]
 },
 {
 "type": "Column",
 "children": [

```

```

 {
 "type": "PushButton",
 "action": "openModelConfigParamAction"
 },
 {
 "type": "PushButton",
 "action": "updateDiagramAction"
 },
 {
 "type": "PushButton",
 "action": "findInModelAction"
 }
]
}
],
},
{
 "type": "Section",
 "title": "Simulation",
 "children": [
 {
 "type": "Column",
 "children": [
 {
 "type": "PushButton",
 "action": "playSimulationAction"
 }
]
 },
 {

 "text": "Save"
 },
 {
 "type": "MenuItem",
 "action": "saveModelAction"
 }
]
 }
]
}

```

```

 {
 "type": "ListItem",
 "action": "saveModelAsAction"
 },
 {
 "type": "ListHeader",
 "text": "Export"
 },
 {
 "type": "ListItemWithPopup",
 "action": "exportPopUpAction",
 "popupName": "exportPopUpList"
 }
]
},
{
 "type": "PopupList",
 "id": "exportPopUpList",
 "children": [
 {
 "type": "ListItem",
 "action": "createProtectedModelAction"
 },
 {
 "type": "ListItem",
 "action": "exportModelToTemplateAction"
 },
 {
 "type": "ListSeparator"
 },
 {
 "type": "ListItem",
 "action": "exportModelToPreviousVersionAction"
 }
]
}
]
}

```

The script that the action references must be on the MATLAB path. The script cannot be in the resources folder for the custom tab.

```
type openMathWorksWebsite.m
```

```
web('https://www.mathworks.com')
```

### Edit Prepopulated Custom Tab

- 1 Copy the resourcesExample folder and the openMathWorksWebsite.m script to a folder on the MATLAB® path.
- 2 Rename the folder from resourcesExample to resources. For a custom tab to register as a Simulink Toolstrip customization, the folder name must be resources.
- 3 In the MATLAB Command Window, enter `slReloadToolstripConfig`.
- 4 To interact with the custom tab, open a Simulink model.
- 5 To edit the custom tab, edit the JSON files in the json folder.

- 6 To see your changes, reload the Simulink Toolstrip configuration by entering `slReloadToolstripConfig`.

For more information, see “Create Custom Simulink Toolstrip Tabs” on page 79-5.

## Add Items to Model Editor Menus

### In this section...

“Code for Adding Menu Items” on page 79-36  
 “Define Menu Items” on page 79-37  
 “Register Menu Customizations” on page 79-41  
 “Callback Info Object” on page 79-42  
 “Debugging Custom Menu Callbacks” on page 79-42  
 “Menu Tags” on page 79-42

You can add commands and submenus to a menu bar and context menus for the Simulink Editor and Stateflow Editor.

To add an item to a menu:

- 1 For each item, create a function, called a schema function, that defines the item (see “Define Menu Items” on page 79-37).
- 2 Register the menu customizations with the Simulink customization manager at startup, e.g., in an `sl_customization.m` file on the MATLAB path (see “Register Menu Customizations” on page 79-41).
- 3 Create callback functions that implement the commands triggered by the items that you add to the menus.

### Code for Adding Menu Items

The following `sl_customization.m` file adds four items to a **Tools** menu that appears below the Simulink Toolstrip.

```
function sl_customization(cm)

 %% Register custom menu function.
 cm.addCustomMenuFcn('Simulink:ToolsMenu', @getMyMenuItems);
end

%% Define the custom menu function.
function schemaFcns = getMyMenuItems(callbackInfo)
 schemaFcns = {@getItem1, ...
 @getItem2, ...
 {@getItem3,3}, ... %% Pass 3 as user data to getItem3.
 @getItem4};
end

%% Define the schema function for first menu item.
function schema = getItem1(callbackInfo)
 schema = sl_action_schema;
 schema.label = 'Item One';
 schema.userdata = 'item one';
 schema.callback = @myCallback1;
end

function myCallback1(callbackInfo)
 disp(['Callback for item ' callbackInfo.userdata ' was called']);
end

function schema = getItem2(callbackInfo)
 % Make a submenu label 'Item Two' with
 % the menu item above three times.
```

```

 schema = sl_container_schema;
 schema.label = 'Item Two';
 schema.childrenFcns = {@getItem1, @getItem1, @getItem1};
end

function schema = getItem3(callbackInfo)
% Create a menu item whose label is
% 'Item Three: 3', with the 3 being passed
% from getMyItems above.

 schema = sl_action_schema;
 schema.label = ['Item Three: ' num2str(callbackInfo.userdata)];
end

function myToggleCallback(callbackInfo)
 if strcmp(get_param(gcs, 'ScreenColor'), 'red') == 0
 set_param(gcs, 'ScreenColor', 'red');
 else
 set_param(gcs, 'ScreenColor', 'white');
 end
end

%% Define the schema function for a toggle menu item.
function schema = getItem4(callbackInfo)
 schema = sl_toggle_schema;
 schema.label = 'Red Screen';
 if strcmp(get_param(gcs, 'ScreenColor'), 'red') == 1
 schema.checked = 'checked';
 else
 schema.checked = 'unchecked';
 end
 schema.callback = @myToggleCallback;
end

```

## Define Menu Items

You define a menu item by creating a function that returns an object, called a *schema* object, that specifies the information needed to create the menu item. The menu item that you define may trigger a custom action or display a custom submenu. See the following sections for more information.

- “Defining Menu Items That Trigger Custom Commands” on page 79-37
- “Defining Custom Submenus” on page 79-40

### Defining Menu Items That Trigger Custom Commands

To define an item that triggers a custom command, your schema function must accept a callback info object (see “Callback Info Object” on page 79-42) and create and return an action schema object (see “Action Schema Object” on page 79-38) that specifies the item label and a function, called a *callback*, to be invoked when the user selects the item. For example, the following schema function defines a menu item that displays a message when selected by the user.

```

function schema = getItem1(callbackInfo)

 %% Create an instance of an action schema.
 schema = sl_action_schema;

 %% Specify the menu item label.
 schema.label = 'My Item 1';
 schema.userdata = 'item1';

 %% Specify the menu item callback function.
 schema.callback = @myCallback1;

```

```
end

function myCallback1(callbackInfo)
 disp(['Callback for item ' callbackInfo.userdata
 ' was called']);
end
```

### Action Schema Object

This object specifies information about menu items that trigger commands that you define, including the label that appears on the menu item and the function to be invoked when the user selects the menu item. Use the function `sl_action_schema` to create instances of this object in your schema functions. Its properties include:

- `tag`  
Optional character vector that identifies this action, for example, so that it can be referenced by a filter function.
- `label`  
Character vector specifying the label that appears on a menu item that triggers this action.
- `state`  
Property that specifies the state of this action. Valid values are 'Enabled' (the default), 'Disabled', and 'Hidden'.
- `statustip`  
Character vector specifying text to appear in the editor status bar when the user selects the menu item that triggers this action.
- `userdata`  
Data that you specify. May be of any type.
- `accelerator`  
Character vector specifying a **Ctrl** and key combination to use to trigger this action. You can add a keyboard shortcut only for custom menu items that appear on menu bar menus and cannot redefine accelerators that come with the Simulink Editor. For example, **Ctrl+D** is an accelerator for **Update Diagram** in the Simulink Editor, so you cannot redefine it.  
  
To specify this value, use the form 'Ctrl+K', where *K* is the shortcut key. For example, use 'Ctrl+Alt+T' for an accelerator invoked by holding down **Ctrl** and **Alt** and pressing **T**.
- `callback`  
Character vector specifying a MATLAB expression to be evaluated or a handle to a function to be invoked when a user selects the menu item that triggers this action. This function must accept one argument: a callback info object.
- `autoDisableWhen`  
Property that controls when a menu item is automatically disabled.

| Setting  | When Menu Items Are Disabled                                         |
|----------|----------------------------------------------------------------------|
| 'Locked' | (default) When the active editor is locked or when the model is busy |
| 'Busy'   | Only if the model is busy                                            |
| 'Never'  | Never                                                                |

### Toggle Schema Object

This object specifies information about a menu item that toggles some object on or off. Use the function `sl_toggle_schema` to create instances of this object in your schema functions. Its properties include:

- `tag`  
Optional character vector that identifies this toggle action, for example, so that it can be referenced by a filter function.
- `label`  
Character vector specifying the label that appears on a menu item that triggers this toggle action.
- `checked`  
Specify whether the menu item displays a check mark. Valid values are 'unchecked' (default) and 'checked'
- `state`  
State of this toggle action, specified as 'Enabled' (default), 'Disabled', and 'Hidden'.
- `statustip`  
Character vector specifying text to appear in the editor status bar when the user selects the menu item that triggers this toggle action.
- `userdata`  
Data that you specify. May be of any type.
- `accelerator`  
Character vector specifying a **Ctrl** and key combination to use to trigger this action. You can add a keyboard shortcut only for custom menu items that appear on menu bar menus and cannot redefine accelerators that come with the Simulink Editor. For example, **Ctrl+D** is an accelerator for **Update Diagram** in the Simulink Editor, so you cannot redefine it.  
  
To specify this value, use the form 'Ctrl+K', where *K* is the shortcut key. For example, use 'Ctrl+Alt+T' for an accelerator invoked by holding down **Ctrl** and **Alt** and pressing **T**.
- `callback`  
Character vector specifying a MATLAB expression to be evaluated or a handle to a function to be invoked when a user selects the menu item that triggers this action. This function must accept one argument: a callback info object.
- `autoDisableWhen`  
Property that controls when a menu item is automatically disabled.

| Setting  | When Menu Items Are Disabled                                         |
|----------|----------------------------------------------------------------------|
| 'Locked' | (default) When the active editor is locked or when the model is busy |
| 'Busy'   | Only if the model is busy                                            |
| 'Never'  | Never                                                                |

### Defining Custom Submenus

To define a submenu, create a schema function that accepts a callback info object and returns a container schema object (see “Container Schema Object” on page 79-40) that specifies the schemas that define the items on the submenu. For example, the following schema function defines a submenu that contains three instances of the menu item defined in the example in “Defining Menu Items That Trigger Custom Commands” on page 79-37.

```
function schema = getItem2(callbackInfo)
 schema = sl_container_schema;
 schema.label = 'Item Two';
 schema.childrenFcns = {@getItem1, @getItem1, @getItem1};
end
```

### Container Schema Object

A container schema object specifies a submenu label and its contents. Use the function `sl_container_schema` to create instances of this object in your schema functions. Properties of the object include

- `tag`  
Optional character vector that identifies this submenu.
- `label`  
Character vector specifying the submenu label.
- `state`  
Character vector that specifies the state of this submenu. Valid values are 'Enabled' (the default), 'Disabled', and 'Hidden'.
- `statustip`  
Character vector specifying text to appear in the editor status bar when the user selects this submenu.
- `childrenFcns`  
Cell array that specifies the contents of the submenu. Each entry in the cell array can be
  - A pointer to a schema function that defines an item on the submenu (see “Define Menu Items” on page 79-37)
  - A two-element cell array whose first element is a pointer to a schema function that defines an item entry and whose second element is data to be inserted as user data in the callback info object (see “Callback Info Object” on page 79-42) passed to the schema function
  - 'separator', which causes a separator to appear between the item defined by the preceding entry in the cell array and the item defined in the following entry. The case is ignored for this entry (for example, 'SEPARATOR' and 'Separator' are both valid entries). A separator is

also suppressed if it appears at the beginning or end of the submenu and separators that would appear successively are combined into a single separator (for example, as a result of an item being hidden).

For example, the following cell array specifies two submenu entries:

```
{@getItem1, 'separator', {@getItem2, 1}}
```

In this example, a 1 is passed to `getItem2` via a callback info object.

- **generateFcn**

Pointer to a function that returns a cell array defining the contents of the submenu. The cell array must have the same format as that specified for the container schema objects `childrenFcns` property.

---

**Note** The `generateFcn` property takes precedence over the `childrenFcns` property. If you set both, the `childrenFcns` property is ignored and the cell array returned by the `generateFcn` is used to create the submenu.

---

- **userdata**

Data of any type that is passed to `generateFcn`.

- **autoDisableWhen**

Property that controls when a menu item is automatically disabled.

| Setting  | When Menu Items Are Disabled                                         |
|----------|----------------------------------------------------------------------|
| 'Locked' | (default) When the active editor is locked or when the model is busy |
| 'Busy'   | Only if the model is busy                                            |
| 'Never'  | Never                                                                |

## Register Menu Customizations

You must register custom items to be included on a Simulink menu with the customization manager. Use the `sl_customization.m` file for a Simulink installation (see “Register Customizations with Simulink” on page 79-56) to perform this task. In particular, for each menu that you want to customize, your system `sl_customization` function must invoke the customization manager `addCustomMenuFcn` method. Each invocation should pass the tag of the menu (see “Menu Tags” on page 79-42) to be customized and a custom menu function that specifies the items to be added to the menu (see “Creating the Custom Menu Function” on page 79-41). For example, the following `sl_customization` function adds custom items to the Simulink Tools menu.

```
function sl_customization(cm)
 %% Register custom menu function.
 cm.addCustomMenuFcn('Simulink:ToolsMenu', @getMyItems);
```

### Creating the Custom Menu Function

The custom menu function returns a cell array of schema functions that define custom items that you want to appear on the model editor menus (see “Define Menu Items” on page 79-37 ). The custom menu function returns a cell array similar to that returned by the `generateFcn` function.

Your custom menu function should accept a callback info object (see “Callback Info Object” on page 79-42) and return a cell array that lists the schema functions. Each element of the cell array can be either a handle to a schema function or a two-element cell array whose first element is a handle to a schema function and whose second element is user-defined data to be passed to the schema function. For example, the following custom menu function returns a cell array that lists three schema functions.

```
function schemas = getMyItems(callbackInfo)
 schemas = {@getItem1, ...
 @getItem2, ...
 {@getItem3,3} }; % Pass 3 as userdata to getItem3.
end
```

## Callback Info Object

Instances of these objects are passed to menu customization functions. Methods and properties of these objects include:

- `uiObject`

Method to get the handle to the owner of the menu for which this is the callback. The owner can be the Simulink Editor or the Stateflow Editor.

- `model`

Method to get the handle to the model being displayed in the editor window.

- `userdata`

User data property. The value of this property can be any type of data.

## Debugging Custom Menu Callbacks

On systems using the Microsoft Windows operating system, selecting a custom menu item whose callback contains a breakpoint can cause the mouse to become unresponsive or the menu to remain open and on top of other windows. To fix these problems, use the MATLAB code debugger keyboard commands to continue execution of the callback.

## Menu Tags

A menu tag identifies a Simulink Editor or the Stateflow Editor menu bar or menu. You need to know the tag for a menu to add custom items to it (see “Register Menu Customizations” on page 79-41).

| Tag                                  | What It Adds                                            |
|--------------------------------------|---------------------------------------------------------|
| Simulink tags                        |                                                         |
| <code>Simulink:MenuBar</code>        | Menu to the Simulink Editor menu bar                    |
| <code>Simulink:PreContextMenu</code> | Item to the beginning of a Simulink Editor context menu |
| <code>Simulink:ContextMenu</code>    | Item to the end of a Simulink Editor context menu       |
| <code>Simulink:FileMenu</code>       | Item to the end of a Simulink Editor <b>File</b> menu   |
| <code>Simulink&gt;EditMenu</code>    | Item to the end of a Simulink Editor <b>Edit</b> menu   |

| Tag                      | What It Adds                                                 |
|--------------------------|--------------------------------------------------------------|
| Simulink:ViewMenu        | Item to the end of a Simulink Editor <b>View</b> menu        |
| Simulink:DisplayMenu     | Item to the end of a Simulink Editor <b>Display</b> menu     |
| Simulink:DiagramMenu     | Item to the end of a Simulink Editor <b>Diagram</b> menu     |
| Simulink:SimulationMenu  | Item to the end of a Simulink Editor <b>Simulation</b> menu  |
| Simulink:AnalysisMenu    | Item to the end of a Simulink Editor <b>Analysis</b> menu    |
| Simulink:CodeMenu        | Item to the end of a Simulink Editor <b>Code</b> menu        |
| Simulink:ToolsMenu       | Item to the end of a Simulink Editor <b>Tools</b> menu       |
| Simulink:HelpMenu        | Item to the end of a Simulink Editor <b>Help</b> menu        |
| Stateflow tags           |                                                              |
| Stateflow:MenuBar        | Menu to the Stateflow Editor menu bar                        |
| Stateflow:PreContextMenu | Item to the beginning of a Stateflow Editor context menu.    |
| Stateflow:ContextMenu    | Items to the end of a Stateflow Editor context menu.         |
| Stateflow:FileMenu       | Item to the end of a Stateflow Editor <b>File</b> menu       |
| Stateflow>EditMenu       | Item to the end of a Stateflow Editor <b>Edit</b> menu       |
| Stateflow:ViewMenu       | Item to the end of a Stateflow Editor <b>View</b> menu       |
| Stateflow:DisplayMenu    | Item to the end of a Stateflow Editor <b>Display</b> menu    |
| Stateflow:ChartMenu      | Item to the end of a Stateflow Editor <b>Chart</b> menu      |
| Stateflow:SimulationMenu | Item to the end of a Stateflow Editor <b>Simulation</b> menu |
| Stateflow:AnalysisMenu   | Item to the end of a Stateflow Editor <b>Analysis</b> menu   |
| Stateflow:CodeMenu       | Item to the end of a Stateflow Editor <b>Code</b> menu       |
| Stateflow:ToolsMenu      | Item to the end of a Stateflow Editor <b>Tools</b> menu      |
| Stateflow:HelpMenu       | Item to the end of a Stateflow Editor <b>Help</b> menu       |

### Simulink and Stateflow Editor Menu Customization

Use the same general procedures to customize Stateflow Editor menus as you use for Simulink Editor. The addition of custom menu functions to the ends of top-level menus depends on the active editor:

- Menus bound to `Simulink:FileMenu` only appear when the Simulink Editor is active.
- Menus bound to `Stateflow:FileMenu` only appear when the Stateflow Editor is active.
- To have a menu to appear in both of the editors, call `addCustomMenuFcn` twice, once for each tag. Check that the code works in both editors.

- “Disable Simulink Toolstrip and Context Menu Actions” on page 79-45
- “Disable and Hide Dialog Box Controls” on page 79-48
- “Customize Library Browser Appearance” on page 79-52

- “Register Customizations with Simulink” on page 79-56

## Disable Simulink Toolstrip and Context Menu Actions

You can disable items that appear in the Simulink Toolstrip and context menus. For context menus, you can also hide actions. To disable or hide an action, you must:

- 1 Get the name of the built-in action that you want to disable or hide.
- 2 Create or edit a customization file.
- 3 Create a filter function that disables or hides the item.
- 4 Register the filter function with the customization manager.
- 5 Refresh the Simulink customization file (`sl_customization.m`).

For example, this code creates and registers a filter function to disable the **New Model** button in the Simulink Toolstrip.

```
function sl_customization(cm)
 cm.addCustomFilterFcn('Simulink:NewModel',@myFilter);
end

function state = myFilter(callbackInfo)
 state = 'Disabled';
end
```

### Get Built-In Simulink Actions

To get the name and icon for a built-in action from the Simulink Toolstrip, use the `slToolstripDeveloperMode` function.

In the MATLAB Command Window, enter this command:

```
slToolstripDeveloperMode('on')
```

```
ans =
 logical
 0
```

The command enables developer mode for the Simulink Toolstrip. The returned value indicates that developer mode was disabled before you entered the command.

Pause on an item in the Simulink Toolstrip and press **Ctrl**. On a Mac, press **command** (⌘) instead of **Ctrl**.

For example, pause on the **Open** button and press **Ctrl**.

```
Action: openModelAction
Icon: open

```

The names of the corresponding action and icon appear in the MATLAB Command Window.

## Set Up Customization File

To register customizations, use a MATLAB function file named `sl_customization.m`. Place the function on the MATLAB path of the Simulink installation that you want to customize or in the current folder.

You can have more than one `sl_customization.m` file. The customizations in each file take effect, with conflicts handled by each customization. For example, if you specify priorities for libraries in multiple `sl_customization.m` files, only one takes effect. If you add the same menu item twice, it appears twice. To ensure that customizations load as expected, refresh the customizations as described in “Read and Refresh Customization Files” on page 79-47.

The `sl_customization` function accepts one argument: a handle to the customization manager object (`cm`). For example:

```
function sl_customization(cm)
```

## Create Filter Functions

In the `sl_customization.m` file, create a filter function. Your filter function must accept a callback info object and return the state that you want to assign to the item. Valid states are:

- 'Hidden' — Hide the item.
- 'Disabled' — Disable the item.
- 'Enabled' — Enable the item.

For example, this filter function assigns the 'Disabled' state.

```
function state = myFilter(callbackInfo)
 state = 'Disabled';
end
```

Your filter function may have to compete with other filter functions and with Simulink to assign a state to an item. Which one succeeds depends on the strength of the state that each assigns to the item.

- 'Hidden' is the strongest state. If any filter function or Simulink assigns 'Hidden' to a menu item, it is hidden. For Simulink Toolstrip items, specifying 'Hidden' disables the item instead of hiding it.
- 'Disabled' overrides 'Enabled', but is itself overridden by 'Hidden'.
- 'Enabled' is the weakest state. For an item to be enabled, all filter functions and the Simulink or Stateflow products must assign 'Enabled' to the item.

## Register Filter Functions

Use the customization manager `addCustomFilterFcn` method to register a filter function. The `addCustomFilterFcn` method takes two arguments: a tag that identifies the menu or item to be filtered and a pointer to the filter function itself.

For example, the following code registers a filter function for the **New Model** item on the Simulink Toolstrip.

```
function sl_customization(cm)
 cm.addCustomFilterFcn('Simulink:NewModel',@myFilter);
end
```

## Read and Refresh Customization Files

The `sl_customization.m` file is read when Simulink starts. If you change the `sl_customization.m` file, either restart Simulink or enter this command to see the changes:

```
sl_refresh_customizations
```

This command runs all `sl_customization.m` files on the MATLAB path and in the current folder. Some side effects of running `sl_refresh_customizations` include:

- Rebuilding the Simulink Toolstrip
- Rebuilding all Simulink Editor menus
- Rebuilding the Library Browser menus and toolbars
- Clearing the Library Browser cache and refreshing the Library Browser
- Reloading the Viewers and Generators Manager data

## Disable and Hide Dialog Box Controls

### In this section...

“About Disabling and Hiding Controls” on page 79-48

“Disable a Button on a Dialog Box” on page 79-48

“Write Control Customization Callback Functions” on page 79-49

“Dialog Box Methods” on page 79-49

“Widget IDs” on page 79-49

“Register Control Customization Callback Functions” on page 79-50

### About Disabling and Hiding Controls

Simulink includes a customization API that allows you to disable and hide controls (also referred to as widgets), such as text fields and buttons, on most dialog boxes. The customization API allows you to disable or hide controls on an entire class of dialog boxes, for example, parameter dialog boxes, by way of a single method call.

Before you customize a Simulink dialog box or class of dialog boxes, first make sure that the dialog box or class of dialog boxes is customizable. Any dialog box that appears in the dialog pane of Model Explorer is customizable. In addition, any dialog box that has dialog and widget IDs is customizable. To determine whether a dialog box is customizable, open the dialog box, enable dialog and widget ID display (see “Widget IDs” on page 79-49), and hover over a widget. If a widget ID appears, you can customize the dialog box.

Once you have determined that a dialog box or class of dialog boxes is customizable, write MATLAB code to customize the dialog boxes. This entails writing callback functions that disable or hide controls for a specific dialog box or class of dialog boxes (see “Write Control Customization Callback Functions” on page 79-49) and registering the callback functions using the customization manager (see “Register Control Customization Callback Functions” on page 79-50). Simulink invokes the callback functions to disable or hide the controls whenever you open the dialog boxes.

### Disable a Button on a Dialog Box

This `sl_customization.m` file disables the **Browse** button on the **Code Generation** pane of the Configuration Parameters dialog box for any model whose name contains `engine`.

```
function sl_customization(cm)

% Disable for standalone Configuration Parameters dialog box
configset.dialog.Customizer.addCustomization(@disableRTWBrowseButton,cm);

end

function disableRTWBrowseButton(dialogH)
 hSrc = dialogH.getSource; % Simulink.RTWCC
 hModel = hSrc.getModel;
 modelName = get_param(hModel,'Name');

 if ~isempty(strfind(modelName,'engine'))
 % Takes a cell array of widget Factory ID.
 dialogH.disableWidgets({'STF_Browser'})
 end
end

end
```

To test this customization:

- 1 Save the `sl_customization.m` file on the MATLAB path.
- 2 Refresh the customizations by entering `sl_refresh_customizations` at the command line or by restarting MATLAB (see “Register Customizations with Simulink” on page 79-56).
- 3 Open the `sldemo_engine` model in the “Modeling Engine Timing Using Triggered Subsystems” example.
- 4 Open the Configuration Parameters dialog box and look at the **Code Generation** pane to see if the **Browse** button is disabled.

## Write Control Customization Callback Functions

A callback function for disabling or hiding controls on a dialog box accepts one argument: a handle to the dialog box object that contains the controls you want to disable or hide. The dialog box object provides methods that the callback function can use to disable or hide the controls that the dialog box contains.

The dialog box object also provides access to objects containing information about the current model. Your callback function can use these objects to determine whether to disable or hide controls. For example, this callback function uses these objects to disable the **Browse** button on the **Code Generation** pane of the Configuration Parameters dialog box for any model whose name contains `engine`.

```
function disableRTWBrowseButton(dialogH)

 hSrc = dialogH.getSource; % Simulink.RTWCC
 hModel = hSrc.getModel;
 modelName = get_param(hModel, 'Name');

 if ~isempty(strfind(modelName, 'engine'))
 % Takes a cell array of widget Factory ID.
 dialogH.disableWidgets({'STF_Browser'})
 end
```

## Dialog Box Methods

Dialog box objects provide these methods for enabling, disabling, and hiding controls:

- `disableWidgets(widgetIDs)`
- `hideWidgets(widgetIDs)`

`widgetIDs` is a cell array of widget identifiers (see “Widget IDs” on page 79-49) that specify the widgets to disable or hide.

## Widget IDs

Widget IDs identify a control on a Simulink dialog box. To determine the widget ID for a particular control, execute the following code at the command line:

```
cm = sl_customization_manager;
cm.showWidgetIdAsToolTip = true
```

Open the dialog box that contains the control and hover over the control to display a tooltip listing the widget ID. For example, hovering over the **Start time** field on the **Solver** pane of the Configuration Parameters dialog box shows that the widget ID for the **Start time** field is `StartTime`.

---

**Note** The tooltip displays not customizable for controls that are not customizable.

---

## Register Control Customization Callback Functions

To register control customization callback functions for an installation of Simulink, include code in the installation `sl_customization.m` file (see “Register Customizations with Simulink” on page 79-56) that invokes the `configset.dialog.Customizer.addCustomization` method on the callbacks.

This method takes as an argument a pointer to the callback function to register. Invoking this method causes the registered function to be invoked before the dialog box is opened.

This example registers a callback that disables the **Browse** button on the **Code Generation** pane of the Configuration Parameters dialog box (see “Write Control Customization Callback Functions” on page 79-49).

```
function sl_customization(cm)

% Disable for standalone Configuration Parameters dialog box
configset.dialog.Customizer.addCustomization(@disableRTWBrowseButton,cm);

end
```

**Note** Registering a customization callback causes Simulink to invoke the callback for every instance of the class of dialog boxes specified by the method dialog box ID argument. You can therefore use a single callback to disable or hide a control for an entire class of dialog boxes. In particular, you can use a single callback to disable or hide the control for a parameter that is common to most built-in blocks. Most built-in block dialog boxes are instances of the same dialog box super class.

- “Register Customizations with Simulink” on page 79-56

## Customize Library Browser Appearance

### In this section...

“Reorder Libraries” on page 79-52

“Disable and Hide Libraries” on page 79-52

“Expand or Collapse Library in Browser Tree” on page 79-53

### Reorder Libraries

The library name and sort priority determines its order in the tree view of the Library Browser. Libraries appear in ascending order of priority. Libraries that have the same priority are sorted alphabetically.

The Simulink library has a sort priority of -1 by default. All other libraries have a sort priority of 0 by default. These sort priorities cause the Simulink library to display first in the Library Browser by default.

You can reorder libraries by changing their sort priorities. To change library sort priorities, add code in this form to an `sl_customization.m` file on the MATLAB path:

```
cm.LibraryBrowserCustomizer.applyOrder({'LIBNAME1',PRIORITY1, ...
 'LIBNAME2',PRIORITY2, ...
 .
 .
 'LIBNAMEN',PRIORITYN});
```

`LIBNAMEn` is the name of the library (or its model file) and `PRIORITYn` is an integer indicating the library sort priority. For example, this code moves the Simulink Extras library to the top of the Library Browser tree view.

```
cm.LibraryBrowserCustomizer.applyOrder({'Simulink Extras',-2});
```

After adding or modifying the `sl_customization.m` file, enter `sl_refresh_customizations` at the MATLAB command prompt to see the customizations take effect.

For more information on the customization functions, see “Register Customizations with Simulink” on page 79-56.

### Disable and Hide Libraries

To disable or hide libraries, sublibraries, or library blocks, insert code in this form in an `sl_customization.m` file (see “Register Customizations with Simulink” on page 79-56) on the MATLAB path. Blocks that you disable or hide in a library also do not appear on the quick insert menu that you invoke in the model.

```
cm.LibraryBrowserCustomizer.applyFilter({'Item1','State', ...
 'Item2','State', ...
 .
 .
 'ItemN','State'});
```

- `ItemN` is the library, sublibrary, or block to disable or hide. Specify the item in the form `'LibraryName/Sublibrary/Block'`.

- `LibraryName` is the library name as it appears in the browser. For a custom library, you set this value in the `slblocks.m` file with the `Browser.Name` property.
- `Sublibrary` is the name of the sublibrary or, for a custom library, a `Subsystem` block. You can specify a block inside the subsystem in your library or in a library that you open by way of the subsystem `OpenFcn` callback. See “Create Custom Library” on page 41-2.
- `Block` is the block name.
- `'State'` is `'Disabled'` or `'Hidden'`.

For example, this code hides the `Sources` sublibrary of the `Simulink` library and disables the `Sinks` sublibrary.

```
cm.LibraryBrowserCustomizer.applyFilter({'Simulink/Sources','Hidden'});
cm.LibraryBrowserCustomizer.applyFilter({'Simulink/Sinks','Disabled'});
```

This code disables the `Sqrt` block in the sublibrary opened by way of the `Subsystem2` block in the custom library `'My Library'`.

```
cm.LibraryBrowserCustomizer.applyFilter(...
{'My Library/Subsystem2/Sqrt','Disabled'});
```

After adding or modifying the `sl_customization.m` file, enter `sl_refresh_customizations` at the MATLAB command prompt to see the customizations take effect.

## Expand or Collapse Library in Browser Tree

You can add a customization to expand or collapse any library in the Library Browser tree by default. For example, the `Simulink` library is expanded by default. You can specify to instead collapse it by default. Add code in this form to your `sl_customization.m` file:

```
cm.LibraryBrowserCustomizer.applyNodePreference(...
{'libraryName',logical});
```

Use `true` to expand the library and `false` to collapse it.

For example, this code collapses the `Simulink` library and expands the `Simscape` library:

```
function sl_customization(cm)
 cm.LibraryBrowserCustomizer.applyNodePreference(...
{'Simulink',false,'Simscape',true});
end
```

This code collapses a custom library named `'My Library'`.

```
function sl_customization(cm)
 cm.LibraryBrowserCustomizer.applyNodePreference(...
{'My Library',false});
end
```

After adding or modifying the `sl_customization.m` file, enter `sl_refresh_customizations` at the MATLAB command prompt to see the customizations take effect.

## Improve Quick Block Insert Results

You can double-click the end of a signal line that you draw from an existing block to add a block. A menu of possible blocks to insert appears. For example, at the end of a signal line out of a Gain block, the quick insert menu suggests other math blocks. Simulink comes with default suggestions.

You can improve the suggestions on this menu by updating the engine with information about your models. To do so, run a command on a single model or on all the models in a folder. Information about your model designs updates the engine. You can also remove this customization using a command.

| Goal                                                              | Command                                           |
|-------------------------------------------------------------------|---------------------------------------------------|
| Improve results based on one model                                | <code>slblocksearchdb.trainfrommodel</code>       |
| Improve results based on all the models in a folder               | <code>slblocksearchdb.trainfrommodelsindir</code> |
| Remove the effects of a single model from the results             | <code>slblocksearchdb.untrainmodel</code>         |
| Remove the effects of all the models in a folder from the results | <code>slblocksearchdb.untrainmodelsindir</code>   |
| Revert to the default results that come with Simulink             | <code>slblocksearchdb.untrainall</code>           |

## Register Customizations with Simulink

In Simulink, you can register multiple customizations with an `sl_customization` function.

### Set Up Customization File

To register customizations, use a MATLAB function file named `sl_customization.m`. Place the function on the MATLAB path of the Simulink installation that you want to customize or in the current folder.

You can have more than one `sl_customization.m` file. The customizations in each file take effect, with conflicts handled by each customization. For example, if you specify priorities for libraries in multiple `sl_customization.m` files, only one takes effect. If you add the same menu item twice, it appears twice. To ensure that customizations load as expected, refresh the customizations as described in “Read and Refresh Customization Files” on page 79-56.

The `sl_customization` function accepts one argument: a handle to the customization manager object (`cm`). For example:

```
function sl_customization(cm)
```

### Edit the Customization File

In your `sl_customization` function, use customization manager object properties and methods specific to your application to register customizations. You can use customization properties and methods to:

- “Add Items to Model Editor Menus” on page 79-36
- “Disable Simulink Toolstrip and Context Menu Actions” on page 79-45
- “Disable and Hide Dialog Box Controls” on page 79-48
- “Add Libraries to the Library Browser” on page 41-8
- “Customize Library Browser Appearance” on page 79-52
- “Customize Bus Object Import and Export” on page 77-57
- “Import Lookup Table Data from MATLAB” on page 38-24

Additional MathWorks products use the customization manager object and the `sl_customization.m` file. Refer to the product documentation to learn about the methods and properties that apply to a product other than Simulink.

### Read and Refresh Customization Files

The `sl_customization.m` file is read when Simulink starts. If you change the `sl_customization.m` file, either restart Simulink or enter this command to see the changes:

```
sl_refresh_customizations
```

This command runs all `sl_customization.m` files on the MATLAB path and in the current folder. Some side effects of running `sl_refresh_customizations` include:

- Rebuilding the Simulink Toolstrip

- Rebuilding all Simulink Editor menus
- Rebuilding the Library Browser menus and toolbars
- Clearing the Library Browser cache and refreshing the Library Browser
- Reloading the Viewers and Generators Manager data

# Frames for Printed Models

---

## Create Print Frames for Printed Pages

Print frames are borders of a printed page that contain information about a block diagram, such as the model name or the date of printing. After you create a print frame, use the Simulink or Stateflow Editor to print a block diagram or chart with that print frame.

The default print frame has two rows:

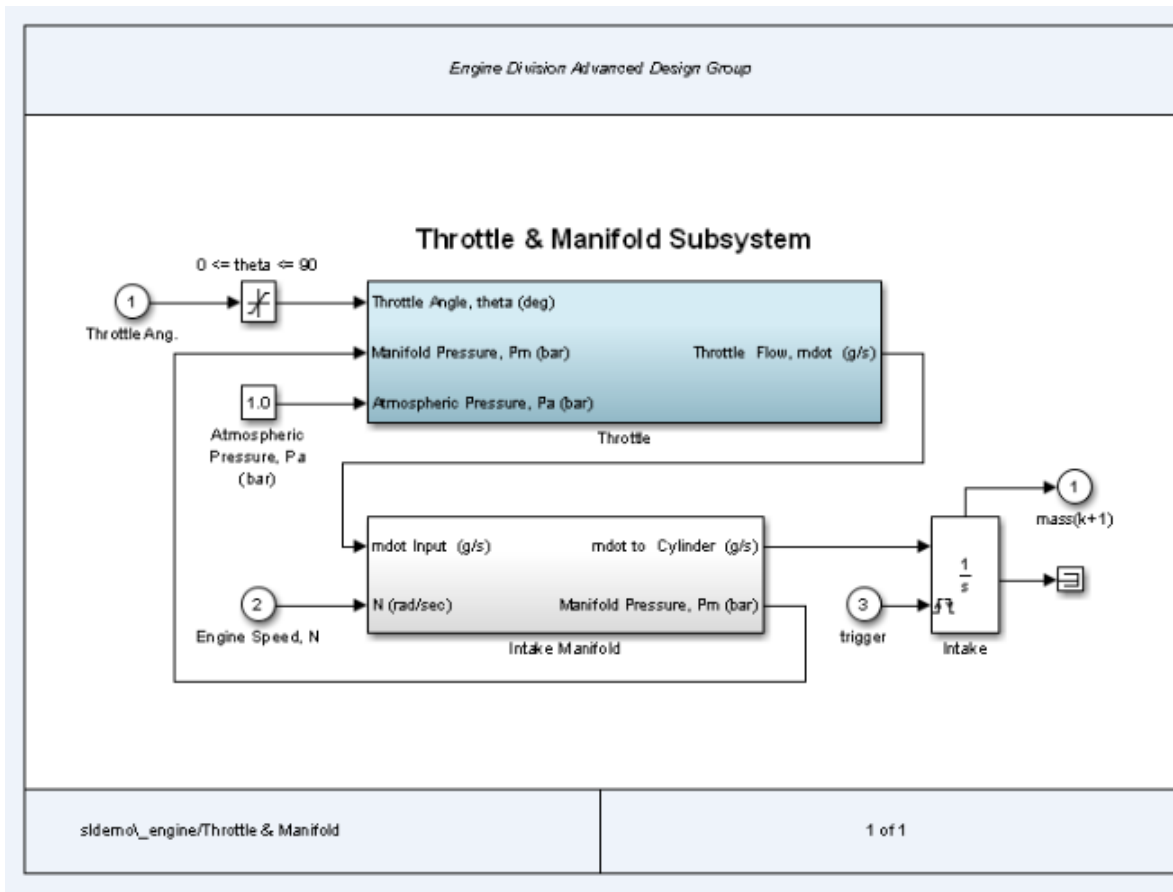

Rows contain one or more cells. You can add content entries to cells. You can also add new rows and cells. Within cells, you can include text (such as the name and address of your organization) and variable content (such as the current date).

For example, the print frame below includes:

- An additional row at the top of the frame for a title
- A middle row, which includes the block diagram
- A bottom row, in which one cell has the path to the subsystem and another cell has the page number

You can design a print frame for one particular block diagram, or you can design a more generic print frame for printing multiple block diagrams.

## PrintFrame Editor

Use the **PrintFrame Editor** to create and edit print frames.

To open the **PrintFrame Editor**, at the MATLAB Command Window, enter the `frameedit` command.

Use the **PrintFrame Editor** to:

- Set up the printed page.
- Add or remove rows and cells in the print frame.
- Add content to cells, such as text, the date, and page numbers.
- Format cell content.

To open an existing print frame, use `frameedit` with the `filename` parameter, where `filename` is an existing print frame (a `.fig` file).

## Create a Print Frame

- 1 At the MATLAB prompt, type `frameedit` to open the **PrintFrame Editor**.
- 2 In the **PrintFrame Editor**, select **File > Page Setup**.

If necessary, change default page setup for the print frame, which is:

- Paper type — `usletter`
- Orientation — **landscape**

---

**Note** The paper orientation you specify does not control the paper orientation used for printing. For example, assume you specify a landscape-oriented print frame in the

**PrintFrame Editor.** If you want the printed page to have a landscape orientation, you must specify that using the Print Model dialog box.

---

- Margins — 0.75 inches on all sides
- 3 Set up the layout of the print frame and add content.
  - 4 Save the print frame as a .fig file. Select **File > Save As**.

## Add Rows and Cells to Print Frames

To add a row above the row that you select:

- 1 Click in a cell to select a row.

When you select a row, handles appear on all four corners. If you select only a line, handles appear on two corners.

- 2 Click **Add Row**.

The new row appears above the row that you selected.

To remove a row, select the row and click **Delete Row**.

To add cells within a row:

- 1 Select the cell that you want to split.
- 2 Click **Split Cell**.

The cell splits into two cells.

To remove a cell, select the cell and click **Delete Cell**.

To change the dimensions of a row or cell by selecting the bordering line:

- 1 Click the line you want to move.

A handle appears on both ends of the line.

- 2 Drag the line to resize the row or cell.

For example, to make a row taller, click the top line that forms the row. Drag the line up, and the height of the row increases.

## Add Content to Print Frame Cells

You can add text, variables, or both to a cell.

To add content to print frame cells:

- 1 Select the cell that you want to add content to.
- 2 From the list, select the type of content that you want to add.
- 3 Click **Add**.

The type of content that you added appears in the cell.

---

**Tip** If you click **Add** and nothing happens, it might be because you did not select a cell first.

---

- 4 If you add text, select the edit box and type in the text.

---

**Tip** To make it easier to read and edit the content that you add, you can click the **Zoom in +** button.

---

To include multiple entries in a cell:

- 1 Select a cell that has a content entry.
- 2 Add another content type item from the list.

The new entry is added after the last entry in that cell.

Every print frame must include one **Block Diagram** variable. If you do not specify a **Block Diagram** in one of the cells, you cannot save the print frame and cannot print a block diagram with it. In addition to the **Block Diagram** variable, you can add other variables, such as the current date, to cells. Simulink supplies variable content at the time of printing.

The following table describes the variables you can add to cells.

| Variable Entries | Description                                                                                                                                                                                                                                        |
|------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Block Diagram    | Add this variable in the cell in which you want the block diagram to print.<br><br>You cannot include multiple entries or text in the cell that contains the <b>Block Diagram</b> variable. %<blockdiagram> must be the only content in that cell. |
| Date             | The date that the block diagram and print frame are printed, in dd-mmm-yyyy format.                                                                                                                                                                |
| Time             | The time that the block diagram and print frame are printed, in hh:mm format.                                                                                                                                                                      |
| Page Number      | The page of the block diagram being printed.                                                                                                                                                                                                       |
| Total Pages      | The total number of pages being printed for the block diagram, which depends on the printing options specified.                                                                                                                                    |
| System Name      | The name of the block diagram being printed.                                                                                                                                                                                                       |
| Full System Name | The name of the block diagram being printed, including its position from the root system through the current system, for example, engine/Throttle & Manifold.                                                                                      |
| File Name        | The file name of the block diagram, for example, sldemo_engine.slx.                                                                                                                                                                                |
| Full File Name   | The full path and file name for the block diagram, for example, \\matlab\matlab\examples\simulink_automotive\main\sldemo_engine.slx.                                                                                                               |

| Variable Entries | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Text             | <p>The text that you want to include in that cell, for example, the name of your organization. To type additional text on a new line, press the <b>Enter</b> key. When you are finished editing, click outside of the edit box.</p> <p>You can copy and paste text from another document into a cell. Any formatting of the copied text is lost.</p> <p>To type special characters (for example, superscripts and subscripts, Greek letters, and mathematical symbols), use embedded TeX sequences. For a list of allowable sequences, see the <code>text</code> command <code>String</code> property (in <code>Text</code>).</p> |

When you enter a variable, the cell displays the type of content in brackets, `<>`, preceded by a percent sign, `%`. For example, if you add a `Page Number` variable, it appears as `%<page>`.

---

**Note** Do not edit the text of a variable entry, because then the variable content does not print. For example, if you accidentally remove the `%` from the `%<page>` entry, the text `<page>` prints instead of the actual page number.

---

You can also add descriptive text to any of the variable entries without using the **Text** item.

- 1 Double-click in the cell.
- 2 Type text in the edit box before or after the entry.
- 3 To end editing mode, click outside of the cell.

## Format Content in Cells

You can align cell contents using the left, center, and right alignment buttons.

---

**Note** Block diagrams are always center aligned.

---

You can change font properties such as size or style (for example, italics or bold). To change font properties, select the cell, then right-click the contents and use the context menu to format the text.

## Simulink Supported Hardware

As of this release, Simulink supports the following hardware.

| Support Package              | Vendor       | Earliest Release Available | Last Release Available |
|------------------------------|--------------|----------------------------|------------------------|
| Android Devices              | Android      | R2014a                     | Current                |
| Apple iOS Devices            | Apple        | R2015a                     | Current                |
| Arduino Hardware             | Arduino      | R2013a                     | Current                |
| BeagleBoard Hardware         | BeagleBoard  | R2012a                     | R2016a                 |
| LEGO MINDSTORMS EV3 Hardware | LEGO         | R2014a                     | Current                |
| Raspberry Pi Hardware        | Raspberry Pi | R2013a                     | Current                |
| Parrot Minidrones            | Parrot®      | R2017a                     | Current                |

For a complete list of supported hardware, see Hardware Support.

## Block Produces Zeros or Does Nothing in Simulation

If you simulate a model on your host computer without running it on your target hardware:

- Input blocks produce zeros.
- Output blocks do nothing.

This is the expected behavior.

For example, in a model, on the **Simulation** tab, if you select `Normal` in the **Simulate** section, and then click **Run**, the following happens:

- The sensor block and Digital Input block send zeros to the model.
- The Digital Output block does nothing.

To see the blocks work normally, run your model on target hardware or use External mode.

To run the model on target hardware, on the **Modeling** tab, click **Model Settings**. In the Configuration Parameters dialog box, open the **Hardware Implementation** pane, select your hardware board from the list, and click **Apply**. Then, in the Simulink Editor, on the **Hardware** tab, click **Build, Deploy & Start**.

To use External mode, on the **Modeling** tab, click **Model Settings**. In the Configuration Parameters dialog box, open the **Hardware Implementation** pane, select your hardware board from the list, and click **Apply**. Then expand **Target hardware resources**, and under **Groups** select **External mode**. Review the configuration parameter settings, such as the **Communication interface**. Then, in the Simulink Editor, on the **Modeling** tab, change the simulation mode to `External`, and click **Run**.

# Running Simulations in Fast Restart

---

- “How Fast Restart Improves Iterative Simulations” on page 82-2
- “Get Started with Fast Restart” on page 82-5

## How Fast Restart Improves Iterative Simulations

In the classic Simulink workflow, when you simulate a model, Simulink:

- 1 Compiles the model
- 2 Simulates the model
- 3 Terminates the simulation

While developing a model, you typically simulate a model repeatedly as you iterate the design. For example, you might calibrate input values or block parameters for a particular response. Changing these values or parameters does not always require compiling the model before simulating again. However, in the classic workflow, each simulation compiles the model, even if the changes do not alter the model structurally. Each compile slows down the process and increases overall simulation time.

Fast restart allows you to perform iterative simulations without compiling a model or terminating the simulation each time. Using fast restart, you compile a model only once. You can then change values for root inputs, values for model initial state, and from Workspace block data, tune parameters and root inputs and simulate the model again without spending time on recompiling. Fast restart associates multiple simulation phases to a single compile phase to make iterative simulations more efficient.

Use fast restart when your workflow does not require structural changes to the model. Also, fast restart is better suited if the workflow involves any of these factors:

- The model requires multiple simulations in which simulation inputs or parameters change in every iteration.
- The compile time of the model is several seconds or longer.
- You need to switch solvers during runtime to pick the appropriate solvers without having to go through an expensive recompilation process.

You can use fast restart in normal and accelerator simulation modes. When you use fast restart in accelerator mode, you reduce simulation time and perform only a single compilation.

### Limitations

These are the limitations to simulating in fast restart.

- Fast restart does not support these modes:
  - Rapid Accelerator
  - External
- When a model is in the reinitialized state, you cannot:
  - Make structural changes.
  - Make changes to nontunable parameters such as sample time.
  - Save changes to the model. You must turn off fast restart to save any changes to the model.
- You cannot turn on fast restart in a model if it contains blocks that do not support `ModelOperatingPoint` object. These blocks include:

- Legacy (pre-R2016a) SimEvents blocks
- Simscape Multibody First Generation blocks
- MATLAB function blocks that contain system objects
- S-functions that do not implement the model operating point `get` and `set` methods but have `Pwork` vectors declared
- From Multimedia File
- To Multimedia File
- From Audio Device
- To Audio Device
- Multipath Rician Fading Channel
- Multipath Rayleigh Fading Channel
- Derepeat
- DC Blocker
- Stack
- Queue
- Read Binary File
- Write Binary File
- Video Viewer
- Frame Rate Display
- Video From Workspace
- Video To Workspace
- Between simulations, fast restart does not handle changes to design data, such as bus properties.
- Parameter tunability limitations apply. See “Tunability Considerations and Limitations for Other Modeling Goals” on page 37-36.
- The Fixed-Point Tool provides limited support when a model is simulated in fast restart. You must exit fast restart to collect simulation and derived ranges, and propose data types.
- When fast restart is on, you cannot change the variant that a variant subsystem or variant model uses. This is because the inactive subsystems are not compiled in the first simulation.
- When there are multiple model references to the same referenced model, you cannot change the model visibility when the model is in the reinitialized state.
- Fast restart is not compatible with these tools:
  - Simulink Profiler
  - Simulink Debugger
- When simulating a model in fast restart, you cannot run checks using Model Advisor.
- When you enable fast restart, the `sim` command supports only the single output `Simulink.SimulationOutput` form, regardless of the syntax you use in the command.
- When you enable fast restart, you cannot pass non-tunable parameters as arguments to `sim`.

## Get Started with Fast Restart

### In this section...

“Prepare a Model to Use Fast Restart” on page 82-6

“Fast Restart Methodology” on page 82-7

When you need to simulate a model iteratively to tune parameters, achieve a desired response, or automate testing, use fast restart to avoid compiling again. Fast restart allows you to perform iterative simulations without compiling a model or terminating the simulation each time. A generic workflow using fast restart involves the following steps.

- 1 Turn on fast restart using the **Fast Restart** button on the Simulink Toolstrip or from the command line.
- 2 Simulate the model. The first simulation requires the model to compile, initialize and save a `ModelOperatingPoint` object. Once the simulation is complete, it does not terminate. Instead, the model is initialized again in fast restart.
- 3 Perform any of these actions:
  - Change tunable parameters.
  - Switch between variable-step solvers.
  - Tune root-level inputs.
  - Modify base workspace, model workspace variables and data dictionary entries that are referenced by tunable parameters.
  - Change inputs to From File and From Workspace blocks.
  - Change the **Initial state** parameter for the next simulation.
  - Using the Signal Builder block, change data, rename signals and signal groups, and add new groups.
  - Change the signal logging override values for the model programmatically by using the `set_param` command and the `DataLoggingOverride` parameter. See “Override Signal Logging Settings from MATLAB” on page 73-63.

Once you have initialized a model in fast restart, you cannot

- Change the dimension, type, or complexity of a signal or variable.
- Make changes to a nontunable parameter such as sample time.
- Make structural changes such as adding or deleting blocks or connections.

These changes require you to compile the model again. To make changes like these, turn off fast restart, make your changes, and repeat this procedure.

- 4 You do not need to recompile the model if you change the solver. You can pick appropriate solvers during runtime without having to go through an expensive recompilation process.
- 5 Simulate the model. The model uses the new values of parameters and inputs that you provided but does not compile again.
- 6 Once you have achieved the desired response, turn off fast restart.

---

**Note** When you turn off fast restart, Simulink does not store any compile information for the model. The model compiles when you next simulate the model.

---

## Prepare a Model to Use Fast Restart

Before you simulate a model in fast restart, ensure that the model meets these requirements:

- If you have enabled callbacks in the model, make sure they do not attempt to make structural changes when the model is reinitialized. For example, callbacks such as mask initialization commands get called at the beginning of each simulation. Therefore, avoid using mask initialization code that makes structural changes to the model.
- All blocks in the model must support `ModelOperatingPoint` object.
- The simulation mode is Normal or Accelerator mode.

---

**Note** When fast restart is on, you cannot save changes to the model after it compiles. Saving changes requires Simulink to discard information about the compiled state. To save any changes to the model, turn off fast restart first.

---

### Enable Fast Restart

Use one of these methods to enable fast restart:

- Click the **Fast restart** button  on the Simulink Editor toolbar.
- At the MATLAB Command prompt, use `set_param` to enable fast restart. Type
 

```
set_param(model, 'FastRestart', 'on')
```

### Simulate a Model using Fast Restart

After you load your model and turn on fast restart, simulate the model.

- 1 Simulate the model by calling `sim` or clicking the **Run** button  in the Simulink Editor toolstrip. The first simulation in fast restart requires the model to compile and save a `ModelOperatingPoint` object.

Once the simulation is complete, the status bar shows that the model is initialized in fast restart.

- 2 Adjust tunable parameters in the model, such as the gain value of a Gain block, or tune root-level input values. You can also make changes to base workspace variables. You cannot adjust nontunable parameters such as sample time, because doing so requires the model to compile once more.
- 3 Simulate the model again. This time, the model does not compile. When you click the **Play** button or step forward, Simulink updates blocks that have new values as well as blocks that reference workspace variables.
- 4 When you are satisfied with your results, turn off fast restart by clicking the **Fast restart** button off.

- 5 To keep your changes, save the model.

---

**Note** After a model is initialized in fast restart, Simulink displays a warning if you attempt to make a structural change to the model. To make such changes, you must turn off fast restart.

---

### Stop a Simulation

When you click **Stop** in the middle of a fast restart simulation:

- Simulation does not terminate.
- The model is in the initialized state.
- You can now change tunable parameters in the model
- You can terminate the simulation and exit fast restart by clicking the **Fast restart** button off.

### Exit Fast Restart

You can exit fast restart only when the model is in the initialized state. After simulating, click the **Fast restart** button off. To do this programmatically, type:

```
set_param(model, 'FastRestart', 'off')
```

- Simulink terminates simulation.
- Simulink discards any compiled information about the model.
- The model must compile again the next time you simulate.

## Fast Restart Methodology

### Tuning Parameters Between Simulations

- When a model is initialized in fast restart, in addition to block values and base workspace variables, you can tune parameters in the **Data Import/Export** and **Solver** panes in the Configuration Parameters dialog box (on the **Simulation** tab, under **Prepare**, click **Model Settings**).
- Certain parameters are tunable between simulations only when the model is initialized in fast restart. They include:
  - **Initial Value** parameter of the IC block
  - **Initial Output** parameter of the Merge block
  - **Data** parameter of the From Workspace block
  - **Signal** parameter and signal groups of the Signal Builder block.

### Switching Solvers Between Simulations

When fast restart is on, you can switch solvers between simulations. Only valid solvers that can be switched to are listed in the Solver list in the Configuration Parameters dialog box. If you switch solvers using `set_param` command between simulations and set to an invalid solver, you will see a warning and the invalid solver will be ignored.

## Model Methods and Callbacks in Fast Restart

When fast restart is on, Simulink calls model and block methods and callbacks as follows:

- 1 Call model `InitFcn` callback.
- 2 Call model `SetupRuntimeResources` method.
  - a Call `mdlSetupRuntimeResources` S-function method.
- 3 Call model `Start` method.
  - a Call `mdlStart` S-function method.
- 4 Call model `Initialize` method.
  - a Call `mdlInitializeConditions` S-function method.

---

**Note** Use the `ssIsFirstInitCond` flag to guard code that should run only during the initialization phase of any simulation, including the first and subsequent initializations in fast restart.

---

- 5 Call model and block `StartFcn` callbacks.

---

**Note** Steps 1-5 apply to all simulations in Simulink (with or without fast restart).

---

- 6 For the first simulation in fast restart, capture a simulation snapshot. A simulation snapshot contains simulation state (`ModelOperatingPoint`) and information related to logged data and visualization blocks. As part of the snapshot capture, call `ModelOperatingPoint` S-function method.
- 7 This is a standard execution phase of any simulation, with or without fast restart.
  - Call model `Outputs`.
  - Call model `Update`.
  - Call model `Derivatives`.
  - Repeat these steps in a loop until stop time or a stop is requested.
- 8 Call model `Terminate` method.
  - a Call `mdlTerminate` S-function method.
- 9 After simulation ends, call model and block `StopFcn` callbacks. This is a standard phase of any simulation, with or without fast restart.
- 10 Restore the simulation snapshot taken for fast restart. As part of the restore, call `set` S-function method.
- 11 Wait in a reinitialized state until one of these actions:
  - To run another simulation (programmatically or using the Simulink Editor) in fast restart, return to step 3.
  - To end Fast Restart mode and uncompile the model:
    - a Call the model method `CleanupRuntimeResources` and the `mdlCleanupRuntimeResources` S-function method.
    - b Do not call `StopFcn` callbacks again at this point.

In some cases, the `Start` and `Terminate` methods are only called once and not for each successive Fast Restart simulation. In these cases, these method calls are combined with calls to `SetupRuntimeResources` and `CleanupRuntimeResources`, respectively. These cases are as follows:

- When an S-function contains custom `ModelOperatingPoint` save and restore methods.
- When an S-function sets the flag `SS_OPTION_CALL_TERMINATE_ON_EXIT`.
- When an S-function is placed inside the accelerated mode of a referenced model.

For more information on model callbacks, see “Callbacks for Customized Model Behavior” on page 4-51.

### Operating Point and Initial State Values

You can change initial state values, including `ModelOperatingPoint`, in between fast restart simulations.

When a `ModelOperatingPoint` object for initial state is used in fast restart, every new simulation resets to the start time of the model and not the snapshot time of each `ModelOperatingPoint` object. Thereafter, on the first step forward, Simulink checks to see if a `ModelOperatingPoint` has been specified. If yes, Simulink restores it before computing the next step. Thus, the first simulation step effectively fast forwards to the snapshot time of the specified `ModelOperatingPoint` object.

### Analyze Data Using the Simulation Data Inspector

Fast restart supports data logging using the Simulation Data Inspector. Every simulation in fast restart creates an SDI object with the name `<modelname> fast restart run <number>`. The value of `number` increments for each simulation.

### Custom Code in the Initialize Function

When you place custom code in the **Configuration Parameters > Simulation Target > Custom Code > Initialize function** pane in the **Model Configuration Parameters** dialog box, this gets called only during the first simulation in fast restart.

## Component Verification

### In this section...

“Use Foundational Blocks” on page 83-2

“Perform Rigorous Component Verification” on page 83-2

When testing models, you may find that your models do not meet design requirements. Resolving these problems requires additional component verification. Depending on your needs, you can use the Signal Editor block, blocks in the Model Verification library, or products such as Simulink Test, Simulink Design Verifier, and Simulink Coverage to test model components.

### Use Foundational Blocks

You can use the “Model Verification” library to verify the behavior of your model components. These blocks check if model signals meet specified requirements. If those requirements are not met during simulation, the blocks can stop the simulation or display a warning. For more information, see “Test Model Components”.

You can also create test cases by using the Signal Editor block to configure your input signals and then log the system outputs. For more information, see “Create and Edit Signal Data” on page 70-2. After creating the signal data, you can log the outputs and save the test cases for later use. For more information, see “Configure a Signal for Logging” on page 73-45.

### Perform Rigorous Component Verification

Some components require a large number of tests that are difficult to manage using only the Model Verification library and the Signal Editor block. If you require more rigorous component verification, use “Simulink Test”.

You can generate test case data for either a component in isolation or for a component that is part of a model.

#### Create Test Cases for an Isolated Component

To verify how a component behaves in absence of other components, you can test isolated components.

To create test case data for an isolated component:

- 1 Create a test harness for the component with Simulink Test and add the appropriate test cases. For more information on how to create a test harness, see “Create a Test Harness” (Simulink Test).
- 2 Log the test signals.
- 3 Repeat steps 1-2 until you configure the test cases to meet your design goals.

### Create Test Cases for a Component in a Model

You can also create test case data for a component in a larger model, such as when the component is in a closed-loop controller or part of a broader container model.

To create test case data for a component in a model:

- 1 Use Simulink Test to add the appropriate test cases to the model.
- 2 Add the component to a test harness and generate the component test cases directly from the model. For more information, see “Generate Tests and Test Harnesses for a Component or Model” (Simulink Test).
- 3 If the test cases are not comprehensive, create a harness for the component and add or modify test cases.
- 4 Repeat steps 1-3 until you configure the test cases to meet your design goals.

### Run the Test Suite on the Component

If you create test cases for both isolated components and components in a model by using Simulink Test, the resulting test suite contains all of the test cases. The Test Manager in Simulink Test allows you to manage and execute the test cases you created. For more information, see “Create and Run a Baseline Test” (Simulink Test). The Test Manager also allows you to perform additional verification activities, such as analyzing coverage. For more information, see “Collect Coverage in Tests” (Simulink Test). Once the results meet your design goals, you can prepare the component for additional testing.

### Use Other Products for Additional Test Case Management

If the component coverage is incomplete, you can use Simulink Design Verifier to automatically create test cases that can supplement missing test coverage. For more information, see “What Is Test Case Generation?” (Simulink Design Verifier). You can then rerun the analysis in Simulink Test. If you are satisfied with the results, you can use the test case data to verify additional design objectives by using Simulink Coverage and Simulink Check.

You can also perform some of the activities available in Simulink Test with other products, although these options have more limited functionality. For example, you can create a test harness with the

`slvnmakeharness` function. If you are only interested in the simulation outputs, you can run the test case input signals by creating a `Simulink.SimulationInput` object and running multiple simulations. For more information, see “Running Multiple Simulations” on page 27-2.

## Run Polyspace Analysis on Generated Code by Using Packaged Options Files

When you start a Polyspace analysis directly from the Simulink toolstrip, the analysis takes the model-specific context, such as design ranges, into consideration. When running a Polyspace analysis without access to Simulink, you must specify the model-specific information by using options files. Instead of authoring these options files, use the options files generated and packaged by the function `polyspacePackNGo`.

Preserving the Simulink model context information when running a Polyspace analysis can be useful in various situations. For instance:

- **Distributed workflow:** A Simulink user generates code from a model and sends the code to another development environment. In this environment, a Polyspace user, who might not have Simulink, runs a separate analysis of the generated code. By using the packaged options files, the design ranges and other model-specific information is preserved in the Polyspace analysis.
- **Analysis options not available in Simulink:** Some Polyspace analysis options are available only when the Polyspace analysis is run separately from Simulink. Use packaged options files to run a separate Polyspace analysis while preserving the model-specific information. For instance, analyze concurrent threads in generated code by running a Polyspace analysis in the generated code by using the packaged options files.

You must have Simulink to run the function `polyspacePackNGo`. You do not need Polyspace to generate the options files from a Simulink model. The `polyspacePackNGo` function supports code generated by Embedded Coder and TargetLink®. For a tutorial on using `polyspacePackNGo`, see “Analyze Code Generated as Standalone Code in a Distributed Workflow” on page 83-8.

### Generate and Package Polyspace Options Files

To generate and package Polyspace options file for analyzing code generated from a Simulink model, use `polyspacePackNGo`.

- 1 In the Simulink Editor, open the Configuration Parameters dialog box and configure the model for code generation.
- 2 To configure the model for compatibility with Polyspace, select `ert.tlc` as the **System target file**
- 3 To enable generating a code archive, select the option **Package code and artifacts**. Optionally, provide a name for the options package in the field **Zip file name**. If your code contains a custom code block, select **Use the same custom code settings as Simulation target** in the **Code Generation > Custom Code** pane.

Alternatively, in the MATLAB Command Window, enter:

```
% Configure the Simulink model mdlName for code generation
configSet = getActiveConfigSet(mdlName);
set_param(configSet, 'PackageGeneratedCodeAndArtifacts', true);
set_param(configSet, 'PackageName', 'CodeArchive.zip');
set_param(configSet, 'SystemTargetFile', 'ert.tlc');
set_param(configSet, 'RTWUseSimCustomCode', 'on');
```

- 4 Generate the code archive.
  - To generate an archive of standalone generated code from the top model, use the function `slbuild`.

- To generate code as a model reference, use the function `slbuild`. After generating code as model reference, create the code archive by using the function `packNGo`.
- Alternatively, you can use `TargetLink` to generate the code. Create the code archive by archiving the generated code into a zip file.

- 5 To generate and package the Polyspace option files, in the MATLAB Command Window ,use the `polyspacePackNGo` function :

```
zipFile = polyspacePackNGo mdlName);
```

See “Generate and Package Polyspace Options Files”.

If you use `TargetLink` to generate code, then use the `TargetLink` subsystem name as the input argument to `polyspacepacknGo`.

- 6 Optionally, you can use a `pslinkoptions` object as a second argument to modify the default model configuration for the Polyspace analysis. Create a `pslinkoptions` object, modify model configurations and specify the object when creating the archive:

```
psOpt = pslinkoptions(mdlName);
psOpt.InputRangeMode = 'FullRange';
psOpt.ParamRangeMode = 'DesignMinMax';
zipFile = polyspacePackNGo(mdlName,psOpt);
```

See “Package Polyspace Options Files That Have Specific Polyspace Analysis Options”.

- 7 Use the optional third argument to specify whether to generate and package Polyspace options files for code generated as a model reference. Suppose you generated code as a model reference by using the `slbuild` function. To generate and package Polyspace options for the code, at the MATLAB Command Window, enter:

```
zipFile = polyspacePackNGo(mdlName,[],true);
```

See “Package Polyspace Options Files for Code Generated as a Model Reference”.

The function `polyspacepackNGo` returns the full path to the archive containing the options files. The files are located in the `polyspace` folder within the archived folder hierarchy. The content of the `polyspace` folder depends on the inputs of `polyspacePackNGo` function.

- If you do not specify the optional second and third arguments, then the folder `polyspace` contains these options files in a flat hierarchy:
  - `optionsFile.txt`: This file specifies the source files, the include files, data range specifications, and analysis options required for analyzing the generated code by using Polyspace. If your code contains custom C code, then this file specifies the relative paths of the custom source and header files.
  - `modelName_drs.xml`: This file specifies the design range specification of the model.
  - `linksData.xml`: This file links the generated code to the components of the model.
- If you specify `psOpts.ModelbyModelRef = true`, then corresponding options files are generated for all referenced models. These options files are stored in separate folders named `polyspace_<referenced model name>` within the code archive. The folder `polyspace` contains the options files for the top model.

## Run Polyspace Analysis by Using the Packaged Options Files

Once the code archive and the Polyspace option files are generated, you can use the archive to run a Polyspace analysis on the generated code in a different development environment without Simulink.

- 1 Unzip the code archive and locate the `polyspace` folder.
- 2 On a Windows or Linux command line, run: `productname -options-file optionsFile.txt -results-dir resultdir`.
  - `productname` corresponds to one of: `polyspace-bug-finder`, `polyspace-code-prover`, `polyspace-bug-finder-server`, or `polyspace-code-prover-server`.
  - `resultdir` corresponds to the location of the Polyspace results. This argument is optional.

To link the generated code with the Simulink model, the file `linksData.xml` is required. In case the file `linksData.xml` is not generated in the options file archive, use the option **Code Generator Support** in Polyspace desktop User Interface to specify which comments in the code act as links to the Simulink model. In the Polyspace desktop User Interface, select **Tools > Preferences** and locate the **Miscellaneous** tab. From the context menu **Code comments that act as code-to-model-link**, select the code generator that you used. If you select **User defined**, then specify the comments that act as a code-to-model link by specifying their prefix in the field **Comments beginning with**. For instance, if you specify the prefix as `//Link_to_model`, then Polyspace interprets comments starting with `//Link_to_model` as links to model.

If you are using Polyspace Access to view the results, upload the file `linksData.xml` in the same folder as your Polyspace results. You cannot link the code with Simulink model if you do not have the file `linksData.xml` or if you upload it outside the Polyspace result folder.

- 3 To review the result, upload it to Polyspace Access and view the results in a web browser. Alternatively, view the result by using the user interface of the Polyspace desktop products.

## More About

- “Analyze Code Generated as Standalone Code in a Distributed Workflow” on page 83-8

## Analyze Code Generated as Standalone Code in a Distributed Workflow

Generate and package Polyspace options files from a Simulink model by using the function `polyspacepackNGo`. Use these options files to run a Polyspace analysis on the generated code that uses model-specific information, such as design range specifications, without requiring Simulink.

### Open Model

The model `demo_math_operations` performs various mathematical operations on the model inputs. The model has a C Function block that executes a custom C code. The model also has a C Caller block that calls the C function `GMean`, which is implemented in the source file `GMean.c`. To open the model for code generation and packaging Polyspace options file, search for the current topic in the MATLAB help browser and click the **Open Model** button. Alternatively, in the MATLAB Command Window, paste and run the following code.

```
openExample('simulink_general/PPNGStandAloneExample');
open_system('demo_math_operations');
```

Copyright 1990-2020 The MathWorks, Inc.

## Configure Model

To configure the model for generating code and packaging Polyspace options files, specify these configuration parameters:

- To create an archive containing the generated code, set 'PackageGeneratedCodeAndArtifacts' to true.
- Specify a name for the code archive. For instance, set the name to `genCodeArchive.zip`.
- To use the custom code setting specified in **Simulation Target** during code generation, set 'RTWUseSimCustomCode' to 'on'.
- To make the model and the generated code compatible with Polyspace, set `ert.tlc` as the system target file. See "Recommended Model Configuration Parameters for Polyspace Analysis" (Polyspace Bug Finder).

In Command Window or Editor, enter these parameter configurations:

```
configSet = getActiveConfigSet('demo_math_operations');
set_param(configSet, 'PackageGeneratedCodeAndArtifacts', true);
set_param(configSet, 'PackageName', 'genCodeArchive.zip');
```

```
set_param(configSet, 'SystemTargetFile', 'ert.tlc');
set_param(configSet, 'RTWUseSimCustomCode', 'on')
```

## Generate Code Archive

Specify a folder for storing the generated code. To start code generation, in the Command Window or in the Editor, enter:

```
codegenFolder = 'demo_math_operations_ert_rtw';
if exist(fullfile(pwd,codegenFolder), 'dir') == 0
 slbuild('demo_math_operations')
end
```

Because `PackageGeneratedCodeAndArtifacts` is set to `true`, the generated code is packed into the archive `genCodeArchive.zip`.

## Generate and Package Polyspace Options File

To generate Polyspace options files for the generated code, in the Command Window or in the Editor, enter:

```
zipFile = polyspacePackNGo('demo_math_operations');
```

In the archive `genCodeArchive.zip`, find the options files in the folder `<current folder>/polyspace`.

## Run Polyspace Analysis by Using the Packaged Options Files

- 1 Unzip the code archive `genCodeArchive.zip` and locate the `<current folder>/polyspace` folder.
- 2 Open a command-line terminal and change your working folder to the `polyspace` subfolder of the unzipped folder by using the `cd` command.
- 3 Start a Polyspace analysis.
  - To run a desktop Polyspace analysis, use either `polyspace-code-prover` or `polyspace-bug-finder`. To run the Polyspace analysis in a server, use either `polyspace-bug-finder-server` or `polyspace-code-prover-server`. Polyspace Bug Finder and Code Prover analyze the code differently. See “Choose Between Polyspace Bug Finder and Polyspace Code Prover” (Polyspace Bug Finder).
  - Specify the file `optionsFile.txt` as the argument to `-options-file`.

To run a Code prover analysis, run this command: `polyspace-code-prover -options-file optionsFile.txt -results-dir Results`.

- 4 Follow the progress of the analysis in the log file that is generated in the `Results` folder.
- 5 To view the results in the desktop user interface, in the command-line interface, enter: `polyspace Results\ps_results.pscp`. The extension of the `ps_results` file changes depending on whether you run a Code Prover analysis or a Bug Finder analysis. The result contains several orange checks.

| Family           | Information | File     |
|------------------|-------------|----------|
| -Run-time Check  |             | 3 15 118 |
| -Gray Check      |             | 3        |
| -Orange Check    |             | 15       |
| -Green Check     |             | 118      |
| -Global Variable |             | 2        |
| -Not shared      |             | 2        |

Alternatively, upload the result to Polyspace Access. See “Upload Results to Polyspace Access” (Polyspace Bug Finder).

- Address the results. For more information, see “Address Results Through Bug Fix or Comments” (Polyspace Bug Finder).

# Simulation Testing Using Model Verification Blocks

---

## Construct Simulation Tests by Using the Verification Manager

### In this section...

“Use Model Verification Block to Check for Out-of-Bounds Signal” on page 84-2

“View Model Verification Blocks in Verification Manager” on page 84-3

“Manage Verification Blocks and Requirement Links” on page 84-5

“Enable and Disable Individual Model Verification Blocks” on page 84-6

“Enable and Disable Model Verification Blocks by Subsystem” on page 84-7

“Linear System Modeling Blocks in Simulink Control Design” on page 84-8

Simulink Model Verification library blocks assess time-domain signals in your model, according to the specifications that you assign to the blocks. Model verification blocks return an assertion when signals fall outside the specified limit or range. During simulation, when the signal crosses the limit, the verification block can:

- Stop the simulation and bring immediate focus to that part of the model.
- Report the failure with a logical signal. If the simulation does not fail, the signal output is `true`. If the simulation fails, the signal output is `false`.

For reference information on individual model verification blocks, see “Model Verification”.

If you use a Signal Builder block to provide test signals for your model, you can enable and disable Model Verification blocks through the Verification Manager graphical interface. To open the Verification Manager, on the Signal Builder dialog box toolbar, select the **Show Verification Settings** icon .

### Use Model Verification Block to Check for Out-of-Bounds Signal

This example uses a Check Static Lower Bound block to stop the model simulation when a signal from a Sine Wave block crosses its lower bound limit.

In the model, the Check Static Lower Bound block has a **Lower bound** parameter of  $-0.8$ . The assertion is disabled, so the block appears crossed out.

1. Double-click the Check Static Lower Bound block and select the **Enable assertion** check box. This parameter enables the assertion of the verification block. In the model, the block is no longer crossed out.

2. Run the simulation. After 1.29517 seconds, when the signal from the Sine Wave block reaches the lower bound of -0.8, the verification block stops the simulation with this diagnostic message:

```
An error occurred while running the simulation and the simulation was terminated
Caused by:
Assertion detected in 'ex_model_verif_block_check_static_lower_errwarn/Check Static Lower Bound'
```

3. To verify the signal value, double-click the Scope block.

## View Model Verification Blocks in Verification Manager

This model contains a Signal Builder block that feeds five test signals to Model Verification blocks. The first four signals connect directly to Check Static Upper Bound blocks.

The fifth signal connects to a subsystem that contains a Check Static Upper Bound block.

Only the assertion for the Check Static Upper Bound3 block is enabled. The other Model Verification blocks appear crossed out in the model because their assertions are disabled.

To open the Verification Manager, double-click the Signal Builder block and select the **Show Verification Settings** icon.

The screenshot shows the Signal Builder application window titled "Signal Builder (ex\_verif\_mgr\_test\_signals/Signal Builder)". The interface includes a menu bar (File, Edit, Group, Signal, Axes, Help) and a toolbar with various icons. The main workspace displays five stacked signal waveforms over a 10-second time period:

- Signal 1 (Red):** Starts at 0, jumps to 1 at 4 seconds, and returns to 0 at 6 seconds.
- Signal 2 (Purple):** Starts at 0 and jumps to 1 at 5 seconds.
- Signal 3 (Blue):** Starts at 0 and jumps to 1 at 5 seconds.
- Signal 4 (Dark Purple):** Remains constant at 0.
- Signal 5 (Yellow):** Starts at 0 and jumps to 1 at 5 seconds.

On the right side, there are two panes:

- Verification block settings:** A tree view showing "ex\_verif\_mgr\_test\_signals" with five "Check Static Upper Bound" blocks. One block under a "Subsystem" is currently selected.
- Requirements:** A list showing "No requirements in this group".

At the bottom, there is a control panel for the selected signal (Signal 1):

- Name:** Signal 1
- Index:** 1
- Left Point:** T: [ ] Y: [ ]
- Right Point:** T: [ ] Y: [ ]
- Legend:** A list of checkboxes for Signal 1, Signal 2, Signal 3, Signal 4, and Signal 5, all of which are checked.

The status bar at the bottom left says "Click to select, Shift+click to add" and the bottom right shows "Signal 1 (#1) [YMin YMax]".

## Manage Verification Blocks and Requirement Links

The Verification Manager consists of the **Verification block settings** pane and the **Requirements** pane.

The **Verification block settings** pane lists all Model Verification blocks in the model, grouped by subsystem. For example, in the `ex_verif_mgr_test_signals` model, the **Verification block settings** pane displays five Check Static Upper Bound blocks. Four are in the top level of the model, and one is in a subsystem.

- To display all of the Model Verification blocks, click the **Show verification block hierarchy** icon .
- To display only the blocks that are enabled for the current signal group, click the **List enabled verifications** icon .

You can select additional options for viewing Model Verification blocks by right-clicking in the **Verification block settings** pane:

- **Display > Tree format** — List the blocks as they appear in the model hierarchy.
- **Display > Overridden blocks only** — List only the blocks that are not enabled for all test groups.
- **Display > Active blocks only** — List only the blocks that are enabled for the current signal group.

The **Requirements** pane lists the requirements document links for the current signal group. If you have Simulink Requirements, you can link requirements documents to test cases and their corresponding Model Verification blocks through this pane.

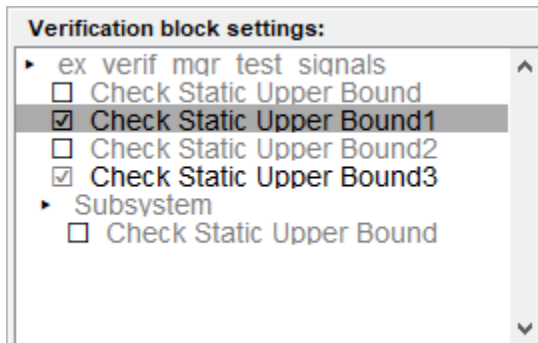

- To open or close the **Requirements** pane, click the **Requirements display** icon .
- To link a requirements document to a test case, in the **Requirements** pane, right-click and select **Open Outgoing Links Dialog** from the context menu. In the Outgoing Links dialog box, you can browse and select a requirements document. For more information, see “Link Test Cases to Requirements Documents” (Simulink Requirements).

## Enable and Disable Individual Model Verification Blocks

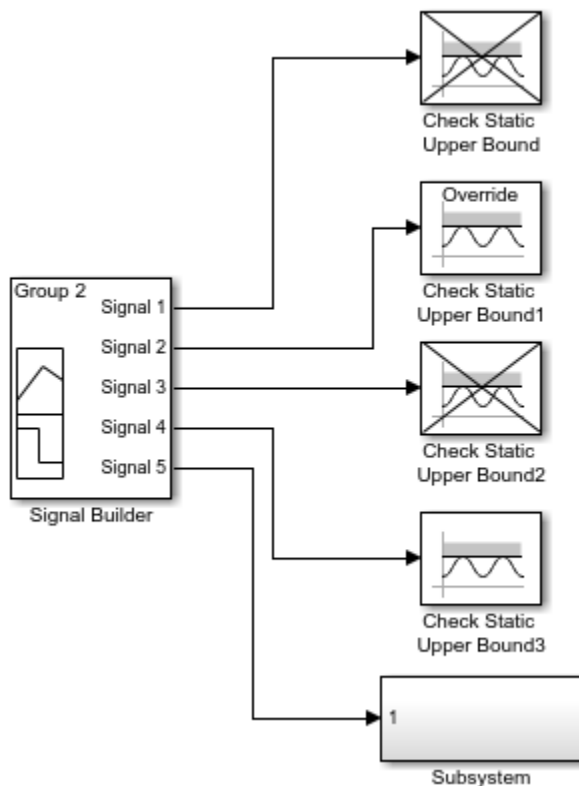

In the Verification Manager, each verification block has a status node that indicates whether its assertion is enabled or disabled. The status node also indicates whether the enabled setting applies universally or only to the current active group. This table describes the different types of status nodes and the context menu options that are available when you right-click a node.

| Node                                | Status                                                                                                     | Context Menu Options                                                                                                                                                                                                                                                                                                                                     |
|-------------------------------------|------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <input type="checkbox"/>            | Verification block is disabled for the current active group. Click to enable for the current active group. | <p><b>Block enable for all groups</b> — Enable the verification block for all test groups. The node type changes to enabled for all groups <input checked="" type="checkbox"/>.</p> <p><b>Block group enable</b> — Enable the verification block for the current active group. The node type changes to enabled <input checked="" type="checkbox"/>.</p> |
| <input checked="" type="checkbox"/> | Verification block is enabled for the current active group. Click to disable for the current active group. | <p><b>Block enable for all groups</b> — Enable the verification block for all test groups. The node type changes to enabled for all groups <input checked="" type="checkbox"/>.</p> <p><b>Block group disable</b> — Disable the verification block for the current active group. The node type changes to disabled <input type="checkbox"/>.</p>         |
| <input checked="" type="checkbox"/> | Verification block is enabled for all test groups.                                                         | <b>Block enable by group</b> — Restore the individually enabled/disabled settings to this block for all test groups. Depending on your previous selection, the node type changes to enabled <input checked="" type="checkbox"/> or disabled <input type="checkbox"/> .                                                                                   |

When you use the Verification Manager to enable a model verification block for the current active group, in the model, the block displays an **Override** label. For example, in the `ex_verif_mgr_test_signals` model, when you select Group 2 from the **Active Group** list, the Verification Manager shows that the Check Static Upper Bound1 block is enabled.

In the model, the Check Static Upper Bound1 block is not crossed out, but displays an **Override** label. The Signal Builder block also updates the selected **Active Group** in the top left corner.

## Enable and Disable Model Verification Blocks by Subsystem

If your model contains many verification blocks, it is tedious to enable and disable blocks individually. Using the Verification Manager, you can enable and disable all blocks in a subsystem or an entire model. In the **Verification block settings** pane, right-click the model or the subsystem name and select from these context menu options:

- **Contents enable for all groups** — Enable all verification blocks in this subsystem for all test groups.

- **Contents enable by group** — Restore the individually enabled/disabled settings to each verification block in this subsystem for all test groups.
- **Contents group enable** — Individually enable all verification blocks in this subsystem for the current active group.
- **Contents group disable** — Individually disable all verification blocks in this subsystem for the current active group.

For example, in the `ex_verif_mgr_test_signals` model, you can enable all of the verification blocks for all test groups by right-clicking the model name and selecting **Contents enable for all groups**. In the Verification Manager, all nodes change to enabled for all groups .

To restore the individually enabled/disabled settings for each verification block in each group, right-click the model name and select **Contents enable by group**.

## Linear System Modeling Blocks in Simulink Control Design

If you have Simulink Control Design, you can:

- Monitor time-domain and frequency-domain characteristics.
- Specify bounds on linear system characteristics.
- Check that the bounds are satisfied during simulation.

For reference information on individual blocks, see “Model Verification” (Simulink Control Design).
