- “Compare and Merge Simulink Models Containing Stateflow”
- Resolve Conflicts with Simulink Three-Way Merge

For more information on using and understanding the comparison reports, see “Compare Simulink Models” on page 21-6.

Using Model Comparison Reports

You can display comparison reports in the Comparison Tool. In the interactive report, you can click items in the report to display the corresponding items highlighted in the original models.

The comparison report shows a hierarchical view of the portions of the two files that differ. The report does not show sections of the files that are identical.

If the files are identical you see a message reporting there are no differences.

If files have not been saved, you see an error message informing you that you must save modified or newly created models before running a comparison.

Note It might not be possible for the analysis to detect matches between previously corresponding sections of files that have diverged too much.

Change detection is based on a scoring algorithm. Items match if their score is above a threshold. The tool's algorithm uses a comparison pattern that defines the thresholds assigned to particular node types (e.g., block).

For more information on using the report, see “Compare Simulink Models” on page 21-6.

To control highlighting, see “Display Differences in Original Models” on page 21-14.

To merge differences, see “Merge Simulink Models from the Comparison Report” on page 21-16.

For more information about the Comparison Tool, see “Compare Files and Folders and Merge Files”.

Select Simulink Models to Compare

- “Select Files from the Simulink Editor” on page 21-3
- “Select Files from the Current Folder Browser” on page 21-4
- “Select Files from a Project” on page 21-4
- “Select Files from the Comparison Tool” on page 21-4
- “Select Files from the Command Line” on page 21-4
- “Choose a Comparison Type” on page 21-4

To learn what you can do with comparison reports, see “About Simulink Model Comparison” on page 21-2.

Select Files from the Simulink Editor

To compare files using the Simulink Editor:

- 1** On the **Modeling** tab, in the **Evaluate & Manage** section, select **Compare > Compare Models**.

The Select Files or Folders for Comparison dialog box opens.

- 2** If the Editor currently displays a model, the current model name and path appear automatically selected in the **First file or folder** edit box. Use the browse buttons to locate and select files for the first and second model files.
- 3** When you click **Compare**, the comparison tool performs the analysis, and displays the resulting report in the Comparison Tool.

Select Files from the Current Folder Browser

To compare two files from the Current Folder browser:

- For two files in the same view, select two files, right-click and select **Compare Selected Files/Folders**.
- Alternatively, you can browse to select the second file to compare:
 - 1 Select a file, right-click and select **Compare Against**
 - 2 Select the second file to compare in the Select Files or Folders for Comparison dialog box.
 - 3 For models, leave the default **Comparison type**, Simulink Model Comparison.
 - 4 Click **Compare**.

For more information about comparisons of other file types (e.g., text, MAT, or binary) with the Comparison Tool, see “Compare Files and Folders and Merge Files”.

Select Files from a Project

If you have a project using source control, you can create a model comparison report from the Modified Files view of the project. For details, see “Project Management”.

Select Files from the Comparison Tool

To compare files using the Comparison Tool, from the MATLAB Toolstrip, in the **File** section, select the **Compare** button. In the dialog box select files to compare.

Select Files from the Command Line

To compare XML files from the command line, enter

```
visdiff(filename1, filename2)
```

where `filename1` and `filename2` are XML files or Simulink models.

`visdiff` produces a report in the Comparison Tool.

To create an `xmlcomp.Edits` object at the command line without opening the Comparison Tool, enter:

```
Edits = slxmlcomp.compare(modelname_A,modelname_B)
```

See “Export Results to the Workspace” on page 21-22 for information about the `xmlcomp.Edits` object.

Choose a Comparison Type

To change comparison type, either create a new comparison from the Comparison Tool, or use the **Compare Against** option from the Current Folder browser. You can change comparison type in the Select Files or Folders for Comparison dialog box. For example, if you want the MATLAB text differences report for XML or model files, change the comparison type to `Text comparison` in the dialog before clicking **Compare**. Alternatively, see the `visdiff` function.

 “Limitations” on page 21-13

Navigate the Simulink Model Comparison Report

You can compare models from any version of Simulink. The comparison tool produces a comparison report based on the SLX files, resaved in the current version if necessary. Use the report to explore the differences, view the changes highlighted in the original models, and merge differences.

The Comparison report shows changes only, not the entire file contents. The report shows a hierarchical view of the portions of the files that differ, and does not show sections of the files that are identical. To learn about the report, see “About Simulink Model Comparison” on page 21-2.

To *step through differences*, on the **Comparison** tab, in the **Navigate** section, click **Next** or **Previous**. See “Step Through Changes” on page 21-7.

You can also click to select items in the hierarchical trees and observe the following display features:

- Selected items appear highlighted in a box.
- If the selected item is part of a matched pair it is highlighted in a box in both left and right trees.
- When you select an item, the original model displays and the corresponding item is highlighted. See “Explore Changes in the Original Models” on page 21-8.

Report item highlighting indicates the nature of each difference as follows:

Type of report item	Highlighting	Notes
Modified	Purple	Modified items are matched pairs that differ between the two files. When you select a modified item it is highlighted in a box in both trees. Changed parameters for the selected pair are displayed underneath.
Inserted	Blue	When you select an unmatched item it is highlighted in a box in one tree only.
Deleted	Yellow	

Type of report item	Highlighting	Notes
Container	None	Rows with no highlighting indicate a container item that contains other modified or unmatched items.

Icons indicate the category of item, for example: model, subsystem, Stateflow machine or chart, block, line, parameter, etc.

To expand or filter the tree view, use the toolstrip for the following functions:

- **Filter** — Use filters to show only the changes you are interested in. By default the report hides all nonfunctional changes, such as repositioning of items. Turn off filters to explore *all* differences including nonfunctional changes. See “Filter Comparison Reports” on page 21-9.
- **Find** — Opens the Find dialog box where you can search for items.
- If you want to swap the files, on the **Comparison** tab, select **Swap**. The report swaps the sides and reruns the comparison. **Refresh** also runs the analysis again.

To create a new report, see “Select Simulink Models to Compare” on page 21-3.

For examples with instructions, see also “Examples of Model Comparison” on page 21-2.

Step Through Changes

On the **Comparison** tab, in the **Navigate** section, when you click the **Next** arrow button (or press the Down key when the report has focus), you step through groups of changes in the report, in the following order:

- 1 The first time you click **Next**, it selects the first changed (purple) or inserted (blue) node.
- 2 Step through the differences with the **Next** button.
 - When selected items have a match in the right tree then they are also highlighted.
 - Next skips white nodes with no color background, if they have no parameter changes underneath. White nodes are parts of the hierarchy that contain no differences.
 - If there is an insertion or deletion with child nodes, **Next** skips the child nodes if they are all also insertions or deletions. For example, if you insert a subsystem, **Next** selects the top subsystem node, then skips all the nodes inside the subsystem (if they are all also insertions) and selects the next difference.
 - **Next** minimizes context switching when highlighting in models. When you click **Next**, the report steps through all differences at the same level of the model, subsystem, or chart, in both left and right trees in the report, before moving to the next level of the report. For example, you step through all differences in a subsystem in the left and right trees, before moving to another subsystem.
- 3 When you have stepped through all changes, **Next** stops at the end.

If you click an item in the report, the **Next/Previous** controls will step through changes from the point you selected.

Explore Changes in the Original Models

When you compare Simulink models, you can choose to display the corresponding items in the original models when you select report items. You can use this highlighting function to explore the changes in the original models. When you select an item, the report highlights the corresponding item in the model.

Control the display by using the **Highlight Now** button and the **Always Highlight** check box.

For details, see “Display Differences in Original Models” on page 21-14.

Merge Differences

To merge, on the **Comparison** tab, click **Merge Mode**. The Target pane appears at the bottom of the report. Use the buttons to select differences to keep in the target. For more information, see “Merge Simulink Models from the Comparison Report” on page 21-16.

Open Child Comparison Reports for Selected Nodes

If additional comparisons are available for particular parameters, you see a **Compare** button to open a report for that pair of nodes. For example, if there are differences in the Model Workspace, you can click **Compare** to open a new report to explore differences in variables.

- You can open a new comparison for parameters when the report cannot display all the details, e.g., long strings or a script.
- If the original models contain MATLAB Function block components, and if differences are found, click the **Compare** button at the end of the MATLAB Function block report items to open new comparisons in the Comparison Tool, showing the text difference reports for the MATLAB Function block components. You can merge differences in MATLAB Function block code from the text comparison report. See “Merge Simulink Models from the Comparison Report” on page 21-16.
- If the original models contain truth tables, and if differences are found:
 - Click the **Compare** button at the end of the MATLAB Function node to see a summary of all changes.
 - Click the **truthtable** node to reverse annotate and display both truth table editors.
 - Click the **Compare** button on the parameter to open a new text comparison showing only Condition table differences.
 - Similarly click the **Compare** button for **Action Table** to view only Action changes.

Understand the Report Hierarchy and Matching

Note It might not be possible for the analysis to detect matches between previously corresponding sections of files that have diverged too much.

If you cannot see changes you expected to see in the report, turn off filters and see *all* identified changes. See “Filter Comparison Reports” on page 21-9.

Filter Comparison Reports

You can define custom filters to simplify reports and focus on specified elements. You can import and export filters for sharing. Use built-in filters to control display of categories of changes. Turn off filtering to view all identified changes.

To see the available filters, and whether or not they apply to the current report, on the **Comparison** tab, in the **Filter** section, click the down arrow to expand the filter gallery. Click filter names to toggle whether they are applied. In the **Filter** section, click **Show** to include the selected filters changes in the report or **Hide** to exclude the selected filters changes from the report.

Use the filters to include only the changes you are interested in. By default the report hides all nonfunctional changes. These changes have no impact on the design behavior, such as repositioning of items. Turn off filters to explore all differences including nonfunctional changes. Try this if you cannot see changes you expected to see in the report.

Built-in filters include:

- **Lines.** Select all changes to signal lines, including functional changes.
- **Nonfunctional Changes.** The report identifies certain items in the model file as nonfunctional, for example, items representing parameters such as block, system, chart, or label positions; font and color settings for blocks and lines; and system print and display settings.
- **Block Defaults.** Block defaults rarely change and cause longer reports when there are added or deleted blocks. Often the report is simpler when you hide block defaults.

To show all changes, use either of these methods:

- Hide nothing - Click **Hide** and disable all filters in the gallery.
- Show everything - Create a custom filter. In the New Filter dialog box, delete the contents of the first column so it shows Any, then remove the rest of the row under **Parameter Name**. Click **Show** and enable the "everything" filter in the gallery.

To define a new custom filter:

- 1 On the **Comparison** tab, in the **Filter** section, click **New Filter**.
- 2 In the New Filter dialog box, define one or more rules for your new filter. For example, you can select parameters or blocks of particular types or values. Suggested values depend on the items in your comparison report. Specify a unique name for your filter and click **Apply**.
- 3 To check if your filter applies to the items you expect, enable only the new filter in the filter gallery and then click **Show**. This is often easier than checking that a filter is hiding the changes you expect to see in the report.

Observe how these custom filters are defined.

Purpose	Select Column	Parameter Name	Parameter Value
Filter out Annotation changes	Annotation	Click the minus button to clear the row.	Leave blank
Filter out Inport and Outport block changes	Block	BlockType	Inport
	To add a row, click Add Rule , then select Block	BlockType	Outport

Purpose	Select Column	Parameter Name	Parameter Value
Filter out sample time parameter changes	Parameter	SampleTime	Any

- Annotation changes:

- Inport and Outport block changes:

New Filter

Name:

Rules:

Select	Parameter Name	Parameter Value
Block ▼	BlockType	Inport ▼
	<input type="button" value="+"/> <input type="button" value="-"/>	
Block ▼	BlockType	Output ▼
	<input type="button" value="+"/> <input type="button" value="-"/>	

- Sample time parameter changes:

New Filter

Name:

Rules:

Select	Parameter Name	Parameter Value
Parameter ▼	SampleTime	Any ▼

Exceptions

The report does *not* filter out changes to Block and System names, annotations, and Stateflow Notes as nonfunctional, even though changes to these items do not affect the outcome of simulation. The report always displays these changes to facilitate review of code changes, because they can contain important information about users' intentions.

In rare cases, the report filters out changes that can impact the behavior of the design. By default, moves are filtered as nonfunctional, but in these cases moves can change design behavior:

- Moving blocks can in some cases change the execution order.
- In a Stateflow chart, if you move states or junctions so that they intersect, the model fails to simulate.

To view these types of changes in the report, turn off the filter for nonfunctional changes.

Change Color Preferences

You can change and save your diff color preferences for the Comparison tool. You can apply your color preferences to all comparison types.

- 1 On the MATLAB Home tab, click **Preferences**.
- 2 In the Preferences dialog box, under **MATLAB**, click **Comparison**.
- 3 Edit color settings as desired for differences and merges. View the colors in the **Sample** pane.

The **Active Settings** list displays **Default (modified)**.

- 4 To use your modified settings in the comparison, click **Apply** and refresh the comparison report.
- 5 To return to the default color settings, in the Preferences dialog box, click **Reset** and click **Apply**. Refresh the comparison report.
- 6 If you want to save your modified color preferences for use in future MATLAB sessions, click **Save As**. Enter a name for your color settings profile and click **OK**.

After saving settings, you can select them in the **Active Settings** list.

Save Comparison Results

To save your comparison results, use these **Comparison** tab buttons:

- **Publish > HTML, Word, or PDF** — Open the Save dialog box, where you can choose to save a printable version of the comparison report. See “Save Printable Report” on page 21-22.
- **Publish > Workspace Variable** — Export comparison results to workspace. See “Export Results to the Workspace” on page 21-22.

Alternatively, you can publish a comparison report to a file using the `visdiff` function.

Examples of Model Comparison

For examples with instructions, see:

- “Compare and Merge Simulink Models”

- “Compare and Merge Simulink Models Containing Stateflow”
- Resolve Conflicts with Simulink Three-Way Merge

Limitations

MATLAB Online does not support functionalities such as refreshing or publishing comparison reports, merging, swapping sides, or creating custom filters. In MATLAB Online, Model Comparison does not support Stateflow and test harness comparisons.

Display Differences in Original Models

In this section...

“Highlighting in Models” on page 21-14

“Control Highlighting in Models” on page 21-14

“View Changes in Model Configuration Parameters” on page 21-15

Highlighting in Models

When you compare Simulink models, you can choose to display the corresponding items in the original models when you select report items. You can use this highlighting to explore the changes in the original models. When you select an item, the report highlights the corresponding item in the model.

Click a report entry to view the highlighted item (or its parent) in the model:

- If the item occurs in both models, they both appear with highlighting.
- When there is no match in the other model, the report highlights the first matched ancestor to show the context of the missing item.
- If the comparison tool cannot highlight an item directly (e.g., configuration parameters), then it highlights the nearest ancestor of the selected node.

Try highlighting items in original models using the example “Compare and Merge Simulink Models Containing Stateflow”.

Control Highlighting in Models

To control highlighting in models, in the Comparison Tool, select or clear the check box **Always Highlight**. You can click the **Highlight Now** button to highlight the currently selected report node at any time. This can be useful if you turn off automatic highlighting and only want to display specific nodes.

By default, models display to the right of the comparison report, with the model corresponding to the left side of the report on top, and the right below. If you move or resize the models your position settings are respected by subsequent model highlighting operations within the same session. The tool remembers your window positions.

If you want to preserve window positions across sessions, position the window, and then enter:

```
slxmlcomp.storeWindowPositions
```

This preserves the placement of any Simulink windows, Stateflow windows, and truth table windows.

To stop storing window positions and return to the defaults, enter:

```
slxmlcomp.clearWindowPositions
```

View Changes in Model Configuration Parameters

You can use the report to explore differences in the model Configuration Parameters. If you select a Configuration Parameter item, the report displays the appropriate root node pane, if possible, of both Configuration Parameters dialog boxes.

Parameters display the label text from the dialog controls (or the parameter name if it is command line only), and the parameter values. You can merge selected parameters using merge mode.

More About

- “About Simulink Model Comparison” on page 21-2

Merge Simulink Models from the Comparison Report

In this section...

“Resolve Conflicts Using Three-Way Model Merge” on page 21-16

“Use Three-Way Merge with External Source Control Tools” on page 21-19

“Open Three-Way Merge Without Using Source Control” on page 21-19

“Two-Way Model Merge” on page 21-20

“Merge MATLAB Function Block Code” on page 21-21

Merge tools enable you to:

- Resolve conflicts in model files under source control using three-way merge. Open by selecting **View Conflicts**.
- Merge any two model files using two-way merge. Open by selecting **Compare** context menu items.
- Merge MATLAB Function block code using text comparison reports.

Resolve Conflicts Using Three-Way Model Merge

If you have a conflicted model file under source control in a project or in the Current Folder browser, right-click and select **View Conflicts**. You can resolve the conflicts in the Three-Way Model Merge tool. Examine your local file compared to the conflicting revision and the base ancestor file, and decide which changes to keep. You can resolve the conflict and submit your changes.

- 1 To try an example three-way merge, see *Resolve Conflicts with Simulink Three-Way Merge*.
- 2 In the project, locate the conflicted model file, right-click and select **View Conflicts**. You can only see **View Conflicts** in the context menu if your file is marked conflicted by the source control.

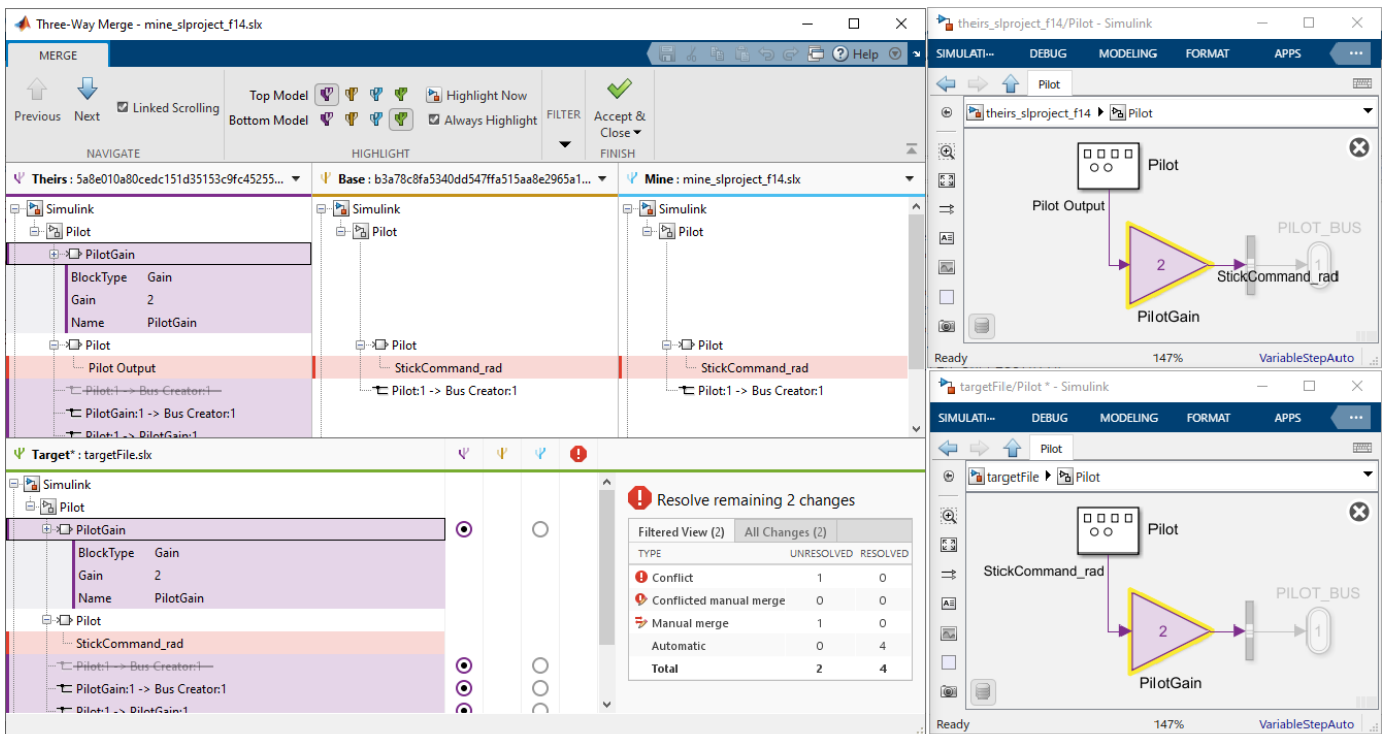

The Merge tool automatically resolves every difference that it can, and shows the results in the **Target** pane. Review the automerge choices, edit if desired, and decide how to resolve any remaining conflicts.

- 1 Examine the Merge report columns.
 - At the top, **Theirs**, **Base**, and **Mine** columns show the differences in the conflicting revision, your revision, and the base ancestor of both files.
 - Underneath, the **Target** shows the local file that you will merge changes into. The Merge tool already automerged the differences it can merge.

- 2 Examine a difference by clicking **Next** or by clicking a row in the **Theirs**, **Base**, and **Mine** columns.

The merge tool displays two models (or if you selected a configuration setting, you see two model Configuration Parameters dialog boxes). By default, you see **Theirs** and **Target** models.

- 3 Choose the models to display with the toolbar buttons on the **Merge** tab: **Top Model** or **Bottom Model**. View the models to help you decide what to merge.

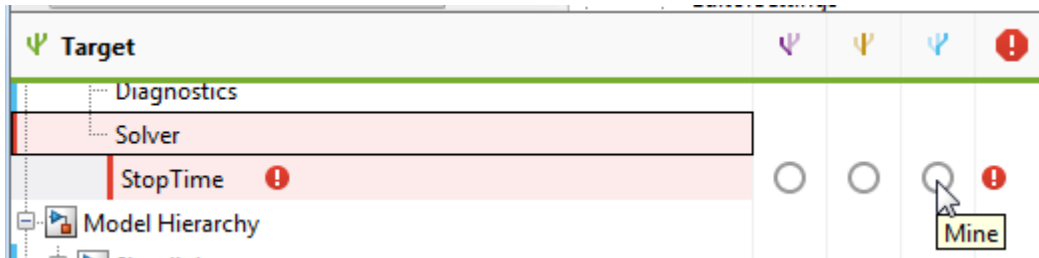

Note If you open the merge tool using **View Conflicts**, then the models **Theirs**, **Base**, and **Mine** are temporary files showing the conflicting revisions. Examine them to decide how to merge. The **Target** model is a copy of **Mine** containing the results of your merges in the report.

- 4 Select a version to keep for each change by clicking the buttons in the **Target** pane. You can merge modified, added, or deleted nodes, and you can merge individual parameters. The Merge tool selects a choice for every difference it could resolve automatically. Review the selections and change them if you want.

Look for warnings in the Conflicts column. Select a button to use **Theirs**, **Base**, or **Mine** for each conflicted item.

Tip Merge blocks before lines, and merge states and junctions before merging transitions. Merge tool then attempts to connect all lines to blocks for you. See “Merging Tips” on page 21-20.

- 5 Some differences you must merge manually. In the **Target** pane, look for the manual merge icon in the Conflicts column that shows you must take action.

Make manual changes in the Editor. The comparison report cannot update to show any changes that you make in the Editor, so try to make manual changes after addressing all the simpler merges in the report.

After you have resolved the conflict using the Editor, in the **Target** pane, select the check option to mark the node as complete.

- Examine the summary table to see the number of automatic merges and remaining conflicts you need to resolve.

Resolve remaining 5 changes

Filtered View (3) All Changes (5)

TYPE	UNRESOLVED	RESOLVED
Conflict	1	0
Conflicted manual merge	0	0
Manual merge	2	0
Automatic	0	8
Total	3	8

Check for changes that are filtered out of the current view by looking at the summary table tab titles. The Filtered View and All Changes tab titles show the number of changes. By default the report hides all nonfunctional changes. Turn off active filters to view all identified changes.

- When you are happy with your merge selections and any manual merges in the **Target** file, click **Accept and Close**. This action saves the target file with all your merges and marks the conflicted file resolved in the source control tool.

To save and not mark the conflict resolved, select **Accept and Close > Save and Close**.

To learn more about resolving conflicts in a change list of modified files in a project, see “Resolve Conflicts” on page 19-54.

Use Three-Way Merge with External Source Control Tools

If you are using source control outside of MATLAB, then you can customize external source control tools to open Three-Way Merge (or two-way merge for diffs).

For instructions, see “Customize External Source Control to Use MATLAB for Diff and Merge” on page 19-59.

Open Three-Way Merge Without Using Source Control

If you are not using source control or you want to choose three files to merge, then you can open Three-Way Merge using the function `slxmlcomp.slMerge`. Specify the files to merge, for example:

```
slxmlcomp.slMerge(baseFile, mineFile, theirsFile, targetFile);
```

Three-Way Merge opens, where you can merge the changes in `baseFile`, `mineFile`, and `theirsFile` into the `targetFile`.

Two-Way Model Merge

You can merge two Simulink models from a comparison report. The **Compare** context menu items from a project or the Current Folder browser open a two-way model merge. If you are using source control and want to resolve conflicts using a three-way model merge instead, see “Resolve Conflicts Using Three-Way Model Merge” on page 21-16.

The merge feature enables you to merge two versions of a design modeled in Simulink. You can merge individual parameters, blocks, or entire subsystems. Entire subsystems can only be merged as a whole if they are fully inserted or deleted subsystems.

- 1 On the **Comparison** tab, click **Merge Mode**. The Target pane appears at the bottom of the report.
- 2 Use the same workflow as three-way merge. Use the buttons to select the differences to keep in the target file.

Tip Merge blocks before lines, and merge states and junctions before merging transitions. See “Merging Tips” on page 21-20.

- 3 View the results in the report and the models. Click **Save File**. **Save File** copies the temporary target file over the right file in the comparison and reruns the comparison.
- 4 (Optional) To revert all merge operations, click **Close Merge** without saving the file.
- 5 Inspect your merge changes in the Simulink Editor. If necessary, connect any lines that the software did not connect automatically. The comparison report does not update to show any changes that you make in the Editor.

Merging Tips

- In the Simulink part of the report, merge models in the following order. In the target file:

- 1 Delete the lines you do not want to keep.
- 2 Delete the blocks you do not want to keep.
- 3 Add the blocks you want to keep.
- 4 Add the lines you want to keep.
- 5 Select the parameters you want to keep.

You must merge states and junctions before merging transitions, or the report cannot make the connections.

For an example showing how to merge a change involving multiple nodes, see “Compare and Merge Simulink Models Containing Stateflow”.

- Not all parameters can be merged. In this case, only one radio button is shown in the target pane indicating the version that is in the target model.
- For information on merging between models with identical names, see “Comparing Models with Identical Names” on page 21-24.

Merge MATLAB Function Block Code

- 1 To merge differences in MATLAB Function block code, create a comparison report for the parent models.
- 2 Click the **Merge Mode** button.

This creates and opens a third file called targetFile. It can contain the changes from either the left or right model.
- 3 Use the buttons in the right of the report to select changes you want in the target file.
- 4 Save these changes over the right model using the **Save File** toolbar button.

Export, Print, and Save Model Comparison Results

In this section...

“Save Printable Report” on page 21-22

“Export Results to the Workspace” on page 21-22

Save Printable Report

To save a printable version of a model comparison report,

- 1 On the **Comparison** tab, select **Publish > HTML, Word, or PDF**.

The Save dialog box opens, where you can choose to save a printable version of the model comparison report.

- 2 Select a file name and location to save the report.

The report is a non-interactive document of the differences detected by the algorithm for printing, sharing, or archiving a record of the comparison. If you have applied filters, your filtered results appear in the printable report.

Alternatively, you can publish a comparison report to a file using the `visdiff` function.

Export Results to the Workspace

To export the comparison results to the MATLAB base workspace,

- 1 On the **Comparison** tab, select **Publish > Workspace Variable**.

The Input Variable Name dialog box appears.

- 2 Specify a name for the export object in the dialog and click **OK**. This action exports the results of the model comparison to an `xmlcomp.Edits` object in the workspace.

The `xmlcomp.Edits` object contains information about the comparison including file names, filters applied, and hierarchical nodes that differ between the two files.

To create an `xmlcomp.Edits` object at the command line without opening the Comparison Tool, enter:

```
Edits = slxmlcomp.compare(modelname_A,modelname_B)
```

Property of <code>xmlcomp.Edits</code>	Description
Filters	Array of filter structure arrays. Each structure has two fields, Name and Value.
LeftFileName	File name of left model.
LeftRoot	<code>xmlcomp.Node</code> object that references the root of the left tree.
RightFileName	File name of right model.
RightRoot	<code>xmlcomp.Node</code> object that references the root of the right tree.

Property of <code>xmlcomp.Edits</code>	Description
TimeSaved	Time when results exported to the workspace.
Version	MathWorks release-specific version number of <code>xmlcomp.Edits</code> object.

Property of <code>xmlcomp.Node</code>	Description
Children	Array of <code>xmlcomp.Node</code> references to child nodes, if any.
Edited	Boolean — If <code>Edited = true</code> then the node is either inserted or part of a modified matched pair.
Name	Name of node.
Parameters	Array of parameter structure arrays. Each structure has two fields, <code>Name</code> and <code>Value</code> .
Parent	<code>xmlcomp.Node</code> reference to parent node, if any.
Partner	If matched, <code>Partner</code> is an <code>xmlcomp.Node</code> reference to the matched partner node in the other tree. Otherwise empty <code>[]</code> .

`visdiff`

Comparing Models with Identical Names

You can compare model files of the same name. To complete the operation, the comparison tool copies one of the models to a temporary folder, because Simulink cannot have two models of the same name in memory at the same time. The comparison tool creates a read-only copy of one model named `modelName_TEMPORARY_COPY`, and compares the resulting XML files.

Warning When you use highlighting from the report, one of the models displayed is a temporary copy with a new name. The temporary copy is read-only, to avoid making changes that can be lost.

Alternatively, you can run the comparison by renaming or copying one of the files.

If one of the models is open when you try to compare them, a dialog box appears where you can click **Yes** to close the file and proceed, or **No** to abort. You must close open models before the comparison tool can compare two models with the same name. The problem requiring you to close the loaded model is called “shadowed files”. In some cases, another model with the same name might be in memory, but not visible. See “Shadowed Files” on page 15-3 for more information.

If you want to automatically close open models of the same name when comparing them and not see the dialog box again, run these commands:

```
opt = slxmlcomp.options
opt.setCloseSameNameModel(true)
```

This is persistent across MATLAB sessions. To revert to default behavior and be prompted whether or not to close the open model every time, enter:

```
opt = slxmlcomp.options
opt.setCloseSameNameModel(false)
```

If you open a comparison report from a project (for example, using **Compare to Revision**), the project handles files of the same name and does not prompt you to close models.

Work with Referenced Models and Library Links

The model comparison report applies only to the currently selected models, and does not include changes to any referenced models or linked libraries. The comparison report shows only changes in the files selected for comparison.

Tip If you want to examine your whole hierarchy instead, try using a project, where you can examine modified files and dependencies across your whole project, and compare to selected revisions. See “Project Management”.

If you are comparing models that contain referenced models with the same name, then your MATLAB path can affect the results. For example, this can happen if you generate a model comparison report for the current version of your model and a previous baseline. Make sure that your referenced models are not on your MATLAB path before you generate the report.

The reason why results can change is that Simulink records information in the top model about the interface between the top model and the child model. This interface information in the top model enables incremental loading and diagnostic checks without any need to load child models.

When you load a model (for example, to compare) then Simulink refreshes the interface information for referenced models if it can find the child model. Simulink can locate the child model if it is on the path. If another model of the same name is higher on the path, Simulink updates the interface information for that other model before comparing. This can produce entries for interface changes for model reference blocks in the comparison report. Make sure your referenced models are not on your path before you generate the report, to avoid these interface changes in the results. If both model versions are off the path, the interface information in the top model is not refreshed during the comparison process. Instead the cached information is used, resulting in a valid comparison report.

With library links, Simulink does not update the cached interface information when comparing, and so the report correctly captures library interfaces. However with both referenced models and library links, Simulink updates the information when displaying the model. When displaying report items in original models, you may see that Simulink finds another model or library that is higher in the path. To obtain the clearest results, make sure that the models and associated libraries are temporarily removed from the path. By removing the files from the path you will see unresolved library links and referenced models when you view the original models, but their interfaces will be correct and will correctly align with the comparison report.

Compare Project or Model Templates

In this section...
“Compare Project Templates” on page 21-26
“Compare Model Templates” on page 21-26

Compare Project Templates

You can compare project templates (SLTX files). If you select two project template files to compare, you see a comparison report showing differences in template properties and project metadata. You can open a new report to investigate project file and folder differences.

- Click **Template Properties** to view differences in the Parameters, such as the description or date modified.
- Expand the **Project Metadata** node to view metadata differences such as label changes.
- Next to **Project Files**, click **Compare** to open a folder comparison where you can investigate changed, added, or removed files and folders.

Compare Model Templates

You can compare model templates (SLTX files). If you select two model template files to compare, you see a comparison report showing differences in template properties. You can open a new comparison report to compare the Simulink models.

- Click **Template Properties** to view differences in the Parameters, such as the description or date modified.
- Next to **Model**, click **Compare** to open a Simulink model comparison report where you can investigate differences.

Component-Based Modeling Guidelines

Componentization benefits organizations developing Simulink models that consist of many functional pieces. Using model components can enable:

- Team-based development — Reduce file contention and elaborate components independently through well-defined interfaces.
- Reduced design complexity — Each component solves smaller problems.
- Component reuse — Reuse algorithms and environment models within a project and across multiple projects.
- Unit testing — Eliminate retesting for unchanged components and reduce the cost of verification.
- Performance benefits that scale — Reduce memory usage and the time required to load and simulate models.
- Component variants — Choose among multiple implementations of a component.
- Intellectual property protection — Limit functionality and content visibility for components that you share with third parties.

Should You Create Model Components?

Considering the work required to define and manage components, you should use component-based modeling only when the benefits outweigh the cost.

Separating an existing Simulink model into components is analogous to taking a large piece of code (C, Java, or MATLAB code) and breaking it down into multiple functions. The conversion can require significant effort and extensive modifications if the design is not modular from the beginning.

Considering model scalability and potential requirements upfront makes separating a Simulink model into components easier. Identifying components upfront can help you avoid these difficulties:

- Poor component definition — The scope of subsystems that are grown over time can fail to meet component requirements. For example, they might contain too much or too little functionality to be reused, to generate code that integrates with legacy functionality, or to support hardware-in-the-loop tests.
- Merge conflicts — If additional engineers begin to work on a model that was originally designed for development by a single engineer, they can encounter time-consuming and error-prone merges.
- Algebraic loops — If a single engineer develops a model from the bottom up, they are likely to group blocks into subsystems as model complexity increases. The subsystems within the model are likely visual groupings that do not affect model execution. When you make these subsystems atomic, or convert them to referenced models, you can introduce unwanted algebraic loops that are difficult to diagnose and fix.

Components are also useful when a design becomes too complicated for one person to manage all of the details. For example, a complicated model can be a model that has:

- Thousands of blocks
- Hundreds of logical decisions
- Multiple variant configurations of the same functionality

Projects and source control can help you manage components. For more information, see “What Are Projects?” on page 16-3 and “Configuration Management” on page 22-23.

Define Model Components

1. “Choose Among Types of Model Components” on page 22-4	Identify Simulink components that align with your high-level modeling requirements.
2. “Compare Capabilities of Model Components” on page 22-8	Investigate which types of model components meet your low-level modeling requirements.
3. “Define Interfaces of Model Components” on page 22-19	Configure design attributes at interfaces and manage data for model components.

Choose Among Types of Model Components

Useful model components have a well-defined scope, perform functionality defined by requirements, and form part of a larger system.

As you define a component, consider these potential requirements.

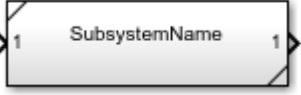

- File contention — You can have larger components if only one person is working on each. If you must share components between several people, you should divide the design into smaller logical pieces. If multiple people must edit the same file, see “Merge Simulink Models from the Comparison Report” on page 21-16.
- Reusability — If you expect to use a group of blocks multiple times in a model, define the group of blocks in a reusable component. By avoiding duplication, you make maintaining the model easier. To refactor an existing model with duplication, see “Refactor Models to Improve Component Reuse” (Simulink Check).
- Code generation — If you must generate standalone code for a physical component, such as a digital controller, you should have one component that represents the physical component and has a well-defined interface.
- Verification cost — If part of a model changes frequently and has high testing costs, you should manage this part of the model as a component in a separate file. When components are defined in separate files, you can control and trace changes using project source control. For more information on source control, see “Configuration Management” on page 22-23.
- Simulation speed — Using different solvers for components with different numerical properties can increase simulation speed. Similarly, grouping blocks based on their sample rate can increase simulation speed. For more information, see Solver Profiler and “Improve Simulation Performance Using Performance Advisor” on page 32-2.

Modeling requirements can influence the size of your components. For example, models with fewer than 500 blocks are easier to test than larger models. However, simulation can be faster for model hierarchies when referenced models contain more than 500 blocks.

Simulink Components

The different types of Simulink components serve a variety of modeling requirements.

Type of Component	Definition	Source of Contents	Implementation in Model
Subsystem	A subsystem is a unique group of blocks with a dynamic interface that can inherit the properties of its inputs and outputs.	None — Contents must be manually added to each subsystem	Subsystem block 
Linked subsystem	A linked subsystem is a linked instance of a Subsystem block that is stored in a library. If you disable the library link, each instance of a linked block can be unique.	Library file (.slx or .mdl) that contains the parent library block, or prototype block	Subsystem block with a library link 

Type of Component	Definition	Source of Contents	Implementation in Model
Subsystem reference	A subsystem reference is a reference to a reusable group of blocks with a dynamic interface that can inherit the properties of its inputs and outputs.	Subsystem file (.slx or .mdl) that contains the referenced subsystem	Subsystem Reference block 
Model reference	A model reference is a reference to a model with a defined interface that specifies the properties of its inputs and outputs.	Model file (.slx, .mdl, or .slxp) that contains the referenced model, which may be a protected model	Model block 

Simulink models can use any combination of these components. For example, to minimize file contention for a large model, you can convert subsystems to referenced subsystems and models, both of which are saved in separate files.

When you drag a subsystem reference or model reference from a library into a model, it directly references the subsystem file or model file that defines its contents. It has a library link only when the parent library block has a mask applied directly to it. Typically, you should use model masks, which are saved in the referenced file and do not require a library link.

High-Level Component Selection Guidelines

Each of the types of model components has an ideal use case:

- Subsystem — Ideal for simplifying the block diagrams of other components
- Linked subsystem — Ideal for utilities and blocksets
- Subsystem reference — Ideal for reducing file contention and merge issues
- Model reference — Ideal for code reuse, unit testing, parallel builds, and large components

The ideal use cases are a subset of the possible use cases for each type of component. For example, you can also reduce file contention and merge issues with a model reference, and you can also unit test a subsystem.

Tip If you expect a subsystem to grow, make it atomic so that it functionally groups the blocks. An atomic subsystem behaves like a single block, or atomic unit, when the parent model executes. Atomic behavior is necessary for you to convert a subsystem to a model reference.

This flow chart provides a starting point for choosing a component type.

Consider a subsystem if the component meets all of these conditions:

- The component will not require a defined interface or standalone behavior.
- The component will not be managed in a source control system.
- The component will not be reused.

Consider a linked subsystem if the component meets all of these conditions:

- The component will not require a defined interface or standalone behavior.
- The component will either be managed in a source control system or be reused.
- The component will not contain enough blocks and be reused enough to benefit from accelerator mode simulation of referenced models.

- The component will be a published utility, which rarely changes.

Consider a subsystem reference if the component meets all of these conditions:

- The component will not require a defined interface or standalone behavior.
- The component will either be managed in a source control system or be reused.
- The component will not contain enough blocks and be reused enough to benefit from accelerator mode simulation of referenced models.
- The component will not be a published utility, which rarely changes.

Consider a model reference if the component meets either of these conditions:

- The component will require a defined interface or standalone behavior.
- The component will contain enough blocks and be reused enough to benefit from accelerator mode simulation of referenced models.

Whether a model hierarchy benefits from accelerator mode simulation of referenced models depends on many factors. For each referenced model that simulates in accelerator mode, Simulink must build and compile a simulation target. These targets are reused for additional instances of the referenced model, which accelerates simulation when the model hierarchy contains many instances of the referenced model. If the referenced model is unchanged, you can reuse its simulation target, which is stored in a Simulink cache file (.slxc). For more information, see “Share Simulink Cache Files for Faster Simulation” on page 8-54.

Modeling Requirement Considerations

Before implementing a component based on the high-level guidelines, consider additional modeling requirements. For example, if you require physical connections at the component interface, you must use a subsystem, linked subsystem, or referenced subsystem. If you require intellectual property protection, you must create a protected model, which can be referenced.

To determine whether a component meets your modeling requirements, see “Compare Capabilities of Model Components” on page 22-8.

Development Process

Modeling Requirement	Subsystems	Linked Subsystems	Subsystem References	Model References
Separate Files	<p>Not supported</p> <p>You save a subsystem in the same file as its parent.</p> <p>To create or change a subsystem, you must edit the parent file, which can lead to file contention and merge problems.</p>	<p>Supported</p> <p>You save the parent library block of a linked block in a separate file.</p> <p>Using separate files helps to avoid file contention.</p>	<p>Supported</p> <p>You save a referenced subsystem in a separate file.</p> <p>Using separate files helps to avoid file contention.</p>	<p>Supported</p> <p>You save a referenced model in a separate file.</p> <p>Using separate files helps to avoid file contention.</p>
Component Reuse	<p>Not supported</p> <p>While you can copy a subsystem to reuse it in a model, the copies are independent of each other.</p>	<p>Supported</p> <p>You can link to the same parent library block multiple times in multiple models without creating copies.</p> <p>Managing library links adds some overhead, such as managing broken, disabled, or parameterized links.</p>	<p>Supported</p> <p>You can reference the same subsystem multiple times in multiple models without creating copies.</p>	<p>Supported</p> <p>You can reference the same model multiple times in multiple models without creating copies. See “Model Reuse” on page 8-6.</p>
Shared Data	<p>Supported</p> <p>You can share data among instances by defining the data outside the component. For example, by using a data store in a common parent subsystem.</p>	<p>Supported</p> <p><i>Same behavior as subsystems.</i></p>	<p>Supported</p> <p><i>Same behavior as subsystems.</i></p>	<p>Supported</p> <p>You can share data among instances of the referenced model by creating a data store inside the model. See “Share Data Among Referenced Model Instances” on page 8-34.</p>

Modeling Requirement	Subsystems	Linked Subsystems	Subsystem References	Model References
Instance-Specific Edits	Supported Subsystem copies are independent of each other.	Supported When you edit a parent library block, the changes apply to the library file and propagate to all blocks that link to that block. To edit an instance of the block, you can disable the library link. You cannot disable library links when the parent library block has restricted write access.	Not supported When you edit an instance of a referenced subsystem, the changes apply to the subsystem file and propagate to all other instances of the referenced subsystem.	Not supported When you edit an instance of a referenced model, the changes apply to the model file and propagate to all other instances of the referenced model. You can specify instance-specific parameter values for referenced models. For more information, see “Parameterize Instances of a Reusable Referenced Model” on page 8-63.
Variants	Supported Add subsystem variants to a Variant Subsystem or Variant Model block. For more information, see “Define, Configure, and Activate Variant Choices in a Variant Subsystem Block” on page 12-71.	Supported <i>Same behavior as subsystems.</i>	Supported <i>Same behavior as subsystems.</i>	Supported Add model variants to a Variant Subsystem or Variant Model block. For more information, see “Define, Configure, and Activate Variant Choices in a Variant Subsystem Block” on page 12-71.

Modeling Requirement	Subsystems	Linked Subsystems	Subsystem References	Model References
Version Control and Configuration Management	<p>Not supported</p> <p>You cannot directly place subsystems in a source control system.</p> <p>To reduce file contention and use separate version control for each subsystem, use a subsystem reference.</p>	<p>Supported</p> <p>You can place library files in a source control system.</p> <p>To provide individual version control for each library block, use subsystem references and model references in the library. When you drag these blocks from the library into your model, they reference the subsystem file or model file.</p> <p>Forwarding tables allow you to map old library blocks to new versions of the blocks.</p>	<p>Supported</p> <p>You can place subsystem files in a source control system.</p>	<p>Supported</p> <p>You can place model files in a source control system.</p>

Modeling Requirement	Subsystems	Linked Subsystems	Subsystem References	Model References
Intellectual Property Protection	Not supported Use model references instead.	Not supported <i>Same behavior as subsystems.</i>	Not supported <i>Same behavior as subsystems.</i>	Supported Protected models obscure model contents, which can be useful when distributing models. Creating a protected model requires a Simulink Coder license. For more information, see “Protect Models to Conceal Contents” (Simulink Coder). Using a protected model does <i>not</i> require a Simulink Coder license. For more information, see “Reference Protected Models from Third Parties” on page 8-13.

Modeling Requirement	Subsystems	Linked Subsystems	Subsystem References	Model References
Unit Testing	<p>Supported</p> <p>Subsystems are dependent on their context in a model. If the context of a subsystem changes, such as the data type of an input signal, the related test harness must be updated.</p> <p>For subsystems that are not atomic, the test harness may use different block execution orders, due to virtual boundaries.</p> <p>For tools that support authoring, managing, and executing systematic, simulation-based tests of subsystems, see “Create Test Harnesses and Select Properties” (Simulink Test).</p> <p>To measure how thoroughly model components are tested, see “Model Coverage” (Simulink Coverage).</p>	<p>Supported</p> <p><i>Same behavior as subsystems.</i></p>	<p>Supported</p> <p><i>Same behavior as subsystems.</i></p>	<p>Supported</p> <p>You can test a referenced model independently to isolate behavior by simulating it as a top model.</p> <p>You can use a data-defined test harness, with MATLAB test vectors and direct coverage collection.</p> <p>For tools that support authoring, managing, and executing systematic, simulation-based tests of subsystems, see “Create Test Harnesses and Select Properties” (Simulink Test).</p> <p>To measure how thoroughly model components are tested, see “Model Coverage” (Simulink Coverage).</p>

Performance Requirements

Modeling Requirement	Subsystems	Linked Subsystems	Subsystem References	Model References
Incremental Model Loading	Not supported Loading a model loads all subsystem contents that are saved in the model.	Supported Simulink incrementally loads a library at the point needed during editing, updating a diagram, or simulating a model.	Supported Simulink incrementally loads a referenced subsystem at the point needed during editing, updating a diagram, or simulating a model.	Supported Simulink incrementally loads a referenced model at the point needed during editing, updating a diagram, or simulating a model.
Build Artifact Reuse	Not supported Build artifacts, such as simulation targets, are not generated for subsystems.	Not supported <i>Same behavior as subsystems.</i>	Not supported <i>Same behavior as subsystems.</i>	Supported You can share and reuse build artifacts, such as simulation targets, using Simulink cache files. For more information, see “Share Simulink Cache Files for Faster Simulation” on page 8-54.
Reduced Memory Usage for Large Models	Not supported Subsystems do not reduce memory usage for simulation and code generation.	Not supported Linked subsystems do not reduce memory usage for simulation and code generation. Simulink duplicates library block instances during block update.	Not supported Subsystem references do not reduce memory usage for simulation and code generation. Simulink duplicates subsystem reference instances during block update.	Supported Models referenced in accelerator mode reduce memory usage for simulation and code generation because Simulink incrementally loads compiled versions of them.

Modeling Requirement	Subsystems	Linked Subsystems	Subsystem References	Model References
Artificial Algebraic Loop Elimination	<p>Supported</p> <p>Subsystems that are not atomic avoid artificial algebraic loops.</p> <p>If a subsystem is atomic, you can try to eliminate artificial algebraic loops by enabling the Subsystem block parameter Minimize algebraic loop occurrences.</p>	<p>Supported</p> <p><i>Same behavior as subsystems.</i></p>	<p>Supported</p> <p><i>Same behavior as subsystems.</i></p>	<p>Supported</p> <p>You can try to eliminate artificial algebraic loops by enabling Configuration Parameters > Model Referencing > Minimize algebraic loop occurrences.</p>

Features

Modeling Requirement	Subsystems	Linked Subsystems	Subsystem References	Model References
Compatible Configuration Parameter Settings	<p>Supported</p> <p>Subsystems use the configuration parameter settings of the model that contains them.</p>	<p>Supported</p> <p><i>Same behavior as subsystems.</i></p>	<p>Supported</p> <p><i>Same behavior as subsystems.</i></p>	<p>Supported</p> <p>Configuration parameter settings can generally be different for a parent model and its referenced models. For compatibility information, see “Set Configuration Parameters for Model Hierarchies” on page 8-59.</p>

Modeling Requirement	Subsystems	Linked Subsystems	Subsystem References	Model References
<p>Signal Property Specification at Interfaces</p>	<p>Supported</p> <p>You can specify signal properties at a subsystem interface.</p> <p>For signal properties that you do not specify, subsystems inherit the signal properties from their context. Propagation of signal properties can lead to Simulink using signal properties that you do not anticipate.</p>	<p>Supported</p> <p><i>Same behavior as subsystems.</i></p>	<p>Supported</p> <p><i>Same behavior as subsystems.</i></p>	<p>Supported</p> <p>You must specify most signal properties at a referenced model interface.</p> <p>Referenced models are context-independent with a defined boundary, so they do not inherit most signal properties.</p> <p>Referenced models can inherit discrete sample times when the referenced model is sample-time independent.</p>
<p>Physical Connections at Interfaces</p>	<p>Supported</p> <p>You can specify physical connections at a subsystem interface.</p>	<p>Supported</p> <p><i>Same behavior as subsystems.</i></p>	<p>Supported</p> <p><i>Same behavior as subsystems.</i></p>	<p>Not supported</p> <p>Physical connections must be fully contained within a referenced model. They cannot cross the model interface.</p>
<p>Bus Specification</p>	<p>Supported</p> <p>You can use a Simulink.Bus object to specify the data type of a bus that passes into a subsystem.</p> <p>Subsystems do not require the use of Bus objects for virtual buses.</p>	<p>Supported</p> <p><i>Same behavior as subsystems.</i></p>	<p>Supported</p> <p><i>Same behavior as subsystems.</i></p>	<p>Supported</p> <p>You can use a Simulink.Bus object to specify the data type of a bus that passes into a referenced model.</p> <p>Model references do not require the use of Bus objects for virtual buses when you use In Bus Element and Out Bus Element blocks.</p>

Modeling Requirement	Subsystems	Linked Subsystems	Subsystem References	Model References
State Initialization	Supported You can initialize states of subsystems.	Supported <i>Same behavior as subsystems.</i>	Supported <i>Same behavior as subsystems.</i>	Supported You can initialize states from the top model using either the structure format or structure-with-time format. For more information, see “State Information for Referenced Models” on page 73-80.
Conditional Execution	Supported Subsystems support conditional execution. For more information, see “Conditionally Executed Subsystems Overview” on page 10-3.	Supported <i>Same behavior as subsystems.</i>	Supported <i>Same behavior as subsystems.</i>	Supported Referenced models support conditional execution. For more information, see “Conditionally Execute Referenced Models” on page 8-24.
Event-Based Behavior	Supported Subsystems support event-based behavior. For more information, see “Using Initialize, Reset, and Terminate Functions” on page 10-171.	Supported <i>Same behavior as subsystems.</i>	Supported <i>Same behavior as subsystems.</i>	Supported Referenced models support event-based behavior. For more information, see “Using Initialize, Reset, and Terminate Functions” on page 10-171.
Independent Functions	Supported You can define independent functions in subsystems. For more information, see “Simulink Functions Overview” on page 10-116.	Supported <i>Same behavior as subsystems.</i>	Supported <i>Same behavior as subsystems.</i>	Supported You can define independent functions in a referenced model. For more information, see “Export-Function Models Overview” on page 10-98.

- 11 Best Practices for Developing ISO 26262 Applications with Simulink

Define Interfaces of Model Components

Defining the interface of a model component, such as a Simulink subsystem, subsystem reference, or model reference, is a key first step before others can use it.

- Agreeing on an interface helps determine how to break down the functionality of a large system into components.
- After you define interfaces between components, you can develop the components in parallel. If the interface remains stable, then it is easy to integrate those components into a larger system.
- Changing the interface between components is expensive. Changing an interface requires changes to at least two components (the source and any sinks) and to any test harnesses. It also makes all previous versions of those components incompatible with the current and future versions.

Changing an interface is much easier if the components are stored under configuration management. You can track configurations of compatible component versions to prevent incompatible combinations of components.

Note This topic focuses on design interfaces for modeling and simulation. To configure an interface for code generation and deployment, see:

- “Design Data Interface by Configuring Inport and Outport Blocks” (Simulink Coder)
 - “Choose Storage Class for Controlling Data Representation in Generated Code” (Simulink Coder)
 - “C Code Generation Configuration for Model Interface Elements” (Simulink Coder)
 - “Interactively Configure C++ Interface” (Embedded Coder)
 - “Programmatically Configure C++ Interface” (Embedded Coder)
-

Identify Component Boundaries

Base the boundaries of the components upon the boundaries of the corresponding real systems. This guideline is especially useful when the model contains:

- Both physical (plant and environment) and control systems
- Algorithms that run at different rates
- A system that you want to reuse multiple times

If you intend to add sensors or other components as you elaborate your model, create components to represent them. You can configure these components to pass signals straight through or perform a unit delay or name conversion.

Simplify Interfaces with Buses

To simplify interfaces, group signals and messages into buses. Buses simplify subsystem and model interfaces by letting you associate multiple signals or messages with one port. They reduce line complexity and clutter in a block diagram and make it easier to change the interface incrementally. For example, if you must add or remove elements from a component interface, modifying a bus can be simpler than adding or removing ports. To logically group or define the properties of a portion of the interface, use multiple bus ports.

Buses are well suited for components that have many input and output signals and do not use all of the available signals. Buses pass only the required data to each component from the inputs and outputs. If you define the bus at the interface with a `Simulink.Bus` object, the interface requires data for the entire bus.

To access an element from an input bus, use an In Bus Element block. To create an output bus, use Out Bus Element blocks. For more information, see “Simplify Subsystem and Model Interfaces with Buses” on page 77-26.

How you implement buses at an interface depends on your modeling requirements.

Modeling Requirement	Bus Implementation
Provide name-based matching among elements at the interface and simplify line routing	Use virtual buses. While nonvirtual buses also satisfy this modeling requirement, virtual buses provide a simpler solution. For more information, see “Types of Composite Signals” on page 77-2.
Enable robust component integration with defined interfaces	Use <code>Simulink.Bus</code> objects to define the properties of the virtual buses at the interface. Use a rigorous naming convention for the bus elements and <code>Bus</code> objects. To place the <code>Bus</code> objects under revision control, save them in a data dictionary, function, script, or MAT file.
Replicate structure type in generated code	Use nonvirtual buses to describe a structured data type for an element in the interface.
Package signals or parameters into structures that correspond to a <code>struct</code> type definition that your external C code defines	Import the type as a <code>Bus</code> object and use the object as a data type for buses and MATLAB structures. To create the object, use the <code>Simulink.importExternalCTypes</code> function.

Partition Interface Data

Explicitly control the scope of data for your components with global and nonglobal parameters.

- Global parameters — A common approach in the automotive world is to completely separate parameter storage from model storage. The parameters for a model come from a database of calibration data, and the specific calibration file used becomes part of the configuration. The calibration data is treated as global data, and resides in the base MATLAB workspace. You can migrate base workspace data to a data dictionary for more control.
- Nonglobal parameters — Combining components that store their own parameter data has the risk of parameter name collisions. If you do not use a naming convention for parameters or a list of unique parameter names and definitions, then two components may use a parameter with the same name but with different meanings.

To store local parameter data:

- Partition data into reference dictionaries for each component.
- For referenced models, you can use model workspaces.

- Use parameter files (.m or .mat) and callbacks of the individual Simulink models (for example, the `preLoad` function).

You can also automatically load required data using project shortcuts.

- Use mask workspaces with or without the use of mask initialization functions.
- For subsystems, you can control the scope of data for a subsystem using the **Permit hierarchical resolution** parameter of the Subsystem block.

Configure Data Interfaces

Explicitly configure design attributes of the interface, such as data type and numeric complexity, to prevent modeling errors and make component integration easier. You can configure the interface of a component before you develop the internal algorithm, in which case the component contains unconnected blocks. After you create the blocks that correspond to the component interface, use:

- The **Model Data Editor** to configure the design attributes of the blocks.

To open the Model Data Editor, on the **Modeling** tab of the Simulink Toolstrip, click **Model Data Editor**. On the **Inports/Outports** tab of the Model Data Editor, each row corresponds to an input or output block and the columns correspond to attributes that you can set for the blocks.

- The interface display perspective to view the component interface in its entirety and trace elements of the interface to usage points in the internal block algorithm.

To open the interface display perspective, on the **Modeling** tab, in the **Design** gallery, click **Model Interface**. For more information, see “Trace Connections Using Interface Display” on page 77-114.

By default, the **Change view** list of the Model Data Editor is set to **Design**, which configures the columns to correspond to design attributes. Use the columns to explicitly configure the design attributes of the interface. For example, specify minimum and maximum values for each block with the **Min** and **Max** columns.

Alternatively, you can specify a reusable set of design attributes at component interfaces instead of individually specifying each attribute.

- Use `Simulink.ValueType` objects to assign or validate properties of a signal based on application-specific value types such as wind velocity, tire pressure, or water temperature.
- Use `Simulink.Bus` objects to assign or validate the properties of each element of a bus.

To display the input and output blocks of the subsystems, select the **Change Scope** button . Alternatively, view only the input and output blocks at the root level of the model by excluding the blocks inside the subsystems.

Configuration Management

In this section...

“Manage Designs Using Source Control” on page 22-23

“Determine the Files Used by a Component” on page 22-23

“Manage Model Versions” on page 22-24

“Create Configurations” on page 22-24

Manage Designs Using Source Control

Projects can help you work with configuration management tools for team collaboration. You can use projects to help you manage all the models and associated files for model-based design.

You can control and trace the changes in each component using project source control. Using source control directly from a project provides these benefits:

- Engineers do not have to remember to use two separate tools, avoiding the common mistake of beginning work in Simulink without checking out the required files first.
- You can perform analysis within MATLAB and Simulink to determine the dependencies of files upon each other. Third-party tools are unlikely to understand such dependencies.
- You can compare revisions and use tools to merge models.

If each component is a single file, you can achieve efficient parallel development, where different engineers can work on the different components of a larger system in parallel. Using model components allows you to avoid or minimize time-consuming merging. One file per component is not strictly necessary to perform configuration management, but it makes parallel development much easier.

If you break down a model into components, it is easier to reuse those components in different projects. If the components are kept under revision control and configuration management, then you can reuse components in multiple projects simultaneously.

To find out about source control support, see “Source Control in Projects”.

Determine the Files Used by a Component

You can use a project to determine the set of files you must place under configuration management. You can analyze the set of files that are required for the model to run, such as model references, library links, block and model callbacks (preload functions, init functions, etc.), S-functions, From Workspace blocks, etc. Any MATLAB code found is also analyzed to determine additional file dependencies. You can use the Dependency Analyzer to report which toolboxes are required by a model, which can be a useful artifact to store.

You can also perform a file dependency analysis of a model programmatically from MATLAB using `dependencies.fileDependencyAnalysis` to get a cell array of paths to required files.

For more information, see “Dependency Analysis”.

Manage Model Versions

Simulink can help you to manage multiple versions of a model.

- Use a project to manage your project files, connect to source control, review modified files, and compare revisions. See “Project Management”.
- Simulink notifies you if a model has changed on disk when updating, simulating, editing, or saving the model. Models can change on disk, for example, with source control operations and multiple users. Control this notification with the Model File Change Notification preference. See “Model File Change Notification” on page 4-65.
- As you edit a model, Simulink generates version information about the model, including a version number, who created and last updated the model, and an optional comments history log. Simulink saves these version properties with the model.
 - Use the Model Properties dialog box to view and edit some of the version information stored in the model and specify history logging.
 - The Model Info block lets you display version information as an annotation block in a model diagram.
- Use `Simulink.MDLInfo` to extract information from a model file without loading the block diagram into memory. You can use `MDLInfo` to query model version and Simulink version, find the names of referenced models without loading the model into memory, and attach arbitrary metadata to your model file.

Create Configurations

You can use a project to work with the revision control parts of the workflow: retrieving files, adding files to source control, checking out files, and committing edited files to source control.

To define configurations of files, you can label several files as a new mutually consistent configuration. Team members can get this set of files from the revision control system.

Configurations are different from revisions. Individual components can have revisions that work together only in particular configurations.

Tools for creating configurations in Simulink:

- Variant modeling. See “Variant Systems”.
- Project tools:
 - Label — Label project files. Use labels to apply metadata to files. You can group and sort by labels, label folders for adding to the path using shortcut functions, or create batch jobs to export files by label, for example, to manage files with the label `Diesel`. You cannot retrieve from source control by label, and labels persist across revisions.
 - Revision Log — Use Revert Project to choose a revision to revert to (SVN source control only).
 - Branch — Create branches of file versions, and switch to any branch in the repository (Git source control only).
 - Tag — You can tag all project files (SVN source control only) to identify a particular configuration of a project, and retrieve tagged versions from source control. However, continued development is limited. That is, you cannot tag again, and you must check out from trunk to apply tags.

- Archive — Package all project files in a zip file that you can create a project from. However, this packaging removes all source control information, because archiving is for exporting, sharing, and changing to another source control. You can commit the new zip file to source control.

Study Power Windows

Automobiles use electronics for control operations such as:

- Opening and closing windows and sunroof
- Adjusting mirrors and headlights
- Locking and unlocking doors

These systems are subject to stringent operation constraints. Failures can cause dangerous and possibly life-threatening situations. As a result, careful design and analysis are needed before deployment.

This example focuses on the design of a power window system of an automobile, in particular, the passenger-side window. A critical aspect of this system is that it cannot exert a force of more than 100 N on an object when the window closes. When the system detects such an object, it must lower the window by about 10 cm.

As part of the design process, the example considers:

- Quantitative requirements for the window control system, such as timing and force requirements

- System requirements, captured in activity diagrams
- Data definitions for the signals used in activity diagrams

Other aspects of the design process that this example contains are:

- Managing the components of the system
- Building the model
- Validating the results of system simulation
- Generating code

MathWorks Software Used in This Example

In addition to Simulink, this example uses these additional MathWorks products:

- DSP System Toolbox
- Fixed-Point Designer
- Simscape Multibody
- Simscape Electrical™
- Simscape
- Simulink 3D Animation™
- Simulink Real-Time
- Simulink Coverage
- Stateflow

Quantitative Requirements

Quantitative requirements for the control are:

- The window must fully open and fully close within 4 s.
- If the up is issued for between 200 ms and 1 s, the window must fully open. If the down command is issued for between 200 ms and 1 s, the window must fully close.
- The window must start moving 200 ms after the command is issued.
- The force to detect when an object is present is less than 100 N.
- When closing the window, if an object is in the way, stop closing the window and lower the window by approximately 10 cm.

Capturing Requirements in Activity and Context Diagrams

Activity diagrams help you graphically capture the specification and understand how the system operates. A hierarchical structure helps with analyzing even large systems. At the top level, a context diagram describes the system environment and its interaction with the system under study in terms of data exchange and control operations. Then you can decompose the system into an activity diagram with processes and control specifications (CSPEC).

The processes guide the hierarchical decomposition. You specify each process using another activity diagram or a primitive specification (PSPEC). You can specify a PSPEC in a number of representations with a formal semantic, such as a Simulink block diagram. In addition, context diagrams graphically capture the context of system operation.

Context Diagram: Power Window System

The figure represents the context diagram of a power window system. The square boxes capture the environment, in this case, the driver, passenger, and window. Both the driver and passenger can send commands to the window to move it up and down. The controller infers the correct command to send to the window actuator (e.g., the driver command has priority over the passenger command). In addition, diagram monitors the state of the window system to establish when the window is fully opened and closed and to detect if there is an object between the window and frame.

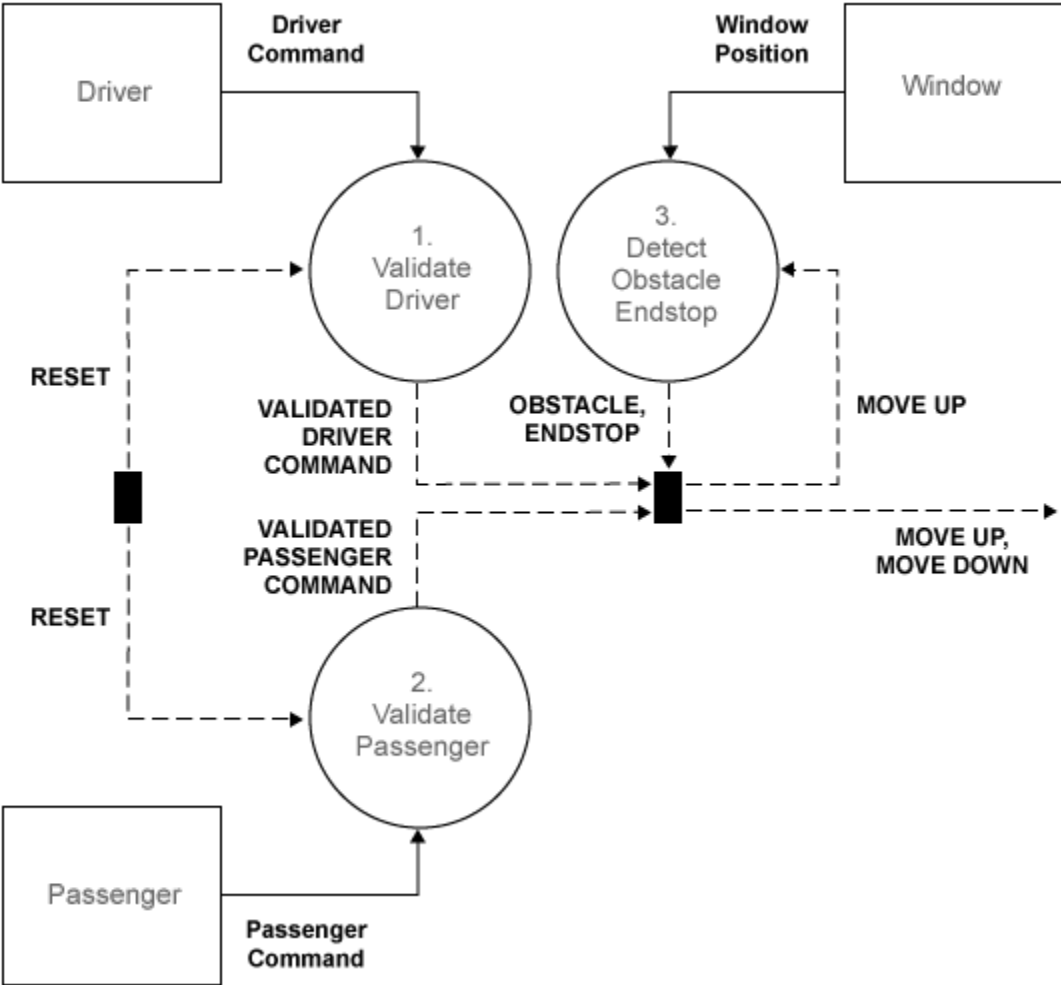

The circle (also known as a bubble) represents the power window controller. The circle is the graphical notation for a process. Processes capture the transformation of input data into output data. Primitive process might also generate. CSPECs typically consist of combinational or sequential logic to infer output control signals from input control.

For implementation in the Simulink environment, see “Implementation of Context Diagram: Power Window System” on page 23-26.

Activity Diagram: Power Window Control

The power window control consists of three processes and a CSPEC. Two processes validate the driver and passenger input to ensure that their input is meaningful given the state of the system. For example, if the window is completely opened, the MOVE DOWN command does not make sense. The remaining process detects if the window is completely opened or completely closed and if an object is present. The CSPEC takes the control signals and infers whether to move the window up or down (e.g., if an object is present, the window moves down for about one second or until it reaches an endstop).

For implementation in the Simulink environment, see “Implementation of Activity Diagram: Power Window Control” on page 23-11.

Activity Diagram: Validate Driver

Each process in the VALIDATE DRIVER activity chart is primitive and specified by the following PSPEC. In the MAKE EXCLUSIVE PSPEC, for safety reasons the DOWN command takes precedence over the UP command.

PSPEC 1.1.1: CHECK DOWN
 CHECKED_DOWN = DOWN and not RESET

PSPEC 1.1.2: CHECK UP
 CHECKED_UP = UP and not RESET

PSPEC 1.1.3: MAKE EXCLUSIVE
 VALIDATED_DOWN = CHECKED_DOWN
 VALIDATED_UP = CHECKED_UP and not CHECKED_DOWN
 VALIDATED_NEUTRAL = (NEUTRAL and not (CHECKED_UP and not CHECKED_DOWN))
 or not (CHECKED_UP or CHECKED_DOWN)

For implementation in the Simulink environment, see “Implementation of Activity Diagram: Validate” on page 23-28.

Activity Diagram: Validate Passenger

The internals of the VALIDATE PASSENGER process are the same as the VALIDATE DRIVER process. The only difference is the different input and output.

PSPEC 1.2.1: CHECK DOWN
 CHECKED_DOWN = DOWN and not RESET

PSPEC 1.2.2: CHECK UP
 CHECKED_UP = UP and not RESET

PSPEC 1.2.3: MAKE EXCLUSIVE
 VALIDATED_DOWN = CHECKED_DOWN
 VALIDATED_UP = CHECKED_UP and not CHECKED_DOWN
 VALIDATED_NEUTRAL = (NEUTRAL and not (CHECKED_UP and not CHECKED_DOWN))
 or not (CHECKED_UP or CHECKED_DOWN)

For implementation in the Simulink environment, see “Activity Diagram: Validate Passenger” on page 23-6.

Activity Diagram: Detect Obstacle Endstop

The third process in the POWER WINDOW CONTROL activity diagram detects the presence of an obstacle or when the window reaches its top or bottom (ENDSTOP). The detection mechanism is based on the armature current of the window actuator. During normal operation, this current is within certain bounds. When the window reaches its top or bottom, the electromotor draws a large current (more than 15 A or less than -15 A) to try and sustain its angular velocity. Similarly, during normal operation the current is about 2 A or -2 A (depending on whether the window is opening or closing). When there is an object, there is a slight deviation from this value. To keep the window force on the object less than 100 N, the control switches to its emergency operation when it detects a current that is less than -2.5 A. This operations is necessary only when the window is rolling up, which

corresponds to a negative current in the particular wiring of this model. The DETECT OBSTACLE ENDSTOP activity diagram embodies this functionality.

CSPEC 1.3: DETECT OBSTACLE ENDSTOP
 RESET = OBSTACLE or ENDSTOP

PSPEC 1.3.1: DETECT ENDSTOP
 ENDSTOP = WINDOW_POSITION > ENDSTOP_MAX

PSPEC 1.3.2: DETECT OBSTACLE
 OBSTACLE = (WINDOW_POSITION > OBSTACLE_MAX) and MOVE_UP for 500 ms

For implementation in the Simulink environment, see “Activity Diagram: Detect Obstacle Endstop” on page 23-7.

Data Definitions

The functional decomposition unambiguously specifies each process by its decomposition or primitive specification (PSPEC). In addition, it must also formally specify the signals in the activity diagrams. Use data definitions for these specifications.

The following tables are data definitions for the signals used in the activity diagrams.

For the associated activity diagram, see “Context Diagram: Power Window System” on page 23-4.

Context Diagram: Power Window System Data Definitions

Signal	Information Type	Continuous/ Discrete	Data Type	Values
DRIVER_COMMAND	Data	Discrete	Aggregate	Neutral, up, down
PASSENGER_COMMAND	Data	Discrete	Aggregate	Neutral, up, down
WINDOW_POSITION	Data	Continuous	Real	0 to 0.4 m
MOVE_UP	Control	Discrete	Boolean	'True', 'False'
MOVE_DOWN	Control	Discrete	Boolean	'True', 'False'

For the associated activity diagram, see “Activity Diagram: Power Window Control” on page 23-4.

Activity Diagram: Power Window Control Data Definitions

Signal	Information Type	Continuous/ Discrete	Data Type	Values
DRIVER_COMMAND	Data	Discrete	Aggregate	Neutral, up, down
PASSENGER_COMMAND	Data	Discrete	Aggregate	Neutral, up, down
WINDOW_POSITION	Data	Continuous	Real	0 to 0.4 m
MOVE_UP	Control	Discrete	Boolean	'True', 'False'
MOVE_DOWN	Control	Discrete	Boolean	'True', 'False'

For the associated activity diagram, see “Activity Diagram: Validate Driver” on page 23-5.

Activity Diagram: Validate Driver Data Definitions

Signal	Information Type	Continuous/ Discrete	Data Type	Values
DRIVER_COMMAND	Data	Discrete	Aggregate	Neutral, up, down
PASSENGER_COMMAND	Data	Discrete	Aggregate	Neutral, up, down
WINDOW_POSITION	Data	Continuous	Real	0 to 0.4 m
MOVE_UP	Control	Discrete	Boolean	'True', 'False'
MOVE_DOWN	Control	Discrete	Boolean	'True', 'False'

For the associated activity diagram, see “Activity Diagram: Validate Passenger” on page 23-6.

Activity Diagram: Validate Passenger Data Definitions

Signal	Information Type	Continuous/ Discrete	Data Type	Values
NEUTRAL	Data	Discrete	Boolean	'True', 'False'
UP	Data	Discrete	Boolean	'True', 'False'
DOWN	Data	Discrete	Boolean	'True', 'False'
CHECKED_UP	Data	Discrete	Boolean	'True', 'False'
CHECKED_DOWN	Data	Discrete	Boolean	'True', 'False'

For the associated activity diagram, see “Activity Diagram: Detect Obstacle Endstop” on page 23-7.

Activity Diagram: Detect Obstacle Endstop Data Definitions

Signal	Information Type	Continuous/ Discrete	Data Type	Values
ENDSTOP_MIN	Data	Constant	Real	0.0 m
ENDSTOP_MAX	Data	Constant	Real	0.4 m
OBSTACLE_MAX	Data	Constant	Real	0.3 m

The model design iterates as we examine more detailed implementations. For information about how the model design iterates as you introduce more detail, see “Iterate on the Design” on page 23-35.

Simulink Power Window Controller Project

MATLAB and Simulink support Model-Based Design for embedded control design, from initial specification to code generation. To organize large projects and share your work with others, use “Project Management”.

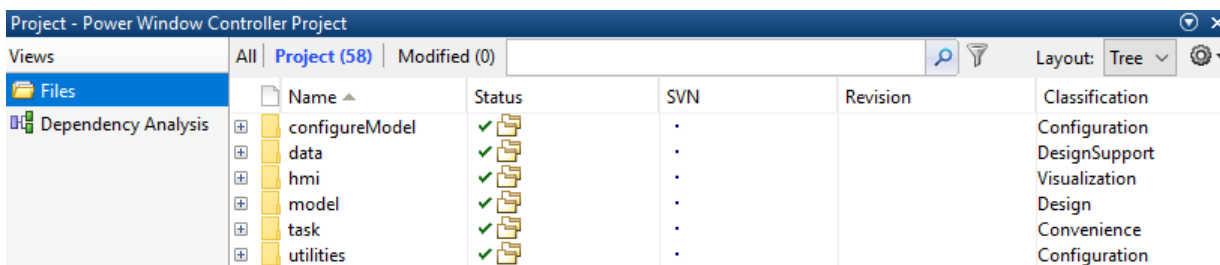

“Power Window Control Project” shows how you can use MathWorks tools and the Model-Based Design process to go from concept through implementation for an automobile power window system. It uses projects to organize the files and other model components.

In addition, this example shows how to link models to system documentation.

Explore the Power Window Controller Project

- 1 To open the Power Window Controller project, in the MATLAB Command Window, type:

```
slexPowerWindowStart
```

- 2 Explore the project folders. In particular, note the **task** folders. This folder contains scripts that run frequent tasks for a model. For the Power Window Controller Project, these scripts:

- Set up the model to control window movement on a controller area network (CAN).
- Set up the model to use the Stateflow and Simulink software to model discrete-event reactive behavior and continuous time behavior, with a low-order plant model.
- Set up the model with a more detailed plant model that includes power effects in the electrical and mechanical domains. The plant model validates the force exerted by the window on a trapped object.
- Set up the model with a model that includes other effects that may change the model, such as quantization of the measurements.

Note These scripts also simulate the model. To only configure the model, see the scripts in the **configureModel** folder.

- Use the increase coverage model to generate the model coverage report.
- 3** The **Project Shortcuts** section contains quick-access commands that you can double-click to perform common tasks such as:
- Add projects to MATLAB paths.
 - Perform interactive testing.
 - Validate model testing with model coverage.
 - Open the main model.
 - Simulate the model with various configurations.
 - Generate a model coverage report for increased coverage of the model.
 - Open the model used for increasing model coverage.

Simulink Power Window Controller

- “Implementation of Activity Diagram: Power Window Control” on page 23-11
- “Interactive Testing” on page 23-13
- “Experimental Results from Interactive Testing” on page 23-14
- “Model Coverage” on page 23-22

Implementation of Activity Diagram: Power Window Control

This topic describes the high-level discrete-event control specification for a power window control.

You can model the discrete-event control of the window with a Stateflow chart. A Stateflow chart is a finite state machine with hierarchy and parallelism. This state machine contains the basic states of the power window system: up, auto-up, down, auto-down, rest, and emergency. It models the state transitions and accounts for the precedence of driver commands over the passenger commands. It also includes emergency behavior that activates when the software detects an object between the window and the frame while moving up.

The initial Simulink model for the power window control, `slexPowerWindowControl`, is a discrete-event controller that runs at a given sample rate.

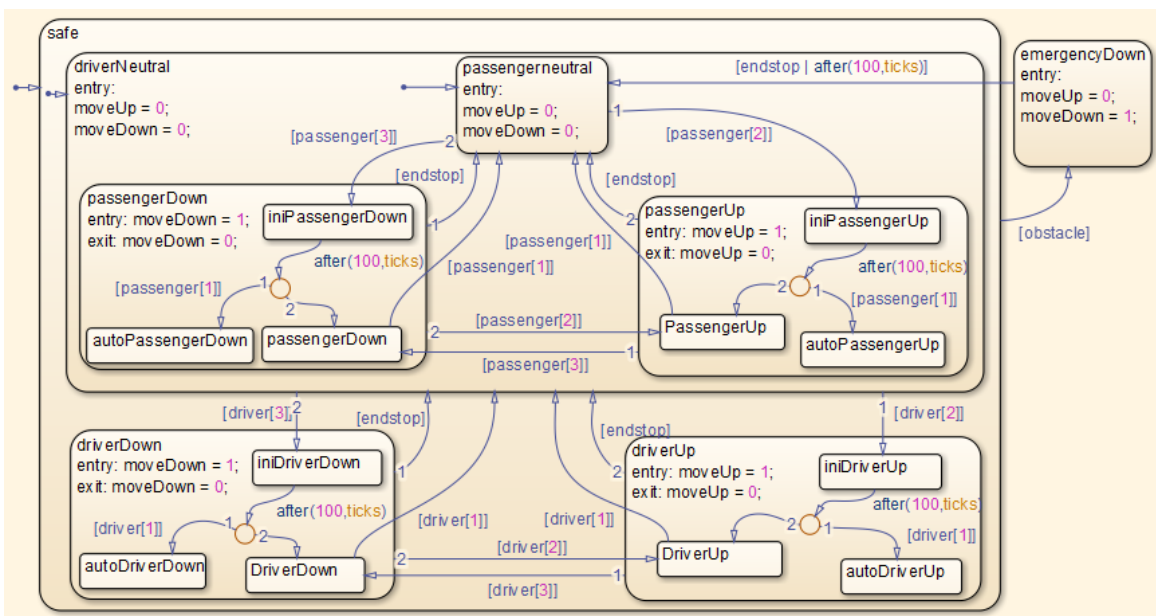

In this implementation, open the power window control subsystem and observe that the Stateflow chart with the discrete-event control forms the CSPEC, represented by the tilted thick bar in the bottom right corner. The `detect_obstacle_endstop` subsystem encapsulate the threshold detection mechanisms.

The discrete-event control is a Stateflow model that extends the state transition diagram notion with hierarchy and parallelism. State changes because of passenger commands are encapsulated in a *super state* that does not correspond to an active driver command.

Consider the control of the passenger window. The passenger or driver can move this window up and down.

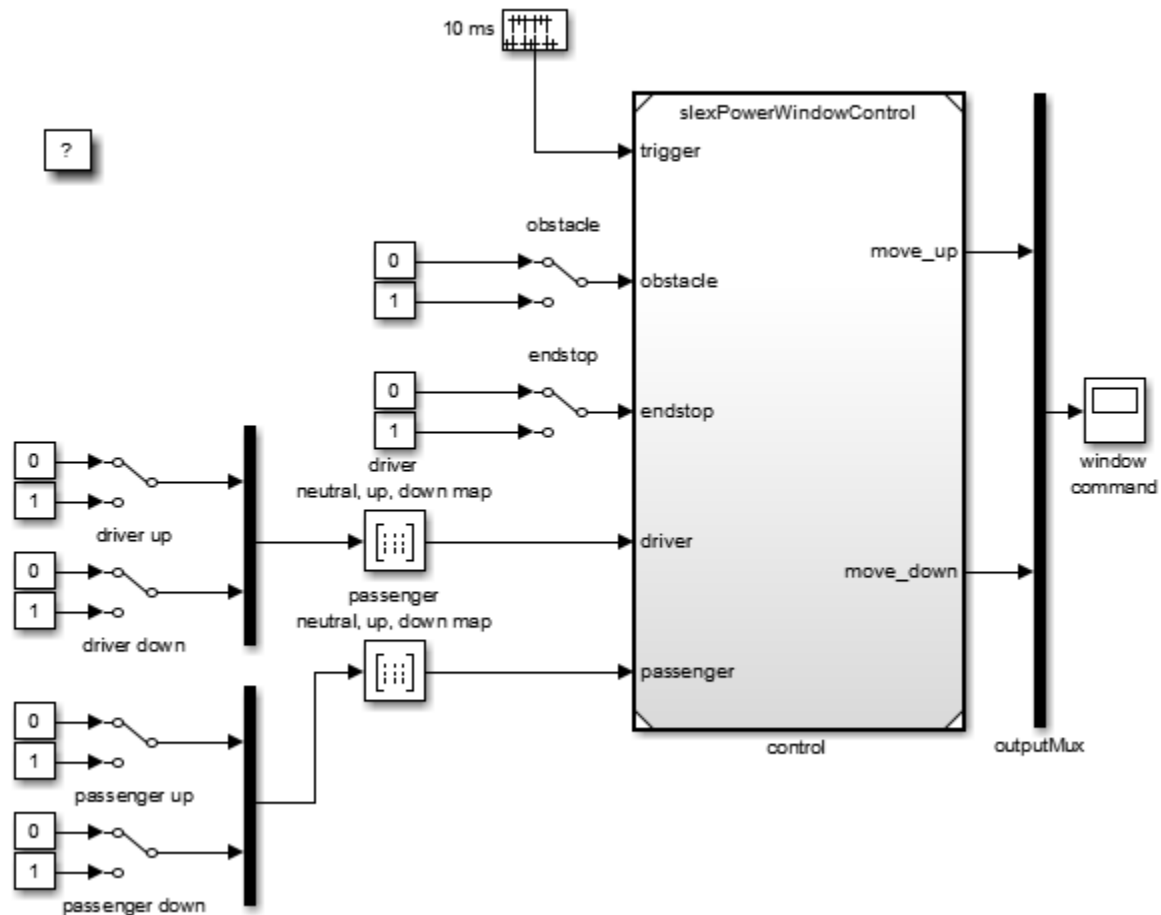

This state machine contains the basic states of the power window system: up, auto-up, down, auto-down, rest, and emergency.

Interactive Testing

Control Input

The `slexPowerWindowCntlInteract` model includes this control input as switches. Double-click these switches to manually operate them.

Test the state machine that controls a power window by running the input test vectors and checking that it reaches the desired internal state and generates output. The power window has the following external inputs:

- Passenger input
- Driver input
- Window up or down
- Obstacle in window

Each input consists of a vector with these inputs.

Passenger Input

Element	Description
neutral	Passenger control switch is not depressed.
up	Passenger control switch generates the up signal.
down	Passenger control switch generates the down signal.

Driver Input

Element	Description
neutral	Driver control switch is not depressed.
up	Driver control switch generates the up signal.
down	Driver control switch generates the down signal.

Window Up or Down

Element	Description
0	Window moves freely between top or bottom.
1	Window is stuck at the top or bottom because of physical limitations.

Obstacle in Window

Element	Description
0	Window moves freely between top or bottom.
1	Window has obstacle in the frame.

Generate the passenger and driver input signals by mapping the up and down signals according to this table:

Inputs		Outputs		
up	down	up	down	neutral
0	0	0	0	1
0	1	0	1	0
1	0	1	0	0
1	1	0	0	1

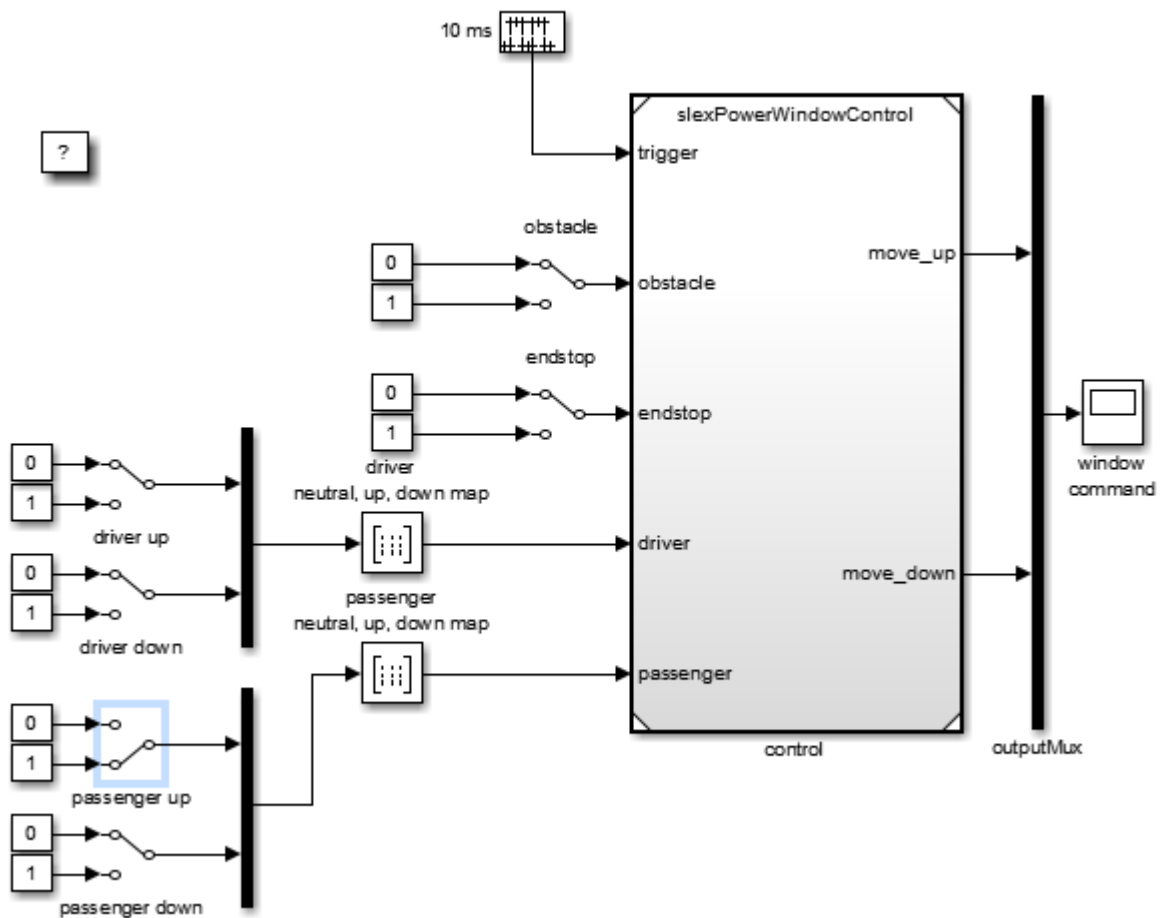

The inputs explicitly generate the `neutral` event from the `up` and `down` events, generated by pressing a power window control switch. The inputs are entered as a truth table in the passenger `neutral, up, down` map and the driver `neutral, up, down` map.

Experimental Results from Interactive Testing**Case 1: Window Up**

To observe the state machine behavior:

- 1 Open the `slexPowerWindowCntlInteract` model.

- Run the simulation and then double-click the passenger up switch.

If you press the physical window switch for more than one second, the window moves up until the up switch is released (or the top of the window frame is reached and the endstop event is generated).

- Double-click the selected passenger up switch to release it.

4 Simulate the model.

Setting the endstop switch generates the endstop event.

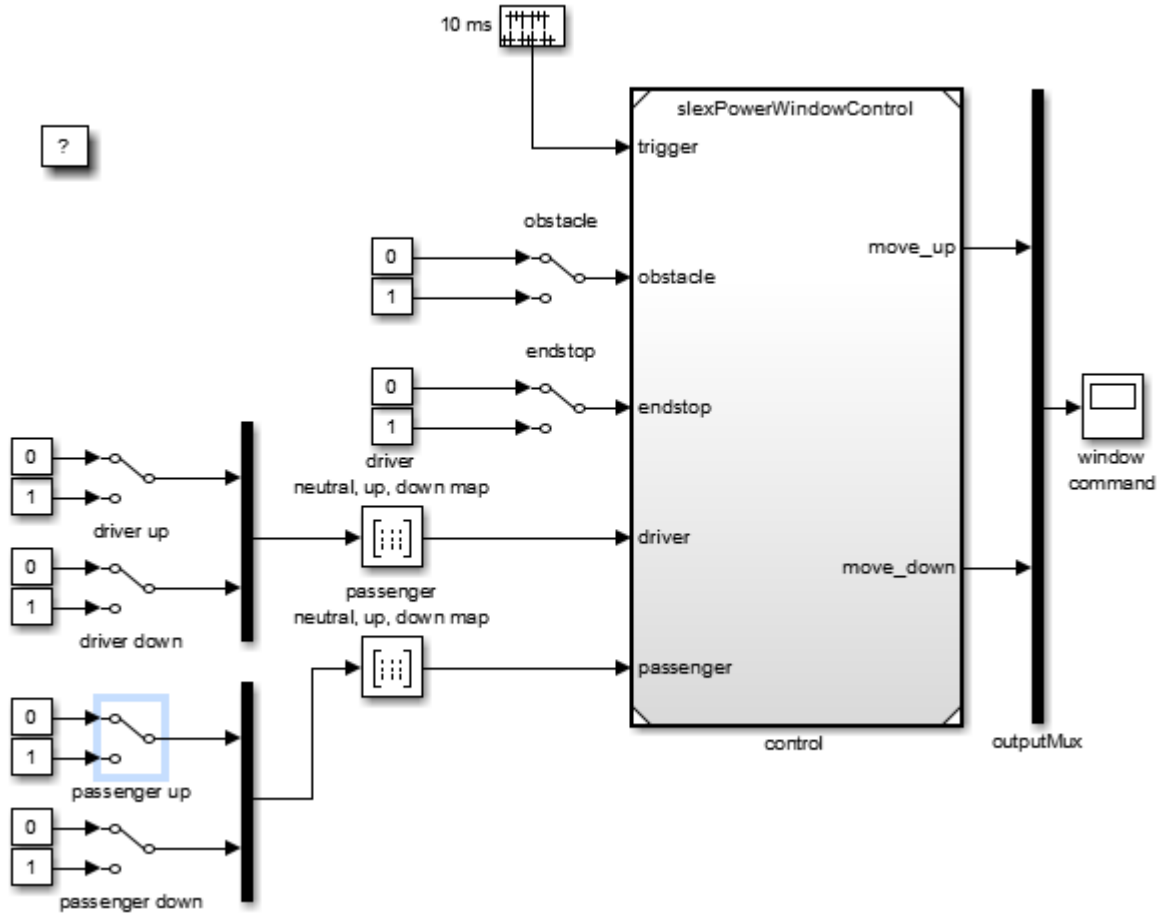

Case 2: Window Auto-Up

If you press the physical passenger window up switch for a short period of time (less than a second), the software activates auto-up behavior and the window continues to move up.

- 1 Press the physical passenger window up switch for a short period of time (less than a second).

Ultimately, the window reaches the top of the frame and the software generates the endstop event. This event moves the state machine back to its neutral state.

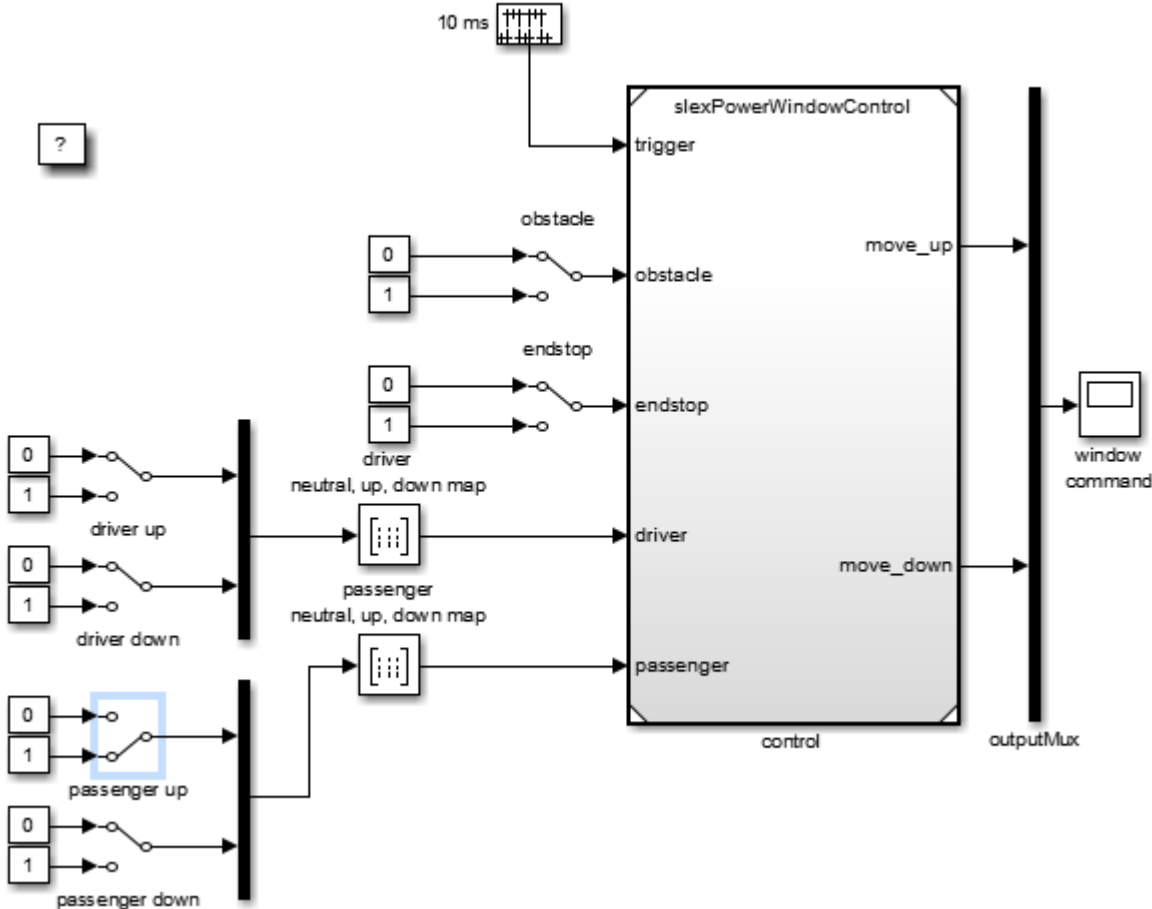

2 Simulate the model.

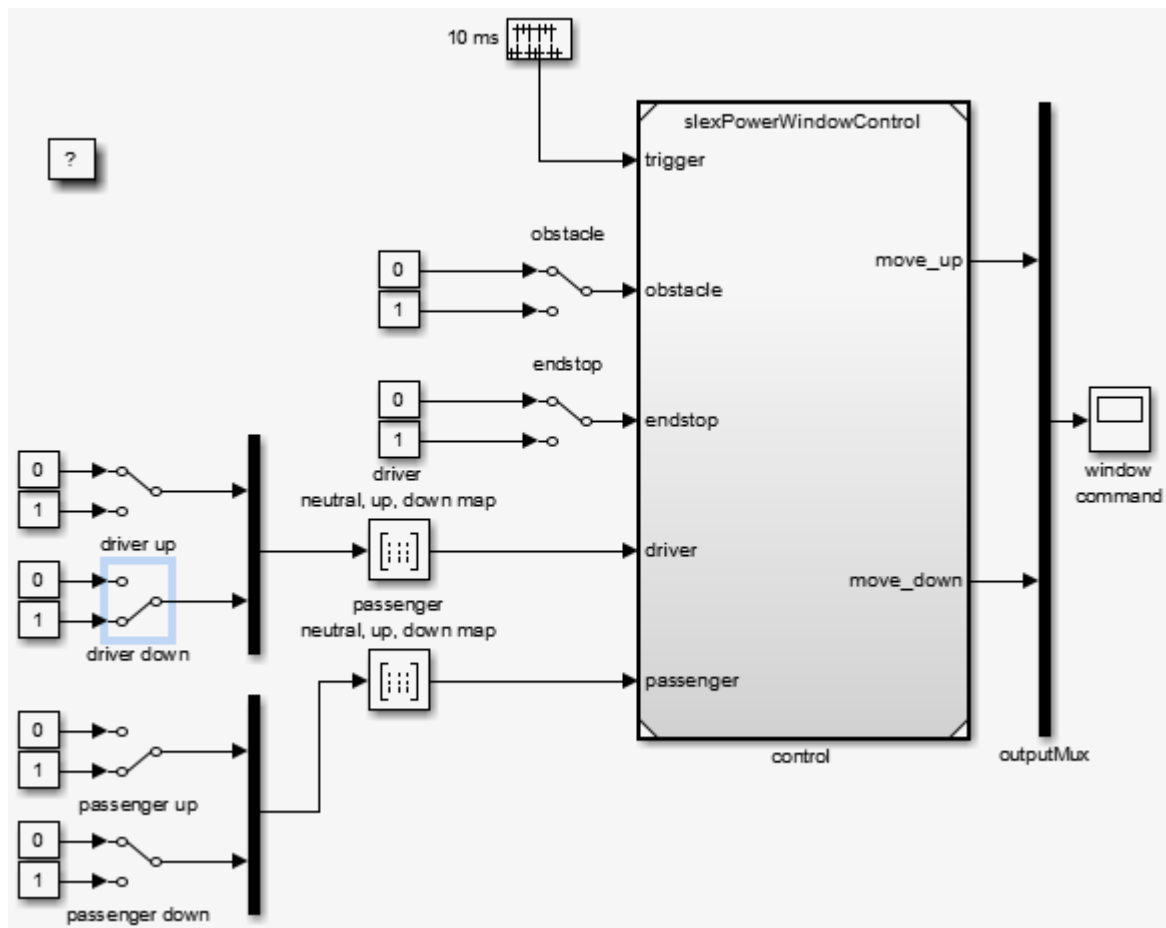

Case 3: Driver-Side Precedence

The driver switch for the passenger window takes precedence over the driver commands. To observe the state machine behavior in this case:

- 1 Run the simulation, and then move the system to the `passenger up` state by double-clicking the passenger window up switch.

2 Double-click the driver down switch.

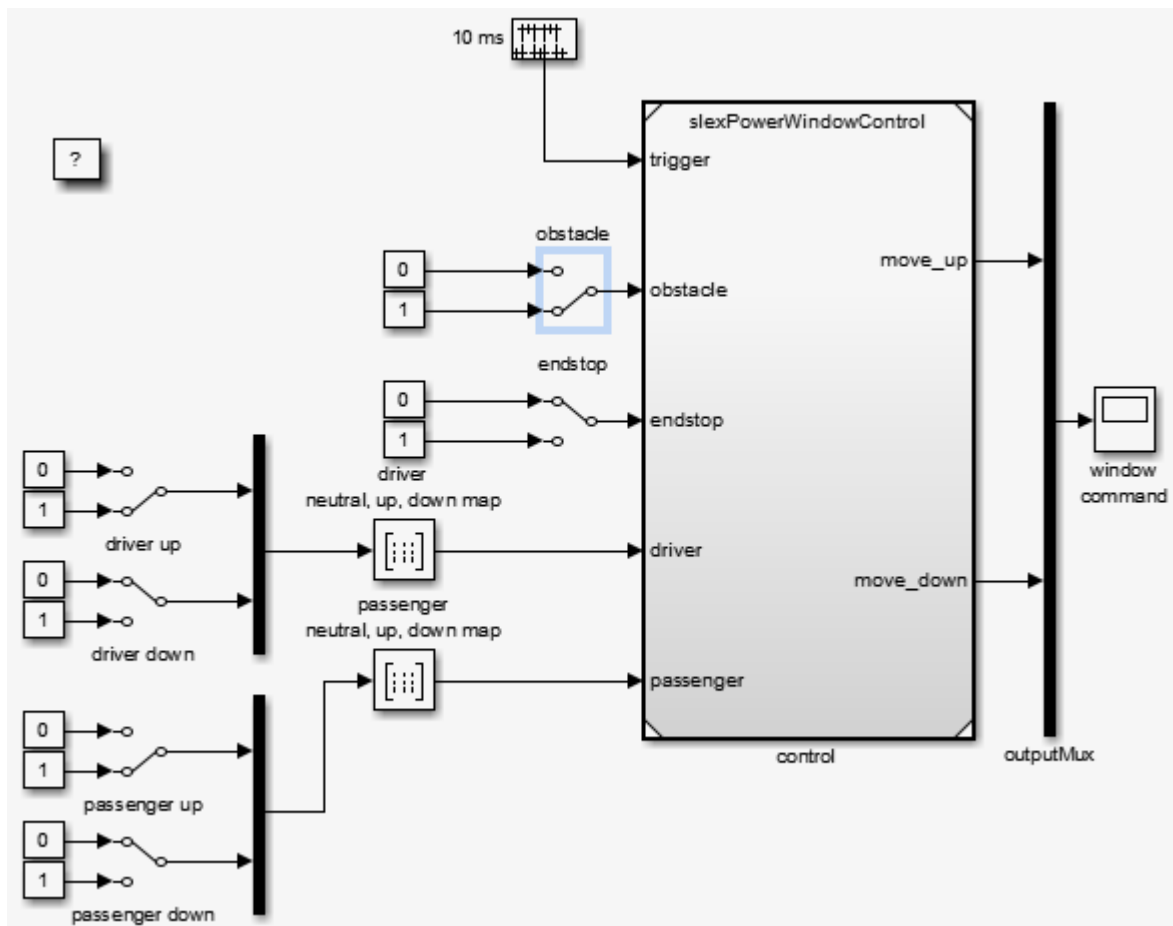

- 3 Simulate the model.
- 4 Notice how the state machine moves to the driver control part to generate the window down output instead of the window up output.
- 5 Double-click the driver control to driver up. Double-click the driver down switch.

The driver window up state is reached, which generates the window up output again, i.e., $windowUp = 1$.

- 6 To observe state behavior when an object is between the window and the frame, double-click the obstacle switch.

7 Simulate the model.

On the next sample time, the state machine moves to its `emergencyDown` state to lower the window a few inches. How far the software lowers the window depends on how long the state machine is in the `emergencyDown` state. This behavior is part of the next analysis phase.

If a driver or passenger window switch is still active, the state machine moves into the up or down states upon the next sample time after leaving the emergency state. If the obstacle switch is also still active, the software again activates the emergency state at the next sample time.

Model Coverage

Validation of the Control Subsystem

Validate the discrete-event control of the window using the model coverage tool. This tool helps you determine the extent to which a model test case exercises the conditional branches of the controller. It helps evaluate whether all transitions in the discrete-event control are taken, given the test case, and whether all clauses in a condition that enables a particular transition have become true. Multiple clauses can enable one transition, e.g., the transition from `emergency` back to `neutral` occurs when either 100 ticks have occurred or if the endstop is reached.

To achieve full coverage, each clause evaluates to true and false for the test cases used. The percentage of transitions that a test case exercises is called its model coverage. Model coverage is a measure of how thoroughly a test exercises a model.

Using Simulink Coverage software, you can apply the following test to the power window controller.

Position	Step						
	0	1	2	3	4	5	6
Passenger up	0	0	0	0	0	0	0
Passenger down	0	0	0	1	0	1	1
Driver up	0	0	1	0	1	0	1
Driver down	0	1	0	0	1	1	0

With this test, all switches are inactive at time 0. At regular 1 s steps, the state of one or more switches changes. For example, after 1 s, the driver down switch becomes active. To automatically run these input vectors, replace the manual switches by prescribed sequences of input. To see the preconstructed model:

- 1 In the MATLAB Command Window, type:

```
slexPowerWindowCntlCoverage
```

- 2 Simulate the model to generate the Simulink Coverage coverage report.

For the `sllexPowerWindowCntlCoverage` model, the report reveals that this test handles 100% of the decision outcomes from the driver neutral, up, down map block. However, the test achieves only 50% coverage for the passenger neutral, up, down map block. This coverage means the overall

coverage for `slexPowerWindowCntlCoverage` is 45% while the overall coverage for the `slexPowerWindowControl` model is 42%. A few of the contributing factors for the coverage levels are:

- Passenger up block does not change.
- Endstop and obstacle blocks do not change.

Increase Model Coverage

To increase total coverage to 100%, you need to take into account all possible combinations of driver, passenger, obstacle, and endstop settings. When you are satisfied with the control behavior, you can create the power window system. For more information, see “Create Model Using Model-Based Design” on page 23-26.

This example increases the model coverage for the validation of the discrete-event control of the window. To start, the example uses inputs from `slexPowerWindowCntlCoverage` as a baseline for the model coverage. Next, to further exercise the discrete-event control of the window, it creates more input sets. The spreadsheet file, `inputCntlCoverageIncrease.xlsx`, contains these input sets using one input set per sheet.

In the example, the `slexPowerWindowSpreadsheetGeneration` utility function, which creates a spreadsheet template from the controller model, `slexPowerWindowControl`, creates the `inputCntlCoverageIncrease.xlsx`. In `inputCntlCoverageIncrease.xlsx`, the function uses the block names in the controller model as signal names. `slexPowerWindowSpreadsheetGeneration` defines the sheet names. The `slexWindowSpreadsheetAddInput` utility function populates `inputCntlCoverageIncrease.xlsx` with signal data.

The sheet names of these input sets and their descriptions are:

Sheet Name	Description
Logged	Inputs logged from <code>slexPowerWindowCntlCoverage</code>
LoggedObstacleOffEndStopOn	Inputs logged from <code>slexPowerWindowCntlCoverage</code> with ability to hit endstop
LoggedObstacleOnEndStopOff	Inputs logged from <code>slexPowerWindowCntlCoverage</code> with obstacle in window
LoggedObstacleOnEndStopOn	Inputs logged from <code>slexPowerWindowCntlCoverage</code> with obstacle in window and ability to hit endstop
DriverLoggedPassengerNeutral	Inputs logged from <code>slexPowerWindowCntlCoverage</code> for driver only and passenger takes no action
DriverDownPassengerNeutral	Driver is putting down window and passenger takes no action
DriverUpPassengerNeutral	Driver is putting up window and passenger takes no action
DriverAutoDownPassengerNeutral	Driver is putting down window for one second (auto-down) and passenger takes no action
DriverAutoUpPassengerNeutral	Driver is putting up window for one second (auto-up) and passenger takes no action
PassengerAutoDownDriverNeutral	Passenger is putting down window for one second (auto-down) and driver takes no action

Sheet Name	Description
PassengerAutoUpDriverNeutral	Passenger is putting up window for one second (auto-up) and driver takes no action

To automatically run these input vectors, replace the inputs to the discrete-event control with the From Spreadsheet block using the file, `inputCntlCoverageIncrease.xlsx`. This file contains the multiple input sets. To see the preconstructed model:

- 1 In the MATLAB Command Window, type:

```
slexPowerWindowCntlCoverageIncrease
```

- 2 To generate the Simulink Coverage coverage report for multiple input set, double click the Run Coverage subsystem in the model.

For the `slexPowerWindowCntlCoverageIncrease` model, the report reveals that using multiple input sets has successfully raised the overall coverage for the `slexPowerWindowControl` model from 42% to 78%. Coverage levels are less than 100% because of missing input sets for:

- Passenger up state

- Driver up and down states
- Passenger automatic down and automatic up states

Create Model Using Model-Based Design

Why Use Model-Based Design?

In Model-Based Design, a system model is at the center of the development process, from requirements development, through design implementation, and testing. Use Model-Based Design to:

- Use a common design environment across project teams.
- Link designs directly to requirements.
- Integrate testing with design to continuously identify and correct errors.
- Refine algorithms through multidomain simulation.
- Automatically generate embedded software code.
- Develop and reuse test suites.
- Automatically generate documentation for the model.
- Reuse designs to deploy systems across multiple processors and hardware targets.

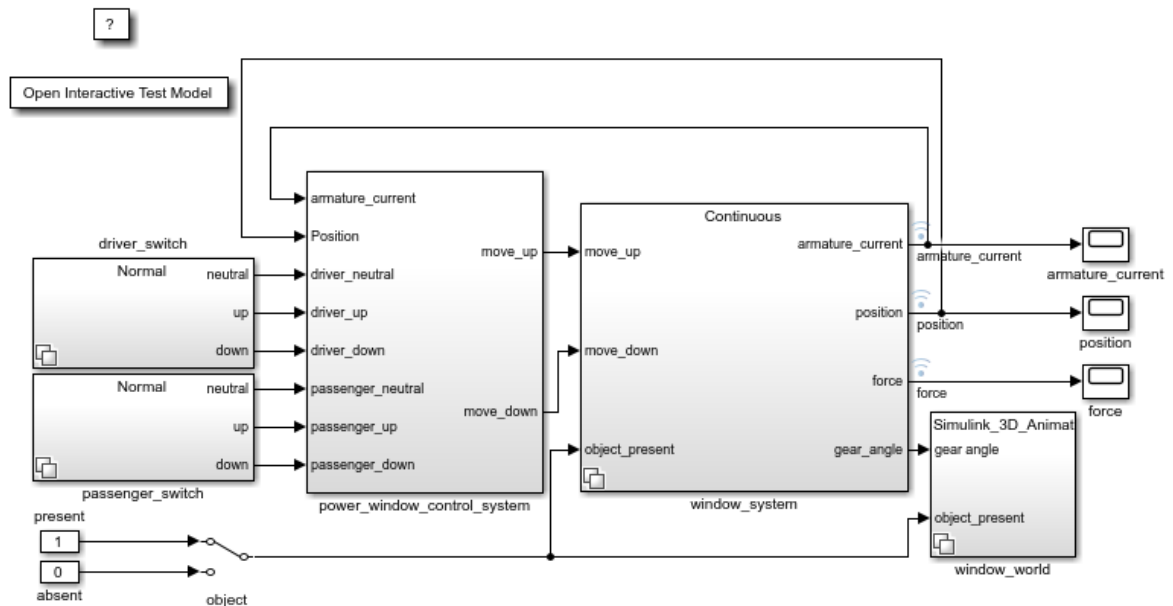

Implementation of Context Diagram: Power Window System

For requirements presented as a context diagram, see “Context Diagram: Power Window System” on page 23-4.

Create a Simulink model to resemble the context diagram.

- 1** Place the plant behavior into one subsystem.
- 2** Create two subsystems that contain the driver and passenger switches.
- 3** Add a control mechanism to conveniently switch between the presence and absence of the object.
- 4** Put the control in one subsystem.
- 5** Connect the new subsystems.
- 6** To see an implementation of this model, in the MATLAB Command Window, type:

```
slexPowerWindowStart
```

You can use the power window control activity diagram (“Activity Diagram: Power Window Control” on page 23-4) to decompose the power window controller of the context diagram into parts. This diagram shows the input and output signals present in the context diagram for easier tracing to their origins.

Implement Power Window Control System

To satisfy full requirements, the power window control must work with the validation of the driver and passenger inputs and detect the endstop.

For requirements presented as an activity diagram, see “Activity Diagram: Power Window Control” on page 23-4.

Double-click the `slexPowerWindowExample/power_window_control_system` block to open the following subsystem:

Implementation of Activity Diagram: Validate

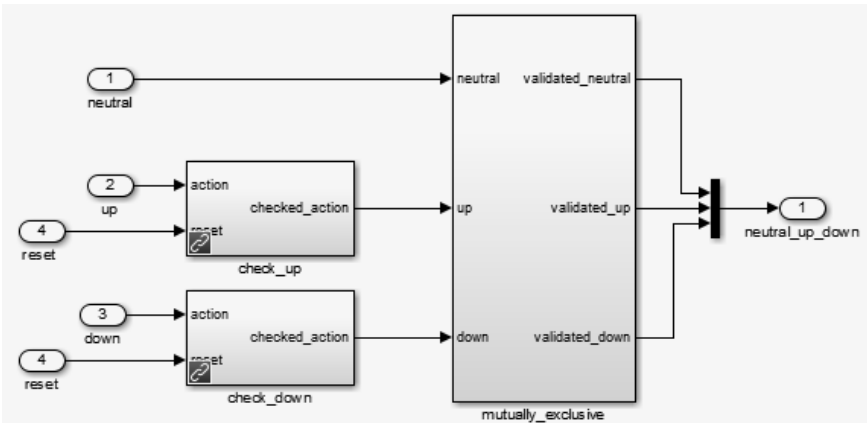

For requirements presented as activity diagrams, see “Activity Diagram: Validate Driver” on page 23-5 and “Activity Diagram: Validate Passenger” on page 23-6.

The activity diagram adds data validation functionality for the driver and passenger commands to ensure correct operation. For example, when the window reaches the top, the software blocks the up command. The implementation decomposes each validation process in new subsystems. Consider the validation of the driver commands (validation of the passenger commands is similar). Check if the model can execute the up or down commands, according to the following:

- The model allows the down command only when the window is not completely opened.
- The model allows the up command only when the window is not completely closed and no object is detected.

The third activity diagram process checks that the software sends only one of the three commands (`neutral`, `up`, `down`) to the controller. In an actual implementation, both up and down can be simultaneously true (for example, because of switch bouncing effects).

From the `power_window_control_system` subsystem, this is the `validate_driver_state` subsystem:

From the power_window_control_system subsystem, this is the validate_passenger_state subsystem:

Implementation of Activity Diagram: Detect Obstacle Endstop

For requirements presented as an activity diagram, see “Activity Diagram: Detect Obstacle Endstop” on page 23-7.

In the slxPowerWindowExample model, the power_window_control_system/detect_obstacle_endstop block implements this activity diagram in the continuous variant of the Variant Subsystem block. During design iterations, you can add additional variants.

Double-click the slxPowerWindowExample model power_window_control_system/detect_obstacle_endstop/Continuous/verify_position block:

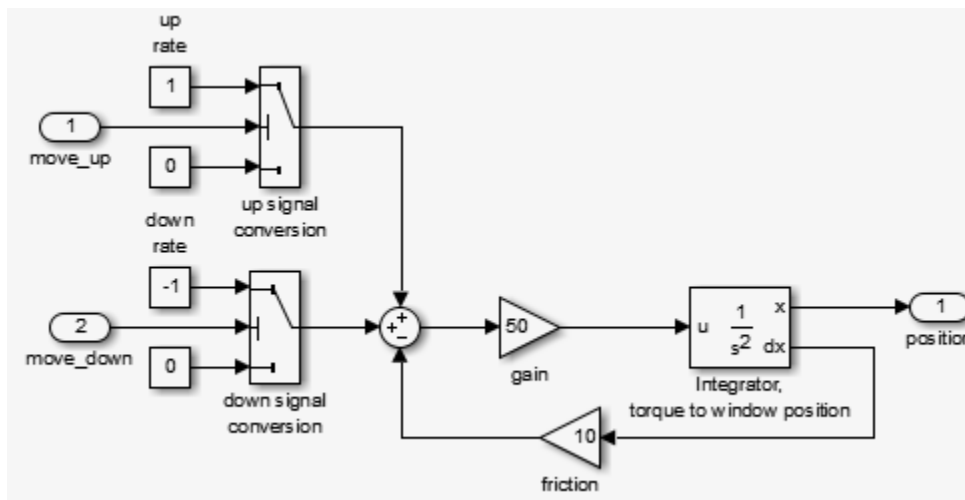

Hybrid Dynamic System: Combine Discrete-Event Control and Continuous Plant

After you have designed and verified the discrete-event control, integrate it with the continuous-time plant behavior. This step is the first iteration of the design with the simplest version of the plant.

In the project, navigate to **Files** and click **Project**. In the **configureModel** folder, run the `slexPowerWindowContinuous` utility to open and initialize the model.

The `window_system` block uses the Variant Subsystem block to allow for varying levels of fidelity in the plant modeling. Double-click the `window_system/Continuous/2nd_order_window_system` block to see the continuous variant.

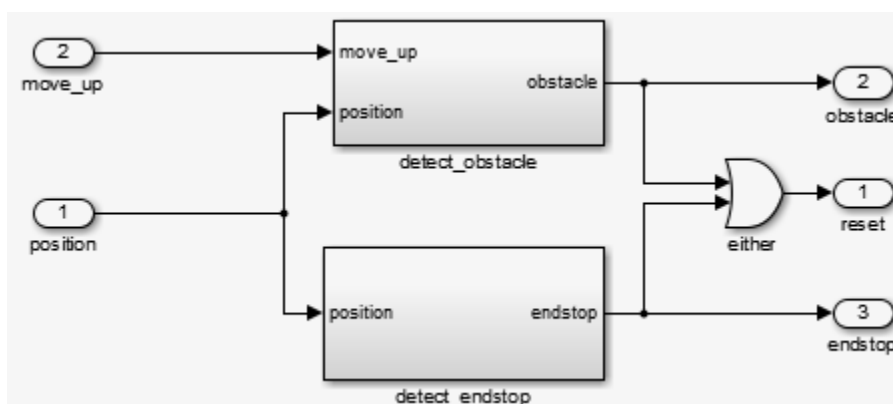

The plant is modeled as a second-order differential equation with step-wise changes in its input:

- When the Stateflow chart generates `windowUp`, the input is 1.
- When the Stateflow chart generates `windowDown`, the input is -1.
- Otherwise, the input is 0.

This phase allows analysis of the interaction between the discrete-event state behavior, its sample rate, and the continuous behavior of the window movement. There are threshold values to generate the window frame top and bottom:

- `endStop`
- Event when an obstacle is present, that is, `obstacle`
- Other events

Double-click the `slexPowerWindowExample` model `power_window_control_system/-detect_obstacle_endstop/Continuous/verify_position` block to see the continuous variant.

When you run the `slexPowerWindowContinuous` `configureModel` utility, the model uses the continuous time solver `ode23` (Bogacki-Shampine).

A structure analysis of a system results in:

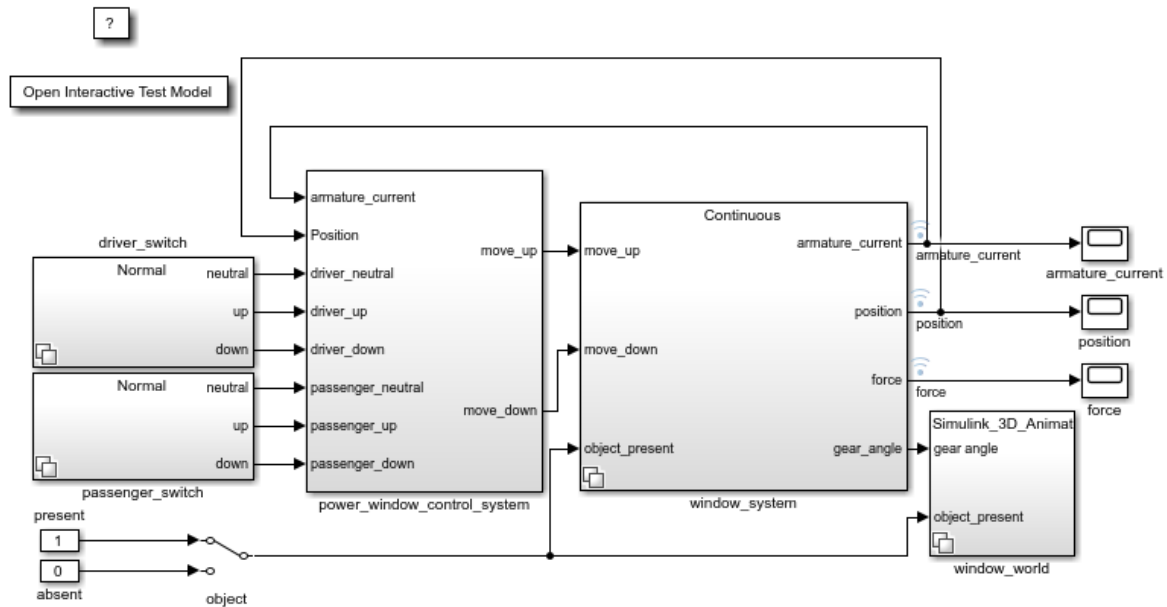

- A functional decomposition of the system
- Data definitions with the specifics of the system signals
- Timing constraints

A structure analysis can also include the implementation architecture (outside the scope of this discussion).

The implementation also adds a control mechanism to conveniently switch between the presence and absence of the object.

Expected Controller Response

To view the window movement, in **Project Shortcuts**, double-click SimHybridPlantLowOrder. Alternatively, you can run the task `slexPowerWindowContinuousSim`.

The position scope shows the expected result from the controller. After 30 cm, the model generates the `obstacle` event and the Stateflow chart moves into its `emergencyDown` state. In this state, `windowDown` is output until the window lowers by about 10 cm. Because the passenger window up switch is still on, the window starts moving up again and this process repeats. Stop the simulation and open the position scope to observe the oscillating process. In case of an emergency, the discrete-event control rolls down the window approximately 10 cm.

Detailed Modeling of Power Effects

After an initial analysis of the discrete-event control and continuous dynamics, you can use a detailed plant model to evaluate performance in a more realistic situation. It is best to design models at such a level of detail in the power domain, in other words, as energy flows. Several domain-specific MathWorks blocksets can help with this.

To take into account energy flows, add a more detailed variant consisting of power electronics and a multibody system to the `window_system` variant subsystem.

To open the model and explore the more detailed plant variant, in the project, run `configureModel slexPowerWindowPowerEffects`.

Double-click the `slexPowerWindowExample` model `window_system/Power Effects - Visualization/detailed_window_system` block.

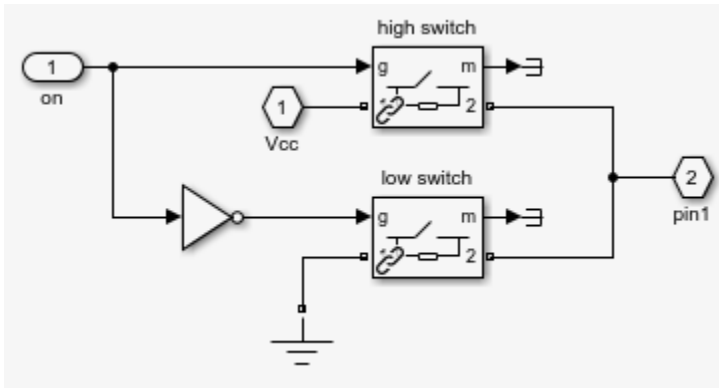

Power Electronics Subsystem

The model must amplify the control signals generated by the discrete-event controller to be powerful enough to drive the DC motor that moves the window.

The amplification modules model this behavior. They show that a switch either connects the DC motor to the battery voltage or ground. By connecting the battery in reverse, the system generates a negative voltage and the window can move up, down, or remain still. The window is always driven at maximum power. In other words, no DC motor controller applies a prescribed velocity.

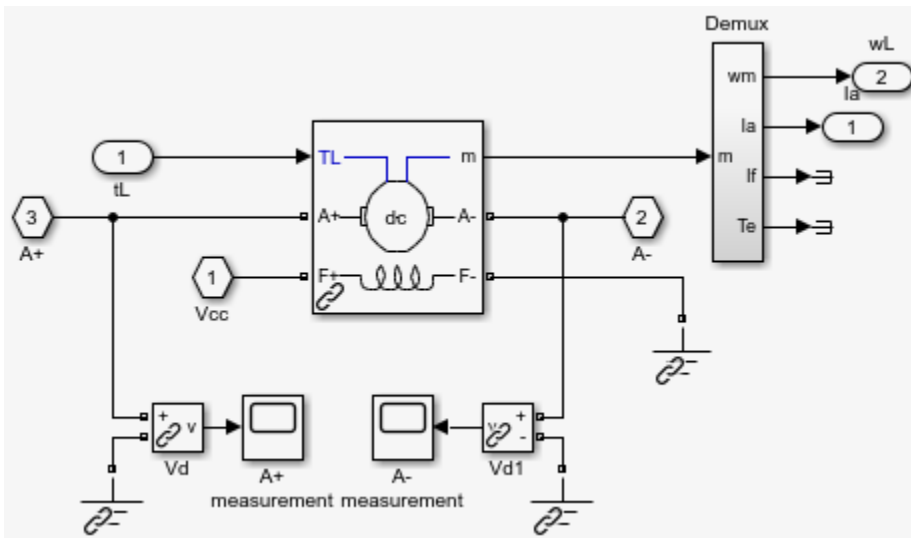

To see the implementation, double-click the `slexPowerWindowExample` model `window_system/Power Effects - Visualization/detailed_window_system/amplification_up` block.

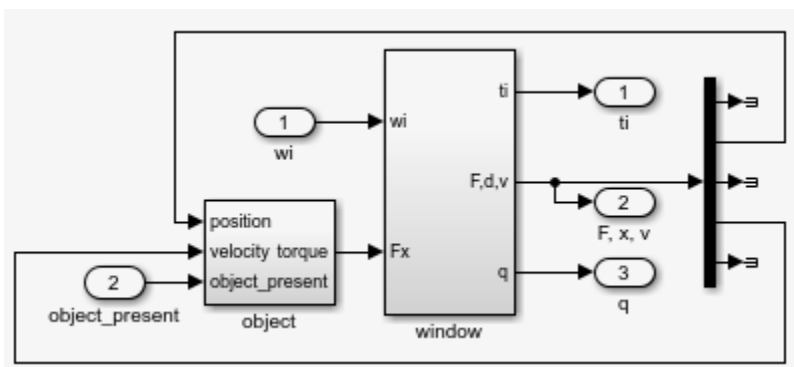

Multibody System

This implementation models the window using Simscape Multibody blocks.

To see the actuator implementation, double-click the `slexPowerWindowExample` model `window_system/Power Effects - Visualization/detailed_window_system/actuator` block.

To see the window implementation, double-click the `slexPowerWindowExample` model `window_system/Power Effects - Visualization/detailed_window_system/plant` block.

This implementation uses Simscape Multibody blocks for bodies, joints, and actuators. The window model consists of:

- A worm gear
- A lever to move the window holder in the vertical direction

The figure shows how the mechanical parts move.

Iterate on the Design

An important effect of the more detailed implementation is that there is no window position measurement available. Instead, the model measures the DC motor current and uses it to detect the endstops and to see if an obstacle is present. The next stage of the system design analyzes the control to make sure that it does not cause excessive force when an obstacle is present.

In the original system, the design removes the obstacle and endstop detection based on the window position and replaces it with a current-based implementation. It also connects the process to the controller and position and force measurements. To reflect the different signals used, you must modify the data definition. In addition, observe that, because of power effects, the units are now amps.

PSPEC 1.3.1: DETECT ENDSTOP
 $ENDSTOP = ARMATURE_CURRENT > ENDSTOP_MAX$

PSPEC 1.3.2: DETECT OBSTACLE
 $OBSTACLE = (ARMATURE_CURRENT > OBSTACLE_MAX) \text{ and } MOVE_UP \text{ for } 500 \text{ ms}$

PSPEC 1.3.3: ABSOLUTE VALUE
 $ABSOLUTE_ARMATURE_CURRENT = abs(ARMATURE_CURRENT)$

This table lists the additional signal for the Context Diagram: Power Window System data definitions.

Context Diagram: Power Window System Data Definition Changes

Signal	Information Type	Continuous/ Discrete	Data Type	Values
ARMATURE_CURRENT	Data	Continuous	Real	-20 to 20 A

This table lists the changed signals for the Activity Diagram: Detect Obstacle Endstop data definitions.

Activity Diagram: Detect Obstacle Endstop Data Definition Changes

Signal	Information Type	Continuous/Constant	Data Type	Values
ABSOLUTE_ARMATURE_CURRENT	Data	Continuous	Real	0 to 20 A
ENDSTOP_MAX	Data	Constant	Real	15 A
OBSTACLE_MAX	Data	Constant	Real	2.5 A

To see the window subsystem, double-click the `slexPowerWindowExample` model `window_system/Power Effects - Visualization/detailed_window_system/plant/window` block.

The implementation uses a lookup table and adds noise to allow evaluation of the control robustness. To see the implementation of the friction subsystem, double-click the `slexPowerWindowExample` model `window_system/Power Effects - Visualization/detailed_window_system/plant/window/friction` block.

Control Law Evaluation

The idealized continuous plant allows access to the window position for `endStop` and `obstacle` event generation. In the more realistic implementation, the model must generate these events from accessible physical variables. For power window systems, this physical variable is typically the armature current, I_a , of the DC motor that drives the worm gear.

When the window is moving, this current has an approximate value of 2 A. When you switch the window on, the model draws a transient current that can reach a value of approximately 10 A. When the current exceeds 15 A, the model activates endstop detection. The model draws this current when the angular velocity of the motor is kept at almost 0 despite a positive or negative input voltage.

Detecting the presence of an object is more difficult in this setup. Because safety concerns restrict the window force to no more than 100 N, an armature current much less than 10 A should detect an object. However, this behavior conflicts with the transient values achieved during normal operation.

Implement a control law that disables object detection during achieved transient values. Now, when the system detects an armature current more than 2 A, it considers an object to be present and enters the `emergencyDown` state of the discrete-event control. Open the force scope window (measurements are in newtons) to check that the force exerted remains less than 100 N when an object is present and the window reverses its velocity.

In reality, far more sophisticated control laws are possible and implemented. For example, you can implement neural-network-based learning feedforward control techniques to emulate the friction characteristic of each individual vehicle and changes over time.

Visualization of the System in Motion

If you have Simulink 3D Animation software installed, you can view the geometrics of the system in motion via a virtual reality world. If the VR Sink block is not yet open, in the `slexPowerWindowExample/window_world/Simulink_3D_Animation` View model, double-click the VR Sink block.

To simulate the model with a stiff solver:

- 1 In a project, run the task, `slexPowerWindowPowerEffectsSim`. This batch job sets the solver to `ode23tb` (stiff/TR-BDF2).
- 2 In the `slexPowerWindowExample` model `passenger_switch/Normal` block, set the passenger up switch to on.
- 3 In the `slexPowerWindowExample` model `driver_switch/Normal` block, set the driver up switch to off.
- 4 Simulate the model.
- 5 Between 10 ms and 1 s in simulation time, switch off the `slexPowerWindowExample/passenger_switch/Normal` block passenger up switch to initiate the auto-up behavior.

- 6 Observe how the window holder starts to move vertically to close the window. When the model encounters the object, it rolls the window down.
- 7 Double-click the `slexPowerWindowExample` model `passenger_switch/Normal` block driver down switch to roll down the window completely and then simulate the model. In this block, at less than one second simulation time, switch off the driver down switch to initiate the auto-down behavior.

- 8 When the window reaches the bottom of the frame, stop the simulation.
- 9 Look at the position measurement (in meters) and at the armature current (I_a) measurement (in amps).

Note The absolute value of the armature current transient during normal behavior does not exceed 10 A. The model detects the obstacle when the absolute value of the armature current required to move the window up exceeds 2.5 A (in fact, it is less than -2.5 A). During normal operation, this is about 2 A. You might have to zoom into the scope to see this measurement. The model detects the window endstop when the absolute value of the armature current exceeds 15 A.

Variation in the armature current during normal operation is due to friction that is included by sensing joint velocities and positions and applying window specific coefficients.

Realistic Armature Measurement

The armature current as used in the power window control is an ideal value that is accessible because of the use of an actuator model. In a more realistic situation, data acquisition components must measure this current value.

To include data acquisition components, add the more realistic measurement variant to the window_system variant subsystem. This realistic measurement variant contains a signal conditioning block in which the current is derived based on a voltage measurement.

To open a model and configure the realistic measurement, in the project, run the configureModel task `slexPowerWindowRealisticArmature`.

To view the contents of the Realistic Armature - Communications Protocol block, double-click the `SlexPowerWindowExample` model `window_system/Realistic Armature - Communications Protocol/detailed_window_system_with_DAQ`.

The measurement voltage is within the range of an analog-to-digital converter (ADC) that discretizes based on a given number of bits. You must scale the resulting value based on the value of the resistor and the range of the ADC.

Include these operations as fixed-point computations. To achieve the necessary resolution with the given range, 16 bits are required instead of 8.

Study the same scenario:

- 1 In the `slexPowerWindowExample/passenger_switch/Normal` block, set the passenger up switch.
- 2 Run the simulation.
- 3 After some time, in the `slexPowerWindowExample/passenger_switch/Normal` block, switch off the passenger up switch.
- 4 When the window has been rolled down, click the `slexPowerWindowExample/passenger_switch/Normal` block driver down switch.

- 5 After some time, switch off the `slexPowerWindowExample/passenger_switch/Normal` block driver down switch.
- 6 When the window reaches the bottom of the frame, stop the simulation.
- 7 Zoom into the `armature_current` scope window and notice the discretized appearance.

Communication Protocols

Similar to the power window output control, hardware must generate the input events. In this case, the hardware is the window control switches in the door and center control panels. Local processors generate these events and then communicate them to the window controller via a CAN bus.

To include these events, add a variant containing input from a CAN bus and switch components that generate the events delivered on the CAN bus to the driver switch and passenger switch variant subsystems. To open the model and configure the CAN communication protocols, run the `configureModel` task, `slexPowerWindowCommunicationProtocolSim`.

To see the implementation of the switch subsystem, double-click the `slexPowerWindowExample/driver_switch/Communication Protocol/driver window control switch` block.

Observe a structure that is very similar to the window control system. This structure contains a:

- Plant model that represents the control switch
- Data acquisition subsystem that includes, among other things, signal conditioning components
- Control module to map the commands from the physical switch to logical commands
- CAN module to post the events to the vehicle data bus

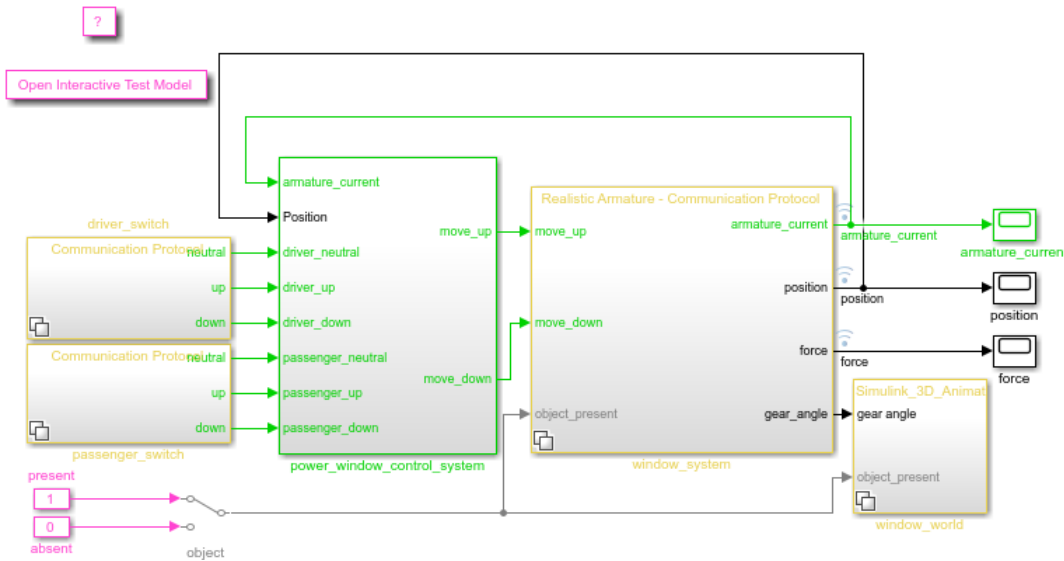

You can add communication effects, such as other systems using the CAN bus, and more realism similar to the described phases. Each phase allows analysis of the discrete-event controller in an increasingly realistic situation. When you have enough detail, you can automatically generate controller code for any specific target platform.

Automatic Code Generation for Control Subsystem

You can generate code for the designed control model, `slexPowerWindowExample`.

- 1 Display the sample rates of the controller. In the Simulink Editor, on the **Debug** tab, select **Information Overlays > Sample Time > Colors**. Observe that the controller runs at a uniform sample rate.

- 2 Right-click the power_window_control_system block and select **C/C++ Code > Build This Subsystem**.

What are Partitions?

Partitions are components of a model that execute independently as atomic tasks. In multi-tasking models, partitions are created from model components. Periodic partitions are scheduled as a function of sample times in a model. In export-function models, the root function-call inputs are defined as partitions. These partitions have a schedule associated with it, which tells order in which the partitions execute.

With partitions, you can separate parts of the model which you can explicitly control. You can think of periodic partitions as components that run at specific rates in a model. Aperiodic partitions are components that run at specified hit times. The schedule of these partitions have an impact on simulation and code generation.

The Schedule Editor enables you to partition the model and interact with those partitions. The Schedule Editor shows partitions, the connections between them, and the ordering of the partitions

There are three types of partitions:

Types of Partitions	Image	Description
Implicit		Automatically created by Simulink. Blocks running at the base rate show up as an implicit partition.
Periodic		User-defined partitions from the atomic subsystems and/or Model blocks. Periodic partitions can also be defined by export-functions. These partitions execute based on their sample time and thus their execution is periodic.
Aperiodic		Aperiodic partitions are partitions which have no constraints and can be made to execute at any time. Specify the hit times in the Property Inspector of the Schedule Editor, at which you want to run the aperiodic partition. You can also use events in the Schedule Editor to schedule execution of the aperiodic partitions.

The blocks running at the base rate in the model is shown as an implicit partition in the Schedule Editor. The base rate is the fastest discrete rate in the model. *D1* denotes the base rate. *D1* annotation also appears in the Timing Legend. The *D1* partition or implicit partition always remains the first discrete partition in the order.

The default partitions that are already present in the model are also implicit partitions.

The partition colors match their rate.

Create Partitions

Partitioning a Model

Partitions are components of a model that execute independently as atomic tasks. In multi-tasking models, partitions are created from model components. Periodic partitions are scheduled as a function of sample times in a model. In export-function models, the root function-call inputs are defined as partitions. These partitions have a schedule associated with them, which tells what order the partitions execute.

With partitions, you can separate parts of the model which you can explicitly control. You can think of periodic partitions as components that run at specific rates in a model. Aperiodic partitions are components that run at specified hit times or specified events. The schedule of these partitions have an impact on simulation and code generation.

The Schedule Editor enables you to partition the model and interact with those partitions. The Schedule Editor shows partitions, the connections between them, and the order of the partitions.

There are three types of partitions:

Types of Partitions	Image	Description
Implicit		Automatically created by Simulink. Blocks running at the base rate show up as an implicit partition.
Periodic		User-defined partitions from the atomic subsystems and/or Model blocks. Periodic partitions can also be defined by export-functions. These partitions execute based on their sample time and thus their execution is periodic.
Aperiodic		Aperiodic partitions are partitions which have no constraints and can be made to execute at any time. Specify the hit times in the Property Inspector of the Schedule Editor, at which you want to run the aperiodic partition. You can also use events in the Schedule Editor to schedule execution of the aperiodic partitions.

The blocks running at the base rate in the model is shown as an implicit partition in the Schedule Editor. The base rate is the fastest discrete rate in the model. *D1* denotes the base rate. *D1* annotation also appears in the Timing Legend. The *D1* partition or implicit partition always remains the first discrete partition in the order.

The default partitions that are already present in the model are also implicit partitions.

The partition colors match their rate.

Create Partitions from a Rate-Based Model

Partitioning is enabled only on multitasking, fixed-step and variable-step solver models. To choose multitasking execution mode, in Solver selection on the **Solver** pane, select the **Type** to be **Fixed-step** or **Variable-step**. Select the **Treat each discrete rate as a separate task** check box on the **Solver** pane of the Configuration Parameters dialog box. For more information on multitasking execution mode, see “Time-Based Scheduling and Code Generation” (Embedded Coder).

As a best practice, enable the **Automatically handle rate transition for data transfer** setting in the **Solver** pane. When you check **Automatically handle rate transition for data transfer**, Simulink inserts Rate Transition blocks between blocks when rate transitions are detected. Simulink handles rate transitions for asynchronous and periodic tasks. Simulink adds the hidden blocks configured to ensure data integrity and determinism for data transfers. When you check **Treat each discrete rate as a separate task**, Simulink selects multitasking execution for models operating at different rates. It also specifies that groups of blocks with the same execution priority are processed through each stage of simulation (for example, calculating output and updating states) based on task priority.

To see default partitions in the Schedule Editor, open the Schedule Editor. On the **Modeling** tab, click

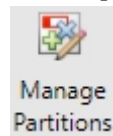

Schedule Editor. Update the diagram by clicking the  icon on the toolbar. The default partitions in the model are called implicit partitions. You can also create partitions in the model through an atomic subsystem or a model block.

Create Partitions Using Manage Partitions

In the Schedule Editor, use the **Manage Partitions** panel to create partitions. To open the **Manage**

Partitions panel, click **Manage Partitions**,  on the Schedule Editor toolbar. The changes made in **Manage Partitions** are applied to the model to create partitions after updating the diagram. **Manage Partitions** shows the model hierarchy with the Subsystem blocks and Model blocks which can be explicitly partitioned.

To create partitions from Subsystem blocks, select the subsystems and click the . To create partitions from Model blocks, select the Model blocks and click . Enter partition names in the column **Partition Name**, and sample times in the column **Sample Time**. Repeat the steps for all the subsystems and Model blocks in the model that you want to partition. Update the diagram to see the created partitions in the Schedule Editor. The partitions appear in the graph with their deduced data dependencies and order.

Note Creating partitions using the **Manage Partitions** panel makes changes to the subsystem or model block parameters.

The following example shows how to configure a model for partitioning and create partitions by using **Manage Partitions** panel in the Schedule Editor.

- 1 Open the model.

sldemo_fuelsys

- 2 Open the Schedule Editor.

Open the Schedule Editor On the **Modeling** tab, click **Schedule Editor**. To see the default partitions, click **Update Diagram** in the Schedule Editor. Two implicit partitions, created automatically by Simulink, are seen in the Schedule Editor.

- 3 Create partitions.

Open the **Manage Partitions** panel. In the panel, expand the `fuel_rate_control` subsystem.

Select the `airflow_calc` subsystem and click . To change the default partition name and sample time, click the default name and sample time.

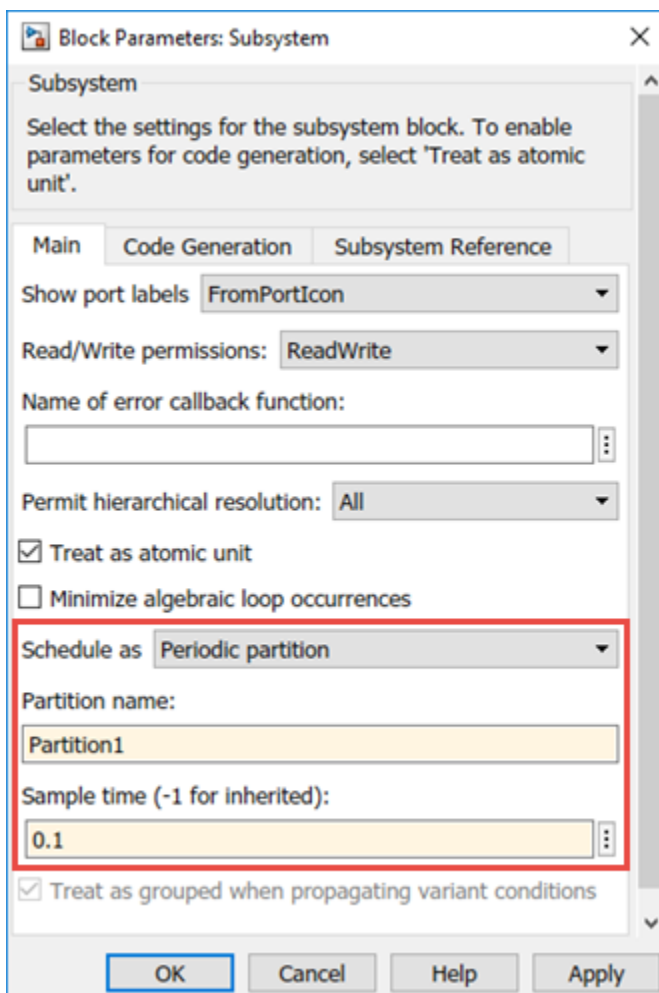

To create a partition for the `fuel_calc` subsystem, select the `fuel_calc` subsystem and click .

The **Manage Partitions** panel gives you the default partition names and sample times.

Update the diagram to see the newly created partitions.

Create Partitions from Atomic Subsystem Blocks

You can partition an atomic subsystem. An atomic subsystem is treated by Simulink as a unit when determining the execution order of block methods (partitioning is enabled only on multitasking, fixed-step and variable-step solver models). To create partitions from an atomic subsystem block, go to the Block Parameters dialog box. Select **Periodic partition** from the **Schedule as** drop-down. Give the partition a name and a discrete sample time and click OK. This creates an explicit partition for this block. To see this partition in the Schedule Editor, update the diagram. The partition appears in the graph and in the **Order** with the connections based on the signals in the model.

Create Partitions from Model Blocks

To create partitions from a Model block, in the **Model events simulation**, select **Schedule rates** and **Schedule Editor** from the **Schedule rates with** drop-down. When you enable partitioning

from a referenced model, partitions are created from all the Model blocks present in the referenced model. These partitions are scoped by the model block name. To see this partition in the Schedule Editor, update the diagram. The partitions appear in the graph and in the **Order** column with the connections based on the design of your model.

Export-Function Partitions

In export-function models, partitions are created from the function calls present in the model. To create partitions from the function calls in the export-function models, reference the export-function model in a top model. Schedule the Model block using the Schedule Editor through the block parameters. Partitions are then created from the function calls and their order is determined by the Schedule Editor.

- 1 Create an export-function model.
- 2 Add a Model block that references the export-function model.
- 3 Set the parameter to partition the export-function model.

Referencing an export-function model from a Model block allows you to partition the function calls without changing the model itself. To create the model for this example, see “Create an Export-Function Model” on page 10-73. Simulink functions in an export-functions model cannot be scheduled, and do not appear as partitions in the Schedule Editor.

- 1 Add a model block to a new Simulink model. In the **Model name** box, enter `export_function_model`. To enable the use of the Schedule Editor, configure the model to be multitasking. Open the Model Configuration Parameters. In **Solver selection** on the **Solver** pane, set the **Type** to **Fixed-step**. Check the **Treat each discrete rate as a separate task** and **Automatically handle rate transition for data transfer** parameters. Click **OK**. The model is enabled for partitioning.

Note Do not convert a subsystem into a model because it automatically creates Inport blocks.

- 2 Add Outport blocks to the **output_100ms** and **output_10ms** ports for saving simulation data to MATLAB. For this example, in the `export_function_model`, set the sample time of both the function calls to -1.
- 3 Add a Sine Wave block to provide data input. Set **Amplitude** to 2 and **Sample time** to 0.01.
- 4 To partition the function calls of the export-function model, in the Block Parameters of the model block, select **Schedule Editor** option from the **Schedule Rates with** drop-down menu.
- 5 Open the Schedule Editor and update the diagram to see the function calls as partitions.

The screenshot shows the MATLAB Schedule Editor interface. The main workspace displays a sequence of three blocks: a green arrow labeled 'A' pointing to 'Model.function_call_1', a red box containing '0.01' and 'D1', and another green arrow labeled 'A' pointing to 'Model.function_call_2'. An arrow points from the red box to the second block. The right-hand side contains an 'ORDER' table and a 'PROPERTY INSPECTOR' for the selected partition.

Order	Name	Trigger
1	D1 <i>implicit</i>	0.01
2	Model.function_call_1	[0:0.1:1]
3	Model.function_call_2	[0:0.01:

Partition	
Name	Model.function_call_1
Rate	A
Hit Times	[0:0.1:10]
Type	Explicit aperiodic partition

More About

- “Schedule the Partitions” on page 24-15
- “Generate Code from a Partitioned Model” on page 24-22

Using the Schedule Editor

The Schedule Editor is a scheduling tool that represents the components in the model known as partitions, the data connections between them, and the order of those partitions.

Partitions are the components of the model that execute independently as tasks. The data connections between the partitions show the flow of the data between those partitions. The scheduling of these partitions is based on the rates and the events in the model. This schedule is shown in the **Order** table in the Schedule Editor.

Using the Schedule Editor you can:

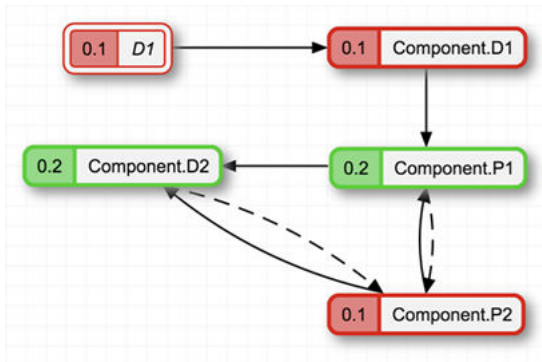

- Create partitions and specify their order
- Edit and analyze the schedule of the executable partitions without disturbing the structure of the model.
- Visualize how Simulink executes partitions

Changes made in the Schedule Editor affect both, simulation and code generation.

Using the Schedule Editor

The Schedule Editor consists of two parts representing two different views of partitions in the model.

- A graph that shows the partitions and the data connections between them.

- A table that shows the order in which the partitions execute.

Note Aperiodic partitions are listed in the order of their priority.

ORDER		
Order	Name	Trigger
1	■ Cont <i>implicit</i>	0
	■ D1 <i>implicit</i>	0.001
2	■ D2 <i>implicit</i>	0.005
3	▶ ThrottleControl.APPSnsrRun	
4	■ ThrottleControl.ActuatorRun5ms	0.005
5	■ ThrottleControl.TPSSecondaryRun5ms	0.005
6	■ ThrottleControl.MonitorRun5ms	0.005
7	■ ThrottleControl.ControllerRun5ms	0.005
8	■ D3 <i>implicit</i>	0.01
9	■ ThrottleControl.TPSPrimaryRun10ms	0.01

Changing one of the views impacts the other.

To use the Schedule Editor, on the **Modeling** tab, click **Schedule Editor**. If the model is already partitioned, you can open the Schedule Editor by clicking the badge, , which appears above the blocks. To see the default partitions present in the model in the Schedule Editor, update the diagram with  icon, on the toolbar or by selecting **Ctrl+D**. As you create partitions in the model and update the diagram, partitions appear in the Schedule Editor.

To check how the partitions map to the model, right-click the partitions and select **Show Source**. The Simulink model window appears with every block corresponding to the partition highlighted.

Order

The **Order** pane shows the order in which the partitions execute. To change the order, you can drag and drop the partitions. You can also use the **Up** and **Down** arrows on the toolbar. Partitions are sorted based on their rates. You can only reorder the partitions with the same rate. Clicking a partition in the **Order**, highlights the corresponding partition in the graph. On changing the order, the connections that are affected by this specified change get highlighted.

Note Aperiodic partitions are listed in the order of their priority.

3	▶ ThrottleControl.APPSnsrRun	
4	■ ThrottleControl.ActuatorRun5ms	0.005
5	■ ThrottleControl.TPSSecondaryRun5ms	0.005
6	■ ThrottleControl.MonitorRun5ms	0.005
7	■ ThrottleControl.ControllerRun5ms	0.005
8	■ D3 <i>implicit</i>	0.01
9	■ ThrottleControl.TPSPPrimaryRun10ms	0.01

Connections

Connections between the partitions show data dependencies. You can right-click the connections between the partitions to change the constraints on data connections. The different types of connections illustrate how the partitions behave with each other.

The types of connections are:

- **Dependency** - Indicates that the source always runs before the destination. The dependency connection is a solid line.

- **Delay** - Indicates that the destination runs before the source. When the destination runs before the source, a scheduling delay is introduced. The delay connection is a dashed line.

You can put these types of constraints on connections:

- **Allow Delay** - Inserts a delay when required. When you specify this constraint for a connection, Simulink inserts a delay for that connection only when necessary. The unlock icon on the connections signifies an allowed delay. When you select this constraint on a connection, Simulink prefers these connections to be turned into a delay if necessary over other connections.

This constraint is displayed as one of these options.

- **Prevent Delay** - Prevents delay from being inserted in the connection. When you specify this constraint for a connection, Simulink ensures that the connection always remains as a dependency. The lock icon on the connection indicates that the connection is locked to be a dependency and is not changed to a delay.

- “Create Partitions” on page 24-4
- “Schedule the Partitions” on page 24-15
- “Generate Code from a Partitioned Model” on page 24-22

Schedule the Partitions

These two examples walk through the workflow of partitioning a model, scheduling the partitions and analyzing the simulations before and after editing the schedule of the partitions.

Schedule an Export-Function Model Using the Schedule Editor

This example shows how to view and edit the order of function-calls in an export-function model using the Schedule Editor. As in all export-function models, the desired functionality is modeled as function-call subsystems. These function-call subsystems define the partitions that are scheduled by the Schedule Editor.

With the Schedule Editor, you can easily view and edit the schedule of the function-calls. The behavior of the system depends on the order of these partitions. In this example, we change the order and observe its effects on the behavior of the system by simulating the model. To see the impact of editing the schedule on the simulation, we compare the model simulations before and after scheduling.

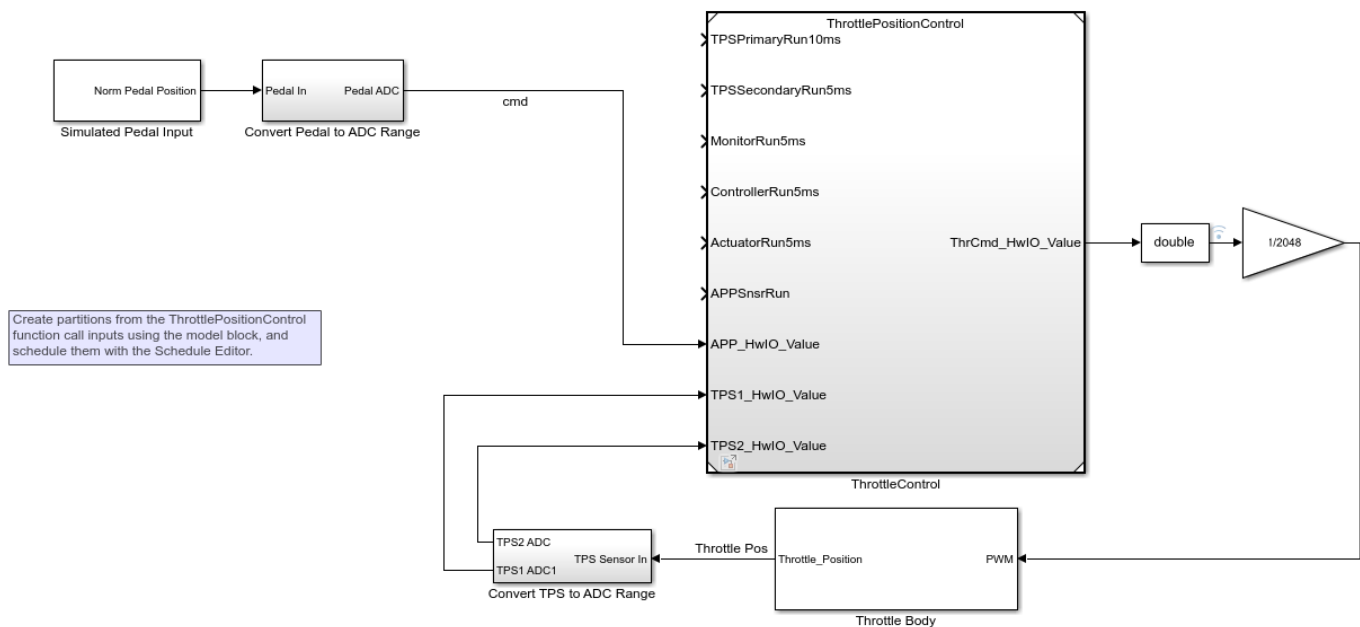

Create Partitions from Referenced Export-Function Model

To view and edit the schedule of the export-function model, reference the model.

```
open_system('ThrottlePositionControlTop.slx');
```

Schedule an Export-Function Model with the Schedule Editor

Copyright 2018 The MathWorks, Inc.

`ThrottlePositionControl` is the referenced export-function model. By default, each function has an input port that can be used to trigger these functions. The Schedule Editor automatically handles these ports. To use the Schedule Editor, set the Schedule Rates With parameter to Schedule Editor.

```
set_param('ThrottlePositionControlTop/ThrottleControl', 'ScheduleRatesWith', 'Schedule Editor');
```

Establish a Simulation Baseline

To observe the impact of scheduling on the model behavior, establish a baseline by simulating the model before editing the schedule. Simulate the model.

```
sim('ThrottlePositionControlTop');
```

Open the Schedule Editor

To open the Schedule Editor, click **Schedule Editor** in the **Design** section of the **Modeling** tab. In the Schedule Editor, different components of the model are represented as partitions. Update the diagram to see the partitions. Partitions are the entry-points in the model. The Schedule Editor shows the order and data communications of these partitions. The arrows are data connections between the partitions that show the data flow. The dashed lines indicate that there is a delay because the source runs after the destination. The solid lines indicate that there is no delay as the source runs before the destination.

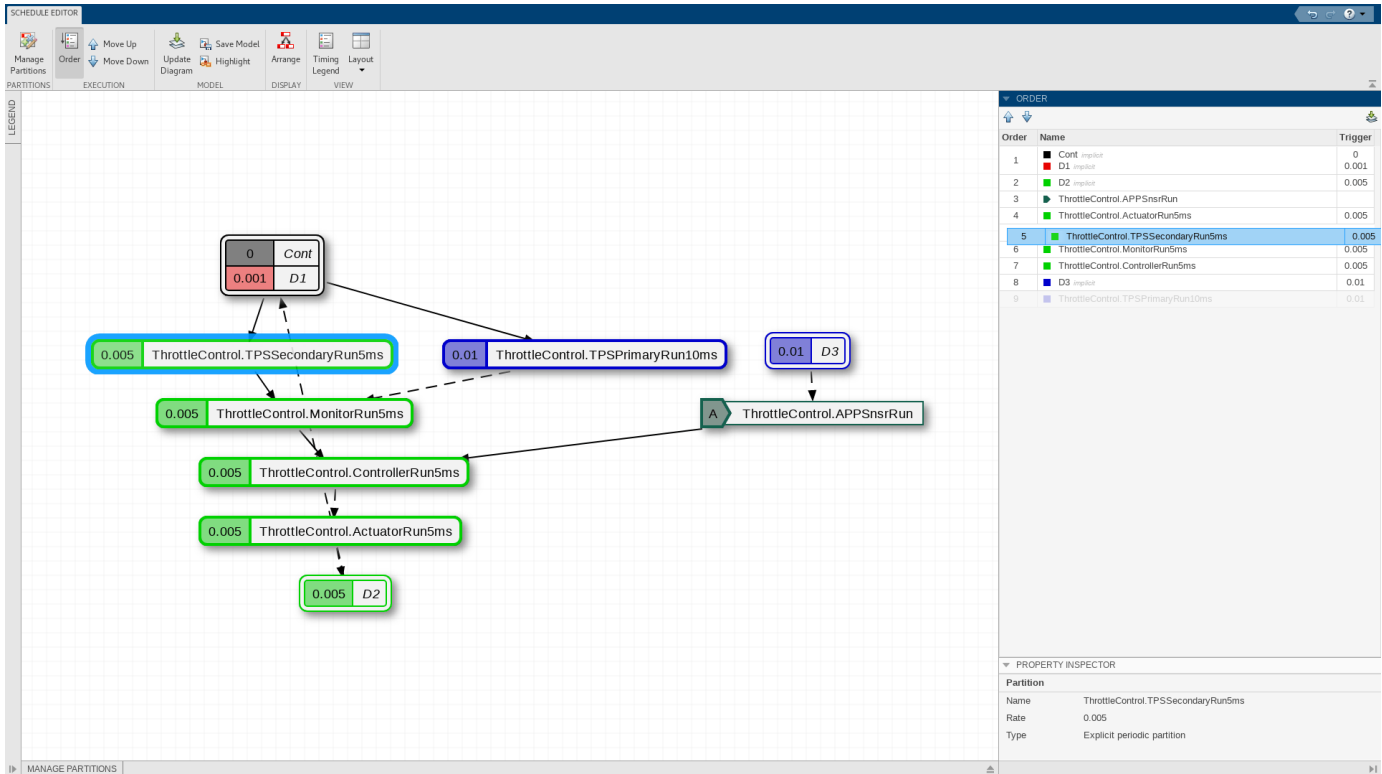

Edit Partition Schedule

The Order pane shows the order the partitions run in at a given time step. Assume that the order of the partitions is in an imperfect state. In this case, to remove the delay, you want to run the `ThrottleControl.ActuatorRun5ms` partition after the `ThrottleControl.ControllerRun5ms` partition.

Drag `ThrottleControl.ActuatorRun5ms` after the `ThrottleControl.ControllerRun5ms` in the Order pane. Observe that the delay between the `ThrottleControl.ControllerRun5ms` and the `ThrottleControl.ActuatorRun5ms` partitions changes to a dependency. Observe that now

there is no delay between the executions of `ThrottleControl.ControllerRun5ms` and `ThrottleControl.ActuatorRun5ms`.

Schedule the Execution of Aperiodic Partitions

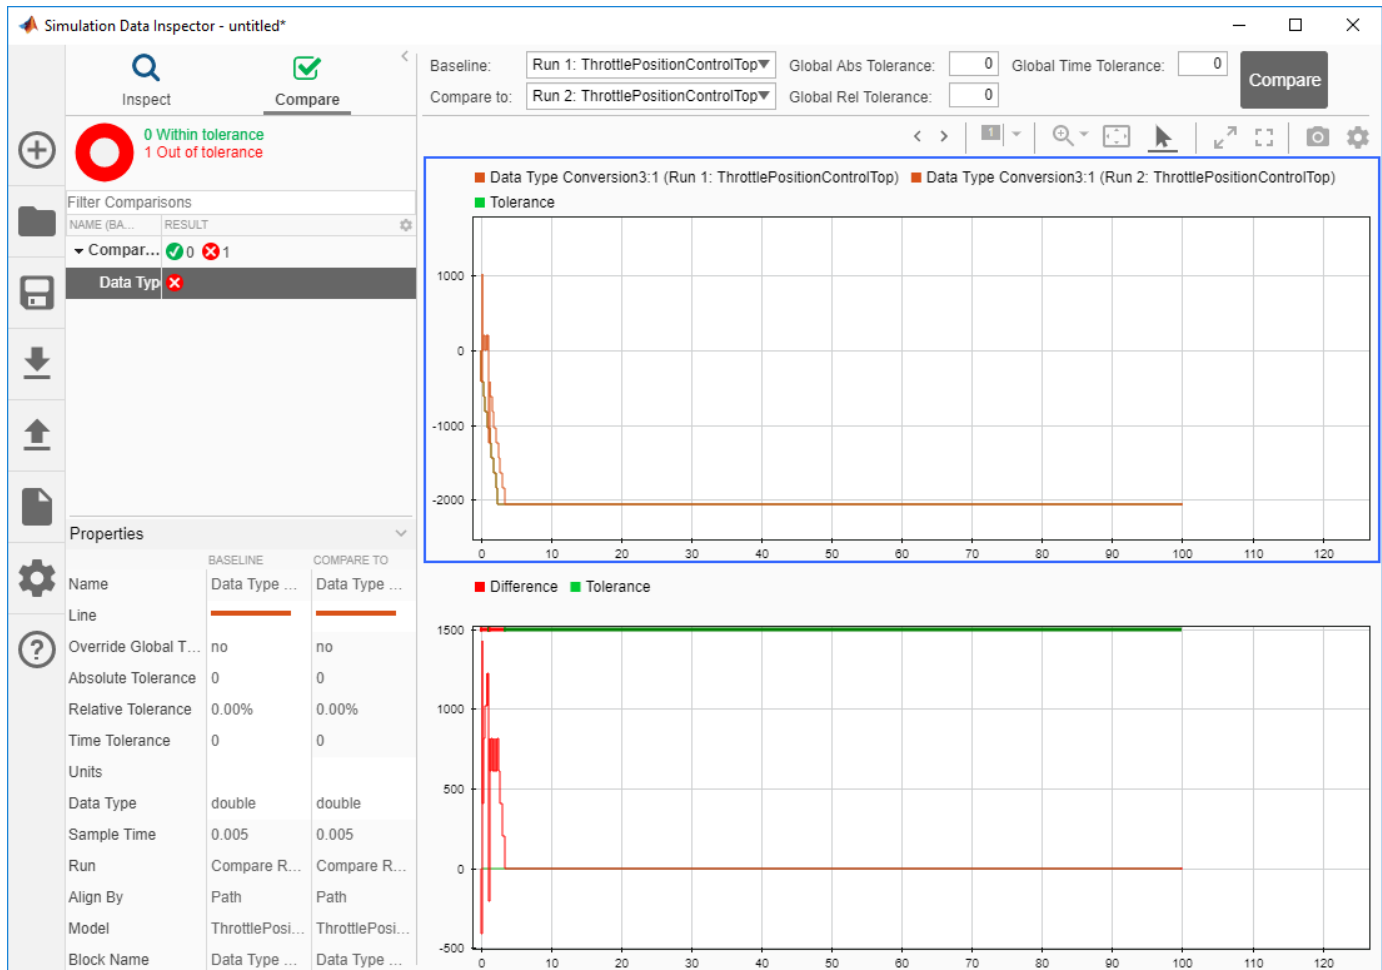

The export-function model contains an unconstrained partition, `AccelerationPedalPositionSensor`. Suppose you want to schedule an unconstrained partition to simulate as if it were discrete. Schedule `ThrottleControl.APPSnsrRun` partition to run at `[0:0.02:100]` to observe its behavior at different instances of time. Click the unconstrained partition and enter `[(1:5000)*.02]` for Hit Times in the Property Inspector.

Compare the Runs in Simulation Data Inspector

Now, simulate the model with the changed schedule.

Open the Simulation Data Inspector. Select the two runs and compare. You can see how changing the schedule impacts the model behavior.

Copyright 2018-2019 The MathWorks, Inc.

Schedule a Rate-Based Model Using the Schedule Editor

This example shows how to partition a rate-based model using the Schedule Editor. Partitions are the components of the model that can execute independently. In this example, we convert the subsystems into partitions and view and edit their schedule.

With the Schedule Editor, you can easily view and edit the schedule of the partitions. The behavior of the system depends on the order of these partitions. In this example, we observe the effects of scheduling this model on the simulation. To see the impact of partitioning and scheduling the model, we compare the model simulations before and after creating partitions and scheduling them.

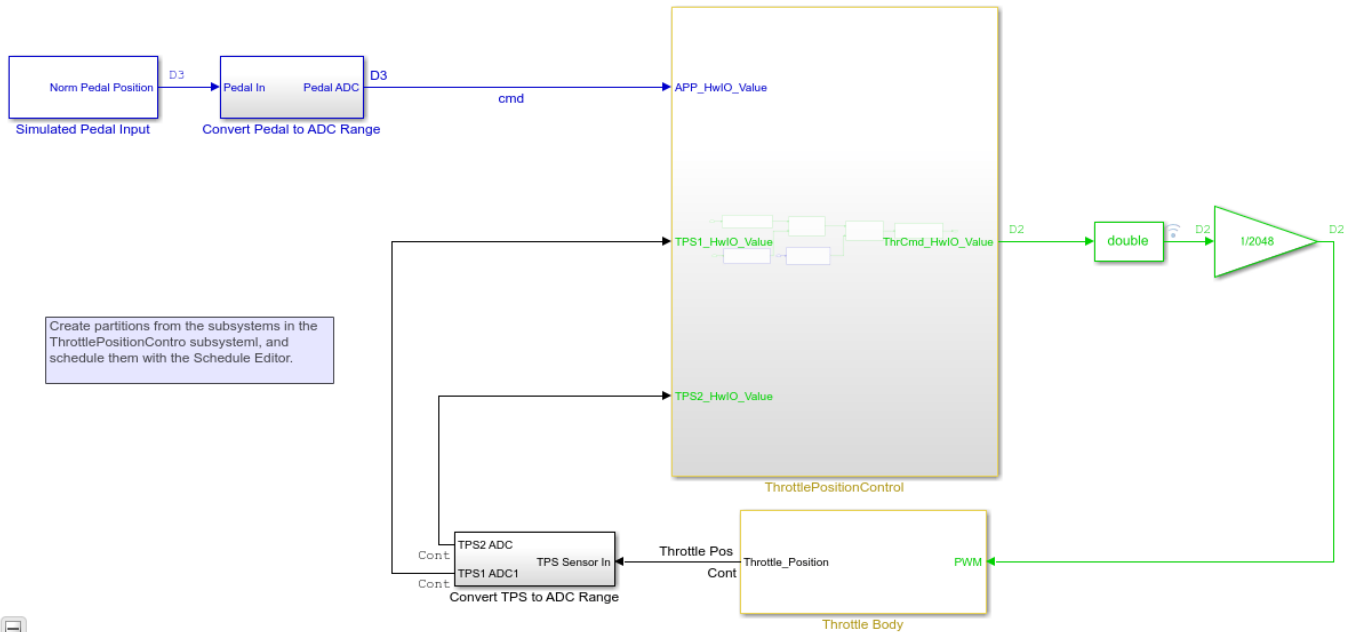

Open the Model and Establish a Simulation Baseline

Open the model of a Throttle Position Control system and simulate it to establish a baseline for comparison

```
open_system('ScheduleEditorWithSubsystemPartitions');
sim('ScheduleEditorWithSubsystemPartitions');
```

Schedule Subsystem Partitions with the Schedule Editor

Copyright 2018 The MathWorks, Inc.

Open the Schedule Editor and Create Partitions

To open the Schedule Editor, click **Schedule Editor** in the **Design** section of the **Modeling** tab. Use **Manage Partitions** to create partitions from the subsystems in your model. Select all the subsystems in **ThrottlePositionControl**, and click the **Create Partitions** icon on the top of the **Manage Partitions** panel. Specify the names for the partitions and their sample time. Update the diagram to see the partitions in the Schedule Editor.

The arrows are data connections between the partitions that show the data flow. The dashed lines always indicate that there is a delay as the source runs after the destination. The solid lines indicate that there is no delay as the source runs before the destination.

Order	Name	Trigger
0	Cont	0
1	D1	0.001
2	TPSSecondaryRun5ms	0.005
3	MonitorRun5ms	0.005
4	ControllerRun5ms	0.005
5	ActuatorRun5ms	0.005
6	D2	0.005
7	D3	0.01
8	APPSnsrRun	0.01
9	TPSPPrimaryRun10ms	0.01

Edit Partition Schedule

The Order shows the order the partitions run at a given time step. Assume that the order of the partitions is in an imperfect state. In this case, you want to run the ActuatorRun5ms partition before the ControllerRun5ms partition. Drag ActuatorRun5ms before the ControllerRun5ms in the order. Observe that the dependency between the ControllerRun5ms and the ActuatorRun5ms partitions changes to a delay.

Order	Name	Trigger
0	Cont	0
1	D1	0.001
2	TPSSecondaryRun5ms	0.005
3	MonitorRun5ms	0.005
4	ActuatorRun5ms	0.005
5	ControllerRun5ms	0.005
6	D2	0.005
7	D3	0.01
8	APPSnsrRun	0.01
9	TPSPPrimaryRun10ms	0.01

Compare Runs in Simulation Data Inspector

Now, simulate the model with the changed schedule.

Open the Simulation Data Inspector. Select the two runs and compare. You can see how changing the schedule impacts the model behavior.

- “Generate Code from a Partitioned Model” on page 24-22

Generate Code from a Partitioned Model

Partitioning and scheduling a model has an impact on the order of the function calls in the generated code. Using the Schedule Editor to edit the schedule of a rate-based model or a referenced export-function model, the order of the functions in the generated code depends on the specified schedule in the Schedule Editor. The resulting code shows every partition as an entry point.

Note To use the code generation functionality, Embedded Coder and Simulink Coder are required.

To see the impact of the Schedule Editor on the generated code, use the model that is created in “Create A Rate-Based Model” on page 10-41.

- 1 Open the Schedule Editor from the **Design** section of the **Modeling** tab. Use the **Manage Partitions** panel to create partitions for Scheduled Subsystem 1 and Scheduled Subsystem 2 with 0.01 sample time. Update the diagram.
- 2 Change the order of the partitions by dragging Scheduled_Subsystem_2 above Scheduled_Subsystem_1.

The screenshot shows the SCHEDULE EDITOR interface. The main workspace is a grid containing three components, each with a red border and a rate of 0.01:

- D1**: A small red-bordered box with "0.01" and "D1".
- Scheduled_Subsystem_1**: A larger red-bordered box with "0.01" and "Scheduled_Subsystem_1".
- Scheduled_Subsystem_2**: A large blue-bordered box with "0.01" and "Scheduled_Subsystem_2".

The right-hand panel contains the following sections:

ORDER

Order	Name	Trigger
1	D1 <i>implicit, empty</i>	0.01
2	d_Subsystem_1	0.01
3	d_Subsystem_2	0.01

PROPERTY INSPECTOR

Partition

Name	Scheduled_Subsystem_2
Rate	0.01
Type	Explicit periodic partition

- 3 Generate code for the component model. From the **Apps** tab, select **C/C++ Code > Build Model**.

In the generated code, the order of the functions depends on the schedule specified in the Schedule Editor.

```

#include "rate_based_model.h"
#include "rate_based_model_private.h"

/* External inputs (root inport signals with default storage) */
ExtU_rate_based_model_T rate_based_model_U;

/* External outputs (root outports fed by signals with default storage) */
ExtY_rate_based_model_T rate_based_model_Y;

/* Real-time model */
RT_MODEL_rate_based_model_T rate_based_model_M;
RT_MODEL_rate_based_model_T *const rate_based_model_M = &rate_based_model_M;

/* Model step function for TID0 */
void rate_based_model_step0(void) /* Sample time: [0.01s, 0.0s] */
{
    /* (no output/update code required) */
}

/* Model step function for TID1 */
void rate_based_model_step1(void) /* Explicit Task: Scheduled_Subsystem_2 */
{
    /* Output: '<Root>/Out2' incorporates:
     * Inport: '<Root>/In2_100ms'
     */
    rate_based_model_Y.Out2 = rate_based_model_U.In2_100ms;
}

/* Model step function for TID2 */
void rate_based_model_step2(void) /* Explicit Task: Scheduled_Subsystem_1 */
{
    /* Output: '<Root>/Out1' incorporates:
     * Inport: '<Root>/In1_10ms'
     */
    rate_based_model_Y.Out1 = rate_based_model_U.In1_10ms;
}

```

Note Changing the constraints on the connections does impact the generated code. The changes with respect to connections are useful to set preferences about delays and dependencies.

- “Schedule the Partitions” on page 24-15

Export-Function Conversion

To use the **Schedule rates with** option with the Schedule Editor, the model can not be an export-function model. To enable **Schedule rates with** option, convert your model to a rate-based model. To convert your model to a rate-based model, remove the function call input ports. For more information, see “Export-Function Models” on page 10-48.

Create and Analyze Random Schedules for a Model Using the Schedule Editor API

This example uses the Schedule Editor API to perform operations on the schedule. Then it uses a function to generate random schedules and analyze them in Simulation Data Inspector

Open the Model and get the Schedule Object

Open a model of a Throttle Position Control system and use `get_param` to obtain the `simulink.schedule.OrderedSchedule` object. This object contains the current schedule.

```
model = 'ScheduleEditorAPIWithSubsystemPartitions';
open_system(model);
schedule = get_param(model, 'Schedule')
```

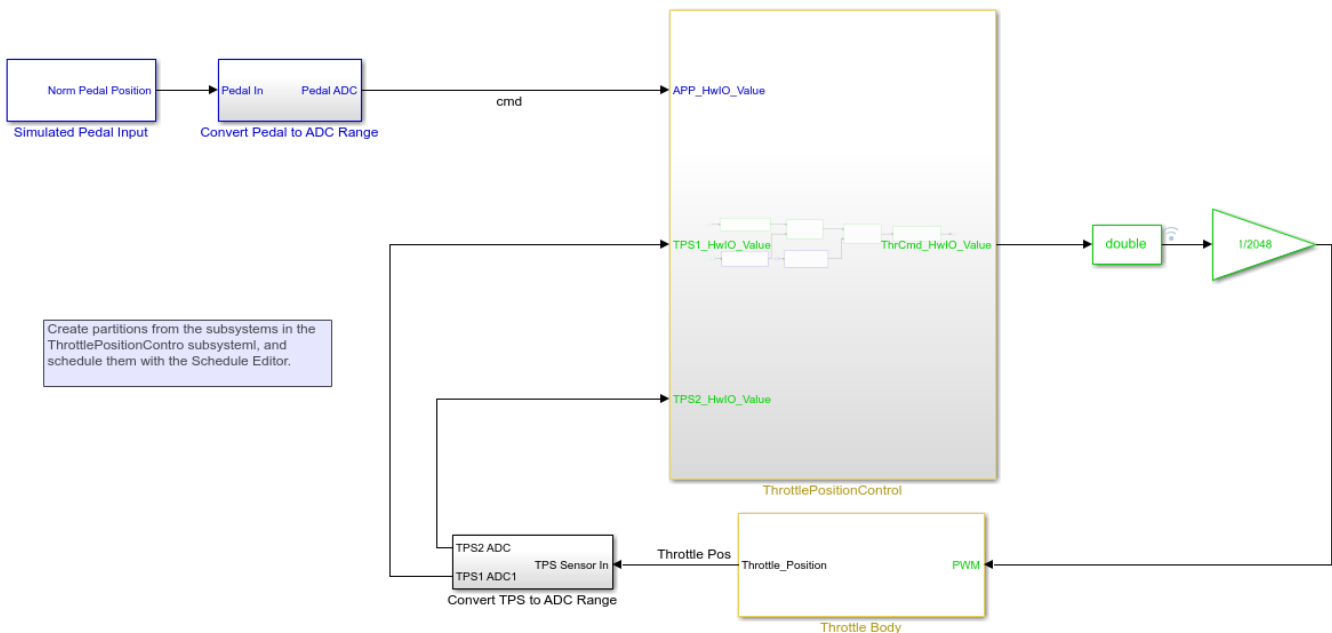

`schedule =`

OrderedSchedule with properties:

```
Order: [9x3 table]
RateSections: [3x1 simulink.schedule.RateSection]
Events: [0x1 simulink.schedule.Event]
Description: ''
```

Schedule Subsystem Partitions with the Schedule Editor

Copyright 2018 The MathWorks, Inc.

Examine the Schedule Object

The schedule object has an `Order` property that contains the execution order of the partitions in the model. The `Order` property displays a table that contains partition names, their index, type, and their trigger.

```
schedule.Order
```

```
ans =
```

```
9x3 table
```

	Index	Type	Trigger
Cont	1	Periodic	"0"
TPSSecondaryRun5ms	2	Periodic	"0.005"
MonitorRun5ms	3	Periodic	"0.005"
ControllerRun5ms	4	Periodic	"0.005"
ActuatorRun5ms	5	Periodic	"0.005"
D2	6	Periodic	"0.005"
D3	7	Periodic	"0.01"
APPSnsrRun	8	Periodic	"0.01"
TPSPPrimaryRun10ms	9	Periodic	"0.01"

Use the index variable in the `Order` table to change the execution order of the model

```
schedule.Order.Index('ActuatorRun5ms') = 2;  
schedule.Order
```

```
ans =
```

```
9x3 table
```

	Index	Type	Trigger
Cont	1	Periodic	"0"
ActuatorRun5ms	2	Periodic	"0.005"
TPSSecondaryRun5ms	3	Periodic	"0.005"
MonitorRun5ms	4	Periodic	"0.005"
ControllerRun5ms	5	Periodic	"0.005"
D2	6	Periodic	"0.005"
D3	7	Periodic	"0.01"
APPSnsrRun	8	Periodic	"0.01"
TPSPPrimaryRun10ms	9	Periodic	"0.01"

Any moves within the `Order` property that are made to modify the schedule should result in valid schedule. To perform the schedule modifications and valid moves easier, each partition is grouped with partitions of the same rate in the `RateSections` property. Each element of the `RateSection` property contains an order table with partitions of the same rate.

```
schedule.RateSections(2)  
schedule.RateSections(2).Order
```

```
ans =
```

```
RateSection with properties:
```

```
Rate: "0.005"
Order: [5x3 table]
```

```
ans =
```

```
5x3 table
```

	Index	Type	Trigger
ActuatorRun5ms	2	Periodic	"0.005"
TPSSecondaryRun5ms	3	Periodic	"0.005"
MonitorRun5ms	4	Periodic	"0.005"
ControllerRun5ms	5	Periodic	"0.005"
D2	6	Periodic	"0.005"

Use the index variable to move the partitions within RateSections.

```
schedule.RateSections(2).Order.Index('ActuatorRun5ms') = 5;
schedule.Order
```

```
ans =
```

```
9x3 table
```

	Index	Type	Trigger
Cont	1	Periodic	"0"
TPSSecondaryRun5ms	2	Periodic	"0.005"
MonitorRun5ms	3	Periodic	"0.005"
ControllerRun5ms	4	Periodic	"0.005"
ActuatorRun5ms	5	Periodic	"0.005"
D2	6	Periodic	"0.005"
D3	7	Periodic	"0.01"
APPSnsrRun	8	Periodic	"0.01"
TPSPPrimaryRun10ms	9	Periodic	"0.01"

Create a Function to Generate Random Schedules

In this section, we create three different functions: `randomSchedule`, `generateSimulationInputs` and `simulateRandomSchedules`

`randomSchedule` function is used to create random schedules by using random permutations of index modifications in the `schedule` object. Using the `Order` and the `RateSections` properties of the `schedule` object, partitions in the schedules are moved around in different, random combinations. With these randomly created schedules, models are simulated and compared to study the effect of different schedules on simulation. In the function `randomSchedule`, the input is the model name. Then use `get_param` to obtain the `simulink.schedule.OrderedSchedule` object of

the model. The schedule object and its properties are used to modify and randomize the schedules. Create a variable `firstExecutionOrder` for the first rate section of the model. The `rateSections(1).ExecutionOrder = [firstExecutionOrder(1,:); reSchedule(firstExecutionOrder(2:end,:))]` line of code calls the function `reSchedule` which creates random permutations of the indexes.

type `randomSchedule`

```
function schedule = randomSchedule(model)
    % schedule = randomSchedule(model) Produces a
    % simulink.schedule.OrderedSchedule that has a randomized permutation
    % of the model's original execution order schedule

    arguments
        model char = bdroot
    end

    schedule = get_param(model, 'Schedule');

    rateSections = schedule.RateSections;
    firstOrder = rateSections(1).Order;

    % This assumes that the slowest discrete rate is at index 1. This may
    % not be the case for all models (ex. JMAAB-B).
    rateSections(1).Order = [firstOrder(1,:); reSchedule(firstOrder(2:end,:))];

    for i=2:length(rateSections)
        rateSections(i).Order = reSchedule(rateSections(i).Order);
    end

    schedule.RateSections = rateSections;
end

function out = reSchedule(in)
    numPartitions = height(in);
    in.Index = in.Index(randperm(numPartitions));
    out = in;
end
```

To analyze the effects of different schedules on the model, simulate the model with the different schedules. In this function, create an array of `Simulink.SimulationInput` objects. Through this array of `Simulink.SimulationInput` objects, you can apply the schedules to the model with the `setModelParameters` method of the `Simulink.SimulationInput` object.

type `generateSimulationInputs`

```
function in = generateSimulationInputs(model, numSimulations)
    % in = generateSimulationInputs(model, numSimulations) Generates
    % numSimulations Simulink.SimulationInput objects each containing a
    % different, randomized execution order schedule
    arguments
        model char = bdroot
        numSimulations double = 10
    end

    in(numSimulations) = Simulink.SimulationInput();
```

```

    in = in.setModelName(model);
    for idx = 1:numSimulations
        in(idx) = in(idx).setModelParameter('Schedule', randomSchedule(model));
    end
end

```

In the last function, use the array of `Simulink.SimulationInput` objects to run multiple simulations. Once the simulations are complete, you can plot the output of all the simulations in Simulation Data Inspector.

type `simulateRandomSchedules`

```

function out = simulateRandomSchedules(model, numSimulations)
    % out = simulateRandomSchedules(model, numSimulations) Simulates a
    % model numSimulations number of times. Each simulation has a
    % randomized execution order schedule.
    arguments
        model char = bdroot
        numSimulations double = 10
    end

    in = generateSimulationInputs(model, numSimulations);
    out = sim(in);
    plot(out);
end

```

Execute the Functions

Now run the above functions for the `ScheduleEditorAPIWithSubsystemPartitions` model. First, use the `randomSchedule` function to create randomly generated schedules, then, use the `generateSimulationInputs` function to generate an array of `Simulink.SimulationInput` objects, and use the `simulateRandomSchedule` function to simulate the model with different schedules and plot their results for comparison. Let's run simulations with 15 randomly generated schedules.

```
simulateRandomSchedules(model, 15)
```

```

Events in Schedule Editor

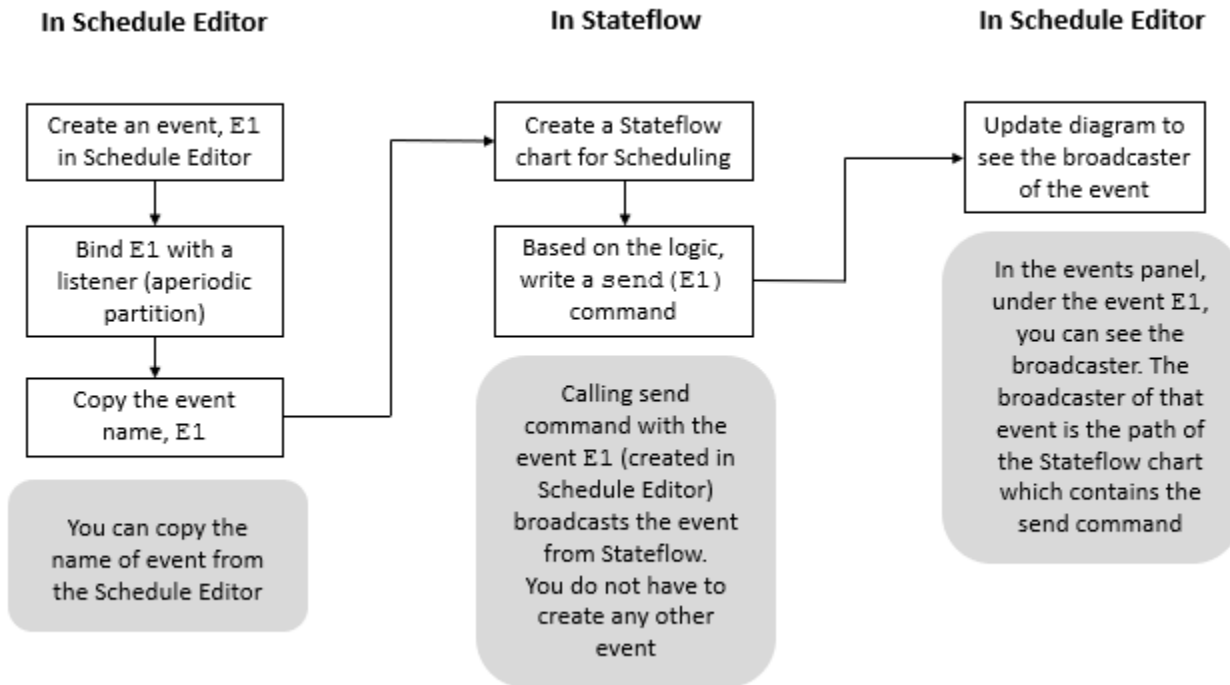

An event is a construct that represents an action, transition, or condition. You can broadcast events from within a model hierarchy. Events can connect blocks that detect important conditions with a partition to schedule the execution of the partition when the conditions occurs. The Schedule Editor allows you to create and manage partitions and schedule the execution of your model. You can bind an event to an aperiodic partition that is scheduled, based on priority, for execution when the event is broadcast. Starting in R2020b, Schedule Editor events can be sent from Stateflow charts by using the send keyword. Events simplify system creation and provide more flexibility during scheduling.

Event Management in the Schedule Editor

Each model in a model hierarchy has its own **Events** panel in the Schedule Editor, that contains all the events present in the model and the model's children. When you open the Schedule Editor and update the diagram, all partitions and events present in the model appear in the Schedule Editor. Through the **Events** panel, you can:

- Create an event.
- Delete an event.
- Rename an event.
- Get an event.
- Bind an event to a partition.
- Unbind an event from a partition.

You can schedule the execution of an aperiodic partition based on broadcasting of a particular event in the Stateflow Chart as shown below:

The **Events** panel in the Schedule Editor shows you the event tree. Under every event, you can see the broadcasters and listeners of that event.

When an event is bound to a partition, the event name appears on the left side of the partition and in the **Trigger** column of the **Order** table.

The screenshot shows the Schedule Editor interface. On the left is the **EVENTS** panel with a search bar and a list of events. In the center is a diagram showing three partitions: PartitionA, PartitionB, and PartitionC. PartitionA is at the top, with arrows pointing to PartitionB and PartitionC. PartitionB has the letter 'A' on its left side. PartitionC has '0.1' on its left side and is highlighted with a red border. On the right is the **ORDER** table, which lists the partitions in order.

Order	Name	Trigger
1	▶ PartitionA	
2	▶ PartitionB	
3	■ PartitionC	0.1

Naming

Unique names are enforced for events within a model and within a model hierarchy. Within a model hierarchy, the model name prepends the event name. For example, if the model reference named `ModelName` contains an event, `E1`, then that event appears as `ModelName.E1` in the Schedule Editor.

Scope

A scoped event indicates that the event is used within the context of the parent model. A scoped event is visible in the **Events** panel for the parent model. A scoped event with the name `E1`, that's present in the model named `ModelName`, is displayed as `ModelName.E1` in the **Events** panel.

You can set the scope of the event in the **Events** panel. To set the scope of the event, right click the event in the **Events** panel.

The screenshot shows the **EVENT** configuration panel. It has two radio button options: **Global** (unselected) and **Scoped** (selected). The **Global** option is described as 'Configure event to be accessible globally'. The **Scoped** option is described as 'Configure event to be scoped to current model'.

There are two options:

Global,  - A global event indicates that an event is available for use anywhere in the model hierarchy. You can use and connect the global event anywhere within the model hierarchy. A global

event is visible in the **Events** panel for the parent model. A global event with the name `EventName` is referred to as `EventName` in all parent models. All global events must have a unique name. These multiple instances of the events can then be triggered by the same Stateflow chart to unify scheduling.

Scoped (default),  - When the event is scoped, it indicates that the event is used within the context of the parent model. A scoped event is visible in the **Events** panel for the parent model. A scoped event with the name `E1`, that's present in the model named `ModelName`, is displayed as `ModelName.E1` in the **Events** panel.

Scoped	Global
Event available for use only in the context of the model where it is present.	Event available for use anywhere in the model hierarchy
Visible in the Events panel for the model where the event is.	Visible in the Events panel for the parent model
Displayed as <code>ModelName.E1</code> in the Events panel.	Displayed as <code>EventName</code> in the Events panel for the parent model.

Execution of Aperiodic Partitions with Events

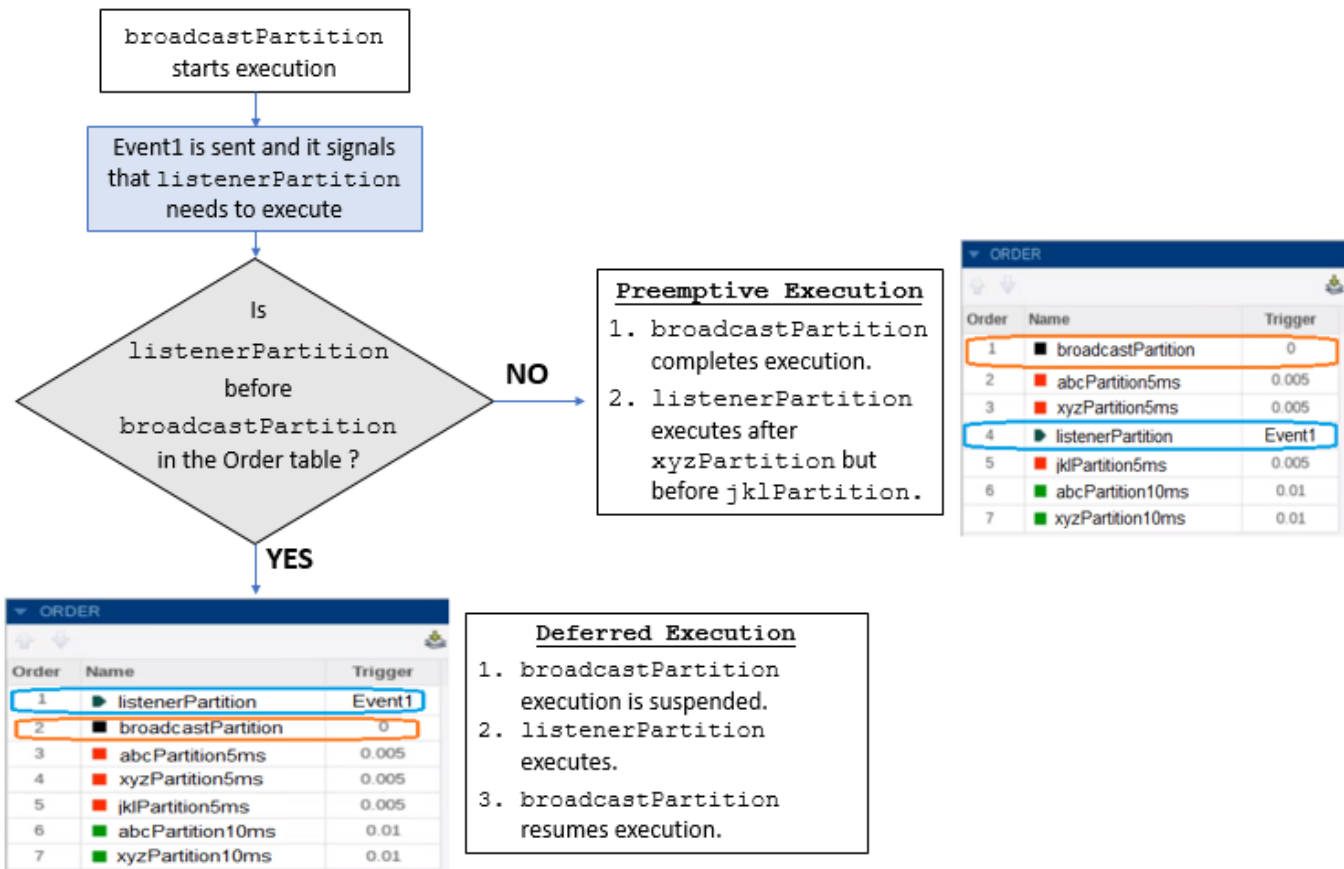

Bind Events

An event and a partition can be bound together to indicate that the partition executes in response to the broadcasting of the event. A partition may only be bound to a single event.

Priority Based Execution

If the event-bound partition is scheduled to run before the partition driving the event, then the event-bound partition execution preempts the execution of the partition sending the event. If the triggered partition is scheduled to run after the partition driving the event, then the triggered partition executes when the scheduler reaches its position in the execution order.

In the flochart below, for example, `listenerPartition` is an aperiodic partition and a listener to the event, `Event1`. Suppose that `Event1` comes from a Stateflow Chart present in the model and is a part of the partition called, `broadcastPartition`. When `broadcastPartition` starts executing, `Event1` occurs, which then triggers the execution of `listenerPartition`.

Hit Times

You can trigger an aperiodic partition at specified hit times. If a partition has hit times and gets bound to an event, the hit times are replaced with the specified event. Likewise, if a partition is bound to an event and hit times are added, then the bound event is removed from the partition. Variables can also specify hit times for the aperiodic partitions. In case of ambiguous variable and events names, events are given precedence.

Schedule Partitions with Events

This example shows how you can use events to schedule the execution of aperiodic partitions via a Stateflow chart. You can send events from Stateflow and use those events to control the execution of the partitions in the model by using events in Schedule Editor.

Open the Model

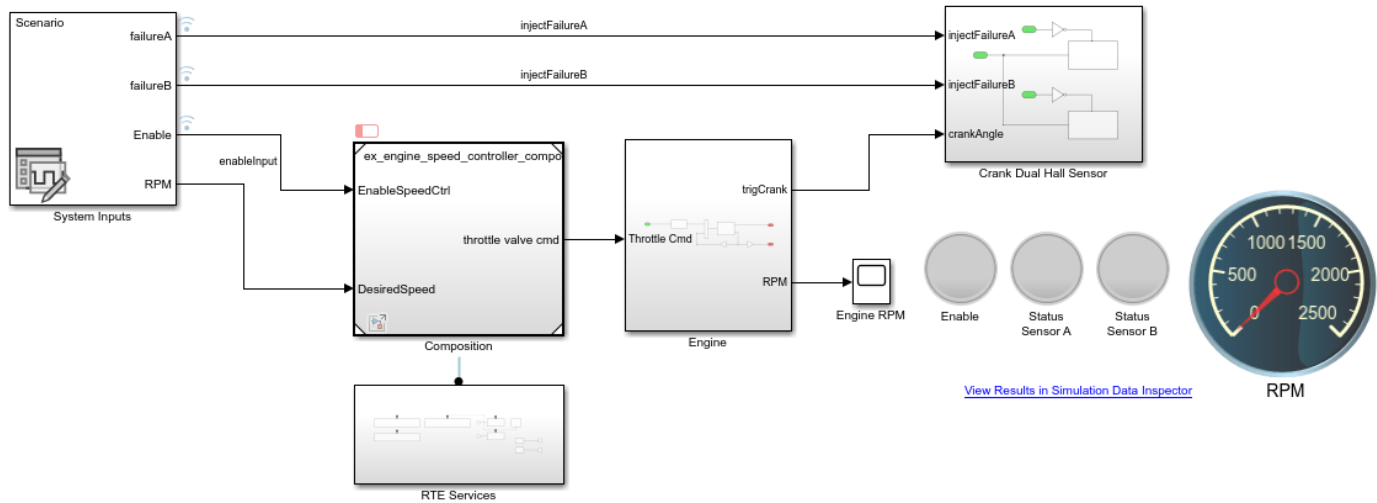

In this example, we simulate the digital speed control of an internal combustion engine. In this model, the angular velocity of the engine is measured using two redundant Hall sensors, and we simulate the failure of the Hall sensors.

The model primarily contains the following main components:

- **System Inputs:** Inputs and signals to exercise the system.

- **Engine:** Simplified representation of internal combustion engine.
- **Composition:** Digital controller intended to deploy on an Engine Control Unit (ECU), with a Runtime Environment (RTE).
- **Crank Dual Hall Sensor:** Emulation of two redundant sensors, sensor A and sensor B.
- **RTE Services:** Emulation of the services provided by Engine Control Unit.

```
open_system("ex_engine_speed_control_system");
```

System Inputs

The system inputs for this model are designed using the Signal Editor block. The `ex_engine_speed_control_external_inputs.mat` file contains the following scenario:

- The desired angular velocity is set to 2000 rpm for the entire simulation.
- At $t = 01$ sec, the speed controller is enabled. As a result, Hall sensor A is being used to compute the angular velocity and the engine speed increases to 2000 rpm.
- At $t = 06$ sec, a failure of the first Hall sensor is injected. As a result, Hall sensor B is now being used to compute the angular velocity, the engine speed remains at 2000 rpm.
- At $t = 11$ sec, a failure of the second sensor is injected. As a result, the speed controller is disabled, the engine speed falls toward zero.
- At $t = 15$ sec, the failure of sensors A and B gets resolved.
- At $t = 21$ sec, the command to enable speed control is cycled back to zero for one second and back to one. As a result, the engine speed increases to 2000 rpm.

Engine

The engine dynamics are represented by a Transfer Function that receives a throttle command and converts it into torque, and a Second Order Integrator to integrate the motion.

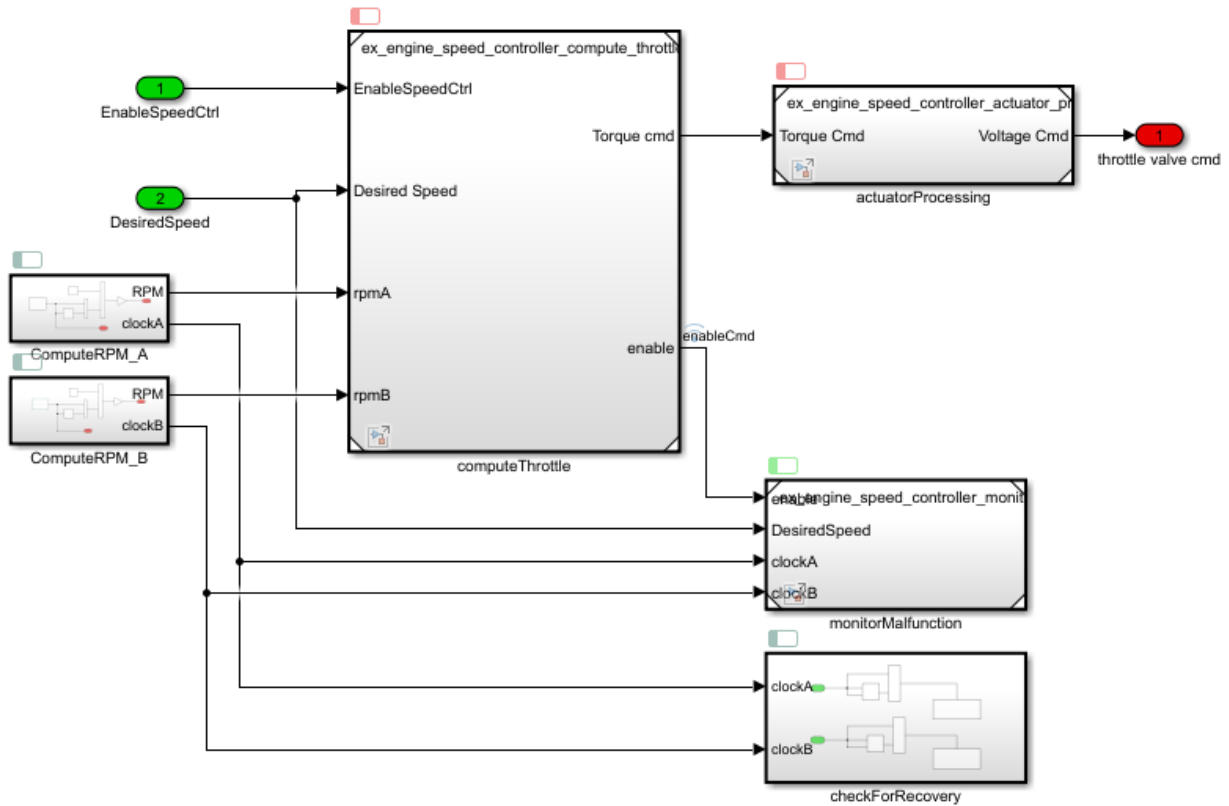

Composition

`ex_engine_speed_controller_composition` implements the digital control algorithm. It contains the following components:

- **ComputeRPM_A and ComputeRPM_B:** Aperiodic partitions registered as hardware interrupts. Hall sensors A and B trigger these partitions when the engine shaft rotates by every increment of 10 degrees.
- **computeThrottle and actuatorProcessing:** Periodic partitions executing at 0.001 sec. `computeThrottle` interrogates the RTE at every time step.
- **monitorMalfunction:** Periodic partition executing at 0.01 sec. Monitors output signals of `ComputeRPM_A` and `ComputeRPM_B` to identify potential hardware failures. If a failure is detected, it calls a function provided by the RTE to register the failure.
- **checkForRecovery:** Aperiodic partition that is triggered by RTE once a failure has been detected. Upon detection, `checkForRecovery` is called by the RTE at a rate of 1 sec. It calls a function provided by the RTE if a recovery is detected.

Using the Schedule Editor, the events `checkForRecovery`, `trigCrankA`, and `trigCrankB` are created and bound to aperiodic partitions `checkForRecovery`, `ComputeRPM_A`, and `ComputeRPM_B` respectively. These events are broadcast from the top model.

Crank Dual Hall Sensor

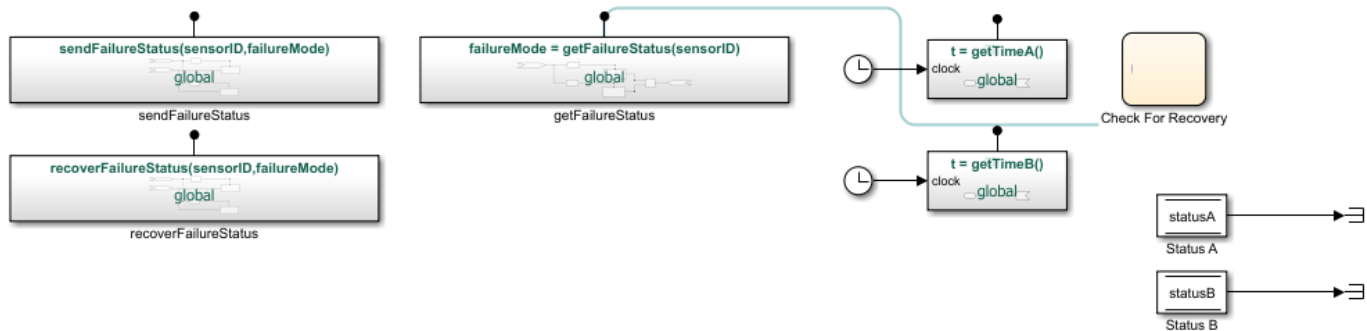

The Hall sensors are modeled using Hit Crossing blocks that generate a function-call every time the engine shaft rotates by increments of 10 degrees. When the Stateflow chart gets triggered, it sends events `trigCrankA` and `trigCrankB`, which have been bound to execute aperiodic partitions, `ComputeRPM_A` and `ComputeRPM_B` respectively.

RTE Services

The RTE Services subsystem emulates functionalities available on the Run-time Environment onto which the code generated from the digital controller is deployed. For simulation purposes, those services are emulated using Simulink Functions.

- **sendFailureStatus** and **recoverFailureStatus** are called respectively by the `monitorMalfunctions` and `checkForRecovery` partitions when a failure or a recovery is detected. The global failure statuses are stored using Data Store Memory blocks for simulation purposes.
- **getFailureMode** is called by the `computeThrottle` to verify if a failure has been detected in one of the sensors.
- **getTimeA** and **getTimeB** simulate the RTE clock.
- **Check for Recovery** simulates the logic to determine when the `checkForRecovery` aperiodic partition of the digital controller should be triggered. Triggering is done by broadcasting the event `checkForRecovery`.

Open the Schedule Editor

To open the Schedule Editor, on the **Modeling** tab in the **Design Section**, click **Schedule Editor**. Doing an Update Diagram compiles the models and shows you the existing partitions in the Schedule Editor.

The screenshot shows the Schedule Editor interface for the system 'ex_engine_speed_control_system'. The main workspace displays a state transition diagram with several nodes and transitions. A legend on the left side identifies event types: Cont (black), FiM (grey), D2 (green), and D3 (blue). On the right side, the 'ORDER' panel lists partitions in execution order, and the 'PROPERTY INSPECTOR' is empty.

Order	Name	Trigger
1	Composition.computeRPM_A	trigCrankA
2	Composition.computeRPM_B	trigCrankB
3	Cont implicit	0
	FiM implicit	[0, 1]
	D2 implicit	0.01
	D3 implicit	1
4	Composition.computeThrottle.D1	0.001
5	Composition.actuatorProcessing.D1	0.001
6	Composition.checkForRecovery	checkForRecovery
7	Composition.D1	0.001
8	Composition.Model.D1	0.01

Events Panel in the Schedule Editor

The events broadcast by the send keyword in Stateflow are shown in the **Events** panel of the Schedule Editor, these events are bound to aperiodic partitions, so that these partitions can be triggered from the top model. In the **Events** panel, you can expand each event to see the listeners

and the broadcasters of that event. The icon,  indicates broadcaster of the event and the icon,

 indicates the listener. In this example, the sender of the event checkForRecovery is the Stateflow Chart in RTE Services subsystem, the sender of the events trigCrankA and trigCrankB is the Stateflow chart in the Crank Dual Hall -> Sensor A and Sensor B.

In the **Order** panel, the partitions are arranged in the order of priority of execution. Since ComputerRPM_A and ComputerRPM_B are time sensitive, their priority is the highest. Therefore, when the events trigCrankA and trigCrankB are broadcast, the corresponding partitions ComputerRPM_A and ComputerRPM_B are executed immediately. In contrast, the aperiodic partition checkForRecovery is less time sensitive, and is lower in the priority order. Therefore, when the event checkForRecovery is broadcast, the execution of the corresponding partition checkForRecovery is deferred until all the partitions with higher priority complete execution.

The screenshot displays the Schedule Editor for the 'ex_engine_speed_control_system'. The central workspace shows a diagram with several blocks and their connections. A block labeled 'trigCrankA' is connected to 'Composition.computeRPM_A'. Below this, there are two blocks labeled '0.001 Composition.computeThrottle.D1' and '0.001 Composition.actuatorProcessing.D1'. The 'EVENTS' pane on the left lists the following events:

- checkForRecovery
 - ex_engine_speed_control_system/Ch
 - Composition.checkForRecovery
 - + add listener
- trigCrankA
 - ex_engine_speed_control_system/Cr
 - Composition.computeRPM_A (selected)
 - + add listener
- trigCrankB
 - ex_engine_speed_control_system/Cr
 - Composition.computeRPM_B
 - + add listener

The 'ORDER' pane on the right shows the following table:

Order	Name	Trigger
1	computeRPM_A	trigCrankA
2	computeRPM_B	trigCrankB
3	Cont implicit	0
	FiM implicit	[0, 1]
	D2 implicit	0.01
	D3 implicit	1
4	uteThrottle.D1	0.001
5	Processing.D1	0.001
6	kForRecovery	checkForRecovery
7	omposition.D1	0.001
8	ition.Model.D1	0.01

The 'PROPERTY INSPECTOR' at the bottom right shows the following details for the selected event:

Partition	
Name	Composition.computeRPM_A
Rate	A
Trigger	trigCrankA
Type	Explicit aperiodic partition

You can view this event connection in the Simulink model, this connection conveys the flow of execution between a block broadcasting an event and another block listening to that event. To view this connection, on the Simulink Toolstrip, on the **Debug** tab, select **Information Overlays** in the

Diagnostic section. From the drop-down menu, select **Schedule Connectors**  in the **Blocks** section.

Simulation Results

Click on **View Results in Simulation Data Inspector** in the model to view the results of the simulation.

Test Harness Generation

You can use the Schedule Editor to generate a test harness for a model with events. Using events with test harnesses helps you avoid complex wiring between the test sequence block and the entire system.

The generated test harness gets its own Schedule Editor, which enables you to easily send events through the test harness. Through the test harness scheduler, you can test the model under different scenarios by triggering events at specific times.

The Events panel also allows you to bind existing events to other aperiodic partitions. You can do this by dragging and dropping the event over a valid aperiodic partition, or by adding the partition

directly using the dropdown. You can order the partitions that have events as their Trigger in the Order table relative to the other partitions. You can also create events in Schedule Editor. Click the plus icon. Double click Add Row to create a new event. You can use this event to send from Stateflow to schedule execution of an aperiodic partition.

Limitations and Error Conditions

- Events in the Schedule Editor cannot be used in models with export-functions.
- Events do not support code generation and do not impact the generated code.

Events in the Schedule Editor use the following guidelines:

- An event cannot be raised before that event has processed.
- Duplicate event names in the parent model caused by giving two model references the same name are not allowed.
- Infinite looping is not allowed.
- A partition cannot raise an event that triggers itself.

Simulate a Model Interactively

Simulation Basics

You can simulate a model in the Simulink Editor using the **Run** button  on the toolbar. The **Run** button also appears in tools within the Simulink Editor. You can simulate from any tool that includes the button, such as the Scope viewer.

Before you start a simulation, you can specify options like simulation start time, stop time, and the solver for solving the model. (See “Solver Selection Criteria” on page 25-5) You specify these options in the Configuration Parameters dialog box, which you can open by clicking **Model Settings**  on the **Modeling** tab. These settings are saved with the model in a configuration set. You can create multiple configuration sets for each model and switch between them to see the effects of different settings. See “Model Configuration Sets”.

By default, simulations start at 0.0 s and end at 10.0 s.

Note In the Simulink software, time and all related parameters (such as sample times) are implicitly in seconds. If you choose to use a different time unit, scale parameters accordingly.

The **Solver** configuration pane allows you to specify other start and stop times for the currently selected simulation configuration. See “Solver Pane” for more information.

Note Simulation time and actual clock time are not the same. For example, if running a simulation for 10 s usually does not take 10 s as measured on a clock. The amount of time it actually takes to run a simulation depends on many factors including the complexity of the model, the step sizes, and the computer speed.

After you set your model configuration parameters, you can start the simulation. You can pause, resume, and stop simulation using toolbar controls. You can also simulate more than one model at a time, so you can start another simulation while one is running.

During simulation, you cannot make changes to the structure of the model, such as adding or deleting lines or blocks. However, you can make these changes while a simulation is running:

- Modify some configuration parameters, including the stop time and the maximum step size.
- Modify the parameters of a block, as long as you do not cause a change in:
 - Number of states, inputs, or outputs
 - Sample time
 - Number of zero crossings
 - Vector length of any block parameters
 - Length of the internal block work vectors
 - Dimension of any signals

You can also examine the model visually as it simulates. For example, you can click a line to see the signal carried on that line on a Floating Scope or Display block. You can also display port values as a model simulates. See “Display Port Values for Debugging” on page 36-18.

Run, Pause, and Stop a Simulation

To start simulating your model, click the **Run** button . You can pause, resume, or stop a simulation using the corresponding controls on the toolstrip.

The model starts simulating at the specified start time and runs until the specified end time. While the simulation is running, information at the bottom of the editor shows the percentage of simulation completed and the current simulation time.

- If an error occurs, simulation stops and a message appears. If a warning condition occurs, simulation completes. In both cases, click the diagnostics link at the bottom of the editor to see the message, which helps you to locate errors.
- Pausing takes effect after the current time step finishes executing. Resuming a paused simulation occurs at the next time step.
- If you stop a simulation, the current time step completes, and then simulation stops.
- If the model outputs to a file or to the workspace, stopping or pausing simulation writes the data.

Use Blocks to Stop or Pause a Simulation

Stop Simulation Using Stop Simulation Blocks

You can use the Stop Simulation block to stop a simulation when the input to the block is nonzero. If the block input is a vector, any nonzero element stops the simulation.

- 1 Add a Stop Simulation block to your model.
- 2 Connect the Stop Simulation block to a signal whose value becomes nonzero at the specified stop time.

For example, this model stops the simulation when the simulation time reaches 10.

Pause Simulation Using Assertion Blocks

You can use an Assertion block to pause the simulation when the input signal to the block is zero. The Assertion block uses the `set_param` command to pause the simulation. See “Run Simulations

Programmatically” on page 26-2 for more information on using the `set_param` command to control the execution of a Simulink model.

- 1 Add an Assertion block to your model.
- 2 Connect the Assertion block to a signal whose value becomes zero at the desired pause time.
- 3 In the Assertion block dialog box, clear the **Stop simulation when assertion fails** check box. Enter this command as the value of **Simulation callback when assertion fails**:

```
set_param(bdroot,'SimulationCommand','pause'),
disp(sprintf('\nSimulation paused.'))
```

This model uses an Assertion block with these settings to pause the simulation when the simulation time reaches 5.

When the simulation pauses, a message appears that shows the time the block paused the simulation.

You can resume the simulation using **Continue** as you can for any paused simulation.

Choose a Solver

To simulate a dynamic system, you compute its states at successive time steps over a specified time span. This computation uses information provided by a model of the system. Time steps are time intervals when the computation happens. The size of this time interval is called step size. The process of computing the states of a model in this manner is known as solving the model. No single method of solving a model applies to all systems. Simulink provides a set of programs called solvers. Each solver embodies a particular approach to solving a model.

A solver applies a numerical method to solve the set of ordinary differential equations that represent the model. Through this computation, it determines the time of the next simulation step. In the process of solving this initial value problem, the solver also satisfies the accuracy requirements that you specify.

Mathematicians have developed a wide variety of numerical integration techniques for solving the ordinary differential equations (ODEs) that represent the continuous states of dynamic systems. An extensive set of fixed-step and variable-step continuous solvers are provided, each of which implements a specific ODE solution method (see “Compare Solvers” on page 3-6). Select solvers in the **Solver** pane of model configuration parameters.

All solvers provided by MATLAB and Simulink follow a similar naming convention: **ode**, followed by two or three numerals indicating the orders of the solver. Some solvers can solve stiff differential equations and the methods used by them are expressed by the **s**, **t**, or **tb** suffixes.

Solver Selection Criteria

The appropriate solver for simulating a model depends on these characteristics:

- System dynamics
- Solution stability
- Computation speed
- Solver robustness

As such, the numerical solvers provided by Simulink can be broadly classified by two properties.

Computation Step Size Type

- Fixed-step solvers, as the name suggests, solve the model using the same step size from the beginning to the end of the simulation. You can specify the step size or let the solver choose it. Generally, decreasing the step size increases the accuracy of the results and the time required to simulate the system.
- Variable-step solvers vary the step size during the simulation. These solvers reduce the step size to increase accuracy at certain events during the simulation of the model, such as rapid state changes, zero-crossing events, etc. Also, they increase the step size to avoid taking unnecessary steps when the states of a model change slowly. Computing the step size adds to the computational overhead at each step. However, it can reduce the total number of steps, and hence the simulation time required to maintain a specified level of accuracy for models with zero-crossings, rapidly changing states, and other events requiring extra computation.

Model States

- Continuous solvers use numerical integration to compute continuous states of a model at the current time step based on the states at previous time steps and the state derivatives. Continuous solvers rely on individual blocks to compute the values of the discrete states of the model at each time step.
- Discrete solvers are primarily used for solving purely discrete models. They compute only the next simulation time step for a model. When they perform this computation, they rely on each block in the model to update its individual discrete state. They do not compute continuous states.

Use an iterative approach to choose a solver for your requirements. Compare simulation results from several solvers and select a solver that offers the best performance with minimal tradeoffs.

Select a solver for your model in these ways:

- Use auto solver. New models have their solver selection set to auto solver by default. Auto solver recommends a fixed-step or variable-step solver for your model as well as the maximum step size. For more information, see “Select Solver Using Auto Solver” on page 25-38.
- If you are not satisfied with the simulation results using auto solver, select a solver in the **Solver** pane in the model configuration parameters.

When you build and simulate a model, you can choose the solver based on the dynamics of your model. A variable-step solver is better suited for purely continuous models, like the dynamics of a mass spring damper system. A fixed-step solver is recommended for a model that contains several switches, like an inverter power system, due to the number of solver resets that would cause a variable-step solver to behave like a fixed-step solver.

Note When you deploy a model as generated code, you can use only a fixed-step solver. If you select a variable-step solver during simulation, use it to calculate the step size required for the fixed-step solver that you need at deployment.

This chart provides a broad classification of solvers in the Simulink library.

To tailor the selected solver to your model, see “Check and Improve Simulation Accuracy” on page 31-11.

Ideally, the solver you select should:

- Solve the model successfully.
- For variable-step solvers, provide a solution within the tolerance limits you specify.
- Solve the model in a reasonable duration.

A single solver might not meet all of these goals. Try simulating using different solvers before making a selection.

The Simulink library provides several solvers, all of which can work with the algebraic loop solver. For more information, see “How the Algebraic Loop Solver Works” on page 3-30.

Solver Type	Explicit/ Implicit	Discrete	Continuous	Variable-Order

Choose a Jacobian Method for an Implicit Solver

For implicit solvers, Simulink must compute the *solver Jacobian*, which is a submatrix of the Jacobian matrix associated with the continuous representation of a Simulink model. In general, this continuous representation is of the form:

$$\begin{aligned}\dot{x} &= f(x, t, u) \\ y &= g(x, t, u).\end{aligned}$$

The Jacobian, J , formed from this system of equations is:

$$J = \begin{pmatrix} \frac{\partial f}{\partial x} & \frac{\partial f}{\partial u} \\ \frac{\partial g}{\partial x} & \frac{\partial g}{\partial u} \end{pmatrix} = \begin{pmatrix} A & B \\ C & D \end{pmatrix}.$$

In turn, the solver Jacobian is the submatrix, J_x .

$$J_x = A = \frac{\partial f}{\partial x}.$$

Sparsity of Jacobian

For many physical systems, the solver Jacobian J_x is *sparse*, meaning that many of the elements of J_x are zero.

Consider the following system of equations:

$$\begin{aligned}\dot{x}_1 &= f_1(x_1, x_3) \\ \dot{x}_2 &= f_2(x_2) \\ \dot{x}_3 &= f_3(x_2).\end{aligned}$$

From this system, you can derive a sparsity pattern that reflects the structure of the equations. The pattern, a Boolean matrix, has a 1 for each x_i that appears explicitly on the right-hand side of an equation. Therefore, you obtain:

$$J_{x, pattern} = \begin{pmatrix} 1 & 0 & 1 \\ 0 & 1 & 0 \\ 0 & 1 & 0 \end{pmatrix}$$

The sparse perturbation and the sparse analytical methods may be able to take advantage of this sparsity pattern to reduce the number of computations necessary and improve performance.

Solver Jacobian Methods

When you choose an implicit solver from the **Solver** pane of the configuration parameters dialog box, a parameter called Solver Jacobian method and a drop-down menu appear. This menu has five options for computing the solver Jacobian.

Note If you set **Automatic solver parameter selection** to **error** in the Solver Diagnostics pane, and you choose a different solver than that suggested by Simulink, you may receive an error.

Limitations

The solver Jacobian methods have these limitations associated with them.

- If you select an analytical Jacobian method, but one or more blocks in the model do not have an analytical Jacobian, then Simulink applies a perturbation method.
- If you select sparse perturbation and your model contains data store blocks, Simulink applies the full perturbation method.

Heuristic 'auto' Method

The default setting for the Solver Jacobian method is **auto**. Selecting this choice causes Simulink to determine which of the remaining four methods best suits your model. This flowchart depicts the algorithm.

Sparse methods are beneficial for models that have a large number of states. If 50 or more states exist in your model, `auto` chooses a sparse method. Unlike other implicit solvers, `ode23s` is a sparse method because it generates a new Jacobian at every time step. A sparse analytical or a sparse perturbation method is, therefore, advantageous. Selecting `auto` also ensures that the analytical methods are used only if every block in your model can generate an analytical Jacobian.

Full and Sparse Perturbation Methods

The full perturbation method solves the full set of perturbation equations and uses LAPACK for linear algebraic operations. This method is costly from a computational standpoint, but remains a recommended method for establishing baseline results.

The sparse perturbation method attempts to improve the run-time performance by taking mathematical advantage of the sparse Jacobian pattern. Returning to the sample system of three equations and three states,

$$\dot{x}_1 = f_1(x_1, x_3)$$

$$\dot{x}_2 = f_2(x_2)$$

$$\dot{x}_3 = f_3(x_2).$$

The solver Jacobian is:

$$J_x = \begin{pmatrix} \frac{\partial f_1}{\partial x_1} & \frac{\partial f_1}{\partial x_2} & \frac{\partial f_1}{\partial x_3} \\ \frac{\partial f_2}{\partial x_1} & \frac{\partial f_2}{\partial x_2} & \frac{\partial f_2}{\partial x_3} \\ \frac{\partial f_3}{\partial x_1} & \frac{\partial f_3}{\partial x_2} & \frac{\partial f_3}{\partial x_3} \end{pmatrix}$$

$$= \begin{pmatrix} \frac{f_1(x_1 + \Delta x_1, x_2, x_3) - f_1}{\Delta x_1} & \frac{f_1(x_1, x_2 + \Delta x_2, x_3) - f_1}{\Delta x_2} & \frac{f_1(x_1, x_2, x_3 + \Delta x_3) - f_1}{\Delta x_3} \\ \frac{f_2(x_1 + \Delta x_1, x_2, x_3) - f_2}{\Delta x_1} & \frac{f_2(x_1, x_2 + \Delta x_2, x_3) - f_2}{\Delta x_2} & \frac{f_2(x_1, x_2, x_3 + \Delta x_3) - f_2}{\Delta x_3} \\ \frac{f_3(x_1 + \Delta x_1, x_2, x_3) - f_3}{\Delta x_1} & \frac{f_3(x_1, x_2 + \Delta x_2, x_3) - f_3}{\Delta x_2} & \frac{f_3(x_1, x_2, x_3 + \Delta x_3) - f_3}{\Delta x_3} \end{pmatrix}$$

It is, therefore, necessary to perturb each of the three states three times and to evaluate the derivative function three times. For a system with n states, this method perturbs the states n times.

By applying the sparsity pattern and perturbing states x_1 and x_2 together, this matrix reduces to:

$$J_x = \begin{pmatrix} \frac{f_1(x_1 + \Delta x_1, x_2 + \Delta x_2, x_3) - f_1}{\Delta x_1} & 0 & \frac{f_1(x_1, x_2, x_3 + \Delta x_3) - f_1}{\Delta x_3} \\ 0 & \frac{f_2(x_1 + \Delta x_1, x_2 + \Delta x_2, x_3) - f_2}{\Delta x_2} & 0 \\ 0 & \frac{f_3(x_1 + \Delta x_1, x_2 + \Delta x_2, x_3) - f_3}{\Delta x_2} & 0 \end{pmatrix}$$

The solver can now solve columns 1 and 2 in one sweep. While the sparse perturbation method saves significant computation, it also adds overhead to compilation. It might even slow down the simulation if the system does not have a large number of continuous states. A tipping point exists for which you obtain increased performance by applying this method. In general, systems having a large number of continuous states are usually sparse and benefit from the sparse method.

The sparse perturbation method, like the sparse analytical method, uses UMFPACK to perform linear algebraic operations. Also, the sparse perturbation method supports both RSim and rapid accelerator mode.

Full and Sparse Analytical Methods

The full and sparse analytical methods attempt to improve performance by calculating the Jacobian using analytical equations rather than the perturbation equations. The sparse analytical method, also uses the sparsity information to accelerate the linear algebraic operations required to solve the ordinary differential equations.

For details on how to access and interpret the sparsity pattern in MATLAB, see “Exploring the Solver Jacobian Structure of a Model”.

Code Generation Support

While the sparse perturbation method supports RSim, the sparse analytical method does not. Consequently, regardless of which sparse method you select, any generated code uses the sparse perturbation method. This limitation applies to rapid accelerator mode as well.

Variable Step Solvers in Simulink

Variable-step solvers vary the step size during the simulation, reducing the step size to increase accuracy when model states are changing rapidly and increasing the step size to avoid taking unnecessary steps when model states are changing slowly. Computing the step size adds to the computational overhead at each step but can reduce the total number of steps, and hence simulation time, required to maintain a specified level of accuracy for models with rapidly changing or piecewise continuous states.

When you set the **Type** control of the **Solver** configuration pane to **Variable-step**, the **Solver** control allows you to choose one of the variable-step solvers. As with fixed-step solvers, the set of variable-step solvers comprises a discrete solver and a collection of continuous solvers. However, unlike the fixed-step solvers, the step size varies dynamically based on the local error.

The choice between the two types of variable-step solvers depends on whether the blocks in your model define states and, if so, the type of states that they define. If your model defines no states or defines only discrete states, select the discrete solver. If the model has continuous states, the continuous solvers use numerical integration to compute the values of the continuous states at the next time step.

Note If a model has no states or only discrete states, Simulink uses the discrete solver to simulate the model even if you specify a continuous solver.

Variable-Step Discrete Solver

Use the variable-step discrete solver when your model does not contain continuous states. For such models, the variable-step discrete solver reduces its step size in order to capture model events such as zero-crossings, and increases the step size when it is possible to improve simulation performance.

The model shown in the figure contains two discrete sine wave signals at 0.5 and 0.75 sample times. The graphs below show the signals in the model along with the solver steps for the variable-step discrete and the fixed-step discrete solvers respectively. You can see that the variable-step solver only

takes the steps needed to record the output signal from each block. On the other hand, the fixed-step solver will need to simulate with a fixed-step size—or fundamental sample time—of 0.25 to record all the signals, thus taking more steps overall.

Variable-Step Continuous Solvers

Variable-step solvers dynamically vary the step size during the simulation. Each of these solvers increases or reduces the step size using its local error control to achieve the tolerances that you specify. Computing the step size at each time step adds to the computational overhead. However, it can reduce the total number of steps, and the simulation time required to maintain a specified level of accuracy.

You can further categorize the variable-step continuous solvers as one-step or multistep, single-order or variable-order, and explicit or implicit. See “One-Step Versus Multistep Continuous Solvers” on page 3-8 for more information.

Variable-Step Continuous Explicit Solvers

The variable-step explicit solvers are designed for nonstiff problems. Simulink provides four such solvers:

- ode45
- ode23
- ode113
- odeN

ODE Solver	One-Step Method	Multistep Method	Order of Accuracy	Method
ode45	X		Medium	Runge-Kutta, Dormand-Prince (4,5) pair
ode23	X		Low	Runge-Kutta (2,3) pair of Bogacki & Shampine

ODE Solver	One-Step Method	Multistep Method	Order of Accuracy	Method
ode113		X	Variable, Low to High	PECE Implementation of Adams-Bashforth-Moulton
odeN	X		See Order of Accuracy in “Fixed-Step Continuous Explicit Solvers” on page 25-22	See Integration Technique in “Fixed-Step Continuous Explicit Solvers” on page 25-22

ODE Solver	When to Use
ode45	In general, the ode45 solver is the best to apply as a first try for most problems. The Runge-Kutta (4,5) solver is a fifth-order method that performs a fourth-order estimate of the error. This solver also uses a fourth-order interpolant, which allows for event location and smoother plots. If the ode45 is computationally slow, the problem may be stiff and thus require an implicit solver.
ode113	For problems with stringent error tolerances or for computationally intensive problems, the Adams-Bashforth-Moulton PECE solver can be more efficient than ode45.
ode23	The ode23 can be more efficient than the ode45 solver at crude error tolerances and in the presence of mild stiffness. This solver provides accurate solutions by applying a cubic Hermite interpolation to the values and slopes computed at the ends of a step.
odeN	The odeN solver uses a nonadaptive Runge-Kutta integration whose order is determined by the Solver order parameter. odeN uses a fixed step size determined by the Max step size parameter, but the step size can be reduced to capture certain solver events, such as zero-crossings and discrete sample hits.

Note Select the odeN solver when simulation speed is important, for example, when

- The model contains lots of zero-crossings and/or solver resets
- The **Solver Profiler** does not detect any failed steps when profiling the model

Variable-Step Continuous Implicit Solvers

If your problem is stiff, try using one of the variable-step implicit solvers:

- ode15s
- ode23s
- ode23t
- ode23tb

ODE Solver	One-Step Method	Multistep Method	Order of Accuracy	Solver Reset Method	Max. Order	Method
ode15s		X	Variable, low to medium	X	X	Numerical Differentiation Formulas (NDFs)
ode23s	X		Low			Second-order, modified Rosenbrock formula
ode23t	X		Low	X		Trapezoidal rule using interpolant
ode23tb	X		Low	X		TR-BDF2

Solver Reset Method

For ode15s, ode23t, and ode23tb a drop-down menu for the **Solver reset method** appears in the **Solver details** section of the Configuration pane. This parameter controls how the solver treats a reset caused, for example, by a zero-crossing detection. The options allowed are **Fast** and **Robust**. **Fast** specifies that the solver does not recompute the Jacobian for a solver reset, whereas **Robust** specifies that the solver does. Consequently, the **Fast** setting is computationally faster but it may use a small step size in certain cases. To test for such cases, run the simulation with each setting and compare the results. If there is no difference in the results, you can safely use the **Fast** setting and save time. If the results differ significantly, try reducing the step size for the fast simulation.

Maximum Order

For the ode15s solver, you can choose the maximum order of the numerical differentiation formulas (NDFs) that the solver applies. Since the ode15s uses first- through fifth-order formulas, the **Maximum order** parameter allows you to choose orders 1 through 5. For a stiff problem, you may want to start with order 2.

Tips for Choosing a Variable-Step Implicit Solver

The following table provides tips for the application of variable-step implicit solvers. For an example comparing the behavior of these solvers, see “Exploring Variable-Step Solvers Using a Stiff Model”.

ODE Solver	Tips on When to Use
ode15s	ode15s is a variable-order solver based on the numerical differentiation formulas (NDFs). NDFs are related to, but are more efficient than the backward differentiation formulas (BDFs), which are also known as Gear's method. The ode15s solver numerically generates the Jacobian matrices. If you suspect that a problem is stiff, or if ode45 failed or was highly inefficient, try ode15s. As a rule, start by limiting the maximum order of the NDFs to 2.
ode23s	ode23s is based on a modified Rosenbrock formula of order 2. Because it is a one-step solver, it can be more efficient than ode15s at crude tolerances. Like ode15s, ode23s numerically generates the Jacobian matrix for you. However, it can solve certain kinds of stiff problems for which ode15s is not effective.
ode23t	The ode23t solver is an implementation of the trapezoidal rule using a “free” interpolant. Use this solver if your model is only moderately stiff and you need a solution without numerical damping. (Energy is not dissipated when you model oscillatory motion.)

ODE Solver	Tips on When to Use
ode23tb	ode23tb is an implementation of TR-BDF2, an implicit Runge-Kutta formula with two stages. The first stage is a trapezoidal rule step while the second stage uses a backward differentiation formula of order 2. By construction, the method uses the same iteration matrix in evaluating both stages. Like ode23s, this solver can be more efficient than ode15s at crude tolerances.

Note For a stiff problem, solutions can change on a time scale that is very small as compared to the interval of integration, while the solution of interest changes on a much longer time scale. Methods that are not designed for stiff problems are ineffective on intervals where the solution changes slowly because these methods use time steps small enough to resolve the fastest possible change. For more information, see Shampine, L. F., *Numerical Solution of Ordinary Differential Equations*, Chapman & Hall, 1994.

Error Tolerances for Variable-Step Solvers

Local Error

The variable-step solvers use standard control techniques to monitor the local error at each time step. During each time step, the solvers compute the state values at the end of the step and determine the *local error*—the estimated error of these state values. They then compare the local error to the *acceptable error*, which is a function of both the relative tolerance (*rtol*) and the absolute tolerance (*atol*). If the local error is greater than the acceptable error for *any one* state, the solver reduces the step size and tries again.

- Relative tolerance measures the error relative to the size of each state. The relative tolerance represents a percentage of the state value. The default, 1e-3, means that the computed state is accurate to within 0.1%.
- Absolute tolerance is a threshold error value. This tolerance represents the acceptable error as the value of the measured state approaches zero.

The solvers require the error for the i th state, e_i , to satisfy:

$$e_i \leq \max(\text{rtol} \times |x_i|, \text{atol}_i).$$

The following figure shows a plot of a state and the regions in which the relative tolerance and the absolute tolerance determine the acceptable error.

Absolute Tolerances

Your model has a global absolute tolerance that you can set on the Solver pane of the Configuration Parameters dialog box. This tolerance applies to all states in the model. You can specify `auto` or a

real scalar. If you specify `auto` (the default), Simulink initially sets the absolute tolerance for each state based on the relative tolerance. If the relative tolerance is larger $1e-3$, `abstol` is initialized at $1e-6$. However, for `reltol` smaller than $1e-3$, `abstol` for the state is initialized at `reltol * 1e-3`. As the simulation progresses, the absolute tolerance for each state resets to the maximum value that the state has assumed so far, times the relative tolerance for that state. Thus, if a state changes from 0 to 1 and `reltol` is $1e-3$, `abstol` initializes at $1e-6$ and by the end of the simulation reaches $1e-3$ also. If a state goes from 0 to 1000, then `abstol` changes to 1.

Now, if the state changes from 0 to 1 and `reltol` is set at $1e-4$, then `abstol` initializes at $1e-7$ and by the end of the simulation reaches a value of $1e-4$.

If the computed initial value for the absolute tolerance is not suitable, you can determine an appropriate value yourself. You might have to run a simulation more than once to determine an appropriate value for the absolute tolerance. You can also specify if the absolute tolerance should adapt similarly to its `auto` setting by enabling or disabling the `AutoScaleAbsTol` parameter. For more information, see “Auto scale absolute tolerance”.

Several blocks allow you to specify absolute tolerance values for solving the model states that they compute or that determine their output:

- Integrator
- Second-Order Integrator
- Variable Transport Delay
- Transfer Fcn
- State-Space
- Zero-Pole

The absolute tolerance values that you specify for these blocks override the global settings in the Configuration Parameters dialog box. You might want to override the global setting if, for example, the global setting does not provide sufficient error control for all of your model states because they vary widely in magnitude. You can set the block absolute tolerance to:

- `auto`
- `-1` (same as `auto`)
- `positive scalar`
- `real vector` (having a dimension equal to the number of corresponding continuous states in the block)

Tips

If you do choose to set the absolute tolerance, keep in mind that too low of a value causes the solver to take too many steps in the vicinity of near-zero state values. As a result, the simulation is slower.

On the other hand, if you set the absolute tolerance too high, your results can be inaccurate as one or more continuous states in your model approach zero.

Once the simulation is complete, you can verify the accuracy of your results by reducing the absolute tolerance and running the simulation again. If the results of these two simulations are satisfactorily close, then you can feel confident about their accuracy.

Fixed Step Solvers in Simulink

Fixed-step solvers solve the model at regular time intervals from the beginning to the end of the simulation. The size of the interval is known as the step size. You can specify the step size or let the solver choose the step size. Generally, a smaller the step size increases the accuracy of the results but also increases the time required to simulate the system.

Fixed-Step Discrete Solver

The fixed-step discrete solver computes the time of the next simulation step by adding a fixed step size to the current time. The accuracy and the length of time of the resulting simulation depends on the size of the steps taken by the simulation: the smaller the step size, the more accurate the results are but the longer the simulation takes. By default, Simulink chooses the step size or you can choose the step size yourself. If you choose the default setting of `auto`, and if the model has discrete sample times, then Simulink sets the step size to the fundamental sample time of the model. Otherwise, if no discrete rates exist, Simulink sets the size to the result of dividing the difference between the simulation start and stop times by 50.

Fixed-Step Continuous Solvers

The fixed-step continuous solvers, like the fixed-step discrete solver, compute the next simulation time by adding a fixed-size time step to the current time. For each of these steps, the continuous solvers use numerical integration to compute the values of the continuous states for the model. These values are calculated using the continuous states at the previous time step and the state derivatives at intermediate points (minor steps) between the current and the previous time step.

Note Simulink uses the fixed-step discrete solver for a model that contains no states or only discrete states, even if you specify a fixed-step continuous solver for the model.

Simulink provides two types of fixed-step continuous solvers — explicit and implicit.

The difference between these two types lies in the speed and the stability. An implicit solver requires more computation per step than an explicit solver but is more stable. Therefore, the implicit fixed-step solver that Simulink provides is more adept at solving a stiff system than the fixed-step explicit solvers. For a comparison of explicit and implicit solvers, see “Explicit Versus Implicit Continuous Solvers” on page 3-8.

Fixed-Step Continuous Explicit Solvers

Explicit solvers compute the value of a state at the next time step as an explicit function of the current values of both the state and the state derivative. A fixed-step explicit solver is expressed mathematically as:

$$x(n + 1) = x(n) + h * Dx(n)$$

where

- x is the state.
- Dx is a solver-dependent function that estimates the state derivative.
- h is the step size.

- n indicates the current time step.

Simulink provides a set of fixed-step continuous explicit solvers. The solvers differ in the specific numerical integration technique that they use to compute the state derivatives of the model. This table lists each solver and the integration technique it uses. The table lists the solvers in the order of the computational complexity of the integration methods they use, from the least complex (ode1) to the most complex (ode8).

Solver	Integration Technique	Order of Accuracy
ode1	Euler's method	First
ode2	Heun's method	Second
ode3	Bogacki-Shampine formula	Third
ode4	Fourth-order Runge-Kutta (RK4) formula	Fourth
ode5	Dormand-Prince (RK5) formula	Fifth
ode8	Dormand-Prince RK8(7) formula	Eighth

None of these solvers have an error control mechanism. Therefore, the accuracy and the duration of a simulation depend directly on the size of the steps taken by the solver. As you decrease the step size, the results become more accurate, but the simulation takes longer. Also, for any given step size, the higher the order of the solver, the more accurate the simulation results.

If you specify a fixed-step solver type for a model, then by default, Simulink selects the `FixedStepAuto` solver. Auto solver then selects an appropriate fixed-step solver that can handle both continuous and discrete states with moderate computational effort. As with the discrete solver, if the model has discrete rates (sample times), then Simulink sets the step size to the fundamental sample time of the model by default. If the model has no discrete rates, Simulink automatically uses the result of dividing the simulation total duration by 50. Consequently, the solver takes a step at each simulation time at which Simulink must update the discrete states of the model at its specified sample rates. However, it does not guarantee that the default solver accurately computes the continuous states of a model. Therefore, you may need to choose another solver, a different fixed step size, or both to achieve acceptable accuracy and an acceptable simulation time.

Fixed-Step Continuous Implicit Solvers

An implicit solver computes the state at the next time step as an implicit function of the state at the current time step and the state derivative at the next time step, as described by the following expression.

$$x(n+1) - x(n) - h * Dx(n+1) = 0$$

Simulink provides one fixed-step implicit solver: `ode14x`. This solver uses a combination of Newton's method and extrapolation from the current value to compute the value of a state at the next time step. You can specify the number of Newton's method iterations and the extrapolation order that the solver uses to compute the next value of a model state. See "Fixed-step size (fundamental sample time)". The more iterations and the higher the extrapolation order that you select, the greater the accuracy you obtain. However, you simultaneously create a greater computational burden per step size.

Choose a Fixed-Step Solver

This example shows an algorithmic method of selecting an appropriate fixed-step solver for your model. For simulation workflows in Simulink, the default setting for the **Solver** parameter in the Model Configuration Parameters is `auto`. The heuristics used by Simulink to select a variable-step solver is shown in the figure below.

Auto Solver Heuristics

The solver type is		The system has		Continuous states	
		Only discrete states			The system is an ordinary differential equation (ODE)
Fixed-Step	FixedStepDiscrete			ode3	
				ode14x	
Variable-Step	VariableStepDiscrete			The model is stiff	The model is non-stiff
				ode15s	ode45

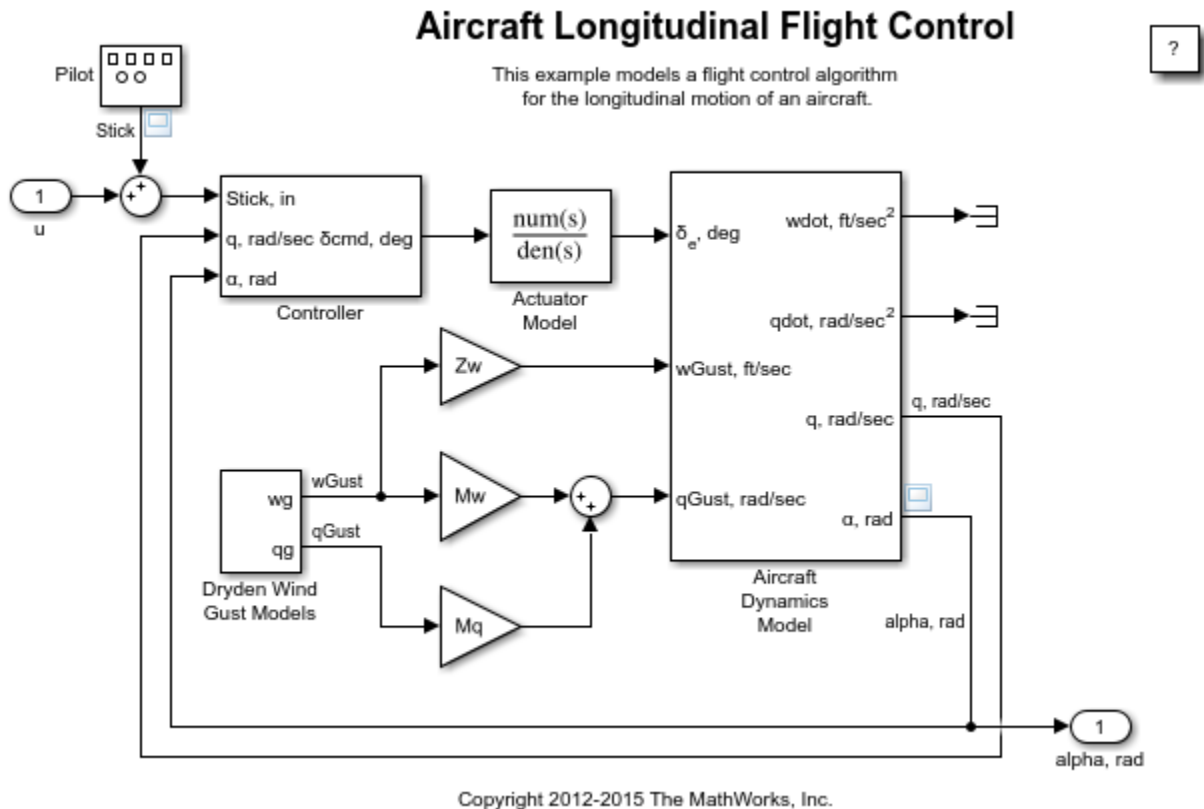

When to Use a Fixed-Step Solver

One common case to use a fixed-step solver is for workflows where you plan to generate code from your model and run the code on a real-time system.

With a variable-step solver, the step size can vary from step to step, depending on the model dynamics. In particular, a variable-step solver increases or reduces the step size to meet the error tolerances that you specify and as such, the variable step sizes cannot be mapped to the real-time clock of a target system.

Any of the fixed-step continuous solvers in the Simulink product can simulate a model to any desired level of accuracy, given a small enough step size. Unfortunately, it is not possible or practical to decide without trial, the combination of solver and step size that will yield acceptable results for the continuous states in the shortest time. Determining the best solver for a particular model generally requires experimentation.

The example model represents the flight control algorithm for the longitudinal flight of an aircraft.

Establish Baseline Results Using a Variable-Step Solver

Before you begin simulation, determine acceptable error tolerances for your variable-step solver. The model is currently set up with the default values of absolute and relative tolerances of $1e-6$ and $1e-4$ respectively.

If these values are acceptable, continue with the example. Otherwise, you can change them to your specification using the Model Configuration Parameters.

Select a variable-step solver from the list of solvers in the **Solver** dropdown in the **Solver** pane of the Model Configuration Parameters to simulate the model. The default setting in Simulink for the **Solver** parameter is `VariableStepAuto`. Simulink selects a solver and the maximum step size of the simulation based on the contents and dynamics of the model.

Simulate the model using the auto solver, or pick another solver. Additionally, enable the **Save states**, **Save time**, and **Save outputs** parameters in the **Data Import/Export** pane of the Model Configuration Parameters. Set the logging format for your model to `Dataset` to allow the Simulation Data Inspector to log the signals.

The simulation results from this run will be designated the baseline results for this task. The model contains 13 signals, but this example focuses on only a few signals plotted below.

Profile the model using the **Solver Profiler** to find an appropriate step size for the candidate fixed-step simulations of the model. See Solver Profiler for information on how to launch and use the tool. For command-line usage, see `solverprofiler.profileModel`.

Note the maximum and average step sizes returned by the **Solver Profiler**.

```

solver: 'ode45'
tStart: 0
tStop: 60
absTol: 1.0000e-06
relTol: 1.0000e-04
hMax: 0.1000
hAverage: 0.0447
steps: 1342
profileTime: 0.0665
zcNumber: 0
resetNumber: 600
jacobianNumber: 0
exceptionNumber: 193

```

Run Fixed-Step Simulations of the Model

Once you obtain the results of the variable-step simulation of the model, simulate it using one or more of the fixed-step solvers. In this example, the model is simulated using all the non-stiff fixed-step solvers: ode1, ode2, ode3, ode4, ode5, and ode8. You can also select a specific solver from the **Solver** dropdown in the Model Configuration Parameters to run against the variable-step baseline.

Considerations for Selecting a Fixed Step Size

The optimal step size for a fixed-step simulation of your model strikes a balance between speed and accuracy, given constraints such as code-generation objectives, physics or dynamics of the model, and modeling patterns used. For example, code generation would dictate the step size must be greater than or equal to the clock speed of the processor (the reciprocal of the CPU frequency). For pure simulation objectives, the step size must be less than the discrete sample times specified by individual blocks in the model. For models with periodic signals, the step size must be such that the signal is sampled at twice its highest frequency; this is known as the Nyquist frequency.

For this specific example, set the fixed-step size of the solver to 0.1 (the maximum step size detected by the **Solver Profiler**). This takes into account the discrete sample time 0.1 of the Dryden Wind-Gust block, as well as the periodic nature of the stick movements and the aircraft response.

Make sure that the model states, outputs, and simulation time are enabled for logging and that the logging format is set to Dataset in the Model Configuration Parameters.

Simulate the model by selecting any one or all the non-stiff fixed-step solvers from the **Solver** dropdown of the Model Configuration Parameters when the solver **Type** is set to Fixed-step.

A Simulink.sdi.Run object is created for the fixed-step solver simulation(s) and stored in the fsRuns struct in the base workspace.

Compare Fixed-Step Simulations with the Variable-Step Baseline

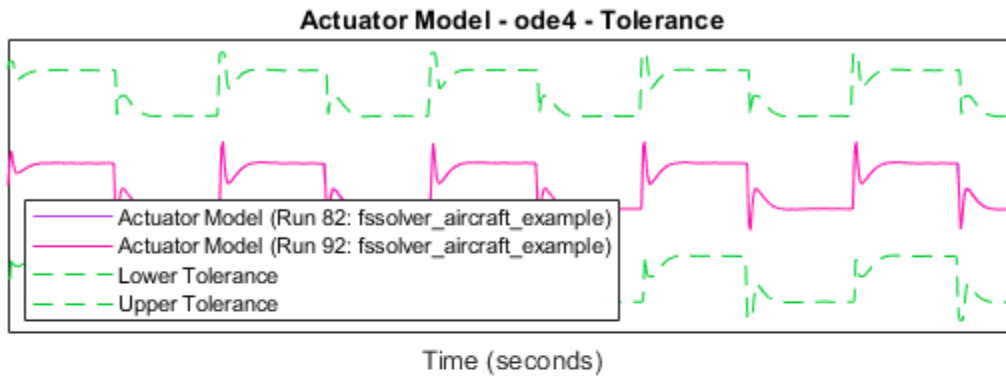

Use the **Simulation Data Inspector** to visualize and inspect logged signals in your model. You can also compare signals across simulations, or runs, using the **Compare** feature. For more information on using the **Simulation Data Inspector**, see *Simulation Data Inspector*. For more information on how to compare simulations using the Simulation Data Inspector, see “Compare Simulation Data” on page 29-171.

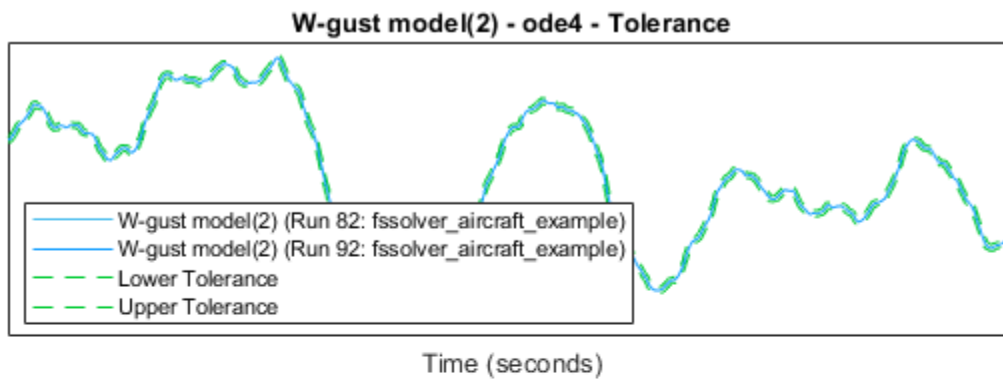

To compare signals, switch to the **Compare** tab in the **Simulation Data Inspector**. Set the **Baseline** run to the variable-step simulation and select a fixed-step simulation from the **Compare to** dropdown. Set the **Global Abs Tolerance**, **Global Rel Tolerance**, and **Global Time Tolerance** based on your requirements.

For this example, **Global Abs Tolerance** is set to 0.065 , **Global Rel Tolerance** is set to 0.005 , and **Global Time Tolerance** is set to 0.1 .

The comparison plots display the results for the lowest order fixed-step solver simulation where all signals fell within tolerance, when compared to the baseline variable-step simulation. For the selected solver, comparison results of a few of the signals are plotted below.

The lowest order with all signals within tolerance is determined to be ode4. Consider the results for the ode1 fixed-step solver, where the comparison results showed 11 signals out of tolerance. Observe that there are 11 signals out of tolerance when the signal comparison parameters are set as:

- **Signal Abs Tolerance:** 0.065
- **Signal Rel Tolerance:** 0.065
- **Signal Time Tolerance:** 0.1

Actuator Model - ode1 (11 signals out of tolerance) - Tolerance

q, rad/sec - ode1 (11 signals out of tolerance) - Difference

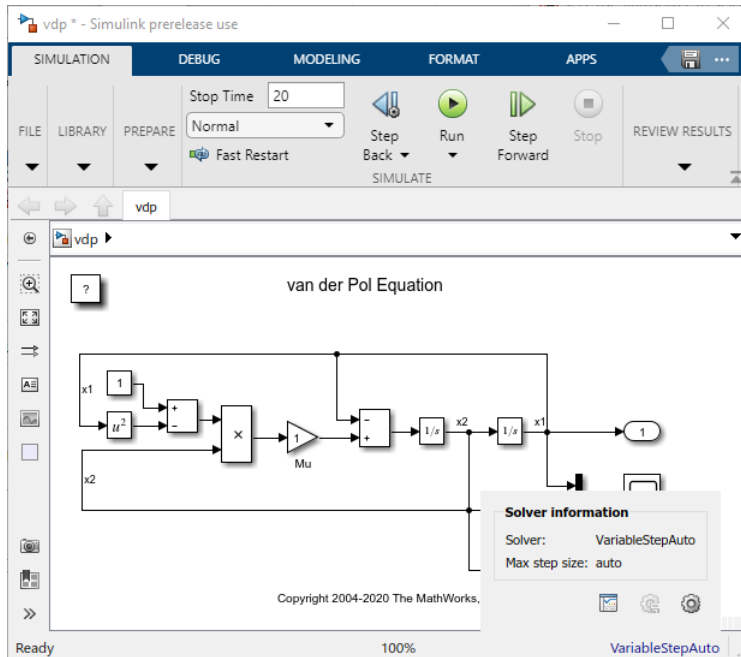

Time (seconds)

Select Solver Using Auto Solver

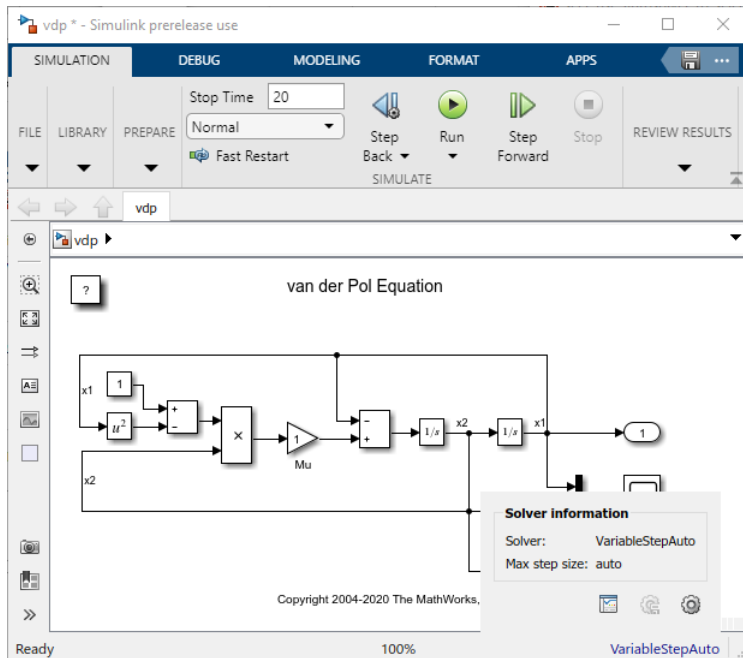

When you want Simulink to select a solver for simulating the model, use auto solver. Auto solver chooses a suitable solver and sets the maximum step size of the simulation.

For new models, Simulink selects auto solver and sets the type to variable-step by default. For an existing model, you can use auto solver to select a solver.

- 1 Open vdp and click the solver link in the lower-right corner.

- 2 In the **Solver Information** pane, click the **View solver settings** button  to open the **Solver** pane of the model configuration parameters.
- 3 Under **Solver selection**, set **Type** to fixed or variable-step according to your preference and set **Solver** to auto.
- 4 When you simulate the model, auto solver selects a fixed-step or variable-step solver according to your preference and calculates the maximum step size it recommends. To see the results, open the **Solver information** pane.

- 5 Click the **Accept suggested settings** button  to apply the recommendations of auto solver. To select different settings, click the **View solver settings** button and make changes in the configuration parameters **Solver** pane.

This chart describes the selection process of the auto solver.

Auto Solver Heuristics

The solver type is		The system has		Continuous states	
		Only discrete states	The system is an ordinary differential equation (ODE)		The system has differential algebraic equations (DAE)
Fixed-Step	FixedStepDiscrete	ode3		ode14x	
		Variable-Step	Variable StepDiscrete	The model is stiff ode15s	The model is non-stiff ode45

- For Simscape Electrical models, auto solver selects **ode23tb**. These systems can have circuits with nonlinear models, especially circuit breakers and power electronics. Such nonlinear models require a stiff solver.

- If the number of continuous states in the model exceeds the `NumStatesForStiffnessChecking` value, auto solver uses `ode15s`. It does not calculate the stiffness of the model. The default value for this parameter is 1000. You can change this value using `set_param`.
- If the number of continuous states in the model is less than the `NumStatesForStiffnessChecking` value, auto solver calculates the stiffness of the model. A model is stiff if the stiffness exceeds the `StiffnessThreshold` value. The default value for this parameter is 1000. You can change this value using `set_param`.

Save and Restore Simulation Operating Point

In this section...
"Benefits of Using Operating Point" on page 25-42
"Save an Operating Point" on page 25-43
"Restore Operating Point" on page 25-44

Note In R2019a, the `SimState` object was renamed to `ModelOperatingPoint`.

To effectively design a system, you simulate a model iteratively, so you can analyze the system based on different inputs, boundary conditions, or operating conditions. In many applications, when performing multiple simulations, a startup phase with significant dynamic behavior is common. For example, the cold start takeoff of a gas turbine engine occurs before each set of aircraft maneuvers. In multiple simulations, you ideally:

- 1 Simulate the startup phase once.
- 2 Save the simulation snapshot at the end of the startup phase.
- 3 Use this snapshot as the initial state for each set of conditions or maneuvers.

Use the `ModelOperatingPoint` object to save the snapshot of a simulation. Once you save the snapshot, in future simulations, restore the `ModelOperatingPoint` object and use it to set initial conditions.

The `ModelOperatingPoint` object contains information about:

- Logged states
- State of the solver and execution engine
- Zero-crossing signals for blocks that register zero crossings
- Output values of certain blocks in the model

Simulink analyzes block connections and other information to determine whether it is using the output values effectively as state information.

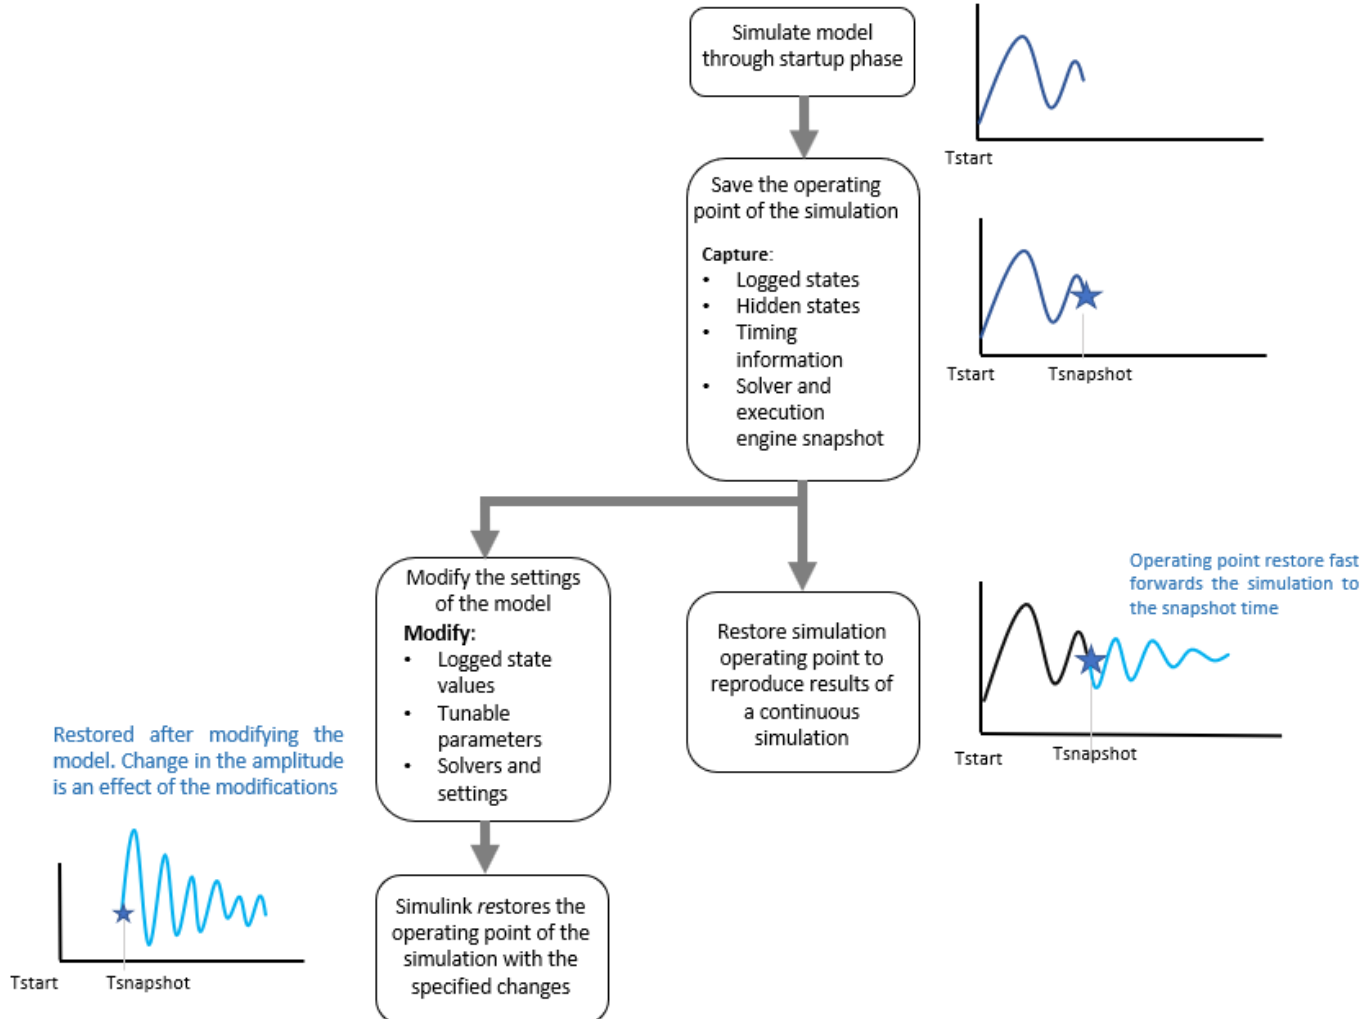

The `ModelOperatingPoint` object also stores the hidden states of these blocks:

- Transport Delay
- Variable Transport Delay
- From Workspace
- For Each subsystem
- Conditionally executed subsystems
- Stateflow
- MATLAB System
- Simscape Multibody Second Generation

By storing this information, the `ModelOperatingPoint` object ensures that the result of a simulation that starts from the operating point is the same as a simulation that runs from the beginning.

Benefits of Using Operating Point

- When the `ModelOperatingPoint` object saves the snapshot of a simulation, it saves information in addition to the logged states in the model. Restore all of this information to ensure that the simulation matches the uninterrupted simulation. For example, if solver information affected the simulation, then changing the state of a block without using `ModelOperatingPoint` can produce different results.
- You can save several operating points during a simulation, then resume the simulation from any of those operating points.
- The `ModelOperatingPoint` object restores the state of blocks that are typically difficult to restore to a particular state, for example, the Transport delay block. The state of the Transport Delay block is not saved in the structure format or the array format when you log data using the **Final states** configuration parameter. With dataset logging format, the answers returned by `ModelOperatingPoint` always match those returned by state logging (non-Operating Point save). Logged states for blocks inside of accelerator-mode model reference are visible and editable. Logged states for many blocks with custom operating point functions, for example, Simscape, model reference accel and variable transport delay are editable.

You can also use the **Final states** option in the Configuration Parameters **Data Import/Export** pane to save a simulation state. However, this option saves only *logged* states—the continuous and discrete states of blocks. These states are only subsets of the complete simulation state of the model. They do not include information about hidden states of blocks, which required for the proper execution of a block.

Save an Operating Point

Save an operating point at the beginning of the final step using one of these options:

- At the final **Stop time**.
- When you interrupt a simulation with the **Pause** or **Stop** button. You can also save an operating point when you pause a simulation using `get_param('modelName','CurrentOperatingPoint')`.
- When you use `set_param` or a block, like the Stop block, to stop a simulation.

Interactive Save

- 1 In the Configuration Parameters dialog box, in the **Data Import/Export** pane, select the **Final states** check box. The **Save final Operating Point** check box becomes available.
- 2 Select the **Save final Operating Point** check box.
- 3 In the **Final states** text box, enter a variable name for the `ModelOperatingPoint` object.
- 4 Simulate the model.

Save and Restore an Operating Point

Use the `sim` command with `set_param`. Set the `SaveOperatingPoint` parameter to 'on'.

```
sldemo_tonegen
set_param('sldemo_tonegen','SaveFinalState','on','FinalStateName',...
'myOperPoint','SaveOperatingPoint','on');
simOut = sim('sldemo_tonegen','StopTime','10');
myOperPoint = simOut.myOperPoint;
```

To configure the simulation to restore the operating point that you saved, use `LoadInitialState`. Simulink® restores the `ModelOperatingPoint` object when you simulate the model.

```
set_param('sldemo_tonegen','LoadInitialState','on','InitialState',...
'myOperPoint');
myOperPoint = simOut.myOperPoint;
```

Tip

Before you save the operating point, disable the **Block Reduction** parameter in **Configuration Settings > Simulation Target > Advanced Parameters**.

Restore Operating Point

Restore the simulation snapshot using the `ModelOperatingPoint` object after modifying the model. The **Start time** does not change from the value in the simulation that generated the operating point. It is a reference value for all time and time-dependent variables in both the original and the current simulation. For example, a block can save and restore the number of sample time hits that occurred since the beginning of simulation as its `ModelOperatingPoint` object.

Consider a model that you ran from 0 to 100 s and that you now want to run from 100 to 200 s. The **Start time** is 0 s for both the original simulation and for the current simulation. The initial time of the current simulation is 100 s. Also, if the block had 10 sample time hits during the original simulation, Simulink recognizes that the next sample time hit is the 11th, relative to 0, not 100 s.

Note If you change the **Start time** before restoring the `ModelOperatingPoint`, Simulink overwrites the **Start time** with the value saved in the `ModelOperatingPoint`.

Interactive Restore

- 1 In the Configuration Parameters dialog box, in the **Data Import/Export** pane, under **Load from workspace**, select the **Initial state** check box. The text box becomes available.
- 2 Enter the name of the variable containing the `ModelOperatingPoint` in the text box.

- 3 Set the **Stop time** to a value greater than the time at which the operating point was saved.

Restore from Different Simulink Versions

You can use `ModelOperatingPoint` objects saved in releases starting with R2010a to restore the `ModelOperatingPoint` of a model. However, this option restores only the logged states of the model. To see the version of Simulink used to save the `ModelOperatingPoint`, examine the **version** parameter of the `ModelOperatingPoint` object.

Simulink detects if the `ModelOperatingPoint` object you provided as the initial state was saved in the current release. By default, Simulink displays an error message if the `ModelOperatingPoint` was not saved in the current release. You can configure the diagnostic to allow Simulink to display the message as a warning and try to restore as many of the values as possible. To enable this best-effort restoration, in the Configuration Parameters dialog box set the message for **Operating Point object from earlier release** to warning. Previously named `SimState` objects are loaded as `ModelOperatingPoint` objects in 19a.

More About

- “Operating Point Behavior” on page 25-46

Operating Point Behavior

Use operating point with a block, S-functions and model changes.

Change the States of a Block Within Operating Point

- Use `loggedStates` to get or set the states of blocks. If `xout` is the state log that Simulink exports to the workspace, then the `loggedStates` field has the same structure as `xout.signals`.
- With dataset logging, `ModelOperatingPoint` captures the current logged states snapshot, as a non-`ModelOperatingPoint` final state save would, and stores it on the `ModelOperatingPoint` object. When you query this logged state, a copy of the saved dataset is returned.
- With dataset logging format, the answers returned by `ModelOperatingPoint` always match those returned by state logging (non-Operating Point save). Logged states for blocks inside of accelerator-mode model reference are visible and editable. Logged states for many blocks with custom operating point functions, for example, Simscape, model reference accel and variable transport delay are editable.
- You cannot change the states that are not logged. Simulink does not allow this modification as it could cause the state to be inconsistent with the simulation.

S-Functions

You can use APIs for C-MEX and Level-2 MATLAB S-functions to enable S-functions to work with the `ModelOperatingPoint` object. For information on how to implement these APIs within S-functions, see “S-Function Compliance with the `ModelOperatingPoint`”.

S-functions that have `PWork` vectors, which store pointers to data structures but do not declare their operating point compliance level or declare it to be unknown or disallowed do not support operating point. For more information, see “S-Function Compliance with the `ModelOperatingPoint`”.

Model Changes and Operating Point Restore

After saving the operating point of a model, you can change the model and restore an operating point with those changes.

- You can rename a model between saving and restoring its operating point.
- The operating point interface checksum is primarily based on the configuration settings in a model and sample times used in the model. You can make some nonstructural changes to the model between saving and restoring an operating point. In the Configuration Parameters dialog box, in the **Diagnostics** pane, use the **Operating point interface checksum mismatch** diagnostic to track such changes. You can then find out if the interface checksum of the restored operating point matches the current interface checksum. See “Operating point interface checksum mismatch”.

You can make the following nonstructural changes to the model without affecting your ability to restore a previously saved operating point:

- Changes to model-level signal logging settings in the “Model Configuration Parameters: Data Import/Export”.

- Logging of specific signals.
- Addition and removal of Scope, Floating Scope and Scope Viewer, To Workspace, To File, and Display blocks.
- Addition and removal of Level-2 MATLAB or C S-Functions that are configured as simulation viewing devices and do not set the operating point compliance to Custom or Disallowed. See “S-Function Compliance with the ModelOperatingPoint” for more information.

Note These modifications may change the number of sample times in the model. This can cause the model's interface checksum to be different from the operating point save and restore checksum. Configure the **Operating point interface checksum mismatch diagnostic** to display a warning (default), error, or none to not compare the checksums.

- You cannot make structural changes to the model between the time you save the operating point and the time you restore the simulation using the operating point. Examples include, adding or removing a block after saving the operating point, changing the sample time of a model, and changing the type of solver from variable-step to fixed-step.
- Mismatches can occur when you try to simulate using a solver that is different from the one that generated the saved operating point. Simulink permits solver changes. For example, you can use the `ode15s` solver to solve the initial stiff portion of a simulation and save the final operating point. You can then continue the simulation with the restored operating point using `ode45`. In other words, this diagnostic helps you see the solver changes but does not signal a problem with the simulation.

Note When you use a variable-step solver with the maximum step size set to `auto`, Simulink uses the maximum step size from the restored `ModelOperatingPoint` object for the new simulation. To ensure that the concatenated operating point trajectory of two simulations matches that of an uninterrupted simulation, specify a value for the maximum step size.

Limitations of Saving and Restoring Operating Point

Note In some cases, saving partial state information avoids some of the limitations of using operating point. For a comparison of the two ways to save state data, see “Comparison of Operating Point and Final State Logging” on page 73-78.

Block Support

The following blocks do not support operating point:

- In the Stack and Queue blocks, the default setting for the **Push full stack** option is **Dynamic reallocation**. This default setting does not support `ModelOperatingPoint` object. Other settings (**Ignore**, **Warning** and **Error**) support `ModelOperatingPoint` object.
- Simscape Multibody First Generation blocks

Simulink tries to save the output of a block as part of an operating point. For S-functions, this happens even if the functions declare that no operating point is required. If the block output is of custom type, Simulink cannot save the operating point and displays an error. For more information about operating point use with S-functions, see “S-Functions” on page 25-46.

Model reference offers partial support for operating point. For details, see “Model Referencing” on page 25-48.

Simulation

- You can use only the normal or the accelerator simulation mode.
- You cannot save operating point in normal mode and restore it in accelerator mode, or vice versa.
- You cannot change the states of certain blocks that are not logged. For more information, see “Change the States of a Block Within Operating Point” on page 25-46.

Code Generation

The operating point feature does not support Simulink Coder or Embedded Coder code generation.

Model Referencing

- You cannot modify logged states of blocks that are inside a referenced model in accelerator mode.
- The following blocks do not support operating point when included in a model referenced in accelerator mode:
 - Level 2 MATLAB S-Function
 - MATLAB System
 - n-D Lookup Table
 - S-Function (with custom operating point or PWork vectors)
 - To File
 - Simscape blocks

For additional information, see “State Information for Referenced Models” on page 73-80.

Model Function

You cannot input the operating point to the `model` function.

More About

- “Save and Restore Simulation Operating Point” on page 25-41

View Diagnostics

You can view and diagnose errors and warnings generated by your model using the **Diagnostic Viewer**. The **Diagnostic Viewer** displays three types of diagnostic messages: errors, warnings, and information. A model generates these messages during a runtime operation, like model load, simulation, or update diagram. You can choose to dock the Diagnostic Viewer to a model so that you can see the messages specific to the model. Go to **Debug > Diagnostics > Docked Diagnostic Viewer**

The diagnostic viewer window is divided into:

- **Toolbar menu:** Displays various commands to help you manage the diagnostic messages. For more information, see “Toolbar” on page 25-49.
- **Diagnostic Message pane:** Displays the error, warning, and information messages. For more information, see “Diagnostic Message Pane” on page 25-50.
- **Suggested Actions:** Displays suggestions and fixes to correct the diagnostic errors and warnings. For more information, see “Suggested Actions” on page 25-52.

Toolbar

To manage the diagnostic messages, use the **Diagnostic Viewer** toolbar.

Menu	Action
	View all error messages
	View all warning messages
	View all information messages
	Search messages for specific keywords and navigate between messages
Reports	You can <ul style="list-style-type: none"> • Expand or collapse messages • Save all or latest messages in a log file • Copy all or latest messages

Menu	Action
Settings	Group similar warnings. Set maximum number of models to display in tabbed panes and the maximum number of events to display per model

Diagnostic Message Pane

The diagnostic message pane displays the error, warning, and information messages in a tabbed format. These messages are color-coded for distinction and are hierarchical.

A new stage is generated for each successive event, you can save or clear stage. Each stage represents a single event such as model load, update diagram, or simulation.

Different types of diagnostic messages are:

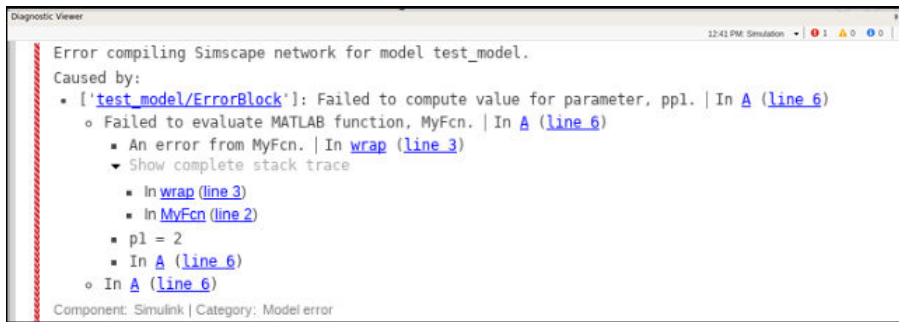

- Information message: Displays the information related to a model load. Information messages are marked as .
- High priority warning: Displays the errors encountered during model load as a high priority warning. Any subsequent operation, like update on the model without rectifying the high priority warning messages are marked as errors. High priority warnings are marked as .
- Warning: Displays the warnings associated during an operation on a model. Warnings are marked as .
- Error: Displays the errors associated during an operation on a model. Errors are marked as .

Tip To locate the source of error, click the hyperlink in the message. The source of error in the model is highlighted.

Trace Diagnostics Location

The Diagnostic Viewer can trace the location of an error so that you can investigate the errors in your model easily. If the error is in a file that is being called from another file, the diagnostic shows up as an expandable stack. You can expand or collapse the stack, as required. Expanding the stack displays information about the file and the line in which the error or warning is located. You can click any of the links to go the error or warning. You can also see the same diagnostic message with stack trace enabled, while using the `sim` command in MATLAB.

Note Tracing the exact location of an error is not applicable for protected files.

Identify Diagnostics from Custom Compilers

Diagnostic viewer can recognize errors and warnings from builds generated by custom compilers. You can specify compiler-specific patterns using the following directives:

```
% Here tool is the buildtool obtained from the toolchain
tool.setDirective ('WarningPattern','warning #(\d+):'); %Specifies warning patterns
tool.setDirective ('ErrorPattern','error:'); %Specifies error pattern
tool.setDirective ('FileNamePattern','[^\s]*w+\.(\.c|h)'); %Specifies file name pattern
tool.setDirective ('LineNumberPattern','\(\d+\)'); %Specifies line number pattern
```

For more information about creating a ToolchainInfo object, see “Register Custom Toolchain and Build Executable” (Simulink Coder).

Suppress Diagnostics

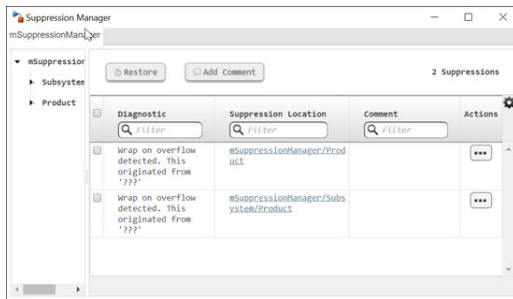

Use the **Suppression Manager** to suppress certain numerical diagnostics (for example, overflow, saturation, precision loss) for specific objects in your models. You can also suppress certain errors that have the diagnostic level set to **error** in the **Diagnostics** section of the Model Configuration Parameters. You can add a comment for the suppressed diagnostics.

To suppress a diagnostic from the specified source, click **Suppress** in the Diagnostic Viewer. Add appropriate comments to the suppressed diagnostic.

To view the suppressed diagnostic, on the **Debug** tab, click **Diagnostics > Suppression Manager**. To restore the suppressed diagnostic, select **Restore**. Diagnostic suppressions are saved with the model and persist across sessions.

The **Suppression Manager** displays the model name, suppression location, and comments of the diagnostic in tabular format. Using the **Actions** menu, you can add and edit comments, suppress a diagnostic, or move a diagnostic to the subsystem level from the block level (**Add to Parent Level**).

For more information, see “Suppress Diagnostic Messages Programmatically” on page 25-57.

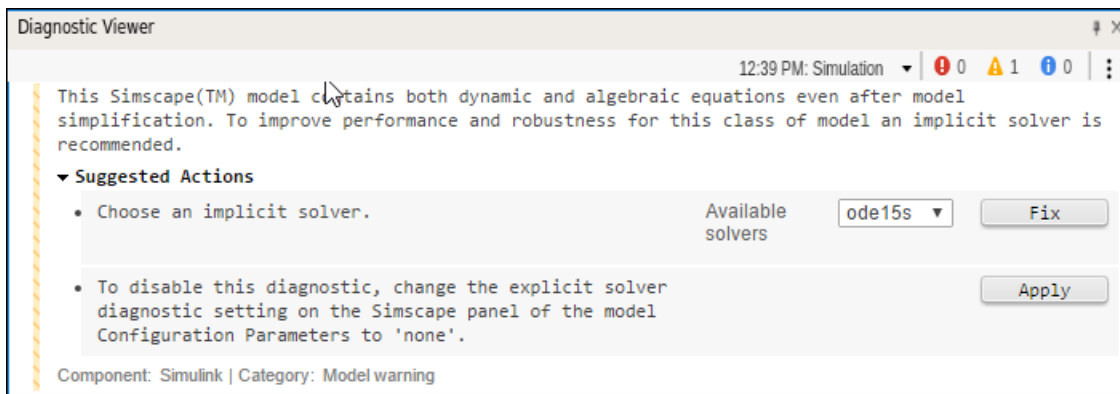

Suggested Actions

Diagnostic viewer provides suggestions and fixes for diagnostic error and warning messages. These suggestions and fixes are provided in the **Suggested Actions** section of diagnostic message pane.

A diagnostic error or warning can have multiple fixes and suggestions. Each fix is associated with a **Fix** button.

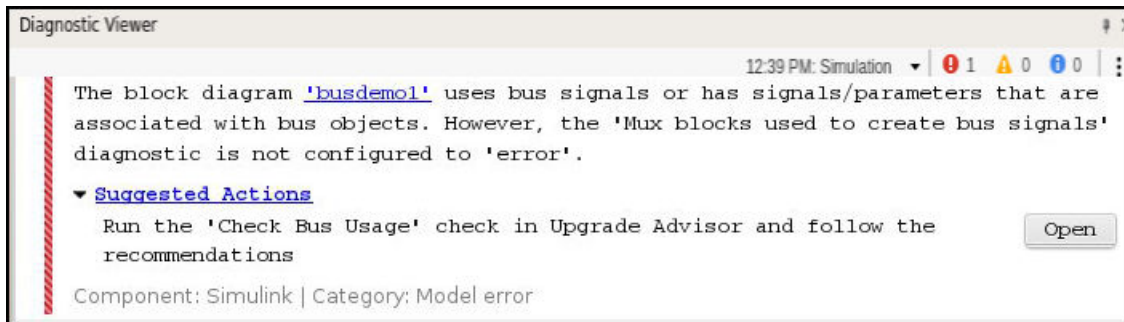

You can click the **Fix** button for the most suitable fix to rectify the error automatically. In some cases, you can provide the fix by one of these ways:

- Enter the values in the available edit boxes.
- Select a value from one of the listed values from a combo box.

The **Fix** buttons for a diagnostic error or warning are no longer available after a fix is successfully applied. If a fix was unsuccessful, a failure message is displayed in the **Suggested Actions** section.

Suggestions are provided for errors and warnings that cannot be fixed automatically.

Note The **Suggested Actions** section is available only for the diagnostic errors or warnings that have a predefined fix.

- "Customize Diagnostic Messages" on page 25-64
- "Report Diagnostic Messages Programmatically" on page 25-66

Systematic Diagnosis of Errors and Warnings

This example shows how to use the Diagnostic Viewer to identify and locate simulation errors and warnings systematically.

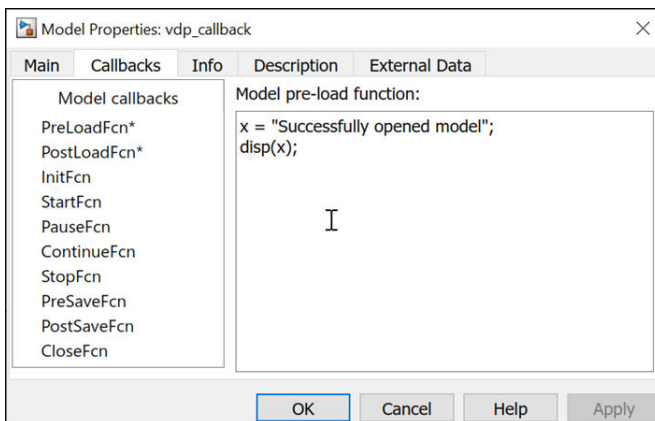

- 1 Open your model.

If your model contains errors related to callback functions, the **Diagnostic Viewer** opens and displays the following errors in **Model Load** stage.

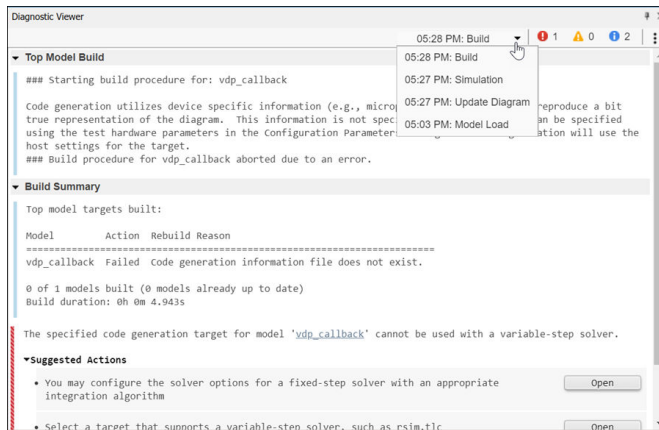

Tip To open the Diagnostic Viewer window, in the **Debug** tab, click **Diagnostics** or click the view errors or warnings link displayed at the bottom of the Simulink Editor window.

- 2 In the Simulink Editor, in the **Modeling** tab, select **Model Settings > Model Properties**, and examine the callback error.

- 3 After fixing any callback errors, simulate the model to diagnose simulation errors and warnings.

Diagnostic Viewer lists errors and warnings in stages. Each stage in **Diagnostic Viewer** represents a single event such as model load, update diagram, simulation, or build.

- 4 Filter out warnings by clicking  so that you can address errors first.
- 5 To locate the source of the error, click the hyperlink in the message. The model in the source is highlighted. If a block has multiple ports, you can hover over each port to see the port number.

- 6 After fixing all errors, simulate your model again and view the **Diagnostic Viewer** to identify remaining problems.

Note If an error or warning has a predefined fix, the diagnostic message pane displays a **Suggested Actions** section. You can use the **Fix** button provided in this section to rectify the related error or warning. For more information see, “Suggested Actions” on page 25-52.

- 7 If an object in your model generates a warning that you do not want to be notified of, sometimes, you can suppress the warning from the specified source using the **Suppress** button. You can restore the warning from that source using the **Restore** button. For example, if a Counter Free-Running block generates an overflow warning that is intentional in your design, you can suppress only overflow warnings from this particular block, without sacrificing notification of other overflows in your model.
- 8 To generate code for your model, in the **C Code** tab, click **Build**.

Note If there is a failure during code generation, Diagnostic Viewer provides hyperlinks for easy navigation to the source of the error or warning message.

- “Report Diagnostic Messages Programmatically” on page 25-66

Suppress Diagnostic Messages Programmatically

The following examples show how to manage diagnostic suppressions programmatically.

In this section...

“Suppress Diagnostic Messages Programmatically” on page 25-57

“Suppress Diagnostic Messages of a Referenced Model” on page 25-60

Suppress Diagnostic Messages Programmatically

This example shows how to access simulation metadata to manage diagnostic suppressions and to restore diagnostic messages programmatically.

Create a New Folder and Copy Relevant Files

- 1 Create a local working folder, for example, `c:\diagnostic_suppressor_demo`.
- 2 Change to the `docroot\toolbox\simulink\examples` folder. At the MATLAB command line, enter:

```
cd(fullfile(docroot, 'toolbox', 'simulink', 'examples'))
```

- 3 Copy the `getDiagnosticObjects.m`, `suppressor_script.m`, and `Suppressor_CLI_Demo.slx` files to your local working folder.

The `getDiagnosticObjects.m` function queries the simulation metadata to access diagnostics that were thrown during simulation. The `suppressor_script.m` script contains the commands for suppressing and restoring diagnostics to the `Suppressor_CLI_Demo` model.

getDiagnosticObjects.m

```
function y = getDiagnosticObjects(in)
Warningdata = in.getSimulationMetadata.ExecutionInfo.WarningDiagnostics;
Errordata = in.getSimulationMetadata.ExecutionInfo.ErrorDiagnostic;

index = 1;

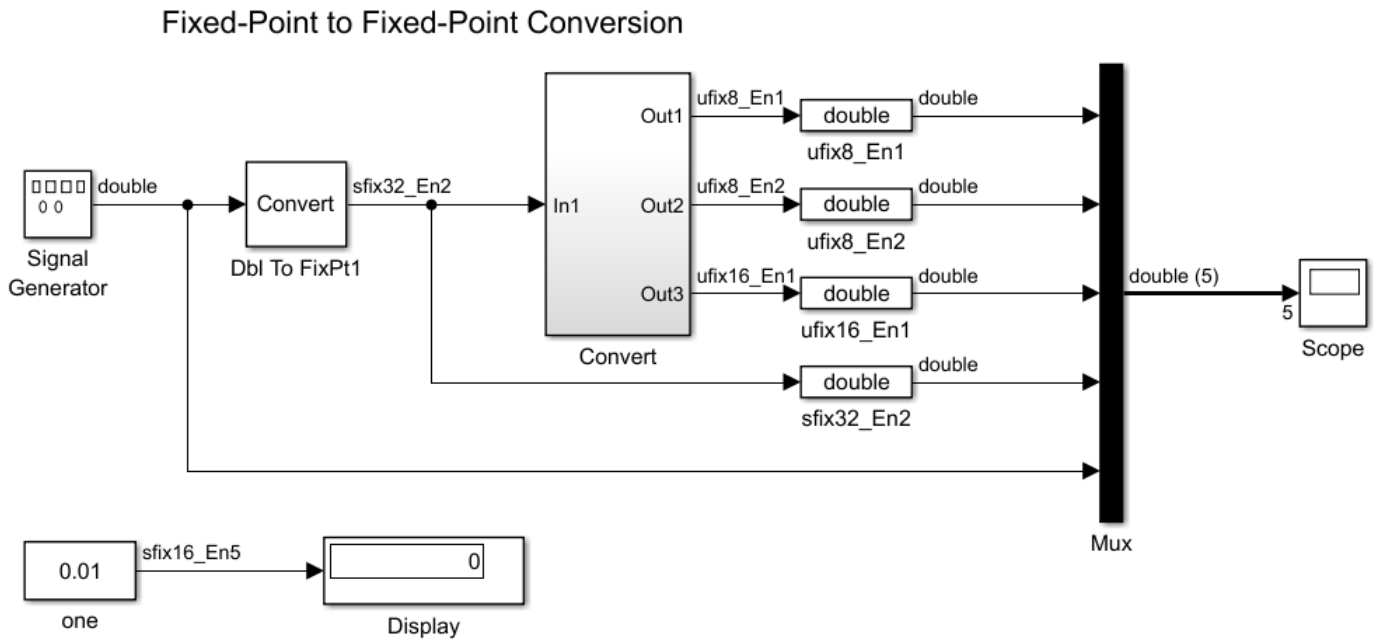

for i = 1 : numel(Warningdata)
    y(index) = Warningdata(i).Diagnostic;
    index = index + 1;
end

for i = 1 : numel(Errordata)
    y(index) = Errordata(i).Diagnostic;
    index = index + 1;
end
```

Open and Simulate the Model

Open the model. To access `Simulink.SimulationMetadata`, set the `ReturnWorkspaceOutputs` parameter value to `'on'`. Simulate the model.

```
model = 'Suppressor_CLI_Demo';
open_system(model);
set_param(model, 'ReturnWorkspaceOutputs', 'on');
out = sim(model);
```

Get Message Identifiers from Simulation Metadata

Find the names of diagnostic message identifiers using the simulation metadata stored in the `MSLDiagnostic` object.

```
if (exist('out', 'var'))
    diag_objects = getDiagnosticObjects(out);
end
```

Several warnings were generated during simulation, including a saturation of the Data Type Conversion block. Query the `diag_objects` variable to get more information on the identifiers.

```
diag_objects(5)
```

```
ans =
```

```
MSLDiagnostic with properties:
```

```
  identifier: 'SimulinkFixedPoint:util:Saturationoccurred'
  message: 'Saturation occurred. This originated from 'Suppressor_CLI_Demo/Con...'
  paths: {'Suppressor_CLI_Demo/Convert/FixPt To FixPt3'}
  cause: {}
  stack: [0x1 struct]
```

Suppress Saturation Diagnostic on a Block

Use the `Simulink.suppressDiagnostic` function to suppress the saturation diagnostic on the data type conversion block only. Simulate the model.

```
Simulink.suppressDiagnostic('Suppressor_CLI_Demo/Convert/FixPt To FixPt3', ...
'SimulinkFixedPoint:util:Saturationoccurred');
set_param(model, 'SimulationCommand', 'start');
```

Restore the Saturation Diagnostic

Use the `Simulink.restoreDiagnostic` function to restore the saturation diagnostic of the same block.

```
Simulink.restoreDiagnostic('Suppressor_CLI_Demo/Convert/FixPt To FixPt3',...
'SimulinkFixedPoint:util:Saturationoccurred');
set_param(model,'SimulationCommand','start');
```

Suppress Multiple Diagnostics on a Source

You can suppress multiple warnings on a single source by creating a cell array of message identifiers. Suppress the precision loss and parameter underflow warnings of the Constant block, one, in the model.

```
diags = {'SimulinkFixedPoint:util:fxpParameterPrecisionLoss',...
'SimulinkFixedPoint:util:fxpParameterUnderflow'};
Simulink.suppressDiagnostic('Suppressor_CLI_Demo/one',diags);
set_param(model,'SimulationCommand','start');
```

Restore All Diagnostics on a Block

Restore all diagnostics on a specified block using the `Simulink.restoreDiagnostic` function.

```
Simulink.restoreDiagnostic('Suppressor_CLI_Demo/one');
set_param(model,'SimulationCommand','start');
```

Suppress a Diagnostic on Many Blocks

You can suppress one or more diagnostics on many blocks. For example, use the `find_system` function to create a cell array of all Data Type Conversion blocks in a system, and suppress all saturation warnings on the specified blocks.

```
dtc_blocks = find_system('Suppressor_CLI_Demo/Convert',...
'BlockType','DataTypeConversion');
Simulink.suppressDiagnostic(dtc_blocks, 'SimulinkFixedPoint:util:Saturationoccurred');
set_param(model,'SimulationCommand','start');
```

Restore All Diagnostics Inside a Subsystem

You can also use the `Simulink.restoreDiagnostic` function to restore all diagnostics inside a specified subsystem.

```
Simulink.restoreDiagnostic('Suppressor_CLI_Demo/Convert',...
'FindAll','On');
set_param(model,'SimulationCommand','start');
```

Add Comments and User Information to a Suppression

A `SuppressedDiagnostic` object contains information on the source of the suppression and the suppressed diagnostic message identifier. You can also include comments, and the name of the user who last modified the suppression.

```
Object = Simulink.SuppressedDiagnostic('Suppressor_CLI_Demo/Convert/FixPt To FixPt1',...
'SimulinkFixedPoint:util:Saturationoccurred');
Object.Comments = 'Reviewed: John Doe';
Object.LastModifiedBy = 'Joe Schmoe';
set_param(model,'SimulationCommand','start');
```

```
Object =
```

```
SuppressedDiagnostic with properties:
```

```
Source: 'Suppressor_CLI_Demo/Convert/FixPt To FixPt1'
Id: 'SimulinkFixedPoint:util:Saturationoccurred'
LastModifiedBy: 'Joe Schmoe'
Comments: 'Reviewed: John Doe'
LastModified: '2016-Jun-21 18:23:01'
```

Get Suppression Data

To get suppression data for a certain subsystem or block, use the `Simulink.getSuppressedDiagnostics` function.

```
Object = Simulink.getSuppressedDiagnostics('Suppressor_CLI_Demo/Convert/FixPt To FixPt1');  
set_param(model, 'SimulationCommand', 'start');
```

Restore All Diagnostics on a Model

When a model contains many diagnostic suppressions, and you want to restore all diagnostics to a model, use the `Simulink.getSuppressedDiagnostics` function to return an array of `Simulink.SuppressedDiagnostic` objects. Then use the `restore` method as you iterate through the array.

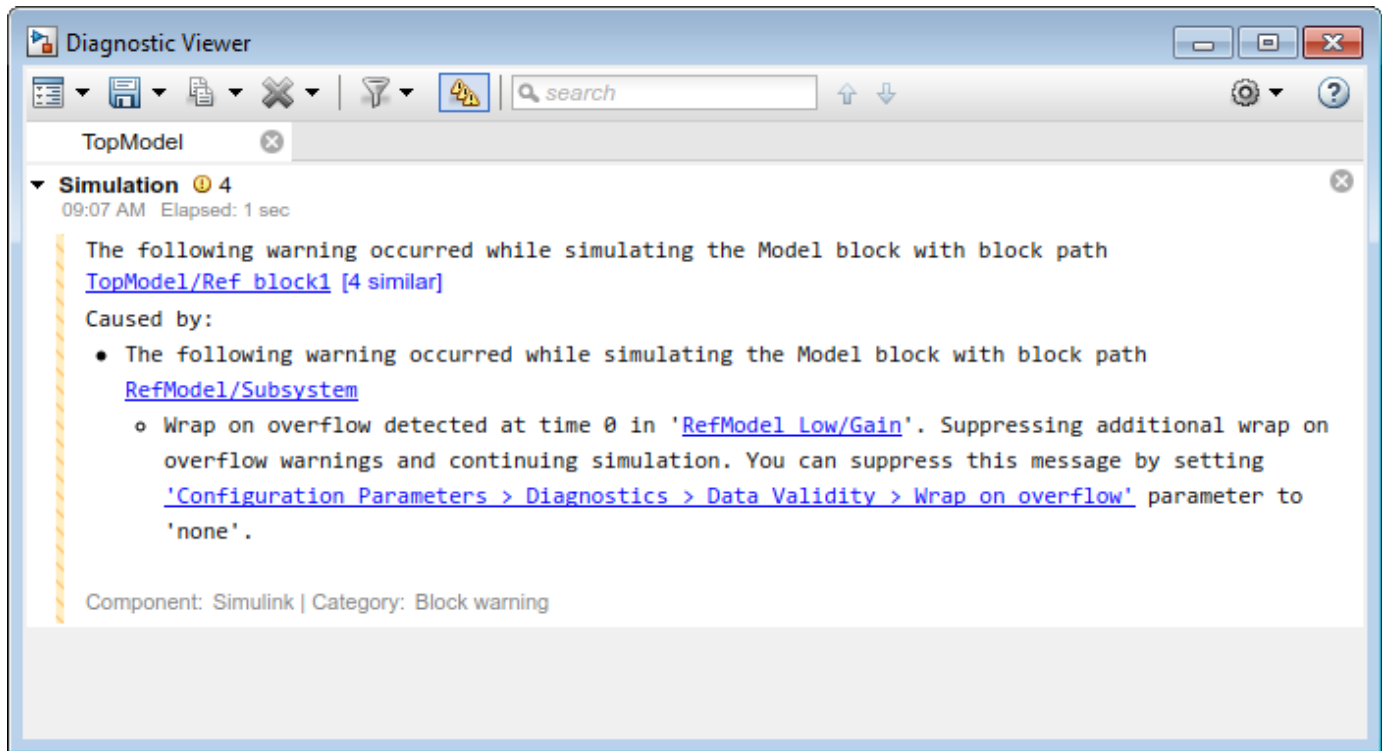

```
Objects = Simulink.getSuppressedDiagnostics('Suppressor_CLI_Demo');  
for iter = 1:numel(Objects)  
    restore(Objects(iter));  
end  
set_param(model, 'SimulationCommand', 'start');
```

Suppress Diagnostic Messages of a Referenced Model

This example shows how to suppress a diagnostic when the diagnostic originates from a referenced model. By accessing the `MSLDiagnostic` object of the specific instance of the warning, you can suppress the warning only for instances when the referenced model is simulated from the specified top model.

This example model contains two instances of the same referenced model, `RefModel`. The model `RefModel` references yet another model, `RefModel_Low`. `RefModel_Low` contains two Gain blocks that each produce a wrap on overflow warning during simulation. Suppress one of the four instances of this warning in the model by accessing the `MSLDiagnostic` object associated with the wrap on overflow warning produced by one of the Gain blocks in the `RefModel_Low` model only when it is referenced by `Ref_block1`.

Open the top model. Simulate the model and store the output in a variable, `out`.

```
out = sim('TopModel');
```

Access the simulation metadata stored in the `MSLDiagnostic` object.

```
diag = getDiagnosticObjects(out)
```

```
diag =
```

```
1x4 MSLDiagnostic array with properties:
```

```
    identifier
    message
    paths
    cause
    stack
```

You can view the diagnostics and their causes in the Diagnostic Viewer or at the command-line.

```
for i = 1 : numel(diag)
    disp(diag(i));
    disp(diag(i).cause{1});
end
```

Suppress one of the wrap on overflow warnings from `RefModel_Low` only when it is simulated from `TopModel/Ref_block1` by accessing the specific diagnostic. Simulate the model.

```
Simulink.suppressDiagnostic(diag(1));
out = sim('TopModel')
```

Access the simulation metadata. This simulation produced only three warnings.

```
diag = getDiagnosticObjects(out)
```

```
diag =
```

```
1×3 MSLDiagnostic array with properties:
```

```
  identifier  
  message  
  paths  
  cause  
  stack
```

Restore the diagnostic to the model.

```
Simulink.restoreDiagnostic(diag(1));
```

Customize Diagnostic Messages

In this section...

“Display Custom Text” on page 25-64

“Create Hyperlinks to Files, Folders, or Blocks” on page 25-64

“Create Programmatic Hyperlinks” on page 25-65

The **Diagnostic Viewer** displays the output of MATLAB error functions executed during simulation.

You can customize simulation error messages in the following ways by using MATLAB error functions in callbacks, S-functions, or MATLAB Function blocks.

Display Custom Text

This example shows how to can customize the MATLAB function `check_signal` to display the text `Signal is negative`.

- 1 Open the MATLAB Function for editing.

- 2 In the MATLAB Editor, create a function to display custom text.

```

function y = check_signal(x)
    if x < 0
        error('Signal is negative');
    else
        y = x;
    end
  
```

- 3 Simulate the model.

A runtime error appears and you are prompted to start the debugger. Click **OK**.

- 4 To view the following error in **Diagnostic Viewer**, close the debugger.

Create Hyperlinks to Files, Folders, or Blocks

To create hyperlinks to files, folders, or blocks in an error message, include the path to these items within customized text.

Example error message	Hyperlink
<code>error('Error reading data from "C:/Work/designData.mat"')</code>	Opens <code>designData.data</code> in the MATLAB Editor.
<code>error('Could not find data in folder "C:/Work"')</code>	Opens a Command Window and sets <code>C:\Work</code> as the working folder.
<code>error('Error evaluating parameter in block "myModel/Mu"')</code>	Displays the block <code>Mu</code> in model <code>myModel</code> .

Create Programmatic Hyperlinks

This example shows how to can customize the MATLAB function `check_signal` to display a hyperlink to the documentation for `find_system`.

- 1 Open the MATLAB Function for editing.

- 2 In the MATLAB Editor, create a function to display custom text.

```

function y = check_signal(x)
    if x < 0
        error('See help for <a href="matlab:doc find_system">find_system</a>');
    else
        y = x;
    end
end
  
```

- 3 Simulate the model.

A runtime error appears and you are prompted to start the debugger. Click **OK**.

- 4 To view the following error in **Diagnostic Viewer**, close the debugger.

Related Examples

- “Systematic Diagnosis of Errors and Warnings” on page 25-54
- “Report Diagnostic Messages Programmatically” on page 25-66

Report Diagnostic Messages Programmatically

The `sldiagviewer` functions enable you to generate, display, and log diagnostic messages in the Diagnostic Viewer.

You can use these functions to report the diagnostic messages programmatically:

- Function to create a stage: `sldiagviewer.createStage`
- Functions to report diagnostic messages:
 - `sldiagviewer.reportError`
 - `sldiagviewer.reportWarning`
 - `sldiagviewer.reportInfo`
- Function to log the diagnostics: `sldiagviewer.diary`

Create Diagnostic Stages

In the Diagnostic Viewer, errors, warnings, and information messages are displayed in groups based on the operation, such as model load, simulation, and build. These groups are called stages. The `sldiagviewer.createStage` function enables you to create stages. You can also create child stages for a stage object. A parent stage object must be active to create a child stage. When you create a stage object, Simulink initializes a stage. When you close the stage object, Simulink ends the stage. If you delete a parent stage object, the corresponding parent and its child stage close in the Diagnostic Viewer. The syntax for creating a stage is:

```
stageObject = sldiagviewer.createStage(StageName, 'ModelName', ModelNameValue)
```

In this syntax,

- `StageName` specifies the name of a stage and is a required argument, for example, `'Analysis'`.
- Use the `'ModelName', ModelNameValue` pair to specify the model name of a stage, for example `'ModelName', 'vdp'`. All the child stages inherit the model name from their parent.

Example to Create Stage

```
my_stage = sldiagviewer.createStage('Analysis', 'ModelName', 'vdp');
```

Report Diagnostic Messages

You can use the `sldiagviewer` functions to report error, warning, or information messages in the Diagnostic Viewer. The syntaxes for reporting diagnostic messages are:

- `sldiagviewer.reportError(Message)`: Reports the error messages.
- `sldiagviewer.reportWarning(Message)`: Reports the warnings.
- `sldiagviewer.reportInfo(Message)`: Reports the information messages.

`Message` describes the error, warning, or build information and is a required argument. `Message` can have values in these formats:

- String

- MSLErrorException or MException object

Optionally, you can use the 'Component' argument and its corresponding value in the syntax to specify the component or product that generates the message, for example, 'Simulink' and 'Stateflow'.

Example to Report Diagnostics

```
% Create a Stage to display all the messages

my_stage = sldiagviewer.createStage('Analysis', 'ModelName', 'vdp');

% Catch the error introduced in vdp as an exception.

try
sim('vdp');
catch error
% Report the caught exception as warning

sldiagviewer.reportWarning(error);
end

% Report a custom info message to Diagnostic Viewer

sldiagviewer.reportInfo('My Info message');
```

Log Diagnostic Messages

You can use the `sldiagviewer.diary` function to log the simulation warning, error, and build information to a file. The syntaxes for generating log files are:

- `sldiagviewer.diary`: Intercepts the build information, warnings, and errors transmitted to the Diagnostic Viewer and logs them to a text file `diary.txt` in the current directory.
- `sldiagviewer.diary(filename)`: Toggles the logging state of the text file specified by `filename`.
- `sldiagviewer.diary(toggle)`: Toggles the logging ability. Valid values are 'on' and 'off'. If you have not specified a log file name, the toggle setting applies to the last file name that you specified for logging or to the `diary.txt` file.
- `sldiagviewer.diary(filename, 'UTF-8')`: Specifies the character encoding for the log file.

In this syntax,

- `filename` specifies the file to log the data to.
- `toggle` specifies the logging state 'on' or 'off'.

Log Diagnostic Messages

```
% Start logging build information and simulation warnings and errors to diary.txt

sldiagviewer.diary
open_system('vdp')
set_param('vdp/Mu', 'Gain', 'xyz')
set_param('vdp', 'SimulationCommand', 'Start')
% This introduces an error and do UI simulation which you can see in the diary log

% Open diary.txt to view logs.

%### Starting build procedure for model: vdp
```

```
### Build procedure for model: 'vdp' aborted due to an error.
%...

% Set up logging to a specific file

sdiagviewer.diary('C:\MyLogs\log1.txt') % Make sure you have write permission for this location

% Switch the logging state of a file

sdiagviewer.diary('C:\MyLogs\log2.txt') % Switch on logging and specify a log file.
open_system('vdp')
set_param('vdp/Mu', 'Gain', 'xyz')
set_param('vdp', 'SimulationCommand', 'Start')

sdiagviewer.diary('off') % Switch off logging.
open_system('sldemo_fuelsys') % Any operation you do after the previous command will not be logged
slbuild('sldemo_fuelsys')

sdiagviewer.diary('on') % Resume logging in the previously specified log file.

% Specify the filename to log to and character encoding to be used
sdiagviewer.diary('C:\MyLogs\log3.txt', 'UTF-8')
```

Running a Simulation Programmatically

- “Run Simulations Programmatically” on page 26-2
- “Run Parallel Simulations” on page 26-8
- “Using sim function within parfor” on page 26-11
- “Error Handling in Simulink Using MSLErrorException” on page 26-20

Run Simulations Programmatically

You can simulate a model programmatically in two ways:

- Via `sim` command.
- Via the run button

When performing simulations with the `sim` command, you use the command line to perform operations on your simulation. Performing simulations with the **Run** button implies that you can interact with the simulation using the Simulink UI to perform any other additional operations. The following table elaborates the differences between these two approaches.

Actions	Non-Interactive Simulation (<code>sim</code> Command Simulations)	Interactive Simulation (Run Button Simulations)
Allowed level of interaction	Low	High
Start a simulation	<code>sim</code> command	Run / <code>set_param mdl, 'SimulationCommand', 'Start'</code>
Stopping a simulation	Ctrl-C on the command line	<code>set_param mdl, 'SimulationCommand', 'Stop'</code> / Stop
Pausing a simulation	No	Yes. <code>set_param mdl, 'SimulationCommand', 'Pause'</code> / Pause
MATLAB prompt available while simulation runs	No	Yes
Scopes update while simulation runs	Yes, except in Rapid Accelerator Mode	Yes
Simulation Stepper	No	Yes, except in Rapid Accelerator Mode
Conditional Pauses	No	Yes, except in Rapid Accelerator Model
Port value displays available while simulation runs?	No	Yes
Supports simulation pacing	Yes	Yes
Supports Timeout option	Yes	No
Error handling	MATLAB exception, unless <code>CaptureErrors</code> is on	Reported to the Diagnostic Viewer

sim Command Simulations

You can programmatically simulate a model with the `sim` function by using the specified techniques to specify parameter values. In addition to simulating a model, you can use the `sim` command to enable simulation timeout, capture simulation errors, and access simulation metadata when your simulation is complete.

Specify Parameter Name-Value Pairs

This example shows how to programmatically simulate a model, specifying model parameters as name-value pairs.

Simulate the vdp model with parameter values specified as consecutive name-value pairs.

```
simOut = sim('vdp','SimulationMode','normal',...
            'SaveState','on','StateSaveName','xout',...
            'SaveOutput','on','OutputSaveName','yout',...
            'SaveFormat','Dataset');
outputs = simOut.yout
```

```
outputs =
```

```
Simulink.SimulationData.Dataset
Package: Simulink.SimulationData
```

```
Characteristics:
    Name: 'yout'
    Total Elements: 2
```

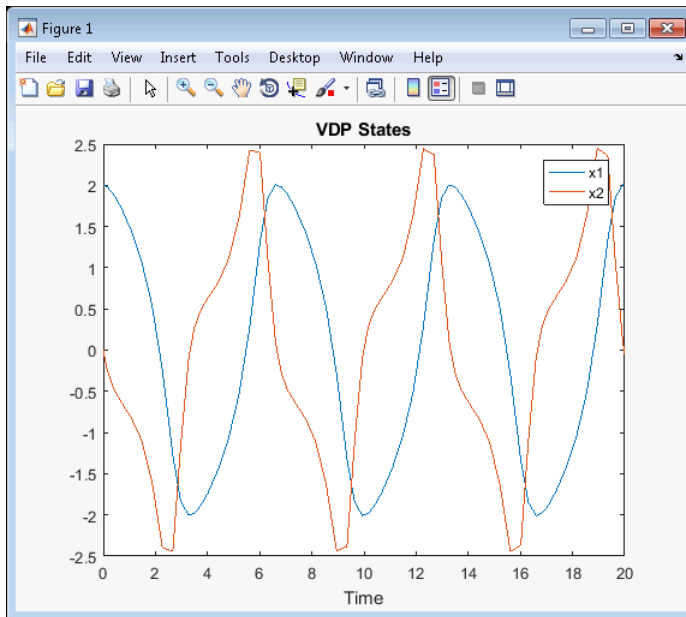

```
Elements:
    1 : 'x1'
    2 : 'x2'
```

```
-Use get or getElement to access elements by index or name.
-Use addElement or setElement to add or modify elements.
```

You simulate the model in `Normal` mode, specifying an absolute tolerance for solver error. The `sim` function returns `SimOut`, a single `Simulink.SimulationOutput` object that contains all of the simulation outputs: logged time, states, and signals.

Plot the output signal values against time.

```
x1 = (outputs.get('x1').Values);
x2 = (outputs.get('x2').Values);
plot(x1); hold on;
plot(x2);
title('VDP States')
xlabel('Time'); legend('x1','x2')
```

Enable Simulation Timeouts

If you are running multiple simulations in a loop and are using a variable-step solver, consider using `sim` with the `timeout` parameter. If, for some reason, a simulation hangs or begins to take unexpectedly small time steps, it will time out. Then, the next simulation can run.

```
N = 100;
simOut = repmat(Simulink.SimulationOutput, N, 1);
for i = 1:N
    simOut(i) = sim('vdp', 'timeout', 1000);
end
```

Capture Simulation Errors

If an error causes your simulation to stop, you can see the error in the simulation metadata. In this case, `sim` captures simulation data in the simulation output object up to the time it encounters the error, enabling you to do some debugging of the simulation without rerunning it. To enable this feature, use the `CaptureErrors` parameter with the `sim` function.

Another advantage of this approach is that the simulation error does not also cause `sim` to stop. Therefore, if you are using `sim` in a `for` loop, for example, subsequent iterations of the loop will still run.

```
simOut = sim('my_model', 'CaptureErrors', 'on');
simOut.getSimulationMetadata.ExecutionInfo

ans =

    struct with fields:
        StopEvent: 'DiagnosticError'
        StopEventSource: []
        StopEventDescription: 'Division by zero in 'my_model/Divide''
```

```
ErrorDiagnostic: [1x1 struct]
WarningDiagnostics: [0x1 struct]
```

Access Simulation Metadata

This example shows you how to access simulation metadata once your simulation is complete. You can run any kind of simulation and access its metadata.

This example simulates the model with parameter values specifies as name-value pairs. Run the simulation.

```
simOut = sim('vdp','SimulationMode','normal','AbsTol','1e-5',...
            'SaveState','on','StateSaveName','xoutNew',...
            'SaveOutput','on','OutputSaveName','youtNew',...
            'SaveFormat','StructureWithTime');
```

Access the `ModelInfo` property, which has basic information about the model and solver.

```
simOut.getSimulationMetadata.ModelInfo
ans =
    struct with fields:
        ModelName: 'vdp'
        ModelVersion: '1.6'
        ModelFilePath: 'C:\MyWork'
        UserID: 'User'
        MachineName: 'MyMachine'
        Platform: 'PCWIN64'
        ModelStructuralChecksum: [4x1 uint32]
        SimulationMode: 'normal'
        StartTime: 0
        StopTime: 20
        SolverInfo: [1x1 struct]
        SimulinkVersion: [1x1 struct]
        LoggingInfo: [1x1 struct]
```

Inspect the solver information.

```
simOut.getSimulationMetadata.ModelInfo.SolverInfo
ans =
    struct with fields:
        Type: 'Variable-Step'
        Solver: 'ode45'
        MaxStepSize: 0.4000
```

Review timing information for your simulation, such as when your simulation started and finished, and the time the simulation took to initialize, execute, and terminate.

```
simOut.getSimulationMetadata.TimingInfo
ans =
    struct with fields:
```

```

WallClockTimestampStart: '2016-06-17 10:26:58.433686'
WallClockTimestampStop: '2016-06-17 10:26:58.620687'
InitializationElapsedWallTime: 0.1830
ExecutionElapsedWallTime: 1.0000e-03
TerminationElapsedWallTime: 0.0030
TotalElapsedWallTime: 0.1870

```

Add notes to your simulation.

```

simOut=simOut.setUserString('Results from simulation 1 of 10');
simOut.getSimulationMetadata

```

ans =

SimulationMetadata with properties:

```

ModelInfo: [1x1 struct]
TimingInfo: [1x1 struct]
ExecutionInfo: [1x1 struct]
UserString: 'Results from simulation 1 of 10'
UserData: []

```

You can also add your own custom data using the `UserData` property.

Run-Button Simulations

For an interactive simulation, you can use `set_param` and `get_param`. With `set_param` and `get_param`, you can check the status of a running simulation and control how the simulation works by using block callbacks.

Control and Check Status of Simulation

This example shows how to use `set_param` to control the status of your simulation. `set_param` allows you to update the variables dynamically as well as write data-logging variables to the workspace.

Start a simulation.

```

set_param('vdp', 'SimulationCommand', 'start')

```

When you start a simulation using `set_param` and the `'start'` argument, you must use the `'stop'` argument to stop it. Not using the `'stop'` argument causes the simulation to stop only once its finished.

Pause, continue, and stop a simulation.

```

set_param('vdp', 'SimulationCommand', 'pause')
set_param('vdp', 'SimulationCommand', 'continue')
set_param('vdp', 'SimulationCommand', 'stop')

```

When you use `set_param` to pause or stop a simulation, the simulation does not execute the commands immediately. You can use `set_param` to start a simulation after the `stop` command and to continue a simulation after the `pause` command. Simulink first completes uninterruptable work, such as solver steps and other commands that preceded the `set_param` command. Then, simulation starts, pauses, continues, or stops as specified by the `set_param` command.

Check the status of a simulation.

```
get_param('vdp', 'SimulationStatus')
```

The software returns 'stopped', 'initializing', 'running', 'paused', 'compiled', 'updating', 'terminating', or 'external' (used with the Simulink Coder product).

To update the changed workspace variables dynamically while a simulation is running, use the `update` command.

```
set_param('vdp', 'SimulationCommand', 'update')
```

Write all data-logging variables to the base workspace.

```
set_param('vdp', 'SimulationCommand', 'WriteDataLogs')
```

Automate Simulation Tasks Using Callbacks

A callback executes when you perform various actions on your model, such as starting, pausing, or stopping a simulation. You can use callbacks to execute a MATLAB script or other MATLAB commands. For more information, see “Callbacks for Customized Model Behavior” on page 4-51 and “Block Callback Parameters” on page 4-57.

This example shows how to use the model `StartFcn` callback to automatically execute MATLAB code before the simulation starts.

Write a MATLAB script that finds Scope blocks in your model and opens them in the foreground when you simulate the model. Save the script in the current folder.

```
% openscopes.m
% Brings scopes to forefront at beginning of simulation.

blocks = find_system(bdroot, 'BlockType', 'Scope');

% Finds all of the scope blocks in the top level of your
% model. To find scopes in subsystems, provide the subsystem
% names. Type help find_system for more on this command.

for i = 1:length(blocks)
    set_param(blocks{i}, 'Open', 'on')
end

% Loops through all of the scope blocks and brings them
% to the forefront.
```

Set the `StartFcn` parameter for the model to call the `openscopes` script.

```
set_param('my_model', 'StartFcn', 'openscopes')
```

Run Parallel Simulations

The `parsim` command allows you to run parallel (simultaneous) Simulink simulations of your model (design). In this context, parallel runs mean multiple simulations at the same time on different workers. `parsim` makes it easy for you to run the same model with different inputs or different parameter settings in scenarios such as Monte Carlo analyses, parameter sweeps, model testing, experiment design, and model optimization. Running a single simulation in parallel by decomposing the model into smaller components and running those individual pieces simultaneously on multiple workers is currently not supported.

To run the simulations in parallel with `parsim`, you need a Parallel Computing Toolbox for local workers. In addition, you can use MATLAB Parallel Server for multiple computer clusters, clouds, and grids. In the absence of Parallel Computing Toolbox and MATLAB Parallel Server, `parsim` runs the simulations in serial. For more information, see “Parallel Computing Toolbox” and “MATLAB Parallel Server”.

If no parallel pool exists, `parsim` creates a pool from the default cluster profile. To use a cluster other than the default, create a pool with that cluster profile before calling `parsim`.

This example runs multiple simulations in parallel for a set of sweep parameters.

```
% 1) Load model
model = 'sldemo_susp_n_3dof';
load_system(model);

% 2) Set up the sweep parameters
Cf_sweep = 2500*(0.05:0.1:0.95);
numSims = numel(Cf_sweep);

% 3) Create an array of SimulationInput objects and specify the sweep value for each simulation
simIn(1:numSims) = Simulink.SimulationInput(model);
for idx = 1:numSims
    simIn(idx) = simIn(idx).setBlockParameter([model '/Road-Suspension Interaction'], 'Cf', num2str(Cf_sweep(idx)))
end

% 4) Simulate the model
simOut = parsim(simIn)
```

How `parsim` works

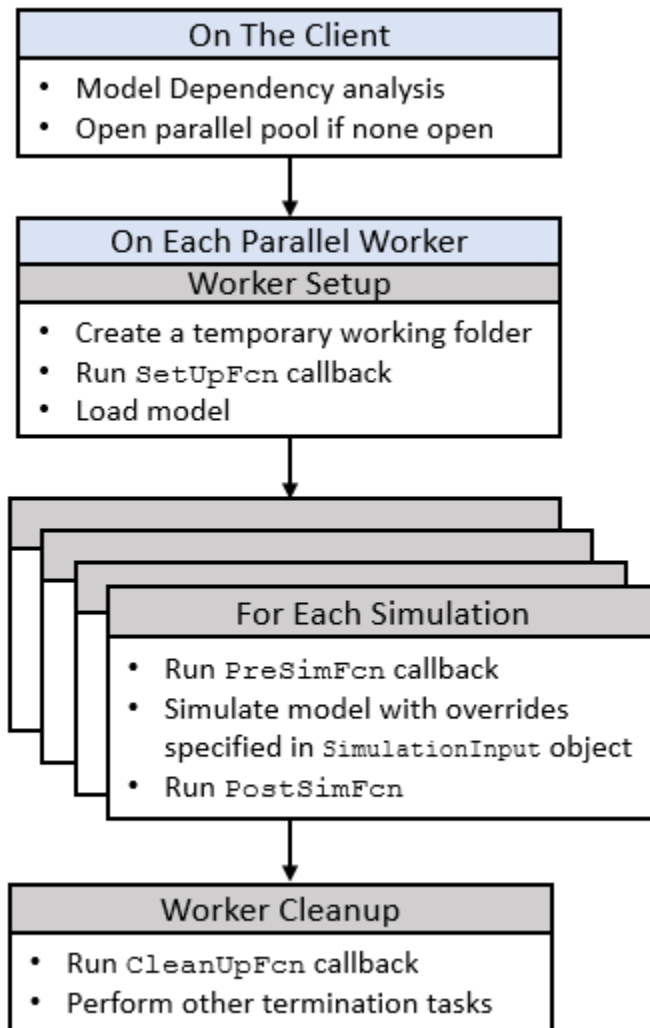

`parsim` runs simulations with different parameters and values based on the `Simulink.SimulationInput` object. Each `SimulationInput` object specifies one simulation of the model. An array of these objects can be created for multiple simulations. For more information, see “Running Multiple Simulations” on page 27-2.

You can use the following methods and properties on `Simulink.SimulationInput` object:

- `setVariables` - Change variables in base workspace, data dictionary, or model workspace
- `setBlockParameters` - Change block parameters
- `setModelParameters` - Change model parameters
- `setPreSimFcn` - Specify MATLAB functions to run before each simulation for customization and post-processing results on the cluster
- `setPostSimFcn` - Specify MATLAB functions to run after each simulation for customization and post-processing results on the cluster
- `InitialState` - Change the Initial State

- `ExternalInput` - Specify a numerical array, timeseries, or Dataset object as external inputs to the model

This flowchart shows a general sequence of events that occur when `parsim` is executed

Changes to model library blocks can be overwritten when using `parsim`. When models are set up on new workers, model inherits properties directly from the worker library. Use `SetupFcn` with `parsim` to transfer the model library block changes to the workers.

Using sim function within parfor

Note Using `sim` function within `parfor` loop is no longer recommended. For running parallel simulations, use `parsim`. Please see “Run Parallel Simulations” on page 26-8.

Overview of Calling sim from Within parfor

The `parfor` command allows you to run parallel (simultaneous) Simulink simulations of your model (design). In this context, parallel runs mean multiple model simulations at the same time on different workers. Calling `sim` from within a `parfor` loop often helps for performing multiple simulation runs of the same model for different inputs or for different parameter settings. For example, you can save simulation time performing parameter sweeps and Monte Carlo analyses by running them in parallel. Note that running parallel simulations using `parfor` does not currently support decomposing your model into smaller connected pieces and running the individual pieces simultaneously on multiple workers.

Normal, Accelerator, and Rapid Accelerator simulation modes are supported by `sim` in `parfor`. (See “Choosing a Simulation Mode” on page 35-10 for details on selecting a simulation mode and “Design Your Model for Effective Acceleration” on page 35-14 for optimizing simulation run times.) For other simulation modes, you need to address any workspace access issues and data concurrency issues to produce useful results. Specifically, the simulations need to create separately named output files and workspace variables. Otherwise, each simulation overwrites the same workspace variables and files, or can have collisions trying to write variables and files simultaneously.

For information on code regeneration and parameter handling in Rapid Accelerator mode, see “Parameter Tuning in Rapid Accelerator Mode” on page 35-7.

Also, see `parfor`.

Note If you open models inside a `parfor` statement, close them again using `bdclose all` to avoid leaving temporary files behind.

sim in parfor with Normal Mode

This code fragment shows how you can use `sim` and `parfor` in Normal mode. Save changes to your model before simulating in `parfor`. The saved copy of your model is distributed to parallel workers when simulating in `parfor`.

```
% 1) Load model and initialize the pool.
model = 'sldemo_suspn_3dof';
load_system(model);
parpool;

% 2) Set up the iterations that we want to compute.
Cf = evalin('base', 'Cf');
Cf_sweep = Cf*(0.05:0.1:0.95);
iterations = length(Cf_sweep);
simout(iterations) = Simulink.SimulationOutput;

% 3) Need to switch all workers to a separate tempdir in case
% any code is generated for instance for StateFlow, or any other
```

```

% file artifacts are created by the model.
spm
    % Setup tempdir and cd into it
    currDir = pwd;
    addpath(currDir);
    tmpDir = tempname;
    mkdir(tmpDir);
    cd(tmpDir);
    % Load the model on the worker
    load_system(model);
end

% 4) Loop over the number of iterations and perform the
% computation for different parameter values.
parfor idx=1:iterations
    set_param([model '/Road-Suspension Interaction'],'MaskValues',...
        {'Kf',num2str(Cf_sweep(idx)),'Kr','Cr'});
    simout(idx) = sim(model, 'SimulationMode', 'normal');
end

% 5) Switch all of the workers back to their original folder.
spm
    cd(currDir);
    rmdir(tmpDir,'s');
    rmpath(currDir);
    close_system(model, 0);
end

close_system(model, 0);
delete(gcp('nocreate'));

```

sim in parfor with Normal Mode and MATLAB Parallel Server Software

This code fragment is identical to the one in “sim in parfor with Normal Mode” on page 26-11

. Modify it as follows for using `sim` and `parfor` in Normal mode:

- In item 1, modify the `parpool` command as follows to create an object and use it to call a cluster name.

```

p = parpool('clusterProfile');
% 'clusterProfile' is the name of the distributed cluster

```

- In item 1, find files on which the model depends and attach those files to the model for distribution to cluster workers on remote machines.

```

files = dependencies.fileDependencyAnalysis(modelName);
p.addAttachedFiles(files);

```

- If you do not have a MATLAB Parallel Server cluster, use your local cluster. For more information, see “Discover Clusters and Use Cluster Profiles” (Parallel Computing Toolbox).

Start your cluster before running the code.

```

% 1) Load model and initialize the pool.
model = 'sldemo_suspn_3dof';
load_system(model);
parpool;

```

```

% 2) Set up the iterations that we want to compute.
Cf = evalin('base', 'Cf');
Cf_sweep = Cf*(0.05:0.1:0.95);
iterations = length(Cf_sweep);
simout(iterations) = Simulink.SimulationOutput;

% 3) Need to switch all workers to a separate tempdir in case
% any code is generated for instance for StateFlow, or any other
% file artifacts are created by the model.
spmd
    % Setup tempdir and cd into it
    addpath(pwd);
    currDir = pwd;
    addpath(currDir);
    tmpDir = tempname;
    mkdir(tmpDir);
    cd(tmpDir);
    % Load the model on the worker
    load_system(model);
end

% 4) Loop over the number of iterations and perform the
% computation for different parameter values.
parfor idx=1:iterations
    set_param([model '/Road-Suspension Interaction'],'MaskValues',...
        {'Kf',num2str(Cf_sweep(idx)),'Kr','Cr'});
    simout(idx) = sim(model, 'SimulationMode', 'normal');
end

% 5) Switch all of the workers back to their original folder.
spmd
    cd(currDir);
    rmdir(tmpDir,'s');
    rmpath(currDir);
    close_system(model, 0);
end

close_system(model, 0);
delete(gcf('nocreate'));

```

sim in parfor with Rapid Accelerator Mode

Running Rapid Accelerator simulations in `parfor` combines speed with automatic distribution of a prebuilt executable to the `parfor` workers. As a result, this mode eliminates duplication of the update diagram phase.

To run parallel simulations in Rapid Accelerator simulation mode using the `sim` and `parfor` commands:

- Configure the model to run in Rapid Accelerator simulation mode.
- Save changes to your model before simulating in `parfor`. The saved copy of your model is distributed to parallel workers when simulating in `parfor`.
- Ensure that the Rapid Accelerator target is already built and up to date.
- Disable the Rapid Accelerator target up-to-date check by setting the `sim` command option `RapidAcceleratorUpToDateCheck` to `'off'`.

To satisfy the second condition, you can change parameters only between simulations that do not require a model rebuild. In other words, the structural checksum of the model must remain the same. Hence, you can change only tunable block diagram parameters and tunable run-time block parameters between simulations. For a discussion on tunable parameters that do not require a rebuild subsequent to their modifications, see “Determine If the Simulation Will Rebuild” on page 35-7.

To disable the Rapid Accelerator target up-to-date check, use the `sim` command, as shown in this sample.

```
parpool;
% Load the model and set parameters
model = 'vdp';
load_system(model);
% Build the Rapid Accelerator target
rtp = Simulink.BlockDiagram.buildRapidAcceleratorTarget(model);
% Run parallel simulations
parfor i=1:4
    simOut{i} = sim(model,'SimulationMode', 'rapid',...
        'RapidAcceleratorUpToDateCheck', 'off',...
        'SaveTime', 'on',...
        'StopTime', num2str(10*i));
    close_system(model, 0);
end

close_system(model, 0);
delete(gcf('nocreate'));
```

In this example, the call to the `buildRapidAcceleratorTarget` function generates code once. Subsequent calls to `sim` with the `RapidAcceleratorUpToDateCheck` option `off` guarantees that code is not regenerated. Data concurrency issues are thus resolved.

When you set `RapidAcceleratorUpToDateCheck` to `'off'`, changes that you make to block parameter values in the model (for example, by using block dialog boxes, by using the `set_param` function, or by changing the values of MATLAB variables) do not affect the simulation. Instead, use `RapidAcceleratorParameterSets` to pass new parameter values directly to the simulation.

Workspace Access Issues

Workspace Access for MATLAB worker sessions

By default, to run `sim` in `parfor`, a parallel pool opens automatically, enabling the code to run in parallel. Alternatively, you can also first open MATLAB workers using the `parpool` command. The `parfor` command then runs the code within the `parfor` loop in these MATLAB worker sessions. The MATLAB workers, however, do not have access to the workspace of the MATLAB client session where the model and its associated workspace variables have been loaded. Hence, if you load a model and define its associated workspace variables outside of and before a `parfor` loop, then neither is the model loaded, nor are the workspace variables defined in the MATLAB worker sessions where the `parfor` iterations are executed. This is typically the case when you define model parameters or external inputs in the base workspace of the client session. These scenarios constitute workspace access issues.

Transparency Violation

When you run `sim` in `parfor` with `srcWorkspace` set to `current`, Simulink uses the `parfor` workspace, which is a transparent workspace. Simulink then displays an error for transparency

violation. For more information on transparent workspaces, see “Ensure Transparency in parfor-Loops or spmd Statements” (Parallel Computing Toolbox) .

Data Dictionary Access

When a model is linked to a data dictionary (see “What Is a Data Dictionary?” on page 75-2), to write code in `parfor` that accesses a variable or object that you store in the dictionary, you must use the functions `Simulink.data.dictionary.setupWorkerCache` and `Simulink.data.dictionary.cleanupWorkerCache` to prevent access issues. For an example, see “Sweep Variant Control Using Parallel Simulation” on page 26-16.

Resolving Workspace Access Issues

When a Simulink model is loaded into memory in a MATLAB client session, it is only visible and accessible in that MATLAB session; it is not accessible in the memory of the MATLAB worker sessions. Similarly, the workspace variables associated with a model that are defined in a MATLAB client session (such as parameters and external inputs) are not automatically available in the worker sessions. You must therefore ensure that the model is loaded and that the workspace variables referenced in the model are defined in the MATLAB worker session by using the following two methods.

- In the `parfor` loop, use the `sim` command to load the model and to set parameters that change with each iteration. (Alternative: load the model and then use the `g(s)et_param` command(s) to set the parameters in the `parfor` loop)
- In the `parfor` loop, use the MATLAB `evalin` and `assignin` commands to assign data values to variables.

Alternatively, you can simplify the management of workspace variables by defining them in the model workspace. These variables will then be automatically loaded when the model is loaded into the worker sessions. There are, however, limitations to this method. For example, you cannot store signal objects that use a storage class other than `Auto` in a model workspace. For a detailed discussion on the model workspace, see “Model Workspaces” on page 68-120.

Specifying Parameter Values Using the sim Command

Use the `sim` command in the `parfor` loop to set parameters that change with each iteration.

`%Specifying Parameter Values Using the sim Command`

```
model = 'vdp';
load_system(model)

%Specifying parameter values.
paramName = 'StopTime';
paramValue = {'10', '20', '30', '40'};

% Run parallel simulations
parfor i=1:4
    simOut{i} = sim(model, ...
                    paramName, paramValue{i}, ...
                    'SaveTime', 'on'); %#ok
end

close_system(model, 0);
```

An equivalent method is to load the model and then use the `set_param` command to set the `paramName` in the `parfor` loop.

Specifying Variable Values Using the assignin Command

You can pass the values of model or simulation variables to the MATLAB workers by using the `assignin` or the `evalin` command. The following example illustrates how to use this method to load variable values into the appropriate workspace of the MATLAB workers.

```
parfor i = 1:4
    assignin('base', 'extInp', paramValue{i})%#ok
    % 'extInp' is the name of the variable in the base
    % workspace which contains the External Input data
    simOut{i} = sim(model, 'ExternalInput', 'extInp'); %#ok
end
```

Sweep Variant Control Using Parallel Simulation

To use parallel simulation to sweep a variant control (a `Simulink.Parameter` object whose value influences the variant condition of a `Simulink.Variant` object) that you store in a data dictionary, use this code as a template. Change the names and values of the model, data dictionary, and variant control to match your application.

To sweep block parameter values or the values of workspace variables that you use to set block parameters, use `Simulink.SimulationInput` objects instead of the programmatic interface to the data dictionary. See “Optimize, Estimate, and Sweep Block Parameter Values” on page 37-38.

You must have a Parallel Computing Toolbox license to perform parallel simulation.

```
% For convenience, define names of model and data dictionary
model = 'mySweepMdl';
dd = 'mySweepDD.sldd';

% Define the sweeping values for the variant control
CtrlValues = [1 2 3 4];

% Grant each worker in the parallel pool an independent data dictionary
% so they can use the data without interference
spmc
    Simulink.data.dictionary.setupWorkerCache
end

% Determine the number of times to simulate
numberOfSims = length(CtrlValues);

% Prepare a nondistributed array to contain simulation output
simOut = cell(1,numberOfSims);

parfor index = 1:numberOfSims
    % Create objects to interact with dictionary data
    % You must create these objects for every iteration of the parfor-loop
    dictObj = Simulink.data.dictionary.open(dd);
    sectObj = getSection(dictObj, 'Design Data');
    entryObj = getEntry(sectObj, 'MODE');
    % Suppose MODE is a Simulink.Parameter object stored in the data dictionary

    % Modify the value of MODE
    temp = getValue(entryObj);
    temp.Value = CtrlValues(index);
    setValue(entryObj, temp);
end
```

```

% Simulate and store simulation output in the nondistributed array
simOut{index} = sim(model);

% Each worker must discard all changes to the data dictionary and
% close the dictionary when finished with an iteration of the parfor-loop
discardChanges(dictObj);
close(dictObj);
end

% Restore default settings that were changed by the function
% Simulink.data.dictionary.setupWorkerCache
% Prior to calling cleanupWorkerCache, close the model

spsmd
    bdclose(model)
    Simulink.data.dictionary.cleanupWorkerCache
end

```

Note If data dictionaries are open, you cannot use the command `Simulink.data.dictionary.cleanupWorkerCache`. To identify open data dictionaries, use `Simulink.data.dictionary.getOpenDictionaryPaths`.

Data Concurrency Issues

Data concurrency issues refer to scenarios for which software makes simultaneous attempts to access the same file for data input or output. In Simulink, they primarily occur as a result of the nonsequential nature of the `parfor` loop during simultaneous execution of Simulink models. The most common incidences arise when code is generated or updated for a simulation target of a Stateflow, Model block or MATLAB Function block during parallel computing. The cause, in this case, is that Simulink tries to concurrently access target data from multiple worker sessions. Similarly, To File blocks may simultaneously attempt to log data to the same files during parallel simulations and thus cause I/O errors. Or a third-party blockset or user-written S-function may cause a data concurrency issue while simultaneously generating code or files.

A secondary cause of data concurrency is due to the unprotected access of network ports. This type of error occurs, for example, when a Simulink product provides blocks that communicate via TCP/IP with other applications during simulation. One such product is the HDL Verifier™ for use with the Mentor Graphics® ModelSim® HDL simulator.

Resolving Data Concurrency Issues

The core requirement of `parfor` is the independence of the different iterations of the `parfor` body. This restriction is not compatible with the core requirement of simulation via incremental code generation, for which the simulation target from a prior simulation is reused or updated for the current simulation. Hence during the parallel simulation of a model that involves code generation (such as Accelerator mode simulation), Simulink makes concurrent attempts to access (update) the simulation target. However, you can avoid such data concurrency issues by creating a temporary folder within the `parfor` loop and then adding several lines of MATLAB code to the loop to perform the following steps:

- 1 Change the current folder to the temporary, writable folder.
- 2 In the temporary folder, load the model, set parameters and input vectors, and simulate the model.

- 3 Return to the original, current folder.
- 4 Remove the temporary folder and temporary path.

In this manner, you avoid concurrency issues by loading and simulating the model within a separate temporary folder. Following are examples that use this method to resolve common concurrency issues.

A Model with Stateflow, MATLAB Function Block, or Model Block

In this example, either the model is configured to simulate in Accelerator mode or it contains a Stateflow, a MATLAB Function block, or a Model block (for example, `sf_bounce`, `sldemo_autotrans`, or `sldemo_mdhref_basic`). For these cases, Simulink generates code during the initialization phase of simulation. Simulating such a model in `parfor` would cause code to be generated to the same files, while the initialization phase is running on the worker sessions. As illustrated below, you can avoid such data concurrency issues by running each iteration of the `parfor` body in a different temporary folder.

```
parfor i=1:4
    cwd = pwd;
    addpath(cwd)
    tmpdir = tempname;
    mkdir(tmpdir)
    cd(tmpdir)
    load_system(model)
    % set the block parameters, e.g., filename of To File block
    set_param(someBlkInMdl, blkParamName, blkParamValue{i})
    % set the model parameters by passing them to the sim command
    out{i} = sim(model, mdlParamName, mdlParamValue{i});
    close_system(model,0);
    cd(cwd)
    rmdir(tmpdir, 's')
    rmpath(cwd)
end
```

Note the following:

- You can also avoid other concurrency issues due to file I/O errors by using a temporary folder for each iteration of the `parfor` body.
- On Windows platforms, consider inserting the `evalin('base', 'clear mex');` command before `rmdir(tmpdir, 's')`. This sequence closes MEX-files first before calling `rmdir` to remove `tmpdir`.

```
evalin('base', 'clear mex');
rmdir(tmpdir, 's')
```

A Model with To File Blocks

If you simulate a model with To File blocks from inside of a `parfor` loop, the nonsequential nature of the loop may cause file I/O errors. To avoid such errors during parallel simulations, you can either use the temporary folder idea above or use the `sim` command in Rapid Accelerator mode with the option to append a suffix to the file names specified in the model To File blocks. By providing a unique suffix for each iteration of the `parfor` body, you can avoid the concurrency issue.

```
rtp = Simulink.BlockDiagram.buildRapidAcceleratorTarget(model);
parfor idx=1:4
    sim(model, ...
```

```
        'ConcurrencyResolvingToFileSuffix', num2str(idx),...  
        'SimulationMode', 'rapid',...  
        'RapidAcceleratorUpToDateCheck', 'off');  
    end
```

Error Handling in Simulink Using MSLException

Error Reporting in a Simulink Application

Simulink allows you to report an error by throwing an exception using the `MSLException` object, which is a subclass of the MATLAB `MException` class. As with the MATLAB `MException` object, you can use a try-catch block with a `MSLException` object construct to capture information about the error. The primary distinction between the `MSLException` and the `MException` objects is that the `MSLException` object has the additional property of `handles`. These handles allow you to identify the object associated with the error.

The MSLException Class

The `MSLException` class has five properties: `identifier`, `message`, `stack`, `cause`, and `handles`. The first four of these properties are identical to those of `MException`. For detailed information about them, see `MException`. The fifth property, `handles`, is a cell array with elements that are double array. These elements contain the handles to the Simulink objects (blocks or block diagrams) associated with the error.

Methods of the MSLException Class

The methods for the `MSLException` class are identical to those of the `MException` class. For details of these methods, see `MException`.

Capturing Information about the Error

The structure of the Simulink try-catch block for capturing an exception is:

```
try
    Perform one or more operations
catch E
    if isa(E, 'MSLException')
    ...
end
```

If an operation within the `try` statement causes an error, the `catch` statement catches the exception (`E`). Next, an `if isa` conditional statement tests to determine if the exception is Simulink specific, i.e., an `MSLException`. In other words, an `MSLException` is a type of `MException`.

The following code example shows how to get the handles associated with an error.

```
errHndls = [];
try
    sim('modelName', ParamStruct);
catch e
    if isa(e, 'MSLException')
        errHndls = e.handles{1}
    end
end
```

You can see the results by examining `e`. They will be similar to the following output:

```
e =
```

MSLException

Properties:

```
handles: {[7.0010]}
identifier: 'Simulink:Parameters:BlkParamUndefined'
message: [1x87 char]
cause: {0x1 cell}
stack: [0x1 struct]
```

Methods, Superclasses

To identify the name of the block that threw the error, use the `getfullname` command. For the present example, enter the following command at the MATLAB command line:

```
getfullname(errHndls)
```

If a block named Mu threw an error from a model named *vdp*, MATLAB would respond to the `getfullname` command with:

```
ans =
vdp/Mu
```

Multiple Simulations

Running Multiple Simulations

For workflows that involve multiple parallel simulations and logging of large amounts of data, you can use the `parsim` or `batchsim` functions, or run the simulations with the **Multiple Simulations** panel in the Simulink Editor. This approach is useful in scenarios like model testing, experiment design, Monte Carlo analysis, and model optimization.

For the command line workflow (`parsim` or `batchsim` functions), you can create simulation sets by using an array of `Simulink.SimulationInput` objects to run multiple simulations. Alternatively, you can use the **Multiple Simulations** panel in Simulink.

In the **Multiple Simulations** panel, you can create design studies to make specify values for simulations. The panel allows you to specify values for block parameters, and variables for the simulations.

With the Parallel Computing Toolbox, you can also use the `parsim` and `batchsim` functions, and **Multiple Simulations** panel to run the simulations in parallel.

- To run multiple simulations with `Simulink.SimulationInput` object and `parsim` function, see “Run Parallel Simulations for a Thermal Model of a House Using `parsim`” on page 27-5. To learn more about how the `parsim` function runs simulations in parallel, see “Run Parallel Simulations” on page 26-8.
- To learn about running multiple simulations in batch, see `batchsim`.
- To understand the differences between the command line workflows and how they work, see “Comparison Between Multiple Simulation Workflows” on page 27-10.
- To use the graphical user interface for running multiple simulations, see “Configure and Run Simulations with Multiple Simulations Panel” on page 27-19.
- To learn how to monitor the simulations and view the results, see “Analyze Data from Multiple Simulations” on page 29-111.

Note When the pool is not already open and simulations are run for the first time, simulations take an additional time to start. Subsequent parallel simulations are faster.

Multiple Simulations with Simulink Editor

The **Multiple Simulations** panel allows you to set up multiple simulations for different values of block parameters and variables. You can pick a block parameter of interest from the model canvas and specify values that you want to use for the simulations. You can also provide variables for simulations. To run the simulations that you have set up, first, select the design study, then click **Run All** button on **Simulation** tab on the Simulink toolstrip. To learn more, see the “Multiple Simulations Panel: Simulate for Different Values of Stiffness for a Vehicle Dynamics System” on page 27-24 example.

Multiple Simulations with Parallel Computing Toolbox

The `parsim` function and the **Multiple Simulations** panel distributes each simulation to parallel pool workers to decrease your overall simulation time when running in parallel. Using the `parsim` function and the **Multiple Simulations** panel creates a parallel pool, which allows you to identify file dependencies and manage build artifacts for simulations in accelerator and rapid accelerator mode.

The `batchsim` function offloads the simulations to the compute cluster. The simulations are executed on the cluster, which allows you to carry out other tasks while the batch job is processing. You can also close the client MATLAB session and access the batch job later.

The `batchsim` function uses the Parallel Computing Toolbox™ license to run the simulations on compute cluster. The `batchsim` function runs the simulations in serial if a parallel pool cannot be created. If Parallel Computing Toolbox license, `batchsim` function gives an errors.

Multiple Simulations with the `sim` Function

In the absence of a Parallel Computing Toolbox license, the `parsim` function and the **Multiple Simulations** panel behave like the `sim` command. The simulations run in serial.

Multiple Simulations with `Simulink.SimulationInput` Object

In command line workflows, you can make changes to your model using the `Simulink.SimulationInput` object and run a simulation in parallel with those changes. Changing the values in the `Simulink.SimulationInput` object, overrides the values in the model, which allows you to modify the model without dirtying it. Through the `Simulink.SimulationInput` object, you can also specify MATLAB functions to run at the start and the end of each simulation by using the `PreSimFcn` and `PostSimFcn` functions, respectively. When you use `Simulink.SimulationInput` objects, the model parameters are restored after the simulation ends. See “Run Parallel Simulations for a Thermal Model of a House Using `parsim`” on page 27-5. The `Simulink.SimulationInput` object allows you to change these settings in your model:

- Initial state
- External inputs
- Model parameters
- Block parameters
- Variables

Simulation Manager to Monitor Simulations

The Simulation Manager allows you to monitor multiple parallel simulations. It shows the progress of the runs as they are running in parallel. You can view the details of every run such as parameters, elapsed time, and diagnostics. The Simulation Manager acts as a useful tool by giving you the option to analyze and compare your results in the Simulation Data Inspector. You can also select a run and apply its values to the model. For more information, see **Simulation Manager**.

The `parsim/batchsim` Function Capabilities

- Outputs errors in the simulation output object for easier debugging
- Compatible with rapid accelerator and fast restart
- Compatible with file logging (to facilitate big data)
- Compatible with MATLAB Parallel Server in addition to local parallel pools
- Capable of transferring base workspace variables to workers
- Avoids transparency errors

Data Logging for Multiple Simulations

The resulting `Simulink.SimulationOutput` object, which contains the simulation outputs, captures error messages and the simulation metadata. When you select the **Data Import/Export > Log Dataset data to file** configuration parameter, Simulink creates a `Simulink.SimulationData.DatasetRef` object for each `Dataset` stored in the resulting MAT file. You can use the `DatasetRef` object to access the data for a `Dataset` element. For simulations that are run using the `Simulink.SimulationInput` objects, the `DatasetRef` object is returned as part of the `SimulationOutput` object. As a result, you have quicker access to and do not need to create them.

Parallel simulations can produce more logged data than the MATLAB memory can hold. Consider logging to persistent storage for parallel simulations to reduce the memory requirement. When you select the **Data Import/Export > Log Dataset data to file** configuration parameter (`LoggingToFile`), for parallel simulations in Simulink:

- Data is logged in Dataset format in a MAT-file
- A `Simulink.SimulationData.DatasetRef` object is created for each `Dataset` element (for example, `logout`) for each simulation

You can use `DatasetRef` objects to access data for a specific signal. You can create `matlab.io.datasetore.SimulationDatastore` objects to use for streaming logged data from persistent storage in to a model.

Run Parallel Simulations for a Thermal Model of a House Using parsim

This example shows how to use a `Simulink.SimulationInput` object to change block and model parameters and run simulations in parallel with those changes.

The example model `sldemo_househeat` is a system that models the thermal characteristics of a house, its outdoor environment, and a house heating system. This model calculates heating costs for a generic house.

Set Point block, Thermostat subsystem, Heater subsystem, House subsystem, and Cost Calculator component are the main components. For a detailed explanation of the model, see “Thermal Model of a House”.

Run Multiple Parallel Simulations with Different Set Points

This model uses a Constant block to specify a temperature set point that must be maintained indoors. The default value of set point value is 70 degrees Fahrenheit. This example shows you how to simulate the model in parallel using different values of Set Point.

Open the example and the model

```
openExample('simulink_general/sldemo_househeatExample');
open_system('sldemo_househeat');
```

Define a set of values for Set Point.

```
SetPointValues = 65:2:85;
spv_length = length(SetPointValues);
```

Using the defined values, initialize an array of `Simulink.SimulationInput` objects. Use these `Simulink.SimulationInput` objects to specify the Set Point values. In this step, to preallocate the array, the loop index is made to start from the largest value.

```
for i = spv_length:-1:1
    in(i) = Simulink.SimulationInput('sldemo_househeat');
    in(i) = in(i).setBlockParameter('sldemo_househeat/Set Point',...
        'Value',num2str(SetPointValues(i)));
end
```

This example produces an array of 10 `Simulink.SimulationInput` objects, each corresponding to a different value of Set Point.

Now, run these multiple simulations in parallel using the command `parsim`. To monitor and analyze the runs, open the Simulation Manager by setting the `ShowSimulationManager` argument to `on`. The `ShowProgress` argument when set to `on` shows the progress of the simulations.

```
out = parsim(in, 'ShowSimulationManager', 'on', 'ShowProgress', 'on')
```

The output is generated as a `Simulink.SimulationOutput` object. To see all of the different set point values, open the plot of the Temperatures (Indoor and Outdoor) and the Heat Cost component. The constant block Avg Outdoor Temp specifies the average air temperature outdoors. The Daily Temp Variation Sine Wave block generates daily temperature fluctuations of outdoor temperature. The indoor temperature is derived from the House subsystem. The temperature outdoor varies sinusoidally, whereas the temperature indoors is maintained within 5 degrees Fahrenheit of the set point.

In the absence of the Parallel Computing Toolbox licenses, the `parsim` command behaves like the `sim` command. The simulations run in serial.

View the Runs in the Simulation Manager

Setting the `ShowSimulationManager` argument to `on` enables the Simulation Manager. For more information, see **Simulation Manager**.

You can view the status of all the runs and detailed information about them.

More About

- “Run Parallel Simulations” on page 26-8
- “Comparison Between Multiple Simulation Workflows” on page 27-10

- “Running Multiple Simulations” on page 27-2

Comparison Between Multiple Simulation Workflows

When running a set of multiple simulations, you can run them in parallel on multiple MATLAB workers in a parallel pool. To run multiple simulations, you can use `parsim`, `parsim` with 'RunInBackground' option turned on, or `batchsim`.

The flow chart shows how running multiple simulations with `parsim`, `parsim` with `RunInBackground` and `batchsim` differ.

The `parsim` and `batchsim` commands use the Parallel Computing Toolbox license to run the simulations in parallel. `parsim` runs the simulations in serial if a parallel pool cannot be created or if the Parallel Computing Toolbox license is not available. `batchsim` commands cannot run without Parallel Computing Toolbox license.

parsim Workflow

Using `parsim` command with Parallel Computing Toolbox to run multiple simulations sets up a parallel pool automatically and runs simulations in parallel. The client is always tied to the MATLAB workers.

Basic parsim Workflow

- 1 Create an array of `Simulink.SimulationInput` objects, `in`, to specify changes to the model.
- 2 Specify one-time setup required for running multiple simulations. You can use `SetupFcn` and `TransferBaseWorkspaceVariables` to perform setup on the parallel workers.
- 3 Run `parsim(in)` to execute these multiple simulations in parallel. If a parallel pool does not exist, `parsim` creates it. `parsim` uses default settings.
- 4 You can open Simulation Manager by setting the `'SimulationManager'` argument to `'on'` with `parsim, parsim(in, 'SimulationManager', 'on')`. Simulation Manager enables you to monitor the simulations as they are running and gives you access to outputs of the simulations when they are ready. Simulation Manager provides you with information about the simulations running on the workers. For more information, see **Simulation Manager**.
- 5 Once all the simulations are complete, you get an array of `Simulink.SimulationOutput` objects.

Limitations

- Closing the MATLAB session terminates simulations on the workers, disabling retrieval of partial results.

parsim with RunInBackground Workflow

- 1 Create an array of `Simulink.SimulationInput` objects, `in`, to specify changes to the model.
- 2 Specify one-time setup required for running multiple simulations. You can use `SetupFcn` and `TransferBaseWorkspaceVariables` to perform setup on the parallel workers.

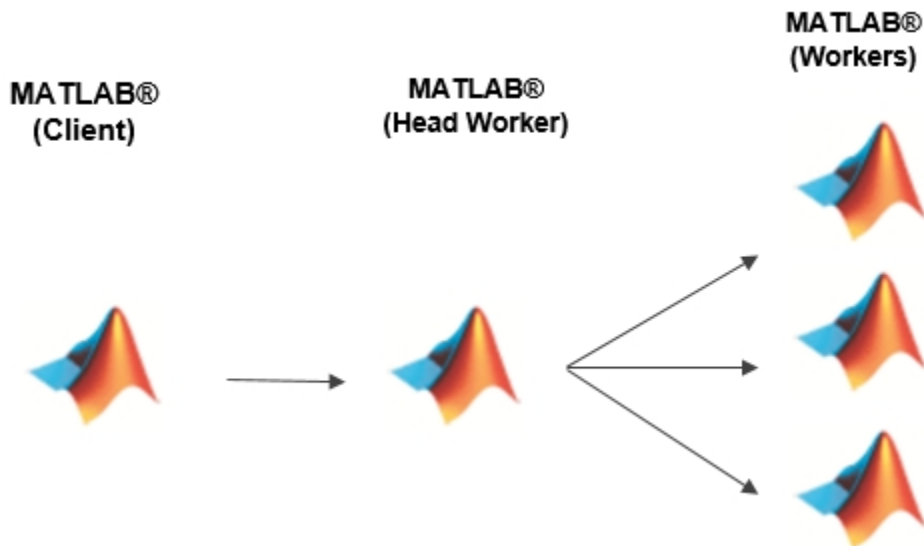

- 3 Run `parsim` with `RunInBackground` option set to `'on'`:
`parsim(in, 'RunInBackground', 'on')`. Setting the `'RunInBackground'` option to `'on'` runs the simulations asynchronously. This keeps the MATLAB command prompt available enabling you to work on other tasks.
- 4 With `'RunInBackground'` option set to `'on'`, `parsim` returns a `Simulink.Simulation.Future` object. You can poll this object to check the status of simulations, fetch the outputs of simulations when they are completed, or cancel simulations. For more information, see `Simulink.Simulation.Future`.

Limitations

- Closing the MATLAB session terminates simulations on the workers, disabling retrieval of partial results. If the `future` object is cleaned, you are subsequently unable to access the results of the simulations.
- Using a `fetchNext` method loop on `Future` objects, along with Simulation Manager causes them to compete for retrieval of `Future` objects. Use either a `fetchNext` method loop or Simulation Manager to get the outputs of completed simulations.

batchsim Workflow

A batch workflow typically means submitting jobs to run simulations on MATLAB workers and subsequently accessing the results of those simulations. When you run simulations in batches, you offload the execution of simulations onto a compute cluster. To learn more about batch processing, see “Simple Batch Processing” (Parallel Computing Toolbox).

- 1 Create an array of `Simulink.SimulationInput` objects, `in`, to specify changes to the model.
- 2 Specify one-time setup required for running multiple simulations. You can use `SetupFcn` and `TransferBaseWorkspaceVariables` to perform setup on the parallel workers.
- 3 To run on a cluster or desktop background, call `batchsim` to offload the execution of simulations. With `batchsim`, you can use most of the arguments that are compatible with `parsim` and `batch` commands. For more information, see `batchsim`.

Using `batchsim`, you offload simulations to a MATLAB worker. To run the batch job on multiple workers, specify a pool size, `N`, that is an integer specifying the number of workers to make into a parallel pool for the job: `batchsim(in, 'Pool', N)`. There must be at least `N+1` workers available on the cluster. If the pool size is not specified, `batchsim(in)` runs the simulations on a single worker in the cluster specified by the default cluster profile.

Note `batchsim` errors out when used with a pool size if Parallel Computing Toolbox license is not available.

- 4** `batchsim` offloads simulations to the compute cluster, enabling you to carry out other tasks while the batch job is processing, or close the client MATLAB and access the batch job later.
- 5** On submitting a batch job, `batchsim` returns a job object containing a job ID and other information that you can use to access the batch job at a later time. Access this job again to check the progress of simulations.

Limitations

- Because the client session is not tied to the workers, you cannot access the outputs unless the job is finished.
- `batchsim` does not give you the ability to monitor simulations with Simulation Manager. For batch jobs, you can use a batch job monitor that tells you if the job is queued, in progress, or completed. For more information, see “Job Monitor” (Parallel Computing Toolbox)

Analyze Results Using Simulation Manager

The Simulation Manager allows you to monitor multiple simulations, in serial or in parallel, and their progress. You can view the details of every run, such as parameters, elapsed time, and diagnostics. The Simulation Manager provides the option to analyze and compare your logged signal results in the **Simulation Data Inspector**. Through Simulation Manager, you can select a run and apply its values to the model. Simulation Manager opens when you run a `parsim` or a `sim` command with `ShowSimulationManager` argument set to `on`. For more information, see **Simulation Manager**.

The dimensions of the tank have an impact on the total cost of production of the product. For this example, we observe the behavior of `TotalCost` for different values of the width and the height. By analyzing the behavior of the parameters, we find the combination of `A` and `h` that results in lowest `TotalCost`. To solve this design problem, we run multiple simulations (in parallel or in serial) with different values of the parameters `A` and `h`.

This example shows how you can use the Simulation Manager to analyze the simulations and solve a design problem using a model of a continually stirred tank reactor. The reactors are specialized tanks that are used to mix various chemicals or compounds to create a product. The important variables used in this model are:

- Variable `A`, which represents the cross-sectional area of the tank (width).
- Variable `h`, which represents the height.
- Variable `TotalCost`, which represents the cost, in dollars, to produce a tankful of product.

Simulation Manager enables you to analyze the simulations as they are running. When the simulations are in progress, you can visualize the simulation data of the model by plotting the simulation outputs against the input parameters. Visualizing trend of the simulations as they are happening allows you to learn about the design space of the simulations and evaluate whether the simulations are running as required. You can stop the simulations if the progress is not as desired thus saving time.

Open Simulation Manager

In this example, use a set of sweep parameters provided to the model through `Simulink.SimulationInput` objects and then use the `parsim` command to run the simulations in parallel.

Create a `PostSimFcn` function as follows in a MATLAB script to call later in the parameter sweep. Name the file `calculateCost.m`. The `PostSimFcn` function calculates `TotalCost` from the variables `A` and `h`, and its calculation can vary depending on the application.

```
function costOutput = calculateCost(out)

    costOutput.yout = out.yout;

    coolantOutput = out.yout.get('Coolant').Values.Data;
    costCoolant = abs(mean(coolantOutput - 294))/30;
    costOutput.costFromCoolant = costCoolant;

    concentrationOutput = out.yout.get('Residual Concentration').Values.Data;
    costConcentration = 10*std(concentrationOutput - 2);
    costOutput.costFromConcentration = costConcentration;

    costOutput.TotalCost = costCoolant + costConcentration;

end
```

Open the model.

```
openExample('simulink/OpenTheModelToUseWithSimulationManagerExample');
open_system('simManagerCSTR');
```

Create a sample of values for parameter sweep.

```
rangeA = [0.1, 5];
rangeH = [0.1, 5];

rng default;

numSamples = 60;
allAValues = rangeA(1) + (rangeA(2) - rangeA(1)).*rand(numSamples, 1);
allHValues = rangeH(1) + (rangeH(2) - rangeH(1)).*rand(numSamples, 1);
```

Create an array of Simulink.SimulationInput objects. For this example, the TotalCost is calculated and returned using the PostSimFcn.

```
in(1:numSamples) = Simulink.SimulationInput('simManagerCSTR');
in = in.setPostSimFcn(@(out) calculateCost(out));
```

Run the simulations in parallel and open the Simulation Manager.

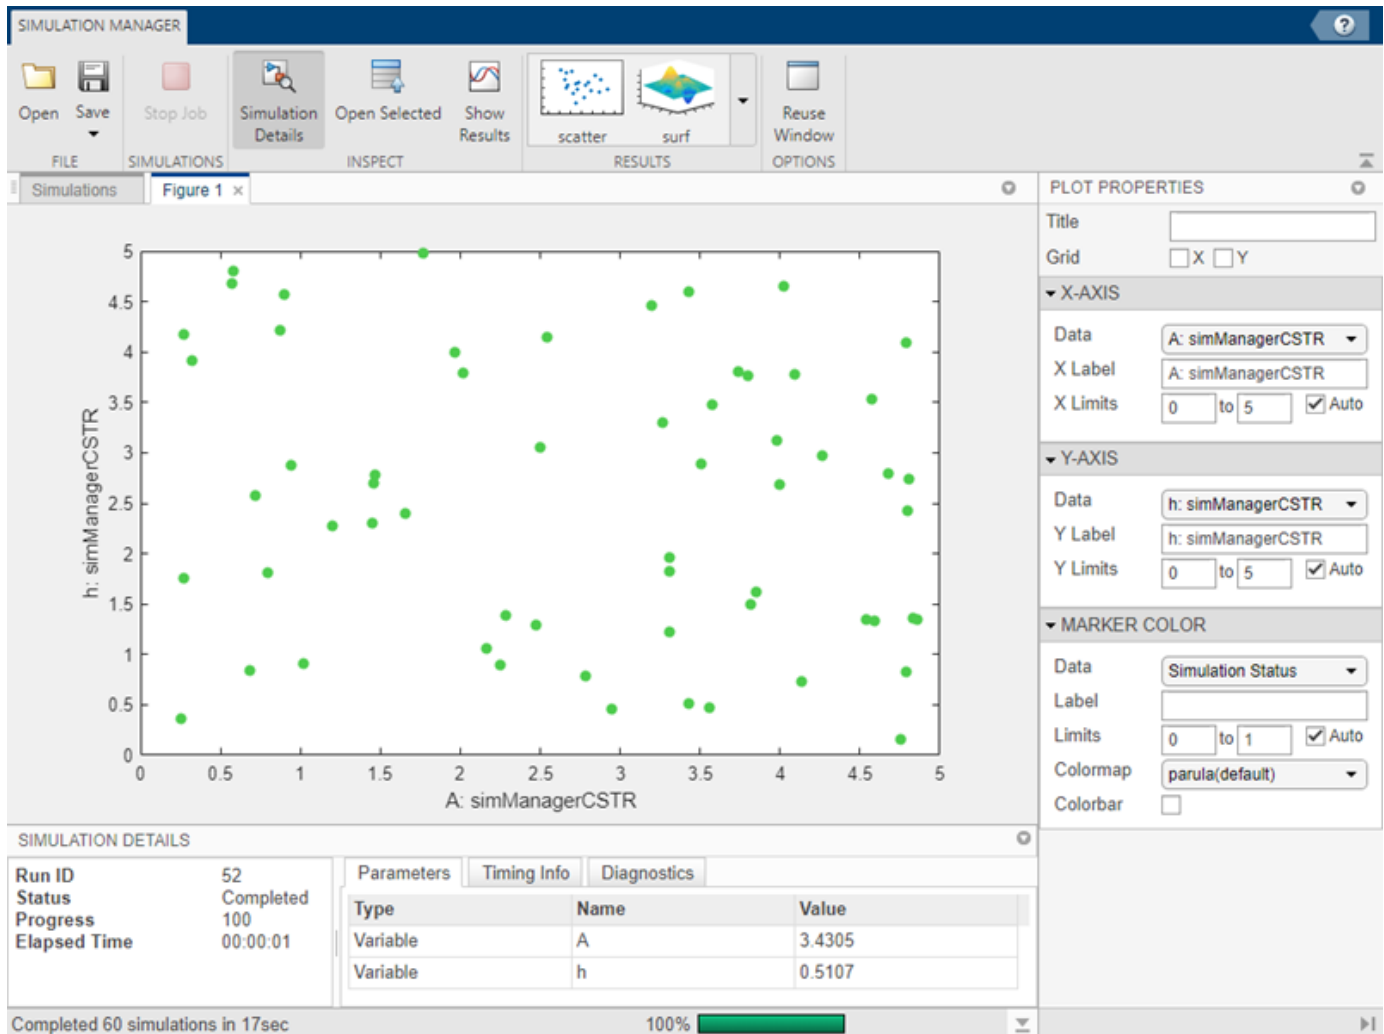

```
for k = 1:numSamples
    in(k) = in(k).setVariable('A', allAValues(k), 'Workspace', 'simManagerCSTR');
    in(k) = in(k).setVariable('h', allHValues(k), 'Workspace', 'simManagerCSTR');
end

out = parsim(in, 'ShowSimulationManager', 'on');
```

The default view in the Simulation Manager shows a scatter plot with two parameters on its X and Y axes. In this case, the variable A is on the X-axis and variable h is on the Y-axis. When the simulations are running you can see dots appear on the plot, color coded according to the simulation status. Completed simulations are marked in green, in-progress simulations are blue, and simulations with errors are red.

The **Plot Properties** panel on the right enables you to edit and configure the data that plot shows. By selecting grid for X and Y axes, the plot appears with grid lines.

If a particular parameter is a time-series, the Simulation Manager plots only the last value of the time series.

With the Simulation Manager, you can visualize the above data in a surf plot. Click the **surf** plot in the **Results** section of the toolbar.

Add and Configure Plots

The **Results** section of the Simulation Manager allows you to add multiple plots and configure them. Click the **surface plot** in **Results** section of the Simulation Manager toolbar. Using the plot properties, change the parameters to display on the plots. You can change properties such as the plot labels, axes labels and you can add a colormap to denote the third parameter. You can also change the value limits of the colormap.

With the second plot and the first plot together, you can determine the value of the variables A and h, that gives the best TotalCost.

For the Z-axis of the surf plot, change the **Data** to TotalCost. By observing the surf plot, you can find the lowest point of TotalCost. Clicking the lowest point shows the values for X-axis and Y-axis, which is h and A, respectively.

Save and Load Simulation Manager

Save the session information, which includes simulation data all the plot configurations. To save the session, click the **Save** button on the toolbar. The session saves as a `.mldatx` file. To reopen the saved session, navigate to the location where the file is saved and double-click the `.mldatx` file.

The Simulation Manager allows you to reuse the plot configuration when you want to run similar simulations with different sets of values. To reuse the plot configuration, click the **Reuse Window** button on the toolbar. Selecting the **Reuse Window** saves the plot configurations, such as labels, axis orientation, which parameters to display on which axis that you can reuse with the next simulation of the same model. When you use this functionality while running simulations for different models, the simulation errors out due to a limitation.

Configure and Run Simulations with Multiple Simulations Panel

The **Multiple Simulations** panel allows you to set up multiple simulations for a block parameter that you want to vary, for example, for a parameter sweep or Monte-Carlo simulations. You can pick a block parameter of interest from the model canvas and specify values that you want to use for the simulations. With the Multiple Simulations panel, you can provide configurations such as **Use Parallel** to run your simulations in parallel. To run the simulations that you have set up, first, select the design study, then click **Run All** button on **Simulation** tab on the Simulink toolstrip. Once the simulations are complete, you can view and manage the results in **Simulation Manager**.

Workflow for Multiple Simulations Panel

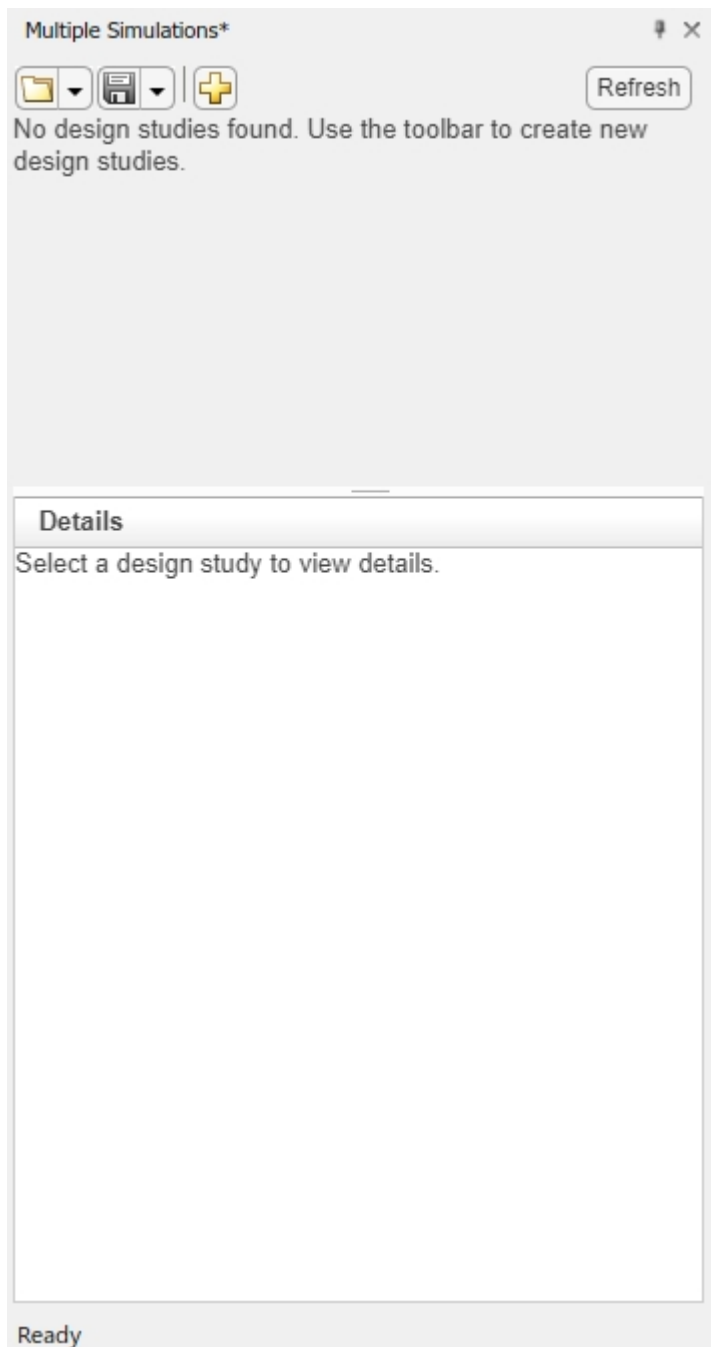

To configure and run multiple simulations from the Simulink Editor:

- 1 First, check that you have made all the desired changes to your model.
- 2 The **Multiple Simulations** panel allows you to perform similar operations as the `parsim` command line API, but through the Simulink Editor. To open the **Multiple Simulations** panel, navigate to the **Prepare** section on the Simulink toolstrip. In the **Inputs & Parameter Tuning**

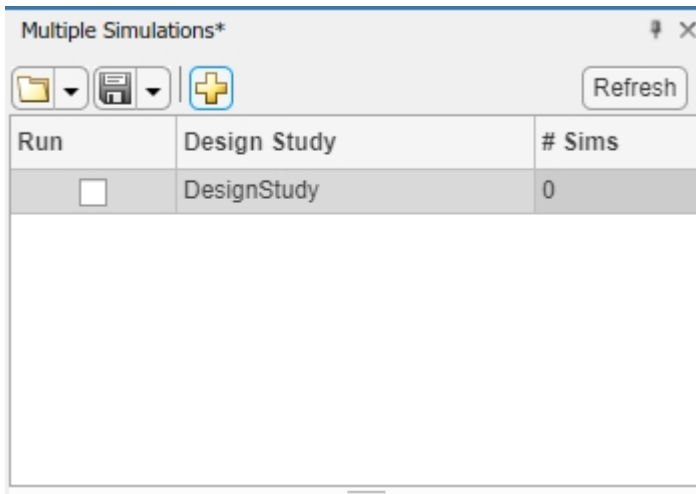

section, click **Multiple Simulations**.

- 3 The **Multiple Simulations** panel appears docked on the right side of the Simulink canvas.

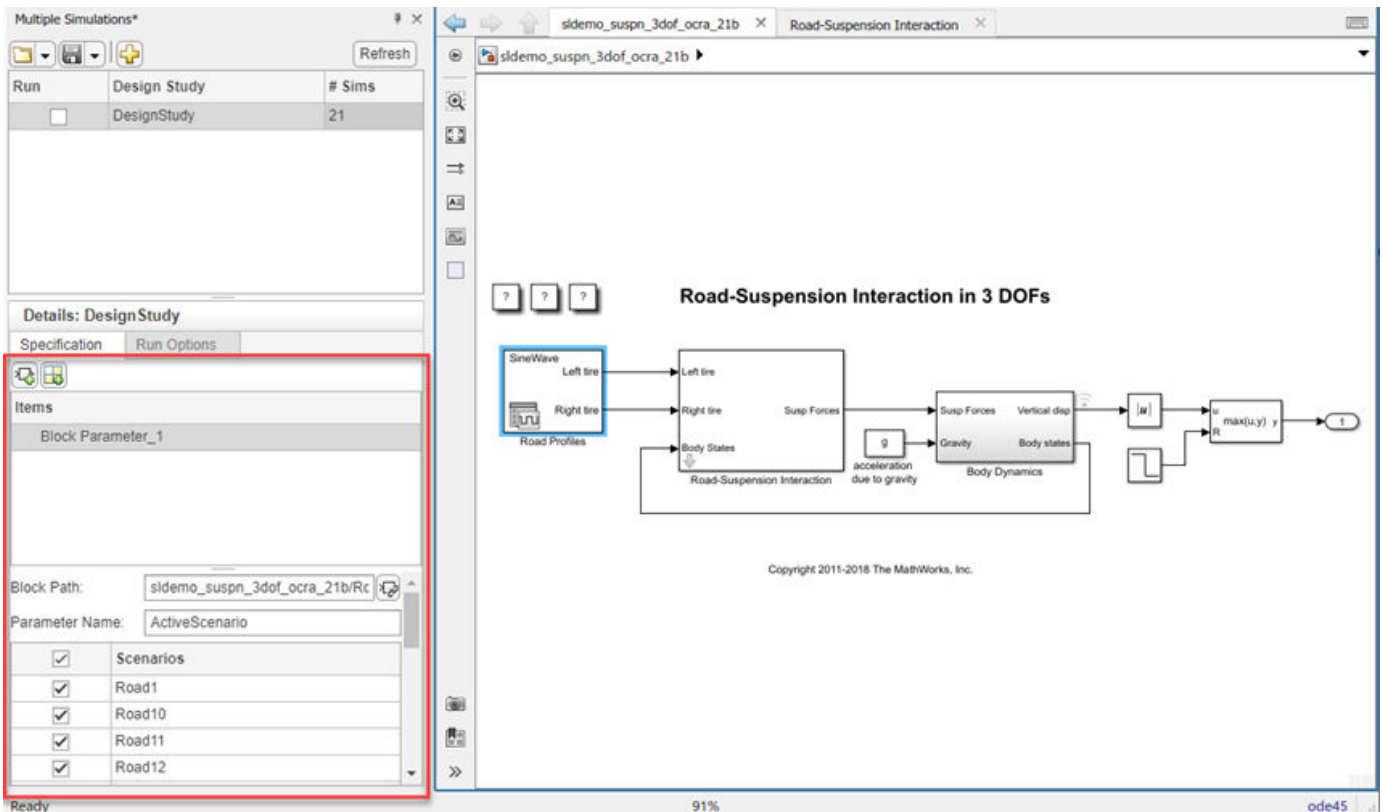

- 4 In the panel, click the right most button to create a new design study. A design study is an object that allows you to set up simulations. The name of the new design study is automatically populated as `DesignStudy`. To change the name, double-click on the name and enter your preferred name. Once you configure and enter the values for the simulations, select the design study and click **Run All** on the Simulink toolstrip to run the simulations.

5

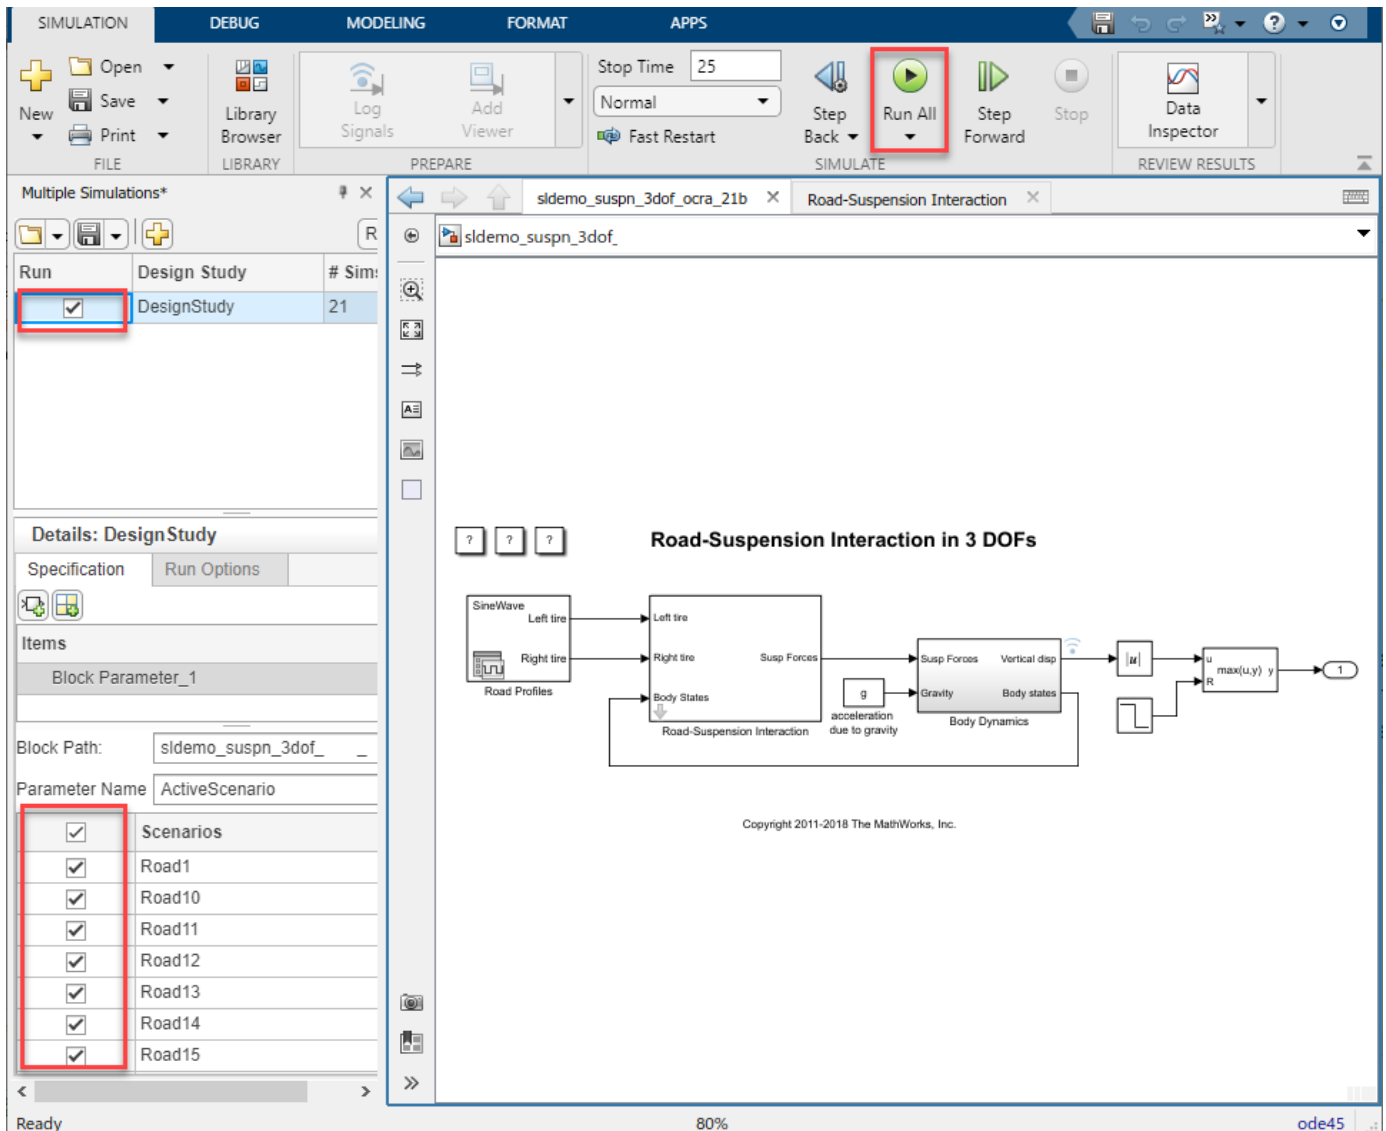

Now, you can add a block parameter to the created design study. Click  to add a new block parameter to the design study. You can enter the block path or use a picker to select a block from the model canvas, or you can enter the block parameter name. Once you have added the block parameter, specify its values. If the block is a Signal Editor block, you can choose your specification from the list of scenarios. By default, all scenarios will be selected.

You can also add variables for your simulations by clicking . In the **Details: Design Study** section, the **Run Options** tab, you can also specify the option to run in parallel.

- Now that you entered specifications, select the scenarios and the design study that you want to run. Once you select the design study, the **Run** button on the Simulink toolstrip changes to **Run All**. Click **Run All** to run the simulations.

- Once the simulations complete, you can view and manage the results in the **Simulation Manager**. To open the Simulation Manager, click **Open Simulation Manager** on the status bar at the bottom of the canvas.

- 8 Click the save button in the **Multiple Simulations** panel to save the design study that you have set up. The design study is saved in `.mldatx` format. To reuse the design study, open the **Multiple Simulations** panel, click the open button, and select the design study file from the file browser.

You can also save the Simulation Manager session information, which includes simulation data all the plot configurations. To save the Simulation Manager session, use the save button on the Simulation Manager toolbar.

Multiple Simulations Panel: Simulate for Different Values of Stiffness for a Vehicle Dynamics System

This example shows how to use the **Multiple Simulations** panel in the Simulink® Editor to run multiple simulations with varying values of stiffness of the suspension for a road profile that has a sinusoidal shape.

Open the Model

The model simulates the vehicle dynamics based on the road-suspension interaction for different road profiles. The road profile data for the left and right tires is imported into the Signal Editor block as a sinusoidal shape. The Road-Suspension Interaction subsystem calculates the suspension forces on the vehicle at the four tire locations based on the road data and the current vehicle state. In the Body Dynamics subsystem, these forces and the resulting pitch and roll movements are used to determine the vehicle motion in three degrees of freedom: vertical displacement, roll, and pitch. The model is simulated using different values of stiffness of the suspension to determine if the design meets desired performance goals.

```
open_system('ex_multisim_sldemo_suspn_3dof');
```

Set Up Simulations

To configure and set up simulations, use the **Multiple Simulations** panel. To open the **Multiple Simulations** panel, go to the **Prepare** section on the Simulink toolstrip. In the **Inputs & Parameter**

Tuning section, click **Multiple Simulations**. In the panel, click  to create a new design study.

The screenshot displays the MATLAB/Simulink environment. The top menu bar includes SIMULATION, DEBUG, MODELING, FORMAT, and APPS. The toolbar contains various simulation controls like 'Run', 'Step Back', and 'Step Forward'. On the left, the 'Multiple Simulations*' panel shows a table with one entry: 'Design Study' with 0 simulations. Below this, the 'Details: Design Study' section has tabs for 'Specification' and 'Run Options'. The main workspace shows a Simulink model titled 'Road-Suspension Interaction in 3 DOFs'. The model includes blocks for 'SineWave' (Left tire, Right tire), 'Road Profiles', 'Body States', 'Road-Suspension Interaction', 'Suspension Forces', 'Gravity', 'Body Dynamics', and a 'max(u,y)' block. The status bar at the bottom indicates 'Ready', '100%', and 'ode45'.

A new design study object is added to the panel. The name of this design study is automatically populated. Double-click the design study to change the name. Use this design study to specify the parameters for the simulations. In this design study, we set up the values for the variable K which represents stiffness. By running multiple simulations, we want to see how the amplitude at which the car oscillates is affected by different values of stiffness.

To add variable to this design study, click  on the **Specification** tab of the **Details:Design Study** section. Once you add the variable, double-click to label the variable as **Suspension stiffness**. Specify the variable name as K , which is the stiffness of the suspension. Run simulations for multiple values of the stiffness, K . Simulate for values ranging from $2e4$ to $8e4$, with one hundred separate points. Add `linspace(2e4, 8e4, 100)` as the values of the variable K .

Run Multiple Simulations

Now that you have set up the values for our simulations, select the design study. The **Run** button in

the Simulation section of the Simulink toolstrip changes to **Run All**, to indicate that you have setup multiple simulations. Click the **Run All** button to start the simulations. You can open Simulation Manager by clicking **Open Simulation Manager** on the Simulink status bar at the bottom of the canvas.

View the Results in Simulation Manager

Inspect how the amplitude at which the car oscillates is affected by different values of stiffness. To see the plot, in **Plot Properties**, select `yout` from the list for Data for the Y-Axis. `yout` represents the resulting amplitude of oscillations. The road pattern for this simulation is a sine wave with fixed frequency. By varying the stiffness values, you vary the natural frequency of the system. Based on the stiffness values, you start below the natural frequency. As you increase the values of the stiffness, you cross the natural frequency, thus entering resonance. As you increase the stiffness values above the natural frequency, the amplitude starts to decrease again.

By configuring and specifying values through the Multiple Simulations panel, you can easily run many simulations with different values for parameter sweep and Monte-Carlo simulations directly through the Simulink Editor.

Save the Design Study and the Plot

Click  in the **Multiple Simulations** panel to save the design study that you have set up. The design study is saved in `mldatax` format. To reuse the design study, open the **Multiple Simulations** panel, click , and select the design study file from the file browser.

You can also save the Simulation Manager session information, which includes simulation data all the plot configurations. The Simulation Manager allows you to reuse the plot configuration when you want to run similar simulations with different sets of values. To reuse the plot configuration, click .

on the Simulation Manager toolstrip. To reopen the saved session, navigate to the location where the file is saved and double-click the `.mldatx` file.

Prototype and Debug Models with Scopes

Simulink scope blocks and viewers offer a quick and lightweight way to visualize your simulation data over time. If you are prototyping a model design, you can attach signals to a Scope block. After simulating the model, you can use the results to validate your design. See “Scope Blocks and Scope Viewer Overview” on page 28-6 and “Model and Validate a System”.

A Scope block or Scope viewer opens to a Scope window where you can display and evaluate simulation data.

The toolbar contains controls for starting, stopping, and stepping forward through a simulation

. You can use these controls to debug a model by viewing signal data at each time interval. See “How Stepping Through a Simulation Works” on page 2-3.

Connect signal lines to a Scope block using multiple input ports, see “Number of input ports”.

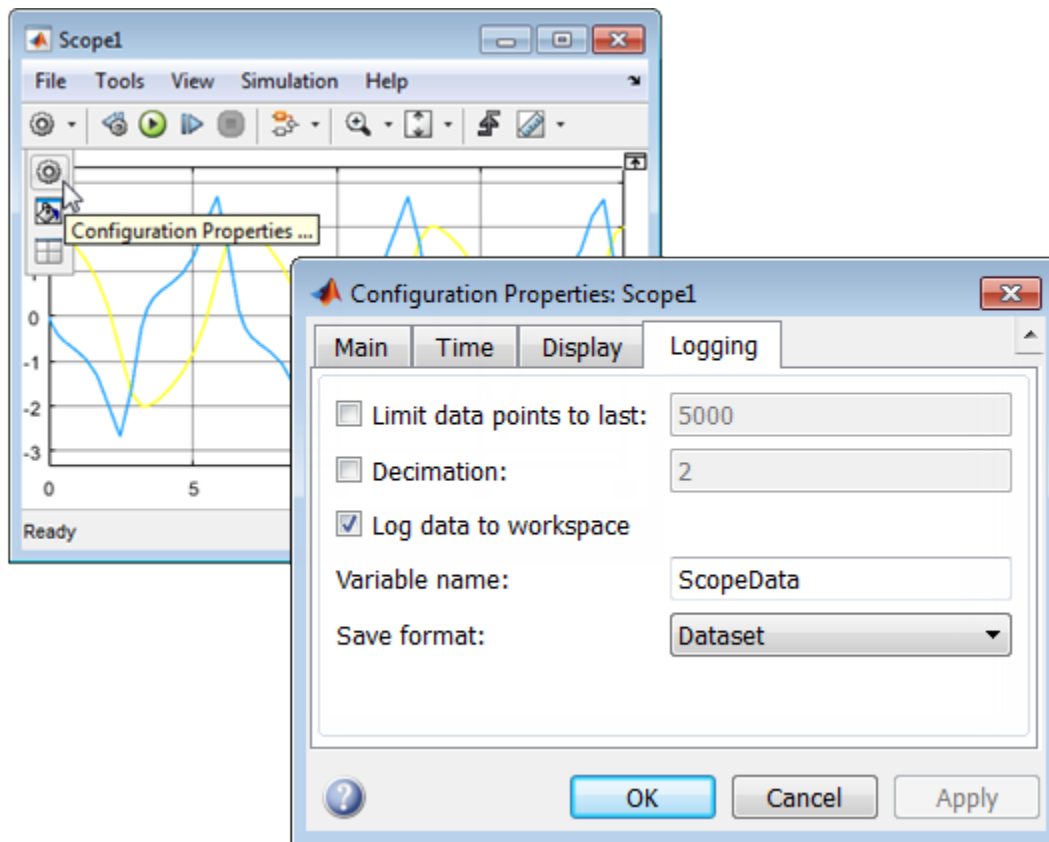

Attach signals to a Floating Scope block or signal viewer directly from the model. See “Add Signals to an Existing Floating Scope or Scope Viewer” on page 28-71.

Use the oscilloscope-like tools available with a scope to debug your model. Set triggers to capture events, use interactive cursors to measure signal values at various points, and review signal statistics such as maximum and mean values. See “Scope Triggers Panel” on page 28-12 and “Cursor Measurements Panel” on page 28-23.

Save or log signal data to the MATLAB workspace, and then plot data in a MATLAB figure window. Use MATLAB functions or your own scripts to analyze the data. See “Save Simulation Data from Floating Scope” on page 28-72.

Scope Blocks and Scope Viewer Overview

In this section...

“Overview of Methods” on page 28-6

“Simulink Scope Versus Floating Scope” on page 28-6

“Simulink Scope Versus DSP System Toolbox Time Scope” on page 28-8

Overview of Methods

Simulink scopes provide several methods for displaying simulation data and capturing the data for later analysis. Symbols on your block diagram represent the various data display and data capture methods.

For more information about these methods:

- Scope and Floating Scope blocks — Scope, Floating Scope, “Common Scope Block Tasks” on page 28-51, “Floating Scope and Scope Viewer Tasks” on page 28-70.
- Scope Viewer — “Viewers and Generators Manager” on page 28-80, “Floating Scope and Scope Viewer Tasks” on page 28-70.
- Signal Logging — “Save Simulation Data from Floating Scope” on page 28-72.
- Signal Test Point — “Configure Signals as Test Points” on page 76-46.

Simulink Scope Versus Floating Scope

Scope blocks and Floating Scope blocks both display simulation results, but they differ in how you attach signals and save data. Simulation behavior for a Floating Scope and a Scope Viewer is identical, but you manage them differently in your model.

Capability	Simulink Scope	Simulink Floating Scope	Simulink Scope Viewer
Attaching signals	Connect signal lines to a Scope block using input ports.	Attach signals interactively from the model before and during a simulation. See “Add Signals to an Existing Floating Scope or Scope Viewer” on page 28-71 and “Quickly Switch Visualization of Different Signals on a Floating Scope” on page 28-76.	Attach signals from the Viewers and Generators Manager, interactively from the toolstrip, or using the signal line context menu.
Access to signals	Because signals lines are connected to a Scope block, access signals at different levels of a model hierarchy using GoTo blocks.	Because signals are attached without signal lines, you do not have to route lines to a Floating Scope block. You can access most signals inside the model hierarchy, including referenced models and Stateflow charts. You cannot access optimized signals.	Scope viewers are attached to signal lines. You can access most signals inside the model hierarchy, including referenced models and Stateflow charts. You cannot access optimized signals.
Data logging	Save data to a MATLAB variable as an array, structure, or object.	Save data to a MATLAB variable as an object.	Save data to a MATLAB variable as an object.
Simulation control	Run, forward, and back toolbar buttons.	Run, forward, and back toolbar buttons.	Run, forward, and back toolbar buttons.
Scale axes after simulation	Toolbar buttons to scale X-axis and Y-axis limits Axes scaling set to Auto for the X-axis and Y-axis.	Toolbar buttons to scale X-axis and Y-axis limits. Axes scaling set to Auto for only the Y-axis.	Toolbar buttons to scale X-axis and Y-axis limits. Axes scaling set to Auto for the X-axis and Y-axis.
Add to model	Add block from Simulink sinks library.	Add block from Simulink sinks library.	Add using “Viewers and Generators Manager” on page 28-80.
Visual indication in model	Scope block connected to signals.	Floating Scope block not attached to any signal lines.	Viewer icons located above signal lines for all attached signals.

Capability	Simulink Scope	Simulink Floating Scope	Simulink Scope Viewer
Manage scopes centrally	No.	No.	Use the Viewers and Generators Manager to add or delete viewers, and attach or remove signals.
Manage scopes locally	Attach signal lines to Scope block in ports.	Attach signals from the Floating Scope window.	Add viewers and attach additional signals within a model hierarchy using the context menus or from the Scope viewer window.
Simulink Report Generator support	Yes.	Yes.	No.
Connecting Constant block with Sample time set to inf (constant sample time)	Plots the data value at the first time step and anytime you tune a parameter.	Plots all data values.	Plots the data value at the first time step and anytime you tune a parameter.

Simulink Scope Versus DSP System Toolbox Time Scope

If you have a Simulink and a DSP System Toolbox license, you can use either the Simulink Scope or DSP System Toolbox Time Scope. Choose the scope based on your application requirements, how the blocks work, and the default values of each block.

If you have a DSP System Toolbox license and you have been using Time Scopes, continue to do so in your applications. Using the Time Scope block requires a DSP System Toolbox license.

Feature	Scope	Time Scope
Location in block library	Simulink Sinks library	DSP System Toolbox Sinks library
Trigger and measurement panels	With Simulink only: <ul style="list-style-type: none"> • Trigger • Cursor Measurement With DSP System Toolbox or Simscape license: <ul style="list-style-type: none"> • Signal Statistics • Bilevel Measurements • Peak Finder 	<ul style="list-style-type: none"> • Trigger • Cursor Measurements • Signal Statistics • Bilevel Measurements • Peak Finder

Feature	Scope	Time Scope
<p>Simulation mode support for block-based sample times</p> <p>For block-based sample times, all the inputs of the block run at the same rate.</p> <p>For rapid-accelerator mode, see “Behavior of Scopes and Viewers with Rapid Accelerator Mode” on page 35-16.</p>	<ul style="list-style-type: none"> • Normal • Accelerator • Rapid-Accelerator • External 	<ul style="list-style-type: none"> • Rapid-Accelerator • External
<p>Simulation mode support for port-based sample times</p> <p>For port-based sample times, the input ports can run at different rates.</p>	No.	<ul style="list-style-type: none"> • Normal • Accelerator
Frame processing of signals	Included in Scope block with DSP System Toolbox license.	Included in Time Scope block.
Sample time propagation	If the different ports have different sample rates, the scope uses the greatest common divisor of the rates.	When using port-based sample times, the different ports of the Scope block inherit the different rates and plots the signals according to those rates.
Save model to previous Simulink release	If saving to a release before R2015a, the Scope block is converted to a scope with the features available in that release.	No change in features.

This table lists the differences in Configuration Property default values between the Scope and Time Scope blocks.

Property	Scope Default	Time Scope Default
Open at start of simulation	Cleared	Selected
Input processing	Elements as channels (sample based)	Columns as channels (frame based)
Maximize Axes	Off	Auto
Time Units	None	Metric (based on Time Span)
Time-axis labels	Bottom displays only	All
Show time-axis label	Cleared	Selected
Plot Type	Auto	Line
Title	%<Signal Label>	No title
Y label	No label	Amplitude

Scope Triggers Panel

In this section...

- “What Is the Trigger Panel” on page 28-12
- “Main Pane” on page 28-12
- “Source/Type and Levels/Timing Panes” on page 28-13
- “Hysteresis of Trigger Signals” on page 28-21
- “Delay/Holdoff Pane” on page 28-22

What Is the Trigger Panel

The Trigger panel defines a trigger event to synchronize simulation time with input signals. You can use trigger events to stabilize periodic signals such as a sine wave or capture non-periodic signals such as a pulse that occurs intermittently.

To open the Trigger panel:

- 1 Open a Scope block window.
- 2 On the toolbar, click the Triggers button .
- 3 Run a simulation.

Triangle trigger pointers indicate the trigger time and trigger level of an event. The marker color corresponds to the color of the source signal.

Main Pane

Mode — Specify when the display updates.

- **Auto** — Display data from the last trigger event. If no event occurs after one time span, display the last available data.

Normal — Display data from the last trigger event. If no event occurs, the display remains blank.

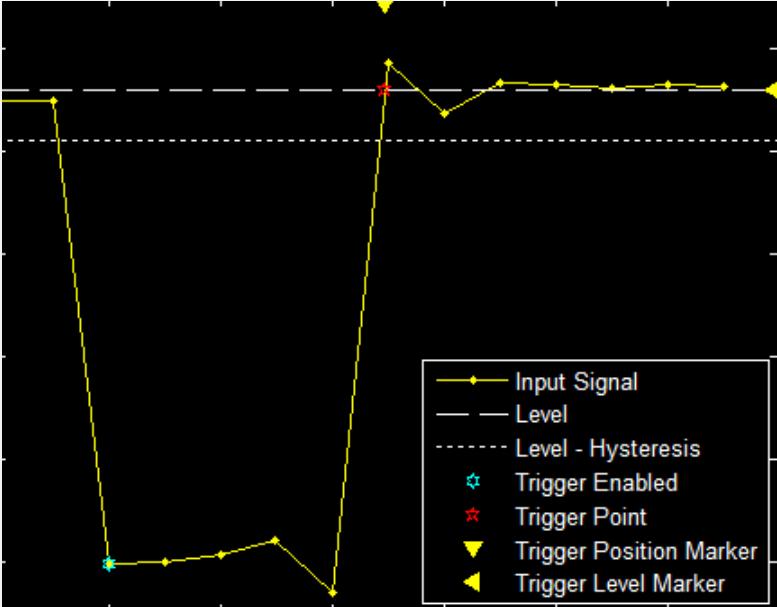

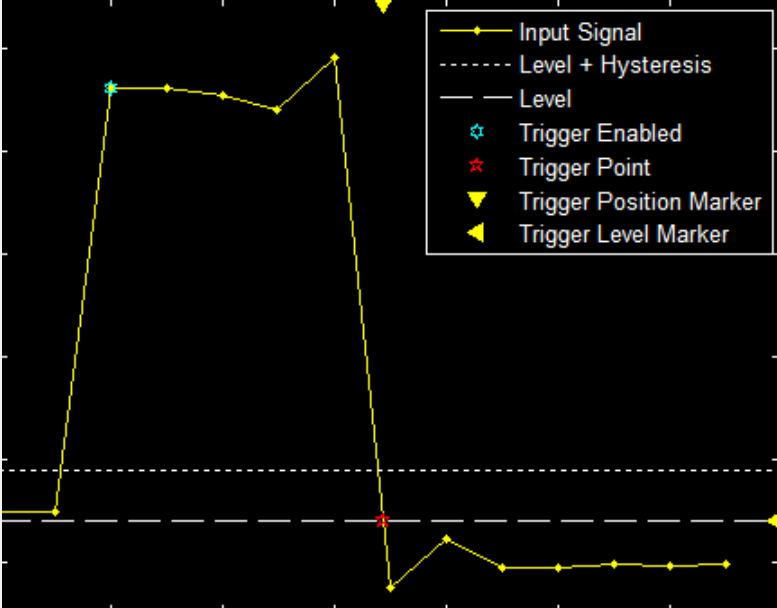

- **Once** — Display data from the last trigger event and freeze the display. If no event occurs, the display remains blank. Click the **Rearm** button to look for the next trigger event.
- **Off** — Disable triggering.

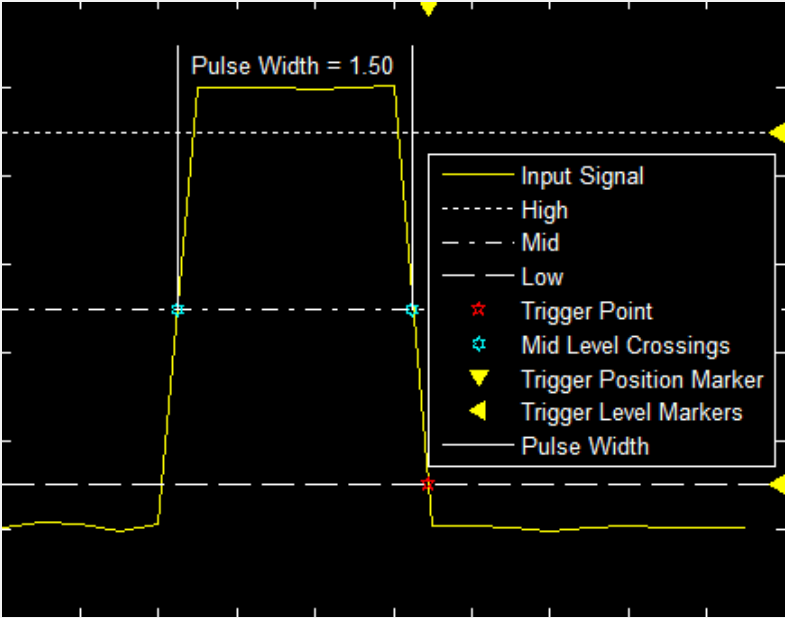

Position (%) — Specify the position of the time pointer along the y-axis. You can also drag the time pointer to the left or right to adjust its position.

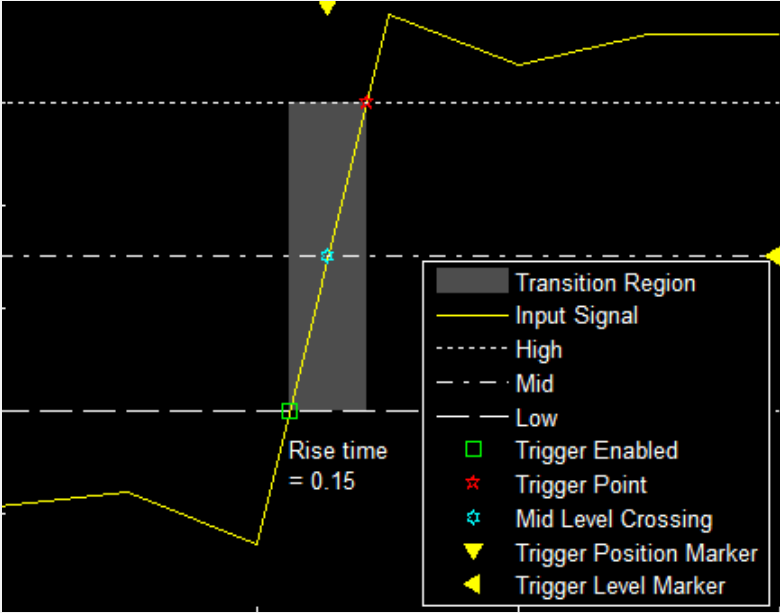

Source/Type and Levels/Timing Panes

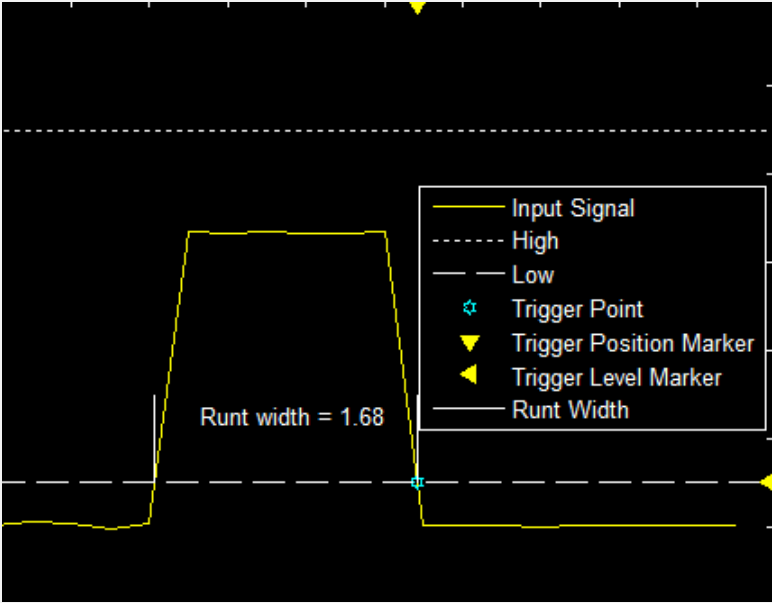

Source — Select a trigger signal. For magnitude and phase plots, select either the magnitude or the phase.

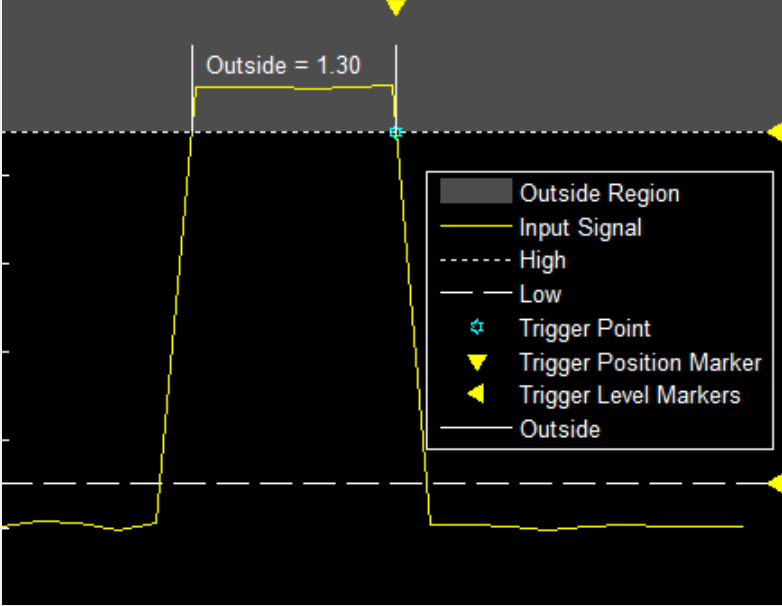

Type — Select the type of trigger.

Trigger Type	Trigger Parameters
<p>Edge — Trigger when the signal crosses a threshold.</p>	<p>Polarity — Select the polarity for an edge-triggered signal.</p> <ul style="list-style-type: none"> • Rising — Trigger when the signal is increasing. 
	<ul style="list-style-type: none"> • Falling — Trigger when the signal value is decreasing. 
	<ul style="list-style-type: none"> • Either — Trigger when the signal is increasing or decreasing. <p>Level — Enter a threshold value for an edge triggered signal. Auto level is 50%</p>

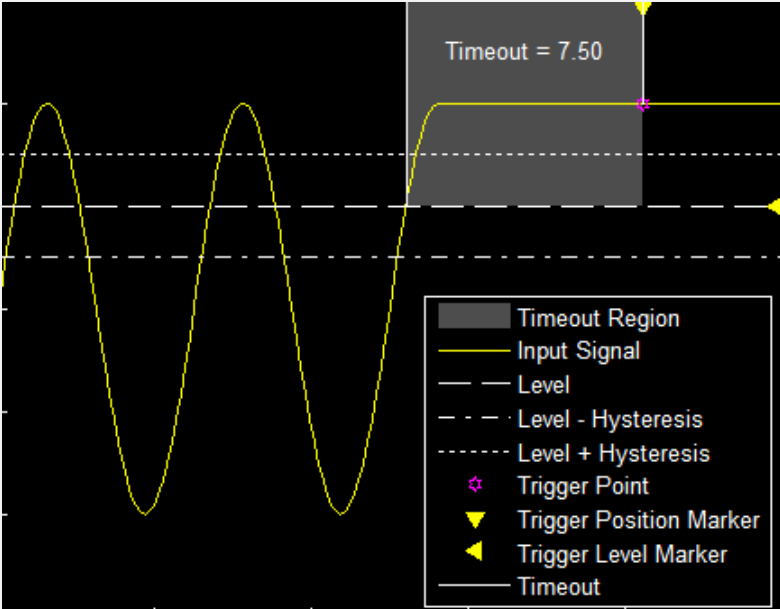

Trigger Type	Trigger Parameters
<p>Pulse Width — Trigger when the signal crosses a low threshold and a high threshold twice within a specified time.</p>	<p>Hysteresis — Enter a value for an edge-triggered signal. See “Hysteresis of Trigger Signals” on page 28-21</p> <p>Polarity — Select the polarity for a pulse width-triggered signal.</p> <ul style="list-style-type: none"> • Positive — Trigger on a positive-polarity pulse when the pulse crosses the low threshold for a second time.  <ul style="list-style-type: none"> • Negative — Trigger on a negative-polarity pulse when the pulse crosses the high threshold for a second time. • Either — Trigger on both positive-polarity and negative-polarity pulses. <p>Note A glitch-trigger is a special type of a pulse width-trigger. A glitch-trigger occurs for a pulse or spike whose duration is less than a specified amount. You can implement a glitch trigger by using a pulse width-trigger and setting the Max Width parameter to a small value.</p> <p>High — Enter a high value for a pulse width-triggered signal. Auto level is 90%.</p> <p>Low — Enter a low value for a pulse width-triggered signal. Auto level is 10%.</p> <p>Min Width — Enter the minimum pulse-width for a pulse width triggered signal. Pulse width is measured between the first and second crossings of the middle threshold.</p> <p>Max Width — Enter the maximum pulse width for a pulse width triggered signal.</p>

Trigger Type	Trigger Parameters
<p>Transition — Trigger on the rising or falling edge of a signal that crosses the high and low levels within a specified time range.</p>	<p>Polarity — Select the polarity for a transition-triggered signal.</p> <ul style="list-style-type: none"> Rise Time — Trigger on an increasing signal when the signal crosses the high threshold.  <ul style="list-style-type: none"> Fall Time — Trigger on a decreasing signal when the signal crosses the low threshold. Either — Trigger on an increasing or decreasing signal. <p>High — Enter a high value for a transition-triggered signal. Auto level is 90%.</p> <p>Low — Enter a low value for a transition-triggered signal. Auto level is 10%.</p> <p>Min Time — Enter a minimum time duration for a transition-triggered signal.</p> <p>Max Time — Enter a maximum time duration for a transition-triggered signal.</p>

Trigger Type	Trigger Parameters
<p>Runt— Trigger when a signal crosses a low threshold or a high threshold twice within a specified time.</p>	<p>Polarity — Select the polarity for a runt-triggered signal.</p> <ul style="list-style-type: none"> • Positive — Trigger on a positive-polarity pulse when the signal crosses the low threshold a second time, without crossing the high threshold.  <ul style="list-style-type: none"> • Negative — Trigger on a negative-polarity pulse. • Either — Trigger on both positive-polarity and negative-polarity pulses. <p>High — Enter a high value for a runt-triggered signal. Auto level is 90%.</p> <p>Low — Enter a low value for a runt-triggered signal. Auto level is 10%.</p> <p>Min Width — Enter a minimum width for a runt-triggered signal. Pulse width is measured between the first and second crossing of a threshold.</p> <p>Max Width — Enter a maximum pulse width for a runt-triggered signal.</p>

Trigger Type	Trigger Parameters
<p>Window — Trigger when a signal stays within or outside a region defined by the high and low thresholds for a specified time.</p>	<p>Polarity — Select the region for a window-triggered signal.</p> <ul style="list-style-type: none"> <p>Inside — Trigger when a signal leaves a region between the low and high levels.</p>  <p>Outside — Trigger when a signal enters a region between the low and high levels.</p>  <p>Either — Trigger when a signal leaves or enters a region between the low and high levels.</p>

Trigger Type	Trigger Parameters
	<p>High — Enter a high value for a window-triggered signal. Auto level is 90%.</p> <p>Low — Enter a low value for a window-trigger signal. Auto level is 10%.</p> <p>Min Time — Enter the minimum time duration for a window-triggered signal.</p> <p>Max Time — Enter the maximum time duration for a window-triggered signal.</p>

Trigger Type	Trigger Parameters
<p>Timeout — Trigger when a signal stays above or below a threshold longer than a specified time</p>	<p>Polarity — Select the polarity for a timeout-triggered signal.</p> <ul style="list-style-type: none"> • Rising — Trigger when the signal does not cross the threshold from below. For example, if you set Timeout to 7.50 seconds, the scope triggers 7.50 seconds after the signal crosses the threshold.  <ul style="list-style-type: none"> • Falling — Trigger when the signal does not cross the threshold from above. • Either — Trigger when the signal does not cross the threshold from either direction <p>Level — Enter a threshold value for a timeout-triggered signal.</p> <p>Hysteresis — Enter a value for a timeout-triggered signal. See “Hysteresis of Trigger Signals” on page 28-21.</p> <p>Timeout — Enter a time duration for a timeout-triggered signal.</p> <p>Alternatively, a trigger event can occur when the signal stays within the boundaries defined by the hysteresis for 7.50 seconds after the signal crosses the threshold.</p>

Hysteresis of Trigger Signals

Hysteresis (V) — Specify the hysteresis or noise reject value. This parameter is visible when you set **Type** to Edge or Timeout. If the signal jitters inside this range and briefly crosses the trigger level, the scope does not register an event. In the case of an edge trigger with rising polarity, the scope ignores the times that a signal crosses the trigger level within the hysteresis region.

You can reduce the hysteresis region size by decreasing the hysteresis value. In this example, if you set the hysteresis value to 0.07, the scope also considers the second rising edge to be a trigger event.

Delay/Holdoff Pane

Offset the trigger position by a fixed delay, or set the minimum possible time between trigger events.

- **Delay (s)** — Specify the fixed delay time by which to offset the trigger position. This parameter controls the amount of time the scope waits after a trigger event occurs before displaying a signal.
- **Holdoff (s)** — Specify the minimum possible time between trigger events. This amount of time is used to suppress data acquisition after a valid trigger event has occurred. A trigger holdoff prevents repeated occurrences of a trigger from occurring during the relevant portion of a burst.

Related Examples

- “Cursor Measurements Panel” on page 28-23

Cursor Measurements Panel

The **Cursor Measurements** panel displays screen cursors. The panel provides two types of cursors for measuring signals. Waveform cursors are vertical cursors that track along the signal. Screen cursors are both horizontal and vertical cursors that you can place anywhere in the display.

Note If a data point in your signal has more than one value, the cursor measurement at that point is undefined and no cursor value is displayed.

Display screen cursors with signal times and values. To open the Cursor measurements panel:

- From the menu, select **Tools > Measurements > Cursor Measurements**.
- On the toolbar, click the Cursor Measurements  button.

In the **Settings** pane, you can modify the type of screen cursors used for calculating measurements. When more than one signal is displayed, you can assign cursors to each trace individually.

- **Screen Cursors** — Shows screen cursors (for spectrum and dual view only).
- **Horizontal** — Shows horizontal screen cursors (for spectrum and dual view only).
- **Vertical** — Shows vertical screen cursors (for spectrum and dual view only).
- **Waveform Cursors** — Shows cursors that attach to the input signals (for spectrum and dual view only).
- **Lock Cursor Spacing** — Locks the frequency difference between the two cursors.
- **Snap to Data** — Positions the cursors on signal data points.

The Measurements pane displays time and value measurements.

	Time (secs)	Value
1	2.500	-9.027e+01
2	7.500	-1.175e+02
ΔT	5.000 s	ΔY 2.722e+01
$1 / \Delta T$		200.000 mHz
$\Delta Y / \Delta T$		5.444 (/s)

- **1** — View or modify the time or value at cursor number one (solid line cursor).
- **2** — View or modify the time or value at cursor number two (dashed line cursor).
- ΔT or ΔX — Shows the absolute value of the time (x-axis) difference between cursor number one and cursor number two.
- ΔY — Shows the absolute value of the signal amplitude difference between cursor number one and cursor number two.
- $1/\Delta T$ or $1/\Delta X$ — Shows the rate. The reciprocal of the absolute value of the difference in the times (x-axis) between cursor number one and cursor number two.
- $\Delta Y/\Delta T$ or $\Delta Y/\Delta X$ — Shows the slope. The ratio of the absolute value of the difference in signal amplitudes between cursors to the absolute value of the difference in the times (x-axis) between cursors.

See Also

Scope | Floating Scope

Related Examples

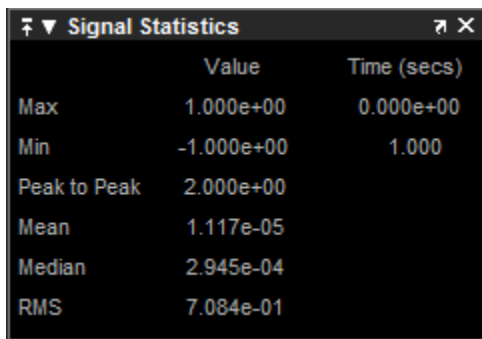

- “Scope Triggers Panel” on page 28-12

Scope Signal Statistics Panel

Note The Signal Statistics panel requires a DSP System Toolbox or Simscape license.

Display signal statistics for the signal selected in the **Trace Selection** panel. To open the Signal Statistics panel:

- From the menu, select **Tools > Measurements > Signal Statistics**.
- On the toolbar, click the Signal Statistics  button.

	Value	Time (secs)
Max	1.000e+00	0.000e+00
Min	-1.000e+00	1.000
Peak to Peak	2.000e+00	
Mean	1.117e-05	
Median	2.945e-04	
RMS	7.084e-01	

The statistics shown are:

- **Max** — Maximum or largest value within the displayed portion of the input signal.
- **Min** — Minimum or smallest value within the displayed portion of the input signal.
- **Peak to Peak** — Difference between the maximum and minimum values within the displayed portion of the input signal.
- **Mean** — Average or mean of all the values within the displayed portion of the input signal.
- **Median** — Median value within the displayed portion of the input signal.
- **RMS** — Root mean squared of the input signal.

When you use the zoom options in the scope, the Signal Statistics measurements automatically adjust to the time range shown in the display. In the scope toolbar, click the **Zoom In** or **Zoom X** button to constrict the x-axis range of the display, and the statistics shown reflect this time range. For example, you can zoom in on one pulse to make the **Signal Statistics** panel display information about only that particular pulse.

The Signal Statistics measurements are valid for any units of the input signal. The letter after the value associated with each measurement represents the appropriate International System of Units (SI) prefix, such as *m* for *milli*-. For example, if the input signal is measured in volts, an *m* next to a measurement value indicates that this value is in units of millivolts.

- **Auto State Level** — When this check box is selected, the Bilevel measurements panel detects the high- and low- state levels of a bilevel waveform. When this check box is cleared, you can enter in values for the high- and low- state levels manually.
 - **High** — Used to specify manually the value that denotes a positive polarity, or high-state level.

- **Low** — Used to specify manually the value that denotes a negative polarity, or low-state level.

- **State Level Tolerance** — Tolerance within which the initial and final levels of each transition must be within their respective state levels. This value is expressed as a percentage of the difference between the high- and low-state levels.
- **Upper Ref Level** — Used to compute the end of the rise-time measurement or the start of the fall time measurement. This value is expressed as a percentage of the difference between the high- and low-state levels.
- **Mid Ref Level** — Used to determine when a transition occurs. This value is expressed as a percentage of the difference between the high- and low- state levels. In the following figure, the mid-reference level is shown as the horizontal line, and its corresponding mid-reference level instant is shown as the vertical line.

- **Lower Ref Level** — Used to compute the end of the fall-time measurement or the start of the rise-time measurement. This value is expressed as a percentage of the difference between the high- and low-state levels.
- **Settle Seek** — The duration after the mid-reference level instant when each transition occurs used for computing a valid settling time. This value is equivalent to the input parameter, D, which you can set when you run the `settlingtime` function. The settling time is displayed in the **Overshoots/Undershoots** pane.

Transitions Pane

Display calculated measurements associated with the input signal changing between its two possible state level values, high and low.

A positive-going transition, or rising edge, in a bilevel waveform is a transition from the low-state level to the high-state level. A positive-going transition has a slope value greater than zero. The following figure shows a positive-going transition.

When there is a plus sign (+) next to a text label, the measurement is a rising edge, a transition from a low-state level to a high-state level.

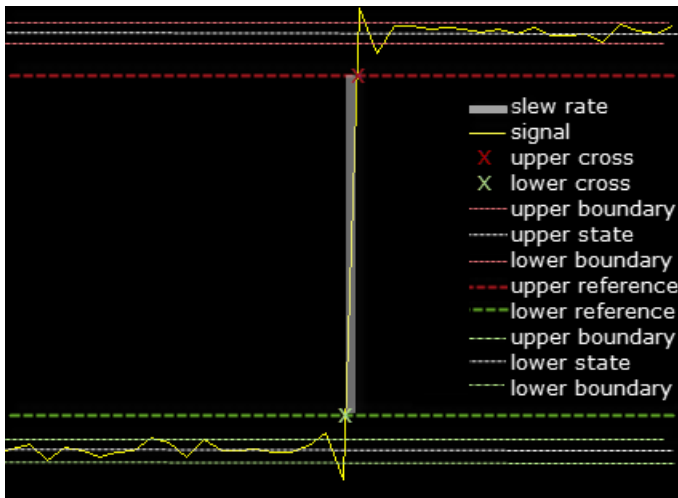

A negative-going transition, or falling edge, in a bilevel waveform is a transition from the high-state level to the low-state level. A negative-going transition has a slope value less than zero. The following figure shows a negative-going transition.

When there is a minus sign (-) next to a text label, the measurement is a falling edge, a transition from a high-state level to a low-state level.

The Transition measurements assume that the amplitude of the input signal is in units of volts. For the transition measurements to be valid, you must convert all input signals to volts.

- **High** — The high-amplitude state level of the input signal over the duration of the **Time Span** parameter. You can set **Time Span** in the **Main** pane of the Visuals—Time Domain Properties dialog box.
- **Low** — The low-amplitude state level of the input signal over the duration of the **Time Span** parameter. You can set **Time Span** in the **Main** pane of the Visuals—Time Domain Properties dialog box.
- **Amplitude** — Difference in amplitude between the high-state level and the low-state level.
- **+ Edges** — Total number of positive-polarity, or rising, edges counted within the displayed portion of the input signal.
- **+ Rise Time** — Average amount of time required for each rising edge to cross from the lower-reference level to the upper-reference level.
- **+ Slew Rate** — Average slope of each rising-edge transition line within the upper- and lower-percent reference levels in the displayed portion of the input signal. The region in which the slew rate is calculated appears in gray in the following figure.

- - **Edges** — Total number of negative-polarity or falling edges counted within the displayed portion of the input signal.
- - **Fall Time** — Average amount of time required for each falling edge to cross from the upper-reference level to the lower-reference level.
- - **Slew Rate** — Average slope of each falling edge transition line within the upper- and lower-percent reference levels in the displayed portion of the input signal.

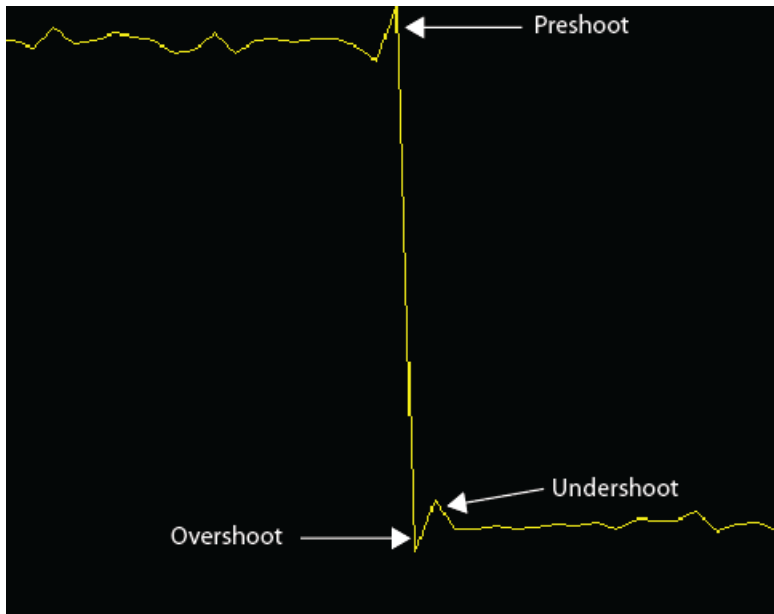

Overshoots / Undershoots Pane

The **Overshoots/Undershoots** pane displays calculated measurements involving the distortion and damping of the input signal. Overshoot and undershoot refer to the amount that a signal respectively exceeds and falls below its final steady-state value. Preshoot refers to the amount before a transition that a signal varies from its initial steady-state value.

This figure shows preshoot, overshoot, and undershoot for a rising-edge transition.

The next figure shows preshoot, overshoot, and undershoot for a falling-edge transition.

- **+ Preshoot** — Average lowest aberration in the region immediately preceding each rising transition.
- **+ Overshoot** — Average highest aberration in the region immediately following each rising transition.
- **+ Undershoot** — Average lowest aberration in the region immediately following each rising transition.
- **+ Settling Time** — Average time required for each rising edge to enter and remain within the tolerance of the high-state level for the remainder of the settle-seek duration. The settling time is the time after the mid-reference level instant when the signal crosses into and remains in the tolerance region around the high-state level. This crossing is illustrated in the following figure.

You can modify the settle-peek duration parameter in the **Settings** pane.

- - **Preshoot** — Average highest aberration in the region immediately preceding each falling transition.
- - **Overshoot** — Average highest aberration in the region immediately following each falling transition.
- - **Undershoot** — Average lowest aberration in the region immediately following each falling transition.
- - **Settling Time** — Average time required for each falling edge to enter and remain within the tolerance of the low-state level for the remainder of the settle-peek duration. The settling time is the time after the mid-reference level instant when the signal crosses into and remains in the tolerance region around the low-state level. You can modify the settle-peek duration parameter in the **Settings** pane.

Cycles Pane

The **Cycles** pane displays calculated measurements pertaining to repetitions or trends in the displayed portion of the input signal.

Properties to set:

- **Period** — Average duration between adjacent edges of identical polarity within the displayed portion of the input signal. The Bilevel measurements panel calculates period as follows. It takes the difference between the mid-reference level instants of the initial transition of each positive-polarity pulse and the next positive-going transition. These mid-reference level instants appear as red dots in the following figure.

- **Frequency** — Reciprocal of the average period. Whereas period is typically measured in some metric form of seconds, or seconds per cycle, frequency is typically measured in hertz or cycles per second.
- **+ Pulses** — Number of positive-polarity pulses counted.
- **+ Width** — Average duration between rising and falling edges of each positive-polarity pulse within the displayed portion of the input signal.

- **+ Duty Cycle** — Average ratio of pulse width to pulse period for each positive-polarity pulse within the displayed portion of the input signal.
- **- Pulses** — Number of negative-polarity pulses counted.
- **- Width** — Average duration between rising and falling edges of each negative-polarity pulse within the displayed portion of the input signal.
- **- Duty Cycle** — Average ratio of pulse width to pulse period for each negative-polarity pulse within the displayed portion of the input signal.

When you use the zoom options in the Scope, the bilevel measurements automatically adjust to the time range shown in the display. In the Scope toolbar, click the **Zoom In** or **Zoom X** button to constrict the x-axis range of the display, and the statistics shown reflect this time range. For example, you can zoom in on one rising edge to make the **Bilevel Measurements** panel display information about only that particular rising edge. However, this feature does not apply to the **High** and **Low** measurements.

Related Examples

- “Scope Triggers Panel” on page 28-12

Peak Finder Measurements Panel

Note Peak Finder measurements require a DSP System Toolbox or Simscape license.

The **Peak Finder** panel displays the maxima, showing the x-axis values at which they occur. Peaks are defined as a local maximum where lower values are present on both sides of a peak. Endpoints are not considered peaks. This panel allows you to modify the settings for peak threshold, maximum number of peaks, and peak excursion.

- From the menu, select **Tools > Measurements > Peak Finder**.
- On the toolbar, click the Peak Finder  button.

The **Settings** pane enables you to modify the parameters used to calculate the peak values within the displayed portion of the input signal. For more information on the algorithms this pane uses, see the `findpeaks` function reference.

Properties to set:

- **Peak Threshold** — The level above which peaks are detected. This setting is equivalent to the `MINPEAKHEIGHT` parameter, which you can set when you run the `findpeaks` function.
- **Max Num of Peaks** — The maximum number of peaks to show. The value you enter must be a scalar integer from 1 through 99. This setting is equivalent to the `NPEAKS` parameter, which you can set when you run the `findpeaks` function.
- **Min Peaks Distance** — The minimum number of samples between adjacent peaks. This setting is equivalent to the `MINPEAKDISTANCE` parameter, which you can set when you run the `findpeaks` function.
- **Peak Excursion** — The minimum height difference between a peak and its neighboring samples. Peak excursion is illustrated alongside peak threshold in the following figure.

The peak threshold is a minimum value necessary for a sample value to be a peak. The peak excursion is the minimum difference between a peak sample and the samples to its left and right in the time domain. In the figure, the green vertical line illustrates the lesser of the two height differences between the labeled peak and its neighboring samples. This height difference must be greater than the **Peak Excursion** value for the labeled peak to be classified as a peak. Compare this setting to peak threshold, which is illustrated by the red horizontal line. The amplitude must be above this horizontal line for the labeled peak to be classified as a peak.

The peak excursion setting is equivalent to the **THRESHOLD** parameter, which you can set when you run the `findpeaks` function.

- **Label Format** — The coordinates to display next to the calculated peak values on the plot. To see peak values, you must first expand the **Peaks** pane and select the check boxes associated with individual peaks of interest. By default, both x-axis and y-axis values are displayed on the plot. Select which axes values you want to display next to each peak symbol on the display.
 - X+Y — Display both x-axis and y-axis values.
 - X — Display only x-axis values.
 - Y — Display only y-axis values.

The **Peaks** pane displays the largest calculated peak values. It also shows the coordinates at which the peaks occur, using the parameters you define in the **Settings** pane. You set the **Max Num of Peaks** parameter to specify the number of peaks shown in the list.

The numerical values displayed in the **Value** column are equivalent to the `pks` output argument returned when you run the `findpeaks` function. The numerical values displayed in the second column are similar to the `locs` output argument returned when you run the `findpeaks` function.

The Peak Finder displays the peak values in the **Peaks** pane. By default, the **Peak Finder** panel displays the largest calculated peak values in the **Peaks** pane in decreasing order of peak height.

Use the check boxes to control which peak values are shown on the display. By default, all check boxes are cleared and the **Peak Finder** panel hides all the peak values. To show or hide all the peak values on the display, use the check box in the top-left corner of the **Peaks** pane.

The Peaks are valid for any units of the input signal. The letter after the value associated with each measurement indicates the abbreviation for the appropriate International System of Units (SI) prefix, such as *m* for *milli-*. For example, if the input signal is measured in volts, an *m* next to a measurement value indicates that this value is in units of millivolts.

Related Examples

- “Scope Triggers Panel” on page 28-12

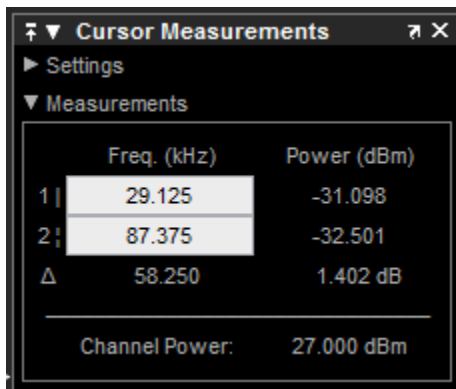

Spectrum Analyzer Cursor Measurements Panel

The **Cursor Measurements** panel displays screen cursors. The panel provides two types of cursors for measuring signals. Waveform cursors are vertical cursors that track along the signal. Screen cursors are both horizontal and vertical cursors that you can place anywhere in the display.

Note If a data point in your signal has more than one value, the cursor measurement at that point is undefined and no cursor value is displayed.

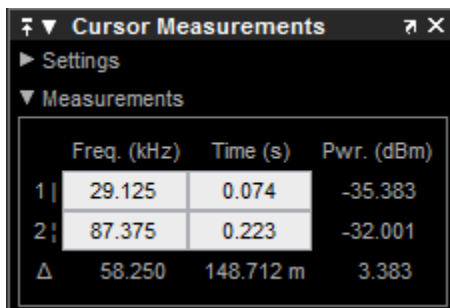

In the Scope menu, select **Tools > Measurements > Cursor Measurements**. Alternatively, in the Scope toolbar, click the Cursor Measurements  button.

The **Cursor Measurements** panel for the spectrum and dual view:

	Freq. (kHz)	Power (dBm)
1	29.125	-31.098
2	87.375	-32.501
Δ	58.250	1.402 dB
Channel Power:		27.000 dBm

The **Cursor Measurements** panel for the spectrogram view. You must pause the spectrogram display before you can use cursors.

	Freq. (kHz)	Time (s)	Pwr. (dBm)
1	29.125	0.074	-35.383
2	87.375	0.223	-32.001
Δ	58.250	148.712 m	3.383

You can use the mouse or the left and right arrow keys to move vertical or waveform cursors and the up and down arrow keys for horizontal cursors.

In the **Settings** pane, you can modify the type of screen cursors used for calculating measurements. When more than one signal is displayed, you can assign cursors to each trace individually.

- **Screen Cursors** — Shows screen cursors (for spectrum and dual view only).
- **Horizontal** — Shows horizontal screen cursors (for spectrum and dual view only).
- **Vertical** — Shows vertical screen cursors (for spectrum and dual view only).
- **Waveform Cursors** — Shows cursors that attach to the input signals (for spectrum and dual view only).
- **Lock Cursor Spacing** — Locks the frequency difference between the two cursors.
- **Snap to Data** — Positions the cursors on signal data points.

The **Measurements** pane displays the frequency (Hz), time (s), and power (dBm) value measurements. Time is displayed only in spectrogram mode. **Channel Power** shows the total power between the cursors.

- **1** — Shows or enables you to modify the frequency, time (for spectrograms only), or both, at cursor number one.
- **2** — Shows or enables you to modify the frequency, time (for spectrograms only), or both, at cursor number two.
- **Δ** — Shows the absolute value of the difference in the frequency, time (for spectrograms only), or both, and power between cursor number one and cursor number two.
- **Channel Power** — Shows the total power in the channel defined by the cursors.

The letter after the value associated with a measurement indicates the abbreviation for the appropriate International System of Units (SI) prefix.

Spectrum Analyzer Channel Measurements Panel

The **Channel Measurements** panel displays occupied bandwidth or adjacent channel power ratio (ACPR) measurements.

- From the menu, select **Tools > Measurements > Channel Measurements**.
- On the toolbar, click the Channel Measurements  button.

In addition to the measurements, the **Channel Measurements** panel has an expandable **Channel Settings** pane.

- **Measurement** — The type of measurement data to display. Available options are Occupied BW or ACPR. See “Algorithms” (DSP System Toolbox) for information on how Occupied BW is calculated. ACPR is the adjacent channel power ratio, which is the ratio of the main channel power to the adjacent channel power.

When you select Occupied BW as the **Measurement**, the following fields appear.

- **Channel Settings** — Modify the parameters for calculating the channel measurements.

Channel Settings for Occupied BW

- Select the frequency span of the channel, **Span (Hz)**, and specify the center frequency **CF (Hz)** of the channel. Alternatively, select the starting frequency, **FStart (Hz)**, and specify the starting frequency and ending frequency (**FStop (Hz)**) values of the channel.
- **CF (Hz)** — The center frequency of the channel.
- **Occupied BW (%)** — The percentage of the total integrated power of the spectrum centered on the selected channel frequency over which to compute the occupied bandwidth.
- **Channel Power** — The total power in the channel.
- **Occupied BW** — The bandwidth containing the specified **Occupied BW (%)** of the total power of the spectrum. This setting is available only if you select Occupied BW as the **Measurement** type.
- **Frequency Error** — The difference between the center of the occupied band and the center frequency (**CF**) of the channel. This setting is available only if you select Occupied BW as the **Measurement** type.

When you select ACPR as the **Measurement**, the following fields appear.

- **Channel Settings** — Enables you to modify the parameters for calculating the channel measurements.

Channel Settings for ACPR

- Select the frequency span of the channel, **Span (Hz)**, and specify the center frequency **CF (Hz)** of the channel. Alternatively, select the starting frequency, **FStart (Hz)**, and specify the starting frequency and ending frequency (**FStop (Hz)**) values of the channel.
- **CF (Hz)** — The center frequency of the channel.
- **Number of Pairs** — The number of pairs of adjacent channels.
- **Bandwidth (Hz)** — The bandwidth of the adjacent channels.
- **Filter** — The filter to use for both main and adjacent channels. Available filters are None, Gaussian, and RRC (root-raised cosine).
- **Channel Power** — The total power in the channel.
- **Offset (Hz)** — The center frequency of the adjacent channel with respect to the center frequency of the main channel. This setting is available only if you select ACPR as the **Measurement** type.
- **Lower (dBc)** — The power ratio of the lower sideband to the main channel. This setting is available only if you select ACPR as the **Measurement** type.
- **Upper (dBc)** — The power ratio of the upper sideband to the main channel. This setting is available only if you select ACPR as the **Measurement** type.

Spectrum Analyzer Distortion Measurements Panel

The **Distortion Measurements** panel displays harmonic distortion and intermodulation distortion measurements.

- From the menu, select **Tools > Measurements > Distortion Measurements**.
- On the toolbar, click the Distortion Measurements  button.

The **Distortion Measurements** panel has an expandable **Harmonics** pane, which shows measurement results for the specified number of harmonics.

Note For an accurate measurement, ensure that the fundamental signal (for harmonics) or primary tones (for intermodulation) is larger than any spurious or harmonic content. To do so, you may need to adjust the resolution bandwidth (RBW) of the spectrum analyzer. Make sure that the bandwidth is low enough to isolate the signal and harmonics from spurious and noise content. In general, you should set the RBW so that there is at least a 10dB separation between the peaks of the sinusoids and the noise floor. You may also need to select a different spectral window to obtain a valid measurement.

- **Distortion** — The type of distortion measurements to display. Available options are **Harmonic** or **Intermodulation**. Select **Harmonic** if your system input is a single sinusoid. Select **Intermodulation** if your system input is two equal amplitude sinusoids. Intermodulation can help you determine distortion when only a small portion of the available bandwidth will be used.

See “Distortion Measurements” (DSP System Toolbox) for information on how distortion measurements are calculated.

When you select **Harmonic** as the **Distortion**, the following fields appear.

The harmonic distortion measurement automatically locates the largest sinusoidal component (fundamental signal frequency). It then computes the harmonic frequencies and power in each harmonic in your signal. Any DC component is ignored. Any harmonics that are outside the spectrum analyzer's frequency span are not included in the measurements. Adjust your frequency span so that it includes all the desired harmonics.

Note To view the best harmonics, make sure that your fundamental frequency is set high enough to resolve the harmonics. However, this frequency should not be so high that aliasing occurs. For the best display of harmonic distortion, your plot should not show skirts, which indicate frequency leakage. Also, the noise floor should be visible.

For a better display, try a Kaiser window with a large sidelobe attenuation (e.g. between 100–300 db).

- **Num. Harmonics** — Number of harmonics to display, including the fundamental frequency. Valid values of **Num. Harmonics** are from 2 to 99. The default value is 6.

- **Label Harmonics** — Select **Label Harmonics** to add numerical labels to each harmonic in the spectrum display.
- **1** — The fundamental frequency, in hertz, and its power, in decibels of the measured power referenced to 1 milliwatt (dBm).
- **2, 3, ...** — The harmonics frequencies, in hertz, and their power in decibels relative to the carrier (dBc). If the harmonics are at the same level or exceed the fundamental frequency, reduce the input power.
- **THD** — The total harmonic distortion. This value represents the ratio of the power in the harmonics, D , to the power in the fundamental frequency, S . If the noise power is too high in relation to the harmonics, the THD value is not accurate. In this case, lower the resolution bandwidth or select a different spectral window.

$$THD = 10 \cdot \log_{10}(D/S)$$

- **SNR** — Signal-to-noise ratio (SNR). This value represents the ratio of power in the fundamental frequency, S , to the power of all nonharmonic content, N , including spurious signals, in decibels relative to the carrier (dBc).

$$SNR = 10 \cdot \log_{10}(S/N)$$

If you see — as the reported SNR, the total non-harmonic content of your signal is less than 30% of the total signal.

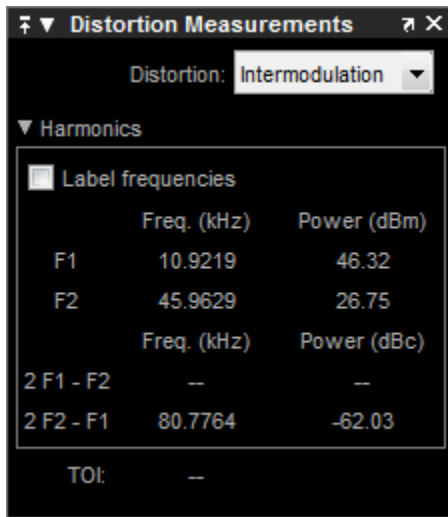

- **SINAD** — Signal-to-noise-and-distortion. This value represents the ratio of the power in the fundamental frequency, S to all other content (including noise, N , and harmonic distortion, D), in decibels relative to the carrier (dBc).

$$SINAD = 10 \cdot \log_{10}\left(\frac{S}{N+D}\right)$$

- **SFDR** — Spurious free dynamic range (SFDR). This value represents the ratio of the power in the fundamental frequency, S , to power of the largest spurious signal, R , regardless of where it falls in the frequency spectrum. The worst spurious signal may or may not be a harmonic of the original signal. SFDR represents the smallest value of a signal that can be distinguished from a large interfering signal. SFDR includes harmonics.

$$SNR = 10 \cdot \log_{10}(S/R)$$

When you select Intermodulation as the **Distortion**, the following fields appear.

The intermodulation distortion measurement automatically locates the fundamental, first-order frequencies (F1 and F2). It then computes the frequencies of the third-order intermodulation products ($2F1 - F2$ and $2F2 - F1$).

- **Label frequencies** — Select **Label frequencies** to add numerical labels to the first-order intermodulation product and third-order frequencies in the spectrum analyzer display.
- **F1** — Lower fundamental first-order frequency
- **F2** — Upper fundamental first-order frequency
- **2F1 - F2** — Lower intermodulation product from third-order harmonics
- **2F2 - F1** — Upper intermodulation product from third-order harmonics
- **TOI** — Third-order intercept point. If the noise power is too high in relation to the harmonics, the TOI value will not be accurate. In this case, you should lower the resolution bandwidth or select a different spectral window. If the TOI has the same amplitude as the input two-tone signal, reduce the power of that input signal.

Spectral Masks

Add upper and lower masks to the Spectrum Analyzer to visualize spectrum limits and compare spectrum values to specification values.

To open the **Spectral Mask** pane, in the toolbar, select the spectral mask button .

Set Up Spectral Masks

In the Spectrum Analyzer window:

- 1 In the **Spectral Mask** pane, select a **Masks** option.
- 2 In the **Upper limits** or **Lower limits** box, enter the mask limits as a constant scalar, an array, or a workspace variable name.
- 3 (Optional) Select additional properties:
 - **Reference level** — Set a reference level for the mask. Enter a specific value or select Spectrum peak.
 - **Channel** — Select a channel to use for the mask reference.
 - **Frequency offset** — Set a frequency offset for mask.

From the command-line, to add a spectral mask to the `dsp.SpectrumAnalyzer` System object or the `SpectrumAnalyzerConfiguration` block configuration object:

- 1 Create a `SpectralMaskSpecification` object.
- 2 Set properties, such as `EnabledMasks`, `LowerMask`, or `UpperMask`. For a full list of properties, see `SpectralMask` (block) and `SpectralMask` (System object™).
- 3 In the `dsp.SpectrumAnalyzer` or `SpectrumAnalyzerConfiguration` object, set the `SpectralMask` property equal to your `SpectralMaskSpecification` object.

For example:

```
mask = SpectralMaskSpecification();
mask.EnabledMasks = 'Upper';
mask.UpperMask = 10;
scope = dsp.SpectrumAnalyzer();
scope.SpectralMask = mask;
scope.SpectralMask
```

ans =

SpectralMaskSpecification with properties:

```
    EnabledMasks: 'Upper'
        UpperMask: 10
        LowerMask: -Inf
    ReferenceLevel: 'Custom'
CustomReferenceLevel: 0
    MaskFrequencyOffset: 0
```

Events for class SpectralMaskSpecification: MaskTestFailed

Check Spectral Masks

You can check the status of the spectral mask in several different ways:

- In the Spectrum Analyzer window, select the spectral mask button . In the **Spectral Mask** pane, the **Statistics** section shows statistics about how often the masks fail, which channels have caused a failure, and which masks are currently failing.
- To get the current status of the spectral masks, call `getSpectralMaskStatus`.
- To perform an action every time the mask fails, use the `MaskTestFailed` event. To trigger a function when the mask fails, create a listener to the `MaskTestFailed` event and define a callback function to trigger. For more details about using events, see “Events”.

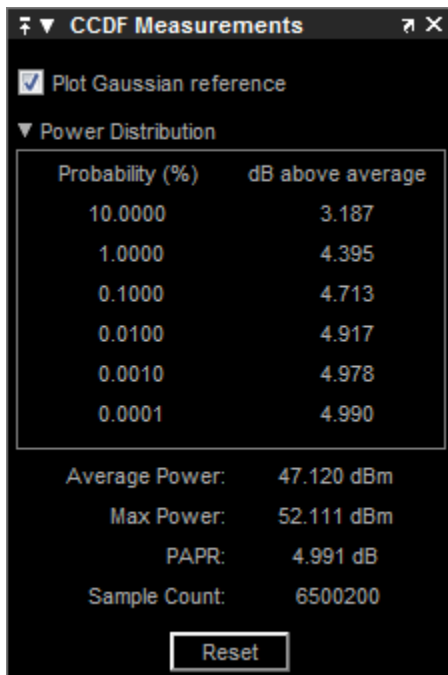

Spectrum Analyzer CCDF Measurements Panel

The **CCDF Measurements** panel displays complimentary cumulative distribution function measurements. CCDF measurements in this scope show the probability of the instantaneous power of a signal being a specified level above the average power of the signal. These measurements are useful indicators of the dynamic range of a signal.

To compute the CCDF measurements, each input sample is quantized to 0.01 dB increments. Using a histogram 100 dB wide (10,000 points at 0.01 dB increments), the largest peak encountered is placed in the last bin of the histogram. If a new peak is encountered, the histogram shifts to make room for that new peak.

To open this dialog box:

- From the menu, select **Tools > Measurements > CCDF Measurements**
- In the toolbar, click the CCDF Measurements  button.

- **Plot Gaussian reference** — Show the complex white Gaussian noise reference signal on the plot.
- **Probability (%)** — Percentage of the signal that contains the power level above the value listed in the **dB above average** column
- **dB above average** — Expected minimum power level at the associated **Probability (%)**.
- **Average Power** — Average power level of the signal since the start of simulation or from the last reset.

Max Power — Maximum power level of the signal since the start of simulation or from the last reset.

- **PAPR** — Ratio of the peak power to the average power of the signal. PAPR should be less than 100 dB to obtain accurate CCDF measurements. If PAPR is above 100 dB, only the highest 100 dB power levels are plotted in the display and shown in the distribution table.

- **Sample Count** — Total number of samples used to compute the CCDF.
- **Reset** — Clear all current CCDF measurements and restart.

Common Scope Block Tasks

In this section...

“Connect Multiple Signals to a Scope” on page 28-51
 “Save Simulation Data Using Scope Block” on page 28-53
 “Pause Display While Running” on page 28-55
 “Copy Scope Image” on page 28-55
 “Plot an Array of Signals” on page 28-57
 “Scopes in Referenced Models” on page 28-58
 “Scopes Within an Enabled Subsystem” on page 28-62
 “Modify x-axis of Scope” on page 28-63
 “Show Signal Units on a Scope Display” on page 28-66
 “Select Number of Displays and Layout” on page 28-68
 “Dock and Undock Scope Window to MATLAB Desktop” on page 28-69

To visualize your simulation results over time, use a Scope block or Time Scope block

Connect Multiple Signals to a Scope

To connect multiple signals to a scope, drag additional signals to the scope block. An additional port is created automatically.

To specify the number of input ports:

- 1 Open a scope window.
- 2 From the toolbar, select **File > Number of Input Ports > More**.
- 3 Enter the number of input ports, up to 96.

Signals from Nonvirtual Buses and Arrays of Buses

You can connect signals from nonvirtual buses and arrays of buses to a Scope block. To display the bus signals, use normal or accelerator simulation mode. The Scope block displays each bus element

signal, in the order the elements appear in the bus, from the top to the bottom. Nested bus elements are flattened. For example, in this model the `nestedBus` signal has the `const`, `subSignal`, and `step` signals as elements. The `subSignal` sub-bus has the `chirp` and `sine` signals as its bus elements. In the Scope block, the two elements of the `subSignal` bus display between the `const` and `step` signals.

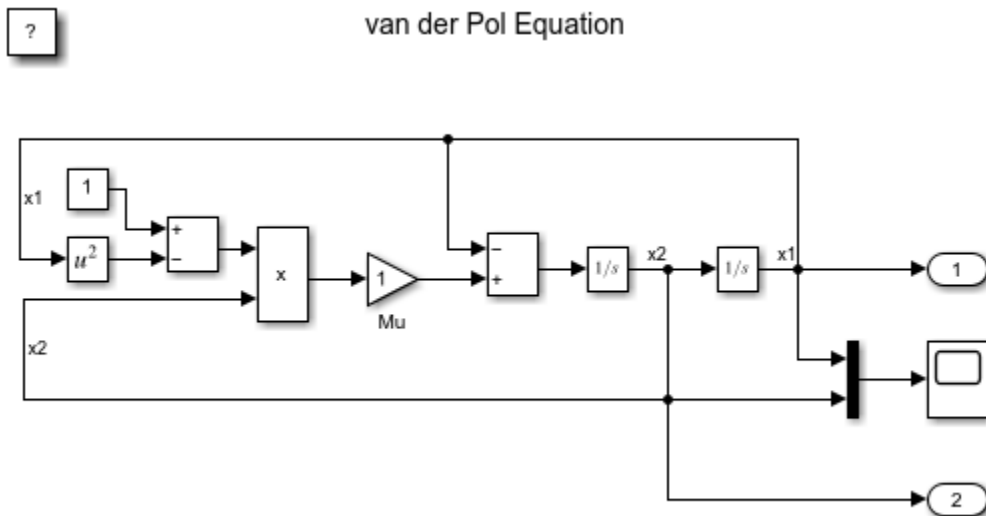

Save Simulation Data Using Scope Block

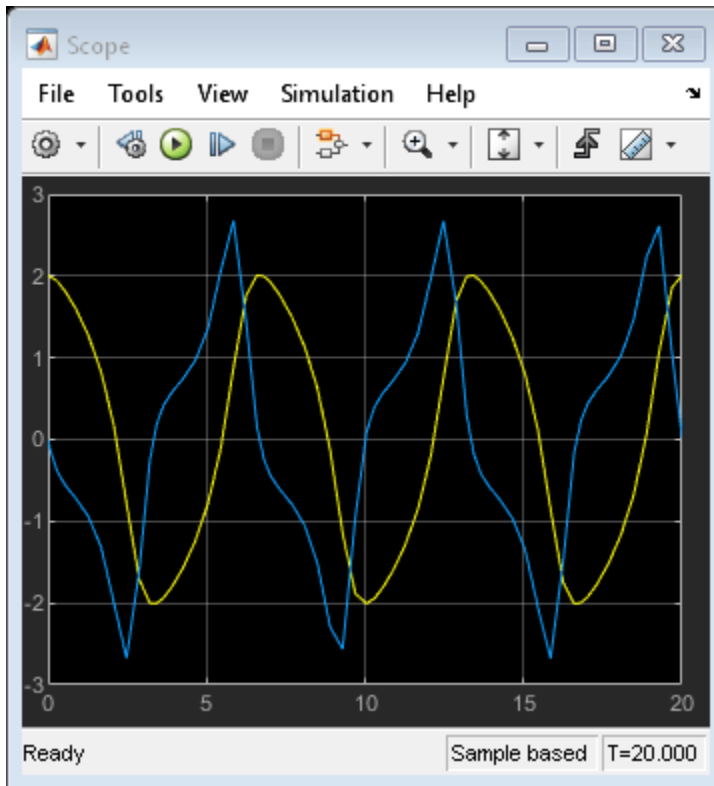

This example shows how to save signals to the MATLAB Workspace using the Scope block. You can use these steps for the Scope or Time Scope blocks. To save data from the Floating Scope or Scope viewer, see “Save Simulation Data from Floating Scope” on page 28-72.

Using the vdp model, turn on data logging to the workspace. You can follow the commands below, or in the Scope window, click the Configuration Properties button and navigate to the Logging tab, turn on **Log data to workspace**.

```
vdp
scopeConfig = get_param('vdp/Scope', 'ScopeConfiguration');
scopeConfig.DataLogging = true;
scopeConfig.DataLoggingSaveFormat = 'Dataset';
out = sim('vdp');
```

Copyright 2004-2020 The MathWorks, Inc.

In the MATLAB Command window, view the logged data from the `out.ScopeData` structure.

```
x1_data = out.ScopeData{1}.Values.Data(:,1);  
x1_time = out.ScopeData{1}.Values.Time;  
plot(x1_time,x1_data)
```

Pause Display While Running

Use the Simulink Snapshot to pause the scope display while the simulation keeps running in the background.

- 1 Open a scope window and start the simulation.
- 2 Select **Simulation > Simulink Snapshot**.

The scope window status in the bottom left is **Frozen**, but the simulation continues to run in the background.

- 3 Interact with the paused display. For example, use measurements, copy the scope image, or zoom in or out.
- 4 To unfreeze the display, select **Simulation > Simulink Snapshot** again.

Copy Scope Image

This example uses the model vdp to demonstrate how to copy and paste a scope image.

- 1 Add a scope block to your model.
- 2 Connect signals to scope ports. See “Connect Multiple Signals to a Scope” on page 28-51. For example, in the vdp model, connect the signals x1 and x2 to a scope.
- 3 Open the scope window and run the simulation.

- 4 Select **File > Copy to Clipboard**.
- 5 Paste the image into a document.

The van der Pol Equation results from my model:

By default, **Copy to Clipboard** saves a printer-friendly version of the scope with a white background and visible lines. If you want to paste the exact scope plot displayed, select **View > Style**, then select the **Preserve colors for copy to clipboard** check box.

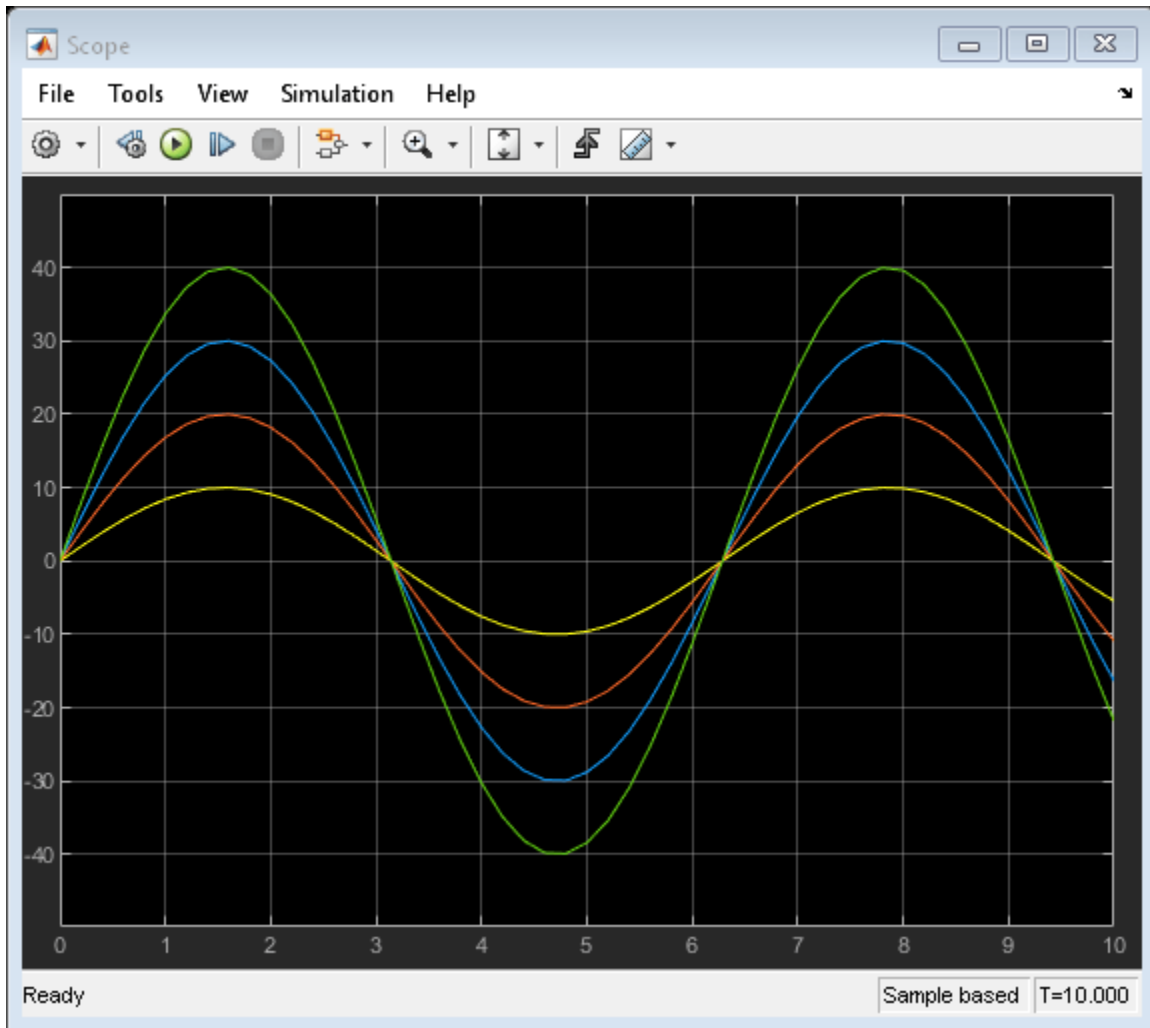

Plot an Array of Signals

This example shows how the scope plots an array of signals.

Copyright 2019 The MathWorks, Inc.

In this simple model, a Sine Wave block is connected to a scope block. The Sine Wave block outputs four signals with the amplitudes $[10, 20; 30 40]$. The scope displays each sine wave in the array separately in the matrix order (1,1), (2,1), (1,2), (2,2).

Scopes in Referenced Models

This example shows the behavior of scopes in referenced models. When you use a scope in a referenced model, you see different output in the scope depending on where you started the simulation: from the top model or the scope in the referenced model.

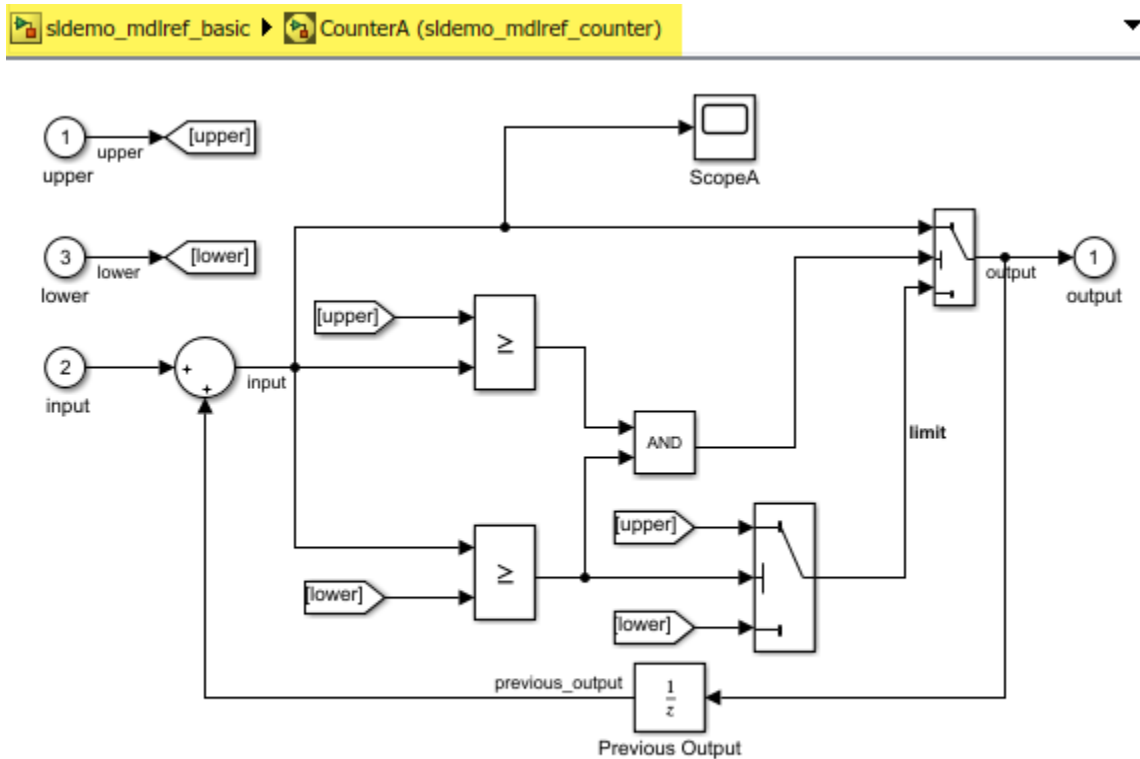

Note Scope windows display simulation results for the most recently opened top model. Playback controls in scope blocks and viewers simulate the model containing that block or viewer.

This example uses the `sldemo_mdref_counter` model both as a top model and as a referenced model from the `sldemo_mdref_basic` model.

Open the model:

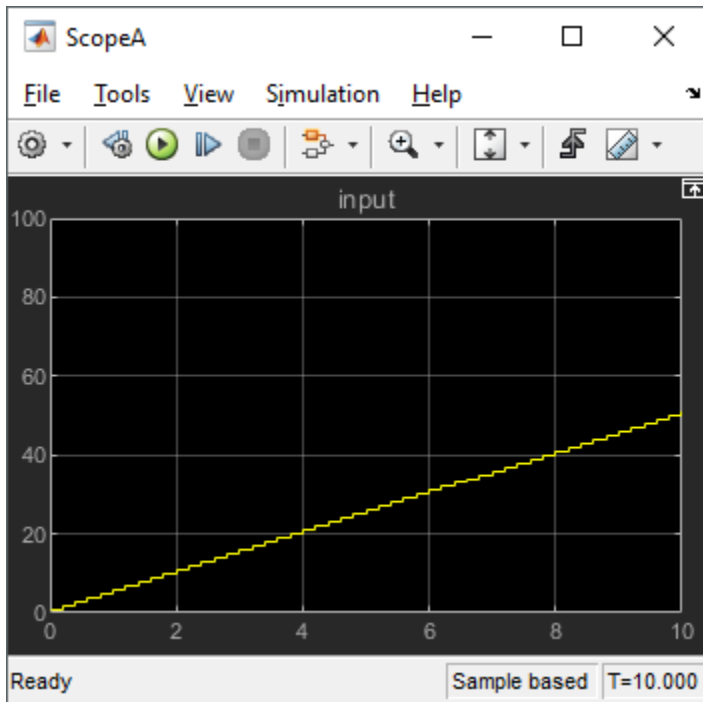

```
openExample('sldemo_mdref_basic')
```

Double-click the CounterA block. The `sldemo_mdref_counter` model opens as a referenced model, as evidenced by the breadcrumb above the canvas.

Copyright 1990-2014 The MathWorks, Inc.

Run the simulation using the main run button, then open up the ScopeA scope. The scope visualizes the data from the entire model.

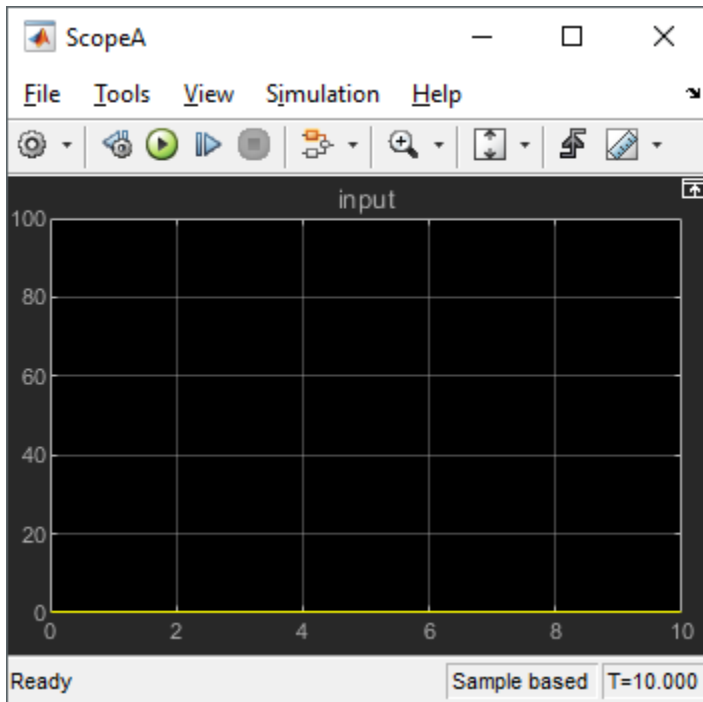

If you specifically want to visualize a referenced model in isolation, open the model as a top model. In this example, right-click the CounterA block and select `Open as Top Model`. The model opens in another window and the breadcrumb only shows the referenced model name.

Copyright 1990-2014 The MathWorks, Inc.

When you run the simulation from either the Simulink window or the scope window, the scope visualizes the model without any reference to another model. In this case, the model input is zero the entire time.

Scopes Within an Enabled Subsystem

When placed within an Enabled Subsystem block, scopes behave differently depending on the simulation mode:

- Normal mode — A scope plots data when the subsystem is enabled. The display plot shows gaps when the subsystem is disabled.

- External, Accelerator, and Rapid modes — A scope plots data when the subsystem is enabled. The display connects the gaps with straight lines.

Modify x-axis of Scope

This example shows how to modify the x-axis values of the Scope block using the **Time span** and **Time display offset** parameters. The **Time span** parameter modifies how much of the simulation time is shown and offsets the x-axis labels. The **Time display offset** parameter modifies the labels used on the x-axis.

You can also use this procedure for the Time Scope block, Floating Scope block, or Scope viewer.

Open the model and run the simulation to see the original scope output. The simulation runs for 10 time steps stepping up by 1 at each time step.

```
model = 'ModifyScopeXAxis';
open_system(model);
sim(model);
open_system([model, '/Scope']);
```

Copyright 2020 The MathWorks, Inc

Modify Time Span Shown

Modify the **Time span** parameter to 2. You can follow the commands below, or in the Scope window, click the Configuration Properties button and navigate to the Time tab.

```
scopeConfig = get_param([model, '/Scope'], 'ScopeConfiguration');  
scopeConfig.TimeSpan = '2';  
sim(model);  
open_system([model, '/Scope']);
```

The x-axis of the scope now shows only the last 2 time steps and offsets the x-axis labels to show 0-2. The bottom toolbar shows that the x-axis is offset by 8. This offset is different from the **Time display offset** value.

The **Time span** parameter is useful if you do not want to visualize signal initialization or other start-up tasks at the beginning of a simulation. You can still see the full simulation time span if you click the **Span x-axis** button.

Offset x-axis Labels

Modify the **Time display offset** parameter to 5. Again, use the commands below, or in the Scope window, click the Configuration Properties button and navigate to the Time tab.

```
scopeConfig.TimeDisplayOffset = '5';
sim(model);
open_system([model, '/Scope']);
```

Now, the same time span of 2 is shown in the scope, but the x-axis labels are offset by 5, starting at 5 and ending at 7. If you click the **Span x-axis** button, the x-axis labels still start at 5.

Show Signal Units on a Scope Display

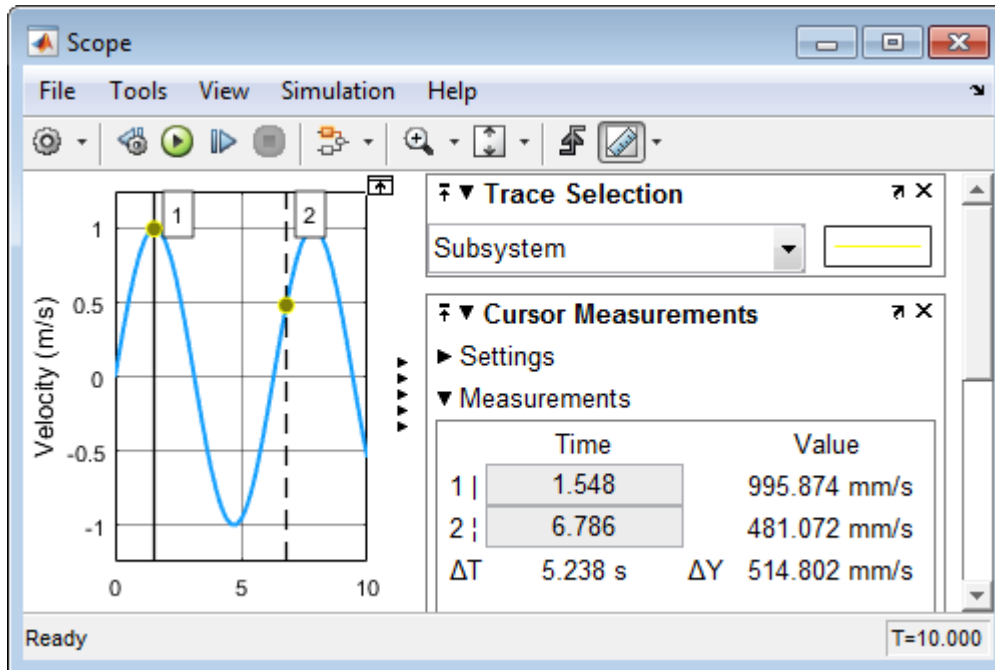

You can specify signal units at a model component boundary (Subsystem and Model blocks) using Inport and Outport blocks. See “Unit Specification in Simulink Models” on page 9-2. You can then connect a Scope block to an Outport block or a signal originating from an Outport block. In this example, the **Unit** property for the Out1 block was set to m/s.

Show Units on a Scope Display

- 1 From the Scope window toolbar, select the Configuration Properties button .
- 2 In the Configuration Properties: Scope dialog box, select the **Display** tab.
- 3 In the **Y-label** box, enter a title for the y-axis followed by (%<SignalUnits>). For example, enter
Velocity (%<SignalUnits>)
- 4 Click **OK** or **Apply**.

Signal units display in the y-axis label as meters per second (m/s) and in the Cursor Measurements panel as millimeters per second (mm/s).

From the Simulink toolstrip, you can also select **Debug > Information Overlays > Units**. You do not have to enter (%<SignalUnits>) in the **Y-Label** property.

Show Units on a Scope Display Programmatically

- 1 Get the scope properties. In the Command Window, enter

```
load_system('my_model')
s = get_param('my_model/Scope', 'ScopeConfiguration');
```

- 2 Add a y-axis label to the first display.

```
s.ActiveDisplay = 1
s.YLabel = 'Velocity (%<SignalUnits>);'
```

You can also set the model parameter ShowPortUnits to 'on'. All scopes in your model, with and without (%<SignalUnits>) in the **Y-Label** property, show units on the displays.

```
load_system('my_model')
get_param('my_model', 'ShowPortUnits')

ans =
off

set_param('my_model', 'ShowPortUnits', 'on')

ans =
on
```

Determine Units from a Logged Data Object

When saving simulation data from a scope with the `Dataset` format, you can find unit information in the `DataInfo` field of the timeseries object.

Note Scope support for signal units is only for the `Dataset` logging format and not for the legacy logging formats `Array`, `Structure`, and `Structure With Time`.

- 1 From the Scope window toolbar, select the Configuration Properties button .
- 2 In the Configuration Properties window, select the **Logging** tab.
- 3 Select the **Log data to workspace** check box. In the text box, enter a variable name for saving simulation data. For example, enter `ScopeData`.
- 4 From the Scope window toolbar, select the run button .
- 5 In the Command Window, enter

```
ScopeData.getElement(1).Values.DataInfo
```

```
Package: tsdata
Common Properties:
    Units: m/s (Simulink.SimulationData.Unit)
    Interpolation: linear (tsdata.interpolation)
```

Connect Signals with Different Units to a Scope

When there are multiple ports on a scope, Simulink ensures that each port receives data with only one unit. If you try to combine signals with different units (for example by using a `Bus Creator` block), Simulink returns an error.

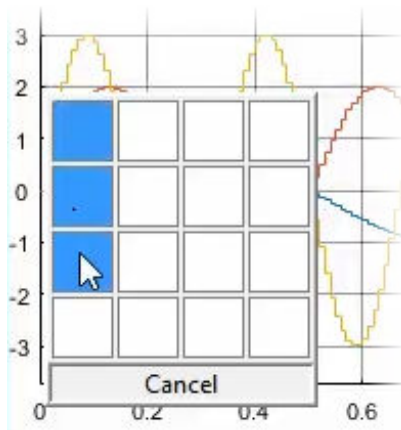

Scopes show units depending on the number of ports and displays:

- **Number of ports equal to the number of displays** — One port is assigned to one display with units for the port signal shown on the y-axis label.
- **Greater than the number of displays** — One port is assigned to one display, with the last display assigned the remaining signals. Different units are shown on the last y-axis label as a comma-separated list.

Select Number of Displays and Layout

- 1 From a Scope window, select the Configuration Properties button .
- 2 In the Configuration Properties dialog box, select the **Main** tab, and then select the **Layout** button.
- 3 Select the number of displays and the layout you want.

You can select more than four displays in a row or column. Click within the layout, and then drag your mouse pointer to expand the layout to a maximum of 16 rows by 16 columns.

- 4 Click to apply the selected layout to the Scope window.

Dock and Undock Scope Window to MATLAB Desktop

- 1 In the right corner of a Scope window, click the Dock Scope button.

The Scope window is placed above the Command Window in the MATLAB desktop.

- 2 Click the Show Scope Actions button, and then click **Undock Scope**.

Floating Scope and Scope Viewer Tasks

In this section...

“Add Floating Scope Block to Model and Connect Signals” on page 28-70

“Add Scope Viewer to a Signal” on page 28-71

“Add Signals to an Existing Floating Scope or Scope Viewer” on page 28-71

“Save Simulation Data from Floating Scope” on page 28-72

“Add and Manage Viewers” on page 28-75

“Quickly Switch Visualization of Different Signals on a Floating Scope” on page 28-76

These tasks walk through frequently used Floating Scope and Scope Viewer procedures.

Add Floating Scope Block to Model and Connect Signals

To add a Floating Scope block from the Simulink block library:

- 1 From the **Simulation** tab, click **Library Browser** .
- 2 From Simulink / Sinks, drag a copy of the Floating Scope block into your model.

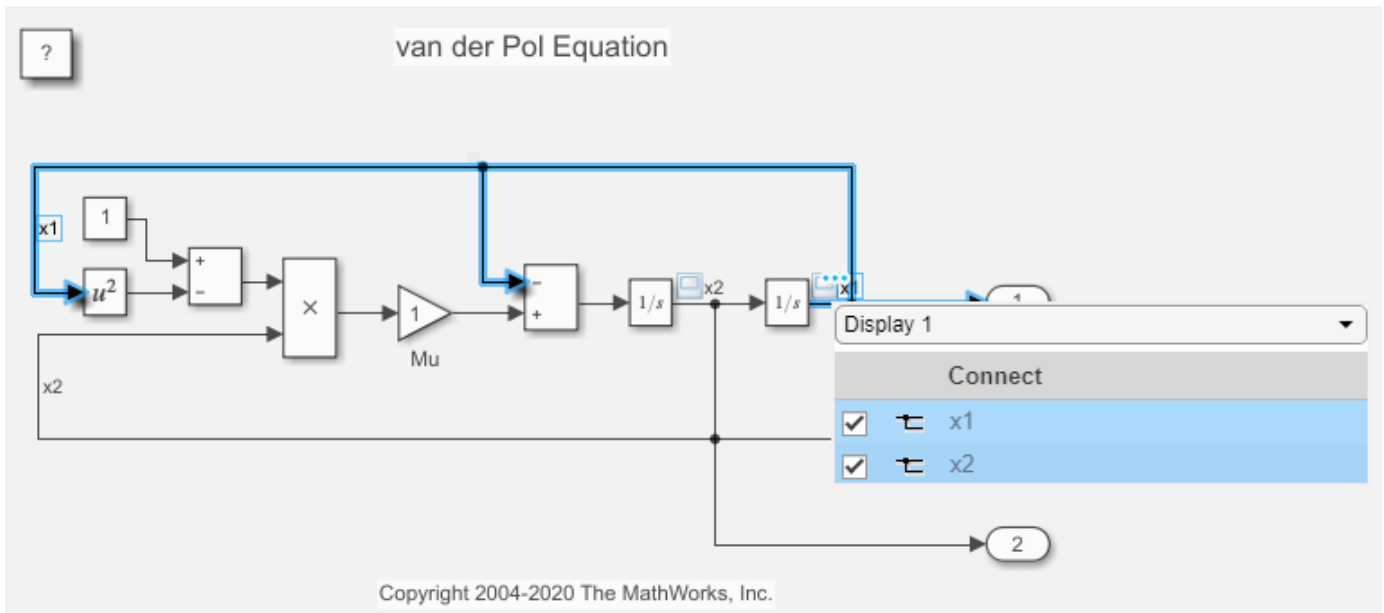

To connect signals to your floating scope:

- 1 Double-click the Floating Scope block.
- 2 In the scope window toolbar, click the signal selection button . You may need to select the dropdown next to the lock button to see signal selection.

The Simulink Editor canvas grays, indicating you can interactively select signals to connect to the scope.

- 3 Select the signals you want to connect to the scope. To select multiple signals, click and drag.
- 4 In the **Connect** pop-up, select the check box next to the signals you want to connect.

- 5 For scopes with multiple displays (subplots), select the desired display from the drop-down at the top of the Connect pop-up and connect the signals.
- 6 Click the **X** in the upper-right of the Simulink canvas.

Your signals are now connected to the floating scope. Run a simulation to see the plotted signals.

Add Scope Viewer to a Signal

- 1 Select a signal to view.
- 2 In the **Simulation** tab, in the **Prepare** gallery, select **Add Viewer**.
- 3 From the Add Viewer window, select a viewer, for example **Scope**.

Add Signals to an Existing Floating Scope or Scope Viewer

Connect signals to an existing Floating Scope or Scope viewer.

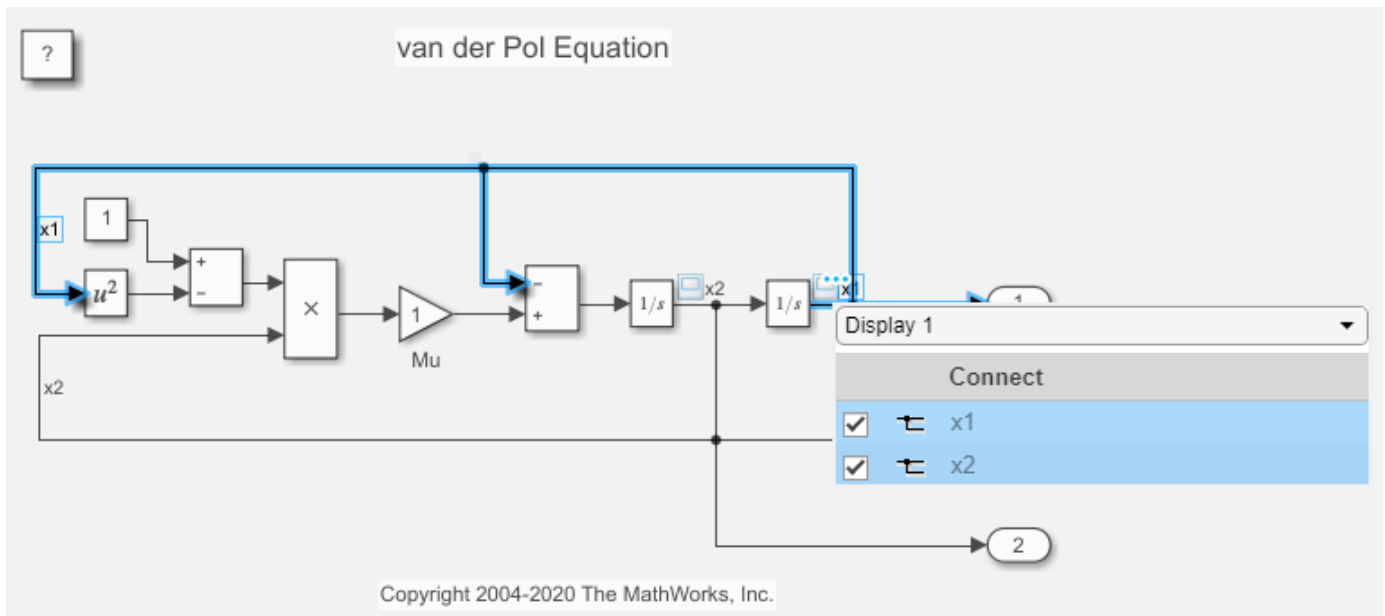

- 1 Open the scope by double-clicking a Floating Scope block or Scope viewer icon .
- 2 In the scope window toolbar, click the signal selection button . You may need to select the drop-down next to the lock button to see signal selection.

The Simulink Editor canvas grays, indicating you can interactively select signals to connect to the scope.

- 3 Select the signals you want to connect to the scope. To select multiple signals, click and drag.

- 4 In the **Connect** pop-up, select the check box next to the signals you want to connect.

- 5 For scopes with multiple displays (subplots), select the desired display from the drop-down at the top of the Connect pop-up and connect the signals.
- 6 Click the **X** in the upper-right of the Simulink canvas.

Your signals are now connected to the scope. Run a simulation to see the plotted signals.

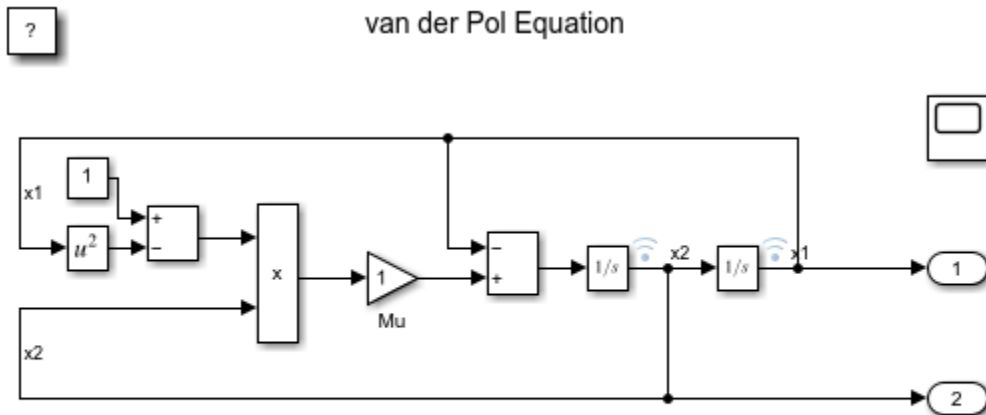

Save Simulation Data from Floating Scope

This example shows how to save signals to the MATLAB® Workspace using a Floating Scope block. You can follow the same procedure to save data from a Scope Viewer. To save data from a Scope or Time Scope block, see “Save Simulation Data Using Scope Block” on page 28-53.

This example uses a modified version of the vdp model. In this example, a floating scope is connected to the x1 and x2 signals.

Set Up Signal Logging from the Floating Scope

```
model = 'vdpFloatingScope';
open_system(model);
```

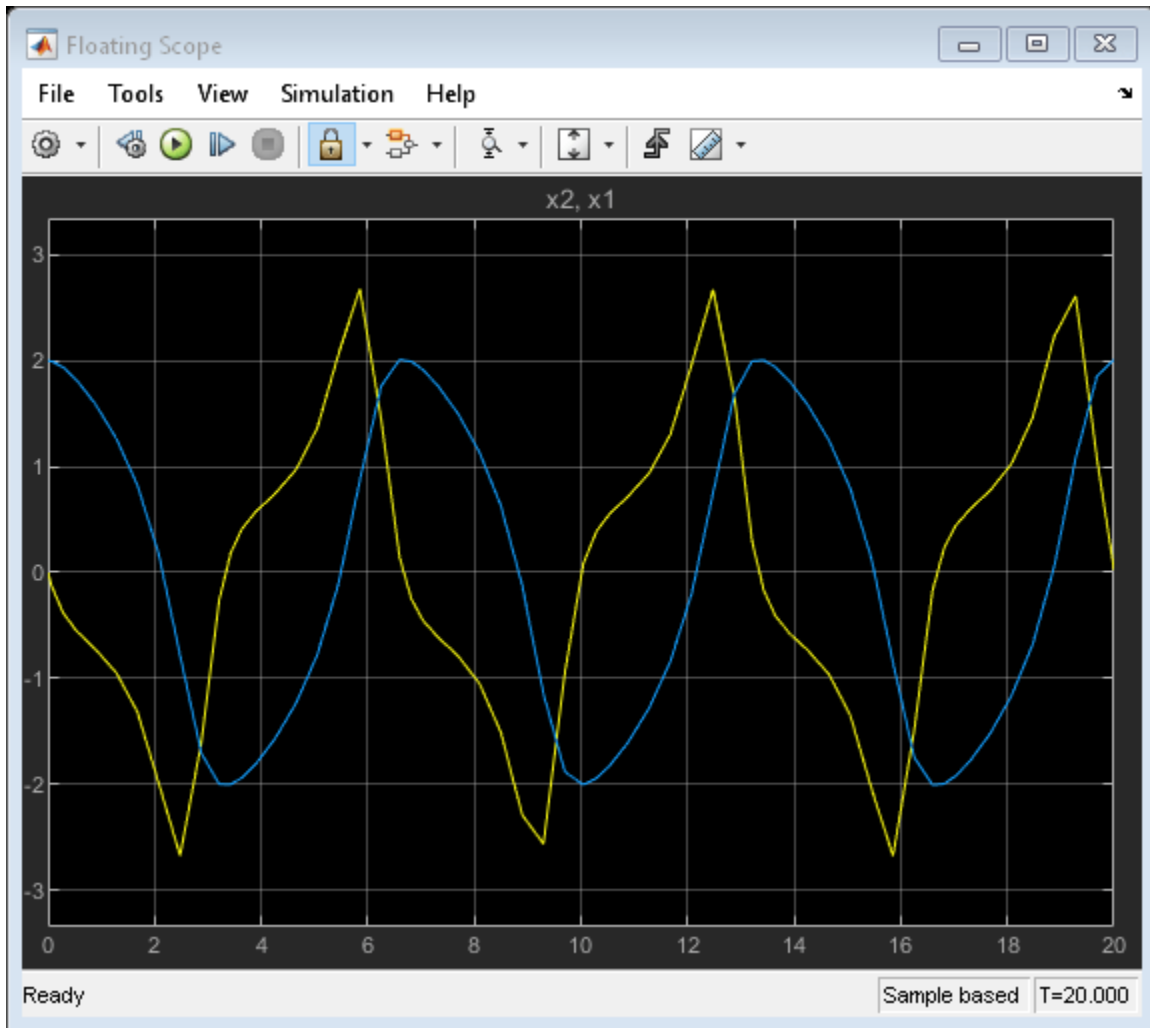

Copyright 2004-2019 The MathWorks, Inc.

- 1 From the Floating Scope window, select **View > Configuration Properties**.
- 2 On the **Logging** tab, select **Log/Unlog Viewer Signals to Workspace**. When you click this button, Simulink places logging symbols on the signals connected to the Floating Scope.
- 3 From the Simulink Editor, on the **Modeling** tab, click **Model Settings**.
- 4 In the Configuration Properties window, select **Data Import/Export**.
- 5 Select the **Signal logging** check box. You can also set the parameter name from this window. The default parameter name is `logout`.

Use Saved Simulation Data

Run a simulation. Simulink saves data to the MATLAB Workspace in a variable `out`.

```
out = sim(model);
```

Simulink saves all logged or saved simulation data as one structure. In `out`, the scope data object `logscope` has one element for each logged signal.

In the MATLAB Command Window, plot the log data for `x1`.

```
x1_data = out.logscope.get('x1').Values.Data;  
x1_time = out.logscope.get('x1').Values.Time;  
plot(x1_time,x1_data);
```

Add and Manage Viewers

Open the Viewers and Generators Manager. From the Simulink toolstrip **Simulation** tab, expand the **Prepare** gallery and select **Viewers Manager**.

You can see any viewers or generators you added in the Viewers and Generators Manager.

- To add viewers or generators, click and choose a viewer. New viewers and generators are not connected to any signals.
- To connect signals, click on a viewer or generator, and click .
- To delete a viewer or generator, click .

Quickly Switch Visualization of Different Signals on a Floating Scope

- 1 Open a Floating Scope window.
- 2 On the toolbar, click the Lock button so that the icon is unlocked .
- 3 In the model, click a signal line to select and highlight the signal line. To select multiple signals, hold down the **Shift** key while selecting signals.

After clicking on the canvas, the selected display removes connections to any previously selected signals.

- 4 Run a simulation. As long as the unlock icon is showing, you can click between signals to switch which signal appears in the Floating Scope.

Generate Signals Without Source Blocks

Signal generators create signals without adding a block to your model. Generators are added and managed through the Viewers and Generators Manager.

Attach Signal Generator

Context Menu

- 1 In the Simulink Editor, right-click the input to a block.
- 2 From the context menu, select **Create And Connect Generator** > *product* > *generator*.

The name of the generator you choose appears in a box connected to the block input.

Viewers and Generators Manager

- 1 From the **Simulation** tab, open the **Prepare** gallery and select **Viewers Manager**. The Viewers and Generators Manager panel opens to the side of the Simulink editor.
- 2 In the Viewers and Generators panel, select the **Generators** tab.
- 3 Click the  button and select a generator.

The generator is added to the list of generators.

- 4 Click the generator you just added from the list and select the  button.
- 5 The canvas grays, indicating you are now in connect mode. Click the block you want to connect the generator to and in the pop-up, select the check box for the input port you want to attach the generator to.
- 6 Close connect mode by clicking the **X** in the upper right corner of the canvas.

Modify Signal Generator Parameters

Context Menu

- 1 Right-click the generator name and select **Generator Parameters**. In the Generator Parameters dialog box, enter parameters for this generator.
- 2 To rename a signal generator, double-click the generator label and type your new name for the generator.

Viewers and Generators Manager

- 1 From the Viewers and Generators Manager panel, select the generator from the **Generator** tab.
- 2 Click  and enter parameter values for this generator.
- 3 To rename a signal generator, double-click the generator name in the Generators list and type your new name for the generator.

Remove Signal Generator

Context Menu

- 1 Right-click a generator.
- 2 From the context menu, select **Disconnect Generator**.

To also delete the generator, select **Disconnect and Delete Generator**

Viewers and Generators Manager

- 1 From the Viewers and Generators Manager panel, select the generator from the **Generator** tab.
- 2 Enter connect mode by selecting the  button
- 3 On the grayed canvas, select the generator and, in the pop-up, clear the check box next to the port you want to disconnect.
- 4 To delete the generator completely, in the Viewers and Generators Manager panel, also click .

Scope Viewer

Related Examples

- “Common Scope Block Tasks” on page 28-51
- “Floating Scope and Scope Viewer Tasks” on page 28-70
- “Viewers and Generators Manager” on page 28-80

Viewers and Generators Manager

Using the Viewers and Generators Manager, you can manage viewers and generators from a central point.

Viewers and generators are not blocks. Blocks are dragged from the Library Browser and managed with block dialog boxes. Viewers and generators are mechanisms that create or visualize signals, but are added and managed through the Viewers and Generators Manager.

Symbols identify a viewer attached to a signal line, and signal names identify generators.

Open the Viewers and Generators Manager

From the **Simulation** tab, open the **Prepare** gallery and select **Viewers Manager**. The Viewers and Generators Manager panel opens to the side of the Simulink editor.

You can also access the Viewers and Generators Manager by right-clicking a signal or block input and selecting **Viewers and Generators Manager**.

Change Parameters

- 1 Open the Viewers and Generators Manager.
- 2 In the list of **Generators** or **Viewers**, select the viewer or generator you want to modify.
- 3 Select the  button.
 - For a generator, the parameters dialog box opens for that generator type.
 - For a viewer, either a parameter dialog opens or the viewer itself opens. If the viewer opens, you can access parameters from the  button.
- 4 Review and change parameters.

Connect Viewers and Generators

Connect signals to a new viewer or generator using the Viewers and Generators Manager.

- 1 Open the Viewers and Generators Manager panel.
- 2 Select either the **Viewers** or **Generators** tab.
- 3 Click .
- 4 From the list of viewers or generators, select the viewer or generator you just added.

- 5 Select the  button. The canvas grays, indicating you are now in connect mode.
- 6 For generators, click the block you want to connect the generator to and in the pop-up, select the check box for the input port you want to attach to.

For viewers, click the signal or signals you want to visualize and in the pop-up, select the check box next to the signals you want to connect. If you have multiple displays or specific inputs, select the display you want to connect to from the drop down before selecting the check box.
- 7 Close connect mode by clicking the **X** in the upper right corner of the canvas.

View Test Point Data

Use a Scope viewer available from the Viewers and Generators Manager to view any signal that is defined as a test point in a referenced model. A test point is a signal that you can always see when using a Scope viewer in a model.

Note With some viewers (for example, To Video Display, Matrix Viewer), you cannot use the Signal Selector to select signals with test points in referenced models.

For more information, see “Configure Signals as Test Points” on page 76-46.

Customize Viewers and Generators Manager

You can add custom signal viewers or generators so that they appear in the Viewers and Generators Manager. This procedure adds a custom viewer named `newviewer` to the Viewers and Generators Manager:

- 1 Create a new Simulink library by selecting **Simulation > New > Library**.
- 2 Save the library as `newlib`.
- 3 In the MATLAB Command Window, set the library type to a viewer library:

```
set_param('newlib','LibraryType','SSMgrViewerLibrary')
```

To set the library type for generators, use the type `'SSMgrGenLibrary'`. For example:

```
set_param('newlib','LibraryType','SSMgrGenLibrary')
```
- 4 Set the display name of the library:

```
set_param('newlib','SSMgrDisplayString','My Custom Library')
```
- 5 Add your custom viewer or generator to the library by dragging and dropping into the Simulink canvas.

Note If the viewer is a compound viewer, such as a subsystem with multiple blocks, make the top-level subsystem an atomic one.

- 6 Set the `iotype` of the viewer. For example:

```
set_param('newlib/newviewer','iotype','viewer')
```
- 7 Save the library `newlib`.

- 8 Using the MATLAB editor, create a file named `sl_customization.m`. In this file, enter a directive to incorporate the new library as a viewer library.

For example, to save `newlib` as a viewer library, add these lines:

```
function sl_customization(cm)
cm.addSigScopeMgrViewerLibrary('newlib')
%end function
```

To add a library as a generator library, use this syntax instead:

```
cm.addSigScopeMgrGeneratorLibrary('newlib')
```

- 9 Add a corresponding `cm.addSigScope` line for each viewer or generator library you want to add.
- 10 Save the `sl_customization.m` file on your MATLAB path. Edit this file to add new viewer or generator libraries.
- 11 To see the new custom libraries, restart MATLAB and start the Viewers and Generators Manager.

Control Scope Blocks Programmatically

This example shows how to control scopes with programming scripts.

Use Simulink Configuration Object

Use a Scope Configuration object for programmatic access to scope parameters.

- Modify the title, axis labels, and axis limits
- Turn on or off the legend or grid
- Control the number of inputs
- Change the number of displays and which display is active

Create a model and add a Scope and Time Scope block. Then, use `get_param` to create the Scope Configuration object `myConfiguration`.

```
mdl = 'myModel';
new_system(mdl);
add_block('simulink/Sinks/Scope', [mdl '/myScope']);
add_block('dspsnks4/Time Scope', [mdl '/myTimeScope']);
myConfiguration = get_param([mdl '/myScope'],'ScopeConfiguration')
```

```
myConfiguration =
Scope configuration with properties:
```

```

        Name: 'myScope'
        Position: [360 302 560 420]
        Visible: 0
    OpenAtSimulationStart: 0
        DisplayFullPath: 0
    PreserveColorsForCopyToClipboard: 0
        NumInputPorts: '1'
    LayoutDimensions: [1 1]
        SampleTime: '-1'
    FrameBasedProcessing: 0
        MaximizeAxes: 'Off'
    MinimizeControls: 0
        AxesScaling: 'Manual'
    AxesScalingNumUpdates: '10'
        TimeSpan: 'Auto'
    TimeSpanOverrunAction: 'Wrap'
        TimeUnits: 'none'
    TimeDisplayOffset: '0'
        TimeAxisLabels: 'Bottom'
    ShowTimeAxisLabel: 0
        ActiveDisplay: 1
        Title: '%<SignalLabel>'
        ShowLegend: 0
        ShowGrid: 1
    PlotAsMagnitudePhase: 0
        YLimits: [-10 10]
        YLabel: ''
        DataLogging: 0
    DataLoggingVariableName: 'ScopeData'
    DataLoggingLimitDataPoints: 0
    DataLoggingMaxPoints: '5000'
```

```
DataLoggingDecimateData: 0  
DataLoggingDecimation: '2'  
DataLoggingSaveFormat: 'Dataset'
```

Set a property.

```
myConfiguration.DataLoggingMaxPoints = '10000';
```

Find the Scope and Time Scope blocks.

```
find_system mdl, 'LookUnderMasks', 'on', 'IncludeCommented', 'on', ...  
'AllBlocks', 'on', 'BlockType', 'Scope')  
  
ans = 2x1 cell  
    {'myModel/myScope' }  
    {'myModel/myTimeScope' }
```

Find only Simulink Scope blocks.

```
find_system mdl, 'LookUnderMasks', 'on', 'IncludeCommented', 'on', ...  
'AllBlocks', 'on', 'BlockType', 'Scope', 'DefaultConfigurationName', ...  
'Simulink.scopes.TimeScopeBlockCfg')  
  
ans = 1x1 cell array  
    {'myModel/myScope' }
```

Find only the DSP Time Scope blocks.

```
find_system mdl, 'LookUnderMasks', 'on', 'IncludeCommented', 'on', ...  
'AllBlocks', 'on', 'BlockType', 'Scope', 'DefaultConfigurationName', ...  
'spbscopes.TimeScopeBlockCfg')  
  
ans = 1x1 cell array  
    {'myModel/myTimeScope' }
```

Scope Configuration Properties

For details about the Scope Configuration object properties, see [TimeScopeConfiguration](#).

Plot a Circle Using the XY Graph Block

This example shows how to plot data using the XY Graph block. The XY Graph block is an alternative configuration of the Record block that plots two input signals on an XY plot. The XY plot used by the Record block is also available in the Simulation Data Inspector. The XY Graph block has all the capabilities of the Record block, including the ability to log data to the workspace and a file.

The model computes x and y data to plot a circle using a third variable, θ . Using a polar coordinate system, you can express the equation for a circle of radius a centered on the origin as:

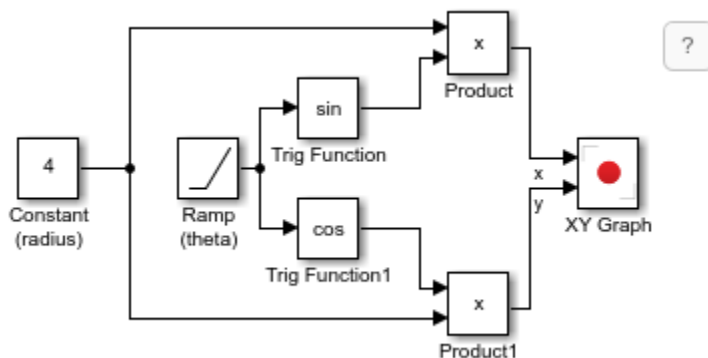

$$r(\theta) = a$$

Converting the equation to use Cartesian coordinates results in these equations for the x and y data:

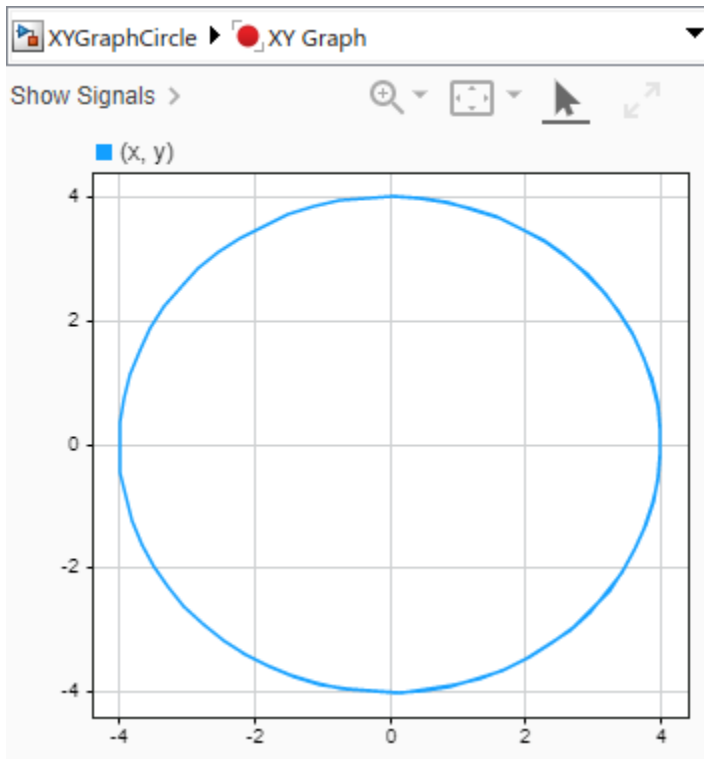

$$x = a \cos(\theta)$$

$$y = a \sin(\theta)$$

The model computes the x data and the y data using Trigonometric Function blocks. The Ramp block provides the input, θ , and the Constant block sets the radius of the circle.

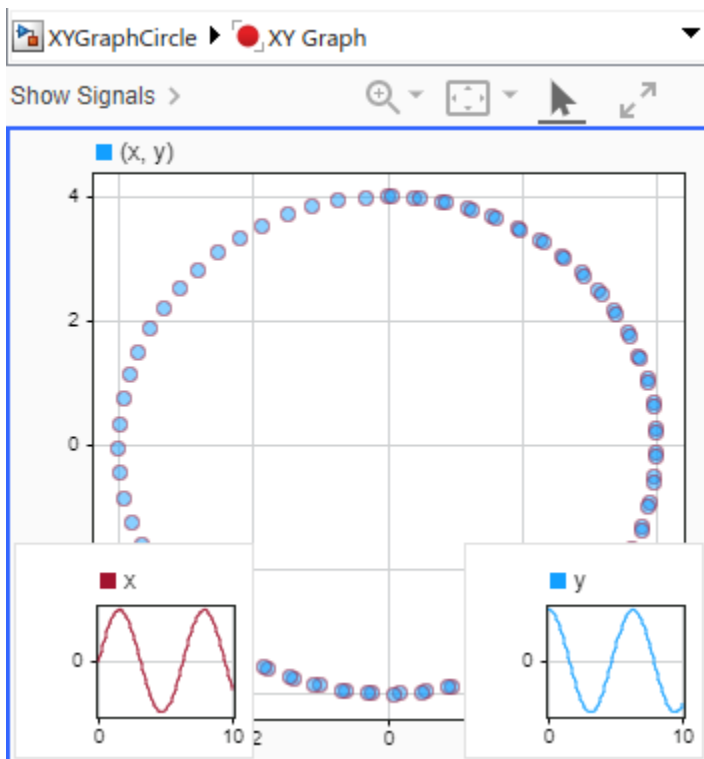

To view the plotted results, simulate the model, then double-click the XY Graph block.

You can add subplots to the layout in the XY Graph block to view the x data and the y data variations against time. For example, select **Layouts**. Then, under **Overlays**, select **Bottom**. Click **Show Signals** to view the signals. To plot the x signal, select the left overlay, then select the check box next to the x signal. Then, to plot the y signal, select the right overlay, then select the y signal.

You can also update the styling of the data plotted on the XY plot. For example, remove the connecting line and add data markers. To add markers to the plot, on the **Format** tab, under **Markers**, click **Markers**. To remove the line from the plot, on the **Format** tab, under **Line**, click **Line**.

The XY plot supports other analysis and visualization features including trend lines and the ability to plot more than one series. For more information, see “Visualize Simulation Data on an XY Plot” on page 29-29 and “Analyze Data Using the XY Plot” on page 29-38.

Sample Time with Scope Blocks

The Scope block and Time Scope block inherit and propagate sample time differently. This example helps you understand how sample time inheritance works when using a Scope block versus a Time Scope block. This example also shows what to do when you want to control the sample time propagation in the model.

The Time Scope block is available with the DSP System Toolbox™.

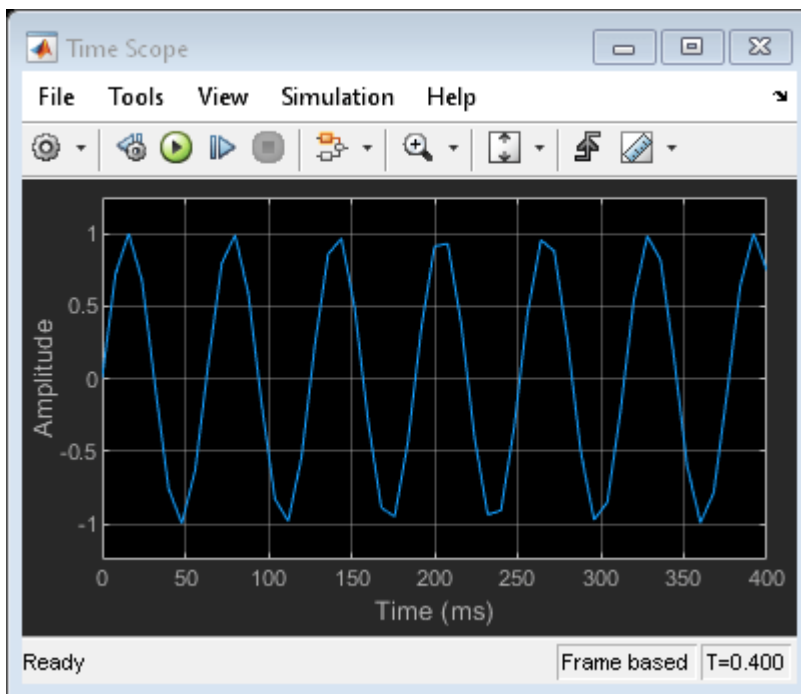

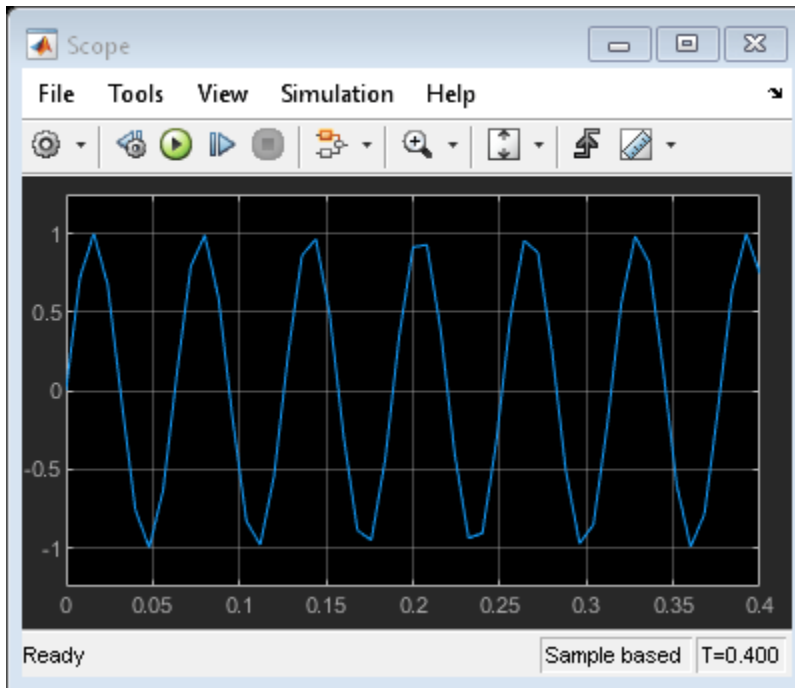

Default Behavior with Inherited Sample Time

This model shows two sine waves connected to a Time Scope block. The same sine waves are also connected to a Scope block. All blocks have the default inherited sample time (the **Sample Time** parameter equal to -1).

When you run this model, all blocks have continuous sample time. Continuous sample time occurs because the solver is set to variable step by default and all the blocks are set to inherited sample time. When you compile the model, Simulink® gives you four warnings that say, "Source block specifies that its sample time (-1) is back-inherited. You should explicitly specify the sample time of sources." This warning helps avoid unwanted sample time propagation from an incorrectly configured model. To improve clarity, these warnings have been hidden in this example.

The screenshot displays a simulation environment window titled "ScopeMultiRate". The main workspace contains two scope blocks. The top block, labeled "Time Scope", has two input channels. The first channel is connected to a "Sine Wave" block, and the second channel is connected to a "Sine Wave1" block. Both sine wave blocks have a "Cont" label next to them. The bottom block, labeled "Scope", has two input channels. The first channel is connected to a "Sine Wave2" block, and the second channel is connected to a "Sine Wave3" block. Both sine wave blocks also have a "Cont" label next to them. To the right of the workspace is a "Timing Legend" panel. It features a "Highlight" dropdown menu set to "None" and a refresh icon. Below this, a section titled "Continuous" is expanded, showing a legend entry with a black square icon, the label "Cont", and the text "Continuous".

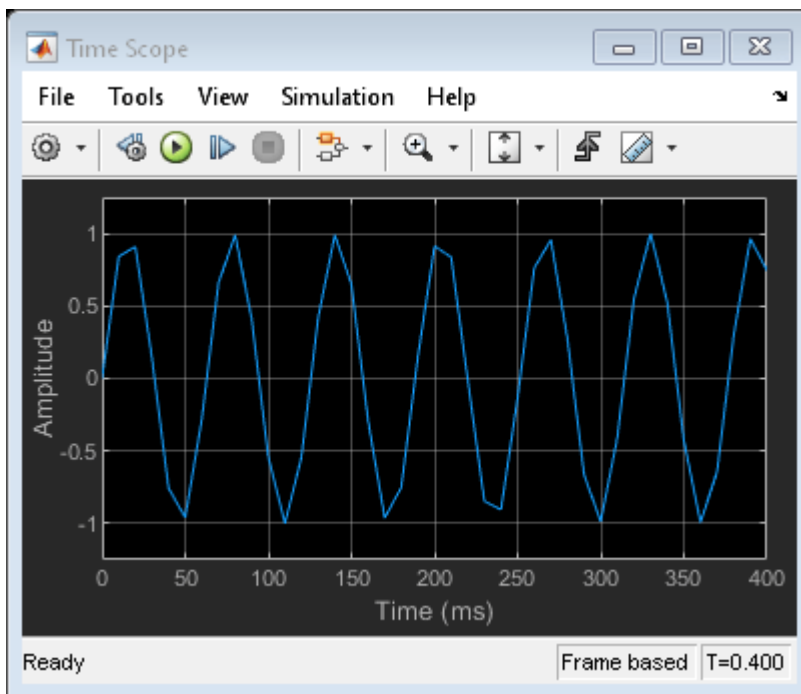

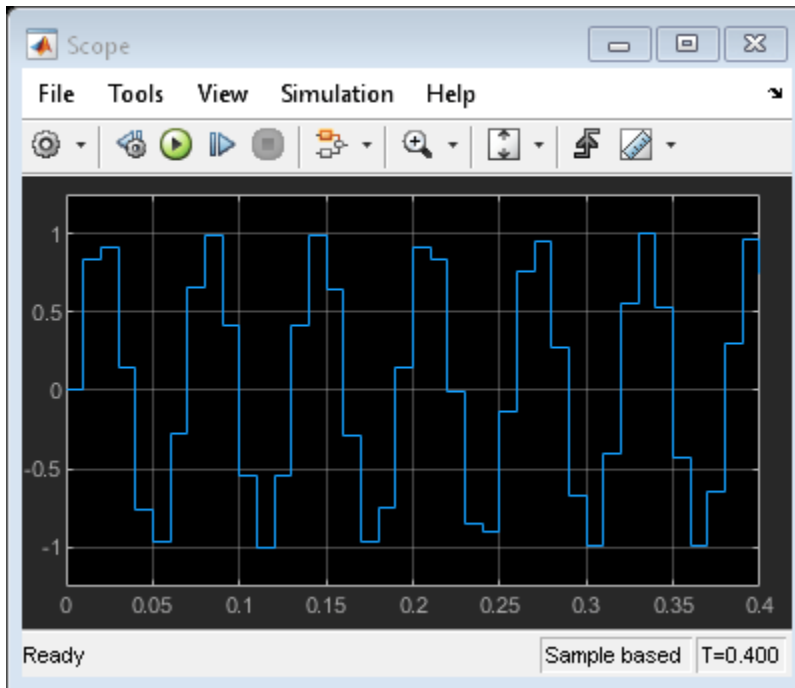

Default Behavior with Fixed-Step Solver and Inherited Sample Time

Change the model to discrete sample time by setting the solver to fixed step.

The default plot type for the Scope block is Auto, which means that the plot changes type depending on the inputs. Because the sample time is now discrete, the Scope block shows a stair plot. The default plot type of the Time Scope block is a Line plot, so the signal visualization does not change when the sample time changes to discrete.

One Specified Sample Time On the Model

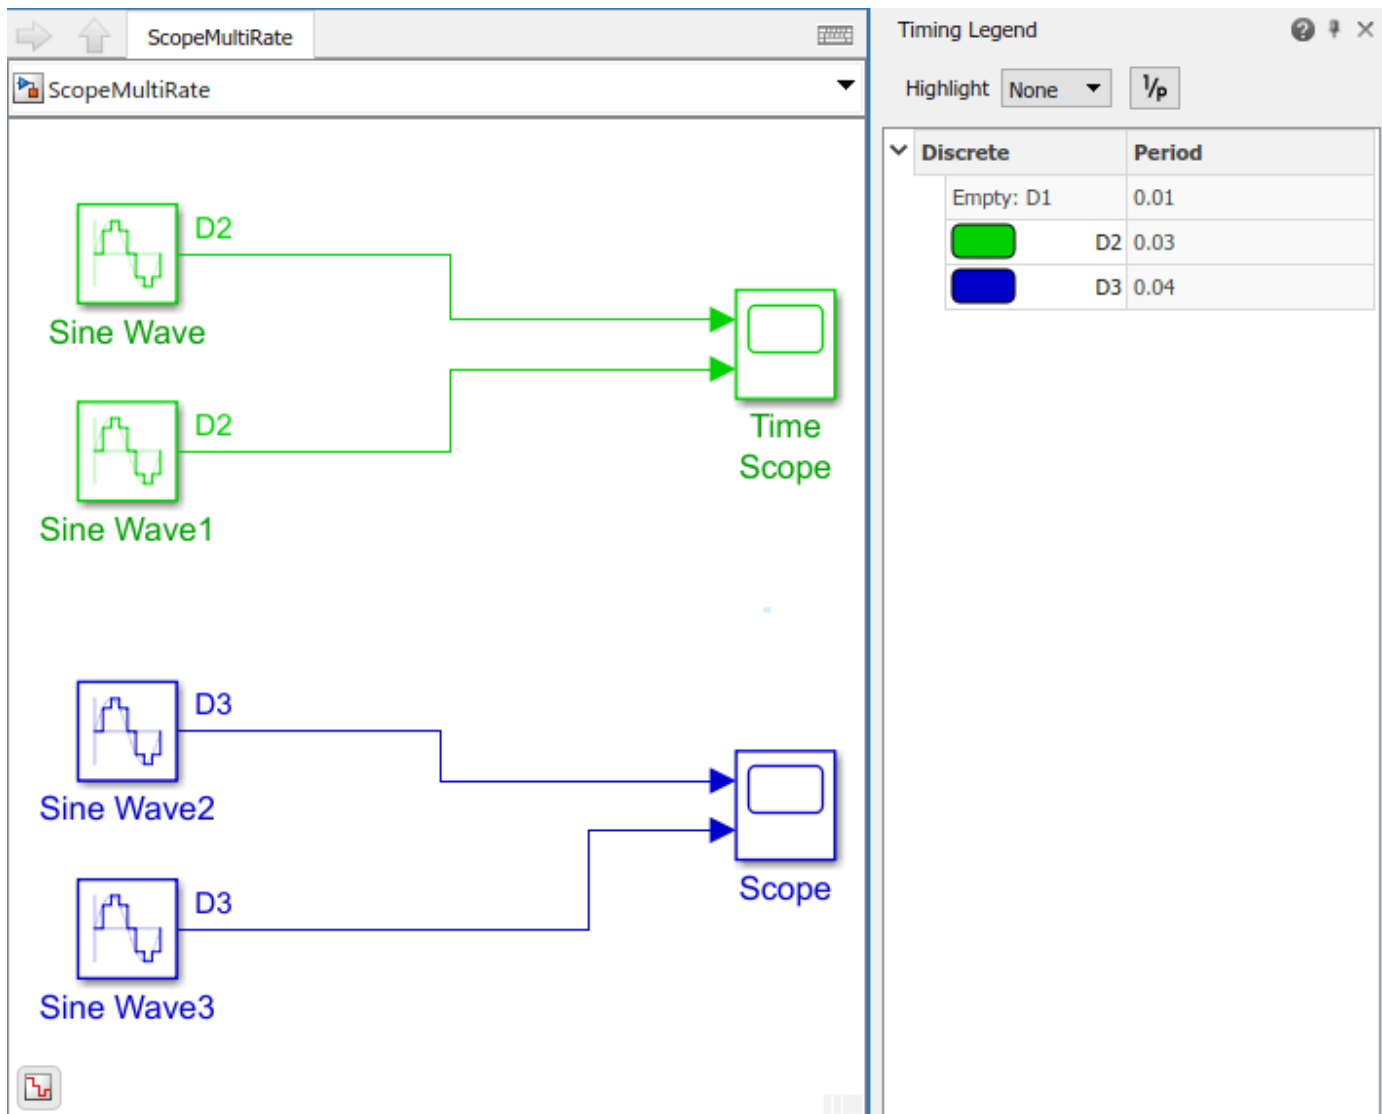

Set the sample time of the first Sine Wave block to 0.03. Specifying one sample time changes the sample time of the entire model, changing the sample time for the blocks connected to the Sine Wave block and the ones not connected to the block. Simulink changes the sample rates for all the blocks in the model because the lowest specified sample time takes precedence over a solver-determined

sample time. The number of warnings drops to three. To improve clarity, these warnings have been hidden in this example.

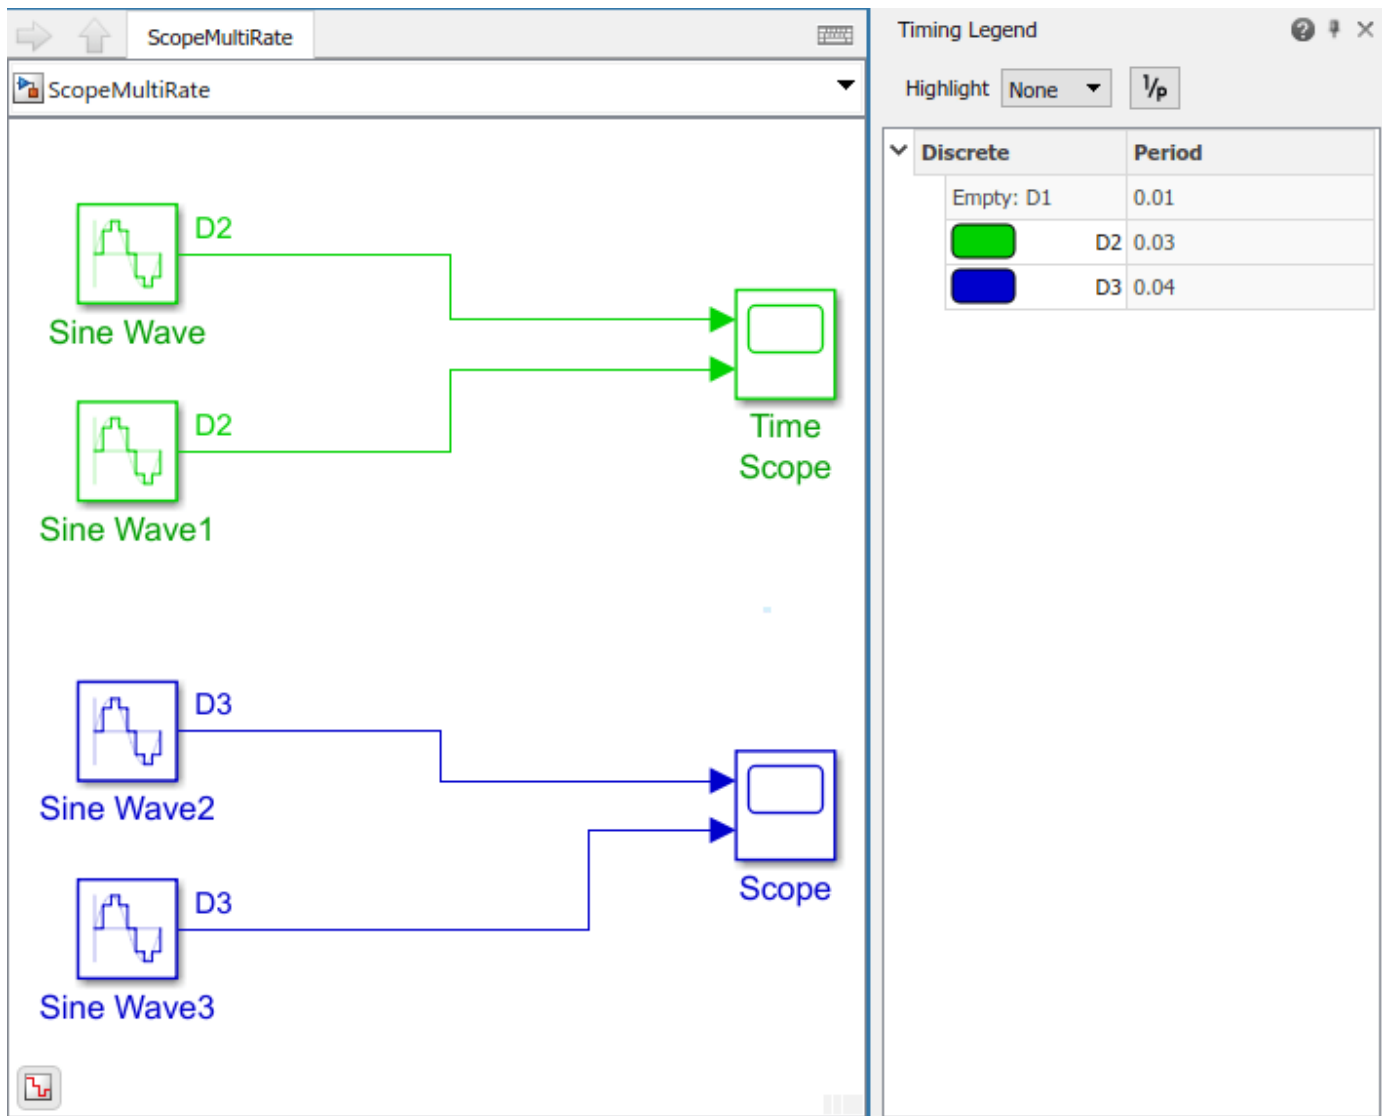

One Scope Input with Specified Sample Time

Set the sample time of the Sine Wave2 block to 0.04. Now the Sine Wave and Sine Wave2 blocks have specified sample times of 0.03 and 0.04 respectively. The scope blocks and Sine Wave input blocks with inherited sample time, they inherit the sample from the Sine Wave block with the specified sample time. Now each submodel within this model has a different sample time. All sample times are based on the sample times specified in the Sine Wave and Sine Wave2 blocks. The number of warnings drops to two. To improve clarity, these warnings have been hidden in this example.

All Inputs with Specified Sample Time

Set the sample time of the Sine Wave1 block to 0.03, and the sample time of the Sine Wave3 block to 0.04. Now the Sine Wave and Sine Wave1 blocks have a sample time of 0.03 and the Sine Wave2 and Sine Wave3 blocks have a sample time of 0.04. There are no warnings now because you have specified the sample times for all the source blocks.

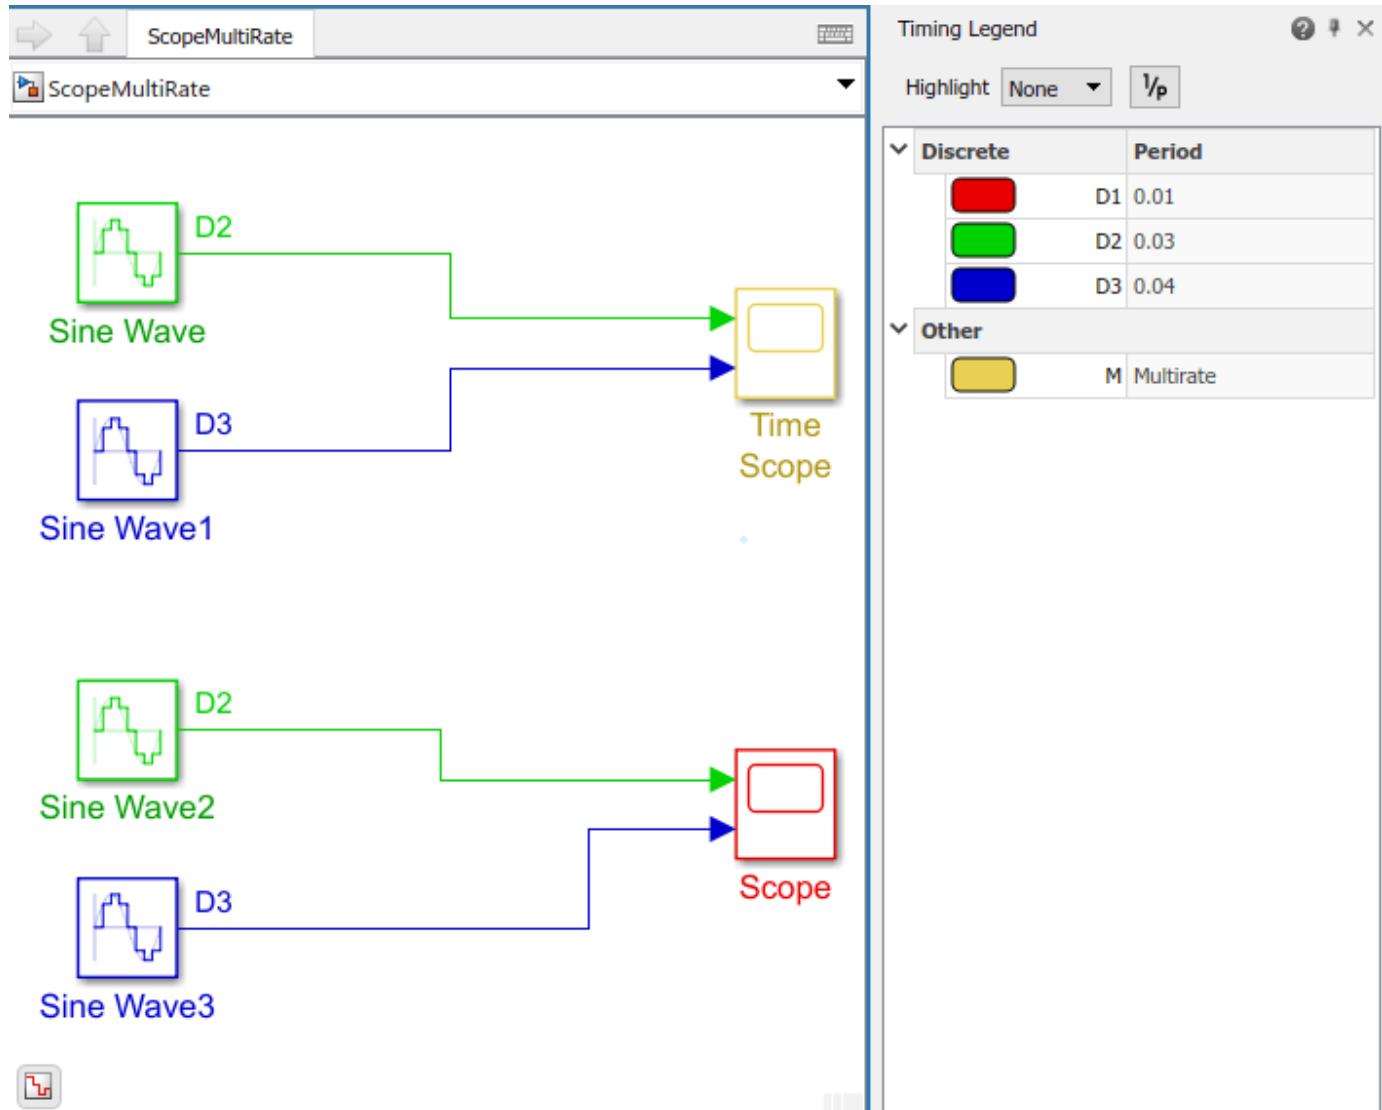

Inputs with Different Sample Times

Set the sample time for the Sine Wave blocks so that the two inputs to each scope have a different sample time. Set the sample time in the Sine Wave and Sine Wave2 blocks to 0.03, and the sample time for the Sine Wave1 and Sine Wave3 blocks to 0.04. When you compile the model, you see that the Time Scope and Scope behave differently. The sample time for the Simulink Scope resolves to the fastest discrete rate (FDR). The FDR sample time is 0.01, the greatest common denominator of the two input rates 0.03 and 0.04. This smaller sample rate means that each signal is oversampled. By contrast, the sample time for the Time Scope resolves to multirate sample time, meaning each input is sampled at its own sample time.

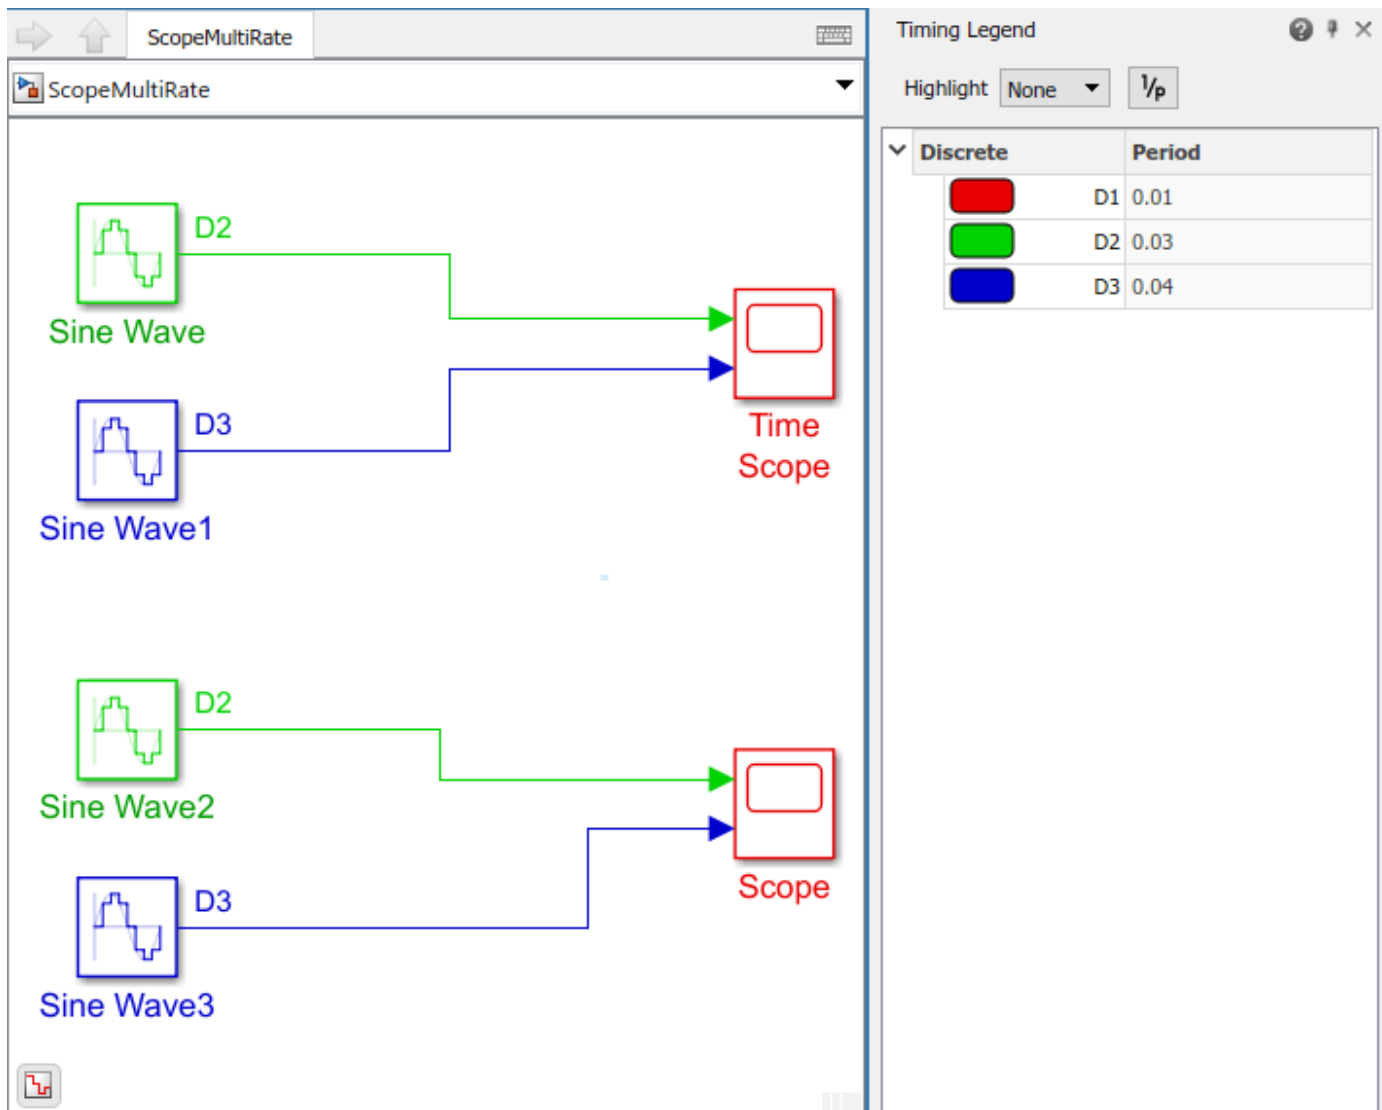

In general, the DSP System Toolbox Time Scope uses port-based sample time, which processes the sample time for each input individually during initialization. Port-based sample time allows for multiple sample times and sample time offsets. The Simulink Scope uses block-based sample time, which resolves to a FDR sample time for the block as a whole during the initialization phase of the simulation.

During the simulation phase, the Scope block processes all inputs at the FDR sample rate. This sample rate can cause oversampling of some inputs. By contrast, during simulation, the Time Scope block processes a particular port only when a sample hit occurs for that port.

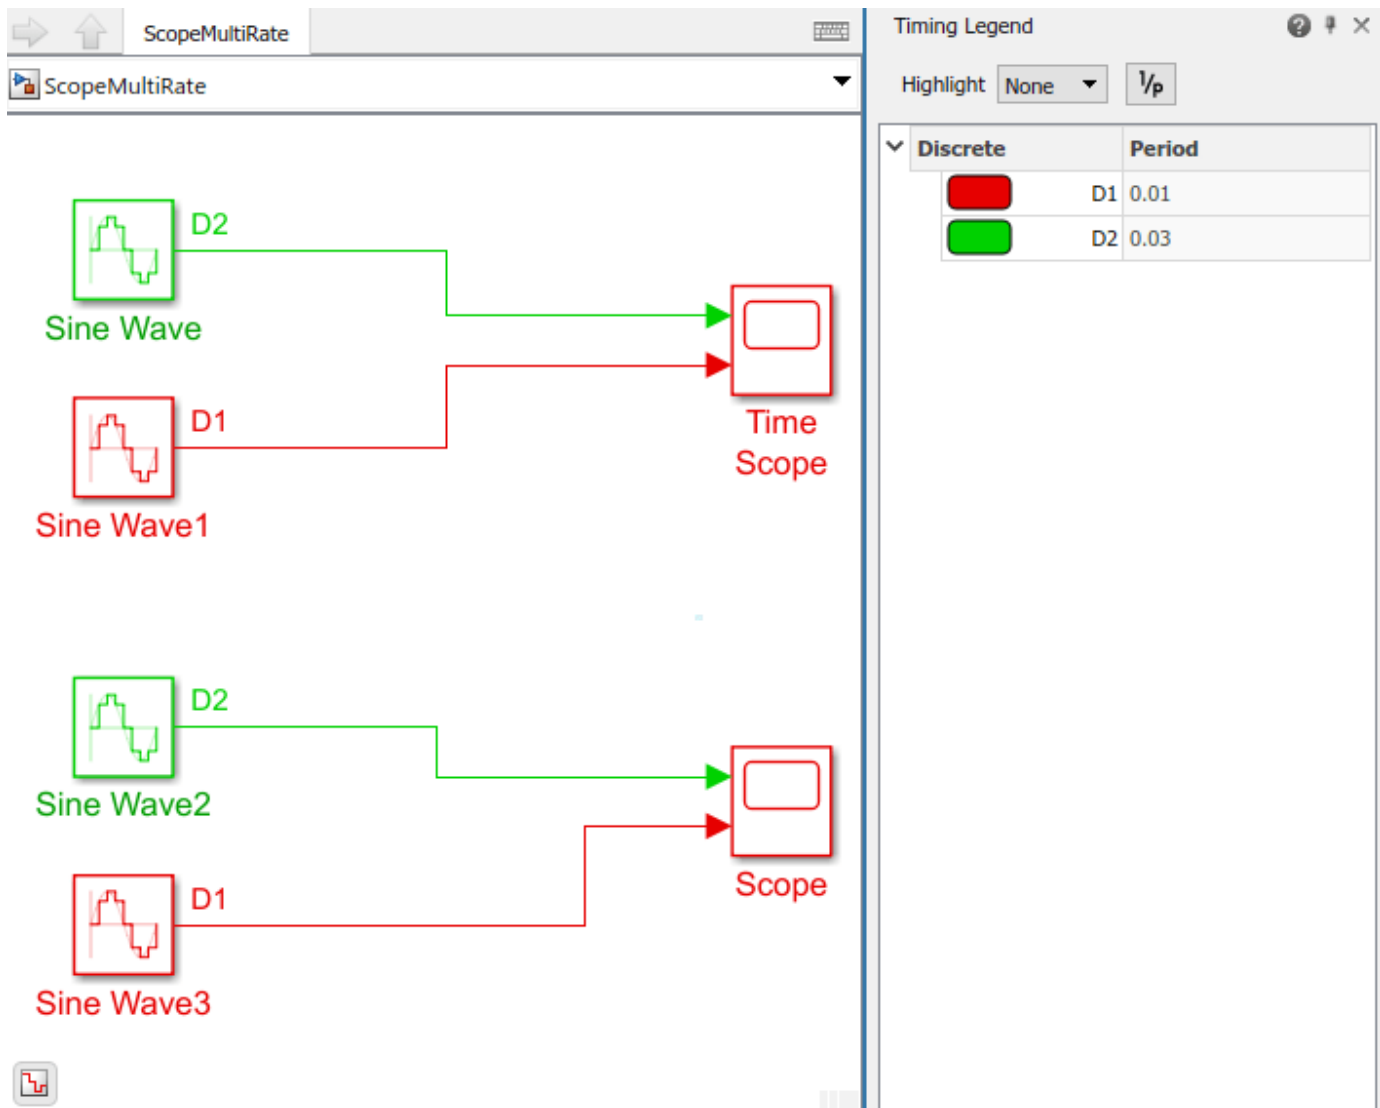

Set Sample Time on Scope Blocks

Until now, the sample times for the scopes were inherited (-1). Set the sample time on both scopes to 0.01 the FDR in the previous section. Simulink issues two warnings, one per scope block, about "Inconsistent sample times." There is a mismatch between the specified sample time in the scopes and their input ports. The warning lets you know the scope decides the sample hits and not the Simulink engine.

Inputs Inherit Sample Time From Scope

Set the sample time for the Sine Wave1 and Sine Wave4 blocks to inherited (-1). The scope blocks backpropagate their sample time of 0.01 to these Sine Wave blocks. This change causes the two inherited sample time warning messages to appear again.

Avoid Backpropagation From Scope with Rate Transition Blocks

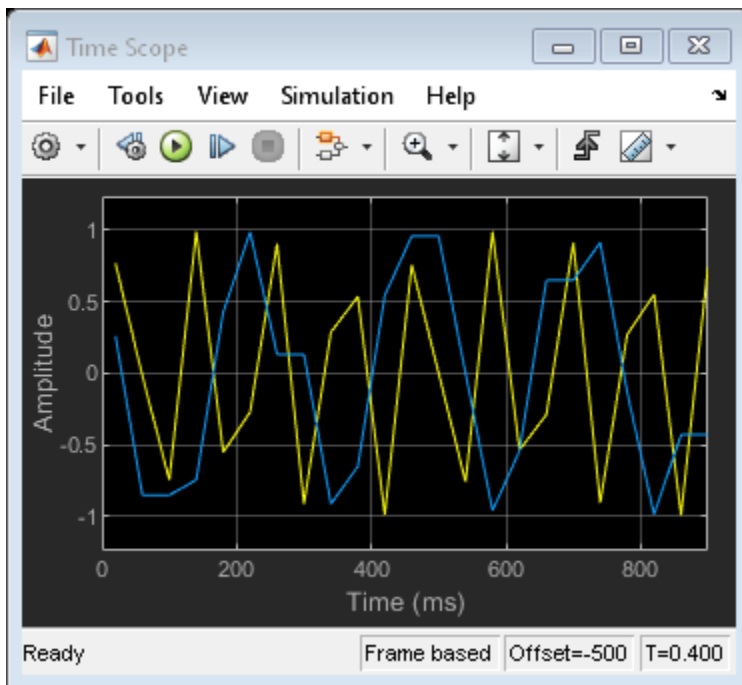

To avoid backpropagating sample time from the Scope to the blocks connected to it, either set the sample time on the connected blocks or use rate transition blocks. To specify the sample time on the connected blocks, set the sample time of Sine Wave1 and Sine Wave3 to 0.04 again.

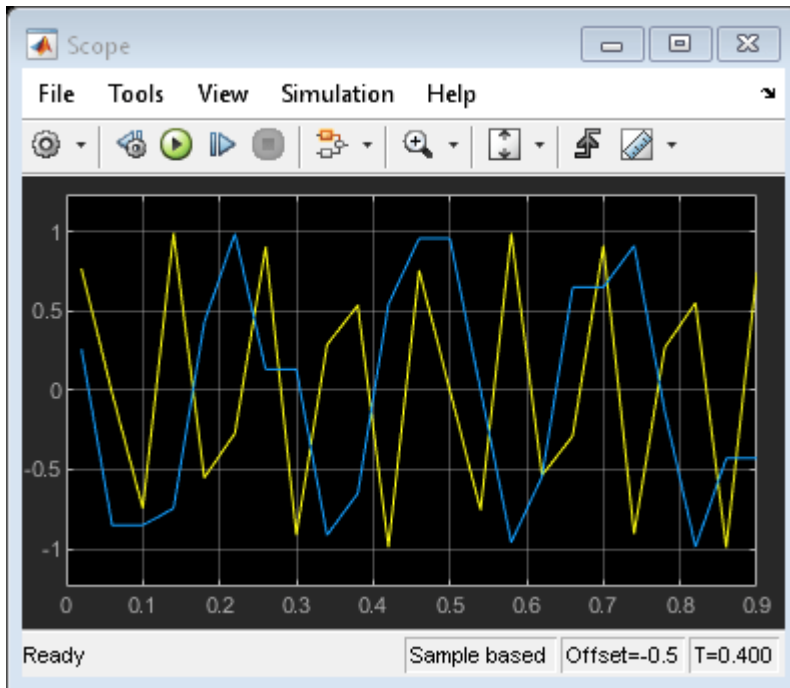

To use rate transition blocks, insert a Rate Transition block before the Scope and Time Scope blocks. When you add the rate transition blocks, the two scopes behave identically. Each source with a specified sample time is connected to a Rate Transition block that resamples the signals at the output port according to its own rules. A Rate Transition block also prevents propagation of sample times from one input to another through the scope block.

In this model, each input has a specified sample time and the scope blocks have inherited sample time.

View Data in the Simulation Data Inspector

You can use the Simulation Data Inspector to visualize the data you generate throughout the design process. Simulation data that you log in a Simulink model logs to the Simulation Data Inspector. You can also import test data and other recorded data into the Simulation Data Inspector to inspect and analyze it alongside the logged simulation data. The Simulation Data Inspector offers several types of plots, which allow you to easily create complex visualizations of your data.

View Logged Data

Logged signals as well as outputs and states logged using the `Dataset` format automatically log to the Simulation Data Inspector when you simulate a model. You can also record other kinds of simulation data so the data appears in the Simulation Data Inspector at the end of the simulation. To see states and output data logged using a format other than `Dataset` in the Simulation Data Inspector, in the **Model Configuration Parameters Data Import/Export** pane, select the **Record logged workspace data in Simulation Data Inspector** option.

Note When you log states and outputs using the `Structure` or `Array` format, you must also log time for the data to record to the Simulation Data Inspector.

The Simulation Data Inspector displays available data in the table in the **Inspect** pane. To plot a signal, select the check box next to the signal. You can modify the layout and add different visualizations to analyze the simulation data. For more information, see “Create Plots Using the Simulation Data Inspector” on page 29-135.

The Simulation Data Inspector manages incoming simulation data using the archive. By default, the previous run moves to the archive when you start a new simulation. You can plot signals from the archive, or you can drag runs of interest back into the work area.

Import Data from the Workspace or a File

You can import data from the base workspace or from a file to view on its own or alongside simulation data. The Simulation Data Inspector supports all built-in data types and many data formats for importing data from the workspace. In general, whatever the format, sample values must be paired with sample times. The Simulation Data Inspector allows up to 8000 channels per signal in a run created from imported workspace data.

You can also import data from these types of files:

- MAT file
- CSV file — Format data as shown in “Import Data from a CSV File into the Simulation Data Inspector” on page 29-68.
- Microsoft Excel file — Format data as described in “Microsoft Excel Import, Export, and Logging Format” on page 29-60.
- MDF file — MDF file import is supported for Linux and Windows operating systems. The MDF file must have a .mdf, .mf4, .mf3, .data, or .dat file extension and contain data with only integer and floating data types.

- ULG file — Flight log data import requires a UAV Toolbox license.

To import data from the workspace or from a file that is saved in a data or file format that the Simulation Data Inspector does not support, you can write your own workspace data or file reader to import the data using the `io.reader` class. You can also write a custom reader to use instead of the built-in reader for supported file types. For examples, see:

- “Import Data Using a Custom File Reader” on page 29-17
- “Import Workspace Variables Using a Custom Data Reader” on page 29-11

To import data, select the **Import** button in the Simulation Data Inspector.

In the Import dialog, you can choose to import data from the workspace or from a file. The table below the options shows data available for import. If you do not see your workspace variable or file contents in the table, that means the Simulation Data Inspector does not have a built-in or registered reader that supports that data. You can select which data to import using the check boxes, and you can choose whether to import that data into an existing run or a new run.

When you import data into a new run, the run always appears in the work area. You can manually move imported runs to the archive.

View Complex Data

To view complex data in the Simulation Data Inspector, import the data or log the signals to the Simulation Data Inspector. You can control how to visualize the complex signal using the **Properties** pane in the Simulation Data Inspector and in the **Instrumentation Properties** for the signal in the model. To access the **Instrumentation Properties** for a signal, right-click the logging badge for the signal and select **Properties**.

You can specify the **Complex Format** as Magnitude, Magnitude-Phase, Phase, or Real-Imaginary. If you select Magnitude-Phase or Real-Imaginary for the **Complex Format**, the Simulation Data Inspector plots both components of the signal when you select the check box for the signal. For signals in Real-Imaginary format, the **Line Color** specifies the color of the real component of the signal, and the imaginary component is a different shade of the **Line Color**. For example, the Rectangular QAM Modular Baseband signal on the lower graph displays the real component of

the signal in light blue, matching the **Line Color** parameter, and the imaginary component is shown in a darker shade of blue.

For signals in Magnitude-Phase format, the **Line Color** specifies the color of the magnitude component, and the phase is displayed in a different shade of the **Line Color**.

View String Data

You can log and view string data with your signal data in the Simulation Data Inspector. For example, consider this simple model. The value of the sine wave block controls whether the switch sends a string reading Positive or Negative to the output.

The plot shows the results of simulating the model. The string signal is shown at the bottom of the graphical viewing area. The value of the signal is displayed inside a band, and transitions in the string signal's value are marked with criss-crossed lines.

You can use cursors to inspect how the string signal values correspond with the sine signal's values.

When you plot multiple string signals on a plot, the signals stack in the order they were simulated or imported, with the most recent signal positioned at the top. For example, you might consider the effect of changing the phase of the sine wave controlling the switch.

View Frame-Based Data

Processing data in frames rather than point by point provides a performance boost needed in some applications. To view frame-based data in the Simulation Data Inspector, you have to specify that the signal is frame-based in the **Instrumentation Properties** for the signal. To access the **Instrumentation Properties** dialog for a signal, right-click the signal's logging badge and select **Properties**. To specify a signal as frame-based, select **Columns as channels (frame based)** for **Input processing**.

View Event-Based Data

You can log or import event data to the Simulation Data Inspector. To view the logged event-based data, select the check box next to **Send: 1**. The Simulation Data Inspector displays the data as a stem plot, with each stem representing the number of events that occurred for a given sample time.

Import Workspace Variables Using a Custom Data Reader

When your workspace data is in a format that built-in readers do not support, you can write a custom data reader to import the data into the Simulation Data Inspector. This example explains the parts of the class definition for a custom workspace reader and shows how to register the reader with the Simulation Data Inspector. Open the `SimpleStructReader.m` file to view the complete class definition.

Create Workspace Data

First, create workspace data to import into the Simulation Data Inspector using the custom reader. Suppose you store each signal as a structure with fields for the data (`d`), the time values (`t`), and the signal name (`n`).

```
time = 0:0.1:100;
time = time';
lineData = 1/4*time;
sineWave = sin((2*pi)/50*time);
squareWave = square((2*pi)/30*time);

mySineVar.d = sineWave;
mySineVar.t = time;
mySineVar.n = "Sine Wave";

myLineVar.d = lineData;
myLineVar.t = time;
myLineVar.n = "Line";

mySquareVar.d = squareWave;
mySquareVar.t = time;
mySquareVar.n = "Square Wave";
```

Write the Class Definition for a Custom Reader

Write a class definition that specifies how the custom reader extracts relevant data and metadata from the workspace variables. Save the class definition file in a location on the MATLAB™ path.

The class definition starts by inheriting from the `io.reader` class, followed by property and method definitions. The custom reader in this example defines the property `ChannelIndex`. You can use the reader to import individual structures or an array of structures from the workspace. The `ChannelIndex` property is used when importing an array of structures.

```
classdef SimpleStructReader < io.reader
    properties
        ChannelIndex
    end
```

Every custom reader must define the `getName`, `getTimeValues`, and `getDataValues` methods. When you write a custom reader to import data from the workspace, you must also define the `supportsVariable` method. The reader in this example also defines the `getChildren` method to support importing an array of structures.

The `supportsVariable` method checks which variables in the workspace are supported by the reader. In this example, the `supportsVariable` returns true when:

- 1 The structure contains the appropriate fields.
- 2 The n field of the structure contains a string or character array that represents the signal name.
- 3 The t field of the structure is a column vector of double data.
- 4 The d field contains numeric data.
- 5 The d field is the same size as the t field, meaning there is a sample value for each time step.

```
function supported = supportsVariable(~, val)
    % Support structure with fields t (time), d (data), and n (name)
    supported = ...
        isstruct(val) && ...
        isfield(val,'t') && ...
        isfield(val,'d') && ...
        isfield(val,'n');
    if supported
        for idx = 1:numel(val)
            varName = val(idx).n;
            time = val(idx).t;
            varData = val(idx).d;

            % Name must be string or character array
            if ~ischar(varName) && ~isstring(varName)
                supported = false;

            % Time must be double column vector
            elseif ~isa(time,'double') || ~iscolumn(time)
                supported = false;

            % Data size must match time size
            else
                timeSz = size(time);
                dataSz = size(varData);

                if ~isnumeric(varData) || ~isequal(dataSz, timeSz)
                    supported = false;
                end
            end
        end
    end
end
```

The `getChildren` method creates a `SimpleStructReader` object for each structure in an array of structures. When the variable to import is not scalar, the `getChildren` method assigns a value to the `ChannelIndex` property added to the class for the custom reader. The `VariableValue` property for each `SimpleStructReader` object returned by the `getChildren` method is the array of structures. Other methods use the `ChannelIndex` property to extract the appropriate signal name, signal data, and time values from each object.

```
function childObj = getChildren(obj)
    childObj = {};
    if ~isscalar(obj.VariableValue) && isempty(obj.ChannelIndex)
        numChannels = numel(obj.VariableValue);
        childObj = cell(numChannels,1);
        for idx = 1:numChannels
            childObj{idx} = SimpleStructReader;
            childObj{idx}.VariableName = sprintf('%s(%d)',obj.VariableName,idx);
            childObj{idx}.VariableValue = obj.VariableValue;
        end
    end
end
```

```

        childObj{idx}.ChannelIndex = idx;
    end
end
end

```

The `getName` method assigns the name stored in the `n` field of the structure to each imported signal. When the imported variable is scalar, the method gets the name from the `VariableValue` property of the `SimpleStructReader` object. When the imported data is an array of structures, the appropriate structure is extracted from the `VariableValue` property using the `ChannelIndex` property. The top-level node of the array is named `Signal Array`.

```

function retName = getName(obj)
    if isscalar(obj.VariableValue)
        retName = char(obj.VariableValue.n);
    elseif ~isempty(obj.ChannelIndex)
        varVal = obj.VariableValue(obj.ChannelIndex);
        retName = char(varVal.n);
    else
        retName = 'Signal Array';
    end
end
end

```

The `getTimeVals` and `getDataVals` methods handle scalar and nonscalar structures similar to how the `getName` method does. For a scalar structure, both methods extract the appropriate field from the `VariableValue` property of the `SimpleStructReader` object. For a nonscalar structure, both methods access the appropriate structure in the `VariableValue` property using the `ChannelIndex` property. Finally, for the top-level node of the array, time and data are both returned as empty.

```

function timeVals = getTimeValues(obj)
    if isscalar(obj.VariableValue)
        timeVals = obj.VariableValue.t;
    elseif ~isempty(obj.ChannelIndex)
        varVal = obj.VariableValue(obj.ChannelIndex);
        timeVals = varVal.t;
    else
        timeVals = [];
    end
end

function dataVals = getDataValues(obj)
    if isscalar(obj.VariableValue)
        dataVals = obj.VariableValue.d;
    elseif ~isempty(obj.ChannelIndex)
        varVal = obj.VariableValue(obj.ChannelIndex);
        dataVals = varVal.d;
    else
        dataVals = [];
    end
end
end

```

Register a Custom Reader

After you write the class definition for the custom reader, you must register the reader before you can use it to import data into the Simulation Data Inspector. The Simulation Data Inspector does not store registered readers between MATLAB sessions, so you need to register a custom reader at the start of each new MATLAB session. To register the workspace data reader in this example, use the `registerWorkspaceReader` method.

```
registerWorkspaceReader(SimpleStructReader);
```

To confirm that the reader is registered, use the `io.reader.getRegisteredWorkspaceReaders` method.

```
io.reader.getRegisteredWorkspaceReaders
```

```
ans =  
"SimpleStructReader"
```

Import Workspace Data in a Custom Format

Once you register the custom workspace data reader, you can import workspace variables stored using the custom format into the Simulation Data Inspector using the UI or the `Simulink.sdi.createRun` function.

To import data using the UI, open the Simulation Data Inspector. You can use the `Simulink.sdi.view` function to open the Simulation Data Inspector from the MATLAB Command Window. Then, select **Import**.

The Import dialog shows the data in the base workspace that the Simulation Data Inspector is able to import using built-in and registered custom readers. Because the custom reader is registered, the `Line`, `Sine Wave`, and `Square Wave` signals are available for import, while the `lineData`, `sineWave`, and `squareWave` variables are not. Select the data you want to import and select **Import**. The data imports into a run called `Imported_Data`.

To import data from the workspace programmatically, use the `Simulink.sdi.createRun` function.

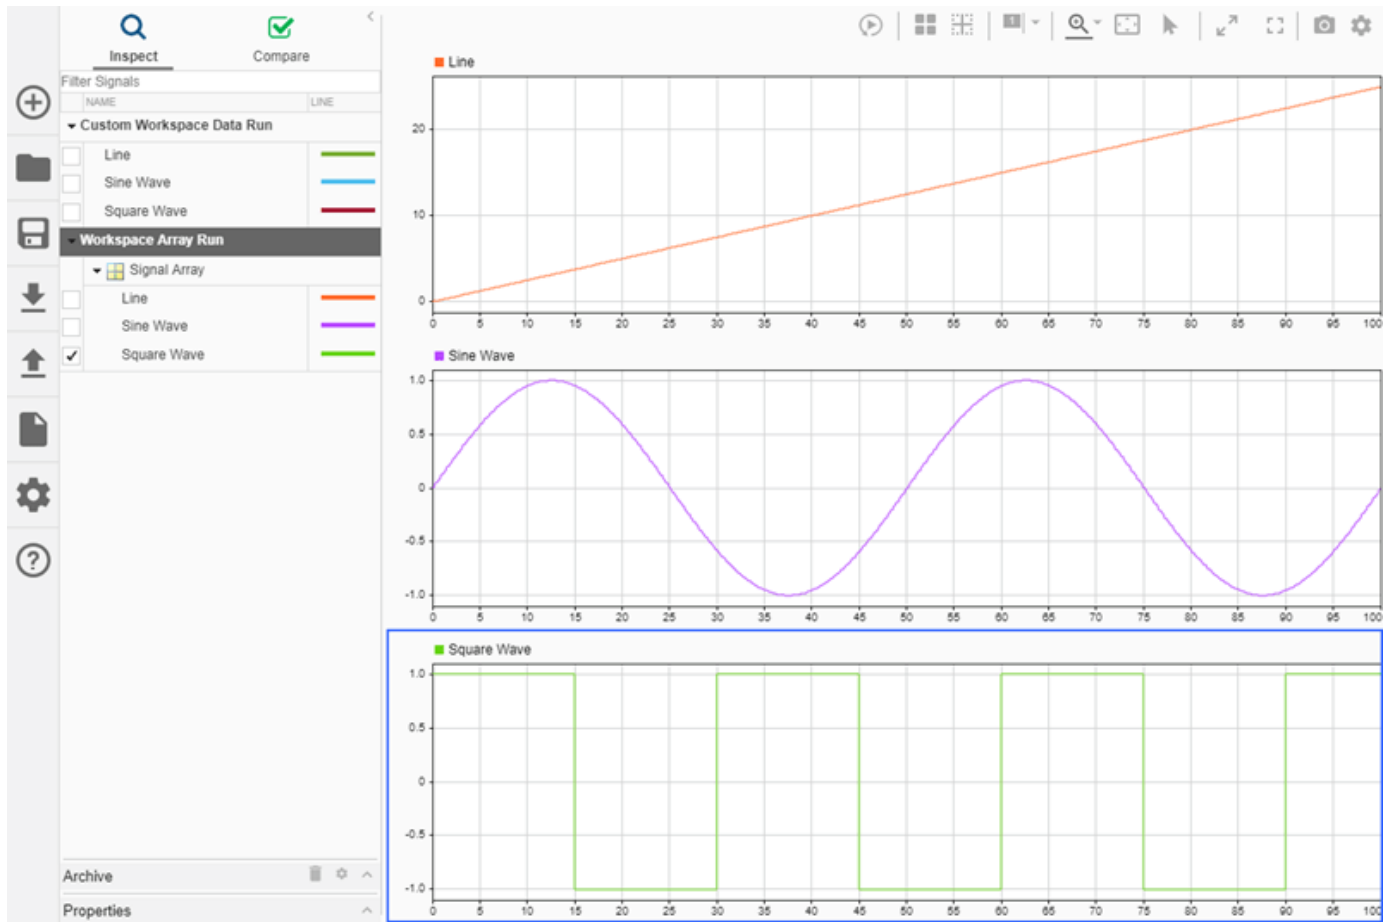

```
Simulink.sdi.createRun('Custom Workspace Data Run', 'vars', myLineVar, mySineVar, mySquareVar);
```

The custom reader in this example can also import an array of structures. Importing an array of workspace variables rather than importing them individually groups the variables together when you import the data to an existing run. Create an array that contains the `myLineVar`, `mySineVar`, and `mySquareVar` structures, and import the array using the `Simulink.sdi.createRun` function.

```
myVarArray = [myLineVar; mySineVar; mySquareVar];
Simulink.sdi.createRun('Workspace Array Run', 'vars', myVarArray);
```

Inspect and Analyze Imported Data

After importing data, you can use the Simulation Data Inspector to inspect and analyze the imported data on its own or alongside related simulation data.

More About

- “View Data in the Simulation Data Inspector” on page 29-2
- “Import Data Using a Custom File Reader” on page 29-17

Import Data Using a Custom File Reader

When you want to visualize data stored in a data or file format the Simulation Data Inspector does not support, you can use the `io.reader` class to write your own custom file reader for the Simulation Data Inspector. This example explains the parts of a class definition for a custom file reader and demonstrates how to register the reader with the Simulation Data Inspector. Open the `ExcelFirstColumnTimeReader.m` file to view the complete class definition.

Write the Class Definition for a Custom Reader

Write a class definition that specifies how your custom reader extracts relevant data and metadata from files and variables that use custom formats. Save the class definition file in a location on the MATLAB™ path.

The custom reader in this example uses the `readtable` function to load data from a Microsoft Excel™ file and uses the first column in the file as time data.

The class definition starts by inheriting from the `io.reader` class, followed by method definitions that return required and relevant data and metadata.

```
classdef ExcelFirstColumnTimeReader < io.reader
```

Every custom reader must define the `getName`, `getTimeValues`, and `getDataValues` methods. Additional methods are available to access certain metadata that might exist in the custom file. The class definition for this example defines the abstract methods as well as the `supportsFile` and `getChildren` methods.

The `supportsFile` method checks the file contents to make sure the file contains signal data.

```
function supported = supportsFile(~,filename)
    try
        t = readtable(filename);
        supported = height(t) > 0 && numel(t.Properties.VariableNames) > 1;
    catch
        supported = false;
    end
end
```

To import multiple signals from a file, treat the data as hierarchical with the file being the top node. The reader uses the `getChildren` method to create an `ExcelFirstColumnTimeReader` object for each signal in the file.

```
function childObj = getChildren(obj)
    childObj = {};
    if isempty(obj.VariableName)
        t = readtable(obj.FileName);
        vars = t.Properties.VariableNames;
        vars(1) = [];
        childObj = cell(size(vars));
        for idx = 1:numel(vars)
            childObj{idx} = ExcelFirstColumnTimeReader;
            childObj{idx}.FileName = obj.FileName;
            childObj{idx}.VariableName = vars{idx};
        end
    end
end
```

The `getTimeValues` method reads the data in the file using the `readtable` function and returns the data in the first column for the Simulation Data Inspector to use as time data.

```
function timeVals = getTimeValues(obj)
    timeVals = [];
    if ~isempty(obj.VariableName)
        t = readtable(obj.FileName);
        timeName = t.Properties.VariableNames{1};
        timeVals = t.(timeName);
    end
end
```

The `getName` method uses the file name as the name for the top-level node of the imported data. Signals are named using the `VariableName` property for the corresponding `ExcelFirstColumnTimeReader` object returned by the `getChildren` method.

```
function retName = getName(obj)
    if isempty(obj.VariableName)
        fullName = obj.FileName;
        [filepath,name,ext] = fileparts(fullName);
        retName = strcat(name,ext);
    else
        retName = obj.VariableName;
    end
end
```

The `getDataValues` method returns the data in each column that has data besides the first as signal data. Data for each signal is accessed using the `VariableName` property for the corresponding object returned by the `getChildren` method.

```
function dataVals = getDataValues(obj)
    dataVals = [];
    if ~isempty(obj.VariableName)
        t = readtable(obj.FileName);
        dataVals = t.(obj.VariableName);
    end
end
```

Register a Custom Reader for the Simulation Data Inspector

After you write the class definition file for the custom data reader, you need to register the reader with the Simulation Data Inspector before you can use it to import data. The Simulation Data Inspector does not store registered readers between MATLAB sessions, so you need to register a custom reader at the start of each new MATLAB session. You can register a custom reader to read data from the workspace or to read data from a file. To register the file reader in this example, use the `registerFileReader` method.

```
registerFileReader(ExcelFirstColumnTimeReader,['.xlsx' 'xls']);
```

To confirm that the file reader is registered, use the `io.reader.getRegisteredFileReaders` method.

```
io.reader.getRegisteredFileReaders
ans =
"ExcelFirstColumnTimeReader"
```

Import Data from a File in a Custom Format

Once you register the custom file reader, you can import data from a file in a custom format using the Simulation Data Inspector UI or using the `Simulink.sdi.createRun` function. This example imports a simple data set from a file that contains four columns of data. The custom file reader in this example always loads the first column, in this case `a`, as time data.

	A	B	C	D
1	a	b	c	d
2	1	6	6	1
3	2	5	4	7
4	3	4	2	6
5	4	3	6	1
6	5	2	7	3
7	6	1	2	4

To import the data using the UI, open the Simulation Data Inspector. You can use the `Simulink.sdi.view` function to open the Simulation Data Inspector from the MATLAB Command Window. Then, click the **Import** button.

In the Import dialog, select the **File** option and import the data from the file into a new run. Click the folder to browse the file system and select the file you want to import. The file for this example is called `CustomFile.xlsx`.

After you select a file with an extension that corresponds to one or more registered custom readers, an option to select the reader you want to use appears in the dialog. In this example, you can choose between the built-in Microsoft Excel file reader or the custom reader written for this example. By default, a custom reader is selected when one is available for the extension of the selected file.

You can choose which signals you want to import from the file. After making your selection, click **Import**. The data is imported to a new run called `Imported_Data`.

To import data programmatically, you can use the `Simulink.sdi.createRun` function. The Simulation Data Inspector has a built-in reader for Microsoft Excel files. You can specify which reader to use to import the data in the call to the `Simulink.sdi.createRun` function. When you do not specify the reader you want to use to import the data, the Simulation Data Inspector uses the first custom reader that supports the file extension.

```
Simulink.sdi.createRun('Custom File Run','file','CustomFile.xlsx','ExcelFirstColumnTimeReader');
```

Inspect and Analyze Imported Data

After importing your data, you can use the Simulation Data Inspector to inspect and analyze the imported data on its own or alongside related simulation data.

View and Replay Map Data

You can add a map to your layout in the Simulation Data Inspector to view routes of longitude and latitude data. The map data is synchronized with signal data in the Simulation Data Inspector, allowing you to analyze signal activity throughout the route. To analyze the relationship between the route and signal values, you can replay the data. When you replay data in the Simulation Data Inspector, synchronized cursors and markers move across the plots in the view.

To view map data in the Simulation Data Inspector, you must have an active internet connection.

If your model includes latitude and longitude signals, you can log data to the Simulation Data Inspector and visualize it during simulation. You can also import the data from the workspace or a file using the instructions in “Import Data from the Workspace or a File” on page 29-3 or the `Simulink.sdi.createRun` function. For this example, import a file of recorded map and speed data using `Simulink.sdi.createRun`. Then, open the Simulation Data Inspector.

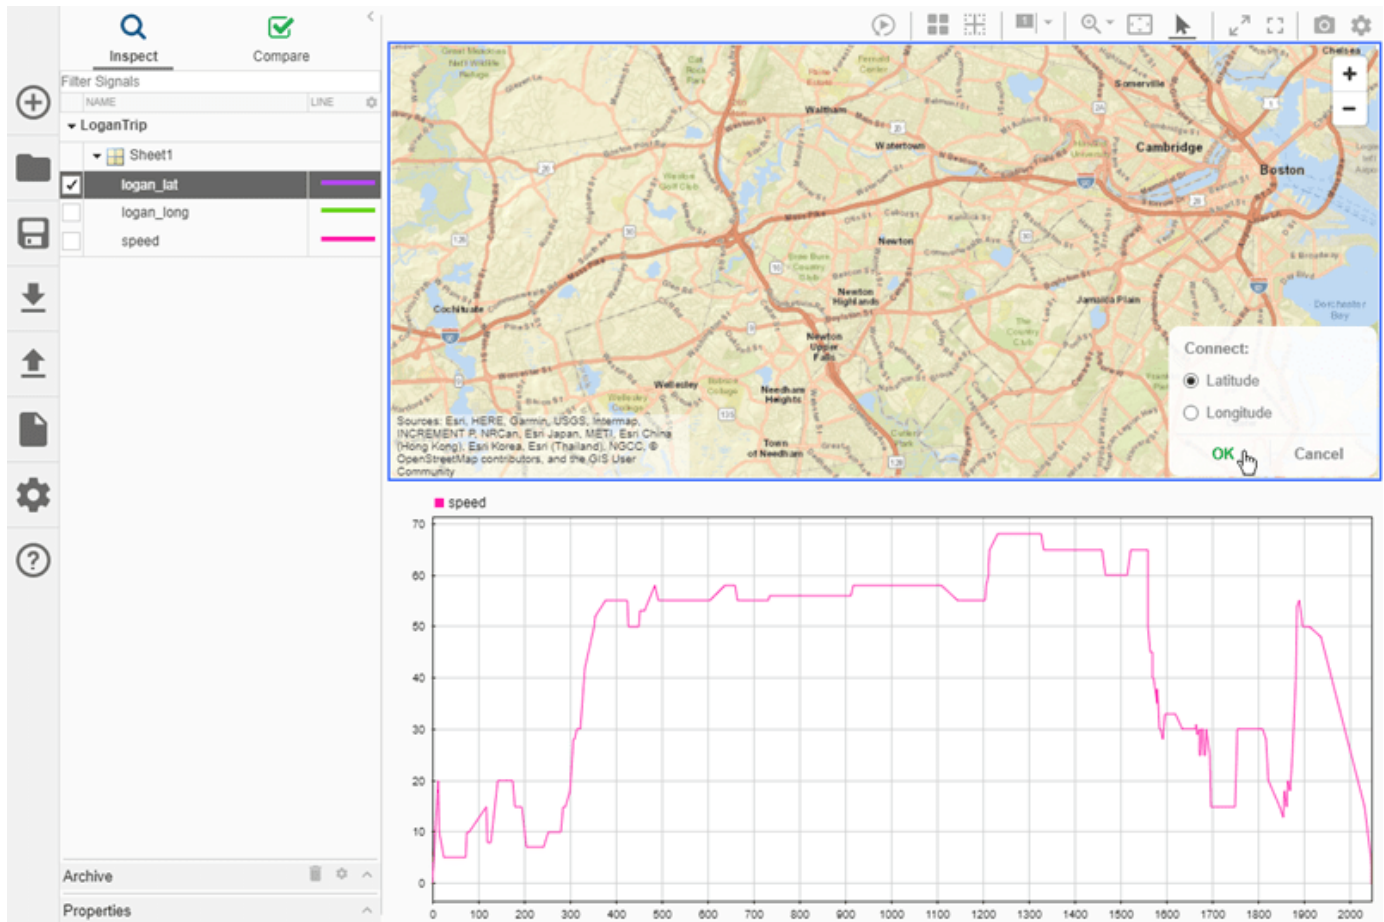

```
mapRun = Simulink.sdi.createRun('LoganTrip', 'file', 'logan_ah_gps_data.xlsx');  
Simulink.sdi.view
```

View Map Data

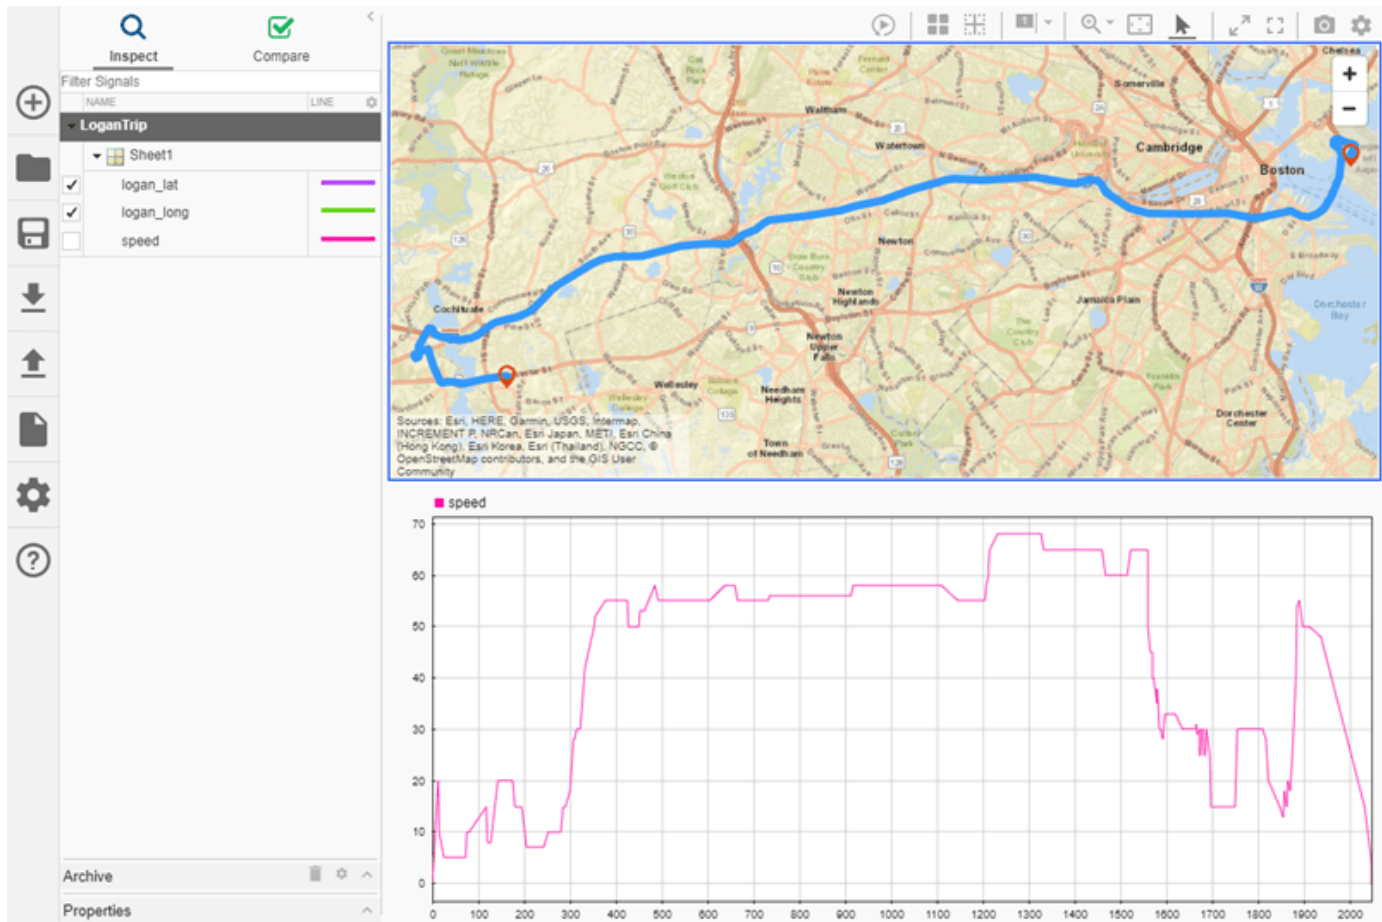

Configure the plot area in a 2x1 layout so you can view the speed data and map data together. To plot the speed data on the lower plot, select the plot and then select the check box next to the speed signal. To add a map to the layout, open the **Visualization Gallery** by clicking **Edit View** on the **Layout** menu.

From the visualization gallery, drag a map onto the top subplot in the layout. Check the `logan_lat` signal and click **OK** on the dialog in the bottom-right of the map to use the signal to specify the latitude data on the map.

Then, check the `logan_long` signal and click **OK** to use the signal as longitude data on the map.

You can also plot map data by selecting multiple signals while holding **Ctrl** and then dragging those signals onto the map. The menu in the lower-right shows drop-downs you can use to specify which signal to use for the latitude data and which to use for the longitude data.

You can add cursors to the plots to analyze the relationship between the speed signal and the route shown on the map. To add two cursors to the layout, click the drop-down arrow on the cursors button in the toolbar and select **Two Cursors**. Move the cursor on the left. The marker on the right of the map moves as you move the left cursor because the route starts in Boston and moves East to West with time.

To remove the cursors from the plot, click the **Show/hide data cursors** button.

Replay Map Data

You can replay data in the Simulation Data Inspector to automate moving cursors across the visualizations in your view. To add the replay controls to the view, click the **Show/hide replay**

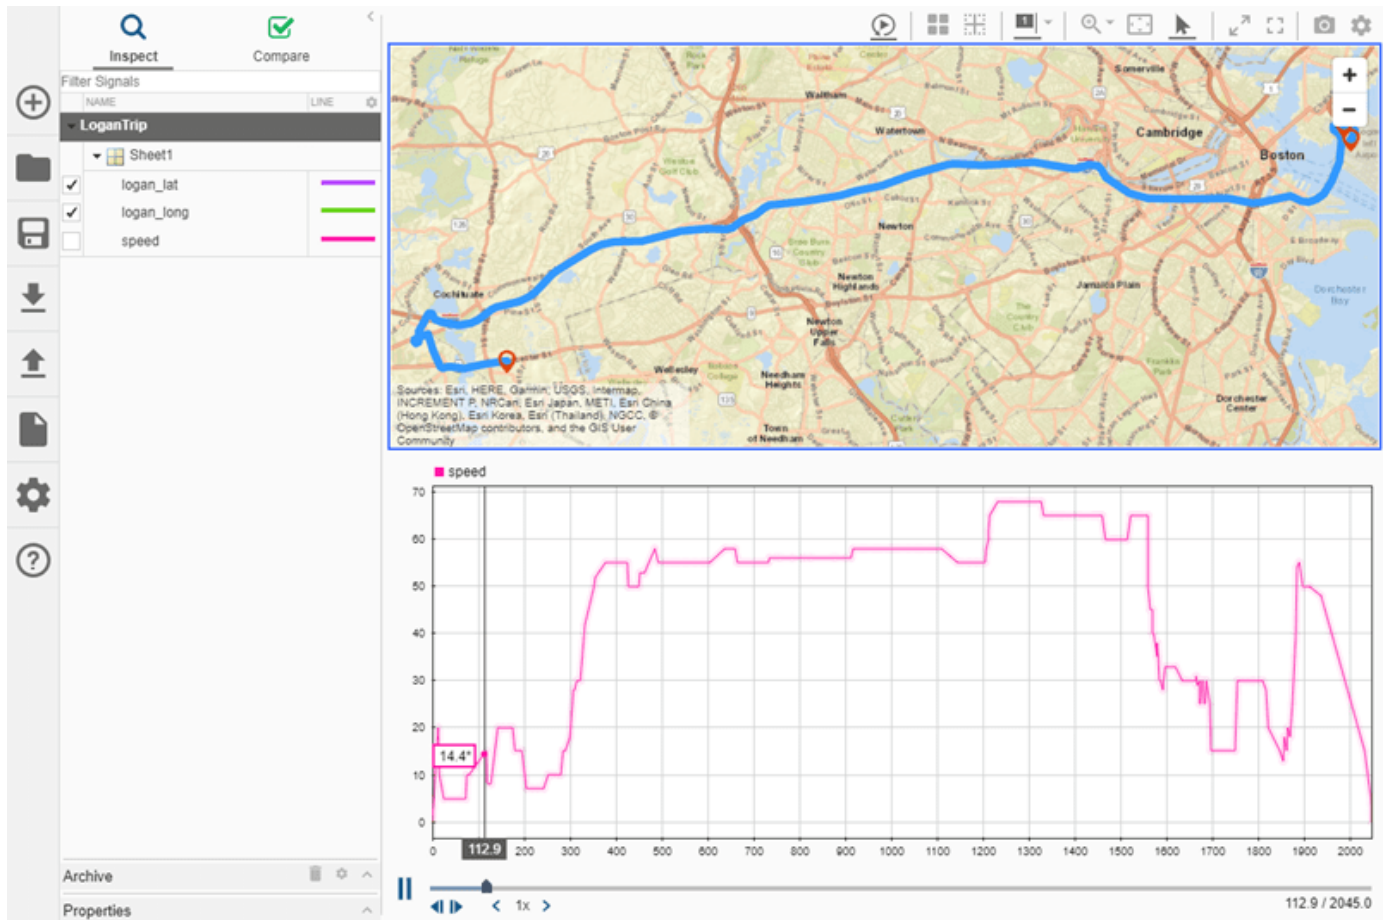

controls button.

Then, press the **Replay** button.

A data marker on the map and a cursor on the time plot sweep synchronously across the screen. The synchronous replay facilitates an intuitive understanding of the relationship between speed and position throughout the trip.

By default, the Simulation Data Inspector replays data at one second per second, meaning that the cursor moves through one second of data in one second of clock time. The data for this trip spans approximately 34 minutes. You can increase the replay speed using the arrow to the right of the label or by clicking the label and typing the desired speed. Increase the replay speed to 32x using the arrow.

For another example, see “Replay Data in the Simulation Data Inspector” on page 29-166.

Visualize Simulation Data on an XY Plot

When you log simulation data in a model, you can view the simulation results on an XY plot in the Simulation Data Inspector. Then, you can replay the simulation to animate the relationships between the signals in your model. This example simulates a model and plots data logged in the simulation using time plots and XY plots in the Simulation Data Inspector. The example also shows how to inspect the plotted data using replay controls and cursors. The XY plot used in this example is also available in the Record and XY Graph blocks.

Simulate the Model and Open the Simulation Data Inspector

The model in this example simulates the dynamics of a bouncing ball, logging the velocity and position of the ball as outputs.

```
open_system('ex_sl-demo_bounce')
```

Because the model is configured to log output data, the signals connected to the Output blocks log to the workspace and the Simulation Data Inspector. To simulate the model, click **Run**. Then, under **Review Results**, click **Data Inspector** to open the Simulation Data Inspector.

```
sim('ex_sl-demo_bounce');
Simulink.sdi.view
```

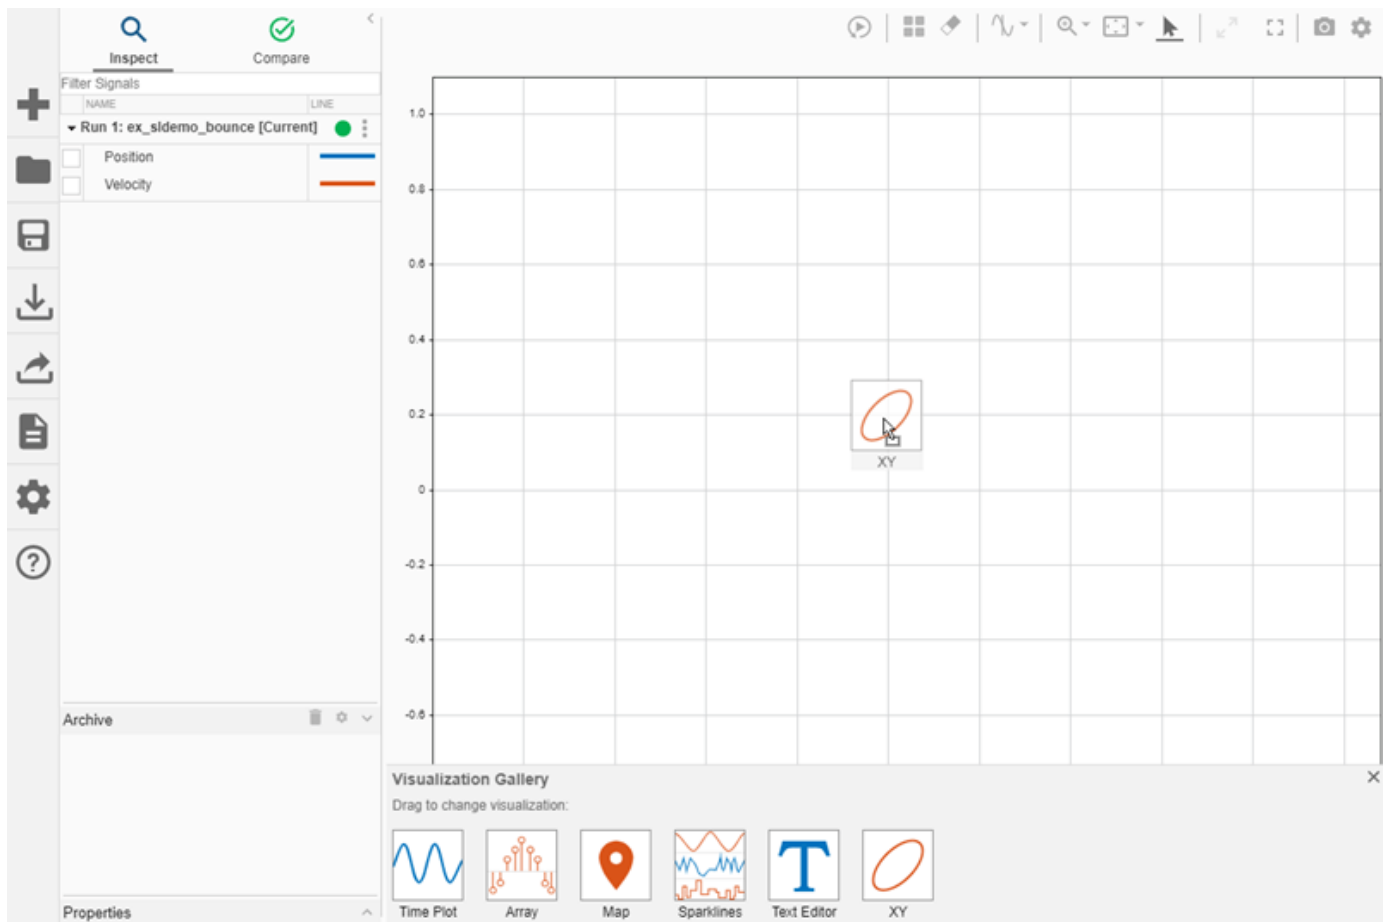

Plot Data on an XY Plot

To plot the data on an XY plot, you need to add the visualization to the layout. By default, the Simulation Data Inspector uses time plots for each subplot in the layout.

To add an XY plot to your layout, open the Layout menu and click **Edit View** to open the **Visualization Gallery**.

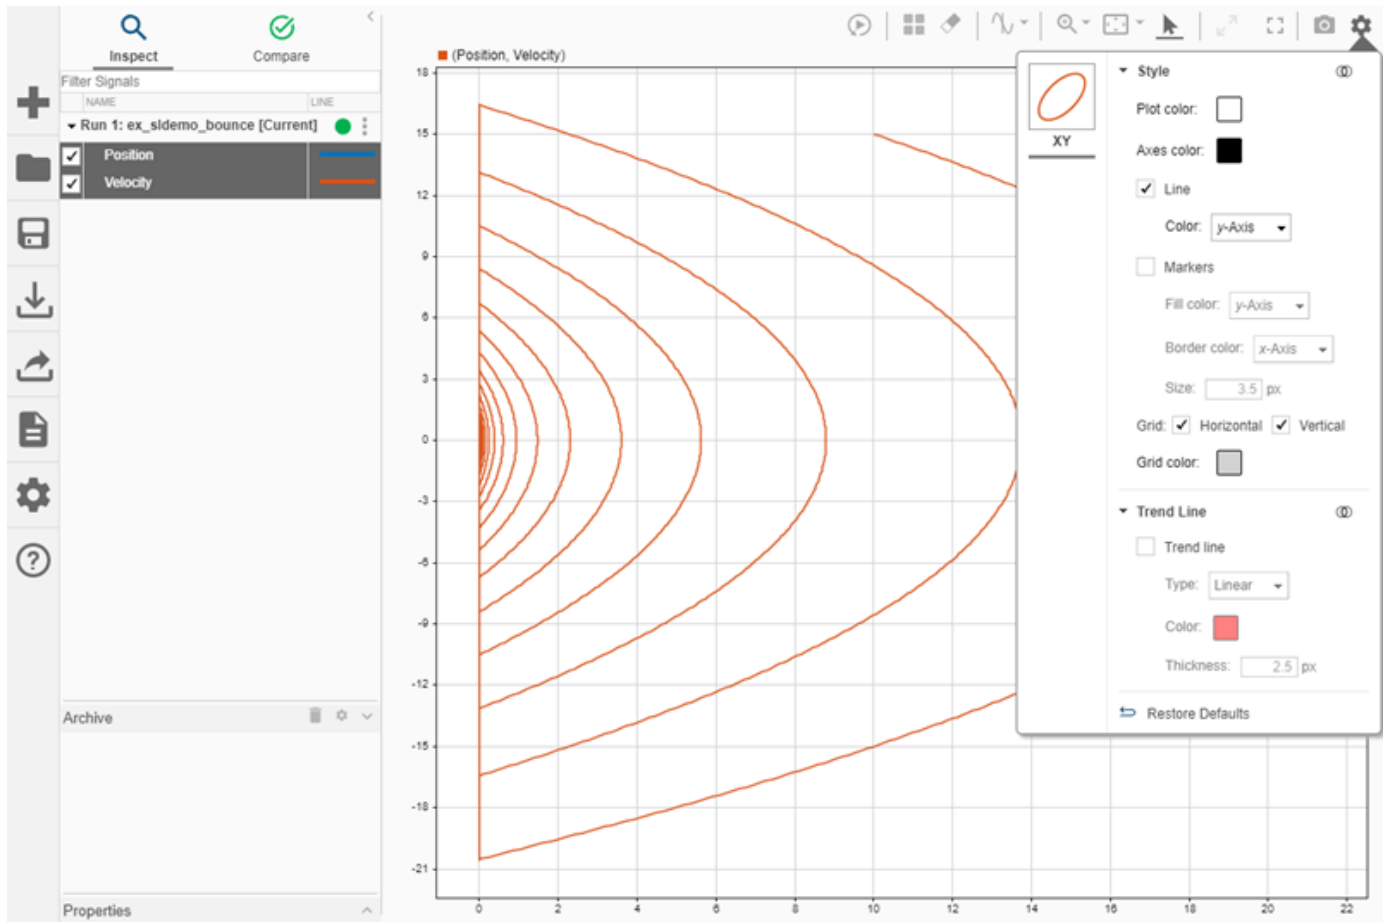

From the **Visualization Gallery**, drag and drop the **XY** icon onto the plot.

To plot the signals on the XY plot, select both signals then drag and drop them onto the plot. You can specify which signal to use as the x data and which to use as the y data. For this example, use **Position** as the x data and **Velocity** for the y data.

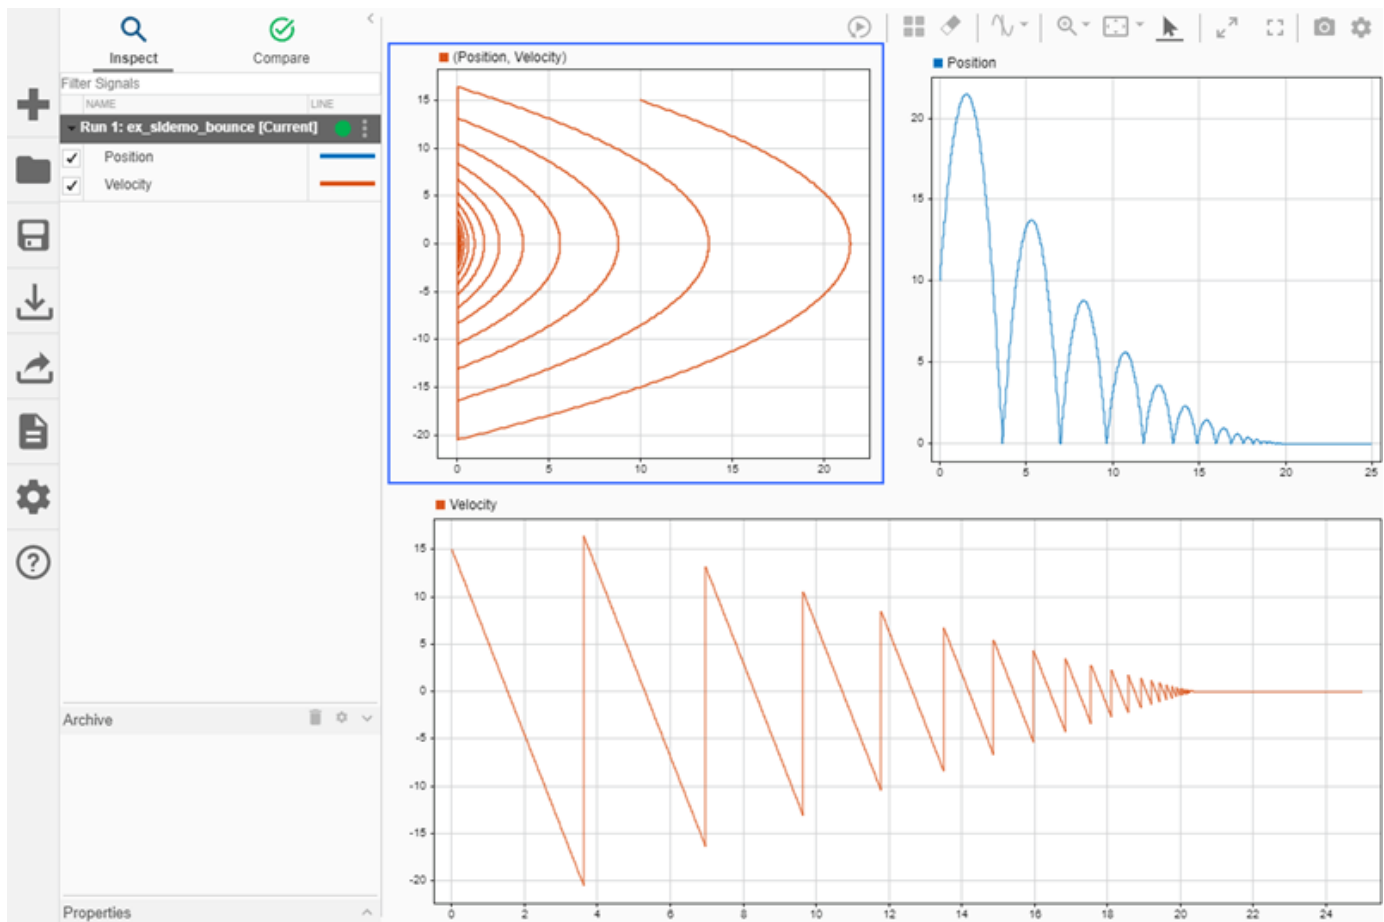

You can modify the appearance of the XY plot by opening the Visualization Settings. The line and marker colors match the color of the signal that provides the x data or the signal that provides the y data. By default, the line uses the y-axis signal color.

Add Time Plots and Inspect the Data

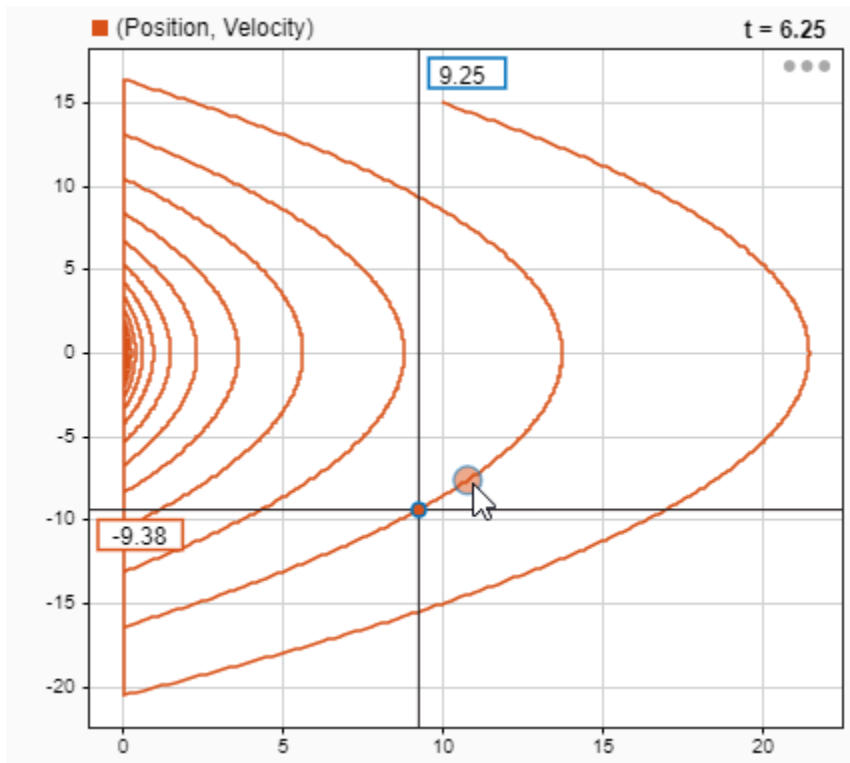

You can include multiple visualizations in a layout in the Simulation Data Inspector. For example, you can choose to use a layout with three subplots so you can see each signal on a time plot alongside the XY plot.

In the Layout menu, from the **Basic Layouts** section, select the layout with two subplots on top of a third. Then, plot the **Position** signal in the upper-right time plot, and plot the **Velocity** signal on the bottom time plot.

To inspect the data, add a cursor. In the XY plot, the vertical line of the cursor shows the x-axis value, and the horizontal line shows the y-axis value. The time corresponding to the point is displayed in the upper-right of the plot.

Move the cursor in the XY plot along the plotted line. As you move the cursor, the next data point for the cursor to snap to is highlighted. You can also move the cursor in the XY plot using the arrow keys on your keyboard or by pausing on a point on the line and clicking the highlighted point.

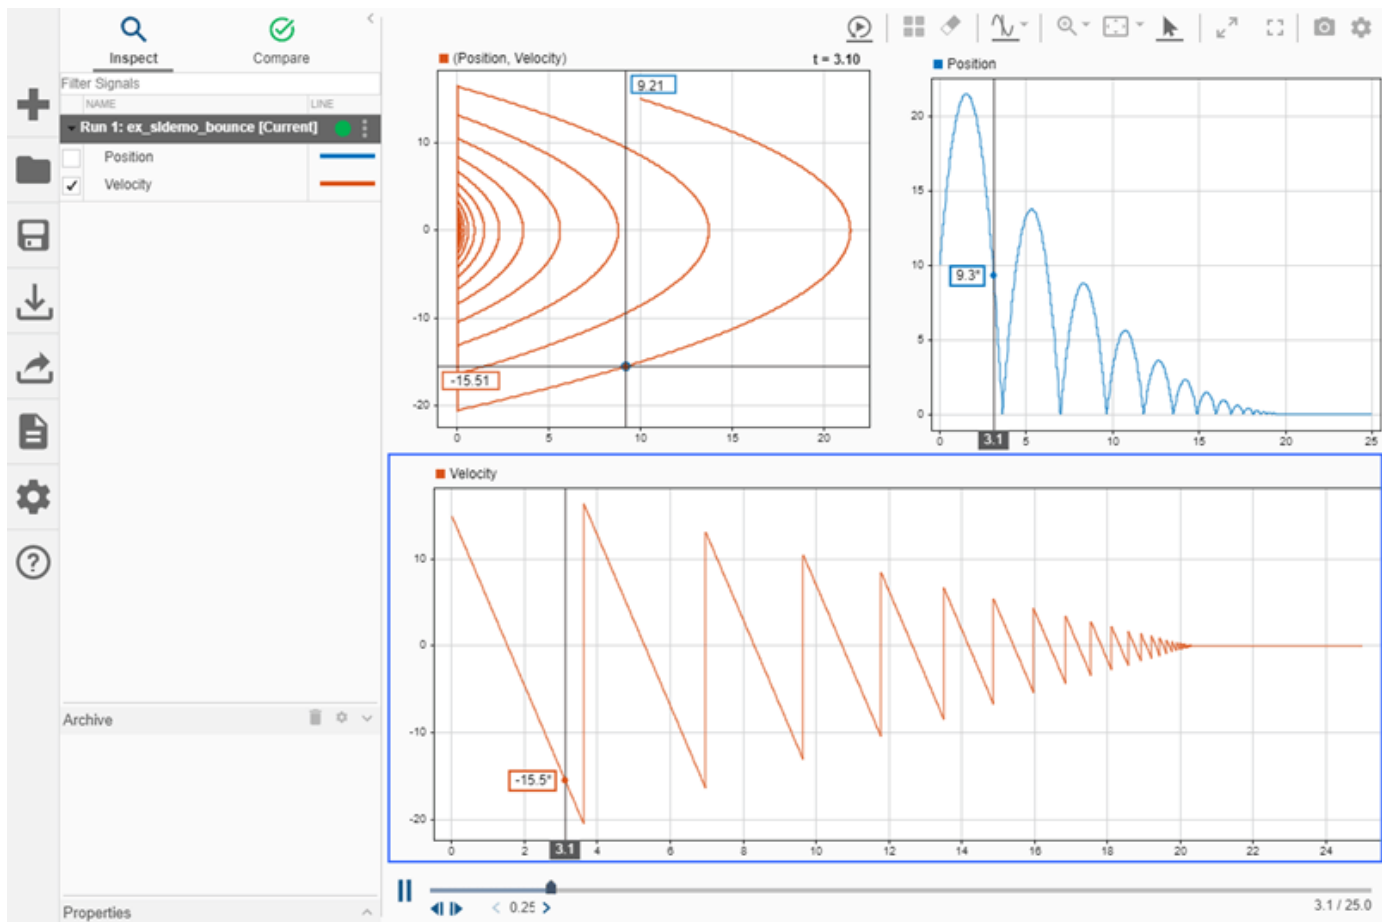

When you drag a cursor in a time plot, the cursor in the XY plot moves synchronously through the plotted data. The XY plot can only have one cursor. When you add two cursors to the layout, the XY cursor moves with the left cursor in the time plot.

Replay the Data

Now that you have a comprehensive visualization of the simulation data, replaying the data can help you understand the relationship between the signals. When you replay data in the Simulation Data Inspector, animated cursors sweep through the logged simulation data from the start time to the end time. Add the replay controls to the view by clicking Show/hide replay controls.

You can control the speed of the replay and pause at any time. By default, the Simulation Data Inspector replays data at one second per second, meaning the cursor moves through one second of data in one second of clock time. The data in this example spans 25 seconds. Slow the replay speed by clicking the arrow to the left of the label.

For more information about using replay controls, see “Replay Data in the Simulation Data Inspector” on page 29-166.

Analyze Data from Multiple Simulations

To analyze how changes in simulation parameters affect the data, you can plot multiple series on an XY plot. Using the Simulink® Editor or the MATLAB™ Command Window, change the **Initial value** parameter of the Initial Velocity block to 25 and simulate the model.

```
set_param('ex_sl-demo_bounce/Initial Velocity', 'Value', '25')
sim('ex_sl-demo_bounce');
```

The Simulation Data Inspector moves the first run to the archive and transfers the view to the new run. Drag the first run from the archive into the work area.

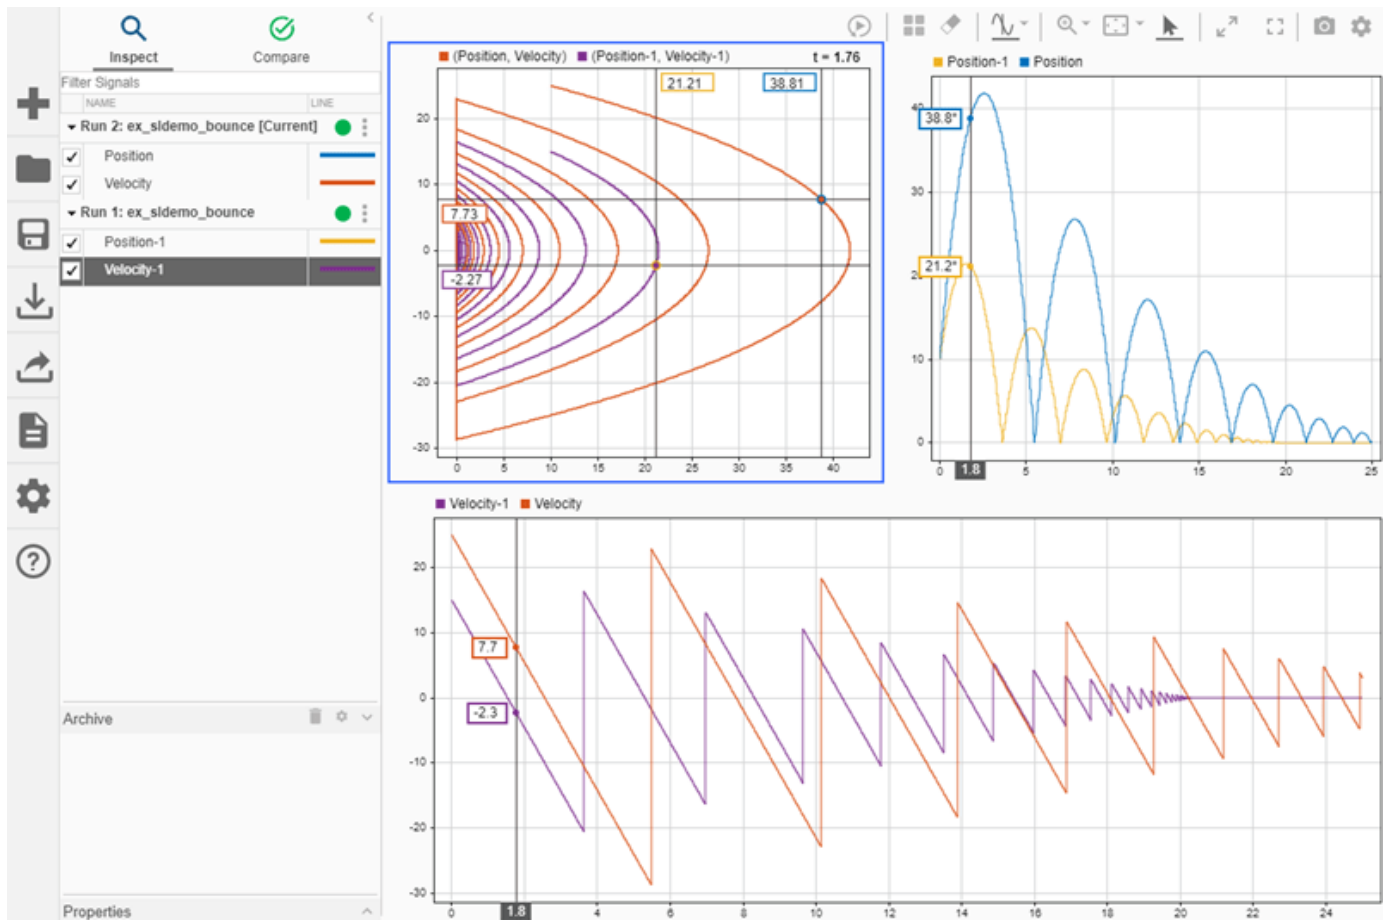

The signals in both runs have the same names and the same signal colors. Before you add data from the first run to the plots, change the signal names and colors. For example, you can rename the signals from the first run **Position-1** and **Velocity-1**. To modify a signal color, click the line representation in the table, select a new color, and click **Set**. To modify the signal names, double-click the name in the table and enter the new name.

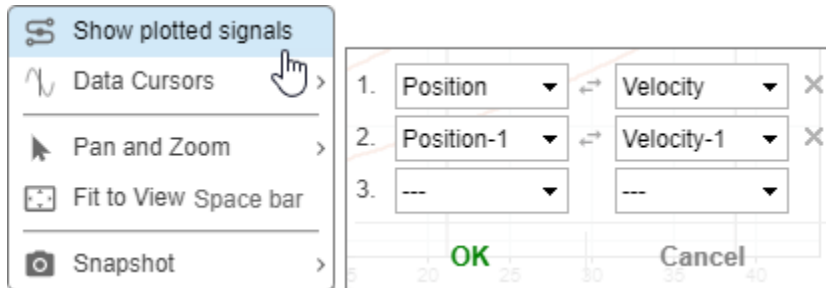

Now, add the data from the first run to the plots in the layout. Plot the signals from the first run on the time plots. To add another series to the XY plot, select both signals and drag them onto the XY plot. The series menu shows the first series that is already plotted. Select the `Position-1` signal as the x-data for series 2 and `Velocity-1` as the series 2 y-data. Then, click **OK**.

When you add multiple series to an XY plot, each series gets a cursor. All cursors on the XY plot move synchronously, so all signal values displayed on the cursors correspond to the same time.

You can manage the signals plotted on an XY plot using the subplot context menu. Right-click the XY plot and select **Show plotted signals**. From the series menu, you can remove series from the plot or modify which signals provide the x-data and y-data for each series.

Analyze Data Using the XY Plot

In the Simulation Data Inspector, you can plot time series data on an XY plot to analyze relationships between signals. This example demonstrates how to view and analyze data on an XY plot using trend lines. The example data file attached includes more data than the example covers. You can apply the steps in the following sections to each set of signals to use each trend line option.

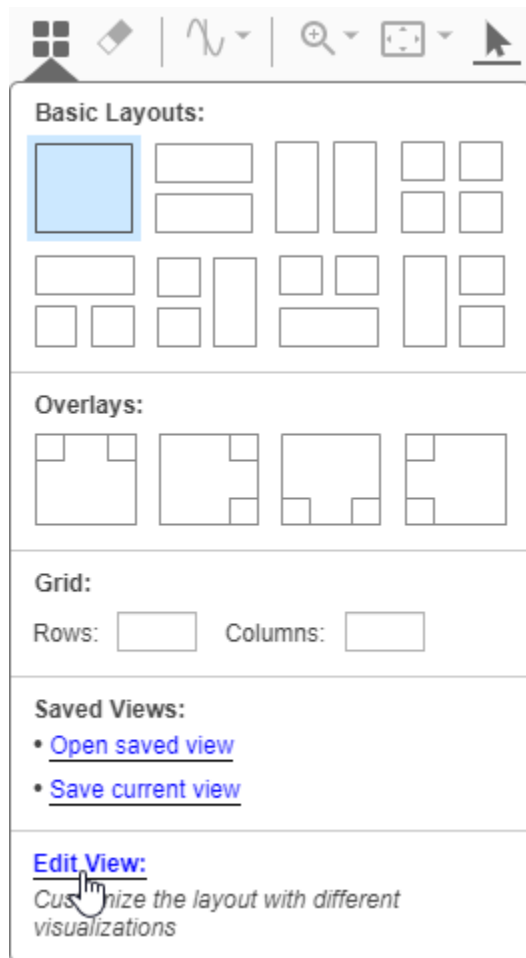

Import and Plot Data on the XY Plot

The data for this example is stored in a MAT file. You can import the data using the UI, or you can use the `Simulink.sdi.createRun` function. Then, open the Simulation Data Inspector to view the data.

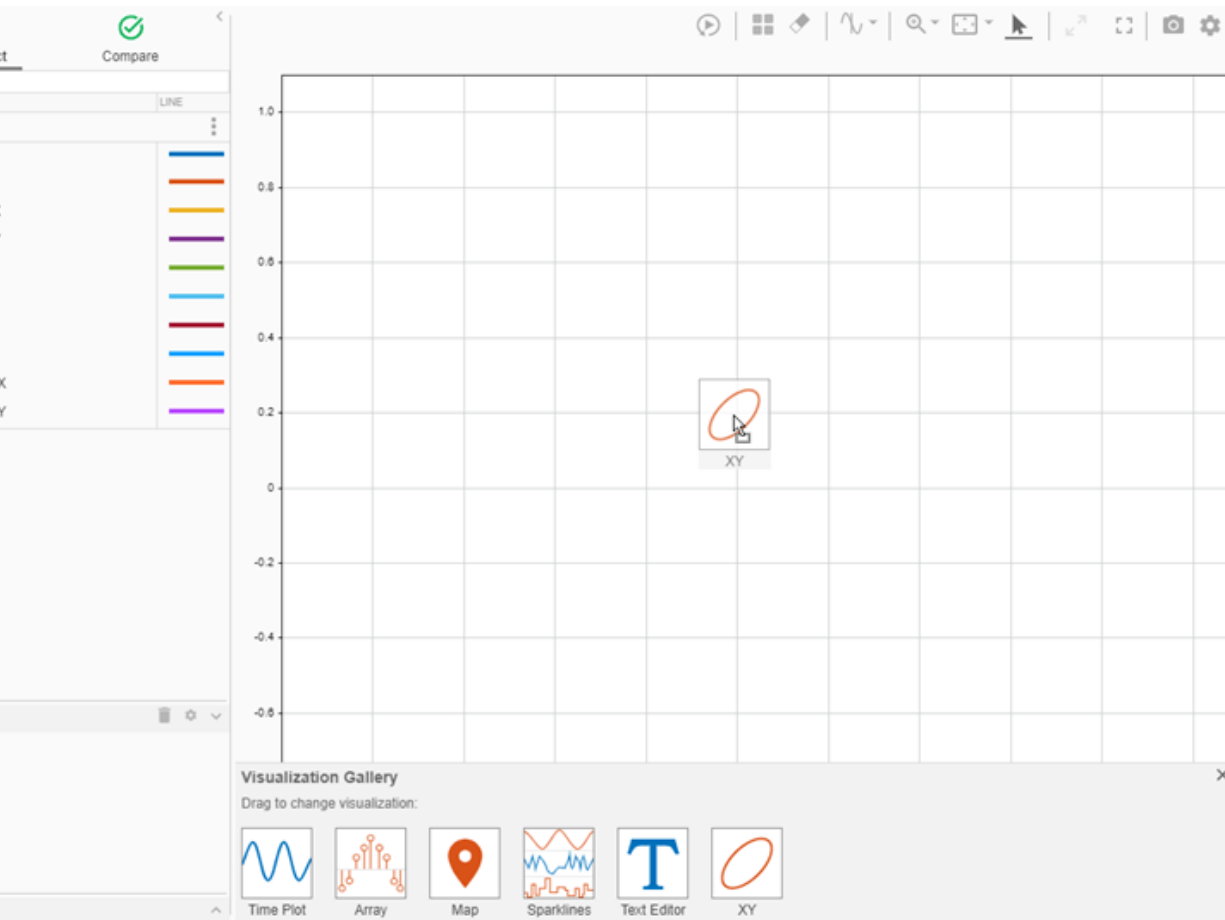

```
xyRunID = Simulink.sdi.createRun('XY signals', 'file', 'ex_xy_data.mat');
Simulink.sdi.view
```

To plot the data on an XY plot, you need to add the visualization to the layout. By default, the Simulation Data Inspector uses time plots for each subplot in the layout.

To add an XY plot to your layout, open the Layouts menu and select **Edit View**.

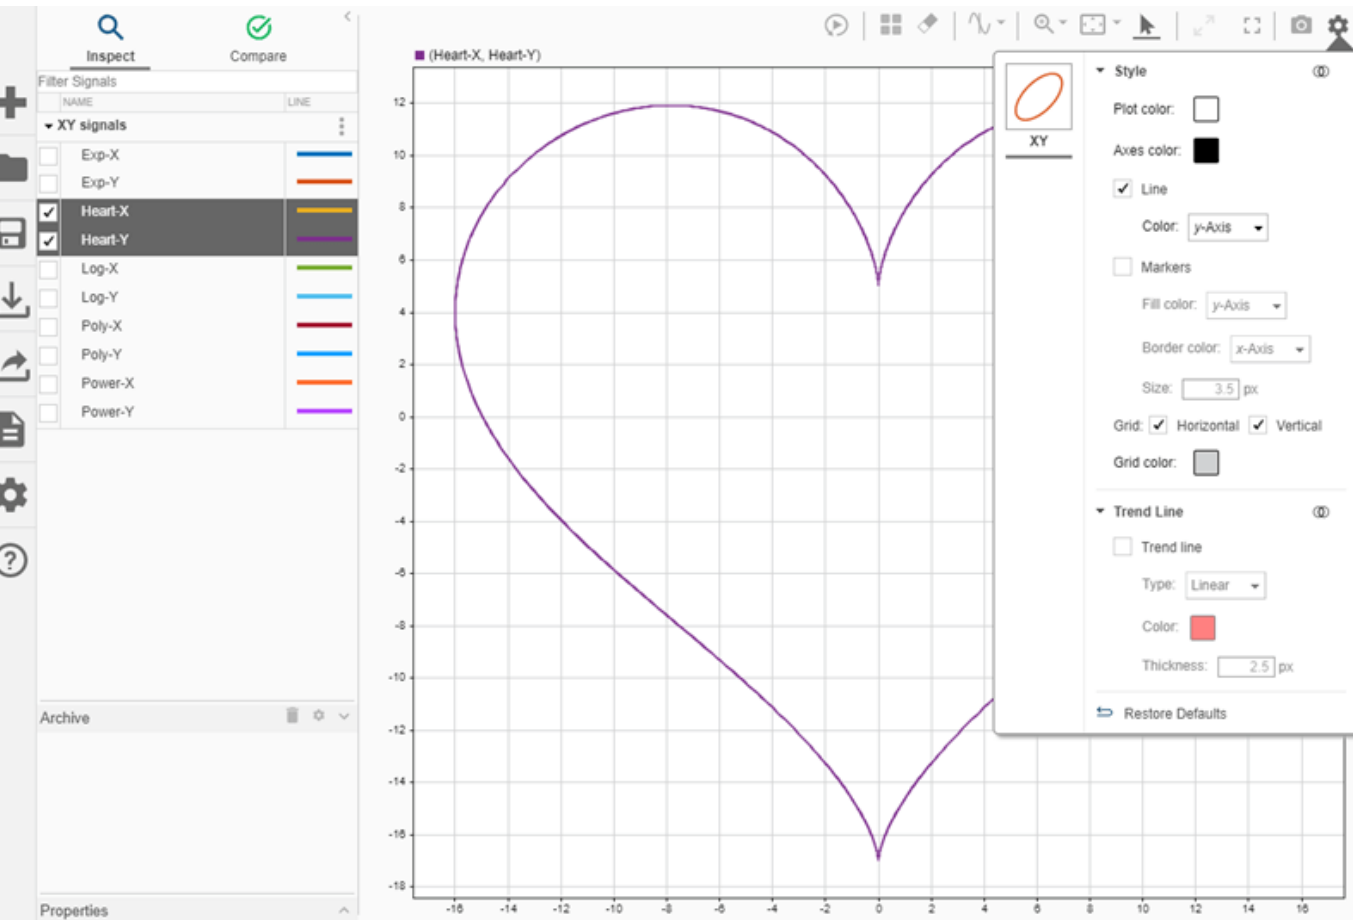

From the **Visualization Gallery**, drag and drop the **XY** icon onto the plot.

To plot signals on the XY plot, select two signals and drag them onto the plot. For example, drag and drop the Heart-X and Heart-Y signals onto the plot. Specify which signal to use as x-data and which to use as y-data in the menu that appears in the lower-right of the plot.

You can customize the appearance of the XY plot using the **Visualization Settings**. The line and marker colors can match the color for the signal that provides the x data or the color for the signal that provides the y data. By default, the line and markers use the y-axis signal color. Specified settings apply for all XY plots in the layout.

Analyze XY Data Using a Trend Line

You can add a trend line to an XY plot to analyze the relationship between the x- and y-data. The trend line is most useful when the relationship can be expressed as a function. The Heart -X and Heart -Y data plotted in the prior section is not well-suited for trend line analysis because the y-data is not well correlated with the x-data.

The example data includes x- and y-data well-suited for each available type of trend line. You can try plotting each pair of signals to see how each trend line helps you analyze the data. For example, plot the Poly-X and Poly-Y signals on the **XY** visualization:

- 1 Select both signals.
- 2 Drag and drop the signals onto the plot.
- 3 Select Poly-X from the first list for series 1 and Poly-Y from the second list for series 1.
- 4 Click **OK**.

To add a trend line, open the **Visualization Settings** and select **Show trend line**. The default trend line type is **Linear**. From the **Type** list, select **Polynomial**.

By default, the Simulation Data Inspector computes the trend line in the form of a third-order polynomial. You can use the text box next to the selected trend line type to specify the order of the polynomial, between 2 and 6. Modify the order of the trend line polynomial to see how it affects the fit of the trend line. For example, when you change to use a second-order polynomial, the trend line does not fit the start of the data as well.

Try out other trend line options to see how they fit the Poly-X and Poly-Y data. You can add these types of trend line to the XY plot:

- **Linear:** The trend line equation is of the form $y = mx + b$.
- **Logarithmic:** The trend line equation is of the form $y = a \ln(x) + b$. The x-data must not contain 0 or negative values.
- **Polynomial:** The trend line equation is of the form $y = b_6x^6 + \dots + b_2x^2 + b_1x + a$, where the number of terms is determined by the specified order.
- **Exponential:** The trend line equation is of the form $y = ae^{bx}$. The y-data must not contain 0 or negative values.
- **Power:** The trend line equation is of the form $y = ax^b$. The x- and y-data must not contain 0 or negative values.

Try plotting other pairs of signals in the XY plot and explore how each trend line option fits each data set.

View Many Signals Together Using Sparklines

Use sparklines in the Record block or Simulation Data Inspector to easily plot and view many signals at once. The sparklines visualization adds a sparkline for each signal you plot. Once sparklines fill the visible space, a scroll bar allows you to continue plotting more signals.

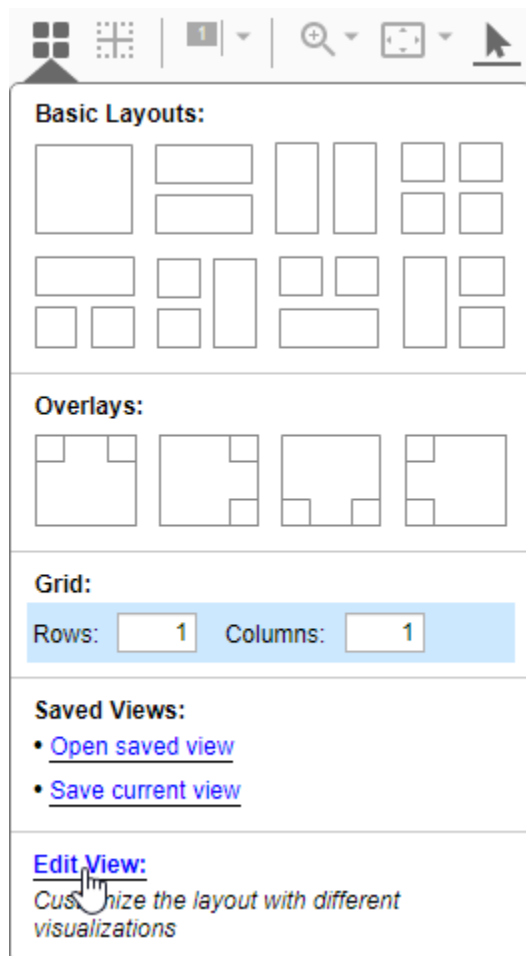

This example shows how to add a sparklines visualization to your layout in the Simulation Data Inspector, plot signals, and adjust the appearance of the sparklines. The Record block uses a sparklines visualization by default and has the same options for modifying the sparkline appearance.

For this example, simulate the `sldemo_fuelsys` model to create a run of data to plot in the Simulation Data Inspector. Then, open the Simulation Data Inspector using the `Simulink.sdi.view` function.

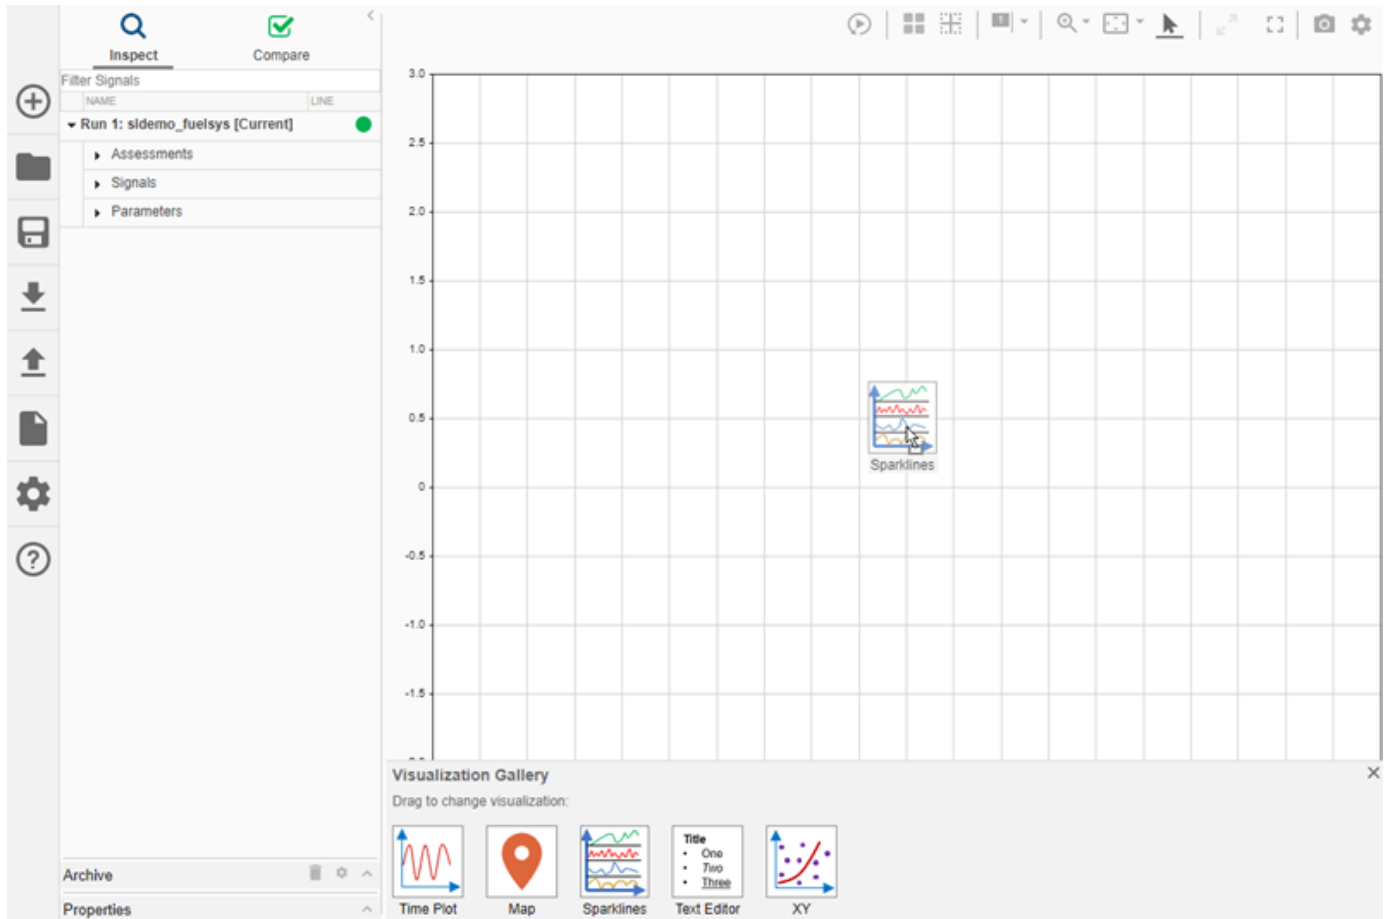

```
open_system('sldemo_fuelsys');
out = sim('sldemo_fuelsys');
```

Plot Data on a Sparklines Plot

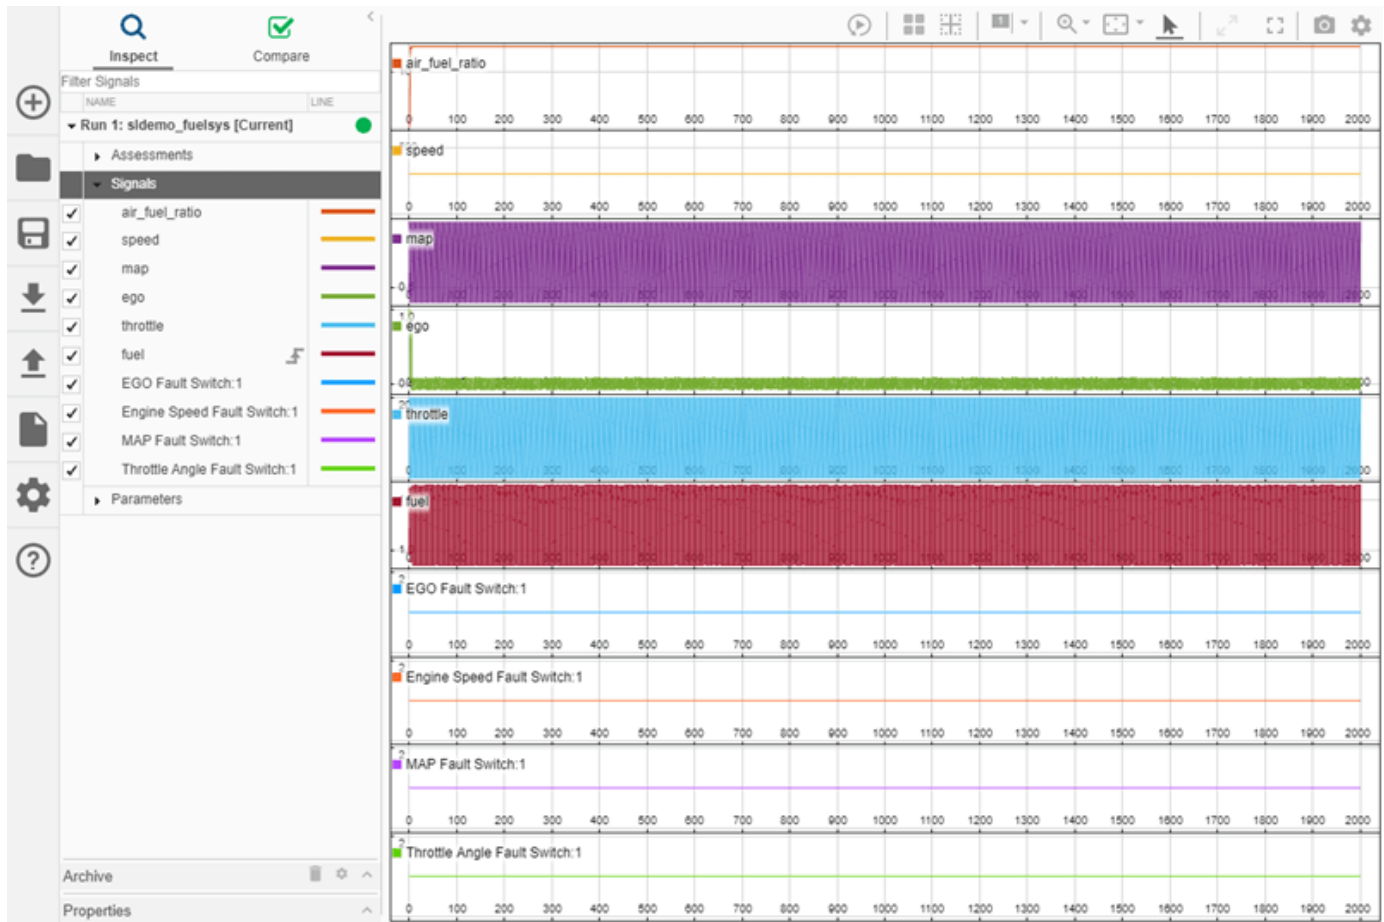

By default, the Simulation Data Inspector shows a single time plot. To replace the time plot with a sparklines visualization, open the **Layout** menu and click **Edit View** to open the **Visualization Gallery**.

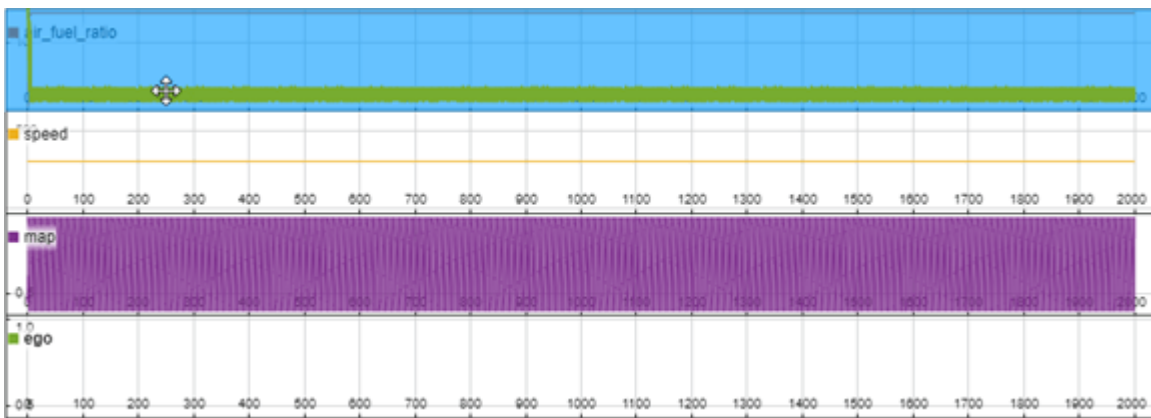

From the **Visualization Gallery**, drag and drop the **Sparklines** icon onto the time plot.

The Simulation Data Inspector groups logged data by its domain, which can indicate the type or source of the data. Expand the **Signals** group. You can add sparklines for the signals one by one by selecting the check box next to each signal you want to plot, or you can select a group of signals to drag and drop onto the plot. Each signal is shown on its own sparkline.

If you want to view more than one signal in a single sparkline, you can drag the signal line from one sparkline onto another. The sparkline for the signal you moved disappears, and both signals are shown together in the sparkline where you dragged the signal. For example, drag the ego signal into the top sparkline.

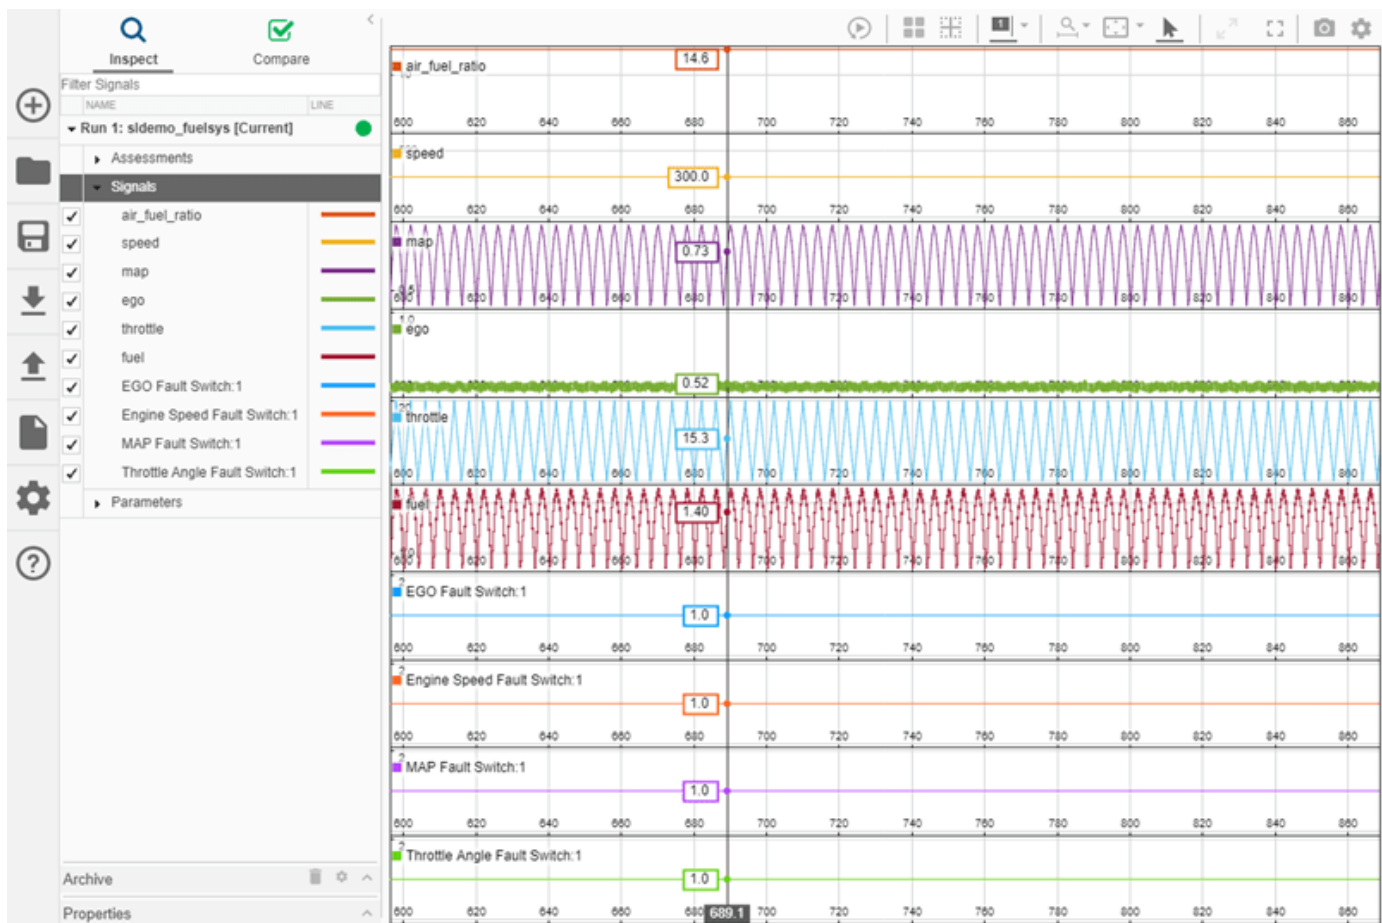

You can also reorder the sparklines by dragging the signal line and dropping it between two sparklines where you want that signal to appear. For example, drag the ego signal out of the top sparkline and drop it in between the first and second sparklines.

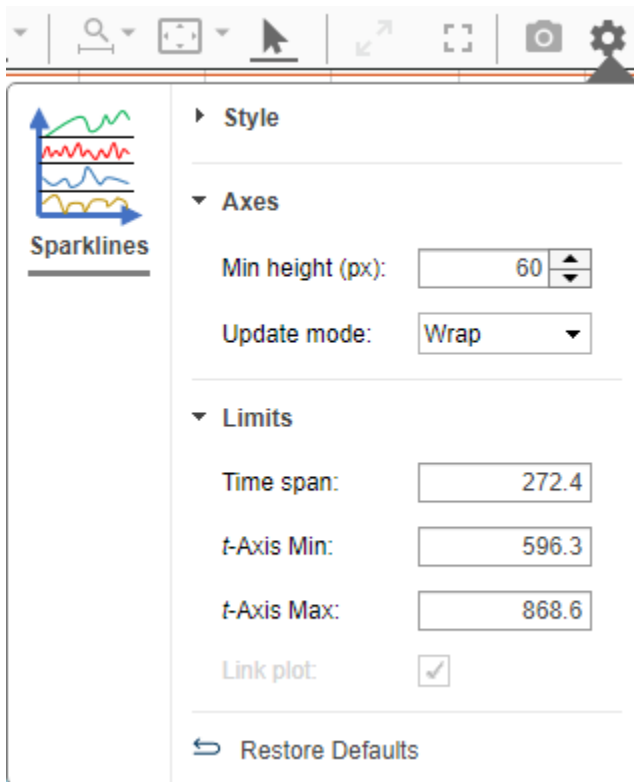

Inspect Data on Sparklines

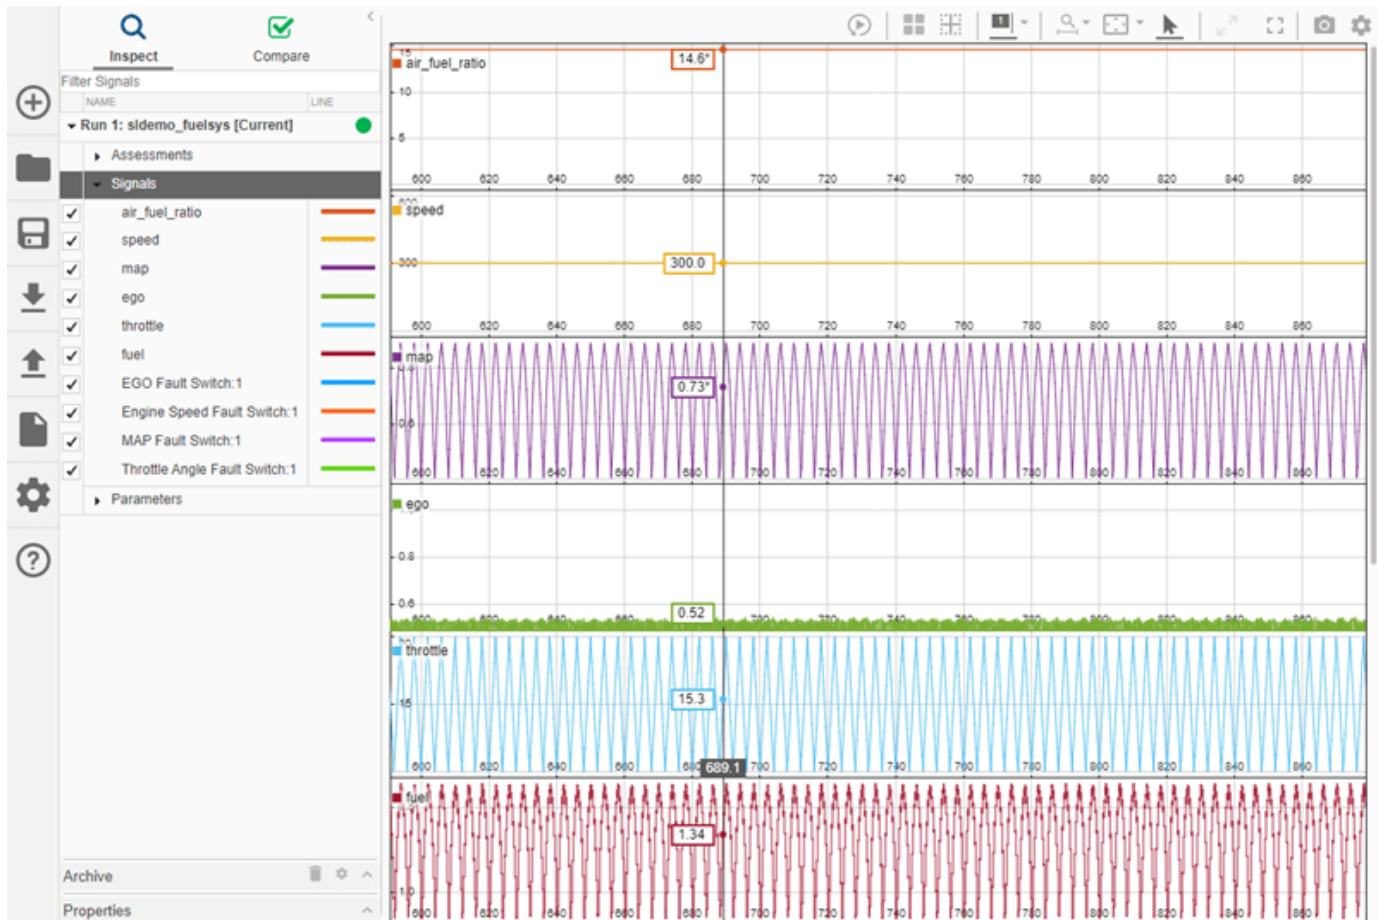

You can add cursors to your plot to see the value for each signal at a given time. You can also use the replay controls with sparklines to inspect how the signal values change relative to each other over time. When you pan or zoom in a given sparkline, all other sparklines remain synchronized.

You can adjust the minimum height for a sparkline using the **Visualization Settings**. For example, increase the minimum height to 130 px. The values you specify in the **Visualization Settings** are specific to a single sparklines visualization.

With the larger minimum height, all the sparklines are not visible at once, and a scroll bar allows you to view all the signals. To scroll down, select the scroll bar with your mouse and drag.

View Data on a Sparklines Plot During Simulation

During simulation, plotted signals stream data to the sparklines visualization. You can control how the signal data is displayed as well as how and when the sparklines update using the **Update mode** and **Time span** settings in the **Visualization Settings**. Change **Update mode** to **Scroll** and set **Time span** to 100. Then, simulate the model again.

```
out = sim('sldemo_fuelsys');
```

By default, the Simulation Data Inspector automatically moves the archive to the previous run and plots signals from the current simulation in the place of plotted signals from the prior simulation. To inspect a signal of interest during simulation, you can freeze the display using the **Freeze display** button.

Alternatively, you could use a trigger to control when the sparklines update. For more information, see “Control Display of Streaming Data Using Triggers” on page 29-81

View Multidimensional Signals Using the Array Plot

You can use an Array plot to view multidimensional signals, including variable-size signals, that you log from simulation or import from another source in the Simulation Data Inspector. This example plots and analyzes imported data from a system that:

- 1 Samples a signal contaminated with noise using an analog to digital converter.
- 2 Performs a discrete Fourier transform (DFT) on the sampled signal.
- 3 Removes the noise from the signal in the frequency domain.
- 4 Performs an inverse DFT on the filtered signal to return to the time domain.

The signal samples are processed using frames, which buffer several samples into an array. You can use the Array plot to view the frames of the time domain signal and to view the frequency domain representation of the signal.

Import the Data into the Simulation Data Inspector

The data for this example is stored in a MAT file. Import the MAT file into the Simulation Data Inspector using the `Simulink.sdi.Run.create` function or using the Simulation Data Inspector UI. When you import data using the UI, the run is automatically named. You can change the name after importing the data by double-clicking the run name and specifying a new one. When you import data programmatically, you can specify the name for the run.

```
runObj = Simulink.sdi.Run.create('Noise Filtering Data Run','file','NoiseFilteringData.mat');
```

To import the data using the UI, open the Simulation Data Inspector.

```
Simulink.sdi.view;
```

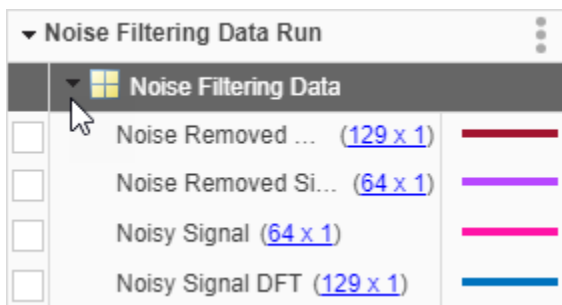

In the Simulation Data Inspector, click Import.

In the Import dialog box, select the option to import from a file. Click the folder icon and select the file `NoiseFilteringData.mat`, then click **Import**.

Plot the Data Using the Array Plot

By default, the Simulation Data Inspector groups signals according to data hierarchy, and groups of signals are collapsed. To view the signals that were imported, click the arrow next to **Noise Filtering Data**. Because the signals contain multidimensional data, the dimensions of each sample are indicated to the right of the signal name.

To plot **Noisy Signal**, select the check box next to it. A dialog appears in the plot area with actions you can perform on the multidimensional signal. By default, the Simulation Data Inspector uses time plots for all subplots in the layout. Time plots do not support displaying multidimensional data. To view the signal data, select **Change active subplot to array plot** and click **OK**.

Each 64-by-1 sample of **Noisy Signal** is a frame of time-domain data for a sine wave contaminated by noise. The array plot uses the row index of the sample as the x data and the sample value as the y data.

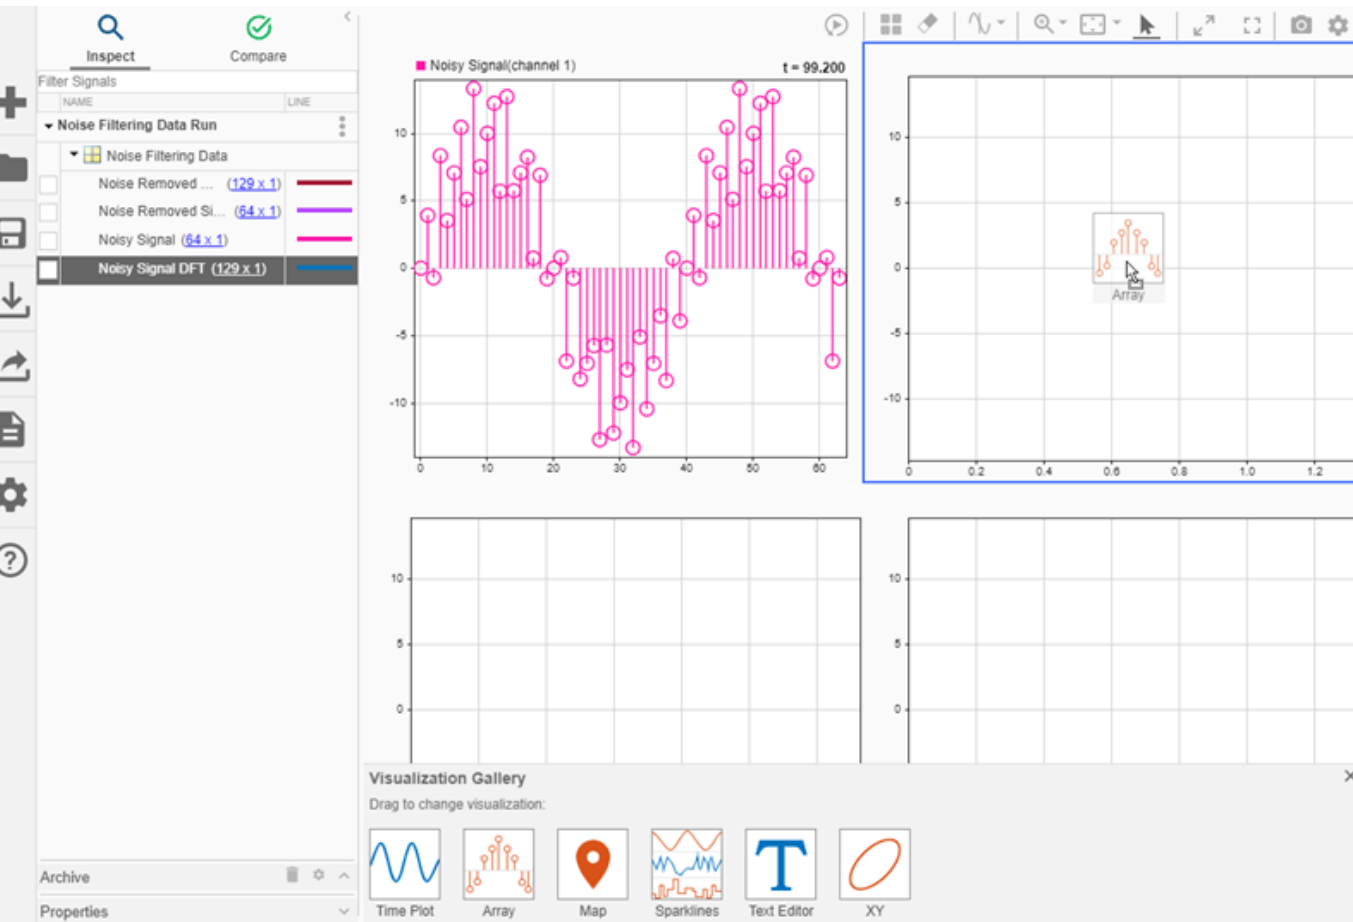

To plot the other signals, first change the subplot layout to include four subplots. Click **Layout**. Then, under **Basic Layouts**, select the four-subplot layout.

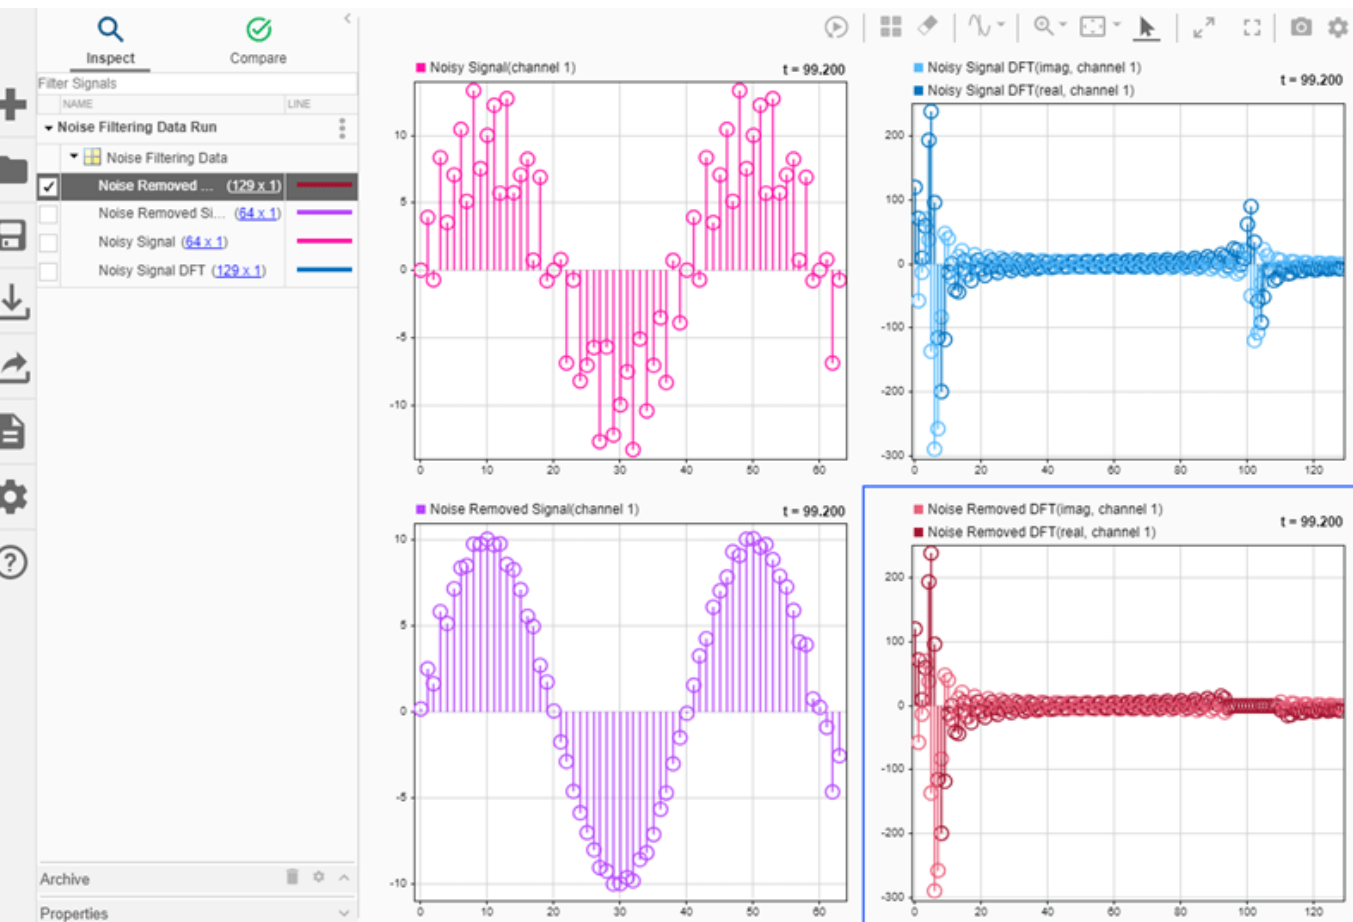

You can plot the other signals the same way as the first:

- 1 Select the subplot where you want to plot the signal.
- 2 Select the check box next to the signal you want to plot.
- 3 Select the option to change the active subplot to an array plot.

You can also start by changing the time plots to array plots manually. To manually change a time plot to an array plot, click **Layout** then select **Edit View**. From the **Visualization Gallery**, drag and drop the **Array** icon onto a subplot.

Using either strategy, plot the remaining signals with the time-domain signals on the right and then frequency-domain data on the right. The frequency domain data is complex, and the array plot uses different shades of the same color to display the real and imaginary components separately. In the time domain, you can see the sine wave is smoother after the frequency domain processing. In the frequency domain, you can see the peak that corresponds to the high-frequency noise and its removal.

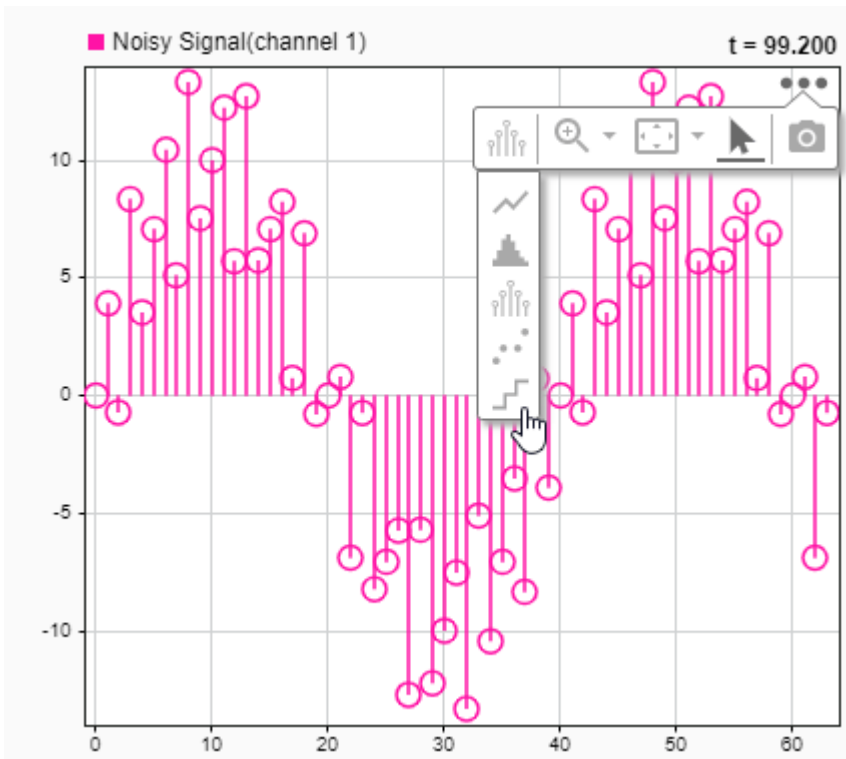

Modify the Array Plot Settings

You can modify how the array plot displays the data by changing the plot type, and you can control the values on the x-axis by specifying an offset and an increment value that defines the space between values on the x-axis. For example, change the settings for the time domain plots to better suit the plotted data.

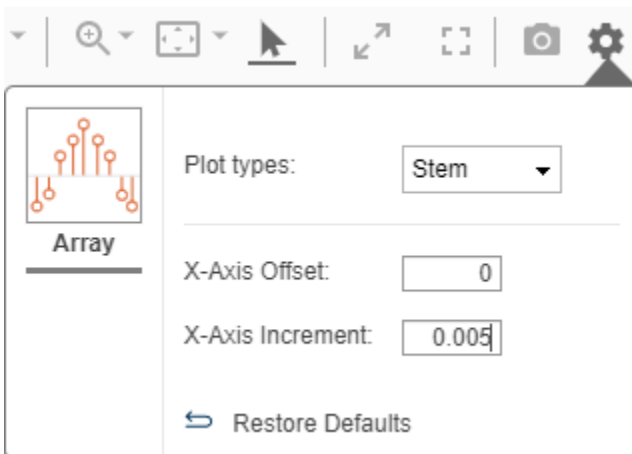

By default, the array plot uses a stem plot type. Because the frequency domain data is discrete, a stem plot makes sense. The time domain data represents an analog signal that is sampled, which is better represented as a stair plot. You can change the plot type using the subplot menu. To change the `Noisy Signal` array plot type to stair:

- 1 Pause on the subplot that displays `Noisy Signal`.
- 2 Click the three dots that appear.
- 3 Expand the Plot Type list and select Stair.

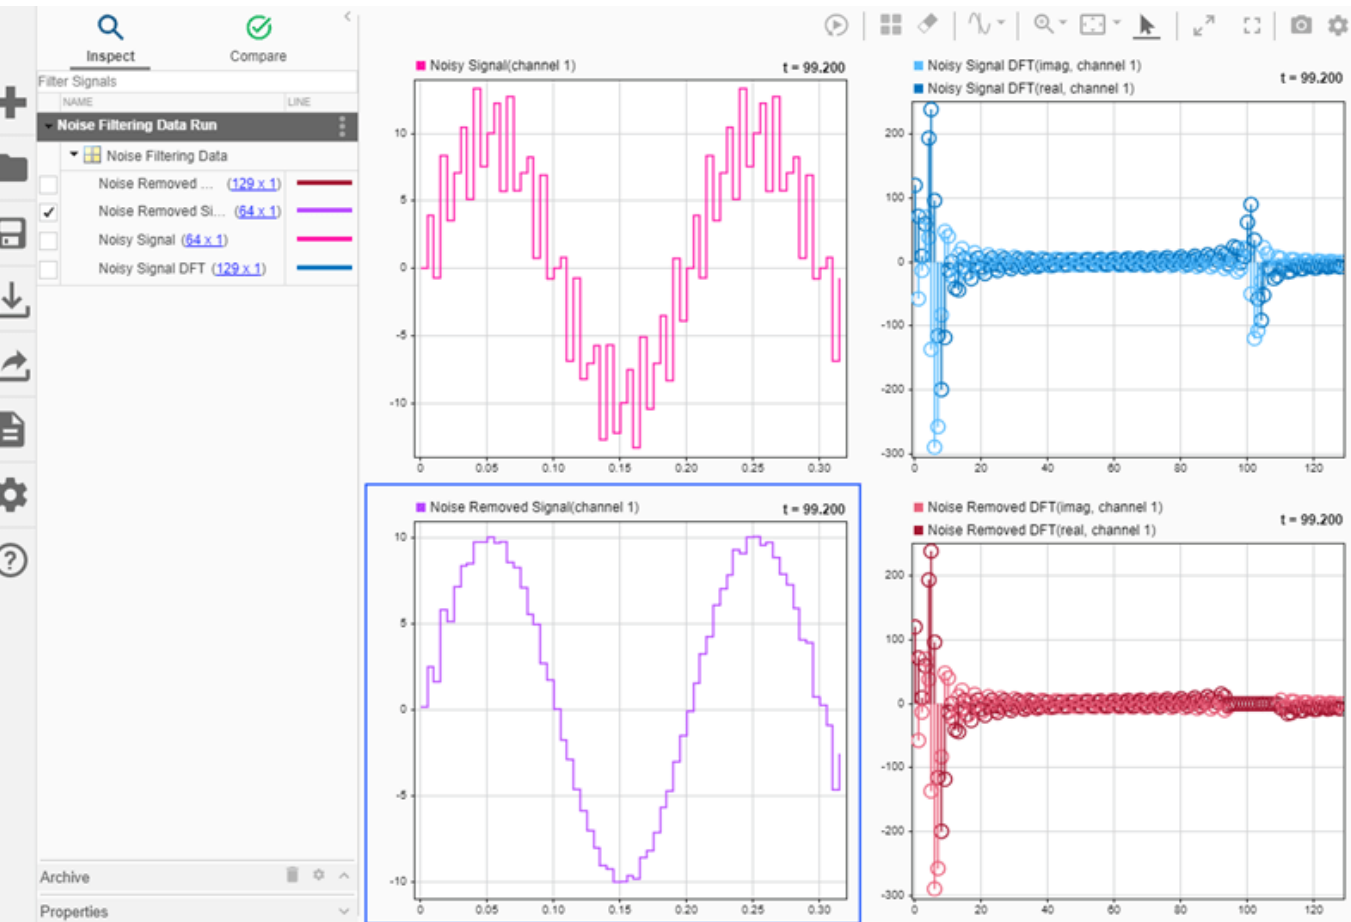

Then, change the plot type for the array plot that displays Noise Removed Signal to stair as well.

Next, adjust the x-axes for the time domain plots to accurately reflect the relative sample times for each frame. Change the x-axis increment to match the sample rate of 0.005s used to generate the data using the array plot settings. First, select the subplot you want to modify, then open the Visualization Settings menu and specify the **X-Axis Increment**.

The x-axis labels update to indicate that each frame represents a bit more than 300ms of signal data.

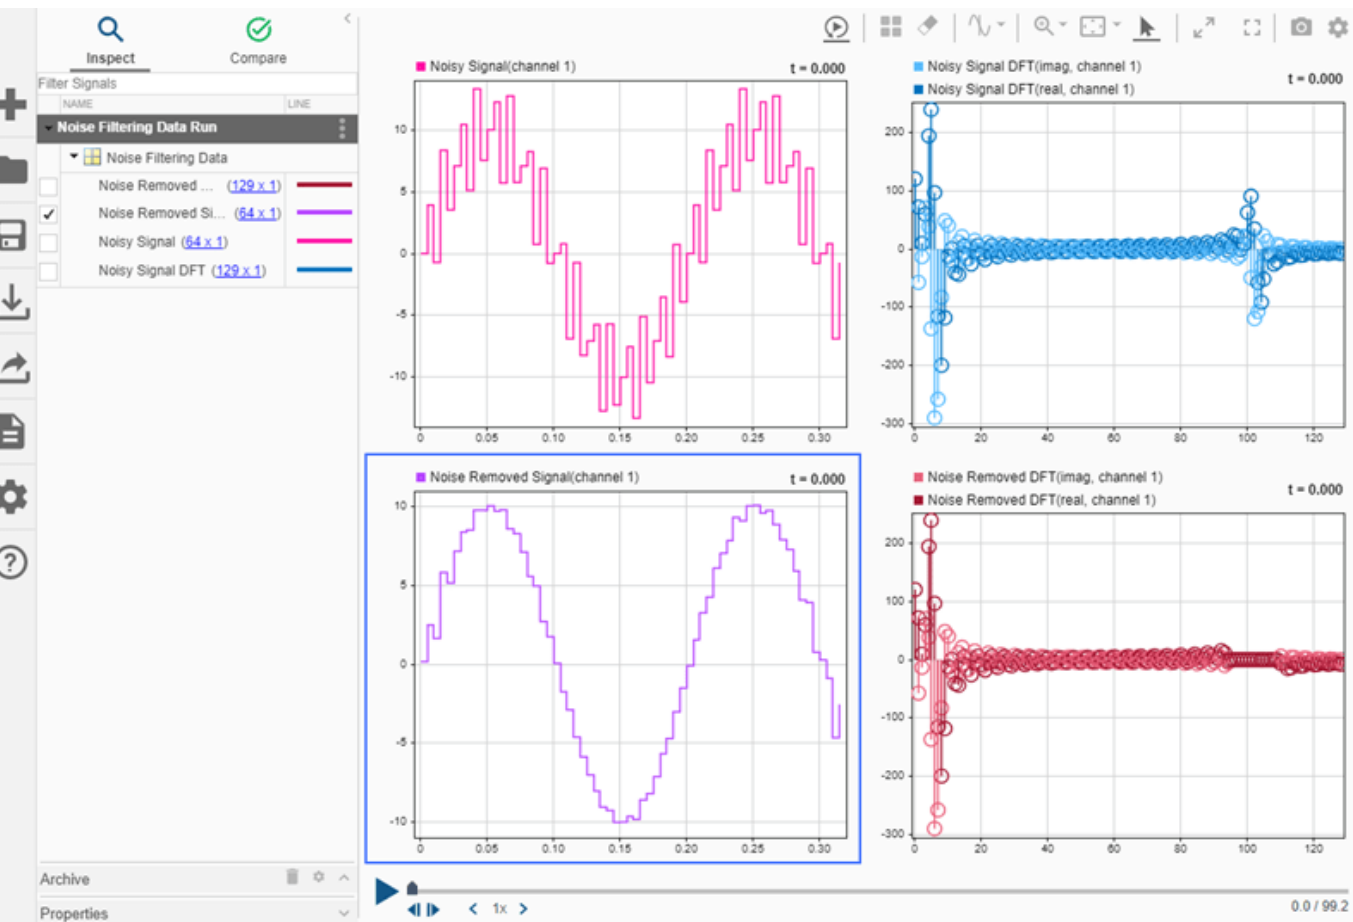

Analyze the Multidimensional Data Over Time

The array plot provides a two-dimensional representation of one sample of a multidimensional signal, plotting the values in a column evenly spaced along the x-axis. The signals also have a time component, and the data in each multidimensional sample can vary with time.

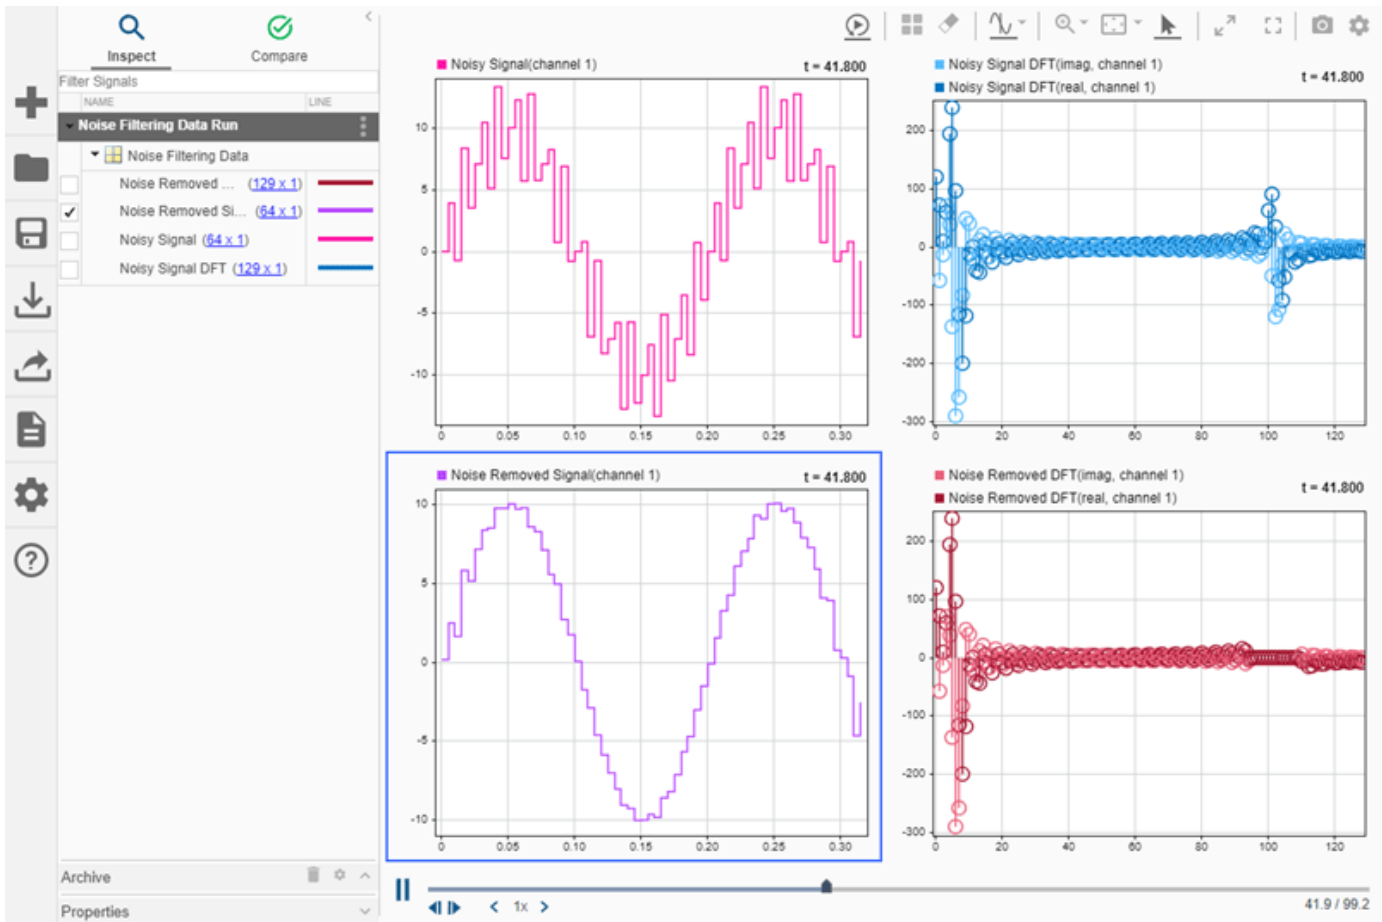

When a view contains visualizations that support cursors, the array plot synchronizes with the cursor to display the sample that corresponds to the cursor position in time. You can also use the replay controls to analyze the sample values on an array plot over time.

The array plot indicates the time that corresponds to the plotted sample in the upper-right of the plot. By default, the array plot displays the last sample of data. When you enable the replay controls, the array plots update to display the sample value for the first time point. To show the replay controls,

click Show/hide replay controls. 

You can manually control which sample is displayed on the plots using the Step forward and Step backward buttons or by dragging the progress indicator. To replay the data, press the Replay button.

The replay sweeps through the sample values at a rate you can adjust using the arrows on either side of the replay speed or specify by clicking the replay speed and entering a new value. By default, the replay updates plots matching one second of time in the data to one second of wall clock time.

As the plots update, you can see how the sine wave shifts within each frame and how that affects the results of the DFT.

Simulation Data Inspector

More About

- “View Data in the Simulation Data Inspector” on page 29-2

Microsoft Excel Import, Export, and Logging Format

Using the Simulation Data Inspector or Simulink Test, you can import data from a Microsoft Excel file or export data to a Microsoft Excel file. You can also log data to an Excel file using the Record block. The Simulation Data Inspector, Simulink Test, and the Record block all use the same file format, so you can use the same Microsoft Excel file with multiple applications.

Tip When the format of the data in your Excel file does not match the specification in this topic, you can write your own file reader to import the data using the `io.reader` class.

Basic File Format

In the simplest format, the first row in the Excel file is a header that lists the names of the signals in the file. The first column is time. The name for the time column must be `time`, and the time values must increase monotonically. The rows below the signal names list the signal values that correspond to each time step.

	A	B	C	D
1	<code>time</code>	<code>signal1</code>	<code>signal2</code>	<code>signal3</code>
2	0	1	1	4
3	1	2	4	8
4	2	3	9	15
5	3	3	9	16
6	3	4	16	23
7	4	5	25	42

The import operation does not support time data that includes `Inf` or `NaN` values or signal data that includes `Inf` values. Empty or `NaN` signal values imported from the Excel file render as missing data in the Simulation Data Inspector. All built-in data types are supported.

Multiple Time Vectors

When your data includes signals with different time vectors, the file can include more than one time vector. Every time column must be named `time`. Time columns specify the sample times for signals to the right, up to the next time vector. For example, the first time column defines the time for `signal1` and `signal2`, and the second time column defines the time steps for `signal3`.

	A	B	C	D	E
1	<code>time</code>	<code>signal1</code>	<code>signal2</code>	<code>time</code>	<code>signal3</code>
2	0	1	1	0	4
3	1	2	4	2	8
4	2	3	9	3	15
5	3	3	9	5	16
6	3	4	16		
7	4	5	25		

Signal columns must have the same number of data points as the associated time vector.

Signal Metadata

The file can include metadata for signals such as data type, units, and interpolation method. Metadata for each signal is listed in rows between the signal names and the signal data. You can specify any combination of metadata for each signal. Leave a blank cell for signals with less specified metadata.

	A	B	C	D	E
1	time	signal1	signal2	time	signal3
2		Interp: zoh			Interp: zoh
3		Type: int8	Type: int32		
4		Unit: m			Unit: m/s
5	0	1	1	0	4
6	1	2	4	2	8
7	2	3	9	3	15
8	3	3	9	5	16
9	3	4	16		
10	4	5	25		

Label each piece of metadata according to this table. The table also indicates which tools and operations support each piece of metadata.

Property Descriptions

Signal Property	Label	Values	Simulation Data Inspector Import	Record Block Logging and Simulation Data Inspector Export	Simulink Test Import and Export
Data type	Type:	Built-in data type.	Supported	Supported	Supported
Units	Unit:	Supported unit. For example, Unit: m/s specifies units of meters per second. For a list of supported units, enter showunitslist in the MATLAB Command Window.	Supported	Supported	Supported
Interpolation method	Interp:	linear, zoh for zero order hold, or none.	Supported	Supported	Supported
Synchronization method	Sync:	union or intersection.	Supported	Not Supported <i>Metadata not included in exported file.</i>	Supported
Relative tolerance	RelTol:	Percentage, represented as a decimal. For example, RelTol: 0.1 specifies a 10% relative tolerance.	Supported	Not Supported <i>Metadata not included in exported file.</i>	Supported
Absolute tolerance	AbsTol:	Numeric value.	Supported	Not Supported <i>Metadata not included in exported file.</i>	Supported
Time tolerance	TimeTol:	Numeric value, in seconds.	Supported	Not Supported <i>Metadata not included in exported file.</i>	Supported

Signal Property	Label	Values	Simulation Data Inspector Import	Record Block Logging and Simulation Data Inspector Export	Simulink Test Import and Export
Leading tolerance	LeadingTol :	Numeric value, in seconds.	Supported <i>Only visible in Simulink Test.</i>	Not Supported <i>Metadata not included in exported file.</i>	Supported
Lagging tolerance	LaggingTol :	Numeric Value, in seconds.	Supported <i>Only visible in Simulink Test.</i>	Not Supported <i>Metadata not included in exported file.</i>	Supported
Block Path	BlockPath :	Path to the block that generated the signal.	Supported	Supported	Supported
Port Index	PortIndex :	Integer.	Supported	Supported	Supported
Name	Name :	Signal name	Supported	Not Supported <i>Metadata not included in exported file.</i>	Supported

When an imported file does not specify signal metadata, double data type, linear interpolation, and union synchronization are used.

User-Defined Data Types

In addition to built-in data types, you can use other labels in place of the DataType: label to specify fixed-point, enumerated, alias, and bus data types.

Property Descriptions

Data Type	Label	Values	Simulation Data Inspector Import	Record Block Logging and Simulation Data Inspector Export	Simulink Test Import and Export
Enumeration	Enum:	Name of the enumeration class.	Supported <i>Enumeration class definition must be saved on the MATLAB path.</i>	Supported <i>Enumeration class definition must be saved on the MATLAB path.</i>	Supported <i>Enumeration class definition must be saved on the MATLAB path.</i>
Alias	Alias:	Name of a Simulink.AliasType object in the MATLAB workspace.	Supported <i>For matrix and complex signals, specify the alias data type on the first channel.</i>	Not Supported	Supported <i>For matrix and complex signals, specify the alias data type on the first channel.</i>
Fixed-point	Fixdt:	<ul style="list-style-type: none"> • fixdt constructor. • Name of a Simulink.NumericType object in the MATLAB workspace. • Name of a fixed-point data type as described in “Fixed-Point Numbers in Simulink” (Fixed-Point Designer). 	Supported	Not Supported	Supported
Bus	Bus:	Name of a Simulink.Bus object in the MATLAB workspace.	Supported	Not Supported	Supported

When you specify the type using the name of a Simulink.Bus object and the object is not in the MATLAB workspace, the data still imports from the file. However, individual signals in the bus use data types described in the file rather than data types defined in the Simulink.Bus object.

Complex, Multidimensional, and Bus Signals

You can import and export complex, multidimensional, and bus signals using an Excel file. The signal name for a column of data indicates whether that data is part of a complex, multidimensional, or bus signal. Excel file import and export do not support array of bus signals.

Multidimensional signal names include index information in parentheses. For example, the signal name for a column might be `signal1(2,3)`. When you import data from a file that includes multidimensional signal data, elements in the data not included in the file take zero sample values with the same data type and complexity as the other elements.

Complex signal data is always in real-imaginary format. Signal names for columns containing complex signal data include `(real)` and `(imag)` to indicate which data each column contains. When you import data from a file that includes imaginary signal data without specifying values for the real component of that signal, the signal values for the real component default to zero.

Multidimensional signals can contain complex data. The signal name includes the indication for the index within the multidimensional signal and the real or imaginary tag. For example, `signal1(1,3) (real)`.

Dots in signal names specify the hierarchy for bus signals. For example:

- `bus.y.a`
- `bus.y.b`
- `bus.x`

	A	B	C	D	E
1	time	bus.y.a	bus.y.b	time	bus.x
2		Interp: zoh			Interp: zoh
3		Type: int8	Type: int32		
4		Unit: m			Unit: m/s
5	0	1	1	0	4
6	1	2	4	2	8
7	2	3	9	3	15
8	3	3	9	5	16
9	3	4	16		
10	4	5	25		

Tip When the name of your signal includes characters that could make it appear as though it were part of a matrix, complex signal, or bus, use the **Name** metadata option to specify the name you want the imported signal to use in the Simulation Data Inspector and Simulink Test.

Function-Call Signals

Signal data specified in columns before the first time column is imported as one or more function-call signals. The data in the column specifies the times at which the function-call signal was enabled. The imported signals have a value of 1 for the times specified in the column. The time values for function-call signals must be double, scalar, and real, and must increase monotonically.

When you export data from the Simulation Data Inspector, function-call signals are formatted the same as other signals, with a time column and a column for signal values.

Simulation Parameters

You can import data for parameter values used in simulation. In the Simulation Data Inspector, the parameter values are shown as signals. Simulink Test uses imported parameter values to specify values for those parameters in the tests it runs based on imported data.

Parameter data is specified using two or three columns. The first column specifies the parameter names, with the cell in the header row for that column labeled `Parameter:`. The second column specifies the value used for each parameter, with the cell in the header row labeled `Value:`. Parameter data may also include a third column that contains the block path associated with each parameter, with the cell in the header row labeled `BlockPath:`. Specify names, values, and block paths for parameters starting in the first row that contains signal data, below rows used to specify signal metadata. For example, this file specifies values for two parameters, X and Y.

	A	B	C	D	E	F	G
1	time	signal1	signal2	time	signal3	Parameter: Value:	
2		Interp: zoh			Interp: zoh		
3		Type: int8	Type: int32				
4		Unit: m			Unit: m/s		
5	0	1	1	0	4 X		2
6	1	2	4	2	8 Y		1.2
7	2	3	9	3	15		
8	3	3	9	5	16		
9	3	4	16				
10	4	5	25				

Multiple Runs

You can include data for multiple runs in a single file. Within a sheet, you can divide data into runs by labeling data with a simulation number and a source type, such as `Input` or `Output`. Specify the simulation number and source type as additional signal metadata, using the label `Simulation:` for the simulation number and the label `Source:` for the source type. The Simulation Data Inspector uses the simulation number and source type only to determine which signals belong in each run. Simulink Test uses the information to define inputs, parameters, and acceptance criteria for tests to run based on imported data.

You do not need to specify the simulation number and output type for every signal. Signals to the right of a signal with a simulation number and source use the same simulation number and source until the next signal with a different source or simulation number. For example, this file defines data for two simulations and imports into four runs in the Simulation Data Inspector:

- **Run 1** contains `signal1` and `signal2`.
- **Run 2** contains `signal3`, X, and Y.
- **Run 3** contains `signal4`.

- **Run 4** contains signal5.

	A	B	C	D	E	F	G	H	I	J
1	time	signal1	signal2	time	signal3	Parameter:	Values:	time	signal4	signal5
2		Interp: zoh			Interp: zoh					
3		Type: int8	Type: int32							
4		Unit: m			Unit: m/s					
5		Simulation: 1							Simulation: 2	
6		Source: Input			Source: Output				Source: Input	Source: Output
7	0	1	1	0	4 X		2	1	2	1
8	1	2	4	2	8 Y		1.2	2	6	3
9	2	3	9	3	15			3	4	5
10	3	3	9	5	16			4	8	7
11	3	4	16					5	10	2
12	4	5	25							

You can also use sheets within the Microsoft Excel file to divide the data into runs and tests. When you do not specify simulation number and source information, the data on each sheet is imported into a separate run in the Simulation Data Inspector. When you export multiple runs from the Simulation Data Inspector, the data for each run is saved on a separate sheet. When you import a Microsoft Excel file that contains data on multiple sheets into Simulink Test, you are prompted to specify how to import the data.

More About

- “View Data in the Simulation Data Inspector” on page 29-2
- “Import Data from a CSV File into the Simulation Data Inspector” on page 29-68
- “Import Data Using a Custom File Reader” on page 29-17

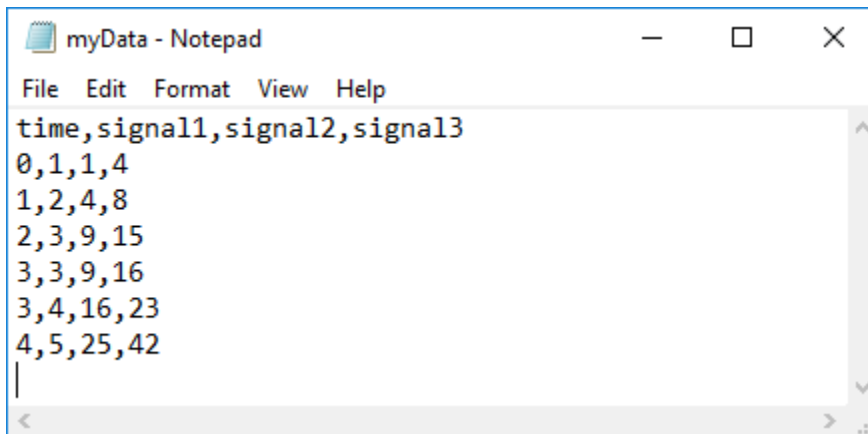

Import Data from a CSV File into the Simulation Data Inspector

To import data into the Simulation Data Inspector from a CSV file, format the data in the CSV file. Then, you can import the data using the Simulation Data Inspector UI or the `Simulink.sdi.createRun` function.

Tip When you want to import data from a CSV file where the data is formatted differently from the specification in this topic, you can write your own file reader for the Simulation Data Inspector using the `io.reader` class.

Basic File Format

In the simplest format, the first row in the CSV file is a header that lists the names of the signals in the file. The first column is time. The name for the time column must be `time`, and the time values must increase monotonically. The rows below the signal names list the signal values that correspond to each time step.

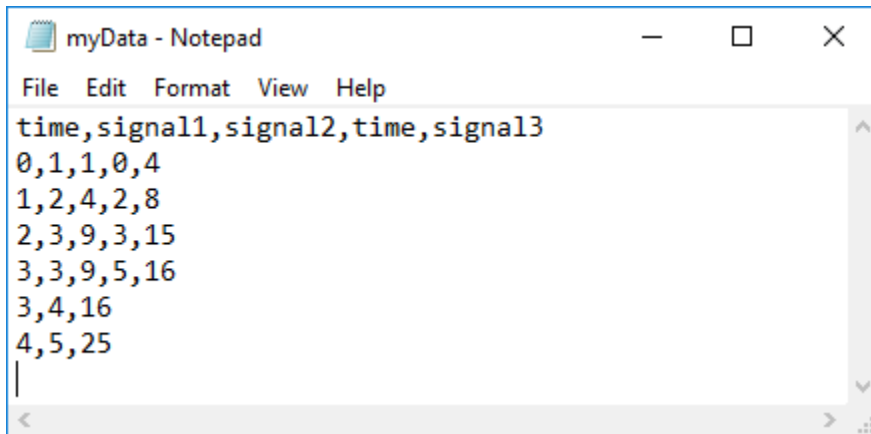

```
myData - Notepad
File Edit Format View Help
time,signal1,signal2,signal3
0,1,1,4
1,2,4,8
2,3,9,15
3,3,9,16
3,4,16,23
4,5,25,42
```

The import operation does not support time data that includes `Inf` or `NaN` values or signal data that includes `Inf` values. Empty or `NaN` signal values render as missing data. All built-in data types are supported.

Multiple Time Vectors

When your data includes signals with different time vectors, the file can include more than one time vector. Every time column must be named `time`. Time columns specify the sample times for signals to the right, up to the next time vector. For example, the first time column defines the time for `signal1` and `signal2`, and the second time column defines the time steps for `signal3`.

```

myData - Notepad
File Edit Format View Help
time,signal1,signal2,time,signal3
0,1,1,0,4
1,2,4,2,8
2,3,9,3,15
3,3,9,5,16
3,4,16
4,5,25

```

Signal columns must have the same number of data points as the associated time vector.

Signal Metadata

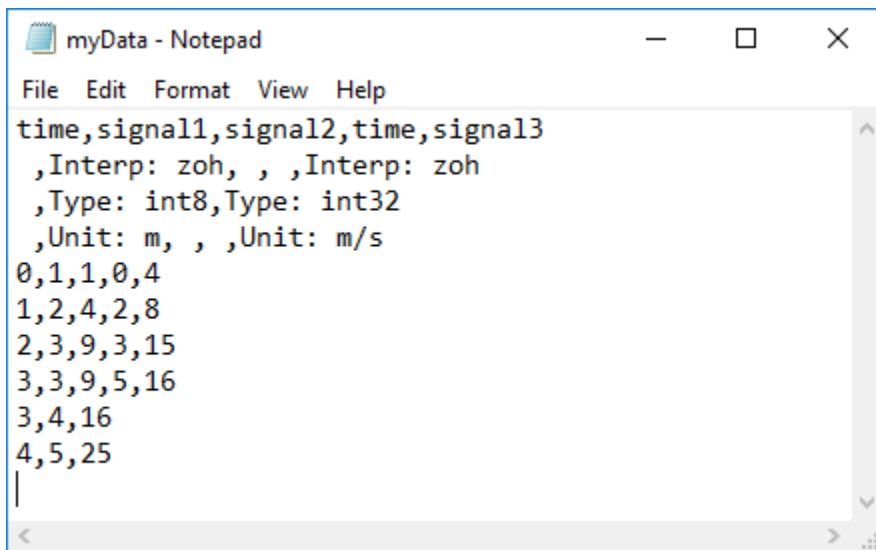

You can specify signal metadata in the CSV file to indicate the signal data type, units, interpolation method, block path, and port index. List metadata for each signal in rows between the signal name and the signal data. Label metadata according to this table.

Signal Property	Label	Value
Data type	Type:	Built-in data type.
Units	Unit:	Supported unit. For example, Unit: m/s specifies units of meters per second. For a list of supported units, enter <code>showunitslist</code> in the MATLAB Command Window.
Interpolation method	Interp:	linear, zoh for zero order hold, or none.
Block Path	BlockPath:	Path to the block that generated the signal.
Port Index	PortIndex:	Integer.

You can also import a signal with a data type defined by an enumeration class. Instead of using the Type: label, use the Enum: label and specify the value as the name of the enumeration class. The definition for the enumeration class must be saved on the MATLAB path.

When an imported file does not specify signal metadata, the Simulation Data Inspector assumes double data type and linear interpolation. You can specify the interpolation method as linear, zoh (zero-order hold), or none. If you do not specify units for the signals in your file, you can assign units to the signals in the Simulation Data Inspector after you import the file.

You can specify any combination of metadata for each signal. Leave a blank cell for signals with less specified metadata.

```

Import Data from a CSV File

You can import data from a CSV file using the Simulation Data Inspector UI or using the `Simulink.sdi.createRun` function.

To import data using the UI, open the Simulation Data Inspector using the `Simulink.sdi.view` function or the **Data Inspector** button in the Simulink™ toolstrip. Then, click the **Import** button.

In the Import dialog, select the option to import data from a file and navigate in the file system to select the file. After you select the file, data available for import shows in the table. You can choose which signals to import and whether to import them to a new or existing run. This example imports all available signals to a new run. After selecting the options, click the **Import** button.

When you import data into a new run using the UI, the new run name includes the run number followed by `Imported_Data`.

When you import data programmatically, you can specify the name of the imported run.

```
csvRunID = Simulink.sdi.createRun('CSV File Run', 'file', 'csvExampleData.csv');
```

More About

- “View Data in the Simulation Data Inspector” on page 29-2

- “Microsoft Excel Import, Export, and Logging Format” on page 29-60
- “Import Data Using a Custom File Reader” on page 29-17

Configure the Simulation Data Inspector

The Simulation Data Inspector supports a wide range of use cases for analyzing and visualizing data. You can modify preferences in the Simulation Data Inspector to match your visualization and analysis requirements. The preferences that you specify persist between MATLAB sessions.

By specifying preferences in the Simulation Data Inspector, you can configure options such as:

- How signals and metadata are displayed.
- Which data automatically imports from parallel simulations.
- Where prior run data is retained and how much prior data to store.
- How much memory is used during save operations.
- The system of units used to display signals.

Open the Simulation Data Inspector preferences by selecting the **Preferences** button.

Note You can restore all preferences in the Simulation Data Inspector to default values by clicking **Restore Defaults** in the dialog or by using the `Simulink.sdi.clearPreferences` function.

Logged Data Size and Location

By default, simulation data logs to disk with data loaded into memory on demand, and the maximum size of logged data is constrained only by available disk space. You can use the **Disk Management** settings in the Simulation Data Inspector to directly control the size and location of logged data.

The **Record mode** setting specifies whether logged data is retained after simulation. When you change the **Record mode** setting to **View during simulation only**, no logged data is available in the Simulation Data Inspector or the workspace after the simulation completes. Only use this mode when you do not want to save logged data. The **Record mode** setting reverts to **View and record data** each time you start MATLAB. Changing the **Record mode** setting can affect other applications, such as visualization tools. For details, see “View Data Only During Simulation” on page 73-27.

To directly limit the size of logged data, you can specify a minimum amount of free disk space or a maximum size for the logged data. By default, logged data must leave at least 100 MB of free disk space with no maximum size limit. Specify the required disk space and maximum size in GB, and specify 0 to apply no disk space requirement or no maximum size limit.

When you specify a minimum disk space requirement or a maximum size for logged data, you can also specify whether to prioritize retaining data from the current simulation or data from prior simulations when approaching the limit. By default, the Simulation Data Inspector prioritizes retaining data for the current run by deleting data for prior runs. To prioritize retaining prior data, change the **When low on disk space** setting to **Keep prior runs and stop recording**. You see a warning message when prior runs are deleted and when recording is disabled. If recording is disabled due to the size of logged data, you need to change the **Record Mode** back to **View and record data** to continue logging data, after you have freed up disk space. For more information, see “Specify a Minimum Disk Space Requirement or Maximum Size for Logged Data” on page 73-26.

The **Storage Mode** setting specifies whether to log data to disk or to memory. By default, data logs to disk. When you configure a parallel worker to log data to memory, data transfer back to the host is

not supported. Logging data to memory is not supported for rapid accelerator simulations or models deployed using Simulink Compiler™.

You can also specify the location of the temporary file that stores logged data. By default, data logs to the temporary files directory on your computer. You may change the file location when you need to log large amounts of data and a secondary drive provides more storage capacity. Logging data to a network location can degrade performance.

Programmatic Use

You can programmatically configure and check each preference value.

Preference	Functions
Record mode	Simulink.sdi.setRecordData Simulink.sdi.getRecordData
Required Free Space	Simulink.sdi.setRequiredFreeSpace Simulink.sdi.getRequiredFreeSpace
Max Disk Usage	Simulink.sdi.setMaxDiskUsage Simulink.sdi.getMaxDiskUsage
When low on disk space	Simulink.sdi.setDeleteRunsOnLowSpace Simulink.sdi.getDeleteRunsOnLowSpace
Storage Mode	Simulink.sdi.setStorageMode Simulink.sdi.getStorageMode
Storage Location	Simulink.sdi.setStorageLocation Simulink.sdi.getStorageLocation

Archive Behavior and Run Limit

The Simulation Data Inspector archive stores runs in a collapsible pane, allowing you to manage the contents of the work area without deleting run data. You can configure whether the Simulation Data Inspector automatically moves prior simulation runs to the archive. You can also limit the number of runs stored in the archive.

Manage Runs in the Archive

By default, the Simulation Data Inspector automatically archives simulation runs. When you simulate a model, the prior simulation run moves to the archive, and the Simulation Data Inspector updates the view to show the data for aligned signals in the current run.

The archive does not impose functional limitations on the runs and signals it contains. You can plot signals from the archive, and you can use runs and signals in the archive in comparisons. You can drag runs of interest from the archive to the work area and vice versa whether the **Automatically Archive** setting is enabled or disabled. To prevent the Simulation Data Inspector from automatically moving prior simulations runs to the archive, clear the **Automatically archive** setting.

When you import runs into the Simulation Data Inspector, the imported runs appear in the work area, and the **Current** tag remains on the most recent simulation run. You can import signals to existing runs in the work area and in the archive.

Tip You can delete the contents of the archive manually using the trash  icon.

Limit Data Retention

To reduce the amount of data the Simulation Data Inspector retains, you can configure a limit for the number of runs stored in the archive. When the number of runs in the archive reaches the size limit, the Simulation Data Inspector starts to delete runs on a first-in, first-out basis.

The size limit applies only to runs in the archive. For the Simulation Data Inspector to automatically limit the data it retains by deleting old runs, select **Automatically archive** and specify a size limit.

By default, the Simulation Data Inspector retains the last 20 runs moved to the archive. To remove the limit, select **No limit**. To specify the maximum number of runs to store in the archive, select **Last n runs** and enter the desired limit. The Simulation Data Inspector warns you when you specify a limit that would delete runs already in the archive.

Programmatic Use

Configure the **Automatically archive** setting programmatically using the `Simulink.sdi.setAutoArchiveMode` function.

Specify the number of runs to retain in the archive using the `Simulink.sdi.setArchiveRunLimit` function.

Incoming Run Names and Location

You can configure how the Simulation Data Inspector handles incoming runs from import or simulation. You can choose whether new runs are added at the top of the work area or the bottom and specify a naming rule to use for runs created from simulation.

By default, the Simulation Data Inspector adds new runs below prior runs in the work area. The **Archive** settings also affect the location of runs. By default, prior runs are moved to the archive when a new simulation run is created.

The run naming rule is used to name runs created from simulation. You can create the run naming rule using a mix of literal text that is used in the run name as-is and one or more tokens that represent metadata about the run. By default, the Simulation Data Inspector names runs using the run index and model name: `Run <run_index>: <model_name>`.

Tip To rename an existing run, double-click the name in the work area and enter the new name, or modify the run name in the **Properties** pane.

Programmatic Use

You can programmatically check and modify the naming rule using the `Simulink.sdi.getRunNamingRule` and `Simulink.sdi.setRunNamingRule` functions. Restore

the naming rule to its default programmatically using the `Simulink.sdi.resetRunNamingRule` function.

Signal Metadata to Display

You can control which signal metadata is displayed in the work area of the **Inspect** pane and in the results section on the **Compare** pane in the Simulation Data Inspector. You specify the metadata to display separately for each pane using the **Table Columns** preferences in the **Inspect** and **Compare** sections of the Preferences dialog, respectively.

Inspect Pane

By default, the signal name and the line style and color used to plot the signal are displayed on the **Inspect** pane. To display different or additional metadata in the work area on the **Inspect** pane, select the check box next to each piece of metadata you want to display in the **Table Columns** preference in the **Inspect** section. You can always view complete metadata for the selected signal in the **Inspect** pane using the **Properties** pane.

Note Metadata displayed in the work area on **Inspect** pane is included when you generate a report of plotted signals. You can also specify metadata to include in the report regardless of what is displayed in the work area when you create the report programmatically using the `Simulink.sdi.report` function.

Compare Pane

By default, the **Compare** pane shows the signal name, the absolute and relative tolerances used in the signal comparison, and the maximum difference from the comparison result. To display different or additional metadata in the results on the **Compare** pane, select the check box next to each piece of metadata you want to display in the **Table Columns** preference in the **Compare** section. You can always view complete metadata for the signals compared for a selected signal result using the **Properties** pane, where metadata that differs between the compared signals is highlighted. Signal metadata displayed on the **Compare** pane does not affect the contents of comparison reports.

Signal Selection on the Inspect Pane

You can configure how you select signals to plot on the selected subplot in the Simulation Data Inspector. By default, you use check boxes next to each signal to plot. You can also choose to plot signals based on selection in the work area. Use **Check Mode** when creating views and visualizations that represent findings and analysis of a data set. Use **Browse Mode** to quickly view and analyze data sets with a large number of signals.

For more information about creating visualizations using **Check Mode**, see “Create Plots Using the Simulation Data Inspector” on page 29-135.

For more information about using **Browse Mode**, see “Visualize Many Logged Signals” on page 29-99.

Note To use **Browse Mode**, your layout must include only **Time Plot** visualizations.

How Signals Are Aligned for Comparison

When you compare runs using the Simulation Data Inspector, the comparison algorithm pairs signals for signal comparison through a process called alignment. You can align signals between the compared runs using one or more of the signal properties shown in the table.

Property	Description
Data Source	Path of the variable in the MATLAB workspace for data imported from the workspace
Path	Block path for the source of the data in its model
SID	Simulink identifier For more information about SIDs, see “Simulink Identifiers” on page 1-8
Signal Name	Name of the signal

You can specify the priority for each piece of metadata used for alignment. The **Align By** field specifies the highest priority property used to align signals. The priority drops with each subsequent **Then By** field. You must specify a primary alignment property in the **Align By** field, but you can leave any number of **Then By** fields blank.

By default, the Simulation Data Inspector aligns signals between runs according to this flow chart.

For more information about configuring comparisons in the Simulation Data Inspector, see “How the Simulation Data Inspector Compares Data” on page 29-182.

Colors Used to Display Comparison Results

You can configure the colors used to display comparison results using the Simulation Data Inspector preferences. You can specify whether to use the signal color from the **Inspect** pane or a fixed color for the baseline and compared signals. You can also choose colors for the tolerance and the difference signal.

By default, the Simulation Data Inspector displays comparison results using fixed colors for the baseline and compared signals. Using a fixed color allows you to avoid the baseline signal color and compared signal color being either the same or too similar to distinguish.

Signal Grouping

You can specify how to group signals within a run in the Simulation Data Inspector. The preferences apply to both the **Inspect** and **Compare** panes. You can group signals by:

- Domain — Signal type. For example, signals created by signal logging have a domain of **Signal**, while signals created from logging model outputs have a domain of **Outputs**.
- Physical System Hierarchy — Signal Simscape physical system hierarchy. The option to group by physical system hierarchy is available when you have a Simscape license.
- Data Hierarchy — Signal location within structured data. For example, data hierarchy grouping reflects the hierarchy of a bus.
- Model Hierarchy — Signal location within model hierarchy. Grouping by model hierarchy can be helpful when you log data from a model that includes model or subsystem references.

Grouping signals adds rows for the hierarchical nodes, which you can expand to show the signals within that node. By default, the Simulation Data Inspector groups signals by domain, then by physical system hierarchy (if you have a Simscape license), and then by data hierarchy.

To remove grouping and display a flat list of signals in each run, select **None** for all grouping options.

Programmatic Use

To specify how to group signals programmatically, use the `Simulink.sdi.setTableGrouping` function.

Data to Stream from Parallel Simulations

When you run parallel simulations using the `parsim` function, you can stream logged simulation data to the Simulation Data Inspector. A dot next to the run name in the **Inspect** pane indicates the status of the simulation that corresponds to the run, so you can monitor simulation progress while visualizing the streamed data. You can control whether data streams from a parallel simulation based on the type of worker the data comes from.

By default, the Simulation Data Inspector is configured for manual import of data from parallel workers. You can use the Simulation Data Inspector programmatic interface to inspect the data on the worker and decide whether to send it to the client Simulation Data Inspector for further analysis. To manually move data from a parallel worker to the Simulation Data Inspector, use the `Simulink.sdi.sendWorkerRunToClient` function.

You may want to automatically stream data from parallel simulations that run on local workers or on local and remote workers. Streaming data from both local and remote workers may affect simulation performance, depending on how many simulations you run and how much data you log. When you choose to stream data from local workers or all parallel workers, all logged simulation data automatically shows in the Simulation Data Inspector.

Programmatic Use

You can configure Simulation Data Inspector support for parallel worker data programmatically using the `Simulink.sdi.enablePCTSupport` function.

Options for Saving and Loading Session Files

You can specify a maximum amount of memory to use while loading or saving a session file. By default, the Simulation Data Inspector uses a maximum of 100 MB of memory when you load or save a session file. You can specify a memory use limit as low as 50 MB.

To reduce the size of the saved session file, you can specify a compression option.

- **None** — Do not compress saved data.
- **Normal** — Compress the saved file as much as possible.
- **Fastest** — Compress the saved file less than **Normal** compression for faster save time.

Signal Display Units

Signals in the Simulation Data Inspector have two units properties: stored units and display units. The stored units represent the units of the data saved to disk. The display units specify how the Simulation Data Inspector displays the data. You can configure the Simulation Data Inspector to use a system of units to define the display units for all signals. You can choose either the **SI** or **US Customary** system of units, or you can display data using its stored units.

When you use a system of units to define display units for signals in the Simulation Data Inspector, the display units update for any signal with display units that are not valid for that unit system. For example, if you select **SI** units, the display units for a signal may update from **ft** to **m**.

Note The system of units you choose to use in the Simulation Data Inspector does not affect the stored units for any signal. You can convert the stored units for a signal using the `convertUnits` function. Conversion may result in loss of precision.

In addition to selecting a system of units, you can specify override units so that all signals of a given measurement type are displayed using consistent units. For example, if you want to visualize all signals that represent weight using units of **kg**, specify **kg** as an override unit.

Tip For a list of units supported by Simulink, enter `showunitslist` in the MATLAB Command Window.

You can also modify the display units for a specific signal using the **Properties** pane. For more information, see “Modify Signal Properties in the Simulation Data Inspector” on page 29-161.

Programmatic Use

Configure the unit system and override units using the `Simulink.sdi.setUnitSystem` function. You can check the current units preferences using the `Simulink.sdi.getUnitSystem` function.

Control Display of Streaming Data Using Triggers

A *trigger* is an event that determines when to draw the plot of a streaming signal. Trigger settings specify criteria for the trigger event and where the trigger event is displayed within the updated data. Triggers facilitate viewing and analyzing streaming data by allowing you to capture transient changes in signals and stabilize the display of steady-state periodic signals. You can use triggers to inspect streaming data using several tools, such as the Scope block and the Simulation Data Inspector. This example uses the Simulation Data Inspector add, configure, and modify triggers on signals streaming from a model simulation.

Note The following examples add a trigger to signals that are plotted in the Simulation Data Inspector. However, you can add a trigger to a signal from the active simulation that is not plotted.

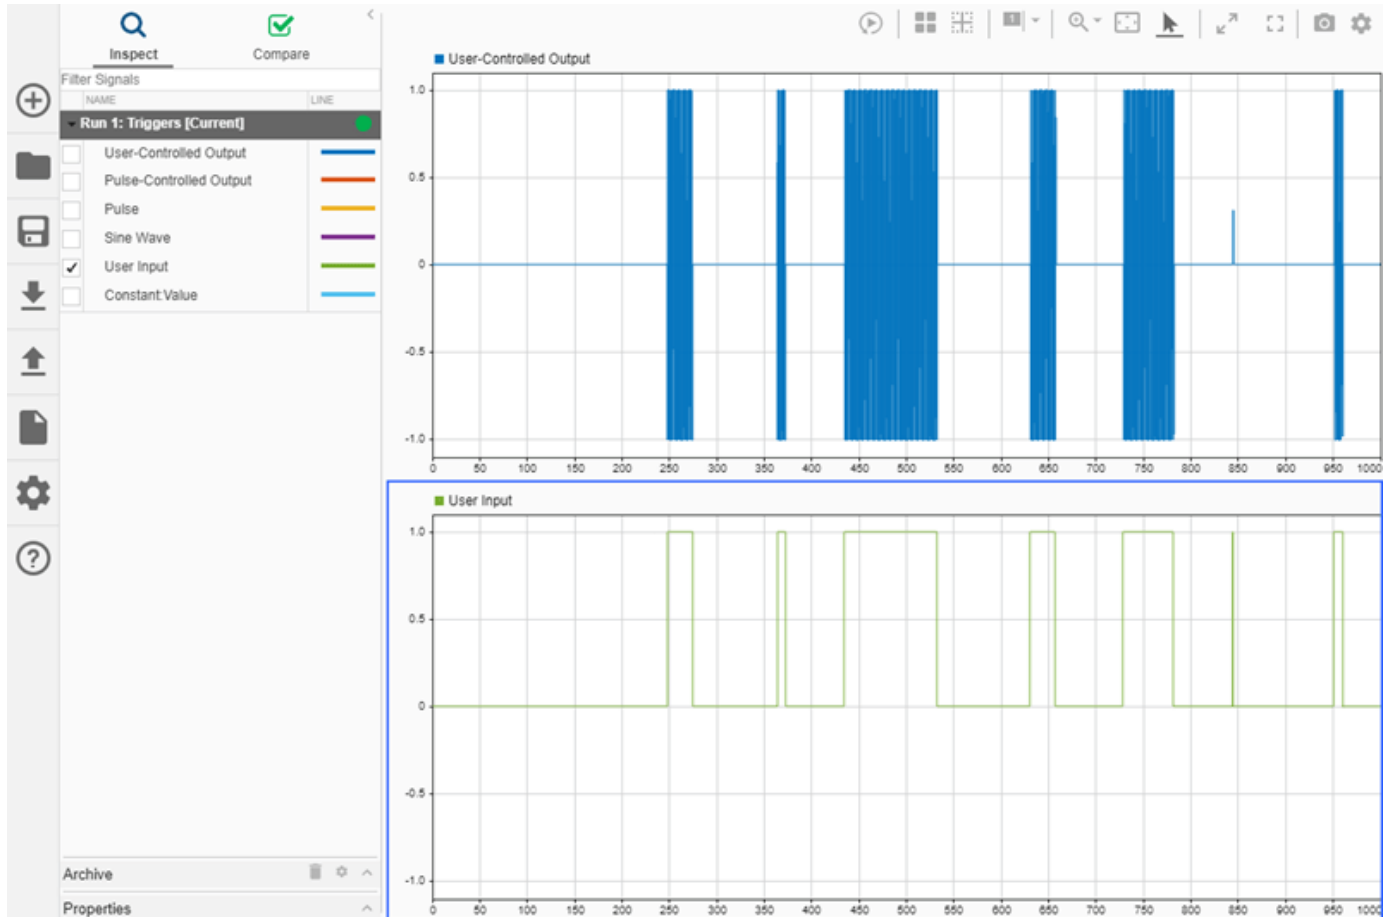

For complete descriptions of all trigger types and options, see “Scope Triggers Panel” on page 28-12.

Examine the Model

The model in this example generates two logged output signals. Both signals are created by passing the output of a Sine Wave block through a switch. Both switches are configured to allow the sine signal through when the control signal is greater than zero. The switch for the first output is controlled by user input supplied using the Push Button block. The switch for the second output is controlled by the output of a Pulse Generator block.

The model uses simulation pacing so the model behavior and signal display are responsive to user interaction. Click **Run** to start a simulation. Then, click **Data Inspector** to open the Simulation Data Inspector. In the Simulation Data Inspector, change the layout to show two subplots. Plot the **User-Controlled Output** signal on the top subplot and the **User Input** signal on the bottom subplot. Press and hold the Push Button block periodically throughout the simulation to pass the Sine Wave block output to the Output block.

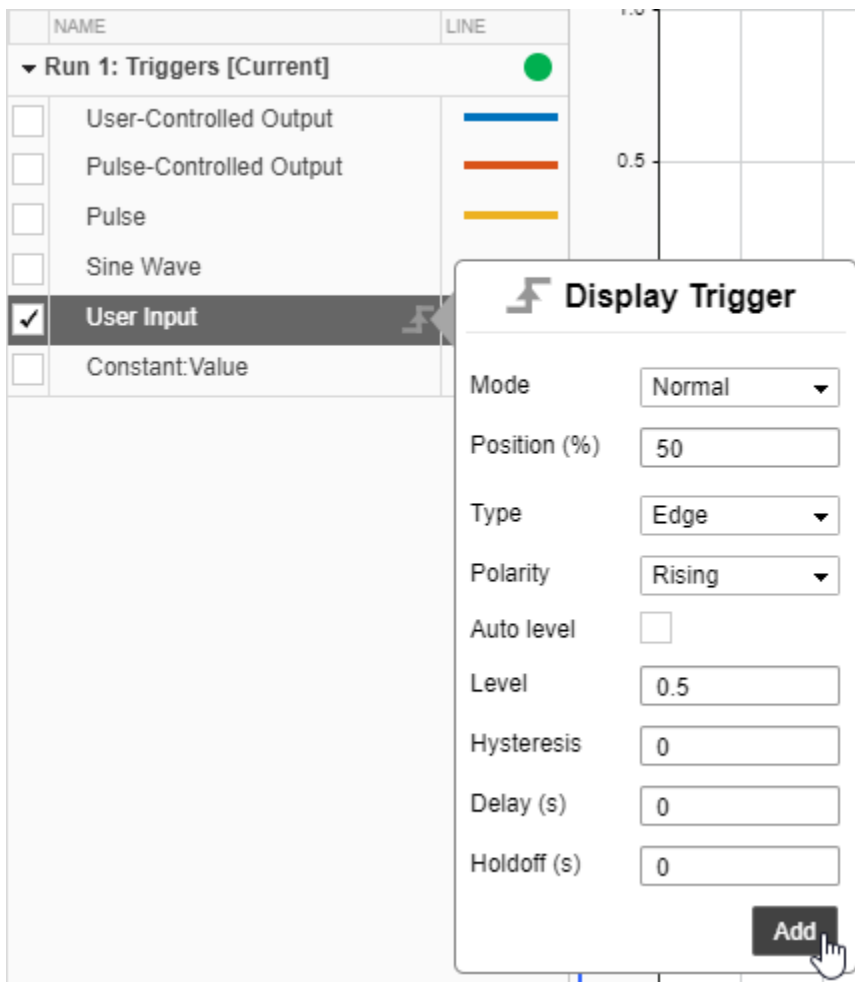

Interactively Generate Trigger Events

The sine wave characteristics are difficult to see when you view the signals over the entire simulation time. When you use a trigger to control when the plot updates, you can view the streaming data over a smaller time range, which allows you to see the sine wave more clearly. Using the trigger ensures that you see the signal behavior of interest in the smaller time range. In this example, you want to see the change in the output signal when you press the Push Button block.

To trigger plot updates based on button presses, add a trigger to the **User Input** signal. To add a trigger, pause on the row for the **User Input** signal in the Simulation Data Inspector and click the trigger icon that appears.

The default settings in the Display Trigger dialog configure an auto-leveled rising-edge trigger, with the trigger event positioned in the middle of the displayed data. Change **Mode** to **Normal**, then clear the **Auto level** check box and set the **Level** to 0.5. Then, click **Add**.

Using normal mode for the trigger means that the plot only updates when a trigger occurs. In auto mode, the display also updates when a trigger is not detected for the duration of the time span. The trigger level of 0.5 puts the level in the middle of the signal range.

Before simulating the model, adjust the time range displayed in the plots. In the **Visualization Settings**, set **Time span** to 50.

Simulate the model and view the streaming signals in the Simulation Data Inspector. When you start a new simulation, the trigger configured in the Simulation Data Inspector automatically transfers to the corresponding signal in the current simulation. The display updates in response to the trigger events you cause by pressing the Push Button block in the model. On the smaller time span, you can see the shape of the sine wave in the output signal. The trigger position and level are marked with green triangles. You can click and drag the trigger markers to adjust the level and position. A new value is applied for the level or position when you let go of the marker after dragging.

Experiment with this configuration to test out different kinds of triggers and different trigger settings. For example, try using a falling-edge trigger. You can also adjust the simulation pacing in the model to explore how timing can affect trigger behavior. When the trigger occurs, the Simulation Data Inspector collects all the data to display before updating the plot. If you slow the simulation pacing closer to a rate where one simulation second takes one second of clock time, you can see the delay between causing a trigger by pressing the Push Button block and the plot update in the Simulation Data Inspector.

Capture Signal Transient Response

A trigger allows you to capture transient signal responses to changes in the system under test. For example, you can use the input signal to an inverter as a trigger when you want to measure the rise

or fall time for the inverter output signal. The display updates only when the trigger occurs, so the data is displayed long enough for you to make a measurement. When you interactively generate trigger events, you capture the output signal transient response to the user input. Systems often do not have user input and respond to changes in upstream signals, such as the Pulse signal that controls the switch that generates the Pulse-Controlled Output signal.

Add a trigger to the Pulse signal in the Simulation Data Inspector. Use a rising-edge trigger in normal mode with a level of 0.5 again. Click **Add Trigger** in the warning dialog that appears.

Before simulating the model, update the plots so that the Pulse-Controlled Output is shown on the top plot and the Pulse signal is shown on the bottom plot.

Simulate the model. The Simulation Data Inspector display updates are not triggered by the user input in this simulation, so you do not need to press the Push Button block. Observe how the Pulse-Controlled Output signal is different from the User-Controlled Output signal from the previous simulation and how the plot updates occur in response to the periodic Pulse signal.

You can experiment in additional simulations by adjusting the pulse width or period of the Pulse signal. You can also try out different types of triggers, such as a pulse width trigger.

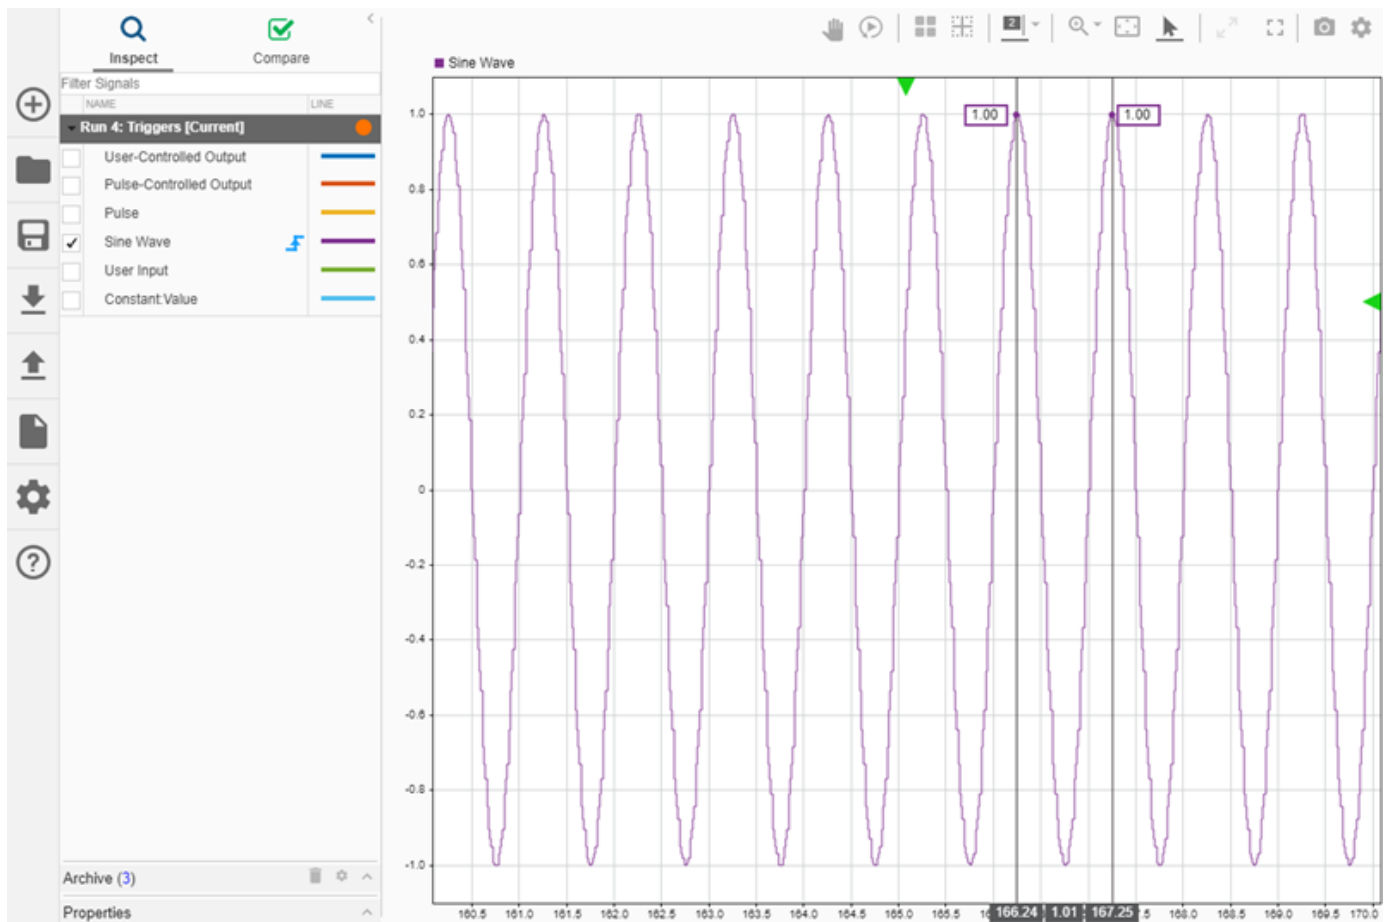

Stabilize a Steady-State Periodic Signal

Using a trigger can stabilize the display of a periodic steady-state signal that you want to view and analyze. Because the trigger event is always in the stable position in the plot, a streaming periodic signal can appear still in the plot, rather than shifting or scrolling. When the display is stable, you can inspect and analyze signal characteristics, such as frequency and amplitude.

To see how a trigger can stabilize the display of a periodic signal, trigger display updates using the Sine Wave signal. Use the same settings to configure the rising-edge trigger in normal mode with a level of 0.5.

Before simulation, update the plot layout to show a single plot. Plot the Sine Wave signal, and set the **Time span** to 10.

Simulate the model. During simulation, you can add cursors in the Simulation Data Inspector and measure the amplitude and period of the signal.

To contrast, remove the trigger and simulate the model again. Notice the differences in how the display updates. Try simulating with the **Update mode** set to **Wrap** and then set to **Scroll**. Specify **Update mode** in **Visualization Settings**.

Synchronize Cursors in the Simulation Data Inspector with an App Designer App

You can use several functions from the Simulation Data Inspector programmatic interface to synchronize cursors between an App Designer app and the Simulation Data Inspector. Synchronized cursors allow you to easily analyze data plotted in the Simulation Data Inspector alongside data displayed on a custom visualization coded in the App Designer app.

The app in this example is simple and illustrates only the core function of passing information about cursors between the app and the Simulation Data Inspector. Cursor positions are shown on linear gauges in the app. You can use sliders in the app to reposition the cursors on the **Inspect** or **Compare** panes of the Simulation Data Inspector. When you move cursors in the Simulation Data Inspector, the new cursor positions are reflected on the sliders and linear gauges.

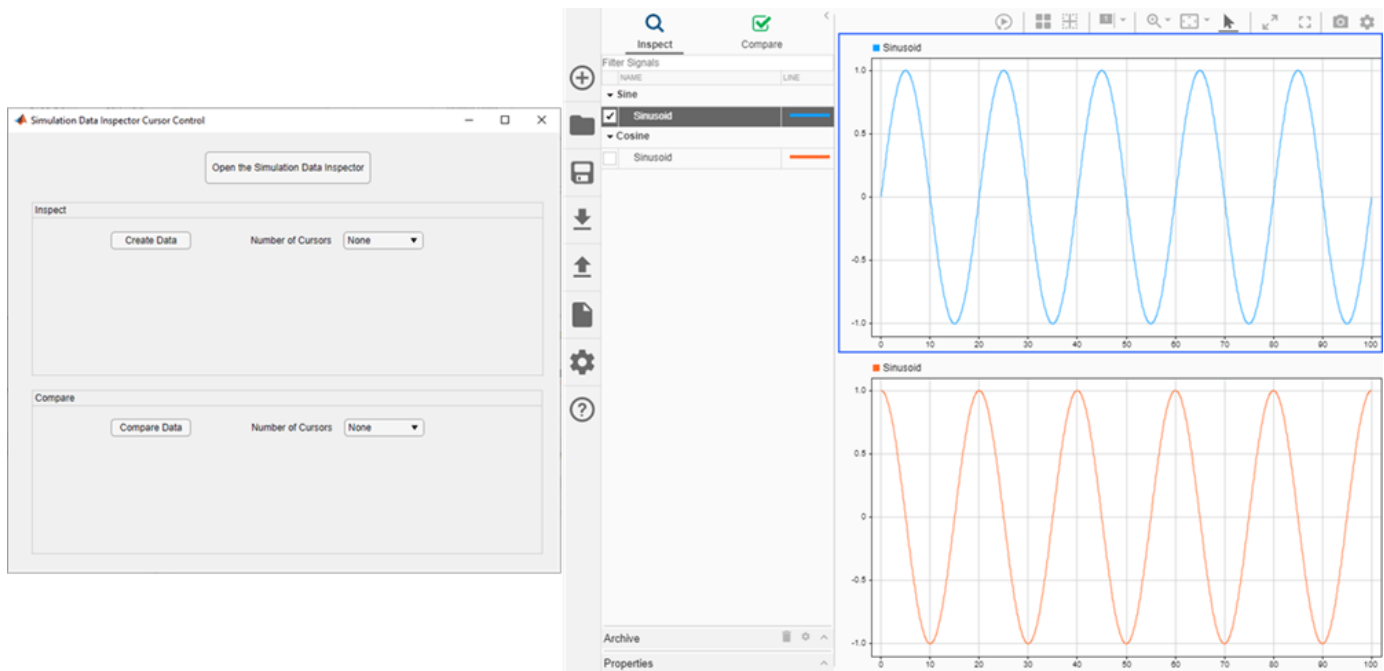

Open and Run the Cursors App

The cursors app opens in App Designer, where you can explore and modify the layout of the user interface and the code that specifies the function of each user interface element.

```
appdesigner('CursorsApp.mlapp');
```

To run the cursors app, click **Run**. A new window opens with the app user interface. To get started using the app, click **Open the Simulation Data Inspector**, then click **Create Data**. The **Create Data** button creates data for and plots two signals in the **Inspect** pane of the Simulation Data Inspector.

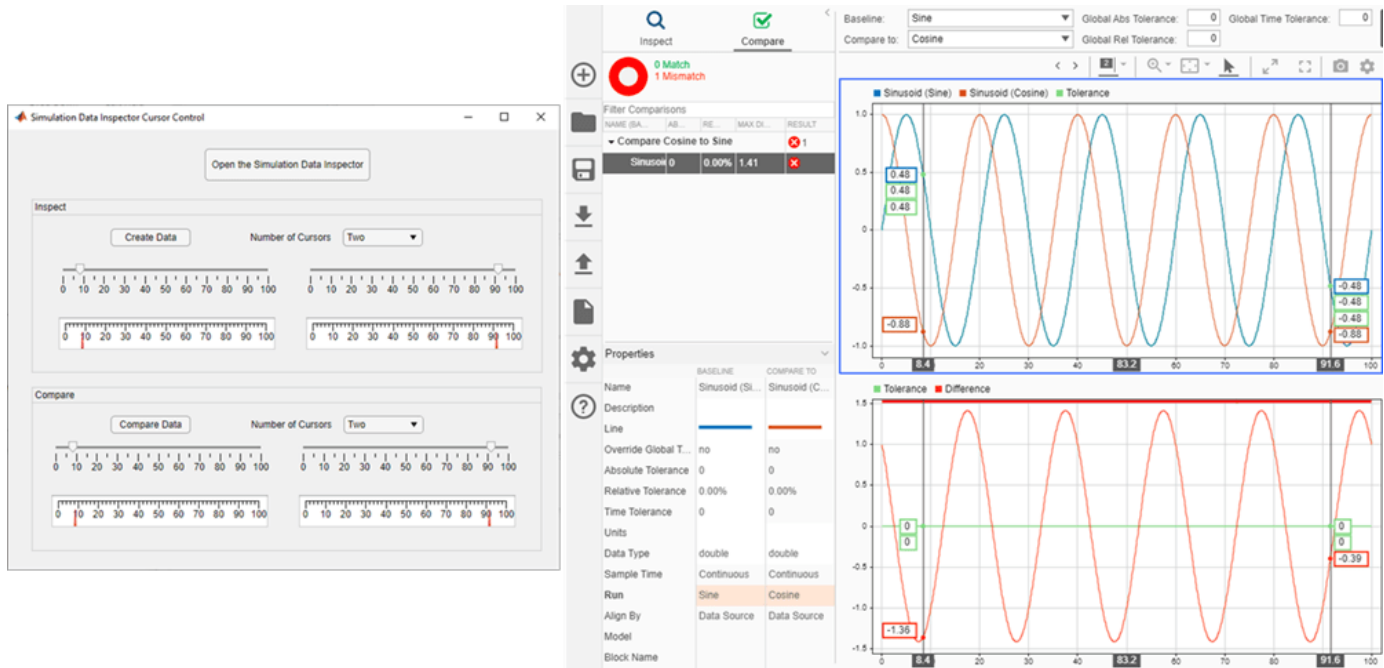

Next, add cursors. You can add cursors using the **Number of Cursors** control in the app or using the **Show/hide data cursors** option in the Simulation Data Inspector. The slider control and gauge display for each cursor becomes visible once the cursor is active in the Simulation Data Inspector. Try moving the cursors using the sliders in the app and by dragging them in the Simulation Data Inspector.

The app also includes controls and displays for cursors on the **Compare** pane of the Simulation Data Inspector. To interact with cursors on the **Compare** pane, start by clicking **Compare Data**. The

Simulation Data Inspector automatically shows the **Compare** pane when you compare data. Then, add cursors to the comparison plots using the app or the Simulation Data Inspector. Try moving the cursors in the Simulation Data Inspector and using the sliders in the app.

When you finish exploring the cursor synchronization, close the app window.

Examine the App Code

To view the code in the App Designer window, click **Code View** in the upper-right of the app canvas.

The code view shows the code that specifies the function of the app. Code in grey areas is automatically programmed by the App Designer when you interactively add components and specify properties in the **Design View**. The code in white areas customizes the function of the app.

Custom App Properties

The cursors app adds two custom properties to the app. The `callbackID` property saves the ID for the cursor callback registered with the Simulation Data Inspector so the app can unregister the callback when you close the app. The `runIDs` property saves the run IDs for the runs created when you click **Create Data**. The run IDs are then used to compare the runs when you click **Compare Data**.

Custom OnCursorMove Method

The `OnCursorMove` function is the cursor callback that the app registers with the Simulation Data Inspector when you start the app. To keep the displays in sync, the function refreshes the app settings each time you move a cursor in the Simulation Data Inspector.

Custom refreshSettings Method

The cursors app also includes the custom method `refreshSettings`, which keeps the values displayed in the app synchronized with the state of the Simulation Data Inspector. The `refreshSettings` method uses the `Simulink.sdi.getNumCursors` function to make sure the **Number of Cursors** controls display the correct number of cursors currently visible in the **Inspect** and **Compare** panes of the Simulation Data Inspector. The `refreshSettings` method also controls the visibility of the sliders and gauges using the cursor positions returned by the `Simulink.sdi.getCursorPositions` function. When a cursor is outside the range of its corresponding slider and gauge, the app hides the slider and gauge for that cursor.

Callbacks That Handle Component Events

Each component in the app user interface has an associated function that implements the component response to user interactions. You can add one or more callbacks for a component in the **Design View**, and you write the code to define the component response in the **Code View**.

Method	Description of Functionality
startupFcn	When you open the cursors app, the app registers a callback for cursors in the Simulation Data Inspector and refreshes the app data. The OnCursorMove cursor callback for both the Inspect and Compare panes executes when you move a cursor in the Simulation Data Inspector. The callback IDs are saved in the callbackID property of the app.
OpentheSimulationDataInspectorButtonPushed	When you click the Open the Simulation Data Inspector button, the app opens the Simulation Data Inspector and refreshes the app data.
CreateDataButtonPushed	When you click the Create Data button, the app creates a sine signal and a cosine signal and plots the signals in the Simulation Data Inspector.
CompareDataButtonPushed	When you click the Compare Data button, the app compares the run with the sine signal and the run with the cosine signal.
SimulationDataInspectorCursorControlUIFigureCloseRequest	When you close the app, the app unregisters the callback functions for cursors in the Simulation Data Inspector.
NumberOfCursorsDropDownValueChanged CompNumCursorsDropDownValueChanged	When you use one of the Number of Cursors controls to change the number of cursors displayed in the Simulation Data Inspector, the app uses the Simulink.sdi.setNumCursors function to display the specified number of cursors in the Simulation Data Inspector.
LeftSliderValueChanging RightSliderValueChanging CompLeftSliderValueChanging CompRightSliderValueChanging	When you adjust a cursor position using the slider, the app uses the Simulink.sdi.setCursorPositions function to update the position of the cursor in the Simulation Data Inspector.

Iterate Model Design Using the Simulation Data Inspector

The Simulation Data Inspector facilitates iterative design, debugging, and optimization by providing easy access to visualizations of logged data during simulation. Using the Simulation Data Inspector archive, you can maintain a focused work area and control data retention for multiple simulations. When you automatically archive simulation runs, you can create a view that is automatically applied to subsequent simulation runs. With **Browse Mode** enabled, you can inspect large amounts of logged signals on **Time Plot** visualizations more quickly.

View and Inspect Signals During Simulation

You can plot logged signals in the Simulation Data Inspector during simulation. Viewing signals during a simulation can help build understanding of the model and allow you to make decisions about model parameters without waiting for a simulation to complete.

When you plot data that is streaming from an active simulation, the Simulation Data Inspector automatically updates the time span of the plot to match the stop time for the simulation. To view the streaming data on a smaller time scale, change the **t-Axis Max** value or zoom in time. To update the

t-Axis Max, open the **Visualization Settings** . To zoom in time, select the **Zoom in time** option from the **Zoom** menu and click and drag in the plot area to specify the time span.

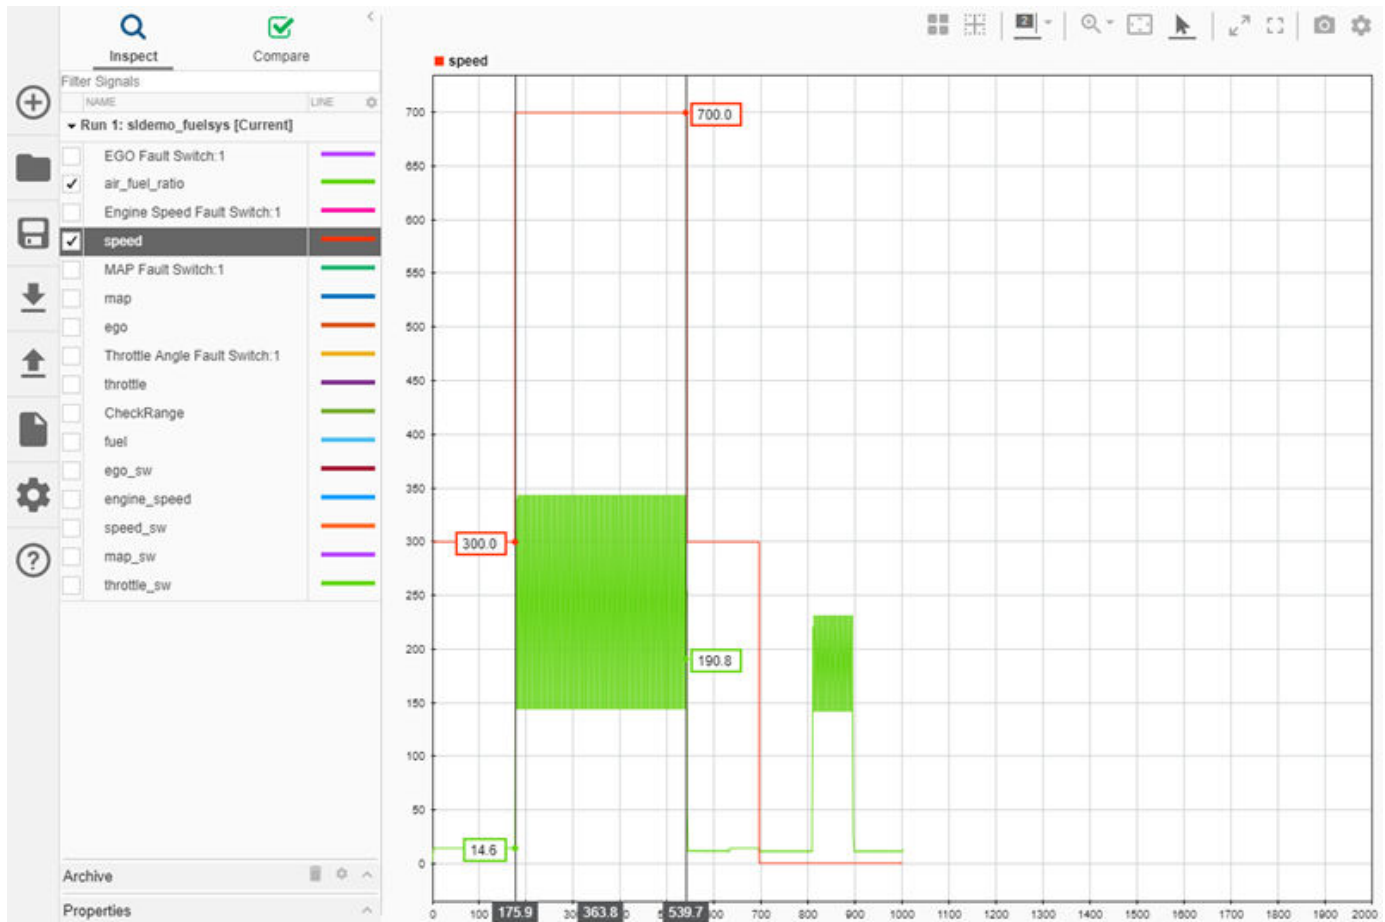

Use the **Update mode** setting to specify whether the Simulation Data Inspector wraps or scrolls the plot after the streaming data reaches the maximum time you specified.

To closely examine signals throughout design iteration, add data cursors to your plots. You can add a data cursor to the plot during simulation, while a simulation is paused, or after the simulation has

finished. To add a data cursor, click the cursor button . Drag the data cursor across the plot to inspect signal values. When you display multiple signals on a plot, the data cursor indicates the value for each signal in a color-coded box.

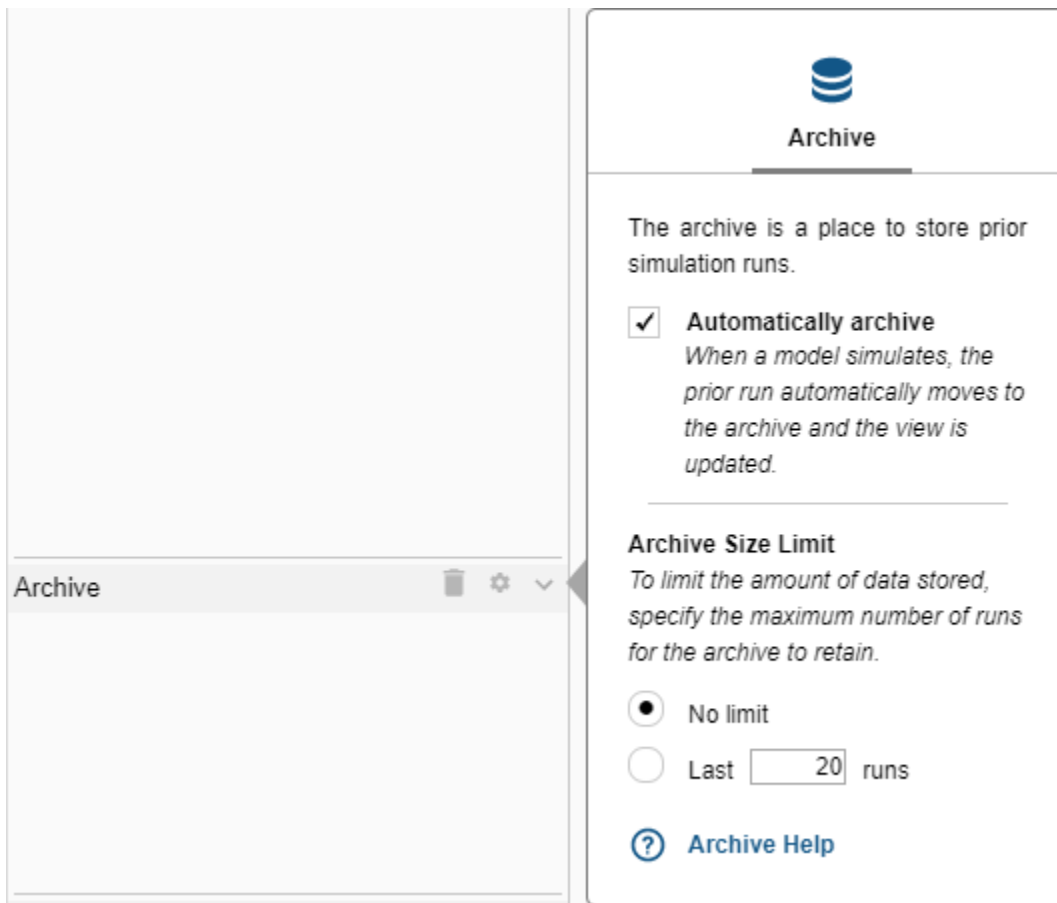

Click the drop-down on the cursors button and select **Two Cursors** to add a second data cursor and explore temporal characteristics of your data. You can move each cursor independently, or you can move them together. The number between the two cursors displays the time difference between the cursors.

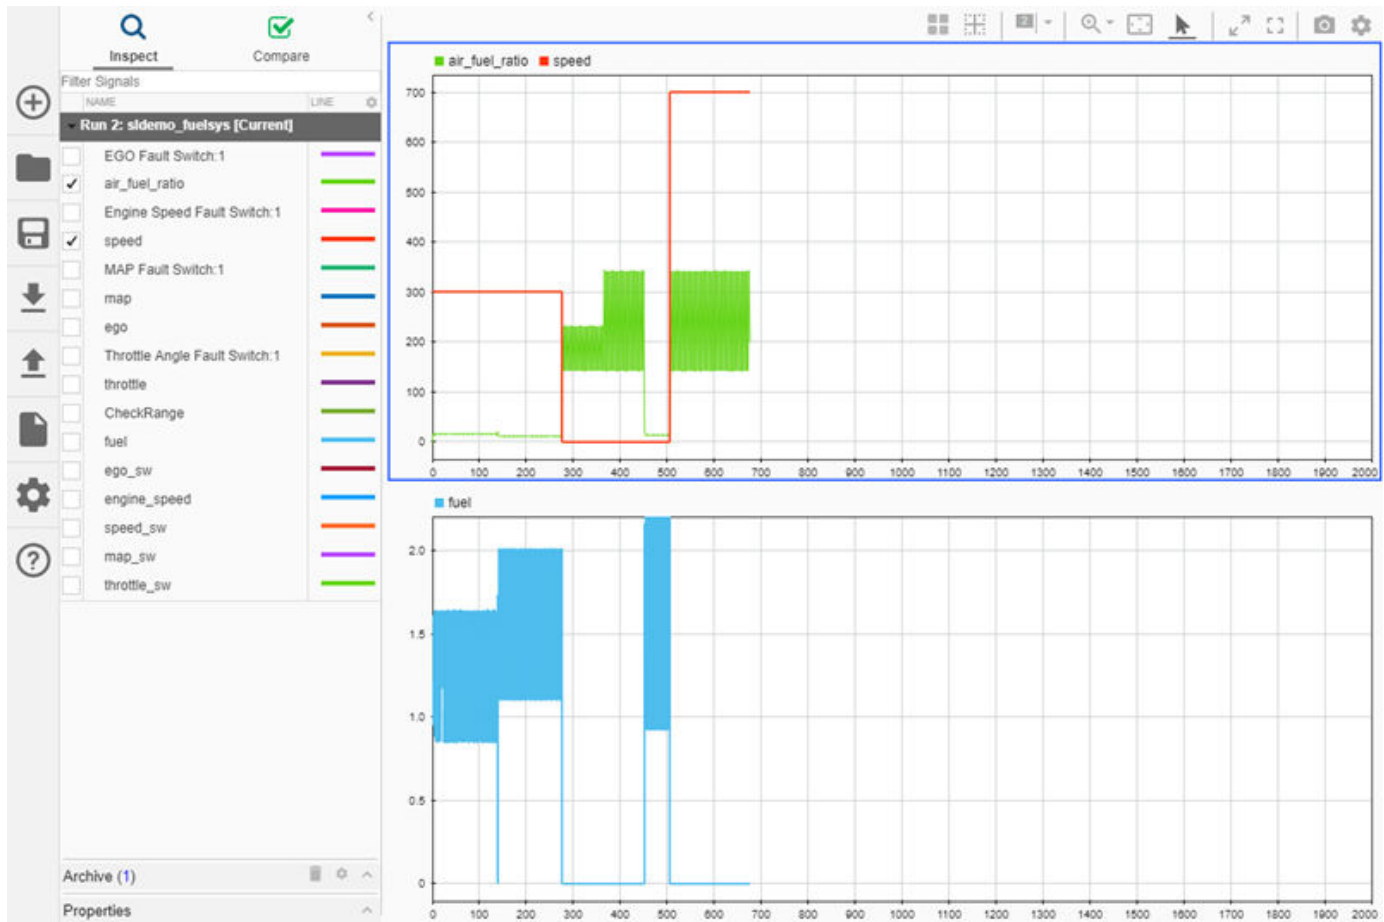

You can type directly into the box to specify a desired cursor separation. To move the cursors together, click and hold the middle number indicator, and drag it across the graphical viewing area to your desired position. For more information about using data cursors, see “Inspect Simulation Data” on page 29-148.

Automatically Transfer View to Current Simulation

By default, the Simulation Data Inspector is configured to automatically archive simulation runs and transfer a view from the previous run to the current simulation. When you run a new simulation, the Simulation Data Inspector moves the prior simulation run to the archive and updates the view to show aligned signals from the current run. You can control the **Automatically archive** setting on the **Archive** settings pane.

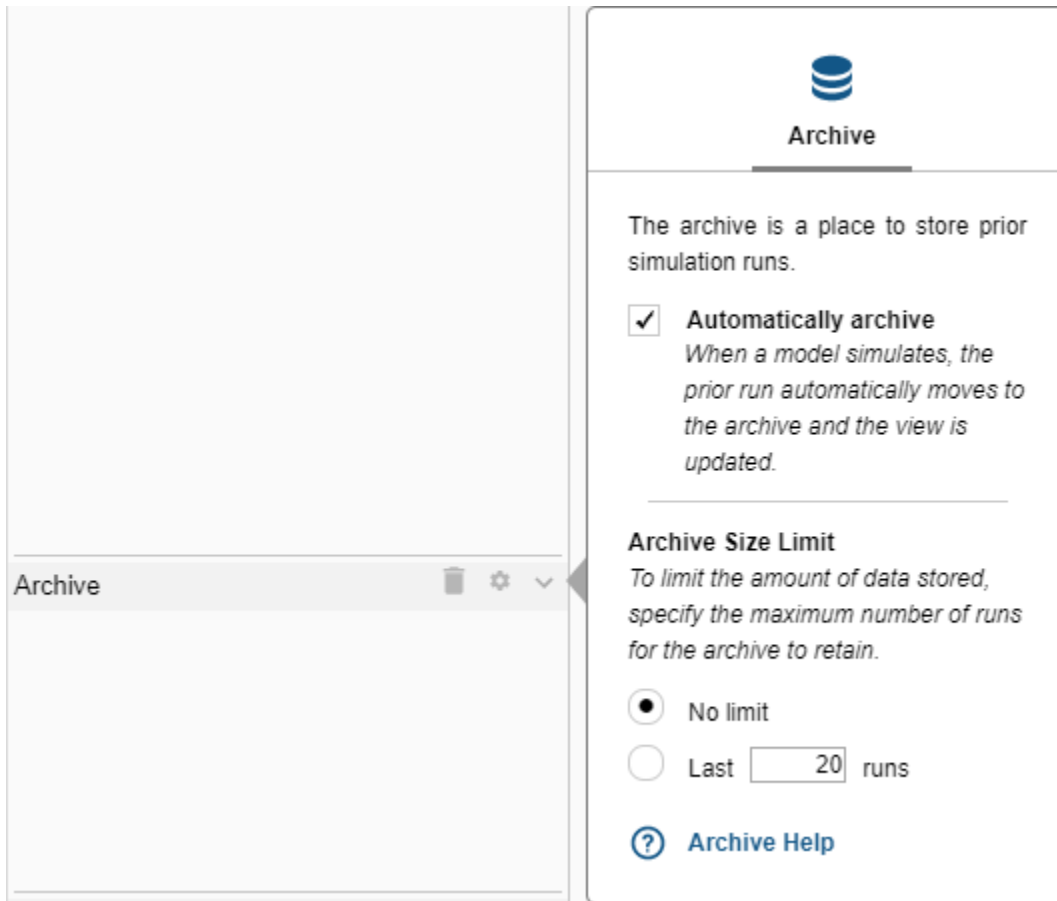

For example, create a view of signals from the `sldemo_fuelsys` model. Then, simulate the `sldemo_fuelsys` model again. The signals from the previous run clear from the plots, and the Simulation Data Inspector plots data from the current simulation as the simulation runs. The previous run also moves into the archive, reducing clutter in the work area.

You can access and plot data from previous runs from within the archive, and you can drag runs of interest into the work area from the archive.

Control Data Retention

Running many simulations with logged signals can create a lot of data, especially during iterative design and debugging workflows. To limit the amount of disk space occupied by logged data, you can limit the amount of data the Simulation Data Inspector stores in the archive on the **Archive** settings pane.

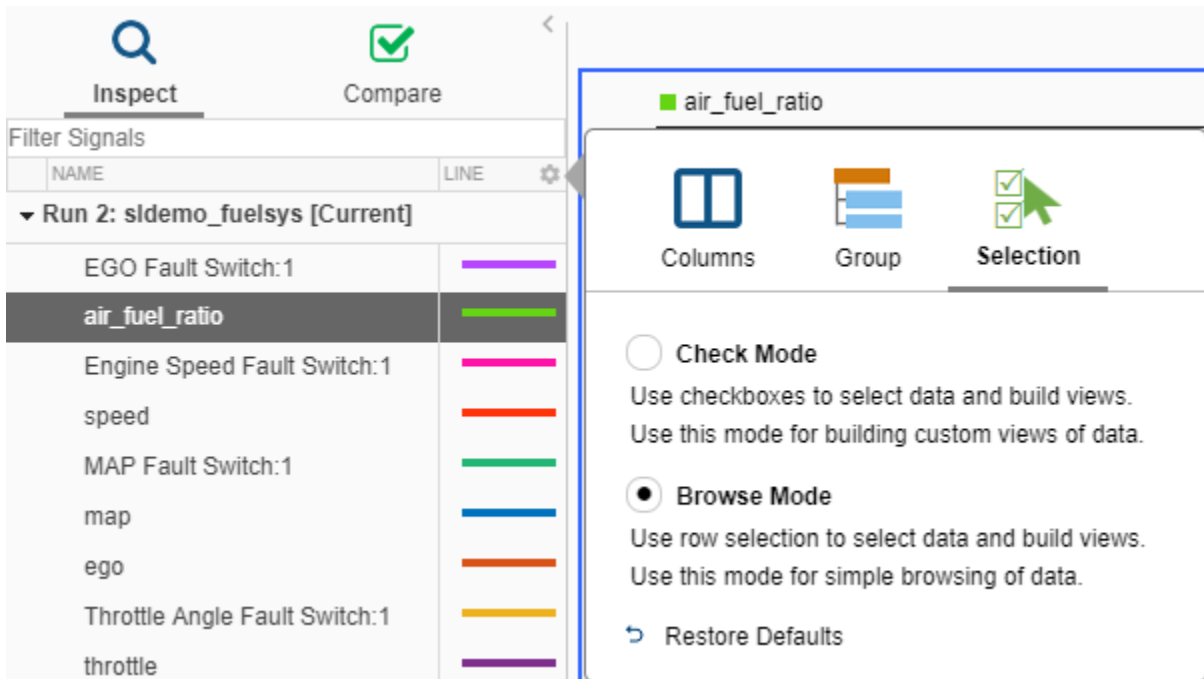

By default, the Simulation Data Inspector does not limit the number of runs stored in the archive. To impose a limit, select the **Last runs** radio button, and specify the desired limit. When the number of runs in the archive reaches the limit, the Simulation Data Inspector deletes the run that has been in the archive the longest. If the archive contains more runs than the limit you specify, the Simulation Data Inspector provides a warning before deleting your run data.

Tip When you do not want the Simulation Data Inspector to store run data, specify an archive limit of 0. With an archive limit of 0 and **Automatically archive** enabled, the Simulation Data Inspector automatically transfers your configured view to the current simulation and only retains the current simulation data.

Visualize Many Logged Signals

You can use **Browse Mode** to inspect many signals quickly on **Time Plot** visualizations. To enable **Browse Mode**, click the gear icon in the navigation pane, and navigate to the **Selection** pane. Click the radio button next to **Browse Mode**.

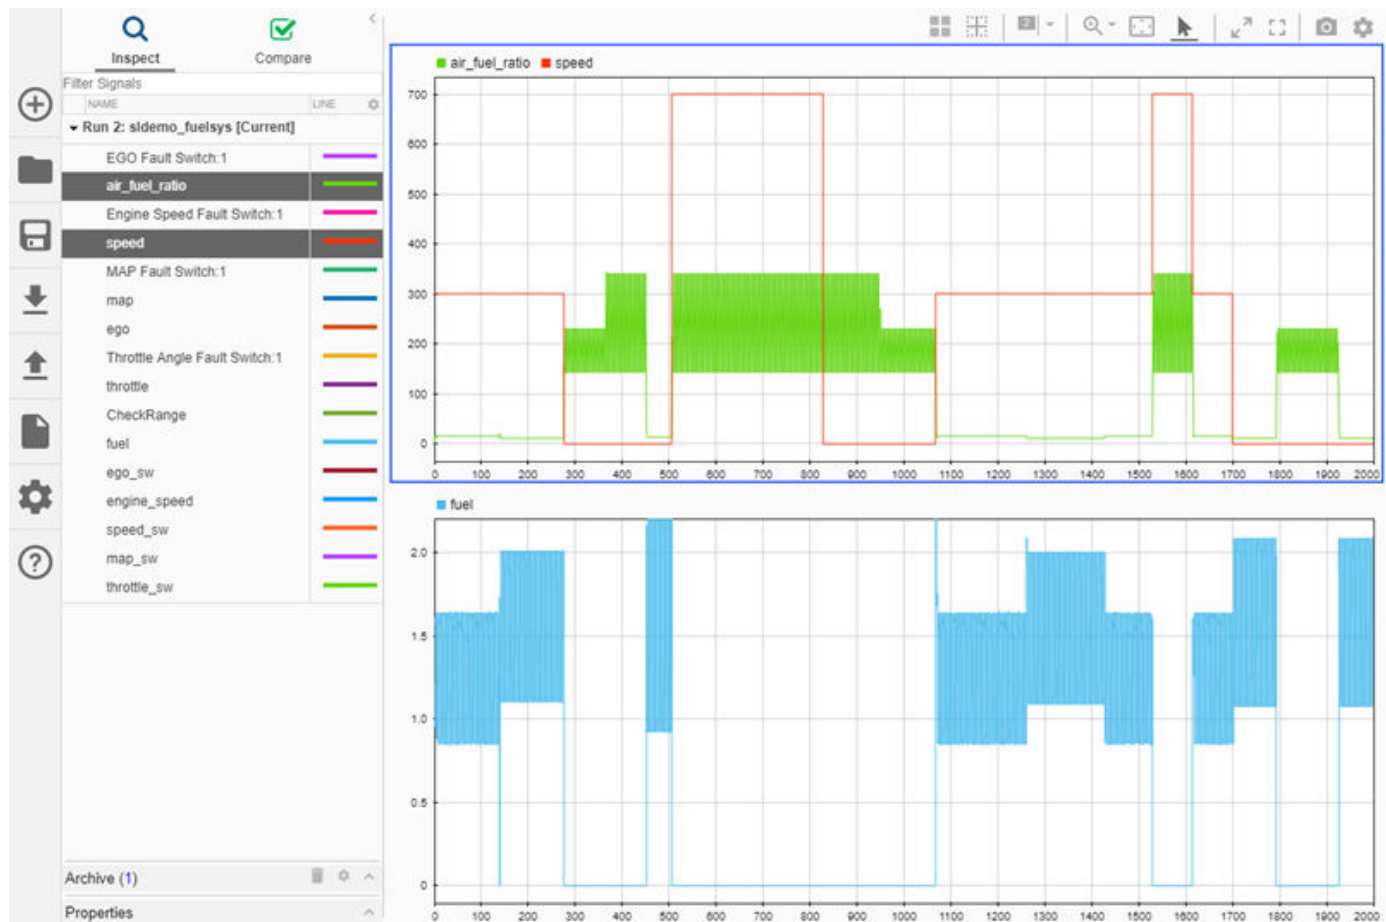

Note To use **Browse Mode**, your layout must include only **Time Plot** visualizations.

In **Browse Mode**, signals selected in the navigation pane are plotted on the active **Time Plot**. You can use the arrow keys on your keyboard to change the selected signals, and you can select multiple signals by holding the **Shift** or **Ctrl** keys. When you select a row for a run or hierarchical organization, no signals are displayed in the graphical viewing area.

You can also use plot layouts in **Browse Mode** to make more complex visualizations. When the graphical viewing area contains multiple subplots, selecting new signals using the mouse or keyboard changes only the active plot.

When you finish browsing your simulation results, enable **Check Mode** on the **Selection** pane of the work area settings to build plots that showcase your data. For more information about creating plots with the Simulation Data Inspector, see “Create Plots Using the Simulation Data Inspector” on page 29-135.

Access Data in a MATLAB Function During Simulation

You can stream signal data to a MATLAB callback function during simulation using the **Data Access** functionality in the **Instrumentation Properties** for a signal. The function you provide receives data in packets asynchronously throughout the simulation. The callback function executes each time it receives new data. You can write a callback function to process signal data during simulation or to create a custom visualization of a signal. The callback function does not affect signal values in your model. This example illustrates the steps required to access signal data during simulation using a simple callback function that plots the signal.

Note Data access does not support Rapid Accelerator mode, referenced models, fixed-point data, or virtual bus signals and only supports 1-D and 2-D matrix signals.

Write a Callback Function for Data Access

The data access callback function always receives signal data as the first argument. You can choose whether to send the simulation time and a parameter. When you include all three arguments, simulation time is the second argument. Your callback function can be specific to a single signal, or you can use the same callback to process and visualize multiple signals. The callback function only has access to data for a single signal at a time. This example creates a callback function that receives signal data, time, and a parameter used to identify which signal the function is processing for a given call.

Note The data access callback function receives nonvirtual bus data as a structure of arrays that matches the hierarchy of the bus.

Author your callback function in an m-file with the same name as your function. For more information about writing MATLAB functions, see “Create Functions in Files”. The example callback function uses the optional parameter to assign a numerical identifier to each signal. The parameter is used to create a unique figure for each signal and assign each signal a different line color. To accumulate signal data on the plot, the callback includes `hold on`. For each call to the callback, the function receives a portion of the signal data. You can use the callback to accumulate the packets if desired.

```
function plotSignals(y,time,sigNum)

    figure(sigNum)

    if isequal(sigNum,1)
        marker = 'ro-';
    elseif isequal(sigNum,2)
        marker = 'go-';
    else
        marker = 'bo-';
    end

    hold on;
    plot(time,y,marker);

end
```

The callback function provides no return values. If you specify the function with returns, the return data is discarded.

Tip Use `assignin` to access data from the callback function in the base workspace.

Save the callback function in a location on the MATLAB path. If the location where you save the callback is not on the path, you can add it to the path. Right-click the directory containing the callback in the **Current Folder** section in MATLAB and select **Add to Path**.

Configure Signals for Data Access

To access data for a signal with the data access callback, you need to log the signal. To mark a signal for logging, right-click the signal in your model and select **Log Selected Signals**. To configure data access for the signal, right-click the logging badge and select **Properties**. On the **Data Access** tab of the **Instrumentation Properties**, you can specify the name of your callback function, whether the callback function takes time as an argument, and the optional parameter value.

For example, open the `vdp` model and configure the `x1` and `x2` signals to use the callback from the previous section.

- 1 Enter `vdp` in the MATLAB **Command Window**.
- 2 Select the `x1` and `x2` signals. Then, right-click the selected signals and choose **Log Selected Signals** from the context menu.
- 3 To open the **Instrumentation Properties**, right-click the logging badge for `x1` and select **Properties**.
- 4 On the **Data Access** pane, enter the name of the callback, check **Include simulation time**, and enter 1 as the **Function parameter**.

- 5 Open the **Instrumentation Properties** for `x2` and configure the **Data Access** pane to use the `plotSignals` callback with a **Function parameter** value of 2.

Simulate the `vdp` model. The callback generates Figures 1 and 2 to display the `x1` and `x2` signals during simulation.

You can modify the callback function to create a custom visualization or to create a plot of processed signal data. Errors related to the data access callback function do not interrupt simulation. The errors surface in the **Diagnostic Viewer** as a warning.

- “View Data in the Simulation Data Inspector” on page 29-2

Analyze Multidimensional Signal Data

When you log multidimensional signal data or import multidimensional data into the Simulation Data Inspector, you can choose to view and analyze the data as:

- A single signal with multidimensional sample values.
- A set of signals with scalar sample values: one signal, called a channel, for each element of the multidimensional data.

When the multidimensional data is frame-based, you can also use the Simulation Data Inspector to remove the buffering from each frame.

You can control how you view and analyze multidimensional signal data using the Record block or the Simulation Data Inspector. When you change the representation of a multidimensional signal in the Record block, the change is reflected in the Simulation Data Inspector and vice versa.

Convert Representation of Multidimensional Data

The way the Simulation Data Inspector initially represents a multidimensional signal depends on the number of elements in each sample of the signal. By default:

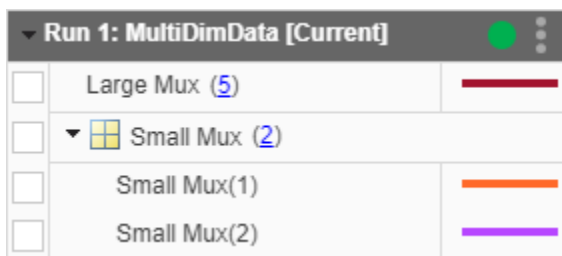

- Signals with samples that contain fewer than four elements are represented as channels.
- Signals with samples that contain more than four elements are represented as a single signal with multidimensional sample values.
- Variable-size signals are always represented as a single signal with multidimensional values.

When the default behavior for a signal with fixed dimensions does not provide the signals you need for your analysis, you can convert the representation from a single signal to channels or from channels to a single signal.

For example, consider this output from a model that creates two composite signals using Mux blocks:

- `Large Mux` contains five elements and is displayed as a single signal by default.
- `Small Mux` contains two elements and displayed as two channels by default.

The run includes one row for the `Large Mux` signal and three rows for the `Small Mux` signal. By default, the Simulation Data Inspector groups signals by data hierarchy, so one row groups the signals for each channel in the `Small Mux` signal, and each channel has a row.

Signals with multidimensional data and the grouping rows for multidimensional signals represented as channels indicate the dimensions. To convert the representation of a signal with multidimensional data, you can click the dimensions and select an option from the menu. For example, to convert the `Large Mux` signal to channels, click the dimensions, 5, and select **Convert to channels**.

To convert the **Small Mux** signal to a single signal, click the dimensions, 2, for the grouping row and select **Convert to multidimensional signal**.

When you convert a signal from channels to a single signal, any plotted channels are cleared from the view because the signals for the channels no longer exist.

You can also convert the representation of multidimensional signals in the Simulation Data Inspector programmatically using the `expand` and `collapse` functions.

Plot Multidimensional Signal Data

Most visualizations in the Simulation Data Inspector, including time plots, XY plots, maps, and sparklines, only support plotting scalar signals. To plot data from a multidimensional signal on one of these visualizations, convert the signal to channels. You can use the conversion menus that you access by clicking the signal dimensions or the menu that appears on a subplot that does not support multidimensional data when you try to plot the signal.

For example, if you try to plot the **Large Mux** signal on a time plot, the menu gives you the option to change the active subplot to an array plot, which does support multidimensional data, or to convert the representation of the signal.

To view multidimensional data, use the array plot in the Simulation Data Inspector. The array plot supports scalar and multidimensional signals, including variable-size signals. You can add an array plot to the subplot layout using the menu that appears when you try to plot a multidimensional signal on a plot that only supports scalar signals or using the **Visualization Gallery**. For more information about using the array plot, see “View Multidimensional Signals Using the Array Plot” on page 29-51. The Record block does not support the array plot.

Only time plots support plotting signals programmatically. You can plot channel data on a time plot programmatically. You cannot plot data for a signal with multidimensional sample values programmatically. Use the `expand` function to convert a single multidimensional signal to channels, which you can plot on a time plot programmatically using the `plotOnSubPlot` function.

Compare Multidimensional Signals

By default, when you compare multidimensional signals represented as a single signal or runs that contain multidimensional signals represented as a single signal, the Simulation Data Inspector converts the multidimensional signal to channels and computes a comparison result for each channel. The conversion happens for the comparison only and does not affect the way the signal is represented on the **Inspect** pane. The Simulation Data Inspector does not support comparing variable-size signals or signals with multidimensional sample values.

If you do not want to compute comparison results for the channels in multidimensional signals, you can configure comparisons to skip multidimensional signals instead of computing the channel results.

To configure a comparison to skip multidimensional signals, on the **Compare** pane, click **More**, then clear **Expand multidimensional channels**.

Baseline: Run 1: MultidimensionalData Compare to: Run 2: MultidimensionalData

Global Tolerances

Absolute: 0 Relative: 0 Time: 0

Constraints

Expand multidimensional channels Signal start and stop times must match

Signal data types must match Signal time vectors must match

Stop comparison on first mismatch of: Metadata [-] Less

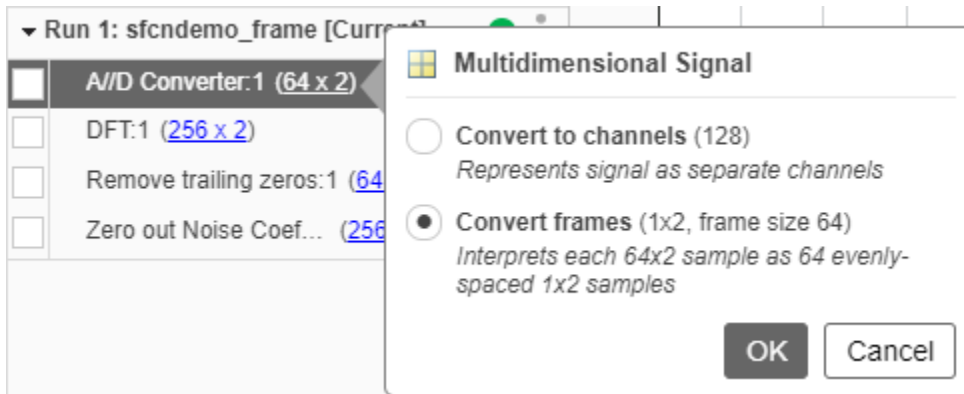

You can also configure whether programmatic comparisons compute results for multidimensional signals using the `Simulink.sdi.compareRuns` function with the `ExpandChannels` name-value argument.

Convert Representation of Frame-Based Data

Some applications buffer several samples of a signal into a frame to process with a single computation instead of processing each sample in the frame separately. When you work with frame-based signals, you can analyze the data frame by frame, or you can remove the buffering and analyze the signal without the frames.

You can remove frame buffering from signals logged to the Simulation Data Inspector using the menu that appears when you click the dimensions next to a multidimensional signal or the menu that appears when you try to plot multidimensional data on a plot that only supports scalar data.

For example, consider this run created by logging data for the analog to digital converter output in the model `sfcdemo_frame`. The model buffers the samples into a frame and performs a discrete Fourier transform on each frame. To remove the frame buffering in the Simulation Data Inspector, click the dimensions for the signal, 64×2 , and select **Convert frames**. The conversion interprets each sample as 64 evenly spaced samples with dimensions 1-by-2. Because the unbuffered signal only contains two elements, conversion also displays the results as separate channels with scalar sample values.

You can also convert the frames for a frame-based signal in the Simulation Data Inspector programmatically using the `convertToFrames` function. The Simulation Data Inspector does not support converting frames for imported data.

When you log frame-based data from a model, you can control how the data is logged by specifying the **Input Processing** setting for the logged signal in the model using the **Instrumentation Properties** dialog box or the `Simulink.sdi.setSignalInputProcessingMode` function. You can configure the input processing for the signal as frame-based or sample-based.

- Sample-based — The logged data retains the buffering, and each sample of the logged signal represents a frame. The Simulation Data Inspector interprets the data as a multidimensional signal, where each element of a sample represents a separate channel.
- Frame-based — Logging removes the buffering and treats each column in the samples as a separate channel.

When you log frame-based signals as sample-based, you can still convert the frames in the Simulation Data Inspector after simulation.

Analyze Data from Multiple Simulations

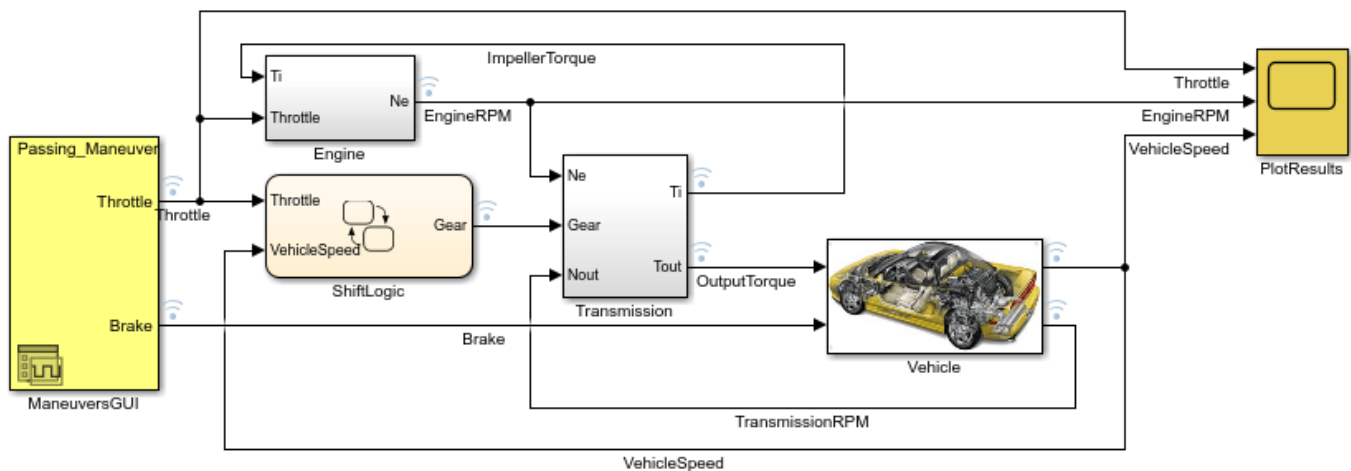

You can analyze data from multiple simulations by viewing the data from each simulation using the same visualizations and subplot layout. With the Simulation Data Inspector, you can save the subplot layout and configuration, including the plotted signal selection, as a view in an MLDATX file that you can load to visualize data from another simulation. When the Simulation Data Inspector contains multiple runs, you can also copy or cut the plotted signal selection from one run and then paste it onto another to plot data from different runs side by side or easily swap which run supplies the data for the plots.

This example shows how to use views and the cut, copy, and paste options in the Simulation Data Inspector to analyze data from several simulations of the model `sldemo_autotrans`. For information about analyzing simulation data using comparisons, see “Compare Simulation Data” on page 29-171.

Open and Simulate the Model

Open the model `sldemo_autotrans`, which models a controller for an automatic transmission system. The model uses a Signal Editor block to load external input data to model the Throttle and Brake signals for different vehicle maneuvers. In this example, you run several simulations and analyze the system response to different vehicle maneuvers. For more information about the model and the system it represents, see “Modeling an Automatic Transmission Controller”.

Modeling an Automatic Transmission Controller

Copyright 1990-2021 The MathWorks, Inc.

Simulate the model for the default input scenario, which represents a passing maneuver. On the **Simulation** tab, click **Run**.

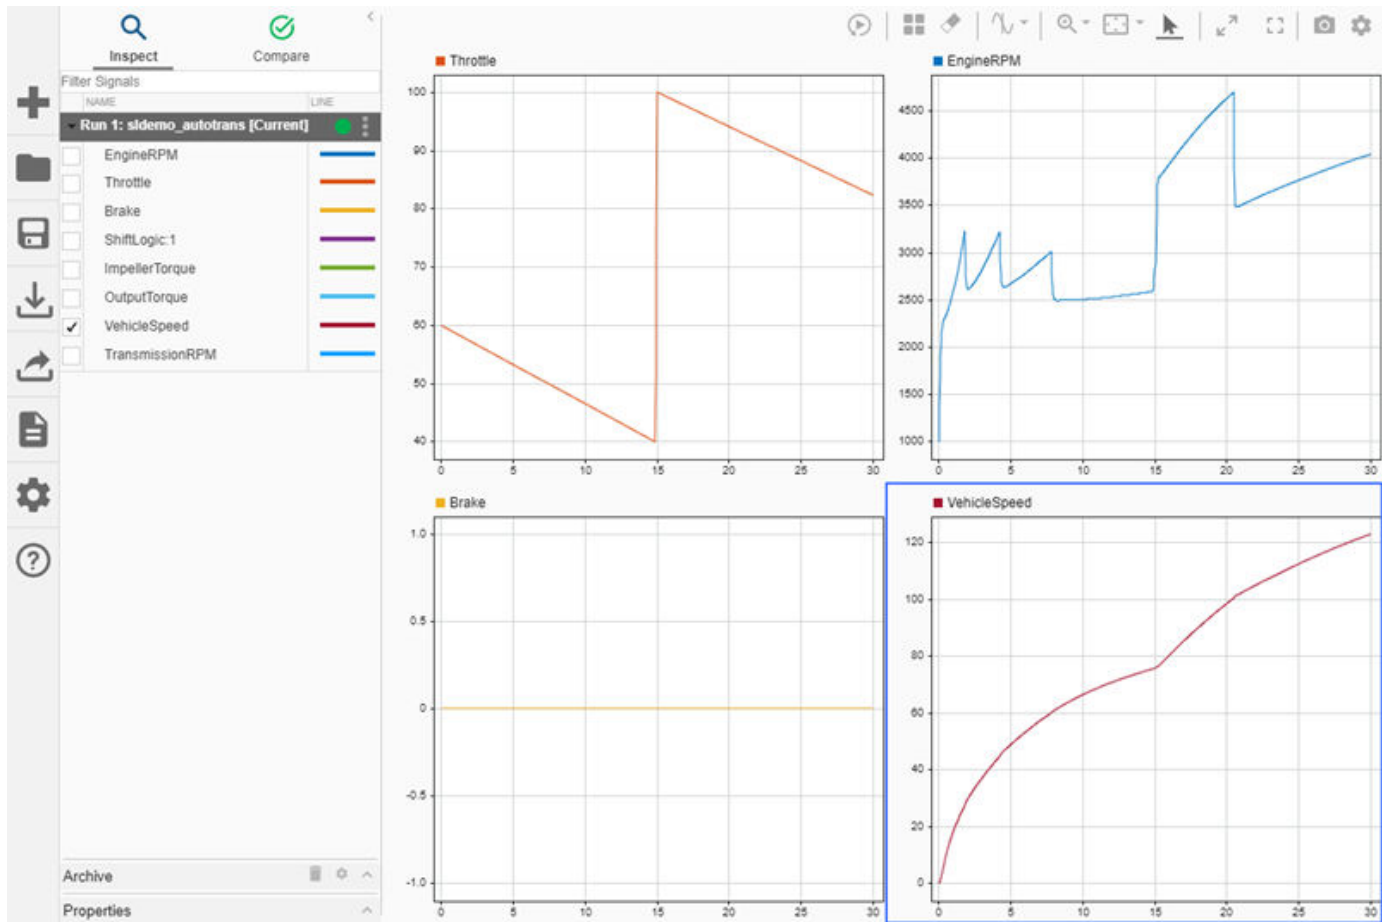

Create and Save Views to Analyze Simulation Results

After simulating the model, analyze the simulation results by plotting signals on multiple time plots in the Simulation Data Inspector. For example, visualize the input signals **Throttle** and **Brake** alongside the **EngineRPM** and **VehicleSpeed** signals to see how the driver input to the vehicle affects the vehicle speed.

Open the Simulation Data Inspector. On the **Simulation** tab, under **Review Results**, click **Data Inspector**. Then, change the subplot layout in the Simulation Data Inspector to include four subplots, one for each signal. To change the subplot layout, click **Layout**. Then, under **Basic Layouts**, select the four-subplot layout.

Plot the **Throttle** signal on the top-left subplot. To plot the signal, select the subplot where you want to plot the signal, then select the check box next to the signal. Plot the **Brake** signal on the subplot below the **Throttle** signal, then plot the **EngineRPM** and **VehicleSpeed** signals on the remaining subplots.

To facilitate building the same visualization for subsequent simulations, save the view. In the Simulation Data Inspector, click **Layout**, then select **Save current view**. Use the dialog box to specify a name for the view and browse to the location where you want to save the view file. Alternatively, you can save the view programmatically using the `Simulink.sdi.saveView` function. This example saves the view with the name `ThrottleBrakeVehicleSpeed`.

After saving the view, clear the subplots so you can visualize another set of signals. Click **Clear Subplot**, then select **Clear all subplots**.

Build another view to analyze the relationships among the `EngineRPM`, `OutputTorque`, `TransmissionRPM`, and `VehicleSpeed` signals.

Save the view using the `Simulink.sdi.saveView` function or using the Simulation Data Inspector UI. In the Simulation Data Inspector, click **Layout**, then select **Save current view**. This example saves the view with the name `RPMTorqueVehicleSpeed`.

Load a View and Plot Signals Side by Side

Simulate the model again, using input data for the hard braking vehicle maneuver. To change the input scenario the Signal Editor block loads, double-click the `ManeuversGUI` block. Then, from the **Active scenario** list, select the `Hard_braking` scenario.

By default, when you simulate the model the second time, the Simulation Data Inspector updates the plots in the current view with data from the current simulation and moves the prior simulation run into the archive. To better understand the vehicle maneuver, load the first view that plots the `Throttle` and `Brake` signals using the Simulation Data Inspector or the `Simulink.sdi.loadView` function. To load the view using the Simulation Data Inspector UI:

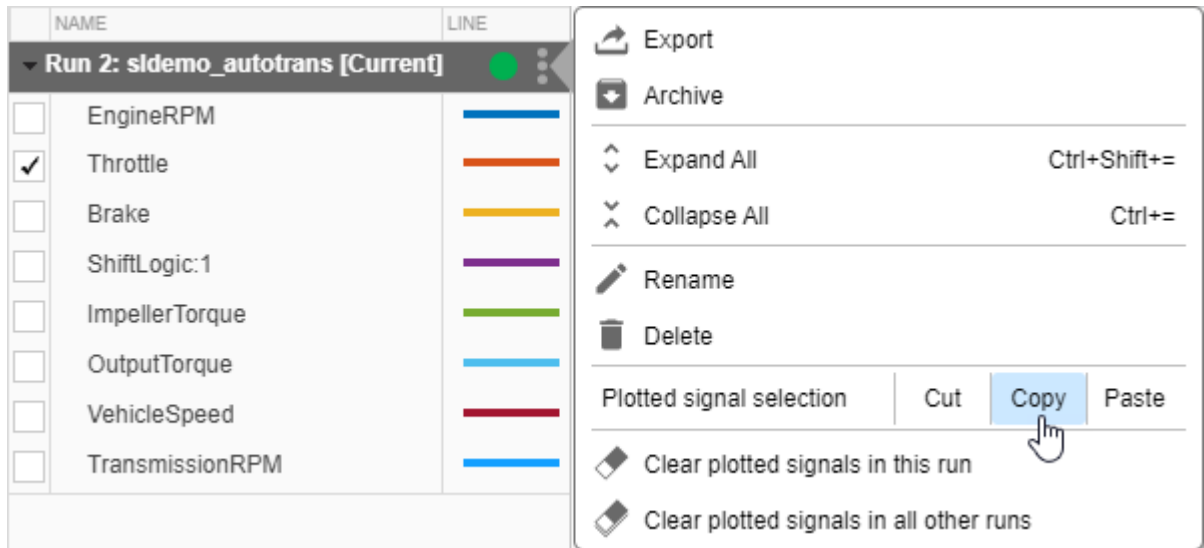

- 1 Click **Layout**, then select **Open saved view**.
- 2 In the dialog box, select `ThrottleBrakeVehicleSpeed.mldatx`.
- 3 Click **Open**.

To adjust the zoom level for the signals from the new run, click Fit to View  or press the space bar.

Analyze the differences between the passing maneuver and hard braking maneuver by plotting the same signals from each simulation side by side. Copy the plotted signal selection for the current run and paste it onto the prior run in the archive.

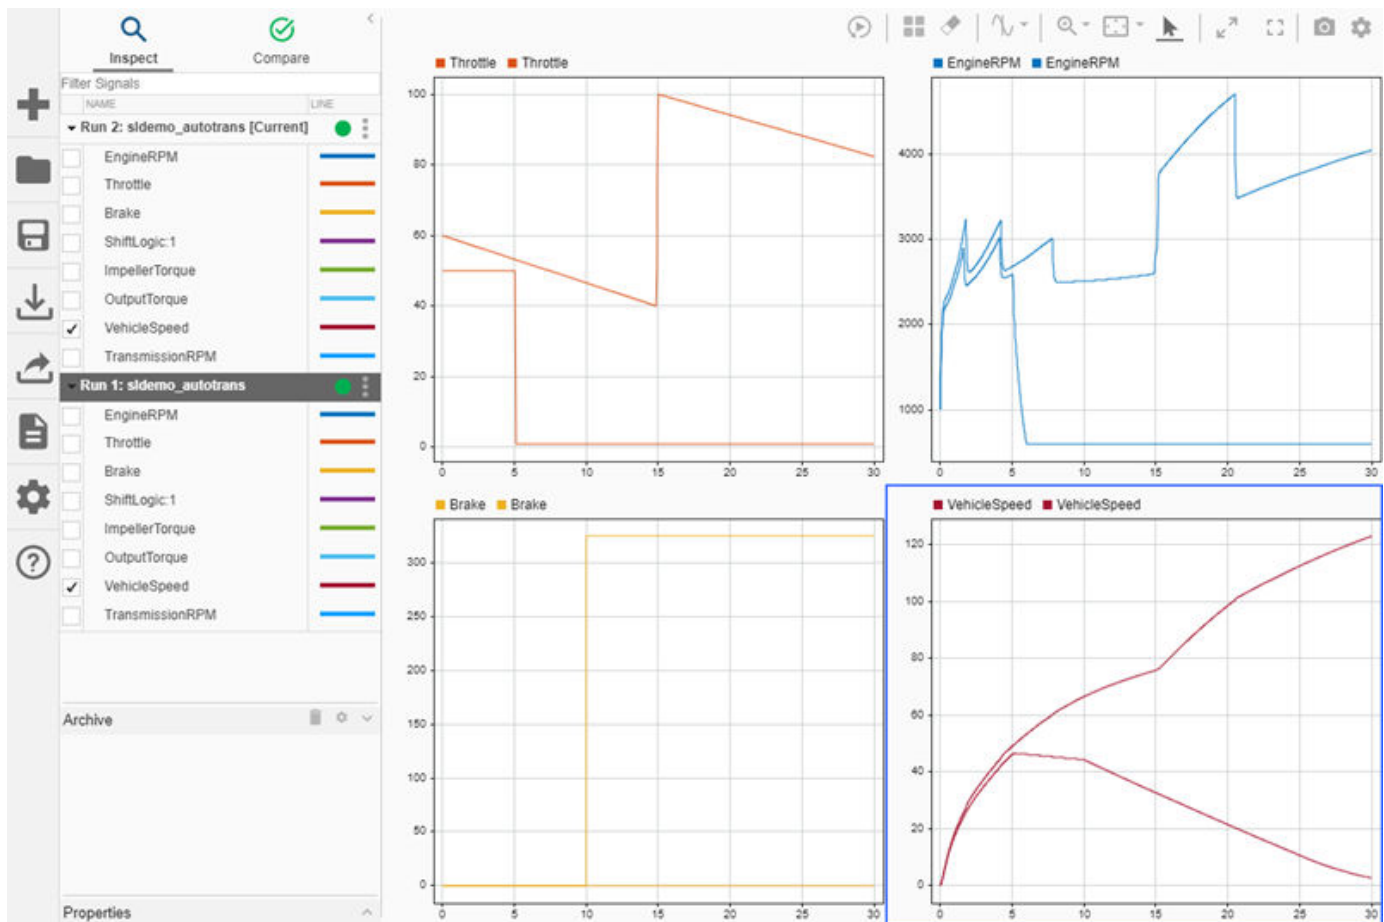

- 1 To open the run actions menu for the current run, click the three dots on the right of the row for the current run. Then, under **Plotted signal selection**, select **Copy**.

- 2 Click the arrow to expand the archive and access the prior run.

- 3 To open the run actions menu for the prior run, click the three dots on the right of the row for the prior run in the archive. Then, under **Plotted signal selection**, select **Paste**.

The cut, copy, and paste options work for all visualizations that plot signal data, including XY plots and Maps.

Note The map visualization only supports displaying one route. When you copy and paste the plotted signals selection for a view that includes a map, the map updates to display the route from the run where you pasted the plotted signal selection.

Analyze the differences between the passing maneuver and hard braking simulations using the second view.

- 1 Load the view `RPMTorqueVehicleSpeed.mldatx`.

Click **Layout**, then select **Open saved view**. Select the file `RPMTorqueVehicleSpeed.mldatx` and click **Open**.

- 2 Click **Fit to View**  or press the space bar.

- 3 Copy the plotted signal selection from the current run.

- 4 Paste the plotted signal selection from the current run onto the first run.

Swap Source Run for Plotted Signals

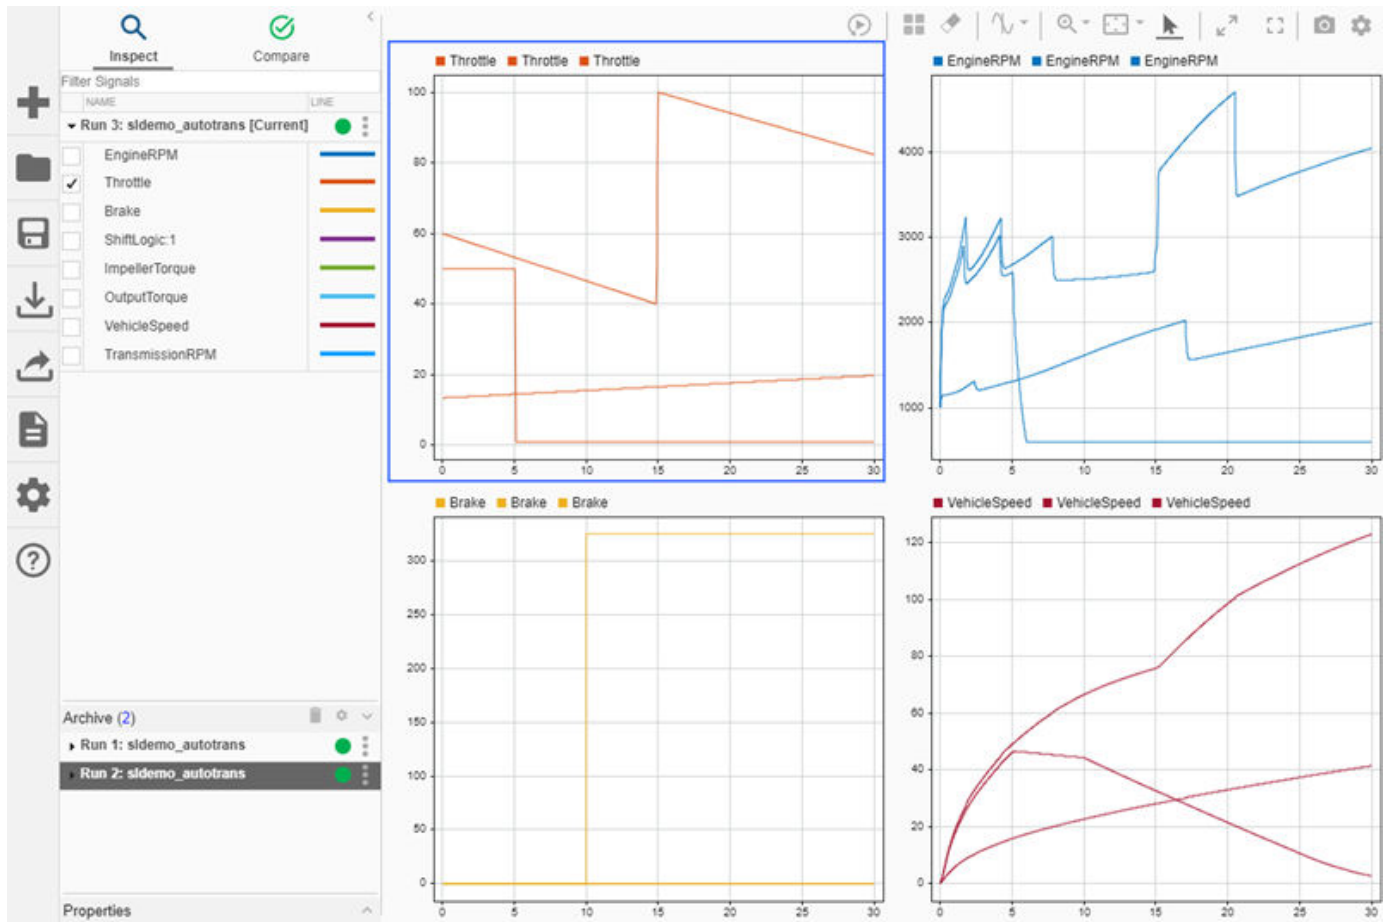

Simulate the model again, using input data for the gradual acceleration maneuver. To change the input scenario the Signal Editor block loads, double-click the ManeuversGUI block. Then, from the **Active scenario** list, select the Gradual_Acceleration scenario.

When you simulate the model again, the plots update to display data from the current run. To analyze the vehicle maneuver, load the first view. Click Layout, then select **Open saved view** and select the ThrottleBrakeVehicleSpeed view file. To adjust the axis limits for the new run data, click Fit to

View  or press the space bar.

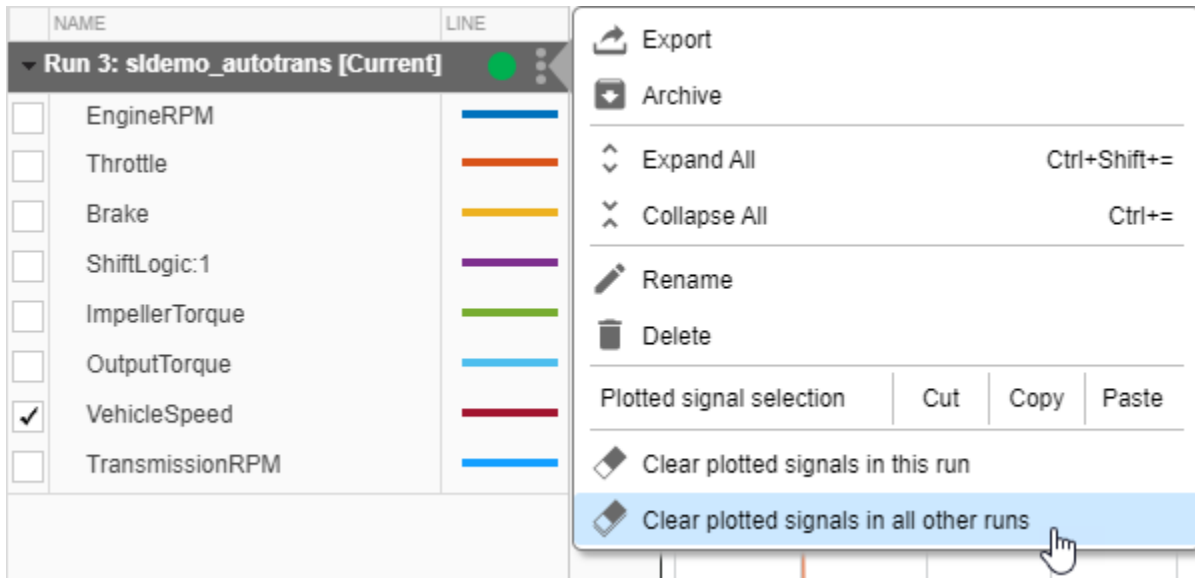

Suppose you want to view data from all three runs together. You can copy the plotted signal selection from the current run and paste it onto both prior runs.

- 1 Open the run actions menu for the current run. Then, under **Plotted signal selection**, select **Copy**.
- 2 Open the run actions menu for Run 1 in the archive. Then, under **Plotted signal selection**, select **Paste**.
- 3 Open the run actions menu for Run 2 in the archive. Then, under **Plotted signal selection**, select **Paste**.

Now suppose you want to analyze each vehicle maneuver on its own. Using the run actions menu, you can easily clear signals from a specific run from the view or clear signals from all runs except a specific run from the view. Then, you can use the cut and paste options to swap which run provides the data for the view.

To remove signals from the passing maneuver and hard braking maneuver simulations, open the run actions menu for the current run and select **Clear plotted signals in all other runs**.

Only signals from the current run remain plotted.

To update the view to plot only signals from the hard braking maneuver simulation, cut the plotted signal selection from the current run and paste it onto Run 2 in the archive.

- 1 Open the run actions menu for the current run. Then, under **Plotted signal selection**, select **Cut**.
- 2 Open the run actions menu for Run 2. Then, under **Plotted signal selection**, select **Paste**.

To update the view to plot only signals from the passing maneuver simulation, cut the plotted signal selection from Run 2 and paste it onto Run 1.

- 1 Open the run actions menu for Run 2. Then, under **Plotted signal selection**, select **Cut**.
- 2 Open the run actions menu for Run 1. Then, under **Plotted signal selection**, select **Paste**.

You can repeat similar steps using the other view, `RPMTorqueVehicleSpeed`. Load the view using the `Simulink.sdi.loadView` function or by clicking **Layout** and then selecting **Open saved view**. Then, use the run actions menu to plot signals from each run side by side or on their own.

Save and Share Simulation Data Inspector Data and Views

After you inspect, analyze, or compare your data in the Simulation Data Inspector, you can share your results with others. The Simulation Data Inspector provides several options for sharing and saving your data and results, depending on your needs. With the Simulation Data Inspector, you can:

- Save your data and layout modifications in a Simulation Data Inspector session.
- Share your layout modifications in a Simulation Data Inspector view.
- Share images and figures of plots you create in the Simulation Data Inspector.
- Create a Simulation Data Inspector report.
- Export data to the workspace.
- Export data to a file.

Save and Load Simulation Data Inspector Sessions

If you want to save or share data along with a configured view in the Simulation Data Inspector, save your data and settings in a Simulation Data Inspector session. You can save sessions as MAT- or MLDATX-files. The default format is MLDATX. When you save a Simulation Data Inspector session, the session file contains:

- All runs, data, and properties from the **Inspect** pane, including which run is the current run and which runs are in the archive.
- Plot display selection for signals in the **Inspect** pane.
- Subplot layout and line style and color selections.

Note Comparison results and global tolerances are not saved in Simulation Data Inspector sessions.

To save a Simulation Data Inspector session:

- 1 Hover over the save icon on the left side bar. Then, click **Save As**.

- 2 Name the file.
- 3 Browse to the location where you want to save the session, and click **Save**.

For large datasets, a status overlay in the bottom right of the graphical viewing area displays information about the progress of the save operation and allows you to cancel the save operation.

The **Save** tab of the Simulation Data Inspector preferences menu on the left side bar allows you to configure options related to save operations for MLDATX-files. You can set a limit as low as 50MB on the amount of memory used for the save operation. You can also select one of three **Compression** options:

- **None**, the default, applies no compression during the save operation.
- **Normal** creates the smallest file size.

- **Fastest** creates a smaller file size than you would get by selecting **None**, but provides a faster save time than **Normal**.

To load a Simulation Data Inspector session, click the open icon on the left side bar. Then, browse to select the MLDATX-file you want to open, and click **Open**.

Alternatively, you can double-click the MLDATX-file. MATLAB and the Simulation Data Inspector open if they are not already open.

When the Simulation Data Inspector already contains runs and you open a session, all of the runs in the session move to the archive. The view updates to reflect show plotted signals from the session file. You can drag runs between the work area and archive as desired.

When the Simulation Data Inspector does not contain runs and you open a session, the Simulation Data Inspector puts runs in the work area and archive as specified in the file.

Share Simulation Data Inspector Views

When you have different sets of data that you want to visualize the same way, you can save a view. A view saves the layout and appearance characteristics of the Simulation Data Inspector without saving the data. Specifically, a view saves:

- Plot layout, axis ranges, linking characteristics, and normalized axes.
- Location of signals in the plots, including plotted signals in the archive.
- Signal grouping and columns on display in the **Inspect** pane.
- Signal color and line styling.

To save a view:

- 1 Click the layout button  .
- 2 Click **Save current view**.
- 3 In the dialog box, specify a name for the view and browse to the location where you want to save the MLDATX-file.
- 4 Click **Save**.

To load a view:

- 1 Click the layout button  .
- 2 Click **Open saved view**.
- 3 Browse to the view you would like to load, and click **Open**.

Share Simulation Data Inspector Plots

Use the snapshot feature to share the plots you generate in the Simulation Data Inspector. You can export your plots to the clipboard to paste into a document, as an image file, or to a MATLAB figure.

You can choose to capture the entire plot area, including all subplots in the plot area, or to capture only the selected subplot.

Click the camera icon  on the toolbar to access the snapshot menu. Use the radio buttons to select the area you want to share and how you want to share the plot. After you make your selections, click **Snapshot** to export the plot.

Snapshot

Take snapshot of:

Entire plot area

Selected plot only

Send to:

Clipboard

Image File

MATLAB Figure

Snapshot

If you create an image, select where you would like to save the image in the file browser.

You can create snapshots of your plots in the Simulation Data Inspector programmatically using `Simulink.sdi.snapshot`.

Create a Simulation Data Inspector Report

To generate documentation of your results quickly, create a Simulation Data Inspector report. You can create a report of your data in either the **Inspect** or the **Compare** pane. The report is an HTML file that includes information about all the signals and plots in the active pane. The report includes all signal information displayed in the signal table in the navigation pane. For more information about configuring the table, see “Inspect Metadata” on page 29-156.

To generate a Simulation Data Inspector Report:

1

Click the create report icon  on the left side bar.

2 Under **Include in report**, specify the type of report you want to create.

- Select **Inspect Signals** to include the plots and signals from the **Inspect** pane.
- Select **Compare Runs** to include the data and plots from the **Compare** pane. When you generate a **Compare Runs** report, you can choose to **Report only mismatched signals** or to **Report all signals**. If you select **Report only mismatched signals**, the report shows only signal comparisons that are not within the specified tolerances.

- 3 Specify a **File name** for the report, and navigate to the **Folder** where you want to save the report.
- 4 Click **Create Report**.

The generated report automatically opens in your default browser.

Export Data to the Workspace or a File

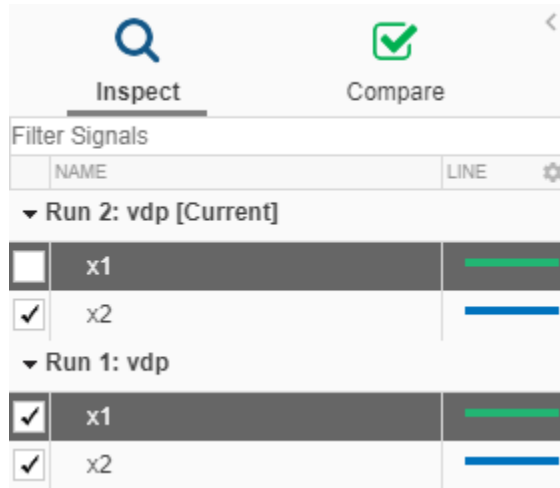

You can use the Simulation Data Inspector to export data to the base workspace, a MAT file, or a Microsoft Excel file. You can export a selection of runs and signals, runs in the work area, or all runs in the **Inspect** pane, including the **Archive**.

When you export a selection of runs and signals, make the selection of data to export before clicking

the export button.

Only the selected runs and signals are exported. In this example, only the x1 signals from Run 1 and Run 2 are exported. The check box selections for plotting data do not affect whether a signal is exported.

When you export a single signal to the workspace or a MAT file, the signal is exported to a `timeseries` object. Data exported to the workspace or a MAT file for a run or multiple signals is stored as a `Simulink.SimulationData.Dataset` object.

To export data to a file, select the **File** option in the **Export** dialog. You can specify a file name and browse to the location where you want to save the exported file. When you export data to a MAT file, a single exported signal is stored as a `timeseries` object, and runs or multiple signals are stored as a `Simulink.SimulationData.Dataset` object. When you export data to a Microsoft Excel file, the data is stored using the format described in “Microsoft Excel Import, Export, and Logging Format” on page 29-60.

To export to a Microsoft Excel file, select the XLSX extension from the drop-down. When you export data to a Microsoft Excel file, you can specify additional options for the format of the data in the exported file. If the file name you provided already exists, you can choose to overwrite the entire file or to only overwrite sheets containing data that corresponds to the exported data. You can also choose which metadata to include and whether signals with identical time data share a time column in the exported file.

Export Video Signal to an MP4 File

You can export a 2D or 3D signal that contains RGB or monochrome video data to an MP4 file using the Simulation Data Inspector. For example, when you log a video signal in a simulation, you can export the data to an MP4 file and view the video using a video player. To export a video signal to an MP4 file:

- 1 Select the signal you want to export.
- 2 Click **Export** in the toolbar on the left or right-click the signal and select **Export**.
- 3 In the Export dialog box, choose to export **Selected runs and signals** to a file.
- 4 Specify a file name and the path to the location where you want to save the file.
- 5 Select **MP4 video file** from the list and click **Export**.

For the option to export to an MP4 file to be available:

- You must export only one signal at a time.
- The selected signal must be 2D or 3D and contain RGB or monochrome video data.
- The selected signal must be represented in the Simulation Data Inspector as a single signal with multidimensional sample values.

You may need to convert the signal representation before exporting the signal data. For more information, see “Analyze Multidimensional Signal Data” on page 29-106.

- The data type for the signal values must be `double`, `single`, or `uint8`.

Exporting a video signal to an MP4 file is not supported for Linux operating systems.

Create an Interactive Comparison Report

When you compare data using the Simulation Data Inspector, you can create an interactive web-based comparison report to share or archive the results. The report is a self-contained HTML file, and viewing the report only requires a web browser. You can use the report to analyze the comparison results similarly to how you would in the Simulation Data Inspector. You can change the layout of the report between the interactive view and a printable view.

This example shows how to create an interactive comparison report using data loaded from a session file. For more information about importing data into the Simulation Data Inspector or logging data from a simulation, see “View Data in the Simulation Data Inspector” on page 29-2.

Load and Compare Data

This example uses data created by simulating the `slexAircraftExample` model that was saved in the session file `dataToCompare.mldatx`. Both simulations used the square wave input from the Pilot block in the model. The first simulation uses the input filter design saved in the model with a time constant of 0.1. The time constant was changed to 1 for the second simulation.

Open the Simulation Data Inspector and the session file to load the data into the Simulation Data Inspector for comparison.

```
Simulink.sdi.view
Simulink.sdi.load('dataToCompare.mldatx');
```

In the Simulation Data Inspector, navigate to the **Compare** tab and compare the two runs.

- 1 Expand the **Baseline** drop-down and select Run 1: `slexAircraftExample`.
- 2 Expand the **Compare to** drop-down and select Run 2: `slexAircraftExample`.
- 3 Click **Compare**.

Alternatively, you can use the `Simulink.sdi.compareRuns` function to perform the comparison.

```
runIDs = Simulink.sdi.getAllRunIDs;
runID1 = runIDs(end-1);
runID2 = runIDs(end);

diffRes = Simulink.sdi.compareRuns(runID1,runID2);
```

Generate the Interactive Comparison Report

To save the comparison results, you can generate an interactive web report. To create the report, click the **Report** button.

In the Create Report dialog, you can specify the type of report you want to create and the data you want to include in the report. Select **Compare** as the **Type**. In this example, all signals in the run comparison did not match, so a report containing only mismatched signals contains all the signals.

You can specify a title and author to include in the header for the report. By default, the title is created from the names of the compared runs. This example provides a different title that describes the variable values evaluated by the simulations and comparison.

Enter a descriptive file name for the report file. You can also specify where to save the report. By default, the Simulation Data Inspector saves the report in a folder called `sdi reports` in the working directory.

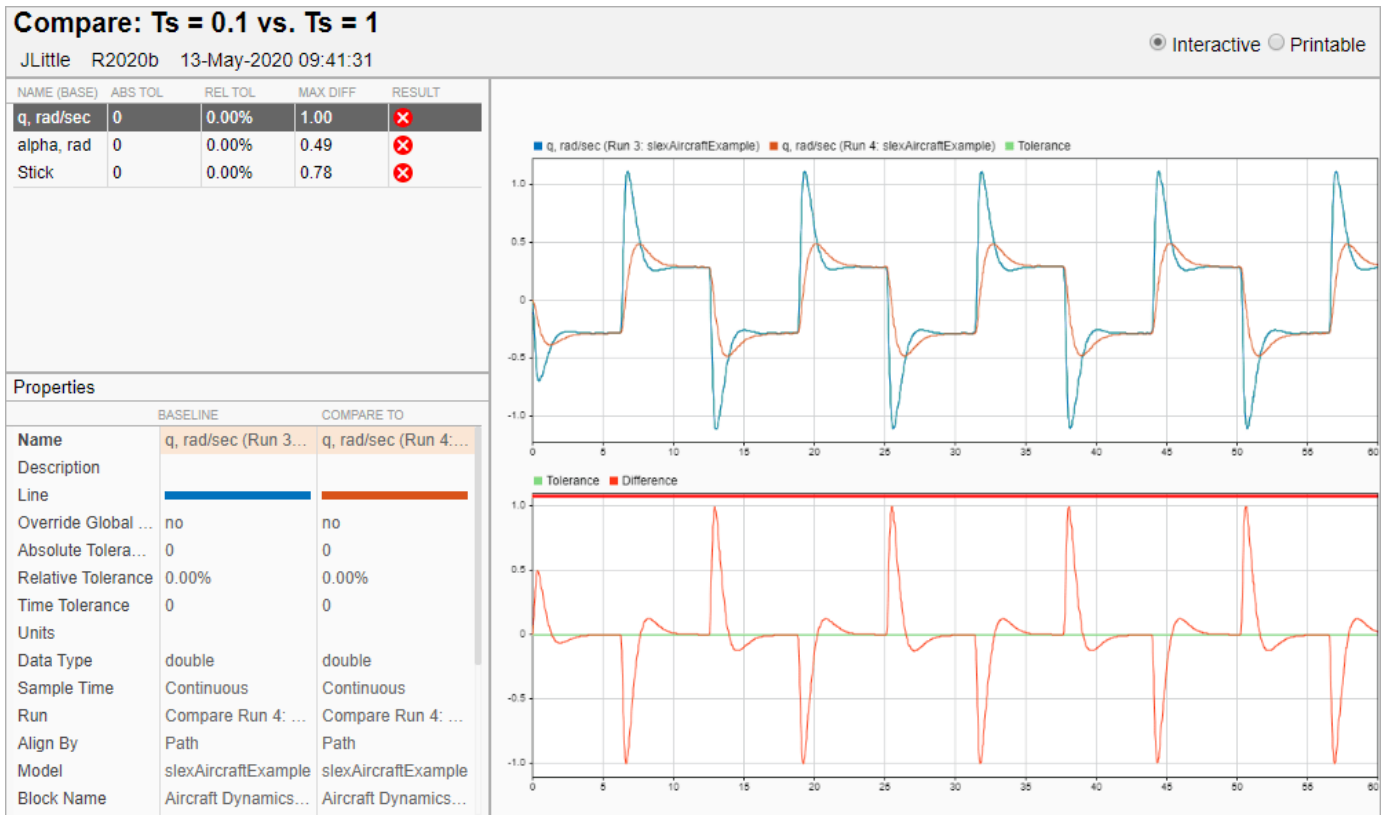

You can also enable the option to add an incrementing number to the end of the specified file name to avoid overwriting existing report files. For models that log signals throughout the model hierarchy, consider enabling the **Display partial block path** option to prevent long block paths from appearing in the report. In this example, the signals are all logged in the top-level of the model hierarchy.

After specifying the options for the report you want to create, click **Create Report**. The generated report automatically opens in the system browser.

Inspect Comparison Results in the Interactive Report

The interactive report information and layout is similar to what you see on the **Compare** pane of the Simulation Data Inspector. In the **Comparisons** table on the left, you can select the signal result you want to view in the plots. The **Properties** table shows all the metadata for the compared signals and highlights metadata that differs. You can scroll in the **Properties** table to see all the metadata. When

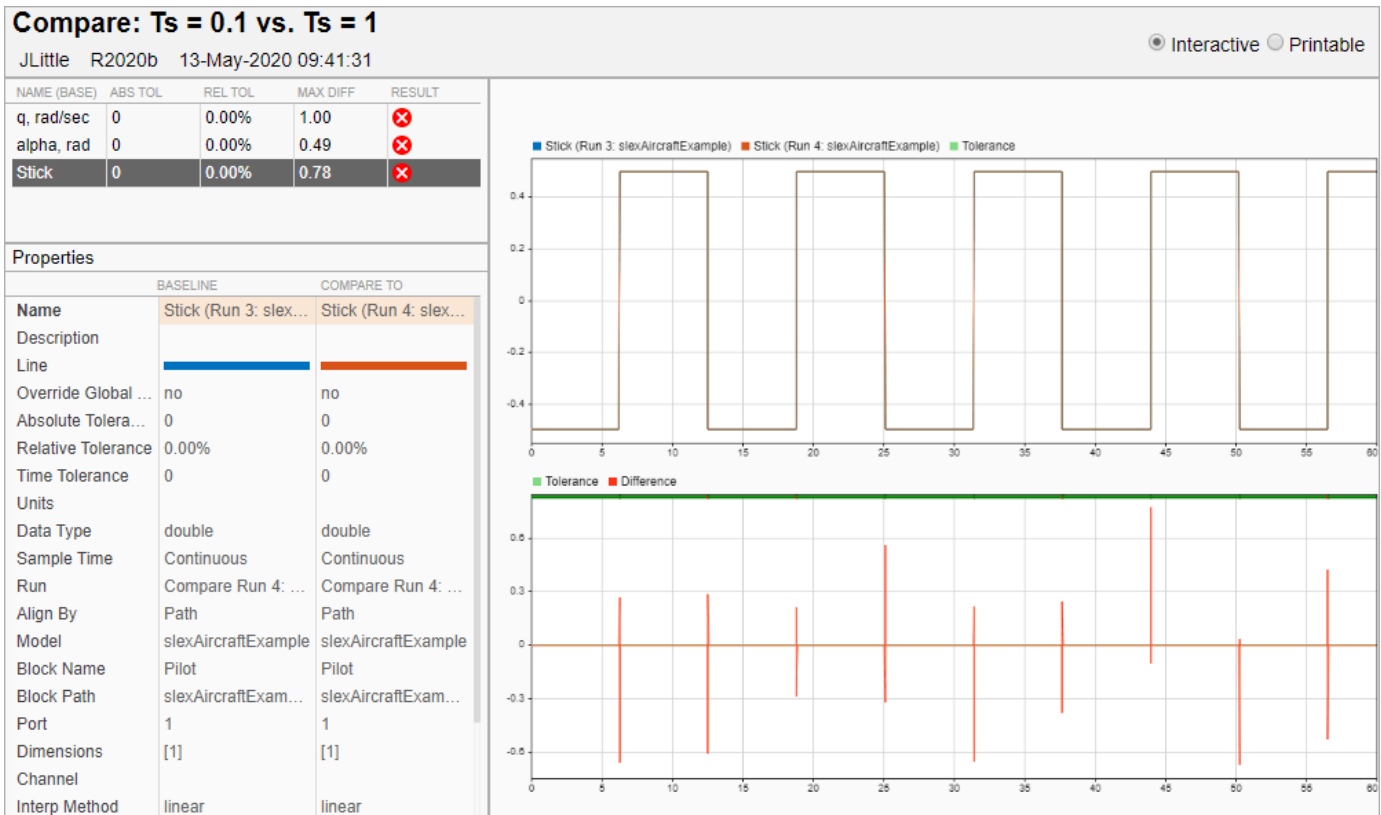

the comparison contains more signals than fit in the results table, you can scroll in the results table as well.

You can adjust the size of the panes in the report by dragging the borders. For example, you could make the **Properties** pane larger, since the table of compared signals does not use all the space in the signals pane.

The information in the table indicates that the comparison results for the **Stick** signal are out of tolerance with a maximum difference of 0.78. In the model, the **Stick** signal is the output from a Signal Generator block, and the filter time constant should not affect the block output. Select the **Stick** signal to investigate the comparison results.

Inspecting the plots in the report allows you to see that the differences occur at the rising and falling edges of the square wave. The `sllexAircraftExample` model uses a variable-step solver. The differences occur because the new time constant value changes the system dynamics, and the solver calculates slightly different time steps for the second simulation. The transition of the square wave is sharp, so small timing differences can result in large magnitude differences.

Because the differences in the `Stick` signal are due to modeling rather than a real change in system dynamics, you could go back to the Simulation Data Inspector and specify a small time tolerance (For example, `0.01`) for the `Stick` signal so the comparison results are within tolerance. To share the updated results, you can generate a new comparison report.

Print Comparison Report

After finalizing the analysis and presentation of the comparison results, you can print a comprehensive view of the results using the interactive web report. To switch to the printable view, select the **Printable** radio button, or press `Ctrl+P` to see a print preview in the browser. In the printable view, the metadata and plots for all signals are stacked, with the summary table at the top.

Create Plots Using the Simulation Data Inspector

Plots can help showcase important features or trends in your data and allow you to share your findings with others. The Simulation Data Inspector allows you to select from a variety of visualization types and layouts and customize plot and signal appearances to present your data most effectively. This topic uses simulation data generated from a simulation of the `slexAircraftExample` model that logs the output of the Actuator Model block and the `Stick`, `alpha`, `rad`, and `q`, `rad/sec` signals.

Select a Plot Layout

You can select from three types of layouts under the layout menu in the Simulation Data Inspector

Basic Layouts:

Overlays:

Grid:

Rows: Columns:

- **Basic Layouts** offer templates for layouts including up to four subplots.
- **Overlays** have overlay subplots in two corners of a main plot.
- **Grid** layouts create a grid of subplots according to dimensions you specify from 1×1 to 8×8.

Select the plot layout that best highlights the characteristics of your data. For example, with a basic three-plot layout, you can use the large plot to show a main result and show intermediate signals on the smaller plots.

Moving Between Subplot Layouts

When you plot a signal on a subplot, the Simulation Data Inspector links the signal to the subplot, identifying the subplot with a number. As you move between subplot layouts, the association between the signal and subplot remains, even as the shape or visibility of the subplot may change.

Subplots of **Grid** layouts follow columnwise numbering, from 1 at the top left subplot to 8 in the bottom left, to 64 at the bottom right. The number system is fixed, regardless of which subplot configuration you select. For example, if you display four subplots in a 2×2 configuration, the bottom right subplot of the configuration is numbered 10, not 4. The number is 10 because in the largest possible 8×8 matrix, that subplot is numbered 10 when you count the subplots in a columnwise manner.

Basic Layouts subplots also use the fixed 8×8 columnwise numbering as a base. For example, the top plot in this three-subplot layout is subplot 1, and the two subplots below it are 2 and 10.

In this three-subplot layout, the index for the right subplot is 9, and the indices for the two subplots on the left are 1 and 2.

For the **Overlays** layouts, the index for the main plot is always 1, and the indices for the overlaid plots are 2 and 9.

Add Visualizations

You can choose from several visualizations to use for your data in the Simulation Data Inspector. To view available visualizations, open the **Visualization Gallery** by clicking **Edit View** on the layout menu.

You can drag the visualization you want to add to the plot where you want to add it. You can choose a **Time Plot**, **Map**, **Text Editor**, or **XY** visualization for each subplot in your layout. For more information about using **Map** and **XY** visualizations, see

- “View and Replay Map Data” on page 29-22
- “Visualize Simulation Data on an XY Plot” on page 29-29

- “Analyze Data Using the XY Plot” on page 29-38

Add a text editor to your plot layout when you want to present conclusions, descriptions, or observations alongside your data. The text editor includes a toolbar for rich text formatting, including:

- Bullet points
- Numbered lists
- Hyperlinks
- LaTeX equations

Customize Time Plot Appearance

After you choose a plot layout, you can customize the appearance of each visualization using the visualization settings menu . The number of menu tabs depends on the visualizations present in your layout. When your layout does not include a **Map** or **XY** visualization, the corresponding settings tabs are not shown.

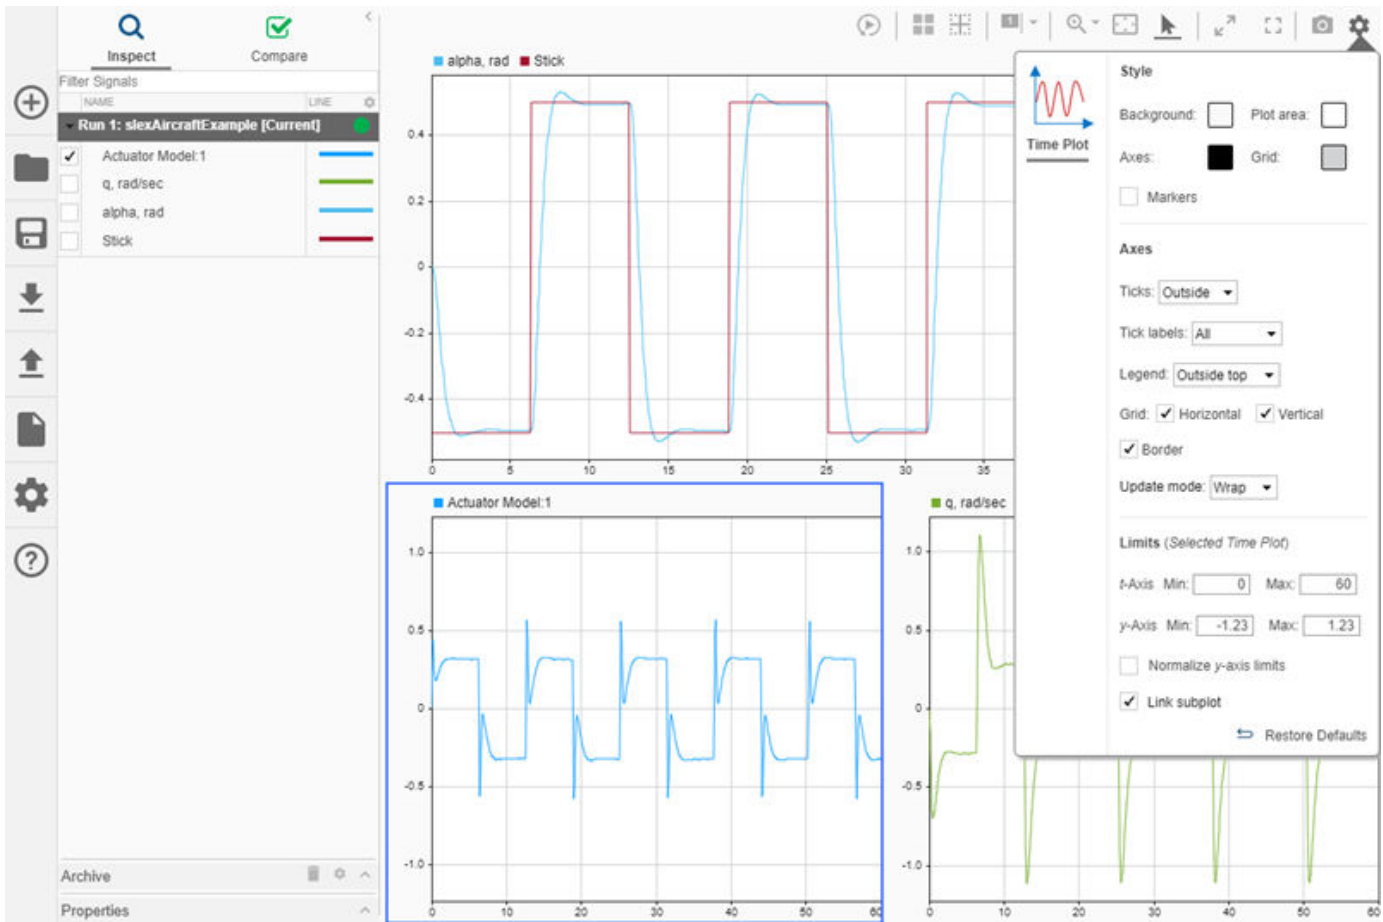

You can customize the appearance of **Time Plot** visualizations in the Simulation Data Inspector, including choosing custom colors, choosing to show or hide attributes such as the grid or legend, and specifying axes limits. To maximize the area in the visualization available for the plot, you can move the tick marks, tick mark labels, and legend inside the plot or hide them.

The **Limits** section gives you control over the limits of the t - and y -axes for individual subplots. You may also choose to normalize the y -axis. Except for the t -axis limits, the settings you configure in the **Limits** section apply to the active subplot. To configure t -axis limits individually for a subplot, unlink the subplot. For more information, see “Linked Subplots” on page 29-152.

To improve the basic layout plot created in the previous section, change the y -axis limits of the left graph to match those on the right.

- 1 Select the q , rad/sec plot to view its y -axis limits in the **Limits** tab.
- 2 Select the Actuator Model : 1 plot as the active plot.
- 3 In the **Limits** section, change the y -axis limits of the Actuator Model : 1 plot to match the limits of the q , rad/sec plot.

You can clear the active subplot or all subplots using the clear subplots menu on the toolbar. 

Customize Signal Appearance

The Simulation Data Inspector allows you to modify the color and style of each signal individually. For each signal, you can select from a palette of standard colors or specify a custom color with RGB values.

You can access the line style menu for a signal in the Simulation Data Inspector or in the Simulink Editor:

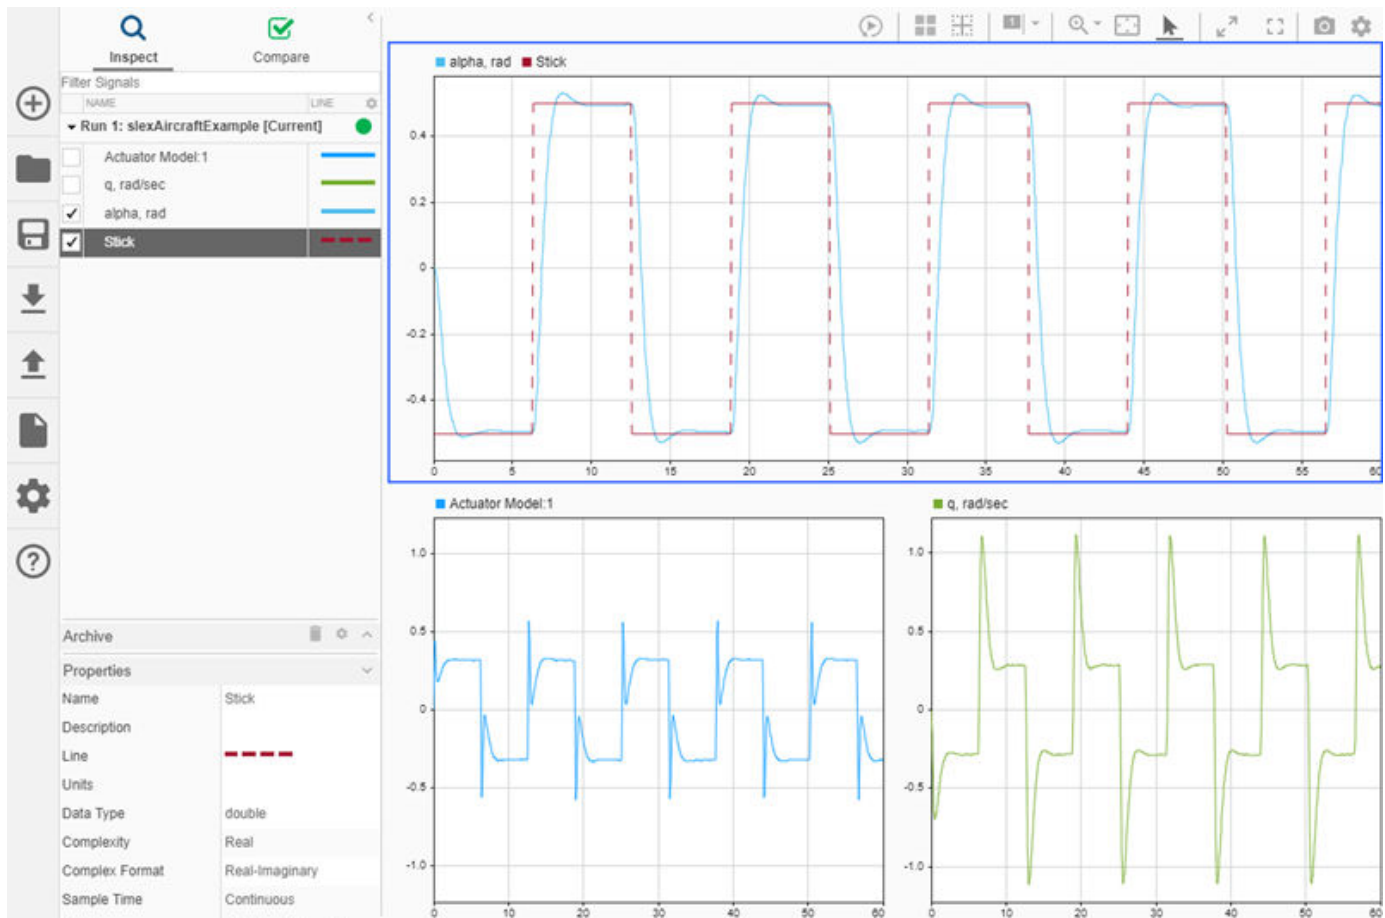

- In the Simulation Data Inspector, click the graphic representation in the **Line** column of the work area or the **Line** row in the **Properties** pane.
- From the Simulink Editor, right-click the logging badge for a signal, and select **Properties** to open the **Instrumentation Properties** for the signal. Then, click the graphic representation of the **Line**.

From the **Instrumentation Properties**, you can also select subplots where you want to plot the signal. Changes made through the **Instrumentation Properties** take effect for subsequent simulations.

If a signal is connected to a Dashboard Scope block, you can also modify the signal line style and color through the Dashboard Scope block dialog box. Changes to line style and color made in the Simulink Editor remain consistent for a signal. When you change the line style and color in the Simulation Data Inspector, the signal line style and color do not change in the Simulink Editor.

Line style customization can help emphasize differences between signals in your plot. For example, change the line style of the **Stick** signal to dashed to visually indicate that it is an ideal, rather than simulated, signal.

- 1 Click the **Line** column for the **Stick** signal.
- 2 Select the dashed option (third in the list).
- 3 Click **Set**.

The `alpha, rad` and `Actuator Model: 1` signals are very close in color. You can select bold, easily distinguishable colors for all of the signals in your plot.

- 1 Select the `Actuator Model: 1` signal in the work area.
- 2 Click the **Line** row entry in the **Properties** pane.
- 3 Specify the desired color. This example uses the dark purple (fourth option) in the standard palette.
- 4 Click **Set**.

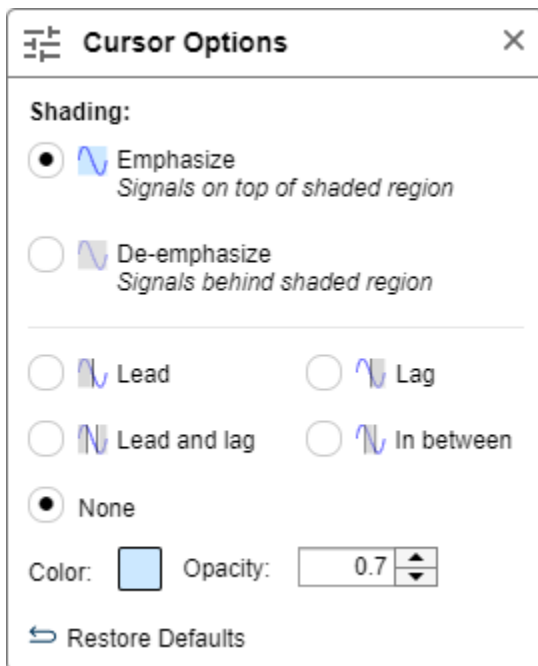

Shade Signal Regions

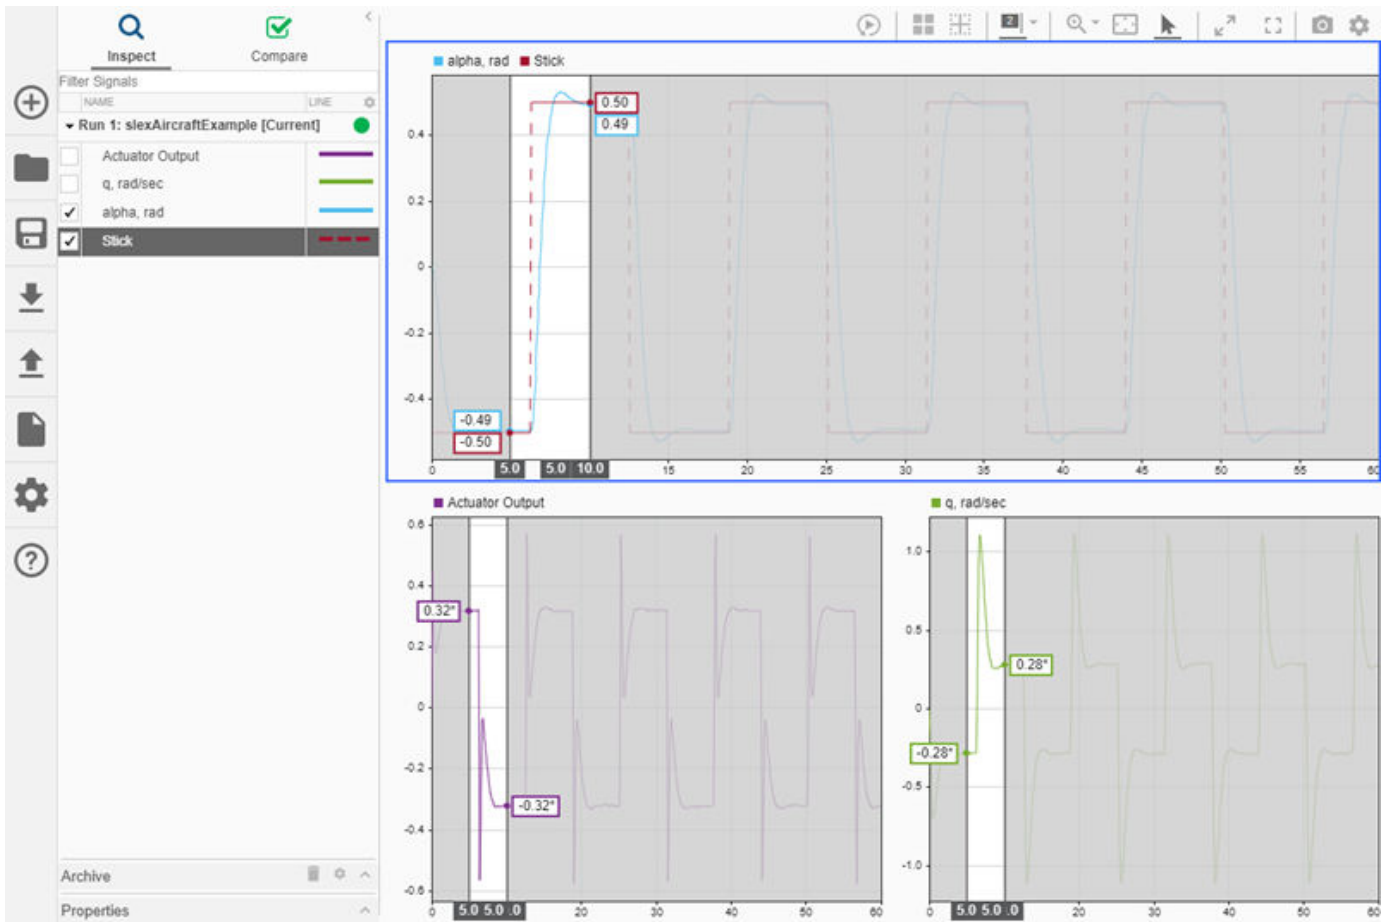

You can shade an area of a time plot to draw attention to a region of interest in the plotted data. For example, you can highlight the area around a signal transition. First, add two cursors to the plot area by clicking the arrow next to the **Show/hide cursors** button and selecting **Two cursors**.

Next, click the arrow again and configure the **Cursor Options** to match your requirements. You can specify whether to emphasize or de-emphasize the shaded area, the area to shade relative to the cursors, and the shading color and opacity. You can specify separate color and opacity settings for the **Emphasize** and **De-emphasize** options.

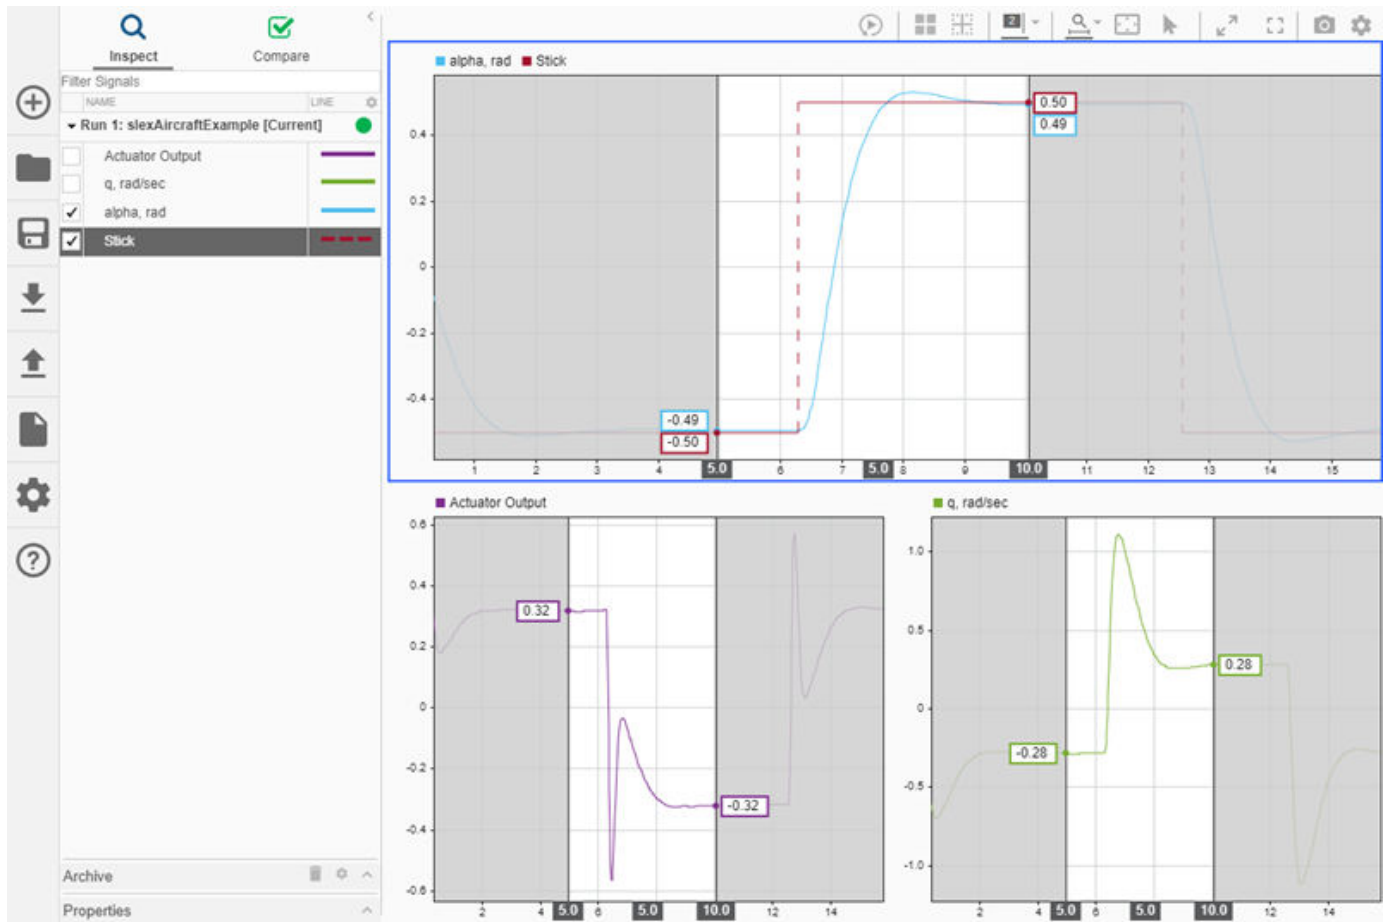

For this example, select the **De-emphasize** and **Lead and lag** options. Click in the plot area to close the **Cursor Options** dialog. The gray shading obscures the area outside of the cursors and highlights the signal region between the cursors. Move the cursors to highlight an area of interest, like the first rising edge of the waveform.

You can use the **Zoom in Time** option to zoom in synchronously on the region of interest. Select **Zoom in Time** from the **Zoom In** menu.

Then click and drag to select a time span.

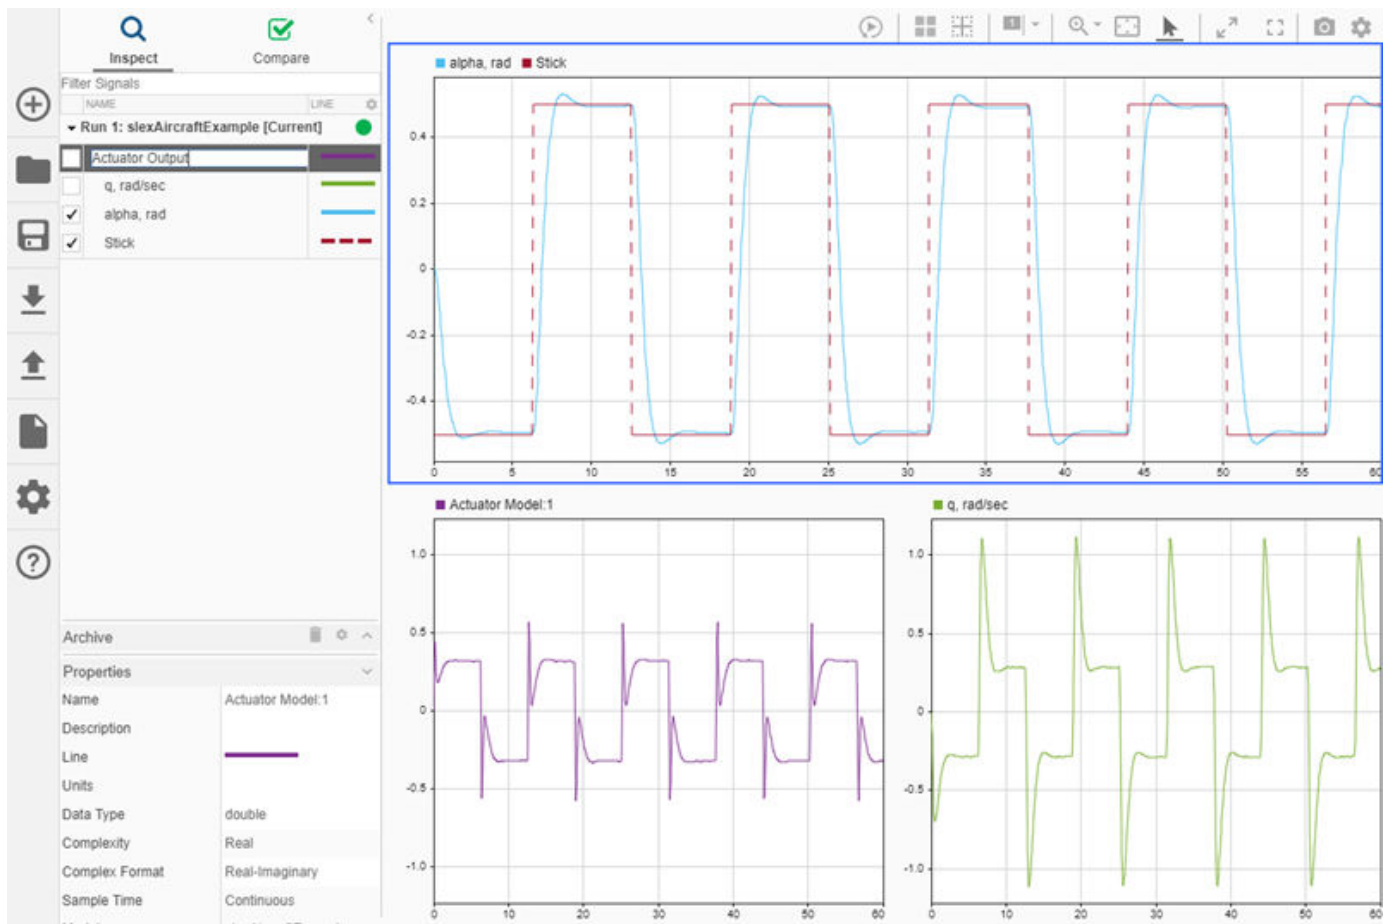

You can use the **Snapshot** menu to save snapshots of highlighted signal regions. For more information, see “Save and Share Simulation Data Inspector Data and Views” on page 29-123.

Rename Signals

You can rename signals in the Simulation Data Inspector when a more descriptive name can help convey information. Changing a signal name in the Simulation Data Inspector does not affect signal names used in models. You cannot rename bus signals in the Simulation Data Inspector.

To change a signal name, double-click the signal name in the work area or archive, or edit the **Name** field in the **Properties** pane. Change the name of the Actuator Model: 1 signal to Actuator Output.

More About

- “Save and Share Simulation Data Inspector Data and Views” on page 29-123
- “Inspect Simulation Data” on page 29-148
- “Compare Simulation Data” on page 29-171

Inspect Simulation Data

You can use the Simulation Data Inspector to view and inspect signals from simulations or imported data. The Simulation Data Inspector provides a comprehensive view of your data by allowing you to group data from multiple simulations and sources on multiple subplots. You can zoom and pan within plots and use data cursors for close examination of signal values, and you can replay data to analyze signal relationships.

This example shows you how to view and inspect signal data from the `slexAircraftExample` model using the Simulation Data Inspector.

Configure Signals for Logging

This example uses signal logging to send data to the Simulation Data Inspector. You can also import signal data from the base workspace or a CSV, MDF, Microsoft Excel, or MAT-file. For more information, see “View Data in the Simulation Data Inspector” on page 29-2.

Open the `slexAircraftExample` model, mark several signals for logging, and run a simulation.

- 1 To open the model, enter `slexAircraftExample` in the MATLAB Command Window.
- 2 To log the `q`, `rad/sec`, the `Stick`, and the `alpha`, `rad` signals, select the signals in the model. Then, click **Log Signals**.

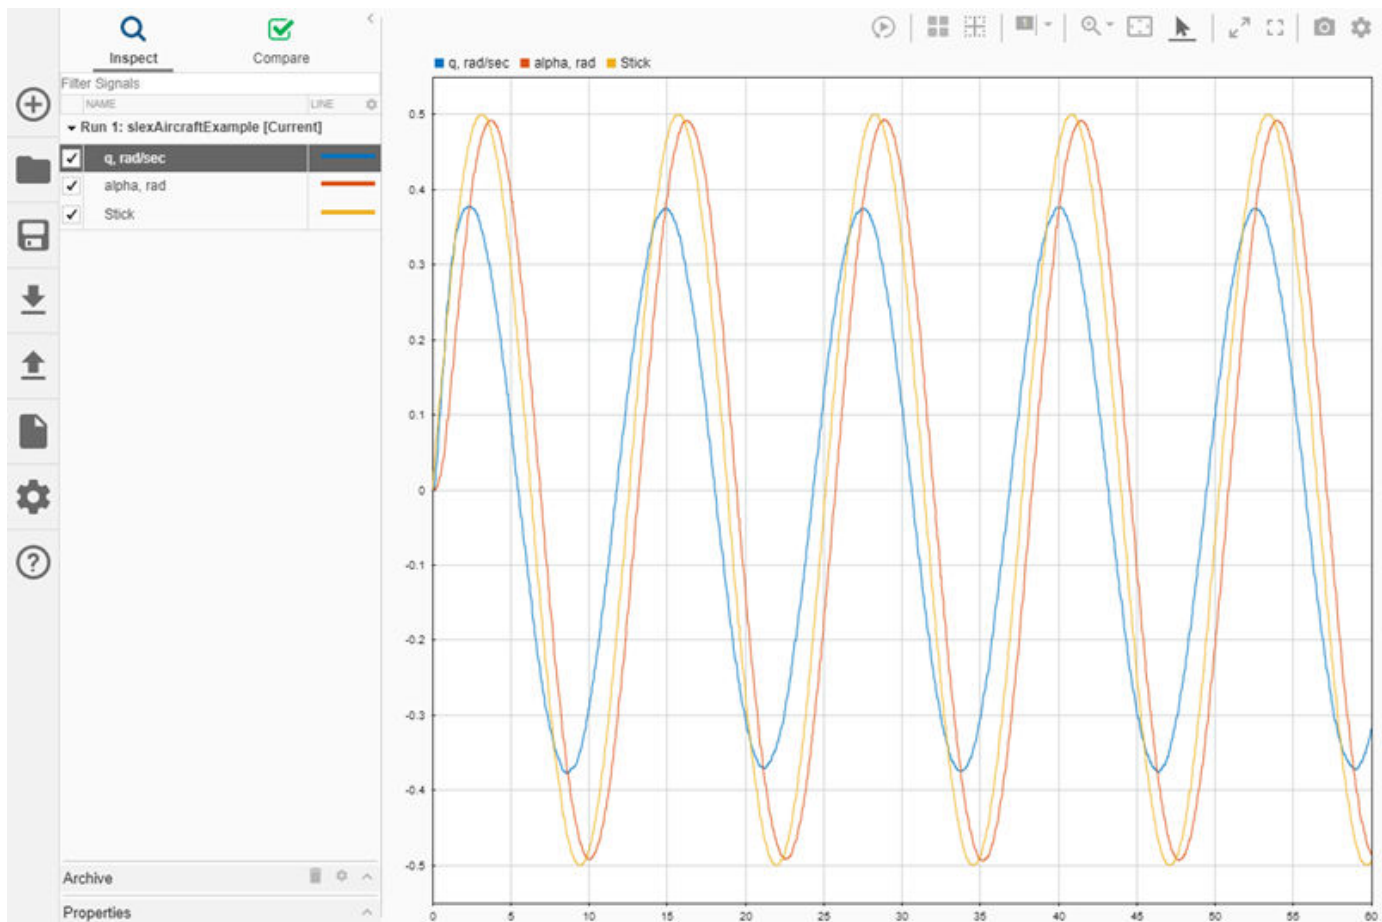

The logging badge  appears above each signal marked for logging.

- 3 Double-click the Pilot block. Set **Wave form** to `sine`, and click **OK**.
- 4 In the Simulink Editor, click the **Data Inspector** button to open the Simulation Data Inspector.
- 5 Simulate the model. The simulation run appears in the Simulation Data Inspector.

By default, the **Inspect** pane lists all logged signals in rows, organized by simulation run. You can expand or collapse any of the runs to view the signals in a run. For more information on signal grouping, see “Configure the Simulation Data Inspector” on page 29-73.

View Signals

To select signals you want to plot, use the check boxes next to the signals in the navigation pane. Select the check boxes next to the `q`, `rad/sec`, `Stick`, and `alpha`, `rad` signals. When the signal you want to plot is easier to find in your model, you can click the logging badge for the signal to plot it in the Simulation Data Inspector.

You can also use signal browsing mode to quickly view all the signals in your run on **Time Plot** visualizations. For more information about how to enable and use **Browse Mode**, see “Visualize Many Logged Signals” on page 29-99.

View Signals on Multiple Plots

You can use subplot layouts to view groups of signals on different subplots. For example, you can group the same signal from different simulation runs or group signals that have a similar range of values.

- 1 In the model, double-click the Pilot block. Set **Wave form** to square, and click **OK**.
- 2 Simulate the model.
- 3 By default, the Simulation Data Inspector automatically moves prior runs into the **Archive** and transfers the view to the current run. Drag Run 1 from the **Archive** into the work area.
- 4 Click the **Layout** button and select the 2×1 plot layout.
- 5 Click the lower subplot in the viewing area. In the **Inspect** pane, select the check boxes for the *q, rad/sec*, *Stick*, and *alpha, rad* signals under Run 1.

The check boxes in the **Inspect** pane indicate the signals plotted in the selected subplot, outlined in blue.

You can also move signals graphically, rather than using the check boxes. Click and drag the signal from the **Inspect** pane or another subplot to the subplot where you want to plot it.

For more information on working with plots, see “Create Plots Using the Simulation Data Inspector” on page 29-135.

Zoom, Pan, and Resize Plots

You can closely inspect signals in a larger viewing area using the **Maximize** and **Full Screen** options on the toolbar above the viewing area.

-  — Select **Maximize** to expand the active subplot to occupy the entire graphical viewing area.
-  — Select **Full Screen** to view your entire layout using your whole screen. The Simulation Data Inspector automatically collapses the navigation pane so the view of the layout is as large as possible.

You can zoom and pan within subplots that use a time plot visualization to inspect signal values and the relationships between signals. The zoom and pan controls in the Simulation Data Inspector are on the toolstrip above the graphical viewing area. Each icon allows you to control aspects of the plot using your mouse.

- You can select the zoom action for the zoom button from the drop-down.

-  When you want to zoom in on a selected area in the plot, select **Zoom In**. While you have **Zoom In** selected, the Simulation Data Inspector adapts the zoom action it performs based on the area of the plot you select. When you select a very narrow area, the Simulation Data Inspector zooms on the y-axis only. When you select a very short area, the Simulation Data Inspector zooms on the x-axis only. The highlight around the selected region indicates the zoom behavior for that selection.

You can click the graphical viewing area to zoom in a fixed amount on both axes. You can also click and drag to select an area to define the y- and t-axes. Scrolling with the mouse wheel zooms in and out on both axes.

-  Select **Zoom Out** to zoom out a fixed amount when you click inside the plot area.
-  **Zoom in Time** makes all the mouse actions zoom on the t-axis. You can click the graphical viewing area to zoom in a fixed amount. You can click and drag the graphical viewing area to select a portion of the plot as the limits for the t-axis. Scrolling with the mouse wheel zooms in and out on the t-axis.
-  When you select **Zoom in Y**, all the mouse actions zoom on the y-axis. You can click in the graphical viewing area to zoom in a fixed amount. You can also click and drag to select a portion of the plot as the limits for the y-axis. Scrolling with the mouse wheel zooms in and out on the y-axis.

-  With the mouse pointer selected, you can select signals by clicking them and pan by clicking anywhere on the plot and dragging the mouse.
-  Click the fit-to-view option to scale the axes to accommodate your plotted data.

Linked Subplots

Subplots are linked by default. Linked plots have a synchronized response when you:

- Click a plot and drag to pan.
- Perform any zoom operation.
- Fit to view.
- Adjust **T-Axis** limits.

To inspect data independently in a subplot, you can unlink the subplot.

- 1 Select the subplot you want to unlink.
- 2 Click the **Visualization Settings** button in the upper right of the viewing area.
- 3 In the **Limits** section, clear the **Link Subplot** option.

The broken link symbol  appears on the unlinked subplot.

Inspect Simulation Data Using Cursors

In the Simulation Data Inspector, you can inspect signals using data cursors. You can use one or two cursors to inspect your data. To add two cursors, select **Two Cursors** from the **Show/hide data cursors** drop-down.

With two cursors, three time values are displayed: the time corresponding to each cursor position and the time spanned by the cursors. You can move the two cursors together by dragging the span label between the two cursors. You can also set the span by typing the desired value into the label field.

Practice inspecting data with cursors using one cursor.

- 1 Select **One Cursor** from the **Show/hide data cursors** drop-down.

- 2 Drag the data cursor left or right to a point of interest. You can also use the arrow keys to move the data cursor from sample to sample.

To inspect the data at a specific point in time, click the cursor time field and enter the desired time value, for example 40.33.

If the signal does not have a sample at the point of interest, the Simulation Data Inspector interpolates the value for the indicated time. An asterisk in the data cursor label indicates that the displayed value is interpolated. For information regarding interpolation methods, see “Interpolation” on page 29-184.

- 3 When you have finished inspecting the data, click the cursor button to remove the cursor from the viewing area.

Replay Data

You can replay data in the Simulation Data Inspector to inspect signal value changes and relationships between signals. Replaying data in the Simulation Data Inspector has no effect on any models or simulations. To replay data, first show the replay controls by clicking the **Show/hide**

replay controls button.  Then, press the **Replay** button.

The Simulation Data Inspector synchronously sweeps a cursor displaying the signal value across all subplots in the view. By default, data replays at a rate of one second per second, which means that replaying one second of data takes one second of clock time. You can adjust the replay speed using the arrows on either side of the label or by clicking the label to type the desired speed. You can also pause the replay and use the **Step forward** and **Step backward** buttons to inspect signal values, sample by sample. For a detailed example, see “Replay Data in the Simulation Data Inspector” on page 29-166.

Inspect Metadata

The Simulation Data Inspector allows you to view run and signal metadata. You can view signal metadata in the **Properties** pane or in the table of signals under each run. You can view run data only in the **Properties** pane.

The **Properties** pane displays the metadata for the selected run or signal. You can edit properties using the white box in the **Values** column. When you view a comparison, the Simulation Data Inspector highlights metadata differences in red.

Properties	
Name	q, rad/sec
Line	
Units	rad/s
Data Type	double
Complexity	Real
Complex Format	Real-Imaginary

Sync Method	union

Columns in the navigation pane allow you to display signal properties in the table of signals under each run. To add or remove columns in the table, select the columns you want to display from the list on the **Columns** tab of the navigation pane's **Preferences** menu. Columns appear in the table in the order in which you select them.

The image shows a software interface for inspecting simulation data. On the left, there are two tabs: 'Inspect' (active) and 'Compare'. Below the tabs is a 'Filter Signals' section with a table of signals. The table has columns for 'NAME' and 'LINE'. Two runs are listed: 'Run 2: slexAircraftExample [Current]' and 'Run 1: slexAircraftExample'. Each run has three signals: 'q, rad/sec' (blue line), 'alpha, rad' (orange line), and 'Stick' (yellow line). The 'q, rad/sec' signal in Run 2 is checked. On the right, a configuration panel is open, showing options for 'Columns', 'Group', and 'Selection'. The 'Columns' section is active, showing a list of columns to display: 'Line' (checked), 'Units', 'Data Type', 'Complexity', 'Complex Format', 'Sample Time', 'Model', and 'Block Name'. A 'Restore Defaults' button is at the bottom of the panel.

Run	Signal Name	Unit	Color	Checked
Run 2: slexAircraftExample [Current]	q, rad/sec	rad/sec	Blue	<input checked="" type="checkbox"/>
	alpha, rad	rad	Orange	<input type="checkbox"/>
	Stick		Yellow	<input type="checkbox"/>
Run 1: slexAircraftExample	q, rad/sec	rad/sec	Blue	<input type="checkbox"/>
	alpha, rad	rad	Orange	<input type="checkbox"/>
	Stick		Yellow	<input type="checkbox"/>

Columns to display:

- Line
- Units
- Data Type
- Complexity
- Complex Format
- Sample Time
- Model
- Block Name

Restore Defaults

Property Descriptions

Property Name	Value
Line	Signal line style and color
Units	Signal measurement units
Data Type	Signal data type
Complexity	Signal type — real or complex
Complex Format	Format for visualizing complex data
Sample Time	Type of sampling
Model	Name of the model that generated the signal
Block Name	Name of the signal's source block
Block Path	Path to the signal's source block
Port	Index of the signal on the block's output port
Dimensions	Dimensions of the matrix containing the signal
Channel	Index of signal within matrix
Run	Name of the simulation run containing the signal
Absolute Tolerance	User-specified, positive-valued absolute tolerance for the signal
Relative Tolerance	User-specified, positive-valued relative tolerance for the signal
Override Global Tolerance	User-specified property that determines whether signal tolerances take priority over global tolerances
Time Tolerance	User-specified, positive-valued time tolerance for the signal
Interp Method	User-specified interpolation method used to plot the signal
Sync Method	User-specified synchronization method used to coordinate signals for comparison
Time Series Root	Name of the variable associated with signals imported from the MATLAB workspace
Time Source	Name of the array containing the time data for signals imported from the MATLAB workspace
Data Source	Name of the array containing the data for signals imported from the MATLAB workspace

On the **Compare** pane, many parameters have a **Baseline** column and a **Compare To** column that you can display independently. If the **Baseline** and **Compare to** signals both have a property, but you can only display one property column, the column shows the **Baseline** property. In addition to the parameters listed for the **Inspect** pane, the **Compare** pane has columns specific to comparisons.

- **Max Difference** — The maximum difference between the **Baseline** and **Compare to** signals
- **Align By** — Primary signal alignment criterion specified in the **Alignment** tab of the Simulation Data Inspector **Preferences** menu

By default, the table displays the baseline name column and a column indicating whether the comparisons passed or failed.

Modify Signal Properties in the Simulation Data Inspector

You can modify signal display units, data type, and names in the Simulation Data Inspector. When you modify the data type for a signal, the Simulation Data Inspector converts the signal values stored on disk. Changes you make to signal properties in the Simulation Data Inspector do not affect any models, files, or workspace variables.

You may want to save the original signal data or export modified signal data to use as simulation input. You can export data from the Simulation Data Inspector to the workspace or a file. For more information, see “Export Data to the Workspace or a File” on page 29-126.

This example uses data from a simulation of the `slexAircraftExample` model. To generate the data for this example:

- 1 Enter `slexAircraftExample` in the MATLAB Command Window.
- 2 To log the `q`, `rad/sec`, the `Stick`, and the `alpha`, `rad` signals to the Simulation Data Inspector, select the signals in the model. Then, right-click the selection, and select **Log Selected Signals** from the context menu.
- 3 Double-click the Pilot block. Set **Wave form** to `sine`, and click **OK**.
- 4 Simulate the model.

Modify Signal Units

Signals in the Simulation Data Inspector have two unit properties: display units and stored units. To analyze sets of data using consistent units, modify the display units for a signal. The Simulation Data Inspector converts data when the stored units and display units for a signal differ such that signals are always plotted using values that correspond to the display units. The units you specify are properties of the signals in the Simulation Data Inspector only and do not affect the signal properties in models. To learn how to specify units in a model, see “Unit Specification in Simulink Models” on page 9-2.

The `slexAircraftExample` model does not specify units for its signals. However, some signal names indicate the intended units.

- 1 In the **Inspect** pane, select the `alpha`, `rad` signal.
- 2 To view the properties for the selected signal, expand the **Properties** pane.
- 3 To specify units of radians for the signal, in the **Properties** pane, type `rad` into the white text box next to the **Display Units** property.

For a list of units supported by Simulink, enter `showunitslist` into the MATLAB Command Window.

Now, the Simulation Data Inspector interprets the data for the `alpha`, `rad` signal as having units of `rad`. When you specify display units for a signal without units, the specified units also set the value for the stored units. Once a signal has units Simulink recognizes, you can convert the display units for the signal to supported compatible units using the Simulation Data Inspector. When you click the **Display Units** text box to modify the units, the Simulation Data Inspector provides a drop-down list of compatible units.

Change the alpha, rad signal display units to deg using the drop-down or by typing the new units into the **Display Units** field. When you change the units, the Simulation Data Inspector performs the conversion, and the plot updates to show the converted signal values.

You can also configure unit preferences in the Simulation Data Inspector to use units from a system of measurement or consistent units for a measurement type, such as length, for all logged and imported data. For more information, see “Signal Display Units” on page 29-79.

Note You can convert the stored units for a signal using the `convertUnits` function. Unit conversion does not support undo and may result in loss of precision.

Modify Signal Data Type

You can modify the data type for a signal to analyze the effect on signal values or to create a signal to use as simulation input. Converting the data type in the Simulation Data Inspector does not affect any signal properties in the model. You can convert signal data types to all built-in data types. If you have a license for Fixed-Point Designer, you can also convert to fixed-point data types. For a list of built-in data types, see “Data Types Supported by Simulink” on page 68-4.

Note When you convert to a lower precision data type, you lose precision in the data that cannot be recovered. You can save a copy of the data in the Simulation Data Inspector before changing signal data types. For more information, see “Save and Share Simulation Data Inspector Data and Views” on page 29-123.

The data type for the `alpha, rad` signal is `double`. Suppose you want to convert the data type to `single`. First, select the `alpha, rad` signal. Then, expand the **Properties** pane and click the white text field next to the **Data Type** property. You can type `single` or select it from the drop-down of data types. The Simulation Data Inspector converts the data when you click outside the drop-down.

Because the `single` data type has less precision than the `double` data type, the Simulation Data Inspector returns a warning about irreversible precision loss. Click **Continue**. The plot shows no visible difference in the signal. If you saved the data for the original signal, you can compare the converted signal to analyze the effect of changing the data type. For more information on comparing data in the Simulation Data Inspector, see “Compare Simulation Data” on page 29-171.

Fixed-Point Conversions

If you have a license for Fixed-Point Designer, you can convert signal data types to fixed-point data types in the Simulation Data Inspector. Specify the data type in the **Data Type** property text box using the `fixdt` function.

Modify Signal Names

You can modify the names of signals in the Simulation Data Inspector. Changing the name of a signal in the Simulation Data Inspector does not affect signal names specified in the model. You can specify a new name from the work area, the **Archive**, or the **Properties** pane. To modify the signal name, click the signal name and type the new name. For example, change the name of the `alpha, rad` signal to `alpha` because the **Units** property now has the units information.

	NAME	LINE	⚙
▼ Run 1: slexAircraftExample [Current]			
<input checked="" type="checkbox"/>	q, rad/sec		—
<input checked="" type="checkbox"/>	alpha		—
<input checked="" type="checkbox"/>	Stick		—

When you export data from the Simulation Data Inspector after modifying the name, the exported data uses the new name.

Replay Data in the Simulation Data Inspector

This example shows how to replay data in the Simulation Data Inspector to inspect and build intuitive understanding of your data. When you replay data, a cursor sweeps synchronously across all the subplots in your view, displaying signal values. You can control the replay speed, pause to move the cursor sample-by-sample, and zoom to inspect your data. You can replay imported data and data logged from a simulation.

This example uses logged simulation data saved in a session. The session contains two runs of data logged from the `ex_vdp_mu` model. Data from Run 1: `ex_vdp_mu` is plotted in the viewing area.

Load the session and open the Simulation Data Inspector to view the data.

```
Simulink.sdi.load('ex_vdp_mu.mldatx');  
Simulink.sdi.view
```

Replay Data

When you replay data, the Simulation Data Inspector animates synchronized cursors to move through a time period defined by the maximum time among the plotted signals. Replaying and pausing in the Simulation Data Inspector has no effect on any models or simulations.

To show the replay controls in the Simulation Data Inspector, click the **Show/hide replay controls**

button. 

Click the **Replay** button. 

Synchronized cursors sweep across the subplots, indicating the signal value as the cursor moves in time. By default, the Simulation Data Inspector replays data at a rate of one second per second, meaning that the cursor moves through one second of data in the span of one second of clock time. You can adjust the replay speed to suit the data you want to inspect. To change the speed, click one of the arrows on either side of the label or click the label and enter your desired replay speed.

The Simulation Data Inspector moves the cursor based on the maximum time in the plotted signals and the replay speed. The position of the cursor at a given time during replay does not depend on the time values for samples in the plotted signals. When the cursor position does not correspond with a sample in a plotted signal, the Simulation Data Inspector interpolates a value to display, using the method defined in the **Interpolation** property of the signal. An asterisk at the end of the cursor value indicates that the value is interpolated.

Inspect Data Values During Replay

To inspect sample values in your data, you can pause the replay. When the replay is paused, you can use the **Step forward** and **Step backward** buttons to move the cursor sample-by-sample. The cursors move to the next time point among all plotted signals. When a plotted signal does not have a sample, the Simulation Data Inspector interpolates the value.

Pause the replay and use the **Step forward** and **Step backward** buttons to view the signal values.

Zoom During Replay

You can zoom in on a region of your data during replay to inspect signal values and relationships more closely. Viewing a portion of your signal can be particularly useful when your data spans a long duration with a high sample rate. For example, plot the signals from Run 2: `ex_vdp_mu`.

The data in run 2 corresponds to a much longer simulation of the `ex_vdp_mu` model, where the value of `Mu` changed over the course of the simulation. Viewing the entire signal at once makes analyzing the changing characteristics of the curve difficult. Before replaying the data, change the **Time span** in the **Visualization settings** to 100 to show the first 100 seconds. You can also collapse the navigation pane to allow the viewing area to occupy more space. Then, replay the data.

When the cursor nears the end of the zoomed portion of the data, click the **Fit to view** button to show the complete signal. Then, you can use the **Zoom in time** option to select another region of the signal to inspect more closely during the replay.

When replaying a long simulation, you can also adjust the replay speed or drag the time marker to replay data in an area of interest.

Compare Simulation Data

The Simulation Data Inspector can compare the data and metadata for runs and individual signals you import from the workspace or a file or log in a simulation. You can analyze comparison results using tolerances, and you can configure the comparison behavior by specifying signal properties and comparison constraints. This example uses data logged from simulations of the model `slexAircraftExample` and shows how to:

- Compare signals and runs.
- Analyze comparison results using the **Compare** pane in the Simulation Data Inspector.
- Specify signal tolerances and global tolerances.
- Configure comparison constraints.

For more information on tolerance calculations and signal properties that affect comparisons, see “How the Simulation Data Inspector Compares Data” on page 29-182. To compare data programmatically, use the `Simulink.sdi.compareRuns` function or the `Simulink.sdi.compareSignals` function.

Setup

This example continues from “Inspect Simulation Data” on page 29-148. You can also use this script to generate the data required for the example.

```
load_system('slexAircraftExample')

% Configure signals to log
Simulink.sdi.markSignalForStreaming('slexAircraftExample/Pilot', 1, 'on')
Simulink.sdi.markSignalForStreaming('slexAircraftExample/Aircraft Dynamics Model', 3, 'on')
Simulink.sdi.markSignalForStreaming('slexAircraftExample/Aircraft Dynamics Model', 4, 'on')

% Change Pilot signal to sine
set_param('slexAircraftExample/Pilot', 'WaveForm', 'sine')

% Simulate model
sim('slexAircraftExample')

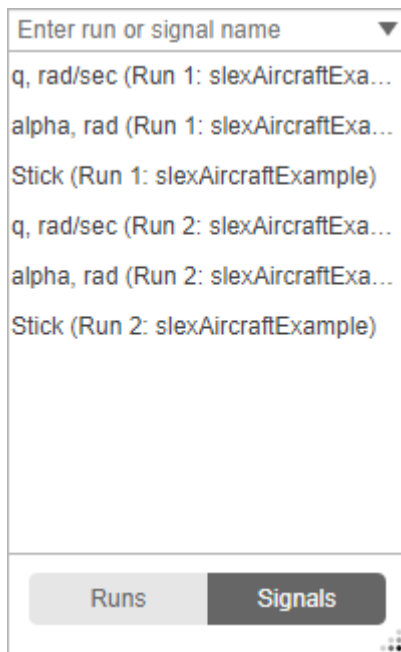

% Change Pilot signal to square
set_param('slexAircraftExample/Pilot', 'WaveForm', 'square')

% Simulate Model
sim('slexAircraftExample')
```

Compare Signals

You can compare signals to analyze the relationship between two signals in a model. For example, compare the `Stick` input signal to the output signal, `alpha`, `rad`.

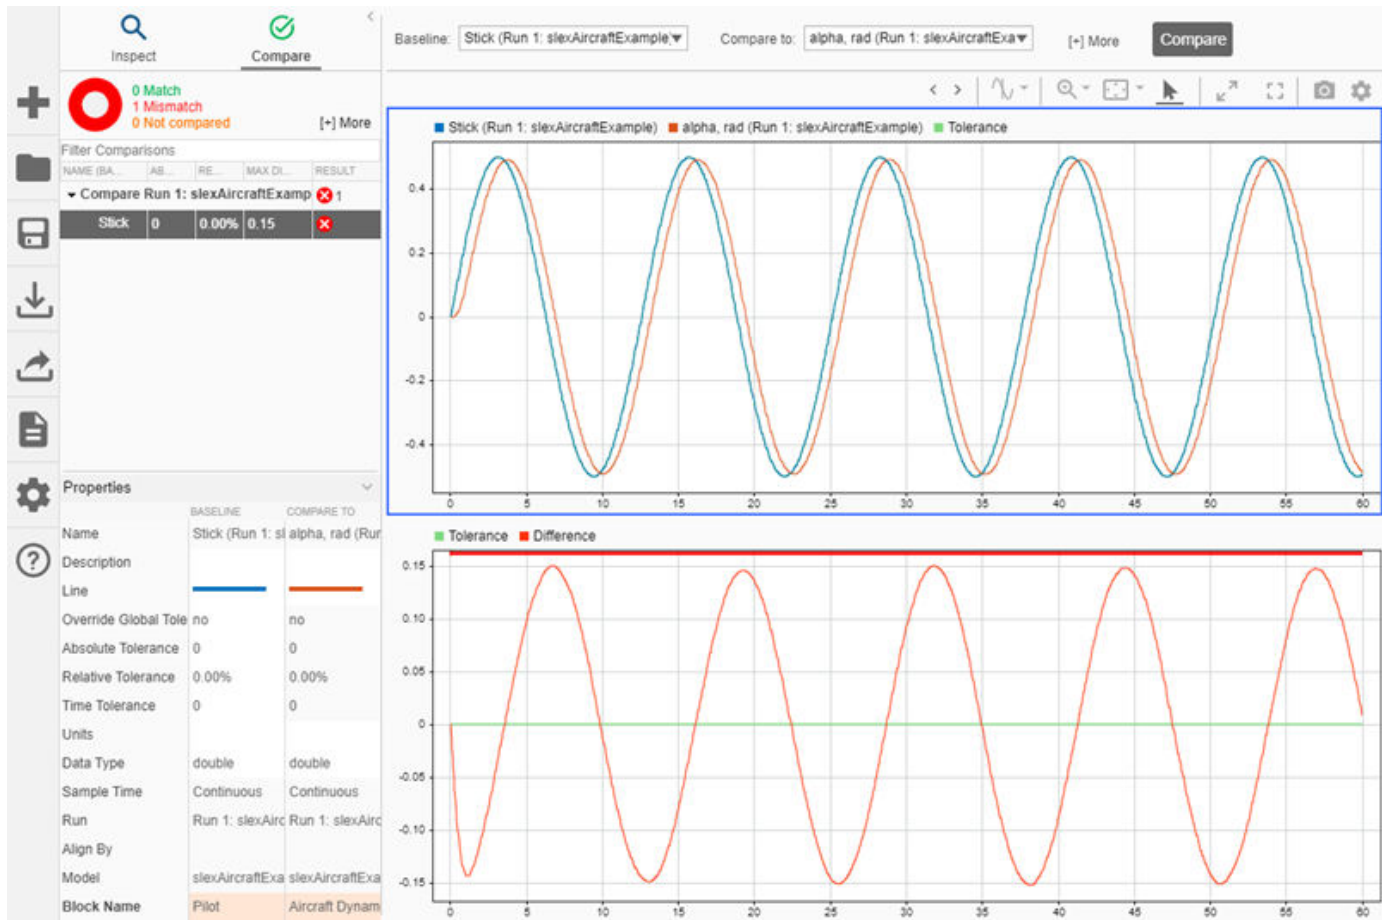

- 1 Navigate to the **Compare** pane.
- 2 To view a list of signals available for comparison, expand the **Baseline** drop-down and select **Signals**.

- 3 Select **Stick (Run 1: slexAircraftExample)**.
- 4 Expand the **Compare to** drop-down and select **alpha, rad (Run 1: slexAircraftExample)**.
- 5 Click **Compare**.

Alternatively, you can select the **Baseline** and **Compare to** signals using the context menu by right-clicking the signal in the **Inspect** pane.

The signals are not identical, so they do not match within the absolute, relative, and time tolerances, all set to 0 by default.

Signal Time Tolerance

Looking at the top plot in the comparison view, you can see the `alpha, rad` signal lags the `Stick` signal. For signal comparisons, the Simulation Data Inspector uses tolerance values specified for the **Baseline** signal. Add a time tolerance to the `Stick` signal to account for the lag.

Select the `Stick` signal and enter `0.5` in the **Time Tolerance** field of the **Properties** pane. When you specify a tolerance for a **Baseline** signal, its **Override Global Tolerance** field automatically changes to `yes`. When you click away from the **Time Tolerance** field, the comparison runs again, using the signal-level tolerance you specified. If you want to use global tolerance values for the signal, click the **Override Global Tolerance** field and select `no` from the drop-down.

The Simulation Data Inspector draws the tolerance band around the plotted **Baseline** signal and around the signed difference signal displayed in the bottom subplot. The bar along the top of the difference plot shows regions within tolerance and out of tolerance for the comparison in green and red.

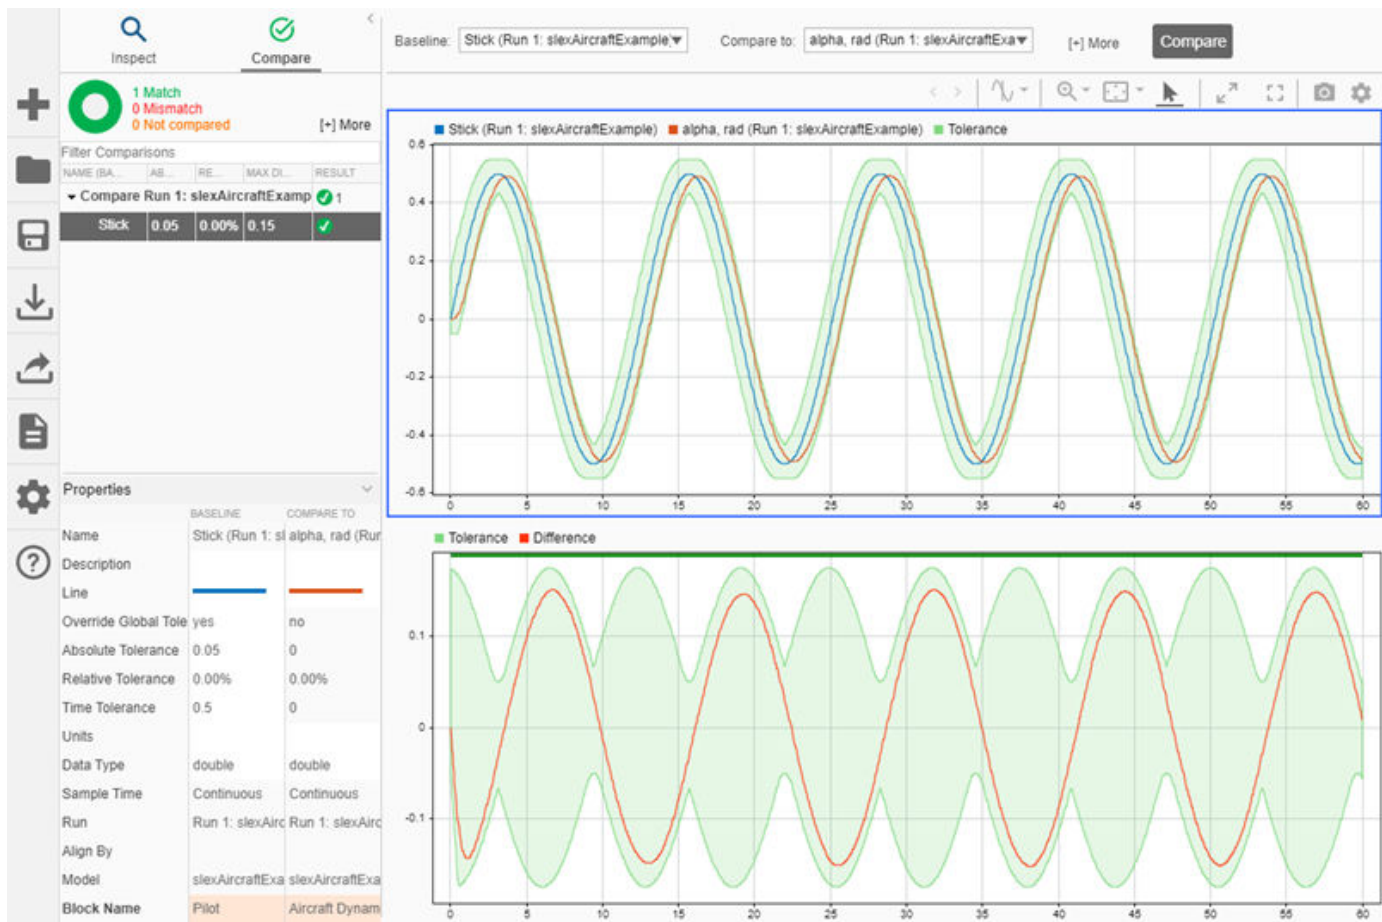

Signal Magnitude Tolerance

The time tolerance covers the phase difference between the two signals, but the comparison still includes regions out of tolerance due to the amplitude difference. You can add a magnitude tolerance as either an **Absolute Tolerance** or **Relative Tolerance**.

To add an absolute tolerance to the `Stick` signal, enter `0.05` into the **Absolute Tolerance** field in the properties pane. With the combination of the absolute and time tolerances, the signal comparison passes.

Note The Simulation Data Inspector draws the tolerance region using the most lenient interpretation of the specified tolerances for each point. For more information on how the Simulation Data Inspector calculates the tolerance band, see “Tolerance Specification” on page 29-184.

Compare Runs

You can also use the Simulation Data Inspector to compare all the signals in a run to all the signals in another run. Run comparisons can provide useful information about the effects of changing model parameters. For example, change the frequency cutoff of the filter for the control stick input signal. Then, evaluate the effect on the logged signals using the Simulation Data Inspector.

- 1 To access the data in the model workspace, on the **Modeling** tab, under **Design**, click **Model Explorer**.
- 2 Click the arrow next to the model name and select **Model Workspace**.
- 3 Change the value of T_s from 0.1 to 1 and close the **Model Explorer**.
- 4 Simulate the model with the new filter.
- 5 In the **Compare** pane in the Simulation Data Inspector, expand the **Baseline** drop-down, and select **Runs**.
- 6 From the list of runs, select Run 2: sllexAircraftExample.
- 7 Expand the **Compare to** drop-down and select Run 3: sllexAircraftExample.
- 8 Click **Compare**.

The **Compare** pane lists all signals from the compared runs and summarizes the results of the comparison in the **Results** column. In this example, all three signals aligned, and none matched. You

can click **More** to see the reason each signal comparison did not match. All three signals are out of tolerance.

 0 Match 3 Mismatch 3 Out of tolerance 0 Not compared				
[-] Less				
Filter Comparisons				
NAME (BA...	AB...	RE...	MAX DI...	RESULT
▼ Compare Run 3: slexAircraftExamp				✖ 3
q, rad/s	0	0.00%	1.00	✖
alpha, r	0	0.00%	0.49	✖
Stick	0	0.00%	0.78	✖

Note The Simulation Data Inspector only compares signals from the **Baseline** run that align with a signal from the **Compare To** run. If a signal from the **Baseline** run does not align with a signal from the **Compare To** run, the signal is listed in the **Compare** pane with a warning.  For more information on signal alignment, see “Signal Alignment” on page 29-182.

To plot a comparison result, select the signal you want to view in the **Compare** pane. For example, select the result for the q, rad/sec signal. The top plot shows the q, rad/sec signals from the **Baseline** and **Compare To** runs. The bottom plot shows the difference between the signals and the calculated tolerance band.

Global Tolerances

To analyze the signals in the run comparison, you can specify global tolerances. To specify global tolerances, click **More**. Under **Global Tolerances**, enter 0.75 for the time tolerance and 0.075 for the absolute tolerance.

Baseline: Run 2: slxAircraftExample ▼ Compare to: Run 3: slxAircraftExample ▼

Global Tolerances

Absolute: 0.075 Relative: 0 Time: 0.75

Constraints

Expand multidimensional channels Signal start and stop times must match

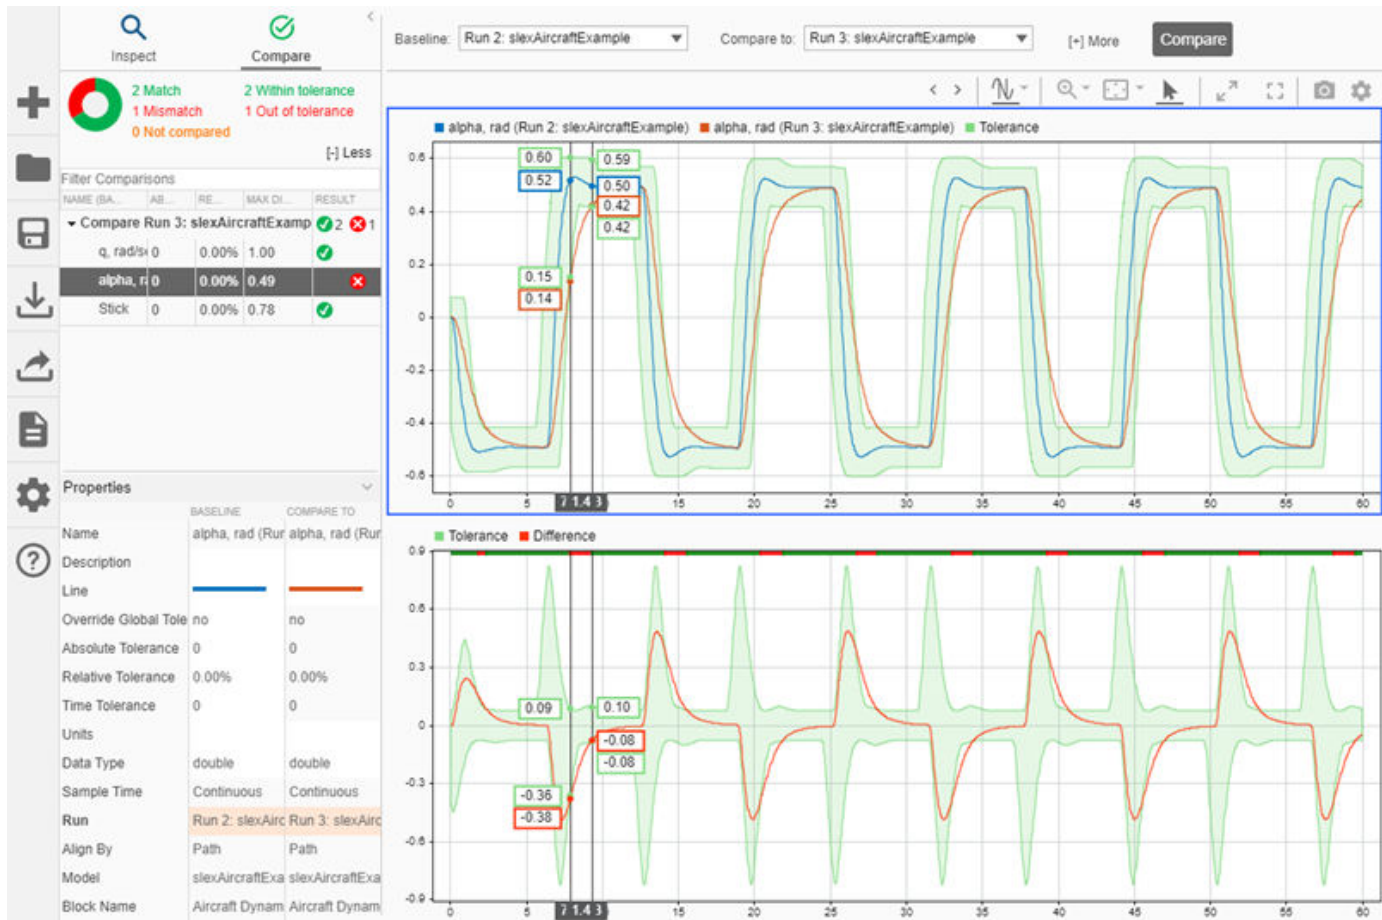

Signal data types must match Signal time vectors must match

Stop comparison on first mismatch of: Metadata ▼ [-] Less

Click the **Compare** button to run the comparison. The Simulation Data Inspector plots the tolerance band around the **Baseline** signal and on the signed difference plot. With the new tolerance values, the Stick and q , rad/sec signals pass the comparison.

View the α , rad signal to analyze the out of tolerance regions in the comparison result. Click the arrow buttons \leftarrow \rightarrow in the toolbar to navigate through the out of tolerance regions. Two cursors on the plot show the beginning and end of the first out of tolerance region. You can use your keyboard arrows to explore the signal and tolerance values throughout each out of tolerance region. To view the next out of tolerance region, click the right arrow button in the tool strip.

To resolve the out of tolerance regions, you can choose to modify the global tolerance values or to add a signal-specific tolerance to the α , rad signal using the signal properties.

Configure Comparison Constraints

You can also apply constraints to comparisons that affect whether the result is a match or mismatch. For example, you can specify that the time vectors for signals must match in order for the result to be a match. To specify the constraint, click **More**, then select **Signal time vectors must match**. To run a new comparison with this constraint, click **Compare**.

The comparison results show all signal results as mismatches now. The time vectors do not match for any of the signals because they were logged from simulations of a model that uses a variable-step solver, and the conditions changed between simulations. When the comparison result is a mismatch due to a constraint, the Simulation Data Inspector does not compute results for that signal. When you select a signal, the plot area shows an explanation of why the signal result is a mismatch.

Baseline: Run 2: slx:AircraftExample Compare to: Run 3: slx:AircraftExample [More] Compare

0 Match
3 Mismatch
3 Time mismatch
0 Not compared

Filter Comparisons

NAME (BA...)	AB...	RE...	MAX DI...	RESULT
▼ Compare Run 3: slx:AircraftExamp 3				
q, rad/s	0	0.00%	0	✗
alpha, r	0	0.00%	0	✗
Stick	0	0.00%	0	✗

Time vectors do not match (see [documentation](#))

RUN	NAME
Run 2: slx:AircraftExample	alpha, rad
Run 3: slx:AircraftExample	alpha, rad

Properties

	BASILINE	COMPARE TO
Name	alpha, rad (Run 2)	alpha, rad (Run 3)
Description		
Line		
Override Global Tole	no	no
Absolute Tolerance	0	0
Relative Tolerance	0.00%	0.00%
Time Tolerance	0	0
Units		
Data Type	double	double
Sample Time	Continuous	Continuous
Run	Run 2: slx:Airc	Run 3: slx:Airc
Align By	Path	Path
Model	slx:AircraftExa	slx:AircraftExa
Block Name	Aircraft Dynam	Aircraft Dynam

You can configure these comparison constraints:

- **Signal data types must match**
- **Signal start and stop times must match**
- **Signal time vectors must match**

When you require a match in signal metadata, specifying a constraint can return a mismatch result more quickly because the comparison does not compute results when the specified metadata does not match.

You can also configure a comparison to stop computing results after detecting the first mismatch result. When you configure a comparison to stop on the first mismatch, the comparison always stops after detecting the first mismatch in the signal metadata. You can also choose to stop the comparison when the first mismatch result is due to an out-of-tolerance result when comparing the signal data.

The Simulation Data Inspector always aligns signals in the baseline and comparison runs and always checks whether signal units match. When you configure a comparison to stop on the first mismatch, signals that do not align and signals with units that do not match always cause a comparison to stop. You can specify additional metadata for the comparison to check by selecting one or more constraints.

Cancel Comparisons

The runs and signals used in this example are relatively small, and comparisons run quickly. When you compare long signals or runs containing many signals, comparisons may take more time. The Simulation Data Inspector displays incremental progress indicators during comparison, and the **Compare** button becomes a **Cancel** button you can click to cancel the comparison at any point. For hierarchical data, the **Results** column in the comparison view summarizes the results on each hierarchical node.

How the Simulation Data Inspector Compares Data

You can tailor the Simulation Data Inspector comparison process to fit your requirements in multiple ways. When comparing runs, the Simulation Data Inspector:

- 1 Aligns signal pairs in the **Baseline** and **Compare To** runs based on the **Alignment** settings.

The Simulation Data Inspector does not compare signals that it cannot align.

- 2 Synchronizes aligned signal pairs according to the specified **Sync Method**.

Values for time points added in synchronization are interpolated according to the specified **Interpolation Method**.

- 3 Computes the difference of the signal pairs.
- 4 Compares the difference result against specified tolerances.

When the comparison run completes, the results of the comparison are displayed in the navigation pane.

Status	Comparison Result
	Difference falls within the specified tolerance.
	Difference violates specified tolerance.
	The signal does not align with a signal from the Compare To run.

When you compare signals with differing time intervals, the Simulation Data Inspector compares the signals on their overlapping interval.

Signal Alignment

In the alignment step, the Simulation Data Inspector decides which signal from the **Compare To** run pairs with a given signal in the **Baseline** run. When you compare signals with the Simulation Data Inspector, you complete the alignment step by selecting the **Baseline** and **Compare To** signals.

The Simulation Data Inspector aligns signals using a combination of their Data Source, Path, SID, and Signal Name properties.

Property	Description
Data Source	Path of the variable in the MATLAB workspace for data imported from the workspace
Path	Block path for the source of the data in its model
SID	Simulink identifier For more information about SIDs, see “Simulink Identifiers” on page 1-8
Signal Name	Name of the signal in the model

With the default alignment settings, the Simulation Data Inspector aligns signals between runs according to this flow chart.

You can specify the priority for each of the signal properties used for alignment in the Simulation Data Inspector **Preferences**. The **Align By** field specifies the highest priority property used to align signals. The priority drops with each subsequent **Then By** field. You must specify a primary alignment property in the **Align By** field, but you can leave any number of the **Then By** fields blank.

Synchronization

Often, signals that you want to compare don't contain the exact same set of time points. The synchronization step in Simulation Data Inspector comparisons resolves discrepancies in signals' time vectors. You can choose **union** or **intersection** as the synchronization method.

When you specify **union** synchronization, the Simulation Data Inspector builds a time vector that includes every sample time between the two signals. For each sample time not originally present in either signal, the Simulation Data Inspector interpolates the value. The second graph in the illustration shows the union synchronization process, where the Simulation Data Inspector identifies samples to add in each signal, represented by the unfilled circles. The final plot shows the signals after the Simulation Data Inspector has interpolated values for the added time points. The Simulation Data Inspector computes the difference using the signals in the final graph, so that the computed difference signal contains all the data points between the signals.

When you specify **intersection** synchronization, the Simulation Data Inspector uses only the sample times present in both signals in the comparison. In the second graph, the Simulation Data Inspector identifies samples that do not have a corresponding sample for comparison, shown as unfilled circles. The final graph shows the signals used for the comparison, without the samples identified in the second graph.

The choice between the synchronization options involves a trade off between speed and accuracy. The interpolation required by `union` synchronization takes time, but provides a more precise result. When you use `intersection` synchronization, the comparison finishes quickly because the Simulation Data Inspector computes the difference for fewer data points and does not interpolate. However, some data is discarded and precision is lost with `intersection` synchronization.

Interpolation

The interpolation property of a signal determines how the Simulation Data Inspector displays the signal and how additional data values are computed in synchronization. You can choose to interpolate your data with a zero-order hold (`zoh`) or a linear approximation. You can also specify no interpolation.

When you specify `zoh` or `none` for the **Interpolation Method**, the Simulation Data Inspector replicates the data of the previous sample for interpolated sample times. When you specify `linear` interpolation, the Simulation Data Inspector uses samples on either side of the interpolated point to linearly approximate the interpolated value. Typically, discrete signals use `zoh` interpolation and continuous signals use `linear` interpolation. You can specify the **Interpolation Method** for your signals in the signal properties.

Tolerance Specification

The Simulation Data Inspector allows you to specify the scope and value of the tolerance for your signal. You can define a tolerance band using any combination of absolute, relative, and time tolerance values, and you can specify whether the specified tolerance applies to an individual signal or to all the signals in a run.

Tolerance Scope

In the Simulation Data Inspector, you can specify the tolerance for your data globally or for an individual signal. Global tolerance values apply to all signals in a run that do not have **Override Global Tol** set to yes. You can specify global tolerance values for your data at the top of the graphical viewing area in the **Compare** view. To specify signal specific tolerance values, edit the signal properties and ensure the **Override Global Tol** property is set to yes.

Tolerance Computation

In the Simulation Data Inspector, you can specify a tolerance band for your run or signal using a combination of absolute, relative, and time tolerance values. When you specify the tolerance for your run or signal using multiple types of tolerances, each tolerance can yield a different answer for the tolerance at each point. The Simulation Data Inspector computes the overall tolerance band by selecting the most lenient tolerance result for each data point.

When you define your tolerance using only the absolute and relative tolerance properties, the Simulation Data Inspector computes the tolerance for each point as a simple maximum.

```
tolerance = max(absoluteTolerance, relativeTolerance*abs(baselineData));
```

The upper boundary of the tolerance band is formed by adding **tolerance** to the **Baseline** signal. Similarly, the Simulation Data Inspector computes the lower boundary of the tolerance band by subtracting **tolerance** from the **Baseline** signal.

When you specify a time tolerance, the Simulation Data Inspector evaluates the time tolerance first, over a time interval defined as $[(t_{\text{samp}} - \text{tol}), (t_{\text{samp}} + \text{tol})]$ for each sample. The Simulation Data Inspector builds the lower tolerance band by selecting the minimum point on the interval for each sample. Similarly, the maximum point on the interval defines the upper tolerance for each sample.

If you specify a tolerance band using an absolute or relative tolerance in addition to a time tolerance, the Simulation Data Inspector applies the time tolerance first, and then applies the absolute and relative tolerances to the maximum and minimum points selected with the time tolerance.

`upperTolerance = max + max(absoluteTolerance, relativeTolerance*max)`

`lowerTolerance = min - max(absoluteTolerance, relativeTolerance*min)`

Limitations

The Simulation Data Inspector does not support comparing:

- Signals of data types `int64` or `uint64`.
- Variable-size signals.

Inspect and Compare Data Programmatically

You can harness the capabilities of the Simulation Data Inspector from the MATLAB command line using the Simulation Data Inspector API.

The Simulation Data Inspector organizes data in runs and signals, assigning a unique numeric identification to each run and signal. Some Simulation Data Inspector API functions use the run and signal IDs to reference data, rather than accepting the run or signal itself as an input. To access the run IDs in the workspace, you can use `Simulink.sdi.getAllRunIDs` or `Simulink.sdi.getRunIDByIndex`. You can access signal IDs through a `Simulink.sdi.Run` object using the `getSignalIDByIndex` method.

The `Simulink.sdi.Run` and `Simulink.sdi.Signal` classes provide access to your data and allow you to view and modify run and signal metadata. You can modify the Simulation Data Inspector preferences using functions like `Simulink.sdi.setSubPlotLayout`, `Simulink.sdi.setRunNamingRule`, and `Simulink.sdi.setMarkersOn`. To restore the Simulation Data Inspector's default settings, use `Simulink.sdi.clearPreferences`.

Create a Run and View the Data

This example shows how to create a run, add data to it, and then view the data in the Simulation Data Inspector.

Create Data for the Run

Create `timeseries` objects to contain data for a sine signal and a cosine signal. Give each `timeseries` object a descriptive name.

```
time = linspace(0,20,100);

sine_vals = sin(2*pi/5*time);
sine_ts = timeseries(sine_vals,time);
sine_ts.Name = 'Sine, T=5';

cos_vals = cos(2*pi/8*time);
cos_ts = timeseries(cos_vals,time);
cos_ts.Name = 'Cosine, T=8';
```

Create a Run and Add Data

Use the `Simulink.sdi.view` function to open the Simulation Data Inspector.

```
Simulink.sdi.view
```

To import data into the Simulation Data Inspector from the workspace, create a `Simulink.sdi.Run` object using the `Simulink.sdi.Run.create` function. Add information about the run to its metadata using the `Name` and `Description` properties of the `Run` object.

```
sinusoidsRun = Simulink.sdi.Run.create;
sinusoidsRun.Name = 'Sinusoids';
sinusoidsRun.Description = 'Sine and cosine signals with different frequencies';
```

Use the `add` function to add the data you created in the workspace to the empty run.

```
add(sinusoidsRun,'vars',sine_ts,cos_ts);
```

Plot the Data in the Simulation Data Inspector

Use the `getSignalByIndex` function to access `Simulink.sdi.Signal` objects that contain the signal data. You can use the `Simulink.sdi.Signal` object properties to specify the line style and color for the signal and plot it in the Simulation Data Inspector. Specify the `LineColor` and `LineDashed` properties for each signal.

```
sine_sig = getSignalByIndex(sinusoidsRun,1);
sine_sig.LineColor = [0 0 1];
sine_sig.LineDashed = '-.';

cos_sig = sinusoidsRun.getSignalByIndex(2);
cos_sig.LineColor = [0 1 0];
cos_sig.LineDashed = '--';
```

Use the `Simulink.sdi.setSubPlotLayout` function to configure a 2-by-1 subplot layout in the Simulation Data Inspector plotting area. Then use the `plotOnSubplot` function to plot the sine signal on the top subplot and the cosine signal on the lower subplot.

```
Simulink.sdi.setSubPlotLayout(2,1);

plotOnSubPlot(sine_sig,1,1,true);
plotOnSubPlot(cos_sig,2,1,true);
```

Close the Simulation Data Inspector and Save Your Data

When you have finished inspecting the plotted signal data, you can close the Simulation Data Inspector and save the session to an MLDATX file.

```
Simulink.sdi.close('sinusoids.mldatx')
```

Compare Two Signals in the Same Run

You can use the Simulation Data Inspector programmatic interface to compare signals within a single run. This example compares the input and output signals of an aircraft longitudinal controller.

First, load the session that contains the data.

```
Simulink.sdi.load('AircraftExample.mldatx');
```

Use the `Simulink.sdi.Run.getLatest` function to access the latest run in the data.

```
aircraftRun = Simulink.sdi.Run.getLatest;
```

Then, you can use the `Simulink.sdi.getSignalsByName` function to access the `Stick` signal, which represents the input to the controller, and the `alpha, rad` signal that represents the output.

```
stick = getSignalsByName(aircraftRun,'Stick');
alpha = getSignalsByName(aircraftRun,'alpha, rad');
```

Before you compare the signals, you can specify a tolerance value to use for the comparison. Comparisons use tolerance values specified for the baseline signal in the comparison, so set an absolute tolerance value of 0.1 on the `Stick` signal.

```
stick.AbsTol = 0.1;
```

Now, compare the signals using the `Simulink.sdi.compareSignals` function. The `Stick` signal is the baseline, and the `alpha, rad` signal is the signal to compare against the baseline.

```
comparisonResults = Simulink.sdi.compareSignals(stick.ID,alpha.ID);
match = comparisonResults.Status

match =
    ComparisonSignalStatus enumeration

    OutOfTolerance
```

The comparison result is out of tolerance. You can use the `Simulink.sdi.view` function to open the Simulation Data Inspector to view and analyze the comparison results.

Compare Runs with Global Tolerance

You can specify global tolerance values to use when comparing two simulation runs. Global tolerance values are applied to all signals within the run. This example shows how to specify global tolerance values for a run comparison and how to analyze and save the comparison results.

First, load the session file that contains the data to compare. The session file contains data for four simulations of an aircraft longitudinal controller. This example compares data from two runs that use different input filter time constants.

```
Simulink.sdi.load('AircraftExample.mldatx');
```

To access the run data to compare, use the `Simulink.sdi.getAllRunIDs` function to get the run IDs that correspond to the last two simulation runs.

```
runIDs = Simulink.sdi.getAllRunIDs;
runID1 = runIDs(end - 1);
runID2 = runIDs(end);
```

Use the `Simulink.sdi.compareRuns` function to compare the runs. Specify a global relative tolerance value of `0.2` and a global time tolerance value of `0.5`.

```
runResult = Simulink.sdi.compareRuns(runID1,runID2,'reltol',0.2,'timetol',0.5);
```

Check the `Summary` property of the returned `Simulink.sdi.DiffRunResult` object to see whether signals were within the tolerance values or out of tolerance.

```
runResult.Summary

ans = struct with fields:
    OutOfTolerance: 0
    WithinTolerance: 3
    Unaligned: 0
    UnitsMismatch: 0
    Empty: 0
    Canceled: 0
    EmptySynced: 0
    DataTypeMismatch: 0
    TimeMismatch: 0
    StartStopMismatch: 0
    Unsupported: 0
```

All three signal comparison results fell within the specified global tolerance.

You can save the comparison results to an MLDATX file using the `saveResult` function.

```
saveResult(runResult, 'InputFilterComparison');
```

Analyze Simulation Data Using Signal Tolerances

You can programmatically specify signal tolerance values to use in comparisons performed using the Simulation Data Inspector. In this example, you compare data collected by simulating a model of an aircraft longitudinal flight control system. Each simulation uses a different value for the input filter time constant and logs the input and output signals. You analyze the effect of the time constant change by comparing results using the Simulation Data Inspector and signal tolerances.

First, load the session file that contains the simulation data.

```
Simulink.sdi.load('AircraftExample.mldatx');
```

The session file contains four runs. In this example, you compare data from the first two runs in the file. Access the `Simulink.sdi.Run` objects for the first two runs loaded from the file.

```
runIDs = Simulink.sdi.getAllRunIDs;  
runIDTs1 = runIDs(end-3);  
runIDTs2 = runIDs(end-2);
```

Now, compare the two runs without specifying any tolerances.

```
noTolDiffResult = Simulink.sdi.compareRuns(runIDTs1, runIDTs2);
```

Use the `getResultByIndex` function to access the comparison results for the `q` and `alpha` signals.

```
qResult = getResultByIndex(noTolDiffResult, 1);  
alphaResult = getResultByIndex(noTolDiffResult, 2);
```

Check the `Status` of each signal result to see whether the comparison result fell within our out of tolerance.

```
qResult.Status
```

```
ans =  
    ComparisonSignalStatus enumeration  
    OutOfTolerance
```

```
alphaResult.Status
```

```
ans =  
    ComparisonSignalStatus enumeration  
    OutOfTolerance
```

The comparison used a value of 0 for all tolerances, so the `OutOfTolerance` result means the signals are not identical.

You can further analyze the effect of the time constant by specifying tolerance values for the signals. Specify the tolerances by setting the properties for the `Simulink.sdi.Signal` objects that

correspond to the signals being compared. Comparisons use tolerances specified for the baseline signals. This example specifies a time tolerance and an absolute tolerance.

To specify a tolerance, first access the `Signal` objects from the baseline run.

```
runTs1 = Simulink.sdi.getRun(runIDTs1);
qSig = getSignalsByName(runTs1, 'q, rad/sec');
alphaSig = getSignalsByName(runTs1, 'alpha, rad');
```

Specify an absolute tolerance of 0.1 and a time tolerance of 0.6 for the `q` signal using the `AbsTol` and `TimeTol` properties.

```
qSig.AbsTol = 0.1;
qSig.TimeTol = 0.6;
```

Specify an absolute tolerance of 0.2 and a time tolerance of 0.8 for the `alpha` signal.

```
alphaSig.AbsTol = 0.2;
alphaSig.TimeTol = 0.8;
```

Compare the results again. Access the results from the comparison and check the `Status` property for each signal.

```
tolDiffResult = Simulink.sdi.compareRuns(runIDTs1, runIDTs2);
qResult2 = getResultByIndex(tolDiffResult, 1);
alphaResult2 = getResultByIndex(tolDiffResult, 2);
```

```
qResult2.Status
```

```
ans =
  ComparisonSignalStatus enumeration
    WithinTolerance
```

```
alphaResult2.Status
```

```
ans =
  ComparisonSignalStatus enumeration
    WithinTolerance
```

Keyboard Shortcuts for the Simulation Data Inspector

You can use several keyboard shortcuts to facilitate working with the Simulation Data Inspector. In the table, where the shortcut looks like **Ctrl+N**, to use the shortcut, you hold down the **Ctrl** key and then press the **N** key.

Note On Macintosh platforms, use the **command** key instead of **Ctrl**.

General Actions

Task	Shortcut
Start a new session	Ctrl+N
Open a session	Ctrl+O
Save a session	Ctrl+S
Compare	Ctrl+E
Link/Unlink a subplot	Ctrl+U
Delete a run or signal	Delete

Plot Zooming

Task	Shortcut
Zoom in T (time)	Ctrl+Shift+T
Zoom in Y	Ctrl+Shift+Y
Zoom in T and Y	Ctrl++ (Numeric keypad only)
Zoom out	Ctrl+- (Numeric keypad only)
Fit to view	Space bar
Cancel zoom operation or signal dragging	Esc

Data Cursors

Task	Shortcut
Show a data cursor	Ctrl+I
Hide all data cursors	Shift+Del
Move a selected data cursor to next data point	Right arrow
Move a selected data cursor to previous data point	Left arrow
Activate first (left) cursor	Ctrl+1
Activate second (right) cursor	Ctrl+2

Import Dialog Box

These actions pertain to the import table.

Task	Shortcut
Expand all nodes	Shift+Ctrl+=
Collapse all nodes	Ctrl+=
Select a node	Space bar
Expand a single node	Right arrow
Collapse a single node	Left arrow

Tune and Visualize Your Model with Dashboard Blocks

In this section...

“Explore Connections Within the Model” on page 29-194

“Simulate Changing Model States” on page 29-195

“View Signal Data” on page 29-196

“Tune Parameters During Simulation” on page 29-197

The blocks in the Dashboard library help you control and visualize your model during simulation and while the simulation is paused. This example uses the Fault-Tolerant Fuel Control System model to showcase the control and visualization capabilities of Dashboard blocks.

To open the model, enter `sldemo_fuel_sys` into the MATLAB command window. To open the Dashboard subsystem, double-click it or click the Open the Dashboard link.

Note Dashboard blocks cannot connect to signals inside referenced models or subsystems.

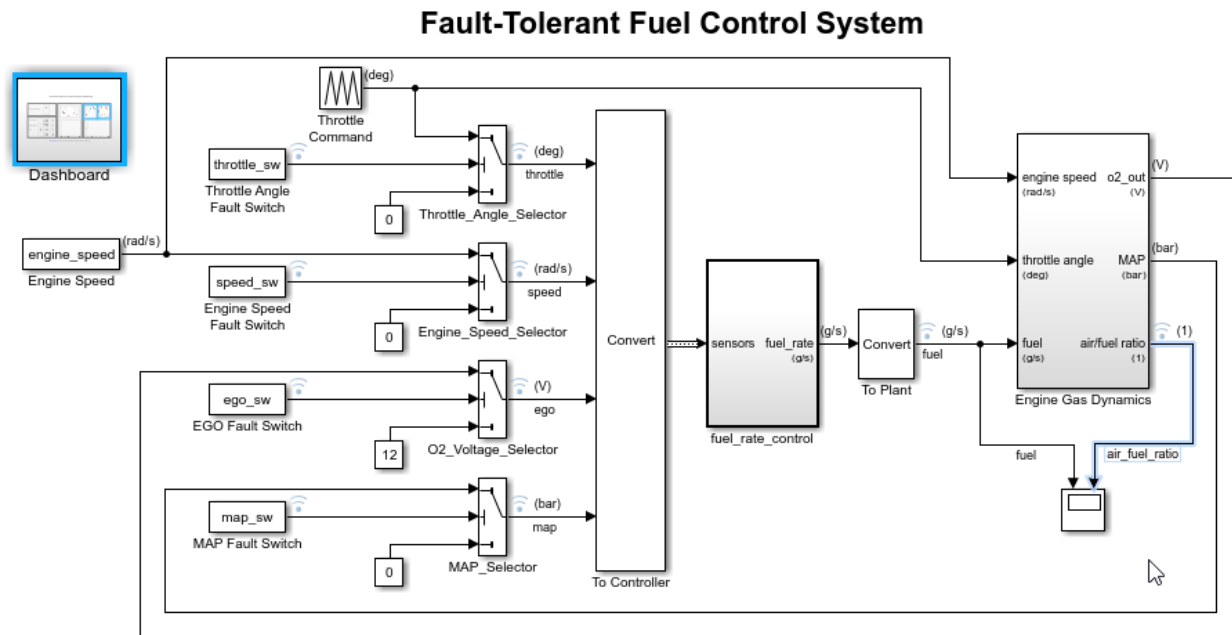

Explore Connections Within the Model

The Dashboard subsystem contains blocks for controlling and visualizing signals in the Fault-Tolerant Fuel Control System model. Explore the connections between the signals and Dashboard blocks. Click either a signal or a Dashboard block to highlight the connections.

From the Dashboard subsystem, click the Toggle Switch in the Fuel panel. Hover the mouse over the ellipsis above the block and then click the arrow above it to jump to the connected block or signal.

From the top level of the model, click the `air_fuel_ratio` signal and see the Dashboard subsystem, Quarter Gauge, and Half Gauge highlighted.

[Open the Dashboard](#) subsystem to simulate any combination of sensor failures.

Copyright 1990-2016 The MathWorks, Inc.

Simulate Changing Model States

In the Dashboard subsystem, switches provide control over the state of the throttle angle, engine speed, EGO, and MAP signals. For each sensor signal, the switch toggles between normal and fail, allowing you to simulate the system response to each single-point failure. Clicking any one of these switches before simulation, during simulation, or while a simulation is paused changes the state in the model.

Run the simulation and observe the control system response to each single-point failure.

- 1 Start the simulation.
- 2 As the simulation runs, click one of the switches to simulate a component failure.

Observe the changes in the `fuel` and `air_fuel_ratio` signals in the Dashboard Scope and Gauge blocks when you flip each switch.

- 3 Stop the simulation when you are finished.

Fault-Tolerant Fuel Control System Dashboard

[Update Diagram](#) (Ctrl+D) to bind switches to model workspace variables.

View Signal Data

Dashboard blocks allow you to view signal data using gauges, lamps, and dashboard scopes. In this example, the Dashboard blocks provide visual feedback about the fuel input and air-to-fuel ratio during simulation, after simulation, and while a simulation is paused.

To capture different types of information and more effectively visualize a signal, connect multiple Dashboard blocks to a single signal. For example, you can visualize the `air_fuel_ratio` signal using the Gauge, Quarter Gauge, and Dashboard Scope blocks.

Use the Quarter Gauge block, labeled Normal Range in the example, to see small fluctuations in the instantaneous `air_fuel_ratio` signal while its value lies within the normal operational range. The Gauge block, labeled Full Range, allows you to see the behavior of the instantaneous `air_fuel_ratio` signal outside of the normal range. The Dashboard Scope block shows the variations of the `air_fuel_ratio` signal over time.

Tune Parameters During Simulation

Dashboard blocks allow you to tune parameters in your model during a simulation. To explore the tuning capability within the fuel system model, replace the engine speed Toggle Switch block with a Knob:

- 1 Delete the engine speed Toggle Switch.
- 2 Add a Knob block from the Dashboard library.
- 3 Click the **Connect** button that appears when you pause on the Knob block. When you click the **Connect** button, the Simulink Editor enters connect mode, which facilitates connecting Dashboard blocks to signals and parameters in your model.

- 4 Navigate to the top level of the model and select the Engine Speed block. The Engine Speed block is a Constant block whose **Constant value** parameter you can tune with the Knob block.

When you select the Engine Speed block, the names of tunable parameters associated with the block appear in a table.

- 5 Select the option button next to `engine_speed` in the table. Then, to exit connect mode, click the **Exit** button in the upper-right of the model canvas.

Now that the Knob block is connected to the `engine_speed` parameter, you can set the tick interval and range to values that make sense for the simulation. Double-click the Knob block to access the block parameters. In this example, set **Minimum** to 75, **Maximum** to 750, and **Tick Interval** to 75. Then, click **OK**.

Simulate the model and tune the `engine_speed` parameter using the Knob.

- 1 Start the simulation.
- 2 As the simulation runs, drag the pointer on the Knob to adjust the value of `engine_speed`.

Notice as you use the Knob to adjust the value of `engine_speed`, the `air_fuel_ratio` value displayed on the Gauge blocks and in the Dashboard Scope block changes.

- 3 Stop the simulation when you have finished tuning the parameter.

Interactively Design and Debug Models Using Panels

You can use a panel containing one or more Dashboard blocks to help you design and debug a model. A panel floats above the model canvas and follows you throughout a model hierarchy. With panels, you can control and monitor components of your model in place, without adding collections of Dashboard blocks throughout the model.

When you use panels, the blocks in the panel are not associated with the model in the same way as blocks in the canvas. For example, you cannot programmatically interact with blocks in panels using `get_param`, `set_param`, `gcb`, or `gcbh`. Otherwise, blocks promoted to panels retain their interactive behavior. You can connect Dashboard blocks in a panel using connect mode, inspect block properties using the Property Inspector, and modify connections during simulation.

This example uses the `sldemo_fuelsys` model to illustrate the steps required to create panels and how you can use panels to debug your models. To open the model, type `sldemo_fuelsys` into the MATLAB Command Window.

Create a New Panel

The `sldemo_fuelsys` model has a Dashboard subsystem that contains controls and indicators for interactively simulating the model. You can use panels in addition to or instead of using a Dashboard subsystem or including Dashboard blocks throughout your model. For example, you can create three panels, each containing a subset of the blocks in the Dashboard subsystem:

- A control panel, including the blocks in the **Inputs** and **Fault Injection** areas.
- A visualization panel for the `fuel` signal, including the blocks in the **Fuel (g/s)** area.
- A visualization panel for the `air_fuel_ratio` signal, including the blocks in the **Air/Fuel Ratio** area.

You do not need to separate controls and visualizations into different panels. A single panel can contain both kinds of blocks. For this example, the modular division allows you to have access to the controls while choosing which signal to monitor, depending on the subsystem you need to understand or debug.

Navigate inside the Dashboard subsystem, and create the controls panel:

- 1 Select the blocks inside the areas labeled **Inputs** and **Fault Injection**.
- 2 To promote the selection of blocks to a panel, pause on the ellipsis that appears at the end of the selection and select **Promote to Panel** from the menu that appears.

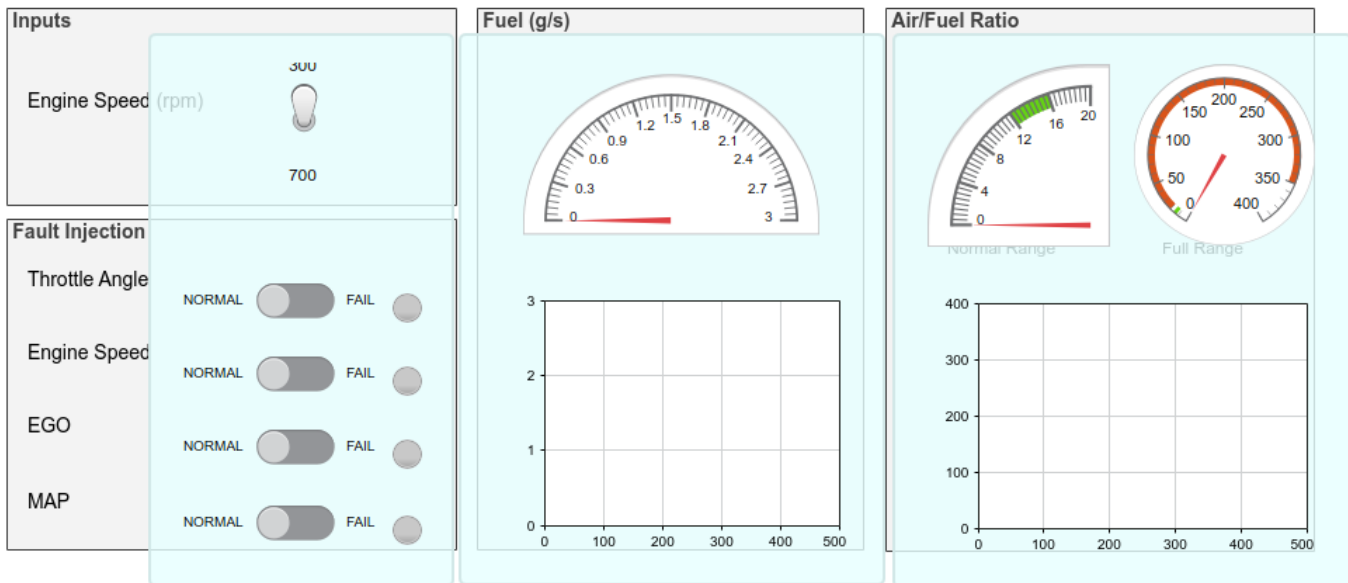

Note You can only promote Dashboard blocks and blocks in the Aerospace Blockset™ Flight Instruments library to a panel. When you try to promote a selection that contains model elements other than Dashboard blocks, only the Dashboard blocks promote to the panel.

When you promote blocks to a panel, the blocks move from the canvas into the panel. If you want to move a block back into the canvas from a panel, enter edit mode and drag the block out of the panel and into the canvas. To enter edit mode for a panel, select the panel, pause on the ellipsis that appears above the selected panel, and select **Edit Panel**.

Follow similar steps to create two more panels: one containing the blocks in the **Fuel (g/s)** area, and another containing the blocks in the **Air/Fuel Ratio** area.

Fault-Tolerant Fuel Control System Dashboard

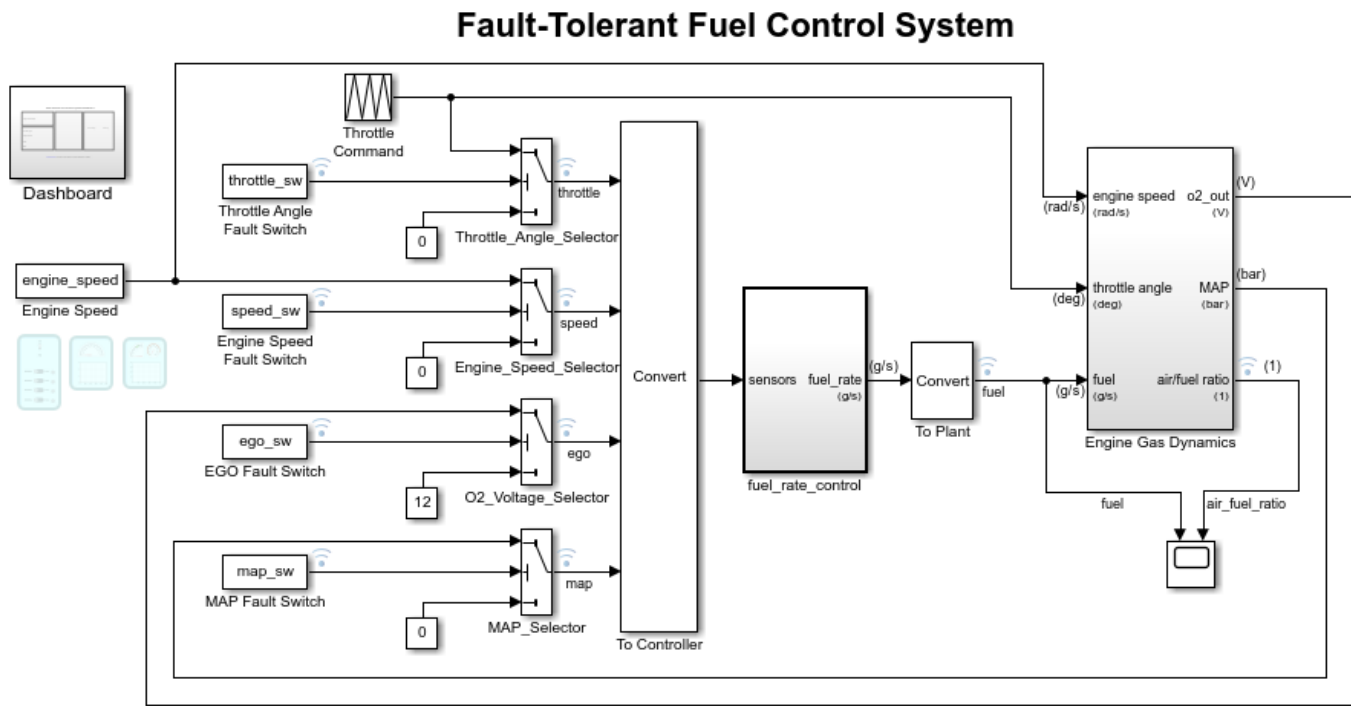

Note To use panels saved in a referenced model, open the referenced model as a top model.

Manage Panels in Your Model

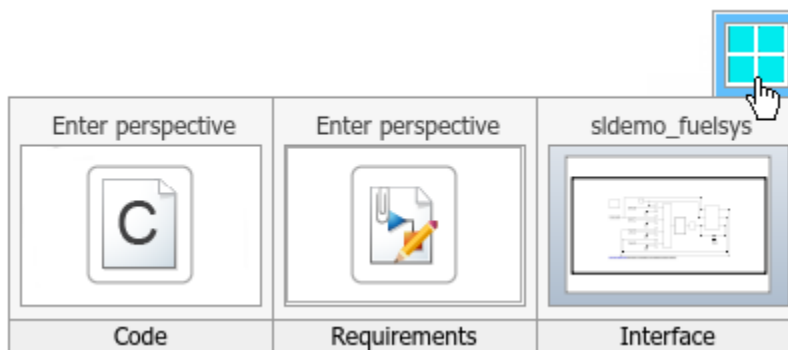

When you use panels in your model, the panel remains accessible, floating over the canvas, no matter where you are in a model hierarchy. For example, navigate to the top level of the `sldemo_fuelsys` model. The panels remain visible and in the same position, similar to a heads-up display.

You can adjust the size of a panel from the corners. When you resize a panel outside of edit mode, the contents of the panel scale proportionally. To resize a panel without scaling the contents, enter edit mode as described in “Edit and Annotate a Panel” on page 29-203. You can reposition a panel by selecting an empty area in the panel and dragging.

If you need to inspect or edit your model, you can minimize one or more panels by double-clicking each panel. Minimized panels remain visible in the model, represented by icons. You can move the icon to a convenient place in your model while you edit or inspect the model contents. When you need to use the panel, you can restore the panel by double-clicking the icon.

You can also use the **Manage Panels** dialog to control panel visibility in the model. To access all panels available in a model or change the visibility of a panel, select **Manage Panels** from the perspectives controls. You can access the perspectives controls by clicking the lower right corner of the Simulink Editor.

The **Manage Panels** dialog is only available when your model includes panels. If there are no panels in your model, the **Manage Panels** dialog does not show in the perspectives controls.

The **Manage Panels** dialog hovers over the canvas and displays an icon for each panel in the model. Because this model contains three panels, you see three icons. You can use the **Manage Panels** dialog to hide or show individual panels in your model, depending on the relevance of each panel to your present workflow. Click an icon to toggle the visibility for the corresponding panel. When panels are hidden, the icon becomes more transparent in the dialog, and the panel is not visible in the model. You can use the menu above the **Manage Panels** dialog to show or hide all panels in the model.

Because panels are positioned relative to the canvas and do not scale with zoom actions, you may lose track of one or more panels in the model as you design and debug. Use the **Fit Visible Panels to View** button to gather all visible panels in your model into the visible canvas.

Edit and Annotate a Panel

You can edit and annotate panels using edit mode. To enter edit mode for a panel, select the panel, pause on the ellipsis that appears above the selected panel, and select **Edit Panel**.

In edit mode, you can resize panels without resizing the panel contents, delete a panel, and change the appearance of a panel. For example, you could specify a background image to use as the panel background, or you can add annotations to label the contents of the panel. You can also add and remove blocks in edit mode by dragging blocks into or out of the panel. When your model has multiple panels, you can move blocks and labels between panels in edit mode.

Add annotations to each panel to label each interactive element. To add an annotation, double-click an empty part of the panel and start typing. Use the rich text menu to modify the annotations. For example, make section labels bold. To edit another panel while in edit mode, select the next panel. Clicking outside of a panel exits edit mode.

When you finish editing and annotating the panel, exit edit mode by selecting the **Done Editing** option in the menu above the panel or clicking outside of the panel.

Interactively Simulate a Model Using Panels

Now you have modular panels to use while interactively simulating the `sldemo_fuelsys` model. Suppose you need to understand and debug the `fuel_rate_control` subsystem. In this subsystem, the controls panel and the panel that visualizes the `fuel` signal are most useful. Before starting a simulation, navigate inside the `fuel_rate_control` subsystem and then inside the `control_logic` Stateflow chart. Minimize or hide the panel that visualizes the `air_fuel_ratio` signal, and arrange the controls panel and fuel panel so you can see the contents of the chart.

Start a simulation. Once the simulation starts, modify the position for one or more **Fault Injection** Slider Switch blocks to induce a failure in the system. To modify the value a Dashboard block passes to the model, select the block and then click to select the new value. Observe the changes in the Stateflow chart as the system state changes in response to one or more failures.

Tip If the simulation progresses too quickly, you can use simulation pacing to slow the progression of simulation time relative to clock time. For more information, see “Simulation Pacing” on page 2-17.

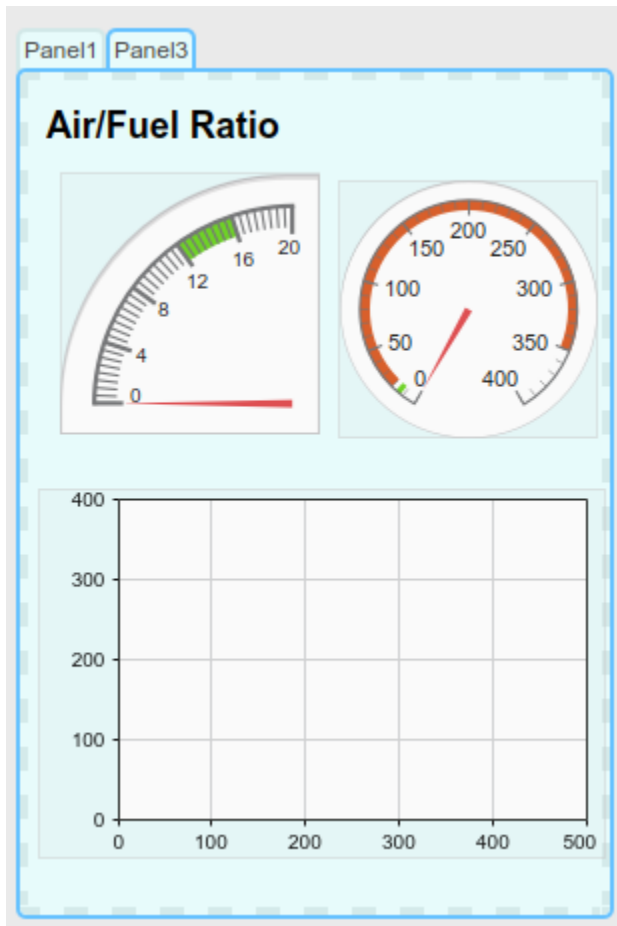

Create Tabbed Panels

Another way to manage multiple panels is by creating a tabbed panel. For example, you can create a tabbed panel that contains one panel for visualizing the fuel signal and another for visualizing the air_fuel_ratio signal.

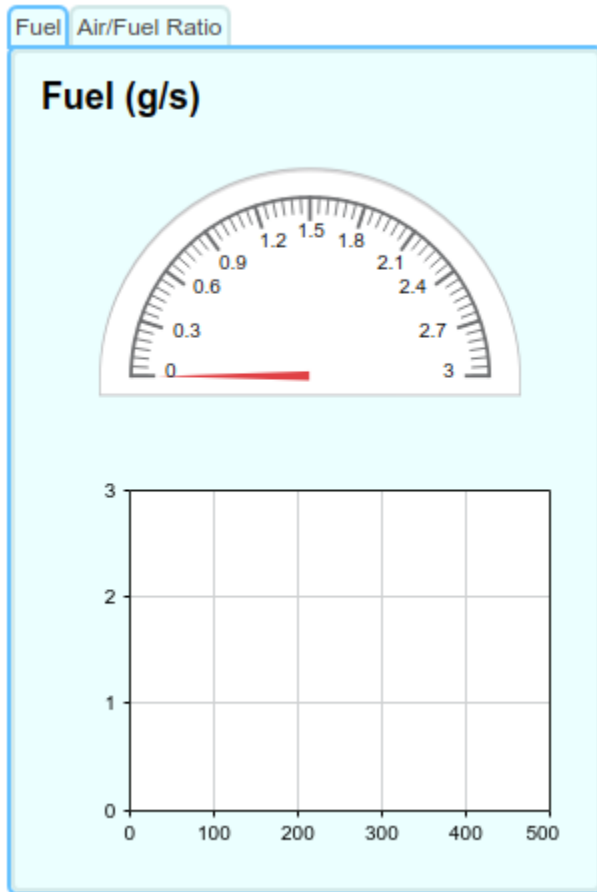

To add a tab to the **Fuel** panel, select the panel and pause on the ellipsis that appears above it. Then, select **Add Tab**.

To add blocks to the new tab, enter edit mode by selecting the panel, pausing on the ellipsis above it, and selecting **Edit Panel**. Drag the contents of the **Air/Fuel Ratio** panel into the new tab you added to the **Fuel** panel. Panels do not support selecting more than one element, so you must move the blocks and labels one by one.

You can name the tabs of the panels using the Property Inspector. To show the Property Inspector, in the **Modeling** tab, under **Design**, select **Property Inspector**. Select the panel and type the name in the Property Inspector. The name applies to the active tab. To name the other tab, select the tab and type the name in the Property Inspector.

You can separate panels by dragging a tab away and combine panels by dragging tabs together.

- "Simulation Pacing" on page 2-17

Design Custom Gauges

You can design custom gauges that look like displays in a real system or animate a signal using the Circular Gauge, Horizontal Gauge, and Vertical Gauge blocks. This example gives step-by-step guidance to design a thermometer using the Vertical Gauge block and an ammeter using the Circular Gauge block.

The model for this example includes several customized gauges connected to the output of a Sine Wave block. The example gives step-by-step instructions to design the gauge blocks in the canvas of the model. The model includes a panel that contains additional customized gauges you can explore on your own. The example directory includes a folder with all the SVG images used to create the gauges.

Design a Thermometer Using the Vertical Gauge Block

The thermometer designed using the Vertical Gauge block uses a background image to define the shape of the thermometer and the value bar of the Vertical Gauge block to indicate the value of the connected signal during simulation. The Battery Level block in the panel uses a similar design strategy.

To design a thermometer, add a Vertical Gauge to the model and use the **Design** tab in the Property Inspector. To display the Property Inspector, on the **Modeling** tab, under **Design**, select **Property Inspector**. Select the Vertical Gauge block. Then, in the Property Inspector, select the **Design** tab and click **Edit Design**. In design mode, the Design tab of the Property Inspector is active, and a toolbar appears above the Vertical Gauge block.

Add the thermometer background image.

- 1 Select the **Background Image** component in the **Design** tab.
- 2 In the **Select Image** section, click the plus button.
- 3 Navigate inside the CustomGaugeImages folder and select the Thermometer .svg file.

The thermometer design uses the value bar, not the needle, to indicate the value of the connected signal. To remove the needle image, in the **Design** tab, select the **Needle** component. Then, in the **Select Image** section, click the X button.

Next, adjust the scale range, color, position, and size.

- 1 In the **Design** tab, select the **Scale** component.
- 2 In the **Range** section, change the **Maximum** to 50.
- 3 In the **Ticks** section and the **Labels** section, change **Color** to black so the tick marks are more visible on the white background.
- 4 Resize the scale so it fits inside the white column of the thermometer background image. You can adjust the width and height of the scale interactively on the block or by using the **Design** tab. To use the **Design** tab, in the **Size and Position** section, adjust the **Width** and **Height**.
- 5 Align the zero point on the scale with the top of the red area of the background image.

Finally, change the value bar width and color.

- 1 In the **Design** tab, select the **Value Bar** component.

- 2 In the **Value Preview** section, adjust the slider to preview what the value bar shows when the input value is greater than the minimum scale value.
- 3 In the **Value Bar** section, change **Color** to red.
- 4 Widen the value bar so it fills the majority of the thermometer. You can use interactive controls on the block or use the **Design** tab. In the **Design** tab, under **Value Bar**, adjust **Size**.
- 5 Decrease the value bar opacity so the labels are easier to read.

When you finish adjusting the design for the thermometer, exit design mode. On the **Design** tab, click **Edit Design**. Before you simulate the model, connect the Vertical Gauge block to the Sine Wave with Offset signal.

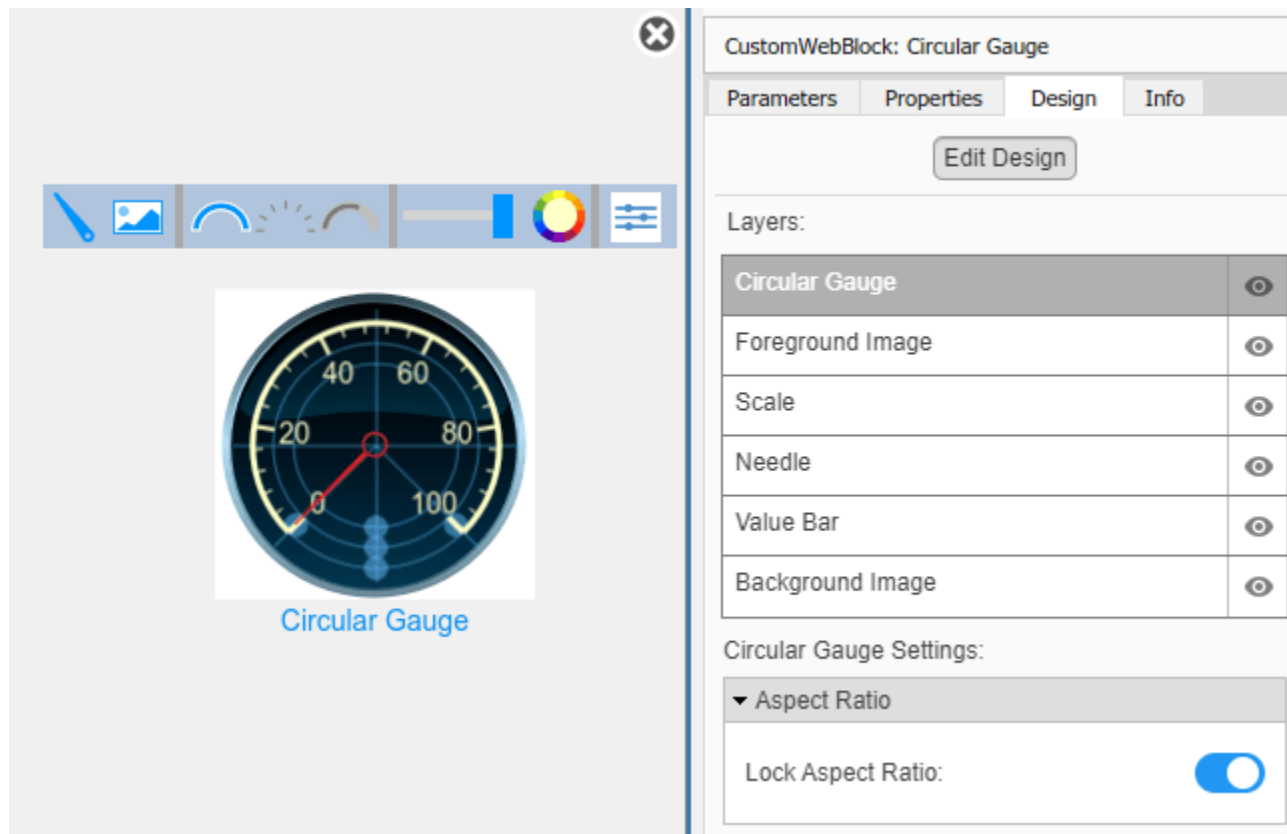

- 1 Select the Vertical Gauge block.
- 2 Click the **Connect** button that appears above the block.
- 3 Select the Sine Wave with Offset signal.
- 4 Select the Sine Wave with Offset option in the table that appears below the selected signal.
- 5 Click the X in the upper-right of the canvas.

To see the thermometer in action, simulate the model.

Design an Ammeter Using the Circular Gauge Block

The ammeter designed using the Circular Gauge block uses a background image to define the appearance of the ammeter and a needle image to indicate the value of the connected signal during simulation. The Pressure Gauge block in the panel uses a similar design strategy.

To design an ammeter, add a Circular Gauge block to the model and use the **Design** tab in the Property Inspector. Select the Circular Gauge block. Then, in the Property Inspector, select the **Design** tab and click **Edit Design**. In design mode, the **Design** tab of the Property Inspector is active, and a toolbar appears above the Circular Gauge block.

First, add the ammeter background image.

- 1 Select the **Background Image** component in the **Design** tab.
- 2 In the **Select Image** section, click the plus button.
- 3 Select the Ammeter .svg file.

Change the scale limits and color, and hide the value bar.

- 1 In the **Design** tab, select the **Scale** component.
- 2 In the **Range** section, change the **Minimum** to -50 and the **Maximum** to 50.
- 3 In the **Ticks** section and the **Labels** section, change the **Color** to black so the tick marks are more visible on the white background.
- 4 Select the **Value Bar** component.
- 5 In the **Value Bar** section, change the **Opacity** to 0.

Adjust the arc of the scale so the scale starts and ends on the horizontal crosshairs. The scale **Start Angle** specifies the position for the scale minimum, and the scale **Arc** specifies the extent of the scale arc, both in degrees. In the **Design** tab, under **Range**, change the **Start Angle** and the **Arc** to 180.

Adjust the scale position so the entire scale fits within the display area of the ammeter background image, with the center of the needle positioned approximately at the center of the semicircle.

Replace the needle image.

- 1 In the **Design** tab, select the Needle component.
- 2 In the **Select Image** section, click the plus button.
- 3 Select the Needle.svg file.

The needle image is a straight black line. The saved image is too large for the size of the block and oriented so that the needle does not point to the zero point on the scale. To rotate the needle image, click the needle rotation button in the block. Then, use the needle grab handles in the block to resize and reposition the needle so it starts at the center of the semicircle in the background image and ends before the label for the scale minimum.

When you finish adjusting the design for the ammeter, exit design mode. On the **Design** tab, click **Edit Design**. Before you simulate the model, connect the Circular Gauge block to the output signal from the Sine Wave block.

- 1 Select the Circular Gauge block.
- 2 Click the **Connect** button that appears above the block.
- 3 Select the Sine Wave block output signal.
- 4 Select the Sine Wave option in the table that appears below the selected signal.
- 5 Click the X in the upper-right of the canvas.

To see the ammeter in action, simulate the model.

Explore More Customized Gauges

The panel in the model contains more examples of customized gauges built using the Circular Gauge, Horizontal Gauge, and Vertical Gauge blocks. To view the panel, double-click the panel icon in the model. You can drag the panel into the canvas or resize the window to view the panel. To see how the gauges respond to changing input values, simulate the model. The `CustomGaugeImages` folder includes the SVG images used to create each gauge so you can try replicating the designs on your own.

Decide How to Visualize Simulation Data

Visualizing simulation data throughout the modeling process helps you understand and tune model behavior. Simulink offers several complementary visualization tools you can use throughout the modeling process. Some visualization tools also offer the ability to save simulation data. Learn about each technique so you can choose the right tools to visualize your model data.

- Simulation Data Inspector — View, analyze, and compare logged data throughout the modeling process.
- Scope block, Floating Scope block, and Scope Viewer — Debug and analyze data using an environment and capabilities similar to a bench-top oscilloscope.
- Dashboard blocks — Build an interactive interface to tune and monitor a model.
- Port value displays — View instantaneous signal values while debugging.
- Custom MATLAB visualization — Write MATLAB code to visualize data.

Simulation Data Inspector

You can use the **Simulation Data Inspector** for most visualization tasks. The Simulation Data Inspector integrates with data logging in your model and works well for visualizing many signals throughout a model. Use comparisons in the Simulation Data Inspector to prototype, debug, tune, calibrate, and test your models. The Simulation Data Inspector supports:

- Viewing signals during simulation
- Logging, importing, and exporting data
- Configurable subplot layouts and visualization settings
- Viewing data using multiple visualization options, including maps and XY plots
- Post-processing and data analysis using comparisons with tolerance values
- Saving plots and data to share or archive results

To visualize simulation data using the Simulation Data Inspector, log data in the model. When you log signals and outputs, the logged data is automatically available in the Simulation Data Inspector during and after simulation. In the model Configuration Parameters, select **Data Import/Export > Record logged workspace data in Simulation Data Inspector** to make logged states and Simscape data available in the Simulation Data Inspector after simulation. When you want to view signals without logging the data, consider using a Scope block, the Floating Scope block, or a Scope Viewer.

Open the Simulation Data Inspector from **Simulation > Data Inspector** or by clicking a signal logging badge. When you open the Simulation Data Inspector by clicking the logging badge on a signal, the signal is automatically plotted.

For more information, see **Simulation Data Inspector**.

Scope Blocks and the Scope Viewer

Scope blocks, Floating Scope blocks, and the Scope Viewer visualize connected signals in a similar way as a bench-top oscilloscope. The scope blocks and Scope Viewer use the same interface to visualize and analyze connected signals. The interface is similar to other domain-specific tools, such as the Spectrum Analyzer and Array Plot blocks. Scope blocks are easy to add and connect in your model, and you do not need to log data in order to view signal data.

Scope blocks, Floating Scope blocks, and the Scope Viewer support:

- Viewing signals during simulation, including rapid accelerator simulations.
- Simple connection and accessibility for lightweight debugging.
- Signal visualization without logging.
- Optional signal logging.
- Starting simulations from the visualization interface using playback controls.
- Oscilloscope measurements, including cursors and triggers. Additional measurements are available when you have a Simscape or DSP System Toolbox license.
- Configurable plots and display.
- Configurable triggers to capture events.

Use the Scope block, the Floating Scope block, and the Scope Viewer for prototyping and lightweight debugging. For example, in the early stages of model development, you can connect a Scope block to a signal to quickly verify component behavior. By adding triggers, you can tune a specific peak or other artifact in a signal. A Scope block may or may not be permanent in your model.

When you need to view data for signals throughout a model hierarchy, consider using the Simulation Data Inspector, especially if you already log the signals you want to view.

For more information, see “Scope Blocks and Scope Viewer Overview” on page 28-6.

Dashboard Blocks

The Dashboard library includes control blocks you can use to tune variables and parameters in your model and visualization blocks you can use to view signal data. Use Dashboard blocks to view instantaneous signal data and build an interactive interface for your model.

You can use Dashboard block controls to modify the values of variables and tunable parameters in your model during simulation. Visualization Dashboard blocks are updated continuously throughout simulation. When you need to debug a model that uses Dashboard blocks, consider using simulation pacing or simulation stepping to slow the simulation so you can view the instantaneous signal values. You can also promote Dashboard blocks to one or more panels so the interactive dashboard can follow you throughout a model hierarchy as you design and debug your model. For more information, see:

- “Simulation Pacing” on page 2-17
- “Step Through a Simulation” on page 2-12
- “Interactively Design and Debug Models Using Panels” on page 29-199

Fault-Tolerant Fuel Control System Dashboard

The Dashboard Scope block provides a simple view of a signal over time. You can zoom, pan, and add cursors to a Dashboard Scope block through the context menu. For more debugging and analysis capabilities, use a Scope block or log data to the Simulation Data Inspector.

For more information about using Dashboard blocks, see “Tune and Visualize Your Model with Dashboard Blocks” on page 29-194.

Port Value Displays

You can enable port value displays to view a signal value at a given time point. Port value displays can supplement existing visualizations while prototyping and debugging models. For example, you can view signal values on port value displays as you step through a simulation while visualizing the temporal behavior using a Scope block. You can also use port value displays on their own to support debugging without adding any blocks to your model or logging data.

To display a signal value, right-click the signal and select **Show Value Label of Selected Port**.

When inspecting signal data by displaying the value on the port, consider using simulation pacing or stepping through the simulation. For more information, see “Simulation Pacing” on page 2-17 and “Step Through a Simulation” on page 2-12.

For more information, see “Display Port Values for Debugging” on page 36-18.

Custom MATLAB Visualizations

When you log simulation data to the workspace or a file, you can write MATLAB code and scripts to create custom visualizations. You can log signals, outputs, and states in a model, and you can also enable data logging for signals connected to Scope Viewers, Floating Scope blocks and Scope blocks. For more information about logging data in your model, see “Export Simulation Data” on page 73-2.

Note When you post-process data using MATLAB code and scripts, you do not need to write custom MATLAB code to visualize the data. You can import the processed data into the Simulation Data Inspector for visualization alongside the logged data.

The visualization code you write can depend on the format of the logged data. By default, logging uses the `Dataset` format and produces a single simulation output. Logged data is returned to the workspace as a `Simulink.SimulationOutput` object that contains a `Simulink.SimulationData.Dataset` object for each type of logging used in the simulation. Each `Dataset` object contains `Simulink.SimulationData.Signal` objects that store the data for an individual signal as a `timeseries` object. For more information, see “Data Format for Logged Simulation Data” on page 73-7.

When you log a signal, you can visualize the signal during simulation using custom MATLAB code. For more information, see “Access Data in a MATLAB Function During Simulation” on page 29-103.

Linearizing Models

In this section...

“About Linearizing Models” on page 30-8

“Linearization with Referenced Models” on page 30-9

“Linearization Using the 'v5' Algorithm” on page 30-11

About Linearizing Models

The Simulink product provides the `linmod`, `linmod2`, and `dlinmod` functions to extract linear models in the form of the state-space matrices A , B , C , and D . State-space matrices describe the linear input-output relationship as

$$\dot{x} = Ax + Bu$$

$$y = Cx + Du,$$

where x , u , and y are state, input, and output vectors, respectively. For example, the following model is called `lmod`.

To extract the linear model of this system, enter this command.

```
[A,B,C,D] = linmod('lmod')
```

A =

```
-2   -1   -1
 1     0     0
 0     1   -1
```

B =

```
1
0
0
```

C =

```
0     1     0
0     0   -1
```

D =

```
0
1
```

Inputs and outputs must be defined using Inport and Outport blocks from the Ports & Subsystems library. Source and sink blocks do not act as inputs and outputs. Inport blocks can be used in conjunction with source blocks, using a Sum block. Once the data is in the state-space form or

converted to an LTI object, you can apply functions in the Control System Toolbox product for further analysis:

- Conversion to an LTI object
`sys = ss(A,B,C,D);`
- Bode phase and magnitude frequency plot
`bode(A,B,C,D)` or `bode(sys)`
- Linearized time response
`step(A,B,C,D)` or `step(sys)`
`impulse(A,B,C,D)` or `impulse(sys)`
`lsim(A,B,C,D,u,t)` or `lsim(sys,u,t)`

You can use other functions in the Control System Toolbox and the Robust Control Toolbox™ products for linear control system design.

When the model is nonlinear, an operating point can be chosen at which to extract the linearized model. Extra arguments to `linmod` specify the operating point.

```
[A,B,C,D] = linmod('sys', x, u)
```

For discrete systems or mixed continuous and discrete systems, use the function `dlinmod` for linearization. This function has the same calling syntax as `linmod` except that the second right-hand argument must contain a sample time at which to perform the linearization.

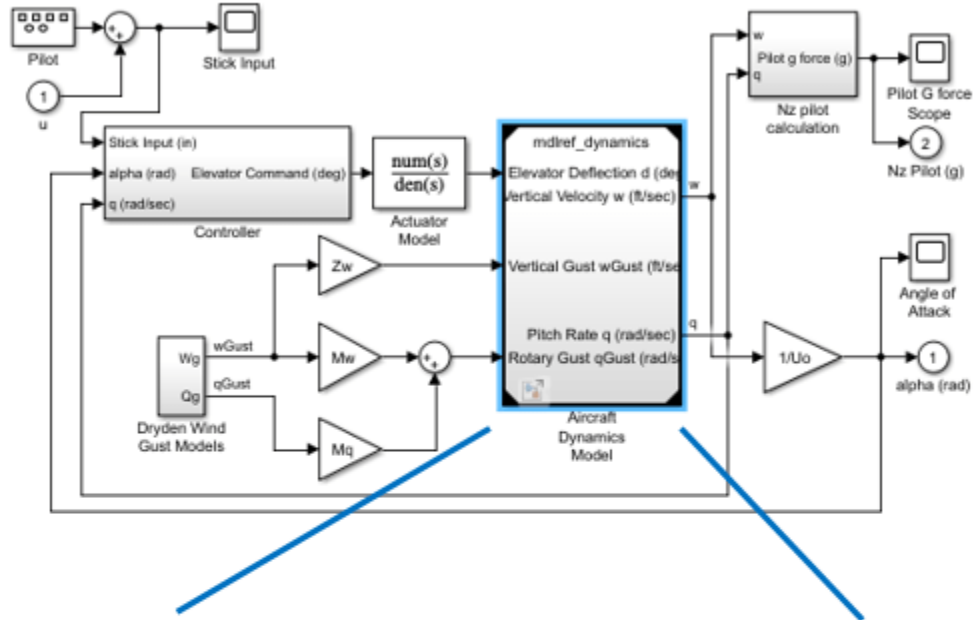

Linearization with Referenced Models

You can use `linmod` to extract a linear model from a Simulink® environment that contains Model blocks. For example, open the referenced model `mdlref_dynamics` and the top model `mdlref_f14`.

```
open_system('mdlref_dynamics');  
open_system('mdlref_f14');
```

In the `mdlref_f14` model, the Aircraft Dynamics Model block references the `mdlref_dynamics` model.

mdlref_f14 ▶

mdlref_dynamics

To linearize the mdlref_f14 model, use the linmod command.

```
[A,B,C,D] = linmod('mdlref_f14');
```

```
### Starting serial model reference simulation build
### Successfully updated the model reference simulation target for: mdlref_dynamics
```

Build Summary

Simulation targets built:

Model	Action	Rebuild Reason
mdlref_dynamics	Code generated and compiled	mdlref_dynamics_msf.mexw64 does not exist.

1 of 1 models built (0 models already up to date)
Build duration: 0h 0m 40.232s

The resulting state-space model corresponds to the complete `mdlref_f14` model, including the referenced model.

You can call `linmod` with a state and input operating point for models that contain Model blocks. When using operating points, the state vector x refers to the total state vector for the top model and any referenced models. You must enter the state vector using the structure format. To get the complete state vector, use `getInitialState`.

```
x = Simulink.BlockDiagram.getInitialState(topmodelName)
```

Tip

In Normal mode, the `linmod` command applies the block-by-block linearization algorithm on blocks inside the referenced model. If the Model block is in Accelerator mode, the `linmod` command uses numerical perturbation to linearize the referenced model. Due to limitations on linearizing multirate Model blocks in Accelerator mode, you should use Normal mode simulation for all models referenced by Model blocks when linearizing with referenced models.

Linearization Using the 'v5' Algorithm

Calling the `linmod` command with the 'v5' argument invokes the perturbation algorithm created prior to MATLAB software version 5.3. This algorithm also allows you to specify the perturbation values used to perform the perturbation of all the states and inputs of the model.

```
[A,B,C,D]=linmod('sys',x,u,para,xpert,upert,'v5')
```

Using `linmod` with the 'v5' option to linearize a model that contains Derivative or Transport Delay blocks can be troublesome. Before linearizing, replace these blocks with specially designed blocks that avoid the problems. These blocks are in the Simulink Extras library in the Linearization sublibrary.

You access the Extras library by opening the Blocksets & Toolboxes icon:

- For the Derivative block, use the Switched derivative for linearization.

When using a Derivative block, you can also try to incorporate the derivative term in other blocks. For example, if you have a Derivative block in series with a Transfer Fcn block, it is better implemented (although this is not always possible) with a single Transfer Fcn block of the form

$$\frac{s}{s+a}$$

In this example, the blocks on the left of this figure can be replaced by the block on the right.

Finding Steady-State Points

The Simulink `trim` function uses a model to determine steady-state points of a dynamic system that satisfy input, output, and state conditions that you specify. Consider, for example, this model, called `ex_lmod`.

You can use the `trim` function to find the values of the input and the states that set both outputs to 1. First, make initial guesses for the state variables (`x`) and input values (`u`), then set the desired value for the output (`y`).

```
x = [0; 0; 0];
u = 0;
y = [1; 1];
```

Use index variables to indicate which variables are fixed and which can vary.

```
ix = [];      % Don't fix any of the states
iu = [];      % Don't fix the input
iy = [1;2];   % Fix both output 1 and output 2
```

Invoking `trim` returns the solution. Your results might differ because of roundoff error.

```
[x,u,y,dx] = trim('lmod',x,u,y,ix,iu,iy)

x =
    0.0000
    1.0000
    1.0000
u =
     2
y =
    1.0000
    1.0000
dx =
    1.0e-015 *
    -0.2220
    -0.0227
    0.3331
```

Note that there might be no solution to equilibrium point problems. If that is the case, `trim` returns a solution that minimizes the maximum deviation from the desired result after first trying to set the derivatives to zero. For a description of the `trim` syntax, see `trim`.

How Optimization Techniques Improve Performance and Accuracy

The design of a model and choice of configuration parameters can affect simulation performance and accuracy. Solvers handle most model simulations accurately and efficiently with default parameter values. However, some models yield better results when you adjust solver parameters. Information about the behavior of a model can help you improve simulation performance, particularly when you provide this information to the solver. Use optimization techniques to better understand the behavior of your model and modify the model settings to improve performance and accuracy.

To optimize your model and achieve faster simulation automatically using Performance Advisor, see “Automated Performance Optimization”.

To learn more about accelerator modes for faster simulation, see “Acceleration”.

More About

- “Modeling Techniques That Improve Performance” on page 31-13

Speed Up Simulation

Several factors can slow simulation. Check your model for some of these conditions.

- The model includes an Interpreted MATLAB Function block. When a model includes an Interpreted MATLAB Function block, the MATLAB execution engine is called at each time step, drastically slowing down the simulation. Use the Math Function block whenever possible.
- Your model includes a MATLAB file S-function. MATLAB file S-functions also call the MATLAB execution engine at each time step. Consider converting the S-function either to a subsystem or to a C-MEX file S-function.
- Your model includes a Memory block. Using a Memory block causes the variable-order solvers (ode15s and ode113) to reset back to order 1 at each time step.
- The maximum step size is too small. If you changed the maximum step size, try running the simulation again with the default value (`auto`).
- Your accuracy requirements are too high. The default relative tolerance (0.1% accuracy) is usually sufficient. For models with states that go to zero, if the absolute tolerance parameter is too small, the simulation can take too many steps around the near-zero state values. See the discussion of this error in “Maximum order” in the online documentation.
- The time scale is too long. Reduce the time interval.
- Your model represents a stiff system, but you are using a nonstiff solver. Try using `ode15s`. For more information, see “Stiffness of System” on page 31-15.
- Your model uses sample times that are not multiples of each other. Mixing sample times that are not multiples of each other causes the solver to take small enough steps to ensure sample time hits for all sample times.
- The model contains an algebraic loop. The solutions to algebraic loops are iteratively computed at every time step. Therefore, they severely degrade performance. For more information, see “Algebraic Loop Concepts” on page 3-27.

You can check the model blocks for the following conditions:

- Your model feeds a Random Number block into an Integrator block. For continuous systems, use the Band-Limited White Noise block in the Sources library.
- Your model contains a scope viewer that displays too many data points. Try adjusting the viewer property settings that can affect performance. For more information, see Scope Viewer.
- You need to simulate your model iteratively. You change tunable parameters between iterations but do not make structural changes to the model. Every iteration requires the model to compile again, thus increasing overall simulation time. Use fast restart to perform iterative simulations. In this workflow, the model compiles only once and iterative simulations are tied to a single compile phase. See “How Fast Restart Improves Iterative Simulations” on page 82-2 for more information.

How Profiler Captures Performance Data

In this section...

“How Profiler Works” on page 31-5

“Start Profiler” on page 31-6

“Save Profiler Results” on page 31-9

How Profiler Works

Profiler captures performance data while your model simulates. It identifies the parts of your model that require the most time to simulate. Use the profiling information to decide where to focus your model optimization efforts.

Note You cannot use Profiler in Rapid Accelerator mode.

Simulink stores performance data in the *simulation profile report*. The data shows the time spent executing each function in your model.

The basis for Profiler is an execution model that this pseudocode summarizes.

```

Sim()
  ModelInitialize().
  ModelExecute()
    for t = tStart to tEnd
      Output()
      Update()
      Integrate()
        Compute states from derivs by repeatedly calling:
          MinorOutput()
          MinorDeriv()
        Locate any zero crossings by repeatedly calling:
          MinorOutput()
          MinorZeroCrossings()
      EndIntegrate
      Set time t = tNew.
    EndModelExecute
  ModelTerminate
EndSim

```

According to this conceptual model, Simulink runs a model by invoking the following functions zero, one, or many times, depending on the function and the model.

Function	Purpose	Level
sim	Simulate the model. This top-level function invokes the other functions required to simulate the model. The time spent in this function is the total time required to simulate the model.	System
ModelInitialize	Set up the model for simulation.	System

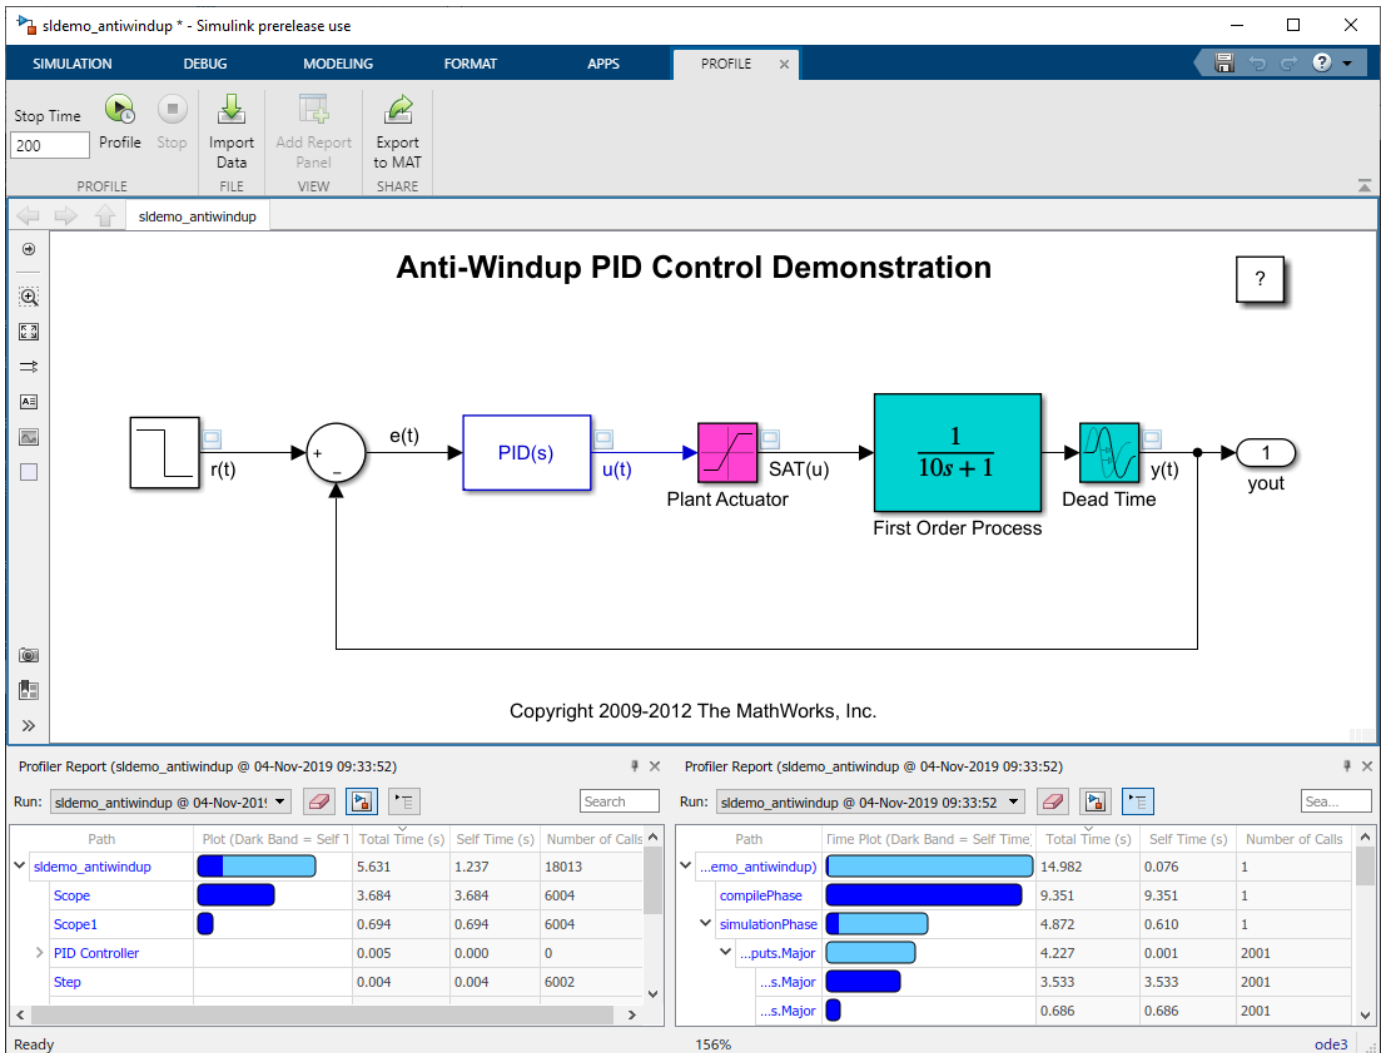

Function	Purpose	Level
ModelExecute	Execute the model by invoking the output, update, integrate, etc., functions for each block at each time step from the start to the end of simulation.	System
Output	Compute the outputs of a block at the current time step.	Block
Update	Update the state of a block at the current time step.	Block
Integrate	Compute the continuous states of a block by integrating the state derivatives at the current time step.	Block
MinorOutput	Compute block output at a minor time step.	Block
MinorDeriv	Compute the state derivatives of a block at a minor time step.	Block
MinorZeroCrossings	Compute zero-crossing values of a block at a minor time step.	Block
ModelTerminate	Free memory and perform any other end-of-simulation cleanup.	System
Nonvirtual Subsystem	Compute the output of a nonvirtual subsystem at the current time step by invoking the output, update, integrate, etc., functions for each block that it contains. The time spent in this function is the time required to execute the nonvirtual subsystem.	Block

Profiler measures the time required to execute each invocation of these functions. After the model simulates, Profiler generates a report that describes the amount of simulation time spent on each function.

Start Profiler

- 1 Open the model.
- 2 On the **Debug** tab, select **Performance Advisor > Simulink Profiler**.
- 3 Simulate the model.

When simulation is complete, Simulink generates and displays the simulation profile for the model in a panel in the Simulink editor.

Block Hierarchy View

The block hierarchy view of the report presents the profiling information of the model in a nested tree form. The first row of the table—which is the top of the tree—corresponds to the entire model. Subsequent rows at the first level of nesting correspond to blocks at the root level of the model.

Save Profiler Results

You can save the Profiler report to a mat file. At a later time, you can import and review the report by either loading the saved mat file to the current workspace or import it into an existing profiler session.

To save a profiling report, select **Export to MAT** in the **Share** section of the **Profile** tab and optionally specify a name for the mat file.

To view a saved report in an open profiling session in the Simulink editor, select **Import from File** in the **Profile** tab.

To view a saved report in the command line, load the mat file containing the report. The profiling information is loaded into the current workspace as a `Simulink.profiler.Data` object. For more information, see `Simulink.profiler.Data`.

Check and Improve Simulation Accuracy

Check Simulation Accuracy

- 1 Simulate the model over a reasonable time span.
- 2 Reduce either the relative tolerance to 1e-4 (the default is 1e-3) or the absolute tolerance.
- 3 Simulate the model again.
- 4 Compare the results from both simulations.

If the results are not significantly different, the solution has converged.

If the simulation misses significant behavior at the start, reduce the initial step size to ensure that the simulation does not step over that behavior.

Unstable Simulation Results

When simulation results become unstable over time,

- The system can be unstable.
- If you are using the ode15s solver, try restricting the maximum order to 2 (the maximum order for which the solver is A-stable). You can also try using the ode23s solver.

Inaccurate Simulation Results

If simulation results are not accurate:

- For a model that has states whose values approach zero, if the absolute tolerance parameter is too large, the simulation takes too few steps around areas of near-zero state values. Reduce this parameter value in the **Solver pane** of model configuration parameters or adjust it for individual states in the function block parameters of the Integrator block.
- If reducing the absolute tolerances does not improve simulation accuracy enough, reduce the size of the relative tolerance parameter. This change reduces the acceptable error and forces smaller step sizes and more steps.

Certain modeling constructs can also produce unexpected or inaccurate simulation results.

- A Source block that inherits sample time can produce different simulation results if, for example, the sample times of the downstream blocks are modified (see “How Propagation Affects Inherited Sample Times” on page 7-30).
- A Derivative block found in an algebraic loop can result in a loss in solver accuracy.

Modeling Techniques That Improve Performance

In this section...

“Accelerate the Initialization Phase” on page 31-13

“Reduce Model Interactivity” on page 31-13

“Reduce Model Complexity” on page 31-14

“Choose and Configure a Solver” on page 31-15

“Save the Simulation State” on page 31-17

Accelerate the Initialization Phase

Speed up a simulation by accelerating the initialization phase, using these techniques.

Simplify Graphics Using Mask Editor

Complex graphics and large images take a long time to load and render. Masked blocks that contain such images can make your model less responsive. Where possible, remove complex drawings and images from masked blocks.

If you want to keep the image, replace it with a smaller, low-resolution version. Use mask editor and edit the icon drawing commands to keep the image that is loaded by the call to `image()`.

For more information on mask editor, see “Mask Editor Overview”.

Consolidate Function Calls

When you open or update a model, Simulink runs the mask initialization code. If your model contains complicated mask initialization commands that contain many calls to `set_param`, consolidate consecutive calls into a single call with multiple argument pairs. Consolidating the calls can reduce the overhead associated with these function calls.

To learn more, see “Mask Callback Code” on page 39-14.

Load Data Using MAT-file

If you use MATLAB scripts to load and initialize data, you can improve performance by loading MAT-files instead. The data in a MAT-file is in binary and can be more difficult to work with than a script. However, the load operation typically initializes data more quickly than the equivalent MATLAB script.

For more information, see “MAT-Files for Signal Data” on page 71-4.

Reduce Model Interactivity

In general, the more interactive a model is, the longer it takes to simulate. Use these techniques to reduce the interactivity of your model.

Disable Debugging Diagnostics

Some enabled diagnostic features can slow simulations considerably. Consider disabling them in the model configuration parameters **Diagnostics** pane.

Note Running **Array bounds exceeded** and **Solver data inconsistency** can slow down model runtime performance. For more information, see “Array bounds exceeded” and “Solver data inconsistency”.

Disable MATLAB Debugging

After verifying that your MATLAB code works correctly, disable these checks in the model configuration parameters **Simulation Target** pane.

- **Enable debugging/animation**
- **Detect wrap on overflow (with debugging)**
- **Echo expressions without semicolons**

For more information, see “Model Configuration Parameters: Simulation Target”.

Use BLAS Library Support

If your simulation involves low-level MATLAB matrix operations, use the Basic Linear Algebra Subprograms (BLAS) libraries to make use of highly optimized external linear algebra routines.

Disable Stateflow Animations

By default, Stateflow charts highlight the current active states in a model and animate the state transitions that take place as the model simulates. This feature is useful for debugging, but it slows the simulation.

To accelerate simulations, either close all Stateflow charts or disable the animation. Similarly, consider disabling animation or reducing scene fidelity when you use:

- Simulink 3D Animation
- Simscape Multibody visualization
- FlightGear
- Any other 3D animation package

To learn more, see “Speed Up Simulation” (Stateflow).

Adjust Scope Viewer Properties

If your model contains a scope viewer that displays a high rate of logging and you cannot remove the scope, adjust the viewer properties to trade off fidelity for rendering speed.

However, when you use decimation to reduce the number of plotted data points, you can miss short transients and other phenomena that you can see with more data points. To have more precise control over enabling visualizations, place viewers in enabled subsystems.

For more information, see Scope Viewer.

Reduce Model Complexity

Use these techniques to improve simulation performance by simplifying a model without sacrificing fidelity.

Replace Subsystems with Lower-Fidelity Alternatives

Replace a complex subsystem with one of these alternatives:

- A linear or nonlinear dynamic model that was created from measured input-output data using the System Identification Toolbox™.
- A high-fidelity, nonlinear statistical model that was created using the Model-Based Calibration Toolbox™.
- A linear model that was created using Simulink Control Design.
- A lookup table. For more information, see A lookup table.

You can maintain both representations of the subsystem in a library and use variant subsystems to manage them. Depending on the model, you can make this replacement without affecting the overall result. For more information, see “Optimize Generated Code for Lookup Table Blocks” on page 38-34.

Reduce Number of Blocks

When you reduce the number of blocks in your model, fewer blocks require updates during simulations and simulation is faster.

- Vectorization is one way to reduce your block count. For example, if you have several parallel signals that undergo a similar set of computations, try to combine them into a vector using a Mux block and perform a single computation.
- You can also enable the **Block Reduction** parameter in the **Configuration Parameters** dialog.

Use Frame-Based Processing

In frame-based processing, Simulink processes samples in batches instead of one at a time. If a model includes an analog-to-digital converter, for example, you can collect output samples in a buffer. Process the buffer in a single operation, such as a fast Fourier transform. Processing data in chunks this way reduces the number of times that the simulation needs to invoke blocks in your model.

In general, the scheduling overhead decreases as frame size increases. However, larger frames consume more memory, and memory limitations can adversely affect the performance of complex models. Experiment with different frame sizes to find one that maximizes the performance benefit of frame-based processing without causing memory issues.

Choose and Configure a Solver

Simulink provides a comprehensive library of solvers, including fixed-step and variable-step solvers, to handle stiff and nonstiff systems. Each solver determines the time of the next simulation step. A solver applies a numerical method to solve ordinary differential equations that represent the model.

The solver you choose and the solver options you select can affect simulation speed. Select and configure a solver that helps boost the performance of your model using these criteria. For more information, see “Choose a Solver” on page 25-5.

Stiffness of System

A stiff system has continuous dynamics that vary slowly and quickly. Implicit solvers are particularly useful for stiff problems. Explicit solvers are better suited for nonstiff systems. Using an explicit

solver to solve a stiff system can lead to incorrect results. If a nonstiff solver uses a very small step size to solve a model, this is a sign that your system is stiff.

Model Step Size and Dynamics

When you are deciding between using a variable-step or fixed-step solver, keep in mind the step size and dynamics of your model. Select a solver that uses time steps to capture only the dynamics that are important to you. Choose a solver that performs only the calculations needed to work out the next time step.

You use fixed-step solvers when the step size is less than or equal to the fundamental sample time of the model. With a variable-step solver, the step size can vary because variable-step solvers dynamically adjust the step size. As a result, the step size for some time steps is larger than the fundamental sample time, reducing the number of steps required to complete the simulation. In general, simulations with variable-step solvers run faster than those that run with fixed-step solvers.

Choose a fixed-step solver when the fundamental sample time of your model is equal to one of the sample rates. Choose a variable-step solver when the fundamental sample time of your model is less than the fastest sample rate. You can also use variable-step solvers to capture continuous dynamics.

Decrease Solver Order

When you decrease the solver order, you reduce the number of calculations that Simulink performs to determine state outputs, which improves simulation speed. However, the results become less accurate as the solver order decreases. Choose the lowest solver order that produces results with acceptable accuracy.

Increase Solver Step Size or Error Tolerance

Increasing the solver step size or error tolerance usually increases simulation speed at the expense of accuracy. Make these changes with care because they can cause Simulink to miss potentially important dynamics during simulations.

Disable Zero-Crossing Detection

Variable-step solvers dynamically adjust the step size, increasing it when a variable changes slowly and decreasing it when a variable changes rapidly. This behavior causes the solver to take many small steps near a discontinuity because this is when a variable changes rapidly. Accuracy improves, but often at the expense of long simulation times.

To avoid the small time steps and long simulations associated with these situations, Simulink uses zero-crossing detection to locate such discontinuities accurately. For systems that exhibit frequent fluctuations between modes of operation—a phenomenon known as chattering—this zero-crossing detection can have the opposite effect and thus slow down simulations. In these situations, you can disable zero-crossing detection to improve performance.

You can enable or disable zero-crossing detection for specific blocks in a model. To improve performance, consider disabling zero-crossing detection for blocks that do not affect the accuracy of the simulation.

For more information, see “Zero-Crossing Detection” on page 3-10.

Save the Simulation State

In the classic workflow, a Simulink model simulates repeatedly for different inputs, boundary conditions, and operating conditions. In many situations, these simulations share a common startup phase in which the model transitions from the initial state to another state. For example, you can bring an electric motor up to speed before you test various control sequences.

Using `SimState`, you can save the simulation state at the end of the startup phase and then restore it for use as the initial state for future simulations. This technique does not improve simulation speed, but it can reduce total simulation time for consecutive runs because the startup phase needs to be simulated only once.

See “Save and Restore Simulation Operating Point” on page 25-41 for more information.

Use Performance Advisor to Improve Simulation Efficiency

Use Performance Advisor to check for conditions and configuration settings that can cause inefficient simulation performance. Performance Advisor analyzes a model and produces a report with suboptimal conditions or settings that it finds. It suggests better model configuration settings where appropriate, and provides mechanisms for fixing issues automatically or manually.

Understanding Total Time and Self Time in Profiler Reports

The Simulink Profiler displays the performance of the components of your model and their simulation phases. Each row of the Profiler Report pane presents the following information:

- **Path**
- **Time Plot (Dark Band = Self Time)**
- **Total Time (s)**
- **Self Time (s)**
- **Number of Calls**

An indicator of the model's performance is the number of times a block is called in conjunction with the time taken by each call. For a model component with any level of hierarchy, it is useful to know how much of its total execution time is taken up by its constituent blocks vis-a-vis the time taken by its own execution, or self-time.

Use the **Total Time(s)** information to identify subsystems or referenced models that are expensive to run within the current model. As subsystems and model references typically correspond to high-level

conceptual entities such as physical models and algorithms, you can identify which component of your model is slowing down overall performance.

The graphic below shows part of the Profiler Report pane for the `sldemo_fuelsys_dd` model.

- 1 To begin, recursively expand the hierarchy of the Engine Gas Dynamics subsystem. For the Throttle subsystem, tally the total time of its constituents (from threshold=0.5 to Sonic Flow), highlighted in red. Observe that the sum of their execution times, along with the self time for Throttle block, is the total time of the Throttle block, shown in yellow.
- 2 Collapse the Throttle row of the hierarchy. Repeat the previous step for the contents of the Throttle & Manifold subsystem—which is highlighted in yellow—and then the Engine Gas Dynamics subsystem.

Component	Self Time	Total Time
sldemo_fuelsys_dd	47.126	13.354
Engine Gas Dynamics	18.284	2.911
Throttle & Manifold	8.025	0.000
Throttle	5.652	0.000
threshold = 0.5	1.382	1.382
f(theta)	1.257	1.257
MinMax	1.128	1.128
g(pratio)	1.039	1.039
Product	0.211	0.211
Sum	0.202	0.202
Product1	0.178	0.178
Product2	0.142	0.142
direction	0.115	0.115
Sonic Flow	0.000	0.000
Intake Manifold	1.870	0.000
Limit to Positive	0.502	0.502
Atmospheric Pressure, Pa (bar)	0.000	0.000
Mixing & Combustion	3.738	0.000
sldemo_fuelsys_dd_plant	3.610	3.610

Improve Simulation Performance Using Performance Advisor

In this section...

- “Performance Advisor Workflow” on page 32-2
- “Prepare Your Model” on page 32-3
- “Create a Performance Advisor Baseline Measurement” on page 32-4
- “Run Performance Advisor Checks” on page 32-5
- “View and Respond to Results” on page 32-6
- “View and Save Performance Advisor Reports” on page 32-8

Whatever the level of complexity of your model, you can make systematic changes that improve simulation performance. Performance Advisor checks for configuration settings that slow down your model simulations. It produces a report that lists the suboptimal conditions or settings it finds and suggests better configuration settings where appropriate.

You can use the Performance Advisor to fix some of these suboptimal conditions automatically or you can fix them manually.

Note Use Performance Advisor on top models. Performance Advisor does not traverse referenced models or library links.

To learn about faster simulation using acceleration modes, see “Acceleration”.

Performance Advisor Workflow

When the performance of a model is slower than expected, use Performance Advisor to help identify and resolve bottlenecks.

- 1 Prepare your model.
- 2 Create a baseline to compare measurements against.
- 3 Select the checks you want to run.
- 4 Run Performance Advisor with the selected checks and see recommended changes.
- 5 Make changes to the model. You can either:
 - Automatically apply changes.
 - Generate advice, and review and apply changes manually.
- 6 After applying changes, Performance Advisor performs a final validation of the model to see how performance has improved.
 - If the performance improves, the selected checks were successful. The performance check is complete.
 - If the performance is worse than the baseline, Performance Advisor reinstates the previous settings of the model.
- 7 Save your model.

Caution Performance Advisor does not automatically save your model after it makes changes. When you are satisfied with the changes to the model from Performance Advisor, save the model.

Prepare Your Model

Before running checks using Performance Advisor, complete the following steps:

- “Start Performance Advisor” on page 32-3
- “Enable Data Logging for the Model” on page 32-3
- “Select How Performance Advisor Applies Advice” on page 32-3
- “Select Validation Actions for the Advice” on page 32-4
- “Specify Runtime for Performance Advisor” on page 32-4

Start Performance Advisor

To get started with Performance Advisor:

- 1 Make a backup of the model.
- 2 Verify that the model can simulate without error.
- 3 Close all applications, including web browsers. Leave only the MATLAB Command Window, the model you want to analyze, and Performance Advisor running.

Running other applications can hinder the performance of model simulation and the ability of Performance Advisor to measure accurately.

- 4 Open Performance Advisor. In the Simulink Editor, on the **Debug** tab, click **Performance Advisor**.

Enable Data Logging for the Model

Make sure the model configuration parameters are set to enable data logging.

- 1 In the model, on the **Modeling** tab, click **Model Settings**.
- 2 In the Configuration Parameters dialog box, in the left pane, select **Data Import/Export**.
- 3 Set up signal logging. The model must log at least one signal for Performance Advisor to work. For example, select the **States** or **Output** check box.
- 4 Click **Configure Signals to Log** and select the signals to log.

Note Select only the signals you are most interested in. Minimizing the number of signals to log can help performance. Selecting too many signals can cause Performance Advisor to run for a longer time.

- 5 Click **OK** in the Configuration Parameters dialog box.
- 6 Run the model once to make sure that the simulation is successful.

Select How Performance Advisor Applies Advice

Choose from these options to apply advice to the model:

- **Use check parameters.** Select the checks for which you want Performance Advisor to automatically apply advice. You can review the remaining checks and apply advice manually.

- **Automatically for all checks.** Performance Advisor automatically applies advice to all selected checks.
- **Generate advice only.** Review advice for each check and apply changes manually.

Select Validation Actions for the Advice

For the checks you want to run, validate an improvement in simulation time and accuracy by comparing against a baseline measurement. Each validation action requires the model to simulate. Use these validation options as global settings for the checks you select:

- **Use check parameters.** From the checks you want to run, select the ones for which you want to validate an improvement in performance. Specify validation action for fixes using individual settings for these checks.
- **For all checks.** Performance Advisor automatically validates an improvement in performance for the checks you select.
- **Do not validate.** Performance Advisor does not validate an improvement in performance. Instead, you can validate manually. When you select this option and also specify for Performance Advisor to apply advice automatically, a warning appears before Performance Advisor applies changes without validation.

These global settings for validation apply to all checks in the left pane except the Final Validation check. The Final Validation check validates the overall performance improvement in a model after you have applied changes. In case you do not want to validate changes resulting from other check results, you can run the Final Validation check to validate model changes for simulation time and accuracy.

Specify Runtime for Performance Advisor

You can specify a **Time Out** value in minutes if you want to limit the runtime duration of Performance Advisor. Use this option when running Performance Advisor on models with long simulation times.

If Performance Advisor times out before completing the checks you specify, in the left pane you can see the checks that failed.

Create a Performance Advisor Baseline Measurement

A baseline measurement is a set of simulation measurements that Performance Advisor measures check results against.

Note Before creating a baseline measurement, set the model configuration parameters to enable data logging. For more information, see “Enable Data Logging for the Model” on page 32-12.

- 1 In the model, select **Performance Tools > Performance Advisor** to start Performance Advisor.
- 2 In the left pane, in the Baseline folder, select **Create Baseline**.
- 3 In the right pane, under **Input Parameters**, enter a value in the **Stop Time** field for the baseline.

When you enter a Stop Time value in Performance Advisor, this overrides the value set in the model. A large stop time can create a simulation that runs longer.

If you do not enter a value, Performance Advisor uses values from the model. Performance Advisor uses values from the model that are less than 10. Performance Advisor rounds values from the model larger than 10 to 10.

- 4 Select the **Check to view baseline signals and set their tolerances** check box to start the Simulation Data Inspector after Performance Advisor runs a check. Using the Simulation Data Inspector, you can compare signals and adjust tolerance levels.
- 5 Click **Run This Check**.

When a baseline has been created, a message like the following appears under **Analysis**:

After the baseline has been created, you can run Performance Advisor checks.

Run Performance Advisor Checks

- 1 After you have created a baseline measurement, select checks to run.
 - In the left pane of Performance Advisor, expand a folder, such as **Simulation** or **Simulation Targets**, to display checks related to specific tasks.
 - In the folder, select the checks you want to run using the check boxes.

Tip If you are unsure of which checks apply, you can select and run all checks. After you see the results, clear the checks you are not interested in.

- 2 Specify input parameters for selected checks. Use one of these methods:
 - Apply global settings to all checks to take action, validate simulation time and validate simulation accuracy.
 - Alternatively, for each check, in the right pane, specify input parameters.

Input Parameter	Description
Take action based on advice	automatically — Allow Performance Advisor to automatically make the change for you. manually — Review the change first. Then manually make the change or accept Performance Advisor recommendations.
Validate and revert changes if time of simulation increases	Select this check box to have Performance Advisor rerun the simulation and verify that the change made based on the advice improves simulation time. If the change does not improve simulation time, Performance Advisor reverts the changes.

Input Parameter	Description
Validate and revert changes if degree of accuracy is greater than tolerance	Select this check box to have Performance Advisor rerun the simulation and verify that, after the change, the model results are still within tolerance. If the result is outside tolerance, Performance Advisor reverts the changes.
Quick estimation of model build time	Select this check box to have Performance Advisor use the number of blocks of a referenced model to estimate model build time.

- 3 To run a single check, click **Run This Check** from the settings for the check. Performance Advisor displays the results in the right pane.

You can also select multiple checks from the left pane and click **Run Selected Checks** from the right pane. Select **Show report after run** to display the results of the checks after they run.

- 4 To limit the run time of Performance Advisor, specify a **Time Out** value in minutes. Use this option for models with long simulation times. The default setting for this option is 60 minutes.

Note The **Time Out** setting does not apply to a Quick Scan diagnosis.

Performance Advisor also generates an HTML report of the current check results and actions in a file with a name in the form *model_name\report_#.html*

To view this report in a separate window, click the **Report** link in the right pane.

Note If you rename a system, you must restart Performance Advisor to check that system.

View and Respond to Results

After you run checks with Performance Advisor, the right pane shows the results:

Identify simulation target settings

Analysis →

Analysis

Disabling simulation target settings, such as 'Echo expression without semicolons', can improve simulation speed.

Input Parameters

Take action based on advice:

Validate and revert changes if time of simulation increases

Validate and revert changes if degree of accuracy is greater than tolerance

Result: Warning

The simulation target setting 'Echo expressions without semicolons' is enabled. Disabling this setting might improve simulation speed. Review the following settings in the Model Configuration of model 'vdp'.

Performance Advisor has taken the necessary actions. For details, see the Action Results section.

Severity	Diagnostics checked	Original Value	New Value
	Simulation Target > Echo expressions without semicolons	on	off

Action →

Action

Review the action results

Result:

Summary of performance validations			
	Before this check	After this check	Improvement
Performance			✓
Accuracy	Within given tolerance	Within given tolerance Click to view	✓
Simulation Time	00:00:34.970	00:00:02.036	94.18%

To view the results of a check, in the left pane, select the check you ran. The right pane updates with the results of the check. This pane has two sections.

The **Analysis** section contains:

- Information about the check
- Option to run the simulation
- Settings to take action based on advice from Performance Advisor
- Result of the check (Passed, Failed or Warning)

The **Action** section contains:

- A setting to manually accept all recommendations for the check
- Summary of actions taken based on the recommendations for the check

Respond to Results

Use the **Take action based on advice** parameter in the **Analysis** section to select how to respond to changes that Performance Advisor suggests.

Value	Response
automatically	<ul style="list-style-type: none"> Performance Advisor makes the change for you. You can evaluate the changes using the links in the summary table. The Modify All button in the Action section is grayed out since Performance Advisor has already made all recommended changes for you.
manually	<ul style="list-style-type: none"> Performance Advisor does not make the change for you. The links in the summary table show recommendations. Use the Modify All button in the Action section to implement all recommendations after reviewing them. Depending on how you set your validation input parameters before you ran the check, the button label can change to Modify All and Validate.

Review Actions

The **Action** section contains a summary of the actions that Performance Advisor took based on the **Input Parameters** setting. If the tool also performed validation actions, this section lists the results in a summary table. If performance has not improved, Performance Advisor reports that it reinstated the model to the settings it had before the check ran.

Summary of performance validations			
	Before this check	After this check	Improvement
Performance			✓
Accuracy	Within given tolerance	Within given tolerance Click to view	✓
Simulation Time	00:00:04.276	00:00:02.412	43.59%

Severity	Description
✓	The actions succeeded. The table lists the percentage of improvement.
✗	The actions failed. For example, if Performance Advisor cannot make a recommended change, it flags it as failed. It also flags a check as failed if performance did not improve and reinstates the model to the settings it had before the check ran.

Caution Performance Advisor does not automatically save your model after it makes changes. When you are satisfied with the changes to the model from Performance Advisor, save the model.

View and Save Performance Advisor Reports

When Performance Advisor runs checks, it generates HTML reports of the results. To view a report, select a folder in the left pane and click the link in the **Report** box in the right pane.

As you run checks, Performance Advisor updates the reports with the latest information for each check in the folder. Time stamps indicate when checks ran.

In the pane for global settings, when you select **Show report after run**, Performance Advisor displays a consolidated set of check results in the report.

Simulink Performance Advisor Report - vdp.slx

Simulink version: 8.3 System: vdp Model version: 1.7 Current run: 24-Oct-2013 06:57:14

Performance Advisor

1 Baseline 1 0 0 0 0

2 Simulation 2 0 0 2 8

2.1 Checks Occurring Before Update 1 0 0 2 6

Identify resource-intensive diagnostic settings

Some diagnostics incur run-time overhead during simulation. Review the following parameters in the Model Configuration of model 'vdp' and the suggested changes for these parameters.

Click link(s) to make changes manually. Alternatively, click the 'Modify all' button below to have Performance Advisor take necessary actions for you.

Severity	Diagnostics checked	Original Value	New Value
Solver	Diagnostics > Solver data inconsistency	none	none
Signals	Diagnostics > Data Validity > Signal resolution	Explicit and warn implicit	Explicit only
	Diagnostics > Data Validity > Division by singular matrix	none	none
	Diagnostics > Data Validity > Inf or nan block output	none	none
	Diagnostics > Data Validity > Simulation range checking	none	none
DSM Blocks	Diagnostics > Data Validity > Detect read before write	UseLocalSettings	DisableAll
	Diagnostics > Data Validity > Detect write after read	UseLocalSettings	DisableAll

You can perform these actions using the Performance Advisor report:

- Use the check boxes under **Filter checks** to view only the checks with the status that you are interested in viewing. For example, to see only the checks that failed or gave warnings, clear the **Passed** and **Not Run** check boxes.
- Perform a keyword search using the search box under **Filter checks**.
- Use the tree of checks under **Navigation** to jump to the category of checks or a specific check result that interests you.
- Expand and collapse content in the right pane of the report to view or hide check results.

Some checks have input parameters that you specify in the right pane of Performance Advisor. For example, **Identify resource intensive diagnostic settings** has several input parameters. When you run checks that have input parameters, Performance Advisor displays the values of the input parameters in the report.

Identify resource-intensive diagnostic settings

Some diagnostics incur run-time overhead during simulation. Review the following parameters in the Model Configuration of model 'vdp' and the suggested changes for these parameters.

Performance Advisor has taken the necessary actions. For details, see the Action Results section.

Severity	Diagnostics checked	Original Value	New Value
Solver	Diagnostics > Solver data inconsistency	none	none
Signals	Diagnostics > Data Validity > Signal resolution	Explicit and warn implicit	Explicit only
	Diagnostics > Data Validity > Division by singular matrix	none	none

More (3 rows)

Input Parameters Selection

Item	Value
Take action based on advice	automatically
Validate and revert changes if time of simulation increases	true
Validate and revert changes if degree of accuracy is greater than tolerance	true

Save Performance Advisor Reports

You can archive a Performance Advisor report by saving it to a new location. Performance Advisor does not update the saved version of a report when you run checks again. Archived reports serve as good points of comparison when you run checks again.

- 1 In the left pane of the Performance Advisor window, select the folder of checks for the report you want to save.
- 2 In the **Report** box, click **Save As**.

- 3 In the **Save As** dialog box, navigate to where you want to save the report, and click **Save**. Performance Advisor saves the report to the new location.

Perform a Quick Scan Diagnosis

Quick Scan is a fast method to diagnose settings in a model and deliver an approximate analysis of performance. A model can compile and simulate several times during a normal run in Performance Advisor. Quick Scan enables you to review performance issues without compiling or changing the model or validating any fixes. In models with long compile times, use Quick Scan to get a rapid analysis of possible improvements.

When you perform a Quick Scan diagnosis, Performance Advisor

- Does not perform a baseline measurement.
- Does not automatically apply advice to the model.
- Does not validate any changes you make to the model.
- Does not time out if the Quick Scan diagnosis takes longer than the **Time Out** duration you specify.

Run Quick Scan on a Model

- 1 Select checks to run.

Tip If you are unsure of which checks apply, you can select and run all checks. After you see the results, clear the checks you are not interested in.

- In the left pane of Performance Advisor, expand a folder, such as **Simulation** or **Simulation Targets**, to display checks related to specific tasks.
 - In the folder, select the checks you want to run using the check boxes.
- 2 Select the **Show report after run** check box to display the results of the checks after they run.
 - 3 Click **Quick Scan** on the right pane.

Checks in Quick Scan Mode

- “Identify resource-intensive diagnostic settings”
- “Check optimization settings”
- “Identify inefficient lookup table blocks”
- “Check MATLAB System block simulation mode”
- “Identify Interpreted MATLAB Function blocks”
- “Identify simulation target settings”
- “Check model reference rebuild setting”

Improve vdp Model Performance

In this section...

“Enable Data Logging for the Model” on page 32-12

“Create Baseline” on page 32-12

“Select Checks and Run” on page 32-13

“Review Results” on page 32-13

“Apply Advice and Validate Manually” on page 32-15

This example shows you how to run Performance Advisor on the vdp model, review advice, and make changes to improve performance.

Enable Data Logging for the Model

- 1 In the vdp model, on the **Modeling** tab, click **Model Settings**.
- 2 In the Configuration Parameters dialog box, click **Data Import/Export** in the left pane.
- 3 Set up signal logging. The model must log at least one signal for Performance Advisor to work. For example, select the **States** or **Output** check box.
- 4 Click **Configure Signals to Log**.
- 5 To select signals to log, select a signal in vdp. Right click and select **Properties**.
- 6 In the Signal Properties dialog box, check the **Log signal data** option and click **OK**.
- 7 Click **OK** in the Configuration Parameters dialog box.
- 8 Run the model once to make sure that the simulation is successful.

Create Baseline

- 1 Open Performance Advisor. In the vdp model, on the **Debug** tab, click **Performance Advisor**.
- 2 In the right pane, under **Set Up**, select a global setting for **Take Action**. To automatically apply advice to the model, select **automatically for all checks**.
- 3 Select global settings to validate any improvements in simulation time and accuracy after applying advice. To select the default setting for validation, for **Validate simulation time** and **Validate simulation accuracy**, select **use check parameters**.

Note To validate any improvements automatically, change the global settings to **For all checks**. However, this can increase simulation time as validating all checks requires more simulation runs.

- 4 Select **Show report after run**. This opens an HTML report of check results.
- 5 In the left pane, select the **Create baseline** check. Clear the other checks.
- 6 In the **Create baseline** pane, set **Stop Time** to 10. Click **Apply**.
- 7 Click **Run This Check**. The right pane updates to show that the baseline was created successfully.

Select Checks and Run

Note The global input parameters to take action and validate improvement apply to all the checks you select.

- 1 In the left pane, clear the baseline check. Select these checks:
 - In **Simulation > Checks Occurring Before Update**, select **Identify resource-intensive diagnostic settings**.
 - In **Simulation > Checks that Require Update Diagram**, select **Check model reference parallel build**.
 - In **Simulation Targets > Check Compiler Optimization Settings**, select **Select compiler optimizations on or off**.
 - Select **Final validation**.
- 2 For every check that you have selected in the left pane, select options in the right pane to validate any improvements in simulation time and accuracy. Note that **Take Action based on advice** is set to automatically, a result of **Take Action** being set to automatically for all checks.
- 3 Select a value for **Time Out** if you want to limit the runtime duration of Performance Advisor.
- 4 Click **Run Selected Checks**.

Performance Advisor runs the checks you selected and opens an HTML report with check results.

Review Results

- 1 In the HTML report, filter the results to see only the checks that passed.

All of the selected checks passed successfully.

- 2 Navigate to the results for a particular check, for example **Check model reference parallel build**. Use the navigation tree in the left pane or scroll to the results for this check in the right pane.
- 3 Performance Advisor gives you information about this check, advice for performance improvement, as well as a list of related model configuration parameters.

✔ **Check model reference parallel build**

Passed

There are less than two reference models in your model. Parallel building is unnecessary. However, consider using model reference for large models. Use more than one model reference to take advantage of parallel building.

Input Parameters Selection

Name	Value
Quick estimation of model build time	true
Parallel build overhead time estimation factor	0.5

- 4 Filter the results to display warnings. See results for the **Identify resource-intensive diagnostic settings** check.

Performance Advisor identified diagnostic settings that incur runtime overhead during simulation. It modified values for some of these diagnostics. A table in the report shows the diagnostics checked and whether Performance Advisor suggested a change to the value.

If the performance of the model improved, the HTML report gives you information about this improvement. If the performance has deteriorated, Performance Advisor discards all changes and reinstates the original settings in the model.

- 5 See details for the **Final Validation** check.

✓ Final validation

Summary of performance validations			
Performance	Before this check	After this check	Improvement
Accuracy	Within given tolerance	Within given tolerance Click to view	✓
Simulation Time	00:00:00.253	00:00:00.100	60.38%

Passed

Overall, Performance advisor has improved the performance of the model.

Input Parameters Selection

Name	Value
Take action based on advice	automatically
Validate and revert changes if time of simulation increases	true
Validate and revert changes if degree of accuracy is greater than tolerance	true

This check validates the overall performance improvement in the model. The check results show changes in simulation time and accuracy, depending on whether performance improved or degraded.

Apply Advice and Validate Manually

Generate advice for a check, apply it, and validate any improvements manually.

- 1 In the left pane, click **Performance Advisor**. Select these settings and click **Apply**:
 - Set **Take Action** to generate advice only.
 - Set **Validate simulation time** to use check parameters.
 - Set **Validate simulation accuracy** to use check parameters.
- 2 For every check that you have selected in the left pane, select options in the right pane to validate any improvements in simulation time and accuracy. Note that **Take Action based on advice** is set to manually, a result of **Take Action** being set to generate advice only.
- 3 Select **Performance Advisor** in the left pane. Click **Run Selected Checks** in the Performance Advisor pane.

If the performance of the model has improved, the **Final Validation** check results show the overall performance improvement.

- 4 In the results for **Identify resource-intensive diagnostic settings**, Performance Advisor suggests new values for the diagnostics it checked. Review these results to accept or reject the values it suggests.

Alternatively, click **Modify all and Validate** to accept all changes and validate any improvement in performance.

Examine Model Dynamics Using Solver Profiler

When model simulation slows down or stops responding, a close examination of the dynamics of the model can help you identify the factors affecting the simulation.

Understanding solver behavior enables you to interpret how the model simulates and what causes the solver to take small steps.

The Solver Profiler analyzes a model for patterns that affect its simulation. The Solver Profiler presents graphical and statistical information about the simulation, solver settings, events, and errors. You can use this data to identify locations in the model that caused simulation bottlenecks.

In addition, there are multiple factors that can limit the simulation speed. The Solver Profiler logs and reports all the major events that occur when simulating a model:

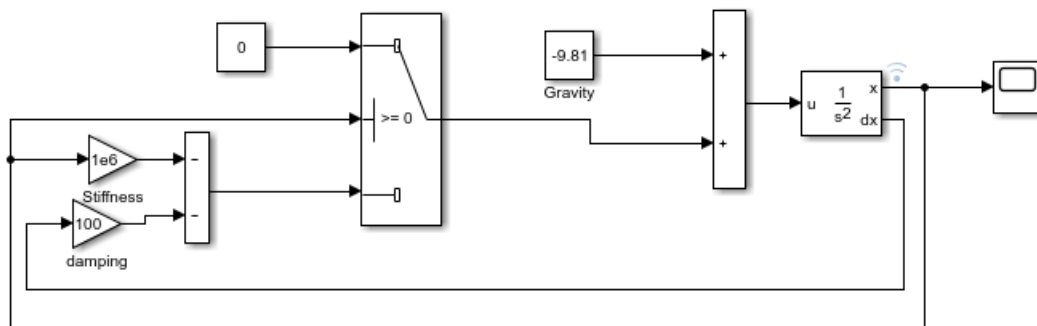

- Zero-crossing events
- Solver exception events
- Solver reset events
- Jacobian computation events

Note In order to accurately profile the solver performance, the **Solver Profiler** may temporarily modify some logging settings of your model. Your settings will be restored after profiling has been completed.

These events are common and necessary for an accurate simulation. However, they do incur computational cost and frequent occurrences can slow down or even stall the simulation.

To examine model dynamics and identify causes that affect the simulation:

- 1 Open the model that is simulating slowly or unsuccessfully.

- 2 Open the Solver Profiler by clicking the hyperlink in the lower-right corner of the Simulink Editor.

- 3 The Solver Profiler provides smart logging and diagnostics of continuous model states and Simscape states. To enable this, select the **States & Zero Crossing** or **Simscape States** option before a run. Disable these options only if you are running out of memory. After the run, access the States Explorer or Simscape Explorer to examine those states.
- 4 Click **Run**. The profiler simulates the model and starts capturing solver performance data.

When the simulation ends, the profiler displays the statistics and exceptions it captured over the duration of the simulation.

Tip You can pause or stop the simulation at any time to view the information captured until that point.

- 5 Use the profiler plot to highlight the parts of the model that caused generate the most events.
- 6 Click **Save** to capture your profiling session, or exit without saving.

Solver Profiler | Zero Crossing Explorer | States Explorer | `solverprofiler.profileModel`

Zero-Crossing Events

This example simulates a ball bouncing on a hard surface.

When you run the Solver Profiler on this model, the model simulates in 2898 steps and that it triggers 67 zero crossing events. To highlight the zero crossing events on the step size plot, click the **Zero Crossing** tab and select the block that is causing the event.

The result indicates that when the ball drops on the hard surface, it bounces 67 times before coming to a stop. The solver resets after each bounce, increasing the computational load. Having many resets improves accuracy at the cost of computation load. Therefore, it is important to know this tradeoff when modeling.

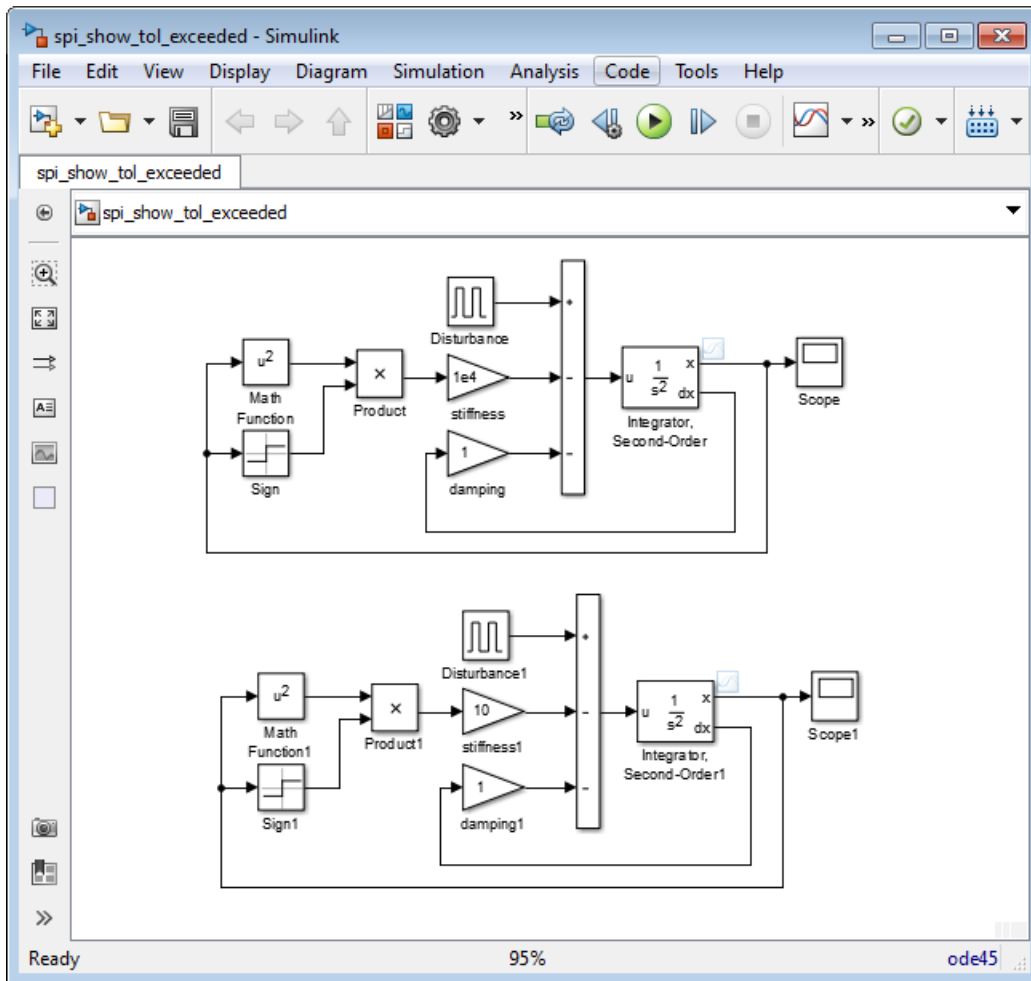

If this modeling construct belonged to a larger model, the Solver Profiler would help you locate it. You could then modify the model to improve solver performance. For example, you can decide to reduce the accuracy of the contact dynamic by increasing the damping factor, which would reduce the number of bounce events. Increasing the damping from 100 to 500 makes the ball bounce only 13 times, allowing the simulation to complete in only 669 steps.

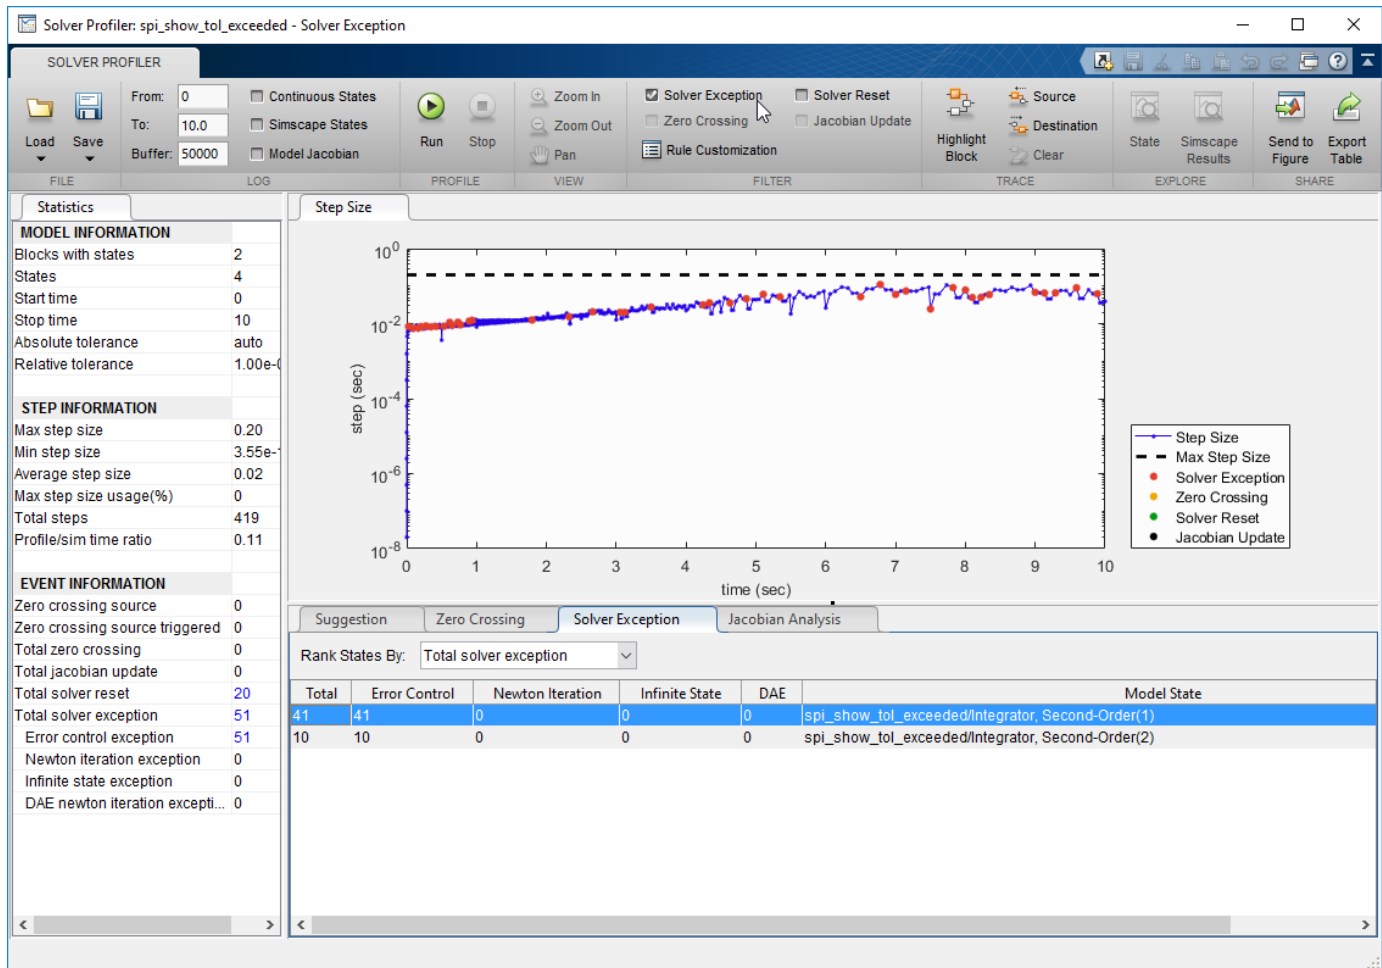

Solver Exception Events

Tolerance-Exceeding Events

This example simulates two identical nonlinear spring-damping systems. The two systems have different spring stiffness.

When you run the Solver Profiler on this model, you can see the tolerance-exceeding events in the **Solver Exception** tab.

The result indicates that the stiffer spring causes the solver tolerance to exceed the limit. Typically, model states that change the fastest tend to be closest to the solver tolerance limit.

The solver attempts to take the largest possible steps while optimally trading off between speed and accuracy. Occasionally, this tradeoff causes the solver to take steps that exceed the tolerance limit and forces it to reduce the step size. Exceeding the tolerance limit is not a poor modeling practice in itself. This profiler statistic is not meant to help you reduce tolerance exceeding events to zero.

This statistic can help you identify parts of your model that are close to exceeding the tolerance limit. You can identify model components that change the fastest or are the stiffest. You can decide to retain this model dynamic in the simulation or simplify it to speed up simulation.

The tolerance-exceeding statistic can also help you identify modeling errors. If you do not expect the highlighted states to change as fast, you can examine your model for errors. In this example, the modeling error could be that the stiffness of the stiffer spring is specified in N/m instead of N/mm. This error makes the spring 1000 times stiffer than expected.

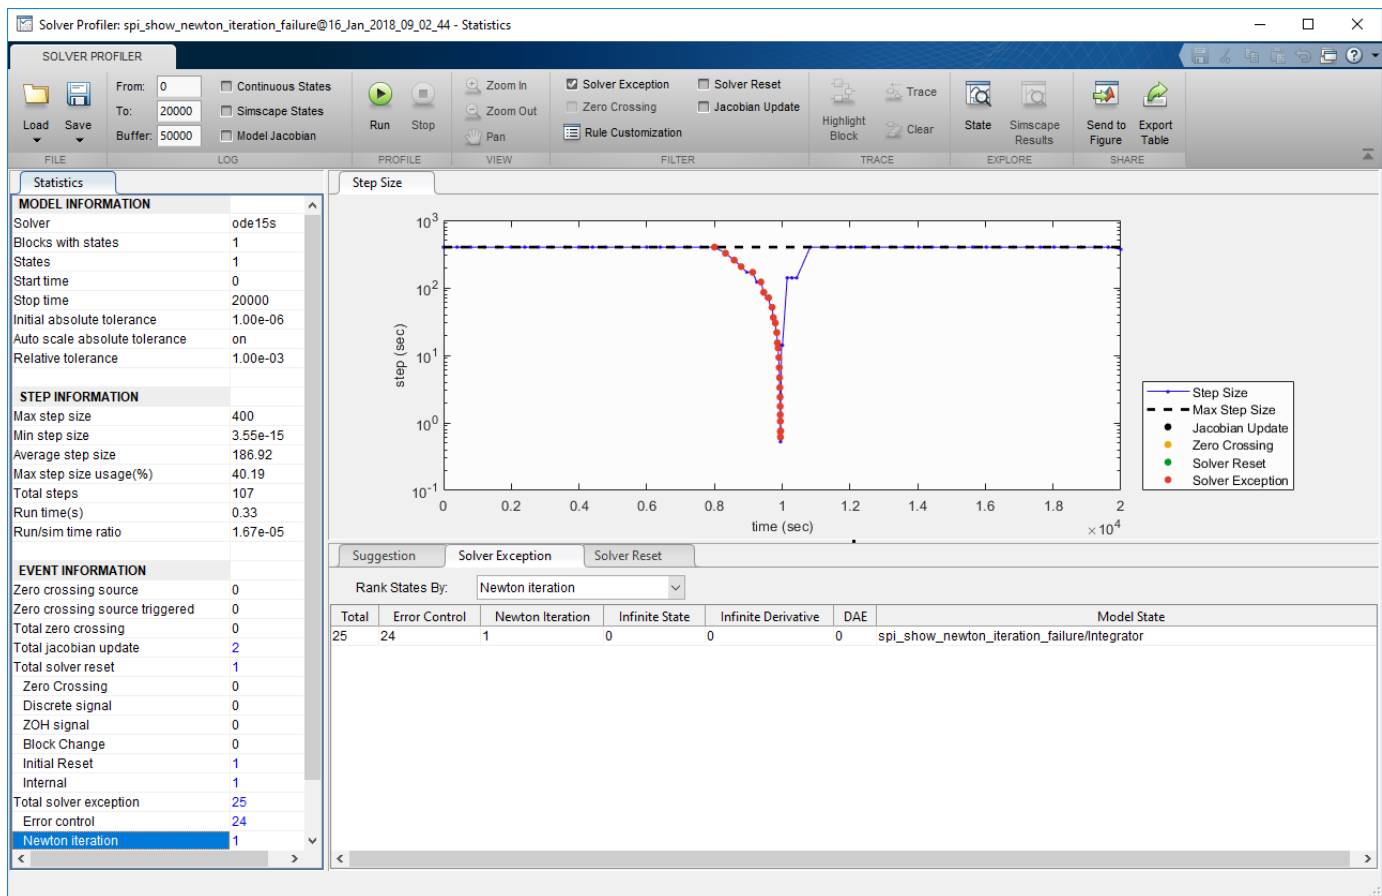

Newton Iteration Failures

Newton iteration failures are specific to implicit solvers like ode15s and ode23t, and they result from Newton iterations not converging after a few trials. Similar to tolerance-exceeding events, these failures tend to occur when a system changes quickly.

This example simulates how the radius of a ball of flame changes when you strike a match. The ball of flame grows rapidly until it reaches a critical size, when the amount of oxygen consumed balances the growth in ball surface.

When you run the Solver Profiler on this model, you can see the Newton iteration failures in the **Solver Exception** tab.

The result indicates that when the combustion begins, the solver tolerance is exceeded multiple times. When equilibrium is attained, the system appears different, and a Newton iteration failure occurs. The Jacobian of the system is recomputed, and the solver continues to move forward.

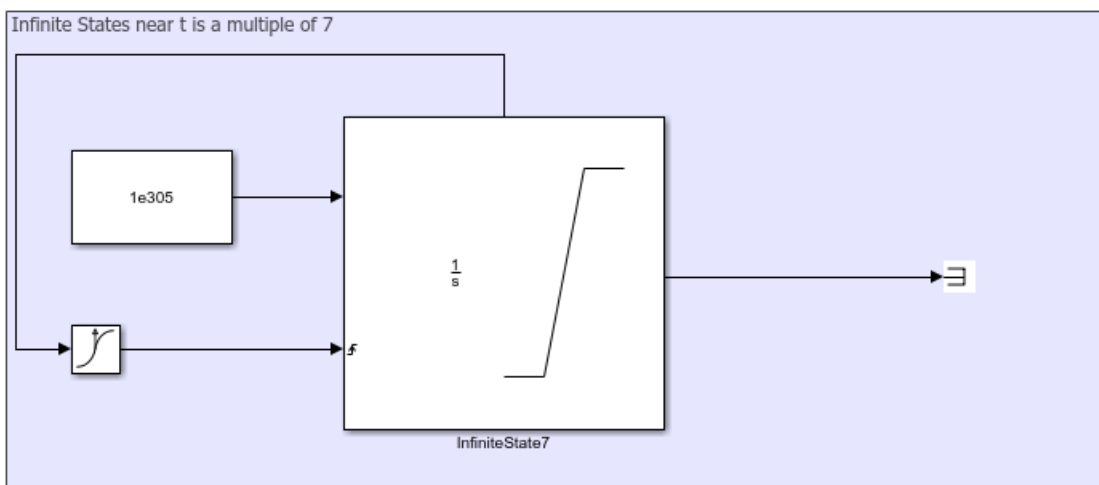

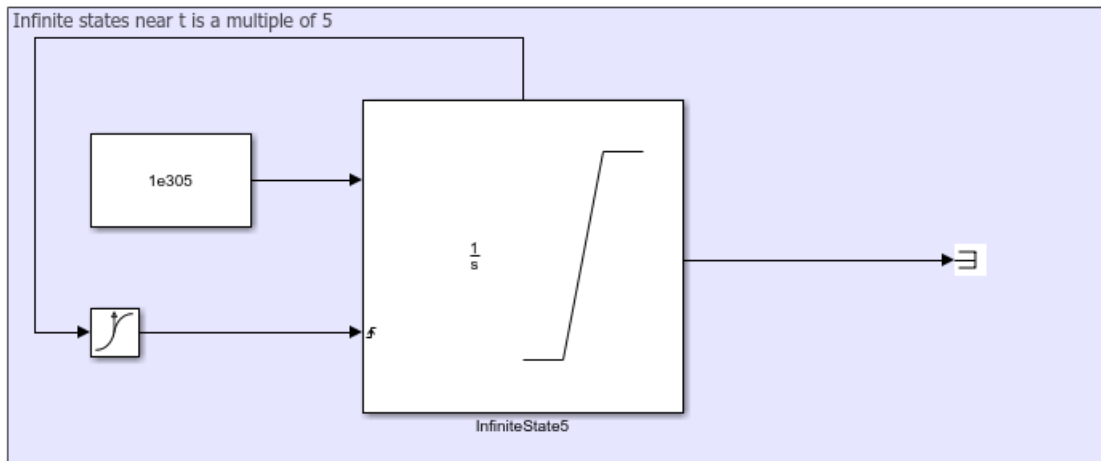

Newton failures are not indicative of poor modeling practices. This profiler statistic is not meant to help you reduce these failures to zero. In this example, you can reduce the solver tolerance to prevent this failure. But the solver then takes small steps unnecessarily, which is counterproductive. Therefore, in this example, this failure is acceptable.

This type of failure becomes problematic when it occurs in large numbers over a short period, especially in Simscape models. Dense failures indicate that your model is not robust numerically. One way to improve numerical robustness is to tighten the solver tolerance. Another way is to modify the model to avoid rapid changes.

Infinite State and Infinite Derivative Exceptions

An infinite state exception occurs when the magnitude of a state approaches infinity. Similarly, when the magnitude of the derivative of a state approaches infinity, an infinite derivative exception occurs. The solver reduces the step size and makes another attempt at integration.

This example shows a set of two Integrator Limited blocks that have initial conditions slightly less than `realmax`. As they integrate the Constant input of `1e305`, the solver quickly reaches the infinite state exception.

When you run the Solver Profiler for this model, you can see that the InfiniteState5 and InfiniteState7 blocks have 188 and 152 infinite state exceptions in the **Solver Exceptions** tab.

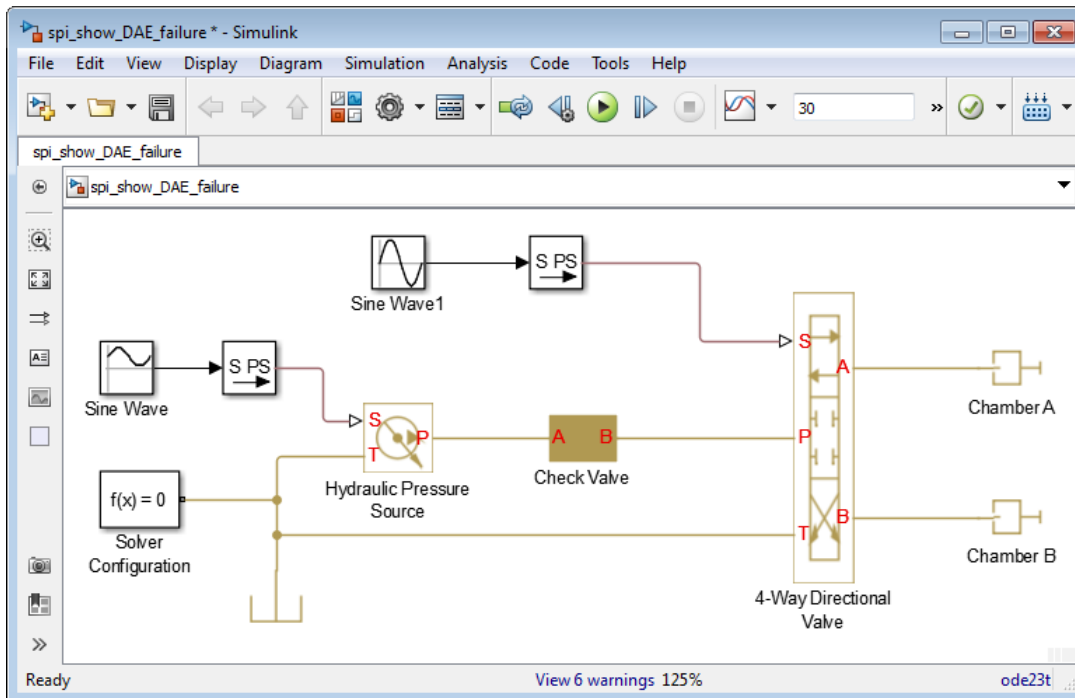

Differential Algebraic Equation Failures

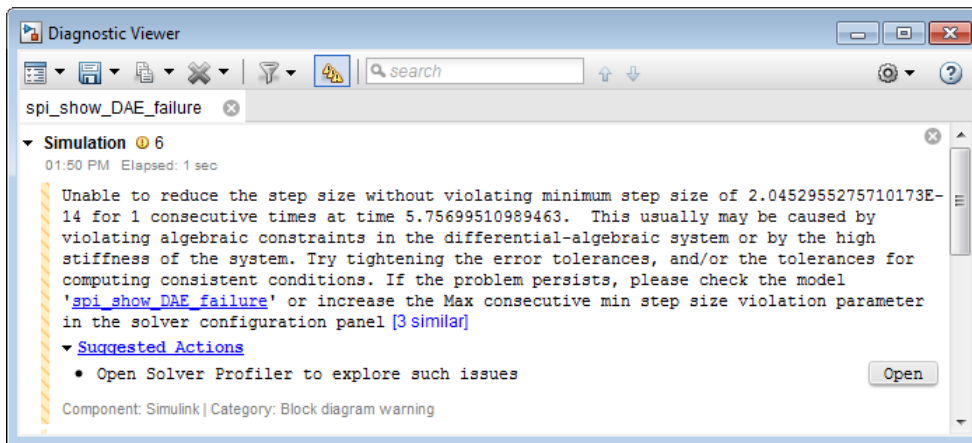

Most Simscape models use differential algebraic equations (DAEs), in contrast to Simulink models, which use ordinary differential equations.

The use of DAEs adds complexity to Simscape models. Solvers like ode15s and ode23t can handle many types of DAEs. However, when the algebraic constraints between Simscape components are complex and changing fast, the Newton iteration process fails to resolve those constraints.

This example simulates a pressure source that can be directed toward one of two hydraulic chambers.

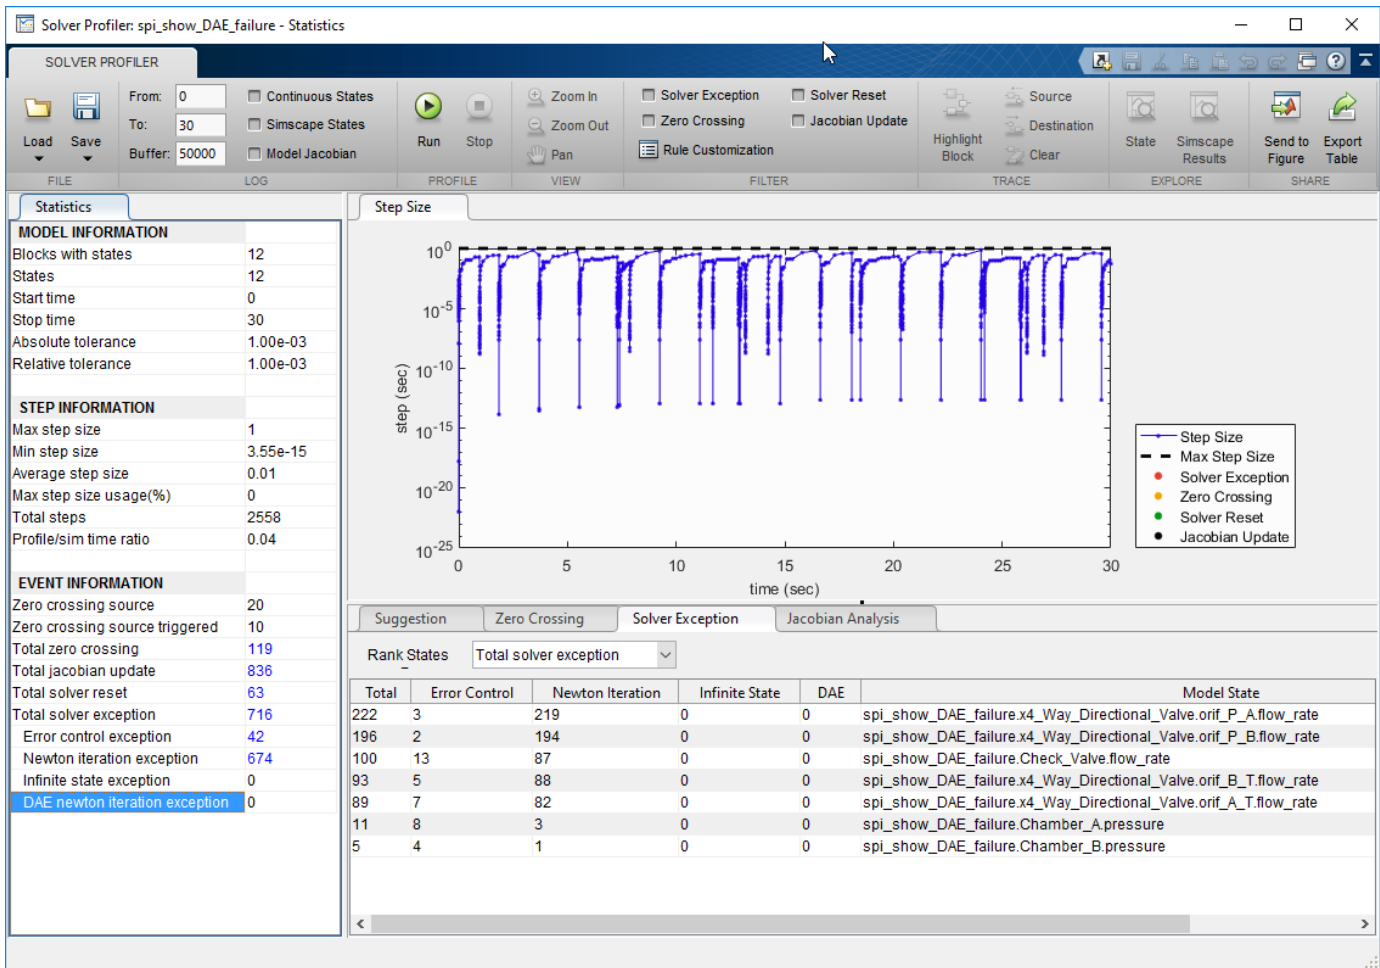

When you simulate this model, Simulink displays several warnings.

Typically, small models can handle such warnings and simulate to completion. However, this warning indicates that the model is not robust numerically. Minor changes to the model, or integration into a larger model, can result in errors.

When you run the Solver Profiler on this model, you can see the DAE failures in the **Solver Exception** tab.

In this case, the exception results from large solver tolerance. Tightening the solver tolerance forces the solver to take smaller steps and better capture the changes in algebraic constraints.

Alternatively, this exception can be avoided by removing the algebraic constraint. In this example, the **Check Valve** and the **4-Way Directional Valve** are directly connected. When their pressure-flow relationship changes rapidly, the solver is unable to capture the changes. Inserting a **Hydraulic Chamber** between those two components makes them compliant. To learn more about dry nodes, see Simscape documentation.

Solver Resets

The Solver Profiler logs events that cause the solver to reset its parameters because solver resets do incur computational cost. In addition to the total number of resets, you can also see a breakdown by type of reset event.

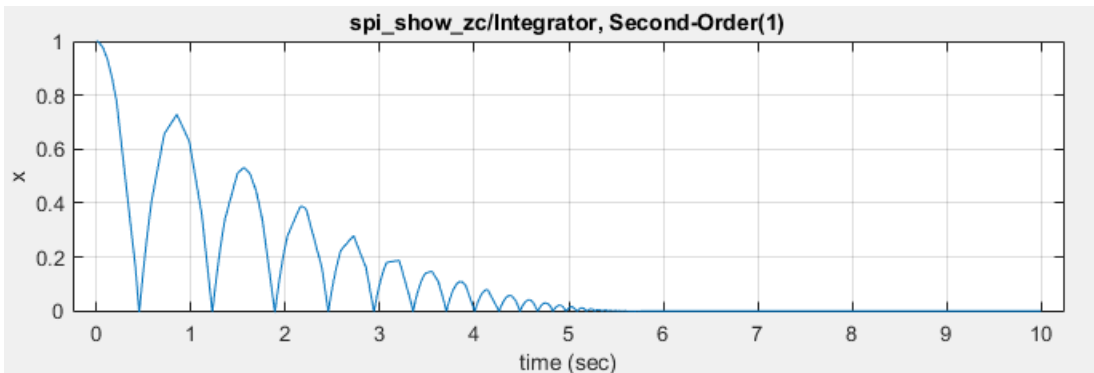

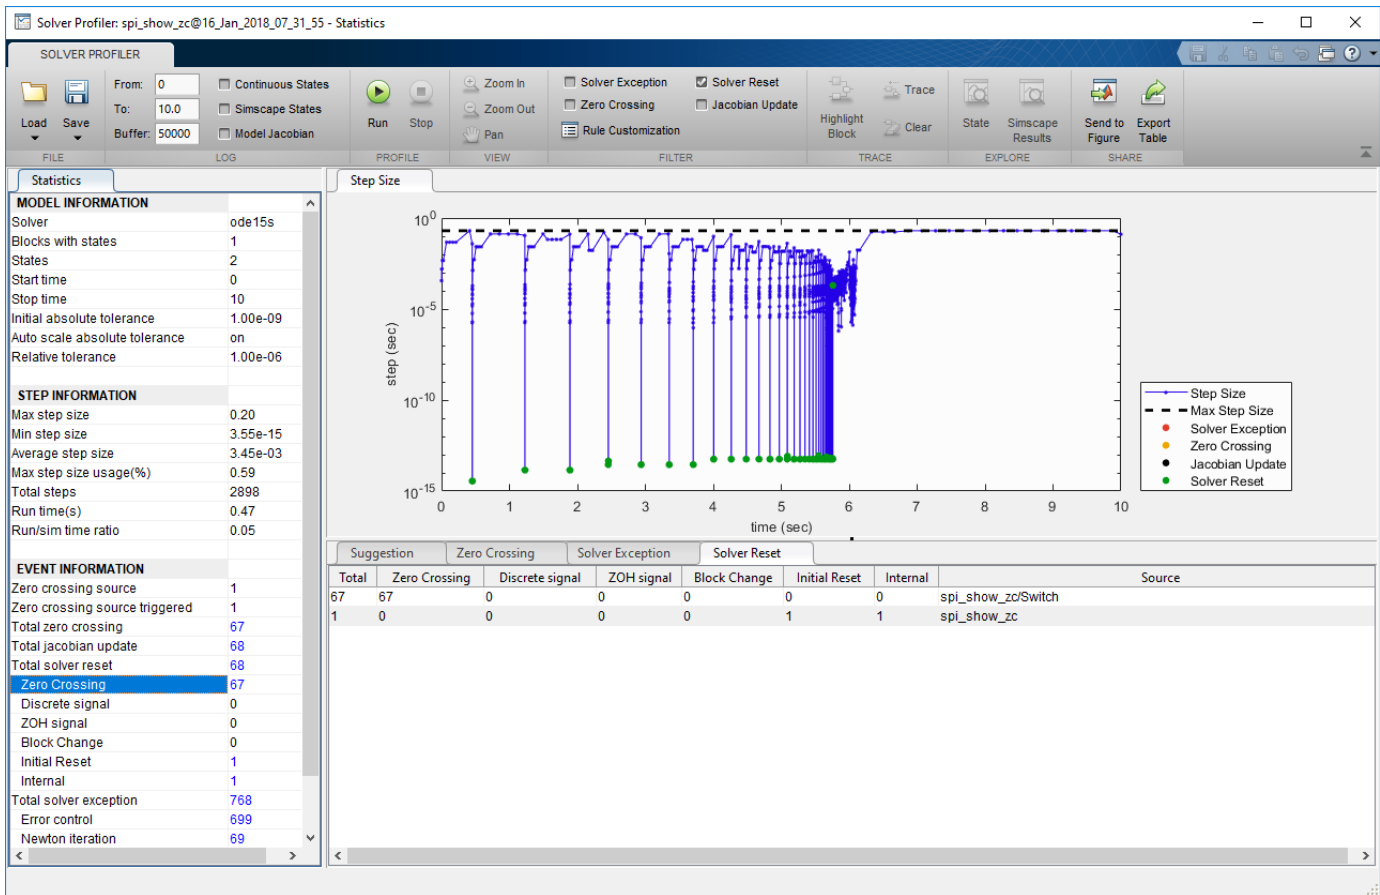

Note A solver reset event can have multiple causes. As a result, the number of **Total solver reset** events in the **Statistics** pane may be less than the sum of the solver resets of each type.

Zero-Crossing

Some zero crossing events occur at discontinuities in the signal. Consider the example model of a bouncing ball from the “Zero-Crossing Events” on page 33-5 section.

The Solver Profiler records 67 solver resets caused by zero crossings from the Switch block in the model. Compare the step-size and the **Solver Reset** highlighting with the output x of the Second-Order Integrator block, which is the height of the ball from the ground. Observe that the solver resets occur when the ball bounces off the ground.

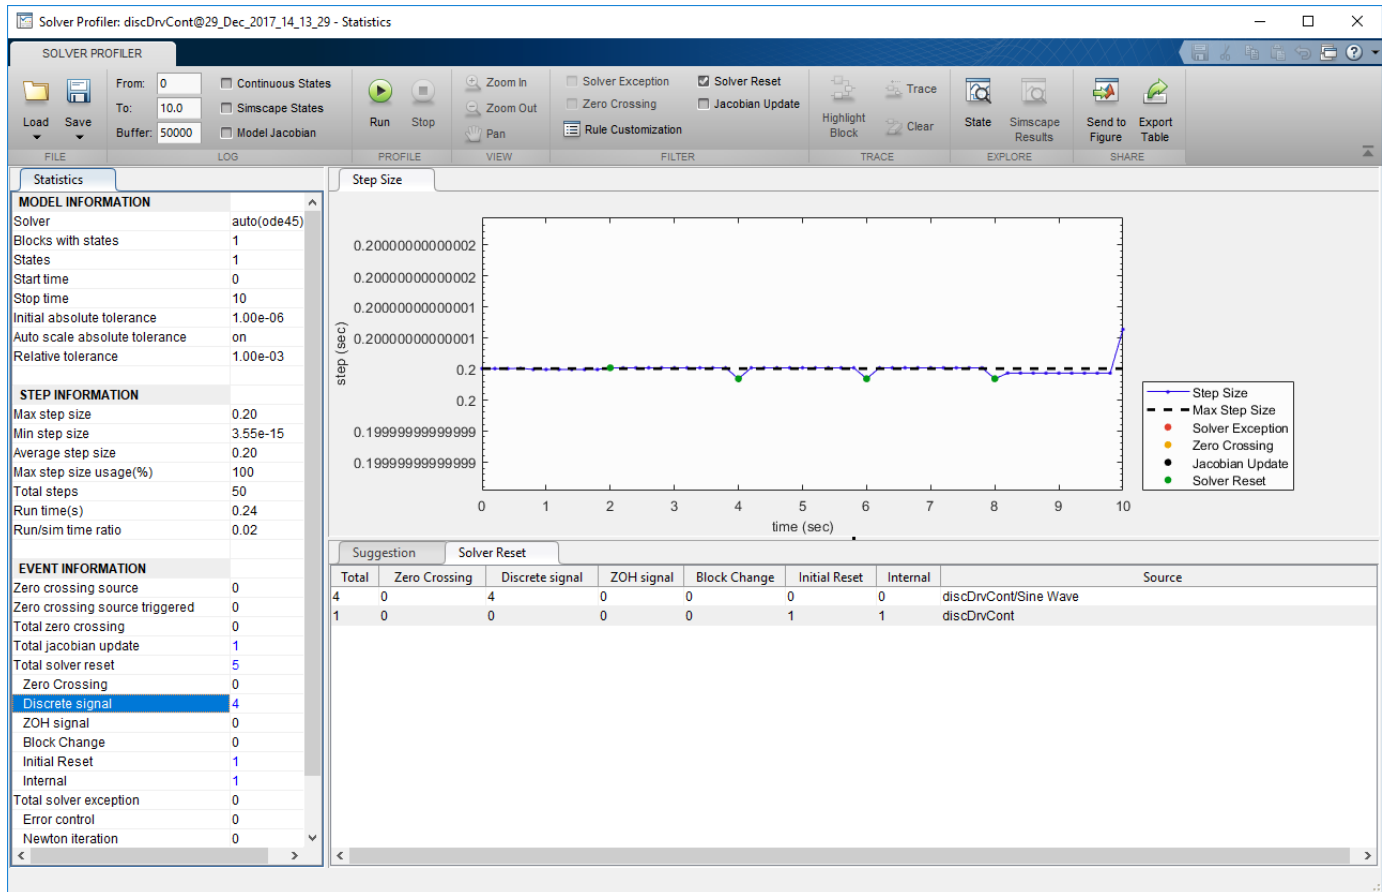

Discrete Signal

Solver resets also occur when your model has a discrete signal driving a block with continuous states, as seen in this example model.

The discrete Sine Wave block outputs a 1 rad/s sine wave with a discrete sample time $t_s = 2$.

The Solver Profiler report shows that four solver resets occur due to discrete signals driving a continuous block. These resets occur at every execution of the Sine Wave block.

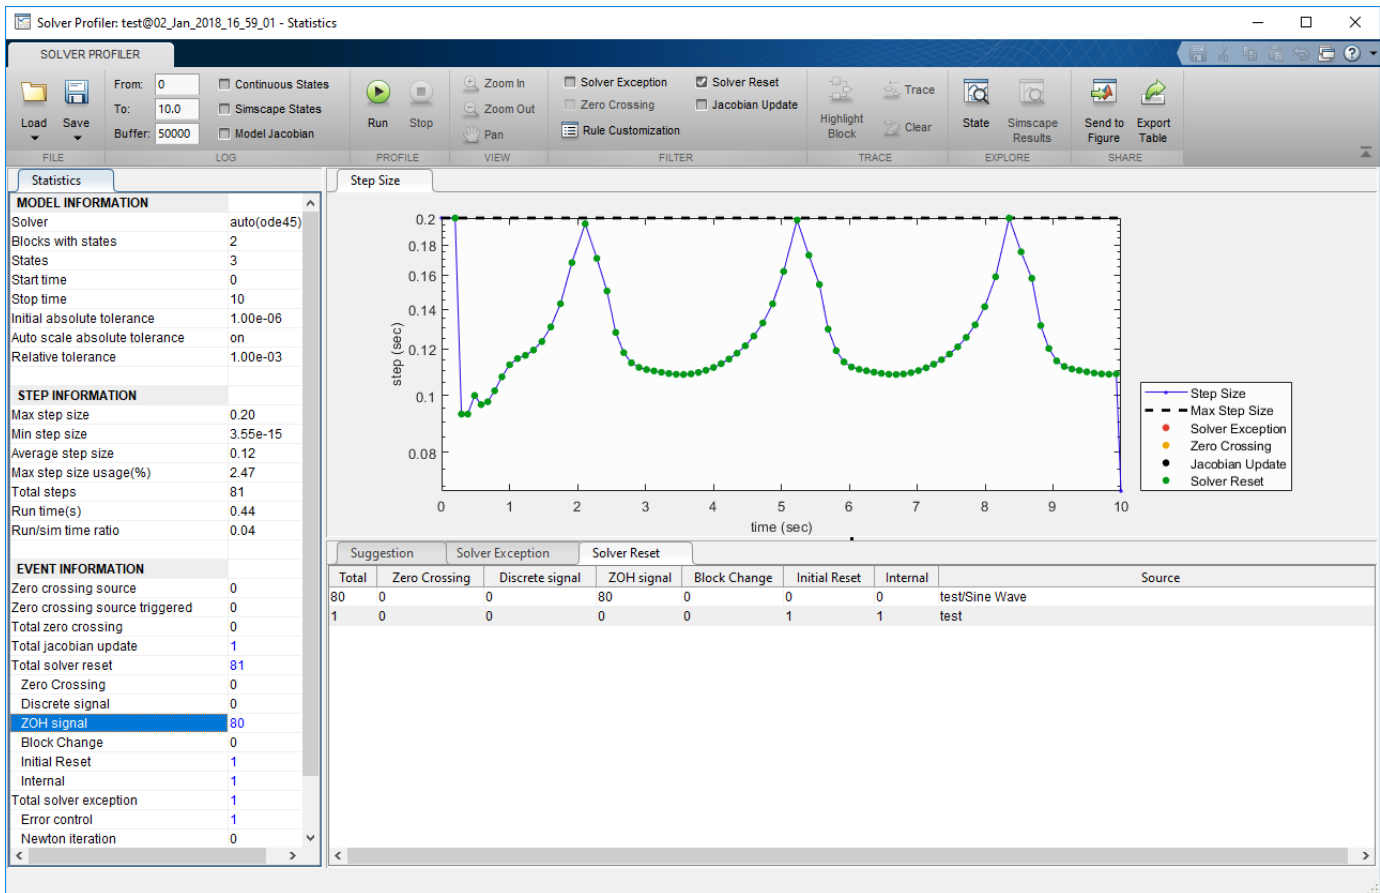

ZOH Signal

This type of solver reset occurs when a block output is not executed during a trial or minor time step and gets updated only during the integration or major time step. As a result, the block output changes discontinuously from one major time step to the other. As a result the solver resets. See “Fixed-in-Minor-Step” on page 7-14 sample time.

This example model shows a simple plant and controller that tracks a sinusoidal reference signal. The source of this signal is a Sine Wave block whose sample time is specified to be fixed-in-minor-step.

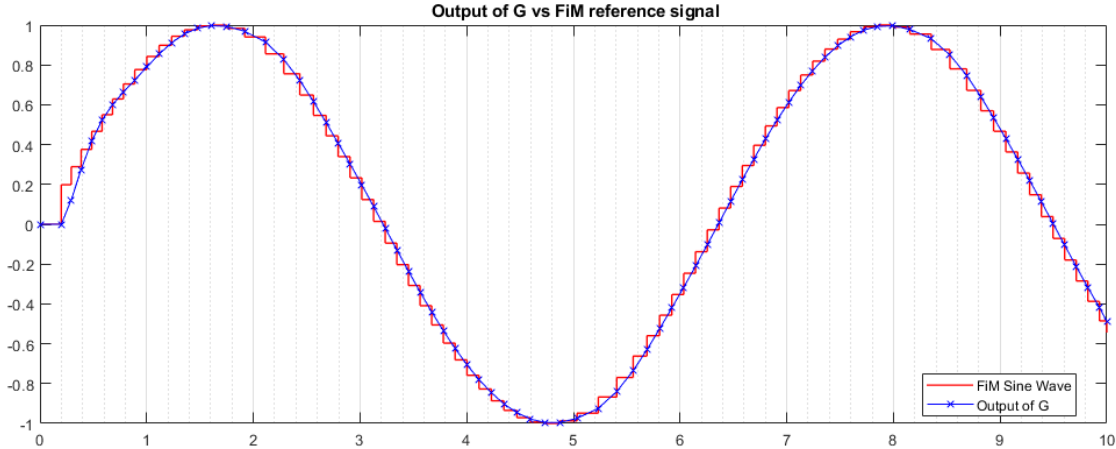

Observe from the results of the profiling session that there are **80 ZOH Signal** solver resets in the simulation.

Note When you select **Continuous States** for logging or enable the **SaveStates** parameter, the derivative of a continuous block driven by a **Fixed-in-Minor-Step** signal is NaN.

This is because the driving “Fixed-in-Minor-Step” on page 7-14 block updates its value only at every major time step. The signal driven to the continuous block is therefore discontinuous and the state is non differentiable.

The plot shows the outputs of the Sine Wave and Integrator blocks in the example model.

Tip Solver resets caused due to ZOH signals are serious compared to solver reset events caused by discrete signals and can significantly slow down the simulation. This is because ZOH signal reset events occur at every major step of the solver. Reconfigure your simulation to avoid these resets, if needed.

Block Signal

Sometimes, the block can be configured to reset the solver when certain conditions are satisfied during its execution. Consider the `sldemo_bouncemodel` of a bouncing ball which can be found in the “Capture the Velocity of a Bouncing Ball with the Memory Block” example.

Observe from the profiling results that there are 130 solver resets triggered by a block. A solver reset event can have multiple causes. In this case, zero crossings and block changes cause a solver reset event.

One setting that causes the **Block Change** solver reset event is the **Reinitialize dx/dt when x reaches saturation** parameter. This setting is necessary to properly simulate the dynamics of a bouncing ball.

Initial Reset

When you run a simulation, the solver needs to reset its parameters for the first time. This event is shown as the **Initial Reset** event in the Solver Profiler report. It occurs once at the start of the simulation.

Internal

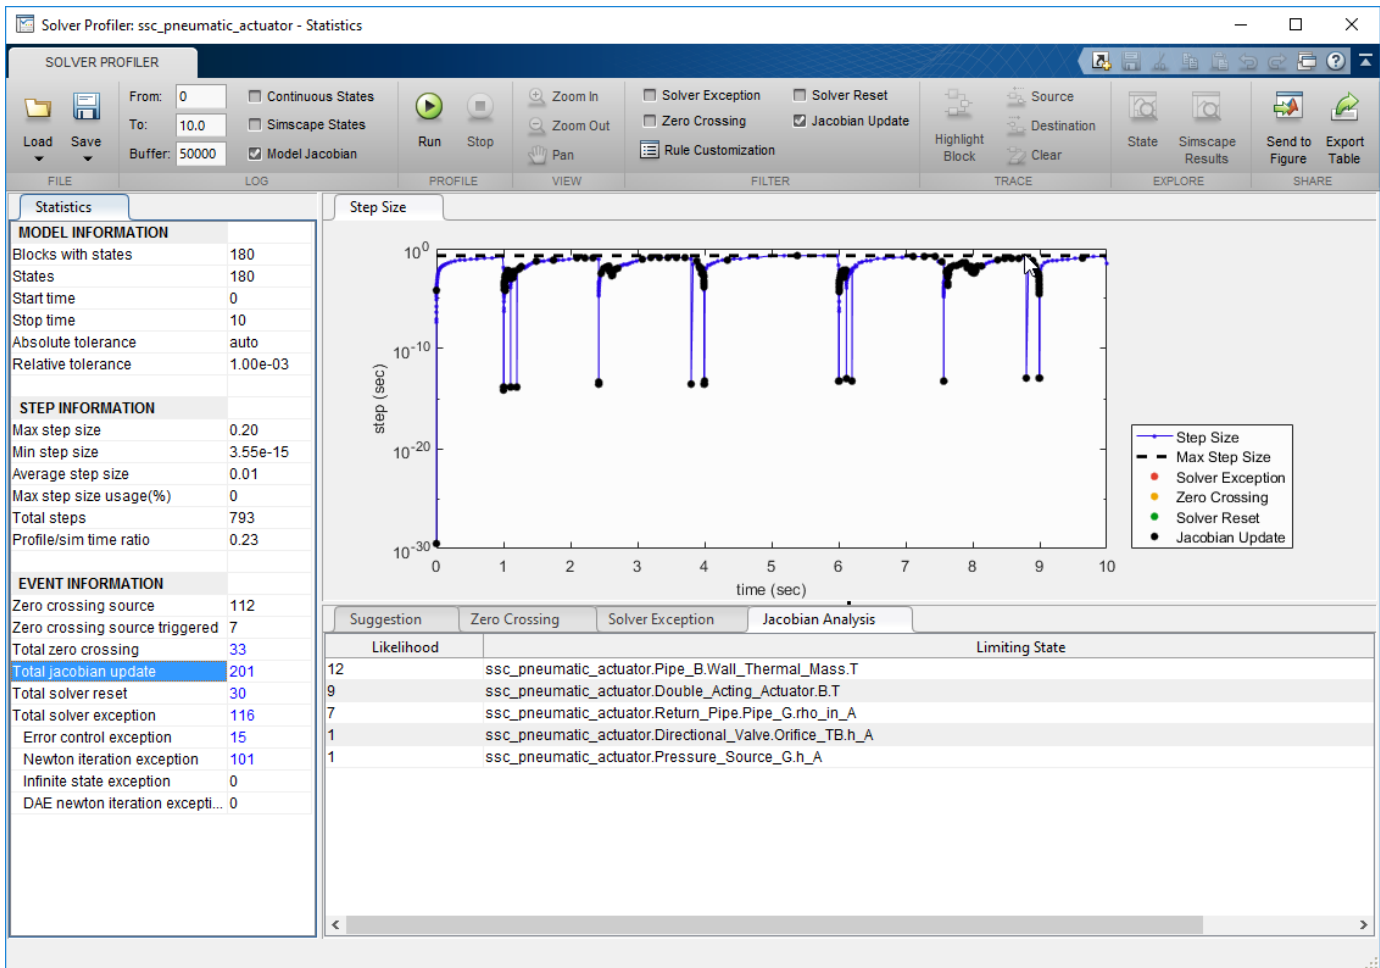

There are some reset events that are internal to the Simulink engine. These reset events are necessary for the engine to correctly configure itself for accurate simulation.

Jacobian Logging and Analysis

The Solver Profiler supports Jacobian logging and analysis for implicit solvers only.

You can select the **Model Jacobian** check box in the Solver Profiler to log updates to the Jacobian matrix for the model. When you run the Solver Profiler on a model, you can see the logs in the **Jacobian Analysis** tab.

The **Jacobian Analysis** tab indicates the states in the model that are likely slowing down the solver.

To investigate the cause of each limiting state, select a row in the **Jacobian Analysis** tab and click **Highlight Block**.

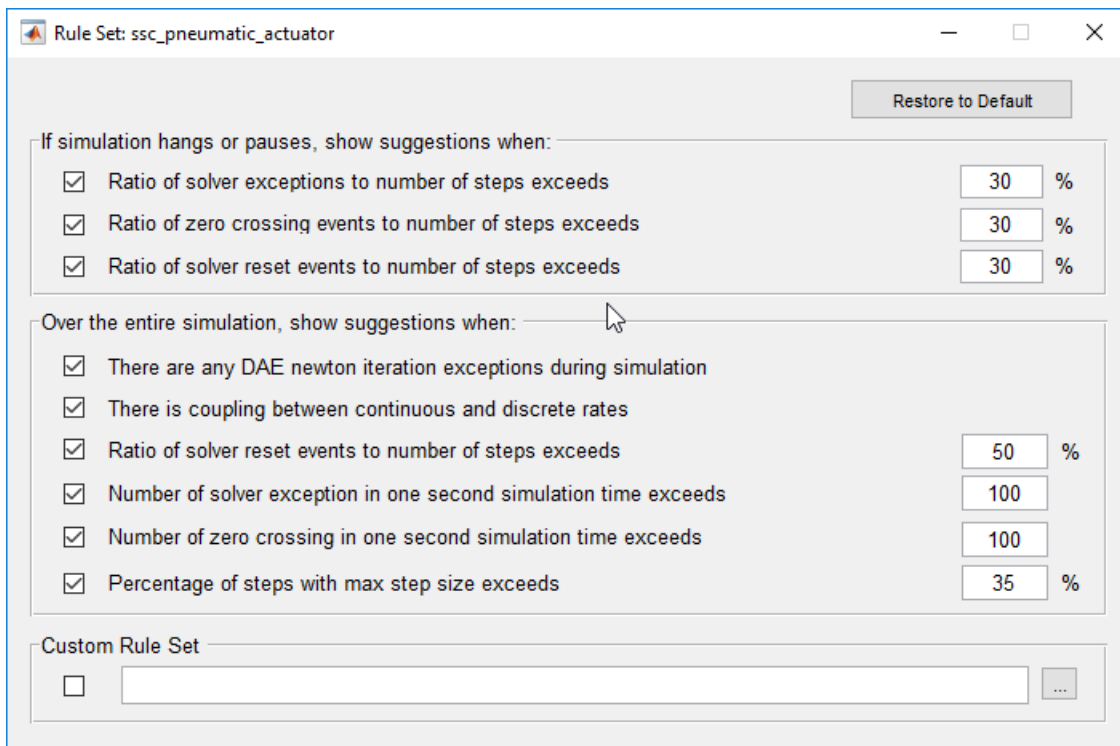

Modify Solver Profiler Rules

You can customize the suggestions that appear in the Solver Profiler in these ways:

- Change the thresholds of the Solver Profiler rules that detect failure patterns.
- Select which rules to apply during a profiling run.
- Author your own rule set as a MATLAB script.

Change Thresholds of Profiler Rules

Click **Rule Customization** in the Solver Profiler to access the rule set. You can change the thresholds for most of these rules and also select which rules you want to apply selectively during a simulation run.

Develop Profiler Rule Set

You can override the settings on the **Rule Set** dialog box by specifying a custom rule set.

Create a rule set as a MATLAB script and specify the path to the script in the **Custom Rule Set** section of the **Rule Set** dialog box.

A simple rule set example looks as follows:

```
function diagnosticsString = customRule(profilerData)
    if isempty(profilerData.zcEvents)
        diagnosticsString{1} = 'No zero crossing event detected.';
    else
```

```

        diagnosticsString{1} = 'Zero-crossing events detected.';
    end
end

```

The input to the function is an array of structures called `profilerData`. This array of structures organizes all the information that the Solver Profiler collects during a profiling run. It contains the following substructures.

Substructure	Fields
<code>stateInfo</code> : Stores information on block states	<ul style="list-style-type: none"> • <code>name</code>: Block name • <code>value</code>: State values • <code>blockIdx</code>: Block ID
<code>blockInfo</code> : Cross-reference of blocks and state IDs	<ul style="list-style-type: none"> • <code>name</code>: Block name • <code>stateIdx</code>: State ID
<code>zcSrcInfo</code> : Stores information on blocks causing zero crossing events	<ul style="list-style-type: none"> • <code>name</code>: Block name • <code>blockIdx</code>: Block ID
<code>zcEvents</code> : Cross-reference of the time stamps of zero crossing events and the corresponding state IDs	<ul style="list-style-type: none"> • <code>t</code>: Event timestamp • <code>srcIdx</code>: Block ID
<code>exceptionEvents</code> : Cross-reference of exception event timestamps, the ID of the corresponding state that caused the event, and the cause.	<ul style="list-style-type: none"> • <code>t</code>: Event timestamp • <code>stateIdx</code>: State ID • <code>cause</code>: Cause of exception
<code>resetTime</code> : Stores timestamps of solver resets.	None
<code>tout</code> : Stores simulation times.	None

Note The structures referenced in this example organize information that the Solver Profiler collects during a profiling run. For more information on the structures, see “Develop Profiler Rule Set” on page 33-22.

```
function [index,score] = customRank(sd,tl,tr)

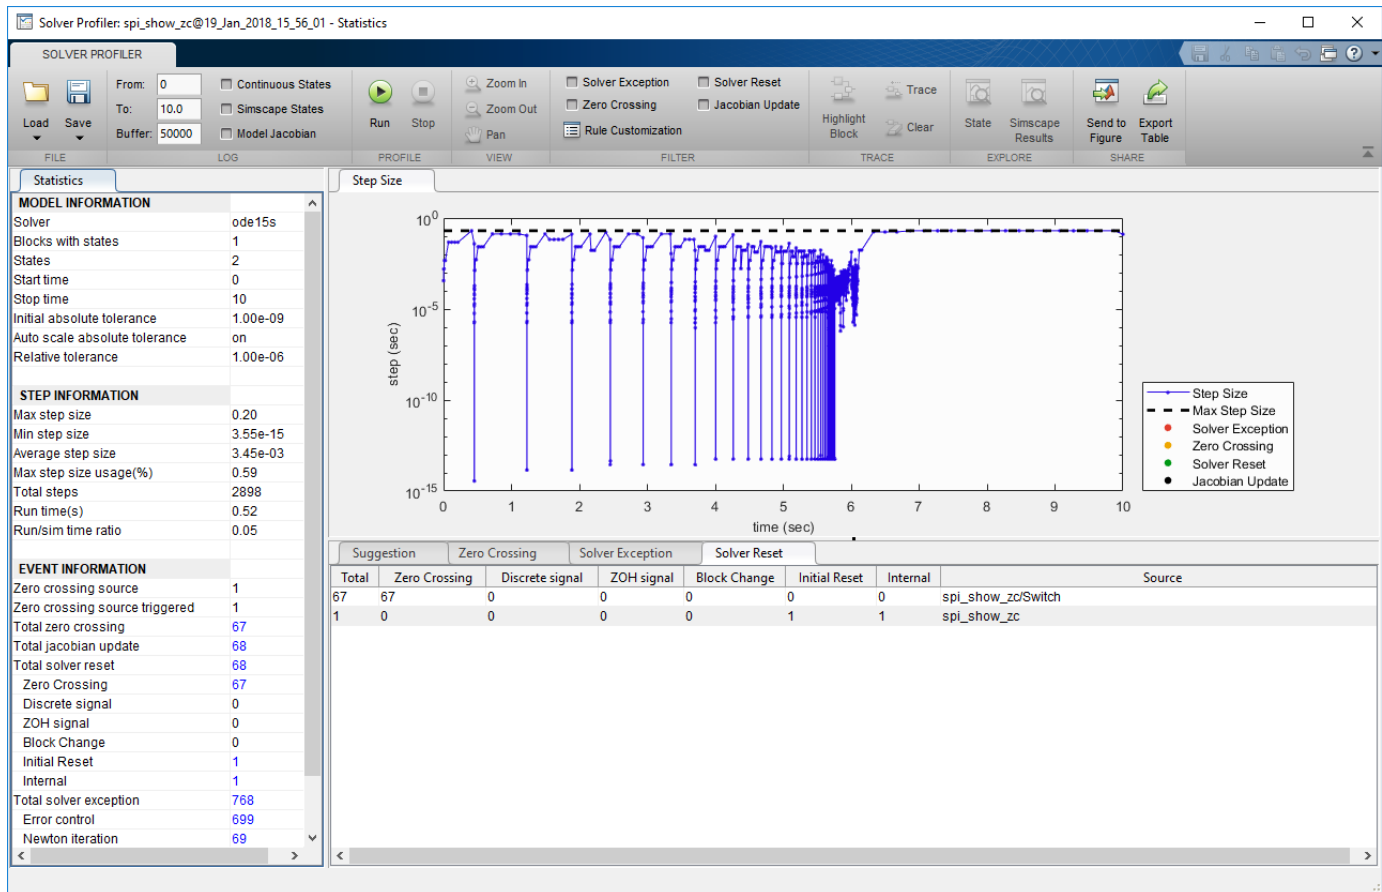

% Allocate storage for index and score list
nStates = length(sd.stateInfo);
index = 1:nStates;
score = zeros(nStates,1);

% Loop through each state to calculate score
for i = 1:nStates
    x = sd.stateInfo(i).value;
    % apply time range constraints
    x = x(sd.tout>=tl & sd.tout<=tr);
    if max(x) > 1
        score(i) = 1;
    else
        score(i) = 0;
    end
end

% Rank the states
[score, order] = sort(score, 'descend');
index = index(order);

end
```

Solver Profiler Interface

The Solver Profiler enables you to:

- Start a profiling session, save a session, or open a saved session.
- Customize and filter the results displayed.
- Interact with the model and trace and highlight the states that contain exceptions.
- Open Simscape Explorer or States Explorer to analyze simulation data further.
- Customize profiler suggestions using your own rules.

Statistics Pane

The statistics pane displays information on model parameters, including:

- **Average step size** — A measure of how fast the solver advances. It is calculated as the total simulation time divided by the number of steps the solver used. It is bounded by the model configuration parameters **Max step size** and **Min step size**.
- **Max step size usage** — The percentage of maximum step sizes used by the solver among all step sizes.

- **Zero crossing** — A solver-specific event that affects model dynamics. During simulation, the solver detects zero crossing. Zero crossing detection incurs computation cost. For more information, see “Zero-Crossing Detection” on page 3-10.
- **Solver reset** — An event that causes the solver to reset its parameters. Solver reset detection incurs computation cost. The solver reset statistics are broken down into **Zero Crossing**, **Discrete Signal**, **ZOH Signal**, **Block Change**, **Initial Reset**, and **Internal** solver reset events. For more information, see “Solver Resets” on page 33-14
- **Solver exception** — An event that renders the solver unable to solve model states to meet accuracy specifications. To solve model states accurately, the solver has to run a few adjusted trials, which incur computation cost.
- **Error control exception** — An event where a solution obtained by the solver has an error that is greater than the tolerance specification.
- **Newton iteration exception** — An event specific to implicit solvers. Newton iterations do not converge after a few trials.
- **Infinite state exception** — An event where one or more states solved by the solver are infinite.
- **DAE newton iteration exception** — An event specific to implicit solvers for Simscape models. The Newton iteration does not converge even though the solver violates the minimum step size constraint.

Suggestions and Exceptions Pane

The suggestions and exceptions pane displays information on exceptions, including:

- **Zero crossing** — A solver-specific event that affects model dynamics. During simulation, the solver detects zero crossing. Zero crossing detection incurs computation cost. For more information, see “Zero-Crossing Detection” on page 3-10.
- **Solver reset** — An event that causes the solver to reset its parameters. Solver reset detection incurs computation cost. The solver reset statistics are broken down into **Zero Crossing**, **Discrete Signal**, **ZOH Signal**, **Block Change**, **Initial Reset**, and **Internal** solver reset events. For more information, see “Solver Resets” on page 33-14
- **Solver exception** — An event that renders the solver unable to solve model states to meet accuracy specifications. To solve model states accurately, the solver has to run a few adjusted trials, which incur computation cost.
- **Error control exception** — An event where a solution obtained by the solver has an error that is greater than the tolerance specification.
- **Newton iteration exception** — An event specific to implicit solvers. Newton iterations do not converge after a few trials.
- **Infinite state exception** — An event where one or more states solved by the solver are infinite.
- **DAE newton iteration exception** — An event specific to implicit solvers for Simscape models. The Newton iteration does not converge even though the solver violates the minimum step size constraint.

- “Display Information About the Model” on page 34-28

Introduction to the Debugger

With the debugger, you run your simulation method by method. You can stop after each method to examine the execution results. In this way, you can pinpoint problems in your model to specific blocks, parameters, or interconnections.

Note Methods are functions that the Simulink software uses to solve a model at each time step during the simulation. Blocks are made up of multiple methods. “Block execution” in this documentation is shorthand for “block methods execution.” Block diagram execution is a multi-step operation that requires execution of the different block methods in all the blocks in a diagram at various points during the process of solving a model at each time step during simulation, as specified by the simulation loop.

The debugger has both a graphical and a command-line user interface. The graphical interface allows you to access the most commonly used features of the debugger. The command-line interface gives you access to all of the capabilities in the debugger. If you can use either to perform a task, the documentation shows you first how to use the graphical interface, “Debugger Graphical User Interface” on page 34-3, and then the command-line interface, “Debugger Command-Line Interface” on page 34-8.

All functions such as `atrace` and `ashow` can only be used within the debugger.

Debugger Graphical User Interface

In this section...

“Displaying the Graphical Interface” on page 34-3

“Toolbar” on page 34-3

“Breakpoints Pane” on page 34-4

“Simulation Loop Pane” on page 34-5

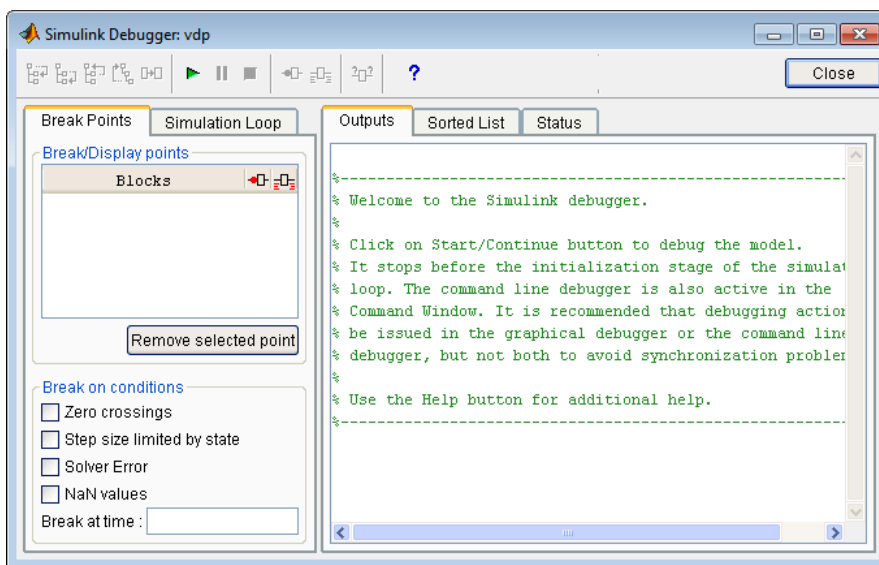

“Outputs Pane” on page 34-6

“Sorted List Pane” on page 34-6

“Status Pane” on page 34-7

Displaying the Graphical Interface

On the **Debug** tab, select **Breakpoints List > Debug Model** to display the debugger graphical interface.

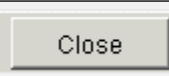

Note The debugger graphical user interface does not display state or solver information. The command line interface does provide this information. See “Display System States” on page 34-26 and “Display Solver Information” on page 34-26.

Toolbar

The debugger toolbar appears at the top of the debugger window.

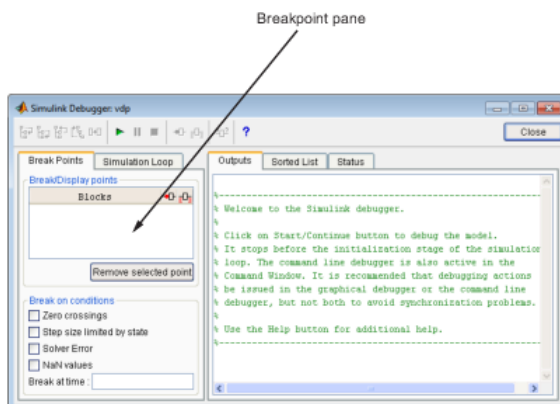

From left to right, the toolbar contains the following command buttons:

Button	Purpose
	Step into the next method (see “Stepping Commands” on page 34-16 for more information on this command, and the following stepping commands).
	Step over the next method.
	Step out of the current method.
	Step to the first method at the start of next time step.
	Step to the next block method.
	Start or continue the simulation.
	Pause the simulation.
	Stop the simulation.
	Break before the selected block.
	Display inputs and outputs of the selected block when executed (same as trace gcb).
	Display the current inputs and outputs of selected block (same as probe gcb).
	Display help for the debugger.
	Close the debugger.

Breakpoints Pane

To display the **Breakpoints** pane, select the **Break Points** tab on the debugger window.

The **Breakpoints** pane allows you to specify block methods or conditions at which to stop a simulation. See “Set Breakpoints” on page 34-19 for more information.

Simulation Loop Pane

To display the **Simulation Loop** pane, select the **Simulation Loop** tab on the debugger window.

The **Simulation Loop** pane contains three columns:

- Method
- Breakpoints
- ID

Method Column

The **Method** column lists the methods that have been called thus far in the simulation as a method tree with expandable/collapsible nodes. Each node of the tree represents a method that calls other methods. Expanding a node shows the methods that the block method calls. Clicking a block method name highlights the corresponding block in the model diagram.

Whenever the simulation stops, the debugger highlights the name of the method where the simulation has stopped as well as the methods that invoked it. The highlighted method names indicate the current state of the method call stack.

Breakpoints Column

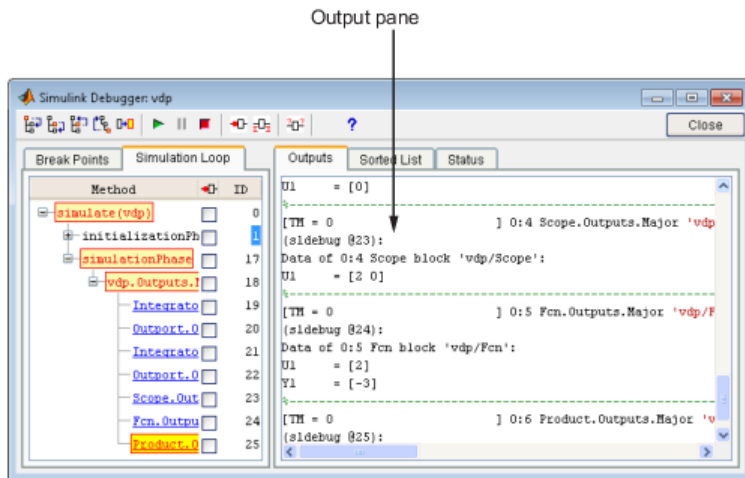

The breakpoints column consists of check boxes. Selecting a check box sets a breakpoint at the method whose name appears to the left of the check box. See “Setting Breakpoints from the Simulation Loop Pane” on page 34-20 for more information.

ID Column

The ID column lists the IDs of the methods listed in the **Methods** column. See “Method ID” on page 34-8 for more information.

Outputs Pane

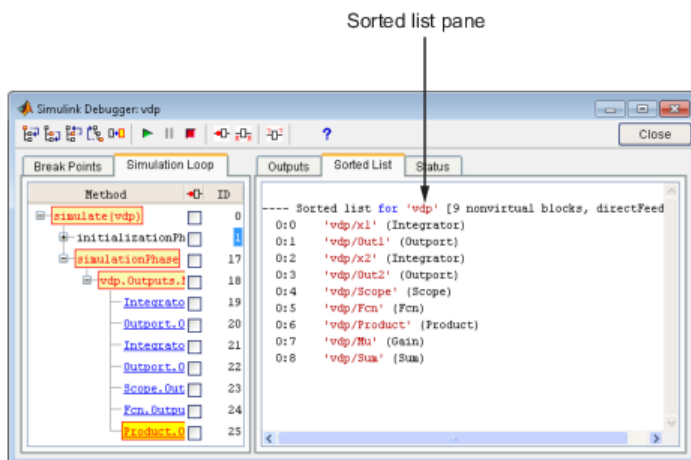

To display the **Outputs** pane, select the **Outputs** tab on the debugger window.

The Outputs pane displays the same debugger output that would appear in the MATLAB command window if the debugger were running in command-line mode. The output includes the debugger command prompt and the inputs, outputs, and states of the block at whose method the simulation is currently paused (see “Block Data Output” on page 34-16). The command prompt displays current simulation time and the name and index of the method in which the debugger is currently stopped (see “Block ID” on page 34-8).

Sorted List Pane

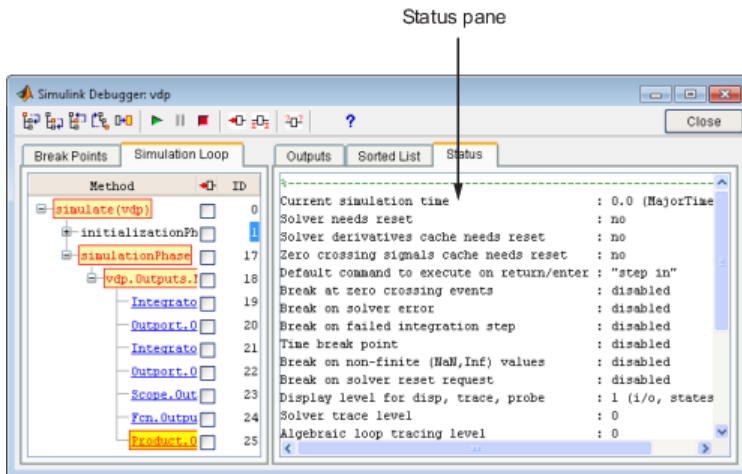

To display the **Sorted List** pane, select the **Sorted List** tab on the debugger window.

The **Sorted List** pane displays the sorted lists for the model being debugged. See “Display Model’s Sorted Lists” on page 34-28 for more information.

Status Pane

To display the **Status** pane, select the **Status** tab on the debugger window.

The **Status** pane displays the values of various debugger options and other status information.

More About

- “Debugger Command-Line Interface” on page 34-8
- “Debugger Online Help” on page 34-10

Debugger Command-Line Interface

In this section...

“Controlling the Debugger” on page 34-8

“Method ID” on page 34-8

“Block ID” on page 34-8

“Accessing the MATLAB Workspace” on page 34-8

Controlling the Debugger

In command-line mode, you control the debugger by entering commands at the debugger command line in the MATLAB Command Window. To enter commands at the debugger command line, you must start the debugger programmatically and not through the GUI. Use `sldebug` for this purpose. The debugger accepts abbreviations for debugger commands. For more information on debugger commands, see “Simulink Debugger”.

Note You can repeat some commands by entering an empty command (i.e., by pressing the **Enter** key) at the command line.

Method ID

Some of the Simulink software commands and messages use method IDs to refer to methods. A method ID is an integer assigned to a method the first time the method is invoked. The debugger assigns method IDs sequentially, starting with 0.

Block ID

Some of the debugger commands and messages use block IDs to refer to blocks. Block IDs are assigned to blocks while generating the model's sorted lists during the compilation phase of the simulation. A block ID has the form `sysIdx:blkIdx`, where `sysIdx` is an integer identifying the system that contains the block (either the root system or a nonvirtual subsystem) and `blkIdx` is the position of the block in the system's sorted list. For example, the block ID `0:1` refers to the first block in the model's root system. The `slist` command shows the block ID for each debugged block in the model.

Accessing the MATLAB Workspace

You can enter any MATLAB expression at the `sldebug` prompt. For example, suppose you are at a breakpoint and you are logging time and output of your model as `tout` and `yout`. The following command creates a plot.

```
(sldebug ...) plot(tout, yout)
```

You cannot display the value of a workspace variable whose name is partially or entirely the same as that of a debugger command by entering it at the debugger command prompt. You can, however, use the `eval` command to work around this problem. For example, use `eval('s')` to determine the value of `s` rather than `step` the simulation.

Debugger Online Help

You can get online help on using the debugger by clicking the **Help** button on the debugger toolbar. Clicking the **Help** button displays help for the debugger in the MATLAB product Help browser.

In command-line mode, you can get a brief description of the debugger commands by typing `help` at the debug prompt.

Start the Simulink Debugger

In this section...
“Starting from a Model Window” on page 34-11
“Starting from the Command Window” on page 34-11

You can start the debugger from either a Simulink model window or from the MATLAB Command Window.

Starting from a Model Window

- 1 In a model window, on the **Debug** tab, select **Breakpoints List > Debug Model**.

The debugger graphical user interface opens. See “Debugger Graphical User Interface” on page 34-3.

- 2 Continue selecting toolbar buttons.

Note When running the debugger in graphical user interface (GUI) mode, you must explicitly start the simulation. For more information, see “Start a Simulation” on page 34-13.

Note When starting the debugger from the GUI, you cannot enter debugger commands in the MATLAB command window. For this, you must start the debugger from the command window using the `sim` or `sldebug` commands.

Starting from the Command Window

- 1 In the MATLAB Command Window, enter either

- the `sim` command. For example, enter

```
sim('vdp', 'StopTime', '10', 'debug', 'on')
```
- or the `sldebug` command. For example, enter

```
sldebug 'vdp'
```

In both cases, the example model `vdp` loads into memory, starts the simulation, and stops the simulation at the first block in the model execution list.

- 2 The debugger opens and a debugger command prompt appears within the MATLAB command window. Continue entering debugger commands at this debugger prompt.

Start a Simulation

To start the simulation, click the **Start/Continue** button on the debugger toolbar.

The simulation starts and stops at the first simulation method that is to be executed. It displays the name of the method in its **Simulation Loop** pane. At this point, you can

- Set breakpoints.
- Run the simulation step by step.
- Continue the simulation to the next breakpoint or end.
- Examine data.
- Perform other debugging tasks.

The debugger displays the name of the method in the Simulation Loop pane, as shown in the following figure:

The following sections explain how to use the debugger controls to perform these debugging tasks.

Note When you start the debugger in GUI mode, the debugger command-line interface is also active in the MATLAB Command Window. However, to prevent synchronization errors between the graphical and command-line interfaces, you should avoid using the command-line interface.

Run a Simulation Step by Step

In this section...

“Introduction” on page 34-15
 “Block Data Output” on page 34-16
 “Stepping Commands” on page 34-16
 “Continuing a Simulation” on page 34-17
 “Running a Simulation Nonstop” on page 34-17

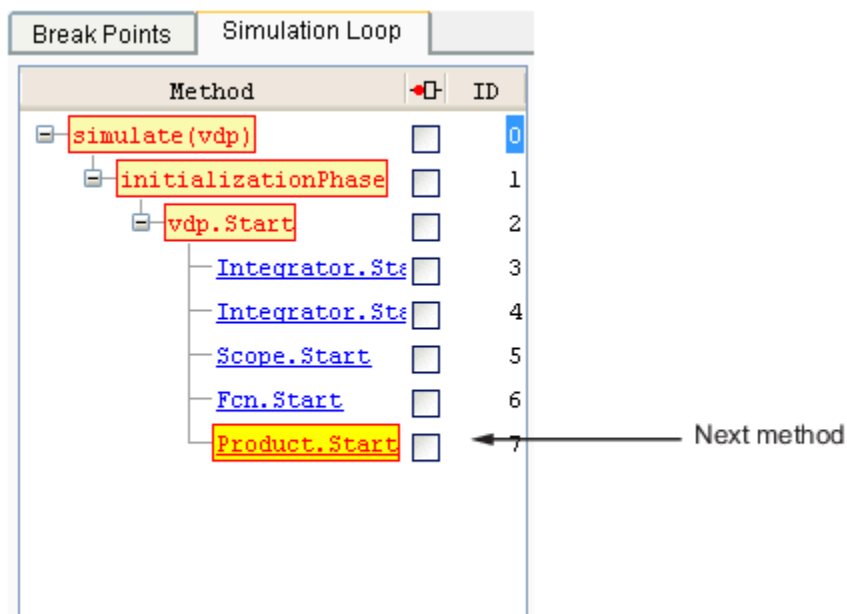

Introduction

The debugger provides various commands that let you advance a simulation from the method where it is currently suspended (the next method) by various increments (see “Stepping Commands” on page 34-16). For example, you can advance the simulation

- Into or over the next method
- Out of the current method
- To the top of the simulation loop.

After each advance, the debugger displays information that enables you to determine the point to which the simulation has advanced and the results of advancing the simulation to that point.

For example, in GUI mode, after each step command, the debugger highlights the current method call stack in the **Simulation Loop** pane. The call stack comprises the next method and the methods that invoked the next method either directly or indirectly. The debugger highlights the call stack by highlighting the names of the methods that make up the call stack in the **Simulation Loop** pane.

In command-line mode, you can use the `where` command to display the method call stack.

Block Data Output

After executing a block method, the debugger prints any or all of the following block data in the debugger **Output** panel (in GUI mode) or, if in command line mode, the MATLAB Command Window:

- $U_n = v$

where v is the current value of the block's n th input.

- $Y_n = v$

where v is the current value of the block's n th output.

- $CSTATE = v$

where v is the value of the block's continuous state vector.

- $DSTATE = v$

where v is the value of the block's discrete state vector.

The debugger also displays the current time, the ID and name of the next method to be executed, and the name of the block to which the method applies in the MATLAB Command Window. The following example illustrates typical debugger outputs after a step command.

```

Current time                                Next method
      ↓                                     ↓
-----
[Tm = 2.009509145207664e-05 ] 0:2 Integrator.Derivatives 'vdp/x2'
(sldebug @49):
Data of 0:2 Integrator block 'vdp/x2':
U1    = [-1.9998794294512876]
Y1    = [-4.0190182904153282e-05]
CSTATE = [-4.0190182904153282e-05]
-----
[Tm = 3.014263717811496e-05 ] vdp.Outputs.Minor

```

Stepping Commands

Command-line mode provides the following commands for advancing a simulation incrementally:

This command...	Advances the simulation...
step [in into]	Into the next method, stopping at the first method in the next method or, if the next method does not contain any methods, at the end of the next method
step over	To the method that follows the next method, executing all methods invoked directly or indirectly by the next method
step out	To the end of the current method, executing any remaining methods invoked by the current method

This command...	Advances the simulation...
step top	To the first method of the next time step (i.e., the top of the simulation loop)
step blockmth	To the next block method to be executed, executing all intervening model- and system-level methods
next	Same as step over

Buttons in the debugger toolbar allow you to access these commands in GUI mode.

Clicking a button has the same effect as entering the corresponding command at the debugger command line.

Continuing a Simulation

In GUI mode, the **Stop** button turns red when the debugger suspends the simulation for any reason. To continue the simulation, click the **Start/Continue** button. In command-line mode, enter `continue` to continue the simulation. By default, the debugger runs the simulation to the next breakpoint (see “Set Breakpoints” on page 34-19) or to the end of the simulation, whichever comes first.

Running a Simulation Nonstop

The `run` command lets you run a simulation to the end of the simulation, skipping any intervening breakpoints. At the end of the simulation, the debugger returns you to the command line. To continue debugging a model, you must restart the debugger.

Note The GUI mode does not provide a graphical version of the `run` command. To run the simulation to the end, you must first clear all breakpoints and then click the **Start/Continue** button.

Set Breakpoints

In this section...

“About Breakpoints” on page 34-19

“Setting Unconditional Breakpoints” on page 34-19

“Setting Conditional Breakpoints” on page 34-21

About Breakpoints

The debugger allows you to define stopping points called breakpoints in a simulation. You can then run a simulation from breakpoint to breakpoint, using the debugger `continue` command. The debugger lets you define two types of breakpoints: unconditional and conditional. An unconditional breakpoint occurs whenever a simulation reaches a method that you specified previously. A conditional breakpoint occurs when a condition that you specified in advance arises in the simulation.

Breakpoints are useful when you know that a problem occurs at a certain point in your program or when a certain condition occurs. By defining an appropriate breakpoint and running the simulation via the `continue` command, you can skip immediately to the point in the simulation where the problem occurs.

Note When you stop a simulation at a breakpoint of a MATLAB S-function in the debugger, to exit MATLAB, you must first quit the debugger.

Setting Unconditional Breakpoints

You can set unconditional breakpoints from the:

- Debugger toolbar
- **Simulation Loop** pane
- MATLAB product Command Window (command-line mode only)

Setting Breakpoints from the Debugger Toolbar

To enable the **Breakpoint** button,

- 1 Simulate the model.
- 2 Click the **Step over current method** button until `simulationPhase` is highlighted.
- 3 Click the **Step into current method** button.

The debugger displays the name of the selected block in the **Break/Display points** panel of the **Breakpoints** pane.

Note Clicking the **Breakpoint** button on the toolbar sets breakpoints on the invocations of a block's methods in major time steps.

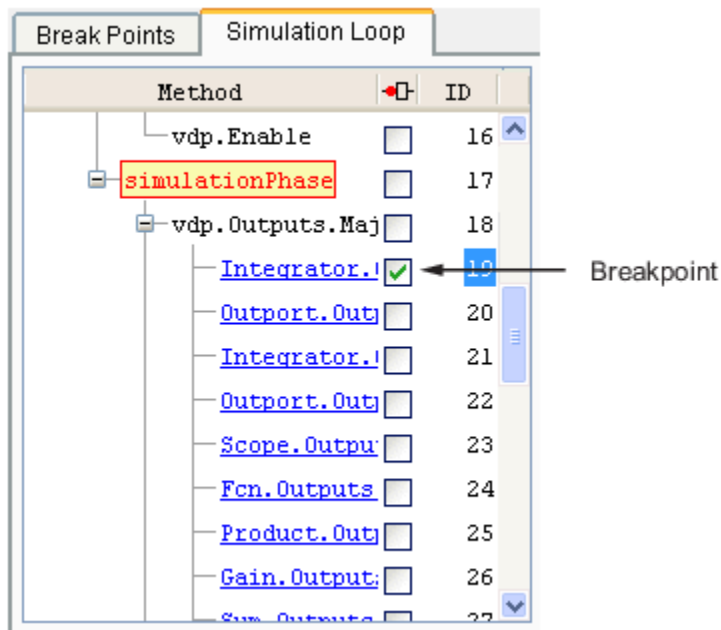

You can temporarily disable the breakpoints on a block by deselecting the check box in the breakpoints column of the panel. To clear the breakpoints on a block and remove its entry from the panel,

- 1 Select the entry.
- 2 Click the **Remove selected point** button on the panel.

Note You cannot set a breakpoint on a virtual block. A virtual block is purely graphical: it indicates a grouping or relationship among a model's computational blocks. The debugger warns you if you try to set a breakpoint on a virtual block. You can get a listing of a model's nonvirtual blocks, using the `slist` command (see "Displaying a Model's Nonvirtual Blocks" on page 34-29).

Setting Breakpoints from the Simulation Loop Pane

To set a breakpoint at a particular invocation of a method displayed in the Simulation Loop pane, select the check box next to the method's name in the breakpoint column of the pane.

To clear the breakpoint, deselect the check box.

Setting Breakpoints from the Command Window

In command-line mode, use the `break` and `bafter` commands to set breakpoints before or after a specified method, respectively. Use the `clear` command to clear breakpoints.

Setting Conditional Breakpoints

You can use either the **Break on conditions** controls group on the debugger **Breakpoints** pane

or the following commands (in command-line mode) to set conditional breakpoints.

This command...	Causes the Simulation to Stop...
<code>tbreak [t]</code>	At a simulation time step
<code>ebreak</code>	At a recoverable error in the model
<code>nanbreak</code>	At the occurrence of an underflow or overflow (NaN) or infinite (Inf) value
<code>xbreak</code>	When the simulation reaches the state that determines the simulation step size
<code>zcbreak</code>	When a zero crossing occurs between simulation time steps

Setting Breakpoints at Time Steps

To set a breakpoint at a time step, enter a time in the debugger **Break at time** field (GUI mode) or enter the time using the `tbreak` command. This causes the debugger to stop the simulation at the `Outputs.Major` method of the model at the first time step that follows the specified time. For example, starting `vdp` in debug mode and entering the commands

```
tbreak 2
continue
```

causes the debugger to halt the simulation at the `vdp.Outputs.Major` method of time step 2.078 as indicated by the output of the `continue` command.

```
%-----%
[tm = 2.034340153847549      ] vdp.Outputs.Minor
(sldebug @37):
```

Breaking on Nonfinite Values

Selecting the debugger **NaN values** option or entering the `nanbreak` command causes the simulation to stop when a computed value is infinite or outside the range of values that is supported by the machine running the simulation. This option is useful for pinpointing computational errors in a model.

Breaking on Step-Size Limiting Steps

Selecting the **Step size limited by state** option or entering the `xbreak` command causes the debugger to stop the simulation when the model uses a variable-step solver and the solver encounters a state that limits the size of the steps that it can take. This command is useful in debugging models that appear to require an excessive number of simulation time steps to solve.

Breaking at Zero Crossings

Selecting the **Zero crossings** option or entering the `zcbreak` command causes the simulation to halt when a nonsampled zero crossing is detected in a model that includes blocks where zero crossings can arise. After halting, the ID, type, and name of the block in which the zero crossing was detected is displayed. The block ID (`s:b:p`) consists of a system index `s`, block index `b`, and port index `p` separated by colons (see “Block ID” on page 34-8).

For example, setting a zero-crossing break at the start of execution of the `zeroxing` example model,

```
>> sldebug zeroxing
%-----%
%
[tm = 0                      ] zeroxing.Simulate
(sldebug @0): >> zcbreak
Break at zero crossing events      : enabled
```

and continuing the simulation

```
(sldebug @0): >> continue
```

results in a zero-crossing break at

```
Interrupting model execution before running mdlOutputs at the left post of
(major time step just before) zero crossing event detected at the following location:
 6[-0] 0:5:2 Saturate 'zeroxing/Saturation'
%-----%
```

```
[TzL= 0.3435011087932808 ] zeroxing.Outputs.Major  
(sldebug @16): >>
```

If a model does not include blocks capable of producing nonsampled zero crossings, the command prints a message advising you of this fact.

Breaking on Solver Errors

Selecting the debugger **Solver Errors** option or entering the `ebreak` command causes the simulation to stop if the solver detects a recoverable error in the model. If you do not set or disable this breakpoint, the solver recovers from the error and proceeds with the simulation without notifying you.

Display Information About the Simulation

In this section...

“Display Block I/O” on page 34-24

“Display Algebraic Loop Information” on page 34-25

“Display System States” on page 34-26

“Display Solver Information” on page 34-26

Display Block I/O

The debugger allows you to display block I/O by clicking the appropriate buttons on the debugger toolbar

or by entering the appropriate debugger command.

This command...	Displays a Blocks I/O...
probe	Immediately
disp	At every breakpoint any time execution stops
trace	Whenever the block executes

Note The two debugger toolbar buttons, Watch Block I/O () and Display Block I/O () correspond, respectively, to `trace gcb` and `probe gcb`. The `probe` and `disp` commands do not have a one-to-one correspondence with the debugger toolbar buttons.

Displaying I/O of a Selected Block

To display the I/O of a block, select the block and click  in GUI mode or enter the `probe` command in command-line mode. In the following table, the `probe gcb` command has a corresponding toolbar button. The other commands do not.

Command	Description
probe	Enter or exit probe mode. Typing any command causes the debugger to exit probe mode.
probe gcb	Display I/O of selected block. Same as  .
probe s:b	Print the I/O of the block specified by system number <code>s</code> and block number <code>b</code> .

The debugger prints the current inputs, outputs, and states of the selected block in the debugger **Outputs** pane (GUI mode) or the Command Window of the MATLAB product.

The `probe` command is useful when you need to examine the I/O of a block whose I/O is not otherwise displayed. For example, suppose you are using the `step` command to run a model method by method. Each time you step the simulation, the debugger displays the inputs and outputs of the current block. The `probe` command lets you examine the I/O of other blocks as well.

Displaying Block I/O Automatically at Breakpoints

The `disp` command causes the debugger to display a specified block's inputs and outputs whenever it halts the simulation. You can specify a block by entering its block index and entering `gcb` as the `disp` command argument. You can remove any block from the debugger list of display points, using the `undisp` command. For example, to remove block `0:0`, enter `undisp 0:0`.

Note Automatic display of block I/O at breakpoints is not available in the debugger GUI mode.

The `disp` command is useful when you need to monitor the I/O of a specific block or set of blocks as you step through a simulation. Using the `disp` command, you can specify the blocks you want to monitor and the debugger will then redisplay the I/O of those blocks on every step. Note that the debugger always displays the I/O of the current block when you step through a model block by block, using the `step` command. You do not need to use the `disp` command if you are interested in watching only the I/O of the current block.

Watching Block I/O

To watch a block, select the block and click  in the debugger toolbar or enter the `trace` command. In GUI mode, if a breakpoint exists on the block, you can set a watch on it as well by selecting the check box for the block in the watch column  of the **Break/Display points** pane. In command-line mode, you can also specify the block by specifying its block index in the `trace` command. You can remove a block from the debugger list of trace points using the `untrace` command.

The debugger displays a watched block's I/O whenever the block executes. Watching a block allows you obtain a complete record of the block's I/O without having to stop the simulation.

Display Algebraic Loop Information

The `atrace` command causes the debugger to display information about a model's algebraic loops (see "Algebraic Loop Concepts" on page 3-27) each time they are solved. The command takes a single argument that specifies the amount of information to display.

This command...	Displays for each algebraic loop...
<code>atrace 0</code>	No information
<code>atrace 1</code>	The loop variable solution, the number of iterations required to solve the loop, and the estimated solution error
<code>atrace 2</code>	Same as level 1
<code>atrace 3</code>	Level 2 plus the Jacobian matrix used to solve the loop
<code>atrace 4</code>	Level 3 plus intermediate solutions of the loop variable

Display System States

The `states` debug command lists the current values of the system states in the MATLAB Command Window. For example, the following sequence of commands shows the states of the bouncing ball example (`sldemo_bounce`) after its first, second, and third time steps. However, before entering the debugger, open the Configuration Parameters dialog box and clear the **Block reduction** and **Signal storage reuse** check boxes.

```
sldebug sldemo_bounce
%-----%
[TM = 0 ] simulate(sldemo_bounce)
(sldebug @0): >> step top
%-----%
[TM = 0 ] sldemo_bounce.Outputs.Major
(sldebug @16): >> next
%-----%
[TM = 0 ] sldemo_bounce.Update
(sldebug @23): >> states

Continuous States:
Idx Value (system:block:element Name 'BlockName')
 0 10 (0:4:0 CSTATE 'sldemo_bounce/Second-Order Integrator')
 1. 15 (0:4:1)

(sldebug @23): >> next
%-----%
[tm = 0 ] solverPhase
(sldebug @26): >> states

Continuous States:
Idx Value (system:block:element Name 'BlockName')
 0 10 (0:4:0 CSTATE 'sldemo_bounce/Second-Order Integrator')
 1. 15 (0:4:1)

(sldebug @26): >> next
%-----%
[TM = 0.01 ] sldemo_bounce.Outputs.Major
(sldebug @16): >> states

Continuous States:
Idx Value (system:block:element Name 'BlockName')
 0 10.1495095 (0:4:0 CSTATE 'sldemo_bounce/Second-Order Integrator')
 1. 14.9019 (0:4:1)
```

Display Solver Information

The `strace` command allows you to pinpoint problems in solving a models differential equations that can slow down simulation performance. Executing this command causes the debugger to display solver-related information at the command line of the MATLAB product when you run or step through a simulation. The information includes the sizes of the steps taken by the solver, the estimated integration error resulting from the step size, whether a step size succeeded (i.e., met the accuracy requirements that the model specifies), the times at which solver resets occur, etc. If you are concerned about the time required to simulate your model, this information can help you to decide whether the solver you have chosen is the culprit and hence whether choosing another solver might shorten the time required to solve the model.

Display Information About the Model

In this section...

"Display Model's Sorted Lists" on page 34-28

"Display a Block" on page 34-29

Display Model's Sorted Lists

In GUI mode, the debugger **Sorted List** pane displays lists of blocks for a model's root system and each nonvirtual subsystem. Each list lists the blocks that the subsystem contains sorted according to their computational dependencies, alphabetical order, and other block sorting rules. In command-line mode, you can use the `slist` command to display a model's sorted lists.

```

---- Sorted list for 'vdp' [11 nonvirtual block(s), directFeed=0]
      Total number of tasks = 2
- Sorted list of task index [0], 10 nonvirtual block(s)
(0)0:1  'vdp/x1' (Integrator)
        Input ports: [0]
        Output ports: [0]
(0)0:2  'vdp/Out1' (Outport)
        Input ports: [0]
        Output ports: []
(0)0:3  'vdp/x2' (Integrator)
        Input ports: [0]
        Output ports: [0]
(0)0:4  'vdp/Out2' (Outport)
        Input ports: [0]
        Output ports: []
(0)0:5  'vdp/Scope' (Scope)
        Input ports: [0]
        Output ports: []
(0)0:6  'vdp/Square' (Math)
        Input ports: [0]
        Output ports: [0]
(0)0:7  'vdp/Sum1' (Sum)
        Input ports: [0 1]
        Output ports: [0]
(0)0:8  'vdp/Product' (Product)
        Input ports: [0 1]
        Output ports: [0]
(0)0:9  'vdp/Mu' (Gain)
        Input ports: [0]
        Output ports: [0]
(0)0:10 'vdp/Sum' (Sum)
        Input ports: [0 1]
        Output ports: [0]

- Sorted list of task index [1], 1 nonvirtual block(s)
(1)0:1  'vdp/Constant' (Constant)
        Input ports: []
        Output ports: [0]

----- Task Index Legend -----
Task Index [0]: Cont

```

Task Index [1]: Constant

These displays include the block index for each command. You can use them to determine the block IDs of the models blocks. Some debugger commands accept block IDs as arguments.

Identifying Blocks in Algebraic Loops

If a block belongs to an algebraic list, the `slist` command displays an algebraic loop identifier in the entry for the block in the sorted list. The identifier has the form

```
algId=s#n
```

where `s` is the index of the subsystem containing the algebraic loop and `n` is the index of the algebraic loop in the subsystem. For example, the following entry for an Integrator block indicates that it participates in the first algebraic loop at the root level of the model.

```
0:1 'test/ss/I1' (Integrator, tid=0) [algId=0#1, discontinuity]
```

When the debugger is running, you can use the `ashow` command at the debugger command-line interface to highlight the blocks and lines that make up an algebraic loop. See “Displaying Algebraic Loops” on page 34-30 for more information.

Display a Block

To determine the block in a models diagram that corresponds to a particular index, enter `bshow s:b` at the command prompt, where `s:b` is the block index. The `bshow` command opens the system containing the block (if necessary) and selects the block in the systems window.

Displaying a Model's Nonvirtual Systems

The `systems` command displays a list of the nonvirtual systems in the model that you are debugging. For example, the `sldemo_clutch` model contains the following systems:

```
openExample('sldemo_clutch')
set_param(gcs, 'OptimizeBlockIOStorage','off')
sldebug sldemo_clutch
(sldebug @0): %-----%
[TM = 0 ] simulate(sldemo_clutch)
(sldebug @0): >> systems
0 'sldemo_clutch'
1 'sldemo_clutch/Locked'
2 'sldemo_clutch/Unlocked'
```

Note The `systems` command does not list subsystems that are purely graphical. That is, subsystems that the model diagram represents as Subsystem blocks but that are solved as part of a parent system. are not listed. In Simulink models, the root system and triggered or enabled subsystems are true systems. All other subsystems are virtual (that is, graphical) and do not appear in the listing from the `systems` command.

Displaying a Model's Nonvirtual Blocks

The `slist` command displays a list of the nonvirtual blocks in a model. The listing groups the blocks by system. For example, the following sequence of commands produces a list of the nonvirtual blocks in the Van der Pol (`vdp`) example model.

```

sldebug vdp
%-----%
[TM = 0                                ] simulate(vdp)
sldebug @0): >> slist

---- Sorted list for 'vdp' [9 nonvirtual blocks, directFeed=0]
 0:0   'vdp/x1' (Integrator)
 0:1   'vdp/Out1' (Outport)
 0:2   'vdp/x2' (Integrator)
 0:3   'vdp/Out2' (Outport)
 0:4   'vdp/Scope' (Scope)
 0:5   'vdp/Fcn' (Fcn)
 0:6   'vdp/Product' (Product)
 0:7   'vdp/Mu' (Gain)
 0:8   'vdp/Sum' (Sum)

```

Note The `slist` command does not list blocks that are purely graphical. That is, blocks that indicate relationships between or groupings among computational blocks.

Displaying Blocks with Potential Zero Crossings

The `zclist` command displays a list of blocks in which nonsampled zero crossings can occur during a simulation. For example, `zclist` displays the following list for the clutch sample model:

```

(sldebug @0): >> zclist
 0 0:4:0   F HitCross 'sldemo_clutch/Friction Mode Logic/Lockup
Detection/Velocities Match'
 1 0:4:1   F
 2 0:10:0  F Abs 'sldemo_clutch/Friction Mode Logic/Lockup
Detection/Required Friction for Lockup/Abs'

Displaying Algebraic Loops

The `ashow` command highlights a specified algebraic loop or the algebraic loop that contains a specified block. To highlight a specified algebraic loop, enter `ashow s#n`, where `s` is the index of the system (see “Identifying Blocks in Algebraic Loops” on page 34-29) that contains the loop and `n` is the index of the loop in the system. To display the loop that contains the currently selected block, enter `ashow gcb`. To show a loop that contains a specified block, enter `ashow s:b`, where `s:b` is the block's index. To clear algebraic-loop highlighting from the model diagram, enter `ashow clear`.

Displaying Debugger Status

In GUI mode, the debugger displays the settings of various debug options, such as conditional breakpoints, in its **Status** panel. In command-line mode, the `status` command displays debugger settings. For example, the following sequence of commands displays the initial debug settings for the `vdp` model:

```

sim('vdp', 'StopTime', '10', 'debug', 'on')
%-----%
[TM = 0                                ] simulate(vdp)
(sldebug @0): >> status
%-----%

```

```
Current simulation time           : 0.0 (MajorTimeStep)
Solver needs reset                : no
Solver derivatives cache needs reset : no
Zero crossing signals cache needs reset : no
Default command to execute on return/enter : ""
Break at zero crossing events     : disabled
Break on solver error             : disabled
Break on failed integration step  : disabled
Time break point                 : disabled
Break on non-finite (NaN,Inf) values : disabled
Break on solver reset request     : disabled
Display level for disp, trace, probe : 1 (i/o, states)
Solver trace level               : 0
Algebraic loop tracing level     : 0
Animation Mode                   : off
Execution Mode                   : Normal
Display level for etrace         : 0 (disabled)
Break points                     : none installed
Display points                   : none installed
Trace points                     : none installed
```

- “How to Improve Performance in Acceleration Modes” on page 35-30

What Is Acceleration?

Acceleration is a mode of operation in the Simulink product that you can use to speed up the execution of your model. The Simulink software includes two modes of acceleration: accelerator mode and the rapid accelerator mode. Both modes replace the normal interpreted code with compiled target code. Using compiled code speeds up simulation of many models, especially those where run time is long compared to the time associated with compilation and checking to see if the target is up to date.

The accelerator mode works with any model, but performance decreases if a model contains blocks that do not support acceleration. The accelerator mode supports the Simulink debugger and profiler. These tools help with debugging and determining relative performance of various parts of your model. For more information, see “Run Accelerator Mode with the Simulink Debugger” on page 35-25 and “How Profiler Captures Performance Data” on page 31-5.

The rapid accelerator mode works with only those models containing blocks that support code generation of a standalone executable. For this reason, rapid accelerator mode does not support the debugger or profiler. However, this mode generally results in faster execution than the accelerator mode. When used with dual-core processors, the rapid accelerator mode runs Simulink and the MATLAB technical computing environment from one core while the rapid accelerator target runs as a separate process on a second core.

For more information about the performance characteristics of the Accelerator and rapid accelerator modes, and how to measure the difference in performance, see “Comparing Performance” on page 35-27.

To optimize your model and achieve faster simulation automatically using Performance Advisor, see “Automated Performance Optimization”.

To employ modeling techniques that help achieve faster simulation, see “Manual Performance Optimization”.

How Acceleration Modes Work

In this section...

“Overview” on page 35-3

“Normal Mode” on page 35-3

“Accelerator Mode” on page 35-4

“Rapid Accelerator Mode” on page 35-5

Overview

The Accelerator and rapid accelerator modes use portions of the Simulink Coder product to create an executable.

The Accelerator and rapid accelerator modes replace the interpreted code normally used in Simulink simulations, shortening model run time.

Although the acceleration modes use some Simulink Coder code generation technology, you do not need the Simulink Coder software installed to accelerate your model.

Note The code generated by the accelerator and rapid accelerator modes is suitable only for speeding the simulation of your model. Use Simulink Coder to generate code for other purposes.

Normal Mode

In normal mode, the MATLAB technical computing environment is the foundation on which the Simulink software is built. Simulink controls the solver and model methods used during simulation. Model methods include such things as computation of model outputs. Normal mode runs in one process.

One Process

Accelerator Mode

By default, the accelerator mode uses Just-in-Time (JIT) acceleration to generate an execution engine in memory instead of generating C code or MEX files. You can also have your model fall back to the classic accelerator mode, in which Simulink generates and links code into a C-MEX S-function.

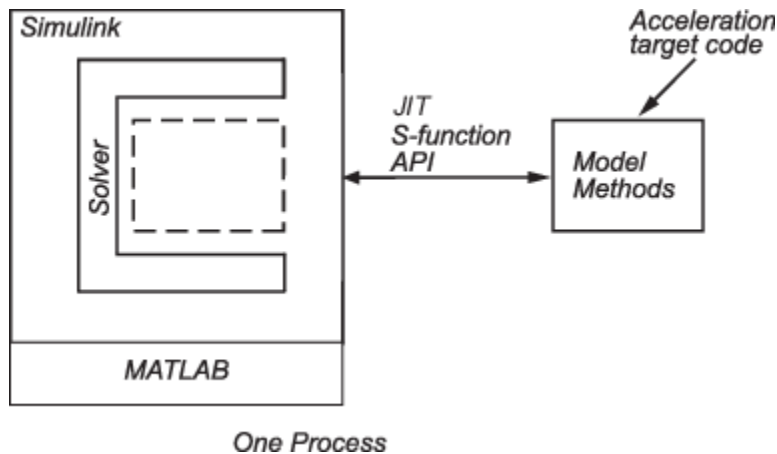

In the accelerator mode, the model methods are separate from the Simulink software and are part of the *acceleration target code*, which is used in later simulations.

Simulink checks that the acceleration target code is up to date before reusing it. For more information, see “Code Regeneration in Accelerated Models” on page 35-7 .

There are two modes of operation in accelerator mode.

Just-In-Time Accelerator Mode

In this default mode, Simulink generates an execution engine in memory for the top-level model only and not for referenced models. As a result, a C compiler is not required during simulation.

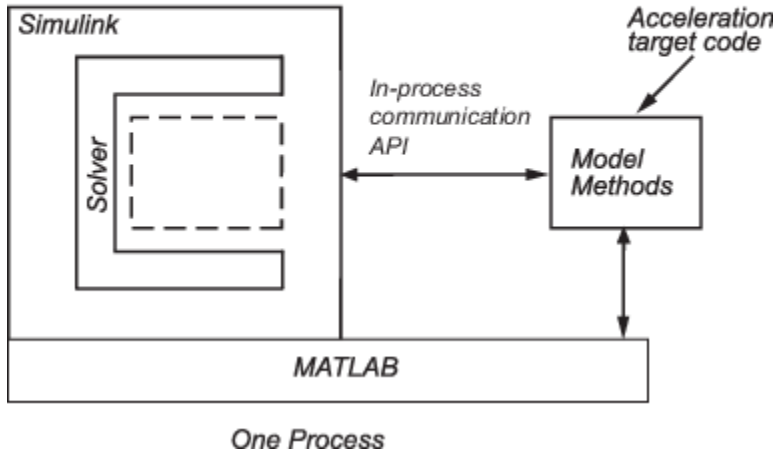

Because the acceleration target code is in memory, it is available for reuse as long as the model is open. Simulink also serializes the acceleration target code so that the model does not need rebuilding when it is opened.

Classic Accelerator Mode

If you want to simulate your model using the classic, C-code generating, accelerator mode, run the following command:

```
set_param(0, 'GlobalUseClassicAccelMode', 'on');
```

In this mode, Simulink generates and links code into a shared library, which communicates with the Simulink software. The target code executes in the same process as MATLAB and Simulink.

Rapid Accelerator Mode

The rapid accelerator mode creates a *Rapid Accelerator standalone executable* from your model. This executable includes the solver and model methods, but it resides outside of MATLAB and Simulink. It uses external mode (see "External Mode Communication" (Simulink Coder)) to communicate with Simulink.

MATLAB and Simulink run in one process, and if a second processing core is available, the standalone executable runs there.

Code Regeneration in Accelerated Models

In this section...

“Determine If the Simulation Will Rebuild” on page 35-7

“Parameter Tuning in Rapid Accelerator Mode” on page 35-7

Changing the structure of your model causes the Rapid Accelerator mode to regenerate the standalone executable, and for the Accelerator mode to regenerate the target code and update (overwrite) the existing MEX-file. Changing the value of a tunable parameter does not trigger a rebuild.

Determine If the Simulation Will Rebuild

The Accelerator and Rapid Accelerator modes use a checksum to determine if the model has changed, indicating that the code should be regenerated. The checksum is an array of four integers computed using an MD5 checksum algorithm based on attributes of the model and the blocks it contains.

- 1 Use the `Simulink.BlockDiagram.getChecksum` command to obtain the checksum for your model. For example:

```
cs1 = Simulink.BlockDiagram.getChecksum('myModel');
```

- 2 Obtain a second checksum after you have altered your model. The code regenerates if the new checksum does not match the previous checksum.
- 3 Use the information in the checksum to determine why the simulation target rebuilt.

For a detailed explanation of this procedure, see the example model `s1AcceLDemoWhyRebuild`.

Parameter Tuning in Rapid Accelerator Mode

In model rebuilds, Rapid Accelerator Mode handles block diagram and runtime parameters differently from other parameters.

Tuning Block Diagram Parameters

You can change some block diagram parameters during simulation without causing a rebuild. Tune these parameters using the `set_param` command or using the **Model Configuration Parameters** dialog box. These block diagram parameters include:

Solver Parameters		
AbsTol	MaxNumMinSteps	RelTol
ConsecutiveZCsStepRelTol	MaxOrder	StartTime
ExtrapolationOrder	MaxStep	StopTime
InitialStep	MinStep	ZCDetectionTol
MaxConsecutiveMinStep	OutputTimes	
MaxConsecutiveZCs	Refine	

Loading and Logging Parameters		
ConsistencyChecking	MinStepSizeMsg	SaveTime
Decimation	OutputOption	StateSaveName
FinalStateName	OutputSaveName	TimeSaveName
LimitDataPoints	SaveFinalState	
LoadExternalInput	SaveFormat	
MaxConsecutiveZCsMsg	SaveOutput	
MaxDataPoints	SaveState	

Tuning Runtime Parameters

To tune runtime parameters for maximum acceleration in Rapid Accelerator mode, follow this procedure which yields better results than using `set_param` for the same purpose:

- 1 Collect the runtime parameters in a runtime parameter structure while building a rapid accelerator target executable using the `Simulink.BlockDiagram.buildRapidAcceleratorTarget` function.
- 2 To change the parameters, use the `Simulink.BlockDiagram.modifyTunableParameters` function.
- 3 To specify the modified parameters to the `sim` command, use the `RapidAcceleratorParameterSets` and `RapidAcceleratorUpToDateCheck` parameters.

All other parameter changes can necessitate a rebuild of the model.

Parameter Changes	Passed Directly to sim command	Passed Graphically via Block Diagram or via <code>set_param</code> command
Runtime	Does not require rebuild	Can require rebuild
Block diagram (logging parameters)	Does not require rebuild	Does not require rebuild

For information about parameter tunability limitations with accelerated simulation modes, see “Tunability Considerations and Limitations for Other Modeling Goals” on page 37-36.

Choosing a Simulation Mode

In this section...

“Simulation Mode Tradeoffs” on page 35-10

“Comparing Modes” on page 35-11

“Decision Tree” on page 35-12

Simulation Mode Tradeoffs

In general, you must trade off simulation speed against flexibility when choosing either Accelerator mode or Rapid Accelerator mode instead of Normal mode.

Normal mode offers the greatest flexibility for making model adjustments and displaying results, but it runs the slowest.

Accelerator mode lies between Normal and Rapid Accelerator modes in performance and in interaction with your model. Accelerator mode does not support most runtime diagnostics.

Rapid Accelerator mode runs the fastest, but this mode does not support the debugger or profiler, and works only with those models for which C code or MEX file is available for all of the blocks in the model.

Note An exception to this rule occurs when you run multiple simulations, each of which executes in less than one second in Normal mode. For example:

```
for i=1:100
sim(model); % executes in less than one second in Normal mode
end
```

For this set of conditions, you will typically obtain the best performance by simulating the model in Normal mode.

Tip To gain additional flexibility, consider using model referencing to componentize your model. If the top-level model uses Normal mode, then you can simulate a referenced model in a different simulation mode than you use for other portions of a model. During the model development process, you can choose different simulation modes for different portions of a model. For details, see “Choose Simulation Modes for Model Hierarchies” on page 8-39.

Comparing Modes

The following table compares the characteristics of Normal mode, Accelerator mode, and Rapid Accelerator mode.

If you want to...	Then use this mode...		
	Normal	Accelerator	Rapid Accelerator
Performance			
Run your model in a separate address space			✓
Efficiently run batch and Monte Carlo simulations			✓
Model Adjustment			
Change model parameters such as solver, stop time without rebuilding	✓	✓	✓
Change block tunable parameters such as gain	✓	✓	✓
For more information on configuration set parameters which can be modified without requiring rebuild, see “Code Regeneration in Accelerated Models” on page 35-7			
Model Requirement			
Accelerate your model even if C code or MEX file are not used for all blocks		✓	
Support Interpreted MATLAB Function blocks	✓	✓	
Support Non-Inlined MATLAB language or Fortran S-Functions	✓	✓	
Permit algebraic loops in your modelp	✓	✓	
Have your model work with the debugger or profiler	✓	✓	
Have your model include C++ code	✓	✓	
Data Display			

If you want to...	Then use this mode...		
	Normal	Accelerator	Rapid Accelerator
Use scopes and signal viewers	✓	✓	See “Behavior of Scopes and Viewers with Rapid Accelerator Mode” on page 35-16
Use scopes and signal viewers when running your model from the command line	✓	✓	

Note Scopes and viewers do not update if you run your model from the command line in Rapid Accelerator mode.

Decision Tree

Use this decision tree to select between Accelerator, or Rapid Accelerator modes.

See “Comparing Performance” on page 35-27 to understand how effective the accelerator modes will be in improving the performance of your model.

Select Blocks for Accelerator Mode

The Accelerator simulation mode runs the following blocks as if you were running Normal mode because these blocks do not generate code for the accelerator build. Consequently, if your model contains a high percentage of these blocks, the Accelerator mode may not increase performance significantly. All of these Simulink blocks use interpreted code.

- Display
- From File
- From Workspace
- Inport (root level only)
- Interpreted MATLAB Function
- Outport (root level only)
- Scope
- To File
- To Workspace

Note In some instances, Normal mode output might not precisely match the output from Accelerator mode because of slight differences in the numerical precision between the interpreted and compiled versions of a model.

The following blocks can cause poor simulation runtime performance when run in the default JIT Accelerator mode.

- Transport Delay
- Variable Transport Delay

Select Blocks for Rapid Accelerator Mode

Blocks that do not support code generation (such as SimEvents) or blocks that generate code only for a specific target cannot be simulated in Rapid Accelerator mode.

Additionally, Rapid Accelerator mode does not work if your model contains any of the following blocks:

- Interpreted MATLAB Function
- Device driver S-functions, such as blocks from the Simulink Real-Time product, or those targeting Freescale™ MPC555

Note In some instances, Normal mode output might not precisely match the output from Rapid Accelerator mode because of slight differences in the numerical precision between the interpreted and compiled versions of a model.

Control S-Function Execution

Note In the default JIT Accelerator mode, inlining of user-written TLC S-Functions is not supported. If you run a model containing TLC S-Functions in the JIT Accelerator mode, there is a possibility of the execution speed reducing. The code generation speed, however, will be high due to JIT acceleration.

Inlining S-functions using the Target Language Compiler increases performance with the classic Accelerator mode by eliminating unnecessary calls to the Simulink API. By default, however, the classic Accelerator mode ignores an inlining TLC file for an S-function, even though the file exists. The Rapid Accelerator mode always uses the TLC file if one is available.

A device driver S-Function block written to access specific hardware registers on an I/O board is one example of why this behavior was chosen as the default. Because the Simulink software runs on the host system rather than the target, it cannot access the targets I/O registers and so would fail when attempting to do so.

To direct the classic Accelerator mode to use the TLC file instead of the S-function MEX-file, specify `SS_OPTION_USE_TLC_WITH_ACCELERATOR` in the `mdlInitializeSizes` function of the S-function, as in this example:

```
static void mdlInitializeSizes(SimStruct *S)
{
/* Code deleted */
ssSetOptions(S, SS_OPTION_USE_TLC_WITH_ACCELERATOR);
}
```

The Rapid Accelerator mode will make use of the MEX file if the S-Function's C file is not present in the same folder.

Note to use the `.c` or `.cpp` code for your S-Function, ensure that they are in the same folder as the S-Function MEX-file, otherwise, you can include additional files to an S-function or bypass the path limitation by using the `rtwmakecfg.m` file. For more information, see [Use `rtwmakecfg.m` API to Customize Generated Makefiles \(Simulink Coder\)](#).

Accelerator and Rapid Accelerator Mode Data Type Considerations

- Accelerator mode supports fixed-point signals and vectors up to 128 bits.
- Rapid Accelerator mode supports fixed-point parameters up to 128 bits.

- Rapid Accelerator mode supports fixed-point root inputs up to 32 bits
- Rapid Accelerator mode supports root inputs of Enumerated data type
- Rapid Accelerator mode does not support fixed-point data for the From Workspace block.
- Rapid Accelerator mode ignores the selection of the **Log fixed-point data as a fi object** (FixptAsFi) check box for the To Workspace block.
- Rapid Accelerator mode supports bus objects as parameters.
- The Accelerator mode and Rapid Accelerator mode store integers as compactly as possible.
- Fixed-Point Designer does not collect min, max, or overflow data in the Accelerator or Rapid Accelerator modes.
- Accelerator mode supports a limited set of runtime diagnostics, including the assertion block.
- Rapid Accelerator mode supports a limited set of runtime diagnostics, including the assertion block.

Behavior of Scopes and Viewers with Rapid Accelerator Mode

Running the simulation from the command line or the menu determines the behavior of scopes and viewers in Rapid Accelerator mode.

Scope or Viewer Type	Simulation Run from Menu	Simulation Run from Command Line
Simulink Scope block	Same support as Normal mode	<ul style="list-style-type: none"> • Logging is supported • Scope window is not updated
Simulink signal viewer scopes	Graphics are updated, but logging is not supported	Not supported
Other signal viewer scopes	Support limited to that available in External mode	Not supported
Signal logging	Supported.	Supported.
Visualizers with inputs from logging (Such as the Data Inspector or Logic Analyzer)	Data not visualized during simulation.	Data not visualized during simulation.
Stateflow Chart blocks	Same support for chart animation as Normal mode	Not supported

Note Although scopes and viewers do not update when you run Rapid Accelerator mode from the command line, they do update when you run the model from the menu. “Run Acceleration Mode from the User Interface” on page 35-19 shows how to run Rapid Accelerator mode from the menu. “Interact with the Acceleration Modes Programmatically” on page 35-22 shows how to run the simulation from the command line.

Factors Inhibiting Acceleration

- You cannot use the Accelerator or Rapid Accelerator mode if your model:

- Passes array parameters to MATLAB S-functions that are not numeric, logical, or character arrays, are sparse arrays, or that have more than two dimensions.
- Uses Fcn blocks containing trigonometric functions having complex inputs.
- In some cases, changes associated with external or custom code do not cause Accelerator or Rapid Accelerator simulation results to change. These include:
 - TLC code
 - S-function source code, including `rtwmakecfg.m` files
 - Integrated custom code
 - S-Function Builder

In such cases, consider force regeneration of code for a top model. Alternatively, you can force regeneration of top model code by deleting code generation folders, such as `slprj` or the generated model code folder.

Note With JIT acceleration, the acceleration target code is in memory. It is therefore available for reuse as long as the model is open, even if you delete the `slprj` folder.

Rapid Accelerator Mode Limitations

- Rapid Accelerator mode does not support:
 - Algebraic loops.
 - Targets written in C++.
 - Interpreted MATLAB Function blocks.
 - Noninlined MATLAB language or Fortran S-functions. You must write S-functions in C or inline them using the Target Language Compiler (TLC) or you can also use the MEX file. For more information, see “Write Fully Inlined S-Functions” (Simulink Coder).
 - Debugger or Profiler.
 - Run time objects for `Simulink.RunTimeBlock` and `Simulink.BlockCompOutputPortData` blocks.
- Model parameters must be one of these data types:
 - `boolean`
 - `uint8` or `int8`
 - `uint16` or `int16`
 - `uint32` or `int32`
 - `single` or `double`
 - Fixed-point
 - Enumerated
- You cannot pause a simulation in Rapid Accelerator mode.
- If a Rapid Accelerator build includes referenced models (by using Model blocks), set up these models to use fixed-step solvers to generate code for them. The top model, however, can use a variable-step solver as long as the blocks in the referenced models are discrete.
- In certain cases, changing block parameters can result in structural changes to your model that change the model checksum. An example of such a change is changing the number of delays in a DSP simulation. In these cases, you must regenerate the code for the model. See “Code Regeneration in Accelerated Models” on page 35-7 for more information.

- For root inports, Rapid Accelerator mode supports only base as the Srcworkspace.
- For root inports, when you specify the minimum and maximum values that the block should output, Rapid Accelerator mode does not recognize these limits during simulation.
- In Rapid Accelerator mode, To File or To Workspace blocks inside function-call subsystems do not generate any logging files if the function-call port is connected to Ground or unconnected.
- Rapid Accelerator mode does not support systems that run RHEL / CentOS 6.x or 7.x.

Reserved Keywords

Certain words are reserved for use by the Simulink Coder code language and by Accelerator mode and Rapid Accelerator mode. These keywords must not appear as function or variable names on a subsystem, or as exported global signal names. Using the reserved keywords results in the Simulink software reporting an error, and the model cannot be compiled or run.

The keywords reserved for the Simulink Coder product are listed in “Construction of Generated Identifiers” (Simulink Coder). Additional keywords that apply only to the Accelerator and Rapid accelerator modes are:

muDoubleScalarAbs	muDoubleScalarCos	muDoubleScalarMod
muDoubleScalarAcos	muDoubleScalarCosh	muDoubleScalarPower
muDoubleScalarAcosh	muDoubleScalarExp	muDoubleScalarRound
muDoubleScalarAsin	muDoubleScalarFloor	muDoubleScalarSign
muDoubleScalarAsinh	muDoubleScalarHypot	muDoubleScalarSin
muDoubleScalarAtan,	muDoubleScalarLog	muDoubleScalarSinh
muDoubleScalarAtan2	muDoubleScalarLog10	muDoubleScalarSqrt
muDoubleScalarAtanh	muDoubleScalarMax	muDoubleScalarTan
muDoubleScalarCeil	muDoubleScalarMin	muDoubleScalarTanh

Perform Acceleration

In this section...

- “Customize the Build Process” on page 35-19
- “Run Acceleration Mode from the User Interface” on page 35-19
- “Making Run-Time Changes” on page 35-20
- “Switching Solvers between Runs” on page 35-21

Customize the Build Process

Compiler optimizations are off by default. This results in faster build times, but slower simulation times. You can optimize the build process toward a faster simulation.

- 1 From the **Simulation** menu, select **Model Configuration Parameters**.
- 2 In the Configuration Parameters dialog box, from the **Compiler optimization level** drop-down list, select **Optimizations on (faster runs)**.

Code generation takes longer with this option, but the model simulation runs faster.

- 3 Select **Verbose accelerator builds** to display progress information using code generation, and to see the compiler options in use.

Changing the Location of Generated Code

By default, the Accelerator mode places the generated code in a subfolder of the working folder called `s\prj\accel\modelname` (for example, `s\prj\accel\f14`). To change the name of the folder into which the Accelerator Mode writes generated code:

- 1 In the Simulink Editor window, on the **Modeling** tab, select **Environment > Simulink Preferences**.

The Simulink Preferences window appears.

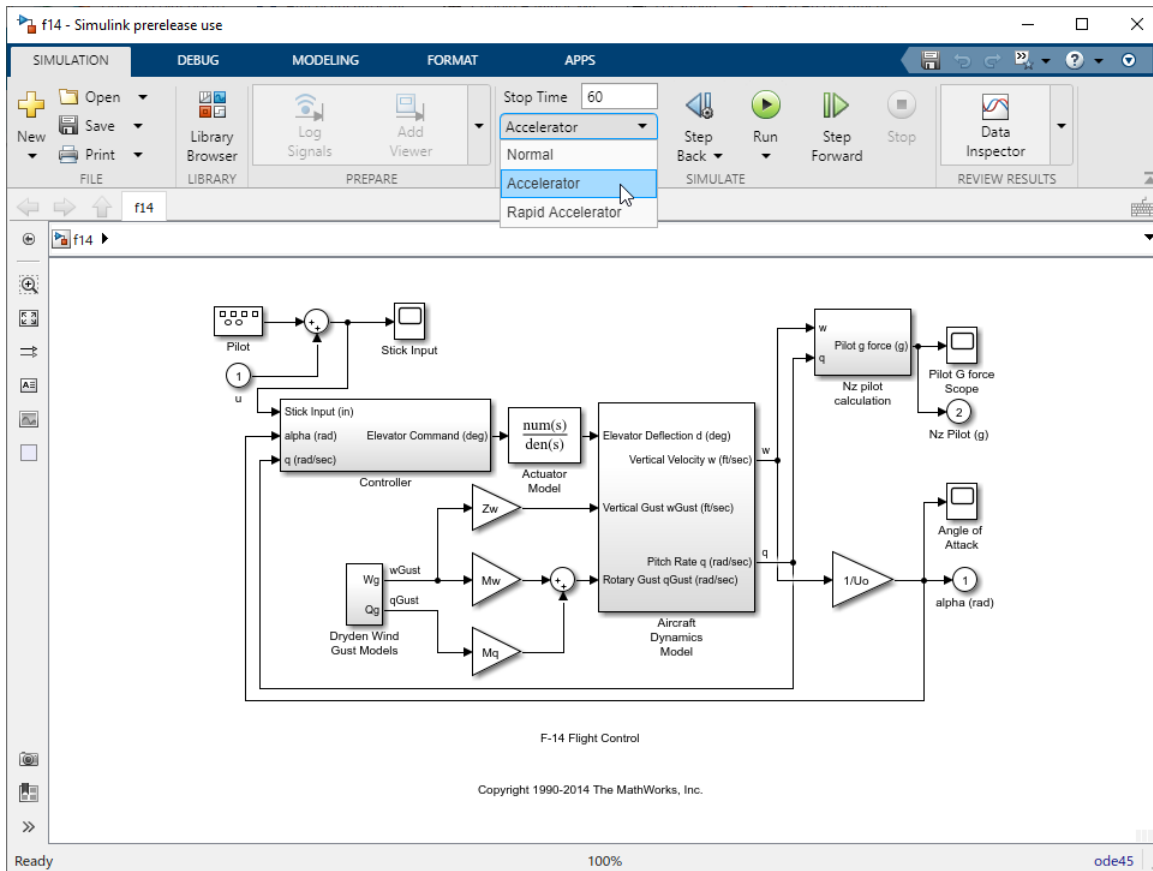

- 2 In the Simulink Preferences window, navigate to the **Simulation cache folder** parameter.
- 3 Enter the absolute or relative path to your subfolder and click **Apply**.

Run Acceleration Mode from the User Interface

To accelerate a model, first open it, and then on the **Simulation** tab, in the **Simulate** section, select **Accelerator** or **Rapid Accelerator** from the drop-down menu. Then start the simulation.

The following example shows how to accelerate the already opened `f14` model using the Accelerator mode:

- 1 On the **Simulation** tab, in the **Simulate** section, select **Accelerator** from the drop-down menu.

2 On the **Simulation** tab, click **Run**.

The Accelerator and Rapid Accelerator modes first check to see if code was previously compiled for your model. If code was created previously, the Accelerator or Rapid Accelerator mode runs the model. If code was not previously built, they first generate and compile the C code, and then run the model.

For an explanation of why these modes rebuild your model, see “Code Regeneration in Accelerated Models” on page 35-7.

The Accelerator mode places the generated code in a subfolder of the working folder called `slprj/accel/modelname` (for example, `slprj/accel/f14`). If you want to change this path, see “Changing the Location of Generated Code” on page 35-19.

The Rapid Accelerator mode places the generated code in a subfolder of the working folder called `slprj/raccel/modelname` (for example, `slprj/raccel/f14`).

Note The warnings that blocks generate during simulation (such as divide-by-zero and integer overflow) are not displayed when your model runs in Accelerator or Rapid Accelerator mode.

Making Run-Time Changes

A feature of the Accelerator and Rapid Accelerator modes is that simple adjustments (such as changing the value of a Gain or Constant block) can be made to the model while the simulation is still

running. More complex changes (for example, changing from a `sin` to `tan` function) are not allowed during run time.

The Simulink software issues a warning if you attempt to make a change that is not permitted. The absence of a warning indicates that the change was accepted. The warning does not stop the current simulation, and the simulation continues with the previous values. If you wish to alter the model in ways that are not permitted during run time, you must first stop the simulation, make the change, and then restart the simulation.

In general, simple model changes are more likely to result in code regeneration when in Rapid Accelerator mode than when in Accelerator mode.

Switching Solvers between Runs

You can switch variable-step solvers between runs and Simulink will automatically determine if a solver change will trigger a rebuild, based on the mathematical structure of the model, such as whether the model is an Ordinary Differential of Equation (ODE) or a Differential Algebraic of Equation (DAE) model, if the solver needs a Jacobian, whether it handles mass matrices, or if the model contains rate limiter blocks.

Interact with the Acceleration Modes Programmatically

In this section...

“Why Interact Programmatically?” on page 35-22

“Build JIT Accelerated Execution Engine” on page 35-22

“Control Simulation” on page 35-22

“Simulate Your Model” on page 35-23

“Customize the Acceleration Build Process” on page 35-23

Why Interact Programmatically?

You can build an accelerated model, select the simulation mode, and run the simulation from the command prompt or from MATLAB script. With this flexibility, you can create Accelerator mode MEX-files in batch mode, allowing you to build the C code and executable before running the simulations. When you use the Accelerator mode interactively at a later time, it will not be necessary to generate or compile MEX-files at the start of the accelerated simulations.

Build JIT Accelerated Execution Engine

With the `accelbuild` command, you can build a JIT accelerated execution engine without actually simulating the model. For example, to build an Accelerator mode simulation of `myModel`:

```
accelbuild myModel
```

Control Simulation

You can control the simulation mode from the command line prompt by using the `set_param` command:

```
set_param('modelName', 'SimulationMode', 'mode')
```

The simulation mode can be `normal`, `accelerator`, `rapid`, or `external`.

For example, to simulate your model with the Accelerator mode, you would use:

```
set_param('myModel', 'SimulationMode', 'accelerator')
```

However, a preferable method is to specify the simulation mode within the `sim` command:

```
simOut = sim('myModel', 'SimulationMode', 'accelerator');
```

You can use `bdroot` to set parameters for the currently active model (that is, the active model window) rather than `modelName` if you do not wish to explicitly specify the model name.

For example, to simulate the currently opened system in the Rapid Accelerator mode, you would use:

```
simOut = sim(bdroot, 'SimulationMode', 'rapid');
```

Simulate Your Model

You can use `set_param` to configure the model parameters (such as the simulation mode and the stop time), and use the `sim` command to start the simulation:

```
sim('modelName', 'ReturnWorkspaceOutputs', 'on');
```

However, the preferred method is to configure model parameters directly using the `sim` command, as shown in the previous section.

You can substitute `gcs` for `modelName` if you do not want to explicitly specify the model name.

Unless target code has already been generated, the `sim` command first builds the executable and then runs the simulation. However, if the target code has already been generated and no significant changes have been made to the model (see “Code Regeneration in Accelerated Models” on page 35-7 for a description), the `sim` command executes the generated code without regenerating the code. This process lets you run your model after making simple changes without having to wait for the model to rebuild.

Simulation Example

The following sequence shows how to programmatically simulate `myModel` in Rapid Accelerator mode for 10,000 seconds.

First open `myModel`, and then type the following in the Command Window:

```
simOut = sim('myModel', 'SimulationMode', 'rapid'...
'StopTime', '10000');
```

Use the `sim` command again to simulate after making a change to your model. If the change is minor (adjusting the gain of a gain block, for instance), the simulation runs without regenerating code.

Customize the Acceleration Build Process

You can programmatically control the Accelerator mode and Rapid Accelerator mode build process and the amount of information displayed during the build process. See “Customize the Build Process” on page 35-19 for details on why doing so might be advantageous.

Controlling the Build Process

Use `SimCompilerOptimization` to set the degree of optimization used by the compiler when generating code for acceleration. The permitted values are `on` or `off`. The default is `off`.

Enter the following at the command prompt to turn on compiler optimization:

```
set_param('myModel', 'SimCompilerOptimization', 'on')
```

When `SimCompilerOptimization` is set to `on` in JIT accelerated mode, the simulation time for some models improves, while the build time can become slower.

Controlling Verbosity During Code Generation

Use the `AccelVerboseBuild` parameter to display progress information during code generation. The permitted values are `on` or `off`. The default is `off`.

Enter the following at the command prompt to turn on verbose build:

```
set_param('myModel', 'AccelVerboseBuild', 'on')
```

Run Accelerator Mode with the Simulink Debugger

In this section...

“Advantages of Using Accelerator Mode with the Debugger” on page 35-25

“How to Run the Debugger” on page 35-25

“When to Switch Back to Normal Mode” on page 35-25

Advantages of Using Accelerator Mode with the Debugger

The Accelerator mode can shorten the length of your debugging sessions if you have large and complex models. For example, you can use the Accelerator mode to simulate a large model and quickly reach a distant break point.

For more information, see “Accelerator Mode” on page 35-4.

Note You cannot use the Rapid Accelerator mode with the debugger.

How to Run the Debugger

To run your model in the Accelerator mode with the debugger:

- 1 On the **Simulation** tab, in the **Simulate** section, select **Accelerator** from the drop-down menu.
- 2 At the command prompt, enter:

```
sldebug modelname
```
- 3 At the debugger prompt, set a time break:

```
tbreak 10000  
continue
```
- 4 Once you reach the breakpoint, use the debugger command `emode` (execution mode) to toggle between Accelerator and Normal mode.

When to Switch Back to Normal Mode

You must switch to Normal mode to step through the simulation by blocks, and when you want to use the following debug commands:

- `trace`
- `break`
- `zcbreak`
- `nanbreak`

Comparing Performance

In this section...

“Performance of the Simulation Modes” on page 35-27

“Measure Performance” on page 35-28

Performance of the Simulation Modes

The Accelerator and Rapid Accelerator modes give the best speed improvement compared to Normal mode when simulation execution time exceeds the time required for code generation. For this reason, the Accelerator and Rapid Accelerator modes generally perform better than Normal mode when simulation execution times are several minutes or more. However, models with a significant number of Stateflow or MATLAB Function blocks might show only a small speed improvement over Normal mode because in Normal mode these blocks also simulate through code generation.

Including tunable parameters in your model can also increase the simulation time.

The figure shows in general terms the performance of a hypothetical model simulated in Normal, Accelerator, and Rapid Accelerator modes.

Performance When the Target Must Be Rebuilt

The solid lines in the figure show performance when the target code must be rebuilt (“all targets out of date”). For this hypothetical model, the time scale is on the order of minutes, but it could be longer for more complex models.

As generalized in the figure, the time required to compile the model in Normal mode is less than the time required to build either the Accelerator target or Rapid Accelerator executable. It is evident from the figure that for small simulation stop times Normal mode results in quicker overall simulation times than either Accelerator mode or Rapid Accelerator mode.

The crossover point where Accelerator mode or Rapid Accelerator mode result in faster execution times depends on the complexity and content of your model. For instance, those models running in Accelerator mode containing large numbers of blocks using interpreted code (see “Select Blocks for Accelerator Mode” on page 35-14) might not run much faster than they would in Normal mode unless the simulation stop time is very large. Similarly, models with a large number of Stateflow Chart blocks or MATLAB Function blocks might not show much speed improvement over Normal mode unless the simulation stop times are long. You can accelerate models with Stateflow Chart blocks or MATLAB Function blocks through code generation.

For illustration purposes, the graphic represents a model with a large number of Stateflow Chart blocks or MATLAB Function blocks. The curve labeled “Normal” would have much smaller initial elapsed time than shown if the model did not contain these blocks.

Performance When the Targets Are Up to Date

As shown by the broken lines in the figure (“all targets up to date”) the time for the Simulink software to determine if the Accelerator target or the Rapid Accelerator executable are up to date is significantly less than the time required to generate code (“all targets out of date”). You can take advantage of this characteristic when you wish to test various design tradeoffs.

For instance, you can generate the Accelerator mode target code once and use it to simulate your model with a series of gain settings. This is an especially efficient way to use the Accelerator or Rapid Accelerator modes because this type of change does not result in the target code being regenerated. This means the target code is generated the first time the model runs, but on subsequent runs the Simulink code spends only the time necessary to verify that the target is up to date. This process is much faster than generating code, so subsequent runs can be significantly faster than the initial run.

Because checking the targets is quicker than code generation, the crossover point is smaller when the target is up to date than when code must be generated. This means subsequent runs of your model might simulate faster in Accelerator or Rapid Accelerator mode when compared to Normal mode, even for short stop times.

Measure Performance

You can use the `tic`, `toc`, and `sim` commands to compare Accelerator mode or Rapid Accelerator mode execution times to Normal mode.

- 1 Open your model.
- 2 On the **Simulation** tab, in the **Simulate** section, select `Normal` from the drop-down menu.
- 3 Use the `tic`, `toc`, and `sim` commands at the command line prompt to measure how long the model takes to simulate in Normal mode:

```
tic,[t,x,y]=sim('myModel',10000);toc
```

`tic` and `toc` work together to record and return the elapsed time and display a message such as the following:

```
Elapsed time is 17.789364 seconds.
```

- 4 On the **Simulation** tab, in the **Simulate** section, select **Accelerator** or **Rapid Accelerator** from the drop-down menu. Build an executable for the model by clicking **Run**. The acceleration modes use this executable in subsequent simulations as long as the model remains structurally unchanged. “Code Regeneration in Accelerated Models” on page 35-7 discusses the things that cause your model to rebuild.
- 5 Rerun the compiled model at the command prompt:

```
tic,[t,x,y]=sim('myModel',10000);toc
```
- 6 The elapsed time displayed shows the run time for the accelerated model. For example:

```
Elapsed time is 12.419914 seconds.
```

The difference in elapsed times (5.369450 seconds in this example) shows the improvement obtained by accelerating your model.

How to Improve Performance in Acceleration Modes

In this section...

“Techniques” on page 35-30

“C Compilers” on page 35-30

Techniques

To get the best performance when accelerating your models:

- Verify that the Configuration Parameters dialog box settings are as follows:

Set...	To...
Solver data inconsistency	none
Array bounds exceeded	none
Signal storage reuse	selected

- Disable Stateflow debugging and animation.
- When logging large amounts of data (for instance, when using the Workspace I/O, To Workspace, To File, or Scope blocks), use decimation or limit the output to display only the last part of the simulation.
- Customize the code generation process to improve simulation speed. For details, see “Customize the Build Process” on page 35-19.

C Compilers

On computers running the Microsoft Windows operating system, the Accelerator and Rapid Accelerator modes use the default 64-bit C compiler supplied by MathWorks to compile your model. If you have a C compiler installed on your PC, you can configure the mex command to use it instead. You might choose to do this if your C compiler produces highly optimized code since this would further improve acceleration.

Note For an up-to-date list of 32- and 64-bit C compilers that are compatible with MATLAB software for all supported computing platforms, see:

https://www.mathworks.com/support/compilers/current_release/

Managing Blocks

Working with Blocks

- “Nonvirtual and Virtual Blocks” on page 36-2
- “Specify Block Properties” on page 36-4
- “Format a Model” on page 36-7
- “Display Port Values for Debugging” on page 36-18

Nonvirtual and Virtual Blocks

When creating models, you need to be aware that Simulink blocks fall into two basic categories: nonvirtual blocks and virtual blocks. Nonvirtual blocks play an active role in the simulation of a system. If you add or remove a nonvirtual block, you change the model's behavior. Virtual blocks, by contrast, play no active role in the simulation; they help organize a model graphically. Some Simulink blocks are virtual in some circumstances and nonvirtual in others. Such blocks are called conditionally virtual blocks. The table lists Simulink virtual and conditionally virtual blocks.

Block Name	Condition Under Which Block Is Virtual
Bus Assignment	Virtual if input bus is virtual.
Bus Creator	Virtual if output bus is virtual.
Bus Selector	Virtual if input bus is virtual.
Demux	Always virtual.
Enable	Virtual unless connected directly to an Outport block.
From	Always virtual.
Goto	Always virtual.
Goto Tag Visibility	Always virtual.
Ground	Always virtual.
In Bus Element	Virtual <i>unless</i> input bus is nonvirtual <i>and</i> contains a variable-size signal.
Inport	Virtual <i>unless</i> the block resides in a conditionally executed or atomic subsystem <i>and</i> has a direct connection to an Outport block.
Mux	Always virtual.
Out Bus Element	Virtual <i>unless</i> output bus is nonvirtual.
Outport	Virtual when the block resides within any subsystem (conditional or not), and does <i>not</i> reside in the root (top-level) Simulink window.
Selector	Virtual only when Number of input dimensions specifies 1 and Index Option specifies Select all, Index vector (dialog), or Starting index (dialog).
Signal Specification	Always virtual.
Subsystem	Virtual unless the block is conditionally executed or the Treat as atomic unit check box is selected. You can check if a block is virtual with the <code>IsSubsystemVirtual</code> block property. See “Block-Specific Parameters”.
Terminator	Always virtual.
Trigger	Virtual when the output port is <i>not</i> present.

Specify Block Properties

For each block in a model, you can set general block properties, such as:

- A description of the block
- The block execution priority
- A block annotation
- Block callback functions

To set block properties, use the Property Inspector. You can set properties in the **Properties** and **Info** tabs of the Property Inspector when the block is selected. Alternatively, you can use the Block Properties dialog box.

Set Block Annotation Properties

In the Property Inspector, use the **Block Annotation** section to display the values of selected block parameters in an annotation. The annotation appears below the block icon.

Enter the text of the annotation in the text box. You can use a block property token in the annotation. The value for the property replaces the token in the annotation in the model. To display a list of tokens that you can use in an annotation, type % in the text box. The parameters that are valid for the selected block appear. See “Common Block Properties” and “Block-Specific Parameters”.

Suppose that you specify the following annotation text and tokens for a Product block:

```
Multiplication = %<Multiplication>
Sample time = %<SampleTime>
```

In the Simulink Editor, the block displays this annotation:

You can also create block annotations programmatically. See “Create Block Annotations Programmatically” on page 36-6.

Specify Block Callbacks

Use the **Callbacks** section to specify block callbacks. Callbacks are MATLAB commands that execute when a specific model action occurs, such as when you select or delete a block. For more information on callbacks, see “Callbacks for Customized Model Behavior” on page 4-51.

- 1 Select the block whose callback you want to set.
- 2 In **Properties** tab of the Property Inspector, in the **Callbacks** section, select the function that you want to assign the callback to. For example, select `OpenFcn` to specify a behavior for double-clicking a block.

- 3 In the text box, enter the command that you want to execute when that block function occurs.

After you assign a callback to a function, the function displays an asterisk next to it in the list. The asterisks helps you to see the functions that have callbacks assigned to them.

Note After you add an `OpenFcn` callback to a block, double-clicking the block does not open the block dialog box. Also, the block parameters do not appear in the Property Inspector when the block is selected. To set the block parameters, select **Block Parameters** from the block context menu.

Set a Block Callback Programmatically

This example shows how to use the `OpenFcn` callback to execute MATLAB scripts when you double-click a block. For example, in a MATLAB script you can define variables or open a plot of simulated data.

To create a callback programmatically, select the block to which you want to add this property. Then, at the MATLAB command prompt, enter a command in this form:

```
set_param(gcf, 'OpenFcn', 'myfunction')
```

In this example, `myfunction` represents a valid MATLAB command or a MATLAB script on your MATLAB search path.

Specify Block Execution Priority and Tag

In the **Advanced Properties** section of the block properties, you can specify the block priority and identify the block by assigning a value to the **Tag** property.

- **Priority** — Specify the execution priority of the block relative to other blocks. Specify a numerical value. A smaller number indicates a higher priority.
- **Tag** — Specify an identifier for the block. Specify text to assign to the block **Tag** property. Setting this property is useful for finding the block in the model by searching or programmatically using `find_system`. See “Explore Model Hierarchy”.

Note In determining execution priority, Simulink compares the **Priority** of blocks only to that of other blocks in the same block diagram, even if the block diagram is a virtual subsystem, and only to other blocks that have their **Priority** explicitly set.

Use Block Description to Identify a Block

The **Info** tab displays information about the block type. The block author provides this description.

You can also enter a description in the **Description** box to provide information about the block instance.

- If you add a description, you can set up your model display so that the description appears in a tooltip when you hover over the block. To enable this tooltip, on the **Debug** tab, select **Information Overlays > Description in Tooltip**.
- The **Description** property can help you to find a block by searching. See **Simulink Editor**.

Create Block Annotations Programmatically

You can use a block `AttributesFormatString` parameter to display specified block parameter values below the block. “Common Block Properties” and “Block-Specific Parameters” describe the parameters that a block can have. Use the Simulink `set_param` function to set this parameter to the attributes format that you want.

The attributes format can be any text that has embedded parameter names. An embedded parameter name is a parameter name preceded by `%<` and followed by `>`, for example, `%<priority>`. Simulink displays the attributes format text below the block icon, replacing each parameter name with the corresponding value. You can use line-feed characters (`\n`) to display each parameter on a separate line. For example, select a Gain block and enter this command at the MATLAB command prompt:

```
set_param(gcf, 'AttributesFormatString', 'pri=%<priority>\ngain=%<Gain>')
```

The Gain block displays this block annotation:

If a parameter value is not text or an integer, N/S (for not supported) appears in place of the value. If the parameter name is not valid, Simulink displays ??? in place of the value.

More About

- “Add Blocks and Set Parameters” on page 1-14
- “Callbacks for Customized Model Behavior” on page 4-51

Format a Model

As you build a model, you can adjust block positions, change block colors, place block names and ports on any side of the block, adjust fonts, and add elements that help to improve model readability. These changes can help to organize the model visually and help others understand the model.

You can make these types of changes to your model format:

- Improve the model layout. See “Improve Model Layout” on page 36-7.
- Flip or rotate blocks or groups of blocks. These adjustments help blocks to fit in the model and connect with other blocks. See “Flip or Rotate Blocks” on page 36-9.
- Reposition or hide block names, edit port labels, and move ports to any side of the block. See “Manage Block Names and Ports” on page 36-12.
- Add colors to blocks and to the background. See “Specify Model Colors” on page 36-13.
- Adjust aesthetics by changing fonts and deepening the intensity of drop shadows. See “Specify Fonts in Models” on page 36-14 and “Increase Drop Shadow Depth” on page 36-15.
- Surround groups of blocks with a box to show that the blocks are related. See “Box and Label Areas of a Model” on page 36-15.
- Copy formatting from a block, line, or area to another model element. See “Copy Formatting Between Model Elements” on page 36-16.
- Document a model using text, image, and math annotations. See “Describe Models Using Notes and Annotations” on page 4-4.
- Annotate a block. See “Set Block Annotation Properties” on page 36-4.
- Change the block icon. For example, you can use a mask to display a graphic on a block. A mask also enables you to design a custom interface for a block. To learn about masks, see “Masking Fundamentals” on page 39-2.

Improve Model Layout

To improve your diagram layout and appearance, in the **Format** tab, click **Auto Arrange**. This option:

- Aligns blocks in your model from left to right, starting with inputs and ending with outputs
- Resizes blocks, such as the Constant block, to display long parameter values
- Standardizes block size among similar blocks
- Straightens signal lines by moving blocks

Alternatively, you can try improving the shapes of individual signal lines. Select the signal line and, from the action bar, select **Auto-route Line**. The line redraws if a better route between model elements is possible.

You can try to improve multiple lines by using **Auto-route Lines**. To access **Auto-route Lines** from the action bar, select a block or select multiple model elements by dragging a box around the elements.

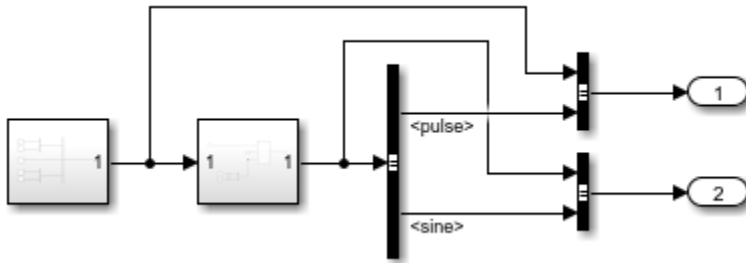

Move Multiple Model Elements Together

To move multiple model elements while maintaining their relationship with each other:

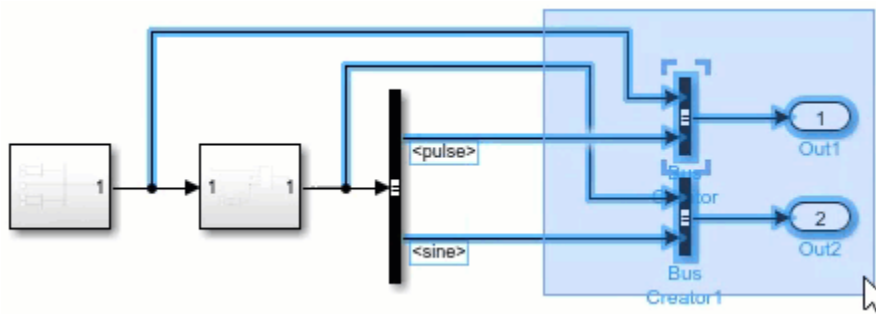

- 1 Select the model elements by dragging a selection box around them.
- 2 Move the model elements by dragging an edge of the selection box to a new position.

The contents of the selection box move as a unit. The relationship among lines, blocks, and other elements in the selection box remains the same as you move them. Line segments outside of the selection box reroute.

For example, suppose you have this model:

When you drag a selection box that includes line bends, the included line bends remain the same when you move the selection.

When you drag a selection box that excludes line bends, the excluded line bends may change when you move the selection.

To move multiple lines together, drag the selection box around the line segments you want to move.

Flip or Rotate Blocks

You can change the orientation of a block or a group of blocks by rotating blocks in 90-degree increments or by flipping the blocks. Rotating or flipping blocks can help them fit better in the model, such as in feedback loops, where the blocks are connected to each other in a loop. You might also need to rotate a block so that the block input ports align with output ports or to make better use of the model canvas.

The figure shows a Gain block flipped to simplify a feedback loop diagram.

To rotate a block, select the block and, on the **Format** tab, click **Rotate 90 clockwise**  or **Rotate 90 counterclockwise** .

Blocks automatically rotate when you place them on a signal line that has an orientation other than left to right. For example, if the signal goes from bottom to top and you place a block on it, the block rotates to align with the signal.

To flip a block, select the block and, on the **Format** tab, click **Flip left-right**  or **Flip up-down** . You can flip a block horizontally or vertically based on the orientation of the block ports. For example, if the ports are on the sides, the block flips left to right.

To rotate or flip a group of blocks, select multiple blocks before rotating or flipping them. You can only flip groups of blocks to the left or right.

After you rotate or flip a group of blocks, you can improve the readability of the model by editing the signal lines. The **Auto Arrange** option might improve the appearance of signals. (For information on rotation with multiple ports, see “Port Location After Rotating or Flipping” on page 36-11.)

For example, suppose you rotate these selected blocks clockwise.

After you rotate the blocks, the model might contain overlapping elements.

With the blocks and signals selected, on the **Format** tab, select **Auto Arrange**.

Port Location After Rotating or Flipping

Rotating moves block ports from the sides to top and bottom or the reverse, depending on the placement of the ports. The resulting positions of the block ports depend on the block port rotation type.

Rotating can reposition the ports on some blocks to maintain left-to-right or top-to-bottom port numbering order. A block whose ports are reordered after a rotation has the default port rotation type. This policy helps to maintain the left-right and top-down block diagram orientation convention used in control system modeling applications. The figure shows the effect of clockwise rotation on a block with the default port rotation policy.

A masked block can specify that ports keep their order after rotation (see “Port rotation”). These blocks have a physical port rotation type. This policy helps when designing blocks to use when modeling physical systems and other applications where diagrams do not have a preferred orientation. The figure shows the effect of clockwise rotation on a block with a physical port rotation type.

Flipping a block moves the ports to the opposite side of the block, creating a mirror image, regardless of port rotation type.

Manage Block Names and Ports

You can manage block names by displaying or hiding them and by changing their location on the block.

Note Copying and pasting blocks whose names follow numeric order (Gain1, Gain2, and so on) creates names that follow standard sorting order conventions for ASCII characters. This sorting order can result in a sequence of numbers on the block names that is hard to understand. If the numbering scheme is important to you, name your blocks explicitly such that copying and pasting them creates names that follow a typical reading order. To do so, use a leading zero in the block names, for example Gain001, Gain002, and so on.

Hide or Display Block Names

The Simulink Editor names blocks when you create them. The first occurrence of the block is the library block name, for example, Gain. The next occurrence is the block name with a number appended. Each new block increments the number, for example, Gain1, Gain2, and so on. These names are called automatic names. By default, the editor hides these names.

You can choose whether to hide or display block names. You can:

- Display all automatic names. Select one or multiple blocks and, on the **Format** tab, select the button that says **Auto Name, Name On**, or **Name Off** depending on its current setting. Then, clear **Hide Automatic Block Names**.
- Temporarily display a hidden automatic block name by selecting the block.
- Name the block explicitly. The **Hide Automatic Names** setting does not affect blocks that you name explicitly. To name a block, select it, double-click the name, and type a new name.

In addition, you can explicitly hide or display any block name. Explicitly hidden or displayed block names are not affected by the **Hide Automatic Block Names** setting. To explicitly hide or display a block name, select the block, then on the **Format** tab, select the button that says **Auto Name, Name On**, or **Name Off** depending on its current setting. Then, select:

- **Name On** to always display the block name.
- **Name Off** to always hide the block name.
- **Auto Name** to return to the default state. If the block has a default name, the **Hide Automatic Block Names** setting affects the block.

Tip You can pause on a block to display the block name irrespective of the name settings at the block and model levels. You can edit the block name when it displays.

To display and hide block names programmatically, use `set_param` with the `'HideAutomaticNames'` option for models and the `'HideAutomaticName'` and `'ShowName'` options for blocks. For more information on these parameters, see “Common Block Properties”. The table shows how these parameters interact.

'ShowName' (block setting)	'HideAutomaticName' (block setting)	'HideAutomaticNames' (model setting)	Result
'off'	Any	Any	Name is hidden
'on'	'on'	'on'	Name is hidden
'on'	'off'	Any	Name is shown
'on'	'on'	'off'	Name is shown

Move Block Names

By default, block names appear below blocks whose ports are on the sides and to the left on blocks whose ports are on the top and bottom. To change the location of a block name, you can:

- Drag the block name to any side of the block.
- Select the block and, on the **Format** tab, click **Flip Name**.

Move Ports

You can put ports in any order on any side of these blocks:

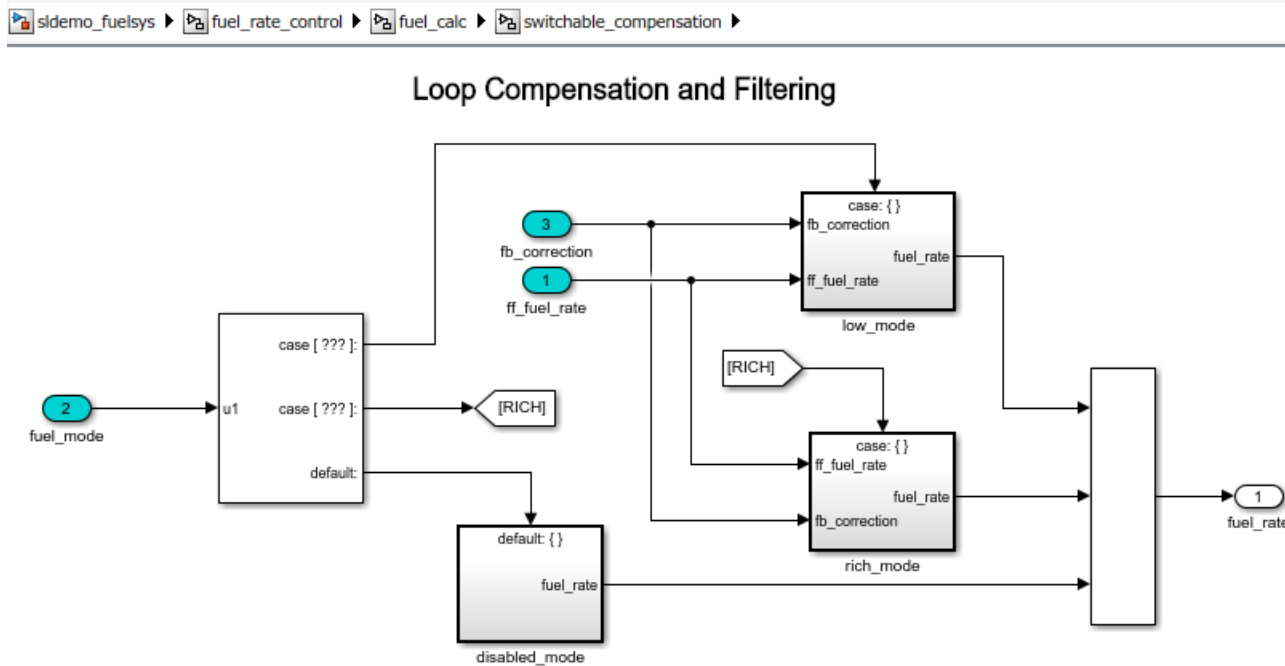

- Subsystem block
- Subsystem Reference block
- Model block
- Chart block
- Truth Table block
- State Transition Table block

You can move ports by clicking and dragging the port. For Subsystem blocks, the port index will automatically be renumbered after each move. For port label editing on Subsystem blocks, see “Edit Port Labels on Subsystems” on page 4-20.

Specify Model Colors

You can specify the outline and interior colors of any block, and you can change the background color for any system in a model. You can also change the text color and background color for annotations and the background fill color for areas.

This subsystem uses color to identify the input ports.

- To change the outline color of a block, text color in an annotation, or interior color for an area, select the element, and then, on the **Format** tab, select a color from the **Foreground** menu. Changing the foreground color of a block also changes the color of its output signals.
- To change the interior color of a block or background color in an annotation, select the element, and then, on the **Format** tab, select a color from the **Background** menu.
- To change a background color in a system, open the system and, on the **Format** tab, select a color from the **Background** menu.

You can select a color from the menu or select **Custom Color**  to define your own color.

You can also use the Property Inspector to change color for an area or an annotation. To specify colors programmatically, see “Specify Colors Programmatically” on page 1-6

Specify Fonts in Models

Change the font family, style, and size for any model element to make your model easier to read or to comply with company standards. You can modify the font for selected blocks, signal labels, areas, and annotations. Some blocks display text according to the font style settings, and some blocks have fixed fonts and styles. To increase the font size of those blocks, zoom in.

You can also change the default font for the model. The default font affects any elements whose font you have not changed and any new elements you create. If you want to use the same default font in all new models, change the default model font in your default template. See “Set Default Template for New Models” on page 1-10.

- To change the font of a block, signal label, area, or annotation, select the element, and then specify font information on the **Format** tab in the **Font & Paragraph** section.

- To change the default fonts for the model, on the **Format** tab, click the **Font Properties** button arrow , then click **Fonts for Model**. Use the Font Styles dialog box to specify the font information.

You can also use the Property Inspector to change font for an area or an annotation.

Select Font Dialog Box on Linux Machines

On Linux machines configured for English, the **Font style** list in the Select Font dialog box can appear out of order or in another language in some fonts. If the characters in your **Font style** list appear in another language, set the LANG environment variable to `en_US.utf-8` before you start MATLAB. For example, at a Linux terminal, enter:

```
setenv LANG en_US.utf-8
matlab
```

Increase Drop Shadow Depth

By default, blocks have a drop shadow. To make the block stand out more against the background, you can increase the depth of the drop shadow.

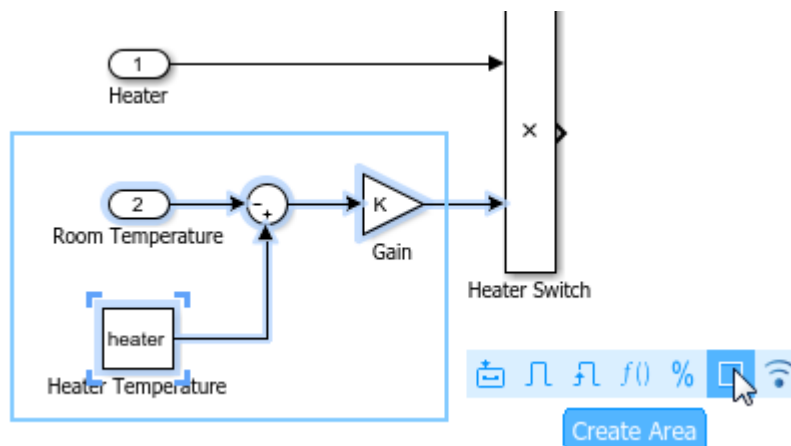

Select the blocks whose drop shadow depth you want to increase and, on the **Format** tab, click **Shadow**.

Tip To remove the default drop shadow for all blocks, in the Simulink Toolstrip, on the **Modeling** tab, select **Environment > Simulink Preferences**. In the **Editor** pane of the Simulink Preferences dialog box, select **Use classic diagram theme**.

Box and Label Areas of a Model

Add an area to your model to visually group related model elements in a box. An area can move with the blocks it surrounds. You can add text to an area to briefly describe or label the area.

- Drag a box around the area of interest in the model. Alternatively, drag on a blank area of the canvas to draw the area shape.
- From the action bar, select the option to create an area.

- 3 Type the name of the area. The name appears in the upper-left corner of the area.

To enter the name later, select the area, click the **?**, and start typing, or use the **Name** property in the Property Inspector.

- 4 Optionally, add a description of the area contents using the Property Inspector.
- 5 To move the area and its contents, drag the area near the border.

Tip To move an area without moving its contents, hold **Alt** (**option** on a Mac) and drag.

Convert Area to a Subsystem

An area is similar to a subsystem in that it is a way to group related blocks. However, a subsystem creates a hierarchy, replacing multiple blocks in a model with a single block. You can initially group related blocks in an area and later decide to put those blocks in a subsystem by converting the area to a subsystem. The resulting subsystem has the same name, blocks, description, and requirements traceability information as the area.

To convert an area to a subsystem, right-click the area and select **Create Subsystem from Area**.

Copy Formatting Between Model Elements

If you have applied formatting to a block, signal line, or area in a model, you can copy the formatting and apply it to another model element. Examples of formatting include font changes, foreground and background color selections, and drop shadow effects.

- 1 Select the block, line, or area whose formatting you want to copy.
- 2 From the action bar, select **Copy Formatting**. The cursor becomes a paintbrush.

- 3 Using the paintbrush, click each element that you want to copy the formatting to.
- 4 To cancel the paintbrush cursor, click a blank spot on the canvas or press **Esc**.

Display Port Values for Debugging

In this section...

“Display Port Values for Easy Debugging” on page 36-18

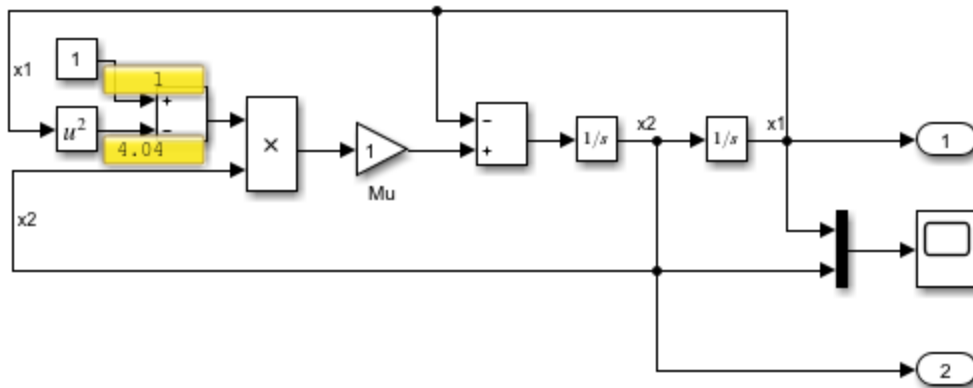

“Display Value for a Specific Port” on page 36-21

“Display Port Values for a Model” on page 36-24

“Port Value Display Limitations” on page 36-25

Display Port Values for Easy Debugging

For many blocks whose signals carry data, Simulink can display signal values (block output) as port value labels (similar to tool tips) on the block diagram during and after a simulation. Port value labels display block output values when Simulink runs block output methods. This model shows a port value label for the ports on the Constant and Math blocks, output values of 1 and 4.04.

If the port value label appears empty, this means that no port value is currently available. For example, toggling a port value label on a continuous block when paused during simulation does not display any values in the label.

Port value labels are also empty when you have not yet simulated the model. This is because the block output methods do not run when the model does not simulate.

If you toggle or hover on a block that Simulink optimizes out of a simulation (such as a virtual subsystem block), while you simulate, the model displays the text *optimized*.

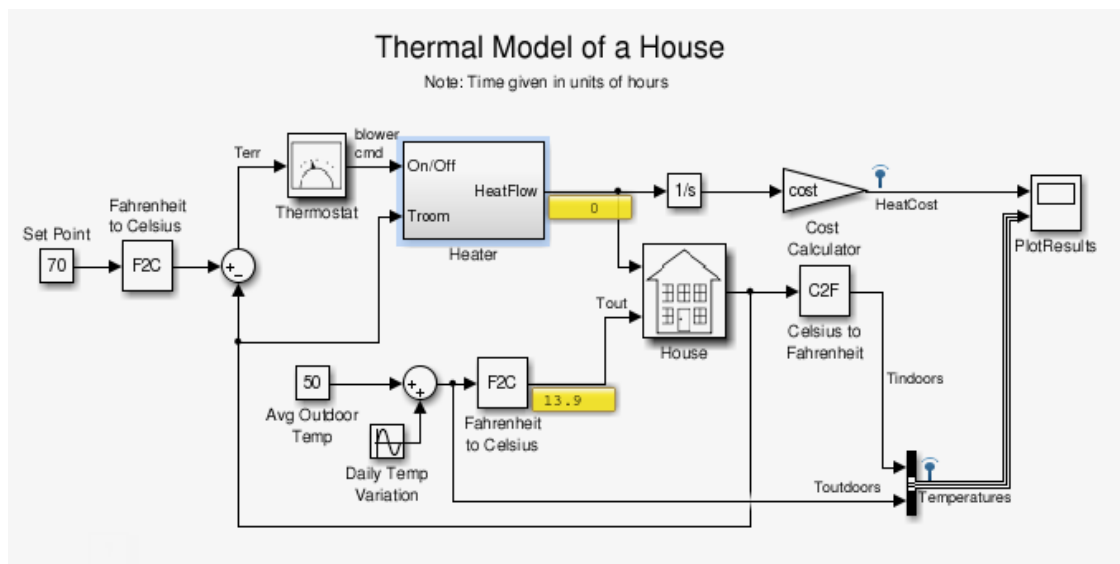

Displaying port value data tips can help during interactive debugging of a model. For example, the figure shows the output of a thermal model for a house.

These results suggest a problem with the model because:

- The heating cost is 0 at all temperatures.
- The temperature inside the house matches ambient temperature almost exactly.

In such cases, debugging the blocks in the model interactively can help isolate the error. Port value labels provide information at the output of every block in the model. So in this example, if you step forward using Simulation Stepper, you can see that the output of the Heater subsystem is 0 at every time step.

To learn more, you can enable port value labels for blocks inside the Heater subsystem. Using Simulation Stepper, if you step forward again to display the values, you can see that there is an issue with the HeatGain block. The output is constant at 0.

This technique helps you isolate the issue.

To simplify debugging, you can turn on and off port value labels during simulation. Besides providing useful information for debugging, port value displays can help you monitor a signal value during simulation. However, these labels are not saved with a model.

For nonnumeric data display, Simulink uses these values:

Message	Explanation
action	The signal executes action subsystems.
fcn-call	The signal is a function-call signal, e.g., Function Call Generator output.
ground	The signal is coming from a Ground block.
not a data signal	The signal does not contain valid data, e.g., the signal is from a block that is commented out.

In some cases:

- The port value display may not be able to acquire the value signal or
- The signal's value cannot be easily displayed

In such cases, Simulink uses these values.

Message	Explanation
...	The signal dimension exceeds the maximum number of elements Simulink can display. For more information, see "Display Port Values for a Model" on page 36-24.
(no message)	The simulation data available is insufficient. Step forward or press play to obtain more data.
click to add signals	You have enabled a port value label on a bus. However, you have not selected a signal to display. Click the label to select bus signals.
inaccessible	Simulink cannot obtain the port value. For an example, see "Signal Storage Reuse" on page 36-25.
[m*n]	This is a nonvector signal. Simulink cannot display the actual values of the matrix. It displays the matrix dimension instead.

Message	Explanation
no data yet	This message appears when: <ul style="list-style-type: none"> The simulation data is not available. Start the simulation to see values. If the model contains subsystems (for example, an enabled subsystem) and model references and they are not executed during a simulation.
not used	Simulink cannot obtain the signal value due to optimization.
removed	Simulink cannot obtain the signal value due to block reduction.
optimized	Simulink cannot obtain the signal value due to optimization. In Normal mode, this message appears for blocks with Conditional input branch execution enabled. For more information, see “Conditionally Executed Subsystems Overview” on page 10-3.
unavailable	The simulation data available is insufficient. For example, see “Simulation Stepper” on page 36-26.

Note You can force a value label to display the signal value by designating the signal as a test point. Use the **Properties** dialog box to do this.

Display Value for a Specific Port

To display the value of a specific port or port values for a block before simulation, select one or more signals, right-click the selection, and select **Show Value Label of Selected Port**.

By default, Simulink displays the value of a signal when you click it during simulation. You can control this behavior. On the **Debug** tab, select the **Remove all simulation output Value Displays from**

canvas button arrow , then select **Options**. In the Value Label Display Options dialog box, select **Enable by default during simulation**.

Note To remove all data tips, on the **Debug** tab, select the **Remove all simulation output Value Displays from canvas** button arrow , then select **Remove Value Displays**.

For bus signals, the **Show Value Label of Selected Port** option opens a dialog box where you can select from all signals in the bus. For example, in this model, you can see the dialog box for all signals that are contained in ModelBus.

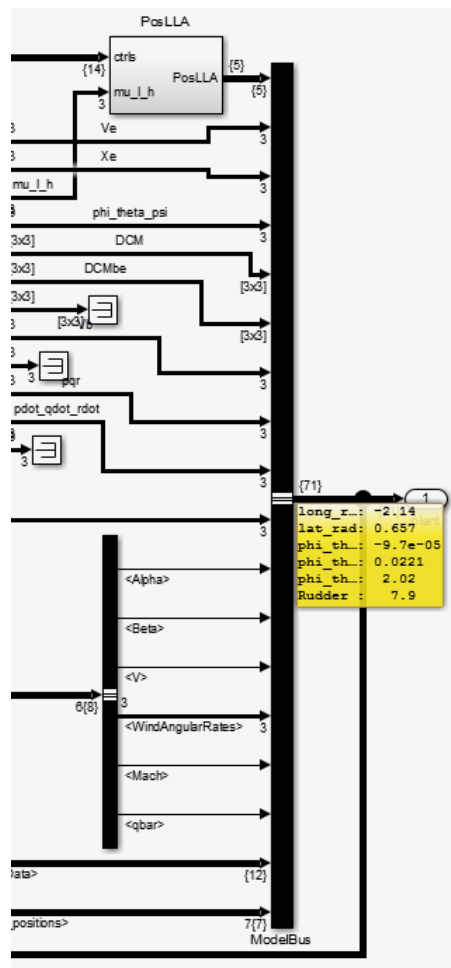

You can search for a signal by name or filter through the hierarchy. Select a parent signal to include all of the signals it contains. You can also filter the display to view only those signals you have selected.

Click anywhere outside the dialog box to close it. The port value label appears. The label has no data; it displays values when you simulate the model.

When you simulate the model, the port value label displays the names and values of the signals you chose. To change the signals to display, click on the port value label to reopen the dialog. You can also click on another signal to display its value.

Note Simulink does not save the values of a signal when you remove the port value label.

Display Port Values for a Model

Specify port value display formatting and the frequency of updates. The Value Label Display Options dialog box controls these settings on the entire model.

- 1 In the model whose port values you want to display, on the **Debug** tab, select the **Remove all simulation output Value Displays from canvas** button arrow , then select **Options**.
- 2 In the Value Label Display Options dialog box, specify your preferences for:
 - The display options, including font size, the refresh frequency, and the number of elements displayed for vector signals with signal widths greater than 1
 - The display mode
 - Floating-point or fixed-point format

Port Value Display Limitations

Performance

Enabling the hovering option for a model or setting at least one block to **Toggle Value Labels When Clicked** slows down simulation.

Accelerated Modes

Port values work in Normal and Accelerator modes only. They do not work in Rapid Accelerator and External modes. The table shows how accelerator modes affect the display of port values.

Accelerated Mode	Port Values
Accelerator	<ul style="list-style-type: none"> Signals not optimized in Accelerator mode display port values as in Normal mode. Signals optimized in Accelerator mode display port values as optimized. For more information, see “Display Port Values for Easy Debugging” on page 36-18. Model reference blocks simulated in Accelerator mode do not get their port value displays updated.
Rapid Accelerator	Incompatible. The limitation exists whether the model or its parent specifies accelerated simulation. For more information, see “Accelerate, Refine, and Test Hybrid Dynamic System on Host Computer by Using RSim System Target File” (Simulink Coder).

Signal Storage Reuse

If the output port buffer of a block is shared with another block through the optimization of signal storage reuse, the port value displays as **inaccessible**. You can disable signal storage reuse using the **Signal storage reuse** check box. However, disabling signal storage reuse increases the memory used during simulation.

Signal Data Types

- Simulink displays the port value for ports connected to most kinds of signals, including signals with built-in data types (such as `double`, `int32`, or `Boolean`), `DYNAMICALLY_TYPED`, and several other data types.
- Simulink shows the floating format for only noncomplex signal value displays.
- Simulink displays the port value of fixed point data types based on the converted double value.
- Simulink does not display data for signals with some composite data types, such as bus signals.

Subsystems

- You cannot display port values for subsystems contained in a variant subsystem when there are no signal lines connecting to them. In such cases, during simulation, Simulink automatically determines block connectivity based on the active variant. However, you can display port values within the subsystems contained in the variant subsystem. You can also display values on signal lines outside of the variant subsystem.
- When you disable a conditionally executed subsystem, the port value display for a signal that goes into an Output block displays the value of the Output block, depending on the **Output when disabled** setting.

- Simulink does not display data for the ports of an enabled subsystem that is not enabled.

Simulation Stepper

If you do not enable port value display when stepping forward, the display will not be available when stepping back. When stepping back, if the port value is unavailable, the `unavailable` label is displayed.

Refine Factor

Port value displays do not honor refine factor values (**Configuration Parameters > Data Import/Export > Additional parameters > Refine factor**) because Simulink updates port value displays only during major time steps.

Signal Specification Block and Inport Block

When you display port values on Signal Specification and Inport blocks in a subsystem, the value that is driving the blocks displays instead of the block values.

Command-Line Simulations

For efficiency, Simulink does not support port value displays during a command-line simulation using the `sim` command.

Merge Block

Simulink does not display the input values to the merge block. To see this value, refer to the source block.

Command Line Interface

You cannot specify port value displays through the command line interface.

Non-Simulink signals

You cannot place port values on non-Simulink signals, such as Simscape or SimEvents signals. This limitation applies to conditional breakpoints as well.

- “Access Block Data During Simulation” on page 36-39
- “Block Libraries”

Control and Display Execution Order

The execution order for a model is the order in which Simulink invokes the block output methods during simulation. Simulink determines this order during a model update, which you can initiate by clicking **Update Model** on the **Modeling** tab. Simulink also updates the model during simulation.

You cannot set the execution order, but you can assign priorities to nonvirtual blocks to indicate their execution order relative to other blocks in the corresponding block diagram. Simulink tries to honor block priority settings unless there is a conflict with data dependencies. To confirm the results of the priorities you have set or to debug your model, display and review the execution order of your nonvirtual blocks and subsystems.

Note For more information about block methods and execution, see:

- “Block Methods”
- “Conditionally Executed Subsystems Overview” on page 10-3
- “Specify Block Execution Priority and Tag” on page 36-5

Execution Order Viewer

On the **Debug** tab, select **Information Overlays > Execution Order**. The Execution Order viewer opens in a pane on the right side of the Simulink Editor.

Task ID	Details
Task 0	Continuous
	Fixed in Minor Step
Task 1	Constant

The Execution Order viewer displays a list of tasks for the current system.

Each nonvirtual subsystem has its own **System Index** value that is unique within the model. Blocks that are directly inside the nonvirtual subsystem have the same **System Index** value as the subsystem. In model reference hierarchies, the same **System Index** value may be used multiple

times, but it remains unique within each model in that hierarchy. To determine whether subsystems are part of the same system within a model, compare their **System Index** values.

Each task listed in the **Task ID** column corresponds to a group of blocks that execute in the same task. For fixed-step sizes, the **Treat each discrete rate as a separate task** configuration parameter determines whether Simulink executes blocks with discrete rates in one or multiple tasks.

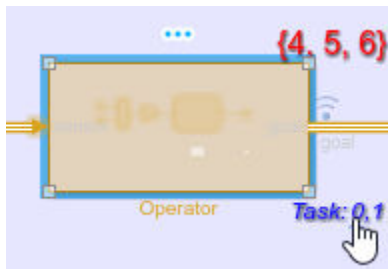

Selecting a task in the Execution Order viewer highlights the blocks that belong to the task and displays their execution order. By default, Simulink selects the first task that corresponds to the active block diagram.

When the active block diagram does not contain any blocks that execute as part of a given task, you cannot select the task in the Execution Order viewer. The active block diagram may contain virtual blocks, such as Inport blocks, that are part of this task.

To hide the highlighting and execution order, click the **Clear Highlighting** button .

Navigation from Blocks to Tasks

To display the tasks in which a block executes, click on a block.

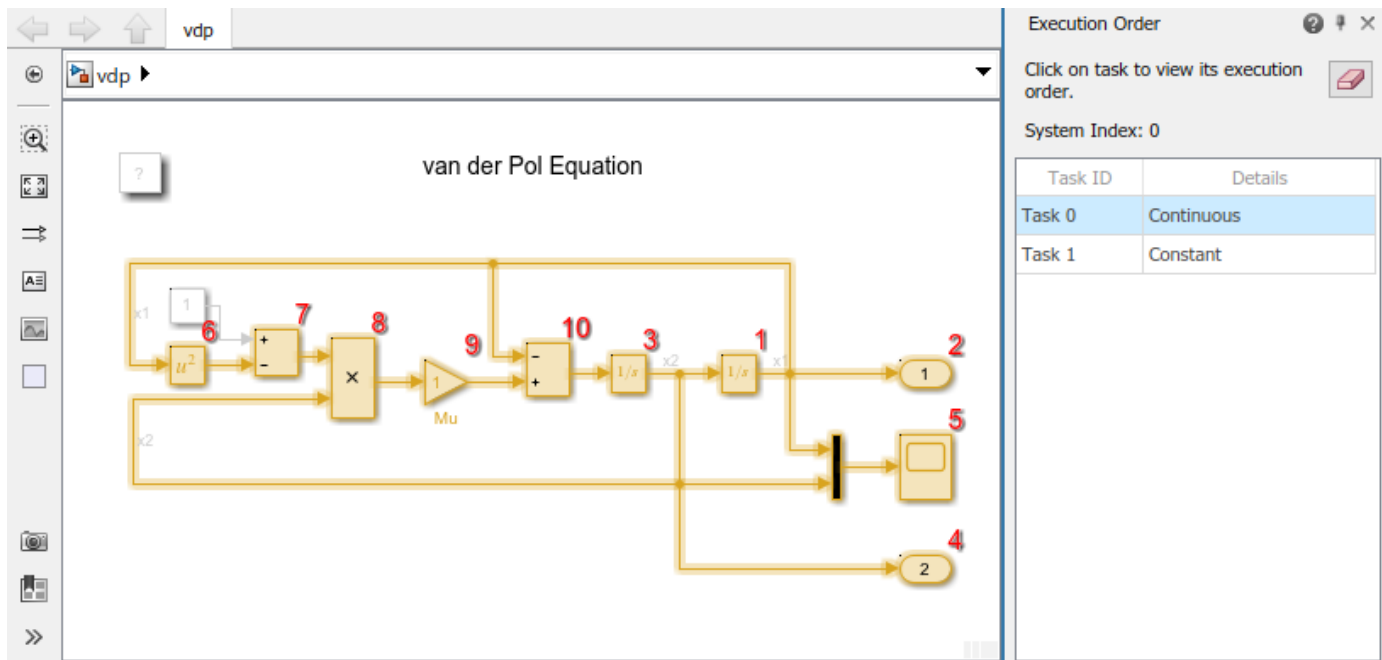

The task numbers in the label are links that you can click to select the corresponding task in the Execution Order viewer. When a model has many tasks, these links provide an alternative to scrolling through the list of tasks in the Execution Order viewer.

To compare tasks among blocks, select multiple blocks.

Execution Order Notation

Simulink displays a number at the top-right corner of each nonvirtual block. These numbers indicate the order in which the blocks execute. The first block to execute has the lowest execution order, which is usually 1. The displayed execution order may skip numbers, but the blocks always execute in order of the visible numbers. Suppose a task displays execution orders 1, 2, and 4. The block labeled 1 executes before the block labeled 2, which executes before the block labeled 4.

For example, in the vdp model, the block execution order ranges from 1 to 9, with each nonvirtual block receiving an execution order.

Virtual and Nonvirtual Subsystems

Virtual Subsystem blocks exist only graphically and do not execute. Consequently, they are not part of the execution order, and each block within a virtual subsystem still executes as an atomic unit. The blocks inside a virtual subsystem have an execution order in the context of the root-level model or, if the virtual subsystem is inside a nonvirtual subsystem, in the context of the parent nonvirtual subsystem. For virtual subsystems, block execution order within the subsystem is listed in curly brackets {}.

Nonvirtual Subsystem blocks exist functionally and execute as a unit. They have a single execution order and a different system index than the root-level model or any parent nonvirtual subsystem. The blocks inside a nonvirtual subsystem have their own execution orders, which are independent of the root-level model or any parent nonvirtual subsystem.

For example, this model contains a virtual subsystem named Car Dynamics and an atomic, nonvirtual subsystem named Discrete Cruise Controller.

The virtual Car Dynamics subsystem shows a list of execution orders within curly brackets for the blocks it contains. The blocks it contains execute at the same level as the Step, Sum, and Scope blocks and the Discrete Cruise Controller nonvirtual subsystem. The Integrator block executes first and sends its output to the Scope block, which executes second.

The nonvirtual Discrete Cruise Controller subsystem has a single execution order (5), which indicates that the subsystem and the blocks within it are the fifth to execute relative to the blocks at the same level.

Note Depending on your model configuration, Simulink can insert hidden, nonvirtual subsystems in your model. As a result, the visible blocks inside the hidden Subsystem block can have a system index that is different from the current system index. For example, if you select the **Conditional input branch execution** configuration parameter, Simulink may create hidden, nonvirtual subsystems for optimization, which can affect the sorted execution order.

Algebraic Loops

Blocks within an algebraic loop are moved into a hidden nonvirtual subsystem. Simulink first determines the execution order of the hidden subsystem within the context of the other blocks, then determines the execution order of the blocks within the hidden subsystem. See “Algebraic Loop Concepts” on page 3-27.

Function-Call and Action Subsystems

For function-call and action subsystems, the execution of the subsystem is controlled by the execution of its initiator. The subsystem and its initiator therefore share an execution order.

Simulink ignores any block priority set on Function-Call Subsystem, If Action Subsystem, or Switch Case Action Subsystem blocks, but you can set the block priority on the blocks that initiate these subsystems.

At the root-level of export-function models, function-call execution orders have an F prefix.

For more information, see “Export-Function Models Overview” on page 10-98.

Buses and Multiple Initiators

A block has multiple execution orders when the block executes multiple times based on different execution paths to that block. For example:

- A block connected to a bus has an execution order corresponding to each signal that the bus contains.

- A function-call or action subsystem with multiple initiators has an execution order corresponding to each initiator.

How Simulink Determines Execution Order

Simulink uses task-based sorting to set the execution order of blocks and ports based on their derived sample time information. Task-based sorting provides an efficient and simpler process for determining the execution order of blocks.

With task-based sorting:

- Tasks are sorted individually based on sample time.
- Multiple sorted lists are generated instead of one flattened, sorted list of blocks across all tasks.
- Rate transition handling is simplified.
- False data dependency violations involving blocks in different tasks are avoided.
- Code generation results are in efficient rate groupings.
- One subsystem can belong to different sorted lists in multiple tasks.

Direct-Feedthrough Input Impact on Execution Order

To ensure that the execution order reflects data dependencies among blocks, Simulink categorizes block input ports according to the dependency of the block outputs on the block input ports. An input port whose current value determines the current value of one of the block outputs is a *direct-feedthrough* input. See “Algebraic Loop Concepts” on page 3-27. Examples of blocks that have direct-feedthrough inputs include:

- Gain
- Product
- Sum

Examples of blocks without direct-feedthrough inputs include:

- Integrator
- Unit Delay
- Constant

Rules for Determining Block Execution Order

To sort blocks, Simulink uses these rules:

- If a block drives the direct-feedthrough input of another block, the driving block must appear in the execution order ahead of the block that it drives.

This rule ensures that the direct-feedthrough inputs to blocks are valid when Simulink invokes block output methods that require current inputs.

- If a block drives the input of another block that is not a direct-feedthrough input, there is no data dependency between the two blocks, so their relative execution order does not matter.

This model illustrates this result.

- The Integrator block $1/s$ in the Car Dynamics virtual subsystem has no direct-feedthrough input. Therefore, even though its input is connected to the Gain block $1/m$, the Integrator block is sorted before the Gain block $1/m$. The output of the Integrator block drives the input of the Gain block b , so the Integrator block is sorted before that Gain block.

- In the root-level model, the Step block `step` response drives a Sum block, so the Step block is sorted before the Sum block. The Sum block drives the direct-feedthrough input of the Discrete Cruise Controller nonvirtual subsystem, so the subsystem is sorted after the Sum block.

The Discrete Cruise Controller nonvirtual subsystem is treated as a block with a direct-feedthrough input because its output depends on the current value of the input via the branch with the K_p Gain block. Inside the subsystem, all the Gain blocks, which have direct-feedthrough inputs, run before the Sum block that they drive.

Rules for Determining Block Execution Order in Models Containing Asynchronous Tasks

In simulation, asynchronous function call initiators have the highest priority when determining block sorting order within a task. For more information, see “Asynchronous Sample Time” on page 7-15 and “Rate Transitions and Asynchronous Blocks” (Simulink Coder).

To determine the block execution order in models containing asynchronous sample times, Simulink uses these rules:

- If an asynchronous function call initiator is triggered by a discrete rate shared by the corresponding rate transition block, then in the task of the common discrete rate, the asynchronous function call initiator will be sorted first.

For example, in the below model, there is one asynchronous function call initiator that is triggered by the discrete rate D1. Within the discrete task, the asynchronous function call initiator is sorted first. The Rate Transition blocks convert between the asynchronous rate, A1, and the discrete rate, D1.

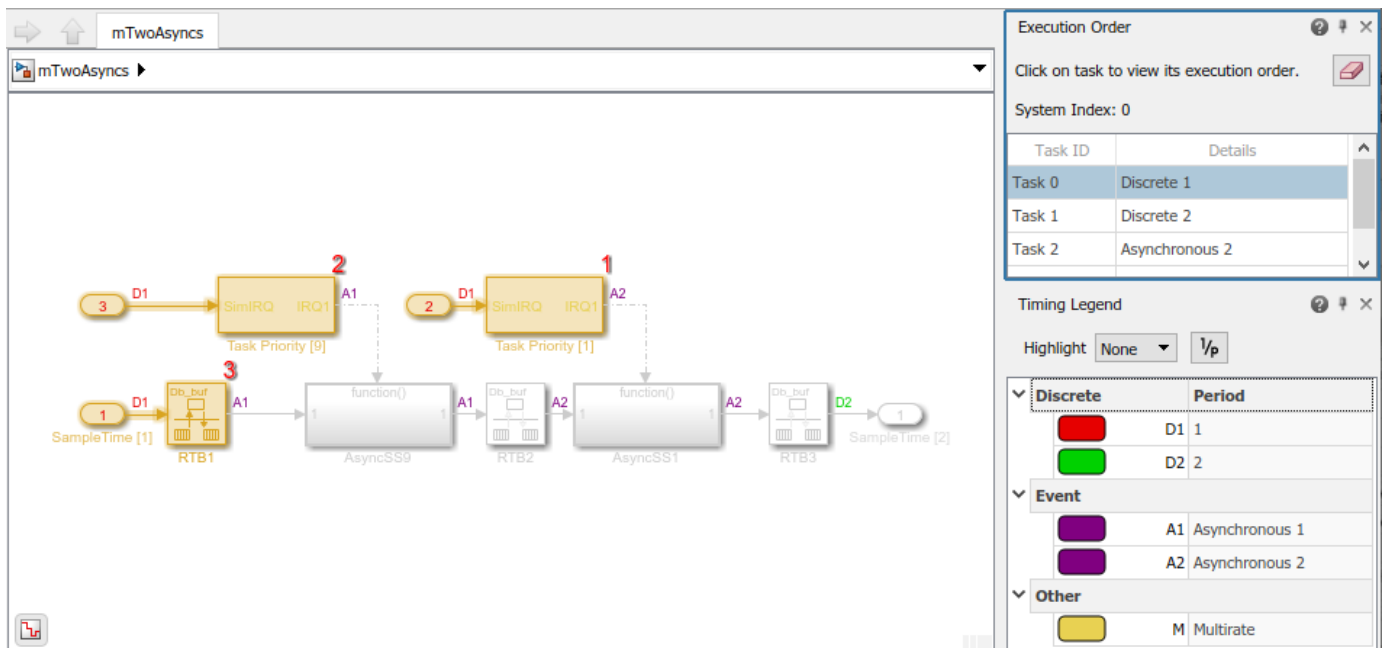

- If a Rate Transition block is reduced to NoOp, the Rate Transition block does not execute, and its position in the sorted order within the discrete task is transferred to the upstream or downstream discrete block to which it is connected.

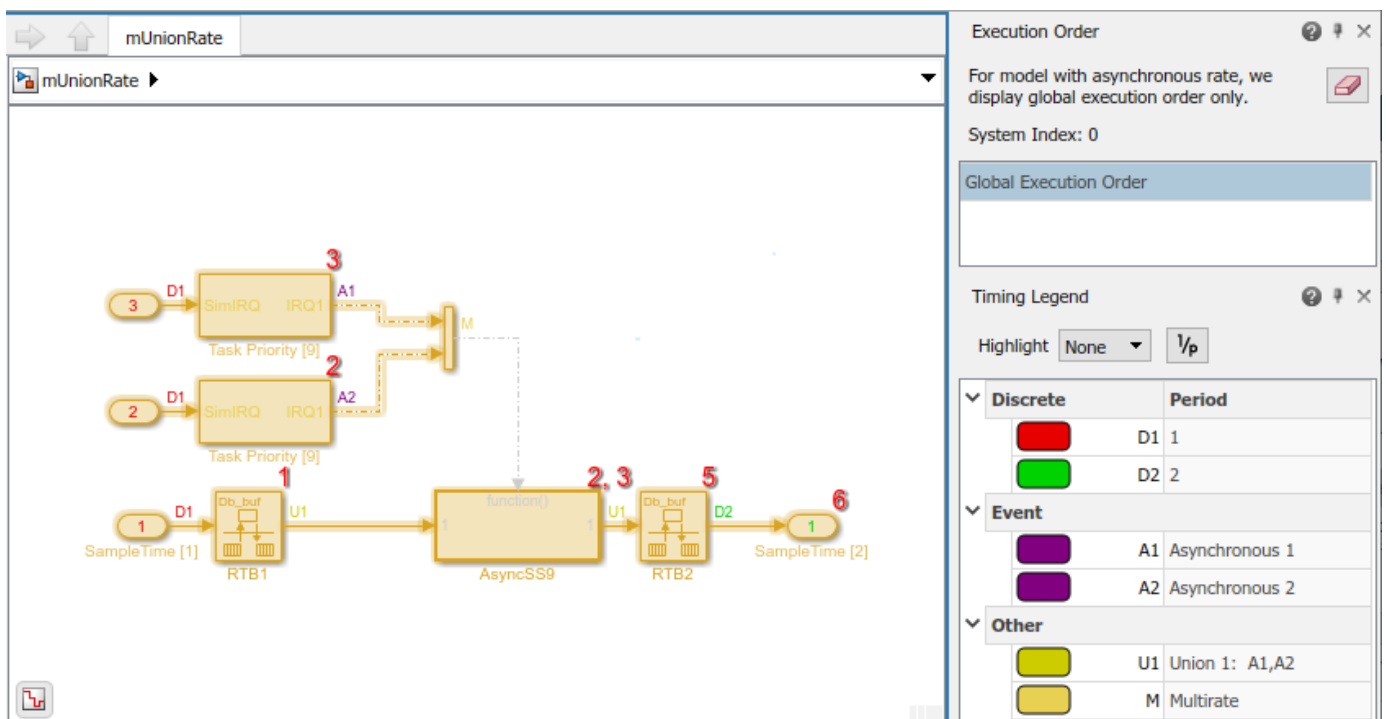

For example, in the above model, RTB2 is reduced to NoOp, so its position in the sorted order is transferred to the downstream Gain block.

- If two asynchronous function call initiators share a common discrete rate task, then asynchronous function call initiator with higher priority executes first within the discrete rate task.

For example, in the below model, two asynchronous function call initiators are triggered by the same discrete rate, D1. The one with higher task priority is sorted first.

- The union of asynchronous sample times is not supported by task-based sorting. Models containing the union of multiple asynchronous sample times default to a global execution order, in which all blocks are sorted within a single task.

Checks for Execution Order Changes Involving Data Store Memory Blocks

Model Upgrades

Using task-based sorting instead of legacy (block) sorting can change the relative execution order involving Data Store Memory blocks. An Upgrade Advisor check detects the changes and provides an option to keep the original execution order when upgrading your model from earlier versions of Simulink.

- 1 Open the Upgrade Advisor. On the **Modeling** tab, select **Model Advisor > Upgrade Advisor**.
- 2 Select the check box for **Check relative execution orders for Data Store Read and Data Store Write blocks**.

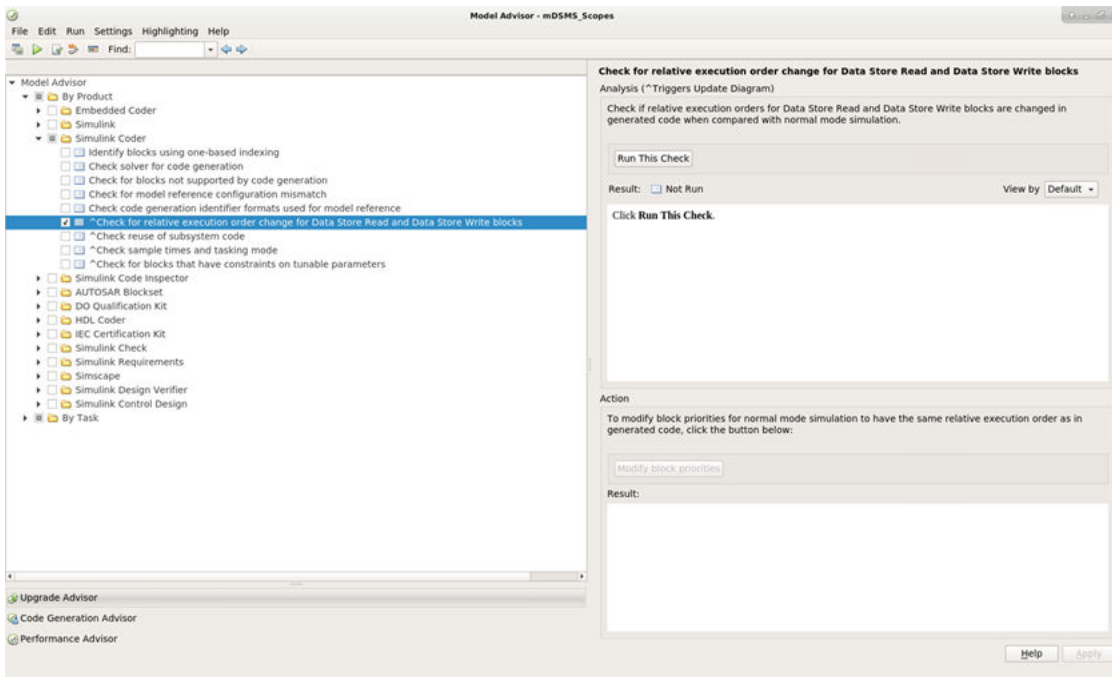

- 3 Click **Run This Check**.
- 4 Review any changes in the **Result** table. If you want to keep the original execution order, click **Modify**.

Code Generation

When a model is compiled for code generation, the relative execution order of Data Store Read and Data Store Write blocks can differ in the generated code from the order in normal simulation mode. A Model Advisor check detects these differences and provides an option to change the execution order in normal simulation mode to match the order in the generated code.

- 1 Open the Model Advisor. On the **Modeling** tab, select **Model Advisor > By Product > Simulink Coder**.
- 2 Select the check box for **Check for relative execution order change for Data Store Read and Data Store Write blocks**.

3 Click **Run This Check**.

4 Review any changes in the **Result** table. If there are discrepancies listed and you want to change the execution order in normal simulation to conform with the execution order in generated code, click **Modify block priorities**.

Access Block Data During Simulation

In this section...

“About Block Run-Time Objects” on page 36-39

“Access a Run-Time Object” on page 36-39

“Listen for Method Execution Events” on page 36-39

“Synchronizing Run-Time Objects and Simulink Execution” on page 36-40

About Block Run-Time Objects

Simulink provides an application programming interface, called the block run-time interface, that enables programmatic access to block data, such as block inputs and outputs, parameters, states, and work vectors, while a simulation is running. You can use this interface to access block run-time data from the MATLAB command line, the Simulink Debugger, and from Level-2 MATLAB S-functions (see “Write Level-2 MATLAB S-Functions” in the online Simulink documentation).

Note You can use this interface even when the model is paused or is running or paused in the debugger.

The block run-time interface consists of a set of Simulink data object classes (see “Data Objects” on page 68-59) whose instances provide data about the blocks in a running model. In particular, the interface associates an instance of `Simulink.RunTimeBlock`, called the block's run-time object, with each nonvirtual block in the running model. A run-time object's methods and properties provide access to run-time data about the block's I/O ports, parameters, sample times, and states.

Access a Run-Time Object

Every nonvirtual block in a running model has a `RuntimeObject` parameter whose value, while the simulation is running, is a handle for the run-time object of the block. This allows you to use `get_param` to obtain a block's run-time object. For example, the following statement

```
rto = get_param(gcb, 'RuntimeObject');
```

returns the run-time object of the currently selected block. Run-time object data is read-only. You cannot use run-time objects to change a block's parameters, input, output, and state data.

Note Virtual blocks (see “Nonvirtual and Virtual Blocks” on page 36-2) do not have run-time objects. Blocks eliminated during model compilation as an optimization also do not have run-time objects (see “Block reduction”). A run-time object exists only while the model containing the block is running or paused. If the model is stopped, `get_param` returns an empty handle. When you stop a model, all existing handles for run-time objects become empty.

Listen for Method Execution Events

One application for the block run-time API is to collect diagnostic data at key points during simulation, such as the value of block states before or after blocks compute their outputs or derivatives. The block run-time API provides an event-listener mechanism that facilitates such

applications. For more information, see the documentation for the `add_exec_event_listener` command. For an example of using method execution events, enter

```
sldemo_msfcn_lms
```

at the MATLAB command line. This Simulink model contains the S-function `adapt_lms.m`, which performs a system identification to determine the coefficients of an FIR filter. The S-function's `PostPropagationSetup` method initializes the block run-time object's `DWork` vector such that the second vector stores the filter coefficients calculated at each time step.

In the Simulink model, double-clicking on the annotation below the S-function block executes its `OpenFcn`. This function first opens a figure for plotting the FIR filter coefficients. It then executes the function `add_adapt_coef_plot.m` to add a `PostOutputs` method execution event to the S-function's block run-time object using the following lines of code.

```
% Add a callback for PostOutputs event
blk = 'sldemo_msfcn_lms/LMS Adaptive';

h = add_exec_event_listener(blk, ...
    'PostOutputs', @plot_adapt_coefs);
```

The function `plot_adapt_coefs.m` is registered as an event listener that is executed after every call to the S-function's `Outputs` method. The function accesses the block run-time object's `DWork` vector and plots the filter coefficients calculated in the `Outputs` method. The calling syntax used in `plot_adapt_coefs.m` follows the standard needed for any listener. The first input argument is the S-function's block run-time object, and the second argument is a structure of event data, as shown below.

```
function plot_adapt_coefs(block, ei) %#ok<INUSD>
%
% Callback function for plotting the current adaptive filtering
% coefficients.

stemPlot = get_param(block.BlockHandle,'UserData');

est = block.Dwork(2).Data;
set(stemPlot(2),'YData',est);
drawnow('expose');
```

Synchronizing Run-Time Objects and Simulink Execution

You can use run-time objects to obtain the value of a block output and display in the MATLAB Command Window by entering the following commands.

```
rto = get_param(gcf,'RuntimeObject')
rto.OutputPort(1).Data
```

However, the displayed data may not be the true block output if the run-time object is not synchronized with the Simulink execution. Simulink only ensures the run-time object and Simulink execution are synchronized when the run-time object is used either within a Level-2 MATLAB S-function or in an event listener callback. When called from the MATLAB Command Window, the run-time object can return incorrect output data if other blocks in the model are allowed to share memory.

To ensure the Data field contains the correct block output, open the Configuration Parameters dialog box, and then clear the **Signal storage reuse** check box (see “Signal storage reuse” (Simulink Coder)).

Set Block Parameter Values

Blocks have numeric parameters that determine how they calculate output values. To control the calculations that blocks perform, you can specify parameter values. For example, a Gain block has a **Gain** parameter, and a Transfer Fcn block has multiple parameters that represent the transfer function coefficients.

You can use numbers, variables, and expressions to set block parameter values. Choose a technique based on your modeling goals. For example, you can:

- Share parameter values between blocks and models by creating variables.
- Control parameter characteristics such as data type and dimensions by creating parameter objects.
- Model an algorithm as code by using mathematical expressions.

Set block parameters using the **Parameters** tab in the Model Data Editor (on the **Modeling** tab, click **Model Data Editor**), the Property Inspector (on the **Modeling** tab, under **Design**, click **Property Inspector**), or the block dialog box. For more information, see “Add Blocks and Set Parameters” on page 1-14. To set block sample times, see “Specify Sample Time” on page 7-3.

Tip You can use the Model Explorer to make batch changes to many block parameter values at once. For more information, see **Model Explorer**.

Programmatically Access Parameter Values

To programmatically access block parameter values, use the `get_param` and `set_param` functions. You can use this technique to:

- Construct a model programmatically.
- Adjust parameter values during a simulation run when you simulate a model programmatically.

To sweep parameter values between simulation runs by using a script, use `Simulink.SimulationInput` objects instead of `get_param` and `set_param`. See “Optimize, Estimate, and Sweep Block Parameter Values” on page 37-38.

Suppose you create a model named `myModel` that contains a Constant block named `My Constant`. Next, you use the block dialog box to set the **Constant value** parameter to 15. To programmatically return the parameter value, use the function `get_param`. You specify the block path and the equivalent programmatic parameter name, `Value`.

```
paramValue = get_param('myModel/My Constant', 'Value')
```

```
paramValue =
```

```
15
```

To programmatically change the value, for example to 25, use the function `set_param`. Use the character vector `'25'` as the input to the function.

```
set_param('myModel/My Constant', 'Value', '25')
```

For a list of programmatic names of block parameters, see “Block-Specific Parameters”.

For more information about programmatic simulation, see “Run Simulations Programmatically” on page 26-2.

To avoid using the `get_param` and `set_param` functions, use the name of a MATLAB variable or `Simulink.Parameter` object as the parameter value, and change the value of the variable or object at the command prompt. See “Share and Reuse Block Parameter Values by Creating Variables” on page 37-9.

Specify Parameter Values

Goal	Block Parameter Value	Description
Store the parameter value in the model file.	2.3 [1.2 2.3 4.5; 7.9 8.7 6.5] 2 + 3i	Literal numeric value. Specify a scalar, vector, matrix, or multidimensional array. Use <code>i</code> to specify complex values.
<ul style="list-style-type: none"> • Access the parameter value without having to locate or identify the block in the model. • Change the parameter value without having to modify the model file. • Share the parameter value between blocks or between models. • Identify the parameter by a specific name when sweeping or tuning the value. 	myVar	<p>MATLAB variable that exists in a workspace.</p> <p>For more information, see “Share and Reuse Block Parameter Values by Creating Variables” on page 37-9.</p>
<ul style="list-style-type: none"> • Avoid name clashes between workspace variables. • Organize parameter values using hierarchies and meaningful names. • Reduce the number of workspace variables that a model uses. 	myParam.a.SpeedVect	<p>Field of parameter structure.</p> <p>For more information, see “Organize Related Block Parameter Definitions in Structures” on page 37-19.</p>
Use a portion of a matrix or array variable. For example, set the parameters of a n-D Lookup Table block.	myMatrixParam(:,2)	Index operation.

Goal	Block Parameter Value	Description
<ul style="list-style-type: none"> Define parameter characteristics, such as data type, complexity, units, allowed value range, and dimensions, separately from the parameter value. Define a system constant with custom documentation. Create a tunable parameter in the generated code. Use Parameter Objects

Parameter objects are `Simulink.Parameter` objects and objects of the subclasses that you create. The parameter object exists in a workspace such as the base workspace or a data dictionary.

You can use parameter objects to define system constants. For example, use a parameter object to represent the radius of the Earth. Use the properties of the object to specify the physical units and to document the purpose of the value.

Create parameter objects to prepare your model for code generation. You can configure parameter objects to appear as tunable global variables in the generated code. You can also control the parameter data type through the object.

To create and use parameter objects in models, see “Data Objects” on page 68-59. For information about using variables to set block parameter values, see “Share and Reuse Block Parameter Values by Creating Variables” on page 37-9.

Use Mathematical Expressions, MATLAB Functions, and Custom Functions

You can set a block parameter value to an expression that calls MATLAB functions and operators such as `sin` and `max`. You can also call your own custom functions that you write on the MATLAB path.

Suppose that a section of your block algorithm uses variables to calculate a single constant number used by the rest of the algorithm. You can perform the calculation by creating multiple blocks.

Instead, create a single Constant block that uses an expression written in MATLAB code. This technique reduces the size of the block algorithm and improves readability.

You can model a complicated portion of an algorithm by using an expression instead of many blocks. To operate on an existing signal, use a mathematical expression as the value of a parameter in an algorithmic block, such as the **Gain** parameter of a Gain block.

With expressions, you can also call your custom functions to set block parameter values. Suppose that you write a MATLAB function that calculates optimal P, I, and D parameters for a control algorithm by accepting a single input number.

```

paramFcn.m  x  +
1  function paramValue = paramFcn(performance,parameter)
2  %PARAMVALUE = paramFcn(PERFORMANCE,PARAMETER) returns the P, I, or D
3  %value PARAMVALUE that you request using PARAMETER. Specify performance
4  %criteria using PERFORMANCE.
5
6  % Initialize output.
7  paramValue = [];
8
9  % Calculate parameter value.
10 switch parameter
11     case 'P'
12         paramValue = performance*3;
13     case 'I'
14         paramValue = sqrt(performance)/0.175;
15     case 'D'
16         paramValue = performance^0.25;
17
18 % Validation

```

You can parameterize a PID Controller block by using the function to set the parameter values.

Controller parameters

Integral (I):

Derivative (D):

To make the best use of expressions, consider these tips:

- If you use variables and parameter objects, you can explicitly model the algebraic relationships between the real-world quantities that the variables and objects represent. Use expressions in parameter objects as described in “Set Variable Value by Using a Mathematical Expression” on page 37-10.
- While you edit an expression in a block parameter value, to navigate to the documentation for a function, use the button  next to the parameter value. You can also navigate to the source code of a custom function.

Considerations for Other Modeling Goals

Choose a technique to set block parameter values based on your modeling goals.

Goal	Features or Products	Best Practice
Run multiple simulations quickly.	Simulink.SimulationInput objects and the sim function	Use variables or parameter objects to set block parameter values. This technique helps you to assign meaningful names to the parameters and to avoid having to identify or locate the blocks in the model. See “Optimize, Estimate, and Sweep Block Parameter Values” on page 37-38.
Sweep parameter values during testing.	Simulink Test	Use variables or parameter objects to set block parameter values. Use iterations and parameter overrides to run multiple tests. See “Parameter Overrides” (Simulink Test) and “Test Iterations” (Simulink Test).
Estimate and optimize parameter values.	Simulink Design Optimization™	Use variables or parameter objects to set block parameter values. To estimate or optimize a parameter that uses a data type other than double, use a parameter object to separate the value from the data type. For parameter estimation, see “Parameter Estimation” (Simulink Design Optimization). For response optimization, see “Optimize Model Response” (Simulink Design Optimization).

Goal	Features or Products	Best Practice
Generate code from a model. Simulate an external program through SIL/PIL or External mode simulations.	Simulink Coder	<p>Use parameter objects to set block parameter values. This technique helps you to declare and identify tunable parameters in the generated code and to control parameter data types. See “Create Tunable Calibration Parameter in the Generated Code” (Simulink Coder).</p> <p>When you use expressions to set block parameter values, avoid using operators and functions that result in loss of tunability in the generated code. See “Tunable Expression Limitations” (Simulink Coder).</p>

- “Add Blocks and Set Parameters” on page 1-14

Share and Reuse Block Parameter Values by Creating Variables

To set a block parameter value, such as the **Gain** parameter of a Gain block, you can use numeric variables that you create and store in workspaces such as the base workspace, a model workspace, or a Simulink data dictionary. You can use the variable to set multiple parameter values in multiple blocks, including blocks in different models. To change the values of the block parameters, you change the value of the variable in the workspace.

Using a variable to set a block parameter value also enables you to:

- Change the parameter value without having to modify the model file (if you store the variable outside the model workspace).
- Identify the parameter by a specific, meaningful name when sweeping or tuning the value.

For basic information about setting block parameter values, see “Set Block Parameter Values” on page 37-2.

Reuse Parameter Values in Multiple Blocks and Models

You can create a numeric MATLAB variable in a workspace, such as the base workspace or a data dictionary, and use it to specify one or more block parameter values.

If a block parameter value is set to a simple numeric expression, you can create a variable for that expression in the Model Data Editor (on the **Modeling** tab, click **Model Data Editor**). Click  in the right side of the cell that corresponds to the value, then select **Create variable**. In the Create New Data dialog box, set the name and location for the new variable, then click **Create**. The cell now displays the new variable.

You can also create a variable to represent a constant that is used in multiple expressions. The example model `sldemo_fuelsys` represents the fueling system of a gasoline engine. A subsystem in the model, `feedforward_fuel_rate`, calculates the fuel demand of the engine by using the constant number `14.6`, which represents the ideal (stoichiometric) ratio of air to fuel that the engine consumes. Two blocks in the subsystem use the number to set the values of parameters. In this example, to share the number between the blocks, you create a variable named `myParam`.

- 1 Open the model.

```
sldemo_fuelsys
```

- 2 In the model, on the **Modeling** tab, click **Model Data Editor**. In the Model Data Editor, inspect the **Parameters** tab.
- 3 In the model, navigate into the subsystem.

```
open_system(...
    'sldemo_fuelsys/fuel_rate_control/fuel_calc/feedforward_fuel_rate')
```

- 4 In the Model Data Editor, in the **Filter contents** box, enter `14.6`.

The data table contains two rows, which correspond to the **Constant value** parameters of two of the Constant blocks in the subsystem.

- 5 Use the **Value** column to replace the literal number `14.6` with `myParam`. Perform the replacement for both parameters.
- 6 In the **Filter contents** box, enter `myParam`.

- 7 While editing the value of one of the parameters, click the action button  and select **Create**.
- 8 In the **Create New Data** dialog box, set **Value** to 14.6 and click **Create**.

The variable, myParam, appears in the base workspace.

Because the variable exists in the base workspace, you can use it in multiple models. However, when you end your MATLAB session, you lose the contents of the base workspace. Consider permanently storing the variable in a model workspace or data dictionary.

Define a System Constant

To define a system constant, such as a variable that represents the radius of the Earth, consider creating a `Simulink.Parameter` object instead of a numeric MATLAB variable. Parameter objects allow you to specify physical units and custom documentation as well as other characteristics.

- To create and use parameter objects in models, see “Data Objects” on page 68-59.
- Typically, the value of a system constant influences the values of other parameters and signals through mathematical relationships. To model these relationships explicitly, set the values of the dependent data by using expressions. See “Set Variable Value by Using a Mathematical Expression” on page 37-10.

Set Variable Value by Using a Mathematical Expression

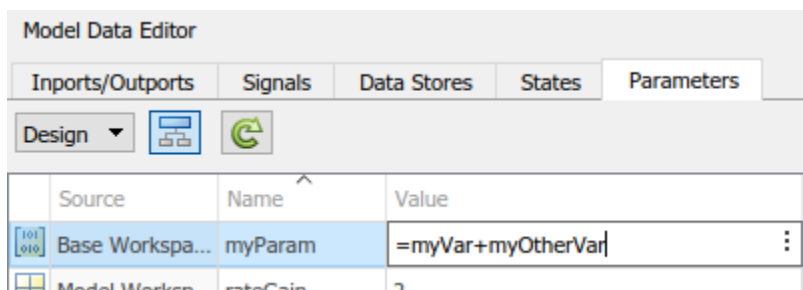

You can set the value of a variable to an expression involving literal numbers and other variables. With expressions, you can:

- Express the value as a relationship between known physical constants instead of as an unidentifiable literal number.
- Explicitly model algebraic dependencies between parameter data. When you change the values of independent data, you do not need to remember to adjust the values of dependent data.

General Technique

Convert the variable to a `Simulink.Parameter` object. Then, set the `Value` property of the object by using an expression:

- Interactively — For example, with the Model Data Editor or the Model Explorer, precede the expression with an equals sign, `=`. The figure shows how to specify the expression `myVar + myOtherVar`.

- Programmatically — Use the `slexpr` function, specifying the expression in a character vector or string. For example, to set the value of a parameter object named `myParam` to the expression `myVar + myOtherVar`:

```
myParam.Value = slexpr('myVar + myOtherVar')
```

Explicitly Model Algebraic Relationship Between Variables

The example `sldemo_metro` (see “Exploring the Solver Jacobian Structure of a Model”) models a system of three identical, pointlike metronomes suspended from a moving platform. Blocks in the model use these MATLAB variables from the base workspace:

- `m` — Mass of each metronome, initial value 0.1 kg
- `r` — Length of each metronome, initial value 1.0 m
- `J` — Moment of inertia of each metronome, initial value 0.1 kg/m²

These variables share an algebraic relationship: the moment of inertia of each metronome is equal to the mass times the length squared. In this example, you record this relationship in the value of `J`.

- 1 Open the model.

```
sldemo_metro
```

- 2 Update the block diagram. A model callback creates the variables in the base workspace.
- 3 To prevent the callback from overwriting changes that you make to the variables, for this example, remove the callback code.

```
set_param('sldemo_metro','InitFcn','')
```

- 4 In the model, on the **Modeling** tab, click **Model Data Editor**.
- 5 On the Model Data Editor **Parameters** tab, activate the **Change scope** button.

The blocks that use the variables are in the subsystems, so you must configure the Model Data Editor to show data in subsystems.

- 6 Click the **Show/refresh additional information** button.

The data table contains rows that correspond to the variables in the base workspace.

- 7 In the **Filter contents** box, enter `J`.
- 8 In the data table, find the row that corresponds to `J`. In the **Value** column, set the value of the variable to `Simulink.Parameter(J)`.

Simulink converts `J` to a `Simulink.Parameter` object.

- 9 In the **Value** column, set the value of the parameter object to `=m*r^2`.
- 10 Optionally, simulate the model with different metronome masses and lengths. As you change the values of `m` and `r`, you do not have to remember to correct the value of `J`.

Limitations and Considerations for Other Modeling Goals

- If the expression contains fixed-point data or data of an enumerated type, the expression can operate on only one variable or object.
- You cannot set the data type (`DataType` property) of the parameter object that uses the expression to `auto` (the default) and set the data types of parameter objects that appear in the expression to a value other than `auto`. For example, in the expression `J = m*r^2`, you cannot set the data type of `J` to `auto` and the data types of `m` and `r` to `single`.

- To retain the benefits of `auto` (described in “Context-Sensitive Data Typing” on page 37-44) for the object that uses the expression, set the data types of the objects in the expression to `auto`. In other words, use `auto` for all of the involved objects. The objects in the expression acquire the same data type as the object that uses the expression.
- To use a value other than `auto` for an object that appears in the expression, set the data types of all dependent parameter objects to a value other than `auto`. In other words, do not use `auto` for any involved objects.

You must use the same data type for all objects used in the expression.

- If you have Simulink Coder and Embedded Coder licenses, you can generate code that initializes a global variable by using the expression. However, the code generator can preserve the expression only if it conforms to certain requirements. See “Expression Preservation” (Simulink Coder).

Control Scope of Parameter Values

The scope of a variable is the set of models and blocks that can use the variable. For example, variables that you create in the base workspace have global scope because all blocks in all open models can use the variables. Variables that you store in a model workspace have limited scope because only the blocks in the host model can use the variables.

You cannot create two variables that have the same name in the same scope. Controlling the scope of a variable helps you to avoid name conflicts and establish clear ownership of the variable.

The table describes the different ways that you can control the scope of a reusable parameter value.

Scope	Technique
All open models	Create a variable in the base workspace.
One or more targeted models	Create a variable in a data dictionary. To reuse the variable in multiple models, create a referenced dictionary. See “What Is a Data Dictionary?” on page 75-2
One model, including all subsystems in the model	Create a variable in the model workspace. See “Model Workspaces” on page 68-120.
Multiple blocks inside a subsystem, including blocks in nested subsystems	<p>Mask the subsystem and create a mask parameter instead of a workspace variable.</p> <p>To prevent blocks inside a subsystem from using workspace variables, in the subsystem block dialog box, set Permit Hierarchical Resolution to None. This technique allows you to use the same name to create both a variable in a workspace and a mask parameter in the subsystem mask. The blocks in the subsystem can use only the mask parameter.</p> <p>For information about subsystems, see Subsystem. For information about masking, see “Masking Fundamentals” on page 39-2.</p>

To avoid name conflicts when you have a large model with many variables in the same scope, consider packaging the variables into a single structure. For more information, see “Organize Related Block Parameter Definitions in Structures” on page 37-19.

For basic information about how blocks use the variable names that you specify, see “Symbol Resolution” on page 68-128.

Permanently Store Workspace Variables

Variables that you create in the base workspace do not persist between MATLAB sessions. However, you can store the variables in a MAT-file or script file, and load the file whenever you open the model using a model callback. A model callback is a set of commands that Simulink executes when you interact with a model in a particular way, such as opening the model. You can use a callback to load variables when you open the model. Use this technique to store variables while you learn about Simulink and experiment with models.

- 1 In a model that contains a Gain block, set the value of the **Gain** parameter to K.
- 2 At the command prompt, create a variable K in the base workspace.

```
K = 27;
```

- 3 In the Workspace browser, right-click the variable and select **Save As**.

To save multiple variables in one file, select all of the target variables in the Workspace browser, and then right-click any of the selected variables.

- 4 In the dialog box, set **Save as type** to MATLAB Script. Set **File name** to loadvar and click **Save**.

The script file loadvar.m appears in your current folder. You can open the file to view the command that creates the variable K.

- 5 In the model, on the **Modeling** tab, select **Model Settings > Model Properties**.
- 6 In the **Callbacks** tab of the Model Properties dialog box, select PreLoadFcn as the callback that you want to define. In the **Model pre-load function** pane, enter loadvar and click **OK**.
- 7 Save the model.

The next time that you open the model, the PreloadFcn callback loads the variable K into the base workspace. You can also save the variable to a MAT-file, for example loadvar.mat, and set the model callback to load loadvar.

To learn about callbacks, see “Callbacks for Customized Model Behavior” on page 4-51. To programmatically define a callback for loading variables, see “Programmatically Store Workspace Variables for a Model” on page 37-13.

When you save variables to a file, you must save the changes that you make to the variables during your MATLAB session. To permanently store variables for a model, consider using a model workspace or a data dictionary instead of a MAT-file or script file. For more information about permanently storing variables, see “Determine Where to Store Variables and Objects for Simulink Models” on page 68-101.

Programmatically Store Workspace Variables for a Model

In the example above, you define a model callback that creates variables when you open a model. You can programmatically save the variable and set the model callback.

- 1 At the command prompt, create the variable K in the base workspace.

```
K = 27;
```

- 2 Save the variable to a new script file named `loadvar.m`.

```
matlab.io.saveVariablesToScript('loadvar.m','K')
```

- 3 Set the model callback to load the script file.

```
set_param('myModel','PreloadFcn','loadvar')
```

- 4 Save the model.

```
save_system('myModel')
```

The function `matlab.io.saveVariablesToScript` saves variables to a script file. To save variables to a MAT-file, use the function `save`. To programmatically set model properties such as callbacks, use the function `set_param`.

Manage and Edit Workspace Variables

When you use variables to set block parameter values, you store the variables in a workspace or data dictionary. You can use the command prompt, the Model Explorer, and the Model Data Editor to create, move, copy, and edit variables. You can also determine where a variable is used in a model, list all of the variables that a model uses, and list all of the variables that a model does not use. For more information, see “Create, Edit, and Manage Workspace Variables” on page 68-107.

Package Shared Breakpoint and Table Data for Lookup Tables

To share breakpoint vectors or table data between multiple n-D Lookup Table, Prelookup, and Interpolation Using Prelookup blocks, consider storing the data in `Simulink.LookupTable` and `Simulink.Breakpoint` objects instead of MATLAB variables or `Simulink.Parameter` objects. This technique improves model readability by clearly identifying the data as parts of a lookup table and explicitly associating breakpoint data with table data.

Store Standalone Lookup Table in `Simulink.LookupTable` Object

A standalone lookup table consists of a set of table data and one or more breakpoint vectors. You do not share the table data or any of the breakpoint vectors with other lookup tables.

When you share a standalone lookup table, you use all of the table and breakpoint data together in multiple n-D Lookup Table blocks. To store this data in a `Simulink.LookupTable` object:

- 1 Create the object in a workspace or data dictionary. For example, at the command prompt, enter:

```
myLUTObj = Simulink.LookupTable;
```

- 2 Use the properties of the object to store the values of the table and breakpoint data.
- 3 Use the properties of the object to configure a unique name for the structure type in the generated code. In the property dialog box, under **Struct Type definition**, specify **Name**.
- 4 In the n-D Lookup Table blocks, set **Data specification** to `Lookup table object`.
- 5 To the right of **Data specification**, set **Name** to the name of the `Simulink.LookupTable` object.

For ways to create and configure `Simulink.LookupTable` objects, see `Simulink.LookupTable`

Store Shared Data in Simulink.LookupTable and Simulink.Breakpoint Objects

When you use Prelookup and Interpolation Using Prelookup blocks to more finely control the lookup algorithm, you can share breakpoint vectors and sets of table data. For example, you can share a breakpoint vector between two separate sets of table data. With this separation of the breakpoint data from the table data, you can share individual parts of a lookup table instead of sharing the entire lookup table.

To store breakpoint and table data:

- 1 Create a `Simulink.LookupTable` object for each unique set of table data. Create a `Simulink.Breakpoint` object for each unique breakpoint vector, including breakpoint vectors that you do not intend to share.
- 2 Use the properties of the objects to store the values of the table and breakpoint data.
- 3 Configure the `Simulink.LookupTable` objects to refer to the `Simulink.Breakpoint` objects for breakpoint data. In the `Simulink.LookupTable` objects, set **Specification** to Reference. Specify the names of the `Simulink.Breakpoint` objects.
- 4 In the Interpolation Using Prelookup blocks, set **Specification** to Lookup table object. Set **Name** to the name of a `Simulink.LookupTable` object.

In the Prelookup blocks, set **Specification** to Breakpoint object. Set **Name** to the name of a `Simulink.Breakpoint` object.

The example model `fxpdemo_lookup_shared_param` contains two Prelookup and two Interpolation Using Prelookup blocks. Configure the blocks so that each combination of a Prelookup and an Interpolation Using Prelookup block represents a unique lookup table. Share the breakpoint vector between the two lookup tables. In this case, each lookup table has unique table data but shared breakpoint data.

- 1 Open the example model.
- 2 In the Prelookup block dialog box, set **Specification** to Breakpoint object. Set **Name** to `sharedBkpts`.
- 3 Click the button  next to the value of the **Name** parameter. Select **Create Variable**.
- 4 In the **Create New Data** dialog box, set **Value** to `Simulink.Breakpoint` and click **Create**.

A `Simulink.Breakpoint` object appears in the base workspace.

- 5 In the property dialog box for `sharedBkpts`, specify **Value** as a vector such as `[1 2 3 4 5 6 7 8 9 10]`. Click **OK**.
- 6 In the Prelookup block dialog box, click **OK**.
- 7 In the Prelookup1 block dialog box, set **Specification** to Breakpoint object. Set **Name** to `sharedBkpts`.
- 8 In the Interpolation Using Prelookup block dialog box, set **Specification** to Lookup table object. Set **Name** to `dataForFirstTable`.
- 9 Click the button  next to the value of the **Name** parameter. Select **Create Variable**.
- 10 In the **Create New Data** dialog box, set **Value** to `Simulink.LookupTable` and click **Create**.

A `Simulink.LookupTable` object appears in the base workspace.

- 11 In the property dialog box for `dataForFirstTable`, specify **Value** as a vector, such as `[10 9 8 7 6 5 4 3 2 1]`.

- 12** Set **Specification** to Reference.
- 13** In the table under **Specification**, set **Name** to `sharedBkpts` and click **OK**.
- 14** In the Interpolation Using Prelookup block dialog box, click **OK**.
- 15** Configure the Interpolation Using Prelookup1 block to use a `Simulink.LookupTable` object named `dataForSecondTable`. In the object property dialog box, specify **Value** as a vector, such as `[0 0.5 1 1.5 2 2.5 3 3.5 4 4.5]`. Configure the object to refer to `sharedBkpts` for the breakpoint data.

The model now represents two unique lookup tables:

- A combination of `sharedBkpts` and `dataForFirstTable`.
- A combination of `sharedBkpts` and `dataForSecondTable`.

These lookup tables share the same breakpoint data through `sharedBkpts`.

Parameter Interfaces for Reusable Components

You can use subsystems, referenced models, and custom library blocks as reusable components in other models. For guidelines to help you decide how to componentize a system, see “Choose Among Types of Model Components” on page 22-4.

Typically, a reusable algorithm requires that numeric block parameters, such as the **Gain** parameter of a Gain block, either:

- Use the same value in all instances of the component.
- Use a different value in each instance of the component. Each value is instance specific.

By default, if you use a literal number or expression to set the value of a block parameter, the parameter uses the same value in all instances of the component. If you set multiple block parameter values by using a MATLAB variable, Simulink.Parameter object, or other parameter object in a workspace or data dictionary, these parameters also use the same value in all instances of the component.

Referenced Models

If you use model referencing to create a reusable component, to set parameter values that are specific to each instance, configure model arguments for the referenced model. When you instantiate the model by adding a Model block to a different model, you set the values of the arguments in the Model block. When you add another Model block to the same parent model or to a different model, you can set different values for the same arguments. Optionally, if you create more than two instances, you can set the same value for some of the instances and different values for the other instances.

If a model has many model arguments, consider packaging the arguments into a single structure. Instead of configuring many arguments, configure the structure as a single argument. Without changing the mathematical functionality of the component, this technique helps you to reduce the number of model argument values that you must set in each instance of the component.

For more information about model arguments, see “Parameterize Instances of a Reusable Referenced Model” on page 8-63.

Subsystems

If you use subsystems or custom libraries to create reusable components, to set parameter values that are specific to each instance, use masks, mask parameters, and parameter promotion. When you instantiate the component in a model, you set the values of the mask parameters in the Subsystem block. When you instantiate the component again in the same model or a different model, you can set different values for the same mask parameters. Optionally, if you create more than two instances, you can set the same value for some of the instances and different values for the other instances.

If the subsystem has many mask parameters, consider packaging the parameters into a single structure. Instead of configuring many mask parameters, configure the structure as a single parameter. Without changing the mathematical functionality of the component, this technique helps you to reduce the number of mask parameter values that you must set in each instance of the component.

For more information about subsystems, see Subsystem. For more information about custom block libraries, see “Design and Create a Custom Block” on page 40-12. For more information about

masks, see “Masking Fundamentals” on page 39-2. For more information about structures, see “Organize Related Block Parameter Definitions in Structures” on page 37-19.

- “Set Block Parameter Values” on page 37-2

Organize Related Block Parameter Definitions in Structures

When you use numeric MATLAB variables to set block parameter values in a model, large models can accumulate many variables, increasing the effort of maintenance and causing the variable names to grow in length.

Instead, you can organize these parameter values into structures. Each structure is a single variable and each field of the structure stores a numeric parameter value. You can assign meaningful names to the structures, substructures, and fields to indicate the purpose of each value.

Use structures to:

- Reduce the number of workspace variables that you must maintain.
- Avoid name conflicts between workspace variables.

You cannot create two variables that have the same name in the same scope, such as in the base workspace. When you create structures, you must provide each field a name, but multiple structures can each contain a field that uses the same name. Therefore, you can use each structure and substructure as a namespace that prevents the field names from conflicting with each other and with other variable names in the same scope.

- Logically group sets of block parameter values. For example, use nested structures to clearly identify the parameter values that each subsystem or referenced model uses.

If you use mask parameters or model arguments to pass parameter values to the components of a system, you can use structures to reduce the number of individual mask parameters or model arguments that you must maintain. Instead of passing multiple variables, you can pass a single structure variable.

For basic information about creating and manipulating MATLAB structures, see [Structures](#). For basic information about setting block parameter values in a model, see “Set Block Parameter Values” on page 37-2.

To use structures to initialize bus signals, see “Specify Initial Conditions for Bus Elements” on page 77-61.

Create and Use Parameter Structure

This example shows how to create and use a parameter structure in a model.

The example model `f14` uses multiple variables from the base workspace to set block parameter values. For example, when you open the model, it creates the variables `Zw`, `Mw`, and `Mq` in the base workspace. To organize these variables into a single structure variable:

- 1 At the command prompt, open the example model.

```
f14
```

- 2 At the command prompt, create the parameter structure `myGains`. Set the field values by using the values of the target variables.

```
myGains.Zw = Zw;  
myGains.Mw = Mw;  
myGains.Mq = Mq;
```

- 3 In the Model Explorer, on the **Model Hierarchy** pane, click **Base Workspace**. In the **Contents** pane, right-click the variable `Mq` and select **Find Where Used**.
- 4 In the **Select a system** dialog box, click the node `f14` and click **OK**. Click **OK** when asked about updating the diagram.
- 5 In the **Contents** pane, right-click the row corresponding to the block labeled `Gain1` and select **Properties**. The `Gain1` block dialog box opens.
- 6 Change the value of the **Gain** parameter from `Mq` to `myGains.Mq` and click **OK**.
- 7 In the **Contents** pane, right-click the row corresponding to the `Transfer Fcn.1` block and select **Properties**.
- 8 Change the value of the **Denominator coefficients** parameter from `[1, -Mq]` to `[1, -myGains.Mq]` and click **OK**.
- 9 In the **Model Hierarchy** pane, click **Base Workspace**. Use **Find Where Used** to locate the blocks that use the variables `Mw` and `Zw`. In the block dialog boxes, replace the references to the variable names according to the table.

Variable Name	Replacement Name
<code>Mw</code>	<code>myGains.Mw</code>
<code>Zw</code>	<code>myGains.Zw</code>

- 10 Clear the old variables.

```
clear Zw Mw Mq
```

Each of the modified block parameters now uses a field of the `myGains` structure. The numeric value of each structure field is equal to the value of the corresponding variable that you cleared.

You can migrate a model to use a single parameter structure instead of multiple workspace variables.

Store Data Type Information in Field Values

To use a structure or array of structures to organize parameter values that use a data type other than `double`, you can explicitly specify the type when you create the structure. When you create the structure, use typed expressions such as `single(15.23)` to specify the field values.

```
myParams.Gain = single(15.23);
```

If you want to change the field value later, you must remember to explicitly specify the type again. If you do not specify the type, the field value uses the data type `double` instead:

```
myParams.Gain = 15.23;
% The field 'Gain' now uses the data type 'double' instead of 'single'.
```

To preserve the type specification, you can use subscripted assignment to assign a new value to the field:

```
% Assign value of type 'single'.
myParams.Gain = single(15.23);

% Assign new value while retaining type 'single'.
myParams.Gain(:) = 11.79;
```

To match a fixed-point data type, set the field value by using an `fi` object.

Control Field Data Types and Characteristics by Creating Parameter Object

A `Simulink.Parameter` object allows you to separate the value of a block parameter from its data type. If you use a parameter object to store a structure or array of structures, you can create a `Simulink.Bus` object to use as the data type of the entire structure.

You can use the bus object and the parameter object to explicitly control:

- The data type of each field. When you use this technique, you do not have to remember to use typed expressions or subscripted assignment to set the field values.
- The complexity, dimensions, and units of each field.
- The minimum and maximum value of each field if the field represents a tunable parameter value.
- The shape of the entire structure. The shape of the structure is the number, names, and hierarchy of fields.
- The tunability of the structure in the code that you generate from the model.

- 1 Create a parameter structure `myParams`.

```
myParams = struct(...
    'SubsystemA', struct(...
        'Gain', 15.23, ...
        'Offset', 89, ...
        'Init', 0.59), ...
    'SubsystemB', struct(...
        'Coeffs', [5.32 7.99], ...
        'Offset', 57, ...
        'Init1', 1.76, ...
        'Init2', 2.76) ...
);
```

- 2 Use the function `Simulink.Bus.createObject` to create `Simulink.Bus` objects that represent the structure and substructures.

```
Simulink.Bus.createObject(myParams)
```

Because `myParams` contains two unique substructures, the function creates three `Simulink.Bus` objects: one named `slBus1` to represent the parent structure `myParams`, one named `SubsystemA` for the substructure `SubsystemA`, and one named `SubsystemB` for the substructure `SubsystemB`.

- 3 Rename the bus object `slBus1` as `myParamsType`.

```
myParamsType = slBus1;
clear slBus1
```

- 4 Store the structure `myParams` in a `Simulink.Parameter` object.

```
myParams = Simulink.Parameter(myParams);
```

The `Value` property of the parameter object contains the structure.

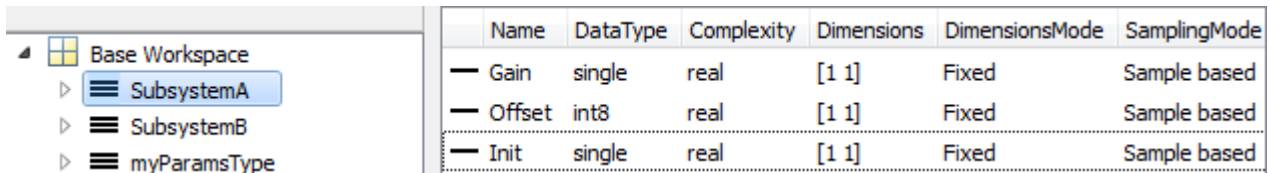

- 5 Set the data type of the parameter object to the bus object `myParamsType`.

```
myParams.DataType = 'Bus: myParamsType';
```

- 6 Open the Bus Editor to view the bus objects.

```
buseditor
```

- 7 In the **Model Hierarchy** pane, click the node `SubsystemA`. In the **Contents** pane, set the field data types according to the figure.

Name	DataType	Complexity	Dimensions	DimensionsMode	SamplingMode
Gain	single	real	[1 1]	Fixed	Sample based
Offset	int8	real	[1 1]	Fixed	Sample based
Init	single	real	[1 1]	Fixed	Sample based

- 8 Optionally, set the field data types for the substructure `SubsystemB`.

The parameter object `myParams` stores the parameter structure. The data type of the parameter object is the bus object `myParamsType`. Prior to simulation and code generation, the parameter object casts the field values to the data types that you specified in the bus object.

To use one of the fields to set a block parameter value, specify an expression such as `myParams.SubsystemB.Init1`.

To access the field values at the command prompt, use the `Value` property of the parameter object. Because the bus object controls the field data types, you do not need to use a typed expression to set the field value.

```
myParams.Value.SubsystemA.Gain = 12.79;
```

The bus object strictly controls the field characteristics and the shape of the structure. For example, if you set the value of the two-element field `myParams.SubsystemB.Coeffs` to a three-element array, the model generates an error when you set a block parameter value. To change the dimensions of the field, modify the element `Coeffs` in the bus object `SubsystemB`.

To manipulate bus objects after you create them, see “Create and Specify Simulink.Bus Objects” on page 77-52 and “Save Simulink.Bus Objects” on page 77-53.

Match Field Data Type with Signal Data Type

Suppose that you use the field `myParams.SubsystemA.Gain` to set the value of the **Gain** parameter in a Gain block. If you want the data type of the field to match the data type of the output signal of the block, you cannot rely on context-sensitive data typing (see “Context-Sensitive Data Typing” on page 37-44). Consider using a `Simulink.AliasType` or a `Simulink.NumericType` object to set the data type of the field and the signal. If you do not use a data type object, you must remember to change the data type of the field whenever you change the data type of the signal.

- 1 At the command prompt, create a `Simulink.AliasType` object that represents the data type `single`.

```
myType = Simulink.AliasType;
myType.BaseType = 'single';
```

- 2 In the Gain block dialog box, on the **Signal Attributes** tab, set **Output data type** to `myType`.

- 3 At the command prompt, open the Bus Editor.

```
buseditor
```

- 4 In the **Model Hierarchy** pane, select the bus object `SubsystemA`. In the **Contents** pane, set the data type of the field `Gain` to `myType`.

Now, both the output signal of the Gain block and the structure field `myParams.SubsystemA.Gain` use the data type that you specify by using the `BaseType` property of `myType`.

For more information about data type objects, see `Simulink.AliasType` and `Simulink.NumericType`.

Manage Structure Variables

To create, modify, and inspect a variable whose value is a structure, you can use the Variable Editor. For more information, see “Modify Structure and Array Variables Interactively” on page 68-108.

Define Parameter Hierarchy by Creating Nested Structures

To further organize block parameter values, create a hierarchy of nested structures.

For example, suppose that you create subsystems named `SubsystemA` and `SubsystemB` in your model. You use variables such as `Offset_SubsystemA` and `Offset_SubsystemB` to set block parameter values in the subsystems.

```
Gain_SubsystemA = 15.23;
Offset_SubsystemA = 89;
Init_SubsystemA = 0.59;

Coeffs_SubsystemB = [5.32 7.99];
Offset_SubsystemB = 57;
Init1_SubsystemB = 1.76;
Init2_SubsystemB = 2.76;
```

Create a parameter structure that contains a substructure for each subsystem. Use the values of the existing variables to set the field values.

```
myParams = struct(...
    'SubsystemA', struct(...
        'Gain', Gain_SubsystemA, ...
        'Offset', Offset_SubsystemA, ...
        'Init', Init_SubsystemA), ...
    'SubsystemB', struct(...
        'Coeffs', Coeffs_SubsystemB, ...
        'Offset', Offset_SubsystemB, ...
        'Init1', Init1_SubsystemB, ...
        'Init2', Init2_SubsystemB)...
);
```

The single structure variable `myParams` contains all of the parameter information for the blocks in the subsystems. Because each substructure acts as a namespace, you can define the `Offset` field more than once.

To use the `Offset` field from the substructure `SubsystemB` as the value of a block parameter, specify the parameter value in the block dialog box as the expression `myParams.SubsystemB.Offset`.

Group Multiple Parameter Structures into an Array

To organize parameter structures that have similar characteristics, you can create a single variable whose value is an array of structures. This technique helps you to parameterize a model that contains multiple instances of an algorithm, such as a library subsystem or a referenced model that uses model arguments.

Suppose that you create two identical subsystems in a model.

Suppose that the blocks in each subsystem require three numeric values to set parameter values. Create an array of two structures to store the values.

```
myParams(1).Gain = 15.23;
myParams(1).Offset = 89;
myParams(1).Init = 0.59;
```

```
myParams(2).Gain = 11.93;
myParams(2).Offset = 57;
myParams(2).Init = 2.76;
```

Each structure in the array stores the three parameter values for one of the subsystems.

To set the value of a block parameter in one of the subsystems, specify an expression that references a field of one of the structures in the array. For example, use the expression `myParams(2).Init`.

Organize Parameter Values for Reusable Components and Iterative Algorithms

You can also partition an array of structures in a For Each Subsystem block. This technique helps you to organize workspace variables when a model executes an algorithm repeatedly, for example by iterating the algorithm over a vector signal. For an example, see “Repeat an Algorithm Using a For Each Subsystem” on page 77-81.

If you use model arguments to specify different parameter values across multiple instances of a referenced model, you can use arrays of structures to organize the model argument values. In the referenced model workspace, create a structure variable and configure the model to use the structure as a model argument. Use the fields of the structure to set block parameter values in the model. Then, create an array of structures in the base workspace or a data dictionary to which the parent model or models are linked. In the parent model or models, use each of the structures in the array as the value of the model argument in a Model block. Each structure in the array stores the parameter values for one instance of the referenced model.

The example model `sldemo_mdhref_datamngt` contains three instances (Model blocks) of the masked referenced model `sldemo_mdhref_counter_datamngt`. The base workspace variables `IC1`, `IC2`, `Param1`, and `Param2` are `Simulink.Parameter` objects whose values are structures. The parent model uses these variables to set the values of mask parameters on the Model blocks. Since

IC1 is structurally identical to IC2, and Param1 to Param2, you can combine these four structures into two arrays of structures.

- 1 Open the example parent model.

```
sldemo_mdref_datamngt
```

The model creates the four `Simulink.Parameter` objects in the base workspace.

- 2 Open the example referenced model.

```
sldemo_mdref_counter_datamngt
```

The model workspace defines two model arguments, `CounterICs` and `CounterParams`, whose values are structures. The blocks in the model use the fields of these structures to set parameter values.

- 3 In the model `sldemo_mdref_datamngt`, open the Model Data Editor (on the **Modeling** tab, click **Model Data Editor**). In the Model Data Editor, inspect the **Parameters** tab.
- 4 In the model, click one of the Model blocks.

The Model Data Editor highlights rows that correspond to two mask parameters on the selected Model block. The block uses the mask parameters to set the values of the two model arguments defined by the referenced model, `sldemo_mdref_counter_datamngt`. Each Model block uses a different combination of the four parameter objects from the base workspace to set the argument values.

- 5 In the Model Data Editor **Value** column, click one of the cells to begin editing the value of the corresponding mask parameter (for example, IC1). Next to the parameter value, click the action button  and select **Open**. The property dialog box for the parameter object opens.
- 6 In the property dialog box, next to the **Value** box, click the action button and select **Open Variable Editor**.

The Variable Editor shows that the parameter object stores a structure. The structures in `Param2` and `IC2` have the same fields as the structures in `Param1` and `IC1` but different field values.

- 7 At the command prompt, combine the four parameter objects into two parameter objects whose values are arrays of structures.

```
% Create a new parameter object by copying Param1.
Param = Param1.copy;
```

```
% Use the structure in Param2 as the second structure in the new object.
Param.Value(2) = Param2.Value;
% The value of Param is now an array of two structures.
```

```
% Delete the old objects Param1 and Param2.
clear Param1 Param2
```

```
% Create a new parameter object by copying IC1.
% Use the structure in IC2 as the second structure in the new object.
IC = IC1.copy;
IC.Value(2) = IC2.Value;
clear IC1 IC2
```

- 8 In the parent model, in the Model Data Editor, use the **Value** column to replace the values of the mask parameters according to the table

Previous Value	New Value
Param1	Param(1)
IC1	IC(1)
Param2	Param(2)
IC2	IC(2)

Each Model block sets the value of the model argument CounterICs by using one of the structures in the array IC. Similarly, each block sets the value of CounterParams by using one of the structures in Param.

Enforce Uniformity in an Array of Structures

All of the structures in an array of structures must have the same hierarchy of fields. Each field in the hierarchy must have the same characteristics throughout the array. You can use a parameter object and a bus object to enforce this uniformity among the structures.

To use a parameter object to represent an array of parameter structures, set the value of the object to the array of structures:

```
% Create array of structures.
myParams(1).Gain = 15.23;
myParams(1).Offset = 89;
myParams(1).Init = 0.59;
myParams(2).Gain = 11.93;
myParams(2).Offset = 57;
myParams(2).Init = 2.76;

% Create bus object.
Simulink.Bus.createObject(myParams);
myParamsType = slBus1;
clear slBus1

% Create parameter object and set data type.
myParams = Simulink.Parameter(myParams);
myParams.DataType = 'Bus: myParamsType';
```

To use one of the fields to set a block parameter value, specify an expression such as `myParams(2).Offset`.

To access the field values at the command prompt, use the `Value` property of the parameter object.

```
myParams.Value(2).Offset = 129;
```

Create a Structure of Constant-Valued Signals

You can use a structure in a Constant block to create a single bus signal that transmits multiple numeric constants. For more information, see `Constant`. For information about bus signals, see “Virtual Bus” on page 77-2.

Considerations Before Migrating to Parameter Structures

- Before you migrate a model to use parameter structures, discover all of the blocks in the target model and in other models that use the variables that you intend to replace.

For example, suppose two blocks in a model use the workspace variable `myVar`. If you create a structure `myParams` with a field `myVar`, and set the parameter value in only one of the blocks to `myParams.myVar`, the other block continues to use the variable `myVar`. If you delete `myVar`, the model generates an error because the remaining block requires the deleted variable.

To discover all of the blocks that use a variable:

- 1 Open all models that might use the variable. If the models are in a model reference hierarchy, you can open only the top model.
- 2 In the Model Data Editor or in the Model Explorer **Contents** pane, right-click the variable and select **Find Where Used**. The Model Explorer displays all of the blocks that use the variable.

You can discover variable usage only in models that are open. Before you migrate to parameter structures, open all models that might use the target variables. For more information about determining variable usage in a model, see “Finding Blocks That Use a Specific Variable” on page 68-112.

Alternatively, you can refrain from deleting `myVar`. However, if you change the value of the `myParams.myVar` structure field, you must remember to change the value of `myVar` to match.

- You can combine multiple separate variables or parameter objects (such as `Simulink.Parameter`) into a structure that you store in a single variable or parameter object (to combine parameter objects, see “Combine Existing Parameter Objects Into a Structure” on page 37-27). However, the resulting variable or object acts as a single entity. As a result, you cannot apply different code generation settings, such as storage classes, to individual fields in the structure.

Combine Existing Parameter Objects Into a Structure

When you use parameter objects to set block parameter values (for example, so you can apply storage classes), to combine the objects into a single structure:

- 1 Create a MATLAB structure and store it in a variable. To set the field values, use the parameter values that each existing parameter object stores.
- 2 Convert the variable to a parameter object. Create and use a `Simulink.Bus` object as the data type of the parameter object (see “Control Field Data Types and Characteristics by Creating Parameter Object” on page 37-21).
- 3 Choose a storage class to apply to the resulting parameter object. You can choose only one storage class, which applies to the entire structure.
- 4 Transfer parameter metadata, such as the `Min` and `Max` properties of the existing parameter objects, to the corresponding properties of the `Simulink.BusElement` objects in the bus object.

For example, suppose you have three individual parameter objects.

```
coeff = Simulink.Parameter(17.5);
coeff.Min = 14.33;
coeff.DataType = 'single';
coeff.StorageClass = 'ExportedGlobal';

init = Simulink.Parameter(0.00938);
init.Min = -0.005;
init.Max = 0.103;
init.DataType = 'single';
```

```
init.StorageClass = 'Model default';
```

```
offset = Simulink.Parameter(199);
offset.DataType = 'uint8';
offset.StorageClass = 'ExportedGlobal';
```

- 1 Create a structure variable.

```
myParams.coeff = coeff.Value;
myParams.init = init.Value;
myParams.offset = offset.Value;
```

- 2 Convert the variable to a parameter object.

```
myParams = Simulink.Parameter(myParams);
```

- 3 Create a bus object and use it as the data type of the parameter object.

```
Simulink.Bus.createObject(myParams.Value);
paramsDT = copy(slBus1);
```

```
myParams.DataType = 'Bus: paramsDT';
```

- 4 Transfer metadata from the old parameter objects to the bus elements in the bus object.

```
% coeff
paramsDT.Elements(1).Min = coeff.Min;
paramsDT.Elements(1).DataType = coeff.DataType;
```

```
% init
paramsDT.Elements(2).Min = init.Min;
paramsDT.Elements(2).Max = init.Max;
paramsDT.Elements(2).DataType = init.DataType;
```

```
% offset
paramsDT.Elements(3).DataType = offset.DataType;
```

To help you write a script that performs this transfer operation, you can use the `properties` function to find the properties that the bus elements and the old parameter objects have in common. To list the structure fields so that you can iterate over them, use the `fieldnames` function.

- 5 Apply a storage class to the parameter object.

```
myParams.StorageClass = 'ExportedGlobal';
```

Now, you can use the fields of `myParams`, instead of the old parameter objects, to set the block parameter values.

Parameter Structures in the Generated Code

You can configure parameter structures to appear in the generated code as structures and arrays of structures. For information about generating code with parameter structures, see “Organize Data into Structures in Generated Code” (Simulink Coder).

Parameter Structure Limitations

- The value of a field that you use to set a block parameter must be numeric or of an enumerated type. The value of a field can be a real or complex scalar, vector, or multidimensional array.
- If the value of any of the fields of a structure is a multidimensional array, you cannot tune any of the field values during simulation.
- All of the structures in an array of structures must have the same hierarchy of fields. Each field in the hierarchy must have the same characteristics throughout the array:
 - Field name
 - Numeric data type, such as `single` or `int32`
 - Complexity
 - Dimensions

Suppose that you define an array of two structures.

```
paramStructArray = ...
[struct('sensor1',int16(7), 'sensor2',single(9.23)) ...
 struct('sensor1',int32(9), 'sensor2',single(11.71))];
```

You cannot use any of the fields in a block parameter because the field `sensor1` uses a different data type in each structure.

- Parameter structures do not support context-sensitive data typing in the generated code. If the parameter structure is tunable in the code, the fields of the structure use the numeric data types that you specify by using either typed expressions or a `Simulink.Bus` object. If you do not use typed expressions or a `Simulink.Bus` object, the fields of the structure use the `double` data type.

Package Shared Breakpoint and Table Data for Lookup Tables

When you share data between lookup table blocks, consider using `Simulink.LookupTable` and `Simulink.Breakpoint` objects instead of structures to store and group the data. This technique improves model readability by clearly identifying the data as parts of a lookup table and explicitly associating breakpoint data with table data. See “Package Shared Breakpoint and Table Data for Lookup Tables” on page 37-14.

Create Parameter Structure According to Structure Type from Existing C Code

You can create a parameter structure that conforms to a `struct` type definition that your existing C code defines. Use this technique to:

- Replace existing C code with a Simulink model.
- Integrate existing C code for simulation in Simulink (for example, by using the Legacy Code Tool). For an example, see “Integrate C Function Whose Arguments Are Pointers to Structures”.
- Generate C code (Simulink Coder) that you can compile with existing C code into a single application. For an example, see “Exchange Structured and Enumerated Data Between Generated and External Code” (Embedded Coder).

In MATLAB, store the parameter structure in a parameter object and use a bus object as the data type (see “Control Field Data Types and Characteristics by Creating Parameter Object” on page 37-21). To create the bus object according to your C-code `struct` type, use the `Simulink.importExternalCTypes` function.

Tune and Experiment with Block Parameter Values

As you construct a model you can experiment with block parameters, such as the coefficients of a Transfer Fcn block, to help you decide which blocks to use. You can simulate the model with different parameter values, and capture and observe the simulation output.

You can change the values of most numeric block parameters during a simulation. To observe the effects, you can visualize the simulation output in real time. This technique allows you to quickly test parameter values while you develop an algorithm. You can visually:

- Tune and optimize control parameters.
- Calibrate model parameters.
- Test control robustness under different conditions.

When you begin a simulation, Simulink first updates the model diagram. This operation can take time for larger models. To test parameter values without repeatedly updating the model diagram, you can tune the parameter values during a single simulation run.

Alternatively, to avoid updating the model diagram, use Fast Restart. For more information about Fast Restart, see “Get Started with Fast Restart” on page 82-5.

If you cannot visually analyze the simulation output in real time, or if you must run many simulations, consider using a programmatic approach to sweeping parameter values. You can capture the simulation output data and perform analysis later. For more information, see “Optimize, Estimate, and Sweep Block Parameter Values” on page 37-38.

For basic information about accessing and setting block parameter values, see “Set Block Parameter Values” on page 37-2.

Iteratively Adjust Block Parameter Value Between Simulation Runs

This example shows how to prototype a model by changing block parameter values between simulation runs. You can experiment with parameter values and observe simulation results to help you decide which blocks to use and how to build your model.

The example model `sldemo_fuelsys` represents the fueling system of a gasoline engine. A subsystem in the model, `feedforward_fuel_rate`, calculates the fuel demand of the engine by using the constant number 14.6, which represents the ideal (stoichiometric) ratio of air to fuel that the engine consumes. Two blocks in the subsystem use the number to set the values of parameters.

Suppose that you want to change the design value of the ideal air-to-fuel ratio from 14.6 to 17.5 to observe the effect on the fuel demand. To store the design value in the model, you can modify the value in the block dialog boxes. Alternatively, you can store the value in a variable with a meaningful name, which allows you to reuse the value in the two blocks.

To observe the change in simulation outputs by changing the value in the block dialog boxes:

- 1 Open the example model.
`sldemo_fuelsys`
- 2 Set the model simulation time from 2000 to 50 for a faster simulation.
- 3 In the model, open the Scope block dialog box.

- 4 Simulate the model. Resize the window in the Scope dialog box to see all of the simulation results.

The scope display shows that throughout the simulation, the `fuel` signal oscillates between approximately 0.9 and 1.6. The `air_fuel_ratio` signal quickly climbs to 15 without overshoot.

- 5 In the model, open the Model Data Editor. On the **Modeling** tab, click **Model Data Editor**. In the Model Data Editor, inspect the **Parameters** tab.
- 6 In the model or at the command prompt, navigate to the target subsystem.

```
open_system(...
    'sldemo_fuelsys/fuel_rate_control/fuel_calc/feedforward_fuel_rate')
```

- 7 In the Model Data Editor, use the **Value** column to change the **Constant value** (Value) parameter of the Constant block labeled `rich` from $1/(14.6*0.8)$ to $1/(17.5*0.8)$.
- 8 Similarly, change the **Constant value** parameter of the block labeled `normal` from $1/14.6$ to $1/17.5$.
- 9 Simulate the model.

The scope display shows that the signals now respond differently.

To replace the literal values in the block dialog boxes with a numeric variable:

- 1 Use the Model Data Editor to set the value of the `normal` Constant block to $1/mixture$.
- 2 Set the value of the `rich` block to $1/(mixture*0.8)$.
- 3 While editing the `rich` value, next to $1/(mixture*0.8)$, click the action button  and select **Create**.
- 4 In the **Create New Data** dialog box, set **Value** to 17.5 and click **Create**.

The numeric variable `mixture` appears in the base workspace with value 17.5. Between simulation runs, you can change the value of `mixture` in the base workspace instead of changing the parameter values in the block dialog boxes.

Tune Block Parameter Value During Simulation

This example shows how to observe the effect of changing a block parameter value during a simulation. This technique allows you to avoid updating the model diagram between simulation runs and to interactively test and debug your model.

The example model `sldemo_fuelsys` contains a Constant block, `Throttle Command`, that represents the throttle command. To observe the effect of increasing the magnitude of the command during simulation:

- 1 Open the example model.

```
sldemo_fuelsys
```

- 2 In the model, open the Scope block dialog box.

- 3 Begin a simulation.

The model is configured to simulate 2000 seconds. During the simulation, the values of the `fuel` and `air_fuel_ratio` signals appear on the scope graph in real time.

- 4 In the model, when the status bar indicates approximately 1000 (1000 seconds), click the Pause button  to pause the simulation.
- 5 In the scope display, the **fuel** graph plots the simulation output prior to the pause time.
- 6 In the model, on the **Modeling** tab, click **Model Data Editor**.
- 7 In the Model Data Editor, select the **Parameters** tab.
- 8 In the model, select the Throttle Command block.
- 9 In the Model Data Editor, select the `rep_seq_y` row. Make sure that you do not select the `rep_seq_t` row as well.
- 10 For the `rep_seq_y` row, change the value in the **Value** column from `[10 20 10]` to `[10 30 10]`.
- 11 Click the Step Forward button  to advance the simulation step by step. Click the button about 15 times or until you see a change in the **fuel** graph in the scope display.

The plot of the signal `fuel` indicates a sharp increase in fuel demand that corresponds to the increased throttle command.

- 12 In the model, resume the simulation by clicking the Continue button .

The scope display shows the significant periodic increase in fuel demand, and the periodic reduction in the air-to-fuel ratio, throughout the rest of the simulation.

During the simulation, you must update the model diagram after you change the value of a workspace variable. For more information about updating the model diagram, see “Update Diagram and Run Simulation” on page 1-25.

Prepare for Parameter Tuning and Experimentation

- Use workspace variables to set block parameter values.

To access the value of a block parameter, such as the **Constant value** parameter of a Constant block, you must navigate to the block in the model and open the block dialog box, search for the block by using the Model Explorer, or use the function `set_param` at the command prompt.

Alternatively, if you set the block parameter value by creating a workspace variable, you can change the value of the variable by using the command prompt, the MATLAB Workspace browser, or the Model Explorer. You can also create a variable to set the same value for multiple block parameters. When you change the variable value, all of the target block parameters use the new value. For more information about accessing and setting block parameter values, see “Set Block Parameter Values” on page 37-2.

- Visualize simulation output.

To observe simulation output in real time while you tune block parameter values, you can use blocks in a model such as the Scope block. You can also capture simulation output at the end of a simulation run, and view the data in the Simulation Data Inspector. For more information, see “Decide How to Visualize Simulation Data” on page 30-2.

- Specify value ranges for block parameters that you expect to tune during simulation.

If you expect another person to use your model and tune the parameter, you can control the allowed tuning values by specifying a range. Also, it is a best practice to specify value ranges for all fixed-point block parameters that you expect to tune. To specify block parameter value ranges, see “Specify Minimum and Maximum Values for Block Parameters” on page 37-52.

- Control simulation duration and pace.

A simulation run can execute so quickly that you cannot tune block parameter values. Also, if you want to change a parameter value at a specific simulation time, you must learn to control the simulation pace. You can configure the simulation to run for a specific duration or to run forever, and pause and advance the simulation when you want to. For more information, see “Simulate a Model Interactively” on page 25-2 and “Run Simulations Programmatically” on page 26-2.

Interactively Tune Using Dashboard Blocks

You can tune block parameter values by adding blocks from the Dashboard library to your model. Dashboard blocks allow you to adjust the parameter values of other blocks, and to observe simulation output in real time, by interacting with knobs, switches, and readouts that mimic the appearance of industrial controls. You can interact with the Dashboard blocks without having to locate the target block parameters in the model. For more information, see “Tune and Visualize Your Model with Dashboard Blocks” on page 29-194.

Which Block Parameters Are Tunable During Simulation?

Nontunable block parameters are parameters whose values you cannot change during simulation. For example, you cannot tune the **Sample time** block parameter. If a parameter is nontunable, you cannot change its value during simulation by changing the value in the block dialog box or by changing the value of a workspace variable.

Nontunable block parameters include:

- Sample times.
- Parameters that control the appearance or structure of a block such as the number of inputs of a Sum block.
- Priority, which allows you to control block execution order.
- Parameters that control the block algorithm, such as the **Integrator method** parameter of a Discrete-Time Integrator block.

To determine whether a block parameter is tunable during simulation, use one of these techniques:

- Begin a simulation and open the block dialog box. If the value of the target block parameter is gray during simulation, you cannot tune the parameter.
- At the command prompt, determine whether the flags `read-write` and `read-only-if-compiled` describe the parameter.

- 1 Select the block in the model.
- 2 At the command prompt, use the function `get_param` to return information about the block dialog box parameters. The function returns a structure that has a field for each parameter in the block dialog box.

```
paramInfo = get_param(gcb, 'DialogParameters');
```

Alternatively, rather than locating and selecting the block in the model, you can replace `gcb` with the block path, such as `'myModel/mySubsystem/myBlock'`.

- 3 View the information about the target block parameter. For example, to view the information about the **Sample time** parameter of a block, view the value of the field `SampleTime`, which is also a structure.

```
paramInfo.SampleTime
```

```
ans =
```

```

    Prompt: 'Sample time:'
      Type: 'string'
      Enum: {}
Attributes: {'read-write' 'read-only-if-compiled' 'dont-eval'}
```

- 4 Inspect the structure's `Attributes` field, whose value is a cell array of character vectors. If the flag `read-write` appears in the cell array, you can modify the parameter value. However, if the flag `read-only-if-compiled` also appears in the cell array, you cannot modify the parameter value during simulation.

If you use masks to create custom interfaces for blocks and subsystems, you can control the tunability of individual mask parameters. If you use model arguments to parameterize referenced models, you can tune the value of each model argument in each Model block.

Why Did the Simulation Output Stay the Same?

If the output of your simulation does not change after you change a parameter value, use these troubleshooting techniques:

- Locate the definition of a workspace variable.

If you use a workspace variable to set block parameter values, determine where the variable definition resides. For example, if you define a variable `myVar` in a model workspace and use it to set a block parameter value in the model, you cannot change the parameter value by changing the value of a variable named `myVar` in the base workspace. You must access the variable definition in the model workspace.

To locate the definition of a variable, while editing the value of a block parameter that uses the variable, click the nearby action button  and select **Explore**. A dialog box opens, such as the Model Explorer, which displays the definition of the variable in the appropriate workspace. For more information about how models use variables, see “Symbol Resolution” on page 68-128.

- Specify value ranges for fixed-point parameters that you want to tune during simulation.

If the block parameter you want to tune uses a fixed-point data type with best-precision scaling, specify a minimum and maximum value for the parameter so that Simulink can calculate and apply an appropriate scaling. If you do not specify a value range, Simulink might apply a scaling that

excludes the tuning values that you want to use. To specify value ranges, see “Specify Minimum and Maximum Values for Block Parameters” on page 37-52.

- Update the model diagram during a simulation run. If you use a workspace variable to set the value of one or more block parameters, after you change the value of the variable during a simulation, you must update the model diagram.

To learn how to update a model diagram, see “Update Diagram and Run Simulation” on page 1-25.

Tunability Considerations and Limitations for Other Modeling Goals

Referenced Models

When you use Model blocks, these parameter tunability limitations apply:

- If you set the simulation mode of a Model block to an accelerated mode or if you simulate the parent model in an accelerated mode, you cannot tune block parameters in the referenced model during simulation. However, if the referenced model uses variables in the base workspace or a data dictionary to set parameter values, you can tune the values of the variables.
- Suppose you use a MATLAB variable or `Simulink.Parameter` object in a model workspace to set the value of a block parameter in a model. If you use a Model block to refer to this model:
 - And you set the simulation mode of the Model block to an accelerated mode or simulate the parent model in an accelerated mode, you cannot change the value of the variable or object during the simulation.
 - When you simulate the parent model in an accelerated mode, changing the value of the variable or object between simulation runs causes Simulink to regenerate code.
 - And you use additional Model blocks to refer to the model multiple times in the parent model, you can choose a different simulation mode for each Model block. If at least one block uses normal simulation mode and any other block uses a different simulation mode, you cannot change the value of the variable or object during simulation. Also, when you simulate the parent model with fast restart on, you cannot change the value of the variable or object between fast-restart simulation runs.

As a workaround, move the variable or object to the base workspace or a data dictionary.

Accelerator and SIL/PIL Simulations

These tunability limitations apply to accelerator, rapid accelerator, SIL, and PIL simulations:

- Suppose you use a MATLAB variable or `Simulink.Parameter` object in a model workspace to set the value of a block parameter in a model. If you use the `sim` function to simulate the model in rapid accelerator mode and set the `RapidAcceleratorUpToDateCheck` pair argument to `'off'`, you cannot use the `RapidAcceleratorParameterSets` pair argument to specify different values for the variable or object. The structure returned by `Simulink.BlockDiagram.buildRapidAcceleratorTarget` does not contain information about the variable or object.
- If a block parameter value references workspace variables, you cannot change the block parameter value during rapid accelerator simulation, such as by using the function `set_param`. Instead, you can tune the values of the referenced variables.

Alternatively, use parameter sets to tune runtime parameters in between rapid accelerator simulations. For more information, see “Tuning Runtime Parameters” on page 35-8.

For more information about parameter tunability during accelerated simulations, see “Tuning Runtime Parameters” on page 35-8 and “sim in parfor with Rapid Accelerator Mode” on page 26-13. For more information about parameter tunability during SIL and PIL simulations, see “Tunable Parameters and SIL/PIL” (Embedded Coder).

Fast Restart

For more information about parameter tunability when you use fast restart, see “Get Started with Fast Restart” on page 82-5 .

Code Generation and Simulation of External Programs

Parameters that are tunable during simulation can appear as nontunable inlined parameters in the generated code. If you simulate an external program by using SIL, PIL, or External mode simulation, parameter tunability during the simulation and between simulation runs can depend on your code generation settings.

To control parameter tunability in the generated code, you can adjust the code generation settings for a model by using the configuration parameter **Default parameter behavior**. You can also adjust settings for individual MATLAB variables, `Simulink.Parameter` objects, and other parameter objects. For more information, see “Preserve Variables in Generated Code” (Simulink Coder).

Stateflow Charts

To debug a Stateflow chart by changing data during simulation, see “Debugging Stateflow Charts” (Stateflow).

Optimize, Estimate, and Sweep Block Parameter Values

When you sweep one or more parameters, you change their values between simulation runs, and compare and analyze the output signal data from each run. Use parameter sweeping to tune control parameters, estimate unknown model parameters, and test the robustness of a control algorithm by taking into consideration uncertainty in the real-world system.

You can sweep block parameter values or the values of workspace variables that you use to set the parameter values. Use the **Parameters** tab on the Model Data Editor (on the **Modeling** tab, click **Model Data Editor**), the Property Inspector (on the **Modeling** tab, under **Design**, click **Property Inspector**), the command prompt, or scripts to change parameter values between simulation runs.

If you want to repeatedly change the value of a block parameter, consider creating a variable in a workspace. You can use the Model Explorer or programmatic commands to change the value of the variable instead of locating or identifying the block in the model. Also, several features and products that facilitate parameter optimization, estimation, and sweeping require that you set block parameter values by creating workspace variables.

To learn how to manipulate parameter values during the iterative process of creating a model, see “Tune and Experiment with Block Parameter Values” on page 37-31.

For basic information about accessing and setting block parameter values as you design a model, see “Set Block Parameter Values” on page 37-2. For basic information about programmatically simulating a model, such as by using a script, see “Run Simulations Programmatically” on page 26-2.

Sweep Parameter Value and Inspect Simulation Results

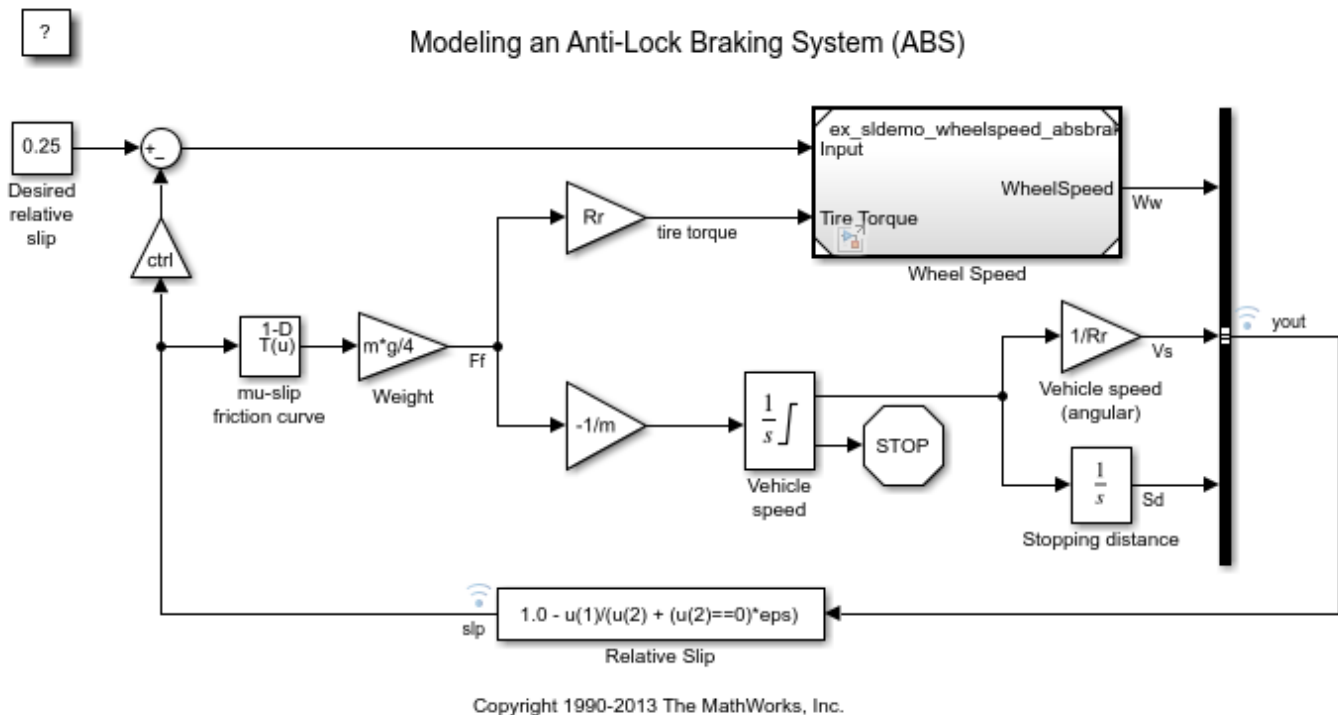

This example shows how to change a block parameter value between multiple programmatic simulation runs. Use this technique to determine an optimal parameter value by comparing the output signal data of each run.

The example model `ex_slldemo_absbrake` uses a Constant block to specify a slip setpoint for an anti-lock braking system. Simulate the model with two different slip setpoint values, 0.24 and 0.25, and compare the output wheel speed of each simulation run.

To store the setpoint value, create a variable in the base workspace. This technique enables you to assign a meaningful name to the value.

Open the example model.

```
open_system('ex_slldemo_absbrake');
```

On the **Modeling** tab, click **Model Data Editor**.

In the Model Data Editor, select the **Signals** tab.

Set the **Change view** drop-down list to **Instrumentation**. The **Log Data** column shows that the signals `yout` (which is a virtual bus) and `slp` are configured for logging. When you simulate the model, you can collect and later inspect the values of these signals by using the Simulation Data Inspector.

In the Model Data Editor, select the **Parameters** tab. Set **Change view** to **Design**.

In the model, select the Constant block labeled `Desired relative slip`. The Model Data Editor highlights the row that corresponds to the **Constant value** parameter of the block.

Use the **Value** column to set the parameter value to `relSlip`.

While editing the value, next to `relSlip`, click the action button (with three vertical dots) and select **Create**.

In the Create New Data dialog box, set **Value** to `0.2` and click **Create**. A variable, whose value is `0.2`, appears in the base workspace. The model now acquires the relative slip setpoint from this variable.

Alternatively, you can use these commands at the command prompt to create the variable and configure the block:

```
relSlip = 0.2;
set_param('ex_slidemo_absbrake/Desired relative slip','Value','relSlip')
```

At the command prompt, create an array to store the two experimentation values for the relative slip setpoint, 0.24 and 0.25.

```
relSlip_vals = [0.24 0.25];
```

Create a `Simulink.SimulationInput` object for each simulation that you want to run (in this case, two). Store the objects in a single array variable, `simIn`. Use the `setVariable` method of each object to identify each of the two experimentation values.

```
for i = 1:length(relSlip_vals)
    simIn(i) = Simulink.SimulationInput('ex_sl_demo_absbrake');
    simIn(i) = setVariable(simIn(i), 'relSlip', relSlip_vals(i));
end
```

Use the `sim` function to simulate the model. Optionally, store the output in a variable named `simOutputs`.

```
simOutputs = sim(simIn);
```

```
[01-Sep-2021 18:55:36] Running simulations...
[01-Sep-2021 18:55:37] Completed 1 of 2 simulation runs
[01-Sep-2021 18:55:38] Completed 2 of 2 simulation runs
```

The model streams the logged signals, `yout` and `slp`, to the Simulation Data Inspector. You can view the signal data in the Simulation Data Inspector.

Compare the output data of the two latest simulation runs.

```
runIDs = Simulink.sdi.getAllRunIDs();
runResult = Simulink.sdi.compareRuns(runIDs(end-1), runIDs(end));
```

Plot the difference between the values of the `Ww` signal (which is an element of the virtual bus signal `yout`) by specifying the result index 1.

```
signalResult = getResultByIndex(runResult,1);
plot(signalResult.Diff);
```

Store Sweep Values in Simulink.SimulationInput Objects

When you write a script to run many simulations, create an array of `Simulink.SimulationInput` objects (one object for each simulation that you want to run). Use the `setVariable` and `setBlockParameter` methods of each object to identify the parameter values to use for the corresponding simulation run. With this technique, you avoid having to use the `set_param` function to modify block parameter values and assignment commands to modify workspace variable values between simulation runs.

For more information about using `Simulink.SimulationInput` objects to run multiple simulations, see `sim`.

Sweep Nonscalars, Structures, and Parameter Objects

If you use nonscalar variables, structure variables, or `Simulink.Parameter` objects to set block parameter values, use the `setVariable` method of each `Simulink.SimulationInput` object. Refer to the examples in the table.

Scenario	Example
MATLAB variable, <code>myArray</code> , whose value is an array. You want to set the third element in the array (assuming one-based indexing).	<code>setVariable(simIn, 'myArray(3)', 15.23)</code>

Scenario	Example
MATLAB variable, myStruct, that has a field named field1.	<code>setVariable(simIn, 'myStruct.field1', 15.23)</code>
Parameter object, myParam, whose Value property is a scalar.	<code>setVariable(simIn, 'myParam.Value', 15.23)</code>
Parameter object, myArrayParam, whose Value property is an array. You want to set the third element in the array.	<code>setVariable(simIn, 'myArrayParam.Value(3)', 15.23)</code>
Parameter object, myStructParam, whose Value property is a structure. The structure has a field named field1.	<code>setVariable(simIn, 'myStructParam.Value.field1', 15.23)</code>

Sweep Value of Variable in Model Workspace

If you use the model workspace to store variables, when you use the `setVariable` method of a `Simulink.SimulationInput` object to modify the variable value, use the `Workspace` pair argument to identify the containing model:

```
setVariable(simIn, 'myVar', 15.23, 'Workspace', 'myModel')
```

Capture and Visualize Simulation Results

Each simulation run during a parameter sweep produces outputs, such as signal values from Output blocks and from logged signals.

You can capture these outputs in variables and objects for later analysis. For more information, see “Export Simulation Data” on page 73-2.

To visualize simulation output data so you can compare the effect of each parameter value, see “Decide How to Visualize Simulation Data” on page 30-2.

Improve Simulation Speed

To perform many simulations that each use different parameter values, you can use accelerated simulation modes. For larger models, accelerated simulations take less time to execute than normal simulations. If you also have Parallel Computing Toolbox, you can use the multiple cores of your processor to simultaneously execute simulations. Use arguments of the `sim` and `parsim` functions.

To improve the simulation speed of your model by using accelerated simulations and other techniques, see “Optimize Performance”. For examples and more information, see “Running Multiple Simulations” on page 27-2.

Sweep Parameter Values to Test and Verify System

If you have Simulink Test, you can confirm that your model still meets requirements when you use different parameter values. Parameter overrides and test iterations enable you to set different parameter values for each test case. For more information, see “Parameter Overrides” (Simulink Test) and “Test Iterations” (Simulink Test).

Estimate and Calibrate Model Parameters

If you have Simulink Design Optimization, you can estimate model parameter values so that simulation outputs closely fit the data that you measure in the real world. Use this technique to estimate the real-world values of parameters in a plant model, which represents the dynamics of a real-world system, when you cannot directly measure the values. This estimation improves the accuracy of the plant model. For more information, see “Estimate Parameters from Measured Data” (Simulink Design Optimization).

Tune and Optimize PID and Controller Parameters

If you have Simulink Control Design, you can use PID Tuner to tune the parameters of a PID Controller block. For more information, see “PID Controller Tuning in Simulink” (Simulink Control Design).

If you have Simulink Design Optimization, you can optimize control parameter values so that simulation outputs meet response requirements that you specify. For more information, see “Design Optimization to Meet Step Response Requirements (GUI)” (Simulink Design Optimization).

Control Block Parameter Data Types

A block parameter, such as the **Gain** parameter of a Gain block, has a data type in the same way that a signal has a data type (see “Control Data Types of Signals” on page 68-6). MATLAB variables, `Simulink.Parameter` objects, and other parameter objects that you use to set block parameter values also have data types. Control block parameter data types to:

- Accurately simulate the execution of your control algorithm on hardware.
- Generate efficient code.
- Integrate the generated code with your custom code.
- Avoid using data types that your target hardware does not support.

Reduce Maintenance Effort with Data Type Inheritance

By default, block parameters, numeric MATLAB variables that use the data type `double`, and `Simulink.Parameter` objects acquire a data type through inherited and context-sensitive data typing. For example, if the input and output signals of a Gain block use the data type `single`, the **Gain** parameter typically uses the same data type. If you use a `Simulink.Parameter` object to set the value of the block parameter, by default, the object uses the same data type as the parameter. You can take advantage of this inheritance to avoid explicitly specifying data types for parameters.

Some inheritance rules choose a parameter data type other than the data type that the corresponding signals use. For example, suppose that:

- The input and output signals of a Gain block use fixed-point data types with binary-point-only scaling.
- On the **Parameter Attributes** tab, **Parameter data type** is set to `Inherit: Inherit via internal rule` (the default).
- On the **Parameter Attributes** tab, you specify a minimum and maximum value for the parameter by using **Parameter minimum** and **Parameter maximum**.

The data type setting `Inherit: Inherit via internal rule` can cause the block to choose a different data type, with a different word length or scaling, than the data type that the signals use. The minimum and maximum values that you specified for the parameter influence the scaling that the block chooses.

When you select internal rules (`Inherit: Inherit via internal rule`) to enable Simulink to choose data types, before simulating or generating code, configure the characteristics of your target hardware. The internal rules can use these settings to choose data types that yield efficient generated code.

Context-Sensitive Data Typing

When you use a MATLAB variable or `Simulink.Parameter` object to set the value of a block parameter, you can configure the variable or parameter object to use context-sensitive data typing. When you simulate or generate code, the variable or parameter object uses the same data type as the block parameter. With this technique, you can match the data type of the variable or parameter object with the data type of the block parameter. To control the data type of the block parameter and the variable or object, you specify only the data type of the block parameter.

To use context-sensitive data typing, set the value of a MATLAB variable to a double value. For a `Simulink.Parameter` object, set the `Value` property by using a double value and set the `DataType` property to `auto` (the default).

Context-Sensitive Data Typing for Structure Fields

As described in “Organize Related Block Parameter Definitions in Structures” on page 37-19, you can organize multiple block parameter values into a structure.

The fields of parameter structures do not support context-sensitive data typing. However, to match the data type of a field with the data type of another data item in a model, you can use a bus object and a data type object.

- 1 Use a `Simulink.Bus` object as the data type of the structure.
- 2 Use a `Simulink.AliasType` or `Simulink.NumericType` object as the data type of the element in the bus object and as the data type of the target data item.

Techniques to Explicitly Specify Parameter Data Types

Many blocks supported for discrete-time simulation and code generation (such as those in the built-in Discrete library) enable you to explicitly specify parameter data types. For example, in an **n-D Lookup Table** block dialog box, on the **Data Types** tab, you can specify a data type for the lookup table data by using the **Table data** parameter. In a Gain block dialog box, use the **Parameter Attributes** tab to set **Parameter data type**, which controls the data type of the **Gain** parameter.

Some blocks, such as those in the Continuous library, do not enable you to specify parameter data types. These block parameters use internal rules to choose a data type. To indirectly control the data type of such a parameter, apply the data type to a `Simulink.Parameter` object instead.

When you use a `Simulink.Parameter` object or other parameter object to set the value of a block parameter, you can use the `DataType` property of the object to specify a data type.

If you use model arguments, you can specify a data type:

- For the model argument that you store in the model workspace.
- With some blocks (such as those in the Discrete library), for the block parameter that uses the model argument.
- For the argument value that you specify in a Model block.

The default settings for these data types typically use inheritance and context-sensitive data typing. For example, the default value of the `DataType` property of a `Simulink.Parameter` object is `auto`, which causes the parameter object to acquire a data type from the block parameter or parameters that use the object.

To explicitly specify a data type, you can use the Data Type Assistant in block dialog boxes and property dialog boxes. For information about the Data Type Assistant, see “Specify Data Types Using Data Type Assistant” on page 68-30.

Use the Model Data Editor for Batch Editing

Using the Model Data Editor (on the **Modeling** tab, click **Model Data Editor**), you can specify the same data type for multiple block parameters simultaneously. On the **Parameters** tab, set the **Change view** drop-down list to **Design** and specify data types by using the **Data Type** column.

For more information, see **Model Data Editor**.

Calculate Best-Precision Fixed-Point Scaling for Tunable Block Parameters

When you apply fixed-point data types to a model, you can use the Data Type Assistant and the Fixed-Point Tool to calculate best-precision scaling for tunable block parameters. A block parameter, `Simulink.Parameter` object, or other parameter object is tunable if it appears in the generated code as a variable stored in memory.

The chosen scaling must accommodate the range of values that you expect to assign to the parameter. To enable the tools to calculate an appropriate scaling, specify the range information in the block or in a parameter object. Then, use one of these techniques to calculate the scaling:

- Use the Fixed-Point Tool to autoscale the entire model or subsystem. The tool can propose and apply fixed-point data types for data items including block parameters, `Simulink.Parameter` objects, signals, and states.
- Configure individual block parameters or parameter objects to calculate their own scaling.

When you later change value ranges for parameters, this technique enables you or the model to recalculate the scaling without having to autoscale the entire model. However, if changing the value range of the parameter also changes the value range of an associated signal, you must manually calculate and apply a new scaling for the signal or use the Fixed-Point Tool to autoscale the model or subsystem.

For basic information about fixed-point data types, block parameters, and other tools and concepts, use the information in the table.

How to specify value range information for block parameters and parameter objects	"Specify Minimum and Maximum Values for Block Parameters" on page 37-52
How to use the Data Type Assistant	"Specify Data Types Using Data Type Assistant" on page 68-30
Tunability and block parameter representation in the generated code	"How Generated Code Stores Internal Signal, State, and Parameter Data" (Simulink Coder) and "Create Tunable Calibration Parameter in the Generated Code" (Simulink Coder)

Autoscale Entire Model by Using the Fixed-Point Tool

You can use the Fixed-Point Tool to autoscale data items in your model, including tunable parameters and signals whose values depend on those parameters. If you use this technique:

- To configure parameters as tunable, use parameter objects (for example, `Simulink.Parameter`) instead of the Model Parameter Configuration dialog box. The Fixed-Point Tool can autoscale parameter objects, but cannot autoscale numeric variables that you select through the Model Parameter Configuration dialog box.

If your model already uses the Model Parameter Configuration dialog box, use the `tunablevars2parameterobjects` function to create parameter objects instead.

- When you use `Simulink.Parameter` objects to set block parameter values, specify the value range information in the objects instead of the blocks. The Fixed-Point Tool uses the range information in each object to propose a data type for that object.
- To enable the tool to autoscale parameter values that you store as fields of a structure, use a `Simulink.Bus` object as the data type of the entire structure. Specify the range information for each field by using the `Min` and `Max` properties of the corresponding element in the bus object. The tool can then apply a data type to each element by using the `DataType` property.

To use a bus object as the data type of a parameter structure, see “Control Field Data Types and Characteristics by Creating Parameter Object” on page 37-21.

- Before you apply the data types that the Fixed-Point Tool proposes, clear the proposals for parameters and parameter objects whose data types you do not want the tool to change. For example, clear the proposals for these entities:
 - Parameter objects that you import into the generated code from your own handwritten code by applying a storage class such as `ImportedExtern`.
 - `Simulink.Parameter` model arguments in a model workspace.

Alternatively, before autoscaling the model, consider replacing these parameter objects with numeric MATLAB variables to prevent the Fixed-Point Tool from autoscaling them.

Allowing the tool to autoscale model arguments can increase the risk of unintentional data type mismatches between the model argument values (which you specify in Model blocks in a parent model), the model arguments in the model workspace, and the client block parameters in the model.

- Parameter objects whose `DataType` property is set to `auto` (context-sensitive). Clear the proposals if you want the parameter objects to continue to use context-sensitive data typing.

For more information about using the Fixed-Point Tool to autoscale `Simulink.Parameter` objects, see “Autoscaling Data Objects Using the Fixed-Point Tool” (Fixed-Point Designer).

Calculate Best-Precision Scaling for Individual Parameters

You can configure a block parameter or `Simulink.Parameter` object to calculate its own best-precision scaling. First, specify value range information for the target parameter or parameter object. Then, use the Data Type Assistant or the function `fixdt` to apply a data type to the parameter or object. Use these techniques when you do not want to use the Fixed-Point Tool to autoscale the model.

Enable Block Parameter to Automatically Calculate Best-Precision Scaling

You can enable the parameters of some blocks (typically blocks in the Discrete library) to automatically calculate best-precision fixed-point scaling. Use this technique to store the range and data type information in the model instead of a parameter object. When you use this technique, if you later change the range information, the block parameter automatically recalculates best-precision scaling.

In the block dialog box, use the function `fixdt` to specify a fixed-point data type with unspecified scaling. For example, use best-precision scaling for lookup table data, and store the data in a 16-bit word:

- 1 On the **Data Types** tab of an n-D Lookup Table block, under the **Minimum** and **Maximum** columns, specify a value range for the elements of the table data.
- 2 Under the **Data Type** column, set the table data type to `fixdt(1,16)`.
- 3 If you use a tunable `Simulink.Parameter` object to set the value of the table data parameter, set the `DataType` property of the object to `auto`. In the generated code, the parameter object uses the same scaling as the block parameter.

When you simulate or generate code, the lookup table data uses a signed 16-bit fixed-point data type whose binary-point scaling depends on the range information that you specify. The calculated scaling allows the fixed-point type to represent values that lie within the range. If you later change the minimum or maximum values, the block recalculates the scaling when you simulate or generate code.

Calculate Scaling for Parameter Object

If you use a `Simulink.Parameter` object to set the values of multiple block parameters, and if the block parameters use different data types (including different fixed-point scaling), you cannot set the `DataType` property of the object to `auto` (the default). Instead, you can calculate best-precision fixed-point scaling for the parameter object by specifying range and data type information in the object. You can also use this technique to store range and data type information in a parameter object instead of a block dialog box. When you use this technique, if you later change the range information, you must recalculate the best-precision scaling by using the Data Type Assistant.

Suppose that you create a parameter object to represent the value `15.25`, and that the design range of the value is between `0.00` and `32.00`. To calculate best-precision scaling, use the Data Type Assistant.

- 1 At the command prompt, create a parameter object in the base workspace whose value is `15.25`.

```
myParam = Simulink.Parameter(15.25);
```
- 2 In the MATLAB Workspace browser, double-click the object `myParam`. The property dialog box opens.
- 3 Specify range information in the object. For example, set **Minimum** to `0.00` and **Maximum** to `32.00`.
- 4 Set **Data type** to `fixdt(0,16,0)`.
- 5 Expand the Data Type Assistant and click **Calculate Best-Precision Scaling**.

The data type changes from `fixdt(0,16,0)` to `fixdt(0,16,10)`.

The calculated scaling (a fraction length of 10 bits) enables the fixed-point data type to represent parameter values that lie within the range that you specified.

If you specify range and data type information in a parameter object, consider removing the range and data type information from the blocks that use the object. Some tools, such as the Fixed-Point Tool, ignore the range information that you specify in the block and use only the information in the parameter object. Removing the information from the block prevents confusion and user errors.

For example, on the **Parameter Attributes** tab of a Gain block dialog box, set **Parameter minimum** and **Parameter maximum** to `[]`. Set **Parameter data type** to an inherited data type such as `Inherit: Inherit from 'Gain'` so that the block parameter uses the same data type as the parameter object.

Detect Numerical Accuracy Issues Due to Quantization and Overflow

When the data type of a block parameter, MATLAB variable, or parameter object cannot represent the value that you specify, the data type quantizes the value, compromising numerical accuracy. For example, the 32-bit floating-point data type `single` (`float` in C code) cannot exactly represent the parameter value 1.73. When the real-world value of a data item lies outside the range of values that the data type can represent, overflow can cause loss of information.

To detect these issues, use the diagnostic configuration parameters under **Configuration Parameters > Diagnostics > Data Validity > Parameters**. Set the values of these diagnostic configuration parameters to warning or error:

- **Detect downcast**
- **Detect precision loss**
- **Detect underflow**
- **Detect overflow**

Reuse Custom C Data Types for Parameter Data

In a model, you can create parameter data that conform to custom C data types, such as structures, that your existing C code defines. Use these data to:

- Replace existing C code with a Simulink model.
- Integrate C code for simulation in Simulink (for example, by using the Legacy Code Tool).
- Prepare to generate code (Simulink Coder) that you can integrate with existing code.

Use these techniques to match your custom data types:

- For a structure type, create a `Simulink.Bus` object. Use the object as the data type for a structure that you store in a `Simulink.Parameter` object. See “Organize Related Block Parameter Definitions in Structures” on page 37-19.
- For an enumeration, create an enumeration class and use it as the data type for block parameters. See “Use Enumerated Data in Simulink Models” on page 69-6.
- To match a `typedef` statement that represents an alias of a primitive, numeric data type, use a `Simulink.AliasType` object as the data type for block parameters. See `Simulink.AliasType`.

To create these classes and objects, you can use the function `Simulink.importExternalCTypes`.

If a MATLAB Function block or Stateflow chart in your model uses an imported enumeration or structure type, configure the model configuration parameters to include (`#include`) the type definition from your external header file. See “Control Imported Bus and Enumeration Type Definitions” on page 45-112 (for a MATLAB Function block) and “Access Custom Code Variables and Functions in Stateflow Charts” (Stateflow) and “Integrate Custom Structures in Stateflow Charts” (Stateflow) (for a chart).

Data Types of Mathematical Expressions

If you specify a block parameter using a mathematical expression, the block determines the final parameter data type using a combination of MATLAB and Simulink data typing rules.

Suppose that you define two parameter objects `int8Param` and `doubleParam`, and use the objects to specify the **Constant value** parameter in a Constant block.

```
int8Param = Simulink.Parameter(3);
int8Param.DataType = 'int8';

doubleParam = Simulink.Parameter(9.36);
doubleParam.DataType = 'double';
```

The Constant block determines the data type of the **Constant value** parameter using these steps:

- 1 Each parameter object casts the specified numeric value to the specified data type.

Parameter object	Data type	Numeric value	Result
<code>int8Param</code>	<code>int8</code>	3	<code>int8(3)</code>
<code>doubleParam</code>	<code>double</code>	9.36	<code>double(9.36)</code>

- 2 The block evaluates the specified expression, `int8Param * doubleParam`, using MATLAB rules.

An expression that involves a `double` data type and a different type returns a result of the different type. Therefore, the result of the expression `int8(3) * double(9.36)` is `int8(28)`.

If you use an expression to set the value of a parameter object (such as `Simulink.Parameter`), parameter objects used in the expression follow different data typing rules. The `auto` setting of the `DataType` property has a slightly different meaning. See “Set Variable Value by Using a Mathematical Expression” on page 37-10.

Block Parameter Data Types in the Generated Code

For more information about controlling parameter data types in the generated code, see “Parameter Data Types in the Generated Code” (Simulink Coder).

Specify Minimum and Maximum Values for Block Parameters

You can protect your model design by preventing block parameters from using values outside of a range. For example, if the value of a parameter that represents the angle of an aircraft aileron cannot feasibly exceed a known magnitude, you can specify a design maximum for the parameter in the model.

Fixed-Point Designer enables Simulink to use your range information to calculate best-precision fixed-point scaling for:

- Tunable parameters.
- Signals, by taking into consideration the range of values that you intend to assign to tunable parameters.

For basic information about block parameters, see “Set Block Parameter Values” on page 37-2.

Specify Parameter Value Ranges

When you specify a value range for a block parameter, typically, you can choose to store the information in the block (the model file) or in an external variable or parameter object. Choose a technique based on your modeling goals.

- Use other parameters of the same block, if available. For example, you can control the value range of the **Gain** parameter of a Gain block by using the **Parameter minimum** and **Parameter maximum** parameters in the **Parameter Attributes** tab in the block dialog box. For other blocks, such as n-D Lookup Table and PID Controller, use the **Data Types** tab.

Use this technique to:

- Store the range information in the model file.
- Store the range information when you store fixed-point data type information in the block (for example, by setting the **Parameter data type** parameter of a Gain block to a fixed-point type, including best-precision scaling). This technique more clearly associates the range information with the data type information.
- Use parameter objects (for example, `Simulink.Parameter`) to set the parameter value. You can specify the range information in the object, instead of the block, by using the `Min` and `Max` properties of the object.

Use this technique to:

- Specify range information for blocks that cannot store minimum or maximum information, for example, many blocks in the Continuous library.
- Specify range information for a single value that you share between multiple block parameters (see “Share and Reuse Block Parameter Values by Creating Variables” on page 37-9). Instead of using a numeric MATLAB variable, use a parameter object so that you can specify the `Min` and `Max` properties.
- Store the range information when you store fixed-point data type information in a parameter object (by setting the `DataType` property to a fixed-point type instead of `auto`). This technique more clearly associates the range information with the data type information.

If you specify the range information in a parameter object, consider removing the range information from the block. For example, on the **Parameter Attributes** tab of a Gain block dialog

box, set **Parameter minimum** and **Parameter maximum** to `[]`. Some tools, such as the Fixed-Point Tool, use the range information that you specify in the block only if you do not specify the range information in the parameter object. If you specify the range information in the parameter object, the tools ignore the range information that you specify in the block.

For basic information about creating and using data objects, see “Data Objects” on page 68-59.

Specify Valid Range Information

Specify a minimum or maximum as an expression that evaluates to a scalar, real number with double data type. For example, you can specify a minimum value for the **Gain** parameter in a Gain block by setting **Parameter minimum**:

- A literal number such as `98.884`. Implicitly, the data type is `double`.
- A numeric workspace variable (see “Share and Reuse Block Parameter Values by Creating Variables” on page 37-9) whose data type is `double`. Use this technique to share a minimum or maximum value between multiple data items.

However, you cannot use variables to set the **Min** or **Max** properties of a parameter object.

To leave the minimum or maximum of a block parameter or parameter object unspecified, use an empty matrix `[]`, which is the default value.

Specify Range Information for Nonscalar Parameters

If the value of a block parameter is a vector or matrix, the range information that you specify applies to each element of the vector or matrix. If the value of any of the elements is outside the specified range, the model generates an error.

If the value of a block parameter is a structure or a field of a structure, specify range information for the structure fields by creating a `Simulink.Parameter` object whose data type is a `Simulink.Bus` object. Specify the range information by using the properties of the signal elements in the bus object. For more information, see “Control Field Data Types and Characteristics by Creating Parameter Object” on page 37-21.

Specify Range Information for Complex-Valued Parameters

If the value of a block parameter is complex (i), the range information that you specify applies separately to the real part and to the imaginary part of the complex number. If the value of either part of the number is outside the range, the model generates an error.

Specify Ranges for Multiple Parameters by Using the Model Data Editor

Using the Model Data Editor (on the **Modeling** tab, click **Model Data Editor**), you can specify value ranges for multiple block parameters and variables with a searchable, sortable table. On the **Parameters** tab, set the **Change view** drop-down list to **Design** and specify values in the **Min** and **Max** columns.

For more information, see **Model Data Editor**.

Restrict Allowed Values for Block Parameters

To protect your design by preventing block parameters from using values outside of a range, you can specify the minimum and maximum information by using other parameters of the same block. If you

or your users set the value of the target parameter outside the range that you specify, the model generates an error.

Whether a block allows you to specify a value range for a parameter, consider using a parameter object (for example, `Simulink.Parameter`) to set the value of the target parameter. Use the properties of the object to specify the range information. This technique helps you to specify range information for a variable that you use to set multiple block parameter values.

Specify Range Information for Tunable Fixed-Point Parameters

When you use fixed-point data types in your model, you can enable Simulink to choose a best-precision scaling for block parameters and `Simulink.Parameter` objects. If you intend to tune such a parameter by changing its value during simulation or during execution of the generated code, the fixed-point scaling chosen by Simulink must accommodate the range of values that you expect to assign to the parameter.

Also, if you expect to change the value of a parameter, signal data types in the model must accommodate the corresponding expanded range of possible signal values. If you use the Fixed-Point Tool to propose and apply fixed-point data types for a model, to allow the tool to accurately autoscale the signals, specify range information for tunable parameters.

To specify range information for tunable parameters, see “Calculate Best-Precision Fixed-Point Scaling for Tunable Block Parameters” on page 37-46. To learn how the Fixed-Point Tool autoscales signals by taking into account the value ranges of tunable parameters, see “Derive Ranges for `Simulink.Parameter` Objects” (Fixed-Point Designer).

Unexpected Errors or Warnings for Data with Greater Precision or Range than double

When a data item (signal or parameter) uses a data type other than `double`, before comparison, Simulink casts the data item and each design limit (minimum or maximum value that you specify) to the `nondouble` data type. This technique helps prevent the generation of unnecessary, misleading errors and warnings.

However, Simulink stores design limits as `double` before comparison. If the data type of the data item has higher precision than `double` (for example, a fixed-point data type with a 128-bit word length and a 126-bit fraction length) or greater range than `double`, and `double` cannot exactly represent the value of a design limit, Simulink can generate unexpected warnings and errors.

If the `nondouble` type has higher precision, consider rounding the design limit to the next number furthest from zero that `double` can represent. For example, suppose that a signal generates an error after you set the maximum value to `98.8847692348509014`. At the command prompt, calculate the next number furthest from zero that `double` can represent.

```
format long
98.8847692348509014 + eps(98.8847692348509014)

ans =

    98.884769234850921
```

Use the resulting number, `98.884769234850921`, to replace the maximum value.

Optimize Generated Code

If you have Embedded Coder, Simulink Coder can optimize the code that you generate from the model by taking into account the minimum and maximum values that you specify for signals and parameters. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values” (Embedded Coder).

Switch Between Sets of Parameter Values During Simulation and Code Execution

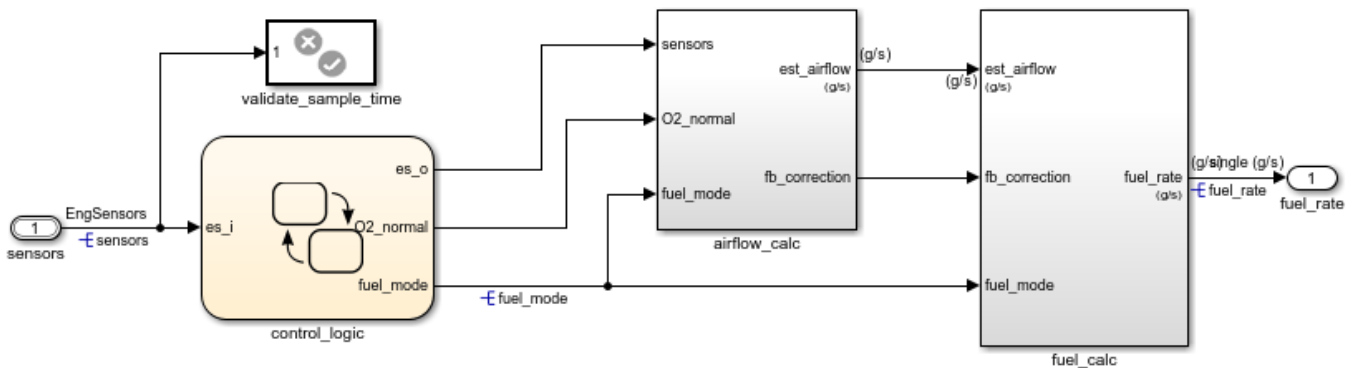

To store multiple independent sets of values for the same block parameters, you can use an array of structures. To switch between the parameter sets, create a variable that acts as an index into the array, and change the value of the variable. You can change the value of the variable during simulation and, if the variable is tunable, during execution of the generated code.

Explore Example Model

Open the example model.

```
open_system('sldemo_fuelsys_dd_controller')
```

Fuel Rate Controller

Copyright 1990-2017 The MathWorks, Inc.

This model represents the fueling system of a gasoline engine. The output of the model is the rate of fuel flow to the engine.

Navigate to the `switchable_compensation` nested subsystem.

```
open_system(['sldemo_fuelsys_dd_controller/fuel_calc/', ...
            'switchable_compensation'])
```

Loop Compensation and Filtering

This subsystem corrects and filters noise out of the fuel rate signal. The subsystem uses different filter coefficients based on the fueling mode, which the control logic changes based on sensor failures in the engine. For example, the control algorithm activates the `low_mode` subsystem during normal operation. It activates the `rich_mode` subsystem in response to sensor failure.

Open the `low_mode` subsystem.

```
open_system(['sldemo_fuelsys_dd_controller/fuel_calc/', ...
            'switchable_compensation/low_mode'])
```

The Discrete Filter block filters the fuel rate signal. In the block dialog box, the **Numerator** parameter sets the numerator coefficients of the filter.

The sibling subsystem `rich_mode` also contains a Discrete Filter block, which uses different coefficients.

Update the model diagram to display the signal data types. The input and output signals of the block use the single-precision, floating-point data type `single`.

In the lower-left corner of the model, click the model data badge, then click the **Data Dictionary** link. The data dictionary for this model, `sldemo_fuelsys_dd_controller.slidd`, opens in the Model Explorer.

In the Model Explorer **Model Hierarchy** pane, select the **Design Data** node.

In the **Contents** pane, view the properties of the Simulink.NumericType objects, such as `s16En15`. All of these objects currently represent the single-precision, floating-point data type `single`. The model uses these objects to set signal data types, including the input and output signals of the Discrete Filter blocks.

Suppose that during simulation and execution of the generated code, you want each of these subsystems to switch between different numerator coefficients based on a variable whose value you control.

Store Parameter Values in Array of Structures

Store the existing set of numerator coefficients in a Simulink.Parameter object whose value is a structure. Each field of the structure stores the coefficients for one of the Discrete Filter blocks.

```
lowBlock = ['sldemo_fuelsys_dd_controller/fuel_calc/'...
            'switchable_compensation/low_mode/Discrete Filter'];
richBlock = ['sldemo_fuelsys_dd_controller/fuel_calc/'...
             'switchable_compensation/rich_mode/Discrete Filter'];
params.lowNumerator = eval(get_param(lowBlock, 'Numerator'));
params.richNumerator = eval(get_param(richBlock, 'Numerator'));
params = Simulink.Parameter(params);
```

Copy the value of `params` into a temporary variable. Modify the field values in this temporary structure, and assign the modified structure as the second element of `params`.

```
temp = params.Value;
temp.lowNumerator = params.Value.lowNumerator * 2;
temp.richNumerator = params.Value.richNumerator * 2;
params.Value(2) = temp;
clear temp
```

The value of `params` is an array of two structures. Each structure stores one set of filter coefficients.

Create Variable to Switch Between Parameter Sets

Create a Simulink.Parameter object named `Ctrl`.

```
Ctrl = Simulink.Parameter(2);
Ctrl.DataType = 'uint8';
```

In the `low_mode` subsystem, in the Discrete Filter block dialog box, set the **Numerator** parameter to the expression `params(Ctrl).lowNumerator`.

```
set_param(lowBlock, 'Numerator', 'params(Ctrl).lowNumerator');
```

In the Discrete Filter block in the `rich_mode` subsystem, set the value of the **Numerator** parameter to `params(Ctrl).richNumerator`.

```
set_param(richBlock, 'Numerator', 'params(Ctrl).richNumerator');
```

The expressions select one of the structures in `params` by using the variable `Ctrl`. The expressions then dereference one of the fields in the structure. The field value sets the values of the numerator coefficients.

To switch between the sets of coefficients, you change the value of `Ctrl` to the corresponding index in the array of structures.

Use Bus Object as Data Type of Array of Structures

Optionally, create a `Simulink.Bus` object to use as the data type of the array of structures. You can:

- Control the shape of the structures.
- For each field, control characteristics such as data type and physical units.
- Control the name of the `struct` type in the generated code.

Use the function `Simulink.Bus.createObject` to create the object and rename the object as `paramsType`.

```
Simulink.Bus.createObject(params.Value)
paramsType = slBus1;
clear slBus1
```

You can use the `Simulink.NumericType` objects from the data dictionary to control the data types of the structure fields. In the bus object, use the name of a data type object to set the `DataType` property of each element.

```
paramsType.Elements(1).DataType = 's16En15';
paramsType.Elements(2).DataType = 's16En7';
```

Use the bus object as the data type of the array of structures.

```
params.DataType = 'Bus: paramsType';
```

Use Enumerated Type for Switching Variable

Optionally, use an enumerated type as the data type of the switching variable. You can associate each of the parameter sets with a meaningful name and restrict the allowed values of the switching variable.

Create an enumerated type named `FilterCoeffs`. Create an enumeration member for each of the structures in `params`. Set the underlying integer value of each enumeration member to the corresponding index in `params`.

```
Simulink.defineIntEnumType('FilterCoeffs',{'Weak','Aggressive'},[1 2])
```

Use the enumerated type as the data type of the switching variable. Set the value of the variable to `Aggressive`, which corresponds to the index 2.

```
Ctrl.Value = FilterCoeffs.Aggressive;
```

Add New Objects to Data Dictionary

Add the objects that you created to the data dictionary `sldemo_fuelsys_dd_controller.slidd`.

```
dictObj = Simulink.data.dictionary.open('sldemo_fuelsys_dd_controller.slidd');
sectObj = getSection(dictObj,'Design Data');
addEntry(sectObj,'Ctrl',Ctrl)
```

```
addEntry(sectObj, 'params', params)
addEntry(sectObj, 'paramsType', paramsType)
```

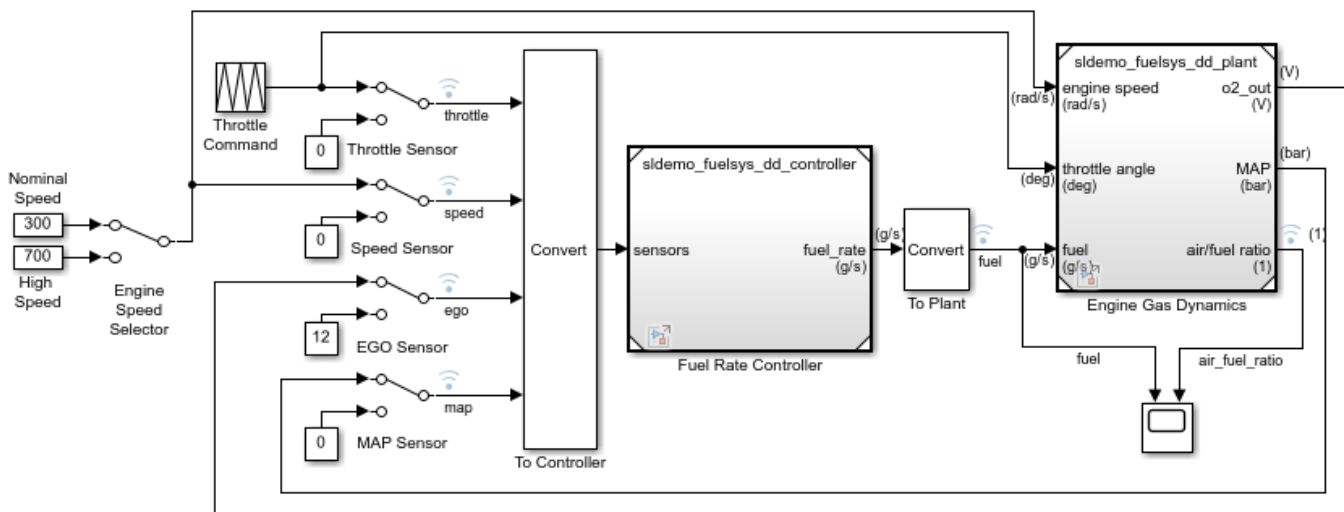

You can also store enumerated types in data dictionaries. However, you cannot import the enumerated type in this case because you cannot save changes to `sldemo_fuelsys_dd_controller.sldd`. For more information about storing enumerated types in data dictionaries, see “Enumerations in Data Dictionary” on page 75-12.

Switch Between Parameter Sets During Simulation

Open the example model `sldemo_fuelsys_dd`, which references the controller model `sldemo_fuelsys_dd_controller`.

```
open_system('sldemo_fuelsys_dd')
```

Fault-Tolerant Fuel Control System

The sensor switches simulate any combination of sensor failures. The Engine Speed Selector switch simulates different engine speeds (rad/s).

Copyright 1990-2017 The MathWorks, Inc.

Set the simulation stop time to `Inf` so that you can interact with the model during simulation.

Begin a simulation run and open the Scope block dialog box. The scope shows that the fuel flow rate (the `fuel` signal) oscillates with significant amplitude during normal operation of the engine.

In the Model Explorer, view the contents of the data dictionary `sldemo_fuelsys_dd_controller.sldd`. Set the value of `Ctrl` to `FilterCoeffs.Weak`.

Update the `sldemo_fuelsys_dd` model diagram. The scope shows that the amplitude of the fuel rate oscillations decreases due to the less aggressive filter coefficients.

Stop the simulation.

Generate and Inspect Code

If you have Simulink Coder software, you can generate code that enables you to switch between the parameter sets during code execution.

In the Model Explorer, view the contents of the data dictionary `sldemo_fuelsys_dd_controller.sldd`. In the **Contents** pane, set **Column View** to **Storage Class**.

Use the **StorageClass** column to apply the storage class `ExportedGlobal` to `params` so that the array of structures appears as a tunable global variable in the generated code. Apply the same storage class to `Ctrl` so that you can change the value of the switching variable during code execution.

Alternatively, to configure the objects, use these commands:

```
tempEntryObj = getEntry(sectObj, 'params');
params = getValue(tempEntryObj);
params.StorageClass = 'ExportedGlobal';
setValue(tempEntryObj, params);

tempEntryObj = getEntry(sectObj, 'Ctrl');
Ctrl = getValue(tempEntryObj);
Ctrl.StorageClass = 'ExportedGlobal';
setValue(tempEntryObj, Ctrl);
```

Generate code from the controller model.

```
slbuild('sldemo_fuelsys_dd_controller')

### Starting build procedure for: sldemo_fuelsys_dd_controller
### Successful completion of code generation for: sldemo_fuelsys_dd_controller
```

Build Summary

Top model targets built:

Model	Action	Rebuild Reason
sldemo_fuelsys_dd_controller	Code generated	Code generation information file does not exist.

1 of 1 models built (0 models already up to date)
Build duration: 0h 1m 0.09s

In the code generation report, view the header file `sldemo_fuelsys_dd_controller_types.h`. The code defines the enumerated data type `FilterCoeffs`.

```
file = fullfile('sldemo_fuelsys_dd_controller_ert_rtw', ...
    'sldemo_fuelsys_dd_controller_types.h');
rtwmodbtype(file, '#ifndef DEFINED_TYPEDEF_FOR_FilterCoeffs_', ...
    '/* Forward declaration for rtModel */', 1, 0)

#ifndef DEFINED_TYPEDEF_FOR_FilterCoeffs_
#define DEFINED_TYPEDEF_FOR_FilterCoeffs_

typedef enum {
    Weak = 1, /* Default value */
    Aggressive
} FilterCoeffs;

#endif
```

The code also defines the structure type `paramsType`, which corresponds to the `Simulink.Bus` object. The fields use the single-precision, floating-point data type from the model.

```
rtwdemodbtype(file, '#ifndef DEFINED_TYPEDEF_FOR_paramsType_', ...
              '#ifndef DEFINED_TYPEDEF_FOR_FilterCoeffs_', 1, 0)
```

```
#ifndef DEFINED_TYPEDEF_FOR_paramsType_
#define DEFINED_TYPEDEF_FOR_paramsType_
```

```
typedef struct {
    real32_T lowNumerator[2];
    real32_T richNumerator[2];
} paramsType;
```

```
#endif
```

View the source file `sldemo_fuelsys_dd_controller.c`. The code uses the enumerated type to define the switching variable `Ctrl`.

```
file = fullfile('sldemo_fuelsys_dd_controller_ert_rtw', ...
               'sldemo_fuelsys_dd_controller.c');
rtwdemodbtype(file, 'FilterCoeffs Ctrl = Aggressive;', ...
              '/* Block signals (default storage) */', 1, 0)
```

```
FilterCoeffs Ctrl = Aggressive;          /* Variable: Ctrl
                                          * Referenced by:
                                          *   '<S12>/Discrete Filter'
                                          *   '<S13>/Discrete Filter'
                                          */
```

The code also defines the array of structures `params`.

```
rtwdemodbtype(file, '/* Exported block parameters */', ...
              '/* Variable: params', 1, 1)
```

```
/* Exported block parameters */
paramsType params[2] = { {
    { 8.7696F, -8.5104F },

    { 0.0F, 0.2592F }
}, { { 17.5392F, -17.0208F },

    { 0.0F, 0.5184F }
} };                                     /* Variable: params
```

The code algorithm in the model `step` function uses the switching variable to index into the array of structures.

To switch between the parameter sets stored in the array of structures, change the value of `Ctrl` during code execution.

Close the connections to the data dictionary. This example discards unsaved changes. To save the changes, use the `'-save'` option.

```
Simulink.data.dictionary.closeAll('sldemo_fuelsys_dd_controller.slidd', '-discard')
```

About Lookup Table Blocks

A lookup table is an array of data that maps input values to output values, thereby approximating a mathematical function. Given a set of input values, a lookup operation retrieves the corresponding output values from the table. If the lookup table does not explicitly define the input values, Simulink can estimate an output value using interpolation, extrapolation, or rounding, where:

- An interpolation is a process for estimating values that lie between known data points.
- An extrapolation is a process for estimating values that lie beyond the range of known data points.
- A rounding is a process for approximating a value by altering its digits according to a known rule.

A lookup table block uses an array of data to map input values to output values, approximating a mathematical function. Given input values, Simulink performs a “lookup” operation to retrieve the corresponding output values from the table. If the lookup table does not define the input values, the block estimates the output values based on nearby table values.

The following example illustrates a one-dimensional lookup table that approximates the function $y = x^3$. The lookup table defines its output (y) data discretely over the input (x) range $[-3, 3]$. The following table and graph illustrate the input/output relationship:

An input of -2 enables the table to look up and retrieve the corresponding output value (-8). Likewise, the lookup table outputs 27 in response to an input of 3.

When the lookup table block encounters an input that does not match any of the table's x values, it can interpolate or extrapolate the answer. For instance, the lookup table does not define an input value of -1.5; however, the block can linearly interpolate the nearest adjacent data points (x_i, y_i) and (x_{i+1}, y_{i+1}) . For example, given these two points:

- (x_i, y_i) is (-2, -8)
- (x_{i+1}, y_{i+1}) is (-1, -1)

The lookup table estimates and returns a value of -4.5.

Similarly, although the lookup table does not include data for x values beyond the range of $[-3, 3]$, the block can extrapolate values using a pair of data points at either end of the table. Given an input value of 4, the lookup table block linearly extrapolates the nearest data points $(2, 8)$ and $(3, 27)$ to estimate an output value of 46.

Since table lookups and simple estimations can be faster than mathematical function evaluations, using lookup table blocks might result in speed gains when simulating a model. Consider using lookup tables in lieu of mathematical function evaluations when:

- An analytical expression is expensive to compute.
- No analytical expression exists, but the relationship has been determined empirically.

Simulink provides a broad assortment of lookup table blocks, each geared for a particular type of application. The sections that follow outline the different offerings, suggest how to choose the lookup table best suited to your application, and explain how to interact with the various lookup table blocks.

Anatomy of a Lookup Table

The following figure illustrates the anatomy of a two-dimensional lookup table. Vectors or breakpoint data sets and an array, referred to as table data, constitute the lookup table.

A breakpoint is a single element of a breakpoint data set. A breakpoint represents a particular input value to which a corresponding output value in the table data is mapped. Each breakpoint data set is an index of input values for a particular dimension of the lookup table. The array of table data serves as a sampled representation of a function evaluated at the breakpoint values. Lookup table blocks use breakpoint data sets to relate a table's input values to the output values that it returns.

A breakpoint data set is a vector of input values that indexes a particular dimension of a lookup table. A lookup table uses breakpoint data sets to relate its input values to the output values that it returns.

Table data is an array that serves as a sampled representation of a function evaluated at a lookup table's breakpoint values. A lookup table uses breakpoint data sets to index the table data, ultimately returning an output value.

Lookup Tables Block Library

Several lookup table blocks appear in the Lookup Tables block library.

The following table summarizes the purpose of each block in the library.

Block Name	Description
1-D Lookup Table	Approximate a one-dimensional function.
2-D Lookup Table	Approximate a two-dimensional function.
n-D Lookup Table	Approximate an N-dimensional function.
Prelookup	Compute index and fraction for Interpolation Using Prelookup block.
Interpolation Using Prelookup	Use precalculated index and fraction values to accelerate approximation of N-dimensional function.
Direct Lookup Table (n-D)	Index into an N-dimensional table to retrieve the corresponding outputs.
Lookup Table Dynamic	Approximate a one-dimensional function using a dynamically specified table.
Sine	Use a fixed-point lookup table to approximate the sine wave function.
Cosine	Use a fixed-point lookup table to approximate the cosine wave function.

Guidelines for Choosing a Lookup Table

In this section...

“Data Set Dimensionality” on page 38-7

“Data Set Numeric and Data Types” on page 38-7

“Data Accuracy and Smoothness” on page 38-7

“Dynamics of Table Inputs” on page 38-7

“Efficiency of Performance” on page 38-8

“Summary of Lookup Table Block Features” on page 38-8

Data Set Dimensionality

In some cases, the dimensions of your data set dictate which of the lookup table blocks is right for your application. If you are approximating a one-dimensional function, consider using either the 1-D Lookup Table or Lookup Table Dynamic block. If you are approximating a two-dimensional function, consider the 2-D Lookup Table block. Blocks such as the n-D Lookup Table and Direct Lookup Table (n-D) allow you to approximate a function of N variables.

Data Set Numeric and Data Types

The numeric and data types of your data set influence the decision of which lookup table block is most appropriate. Although all lookup table blocks support real numbers, the Direct Lookup Table (n-D), 1-D Lookup Table, 2-D Lookup Table, and n-D Lookup Table blocks also support complex table data. All lookup table blocks support integer and fixed-point data in addition to double and single data types.

Note For the Direct Lookup Table (n-D) block, fixed-point types are supported for the table data, output port, and optional table input port.

Data Accuracy and Smoothness

The desired accuracy and smoothness of the data returned by a lookup table determine which of the blocks you should use. Most blocks provide options to perform interpolation and extrapolation, improving the accuracy of values that fall between or outside of the table data, respectively. For instance, the Lookup Table Dynamic block performs linear interpolation and extrapolation, while the n-D Lookup Table block performs either linear, cubic spline interpolation and extrapolation, or Akima spline interpolation and extrapolation. In contrast, the Direct Lookup Table (n-D) block performs table lookups without any interpolation or extrapolation. You can achieve a mix of interpolation and extrapolation methods by using the Prelookup block with the Interpolation Using Prelookup block.

Dynamics of Table Inputs

The dynamics of the lookup table inputs impact which of the lookup table blocks is ideal for your application. The blocks use a variety of index search methods to relate the lookup table inputs to the table's breakpoint data sets. Most of the lookup table blocks offer a binary search algorithm, which performs well if the inputs change significantly from one time step to the next. The 1-D Lookup Table,

2-D Lookup Table, n-D Lookup Table, and Prelookup blocks offer a linear search algorithm. Using this algorithm with the option that resumes searching from the previous result performs well if the inputs change slowly. Some lookup table blocks also provide a search algorithm that works best for breakpoint data sets composed of evenly spaced breakpoints. You can achieve a mix of index search methods by using the Prelookup block with the Interpolation Using Prelookup block.

Efficiency of Performance

When the efficiency with which lookup tables operate is important, consider using the Prelookup block with the Interpolation Using Prelookup block. These blocks separate the table lookup process into two components — an index search that relates inputs to the table data, followed by an interpolation and extrapolation stage that computes outputs. These blocks enable you to perform a single index search and then reuse the results to look up data in multiple tables. Also, the Interpolation Using Prelookup block can perform sub-table selection, where the block interpolates a portion of the table data instead of the entire table. For example, if your 3-D table data constitutes a stack of 2-D tables to be interpolated, you can specify a selection port input to select one or more of the 2-D tables from the stack for interpolation. A full 3-D interpolation has 7 sub-interpolations but a 2-D interpolation requires only 3 sub-interpolations. As a result, significant speed improvements are possible when some dimensions of a table are used for data stacking and not intended for interpolation. These features make table lookup operations more efficient, reducing computational effort and simulation time.

Summary of Lookup Table Block Features

Use the following table to identify features that correspond to particular lookup table blocks, then select the block that best meets your requirements.

Feature	1-D Lookup Table	2-D Lookup Table	Lookup Table Dynamic	n-D Lookup Table	Direct Lookup Table (n-D)	Prelookup	Interpolation Using Prelookup

Enter Breakpoints and Table Data

In this section...

“Entering Data in a Block Parameter Dialog Box” on page 38-10

“Entering Data in the Lookup Table Editor” on page 38-10

“Entering Data Using Inports of the Lookup Table Dynamic Block” on page 38-11

Entering Data in a Block Parameter Dialog Box

This example shows how to populate a 1-D Lookup Table block using the parameter dialog box. The lookup table in this example approximates the function $y = x^3$ over the range $[-3, 3]$.

- 1 Copy a 1-D Lookup Table block from the Lookup Tables block library to a Simulink model.
- 2 In the 1-D Lookup Table block dialog box, enter the table dimensions and table data in the specified fields of the dialog box:
 - Set **Number of table dimensions** to 1.
 - Set **Table data** to $[-27 \ -8 \ -1 \ 0 \ 1 \ 8 \ 27]$.

Alternatively, to use an existing lookup table (`Simulink.LookupTable`) object, select **Data specification > Lookup table object**.

- 3 Enter the breakpoint data set using either of two methods:
 - To specify evenly spaced data points, set **Breakpoint specification** to `Even spacing`. Set **First point** to `-3` and **Spacing** to `1`. The block calculates the number of evenly spaced breakpoints based on the table data.
 - To specify breakpoint data explicitly, set **Breakpoint specification** to `Explicit values` and set **Breakpoints 1** to $[-3:3]$.

Entering Data in the Lookup Table Editor

Use the following procedure to populate a 2-D Lookup Table block using the Lookup Table Editor. In this example, the lookup table approximates the function $z = x^2 + y^2$ over the input ranges $x = [0, 2]$ and $y = [0, 2]$.

- 1 Copy a 2-D Lookup Table block from the Lookup Tables block library to a Simulink model.
- 2 Open the Lookup Table Editor by selecting **Lookup Table Editor** from the **Modeling** tab or by clicking **Edit table and breakpoints** on the dialog box of the 2-D Lookup Table block.
- 3 Under **Viewing "n-D Lookup Table" block data**, enter the breakpoint data sets and table data in the appropriate cells. To change data, click a cell, enter the new value, and press **Enter**.
 - In the cells associated with the **Row Breakpoints**, enter each of the values $[0 \ 1 \ 2]$.
 - In the cells associated with the **Column Breakpoints**, enter each of the values $[0 \ 1 \ 2]$.
 - In the table data cells, enter the values in the array $[0 \ 1 \ 4; \ 1 \ 2 \ 5; \ 4 \ 5 \ 8]$.

The Lookup Table Editor looks like this:

- 4 In the Lookup Table Editor, select **File > Update Block Data** to update the data in the 2-D Lookup Table block.
- 5 Close the Lookup Table Editor.

Entering Data Using Inports of the Lookup Table Dynamic Block

Use the following procedure to populate a Lookup Table Dynamic block using that block's inports. In this example, the lookup table approximates the function $y = 3x^2$ over the range $[0, 10]$.

- 1 Copy a Lookup Table Dynamic block from the Lookup Tables block library to a Simulink model.
- 2 Copy the blocks needed to implement the equation $y = 3x^2$ to the Simulink model:
 - One Constant block to define the input range, from the Sources library
 - One Math Function block to square the input range, from the Math Operations library
 - One Gain block to multiply the signal by 3, also from the Math Operations library
- 3 Assign the following parameter values to the Constant, Math Function, and Gain blocks using their dialog boxes:

Block	Parameter	Value
Constant	Constant value	0 : 10

Block	Parameter	Value
Math Function	Function	square
Gain	Gain	3

- Input the breakpoint data set to the Lookup Table Dynamic block by connecting the output port of the Constant block to the input port of the Lookup Table Dynamic block labeled **xdat**. This signal is the input breakpoint data set for x .
- Input the table data to the Lookup Table Dynamic block by branching the output signal from the Constant block and connecting it to the Math Function block. Then connect the Math Function block to the Gain block. Finally, connect the Gain block to the input port of the Lookup Table Dynamic block labeled **ydat**. This signal is the table data for y .

Characteristics of Lookup Table Data

In this section...

“Sizes of Breakpoint Data Sets and Table Data” on page 38-13

“Monotonicity of Breakpoint Data Sets” on page 38-14

“Formulation of Evenly Spaced Breakpoints” on page 38-14

Sizes of Breakpoint Data Sets and Table Data

The following constraints apply to the sizes of breakpoint data sets and table data associated with lookup table blocks:

- The memory limitations of your system constrain the overall size of a lookup table.
- Lookup tables must use consistent dimensions so that the overall size of the table data reflects the size of each breakpoint data set.

To illustrate the second constraint, consider the following vectors of input and output values that create the relationship in the plot.

Vector of input values: [-3 -2 -1 0 1 2 3]
 Vector of output values: [-3 -1 0 -1 0 1 3]

In this example, the input and output data are the same size (1-by-7), making the data consistently dimensioned for a 1-D lookup table.

The following input and output values define the 2-D lookup table that is graphically shown.

Row index input values: [1 2 3]
 Column index input values: [1 2 3 4]
 Table data: [11 12 13 14; 21 22 23 24; 31 32 33 34]

	1	2	3	4
1	11	12	13	14
2	21	22	23	24
3	31	32	33	34

In this example, the sizes of the vectors representing the row and column indices are 1-by-3 and 1-by-4, respectively. Consequently, the output table must be of size 3-by-4 for consistent dimensions.

Monotonicity of Breakpoint Data Sets

The first stage of a table lookup operation involves relating inputs to the breakpoint data sets. The search algorithm requires that input breakpoint sets be strictly monotonically increasing, that is, each successive element is greater than its preceding element. For example, the vector

$$A = [0 \quad 0.5 \quad 1 \quad 1.9 \quad 2.1 \quad 3]$$

is a valid breakpoint data set as each element is larger than its predecessors.

Note Although a breakpoint data set is strictly monotonic in double format, it might not be so after conversion to a fixed-point data type.

Formulation of Evenly Spaced Breakpoints

You can represent evenly spaced breakpoints in a data set by using one of these methods.

Formulation	Example	When to Use This Formulation
<code>[first_value:spacing:last_value]</code>	<code>[10:10:200]</code>	The lookup table does <i>not</i> use double or single.
<code>first_value + spacing * [0:(last_value-first_value)/spacing]</code>	<code>1 + (0.02 * [0:450])</code>	The lookup table uses double or single.

Because floating-point data types cannot precisely represent some numbers, the second formulation works better for double and single. For example, use `1 + (0.02 * [0:450])` instead of `[1:0.02:10]`. For a list of lookup table blocks that support evenly spaced breakpoints, see “Summary of Lookup Table Block Features” on page 38-8.

Among other advantages, evenly spaced breakpoints can make the generated code division-free and reduce memory usage. For more information, see:

- `fixpt_evenspace_cleanup` in the Simulink documentation
- “Effects of Spacing on Speed, Error, and Memory Usage” (Fixed-Point Designer)
- “Identify questionable fixed-point operations” (Embedded Coder)

Tip Do not use the MATLAB `linspace` function to define evenly spaced breakpoints. Simulink uses a tighter tolerance to check whether a breakpoint set has even spacing. If you use `linspace` to define breakpoints for your lookup table, Simulink considers the breakpoints to be unevenly spaced.

Methods for Approximating Function Values

In this section...

“About Approximating Function Values” on page 38-16

“Interpolation Methods” on page 38-16

“Extrapolation Methods” on page 38-17

“Rounding Methods” on page 38-18

“Example Output for Lookup Methods” on page 38-18

About Approximating Function Values

The second stage of a table lookup operation involves generating outputs that correspond to the supplied inputs. If the inputs match the values of indices specified in breakpoint data sets, the block outputs the corresponding values. However, if the inputs fail to match index values in the breakpoint data sets, Simulink estimates the output. In the block parameter dialog box, you can specify how to compute the output in this situation. The available lookup methods are described in the following sections.

Interpolation Methods

When an input falls between breakpoint values, the block interpolates the output value using neighboring breakpoints. Most lookup table blocks have the following interpolation methods available:

- **Flat** — Disables interpolation and uses the rounding operation titled `Use Input Below`. For more information, see “Rounding Methods” on page 38-18.
- **Nearest** — Disables interpolation and returns the table value corresponding to the breakpoint closest to the input. If the input is equidistant from two adjacent breakpoints, the breakpoint with the higher index is chosen.
- **Linear point-slope** — Fits a line between the adjacent breakpoints, and returns the point on that line corresponding to the input. This is the equation for linear point-slope, where x is the input data, y is the output table data (x_i, y_i is the coordinate of the table data), and f is the fraction. For more information on x_i, y_i , see “About Lookup Table Blocks” on page 38-2.

$$f = \frac{x - x_i}{x_{i+1} - x_i}$$

$$y = y_i + f(y_{i+1} - y_i)$$

- **Cubic spline** — Fits a cubic spline to the adjacent breakpoints, and returns the point on that spline corresponding to the input.
- **Linear Lagrange** — Fits a line between the adjacent breakpoints using first-order Lagrange interpolation, and returns the point on that line corresponding to the input. This is the equation for linear Lagrange, where x is the input data, y is the output table data, and f is the fraction. f is constrained to range from 0 to less than 1 ($[0, 1)$). For more information on x and y , see “About Lookup Table Blocks” on page 38-2.

$$f = \frac{x - x_i}{x_{i+1} - x_i}$$

$$y = (1 - f)y_i + f y_{i+1}$$

If the extrapolation method is **Linear**, the extrapolation value is calculated based on the selected linear interpolation method. For example, if the interpolation method is **Linear Lagrange**, the extrapolation method inherits the **Linear Lagrange** equation to compute the extrapolated value.

- **Akima spline** — Fits an Akima spline to the adjacent breakpoints, and returns the point on that spline corresponding to the input. The interpolation method works only with the **Akima spline** extrapolation method. The modified Akima cubic Hermite interpolation method has these properties:
 - It produces fewer undulations than **Cubic spline**.
 - It is more efficient for real-time applications than **Cubic spline**.
 - Unlike **Cubic spline**, it does not produce overshoots.
 - Unlike **Cubic spline**, it supports nonscalar signals.

Note The **Lookup Table Dynamic** block does not let you select an interpolation method. The **Interpolation-Extrapolation** option in the **Lookup Method** field of the block parameter dialog box performs linear interpolation.

Each interpolation method includes a trade-off between computation time and the smoothness of the result. Although rounding is quickest, it is the least smooth. Linear interpolation is slower than rounding but generates smoother results, except at breakpoints where the slope changes. Cubic spline interpolation is the slowest method but produces smooth results. Akima spline produces the smoothest results.

Extrapolation Methods

When an input falls outside the range of a breakpoint data set, the block extrapolates the output value from a pair of values at the end of the breakpoint data set. Most lookup table blocks have the following extrapolation methods available:

- **Clip** — Disables extrapolation and returns the table data corresponding to the end of the breakpoint data set range. This does not provide protection against out-of-range values.
- **Linear** — If the interpolation method is **Linear**, this extrapolation method fits a line between the first or last pair of breakpoints, depending on whether the input is less than the first or greater than the last breakpoint. If the interpolation method is **Cubic spline** or **Akima spline**, this extrapolation method fits a linear surface using the slope of the interpolation at the first or last breakpoint, depending on whether the input is less than the first or greater than the last breakpoint. The extrapolation method returns the point on the generated linear surface corresponding to the input.

If the extrapolation method is **Linear**, the extrapolation value is calculated based on the selected linear interpolation method. For example, if the interpolation method is **Linear Lagrange**, the extrapolation method inherits the **Linear Lagrange** equation to compute the extrapolated value.

- **Cubic spline** — Fits a cubic spline to the first or last pair of breakpoints, depending if the input is less than the first or greater than the last breakpoint, respectively. This method returns the point on that spline corresponding to the input.

- **Akima spline** — Fits an Akima spline to the first or last pair of breakpoints, depending if the input is less than the first or greater than the last breakpoint, respectively. This method returns the point on that spline corresponding to the input.

Note The Lookup Table Dynamic block does not let you select an extrapolation method. The **Interpolation-Extrapolation** option in the **Lookup Method** field of the block parameter dialog box performs linear extrapolation.

In addition to these methods, some lookup table blocks, such as the n-D Lookup Table block, allow you to select an action to perform when encountering situations that require extrapolation. For instance, you can specify that Simulink generate either a warning or an error when the lookup table inputs are outside the ranges of the breakpoint data sets. To specify such an action, select it from the **Diagnostic for out-of-range input** list on the block parameter dialog box.

Rounding Methods

If an input falls between breakpoint values or outside the range of a breakpoint data set and you do not specify interpolation or extrapolation, the block rounds the value to an adjacent breakpoint and returns the corresponding output value. For example, the Lookup Table Dynamic block lets you select one of the following rounding methods:

- **Use Input Nearest** — Returns the output value corresponding to the nearest input value.
- **Use Input Below** — Returns the output value corresponding to the breakpoint value that is immediately less than the input value. If no breakpoint value exists below the input value, it returns the breakpoint value nearest the input value.
- **Use Input Above** — Returns the output value corresponding to the breakpoint value that is immediately greater than the input value. If no breakpoint value exists above the input value, it returns the breakpoint value nearest the input value.

Example Output for Lookup Methods

In the following model, the Lookup Table Dynamic block accepts a vector of breakpoint data given by $[-5:5]$ and a vector of table data given by $\sinh([-5:5])$.

The Lookup Table Dynamic block outputs the following values when using the specified lookup methods and inputs.

Lookup Method	Input	Output	Comment
Interpolation- Extrapolation	1.4	2.156	N/A
	5.2	83.59	N/A
Interpolation- Use End Values	1.4	2.156	N/A
	5.2	74.2	The block uses the value for $\sinh(5.0)$.
Use Input Above	1.4	3.627	The block uses the value for $\sinh(2.0)$.
	5.2	74.2	The block uses the value for $\sinh(5.0)$.
Use Input Below	1.4	1.175	The block uses the value for $\sinh(1.0)$.
	-5.2	-74.2	The block uses the value for $\sinh(-5.0)$.
Use Input Nearest	1.4	1.175	The block uses the value for $\sinh(1.0)$.

- “Guidelines for Choosing a Lookup Table” on page 38-7

Edit Lookup Tables

In this section...
“Edit N-Dimensional Lookup Tables” on page 38-20
“Edit Custom Lookup Table Blocks” on page 38-21

You can edit a lookup table using:

- Lookup Table block dialog box
- Lookup Table Editor

To edit the lookup table in a block:

- 1 Open the subsystem that contains the lookup table block.
- 2 Open the lookup table block’s dialog box.
- 3 In the Table and Breakpoints tab, edit the **Table data** and relevant **Breakpoints** parameters as needed.

With the Lookup Table Editor, you can skip these steps and edit the desired lookup table without navigating to the block that uses it. However, you cannot use the Lookup Table Editor to change the dimensions of a lookup table. You must use the block parameter dialog box for this purpose.

Edit N-Dimensional Lookup Tables

If the lookup table of the block currently selected in the Lookup Table Editor tree view has more than two dimensions, the table view displays a two-dimensional slice of the lookup table.

The **Dimension Selector** specifies which slice currently appears and lets you select another slice. The selector consists of a 2-by-N array of controls, where N is the number of dimensions in the lookup table. Each column corresponds to a dimension of the lookup table. The first column corresponds to the first dimension of the table, the second column to the second dimension of the table, and so on. The **Dimension size** row of the selector array displays the size of each dimension. The **Select 2-D slice** row specifies which dimensions of the table correspond to the row and column axes of the slice and the indices that select the slice from the remaining dimensions.

To select another slice of the table, specify the row and column axes of the slice in the first two columns of the **Select 2-D slice** row. Then select the indices of the slice from the pop-up index lists in the remaining columns.

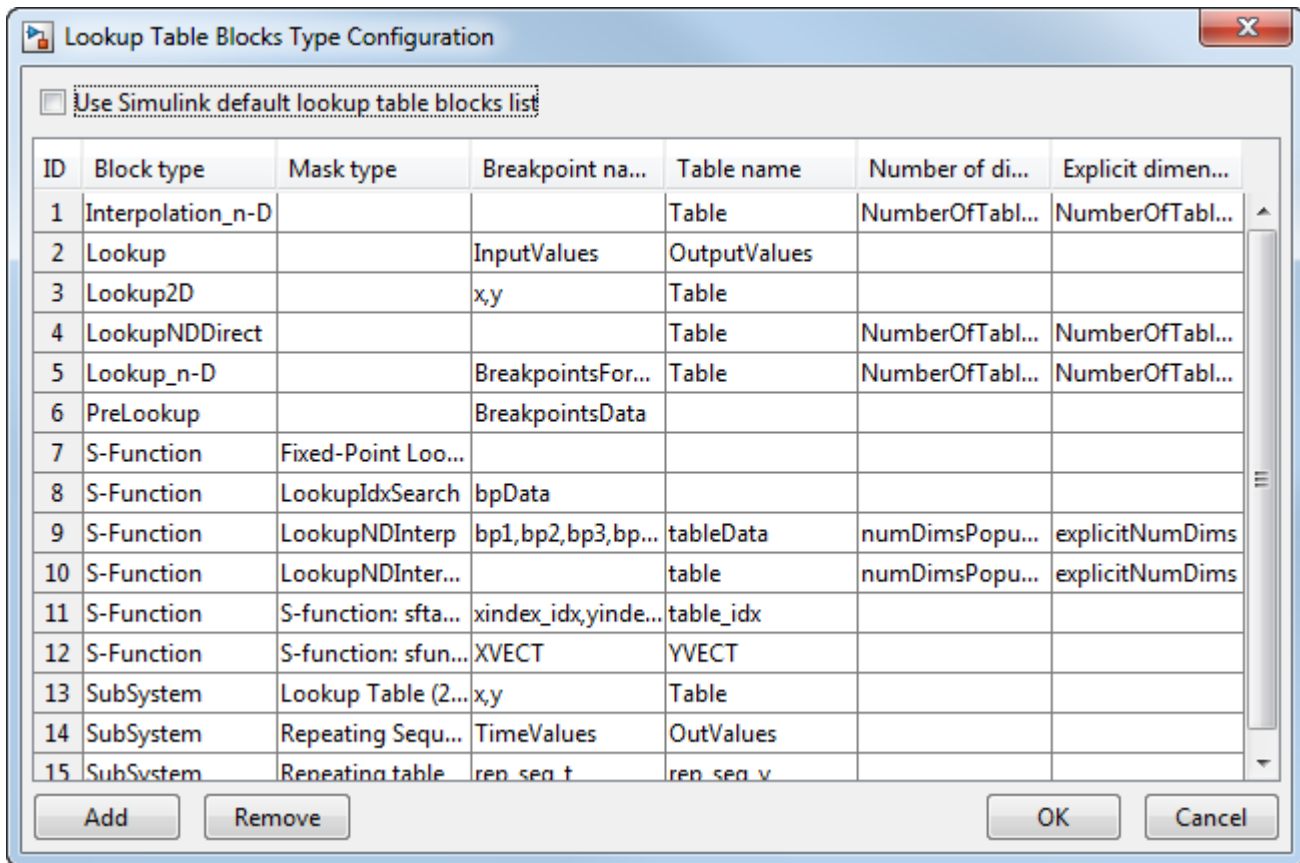

For example, the following selector displays slice $(:,:,1)$ of a 3-D lookup table, as shown under Dimension Selector in the Lookup Table Editor.

To transpose the table display, select the **Transpose display** check box.

Edit Custom Lookup Table Blocks

You can use the Lookup Table Editor to edit custom lookup table blocks that you have created. To do this, you must first configure the Lookup Table Editor to recognize the custom lookup table blocks in your model.

- 1 Select **File > Configure**. The Lookup Table Blocks Type Configuration dialog box appears.

The dialog box displays a table of the lookup table block types that the Lookup Table Editor currently recognizes. This table includes the standard blocks. Each row of the table displays key attributes of a lookup table block type.

- 2 Click **Add** on the dialog box. A new row appears at the bottom of the block type table.
- 3 Enter information for the custom block in the new row under these headings.

Field Name	Description
Block type	Block type of the custom block. The block type is the value of the block's <code>BlockType</code> parameter.
Mask type	Mask type of the custom block. The mask type is the value of the block's <code>MaskType</code> parameter.
Breakpoint name	Names of the block parameters that store the breakpoints.
Table name	Name of the block parameter that stores the table data.
Number of dimensions	Leave empty.
Explicit dimensions	Leave empty.

- 4 Click **OK**.

To remove a custom lookup table block type from the list that the Lookup Table Editor recognizes, select the custom entry in the table of the Lookup Table Blocks Type Configuration dialog box and click **Remove**. To remove all custom lookup table block types, select the **Use Simulink default lookup table blocks list** check box at the top of the dialog box.

Import Lookup Table Data from MATLAB

In this section...

“Import Standard Format Lookup Table Data” on page 38-24

“Propagate Standard Format Lookup Table Data” on page 38-25

“Import Nonstandard Format Lookup Table Data” on page 38-25

“Propagate Nonstandard Format Lookup Table Data” on page 38-27

You can import table and breakpoint data from variables in the MATLAB workspace by referencing them in the **Table and Breakpoints** tab of the dialog box. The following examples show how to import and export standard format and non-standard format data from the MATLAB workspace.

Import Standard Format Lookup Table Data

Suppose you specify a 3-D lookup table in your n-D Lookup Table block.

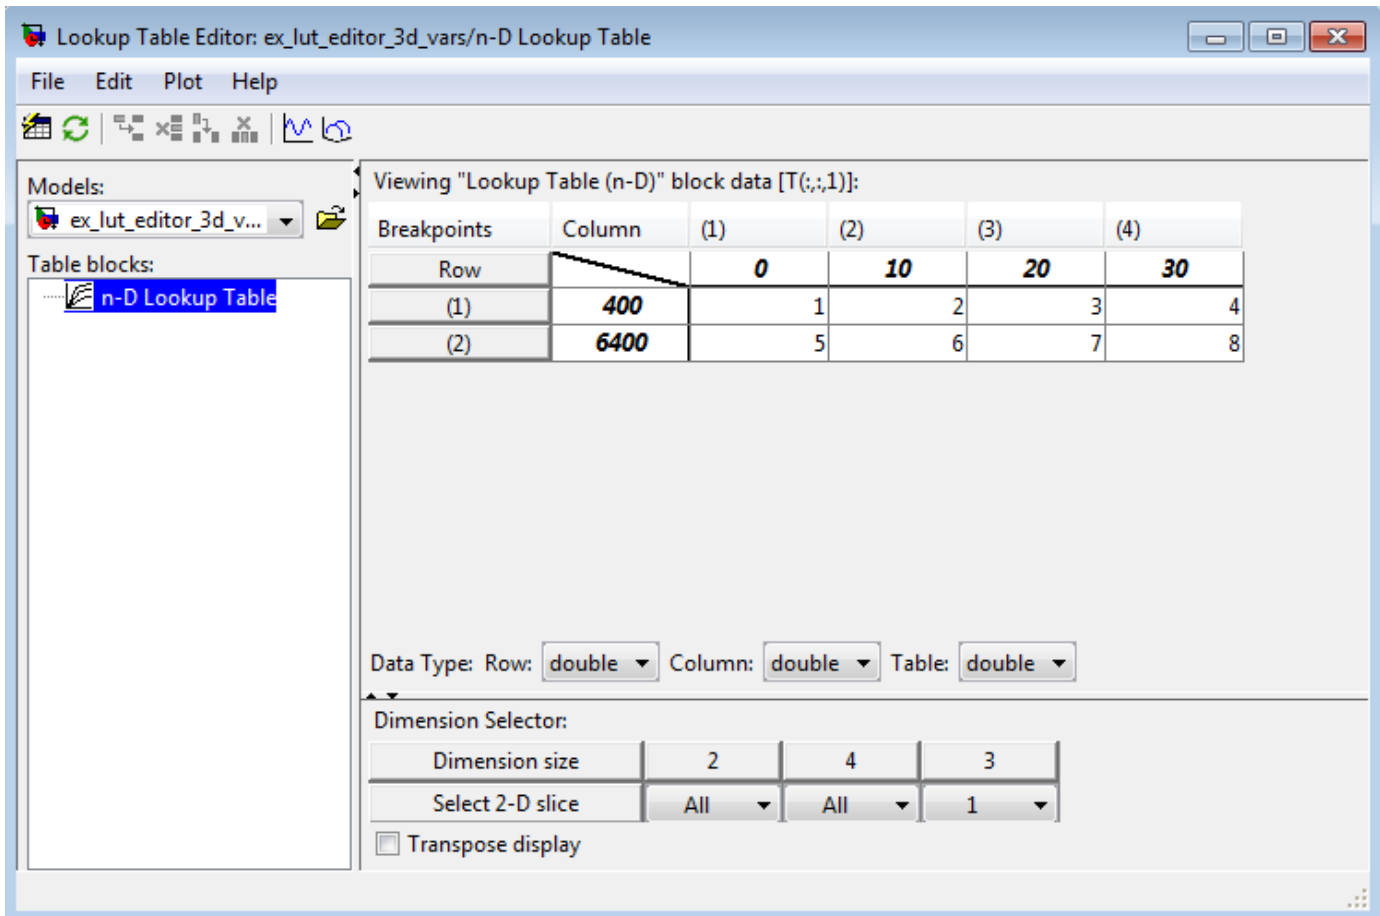

Create workspace variables to use as breakpoint and table data for the lookup table.

```
table3d_map = zeros(2,4,3);
table3d_map(:,:,1) = [ 1 2 3 4; 5 6 7 8];
table3d_map(:,:,2) = [ 11 12 13 14; 15 16 17 18];
table3d_map(:,:,3) = [ 111 112 113 114; 115 116 117 118];
bp3d_z = [ 0 10 20];
bp3d_x = [ 0 10 20 30];
bp3d_y = [ 400 6400];
```

Open the n-D Lookup Table block dialog box, and enter the following parameters in the Table and Breakpoints tab:

- Table data: table3d_map
- Breakpoints 1: bp3d_y
- Breakpoints 2: bp3d_x
- Breakpoints 3: bp3d_z

Click **Edit table and breakpoints** to open the Lookup Table Editor and show the data from the workspace variables.

Propagate Standard Format Lookup Table Data

When you make changes to your lookup table data, consider propagating the changes back to the MATLAB workspace variables the data was imported from using **File > Update Block Data**.

You can also use the Lookup Table Editor to edit the table data and breakpoint data set of `Simulink.LookupTable` and the breakpoint data set of `Simulink.Breakpoint` objects and propagate the changes back to the object.

Suppose you make a change to the lookup table variables imported from the MATLAB workspace variables in "Import Standard Format Lookup Table Data" on page 38-24. For example, change the value of the data in (1,1,1) from 1 to 33. To propagate this change back to `table3d_map` in the workspace, select **File > Update Block Data**. Click **Yes** to confirm that you want to overwrite `table3d_map`.

Import Nonstandard Format Lookup Table Data

Suppose you specify a 3-D lookup table in your n-D Lookup Table block. Create workspace variables to use as breakpoint and table data for the lookup table. The variable for table data, `table3d_map_custom`, is a two-dimensional matrix.

```
table3d_map_custom = zeros(6,4);
table3d_map_custom = [ 1 2 3 4; 5 6 7 8;
```

```

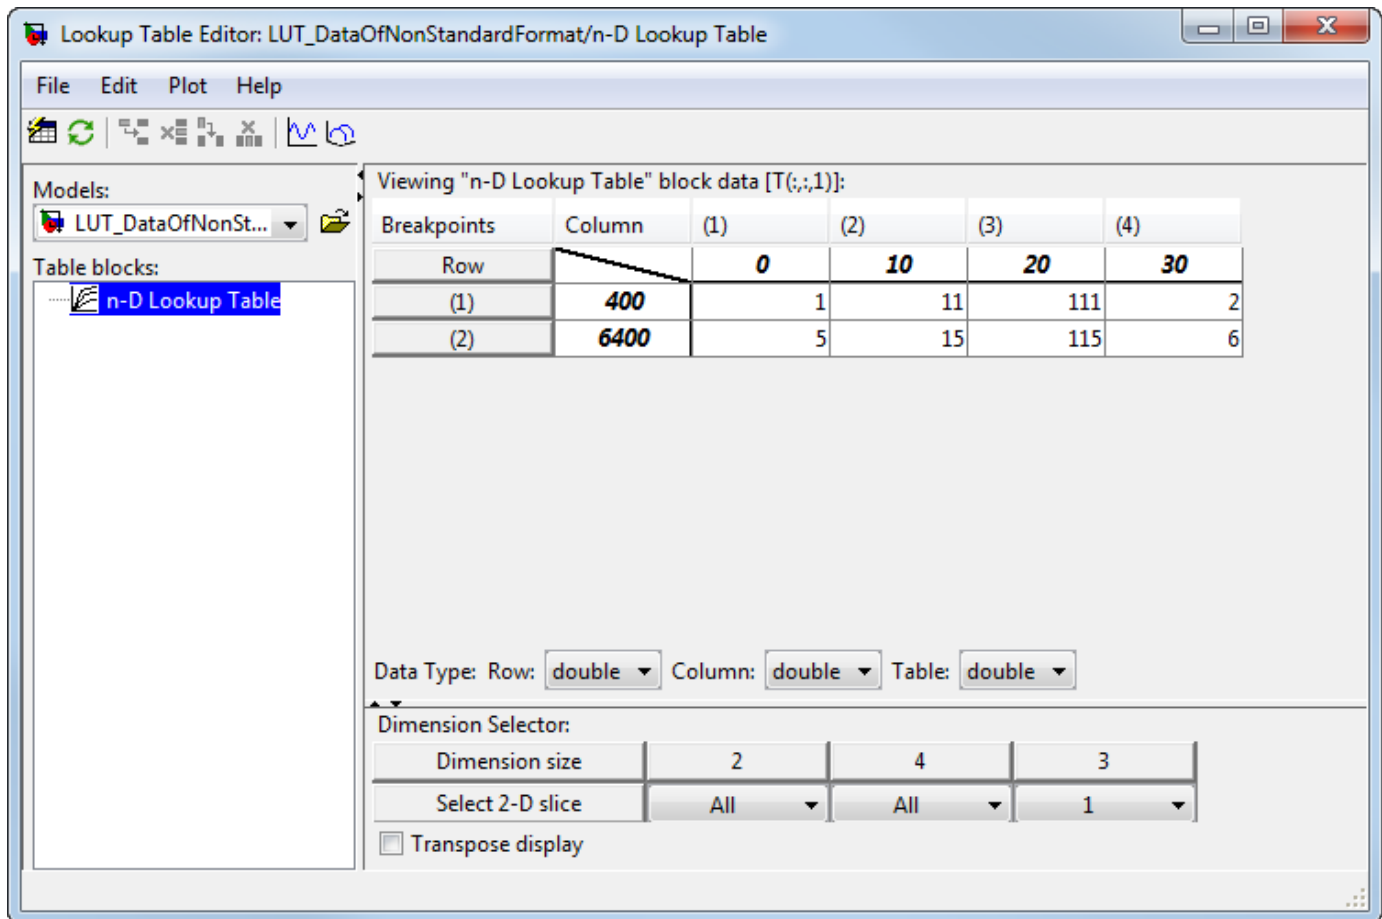

11    12    13    14;    15    16    17    18;
111  112  113  114;  115  116  117  118];
bp3d_z = [ 0    10    20];
bp3d_x = [ 0    10    20    30];
bp3d_y = [ 400  6400];

```

Open the n-D Lookup Table block dialog box, and enter the following parameters in the Table and Breakpoints tab. Transform `table3d_map_custom` into a three-dimensional matrix for the table data input using the reshape command.

- Table data: `reshape(table3d_map_custom, [2,4,3])`
- Breakpoints 1: `bp3d_y`
- Breakpoints 2: `bp3d_x`
- Breakpoints 3: `bp3d_z`

Click **Edit table and breakpoints** to open the Lookup Table Editor and show the data from the workspace variables.

Change 1 to 33 in the Lookup Table Editor. The Lookup Table Editor records your changes by maintaining a copy of the table. To restore the variable values from the MATLAB workspace, select **File > Reload Block Data**. To update the MATLAB workspace variables with the edited data, select **File > Update Block Data** in the Lookup Table Editor. You cannot propagate the change to `table3d_map_custom`, the workspace variable that contains the nonstandard table data for the n-D Lookup Table block. To propagate the change, you must register a customization function that resides

on the MATLAB search path. For details, see “Propagate Nonstandard Format Lookup Table Data” on page 38-27.

Propagate Nonstandard Format Lookup Table Data

This example shows how to propagate changes from the Lookup Table Editor to workspace variables of nonstandard format. Suppose your Simulink model from “Import Nonstandard Format Lookup Table Data” on page 38-25 has a three-dimensional lookup table that gets its table data from the two-dimensional workspace variable `table3d_map_custom`. Update the lookup table in the Lookup Table Editor and propagate these changes back to `table3d_map_custom` using a customization function.

- 1 Create a file named `sl_customization.m` with these contents.

```
function sl_customization(cm)
cm.LookupTableEditorCustomizer.getTableConvertToCustomInfoFcnHandle{end+1} = ...
@myGetTableConvertInfoFcn;
end
```

In this function:

- The argument `cm` is the handle to a customization manager object.
- The handle `@myGetTableConvertInfoFcn` is added to the list of function handles in the cell array for `cm.LookupTableEditorCustomizer.getTableConvertToCustomInfoFcnHandle`. You can use any alphanumeric name for the function whose handle you add to the cell array.

- 2 In the same file, define the `myGetTableConvertInfoFcn` function.

```
function blkInfo = myGetTableConvertInfoFcn(blk,tableStr)
    blkInfo.allowTableConvertLocal = true;
    blkInfo.tableWorkSpaceVarName = 'table3d_map_custom';
    blkInfo.tableConvertFcnHandle = @myConvertTableFcn;
end
```

The `myGetTableConvertInfoFcn` function returns the `blkInfo` object containing three fields.

- `allowTableConvertLocal` — Allows table data conversion for a block.
- `tableWorkSpaceVarName` — Specifies the name of the workspace variable that has a nonstandard table format.
- `tableConvertFcnHandle` — Specifies the handle for the conversion function.

When `allowTableConvertLocal` is set to `true`, the table data for that block is converted to the nonstandard format of the workspace variable whose name matches `tableWorkSpaceVarName`. The conversion function corresponds to the handle that `tableConvertFcnHandle` specifies. You can use any alphanumeric name for the conversion function.

- 3 In the same file, define the `myConvertTableFcn` function. This function converts a three-dimensional lookup table of size *Rows* * *Columns* * *Height* to a two-dimensional variable of size *(Rows*Height)* * *Columns*.

```
% Converts 3-dimensional lookup table from Simulink format to
% nonstandard format used in workspace variable
function cMap = myConvertTableFcn(data)

% Determine the row and column number of the 3D table data
mapDim = size(data);
numCol = mapDim(2);
numRow = mapDim(1)*mapDim(3);
```

```

    cMap = zeros(numRow, numCol);
    % Transform data back to a 2-dimensional matrix
    cMap = reshape(data, [numRow, numCol]);
end

```

- 4 Put `sl_customization.m` on the MATLAB search path. You can have multiple files named `sl_customization.m` on the search path. For more details, see “Behavior with Multiple Customization Functions” on page 38-28.
- 5 Refresh Simulink customizations at the MATLAB command prompt.

```
sl_refresh_customizations
```

- 6 Open the Lookup Table Editor for your lookup table block and select **File > Update Block Data**. Click **Yes** to overwrite the workspace variable `table3d_map_custom`.
- 7 Check the value of `table3d_map_custom` in the base workspace.

```
table3d_map_custom =
```

```

    33     2     3     4
     5     6     7     8
    11    12    13    14
    15    16    17    18
   111   112   113   114
   115   116   117   118

```

The change in the Lookup Table Editor has propagated to the workspace variable.

Note If you do not overwrite the workspace variable `table3d_map_custom`, you are prompted to replace it with numeric data. Click **Yes** to replace the expression in the **Table data** field with numeric data. Click **No** if you do not want your Lookup Table Editor changes for the table data to appear in the block dialog box.

Behavior with Multiple Customization Functions

At the start of a MATLAB session, Simulink loads each `sl_customization.m` customization file on the path and executes the `sl_customization` function. Executing each function establishes the customizations for that session.

When you select **File > Update Block Data** in the Lookup Table Editor, the editor checks the list of function handles in the cell array for `cm.LookupTableEditorCustomizer.getTableConvertToCustomInfoFcnHandle`. If the cell array contains one or more function handles, the `allowTableConvertLocal` property determines whether changes in the Lookup Table Editor can be propagated.

- If the value is set to `true`, then the table data is converted to the nonstandard format in the workspace variable.
- If the value is set to `false`, then table data is not converted to the nonstandard format in the workspace variable.
- If the value is set to `true` and another customization function specifies it to be `false`, the Lookup Table Editor reports an error.

- “Import Lookup Table Data from Excel” on page 38-30

Import Lookup Table Data from Excel

This example shows how to use the MATLAB `xlsread` function in a Simulink model to import data into a lookup table.

- 1 Save the Excel file in a folder on the MATLAB path.
- 2 Open the model containing the lookup table block and in the **Modeling** tab, select **Model Settings**.
- 3 In the Model Properties dialog box, in the **Callbacks** tab, click **PostLoadFcn** callback in the model callbacks list.
- 4 Enter the code to import the Excel Spreadsheet data in the text box. Use the MATLAB `xlsread` function, as shown in this example for a 2-D lookup table.

```
% Import the data from Excel for a lookup table
data = xlsread('MySpreadsheet', 'Sheet1');
% Row indices for lookup table
breakpoints1 = data(2:end,1)';
% Column indices for lookup table
breakpoints2 = data(1,2:end);
% Output values for lookup table
table_data = data(2:end,2:end);
```

- 5 Click **OK**.

After you save your changes, the next time you open the model, Simulink invokes the callback and imports the data.

- “Import Lookup Table Data from MATLAB” on page 38-24

Create a Logarithm Lookup Table

Suppose you want to approximate the common logarithm (base 10) over the input range [1, 10] without performing an expensive computation. You can perform this approximation using a lookup table block as described in the following procedure.

- 1 Copy the following blocks to a Simulink model:
 - One Constant block to input the signal, from the Sources library
 - One n-D Lookup Table block to approximate the common logarithm, from the Lookup Tables library
 - One Display block to display the output, from the Sinks library
- 2 Assign the table data and breakpoint data set to the n-D Lookup Table block:
 - a In the **Number of table dimensions** field, enter 1.
 - b In the **Table data** field, enter [0 .301 .477 .602 .699 .778 .845 .903 .954 1].
 - c In the **Breakpoints 1** field, enter [1:10].
 - d Click **Apply**.

The dialog box looks something like this:

- 3 Double-click the Constant block to open the parameter dialog box, and change the **Constant value** parameter to 5. Click **OK** to apply the changes and close the dialog box.
- 4 Connect the blocks as follows.

- 5 Start simulation.

The following behavior applies to the n-D Lookup Table block.

Value of the Constant Block	Action by the n-D Lookup Table Block	Example of Block Behavior	
		Input Value	Output Value
Equals a breakpoint	Returns the corresponding output value	5	0.699
Falls between breakpoints	Linearly interpolates the output value using neighboring breakpoints	7.5	0.874
Falls outside the range of the breakpoint data set	Linearly extrapolates the output value from a pair of values at the end of the breakpoint data set	10.5	1.023

For the n-D Lookup Table block, the default settings for **Interpolation method** and **Extrapolation method** are both **Linear**.

Prelookup and Interpolation Blocks

The following examples show the benefits of using Prelookup and Interpolation Using Prelookup blocks.

Action	Benefit	Example
Use an index search to relate inputs to table data, followed by an interpolation and extrapolation stage that computes outputs	Enables reuse of index search results to look up data in multiple tables, which reduces simulation time	For more information, see “Using the Prelookup and Interpolation Blocks”.
Set breakpoint and table data types explicitly	Lowers memory required to store: <ul style="list-style-type: none"> • Breakpoint data that uses a smaller type than the input signal • Table data that uses a smaller type than the output signal 	For more information, see “Saving Memory in Prelookup and Interpolation Blocks by Using Smaller Data”.
	Provides easier sharing of: <ul style="list-style-type: none"> • Breakpoint data among Prelookup blocks • Table data among Interpolation Using Prelookup blocks 	For more information, see “Sharing Parameters in Prelookup and Interpolation Blocks” (Fixed-Point Designer).
	Enables reuse of utility functions in the generated code	For more information, see “Shared Utility Functions for Prelookup Blocks” (Fixed-Point Designer).
Set the data type for intermediate results explicitly	Enables use of higher precision for internal computations than for table data or output data	For more information, see “High Precision Calculations in Interpolation Block” (Fixed-Point Designer).

Optimize Generated Code for Lookup Table Blocks

In this section...

“Remove Code That Checks for Out-of-Range Inputs” on page 38-34

“Optimize Breakpoint Spacing in Lookup Tables” on page 38-35

“Reduce Data Copies for Lookup Table Blocks” on page 38-35

“Efficient Code for Row-Major Array Layout” on page 38-36

Remove Code That Checks for Out-of-Range Inputs

By default, generated code for the following lookup table blocks include conditional statements that check for out-of-range breakpoint or index inputs:

- 1-D Lookup Table
- 2-D Lookup Table
- n-D Lookup Table
- Prelookup
- Interpolation Using Prelookup

To generate code that is more efficient, you can remove the conditional statements that protect against out-of-range input values.

Block	Check Box to Select
1-D Lookup Table	Remove protection against out-of-range input in generated code
2-D Lookup Table	
n-D Lookup Table	
Prelookup	
Interpolation Using Prelookup	Remove protection against out-of-range index in generated code

Selecting the check box on the block dialog box improves code efficiency because there are fewer statements to execute. However, if you are generating code for safety-critical applications, you should not remove the range-checking code.

To verify the usage of the check box, run the following Model Advisor checks and perform the recommended actions.

Model Advisor Check	When to Run the Check
By Product > Embedded Coder > Identify lookup table blocks that generate expensive out-of-range checking code	For code efficiency
By Product > Simulink Check > Modeling Standards > DO-178C/DO-331 Checks > Check usage of lookup table blocks	For safety-critical applications

For more information about the Model Advisor, see “Check Your Model Using the Model Advisor” on page 5-2 in the Simulink documentation.

Optimize Breakpoint Spacing in Lookup Tables

When breakpoints in a lookup table are tunable, the spacing does not affect efficiency or memory usage of the generated code. When breakpoints are *not* tunable, the type of spacing can affect the following factors.

Factor	Even Power of 2 Spaced Data	Evenly Spaced Data	Unevenly Spaced Data
Execution speed	The execution speed is the fastest. The position search and interpolation are the same as for evenly-spaced data. However, to increase speed a bit more for fixed-point types, a bit shift replaces the position search, and a bit mask replaces the interpolation.	The execution speed is faster than that for unevenly-spaced data because the position search is faster and the interpolation uses a simple division.	The execution speed is the slowest of the different spacings because the position search is slower, and the interpolation requires more operations.
Error	The error can be larger than that for unevenly-spaced data because approximating a function with nonuniform curvature requires more points to achieve the same accuracy.	The error can be larger than that for unevenly-spaced data because approximating a function with nonuniform curvature requires more points to achieve the same accuracy.	The error can be smaller because approximating a function with nonuniform curvature requires fewer points to achieve the same accuracy.
ROM usage	Uses less command ROM, but more data ROM.	Uses less command ROM, but more data ROM.	Uses more command ROM, but less data ROM.
RAM usage	Not significant.	Not significant.	Not significant.

Follow these guidelines:

- For fixed-point data types, use breakpoints with even, power-of-2 spacing.
- For non-fixed-point data types, use breakpoints with even spacing.

To identify opportunities for improving code efficiency in lookup table blocks, run the following Model Advisor checks and perform the recommended actions:

- **By Product > Embedded Coder > Identify questionable fixed-point operations**
- **By Product > Embedded Coder > Identify blocks that generate expensive saturation and rounding code**

For more information about the Model Advisor, see “Check Your Model Using the Model Advisor” on page 5-2 in the Simulink documentation.

Reduce Data Copies for Lookup Table Blocks

When you use workspace variables to store table and breakpoint data for Lookup Table blocks, and then configure these variables for tunability, you can avoid data copies by using the same data type for the block parameter and variable. Workspace variables include numeric MATLAB variables and Simulink.Parameter objects that you store in a workspace, such as the base workspace, or in a

data dictionary. If the data type of the variable is smaller than the data type of the block parameter, the generated code implicitly casts the data type of the variable to the data type of the block parameter. This implicit cast requires a data copy which can potentially significantly increase RAM consumption and slow down code execution speed for large vectors or matrices.

For more information, see “Parameter Data Types in the Generated Code” (Embedded Coder) and “Create Tunable Calibration Parameter in the Generated Code” (Simulink Coder).

Efficient Code for Row-Major Array Layout

To generate efficient code for row-major array layout, select the model configuration parameter **Math and Data Types > Use algorithms optimized for row-major array layout**. The row-major algorithms perform with the best speed and memory usage when operating on table data with row-major array layout. Similarly, the default column-major algorithms perform best with column-major array layout. Consider using the algorithm that is optimized for the specified array layout to achieve best performance. For example, use row-major algorithms when array layout is set as row-major during code generation.

Array Layout	Algorithm	Cache-Friendly Algorithm
Column-major	Column-major	Recommended
Row-major	Row-major	Recommended
Row-major	Column-major	Not recommended
Column-major	Row-major	Not recommended

For more information, see “Column-Major Layout to Row-Major Layout Conversion of Models with Lookup Table Blocks” (Simulink Coder).

- “Lookup Tables Block Library” on page 38-5
- “Edit Lookup Tables” on page 38-20
- “Guidelines for Choosing a Lookup Table” on page 38-7
- “Column-Major Layout to Row-Major Layout Conversion of Models with Lookup Table Blocks” (Simulink Coder)

Row-Major Algorithm in Existing Models Containing Lookup Table Blocks

The Direct Lookup Table (n-D), Interpolation Using Prelookup, and n-D Lookup Table blocks have algorithms that work with row-major array layouts or column-major array layouts. This capability requires a Simulink Coder license. For more information on row-major support, see “Code Generation of Matrices and Arrays” (Simulink Coder).

Prior to R2018b, lookup table blocks supported only column-major array layouts. When selecting algorithms optimized for row-major array layout for a model previously configured for algorithms optimized for column-major array layout, you may need to preserve lookup table block semantics. For example, if a model contains lookup table blocks configured like these:

- An Interpolation Using Prelookup block configured with a subtable selection before interpolation.
- A Direct Lookup Table (n-D) configured for a vector or 2-D matrix output

Use the `permute` function to rearrange the dimensions of the array and preserve the semantics.

For an example of preserving semantics by using table permutations, see “Direct Lookup Table Algorithm for Row-Major Array Layout” (Simulink Coder) .

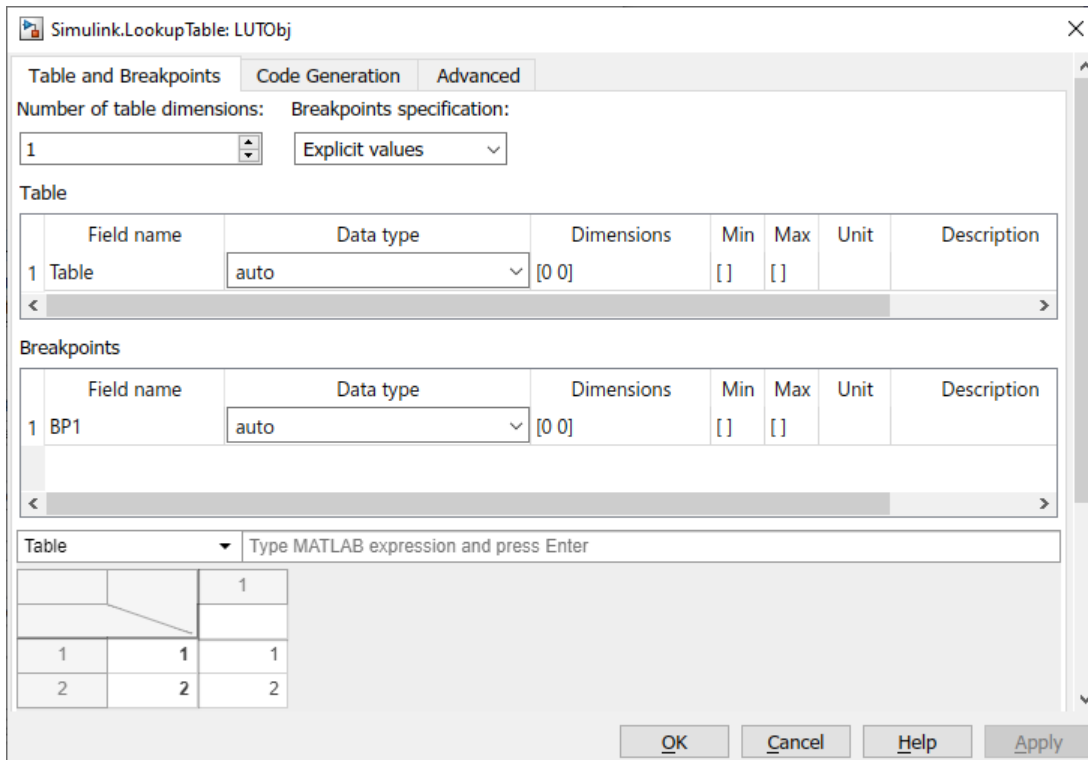

For an example of converting column-major arrays to row-major arrays see “Column-Major Layout to Row-Major Layout Conversion of Models with Lookup Table Blocks” (Simulink Coder).

View Lookup Table Data

You can use a lookup table viewer to view lookup table and breakpoint data. The lookup table view is shared by multiple , including the `Simulink.LookupTable` property dialog box and the lookup table control. This topic and its examples are presented using the `Simulink.LookupTable` property dialog box. Here is lookup table data as soon through the `Simulink.LookupTable` property dialog box.

When the **Breakpoints specification** property is set to **Explicit values**, use the tabular interface and MATLAB expression text box at the bottom of the viewer to:

- View, add, manipulate, and remove table and breakpoint data.
- Create or modify table or breakpoint data using MATLAB expressions.

Simulink.LookupTable: LUTObj

Table and Breakpoints Code Generation Advanced

Number of table dimensions: 3 Breakpoints specification: Explicit values

- View and edit 2-D slices of data from multiple dimensions.

This topic describes:

- Supported data types for the viewer tabular Interface
- How to create, edit, and view table and breakpoint data in the tabular interface
- How to view multidimensional 2-D slices
- How the tabular interface handles data overflows
- How the tabular interface handles invalid data
- Supported keyboard shortcuts

Lookup Table Viewer Data Type Support

The viewer supports these data types:

- Built-in data types (int8, uint8, int16, uint16, int32, uint32, double, single, boolean)

- Fixed-point data types
- `uint64`, `int64`
- `half`

It does not support other data types that Simulink supports.

Create Simulink.LookupTable Objects

To start working with a `Simulink.LookupTable` object, create one at the MATLAB command line:

```
LUTObj = Simulink.LookupTable;
```

How to Open the Simulink.LookupTable Object Property Dialog Box

To work with the `Simulink.LookupTable` object, start its property dialog box in one of these ways from the MATLAB Command Window:

- In the workspace, double-click the `Simulink.LookupTable` object.
- In the Model Explorer, double-click the object in the specific workspace for the object.
- In the command line, use the `open` function, for example:

```
open LUTObj
```

Create Table and Breakpoint Data

Generate data and manipulate it using standard table editing actions. You can generate lookup table data in multiple ways, such as in the workspace, from Microsoft Excel, and so forth, and copy that data into the tabular area. You can also generate data from within the property dialog box using MATLAB expressions.

This example describes how to create data in the MATLAB Command Window workspace and how to set up the property dialog box using an example with that data.

- 1 To create table and breakpoint data, at the MATLAB command line, type:

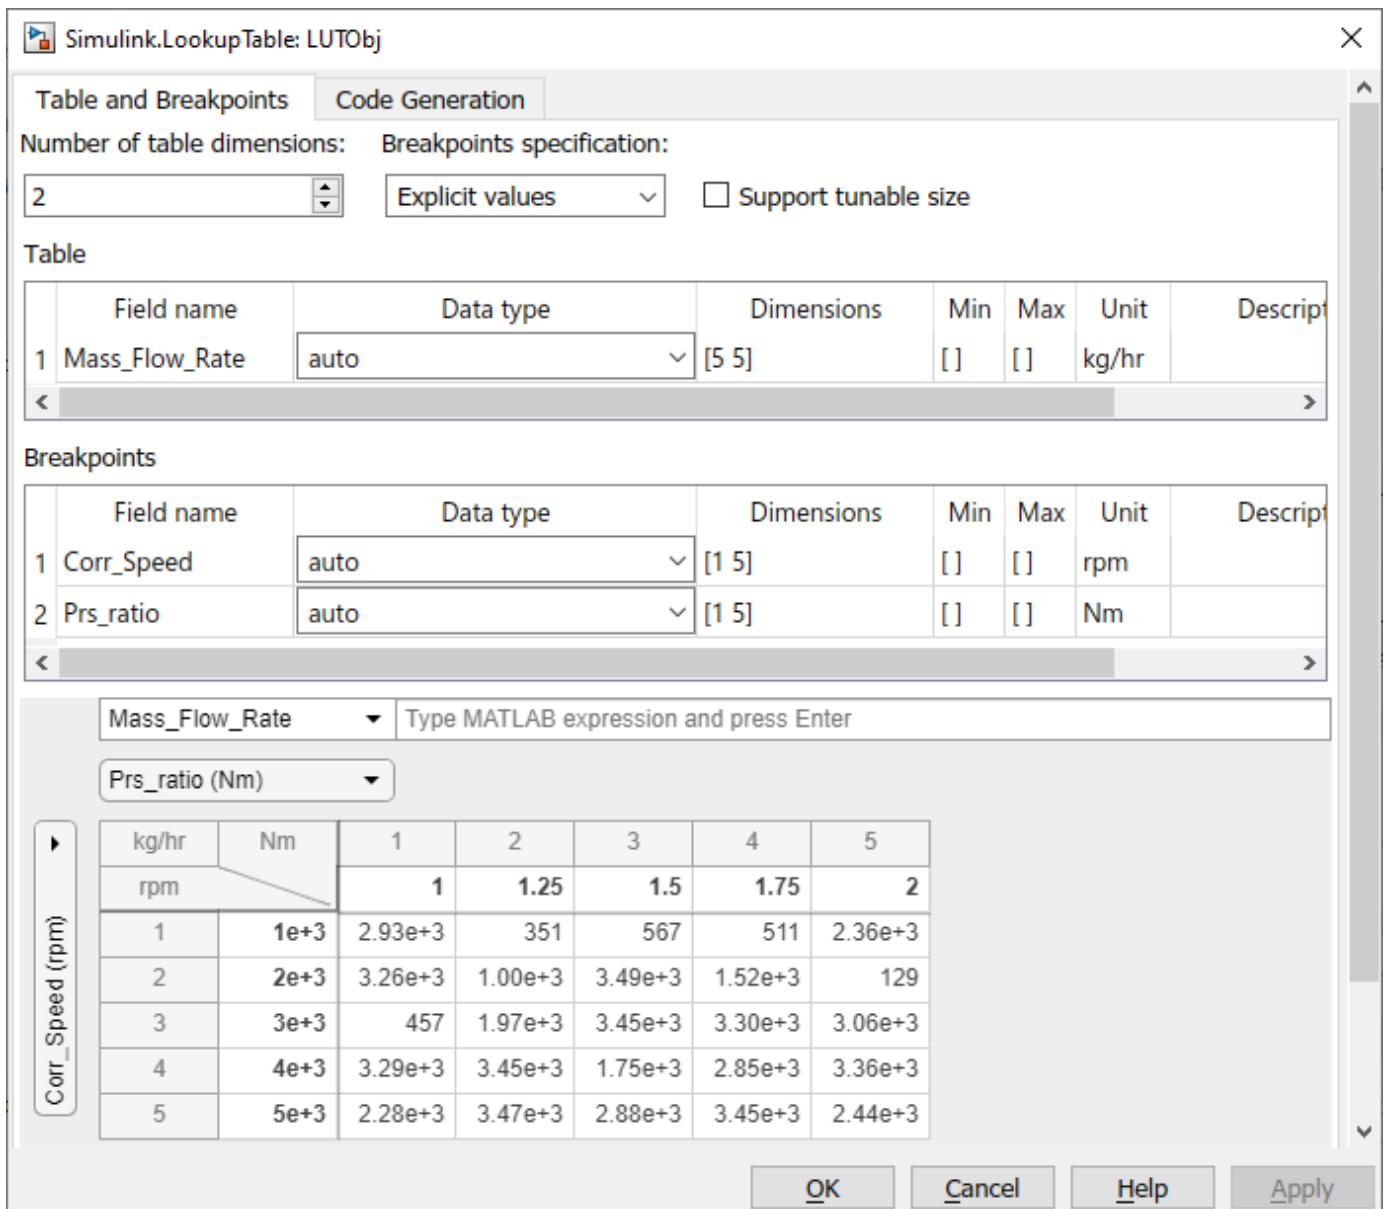

```
LUTObj.Breakpoints(1).Value = fi(linspace(1000,5000,5),1,16,2);
LUTObj.Breakpoints(2).Value = single(linspace(1,2,5));
LUTObj.Table.Value = uint16(rand(5,5)*60*60);
```

- 2 Set up the **Unit** and **Field name** properties for the object.

```
LUTObj.Breakpoints(1).Unit = 'rpm';
LUTObj.Breakpoints(2).Unit = 'Nm';
LUTObj.Table.Unit = 'kg/hr';
LUTObj.Breakpoints(1).FieldName = 'Corr_Speed';
LUTObj.Breakpoints(2).FieldName = 'Prs_ratio';
LUTObj.Table.FieldName = 'Mass_Flow_Rate';
```

- 3 Open the property dialog box.

```
open LUTObj;
```

- 4 From within the tabular area, you can perform typical table edits on particular breakpoint data, such as copying and pasting. When you are done, click **Apply**.

View Multidimensional Slices of Data

The viewer lets you view and edit 2-D slices of data. This example describes how to use the slice selector to navigate through the 2-D slices of 3-D data.

To view a multidimensional slice, use the dropdown lists under the MATLAB expression parameter. There is a dropdown list for each breakpoint. To view a two-dimensional slice, choose a combination of the breakpoint data from the vertical and horizontal dropdown lists.

- 1 Change the table dimensions to 3.

Mass_Flow_Rate		Type MATLAB expression and press Enter				
Prs_ratio (Nm)		BP3 1				
kg/hr	Nm	1	2	3	4	5
rpm		1	1.25	1.5	1.75	2
1	1e+3	2.93e+3	351	567	511	2.36e+3
2	2e+3	3.26e+3	1.00e+3	3.49e+3	1.52e+3	129
3	3e+3	457	1.97e+3	3.45e+3	3.30e+3	3.06e+3
4	4e+3	3.29e+3	3.45e+3	1.75e+3	2.85e+3	3.36e+3
5	5e+3	2.28e+3	3.47e+3	2.88e+3	3.45e+3	2.44e+3

- In the tabular area at the bottom, change the horizontal breakpoint slice to BP3. Observe the changed view of the slice of data.

Mass_Flow_Rate		Type MATLAB expression and press Enter	
BP3		Prs_ratio (Nm) 1	
kg/hr	Nm	1	2
rpm		1	2
1	1e+3	2.93e+3	0
2	2e+3	3.26e+3	0
3	3e+3	457	0
4	4e+3	3.29e+3	0
5	5e+3	2.28e+3	0

Edit Table and Breakpoint Data with MATLAB Expressions

Edit table and breakpoint data using standard table editing actions, such as cutting or copying and pasting, or directly editing table cells. You can also edit table and breakpoint data with MATLAB expressions.

This example shows how to replace the table and breakpoint using a MATLAB expression.

- In the viewer dialog box, in the tabular area at the bottom, select BP3 from the horizontal dimension dropdown list.
- In the MATLAB expression field, enter `linspace(1000,9999,5)`.
- Observe the changed view of the slice of data.

BP3

Edit Table and Breakpoint Data

You can perform standard table edits in the viewer. This example shows how to apply the same value to multiple cells.

Replace a column of data with the same value.

- 1 In the viewer tabular area, select row 1, column 2 of the table data.
- 2 Select the entire column by dragging down the column.
- 3 Enter 324.
- 4 Press **Ctrl+Enter**.
- 5 Observe that the entire column of data is now 324.

	6	0	0	0	0

Overflow Handling

The `Simulink.LookupTable` object property dialog box handles data overflows in the tabular area by automatically changing values to ones that do not cause overflows. For example, if you enter a value of 70000 in a cell for a data type of `uint16`, the property dialog box automatically changes the value to 65535, which is the maximum number for `uint16`. For a list of supported `Simulink.LookupTable` object property dialog box data types, see “Lookup Table Viewer Data Type Support” on page 38-40.

Data Validation

The lookup table viewer performs data validation when you enter a table cell value and press **Enter**. For example, if you enter `NaN`, `Inf` or `-Inf` as a table cell value, an error is displayed.

The MATLAB expression area also validates expressions. For example, if you enter an invalid expression, the text box is outlined in red and displays an error message on an expected expression. If you enter an expression for fixed-point data with a bias, the software evaluates and, as necessary, saturates the value to the nearest available fixed-point value before displaying the corrected value in the table.

Update Lookup Table Blocks to New Versions

In this section...

“Comparison of Blocks with Current Versions” on page 38-50

“Compatibility of Models with Older Versions of Lookup Table Blocks” on page 38-51

“How to Update Your Model” on page 38-51

“What to Expect from the Model Advisor Check” on page 38-52

Comparison of Blocks with Current Versions

In R2011a, the following lookup table blocks were replaced with newer versions in the Simulink library:

Block	Changes	Enhancements
Lookup Table	<ul style="list-style-type: none"> Block renamed as 1-D Lookup Table Icon changed 	<ul style="list-style-type: none"> Default integer rounding mode changed from <code>Floor</code> to <code>Simplest</code> Support for the following features: <ul style="list-style-type: none"> Specification of parameter data types different from input or output signal types Reduced memory use and faster code execution for nontunable breakpoints with even spacing Cubic-spline interpolation and extrapolation Table data with complex values Fixed-point data types with word lengths up to 128 bits Specification of data types for fraction and intermediate results Specification of index search method Specification of diagnostic for out-of-range inputs

Block	Changes	Enhancements
Lookup Table (2-D)	<ul style="list-style-type: none"> Block renamed as 2-D Lookup Table Icon changed 	<ul style="list-style-type: none"> Default integer rounding mode changed from Floor to Simplest Support for the following features: <ul style="list-style-type: none"> Specification of parameter data types different from input or output signal types Reduced memory use and faster code execution for nontunable breakpoints with even spacing Cubic-spline interpolation and extrapolation Table data with complex values Fixed-point data types with word lengths up to 128 bits Specification of data types for fraction and intermediate results Specification of index search method Specification of diagnostic for out-of-range inputs Check box for Require all inputs to have the same data type now selected by default
Lookup Table (n-D)	<ul style="list-style-type: none"> Block renamed as n-D Lookup Table Icon changed 	<ul style="list-style-type: none"> Default integer rounding mode changed from Floor to Simplest

Compatibility of Models with Older Versions of Lookup Table Blocks

When you load existing models that contain the Lookup Table, Lookup Table (2-D), and Lookup Table (n-D) blocks, those versions of the blocks appear. The current versions of the lookup table blocks appear only when you drag the blocks from the Simulink Library Browser into new models.

If you use the `add_block` function to add the Lookup Table, Lookup Table (2-D), or Lookup Table (n-D) blocks to a model, those versions of the blocks appear. If you want to add the *current* versions of the blocks to your model, change the source block path for `add_block`:

Block	Old Block Path	New Block Path
Lookup Table	simulink/Lookup Tables/Lookup Table	simulink/Lookup Tables/1-D Lookup Table
Lookup Table (2-D)	simulink/Lookup Tables/Lookup Table (2-D)	simulink/Lookup Tables/2-D Lookup Table
Lookup Table (n-D)	simulink/Lookup Tables/Lookup Table (n-D)	simulink/Lookup Tables/n-D Lookup Table

How to Update Your Model

To update your model to use current versions of the lookup table blocks, follow these steps:

Step	Action	Reason
1	Run the Upgrade Advisor.	Identify blocks that do not have compatible settings with the 1-D Lookup Table and 2-D Lookup Table blocks.
2	For each block that does not have compatible settings: <ul style="list-style-type: none"> Decide how to address each warning. Adjust block parameters as needed. 	Modify each Lookup Table or Lookup Table (2-D) block to ensure compatibility with the current versions.
3	Repeat steps 1 and 2 until you are satisfied with the results of the Upgrade Advisor check.	Ensure that block replacement works for the entire model.

After block replacement, the block names that appear in the model remain the same. However, the block icons match the ones for the 1-D Lookup Table and 2-D Lookup Table blocks. For more information about the Upgrade Advisor, see “Model Upgrades”.

What to Expect from the Model Advisor Check

The Model Advisor check groups all Lookup Table and Lookup Table (2-D) blocks into three categories:

- Blocks that have compatible settings with the 1-D Lookup Table and 2-D Lookup Table blocks
- Blocks that have incompatible settings with the 1-D Lookup Table and 2-D Lookup Table blocks
- Blocks that have repeated breakpoints

Blocks with Compatible Settings

When a block has compatible parameter settings, automatic block replacement can occur without backward incompatibilities.

Lookup Method in the Lookup Table or Lookup Table (2-D) Block	Parameter Settings After Automatic Block Replacement	
	Interpolation	Extrapolation
Interpolation-Extrapolation	Linear	Linear
Interpolation-Use End Values	Linear	Clip
Use Input Below	Flat	Not applicable

Depending on breakpoint spacing, one of two index search methods can apply.

Breakpoint Spacing in the Lookup Table or Lookup Table (2-D) Block	Index Search Method After Automatic Block Replacement
Not evenly spaced	Binary search
Evenly spaced and tunable	A prompt appears, asking you to select Binary search or Evenly spaced points.
Evenly spaced and not tunable	

Blocks with Incompatible Settings

When a block has incompatible parameter settings, the Model Advisor shows a warning and a recommended action, if applicable.

- If you perform the recommended action, you can avoid incompatibility during block replacement.
- If you use automatic block replacement without performing the recommended action, you might see numerical differences in your results.

Incompatibility Warning	Recommended Action	What Happens for Automatic Block Replacement
The Lookup Method is Use Input Nearest or Use Input Above. The replacement block does not support these lookup methods.	Change the lookup method to one of the following options: <ul style="list-style-type: none"> • Interpolation - Extrapolation • Interpolation - Use End Values • Use Input Below 	The Lookup Method changes to Interpolation - Use End Values. In the replacement block, this setting corresponds to: <ul style="list-style-type: none"> • Interpolation set to Linear • Extrapolation set to Clip
The Lookup Method is Interpolation - Extrapolation, but the input and output are not the same floating-point type. The replacement block supports linear extrapolation only when all inputs and outputs are the same floating-point type.	Change the extrapolation method or the port data types of the block.	You also see a message that explains possible numerical differences.
The block uses small fixed-point word lengths, so that interpolation uses only one rounding operation. The replacement block uses two rounding operations for interpolation.	None	You see a message that explains possible numerical differences.

Blocks with Repeated Breakpoints

When a block has repeated breakpoints, the Model Advisor recommends that you change the breakpoint data and rerun the check. You cannot perform automatic block replacement for blocks with repeated breakpoints.

Masking Fundamentals

A mask is a custom interface for a block that hides the block content, making it appear as an atomic block with its own icon and parameter dialog box. It encapsulates the block logic, provides controlled access to the block data, and simplifies the graphical appearance of a model.

When you mask a block, a mask definition is created and saved along with the block. A mask changes only the block interface, and not the underlying block characteristics. You can provide access to one or more underlying block parameters by defining corresponding mask parameters on the mask.

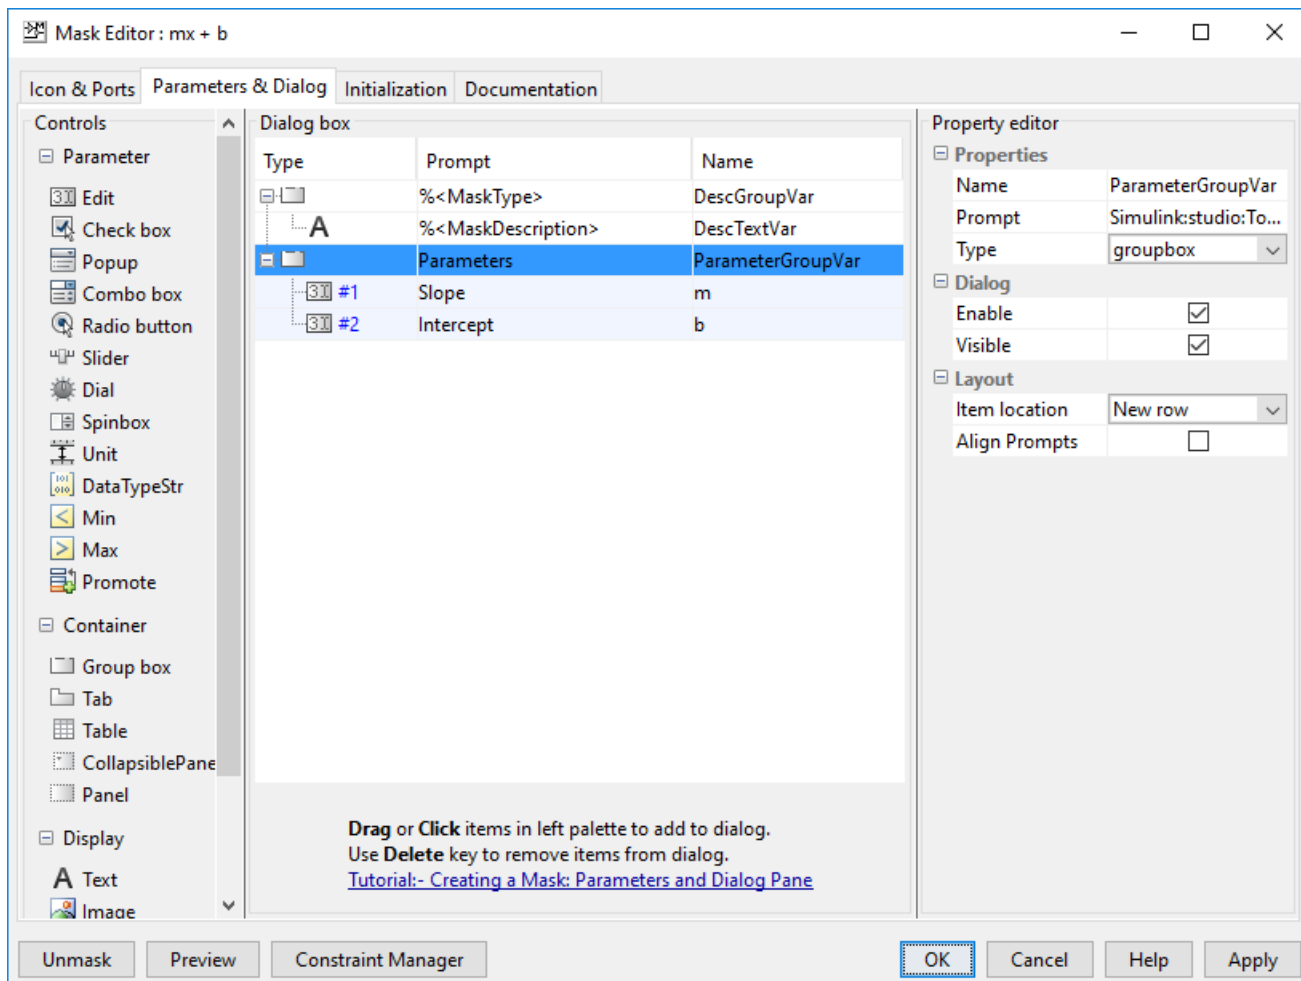

Mask a Simulink block to:

- Display a meaningful icon on a block
- Provide a customized dialog box for the block
- Provide a dialog box that enables you to access only select parameters of the underlying blocks
- Provide users customized description that is specific to the masked block
- Initialize parameters using MATLAB code

Consider the model `masking_example` that represents the equation of line $y = mx + b$.

Each block has its own dialog box, making it complicated to specify the values for the line equation variables. To simplify the user interface, a mask is applied on the top-level subsystem block.

Here the variable m represents slope and the variable b represents the intercept for the line equation $y = mx + b$.

The mask dialog box displays the fields for **Slope** and **Intercept** that are internally mapped to variables m and b .

Masked blocks do not support content preview. To preview the contents of a subsystem, see “Preview Content of Model Components” on page 1-36.

Tip For masking examples, see Simulink Masking Examples. The examples are grouped by type. In an example model:

- To view the mask definition, double-click the View Mask block.
- To view the mask dialog box, double-click the block.

Examples of few blocks that cannot be masked are:

- Scope blocks
- Simulink Function block
- Initialize, Terminate and Reset Function blocks
- Gauge blocks

Masking Terminology

Term	Description
Mask icon	The masked block icon generated using drawing commands. Mask icon can be static or change dynamically with underlying block parameter values.

Term	Description
Mask parameters	The parameters that are defined in the Mask Editor and appear on the mask dialog box. Setting the value of a mask parameter on the mask dialog box sets the corresponding block parameter value.
Mask initialization code	MATLAB Code that initializes a masked block or reflects current parameter values. Add mask initialization code in the Initialization pane of the Mask Editor dialog box. For example, add initialization code to set a parameter value automatically.
Mask dialog callback code	MATLAB Code that runs in the base workspace when the value of a mask parameter changes. Use callback code to change the appearance of a mask dialog box dynamically and reflect current parameter values. For example, enable visible parameters on the dialog box.
Mask documentation	Description and usage information for a masked block defined in the Mask Editor.
Mask dialog box	A dialog box that contains fields for setting mask parameter values and provides mask description.
Mask workspace	Masks that define mask parameters or contain initialization code have a mask workspace. This workspace stores the evaluated values of the mask parameters and temporary values used by the mask.

More About

- “Create Block Masks”
- “Create a Simple Mask” on page 39-6
- “Mask Editor Overview”
- Set mask parameters
- Creating a Mask: Masking Fundamentals (3 min, 46 sec)

Create a Simple Mask

You can mask a block interactively by using the Mask Editor or mask it programmatically. This example describes how to mask a block by using the **Mask Editor**. To mask a block programmatically, see “Control Masks Programmatically” on page 39-29.

For masking examples, see Simulink Masking Examples.

Step 1: Open Mask Editor

- 1 Open the model in which you want to mask a block. For example, open `subsystem_example`.

This model contains a Subsystem block that models the equation for a line: $y = mx + b$.

- 2 Select the Subsystem block and on the **Subsystem** tab, in the **Mask** group, click **Create Mask**.

Step 2: Define the Mask

The **Mask Editor** contains four tabs that enable you to define the block mask and customize the dialog box for the mask.

For detailed information on each pane, see “Mask Editor Overview”.

Icon & Ports Tab

Use this tab to create an icon for the block mask. You can use the **Options** pane on the left to specify icon properties and icon visibility.

Add an image to the block mask.

- 1 In the **Block frame** drop-down box, select **Visible**.
- 2 In the **Icon transparency** drop-down box, select **Opaque**.
- 3 In the **Icon units** drop-down box, select **Autoscale**.
- 4 To restrict the icon rotation, select **Fixed** from the **Icon rotation** list.
- 5 In the **Icon drawing commands** text box, type,

```
x = [0 0.5 1 1.5];y = [0 0.5 1 1.5];
% An example to defines the variables x and y
plot(y,x) % Command to plot the graph
```

For more information on drawing command syntax, see “Icon drawing commands”.

- 6 To save the changes, click **Apply**. To preview the block mask icon without exiting the **Mask Editor**, click **Preview**

Note For detailed information, see “Icon & Ports Pane”.

You can create static or dynamic block mask icons. For more information, see “Draw Mask Icon” on page 39-17 and `slexMaskDisplayAndInitializationExample`.

Parameters & Dialog Tab

Use this tab to add controls like parameters, displays, and action items to the mask dialog box.

To add **Edit** boxes to the block mask.

- 1 In the left pane, under **Parameter**, click **Edit** twice to add two new rows in the **Dialog box** pane.
- 2 Type **Slope** and **Intercept** in the **Prompt** column for the two **Edit** parameters. The value that you enter in **Prompt** column appears on the mask dialog box. Similarly, type **m** and **b** in the **Name** column. The value you enter in **Name** column is the mask parameter name. The mask parameter name must be a valid MATLAB name.
- 3 In the right pane, under **Property editor**, provide values in the **Properties**, **Dialog**, and **Layout** sections.
- 4 Click **Apply**.

5 To preview the mask dialog box without exiting the Mask Editor, click **Preview**.

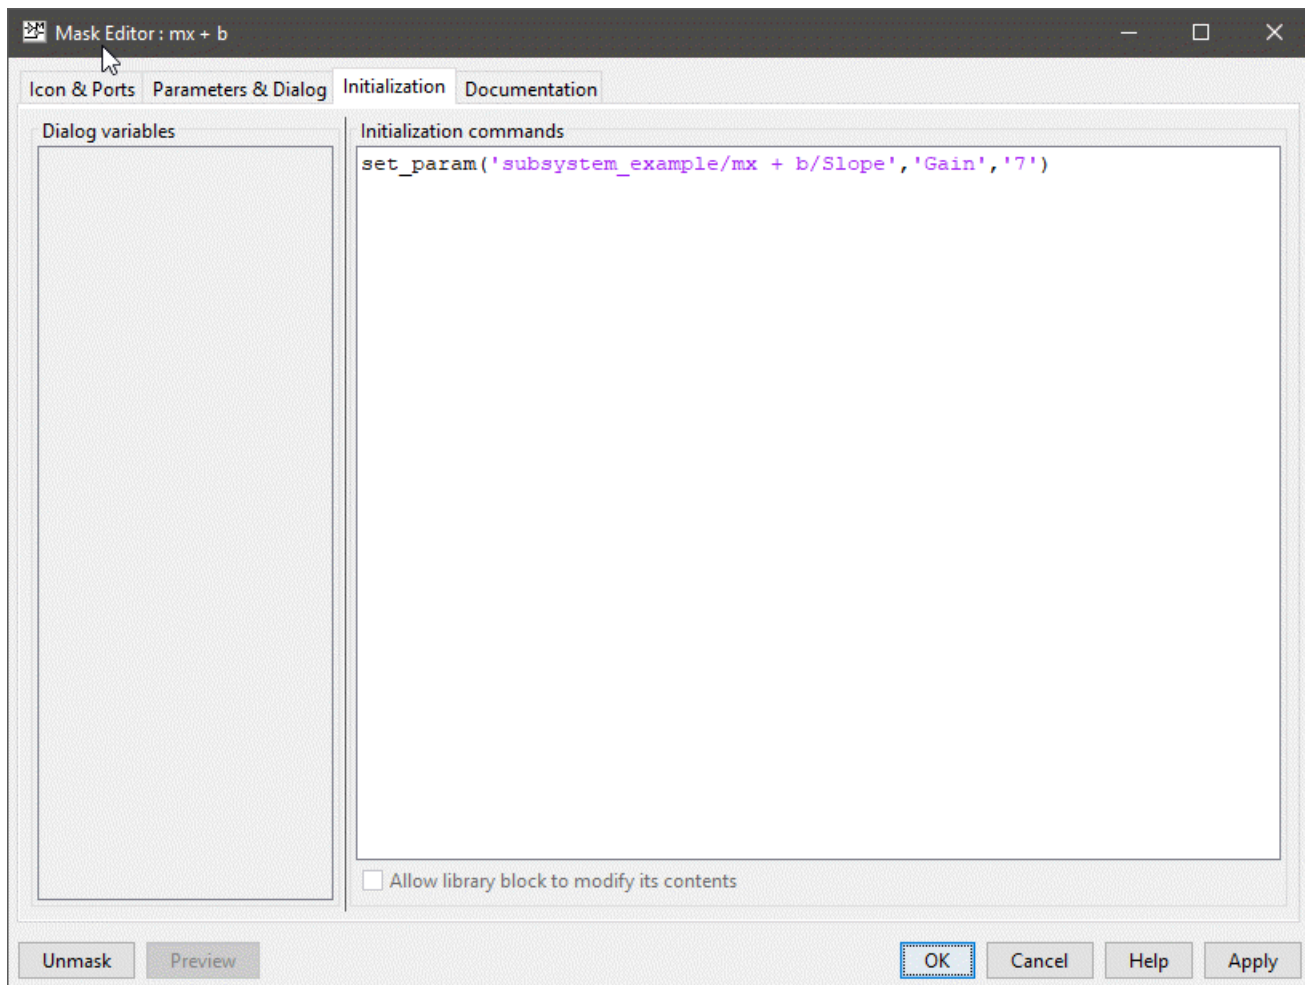

For detailed information, see "Parameters & Dialog Pane".

Note A Simulink mask parameter cannot reference another parameter on the same mask.

Initialization Tab

Use this pane to specify MATLAB code to control the mask parameters. For example, you can provide a predefined value for a mask parameter.

Consider the equation $y = mx + b$ in the example. To set the value of the child block corresponding to 'm', you can use the `set_param` function in the initialization pane.

Note For detailed information, see “Initialization Pane”.

Documentation Tab

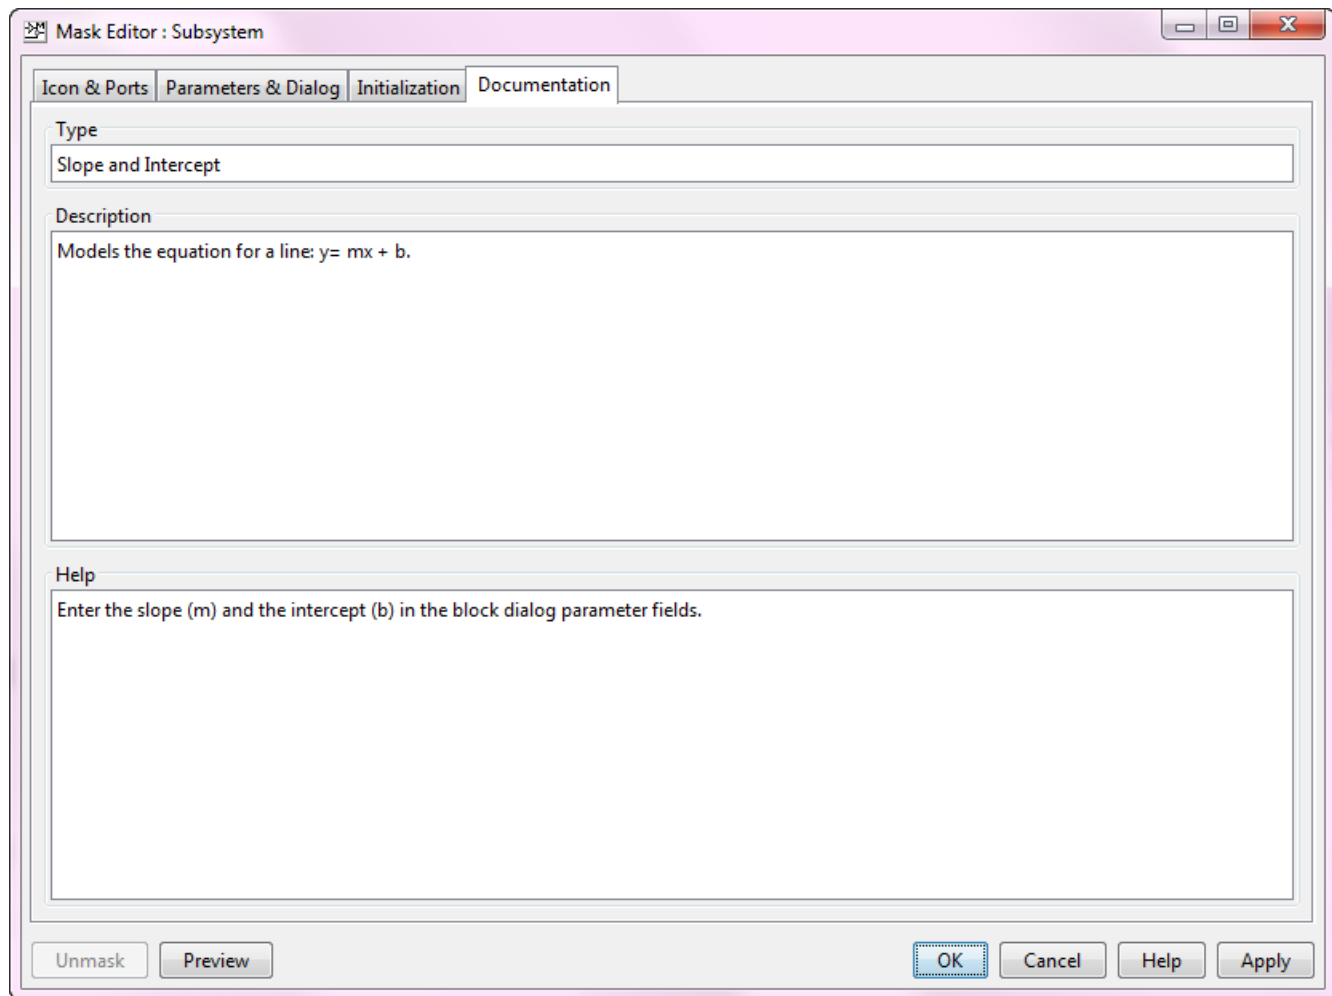

Use this tab to add a name, description, and additional information for the mask.

The **Documentation** tab contains these fields:

- 1 **Type:** You can add a name for the block mask in this box. The mask name appears on top of the mask dialog box. You cannot add new lines.
- 2 **Description:** You can add a description for the block mask in this box. By default, the description is displayed below the mask name, and it can contain new lines and spaces.
- 3 **Help.** You can add additional information for the block mask in this box. You click **Help** on the mask dialog box, this information is displayed. You can use plain text, HTML and graphics, URLs, and web or eval commands to add information in the **Help** field.

After you have added information in the **Mask Editor**, click **Apply** or **OK**.

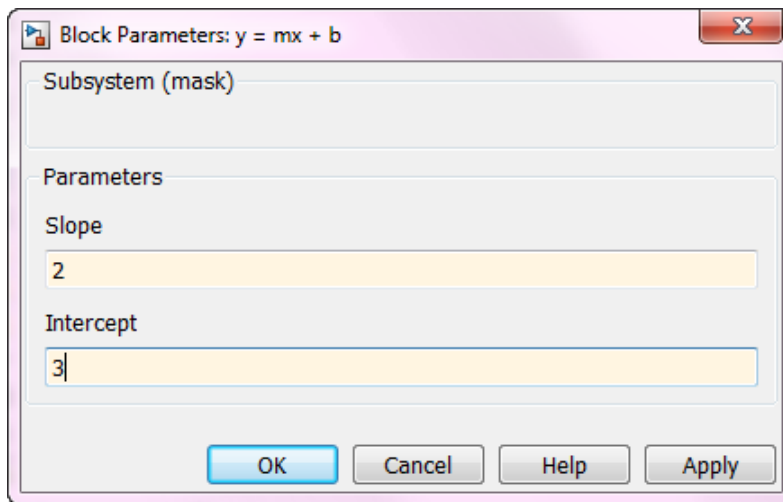

The block is now masked.

Note For detailed information, see "Documentation Pane".

Step 3: Operate on Mask

- 1 You can preview the mask and choose to unmask the block or edit the block mask.
- 2 Double-click the masked block.

The mask dialog box appears.

- 3 Type values in the **Slope** and **Intercept** boxes of the mask dialog box. To view the output, simulate the model.
- 4 Click **OK**.
- 5 To edit the mask definition, select the subsystem block and click **Edit Mask** from the **Subsystem** tab in the Toolstrip. For more information, see “Manage Existing Masks” on page 39-12.
- 6 Select the masked block and on the **Subsystem Block** tab, in the **Mask** group, click **Look Under Mask** to view:
 - The blocks inside the masked subsystem
 - The built-in block dialog box of a masked block
 - The base mask dialog box of a linked masked block

- Creating a Mask: Masking Fundamentals (3 min, 46 sec)
- “Mask Editor Overview”
- “Masking Fundamentals” on page 39-2

Manage Existing Masks

Change a Block Mask

You can change an existing mask by reopening the Mask Editor and using the same techniques that you used to create the mask:

- 1 Select the masked block.
- 2 On the **Subsystem Block** tab, in the **Mask** group, click **Edit Mask**.

The Mask Editor reopens, showing the existing mask definition. Change the mask as needed. After you change a mask, click **Apply** to preserve the changes.

View Mask Parameters

To display a mask dialog box, double-click the block. Alternatively, select the block and on the **Block** tab, in the **Mask** group, click **Mask Parameters**.

Tip Each block has a block parameter dialog box. To view the block parameters dialog box of a masked block, right-click the masked block and select **Block Parameters (BlockType)**.

Look Under Block Mask

To see the block diagram under a masked Subsystem block, built-in block, or the model referenced by a masked model block, select the block and on the **Subsystem** tab, click **Look Under Mask**.

Remove Mask

To remove a mask from a block,

- 1 Select the block.
- 2 On the **Block** tab, in the **Mask** group, click **Edit Mask**.

The Mask Editor opens and displays the existing mask, for example:

- 3 Click **Unmask** in the lower left corner of the Mask Editor.

The Mask Editor removes the mask from the block.

Mask Callback Code

In this section...

“Add Mask Code” on page 39-14
 “Execute Drawing Command” on page 39-14
 “Execute Initialization Command” on page 39-14
 “Execute Callback Code” on page 39-15

Add Mask Code

You can use MATLAB code to initialize a mask and to draw mask icons. Since the location of code affects model performance, add your code to reflect the functionality you need.

Purpose	Add in Mask Editor	Programmatic Specification
Initialize the mask	Initialization pane	MaskInitialization parameter
Draw mask icon	Icon & Ports pane	MaskDisplay parameter
Callback code for mask parameters	Parameters & Dialog pane	MaskCallbacks parameter

Execute Drawing Command

Place MATLAB code for drawing mask icons in the **Icon Drawing Commands** section of the **Icon & Ports** pane. Simulink executes these commands sequentially to redraw the mask icon when:

- Block is rendered first on the Mask Editor canvas.
- Mask parameters and values that depend on drawing commands change.
- Block appearance is altered due to rotation or other changes.

Note Placing MATLAB code for drawing mask icons in the **Initialization** pane affects model performance. This behavior is because Simulink redraws the icon each time the masked block is evaluated in the model.

Execute Initialization Command

Initialization commands for all masked blocks in a model run when you:

- Update the diagram
- Start simulation
- Start code generation
- Apply mask changes
- Change any of the parameters that define the mask, such as MaskDisplay and MaskInitialization, using the Mask Editor or `set_param`.
- Rotate or flip the masked block, if the icon depends on initialization commands.

- Cause the icon to be drawn or redrawn, and the icon drawing depends on initialization code.
- Change the value of a mask parameter by using the block dialog box or `set_param`.
- Copy the masked block within the same model or between different models.

When you open a model, Simulink locates visible masked blocks that reside at the top level of the model or in an open subsystem.

Simulink only executes the initialization commands for these visible masked blocks if they meet either of the following conditions:

- The masked block has icon drawing commands.

Note Simulink does not initialize masked blocks that do not have icon drawing commands, even if they have initialization commands during model load.

- The masked subsystem belongs to a library and has the **Allow library block to modify its contents** parameter enabled.

When you load a model into memory without displaying it graphically, no initialization commands initially run for any masked blocks. See “Load a Model” on page 1-2 and `load_system` for information about loading a model without displaying it.

Note The non-tunable parameters of a masked block are not evaluated if the model is already compiled (initialized).

Execute Callback Code

Mask parameter callback codes are executed in a temporary workspace and not in the base workspace. If you need a variable created in the callback to be available later(not during callback processing), you must explicitly assign those variables to the base workspace.

Simulink executes the callback commands when:

- You open the mask dialog box. Callback commands execute sequentially, starting with the top mask dialog box.
- You modify a parameter value in the mask dialog box and then change the cursor location. For example, you press the **Tab** key or click into another field in the dialog box after changing the parameter value.
- You modify the parameter value by using the `set_param` command, the callback commands execute.
- You modify the parameter value, either in the mask dialog box or using `set_param`, and then apply the change by clicking **Apply** or **OK**. Mask initialization commands execute after callback commands. For more information, see “Initialization Pane”.
- You hover over a masked block to see the tool tip for the block, when the tool tip contains parameter names and values.

Note Callback commands do not execute if the mask dialog box is open when the block tool tip appears.

- You update a diagram by pressing **Ctrl+D** or by clicking **Update Model** on the **Modeling** tab in the Simulink Editor.
- If you close a mask dialog box without saving the changes, the Callback command for parameters is executed sequentially.

Note Buttons on mask dialog box are unavailable when the callback code associated with the button is being executed.

For related Simulink example models, see:

- Sequence mask callbacks
- Unsafe mask callbacks
- Unsafe nested mask callbacks

Draw Mask Icon

Create icons for the masked blocks. You can either create static or dynamic icons. Static icons remain unchanged. Dynamic icons are created with the mask parameters, hence the icon changes with a change in the mask parameters. This example shows how to use drawing commands to create a mask icon.

In this section...

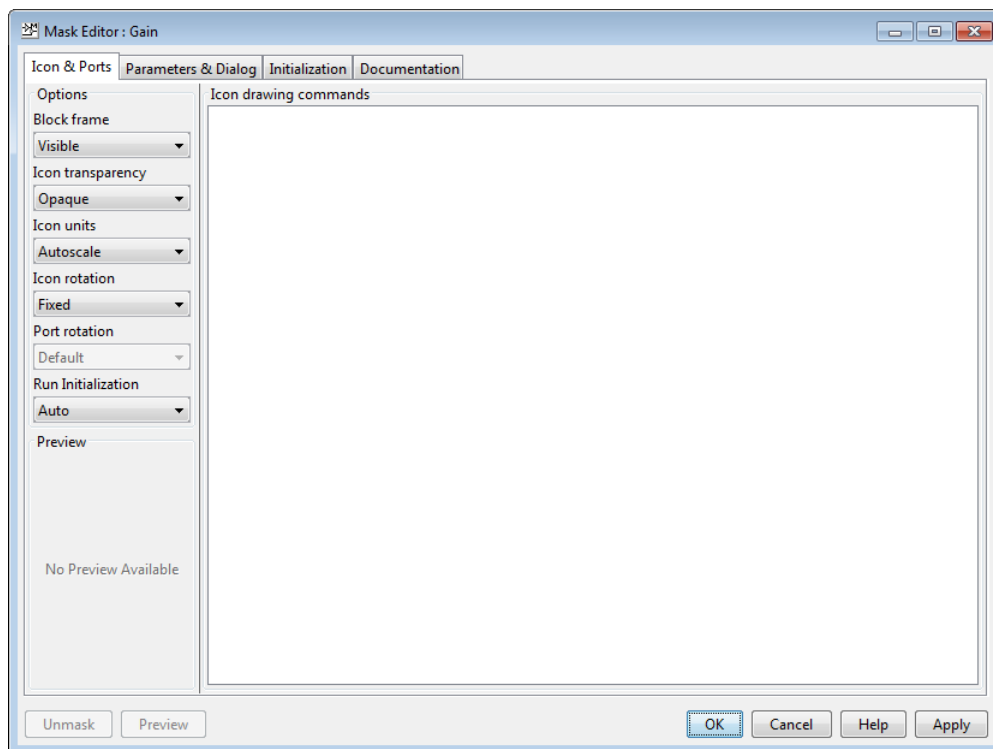

“Draw Static Icon” on page 39-17

“Draw Dynamic Icon” on page 39-18

Draw Static Icon

A static mask icon remains unchanged, independent of the value of the mask parameters.

- 1 Select the masked block that requires the icon.
- 2 On the **Block** tab, in the **Mask** group, click **Edit Mask**.

- 3 In the **Icons & Ports** tab, enter this command in the **Icon Drawing commands** pane:

```
% Use specified image as mask icon
image('engine.jpg')
```

The image file must be on the MATLAB path.

For more examples of drawing command syntax, see “Icon drawing commands”.

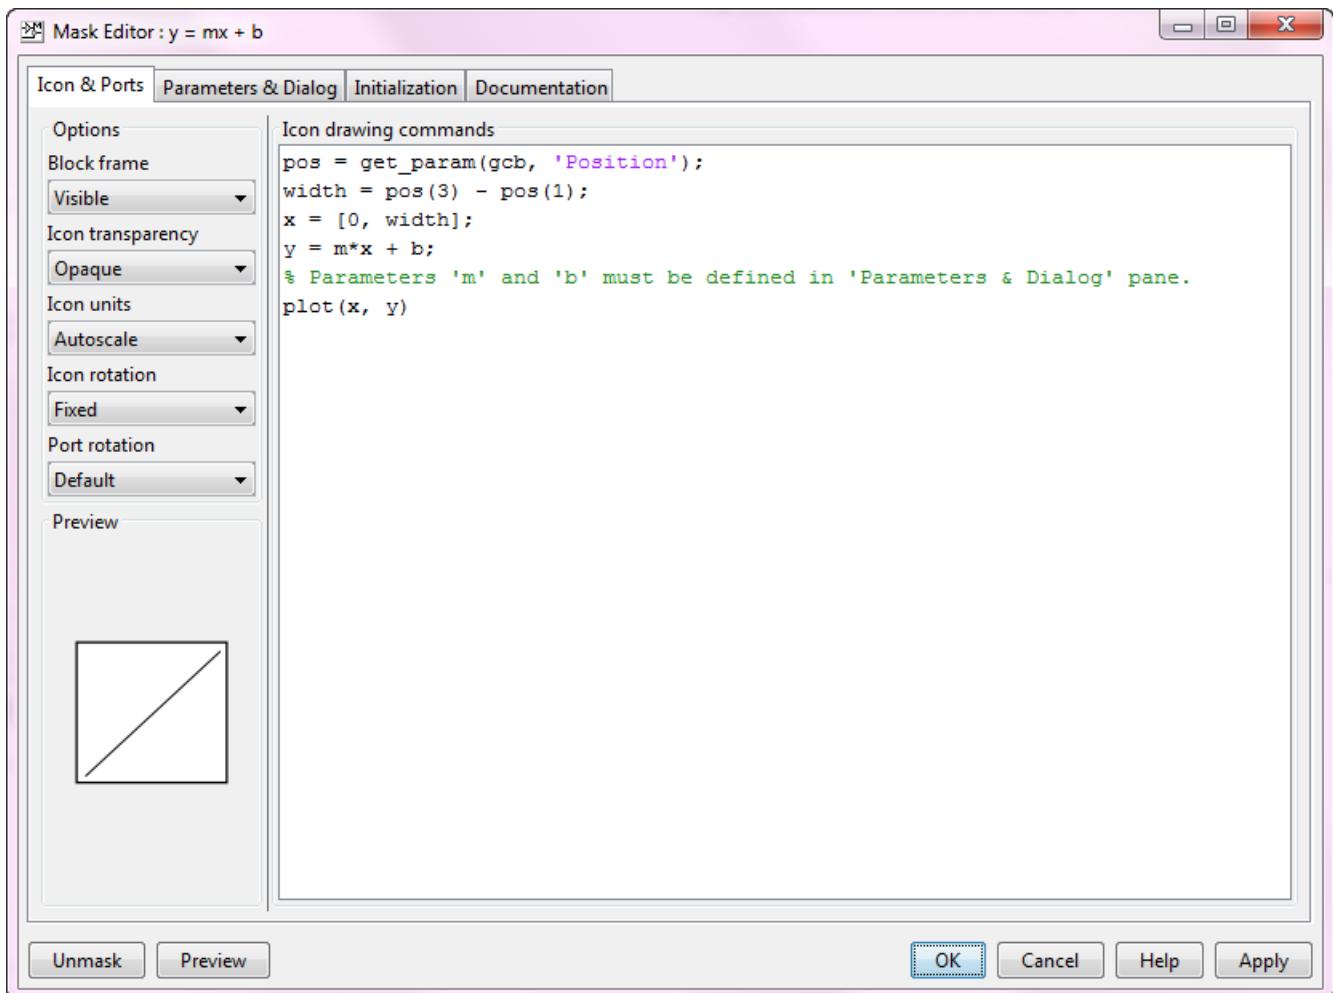

Images in formats `.cur`, `.hdf4`, `.ico`, `.pcx`, `.ras`, `.xwd`, `.svg` cannot be used as block mask images. However, you can use images in these formats if you wrap the file name in the `imread()` function and use the RGB triplet. Using the `imread()` function is not efficient. However, it is still supported for backward compatibility.

Draw Dynamic Icon

A dynamic icon changes with the values of the mask parameters. Use it to represent the purpose of the masked block.

- 1 Select the masked block that requires the icon.
- 2 On the **Block** tab, in the **Mask** group, click **Edit Mask**.

The Mask Editor opens.

- 3 In the **Icons & Ports** tab, enter this command in the **Icon Drawing commands** pane:

```
pos = get_param(gcf, 'Position');
width = pos(3) - pos(1);
x = [0, width];
y = m*x + b;
% Parameters 'm' and 'b' must be defined in 'Parameters & Dialog' pane.
plot(x,y)
```

- 4 Under **Options**, set **Icon Units** to **Pixels**.

The drop-down lists under **Options** allow you to specify icon frame visibility, icon transparency, drawing context, icon rotation, and port rotation.

- 5 Click **Apply**. To view the icon generated, see `model_masking_example`.

Note If Simulink cannot evaluate all commands in the **Icon Drawing commands** pane to generate an icon, three question marks (? ? ?) appear on the mask.

See `slexMaskDisplayAndInitializationExample` for more examples of icon drawing commands. This model shows how to draw:

- Static mask
- Dynamic shape mask
- Dynamic text mask
- Image mask

More About

- “Create Block Masks”

Initialize Mask

You can add MATLAB code in the Initialization pane of the Mask Editor to initialize a masked block. Simulink executes these initialization commands to initialize a masked subsystem at critical times, such as model loading and start of a simulation run. For more information, see “Execute Initialization Command” on page 39-14.

You can add mask initialization code for these cases:

- To specify the initial values of mask parameters. For example to specify an initial value of parameter *a*, type `a = 5` in the Initialization pane.
- To specify the value of a child block. For example,

```
set_param('Child block Name','Parameter name','Parameter Value')
```

- To create a self-modifiable mask. For more information, see Self-Modifying Mask.

The initialization code of a masked subsystem can refer only to the variables in its local workspace.

When you reference a block with, or copy a block into, a model, the mask dialog box displays the specified default values. You cannot use mask initialization code to change mask parameter default values in a library block or any other block.

Ensure that the mask parameters used in the mask initialization code are defined. Errors in mask initialization are displayed when editing the mask initialization commands, but this is only possible if all the mask parameter values are evaluated without errors.

Note

- Blocks that contain initialization code do not work as expected when using model reference.
 - When you use `set_param` in the mask initialization code of a Subsystem block, all the child blocks are also evaluated.
-

Use the Mask Editor **Initialization** pane to add MATLAB commands that initialize a masked block.

The **Initialization** pane contains these sections:

- **Dialog variables**
- **Initialization commands**

Dialog Variables

The **Dialog variables** section displays the names of the variables associated with the mask parameters of the masked block that are defined in the **Parameters** pane.

You can copy the name of a parameter from this list and paste it into the **Initialization commands** section.

You can change the name of the mask parameter variable in the list by double-clicking and editing the name.

Initialization Commands

You can add the initialization commands in this section. The initialization code must be a valid MATLAB expression, consisting of MATLAB functions and scripts, operators, and variables defined in the mask workspace. Initialization commands cannot access base workspace variables.

To avoid echoing results to the MATLAB Command Window, terminate initialization commands with a semicolon.

To view related examples, see

- Define mask display and initialization
- Use MATLAB graphics in masking

Mask Initialization Best Practices

Mask initialization commands must observe the following rules:

- Do not use initialization code to create dynamic mask dialog boxes (Dialog boxes whose appearance or control settings change depending on changes made to other control settings). Instead, use the mask callbacks that are intended for this purpose. For more information, see “Dynamic Mask Dialog Box” on page 39-38.
- Do not use initialization code to add or delete blocks during model load time.
- For nested masked subsystem, do not use `set_param` on a parent block from a child block. The child block mask and the parent block mask both could be initializing the same parameter of the block leading to unexpected behavior. For more information, see Unsafe Mask Callback Error.
- Do not use `set_param` commands on blocks that reside in another masked subsystem that you are initializing. Trying to set parameters of blocks in lower-level masked subsystems can trigger unresolved symbol errors if lower-level masked subsystems reference symbols defined by higher-level masked subsystems.

Suppose, for example, a masked subsystem A contains a masked subsystem B which contains Gain block C, whose Gain parameter references a variable defined by B. Suppose also that subsystem A has initialization code that contains this command:

```
set_param([gcb '/B/C'], 'SampleTime', '-1');
```

Simulating or updating a model containing A causes an unresolved symbol error.

- You cannot use mask initialization code to create data objects. Data objects are objects of these classes:
 - `Simulink.Parameter` and subclasses
 - `Simulink.Signal` and subclasses
- Do not add initialization code to delete the same masked block.
- Use mask initialization code to control direct child blocks only.

Note Do not use mask initialization code to comment or uncomment a block.

Promote Parameter to Mask

In this section...

“Promote Underlying Parameters to Block Mask” on page 39-24

“Promote Underlying Parameters to Subsystem Mask” on page 39-26

“Unresolved Promoted Parameter” on page 39-27

“Best Practices” on page 39-27

“Promote Block Parameters on a Mask” on page 39-27

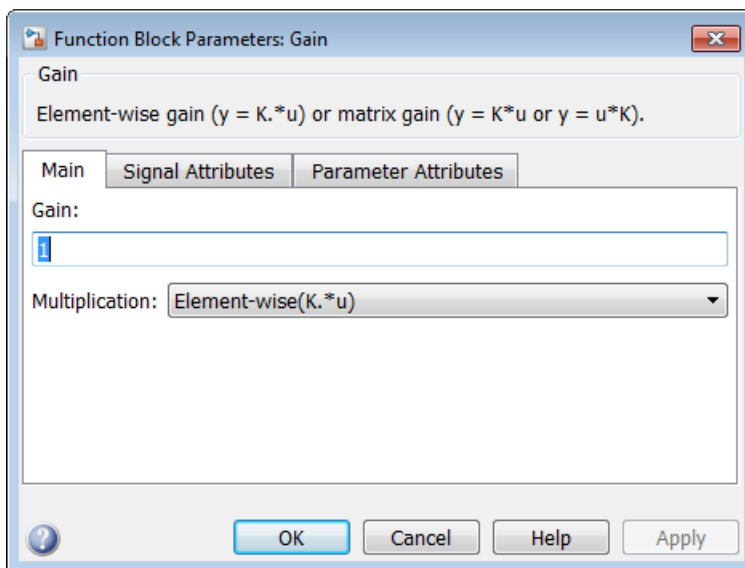

Blocks and subsystems can have multiple parameters associated with them. Block masks allow you to expose one or more of these parameters while hiding others from view. Promoting specific parameters to the mask block simplifies the interface and enables you to specify the parameters the user of the block can view and set.

You can use the **Promote** button on the Mask Editor to promote any underlying parameter of a block either to a block mask or to a subsystem mask. The promoted block parameter gets associated with a parameter in the mask, enabling you to edit the parameter value from the mask dialog box.

Promote parameters from the block dialog box to the mask:

- To customize the mask dialog box by moving the required parameters from the block dialog box to the mask dialog box.
- To reuse a library block at different instances of a model. For each instance of the library block, you can create individual mask dialog box by promoting parameters for each block.

Consider the block dialog box of the Gain block, which has parameters such as **Gain**, **Multiplication**.

To expose only the Gain parameter, mask the Gain block and promote the Gain parameter to the mask dialog box.

Similarly, you can mask a subsystem block and promote parameters to the mask from child blocks of the subsystem block. If the data type of subsystem child block parameters is same, you can associate a single mask parameter with multiple promoted parameters. For example, you can promote multiple **Gain** parameters in a subsystem to a single dialog box on your mask.

If the parameter is of data type `popup` or `DataType`, the options must also be the same for the parameters to be promoted together. The **Evaluate** attribute for all the parameters to be promoted must be similar.

For a related example, see [Promote mask parameters](#)

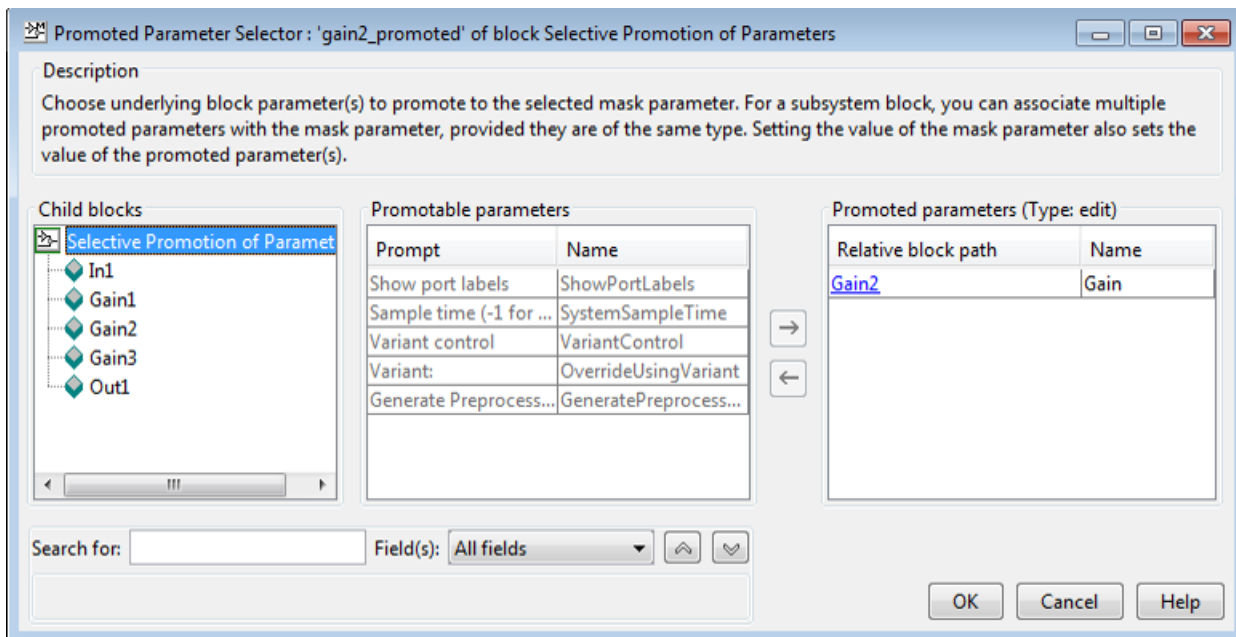

You can also change the attributes of a promoted parameter. For example, you can make a promoted parameter read only or hidden. For more information on attributes, see ["Property editor"](#).

Promote Underlying Parameters to Block Mask

- 1 Select the block whose parameter you want to promote.
- 2 On the **Block** tab, click **Create Mask**.
- 3 In the **Mask Editor** dialog box, click the **Parameters & Dialog** tab.
- 4 In the **Controls** pane, click **Promote**.
- 5 In the **Property editor** pane, next to **Type options**, click .

Use the **Promoted Parameter Selector** dialog box to select the parameters that you want to promote.

- To add a parameter to the **Promoted parameters** list, select a parameter from the **Promotable parameters** table and click the **Add to promoted parameter list** button .

To view the parameter properties such as **Type**, hover over the parameter name in the **Promotable parameter** pane.

Tip

- You can use the **Child blocks** list or the **Search** box to find underlying block parameters to promote.
- To prevent tuning of a property during simulation, you can disable the **Tunable** attribute while promoting a tunable parameter.

- Click **OK**.
- In the **Mask Editor** dialog box, edit the prompt names for the promoted parameters and click **OK**. You cannot edit the variable names. You can change the attributes of the promoted parameter in the Property editor section. For example, you can mark the promoted parameter as read-only, evaluate, hidden, and tunable. For more information, see "Property editor".
- Click **OK**. Look at the block mask. Only the parameters you promoted are available to set.

Note

- You can use **Promote all**  to promote all parameters. **Promote all** is available for all block masks except for subsystem masks.
- To remove a promoted parameter, select the parameter and press **Delete** key.
- You cannot view or promote parameters of a nested masked or linked child block.

- Do not promote the parameters of built-in Simulink blocks, as these blocks may have internal callbacks associated with them.

Promote Underlying Parameters to Subsystem Mask

- 1 Select the subsystem.
- 2 On the **Subsystem Block** tab, in the **Mask** group, click **Create Mask**.
- 3 In the **Mask Editor** dialog box, click the **Parameters & Dialog** tab.
- 4 In the **Controls** pane, click **Promote**.
- 5 In the **Property editor** pane, next to **Type options**, click .
- 6 In the **Promoted Parameter Selector** dialog box, select the parameters that you want to promote.
- 7 To add a parameter to the **Promoted parameters** list, select a parameter from the **Promotable parameters** table and click the **Add to promoted parameter list** button .

You can add parameters of the same data type from different child blocks to the **Promoted parameters** list. For example, the **Gain** parameter from a different child block can be added to the **Promoted parameters** list to promote to the single **Gain** parameter on the mask.

- 8 Click **OK**.
- 9 In the **Mask Editor** dialog box, edit the prompt names for the promoted parameters and click **OK**. You cannot edit the variable names.
- 10 Click **OK**. Look at the block mask. Only the parameters you promoted are available to set.

Unresolved Promoted Parameter

When a promoted parameter is disconnected from the underlying block parameter, the promoted parameter is unresolved. Unresolved promoted parameters can cause the model to be erroneous as the promoted parameter cannot find the corresponding block parameter. Promoted parameters can become unresolved for any of these reasons:

- The underlying block is deleted.
- The underlying block is replaced with another block of same name but does not have the specified parameter.
- The underlying block is moved within another mask.

Best Practices

- Set the value of a promoted parameter only in the mask dialog box and not in the underlying block dialog box or from the command line.
- Parameters once promoted cannot be promoted again to any other mask.
- Do not edit the **Evaluate** attribute of the promoted parameter. This property is inherited from the block parameter.
- If you are promoting a nontunable parameter, do not edit the **Tunable** attribute.
- Parameters of a masked or linked child block cannot be viewed or promoted.
- Callbacks associated with a block parameter are promoted to the block mask and not to the subsystem mask. User-defined callbacks are sequentially executed after the dynamic dialog callback execute.

Promote Block Parameters on a Mask

You can use Parameter Promotion to promote any underlying parameter of a block either to a block mask or to a subsystem mask. This model contains a subsystem that has 3 Gain blocks (**Gain1**, **Gain2**, and ***Gain3**). The variable K represents the Gain parameter for these Gain blocks. You can promote only the Gain parameter of each of these Gain blocks to the block mask as a single parameter. When you do so, the parameter K is available on the mask for editing and its value will be applied to **Gain1** , **Gain2** , and **Gain3** blocks.

- 1 Select the Subsystem block.
- 2 On the **Subsystem Block** tab, in the **Mask** group, click **Create Mask/Edit Mask**.
- 3 In the Mask Editor dialog box, click the **Parameters & Dialog** tab.
- 4 In the **Controls** pane, click **Promote** .
- 5 In the **Property editor** pane, **Type options** field, click
- 6 In the **Promoted Parameter Selector** dialog box, select **Gain1** .
- 7 Select **Gain** from the **Promotable parameters** table and click the Add to promoted parameter list button. Similarly, add Gain parameter for **Gain2**.
- 8 Click **OK** .
- 9 In the Mask Editor dialog box, edit the prompt names for the **Gain** parameter. Here the Prompt used is **Common gain** .
- 10 Click **OK** to finish creating subsystem mask with many-to-one promotion.
- 11 Simulate the model. Notice that the value 4 is passed from the mask to the underlying block **Gain1**, **Gain2** , and **Gain3** . In this case, the output shows 64.

Control Masks Programmatically

Simulink® defines a set of parameters that help in setting and editing masks. To set and edit a mask from the MATLAB® command line, you can use `Simulink.Mask` and `Simulink.MaskParameter` class methods. You can also use the `get_param` and `set_param` functions to set and edit masks. However, since these functions use delimiters that do not support Unicode® (Non-English) characters it is recommended that you use methods of the `Simulink.Mask` and `Simulink.MaskParameter` class methods to control masks.

Use `Simulink.Mask` and `Simulink.MaskParameter`

Use methods of `Simulink.Mask` and `Simulink.MaskParameter` classes to perform the following mask operations:

- Create, copy, and delete masks
- Create, edit, and delete mask parameters
- Determine the block that owns the mask
- Get workspace variables defined for a mask
- In this example the `Simulink.Mask.create` method is used to create a block mask:

```
new_system('mask_example');
add_block('built-in/subsystem','mask_example/subsystem');
save_system;
open_system('mask_example');
maskObj = Simulink.Mask.create(gcf);
```

In this example the mask object is assigned to variable `maskObj` using the `Simulink.Mask.get` method:

```
maskObj = Simulink.Mask.get(gcf);
maskObj
```

```
maskObj =
  Mask with properties:
      Type: ''
  Description: ''
      Help: ''
 Initialization: ''
 SelfModifiable: 'off'
   ImageFile: ''
      Display: ''
   IconFrame: 'on'
   IconOpaque: 'opaque'
 RunInitForIconRedraw: 'analyze'
   IconRotate: 'none'
   PortRotate: 'default'
   IconUnits: 'autoscale'
   Parameters: [0x0 Simulink.MaskParameter]
 ParameterConstraints: [0x0 Simulink.Mask.Constraints]
 CrossParameterConstraints: [0x0 Simulink.Mask.CrossParameterConstraints]
      BaseMask: [0x0 Simulink.Mask]
```

For examples of other mask operations, like creating and editing mask parameters and copying and deleting masks see `Simulink.Mask` and `Simulink.MaskParameter`.

Use `get_param` and `set_param`

The `set_param` and `get_param` functions have parameters for setting and controlling the mask. You can use these functions to set the mask of any block in the model or library based on a value passed from the MATLAB command line:

```
set_param(gcb, 'MaskStyleString', 'edit,edit', ...
'MaskVariables', 'maskparameter1=@1;maskparameter2=&2;', ...
'MaskPromptString', 'Mask Parameter 1:|Mask Parameter 2:', ...
'MaskValues', {'1', '2'});
get_param(gcb, 'MaskStyleString');
set_param(gcb, 'MaskStyles', {'edit', 'edit'}, 'MaskVariables', ...
'maskparameter1=@1;maskparameter2=&2;', 'MaskPrompts', ...
{'Mask Parameter 1:', 'Mask Parameter 2:'}, ...
'MaskValueString', '1|2');
get_param(gcb, 'MaskStyles');
```

where

- | separates individual character vector values for the mask parameters.
- @ indicates that the parameter field is evaluated.
- & indicates that the parameter field is not evaluated but assigned as a character vector.

Note

- When you use `get_param` to get the Value of a mask parameter, Simulink returns the value that was last applied using the mask dialog. Values that you have entered into the mask dialog box but not applied are not reflected when you use the `get_param` command.
- To specify the value of a mask parameter programmatically, it is recommended to use `set_param` command on the **mask parameter** instead of using `set_param` on **MaskValues**.

To control the mask properties programmatically for a release before R2014a, see Mask Parameters.

Restrictions Using `set_param` and Mask Object APIs on Linked Blocks

Simulink imposes certain constraints while modifying the mask parameters using `set_param` and mask object APIs on linked blocks. On a non-self-modifiable linked block, you can change the properties of a mask parameter such as Value, Visible, and Enable. On a self-modifiable linked block, you can change few other properties in addition to Value, Visible, and Enable.

Programmatically Create Mask Parameters and Dialogs

This example shows how to create this simple mask dialog, add controls to the dialog, and change the properties of the controls.

Step 1: Create the mask for a block you selected in the model.

Step 2: To customize the dialog and to use tabs instead of the default group, remove the **Parameters** group box.

```
maskObj.removeDialogControl('ParameterGroupVar');
open_system('mask_example/subsystem');
```

Simulink preserves the child dialog controls– the two check boxes in this example– even when you delete the ParametersGroupVargroup surrounding them. These controls are parameters, that cannot be deleted using dialog control methods.

You can delete parameters using methods such as `removeAllParameters`, which belongs to the `Simulink.Mask` class.

Step 3: Create a tab container and get its handle.

```
tabgroup = maskObj.addDialogControl('tabcontainer','tabgroup');
```

Step 4: Create tabs within this tab container.

```
tab1 = tabgroup.addDialogControl('tab','tab1');
tab1.Prompt = 'First';
maskObj.addParameter('Type','checkbox','Prompt','Option 1',...
    'Name','option1','Container','tab1');
maskObj.addParameter('Type','checkbox','Prompt','Option 2',...
    'Name','option2','Container','tab1');
tab2 = tabgroup.addDialogControl('tab','tab2');
tab2.Prompt = 'Second';
tab3 = tabgroup.addDialogControl('tab','tab3');
tab3.Prompt = 'Third (invisible)';
```

Make the third tab invisible.

```
tab3.Visible = 'off';
tab3
```

```
tab3 =
  Tab with properties:
      Name: 'tab3'
      Prompt: 'Third (invisible)'
      Enabled: 'on'
      Visible: 'off'
      AlignPrompts: 'off'
      DialogControls: [0x0 Simulink.dialog.Control]
```

You can change the location and other properties of the parameters on the dialog by using the `Simulink.dialog.Control` commands.

For example, to change the dialog layout options, consider a Gain block with a Popup parameter named Parameter2 added. To set the dialog layout options of the parameter, you can use an instance of `Simulink.dialog.parameter.Popup` class. The following code shows how to set the prompt location in dialog layout:

```
add_block('built-in/gain','mask_example/gain2');
maskobj = Simulink.Mask.create(gcf);
set_param(gcf,'MaskStyleString','popup',...
'MaskVariables','maskparameter2=&2;',...
'MaskPromptString','Mask Parameter 2:');
a = Simulink.Mask.get('mask_example/gain2');
d = a.Parameters(1).DialogControl;
d
d =
  Popup with properties:
```

```
        Name: 'Parameter1'  
    PromptLocation: 'left'  
        Row: 'new'  
HorizontalStretch: 'on'  
        Tooltip: ''
```

Now, to set the `PromptLocation` property, use the command:

```
d.PromptLocation = 'left';
```

This sets the `PromptLocation` as 'left'. The available values are 'left' and 'top'. The output confirms the change of the `PromptLocation` property value to left:

```
d  
  
d =  
  Popup with properties:  
  
        Name: 'Parameter1'  
    PromptLocation: 'left'  
        Row: 'new'  
HorizontalStretch: 'on'  
        Tooltip: ''
```

```
save_system;
```

For more information on dialog controls and their properties, see `Simulink.dialog.Control`.

- “Initialize Mask” on page 39-20

Pass Values to Blocks Under the Mask

A masked block can pass values to the block parameters under the mask. The underlying blocks use the passed values during simulation to execute the block logic.

A masked block has variables associated with mask parameters. These variables are stored in the mask workspace for a model and can correspond to a block parameter under the mask. When such a block is evaluated, the block variables look for matching values in the mask workspace to get a value.

The mapping of variables from the mask workspace to the base workspace must be correct. A correct mapping ensures that the right block variable is assigned the value that is passed from the mask.

Use any of these options to pass values to blocks under the mask:

- Parameter promotion (recommended)
- Mask initialization
- Referencing block parameters using variable names (For the Edit Parameter only)

Parameter Promotion

When you promote a block parameter to its mask, the block parameter becomes accessible from the mask dialog box, allowing you to pass a value for the block parameter. Parameter promotion ensures correct mapping of parameter values and is a recommended way to pass values to the block from the mask dialog box. Note that, when you promote parameters of an in-built block, the internal callbacks associated with these parameters are also inherited in the new parameter. For more information on promoting a parameter, see “Promote Parameter to Mask” on page 39-23.

Mask Initialization

You can use MATLAB code in the Initialization pane of the Mask Editor to assign or pass values to the block parameters under the mask. You can assign a fixed value to a block parameter, specify an acceptable range for the input values, or specify a value for the child block. For more information, see “Initialize Mask” on page 39-20.

Referencing Block Parameters Using Variable Names

You can add an Edit parameter to the mask dialog box and pass values to the block parameters through it. The values that you provide for the Edit parameter in the mask dialog box automatically becomes associated with the block parameter, by using the techniques described in “Symbol Resolution” on page 68-128.

Consider the model `masking_example`, which contains a masked Subsystem block and governs the equation $y = mx + b$. Here, m and b are variables controlling the slope and intercept of the equation and are associated with the Gain and the Constant block, respectively.

The variables m and b are assigned to the mask parameters **Slope** and **Intercept**, respectively, as parameter names in the Mask Editor.

When you type values for **Slope** and **Intercept** in the mask dialog box, these values are internally assigned to the variables m and b . When the model is simulated, the Gain block and the Constant block search for numeric values of m and b and apply them to resolve the equation $y = mx + b$.

Mask Linked Blocks

In this section...

“Guidelines for Mask Parameters” on page 39-36

“Mask Behavior for Masked, Linked Blocks” on page 39-36

“Mask a Linked Block” on page 39-37

Simulink libraries can contain blocks that have masks. An example of this type of block is the Ramp block. These blocks become library links when copied to a model or another library. You can add a mask on this linked block. If this linked block is in a library and copied again, you can add another mask to this new linked block thus creating a stack of masks. Masking linked blocks allows you to add a custom interface to the link blocks similar to other Simulink blocks.

You can also apply a mask to a block, then include the block in a library. Masking a block that is later included in a library requires no special provisions. For more information, see “Create Custom Library” on page 41-2.

The block mask that is present as part of the library is the base mask. A derived mask is the one created on top of the base mask.

For example, in the figure, Library A contains Block A, which has a Mask A. Block A is copied to Library B, and Mask B is added to it. When Block A is copied to Library B, a library link from Library B to Library A is created.

Block B is then copied to a model, and Mask C is added to it. This creates a library link from Block C to Library B. Block C now has Mask A, Mask B, and Mask C. Mask C is the derived mask and Mask B is the base mask.

For Block C:

- Mask parameter names are unique in the stack.
- You can set mask parameters for Mask B and Mask C.

- Mask B and Mask C inherit `MaskType` and `MaskSelfModifiable` parameters from Mask A.
- Mask initialization code for Mask C executes first, followed by Mask B and Mask A.
- Variables are resolved starting from the mask immediately above the current mask in the stack. If the current mask is the top mask, it follows the regular variable resolution rules.

Creating or changing a library block mask changes the block interface in all models that access the block using a library reference, but has no effect on instances of the block that exist as separate copies.

To view related example, see [Use self-modifying library masks](#).

Guidelines for Mask Parameters

- You cannot use same names for the mask parameters. The exception is the `Promote` type mask parameter, for which the name is inherited and is the same as that of the parameter promoted to it.
- You cannot set mask parameters for masks below the base mask. Mask parameters for masks below the base mask are inherited from the library.

Mask Behavior for Masked, Linked Blocks

The following are some of the behaviors that are important to understand about masked, linked blocks.

- The `MaskType` and the `MaskSelfModifiable` parameters are inherited from the base mask.
- The mask display code for the derived mask executes first, followed by the display code for the masks below it until we come across a mask whose `MaskIconFrame` parameter is set to `opaque`.
- The mask initialization code for the derived mask executes first, followed by the initialization code for the masks below it.
- Variables are resolved starting from the mask immediately above the current mask in the stack. If the current mask is the top mask, the regular variable resolution rules apply.
- When you save a Simulink model or library containing a block with multiple masks, using **Save > Export Model to > Previous Version** on the **Simulation** tab, the `SourceBlock` parameter is modified to point to the library block having the bottom-most mask.
- The following occurs when you disable, break, or reestablish links to libraries:
 - If you disable the link to the library block, the entire mask hierarchy is saved to the model file so that the block can act as a standalone block.
 - If you break the link to the library block, the block becomes a standalone block.
 - If you reestablish the link after disabling by doing a restore, all changes to the mask are discarded. If you mask subsystems, you must reestablish the link after disabling by doing a push. When you do a push, subsystem changes are pushed to the library block and top mask changes are pushed to the immediate library.

Mask a Linked Block

Step 1: Create Custom Library with Masked Linked Block

- 1 In the **Simulink Library Browser**, click the arrow next to  and select **New Library**.
- 2 Open the Ramp block in the Library editor window.
- 3 Select the Ramp block and on the **Block** tab, in the **Mask** group, click **Create Mask**.

The **Mask Editor** opens.

- 4 In the **Icon drawing commands** section of the **Icons & Ports** pane, type:

```
plot ([0:10],[0,1:10])
```

- 5 In the **Parameter & Dialog** pane, select  **Promote** to promote the Slope and Initial Output parameters.
- 6 Click **OK**.
- 7 Rename the block to Derived Ramp block.

Step 2: Add a Mask to the Masked, Link Block

- 1 In the **Simulink Library Browser**, click the arrow next to  and select **New Model**. The Model editor window opens.
- 2 Drag the Derived Ramp block from the Library editor to the Model editor.

The Derived Ramp block in the model has multiple masks on it. You can set parameters of the derived mask.

Step 3: View Masks Below the Top Mask

- Right-click the Derived Ramp block in the model and select **Mask > View Base Mask**. This opens the **Mask Editor** displaying the base mask definition.

Dynamic Mask Dialog Box

In this section...

- “Show Parameter” on page 39-38
- “Enable Parameter” on page 39-38
- “Create Dynamic Mask Dialog Box” on page 39-38
- “Set Up Nested Masked Block Parameters” on page 39-40

You can create dialogs for masked blocks whose appearance changes in response to user input. Features of masked dialog boxes that can change in this way include:

- Visibility of parameter controls — Changing a parameter can cause the control for another parameter to appear or disappear. The dialog expands or shrinks when a control appears or disappears, respectively.
- Enabled state of parameter controls — Changing a parameter can cause the control for another parameter to be enabled or disabled for input. A disabled control is grayed to indicate visually that it is disabled.
- Parameter values — Changing a mask dialog box parameter can cause related mask dialog box parameters to be set to appropriate values.

Note Mask parameter addition, deletion, or modification is restricted from mask callback.

Creating a dynamic masked dialog box entails using the Mask Editor with the `set_param` command. Specifically, you use the Mask Editor to define parameters of the dialog box, both static and dynamic. For each dynamic parameter, you enter a callback function that defines how the dialog box responds to changes to that parameter (see “Execute Callback Code” on page 39-15). The callback function can in turn use the `set_param` command to set mask parameters that affect the appearance and settings of other controls on the dialog box (see “Create Dynamic Mask Dialog Box” on page 39-38). Finally, you save the model or library containing the masked subsystem to complete the creation of the dynamic masked dialog box.

To view related example, see [Create dynamic mask dialog boxes](#).

Show Parameter

The selected parameter appears on the mask dialog box only if this option is checked (the default).

Enable Parameter

Clearing this option grays the prompt of the selected parameter and disables the edit control of the prompt.

Create Dynamic Mask Dialog Box

This example shows how to create a mask dialog blocks whose appearance changes in response to your input.

You can set two parameters using this mask dialog box. The first parameter is a popup menu through which you select one of three gain values: 2, 5, or User-defined. Depending on the value that you select in this popup menu, an edit field for specifying the gain appears or disappears.

- 1 Select a subsystem and on the **Subsystem Block** tab, in the **Mask** group, click **Create Mask**.
- 2 Select the **Parameters & Dialog** pane on the Mask Editor.
- 3 Drag and drop a **Popup** parameter and select it in the **Dialog box** pane.

- a In the **Prompt** field, enter Gain.
- b In the **Name** field, enter gainpopup.
- c In the Property editor pane, clear **Evaluate** so that Simulink uses the literal values you specify for the popup.
- d In the **Type options** field, click the **Edit** button to enter these three values in the Popup Options dialog box:

```
2
5
User-defined
```

- 4 Enter this code in the **Dialog callback** field:

```
% Get the mask parameter values. This is a cell
% array of character vectors.
maskStr = get_param(gcb,'gainpopup');

% The pop-up menu is the first mask parameter.
% Check the value selected in the pop-up
if strcmp(maskStr(1),'U'),

    % Set the visibility of both parameters on when
    % User-defined is selected in the pop-up.

    set_param(gcb,'MaskVisibilities',{'on';'on'}),

else

    % Turn off the visibility of the Value field
    % when User-defined is not selected.

    set_param(gcb,'MaskVisibilities',{'on';'off'}),

    % Set the character vector in the Values field equal to the
    % character vector selected in the Gain pop-up menu.

    %maskStr{2}=maskStr{1};
    set_param(gcb,'editvalue',maskStr);
end
```

- 5 Drag and drop an **Edit** parameter and select it in the **Dialog box** pane.
 - a In the **Prompt** field, enter Value.
 - b In the **Name** field, enter editvalue.
 - c In the Property editor pane, clear **Visible** so that Simulink turns off the visibility of this property by default.
- 6 Click **Apply**.

- 7 To open the mask dialog box, double-click the masked subsystem.

If you select 2 or 5 as the **Gain**, Simulink hides the **Value**. If you select **User-defined** as the **Gain** the **Value** is visible.

Set Up Nested Masked Block Parameters

If lower-level masked subsystems reference symbols defined by higher-level masked subsystems and you try to set parameters of blocks in lower-level masked subsystems, unresolved symbol errors can occur. Therefore, avoid using `set_param` commands to set parameters of blocks residing in masked subsystems that reside in the masked subsystem being initialized. Trying if lower-level masked subsystems reference symbols defined by higher-level masked subsystems.

Suppose, for example, a masked subsystem A contains masked subsystem B, which contains Gain block C, whose Gain parameter references a variable defined by B. Suppose also that subsystem A's initialization code contains this command:

```
set_param([gcb '/B/C'], 'SampleTime', '-1');
```

Simulating or updating a model containing A causes an unresolved symbol error.

Dynamic Masked Subsystem

In this section...

“Allow Library Block to Modify Its Contents” on page 39-41

“Create Self-Modifying Masks for Library Blocks” on page 39-41

“Passing Mask Parameter Values from Parent Subsystem to Child Block” on page 39-44

Allow Library Block to Modify Its Contents

This check box is enabled only if the masked subsystem resides in a library. Checking this option allows the block initialization code to modify the contents of the masked subsystem (that is, it lets the code add or delete blocks and set the parameters of those blocks). Otherwise, an error is generated when a masked library block tries to modify its contents in any way. To set this option at the MATLAB prompt, select the self-modifying block and enter the following command.

```
set_param(gcf, 'MaskSelfModifiable', 'on');
```

Then save the block.

Create Self-Modifying Masks for Library Blocks

You can create masked library blocks that can modify their structural contents. These self-modifying masks allow you to:

- Modify the contents of a masked subsystem based on parameters in the mask dialog box or when the subsystem is initially dragged from the library into a new model.
- Vary the number of ports on a multiport S-Function block that resides in a library.

Simulink runs the mask-initialization code for a self-modifiable library block when you load the block. If the mask-initialization code controls the number of input/output ports for a block, mark the block as self-modifiable. Otherwise, the mask-initialization code will not execute and will not set the right number of ports, which will disconnect the block.

Creating Self-Modifying Masks Using the Mask Editor

To create a self-modifying mask using the Mask Editor:

- 1 Unlock the library (see “Lock and Unlock Libraries” on page 41-6).
- 2 Select the block in the library.
- 3 On the **Block** tab, in the **Mask** group, click **Edit Mask**. The Mask Editor opens.
- 4 In the Mask Editor **Initialization** pane, select the **Allow library block to modify its contents** option.
- 5 Enter the code that modifies the masked subsystem in the mask **Initialization** pane.

Do not enter code that structurally modifies the masked subsystem in a dialog parameter callback (see “Add Mask Code” on page 39-14). Doing so triggers an error when you edit the parameter.

- 6 Click **Apply** to apply the change or **OK** to apply the change and close the Mask Editor.

- 7 Lock the library.

Creating Self-Modifying Masks from the Command Line

To create a self-modifying mask from the command line:

- 1 Unlock the library using the following command:

```
set_param(gcs, 'Lock', 'off')
```

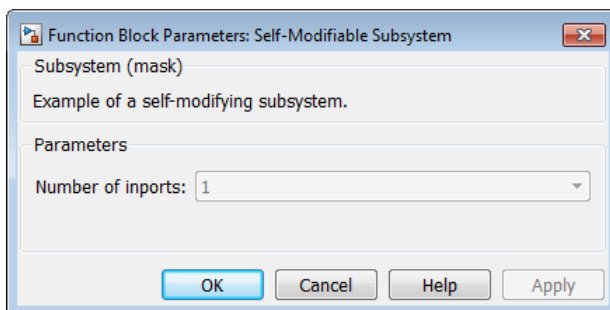

- 2 Specify that the block is self-modifying by using the following command:

```
set_param(block_name, 'MaskSelfModifiable', 'on')
```

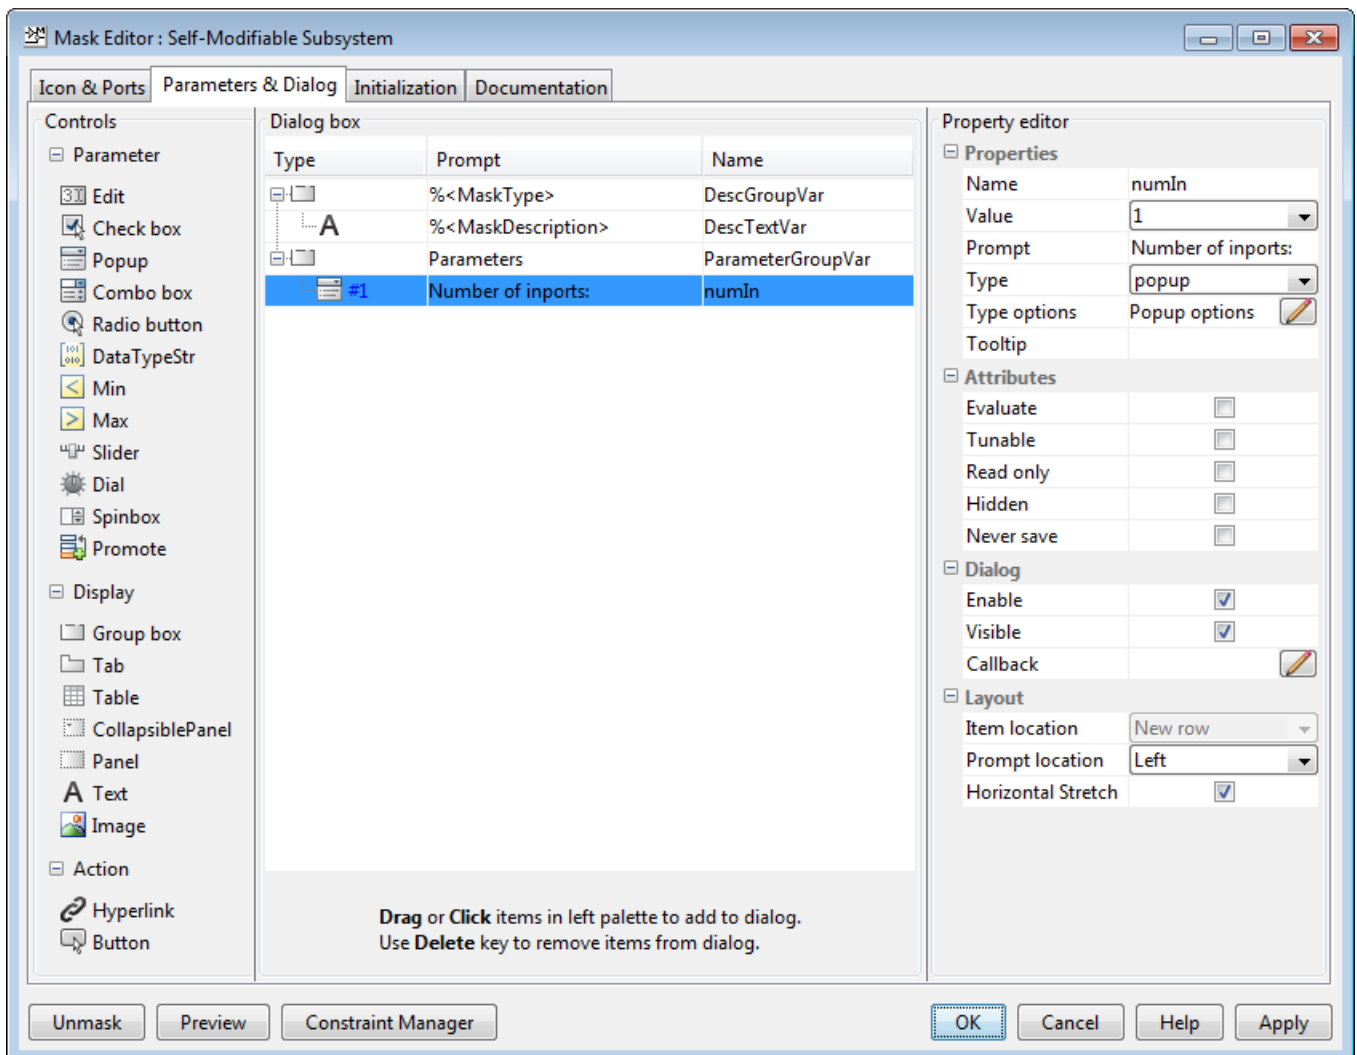

where `block_name` is the full path to the block in the library.

Create Self-Modifying Mask

The library `selfModifying_example` contains a masked subsystem that modifies its number of input ports based on a selection made in the subsystem mask dialog box.

- 1 In the Library window, on the **Library** tab, click **Locked Library** to unlock the library.
- 2 On the **Subsystem Block** tab, in the **Mask** group, click **Edit Mask**. The Mask Editor opens.
- 3 The Mask Editor **Parameters & Dialog** pane defines a parameter `numIn` that stores the value for the **Number of inports** option. This mask dialog box callback adds or removes Input ports inside the masked subsystem based on the selection made in the **Number of inports** list.

- To allow the dialog box callback to function properly, the **Allow library block to modify its contents** option on the Mask Editor **Initialization** pane is selected. If this option is not selected, copy of the library block could not modify their structural contents. Also, changing the selection in the **Number of inports** list would produce an error.

Passing Mask Parameter Values from Parent Subsystem to Child Block

You can pass mask parameter values from a parent subsystem to a child block in three ways:

- Using parameter promotion.
- Using the mask initialization code. This is done by using the `set_param` command on the child block.
- Having the child block parameters reference the parent mask parameter name. This is applicable only for the edit parameters.

Debug Masks That Use MATLAB Code

In this section...
“Code Written in Mask Editor” on page 39-46
“Code Written Using MATLAB Editor/Debugger” on page 39-46

Code Written in Mask Editor

Debug initialization commands and parameter callbacks entered directly into the Mask Editor by:

- Removing the terminating semicolon from a command to echo its results to the MATLAB Command Window.
- Placing a keyboard command in the code to stop execution and give control to the keyboard.

Tip To stop debugging the mask initialization callback code when an error is encountered, use the command `dbstop if caught error`.

Code Written Using MATLAB Editor/Debugger

Note You cannot debug icon drawing commands using the MATLAB Editor/Debugger. For information on icon drawing commands syntax, see “Icon drawing commands”.

Debug initialization commands and parameter callbacks written in files using the MATLAB Editor/Debugger in the same way that you would with any other MATLAB program file.

When debugging initialization commands, you can view the contents of the mask workspace. However, when debugging parameter callbacks, you can only access the base workspace of the block. If you need the value of a mask parameter, use `get_param`.

Introduction to System Mask

A model consists of multiple blocks, with each block containing its own parameter and block dialog box. Simulink enables you to mask a model. By masking a model you encapsulate the model to have its own mask parameter dialog box. You can customize the mask parameter dialog box. When you mask a model, the model arguments become the mask parameters. Referencing a masked model helps in having a better user interface for a model with ease of controlling the model parameters through the mask.

When you reference a masked model from a Model block, a mask is generated automatically on the Model block. The generated mask on the Model block is a copy of the model mask that it is referencing. You can reference a masked model from multiple Model block instances.

Consider a model that represents the DC motor equation. `Plant` in this model is a Model block that references a masked model, simplifying the user interface.

The `Plant` block contains the same mask as that of the masked model and the mask is uneditable. The mask can only be edited from the Mask Editor dialog box of the masked model.

- “Masking Fundamentals” on page 39-2

Create and Reference a Masked Model

This example shows how to mask a model and reference the masked model from the Model block.

Step 1: Define Mask Arguments

- 1 Open the model in Simulink. For example, consider a simple model containing two Gain blocks, a Constant block, and a Display block.

- 2 On the **Modeling** tab, under **Design**, click **Model Explorer > Model Workspace**.
- 3 Click **Add > MATLAB Variable**. A variable of data type `double` is created in the Model Workspace.
- 4 Select the **Argument** check box corresponding to the MATLAB variables to make it a model argument, for example, `k` and `l`.

Step 2: Create Model Mask

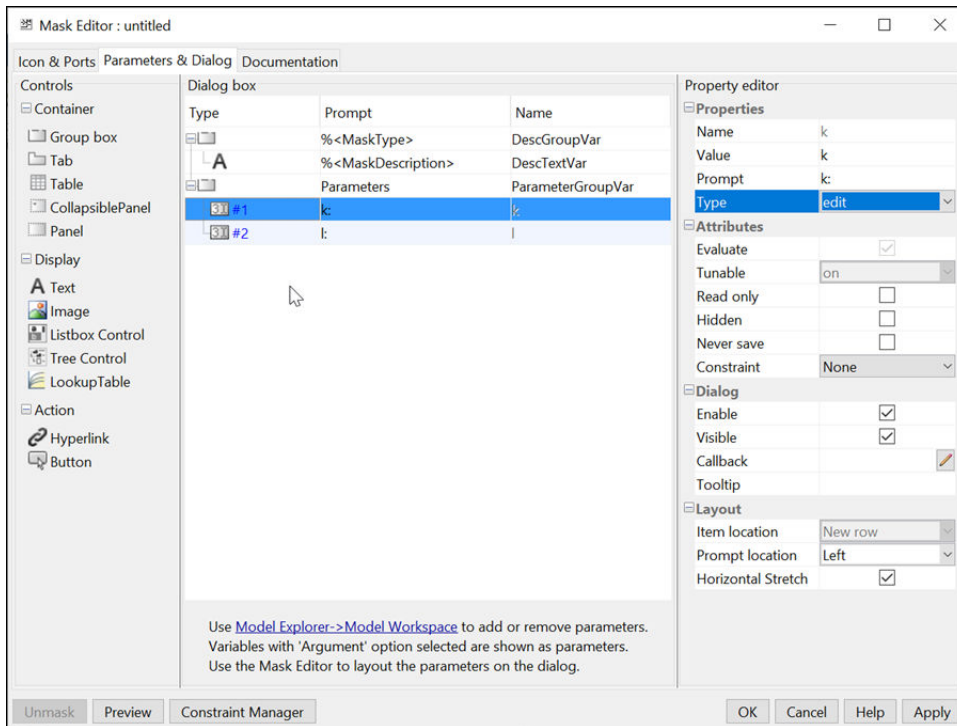

- 1 In the **Model Workspace** pane, click **Create System Mask**.

Alternatively, in Simulink, on the **Modeling** tab, under **Component**, click **Create Model Mask**, or right-click the model, and select **Mask > Create System Mask**.

The Mask Editor dialog box opens.

- 2 Click the **Parameters & Dialog** tab. The model arguments that you select in Model Explorer appear in the Mask Editor dialog box as mask parameters.

Tip Ensure that the model arguments you have selected in the Model Explorer dialog box are added as block parameters in the model. For example, the arguments *k* and *l* are passed to **Gain A** and **Gain B** blocks, respectively.

Note The Mask Editor dialog box for system mask does not contain the **Initialization** tab. Initialization code can alter the model and other model reference blocks, and thus affect the simulation results.

- 3 Select a mask parameter (*k* or *l*) on the **Dialog box** pane and edit its properties in the Property editor, as required. For example, you can change the prompt name, parameter type, value, or orientation.

By default, the **Edit** parameter type is assigned to a model mask parameter. You can change the parameter type by editing the **Type** property in the **Property editor** section.

Note

- Simulink supports only the **Edit**, **Slider**, **Dial**, and **Spinbox** parameter types for system mask.
- System mask supports all types of display and action controls.

- 4 Click **OK**. The Simulink model is now masked and contains the model arguments as the mask parameter.
- 5 Save the model.

Step 3: View System Mask Parameters

- 1 To view the mask parameter dialog box, on the **Component** tab, under **System Mask**, click **Mask Parameters**.

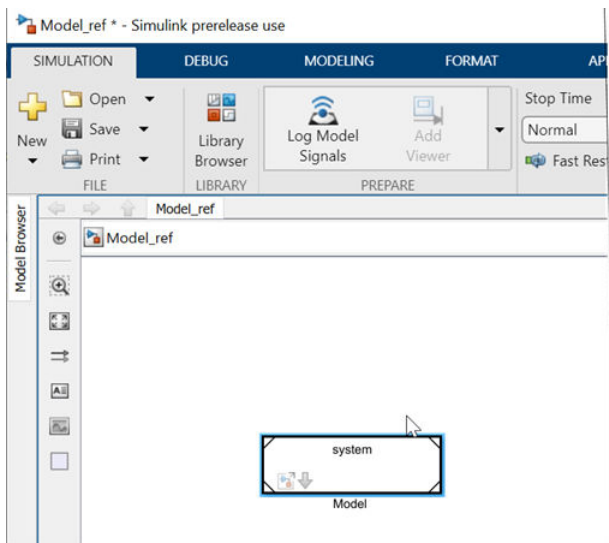

Tip To edit the system mask parameters, on the **Component** tab, under **System Mask**, click **Edit System Mask**.

- 2 Save the masked model.

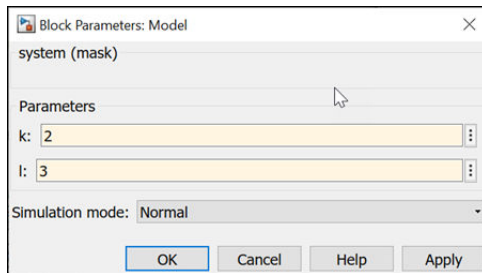

Step 4: Reference Masked Model

- 1 Open a blank model in Simulink and add the Model block from the library.
- 2 To reference the masked model from the Model block, specify the name of the masked model as the **Model name** in the **Block parameter** dialog box.

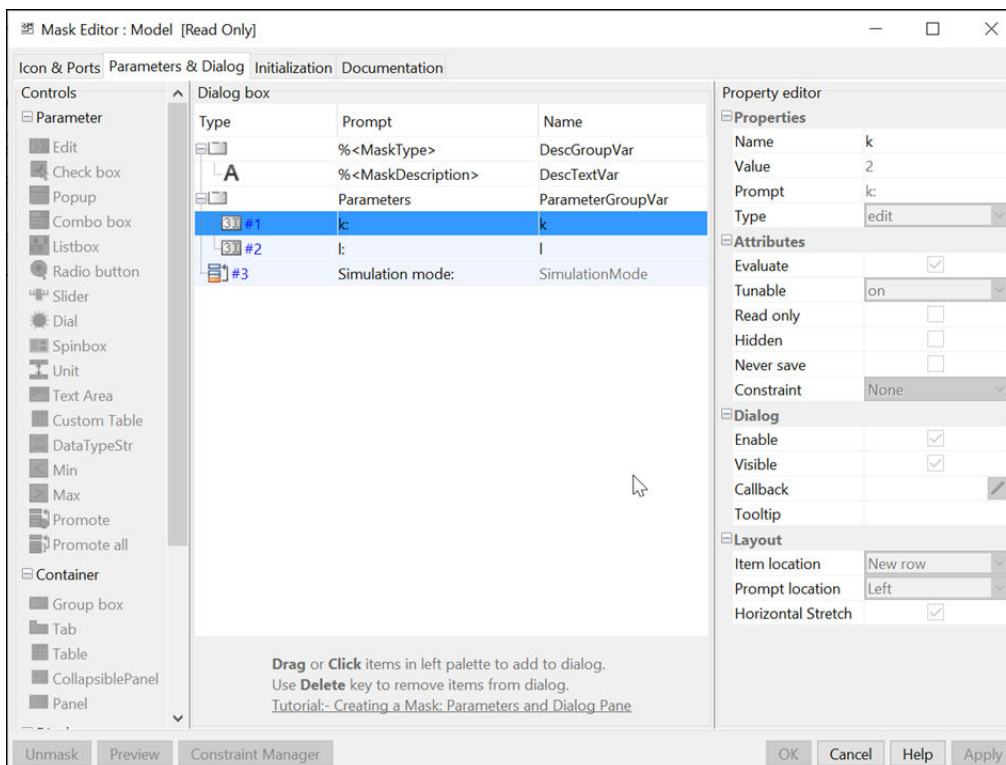

Masked model referenced by the Model block

- 3 To view the parameter dialog box of the referenced model, right-click the Model block, and in the context menu, click **Mask > Mask Parameters**. Alternatively, double-click the Model block.
- 4 Type 2 and 3 as the parameter values for k and l respectively.

- 5 Click **OK**.
- 6 Simulate the model and view the result on the display block.
- 7 To view the referenced model from the Model block, click **Mask > Look Under Mask**.
- 8 To view the mask, select the Model block and click **Mask > View Mask**. The **Mask Editor** dialog box opens. The Mask Editor dialog box displays the uneditable mask parameters of the referenced model.

More About

- “Introduction to System Mask” on page 39-47
- “Control Model Mask Programmatically” on page 39-52
- “Masking Fundamentals” on page 39-2

Control Model Mask Programmatically

Simulink defines a set of parameters to configure and edit a model mask.

Note Adding, removing, and renaming parameters on a model mask using these methods is not supported:

- `addParameter`
 - `removeParameter`
 - `removeAllParameters`
 - `MaskParameter.Name`
-

Simulink.Mask.create

Use the `Simulink.Mask.create` method to create mask on a model. The syntax to mask a model is,

- Using the model name:

```
Simulink.Mask.create(ModelName)
```

- Using the model handle

```
ModelHandle = get_param(gcs, 'Handle') %To get the model handle
Simulink.Mask.create(ModelHandle) %To create mask using model handle
```

An example follows,

```
maskObj = Simulink.Mask.create('vdp');

      Type: 'vdp'
      Description: 'The van der Pol Equation...'
      Help: ''
      Initialization: ''
      SelfModifiable: 'off'
      Display: ''
      IconFrame: 'on'
      IconOpaque: 'opaque'
      RunInitForIconRedraw: 'off'
      IconRotate: 'none'
      PortRotate: 'default'
      IconUnits: 'autoscale'
      Parameters: [0x0 Simulink.MaskParameter]
      BaseMask: [0x0 Simulink.Mask]
```

Simulink.Mask.get

Use the `Simulink.Mask.get` method to get the mask on a model as a mask object. The syntax to get the existing mask of a model is,

- Using the model name:

```
Simulink.Mask.get(ModelName)
```

- Using the model handle

```
ModelHandle = get_param(gcs,'Handle') %To get the model handle
Simulink.Mask.get(ModelHandle) %To create mask using model handle
```

An example follows:

```
maskObj = Simulink.Mask.get('vdp');

      Type: 'vdp'
      Description: 'The van der Pol Equation...'
      Help: ''
      Initialization: ''
      SelfModifiable: 'off'
      Display: ''
      IconFrame: 'on'
      IconOpaque: 'opaque'
      RunInitForIconRedraw: 'off'
      IconRotate: 'none'
      PortRotate: 'default'
      IconUnits: 'autoscale'
      Parameters: [0x0 Simulink.MaskParameter]
      BaseMask: [0x0 Simulink.Mask]
```

Note To get the model mask as a mask object in the mask callback, you can use `Simulink.Mask.get()` without passing a system name or system handle. Simulink does not require the system name (`gcb`) or the system handle (`gcs`) to query the mask object for the model mask.

Handling Large Number of Mask Parameters

The **Table** control in Mask Editor dialog box allows you to organize large number of mask parameters. The **Table** control can handle large (500+) number of mask parameters. You can include **Edit**, **Checkbox**, and **Popup** parameters within a **Table**.

You can also add large number of mask parameters in a **Table** programmatically. An example follows,

```
% Get mask object.
aMaskObj = Simulink.Mask.get(gcbh);

% Add Table controls to the mask.
aMaskObj.addDialogControl('Table', 'MyTable');

% Add parameters to table container.
for i = 1:length(Parameters) % To import values from an array called 'Parameters'
    aMaskObj.addParameter('Name', Parameters(i).Name, 'Type', Parameters(i).Type, 'Container', 'MyTable');
end
```

- “Mask Editor Overview”

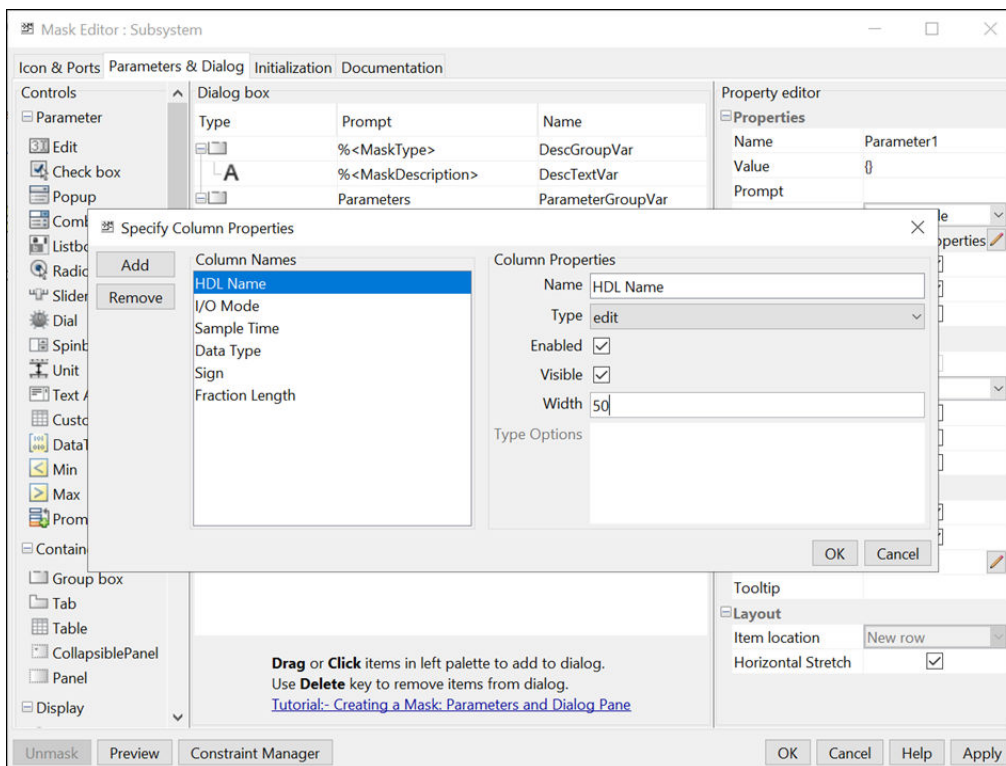

Customize Tables for Masked Blocks

The **Custom Table** parameter allows you to add customized table with structured data on a mask dialog box without writing custom codes. As a mask parameter, the custom table widget supports parameter promotion unlike the tables created using custom block dialog code.

You can provide input to the **Custom Table** parameter as a string in the cell array format.

Adding a Custom Table Parameter

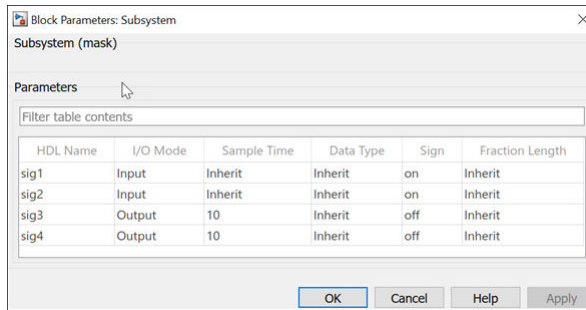

- 1 Open a Simulink model.
- 2 Select any block and on the **Block** tab, in the **Mask** group, click **Create Mask**. The Mask Editor opens.
- 3 In the **Parameters & Dialog** tab, click **Custom Table** to add it to the mask as a parameter. Specify a name and prompt for the parameter, as required.
- 4 In the **Property Editor** pane, click the Edit icon in the **Columns** field to specify the column properties like the number of columns, name of each column, and type of column. The available column types are **edit**, **checkbox**, and **popup**. Use the **Add** button to add a column and **Remove** button to remove an existing column.

- 5 Enter the values for the table in the **Value** field of **Property Editor** as a string in the cell array format. For example, if the value is given as:

```
{ 'sig1', 'Input', 'Inherit', 'Inherit', 'on', 'Inherit';...
  'sig2', 'Input', 'Inherit', 'Inherit', 'on', 'Inherit';...
  'sig3', 'Output', '10', 'Inherit', 'off', 'Inherit';...
  'sig4', 'Output', '10', 'Inherit', 'off', 'Inherit' }
```

The table created is:

HDL Name	I/O Mode	Sample Time	Data Type	Sign	Fraction Length
sig1	Input	Inherit	Inherit	on	Inherit
sig2	Input	Inherit	Inherit	on	Inherit
sig3	Output	10	Inherit	off	Inherit
sig4	Output	10	Inherit	off	Inherit

- 6 Click **Apply** to save the changes to the mask. If you want to edit the table, right click and select **Mask > Edit Mask**.

See Also

More About

- “Control Custom Table Programmatically” on page 39-57

Control Custom Table Programmatically

Use Command Line Interface to control custom tables. You can add a custom table on the mask dialog box programmatically and control its properties using command line interface. For information on creating a custom table from the Mask Editor, see “Customize Tables for Masked Blocks” on page 39-55

Add a Custom Table Parameter

You can add a custom table parameter to a mask dialog box using these commands:

```
new_system('mask_custom_table');
add_block('built-in/subsystem','mask_custom_table/subsystem');
save_system;
open_system('mask_custom_table');
% Mask Object
maskObj = Simulink.Mask.create(gcb);

% Add custom table parameter
tableParam = maskObj.addParameter( 'Name', 'myTable', 'Type', 'customtable' );
```

Add Columns to a Table

You can add columns to a custom table using the addColumn command:

```
tableControl = maskObj.getDialogControl('myTable');
tableControl.addColumn( 'Name', 'HDL Name', 'Type', 'edit' );
tableControl.addColumn( 'Name', 'I/O Mode', 'Type', 'popup', 'TypeOptions', {'Input', 'Output'} );
tableControl.addColumn( 'Name', 'Sample Time', 'Type', 'edit' );
tableControl.addColumn( 'Name', 'Data Type', 'Type', 'popup', 'TypeOptions', {'Inherit', 'FixedP'} );
tableControl.addColumn( 'Name', 'Sign', 'Type', 'checkbox' );
tableControl.addColumn( 'Name', 'Fraction Length', 'Type', 'edit' );
tableControl.Columns(2).Width=500
```

```
tableControl =
  CustomTable with properties:
      Name: 'myTable'
      Row: 'new'
  HorizontalStretch: 'on'
      Tooltip: ''
      ShowFilter: 'on'
  Multiselect: 'on'
      Sortable: 'off'
      Columns: [1x6 Simulink.Mask.TableParamColumnInfo]
```

```
% Add values to the table
tableParam.Value = join( [ '{'sig1', 'Input', 'Inherit', 'Inherit', 'on', 'Inherit';", ...
                          "'sig2', 'Input', 'Inherit', 'Inherit', 'on', 'Inherit';", ...
                          "'sig3', 'Output', '10', 'Inherit', 'off', 'Inherit';", ...
                          "'sig4', 'Output', '10', 'Inherit', 'off', 'Inherit'}" ] );
```

Set and Get Table Properties

You can fetch the value of a cell if it had a change and set a new value for a cell in the table using these commands:

```
% get values of the changed cell
open_system('mask_custom_table/subsystem')

% get value of a particular cell
tableControl.getValue( [1 3] );

% Set value for a particular cell
tableControl.setValue( [1 3], '20' );

changedCells = tableControl.getChangedCells();
```

Set and Get Cell Level Specifications

You can set and fetch the value of a particular cell in a custom table. The commands used are:

```
% set value for a particular table cell
tableControl.setTableCell( [1 3], 'Type', 'checkbox', 'Value', 'off', 'Enabled', 'off' )

% get value from a particular table cell
tableCell = tableControl.getTableCell( [1 5] )

tableCell =
  CustomTableParamCellObject with properties:
      Value: 'on'
      Type: 'checkbox'
      Enabled: 'on'
      TypeOptions: {0x1 cell}
```

Note:

- The `setTableCell` and `getTableCell` APIs must be used as part of mask parameter call backs while getting the number of rows in a table.
- The `setTableCell` and `getTableCell` APIs displays the correct result only when the dialog with the custom table parameter is opened.

Edit Rows in a Custom Table

You can insert, remove, swap, and get the value of a specific row in a custom table. The commands used are:

```
% add a row to the table
tableControl.addRow( 'sig5', 'Input', 'Inherit', 'Inherit', 'on', 'Inherit' )

% Insert a row at a specific location in the table
tableControl.insertRow( 4, 'insertSig4', 'Input', 'Inherit', 'Inherit', 'on', 'Inherit' )

% Remove a particular row
tableControl.removeRow( 2 )

% Swap two rows
tableControl.swapRows( 3, 4 )

tableControl.getSelectedRows()
```

Get and Set Table Parameter

You can use the `set_param` and `get_param` commands to set or get the values of the custom table parameter you created in a mask dialog box.

```
get_param( gcb, 'myTable' )

ans =
'{ 'sig1', 'Input', 'off', 'Inherit', 'on', 'Inherit'; 'sig3', 'Output', '10', 'Inherit', 'off',
set_param( gcb, 'myTable', "{ 'sig1', 'Input', 'Inherit', 'Inherit', 'on', 'Inherit' }" )
```

Edit Columns in a Custom Table

You can insert, remove, swap, and get the value of a specific column in a custom table. The commands used are

```
% add a column to the table
tableControl.addColumn( 'Name', 'Hardware Name', 'Type', 'edit' );
% Remove a column from the table
tableControl.removeColumn( 1 );
% Insert a column at a particular location in the table
tableControl.insertColumn( 1, 'Name', 'HDL Name', 'Type', 'edit' );
tableControl.getColumn( 4 );
```

Add Images in Masks

You can add images as icons on a Simulink mask and save them in the SLX file.

- 1 Select any masked block and on the **Block** tab, click **Add Image**.
- 2 In the **Add mask icon image** dialog box, click **Browse** to select an image from your local repository. You can also set the transparency using the **Icon transparency** field. Available options are: Opaque, Transparent, and Opaque with ports.

- 3 Select the **Store a copy of the image in the SLX file** check box if you want to store the mask image in the SLX file.

Note You cannot store mask images in an MDL file.

- 4 Click **OK** to save your changes.

Store Mask Images Programmatically

- Convert mask image to internal for one block
`Simulink.Mask.convertToInternalImage`
- Convert mask image to internal for the whole model
`Simulink.Mask.convertToInternalImages`
- Convert mask image to external for one block
`Simulink.Mask.convertToExternalImage`

Create Hierarchical List in Mask Dialog

You can use the **Tree Control** option available in the **Display** section of the Mask Editor to create the hierarchical list of data in mask dialog box.

Consider a scenario in which you want to create a parent-child hierarchy on a mask dialog box as shown here:

To do so,

- 1 Right-click a block and in the content menu click **Mask > Create Mask** or **Mask > Edit Mask**.
- 2 In the **Parameters & Dialog** pane, click **Tree Control** from the **Display** section.
- 3 In the **Property editor** section, specify these in the **Tree Items** field:

```
{ 'Node1', {'ChildNode1', 'ChildNode2'}, 'Node2', {'ChildNode1',
'ChildNode2'}, 'Node3', {'ChildNode1', 'ChildNode2'}, 'Node4',
{'ChildNode1', 'ChildNode2'}}
```

- 4 Click **Apply**.

Validating Mask Parameters Using Constraints

A mask can contain parameters that accept user input values. You can provide input values for mask parameters using the mask dialog box. Mask parameter constraints help you to create validations on a mask parameter without having to write your own validation code. Constraints ensure that the input for the mask parameter is within a specified range. For example, consider a masked Gain block. You can set a constraint where the input value must be between 1 and 10. If you provide an input that is outside the specified range, an error displays.

Create and Associate a Constraint

Launch Constraint Manager

Mask Editor contains a Constraint Manager with attributes and options to create your constraints. You can launch the Constraint Manager in two ways:

- Click the **Constraint Manager** button in Mask Editor
- While editing a parameter, select **Add New Constraint** from the Constraint drop-down menu under **Property Editor**.

Create a Constraint

You can create constraints according to your specification using the built-in attributes in the Constraint Manager. To create a constraint:

- 1 In the Constraint Manager, click **Create Constraint**.
- 2 Select attributes for the constraint in the **Rule** section. Depending on the data type selected the rule attributes change.

For more details on rule attributes, see “Rule Attributes in Constraint Manager” on page 39-66.

- 3 Click **Apply** to create the constraint.

Associate the Constraint to a Mask Parameter

Once a constraint is created, you can associate it with any **Edit** or **Combobox** parameters in the **Mask Editor**.

- 1 In the **Mask Editor**, select the parameter you want to associate a constraint with.
- 2 Select the constraint name from the **Constraint** drop-down menu.
- 3 Click **Apply** to associate the constraint.

Validate the Constraint

To check if the parameter is in adherence with the associated constraint:

- 1 Select a parameter with a constraint associated with it.
- 2 Provide the input values for the parameter in the Property editor. If the input is outside the specification for the associated constraint, an error displays.

Note The parameter callback code gets executed after validating the parameter value against the associated constraint. If the validation fails, the callback code is not executed.

Create a Cross-Parameter Constraint

Cross-parameter constraints are applied among two or more **Edit** or **Combobox** type mask parameters. You can use a cross parameter constraint when you want to specify scenarios such as, Parameter1 must be greater than Parameter2.

- 1 Launch Constraint Manager.
- 2 Click the **Cross-Parameter Constraints** tab.
- 3 Click **Create Constraint**. A new cross-parameter constraint is created with a default name (Constraint_1). You can change the constraint name.
- 4 Specify the following values for the new constraint:
 - Name - Specify a name for the constraint
 - MATLAB Expression - Specify a valid MATLAB expression. This expression is evaluated during edit time and simulation
 - Error Message - Specify the error message to be displayed when the constraint rule is not met. If no error message is specified, a default error message displays.

- 5 Click **Apply**.

Rule Attributes in Constraint Manager

Rule attributes available in the Constraint Manager to create constraints are shown in the table:

Rule Attribute	Attribute Value	Description
Data type	double, single, numeric, integer, int8, uint8, int16, uint16, int32, uint32, int64, uint64, boolean, enum, fixdt, string, half	Specify the acceptable data type of the mask parameter value. For example, if the data type specified is uint8, the acceptable value is in the range of uint8, that is, 0–255.
Complexity	real, complex	Specify if the mask parameter value can be a real or complex number.
Dimensions	scalar, row vector, column vector, 2-D matrix, n-D matrix	Specify the acceptable dimensions for the mask parameter.
Sign	positive, negative, zero	Specify if the input value can be positive, negative, or zero.
Finiteness	finite, inf, -inf, NaN	Specify the acceptable finiteness of mask parameter value.
Range	Minimum, Maximum	Specify the acceptable range of mask parameter value.
Custom Constraint	Valid MATLAB expression	Specify custom constraint for the mask parameter using a valid MATLAB expression. You can use the value token to parameterize the expression. During validation, the evaluated value of the parameter replaces the value token.
Custom Error Message	Character vector	Specify a custom error message for the custom constraint. You can specify the error message as character vector or as a message catalog ID.

- `slexMaskConstraints`
- “Shared Constraints” on page 39-68
- “Custom Constraints” on page 39-67

Custom Constraints

If the constraint you need cannot be created with the built-in attributes, you can create your custom constraint by writing your own MATLAB expression. To create a custom constraint:

- 1 Launch Constraint Manager.
- 2 Click **Create Constraint**.
- 3 In the **Custom Constraint** section, enter a valid MATLAB expression in the **MATLAB Expression** field.

You can use the `value` token to parameterize the expression. During validation, the evaluated value of the parameter replaces the `value` token. For example, if the MATLAB expression for a constraint is `value > 100` and is associated with the **Edit** type mask parameter, `Parameter1`, the MATLAB expression evaluates as `Parameter1 > 100`. This helps in assigning the constraint to multiple parameters.

For example, to set a custom constraint for a Gain block with an edit mask parameter that must accept only even numbers, in the **MATLAB Expression** enter the MATLAB command:

```
"mod(value,2) ==0"
```

- 4 Write the error message for your custom constraint in the **Error Message** field.
- 5 Click **Apply**.

Note

- Use the `value` token instead of parameter name in the MATLAB Expression. This helps to associate the same constraint with multiple parameters.
 - If you want to create a constraint that involves multiple parameters, then use cross parameter constraint instead of custom constraint.
-

- “Validating Mask Parameters Using Constraints” on page 39-62

Shared Constraints

You can create and save parameter constraints in a MAT file. You can save a constraint in a MAT file either from the Mask Editor or programmatically. Multiple block masks can share a parameter constraint saved in a MAT file. To create a shared constraint:

- 1 Launch Constraint Manager.
- 2 Click **Create Constraint**.
- 3 Create a constraint with the required attributes.
- 4 Select the **Save constraint to MAT file** check box and specify the MAT file name.
- 5 Click **Apply**.

A shared constraint is listed in the Property editor section in the format `<MATFileName>:<ConstraintName>`. You can select any available constraint as required and associate it with an **Edit** parameter.

While creating shared constraints it is recommended that you:

- Save constraints to MAT files that are in the MATLAB path.
- Provide meaningful names to constraints so that other users can understand the nature of the constraint easily.

- “Validating Mask Parameters Using Constraints” on page 39-62

Control Constraints Programmatically

You can create a custom constraint programmatically from the MATLAB command window

To create a custom constraint:

```
% Get mask constraint handle
paramConstraint = maskObj.getParameterConstraint('const1');

% Add rules to the constraint.
paramConstRule = paramConstraint.addParameterConstraintRule('CustomConstraint','mod(value,2) ==0')
```

This creates a custom constraint:

ans =

ParameterConstraintRules with properties:

```
    DataType: ''
    Dimension: {0x1 cell}
    Complexity: {0x1 cell}
        Sign: {0x1 cell}
    Finiteness: {0x1 cell}
        Minimum: ''
        Maximum: ''
    CustomConstraint: 'mod(value,2) ==0'
```

You can create and save constraints in a MAT file and load constraints from a MAT file programmatically from the MATLAB command window:

To save a constraint in a MAT file:

```
uint16Constraint = Simulink.Mask.Constraints;
uint16Constraint.Name = 'uint16Constraint';
uint16Constraint.addParameterConstraintRule('DataType', 'uint16');
save('constraintList.mat', 'uint16Constraint','-append'); % appends 'uint16Constraint'
save('constraintList.mat', 'uint16Constraint') % overwrites the MAT file with 'uint16Constraint'
```

Note It is recommended that the constraint name (for example, `uint16Constraint.Name = 'uint16Constraint'`) and the variable used for storing the constraint (for example, `uint16Constraint = Simulink.Mask.Constraints`) have the same name.

To load a constraint from a MAT file:

```
myConstraints = load('constraintList') % loads constraints into the variable 'myConstraints'
```

Define Measurement Units for Masked Blocks

Measurement units translate the amount of entities supplied to your computations. They are also crucial when diverse users using different systems of measurement are using the same equation. You can add measuring units to a Simulink model to enhance the usability and to avoid confusion while analyzing equations.

To specify measuring units for masked blocks, you can:

- Promote a `Unit` parameter from the underlying block to the mask. For more information, see “Promote Parameter to Mask” on page 39-23.
- Add a **Unit** parameter to the mask dialog box as shown in the following steps:
 - 1 Open a Simulink Model.
 - 2 Select the block to be masked and press **Ctrl+M**. The Mask Editor opens.
 - 3 In the Mask Editor, click the **Parameters & Dialog** tab.
 - 4 In the Parameters section, click **Unit**.
 - 5 Click the **Initialization** tab in the Mask Editor dialog box.
 - 6 To define the measurement unit for the **Unit** parameter, specify the initialization command by using the following syntax:

```
set_param([gcb '<blockname>'], '<unit parameter name>', get_param(gcb, '<unit parameter name>'));
```

For example, to associate the **Unit** parameter with the measuring unit of the Inport block, use:

```
set_param([gcb '/In1'], 'Unit', get_param(gcb, 'Unit'));
```

- 7 Click **Apply**, and then click **OK**. For more information, see `slexMaskParameterOptionsExample`.

Create a Custom Table in the Mask Dialog

This example shows how to create a custom table in a mask dialog. This model includes a Subsystem block with a mask on it. The mask has a callback that modifies the table content based on the values provided in the cells. The callback comes from an external supporting file. To create this table, start by adding a mask to the block or editing an existing mask.

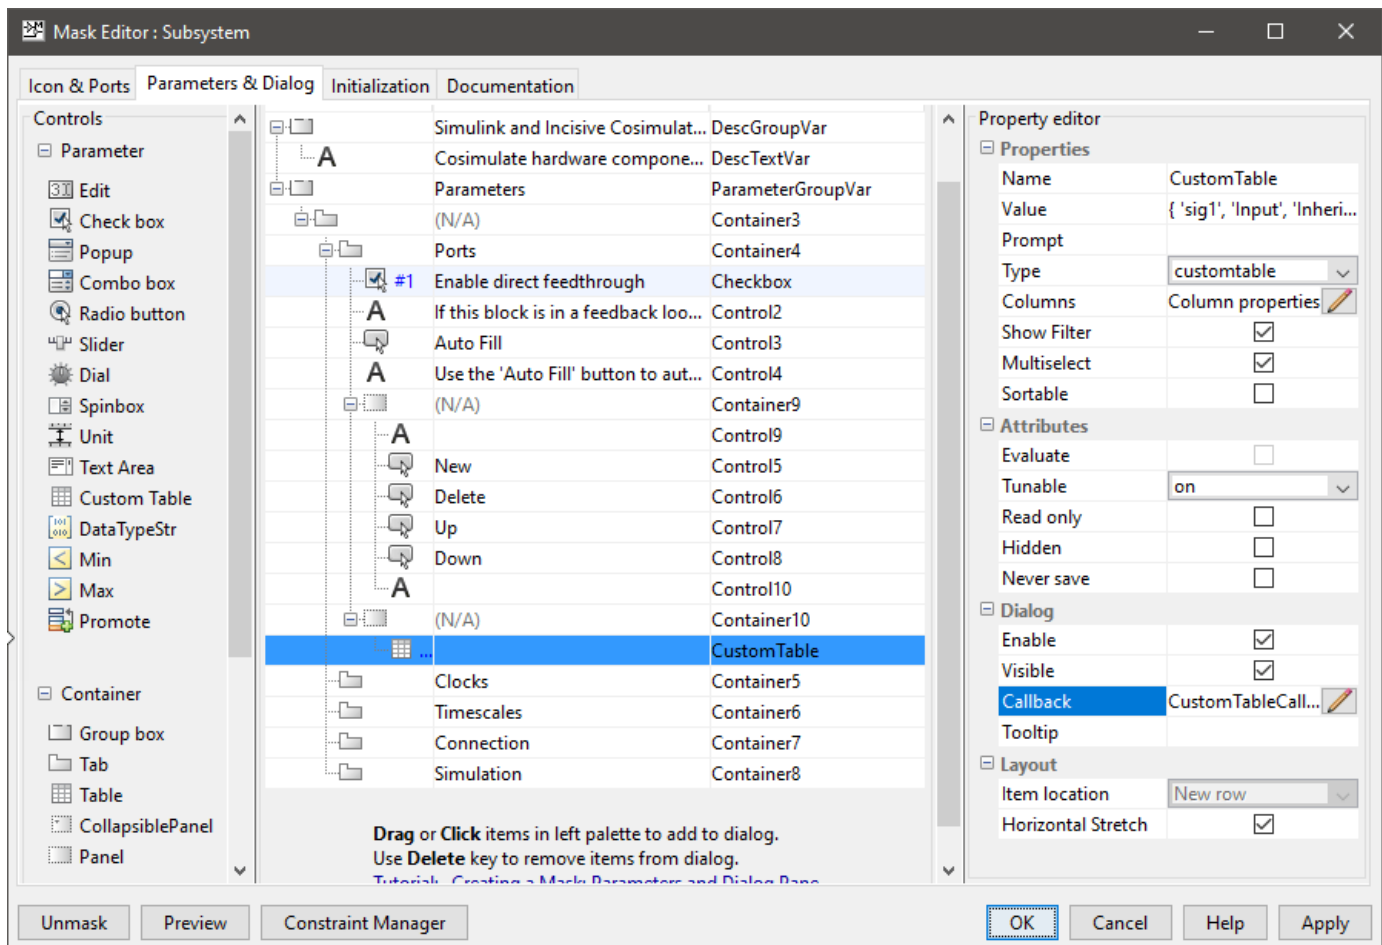

Add and Configure a Custom Table parameter

To add a Custom Table parameter, open the Mask Editor, go to the **Parameters & Dialog** tab and click **Custom Table**. Then, add values in the **Property editor** section. For this example, in the **Value** field, add:

```
{ 'sig1', 'Input', 'Inherit', 'Inherit', 'Signed', 'Inherit'; 'sig2',  
'Input', 'Inherit', 'Inherit', 'Signed', 'Inherit'; 'sig3', 'Output', '10',  
'Inherit', 'Signed', 'Inherit'; 'sig4', 'Output', '10', 'Inherit', 'Signed',  
'Inherit' }.
```

In the **Columns** field, click the Edit icon and add the name of columns. The column names used in this example are: HDL Name, I/O Mode, Sample Time, Data Type, Sign, and Fraction Length.

In the **Dialog** section, edit the **Callback** field to add your callback. The callback used in this example is from an external file named `CustomTableCallback.m`. Enter the filename in the callback field. This callback defines how the values change in a cell based on the value from other cells and columns.

Add Buttons and Options to Control the Custom Table

In this example, four buttons are added to add a new row, delete a selected row, and move a row up or down. To add the buttons, in the **Action** section click the Button parameter four times. Name the buttons as **New**, **Delete**, **Up**, and **Down**. To configure the buttons, edit the **Callback** field in the Property editor and add the appropriate callbacks. The callback used for each button is:

New

```
maskObj = Simulink.Mask.get(gcb);
tableControl = maskObj.getDialogControl( 'CustomTable' );

hdlName = 'sig';
rowIndex = tableControl.getNumberOfRows();
hdlName = strcat( 'sig', num2str( rowIndex + 1 ) );
tableControl.addRow( hdlName, 'Input', 'Inherit', 'Inherit', 'Signed', 'Inherit' )
```

Delete

```
maskObj = Simulink.Mask.get(gcb);
tableControl = maskObj.getDialogControl( 'CustomTable' );

rowIndex = tableControl.getSelectedRows();
hdlName = 'sig';
```

```
if ( ~isempty(rowIndex) )
    tableControl.removeRow( rowIndex(1) );
end
```

Up

```
maskObj = Simulink.Mask.get(gcf);
tableControl = maskObj.getDialogControl( 'CustomTable' );

rowIndex = tableControl.getSelectedRows();

if ( ~isempty(rowIndex) )
    tableControl.swapRows( rowIndex(1)-1, rowIndex(1) );
end
```

Down

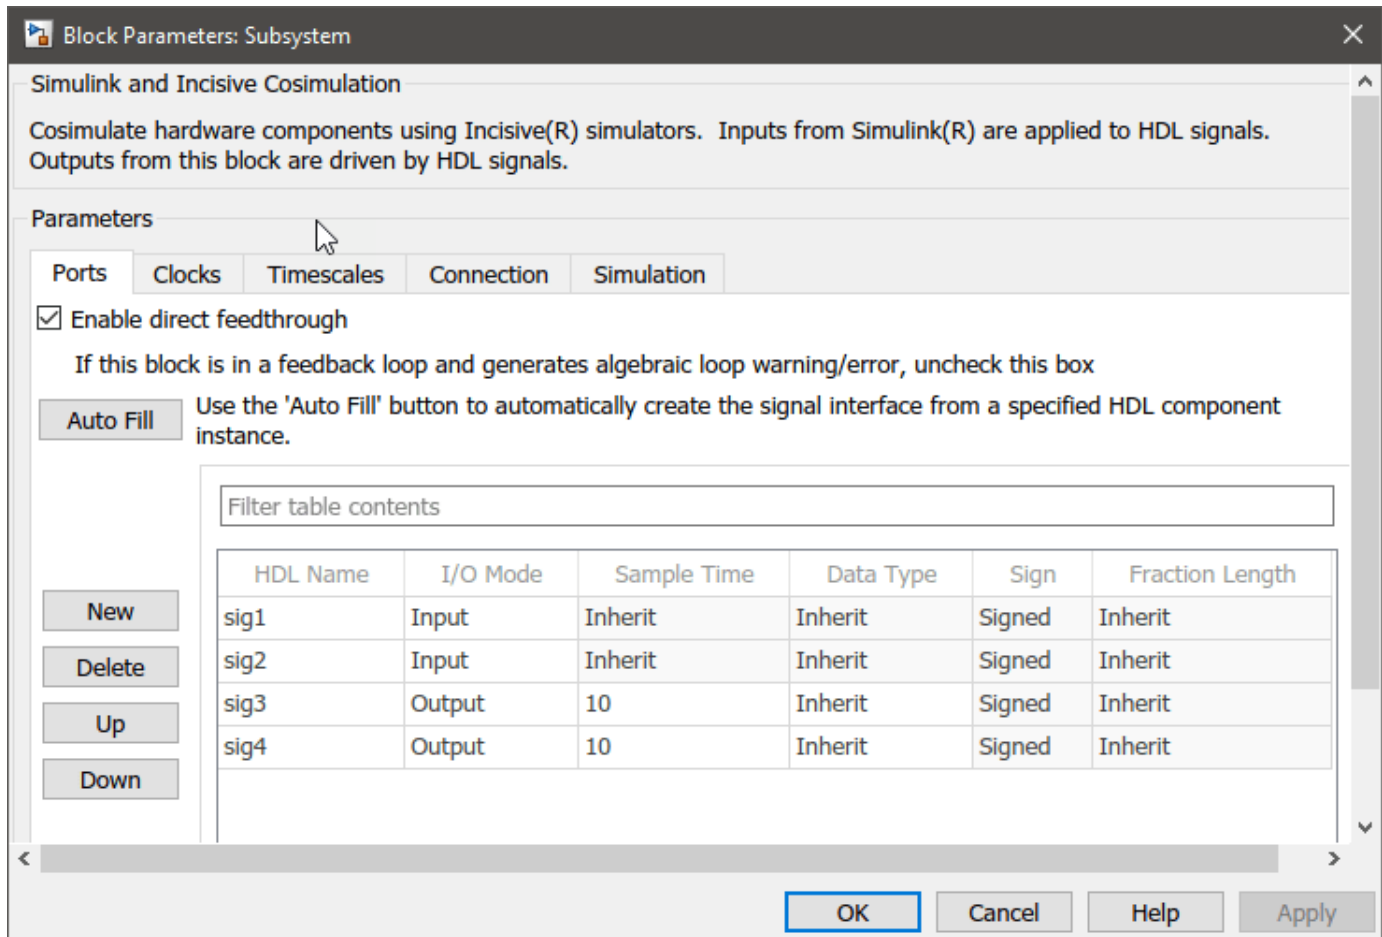

```
maskObj = Simulink.Mask.get(gcf);
tableControl = maskObj.getDialogControl( 'CustomTable' );

rowIndex = tableControl.getSelectedRows();

if ( ~isempty(rowIndex) )
    tableControl.swapRows( rowIndex(1)+1, rowIndex(1) );
end
```

In addition to these buttons, the table also has a checkbox to enable direct feedthrough and an autofill button that automatically creates the signal interface from a specified HDL component instance. To add these options, add a checkbox and a button control and add the appropriate configurations.

After adding all the values, click **OK** to save the changes. You can preview the table using the **Preview** button. This is a preview of the final table created in this example:

Create a Block Mask Icon

You can create block icons on mask using various mask drawing commands. This model contains a collection of subsystem blocks, each showing a particular mask drawing command in use. To create a mask icon on a block, you must create a mask and add the icon drawing command to the mask in the mask editor. To create a mask:

- 1 Select a **Subsystem block** . For example, the Graph as Icon block.
- 2 On the **Subsystem Block** tab, in the **Mask** group, click **Create Mask/Edit Mask**.
- 3 In the Mask Editor dialog box, click the **Icon & Ports** tab.
- 4 Enter the command in the Icon drawing commands pane on the right. You can set the Run Initialization value to On, Off or Analyze based on the dependency on mask workspace.

Plotted function as Icon

This command let you plot a graph and set it as the mask icon. Select the subsystem Graph as Icon. In the Mask Editor > Icon and Ports tab, enter **plot([10 20 30 40], [10 20 10 15])**. Run Initialization can be set to Off as there is no mask workspace dependency.

Transfer Function as Icon

This command helps to set a Transfer function as the mask icon. Select the subsystem Transfer Function as Icon. In the Mask Editor > Icon and Ports tab, enter **roots([-1], [-4 -5], 4)**. Run Initialization can be set to Off as there is no mask workspace dependency.

Color patch as Icon

This command lets you to set a color patch as mask icon. Select the subsystem Color patch as Icon. In the Mask Editor > Icon and Ports tab, enter **patch([0 10 20 30 30 0], [10 30 20 25 10 10],[1 0 0])**. Run Initialization can be set to Off as there is no mask workspace dependency.

Image as Icon

This command lets you to set a color patch as mask icon. Select the subsystem Image as Icon. In the Mask Editor > Icon and Ports tab, enter **image('maskimage.png','center')**. Run Initialization is set to On. Make sure the image is available in the current folder in MATLAB.

Contained block icon as Icon

This command lets you promote the icon of a block contained in a subsystem to the subsystem mask. Select the subsystem Promoted block Icon . In the Mask Editor > Icon and Ports tab, enter **block_icon(Assertion)**.

```
open_system('mask_icon_drawing_example');
```

Mask Icon Drawing Commands

Plotted Function as Icon

Port Label as icon

$$\frac{4(s+1)}{(s+4)(s+5)}$$

Transfer Function as Icon

Promote Block Parameters on a Mask

You can use Parameter Promotion to promote any underlying parameter of a block either to a block mask or to a subsystem mask. This model contains a subsystem that has 3 Gain blocks (**Gain1**, **Gain2**, and ***Gain3**). The variable K represents the Gain parameter for these Gain blocks. You can promote only the Gain parameter of each of these Gain blocks to the block mask as a single parameter. When you do so, the parameter K is available on the mask for editing and its value will be applied to **Gain1** , **Gain2** , and **Gain3** blocks.

- 1 Select the Subsystem block.
- 2 On the **Subsystem Block** tab, in the **Mask** group, click **Create Mask/Edit Mask**.
- 3 In the Mask Editor dialog box, click the **Parameters & Dialog** tab.
- 4 In the **Controls** pane, click **Promote** .
- 5 In the **Property editor** pane, **Type options** field, click
- 6 In the **Promoted Parameter Selector** dialog box, select **Gain1** .
- 7 Select **Gain** from the **Promotable parameters** table and click the Add to promoted parameter list button. Similarly, add Gain parameter for **Gain2**.
- 8 Click **OK** .
- 9 In the Mask Editor dialog box, edit the prompt names for the **Gain** parameter. Here the Prompt used is **Common gain** .
- 10 Click **OK** to finish creating subsystem mask with many-to-one promotion.
- 11 Simulate the model. Notice that the value 4 is passed from the mask to the underlying block **Gain1**, **Gain2** , and **Gain3** . In this case, the output shows 64.

Mask a Variant Subsystem

This example shows how to use a masked Variant Subsystem block in a Simulink model. Click the **Open Model** button located on the top right corner to view the related example model. This example model references masked library blocks.

Masking a Variants Subsystem

This model contains masked Subsystem block (MaskedSubsystem) as a linked block. The masked Subsystem block contains a masked Variant Subsystem block within. Initialization code in the Variant Subsystem block mask sets the variant choice that is passed from the Subsystem block (MaskedSubsystem). Parameter promotion is used to record the variant choice (V1 & V2) on the masked Subsystem block.

This model contains a masked Variant Subsystem (VariantSubsystem2) as a linked block. Initialization code in the mask sets the variant choice that is passed from the mask. Popup mask parameter is used to record variant choice V1 and V2.

This model contains a Subsystem block (Subsystem3) as a linked block. This block contains linked Variant Subsystem block nested within, in two levels. lv1_1 and lv1_2 are the variant choices of first level nested Variant Subsystem block and lv2_1 and lv2_2 are the variant choices of second level nested Variant Subsystem block. Popup mask parameter is used to record variant choices lv1_1, lv1_2, lv2_1, and lv2_2.

This model contains masked Subsystem block (MaskedSubsystem1) as a linked block. The masked Subsystem block contains a masked Variant Subsystem block within. Initialization code in the Variant Subsystem block mask sets the parameter value that is passed from the Subsystem block (MaskedSubsystem1). Parameter promotion is used to record the choice from the parent block on the masked Subsystem block.

Copyright 2015 - 2020 The MathWorks, Inc.

When you mask a Variant Subsystem block, you can specify the variant choice from the mask dialog box. The variant choice that you specify on the mask dialog box is applied on the underneath Variant Subsystem block.

To pass the variant choice from the mask to the Variant Subsystem block, you can either use the `set_param` command or the parameter promotion option.

Let us consider the cases described in the example model.

- Case 1: The mask parameter promotion option is used to promote the Variant Subsystem block parameter to the mask. The Variant Subsystem block is wrapped within a masked Subsystem block. Initialization code (`set_param`) is used in the Variant Subsystem block to define the variant choice which is further passed on to the mask on the Subsystem block using parameter promotion. This promoted parameter records the variant choice specified from the masked Subsystem block.
- Case 2: The Popup mask parameter is used to create the choice option on the top level masked Subsystem block. This masked Subsystem block contains a Variant Subsystem block. Initialization code (`set_param`) is used in the Variant Subsystem block to define the variant choice. The value that you specify as a variant choice from the mask dialog box (**Popup** parameter) is transferred to the underneath Variant Subsystem block to set its choices.
- Case 3: This case is similar to Case 2 with an additional layer of Variant Subsystem block in the model. Initialization code (`set_param`) in the Subsystem block is used to define the variant choice.
- Case 4: Parameter promotion is used to record the choice from the parent block on the masked Subsystem block. The masked Subsystem block contains a masked Variant Subsystem block within. Initialization code (`set_param`) in the Variant Subsystem block mask sets the parameter value that is passed from the Subsystem block (MaskedSubsystem1).

- “Initialization Function” on page 12-140

Tune Mask Popup Parameters by Referencing an External Enumeration File

You can visualize the behavior of a Simulink model under different conditions by tuning block parameter values. This example shows how to associate values with popup parameters and achieve code generation time tunability. Referencing an external enumeration file to tune a mask popup parameter allows you to:

- Associate numeric values with the popup options.
- Associate a variable with the popup parameter.
- Simulate and generate code corresponding to the selected popup option.

Consider this example where a subsystem containing a Constant block is connected to an output port.

Associate External Enumeration File to Popup Parameter

An external enumeration file can have multiple members with different display names and values. When the enumeration file is associated with a popup parameter:

- The display name of the enumeration member becomes the popup parameter option.
- The enumeration member value becomes the value assigned to the popup parameter.

In this example, numeric values are associated with pop-up options from the enumerated file `Xfactor.m`. The enumeration class of the file `Xfactor`, is derived from `Simulink.Mask.EnumerationBase`. The class has three enumeration members, `alpha`, `beta`, and `gamma`. These enumerated members have numeric values `.001`, `.0001`, and `.00001`.

```
classdef XFactor < Simulink.Mask.EnumerationBase
    enumeration
        alpha(.001, 'alpha (.001)')
        beta (.0001, 'beta (.0001)')
        gamma(.00001, 'gamma (.00001)')
    end
end
```

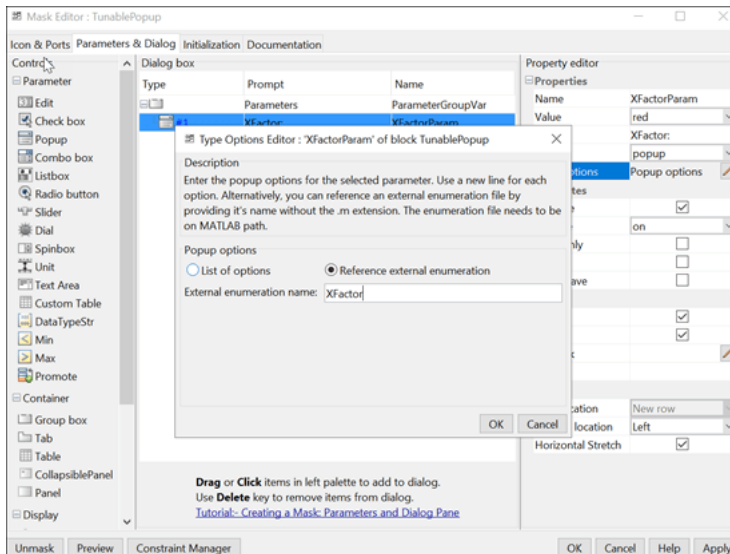

Specify datatype for numerical values associated with the enumeration member

In the generated code, the default datatype for the enumeration member is double. Alternatively, you can also specify a datatype for the enumeration members. For example, `alpha (int32(0.001), 'alpha (.001)')`. All members of the enumeration class must be of the same data type.

Associate Numeric Values to Popup Parameter Options

1. In the Mask Editor of the Tunable Popup Subsystem block, create a popup parameter named XFactorParam.
2. In the **Property editor**, select the **Reference external enumeration** option and specify the name of the enumeration class that was created in the previous step. In this example, the name of the enumeration class is Xfactor.

Note: The referencing enumeration class Xfactor must be in the MATLAB path.

Upon referencing the enumeration class file, the options for the popup parameter in the mask dialog box of the Subsystem block are populated with the display names in the enumeration file.

Reference the Popup Parameter in Child Blocks

The parameter value is evaluated as the enumeration member corresponding to the display name you select. For example, if you select `alpha (.0001)` from the Parameters drop-down, the value of XFactorParam is set to `XFactor.alpha`. During model compilation, in order to get the numeric value corresponding to an option, Simulink creates an internal array that holds the value corresponding to each option. Therefore, when you select an option, the value corresponding to the option is selected from the array.

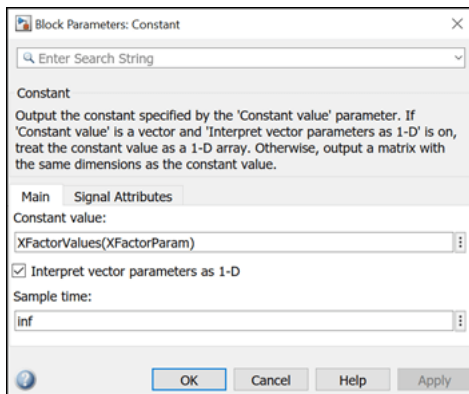

In this example, the array appears `XFactorValues = {.001, .0001, .00001}`

Note: To get the value corresponding to the selected option, use this format:

`<enumerationClassName>Values(<ParameterName>)`

enumerationClassName is the name of the enumeration class, and ParameterName is the name of the pop-up parameter that you specified in the mask editor.

In this example, the value of the **Constant** parameter inside the subsystem is set as `XFactorValues(XFactorParam)`. During model compilation, `XFactorValues(XFactorParam)` evaluates to `XFactorValues(XFactor.alpha)`, thus setting the value of the **Constant** parameter to `.001`.

You can customize a name for the array in the enumeration file as the return value of the `getValueArrayName()` function.

```
classdef XFactor < Simulink.Mask.EnumerationBase
    enumeration
        alpha(.001, 'alpha (.001)')
        beta (.0001, 'beta (.0001)')
        gamma(.00001, 'gamma (.00001)')
    end
    methods(Static)
        function valueArrayName = getValueArrayName()
            valueArrayName = 'customValueArrayName';
        end
    end
end
```

Tune Parameter During Simulation and Code Generation

Change the value of the parameter in the dialog between alpha (0.001), beta (0.0001), and gamma (0.00001) and observe that during simulation, the value corresponding to the selected option appears as the output of the simulation.

You can generate code using Simulink Coder or Embedded Coder. In the generated code:

- The value array `XFactorValues` is generated in the `modelName.c` file.

```
const real_T XFactorValues[3] = { 0.001, 0.0001, 1.0E-5 } ;
```

- Enumeration is generated in the code corresponding to the referenced enumeration file.

```
typedef enum {
XFactor_alpha = 1,                /* Default value */
XFactor_beta,
XFactor_gamma
} XFactor;
```

- The mask parameter (XFactorParam) appears in the parameter structure.

```
/* Parameters (default storage) */
struct P_slexMaskTunablePopupExample_T_ {
XFactor TunablePopup_XFactorParam; /* Mask Parameter: TunablePopup_XFactorParam
* Referenced by: '<S1>/Constant'
*/
};
```

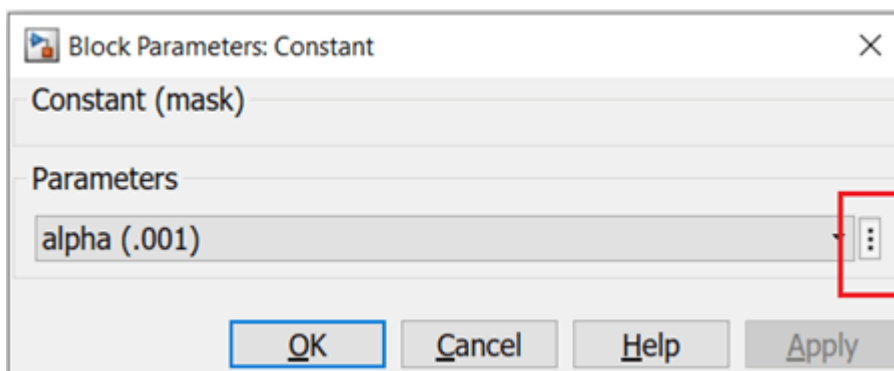

- Tunable variable XFactorParam is referenced while generating the output. You can specify different values to XFactorParam and thus tunability is achieved.

```
/* Model step function */
void slexMaskTunablePopupExample_step(void)
{
/* Output: '<Root>/Out1' incorporates:
* Constant: '<S1>/Constant'
*/
slexMaskTunablePopupExample_Y.Out1 = XFactorValues[(int32_T)
slexMaskTunablePopupExample_P.TunablePopup_XFactorParam - 1];
}
```

Create and Associate Variables Using the Mask Dialog

When the default parameter behavior in the code generation optimization is inlined, all the parameters are inlined in the generated code. To achieve tunability for a specific parameter, create a variable of type `Simulink.Parameter` with specific storage class (anything other than `Auto`) in the workspace and associate with the mask popup parameter.

1. Open the mask dialog. Click the action widget (...).

2. You can associate an existing variable with the popup parameter or create the variable in one of the available locations and associate with the popup parameter.

After associating the variable with the popup parameter, the variable appears next to the popup option.

The value of the associated variable and the pop-up value are always synchronized. For example, if you change the popup option from `alpha (.001)` to `beta (.0001)`, the `workspaceVar` is updated to `XFactor.beta`. Similarly, when you change the value of the variable, the value of the parameter reflects the change in the mask dialog.

Generate Code With the Associated Variable

The associated variable value appears in the parameter structure corresponding to the tunable popup parameter.

```
/* Block parameters (default storage) */
P_slexMaskTunablePopupExample_T slexMaskTunablePopupExample_P = {
    /* Variable: workspaceVar
     * Referenced by: '<S2>/Constant'
     */
    XFactor_alpha,
};
```

The associated variable is referenced in the step function to generate output.

```
/* Model step function */
void slexMaskTunablePopupExample_step(void)
{
    /* Outport: '<Root>/Out2' incorporates:
     * Constant: '<S2>/Constant'
     */
    slexMaskTunablePopupExample_Y.Out2 = XFactorValues[(int32_T)
        slexMaskTunablePopupExample_P.workspaceVar - 1];
}
```

Use APIs to Reference External Enumeration File

Create a type option object using this API.

```
enumObj =
Simulink.Mask.EnumerationTypeOptions(ExternalEnumerationClass,
'<enumName>')
```

Create an instance of `Simulink.Mask.EnumerationTypeOptions` to parse the information from the enumeration file into the object `enumObj`.

Example

```
>> enumObj = Simulink.Mask.EnumerationTypeOptions('ExternalEnumerationClass', 'XFactor')

enumObj =
  EnumerationTypeOptions with properties:
    ExternalEnumerationClass: 'XFactor'
    EnumerationMembers: [1*3 Simulink.Mask.EnumerationMembers]

>> enumObj.EnumerationMembers(1)

ans =
  EnumerationMembers with properties:
    MemberName: 'alpha'
    DescriptiveName: 'alpha (.001)'
    Value: 0.001
```

Associate the enum object with the **Type Options** attribute.

```
maskobj = Simulink.Mask.create(<blockName>);
maskobj.addParameter('Type', 'popup', 'TypeOptions', enumObj );
```

If a mask parameter already exists, use the these APIs.

```
maskobj = Simulink.Mask.get(<blockName>);
paramHandle = maskobj.getParameter('<parameterName>');
paramHandle.TypeOptions = enumObj
```

Use this command to associate the variable to the value of the parameter.

```
set_param(<blockName>, '<ParameterName>', 'workspaceVar')
```

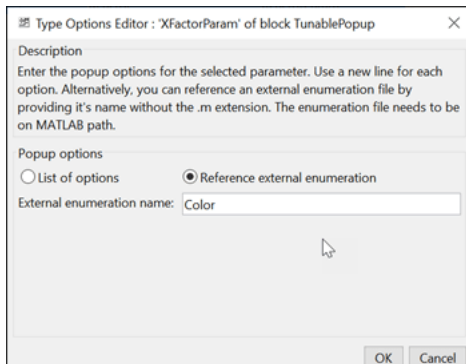

Note: Use `slResolve` to get the evaluated value of the parameter in case it is referencing a workspace variable.

Associate Enumeration File Derived from `Simulink.IntEnumType`

If you have an existing enumeration class derived from `Simulink.IntEnumType`, you can use the enumeration file to associate numeric values to the popup parameter instead of creating a new enumeration class derived from `Simulink.Mask.EnumerationBase`. To associate enumeration file derived from `Simulink.IntEnumType`, follow these steps.

```
classdef Color < Simulink.IntEnumType
  enumeration
    red(1)
    green(100)
    blue(1000)
  end
  methods(Static)
    function aOut = addClassNameToEnumNames()
      aOut = false;
    end
  end
end
```

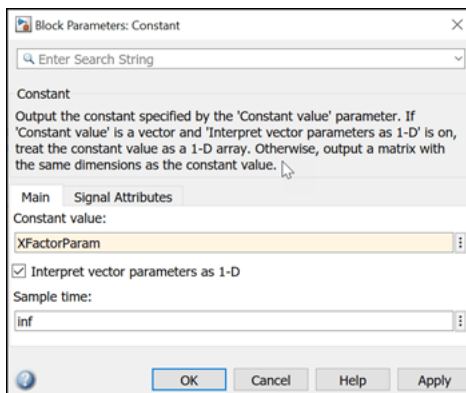

1. Specify the name of the enumeration class.

2. The popup options will be populated with enumeration members prefixed with the enumeration class name.

3. Set the **Constant** parameter value to the popup parameter XFactorParam.

`Simulink.Mask.EnumerationTypeOptions`

Visualize and Edit N-Dimensional Data Using Mask Lookup Table Control

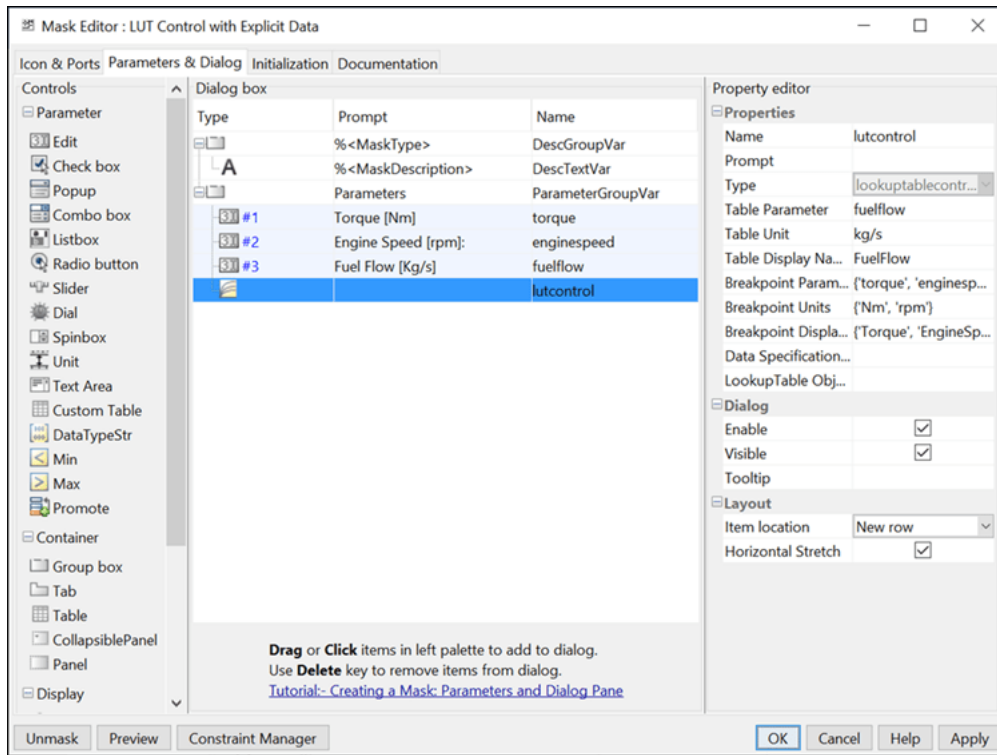

You can visualize and edit N-dimensional lookup table data in mask dialog using the lookup table control. Lookup tables approximate the functions and significantly reduce the computation time using simple lookup operations.

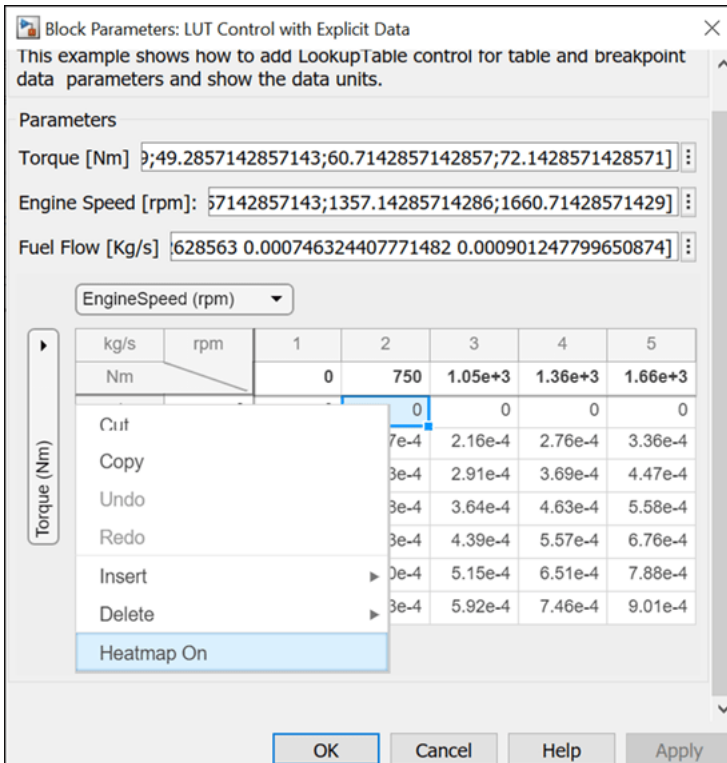

Visualize and Edit Table and Breakpoint Data Using the Lookup Table Control

Consider a scenario where the fuel flow is determined by the torque and engine Speed. To specify the data explicitly for table data and breakpoint parameters:

1. Right-click on the block, click **Edit Mask** to open the Mask Editor. In the Mask Editor go to **Parameters & Dialog** pane, create edit parameters Torque and Engine Speed for breakpoints. In the **Property editor** pane, enter the values for the breakpoints in the **Values** box.
2. Create an Edit parameter Fuel Flow for table data in the **Property editor** pane, enter the values in the **Value** box.
3. Add a lookup table control. Enter the table properties **Table Parameter**, **Table Unit**, **Table Display Name**, **Breakpoint Parameters**, **Breakpoint Units**, and **Breakpoints Display Name**. Click **OK**.

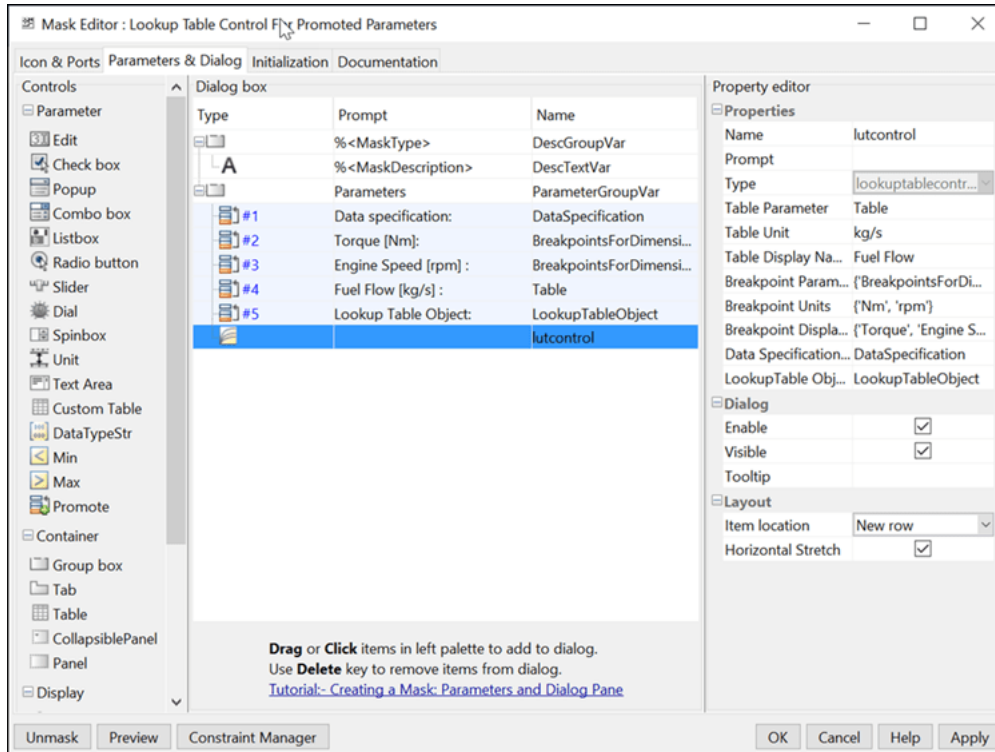

4. Double-click the masked block to view the lookup table. Click on a cell to edit the value. To view the heat map of the table, right-click on a cell, then click **Heatmap On**.

Reference Promoted Parameters for Table and Breakpoint Data

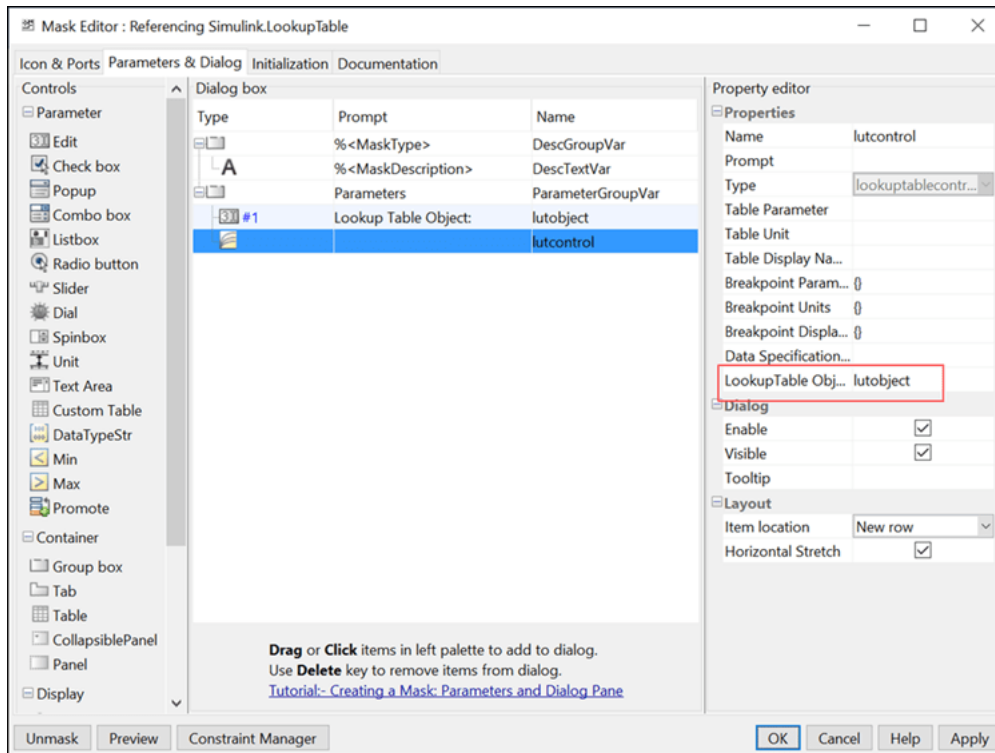

You can follow the same steps to reference promoted parameters to build a lookup table.

Specify Table Data and Breakpoint Data Using Lookup Table Object

To reference an object in the Lookup Table Control:

1. Create an object named `lutobject` in the model or base workspace with table and breakpoint data.
2. Create an Edit parameter and enter the **Value** as `lutobject` created in the model workspace.
3. Create the lookup table control, `lutcontrol` and reference the Edit parameter.
4. The lookup table is now populated with the table and breakpoints data.

Switch Between Explicit Data Specification Mode and Data Referencing Mode

You can switch between Explicit data specification mode and Data referencing mode using a Popup parameter. Create a Popup parameter and use it in the lookup table control to choose between explicit data specification mode and object referencing mode.

Use callback code for the Popup parameter.

```

dataspec_paramName = 'dataspec';
bp1_paramName = 'torque';
bp2_paramName = 'enginespeed';
tbl_paramName = 'fuelflow';
lutobj_paramName = 'lutobject';
underlyingLUTblock = 'slexMaskLookupTableControlExample/LUT Control with Data Specification Mo

dataSpec = get_param(gcb, dataspec_paramName);
maskObj = Simulink.Mask.get(gcb);
lutoParam = maskObj.getParameter(lutobj_paramName);
bp1Param = maskObj.getParameter(bp1_paramName);
bp2Param = maskObj.getParameter(bp2_paramName);
tableParam = maskObj.getParameter(tbl_paramName);
set_param(underlyingLUTblock, 'DataSpecification', dataSpec);

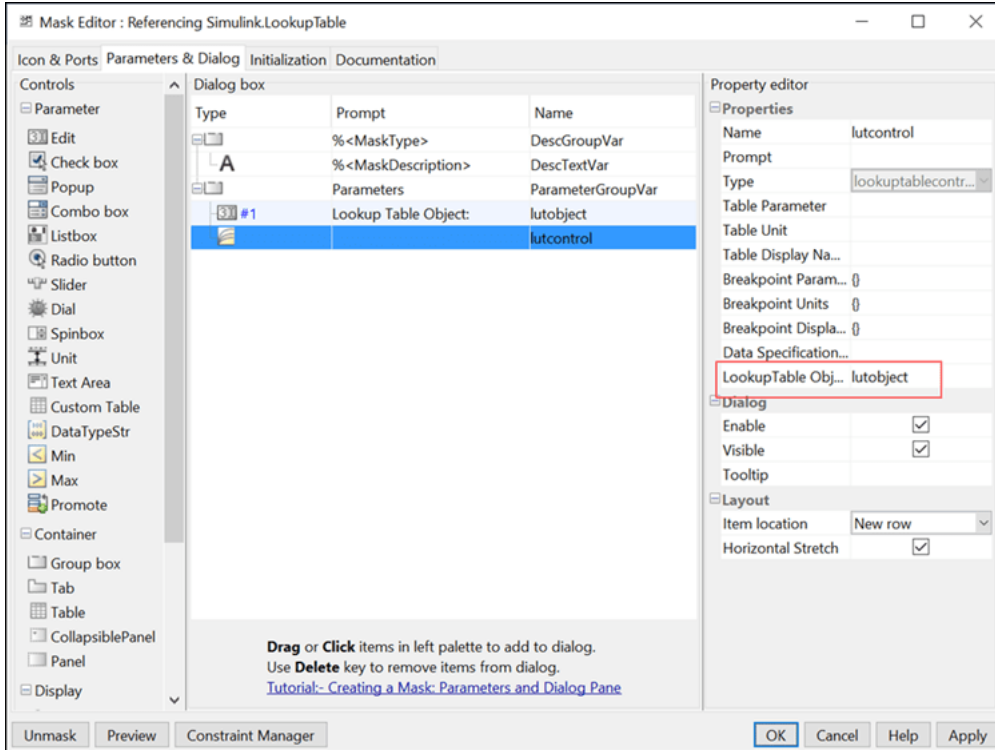

if strcmp(dataSpec, 'Lookup table object')
    bp1Param.Visible = 'off';
    bp2Param.Visible = 'off';
    tableParam.Visible = 'off';
    lutoParam.Visible = 'on';
else
    bp1Param.Visible = 'on';
    bp2Param.Visible = 'on';

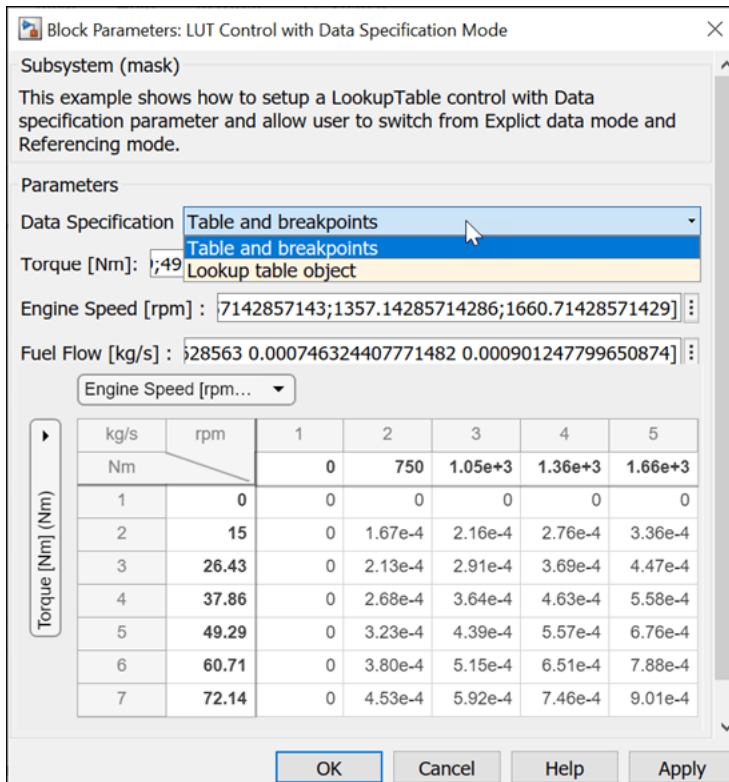

```

```

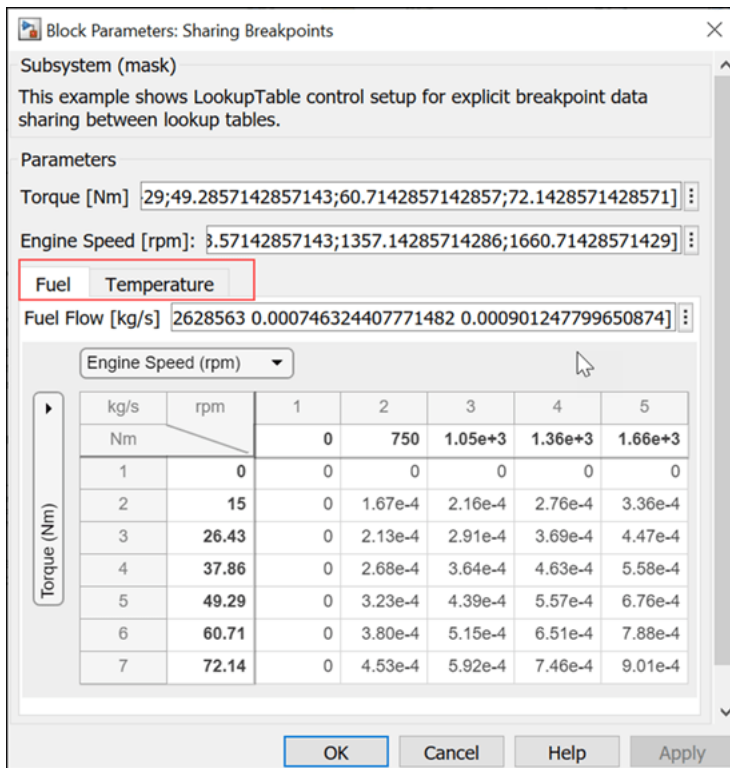

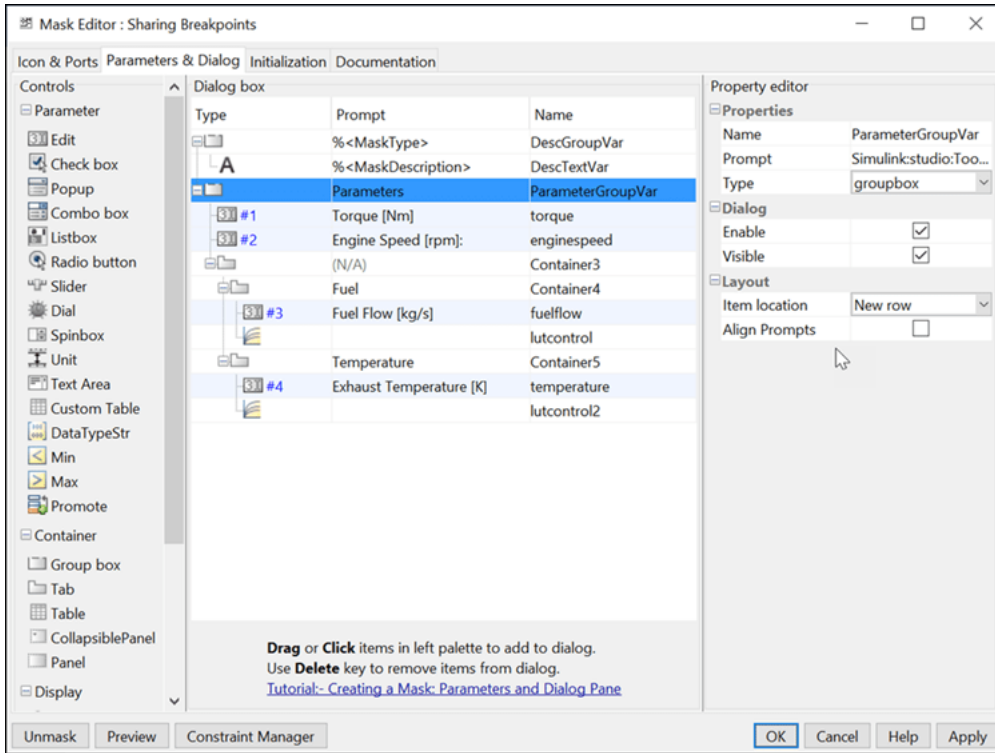

tableParam.Visible = 'on';
lutoParam.Visible = 'off';
end
    
```

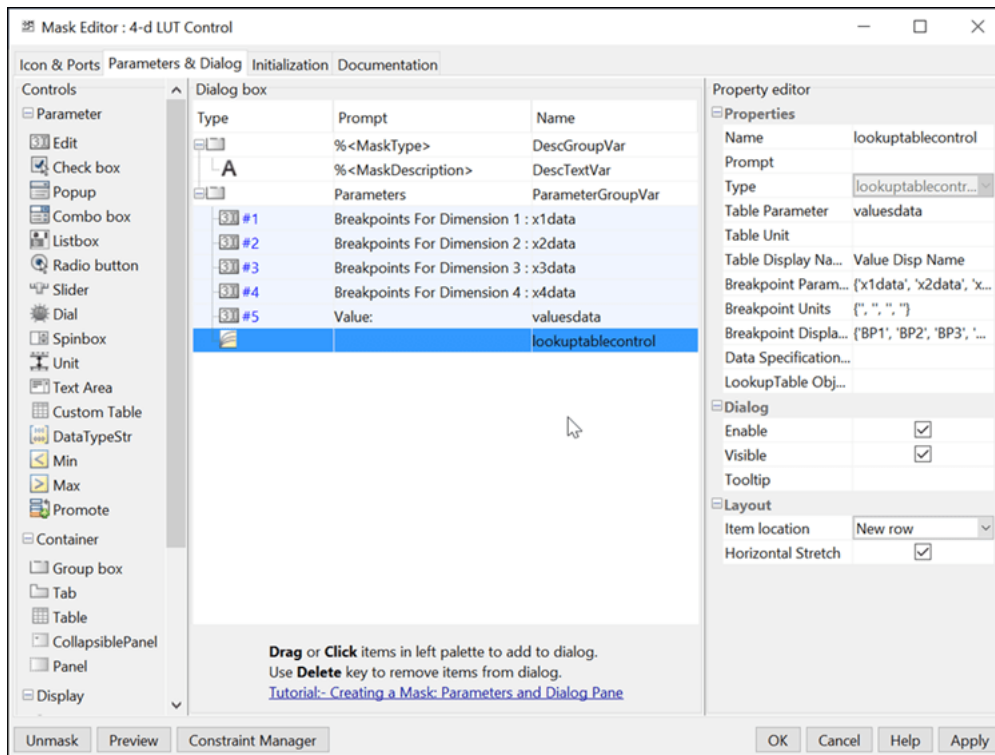

Share Explicit Breakpoint Data Between Lookup Tables

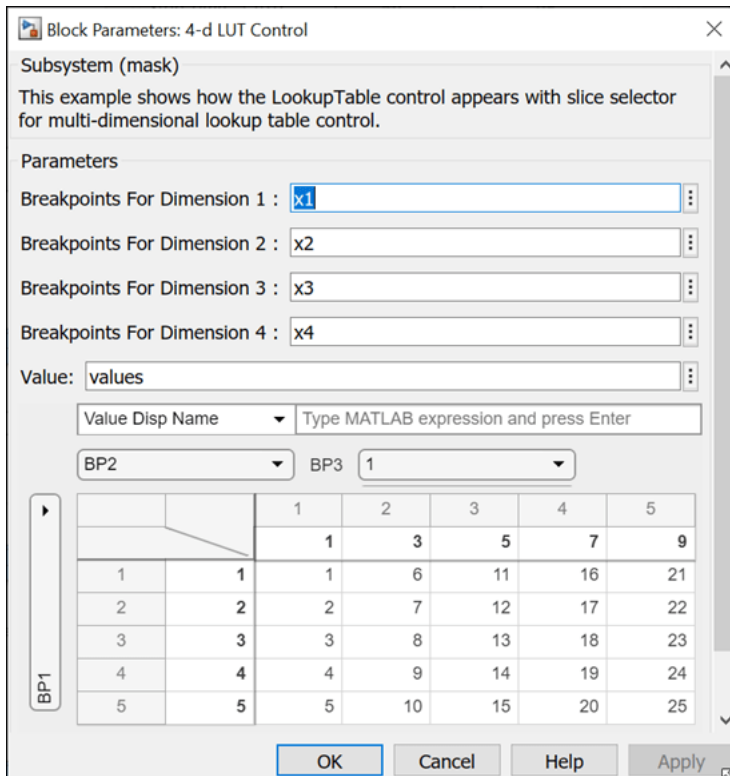

Many applications use the same breakpoints for different kinds of data. You can create multiple lookup tables by sharing breakpoint data. For example, **Exhaust Temperature**, **Air Pressure**, and **Fuel Flow** use the same breakpoints **Torque** and **Engine Speed**. Create multiple containers in the Mask Editor for each lookup table and use the same breakpoints in each table.

Visualize Multidimensional Data

To visualize multidimensional data, create Edit parameters for table and breakpoints and enter the values. To visualize the data for a dimension, select the parameter for that dimension from the list.

Add Lookup Table Control Programmatically

To add a mask lookup table control programmatically:

1. Get the mask object.

```
maskObj = Simulink.Mask.get(blkhndl);
```

2. Add table data and breakpoint parameters to the mask.

```
maskObj.addParameter('Name', 'torque', 'Prompt', 'Torque:', 'Type', 'edit');
maskObj.addParameter('Name', 'speed', 'Prompt', 'Engine speed:', 'Type', 'edit');
maskObj.addParameter('Name', 'fuelflowtable', 'Prompt', 'Fuel Flow Map:', 'Type', 'edit');
```

3. Set the table properties.

```
lutControl.Table.Name = 'fuelflowtable';
lutControl.Table.Unit = 'kg/s';
lutControl.Table.FieldName = 'Fuel Flow';
```

Set breakpoint properties of Dimension 1.

```
lutControl.Breakpoints(1).Name = 'torque';
lutControl.Breakpoints(1).Unit = 'Nm';
lutControl.Breakpoints(1).FieldName = 'Torque';
```

Set Breakpoint properties of Dimension 2

```
lutControl.Breakpoints(2).Name = 'speed';
lutControl.Breakpoints(2).Unit = 'rpm';
lutControl.Breakpoints(2).FieldName = 'Speed';
```

4. Add lookup table control.

```
lutControl = maskObj.addDialogControl('Name', 'fuelflowlut', 'Type', 'lookuptablecontrol');
```

MATLAB Function Blocks

A MATLAB Function block allows you to use the MATLAB language to define custom functionality. These blocks are a good starting point for creating a custom block if:

- You have an existing MATLAB function that models the custom functionality.
- You find it easier to model custom functionality using a MATLAB function than using a Simulink block diagram.
- The custom functionality does not include continuous or discrete dynamic states.

You can create a custom block from a MATLAB function using one of the following types of MATLAB function blocks.

- The Interpreted MATLAB Function block allows you to use a MATLAB function to define a SISO block.
- The MATLAB Function block allows you to define a custom block with multiple inputs and outputs that you can deploy to an embedded processor.

Each of these blocks has advantages in particular modeling applications. For example, you can generate code from models containing MATLAB Function blocks.

MATLAB System Blocks

A MATLAB System block allows you to use System objects written with the MATLAB language to define custom functionality. These blocks are a good starting point for creating a custom block if:

- You have an existing System object that models the custom functionality.
- You find it easier to model custom functionality using the MATLAB language than using a Simulink block diagram.
- The custom functionality includes discrete dynamic states.

Subsystem Blocks

Subsystem blocks allow you to build a Simulink diagram to define custom functionality. These blocks serve as a good starting point for creating a custom block if:

- You have an existing Simulink diagram that models custom functionality.
- You find it easier to model custom functionality using a graphical representation rather than using handwritten code.
- The custom functionality is a function of continuous or discrete system states.
- You can model the custom functionality using existing Simulink blocks.

Once you have a Simulink subsystem that models the required behavior, you can convert it into a custom block by:

- 1 Masking the block to hide the block contents and provide a custom block dialog box.
- 2 Placing the block in a library to prohibit modifications and allow for easily updating copies of the block.

For more information, see “Custom Libraries” and “Create Block Masks”.

C Caller Block

The C Caller block allows you to integrate C code into Simulink blocks. These blocks serve as a good starting point for creating a custom block if:

- You have existing C code that models custom functionality.
- Your C functions do not read or write global/static variables.
- You want blocks to easily integrate with other Simulink features, such as Simulink Coverage, Simulink Test, and Simulink Coder.
- You are not modeling dynamic systems.

C Function Block

The C Function block allows you to integrate C code into Simulink blocks. These blocks serve as a good starting point for creating a custom block if:

- You have existing C code that models custom functionality.
- You want to call multiple C functions from the block, or call C functions conditionally.
- You want to include C code to preprocess and postprocess data before and after calling C functions.
- You want to specify different code for simulation and code generation.
- You are not modeling dynamic systems with continuous states.

S-Function Blocks

S-function blocks allow you to write MATLAB, C, or C++ code to define custom functionality. These blocks serve as a good starting point for creating a custom block if:

- You have existing MATLAB, C, or C++ code that models custom functionality.
- You use continuous or discrete dynamic states or other system behaviors that require access to the S-function API.
- You cannot model the custom functionality using existing Simulink blocks.

You can create a custom block from an S-function using one of the following types of S-function blocks.

- The Level-2 MATLAB S-Function block allows you to write your S-function using the MATLAB language. (See “Write Level-2 MATLAB S-Functions”). You can debug a MATLAB S-function during a simulation using the MATLAB debugger.
- The S-Function block allows you to write your S-function in C or C++, or to incorporate existing code into your model using a C MEX wrapper. (See “Implement C/C++ S-Functions”).
- The S-Function Builder block assists you in creating a C MEX S-function or a wrapper function to incorporate legacy C or C++ code. (See “Implement C/C++ S-Functions”).
- The Legacy Code Tool transforms existing C or C++ functions into C MEX S-functions. (See “Integrate C Functions Using Legacy Code Tool”).

The S-function target in the Simulink Coder product automatically generates a C MEX S-function from a graphical subsystem. If you want to build your custom block in a Simulink subsystem, but implement the final version of the block in an S-function, you can use the S-function target to convert the subsystem to an S-function. See “Accelerate Simulation, Reuse Code, or Protect Intellectual Property by Using S-Function Target” (Simulink Coder) in the Simulink Coder User's Guide for details and limitations on using the S-function target.

Masked Blocks

You can customize any block by adding a mask to it. A mask is a custom interface to the block. You can customize a block using a mask in many ways, such as:

- Change the block appearance.
- Hide some or all of the parameters from the user of the block.
- Customize block parameters.

To learn more about masked blocks, see “Create Block Masks”.

Comparison of Custom Block Functionality

In this section...
"Model State Behavior" on page 40-6
"Simulation Performance" on page 40-6
"Code Generation" on page 40-8
"Multiple Input and Output Ports" on page 40-9
"Speed of Updating the Simulink Diagram" on page 40-9
"Callback Methods" on page 40-10
"Comparing MATLAB S-Functions to MATLAB Functions for Code Generation" on page 40-10
"Expanding Custom Block Functionality" on page 40-11

When creating a custom block, consider:

- Does the block model continuous or discrete state behavior on page 40-6?
- Is the simulation performance on page 40-6 important?
- Do you need to generate code on page 40-8 for a model containing the custom block?

This table shows how each custom block type addresses the three concerns.

Modelling Considerations

Custom Block Type	Model State Dynamics on page 40-6	Simulation Performance on page 40-6	Code Generation on page 40-8
Interpreted MATLAB Function	No	Less fast	Not supported
Level-2 MATLAB S-Function	Yes	Less fast	Requires a TLC file
MATLAB Function	No	Fast	Supported with exceptions
MATLAB System	Yes	Fast	Supported with exceptions
S-Function	Yes	Fast	Requires a TLC file or non-inline S-Function support
C Caller	No	Fast	Supported
C Function	Yes	Fast	Supported
S-Function Builder	Yes	Fast	Supported
Simulink Function	Yes	Fast	Supported
Subsystem	Yes	Fast	Supported

For detailed design of custom blocks, consider:

- Does the custom block need multiple input and output ports on page 40-9?
- What are the callback methods on page 40-10 to communicate with the Simulink engine and which custom blocks let you implement all or a subset of these callback methods?
- How important is the effect of the custom block on the speed of updating the Simulink diagram on page 40-9?

Model State Behavior

You need to model the state behavior for a block that requires some or all of its previous outputs to compute its current outputs. See “State variables” for more information.

Custom Block Type	Notes
Interpreted MATLAB Function, C Caller	Does not allow you to model state behavior.
MATLAB Function, C Function	Allows you to model a discrete state using <code>persistent</code> variables.
Level-2 MATLAB S-Function	Allows you to model both continuous and discrete state behavior using the <code>ContStates</code> or <code>Dwork</code> run-time object methods in combination with block callback methods. For a list of supported methods, see “Level-2 MATLAB S-Function Callback Methods” in “Write Level-2 MATLAB S-Functions”.
MATLAB System	Allows you to model discrete state behavior using <code>DiscreteState</code> properties of the <code>System</code> object, in combination with block callback methods. This block uses <code>System</code> object methods for callback methods: <code>mdlOutputs</code> (<code>stepImpl</code> , <code>outputImpl</code>), <code>mdlUpdate</code> (<code>updateImpl</code>), <code>mdlInitializeConditions</code> (<code>resetImpl</code>), <code>mdlStart</code> (<code>setupImpl</code>), <code>mdlTerminate</code> (<code>releaseImpl</code>). For more information see “What Are System Objects?”.
C MEX S-Function, S-Function Builder	Allows you to model both continuous and discrete state behavior in combination with block callback methods. For more information, see “Callback Methods for C MEX S-Functions”
Simulink Function	Communicates directly with the engine. You can model the state behavior using appropriate blocks from the continuous and discrete Simulink block libraries. When multiple calls to this function originate from different callers, the state values are also persistent between these calls. For more information, see “Call a Simulink Function block from multiple sites” on page 10-136.
Subsystem	Communicates directly with the engine. You can model the state behavior using appropriate blocks from the continuous and discrete Simulink block libraries.

Simulation Performance

For most applications, all custom block types provide satisfactory simulation performance. Use the Simulink profiler to get the actual performance indication. See “How Profiler Captures Performance Data” on page 31-5 for more information.

The two categories of performance indication are the interface cost and the algorithm cost. The interface cost is the time it takes to move data from the Simulink engine into the block. The algorithm cost is the time it takes to perform the algorithm that the block implements.

Custom Block Type	Notes
Interpreted MATLAB Function	<p>Has a slower performance due to the interface, but has the same algorithm cost as a MATLAB function.</p> <p>When block data (such as inputs and outputs) is accessed or returned from an Interpreted MATLAB Function block, the Simulink engine packages this data into MATLAB arrays. This packaging takes additional time and causes a temporary increase in memory during communication. If you pass large amounts of data across this interface, such as frames or arrays, the performance can be substantially slow.</p> <p>Once the data has been converted, the MATLAB execution engine executes the algorithm. As a result, the algorithm cost is the same as for MATLAB function.</p>
Level-2 MATLAB S-Function	<p>Incurs the same algorithm costs as the Interpreted MATLAB Function block, but with a slightly higher interface cost. Since MATLAB S-Functions can handle multiple inputs and outputs, the packaging is more complicated than for the Interpreted MATLAB Function block. In addition, the Simulink engine calls the MATLAB execution engine for each block method you implement, whereas the Interpreted MATLAB Function block calls the MATLAB execution engine only for the Outputs method.</p>
MATLAB Function	<p>Performs simulation through code generation and incurs the same interface cost as other Simulink built-in blocks.</p> <p>The algorithm cost of this block is harder to analyze because of the block's implementation. On average, a function for this block and the MATLAB function run at about the same speed.</p> <p>If the MATLAB Function block has code that uses <code>coder.extrinsic</code> to call out to the MATLAB execution engine, it incurs all the costs that the MATLAB S-Function or Interpreted MATLAB Function block incur. Calling out to the MATLAB execution engine from a MATLAB Function block produces a warning to prevent you from doing so unintentionally.</p> <p>To reduce the algorithm cost, you can disable debugging for all MATLAB Function blocks.</p>
MATLAB System	<p>In the interpreted execution mode, performance is similar to that of the Level-2 MATLAB S-function because the model simulates the block using the MATLAB execution engine. In the code generation mode, performance is similar to that of the MATLAB Function because the model simulates the block using the generated code. For more information, see the MATLAB Function entry in this table.</p>
C Caller, C Function	<p>First time model simulation with could be slower due to parsing and building of the custom code. To speed up the simulation after the first compile, from Configuration parameters, select Faster Builds for faster compile and select Faster Runs for faster simulation.</p>
C MEX S-Function	<p>Simulates via the compiled code and incurs the same interface cost as Simulink built-in blocks. The algorithm cost depends on the complexity of the S-Function.</p>
S-Function Builder	<p>This block only builds an S-Function from the specifications and C code you supply. You can also use this block as a wrapper for the generated S-Function in models. The algorithm cost of this block compared to C MEX S-Function is incurred only from the wrapper.</p>

Custom Block Type	Notes
Simulink Function, Subsystem	<p>If included in a library, introduces no interface or algorithm costs beyond what would normally be incurred if the block existed as a regular subsystem in the model.</p> <p>Performance is proportional to the complexity of the algorithm implemented in the subsystem. If the subsystem is contained in a library, some cost is incurred when Simulink loads any unloaded libraries the first time the diagram is updated or readied for simulation. If all referenced library blocks remain unchanged, Simulink does not subsequently reload the library. Compiling the model becomes faster than if the model did not use libraries.</p>

Code Generation

You need code generation if your model is part of a bigger system. Not all custom block types support code generation with Simulink Coder.

Custom Block Type	Notes
Interpreted MATLAB Function	Does not support code generation.
C Caller, C Function	Supports code generation.
Level-2 MATLAB S-Function	Generates code only if you implement the algorithm using a Target Language Compiler (TLC) function. In accelerated and external mode simulations, you can choose to execute the S-Function in the interpretive mode by calling back to the MATLAB execution engine without implementing the algorithm in TLC. If the MATLAB S-Function is <code>SimViewingDevice</code> , the Simulink Coder product automatically omits the block during code generation.
MATLAB Function, MATLAB System	Supports code generation. However, if your block calls out to the MATLAB execution engine, it will build with the Simulink Coder product only if the calls to the MATLAB execution engine do not affect the block outputs. Under this condition, the Simulink Coder product omits these calls from the generated C code. This feature allows you to leave visualization code in place, even when generating embedded code.
C MEX S-Function, S-Function Builder	<p>Both supports code generation.</p> <ul style="list-style-type: none"> For non-inlined S-Functions, the Simulink Coder product uses the C MEX function during code generation. In the case of C MEX S-Functions, if you need to either inline the S-Function or create a wrapper for handwritten code, you must write a TLC file for the S-Function. In the case of S-Function Builder, you can choose the Generate wrapper TLC option to automatically generate a TLC file. <p>See “S-Functions and Code Generation” (Simulink Coder) for more information.</p>
Simulink Function	Supports code generation.
Subsystem	Supports code generation as long as the blocks contained within the subsystem support code generation. For more information, see “Control Generation of Functions for Subsystems” (Embedded Coder)

Multiple Input and Output Ports

These types of custom blocks support multiple input and output ports.

Custom Block Type	Notes
Interpreted MATLAB Function	Supports only a single input and a single output port.
MATLAB Function	Supports multiple input and output ports, including bus signals. See “How Structure Inputs and Outputs Interface with Bus Signals” on page 45-61 for more information.
MATLAB System	Supports multiple input and output ports, including bus signals. In addition, you can modify the number of input and output ports based on system object properties using the <code>getNumInputs</code> and <code>getNumOutputs</code> methods.
C Caller, C Function	Supports multiple input and output ports, including bus signals.
Level-2 MATLAB S-Function, C MEX S-Function, S-Function Builder	Supports multiple input and output ports. In addition, you can modify the number of input and output ports based on user-defined parameters. The C MEX S-Function and S-Function Builder support bus signals.
Simulink Function	Supports multiple input and output ports, including bus signals.
Subsystem	Supports multiple input and output ports, including bus signals. In addition, you can modify the number of input and output ports based on user-defined parameters. See “Self-Modifiable Linked Subsystems” on page 41-19 for more information.

Speed of Updating the Simulink Diagram

Simulink updates the diagram before every simulation and when requested by the user. Every block introduces some overhead into the diagram update process.

Custom Block Type	Notes
Interpreted MATLAB Function	Low diagram update cost.
MATLAB Function, C Caller, C Function	Simulation is performed through code generation, so this blocks can take a significant amount of time when first updated. However, because code generation is incremental, Simulink does not repeatedly update the block if the block and the signals connected to it have not changed.
MATLAB System	Faster than MATLAB Function because code is not generated to update the diagram. Since, code generation is incremental, Simulink does not repeatedly update the block if the block and the signals connected to it have not changed.
C MEX S-Function, Level-2 MATLAB S-Function	Incurs greater costs than other Simulink blocks only if it overrides methods executed when updating the diagram. If these methods become complex, they can contribute significantly to the time it takes to update the diagram. For a list of methods executed when updating the diagram, see the process view in “Simulink Engine Interaction with C S-Functions”. When updating the diagram, Simulink invokes all relevant methods in the model initialization phase up to, but not including, <code>mdlStart</code> .

Custom Block Type	Notes
Simulink Function, Subsystem	The speed is proportional to the complexity of the algorithm implemented in the subsystem. If the subsystem is contained in a library, some cost is incurred when Simulink loads any unloaded libraries the first time the diagram is updated or readied for simulation. If all referenced library blocks remain unchanged, Simulink does not subsequently reload the library. Compiling the model becomes faster than if the model does not use libraries.

Callback Methods

Simulink blocks communicate with the Simulink engine through block callback methods, which fully specify the behavior of blocks (except the Simulink Function block). Each custom block type allows you to implement a different set of callback methods. To learn how blocks interact with Simulink engine, see “Simulink Engine Interaction with C S-Functions”. This table uses “S-Function Callback Methods” names as equivalents.

Custom Block Type	Notes
Interpreted MATLAB Function, MATLAB Function, C Caller	All create a <code>mdlOutputs</code> method to calculate the value of outputs given the value of inputs. You cannot implement any other callback methods using one of these blocks and, therefore, cannot model state behavior.
C Function	Allows implementation of start, output, and terminate callback methods. Allows modeling of discrete states with persistent data.
Level-2 MATLAB S-Function	Allows implementation of a larger subset of callback methods, including methods you can use to model continuous and discrete states. For a list of supported methods, see “Level-2 MATLAB S-Function Callback Methods” in “Write Level-2 MATLAB S-Functions”.
MATLAB System	Uses System object methods for callback methods: <code>mdlOutputs</code> (<code>stepImpl</code> , <code>outputImpl</code>), <code>mdlUpdate</code> (<code>updateImpl</code>), <code>mdlInitializeConditions</code> (<code>resetImpl</code>), <code>mdlStart</code> (<code>setupImpl</code>), <code>mdlTerminate</code> (<code>releaseImpl</code>). For more information, see “Simulink Engine Interaction with System Object Methods” on page 46-24
C MEX S-Function	Allows implementation of a complete set of callback methods.
S-Function Builder	Allows implementation of <code>mdlOutputs</code> , <code>mdlDerivatives</code> and <code>mdlUpdate</code> .
Simulink Function	Packaged as a standalone function. Any caller to this function becomes part of one of the callback methods based on the caller’s location.
Subsystem	Communicates directly with the engine. You can model state behaviors using appropriate blocks from the continuous and discrete Simulink block libraries.

Comparing MATLAB S-Functions to MATLAB Functions for Code Generation

MATLAB S-functions and MATLAB functions for code generation have some fundamental differences.

- The Simulink Coder product can generate code for both MATLAB S-functions and MATLAB functions for code generation. However, MATLAB S-functions require a Target Language Compiler (TLC) file for code generation. MATLAB functions for code generation do not require a TLC file.

- MATLAB S-functions can use any MATLAB function whereas MATLAB functions for code generation are a subset of the MATLAB language. For a list of supported functions for code generation, see “Functions and Objects Supported for C/C++ Code Generation” on page 50-2.
- MATLAB S-functions can model discrete and continuous state dynamics whereas MATLAB functions for code generation cannot model state dynamics.

Expanding Custom Block Functionality

You can expand the functionality of any custom block using callbacks and MATLAB graphics.

Block callbacks perform user-defined actions at specific points in the simulation. For example, the callback can load data into the MATLAB workspace before the simulation or generate a graph of simulation data at the end of the simulation. You can assign block callbacks to any of the custom block types. For a list of available callbacks and more information on how to use them, see “Specify Block Callbacks” on page 4-57.

App Designer, the MATLAB graphical user interface development environment, provides tools for easily creating custom user interfaces. See “App Building” for more information on using App Designer.

Design and Create a Custom Block

In this section...

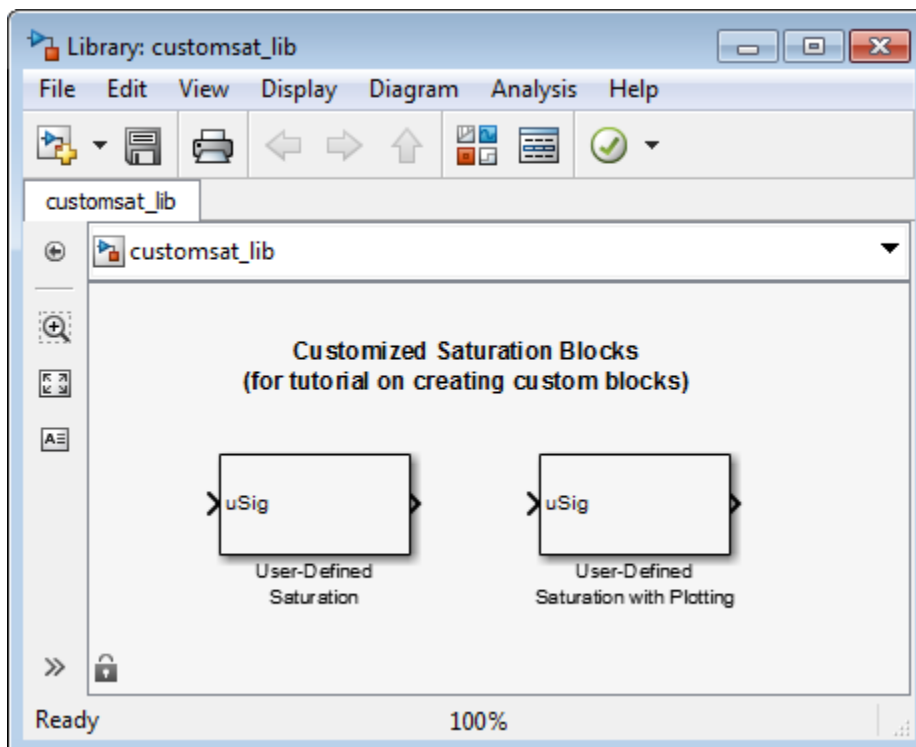

“How to Design a Custom Block” on page 40-12
 “Defining Custom Block Behavior” on page 40-13
 “Deciding on a Custom Block Type” on page 40-14
 “Placing Custom Blocks in a Library” on page 40-17
 “Adding a User Interface to a Custom Block” on page 40-19
 “Adding Block Functionality Using Block Callbacks” on page 40-24

How to Design a Custom Block

In general, use the following process to design a custom block:

- 1 “Defining Custom Block Behavior” on page 40-13
- 2 “Deciding on a Custom Block Type” on page 40-14
- 3 “Placing Custom Blocks in a Library” on page 40-17
- 4 “Adding a User Interface to a Custom Block” on page 40-19

Suppose you want to create a customized saturation block that limits the upper and lower bounds of a signal based on either a block parameter or the value of an input signal. In a second version of the block, you want the option to plot the saturation limits after the simulation is finished. The following tutorial steps you through designing these blocks. The library `ex_customsat_lib` contains the two versions of the customized saturation block.

The example model `sldemo_customsat` uses the basic version of the block.

Defining Custom Block Behavior

Begin by defining the features and limitations of your custom block. In this example, the block supports the following features:

- Turning on and off the upper or lower saturation limit.
- Setting the upper and/or lower limits via a block parameters.
- Setting the upper and/or lower limits using an input signal.

It also has the following restrictions:

- The input signal under saturation must be a scalar.
- The input signal and saturation limits must all have a data type of double.
- Code generation is not required.

Deciding on a Custom Block Type

Based on the custom block features, the implementation needs to support the following:

- Multiple input ports
- A relatively simple algorithm
- No continuous or discrete system states

Therefore, this tutorial implements the custom block using a Level-2 MATLAB S-function. MATLAB S-functions support multiple inputs and, because the algorithm is simple, do not have significant overhead when updating the diagram or simulating the model. See “Comparison of Custom Block Functionality” on page 40-5 for a description of the different functionality provided by MATLAB S-functions as compared to other types of custom blocks.

Parameterizing the MATLAB S-Function

Begin by defining the S-function parameters. This example requires four parameters:

- The first parameter indicates how the upper saturation limit is set. The limit can be off, set via a block parameter, or set via an input signal.
- The second parameter is the value of the upper saturation limit. This value is used only if the upper saturation limit is set via a block parameter. In the event this parameter is used, you should be able to change the parameter value during the simulation, i.e., the parameter is tunable.
- The third parameter indicates how the lower saturation limit is set. The limit can be off, set via a block parameter, or set via an input signal.
- The fourth parameter is the value of the lower saturation limit. This value is used only if the lower saturation limit is set via a block parameter. As with the upper saturation limit, this parameter is tunable when in use.

The first and third S-function parameters represent modes that must be translated into values the S-function can recognize. Therefore, define the following values for the upper and lower saturation limit modes:

- 1 indicates that the saturation limit is off.
- 2 indicates that the saturation limit is set via a block parameter.
- 3 indicates that the saturation limit is set via an input signal.

Writing the MATLAB S-Function

After you define the S-function parameters and functionality, write the S-function. The template `msfuntmpl.m` provides a starting point for writing a Level-2 MATLAB S-function. You can find a completed version of the custom saturation block in the file `custom_sat.m`. Save this file to your working folder before continuing with this tutorial.

This S-function modifies the S-function template as follows:

- The `setup` function initializes the number of input ports based on the values entered for the upper and lower saturation limit modes. If the limits are set via input signals, the method adds input ports to the block. The `setup` method then indicates there are four S-function parameters and sets the parameter tunability. Finally, the method registers the S-function methods used during simulation.

```

function setup(block)

% The Simulink engine passes an instance of the Simulink.MSFcnRunTimeBlock
% class to the setup method in the input argument "block". This is known as
% the S-function block's run-time object.

% Register original number of input ports based on the S-function
% parameter values

try % Wrap in a try/catch, in case no S-function parameters are entered
    lowMode    = block.DialogPrm(1).Data;
    upMode     = block.DialogPrm(3).Data;
    numInPorts = 1 + isequal(lowMode,3) + isequal(upMode,3);
catch
    numInPorts=1;
end % try/catch
block.NumInputPorts = numInPorts;
block.NumOutputPorts = 1;

% Setup port properties to be inherited or dynamic
block.SetPreCompInpPortInfoToDynamic;
block.SetPreCompOutPortInfoToDynamic;

% Override input port properties
block.InputPort(1).DatatypeID = 0; % double
block.InputPort(1).Complexity = 'Real';

% Override output port properties
block.OutputPort(1).DatatypeID = 0; % double
block.OutputPort(1).Complexity = 'Real';

% Register parameters. In order:
% -- If the upper bound is off (1) or on and set via a block parameter (2)
%    or input signal (3)
% -- The upper limit value. Should be empty if the upper limit is off or
%    set via an input signal
% -- If the lower bound is off (1) or on and set via a block parameter (2)
%    or input signal (3)
% -- The lower limit value. Should be empty if the lower limit is off or
%    set via an input signal
block.NumDialogPrms    = 4;
block.DialogPrmsTunable = {'Nontunable','Tunable','Nontunable', ...
    'Tunable'};

% Register continuous sample times [0 offset]
block.SampleTimes = [0 0];

%% -----
%% Options
%% -----
% Specify if Accelerator should use TLC or call back into
% MATLAB script
block.SetAccelRunOnTLC(false);

%% -----
%% Register methods called during update diagram/compilation

block.RegBlockMethod('Terminate',         @Terminate);
%end setup function

```

- The CheckParameters method verifies the values entered into the Level-2 MATLAB S-Function block.

```

function CheckPrms(block)

lowMode = block.DialogPrm(1).Data;
lowVal  = block.DialogPrm(2).Data;

```

```

upMode = block.DialogPrm(3).Data;
upVal  = block.DialogPrm(4).Data;

% The first and third dialog parameters must have values of 1-3
if ~any(upMode == [1 2 3]);
    error('The first dialog parameter must be a value of 1, 2, or 3');
end

if ~any(lowMode == [1 2 3]);
    error('The first dialog parameter must be a value of 1, 2, or 3');
end

% If the upper or lower bound is specified via a dialog, make sure there
% is a specified bound. Also, check that the value is of type double
if isequal(upMode,2),
    if isempty(upVal),
        error('Enter a value for the upper saturation limit.');
```

```

    end
    if ~strcmp(class(upVal), 'double')
        error('The upper saturation limit must be of type double.');
```

```

    end
end

if isequal(lowMode,2),
    if isempty(lowVal),
        error('Enter a value for the lower saturation limit.');
```

```

    end
    if ~strcmp(class(lowVal), 'double')
        error('The lower saturation limit must be of type double.');
```

```

    end
end

% If a lower and upper limit are specified, make sure the specified
% limits are compatible.
if isequal(upMode,2) && isequal(lowMode,2),
    if lowVal >= upVal,
        error('The lower bound must be less than the upper bound.');
```

```

    end
end

%end CheckPrms function

```

- The `ProcessParameters` and `PostPropagationSetup` methods handle the S-function parameter tuning.

```

function ProcessPrms(block)

%% Update run time parameters
block.AutoUpdateRuntimePrms;

%end ProcessPrms function

```

```

function DoPostPropSetup(block)

%% Register all tunable parameters as runtime parameters.
block.AutoRegRuntimePrms;

%end DoPostPropSetup function

```

- The `Outputs` method calculates the block's output based on the S-function parameter settings and any input signals.

```

function Outputs(block)

lowMode  = block.DialogPrm(1).Data;
upMode   = block.DialogPrm(3).Data;

lowPortNum = 2; % Initialize potential input number for lower saturation limit

% Check upper saturation limit
if isequal(upMode,2), % Set via a block parameter

```

```

        upVal = block.RuntimePrm(2).Data;
    elseif isequal(upMode,3), % Set via an input port
        upVal = block.InputPort(2).Data;
        lowPortNum = 3; % Move lower boundary down one port number
    else
        upVal = inf;
    end

    % Check lower saturation limit
    if isequal(lowMode,2), % Set via a block parameter
        lowVal = block.RuntimePrm(1).Data;
    elseif isequal(lowMode,3), % Set via an input port
        lowVal = block.InputPort(lowPortNum).Data;
    else
        lowVal = -inf;
    end

    % Assign new value to signal
    if sigVal > upVal,
        sigVal = upVal;
    elseif sigVal < lowVal,
        sigVal=lowVal;
    end

    block.OutputPort(1).Data = sigVal;

%end Outputs function

```

Placing Custom Blocks in a Library

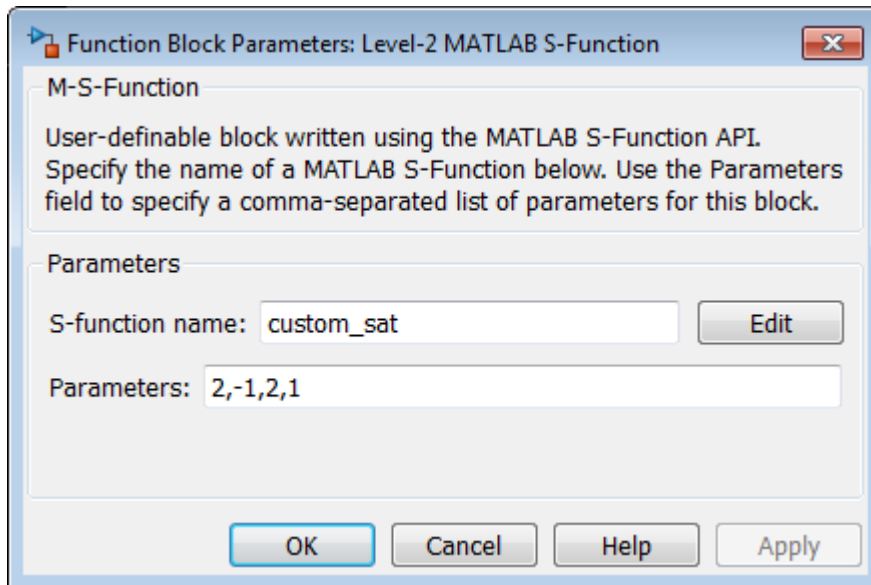

Libraries allow you to share your custom blocks with other users, easily update the functionality of copies of the custom block, and collect blocks for a particular project into a single location. If your custom block requires a bus as an interface, you can share the bus object with library users by creating the bus object in a data dictionary and attaching the dictionary to the library (See “Link Data Dictionary to Custom Libraries” on page 75-34).

This example places the custom saturation block into a library.

- 1 In the Simulink Editor, in the **Simulation** tab, select **New > Library**.
- 2 From the User-Defined Functions library, drag a Level-2 MATLAB S-Function block into your new library.

- 3 Save your library with the filename `saturation_lib`.
- 4 Double-click the block to open its Function Block Parameters dialog box.
- 5 In the **S-function name** field, enter the name of the S-function. For example, enter `custom_sat`. In the **Parameters** field enter `2, -1, 2, 1`.

- 6 Click **OK**.

You have created a custom saturation block that you can share with other users.

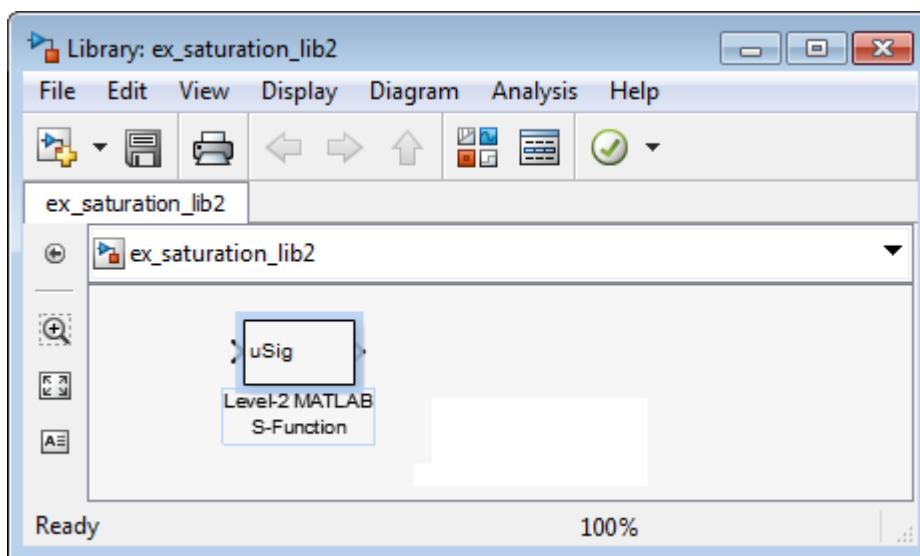

You can make the block easier to use by adding a customized user interface.

Adding a User Interface to a Custom Block

You can create a block dialog box for a custom block using the masking features of Simulink. Masking the block also allows you to add port labels to indicate which ports corresponds to the input signal and the saturation limits.

- 1 Open the library `saturation_lib` that contains the custom block you created,
- 2 Right-click the Level-2 MATLAB S-Function block and select **Mask > Create Mask**.
- 3 On the **Icon & Ports** pane in the **Icons drawing commands** box, enter `port_label('input',1,'uSig')`, and then click **Apply**.

This command labels the default port as the input signal under saturation.

- 4 In the **Parameters & Dialog** pane, add four parameters corresponding to the four S-Function parameters. For each new parameter, drag a popup or edit control to the **Dialog box** section, as shown in the table. Drag each parameter into the Parameters group.

Type	Prompt	Name	Evaluate	Tunable	Popup options	Callback
popup	Upper boundary:	upMode	✓		No limit Enter limit as parameter Limit using input signal	customsat_callback('upperbound_callback', gcb)
edit	Upper limit:	upVal	✓	✓	N/A	customsat_callback('upperparam_callback', gcb)

Type	Prompt	Name	Evaluate	Tunable	Popup options	Callback
popup	Lower boundary: :	lowMode	✓		No limit Enter limit as parameter Limit using input signal	customsat_callback('lowerbound_callback', gcb)
edit	Lower limit:	lowVal	✓	✓	N/A	customsat_callback('lowerparam_callback', gcb)

The MATLAB S-Function script `custom_sat_final.m` contains the mask parameter callbacks. Save `custom_sat_final.m` to your working folder to define the callbacks in this example. This MATLAB script has two input arguments. The first input argument is a character vector indicating which mask parameter invoked the callback. The second input argument is the handle to the associated Level-2 MATLAB S-Function block.

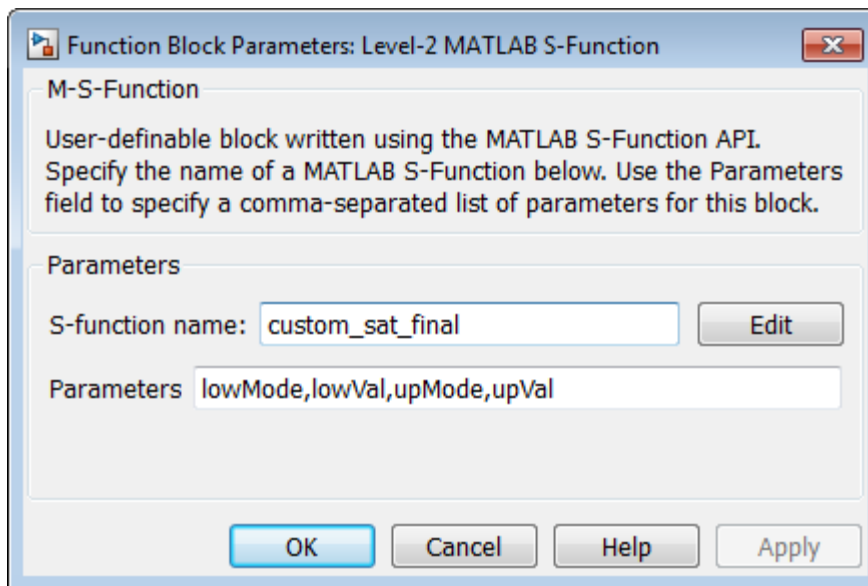

The figure shows the completed **Parameters & Dialog** pane in the Mask Editor.

- In the **Initialization** pane, select the **Allow library block to modify its contents** check box. This setting allows the S-function to change the number of ports on the block.
- In the **Documentation** pane:

- In the **Mask type** field, enter
Customized Saturation
 - In the **Mask description** field, enter
Limit the input signal to an upper and lower saturation value
set either through a block parameter or input signal.
- 7 Click **OK**.
 - 8 To map the S-function parameters to the mask parameters, right-click the Level-2 MATLAB S-Function block and select **Mask > Look Under Mask**.
 - 9 Change the **S-function name** field to `custom_sat_final` and the **Parameters** field to `lowMode,lowVal,upMode,upVal`.

The figure shows the Function Block Parameters dialog box after the changes.

- 10 Click **OK**. Save and close the library to exit the edit mode.
- 11 Reopen the library and double-click the customized saturation block to open the masked parameter dialog box.

To create a more complicated user interface, place a MATLAB graphics user interface on top of the masked block. The block `OpenFcn` invokes the MATLAB graphics user interface, which uses calls to `set_param` to modify the S-function block parameters based on settings in the user interface.

Writing the Mask Callback

The function `customsat_callback.m` contains the mask callback code for the custom saturation block mask parameter dialog box. This function invokes local functions corresponding to each mask parameter through a call to `feval`.

The following local function controls the visibility of the upper saturation limit's field based on the selection for the upper saturation limit's mode. The callback begins by obtaining values for all mask parameters using a call to `get_param` with the property name `MaskValues`. If the callback needed the value of only one mask parameter, it could call `get_param` with the specific mask parameter name, for example, `get_param(block, 'upMode')`. Because this example needs two of the mask parameter values, it uses the `MaskValues` property to reduce the calls to `get_param`.

The callback then obtains the visibilities of the mask parameters using a call to `get_param` with the property name `MaskVisibilities`. This call returns a cell array of character vectors indicating the visibility of each mask parameter. The callback alters the values for the mask visibilities based on the selection for the upper saturation limit's mode and then updates the port label text.

The callback finally uses the `set_param` command to update the block's `MaskDisplay` property to label the block's input ports.

```
function customsat_callback(action,block)
% CUSTOMSAT_CALLBACK contains callbacks for custom saturation block

% Copyright 2003-2007 The MathWorks, Inc.

%% Use function handle to call appropriate callback
feval(action,block)

%% Upper bound callback
```

```

function upperbound_callback(block)

vals = get_param(block,'MaskValues');
vis = get_param(block,'MaskVisibilities');
portStr = {'port_label('input',1,'uSig')}';
switch vals{1}
    case 'No limit'
        set_param(block,'MaskVisibilities',[vis(1);{'off'};vis(3:4)]);
    case 'Enter limit as parameter'
        set_param(block,'MaskVisibilities',[vis(1);{'on'};vis(3:4)]);
    case 'Limit using input signal'
        set_param(block,'MaskVisibilities',[vis(1);{'off'};vis(3:4)]);
        portStr = [portStr;{'port_label('input',2,'up')}'];
end
if strcmp(vals{3},'Limit using input signal'),
    portStr = [portStr;{'port_label('input',',num2str(length(portStr)+1), ...
        ', 'low')'}]];
end
set_param(block,'MaskDisplay',char(portStr));

```

The final call to `set_param` invokes the `setup` function in the MATLAB S-function `custom_sat.m`. Therefore, the `setup` function can be modified to set the number of input ports based on the mask parameter values instead of on the S-function parameter values. This change to the `setup` function keeps the number of ports on the Level-2 MATLAB S-Function block consistent with the values shown in the mask parameter dialog box.

The modified MATLAB S-function `custom_sat_final.m` contains the following new `setup` function. If you are stepping through this tutorial, open the file and save it to your working folder.

```

%% Function: setup =====
function setup(block)

% Register original number of ports based on settings in Mask Dialog
ud = getPortVisibility(block);
numInPorts = 1 + isequal(ud(1),3) + isequal(ud(2),3);

block.NumInputPorts = numInPorts;
block.NumOutputPorts = 1;

% Setup port properties to be inherited or dynamic
block.SetPreCompInpPortInfoToDynamic;
block.SetPreCompOutPortInfoToDynamic;

% Override input port properties
block.InputPort(1).DatatypeID = 0; % double
block.InputPort(1).Complexity = 'Real';

% Override output port properties
block.OutputPort(1).DatatypeID = 0; % double
block.OutputPort(1).Complexity = 'Real';

% Register parameters. In order:
% -- If the upper bound is off (1) or on and set via a block parameter (2)
%    or input signal (3)
% -- The upper limit value. Should be empty if the upper limit is off or
%    set via an input signal
% -- If the lower bound is off (1) or on and set via a block parameter (2)
%    or input signal (3)
% -- The lower limit value. Should be empty if the lower limit is off or
%    set via an input signal
block.NumDialogPrms = 4;
block.DialogPrmsTunable = {'Nontunable','Tunable','Nontunable','Tunable'};

% Register continuous sample times [0 offset]
block.SampleTimes = [0 0];

%% -----
%% Options
%% -----
% Specify if Accelerator should use TLC or call back into

```

```

% MATLAB script
block.SetAccelRunOnTLC(false);

%% -----
%% Register methods called during update diagram/compilation
%% -----

block.RegBlockMethod('CheckParameters', @CheckPrms);
block.RegBlockMethod('ProcessParameters', @ProcessPrms);
block.RegBlockMethod('PostPropagationSetup', @DoPostPropSetup);
block.RegBlockMethod('Outputs', @Outputs);
block.RegBlockMethod('Terminate', @Terminate);
%endfunction

```

The `getPortVisibility` local function in `custom_sat_final.m` uses the saturation limit modes to construct a flag that is passed back to the `setup` function. The `setup` function uses this flag to determine the necessary number of input ports.

```

%% Function: Get Port Visibilities =====
function ud = getPortVisibility(block)

ud = [0 0];

vals = get_param(block.BlockHandle,'MaskValues');
switch vals{1}
    case 'No limit'
        ud(2) = 1;
    case 'Enter limit as parameter'
        ud(2) = 2;
    case 'Limit using input signal'
        ud(2) = 3;
end

switch vals{3}
    case 'No limit'
        ud(1) = 1;
    case 'Enter limit as parameter'
        ud(1) = 2;
    case 'Limit using input signal'
        ud(1) = 3;
end

```

Adding Block Functionality Using Block Callbacks

The User-Defined Saturation with Plotting block in `customsat_lib` uses block callbacks to add functionality to the original custom saturation block. This block provides an option to plot the saturation limits when the simulation ends. The following steps show how to modify the original custom saturation block to create this new block.

- 1 Add a check box to the mask parameter dialog box to toggle the plotting option on and off.
 - a Right-click the Level-2 MATLAB S-Function block in `saturation_lib` and select **Mask + Create Mask**.
 - b On the Mask Editor **Parameters** pane, add a fifth mask parameter with the following properties.

Prompt	Name	Type	Tunabl e	Type options	Callback
Plot saturation limits	plotcheckbox	checkbox	No	NA	customsat_callback('plotsaturation',gcb)

- c Click **OK**.

- 2 Write a callback for the new check box. The callback initializes a structure to store the saturation limit values during simulation in the Level-2 MATLAB S-Function block `UserData`. The MATLAB script `customsat_plotcallback.m` contains this new callback, as well as modified versions of the previous callbacks to handle the new mask parameter. If you are following through this example, open `customsat_plotcallback.m` and copy its local functions over the previous local functions in `customsat_callback.m`.

```

%% Plotting checkbox callback
function plotsaturation(block)

% Reinitialize the block's userdata
vals = get_param(block,'MaskValues');
ud = struct('time',[],'upBound',[],'upVal',[],'lowBound',[],'lowVal',[]);

if strcmp(vals{1},'No limit'),
    ud.upBound = 'off';
else
    ud.upBound = 'on';
end

if strcmp(vals{3},'No limit'),
    ud.lowBound = 'off';
else
    ud.lowBound = 'on';
end

set_param(gcb,'UserData',ud);

```

- 3 Update the MATLAB S-function `Outputs` method to store the saturation limits, if applicable, as done in the new MATLAB S-function `custom_sat_plot.m`. If you are following through this example, copy the `Outputs` method in `custom_sat_plot.m` over the original `Outputs` method in `custom_sat_final.m`

```

%% Function: Outputs =====
function Outputs(block)

lowMode    = block.DialogPrm(1).Data;

```

```

upMode      = block.DialogPrm(3).Data;
sigVal      = block.InputPort(1).Data;
vals = get_param(block.BlockHandle,'MaskValues');
plotFlag = vals{5};
lowPortNum = 2;

% Check upper saturation limit
if isequal(upMode,2)
    upVal = block.RuntimePrm(2).Data;
elseif isequal(upMode,3)
    upVal = block.InputPort(2).Data;
    lowPortNum = 3; % Move lower boundary down one port number
else
    upVal = inf;
end

% Check lower saturation limit
if isequal(lowMode,2),
    lowVal = block.RuntimePrm(1).Data;
elseif isequal(lowMode,3)
    lowVal = block.InputPort(lowPortNum).Data;
else
    lowVal = -inf;
end

% Use userdata to store limits, if plotFlag is on
if strcmp(plotFlag,'on');
    ud = get_param(block.BlockHandle,'UserData');
    ud.lowVal = [ud.lowVal;lowVal];
    ud.upVal = [ud.upVal;upVal];
    ud.time = [ud.time;block.CurrentTime];
    set_param(block.BlockHandle,'UserData',ud)
end

% Assign new value to signal
if sigVal > upVal,
    sigVal = upVal;
elseif sigVal < lowVal,
    sigVal=lowVal;
end

block.OutputPort(1).Data = sigVal;

%endfunction

```

- 4 Write the function `plotsat.m` to plot the saturation limits. This function takes the handle to the Level-2 MATLAB S-Function block and uses this handle to retrieve the block's `UserData`. If you are following through this tutorial, save `plotsat.m` to your working folder.

```

function plotSat(block)

% PLOTSAT contains the plotting routine for custom_sat_plot
% This routine is called by the S-function block's StopFcn.

ud = get_param(block,'UserData');
fig=[];
if ~isempty(ud.time)
    if strcmp(ud.upBound,'on')
        fig = figure;
        plot(ud.time,ud.upVal,'r');
        hold on
    end
    if strcmp(ud.lowBound,'on')
        if isempty(fig),
            fig = figure;
        end
        plot(ud.time,ud.lowVal,'b');
    end
    if ~isempty(fig)
        title('Upper bound in red. Lower bound in blue.')
    end
end

```

```

% Reinitialize userdata
ud.upVal=[];
ud.lowVal=[];
ud.time = [];
set_param(block, 'UserData', ud);
end

```

- 5 Right-click the Level-2 MATLAB S-Function block and select **Properties**. The Block Properties dialog box opens. On the **Callbacks** pane, modify the StopFcn to call the plotting callback as shown in the following figure, then click **OK**.

Create Custom Library

You can create your own library and, optionally, add it to the Simulink **Library Browser**. You save a library as a `.slx` file as you do a model. However, you cannot simulate in a library, and a library becomes locked for editing each time you close it. You must unlock a library before you make changes to it. See “Lock and Unlock Libraries” on page 41-6.

- 1 From the Simulink start page, select **Blank Library** and click **Create Library**.

Note The Library Browser only supports libraries. You cannot display the contents of a model in the Library Browser.

- 2 (Optional) Define data types to be used on block interfaces in a Simulink data dictionary. Then, attach the data dictionary to the library. Library users automatically gain access to the data contained in the dictionary when they drag a block from the library into their model.
- 3 Add blocks to the new library. Make the changes you want to the blocks, such as changing block parameters, adding masks, or adding blocks to subsystems.

Subsystem names in a library hierarchy must be unique. For example, do not create a hierarchy such as `Subsystem_Name1/Subsystem_Name2/Subsystem_Name1`.

- 4 Add annotations or images. Right-click the ones you want to appear in the library in the Library Browser and select **Show in Library Browser**.
- 5 If you plan to add the library to the Library Browser, you can order the blocks and annotations in your library. By default, they appear alphabetically in the Library Browser, with subsystems first, then blocks, and then annotations. The user of your library can use the Library Browser context menu to choose between viewing them in alphabetical order or the order you specified. When the user selects this option, the order in which they appear in your library determines the order they appear on the grid in the library in the Library Browser.
- 6 If you want the library to appear in the Library Browser, enable the `EnableLBRepository` library property before you save the library.

```
set_param(gcs, 'EnableLBRepository', 'on');
```

- 7 Save the library.

Where you save the library depends on how you plan to use it. If you want to add it to the Library Browser, save it to a folder on the MATLAB path or add the location to the MATLAB path. Otherwise, save it to a location where the models that use the blocks can access it.

If you want the library to appear in the Library Browser, you must also create a function `slblocks` on your MATLAB path that adds the library to the browser. For an example that shows complete steps for adding a library to the browser, see “Add Libraries to the Library Browser” on page 41-8.

Note To update the Library Browser with your custom libraries, right-click anywhere in the Library Browser library list and select **Refresh Library Browser**. Refreshing the Library Browser also updates the quick insert menu to include the blocks in custom libraries currently in effect. The quick insert menu lets you add blocks to a model without leaving the canvas. Click the canvas and start typing to add blocks from the quick insert menu.

Data Dictionary for Custom Libraries

When you define data types — such as bus and enumeration types — to be used on block interfaces, you can make these data types available to users by storing them in a data dictionary that is attached to the library. When a user drags a block from the library into their model, the model automatically gains access to the data contained in the dictionary.

- 1 Create a data dictionary.
- 2 In the dictionary, define bus objects, enumeration types, or other data objects that you will use for the interface definitions of your library blocks.
- 3 Attach the dictionary as an external data source for your library programmatically by using `set_param` or in the UI by using the **External Data** tab in the Library Properties dialog box. The Model Explorer displays the attached dictionary and its content as an external data source for the library.
- 4 To save the data dictionary specifications, save the library.

The types that you defined in the library are now available to you while developing library blocks. See “Link Data Dictionary to Custom Libraries” on page 75-34.

Blocks for Custom Libraries

Your library can contain the blocks you need, configured for your purposes. Subsystems, masked blocks, and charts in your library become linked blocks as instances in the model and stay updated if you change them in your library. Knowing about custom blocks is also useful when you create a library. See “Design and Create a Custom Block” on page 40-12.

You can create blocks in custom libraries with settings for specific purposes.

Create a Sublibrary

If your library contains many blocks, you can group the blocks into subsystems or separate sublibraries. To create a sublibrary, you create a library of the sublibrary blocks and reference the library from a Subsystem block in the parent library.

- 1 In the library you want to add a sublibrary to, add a Subsystem block.
- 2 Inside the Subsystem block, delete the default input and output ports.
- 3 If you want, create a mask for the subsystem that displays text or an image that conveys the sublibrary purpose.
- 4 In the subsystem block properties, set the `OpenFcn` callback to the name of the library you want to reference.

To learn more about masks, see “Create a Simple Mask” on page 39-6.

Prevent Library Block from Linking to Instance

You can configure a library block so the instances created from it are not linked blocks and are instead copies. Set the block’s `CopyFcn` callback.

```
set_param(gcbh, 'LinkStatus', 'none');
```

Include Block Description in Linked Block

To add a description that appears in the linked block, mask the library block and add the description in the **Documentation** pane of the mask. Descriptions added to the library block through the block's properties do not appear on the linked block.

Configure Block with Keywords for Quick Insert

You can add one or more keywords to a block in your library. The keyword lets you add the block to your model from the quick insert menu by entering the keyword or the block name.

For example, suppose you have a custom Gain block in your library. You can add the keyword **My Gain** to the block. Then, you can add the block to your model by entering **My Gain** at the quick insert menu.

Note You cannot add keywords to the blocks from **Commonly Used Blocks** as they are a place to view frequently used blocks from various libraries. If you want to add keywords to a block available in **Commonly Used Blocks**, make sure that you set it in the library where the block is defined.

To add the keyword to the block in your library, use `set_param` with the `'BlockKeywords'` parameter. You can use a character vector, string scalar, or string array as the value. For example:

```
set_param(gcb, 'BlockKeywords', {"My Gain", "Your Gain"})
set_param(gcb, 'BlockKeywords', 'My Integrator')
```

Note The supported special characters in keywords are '&', '(', ')', '+', '@', '!'.

Note The quick insert menu also supports searching for blocks in languages other than English by using internationalized keywords.

Configure Subsystems with OpenFcn Callback for Library Browser

A common use of a Subsystem block in a custom library is to set the `OpenFcn` callback property to open a library, creating a library hierarchy. However, you can use the `OpenFcn` callback property of a Subsystem block for other purposes, for example to run MATLAB code or to open a link.

If a Subsystem block in a library is empty and its `OpenFcn` callback contains code that performs an action other than point to a library, then you need to add a `'ShowInLibBrowser'` mask parameter to the subsystem to have it appear in the Library Browser.

- 1 Right-click the subsystem and select **Mask > Create Mask**. If the block already has a mask, select **Edit Mask** instead.

- 2 In the Mask Editor **Parameters & Dialog** tab, on the **Controls** pane, click **Check box**.
- 3 In the **Dialog box** pane, set the prompt and name for the new check box to **ShowInLibBrowser** and click **OK**.

Annotations in Custom Libraries

You can add annotations in your custom library and optionally have them appear in the Library Browser. For example, you can add an annotation that documents the library. You can also add annotations that the user of your library can add to their model from the Library Browser. Annotations can contain text and images or display an equation. Annotations can also perform an action when clicked. Learn more about annotations in “Describe Models Using Notes and Annotations” on page 4-4.

You can add callout lines from annotations to blocks in your library. However, the callouts do not appear in the Library Browser.

If you want the annotation to appear in the Library Browser, after you add it to your library, right-click it and select **Show in Library Browser**. If you want a description to appear in a tooltip when the user hovers over the annotation in the Library Browser, add the description to the annotation programmatically. At the MATLAB command prompt, enter:

```
set_param(annotationHandle,'Description','descriptionText')
```

To get the annotation handle, use `find_system`. This example gets all the annotations in the library `mylib`:

```
ann = find_system('mylib','FindAll','on','Type','annotation');
```

To get a specific annotation, turn on regular expression search and specify part of the annotation text with the `'Name'` argument:

```
ann = find_system('mylib2','FindAll','on','RegExp',...  
'on','Type','annotation','Name','matchingText');
```

“Add Libraries to the Library Browser” on page 41-8 includes instructions for adding an annotation that appears in the Library Browser.

Lock and Unlock Libraries

When you close a library, it becomes locked for editing. When you next open it, unlock it if you want to make changes to it. Click the lock badge in the lower-left corner of the library to unlock it. Additionally, if you try to modify a locked library, a message prompts you to unlock it.

You can unlock a library programmatically. At the MATLAB command prompt, enter:

```
set_param('library_name','Lock','off');
```

To lock the library programmatically, enter:

```
set_param('library_name','Lock','on');
```

Prevent Disabling of Library Links

By default, a user of the blocks in your library can disable the link to library blocks. If you want to control editing of linked blocks and prevent the block user from disabling links, you can lock links to your library. Locking library links prevents the user from making any changes to the block instances.

- In your library, on the **Library** tab, click **Lock Links**.

To understand how the block user interacts with blocks from locked libraries, see “Lock Links to Blocks in a Library” on page 41-25.

Add Libraries to the Library Browser

This example shows how to create a block library and add it to the Simulink **Library Browser**. This example also shows how to add a sublibrary.

To specify information about your library, you create a function named `slblocks`.

Add Library to the Library Browser

- 1 From the Simulink start page, select **Blank Library** and click **Create Library**.

Note The Library Browser only supports libraries. You cannot display the contents of a model in the Library Browser.

- 2 Add a Gain block to the library.
- 3 In the MATLAB Command Window, enter this command to set the `EnableLBRepository` library property to 'on'. Your library will appear in the Library Browser only if this property is on when you save your library.

```
set_param(gcs, 'EnableLBRepository', 'on');
```

- 4 Save the library in a folder on the MATLAB path. For this example, name the library `mylib`.
- 5 In the MATLAB Current Folder Browser, open the folder that contains `mylib`, then click **New Script** in the MATLAB Toolstrip.
- 6 In the MATLAB Editor that opens, add this function, which specifies that the library `mylib` should appear in the Library Browser with the name **My Library**.

```
function blkStruct = slblocks
% This function specifies that the library 'mylib'
% should appear in the Library Browser with the
% name 'My Library'

    Browser.Library = 'mylib';
    % 'mylib' is the name of the library

    Browser.Name = 'My Library';
    % 'My Library' is the library name that appears
    % in the Library Browser

    blkStruct.Browser = Browser;
```

- 7 Save the function as `slblocks.m`.

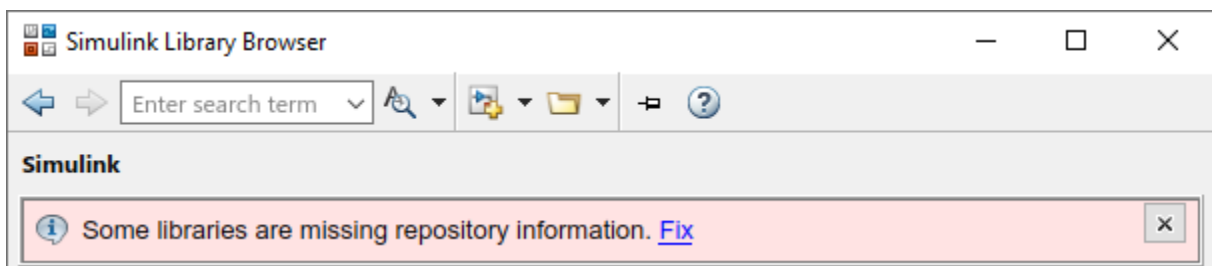

Note You can save the function as an `.m` or `.mlx` file. You cannot save it as a P-code file.

- 8 Open the Library Browser by clicking **Library Browser** in the Simulink Toolstrip.
- 9 To see the new library in the Library Browser, right-click the library list and select **Refresh Library Browser**.

The figure shows the example library `mylib` with the Library Browser name **My Library**.

Note If you saved your library without setting 'EnableLBRepository' to 'on', a message appears at the top of the Library Browser.

Click **Fix** and respond to the prompt as appropriate.

Add Sublibrary to the Library Browser

Follow these steps to add a sublibrary named `mylib2` to your `mylib` library.

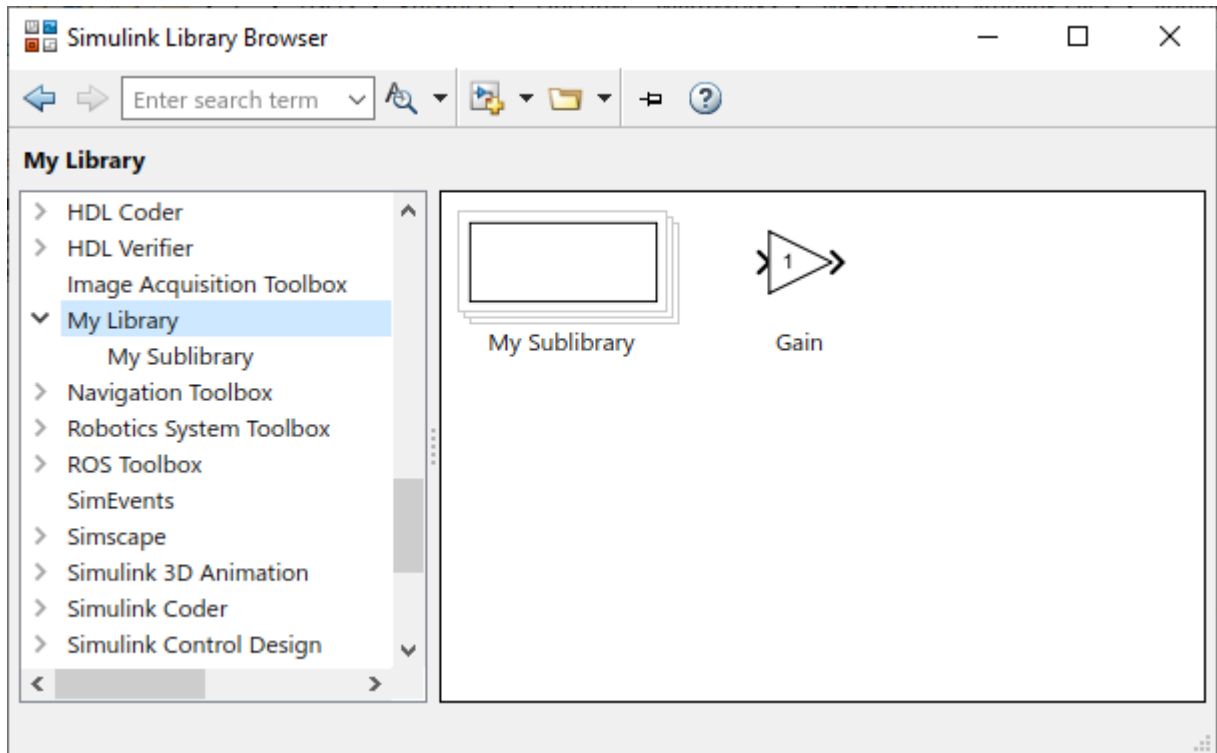

- 1 Create a library named `mylib2`. Add some blocks to it.
- 2 In the MATLAB Command Window, set the `EnableLBRepository` library property to 'on' for the new library.

```
set_param(gcs, 'EnableLBRepository', 'on');
```

- 3 Save mylib2 to the folder that contains mylib.
- 4 Add a Subsystem block to the mylib library.
- 5 Remove the input and output ports from the subsystem by deleting the Inport and Outport blocks inside the subsystem.
- 6 Name the Subsystem block My Sublibrary.
- 7 To link the Subsystem block to the sublibrary, set the OpenFcn callback to mylib2 by using the Property Inspector.

- 8 Save mylib.
- 9 To see the new sublibrary in the Library Browser, right-click the library list and select **Refresh Library Browser**.

The figure shows the example sublibrary `mylib2` with the Library Browser name **My Sublibrary**.

Because of the callback you created, clicking **My Sublibrary** displays the contents of the `mylib2` library.

Specify Library Order in the Library List

You can specify the order of your library relative to the other libraries in the list by adding a `sl_customization.m` file to the MATLAB path and setting the sort priority of your library. For example, to see your library at the top of the list, you can set the sort priority to `-2`. By default, the sort priority of the Simulink library is `-1`. The other libraries have a sort priority of `0` by default, and these libraries appear below the Simulink library. Libraries with the same sort priority appear in alphabetical order.

This sample content of the `sl_customization.m` file places the new library at the top of the list of libraries.

```
function sl_customization(cm)
% Change the order of libraries in the Simulink Library Browser.
cm.LibraryBrowserCustomizer.applyOrder({'My Library', -2});
end
```

To make the customization take effect immediately, in the MATLAB Command Window, enter:

```
sl_refresh_customizations
```

Linked Blocks

In this section...

“Rules for Linked Blocks” on page 41-14

“Linked Block Terminology” on page 41-14

When you add a masked library block or a Subsystem block from a library to a Simulink model, a referenced instance of the library block is created. Such referenced instance of a library block is called a linked block and contains link or path to the parent library block. The link or path allows the linked block to update when the library block is updated.

To optimize the performance, the child blocks (and the parameters) of a linked block are not saved with the Simulink model. When such a model is loaded and viewed, the child blocks are referenced from the parent library. If you change the parameter value of a child block of such a linked block, the changed information is saved as linked data in the model.

To locate the parent library block of a linked block, right-click the block and select **Library Link > Go To Library Link** (Ctrl + L). This option is available only for the blocks that are linked and not for the Simulink built-in blocks. To prevent unintentional disabling of library links, use the locked links option on the library. For more information, see “Lock Links to Blocks in a Library” on page 41-25.

Note The tooltip for a linked block shows the name of the referenced masked library block.

When you edit a library block (either in Simulink Editor or at the command line), Simulink updates the changes in the linked blocks. The outdated links are updated when you:

- Simulate or update the model.
- Use the `find_system` command.
- On the **Modeling** tab, select **Update Model > Refresh Blocks** (or press **Ctrl+K**).
- Load the model or library (only the visible links are updated).
- Use `get_param` to query the link status of the block (see “Control Linked Block Programmatically” on page 41-34).

You can use the `LinkStatus` parameter or the `StaticLinkStatus` parameter to query the link status.

- `LinkStatus`: First updates the linked block and then returns the link status.
- `StaticLinkStatus`: Returns the link status without updating the linked block.

Selective usage of `StaticLinkStatus` over `LinkStatus` can result in better Simulink performance. For more information on `StaticLinkStatus` and `LinkStatus`, see “Control Linked Block Programmatically” on page 41-34.

Rules for Linked Blocks

- You can change the values of a linked block parameter (including the existing mask) in the mask dialog box.
- To allow the library block initialization code to change the values of a linked block parameter, select the **Allow library block to modify its contents** check box in the **Initialization** pane of the library block.
- It is not recommended to set callback parameters for a linked block.
- If the reference library block of a linked block is a subsystem, you can make nonstructural changes such as changing the parameter value of the linked subsystem. To make structural changes to a linked block, disable the link of the linked block from its library block (See “Disable or Break Links to Library Blocks” on page 41-23).

Linked Block Terminology

Terminology	Definition
Parent library block	Library block from which the linked blocks are referenced.
Linked block	Reference instance of a library block that contains links or path to its parent library block.
Locked links	Prevents unintentional modification of a linked block. For more information, see “Lock Links to Blocks in a Library” on page 41-25.
Disabled links	Library links that are temporarily disconnected from their parent library block. For more information, see “Disable or Break Links to Library Blocks” on page 41-23.
Restore links	Restores the disabled link of a linked block to their parent library block. For more information, see “Restore Disabled Links” on page 41-27.
Break links	Permanently breaks the link of a linked block from its parent library block. For more information, see “Disable or Break Links to Library Blocks” on page 41-23.
Self-modifiable links	Linked block with the ability to have structural changes in a linked Subsystem block. For more information, see “Self-Modifiable Linked Subsystems” on page 41-19.
Parameterized links	Created when the parameter values of a linked block are modified using the MATLAB command prompt. For more information, see “Parameterized Links and Self-Modifiable Linked Subsystems” on page 41-16.
Forwarding Tables	Maps the old library block path to new library block path. For more information, see “Maintain Compatibility of Library Blocks Using Forwarding Tables” on page 41-37.

Terminology	Definition
Transformation function	Corrects the mismatch of parameters in the <code>InstanceData</code> of the new and old library links to ensure that the library links continue to work. For more information, see “Maintain Compatibility of Library Blocks Using Forwarding Tables” on page 41-37.

Parameterized Links and Self-Modifiable Linked Subsystems

You can use the MATLAB command prompt to change the value of a parameter in a linked block. Such parameter changes on the linked block result in parameterized links.

Similarly, you can also modify the structure of a linked Subsystem block without changing the parent library block. Such changes can be applied using the mask initialization code and is called self-modifiable linked subsystem.

Parameterized Links

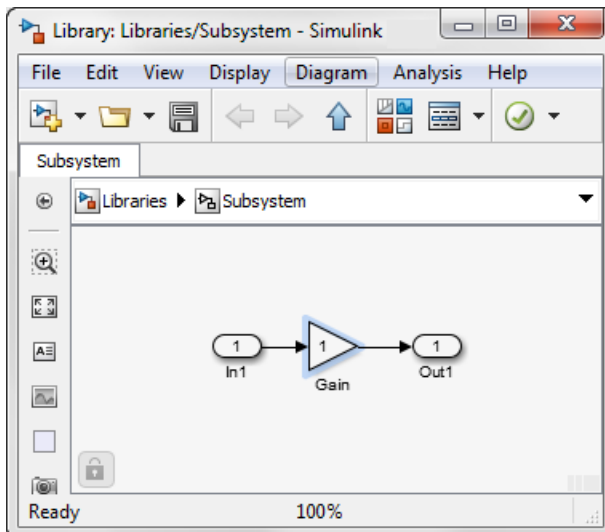

A parameterized link is created when you change the parameter values of the child blocks of a masked subsystem linked block.

A parameterized link allows you to have a different parameter value for the linked block and the parent library block. For such library blocks, the link to the parent block is still retained.

Note Changing the mask value of a parent library block does not create a parameterized link.

For example, you can use the `set_param` command to set a parameter value in the child blocks of a linked subsystem block. The `set_param` command overrides the parameter values of the child blocks of the subsystem linked block. Thus, differentiating the child block value from its parent library block and creating a parameterized link.

Consider a Subsystem library block (see “Subsystem Library Block” on page 41-16) that contains a Gain block within with its parameter value as 1.

Subsystem Library Block

Use this Subsystem block as a linked block in a model.

You can modify the parameter values of the child blocks of the linked block without changing the value of the parent library block. For example, you can change the parameter value of the Gain block within the Subsystem linked block.

To change the Gain parameter value of the Gain block within the Subsystem linked block to 100, sequentially type these commands at MATLAB command prompt:

```
pathName = [modelName, '/Gain_Subsystem1/Gain'];
set_param(pathName, 'Gain', '100')
```

A parameterized link is now created, overriding the parameter value (see “Parameterized Linked Block” on page 41-18). Similarly, change the Gain parameter value of the Subsystem1 linked block.

Parameterized Linked Block

When you save a model containing a parameterized link, Simulink saves the changes to a local copy of the Subsystem with the path to the parent library. When you reopen the model, Simulink copies the library block into the loaded model and applies the saved changes.

Note To view the parameterized changes on a block, right-click the block, and on the context menu, select **View Changes**. The **Link changes** dialog box opens displaying the list of modified blocks. You can also use this dialog box to remove parameterized changes from a block.

Identifying Parameterized Links

A parameterized link displays these identifications:

- The link badge of a parameterized link contains a black link with a red star icon, . For more information, see “Display Library Links” on page 41-21.
- The tooltip of a parameterized linked block displays **Modified parameter in link**.

- Block dialog box of a linked Subsystem block contains **parameterized link**.

Self-Modifiable Linked Subsystems

Tip We recommend using variant blocks over self-modifiable linked subsystems.

A self-modifiable linked subsystem is a linked block with the ability to have structural changes in the subsystem without disabling the link. A self-modifiable linked subsystem is created when you use a library block containing a self-modifiable mask as a linked block. You can use the mask initialization code to change the structural contents.

For more information, see “Dynamic Masked Subsystem” on page 39-41 and Self-Modifiable Mask on page 41-20.

Create a Self-Modifiable Library Block

A self-modifiable linked block is created when you add a self-modifiable masked subsystem block from the library to your model. Such linked blocks allow structural changes within the subsystem block.

You can observe that in this example, if you change the 'Time domain' on the mask dialog box, the block within the Subsystem is replaced accordingly. For example, if you select the 'Time domain' as 'Discrete', the continuous integrator block is replaced with a discrete integrator block and vice-versa.

This dynamic change in the structure of the self-modifiable linked block is controlled using the MATLAB code that is added in the Initialization pane of the Mask Editor.

The structural changes take place only if the option 'Allow library block to modify its contents' available on the Initialization pane is selected.

```
open_system('self_modifiable_mask_example');
```

Display Library Links

Each linked block has a link badge associated with it. The badge makes it easier to identify the linked block in a model and also displays its link status.

To control the display of library link badges in a Simulink model, on the **Debug** tab, select **Information Overlays** and then one of these options:

- **Hide All Links** — Displays no links.
- **Disabled Links** — Displays only disabled links (the default for new models).
- **User-Defined Links** — Displays only links to user libraries.
- **Show All Links** — Displays all links.

If activated, link badges are displayed at the bottom left corner of a linked block. You can right-click the link badge to access link menu options.

The color and icon of the link badge indicates the status of the link.

Link Badge	Status
Black links 	Active link
Gray separated links 	Inactive link
Black links with a red star icon 	Active and modified (parameterized link)
White links, black background 	Locked link

- “Restore Disabled Links” on page 41-27

Disable or Break Links to Library Blocks

Structural changes in a model include addition or deletion of blocks or adding ports while non-structural changes include changes in parameter value.

A linked block does not allow structural changes to it. You can disable the link of a linked block from its parent library block and perform required modifications. A disabled linked block behaves like a local instance of a block and allows you to make structural and nonstructural changes.

To disable a link, right-click the linked block and select **Library Link > Disable Link**. The **Disable Link** menu choice is made available only if the parent block of the linked block is disabled. If the menu option is grayed out, you must disable the link of the parent block first.

Alternatively, you can right-click the link icon in the graph on the bottom left corner of the canvas and click **Disable Link**. This action recursively disables the links of all the blocks up in the hierarchy.

To prevent unintentional disabling of a linked block, you can lock its links to the library. To lock a link, in the Library window, on the **Library** tab, click **Lock Links**. You can later choose to unlock the locked link by clicking **Links Locked**.

Note Simulink offers to disable the library links (unless the link is locked) when you try to make structural changes to a block that contains active library links.

Do not use `set_param` to make structural changes to an active link. The result of this type of change is undefined.

A disabled link of a linked block can be restored. For more information, see “Restore Disabled Links” on page 41-27.

Disabled links can cause merge conflicts and failure to update all instances of the same model component. In a hierarchy of links, you can accidentally disable all links without being aware of it, and only restore one link while leaving others disabled.

Break Links

You can permanently break links to the parent library. Before you break a library link, the link must first be disabled. When you break a link, the linked block is converted to a standalone block, and you cannot detect what the block linked to previously.

To break a link, use any of these options:

- For disabled links, right-click the linked block and select **Library Link > Break Link**.
- To copy and break links to multiple blocks simultaneously, select multiple blocks and then drag. The locked links are ignored and not broken.
- When you save the model, you can break links by supplying arguments to the `save_system` command. For more information, see `save_system`.

Note

- Some models can contain blocks from third-party libraries or optional Simulink block sets. Breaking the link for such models does not guarantee that you can run the model standalone. It is

possible that a library block invokes functions supplied with the library and hence can run only if the library is installed on the system running the model.

- Breaking a link can cause a model to fail when you install a new version of the library on a system. For example, if a model block invokes a function that is supplied from a library. If you break the link for such a block, the function can no longer be invoked from the model, causing simulation to fail. To avoid such problems, avoid breaking links to libraries.
-

“Linked Blocks” on page 41-13 | “Restore Disabled Links” on page 41-27

Lock Links to Blocks in a Library

You can lock links to a library. Lockable library links prevent unintentional disabling of these links. Lockable libraries ensure robust usage of mature stable libraries.

To lock links to a library, in the Library window, on the **Library** tab, click **Lock Links**. The link from the linked block to its parent library is now locked. When you refresh the model, you see a change in the link badge. The locked link badges have a black background.

Locked linked block links cannot be disabled from the parent library block. Such links can only be disabled from the command line by changing the LinkStatus to inactive. For more information, see “Control Linked Block Programmatically” on page 41-34.

The context menu of a locked linked block displays **Locked Library Link** and not **Library Link**. Also notice that the only enabled option on this menu is **Go To Library Block**.

If you open a locked linked block, the window title displays **Locked Link: *blockname***. The bottom left corner shows a lock icon and a link badge. You can also hover over the link badge to view lock information.

To unlock links from the Library window, on the **Library** tab, click **Links Locked**. If the library is locked, the option to lock or unlock the links is disabled. You must unlock the library to enable the option.

Rules for Locked Links

- Locked links cannot be edited. If you try to make a structural change to a locked link (such as editing the diagram), you see a message that you cannot modify the link because it is either locked or inside another locked link.
- The mask and block parameter dialogs are disabled for blocks inside locked links. For a resolved linked block with a mask, its parameter dialog is always disabled.
- You cannot parameterize locked links in the Model Editor.

- When you copy a block, the library status determines the status of a link (locked or not). If you copy a block from a library with locked links, the link is locked. If you later unlock the library links, any existing linked blocks do not change to unlocked links until you refresh the links.
- If you use sublibraries, when you lock links to a library, lock links to the sublibraries.

More About

- “Linked Blocks” on page 41-13

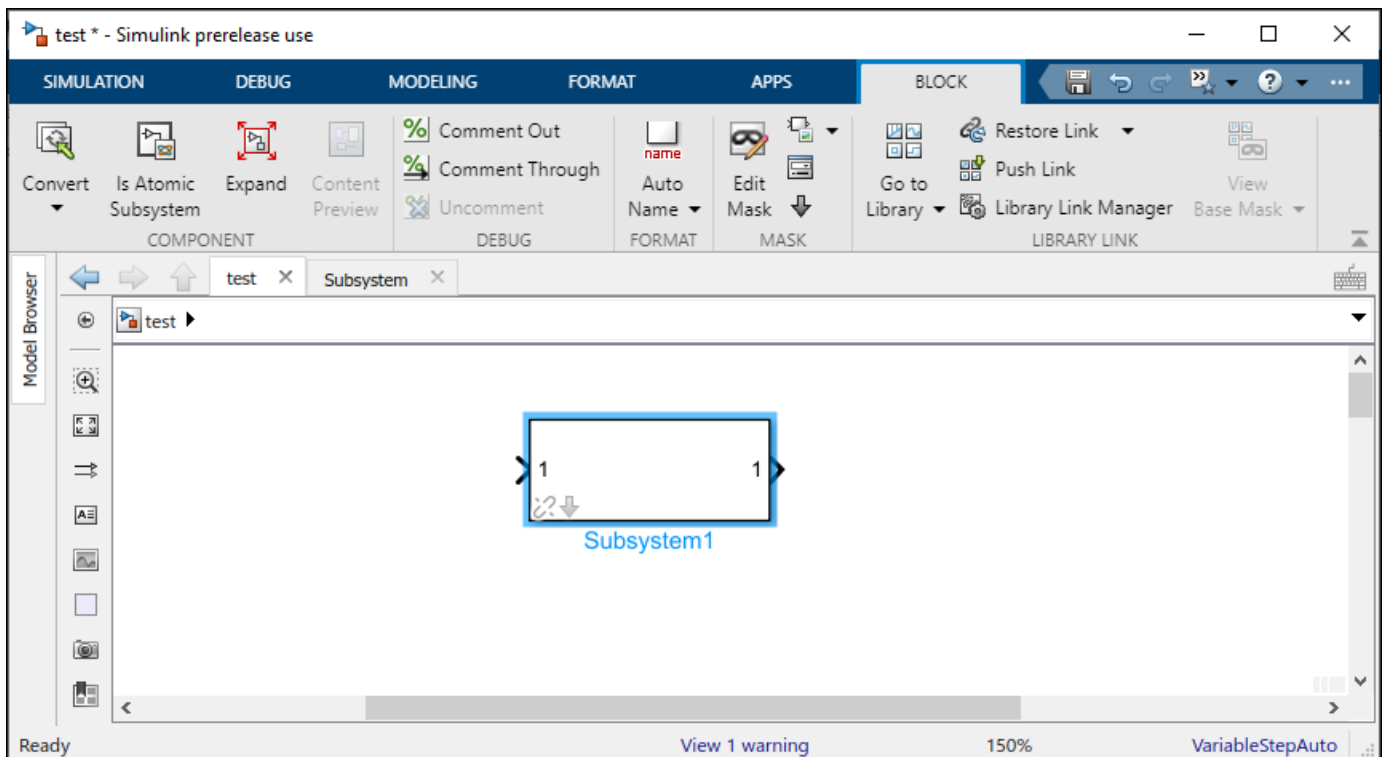

Restore Disabled Links

You can restore a disabled linked block or push a linked block value to the parent library block either individually or hierarchically.

Restore Disabled Links Individually

When you push or restore a disabled block in individual mode, the disabled or edited block is pushed to or restored from the library, preserving the changes inside the block without acting on the hierarchy. All other links are unaffected. You can restore or push individual disabled blocks in three ways:

- Select the disabled linked block and in the Simulink toolstrip, on the **Subsystem Block** tab, select **Push Link** or **Restore Link**.

- Right-click a disabled linked block and from the context menu, select **Library Links** and click **Push Link** to push the changes or **Restore Link** to restore the values from the parent library block.
- Right-click the link badge on the bottom-left corner of a disabled linked block and from the context menu, click **Push Links** to push the changes or **Restore Link** to restore the values from the parent library block.

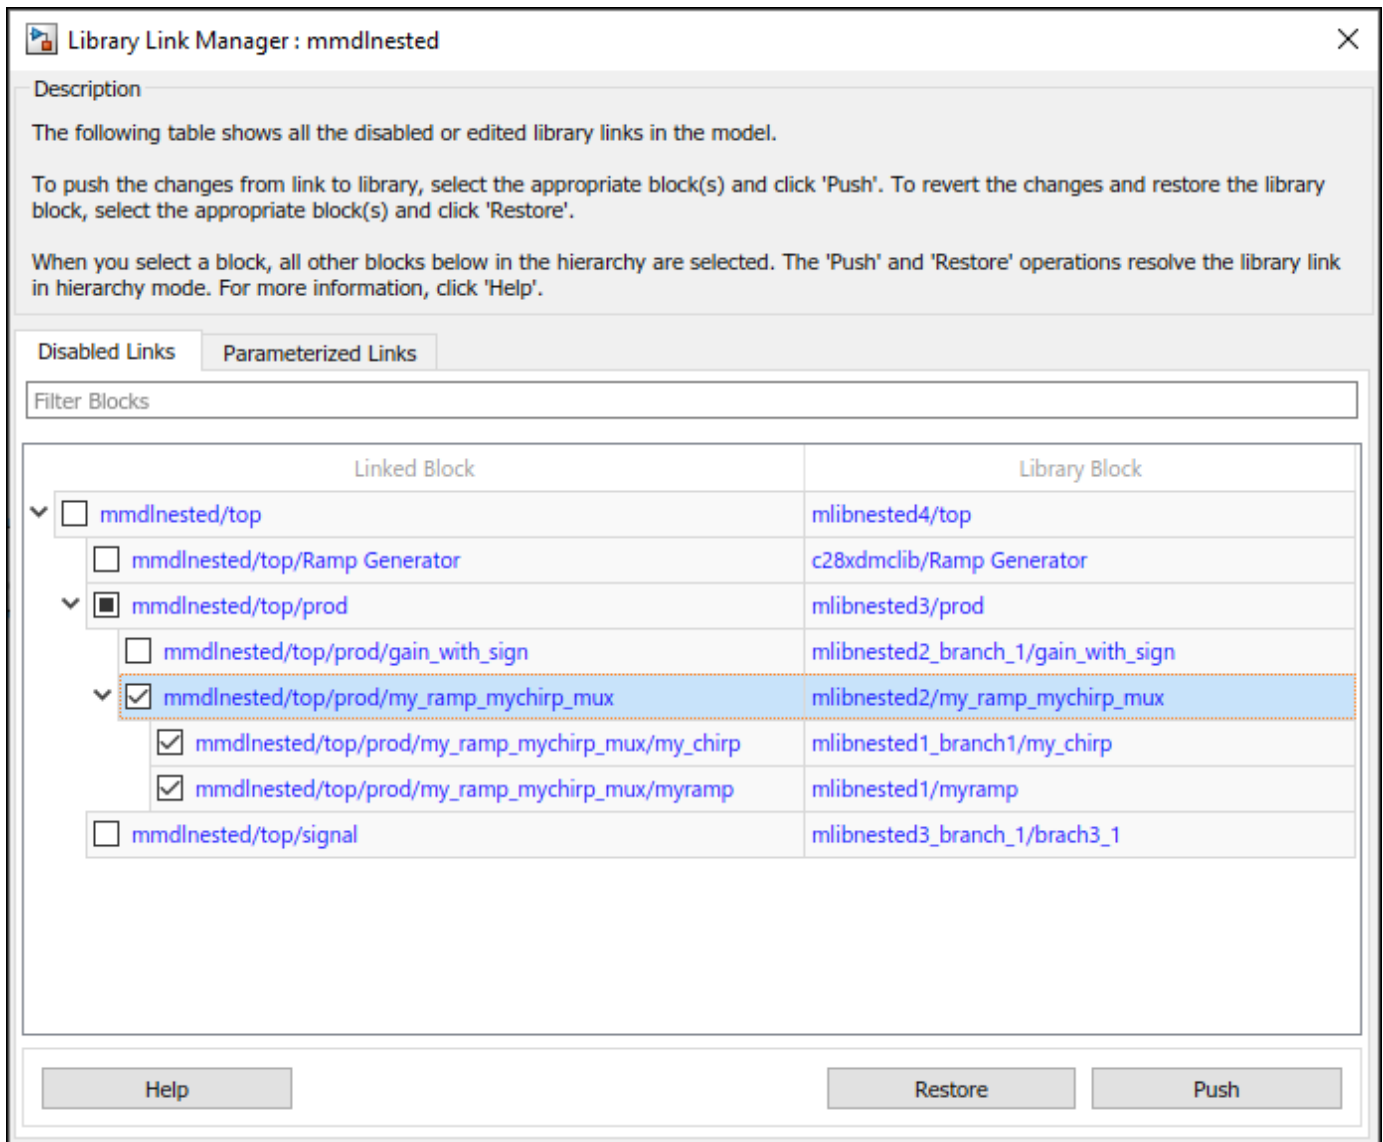

Restore Disabled Links Hierarchically

When you push or restore disabled links in the hierarchy mode, the operation is applied to the whole hierarchy of links. To push or restore in hierarchy mode, use the Library Link Manager tool. The Library Link Manager displays all the disabled and parameterized linked blocks in the model.

You can launch the Library Link Manager in two ways:

- In the Simulink toolstrip, on the **Modeling** Tab, under the **System Design** section, click **Library Link Manager**.
- or
- Select any disabled linked block and in the Simulink toolstrip, on the **Subsystem Block** tab, click **Library Link Manager**.

The Library Link Manager window appears. It has two tabs showing disabled Links and parameterized links in the model. By default, the **Disabled Links** tab is selected.

The table shows two columns where the **Linked Block** column displays the list of linked blocks that have disabled links and the **Library Block** column displays the parent library block of the corresponding linked blocks.

To push or restore disabled blocks,

- 1 Select the disabled block or blocks as per your requirement.
- 2 Click **Push** to replace the version of the block in the library with the version in the model or **Restore** to replace the version of the linked block in the model with the version in the library.

You can use the **Filter Blocks** field to filter the displayed linked blocks based on your preference. This is useful when you have a huge number of blocks in the model.

Pushing or Restoring Link Hierarchies

Pushing a hierarchy of disabled links affects the disabled links inside and outside the hierarchy for a given link. If you push changes from a disabled link in the middle of a hierarchy, the inside links are pushed and the outside links are restored if unchanged. This operation does not affect outer (parent) links with changes unless you also explicitly selected them for push. The Library Link Manager starts to push from the lowest inside links and then moves up in the hierarchy.

For examples:

- 1 Link A contains link B and both have changes.
 - Push A. The Links Tool pushes both A and B.
 - Push B. The Links Tool pushes B and not A.
- 2 Link A contains link B. A has no changes, and B has changes.
 - Push B. The Links Tool pushes B and restores A. When parent links are unmodified, they are restored.

If you have a hierarchy of parameterized links, the Library Links Manager can manipulate only the top level.

Tip To compare files and view structural changes, in the **Modeling** tab, select **Compare > Compare Models**.

More About

- “Linked Blocks” on page 41-13
- “Restore Parameterized Links” on page 41-30

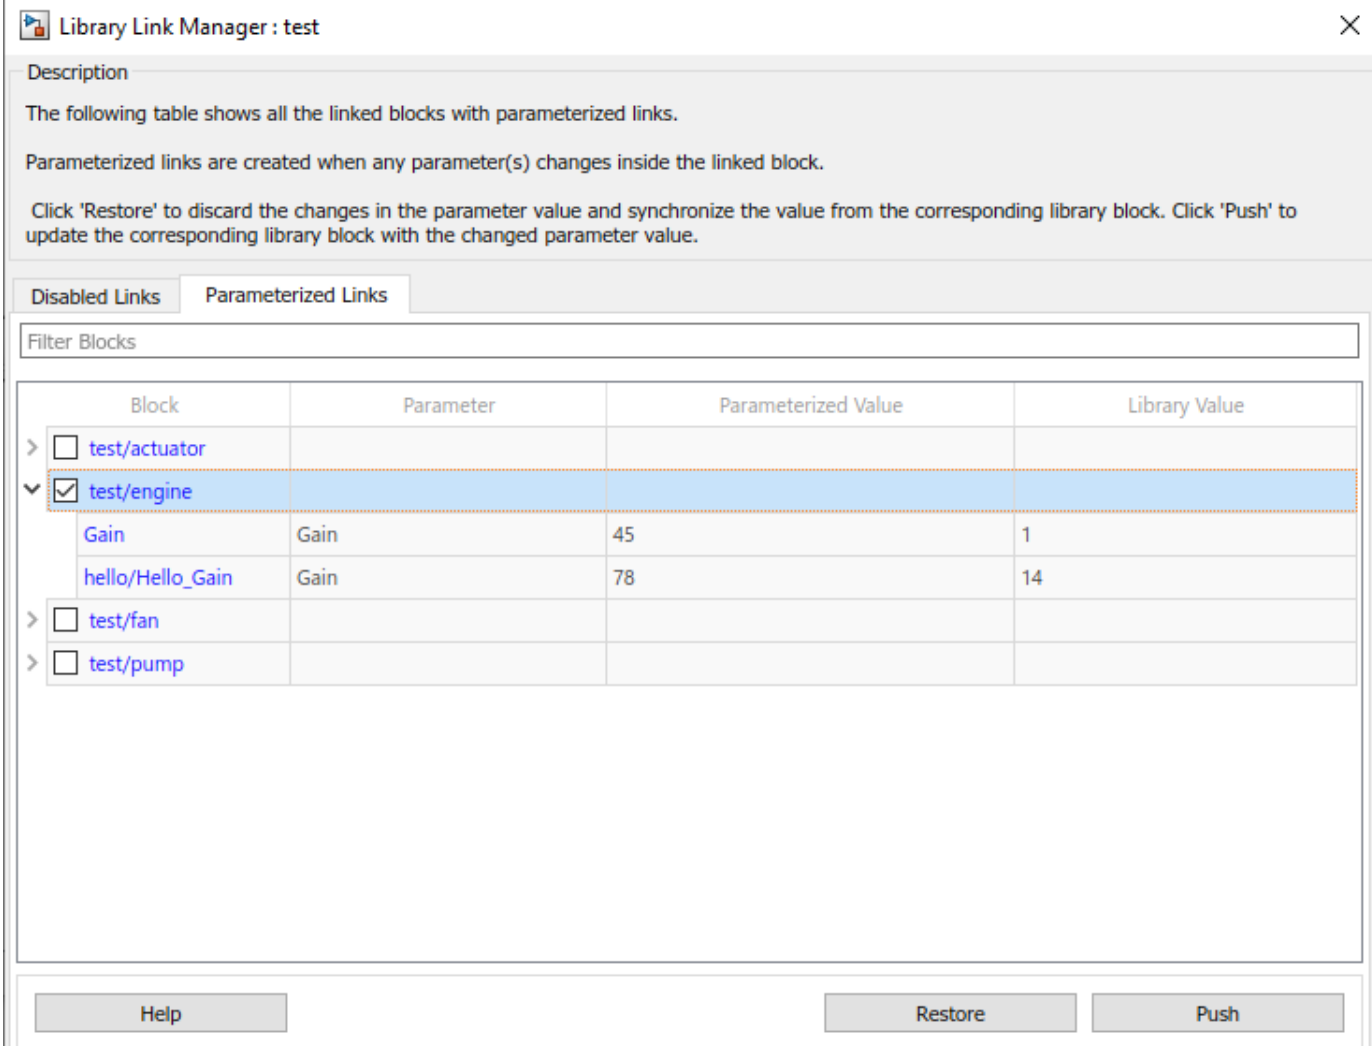

Restore Parameterized Links

A parameterized link is created when you change the parameter values of the child blocks of a masked subsystem linked block. You can choose to push the new values from the linked block to the parent block or restore the linked block with values from the parent block. You can push or restore parameterized links using the Library Links Manager.

To restore or push parameterized links:

- 1 Select the parameterized link and in the Simulink toolstrip, on the **Subsystem Block** tab, click **Library Link Manager**.

The Library Link manager opens. Click the **Parameterized Links** tab to display all the parameterized link in the model.

The screenshot shows the 'Library Link Manager: test' dialog box. It has a 'Description' section with text explaining parameterized links and instructions for 'Restore' and 'Push' buttons. Below the description are two tabs: 'Disabled Links' and 'Parameterized Links', with the latter selected. A 'Filter Blocks' input field is present. The main area contains a table with four columns: 'Block', 'Parameter', 'Parameterized Value', and 'Library Value'. The 'test/engine' block is expanded, showing two parameterized links: 'Gain' with a value of 45 and library value of 1, and 'hello/Hello_Gain' with a value of 78 and library value of 14. At the bottom, there are three buttons: 'Help', 'Restore', and 'Push'.

Block	Parameter	Parameterized Value	Library Value
<input type="checkbox"/> test/actuator			
<input checked="" type="checkbox"/> test/engine			
Gain	Gain	45	1
hello/Hello_Gain	Gain	78	14
<input type="checkbox"/> test/fan			
<input type="checkbox"/> test/pump			

The table has the following columns:

- **Block** - Displays the block name.

- **Parameter** - The name of the parameter in the block.
 - **Parameterized Value** - The changed value of any edited parameter in the model.
 - **Library Value** - The original value of the parameter in the parent library block.
- 2 Select the blocks you want to push or restore.
 - 3 Click **Push** to replace the value of the block in the library with the parameterized value in the model or **Restore** to replace the version of the linked block in the model with the version in the library.

Fix Unresolved Library Links

If Simulink is unable to find either the library block or the source library on your MATLAB path during a linked block update, the link becomes unresolved. Simulink changes the appearance of these blocks.

Install Missing Product

Simulink helps you find and install missing products that a model needs to run.

- Blocks are labeled with missing products (for example, **SimEvents not installed**).
- Tooltips include the name of the missing product.
- Diagnostic messages provide links to open the Add-On Explorer and install any missing products.
- When you double-click the block, the dialog box provides a link to open the Add-On Explorer and install any missing products.

Resolve Path to Source Block

If Simulink is unable to find the library, you can fix the unresolved link using one of these methods:

- Fix the reference to point to the correct location of the library block. Double-click the block to open its dialog box. Then, correct the path of the library block in the **Source block** text box and click **OK**.

- Delete the unresolved block and copy the library block back into your model.
- Add the folder that contains the required library to the MATLAB path. Then, on the **Modeling** tab, click **Update Model**.

Specify Unresolved Block Details for Custom Libraries

You can customize the description that appears in the dialog box for an unresolved link to a custom library. Use the `set_param` function to set the `libraryinfo` property of the library. For example, this command customizes the description to include a URL.

```
set_param(library1, 'libraryinfo', 'https://www.mathworks.com');
```

Here, `library1` is the name of the library for which you want to change the description, and `libraryinfo` is the property that provides the description of the unresolved link.

Control Linked Block Programmatically

Linked Block Information

Use the `libinfo` command to get information about the linked blocks in the model. `libinfo` also provides information about the parent library blocks of a linked block.

For example, here is a model with linked blocks:

Masking variant blocks

When you execute the `libinfo(gcb)` command on this block:

```
Block: 'slexMaskVariantExample/VariantSubsystem2' %Linked block
      Library: 'slexMaskingVariants_libraryblock' %Parent library block
      ReferenceBlock: 'slexMaskingVariants_libraryblock/VariantSubsystem2'
      LinkStatus: 'resolved' %Link status
```

The `ReferenceBlock` property gives the path of the library block to which a block links. You can change this path programmatically by using the `set_param` command. For example:

```
set_param('slexMaskVariantExample/VariantSubsystem2','ReferenceBlock','slexMaskVariantExample2/VariantSubsystem')
```

Here, `slexMaskVariantExample/VariantSubsystem2` is the original library block path and `slexMaskVariantExample2/VariantSubsystem` is the new library block path.

Note It is not recommended to change the properties of a referenced block by using the `set_param` command in the mask initialization code or callback code of the same block. For such modeling patterns, you can use Variant blocks (Masking variant blocks) or use the `ReferenceBlock` parameter on the callback code or the mask initialization code of the parent block of the reference block.

Lock Linked Blocks

Use the `LockLinksToLibrary` command to lock or unlock a linked block in a library from the command line. When you set the value of `LockLinksToLibrary` to `on`, the linked block links to the library are locked.

```
set_param('MyLibraryName', 'LockLinksToLibrary', 'on') %Lock links
```

```
set_param('MyLibraryName', 'LockLinksToLibrary', 'off') %Unlock links
```

Link Status

All blocks have a `LinkStatus` parameter and a `StaticLinkStatus` parameter to indicate whether the block is a linked block.

Use `get_param(gcb, 'StaticLinkStatus')` to query the link status without updating the linked blocks. You can use `StaticLinkStatus` to query the status of a linked block that is either active or outdated.

Use `get_param` to send a query to get the value of the `LinkStatus`.

Get LinkStatus Value	Description
none	Block is not a linked block.
resolved	Resolved link.
unresolved	Unresolved link.
implicit	Block resides in library block and is itself not a link to a library block. Suppose that A is a link to a subsystem in a library that contains the Gain block. If you open A and select the Gain block, <code>get_param(gcb, 'LinkStatus')</code> returns <code>implicit</code> .
inactive	Disabled link.

Use `set_param` to set the `LinkStatus`.

Set LinkStatus Value	Description
none	Breaks link. Use <code>none</code> to break a link, for example, <code>set_param(gcb, 'LinkStatus', 'none')</code> .
<code>breakWithoutHierarchy</code>	Breaks links in place without breaking the nested parent hierarchy of link. For example, <code>set_param(gcb, 'LinkStatus', 'breakWithoutHierarchy')</code> .
inactive	Disables link. Use <code>inactive</code> to disable a link, for example, <code>set_param(gcb, 'LinkStatus', 'inactive')</code> .
restore	Restores an inactive or disabled link to a library block and discards any changes made to the local copy of the library block. For example, <code>set_param(gcb, 'LinkStatus', 'restore')</code> replaces the selected block with a link to a library block of the same type. It discards any changes in the local copy of the library block. <code>restore</code> is equivalent to <code>Restore Individual</code> in the Links Tool.
propagate	Pushes any changes made to the disabled link to the library block and re-establishes its link. <code>propagate</code> is equivalent to <code>Push Individual</code> in the Links Tool.
restoreHierarchy	Restores all disabled links in the hierarchy with their corresponding library blocks. <code>restoreHierarchy</code> is equivalent to <code>Restore</code> in hierarchy mode in the Links Tool.
propagateHierarchy	Pushes all links with changes in the hierarchy to their libraries. <code>propagateHierarchy</code> is equivalent to <code>Push</code> in the Hierarchy mode of the Links Tool. See “Restore Disabled Links” on page 41-27.

Note

- When you use `get_param` to query the link status of a block, the outdated block links also resolve.
- Using the `StaticLinkStatus` command to query the link status when `get_param` is being used in the callback code of a child block is recommended. `StaticLinkStatus` command does not resolve any outdated links.

If you call `get_param` on a block inside a library link, Simulink resolves the link wherever necessary. Executing `get_param` can involve loading part of the library and executing callbacks.

Maintain Compatibility of Library Blocks Using Forwarding Tables

Forwarding Table allow you to check that the changes to blocks in a library do not break the model if you have saved the model with an older version of the library block. Forwarding tables help you to maintain compatibility of library blocks when you change the path or name of the library, or add, remove, or rename the parameters in the library block. For more information see, “Create Custom Library” on page 41-2.

Create a forwarding table entry for mapping old library blocks to new library blocks. When you open the model, the links to the old library block are updated automatically without losing data or functionality. Forwarding tables are executed when you open a model, close a model, or when you execute the `add_block` or `replace_block` command.

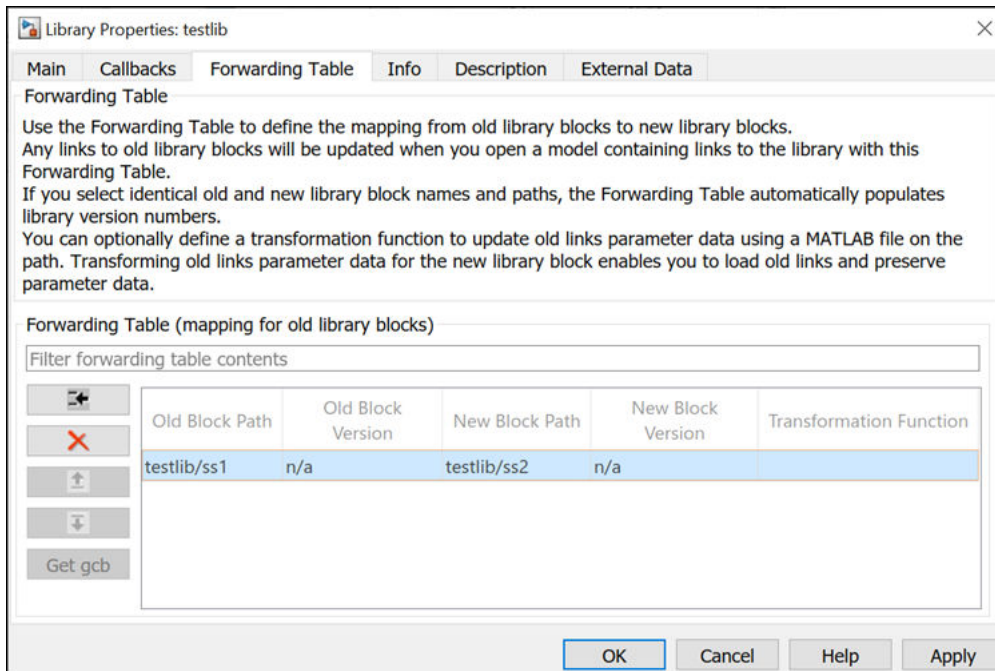

Create a forwarding table entry when you:

- Rename a block.
- Move a block from one library to another library.
- Add or remove parameters from the block.
- Split the functionality of a block.

Forwarding Table Entry for a Renamed Block

Consider an example where the block name in a library `testlib` is renamed from `ss1` to `ss2`.

- 1 Open the locked library `Lib1`.
- 2 In the Library window, on the **Library** tab, click **Locked Library**. The library is now unlocked for editing.
- 3 On the **Modeling** tab, click **Library Properties**. The **Library Properties** dialog box opens.
- 4 Click the **Forwarding Table** tab.
- 5 Click Add New entry. A new row is added in the forwarding table.
- 6 Specify the name of the old block in **Old Block Path** and the corresponding new block path in the **New Block Path**. If you do not know the path, select the block in the model and click **Get gcb** button. The path of the block is automatically populated in the respective columns.

The mapping of the old path to new path is created in the forwarding table. Now, open a model that contains links to the library. The links to the old library blocks in the model are updated automatically. You can use the search bar above the table to filter the table contents. You can sort the columns in ascending or descending order. You can also group columns by their values.

Assign Version Numbers to Library Blocks

In the **Version** column, you can specify a version number for the library block.

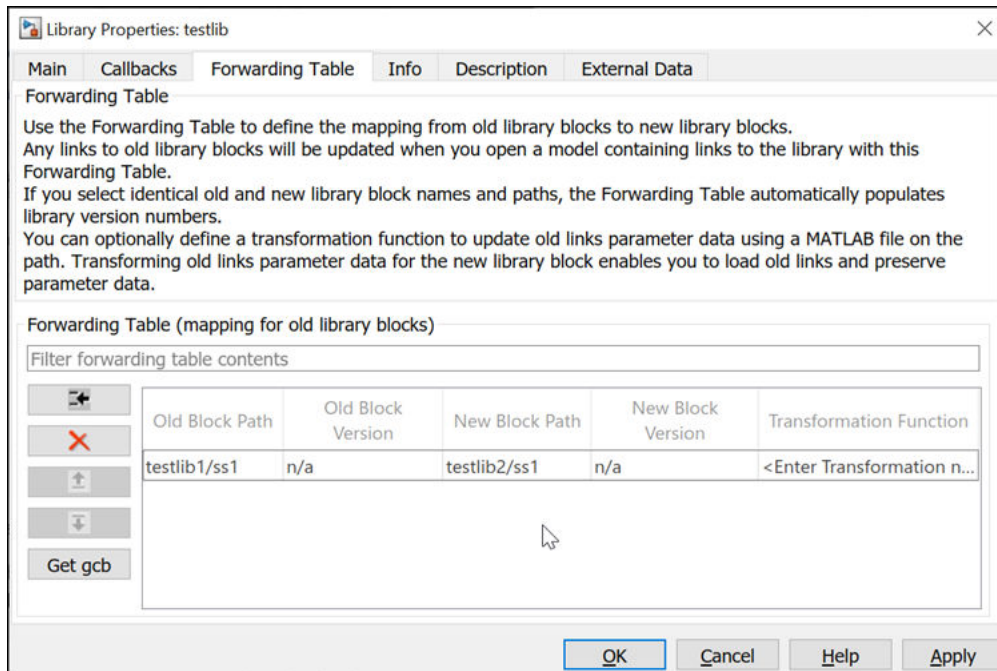

If the old block name is the same as new block name, the forwarding table populates the version number automatically. The initial value of the library version `LibraryVersion` is derived from the `ModelVersion` property of the library at the time the library link is created. Any subsequent updates to the library block will update the library version to match the model version of the library.

The version number:

- Must be a numeric value.
- Must be of the format `<major_version>. <minor_version>` when the old and the new block paths are the same.
- Must not have more than one dot notation. For example, a version number of 1.3 is acceptable. A version number 1.3.1 is not acceptable.
- Format is not critical when you use a forwarding table to move a library block from one library to another.

Move Block from One Library to Another

Consider an example where a block `ss1` is moved from `testlib1` to `testlib2`. The forwarding table entry in this case is shown here:

Add or Remove Parameters from the Block

Consider an example where the **Gain** parameter of `ss1` in library `testlib` is removed, and two other parameters `Initial condition` and `Delay length` are added to it.

To handle this change we use a transformation function. A transformation function corrects the mismatch of parameters between the new and old library links, which ensures that the library links continue to work. You can define a transformation function using a `.m` function file on MATLAB path, then call the function in the **Transformation Function** column of the **Forwarding Table**.

A linked block contains an instance of the block parameters in the form of name-value arguments to instantiate the block. This instance data is passed to transformation function as `InstanceData` along with forwarding entry. This data is stored as `struct` fields.

When you create versions of a library block, parameters are added or removed from the `InstanceData`. In this example, the `InstanceData` before removal of the **Gain** parameter and after the addition of initial condition and delay length looks like this

Before:

```
'RTWMemSecFuncInitTerm' 'Inherit from model'
'RTWMemSecFuncExecute' 'Inherit from model'
```

```
'RTWMemSecDataConstants' 'Inherit from model'  
'RTWMemSecDataInternal' 'Inherit from model'  
'RTWMemSecDataParameters' 'Inherit from model'  
'ContentPreviewEnabled' 'on'  
'Gain' '0'
```

After:

```
'RTWMemSecFuncInitTerm'      'Inherit from model'  
'RTWMemSecFuncExecute'     'Inherit from model'  
'RTWMemSecDataConstants'   'Inherit from model'  
'RTWMemSecDataInternal'   'Inherit from model'  
'RTWMemSecDataParameters' 'Inherit from model'  
'ContentPreviewEnabled'    'on'  
'DelayLength'              '1'  
'InitialCondition'         '0'
```

This is the syntax for transformation function.

```
function outData = TransformationFcn(inData)
```

In this function syntax:

- `inData` is a structure with fields `ForwardingTableEntry` and `InstanceData`. `ForwardingTableEntry` is also a structure.
- • The `ForwardingTableEntry` has the old name, new name, old path, and new path of a block. Refer to the code to access the members of the `ForwardingTableEntry`.
- `outData` is a structure with fields `NewInstanceData` and `NewBlockPath`.

The add or remove parameters from a block:

- 1 Obtain the instance data and the forwarding table entry.
- 2 Extract the list of name-value pair and block names.
- 3 Get the old and new block names.
- 4 Check if the old and new block names are same. If so, then extract the versions of the block.
- 5 Check if the old version is 1.1 and the new version is 1.2. Then, remove the `Gain` parameter and add the parameters `Delay length` and `Initial condition`.

Note You can have only one transformation function for one library or block. However, you can have multiple functions.

To add or remove parameters, use this transformation function.

```
function [outData] = txFcnTestlib(inData)  
    outData.NewBlockPath = '';  
    outData.NewInstanceData = [];  
  
    % Get linked block instance data and forwarding entry for which  
    % function is called  
    instanceData = inData.InstanceData;  
    forwardingTableEntry = inData.ForwardingTableEntry;  
  
    % Get list of name value pair and block names
```

```

[ParamNames{1:length(instanceData)}] = instanceData.Name;

% Get old and new block paths or simply names
oldName = forwardingTableEntry('__slOldName__');
newName = forwardingTableEntry('__slNewName__');

% If block names are same and its subsys block in the lib
if strcmp(oldName, newName)
    % Get old and new block versions from forwarding table
    oldVer = forwardingTableEntry('__slOldVersion__');
    newVer = forwardingTableEntry('__slNewVersion__');

    % Each forwarding entry with different version can have separate
    % entry. Here, for one single entry in forwarding table i.e.
    % 1.2->1.3 or 1.3->2.0, we have separate transformation making one
    % TX Fcn for one library or block.
    if strcmp(oldName, 'testlib/ssl')
        % Forwarding with same block name ssl
        if oldVer == '1.1' && newVer == '1.2'
            % Remove gain param
            if (ismember('Gain',ParamNames))
                for (i = 1:length(instanceData))
                    if (strcmp(instanceData(i).Name,'Gain') == true)
                        instanceData(i) = [];
                        break;
                    end
                end
            end
        end

        % Add delay length param
        if (ismember('DelayLength',ParamNames))
            for (i = 1:length(instanceData))
                if (strcmp(instanceData(i).Name,'Value') == true)
                    instanceData(i).Value = '5';
                    break;
                end
            end
        else
            instanceData(end+1).Name = 'DelayLength';
            instanceData(end).Value = '1';
        end

        % Add initial condition param
        if (ismember('InitialCondition',ParamNames))
            for (i = 1:length(instanceData))
                if (strcmp(instanceData(i).Name,'InitialCondition') == true)
                    instanceData(i).Value = '0';
                    break;
                end
            end
        else
            instanceData(end+1).Name = 'InitialCondition';
            instanceData(end).Value = '0';
        end
    elseif (oldVer == '1.2' && newVer == '1.3')
        % Do version 1.2 to 1.3 specific changes
    elseif (oldVer == '1.3' && newVer == '2.0')
        % Do version 1.3 to 2.0 specific changes
    end
end

```

```

        else
            % Do default changes not applicable to any version if
            % required
        end
    elseif strcmp(oldName, 'testlib/ss2')
        % Forwarding for block ss2 with version upgrade
    end
elseif strcmp(oldName, 'testlib/oldblk') && strcmp(newName, 'testlib2/newblk')
    % Block moved to new library or just block is renamed within same
    % library, no version is checked here. Do transformation is
    % required i.e. is block has been modified while renaming or moving
    % to new lib.
elseif strcmp(oldName, 'testlib/blkX') && isempty(newName)
    % We are splitting the block into 2 different blocks. Hence, kept
    % newName empty in fwd table. Using one of the block param from its
    % instance data (which is name-value pair of all block params) to
    % decide how and what to divide.

    % Get the index of param we are interested in i.e. param X
    i = find(contains({instanceData.Name}, 'X'), true);

    % Based on its value, do block splitting
    switch (instanceData(i).Value)
        case 'op1'
            newName = 'newlibX/blkX';
            % Remove existing param or add new param or modify existing
            % params etc.
        case 'op2'
            newName = 'newlibY/blkX';
        otherwise
            newName = oldName;
    end
end

% Return new instance data and new block path
outData.NewInstanceData = instanceData;
outData.NewBlockPath = newName;
end

```

Split Block Functionality

Splitting the functionality of a block involves adding, removing, or modifying the existing parameter of the block and adding it to the new block. To split the functionality of a block:

- 1 Leave the newName argument empty.
- 2 Get the index and value of the parameter.
- 3 Split the block based on its value.
- 4 Return the NewBlockPath with the updated InstanceData if required.

Create Mask Parameter Aliases

If you rename a mask parameter, you must ensure that the existing MATLAB scripts that use the old parameter names, continues to work. To check compatibility, you can create an alias for a mask parameter name. An alias allows you to change the name of a mask parameter in a library block without having to recreate links to the block in existing models.

Consider a masked block that contains an **Edit** parameter. The mask parameter name for this **Edit** parameter is `p1`.

```
MaskObj = Simulink.Mask.get(gcb);
hEdit = MaskObj.getParameter('p1');
```

```
hEdit=
% MaskParameter with properties:
```

```
    Type: 'edit'
TypeOptions: {0x1 cell}
    Name: 'p1'
    Prompt: 'p1'
    Value: '0'
    Evaluate: 'on'
    Tunable: 'on'
NeverSave: 'off'
    Hidden: 'off'
    Enabled: 'on'
    Visible: 'on'
    ToolTip: 'on'
    Callback: ''
    Alias: ''
```

Notice that the **Edit** mask parameter does not have an alias. To add an alias for the mask parameter, set a value for the **Alias** mask parameter property.

```
MaskObj.Alias = 'pa'
```

You can either use the mask parameter name or the alias to do a function call on the mask parameter. For example, you can either use `set_param(gcb, 'p1', '10')` (mask parameter name) or `set_param(gcb, 'pa', '10')` (mask parameter alias) to set a value for the **Edit** mask parameter.

“Generate Code from Model” on page 42-11
“Simulate Custom Code in a Separate Process” on page 42-11
“Limitations” on page 42-13

You can integrate new or existing C code into Simulink using the C Caller block. To create custom blocks in your Simulink models, the C Caller block allows you to call external C functions specified in external source code and libraries. The advantages of the C Caller block are:

- Automated integration of simple C functions
- Integration with Simulink Coverage, Simulink Test, and Simulink Design Verifier
- Integration with Simulink Coder

The C Caller block and the C Function block allow you to bring C algorithms into Simulink. To model dynamic systems, use the S-Function Builder instead. Next steps describe the workflow to integrate C code into Simulink using the C Caller block.

Note C99 is the standard version of C language supported for custom C code integration into Simulink.

Specify Source Code and Dependencies

Specify your external source code file that contains your C functions.

- 1 From Simulink toolstrip, open the **Configuration Parameters**.
- 2 In the left pane, select **Simulation Target**.
- 3 To enable code parsing by the C Caller block, ensure that the **Import custom code** box is selected.

The directories and file paths can be absolute and relative file paths to model directories or to the current working directory. See “Specify Relative Paths to Your Custom Code” (Stateflow).

- 4 Select **Header file** and enter the name of your header file with the `#include` tag.

Insert custom C code in generated

Header file*	Header file:
Source file	#include "my_func.h"
Initialize function	
Terminate function	

Auto-fill from Source files

Tip After you have entered information for **Source files** in the next step, you can click **Auto-fill from Source files** to have the header file name filled in automatically, using information contained in your source files.

- Under **Additional build information**, select **Source files** and enter the path and the name of the source file. If the model and the source files are in different directories, enter the directory that contains the source file before the file name.

Additional build information

Source files*	Source files:
Include directories	src/my_func.c
Libraries	
Defines	

- Select **Include directories**, and enter the folders where additional build information, such as header files, are stored.

Additional build information

Source files*	Include directories:
Include directories	include
Libraries	
Defines	

Import custom code

To verify that your custom code can be parsed and built successfully, click **Validate**.

Note If your header file declares a function but your source files do not define the function, by default the function is not visible in the C Caller block dialog. You can set the **Undefined function handling** parameter in Configuration Parameters to specify other behaviors in this situation, including throwing an error, generating a stub function, or ignoring the condition.

Note To use a C Caller block in a For Each subsystem or with continuous sample time, or to optimize the use of the block in conditional input branch execution, the custom code function called by the block must be deterministic, that is, always producing the same outputs for the same inputs. Identify which custom code functions are deterministic by using the **Deterministic functions** and **Specify by function** parameters in the **Simulation target** pane. For a conditional input branch execution example, see “Use C Caller Block with Conditional Execution” on page 42-15.

N-D Array Handling

Simulink can pass N-D array data to custom code functions in C Caller blocks, and receive data from such blocks. When you do so, you must specify the correct array layout to achieve the intended results. See **Default function array layout** and **Exception by function**. For examples of the use of array data with C Caller blocks, see “Bring Custom Image Filter Algorithms as Reusable Blocks in Simulink” and “Call a Legacy Lookup Table Function Using C Caller block” on page 43-24.

You can specify the order of how matrix data is handled in your C functions. Matrix data passed to and from your C functions is converted if necessary to the array layout you specify. If the array layout is not specified, the matrix data is passed through the C function in the same order of your Simulink data, and computational errors may occur due to row-column major disagreement. Ensure that you follow the same default function array layout for all Simulink data.

- **Column-Major** — The C function handles input array data in column-major order. Suppose that you have a 3-by-3 matrix. In the C function, this matrix is accessed in this sequence: first column, second column, and third column.
- **Row-Major** — The C function handles input array data in row-major order. Suppose that you have a 3-by-3 matrix. In the C function, this matrix is accessed in this sequence: first row, second row, and third row.
- **Any** — The C function is indifferent to the layout of input array data. This would be the case if, for example, the function performs only element-wise operations on the data.
- **Not specified** — The C function makes no assumption about the layout of input array data. Compared to the **Any** setting, you can generate code only in column-major setting. Attempting to generate code in row-major setting produces an error. See **Array layout**. Select this option only if needed for compatibility with older models.

To learn more about the row-major and column-major array layouts in Simulink, see “Default function array layout”.

- 1 Select an array layout option under **Default function array layout**.
- 2 If you need to apply a specific array layout to some of the functions in your code, click **Exception by function** to select these functions.
- 3 Click **Apply** to accept your changes.

If your C functions accept only scalar and/or vector inputs, the **Default function array layout** setting has no effect.

Call C Caller Block and Specify Ports

You can start your custom C code integration into Simulink by typing `C Caller` in the Simulink canvas. Alternatively, drag a C Caller block from the User-Defined Functions library onto the canvas. Double-click the block to open the Block Parameters dialog box to see the names of your functions and port specifications.

- 1 Click on the Refresh button  to import your source code and its dependencies.
- 2 Your C functions are displayed under **Function Name**. If you do not see your full list of functions, click on the  to reimport your source code.
- 3 To view function definitions in the source file, click the . The source code for the selected function is displayed in the MATLAB Editor. If the source code is not available, the function declaration in the header file is displayed.
- 4 To change source files and their dependencies, or to define and select function array layouts, click the custom code settings button  to open the **Simulation Target** pane in Model Configuration Parameters.

Map C Function Arguments to Simulink Ports

You can map C function arguments from your source code to Simulink ports using the **Port specification** table in the C Caller block and by creating a `FunctionPortSpecification` object through the command line. In your source code, the header file includes the C function arguments to be connected to Simulink ports.

```
extern void mean_filter(const unsigned char* src,
                      unsigned char* dst,
                      unsigned int width, unsigned int height,
                      unsigned int filterSize);
```

Port specification shows the details of your arguments and how they connect to your C Caller block in Simulink.

▼ Port specification:

Arg name	Scope	Label	Type	Size
src	Input	src	uint8	-1
dst	Output	dst	uint8	size(src)
width	Constant	size(src,1)	uint32	1
height	Constant	size(src,2)	uint32	1
filterSize	Parameter	filterSize	uint32	1

Name — Specifies the name of input and output arguments. **Name** is the function argument or parameter name as defined in your C functions from source code. This column is for reference purposes only.

Scope — Specifies how C function arguments map to the Simulink scope. Your arguments have default scopes depending on the function definition and you can change the scopes depending your function definition in the source code.

Simulink Scope	Scope to Block Mapping
Input	Block input port
Output	Block output port
InputOutput	Block input and output port
Global	Global variable used by the block
Parameter	Block tunable parameter
Constant	Constant value

For an argument passed by pointer, when you have a constant qualifier definition such as `const double *u`, the argument can only be an input or a parameter. When there is no constant qualifier, the argument is an `InputOutput` by default, and you can change it to an `Input`, `Output`, or `Parameter` scope. In the case of an `Input` or `Parameter` scope, ensure that the C function does not modify the memory pointed by the pointer. If the argument is of an `Output` scope, every element pointed to by this pointer should be reassigned in every call for the function.

C Argument	Simulink Scope
Function return	Output
double u	Input, Parameter, Constant
double *u	InputOutput (default), Output, Input, Parameter
double u[]	
double u[][2]	
double u[2][3]	

C Argument	Simulink Scope
const double *u	Input (default), Parameter
const double u[]	
const double u[][2]	
const double u[2][3]	

Use the InputOutput port to map an input passed by a pointer in your C functions. Ports created using an InputOutput port have the same name for input and output ports. InputOutput ports enables reuse of buffer for input and output ports. This may optimize the memory use depending on the signal size and the block layout.

To map C function arguments to an InputOutput port, define the variable as a pointer in your function definitions.

```
extern void mean_filter(unsigned char* src,
                      unsigned int width, unsigned int height,
                      unsigned int filterSize);
```

Then, select the port specification to the InputOutput scope in the **Port Specification** table, and assign the resulting function output to the input variable in the custom function.

▼ Port specification:

Arg name	Scope	Label	Type	Size
src	InputOutput	src	uint8	-1
width	Constant	size(src,2)	uint32	1
height	Constant	size(src,1)	uint32	1
filterSize	Parameter	filterSize	uint32	1

You can use global variables in your custom code, mapping them to the appropriate Simulink scope. To enable the use of global variables in your model, select “Enable global variables as function interfaces” from **Model Settings > Configuration Parameters > Simulation Target**. You can map the global variables to an Input, Output, InputOutput or Global scope on the C Caller block. The availability of the these scopes depend on the use of the global variable in your custom code.

A Global scope enables you to transfer data between custom code and the C Caller block and lets you use the global variable during calculations on the block. Values transferred using Global scope are not visible on the block interface. This table shows example code snippets and their default and available ports.

Example Code	Simulink Scope
<pre>double data; void foo(void) { int temp = data; }</pre>	Global variable data only reads the variable data. Available scopes are: Input (default) Global
<pre>double data; void bar(void) { data = 0; }</pre>	Data is written to a global variable. Available scopes are: Output (default) Global InputOutput
<pre>double data; void foo2(void) { data = data + 1; }</pre>	Data is both read and written on a global variable. Available scopes are: Global (default) InputOutput Output

Label — Indicates the label for the corresponding argument in a Simulink block. By default, your argument label is the same as the argument name, unless you change it.

Simulink Scope	Simulink Port Label
input, output	Port name
inputoutput	Port name in both input and output port
Global	Port name and global variable name
parameter	Parameter name
constant	Expression for the constant value. size expressions using input argument names, for example <code>size(in1,1)</code>

Type — Demonstrates the match between the Simulink data type and the C function argument data type.

C Argument Data Type	Simulink Data Type
signed char	int8
unsigned char	uint8
char	int8 or uint8, depending on the compiler
int*	int32
unsigned int*	uint32
short *	int16

C Argument Data Type	Simulink Data Type
long *	int32 or fixdt(1,64,0), depending on the operating system
float	single
double	double
int8_t*	int8
uint8_t*	uint8
int16_t*	int16
uint16_t*	uint16
int32_t*	int32
uint32_t*	uint32
typedef struct {...} AStruct**	Bus: AStruct
typedef enum {...} AnEnum**	Enum: AnEnum
* If the C Caller takes an integer type, for example, int16_t, you can modify it to a fixed-point type with matching base type, for example to fixdt(1, 16, 3).	
** The C Caller sync button prompts you to import struct or enum types used by a C function as Simulink bus and enumeration types.	

Size — Specifies the data dimensions in the argument.

C Argument Dimensions	Simulink Port Dimensions
double u	scalar (1)
double u[]	inherited (-1) (default)
double u[][2]	If the argument is for an output port, the size should be specified. The size of an output port cannot be inherited.
double *u	inherited (-1) (default) If the argument is for an inputoutput port, the size cannot be inherited even though the size in the output port can be inherited. For global variables, size is scalar (1).
double u[2][3]	Size is [2, 3].

Create a FunctionPortSpecification Object and Edit C Caller Block Properties

To change **Port Specification** table properties programmatically, you can create a `FunctionPortSpecification` object and modify its properties. To create a `FunctionPortSpecification` object for a selected C Caller block in a model, type in the command line:

```
myCCallerConfigObj = get_param(gcb, 'FunctionPortSpecification')
myCCallerConfigObj =
```

FunctionPortSpecification with properties:

```
CPrototype: 'real_T add(real_T u1, real_T u2);'
InputArgument: [1x2 Simulink.CustomCode.FunctionArgument]
ReturnArgument: [1x1 Simulink.CustomCode.FunctionArgument]
GlobalArguments: [1x0 Simulink.CustomCode.FunctionArgument]
```

The `CPrototype` property is read-only, and shows the declaration of C function input variables. The `InputArgument` and `ReturnArgument` properties create a `FunctionArgument` object that you can further edit its properties according to the rules defined for **Port Specification** table above. You can See `FunctionPortSpecification` to learn more.

To modify the global arguments in a C Caller block, create a handle to the `GlobalArguments` object using `getGlobalArg` and modify its properties.

Create a Custom C Caller Library

It is recommended to create a library model to group your C Caller blocks and keep your models organized. You can also link a data dictionary to the library to hold custom types defined in your code. Using a library model is especially useful when you have multiple models or a model reference hierarchy that uses custom C code.

- 1 Open a new library model. On the **Simulation** tab, select **New > Library**.
- 2 On the **Modeling** tab, under **Design**, click **Simulation Custom Code**.
- 3 Select C or C++ in the **Language** option, depending on your code, and ensure the **Import custom code** box is selected.
- 4 Follow the instructions in “Specify Source Code and Dependencies” on page 42-2 to add your source files and their dependencies.
- 5 Create C Caller blocks to call C functions.
- 6 To insert a block from your library model to a Simulink model, simply drag the block into your model.

You can also create a library of C Caller blocks from your custom code using the Simulink Code Importer. See “Import Custom C/C++ Code Using the Simulink Code Importer”.

Generate Debug Symbols for Custom Code

To attach an external debugger to the MATLAB process, and debug external C code, make sure that the Model Configuration Parameter **Simulate custom code in a separate process** is cleared, then generate the debug symbols using:

```
clear mex
Simulink.CustomCode.debugSymbols('on')
```

After you turn this setting on and update your model, your debug symbols are generated and you can attach an external debugger to your MATLAB process by attaching the process to `MATLAB.exe`. Set breakpoints in your external C code using the external debugger, and when you simulate your model it should stop at the breakpoints.

Turn this setting off using:

```
Simulink.CustomCode.debugSymbols('off')
```

Generate Code from Model

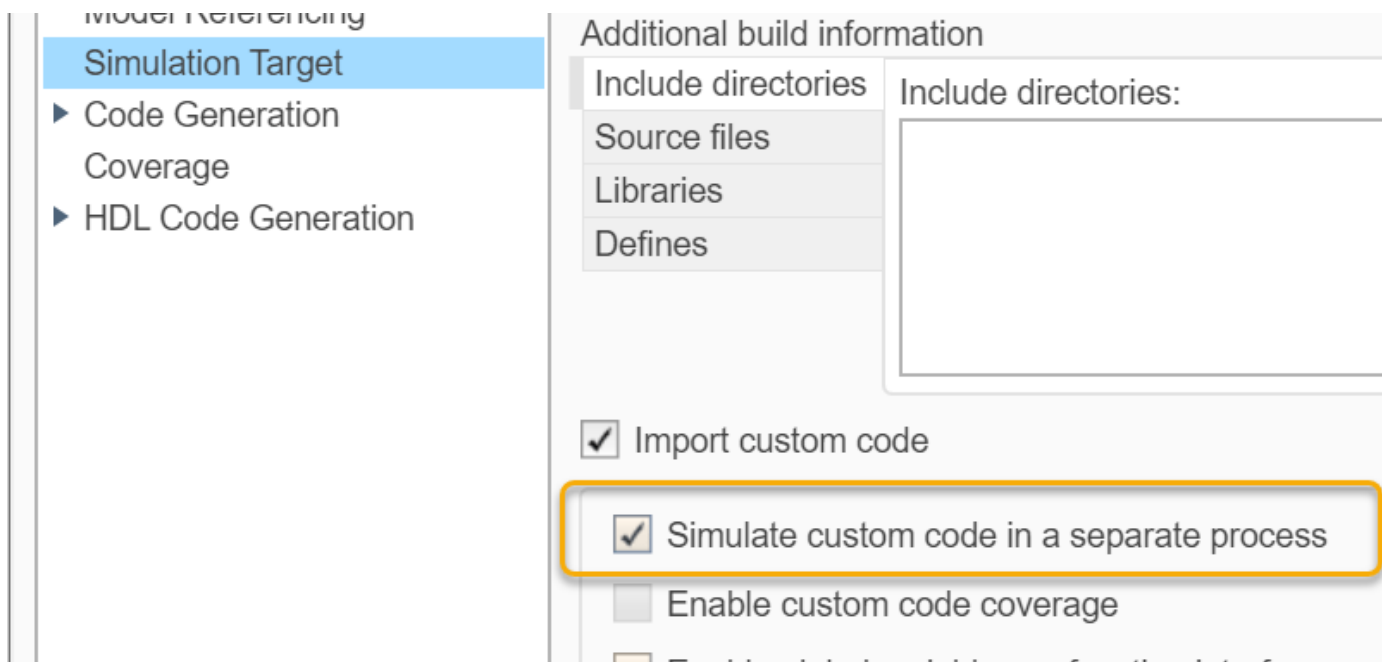

The C Caller supports code generation. In the code generated from your model, each execution of a C Caller block corresponds to a call to the external C function associated with the block. In order to build the generated code, the **Code Generation > Custom Code** pane of the Model Configuration Parameters must be populated with the correct information regarding the custom code. See “Model Configuration Parameters: Code Generation Custom Code” (Simulink Coder).

Simulate Custom Code in a Separate Process

When simulating a model containing custom C or C++ code, you have the option to run the custom code in a separate process outside of MATLAB. This option may be useful when debugging your custom code. By running in a separate process, problems with the custom code do not cause MATLAB to crash, and you can more easily debug and resolve such problems. Problems could arise due to unexpected exceptions in the custom code or errors in the interface between Simulink and the custom code.

To enable this option, in the model configuration parameters, in the **Simulation Target** pane, select “**Simulate custom code in a separate process**”. The option applies to custom C/C++ code integrated into your model using any of these blocks:

- C Caller
- C Function
- MATLAB Function
- MATLAB System
- Stateflow® chart

For example, this model contains a C Caller block that calls the function `adder()`, which accesses an object called `adderObj`. Before calling the function, the object must be created, which can be done

by calling `initAdder()` from the **Initialize function** of the **Simulation Target** pane of the model configuration parameters.

```
#include "myAdder.hpp"

static Adder* adderObj = nullptr;

int Adder::add_one(int increment)
{
    for (int i = 0; i < increment; i++)
    {
        val = val + 1;
    }
    return val;
}

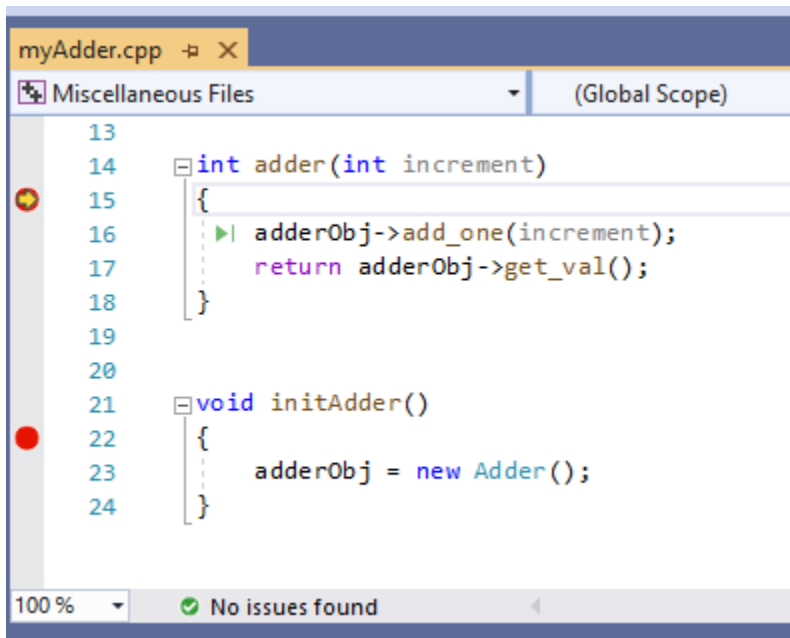

int adder(int increment)
{
    adderObj->add_one(increment);
    return adderObj->get_val();
}

void initAdder()
{
    adderObj = new Adder();
}
```

If `initAdder()` is not called before `adder()`, then `adder()` attempts to access an uninitialized pointer, which causes a run-time exception. If the **Simulate custom code in a separate process** parameter is not selected, this exception could cause MATLAB to crash when you simulate the model. However, if the parameter is selected, simulating the model produces an error message within Simulink.

You can then click **Open** to launch your external debugger and resolve the issue that caused the error.

After the debugger launches, it will restart the simulation and stop at the breakpoints of custom function entries automatically.

Once your custom code is fully debugged, you can clear **Simulate custom code in a separate process** for faster simulation time.

Limitations

- **Global Variables** — Global variables as function input outputs do not support multidimensional arrays.
- **Initialization/Termination of Custom Code Settings** — If you need to allocate and deallocate memory for your custom code, insert allocate and deallocate in the **Initialize function** and **Terminate function** fields of custom code settings, or use a C Function block.
- **Complex Data Support** — The C Caller block does not support complex data types in Simulink.
- **Variable Arguments** — Variable arguments in C are not supported, for example, `int sprintf(char *str, const char *format, ...)`.
- **C++ Syntax** — The C Caller block does not support native C++ syntax directly. You need to write a C function wrapper to interface with C++ code.

To test models that include C Caller blocks, see “Test Integrated C Code” (Simulink Test).

Note If a model has custom code, after the model is updated or run, the `slprj` folder may be locked due to the loaded custom code simulation executable file. The folder cannot be deleted when it is locked. To unload the executable file and unlock the `slprj` folder, use the `clear mex` command. See `clear`.

Use C Caller Block with Conditional Execution

This example shows how to use a C Caller block with conditional execution. The example model contains two C Caller blocks whose outputs are input branches into a Switch block. Each C Caller block calls one of the custom C code functions `sort_ascend()` and `sort_descend()`. Only one of the values from the input branches is passed to the output side of the Switch block. A C Function block with the same settings can also be used in place of a C Caller block to call these custom code functions.

This example illustrates the following concepts:

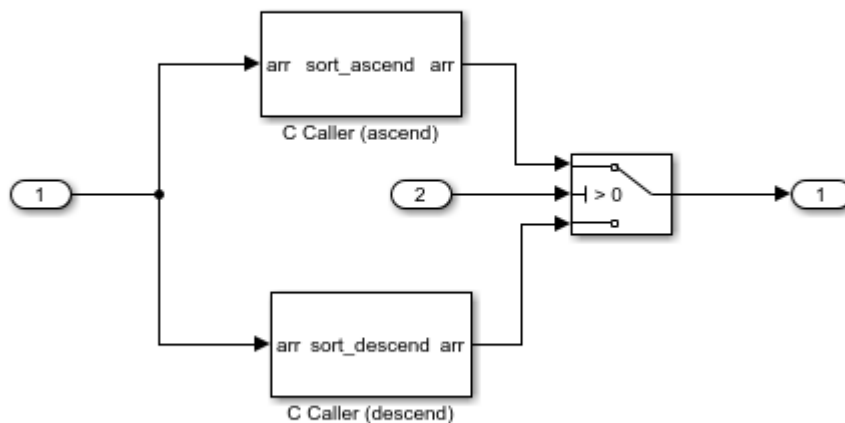

- Calling custom C code from a Simulink® block in a conditional execution context.
- Configuring deterministic functions by function in custom code.

Examine the Model

This model calls custom code through a C Caller block that is connected to an input branch of a Switch block.

```
open_system('slexCCallerConditional');
% Create a temporary folder for the build and inspection process.
currentDir=pwd;
[~,cgDir]=rtwdemodir();
```

Conditional Execution with C Caller block

Copyright 2020 The MathWorks, Inc.

Generate Code

The custom code functions in this model have not been identified as deterministic functions. When code is generated from the model, both C functions are executed during simulation and in the generated code, even though the Switch block requires the output of only one of the functions.

```
slbuild(bdroot);
cfile = fullfile(cgDir,'slexCCallerConditional_grt_rtw','slexCCallerConditional.c');
rtwdemodbtype(cfile,'/* Model step', '/* Matfile logging', 1, 0);
```

```
### Starting build procedure for: sllexCCallerConditional
### Successful completion of build procedure for: sllexCCallerConditional
```

Build Summary

Top model targets built:

Model	Action	Rebuild Reason
sllexCCallerConditional	Code generated and compiled	Code generation information file does not exist

1 of 1 models built (0 models already up to date)
Build duration: 0h 1m 22.304s

```
/* Model step function */
void sllexCCallerConditional_step(void)
{
    real_T rtb_CCallerascend[6];
    real_T rtb_CCallerdescend[6];
    int32_T i;

    /* CCaller: '<Root>/C Caller (ascend)' incorporates:
     * Inport: '<Root>/In2'
     */
    for (i = 0; i < 6; i++) {
        rtb_CCallerascend[i] = sllexCCallerConditional_U.In2[i];
    }

    sort_ascend(&rtb_CCallerascend[0], 6);

    /* End of CCaller: '<Root>/C Caller (ascend)' */

    /* CCaller: '<Root>/C Caller (descend)' incorporates:
     * Inport: '<Root>/In2'
     */
    for (i = 0; i < 6; i++) {
        rtb_CCallerdescend[i] = sllexCCallerConditional_U.In2[i];
    }

    sort_descend(&rtb_CCallerdescend[0], 6);

    /* End of CCaller: '<Root>/C Caller (descend)' */
    for (i = 0; i < 6; i++) {
        /* Switch: '<Root>/Switch' incorporates:
         * Inport: '<Root>/In1'
         */
        if (sllexCCallerConditional_U.In1 > 0.0) {
            /* Outport: '<Root>/Out3' */
            sllexCCallerConditional_Y.Out3[i] = rtb_CCallerascend[i];
        } else {
            /* Outport: '<Root>/Out3' */
            sllexCCallerConditional_Y.Out3[i] = rtb_CCallerdescend[i];
        }
    }

    /* End of Switch: '<Root>/Switch' */
}
}
```

Specify Custom Code Deterministic Functions

Open the Configuration Parameters dialog box.

In the **Simulation Target** pane, set **Deterministic functions** to **By Function**. Click **Specify by function** and add the functions `sort_ascend` and `sort_descend` to the list. This action tells the model that the specified custom code functions have deterministic behavior, that is, the same input values to the functions always give the same outputs. If a function is set to be deterministic, it does not need to be called if it is in the input branch corresponding to a false value of the Switch block.

```
configset.highlightParameter(bdroot, 'DefaultCustomCodeDeterministicFunctions');
set_param(bdroot, 'DefaultCustomCodeDeterministicFunctions', 'ByFunction');
set_param(bdroot, 'CustomCodeDeterministicFunctions', 'sort_ascend,sort_descend');
```

Generate Code Again

Now that you have specified the deterministic functions, the generated code is more efficient because only the C Caller block in the true branch of the Switch block is executed. The same efficiency applies when you simulate the model in Simulink.

```
slbuild(bdroot);
cfile = fullfile(cgDir, 'slexCCallerConditional_grt_rtw', 'slexCCallerConditional.c');
rtwdemodbtype(cfile, '/* Model step', '/* Matfile logging', 1, 0);
close_system(bdroot, 0);
```

```
### Starting build procedure for: slexCCallerConditional
### Successful completion of build procedure for: slexCCallerConditional
```

Call and Integrate External C Algorithms into Simulink Using C Function Blocks

In this section...

“Write External Source Files” on page 43-2

“Enter the External Code Into Simulink” on page 43-3

“Call C Library Functions From C Function Block” on page 43-6

“Specify Simulation or Code Generation Code” on page 43-7

“Specify Declaration for Target-Specific Function for Code Generation” on page 43-7

“Simulate Custom Code in a Separate Process” on page 43-8

You can call and integrate your external C code into Simulink models using C Function blocks. C Function blocks allow you to call external C code and customize the integration of your code using the **Output Code**, **Start Code**, and **Terminate Code** panes in the block parameters dialog. Use C Function block to:

- Call functions from external C code, and customize the code for your Simulink models.
- Preprocess data to call a C function and postprocess data after calling the function.
- Specify different code for simulation and code generation.
- Call multiple functions.
- Initialize and work with persistent data cached in the block.
- Allocate and deallocate memory.

Use the C Function block to call external C algorithms into Simulink that you want to modify. To call a single C function from a Simulink model, use the C Caller block. To integrate dynamic systems that have continuous states or state changes, use the S-Function block.

Note C99 is the standard version of C language supported for custom C code integration into Simulink.

The following examples use C Function blocks to calculate the sum and mean of inputs.

Write External Source Files

Begin by creating the external source files.

- 1 Create a header file named `data_array.h`.

```
/* Define a struct called dataArray */
typedef struct dataArray_tag {
    /* Define a pointer called pData */
    double* pData;
    /* Define the variable length */
    int length;
} dataArray;

/* Function declaration */
double data_sum(dataArray data);
```

- 2 In the same folder, create a new file, `data_array.c`. In this file, write a C function that calculates the sum of input numbers.

```
#include "data_array.h"

/* Define a function that takes in a struct */
double data_sum(DataArray data)
{
    /* Define 2 local variables to use in the function */
    double sum = 0.0;
    int i;
    /* Calculate the sum of values */
    for (i = 0; i < data.length; i++) {
        sum = sum + data.pData[i];
    }
    /* Return the result to the block */
    return sum;
}
```

Enter the External Code Into Simulink

- 1 Create a new, blank model and add a C Function block. The C Function block is in the **User-Defined Functions** library of the Library Browser.

- 2 Double-click the C Function block to open the block dialog. Click  to open the **Configuration Parameters** dialog. In the **Simulation Target** pane, define your header file under **Header file**.

Tip After you have entered information for **Source files** in the next step, you can click **Auto-fill from Source files** to have the header file name filled in automatically, using information contained in your source files.

- 3 Define the source file under **Additional build information > Source files**. To verify that your custom code can be parsed and built successfully, click **Validate**.

Insert custom C code in generated

Import custom code Validate

Note To use a C Function block in a For Each subsystem or with continuous sample time, or to optimize the use of the block in conditional input branch execution, all custom code functions called by the block must be deterministic, that is, always producing the same outputs for the same inputs. Identify which custom code functions are deterministic by using the **Deterministic functions** and **Specify by function** parameters in the **Simulation target** pane. If the block references any custom code global variables, then **Deterministic functions** must set to All in order for the block to be used in a For Each subsystem, in conditional input branch execution, or with continuous sample time.

For an example showing a C Function block in a For Each subsystem, see “Use C Function Block Within For Each Subsystem” on page 43-32.

- 4 In the **Output Code** pane of the C Function block parameters dialog, write the code that the block executes during simulation. In this example, the external C function computes a sum. In the **Output Code** pane, write code that calls the `data_array.c` function to compute the sum, then computes the mean.

```
/* declare the struct dataArr */
dataArray dataArray;
/* store the length and data coming in from the input port */
dataArray.pData = &data[0];
dataArray.length = length;

/* call the function from the external code to calculate sum */
sum = data_sum(dataArray);

/* calculate the mean */
mean = sum / length;
```

You can specify code that runs at the start of a simulation and at the end of a simulation in the **Start Code** and **Terminate Code** panes.

- 5 Use the **Symbols** table to define the symbols used in the external C code. Add or delete a symbol using the **Add** and **Delete** buttons. Define all symbols used in the **Output Code**, **Start Code**, and **Terminate Code** panes to ensure that ports display correctly.

▼ Symbols:

Add Delete

Name	Scope	Label	Type	Size	Port
data	Input	inData	double	-1	1
length	Constant	size(data)	int32	1	-
mean	Output	mean	double	1	2
sum	Output	sum	double	1	1

In the **Symbols** table, define the following:

- **Name** — Symbol name in the source code.
- **Scope** — Scope of the symbols and the order in which they appear. You can change the scope of a symbol at any time.
 - Input — Input symbol to the C Function block.
 - Output — Output symbol to the C Function block.
 - InputOutput — Define a symbol as both input and output to the C Function block.

Use the InputOutput scope to map an input passed by a pointer in your C code. Ports created using an InputOutput scope have the same name for input and output ports. InputOutput scope enables the reuse of buffer for input and output ports. Reusing buffer may optimize memory use and improve code simulation and code generation efficiency, depending on the signal size and the block layout. Limitations include:

- InputOutput symbol cannot be used in Start and Terminate code.
- InputOutput port does not support void* data type.
- InputOutput port does not support size() expressions.
- Persistent — Define a symbol as persistent data.

You can define a void pointer using the Persistent scope in the C Function block. A *void pointer* is a pointer that can store any type of data that you created or allocated.

- Constant — Define a symbol as constant using value-size or numeric expressions.
- Parameter — Define a symbol as parameter. The parameter name is defined by the **Label** of the symbol.

- **Label** — Label of the symbol. For symbols with their scope set to **Input** or **Output**, this label appears as the port name on the block. For symbols with their scope set to **Parameter**, this label is the label that appears on the block parameter mask. You cannot define a label for **Persistent** symbols. If the scope is **Constant**, the label is the constant expression.
- **Type** — Data type of the symbol. Select a data type from the drop-down list or specify custom data type.

To use a custom type such as `Simulink.Bus`, `Simulink.Enum` on page 69-2 or `Simulink.AliasType` that does not have an external header definition associated with a C Function block, set the type correctly on the **Symbol** table.

- **Size** — Size of the symbol data. The C Function block supports only scalars and vectors. Matrices and higher-dimension arrays are not supported. You can use a size expression to define the size of an output. Use -1 to inherit size.
- **Port** — For input and output symbols, **Port** indicates the port index on the block of the symbol data. For parameter symbols, **Port** indicates the order that the symbol appears in the block parameter mask.

Close the block parameters dialog. After filling in the data in the table, the C Function block now has one input port and two output ports with the labels specified in the table.

- 6 Add a Constant block to the Simulink canvas that will be the input to the C Function block. In the Constant block, create a random row array with 100 elements. To display the results, attach display blocks to the outputs of the C Function block.

Call C Library Functions From C Function Block

You can call this subset of the C Math Library functions from the C Function block:

abs	acos	asin	atan	atan2	ceil
cos	cosh	exp	fabs	floor	fmod
labs	ldexp	log	log10	pow	sin
sinh	sqrt	tan	tanh		

When you call these functions, double precision applies unless all the input arguments are explicitly single precision. When a type mismatch occurs, a cast of the input arguments to the expected type replaces the original arguments. For example, if you call the `sin` function with an integer argument,

a cast of the input argument to a floating-point number of type `double` replaces the original argument.

If you want to call other C library functions that are not listed above, create an external wrapper function that calls the C library function.

Call the `abs`, `fabs`, and `labs` Functions

Interpretation of the `abs`, `fabs`, and `labs` functions in C Function block goes beyond the standard C version to include integer and floating-point arguments:

- If `x` is an integer, the standard C function `abs` applies to `x`, or `abs(x)`.
- If `x` is a double, the standard C function `labs` applies to `x`, or `labs(x)`.
- If `x` is a single, the standard C function `fabs` applies to `x`, or `fabs(x)`.

Code Replacement Library (CRL) Based on Type

The call to the function should call the correct CRL based on the type of data passed into the function. If no CRL is specified, the call to the function should call to type-specific library. The CRL for C99 generates a type-specific function. For example:

Type passed in	Code generation call
<code>sin(doubleIn)</code>	<code>sin(doubleIn)</code>
<code>sin(floatIn)</code>	<code>sinf(floatIn)</code>

Specify Simulation or Code Generation Code

You can specify different output code for simulation and code generation for the C Function block by defining `MATLAB_MEX_FILE`. For example, to specify code that only runs during the model simulation, use the following.

```
#ifdef MATLAB_MEX_FILE
/* Enter Sim Code */
#else
/* Enter code generation code */
#endif
```

Specify Declaration for Target-Specific Function for Code Generation

For code generation purposes, if you do not have the external header file with the declaration of a function (such as a target-specific device driver) that you want to call from the C Function block, you can include a declaration with the correct signature in the **Output Code** pane of the block. This action creates a function call to the expected function when code is generated, as in the following example:

```
#ifndef MATLAB_MEX_FILE
extern void driverFcnCall(int16_T in, int16_T * out);
driverFcnCall(blockIn, &blockOut);
#endif
```

Simulate Custom Code in a Separate Process

When simulating a model containing custom C or C++ code, you have the option to run the custom code in a separate process outside of MATLAB. This option may be useful when debugging your custom code. By running in a separate process, problems with the custom code do not cause MATLAB to crash, and you can more easily debug and resolve such problems. Problems could arise due to unexpected exceptions in the custom code or errors in the interface between Simulink and the custom code. For more information, see “Simulate Custom Code in a Separate Process” on page 43-8.

Objects

`SymbolSpec` | `Symbol`

Blocks

C Function

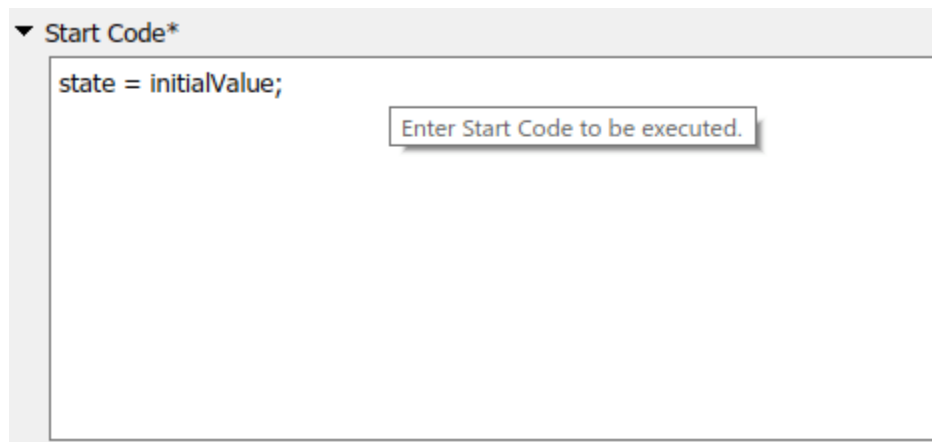

Modify States of a C Function Block Using Persistent Symbols

This example shows a unit delay system where a C Function block takes in a sine wave signal and delays its output by a specified sample period.

```
open_system('CFunctionPersistentExample');
```

An initial value, specified as a parameter, is cached in the block as persistent data in the **Start Code** pane.

In the **Output Code** pane, a calculation is done on this state. A new input is passed to the block as the next state at the next time step.

Output Code

```
y = state * 0.1;
state = u;
```

The **Symbols** table defines the attributes of the symbols used in the code. Note that the scope of the `initialValue` symbol is specified as `Parameter`, so its value can be changed using the block dialog. The state is defined as having `Persistent` scope. This value changes at each time step.

▼ Symbols:

Add

Delete

Name	Scope	Label	Type	Size	Port
initialValue	Parameter	Initial Value	double	1	1
state	Persistent	-	double	1	-
u	Input	u	double	1	1
y	Output	y	double	1	1

Blocks

C Function

Change Values of Signals Using C Function Block and Buses

This example shows how to use buses with a C Function block. In this example two Constant blocks supply values. These signals are combined using a Bus Creator block. Code in the C Function block changes the values of these signals. Using a Bus Selector block, the values are displayed separately in two Display blocks.

```
open_system('mCFunction_BusWithoutCStruct')
```

The **Output Code** pane contains code that changes the values of the signals.

```
Output Code
out.a = data.a * 2;
out.b = data.b + 3;
```

Add the symbols used in the code to the **Symbols** table. To use buses with a C Function block, set the **Type** of the symbol to Bus: SimpleBus.

▼ Symbols:

Name	Scope	Label	Type	Size	Port
data	Input	data	Bus: SimpleBus	1	1
out	Output	out	Bus: SimpleBus	1	1

Blocks

[C Function](#)

Access Elements of a Matrix Using Output Code in a C Function Block

This example shows how to access elements of a matrix from a C Function block using the **Output Code** pane.

```
open_system('mMatrixColumnSumOutputCode')
```

Elements in each column of the input matrix are accessed and added to calculate a sum for each column.

Output Code

```
int r, c;

for (c = 0; c < 3; c++) {
    y[c] = 0;
    for (r = 0; r < 3; r++) {
        y[c] += u[r][c];
    }
}
```

You must define all symbols used in code on the **Symbols** table of the Block Parameters. To set the size of the input matrix, specify size as [r c]. r corresponds to the number of rows in the input matrix and c corresponds to the number of columns in the input matrix.

▼ Symbols:

Add Delete

Name	Scope	Label	Type	Size	Port
u	Input	u	double	[3 3]	1

Blocks

C Function

Use External Functions with Matrix Input in a C Function Block

This example shows how to pass a matrix input to a C Function block and do row-major operations using external custom code.

```
open_system('mMatrixColumnSumExternalCode');
```

In this example, a matrix input is used by external custom code to calculate the sum of the each column of the matrix and the results are passed to the output block. The external function accesses input array `arr` as row-major using `arr[r][c]`.

```
matrixsum.c x +
#include "matrixsum.h"

void column_sum(real_T arr[3][3], real_T sum[3])
{
    int r, c;

    for (c = 0; c < 3; c++) {
        sum[c] = 0;
        for (r = 0; r < 3; r++) {
            sum[c] += arr[r][c];
        }
    }
}
```

The custom code is called in the **Output Code** pane of the C Function block.

```
C Code for Simulation and Code Generation
Output Code
column_sum(u, y);
```

The external source and header files are specified on the **Configuration Parameters > Simulation Target** pane.

Insert custom C code in generated

Source file	Header file:
Header file	#include "matrixsum.h"
Initialize function	
Terminate function	

Additional build information

Include directories	Source files:
Source files	matrixsum.c
Libraries	
Defines	

For the matrix input, the size of the input symbol on the matrix table is specified as $[r \ c]$, where r corresponds to the number of rows in the matrix input and c corresponds to the number of columns.

▼ Symbols:

Add Delete

Name	Scope	Label	Type	Size	Port
u	Input	u	double	[3 3]	1
y	Output	y	double	3	1

Specify the Default Function Array Layout

The external C function accesses input array `a r r` using row-major layout. To ensure the validity of calculations with MATLAB, go to **Default Function Array Layout** under **Configuration Parameters > Simulation Target** and select Row-major.

Import custom code

Enable custom code analysis

Enable custom code globals as function interface

Undefined function handling: Filter out ▼

Default function array layout: Row-major ▼ Exception by function...

Reserved names:

Define an Alias Type in a C Function Block

This example shows how to specify alias data types in a C Function block. The model reads in a source and header file from the **Configuration Parameters** > **Simulation Target** pane. Calculations are performed using the functions in the source file.

```
Simulink.importExternalCTypes('multiply_func.h');
open_system('mCFunction_AliasType');
```

Define an Alias type in the header file

To define an alias type in your C source code to be used in your C Function block, use the `typedef` keyword. In this example, a double alias is defined as `typedef double doubleAlias` in the `multiply_func.h` file.

Specify the alias types in the C Function block

You must define your symbols in the **Symbols** table of the C Function block parameters. Define the symbols in the block as alias types by entering the alias type in the **Type** column of the **Symbols** table.

▼ Symbols:

Add Delete

Name	Scope	Label	Type	Size	Port
u	Input	u	doubleAlias	1	1
y	Output	y	doubleAlias	1	1

Blocks
C Function

Use Enumerated Data in a C Function Block

This example shows how to define and use enumerated data in a C Function block. In this example, a series of traffic lights are defined in an Enumerated Constant block using the Data Type Assistant. The code that controls the traffic lights is written in the **Output Code** pane of the C Function block dialog. In the **Symbols** table, the data types of the block inputs and outputs are defined as Enum: *classname*. In this example, the enumerations are defined in the class `TrafficLightColor_t`, so the type is defined as Enum: `TrafficLightColor_t`.

```
open_system('CFunctionEnum')
```

Output Code to Switch Traffic Lights

Output Code

```
switch(u) {
  case RED:
    out = GREEN;
    break;
  case YELLOW:
    out = RED;
    break;
  case GREEN:
    out = YELLOW;
    break;
  default:
    out = UNKNOWN;
}
```

Symbols Table to Define Enumerations

▼ Symbols:

Name	Scope	Label	Type	Size	Port
out	Output	out	Enum: TrafficLightColor_t	1	1
u	Input	u	Enum: TrafficLightColor_t	1	1

Blocks

C Function

Use Inherited Sizes in a C Function Block

This example shows how to use a C Function block to compute a scaled vector dot product from two input vectors. In this example, the C Function block takes two row vectors as inputs with inherited sizes. The block scales the data using parameters. The vector dimension, which is used to define loop indices in the C code, is defined as a constant. The block calculates the dot product, and displays the results.

```
open_system('CFunctionVectorDotProduct');
```

In the C Function Block Parameters dialog, the **Output Code** pane contains the code that performs the vector dot product calculations on the two input vectors.

```
Output Code

int i;
dotProduct = 0;
for(i = 0; i < vectorDimension; ++i){
    dotProduct = dotProduct + (scaleA*vectorA[i] * scaleB*vectorB[i]);
}
```

You must define all symbols used in the code in the **Symbols** table of the Block Parameters. To specify that the sizes of the input vectors are inherited, specify -1 in the **Size** field of the table. The symbols `scaleA` and `scaleB` are defined as parameters of the block. These parameters appear on the block parameter mask. The definitions of all symbols used in this example are shown in the following table.

Name	Scope	Label	Type	Size	Port
dotProduct	Output	Dot Product	double	1	1
scaleA	Parameter	Scale A by	double	1	1
scaleB	Parameter	Scale B by	double	1	2
vectorA	Input	Vector A	double	-1	1
vectorB	Input	Vector B	double	-1	2
vectorDim...	Constant	size(vecto...	int32	1	-

Blocks

C Function

Call a Legacy Lookup Table Function Using C Caller block

This example shows how to use the C Caller block to call legacy C functions that implement N-dimensional table lookups.

In this example the legacy C functions are defined in `lookupTable.h`, and implemented in `directLookupTableND.c`. The type definitions used in this example can be found in `your_types.h`.

To enable calling the C functions from the C Function block, in the model, specify the header file and the source file in the **Configuration Parameters > Simulation Target** pane. The prototype of the legacy function being called in this example is:

```
FLT directLookupTableND(const FLT *tableND, const UINT32 nbDims, const UINT32 *tableDims, const UINT32 *tableIdx)
```

where FLT is a type definition to a floating-point type, and UINT32 is a type definition to an unsigned 32-bit integer.

- `const FLT *tableND` - Table
- `const UINT32 nbDims` - Dimensionality of the table
- `const UINT32 *tableDims` - Size of the table
- `const UINT32 *tableIdx` - Table index

In the C Caller block, `tableND` and `tableDims` are mapped to C Caller block parameters, `nbDims` is a block constant, and `tableIdx` is the input to the block. The value returned by the legacy C function is the output of the block.

```
model = 'slexCCallerLookupTable';  
open_system(model);  
sim(model);  
slcc('clearCustomCodeModules');
```

This demonstration illustrates how the C Caller Block is used to call legacy functions that implement N-dimensional table lookups

Copyright 2019 The MathWorks, Inc.

Start and Terminate Actions Within a C Function Block

This example shows how to use the C Function block to integrate legacy C functions that have start and terminate actions.

In this example, the legacy C functions are defined in `fault.h`, and implemented in `fault.c`.

To enable calling the C functions from the C Function block, in the model, specify the header file and the source file in the **Configuration Parameters > Simulation Target** pane. This model opens a log file, writes data to it, and then closes the log file. The `openLogFile` function is called in the **Start Code** section and the `closeLogFile` function is called in the **Terminate Code** section of the C Function block. In the **Output Code** section, the `incAndLogFaultCounter` function is called. The prototype of the legacy functions are:

- `void* openLogFile()`
- `closeLogFile(void* fid)`
- `incAndLogFaultCounter(void *fid, unsigned int counter, double time)`

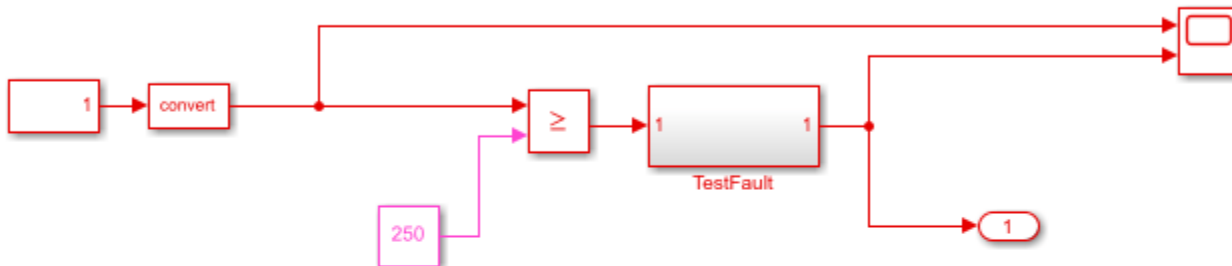

where, `void *fid` is a file pointer, `unsigned int counter` is the fault counter, and `double time` indicates the time.

In this example the ports of the C Function block are configured as follows:

- The file pointer returned by `openLogFile` function and the fault counter are persistent symbols of the C Function block.
- The input of the C Function block is mapped to `time`.

```
model = 'slexCFunctionStartTerm';
open_system(model);
sim(model);
slcc('clearCustomCodeModules');
```

This demonstration illustrates how the C Function Block is used to call legacy functions that have start and terminate actions

Start Code → call `openLogFile()` → open the file 'slex_CFunction_fault.log' for logging faults

Output Code → call `incAndLogFaultCounter()` → increment the fault counter and append one line in the log file

Terminate Code → call `closeLogFile()` → close the logging file

- run the model and edit the generated logging file 'slex_CFunction_fault.log'

Copyright 2019 The MathWorks, Inc.

Call C++ Class Methods Using a C-style Wrapper Function From a C Function Block

This example shows how to use the C Function block to call C++ class methods using a C-style wrapper function. In this example, the C-style wrapper functions are defined in `adder_cpp.h`, and implemented in `adder_cpp.cpp`. To run this example model successfully, you must configure MATLAB® to use a C++ compiler.

This can be done using the `mex -setup` command, and selecting a C++ compiler.

To enable calling of the C functions from the C Function block, in the model, specify the header file and the source file in the **Configuration Parameters > Simulation Target** pane. In this model the custom code header file `adder_cpp.h` declares an `adder` class along with the class member functions. The header file also contains the declaration of the C-style wrapper functions which are called in the C Function block. The prototypes of the C-style wrapper functions are:

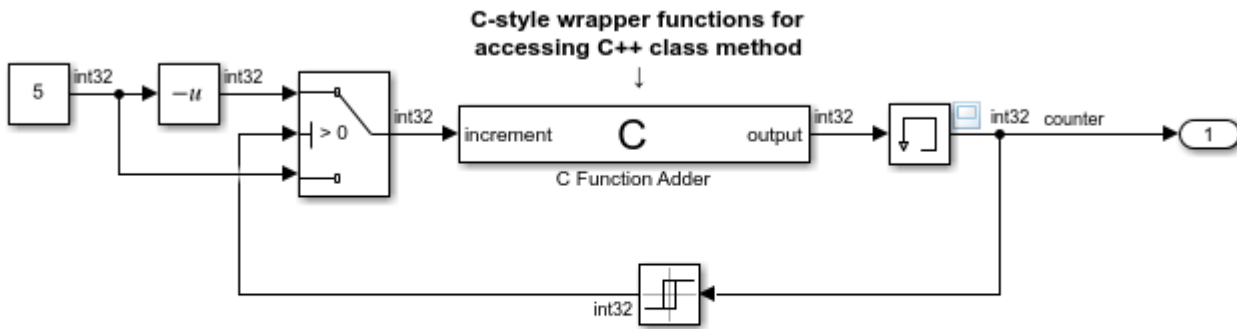

- `void *createAdder()`
- `void deleteAdder(void *obj)`
- `int adderOutput(void *obj, int increment)`

where, `void *obj` is the class object pointer, and `int increment` is an input used by the `adder` function.

The `createAdder` function is called in the **Start Code** section of the Block Parameters to construct an object of the `Adder` class. The `deleteAdder` function is called in the **Terminate Code** section to destruct the created `Adder` class object. In the **Output Code** section, the `adderOutput` function is called. In this example the ports of the C Function block are configured as follows:

- The `Adder` class object, `obj`, return by the `createAdder` function is a persistent symbol of the C Function block.
- The input of the C Function block is mapped to `increment`.
- The output of the C Function block is mapped to the return value of the `adderOutput` function.

```
model = 'slexCFunctionAdder';  
open_system(model);  
sim(model);  
slcc('clearCustomCodeModules');
```

NOTE:

For this demo to run you must go to the MATLAB command prompt and enter: `>> mex -setup` then select a C++ compiler.

Call Legacy Lookup Table Functions Using C Function Block

This example shows how to use the C Function block to call legacy C functions that implement n-dimensional table lookups.

In this example the legacy C functions are defined in `lookupTable.h`, and implemented in `directLookupTableND.c`. The type definitions used in this example can be found in `your_types.h`.

In the model, the header file and the source file are specified in **Model Configuration Parameters > Simulation Target**. Now the C function can be called in the C Function block. The prototype of the function being called in this example is:

```
FLT directLookupTableND(const FLT *tableND, const UINT32 nbDims, const UINT32 *tableDims, const UINT32 *tableIdx)
```

where `FLT` is a type definition to a floating-point type, and `UINT32` is a type definition to an unsigned 32-bit integer.

This example defines two macro functions that use the function `directLookupTableND`, which are called using the C Function blocks. They are:

- `DirectLookupTable3D` - 3D lookup table
- `DirectLookupTable4D` - 4D lookup table

Both these functions take the following input arguments:

- `const FLT *tableND` - Table
- `const UINT32 *tableDims` - Size of the table
- `const UINT32 *tableIdx` - Table index

where the `tableND` and `tableDims` are mapped to C Function block parameters and `tableIdx` is the input to the block. The value returned by the legacy C function is the output of the block.

```
model = 'slexCFunctionLookupTable';  
open_system(model);  
evalc('sim(model)');  
slcc('clearCustomCodeModules');
```

This demonstration illustrates how the C Function block is used to call legacy functions that implement N-dimensional table lookups

Copyright 2020 The MathWorks, Inc.

Use C Function Block Within For Each Subsystem

This example shows how to use a C Function block within a For Each subsystem. The example passes a vector signal into the For Each subsystem, which repeats execution of the C Function block on each element of the input signal and concatenates the results. The C Function block calls the custom code function `customSaturateFcn()`, which implements a saturation algorithm and outputs a clipped version of the input signal. A C Caller block with the same settings can also be used in place of a C Function block in a For Each subsystem.

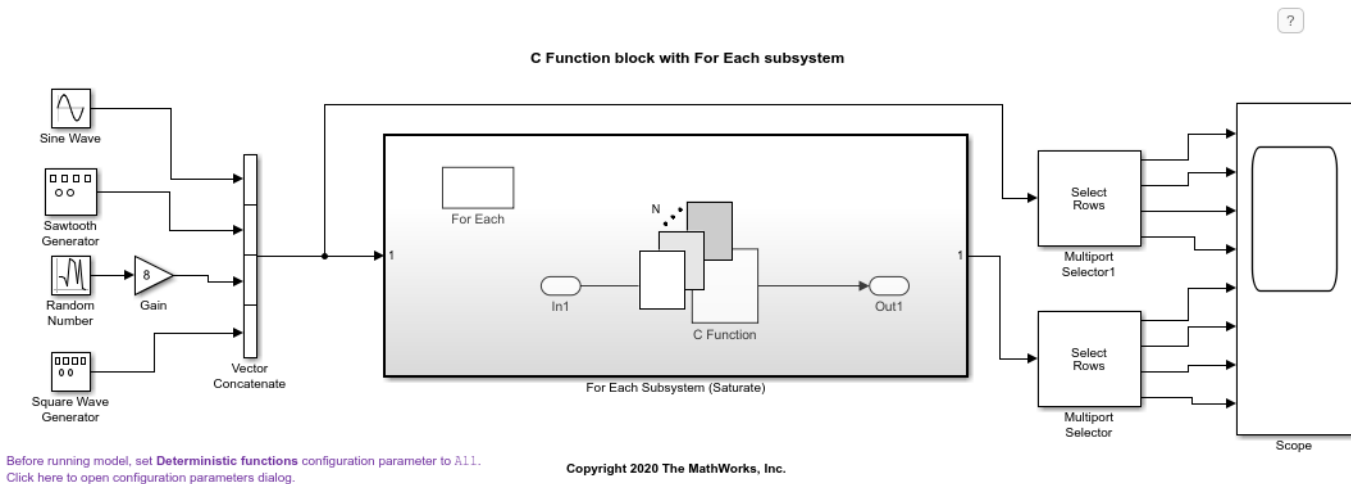

This example illustrates the following concepts:

- Calling a C function from a Simulink® block inside a For Each subsystem.
- Configuring deterministic functions in custom code.

Examine the Model

This model calls custom code from a For Each subsystem. When the model runs, the scope displays the output.

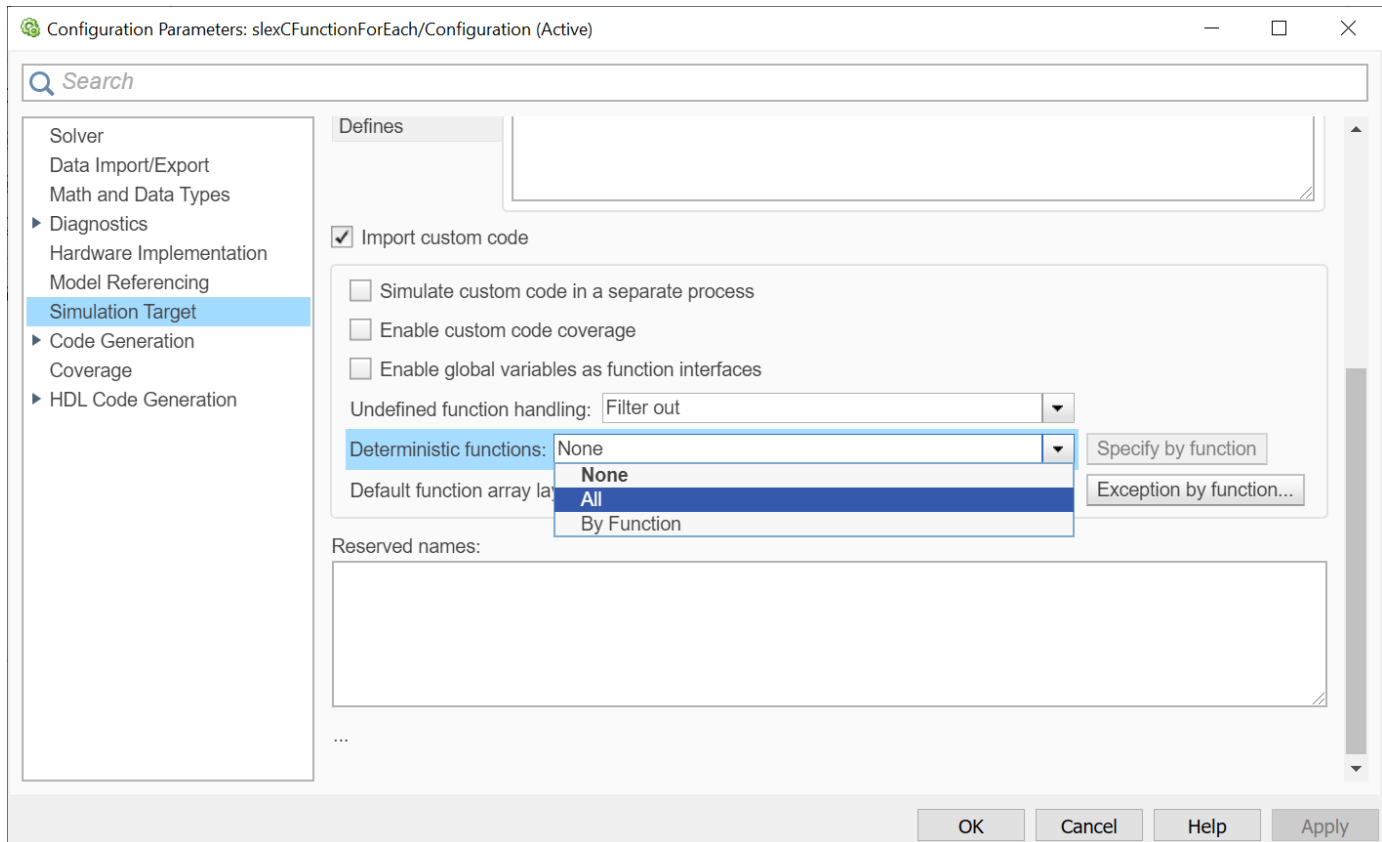

```
open_system('slexCFunctionForEach');
```

Identify Custom Code Deterministic Functions

Open the Configuration Parameters dialog box.

In the **Simulation Target** pane, set the value of **Deterministic functions** to All. This setting tells the model that all custom code functions have deterministic behavior, that is, the same input values to the function always give the same outputs. If a custom code function is specified as deterministic, it can be safely called from a C Function or C Caller block inside a For Each subsystem. If not all custom code functions are deterministic, specific functions can be set to be deterministic with the **By Function** option. If a For Each subsystem contains a C Function or C Caller block that calls a custom code function that is not specified as deterministic, Simulink produces an error.

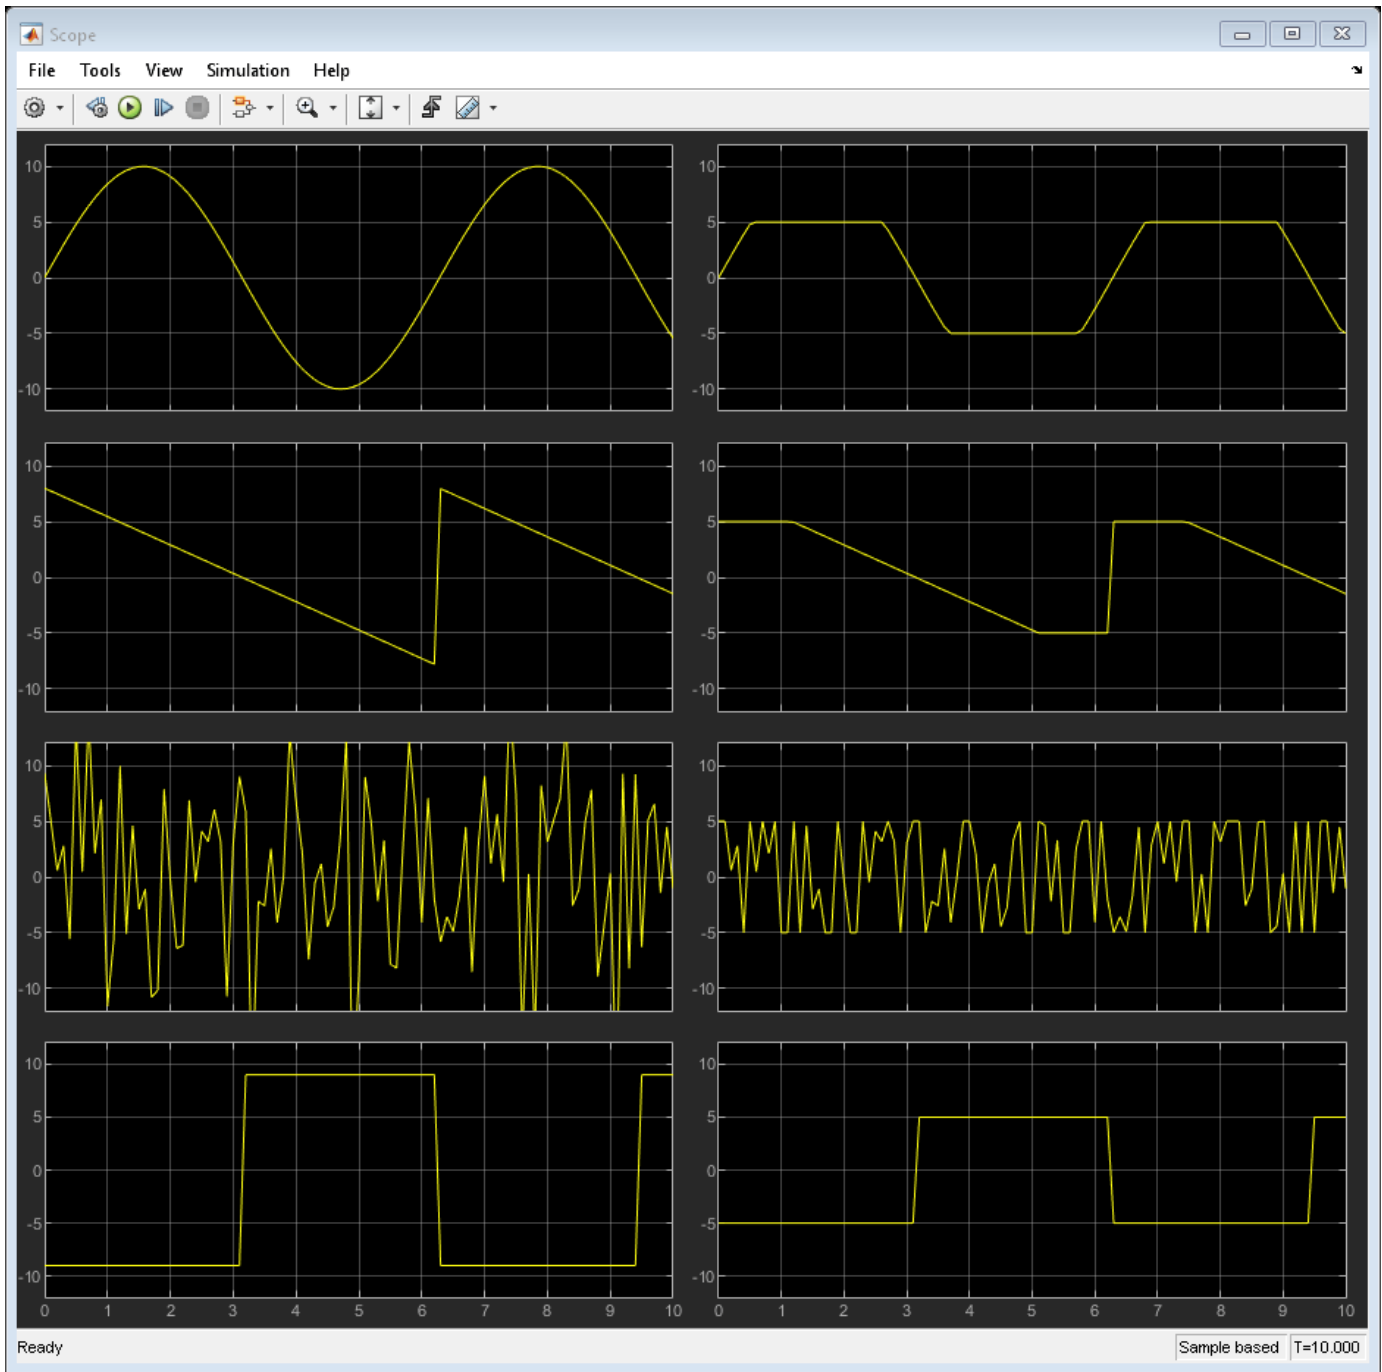

```
configset.highlightParameter(bdroot, 'DefaultCustomCodeDeterministicFunctions');
set_param(bdroot, 'DefaultCustomCodeDeterministicFunctions', 'All');
```

Simulate the Model

Simulate the model and view the results.

```
sim(bdroot);
open_system('slexCFunctionForEach/Scope');
```

Simulink Code Importer

Import Custom Code Using the Simulink Code Importer Wizard

This example uses C code for a heat pump controller to show how to use the Simulink® Code Importer wizard to import custom C/C++ code into a Simulink library. The example also shows how to perform the equivalent actions using the Simulink Code Importer command-line interface in MATLAB®. For more information, see “Import Custom C/C++ Code Using the Simulink Code Importer”.

Heat Pump Controller Custom Code

These C code source and header files contain the complete code for the heat pump controller.

The source files are in the `src` directory:

- `tempController.c`
- `utils.c`

The header files are in the `include` directory:

- `tempController.h`
- `utils.h`
- `controllerTypes.h`

The file `tempController.c` contains the algorithm for the custom C code for a heat pump unit. The `Controller` function in that file uses the room temperature (`Troom_in`) and the set temperature (`Tset`) as inputs. The output is a `pump_control_bus` type structure with signals that control the fan, the heat pump, and the direction of the heat pump (heat or cool). The `pump_control_bus` structure has these fields: `fan_cmd`, `pump_cmd`, and `pump_dir`. The `pump_control_bus` structure type is defined in the file `controllerTypes.h`.

This table summarizes the output of the Controller algorithm.

Temperature Condition	System State	Fan Command	Pump Command
$ T_{room_in} - T_{set} < \Delta T_{fan}$	Idle	0	0
$\Delta T_{fan} \leq T_{room_in} - T_{set} < \Delta T_{pump}$	Fan only	1	0
$ T_{room_in} - T_{set} \geq \Delta T_{pump}$ and $T_{set} < T_{room_in}$	Cooling	1	1
$ T_{room_in} - T_{set} \geq \Delta T_{pump}$ and $T_{set} > T_{room_in}$	Heating	1	1

The `Controller` function uses two utility functions, `absoluteTempDifference` and `pumpDirection`, which are defined in the `utils.c` file. The `absoluteTempDifference` function returns the absolute difference between `Tset` and `Troom_in` as a double. The `pumpDirection` function returns one of these `PumpDirection` type enum values.

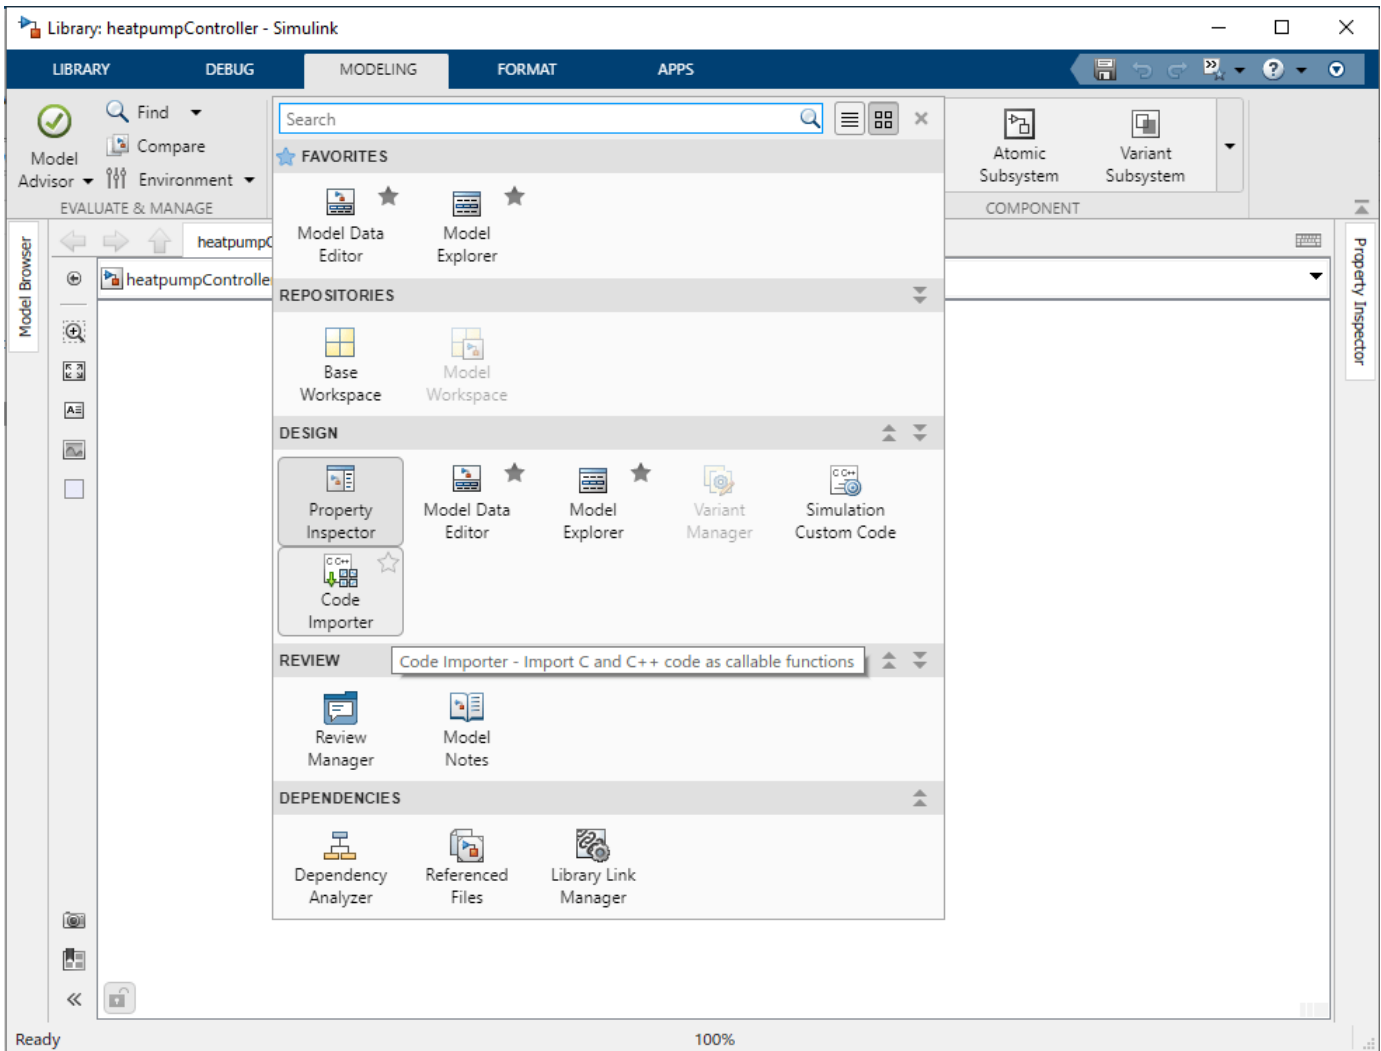

Temperature Condition	Pump Direction
$T_{set} < T_{room_in}$	COOLING
$T_{set} > T_{room_in}$	HEATING

The `PumpDirection` enum type is defined in the file `controllerTypes.h`.

Open the Code Importer Wizard

To open the Code Importer wizard, create an empty Simulink library where the `src` and `include` folders are located and save it. For this example, the library is saved as `heatpumpController`.

Then, on the **Modeling** tab, select **Design > Code Importer**.

Specify the Simulink Library

Once the **Welcome** page loads, click **Start** to begin the import process.

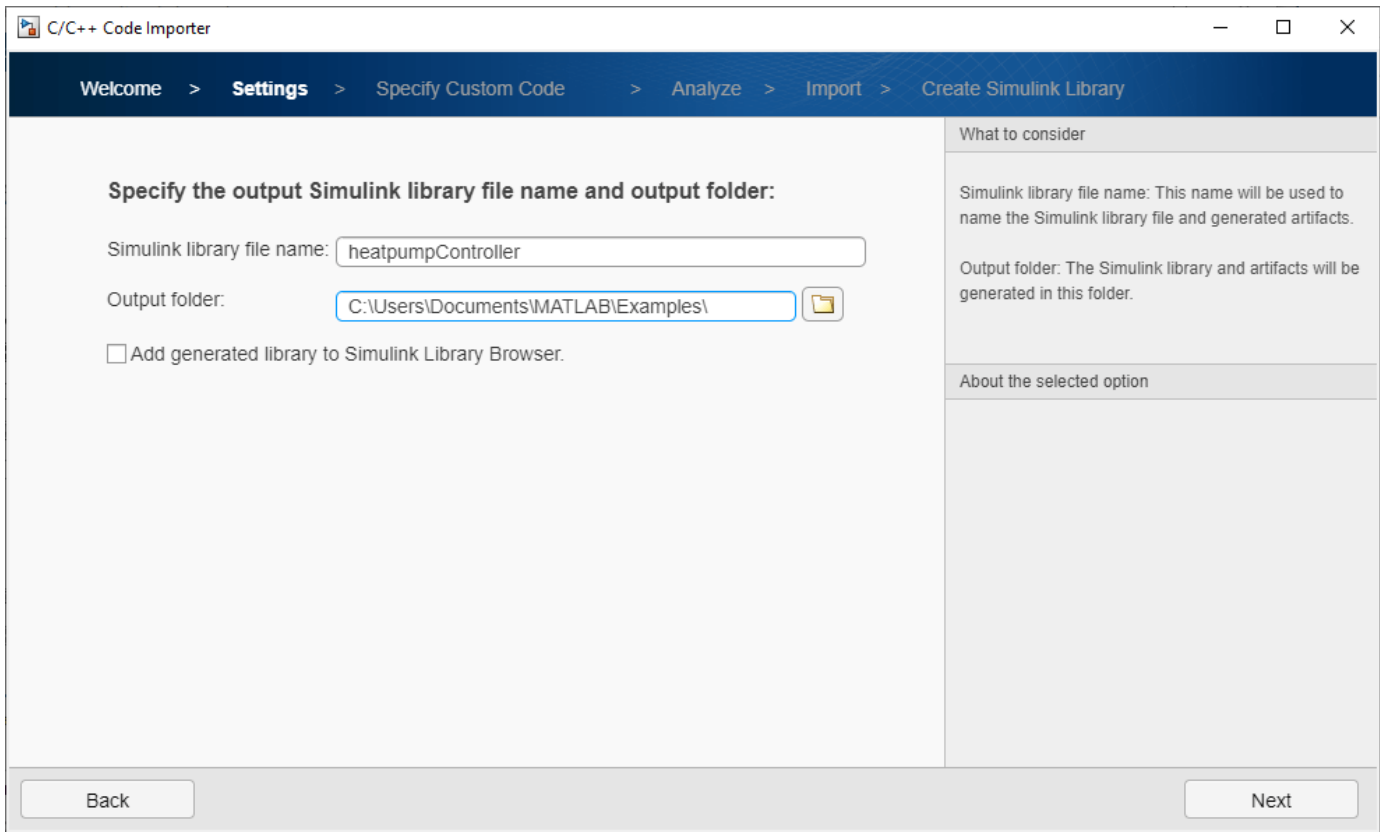

On the **Settings** page:

- 1 The **Simulink library file name** is auto-populated with the saved library name, in this case, `heatpumpController`.
- 2 The **Output folder** is auto-populated with location of the saved Simulink library.

Optionally, select **Add generated library to the Simulink Library Browser** to create an `slblocks.m` file.

The `slblocks.m` file is used to add the generated library into the Simulink library browser. For more information, see “Add Library to the Library Browser” on page 41-8.

Click **Next** to continue.

Note: The following MATLAB code is equivalent to this step.

```
obj = Simulink.CodeImporter('heatpumpController');
obj.LibraryFileName = 'heatpumpController';
obj.OutputFolder = '$pwd$'; %This evaluates to the pwd
```

Specify the Custom Code to Import

On the **Specify Custom Code** page:

- 1 For **Language**, select C.
- 2 For **Interface headers**, specify the required header files. For this example, specify tempController.h.
- 3 For **Source files**, specify the required source files. For this example, specify the tempController.c and utils.c files location in the src folder as .\src\tempController.c; .\src\utils.c.
- 4 For **Include directories**, specify the required include directories. For this example, specify .\include.

Then, click **Next**.

Click **Next** on the **Analyze** page.

Note: The following code is equivalent to this step.

```
% The src and include directories should be located in pwd
obj.CustomCode.InterfaceHeaders = 'tempController.h';
obj.CustomCode.Language = 'C';
obj.CustomCode.SourceFiles = {'.\src\tempController.c', '.\src\utils.c'};
obj.CustomCode.IncludePaths = '.\include';
```

```
% Analyze the specified custom code
obj.parse();
```

Specify Import Settings

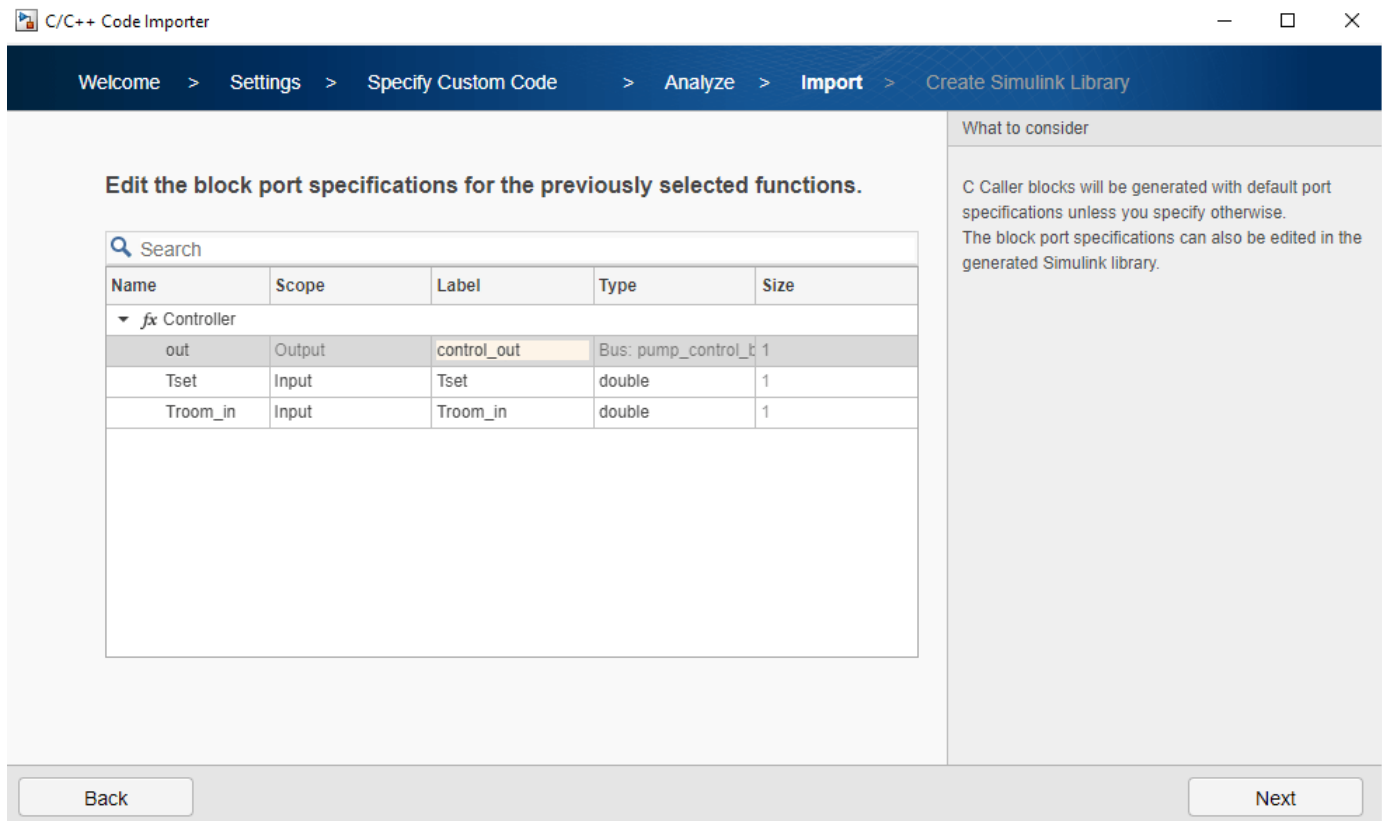

Specify Functions to Import

On the **Import** page, select the functions to import into the Simulink library. For this example, select Controller. Then, click **Next**.

Set the Block Port Specifications

For each function selected on the previous page, the wizard generates a function port specification. The selected ports are used for the generated C Caller block.

In this example, the port specification table lists the formal arguments `Tset`, `Troom_in`, and `out` for the `Controller` function.

Change the label of the `out` argument to `control_out`. Click **Next**.

Note: The following code is equivalent to this step.

```
% Requires a successful obj.parse() to get the function objects
fcnObj = obj.ParseInfo.getFunctions();

%fcnObj =
%
% Function with properties:
%
%           Name: "Controller"
%       CPrototype: "pump_control_bus Controller(real_T Tset, real_T Troom_in);"
%   PortSpecification: [1x1 Simulink.CodeImporter.SimulinkPortSpecification]
%           IsEntry: 1
%           IsDefined: 1
%           IsStub: 0
%       ArrayLayout: NotSpecified
%           IsDeterministic: 0

fcnObj.PortSpecification.ReturnArgument.Label = 'control_out';
```

Specify Types to Import

Next, select the types to import into Simulink. If a type is required by the functions you selected for import, it is selected and dimmed. For this example, `pump_control_bus` is required. The wizard creates a Simulink data dictionary containing this type and links the dictionary to the generated library.

Click **Next**.

Specify Library Update Setting

Since this example uses a saved Simulink library, this page allows you to confirm the update operation to be performed on the library.

- 1 Select **Overwrite** to remove any existing blocks and create new C Caller blocks for the selected custom code functions.
- 2 Select **Update** to preserve existing blocks and add new C Caller blocks for the selected custom code functions.

For this example, select **Update**, then click **Next**.

Create Test Harness

This option is available only if you have a Simulink Test™ license.

To test the imported custom code function using Simulink Test Manager, select **Automatically create test harness for all imported functions**. Each block in the created library will be attached to an internal test harness.

For this example, select **Skip**. Click **Next** to generate the Simulink library.

After the code imports, the wizard creates a library attached to a Simulink data dictionary that defines `pump_control_bus` as a `Simulink.Bus` object.

Note: The following code is equivalent to this step.

```
% Requires Simulink Test license to generate the test harness
obj.Options.CreateTestHarness = true;
obj.import('Functions', 'Controller', ...
          'Types', 'pump_control_bus', ...
          'Overwrite', 'off');
```

If you have an existing project file (PRJ file), you can select **Add**, select the desired project file, and add the generated file to that project.

Click **Finish** to close the wizard.

When you click **Finish**, select whether to save the current import settings to a JSON file. You can use this file to load the Code Importer wizard with the current import settings.

Implementing MATLAB Functions Using Blocks

MATLAB Function blocks enable you to define custom functionality in Simulink models by using the MATLAB language. They are the easiest way to bring MATLAB code into Simulink. MATLAB Function blocks support C/C++ code generation from Simulink Coder and Embedded Coder.

Use these blocks specifically when:

- You have an existing MATLAB function that models custom functionality, or it would be easy for you to create such a function.
- Your model requires custom functionality that is not or cannot be captured in the Simulink graphical language.
- You find it easier to model custom functionality by using a MATLAB function than by using a Simulink block diagram.
- The custom functionality that you want to model does not include continuous or discrete dynamic states. To model dynamic states, use S-functions. See “Create and Configure MATLAB S-Functions”.

How MATLAB Function Blocks Work

When you simulate a model that contains a MATLAB Function block, the software generates binary code or C/C++ MATLAB executable (MEX) code from the block and integrates this code with the model. The MATLAB Function block uses the same infrastructure as MATLAB Coder, which you use to generate C/C++ code from MATLAB code outside of Simulink.

Because the MATLAB Function block relies on code generation technology, it shares much in common with MATLAB Coder. C/C++ code generation limitations for MATLAB Coder also apply to MATLAB Function blocks. However, the MATLAB Function block is self-contained within Simulink, and does not require MATLAB Coder. To generate standalone C/C++ code from a model that contains MATLAB Function blocks, use Simulink Coder.

MATLAB Function Block Capabilities

The following describes *what* you can use a MATLAB Function for in your model. To see *how* to use a MATLAB Function block in an example, see “Create Custom Functionality Using MATLAB Function Blocks” on page 45-5.

Simulink to MATLAB Interface

MATLAB Function blocks provide an intuitive interface between MATLAB code and a Simulink model. The block input and output variables inherit their properties from Simulink input and output signals.

By default, both the size and type of input and output signals to a MATLAB Function block are inherited from the corresponding Simulink signals. You can also choose to specify the size and type of inputs and outputs explicitly in the Ports and Data Manager or in the Model Explorer. See “Define MATLAB Function Block Data” on page 45-30.

Standalone C/C++ Code Generation

MATLAB Function blocks are supported for C/C++ code generation with Simulink Coder and Embedded Coder. By using code generation on a Simulink model that contains a MATLAB Function block, you can deploy MATLAB functionality outside the MATLAB environment.

For more information on C/C++ code generation from a Simulink model, see “Simulink Coder”.

MATLAB Language and Function Support

In a MATLAB Function block, you can only use the subset of the MATLAB language and language features that are supported for C/C++ code generation. For a list of functions supported for code generation, see “Functions and Objects Supported for C/C++ Code Generation” on page 50-2. For supported language features, see “MATLAB Language Features Supported for C/C++ Code Generation” on page 49-18.

Extrinsic Functions

For simulation, you can call *extrinsic* functions from a MATLAB Function block. Extrinsic functions are functions that are not supported for C/C++ code generation but which can be dispatched to the MATLAB environment for execution during run time. Extrinsic functions execute in the workspace during model simulation.

For code generation, Simulink Coder attempts to compile all functions in a MATLAB Function block unless you explicitly declare them as extrinsic. Extrinsic function calls are omitted from generated standalone code, such as standalone C/C++ source code or executable files. See “Resolution of Function Calls for Code Generation” on page 65-2 and “Using the `coder.extrinsic` Construct” on page 65-9.

Simulink Function Block and Stateflow Block Support

From MATLAB Function blocks, you can call functions defined in a Simulink Function block. You can call Stateflow functions when you select the **Export Chart Level Functions (Make Global)** and **Allow exported functions to be called by Simulink** check boxes in the chart Properties dialog box. To learn more about how to call functions defined in Simulink Function and Stateflow blocks, see “Add a Simulink Function to a Model” on page 10-125.

Create Custom Functionality Using MATLAB Function Blocks

In this section...

“Open the Model” on page 45-5

“Program the MATLAB Function Block” on page 45-5

“Build the Function and Check for Errors” on page 45-7

“Define Input and Output Properties” on page 45-8

“Configure MATLAB Function Blocks Programmatically” on page 45-9

“Define Local Variables for Code Generation” on page 45-10

“Generate Code for the MATLAB Function Block” on page 45-10

This example shows how to customize a model that uses the MATLAB Function block to calculate the mean and standard deviation for a vector of values.

Open the Model

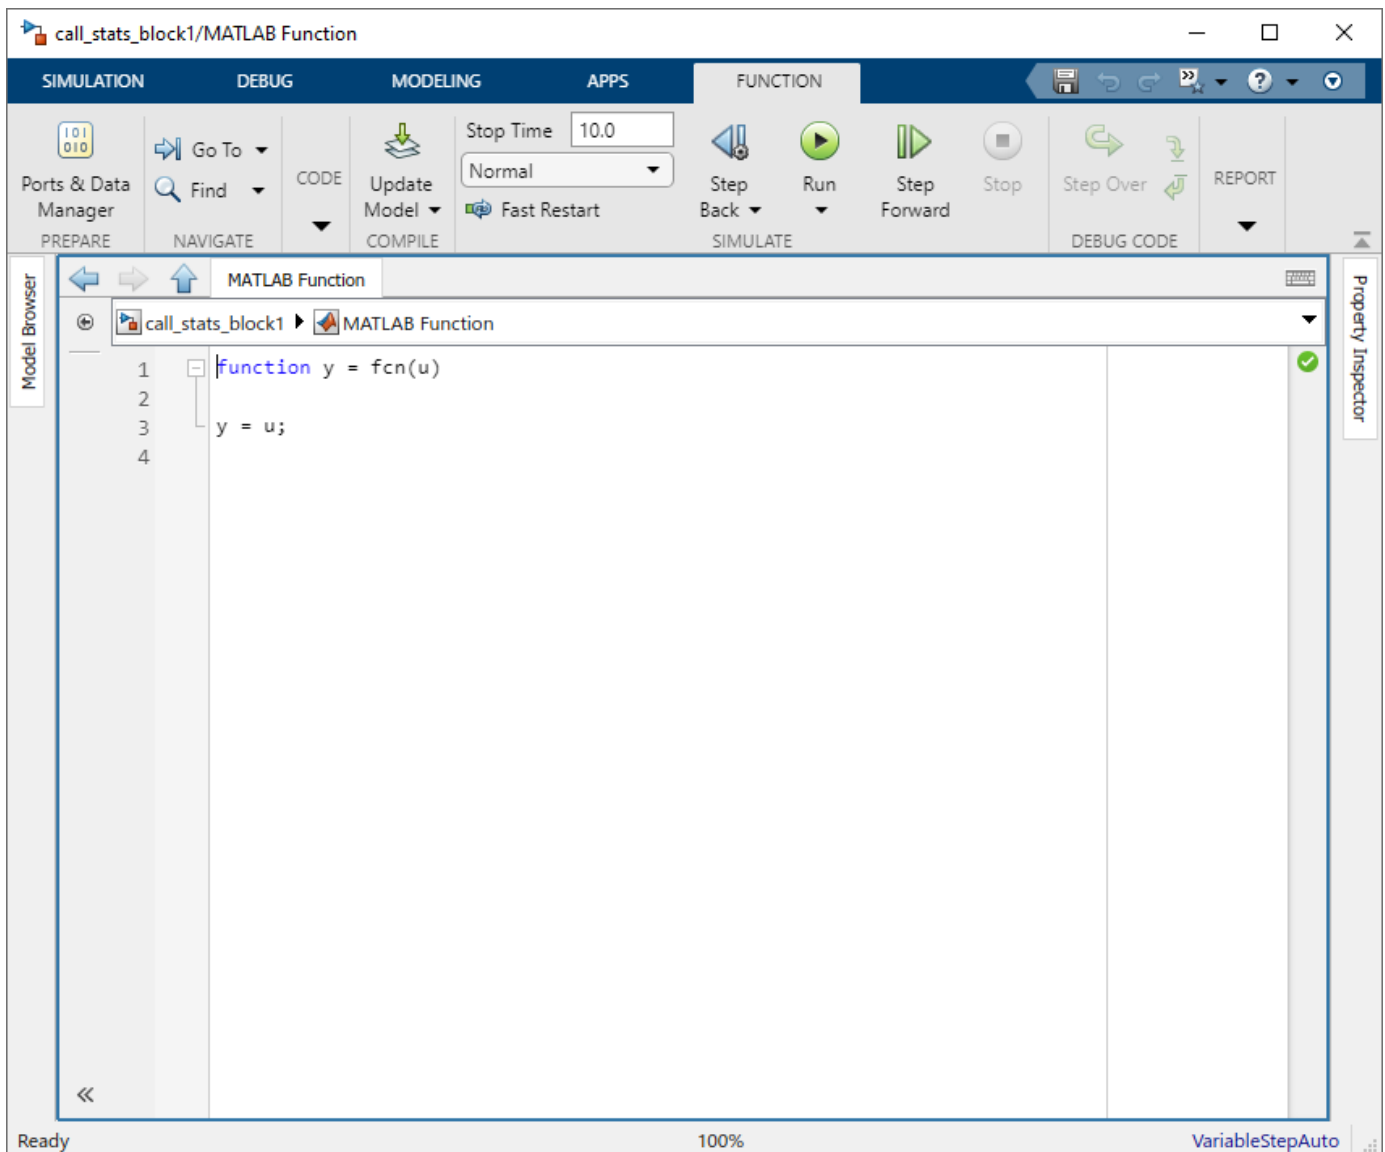

The model `call_stats_block1` includes an empty MATLAB Function block and the blocks you need for the example. Open the model to start.

Program the MATLAB Function Block

Program the block to calculate the mean and standard deviation for a vector of values:

- 1 To open the **MATLAB Function Block Editor**, double-click the MATLAB Function block. A default function appears in the **MATLAB Function Block Editor** with one input and output argument.

- 2 Define the function inputs and outputs by editing the function declaration statement:

```
function [mean, stdev] = stats(vals)
```

From this code, you define a function called `stats`, which calculates a statistical mean and standard deviation for the values in the vector `vals`. The function declaration statement declares `vals` as an argument to the `stats` function, with `mean` and `stdev` as return values.

- 3 In the **MATLAB Function Block Editor**, enter a line space after the function declaration statement and add the following code:

```
% Calculates a statistical mean and a standard
% deviation for the values in vals.

len = length(vals);
mean = avg(vals, len);
stdev = sqrt(sum((vals-avg(vals, len)).^2)/len);
plot(vals, '-+');
```

```
function mean = avg(array,size)
mean = sum(array)/size;
```

- 4 Exit the block. The function outputs `mean` and `stdev` correspond to block outports **mean** and **stdev** and the function input `vals` corresponds to the block input **vals**.
- 5 Complete the connections to the MATLAB Function block as shown.

- 6 Save the model as `call_stats_block2`.

Build the Function and Check for Errors

After programming the block in a Simulink model, you can build the function and test for errors. Building your MATLAB Function block requires a supported compiler. MATLAB automatically selects one as the default compiler. If you have multiple MATLAB-supported compilers installed on your system, you can change the default compiler using the `mex -setup` command. See “Change Default Compiler”.

Supported Compilers for Simulation and Code Generation Builds

View a list of compilers for building models containing MATLAB Function blocks simulation and code generation.

- 1 Navigate to the Supported and Compatible Compilers page and select your platform.
- 2 Scroll to the table under Simulink Product Family.
- 3 To check the table for models that contain MATLAB Function blocks for simulation, find the compilers checked in the column titled Simulink For Model Referencing, Accelerator mode, Rapid Accelerator mode, and MATLAB Function blocks.

To check the table for models that contain MATLAB Function blocks and generate code, find the compilers checked in the column titled Simulink Coder .

Supported Compilers for Code Generation

To generate code for models that contain MATLAB Function blocks, you can use any of the C compilers supported by Simulink software for code generation with Simulink Coder. For a list of these compilers:

- 1 Navigate to the Supported and Compatible Compilers Web page.
- 2 Select your platform.
- 3 In the table for Simulink and related products, find the compilers checked in the column titled Simulink Coder.

Locate and Fix Errors

If errors occur during the build process, the **Diagnostics Viewer** window lists the errors with links to the offending code.

The following exercise shows the way to locate and fix an error in a MATLAB Function block.

- 1 In the `stats` function, change the local function `avg` to a fictitious local function `aug` and then compile again to see the following messages in window. The **Diagnostics Viewer** window displays each detected error with a shaded red line.
- 2 Investigate the error titled `Undefined function or variable 'aug'`. In the diagnostic message for the selected error, click the blue link after the function name to display the offending code. The offending line appears highlighted in the **MATLAB Function Block Editor**.
- 3 The message also links to a report about compile-time type information for variables and expressions in your MATLAB functions. This information helps you diagnose error messages and understand type propagation rules. For more information about the report, see “MATLAB Function Reports” on page 45-38. To see the report, click the highlighted blue link in the line called `Launch diagnostic report`.
- 4 Correct the error by changing `aug` back to `avg` and recompile.

Define Input and Output Properties

Each function argument in MATLAB Function blocks can have a unique data type that is a scalar, vector, or matrix. However, creating the function arguments does not directly specify their data type. By default, function inputs and outputs inherit their data type and size from the signals attached to their ports. Examine input and output data for the MATLAB Function block to verify that it inherits the correct type and size.

- 1 Double-click the MATLAB Function block `stats`.
- 2 In the **MATLAB Function Block Editor**, click **Ports & Data Manager**. The Ports and Data Manager opens to help you define arguments for MATLAB Function blocks.

The left pane displays the argument `vals` and the return values `mean` and `stdev` that you have already created for the MATLAB Function block. Observe that `vals` is assigned a **Scope of Input**, which is short for **Input from Simulink**. `mean` and `stdev` are assigned the **Scope of Output**, which is short for **Output to Simulink**.

- 3 In the left pane of the Ports and Data Manager, click anywhere in the row for `vals` to highlight it.

The right pane displays the **Data** properties dialog box for `vals`. By default, the class, size, units, and complexity of input and output arguments are inherited from the signals attached to each input or output port. Inheritance is specified by setting **Size** to `-1`, **Complexity** to `Inherited`, and **Type** to `Inherit: Same as Simulink`.

The actual inherited values for size and type are set during model compilation, and are reported in the **Compiled Type** and **Compiled Size** columns of the left pane.

You can specify the type of input or output argument in the **Type** field of the **Data** properties dialog box, for example, `double`. You can also specify the size of an input or output argument by entering an expression in the **Size** field. For example, you can enter `[2 3]` in the **Size** field to specify `vals` as a 2-by-3 matrix. For more information, see “Define and Modify Function Argument Types” on page 45-43 and “Specify Size of MATLAB Function Block Data” on page 45-48.

Note The default first index for any arrays that you add to a MATLAB Function block function is 1, just as it would be in MATLAB.

Configure MATLAB Function Blocks Programmatically

There are two programmatic approaches for configuring a MATLAB Function block:

- Use a `MATLABFunctionConfiguration` object to query and modify the properties of the block. You can identify the block in your model by using a block path or calling the `gcb` function.
- Use a `Stateflow.EMChart` object to access the inputs, outputs, and properties of the block. Identify the block in your model by navigating the hierarchy of Stateflow API objects.

Configure Block Properties

Consider the model `call_stats_block1` described in the previous example. You can access the `MATLABFunctionConfiguration` object for the MATLAB Function block in this model by calling the `get_param` function:

```
config = get_param('call_stats_block1/MATLAB Function', ...
    'MATLABFunctionConfiguration');
```

To query or modify the properties in your configuration object, use dot notation with your object name:

```
myConfig.UpdateMethod
```

```
ans =
```

```
    'Inherited'
```

```
config.Description = 'Calculate the mean and standard deviation for a vector of values.';
```

To learn more about the properties you can modify in your MATLAB Function configuration object, see `MATLABFunctionConfiguration`.

Access Block Inputs, Outputs, and Properties

For greater programmatic control of your MATLAB Function block, access its `Stateflow.EMChart` object by calling the `find` function for the `Simulink.Root` object at the top level of the Stateflow hierarchy of objects.

```
rt = sfroot;
block = find(rt, '-isa', 'Stateflow.EMChart', ...
    'Path', 'call_stats_block1/MATLAB Function');
```

To query or modify the properties in your configuration object, use dot notation with your object name:

```
block.ChartUpdate
```

```
ans =
```

```
    'INHERITED'
```

```
block.Description = 'Calculate the mean and standard deviation for a vector of values.';
```

The `Stateflow.EMChart` object gives you access to additional properties that are not available in the `MATLABFunctionConfiguration` object. For example, to create a table of the inputs and outputs of the block, enter:

```
info = get([block.Inputs;block.Outputs],{'Name','Scope','Port'});
T = table(info(:,2),cell2mat(info(:,3)), ...
    'VariableNames',{'Scope','Port'}, ...
    'RowNames',info(:,1));
T.Scope = categorical(T.Scope)
```

T =

3×2 table

	Scope	Port
vals	Input	1
mean	Output	1
stdev	Output	2

For more information, see “Overview of the Stateflow API” (Stateflow).

Define Local Variables for Code Generation

To generate code from the MATLAB algorithm in a MATLAB Function block, you must explicitly assign the class, size, and complexity of local variables before using them in operations or returning them as outputs (see “Data Definition for Code Generation” on page 53-2). In the example function `stats`, the local variable `len` is defined before being used to calculate mean and standard deviation:

```
len = length(vals);
```

Once you assign properties to a variable, you cannot redefine its class, size, or complexity elsewhere in the function body with some exceptions (see “Reassignment of Variable Properties” on page 52-9).

Generate Code for the MATLAB Function Block

- 1 Open the `call_stats_block2` model that you saved at the end of “Program the MATLAB Function Block” on page 45-5.
- 2 Double-click `stats` block.
- 3 Open the Simulink Coder app.
- 4 On the **C Code** tab, **Build** to compile and build the example model.

If you get an error related to the `Variable-step` solver, from **Configuration Parameters > Solver**, change the solver type to a `Fixed-step` solver and rerun the build. To learn more about the differences between fixed-step and variable-step solvers, see “Fixed-Step Versus Variable-Step Solvers” on page 3-6.

If no errors occur, the **Diagnostics Viewer** window displays a message indicating success. Otherwise, this window helps you locate errors, as described in “Locate and Fix Errors” on page 45-8.

More About

- “Implementing MATLAB Functions Using Blocks” on page 45-3
- “Call MATLAB Function Files in MATLAB Function Blocks” on page 45-116
- “Overview of the Stateflow API” (Stateflow)

Code Generation Readiness Tool

The code generation readiness tool screens MATLAB code for features and functions that code generation does not support. The tool provides a report that lists the source files that contain unsupported features and functions. The report also indicates the amount of work required to make the MATLAB code suitable for code generation. It is possible that the tool does not detect all code generation issues. Under certain circumstances, it is possible that the tool can report false errors. Therefore, before you generate C code, verify that your code is suitable for code generation by generating a MEX function.

The code generation readiness tool does not report functions that the code generator automatically treats as extrinsic. Examples of such functions are `plot`, `disp`, and `figure`. See “Use MATLAB Engine to Execute a Function Call in Generated Code” on page 65-8.

Summary Tab

The screenshot shows the 'Code Generation Readiness - call_myfun.m etc.' window. The 'Summary' tab is active, displaying a 'Code Generation Readiness Score' of 4 out of 5. The score is represented by a green progress bar with a '4' in a circle. Below the bar, it says 'Requires some minor changes' and 'Code generation tools might fail unless the issues listed below are fixed.' Under the heading 'Unsupported MATLAB function calls - 2 invocations', there are two entries: 'myfun.m' pointing to 'eval' with a count of 1, and 'myfun.m' pointing to 'calyears' with a count of 1.

The **Summary** tab provides a **Code Generation Readiness Score**, which ranges from 1 to 5. A score of 1 indicates that the tool detects issues that require extensive changes to the MATLAB code to make it suitable for code generation. A score of 5 indicates that the tool does not detect code generation issues; the code is ready to use with minimal or no changes.

On this tab, the tool also displays information about:

- MATLAB syntax issues. These issues are reported in the MATLAB editor. To learn more about the issues and how to fix them, use the Code Analyzer.
- Unsupported MATLAB function calls.
- Unsupported MATLAB language features.

- Unsupported data types.

Code Structure Tab

The screenshot shows the 'Code Structure' tab in the Code Generation Readiness tool. It features a pie chart titled 'Code Distribution' and a table titled 'Call Tree'.

Code Distribution

You may wish to only attempt code generation with the files that are more promising. This chart shows how much of the code is in each file and how suitable each file is for code generation.

The pie chart shows two files: `myfun.m` (yellow, 3 lines) and `call_myfun.m` (green, 2 lines). The legend indicates that yellow represents 'Requires some significant changes' and green represents 'Requires some minor changes'.

Call Tree

Show MATLAB functions

File	Code Generation Readiness	Lines
<input type="checkbox"/> call_myfun.m	4	2
myfun.m	3	5

If the code that you are checking calls other MATLAB functions, or you are checking multiple entry-point functions, the tool displays the **Code Structure Tab**.

This tab displays information about the relative size of each file and how suitable each file is for code generation.

Code Distribution

The **Code Distribution** pane displays a pie chart that shows the relative sizes of the files and how suitable each file is for code generation. During the planning phase of a project, you can use this

information for estimation and scheduling. If the report indicates that multiple files are not suitable for code generation, consider fixing files that require minor changes before addressing files with significant issues.

Call Tree

The **Call Tree** pane displays information about the nesting of function calls. For each called function, the report provides a **Code Generation Readiness** score, which ranges from 1 to 5. A score of 1 indicates that the tool detects issues that require extensive changes to the MATLAB code to make it suitable for code generation. A score of 5 indicates that the tool does not detect code generation issues. The code is ready to use with minimal or no changes. The report also lists the number of lines of code in each file.

Show MATLAB Functions

If you select **Show MATLAB Functions**, the report also lists the MATLAB functions that your function calls. For each of these MATLAB functions, if code generation supports the function, the report sets **Code Generation Readiness** to Yes.

Check Code Using the Code Generation Readiness Tool

In this section...
“Run Code Generation Readiness Tool at the Command Line” on page 45-17
“Run the Code Generation Readiness Tool From the Current Folder Browser” on page 45-17

Run Code Generation Readiness Tool at the Command Line

- 1 Navigate to the folder that contains the file that you want to check for code generation readiness.
- 2 At the MATLAB command prompt, enter:

```
coder.screener('filename')
```

The **Code Generation Readiness** tool opens for the file named `filename`, provides a code generation readiness score, and lists issues that must be fixed prior to code generation.

Run the Code Generation Readiness Tool From the Current Folder Browser

- 1 In the current folder browser, right-click the file that you want to check for code generation readiness.
- 2 From the context menu, select **Check Code Generation Readiness**.

The **Code Generation Readiness** tool opens for the selected file and provides a code generation readiness score and lists issues that must be fixed prior to code generation.

Debug MATLAB Function Blocks

In this section...

- “Debug an Example Function” on page 45-18
- “Set Conditions on Breakpoints” on page 45-20
- “Watch Function Variables During Simulation” on page 45-21
- “Check for Data Range Violations” on page 45-22

You can use the **MATLAB Function Block Editor** to debug MATLAB Function block code. The **MATLAB Function Block Editor** includes some of the same debugging tools available in the MATLAB editor. To debug MATLAB Function block code, set at least one breakpoint and run the simulation.

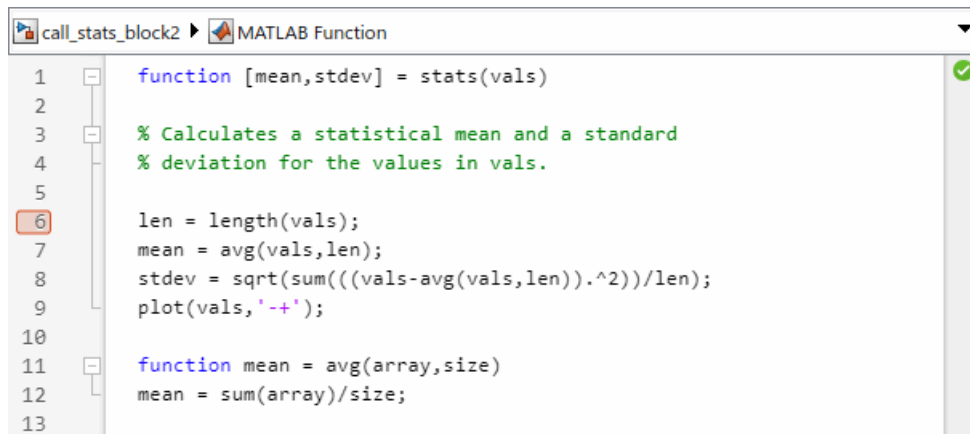

Debug an Example Function

This example uses the model `call_stats_block2`, which you create in “Create Custom Functionality Using MATLAB Function Blocks” on page 45-5. To debug the MATLAB Function block code in this model:

- 1 Open the `call_stats_block2` model. Double-click the MATLAB Function block to open the editor.
- 2 In the **MATLAB Function Block Editor**, click the line number to the left of the line:

```
len = length(vals);
```

The line number is highlighted in red, which indicates the breakpoint.

The screenshot shows the MATLAB Function Block Editor for the model `call_stats_block2`. The editor displays the following code:

```

1 function [mean,stdev] = stats(vals)
2
3 % Calculates a statistical mean and a standard
4 % deviation for the values in vals.
5
6 len = length(vals);
7 mean = avg(vals,len);
8 stdev = sqrt(sum((vals-avg(vals,len)).^2)/len);
9 plot(vals,'-+');
10
11 function mean = avg(array,size)
12 mean = sum(array)/size;
13

```

Line 6 is highlighted in red, indicating a breakpoint. A green checkmark is visible in the top right corner of the editor window.

- 3 Simulate the model.

The simulation pauses when execution reaches the breakpoint. A green arrow points to where the simulation has paused.

```

1  function [mean,stdev] = stats(vals)
2
3  % Calculates a statistical mean and a standard
4  % deviation for the values in vals.
5
6  len = length(vals);
7  mean = avg(vals,len);
8  stdev = sqrt(sum((vals-avg(vals,len)).^2)/len);
9  plot(vals,'-+');
10
11 function mean = avg(array,size)
12 mean = sum(array)/size;
13

```

- 4 On the **Function** tab, click **Step Over** to advance execution.

The execution advances to the next line of `stats`, which calls the local function `avg`.

- 5 On the **Function** tab, click **Step In**.

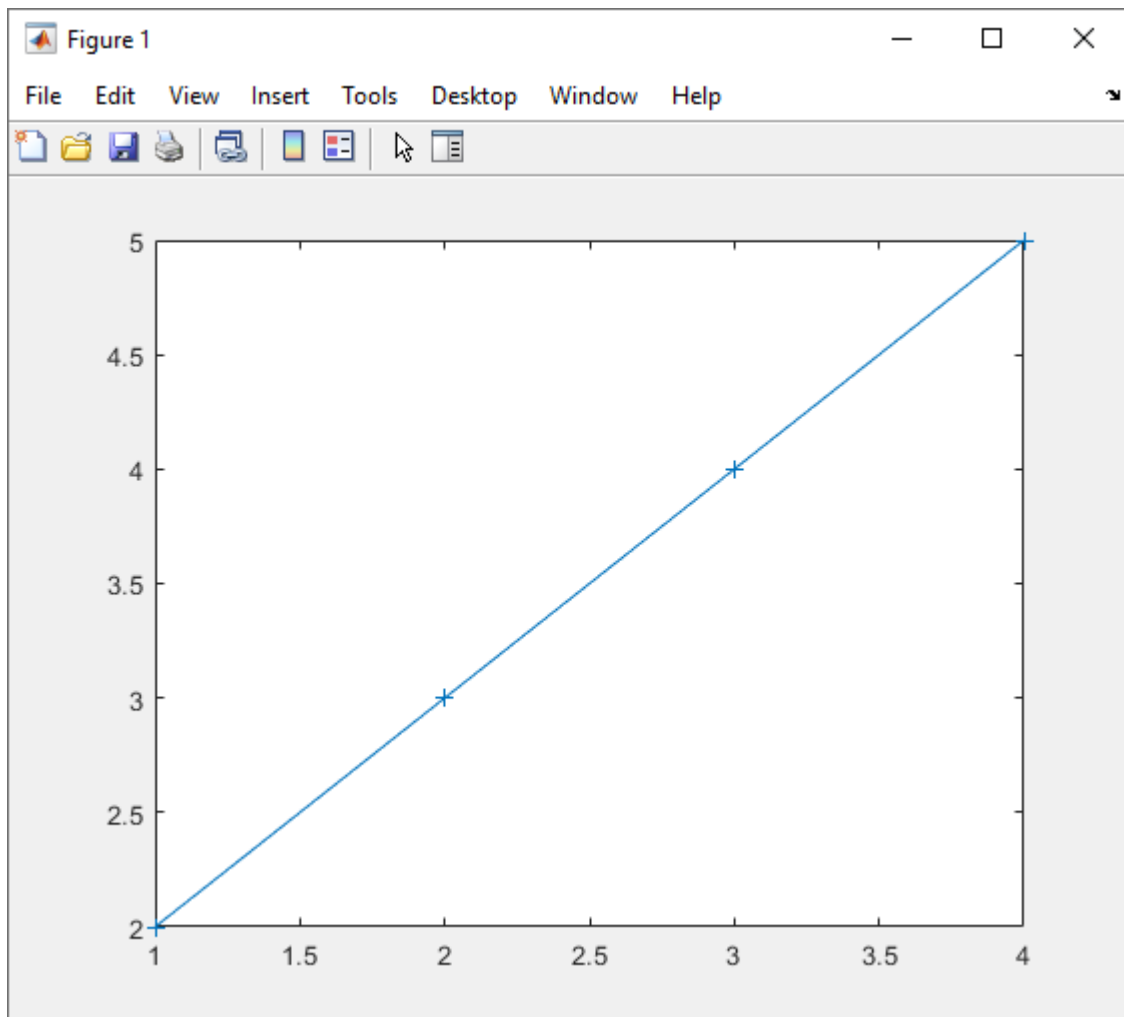

Execution advances to the local function `avg`. Once you are in a local function, you can use the **Step Over** or **Step In** commands to advance execution. If the local function calls another local function, use **Step In** to enter it. If you want to execute the remaining lines of the local function, use **Step Out**.

- 6 Click **Step Over** to execute the only line in `avg`.
- 7 Click **Step Over** to return to the function `stats`.

Execution advances to the line after the call to `avg`.

- 8 Click **Step Over** twice to calculate the `stdev` and to execute the `plot` function.

The `plot` function executes in MATLAB:

- 9 Click **Continue** to continue executing the model.

If you return to the model, the computed values of `mean` and `stdev` appear in the Display blocks.

- 10 In the **MATLAB Function Block Editor**, click **Stop** to stop the simulation.

Note You can debug MATLAB Function blocks in Normal and Accelerator modes. However, if you simulate a model in Accelerator mode that uses a MATLAB Function block in a model reference, the parent model simulation ignores the breakpoints.

Set Conditions on Breakpoints

You can enter a MATLAB expression as a condition on a breakpoint inside a MATLAB Function block. Simulation then pauses on that breakpoint only when the condition is true. To set a conditional breakpoint, in the **MATLAB Function Block Editor**, right-click the line number to the left of a line of code and select **Set Conditional Breakpoint**, and enter the condition in the dialog box. You can use any valid MATLAB expression as a condition. This expression can include numerical values and any data that is in scope at the breakpoint.

To add or modify a condition on an existing breakpoint, right-click the breakpoint and select **Set/Modify Condition**.

Watch Function Variables During Simulation

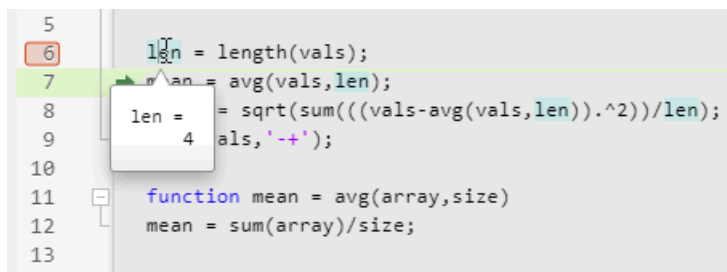

You can use several tools to track the variable values of the function while you simulate a MATLAB Function block.

Watch Function Variables with the Interactive Display

To display the value of a variable in the function of a MATLAB Function block during simulation:

- 1 Add a breakpoint to the **MATLAB Function Block Editor**. Run the model.
- 2 When the simulation pauses, point to a variable name. A tooltip displays the current variable value.

For example, to watch the variable `len` during simulation, point to `len` in the code.

Watching Function Variables with the Command Line Debugger

You can view the values for a function variable in the Command Window during simulation. When you reach a breakpoint, enter the name of a variable at the `debug>>` prompt to see its value.

```
debug>> stdev
```

```
1.1180
```

```
debug>>
```

You can also enter these commands in the command window while debugging:

Command	Description
<code>dbcont</code>	Continue execution to next breakpoint.
<code>dbquit</code>	Quit debugging and terminate the simulation.
<code>dbstep [in out]</code>	Advance to next program step after a breakpoint is encountered. Step over or step into/out of a MATLAB local function.
<code>help</code>	Display help for command line debugging.
<code>print <var></code>	Display the value of the variable <code>var</code> in the current scope. If <code>var</code> is a vector or matrix, you can also index into <code>var</code> . For example, <code>var(1,2)</code> .

Command	Description
save	Saves all variables in the current scope to the specified file. Follows the syntax of the MATLAB <code>save</code> command. To retrieve variables from the MATLAB base workspace, use <code>load</code> command after simulation completes.
<var>	Equivalent to <code>print <var></code> if the variable is in the current scope.
who	Display the variables in the current scope.
whos	Display the size and class (type) of all variables in the current scope.

If you enter other commands at the `debug>>` prompt, the results execute in the workspace of the MATLAB Function block. To issue a command in the MATLAB base workspace, use the `evalin` command with the first argument `'base'` followed by the second argument command, for example, `evalin('base','whos')`. To return to the MATLAB base workspace, use the `dbquit` command.

Display Size Limits

The **MATLAB Function Block Editor** does not display the contents of matrices that have more than two dimensions or more than 200 elements. For matrices that exceed these limits, the **MATLAB Function Block Editor** displays the shape and base type only.

Check for Data Range Violations

MATLAB Function blocks check inputs and outputs for data range violations when the input or output values enter or leave the blocks. To enable data range violation checking, open the Configuration Parameters window, click **Diagnostics > Data Validity**, and set **Simulation range checking** to error or warning.

Specify a Data Range

To specify a range for input and output data, open the **MATLAB Function Block Editor**, click **Ports & Data Manager**, and select the input or output of interest. In the **General** tab, adjust the **Limit range** property by entering the desired values for **Minimum** and **Maximum**.

Prevent Algebraic Loop Errors in MATLAB Function and Stateflow Blocks

You can use Stateflow charts, MATLAB Function blocks, and Stateflow Truth Tables in feedback loops in your model. You can also use these blocks with synchronous subsystems enabled by the State Control block. To prevent algebraic loop or synchronous semantic errors, apply these restrictions.

Simulink Block	Restrictions
Stateflow Chart	Use Moore charts to prevent an algebraic loop. In the Property Inspector, set the State Machine Type to Moore . Moore charts prevent algebraic loops by ensuring that outputs depend only on current state.
MATLAB Function block	<p>Nondirect feedthrough semantics prevent algebraic loop errors by ensuring that outputs depend only on current state. To enable these semantics, clear the Allow direct feedthrough property check box.</p> <p>If your block uses direct feedthrough, do not:</p> <ul style="list-style-type: none"> • Call imported functions. • Define output function-call events. • Define or use persistent variables. <p>When you apply these restrictions, you allow the Simulink solver to try to solve the algebraic loop.</p>
Truth Table	<p>Do not:</p> <ul style="list-style-type: none"> • Call imported functions. • Define local or output function-call events. • Define local or data store memory data. • Define or use persistent variables. • Use machine-parented data or events. <p>When you apply these restrictions, you allow the Simulink solver to try to solve the algebraic loop.</p>

Chart | Truth Table

More About

- “Design Considerations for Moore Charts” (Stateflow)
- “Use Nondirect Feedthrough in a MATLAB Function Block” on page 45-125
- “Algebraic Loop Concepts” on page 3-27
- “Control States in Charts Enabled by Function-Call Input Events” (Stateflow)

Manage Function Call Outputs of a MATLAB Function Block

A function call output is an event on the output port of a MATLAB Function block that causes a Function-Call Subsystem or Stateflow chart in the model to execute. See “Using Function-Call Subsystems” on page 10-35. You can add function call outputs to MATLAB Function blocks by using the Ports and Data Manager or the Model Explorer.

To use the Ports and Data Manager, double-click the MATLAB Function block to open the **MATLAB Function Block Editor** and click **Edit Data**. You can return to the block code by clicking the Go to Block Editor button .

To use the Model Explorer, in the **Modeling** tab, in the **Design** section, click **Model Explorer**. In the **Model Hierarchy** pane, expand the model tree view and select the MATLAB Function block.

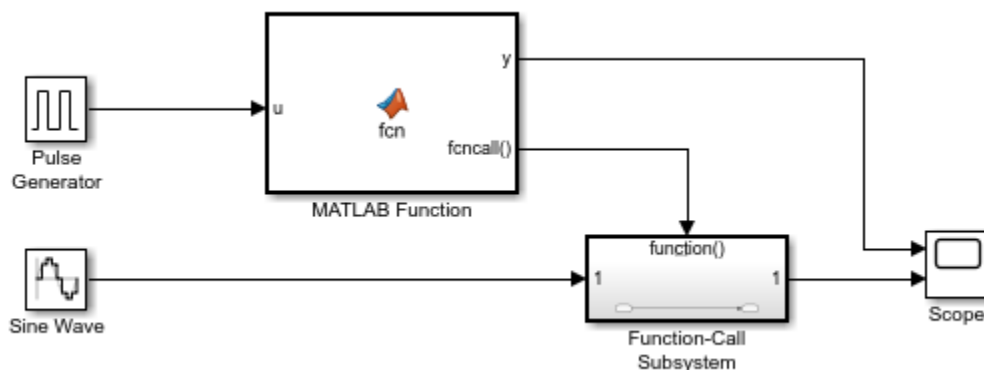

When using the Ports and Data Manager or the Model Explorer, you can create, manage, and delete function call outputs:

- Modify the function call output properties by selecting the function call output in the left pane of the Ports and Data Manager or the **Contents of** pane in the Model Explorer.
- Add a function call output by clicking **Add > Function Call Output** or the Add Function Call Output button .
- Delete a function call output by selecting a function call output and clicking **Edit > Delete** or the Delete button .

After creating a function call output, you need to call the function call output in the MATLAB Function block code.

Enable a Function-Call Subsystem with a MATLAB Function Block

This example uses a MATLAB Function block with a function call output to trigger a subsystem.

When the signal from the Pulse Generator block equals 1, the MATLAB Function block executes the function call output. The block then continues to execute the function call output at each major time step. Double-click the MATLAB Function block to open the code.

```
function y = fcn(u)
```

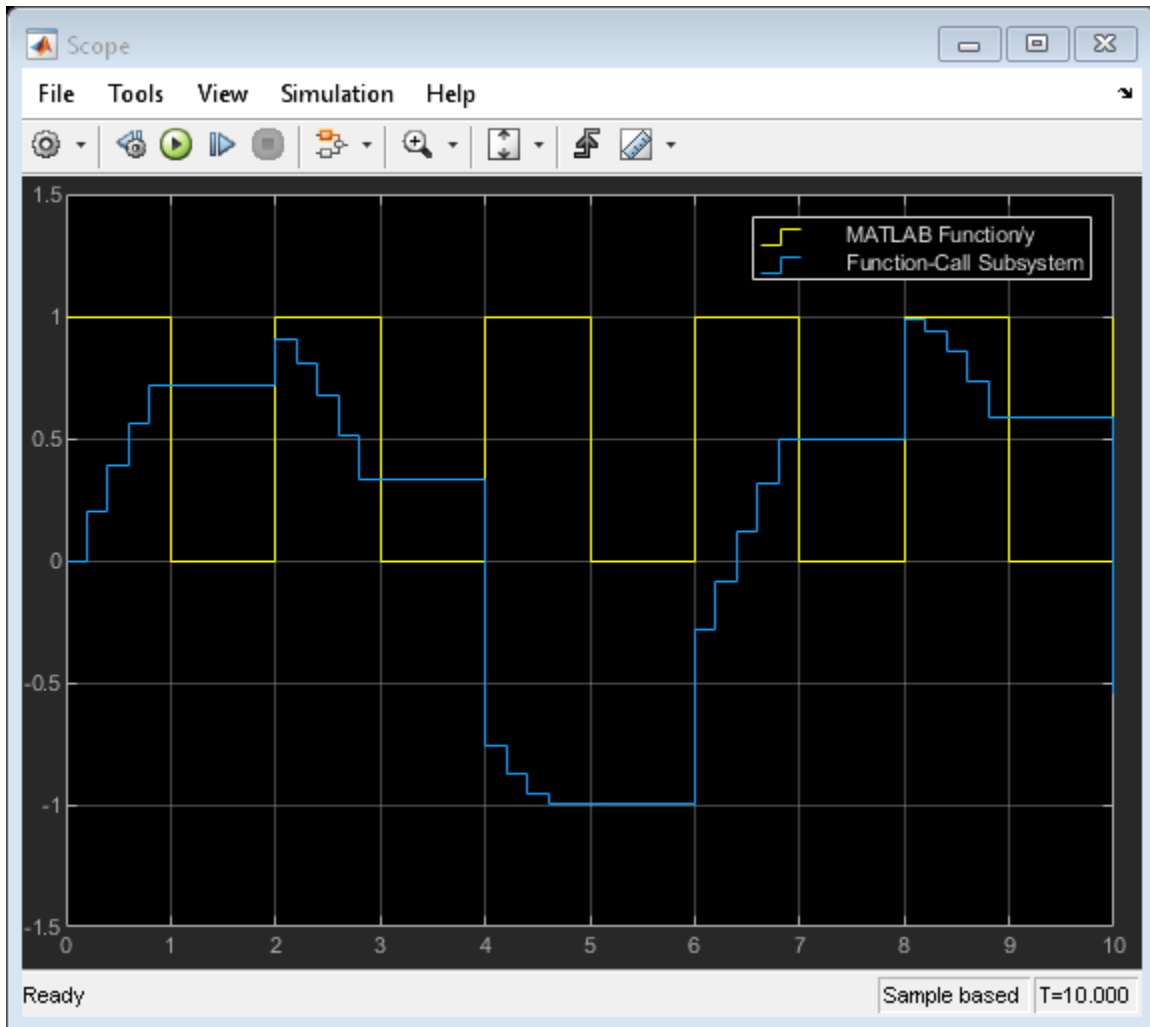

```

y = u;
if u == 1
    fcncall()
end

```

The function-call subsystem allows the signal from the Sine Wave block to propagate when the function-call triggers. When the function call is not triggered, the subsystem outputs the last propagated value. Run the model and open the Scope block to see the outputs.

Considerations When Triggering Function-Call Subsystems

If a MATLAB Function block triggers a function-call subsystem and outputs a signal to the same function-call subsystem, the signal to the function-call subsystem is delayed by one time step compared to the function call. At the moment of the function call output, the function-call subsystem sees the previous MATLAB Function block output port value even if the output data has been updated within the block MATLAB code.

Set Function Call Output Properties

After clicking the output function call you want to modify in the Ports and Data Manager or the Model Explorer, you can set the following properties.

Name

Specifies the name of the function call output, following the naming conventions used in MATLAB.

Port

Specifies the index of the port associated with the function call output. Function call output ports are numbered sequentially after output ports.

Description

Specifies the description of the function call output.

Document link

Specifies the link to documentation for the function call output. You can enter a URL address or a MATLAB command that displays documentation, such as an HTML file or text in the MATLAB Command Window. When you click the **Document link** link, the MATLAB Function block evaluates the link and displays the documentation.

Manage the Input Trigger of a MATLAB Function Block

An input trigger is an input that executes the MATLAB Function block when activated. See “Using Triggered Subsystems” on page 10-17. You can add one input trigger to each MATLAB Function block by using the Ports and Data Manager or the Model Explorer.

To use the Ports and Data Manager, double-click the MATLAB Function block to open the **MATLAB Function Block Editor** and click **Ports & Data Manager**. You can return to the block code by clicking the Go to Block Editor button .

To use the Model Explorer, in the **Modeling** tab, in the **Design** section, click **Model Explorer**. In the **Model Hierarchy** pane, expand the model tree view and select the MATLAB Function block.

When using the Ports and Data Manager or the Model Explorer, you can create, manage, and delete input triggers:

- Modify the input trigger properties by selecting the input trigger in the left pane of the Ports and Data Manager or the **Contents of** pane in the Model Explorer.
- Add an input trigger by clicking **Add > Trigger** or the Add Trigger button .
- Delete the input trigger by selecting the input trigger and clicking **Edit > Delete** or the Delete button .

Set Input Trigger Properties

After clicking the input trigger you want to modify in the Ports and Data Manager or the Model Explorer, you can set the following properties.

Name

Specifies the name of the input trigger, following the naming conventions used in MATLAB.

Port

Specifies the index of the port associated with the input trigger. The property is read-only. Because you can only add one trigger to a MATLAB Function block, this property is always 1.

Trigger

Specifies the type of event that triggers the MATLAB Function block. You can select one of the following types:

Trigger Event	Description
Rising	The trigger signal executes the MATLAB Function block when the signal rises from a negative or zero value to a positive value or from a negative value to zero.
Falling	The trigger signal executes the MATLAB Function block when the signal falls from a positive or zero value to a negative value or from a positive value to zero..

Trigger Event	Description
Either	The trigger signal executes the MATLAB Function block when the control signal is either Rising or Falling.
Function call	A trigger signal from a block that outputs function-call events executes the MATLAB Function block.

Description

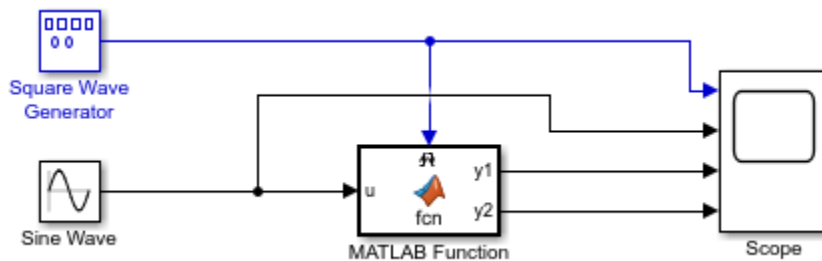

Specifies the description of the input trigger.

Document link

Specifies the link to the documentation for the input trigger. You can enter a URL address or a MATLAB command that displays documentation, such as an HTML file or text in the MATLAB Command Window. When you click the **Document link** link, the MATLAB Function block evaluates the link and displays the documentation.

Enable a MATLAB Function Block with an Input Trigger

This example uses a MATLAB Function block that is controlled by an either input trigger.

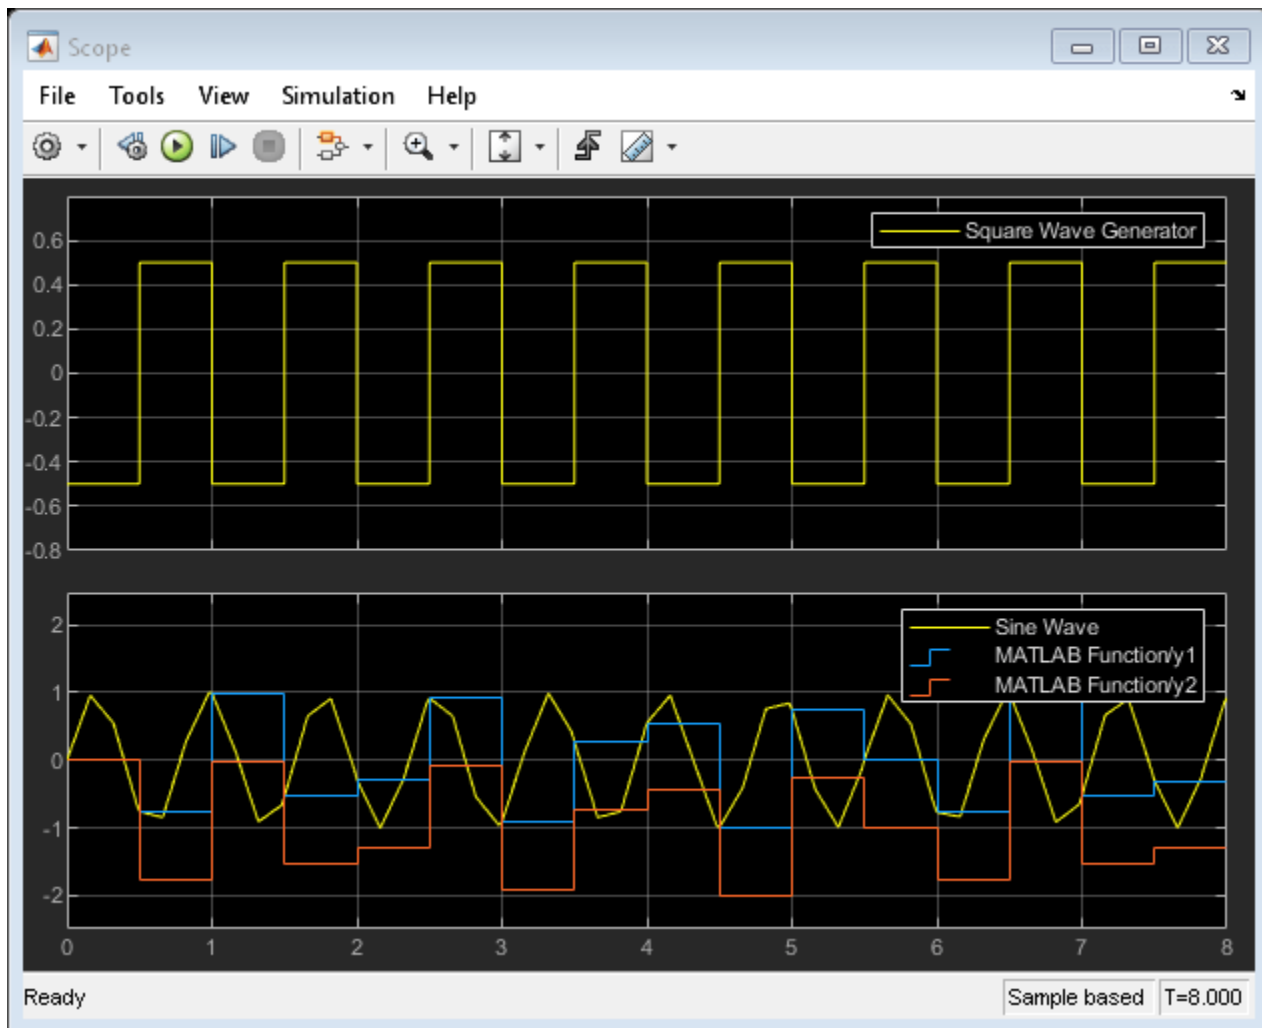

When the signal from the Square Wave Generator block rises or falls below 0, the MATLAB Function block executes. Double-click the MATLAB Function block to open the code.

```
function [y1,y2] = fcn(u)
```

```
y1 = u;  
y2 = u - 1;
```

The MATLAB Function block outputs the last propagated value until the block triggers again. Run the model and open the Scope block to see the outputs.

Define MATLAB Function Block Data

You can define the data for MATLAB Function blocks in the MATLAB Function block code, the Ports and Data Manager, or the Model Explorer.

To adjust data in the MATLAB Function block code, double-click the MATLAB Function block to open the **MATLAB Function Block Editor**. When you specify new input and output arguments, the MATLAB Function block automatically assigns the arguments to the respective input or output port. Similarly, you can remove arguments from the block by deleting them and updating the model.

To use the Ports and Data Manager, double-click the MATLAB Function block to open the **MATLAB Function Block Editor**. Open the Ports and Data Manager by clicking **Ports & Data Manager**. You can return to the block code by clicking the Go to Block Editor button .

To use the Model Explorer, in the **Modeling** tab, in the **Design** section, click **Model Explorer**. In the **Model Hierarchy** pane, expand the model tree view and select the MATLAB Function block.

When using the Ports and Data Manager or the Model Explorer, you can create, manage, and delete data:

- Modify data properties by selecting the data in the left pane of the Ports and Data Manager or the **Contents of** pane in the Model Explorer.
- Add data by clicking **Add > Data** or the Add Data button .
- Delete data by selecting the data and clicking **Edit > Delete** or the Delete button .

Set General Data Properties

After clicking the data you want to modify in the Ports and Data Manager or the Model Explorer, you can set the following properties in the **General** tab.

Name

Specifies the name of the data argument, using the same naming conventions used in MATLAB.

Scope

Specifies where data resides in memory relative to its parent. This property determines the range of functionality of the data. You can set **Scope** to one of the following values:

Scope	Description
Parameter	The data resides in a variable of the same name in the MATLAB workspace, the model workspace, or in the workspace of a masked subsystem containing this block. If a variable of the same name exists in more than one of the workspaces visible to the block, the block uses the variable closest to the block in the workspace hierarchy. For more information, see “Model Workspaces” on page 68-120.

Scope	Description
Input	The data is an input signal to a MATLAB Function block.
Output	The data is an output signal of a MATLAB Function block.
Data Store Memory	The data resides in a Data Store Memory block in the model. For more information, see “Storing Data Using Data Store Memory Blocks” on page 45-93.

For more information, see “Define Input and Output Properties” on page 45-8 and “Configure MATLAB Function Block Parameter Data Arguments” on page 45-50.

Port

Specifies the index of the port associated with the data argument. This property applies only to data with the **Scope** property set to Input or Output.

Data must resolve to signal object

Specifies that the data argument resolves to a Simulink signal object. This property applies only to data with the **Scope** property set to Output. This property appears only if you set the configuration parameter **Signal resolution** to a value other than None. For more information, see “Symbol Resolution” on page 68-128.

Size

Specifies the size of the data. This property can be a scalar value or a MATLAB vector of values. **Size** defaults to -1 , which means that the size is inherited. For more information, see “Inherit Argument Sizes from Simulink” on page 45-48. This property does not apply to data with the **Scope** property set to Data Store Memory. See “Specify Size of MATLAB Function Block Data” on page 45-48.

Variable size

Specifies whether the size of this data item is variable. This property does not apply to data with the **Scope** property set to Data Store Memory or Parameter.

Tunable

Specifies whether the parameter used as the source of this data item is tunable. For more information, see “Tunable Parameters” on page 10-70. This property applies only to data with the **Scope** property set to Parameter. Clear this option if the parameter must be a constant expression, such as for toolbox functions supported for code generation. For more information, see “Functions and Objects Supported for C/C++ Code Generation” on page 50-2.

Complexity

Specifies real or complex data arguments. Set **Complexity** to one of the following values:

Complexity	Description
Inherited	Data argument inherits complexity based on the Scope property. Input and output data inherit complexity from the Simulink signals connected to them. Parameter data inherits complexity from the parameter to which it is bound.
Off	Data argument is a real number.
On	Data argument is a complex number.

This property does not apply to data with the **Scope** property set to Data Store Memory.

Type

Specifies the data type for the data. You can specify the data type by:

- Selecting a built-in type from the **Type** drop down list.
- Entering an expression in the **Type** field that evaluates to a data type. See “About Data Types in Simulink” on page 68-2.
- Using the Data Type Assistant to specify the **Mode** property, then specifying the data type based on that mode.

Note To display the Data Type Assistant, click the Show data type assistant button .

For more information, see “Specify Argument Types” on page 45-43. This property does not apply to data with the **Scope** property set to Data Store Memory.

Unit (e.g., m, m/s², N*m)

Specifies the physical units for data. By default, this property is set to inherit the unit from the Simulink signal on the corresponding input or output port. See “Specify Units in MATLAB Function Blocks” on page 9-5. The property applies only to data with the **Scope** property set to Input or Output.

Limit range

Specifies the range of acceptable values for data with the **Scope** property set to Input or Output. The MATLAB Function block uses this range to validate the data as it enters or leaves the block. You can enter an expression or parameter that evaluates to a numeric scalar.

- **Minimum** — The smallest value allowed for the data during simulation. The default value is `-inf`.
- **Maximum** — The largest value allowed for the data during simulation. The default value is `inf`.

Set Description Properties

After clicking the data you want to modify in the Ports and Data Manager or the Model Explorer, you can set the following properties in the **Description** tab.

Save final value to base workspace

Specifies if the MATLAB Function block assigns the value of the data to a variable of the same name in the MATLAB base workspace after simulation. This property applies only to data with the **Scope** property set to Input or Output.

Description

Specifies the description of the data argument.

Document link

Specifies the link to the documentation for the data argument. You can enter a URL address or a MATLAB command that displays documentation, such as an HTML file or text in the MATLAB Command Window. When you click the **Document link** link, the MATLAB Function block evaluates the link and displays the documentation.

Specify MATLAB Function Block Properties

You can specify how a MATLAB Function block interfaces with a Simulink model by setting the block properties in the Property Inspector, Ports and Data Manager, or Model Explorer.

To specify properties in the Property Inspector, click the **Modeling** tab. In the **Design** section, select **Property Inspector**. Click the MATLAB Function block to see the MATLAB Function block properties.

To specify properties in the Ports and Data Manager, double click the MATLAB Function block to open the **MATLAB Function Block Editor**. Click **Ports & Data Manager**. To access the MATLAB Function block properties, click the Show Block Dialog button .

To specify properties in the Model Explorer, click the **Modeling** tab. In the **Design** section, select **Model Explorer**. In the **Model Hierarchy** pane, expand the model tree view, select the MATLAB Function block, and edit the properties in the **MATLAB Function** pane.

MATLAB Function Block Properties

You can adjust the following properties in the Ports and Data Manager and the Model Explorer, or by navigating to the **Properties** tab of the Property Inspector.

Update method

Specifies the method used for activating the MATLAB Function block.

Update Method	Description
Inherited (default)	Input from the Simulink model activates the MATLAB Function block. If you define an input trigger, the MATLAB Function block executes in response to a Simulink signal or function-call event on the trigger port. If you do not define an input trigger, the MATLAB Function block implicitly inherits triggers from the model. These implicit events are the sample times (discrete or continuous) of the signals that provide inputs to the block. If you define data inputs, the MATLAB Function block samples at the rate of the fastest data input. If you do not define data inputs, the MATLAB Function block samples at the rate defined by the execution behavior of the parent subsystem.
Discrete	Sample the MATLAB Function block using the rate you specify in the Sample time property of the MATLAB Function block. The MATLAB Function block generates an implicit event at regular time intervals that correspond to the specified rate. Note that other blocks in the model can have different sample times.
Continuous	Sample the MATLAB Function block at each major time step of the simulation, as well as at intermediate time points requested by the Simulink solver.

Saturate on integer overflow

Specifies how the MATLAB Function block handles overflow conditions during integer operations.

Setting	Action When Overflow Occurs
Enabled (default)	Saturates an integer by setting it to the maximum positive or negative value allowed by the word size. This setting matches MATLAB behavior.
Disabled	Generates a run-time error in simulation mode. For Simulink Coder code generation, the behavior depends on your C language compiler.

Note The **Saturate on integer overflow** option is relevant only for integer arithmetic. It has no effect on fixed-point or double-precision arithmetic.

When you enable **Saturate on integer overflow**, MATLAB adds additional checks during simulation to detect integer overflow or underflow. Therefore, it is more efficient to disable this option if you are sure that integer overflow and underflow does not occur in your MATLAB Function block code.

Note that the code generated by Simulink Coder does not check for integer overflow or underflow and, therefore, may produce unpredictable results when **Saturate on integer overflow** is disabled. In this situation, simulate your model to test for overflow and underflow before generating code.

Support variable-size arrays

Specifies if the MATLAB Function block supports input and output data that varies in dimension during simulation. For more information, see “Declare Variable-Size Inputs and Outputs” on page 45-73.

Allow direct feedthrough

Specifies if the MATLAB Function block supports direct feedthrough semantics, so that the output of the block is controlled directly by the value of an input. When you disable **Allow direct feedthrough**, nondirect feedthrough semantics ensure that outputs rely only on the current state of the block. Using nondirect feedthrough enables you to use MATLAB Function blocks in a feedback loop and prevent algebraic loops. For more information, see “Use Nondirect Feedthrough in a MATLAB Function Block” on page 45-125.

Interpret output column vectors as one-dimensional data

Specifies if the output of a column vector evaluates as one-dimensional data.

- If you enable this property, the block converts output column vectors of size N -by-1 to one-dimensional signals with a signal size equal to N .
- If you disable this property, the block outputs column vectors of size N -by-1 as signals with a signal size equal to N -by-1.

Note Before R2021b, MATLAB Function blocks always converted output column vectors to one-dimensional signals.

Fixed-Point Properties

You can adjust fixed-point properties for the MATLAB Function block in the Ports and Data Manager and Model Explorer, or by navigating to the **Fixed-point properties** section in the **Properties** tab of the Property Inspector.

Treat these inherited Simulink signal types as fi objects

Specifies whether to treat inherited fixed-point and integer signals as Fixed-Point Designer `fi` objects. For more information, see “Ways to Construct `fi` Objects” (Fixed-Point Designer).

- When you select `Fixed-point`, the MATLAB Function block treats all fixed-point inputs as Fixed-Point Designer `fi` objects.
- When you select `Fixed-point & Integer`, the MATLAB Function block treats all fixed-point and integer inputs as Fixed-Point Designer `fi` objects.

MATLAB Function `fimath`

Specifies `fimath` properties for the MATLAB Function block. The `fimath` on a MATLAB Function block behaves as a global `fimath` (Fixed-Point Designer) for the contents of the MATLAB Function block. The block associates the `fimath` properties in **MATLAB Function `fimath`** with all fixed-point and integer input signals to the MATLAB Function block that you choose to treat as `fi` objects. Constructing `fi` objects in the MATLAB Function block introduces additional considerations.

- If no `fimath` is associated with a `fi` object when it is constructed, then the `fi` constructor uses the default `fimath` settings regardless of the properties in **MATLAB Function `fimath`**. However, if you perform additional operations on the `fi` object after it is constructed, the object will adopt the properties in **MATLAB Function `fimath`**.
- If you specify a `fimath` in the `fi` constructor, then that `fimath` is obeyed when quantizing the value in the `fi` constructor. Any `fimath` settings not specified in the `fi` constructor use the specified properties in **MATLAB Function `fimath`**.

You can select one of these options:

Setting	Description
Same as MATLAB	The block uses the same <code>fimath</code> properties as the current default <code>fimath</code> . The edit box is dimmed and displays the current global <code>fimath</code> in read-only form.
Specify other	<p>You can specify your own <code>fimath</code> object in the edit box. You can do so in one of two ways:</p> <ul style="list-style-type: none"> • Constructing the <code>fimath</code> object inside the edit box. • Constructing the <code>fimath</code> object in the MATLAB or model workspace and then entering its variable name in the edit box. If you use this option and plan to share your model with others, define the variable in the model workspace. See “Sharing Models with Fixed-Point MATLAB Function Blocks” (Fixed-Point Designer). <p>For more information on <code>fimath</code> objects, see “<code>fimath</code> Object Construction” (Fixed-Point Designer).</p>

Description and Document Link Properties

You can set description and document link properties for the MATLAB Function block in the Ports and Data Manager or Model Explorer, or by navigating to the **Info** tab of the Property Inspector.

Description

Specifies the description of the MATLAB Function block. You can enter a brief description and comments.

Document link

Specifies the link to the documentation for the data argument. You can enter a URL address or a MATLAB command that displays documentation, such as an HTML file or text in the MATLAB Command Window. When you click the **Document link** link, the MATLAB Function block evaluates the link and displays the documentation.

MATLAB Function Reports

In this section...

“Open a MATLAB Function Report” on page 45-38

“Analyze MATLAB Source Code” on page 45-38

“View Error and Warning Messages” on page 45-39

“View MATLAB Variables” on page 45-39

“Programmatically Access MATLAB Function Reports” on page 45-41

“Report Limitations” on page 45-42

When you simulate, update, or generate code from a Simulink model that contains MATLAB Function blocks or Stateflow charts with MATLAB functions, Simulink generates a report for each MATLAB function in your model. The report provides type information for the variables and expressions in your functions, which can help you find the sources of errors and warnings.

Stateflow produces one report for each Stateflow chart, regardless of the number of MATLAB functions it contains.

If you have identical MATLAB Function blocks in your model, a single report is generated for the identical blocks.

Open a MATLAB Function Report

To open a MATLAB function report, use one of these methods:

- Open the MATLAB function. On the **Function** tab, click **Function Report**.
- Simulate or update the model. If a compilation error occurs, in the **Diagnostic Viewer** window, select the report link.
- For MATLAB Function blocks, call the `openReport` function on the `MATLABFunctionConfiguration` object associated with the block. For more information, see “Programmatically Access MATLAB Function Reports” on page 45-41.

Note The first time that you open the MATLAB function report, Simulink automatically updates your model. If you make subsequent changes to the MATLAB code in the block, you must update your model before you reopen the report. Otherwise, the report does not reflect your changes. From the **Modeling** tab, select **Update Model**, or press **Ctrl+D**. For more information, see “Update Diagram and Run Simulation” on page 1-25.

Analyze MATLAB Source Code

In the **MATLAB Source** pane, the **Function List** view organizes functions by the file that contains them. To visualize functions according to the call structure, use the **Call Tree** view.

The MATLAB function report is read-only. To edit a function, select the name of the function in the **MATLAB Source** pane and click **Open in Editor**.

To view a MATLAB function in the code pane, click the name of the function in the **MATLAB Source** pane. In the code pane, when you pause on a variable or expression, a tooltip displays information

about its size, type, and complexity. Additionally, syntax highlighting helps you to identify MATLAB syntax elements and certain code generation attributes, such as whether a function is extrinsic or whether an argument is constant.

Extrinsic Functions

The report identifies an extrinsic function with purple text. The tooltip indicates that the function is extrinsic.

The screenshot shows a MATLAB function report for 'callMyExtrinsic'. The code is as follows:

```

Function: callMyExtrinsic
1 function z = callMyExtrinsic(a,b)
2 %#codegen
3 coder.extrinsic('myExtrinsic');
4 z = 0;
5 z = myExtrinsic(a,b);
6 disp(z);
7 end
8

```

The call to `myExtrinsic(a,b)` on line 5 is highlighted in purple. A tooltip titled 'EXPRESSION INFO' is displayed over it, showing:

EXPRESSION INFO	
myExtrinsic(a,b)	
Size:	1 × 1
Class:	mxArray
myExtrinsic is an extrinsic function.	

Constant Arguments

Orange text indicates a compile-time constant argument to an entry-point function or a specialized function. The tooltip includes the constant value.

The screenshot shows a MATLAB function report for 'myadd'. The code is as follows:

```

Function: myadd
1 function c = myadd(a,b)
2 c = a + b;
3 end

```

The argument `a` in the function signature on line 1 is highlighted in orange. A tooltip titled 'CONSTANT INFO' is displayed over it, showing:

CONSTANT INFO	
a	
Size:	1 × 1
Class:	double
Complex:	No
Value:	2

Knowing the value of a constant argument helps you to understand the generated function signatures. It also helps you to see when code generation creates function specializations for different constant argument values.

To export the value to a variable in the workspace, click the Export icon .

View Error and Warning Messages

To view errors and warnings, in the bottom pane of the report, open the **All Messages** tab. To highlight the source code for an error or warning, click the message. It is a best practice to address the first message in the list because subsequent errors and warnings are often related to the first message.

View MATLAB Variables

To view information about the variables for the selected MATLAB function, in the bottom pane of the report, open the **Variables** tab.

The variables table shows:

- Class, size, and complexity
- Properties of fixed-point types

This information helps you to understand type propagation and identify type mismatch errors.

Visual Indicators on the Variables Tab

This table describes the symbols, badges, and other indicators in the variables table.

Column in the Variables Table	Indicator	Description
Name	expander	Variable has elements or properties that you can see by clicking the expander.
Name	{:}	Homogenous cell array (all elements have the same properties).
Name	{n}	nth element of a heterogeneous cell array.
Class	v > n	v is reused with a different class, size, and complexity. The number n identifies a reuse with a unique set of properties. When you pause on a renamed variable, the report highlights only the instances of this variable that share the class, size, and complexity. See “Reuse the Same Variable with Different Properties” on page 52-10.
Size	:n	Variable-size array with an upper bound of n.
Size	:?	Variable-size array with no upper bound.
Size	italics	Variable-size array whose dimensions do not change size during execution.
Class	sparse prefix	Sparse array.
Class	complex prefix	Complex number.
Class		Fixed-point type. To see the fixed-point properties, click the badge.

Programmatically Access MATLAB Function Reports

You can access MATLAB function reports by calling these functions on `MATLABFunctionConfiguration` objects:

- `openReport` opens the MATLAB function report for the block.
- `closeReport` closes the MATLAB function report for the block.
- `getReport` returns a `MATLABFunctionReport` object for the block. You can query report information from this object by accessing its `Functions` property, which is an array of `coder.Function` objects. See `coder.Function` Properties (MATLAB Coder).

For example, to create a custom report that lists the functions and variables in the MATLAB Function block in the model `call_stats_block2` described in “Create Custom Functionality Using MATLAB Function Blocks” on page 45-5, follow these steps:

- 1 Access the `MATLABFunctionConfiguration` object for the MATLAB Function block.

```
config = get_param('call_stats_block2/MATLAB Function', ...
    'MATLABFunctionConfiguration');
```

- 2 Create the `MATLABFunctionReport` object for the MATLAB Function block.

```
report = getReport(config);
```

- 3 Access the `coder.Function` objects in the report.

```
functions = report.Functions;
```

- 4 Create the custom report.

```
for i = 1:numel(functions)
    fprintf('Function %s uses these variables:\n', functions(i).Name)
    variables = functions(i).Variables;
    for j = 1:numel(variables)
        fprintf('%d. %s -- %s\n', j, variables(j).Name, variables(j).Scope)
    end
    fprintf('\n')
end
```

```
Function stats uses these variables:
```

```
1. mean -- Output
2. stdev -- Output
3. vals -- Input
4. len -- Local
```

```
Function avg uses these variables:
```

```
1. mean -- Output
2. array -- Input
3. size -- Input
```

Note The `MATLABFunctionReport` object does not contain information about errors and warnings. To find errors and warnings in a MATLAB Function block, open the report or use the debugger in the **MATLAB Function Block Editor**. For more information, see “Locate and Fix Errors” on page 45-8 and “Debug MATLAB Function Blocks” on page 45-18.

Report Limitations

- The variables table does not show the individual elements of `varargin` and `varargout`.
- The report does not show full information for unrolled loops. It displays data types of one arbitrary iteration.
- The report does not show information about dead code.

Define and Modify Function Argument Types

In this section...

“Specify Argument Types” on page 45-43

“Inheriting Argument Data Types” on page 45-44

“Built-In Data Types for Arguments” on page 45-44

“Specify Argument Types with Expressions” on page 45-45

“Specify Fixed-Point Designer Data Properties” on page 45-45

Create function arguments for a MATLAB Function block by entering them in the function declaration statement in the **MATLAB Function Block Editor**. When you define arguments, Simulink creates corresponding ports on the MATLAB Function block that you can attach to signals. You can select a data type mode for each argument that you define. Each data type mode presents its own set of options.

By default, MATLAB Function blocks inherit their data types from the incoming or outgoing signal. To override the default type, choose a data type mode and then modify the associated properties.

Specify Argument Types

To specify the type of a MATLAB Function block function argument:

- 1 Double-click the MATLAB Function block to open the **MATLAB Function Block Editor**.
- 2 Click **Ports & Data Manager** to open the Ports and Data Manager.
- 3 In the left pane, select the argument of interest.
- 4 In the **Data** pane, click the Show data type assistant button  to display the Data Type Assistant. Then, choose an option from the **Mode** drop-down menu.

The **Data** properties dialog box displays additional fields for each selection for **Mode**.

- 5 Based on the mode you select, specify a desired data type:

Mode	What to Specify
Inherit (default)	<p>The data type is inherited from previously-defined data, based on the Scope you selected for the MATLAB Function block function argument:</p> <ul style="list-style-type: none"> • If Scope is Input, data type is inherited from the input signal on the designated port. • If Scope is Output, data type is inherited from the output signal on the designated port. • If Scope is Parameter, data type is inherited from the associated parameter, which can be defined in the Simulink masked subsystem or the MATLAB workspace. <p>See “Inheriting Argument Data Types” on page 45-44.</p>
Built in	Select from the drop-down list of supported data types, as described in “Built-In Data Types for Arguments” on page 45-44.

Mode	What to Specify
Fixed point	Specify the fixed-point data properties as described in “Specify Fixed-Point Designer Data Properties” on page 45-45.
Expression	Enter an expression that evaluates to a data type, as described in “Specify Argument Types with Expressions” on page 45-45.
Bus Object	<p>In the Bus object field, enter the name of a Simulink.Bus object to define the properties of a MATLAB structure. You must define the bus object in the base workspace. See “How Structure Inputs and Outputs Interface with Bus Signals” on page 45-61.</p> <p>Note You can click the Edit button to create or modify Simulink.Bus objects using the Simulink Bus Editor (see “Attach Bus Signals to MATLAB Function Blocks” on page 45-56).</p>
Enumerated	In the Enumerated field, enter the name of a Simulink.IntEnumType object that you define in the base workspace. See “Code Generation for Enumerations” on page 45-85.

Inheriting Argument Data Types

MATLAB Function block function arguments can inherit their data types, including fixed point types, from their connected signals.

- 1 Select the argument of interest in the Ports and Data Manager
- 2 In the **Data** properties dialog, select **Inherit: Same as Simulink** from the **Type** drop-down menu.

An argument can also inherit complexity (whether its value is a real or complex number) from the signal that is connected to it. To inherit complexity, set the **Complexity** field on the **Data** properties dialog to **Inherited**.

Note Library MATLAB Function blocks can have inherited data types, sizes, and complexities like ordinary MATLAB Function blocks. However, all instances of the library block in a given model must have inputs with the same properties.

After you build the model, the **CompiledType** column of the Ports and Data Manager or Model Explorer gives the actual type inherited from Simulink in the compiled simulation. The diagram actions that store values in the specified output determine the inherited type of output data. If the expected type matches the inferred type, inheritance is successful. In all other cases, a mismatch occurs during build time.

Built-In Data Types for Arguments

When you select **Built-in** for **Mode**, the **Type** property dialog box provides a drop-down list of supported data types. You can also choose a data type from the **Data Type** column in the Ports and Data Manager. The supported data types are:

Data Type	Description
double	64-bit double-precision floating point
single	32-bit single-precision floating point
half	A half-precision data type occupies 16 bits of memory, but its floating-point representation enables it to handle wider dynamic ranges than integer or fixed-point data types of the same size. See “The Half-Precision Data Type in Simulink” (Fixed-Point Designer).
int64	64-bit signed integer
int32	32-bit signed integer
int16	16-bit signed integer
int8	8-bit signed integer
uint64	64-bit unsigned integer
uint32	32-bit unsigned integer
uint16	16-bit unsigned integer
uint8	8-bit unsigned integer
boolean	Boolean (1 = true; 0 = false)

Specify Argument Types with Expressions

You can specify the types of MATLAB Function block function arguments as expressions in the Ports and Data Manager.

- 1 Select `<data type expression>` from the **Type** drop-down menu of the Data properties dialog, or set the **Mode** to Expression.
- 2 In the **Type** field, replace “`<data type expression>`” with an expression that evaluates to a data type. The following expressions are allowed:
 - Alias type from the MATLAB workspace, as described in `Simulink.AliasType`.
 - `fixdt` function to create a `Simulink.NumericType` object describing a fixed-point or floating-point data type.
 - type operator, to base the type on previously defined data.

Specify Fixed-Point Designer Data Properties

MATLAB Function blocks can represent signals and parameter values as fixed-point numbers. To simulate models that use fixed-point data in MATLAB Function blocks, you must install Fixed-Point Designer.

You can set the following fixed-point properties:

Signedness. Select whether you want the fixed-point data to be **Signed** or **Unsigned**. Signed data can represent positive and negative quantities. Unsigned data represents positive values only. The default is **Signed**.

Word length. Specify the size (in bits) of the word that will hold the quantized integer. Large word sizes represent large quantities with greater precision than small word sizes. Word length can be any integer between 0 and 128 bits. The default is 16.

Scaling. Specify the method for scaling your fixed point data to avoid overflow conditions and minimize quantization errors. You can select the following scaling modes:

Scaling Mode	Description
Binary point (default)	<p>If you select this mode, the Data Type Assistant displays the Fraction Length field, specifying the binary point location.</p> <p>Binary points can be positive or negative integers. A positive integer moves the binary point left of the rightmost bit by that amount. For example, an entry of 2 sets the binary point in front of the second bit from the right. A negative integer moves the binary point further right of the rightmost bit by that amount, as in this example:</p> <p>The default is 0.</p>
Slope and bias	<p>If you select this mode, the Data Type Assistant displays fields for entering the Slope and Bias.</p> <ul style="list-style-type: none"> • Slope can be any <i>positive</i> real number. The default is 1.0. • Bias can be any real number. The default value is 0.0. <p>You can enter slope and bias as expressions that contain parameters defined in the MATLAB workspace.</p>

Note You should use binary-point scaling whenever possible to simplify the implementation of fixed-point data in generated code. Operations with fixed-point data using binary-point scaling are performed with simple bit shifts and eliminate the expensive code implementations required for separate slope and bias values.

Data type override. Specify whether the data type override setting is `Inherit` (default) or `Off`.

Calculate Best-Precision Scaling. The Simulink software can automatically calculate “best-precision” values for both `Binary point` and `Slope and bias` scaling, based on the `Limit range` properties you specify.

To automatically calculate best precision scaling values:

- 1 Specify **Minimum**, **Maximum**, or both `Limit range` properties.
- 2 Click **Calculate Best-Precision Scaling**.

The Simulink software calculates the scaling values, then displays them in either the **Fraction Length**, or **Slope** and **Bias** fields.

Note The `Limit range` properties do not apply to data with the **Scope** property set to `Constant` or `Parameter`. Simulink cannot calculate best-precision scaling for these kinds of data.

Fixed-point Details. You can view the following Fixed-point details:

Fixed-point Detail	Description
Representable maximum	The maximum number that can be represented by the chosen data type, sign, word length and fraction length (or data type, sign, slope and bias).
Maximum	The maximum value specified.
Minimum	The minimum value specified.
Representable minimum	The minimum number that can be represented by the chosen data type, sign, word length and fraction length (or data type, sign, slope and bias).
Precision	The precision for the given word length and fraction length (or slope and bias).

Using Data Type Override with the MATLAB Function Block

If you set the Data Type Override mode to `Double` or `Single` in Simulink, the MATLAB Function block sets the type of all inherited input signals and parameters to `fi double` or `fi single` objects respectively (see “MATLAB Function Block with Data Type Override” (Fixed-Point Designer) for more information). You must check the data types of your inherited input signals and parameters and use the Ports and Data Manager to set explicit types for any inputs that should not be fixed-point. Some operations, such as `sin`, are not applicable to fixed-point objects.

Note If you do not set the correct input types explicitly, you may encounter compilation problems after setting Data Type Override.

To set Data Type Override, follow these steps:

- 1 In the Simulink **Apps** tab, select **Fixed-Point Tool**.
- 2 Set the value of the **Data type override** parameter to `Double` or `Single`.

Specify Size of MATLAB Function Block Data

In this section...

“Inherit Argument Sizes from Simulink” on page 45-48

“Customize Data Sizes” on page 45-48

You can specify the size of the data in MATLAB Function blocks with the Ports and Data Manager or the Model Explorer. For more information about specifying data, see “Define MATLAB Function Block Data” on page 45-30. You can specify the data size as a scalar, vector, or matrix.

Inherit Argument Sizes from Simulink

The size defaults to -1, which means that the data inherits its size based on the value of the **Scope** property:

Scope	Description
Input	Inherits size from the Simulink signal connected to the associated input port.
Output	Inherits size from the Simulink signal connected to the associated output port.
Parameter	Inherits size from the associated Simulink or MATLAB parameter. See “Configure MATLAB Function Block Parameter Data Arguments” on page 45-50.

Customize Data Sizes

You can also manually set the size of data to a scalar, vector, or matrix. To specify the data size as a scalar, set **Size** to 1 or clear the parameter. To specify the data size as a vector or a matrix, enter a row vector in [row column] format. For example, to define a row vector of size 5, set the **Size** property to [1 5]. To define a column vector of size 6, set the **Size** property to [6 1]. To define a matrix of size 3-by-3, set the **Size** property to [3 3].

Note Prior to R2021b, MATLAB Function blocks output column vectors as one-dimensional data. In R2021b and later, MATLAB Function blocks retain their dimensionality by default. To maintain the old behavior, clear the **Interpret output column vectors as one-dimensional data** property in the Ports and Data Manager or Model Explorer. Once you clear this property, you can then use a single number in **Size** to define a column vector. See “Interpret output column vectors as one-dimensional data” on page 45-35.

You can also set the **Size** property with an expression, as long as the expression outputs a value that follows the guidelines above. The expressions can include:

- Numeric constants
- Arithmetic operators, restricted to +, -, *, and /
- Names of data with the **Scope** property set to Parameter
- Calls to the MATLAB functions `min`, `max`, and `size`

For example, consider a MATLAB Function block with data `k`, `x`, and `y` that all have the **Scope** property set to Parameter. Here, `k` is a scalar and `x` and `y` are matrices. If you create new data for the block, you can define the **Size** property with any of the following expressions:

```
k+1  
size(x)  
min(size(y))
```

Expressions that do not return scalars or a 2-by-1 array produce an error at model compilation.

Simulation and Size Matching

After you build the model, the **CompiledSize** column in the Model Explorer and **Compiled Size** column in the Ports and Data Manager display the actual data size used in the simulation. If the value of the **Size** property is not -1 and does not match the actual size, a mismatch error occurs during model compilation.

Configure MATLAB Function Block Parameter Data Arguments

You can use parameter data arguments in MATLAB Function blocks to use variables defined in the MATLAB workspace, model workspace, a masked subsystem workspace, or a Simulink data dictionary as input arguments. Simulink searches for and selects variables used by parameter data arguments by using the same rules for symbol resolution. See “Symbol Resolution” on page 68-128. If a variable of the same name exists in more than one of the workspaces visible to the block, the block uses the variable closest to the block in the workspace hierarchy. If the MATLAB Function block is in a masked subsystem, the block uses the variable in the subsystem workspace. Otherwise, the block uses the variable in the model workspace, followed by using the variable in the MATLAB base workspace and in an associated Simulink data dictionary, in that order.

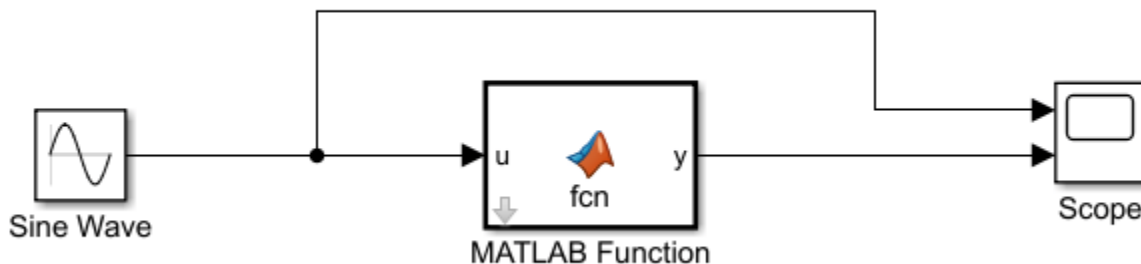

To specify parameter data arguments, in the Model Explorer or the Ports and Data Manager, create or select existing data and set the **Scope** property to **Parameter**. For more information about creating arguments and data in MATLAB Function blocks, see “Define MATLAB Function Block Data” on page 45-30. Parameter data arguments do not create block ports.

Control Parameter Data Arguments with Masks

You can directly assign values to parameter data arguments in a MATLAB Function block by adding a mask to the block, creating a parameter in the mask, and giving the parameter the same name as the parameter data argument. For more information about creating masks for blocks, see “Masking Fundamentals” on page 39-2. After you mask the block, you can adjust the parameter data argument properties by using the Ports and Data Manager, but not the Model Explorer.

Adjust Parameter Data Argument Example

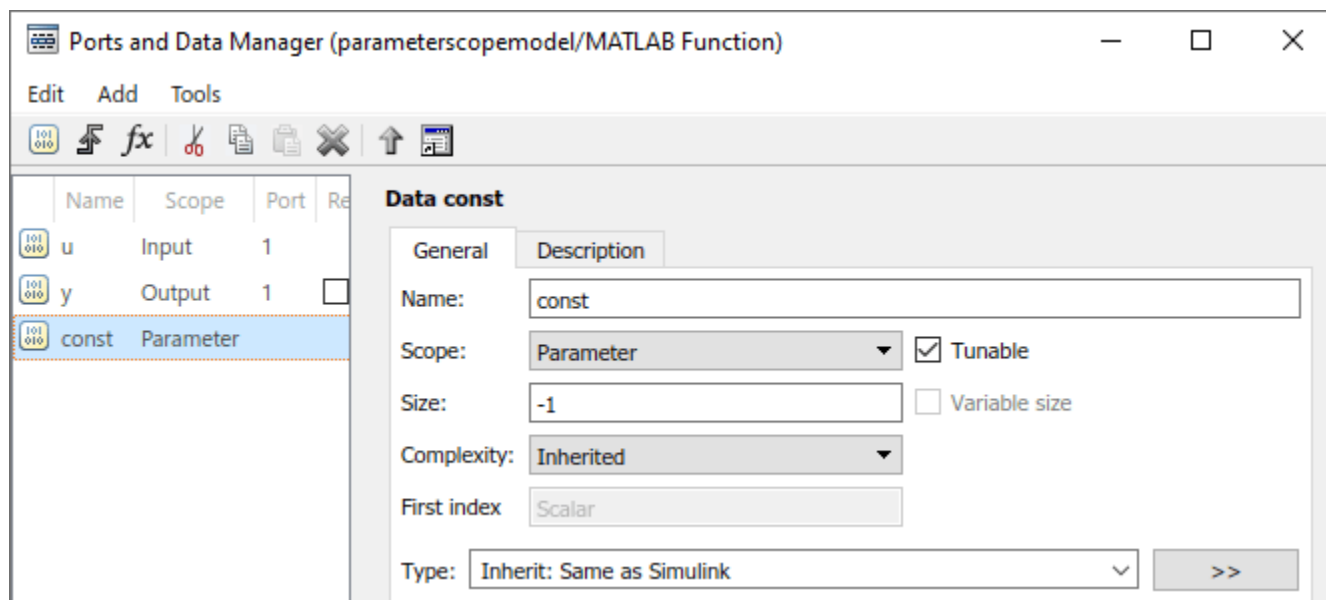

This example uses a masked MATLAB Function block with a parameter data argument.

The MATLAB function multiplies the parameter data argument `const` by the value of the Sine Wave block signal. Click the arrow icon on the MATLAB Function block to view the code.

```
function y = fcn(u, const)
y = const*u;
```

You can adjust the value of `const` by double-clicking the MATLAB Function block. The block mask defines the **Set sine wave multiplier** parameter, which you can edit in the Mask Editor. The MATLAB Function block defines `const` as data with **Scope** set to **Parameter**.

The parameter data argument and the mask parameter must have the same name. In this example, changing the parameter data argument name without changing the parameter name causes an error.

Control Parameter Data Arguments in Workspaces

If you want multiple MATLAB Function blocks to access the same variable in a model, you can define the variable in the model workspace and add parameter data arguments to each MATLAB function that points to that variable. You can define the variable directly in the model workspace, load the variable in a MAT-file or MATLAB file, or create the variable with custom MATLAB code. For more information, see “Specify Source for Data in Model Workspace” on page 68-122.

If you want to use the variable in MATLAB Function blocks in multiple models, you can define the variable in the MATLAB base workspace by defining the variable in the Command Window or by loading a MAT-file. MATLAB Function blocks access variables defined in the MATLAB workspace until you close MATLAB.

You can also define variables using a Simulink data dictionary. For more information, see “What Is a Data Dictionary?” on page 75-2.

Resolve Signal Objects for Output Data

In this section...

“Implicit Signal Resolution” on page 45-53

“Eliminating Warnings for Implicit Signal Resolution in the Model” on page 45-53

“Disabling Implicit Signal Resolution for a MATLAB Function Block” on page 45-53

“Forcing Explicit Signal Resolution for an Output Data Signal” on page 45-53

Implicit Signal Resolution

MATLAB Function blocks participate in signal resolution with Simulink signal objects. By default, output data from MATLAB Function blocks become associated with Simulink signal objects of the same name during a process called *implicit signal resolution*.

By default, implicit signal resolution generates a warning when you update the chart in the Simulink model. The following sections show you how to manage implicit signal resolution at various levels of the model hierarchy. See “Symbol Resolution” on page 68-128 and “Explicit and Implicit Symbol Resolution” on page 68-130 for more information.

Eliminating Warnings for Implicit Signal Resolution in the Model

To enable implicit signal resolution for all signals in a model, but eliminate the attendant warnings, follow these steps:

- 1 In the Simulink Editor, in the **Modeling** tab, click **Model Settings**.
The Configuration Parameters dialog appears.
- 2 In the left pane of the Configuration Parameters dialog, under Diagnostics, select **Data Validity**.
Data Validity configuration parameters appear in the right pane.
- 3 In the Signal resolution field, select **Explicit and implicit**.

Disabling Implicit Signal Resolution for a MATLAB Function Block

To disable implicit signal resolution for a MATLAB Function block in your model, follow these steps:

- 1 In the Simulink Editor, in the **Modeling** tab, click **Model Settings**.
The Configuration Parameters dialog appears.
- 2 In the left pane of the Configuration Parameters dialog, under Diagnostics, select **Data Validity**.
Data Validity configuration parameters appear in the right pane.
- 3 In the Signal resolution field, select **Explicit only** or **None**.

Forcing Explicit Signal Resolution for an Output Data Signal

To force signal resolution for an output signal in a MATLAB Function block, follow these steps:

- 1** In the Simulink model, right-click the signal line connected to the output that you want to resolve and select **Properties** from the context menu.
- 2** In the Signal Properties dialog, enter a name for the signal that corresponds to the signal object.
- 3** Select the **Signal name must resolve to Simulink signal object** check box and click **OK**.

Types of Structures in MATLAB Function Blocks

In MATLAB Function blocks, you can define structure data as inputs or outputs that interact with bus signals. MATLAB Function blocks also support arrays of buses. You can also define structures inside MATLAB functions that are not part of MATLAB Function blocks.

The following table summarizes how to create different types of structures in MATLAB Function blocks:

Scope	How to Create	Details
Input	Create structure data with scope of Input .	You can create structure data as inputs or outputs in the top-level MATLAB function for interfacing to other environments. See “Create Structures in MATLAB Function Blocks” on page 45-64.
Output	Create structure data with scope of Output .	
Local	Create a local variable implicitly in a MATLAB function.	See “Define Scalar Structures for Code Generation” on page 55-4.
Persistent	Declare a variable to be persistent in a MATLAB function.	See persistent .
Parameter	Create structure data with scope of Parameter .	See “Define and Use Structure Parameters” on page 45-70.

Structures in MATLAB Function blocks can contain fields of any type and size, including mux signals, buses, and arrays of structures.

Attach Bus Signals to MATLAB Function Blocks

Structures in a MATLAB Function Block

This example shows how to use structures in a MATLAB Function block to read and write to Simulink® bus signals.

In this model, a MATLAB Function block receives a bus signal using the structure `inbus` at input port 1. The block outputs two bus signals: structure `outbus` at output port 1 and structure `outbus1` at output port 2. The input signal comes from the Bus Creator block `MainBusCreator`, which bundles signals `ele1`, `ele2`, and `ele3`. The signal `ele3` is the output of another Bus Creator block `SubBusCreator`, which bundles the signals `a1` and `a2`. The structures `outbus` and `outbus1` connect to Bus Selector blocks that, in turn, connect to Display blocks.

To explore the MATLAB function `fcn`, double-click the MATLAB Function block. Notice that the code implicitly defines a local structure variable `mystruct` using the `struct` function, and uses this local structure variable to initialize the value of the first output, `outbus`. It initializes the second output, `outbus1`, to the value of field `ele3` of structure `inbus`.

Structure Definitions in Example

Here are the definitions of the structures in the MATLAB Function block in the example, as they appear in the Ports and Data Manager:

Name	Scope	Port	Resolve Signal	Data Type	Size
<code>inbus</code>	Input	1		Inherit: Same as Simulink	-1
<code>outbus</code>	Output	1	<input type="checkbox"/>	Bus: MainBus	1
<code>outbus1</code>	Output	2	<input type="checkbox"/>	Bus: SubBus	1

Bus Objects Define Structure Inputs and Outputs

Each structure input and output must be defined by a `Simulink.Bus` object in the base workspace (see “Create Structures in MATLAB Function Blocks” on page 45-64). This means that the structure shares the same properties as the bus object, including number, name, type, and sequence of fields. In this example, the following bus objects define the structure inputs and outputs:

The screenshot shows the MATLAB workspace with a tree view on the left and a properties table on the right. The tree view shows a 'Base Workspace' containing 'MainBus' (with elements 'ele1', 'ele2', and 'ele3(SubBus)') and 'SubBus' (with elements 'a1' and 'a2'). The properties table lists the following:

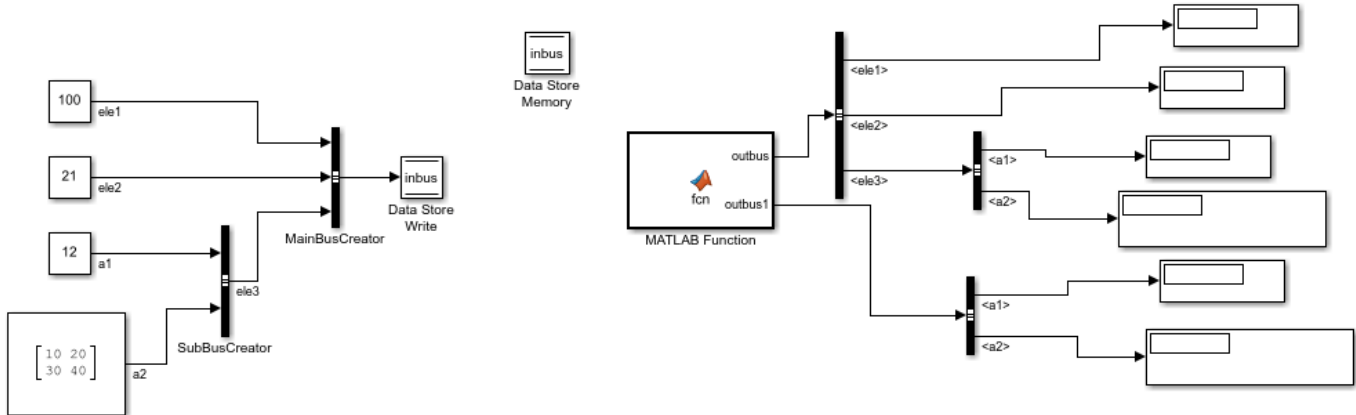

Name	Data Type	Complexity	Dimensions	Dimensionality
ele1	double	real	1	Fixed
ele2	single	real	1	Fixed
ele3(SubBus)	SubBus	real	1	Fixed

The `Simulink.Bus` object `MainBus` defines structure input `inbus` and structure output `outbus`. The `Simulink.Bus` object `SubBus` defines structure output `outbus1`. Based on these definitions, `inbus` and `outbus` have the same properties as `MainBus` and, therefore, reference their fields by the same names as the fields in `MainBus`, using dot notation (see “Index Substructures and Fields” on page 45-63). Similarly, `outbus1` references its fields by the same names as the fields in `SubBus`. Here are the field references for each structure in this example:

Structure	First Field	Second Field	Third Field
<code>inbus</code>	<code>inbus.ele1</code>	<code>inbus.ele2</code>	<code>inbus.ele3</code>
<code>outbus</code>	<code>outbus.ele1</code>	<code>outbus.ele2</code>	<code>outbus.ele3</code>
<code>outbus1</code>	<code>outbus1.a1</code>	<code>outbus1.a2</code>	—

Write Buses From Data Store Memory to a MATLAB Function Block

This example shows how to use bus data stored in a data store as an input to a MATLAB Function block.

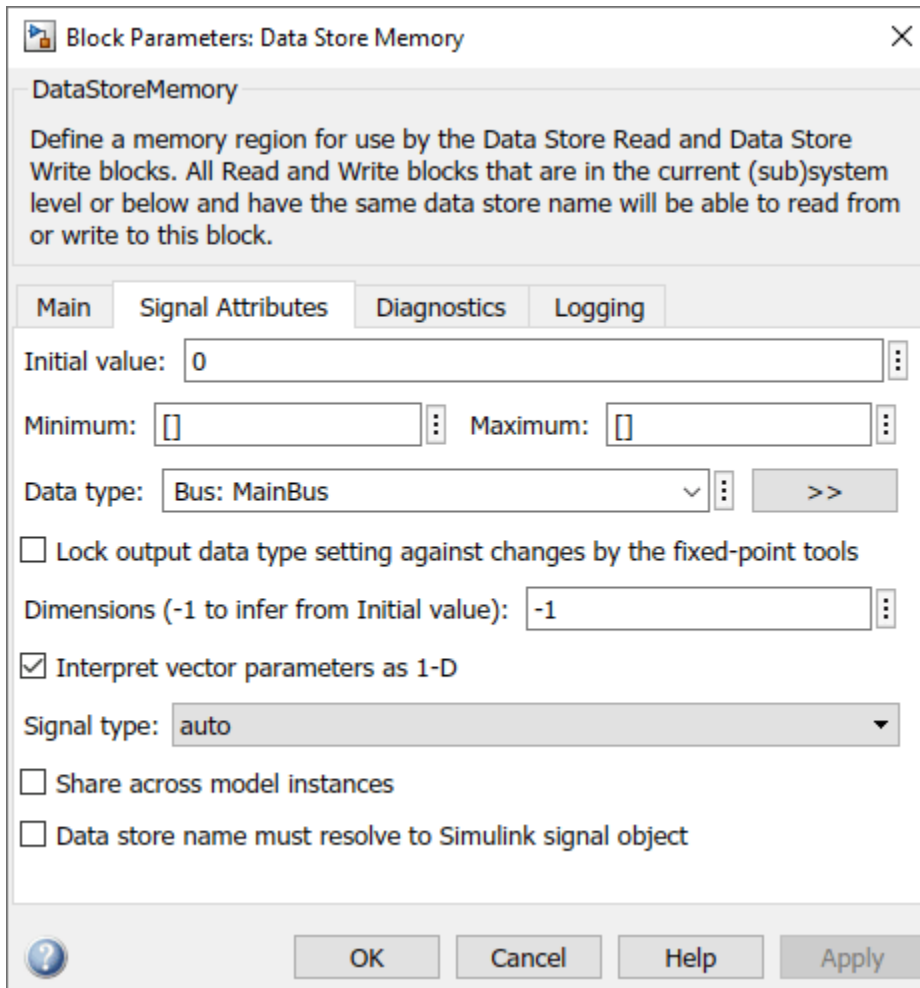

Copyright 2021 The MathWorks, Inc.

Capture the Bus Data in a Data Store Memory Block

In this example, the Bus Creator block `MainBusCreator` creates a bus called `MainBus` because the **Output data type** parameter is `Bus: MainBus`. The Data Store Write block then writes the bus data to a data store named `inbus`, which the **Data store name** parameter specifies.

To store the bus data from the Data Store Write block, the model includes a Data Store Memory block. In the Data Store Memory block, the **Data store name** parameter is `inbus`, the name of the data store defined by the Data Store Write block. The **Data type** parameter is `Bus: MainBus`, the data type specified by the `MainBusCreator` block.

Define the Data Store Memory Data Argument

To use the data store as an input, the MATLAB Function block uses data that has the **Scope** property set to Data Store Memory. The function then calls the data by defining the data as a global variable with the name of the data store, which is `inbus`. Double-click the MATLAB Function block to examine the code.

```
function [outbus, outbus1] = fcn
global inbus;

substruct.a1 = inbus.ele3.a1;
substruct.a2 = int8([1 2;3 4]);

mystruct = struct('ele1',20.5, 'ele2', single(100), 'ele3', substruct);

outbus = mystruct;
outbus.ele3.a2 = 2*(substruct.a2);

outbus1 = inbus.ele3;
```

You can adjust the properties of the data store memory data argument in the Ports and Data Manager or the Model Explorer.

How Structure Inputs and Outputs Interface with Bus Signals

Buses in a Simulink model appear inside the MATLAB Function block as structures; structure outputs from the MATLAB Function block appear as buses in Simulink models. When you create structure inputs, the MATLAB Function block determines the type, size, and complexity of the structure from the input signal. When you create structure outputs, you must define their type, size, and complexity in the MATLAB function.

You connect structure inputs and outputs from MATLAB Function blocks to any bus signal, including:

- Blocks that output bus signals — such as Bus Creator blocks
- Blocks that accept bus signals as input — such as Bus Selector and Gain blocks
- S-Function blocks
- Other MATLAB Function blocks

You can use global bus type data in Data Store Memory blocks with MATLAB Function blocks. For more information on using buses and Data Store Memory, see “Data Stores with Buses and Arrays of Buses” on page 74-22.

Working with Virtual and Nonvirtual Buses

MATLAB Function blocks supports nonvirtual buses only (see “Types of Composite Signals” on page 77-2). For MATLAB Function block bus inputs, incoming virtual bus signals are converted to nonvirtual buses.

Rules for Defining Structures in MATLAB Function Blocks

Follow these rules when defining structures in MATLAB Function blocks:

- For each structure input or output in a MATLAB Function block, you must define a `Simulink.Bus` object in the base workspace to specify its type.
- MATLAB Function blocks support nonvirtual bus outputs but do not support virtual bus outputs.

Index Substructures and Fields

As in MATLAB, you index substructures and fields structures in MATLAB Function blocks by using dot notation. However, for code generation from MATLAB, you must reference field values individually (see “Structure Definition for Code Generation” on page 55-2).

For example, in the “Structures in a MATLAB Function Block” on page 45-56 example, the MATLAB function uses dot notation to index fields and substructures:

```
function [outbus, outbus1] = fcn(inbus)
%#codegen
substruct.a1 = inbus.ele3.a1;
substruct.a2 = int8([1 2;3 4]);

mystruct = struct('ele1',20.5,'ele2',single(100),
                 'ele3',substruct);

outbus = mystruct;
outbus.ele3.a2 = 2*(substruct.a2);

outbus1 = inbus.ele3;
```

The following table shows how the code generation software resolves symbols in dot notation for indexing elements of the structures in this example:

Dot Notation	Symbol Resolution
substruct.a1	Field a1 of local structure substruct
inbus.ele3.a1	Value of field a1 of field ele3, a substructure of structure inputinbus
inbus.ele3.a2(1,1)	Value in row 1, column 1 of field a2 of field ele3, a substructure of structure input inbus

Create Structures in MATLAB Function Blocks

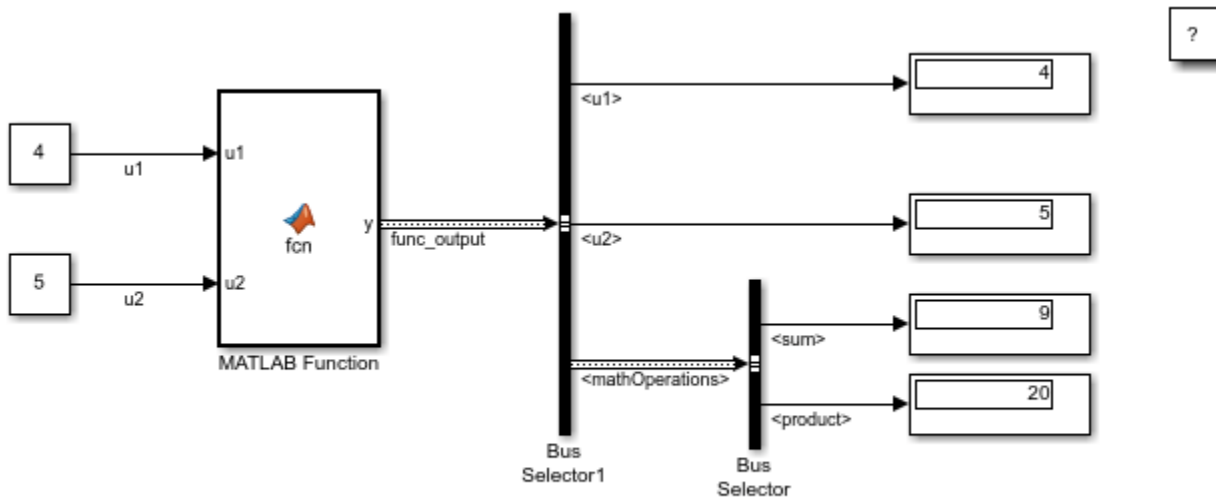

Here is the workflow for creating a structure in a MATLAB Function block:

- 1 Decide on the type (or scope) of the structure (see “Types of Structures in MATLAB Function Blocks” on page 45-55).
- 2 Based on the scope, follow these guidelines for creating the structure:

For Structure Scope:	Follow These Steps:
Input	<p>a Create a <code>Simulink.Bus</code> object in the base workspace to define the structure input.</p> <p>b Add data to the MATLAB Function block, as described in “Define MATLAB Function Block Data” on page 45-30. The data should have the following properties</p> <ul style="list-style-type: none"> • Scope = Input • Type = Bus: <object name> <p>For <object name>, enter the name of the <code>Simulink.Bus</code> object that defines the structure input</p> <p>See “Rules for Defining Structures in MATLAB Function Blocks” on page 45-62.</p>
Output	<p>a Create a <code>Simulink.Bus</code> object in the base workspace to define the structure output.</p> <p>b Add data to the MATLAB Function block with the following properties:</p> <ul style="list-style-type: none"> • Scope = Output • Type = Bus: <object name> <p>For <object name>, enter the name of the <code>Simulink.Bus</code> object that defines the structure output</p> <p>c Define and initialize the output structure implicitly as a variable in the MATLAB function, as described in “Structure Definition for Code Generation” on page 55-2.</p> <p>d Make sure the number, type, and size of fields in the output structure variable definition match the properties of the <code>Simulink.Bus</code> object.</p>
Local	Define the structure implicitly as a local variable in the MATLAB function, as described in “Structure Definition for Code Generation” on page 55-2. By default, local variables in MATLAB Function blocks are temporary.
Persistent	Define the structure implicitly as a persistent variable in the MATLAB function.
Parameter	<p>a Create a structure variable in the base workspace.</p> <p>b Add data to the MATLAB Function block with the following properties:</p> <ul style="list-style-type: none"> • Name = same name as the structure variable you created in step 1. • Scope = Parameter <p>See “Define and Use Structure Parameters” on page 45-70.</p>

Use Nonvirtual Buses with MATLAB Function Blocks

In this example model, the MATLAB Function block includes MATLAB code that creates a structure. If a MATLAB Function block outputs a structure, then you must use a Simulink.Bus object to define the bus output.

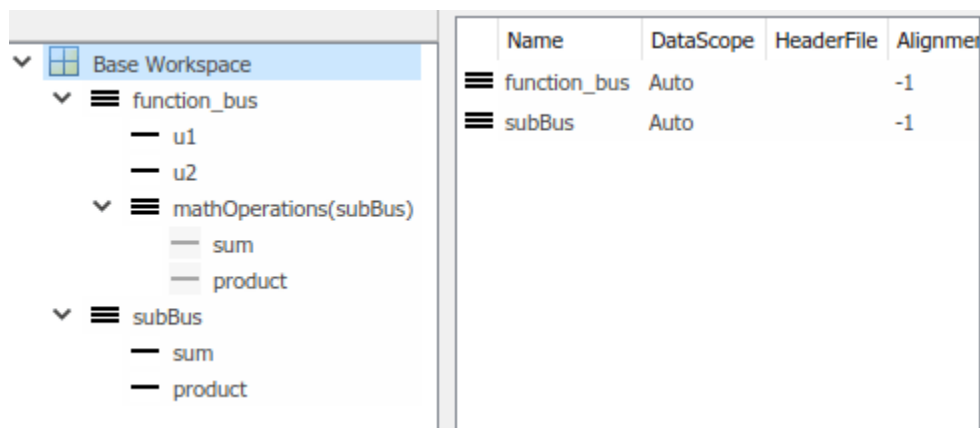

Copyright 2017-2019 The MathWorks, Inc.

To see the structure definition, double-click the MATLAB Function block.

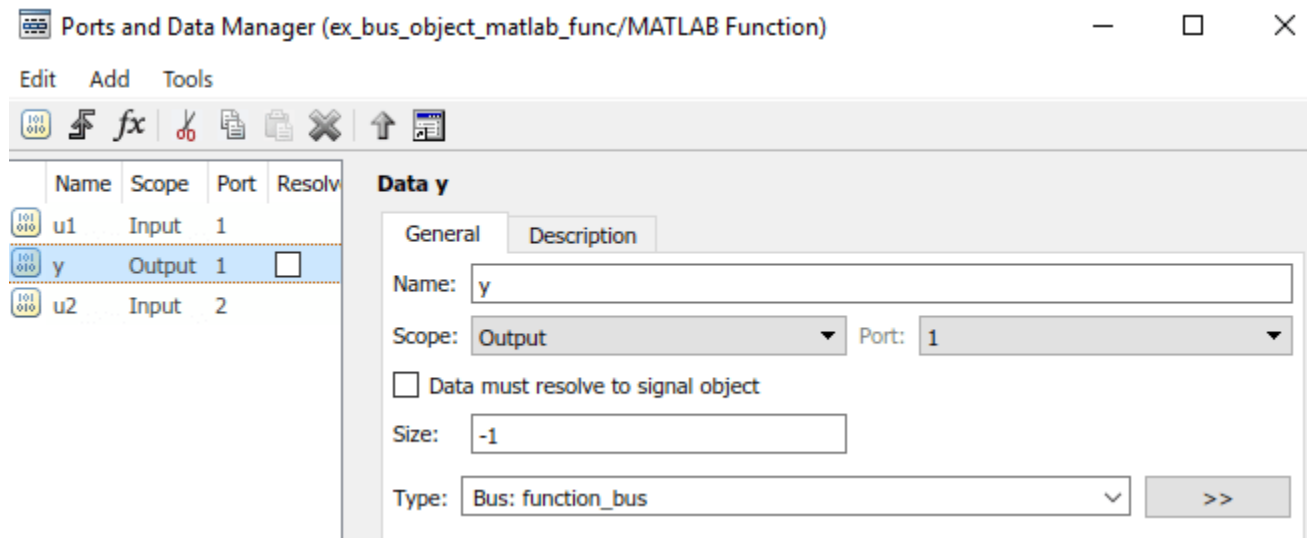

```
function y = fcn(u1,u2)

y.u1 = u1;
y.u2 = u2;
y.mathOperations.sum      = u1+u2;
y.mathOperations.product = u1*u2;
```

Open the Bus Editor and expand the Bus object definition that represents the structure.

To see how the Bus object defines the bus output for the MATLAB Function block, on the Simulink Toolstrip, on the Function tab, click **Ports & Data Manager** and then click **y**. The output **Type** is defined as the `function_bus` Bus object.

Assign Values to Structures and Fields

You can assign values to any structure, substructure, or field in a MATLAB Function block. Here are the guidelines:

Operation	Conditions
Assign one structure to another structure	You must define each structure with the same number, type, and size of fields, either as <code>Simulink.Bus</code> objects in the base workspace or locally as implicit structure declarations (see “Create Structures in MATLAB Function Blocks” on page 45-64).
Assign one structure to a substructure of a different structure and vice versa	You must define the structure with the same number, type, and size of fields as the substructure, either as <code>Simulink.Bus</code> objects in the base workspace or locally as implicit structure declarations.
Assign an element of one structure to an element of another structure	The elements must have the same type and size.

For example, the following table presents valid and invalid structure assignments based on the specifications for the model described in “Attach Bus Signals to MATLAB Function Blocks” on page 45-56:

Assignment	Valid or Invalid?	Rationale
<code>outbus = mystruct;</code>	Valid	Both <code>outbus</code> and <code>mystruct</code> have the same number, type, and size of fields. The structure <code>outbus</code> is defined by the <code>Simulink.Bus</code> object <code>MainBus</code> and <code>mystruct</code> is defined locally to match the field properties of <code>MainBus</code> .
<code>outbus = inbus;</code>	Valid	Both <code>outbus</code> and <code>inbus</code> are defined by the same <code>Simulink.Bus</code> object, <code>MainBus</code> .
<code>outbus1 = inbus.ele3;</code>	Valid	Both <code>outbus1</code> and <code>inbus.ele3</code> have the same type and size because each is defined by the <code>Simulink.Bus</code> object <code>SubBus</code> .
<code>outbus1 = inbus;</code>	Invalid	The structure <code>outbus1</code> is defined by a different <code>Simulink.Bus</code> object than the structure <code>inbus</code> .

Initialize a Matrix Using a Nontunable Structure Parameter

The following simple example uses a nontunable structure parameter input to initialize a matrix output. The model looks like this:

This model defines a structure variable `p` in its pre-load callback function, as follows:

The structure `p` has two fields, `rows` and `cols`, which specify the dimensions of a matrix. The MATLAB Function block uses a constant input `u` to initialize the matrix output `y`. Here is the code:

```
function y = fcn(u, p)
y = zeros(p.rows,p.cols) + u;
```

Running the model initializes each element of the 2-by-3 matrix y to 99, the value of u :

Define and Use Structure Parameters

In this section...

“Defining Structure Parameters” on page 45-70

“FIMATH Properties of Nontunable Structure Parameters” on page 45-70

Defining Structure Parameters

To define structure parameters in MATLAB Function blocks, follow these steps:

- 1 Define and initialize a structure variable

A common method is to create a structure in the base workspace.

- 2 In the Ports and Data Manager, add data in the MATLAB Function block with the following properties:

Property	What to Specify
Name	Enter same name as the structure variable you defined in the base workspace
Scope	Select Parameter
Tunable	Leave checked if you want to change (tune) the value of the parameter during simulation; otherwise, clear to make the parameter nontunable and preserve the initial value during simulation
Type	Select Inherit: Same as Simulink

- 3 Click **Apply**.

FIMATH Properties of Nontunable Structure Parameters

FIMATH properties for nontunable structure parameters containing fixed-point values are based on the initial values of the structure. They do *not* come from the FIMATH properties specified for fixed-point input signals to the parent MATLAB Function block. (These FIMATH properties appear in the properties dialog box for MATLAB Function blocks.)

Limitations of Structures and Buses in MATLAB Function Blocks

- Structures in MATLAB Function blocks support a subset of the operations available for MATLAB structures (see “Structures”).
- You cannot use structures that contain cell arrays or classes for Simulink signals, parameters, or data store memory.
- You cannot use variable-size data with arrays of buses (see “Group Nonvirtual Buses in Arrays of Buses” on page 77-68).

Control Support for Variable-Size Arrays in a MATLAB Function Block

By default, support for variable-size arrays is enabled for a MATLAB Function block. To disable this support:

- 1 In the **MATLAB Function Block Editor**, select **Ports & Data Manager**.
- 2 Clear the **Support variable-size arrays** check box.

Declare Variable-Size Inputs and Outputs

By default, a MATLAB Function block input signal or output signal is not variable-size. To make the signal variable-size:

- 1 In the **MATLAB Function Block Editor**, select **Ports & Data Manager**.
- 2 Select the input or output signal.
- 3 Select the **Variable size** check box.
- 4 Enter the size according to this table.

For:	Specify
Input	To inherit the size from Simulink, enter -1. Otherwise, specify the explicit size and upper bound. For example, to specify a 2-by-4 matrix, enter [2 4].
Output	Specify the explicit size and upper bound.

If the data is not an input or an output, define the variable-size data using the `coder. varsize` function.

“MATLAB Function Block: avg” on page 45-76

“Variable-Size Results” on page 45-77

Variable-Size Data in MATLAB Function Blocks

This example uses a variable-size vector to store the values of a white noise signal. The size of the vector can vary at run time because the signal values get pruned by functions that:

- Filter out signal values that are not unique within a specified tolerance of each other.
- Average every two signal values and output only the resulting means.

Copyright 2009-2021 The MathWorks, Inc.

In this model, a Band-Limited White Noise block generates a set of normally distributed random values as the source of a white noise signal. The MATLAB Function `uniquify` filters out signal values that are not unique to within a specified tolerance of each other. Then, the MATLAB Function `avg` outputs the average of a specified number of unique signal values. The Scope blocks display the output from the `uniquify` function and the `avg` function.

Source Signal

The band-limited white noise signal has these properties:

Parameters

Noise power:
[0.1 0.2 0.3 0.4 0.5 0.6 0.1 0.2 0.3]

Sample time:
0.1

Seed:
[2223334]

Interpret vector parameters as 1-D

The size of the noise power value defines the size of the array that holds the signal values. This array is a 1-by-9 vector of double values.

MATLAB Function Block: `uniquify`

This block filters out signal values that are not within a tolerance of 0.2 of each other. Here is the code:

```
function y = uniquify(u) %#codegen
y = emldemo_uniquetol(u,0.2);
```

The `uniquify` function calls an external MATLAB function `emldemo_uniquetol` to filter the signal values. `uniquify` passes the 1-by-9 vector of white noise signal values as the first argument and the tolerance value as the second argument. Here is the code for `emldemo_uniquetol`:

```
function B = emldemo_uniquetol(A,tol) %#codegen

A = sort(A);
coder.varsize('B',[1 100]);
B = A(1);
k = 1;
for i = 2:length(A)
    if abs(A(k) - A(i)) > tol
        B = [B A(i)];
        k = i;
    end
end
```

`emldemo_uniquetol` returns the filtered values of `A` in an output vector `B` so that $\text{abs}(B(i) - B(j)) > \text{tol}$ for all `i` and `j`. Every time Simulink samples the Band-Limited White Noise block, it generates a different set of random values for `A`. As a result, `emldemo_uniquetol` may produce a different number of output signals in `B` each time it is called. To allow `B` to accommodate a variable number of elements, `emldemo_uniquetol` declares it as variable-size data with an explicit upper bound:

```
coder.varsize('B',[1 100]);
```

In this statement, `coder.varsize` declares `B` as a vector whose first dimension is fixed at 1 and whose second dimension can grow to a maximum size of 100. Accordingly, output `y` of the `uniquify`

block must also be variable-size so that it can pass the values returned from `emldemo_uniqueto1` to the **Unique values** scope. Here are the properties of `y`:

Data y

General Description

Name:

Scope: Port:

Data must resolve to Simulink signal object

Size: Variable size

Complexity:

Sampling mode:

Type:

For variable-size outputs, you must specify an explicit size and upper bound, shown here as `[1 9]`.

MATLAB Function Block: avg

This block averages signal values filtered by the `uniquify` block using the conditions outlined in this table.

Condition	Result
The number of signals is greater than 1 and divisible by 2.	The MATLAB Function block averages every consecutive pair of values.
The number of signals is greater than 1 but <i>not</i> divisible by 2.	The MATLAB Function block drops the first (smallest) value and averages the remaining consecutive pairs.
There is exactly one signal.	The MATLAB Function block returns the value unchanged.

The `avg` function outputs the results to the **Average values** scope. Here is the code:

```
function y = avg(u) %#codegen

if numel(u) == 1
    y = u;
else
    k = numel(u)/2;
    if k ~= floor(k)
        u = u(2:numel(u));
    end
    y = emldemo_navg(u,2);
end
```

Both input `u` and output `y` of `avg` are declared as variable-size vectors because the number of elements varies depending on how the `uniquify` function block filters the signal values. Input `u` inherits its size from the output of `uniquify`.

The `avg` function calls an external MATLAB function `emldemo_navg` to calculate the average of every two consecutive signal values. Here is the code for `emldemo_navg`:

```
function B = emldemo_navg(A,n) %#codegen
assert(n>=1 && n<=numel(A));
B = zeros(1,numel(A)/n);
k = 1;
for i = 1 : numel(A)/n
    B(i) = mean(A(k + (0:n-1)));
    k = k + n;
end
```

Variable-Size Results

Simulating the model produces the following results:

- The `uniquify` block outputs a variable number of signal values each time it executes:

- The avg block outputs a variable number of signal values each time it executes — approximately half the number of the unique values:

Control Memory Allocation for Variable-Size Arrays in a MATLAB Function Block

Dynamic memory allocation allocates memory on the heap as needed at run time, instead of allocating memory statically on the stack. You can use dynamic memory allocation for arrays inside a MATLAB Function block.

You cannot use dynamic memory allocation for:

- Input and output signals. Variable-size input and output signals must have an upper bound.
- Parameters or global variables. Parameters and global variables must be fixed-size.
- Fields of bus arrays. Bus arrays cannot have variable-size fields.
- Discrete state properties of System objects associated with a MATLAB System block.

Dynamic memory allocation is beneficial when:

- You do not know the upper bound of an array.
- You do not want to allocate memory on the stack for large arrays.

Dynamic memory allocation and the freeing of this memory can result in slower execution of the generated code. To control the use of dynamic memory allocation for variable-size arrays in a MATLAB Function block, you can:

- Provide upper bounds for variable-size arrays on page 45-80.
- Disable dynamic memory allocation for MATLAB Function blocks on page 45-80.
- Modify the dynamic memory allocation threshold on page 45-80.

Provide Upper Bounds for Variable-Size Arrays

For an unbounded variable-size array, the code generator allocates memory dynamically on the heap. For a bounded variable-size array, if the size, in bytes, is less than the dynamic memory allocation threshold, the code generator allocates memory statically on the stack. To avoid dynamic memory allocation, provide upper bounds for the array dimensions so that the size of the array, in bytes, is less than the dynamic memory allocation threshold. See “Specify Upper Bounds for Variable-Size Arrays” on page 54-5.

Disable Dynamic Memory Allocation for MATLAB Function Blocks

By default, dynamic memory allocation for MATLAB Function blocks is enabled for GRT-based targets and disabled for ERT-based targets. To change the setting, in the Configuration Parameters dialog box, clear or select **Dynamic memory allocation in MATLAB functions**.

If you disable dynamic memory allocation, you must provide upper bounds for variable-size arrays.

Modify the Dynamic Memory Allocation Threshold

Instead of disabling dynamic memory allocation for all variable-size arrays, you can use the dynamic memory allocation threshold to specify when the code generator uses dynamic memory allocation.

Use the dynamic memory allocation threshold to:

- Disable dynamic memory allocation for smaller arrays. For smaller arrays, static memory allocation can speed up generated code. However, static memory allocation can lead to unused storage space. You can decide that the unused storage space is not a significant consideration for smaller arrays.
- Enable dynamic memory allocation for larger arrays. For larger arrays, when you use dynamic memory allocation, you can significantly reduce storage requirements.

The default value of the dynamic memory allocation threshold is 64 kilobytes. To change the threshold, in the Configuration Parameters dialog box, set the **Dynamic memory allocation threshold in MATLAB functions** parameter.

To use dynamic memory allocation for all variable-size arrays, set the threshold to 0.

Use Dynamic Memory Allocation for Variable-Size Arrays in a MATLAB Function Block

This example shows how to use dynamic memory allocation for variable-size arrays in a MATLAB Function block. Dynamic memory allocation allocates memory on the heap as needed at run time, instead of allocating memory statically on the stack. Dynamic memory allocation is beneficial when:

- You do not know the upper bound of an array.
- You do not want to allocate memory on the stack for large arrays.

You can use dynamic memory allocation only for arrays that are local to the MATLAB Function block.

You cannot use dynamic memory allocation for:

- Input and output signals. Variable-size input and output signals must have an upper bound.
- Parameters or global variables. Parameters and global variables must be fixed-size.
- Fields of bus arrays. Bus arrays cannot have variable-size fields.
- Discrete state properties of System objects associated with a MATLAB System block.

Create Model

Create this Simulink model that has a MATLAB Function block with an unbounded variable-size array.

- 1 Create a Simulink model `mymodel`.
- 2 Add a MATLAB Function block to the model.
- 3 In the MATLAB Function block, add this code:

```
function s = myfcn(n)
Z = rand(1,n);
s = sum(Z);
end
```

- 4 Add a Constant block to the left of the MATLAB Function block.
- 5 Add an Outport block to the right of the MATLAB Function block.
- 6 Connect the blocks.

Configure Model for Dynamic Memory Allocation

Make sure that you configure the model to use dynamic memory allocation for variable-size arrays in MATLAB Function blocks. In the Configuration Parameters dialog box, in the **Simulation Target > Advanced parameters** category, make sure that:

- The **Dynamic memory allocation in MATLAB functions** check box is selected.
- The **Dynamic memory allocation threshold in MATLAB functions** parameter has the default value 65536.

Simulate Model Using Dynamic Memory Allocation

- 1 Simulate the model.
- 2 In the MATLAB Function Editor, to open the MATLAB function report, click **Function Report**.

The variables tab shows that Z is a 1-by-? array. The colon (:) indicates that the second dimension is variable-size. The question mark (?) indicates that the second dimension is unbounded.

Simulation must use dynamic memory allocation for Z because the second dimension of Z does not have an upper bound.

Use Dynamic Memory Allocation for Bounded Arrays

When an array is unbounded, the code generator must use dynamic memory allocation. If an array is bounded, the code generator uses dynamic memory allocation only if the array size, in bytes, is greater than or equal to the dynamic memory allocation threshold. The default value for this threshold is 65536.

Dynamic memory has a run-time performance cost. By controlling its use, you can improve execution speed.

If you make Z a bounded variable-size array with a size that is greater than the threshold, the code generator uses dynamic memory allocation for Z. For example:

- 1 In `mymodel`, modify `myfcn` so that Z has an upper bound of 500.

```
function s = myfcn(n)
assert(n < 500);
Z = rand(1,n);
s = sum(Z);
end
```

- 2 Simulate the model.

In the MATLAB function report, you see that Z is a 1-by-500 array. It is variable-size with an upper bound of 500.

- 3 Lower the dynamic memory allocation to a value less than or equal to 4000, which is the size, in bytes, of Z. In the Configuration Parameters dialog box, in the **Simulation Target > Advanced parameters** category, set the **Dynamic memory allocation threshold in MATLAB functions** parameter to 4000.
- 4 Simulate the model.

The code generator uses dynamic memory allocation because the size of Z is equal to the dynamic memory allocation threshold, 4000.

Generate C Code That Uses Dynamic Memory Allocation

If you have Simulink Coder, you can generate C code for this model. Then, you can see how the code generator represents dynamically allocated arrays.

- 1 Configure the model to use a fixed-step solver. In the Configuration Parameters dialog box, in the **Solver** pane, under **Solver selection**:
 - For **Type**, select Fixed-step.
 - For **Solver**, select discrete (no continuous states).
- 2 Configure the model to create and use a code generation report. In the Configuration Parameters dialog box, in the **Code Generation > Report** pane, select **Create code generation report** and **Open report automatically**.
- 3 Edit the code in the MATLAB Function block so that it looks like this code:

```
function s = myfcn(n)
Z = rand(1,n);
s = sum(Z);
end
```

Z is an unbounded variable-size array.

- 4 Make sure that the model is configured for dynamic memory allocation:
 - The **Dynamic memory allocation in MATLAB functions** check box is selected.
 - The **Dynamic memory allocation threshold in MATLAB functions** parameter has the default value 65536.
- 5 Build the model.
- 6 In the code generation report, open `mymodel.c`. You can tell that the code generator used dynamic memory allocation for Z because you see the `emxArray` type `emxArray_real_T_mymodel_T` and `emxArray` utility functions, such as `mymodel_emxInit_real_T`. The code generator uses an `emxArray` type for variables whose memory is dynamically allocated. The generated code uses the `emxArray` utility functions to manage the `emxArrays`.

If you have Embedded Coder, you can customize the identifiers for `emxArray` types and the utility functions. See “Identifier Format Control” (Embedded Coder).

Code Generation for Enumerations

Enumerations represent a fixed set of named values. Enumerations help make your MATLAB code and generated C/C++ code more readable. For example, the generated code can test equality with code such as `if (x == Red)` instead of using `strcmp`. To generate C/C++ code, you must have Simulink Coder.

When you use enumerations in a MATLAB Function block, adhere to these restrictions:

- Calls to methods of enumeration classes are not supported.
- Passing strings or character vectors to constructors of enumerations is not supported.
- For a MATLAB Function block, you can import an externally defined type by using `Simulink.defineIntEnumType` or you can define an enumeration class. The enumeration class must derive from one of these base types: `Simulink.IntEnumType`, `int8`, `uint8`, `int16`, `uint16`, or `int32`. See “Define Enumerations for MATLAB Function Blocks” on page 45-85.
- You can use only a limited set of operations on enumerations. See “Allowed Operations on Enumerations” on page 45-86.
- Use enumerations with functions that support enumerated types for code generation. See “MATLAB Toolbox Functions That Support Enumerations” on page 45-87.

Define Enumerations for MATLAB Function Blocks

You can define enumerations for MATLAB Function blocks in two ways:

- To import an externally defined enumeration, use the `Simulink.defineIntEnumType` function. See “Import Enumerations Defined Externally to MATLAB” on page 69-10.
- In a class definition file, define an enumerated type. For example:

```
classdef PrimaryColors < Simulink.IntEnumType
    enumeration
        Red(1),
        Blue(2),
        Yellow(4)
    end
end
```

If you define an enumerated type in a class definition file, the class must derive from one of these base types: `Simulink.IntEnumType`, `int8`, `uint8`, `int16`, `uint16`, or `int32`. Then, you can exchange enumerated data between MATLAB Function blocks and other Simulink blocks in a model.

If you use Simulink Coder to generate C/C++ code, you can use the enumeration class base type to control the size of an enumerated type in generated C/C++ code. You can:

- Represent an enumerated type as a fixed-size integer that is portable to different targets.
- Reduce memory usage.
- Interface with legacy code.
- Match company standards.

The base type determines the representation of the enumerated type in generated C/C++ code.

If the base type is `Simulink.IntEnumType`, the code generator produces a C enumeration type. Consider the following MATLAB enumerated type definition:

```

classdef LEDcolor < Simulink.IntEnumType
    enumeration
        GREEN(1),
        RED(2)
    end
end

```

This enumerated type definition results in the following C code:

```

typedef enum {
    GREEN = 1,
    RED
} LEDcolor;

```

For built-in integer base types, the code generator produces a `typedef` statement for the enumerated type and `#define` statements for the enumerated values. Consider the following MATLAB enumerated type definition:

```

classdef LEDcolor < int16
    enumeration
        GREEN(1),
        RED(2)
    end
end

```

This enumerated type definition results in the following C code:

```

typedef int16_T LEDcolor;

#define GREEN ((LEDcolor)1)
#define RED ((LEDcolor)2)

```

To customize the code generated for an enumerated type, see “Customize Simulink Enumeration” on page 69-7.

Allowed Operations on Enumerations

For code generation, you are restricted to the operations on enumerations listed in this table.

Operation	Example	Notes
assignment operator: =		—
relational operators: < > <= >= == ~=	<code>xon == xoff</code>	Code generation does not support using <code>==</code> or <code>~=</code> to test equality between an enumeration member and a string array, a character array, or a cell array of character arrays.
cast operation	<code>double(LEDcolor.RED)</code>	—

Operation	Example	Notes
conversion to character array or string	<pre>y = char(LEDcolor.RED); y1 = cast(LEDcolor.RED,'char'); y2 = string(LEDcolor.RED);</pre>	<ul style="list-style-type: none"> You can convert only compile-time scalar valued enumerations. For example, this code runs in MATLAB, but produces an error in code generation: <pre>y2 = string(repmat(LEDcolor.RED,1,2));</pre> The code generator preserves enumeration names when the conversion inputs are constants. For example, consider this enumerated type definition: <pre>classdef AnEnum < int32 enumeration zero(0), two(2), otherTwo(2) end end</pre> Generated code produces "two" for <pre>y = string(AnEnum.two)</pre> and "otherTwo" for <pre>y = string(AnEnum.two)</pre>
indexing operation	<pre>m = [1 2] n = LEDcolor(m) p = n(LEDcolor.GREEN)</pre>	—
control flow statements: if, switch, while	<pre>if state == sysMode.ON led = LEDcolor.GREEN; else led = LEDcolor.RED; end</pre>	—

MATLAB Toolbox Functions That Support Enumerations

For code generation, you can use enumerations with these MATLAB toolbox functions:

- cast
- cat
- char
- circshift
- enumeration
- fliplr
- flipud
- histc
- intersect
- ipermute

- `isequal`
- `isequaln`
- `isfinite`
- `isinf`
- `ismember`
- `isnan`
- `issorted`
- `length`
- `permute`
- `repmat`
- `reshape`
- `rot90`
- `setdiff`
- `setxor`
- `shiftdim`
- `sort`
- `sortrows`
- `squeeze`
- `string`
- `union`
- `unique`

Add Enumerated Inputs, Outputs, and Parameters to a MATLAB Function Block

When you add enumerated inputs, outputs, or parameters to a MATLAB Function block, follow these guidelines:

- For inputs, inherit the type from the enumerated type of the connected Simulink signal or specify the enumeration explicitly.
- For outputs, specify the enumerated type explicitly.
- For tunable parameters, specify the enumerated type explicitly. For nontunable parameters, derive properties from an enumerated parameter in a parent Simulink masked subsystem or enumerated variable defined in the MATLAB base workspace.

To add enumerated data to a MATLAB Function block:

- 1 In the **MATLAB Function Block Editor**, select **Ports & Data Manager**.
- 2 In the Ports and Data Manager, select **Add > Data**.
- 3 In the **Name** field, enter a name for the enumerated data.

For parameters, the name must match the enumerated masked parameter or workspace variable name.

- 4 In the **Type** field, specify an enumerated type.
 - For an explicit enumerated type, set **Type** to Enum:<class name>. Replace <class name> with the name of an enumerated data type that you defined in a MATLAB file on the MATLAB path.

The **Complexity** field is not visible because enumerated data types do not support complex values.
 - To inherit the enumerated type from a connected Simulink signal (for inputs only), set **Type** to Inherit:Same as Simulink.

Use Enumerations to Control an LED Display

In this section...

“Enumerations in a MATLAB Function Block” on page 45-90

“Enumeration Class Definitions” on page 45-90

“MATLAB Function Block Function” on page 45-91

“Simulation” on page 45-91

Enumerations in a MATLAB Function Block

This example shows how MATLAB Function blocks exchange enumerated data with other Simulink® blocks. The model uses enumerations to represent the modes of a device that controls the colors of an LED display. The MATLAB Function block receives an enumerated input signal that represents the mode. The enumerated output signal represents the color that the LED displays.

Copyright 2009-2021 The MathWorks, Inc.

In this model, the Step block provides the source of the on/off signal. This block outputs an initial value of 0 (off) and, after 10 seconds, steps up to a value of 1 (on). A pair of Data Type Conversion blocks convert this signal, first from type double to type int32, and then from int32 to the enumerated type switchmode. The parameters in the second Data Type Conversion block have these settings:

- Output minimum: []
- Output maximum: []
- Output data type: Enum:switchmode

The MATLAB Function block checkState evaluates the enumerated input state to determine the value of the enumerated output ledval. state inherits its enumerated type switchmode from the incoming Simulink signal, while ledval has the type Enum:led. Finally, a Display block displays the value of ledval.

Enumeration Class Definitions

The switchmode enumeration represents the allowed modes for the input to the checkstate block.

```
classdef switchmode < Simulink.IntEnumType
    enumeration
        OFF(0)
        ON(1)
    end
end
```

The led enumeration represents the colors that the checkstate block can output.

```
classdef led < Simulink.IntEnumType
    enumeration
        GREEN(1),
        RED(8)
    end
end
```

Both enumeration classes inherit from the built-in type `Simulink.IntEnumType` and reside on the MATLAB path.

MATLAB Function Block Function

The function `checkState` uses enumerations to activate an LED display, based on the state of a device. It lights a green LED display to indicate the ON state. It lights a red LED display to indicate the OFF state.

```
function ledval = checkState(state)
    %#codegen

    if state == switchmode.ON
        ledval = led.GREEN;
    else
        ledval = led.RED;
    end
```

Simulation

When you simulate the model, the Display block displays the state of the LED display. If you simulate the model for less than 10 seconds, the state is off. The Display block displays RED. If you simulate the model for more than 10 seconds, the state is on. The Display block displays GREEN.

Share Data Globally

In this section...

- “When Do You Need to Use Global Data?” on page 45-92
- “Using Global Data with the MATLAB Function Block” on page 45-92
- “Choosing How to Store Global Data” on page 45-93
- “Storing Data Using Data Store Memory Blocks” on page 45-93
- “Storing Data Using Simulink.Signal Objects” on page 45-94
- “Using Data Store Diagnostics to Detect Memory Access Issues” on page 45-96
- “Limitations of Using Shared Data in MATLAB Function Blocks” on page 45-96

When Do You Need to Use Global Data?

You might need to use global data with a MATLAB Function block if:

- You have multiple MATLAB functions that use global variables and you want to call these functions from MATLAB Function blocks.
- You have an existing model that uses a large amount of global data and you are adding a MATLAB Function block to this model, and you want to avoid cluttering your model with additional inputs and outputs.
- You want to scope the visibility of data to parts of the model.

Using Global Data with the MATLAB Function Block

In Simulink, you store global data using data store memory. You implement data store memory using either Data Store Memory blocks or `Simulink.Signal` objects. How you store global data depends on the number and scope of your global variables. For more information, see “Local and Global Data Stores” on page 74-2 and “Choosing How to Store Global Data” on page 45-93.

How MATLAB Globals Relate to Data Store Memory

In MATLAB functions in Simulink, global declarations are not mapped to the MATLAB global workspace. Instead, you register global data with the MATLAB Function block to map the data to data store memory. This difference allows global data in MATLAB functions to inter-operate with the Simulink solver and to provide diagnostics if they are misused.

A global variable resolves hierarchically to the closest data store memory with the same name in the model. The same global variable occurring in two different MATLAB Function blocks might resolve to different data store memory depending on the hierarchy of your model. You can use this ability to scope the visibility of data to a subsystem.

How to Use Globals with the MATLAB Function Block

To use global data in your MATLAB Function block, or in any code that this block calls, you must:

- 1 Declare a global variable in your MATLAB Function block, or in any code that is called by the MATLAB Function block.
- 2 Register a Data Store Memory block or `Simulink.Signal` object that has the same name as the global variable with the MATLAB Function block.

For more information, see “Storing Data Using Data Store Memory Blocks” on page 45-93 and “Storing Data Using Simulink.Signal Objects” on page 45-94.

Choosing How to Store Global Data

The following table summarizes whether to use Data Store Memory blocks or `Simulink.Signal` objects.

If you want to:	Use:	For more information:
Use a small number of global variables in a single model that does not use model reference.	Data Store Memory blocks. <hr/> Note Using Data Store Memory blocks scopes the data to the model.	“Storing Data Using Data Store Memory Blocks” on page 45-93
Use a large number of global variables in a single model that does not use model reference.	<code>Simulink.Signal</code> objects defined in the model workspace. <code>Simulink.Signal</code> objects offer these advantages: <ul style="list-style-type: none"> • You do not have to add numerous Data Store Memory blocks to your model. • You can load the <code>Simulink.Signal</code> objects in from a MAT-file. 	“Storing Data Using Simulink.Signal Objects” on page 45-94
Share data between multiple models (including referenced models).	<code>Simulink.Signal</code> objects defined in the base workspace <hr/> Note If you use Data Store Memory blocks as well as <code>Simulink.Signal</code> , note that using Data Store Memory blocks scopes the data to the model.	“Storing Data Using Simulink.Signal Objects” on page 45-94

Storing Data Using Data Store Memory Blocks

This model demonstrates how a MATLAB Function block uses the global data stored in a Data Store Memory block A.

- 1 Open the `dsm_demo` model. At the MATLAB command line, enter:

```
run(docpath(fullfile(docroot, ...
    'toolbox','simulink','examples','dsm_demo.mdl')))
```

- 2 Double-click the MATLAB Function block to open the **MATLAB Function Block Editor**.

The MATLAB Function block code declares a global variable A. The block modifies the value of A during each execution.

```
function y = fcn
%#codegen
global A;
A = A+1;
y = A;
```

- 3 Make sure the global variable is registered to the MATLAB Function block. See “Define MATLAB Function Block Data” on page 45-30.
 - a In the **MATLAB Function Block Editor**, select **Ports & Data Manager** to open the Ports and Data Manager dialog box.
 - b In the Ports and Data Manager, select the data **A** in the left pane. This data uses the same name as the global variable.
 - c The **Scope** of the data is set to **Data Store Memory**.
- 4 Double-click the Data Store Memory block A. In the Block Parameters dialog box, you see that the **Data store name** A matches the global variable name. The block has an initial value of 25.

When you add a Data Store Memory to your model:

- a Set the **Data store name** to match the name of the global variable in your MATLAB Function block code.
 - b Set **Data type** to an explicit data type. The data type cannot be auto.
 - c Set the **Signal type** and specify an **Initial value**.
- 5 Simulate the model.

The MATLAB Function block reads the initial value of global data stored in A and updates the value of A each time it executes.

Storing Data Using Simulink.Signal Objects

This model demonstrates how a MATLAB Function block uses the global data stored in a Simulink.Signal object A.

- 1 Open the simulink_signal_local model.

Open the simulink_signal_local model. At the MATLAB command line, enter:

```
run(docpath(fullfile(docroot, 'toolbox', 'simulink', ...
                    'examples', 'simulink_signal_local.mdl')))
```

The model uses a `Simulink.Signal` object in the model workspace.

Note To use the global data with multiple models, create a `Simulink.Signal` object in the base workspace .

- 2 Make sure that the `Simulink.Signal` object is added to the Model Explorer.
 - a In the **Modeling** tab, click **Model Explorer**.
 - b In the left pane of the Model Explorer, select the model workspace for the `simulink_signal_local` model.

The **Contents** pane displays the data in the model workspace.

- c Click the `Simulink.Signal` object A.

In the right pane, make sure that the Model Explorer displays these attributes for A.

Attribute	Value
Data type	double
Complexity	real
Dimensions	1
Initial value	5

See also **Model Explorer**.

- 3 Double-click the MATLAB Function block to open its editor.

The MATLAB Function block modifies the value of global data A each time it executes.

```
function y = fcn
%#codegen
global A;
A = A+1;
y = A;
```

- 4 Make sure the `Simulink.Signal` object is registered to the MATLAB Function block.
 - a In the **MATLAB Function Block Editor**, select **Ports & Data Manager** to open the Ports and Data Manager dialog box.
 - b In the Ports and Data Manager, select the data **A** in the left pane. This data uses the same name as the global variable.
 - c Set the **Scope** of the data to **Data Store Memory**.
- 5 Simulate the model.

The MATLAB Function block reads the initial value of global data stored in A and updates the value of A each time it executes.

Using Data Store Diagnostics to Detect Memory Access Issues

You can configure your model to provide run-time and compile-time diagnostics for avoiding problems with data stores. Diagnostics are available in the Configuration Parameters dialog box and the parameters dialog box for the Data Store Memory block. These diagnostics are available for Data Store Memory blocks only, not for `Simulink.Signal` objects. For more information on using data store diagnostics, see “Data Store Diagnostics” on page 74-3.

Note If you pass data store memory arrays to functions, optimizations such as `A=foo(A)` might result in the code generation software marking the entire contents of the array as read or written even though only some elements were accessed.

Limitations of Using Shared Data in MATLAB Function Blocks

There is no Data Store Memory block support for:

- MATLAB value classes
- Variable-sized data

- “Implementing MATLAB Functions Using Blocks” on page 45-3

Initialize Persistent Variables in MATLAB Functions

A persistent variable is a local variable in a MATLAB function that retains its value in memory between calls to the function. If you generate code from your model, you must initialize a persistent variable for your MATLAB functions. For more information, see `persistent`.

When using MATLAB functions that contain persistent variables in Simulink models, you should follow these guidelines:

- Initialize the persistent variables in functions only by accessing constants.
- Ensure the control flow of the function does not depend on whether the initialization occurs.

If you do not follow these guidelines, several conditions produce an initialization error:

- MATLAB Function blocks with persistent variables where the **Allow direct feedthrough** property is cleared
- MATLAB Function blocks with persistent variables in models with State Control blocks where **State control** is set to Synchronous
- Stateflow charts that implement Moore machine semantics and that use MATLAB functions with persistent variables

For example, the function `fcn` below uses a persistent variable, `n`. `fcn` violates both guidelines. The initial value of `n` depends on the input `u` and the `return` statement interrupts the normal control flow of the function. Consequently, this code produces an error when used in a model that has one of the conditions described above.

```
function y = fcn(u)
    persistent n

    if isempty(n)
        n = u;
        y = 1;
        return
    end

    y = n;
    n = n + u;
end
```

To prevent the error, initialize the persistent variable by setting it to a constant value and removing the `return` statement. This modified version of `fcn` initializes the persistent variable without producing an error:

```
function y = fcn(u)
    persistent n

    if isempty(n)
        n = 1;
    end

    y = n;
    n = n + u;
end
```

MATLAB Function Block with No Direct Feedthrough

This model contains a MATLAB Function block that uses the first version of `fcn`, described previously. The MATLAB Function block input is a square wave, which is provided by a Sign and Sine Wave block. The MATLAB Function block adds the value of `u` to the persistent variable `n` at each time step.

Simulate the model. The simulation returns an error because:

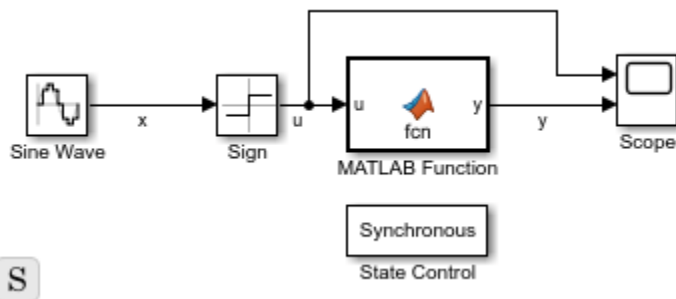

- The initial value of the persistent variable `n` depends on the input `u`.
- The `return` statement interrupts the normal control flow of the function.
- The **Allow direct feedthrough** property of the MATLAB Function block is cleared.

Modify the MATLAB Function block code, as shown in the corrected version of `fcn`. Simulate the model again.

State Control Block in Synchronous Mode

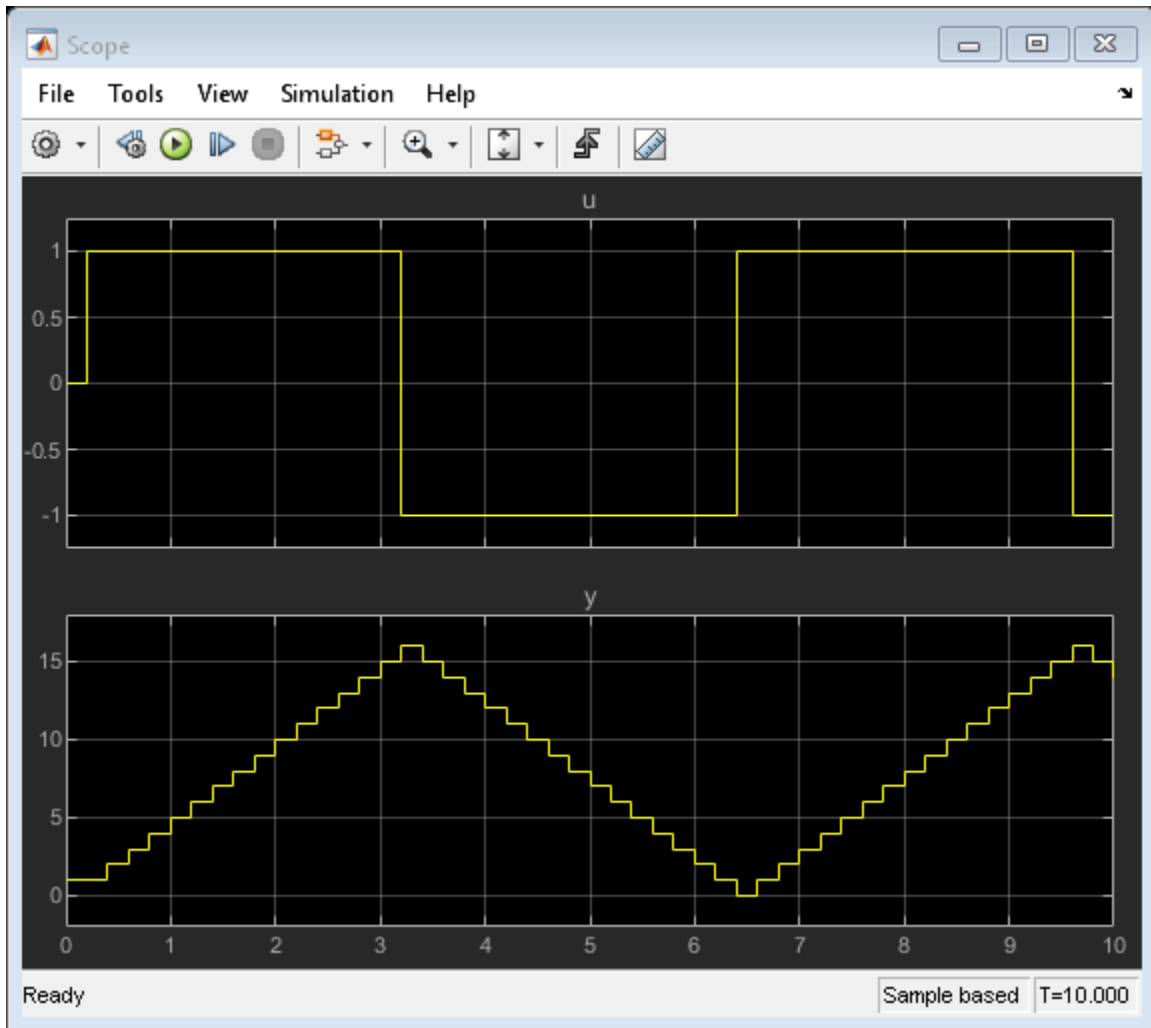

This model contains a MATLAB Function block that uses the first version of fcn, described previously. The MATLAB Function block input is a square wave, which is provided by a Sign and Sine Wave block. The MATLAB Function block adds the value of u to the persistent variable n at each time step. The model contains a State Control block where **State control** is set to Synchronous.

Simulate the model. The simulation returns an error because:

- The initial value of the persistent variable n depends on the input u .
- The `return` statement interrupts the normal control flow of the function.
- the model contains a State Control block where **State control** is set to Synchronous.

Modify the MATLAB Function block code, as shown in the corrected version of `fcn`. Simulate the model again.

Stateflow Chart Implementing Moore Semantics

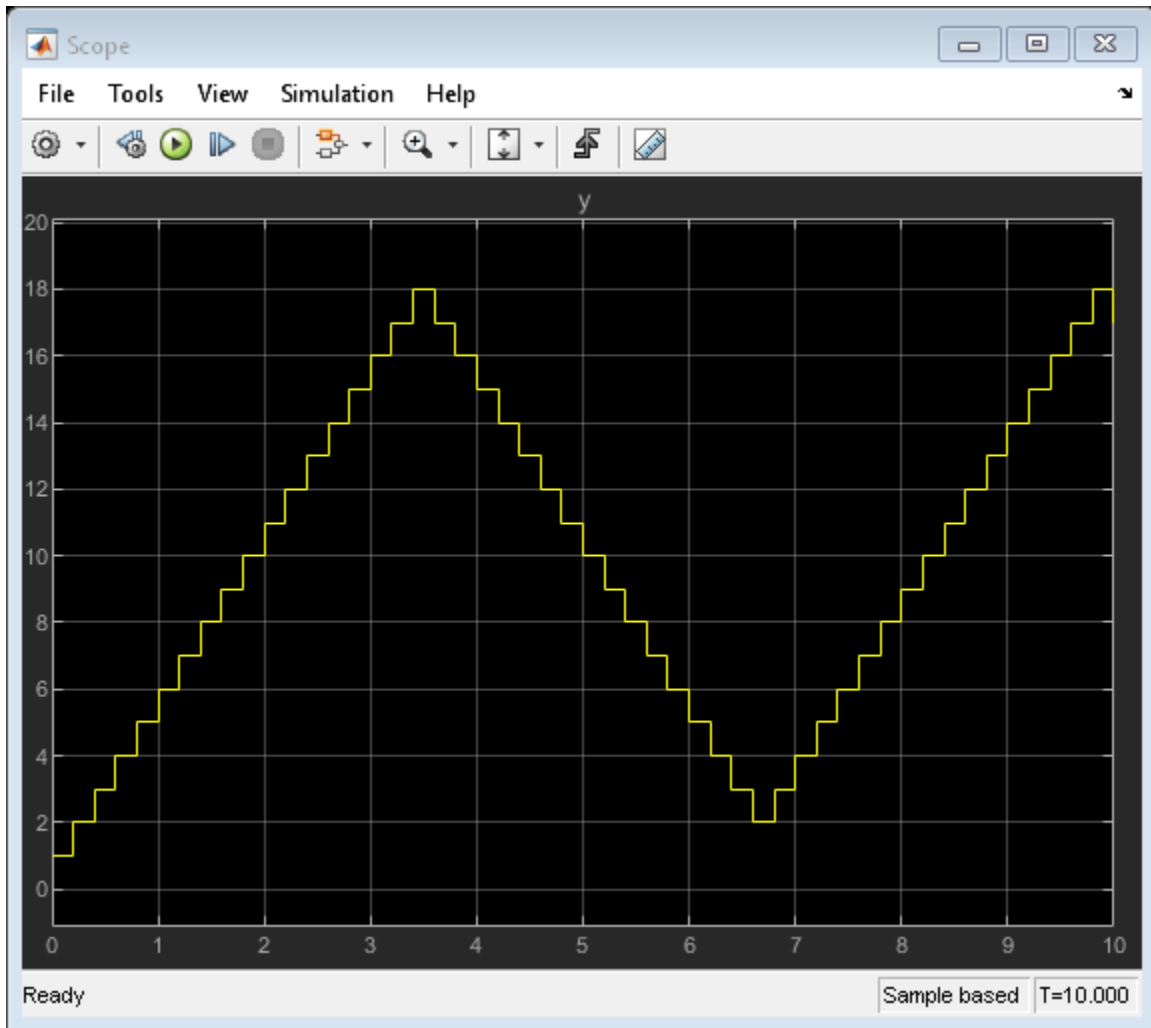

This model contains a Stateflow Chart with a MATLAB function that uses the first version of `fcn`, described previously. The MATLAB function adds the value (1 or -1) determined by the active state to the persistent variable n at each time step.

Simulate the model. The simulation returns an error because:

- The initial value of the persistent variable `n` depends on the input `u`.
- The return statement interrupts the normal control flow of the function.
- The chart implements Moore semantics.

Modify the MATLAB function code, as shown in the corrected version of `fcn`. Simulate the model again.

Run Simulations and Generate Code with Masked Library Subsystems Containing MATLAB Function Blocks

This example shows how to use a masked library subsystem that contains a MATLAB Function block to run simulations and generate C code. Edits to the function code, the subsystem, or the mask properties affect all instances of the block in the model, while changes to the mask parameter affect only the selected block. Use masked library blocks if you need duplications of custom blocks that can generate code. For more information, see “Create Custom Library” on page 41-2 and “Design and Create a Custom Block” on page 40-12.

Copyright 2021, The MathWorks, Inc.

Navigate the Model

The masked subsystem contains a MATLAB Function block that uses the `conv` function to calculate the convolution of two input vectors. The mask parameter **shape** allows you to change the normalization weight to `full`, `same`, or `valid`. The block calculates the convolution using this MATLAB code:

```
function c = my_conv(a, b, shape) if shape == 1
    c = conv(a, b, 'full');
elseif shape == 2
    c = conv(a, b, 'same');
else
    c = conv(a, b, 'valid');
end
```

In this model, the **shape** parameter of the top instance of the block is set to `full`, the middle instance is set to `same`, and the bottom instance is set to `valid`. Run the simulation to calculate the convolution of the vectors and display their values in the Display blocks.

The two top block instances output different vector sizes because each block calculates the convolution with a different weight. Change the **shape** parameter in any of the blocks and simulate again to see the output change.

Generate C Code From the Model

If you have a license for Embedded Coder or Simulink Coder, you can generate code from this example without changing the parameters or the blocks. However, MATLAB Function blocks support code generation for only a restricted subset of MATLAB functions. For more information, see “Functions and Objects Supported for C/C++ Code Generation” (MATLAB Coder).

If the parameters and inputs are identical for multiple instances of the library blocks, you can generate code with reusable functions that represent each identical MATLAB Function block. You can enable this behavior by right-clicking the MATLAB Function block, clicking **Block Parameters (Subsystem)**, and then opening the **Code Generation** tab. Set **Function packaging** to Reusable function. For more information, see “Generate Reusable Code from Library Subsystems Shared Across Models” (Simulink Coder).

Generate code by opening the Embedded Coder or Simulink Coder apps and clicking **Generate Code**. This model generates unique C functions for each block instance. To produce reusable functions, set the **shape** parameter to `full` for each library subsystem instance and generate code. The generated code reuses logic for the `my_conv_filter` and `my_conv_filter1` instances because they have the same block inputs and mask parameter value.

```

/*
 * Output and update for atomic system:
 *   '<S1>/MATLAB Function'
 *   '<S2>/MATLAB Function'
 */
void MATLAB_custom_bl_MATLABFunction(const real_T rtu_a[2], const
real_T rtu_b[5],
real_T rty_c[6])
{
    int32_T b_k; int32_T i; int32_T tmp; for (i = 0; i < 6; i++) {
        rty_c[i] = 0.0;
    }

    for (i = 0; i < 2; i++) {
        for (b_k = 0; b_k < 5; b_k++) {
            tmp = i + b_k; rty_c[tmp] += rtu_a[i] * rtu_b[b_k];
        }
    }
}

```

The `my_conv_filter2` instance uses a different function because it uses different inputs.

```

/* Output and update for atomic system: '<S3>/MATLAB Function' */
void MATLAB_custom_MATLABFunction_p(const real_T rtu_a[3], const
real_T rtu_b[3],
real_T rty_c[5])
{
    int32_T i; for (i = 0; i < 5; i++) {

```

```
    rty_c[i] = 0.0;
}

for (i = 0; i < 3; i++) {
    rty_c[i] += rtu_b[i] * rtu_a[0]; rty_c[i + 1] += rtu_b[i] *
    rtu_a[1]; rty_c[i + 2] += rtu_b[i] * rtu_a[2];
}
}
```

Include MATLAB Code as Comments in Generated Code

If you have a Simulink Coder license, you can include MATLAB source code as comments in the code generated for a MATLAB Function block. Including this information in the generated code enables you to:

- Correlate the generated code with your source code.
- Understand how the generated code implements your algorithm.
- Evaluate the quality of the generated code.

When you select **MATLAB source code as comments** parameter, the generated code includes:

- The source code as a comment immediately after the traceability tag. When you enable traceability and generate code for ERT targets (requires an Embedded Coder license), the traceability tags are hyperlinks to the source code. For more information on traceability for the MATLAB Function block, see “Use Traceability in MATLAB Function Blocks” (Embedded Coder).

For examples and information on the location of the comments in the generated code, see “Location of Comments in Generated Code” on page 45-106.

- The function help text in the function body in the generated code. The function help text is the first comment after the MATLAB function signature. It provides information about the capabilities of the function and how to use it.

Note With an Embedded Coder license, you can also include the function help text in the function banner of the generated code. For more information, see “Including MATLAB user comments in Generated Code” on page 45-108.

How to Include MATLAB Code as Comments in the Generated Code

To include MATLAB source code as comments in the code generated for a MATLAB Function block:

- 1 In the model, in the **Modeling** tab, click **Model Settings**.
- 2 In the **Code Generation > Comments** pane, select **MATLAB source code as comments** and click **Apply**.

Location of Comments in Generated Code

The automatically generated comments containing the source code appear after the traceability tag in the generated code as follows.

```
/* '<S2>:1:18' for y = 1 : 2 : (HEIGHT-4) */
```

Selecting the **Stateflow object comments** parameter generates the traceability comment '`<S2>:1:18`'. Selecting the **MATLAB source code as comments** parameter generates the `for y = 1 : 2 : (HEIGHT-4)` comment.

Straight-Line Source Code

The comment containing the source code precedes the generated code that implements the source code statement. This comment appears after any comments that you add that precede the generated

code. The comments are separated from the generated code because the statements are assigned to function outputs.

MATLAB Code

```
function [x y] = straightline(r,theta)
%#codegen
% Convert polar to Cartesian
x = r * cos(theta);
y = r * sin(theta);
```

Commented C Code

```
/* MATLAB Function 'straightline': '<S1>:1' */
/* Convert polar to Cartesian */
/* '<S1>:1:4' x = r * cos(theta); */
/* '<S1>:1:5' y = r * sin(theta); */
straightline0_Y.x = straightline0_U.r * cos(straightline0_U.theta);

/* Output: '<Root>/y' incorporates:
 * Inport: '<Root>/r'
 * Inport: '<Root>/theta'
 * MATLAB Function Block: '<Root>/straightline'
 */
straightline0_Y.y = straightline0_U.r * sin(straightline0_U.theta);
```

If Statements

The comment for the `if` statement immediately precedes the code that implements the statement. This comment appears after any comments that you add that precede the generated code. The comments for the `elseif` and `else` clauses appear immediately after the code that implements the clause, and before the code generated for statements in the clause.

MATLAB Code

```
function y = ifstmt(u,v)
%#codegen
if u > v
    y = v + 10;
elseif u == v
    y = u * 2;
else
    y = v - 10;
end
```

Commented C Code

```
/* MATLAB Function 'MLFcn': '<S1>:1' */
/* '<S1>:1:3' if u > v */
if (MLFcn_U.u > MLFcn_U.v) {
    /* Output: '<Root>/y' */
    /* '<S1>:1:4' y = v + 10; */
    MLFcn_Y.y = MLFcn_U.v + 10.0;
} else if (MLFcn_U.u == MLFcn_U.v) {
    /* Output: '<Root>/y' */
    /* '<S1>:1:5' elseif u == v */
    /* '<S1>:1:6' y = u * 2; */
    MLFcn_Y.y = MLFcn_U.u * 2.0;
} else {
```

```

/* Output: '<Root>/y' */
/* '<S1>:1:7' else */
/* '<S1>:1:8' y = v - 10; */
MLFcn_Y.y = MLFcn_U.v - 10.0;

```

For Statements

The comment for the `for` statement header immediately precedes the generated code that implements the header. This comment appears after any comments that you add that precede the generated code.

MATLAB Code

```

function y = forstmt(u)
%#codegen
y = 0;
for i=1:u
    y = y + 1;
end

```

Commented C Code

```

/* MATLAB Function 'MLFcn': '<S1>:1' */
/* '<S1>:1:3' y = 0; */
rtb_y = 0.0;

/* '<S1>:1:5' for i=1:u */
for (i = 1.0; i <= MLFcn_U.u; i++) {
    /* '<S1>:1:6' y = y + 1; */
    rtb_y++;
}

```

While Statements

The comment for the `while` statement header immediately precedes the generated code that implements the statement header. This comment appears after any comments that you add that precede the generated code.

Switch Statements

The comment for the `switch` statement header immediately precedes the generated code that implements the statement header. This comment appears after any comments that you add that precede the generated code. The comments for the `case` and `otherwise` clauses appear immediately after the generated code that implements the clause, and before the code generated for statements in the clause.

Including MATLAB user comments in Generated Code

MATLAB user comments include the function help text and other comments. The function help text is the first comment after the MATLAB function signature. It provides information about the capabilities of the function and how to use it. You can include the MATLAB user comments in the code generated for a MATLAB Function block.

- 1 In the model, on the **Modeling** tab, click **Model Settings**.
- 2 In the **Code Generation > Comments** pane, select “MATLAB user comments” (Embedded Coder) and click **Apply**.

Limitations of MATLAB Source Code as Comments

The MATLAB Function block has the following limitations for including MATLAB source code as comments.

- You cannot include MATLAB source code as comments for:
 - MathWorks toolbox functions
 - P-code
 - Simulation targets
 - Stateflow Truth Table blocks
- The appearance or location of comments can vary depending on the following conditions:
 - Comments might still appear in the generated code even if the implementation code is eliminated, for example, due to constant folding.
 - Comments might be eliminated from the generated code if a complete function or code block is eliminated.
 - For certain optimizations, the comments might be separated from the generated code.
 - The generated code always includes legally required comments from the MATLAB source code, even if you do not choose to include source code comments in the generated code.

Integrate C Code by Using the MATLAB Function Block

In this section...

“Call C Code from a Simulink Model” on page 45-110

“Use `coder.ceval` in an Example MATLAB Function Block” on page 45-110

“Control Imported Bus and Enumeration Type Definitions” on page 45-112

If you have C code that you want to use in your Simulink model, you can call external C code to the model using a MATLAB Function block. MATLAB Function blocks call C code using MATLAB commands. You can also generate code from models with MATLAB Function blocks that call external C code.

Call C Code from a Simulink Model

To call external C code in a Simulink model, follow these steps:

- 1 Identify the source (.c) and header (.h) files that contain the C code you want to use in your model.
- 2 Insert a MATLAB Function block into your model.
- 3 In the MATLAB Function block, use the `coder.ceval` function to call the C code. To pass data by reference, use `coder.ref`, `coder.rref`, or `coder.wref`.
- 4 Specify the C source and header files in the **Simulation Target** pane of the Configuration Parameters window. Include the header file using double quotations, for example, `#include "program.h"`. If you need to access C source and header files outside your working folder, list the path in the **Simulation Target** pane, in the **Include Directories** text box.

Alternatively, use the `coder.cinclude` and `coder.updateBuildInfo` functions to specify source and header files in your MATLAB code. To develop an interface to external code, you can use the `coder.ExternalDependency` class. To see which workflow is supported, see “Import custom code”.

- 5 Test your Simulink model and ensure it functions correctly.
- 6 If you have a Simulink Coder license, you can generate code for targets. To use the same source and header files for code generation, open Configuration Parameters, navigate to the **Code Generation > Custom Code** pane, and enable **Use the same custom code settings as Simulation Target**. You can also specify different source and header files.

To conditionalize your code to execute different commands for simulation and code generation, you can use the `coder.target` function.

Use `coder.ceval` in an Example MATLAB Function Block

This example shows how to call the simple C program `doubleIt` from a MATLAB Function block.

- 1 Create the source file `doubleIt.c` in your current working folder.

```
#include "doubleIt.h"

double doubleIt(double u)
{
```

```

    return(u*2.0);
}

```

- 2 Create the header file `doubleIt.h` in your current working folder.

```

#ifndef MYFN
#define MYFN

double doubleIt(double u);

#endif

```

- 3 Create a new Simulink model. Save it as `myModel`.

- 4 In the Library Browser, navigate to the **Simulink > User-Defined Functions** library, and add a MATLAB Function block to the model.

- 5 Double-click the block to open the **MATLAB Function Block Editor**. Enter code that calls the `doubleIt` program:

```

function y = callingDoubleIt(u)

y = 0.0;
y = coder.ceval('doubleIt',u);

```

- 6 Connect a Constant block that has a value of 3.5 to the input port of the MATLAB Function block.

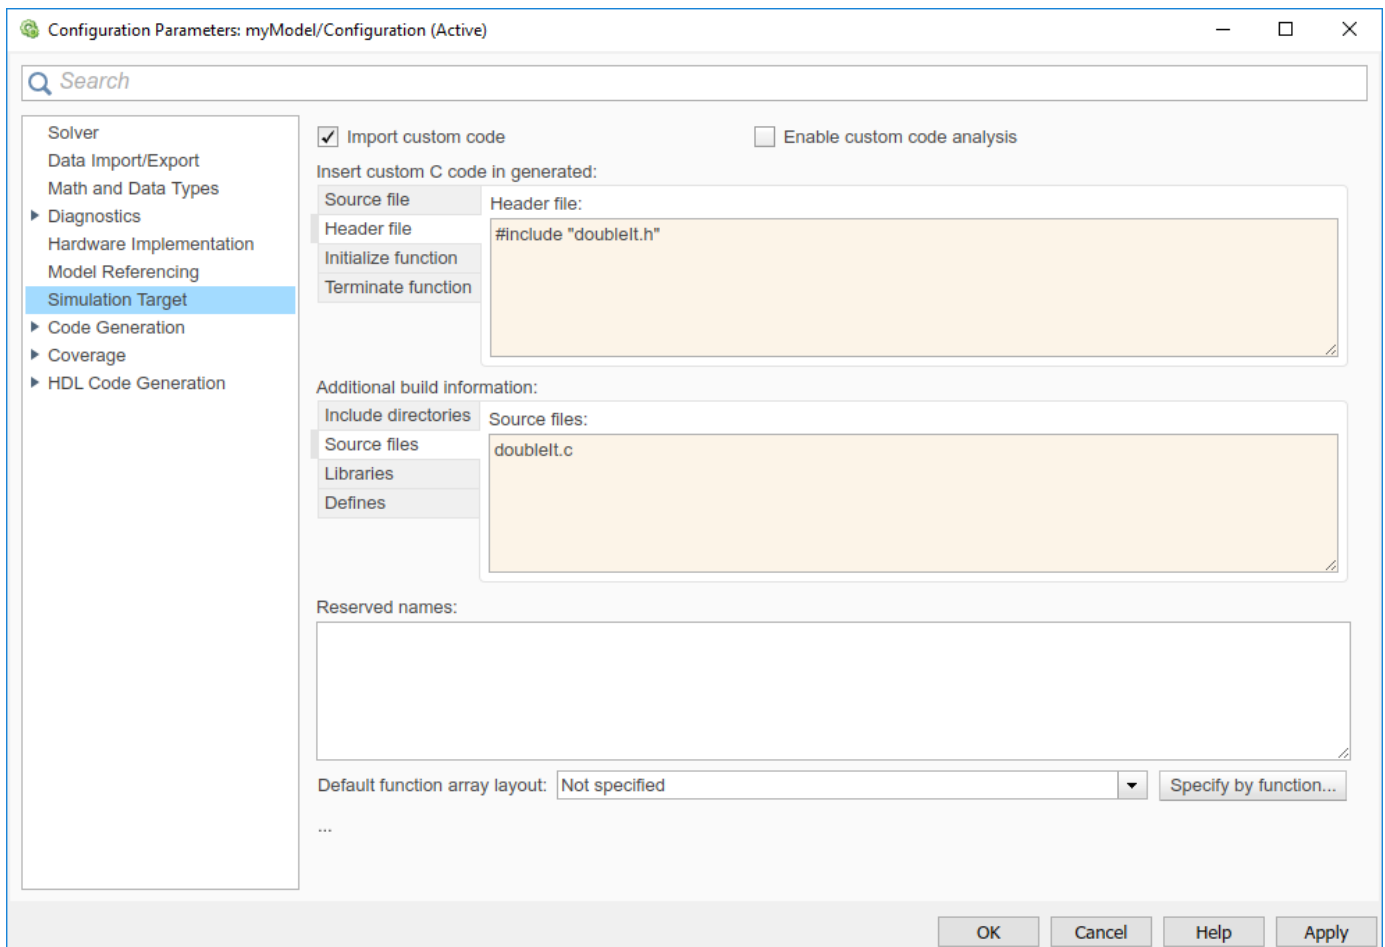

- 7 Connect a Display block to the output port.

- 8 Open the Configuration Parameters window, and navigate to the **Simulation Target** pane.

- 9 In the **Insert custom C code in generated** section, select **Header file** and enter `#include "doubleIt.h"`.

- 10 In the **Additional build information** section, select **Source files**, enter `doubleIt.c`, and click **OK**.

11 Run the simulation. The value 7 appears in the Display block.

Control Imported Bus and Enumeration Type Definitions

When you call external C code by using MATLAB Function blocks or Stateflow, you can control the type definitions for imported buses and enumerations in your model. Simulink can generate type definitions for you, or you can supply a header file containing the type definitions. You can control this behavior by toggling the **Generate typedefs for imported bus and enumeration types** parameter. To find this parameter, open the Configuration Parameters window, navigate to the **Simulation Target** pane, and expand the **Advanced parameters** section.

To configure Simulink to automatically generate type definitions, enable **Generate typedefs for imported bus and enumeration types**. To include a custom header file that defines the enumeration and bus types, clear **Generate typedefs for imported bus and enumeration types** and list the header file in the **Header file** text box.

Control Run-Time Checks

In this section...

“Types of Run-Time Checks” on page 45-114

“When to Disable Run-Time Checks” on page 45-114

“How to Disable Run-Time Checks” on page 45-114

Types of Run-Time Checks

In simulation, the code generated for your MATLAB Function block includes the following run-time checks:

- Memory integrity checks

These checks detect violations of memory integrity in code generated for MATLAB Function blocks and stop execution with a diagnostic message.

Caution For safety, these checks are enabled by default. Without memory integrity checks, violations result in unpredictable behavior.

- Responsiveness checks in code generated for MATLAB Function blocks

These checks enable periodic checks for Ctrl+C breaks in the generated code. Enabling responsiveness checks also enables graphics refreshing.

Caution For safety, these checks are enabled by default. Without these checks, the only way to end a long-running execution might be to terminate MATLAB.

When to Disable Run-Time Checks

Generally, generating code with run-time checks enabled results in more lines of generated code and slower simulation than generating code with the checks disabled. Disabling run-time checks usually results in streamlined generated code and faster simulation, with these caveats:

Consider disabling:	Only if:
Memory integrity checks	You are sure that your code is safe and that all array bounds and dimension checking is unnecessary.
Responsiveness checks	You are sure that you will not need to stop execution of your application using Ctrl+C.

How to Disable Run-Time Checks

MATLAB Function blocks enable run-time checks by default, but you can disable them explicitly for all MATLAB Function blocks in your Simulink model. Follow these steps:

- 1 Open your MATLAB Function block.

- 2 In the **MATLAB Function Block Editor**, select **Simulation Target**.
- 3 In the Configuration Parameters dialog box, clear the **Ensure memory integrity** or **Ensure responsiveness** check boxes, as applicable, and click **Apply**.

Call MATLAB Function Files in MATLAB Function Blocks

The example model uses a MATLAB Function block to estimate the location of a moving object by calling a MATLAB Function file on the path. The model then plots this prediction data against the actual location of the object with another MATLAB Function block. The example then allows you to generate code from the MATLAB Function block that calls the MATLAB function file.

Copyright 2021 The MathWorks, Inc.

Simulate the Model

The model takes the position data of an object stored in a MAT-file and runs the data through a tracking algorithm. The MATLAB Function block labeled Tracking calls a separate MATLAB function file, `ex_kalman_f.m`, to execute the tracking algorithm. In the model, double-click the Tracking block to see the code that calls `ex_kalman_f.m`.

```
function y = kalman(u)
y = ex_kalman_f(u);
end
```

Open `ex_kalman_f.m` to view the algorithm. `ex_kalman_f.m` uses a Kalman filter algorithm to track the location of the object. The algorithm uses two persistent variables. `x_est` stores the state between time steps and `p_est` stores the covariance. The algorithm uses these persistent variables to calculate the estimated location of the object at every time step as the output `y`.

```
function y = ex_kalman_f(z)
%#codegen

% Initialize state transition matrix
dt = 1;
A = [ 1 0 dt 0 0 0;...
      0 1 0 dt 0 0;...
      0 0 1 0 dt 0;...
      0 0 0 1 0 dt;...
      0 0 0 0 1 0 ;...
      0 0 0 0 0 1 ];

% Measurement matrix
H = [ 1 0 0 0 0 0; 0 1 0 0 0 0 ];
Q = eye(6);
R = 1000 * eye(2);

% Initial conditions
persistent x_est p_est
```

```

if isempty(x_est)
    x_est = zeros(6, 1);
    p_est = zeros(6, 6);
end
% Predicted state and covariance
x_prd = A * x_est;
p_prd = A * p_est * A' + Q;

% Estimation
S = H * p_prd' * H' + R;
B = H * p_prd';
klm_gain = (S \ B)';

% Estimated state and covariance
x_est = x_prd + klm_gain * (z - H * x_prd);
p_est = p_prd - klm_gain * H * p_prd;

% Compute the estimated measurements
y = H * x_est;
end

```

MATLAB Function block code, and the function files the block calls, must be supported for code generation. Unlike the MATLAB Function block, MATLAB files called by the MATLAB Function block require the `%%codegen` directive to find code violations that would result in errors during code generation. In this example, `ex_kalman_f.m` does not have any violations.

After Simulink calculates the estimated location of the object, the `Visualizing` block plots the actual and estimated locations of the object by using the MATLAB `plot` function.

```

function plot_me(y,z)

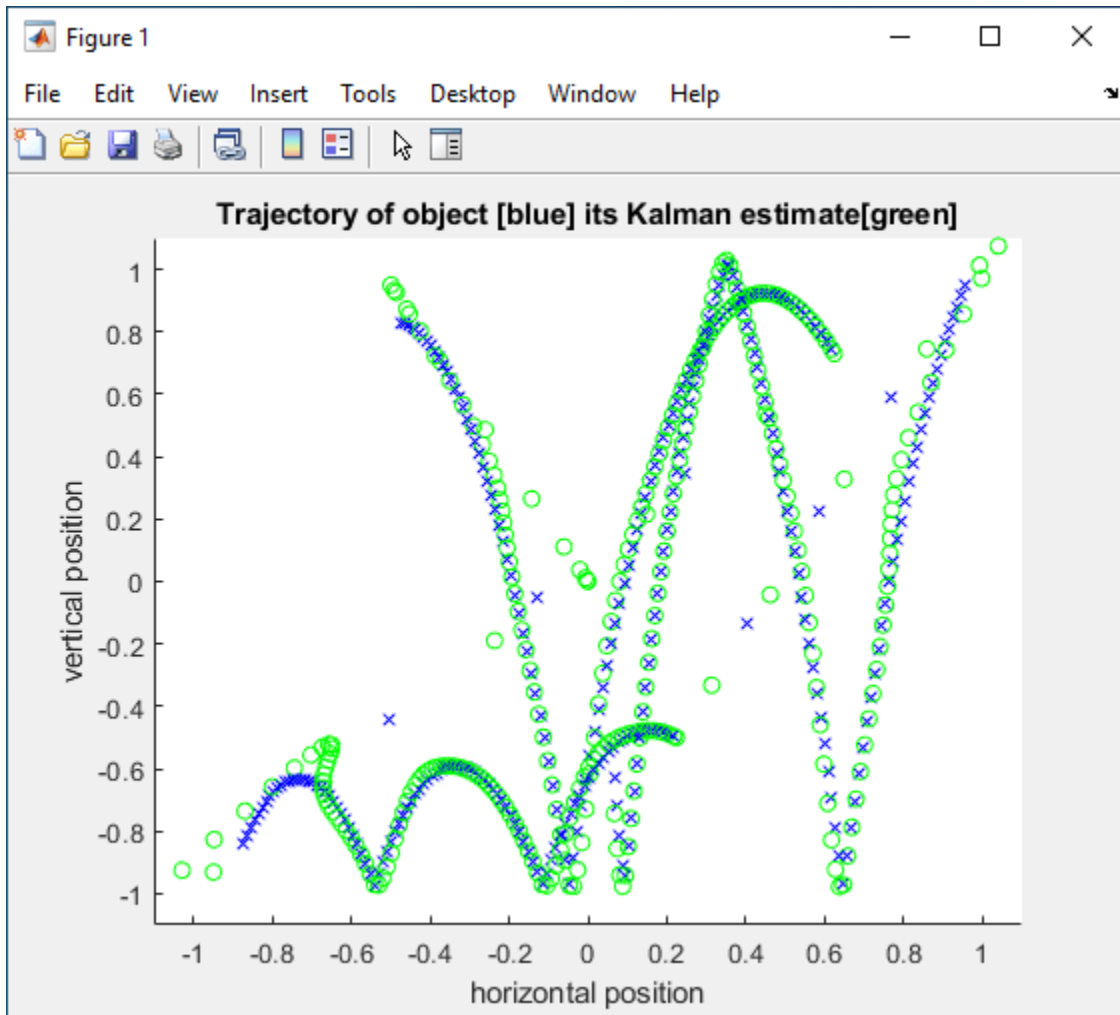

persistent h
if isempty(h)
    h = figure;
    hold;
end

N = size(z,2);
title('Trajectory of object [blue] its Kalman estimate[green]');
xlabel('horizontal position');
ylabel('vertical position');

for i = 1:N
    plot(y(1,i), y(2,i), 'bx-');
    plot(z(1,i), z(2,i), 'go-');
    axis([-1.1, 1.1, -1.1, 1.1]);
    pause(0.02);
end
end

```

Run the model to watch the data during simulation.

Generate C Code

If you have a license for Embedded Coder or Simulink Coder, you can generate C code from MATLAB Function blocks that do not include extrinsic functions. In this example, you cannot generate C code from the Visualizing block because it includes `plot` and `figure`, which MATLAB treats as extrinsic functions. For more information, see “Use MATLAB Engine to Execute a Function Call in Generated Code” (MATLAB Coder). However, you can generate C code for the Tracking block. To generate C code for the Tracking block, right-click the block and click **C/C++ Code > Build This Subsystem**.

Limitations

- The simulation time in this model must match the size of the position data array. If the input data size changes, you must manually adjust the simulation time.

- This model can only estimate the location of a moving point. For more sophisticated motion estimation capabilities, consider using “Computer Vision Toolbox”.

Interface with Row-Major Data in MATLAB Function Block

Array layout can be important for integration, usability, and performance. Simulink uses column-major layout by default, as does the MATLAB Function block. However, many devices, sensors, and libraries use row-major array layout for their data. You can apply your model directly to this data by using the `coder.ceval` function with row-major layout in a MATLAB Function block.

Array layout can also affect performance. Many algorithms perform memory access more efficiently for one specific array layout.

Row-Major Layout in Simulation and Code Generation

For the MATLAB Function block, you can specify row-major array layout inside the block. This specification occurs at the function level and does not alter the array layout of the model outside of the function. The array layout that you specify inside the MATLAB Function block applies to both simulation and C/C++ code generation. See “Specify Array Layout in Functions and Classes” on page 53-13.

For C/C++ code generation using Simulink Coder and Embedded Coder software, you can specify array layout at the model level, which is supported by MATLAB Function blocks. For more information on controlling array layout at the model level, see “Code Generation of Matrices and Arrays” (Simulink Coder). The model code generation setting for array layout has no effect for simulation. See “Array layout” (Simulink Coder). For examples of using row-major layout in MATLAB Function block for code generation, see “Generate Row-Major Code for Model That Contains a MATLAB Function Block” (Simulink Coder).

For the MATLAB Function block, the array layout specification at the function level takes precedence over the array layout specification of the model. However, for global and persistent variables, the array layout specification of the model takes precedence.

Array Layout Conversions

MATLAB and Simulink store data in column-major layout by default. The software automatically inserts array layout conversions as needed when you specify different array layouts in different functions and at different boundaries.

For example, when you simulate a model or generate code for a model that uses column-major layout, and the model contains a MATLAB Function block that uses row-major layout, then the software converts the block input data to row-major and the block output data back to column-major, as needed. Array layout conversions can affect performance. For more information on performance considerations for array layout, see “Code Design for Row-Major Array Layout” on page 53-17.

Array Layout and Algorithmic Efficiency

For certain algorithms, row-major layout provides more efficient memory access. Consider this function for adding two matrices. The algorithm performs the addition through explicit row and column traversal.

```
function [S] = addMatrix(A,B)
coder.rowMajor;
S = zeros(size(A));
for row = 1:size(A,1)
```

```

    for col = 1:size(A,2)
        S(row,col) = A(row,col) + B(row,col);
    end
end

```

If you use this code in a MATLAB Function block, code generation results in this C code for the function:

```

...
/* generated code for addMatrix using row-major */
for (row = 0; row < 20; row++) {
    for (col = 0; col < 10; col++) {
        S[col + 10 * row] = A[col + 10 * row] + B[col + 10 * row];
    }
}
...

```

The arrays are indexed by the generated code using the formula:

```
[col + 10 * row]
```

Because the arrays are stored in row-major layout, adjacent memory elements are separated by single column increments. The *stride length* for the algorithm is equal to one. The stride length is the distance in memory elements between consecutive memory accesses. A shorter stride length provides more efficient memory access.

Using column-major layout for the data results in a longer stride length and less efficient memory access. To see this comparison, consider the generated C code for `addMatrix` that uses column-major layout:

```

...
/* generated code for addMatrix using column-major */
for (row = 0; row < 20; row++) {
    for (col = 0; col < 10; col++) {
        S[row + 20 * col] = A[row + 20 * col] + B[row + 20 * col];
    }
}
...

```

In column-major layout, the column elements are contiguous in memory in the generated code. Adjacent memory elements are separated by single row increments and indexed by the formula:

```
[row + 20 * col]
```

However, the algorithm iterates through the columns in the inner for-loop. Therefore, the column-major C code must make a stride of 20 elements for each consecutive memory access.

The array layout that provides the most efficient memory access depends on the algorithm. For this algorithm, row-major layout of the data provides more efficient memory access. The algorithm traverses over the data row by row. Row-major storage is therefore more efficient.

Row-Major Layout for N-Dimensional Arrays

You can use row-major layout for N-dimensional arrays. When an array is stored in row-major layout, the elements from the last (rightmost) dimension or index are contiguous in memory. In column-major layout, the elements from the first (leftmost) dimension or index are contiguous.

Consider the example function `addMatrix3D`, which accepts three-dimensional inputs.

```
function [S] = addMatrix3D(A,B)
coder.rowMajor;
S = zeros(size(A));
for i = 1:size(A,1)
    for j = 1:size(A,2)
        for k = 1:size(A,3)
            S(i,j,k) = A(i,j,k) + B(i,j,k);
        end
    end
end
end
```

The code generator produces this C code:

```
...
/* row-major layout */
for (i = 0; i < 20; i++) {
    for (j = 0; j < 10; j++) {
        for (k = 0; k < 5; k++) {
            S[(k + 5 * j) + 50 * i] = A[(k + 5 * j) + 50 * i]
                + B[(k + 5 * j) + 50 * i];
        }
    }
}
...
```

In row-major layout, adjacent memory elements are separated by single increments of the last index, `k`. The inner for-loop iterates over adjacent elements separated by only one position in memory.

Remove the `coder.rowMajor` call and generate C code that uses column-major layout:

```
...
/* column-major layout */
for (i = 0; i < 20; i++) {
    for (j = 0; j < 10; j++) {
        for (k = 0; k < 5; k++) {
            S[(i + 20 * j) + 200 * k] = A[(i + 20 * j) + 200 * k]
                + B[(i + 20 * j) + 200 * k];
        }
    }
}
...
```

In column-major layout, adjacent elements are separated by single increments of the first index, `i`. The inner for-loop now iterates over adjacent elements separated by 200 positions in memory. The long stride length can cause performance degradation due to cache misses.

Because the algorithm iterates through the last index, `k`, in the inner for-loop, the stride length is much longer for the generated code that uses column-major layout. For this algorithm, row-major layout of the data provides more efficient memory access.

Specify Array Layout in External Function Calls

To call external C/C++ functions that expect data stored with a specific layout, use `coder.ceval` with the `layout` syntax. If you do not use this syntax, the external function inputs and outputs are assumed to use column-major layout by default.

Consider an external C function designed to use row-major layout called `myCFunctionRM`. To integrate this function into your code, call the function using the `'-layout:rowMajor'` or `'-row'` option. This option ensures that the input and output arrays are stored in row-major order. The code generator automatically inserts array layout conversions as needed.

```
coder.ceval('-layout:rowMajor','myCFunctionRM',coder.ref(in),coder.ref(out))
```

Within a MATLAB function that uses row-major layout, you may seek to call an external function designed to use column-major layout. In this case, use the `'-layout:columnMajor'` or `'-col'` option.

```
coder.ceval('-layout:columnMajor','myCFunctionCM',coder.ref(in),coder.ref(out))
```

You can perform row-major and column-major function calls in the same code. Consider the function `myMixedFn1` as an example:

```
function [E] = myMixedFn1(x,y)
%#codegen
coder.rowMajor;
% specify type of return arguments for ceval calls
D = zeros(size(x));
E = zeros(size(x));

% include external C functions that use row-major & column-major
coder.cinclude('addMatrixRM.h');
coder.updateBuildInfo('addSourceFiles', 'addMatrixRM.c');
coder.cinclude('addMatrixCM.h');
coder.updateBuildInfo('addSourceFiles', 'addMatrixCM.c');

% call C function that uses row-major order
coder.ceval('-layout:rowMajor','addMatrixRM', ...
    coder.rref(x),coder.rref(y),coder.wref(D));

% call C function that uses column-major order
coder.ceval('-layout:columnMajor','addMatrixCM', ...
    coder.rref(x),coder.rref(D),coder.wref(E));
end
```

The external files are:

addMatrixRM.h

```
extern void addMatrixRM(const double x[200], const double y[200], double z[200]);
```

addMatrixRM.c

```
#include "addMatrixRM.h"

void addMatrixRM(const double x[200], const double y[200], double z[200])
{
    int row;
```

```
int col;

/* add two matrices */
for (row = 0; row < 20; row++) {
    /* row by row */
    for (col = 0; col < 10; col++) {
        /* each element in current row */
        z[col + 10 * row] = x[col + 10 * row] + y[col + 10 * row];
    }
}
}
```

addMatrixCM.h

```
extern void addMatrixCM(const double x[200], const double y[200], double z[200]);
```

addMatrixCM.c

```
#include "addMatrixCM.h"

void addMatrixCM(const double x[200], const double y[200], double z[200])
{
    int row;
    int col;

    /* add two matrices */
    for (row = 0; row < 20; row++) {
        /* row by row */
        for (col = 0; col < 10; col++) {
            /* each element in current row */
            z[row + 20 * col] = x[row + 20 * col] + y[row + 20 * col];
        }
    }
}
```

Integration Considerations for MATLAB Function Blocks

Use Nondirect Feedthrough in a MATLAB Function Block

In Simulink blocks, *direct feedthrough* means that the output of a block is controlled directly by the value of an input port signal. In nondirect feedthrough, the value of the output signal does not depend on the value of the input signal in at least one function during the simulation.

By default, MATLAB Function blocks have direct feedthrough enabled. If you disable direct feedthrough, the Simulink semantics ensure that outputs rely only on current state. Using nondirect feedthrough enables you to use MATLAB Function blocks in a feedback loop and prevent algebraic loops.

To use nondirect feedthrough:

- Enable function inlining of the MATLAB Function block by using `coder.inline` in the top-level function body.
- Open the properties for the MATLAB Function block and clear **Allow direct feedthrough**. For more information, see “Specify MATLAB Function Block Properties” on page 45-34.

Limitations of Nondirect Feedthrough

Do not program outputs to rely on inputs or updated persistent variables. For example, do not use this code in a nondirect feedthrough block:

```
counter = counter + 1;      % update state
output = counter;         % compute output based on updated state
```

Instead, use this code:

```
output = counter;         % compute output based on current state
counter = counter + 1;    % update state
```

For more information, see “Initialize Persistent Variables in MATLAB Functions” on page 45-97.

If **Allow direct feedthrough** is disabled, you cannot call custom code functions in MATLAB Function blocks because it is not possible to enforce that the outputs of custom code functions depend only on the current state. Calling a custom code function in a MATLAB Function block triggers an error.

MATLAB System Block

In this section...

“Why Use the MATLAB System Block?” on page 46-2

“Choosing the Right Block Type” on page 46-2

“System Objects” on page 46-2

“Interpreted Execution or Code Generation” on page 46-3

“Default Input Signal Attributes” on page 46-3

“MATLAB System Block Limitations” on page 46-3

“MATLAB System and System Objects Examples” on page 46-4

Why Use the MATLAB System Block?

System objects let you implement algorithms using the MATLAB language. The MATLAB System block enables you to use System objects in Simulink.

The MATLAB System block lets you:

- Share the same System object in MATLAB and Simulink
- Dedicate integration of System objects with Simulink
- Unit test your algorithm in MATLAB before using it in Simulink
- Customize dialog box customization
- Simulate efficiently with better initialization
- Handle states
- Customize block icons with port labels
- Access two simulation modes

Choosing the Right Block Type

There are several mechanisms for including MATLAB algorithms in Simulink, such as:

- MATLAB System block
- MATLAB Function block
- Interpreted MATLAB Function block
- Level-2 MATLAB S-Function block

For help on choosing the right block, see “Comparison of Custom Block Functionality” on page 40-5.

System Objects

Before you use a MATLAB System block, you must have a System object to associate with the block. A System object is a specialized kind of MATLAB class. System objects are designed specifically for implementing and simulating dynamic systems with inputs that change over time.

For more information on creating System objects, see “Customize System Objects for Simulink”.

Note To use your System object in the Simulink environment, it must have a constructor that you can call with no arguments. By default, the System object constructor has this capability and you do not need to define your own constructor. However, if you create your own System object constructor, you must be able to call it with no arguments.

System objects exist in other MATLAB products. MATLAB System block supports only the System objects written in the MATLAB language. In addition, if a System object has a corresponding Simulink block, you cannot implement a MATLAB System block for it.

Interpreted Execution or Code Generation

You can use MATLAB System blocks in Simulink models for simulation via interpreted execution or code generation.

- With interpreted execution, the model simulates the block using the MATLAB execution engine.
- With code generation, the model simulates the block using code generation (requires the use of the subset of MATLAB code supported for code generation). For a list of supported functions, see “Functions and Objects Supported for C/C++ Code Generation” on page 50-2.

Default Input Signal Attributes

If a MATLAB System block has one or more inputs that are unconnected to another block’s output port or connected to a port that has underspecified attributes, the default input signal attributes for the unspecified attributes are:

Data Attribute	Default
Data Type	double
Size	[1 1] scalar
Complexity	real

MATLAB System Block Limitations

These capabilities are currently not supported.

Category	Limitation Description	Workaround
System Objects	Tunable logical and character vector properties of the System object are nontunable parameters in the MATLAB System block.	—
Data Types	<ul style="list-style-type: none"> • The MATLAB System block does not support virtual buses as input or output. • System objects cannot use user-defined opaque data types. • String data type is not supported with code generation. 	—

Category	Limitation Description	Workaround
Sample Time	Cannot use MATLAB System blocks to model continuous time or multirate systems.	—
Linearizations	Cannot use Jacobian based linearization.	—
Global Variables	Global variables defined in the model Configuration Parameters Simulation Target > Custom Code pane and referenced by the System object are not shared with Stateflow and the MATLAB Function block.	Turn on the Import custom code option in the Simulation Target pane of the Configuration Parameters dialog box.
Debugging	MATLAB debugging for code-generation-based simulation.	Set the MATLAB System block Simulate using parameter to Interpreted execution , and then debug. When you are done, set Simulate using back to Code generation .
Fixed-Point Tool	The Fixed-Point Tool does not return design min/max, min/max logging, and autoscaling information for MATLAB System blocks.	—
Model coverage analysis (Simulink Coverage software)	Simulink Coverage cannot perform model analysis for MATLAB System block with Simulate using parameter set to Interpreted execution .	—
Check model compatibility (Simulink Design Verifier software)	Simulink Design Verifier cannot perform compatibility checks for a model or subsystem that contains a MATLAB System block.	—

MATLAB System and System Objects Examples

For examples of MATLAB System and System objects, see:

Example	Description
“Illustration of Law of Large Numbers”	This example shows how to use MATLAB System blocks to illustrate the law of large numbers. Due to the use of MATLAB functions not supported for code generation, the example uses propagation methods and interpreted execution.
“Using Buses with MATLAB System Blocks”	This example shows how to use MATLAB System blocks with nonvirtual buses at input or output. Due to the use Simulink buses, the example uses propagation methods. The example defines the bus types in the MATLAB base workspace using model callbacks.

Implement a MATLAB System Block

Implement a block and assign a System object to it. You can then explore the block to see the effect.

- 1 Create a new model and add the MATLAB System block from the User-Defined Functions library.

- 2 In the block dialog box, from the **New** list, select **Basic**, **Advanced**, or **Simulink Extension** if you want to create a new System object from a template. Modify the template according to your needs and save the System object.
- 3 Enter the full path name for the System object in the **System object name**. Click the list arrow. If valid System objects exist in the current folder, the names appear in the list.

The MATLAB System block icon and port labels update to those of the corresponding System object. For example, suppose you selected a System object named `lmsSysObj` in your current folder. The block updates as shown in the figure:

Note After you associate the block with a System object class name, you cannot assign a new System object using the same MATLAB System block dialog box. Instead, right-click the MATLAB System block, select **Block Parameters (MATLABSystem)** and enter a new class name in **System object name**.

Understanding the MATLAB System Block

- 1 Double-click the block. The MATLAB System dialog box reflects the System object parameters. The dialog box usually includes a **Source code** link that leads to the System object class file. For example:

The **Source code** link appears if the System object uses MATLAB language. It does not appear if you have:

- Converted the System object to P-code
 - Overridden the default behavior using the `getHeaderImpl` method
- 2 Click **Source code** and observe that the public and active properties in the System object appear in the MATLAB System block dialog box as block parameters.
 - 3 Select how you want the model to simulate the block using the **Simulate using** parameter. (This parameter appears at the bottom of each MATLAB System block if there is only one tab, or the bottom of the first of multiple tabs.)

Change Blocks Implemented with System Objects

To implement a block with another System object, right-click the MATLAB System block and select Block Parameters (MATLABSystem). Then, use the block dialog box to identify a new class name in **System object name**. For more information, see “Implement a MATLAB System Block” on page 46-6.

Call Simulink Functions from MATLAB System Block

A Simulink Function is a graphical representation of a computational unit in the Simulink environment. Once you create the Simulink function, it can be executed by any computational unit and can be called in multiple places. You can only call a Simulink function inside the `stepImpl`, `outputImpl`, or `updateImpl` method of a System object. See “Simulink Functions Overview” on page 10-116 for more information on Simulink functions.

Note Interpreted mode is not supported for a model that contains a MATLAB System block calling a Simulink Function.

Create a Simulink Function Block

Set up a Simulink Function block that implements a simple function such as $y = 2 * u$.

- 1 Open a new model from **Simulink Editor** and add a Simulink Function block by typing Simulink Function on Simulink canvas.
- 2 When **Function prototype** window opens, type `y = timestwo_func(u)` as the function definition. This indicates that you define a function called `timestwo_func` that takes `u` as the input argument and produces `y` as the output argument. Alternatively, define the function name from Simulink Function block parameters.
- 3 Double-click the Simulink Function block and observe that a Trigger Port function block appears as well as an input and an output argument block.
- 4 Double-click the Trigger Port block in the Simulink Function, and observe that the **Function visibility** is set to `scoped`. To learn more about `scoped` Simulink Functions, see “Scoped and Global Simulink Function Blocks Overview” on page 10-150.
- 5 Add a Gain block and set its value to 2. Connect it with the input and output argument block. Click **Navigate Up to Parent** to return to the main model.

Note To determine which Simulink Function a MATLAB System block is calling, turn on the function tracing lines. In the **Debug** tab, select **Information Overlays > Function Connectors**.

Create a MATLAB System Block and Define System Object

Drag a MATLAB System block into the model and implement a System object to this block.

- 1 Add a MATLAB System block to your Simulink model.
- 2 In the block dialog box, from the New list, select **Basic**. This opens a basic System object template for you to type your code.
- 3 To subclass an object from `matlab.System`, replace `Untitled` with the name of your System object. For this example, name it `SimulinkFcnCaller`.
- 4 In the `stepImpl` method of your System object, declare the Simulink Function using `getSimulinkFunctionNamesImpl`.

See an example of the System object code below. To learn more about how to write a System object, see “Define Basic System Objects”.

```
classdef SimulinkFcnCaller < matlab.System
    % Public, tunable properties
```

```

% SimulinkFcnCaller calls a Simulink Function from a
% MATLAB System block to multiply the signal's value by 2.

methods(Access = protected)

    function y = stepImpl(obj,u)
        % Implement algorithm. Calculate y as a function of input u and
        % discrete states.
        y = timestwo_func(u);
    end
    function names = getSimulinkFunctionNamesImpl(obj)
        % Use 'getSimulinkFunctionNamesImpl' method to declare
        % the name of the Simulink Function that will be called
        % from the MATLAB System block's System object code.
        names = {'timestwo_func'};
    end
end
end

```

- 5 Save the file and name it `SimulinkFcnCaller.m`.

Call a Simulink Function in a Subsystem from a MATLAB System Block

The hierarchy of the Simulink Function block affects the function calls in the System object. For example, if the Simulink function is defined at a higher hierarchy in the Simulink model, the function is defined for all blocks in that hierarchy. If the Simulink function is defined at a lower hierarchy, you need to qualify the Subsystem and the function name. For example, suppose you have a Subsystem that contains a Simulink Function block at the same level as a MATLAB System block. When a Simulink Function block is placed in a subsystem, the function name is not visible to the outside the subsystem. You can call the Simulink Function block by qualifying the function name using the Subsystem name in your System object. To qualify the Subsystem and the function name follow these steps:

- 1 In the `stepImpl` method of your System object code, call the Simulink Function using dot notation. For example, in the code `y = Subsystem1.timestwo_func(u)`, `Subsystem1` corresponds to the Subsystem, and `timestwo_func` corresponds to the Simulink Function name.
- 2 Similarly, declare the Subsystem and the Simulink Function in the `getSimulinkFunctionNamesImpl` method using the dot notation. The System object code shows the `timestwo` example written for a Simulink Function defined at a lower hierarchy than the MATLAB System block.

```

classdef SimulinkFcnCallerQualified < matlab.System

    % SimulinkFcnCallerQualified calls a Simulink Function embedded in a Subsystem
    % from a MATLAB System block, and multiplies the signal's value by 2.

    methods(Access = protected)

        function y = stepImpl(obj,u)
            % Use the '.' notation to call a scoped Simulink Function from
            % a Simulink Function block.
            % Subsystem1 corresponds to the block name, where
            % timestwo_func is the Simulink Function name.
            y = Subsystem1.timestwo_func(u);
        end

        function names = getSimulinkFunctionNamesImpl(obj)
            % Use the 'getSimulinkFunctionNamesImpl' method with the '.'
            % notation to declare the name of a Simulink Function in
            % MATLAB System block's System object code.
            names = {'Subsystem1.timestwo_func'};
        end
    end
end

```

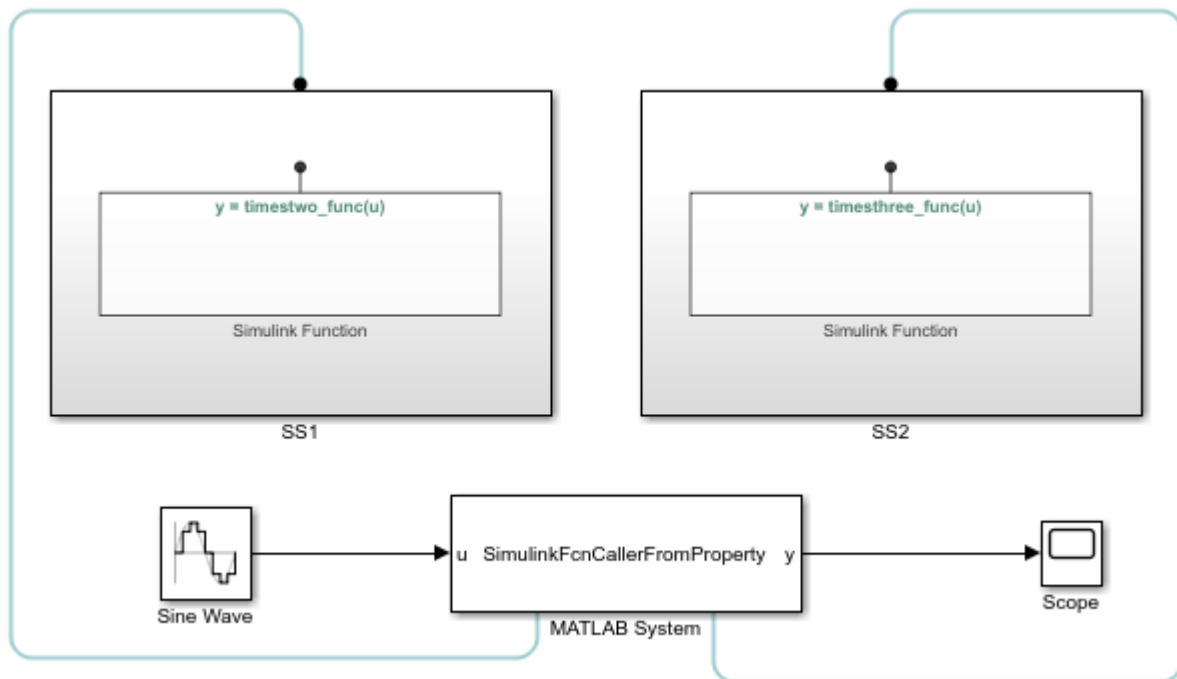

- 3 Save the System object file and name it `SimulinkFcnCallerQualified.m`.

Call Simulink Functions from a MATLAB System Block

This example shows two Simulink Functions conditionally called by a MATLAB System block using the nontunable properties of the System object®.

The MATLAB System block calls one of the Simulink Functions inside two different subsystems, depending on the value of the signal coming from the Sine Wave block. If the value of the signal is less than 10, the MATLAB System block calls the `timestwo_func` Simulink Function inside the SS1 Subsystem block. If the value is larger than 10, it calls the `timesthree_func` in the SS2 Subsystem block.

Function names are defined as nontunable properties, are switched from string to functions using the `str2func` function. Then, these functions are declared as properties in the `getSimulinkFunctionNamesImpl` method.

Specify Sample Time for MATLAB System Block

The sample time of a block is a parameter that indicates when the block produces an output, and eventually updates its internal state. To specify sample time for a MATLAB System block, implement the `getSampleTimeImpl` method with a call to `createSampleTime`. To query the MATLAB System block for current sample time and simulation time, use the `getSampleTime` and `getCurrentTime` methods. For more information, see “Specify Sample Time for MATLAB System Block System Objects” on page 46-98.

Types of Sample Time for MATLAB System Block

If you use discrete sample time on page 7-13 in simulation, Simulink only calculates the output of a simulation for each of the fixed time intervals. To specify discrete sample time, in the `createSampleTime`, set 'Type' to 'Discrete' and set the 'SampleTime' property.

When the sample time is inherited on page 7-14, Simulink determines the best sample time for the block based on the block's role within the model. To specify inherited sample time, in the `createSampleTime`, set 'Type' to 'Inherited'. When using inherited sample time, you can alter or error out on specific sample times by specifying the 'AlternatePropagation' or 'ErrorOnPropagation' Name-Value pair.

In fixed-in-minor-step on page 7-14 sample time, Simulink does not execute the block at the minor time steps, the updates only occur at the major time steps. To specify the fixed-in-minor time step, in the `createSampleTime`, set 'Type' to 'Fixed In Minor Step'.

To use controllable on page 7-15 sample time, configure a block to specify controllable sample time with a resolution T_{base} , where T_{base} is the smallest allowable time interval between block executions. A block using controllable sample time can be dynamically set to execute at n multiples of T_{base} , then the block's next execution is

$$T_{next} = n T_{base} + T$$

To specify T_{base} in MATLAB System block, in the `createSampleTime`, set 'Type' to 'Controllable' and set the 'TickTime' property to T_{base} . You can set the n in your MATLAB System block using `setNumTicksUntilNextHit`.

For more information on types of sample time, see “Types of Sample Time” on page 7-13. To see an example on how to control the sample time of the MATLAB System block using System object methods, see “Specify Sample Time for MATLAB System Block System Objects” on page 46-98.

Change Block Icon and Port Labels

To change the icon appearance of your block, you must add specific methods to your System object. For example, to define port labels, implement `getInputNamesImpl` and `getOutputNamesImpl`.

- 1 To define the icon, implement the `getIconImpl` method.
- 2 To define the port labels, implement `getInputNamesImpl` to change the input and `getOutputNamesImpl` to change the output port labels.

If you do not implement these methods, by default the System object uses the input and output port names from the `stepImpl` method. If you are using nondirect feedthrough, by default the System object uses the input names from `updateImpl` and the output port names from `outputImpl`.

Modify MATLAB System Block Dialog

To change the MATLAB System block dialog, implement `getPropertyGroupsImpl` and inside the method implement the following classes:

Description	matlab.system.display Methods
Define header text for property group.	<code>matlab.system.display.Header</code>
Group properties together.	<code>matlab.system.display.Section</code>
Group properties into a separate tab.	<code>matlab.system.display.SectionGroup</code>

Change the MATLAB System Block Icon to an Image

You can change the image of MATLAB System block in MATLAB Editor. For a list of accepted image files, see `image`. To use an existing image file for the MATLAB System block:

- 1 Double-click your MATLAB System block.
- 2 In the block dialog box, click the **Source code**. The MATLAB Editor that contains the System object code opens.
- 3 In the MATLAB Editor, from the **System Block** drop-down list, select **Add Image Icon**.
- 4 In the **Add image icon** dialog window, click **Browse** to select an image of your choice.
- 5 Click **OK** to insert the corresponding code for the `getIconImpl` method in your System object.

For more information, see “Customize System Block Appearance” on page 46-54.

Nonvirtual Buses and MATLAB System Block

The MATLAB System block supports nonvirtual buses as input and output signals. The corresponding System object input or output must be a MATLAB structure whose fields match those defined by the nonvirtual bus. If the System object output is a MATLAB structure, it must define propagator methods. In addition, the `getOutputDataTypeImpl` method must return the name of the corresponding bus object. This bus object must exist in the base workspace or a data dictionary linked to the model.

Note If the output is the same bus type as the input, do not use the `propagatedInputDataType` method to obtain the name of the bus object. Instead, you must return the name of the bus object directly.

Use System Objects in Feedback Loops

If your algorithm needs to process nondirect feedthrough data through the System object, use the `isInputDirectFeedthroughImpl`, `outputImpl`, and `updateImpl` methods. These methods process nondirect feedthrough data through a System object.

Most System objects use direct feedthrough, where the object's input is needed to generate the output. For these direct feedthrough objects, the `step` method calculates the output and updates the state values. For nondirect feedthrough, however, the object's output depends on internal states and not directly on the inputs. The inputs, or a subset of the inputs, are used to update the object states. For these objects, calculating the output is separated from updating the state values. This enables you to use an object as a feedback element in a feedback loop.

This example shows how to implement a delay object with nondirect feedthrough.

- 1 In MATLAB, select **New > System object > Basic**.
- 2 Select **Insert Method** and implement the `outputImpl` and `updateImpl` methods.

`outputImpl` calculates outputs from states and/or inputs. `updateImpl` updates state values from inputs.

When implementing the `outputImpl` method, do not access the System object inputs for which the direct feedthrough flag is false.

- 3 If the System object supports code generation and does not use propagation, Simulink can automatically infer the direct feedthrough settings from the System object MATLAB code. However, if the System object does not support code generation, the default `isInputDirectFeedthroughImpl` method returns false (no direct feedthrough). In this case, override this method to specify nondirect feedthrough behavior.

The processing of the nondirect feedthrough changes the way that the software calls the System object methods within the context of the Simulink engine.

Simulation Modes

Interpreted Execution vs. Code Generation

You can use MATLAB System block in Simulink models for simulation via interpreted execution or code generation. Implementing a MATLAB System block with a valid System object class name enables the **Simulate using** parameter. This parameter appears at the bottom of the MATLAB System block dialog if there is only one tab, or the bottom of the first of multiple tabs. Use the **Simulate using** parameter to control how the block simulates. The table describes how to choose the right value for your purpose.

- With interpreted execution, the model simulates the block using the MATLAB execution engine.

Note With interpreted execution, if you set the **Use division for fixed-point net slope computation** parameter to On or Use division for reciprocals of integers only in the Configuration Parameters dialog box, you might get unoptimized numeric results. These bad numeric results are because MATLAB code does not support this parameter.

- With code generation, the model simulates the block using code generation, using the subset of MATLAB code supported for code generation.

Action	Select	Pros	Cons
Upon first model run, simulate and generate code for MATLAB System using only the subset of MATLAB functions supported for code generation. Choosing this option causes the simulation to run the generated code.	Code generation (default)	Potentially better performance.	System object is limited to the subset of MATLAB functions supported for code generation. Simulation may start more slowly.
Simulate model using all supported MATLAB functions. Choosing this option can slow simulation performance.	Interpreted execution	System object can contain any supported MATLAB function. Faster startup time.	Potentially slower performance. If the MATLAB functions in the System object do not support code generation, the System object must contain propagation methods.

To take advantage of faster performance, consider using propagation methods in your System object. For more information, see “Add and Implement Propagation Methods” on page 46-27.

Simulation Using Code Generation

While simulating and generating code for one or more simulation targets (in this case, System object blocks), the model displays status messages in the bottom left of the Simulink Editor window. A model can have multiple copies of the same MATLAB System block. Blocks are considered the same if they,

- Use the same System object.
- Have inputs and tunable parameters that have identical signals, data types, and complexities.

- Have nontunable parameters that have the same value.

When the model has multiple copies of the same block, the software does not regenerate the code for each block. It reuses the code from the first time that code was generated for one of these blocks. The status messages reflect this and does not show status messages for each of these blocks.

When the code generation process is complete, Simulink creates a MEX-file for the generated code.

Mapping System Object Code to MATLAB System Block Dialog Box

The System object source code controls the appearance of the block dialog box. This section maps the System object code to the block dialog box. This example code snippet uses two System objects, one that uses default System object to block dialog box mapping, and one that uses a custom mapping.

System Object to Block Dialog Box Default Mapping

The following figure shows how the source code corresponds to the dialog box elements when you do not customize the dialog using the `getHeaderImpl` or `getPropertyGroupsImpl` methods. (The link to open the source code and the **Simulate using** parameter appear on all MATLAB System block dialog boxes.)

The Delay block from the example model snippet uses a System object that draws the dialog box using the default mapping. This block has one input and one output.

This block uses a System object that has direct feedthrough set to false (nondirect feedthrough). This setting means that the System object does not directly use the input to compute the output, enabling the model to use this block safely in a feedback system without introducing an algebraic loop. For more information on nondirect feedthrough, see "Use System Objects in Feedback Loops" on page 46-16.

For an example of a custom block dialog box, see “System Object to Block Dialog Box Custom Mapping” on page 46-20.

System Object to Block Dialog Box Custom Mapping

The LMS Adaptive block is an example of a block with a custom header and property groups. The System object code uses the `getHeaderImpl` and `getPropertyGroupsImpl` methods from `matlab.System` to customize these block dialog elements.

The LMS Adaptive Filter block estimates the coefficients of an unknown system (formed by the Unknown System and Delay blocks). Its inputs are the desired signal and the actual signal. Its outputs are the estimated signal and the vector norm of the error in the estimated coefficients. It uses the `lmsSysObj` System object.

```

classdef lmsSysObj < matlab.System & matlab.system.mixin.CustomIcon
%lmsSysObj Least mean squares (LMS) adaptive filtering.

methods(Static, Access=protected)

function header = getHeaderImpl
    header = matlab.system.display.Header(...
        'lmsSysObj', ...
        'Title', 'LMS Adaptive Filter');
end

function groups = getPropertyGroupsImpl
    firstGroup = matlab.system.display.SectionGroup(...
        'Title', 'General', ...
        'PropertyList', {'Mu'});

    secondGroup = matlab.system.display.SectionGroup(...
        'Title', 'Coefficients', ...
        'PropertyList', {'TrueCoefficients', 'NumCoeff'});

    groups = [firstGroup, secondGroup];
end
end

```

Header description from class help summary

Specified header title overrides class name

Tabs from SectionGroups

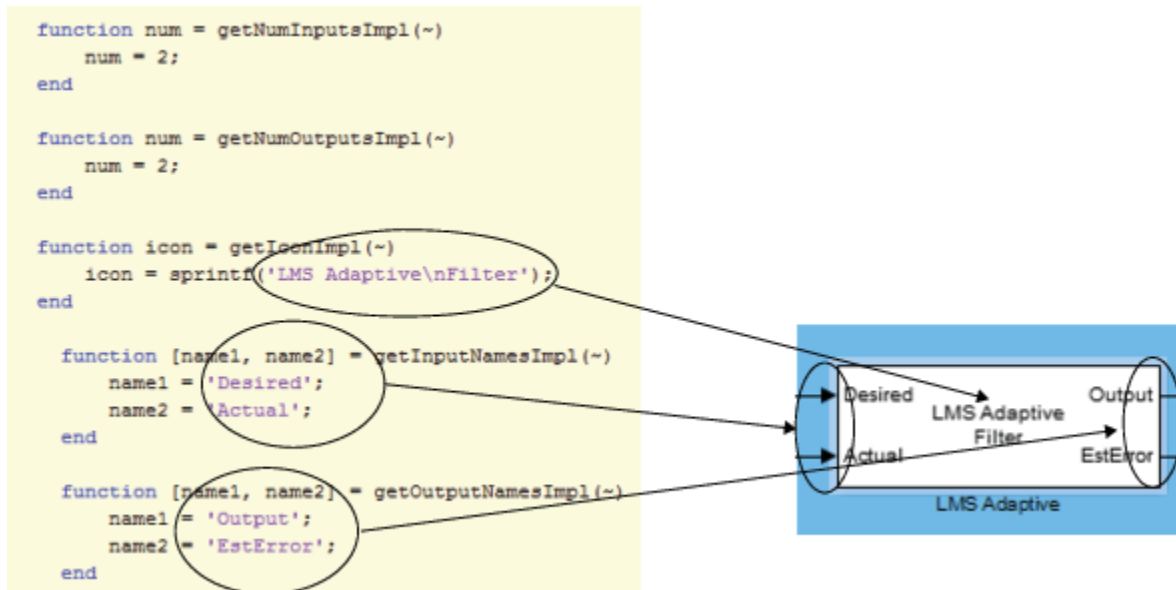

Label from product help summary

```

properties
% Mu Step Size
Mu = 0.005;
end

```

The source code for this System object also defines two input and output ports for the block.

Considerations for Using System Objects in Simulink

In this section...

“Variable-Size Signals” on page 46-22
“Tunable Parameters” on page 46-22
“System Objects as Properties” on page 46-22
“Default Property Values” on page 46-23
“System Objects in For Each Subsystems” on page 46-23
“Input Validation” on page 46-23

There are differences in how you can use System objects in a MATLAB System block in Simulink versus using the same object in MATLAB. You see these differences when working with variable-size signals and tunable parameters and when using System objects as properties.

Variable-Size Signals

To use variable-size signals in a System object, you must implement propagation methods. In particular, use the `isOutputFixedSizeImpl` method to specify if an output is variable-size or fixed-size. This method is needed for interpreted execution and code generation simulation methods.

Tunable Parameters

Simulink registers public tunable properties of a System object as tunable parameters of the corresponding MATLAB System block. If a System object property is tunable, it is also tunable in the MATLAB System block. At runtime, you can change the parameter using one of the following approaches. The change applies at the top of the simulation loop.

- At the MATLAB command line, use the `set_param` to change the parameter value.
- In the Simulink editor, edit the MATLAB System block dialog box to change the parameter value, and then update the block diagram.

You cannot change public tunable properties from System object internal methods such as `stepImpl`.

During simulation, setting an invalid value on a tunable parameter causes an error message and stops simulation.

System Objects as Properties

The MATLAB System block allows a System object to have other System objects as public or private properties. However:

- System objects and other MATLAB objects stored as public properties are read only. As a result, you cannot set the value of the parameter, you can only get the value of a parameter.
- System objects stored as property values appear dimmed in the MATLAB System block dialog box.

Default Property Values

MATLAB does not require that objects assign default values to properties. However, in Simulink, if your System object has properties with no assigned default values, the associated dialog box parameter requires that the value data type be a built-in Simulink data type.

System Objects in For Each Subsystems

To use the MATLAB System block within a For Each Subsystem block, implement the `supportsMultipleInstanceImpl` method. This method should return `true`. The MATLAB System block clones the System object for each For Each Subsystem iteration.

Input Validation

In Simulink, use the `validateInputsImpl` method to validate only attributes (size, data type, and complexity) of the input. Do not use this method to validate the value of the input.

Simulink Engine Interaction with System Object Methods

Simulink Engine Phases Mapped to System Object Methods

This diagram shows a process view of the order in which the MATLAB System block invokes System object methods within the context of the Simulink engine.

Initialization

Note the following:

- Simulink calls the `stepImpl`, `outputImpl`, and `updateImpl` methods multiple times during simulation at each time step. Simulink typically calls other methods once per simulation.
- The Simulink engine calls the `isOutputFixedSizeImpl`, `getDiscreteStateSpecificationImpl`, `isOutputComplexImpl`, `getOutputDataTypeImpl`, and `getOutputSizeImpl` when using propagation methods.
- Simulink calls `saveObjectImpl` and `loadObjectImpl` for saving and restoring `SimState`, the Simulation Stepper, and Fast Restart.
- Default implementations save and restore all properties with public access, including `DiscreteState`.

Add and Implement Propagation Methods

In this section...

“When to Use Propagation Methods” on page 46-27

“Implement Propagation Methods” on page 46-27

When to Use Propagation Methods

Propagation methods define output specifications. Use them when the output specifications cannot be inferred directly from the inputs during Simulink model compilation.

Consider using propagation methods in your System object when:

- The System object requires access to all MATLAB functions that do not support code generation, which means that you cannot generate code for simulation. You must use propagation methods in this case and the interpreted execution mode for simulation. Code generation modes will not be supported.
- You want to use variable-size signals.
- You do not care whether code is generated, but you want to improve startup performance. Use propagation methods to specify information for the inputs and outputs, enabling quicker startup time.

At startup, the Simulink software tries to evaluate the input and output ports of the model blocks for signal attribute propagation. In the case of MATLAB System blocks, if the software cannot perform this evaluation, it displays a message prompting you to add propagation methods to the System object.

Implement Propagation Methods

Simulink evaluates the uses of the propagation methods to evaluate the input and output ports of the MATLAB System block for startup.

Each method has a default implementation, listed in the **Default Implementation Should Suffice if** column. If your System object does not use the default implementation, you must implement a version of the propagation method for your System object.

Description	Propagation Method	Default Implementation Should Suffice if	Example
Gets dimensions of output ports. The associated method is <code>getOutputSize</code> .	<code>getOutputSizeImpl</code>	<ul style="list-style-type: none"> • Only one input • Only one output • An input size that is the same as the output size 	<ul style="list-style-type: none"> • Analysis and Plot block in “Illustration of Law of Large Numbers”
Gets data types of output ports. The associated method is <code>getOutputDataType</code> .	<code>getOutputDataTypeImpl</code>	<ul style="list-style-type: none"> • Only one input • Only one output • Output data type always the same as the input data type 	<ul style="list-style-type: none"> • Analysis and Plot block in “Illustration of Law of Large Numbers”

Description	Propagation Method	Default Implementation Should Suffice if	Example
Indicates whether output ports are complex or not. The associated method is <code>isOutputComplex</code> .	<code>isOutputComplexImpl</code>	<ul style="list-style-type: none"> • Only one input • Only one output • Output complexity always the same as th input complexity 	<ul style="list-style-type: none"> • Analysis and Plot block in “Illustration of Law of Large Numbers”
Whether output ports are fixed size. Share Data with Other Blocks

In this section...

“Data Sharing with the MATLAB System Block” on page 46-29

“Choose How to Store Shared Data” on page 46-30

“How to Use Data Store Memory Blocks for the MATLAB System Block” on page 46-30

“How to Set Up Simulink.Signal Objects” on page 46-32

“Using Data Store Diagnostics to Detect Memory Access Issues” on page 46-34

“Limitations of Using Shared Data in MATLAB System Blocks” on page 46-34

“Use Shared Data with P-Coded System Objects” on page 46-34

Share data between MATLAB System and other blocks using the `global` keyword and the Data Store Memory block or `Simulink.Signal` object. You might need to use global data with a MATLAB System block if:

- You have an existing model that uses a large amount of global data, you are adding a MATLAB System block to this model, and you want to avoid cluttering your model with additional inputs and outputs.
- You want to scope the visibility of data to parts of the model.

Data Sharing with the MATLAB System Block

In Simulink, you store global data using data store memory. You implement data store memory using either Data Store Memory blocks or `Simulink.Signal` objects. How you store global data depends on the number and scope of your global variables.

Scoping Rules for Shared Data in MATLAB System Blocks

The MATLAB System block uses these scoping rules:

- If you use the same name for both Data Store Memory block and `Simulink.Signal` object, Data Store Memory block scopes the data to the model.
- A global variable resolves hierarchically to the closest Data Store Memory block with the same name in the model. The same global variable appearing in two different MATLAB System blocks might resolve to different Data Store Memory blocks depending on the hierarchy of the model. You can use this ability to scope the visibility of data to a subsystem.

Using Shared Data in MATLAB System Blocks

MATLAB System blocks support data store memory for:

- MATLAB structures (buses)
- Enumerated data types

How to Use Data Sharing with the MATLAB System Block

To use shared data in your MATLAB System block:

- 1 Declare a global variable in the System object that you associate with the MATLAB System block.

You can use the `global` keyword in these methods of the System object:

- `stepImpl`
 - `outputImpl`
 - `updateImpl`
- 2 Add a Data Store Memory block or `Simulink.Signal` object that has the same name as the global variable in the System object.

To share data between referenced models using the `Simulink.Signal` object, define the `Simulink.Signal` object in the base workspace and use the same global variable name as in the MATLAB System block.

Choose How to Store Shared Data

You can use Data Store Memory blocks or `Simulink.Signal` objects to store shared data.

Type of Data	Global Data Storage Method	Related Links
A small number of global variables in a single model that does not use model reference.	Data Store Memory blocks. Note Using Data Store Memory blocks scopes the data to the model.	"How to Use Data Store Memory Blocks for the MATLAB System Block" on page 46-30
A large number of global variables in a single model that does not use model reference.	<code>Simulink.Signal</code> objects defined in the model workspace. <code>Simulink.Signal</code> objects offer these advantages: <ul style="list-style-type: none"> • You do not have to add numerous Data Store Memory blocks to your model. • You can load the <code>Simulink.Signal</code> objects in from a MAT-file. 	"How to Set Up <code>Simulink.Signal</code> Objects" on page 46-32
Data shared between multiple models (including referenced models).	<code>Simulink.Signal</code> objects defined in the base workspace Note If you use Data Store Memory blocks as well as <code>Simulink.Signal</code> , note that using Data Store Memory blocks scopes the data to the model.	"How to Set Up <code>Simulink.Signal</code> Objects" on page 46-32

How to Use Data Store Memory Blocks for the MATLAB System Block

- 1 Declare a global keyword in the System object methods that support globals. For example:
- ```
global A;
```

- 2 Add a MATLAB System block to your model.
- 3 Double-click the MATLAB System block and associate the System object.
- 4 Add a Data Store Memory block to your model and set:
  - a **Data store name** to match the name of the global variable in your MATLAB System block code.
  - b **Data type** to an explicit data type.

The data type cannot be auto.

- c **Signal type**.
- d **Initial value**.

The initial value of the Data Store Memory block cannot be unspecified.

### Use Data Store Memory with the MATLAB System Block

This model demonstrates how a MATLAB System block uses the global data stored in Data Store Memory block B. The MATLAB System block is associated with the `globalSysObjMatrix1` System object. To see the completed model, open the `ex_globalsys_objmatrix1` model.

- 1 Drag these blocks into a new model:
  - MATLAB System
  - Data Store Memory
  - Display
- 2 Create a System object to associate with the MATLAB System block. To start, from the MATLAB System block, create a Basic System object template file.
- 3 In MATLAB Editor, create a System object with code like the following. Save the System object as `globalSysObjMatrix1.m`. The System object modifies B each time it executes.

```

classdef globalSysObjMatrix1 < matlab.System
 % Global/DSM support scalar example

 methods(Access = protected)
 function setupImpl(obj)
 % Perform one-time calculations, such as computing constants
 end

 function y = stepImpl(obj)
 global B;
 B(:,1)= B(:,1)+100;
 y = B;
 end
 end
end
end

```

- 4 Double-click the MATLAB System block and associate the `globalSysObjMatrix1` System object with the block.
- 5 In the model, double-click the Data Store Memory block `B`.
- 6 In the Signal Attributes tab, enter an initial value, for example:  
[74 75 5 1;22 23 24 32;33 44 55 22]
- 7 Simulate the model.

The MATLAB System block reads the initial value of global data stored in `B` and updates the value of `B` each time it executes. This model executes for five time steps.

- 8 Save and close your model.

## How to Set Up Simulink.Signal Objects

Create a `Simulink.Signal` object in the model workspace.

---

**Tip** Create a `Simulink.Signal` object in the base workspace to use the global data with multiple models.

---

- 1 In the Model Explorer, navigate to `model_name` > **Model Workspace** in the **Model Hierarchy** pane.

Select **Add > Simulink Signal**.

- 2 Ensure that these settings apply to the `Simulink.Signal` object:

- a Set **Data type** to an explicit data type.

The data type cannot be `auto`.

- b Set **Dimensions** to be fully specified.

The signal dimensions cannot be `-1` or `inherited`.

- c Set the **Complexity**.

- d Specify an **Initial value**.

The initial value of the signal cannot be unspecified.

- e Set **Name** to the name of the global variable.

## Use a Simulink.Signal Object with a MATLAB System Block

This simple model demonstrates how a MATLAB System block uses a `Simulink.Signal` with signal `B`. The MATLAB System block is associated with the `globalSysObjScalar` System object. To see the completed model, open the `ex_globalsys_simulink_signal_share` model.

- 1 Drag these blocks into a new model:
  - MATLAB System
  - Display
- 2 Create a System object to associate with the MATLAB System block. To start, from the MATLAB System block, create a Basic System object template file.
- 3 In MATLAB Editor, create a System object. Save the System object as `globalSysObjScalar.m`. The System object modifies `B` each time it executes.

```

classdef globalSysObjScalar < matlab.System
 % Global/DSM support scalar example

 methods(Access = protected)
 function setupImpl(obj)
 % Perform one-time calculations, such as computing constants
 end

 function y = stepImpl(obj)
 global B;
 B = B+100;
 y = B;
 end
 end
end

```

- 4 Double-click the MATLAB System block and associate the `globalSysObjScalar` System object with the block.
- 5 From the model, on the **Modeling** tab, click **Model Explorer**.
- 6 In the left pane of the Model Explorer, select the model workspace for this model.

The **Contents** pane displays the data in the model workspace.

- 7 In the Model Explorer, in the **Model Hierarchy** pane, navigate to `model_name > Model Workspace`. In the **Contents** pane, set **Name** to `B`.
- 8 Navigate back to `model_name > Model Workspace`.
  - Select **Add > Simulink Signal**.
  - Make these settings for the `Simulink.Signal` object:

| Attribute | Value  |
|-----------|--------|
| Data type | double |

| Attribute     | Value |
|---------------|-------|
| Complexity    | real  |
| Dimensions    | 1     |
| Initial value | 25    |

- 9 Simulate the model.

The MATLAB System block reads the initial value of global data stored in B and updates the value of B each time it executes. The model runs for five time steps.

- 10 Save and close your model.

## Using Data Store Diagnostics to Detect Memory Access Issues

You can configure your model to provide run-time and compile-time diagnostics to avoid problems with data stores. Diagnostics are available in the Configuration Parameters dialog box and the Parameters dialog box for the Data Store Memory block. These diagnostics are available for Data Store Memory blocks only, not for `Simulink.Signal` objects. For more information on using data store diagnostics, see “Data Store Diagnostics” on page 74-3.

## Limitations of Using Shared Data in MATLAB System Blocks

The MATLAB System block does not support data store memory for variable-sized data

## Use Shared Data with P-Coded System Objects

If the System object is P-code, you must implement the `getGlobalNamesImpl` method to provide the global variable names you use in the System object. For example:

```
classdef GlobalSysObjMatrix < matlab.System
 % Matrix DSM support: Increment first row by 1 at each time step
 methods (Access = protected)
 function y = stepImpl(obj)
 global B;
 B(1,:) = B(1,:)+1;
 y = B;
 end

 function globalNames = getGlobalNamesImpl(~)
 globalNames = {'B'};
 end
 end
end
```

## Troubleshoot System Objects in Simulink

### In this section...

“Class Not Found” on page 46-36  
 “Error Invoking Object Method” on page 46-36  
 “Performance” on page 46-36

### Class Not Found

The MATLAB System block **System object name** parameter requires that you enter the full path to the System object class. In addition:

- Check that the System object class is on your MATLAB path.
- Check capitalization to make sure it matches.
- Check that the class name is a supported System object.
- Do not include the file extension.

### Error Invoking Object Method

The MATLAB System block supports only System objects written in the MATLAB language. If the software can identify an alternative block, it suggests that block in the error message, for example:

This message indicates that there is an existing dedicated and optimized block that you should use.

### Performance

For fastest performance, set the block **Simulate using** parameter to **Code generation**. This setting allows the MATLAB System block to run as fast as it can. The parameter is set to this value by default.

This setting causes a slower startup time, as the software generates C code and creates a MEX-file from it. However, after code generation, later simulations have better performance. When the block uses generated code to simulate, performance is typically better than simulation without generated code.

In some cases, the implementation of your System object does not allow you to generate code, which requires you to set **Simulate using** to **Interpreted execution**. For example, your System object can require MATLAB functions beyond the subset supported for code generation. In this case, use

propagation methods to specify the block input and output port information. The MATLAB System block then propagates this signal attribution information.

- “Add and Implement Propagation Methods” on page 46-27

## Customize MATLAB System Block Dialog

This example shows you how to customize the block dialog for a MATLAB System block.

### System objects

System objects allow you to implement algorithms using MATLAB. System objects are a specialized kind of MATLAB object, designed specifically for implementing and simulating dynamic systems with inputs that change over time.

After you define a System object, you can include it in a Simulink model using a MATLAB System block.

### Model Description

This example contains a MATLAB System block that implements the System object `CustomDialog`. Use the MATLAB System block dialog box to modify properties of the System object. This example shows how to customize the prompt for a property and how to create check boxes, lists, groups, tabs, and buttons in the dialog box.

### Customizing the Block Dialog

Double Click on MATLAB System Block to Open Dialog

Copyright 2018 The MathWorks, Inc.

### System Object Class Definition

You can access MATLAB source code used by the MATLAB System block by clicking the "Source Code" hyperlink from the block dialog. The System object `CustomDialog` implements the `getPropertyGroupsImpl` and `getHeaderImpl` methods that are used to customize the appearance of the block dialog and organize the System object properties.

- 1 `PropertyDefault` - Property with no customization
- 2 `PropertyCustomPrompt` - Property with custom prompt
- 3 `PropertyEnum` - Enumeration property with a finite list of options
- 4 `PropertyLogical` - Property validation with `logical` to create check box
- 5 `PropertyInDifferentTab` - Property shown on a different tab of the dialog box

The `getPropertyGroupsImpl` method uses the `matlab.system.display.Section` and `matlab.system.display.SectionGroup` classes to create property sections and tabs in the dialog box. `getPropertyGroupsImpl` also creates a button in the "Group 2" section which calls the `visualize` method of the System object.

```
classdef CustomDialog < matlab.System
% CustomDialog Customize System block dialog

 properties
 PropertyDefault = 10
 % For PropertyDefault, with no comment above, property name is used
```

```
% as prompt

% PropertyCustomPrompt Use comment above property for custom prompt
PropertyCustomPrompt = 20

% PropertyEnum Use enumeration to limit values to finite list
PropertyEnum (1,1) ColorValues = ColorValues.blue

% PropertyInDifferentTab Use getPropertyGroupsImpl to create tabs
PropertyInDifferentTab = 30
end

properties(Nontunable)
% PropertyLogical Use logical property validation to create a checkbox
% Logical properties need to be Nontunable for use in Simulink
PropertyLogical (1,1) logical = true
end

methods(Access = protected)
function y = stepImpl(~, u)
 y = u;
end
end

methods (Static, Access = protected)
function groups = getPropertyGroupsImpl
% Use getPropertyGroupsImpl to create property sections in the
% dialog. Create two sections with titles "Group1" and
% "Group2". "Group1" contains PropertyDefault and
% PropertyCustomPrompt. "Group2" contains PropertyEnum,
% PropertyLogical, and a Visualize button.
 group1 = matlab.system.display.Section(...
 'Title', 'Group 1', ...
 'PropertyList', {'PropertyDefault', 'PropertyCustomPrompt'});

 group2 = matlab.system.display.Section(...
 'Title', 'Group 2', ...
 'PropertyList', {'PropertyEnum', 'PropertyLogical'});

% Add a button that calls back into the visualize method
 group2.Actions = matlab.system.display.Action(@(actionData,obj)...
 visualize(obj,actionData), 'Label', 'Visualize');

 tab1 = matlab.system.display.SectionGroup(...
 'Title', 'Tab 1', ...
 'Sections', [group1, group2]);

 tab2 = matlab.system.display.SectionGroup(...
 'Title', 'Tab 2', ...
 'PropertyList', {'PropertyInDifferentTab'});

 groups = [tab1, tab2];
end

function header = getHeaderImpl
 header = matlab.system.display.Header(mfilename('class'), ...
 'Title', 'AlternativeTitle', ...
 'Text', 'Customize dialog header using getHeaderImpl method.');
```

```
 end
 end

 methods
 function visualize(obj, actionData)
 % Use actionData to store custom data
 f = actionData.UserData;
 if isempty(f) || ~ishandle(f)
 f = figure;
 actionData.UserData = f;
 else
 figure(f); % Make figure current
 end

 d = 1:obj.PropertyCustomPrompt;
 plot(d);
 end
 end
end
```

## Break Algebraic Loops

This example shows how to create a MATLAB System block that can break an algebraic loop in the model.

### System objects

System objects allow you to implement algorithms using MATLAB. System objects are a specialized kind of MATLAB object, designed specifically for implementing and simulating dynamic systems with inputs that change over time.

After you define a System object, you can include it in a Simulink model using a MATLAB System block.

### Model Description

This example has a MATLAB System block that is used in a feedback loop in the model. The feedback loop is used to accumulate input values and the result is displayed in the Scope block. The feedback in the model creates an algebraic loop. To solve the algebraic loop, Simulink needs a block that has nondirect feedthrough. Blocks that have nondirect feedthrough are used in the feedback loops to break algebraic loops. This block can produce an output in the current time step without receiving the input first. In this example, MATLAB System block has nondirect feedthrough.

### Breaking Algebraic Loops

Copyright 2018 The MathWorks, Inc.

The MATLAB System block uses the System object `UnitDelayNondirect` that implements a unit delay. The output shows how the feedback loop accumulates the input signal values.

### System Object Class Definition

You can access MATLAB source code used by the MATLAB System block by clicking the "Source Code" hyperlink from the block dialog. The `UnitDelayNondirect` System object implements the `resetImpl`, `outputImpl`, and `updateImpl` methods. The System object has one property called `State`.

- `resetImpl` initializes the `State` property to 0.
- `outputImpl` returns the value stored in `State`. This System object has nondirect feedthrough because `outputImpl` does not use any inputs.
- `updateImpl` uses the inputs to update `State`.

```
classdef UnitDelayNondirect < matlab.System
% UnitDelayNondirect Delay input by one time step

properties(DiscreteState)
```

```
 State
 end

 methods(Access = protected)
 function resetImpl(obj)
 obj.State = 0; % Initialize states
 end
 function y = outputImpl(obj, ~)
 y = obj.State; % Output current state
 % Input is not used in this method
 end
 function updateImpl(obj,u)
 obj.State = u; % Update state with input
 end
 end
end
```

## Customize MATLAB System Block Appearance

This example shows how to customize the appearance of the MATLAB System block.

### System objects

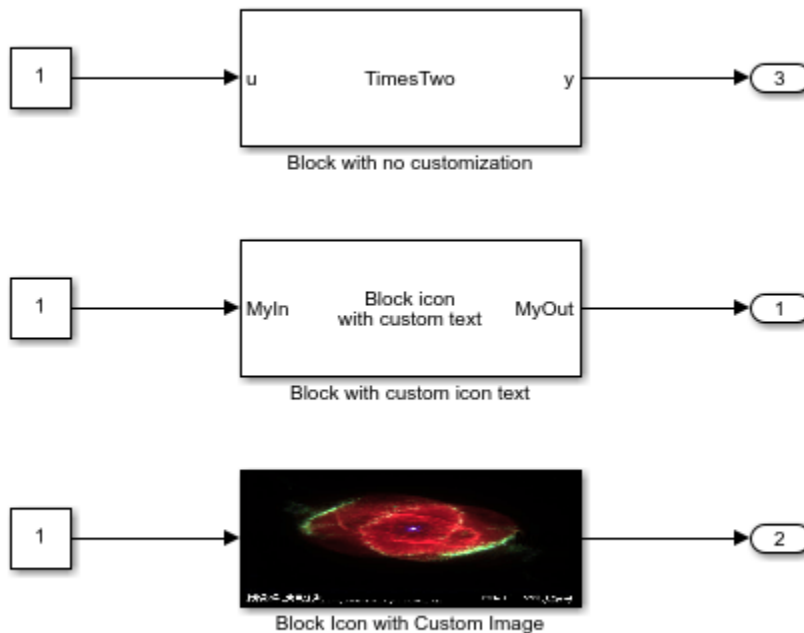

System objects allow you to implement algorithms using MATLAB. System objects are a specialized kind of MATLAB object, designed specifically for implementing and simulating dynamic systems with inputs that change over time.

After you define a System object, you can include it in a Simulink model using a MATLAB System block.

### Model Description

There are three MATLAB System blocks in this model. The first block does not have any customization for block appearance and by default shows the name of the System object on the block. The port labels for this block are obtained from the name of the arguments in the `stepImpl` method of the System object. Second block shows custom text and custom port labels on the block icon. The third block shows a custom block icon image.

### Customizing the Block Icon and Ports

Copyright 2018 The MathWorks, Inc.

### System Object Class Definition

You can access MATLAB source code used by the MATLAB System block by clicking the "Source Code" hyperlink from the block dialog. The `TimesTwo` System object used in the first block has no customization and implements only the `stepImpl` method. The `CustomBlockIconExample` System object implements the following methods for customizing block appearance.

- `getInputNamesImpl` - Customize input port labels
- `getOutputNamesImpl` - Customize output port labels
- `getIconImpl` - Display text or an image on the block

The System object has a `DisplayImage` property to choose between text and image for display on the block.

### TimesTwo System object

```
classdef TimesTwo < matlab.System
%TimesTwo Multiply input by 2
% obj = TimesTwo returns a System object, obj, that
% multiplies its input by two.

 methods(Access = protected)
 function y = stepImpl(~, u)
 y = 2 * u;
 end
 end
end
```

### CustomBlockIconExample System object

```
classdef CustomBlockIconExample < matlab.System
% SystemObjectBlockIconExample Customize Block Icon

 properties(Nontunable)
 % DisplayImage Select to display image as block icon
 DisplayImage (1,1) logical = false
 end

 methods(Access = protected)
 function y = stepImpl(~, u)
 y = u;
 end
 function inputName = getInputNamesImpl(~)
 inputName = "MyIn";
 end
 function outputName = getOutputNamesImpl(~)
 outputName = "MyOut";
 end
 function icon = getIconImpl(obj)
 % Return text or image to be displayed on the block icon
 % Use array of strings to display multiple lines of text
 if obj.DisplayImage
 % Display image
 icon = matlab.system.display.Icon('slexngc6543aPix.jpg');
 else
 % Display text
 icon = ["Block icon", "with custom text"];
 end
 end
 end
end
```

```
 end
end
```

## Implement a Simple Algorithm

### Introduction

This example shows how to use a simple System object in Simulink with the MATLAB System block.

### System objects

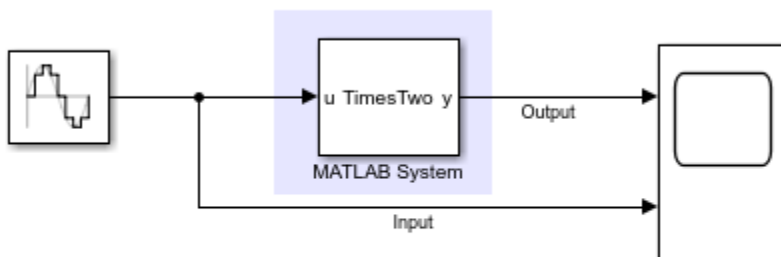

System objects allow you to implement algorithms using MATLAB. System objects are a specialized kind of MATLAB object, designed specifically for implementing and simulating dynamic systems with inputs that change over time.

After you define a System object, you can include it in a Simulink model using a MATLAB System block.

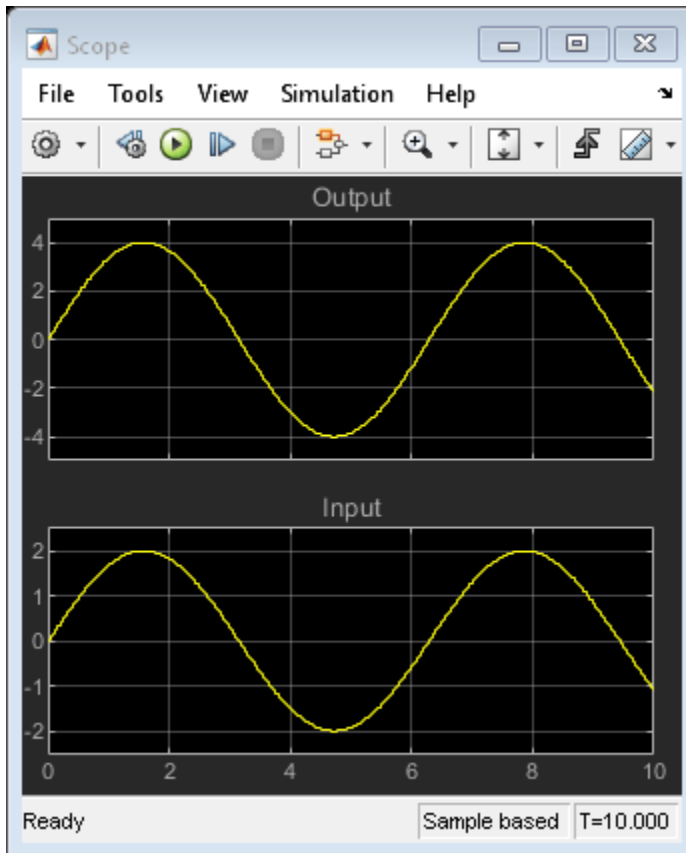

### Model Description

This model has a MATLAB System block using the System object `TimesTwo` that multiplies the input by two. The input to the MATLAB System block is provided by the Sine Wave block. The output along with the input is displayed in the Scope block. When you run the model, you can see that the input to MATLAB System block is multiplied by two in the Scope block.

### Basic MATLAB System Block

Copyright 2018 The MathWorks, Inc.

### System Object Class Definition

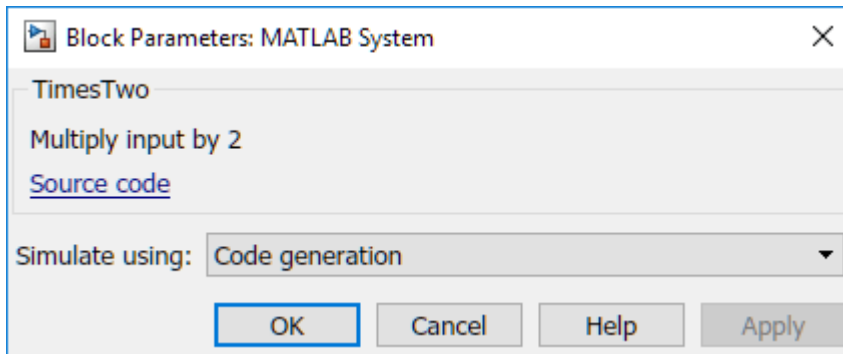

You can access MATLAB source code used by the MATLAB System block by clicking the "Source Code" hyperlink from the block dialog. The System object implements only the `stepImpl` method. The algorithm does not need any properties or additional methods.

```
classdef TimesTwo < matlab.System
%TimesTwo Multiply input by 2
% obj = TimesTwo returns a System object, obj, that
% multiplies its input by two.

 methods(Access = protected)
 function y = stepImpl(~, u)
 y = 2 * u;
 end
 end
end
end
```

### MATLAB System Block Icon and Dialog

The MATLAB System block displays the name of the System object `TimesTwo` on the block and uses the input and output variable names from `stepImpl` method of the `TimesTwo` class as port labels. If you open the MATLAB System block dialog by double clicking on the block, the dialog shows title as `TimesTwo` and a description as "Multiply input by 2" as shown below. The title comes from the name of the System object used and the description is created from the class help summary in the System object.

## Specify Output Characteristics of MATLAB System Block

This example shows how to specify output size, data type and complexity of a MATLAB System block.

### System objects

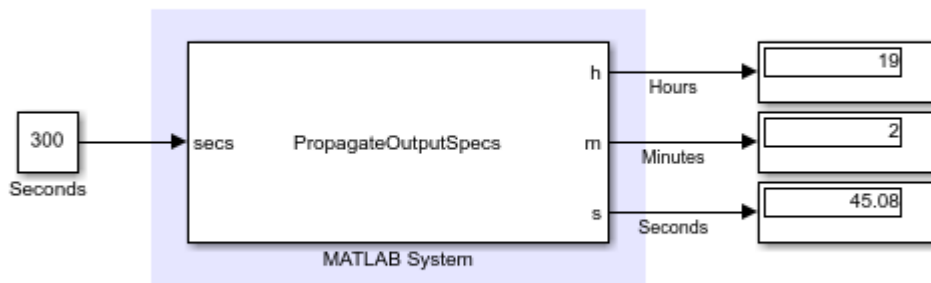

System objects allow you to implement algorithms using MATLAB. System objects are a specialized kind of MATLAB object, designed specifically for implementing and simulating dynamic systems with inputs that change over time.

After you define a System object, you can include it in a Simulink model using a MATLAB System block.

### Model Description

This example has a MATLAB System block that adds input number of seconds to the current time and produces the resulting hours, minutes and seconds as outputs. The output values from each output port are displayed in the Display blocks.

### Propagating Output Data Type

Copyright 2018 The MathWorks, Inc.

This example, shows how to specify output size, data type and complexity of a System object. You specify the output properties when MATLAB System block cannot infer them automatically. The MATLAB System block uses the System object `PropagateOutputSpecs` that implements methods to propagate input data type, size and complexity.

### System Object Class Definition

You can access MATLAB source code used by the MATLAB System block by clicking the "Source code" hyperlink from the block dialog. The System object `PropagateOutputSpecs` implements the `stepImpl` method that adds the input value in seconds to current time and outputs the resulting hours, minutes and seconds. The `stepImpl` method uses `datetime` function to calculate its output. Since `datetime` function is not supported for code generation, MATLAB System block cannot infer the output specifications automatically. The System object implements the following methods to specify output properties:

- `getOutputSizeImpl` - Specify output size

- `getOutputDataTypeImpl` - Specify output data type
- `isOutputComplexImpl` - Specify output complexity
- `isOutputFixedSizeImpl` - Specify whether output can be variable-size

```
classdef PropagateOutputSpecs < matlab.System
% PropagateOutputSpecs Propagation in Simulink

 methods(Access = protected)
 function [h, m, s] = stepImpl(~, secs)
 % Add input hours, minutes and seconds to current time
 d = datetime;
 d = d + seconds(secs);
 h = hour(d);
 m = minute(d);
 s = second(d);
 end

 function [o1, o2, o3] = getOutputSizeImpl(obj)
 % Return size for output port to be same as input port
 inSize = propagatedInputSize(obj, 1);
 o1 = inSize;
 o2 = inSize;
 o3 = inSize;
 end

 function [o1, o2, o3] = getOutputDataTypeImpl(obj)
 % Return data type for output port to be same as input port
 inType = propagatedInputDataType(obj, 1);
 o1 = inType;
 o2 = inType;
 o3 = inType;
 end

 function [o1, o2, o3] = isOutputComplexImpl(~)
 % Return output port complexity to be real
 o1 = false;
 o2 = false;
 o3 = false;
 end

 function [o1, o2, o3] = isOutputFixedSizeImpl(~)
 % Return true for each output port with fixed size
 o1 = true;
 o2 = true;
 o3 = true;
 end
 end
end
```

## Customize System Block Appearance

### In this section...

“Specify Input and Output Names” on page 46-54

“Add Text to Block Icon” on page 46-55

“Add Image to Block Icon” on page 46-56

### Specify Input and Output Names

Specify the names of the input and output ports of a System object-based block implemented using a MATLAB System block.

Use `getInputNamesImpl` and `getOutputNamesImpl` to specify the names of the input port as “source data” and the output port as “count.”

If you do not specify the `getInputNamesImpl` and `getOutputNamesImpl` methods, the object uses the `stepImpl` method input and output variable names for the input and output port names, respectively. If the `stepImpl` method uses *varargin* and *varargout* instead of variable names, the port names default to empty character vectors.

```
methods (Access = protected)
 function inputName = getInputNamesImpl(~)
 inputName = 'source data';
 end

 function outputName = getOutputNamesImpl(~)
 outputName = 'count';
 end
end
```

### Complete Class Definition with Named Inputs and Outputs

```
classdef MyCounter < matlab.System

 % MyCounter Count values above a threshold

 properties
 Threshold = 1
 end
 properties (DiscreteState)
 Count
 end

 methods
 function obj = MyCounter(varargin)
 setProperties (obj,nargin,varargin{:});
 end
 end

 methods (Access = protected)
 function setupImpl(obj)
 obj.Count = 0;
 end
 function resetImpl(obj)
```

```

 obj.Count = 0;
 end
 function y = stepImpl(obj,u)
 if (u > obj.Threshold)
 obj.Count = obj.Count + 1;
 end
 y = obj.Count;
 end
 function inputName = getInputNamesImpl(~)
 inputName = 'source data';
 end
 function outputName = getOutputNamesImpl(~)
 outputName = 'count';
 end
end
end
end

```

## Add Text to Block Icon

Add text to the block icon of a System object-based block implemented using a MATLAB System block.

- 1 Subclass from custom icon class.

```
classdef MyCounter < matlab.System & matlab.system.mixin.CustomIcon
```

- 2 Use `getIconImpl` to specify the block icon as `New Counter` with a line break between the two words.

```

methods (Access = protected)
 function icon = getIconImpl(~)
 icon = {'New', 'Counter'};
 end
end
end

```

### Complete Class Definition File with Defined Icon

```

classdef MyCounter < matlab.System & ...
 matlab.system.mixin.CustomIcon

 % MyCounter Count values above a threshold

 properties
 Threshold = 1
 end
 properties (DiscreteState)
 Count
 end

 methods
 function obj = MyCounter(varargin)
 setProperties(obj, nargin, varargin{:});
 end
 end

 methods (Access = protected)
 function setupImpl(obj)
 obj.Count = 0;
 end
 end
end

```

```

end
function resetImpl(obj)
 obj.Count = 0;
end
function y = stepImpl(obj,u)
 if (u > obj.Threshold)
 obj.Count = obj.Count + 1;
 end
 y = obj.Count;
end
function icon = getIconImpl(~)
 icon = {'New', 'Counter'};
end
end
end
end

```

## Add Image to Block Icon

Define an image on the block icon of a System object-based block implemented using a MATLAB System block.

- 1 Subclass from custom icon class.

```
classdef MyCounter < matlab.System & matlab.system.mixin.CustomIcon
```

- 2 Use `getIconImpl` method to call the `matlab.system.display.Icon` class and specify the image.

```

methods (Access = protected)
 function icon = getIconImpl(~)
 icon = matlab.system.display.Icon('counter.png');
 end
end
end

```

## Complete Class Definition File with Icon Image

```

classdef MyCounter < matlab.System & ...
 matlab.system.mixin.CustomIcon

 % MyCounter Count values above a threshold

 properties
 Threshold = 1
 end
 properties (DiscreteState)
 Count
 end

 methods
 function obj = MyCounter(varargin)
 setProperties(obj,nargin,varargin{:});
 end
 end

 methods (Access = protected)
 function setupImpl(obj)
 obj.Count = 0;
 end
 end
end

```

```
function resetImpl(obj)
 obj.Count = 0;
end
function y = stepImpl(obj,u)
 if (u > obj.Threshold)
 obj.Count = obj.Count + 1;
 end
 y = obj.Count;
end
function icon = getIconImpl(~)
 icon = matlab.system.display.Icon('counter.png');
end
end
end
```

## Customize System Block Dialog Box

### In this section...

“Define Block Dialog Tabs, Sections, and Order of Properties” on page 46-58

“Define Property Sections” on page 46-61

“Add Header Description” on page 46-63

“Control Simulation Type in MATLAB System Block” on page 46-64

“Add Custom Button to MATLAB System Block” on page 46-65

You can customize the dialog box for the MATLAB System block by adding properties and methods in the corresponding System object. You can add tabs, organized properties into groups and sections, add block descriptions, simulation type control, and add custom buttons.

### Define Block Dialog Tabs, Sections, and Order of Properties

This example customizes the block dialog box for the `MultipleGroupsWithTabs` MATLAB System block by specifying property display names and modifying the `getPropertyGroupImpl` method.

#### Change Property Label

To change the property label that appears on the dialog box, add comments before each property in this format `%PropertyName Block Dialog Label` with no space between the comment and the property name. For example, to display the `StartValue` property as **Start Value**, specify:

```
%StartValue Start Value
StartValue = 0
```

The `MultipleGroupsWithTabs` System object in this example relabels each property for display in the MATLAB System block dialog.

#### Organize Dialog Box

The `MultipleGroupsWithTabs` System object class defines a `getPropertyGroupsImpl` method. Inside the `getPropertyGroupsImpl` method, this example defines two tabs (section groups) and three parameter groupings (sections).

```
classdef MultipleGroupsWithTabs < matlab.System
 % MultipleGroupsWithTabs Customize block dialog with multiple tabs and parameter groups.

 % Public, tunable properties
 properties
 %StartValue Start Value
 StartValue = 0

 %EndValue End Value
 EndValue = 10

 Threshold = 1

 %BlockLimit Limit
 BlockLimit = 55
 end
```

```

% Public Nontunable
properties(Nontunable)
 %IC1 First initial condition
 IC1 = 0

 %IC2 Second initial condition
 IC2 = 10

 %IC3 Third initial condition
 IC3 = 100

 %UseThreshold Use threshold
 UseThreshold (1,1) logical = true
end

methods (Static, Access = protected)
 function groups = getPropertyGroupsImpl
 % Section to always display above any tabs.
 alwaysSection = matlab.system.display.Section(...
 'Title', '', 'PropertyList', {'BlockLimit'});

 % Group with no sections
 initTab = matlab.system.display.SectionGroup(...
 'Title', 'Initial conditions', ...
 'PropertyList', {'IC1', 'IC2', 'IC3'});

 % Section for the value parameters
 valueSection = matlab.system.display.Section(...
 'Title', 'Value parameters', ...
 'PropertyList', {'StartValue', 'EndValue'});

 % Section for the threshold parameters
 thresholdSection = matlab.system.display.Section(...
 'Title', 'Threshold parameters', ...
 'PropertyList', {'Threshold', 'UseThreshold'});

 % Group with two sections: the valueSection and thresholdSection sections
 mainTab = matlab.system.display.SectionGroup(...
 'Title', 'Main', ...
 'Sections', [valueSection, thresholdSection]);

 % Return an array with the group-less section, the group with
 % two sections, and the group with no sections.
 groups = [alwaysSection, mainTab, initTab];
 end
end
end

```

### Resulting Dialog Box

```

load_system('ShowSystemBlockDialog')
open_system('ShowSystemBlockDialog/MATLAB System')

```

## Define Property Sections

This example customizes the block dialog box for a MATLAB System block by specifying property display names and modifying the `getPropertyGroupImpl` method. This customization is demonstrated with the System object `AddPropertySections`.

### Change Property Labels

To change the property label that appears on the dialog box, add comments before each property in this format `%PropertyName Block Dialog Label` with no space between the percent sign and the property name. For example, to display the `UseAlpha` property as **Use alpha**, specify:

```
%UseAlpha Use alpha
UseAlpha = 0
```

The `AddPropertySections` System object included with this example relabels properties for display in the MATLAB System block dialog.

### Organize Dialog Box

To organize the properties on the dialog box, the `AddPropertySections` System object class defines a `getPropertyGroupsImpl` method. Inside the `getPropertyGroupsImpl` method, this example defines two sections, each with two properties.

```

classdef AddPropertySections < matlab.System
 % AddPropertySections Customized dialog with two parameter sections

 % Public, tunable properties
 properties
 %NumberOfShapes Number of shapes
 NumberOfShapes = 10

 Alpha = 0.75
 end

 % Public, nontunable properties
 properties(Nontunable)
 Coloring (1, 1) {mustBeMember(Coloring,["red","blue","green"])} = "red"

 %UseAlpha Use alpha
 UseAlpha (1,1) logical = false
 end

 methods (Static, Access = protected)
 function groups = getPropertyGroupsImpl
 % Section for the value parameters
 valueSection = matlab.system.display.Section(...
 'Title', 'Shape parameters',...
 'PropertyList', {'NumberOfShapes', 'Coloring'});

 % Section for the threshold parameters
 shadingSection = matlab.system.display.Section(...
 'Title', 'Shading parameters',...
 'PropertyList', {'UseAlpha', 'Alpha'});

 % Return an array with the two sections.
 groups = [valueSection, shadingSection];
 end
 end
end
end

```

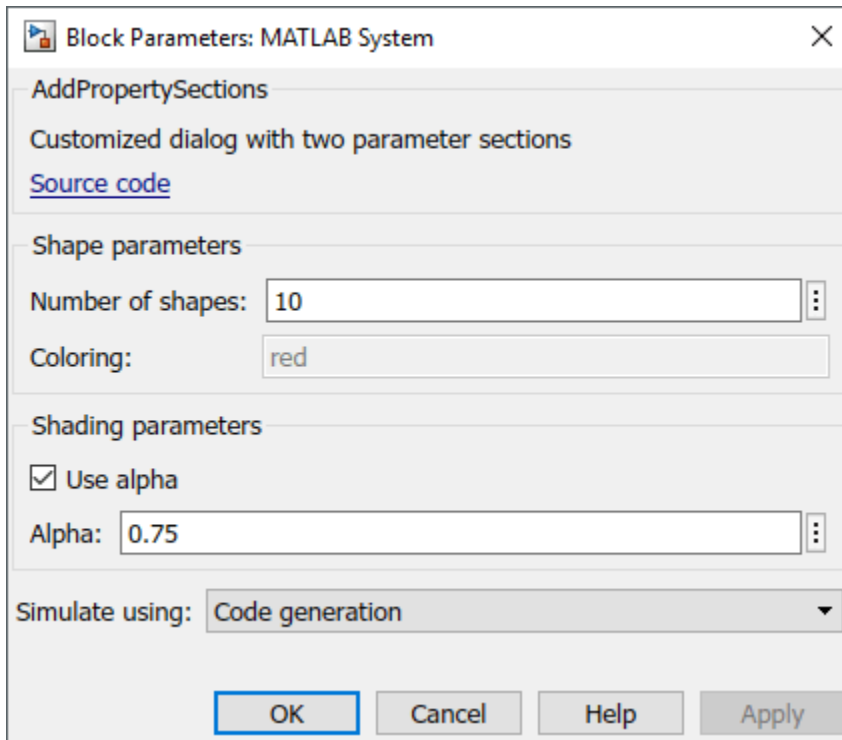

### Resulting Dialog Box

```

load_system('CustomSystemBlockDialog')
open_system('CustomSystemBlockDialog/MATLAB System')

```

## Add Header Description

Add a header panel to a MATLAB System block by adding the `getHeaderImpl` method to your System object.

Use `getHeaderImpl` to specify a panel title and text for the `MyCounter` System object. If you do not specify the `getHeaderImpl`, the block does not display any title or text for the panel.

As for all `Impl` methods, set the `getHeaderImpl` method access to `protected` because the method is only called internally.

```
methods (Static, Access = protected)
 function header = getHeaderImpl
 header = matlab.system.display.Header('MyCounter', ...
 'Title', 'My Enhanced Counter');
 end
end
```

## Complete Class Definition

```
classdef MyCounter < matlab.System

 % MyCounter Count values

 properties
 Threshold = 1
 end
 properties (DiscreteState)
 Count
 end
end
```

```

methods (Static, Access = protected)
 function header = getHeaderImpl
 header = matlab.system.display.Header('MyCounter',...
 'Title','My Enhanced Counter',...
 'Text', 'This counter is an enhanced version. ');
 end
end

methods (Access = protected)
 function setupImpl(obj,u)
 obj.Count = 0;
 end
 function y = stepImpl(obj,u)
 if (u > obj.Threshold)
 obj.Count = obj.Count + 1;
 end
 y = obj.Count;
 end
 function resetImpl(obj)
 obj.Count = 0;
 end
end
end

```

## Control Simulation Type in MATLAB System Block

Specify a simulation type and whether the **Simulate using** parameter appears on the Simulink MATLAB System block dialog box. The simulation options are 'Code generation' and 'Interpreted mode'.

If you do not include the `getSimulateUsingImpl` method in your class definition file, the System object allows both simulation modes and defaults to 'Code generation'. If you do not include the `showSimulateUsingImpl` method, the **Simulate using** parameter appears on the block dialog box.

You must set the `getSimulateUsingImpl` and `showSimulateUsingImpl` methods to static and the access for these methods to protected.

Use `getSimulateUsingImpl` to specify that only interpreted execution is allowed for the System object.

```

methods(Static,Access = protected)
 function simMode = getSimulateUsingImpl
 simMode = 'Interpreted execution';
 end
end

```

### Complete Class Definition

```

classdef PlotRamp < matlab.System
 % Display a button to launch a plot figure.

 properties (Nontunable)
 RampLimit = 10;
 end

 methods(Static, Access=protected)

```

```

function group = getPropertyGroupsImpl
 group = matlab.system.display.Section(mfilename('class'));
 group.Actions = matlab.system.display.Action(@(~,obj)...
 visualize(obj),'Label','Visualize');
end

function simMode = getSimulateUsingImpl
 simMode = 'Interpreted execution';
end

methods
function obj = ActionDemo(varargin)
 setProperties(obj,nargin,varargin{:});
end

function visualize(obj)
 figure;
 d = 1:obj.RampLimit;
 plot(d);
end
methods(Static,Access = protected)
end
end
end

```

The resulting dialog box with the **Simulate using** parameter:

## Add Custom Button to MATLAB System Block

Add a button to the MATLAB System block dialog box. This button opens a figure that plots a ramp function.

Use `matlab.system.display.Action` to define the MATLAB function or code associated with a button in the MATLAB System block dialog box. The example also shows how to set button options and use an `actionData` object input to store a figure handle. This part of the code example uses the

same figure when the button is clicked multiple times, rather than opening a new figure for each button click.

```

methods(Static,Access = protected)
 function group = getPropertyGroupsImpl
 group = matlab.system.display.Section(mfilename('class'));
 group.Actions = matlab.system.display.Action(@(actionData,obj)...
 visualize(obj,actionData),'Label','Visualize');
 end
end

methods
 function obj = ActionDemo(varargin)
 setProperties(obj,nargin,varargin{:});
 end

 function visualize(obj,actionData)
 f = actionData.UserData;
 if isempty(f) || ~ishandle(f)
 f = figure;
 actionData.UserData = f;
 else
 figure(f); % Make figure current
 end

 d = 1:obj.RampLimit;
 plot(d);
 end
end

```

### Complete Class Definition File for Dialog Button

Define a property group and a second tab in the class definition file.

```

classdef PlotRamp < matlab.System
 % Display a button to launch a plot figure.

 properties (Nontunable)
 RampLimit = 10;
 end

 methods(Static,Access = protected)
 function group = getPropertyGroupsImpl
 group = matlab.system.display.Section(mfilename('class'));
 group.Actions = matlab.system.display.Action(@(actionData,obj)...
 visualize(obj,actionData),'Label','Visualize');
 end
 end

 methods
 function obj = ActionDemo(varargin)
 setProperties(obj,nargin,varargin{:});
 end

 function visualize(obj,actionData)
 f = actionData.UserData;
 if isempty(f) || ~ishandle(f)
 f = figure;
 end
 end
 end
end

```

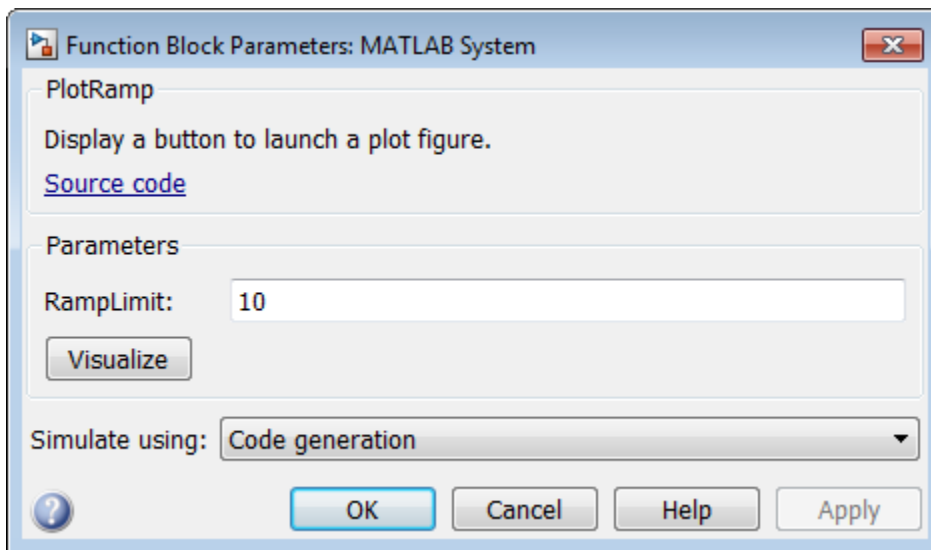

```

 actionData.UserData = f;
 else
 figure(f); % Make figure current
 end

 d = 1:obj.RampLimit;
 plot(d);
end
end
end

```

The resulting dialog box with the **Visualize** button:

## More About

- “Using ~ as an Input Argument in Method Definitions”

## Specify Output

### In this section...

“Set Output Size” on page 46-68  
 “Set Fixed- or Variable-Size Output” on page 46-69  
 “Set Output Data Type” on page 46-71  
 “Set Output Complexity” on page 46-74  
 “Set Discrete State Output Specification” on page 46-75

Sometimes, Simulink cannot infer the output characteristics of your System object during model compilation. To give Simulink more information about the System object output, use these methods.

### Set Output Size

Specify the size of a System object output using the `getOutputSizeImpl` method. Use this method when Simulink cannot infer the output size from the inputs during model compilation. For instance, when the System object has multiple inputs or outputs or has variable-sized output.

For variable-size inputs, the propagated input size from `propagatedInputSizeImpl` differs depending on the environment.

- MATLAB — When you first run an object, it uses the actual sizes of the inputs.
- Simulink — The maximum of all the input sizes is set before the model runs and does not change during the run.

Subclass from the `matlab.System` base class.

```
classdef CounterReset < matlab.System
```

Use the `getOutputSizeImpl` method to specify the output size.

```
methods (Access = protected)
 function sizeout = getOutputSizeImpl(~)
 sizeout = [1 1];
 end
end
```

View the method in the complete class definition file.

```
classdef CounterReset < matlab.System
 % CounterReset Count values above a threshold

 properties
 Threshold = 1
 end

 properties (DiscreteState)
 Count
 end

 methods (Access = protected)
 function setupImpl(obj)
 obj.Count = 0;
 end
 end
end
```

```

end

function y = stepImpl(obj,u1,u2)
 % Add to count if u1 is above threshold
 % Reset if u2 is true
 if (u2)
 obj.Count = 0;
 elseif (any(u1 > obj.Threshold))
 obj.Count = obj.Count + 1;
 end
 y = obj.Count;
end

function resetImpl(obj)
 obj.Count = 0;
end

function [sz,dt,cp] = getDiscreteStateSpecificationImpl(~,name)
 if strcmp(name,'Count')
 sz = [1 1];
 dt = 'double';
 cp = false;
 else
 error(['Error: Incorrect State Name: ', name.']);
 end
end

function dataout = getOutputDataTypeImpl(~)
 dataout = 'double';
end

function sizeout = getOutputSizeImpl(~)
 sizeout = [1 1];
end

function cplxout = isOutputComplexImpl(~)
 cplxout = false;
end

function fixedout = isOutputFixedSizeImpl(~)
 fixedout = true;
end

function flag = isInputSizeMutableImpl(~,idx)
 if idx == 1
 flag = true;
 else
 flag = false;
 end
end
end
end
end

```

## Set Fixed- or Variable-Size Output

Specify the System object output is fixed-size. Fixed-size output is always the same size, while variable-size output can be different size vectors.

Simulink cannot infer the output size for variable-size output. To avoid errors, implement `isOutputFixedSizeImpl` and `getOutputSizeImpl`.

`isOutputFixedSizeImpl` accepts System object handle and returns an array of flags. Array size is equal to the size of the output ports. The value of the flags and their meanings are:

- `true` — the output size is fixed (output port on MATLAB System block creates variable-size signal)
- `false` — the output size is variable (output port on MATLAB System block creates fixed-size signal)

Subclass from the `matlab.System` base class.

```
classdef CounterReset < matlab.System
```

Use the `isOutputFixedSizeImpl` method to specify that the output is fixed size.

```
methods (Access = protected)
 function fixedout = isOutputFixedSizeImpl(~)
 fixedout = true;
 end
end
```

View the method in the complete class definition file.

```
classdef CounterReset < matlab.System
 % CounterReset Count values above a threshold

 properties
 Threshold = 1
 end

 properties (DiscreteState)
 Count
 end

 methods (Access = protected)
 function setupImpl(obj)
 obj.Count = 0;
 end

 function y = stepImpl(obj,u1,u2)
 % Add to count if u1 is above threshold
 % Reset if u2 is true
 if (u2)
 obj.Count = 0;
 elseif (any(u1 > obj.Threshold))
 obj.Count = obj.Count + 1;
 end
 y = obj.Count;
 end

 function resetImpl(obj)
 obj.Count = 0;
 end

 function [sz,dt,cp] = getDiscreteStateSpecificationImpl(~,name)
 if strcmp(name,'Count')
 sz = [1 1];
 dt = 'double';
 cp = false;
 else

```

```

 error(['Error: Incorrect State Name: ', name.']);
 end
end
function dataout = getOutputDataTypeImpl(~)
 dataout = 'double';
end
function sizeout = getOutputSizeImpl(~)
 sizeout = [1 1];
end
function cplxout = isOutputComplexImpl(~)
 cplxout = false;
end
function fixedout = isOutputFixedSizeImpl(~)
 fixedout = true;
end
function flag = isInputSizeMutableImpl(~,idx)
 if idx == 1
 flag = true;
 else
 flag = false;
 end
end
end
end
end

```

## Set Output Data Type

Specify the data type of a System object output using the `getOutputDataTypeImpl` method. A second example shows how to specify a gain object with bus output. Use this method when Simulink cannot infer the data type from the inputs during model compilation or when you want different input and output data types. If you want bus output, also use the `getOutputDataTypeImpl` method. To use bus output, you must define the bus data type in the base workspace and you must include the `getOutputDataTypeImpl` method in your class definition file.

For both examples, subclass from the `matlab.System` base class.

```
classdef DataTypeChange < matlab.System
```

Specify, in your class definition file, how to control the output data type from a MATLAB System block. Use the `getOutputDataTypeImpl` method to change the output data type from double to single, or propagate the input as a double. It also shows how to cast the data type to change the output data type in the `stepImpl` method, if necessary.

```

methods (Access = protected)
 function out = getOutputDataTypeImpl(obj)
 if obj.Quantize == true
 out = 'single';
 else
 out = propagatedInputDataType(obj,1);
 end
 end
end
end

```

```
classdef DataTypeChange < matlab.System
```

```

 properties(Nontunable)
 Quantize = false;
 end

```

```

end

methods(Access = protected)
function y = stepImpl(obj,u)
 if obj.Quantize == true
 % Cast for output data type to differ from input.
 y = single(u);
 else
 % Propagate output data type.
 y = u;
 end
end

function out = getOutputDataTypeImpl(obj)
 if obj.Quantize == true
 out = 'single';
 else
 out = propagatedInputDataType(obj,1);
 end
end
end
end
end
end

```

This model shows propagated double data type.

This model shows the result of changing the data type from double to single. The Display block shows the effect of quantizing the data.

The block mask for the MATLAB System block includes an edit field to switch between using propagation (**Quantize** = false) and switching from double to single (**Quantize** = true).

Use the `getOutputDataTypeImpl` method to specify the output data type as a bus. Specify the bus name in a property.

```
properties(Nontunable)
 OutputBusName = 'bus_name';
end

methods (Access = protected)
 function out = getOutputDataTypeImpl(obj)
 out = obj.OutputBusName;
 end
end
```

View the method in the complete class definition file. This class definition file also includes code to implement a custom icon for this object in the MATLAB System block

```
classdef busGain < matlab.System
% busGain Apply a gain of two to bus input.

 properties
 GainK = 2;
 end

 properties(Nontunable)
 OutputBusName = 'bus_name';
 end

 methods (Access=protected)
 function out = stepImpl(obj,in)
 out.a = obj.GainK * in.a;
 out.b = obj.GainK * in.b;
 end

 function out = getOutputSizeImpl(obj)
 out = propagatedInputSize(obj, 1);
 end

 function out = isOutputComplexImpl(obj)
 out = propagatedInputComplexity(obj, 1);
 end
 end
end
```

```

function out = getOutputDataTypeImpl(obj)
 out = obj.OutputBusName;
end

function out = isOutputFixedSizeImpl(obj)
 out = propagatedInputFixedSize(obj,1);
end
end
end
end

```

## Set Output Complexity

Specify whether a System object output is complex or real using the `isOutputComplexImpl` method. Use this method when Simulink cannot infer the output complexity from the inputs during model compilation.

Subclass from the `matlab.System` base class.

```
classdef CounterReset < matlab.System
```

Use the `isOutputComplexImpl` method to specify that the output is real.

```

methods (Access = protected)
 function cplxout = isOutputComplexImpl(~)
 cplxout = false;
 end
end
end

```

View the method in the complete class definition file.

```

classdef CounterReset < matlab.System
 % CounterReset Count values above a threshold

 properties
 Threshold = 1
 end

 properties (DiscreteState)
 Count
 end

 methods (Access = protected)
 function setupImpl(obj)
 obj.Count = 0;
 end

 function y = stepImpl(obj,u1,u2)
 % Add to count if u1 is above threshold
 % Reset if u2 is true
 if (u2)
 obj.Count = 0;
 elseif (any(u1 > obj.Threshold))
 obj.Count = obj.Count + 1;
 end
 y = obj.Count;
 end
 end
end

```

```

function resetImpl(obj)
 obj.Count = 0;
end

function [sz,dt,cp] = getDiscreteStateSpecificationImpl(~,name)
 if strcmp(name,'Count')
 sz = [1 1];
 dt = 'double';
 cp = false;
 else
 error(['Error: Incorrect State Name: ', name.']);
 end
end

function dataout = getOutputDataTypeImpl(~)
 dataout = 'double';
end

function sizeout = getOutputSizeImpl(~)
 sizeout = [1 1];
end

function cplxout = isOutputComplexImpl(~)
 cplxout = false;
end

function fixedout = isOutputFixedSizeImpl(~)
 fixedout = true;
end

function flag = isInputSizeMutableImpl(~,idx)
 if idx == 1
 flag = true;
 else
 flag = false;
 end
end

end
end
end

```

## Set Discrete State Output Specification

Specify the size, data type, and complexity of a discrete state property using the `getDiscreteStateSpecificationImpl` method. Use this method when your System object has a property with the `DiscreteState` attribute and Simulink cannot infer the output specifications during model compilation.

Subclass from the `matlab.System` base class.

```
classdef CounterReset < matlab.System
```

Use the `getDiscreteStateSpecificationImpl` method to specify the size and data type. Also specify the complexity of a discrete state property `Count`, which is used in the counter reset example.

```

function [sz,dt,cp] = getDiscreteStateSpecificationImpl(~,name)
 if strcmp(name,'Count')
 sz = [1 1];
 dt = 'double';
 cp = false;
 else
 error(['Error: Incorrect State Name: ', name.]);
 end
end

```

```

 end
end

```

View the method in the complete class definition file.

```

classdef CounterReset < matlab.System
 % CounterReset Count values above a threshold

 properties
 Threshold = 1
 end

 properties (DiscreteState)
 Count
 end

 methods (Access = protected)
 function setupImpl(obj)
 obj.Count = 0;
 end

 function y = stepImpl(obj,u1,u2)
 % Add to count if u1 is above threshold
 % Reset if u2 is true
 if (u2)
 obj.Count = 0;
 elseif (any(u1 > obj.Threshold))
 obj.Count = obj.Count + 1;
 end
 y = obj.Count;
 end

 function resetImpl(obj)
 obj.Count = 0;
 end

 function [sz,dt,cp] = getDiscreteStateSpecificationImpl(~,name)
 if strcmp(name,'Count')
 sz = [1 1];
 dt = 'double';
 cp = false;
 else
 error(['Error: Incorrect State Name: ', name.']);
 end
 end

 function dataout = getOutputDataTypeImpl(~)
 dataout = 'double';
 end

 function sizeout = getOutputSizeImpl(~)
 sizeout = [1 1];
 end

 function cplxout = isOutputComplexImpl(~)
 cplxout = false;
 end

 function fixedout = isOutputFixedSizeImpl(~)
 fixedout = true;
 end

 function flag = isInputSizeMutableImpl(~,idx)

```

```
 if idx == 1
 flag = true;
 else
 flag = false;
 end
 end
end
end
end
```

## Set Model Reference Discrete Sample Time Inheritance

Disallow model reference discrete sample time inheritance for a System object. The System object defined in this example has one input, so by default, it allows sample time inheritance. To override the default and disallow inheritance, the class definition file for this example includes the `allowModelReferenceDiscreteSampleTimeInheritanceImpl` method, with its output set to `false`.

```
methods (Access = protected)
 function flag = ...
 allowModelReferenceDiscreteSampleTimeInheritanceImpl(obj)
 flag = false;
 end
end
```

View the method in the complete class definition file.

```
classdef MyCounter < matlab.System

 % MyCounter Count values

 properties
 Threshold = 1;
 end

 properties (DiscreteState)
 Count
 end

 methods (Static, Access = protected)
 function header = getHeaderImpl
 header = matlab.system.display.Header('MyCounter',...
 'Title','My Enhanced Counter',...
 'Text','This counter is an enhanced version.');
```

```
 end
 end

 methods (Access = protected)
 function flag = ...
 allowModelReferenceDiscreteSampleTimeInheritanceImpl(obj)
 flag = false
 end
 function setupImpl(obj,u)
 obj.Count = 0;
 end
 function y = stepImpl(obj,u)
 if (u > obj.Threshold)
 obj.Count = obj.Count + 1;
 end
 y = obj.Count;
 end
 function resetImpl(obj)
 obj.Count = 0;
 end
 end
end
```

```
end
end
```

`allowModelReferenceDiscreteSampleTimeInheritanceImpl` | `matlab.System`

## Use Update and Output for Nondirect Feedthrough

Implement nondirect feedthrough for a System object by using the `updateImpl`, `outputImpl`, and `isInputDirectFeedthroughImpl` methods. In nondirect feedthrough, the outputs depend only on the internal states and properties of the object, rather than the input at that instant in time. You use these methods to separate the output calculation from the state updates of a System object. Implementing these two methods overrides the `stepImpl` method. These methods enable you to use the object in a feedback loop and prevent algebraic loops.

### Subclass from the `matlab.System` Class

To use the `updateImpl`, `outputImpl`, and `isInputDirectFeedthroughImpl` methods, you must subclass from the `matlab.System`.

```
classdef IntegerDelaySysObj < matlab.System
```

### Implement Updates to the Object

Implement an `updateImpl` method to update the object with previous inputs.

```
methods (Access = protected)
 function updateImpl(obj,u)
 obj.PreviousInput = [u obj.PreviousInput(1:end-1)];
 end
end
```

### Implement Outputs from Object

Implement an `outputImpl` method to output the previous, not the current input.

```
methods (Access = protected)
 function [y] = outputImpl(obj,~)
 y = obj.PreviousInput(end);
 end
end
```

### Implement Whether Input Is Direct Feedthrough

Implement an `isInputDirectFeedthroughImpl` method to indicate that the input is nondirect feedthrough.

```
methods (Access = protected)
 function flag = isInputDirectFeedthroughImpl(~,~)
 flag = false;
 end
end
```

### Complete Class Definition File with Update and Output

```
classdef intDelaySysObj < matlab.System
 % intDelaySysObj Delay input by specified number of samples.

 properties
 InitialOutput = 0;
 end
 properties (Nontunable)
 NumDelays = 1;
 end
end
```

```

end
properties (DiscreteState)
 PreviousInput;
end

methods (Access = protected)
 function validatePropertiesImpl(obj)
 if ((numel(obj.NumDelays)>1) || (obj.NumDelays <= 0))
 error('Number of delays must be > 0 scalar value.');
```

```

 end
 if (numel(obj.InitialOutput)>1)
 error('Initial Output must be scalar value.');
```

```

 end
 end
end

function setupImpl(obj)
 obj.PreviousInput = ones(1,obj.NumDelays)*obj.InitialOutput;
end

function resetImpl(obj)
 obj.PreviousInput = ones(1,obj.NumDelays)*obj.InitialOutput;
end

function [y] = outputImpl(obj,~)
 y = obj.PreviousInput(end);
end

function updateImpl(obj, u)
 obj.PreviousInput = [u obj.PreviousInput(1:end-1)];
end

function flag = isInputDirectFeedthroughImpl(~,~)
 flag = false;
end
end
end

```

## Enable For Each Subsystem Support

Enable For Each subsystem support by using a System object in a Simulink For Each subsystem. Include the `supportsMultipleInstanceImpl` method in your class definition file. This method applies only when the System object is used in Simulink via the MATLAB System block.

Use the `supportsMultipleInstanceImpl` method and have it return `true` to indicate that the System object supports multiple calls in a Simulink For Each subsystem.

```
methods (Access = protected)
 function flag = supportsMultipleInstanceImpl(obj)
 flag = true;
 end
end
```

View the method in the complete class definition file.

```
classdef RandSeed < matlab.System
% RANDSEED Random noise with seed for use in For Each subsystem

 properties (DiscreteState)
 count;
 end

 properties (Nontunable)
 seed = 20;
 useSeed (1,1) logical = false;
 end

 methods (Access = protected)
 function y = stepImpl(obj,u1)
 % Initial use after reset/setup
 % and use the seed
 if (obj.useSeed && ~obj.count)
 rng(obj.seed);
 end
 obj.count = obj.count + 1;
 [m,n] = size(u1);
 % Uses default rng seed
 y = rand(m,n) + u1;
 end

 function setupImpl(obj)
 obj.count = 0;
 end
 function resetImpl(obj)
 obj.count = 0;
 end

 function flag = supportsMultipleInstanceImpl(obj)
 flag = obj.useSeed;
 end
 end
end
```

```
end
end
```

## Define System Object for Use in Simulink

### In this section...

“Develop System Object for Use in MATLAB System Block” on page 46-84

“Define Block Dialog Box for Plot Ramp” on page 46-84

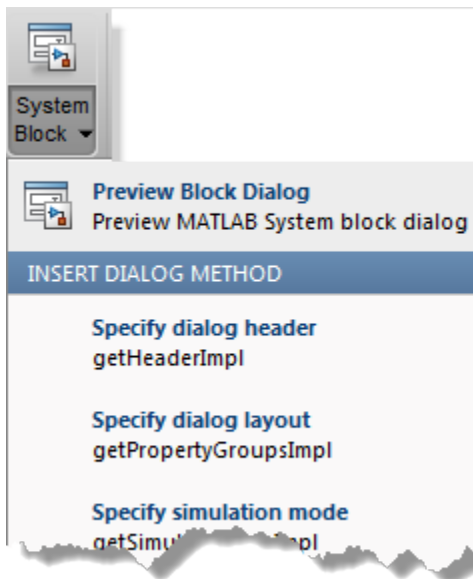

### Develop System Object for Use in MATLAB System Block

You can develop a System object for use in a System block and interactively preview the block dialog box. This feature requires Simulink.

With the **System Block** editing options, the MATLAB Editor inserts predefined code into the System object. This coding technique helps you create and modify your System object faster and increases accuracy by reducing typing errors.

Using these options, you can also:

- View and interact with the block dialog box design as you define the System object.
- Add dialog box customization methods. If the block dialog box is open when you make changes, the block dialog design preview updates the display on saving the file.
- Add icon methods. However, these elements display only on the MATLAB System Block in Simulink, not in the **Preview Block Dialog**.

### Define Block Dialog Box for Plot Ramp

- 1 Create a System object using the menu option **New > System Object > Simulink Extension**.
- 2 Name the System object `PlotRamp` and save the file. This name becomes the block dialog box title.
- 3 Delete the comment at the beginning of the file and replace it with the block description.

```
% Display a button to launch a plot figure.
```

This comment becomes the block parameters dialog box description, under the block title.

- 4 Select **System Block > Preview Block Dialog**. The block dialog box displays as you develop the System object.

- 5 Add a ramp limit by selecting **Insert Property > Numeric**. Then change the property name and set the value to 10.

```
properties (Nontunable)
 RampLimit = 10;
end
```

- 6 Locate the `getPropertyGroupsImpl` method using the **Analyze** button.

```
function group = getPropertyGroupsImpl
 % Define property section(s) for System block dialog
 group = matlab.system.display.Section(mfilename('class'));
end
```

- 7 Create the group for the **Visualize** action.

```
function group = getPropertyGroupsImpl
 % Define property section(s) for System block dialog
 group = matlab.system.display.Section(mfilename('class'));
 group.Actions = matlab.system.display.Action(@(~,obj)...
 visualize(obj), 'Label', 'Visualize');
end
```

- 8 Add a function that adds code to display the **Visualize** button on the dialog box.

```
methods
 function visualize(obj)
 figure;
 d = 1:obj.RampLimit;
 plot(d);
 end
end
```

- 9 As you add elements to the System block definition, save your file. Observe the effects of your code additions to the System block definition.

The **System Block** menu also displays checks next to the methods included in your file.

- 10 Delete any unused methods in the template or modify the methods to further customize the System object and System block. The class definition file now has all the code necessary for the PlotRamp System object.

```
classdef PlotRamp < matlab.System
 % Display a button to launch a plot figure.

 properties (Nontunable)
 RampLimit = 10;
 end

 methods(Static, Access=protected)
 function group = getPropertyGroupsImpl
 group = matlab.system.display.Section(mfilename('class'));
 group.Actions = matlab.system.display.Action(@(~,obj)...
 visualize(obj), 'Label', 'Visualize');
 end
 end
end
```

```
end

methods
 function visualize(obj)
 figure;
 d = 1:obj.RampLimit;
 plot(d);
 end
end
end
```

After you complete your System block definition, save it, and then load it into a MATLAB System block in Simulink.

## Use Global Variables in System Objects

Global variables are variables that you can access in other MATLAB functions or Simulink blocks.

### System Object Global Variables in MATLAB

For System objects that are used only in MATLAB, you define global variables in the System object class definition files in the same way that you define global variables in other MATLAB code (see “Global Variables”).

### System Object Global Variables in Simulink

For System objects that are used in the MATLAB System block in Simulink, you also define global variables as you do in MATLAB. However, to use global variables in Simulink, if you have declared global variables in methods called by `stepImpl`, `updateImpl`, or `outputImpl`, you must declare global variables in the `stepImpl`, `updateImpl`, or `outputImpl` method, respectively.

You set up and use global variables for the MATLAB System block in the same way as you do for the MATLAB Function block (see “Data Stores” and “Share Data Globally” on page 45-92). Like the MATLAB Function block, you must also use variable name matching with a Data Store Memory block to use global variables in Simulink.

For example, this class definition file defines a System object that increments the first row of a matrix by 1 at each time step. If the file is P-coded, you must include `getGlobalNamesImpl`.

```
classdef GlobalSysObjMatrix < matlab.System
 methods (Access = protected)
 function y = stepImpl(obj)
 global B;
 B(1,:) = B(1, :)+1;
 y = B;
 end

 % Include getGlobalNamesImpl only if the class file is P-coded.
 function globalNames = getGlobalNamesImpl(~)
 globalNames = {'B'};
 end
 end
end
```

This model includes the `GlobalSysObjMatrix` object in a MATLAB System block and the associated Data Store Memory block.

### System Design and Simulation in Simulink

You can use System objects in your model to simulate in Simulink.

- 1 Create a System object to be used in your model. See “Define New System Objects for Use in Simulink” on page 46-92 for information.
- 2 Test your new System object in MATLAB. See “Test New System Objects in MATLAB” on page 46-96
- 3 Add the System object to your model by using the MATLAB System block. See “Add System Objects to Your Simulink Model” on page 46-96 for information.
- 4 Add other Simulink blocks as needed and connect the blocks to construct your system.
- 5 Run the system

### Define New System Objects for Use in Simulink

- “Define System Object with Block Customizations” on page 46-92
- “Define System Object with Nondirect Feedthrough” on page 46-94

A System object is a component you can use to create your system in MATLAB. You can write the code in MATLAB and use that code to create a block in Simulink. To define your own System object, you write a class definition file, which is a text-based MATLAB file that contains the code defining your object. See “Integrate System Objects Using MATLAB System Block”.

#### Define System Object with Block Customizations

Create a System object for use in Simulink. The example performs system identification using a least mean squares (LMS) adaptive filter.

Create a class definition text file to define your System object. The code in this example creates a least mean squares (LMS) filter and includes customizations to the block icon and dialog box appearance.

---

**Note** Instead of manually creating your class definition file, you can use the **New > System Object > Simulink Extension** menu option to open a template. This template includes customizations of the System object for use in the Simulink MATLAB System block. You edit the template file, using it as a guideline, to create your own System object.

---

On the first line of the class definition file, specify the name of your System object and subclass from `matlab.System`. The `matlab.System` base class enables you to use all the basic System object methods and specify the block input and output names, title, and property groups.

Add the appropriate basic System object methods to set up, reset, set the number of inputs and outputs, and run your algorithm. See the reference pages for each method and the full class definition file below for the implementation of each of these methods.

- Use the `setupImpl` method to perform one-time calculations and initialize variables.
- Use the `stepImpl` method to implement the block's algorithm.
- Use the `resetImpl` method to reset the state properties or `DiscreteState` properties.
- Use the `getNumInputsImpl` and `getNumOutputsImpl` methods to specify the number of inputs and outputs, respectively.

Add the appropriate methods to define the appearance of the MATLAB System block in Simulink. See the reference pages for each method and the full class definition file below for the implementation of each of these methods.

- Use the `getHeaderImpl` method to specify the title and description to display on the block dialog box.
- Use the `getPropertyGroupsImpl` method to specify groups of properties to display on the block dialog box.
- Use the `getIconImpl` method to specify the text to display on the block icon.
- Use the `getInputNamesImpl` and `getOutputNamesImpl` methods to specify the labels to display for the block input and output ports.

The full class definition file for the least mean squares filter is:

```
classdef lmsSysObj < matlab.System
 % lmsSysObj Least mean squares (LMS) adaptive filtering.
 % #codegen

 properties
 % Mu Step size
 Mu = 0.005;
 end

 properties (Nontunable)
 % Weights Filter weights
 Weights = 0;
 % N Number of filter weights
 N = 32;
 end

 properties (DiscreteState)
 X;
 H;
 end

 methods (Access = protected)
 function setupImpl(obj)
 obj.X = zeros(obj.N,1);
 obj.H = zeros(obj.N,1);
 end

 function [y, e_norm] = stepImpl(obj,d,u)
 tmp = obj.X(1:obj.N-1);
 obj.X(2:obj.N,1) = tmp;
 end
 end
end
```

```

 obj.X(1,1) = u;
 y = obj.X'*obj.H;
 e = d-y;
 obj.H = obj.H + obj.Mu*e*obj.X;
 e_norm = norm(obj.Weights'-obj.H);
end

function resetImpl(obj)
 obj.X = zeros(obj.N,1);
 obj.H = zeros(obj.N,1);
end

end

% Block icon and dialog customizations
methods (Static, Access = protected)
 function header = getHeaderImpl
 header = matlab.system.display.Header(...
 'lmsSysObj', ...
 'Title', 'LMS Adaptive Filter');
 end

 function groups = getPropertyGroupsImpl
 upperGroup = matlab.system.display.SectionGroup(...
 'Title','General',...
 'PropertyList',{'Mu'});

 lowerGroup = matlab.system.display.SectionGroup(...
 'Title','Coefficients', ...
 'PropertyList',{'Weights','N'});

 groups = [upperGroup,lowerGroup];
 end
end

methods (Access = protected)
 function icon = getIconImpl(~)
 icon = sprintf('LMS Adaptive\nFilter');
 end
 function [in1name, in2name] = getInputNamesImpl(~)
 in1name = 'Desired';
 in2name = 'Actual';
 end
 function [out1name, out2name] = getOutputNamesImpl(~)
 out1name = 'Output';
 out2name = 'EstError';
 end
end
end
end

```

### Define System Object with Nondirect Feedthrough

Create a System object for use in Simulink. The example performs system identification using a least mean squares (LMS) adaptive filter and uses feedback loops.

Create a class definition text file to define your System object. The code in this example creates an integer delay and includes feedback loops, and customizations to the block icon. For information on

feedback loops, see “Use System Objects in Feedback Loops” on page 46-16. This example implements a System object that you can use for nondirect feedthrough. Simulink example.

On the first line of the class definition file, subclass from `matlab.System`. The `matlab.System` base class enables you to use all the basic System object methods and specify the block input and output names, title, and property groups.

Add the appropriate basic System object methods to set up and reset the object and set and validate the properties. Since this object supports nondirect feedthrough, you do not implement the `stepImpl` method. You implement the `updateImpl` and `outputImpl` methods instead. See the reference pages for each method and the full class definition file below for the implementation of each of these methods.

- Use the `setupImpl` method to initialize some of the object’s properties.
- Use the `resetImpl` method to reset the property states.
- Use the `validatePropertiesImpl` method to check that the property values are valid.

Add the following class methods instead of the `stepImpl` method to specify how the block updates its state and its output. See the reference pages and the full class definition file below for the implementation of each of these methods.

- Use the `outputImpl` method to implement code to calculate the block output.
- Use the `updateImpl` method to implement code to update the block’s internal states.
- Use the `isInputDirectFeedthroughImpl` method to specify that the block is not direct feedthrough. Its inputs do not directly affect its outputs.

Add the `getIconImpl` method to define the block icon when it is used in Simulink via the MATLAB System block. See the reference page and the full class definition file below for the implementation of this method.

The full class definition file for the delay is:

```
classdef intDelaySysObj < matlab.System
 % intDelaySysObj Delay input by specified number of samples.
 % #codegen

 properties
 % InitialOutput Initial output
 InitialOutput = 0;
 end

 properties (Nontunable)
 % NumDelays Number of delays
 NumDelays = 1;
 end

 properties (DiscreteState)
 PreviousInput;
 end

 methods (Access = protected)
 function setupImpl(obj, ~)
 obj.PreviousInput = ones(1,obj.NumDelays)*obj.InitialOutput;
 end
 end
end
```

```
function [y] = outputImpl(obj, ~)
 % Output does not directly depend on input
 y = obj.PreviousInput(end);
end

function updateImpl(obj, u)
 obj.PreviousInput = [u obj.PreviousInput(1:end-1)];
end

function flag = isInputDirectFeedthroughImpl(~,~)
 flag = false;
end

function validatePropertiesImpl(obj)
 if ((numel(obj.NumDelays)>1) || (obj.NumDelays <= 0))
 error('Number of delays must be positive non-zero ...
 scalar value.');
```

```
 end
 if (numel(obj.InitialOutput)>1)
 error('Initial output must be scalar value.');
```

```
 end
end

function resetImpl(obj)
 obj.PreviousInput = ones(1,obj.NumDelays)*obj.InitialOutput;
end

function icon = getIconImpl(~)
 icon = sprintf('Integer\nDelay');
```

```
end
end
end
```

## Test New System Objects in MATLAB

- 1 Create an instance of your new System object. For example, create an instance of the `lmsSysObj`.
- 2 Run the object multiple times with different inputs. Doing this step tests for syntax errors and other possible issues before you add it to Simulink. For example,

```
desired = 0;
actual = 0.2;
s(desired,actual);
```

## Add System Objects to Your Simulink Model

### System Objects in the MATLAB Function Block

You can include System object code in Simulink models with the MATLAB Function block. Your function can include one or more System objects. Portions of your system may be easier to implement in the MATLAB environment than directly in Simulink. Many System objects have Simulink block counterparts with equivalent functionality. Before writing MATLAB code to include in a Simulink model, check for existing blocks that perform the desired operation.

**System Objects in the MATLAB System Block**

You can include individual System objects that you create with a class definition file into Simulink with the MATLAB System block. This option is one way to add your own algorithm blocks into your Simulink models.

Add your System objects to your Simulink model by using the MATLAB System block as described in “Mapping System Object Code to MATLAB System Block Dialog Box” on page 46-19.

For information, see “Integrate System Objects Using MATLAB System Block”.

## Specify Sample Time for MATLAB System Block System Objects

This example shows how to control the sample time of the MATLAB System block using System object™ methods.

Inside the class definition, use the System object sample time methods to configure the sample time and modify the System object behavior based on the current simulation time. If you want to use inherited sample time, you do not need to specify a sample time in your System object definition.

### Specify Sample Time

To specify the sample time, implement the `getSampleTimeImpl` method and create a sample time specification object with `createSampleTime`.

In this example, a property `SampleTimeTypeProp` is created to assign the sample time based on different property values. The `getSampleTimeImpl` method creates a sample time specification based on the `SampleTimeTypeProp` property. The `getSampleTimeImpl` method returns the sample time specification object `sts` created by `createSampleTime`.

```

18 methods(Access = protected)
19 function sts = getSampleTimeImpl(obj)
20 switch char(obj.SampleTimeTypeProp)
21 case 'Inherited'
22 sts = createSampleTime(obj,'Type','Inherited');
23 case 'InheritedNotControllable'
24 sts = createSampleTime(obj,'Type','Inherited',...
25 'AlternatePropagation','Controllable');
26 case 'InheritedErrorConstant'
27 sts = createSampleTime(obj,'Type','Inherited',...
28 'ErrorOnPropagation','Constant');
29 case 'FixedInMinorStep'
30 sts = createSampleTime(obj,'Type','Fixed In Minor Step');
31 case 'Discrete'
32 sts = createSampleTime(obj,'Type','Discrete',...
33 'SampleTime',obj.SampleTime, ...
34 'OffsetTime',obj.OffsetTime);
35 case 'Controllable'
36 sts = createSampleTime(obj,'Type','Controllable',...
37 'TickTime',obj.TickTime);
38 end
39 end

```

### Query Simulation Time and Sample Time

Use the `getSampleTime` and `getCurrentTime` methods to query the MATLAB System block for the current sample time and simulation time, respectively. `getSampleTime` returns a sample time specification object with properties describing the sample time settings.

```

40
41 function [Count, Time, SampleTime] = stepImpl(obj,u)
42 Count = obj.Count + u;
43 obj.Count = Count;
44 Time = getCurrentTime(obj);
45 sts = getSampleTime(obj);

```

```

46 if strcmp(sts.Type,'Controllable')
47 setNumTicksUntilNextHit(obj,obj.Count);
48 end
49 SampleTime = sts.SampleTime;
50 end

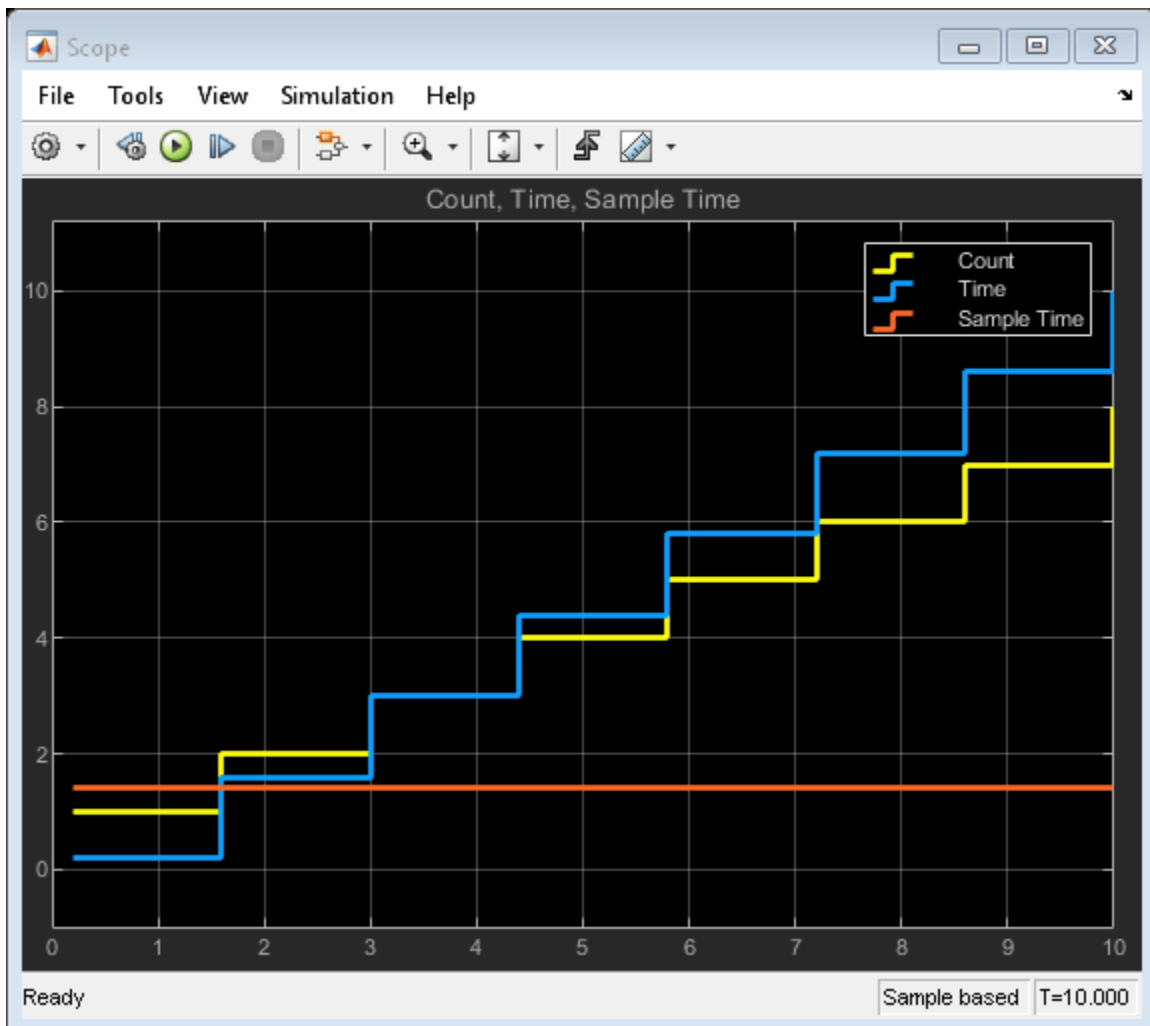

```

### Behavior in Simulink

Include this System object in a MATLAB System block.

In the scope, you can see the effects of the sample time changes to the block.

## Full Class Definition

Full class definition of the CountTime System object.

```

classdef CountTime < matlab.System
 % Counts Hits and Time

 properties(Nontunable)
 SampleTime = 1.4; % Sample Time
 OffsetTime = 0.2; % Offset Time
 TickTime = 0.1;
 SampleTimeTypeProp (1, 1) {mustBeMember(SampleTimeTypeProp, ...
 ["Discrete", "FixedInMinorStep", "Controllable", ...
 "Inherited", "InheritedNotControllable", ...
 "InheritedErrorConstant"])} = "Discrete"
 end

 properties(DiscreteState)
 Count
 end

 methods(Access = protected)
 function sts = getSampleTimeImpl(obj)
 switch char(obj.SampleTimeTypeProp)
 case 'Inherited'
 sts = createSampleTime(obj, 'Type', 'Inherited');
 case 'InheritedNotControllable'
 sts = createSampleTime(obj, 'Type', 'Inherited', ...
 'AlternatePropagation', 'Controllable');
 case 'InheritedErrorConstant'
 sts = createSampleTime(obj, 'Type', 'Inherited', ...
 'ErrorOnPropagation', 'Constant');
 case 'FixedInMinorStep'
 sts = createSampleTime(obj, 'Type', 'Fixed In Minor Step');
 case 'Discrete'
 sts = createSampleTime(obj, 'Type', 'Discrete', ...
 'SampleTime', obj.SampleTime, ...
 'OffsetTime', obj.OffsetTime);
 case 'Controllable'
 sts = createSampleTime(obj, 'Type', 'Controllable', ...
 'TickTime', obj.TickTime);
 end
 end

 function [Count, Time, SampleTime] = stepImpl(obj, u)
 Count = obj.Count + u;
 obj.Count = Count;
 Time = getCurrentTime(obj);
 sts = getSampleTime(obj);
 if strcmp(sts.Type, 'Controllable')
 setNumTicksUntilNextHit(obj, obj.Count);
 end
 SampleTime = sts.SampleTime;
 end

 function setupImpl(obj)
 obj.Count = 0;
 end
 end
end

```

```

end

function resetImpl(obj)
 % Initialize / reset discrete-state properties
 obj.Count = 0;
end

function flag = isInactivePropertyImpl(obj,prop)
 flag = false;
 switch char(obj.SampleTimeTypeProp)
 case {'Inherited', ...
 'InheritedNotControllable', ...
 'FixedInMinorStep'}
 if any(strcmp(prop,{'SampleTime','OffsetTime','TickTime'}))
 flag = true;
 end
 case 'Discrete'
 if any(strcmp(prop,{'TickTime'}))
 flag = true;
 end
 case 'Controllable'
 if any(strcmp(prop,{'SampleTime','OffsetTime'}))
 flag = true;
 end
 end
end
end
end
end
end

```

## Create Moving Average Filter Block with System Object

This example shows how to extend the `movingAverageFilter` System object™ for use in Simulink™. To use a System object in Simulink, include the System object in a MATLAB System block.

### movingAverageFilter System Object

This example extends the `movingAverageFilter` System object built in “Create Moving Average System object”. The `movingAverageFilter` System object computes the unweighted mean of a specified number of previous inputs. Use the `WindowLength` property to specify how many previous samples to use.

### Use in Simulink

The object is already ready to use in Simulink. Create a Simulink model and add a MATLAB System block. Specify `movingAverageFilter` as the System object name. For example, this model uses the moving average filter to eliminate noise from a signal.

```
model = 'movingaveragefilter_sl';
open_system(model);
```

The block dialog window shows the public, tunable parameters:

### Customize MATLAB System Block

Optionally, you can customize the block appearance and block dialog for a MATLAB System block by adding methods to the System object.

#### Add Simulink Block Icon Customization Method

By default the block icon shows the name of the System object, in this case `movingAverageFilter`. Customize the Moving Average Filter block icon with a cleaner name. In the **Editor** toolstrip, select the **System Block** dropdown button, then select **Add Text Icon**. The `getIconImpl` method is added to `movingAverageFilter`. Inside `getIconImpl`, set `icon` equal to the string array `["Moving", "Average", "Filter"]`;

```
function icon = getIconImpl(~)
 % Define icon for the System block.
 icon = ["Moving", "Average", "Filter"];
end
```

#### Customize Block Dialog

You can also customize the block dialog by adding methods and comments to the System object. For details about block dialog customization, see “Customize System Block Appearance” on page 46-54. In this example, rename the `WindowLength` property in the dialog box and add a method to customize the description.

By default, all public properties appear as parameters in the block dialog with their property names. In this example, add comments before the `WindowLength` property so that it appears as **Moving window length** in the dialog. Add a comments above the property in the form: `PropertyName Name in dialog`

```
% WindowLength Moving window length
WindowLength (1,1){mustBeInteger,mustBePositive} = 5
```

To specify the header and description in the block dialog, in the toolstrip select **System Block > Specify Dialog Header**. This option adds the `getHeaderImpl` method to `movingAverageFilter`. Modify the call to `matlab.system.display.Header` to this:

```
methods(Access = protected, Static)
 function header = getHeaderImpl
```

```

% Define header panel for System block dialog
header = matlab.system.display.Header('movingAverageFilter',...
 'Title','Moving Average Filter',...
 'Text','Unweighted moving average filter of 1- or 2D input.');
```

end  
end

You can see a preview of the block dialog by clicking the button in the toolbar above **System Block**.

### Customized Block in Simulink

This is the block with the added customizations:

```

model = 'movingaveragefilter_sl_extended';
open_system(model);
```

To see the completed System object with the Simulink customization methods, type:

edit [movingAverageFilter\\_extended.m](#)

## See Also

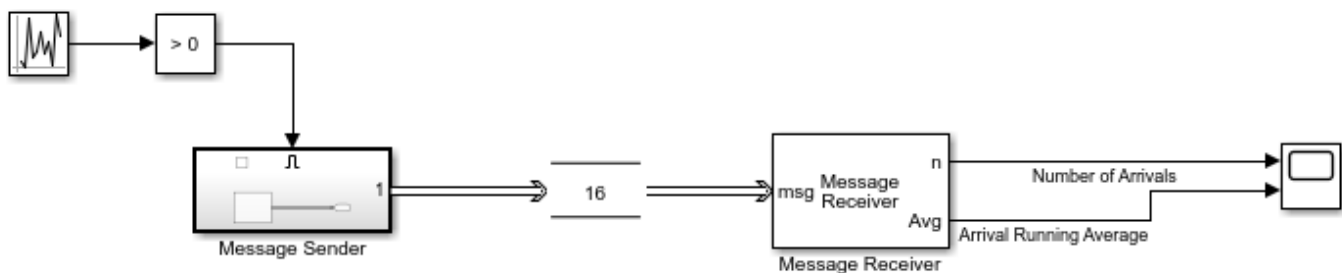

## Process Message Payload Using MATLAB System Block

This example shows how to send, receive, and process messages using the MATLAB System block. Use System objects to author blocks to model custom behavior to send and receive messages and manipulate the message payload.

### Load and Open the Model

Open the model of the Message Send and Receive system. This model contains a random number generator as a data source. Based on that data, the Message Sender sends a message with a sine wave payload to a queue block. The queue block stores the messages, and the Message Receiver converts the message back to data.

```
open_system('slexMessageArrivalExample');
```

### Use getInterfaceImpl System Object API to Specify Message Ports

`getInterfaceImpl` is used in this example to specify the input and output message ports in the MATLAB System block for both the Message Sender and the Message Receiver. For the Message Sender, `getInterfaceImpl` is used to define the output of the MATLAB System block as a message. This action prompts the System object to create a message output. For the Message Receiver, `getInterfaceImpl` is used to define the input of the System object as a message and the output as data.

```
%Function to send messages
function interface = getInterfaceImpl(~)
 import matlab.system.interface.*;
 interface = Output("Out1", Message);
end

%Function to receive messages and output as data
function interface = getInterfaceImpl(obj)
 import matlab.system.interface.*;
 interface = [Input("In1", Message), ...
 Output("Out1", Data), Output("out2", Data)];
end
```

### Set the Propagators and Sample time

The following four propagators need to be set in the Message Sender: `getOutputSizeImpl`, `getOutputDataTypeImpl`, `isOutputComplexImpl`, `isOutputFixedSizeImpl`.

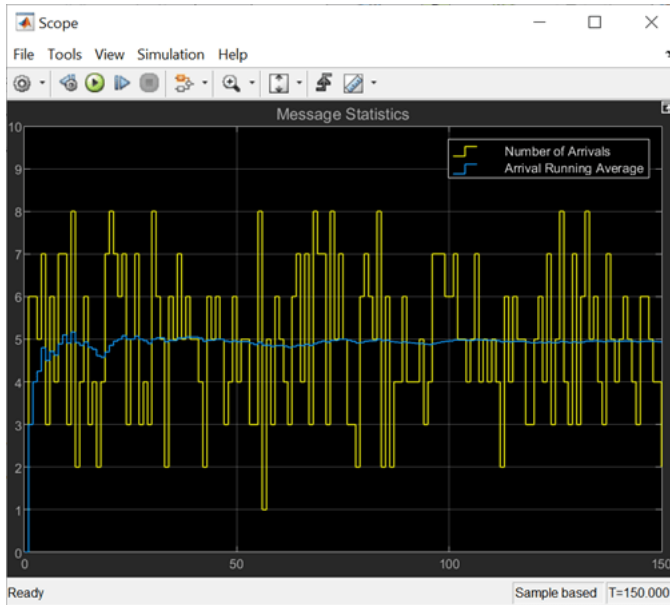

In this example, the message queue has a maximum capacity of 16 messages. The random number generator has a sample time of 0.1. The receiver has a sample time of 1. The Message Receiver sample time is set in the MATLAB System block using the `getSampleTimeImpl` API.

```
function sts = getSampleTimeImpl(obj)
 sts = createSampleTime(obj, 'Type', 'Discrete', ...
 'SampleTime', obj.SampleTime);
end
```

### Simulate the Model and Review Results

The Scope block displays the results. These results show that as you run more simulations, the random number generator produces a number greater than zero 50% of the time, as expected.

## Model Moving Target Visualization by Converting MATLAB Code to Simulink Behavior

This topic shows how to convert MATLAB code to a Simulink model. First, an example shows how to convert a MATLAB algorithm for moving target visualization to a Simulink model with the same functionality. Then, a table shows common conversions from MATLAB code to Simulink behavior.

### Convert Moving Target MATLAB Code to a Simulink Model

This example shows you how to convert MATLAB algorithms to a Simulink model using a moving target example. The conversion allows you to build models containing MATLAB and Simulink components. This example uses MATLAB code for target creation and deletion then shows you how to convert that functionality into Simulink.

#### Moving Target MATLAB Code

Open Script

This example uses MATLAB to create, move, visualize, and delete targets. Two different MATLAB packages generate two separate target databases. The target creator is a System object<sup>®</sup> since it requires the use of states. The target database is a global database. The target checker, which determines if the target is out of range and deletes the target if it is, is a System object because it requires the use of states. The target position updater is a simple algorithm and is therefore a MATLAB function. The target visualizer is a System object and requires the use of states.

For this example, an `initDB` function is used to initialize the global database and create the `Tagret Struct`. Then, the targets are created using the `Target Creator` function and the `Target Creation info Package`. The out-of-range targets are then deleted. The target range is 5 for this example, so any target greater than 5 is deleted, and the remaining target positions are updated. This process is looped over 100 times and visualized as it runs.

#### Moving Target Simulink Model

Open this model

```
open_system('slexTargetIllustrationModel.slx')
```

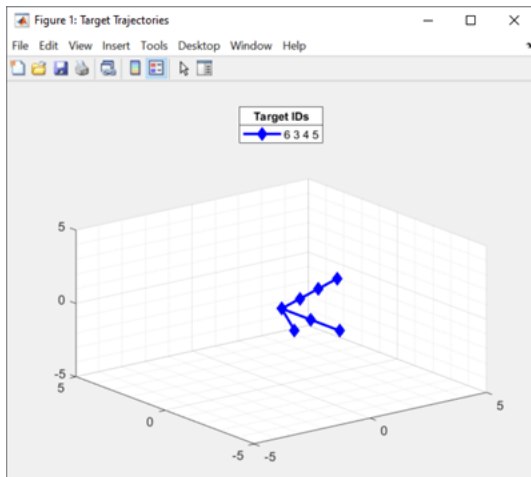

Copyright 2021 The MathWorks, Inc.

The MATLAB script can be converted into a Simulink model that has the same functionality. The Target Database is converted to a DSM using the Model PostLoadFcn and Simulink.Bus.createObject. Convert the Target Creation info Package to a Simulink Function. The target creator, target deleter, and target viewer are each covered into a MATLAB System block since they use System objects in MATLAB. The target viewer also uses a Display block to visualize the targets as the simulation runs. The target updater is converted into a MATLAB Function block since it is a simple MATLAB function that does not use System objects or states. The number of time steps in the loop corresponds with the stop time in the toolbar.

The target creator uses scoped functions in the MATLAB code to call the target creation packages. Use the getGlobalNamesImpl and getSimulinkFunctionNamesImpl APIs in Simulink to declare the function names for the Target Creator System object. These functions declare the target creation package position and velocity names in the target creation package so the package can be called by the System objects in Simulink.

To run the model, click Run. After the model compiles, it produces a visualization just like in the MATLAB code.

## Common Conversions of MATLAB Code to Simulink Behavior

The following table shows some cases of MATLAB code mapping to Simulink blocks and functions. Note: this list is not comprehensive.

| MATLAB Construct                                                                                 | Simulink Construct                                                                |
|--------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------|
| struct                                                                                           | Bus                                                                               |
| Array of struct                                                                                  | Array of buses                                                                    |
| Global                                                                                           | DSM                                                                               |
| Function                                                                                         | MATLAB Function block                                                             |
| System object                                                                                    | MATLAB System block                                                               |
| System object calls to external functions                                                        | System block calls to Simulink functions                                          |
| Scheduling algorithm                                                                             | Stateflow chart                                                                   |
| Top-level loop (for example: "for t=1:0.1:10")                                                   | Simulink start time, stop time, and time step                                     |
| Parameter tuning in MATLAB algorithms                                                            | Simulink tunable parameters                                                       |
| Iteration over an array                                                                          | Foreach subsystem                                                                 |
| if-else loop                                                                                     | If block and If Action subsystem                                                  |
| Switch-case statement                                                                            | Switch Case block and Switch Case Action Subsystem block                          |
| while loop                                                                                       | While Iterator block                                                              |
| Global resource access (for example: database, file handle, communication port, hardware device) | DSM or Simulink functions                                                         |

## Call Python Function Using MATLAB Function and MATLAB System Block

This example shows how to call a Python® function in Simulink® that sorts random numbers using a Python® sorting function and two different blocks: the MATLAB Function block and MATLAB System block. For more on using Python in MATLAB®, see “Access Python Modules from MATLAB - Getting Started”.

MATLAB supports the reference implementation of Python, often called CPython. If you are on a Mac or Linux® platform, you already have Python installed. If you are using Windows®, you need to install a distribution, such as those found at <https://www.python.org/download>. For more information, see “Configure Your System to Use Python”.

### Use Python Functions in Simulink Model

This model contains a random number generator that outputs a 1x5 double containing numbers from 0 to 1, a MATLAB Function and a MATLAB System block that sorts the numbers, and a manual switch that leads to a Display block. The MATLAB Function block calls the `py.sorted` function from Python and outputs a 1x5 double sorted list. The MATLAB System block calls the `py.sorted` function as part of `stepImpl` and outputs a 1x5 double sorted list.

# Manage and Create a Blockset Using Blockset Designer

---

- “Create a Blockset Project” on page 47-2
- “Create and Organize Block Artifacts” on page 47-14
- “Publish the Created Blockset” on page 47-18

## Create a Blockset Project

### In this section...

- “Create a New Blockset Project” on page 47-2
- “Create a Project from an Existing Blockset” on page 47-9
- “Blockset Project File Structure” on page 47-12

A blockset is a collection of blocks organized in Simulink libraries for a purpose. The blocks could be part of a standalone library or may be part of an extensive project.

The Blockset Designer is a Projects-based tool that allows you to create, group and manage custom blocks. After creating different blocks, you can add tests, document your blocks, and run Model Advisor checks. If your model contains any S-function or S-function Builder blocks, you can build them using the interface. In addition, you can import your existing blocksets, and set up a Blockset Designer project. You can create new Subsystem, MATLAB System, S-function, and S-function Builder blocks using the Blockset Designer.

### Create a New Blockset Project

- 1 Open the Simulink start page, and pause on Blockset Designer, and click **Create Project**.

- 2 Specify a name for your project. Note that when you start typing a name for your project, a new folder is automatically created for you in the directory `username\MATLAB\Projects\<foldername>`. If you would like to specify an existing project folder, click the **Browse** button.

If you create a new folder, click **OK** to create a new project folder. Confirm this action by clicking **Yes**.

- 3 Now you are directed to the Blockset Designer project user interface. You are looking at the project at the blockset level. In a Blockset Designer project, the  icon represents the blockset you are working on.

The Blockset Designer consists of these components at the blockset level:

1 — The Views panel shows the project file views and the interface of the Blockset Designer. To view all files in the project root, click **Files**, and then the **All** tab. To only see the files in the project, click **Project**.

2 — The Blockset Tree panel shows the organization of the blocks and sublibraries in the project. When you add a new block or a new sublibrary to your blockset, it will show up in this tree. You can also use this tree to switch between the sublibrary and block control menus.

3 — The **Top Library** corresponds to the **Browser.Library** in the library information file `slblocks.m`, which is the entry point to the blockset. Click **Open** to display the location of the top library. Click **Browse** to change the top library for the blockset. Note that if you change the top library, `slblocks.m` updates accordingly, and your blockset project is reloaded based on the new top library. See “Add Libraries to the Library Browser” on page 41-8 to learn more about `slblocks.m`

4 — The status table shows the status of the blocks and their artifacts. For more information on the status table, see “Create and Organize Block Artifacts” on page 47-14.

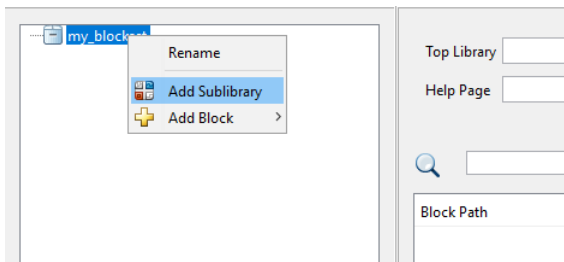

### Add a New Sublibrary

Start building your blockset project by adding a sublibrary. Sublibraries enable you to organize and manage your blocks. In your blockset project, the  icon represents the sublibraries. You can add a new sublibrary to your blockset using in these ways:

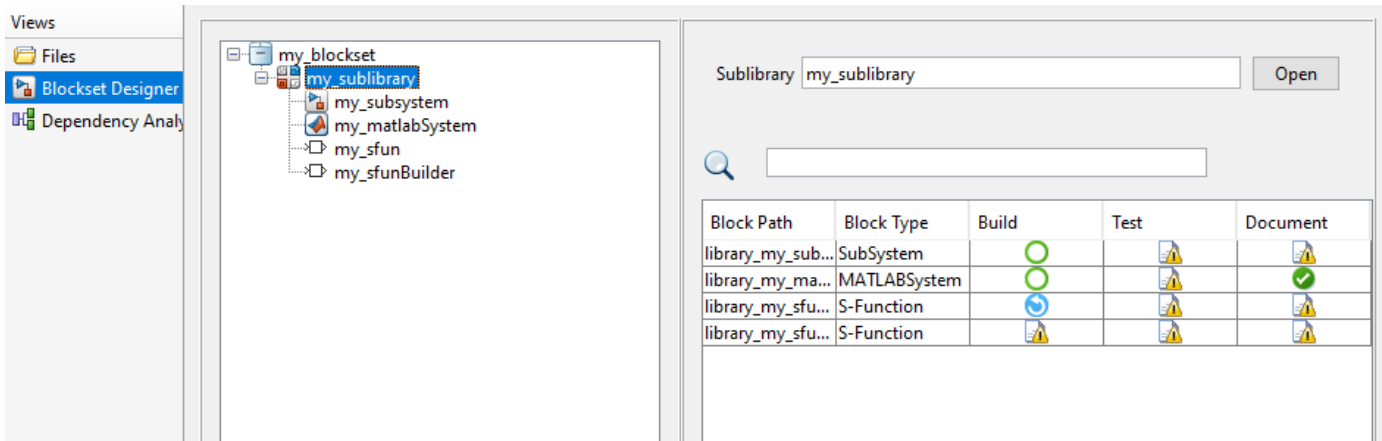

- 1 From the toolstrip, select the **Sublibrary** button.

- 2 Click the blockset from the blockset tree, and from the context menu, select **Sublibrary**.

- 3 Name your sublibrary and close the window. After creating sublibraries, click one of them and see the changes in the working area. Observe that on the top right of the working area, you see **Sublibrary** instead of the **Top Library** and the **Help Page**.

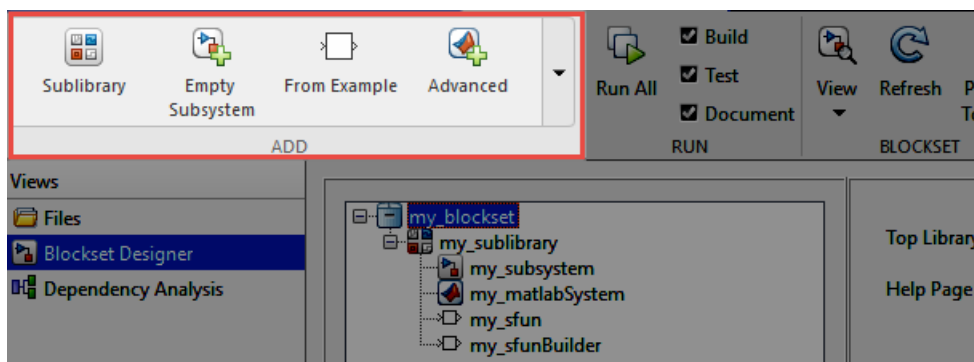

- 4 Click **Open** on the right to open the library model constructed from your sublibrary. This library model contains all blocks from the selected sublibrary.

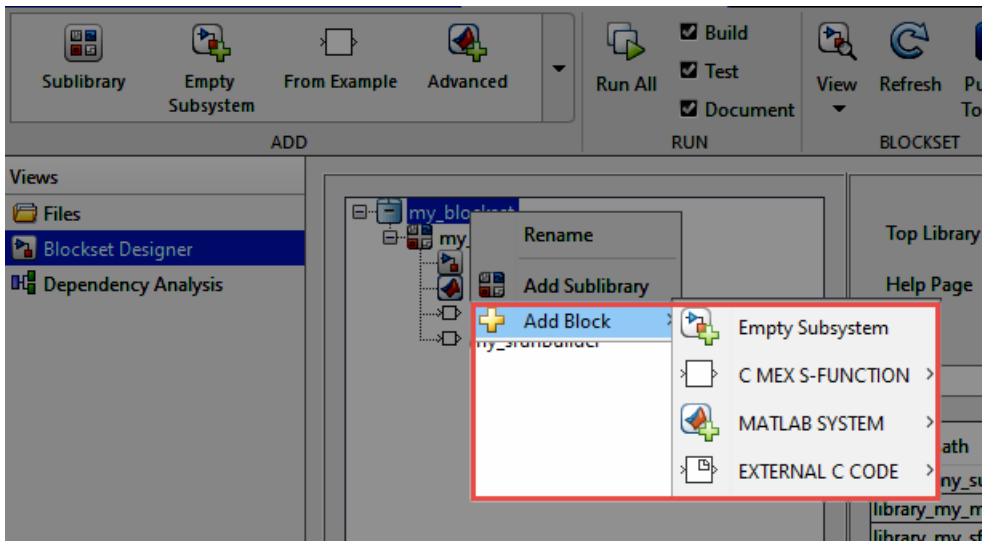

### Add a New Block

Blockset Designer supports many custom blocks.

- You can add a new block to your blockset project from the **ADD** menu on the toolbar

- Alternatively, when you select the blockset or the sublibrary, open the context menu and click **Add Block**.

You can create these blocks in the Blockset Designer:

- C MEX S-function blocks in basic, discrete, continuous templates. You can also create a C MEX S-function from an existing example.

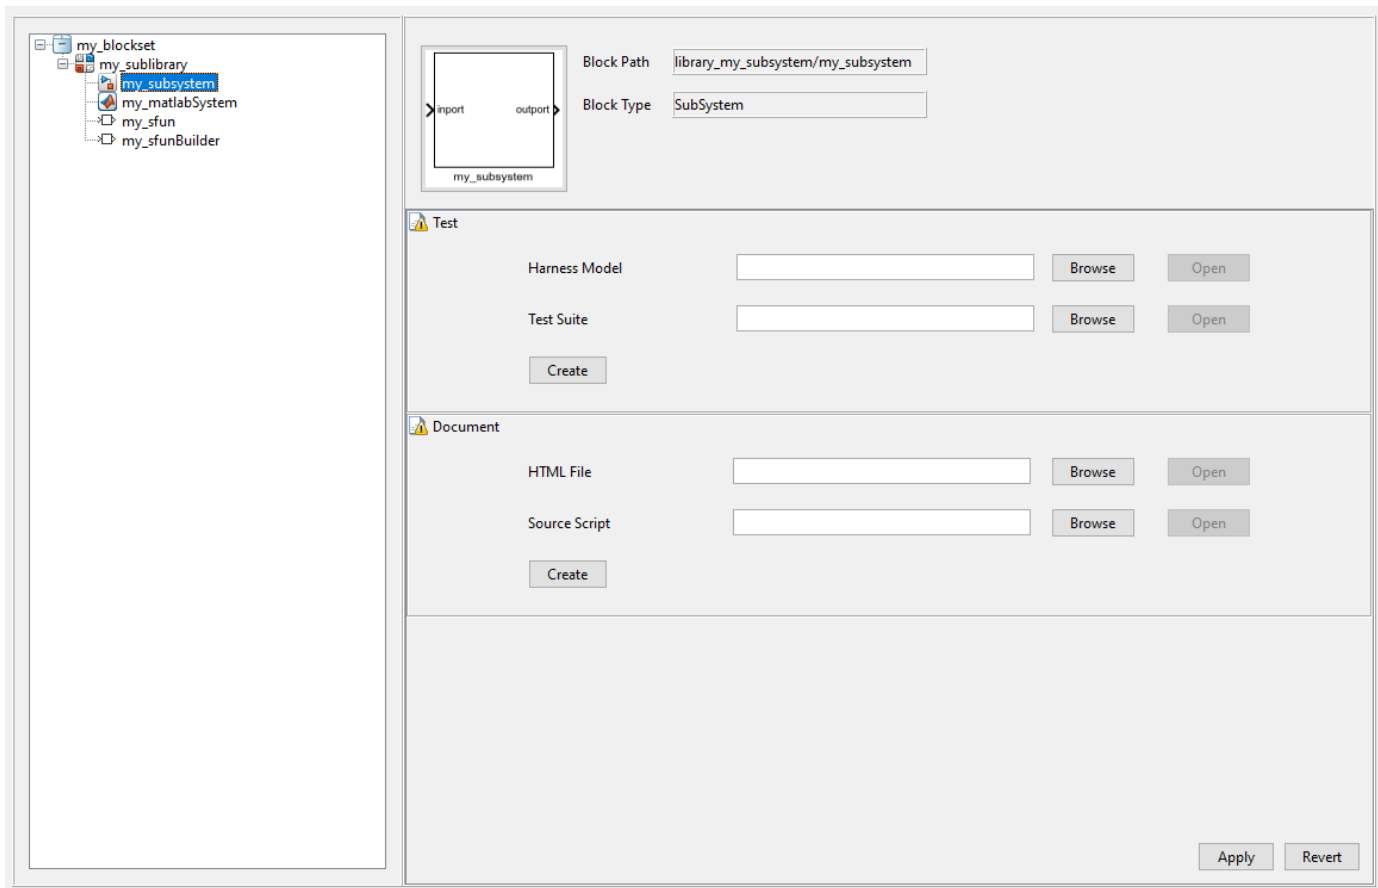

- Subsystem block
- MATLAB System block with basic, advanced, and Simulink Extension System object templates.

- S-functions created using the S-function Builder.

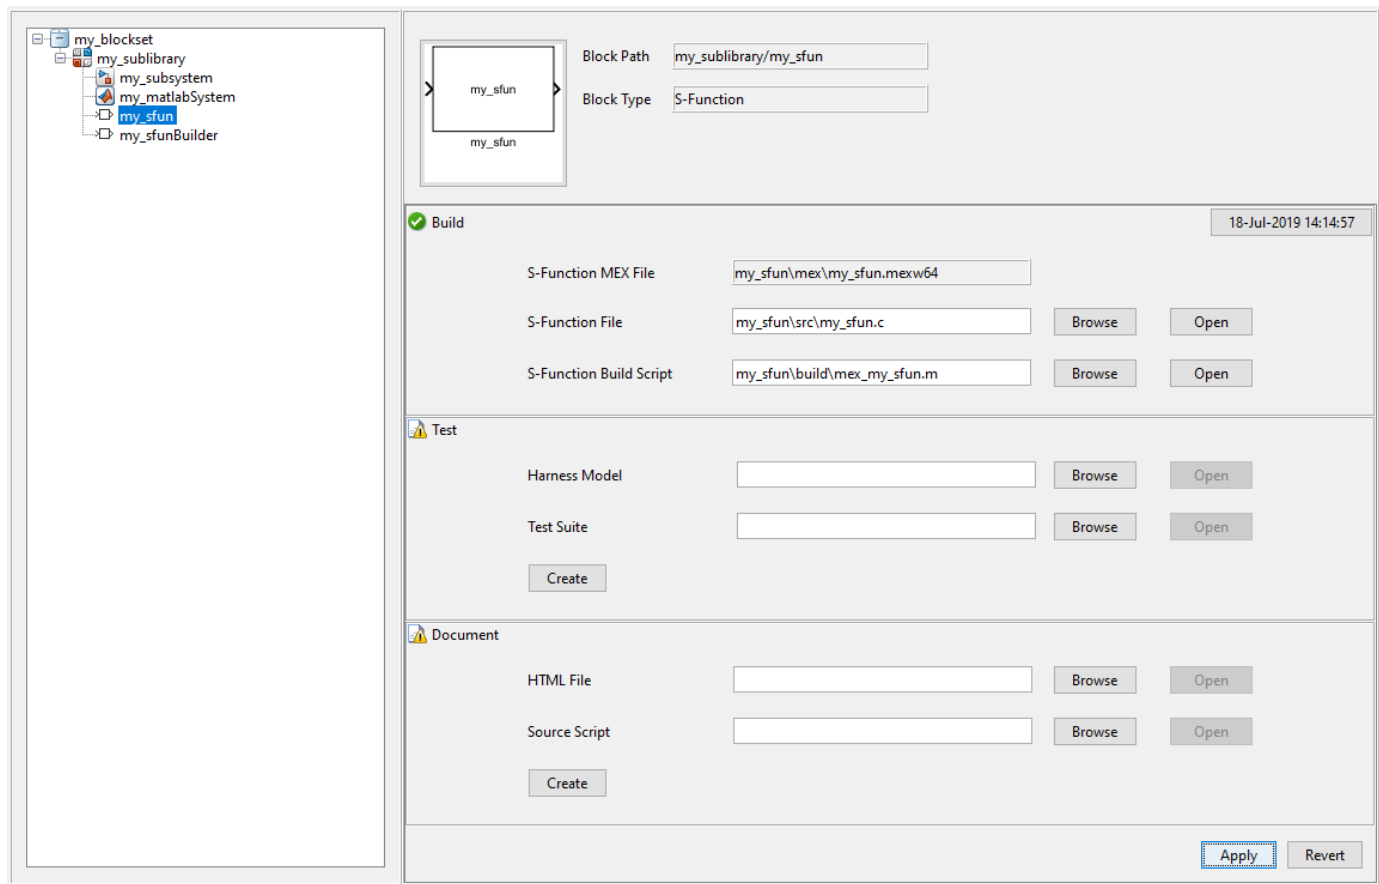

The working area changes according to the blocks added to your project. For a Subsystem block, you see block properties such as the block path and type, **Test**, and **Documentation** in the working area.

When you click a MATLAB System block from the blockset tree, you can edit the System object code and add **Test** using the working area. To add documentation for a MATLAB System block, add comments in the System object code, and they are automatically added to block documentation for you.

If you have an S-function or a S-function Builder block in your blockset project, you can monitor the block properties, build and edit your S-function code, build the script, add test and document to your block.

Note that when you add an S-function to your Blockset Designer project, you need to write the code for your S-function and build it before adding test. To learn more about how to build S-functions using the Blockset Designer, see “S-Function Related Artifacts” on page 47-15.

Besides the blocks mentioned above, you can add and customize other available Simulink library blocks in the project, but you cannot do any operations such as adding test or documentation.

When you are finished creating your project, you can add:

- Test, or a test suite for your blocks.
- Documentation for your sublibraries and/or for your blocks.

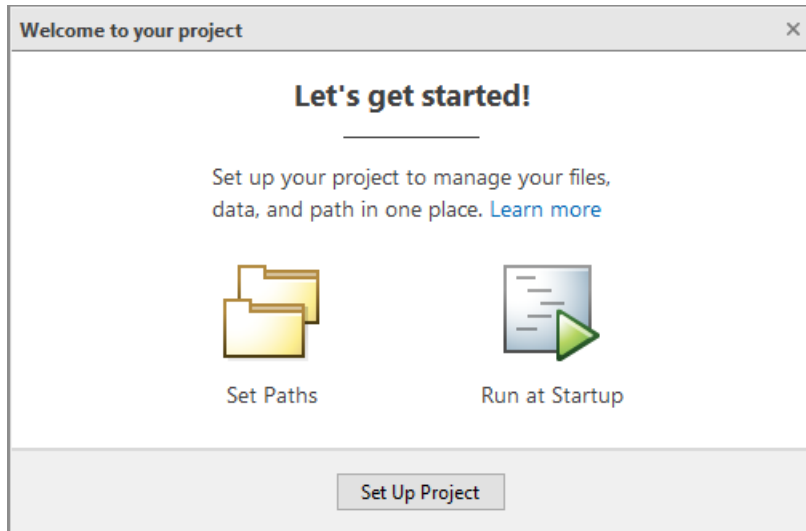

See “Create and Organize Block Artifacts” on page 47-14 for more information.

## Create a Project from an Existing Blockset

Using the Blockset Designer, you can organize blocks, and add tests and documentation to your blocks and blockset. To import your blockset and create a new Blockset Designer project:

- 1 Open the Simulink Start Page. Under **Simulink** select Blockset Designer, and click **Create Project**
- 2 In the New Project dialog box, enter a project name, browse to select the folder containing your files, and click **OK**.

- 3 In the Welcome to your project dialog box, click **Set Up Project** to continue.

- 4 In the Set Up Project (Step 1 of 3) dialog box, choose folders to add to the project path. When you open the project, these folders are added to your MATLAB search path, and removed when you close the project. Add project folders and subfolders to the project path to ensure that you have access to `slblocks.m` and related libraries. `slblocks.m` contains all information about the top library in your project. To learn more, see “Add Libraries to the Library Browser” on page 41-8. To add all project folders, select **Add with Subfolders** and then the project folder containing all your subfolders. Click **Next**.

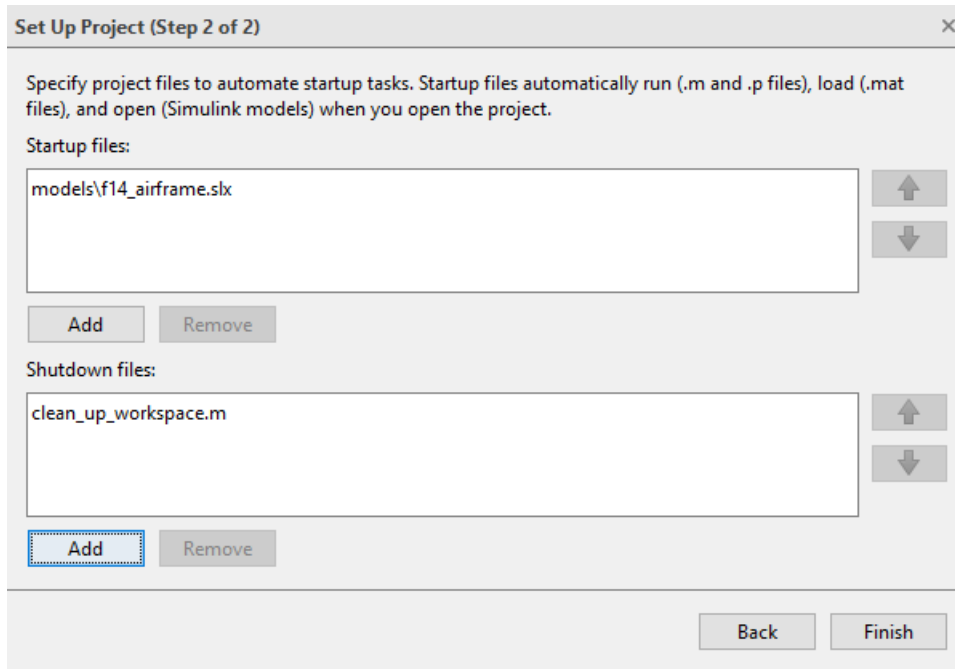

- 5 In the Set Up Project (Step 2 of 3) dialog box, optionally specify startup and shutdown files.
- Use startup files to configure settings when you open the project. Startup files automatically run (.m and .p files), load (.mat files), or open (Simulink models) when you open the project.

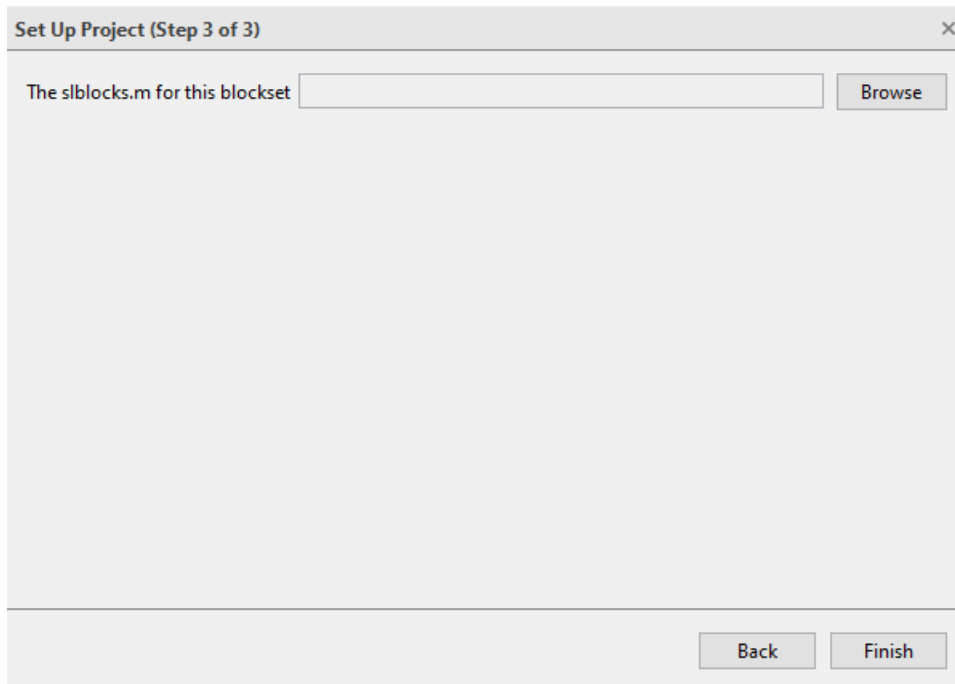

- Use shutdown files to specify MATLAB code to run as the project shuts down. You do not need to use shutdown files to close models when you close a project, because it automatically closes any project models that are open, unless they are dirty. The project prompts you to save or discard changes.

Click **Add** to specify startup or shutdown files.

- 6 In the Set Up Project (Step 3 of 3) dialog box, specify a `slblocks.m` library information file for this blockset. This file contains information on your blockset settings, and the location of your top library. Without this file, your project cannot be set up properly. Click **Browse** to select the file.

- 7 Click **Finish** and a new project opens. The Blockset Designer automatically adds all your files to the project. During the import process, based on the top library, the Blockset Designer explores the hierarchy of the blockset, creates dedicated folders for each type of supported blocks, and adds the folders to project and search corresponding artifacts such as S-function MEX file, source files, and System object files for MATLAB System block automatically. See “Blockset Project File Structure” on page 47-12 for more information.

Now you can start adding more blocks to your project, or add test or documentation to your existing blocks in the project. To learn more about how to build, test and document your blocks, see “Create and Organize Block Artifacts” on page 47-14.

## Blockset Project File Structure

When you create a blockset project, either by creating a new blockset or importing an existing blockset, the Blockset Designer organizes your project in a certain file organization. This organization changes with the different type of blocks you have in your project. Use this table as a guide to determine which folders are created for each block. To see your blockset folder structure, click **Files** in the **Views** panel.

| Block Type    | Folder Name     | Folder Contains                                          |
|---------------|-----------------|----------------------------------------------------------|
| Subsystem     | <b>doc</b>      | Documentation source and html file for the documentation |
|               | <b>library</b>  | Library model for the block                              |
|               | <b>unittest</b> | Unit test model, test suite, and input file for the test |
| MATLAB System | <b>library</b>  | Library model for the block                              |

| Block Type                        | Folder Name     | Folder Contains                                                     |
|-----------------------------------|-----------------|---------------------------------------------------------------------|
|                                   | <b>sysobj</b>   | The System object code for the MATLAB System block                  |
|                                   | <b>unittest</b> | Unit test model, test suite, and input file for the test            |
| S-function and S-function Builder | <b>build</b>    | S-function build script                                             |
|                                   | <b>doc</b>      | Documentation source and HTML file for the documentation            |
|                                   | <b>library</b>  | Library model for the block                                         |
|                                   | <b>mex</b>      | S-function MEX and code generation files                            |
|                                   | <b>src</b>      | S-function source files                                             |
|                                   | <b>unittest</b> | Unit test model, test suite, and input file for the test            |
| Blockset Project (common)         | <b>doc</b>      | Documentation source and HTML file for the documentation            |
|                                   | <b>library</b>  | Library model for the block                                         |
|                                   | <b>script</b>   | <code>blocksetroot.m</code> file to return the blockset root folder |

## More About

- “Create and Organize Block Artifacts” on page 47-14
- “Publish the Created Blockset” on page 47-18

## Create and Organize Block Artifacts

After creating a new blockset or importing your existing blocksets, you can start adding artifacts. In Blockset Designer, there are different artifacts associated with different blocks:

- Subsystem blocks — You can add test and documentation.
- MATLAB System blocks — You can add test using the Blockset Designer working area. To document your blocks, add comments in the System object code.
- S-function and S-function Builder Blocks — You can build S-functions, add test and documentation.

Follow the status of your artifacts by checking the icons in the working area.

| Icon                                                                                | Artifact Status                                                                                                                                                                                                                                                                               |
|-------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|    | No files are specified for the artifact. To resolve, click <b>Create</b> or select an artifact from <b>Browse</b> .                                                                                                                                                                           |
|    | The artifact files have been updated but has not been run yet. To resolve, click <b>Run</b> in the toolbar for the desired artifact.                                                                                                                                                          |
|    | No action needed for the shown status of this block. For example, you do not need to build a MATLAB System or a Subsystem block, and on the status table, <b>Build</b> column shows this icon.                                                                                                |
|  | Build operation of the selected S-function block encountered an error. To resolve, check the S-function build report from the top right of the <b>Build</b> working area, or check your S-function code to resolve issues. See “S-Function Related Artifacts” on page 47-15 for more details. |

### Add Tests to Blocks

To ensure that your custom blocks run seamlessly, you can add a test to your blocks. Blockset Designer gives you the capability to create a test harness automatically, or using you can bring in your own test suite.

 Test

Harness Model

Test Suite

To create a test model and a test suite automatically using Blockset Designer, click **Create**. Your test model opens automatically, investigate this model and verify that it matches your testing needs. Note

that you can only create one test using Blockset Designer, but you can add many tests using test suite. To write your test, open the MATLAB unit test file. This file is just a template for you create your test. If you are going to use the test harness the Blockset Designer created for you, make sure to uncomment the model file.

To bring in your own tests, browse and select your test model and click **Apply**. To bring your own test suite, browse to your test suite and click **Apply**.

### Check Blocks Using Model Advisor

Use **Model Advisor** functionalities to do further checks on your blocks. To use **Model Advisor**, you must have a test harness model for your block. Access it from **Check**, select **Model Advisor**. You can create a test model automatically using the steps above, or you can browse and select your own harness model.

To learn more about Model Advisor checks, see “Check Your Model Using the Model Advisor” on page 5-2.

### Run S-Function Checks

Use S-function Checks to analyze the quality of your S-functions. To use S-function checks, you must have a test harness model for your block. To run these checks, from **Check**, select **Run S-Function Checks** in Simulink toolstrip. The checks generate an S-function check report for your S-function. To learn more about S-function checks, see “Check S-Functions Using S-Function Analyzer APIs”.

## Document the Blocks

The Blockset Designer enables creating documentation for your custom blocks. To create documentation automatically, click **Create** in the **Document** part of the working area.

This creates a Live Editor file for you to write your documentation. After you complete your block documentation, save the Live Editor file. To produce an HTML file for your documentation, from the Simulink toolstrip, confirm that the Document checkbox is selected, and click **Run**.

## S-Function Related Artifacts

In the steps above, you already learned how to create a new S-function block. Here you learn how to build an S-function in a Blockset Designer project.

## Build S-Function Blocks

If you create your S-function as a new block:

- 1 Check the working area and observe that **S-Function File** and **S-Function Build Script** fields are already populated for your S-function.

- 2 To open the S-function code template, click **Open** next to the **S-Function File**. Write the code for your S-function and save your code. Close the MATLAB Editor.

To learn more about writing S-functions, see “Implement C/C++ S-Functions”. If you prefer to create a S-function automatically, see S-Function Builder.

- 3 Return to the Blockset Designer working area.

- 4 From the Blockset Designer toolstrip, confirm the **Build** checkbox is selected and click **Run** .

- 5 During the run, your S-function files are added to the project. A build report for your S-function that contains your S-function build status is generated. If you face any issues during build, check this report. You can reopen this report by clicking on the timestamp in the top right corner of **Build** section.
- 6 Return to the working area and observe that after build operation, an S-function MEX File is generated for this S-function block.

## Build S-Function Builder Blocks

- 1 After creating an S-function Builder block, the S-Function Builder dialog window automatically opens from the library model. Write your code in the panes of the S-function Builder dialog window.
- 2 Click **Build** on the top-right of the S-function Builder dialog window. This will build your S-function, create all S-function artifacts, and communicate with the Blockset Designer.
- 3 Click **Close** to return to Blockset Designer working area.

When you are finished adding and building Blockset Designer artifacts, you are ready to publish your project as a toolbox and share. For more information, see “Publish the Created Blockset” on page 47-18.

## See Also

S-Function | S-Function Builder | MATLAB System | Subsystem, Atomic Subsystem, CodeReuse Subsystem

## **More About**

- “Create a Blockset Project” on page 47-2
- “Publish the Created Blockset” on page 47-18

## Publish the Created Blockset

After you have added artifacts for your blocks in a Blockset Designer project, you can publish and share your project as a toolbox. To publish:

- 1 Click the blockset from the blockset tree, and click **Publish Toolbox** from the Simulink toolstrip.

The Blockset Designer collects your files in the project, and creates the **publish** folder in **Views > Files**. This folder contains all your files from the separate folders in the blockset project based on the dependency analysis, but now collected together under one folder. See “What Is Dependency Analysis?” on page 18-2 to learn more about dependency analysis. The publish folder contains these folders and the associated content:

| Folder Name    | Contains                                                                                                                                                                                                                                                                                                        |
|----------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>doc</b>     | <ul style="list-style-type: none"> <li>• All block documentation HTML files and blockset-level documentation XML files</li> <li>• <code>helpdoc.xml</code> and <code>info.xml</code> is generated to be used in toolbox documentation. See “Display Custom Documentation” for more information.</li> </ul>      |
| <b>extra</b>   | For all blocks: <ul style="list-style-type: none"> <li>• S-function source files and build scripts</li> <li>• Documentation source files</li> <li>• Test models, suites, and their generated input files</li> <li>• All other necessary files based on the dependency analysis, such as block icons.</li> </ul> |
| <b>library</b> | All library models in the blockset all files under <code>&lt;projectroot&gt;/common/library</code> . This includes library models of sublibraries, as well as the blockset project library model.                                                                                                               |
| <b>mex</b>     | All S-function mex files                                                                                                                                                                                                                                                                                        |
| <b>script</b>  | <code>blocksetroot.m</code> file to return blockset root folder and all files under <code>&lt;projectroot&gt;/common/script</code> .                                                                                                                                                                            |
| <b>sysobj</b>  | All System object code for the MATLAB System blocks in the blockset project                                                                                                                                                                                                                                     |

If you have any other files that you would like to include in the publish, manually copy them to the publish folder.

Since the publish folder is added to project path by default, to avoid shadowing files in project, remove this folder from the project path or delete it after the publish process. If you make any changes to your blockset after publishing, click **Publish** again the move the updates files to the publish folder.

- 2 The **Toolbox Information** fields are populated with the project name, author, and description. Edit the information if needed.

- 3 To ensure that MATLAB detects installation components, review the toolbox contents from **Toolbox Files and Folders**. If you want to include files not already included in the project files, edit the **Exclude files and folders**.
- 4 Click **Package** from the toolstrip to package your toolstrip.

To save your toolbox and share it on the MATLAB Central File Exchange, select **Package and Share** from the **Package** menu at the top of the Package a Toolbox dialog box. This option generates a `.mltbx` file in your current MATLAB folder and opens a web page for your toolbox submission to the File Exchange. MATLAB populates the File Exchange submission form with information about the toolbox. Review and submit the form to share your toolbox on File Exchange.

To share your toolbox with others, use the `.mltbx` file. All files you added when you packaged the toolbox are included in the `.mltbx` file. When your toolbox is installed, `.mltbx` file manages the MATLAB path or other installation details.

To learn more about how to create and share toolboxes, and to see the details of the packaging user interface, see “Create and Share Toolboxes”.

## Import FMUs

Use the FMU block to import Functional Mockup Units (FMUs) into Simulink.

The FMU block automatically selects the FMU mode based on the existing FMU you want to import:

- **Co-Simulation** — Integrate FMUs that implement an FMI Co-Simulation interface. These FMUs can contain local solvers used for tool coupling.
- **Model Exchange** — Integrate FMUs that implement an FMI model exchange interface. These FMUs do not contain local solvers. Instead, these FMUs inherit solvers from Simulink.

This block supports FMI versions 1.0 and 2.0. For FMI version 2.0, if your FMU contains both Co-Simulation and Model Exchange elements, the block detects this state and prompts you to select the operation mode for the block.

You can use your FMU block as you do other Simulink blocks. The FMU block supports normal, rapid accelerator, and accelerator modes. Rapid accelerator mode is unsupported for FMU blocks with FMU logging.

This topic assumes that you provide a .fmu file.

### FMU XML File Directives

The default parameter values derive from the corresponding parameter `start` value defined in the FMU `ModelDescription.xml` file. A block parameter value overwrites the initial value of the corresponding parameter defined in the FMU binary implementation.

Simulink interprets these FMU tags accordingly.

| FMU Tag                                                                                                                                                                                                                                                             | Simulink                                                          |
|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------|

| Real                                                                                                                                                                                                                                                                | Interprets block parameter as edit field                          |
| Integer                                                                                                                                                                                                                                                             | Interprets block parameter as edit field                          |
| Boolean                                                                                                                                                                                                                                                             | Interprets block parameter as check box                           |
| Enumeration                                                                                                                                                                                                                                                         | Interprets block parameter as drop-down list                      |
| String                                                                                                                                                                                                                                                              | Interprets as UTF-8 encoded string                                |

The FMU block supports the following encoding formats for the model description XML file:

- ISO-8859-1
- UTF-8
- UTF-16

## Additional Support and Limitations

| Capability                                                       | FMI Version 2.0 Support                                                                                  | FMI Version 1.0 Support                                                                                                                                                                                                                             |

Simulink supports stepping back and forth, tuning parameters in between, and saving states for the FMU Import block as long as the FMU itself supports these features. FMU flags that it supports these features by setting `canGetAndSetFMUstate` and `canSerializeFMUstate` fields in its model description XML to true.

## FMU Import Examples

## Implement an FMU Block

Implement a block and assign a functional mockup unit (FMU) to it. You can then explore the block to see the FMU. This example uses the FMU block with the vehicle FMU.

- 1 Create a model and add the FMU block.
- 2 In the block dialog box, enter the path name for an FMU file in the **FMU name** parameter and click **OK** or **Apply**. The file extension `.fmu` is optional.

The first time you click **OK** or **Apply**, the block identifies which FMU mode to set your FMU to, co-simulation or model exchange.

The block also creates a `slprj/_fmu/fmu_name` folder and unpacks the contents of the FMU file into this folder, which optionally include:

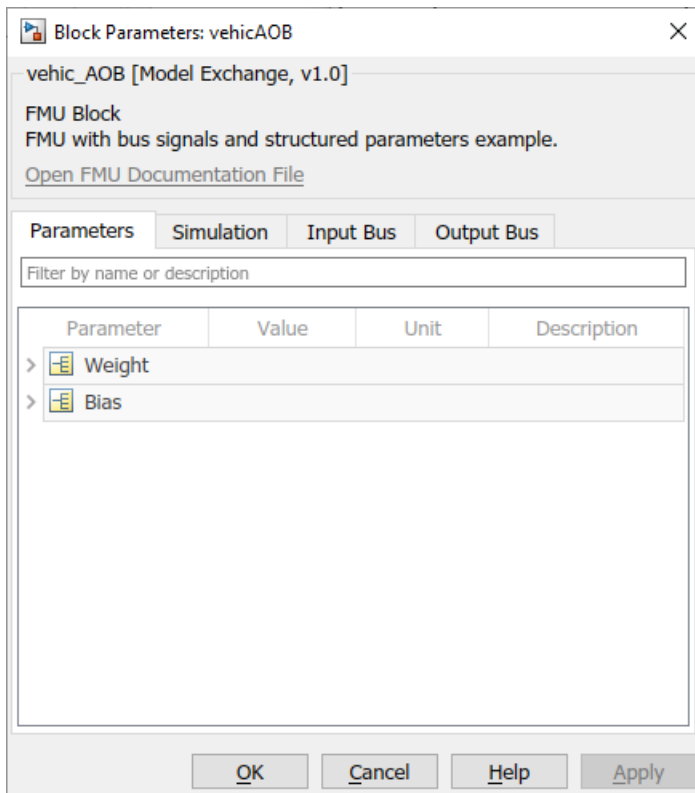

- `binaries` — FMU binary files
- `documentation` — FMU documentation HTML files
- `resources` — FMU source files
- `sources` — FMU source files
- Other supporting files, such as block mask and description files

The FMU block icon and port labels update to the labels of the corresponding FMU. After you associate the block with an FMU, if you want to change the FMU, right-click the FMU block, and select **Block Parameters**, and enter a new FMU name in **FMU name**. The section in this topic use the FMU from the “Simplify Interface for Structured Data with FMU Import Block” example.

### Explore the FMU Block

Double-click the block. Suppose that you entered an FMU named `fmuVehicA0B.fmu` from your current folder. The FMU block dialog box reflects the FMU parameters defined in the `fmuVehicA0B.fmu` file.

## Parameters Tab

Lists the FMU block parameters. Edit the values as necessary. You can edit the elements of a structure parameter by expanding the tree view.

## Simulation Tab

Enables logging and associated customizations.

- To enter a relative tolerance, select **Enable FMU tolerance** and set it.
- To determine the sample time of the block in the model, set **Communication step size**. To inherit the step size from the Simulink solver, set to -1. This option is available only if the FMU is a co-simulation FMU.
- To enable logging, select the **Enable FMU Debug Logging**.
- In **Redirect debug logs to**, select the destination for the logs.
  - File, saved to `slprj\_fmu\_logs_modelname\modelname_blockname.txt`
  - Display, displayed in the MATLAB Command Window.

If the **Enable FMU Debug Logging** check box is selected and the **Redirect debug logs to** parameter is set to **Display**, you cannot use the FMU block for co-simulation. For more information on co-simulation and multiple cores, see “Run Co-Simulation Components on Multiple Cores” on page 48-24

- In the **Filter logs by return status**, select the check box for the return status you want.

## Input and Output Bus Tabs

These two tabs list the input and output bus objects that the block defines.

In the **Bus Object Name** parameter, you can change the bus object names to match the bus objects defined in the workspace.

To create a bus object in the workspace:

```
fmudialog.createBusType(gcb)
```

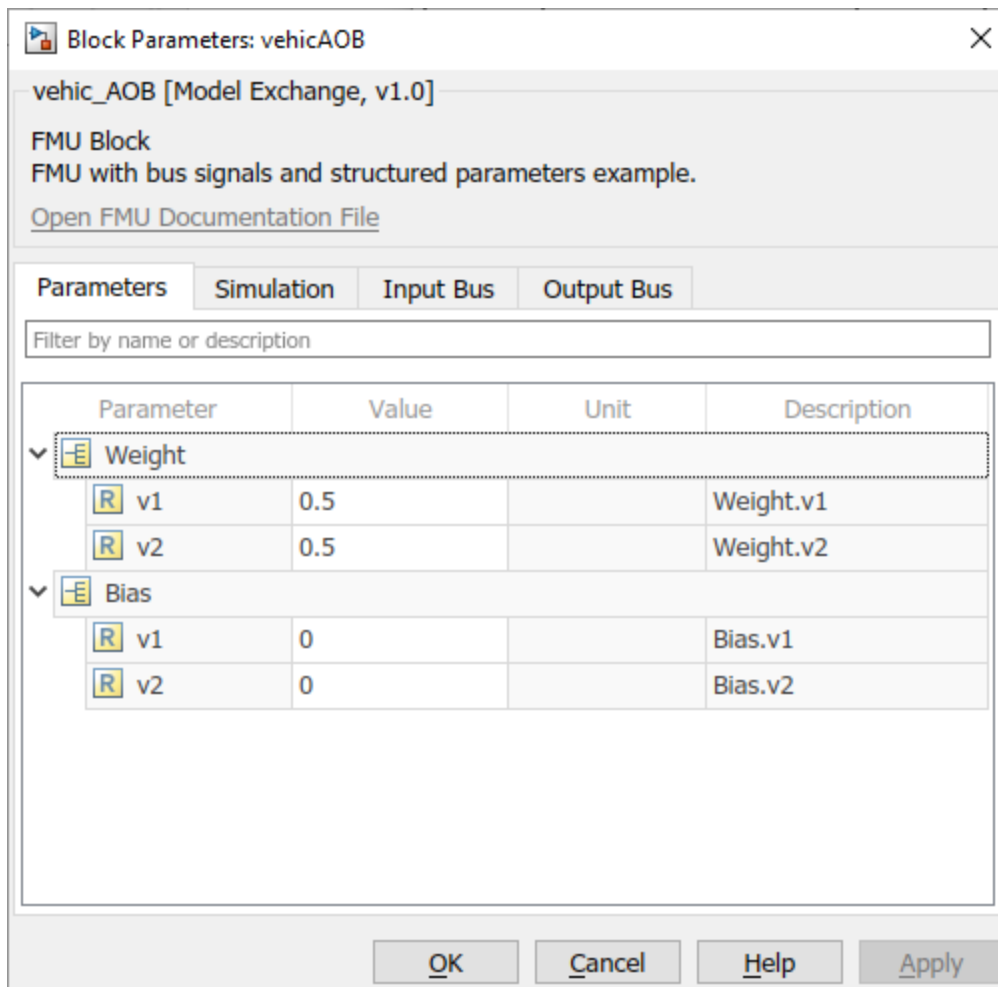

## Change Block Input, Output, and Parameter Structures

You can change the layout of FMU block input ports, output ports, and parameters with these parameters:

| Parameter       | Action                           | Settings                                                                                                                  |
|-----------------|----------------------------------|---------------------------------------------------------------------------------------------------------------------------|
| FMUInputMapping | Change hierarchy of input ports. | 'Flat' — Separates input into individual signals.<br><br>'Structured' — Combines input into a structure of signals (bus). |

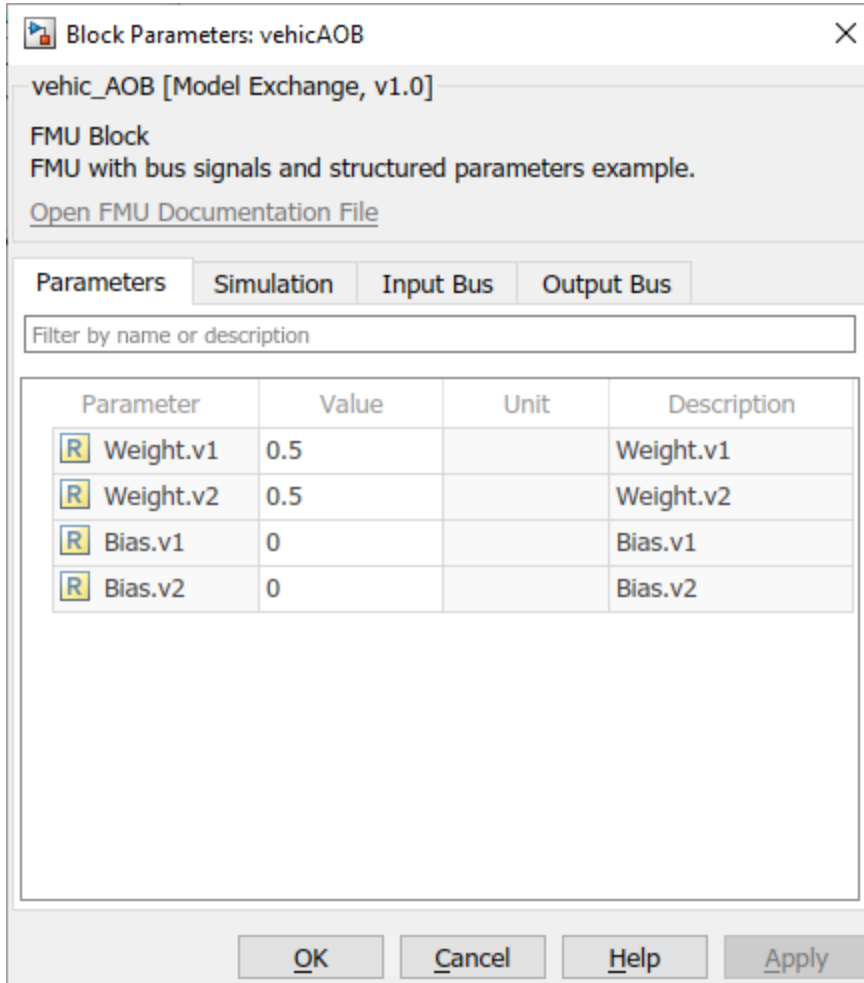

| Parameter        | Action                            | Settings                                                                                                                                                                                   |
|------------------|-----------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| FMUOutputMapping | Change hierarchy of output ports. | 'Flat' — Separates output into individual signals.<br><br>'Structured' — Combines output into a structure of signals (bus).                                                                |
| FMUParamMapping  | Change hierarchy of parameters.   | 'Flat' — Separates parameters into individual parameters, listed by the parameter name and value.<br><br>'Structured' — Combines parameters into a structure of parameter values (struct). |

Use the `get_param` and `set_param` functions to set these values. For example, assume a block parameter tab with a structure construct:

The parameters are contained in a struct. To list the parameters individually, set the `FMUParamMapping` property to 'Flat':

```
set_param(gcf, 'FMUParamMapping', 'Flat')
```

## Timing Considerations

You can set the sample time for the FMU block with the **Communication step size** parameter. This block sample time setting,  $t_C$ , like all Simulink blocks, must be an integer multiple of the model sample time,  $t_M$ . Simulink generates an error if the communication step size  $t_C$  is not a multiple of the model step size  $t_M$ .

The local step size of the FMU  $t_L$ , on the other hand, is part of the FMU specification and is known to the FMU only internally. For proper operation, the communication step size,  $t_C$  must also be an integer multiple of  $t_L$ . If the model sample time  $t_M$  or the block sample time  $t_C$  is incompatible with the FMU local step size  $t_L$ , the FMU may or may not produce an error at run time, depending on its implementation.

## Troubleshooting FMUs

If there are problems with using the FMU:

- Check the compliance of the FMU with the FMI standard. Use the FMU compliance checker.
- Select the **Enable FMU Debug Logging** check box on the FMU block Simulation tab.
- Contact the FMU supplier.

## Export a Model as a Tool-Coupling FMU

To integrate Simulink components into third-party software, export a Simulink model as a tool-coupling functional mockup unit (FMU). When a third-party tool runs the FMU, it checks out required licenses and starts a local installation of Simulink to start the model. Tool-coupling FMUs support the fixed-step and variable-step solvers that the FMU encapsulates.

Use a project to export an FMU. Open the model and select **New > Project > New Project from this Model** to create a project from a model.

You can export a FMU from a project interactively.

- 1 In the project, select **Share > Tool-Coupling FMU**.

- 2 Type in the **Copyright**, **Description**, and **FMU Icon** fields. Click **Save Settings and Export as** and provide a name.

The generated FMU includes model implementation, as well as the metadata provided during export.

```
<?xml version="1.0" encoding="utf-8"?>
<fmiModelDescription author="" copyright="" description="" fmiVersion="2.0"
 generationDateAndTime="2018-08-16T15:51:48Z"
 generationTool="Simulink (R2018b)"
 guid="5bd096be-a08d-020e-fc96-847aa21def5b"
 license=""
 modelName="vdpSlave"
 variableNamingConvention="structured"
 version="1.8">
```

You can also create and export a project to a FMU from the command line as follows:

```
>> p = slproject.create('vdpProject')
>> copyfile(which('vdp'), './vdpSlave.slx')
>> p.addFile('./vdpSlave.slx')
>> Simulink.fmuexport.ExportSimulinkProjectToFMU(p, 'vdpSlave.slx', '-fmuname', 'vdpFMU')
```

For more FMU export options from the command line, type:

```
help Simulink.fmuexport.ExportSimulinkProjectToFMU
```

The model must satisfy these conditions for exporting:

- Model must be in Normal or Accelerator simulation mode.
- Root input and output ports must be one of these numerical data types:
  - double
  - int32
  - Boolean
  - Simulink bus object, where all elements are double, int32, or Boolean
  - Simulink.AliasType, in which the base type resolves to double, int32 or Boolean

If the co-simulation component is an FMU exported from Simulink, the local sample time for that FMU is the sample time of the original model.

## Include Tunable Parameters for Tool-Coupling FMU

To include tunable parameters:

- 1 Open the model from the associated Simulink project.
- 2 From the Simulink model, click the **Modeling** tab and start Model Explorer.
- 3 Select Model Workspace and add a MATLAB variable or Simulink parameter.
- 4 For each parameter you add and want tunable, in the **Data Properties** or **Simulink.Parameter** pane, select the **Argument** check box.
- 5 Click **Apply**.
- 6 Reference the tunable parameters in the model.
- 7 Export the tool-coupling FMU.

## Use the Exported Tool-Coupling FMU

The exported FMU requires a local installation of Simulink to run. The MATLAB version used for co-simulation must be the same as the MATLAB version where the FMU is exported. On Windows, the application that runs the FMU can check out the required licenses automatically. For other operating systems, apply these settings:

- On Linux:

```
setenv LD_LIBRARY_PATH ${LD_LIBRARY_PATH}:<InstallationFolder>/bin/glnxa64:<InstallationFolder>/bin
export LD_LIBRARY_PATH=${LD_LIBRARY_PATH}:<InstallationFolder>/bin/glnxa64:<InstallationFolder>/bin
```

- On Mac OS:

```
setenv DYLD_LIBRARY_PATH ${DYLD_LIBRARY_PATH}:<InstallationFolder>/bin/maci64:<InstallationFolder>/bin
export DYLD_LIBRARY_PATH=${DYLD_LIBRARY_PATH}:<InstallationFolder>/bin/maci64:<InstallationFolder>/bin
```

For Mac OS, due to System Integrity Protection (SIP), `setenv` command does not work for applications that starts new processes, such as MATLAB. Follow `Append library path to "DYLD_LIBRARY_PATH" in MAC` to set `DYLD_LIBRARY_PATH` to `<InstallationFolder>/bin/maci64:<InstallationFolder>/extern/bin/maci64`.

Before you can run the FMU, you must set up a MATLAB session from your operating system console. After you set up this session, start the third-party application and import the tool-coupling FMU. Each FMU instance requires a new MATLAB session.

### Start a Dedicated Session from MATLAB

If the application that imports the FMU runs a single instance of the FMU, you can use MATLAB to start a session.

```
>> shareMATLABForFMUCoSim
```

This dedicates the current MATLAB session available for requests from the external tool to co-simulate an imported FMU. When an FMU is connected this session, Simulink editor and Simulink project are loaded, and co-simulation starts automatically. You can use this session to pause, resume co-simulation, as well as tune parameters or plot signals from the command window while co-simulation is running. If co-simulation is finished, stopped by user, or interrupted by a runtime error, MATLAB closes, unloads Simulink editor and Simulink project, and discards changes to the model. If an error occurs, it displays in the simulation tool that imports this FMU. Each session can connect to one FMU instance at the same time.

### Start a Dedicated Session from the Operating System

If the application that imports the FMU runs multiple FMU instances, you can use the operating system console to start dedicated MATLAB sessions.

- On Windows:

```
<matlabroot>\toolbox\shared\fmu_share\script\fmu-matlab-setup.cmd
```

- On Linux and Mac OS:

```
<matlabroot>/toolbox/shared/fmu_share/script/fmu-matlab-setup
```

Run `matlabroot` in MATLAB to find out `<matlabroot>`. The setup program starts and waits for a command. See available commands by typing `help`:

```
> help
Command list:
quit - Close all shared MATLABs and exit.
list - List shared MATLABs.
start NUMBER_OF_MATLABS - Start NUMBER_OF_MATLABS more MATLABs.
stop NUMBER_OF_MATLABS - Stop NUMBER_OF_MATLABS MATLABs.
ignore - Stop asking about the hardware core count when launching MATLABs.
clean MATLAB_NUMBER - Clean up the MATLAB workspace for MATLAB #MATLAB_NUMBER. Use 0 for all MATLABs.
help - Print the command list.
```

Launch one session for each FMU to run concurrently. If there is a single FMU, type:

```
> start 1
```

If there are three FMUs running concurrently, type:

```
> start 3
```

Only one MATLAB management tool should be running on a single machine.

## Co-Simulation Execution and Numerical Compensation

Simulink supports co-simulation between components with local solvers or involves external simulation tools. For example, co-simulation can involve an S-function implemented as a co-simulation gateway between Simulink and third-party tools or custom code. A co-simulation component can be a Functional Mockup Unit (FMU) in co-simulation mode imported to Simulink.

### Execution Timing

In Simulink simulation, the solver step size must be an integer divisor of each periodic, discrete block sample time. In other words, if a co-simulation component defines its own sample time, Simulink must communicate with the component at those time steps. Co-simulation can involve components whose time steps are determined internally and are not known to Simulink. The only information available to Simulink is the block sample time, either through the communication step size parameter of an FMU block, or the sample time definition in an S-function implementation. The block sample time determines the time steps Simulink must communicate with the co-simulation component. If the solver step size is not automatic, the communication step size must be an integer multiple of the solver step size.

If the co-simulation component internally uses a local solver, then this local solver should also be taken into account when determining the communication step size of the block. The step size of the local solver is not exposed to Simulink, and knowledge of the implementation is necessary to set the communication step size correctly. The behavior of co-simulation in case of a potential incompatibility also depends on this internal solver implementation.

## Numerical Compensation

Co-simulation signals typically represent continuous physical quantities that are discretized due to co-simulation. Data exchanges between co-simulation components such as C MEX S-functions and Co-Simulation FMU blocks can introduce numerical inaccuracies from signal delays. Use numerical compensation to improve numerical behavior for simulation involving components that use their own solver. Model Advisor includes a check that detects co-simulation components and advises numerical compensation.

### Numerical Compensation Prerequisites

Simulink automatically performs numerical compensation for co-simulation signals between co-simulation components. Simulink performs numerical compensation at the input of the destination block. A signal is automatically qualified for numerical compensation if its source port and destination port satisfy these conditions:

- The source port for the signal must satisfy these requirements:
  - S-Function
    - Output port data type is double
    - Output port sample time is periodic and discrete
    - Output port complexity is real
    - `ssSetOutputPortIsContinuousQuantity()` is set to `true` for the port
  - FMU
    - Output port data type is double
    - FMU is in co-simulation mode
    - Block sample time is periodic and discrete
    - Output port maps to a variable with `variability='continuous'` in `modelDescription.xml`
- The destination port for the signal must satisfy these requirements:
  - S-Function
    - Input port data type is double
    - Input port sample time is periodic and discrete
    - Input port complexity is real
    - `ssSetInputPortIsContinuousQuantity()` is set to `true` for this port
    - `ssSetInputPortDirectFeedThrough()` is set to `false` for this port
  - FMU
    - Input port data type is double
    - FMU is in co-simulation mode
    - Block sample time is periodic and discrete
    - Input port maps to a variable with `variability='continuous'` in `modelDescription.xml`

For an example of identifying co-simulation signals for numerical compensation, see the `slexCoSimTripleMassSpringExample` model.

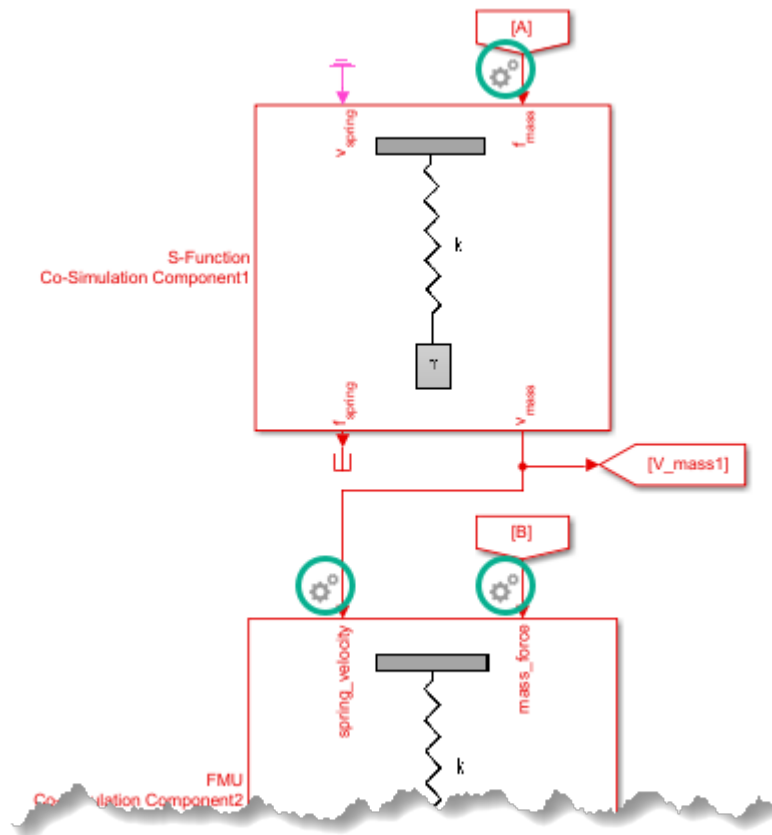

### Manage Numerical Compensation Options Using the Dialog

When Simulink detects the signals that can have numerical compensation, it marks the corresponding input ports with the  icon.

The following model includes co-simulation signals that can have numerical compensation:

- 1 Open the model.  
`slexCoSimTripleMassSpringExample`
- 2 Update the diagram. Simulink detects the signals that can have numerical compensation, and marks the corresponding ports with the  icon.

- 3 Adjust the parameters for compensation accuracy: Right-click the icon and select **Configure Cosimulation Signal Compensation** and adjust the calculation parameters:
  - **Extrapolation Method** — This method computes a compensated signal value for the current time step of simulation using extrapolation of simulation signal values generated from previous time steps. Three types of extrapolations are offered for selection.
    - **Linear** is the default, it uses signal values generated from previous two time steps to linearly estimate the signal value for use in the current time step of simulation.
    - **Quadratic** uses signal values of the previous three time steps to fit the data to a quadratic polynomial.
    - **Cubic** uses signal values of the previous four time steps to fit the data to a cubic polynomial.

In the beginning of the simulation, when there is an insufficient number of past signal values, a lower order extrapolation method is used automatically. Higher order extrapolation methods use more past signal values to predict the current signal value and can improve accuracy of the prediction. However, high order extrapolation methods can also be numerically unstable[1]. The best extrapolation method depends on the nature of the signal.

- **Signal correction coefficient** — This method further adjusts the extrapolated signal value based on past simulation results and past estimated signal values. A correction coefficient is offered for selection between 0 and 1, where 0 means no adjustment to be made to the extrapolated signal value. The default setting for the correction coefficient is 1. For a given extrapolated signal at a given time step, the larger the signal correction coefficient is, the more adjustment is made to the given extrapolated signal.

If numerical compensation is not beneficial, disable it by left-clicking the  icon. When disabled, the icon appears with a red slash.

## Manage Numerical Compensation Options from the Command Line

If automatic compensation is not possible, you can manually enable numerical compensation using the `CoSimSignalCompensationMode` property.

The `CoSimSignalCompensationMode` property has these values:

| Icon                                                                                | Setting      | Behavior                                                                                                                                                                                                       |
|-------------------------------------------------------------------------------------|--------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|    | 'Auto'       | Enable automatic numerical compensation, allowing Simulink to detect if the port has a signal eligible for numerical compensation.                                                                             |
|    | 'Auto_Off'   | Disable automatic numerical compensation. Icon appears with a red slash.                                                                                                                                       |
|    | 'Always'     | Force the port to be considered numerical compensation compliant, even if the signal is not eligible for numerical compensation. This setting lets you add compensation without declaring it to be continuous. |
|  | 'Always_Off' | Disable forcing the port to be considered numerical compensation compliant.                                                                                                                                    |

For example, to disable numerical compensation for the first input port from the previous model:

- 1 Select the block for which you want to select the port for numerical compensation. For example, get all the port handles for the currently selected block, `gcb`.

```
p = get_param(gcb, 'PortHandles')
```

This function returns all the ports for the currently selected block. For example,

```
p =
```

```
struct with fields:
```

```

 Inport: [22.0001 20.0001]
 Outport: [23.0001 25.0001]
 Enable: []
 Trigger: []
 State: []
 LConn: []
 RConn: []
 Ifaction: []
 Reset: []

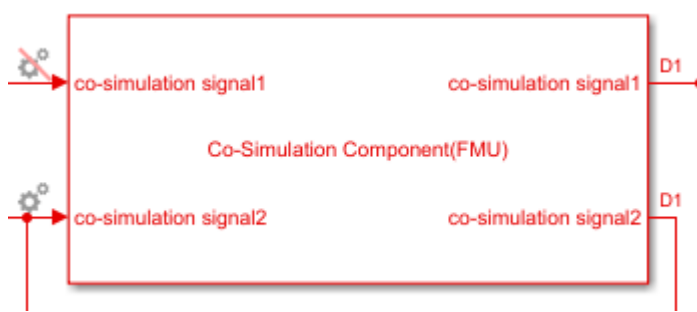

```

- 2 To disable numerical compensation for the first port:

```
set_param(p.Inport(1), 'CoSimSignalCompensationMode', 'Auto_Off')
```

The associated port appears with a red slash.

You can also set signal compensation parameters from the command line. The first step, again, is to obtain the port handles:

```
p = get_param(block, 'PortHandles')
```

Set the compensation parameters using the `CoSimSignalCompensationConfig` parameter, in this format:

```
set_param(p.Inport, 'CoSimSignalCompensationConfig', '{<CompensationParam>:<ParamValue>}')
```

Find compensation parameter names and possible values in this table:

| Compensation parameter  | Parameter name           | Parameter value                                                                |
|-------------------------|--------------------------|--------------------------------------------------------------------------------|
| ExtrapolationMethod     | Extrapolation method     | 'LinearExtrapolation',<br>'QuadraticExtrapolation',<br>or 'CubicExtrapolation' |
| CompensationCoefficient | Compensation coefficient | Scalar between 0 and 1                                                         |

For example, set the extrapolation method for the port:

```
set_param(p.Inport, 'CoSimSignalCompensationConfig', '{"ExtrapolationMethod":"LinearExtrapolation"}'
```

Set both the extrapolation method and the compensation coefficient:

```
set_param(p.Inport, 'CoSimSignalCompensationConfig', '{"ExtrapolationMethod":"QuadraticExtrapolation", "CompensationCoefficient":"0.7"}'
```

## Run Co-Simulation Components on Multiple Cores

Simulink supports co-simulation between components using local solvers or that involves simulation tools. For example, co-simulation can involve an S-function implemented as a co-simulation gateway between Simulink and third-party tools or custom code. It can also involve an FMU in co-simulation mode imported to Simulink or a Model block in accelerator mode.

To improve performance, consider running models that contain co-simulation blocks (components) on multiple threads if:

- You are integrating multiple co-simulation components
- Integration at the component level is computationally intense

This topic assumes that you are familiar with multithreaded programming and concepts.

Simulink lets you run C MEX S-functions, Co-Simulation FMU blocks, and Model blocks configured for accelerator mode on multiple threads if they are threadsafe. Being threadsafe means that the block can work with multiple threads accessing shared data, resources, and objects without any conflicts.

You can also run a model on multiple threads if the model has a nondirect feedthrough block followed by a direct feedthrough block (see “Singlethreaded Versus Multithreaded Simulations” on page 48-24). Direct feedthrough means that the output port signal of a block is computed from the values of its input port signals in the same time step.

---

**Note** Multithreaded co-simulation for Level-2 MATLAB S-Function blocks is not supported.

---

By default, Simulink configures all models to run on multiple threads. If performance can be improved, Simulink automatically runs all models on multiple threads. However, not all models have co-simulation components that can run on multiple threads, and not all models benefit from running on multiple threads.

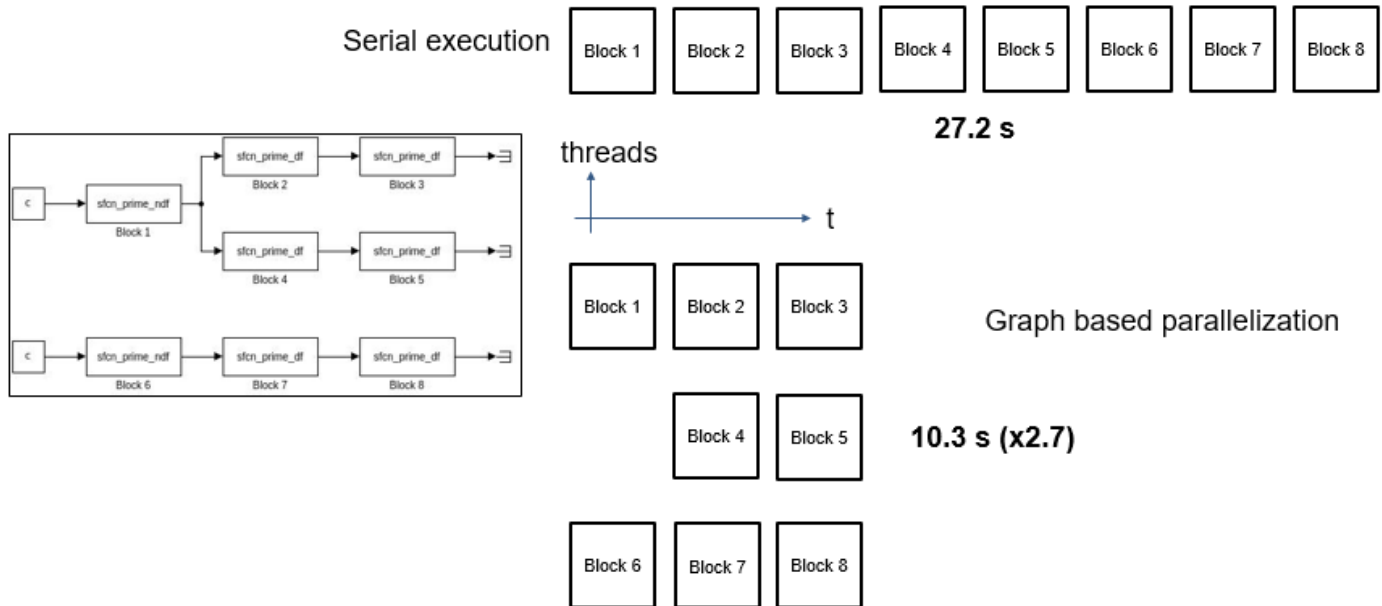

### Singlethreaded Versus Multithreaded Simulations

When evaluating a model for possible concurrencies in your system for multithread execution, Simulink uses a graph-based algorithm to analyze data dependencies among eligible blocks and form multiple task groups. This algorithm ensures that the different task groups:

- Have no data dependencies on each other
- Can execute in parallel using multiple cores

For example, Simulink might look for non-direct feedthrough blocks followed by direct feedthrough blocks. If the following direct feedthrough blocks depend only on a nondirect feedthrough block, the software can group the blocks in the same branch for parallel execution.

This example compares the serial execution of a series of blocks partitioned for parallel execution.

## Using Multithreaded Simulation to Speed up Simulation on Multiple Cores

Consider the Graph-Based Multithread Simulation example, which uses four nondirect feedthrough blocks followed by four direct feedthrough blocks. Direct feedthrough means that the output port signal of a block is computed from the values of its input port signals in the same time step.

Simulink analyzes the data dependencies and forms four branches. Each branch contains nondirect feedthrough blocks followed by direct feedthrough blocks. Then, Simulink uses multithreading to run those four branches. In this way, Simulink can speed up the simulation up to four times on a four or more core machine compared to a singlethreaded simulation on the same machine. You can manually measure the simulation of the model before and after changing the `MultithreadedSim` parameter.

You can manually measure the simulation of the model before and after changing the `MultithreadedSim` parameter. This code shows how to measure simulation for the Graph-Based Multithread Simulation example:

```
openExample('slexGraphBasedMultiThreadSimExample');...
set_param(gcs, 'MultithreadedSim', 'off');
tic; sim('slexGraphBasedMultiThreadSimExample'); toc
```

Elapsed time is 39.406743 seconds.

```
set_param(gcs, 'MultithreadedSim', 'on');
tic; sim('slexGraphBasedMultiThreadSimExample'); toc
```

Elapsed time is 13.619744 seconds.

In this example, the speedup is almost three times (instead of four times) on a four core machine. This is due to the extra overhead introduced by the operating system thread context switch.

## Using the `MultithreadedSim` Parameter

You can specify that an entire model run on multiple threads, or specify that particular blocks run on multiple threads, using the `MultithreadedSim` parameter. Specify that an entire model runs on multiple threads if all the co-simulation blocks in the model are threadsafe. If some, but not all blocks, are threadsafe, identify only those blocks to run on multiple threads. The model and blocks use the `MultithreadedSim` parameter as follows:

| Setting             | Description                                                             |
|---------------------|-------------------------------------------------------------------------|
| 'auto' <sup>a</sup> | (Default) Let Simulink decide if the block can run on multiple threads. |
| 'off'               | Disable the block or model from running on multiple threads.            |

- a. Starting in R2021a, when you open a model created in a previous release, Simulink interprets the 'on' setting to be the same as 'auto'.

Enabling the `MultithreadedSim` parameter does not mean that the block or model simulates on multiple threads. Simulation on multiple threads occurs when `MultithreadedSim` is enabled and:

- The block and/or model operate at a single rate.
- The block and/or model are threadsafe. (For example, they do not use static or global data).
- The block and/or model is exception-free. For S-function blocks, use the `ssSetOptions` function to set `SS_OPTION_EXCEPTION_FREE_CODE`.

Multithreading does not allow solver reset checks, and therefore skips over any use of the `ssSetSolverNeedsReset` and `ssBlockStateForSolverChangedAtMajorStep` functions. Conversely, in accelerator mode, if these functions are used or there are continuous states, multithreading is automatically turned off.

## Configuring S-Function Blocks to Run Single or Multithreaded

Whether an S-function block runs single or multithreaded depends on the `MultithreadedSim` parameter value and the `ssSetRuntimeThreadSafetyCompliance` function.

| MultithreadedSim Setting | ssSetRuntimeThreadSafetyCompliance Setting            | Single or Multithread                                               |
|--------------------------|-------------------------------------------------------|---------------------------------------------------------------------|
| 'auto'                   | <code>RUNTIME_THREAD_SAFETY_COMPLIANCE_UNKNOWN</code> | Single thread                                                       |
| 'auto'                   | <code>RUNTIME_THREAD_SAFETY_COMPLIANCE_TRUE</code>    | Multithread                                                         |
| 'auto'                   | <code>RUNTIME_THREAD_SAFETY_COMPLIANCE_FALSE</code>   | Single thread                                                       |
| 'off'                    | —                                                     | The setting is ignored and the S-function block runs singlethreaded |

## Co-Simulation on Multiple Threads Limitations and Guidelines

- The simulation runs on a single thread for accelerator and rapid accelerator modes. Multithreading is enabled when the simulation mode is normal.

Set model simulation mode to normal.

- There is no code generation for co-simulation components.
- Multithreading is not activated for blocks with constant sample time.
- Multithreading is not enabled when the Simulink debugger is on.

Turn off Simulink debugger.

- A block that depends on a non-thread-safe block cannot be multithreaded. Consider breaking the dependency, for example, by using a Unit Delay block.

### S-Function Block Limitations

- Must have a single rate.

Consider revising your model to break down multirate components into individual single-rate components.

- Multithreading is not enabled when an S-function has variable sample time.

Consider using a different sample time (see “Specify Sample Time” on page 7-3).

- Multithreading is not enabled when an S-function has continuous states and solver is fixed-step, which together trigger a continuous states consistency check. To disable continuous states consistency checks, use the `ssSetSkipContStatesConsistencyCheck` function.
- Must be thread safe — In `ssSetRuntimeThreadSafetyCompliance(SimStruct *S, int_T val)`, `val` must be `RUNTIME_THREAD_SAFETY_COMPLIANCE_TRUE`.

For more information, see “Guidelines for Writing Thread-Safe S-Functions”.

- Must be exception-free — In `ssSetOptions(SimStruct *S, uint_T options)`, `options` must include `SS_OPTION_EXCEPTION_FREE_CODE`.

For more information, see “Guidelines for Writing Thread-Safe S-Functions”.

- Multithreading is not enabled when the S-function Analyzer is on. Try multithreading in normal mode.
- Multithreading is not enabled when S-function has continuous sample time. Consider using a different sample time (see “Specify Sample Time” on page 7-3).
- Multithreading concurrently runs output and update methods. The block must have an output or update method.

### FMU Import Block Limitations

- Must be in co-simulation mode.

Consider switching FMU mode from Model Exchange to Co-Simulation.

- Must be thread-safe, for example, multiple FMUs must not access the same file at the same time.
- Multithreading is not enabled when FMU block logging displays in the MATLAB command window. Redirect FMU block logging to a file using:

```
set_param(blockName, 'FMUDebugLoggingRedirect', 'File')
```

- Multithreading is not supported when FMU is running out-of-process. To disable this setting, use:

```
set_param(blockName, 'DebugExecutionForFMUViaOutOfProcess', 'off')
```

### Model Block Limitations

- Multithreading is not enabled when a Model block has event ports.
- Cannot be inside a For Each Subsystem block.

Consider moving the Model block out of the For Each Subsystem block.

- Must be in accelerator mode.

- Must have single rate.

Consider revising your model to break down multirate components into individual single-rate components.

- Cannot use blocks with variable sample time.

Consider using a different sample time (see “Specify Sample Time” on page 7-3).

- Cannot have continuous states.
- Consider breaking the dependency between blocks, for example, by using a Unit Delay block.
- Must have a fixed-step solver.
- Cannot access any global data stores.
- Multithreading is not enabled when a model contains a Simulink Function block.
- Cannot use any Simulink functions or caller blocks.
- Cannot contain To File blocks. For more information, see “Export Simulation Data” on page 73-2.
- Cannot contain From File blocks.

Consider feeding data into the referenced model via an inport from the top-level model.

## Simulink Community and Connection Partner Program

Simulink supports the integration of multiple third-party functionalities, including apps, models, and toolboxes, from the Simulink community and commercial software tools.

For the integration of third-party functionality, this program includes:

- Simulink community — Provides direct access to all available Simulink apps, models, and toolboxes (Simulink community) using MATLAB Add-Ons. (To open the Add-On Explorer, go to the MATLAB Toolstrip and click **Add-Ons > get Add-Ons.**)
- Third-Party Products — The MathWorks Connections Program includes commercially offered products and services that complement MATLAB and Simulink.

## FMU Block Calling Sequences

During simulation of models containing FMU blocks, as Simulink passes through different Simulink engine phases, the FMU blocks call FMU Co-Simulation and Model Exchange methods for FMI Versions 1.0 and 2.0 (fmi\* and fmi2\* methods). This topic presents the FMI Standard call sequences in those phases.

This topic uses:

- fmiSetXXX (FMI Version 1.0) and fmi2SetXXX (FMI Version 2.0) to represent any of the methods: fmiSetReal/fmi2SetReal, fmiSetInteger/fmi2SetInteger, fmiSetBoolean/fmi2SetBoolean, or fmiSetString/fmi2SetString.
- fmiGetXXX (FMI Version 1.0) and fmi2GetXXX (FMI Version 2.0) to represent any of the methods: fmiGetReal/fmi2GetReal, fmiGetInteger/fmi2GetInteger, fmiGetBoolean/fmi2GetBoolean, or fmiGetString/fmi2GetString.

### Co-Simulation Call Sequence for FMI Version 1.0

These are the call orders for the FMI methods that the S-function callback methods call.

#### Setup Phase

At the end of compilation, the FMU block performs setup activities by calling these FMI methods:

- 1 fmiGetTypesPlatform
- 2 fmiGetVersion
- 3 fmiInstantiateModel
- 4 fmiSetTime
- 5 For variables with start values, fmiSetXXX

#### Initialization Phase

At the start of simulation, the FMU block sets up internal states and performs other initialization activities by calling the fmiSetXXX methods for tunable parameters.

#### Output Phase

During this phase, the FMU block computes outputs at the current time step by calling these FMI methods:

- 1 If the call is the first step:
  - a fmiSetXXX
  - b fmiInitialize
  - c If an event occurs, fmiEventUpdate
- 2 If the call is not the first step:
  - a fmiSetTime
  - b fmiSetXXX (for input)
  - c fmiSetContinuousStates

- d fmiCompletedIntegratorStep
  - e If an event occurs, fmiEventUpdate
- 3 For output, fmiGetXXX

### **Update Phase**

The FMU block computes states at the current time step and performs other major time step activities by calling the fmiSetXXX methods for input.

### **Derivatives Phase**

The FMU block computes derivatives of the FMU continuous states by calling these FMI methods:

- 1 fmiSetTime
- 2 fmiSetContinuousStates
- 3 fmiGetDerivatives

### **Zero-Crossing Signal Phase**

The FMU block computes the zero-crossing vector from the FMU event indicator by calling these FMI functions:

- 1 fmiSetTime
- 2 fmiSetContinuousStates
- 3 fmiGetEventIndicators

### **Termination Phase**

At the end of simulation, the FMU block performs activities before terminating the simulation by calling these FMI methods:

- 1 fmiTerminate
- 2 fmiFreeModelInstance

## **Model Exchange Call Sequence for FMI Version 1.0**

These are the call orders for the FMI methods that the S-function callback methods call.

### **Setup Phase**

At the end of compilation, the FMU block performs setup activities by calling these FMI functions:

- 1 fmiGetTypesPlatform
- 2 fmiGetVersion
- 3 fmiInstantiateModel
- 4 fmiSetTime
- 5 For variables with start values, fmiSetXXX

### **Initialization Phase**

At the start of simulation, the FMU block sets up internal states and performs other initialization activities by calling these fmiSetXXX methods for tunable parameters.

### Output Phase

The FMU block computes outputs at the current time step by calling these FMI functions:

- 1 If the call is the first step:
  - a fmiSetXXX
  - b fmiInitialize
  - c If an event occurs, fmiEventUpdate
- 2 If the call is not the first step, fmiDoStep,
- 3 For output, fmiGetXXX

### Update Phase

The FMU block computes states at the current time step and performs other major time step activities by calling the fmiSetXXX methods for input.

### Termination Phase

At the end of simulation, the FMU block performs activities before terminating the simulation. This method calls these methods:

- 1 fmiTerminate
- 2 fmiFreeModelInstance

## Co-Simulation Call Sequence for FMI Version 2.0

These are the call orders for the FMI methods that the S-function callback methods call.

### Setup Phase

At the end of compilation, the FMU block performs setup activities by calling these FMI methods:

- 1 fmi2GetTypesPlatform
- 2 fmi2GetVersion
- 3 fmi2Instantiate
- 4 For variables with start values, fmi2SetXXX

### Initialization Phase

At the start of simulation, the FMU block sets up internal states and performs other initialization activities by calling these FMI methods:

- 1 For variables with start values, fmi2SetXXX
- 2 fmi2SetupExperiment

### Output Phase

During this phase, the FMU block computes outputs at the current time step by calling these FMI methods:

- 1 If the call is the first step:

- a `fmi2EnterInitializationMode`
  - b For input, `fmi2SetXXX`
  - c `fmi2InitializationMode`
- 2 If the call is not the first step, `fmi2DoStep`
- 3 For output, `fmi2GetXXX`

### **Update Phase**

During this phase, the FMU block computes states at the current time step and performs other major time step activities. This method calls the `fmi2SetXXX` for input.

### **Termination Phase**

At the end of simulation, the FMU block performs activities before terminating the simulation by calling these methods:

- 1 `fmi2Terminate`
- 2 `fmi2FreeModelInstance`

## **Model Exchange Call Sequence for FMI Version 2.0**

These are the call orders for the FMI methods that the S-function callback methods call.

### **Setup Phase**

At the end of compilation, the FMU block performs setup activities by calling these FMI methods:

- 1 `fmi2GetTypesPlatform`
- 2 `fmi2GetVersion`
- 3 `fmi2Instantiate`
- 4 For variables with start values, `fmi2SetXXX`

### **Initialization Phase**

At the start of simulation, the FMU block sets up internal states and performs other initialization activities by calling these FMI methods.

- 1 For tunable parameters, `fmi2SetXXX`
- 2 `fmi2SetupExperiment`

### **Output Phase**

The FMU block computes outputs at the current time step by calling these FMI methods:

- 1 If the call is the first step:
  - a `fmi2EnterIntializationMode`
  - b For input, `fmi2SetXXX`
  - c `fmi2ExitIntializationMode`
- 2 If the call is not the first step:

- a fmi1SetTime
- b For continuous input, fmi2SetXXX
- c fmi2SetContinuousStates
- d fmi2SetContinuousStates
- e fmi2CompletedIntegratorStep
- f If an event occurs:
  - i fmi2EnterEventMode
  - ii For input, fmi2SetXXX
  - iii fmi2NewDiscreteStates
  - iv fmi2EnterContinuousTimeMode
  - v If an event occurs:
    - A fmi2EnterEventMode
    - B For input, fmi2SetXXX
    - C fmi2NewDiscreteStates
    - D fmi2EnterContinuousTimeMode
- 3 For output, fmi2GetXXX

### Update Phase

The FMU block computes states at the current time step and performs other major time step activities by calling the fmi2SetXXX methods for input.

### Derivatives Phase

The FMU block computes derivatives of the FMU continuous states by calling these FMI methods:

- 1 fmi2SetTime
- 2 fmi2SetContinuousStates
- 3 fmi2GetEventIndicators

### Zero-Crossing Signal Phase

The FMU block computes the zero-crossing vector from the FMU event indicator by calling these FMI methods:

- 1 fmi2SetTime
- 2 fmi2SetContinuousStates
- 3 fmi2GetEventIndicators

### Termination Phase

At the end of simulation, the FMU block performs activities before terminating the simulation by calling these methods:

- 1 fmi2Terminate
- 2 fmiFreeInstance

## When to Generate Code from MATLAB Algorithms

Generating code from MATLAB algorithms for desktop and embedded systems allows you to perform your software design, implementation, and testing completely within the MATLAB workspace. You can:

- Verify that your algorithms are suitable for code generation
- Generate efficient, readable, and compact C/C++ code automatically, which eliminates the need to manually translate your MATLAB algorithms and minimizes the risk of introducing errors in the code.
- Modify your design in MATLAB code to take into account the specific requirements of desktop and embedded applications, such as data type management, memory use, and speed.
- Test the generated code and easily verify that your modified algorithms are functionally equivalent to your original MATLAB algorithms.
- Generate MEX functions to:
  - Accelerate MATLAB algorithms in certain applications.
  - Speed up fixed-point MATLAB code.
- Generate hardware description language (HDL) from MATLAB code.

## When Not to Generate Code from MATLAB Algorithms

Do not generate code from MATLAB algorithms for the following applications. Use the recommended MathWorks product instead.

| To:                                                             | Use:                                                                     |
|-----------------------------------------------------------------|--------------------------------------------------------------------------|
| Deploy an application that uses handle graphics                 | MATLAB Compiler                                                          |

## **Prerequisites for C/C++ Code Generation from MATLAB**

To generate C/C++ or MEX code from MATLAB algorithms, you must install the following software:

- MATLAB Coder product
- C/C++ compiler

## MATLAB Code Design Considerations for Code Generation

When writing MATLAB code that you want to convert into efficient, standalone C/C++ code, you must consider the following:

- Data types

C and C++ use static typing. To determine the types of your variables before use, MATLAB Coder requires a complete assignment to each variable.

- Array sizing

Variable-size arrays and matrices are supported for code generation. You can define inputs, outputs, and local variables in MATLAB functions to represent data that varies in size at run time.

- Memory

You can choose whether the generated code uses static or dynamic memory allocation.

With dynamic memory allocation, you potentially use less memory at the expense of time to manage the memory. With static memory, you get better speed, but with higher memory usage. Most MATLAB code takes advantage of the dynamic sizing features in MATLAB, therefore dynamic memory allocation typically enables you to generate code from existing MATLAB code without modifying it much. Dynamic memory allocation also allows some programs to compile even when upper bounds cannot be found.

Static allocation reduces the memory footprint of the generated code, and therefore is suitable for applications where there is a limited amount of available memory, such as embedded applications.

- Speed

Because embedded applications must run in real time, the code must be fast enough to meet the required clock rate.

To improve the speed of the generated code:

- Choose a suitable C/C++ compiler. Do not use the default compiler that MathWorks supplies with MATLAB for Windows 64-bit platforms.
- Consider disabling run-time checks.

By default, for safety, the code generated for your MATLAB code contains memory integrity checks and responsiveness checks. Generally, these checks result in more generated code and slower simulation. Disabling run-time checks usually results in streamlined generated code and faster simulation. Disable these checks only if you have verified that array bounds and dimension checking is unnecessary.

## Differences Between Generated Code and MATLAB Code

To convert MATLAB code to efficient C/C++ code, the code generator introduces optimizations that intentionally cause the generated code to behave differently, and sometimes produce different results, than the original source code.

Here are some of the differences:

### Functions that have Multiple Possible Outputs

Certain mathematical operations, such as singular value decomposition and eigenvalue decomposition of a matrix, can have multiple answers. Two different algorithms implementing such an operation can return different outputs for identical input values. Two different implementations of the same algorithm can also exhibit the same behavior.

For such mathematical operations, the corresponding functions in the generated code and MATLAB might return different outputs for identical input values. To see if a function has this behavior, in the corresponding function reference page, see the **C/C++ Code Generation** section under **Extended Capabilities**. Examples of such functions include `svd` and `eig`.

## Writing to ans Variable

When you run MATLAB code that returns an output without specifying an output argument, MATLAB implicitly writes the output to the `ans` variable. If the variable `ans` already exists in the workspace, MATLAB updates its value to the output returned.

The code generated from such MATLAB code does not implicitly write the output to an `ans` variable.

For example, define the MATLAB function `foo` that explicitly creates an `ans` variable in the first line. The function then implicitly updates the value of `ans` when the second line executes.

```
function foo %#codegen
ans = 1;
2;
disp(ans);
end
```

Run `foo` at the command line. The final value of `ans`, which is 2, is displayed at the command line.

```
foo
2
```

Generate a MEX function from `foo`.

```
codegen foo
```

Run the generated MEX function `foo_mex`. This function explicitly creates the `ans` variable and assigns the value 1 to it. But `foo_mex` does not implicitly update the value of `ans` to 2.

```
foo_mex
1
```

## Logical Short-Circuiting

Suppose that your MATLAB code has the logical operators `&` and `|` placed inside square brackets (`[` and `]`). For such code patterns, the generated code does not employ short-circuiting behavior for these logical operators, but MATLAB execution might employ short-circuiting behavior. See “Logical Short-Circuiting”.

For example, define the MATLAB function `foo` that uses the `&` operator inside square brackets in the conditional expression of an `if . . . end` block.

```
function foo
if [returnsFalse() & hasSideEffects()]
end
end
```

```
function out = returnsFalse
out = false;
end
```

```
function out = hasSideEffects
out = true;
disp('This is my string');
end
```

The first argument of the `&` operator is always `false` and determines the value of the conditional expression. So, in MATLAB execution, short-circuiting is employed and the second argument is not evaluated. So, `foo` does not call the `hasSideEffects` function during execution and does not display anything at the command line.

Generate a MEX function for `foo`. Call the generated MEX function `foo_mex`.

```
foo_mex
```

```
This is my string
```

In the generated code, short-circuiting is not employed. So, the `hasSideEffects` function is called and the string is displayed at the command line.

## Loop Index Overflow

Suppose that a `for`-loop end value is equal to or close to the maximum or minimum value for the loop index data type. In the generated code, the last increment or decrement of the loop index might cause the index variable to overflow. The index overflow might result in an infinite loop.

When memory integrity checks are enabled, if the code generator detects that the loop index might overflow, it reports an error. The software error checking is conservative. It might incorrectly report a loop index overflow. By default, memory-integrity checks are enabled for MEX code and disabled for standalone C/C++ code. See “Why Test MEX Functions in MATLAB?” (MATLAB Coder) and “Generate Standalone C/C++ Code That Detects and Reports Run-Time Errors” (MATLAB Coder).

To avoid a loop index overflow, use the workarounds in this table.

| Loop Conditions Causing the Potential Overflow                                                                                                         | Workaround                                                                                                                                                                                                                                                                           |
|--------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <ul style="list-style-type: none"> <li>The loop index increments by 1.</li> <li>The end value equals the maximum value of the integer type.</li> </ul> | <p>If the loop does not have to cover the full range of the integer type, rewrite the loop so that the end value is not equal to the maximum value of the integer type. For example, replace:</p> <pre>N=intmax('int16') for k=N-10:N</pre> <p>with:</p> <pre>for k=1:10</pre>       |
| <ul style="list-style-type: none"> <li>The loop index decrements by 1.</li> <li>The end value equals the minimum value of the integer type.</li> </ul> | <p>If the loop does not have to cover the full range of the integer type, rewrite the loop so that the end value is not equal to the minimum value of the integer type. For example, replace:</p> <pre>N=intmin('int32') for k=N+10:-1:N</pre> <p>with:</p> <pre>for k=10:-1:1</pre> |

| Loop Conditions Causing the Potential Overflow                                                                                                                                                                                                                    | Workaround                                                                                                                                                                                                                                                                                                                                                                 |
|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <ul style="list-style-type: none"> <li>The loop index increments or decrements by 1.</li> <li>The start value equals the minimum or maximum value of the integer type.</li> <li>The end value equals the maximum or minimum value of the integer type.</li> </ul> | <p>If the loop must cover the full range of the integer type, cast the type of the loop start, step, and end values to a bigger integer or to double. ## Indexing for Loops by Using Single Precision Operands

Suppose in your MATLAB code, you are indexing a for loop that has a colon operator, where at least one of the colon operands is a single type operand and the number of iterations is greater than `flintmax('single') = 16777216`. When all these conditions are true, code generation might generate run-time or compile-time errors because the generated code calculates different values for the loop index variable than the values that MATLAB calculates.

For example, consider this MATLAB code:

```
function j = singlePIndex
n = flintmax('single') + 2;
j = single(0);
for i = single(1):single(n)
 j = i;
end
end
```

This code snippet executes in MATLAB, but it causes a compile-time or run-time error because the value of the loop index variable, `i`, is calculated differently in the generated code. The code generator displays a compile-time or run-time error and stops code generation or execution to prevent this discrepancy.

To avoid this discrepancy, replace the single type operands with double type or integer type operands.

For more information on run-time errors, see “Generate Standalone C/C++ Code That Detects and Reports Run-Time Errors” (MATLAB Coder).

## Index of an Unentered for Loop

In your MATLAB code and generated code, after a `for` loop execution is complete, the value of the index variable is equal to its value during the final iteration of the `for` loop.

In MATLAB, if the loop does not execute, the value of the index variable is stored as `[]` (empty matrix). In generated code, if the loop does not execute, the value of the index variable is different than the MATLAB index variable.

- If you provide the `for` loop start and end variables at run time, the value of the index variable is equal to the start of the range. For example, consider this MATLAB code:

```
function out = indexTest(a,b)
for i = a:b
end
out = i;
end
```

Suppose that `a` and `b` are passed as `1` and `-1`. The `for` loop does not execute. In MATLAB, `out` is assigned `[]`. In the generated code, `out` is assigned the value of `a`, which is `1`.

- If you provide the `for` loop start and end values before compile time, the value of the index variable is assigned `[]` in both MATLAB and the generated code. Consider this MATLAB code:

```
function out = indexTest
for i = 1:-1
end
out = i;
end
```

In both MATLAB and the generated code, `out` is assigned `[]`.

## Character Size

MATLAB supports 16-bit characters, but the generated code represents characters in 8 bits, the standard size for most embedded languages like C. See “Encoding of Characters in Code Generation” on page 53-6.

## Order of Evaluation in Expressions

Generated code does not enforce the order of evaluation in expressions. For most expressions, the order of evaluation is not significant. For expressions that have side effects, the generated code might produce the side effects in a different order from the original MATLAB code. Expressions that produce side effects include those that:

- Modify persistent or global variables
- Display data to the screen
- Write data to files
- Modify the properties of handle class objects

In addition, the generated code does not enforce order of evaluation of logical operators that do not short circuit.

For more predictable results, it is good coding practice to split expressions that depend on the order of evaluation into multiple statements.

- Rewrite

```
A = f1() + f2();
```

as

```
A = f1();
A = A + f2();
```

so that the generated code calls f1 before f2.

- Assign the outputs of a multi-output function call to variables that do not depend on one another. For example, rewrite

```
[y, y.f, y.g] = foo;
```

as

```
[y, a, b] = foo;
y.f = a;
y.g = b;
```

- When you access the contents of multiple cells of a cell array, assign the results to variables that do not depend on one another. For example, rewrite

```
[y, y.f, y.g] = z{:};
```

as

```
[y, a, b] = z{:};
y.f = a;
y.g = b;
```

## Name Resolution While Constructing Function Handles

MATLAB and code generation follow different precedence rules for resolving names that follow the symbol @. These rules do not apply to anonymous functions. The precedence rules are summarized in this table.

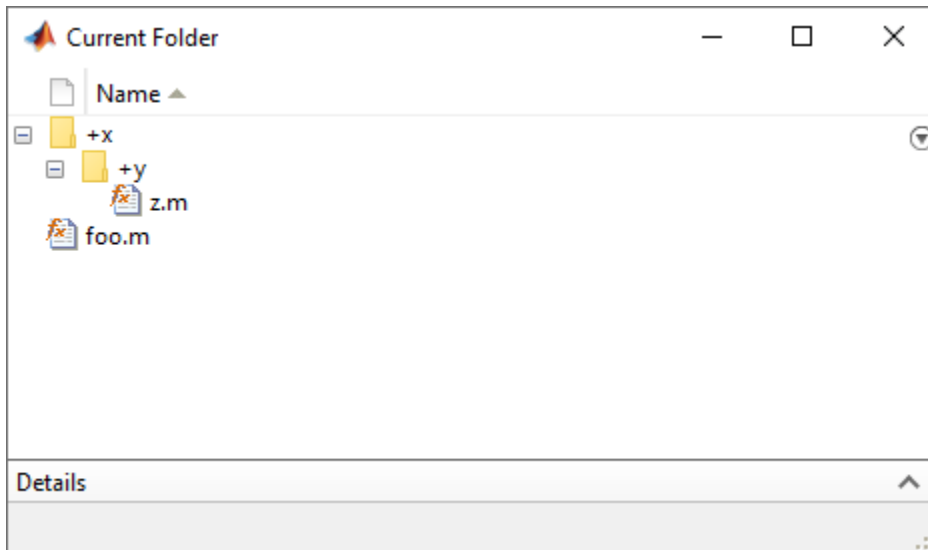

| Expression                                                           | Precedence Order in MATLAB                                       | Precedence Order in Code Generation                                              |
|----------------------------------------------------------------------|------------------------------------------------------------------|----------------------------------------------------------------------------------|
| An expression that does not contain periods, for example @x          | Nested function, local function, private function, path function | Local variable, nested function, local function, private function, path function |
| An expression that contains exactly one period, for example @x.y     | Local variable, path function                                    | Local variable, path function (Same as MATLAB)                                   |
| An expression that contains more than one period, for example @x.y.z | Path function                                                    | Local variable, path function                                                    |

If x is a local variable that is itself a function handle, generated code and MATLAB interpret the expression @x differently:

- MATLAB produces an error.
- Generated code interprets @x as the function handle of x itself.

Here is an example that shows this difference in behavior for an expression that contains two periods.

Suppose that your current working folder contains a package x, which contains another package y, which contains the function z. The current working folder also contains the entry-point function foo for which you want to generate code.

This is the definition for the file foo:

```
function out = foo
 x.y.z = @() 'x.y.z is an anonymous function';
 out = g(x);
end

function out = g(x)
 f = @x.y.z;
 out = f();
end
```

This is the definition for function z:

```
function out = z
 out = 'x.y.z is a package function';
end
```

Generate a MEX function for foo. Separately call both the generated MEX function foo\_mex and the MATLAB function foo.

```
codegen foo
foo_mex
foo

ans =

 'x.y.z is an anonymous function'
```

```
ans =
 'x.y.z is a package function'
```

The generated code produces the first output. MATLAB produces the second output. Code generation resolves `@x.y.z` to the local variable `x` that is defined in `foo`. MATLAB resolves `@x.y.z` to `z`, which is within the package `x.y`.

## Termination Behavior

Generated code does not match the termination behavior of MATLAB source code. For example, if infinite loops do not have side effects, optimizations remove them from generated code. As a result, the generated code can possibly terminate even though the corresponding MATLAB code does not.

## Size of Variable-Size N-D Arrays

For variable-size N-D arrays, the `size` function might return a different result in generated code than in MATLAB source code. The `size` function sometimes returns trailing ones (singleton dimensions) in generated code, but always drops trailing ones in MATLAB. For example, for an N-D array `X` with dimensions `[4 2 1 1]`, `size(X)` might return `[4 2 1 1]` in generated code, but always returns `[4 2]` in MATLAB. See “Incompatibility with MATLAB in Determining Size of Variable-Size N-D Arrays” on page 54-16.

## Size of Empty Arrays

The size of an empty array in generated code might be different from its size in MATLAB source code. See “Incompatibility with MATLAB in Determining Size of Empty Arrays” on page 54-17.

## Size of Empty Array That Results from Deleting Elements of an Array

Deleting all elements of an array results in an empty array. The size of this empty array in generated code might differ from its size in MATLAB source code.

| Case                                                                    | Example Code                                                                    | Size of Empty Array in MATLAB | Size of Empty Array in Generated Code |
|-------------------------------------------------------------------------|---------------------------------------------------------------------------------|-------------------------------|---------------------------------------|
| Delete all elements of an m-by-n array by using the colon operator (:). | <code>coder.varsize('X',[4,4],[1,1]);<br/>X = zeros(2);<br/>X(:) = [];</code>   | 0-by-0                        | 1-by-0                                |
| Delete all elements of a row vector by using the colon operator (:).    | <code>coder.varsize('X',[1,4],[0,1]);<br/>X = zeros(1,4);<br/>X(:) = [];</code> | 0-by-0                        | 1-by-0                                |
| Delete all elements of a column vector by using the colon operator (:). | <code>coder.varsize('X',[4,1],[1,0]);<br/>X = zeros(4,1);<br/>X(:) = [];</code> | 0-by-0                        | 0-by-1                                |

| Case                                                                      | Example Code                                                                              | Size of Empty Array in MATLAB | Size of Empty Array in Generated Code |
|---------------------------------------------------------------------------|-------------------------------------------------------------------------------------------|-------------------------------|---------------------------------------|
| Delete all elements of a column vector by deleting one element at a time. | <pre>coder.varsize('X',[4,1],[1,0]); X = zeros(4,1); for i = 1:4     X(i) = []; end</pre> | 1-by-0                        | 0-by-1                                |

## Binary Element-Wise Operations with Single and Double Operands

If your MATLAB code contains a binary element-wise operation that involves a single type operand and a double type operand, the generated code might not produce the same result as MATLAB.

For such an operation, MATLAB casts both operands to double type and performs the operation with the double types. MATLAB then casts the result to single type and returns it.

The generated code casts the double type operand to single type. It then performs the operation with the two single types and returns the result.

For example, define a MATLAB function `foo` that calls the binary element-wise operation `plus`.

```
function out = foo(a,b)
out = a + b;
end
```

Define a variable `s1` of single type and a variable `d1` of double type. Generate a MEX function for `foo` that accepts a single type input and a double type input.

```
s1 = single(1.4e32);
d1 = -5.305e+32;
codegen foo -args {s1, d1}
```

Call both `foo` and `foo_mex` with inputs `s1` and `d1`. Compare the two results.

```
m1 = foo(s1,d1);
m1c = foo_mex(s1,d1);
m1 == m1c
```

```
ans =
 logical
 0
```

The output of the comparison is a logical `0`, which indicates that the generated code and MATLAB produces different results for these inputs.

## Floating-Point Numerical Results

The generated code might not produce the same floating-point numerical results as MATLAB in these:

### When computer hardware uses extended precision registers

Results vary depending on how the C/C++ compiler allocates extended precision floating-point registers. Computation results might not match MATLAB calculations because of different compiler optimization settings or different code surrounding the floating-point calculations.

### For certain advanced library functions

The generated code might use different algorithms to implement certain advanced library functions, such as `fft`, `svd`, `eig`, `mldivide`, and `mrdivide`.

For example, the generated code uses a simpler algorithm to implement `svd` to accommodate a smaller footprint. Results might also vary according to matrix properties. For example, MATLAB might detect symmetric or Hermitian matrices at run time and switch to specialized algorithms that perform computations faster than implementations in the generated code.

### For implementation of BLAS library functions

For implementations of BLAS library functions, generated C/C++ code uses reference implementations of BLAS functions. These reference implementations might produce different results from platform-specific BLAS implementations in MATLAB.

## NaN and Infinity

The generated code might not produce exactly the same pattern of NaN and Inf values as MATLAB code when these values are mathematically meaningless. For example, if MATLAB output contains a NaN, output from the generated code should also contain a NaN, but not necessarily in the same place.

The bit pattern for NaN can differ between MATLAB code output and generated code output because the C99 language standard that is used to generate code does not specify a unique bit pattern for NaN across all implementations. Avoid comparing bit patterns across different implementations, for example, between MATLAB output and SIL or PIL output.

## Negative Zero

In a floating-point type, the value 0 has either a positive sign or a negative sign. Arithmetically, 0 is equal to -0, but some operations are sensitive to the sign of a 0 input. Examples include `rdivide`, `atan2`, `atan2d`, and `angle`. Division by 0 produces Inf, but division by -0 produces -Inf. Similarly, `atan2d(0, -1)` produces 180, but `atan2d(-0, -1)` produces -180.

If the code generator detects that a floating-point variable takes only integer values of a suitable range, then the code generator can use an integer type for the variable in the generated code. If the code generator uses an integer type for the variable, then the variable stores -0 as +0 because an integer type does not store a sign for the value 0. If the generated code casts the variable back to a floating-point type, the sign of 0 is positive. Division by 0 produces Inf, not -Inf. Similarly, `atan2d(0, -1)` produces 180, not -180.

There are other contexts in which the generated code might treat -0 differently than MATLAB. For example, suppose that your MATLAB code computes the minimum of two scalar doubles `x` and `y` by using `z = min(x, y)`. The corresponding line in the generated C code might be `z = fmin(x, y)`. The function `fmin` is defined in the runtime math library of the C compiler. Because the comparison

operation `0.0 == -0.0` returns `true` in C/C++, the compiler's implementation of `fmin` might return either `0.0` or `-0.0` for `fmin(0.0, -0.0)`.

## Code Generation Target

The `coder.target` function returns different values in MATLAB than in the generated code. The intent is to help you determine whether your function is executing in MATLAB or has been compiled for a simulation or code generation target. See `coder.target`.

## MATLAB Class Property Initialization

Before code generation, at class loading time, MATLAB computes class default values. The code generator uses the values that MATLAB computes. It does not recompute default values. If the property definition uses a function call to compute the initial value, the code generator does not execute this function. If the function has side effects such as modifying a global variable or a persistent variable, then it is possible that the generated code might produce different results than MATLAB. For more information, see “Defining Class Properties for Code Generation” on page 62-4.

## MATLAB Classes in Nested Property Assignments That Have Set Methods

When you assign a value to a handle object property, which is itself a property of another object, and so on, then the generated code can call set methods for handle classes that MATLAB does not call.

For example, suppose that you define a set of variables such that `x` is a handle object, `pa` is an object, `pb` is a handle object, and `pc` is a property of `pb`. Then you make a nested property assignment, such as:

```
x.pa.pb.pc = 0;
```

In this case, the generated code calls the set method for the object `pb` and the set method for `x`. MATLAB calls only the set method for `pb`.

## MATLAB Handle Class Destructors

The behavior of handle class destructors in the generated code can be different from the behavior in MATLAB in these situations:

- The order of destruction of several independent objects might be different in MATLAB than in the generated code.
- The lifetime of objects in the generated code can be different from their lifetime in MATLAB.
- The generated code does not destroy partially constructed objects. If a handle object is not fully constructed at run time, the generated code produces an error message but does not call the `delete` method for that object. For a System object, if there is a run-time error in `setupImpl`, the generated code does not call `releaseImpl` for that object.

MATLAB does call the `delete` method to destroy a partially constructed object.

For more information, see “Code Generation for Handle Class Destructors” on page 62-15.

## Variable-Size Data

See “Incompatibilities with MATLAB in Variable-Size Support for Code Generation” on page 54-15.

## Complex Numbers

See “Code Generation for Complex Data” on page 53-3.

## Converting Strings with Consecutive Unary Operators to double

Converting a string that contains multiple, consecutive unary operators to `double` can produce different results between MATLAB and the generated code. Consider this function:

```
function out = foo(op)
out = double(op + 1);
end
```

For an input value `--`, the function converts the string `--1` to `double`. In MATLAB, the answer is `NaN`. In the generated code, the answer is `1`.

## MATLAB Language Features Supported for C/C++ Code Generation

### MATLAB Features That Code Generation Supports

Code generation from MATLAB code supports many major language features including:

- n-dimensional arrays (see “Array Size Restrictions for Code Generation” on page 53-7)
- matrix operations, including deletion of rows and columns
- variable-size data (see “Code Generation for Variable-Size Arrays” on page 54-2)
- subscripting (see “Incompatibility with MATLAB in Matrix Indexing Operations for Code Generation” on page 54-19)
- complex numbers (see “Code Generation for Complex Data” on page 53-3)
- numeric classes (see “Supported Variable Types” on page 52-12)
- double-precision, single-precision, and integer math
- enumerations (see “Code Generation for Enumerations” on page 45-85)
- fixed-point arithmetic
- program control statements `if`, `switch`, `for`, `while`, and `break`
- arithmetic, relational, and logical operators
- local functions
- persistent variables
- global variables
- structures (see “Structure Definition for Code Generation” on page 55-2)
- cell arrays (see “Cell Arrays”)
- tables (see “Code Generation for Tables” on page 60-2)
- timetables (see “Code Generation for Timetables” on page 61-2)
- characters (see “Encoding of Characters in Code Generation” on page 53-6)
- string scalars (see “Code Generation for Strings” on page 53-10)
- `categorical` arrays (see “Code Generation for Categorical Arrays” on page 57-2)
- `datetime` arrays (see “Code Generation for Datetime Arrays” on page 58-2)
- `duration` arrays (see “Code Generation for Duration Arrays” on page 59-2)
- sparse matrices (see “Code Generation for Sparse Matrices” on page 53-11)
- function handles (see “Function Handle Limitations for Code Generation” on page 63-2)
- anonymous functions (see “Code Generation for Anonymous Functions” on page 64-3)
- recursive functions (see “Code Generation for Recursive Functions” on page 65-14)
- nested functions (see “Code Generation for Nested Functions” on page 64-4)
- variable length input and output argument lists (see “Code Generation for Variable Length Argument Lists” on page 64-2)
- subset of MATLAB toolbox functions (see “Functions and Objects Supported for C/C++ Code Generation” on page 50-2)

- subset of functions and System objects in several toolboxes (see “Functions and Objects Supported for C/C++ Code Generation” on page 50-2)
- MATLAB classes (see “MATLAB Classes Definition for Code Generation” on page 62-2)
- Class aliasing
- function calls (see “Resolution of Function Calls for Code Generation” on page 65-2)

## **MATLAB Language Features That Code Generation Does Not Support**

Code generation from MATLAB does not support the following frequently used MATLAB features (this list is not exhaustive):

- scripts
- GPU arrays

MATLAB Coder does not support GPU arrays. However, if you have GPU Coder™, you can generate CUDA® MEX code that takes GPU array inputs.

- `calendarDuration` arrays
- Java
- Map containers
- time series objects
- tall arrays
- `try/catch` statements
- `import` statements
- Function argument validation

# Functions, Classes, and System Objects Supported for Code Generation

---

## Functions and Objects Supported for C/C++ Code Generation

You can generate efficient C/C++ code for a subset of MATLAB built-in functions and toolbox functions and System objects that you call from MATLAB code.

These functions and System objects are listed in the following tables. In these tables, a  icon before the name of a function or a System object indicates that there are specific usage notes and limitations related to C/C++ code generation for that function or System object. To view these usage notes and limitations, in the corresponding reference page, scroll down to the **Extended Capabilities** section at the bottom and expand the **C/C++ Code Generation** section.

- Functions and Objects Supported for C/C++ Code Generation (Category List)
- Functions and Objects Supported for C/C++ Code Generation (Alphabetical List)

# System Objects Supported for Code Generation

---

## Code Generation for System Objects

You can generate C and C++ code for a subset of System objects provided by the following toolboxes.

| Toolbox Name                  | See                                                                                                                                                                       |
|-------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Communications Toolbox™       | “System Objects in MATLAB Code Generation” (MATLAB Coder)                                                                                                                 |
| Computer Vision Toolbox™      | “System Objects in MATLAB Code Generation” (MATLAB Coder)                                                                                                                 |
| DSP System Toolbox            | “System Objects in MATLAB Code Generation” (MATLAB Coder)                                                                                                                 |
| Image Acquisition Toolbox™    | <ul style="list-style-type: none"> <li>• <code>imaq.VideoDevice</code></li> <li>• “Code Generation with VideoDevice System Object” (Image Acquisition Toolbox)</li> </ul> |
| Phased Array System Toolbox™  | “Code Generation” (Phased Array System Toolbox)                                                                                                                           |
| System Identification Toolbox | “Generate Code for Online Parameter Estimation in MATLAB” (System Identification Toolbox)                                                                                 |
| WLAN Toolbox™                 | “System Objects in MATLAB Code Generation” (MATLAB Coder)                                                                                                                 |

To use these System objects, you need to install the requisite toolbox. For a list of System objects supported for C and C++ code generation, see “Functions and Objects Supported for C/C++ Code Generation” on page 50-2.

System objects are MATLAB object-oriented implementations of algorithms. They extend MATLAB by enabling you to model dynamic systems represented by time-varying algorithms. System objects are well integrated into the MATLAB language, regardless of whether you are writing simple functions, working interactively in the command window, or creating large applications.

In contrast to MATLAB functions, System objects automatically manage state information, data indexing, and buffering, which is particularly useful for iterative computations or stream data processing. This enables efficient processing of long data sets. For general information about MATLAB objects, see “Classes”.

# Defining MATLAB Variables for C/C++ Code Generation

- “Supported Variable Types” on page 52-12
- “Edit and Represent Coder Type Objects and Properties” on page 52-13

## Variables Definition for Code Generation

In the MATLAB language, variables can change their properties dynamically at run time so you can use the same variable to hold a value of any class, size, or complexity. For example, the following code works in MATLAB:

```
function x = foo(c) %#codegen
if(c>0)
 x = 0;
else
 x = [1 2 3];
end
disp(x);
end
```

However, statically-typed languages like C must be able to determine variable properties at compile time. Therefore, for C/C++ code generation, you must explicitly define the class, size, and complexity of variables in MATLAB source code before using them. For example, rewrite the above source code with a definition for `x`:

```
function x = foo(c) %#codegen
x = zeros(1,3);
if(c>0)
 x = 0;
else
 x = [1 2 3];
end
disp(x);
end
```

For more information, see “Best Practices for Defining Variables for C/C++ Code Generation” on page 52-3.

## Best Practices for Defining Variables for C/C++ Code Generation

### In this section...

“Define Variables By Assignment Before Using Them” on page 52-3  
 “Use Caution When Reassigning Variables” on page 52-5  
 “Use Type Cast Operators in Variable Definitions” on page 52-5  
 “Define Matrices Before Assigning Indexed Variables” on page 52-5  
 “Index Arrays by Using Constant Value Vectors” on page 52-5

### Define Variables By Assignment Before Using Them

For C/C++ code generation, you should explicitly and unambiguously define the class, size, and complexity of variables before using them in operations or returning them as outputs. Define variables by assignment, but note that the assignment copies not only the value, but also the size, class, and complexity represented by that value to the new variable. For example:

| Assignment:                              | Defines:                                     |
|------------------------------------------|----------------------------------------------|
| <code>a = 14.7;</code>                   | a as a real double scalar.                   |
| <code>b = a;</code>                      | b with properties of a (real double scalar). |
| <code>c = zeros(5,2);</code>             | c as a real 5-by-2 array of doubles.         |
| <code>d = [1 2 3 4 5; 6 7 8 9 0];</code> | d as a real 5-by-2 array of doubles.         |
| <code>y = int16(3);</code>               | y as a real 16-bit integer scalar.           |

Define properties this way so that the variable is defined on the required execution paths during C/C++ code generation.

The data that you assign to a variable can be a scalar, matrix, or structure. If your variable is a structure, define the properties of each field explicitly.

Initializing the new variable to the value of the assigned data sometimes results in redundant copies in the generated code. To avoid redundant copies, you can define variables without initializing their values by using the `coder.nullcopy` construct as described in “Eliminate Redundant Copies of Variables in Generated Code” on page 52-7.

When you define variables, they are local by default; they do not persist between function calls. To make variables persistent, see `persistent`.

#### Example 52.1. Defining a Variable for Multiple Execution Paths

Consider the following MATLAB code:

```
...
if c > 0
 x = 11;
end
% Later in your code ...
if c > 0
 use(x);
```

```
end
...
```

Here,  $x$  is assigned only if  $c > 0$  and used only when  $c > 0$ . This code works in MATLAB, but generates a compilation error during code generation because it detects that  $x$  is undefined on some execution paths (when  $c \leq 0$ ).

To make this code suitable for code generation, define  $x$  before using it:

```
x = 0;
...
if c > 0
 x = 11;
end
% Later in your code ...
if c > 0
 use(x);
end
...
```

### Example 52.2. Defining Fields in a Structure

Consider the following MATLAB code:

```
...
if c > 0
 s.a = 11;
 disp(s);
else
 s.a = 12;
 s.b = 12;
end
% Try to use s
use(s);
...
```

Here, the first part of the `if` statement uses only the field  $a$ , and the `else` clause uses fields  $a$  and  $b$ . This code works in MATLAB, but generates a compilation error during C/C++ code generation because it detects a structure type mismatch. To prevent this error, do not add fields to a structure after you perform certain operations on the structure. For more information, see “Structure Definition for Code Generation” on page 55-2.

To make this code suitable for C/C++ code generation, define all fields of  $s$  before using it.

```
...
% Define all fields in structure s
s = struct('a',0, 'b', 0);
if c > 0
 s.a = 11;
 disp(s);
else
 s.a = 12;
 s.b = 12;
end
% Use s
use(s);
...
```

## Use Caution When Reassigning Variables

In general, you should adhere to the "one variable/one type" rule for C/C++ code generation; that is, each variable must have a specific class, size and complexity. Generally, if you reassign variable properties after the initial assignment, you get a compilation error during code generation, but there are exceptions, as described in "Reassignment of Variable Properties" on page 52-9.

## Use Type Cast Operators in Variable Definitions

By default, constants are of type `double`. To define variables of other types, you can use type cast operators in variable definitions. For example, the following code defines variable `y` as an integer:

```
...
x = 15; % x is of type double by default.
y = uint8(x); % y has the value of x, but cast to uint8.
...
```

## Define Matrices Before Assigning Indexed Variables

When generating C/C++ code from MATLAB, you cannot grow a variable by writing into an element beyond its current size. Such indexing operations produce run-time errors. You must define the matrix first before assigning values to its elements.

For example, the following initial assignment is not allowed for code generation:

```
g(3,2) = 14.6; % Not allowed for creating g
 % OK for assigning value once created
```

For more information about indexing matrices, see "Incompatibility with MATLAB in Matrix Indexing Operations for Code Generation" on page 54-19.

## Index Arrays by Using Constant Value Vectors

It is a best practice to use constant value vectors to index arrays instead of using ranges that contain nonconstant objects.

In some cases, the code generator is unable to determine whether an expression containing the `colon` operator is fixed-size or variable-size. Use constant value vectors to index arrays to prevent them from being unnecessarily created as variable-size arrays in the generated code.

For example, the array `out` has been created by using the variable `i` indexed through the random row vector `A`.

```
...
% extract elements i through i+5 for processing
A = rand(1,10);
out = A(i:i+5); % If i is unknown at compile time, out is variable-size
...
```

If `i` is a compile-time constant value, the code generator produces a fixed-size object for `out`. If `i` is unknown at compile time, the code generator produces a variable-size array for `out` in the generated code.

To prevent the code generator from creating variable-size arrays, the previous code snippet is rewritten in this pattern:

```
...
% extract elements i through i+5 for processing
A = rand(1,10);
out = A (i+(0:5)); % out is fixed-size, even if i is unknown at compile time
...
```

This pattern enables you to generate fixed-size arrays that have iterator values unknown at compile-time. Another example of the recommended rewrite is:

```
width = 25;
A = A(j-width:j+width); % A is variable-size, if j is unknown at compile time
fsA = A(j+(-width:width)); % This makes A fixed-size, even if j is unknown at compile time
...
```

“When Redundant Copies Occur” on page 52-7

“How to Eliminate Redundant Copies by Defining Uninitialized Variables” on page 52-7

“Defining Uninitialized Variables” on page 52-7

### When Redundant Copies Occur

During C/C++ code generation, the code generator checks for statements that attempt to access uninitialized memory. If it detects execution paths where a variable is used but is potentially not defined, it generates a compile-time error. To prevent these errors, define variables by assignment before using them in operations or returning them as function outputs.

Note, however, that variable assignments not only copy the properties of the assigned data to the new variable, but also initialize the new variable to the assigned value. This forced initialization sometimes results in redundant copies in C/C++ code. To eliminate redundant copies, define uninitialized variables by using the `coder.nullcopy` function, as described in “How to Eliminate Redundant Copies by Defining Uninitialized Variables” on page 52-7.

### How to Eliminate Redundant Copies by Defining Uninitialized Variables

- 1 Define the variable with `coder.nullcopy`.
- 2 Initialize the variable before reading it.

When the uninitialized variable is an array, you must initialize all of its elements before passing the array as an input to a function or operator — even if the function or operator does not read from the uninitialized portion of the array.

#### What happens if you access uninitialized data?

Uninitialized memory contains arbitrary values. Therefore, accessing uninitialized data may lead to segmentation violations or nondeterministic program behavior (different runs of the same program may yield inconsistent results).

### Defining Uninitialized Variables

In the following code, the assignment statement `X = zeros(1,N)` not only defines `X` to be a 1-by-5 vector of real doubles, but also initializes each element of `X` to zero.

```
function X = withoutNullcopy %#codegen

N = 5;
X = zeros(1,N);
for i = 1:N
 if mod(i,2) == 0
 X(i) = i;
 elseif mod(i,2) == 1
 X(i) = 0;
 end
end
```

```
end
end
```

This forced initialization creates an extra copy in the generated code. To eliminate this overhead, use `coder.nullcopy` in the definition of `X`:

```
function X = withNullcopy %#codegen

N = 5;
X = coder.nullcopy(zeros(1,N));
for i = 1:N
 if mod(i,2) == 0
 X(i) = i;
 else
 X(i) = 0;
 end
end
```

## Reassignment of Variable Properties

For C/C++ code generation, there are certain variables that you can reassign after the initial assignment with a value of different class, size, or complexity:

### **Dynamically sized variables**

A variable can hold values that have the same class and complexity but different sizes. If the size of the initial assignment is not constant, the variable is dynamically sized in generated code. For more information, see “Variable-Size Data”.

### **Variables reused in the code for different purposes**

You can reassign the type (class, size, and complexity) of a variable after the initial assignment if each occurrence of the variable can have only one type. In this case, the variable is renamed in the generated code to create multiple independent variables. For more information, see “Reuse the Same Variable with Different Properties” on page 52-10.

## Reuse the Same Variable with Different Properties

### In this section...

“When You Can Reuse the Same Variable with Different Properties” on page 52-10

“When You Cannot Reuse Variables” on page 52-10

“Limitations of Variable Reuse” on page 52-11

### When You Can Reuse the Same Variable with Different Properties

You can reuse (reassign) an input, output, or local variable with different class, size, or complexity if the code generator can unambiguously determine the properties of each occurrence of this variable during C/C++ code generation. If so, MATLAB creates separate uniquely named local variables in the generated code. You can view these renamed variables in the code generation report.

A common example of variable reuse is in `if-elseif-else` or `switch-case` statements. For example, the following function `example1` first uses the variable `t` in an `if` statement, where it holds a scalar double, then reuses `t` outside the `if` statement to hold a vector of doubles.

```
function y = example1(u) %#codegen
if all(all(u>0))
 % First, t is used to hold a scalar double value
 t = mean(mean(u)) / numel(u);
 u = u - t;
end
% t is reused to hold a vector of doubles
t = find(u > 0);
y = sum(u(t(2:end-1)));
```

### When You Cannot Reuse Variables

You cannot reuse (reassign) variables if it is not possible to determine the class, size, and complexity of an occurrence of a variable unambiguously during code generation. In this case, variables cannot be renamed and a compilation error occurs.

For example, the following `example2` function assigns a fixed-point value to `x` in the `if` statement and reuses `x` to store a matrix of doubles in the `else` clause. It then uses `x` after the `if-else` statement. This function generates a compilation error because after the `if-else` statement, variable `x` can have different properties depending on which `if-else` clause executes.

```
function y = example2(use_fixpoint, data) %#codegen
if use_fixpoint
 % x is fixed-point
 x = fi(data, 1, 12, 3);
else
 % x is a matrix of doubles
 x = data;
end
% When x is reused here, it is not possible to determine its
% class, size, and complexity
t = sum(sum(x));
y = t > 0;
end
```

### Example 52.3. Variable Reuse in an if Statement

To see how MATLAB renames a reused variable `t`:

- 1 Create a MATLAB file `example1.m` containing the following code.

```
function y = example1(u) %#codegen
if all(all(u>0))
 % First, t is used to hold a scalar double value
 t = mean(mean(u)) / numel(u);
 u = u - t;
end
% t is reused to hold a vector of doubles
t = find(u > 0);
y = sum(u(t(2:end-1)));
end
```

- 2 Generate a MEX function for `example1` and produce a code generation report.

```
codegen -o example1x -report example1.m -args {ones(5,5)}
```

- 3 Open the code generation report.

On the **Variables** tab, you see two uniquely named local variables `t>1` and `t>2`.

| SUMMARY |        | ALL MESSAGES (0) |        | BUILD LOGS |  | COD |
|---------|--------|------------------|--------|------------|--|-----|
| Name    | Type   | Size             | Class  |            |  |     |
| y       | Output | 1 × 1            | double |            |  |     |
| u       | Input  | 5 × 5            | double |            |  |     |
| t > 1   | Local  | 1 × 1            | double |            |  |     |
| t > 2   | Local  | :25 × 1          | double |            |  |     |
