Color scale of the histogram, specified as 'Linear' or 'Logarithmic'. Change this property if certain areas of the histogram include a disproportionate number of points. Use the 'Logarithmic' option for eye diagrams with sharp peaks, where the signal repetitively matches specific time and amplitude values.

Tunable: Yes

Dependencies

To enable this property, set the DisplayMode property to '2D color histogram'.

Data Types: char

ColorFading — Color fading

false (default) | true

Color fading, specified as true or false. To fade the points in the display as the interval of time after they are first plotted increases, set this property to true. This animation resembles an oscilloscope.

Tunable: Yes

Dependencies

To enable this property, set the DisplayMode property to 'Line plot'.

Data Types: logical

ShowImaginaryEye — Show imaginary signal component

false (default) | true

Show imaginary signal component, specified as true or false. To view the imaginary or quadrature component of the input signal, set this property to true.

Tunable: Yes

Dependencies

To enable this property, set the EnableMeasurements property to false.

Data Types: logical

YLimits — Y-axis limits

[-1.1 1.1] (default) | two-element row vector

Y-axis limits of the eye diagram in volts, specified as a two-element vector. The first element corresponds to *ymin* and the second to *ymax*. The second element must be greater than the first.

Tunable: Yes

Data Types: `double`

ShowGrid — Option to enable grid display

`false` (default) | `true`

Option to enable grid display on the eye diagram, specified as `true` or `false`. To display a grid on the eye diagram, set this property to `true`.

Tunable: Yes

Data Types: `logical`

Position — Scope window position

four-element row vector

Scope window position in pixels, specified as a four-element row vector of the form [*left bottom width height*].

Tunable: Yes

Data Types: `double`

Usage

Syntax

`ed(x)`

Description

`ed(x)` displays and analyzes input signal `x` in an eye diagram.

Input Arguments

x — Input signal

vector | matrix

Input signal to be analyzed and displayed in the eye diagram, specified as a vector or matrix. `x` can be either a real or complex vector, or a real two-column matrix.

Data Types: `double`

Complex Number Support: Yes

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

`release(obj)`

Specific to `comm.EyeDiagram`

`show` Show scope window

hide	Hide scope window
horizontalBathtub	(Removed) Horizontal bathtub curve
verticalBathtub	(Removed) Vertical bathtub curve
jitterHistogram	(Remove) Jitter histogram
noiseHistogram	(Removed) Noise histogram
measurements	(Removed) Measure eye diagram parameters

Common to All System Objects

step	Run System object algorithm
release	Release resources and allow changes to System object property values and input characteristics
reset	Reset internal states of System object

Examples

Eye Diagram of Filtered QPSK Signal

Specify the sample rate and the number of output samples per symbol parameters.

```
fs = 1000;
sps = 4;
```

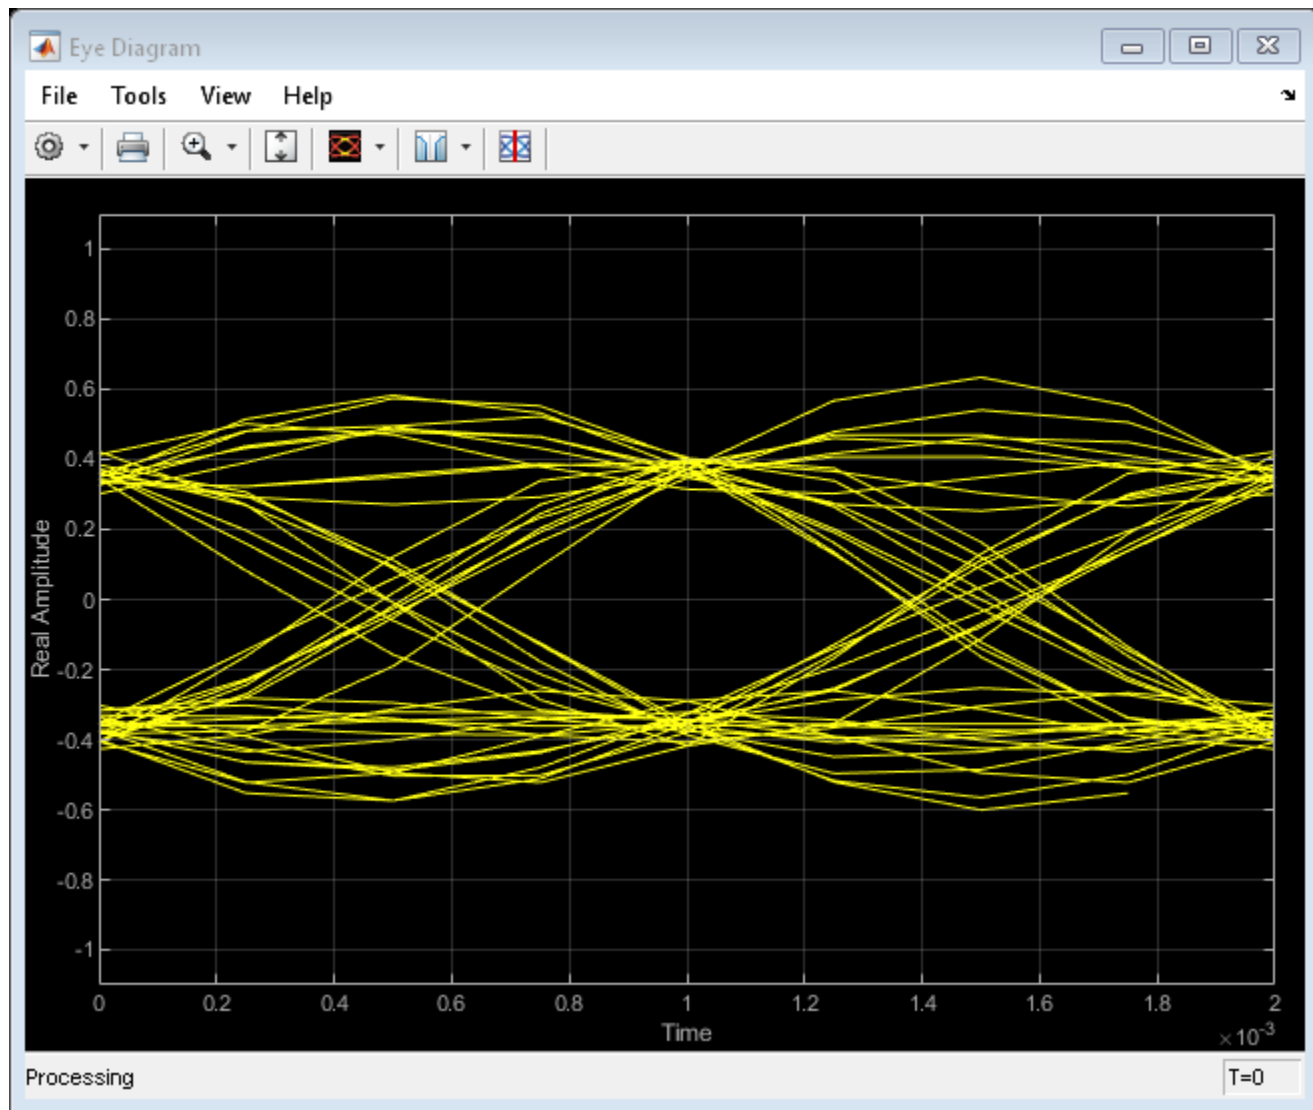

Create transmit filter and eye diagram objects.

```
txfilter = comm.RaisedCosineTransmitFilter(...
    'OutputSamplesPerSymbol', sps);
ed = comm.EyeDiagram('SampleRate', fs*sps, 'SamplesPerSymbol', sps);
```

Generate random symbols and apply QPSK modulation. Then filter the modulated signal and display the eye diagram.

```
data = randi([0 3], 1000, 1);
modSig = pskmod(data, 4, pi/4);

txSig = txfilter(modSig);
ed(txSig)
```

More About

Measurements

Measurements assume that the eye diagram object has valid data. A valid eye diagram has two distinct eye crossing points and two distinct eye levels.

To open the measurements pane, click on the **Eye Measurements** button or select **Tools > Measurements > Eye Measurements** from the toolbar menu.

Note

- For amplitude measurements, at least one bin per vertical histogram must reach 10 hits before the measurement is taken, ensuring higher accuracy.
- For time measurements, at least one bin per horizontal histogram must reach 10 hits before the measurement is taken.

- When an eye crossing time measurement falls within the $[-0.5/F_s, 0)$ seconds interval, the time measurement wraps to the end of the eye diagram, i.e., the measurement wraps by $2 \times T_s$ seconds (where T_s is the symbol time). For a complex signal case, the analyze method issues a warning if the crossing time measurement of the in-phase branch wraps while that of the quadrature branch does not (or vice versa). To avoid time-wrapping or a warning, add a half-symbol duration delay to the current value in the MeasurementDelay property of the eye diagram object. This additional delay repositions the eye in the approximate center of the scope.

Eye Levels - Amplitude level used to represent data bits

Eye level is the amplitude level used to represent data bits. For the displayed NRZ signal, the levels are -1 V and $+1$ V. The eye levels are calculated by averaging the 2-D histogram within the eye level boundaries. For example, when the EyeLevelBoundaries property is set to $[40 \ 60]$, that is, 40% and 60% of the symbol duration, the eye levels are calculated by estimating the mean value of the vertical histogram in this window marked by the eye level boundaries.

Eye Amplitude - Distance between eye levels

Eye amplitude is the distance in V between the mean value of two eye levels.

Eye Height - Statistical minimum distance between eye levels

Eye height is the distance between $\mu - 3\sigma$ of the upper eye level and $\mu + 3\sigma$ of the lower eye level. μ is the mean of the eye level, and σ is the standard deviation.

Vertical Opening - Distance between BER threshold points

The vertical opening is the distance between the two points that correspond to the BERThreshold property. For example, for a BER threshold of 10^{-12} , these points correspond to the 7σ distance from each eye level.

Eye SNR - Signal-to-noise ratio

The eye SNR is the ratio of the eye level difference to the difference of the vertical standard deviations corresponding to each eye level:

$$\text{SNR} = \frac{L_1 - L_0}{\sigma_1 - \sigma_0},$$

where L_1 and L_0 represent the means of the upper and lower eye levels and σ_1 and σ_0 represent their standard deviations.

Q Factor - Quality factor

The Q factor is the quality factor and is calculated using the same formula as the eye SNR. However, the standard deviations of the vertical histograms are replaced with those computed with the dual-Dirac analysis.

Crossing Levels - Amplitude levels for eye crossings

The crossing levels are the amplitude levels at which the eye crossings occur.

The level at which the input signal crosses the amplitude value is specified by the DecisionBoundary property.

Crossing Times - Times for which crossings occur

The crossing times are the times at which the crossings occur. The times are computed as the mean values of the horizontal (jitter) histograms.

Eye Delay - Mean time between eye crossings

Eye delay is the midpoint between the two crossing times.

Eye Width - Statistical minimum time between eye crossings

Eye width is the horizontal distance between $\mu + 3\sigma$ of the left crossing time and $\mu - 3\sigma$ of the right crossing time. μ is the mean of the jitter histogram, and σ is the standard deviation.

Horizontal Opening - Time between BER threshold points

The horizontal opening is the distance between the two points that correspond to the BERThreshold property. For example, for a 10^{-12} BER, these two points correspond to the 7σ distance from each crossing time.

Rise Time - Time to transition from low to high

Rise time is the mean time between the low and high rise/fall thresholds defined in the eye diagram. The default thresholds are 10% and 90% of the eye amplitude.

Fall Time - Time to transition from high to low

Fall time is the mean time between the high and low rise/fall thresholds defined in the eye diagram. The default thresholds are 10% and 90% of the eye amplitude.

Deterministic Jitter - Deterministic deviation from ideal signal timing

Jitter is the deviation of a signal's timing event from its intended (ideal) occurrence in time [2]. Jitter can be represented with a dual-Dirac model. A dual-Dirac model assumes that the jitter has two components: deterministic jitter (DJ) and random jitter (RJ).

DJ is the distance between the two peaks of the dual-Dirac histograms. The probability density function (PDF) of DJ is composed of two delta functions.

Random Jitter - Random deviation from ideal signal timing

RJ is the Gaussian unbounded jitter component. The random component of jitter is modeled as a zero-mean Gaussian random variable with a specified standard-deviation of σ . The RJ is computed as:

$$RJ = (Q_L + Q_R)\sigma,$$

where

$$Q = \sqrt{2} \operatorname{erfc}^{-1} \left(2 \frac{BER}{\rho} \right).$$

BER is the specified BER threshold. ρ is the amplitude of the left and right Dirac function, which is determined from the bin counts of the jitter histograms.

Total Jitter - Deviation from ideal signal timing

Total jitter (TJ) is the sum of the deterministic and random jitter, such that $TJ = DJ + RJ$.

The total jitter PDF is the convolution of the DJ PDF and the RJ PDF.

RMS Jitter - Standard deviation of jitter

RMS jitter is the standard deviation of the jitter calculated in the horizontal (jitter) histogram at the decision boundary.

Peak-to-Peak Jitter - Distance between extreme data points of histogram

Peak-to-peak jitter is the maximum horizontal distance between the left and right nonzero values in the horizontal histogram of each crossing time.

Compatibility Considerations

comm.EyeDiagram has been removed

Errors starting in R2022a

comm.EyeDiagram has been removed. To display the eye diagram of a signal, use the `eyediagram` function instead.

horizontalBathtub

Package: comm

(Removed) Horizontal bathtub curve

Syntax

```
s = horizontalBathtub(ed)
```

Description

`s = horizontalBathtub(ed)` returns a structure containing information of horizontalBathtub curve for the System object.

Note This method is available when both of these conditions apply:

- EnableMeasurements is true
 - ShowBathtub is 'Horizontal' or 'Both'
-

Examples

Horizontal and Vertical Bathtub Curve Methods

Display the eye diagram for a waveform having dual-dirac and random jitter. Generate and plot the horizontal and vertical bathtub curves.

Specify the sample rate, the samples per symbol, and the number of traces parameters.

```
fs = 1000;
sps = 200;
numTraces = 1000;
```

Create an eye diagram object.

```
ed = comm.EyeDiagram('SampleRate',fs,'SamplesPerSymbol',sps, ...
    'SampleOffset',sps/2,'DisplayMode','2D color histogram', ...
    'ColorScale','Logarithmic','EnableMeasurements',true, ...
    'ShowBathtub','Both','YLimits',[-1.2 1.2]);
```

Generate a waveform having dual-dirac and random jitter. Specify 3 ms rise and fall times.

```
src = commsrc.pattern('SamplesPerSymbol',sps, ...
    'RiseTime',3e-3,'FallTime', 3e-3);
src.Jitter = commsrc.combinedjitter('RandomJitter','on', ...
    'DiracJitter','on','DiracDelta',[-5e-04 5e-04],'RandomStd',2e-4);
```

Generate two symbols for each trace.

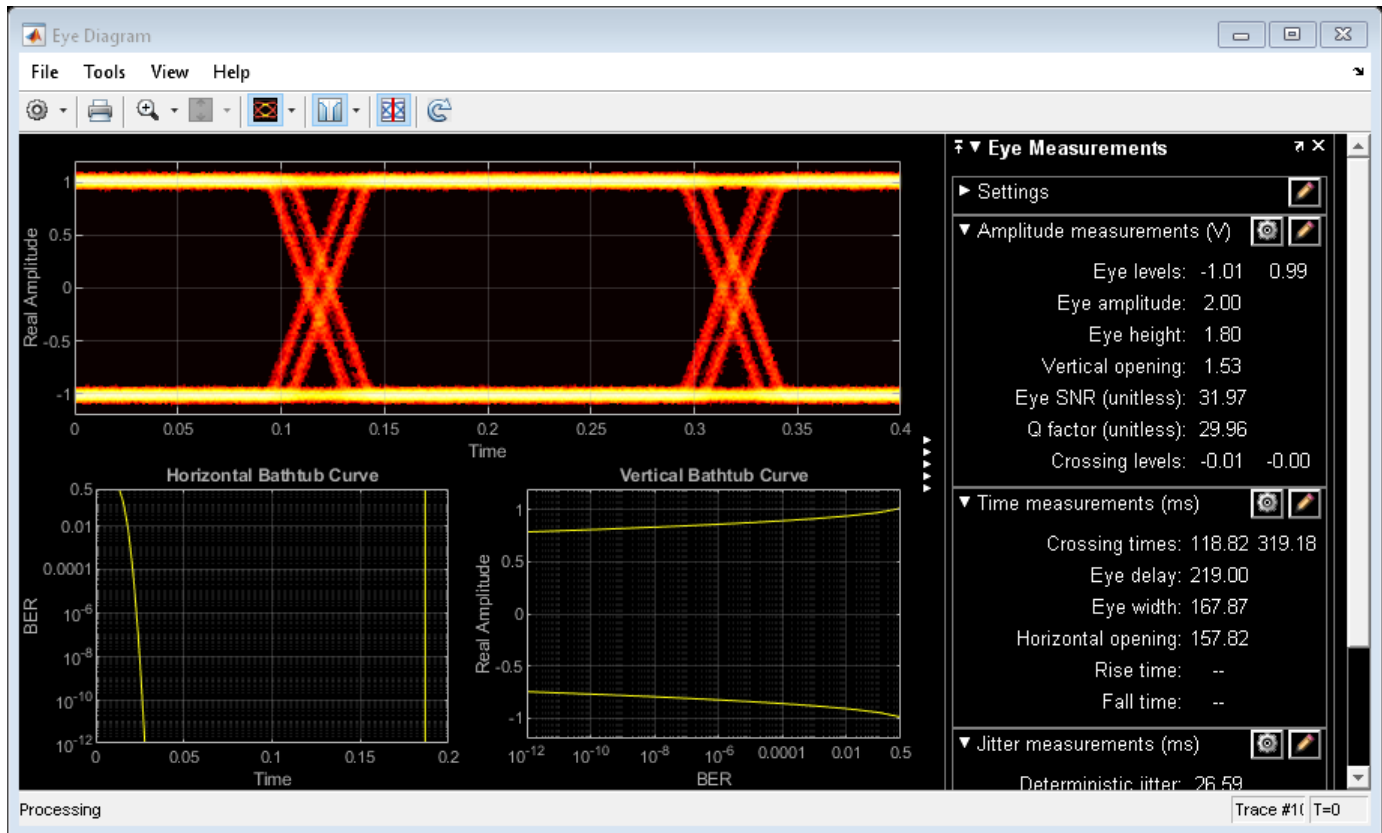

```
x = src.generate(numTraces*2);
```

Pass the signal through an AWGN channel with a fixed seed for repeatable results.

```
randStream = RandStream('mt19937ar', 'Seed', 5489);
y = awgn(x, 30, 'measured', randStream);
```

Display the eye diagram.

```
ed(y)
```

Generate the horizontal bathtub data for the eye diagram. Plot the curve.

```
hb = horizontalBathtub(ed)
semilogy([hb.LeftThreshold], [hb.BER], 'b', ...
         [hb.RightThreshold], [hb.BER], 'b')
grid
hb =
```

1x13 struct array with fields:

```
BER
LeftThreshold
RightThreshold
```

Generate the vertical bathtub data for the eye diagram. Plot the curve.

```
vb = verticalBathtub(ed)
semilogx([vb.BER],[vb.LowerThreshold],'b', ...
         [vb.BER],[vb.UpperThreshold],'b')
grid
```

vb =

1x13 struct array with fields:

```
BER
UpperThreshold
LowerThreshold
```

Input Arguments

ed — Eye Diagram System object
System object

Eye Diagram System object, where you get the bathtub curve information from.

Output Arguments

s — Structure containing information
struct

Structure containing information about the horizontal bathtub curve.

BER — Bit error rate values
scalar

Bit error rate values, mapped on the Y-axis of the horizontalBathtub plot against the corresponding LeftThreshold and RightThreshold values on the x-axis, specified as a scalar.

Data Types: double

LeftThreshold — Left threshold values
scalar

Left threshold values, mapped on the x-axis in the plot against corresponding BER values on the x-axis.

Data Types: double

RightThreshold – Right threshold values

scalar

Right threshold values, mapped on the x-axis in the plot against corresponding BER values on the x-axis.

Data Types: double

Compatibility Considerations

jitterHistogram

Package: comm

(Remove) Jitter histogram

Syntax

```
jh = jitterHistogram(ed)
```

Description

`jh = jitterHistogram(ed)` returns the bin counts for decision boundary crossings set in eye diagram System object.

Note This method is available when `EnableMeasurements` is true.

Examples

Jitter and Noise Histogram Methods

Display the eye diagram for a waveform having dual-dirac and random jitter. Plot the jitter and noise histograms.

Specify the sample rate, the samples per symbol, and the number of traces parameters.

```
fs = 1000;  
sps = 200;  
numTraces = 1000;
```

Create an eye diagram object.

```
ed = comm.EyeDiagram('SampleRate',fs,'SamplesPerSymbol',sps, ...  
    'SampleOffset',sps/2, ...  
    'DisplayMode','2D color histogram','ColorScale','Logarithmic', ...  
    'EnableMeasurements',true,'YLimits',[-1.2 1.2]);
```

Generate a waveform having dual-dirac and random jitter. Specify 3 ms rise and fall times.

```
src = commsrc.pattern('SamplesPerSymbol',sps, ...  
    'RiseTime',3e-3,'FallTime', 3e-3);  
src.Jitter = commsrc.combinedjitter('RandomJitter','on', ...  
    'DiracJitter','on','DiracDelta',[-10e-04 10e-04],'RandomStd',5e-4);
```

Generate two symbols for each trace.

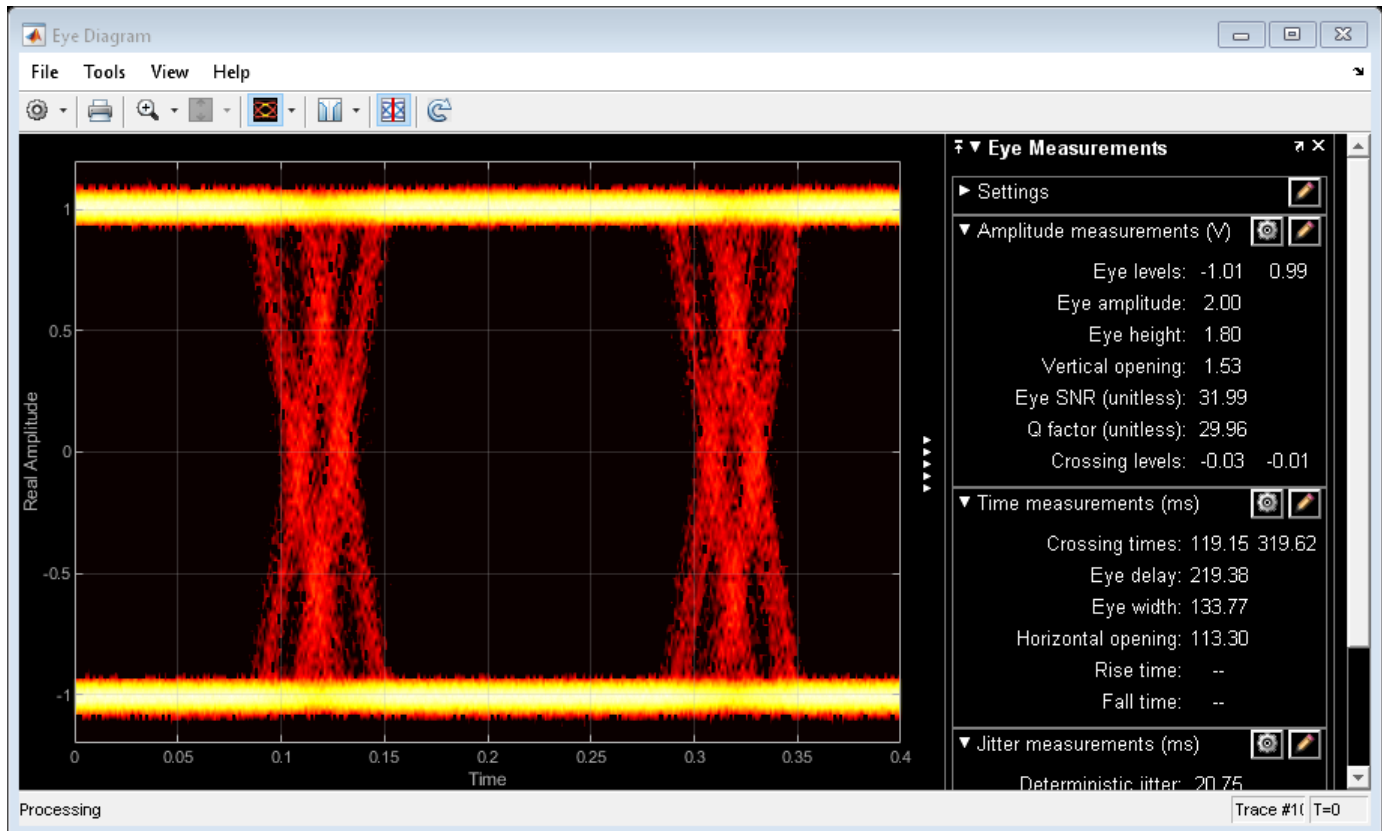

```
x = src.generate(numTraces*2);
```

Pass the signal through an AWGN channel with a fixed seed for repeatable results.

```

randStream = RandStream('mt19937ar','Seed',5489);
y = awgn(x,30,'measured',randStream);
ed(y)

```

Calculate the jitter histogram count for each bin by using the `jitterHistogram` method. Plot the histogram.

```

jbins = jitterHistogram(ed);
plot(jbins)

```

Calculate the noise histogram count for each bin by using the `noiseHistogram` method. Plot the histogram.

```
nbins = noiseHistogram(ed);  
plot(nbins)
```

Input Arguments

ed – Eye Diagram System object

System object

Eye Diagram System object, where the count for decision boundary crossings is set.

Output Arguments

jh – Jitter histogram

nonnegative integer

Jitter histogram, which represent the counts for decision boundary crossings, specified as a nonnegative integer.

Data Types: double

Compatibility Considerations

comm.EyeDiagram has been removed

Errors starting in R2022a

`jitterHistogram` has been removed. To display the eye diagram of a signal, use the `eyediagram` function instead.

measurements

Package: comm

(Removed) Measure eye diagram parameters

Syntax

`m = measurements(ed)`

Description

`m = measurements(ed)` returns the parameter measurements calculated by eye diagram System object.

Note This method is available when `EnableMeasurements` is `true`.

Examples

Rise and Fall Time of NRZ Signal

Create a combined jitter object having random jitter with a $2e-4$ standard deviation.

```
jtr = commsrc.combinedjitter('RandomJitter','on','RandomStd',2e-4);
```

Generate an NRZ signal having random jitter and 3 ms rise and fall times.

```
genNRZ = commsrc.pattern('Jitter',jtr,'RiseTime',3e-3,'FallTime',3e-3);
x = generate(genNRZ,2000);
```

Pass the signal through an AWGN channel with fixed seed for repeatable results.

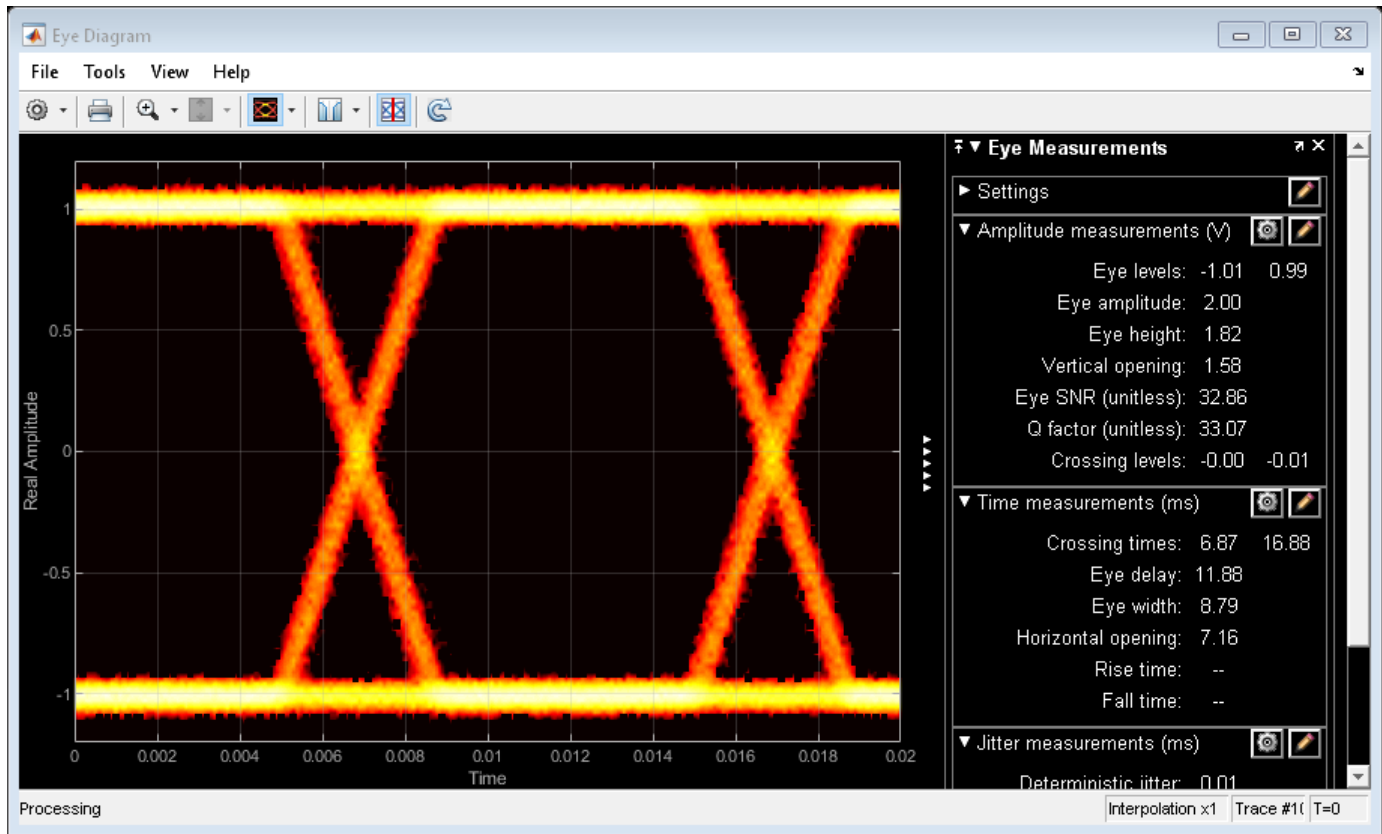

```
randStream = RandStream('mt19937ar','Seed',5489);
y = awgn(x,30,'measured',randStream);
```

Create an eye diagram object. Enable the measurements.

```
ed = comm.EyeDiagram('SamplesPerSymbol',genNRZ.SamplesPerSymbol, ...
    'SampleRate',genNRZ.SamplingFrequency, ...
    'SampleOffset',genNRZ.SamplesPerSymbol/2, ...
    'EnableMeasurements',true,'DisplayMode','2D color histogram', ...
    'OversamplingMethod','Input interpolation', ...
    'ColorScale','Logarithmic','YLimits',[-1.2 1.2]);
```

To compute the rise and fall times, determine the rise and fall thresholds from the eye level and eye amplitude measurements. Plot the eye diagram to calculate these parameters.

```
ed(y)
```

Pass the signal through the eye diagram object again to measure the rise and fall times.

```
ed(y)
hide(ed)
```

Display the data by using the measurements method.

```
eyestats = measurements(ed);
riseTime = eyestats.RiseTime
fallTime = eyestats.FallTime

riseTime =
    0.0030

fallTime =
    0.0030
```

The measured values match the 3 ms specification.

Input Arguments

ed — Eye Diagram System object
System object

Eye Diagram System object, where the parameter measurements are calculated.

Output Arguments

m — Eye Diagram parameters measurement

struct

Eye Diagram parameters measurement, returned as a structure containing all 18 parameters mentioned in “Measurements” on page 3-486, along with their values.

Data Types: double

Compatibility Considerations

comm.EyeDiagram has been removed

Errors starting in R2022a

measurements has been removed. To display the eye diagram of a signal, use the `eyediagram` function instead.

noiseHistogram

Package: comm

(Removed) Noise histogram

Syntax

```
nh = noiseHistogram(ed)
```

Description

`nh = noiseHistogram(ed)` returns the bin counts for the signal values at the vertical opening (eye delay) as set in eye diagram System object.

Note This method is available when both of these conditions apply:

- `EnableMeasurements` is true
 - `DisplayMode` is '2D color histogram'
-

Examples

Jitter and Noise Histogram Methods

Display the eye diagram for a waveform having dual-dirac and random jitter. Plot the jitter and noise histograms.

Specify the sample rate, the samples per symbol, and the number of traces parameters.

```
fs = 1000;  
sps = 200;  
numTraces = 1000;
```

Create an eye diagram object.

```
ed = comm.EyeDiagram('SampleRate',fs,'SamplesPerSymbol',sps, ...  
    'SampleOffset',sps/2, ...  
    'DisplayMode','2D color histogram','ColorScale','Logarithmic', ...  
    'EnableMeasurements',true,'YLimits',[-1.2 1.2]);
```

Generate a waveform having dual-dirac and random jitter. Specify 3 ms rise and fall times.

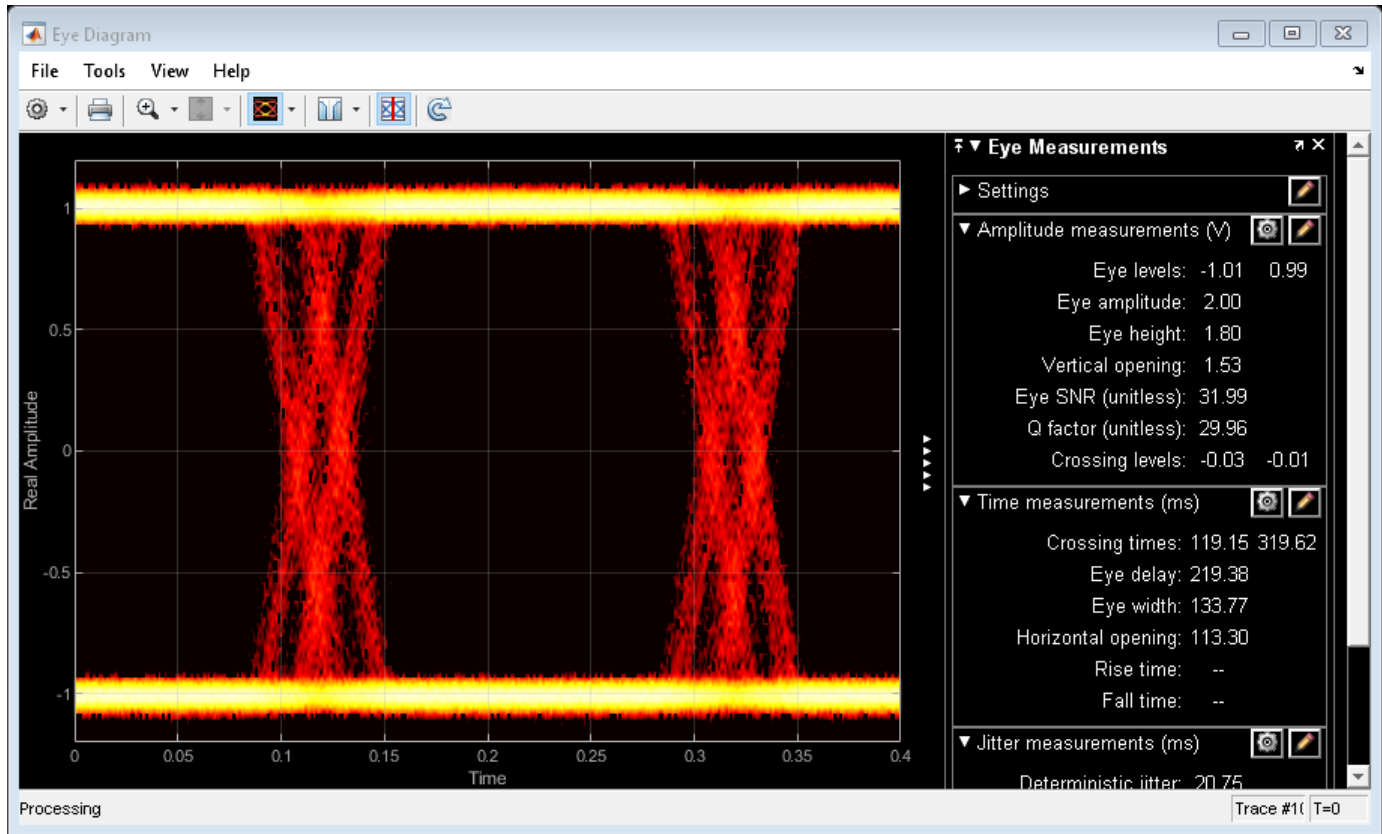

```
src = commsrc.pattern('SamplesPerSymbol',sps, ...  
    'RiseTime',3e-3,'FallTime', 3e-3);  
src.Jitter = commsrc.combinedjitter('RandomJitter','on', ...  
    'DiracJitter','on','DiracDelta',[-10e-04 10e-04],'RandomStd',5e-4);
```

Generate two symbols for each trace.

```
x = src.generate(numTraces*2);
```

Pass the signal through an AWGN channel with a fixed seed for repeatable results.

```
randStream = RandStream('mt19937ar','Seed',5489);
y = awgn(x,30,'measured',randStream);
ed(y)
```

Calculate the jitter histogram count for each bin by using the `jitterHistogram` method. Plot the histogram.

```
jbins = jitterHistogram(ed);
plot(jbins)
```

Calculate the noise histogram count for each bin by using the `noiseHistogram` method. Plot the histogram.

```
nbins = noiseHistogram(ed);  
plot(nbins)
```

Input Arguments

ed — Eye Diagram System object

System object

Eye Diagram System object, where the counts for signal values at the eye delay is set.

Output Arguments

nh — Noise histogram

nonnegative integer

Noise histogram, which represent the counts for the signal values at the vertical opening (eye delay), specified as a nonnegative integer.

Data Types: double

Compatibility Considerations

comm.EyeDiagram has been removed

y = awgn(x, 30, 'measured', randStream);
```

Display the eye diagram.

```
ed(y)
```

Generate the horizontal bathtub data for the eye diagram. Plot the curve.

```
hb = horizontalBathtub(ed)
semilogy([hb.LeftThreshold], [hb.BER], 'b', ...
         [hb.RightThreshold], [hb.BER], 'b')
grid
hb =
```

1x13 struct array with fields:

```
BER
LeftThreshold
RightThreshold
```

Generate the vertical bathtub data for the eye diagram. Plot the curve.

```
vb = verticalBathtub(ed)
semilogx([vb.BER],[vb.LowerThreshold],'b', ...
         [vb.BER],[vb.UpperThreshold],'b')
grid
vb =
```

1x13 struct array with fields:

```
BER
UpperThreshold
LowerThreshold
```

Input Arguments

ed — Eye Diagram System object
System object

Eye Diagram System object, where you get the bathtub curve information from.

Output Arguments

s — Structure containing information
struct

Structure containing information about the vertical bathtub curve.

BER — Bit error rate values
scalar

Bit error rate values, mapped on the Y-axis of the verticalBathtub plot against the corresponding UpperThreshold and LowerThreshold values on the x-axis, specified as a scalar.

Data Types: double

UpperThreshold — Upper threshold value
scalar

Upper threshold value, mapped on the x-axis in the plot against its corresponding BER value on the x-axis.

Data Types: double

LowerThreshold — Lower threshold value

scalar

Lower threshold value, mapped on the x-axis in the plot against its corresponding BER value on the x-axis.

Data Types: double

Compatibility Considerations

comm.EyeDiagram has been removed

Errors starting in R2022a

`horizontalBathtub`

Introduced in R2016b

comm.FMBroadcastDemodulator

Package: comm

Demodulate broadcast FM audio signal

Description

The `comm.FMBroadcastDemodulator` System object demodulates a complex broadcast FM-modulated signal and filters the signal with a de-emphasis filter to produce an audio signal. For more details, see the “Algorithms” on page 3-529 section.

To demodulate a broadcast FM audio signal:

- 1 Create the `comm.FMBroadcastDemodulator` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

Creation

Syntax

```
fmbdemodulator = comm.FMBroadcastDemodulator
fmbdemodulator = comm.FMBroadcastDemodulator(Name,Value)
fmbdemodulator = comm.FMBroadcastDemodulator(fmbmodulator)
```

Description

`fmbdemodulator = comm.FMBroadcastDemodulator` creates an FM broadcast demodulator System object.

`fmbdemodulator = comm.FMBroadcastDemodulator(Name,Value)` sets properties using one or more name-value arguments. For example, `'SampleRate',400e3` specifies a sample rate of 400 kHz.

`fmbdemodulator = comm.FMBroadcastDemodulator(fmbmodulator)` sets properties based on the configuration of the input `comm.FMBroadcastModulator` System object, `fmbmodulator`.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see [System Design in MATLAB Using System Objects](#).

SampleRate — Sample rate

240e3 (default) | positive scalar

Sample rate of the input of the demodulator in Hz, specified as a positive scalar. The sample rate must be greater than twice the frequency deviation (that is, `SampleRate > 2×FrequencyDeviation`).

Data Types: `double`**FrequencyDeviation — Peak deviation of the input signal frequency**

75e3 (default) | positive scalar

Peak deviation of the input signal frequency in Hz, specified a positive scalar. The frequency deviation must be less than half the sample rate (that is, `FrequencyDeviation < SampleRate/2`).

The system bandwidth $B_T = 2 \times (\text{FrequencyDeviation} + B_M)$, where B_M is the message bandwidth in Hz. For more information, see the “Algorithms” on page 3-529 section.

FM broadcast standards specify a value of 75 kHz in the United States and 50 kHz in Europe.

Data Types: `double`**FilterTimeConstant — De-emphasis highpass filter time constant**

7.5e-05 (default) | positive scalar

De-emphasis highpass filter time constant in seconds, specified as a positive scalar. FM broadcast standards specify a value of 75 μs in the United States and 50 μs in Europe.

Data Types: `double`**Stereo — Option to enable stereo demodulation**`false` or 0 (default) | `true` or 1

Option to enable stereo demodulation, specified as a logical 0 (`false`) or 1 (`true`).

- `false` — The output is mono audio.
- `true` — The object performs stereo decoding and outputs stereo audio.

For more information, see the “Algorithms” on page 3-529 section.

Data Types: `logical`**PlaySound — Option to enable audio playback**`false` or 0 (default) | `true` or 1

Option to enable audio playback, specified as a logical 0 (`false`) or 1 (`true`). To playback the output signal on the default audio device connected to the computer, set this property to `true`.

Data Types: `logical`**AudioSampleRate — Sample rate of output audio signal**

48000 (default) | positive scalar

Sample rate of the output audio signal in Hz, specified as a positive scalar.

Data Types: `double`

BufferSize — Size of buffer

4096 (default) | positive integer

Size of the buffer in samples, specified as a positive integer. This property specifies the size of the buffer used by the System object for communication with the audio device.

Dependencies

To enable this property, set the PlaySound property to `true`.

Data Types: `double`

RBDS — Option to enable RDS (or RBDS) waveform demodulation

false or 0 (default) | true or 1

Option to enable RDS (or RBDS) waveform demodulation, specified as a logical 0 (`false`) or 1 (`true`). If you set this property set to `true`, the object demodulates the RDS (or RBDS) waveform. For more information, see the “Algorithms” on page 3-529 section.

Data Types: `logical`

RBDSamplesPerSymbol — Oversampling factor of RDS (or RBDS) output signal

10 (default) | positive integer

Oversampling factor of the RDS (or RBDS) output signal, specified as a positive integer. The sample rate of RDS (or RBDS) broadcast data is 1187.5 Hz. The RDS (or RBDS) signal sample rate is $\text{RBDSsamplesPerSymbol} \times 1187.5$ Hz.

Dependencies

To enable this property, set the RBDS property to `true`.

Data Types: `double`

RBDSCostasLoop — Option to recover phase of RDS (or RBDS) signal

false or 0 (default) | true or 1

Option to recover phase of the RDS (or RBDS) signal, specified as a logical 0 (`false`) or 1 (`true`).

To recover the phase of the RDS (or RBDS) signal by using a Costas loop, set this property to `true`. For radio stations that do not lock the 57 kHz RDS (or RBDS) signal in phase with the third harmonic of the 19 kHz pilot tone, a Costas loop helps recover the phase of the RDS (or RBDS) signal.

Dependencies

To enable this property, set the RBDS property to `true`.

Data Types: `logical`

Usage**Syntax**

```
audiosig = fmbdemodulator(insig)
[audiosig, rbdssig] = fmbdemodulator(insig)
```

Description

`audiosig = fmbdemodulator(insig)` demodulates an FM-modulated baseband audio signal and filters this signal with a de-emphasis filter to produce an audio signal.

`[audiosig, rbdssig] = fmbdemodulator(insig)` also demodulates a baseband RBDS signal at 57 kHz. To enable this syntax, set the `RBDS` property to `true`.

Input Arguments

insig — FM-modulated baseband audio signal

column vector

FM-modulated baseband audio signal, specified as a column vector. For information about signal length restrictions, see “Limitations” on page 3-529.

Data Types: `double` | `single`

Complex Number Support: Yes

Output Arguments

audiosig — Audio signal

N -element column vector | M -by- N matrix

Audio signal, returned as a column vector or an M -by- N matrix. M is the number of stereo channels. N is the number of samples in the audio signal per channel. The output has the same data type as the input signal, `insig`.

If you set the `Stereo` property to `true`, the audio signal must have at least two channels and the System object performs stereo encoding before de-emphasis filtering. The length of the output is $N \times (\text{AudioSampleRate}/\text{SampleRate})$.

rbdssig — RBDS signal

column vector

RBDS signal, returned as a column vector with the same data type as the input signal.

Data Types: `double` | `single`

Complex Number Support: Yes

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Specific to `comm.FMBroadcastDemodulator`

`info` Information about FM broadcast modulator or demodulator

Common to All System Objects

`step` Run System object algorithm

release Release resources and allow changes to System object property values and input characteristics
 reset Reset internal states of System object

Examples

FM Broadcast Streaming Audio Signal

Play back an audio file after applying FM broadcast modulation and demodulation using System objects to process the data in streaming mode.

Load the audio file `guitartune.wav` by using an audio file reader System object™ with the samples per frame set to 4410.

```
audiofilereader = dsp.AudioFileReader('guitartune.wav', ...
    'SamplesPerFrame',4410);
```

Create FM broadcast modulator and demodulator objects. Set the sample rate of the output audio signal to match the sample rate of the input audio signal. Set the sample rate of the demodulator to match the specified sample rate of the modulator. Enable audio playback for the broadcast demodulator.

```
fmbMod = comm.FMBroadcastModulator( ...
    'AudioSampleRate',audiofilereader.SampleRate, ...
    'SampleRate',240e3);
fmbDemod = comm.FMBroadcastDemodulator( ...
    'AudioSampleRate',audiofilereader.SampleRate, ...
    'SampleRate',240e3, 'PlaySound',true);
```

Read the audio data in frames of length 4410, apply FM broadcast modulation, demodulate the FM signal, and play back the demodulated signal (`demodData`).

```
while ~isDone(audiofilereader)
    audioData = audiofilereader();
    modData = fmbMod(audioData);
    demodData = fmbDemod(modData); % Demodulate and play signal
end
```

FM Broadcast Modulate and Demodulate an RBDS Waveform

Generate an RBDS waveform, FM broadcast modulate the RBDS waveform with an audio signal, and FM broadcast demodulate the FM signal.

Specify parameters for an RBDS waveform with 19 groups per frame and 10 samples per symbol. The sample rate of the RBDS waveform is given by 1187.5×10 . Set the audio sample rate to 1187.5×40 .

```
groupLen = 104;
sps = 10;
groupsPerFrame = 19;
rbdsFrameLen = groupLen*sps*groupsPerFrame;
afrRate = 40*1187.5;
rbdsRate = 1187.5*sps;
outRate = 4*57000;
```

Load the audio file `guitartune.wav` by using an audio file reader System object™ while setting the samples per frame. Create RBDS waveform generator, FM broadcast modulator, FM broadcast demodulator, and time scope System objects. Configure the modulator and demodulator objects to process a stereo audio file and an RBDS waveform.

```
afr = dsp.AudioFileReader( ...
    'rbds_capture_47500.wav', ...
    'SamplesPerFrame', rbdFrameLen*afrRate/rbdsRate);
rbds = comm.RBDSWaveformGenerator( ...
    'GroupsPerFrame', groupsPerFrame, ...
    'SamplesPerSymbol', sps);

fmMod = comm.FMBroadcastModulator( ...
    'AudioSampleRate', afr.SampleRate, ...
    'SampleRate', outRate, ...
    'Stereo', true, ...
    'RBDS', true, ...
    'RBDSsamplesPerSymbol', sps);
fmDemod = comm.FMBroadcastDemodulator( ...
    'SampleRate', outRate, ...
    'Stereo', true, ...
    'RBDS', true, ...
    'PlaySound', true);
scope = timescope( ...
    'SampleRate', outRate, ...
    'YLimits', 10^-2*[-1 1]);
```

Read the audio signal. Generate RBDS information at the same configured rate as audio. FM broadcast modulate the stereo audio signal with RBDS information. Add additive white Gaussian noise. FM-demodulate the audio signal and RBDS waveforms. View the waveforms in a time scope.

```
for idx = 1:7
    input = afr();
    rbdWave = rbds();
    yFM = fmMod([input input], rbdWave);
    rcv = awgn(yFM, 40);
    [audioRcv, rbdRcv] = fmDemod(rcv);
    scope(rbdRcv);
end
```

Limitations

The length of the input signal, `insig`, must be an integer multiple of the `AudioDecimationFactor` property. If you set the `RBDS` property to `true`, the length of the input signal, `insig`, also must be an integer multiple of `RBDSDecimationFactor`. For more information on the `AudioDecimationFactor` and `RBDSDecimationFactor` properties, see the `info` object function.

Algorithms

The FM Broadcast demodulator includes the functionality of the baseband FM demodulator, de-emphasis filtering, and the ability to receive stereophonic signals. For more information about the algorithms used for basic FM modulation and demodulation, see the `comm.FMDemodulatorSystem` object.

Filtering

FM amplifies high-frequency noise and degrades the overall signal-to-noise ratio. To compensate, FM broadcasters insert a pre-emphasis filter prior to FM modulation to amplify the high-frequency content. The FM receiver has a reciprocal de-emphasis filter after the FM demodulator to attenuate high-frequency noise and restore a flat signal spectrum. This figure shows the order of processing operations.

The pre-emphasis filter has a highpass characteristic transfer function given by

$$H_p(f) = 1 + j2\pi f\tau_s,$$

where τ_s is the filter time constant. The time constant is 75 μ s in the United States and 50 μ s in Europe. Similarly, the transfer function for the lowpass de-emphasis filter is given by

$$H_d(f) = \frac{1}{1 + j2\pi f\tau_s}.$$

For an audio sample rate of 44.1 kHz, the de-emphasis filter has the response shown in this figure.

Multiplexed Stereo and RDS (or RBDS) FM Signal

The FM broadcast demodulator supports stereophonic and monophonic operations. To support stereo transmission,

- The Left+Right channel information is assigned to the mono portion of the spectrum (0 to 15 kHz).
- The Left-Right channel information is amplitude modulated onto the 23 to 53 kHz region of the baseband spectrum using a 38 kHz subcarrier signal.

A pilot tone at 19 kHz in the multiplexed signal enables the FM receiver to coherently demodulate the stereo and RDS (or RBDS) signals.

This figure shows the spectrum of the multiplex baseband signal.

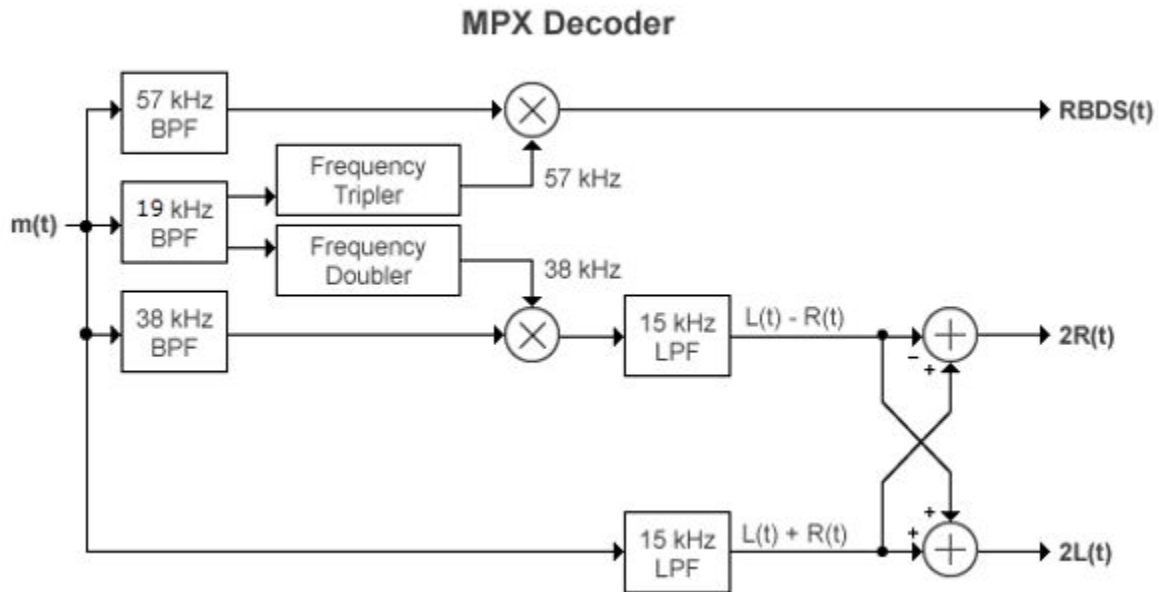

The multiplex message signal, $m(t)$ is given by

$$m(t) = C_0[L(t) + R(t)] + C_1 \cos(2\pi \times 19\text{kHz} \times t) + C_0[L(t) - R(t)]\cos(2\pi \times 38\text{kHz} \times t) + C_2 \text{RBDS}(t) \cos(2\pi \times 57\text{kHz} \times t),$$

where C_0 , C_1 , and C_2 are gains. To generate the appropriate modulation level, these gains scale the amplitudes of the $L(t) \pm R(t)$ signals, the 19 kHz pilot tone, and the RDS (or RBDS) subcarrier, respectively.

The demodulator applies $m(t)$ to three bandpass filters with center frequencies at 19, 38, and 57 kHz and to a lowpass filter with a 3 dB cutoff frequency of 15 kHz. The 19 kHz bandpass filter extracts the pilot tone from the modulated signal. The recovered pilot tone is doubled and tripled in frequency to produce the 38 kHz and 57 kHz signals, which demodulate the $(L - R)$ and RDS (or RBDS) signals, respectively. To generate a scaled version of the left and right channels that produces the stereo sound, the object adds and subtracts the $(L + R)$ and $(L - R)$ signals. To recover the RDS (or RBDS) signal the object mixes $m(t)$ with the 57 kHz signal.

This figure shows the Multiplexing (MPX) decoder block diagram of the FM broadcast demodulator. $L(t)$ and $R(t)$ are the left and right audio signal components of the time-domain waveforms. $\text{RBDS}(t)$ is the time-domain waveform of the RDS (or RBDS) signal.

comm.FMBroadcastModulator

Package: comm

Modulate broadcast FM audio signal

Description

The `comm.FMBroadcastModulator` System object pre-emphasizes an audio signal and modulates it onto a baseband FM signal. For more information, see the “Algorithms” on page 3-542 section.

To modulate a broadcast FM audio signal:

- 1 Create the `comm.FMBroadcastModulator` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

Creation

Syntax

```
fmbmodulator = comm.FMBroadcastModulator  
fmbmodulator = comm.FMBroadcastModulator(Name,Value)  
fmbmodulator = comm.FMBroadcastModulator(fmbdemodulator)
```

Description

`fmbmodulator = comm.FMBroadcastModulator` creates a FM broadcast modulator System object.

`fmbmodulator = comm.FMBroadcastModulator(Name,Value)` sets properties using one or more name-value arguments. For example, `'SampleRate',400e3` specifies a sample rate of 400 kHz.

`fmbmodulator = comm.FMBroadcastModulator(fmbdemodulator)` sets properties based on configuration of the input `comm.FMBroadcastDemodulator` System object, `fmbdemodulator`.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see [System Design in MATLAB Using System Objects](#).

SampleRate — Sample rate

240e3 (default) | positive scalar

Sample rate of the output of the modulator in Hz, specified as a positive scalar. The sample rate must be greater than twice the frequency deviation (that is, $\text{SampleRate} > 2 \times \text{FrequencyDeviation}$).

Data Types: `double`

FrequencyDeviation — Peak deviation of the output signal frequency

75e3 (default) | positive scalar

Peak deviation of the output signal frequency in Hz, specified a positive scalar. The frequency deviation must be less than half the sample rate (that is, $\text{FrequencyDeviation} < \text{SampleRate}/2$).

The system bandwidth $B_T = 2 \times (\text{FrequencyDeviation} + B_M)$, where B_M is the message bandwidth in Hz. For more information, see the “Algorithms” on page 3-542 section.

FM broadcast standards specify a value of 75 kHz in the United States and 50 kHz in Europe.

Data Types: `double`

FilterTimeConstant — Pre-emphasis highpass filter time constant

7.5e-05 (default) | positive scalar

Pre-emphasis highpass filter time constant in seconds, specified as a positive scalar. FM broadcast standards specify a value of 75 μs in the United States and 50 μs in Europe.

Data Types: `double`

AudioSampleRate — Sample rate of input audio signal

48000 (default) | positive scalar

Sample rate of the input audio signal in Hz, specified as a positive scalar.

Data Types: `double`

Stereo — Option to enable stereo modulation

false or 0 (default) | true or 1

Option to enable stereo modulation, specified as a logical 0 (false) or 1 (true).

- Set this property to `false` for monophonic audio signals.
- Set this property to `true` for stereophonic audio signals. The object modulates the audio input ($L - R$) in the 38 kHz band in addition to modulating the audio signal in the baseband ($L + R$).

For more information, see the “Algorithms” on page 3-542 section.

Data Types: `logical`

RBDS — Option to enable RDS (or RBDS) waveform modulation

false or 0 (default) | true or 1

Option to enable RDS (or RBDS) waveform modulation, specified as a logical 0 (false) or 1 (true). If you set this property to `true`, the object accepts the baseband RDS (or RBDS) waveform as its second input and modulates the RDS (or RBDS) signal at 57 kHz. For more information, see the “Algorithms” on page 3-542 section.

Data Types: `logical`

RBDSamplesPerSymbol — Oversampling factor of RDS (or RBDS) input signal

10 (default) | positive integer

Oversampling factor of the RDS (or RBDS) input signal, specified as a positive integer. The sample rate of RDS (or RBDS) broadcast data is 1187.5 Hz. The RDS (or RBDS) signal sample rate is $\text{RBDSSamplesPerSymbol} \times 1187.5$ Hz.

Dependencies

To enable this property, set the `RBDS` property to `true`.

Data Types: `double`

Usage**Syntax**

```
outsig = fmbmodulator(audiosig)
outsig = fmbmodulator(audiosig, rbdssig)
```

Description

`outsig = fmbmodulator(audiosig)` pre-emphasizes the input audio signal and modulates the pre-emphasized signal onto an FM-modulated baseband audio signal.

`outsig = fmbmodulator(audiosig, rbdssig)` also modulates a baseband RBDS signal at 57 kHz. To enable this syntax, set the `RBDS` property to `true`.

Input Arguments**audiosig — Audio signal**

N-element column vector | *M*-by-*N* matrix

Audio signal, specified as one of these options.

- *N*-element column vector for mono signals — If you set the `Stereo` property to `false`, you must specify the audio signal as a column vector. *N* is the number of samples in the audio signal.
- *M*-by-*N* matrix for stereo signals — *M* is the number of stereo channels. *N* is the number of samples in the audio signal per channel.

For information about signal length restrictions, see “Limitations” on page 3-542.

If you set the `Stereo` property to `true`, the audio signal must have at least two channels and the System object performs stereo encoding after pre-emphasis filtering.

Data Types: `double` | `single`
Complex Number Support: Yes

rbdssig — RBDS signal

column vector

RBDS signal, specified as a column vector. For information about RBDS signal length restrictions, see “Limitations” on page 3-542.

To generate the RBDS signal, use the `comm.RBDSWaveformGenerator` System object.

Data Types: `double` | `single`
Complex Number Support: Yes

Output Arguments

outsig — FM-modulated baseband signal

column vector

FM-modulated baseband signal, returned as a column vector of complex values of the same data type as the input signal, `audiosig`. The length of this output is $\text{length}(\text{audiosig}) \times (\text{SampleRate}/\text{AudioSampleRate})$.

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Specific to comm.FMBroadcastModulator

info Information about FM broadcast modulator or demodulator

Common to All System Objects

`step` Run System object algorithm
`release` Release resources and allow changes to System object property values and input characteristics
`reset` Reset internal states of System object

Examples

FM Broadcast Streaming Audio Signal

Play back an audio file after applying FM broadcast modulation and demodulation using System objects to process the data in streaming mode.

Load the audio file `guitartune.wav` by using an audio file reader System object™ with the samples per frame set to 4410.

```
audiofilereader = dsp.AudioFileReader('guitartune.wav', ...
    'SamplesPerFrame',4410);
```

Create FM broadcast modulator and demodulator objects. Set the sample rate of the output audio signal to match the sample rate of the input audio signal. Set the sample rate of the demodulator to match the specified sample rate of the modulator. Enable audio playback for the broadcast demodulator.

```
fmbMod = comm.FMBroadcastModulator( ...
    'AudioSampleRate',audiofilereader.SampleRate, ...
    'SampleRate',240e3);
fmbDemod = comm.FMBroadcastDemodulator( ...
    'AudioSampleRate',audiofilereader.SampleRate, ...
    'SampleRate',240e3,'PlaySound',true);
```

Read the audio data in frames of length 4410, apply FM broadcast modulation, demodulate the FM signal, and play back the demodulated signal (`demodData`).

```

while ~isDone(audiofilereader)
    audioData = audiofilereader();
    modData = fmbMod(audioData);
    demodData = fmbDemod(modData); % Demodulate and play signal
end

```

Plot Spectrum of FM Broadcast Modulate and Demodulate Streaming Audio Signals

Modulate and demodulate an audio signal with the FM broadcast modulator and demodulator System objects. Plot the frequency responses to compare the input and demodulated audio signals.

Load the audio file `guitartune.wav` by using an audio file reader System object™. Set the samples per frame to 44,100, which is large enough to include the entire audio file.

```

audiofilereader = dsp.AudioFileReader('guitartune.wav', ...
    'SamplesPerFrame',44100);
x = audiofilereader();

```

Create spectrum analyzer System objects to plot the spectra of the modulated and demodulated signals.

```

SAaudio = dsp.SpectrumAnalyzer( ...
    'SampleRate',44100, ...
    'ShowLegend',true, ...
    'Title','Audio Signal', ...
    'ChannelNames',{'Input signal' 'Demodulated signal'});
SAfm = dsp.SpectrumAnalyzer( ...
    'SampleRate',152e3, ...
    'Title','FM Broadcast Signal');

```

Create FM broadcast modulator and demodulator objects. Set the sample rate of the output audio signal to match the sample rate of the input audio signal. Configure the demodulator to match the specified modulator.

```

fmbMod = comm.FMBroadcastModulator( ...
    'AudioSampleRate',audiofilereader.SampleRate, ...
    'SampleRate',200e3);
fmbDemod = comm.FMBroadcastDemodulator(fmbMod)

```

```

fmbDemod =
comm.FMBroadcastDemodulator with properties:

```

```

    SampleRate: 200000
  FrequencyDeviation: 75000
  FilterTimeConstant: 7.5000e-05
    AudioSampleRate: 44100
      PlaySound: false
        Stereo: false
          RBDS: false

```

The length of the sequence input to the object must be an integer multiple of the decimation factor. To determine the audio decimation factor of the filter in the modulator and demodulator, use the `info` object function.

```

info(fmbMod)

```

```
ans = struct with fields:
    AudioDecimationFactor: 441
    AudioInterpolationFactor: 2000
    RBDSDecimationFactor: 19
    RBDSInterpolationFactor: 320
```

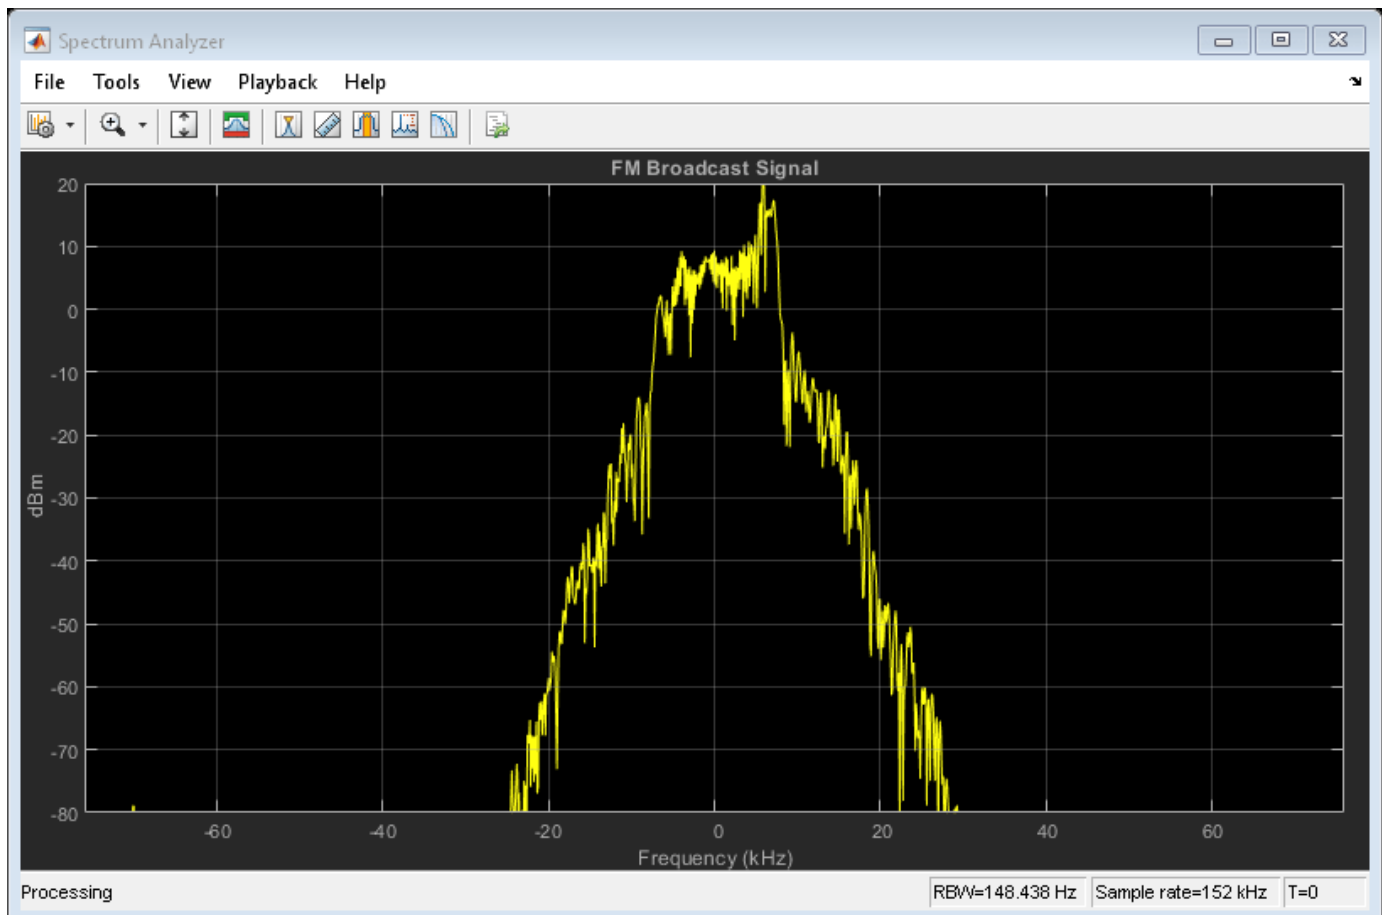

```
info(fmbDemod)
```

```
ans = struct with fields:
    AudioDecimationFactor: 50
    AudioInterpolationFactor: 57
    RBDSDecimationFactor: 50
    RBDSInterpolationFactor: 57
```

The audio decimation factor of the modulator is a multiple of the audio frame length of 44,100. The audio decimation factor of the demodulator is an integer multiple of the 200,000 samples data sequence length of the modulator output.

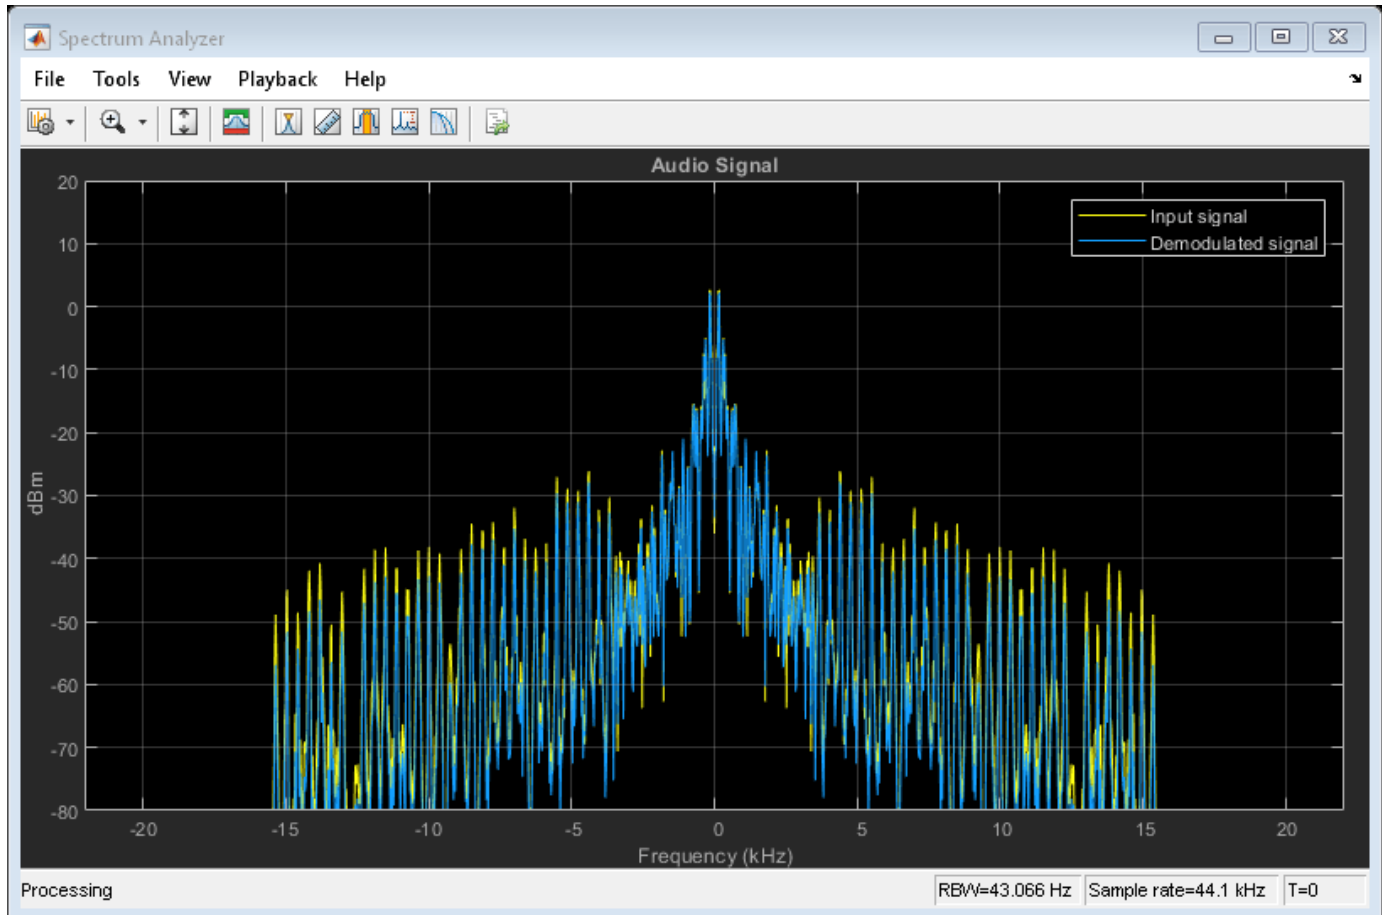

Modulate the audio signal and plot the spectrum of the modulated signal.

```
y = fmbMod(x);
SAfm(y)
```

Demodulate the modulated audio signal and plot the resultant spectrum. Compare the input signal spectrum with the demodulated signal spectrum. The spectra are similar except that the demodulated signal has smaller high-frequency components.

```
z = fmbDemod(y);
SAaudio([x z])
```

FM Broadcast Modulate and Demodulate an RBDS Waveform

Generate an RBDS waveform, FM broadcast modulate the RBDS waveform with an audio signal, and FM broadcast demodulate the FM signal.

Specify parameters for an RBDS waveform with 19 groups per frame and 10 samples per symbol. The sample rate of the RBDS waveform is given by 1187.5×10 . Set the audio sample rate to 1187.5×40 .

```
groupLen = 104;
sps = 10;
groupsPerFrame = 19;
rbdsFrameLen = groupLen*sps*groupsPerFrame;
afrRate = 40*1187.5;
rbdsRate = 1187.5*sps;
outRate = 4*57000;
```

Load the audio file `guitartune.wav` by using an audio file reader System object™ while setting the samples per frame. Create RBDS waveform generator, FM broadcast modulator, FM broadcast demodulator, and time scope System objects. Configure the modulator and demodulator objects to process a stereo audio file and an RBDS waveform.

```
afr = dsp.AudioFileReader( ...
    'rbds_capture_47500.wav', ...
    'SamplesPerFrame', rbdFrameLen*afrRate/rbdsRate);
rbds = comm.RBDSWaveformGenerator( ...
    'GroupsPerFrame', groupsPerFrame, ...
    'SamplesPerSymbol', sps);

fmMod = comm.FMBroadcastModulator( ...
    'AudioSampleRate', afr.SampleRate, ...
    'SampleRate', outRate, ...
    'Stereo', true, ...
    'RBDS', true, ...
    'RBDSsamplesPerSymbol', sps);
fmDemod = comm.FMBroadcastDemodulator( ...
    'SampleRate', outRate, ...
    'Stereo', true, ...
    'RBDS', true, ...
    'PlaySound', true);
scope = timescope( ...
    'SampleRate', outRate, ...
    'YLimits', 10^-2*[-1 1]);
```

Read the audio signal. Generate RBDS information at the same configured rate as audio. FM broadcast modulate the stereo audio signal with RBDS information. Add additive white Gaussian noise. FM-demodulate the audio signal and RBDS waveforms. View the waveforms in a time scope.

```
for idx = 1:7
    input = afr();
    rbdWave = rbds();
    yFM = fmMod([input input], rbdWave);
    rcv = awgn(yFM, 40);
    [audioRcv, rbdRcv] = fmDemod(rcv);
    scope(rbdRcv);
end
```

Limitations

- If you set the RBDS to `true`, both the audio and RDS (or RBDS) inputs must satisfy this equation.

$$\frac{\text{audioLength}}{\text{audioSampleRate}} = \frac{\text{RBDSLengh}}{\text{RBDSSampleRate}}$$

- The RDS (or RBDS) signal sample rate is `RBDSSamplesPerSymbol × 1187.5 Hz`.
- The length of the input RDS (or RBDS) signal, `rbdsig`, must be an integer multiple of the `RBDSDecimationFactor` property. The input length of the audio signal, `audiosig`, must be an integer multiple of the `AudioDecimationFactor` property. For more information on `RBDSDecimationFactor` and `AudioDecimationFactor`, see the `info` object function.

Algorithms

The FM Broadcast modulator includes the functionality of the baseband FM modulator, pre-emphasis filtering, and the ability to transmit stereophonic signals. For more information about the algorithms used for basic FM modulation and demodulation, see the `comm.FMModulator` System object.

Filtering

FM amplifies high-frequency noise and degrades the overall signal-to-noise ratio. To compensate, FM broadcasters insert a pre-emphasis filter prior to FM modulation to amplify the high-frequency

content. The FM receiver has a reciprocal de-emphasis filter after the FM demodulator to attenuate high-frequency noise and restore a flat signal spectrum. This figure shows the order of processing operations.

The pre-emphasis filter has a highpass characteristic transfer function given by

$$H_p(f) = 1 + j2\pi f\tau_s,$$

where τ_s is the filter time constant. The time constant is 75 μs in the United States and 50 μs in Europe. Similarly, the transfer function for the lowpass de-emphasis filter is given by

$$H_d(f) = \frac{1}{1 + j2\pi f\tau_s}.$$

Irrespective of the audio sampling rate, the modulator converts the signal to a 152 kHz output sampling rate. For an audio sample rate of 44.1 kHz, the pre-emphasis filter has the response shown in this figure.

Multiplexed Stereo and RDS (or RBDS) FM Signal

The FM broadcast modulator supports stereophonic and monophonic operations. To support stereo transmission,

- The Left+Right channel information is assigned to the mono portion of the spectrum (0 to 15 kHz).
- The Left-Right channel information is amplitude modulated onto the 23 to 53 kHz region of the baseband spectrum using a 38 kHz subcarrier signal.

A pilot tone at 19 kHz in the multiplexed signal enables the FM receiver to coherently demodulate the stereo and RDS (or RBDS) signals.

This figure shows the spectrum of the multiplex baseband signal.

The multiplex message signal, $m(t)$, is given by

$$m(t) = C_0[L(t) + R(t)] + C_1\cos(2\pi \times 19\text{kHz} \times t) + C_0[L(t) - R(t)]\cos(2\pi \times 38\text{kHz} \times t) + C_2\text{RBDS}(t)\cos(2\pi \times 57\text{kHz} \times t),$$

where C_0 , C_1 , and C_2 are gains. To generate the appropriate modulation level, these gains scale the amplitudes of the $L(t)\pm R(t)$ signals, the 19 kHz pilot tone, and the RDS (or RBDS) subcarrier, respectively.

This figure shows the Multiplexing (MPX) encoder block diagram of the FM broadcast modulator, which is used to generate the multiplex baseband signal. $L(t)$ and $R(t)$ are the left and right audio signal components of the time-domain waveforms. $\text{RBDS}(t)$ is the time-domain waveform of the RDS (or RBDS) signal.

Package: comm

Demodulate baseband FM signal

Description

The `comm.FMDemodulator` System object demodulates a baseband FM signal.

To demodulate a baseband FM signal:

- 1 Create the `comm.FMDemodulator` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

Creation

Syntax

```
fmdemodulator = comm.FMDemodulator  
fmdemodulator = comm.FMDemodulator(Name,Value)  
fmdemodulator = comm.FMDemodulator(fmmodulator)
```

Description

`fmdemodulator = comm.FMDemodulator` creates an FM demodulator System object.

`fmdemodulator = comm.FMDemodulator(Name,Value)` sets properties using one or more name-value arguments. For example, `'Samplerate',400e3` specifies a sample rate of 400 kHz.

`fmdemodulator = comm.FMDemodulator(fmmodulator)` sets properties based on the configuration of the input `comm.FMModulator` System object, `fmmodulator`.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see [System Design in MATLAB Using System Objects](#).

SampleRate — Sample rate

240e3 (default) | positive scalar

Sample rate of the input signal in Hz, specified as a positive scalar. This property specifies the sample rate at the output of a modulator or at the input of a demodulator. The sample rate must be greater than twice the frequency deviation (that is, $\text{SampleRate} > 2 \times \text{FrequencyDeviation}$).

Data Types: `double`

FrequencyDeviation — Peak deviation of output signal frequency

75e3 (default) | positive scalar

Peak deviation of the output signal frequency in Hz, specified a positive scalar. The frequency deviation must be less than half the sample rate (that is, $\text{FrequencyDeviation} < \text{SampleRate}/2$).

The system bandwidth is $B_T = 2 \times (\text{FrequencyDeviation} + B_M)$, where B_M is the message bandwidth in Hz. For more information, see the “Algorithms” on page 3-561 section.

Data Types: `double`

Usage

Syntax

```
outsig = fmdemodulator(insig)
```

Description

`outsig = fmdemodulator(insig)` demodulates a baseband FM signal and outputs message data.

Input Arguments

insig — Baseband FM signal

scalar | column vector

Baseband FM signal, specified as a scalar or column vector.

Data Types: `double` | `single` | `fi`

Complex Number Support: Yes

Output Arguments

outsig — Message data

scalar | column vector

Message data, returned as a scalar or column vector of the same data type and size as the input `insig`.

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Common to All System Objects

step	Run System object algorithm
release	Release resources and allow changes to System object property values and input characteristics
reset	Reset internal states of System object

Examples

Play FM-Demodulated Audio File

Play back an audio file after applying FM modulation and demodulation by using System objects to process the data in streaming mode.

Load the audio file `guitartune.wav` by using an audio file reader System object™.

```
audiofilereader = dsp.AudioFileReader('guitartune.wav', ...  
    'SamplesPerFrame',4410);
```

Create an audio device writer System object for audio playback.

```
audioplayer = audioDeviceWriter;
```

Create default FM modulator and demodulator System objects.

```
fmmod = comm.FMModulator;  
fmdemod = comm.FMDemodulator;
```

Read the audio data, FM-modulate the audio data, FM-demodulate the FM-modulated signal, and play back the demodulated signal (`z`).

```
while ~isDone(audiofilereader)  
    x = audiofilereader();  
    y = fmmod(x);  
    z = fmdemod(y);  
    audioplayer(z);  
end
```

Modulate and Demodulate Sinusoidal Signal Using FM Method

Modulate and demodulate a sinusoidal signal. Plot the demodulated signal and compare it to the original signal.

Initialize parameters for the example.

```
fs = 100; % Sample rate (Hz)  
ts = 1/fs; % Sample period (s)  
fd = 25; % Frequency deviation (Hz)
```

Create a sinusoidal signal with a duration of 0.5 s and frequency of 4 Hz.

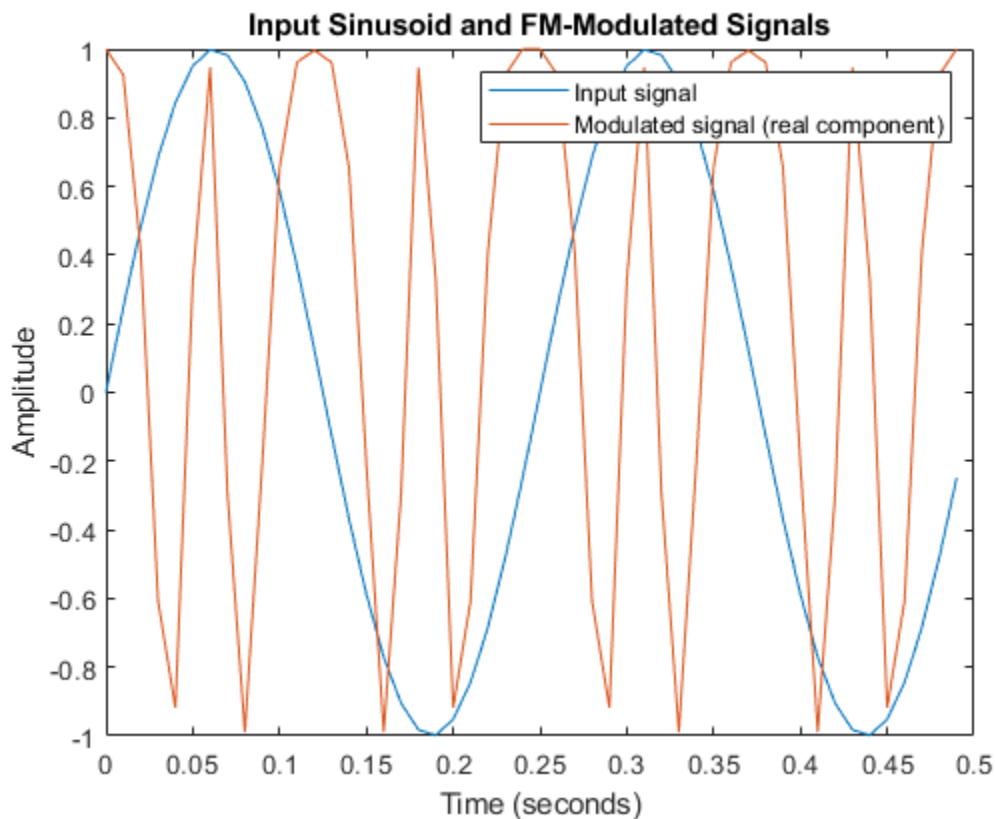

```
t = (0:ts:0.5-ts)';  
x = sin(2*pi*4*t);
```

Create an FM modulator System object, setting the sample rate and frequency deviation. Then, create an FM demodulator System object, using the FM modulator configuration to set the demodulator properties.

```
fmmodulator = comm.FMModulator( ...
    'SampleRate',fs, ...
    'FrequencyDeviation',fd);
fmdemodulator = comm.FMDemodulator(fmmodulator);
```

FM-modulate the signal and plot the real component of the complex signal. The frequency of the modulated signal changes with the amplitude of the input signal.

```
y = fmmodulator(x);
plot(t,[x real(y)])
title('Input Sinusoid and FM-Modulated Signals')
xlabel('Time (seconds)'); ylabel('Amplitude')
legend('Input signal','Modulated signal (real component)')
```

Demodulate the FM-modulated signal.

```
z = fmdemodulator(y);
```

Plot the original and demodulated signals. The demodulator output signal exactly aligns with the original signal.

```
plot(t,x,'r',t,z,'ks')
legend('Original signal','Demodulated signal')
```

```
xlabel('Time (s)')
ylabel('Amplitude')
```

Create FM Demodulator from FM Modulator

Create an FM demodulator System object™ from an FM modulator System object. Modulate and demodulate audio data loaded from a file and compare the spectrum for the demodulated data and the input data.

Initialize parameters for the example.

```
fd = 50e3; % Frequency deviation (Hz)
fs = 300e3; % Sample rate (Hz)
```

Create an FM modulator System object.

```
mod = comm.FMModulator( ...
    'FrequencyDeviation',fd, ...
    'SampleRate',fs);
```

Create an FM demodulator object by using the modulator to configure it.

```
demod = comm.FMDemodulator(mod);
```

Verify that the properties are identical in the two System objects.

mod

```
mod =  
comm.FMModulator with properties:  
    SampleRate: 300000  
    FrequencyDeviation: 50000
```

demod

```
demod =  
comm.FMDemodulator with properties:  
    SampleRate: 300000  
    FrequencyDeviation: 50000
```

Load audio data into the workspace.

```
S = load('handel.mat');  
data = S.y;  
fsamp = S.Fs;
```

Create a spectrum analyzer System object.

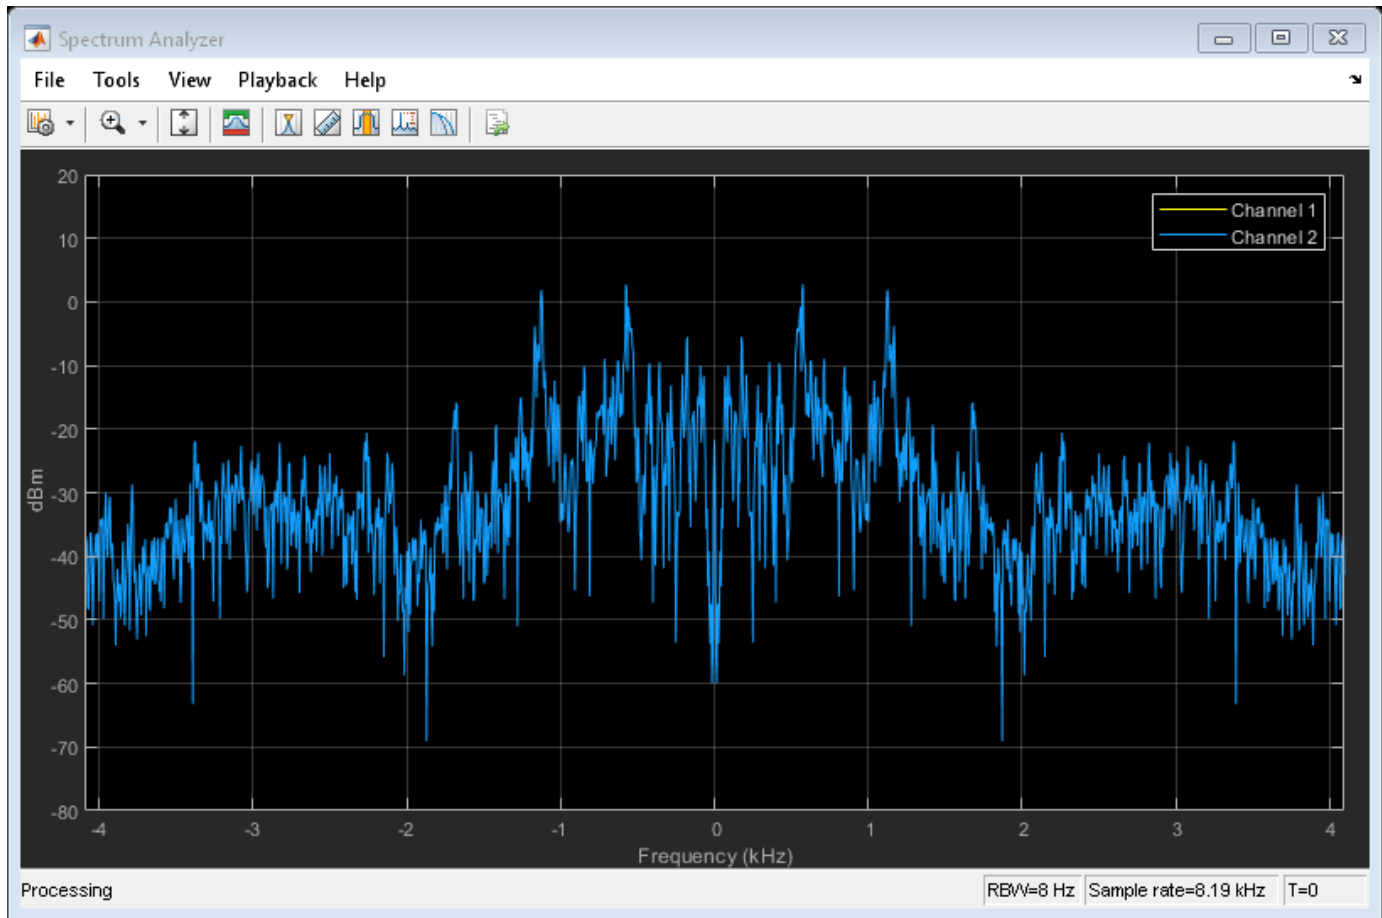

```
specanalyzer = dsp.SpectrumAnalyzer( ...  
    'SampleRate', fsamp, ...  
    'ShowLegend', true);
```

FM-modulate and -demodulate the audio data.

```
modData = mod(data);  
demodData = demod(modData);
```

Verify that the spectrum plot of the input data (Channel 1) aligns with that of the demodulated data (Channel 2).

```
specanalyzer([data demodData])
```

Algorithms

A frequency-modulated passband signal, $Y(t)$, is given as

$$Y(t) = A \cos\left(2\pi f_c t + 2\pi f_\Delta \int_0^t \chi(\tau) d\tau\right),$$

where:

- A is the carrier amplitude.
- f_c is the carrier frequency.
- $\chi(\tau)$ is the baseband input signal.
- f_Δ is the frequency deviation in Hz.

The frequency deviation is the maximum shift from f_c in one direction, assuming $|\chi(\tau)| \leq 1$.

A baseband FM signal can be derived from the passband representation by downconverting the passband signal by f_c such that

$$y_s(t) = Y(t)e^{-j2\pi f_c t} = \frac{A}{2} \left[e^{j\left(2\pi f_c t + 2\pi f_\Delta \int_0^t x(\tau) d\tau\right)} + e^{-j\left(2\pi f_c t + 2\pi f_\Delta \int_0^t x(\tau) d\tau\right)} \right] e^{-j2\pi f_c t}$$

$$= \frac{A}{2} \left[e^{j2\pi f_\Delta \int_0^t x(\tau) d\tau} + e^{-j4\pi f_c t - j2\pi f_\Delta \int_0^t x(\tau) d\tau} \right].$$

Removing the component at $-2f_c$ from $y_s(t)$ leaves the baseband signal representation, $y(t)$, which is given as

$$y(t) = \frac{A}{2} e^{j2\pi f_\Delta \int_0^t x(\tau) d\tau}.$$

The expression for $y(t)$ can be rewritten as $y(t) = \frac{A}{2} e^{j\phi(t)}$, where $\phi(t) = 2\pi f_\Delta \int_0^t x(\tau) d\tau$. Expressing $y(t)$ this way implies that the input signal is a scaled version of the derivative of the phase, $\phi(t)$.

To recover the input signal from $y(t)$, use a baseband delay demodulator, as this figure shows.

Subtracting a delayed and conjugated copy of the received signal from the signal itself results in this equation.

$$w(t) = \frac{A^2}{4} e^{j\phi(t)} e^{-j\phi(t-T)} = \frac{A^2}{4} e^{j[\phi(t) - \phi(t-T)]},$$

where T is the sample period. In discrete terms,

$$w_n = w(nT),$$

$$w_n = \frac{A^2}{4} e^{j[\phi_n - \phi_{n-1}]}, \text{ and}$$

$$v_n = \phi_n - \phi_{n-1}.$$

The signal v_n is the approximate derivative of ϕ_n such that $v_n \approx x_n$.

Modulate signal using FM method

Description

The `comm.FMModulator` System object applies baseband frequency modulation to a signal. For more information, see the “Algorithms” on page 3-561 section.

To modulate a signal using the FM method:

- 1 Create the `comm.FMModulator` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

Creation

Syntax

```
fmmodulator = comm.FMModulator
fmmodulator = comm.FMModulator(Name,Value)
fmmodulator = comm.FMModulator(fmdemodulator)
```

Description

`fmmodulator = comm.FMModulator` creates an FM modulator System object.

`fmmodulator = comm.FMModulator(Name,Value)` sets properties using one or more name-value arguments. For example, `'SampleRate,400e3'` specifies a sample rate of 400 kHz.

`fmmodulator = comm.FMModulator(fmdemodulator)` sets properties based on the configuration of the input `comm.FMDemodulator` System object, `fmdemodulator`.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see [System Design in MATLAB Using System Objects](#).

SampleRate — Sample rate

240e3 (default) | positive scalar

Sample rate of the input signal in Hz, specified as a positive scalar. This property specifies the sample rate at the output of a modulator or at the input of a demodulator. The sample rate must be greater than twice the frequency deviation (that is, $\text{SampleRate} > 2 \times \text{FrequencyDeviation}$).

Data Types: `double`

FrequencyDeviation — Peak deviation of output signal frequency

75e3 (default) | positive scalar

Peak deviation of the output signal frequency in Hz, specified a positive scalar. The frequency deviation must be less than half the sample rate (that is, $\text{FrequencyDeviation} < \text{SampleRate}/2$).

The system bandwidth is $B_T = 2 \times (\text{FrequencyDeviation} + B_M)$, where B_M is the message bandwidth in Hz. For more information, see the “Algorithms” on page 3-561 section.

Data Types: `double`

Usage

Syntax

```
outsig = fmodulator(insig)
```

Description

`outsig = fmodulator(insig)` modulates the input message signal and outputs a baseband FM signal.

Input Arguments

insig — Input signal

scalar | column vector

Input signal, specified as a scalar or column vector.

Data Types: `double` | `single` | `fi`

Complex Number Support: Yes

Output Arguments

outsig — Modulated baseband FM signal

scalar | column vector

Modulated baseband FM signal, returned as a scalar or column vector with complex values. The output signal has the same data type and size as the input `insig`.

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Common to All System Objects

step Run System object algorithm
 release Release resources and allow changes to System object property values and input characteristics
 reset Reset internal states of System object

Examples

FM-Modulate Sinusoidal Signal

Apply baseband modulation to a sine wave. Plot the sine wave and the modulated signals.

Set parameters for the example.

```
fs = 1e3; % Sample rate (Hz)
ts = 1/fs; % Sample period (s)
fd = 50; % Frequency deviation (Hz)
```

Create a sinusoidal signal with a duration of 0.5 s and frequency of 4 Hz.

```
t = (0:ts:0.5-ts)';
x = sin(2*pi*4*t);
```

Create an FM modulator System object™, setting the sample rate and frequency deviation.

```
fmodulator = comm.FMModulator( ...
    'SampleRate', fs, ...
    'FrequencyDeviation', fd);
```

FM-modulate the signal and plot its real part. The frequency of the modulated signal changes with the amplitude of the input signal.

```
y = fmodulator(x);
plot(t,[x real(y)])
```

Plot Spectrum of Baseband FM-Modulated Signal

Apply baseband FM modulation to a white Gaussian noise source and plot the spectrum of the modulated signal.

Initialize parameters for the example.

```
fs = 1e3; % Sample rate (Hz)
ts = 1/fs; % Sample period (s)
fd = 10; % Frequency deviation (Hz)
```

Create a white Gaussian noise source with a duration of 5 s.

```
t = (0:ts:5-ts)';
x = wgn(length(t),1,0);
```

Create two FM modulator System objects, setting the sample rate and frequency deviation. Set the frequency deviation of the second FM modulator object five times higher than the first FM modulator.

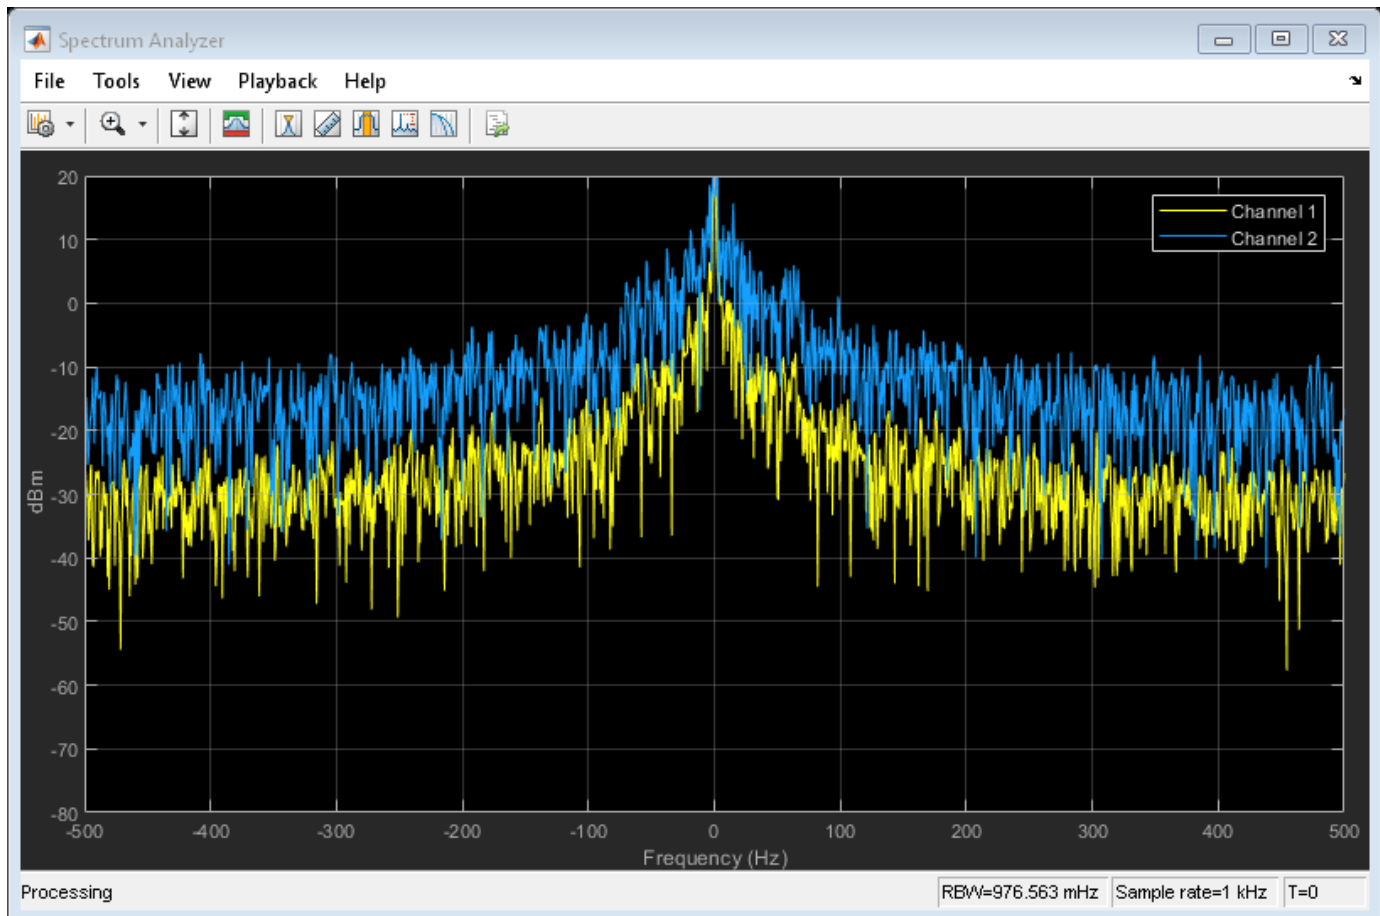

```
fmmod1 = comm.FMModulator( ...
    'SampleRate',fs, ...
    'FrequencyDeviation',fd);
fmmod2 = comm.FMModulator( ...
    'SampleRate',fs, ...
    'FrequencyDeviation',5*fd);
```

Use the FM modulators to apply FM modulation to the signal x .

```
y1 = fmod1(x);
y2 = fmod2(x);
```

Plot the spectra of the two modulated signals. The larger frequency deviation associated with channel 2 results in a noise level that is 10 dB higher than the first channel.

```
specanalyzer = dsp.SpectrumAnalyzer('SampleRate',fs,'ShowLegend',true);
specanalyzer([y1 y2])
```

Modulate and Demodulate Sinusoidal Signal Using FM Method

Modulate and demodulate a sinusoidal signal. Plot the demodulated signal and compare it to the original signal.

Initialize parameters for the example.

```
fs = 100; % Sample rate (Hz)
ts = 1/fs; % Sample period (s)
fd = 25; % Frequency deviation (Hz)
```

Create a sinusoidal signal with a duration of 0.5 s and frequency of 4 Hz.

```
t = (0:ts:0.5-ts)';
x = sin(2*pi*4*t);
```

Create an FM modulator System object, setting the sample rate and frequency deviation. Then, create an FM demodulator System object, using the FM modulator configuration to set the demodulator properties.

```
fmmodulator = comm.FMModulator( ...
    'SampleRate',fs, ...
    'FrequencyDeviation',fd);
fmdemodulator = comm.FMDemodulator(fmmodulator);
```

FM-modulate the signal and plot the real component of the complex signal. The frequency of the modulated signal changes with the amplitude of the input signal.

```
y = fmmodulator(x);
plot(t,[x real(y)])
title('Input Sinusoid and FM-Modulated Signals')
xlabel('Time (seconds)'); ylabel('Amplitude')
legend('Input signal','Modulated signal (real component)')
```

Demodulate the FM-modulated signal.

```
z = fmdemodulator(y);
```

Plot the original and demodulated signals. The demodulator output signal exactly aligns with the original signal.

```

plot(t,x,'r',t,z,'ks')
legend('Original signal','Demodulated signal')
xlabel('Time (s)')
ylabel('Amplitude')

```

Algorithms

A frequency-modulated passband signal, $Y(t)$, is given as

$$Y(t) = A \cos\left(2\pi f_c t + 2\pi f_\Delta \int_0^t \chi(\tau) d\tau\right),$$

where:

- A is the carrier amplitude.
- f_c is the carrier frequency.
- $\chi(\tau)$ is the baseband input signal.
- f_Δ is the frequency deviation in Hz.

The frequency deviation is the maximum shift from f_c in one direction, assuming $|\chi(\tau)| \leq 1$.

A baseband FM signal can be derived from the passband representation by downconverting the passband signal by f_c such that

$$y_s(t) = Y(t)e^{-j2\pi f_c t} = \frac{A}{2} \left[e^{j\left(2\pi f_c t + 2\pi f_\Delta \int_0^t x(\tau) d\tau\right)} + e^{-j\left(2\pi f_c t + 2\pi f_\Delta \int_0^t x(\tau) d\tau\right)} \right] e^{-j2\pi f_c t}$$

$$= \frac{A}{2} \left[e^{j2\pi f_\Delta \int_0^t x(\tau) d\tau} + e^{-j4\pi f_c t - j2\pi f_\Delta \int_0^t x(\tau) d\tau} \right].$$

Removing the component at $-2f_c$ from $y_s(t)$ leaves the baseband signal representation, $y(t)$, which is given as

$$y(t) = \frac{A}{2} e^{j2\pi f_\Delta \int_0^t x(\tau) d\tau}.$$

The expression for $y(t)$ can be rewritten as $y(t) = \frac{A}{2} e^{j\phi(t)}$, where $\phi(t) = 2\pi f_\Delta \int_0^t x(\tau) d\tau$. Expressing $y(t)$ this way implies that the input signal is a scaled version of the derivative of the phase, $\phi(t)$.

To recover the input signal from $y(t)$, use a baseband delay demodulator, as this figure shows.

Subtracting a delayed and conjugated copy of the received signal from the signal itself results in this equation.

$$w(t) = \frac{A^2}{4} e^{j\phi(t)} e^{-j\phi(t-T)} = \frac{A^2}{4} e^{j[\phi(t) - \phi(t-T)]},$$

where T is the sample period. In discrete terms,

$$w_n = w(nT),$$

$$w_n = \frac{A^2}{4} e^{j[\phi_n - \phi_{n-1}]}, \text{ and}$$

$$v_n = \phi_n - \phi_{n-1}.$$

The signal v_n is the approximate derivative of ϕ_n such that $v_n \approx x_n$.

FM Modulator Baseband | FM Broadcast Modulator Baseband

Introduced in R2015a

comm.FSKDemodulator

Package: comm

Demodulate using M-ary FSK method

Description

The `FSKDemodulator` object demodulates a signal that was modulated using the M-ary frequency shift keying method. The input is a baseband representation of the modulated signal. The input and output for this object are discrete-time signals.

To demodulate a signal that was modulated using frequency shift keying:

- 1 Define and set up your FSK demodulator object. See “Construction” on page 3-564.
- 2 Call `step` to demodulate a signal according to the properties of `FSKDemodulator`. The behavior of `step` is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj, x)` and `y = obj(x)` perform equivalent operations.

Construction

`H = comm.FSKDemodulator` creates a demodulator System object, `H`. This object demodulates an M-ary frequency shift keying (M-FSK) signal using a noncoherent energy detector.

`H = comm.FSKDemodulator(Name, Value)` creates an M-FSK demodulator object, `H`, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as `(Name1, Value1, ..., NameN, ValueN)`.

`H = comm.FSKDemodulator(M, FREQSEP, RS, Name, Value)` creates an M-FSK demodulator object, `H`. This object has the `ModulationOrder` property set to `M`, the `FrequencySeparation` property set to `FREQSEP`, the `SymbolRate` property set to `RS`, and the other specified properties set to the specified values.

Properties

ModulationOrder

Number of frequencies in modulated signal

Specify the number of frequencies in the modulated signal as a numeric, positive, integer scalar value that is a power of two. The default is 8.

BitOutput

Output data as bits

Specify whether the output is groups of bits or integer values. The default is `false`.

When you set this property to `false`, the `step` method outputs a column vector of length equal to $N/\text{SamplesPerSymbol}$ on page 3-0 . N is the length of the input data vector to the `step` method. The elements of the output vector are integers between 0 and ModulationOrder on page 3-0 -1. When you set this property to `true`, the `step` method outputs a column vector of length equal to $\log_2(\text{ModulationOrder}) \times (N/\text{SamplesPerSymbol})$. The property's elements are bit representations of integers between 0 and $\text{ModulationOrder}-1$.

SymbolMapping

Symbol encoding

Specify how the object maps an integer or group of $\log_2(\text{ModulationOrder}$ on page 3-0) bits to the corresponding symbol as one of `Binary` | `Gray`. The default is `Gray`.

When you set this property to `Gray`, the object uses Gray-coded ordering.

When you set this property to `Binary`, the object uses natural binary-coded ordering.

For either type of mapping, the object maps the lowest frequency to the integer 0 and maps the highest frequency to the integer $M-1$. In baseband simulation, the lowest frequency is the negative frequency with the largest absolute value.

FrequencySeparation

Frequency separation between successive tones

Specify the frequency separation between successive symbols in the modulated signal in Hertz as a positive, real scalar value. The default is 6 Hz.

SamplesPerSymbol

Number of samples per input symbol

Specify the number of samples per input symbol as a positive, integer scalar value. The default is 17.

SymbolRate

Symbol duration

Specify the symbol rate in symbols per second as a positive, double-precision, real scalar value. The default is 100. To avoid output signal aliasing, specify an output sampling rate, $F_s = \text{SamplesPerSymbol}$ on page 3-0 \times `SymbolRate`, which is greater than ModulationOrder on page 3-0 \times `FrequencySeparation` on page 3-0 . The symbol duration remain the same, regardless of whether the input is bits or integers.

OutputDataType

Data type of output

Specify the output data type as one of `logical` | `int8` | `uint8` | `int16` | `uint16` | `int32` | `uint32` | `double`. The default is `double`. The `logical` type is valid only when you set the `BitOutput` on page 3-0 property to `false` and the `ModulationOrder` on page 3-0 property to two. When you set the `BitOutput` property to `true`, the output data requires a type of `logical` | `double`.

Methods

step Demodulate using M-ary FSK method

Common to All System Objects	
release	Allow System object property value changes
reset	Reset internal states of System object

Examples

FSK Modulation and Demodulation in AWGN

Modulate and demodulate a signal using 8-FSK modulation with a frequency separation of 100 Hz.

Set the modulation order and frequency separation parameters.

```
M = 8;
freqSep = 100;
```

Create FSK modulator and demodulator System objects™ with modulation order 8 and 100 Hz frequency separation.

```
fskMod = comm.FSKModulator(M,freqSep);
fskDemod = comm.FSKDemodulator(M,freqSep);
```

Create an additive white Gaussian noise channel, where the noise is specified as a signal-to-noise ratio.

```
ch = comm.AWGNChannel('NoiseMethod', ...
    'Signal to noise ratio (SNR)', 'SNR', -2);
```

Create an error rate calculator object.

```
err = comm.ErrorRate;
```

Transmit one hundred 50-symbol frames using 8-FSK in an AWGN channel.

```
for counter = 1:100
    data = randi([0 M-1],50,1);
    modSignal = step(fskMod,data);
    noisySignal = step(ch,modSignal);
    receivedData = step(fskDemod,noisySignal);
    errorStats = step(err,data,receivedData);
end
```

Display the error statistics.

```
es1 = 'Error rate = %4.2e\n';
es2 = 'Number of errors = %d\n';
es3 = 'Number of symbols = %d\n';
fprintf([es1 es2 es3],errorStats)
```

```
Error rate = 1.40e-02
Number of errors = 70
Number of symbols = 5000
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the M-FSK Demodulator Baseband block reference page. The object properties correspond to the block parameters, except:

- The **Symbol set ordering** parameter corresponds to the SymbolMapping on page 3-0 property.
- The SymbolRate on page 3-0 property replaces the block sample rate capability.

step

System object: comm.FSKDemodulator

Package: comm

Demodulate using M-ary FSK method

Syntax

$Y = \text{step}(H, X)$

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, $y = \text{step}(\text{obj}, x)$ and $y = \text{obj}(x)$ perform equivalent operations.

$Y = \text{step}(H, X)$ demodulates input data, X , with the FSK demodulator System object, H , and returns Y . X must be a double or single precision data type column vector of length equal to an integer multiple of the number of samples per symbol that you specify in the `SamplesPerSymbol` property. Depending on the `BitOutput` property value, output Y can be integer or bit valued.

Note `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications. For more information on changing property values, see “System Design in MATLAB Using System Objects”.

comm.FSKModulator

Package: comm

Modulate using M-ary FSK method

Description

The `FSKModulator` object modulates using the M-ary frequency shift keying method. The output is a baseband representation of the modulated signal.

To modulate a signal using frequency shift keying:

- 1 Define and set up your FSK modulator object. See “Construction” on page 3-569.
- 2 Call `step` to modulate a signal according to the properties of `comm.FSKModulator`. The behavior of `step` is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`H = comm.FSKModulator` creates a modulator System object, `H`. This object modulates the input signal using the M-ary frequency shift keying (M-FSK) method.

`H = comm.FSKModulator(Name,Value)` creates an M-FSK modulator object, `H`, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as `(Name1,Value1,...,NameN,ValueN)`.

`H = comm.FSKModulator(M,FREQSEP,RS,Name,Value)` creates an M-FSK modulator object, `H`. This object has the `ModulationOrder` property set to `M`, the `FrequencySeparation` property set to `FREQSEP`, the `SymbolRate` property set to `RS`, and the other specified properties set to the specified values.

Properties

ModulationOrder

Number of frequencies in modulated signal

Specify the number of frequencies in the modulated signal as a numeric positive integer scalar value that is a power of two. The default is 8.

BitInput

Assume bit inputs

Specify whether the input is bits or integers. The default is `false`.

When you set this property to `false`, the `step` method input requires a numeric (except single precision data type) column vector of integer values between 0 and `ModulationOrder` on page 3-0 -1. In this case, the input vector can also be of data type logical if `ModulationOrder` equals 2.

When you set this property to `true`, the `step` method input requires a double-precision or logical data type column vector of bit values. The length of this vector is an integer multiple of $\log_2(\text{ModulationOrder})$. This vector contains bit representations of integers between 0 and `ModulationOrder`-1.

SymbolMapping

Symbol encoding

Specify how the object maps an integer or group of $\log_2(\text{ModulationOrder}$ on page 3-0) bits to the corresponding symbol as one of `Binary` | `Gray`. The default is `Gray`.

When you set this property to `Gray`, the object uses Gray-coded ordering.

When you set this property to `Binary`, the object uses natural binary-coded ordering. For either type of mapping, the object maps the lowest frequency to the integer 0 and maps the highest frequency to the integer $M-1$. In baseband simulation, the lowest frequency is the negative frequency with the largest absolute value.

FrequencySeparation

Frequency separation between successive tones

Specify the frequency separation between successive tones in the modulated signal in Hertz as a positive, real scalar value. The default is 6 Hz. To avoid output signal aliasing, specify an output sampling rate, $F_s = \text{SamplesPerSymbol}$ on page 3-0 \times `SymbolRate` on page 3-0 , which is greater than `ModulationOrder` on page 3-0 multiplied by `FrequencySeparation` on page 3-0 .

ContinuousPhase

Phase continuity

Specify if the phase of the output modulated signal is continuous or discontinuous. The default is `true`.

When you set this property to `true`, the modulated signal maintains continuous phase even when its frequency changes.

When you set this property to `false`, the modulated signal comprises portions of `ModulationOrder` on page 3-0 sinusoids of different frequencies. In this case, a change in the input value can cause a discontinuous change in the phase of the modulated signal.

SamplesPerSymbol

Number of samples per output symbol

Specify the number of output samples that the object produces for each integer or binary word in the input as a positive, integer scalar value. The default is 17.

SymbolRate

Symbol duration

Specify the symbol rate in symbols per second as a positive, double-precision, real scalar. The default is 100. To avoid output signal aliasing, specify an output sampling rate, $F_s = \text{SamplesPerSymbol}$ on page 3-0 $\times \text{SymbolRate}$, which is greater than ModulationOrder on page 3-0 $\times \text{FrequencySeparation}$ on page 3-0. The symbol duration remain the same, regardless of whether the input is bits or integers.

OutputDataType

Data type of output

Specify the output data type as one of `double` | `single`. The default is `double`.

Methods

`step` Modulate using M-ary FSK method

Common to All System Objects	
<code>release</code>	Allow System object property value changes
<code>reset</code>	Reset internal states of System object

Examples

FSK Modulation and Demodulation in AWGN

Modulate and demodulate a signal using 8-FSK modulation with a frequency separation of 100 Hz.

Set the modulation order and frequency separation parameters.

```
M = 8;
freqSep = 100;
```

Create FSK modulator and demodulator System objects™ with modulation order 8 and 100 Hz frequency separation.

```
fskMod = comm.FSKModulator(M,freqSep);
fskDemod = comm.FSKDemodulator(M,freqSep);
```

Create an additive white Gaussian noise channel, where the noise is specified as a signal-to-noise ratio.

```
ch = comm.AWGNChannel('NoiseMethod', ...
    'Signal to noise ratio (SNR)', 'SNR', -2);
```

Create an error rate calculator object.

```
err = comm.ErrorRate;
```

Transmit one hundred 50-symbol frames using 8-FSK in an AWGN channel.

```
for counter = 1:100
    data = randi([0 M-1],50,1);
    modSignal = step(fskMod,data);
    noisySignal = step(ch,modSignal);
    receivedData = step(fskDemod,noisySignal);
    errorStats = step(err,data,receivedData);
end
```

Display the error statistics.

```
es1 = 'Error rate = %4.2e\n';
es2 = 'Number of errors = %d\n';
es3 = 'Number of symbols = %d\n';
fprintf([es1 es2 es3],errorStats)
```

```
Error rate = 1.40e-02
Number of errors = 70
Number of symbols = 5000
```

Visualize FSK Modulated Symbol Mapping

Visualize symbol mapping of an FSK modulated signal with a spectrogram.

Specify 20 samples for each symbol. 0 maps to -50 kHz (negative phase slope) and 1 maps to +50 kHz (positive phase slope).

```
mod = comm.FSKModulator;
mod.ModulationOrder = 2;
mod.FrequencySeparation = 100000;
mod.SamplesPerSymbol = 20;
mod.SymbolMapping = 'Gray';
mod.SymbolRate = 1e4
```

```
mod =
    comm.FSKModulator with properties:
```

```
    ModulationOrder: 2
           BitInput: false
           SymbolMapping: 'Gray'
FrequencySeparation: 100000
    ContinuousPhase: true
    SamplesPerSymbol: 20
           SymbolRate: 10000
    OutputDataType: 'double'
```

```
x = mod([0 1 0 1 0 1]');
figure; subplot(1,2,1); plot(unwrap(angle(x)),0:length(x)-1);
grid on; xlabel('Phase'); ylabel('Samples')
subplot(1,2,2);
spectrogram(x,20,0,[],mod.SymbolRate*mod.SamplesPerSymbol,'centered')
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the M-FSK Modulator Baseband block reference page. The object properties correspond to the block parameters, except:

- The **Symbol set ordering** parameter corresponds to the `SymbolMapping` on page 3-0 property.
- The `SymbolRate` on page 3-0 property takes the place of the block sample rate capability.

Modulate using M-ary FSK method

Syntax

$Y = \text{step}(H,X)$

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

$Y = \text{step}(H,X)$ modulates input data, X , with the FSK modulator System object, H . It returns the baseband modulated output, Y . Depending on the value of the `BitInput` property, input X can be an integer or bit-valued column vector with numeric or logical data types. The length of output vector, Y , is equal to the number of input samples times the number of samples per symbol you specify in the `SamplesPerSymbol` property.

Note `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications. For more information on changing property values, see “System Design in MATLAB Using System Objects”.

comm.GeneralQAMDemodulator

Package: comm

Demodulate using arbitrary QAM constellation

Description

The `GeneralQAMDemodulator` object demodulates a signal that was modulated using quadrature amplitude modulation. The input is a baseband representation of the modulated signal.

To demodulate a signal that was modulated using quadrature amplitude modulation:

- 1 Define and set up your QAM demodulator object. See “Construction” on page 3-575.
- 2 Call `step` to demodulate a signal according to the properties of `comm.GeneralQAMModulator`. The behavior of `step` is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`H = comm.GeneralQAMDemodulator` creates a demodulator System object, `H`. This object demodulates the input signal using a general quadrature amplitude modulation (QAM) method.

`H = comm.GeneralQAMDemodulator(Name,Value)` creates a general QAM demodulator object, `H`, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as `(Name1,Value1,...,NameN,ValueN)`.

`H = comm.GeneralQAMDemodulator(CONST,Name,Value)` creates a general QAM demodulator object, `H`. This object has the `Constellation` property set to `CONST`, and the other specified properties set to the specified values.

Properties

Constellation

Signal constellation

Specify the constellation points as a real or complex, double-precision data type vector. The default is $\exp(2 \times \pi \times 1i \times (0:7)/8)$. The length of the vector determines the modulation order.

When you set the `BitOutput` property to `false`, the `step` method outputs a vector with integer values. These integers are between 0 and $M-1$, where M is the length of this property vector. The length of the output vector equals the length of the input signal.

When you set the `BitOutput` property to `true`, the output signal contains bits. For bit outputs, the size of the signal constellation requires an integer power of two and the output length is an integer multiple of the number of bits per symbol.

BitOutput

Output data as bits

Specify whether the output consists of groups of bits or integer symbol values. The default is `false`.

When you set this property to `true` the `step` method outputs a column vector of bit values with length equal to $\log_2(M)$ times the number of demodulated symbols, where M is the length of the signal constellation specified in the `Constellation` property. The length M determines the modulation order.

When you set this property to `false`, the `step` method outputs a column vector, of length equal to the input data vector. The vector contains integer symbol values between 0 and $M-1$.

DecisionMethod

Demodulation decision method

Specify the decision method the object uses as one of `Hard decision` | `Log-likelihood ratio` | `Approximate log-likelihood ratio`. The default is `Hard decision`. When you set the `BitOutput` property to `false` the object always performs hard decision demodulation. This property applies when you set the `BitOutput` property to `true`.

VarianceSource

Source of noise variance

Specify the source of the noise variance as one of `Property` | `Input port`. The default is `Property`. This property applies when you set the `DecisionMethod` property to `Log-likelihood ratio` or `Approximate log-likelihood ratio`.

Variance

Noise variance

Specify the variance of the noise as a nonzero, real scalar value. The default is 1.

The LLR algorithm involves computing exponentials of very large or very small numbers using finite precision arithmetic and would yield:

- `Inf` to `-Inf` if the variance is very high
- `NaN` if the variance and signal power are both very small

In such cases, use approximate LLR because the algorithm does not involve computing exponentials.

This property applies when you set the `VarianceSource` property to `Property`. This property is nontunable for fixed-point inputs.

Tips

The exact LLR algorithm computes exponentials using finite precision arithmetic. For computations involving very large positive or negative magnitudes, the exact LLR algorithm yields:

- `Inf` or `-Inf` if the noise variance is a very large value
- `NaN` if the noise variance and signal power are both very small values

The approximate LLR algorithm does not compute exponentials. You can avoid `Inf`, `-Inf`, and `NaN` results by using the approximate LLR algorithm.

OutputDataType

Data type of output

Specify the output data type as one of `Full precision` | `Smallest unsigned integer` | `double` | `single` | `int8` | `uint8` | `int16` | `uint16` | `int32` | `uint32`. The default is `Full precision`.

This property applies only when you set the `BitOutput` property to `false` or when you set the `BitOutput` property to `true` and the `DecisionMethod` property to `Hard decision` or `Approximate log-likelihood ratio`. In this case, when you set the `OutputDataType` property to `Full precision`, the output data type is the same as that of the input when the input data has a single or double-precision data type.

When the input data is of a fixed-point type, the output data type works as if you had set the `OutputDataType` property to `Smallest unsigned integer`.

When the input signal is an integer data type, you must have a Fixed-Point Designer user license to use this property in `Smallest unsigned integer` or `Full precision` mode.

When you set the `BitOutput` property to `true`, and the `DecisionMethod` property to `Hard Decision` the data type `logical` becomes a valid option.

When you set the `BitOutput` property to `true` and the `DecisionMethod` property to `Approximate log-likelihood ratio` you may only set this property to `Full precision` | `Custom`.

If you set the `BitOutput` property to `true` and the `DecisionMethod` property to `Log-likelihood ratio`, the output data has the same type as that of the input. In this case, that value can be only single or double precision.

Fixed-Point Properties

FullPrecisionOverride

Full precision override for fixed-point arithmetic

Specify whether to use full precision rules. If you set `FullPrecisionOverride` to `true`, which is the default, the object computes all internal arithmetic and output data types using full precision rules. These rules provide the most accurate fixed-point numerics. It also turns off the display of other fixed-point properties because they do not apply individually. These rules guarantee that no quantization occurs within the object. Bits are added, as needed, to ensure that no roundoff or overflow occurs. If you set `FullPrecisionOverride` to `false`, fixed-point data types are controlled through individual fixed-point property settings. For more information, see “Full Precision for Fixed-Point System Objects” on page 3-581.

RoundingMethod

Rounding of fixed-point numeric values

Specify the rounding method as one of `Ceiling` | `Convergent` | `Floor` | `Nearest` | `Round` | `Simplest` | `Zero`. The default is `Floor`. This property applies when the object is not in a full

precision configuration. This property does not apply when you set `BitOutput` to true and `DecisionMethod` to `Log-likelihood ratio`.

OverflowAction

Action when fixed-point numeric values overflow

Specify the overflow action as one of `Wrap | Saturate`. The default is `Wrap`. This property applies when the object is not in a full precision configuration. This property does not apply when you set the `BitOutput` property to true and the `DecisionMethod` property to `Log-likelihood ratio`.

ConstellationDataType

Data type of signal constellation

Specify the constellation fixed-point data type as one of `Same word length as input | Custom`. The default is `Same word length as input`. This property does not apply when you set the `BitOutput` property to true and the `DecisionMethod` property to `Log-likelihood ratio`.

CustomConstellationDataType

Fixed-point data type of signal constellation

Specify the constellation fixed-point type as an unscaled `numericType` object with a `Signedness` of `Auto`. The default is `numericType([], 16)`. This property applies when you set the `ConstellationDataType` property to `Custom`.

Accumulator1DataType

Data type of accumulator 1

Specify the accumulator 1 fixed-point data type as one of `Full precision | Custom`. The default is `Full precision`. This property applies when you set the `FullPrecisionOverride` property to false. This property does not apply when you set the `BitOutput` property to true and the `DecisionMethod` property to `Log-likelihood ratio`.

CustomAccumulator1DataType

Fixed-point data type of accumulator 1

Specify the accumulator 1 fixed-point type as a scaled `numericType` object with a `Signedness` of `Auto`. The default is `numericType([], 32, 30)`. This property applies when you set the `Accumulator1DataType` property to `Custom`.

ProductInputDataType

Data type of product

Specify the product input fixed-point data type as one of `Same as accumulator 1 | Custom`. The default is `Same as accumulator 1`. This property applies when you set the `FullPrecisionOverride` property to false, the `BitOutput` property to true and the `DecisionMethod` property to `Log-likelihood ratio`.

CustomProductInputDataType

Fixed-point data type of product

Specify the product input fixed-point type as a scaled `numericType` object with a Signedness of Auto. The default is `numericType([], 32, 30)`. This property applies when you set the `FullPrecisionOverride` property to false and the `ProductInputDataType` property to Custom.

ProductOutputDataType

Data type of product output

Specify the product output fixed-point data type as one of `Full precision` | `Custom`. The default is `Full precision`. This property applies when you set the `FullPrecisionOverride` property to false, the `BitOutput` property to true and the `DecisionMethod` property to `Log-likelihood ratio`.

CustomProductOutputDataType

Fixed-point data type of product output

Specify the product output fixed-point type as a scaled `numericType` object with a Signedness of Auto. The default is `numericType([], 32, 30)`. This property applies when you set the `FullPrecisionOverride` property to false and the `ProductOutputDataType` property to Custom.

Accumulator2DataType

Data type of accumulator 2

Specify the accumulator 2 fixed-point data type as one of `Full precision` | `Custom`. The default is `Full precision`. This property applies when you set the `FullPrecisionOverride` property to false, the `BitOutput` property to true and the `DecisionMethod` property to `Log-likelihood ratio`.

CustomAccumulator2DataType

Fixed-point data type accumulator 2

Specify the accumulator 2 fixed-point data type as a scaled `numericType` object with a Signedness of Auto. The default is `numericType([], 32, 30)`. This property applies when you set the `FullPrecisionOverride` property to false and the `Accumulator2DataType` property to Custom.

Accumulator3DataType

Data type of accumulator 3

Specify the accumulator 3 fixed-point data type as one of `Full precision` | `Custom`. The default is `Full precision`. This property applies when you set the `FullPrecisionOverride` property to false, the `BitOutput` property to true and the `DecisionMethod` property to `Approximate log-likelihood ratio`.

CustomAccumulator3DataType

Fixed-point data type of accumulator 3

Specify the accumulator 3 fixed-point type as a scaled `numericType` object with a Signedness of Auto. The default is `numericType([], 32, 30)`. This property applies when you set the `FullPrecisionOverride` property to false and the `Accumulator3DataType` property to Custom.

NoiseScalingInputDataType

Data type of noise-scaling input

Specify the noise-scaling input fixed-point data type as one of Same as accumulator 3 | Custom. The default is Same as accumulator 3. This property applies when you set the FullPrecisionOverride property to false, the BitOutput property to true and the DecisionMethod property to Approximate log-likelihood ratio.

CustomNoiseScalingInputDataType

Fixed-point data type of noise-scaling input

Specify the noise-scaling input fixed-point type as a scaled numerictype object with a Signedness of Auto. The default is numerictype([], 32, 30). This property applies when you set the FullPrecisionOverride property to false and the NoiseScalingInputDataType property to Custom.

InverseVarianceDataType

Data type of inverse noise variance

Specify the inverse noise variance fixed-point data type as one of Same word length as input | Custom. The default is Same word length as input. This property applies when you set the BitOutput property to true, the DecisionMethod property to Approximate log-likelihood ratio, and the VarianceSource property to Property.

CustomInverseVarianceDataType

Fixed-point data type of inverse noise variance

Specify the inverse noise variance fixed-point type as a numerictype object with a Signedness of Auto. The default is numerictype([], 16, 8). This property applies when you set the InverseVarianceDataType property to Custom.

CustomOutputDataType

Data type of output

Specify the output fixed-point type as a scaled numerictype object with a Signedness of Auto. The default is numerictype([], 32, 30). This property applies when you set the FullPrecisionOverride property to false and the OutputDataType property to Custom.

Examples

Modulate and demodulate data using an arbitrary three-point constellation.

```

% Setup a three point constellation
c = [1 1i -1];
hQAMMod = comm.GeneralQAMModulator(c);
hAWGN = comm.AWGNChannel('NoiseMethod', ...
    'Signal to noise ratio (SNR)', 'SNR', 15, 'SignalPower', 0.89);
hQAMDemod = comm.GeneralQAMDemodulator(c);

%Create an error rate calculator
hError = comm.ErrorRate;
for counter = 1:100
    % Transmit a 50-symbol frame
    data = randi([0 2], 50, 1);
    modSignal = step(hQAMMod, data);
    noisySignal = step(hAWGN, modSignal);
    receivedData = step(hQAMDemod, noisySignal);
    errorStats = step(hError, data, receivedData);
end
fprintf('Error rate = %f\nNumber of errors = %d\n', ...
    errorStats(1), errorStats(2))

```

More About

Full Precision for Fixed-Point System Objects

`FullPrecisionOverride` is a convenience property that, when you set to `true`, automatically sets the appropriate properties for an object to use full-precision to process fixed-point input.

For System objects, full precision, fixed-point operation refers to growing just enough additional bits to compute the ideal full precision result. This operation has no minimum or maximum range overflow nor any precision loss due to rounding or underflow. It is also independent of any hardware-specific settings. The data types chosen are based only on known data type ranges and not on actual numeric values. Full precision for System objects does not optimize coefficient values. When you set the `FullPrecisionOverride` property to `true`, the other fixed-point properties it controls no longer apply and any of their non-default values are ignored. These properties are also hidden. To specify individual fixed-point properties, first set `FullPrecisionOverride` to `false`.

Algorithms

This object implements the algorithm, inputs, and outputs described on the General QAM Demodulator Baseband block reference page. The object properties correspond to the block parameters.

Extended Capabilities

System object: comm.GeneralQAMDemodulator

Package: comm

Demodulate using arbitrary QAM constellation

Syntax

$Y = \text{step}(H, X)$

$Y = \text{step}(H, X, \text{VAR})$

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, $y = \text{step}(\text{obj}, x)$ and $y = \text{obj}(x)$ perform equivalent operations.

$Y = \text{step}(H, X)$ demodulates the input data, X , with the general QAM demodulator System object, H , and returns Y . Input X must be a scalar or a column vector with double or single precision data type. When you set the `BitOutput` property to true and the `DecisionMethod` property to 'Log-likelihood ratio' the input data type must be single or double precision. Depending on the `BitOutput` property value, output Y can be integer or bit valued.

$Y = \text{step}(H, X, \text{VAR})$ uses soft decision demodulation and noise variance VAR . This syntax applies when you set the `BitOutput` property to true, the `DecisionMethod` property to `Approximate log-likelihood ratio` or `Log-likelihood ratio`, and the `VarianceSource` property to 'Input port'.

Note `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications. For more information on changing property values, see "System Design in MATLAB Using System Objects".

comm.GeneralQAMModulator

Package: comm

Modulate using arbitrary QAM constellation

Description

The `GeneralQAMModulator` object modulates using quadrature amplitude modulation. The output is a baseband representation of the modulated signal.

To modulate a signal using quadrature amplitude modulation:

- 1 Define and set up your QAM modulator object. See “Construction” on page 3-584.
- 2 Call `step` to modulate a signal according to the properties of `comm.GeneralQAMModulator`. The behavior of `step` is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`H = comm.GeneralQAMModulator` creates a modulator System object, `H`. This object modulates the input signal using a general quadrature amplitude modulation (QAM) method.

`H = comm.GeneralQAMModulator(Name,Value)` creates a QAM modulator object, `H`, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as `(Name1,Value1,...,NameN,ValueN)`.

`H = comm.GeneralQAMModulator(CONST,Name,Value)` creates a General QAM modulator object, `H`. This object has the `Constellation` property set to `CONST`, and the other specified properties set to the specified values.

Properties

Constellation

Signal constellation

Specify the constellation points as a vector of real or complex double-precision data type. The default is $\exp(2 \times \pi \times 1i \times (0:7)/8)$. The length of the vector determines the modulation order. The `step` method inputs requires integers between 0 and $M-1$, where M indicates the length of this property vector. The object maps an input integer m to the $(m+1)^{\text{st}}$ value in the `Constellation` vector.

OutputDataType

Data type of output

Specify the output data type as one of `double` | `single` | `Custom`. The default is `double`.

Fixed-Point Properties

CustomOutputDataType

Fixed-point data type of output

Specify the output fixed-point type as a `numericType` object with a signedness of `Auto`. The default is `numericType([],16)`. This property applies when you set the `OutputDataType` on page 3-0 property to `Custom`.

Methods

`step` Modulate using arbitrary QAM constellation

Common to All System Objects	
<code>release</code>	Allow System object property value changes

Examples

Modulate data using an arbitrary 3-point constellation. Then, visualize the data in a scatter plot

```

hQAMMod = comm.GeneralQAMModulator;
% Setup a three point constellation
hQAMMod.Constellation = [1 1i -1];
data = randi([0 2],100,1);
modData = step(hQAMMod, data);
scatterplot(modData)

```

Algorithms

This object implements the algorithm, inputs, and outputs described on the General QAM Modulator Baseband block reference page. The object properties correspond to the block parameters.

Objects

`comm.GeneralQAMDemodulator`

Introduced in R2012a

step

System object: comm.GeneralQAMModulator

Package: comm

Modulate using arbitrary QAM constellation

Syntax

$Y = \text{step}(H,X)$

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, $y = \text{step}(\text{obj}, x)$ and $y = \text{obj}(x)$ perform equivalent operations.

$Y = \text{step}(H,X)$ modulates input data, X , with the general QAM modulator System object, H . It returns the baseband modulated output, Y . The input must be an integer scalar or an integer-valued column vector. The data type of the input can be numeric or unsigned fixed point of word length $\text{ceil}(\log_2(\text{ModulationOrder}))$ (fi object).

Note `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications. For more information on changing property values, see “System Design in MATLAB Using System Objects”.

comm.GeneralQAMTCMDemodulator

Package: comm

Demodulate convolutionally encoded data mapped to arbitrary QAM constellation

Description

The `GeneralQAMTCMDemodulator` object uses the Viterbi algorithm to decode a trellis-coded modulation (TCM) signal that was previously modulated using an arbitrary signal constellation.

To demodulate a signal that was modulated using a trellis-coded, general quadrature amplitude modulator:

- 1 Define and set up your general QAM TCM modulator object. See “Construction” on page 3-588.
- 2 Call `step` to demodulate a signal according to the properties of `comm.GeneralQAMTCMDemodulator`. The behavior of `step` is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`H = comm.GeneralQAMTCMDemodulator` creates a trellis-coded, general quadrature amplitude (QAM TCM) demodulator System object, `H`. This object demodulates convolutionally encoded data that has been mapped to an arbitrary QAM constellation.

`H = comm.GeneralQAMTCMDemodulator(Name, Value)` creates a general QAM TCM demodulator object, `H`, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as `(Name1, Value1, ..., NameN, ValueN)`.

`H = comm.GeneralQAMTCMDemodulator(TRELLIS, Name, Value)` creates a general QAM TCM demodulator object, `H`. This object has the `TrellisStructure` property set to `TRELLIS`, and the other specified properties set to the specified values.

Properties

TrellisStructure

Trellis structure of convolutional code

Specify trellis as a MATLAB structure that contains the trellis description of the convolutional code. Use the `istrellis` function to check if a structure is a valid trellis structure. The default is the value that results from `poly2trellis([1 3], [1 0 0; 0 5 2])`.

TerminationMethod

Termination method of encoded frame

Specify the termination method as one of `Continuous` | `Truncated` | `Terminated`. The default is `Continuous`.

When you set this property to `Continuous`, the object saves the internal state metric at the end of each frame. The next frame uses the same state metric. The object treats each traceback path independently. If the input signal contains only one symbol, use `Continuous` mode.

When you set this property to `Truncated`, the object treats each input vector independently. The traceback path starts at the state with the best metric and always ends in the all-zeros state.

When you set this property to `Terminated`, the object treats each input vector independently, and the traceback path always starts and ends in the all-zeros state.

TracebackDepth

Traceback depth for Viterbi decoder

Specify the scalar, integer number of trellis branches to construct each traceback path. The default is 21. The Traceback depth parameter influences the decoding accuracy and delay. The decoding delay indicates the number of zero symbols that precede the first decoded symbol in the output.

When you set the `TerminationMethod` on page 3-0 property to `Continuous`, the decoding delay consists of `TracebackDepth` zero symbols or `TracebackDepth`× K zero bits for a rate K/N convolutional code.

When you set the `TerminationMethod` property to `Truncated` or `Terminated`, no output delay occurs and the traceback depth must be less than or equal to the number of symbols in each input vector.

ResetInputPort

Enable demodulator reset input

Set this property to `true` to enable an additional input to the `step` method. The default is `false`. When this additional reset input is a nonzero value, the internal states of the encoder reset to their initial conditions. This property applies when you set the `TerminationMethod` on page 3-0 property to `Continuous`.

Constellation

Signal constellation

Specify a double- or single-precision complex vector. This vector lists the points in the signal constellation that were used to map the convolutionally encoded data. The constellation must be specified in set-partitioned order. See documentation for the General TCM Encoder block for more information on set-partitioned order. The length of the constellation vector must equal the number of possible input symbols to the convolutional decoder of the general QAM TCM demodulator object. This corresponds to 2^N for a rate K/N convolutional code. The default corresponds to a set-partitioned order for the points of an 8-PSK signal constellation. This value is expressed as $\exp(2 \times \pi \times j \times [0 \ 4 \ 2 \ 6 \ 1 \ 5 \ 3 \ 7]/8)$.

OutputDataType

Data type of output

Specify output data type as one of `logical` | `double`. The default is `double`.

Methods

`step` Demodulate convolutionally encoded data mapped to arbitrary QAM constellation

Common to All System Objects	
<code>release</code>	Allow System object property value changes
<code>reset</code>	Reset internal states of System object

Examples

Modulate and Demodulate Data Using QAM TCM

Modulate and demodulate noisy data using QAM TCM modulation with an arbitrary 4-point constellation. Estimate the resultant BER.

Define a trellis structure with two input symbols and four output symbols using a [171 133] generator polynomial. Define an arbitrary four-point constellation.

```
qamTrellis = poly2trellis(7,[171 133]);
refConst = exp(pi*1i*[1 2 3 6]/4);
```

Create a QAM TCM modulator and demodulator System object™ pair using `qamTrellis` and `refConst`.

```
hMod = comm.GeneralQAMTCMModulator(qamTrellis,'Constellation', refConst);
hDemod = comm.GeneralQAMTCMDemodulator(qamTrellis,'Constellation',refConst);
```

Create an AWGN channel object in which the noise is set by using a signal-to-noise ratio.

```
hAWGN = comm.AWGNChannel('NoiseMethod','Signal to noise ratio (SNR)', ...
    'SNR',4);
```

Create an error rate calculator with delay (in bits) equal to the product of `TracebackDepth` and the number of bits per symbol

```
hError = comm.ErrorRate(...
    'ReceiveDelay', hDemod.TracebackDepth*log2(qamTrellis.numInputSymbols));
```

Generate random binary data and apply QAM TCM modulation. Pass the signal through an AWGN channel and demodulate. Collect the error statistics.

```
for counter = 1:10
    % Generate binary data
    data = randi([0 1],500,1);
    % Modulate
    modSignal = step(hMod,data);
    % Pass through an AWGN channel
    noisySignal = step(hAWGN,modSignal);
    % Demodulate
    receivedData = step(hDemod,noisySignal);
    % Calculate the error statistics
```

```
    errorStats = step(hError,data,receivedData);  
end
```

Display the BER and the number of bit errors.

```
fprintf('Error rate = %5.2e\nNumber of errors = %d\n', ...  
    errorStats(1), errorStats(2))
```

```
Error rate = 1.16e-02  
Number of errors = 58
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the General TCM Decoder block reference page. The object properties correspond to the block parameters.

Extended Capabilities

comm.GeneralQAMTCModulator | comm.RectangularQAMTCMDemodulator |
comm.ViterbiDecoder

Introduced in R2012a

step

System object: `comm.GeneralQAMTCMDemodulator`

Package: `comm`

Demodulate convolutionally encoded data mapped to arbitrary QAM constellation

Syntax

```
Y = step(H,X)  
Y = step(H,X,R)
```

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(H,X)` demodulates the general QAM modulated input data, `X`, and uses the Viterbi algorithm to decode the resulting demodulated convolutionally encoded bits. `X` must be a complex double or single precision column vector. The `step` method outputs a demodulated binary column data vector, `Y`. When the convolutional encoder represents a rate K/N code, the length of the output vector equals $K \times L$, where L is the length of the input vector, `X`.

`Y = step(H,X,R)` resets the decoder states of the general QAM TCM demodulator System object to the all-zeros state when you input a non-zero reset signal, `R`. `R` must be a double precision or logical scalar integer. This syntax applies when you set the `ResetInputPort` property to `true`.

Note `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications. For more information on changing property values, see “System Design in MATLAB Using System Objects”.

comm.GeneralQAMTCMModulator

Package: comm

Convolutionally encode binary data and map using arbitrary QAM constellation

Description

The `GeneralQAMTCMModulator` object implements trellis-coded modulation (TCM) by convolutionally encoding the binary input signal. The object then maps the result to an arbitrary signal constellation. The `SignalConstellation` property lists the signal constellation points in set-partitioned order.

To modulate a signal using a trellis-coded, general quadrature amplitude modulator:

- 1 Define and set up your general QAM TCM modulator object. See “Construction” on page 3-593.
- 2 Call `step` to modulate a signal according to the properties of `comm.GeneralQAMTCMModulator`. The behavior of `step` is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`H = comm.GeneralQAMTCMModulator` creates a trellis-coded, general quadrature amplitude (QAM TCM) modulator System object, `H`. This object convolutionally encodes a binary input signal and maps the result using QAM modulation with a signal constellation specified in the `Constellation` property.

`H = comm.GeneralQAMTCMModulator(Name,Value)` creates a general QAM TCM modulator System object, `H`, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as `(Name1,Value1,...,NameN,ValueN)`.

`H = comm.GeneralQAMTCMModulator(TRELLIS,Name,Value)` creates a general QAM TCM modulator System object, `H`. This object has the `TrellisStructure` property set to `TRELLIS`, and the other specified properties set to the specified values.

Properties

TrellisStructure

Trellis structure of convolutional code

Specify `trellis` as a MATLAB structure that contains the trellis description of the convolutional code. Use the `istrellis` function to check if a structure is a valid trellis structure. The default is the result of `poly2trellis([1 3], [1 0 0; 0 5 2])`.

TerminationMethod

Termination method of encoded frame

Specify the termination method as one of `Continuous` | `Truncated` | `Terminated`. The default is `Continuous`.

When you set this property to `Continuous`, the object retains the encoder states at the end of each input vector for use with the next input vector.

When you set this property to `Truncated`, the object treats each input vector independently. The encoder is reset to the all-zeros state at the start of each input vector.

When you set this property to `Terminated`, the object treats each input vector independently. For each input vector, the object uses extra bits to set the encoder to the all-zeros state at the end of the vector. For a rate K/N code, the `step` method outputs the vector with length $y = N \times (L + S)/K$, where $S = \text{constraintLength} - 1$. In the case of multiple constraint lengths, $S = \text{sum}(\text{constraintLength}(i) - 1)$. L represents the length of the input to the `step` method.

ResetInputPort

Enable modulator reset input

Set this property to `true` to enable an additional input to the `step` method. The default is `false`. When this additional reset input is a nonzero value, the internal states of the encoder reset to their initial conditions. This property applies when you set the `TerminationMethod` on page 3-0 property to `Continuous`.

Constellation

Signal constellation

Specify a double- or single-precision complex vector that lists the points in the signal constellation that were used to map the convolutionally encoded data. You must specify the constellation in set-partitioned order. See documentation for the General TCM Encoder block for more information on set-partitioned order. The length of the constellation vector must equal the number of possible input symbols to the convolutional decoder of the general QAM TCM demodulator object. This corresponds to 2^N for a rate K/N convolutional code. The default corresponds to a set-partitioned order for the points of an 8-PSK signal constellation. This value is expressed $\exp(2 \times \pi \times j \times [0 \ 4 \ 2 \ 6 \ 1 \ 5 \ 3 \ 7]/8)$.

OutputDataType

Data type of output

Specify the output data type as one of `double` | `single`. The default is `double`.

Methods

`step` Convolutionally encode binary data and map using arbitrary QAM constellation

Common to All System Objects	
<code>release</code>	Allow System object property value changes

Examples**Modulate Data Using QAM TCM with an Arbitrary Constellation**

Modulate data using QAM TCM modulation with an arbitrary 4-point constellation. Display a scatter plot of the modulated data.

Create binary data.

```
data = randi([0 1],1000,1);
```

Use the trellis structure with generating polynomial [171 133] and 4-point arbitrary constellation $\{ e^{j\pi/4}, e^{j\pi/2}, e^{j3\pi/4}, e^{j3\pi/2} \}$ to perform QAM TCM modulation.

```
t = poly2trellis(7,[171 133]);
hMod = comm.GeneralQAMTCMModulator(t,...
    'Constellation',exp(pi*1i*[1 2 3 6]/4));
```

Modulate and plot the data.

```
modData = step(hMod,data);
scatterplot(modData);
```

Convolutionally encode binary data and map using arbitrary QAM constellation

Syntax

$Y = \text{step}(H,X)$

$Y = \text{step}(H,X,R)$

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, $y = \text{step}(\text{obj}, x)$ and $y = \text{obj}(x)$ perform equivalent operations.

$Y = \text{step}(H,X)$ convolutionally encodes and modulates the input data, X , and returns the encoded and modulated data, Y . X must be of data type numeric, logical, or unsigned fixed point of word length 1 (fi object). When the convolutional encoder represents a rate K/N code, the length of the input vector, X , must be $K \times L$, for some positive integer L . The `step` method outputs a complex column vector, Y , of length L .

$Y = \text{step}(H,X,R)$ resets the encoder of the general QAM TCM modulator object to the all-zeros state when you input a non-zero reset signal, R . R must be a double precision or logical scalar integer. This syntax applies when you set the `ResetInputPort` property to true.

Note `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications. For more information on changing property values, see "System Design in MATLAB Using System Objects".

comm.GMSKDemodulator

Package: comm

Demodulate GMSK-modulated signal using Viterbi algorithm

Description

The `comm.GMSKDemodulator` System object uses a Viterbi algorithm to demodulate a signal that was modulated using the Gaussian minimum shift keying (GMSK) method. The input is a baseband representation of the modulated signal.

To demodulate a GMSK-modulated signal using the Viterbi algorithm:

- 1 Create the `comm.GMSKDemodulator` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

Creation

Syntax

```
gmskdemodulator = comm.GMSKDemodulator  
gmskdemodulator = comm.GMSKDemodulator(Name, Value)
```

Description

`gmskdemodulator = comm.GMSKDemodulator` creates a demodulator System object that demodulates the input GMSK-modulated data by using the Viterbi algorithm.

`gmskdemodulator = comm.GMSKDemodulator(Name, Value)` sets properties on page 3-598 using one or more name-value pairs. For example, `'PulseLength', 6` specifies the length of the Gaussian pulse shape as 6 symbol intervals.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see [System Design in MATLAB Using System Objects](#).

BitOutput — Option to output data as bits

`false` or `0` (default) | `true` or `1`

Option to output data as bits, specified as a numeric or logical `0` (`false`) or `1` (`true`).

- When you set this property to `false`, the output of the System object call is a column vector of elements `-1` or `1`.
- When you set this property to `true`, the output of the System object call is a binary column vector of elements `0` or `1`.

Data Types: `logical`

BandwidthTimeProduct — Product of bandwidth and symbol time

0.3 (default) | positive scalar

Product of the bandwidth and symbol time for the Gaussian pulse shape, specified as a positive scalar value. For more details, see Algorithms on page 3-602.

Data Types: `double`

PulseLength — Pulse length

4 (default) | positive integer

Pulse length, specified as a positive integer. The pulse length value represents the length of the Gaussian pulse shape in symbol intervals.

Data Types: `double`

SymbolPrehistory — Symbol prehistory

1 (default) | -1 | vector

Symbol prehistory, specified as `-1`, `1`, or a vector with elements equal those values. If the value is a vector, then its length must be one less than the value of the `PulseLength` property. The symbol prehistory indicates the data symbols that the modulator uses prior to the first call of the System object in reverse chronological order.

Data Types: `double`

InitialPhaseOffset — Initial phase offset

0 (default) | numeric scalar

Initial phase offset of the modulated waveform in radians, specified as a numeric scalar.

Data Types: `double`

SamplesPerSymbol — Number of samples per output symbol

8 (default) | positive integer

Number of samples per symbol, specified as a positive integer. The number of samples per symbol represents the upsampling factor from input samples to output samples.

Data Types: `double`

TracebackDepth — Traceback depth

16 (default) | positive integer

Traceback depth for the Viterbi algorithm, specified as a positive integer.

The traceback depth is the number of trellis branches that the Viterbi algorithm uses to construct each traceback path. The number of zero symbols that precede the first decoded symbol in the output represent a decoding delay.

Data Types: `double`

OutputDataType — Output data type`double (default) | int8 | int16 | int32 | logical`

Output data type, specified as one of these values.

- `int8`, `int16`, `int32`, or `double` — Use one of these values when you set the `BitOutput` property to `false`.
- `logical` or `double` — Use one of these values when you set the `BitOutput` property to `true`.

Usage**Syntax**`Y = gmskdemodulator(X)`**Description**

`Y = gmskdemodulator(X)` applies GMSK demodulation to the GMSK-modulated waveform and returns the demodulated input signal.

Input Arguments**X — GMSK-modulated baseband signal**`column vector`

GMSK-modulated input signal, specified as a column vector.

The length of the input signal must be an integer multiple of the `SamplesPerSymbol` property.

Data Types: `double` | `single`

Output Arguments**Y — Demodulated signal**`column vector`

Demodulated signal, returned as a column vector with length equal to $N / \text{SamplesPerSymbol}$. N is the length of the input signal, X . For more information about the output datatype, see the `OutputDataType` property.

- When you set the `BitOutput` property to `false`, Y is returned as a column vector of elements `-1` or `1`.
- When you set the `BitOutput` property to `true`, Y is returned as a binary column vector of elements `0` or `1`.

Data Types: `double` | `logical`

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

`release(obj)`

Common to All System Objects

step	Run System object algorithm
release	Release resources and allow changes to System object property values and input characteristics
reset	Reset internal states of System object

Examples

GMSK Signal in AWGN

Create a GMSK modulator and demodulator pair. Create an AWGN channel object.

```
gmskmodulator = comm.GMSKModulator('BitInput',true, ...
    'InitialPhaseOffset',pi/4);
channel = comm.AWGNChannel('NoiseMethod', ...
    'Signal to noise ratio (SNR)', ...
    'SNR',0);
gmskdemodulator = comm.GMSKDemodulator('BitOutput',true, ...
    'InitialPhaseOffset',pi/4);
```

Create an error rate calculator and account for the delay between the modulator and demodulator, caused by the Viterbi algorithm.

```
errorRate = comm.ErrorRate('ReceiveDelay', ...
    gmskdemodulator.TracebackDepth);
```

Process 100 frames of data looping through these steps.

- 1 Generate vectors with 300 elements of random binary data.
- 2 GMSK-modulate the data.
- 3 Pass the modulated data through the AWGN channel.
- 4 GMSK-demodulate the data.
- 5 Collect error statistics on the frames of data.

```
for counter = 1:100
    % Transmit 100 3-bit words
    data = randi([0 1],300,1);
    modSignal = gmskmodulator(data);
    noisySignal = channel(modSignal);
    receivedData = gmskdemodulator(noisySignal);
    errorStats = errorRate(data, receivedData);
end
```

Display the error statistics.

```
fprintf('Error rate = %f\nNumber of errors = %d\n', ...
    errorStats(1), errorStats(2))
```

```
Error rate = 0.000133
Number of errors = 4
```

Algorithms

The `BandwidthTimeProduct` property represents bandwidth multiplied by time. Use this property to reduce the bandwidth at the expense of increased intersymbol interference. The `PulseLength` property measures the length of the Gaussian pulse shape in symbol intervals. These equations define the frequency pulse shape. B_b represents the bandwidth of the pulse and T is the symbol durations. $Q(t)$ is the complementary cumulative distribution function.

$$g(t) = \frac{1}{2T} \left\{ Q \left[2\pi B_b \frac{t - \frac{T}{2}}{\sqrt{\ln(2)}} \right] - Q \left[2\pi B_b \frac{t + \frac{T}{2}}{\sqrt{\ln(2)}} \right] \right\}$$

$$Q(t) = \int_t^{\infty} \frac{1}{\sqrt{2\pi}} e^{-\tau^2/2} d\tau$$

For this System object, an input symbol of 1 causes a phase shift of $\pi/2$ radians, which corresponds to a modulation index of 0.5.

Modulate using GMSK method

Description

The `comm.GMSKModulator` System object modulates using the Gaussian minimum shift keying (GMSK) method. The output is a baseband representation of the modulated signal. For more detail, see “Algorithms” on page 3-613.

To modulate a signal by using the GMSK method:

- 1 Create the `comm.GMSKModulator` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

Creation

Syntax

```
gmskmodulator = comm.GMSKModulator
gmskmodulator = comm.GMSKModulator(Name,Value)
```

Description

`gmskmodulator = comm.GMSKModulator` creates a modulator System object that modulates the input signal using the GMSK modulation method.

`gmskmodulator = comm.GMSKModulator(Name,Value)` sets properties on page 3-603 using one or more name-value arguments. For example, `'PulseLength',6` specifies the length of the Gaussian pulse shape as 6 symbol intervals.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see [System Design in MATLAB Using System Objects](#).

BitInput — Option to provide input in bits

`false` or 0 (default) | `true` or 1

Option to provide input in bits, specified as a numeric or logical 0 (`false`) or 1 (`true`).

- When you set this property to `false`, the input to the System object call requires a double-precision or signed integer data type column vector with values of -1 or 1.
- When you set this property to `true`, the input to the System object call requires a double-precision or logical data type column vector of 0s and 1s.

Data Types: `logical`

BandwidthTimeProduct — Product of bandwidth and symbol time

0.3 (default) | positive scalar

Product of the bandwidth and symbol time for the Gaussian pulse shape, specified as a positive scalar value. For more detail, see “Algorithms” on page 3-613.

To observe the effect of this property on the modulated signal, see the “Effect of Bandwidth Time Product on GMSK Modulated Signal” on page 3-607 example.

Data Types: `double`

PulseLength — Pulse length

4 (default) | positive integer

Pulse length, specified as a positive integer. The pulse length value represents the length of the Gaussian pulse shape in symbol intervals.

Data Types: `double`

SymbolPrehistory — Symbol prehistory

1 (default) | -1 | vector

Symbol prehistory, specified as -1, 1, or a vector with elements equal those values. If the value is a vector, then its length must be one less than the value of the PulseLength property. The symbol prehistory indicates the data symbols that the modulator uses prior to the first call of the System object in reverse chronological order.

Data Types: `double`

InitialPhaseOffset — Initial phase offset

0 (default) | numeric scalar

Initial phase offset of the modulated waveform in radians, specified as a numeric scalar.

Data Types: `double`

SamplesPerSymbol — Number of samples per output symbol

8 (default) | positive integer

Number of samples per symbol, specified as a positive integer. The number of samples per symbol represents the upsampling factor from input samples to output samples.

Data Types: `double`

OutputDataType — Output data type

`double` (default) | `single`

Output data type, specified as either `double` or `single`.

Usage

Syntax

```
Y = gmskmodulator(X)
```

Description

`Y = gmskmodulator(X)` applies GMSK modulation to the input data and returns the modulated GMSK baseband signal.

Input Arguments

X — Input data

integer | column vector

Input data, specified as an integer or column vector of integers or bits.

The setting of the `BitInput` property determines the interpretation of the input data.

Data Types: `double` | `logical`

Output Arguments

Y — GMSK-modulated baseband signal

vector

GMSK-modulated baseband signal, returned as a vector.

The length of the vector is equal to the number of input samples times the `SamplesPerSymbol` property. For more information about the output data type, see the `OutputDataType` property.

Data Types: `double` | `single`

Object Functions

To use an object function, specify the `System` object as the first input argument. For example, to release system resources of a `System` object named `obj`, use this syntax:

```
release(obj)
```

Common to All System Objects

<code>step</code>	Run <code>System</code> object algorithm
<code>release</code>	Release resources and allow changes to <code>System</code> object property values and input characteristics
<code>reset</code>	Reset internal states of <code>System</code> object

Examples

Map Binary Data to GMSK Signal

Map binary sequences of zeros and ones to the output of a GMSK modulator. This mapping also applies for MSK modulation.

Create a GMSK modulator that accepts binary inputs and has pulse length and samples per symbol values of 1.

```
gmskmodulator = comm.GMSKModulator('BitInput',true,'PulseLength',1, ...  
                                   'SamplesPerSymbol',1);
```

Create an input sequence of all zeros. Modulate the sequence.

```
x = zeros(5,1);  
y = gmskmodulator(x)
```

y = 5×1 complex

```
 1.0000 + 0.0000i  
-0.0000 - 1.0000i  
-1.0000 + 0.0000i  
 0.0000 + 1.0000i  
 1.0000 - 0.0000i
```

Determine the phase angle for each point. Use the `unwrap` function to show the trend.

```
theta = unwrap(angle(y))
```

theta = 5×1

```
 0  
-1.5708  
-3.1416  
-4.7124  
-6.2832
```

A sequence of zeros causes the phase to shift by $-\pi/2$ between samples.

Reset the modulator. Modulate an input sequence of all ones.

```
reset(gmskmodulator)  
x = ones(5,1);  
y = gmskmodulator(x)
```

y = 5×1 complex

```
 1.0000 + 0.0000i  
-0.0000 + 1.0000i  
-1.0000 - 0.0000i  
 0.0000 - 1.0000i  
 1.0000 + 0.0000i
```

Determine the phase angle for each point. Use the `unwrap` function to show the trend.

```
theta = unwrap(angle(y))
```

theta = 5×1

```
 0  
 1.5708  
 3.1416
```

```
4.7124
6.2832
```

A sequence of ones causes the phase to shift by $+\pi/2$ between samples.

GMSK Signal in AWGN

Create a GMSK modulator and demodulator pair. Create an AWGN channel object.

```
gmskmodulator = comm.GMSKModulator('BitInput',true, ...
    'InitialPhaseOffset',pi/4);
channel = comm.AWGNChannel('NoiseMethod', ...
    'Signal to noise ratio (SNR)', ...
    'SNR',0);
gmskdemodulator = comm.GMSKDemodulator('BitOutput',true, ...
    'InitialPhaseOffset',pi/4);
```

Create an error rate calculator and account for the delay between the modulator and demodulator, caused by the Viterbi algorithm.

```
errorRate = comm.ErrorRate('ReceiveDelay', ...
    gmskdemodulator.TracebackDepth);
```

Process 100 frames of data looping through these steps.

- 1 Generate vectors with 300 elements of random binary data.
- 2 GMSK-modulate the data.
- 3 Pass the modulated data through the AWGN channel.
- 4 GMSK-demodulate the data.
- 5 Collect error statistics on the frames of data.

```
for counter = 1:100
    % Transmit 100 3-bit words
    data = randi([0 1],300,1);
    modSignal = gmskmodulator(data);
    noisySignal = channel(modSignal);
    receivedData = gmskdemodulator(noisySignal);
    errorStats = errorRate(data, receivedData);
end
```

Display the error statistics.

```
fprintf('Error rate = %f\nNumber of errors = %d\n', ...
    errorStats(1), errorStats(2))
```

```
Error rate = 0.000133
Number of errors = 4
```

Effect of Bandwidth Time Product on GMSK Modulated Signal

This example demonstrates the effect of bandwidth time (BT) product on a GMSK modulated signal.

Create a binary data vector and apply GMSK modulation to the data.

```
d = [0 1 1 0 1 0 0 1 1 1]';  
a = comm.GMSKModulator(BitInput=true,SamplesPerSymbol=10)
```

```
a =  
comm.GMSKModulator with properties:
```

```
        BitInput: true  
BandwidthTimeProduct: 0.3000  
        PulseLength: 4  
        SymbolPrehistory: 1  
InitialPhaseOffset: 0  
        SamplesPerSymbol: 10  
        OutputDataType: 'double'
```

```
x = a(d);  
BTa = sprintf('BT=%2.1f',a.BandwidthTimeProduct);
```

Plot the phase angles and use the unwrap function to show the trend better.

```
plot(unwrap(angle(x)), 'red-');  
title('Bandwidth Time Product Effect')  
hold on;  
plot(1:10:length(x),unwrap(angle(x(1:10:end))), '*');  
grid on
```

Set the BT product to 1 and plot the phase angles in the same plot.

```
a = comm.GMSKModulator(BitInput=true, ...  
        SamplesPerSymbol=10,BandwidthTimeProduct=1)
```

```
a =  
comm.GMSKModulator with properties:
```

```
        BitInput: true  
BandwidthTimeProduct: 1  
        PulseLength: 4  
        SymbolPrehistory: 1  
InitialPhaseOffset: 0  
        SamplesPerSymbol: 10  
        OutputDataType: 'double'
```

```
x = a(d);  
BTb = sprintf('BT=%2.1f',a.BandwidthTimeProduct);  
plot(unwrap(angle(x)), 'blue-.');  
plot(1:10:length(x),unwrap(angle(x(1:10:end))), 'o');
```

Set the BT product to 0.1 and plot the phase angles in the same plot.

```
a = comm.GMSKModulator(BitInput=true, ...  
        SamplesPerSymbol=10,BandwidthTimeProduct=0.1)
```

```
a =  
comm.GMSKModulator with properties:
```

```
        BitInput: true
```

```

BandwidthTimeProduct: 0.1000
    PulseLength: 4
    SymbolPrehistory: 1
    InitialPhaseOffset: 0
    SamplesPerSymbol: 10
    OutputDataType: 'double'

```

```
BTc = sprintf('BT=%2.1f',a.BandwidthTimeProduct);
```

The spread of this pulse is inversely proportional to the BT product and a lower BT causes a wider spread over the bit symbol period. The peak amplitude of the pulse is directly proportional to the BT product and a lower peak amplitude causes narrower spread over the bit symbol period. As the bandwidth of the pulse decreases, the pulse duration increases.

```

x = a(d);
plot(unwrap(angle(x)), 'green--');
plot(1:10:length(x),unwrap(angle(x(1:10:end))), 'x');
legend(BTa, '', BTb, '', BTc, '')
hold off;

```

GMSK vs. MSK

Compare Gaussian minimum shift keying (GMSK) and minimum shift keying (MSK) modulation schemes by plotting the eye diagram for GMSK with different pulse lengths and for MSK.

Set the samples per symbol variable.

```
sps = 8;
```

Generate random binary data.

```
data = randi([0 1],1000,1);
```

Create GMSK and MSK modulators that accept binary inputs. Set the `PulseLength` property of the GMSK modulator to 1.

```
gmskMod = comm.GMSKModulator('BitInput',true,'PulseLength',1, ...  
    'SamplesPerSymbol',sps);  
mskMod = comm.MSKModulator('BitInput',true,'SamplesPerSymbol',sps);
```

Modulate the data using the GMSK and MSK modulators.

```
modSigGMSK = gmskMod(data);  
modSigMSK = mskMod(data);
```

Pass the modulated signals through an AWGN channel having an SNR of 30 dB.

```
rxSigGMSK = awgn(modSigGMSK,30);  
rxSigMSK = awgn(modSigMSK,30);
```

Use the `eyediagram` function to plot the eye diagrams of the noisy signals. With the GMSK pulse length set to 1, the eye diagrams are nearly identical.

```
eyediagram(rxSigGMSK,sps,1,sps/2)
```

```
eyediagram(rxSigMSK,sps,1,sps/2)
```

Set the `PulseLength` property for the GMSK modulator object to 3. Because the property is nontunable, the object must be released first.

```
release(gmskMod)
gmskMod.PulseLength = 3;
```

Generate a modulated signal using the updated GMSK modulator object and pass it through the AWGN channel.

```
modSigGMSK = gmskMod(data);
rxSigGMSK = awgn(modSigGMSK,30);
```

With continuous phase modulation (CPM) waveforms, such as GMSK, the waveform depends on values of the previous symbols as well as the present symbol. Plot the eye diagram of the GMSK signal to see that the increased pulse length results in an increase in the number of paths in the eye diagram.

```
eyediagram(rxSigGMSK,sps,1,sps/2)
```

Experiment by changing the `PulseLength` parameter of the GMSK modulator object to other values. If you set the property to an even number, you should set `gmskMod.InitialPhaseOffset` to $\pi/4$ and update the offset argument of the `eyediagram` function from `sps/2` to `0` for a better view of the modulated signal. In order to more clearly view the Gaussian pulse shape, you must use scopes that display the phase of the signal, as described in the “View CPM Phase Tree Using Simulink” example.

Algorithms

The `BandwidthTimeProduct` property represents the bandwidth multiplied by time. Use this property to reduce the bandwidth at the expense of increased intersymbol interference. The `PulseLength` property measures the length of the Gaussian pulse shape in symbol intervals. These equations define the frequency pulse shape. B_b represents the bandwidth of the pulse and T is the symbol durations. $Q(t)$ is the complementary cumulative distribution function.

$$g(t) = \frac{1}{2T} \left\{ Q \left[2\pi B_b \frac{t - \frac{T}{2}}{\sqrt{\ln(2)}} \right] - Q \left[2\pi B_b \frac{t + \frac{T}{2}}{\sqrt{\ln(2)}} \right] \right\}$$

$$Q(t) = \int_t^{\infty} \frac{1}{\sqrt{2\pi}} e^{-\tau^2/2} d\tau$$

For this System object, an input symbol of 1 causes a phase shift of $\pi/2$ radians, which corresponds to a modulation index of 0.5.

Objects

`comm.GMSKDemodulator` | `comm.CPModulator` | `comm.CPMDemodulator`

Blocks

GMSK Modulator Baseband | GMSK Demodulator Baseband

Introduced in R2012a

comm.GMSKTimingSynchronizer

Package: comm

Recover symbol timing phase using fourth-order nonlinearity method

Description

The `GMSKTimingSynchronizer` object recovers the symbol timing phase of the input signal using a fourth-order nonlinearity method. This block implements a general non-data-aided feedback method. This timing synchronization is a non-data-aided feedback method that is independent of carrier phase recovery, but requires prior compensation for the carrier frequency offset. You can use this block for systems that use Gaussian minimum shift keying (GMSK) modulation.

To recover the symbol timing phase of the input signal:

- 1 Define and set up your GMSK timing synchronizer object. See “Construction” on page 3-615.
- 2 Call `step` to recover the symbol timing phase of the input signal according to the properties of `comm.GMSKTimingSynchronizer`. The behavior of `step` is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`H = comm.GMSKTimingSynchronizer` creates a timing phase synchronizer System object, `H`. This object recovers the symbol timing phase of the GMSK input signal using a fourth-order nonlinearity method.

`H = comm.GMSKTimingSynchronizer(Name,Value)` creates a GMSK timing synchronizer object, `H`, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as `(Name1,Value1,...,NameN,ValueN)`.

Properties

SamplesPerSymbol

Number of samples representing each symbol

Specify the number of samples that represent each symbol in the input signal as an integer-valued scalar value greater than 1. The default is 4.

ErrorUpdateGain

Error update step size

Specify the step size for updating successive timing phase estimates as a positive real scalar value. Typically, this number is less than $1/\text{SamplesPerSymbol}$ on page 3-0, which corresponds to a slowly varying timing phase. The default is 0.05. This property is tunable.

ResetInputPort

Enable synchronization reset input

Set this property to `true` to enable resetting the timing phase recovery process based on an input argument value. The default is `false`.

When you set this property to `true`, you must specify a reset input value to the `step` method.

When you specify a nonzero value as the reset input, the object restarts the timing phase recovery process. When you set this property to `false`, the object does not restart.

ResetCondition

Condition for timing phase recovery reset

Specify the conditions to reset the timing phase recovery process as one of `Never` | `Every frame`. The default is `Never`.

When you set this property to `Never`, the phase recovery process never restarts. The object operates continuously, retaining information from one symbol to the next.

When you set this property to `Every frame`, the timing phase recovery restarts at the start of each frame of data. In this case, the restart occurs at each `step` method call. This property applies when you set the `ResetInputPort` on page 3-0 property to `false`.

Methods

`step` Recover symbol timing phase using fourth-order nonlinearity method

Common to All System Objects	
<code>release</code>	Allow System object property value changes
<code>reset</code>	Reset internal states of System object

Examples

Recover Timing Phase of GMSK Signal

Create GMSK modulator, variable fractional delay, and GMSK timing synchronizer System objects.

```
gmskMod = comm.GMSKModulator('BitInput', true, ...
    'SamplesPerSymbol', 14);
timingOffset = 0.2;
varDelay = dsp.VariableFractionalDelay;
gmskTimingSync = comm.GMSKTimingSynchronizer('SamplesPerSymbol', 14, ...
    'ErrorUpdateGain', 0.05);
```

Main processing loop:

```

phEst = zeros(50,1);
for i = 1:50
    data = randi([0 1],100,1); % Generate data
    modData = gmskMod(data); % Modulate data

    % Apply timing offset error
    impairedData = varDelay(modData,timingOffset*14);
    % Perform timing phase recovery
    [~,phase] = gmskTimingSync(impairedData);
    phEst(i) = phase(1)/14;
end

```

Plot the results.

```

plot(1:50,[0.2*ones(50,1) phEst])
legend('Original','Estimated')
title('Original and Estimated timing phases')

```

Algorithms

This object implements the algorithm, inputs, and outputs described on the MSK-Type Signal Timing Recovery block reference page. The object properties correspond to the block parameters, except:

- The object corresponds to the MSK-Type Signal Timing Recovery block with the **Modulation type** parameter set to GMSK.

- The **Reset** parameter corresponds to the `ResetInputPort` on page 3-0 and `ResetCondition` on page 3-0 properties.

`comm.SymbolSynchronizer`

Introduced in R2012a

step

System object: comm.GMSKTimingSynchronizer

Package: comm

Recover symbol timing phase using fourth-order nonlinearity method

Syntax

`[Y,PHASE] = step(H,X)`

`[Y,PHASE] = step(H,X,R)`

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`[Y,PHASE] = step(H,X)` performs timing phase recovery and returns the time-synchronized signal, `Y`, and the estimated timing phase, `PHASE`, for input signal `X`. `X` must be a double or single precision complex column vector.

`[Y,PHASE] = step(H,X,R)` restarts the timing phase recovery process when you input a reset signal, `R`, that is non-zero. `R` must be a logical or double scalar. This syntax applies when you set the `ResetInputPort` property to true.

Note `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications. For more information on changing property values, see “System Design in MATLAB Using System Objects”.

comm.GoldSequence

Package: comm

Generate Gold sequence from set of sequences

Description

The `comm.GoldSequence` System object generates a binary sequence with small periodic cross-correlation properties from a bounded set of sequences. For more information, see “Gold Sequences” on page 3-630.

To generate a Gold sequence from set of sequences:

- 1 Create the `comm.GoldSequence` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

Creation

Syntax

```
goldseq = comm.GoldSequence  
goldseq = comm.GoldSequence(Name,Value)
```

Description

`goldseq = comm.GoldSequence` creates a Gold sequence generator System object. This object generates a pseudorandom Gold sequence of binary numbers.

`goldseq = comm.GoldSequence(Name,Value)` sets properties using one or more name-value arguments. Enclose each property name in quotes. For example, `'Shift',1` specifies a one sample offset of the output sequence from the starting point.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see [System Design in MATLAB Using System Objects](#).

FirstPolynomial — Generator polynomial for first preferred PN sequence

'z⁶ + z + 1' (default) | character vector | string scalar | binary-valued row vector | integer-valued row vector

Generator polynomial for the first preferred PN sequence, specified as one of these options:

- Character vector or string scalar of a polynomial whose constant term is 1. For more information, see “Representation of Polynomials in Communications Toolbox”.
- Binary-valued row vector that represents the coefficients of the polynomial in order of descending powers. The length of this vector must be $N + 1$, where N is the degree of the polynomial. The first and last entries must be 1, indicating the leading term with degree N and a constant term of 1.
- Integer-valued row vector of elements that represent the exponents for the nonzero terms of the polynomial in order of descending powers. The last entry must be 0, indicating a constant term of 1.

This property determines the feedback connections for the shift register of the first preferred PN sequence generator. The degree of the first generator polynomial must equal the degree of the second generator polynomial specified by the `SecondPolynomial` property. For more information, see “Preferred Pairs of Sequences” on page 3-631.

Example: `'z^8 + z^2 + 1'`, `[1 0 0 0 0 0 1 0 1]`, and `[8 2 0]` represent the same polynomial, $p(z) = z^8 + z^2 + 1$.

Data Types: `double` | `char`

FirstInitialConditions — Initial conditions used for shift register of first preferred PN sequence generator

`[0 0 0 0 0 1]` (default) | binary-valued scalar | binary-valued vector

Initial conditions used for the shift register of the first preferred PN sequence generator when the simulation starts, specified as a binary-valued scalar or binary-valued vector.

- If you set this property to a scalar, the initial value of all cells in the shift register are the specified scalar value.
- If you set this property to a vector, each element of the vector corresponds to the initial value of the corresponding cell in the shift register. The length of the vector must equal the degree of the generator polynomial specified by the `FirstPolynomial` property.

Note For the object to generate a nonzero sequence, at least one element of the initial conditions for the first or second preferred PN sequence generator must be nonzero. Specifically, the initial state of at least one of the shift registers must be nonzero.

Data Types: `double`

SecondPolynomial — Generator polynomial for second preferred PN sequence

`'z^6 + z^5 + z^2 + z + 1'` (default) | character vector | string scalar | binary-valued row vector | integer-valued row vector

Generator polynomial for the first preferred PN sequence, specified as one of these options:

- Character vector or string scalar of a polynomial whose constant term is 1. For more information, see “Representation of Polynomials in Communications Toolbox”.
- Binary-valued row vector that represents the coefficients of the polynomial in order of descending powers. The length of this vector must be $N + 1$, where N is the degree of the polynomial. The first and last entries must be 1, indicating the leading term with degree N and a constant term of 1.

- Integer-valued row vector of elements that represent the exponents for the nonzero terms of the polynomial in order of descending powers. The last entry must be 0, indicating a constant term of 1.

This property determines the feedback connections for the shift register of the second preferred PN sequence generator. The degree of the second generator polynomial must equal the degree of the first generator polynomial specified by the `FirstPolynomial` property. For more information, see “Preferred Pairs of Sequences” on page 3-631.

Data Types: `double` | `char`

SecondInitialConditionsSource — Source of initial conditions used for shift register of second preferred PN sequence generator

'Property' (default) | 'Input port'

Source of the initial conditions used for the shift register of the second preferred PN sequence generator, specified as one of these values:

- 'Property' — Specify PN sequence generator initial conditions by using the `SecondInitialConditions` property.
- 'Input port' — Specify PN sequence generator initial conditions by using the `secondinitcond` input argument.

Data Types: `string` | `char`

SecondInitialConditions — Initial conditions used for shift register of second preferred PN sequence generator

[0 0 0 0 0 1] (default) | binary-valued scalar | binary-valued vector

Initial conditions used for the shift register of the second preferred PN sequence generator when the simulation starts, specified as a binary-valued scalar or binary-valued vector.

- If you set this property to a scalar, the initial value of all cells in the shift register are the specified scalar value.
- If you set this property to a vector, each element of the vector corresponds to the initial value of the corresponding cell in the shift register. The length of the vector must equal the degree of the generator polynomial specified by the `SecondPolynomial` property.

Note For the object to generate a nonzero sequence, at least one element of the initial conditions for the first or second preferred PN sequence generator must be nonzero. Specifically, the initial state of at least one of the shift registers must be nonzero.

Dependencies

To enable this property set the `SecondInitialConditionsSource` property to 'Property'.

Data Types: `double`

Index — Sequence index

0 (default) | integer

Sequence index of the output sequence from the set of Gold sequences, specified as an integer in the range $[-2, 2^n - 2]$. n is the degree of the preferred polynomials. For more information, see “Sequence Index” on page 3-632 and “Gold Sequences” on page 3-630.

Data Types: double

Shift — Offset of output sequence from starting point

0 (default) | integer

Offset of the output sequence from the starting point, specified as an integer. Units are in samples. The object wraps shift values that are negative or greater than the length of the Gold sequence. For an example using shift, see “Generate Gold Sequences with Various Shift Values” on page 3-627.

Note Calculate the mask vector by using the `shift2mask` function.

Data Types: double

VariableSizeOutput — Enable variable-size outputs

false (default) | true

Enable variable-size outputs, specified as a numeric or logical 0 (false) or 1 (true). To enable variable-size outputs by using the `outputsize` input argument, set this property to true. The enabled input specifies the output size of the Gold sequence. The input value must be less than or equal to the value of the `MaximumOutputSize` property.

When you set this property to false, the `SamplesPerFrame` property specifies the number of output samples.

Data Types: logical | double

MaximumOutputSize — Maximum output frame size

[10 1] (default) | vector of the form [m 1]

Maximum output frame size, specified as a vector of the form [m 1], where m is a positive integer. The first element of the vector indicates the maximum length of the output frame and the second element of the vector must be 1.

Example: [20 1] specifies a maximum frame output size of 20-by-1.

Dependencies

To enable this property, set the `VariableSizeOutput` property to true.

Data Types: double

SamplesPerFrame — Number of samples output per frame

1 (default) | positive integer

Number of samples output per frame, specified as a positive integer. If you set this property to a value of M , the object outputs M samples of a Gold sequence that has a period of $N = 2^n - 1$, where n is the degree of the generator polynomials specified by the `FirstPolynomial` and `SecondPolynomial` properties.

Dependencies

To enable this property, set the `VariableSizeOutput` property to false.

Data Types: double

ResetInputPort — Enable generator reset input`false (default) | true`

Enable the generator reset input, specified as a numeric or logical 0 (`false`) or 1 (`true`). To enable the ability to reset the sequence generator using the `resetseq` input argument, set this property to `true`. This input resets the states of the two shift registers of the Gold sequence generator to the initial conditions specified by the `FirstInitialConditions` and `SecondInitialConditions` properties. For an example using the `resetseq` input, see “Generate Gold Sequences with Various Reset Values” on page 3-628.

Dependencies

To enable this property, set the `SecondInitialConditionsSource` property to `'Property'`.

Data Types: `logical` | `double`

OutputDataType — Data type of output`'double' (default) | 'logical' | 'Smallest unsigned integer' | 'Smallest integer'`

Data type of the output, specified as `'double'`, `'logical'`, `'Smallest unsigned integer'`, or `'Smallest integer'`.

To use the `Smallest unsigned integer` option, you must have the Fixed-Point Designer product.

Data Types: `string` | `char`

Usage**Syntax**

```
outSequence = goldseq()  
outSequence = goldseq(secondinitcond)  
outSequence = goldseq(outputsize)  
outSequence = goldseq(resetseq)  
outSequence = goldseq(secondinitcond,outputsize)  
outSequence = goldseq(outputsize,resetseq)
```

Description

`outSequence = goldseq()` outputs a frame of the Gold sequence in a column vector based on the configured object.

`outSequence = goldseq(secondinitcond)` uses `secondinitcond` as the initial conditions for the second PN sequence.

To enable this syntax, set the `SecondInitialConditionsSource` property to `'Input port'` and the `ResetInputPort` property to `false`.

`outSequence = goldseq(outputsize)` uses `outputsize` as the output size.

To enable this syntax, set the `VariableSizeOutput` property to `true`.

`outSequence = goldseq(resetseq)` uses `resetseq` as the reset signal.

To enable this syntax, set the `ResetInputPort` property to `true` and the `SecondInitialConditionsSource` property to `'Property'`.

`outSequence = goldseq(secondinitcond, outputsize)` specifies inputs for the second PN sequence initial conditions and the output size.

To enable this syntax, set the `SecondInitialConditionsSource` property to `'Input port'`, the `ResetInputPort` property to `false`, and set the `VariableSizeOutput` property to `true`.

`outSequence = goldseq(outputsize, resetseq)` specifies inputs for the output size and a reset signal.

To enable this syntax, set the `VariableSizeOutput` property to `true`, the `SecondInitialConditionsSource` property to `'Property'`, and the `ResetInputPort` property to `true`.

Input Arguments

secondinitcond — Initial conditions used for shift register of second sequence polynomial
binary scalar | binary vector

Initial conditions used for the shift register of the second preferred PN sequence generator when the simulation starts, specified as a binary-valued scalar or binary-valued vector.

- If you set this input to a scalar, the initial value of all cells in the shift register are the specified scalar value.
- If you set this input to a vector, each element of the vector corresponds to the initial value of the corresponding cell in the shift register. The length of the vector must equal the degree of the generator polynomial specified by the `SecondPolynomial` property.

Note For the object to generate a nonzero sequence, at least one element of the initial conditions for the first or second preferred PN sequence generator must be nonzero. Specifically, the initial state of at least one of the shift registers must be nonzero.

Dependencies

To enable this input argument, set the `SecondInitialConditionsSource` property to `'Input port'`.

Data Types: `double`

outputsize — Length of output sequence

nonnegative integer | vector of the form $[n \ 1]$

Length of the output sequence, specified as a nonnegative integer, n , or a vector of the form $[n \ 1]$, where n is a positive integer. The first element of the vector indicates the length of the output frame and the second element of the vector must be 1.

The scalar or the first element of the row vector must be less than or equal to the first element of the `MaximumOutputSize` property value.

Dependencies

To enable this input argument, set the `VariableSizeOutput` property to `true`.

Data Types: `double`

resetseq — Reset sequence generator

scalar | column vector

Reset sequence generator, specified as a scalar or a column vector with length equal to the number of samples per frame specified by the `SamplesPerFrame` property.

- When you specify this input as a nonzero scalar, the object resets to the specified initial conditions and then generates a new output frame.
- When you specify this input as a column vector, the object resets to the specified initial conditions at each sample in the output frame that aligns with a nonzero value in the reset vector.

For an example using `reset`, see “Generate Gold Sequences with Various Reset Values” on page 3-628.

Dependencies

To enable this input argument, set the `ResetInputPort` property to `true`.

Data Types: `double` | `logical`

Output Arguments

outSequence — Gold sequence

column vector

Gold sequence, returned as a column vector. For more information, see “Gold Sequences” on page 3-630.

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Common to All System Objects

<code>step</code>	Run System object algorithm
<code>release</code>	Release resources and allow changes to System object property values and input characteristics
<code>reset</code>	Reset internal states of System object

Examples

Generate Gold Sequence Samples

Generate 10 samples of a Gold sequence with a period of $2^5 - 1$.

```
goldseq = comm.GoldSequence('FirstPolynomial','x^5+x^2+1', ...  
    'SecondPolynomial','x^5+x^4+x^3+x^2+1', ...  
    'FirstInitialConditions',[0 0 0 0 1], ...  
    'SecondInitialConditions',[0 0 0 0 1], ...
```

```
'Index',4,'SamplesPerFrame',10);
x = goldseq()
```

```
x = 10×1
```

```
1
1
1
0
0
0
0
0
0
1
```

Generate Gold Sequences with Various Shift Values

Generate Gold sequences using different values for the shift input to demonstrate that the object wraps shift values that are negative or greater than the sequence length.

Create a Gold sequence System object™, specifying 15 samples per frame and no shift. Generate the 7-sample Gold sequence. The output frame begins at the start of the Gold sequence.

```
goldseq = comm.GoldSequence( ...
    "FirstPolynomial","x^3+x^2+1", ...
    "SecondPolynomial","x^3+x+1", ...
    "FirstInitialConditions",[0 0 1], ...
    "SecondInitialConditions",[0 1 1], ...
    "Index",3, ...
    "SamplesPerFrame",15)
```

```
goldseq =
comm.GoldSequence with properties:
```

```
    FirstPolynomial: "x^3+x^2+1"
    FirstInitialConditions: [0 0 1]
    SecondPolynomial: "x^3+x+1"
    SecondInitialConditionsSource: 'Property'
    SecondInitialConditions: [0 1 1]
    Index: 3
    Shift: 0
    VariableSizeOutput: false
    SamplesPerFrame: 15
    ResetInputPort: false
    OutputDataType: 'double'
```

```
outseq = goldseq()'
```

```
outseq = 1×15
```

```
1 1 0 0 0 0 0 1 1 0 0 0 0 0 1
```

Release the object, adjust the shift to -1, and generate the shifted output. Repeat this process for shift values of 6 and 13. For each of these shift settings, the output frame begins at the 6th sample of this 7-sample long Gold sequence.

```
release(goldseq);
goldseq.Shift = -1;
outseq = goldseq()'
```

```
outseq = 1×15
```

```
0 1 1 0 0 0 0 0 1 1 0 0 0 0 0
```

```
release(goldseq);
goldseq.Shift = 6;
outseq = goldseq()'
```

```
outseq = 1×15
```

```
0 1 1 0 0 0 0 0 1 1 0 0 0 0 0
```

```
release(goldseq);
goldseq.Shift = 13;
outseq = goldseq()'
```

```
outseq = 1×15
```

```
0 1 1 0 0 0 0 0 1 1 0 0 0 0 0
```

Generate Gold Sequences with Various Reset Values

Generate Gold sequences using different values for the reset input.

Create a Gold sequence System object™, specifying 15 samples per frame and enabling the reset input. Generate the 7-sample Gold sequence. To observe the starting point of frames output by the object relative to the generated Gold sequence, the samples per frame value includes one sample more than two times the sequence length.

```
goldseq = comm.GoldSequence( ...
    "FirstPolynomial","x^3+x^2+1", ...
    "SecondPolynomial","x^3+x+1", ...
    "FirstInitialConditions",[0 0 1], ...
    "SecondInitialConditions",[0 1 1], ...
    "Index",3, ...
    "ResetInputPort",true, ...
    "SamplesPerFrame",15);
```

So that the object does not reset the sequence to the initial conditions, specify a scalar reset input value of 0. Display consecutive 15-sample frames of the sequence. The second frame continues the sequence from where the first frame left off, with the second element of the Gold sequence.

```
resetseq = 0;
x1 = goldseq(resetseq)'
```

```
x1 = 1×15
    1    1    0    0    0    0    0    1    1    0    0    0    0    0    1
```

```
x2 = goldseq(resetseq)'
```

```
x2 = 1×15
    1    0    0    0    0    0    1    1    0    0    0    0    0    1    1
```

To reset the sequence to the initial conditions, specify a scalar reset input value of 1. Display consecutive 15-sample frames of the sequence. The second frame now begins with the first element of the Gold sequence.

```
resetseq = 1;
x3 = goldseq(resetseq)'
```

```
x3 = 1×15
    1    1    0    0    0    0    0    1    1    0    0    0    0    0    1
```

```
x4 = goldseq(resetseq)'
```

```
x4 = 1×15
    1    1    0    0    0    0    0    1    1    0    0    0    0    0    1
```

To reconfigure the reset input of the object to accept a vector, release the object. Specify a reset input vector filled with 0s. Display consecutive 15-sample frames of the sequence. Since the object does not reset the sequence to the initial conditions, the second frame begins with the second element of the Gold sequence.

```
release(goldseq)
resetseq = [0 0 0 0 0 0 0 0 0 0 0 0 0 0 0]';
x5 = goldseq(resetseq)'
```

```
x5 = 1×15
    1    1    0    0    0    0    0    1    1    0    0    0    0    0    1
```

```
x6 = goldseq(resetseq)'
```

```
x6 = 1×15
    1    0    0    0    0    0    1    1    0    0    0    0    0    1    1
```

Specify a reset input vector that has two elements with nonzero values. Display consecutive 15-sample frames of the sequence. The second and third frames continue the sequence from the prior frame but reset the sequence at the third and ninth samples of the frame due to the position of the nonzero entries in the vector specified for the reset input.

```
resetseq = [0 0 1 0 0 0 0 0 1 0 0 0 0 0 0]';
x7 = goldseq(resetseq)'
```

x7 = 1x15

0 0 1 1 0 0 0 0 1 1 0 0 0 0 0

x8 = goldseq(resetseq)'

x8 = 1x15

1 1 1 1 0 0 0 0 1 1 0 0 0 0 0

x9 = goldseq(resetseq)'

x9 = 1x15

1 1 1 1 0 0 0 0 1 1 0 0 0 0 0

More About

Gold Sequences

The characteristic cross-correlation properties of Gold sequences make them useful when multiple devices are broadcasting in the same frequency range. The Gold sequences are defined using a specified pair of sequences, u and v , called a preferred pair, as defined in "Preferred Pairs of Sequences" on page 3-631. The u and v pair of sequences has a period $N = 2^n - 1$, where n is the degree of the generator polynomials specified by the `FirstPolynomial` and `SecondPolynomial` properties. The set $G(u, v)$ of Gold sequences is defined by

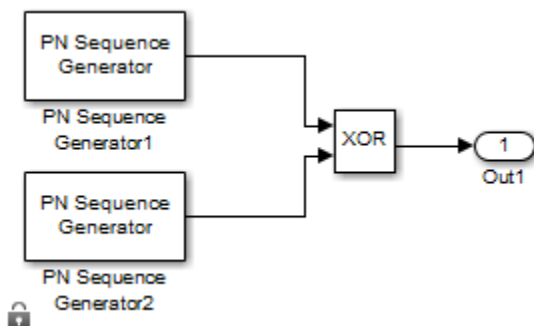

$$G(u, v) = \{u, v, u \oplus v, u \oplus Tv, u \oplus T^2v, \dots, u \oplus T^{N-1}v\}$$

T represents the operator that shifts vectors cyclically to the left by one place, and \oplus represents addition modulo 2. $G(u, v)$ contains $N + 2$ sequences of period N .

Gold sequences have the property that the cross-correlation between any two sequences or between shifted versions of the sequences takes on one of three values: $-t(n)$, -1 , or $t(n) - 2$, where

$$t(n) = \begin{cases} 1 + 2^{(n+1)/2} & n \text{ even} \\ 1 + 2^{(n+2)/2} & n \text{ odd} \end{cases}$$

The object uses two PN sequence generators to generate a preferred pair of sequences. The object then XORs these sequences to produce the output Gold sequence, as shown in this figure.

The `FirstPolynomial` and `SecondPolynomial` properties determine the preferred pair of sequences and the feedback connections for the shift registers used by the PN sequence generators to generate their output. For more details on PN sequence generation, see the “Simple Shift Register Generator” on page 3-1031 section on the `comm.PNSequence` System object reference page.

This table provides examples of preferred pairs.

Degree of Generator Polynomials (n)	Pair of Sequences Period (N)	FirstPolynomial Property Value	SecondPolynomial Property Value
5	31	[5 2 0]	[5 4 3 2 0]
6	63	[6 1 0]	[6 5 2 1 0]
7	127	[7 3 0]	[7 3 2 1 0]
9	511	[9 4 0]	[9 6 4 3 0]
10	1023	[10 3 0]	[10 8 3 2 0]
11	2047	[11 2 0]	[11 8 5 2 0]

The `FirstInitialConditions` property and `SecondInitialConditions` property (or `secondinitcond` input argument) are values that specify the initial values of the shift registers corresponding to `FirstPolynomial` and `SecondPolynomial`, respectively.

Note For the object to generate a nonzero sequence, at least one element of one of the initial conditions vectors must be nonzero. Specifically, the initial state of at least one of the shift registers must be nonzero.

You can offset the starting point of the Gold sequence by setting the `Shift` property to a nonzero value. For an example that adjusts the shift setting, see “Generate Gold Sequences with Various Shift Values” on page 3-627.

Preferred Pairs of Sequences

Preferred pairs of sequences, u and v , comprise the set of Gold sequences $G(u, v)$.

For a pair of sequences, u and v , of period $N = 2^n - 1$ to be a preferred pair, they must satisfy these requirements:

- n is the degree of the generator polynomials specified by the `FirstPolynomial` and `SecondPolynomial` properties.
- n is not divisible by 4.
- $v = u[q]$, where
 - q is odd.
 - $q = 2^k + 1$ or $q = 2^{2k} - 2^k + 1$.
 - v is obtained by sampling every q th symbol of u .
- $\text{gcd}(n, k) = \begin{cases} 1 & n \equiv 1 \pmod{2} \\ 2 & n \equiv 2 \pmod{4} \end{cases}$

For more details on PN sequence generation, see the “Simple Shift Register Generator” on page 3-1031 section on the `comm.PNSequence` System object reference page.

Sequence Index

The sequence index specified by the `Index` property specifies which Gold sequence in the set $G(u, v)$ is output.

The set of available Gold sequences is

$$G(u, v) = \{u, v, u \oplus v, u \oplus Tv, u \oplus T^2v, \dots, u \oplus T^{N-1}v\}$$

u and v are the two preferred PN sequences, T is the operator that shifts vectors cyclically to the left by one place, and \oplus represents addition modulo 2. $G(u, v)$ contains $N+2$ Gold sequences of period $N = 2^n - 1$.

The range of `Index` is $[-2, 2^n - 2]$, where n is the degree of the generator polynomials specified by the `FirstPolynomial` and `SecondPolynomial` properties. The index values `-2` and `-1` correspond to the first and second preferred PN sequences as generated by `FirstPolynomial` and `SecondPolynomial`, respectively. This table shows the correspondence between the sequence index and the output sequence.

Index Property Value	Output Sequence
-2	u
-1	v
0	$u \oplus v$
1	$u \oplus Tv$
2	$u \oplus T^2v$
...	...
$2^n - 2$	$u \oplus T^{2^n - 2}v$

comm.gpu.AWGNChannel

Package: comm

Add white Gaussian noise to input signal with GPU

Description

The GPU `AWGNChannel` object adds white Gaussian noise to an input signal using a graphics processing unit (GPU).

Note To use this object, you must install a Parallel Computing Toolbox license and have access to an appropriate GPU. For more about GPUs, see “GPU Computing” (Parallel Computing Toolbox).

To add white Gaussian noise to an input signal:

- 1 Define and set up your additive white Gaussian noise channel object. See “Construction” on page 3-634.
- 2 Call `step` to add white Gaussian noise to the input signal according to the properties of `comm.gpu.AWGNChannel`. The behavior of `step` is specific to each object in the toolbox.

A GPU-based System object accepts typical MATLAB arrays or objects created using the `gpuArray` class. A GPU-based System object supports input signals with double- or single-precision data types. The output signal inherits its data type from the input signal.

- If the input signal is a MATLAB array, the System object handles data transfer between the CPU and the GPU. The output signal is a MATLAB array.
- If the input signal is a `gpuArray`, the data remains on the GPU. The output signal is a `gpuArray`. When the object is given a `gpuArray`, calculations take place entirely on the GPU, and no data transfer occurs. Passing `gpuArray` arguments provides increased performance by reducing simulation time. For more information, see “Establish Arrays on a GPU” (Parallel Computing Toolbox).

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`H = comm.gpu.AWGNChannel` creates a GPU-based additive white Gaussian noise (AWGN) channel System object, `H`. This object adds white Gaussian noise to a real or complex input signal.

`H = comm.gpu.AWGNChannel(Name,Value)` creates a GPU-based AWGN channel object, `H`, with the specified property name set to the specified value. You can specify additional name-value pair arguments in any order as `(Name1,Value1,...,NameN,ValueN)`.

A GPU-based System object accepts typical MATLAB arrays or objects created using the `gpuArray` class. A GPU-based System object supports input signals with double- or single-precision data types. The output signal inherits its data type from the input signal.

- If the input signal is a MATLAB array, the System object handles data transfer between the CPU and the GPU. The output signal is a MATLAB array.
- If the input signal is a `gpuArray`, the data remains on the GPU. The output signal is a `gpuArray`. When the object is given a `gpuArray`, calculations take place entirely on the GPU, and no data transfer occurs. Passing `gpuArray` arguments provides increased performance by reducing simulation time. For more information, see “Establish Arrays on a GPU” (Parallel Computing Toolbox).

Properties

NoiseMethod

Method to specify noise level

Select the method to specify the noise level as one of `Signal to noise ratio (Eb/No)` | `Signal to noise ratio (Es/No)` | `Signal to noise ratio (SNR)` | `Variance`. The default is `Signal to noise ratio (Eb/No)`.

EbNo

Energy per bit to noise power spectral density ratio (Eb/No)

Specify the Eb/No ratio in decibels. Set this property to a numeric, real scalar or row vector with a length equal to the number of channels. This property applies when you set the `NoiseMethod` property to `Signal to noise ratio (Eb/No)`. The default is `10`. This property is tunable.

EsNo

Energy per symbol to noise power spectral density ratio (Es/No)

Specify the Es/No ratio in decibels. Set this property to a numeric, real scalar or row vector with a length equal to the number of channels. This property applies when you set the `NoiseMethod` property to `Signal to noise ratio (Es/No)`. The default is `10`. This property is tunable.

SNR

Signal to noise ratio (SNR)

Specify the SNR value in decibels. Set this property to a numeric, real scalar or row vector with a length equal to the number of channels. This property applies when you set the `NoiseMethod` property to `Signal to noise ratio (SNR)`. The default is `10`. This property is tunable.

BitsPerSymbol

Number of bits in one symbol

Specify the number of bits in each input symbol. You can set this property to a numeric, positive, integer scalar or row vector with a length equal to the number of channels. This property applies when you set the `NoiseMethod` property to `Signal to noise ratio (Eb/No)`. The default is `1` bit.

SignalPower

Input signal power in Watts

Specify the mean square power of the input signal in Watts. Set this property to a numeric, positive, real scalar or row vector with a length equal to the number of channels. This property applies when you set the `NoiseMethod` property to `Signal to noise ratio (Eb/No)`, `Signal to noise ratio (Es/No)` or `Signal to noise ratio (SNR)`. The default is 1 Watt. The object assumes a nominal impedance of 1 Ohm. This property is tunable.

SamplesPerSymbol

Number of samples per symbol

Specify the number of samples per symbol. Set this property to a numeric, positive, integer scalar or row vector with a length equal to the number of channels. This property applies when you set the `NoiseMethod` property to `Signal to noise ratio (Eb/No)` or `Signal to noise ratio (Es/No)`. The default is 1 sample.

VarianceSource

Source of noise variance

Specify the source of the noise variance as one of `Property | Input port`. The default is `Property`. Set `VarianceSource` to `Input port` to specify the noise variance value via an input to the step method. Set `VarianceSource` to `Property` to specify the noise variance value using the `Variance` property. This property applies when you set the `NoiseMethod` property to `Variance`.

Variance

Noise variance

Specify the variance of the white Gaussian noise. You can set this property to a numeric, positive, real scalar or row vector with a length equal to the number of channels. This property applies when you set the `NoiseMethod` property to `Variance` and the `VarianceSource` property to `Property`. The default is 1. This property is tunable.

RandomStream

Source of random number stream

Specify the source of random number stream. The only valid setting for this property is `Global stream`. The object generates the normally distributed random numbers from the current global random number stream.

Seed

Initial seed of mt19937ar random number stream

The GPU version of the AWGN Channel System object does not use this property.

Methods

`step` Add white Gaussian noise to input signal

Common to All System Objects

release	Allow System object property value changes
---------	--

Algorithm

This object uses the same algorithm as the `comm.AWGNChannel` System object. See the Algorithms section of the `comm.AWGNChannel` help page for more details. The object properties correspond to the related block parameters, except that:

- This object uses `parallel.gpu.RandStream` to provide an interface for controlling the properties of one or more random number streams that the GPU uses. Usage is the same as `RandStream` with the following restrictions:
 - Only the `combRecursive` (MRG32K3A) generator is supported.
 - Only the `Inversion` normal transform is supported.
 - Setting the `substream` property is not allowed.

Enter `help parallel.gpu.RandStream` at the MATLAB command line for more information.

Examples**GPU AWGN Channel**

Specify the modulation order and generate PSK-modulated random data.

```
M = 8;
modData = pskmod(randi([0 M-1],1000,1),M,pi/M);
```

Create an AWGN channel object that uses a GPU. Pass the modulated data through the channel.

```
gpuChannel = comm.gpu.AWGNChannel('EbNo',15,'BitsPerSymbol', ...
    log2(M));
channelOutput = gpuChannel(modData);
```

Visualize the noiseless and noisy data in scatter plots.

```
scatterplot(modData)
scatterplot(channelOutput)
```

Extended Capabilities

GPU Arrays

Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

This System object runs on a GPU, and also supports GPU array inputs. For more information, see “Simulation Acceleration Using GPUs”.

`comm.AWGNChannel`

Introduced in R2012a

step

System object: `comm.gpu.AWGNChannel`

Package: `comm`

Add white Gaussian noise to input signal

Syntax

`Y = step(H,X)`

`Y = step(H,X,VAR)`

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(H,X)` adds white Gaussian noise to input `X` and returns the result in `Y`. The input `X` can be a double or single precision data type scalar, vector, or matrix with real or complex values. The dimensions of input `X` determine single or multichannel processing. For an `M`-by-`N` matrix input, `M` represents the number of time samples per channel and `N` represents the number of channels. `M` and `N` can be equal to 1. The object adds frames of length `M` of Gaussian noise to each of the `N` channels independently.

`Y = step(H,X,VAR)` uses input `VAR` as the variance of the white Gaussian noise. This applies when you set the `NoiseMethod` property to `Variance` and the `VarianceSource` property to `Input port`. Input `VAR` can be a positive scalar or row vector with a length equal to the number of channels. `VAR` must be of the same data type as input `X`.

Note `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications. For more information on changing property values, see “System Design in MATLAB Using System Objects”.

comm.gpu.BlockDeinterleaver

Package: comm

Restore original ordering of block interleaved sequence with GPU

Description

The `comm.gpu.BlockDeinterleaver` System object restores the original ordering of a sequence that was interleaved using the block interleaver System object.

Note To use this object, you must install a Parallel Computing Toolbox license and have access to an appropriate GPU. For more about GPUs, see “GPU Computing” (Parallel Computing Toolbox).

A GPU-based System object accepts typical MATLAB arrays or objects created using the `gpuArray` class. A GPU-based System object supports input signals with double- or single-precision data types. The output signal inherits its data type from the input signal.

- If the input signal is a MATLAB array, the System object handles data transfer between the CPU and the GPU. The output signal is a MATLAB array.
- If the input signal is a `gpuArray`, the data remains on the GPU. The output signal is a `gpuArray`. When the object is given a `gpuArray`, calculations take place entirely on the GPU, and no data transfer occurs. Passing `gpuArray` arguments provides increased performance by reducing simulation time. For more information, see “Establish Arrays on a GPU” (Parallel Computing Toolbox).

To deinterleave the input vector:

- 1 Define and set up your block deinterleaver object. See “Construction” on page 3-641.
- 2 Call `step` to rearrange the elements of the input vector according to the properties of `comm.gpu.BlockDeinterleaver`. The behavior of `step` is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj, x)` and `y = obj(x)` perform equivalent operations.

Construction

`H = comm.gpu.BlockDeinterleaver` creates a GPU-based block deinterleaver System object, `H`. This object restores the original ordering of a sequence that was interleaved using the `BlockInterleaver` System object

`H = comm.gpu.BlockDeinterleaver(Name, Value)` creates a GPU-based block deinterleaver object, `H`, with the specified property name set to the specified value.

`H = comm.gpu.BlockDeinterleaver(PERMVEC)` creates a GPU-based block deinterleaver object, `H`, with the `PermutationVector` property set to `PERMVEC`.

Properties

PermutationVector

Permutation vector

Specify the mapping used to permute the input symbols as a column vector of integers. The default is [5;4;3;2;1]. The mapping is a vector where the number of elements is equal to the length, *N*, of the input to the step method. Each element must be an integer between 1 and *N*, with no repeated values.

Methods

step Deinterleave input sequence

Common to All System Objects	
release	Allow System object property value changes

Algorithm

This object implements the algorithm, inputs, and outputs described on the General Block Deinterleaver block reference page. The object properties correspond to the block parameters.

Examples

Block Interleaving and Deinterleaving with GPU

Create interleaver and deinterleaver objects.

```
interleaver = comm.gpu.BlockInterleaver([3 4 1 2]');
deinterleaver = comm.gpu.BlockDeinterleaver([3 4 1 2]');
```

Pass random data through the interleaver and deinterleaver.

```
data = randi(7,4,1);
intData = interleaver(data);
deIntData = deinterleaver(intData);
```

Display the original sequence, interleaved sequence, and restored sequence.

```
[data intData deIntData]
```

```
ans =
```

```

     6     1     6
     7     7     7
     1     6     1
     7     7     7
```

Confirm the original and deinterleaved data are identical.

```
isequal(data,deIntData)
```

```
ans =  
     1
```

Generate a random vector of unique integers as a permutation vector.

```
permVec = randperm(7)';
```

Specify permVec as the permutation vector for the interleaver and deinterleaver objects.

```
interleaver = comm.gpu.BlockInterleaver(permVec);  
deinterleaver = comm.gpu.BlockDeinterleaver(permVec);
```

Pass random data through the interleaver and deinterleaver.

```
data = randi(10,7,1);  
intData = interleaver(data);  
deIntData = deinterleaver(intData);
```

Confirm the original and deinterleaved data are identical.

```
isequal(data,deIntData)
```

```
ans =  
     1
```

Extended Capabilities

GPU Arrays

Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

This System object runs on a GPU, and also supports GPU array inputs. For more information, see “Simulation Acceleration Using GPUs”.

Blocks

General Block Deinterleaver

Introduced in R2012a

step

System object: `comm.gpu.BlockDeinterleaver`

Package: `comm`

Deinterleave input sequence

Syntax

`Y = step(H,X)`

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(H,X)` restores the original ordering of the sequence, `X`, that was interleaved using a block interleaver. The `step` method forms the output, `Y`, based on the mapping specified by the `PermutationVector` property as `Output(PermutationVector(k))=Input(k)`, for `k = 1:N`, where `N` is the length of the permutation vector. The input `X` must be a column vector of the same length, `N`. The data type of `X` can be numeric, logical, or fixed-point (fi objects). `Y` has the same data type as `X`.

Note `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications. For more information on changing property values, see “System Design in MATLAB Using System Objects”.

comm.gpu.BlockInterleaver

Package: comm

Create block interleaved sequence with GPU

Description

The `comm.gpu.BlockInterleaver` System object permutes the symbols in the input signal using a graphics processing unit (GPU).

Note To use this object, you must install a Parallel Computing Toolbox license and have access to an appropriate GPU. For more about GPUs, see “GPU Computing” (Parallel Computing Toolbox).

A GPU-based System object accepts typical MATLAB arrays or objects created using the `gpuArray` class. A GPU-based System object supports input signals with double- or single-precision data types. The output signal inherits its data type from the input signal.

- If the input signal is a MATLAB array, the System object handles data transfer between the CPU and the GPU. The output signal is a MATLAB array.
- If the input signal is a `gpuArray`, the data remains on the GPU. The output signal is a `gpuArray`. When the object is given a `gpuArray`, calculations take place entirely on the GPU, and no data transfer occurs. Passing `gpuArray` arguments provides increased performance by reducing simulation time. For more information, see “Establish Arrays on a GPU” (Parallel Computing Toolbox).

To interleave the input signal:

- 1 Define and set up your block interleaver object. See “Construction” on page 3-645.
- 2 Call `step` to reorder the input symbols according to the properties of `comm.gpu.BlockInterleaver`. The behavior of `step` is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj, x)` and `y = obj(x)` perform equivalent operations.

Construction

`H = comm.gpu.BlockInterleaver` creates a GPU-based block interleaver System object, `H`. This object permutes the symbols in the input signal based on a permutation vector.

`H = comm.gpu.BlockInterleaver(Name, Value)` creates a GPU-based block interleaver object, `H`, with the specified property `Name` set to the specified `Value`.

`H = comm.gpu.BlockInterleaver(PERMVEC)` creates a GPU-based block deinterleaver object, `H`, with the `PermutationVector` property set to `PERMVEC`.

Properties

PermutationVector

Permutation vector

Specify the mapping used to permute the input symbols as a column vector of integers. The default is [5;4;3;2;1]. The mapping is a vector where the number of elements is equal to the length, *N*, of the input to the step method. Each element must be an integer between 1 and *N*, with no repeated values.

step

System object: `comm.gpu.BlockInterleaver`

Package: `comm`

Permute input symbols using a permutation vector

Syntax

`Y = step(H,X)`

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(H,X)` permutes input sequence, `X`, and returns interleaved sequence, `Y`. The `step` method forms the output `Y`, based on the mapping defined by the `PermutationVector` property as `Output(k)=Input(PermutationVector(k))`, for `k = 1:N`, where `N` is the length of the `PermutationVector` property. The input `X` must be a column vector of length `N`. The data type of `X` can be numeric, logical, or fixed-point (fi objects). `Y` has the same data type as `X`.

Note `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications. For more information on changing property values, see “System Design in MATLAB Using System Objects”.

comm.gpu.ConvolutionalEncoder

Package: comm.gpu

Convolutionally encode binary data with GPU

Note To use this object, you must install Parallel Computing Toolbox™ and have access to an appropriate GPU. For more about GPUs, see “GPU Computing” (Parallel Computing Toolbox).

Description

The `comm.gpu.ConvolutionalEncoder` System object convolutionally encodes a sequence of binary input vectors to produce a sequence of binary output vectors by using a graphics processing unit (GPU).

A GPU-based System object accepts typical MATLAB arrays or objects created using the `gpuArray` class. A GPU-based System object supports input signals with double- or single-precision data types. The output signal inherits its data type from the input signal.

- If the input signal is a MATLAB array, the System object handles data transfer between the CPU and the GPU. The output signal is a MATLAB array.
- If the input signal is a `gpuArray`, the data remains on the GPU. The output signal is a `gpuArray`. When the object is given a `gpuArray`, calculations take place entirely on the GPU, and no data transfer occurs. Passing `gpuArray` arguments provides increased performance by reducing simulation time. For more information, see “Establish Arrays on a GPU” (Parallel Computing Toolbox).

To convolutionally encode a binary signal:

- 1 Create the `comm.gpu.ConvolutionalEncoder` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

Creation

Syntax

```
gpuConvEncoder = comm.gpu.ConvolutionalEncoder
gpuConvEncoder = comm.gpu.ConvolutionalEncoder(trellis)
gpuConvEncoder = comm.gpu.ConvolutionalEncoder( ___,Name,Value)
```

Description

`gpuConvEncoder = comm.gpu.ConvolutionalEncoder` creates a GPU-based convolutional encoder System object.

`gpuConvEncoder = comm.gpu.ConvolutionalEncoder(trellis)` sets the `TrellisStructure` property to `trellis`.

`gpuConvEncoder = comm.gpu.ConvolutionalEncoder(___,Name,Value)` sets “Properties” on page 3-650 using one or more name-value arguments in addition to any of the input argument combinations in previous syntaxes. For example, 'TerminationMethod', 'Continuous' specifies the termination method as continuous to retain the encoder states at the end of each input vector for use with the next input vector.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects.

TrellisStructure — Trellis structure of convolutional code

`poly2trellis(7,[171 133])` (default) | structure

Trellis structure of the convolutional code, specified as a structure that contains the trellis description for a rate K/N code. K is the number of input bit streams, and N is the number of output bit streams.

You can either use the `poly2trellis` function to create the trellis structure or create it manually. For more about this structure, see “Trellis Description of a Convolutional Code” and the `istrellis` function.

The trellis structure contains these fields.

numInputSymbols — Number of symbols input to encoder

2^K

Number of symbols input to the encoder, specified as an integer equal to 2^K , where K is the number of input bit streams.

Data Types: `double`

numOutputSymbols — Number of symbols output from encoder

2^N

Number of symbols output from the encoder, specified as an integer equal to 2^N , where N is the number of output bit streams.

Data Types: `double`

numStates — Number of states in encoder

power of 2

Number of states in the encoder, specified as a power of 2.

Data Types: `double`

nextStates — Next states

matrix of integers

Next states for all combinations of current states and current inputs, specified as a matrix of integers. The matrix size must be numStates-by- 2^K .

Data Types: double

outputs — Outputs

matrix of octal numbers

Outputs for all combinations of current states and current inputs, specified as a matrix of octal numbers. The matrix size must be numStates-by- 2^K .

Data Types: double

Data Types: struct

TerminationMethod — Termination method of encoded frame

'Continuous' (default) | 'Truncated' | 'Terminated'

Termination method of the encoded frame, specified as one of these values.

- 'Continuous' — The System object retains the encoder states at the end of each input vector for use with the next input vector.
- 'Truncated' — The System object treats each input vector independently. The encoder states are reset at the start of each input vector. If you set the InitialStateInputPort property to 0 (false), the object resets its states to the all-zeros state. If you set the InitialStateInputPort property to 1 (true), the object resets its states to the values you specify in the InitialStateInputPort input.
- 'Terminated' — The System object treats each input vector independently. For each input vector, the object uses extra bits to set the encoder states to the all-zeros states at the end of the vector. For a rate K/N code, the object outputs a vector of length $(N \times (L + S))/K$. In this calculation, $S = \text{constraintLength} - 1$ (or, in the case of multiple constraint lengths, $S = \text{sum}(\text{constraintLength}(i) - 1)$. L is the length of the input. $\text{constraintLength} - 1$ is defined as $\log_2(\text{NumStates})$.

Data Types: char | string

ResetInputPort — Option to enable encoder reset input

false or 0 (default)

Option to enable the encoder reset input, specified as a numeric or logical 0 (false). The only valid setting is false.

Data Types: logical | numeric

DelayedResetAction — Option to delay output reset

false or 0 (default)

Option to delay the output reset, specified as a numeric or logical 0 (false). The only valid setting is false.

Data Types: logical | numeric

InitialStateInputPort — Option to enable initial state input

false or 0 (default)

Option to enable the initial state input, specified as a numeric or logical 0 (false). The only valid setting is false.

Data Types: logical | numeric

FinalStateOutputPort — Option to enable final state output

false or 0 (default)

Option to enable the final state output, specified as a numeric or logical 0 (false). The only valid setting is false.

Data Types: logical | numeric

PuncturePatternSource — Source of puncture pattern

'None' (default) | 'Property'

Source of the puncture pattern, specified as one of these values.

- 'None' — The object does not apply puncturing.
- 'Property' — The object punctures the code. This puncturing is based on the puncture pattern vector that you specify for the PuncturePattern property.

Dependencies

To enable this property, set the TerminationMethod property to 'Continuous' or 'Truncated'.

Data Types: char | string

PuncturePattern — Puncture pattern vector

[1; 1; 0; 1; 0; 1] (default) | column vector

Puncture pattern vector to puncture the encoded data, specified as a column vector. The vector must contain 1s and 0s, where 0 indicates the position of punctured bits or excluded bits.

Dependencies

To enable this property, set the TerminationMethod property to 'Continuous' or 'Truncated' and the PuncturePatternSource property to 'Property'.

Data Types: double

NumFrames — Number of independent frames

1 (default) | integer

Number of independent frames present in the input and output data vectors, specified as an integer.

The object segments the input vector into NumFrames segments and encodes them independently. The output contains NumFrames encoded segments.

Dependencies

To enable this property, set the TerminationMethod property to 'Truncated' or 'Terminated'.

Data Types: double

Usage

Syntax

```
codeword = gpuConvEncoder(message)
```

Description

`codeword = gpuConvEncoder(message)` convolutionally encodes the input message specified by the trellis structure by using the GPU on your computer. If no GPU is available, the convolutional encoding processing is performed in the central processing unit (CPU). For more about GPUs, see “GPU Computing” (Parallel Computing Toolbox). The output is the encoded codeword.

Input Arguments

message — Input message

binary-valued column vector

Input message, specified as a binary-valued column vector.

Data Types: `double` | `single` | `logical`

Output Arguments

codeword — Convolutionally encoded message

binary-valued column vector

Convolutionally encoded message, returned as a binary-valued column vector. This output vector has the same data type and orientation as input `message`.

When the convolutional encoder represents a rate K/N code, the length of the input vector equals $K \times L$ for some positive integer L . The object sets the length of this output vector to $L \times N$.

Data Types: `double` | `single` | `logical`

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Common to All System Objects

<code>step</code>	Run System object algorithm
<code>release</code>	Release resources and allow changes to System object property values and input characteristics
<code>reset</code>	Reset internal states of System object

Examples

GPU-Based Convolutionally Encode and Viterbi Decode 8-PSK Modulated Data

Create a GPU-based convolutional encoder System object.

```
conEnc = comm.gpu.ConvolutionalEncoder;
```

Create a GPU-based phase shift keying (PSK) modulator System object that accepts a bit input signal.

```
modPSK = comm.gpu.PSKModulator('BitInput',true);
```

Create a GPU-based additive white Gaussian noise (AWGN) channel System object with a signal-to-noise ratio of seven.

```
chan = comm.gpu.AWGNChannel('NoiseMethod','Signal to noise ratio (SNR)','SNR',7);
```

Create a GPU-based PSK demodulator System object that outputs a column vector of bit values.

```
demodPSK = comm.gpu.PSKDemodulator('BitOutput',true);
```

Create a GPU-based Viterbi decoder System object that accepts an input vector of hard decision values, which are zeros or ones.

```
vDec = comm.gpu.ViterbiDecoder('InputFormat','Hard');
```

Create an error rate System object that ignores 3 data samples before making comparisons. The received data lags behind the transmitted data by 34 samples.

```
error = comm.ErrorRate('ComputationDelay',3,'ReceiveDelay',34);
```

Run the simulation by using this for loop to process data.

```
for counter = 1:20
    data = randi([0 1],30,1);
    encodedData = conEnc(gpuArray(data));
    modSignal = modPSK(encodedData);
    receivedSignal = chan(modSignal);
    demodSignal = demodPSK(receivedSignal);
    receivedBits = vDec(demodSignal);
    errors = error(data,gather(receivedBits));
end
```

Display the number of errors.

```
errors(2)
```

```
ans = 1
```

Permute input symbols using shift registers with GPU

Note To use this object, you must install Parallel Computing Toolbox™ and have access to an appropriate GPU. For more about GPUs, see “GPU Computing” (Parallel Computing Toolbox).

Description

The `comm.gpu.ConvolutionalInterleaver` System object permutes the symbols in the input sequence with a graphics processing unit (GPU).

A GPU-based System object accepts typical MATLAB arrays or objects created using the `gpuArray` class. The output signal inherits its data type from the input signal.

- If the input signal is a MATLAB array, the System object handles data transfer between the CPU and the GPU. The output signal is a MATLAB array.
- If the input signal is a `gpuArray`, the data remains on the GPU. The output signal is a `gpuArray`. When the object is given a `gpuArray`, calculations take place entirely on the GPU, and no data transfer occurs. Passing `gpuArray` arguments provides increased performance by reducing simulation time. For more information, see “Establish Arrays on a GPU” (Parallel Computing Toolbox).

To permute the symbols in the input sequence with GPU:

- 1 Create the `comm.gpu.ConvolutionalInterleaver` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

Creation

Syntax

```
intrlvr = comm.gpu.ConvolutionalInterleaver  
intrlvr = comm.gpu.ConvolutionalInterleaver(Name=Value)  
intrlvr = comm.gpu.ConvolutionalInterleaver(m,b,ic)
```

Description

`intrlvr = comm.gpu.ConvolutionalInterleaver` creates a GPU-based convolutional interleaver System object.

`intrlvr = comm.gpu.ConvolutionalInterleaver(Name=Value)` sets “Properties” on page 3-657 using one or more name-value arguments. For example, `NumRegisters=10` specifies the number of internal shift registers.

`intrlvr = comm.gpu.ConvolutionalInterleaver(m,b,ic)` sets the `NumRegisters` property to `m`, the `RegisterLengthStep` property to `b`, and the `InitialConditions` property to `ic`.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see *System Design in MATLAB Using System Objects*.

NumRegisters — Number of internal shift registers

6 (default) | positive integer

Number of internal shift registers, specified as a positive integer.

Data Types: double

RegisterLengthStep — Number of additional symbols that fit in each successive shift register

2 (default) | positive integer

Number of additional symbols that fit in each successive shift register, specified as a positive integer. The first register holds zero symbols.

Data Types: double

InitialConditions — Initial conditions of shift registers

0 (default) | numeric scalar | column vector

Initial conditions of the shift registers, specified as one of these values.

- Scalar — All shift registers, except the first one, store the same specified value.
- Column vector — If the length of the column vector equals the value of the `NumRegisters` property, then the *i*th shift register stores the *i*th element of the specified vector.

You do not need to specify a value for the first shift register, which has zero delay. Because the first shift register has zero delay, the object ignores the first element of this property.

Data Types: double

Usage

Syntax

```
intrlvseq = intrlvr(inputseq)
```

Description

`intrlvseq = intrlvr(inputseq)` permutes the input sequence of symbols `inputseq` by using a set of shift registers. If the host computer has a GPU configured, processing uses the GPU. Otherwise, processing uses the CPU. The output is the interleaved sequence.

The object consists of N registers, each with a specified delay. N is the total number of shift registers. The object sets the delay value of the k th shift register to $((k-1) \times \text{RegisterLengthStep})$. With each new input symbol, the System object switches the commutator to a new register and shifts in the new symbol while shifting out the oldest symbol in that register. When the commutator reaches the N th register, upon the next new input, the commutator returns to the first register.

Input Arguments

inputseq — Sequence of symbols

column vector

Sequence of symbols, specified as a column vector.

Data Types: `double` | `single` | `uint32` | `int32` | `logical`

Output Arguments

intrlvseq — Interleaved sequence of symbols

column vector

Interleaved sequence of symbols, returned as a column vector with the same data type and size as the `inputseq` input.

Data Types: `double` | `single` | `uint32` | `int32` | `logical`

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Common to All System Objects

<code>step</code>	Run System object algorithm
<code>release</code>	Release resources and allow changes to System object property values and input characteristics
<code>reset</code>	Reset internal states of System object

Examples

GPU-Based Convolutionally Interleave and Deinterleave Sequence

Create a GPU-based convolutional interleaver System object™.

```
intrlvr = comm.gpu.ConvolutionalInterleaver('NumRegisters',2, ...  
                                           'RegisterLengthStep',3);
```

Create a GPU-based convolutional deinterleaver System object™.

```
deintrlvr = comm.gpu.ConvolutionalDeinterleaver('NumRegisters',2, ...  
                                                'RegisterLengthStep',3);
```

Generate a random data sequence. Pass the data sequence through the interleaver and then the deinterleaver.

```
data = (0:20)';
intrlvData = intrlvr(data);
deintrlvData = deintrlvr(intrlvData);
```

Display the original sequence, interleaved sequence, and restored sequence.

```
[data intrlvData deintrlvData]
```

```
ans = 21×3
```

```

0     0     0
1     0     0
2     2     0
3     0     0
4     4     0
5     0     0
6     6     0
7     1     1
8     8     2
9     3     3
:

```

The delay through the interleaver and deinterleaver pair is equal to the product of the `NumRegisters` and `RegisterLengthStep` properties.

```
intrlvDelay = intrlvr.NumRegisters * intrlvr.RegisterLengthStep
```

```
intrlvDelay = 6
```

After accounting for this delay, verify that the original and deinterleaved data are identical.

```
numSymErrors = symerr(data(1:end-intrlvDelay), ...
                      deintrlvData(1+intrlvDelay:end))
```

```
numSymErrors = 0
```

Extended Capabilities

comm.gpu.ConvolutionalDeinterleaver

Package: comm

Deinterleave symbols using set of shift registers with GPU

Note To use this object, you must install Parallel Computing Toolbox™ and have access to an appropriate GPU. For more about GPUs, see “GPU Computing” (Parallel Computing Toolbox).

Description

The `comm.gpu.ConvolutionalDeinterleaver` System object deinterleaves the symbols in the input sequence with a graphics processing unit (GPU).

A GPU-based System object accepts typical MATLAB arrays or objects created using the `gpuArray` class. The output signal inherits its data type from the input signal.

- If the input signal is a MATLAB array, the System object handles data transfer between the CPU and the GPU. The output signal is a MATLAB array.
- If the input signal is a `gpuArray`, the data remains on the GPU. The output signal is a `gpuArray`. When the object is given a `gpuArray`, calculations take place entirely on the GPU, and no data transfer occurs. Passing `gpuArray` arguments provides increased performance by reducing simulation time. For more information, see “Establish Arrays on a GPU” (Parallel Computing Toolbox).

To deinterleave the symbols in the input sequence with GPU:

- 1 Create the `comm.gpu.ConvolutionalDeinterleaver` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

Creation

Syntax

```
deintrlvr = comm.gpu.ConvolutionalDeinterleaver
deintrlvr = comm.gpu.ConvolutionalDeinterleaver(Name=Value)
intrlvr = comm.gpu.ConvolutionalDeinterleaver(m,b,ic)
```

Description

`deintrlvr = comm.gpu.ConvolutionalDeinterleaver` creates a default convolutional deinterleaver System object.

`deintrlvr = comm.gpu.ConvolutionalDeinterleaver(Name=Value)` sets “Properties” on page 3-662 using one or more name-value arguments. For example, `NumRegisters=10` specifies the number of internal shift registers.

`intrlvr = comm.gpu.ConvolutionalDeinterleaver(m,b,ic)` sets the `NumRegisters` property to `m`, the `RegisterLengthStep` property to `b`, and the `InitialConditions` property to `ic`.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see *System Design in MATLAB Using System Objects*.

NumRegisters — Number of internal shift registers

6 (default) | positive integer

Number of internal shift registers, specified as a positive integer.

Data Types: `double`

RegisterLengthStep — Number of additional symbols that fit in each successive shift register

2 (default) | positive integer

Number of additional symbols that fit in each successive shift register, specified as a positive integer. The first register holds zero symbols.

Data Types: `double`

InitialConditions — Initial conditions of shift registers

0 (default) | numeric scalar | column vector

Initial conditions of the shift registers, specified as one of these values.

- Scalar — All shift registers, except the last one, store the same specified value.
- Column vector — If the length of the column vector equals the value of the `NumRegisters` property, then the i th shift register stores the $(N-i+1)$ th element of the specified vector. N is the total number of shift registers.

You do not need to specify a value for the first shift register, which has zero delay. Because the first shift register has zero delay, the object ignores the first element of this property.

Data Types: `double`

Usage

Syntax

```
deintrlvseq = deintrlvr(intrlvseq)
```

Description

`deintrlvseq = deintrlvr(intrlvseq)` deinterleaves the input sequence of symbols `inputseq` by using a set of shift registers. If the host computer has a GPU configured, processing uses the GPU. Otherwise, processing uses the CPU. The output is the deinterleaved sequence.

The object consists of N registers, each with a specified delay. N is the total number of shift registers. The object sets the delay value of the k th shift register to $((k-1) \times \text{RegisterLengthStep})$. With each new input symbol, the System object switches the commutator to a new register and shifts in the new symbol while shifting out the oldest symbol in that register. When the commutator reaches the N th register, upon the next new input, the commutator returns to the first register.

Input Arguments

intrlvseq — Interleaved sequence of symbols

column vector

Interleaved sequence of symbols, specified as a column vector. This sequence must be one that was interleaved using the `comm.gpu.ConvolutionalInterleaver` System object or `comm.ConvolutionalInterleaver` System object.

Data Types: `double` | `single` | `uint32` | `int32`

Output Arguments

deintrlvseq — Deinterleaved sequence of symbols

column vector

Deinterleaved sequence of symbols, returned as a column vector with the same data type and size as the `intrlvseq` argument.

Data Types: `double` | `single` | `uint32` | `int32`

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Common to All System Objects

<code>step</code>	Run System object algorithm
<code>release</code>	Release resources and allow changes to System object property values and input characteristics
<code>reset</code>	Reset internal states of System object

Examples

GPU-Based Convolutionally Interleave and Deinterleave Sequence

Create a GPU-based convolutional interleaver System object™.

```
intrlvr = comm.gpu.ConvolutionalInterleaver('NumRegisters',2, ...  
                                           'RegisterLengthStep',3);
```

Create a GPU-based convolutional deinterleaver System object™.

```
deintrlvr = comm.gpu.ConvolutionalDeinterleaver('NumRegisters',2, ...  
                                                'RegisterLengthStep',3);
```

Generate a random data sequence. Pass the data sequence through the interleaver and then the deinterleaver.

```
data = (0:20)';  
intrlvData = intrlvr(data);  
deintrlvData = deintrlvr(intrlvData);
```

Display the original sequence, interleaved sequence, and restored sequence.

```
[data intrlvData deintrlvData]
```

```
ans = 21×3
```

```
    0     0     0  
    1     0     0  
    2     2     0  
    3     0     0  
    4     4     0  
    5     0     0  
    6     6     0  
    7     1     1  
    8     8     2  
    9     3     3  
    :
```

The delay through the interleaver and deinterleaver pair is equal to the product of the NumRegisters and RegisterLengthStep properties.

```
intrlvDelay = intrlvr.NumRegisters * intrlvr.RegisterLengthStep
```

```
intrlvDelay = 6
```

After accounting for this delay, verify that the original and deinterleaved data are identical.

```
numSymErrors = symerr(data(1:end-intrlvDelay), ...  
                      deintrlvData(1+intrlvDelay:end))
```

```
numSymErrors = 0
```

comm.gpu.LDPCDecoder

Package: comm

Decode binary low-density parity-check (LDPC) code with GPU

Note To use this object, you must install Parallel Computing Toolbox™ and have access to an appropriate GPU. For more about GPUs, see “GPU Computing” (Parallel Computing Toolbox).

Description

A GPU-based System object accepts typical MATLAB arrays or objects created using the `gpuArray` class. A GPU-based System object supports input signals with double- or single-precision data types. The output signal inherits its data type from the input signal.

- If the input signal is a MATLAB array, the System object handles data transfer between the CPU and the GPU. The output signal is a MATLAB array.
- If the input signal is a `gpuArray`, the data remains on the GPU. The output signal is a `gpuArray`. When the object is given a `gpuArray`, calculations take place entirely on the GPU, and no data transfer occurs. Passing `gpuArray` arguments provides increased performance by reducing simulation time. For more information, see “Establish Arrays on a GPU” (Parallel Computing Toolbox).

The `comm.gpu.LDPCDecoder` System object uses the belief propagation algorithm to decode a binary LDPC code, which is input to the object as the soft-decision output (log-likelihood ratio of received bits) from demodulation. The object decodes generic binary LDPC codes where no patterns in the parity-check matrix are assumed. For more information, see “Belief Propagation Decoding” on page 3-672.

To decode an LDPC-encoded signal:

- 1 Create the `comm.gpu.LDPCDecoder` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

Creation

Syntax

```
gpu_ldpcdecoder = comm.gpu.LDPCDecoder
gpu_ldpcdecoder = comm.gpu.LDPCDecoder(parity)
gpu_ldpcdecoder = comm.gpu.LDPCDecoder( ___,Name,Value)
```

Description

`gpu_ldpcdecoder = comm.gpu.LDPCDecoder` creates a GPU-based binary LDPC decoder System object. This object performs LDPC decoding based on the specified parity-check matrix.

`gpu_ldpcdecoder = comm.gpu.LDPCDecoder(parity)` sets the `ParityCheckMatrix` property to `parity` and creates a GPU-based LDPC decoder System object. The `parity` input must be specified as described by the `ParityCheckMatrix` property.

`gpu_ldpcdecoder = comm.gpu.LDPCDecoder(___, Name, Value)` sets properties using one or more name-value pairs, in addition to inputs from any of the prior syntaxes. For example, `comm.LDPCDecoder('DecisionMethod','Soft decision')` configures an LDPC decoder System object to decode data using the soft-decision method and output log-likelihood ratios of data type `double`. Enclose each property name in quotes.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects.

ParityCheckMatrix — Parity-check matrix

`dvbs2ldpc(1/2)` (default) | sparse binary matrix | nonsparse index matrix

Parity-check matrix, specified as a sparse $(N - K)$ -by- N binary-valued matrix. N is the length of the received signal and must be in the range $(0, 2^{31})$. K is the length of the uncoded message and must be less than N . The last $(N - K)$ columns in the parity-check matrix must be an invertible matrix in the Galois field of order 2, `gf(2)`.

You can also specify the parity-check matrix as a two-column nonsparse index matrix, `I`, that defines the row and column indices of the 1s in the parity-check matrix such that `sparse(I(:,1),I(:,2),1)`.

This property accepts numeric data types. When you set this property to a sparse binary matrix, this property also accepts the `logical` data type.

The default value uses the `dvbs2ldpc` function to configure a sparse parity-check matrix for half-rate LDPC coding, as specified in the DVB-S.2 standard.

Example: `dvbs2ldpc(R,'indices')` configures the index matrix for the DVB-S.2 standard, where `R` is the code rate, and `'indices'` specifies the output format of `dvbs2ldpc` as a two-column double-precision matrix that defines the row and column indices of the 1s in the parity-check matrix.

Data Types: `double` | `logical`

OutputValue — Output value format

`'Information part'` (default) | `'Whole codeword'`

Output value format, specified as one of these values:

- `'Information part'` — The object outputs a K -by-1 column vector containing only the information-part of the received log-likelihood ratio vector. K is the length of the uncoded message.
- `'Whole codeword'` — The object outputs an N -by-1 column vector containing the whole log-likelihood ratio vector. N is the length of the received signal.

N and K must align with the dimension of the $(N-K)$ -by- K parity-check matrix.

Data Types: char

DecisionMethod — Decision method

'Hard decision' (default) | 'Soft decision'

Decision method used for decoding, specified as one of these values:

- 'Hard decision' — The object outputs decoded data of data type `logical`.
- 'Soft decision' — The object outputs log-likelihood ratios of data type `double`.

Data Types: char

IterationTerminationCondition — Condition for iteration termination

'Maximum iteration count' (default) | 'Parity check satisfied'

Condition for iteration termination, specified as one of these values:

- 'Maximum iteration count' — Decoding terminates after the number of iterations specified by the `MaximumIterationCount` property.
- 'Parity check satisfied' — Decoding terminates after all parity checks are satisfied. If not all parity checks are satisfied, decoding terminates after the number of iterations specified by the `MaximumIterationCount` property.

Data Types: char

MaximumIterationCount — Maximum number of decoding iterations

50 (default) | positive integer

Maximum number of decoding iterations, specified as a positive integer.

Data Types: double

NumIterationsOutputPort — Output number of iterations performed

false (default) | true

Output number of iterations executed, specified as `false` or `true`. To output the number of iterations executed, set this property to `true`.

Data Types: `logical`

FinalParityChecksOutputPort — Output final parity checks

false (default) | true

Output final parity checks, specified as `false` or `true`. To output the final calculated parity checks, set this property to `true`.

Data Types: `logical`

Usage**Syntax**

`y = gpu_ldpcdecoder(x)`

```
[y,numiter] = gpu_ldpcdecoder(x)
[y,parity] = gpu_ldpcdecoder(x)
[y,numiter,parity] = gpu_ldpcdecoder(x)
```

Description

`y = gpu_ldpcdecoder(x)` decodes input data using an LDPC code based on the default parity-check matrix.

`[y,numiter] = gpu_ldpcdecoder(x)` returns the decoded data, `y`, and number of iterations performed, `numiter`. To use this syntax, set the `NumIterationsOutputPort` property to `true`.

`[y,parity] = gpu_ldpcdecoder(x)` returns the decoded data, `y`, and final parity checks, `parity`. To use this syntax, set the `FinalParityChecksOutputPort` property to `true`.

`[y,numiter,parity] = gpu_ldpcdecoder(x)` returns the decoded data, number of iterations performed, and final parity checks. To use this syntax, set the `NumIterationsOutputPort` and `FinalParityChecksOutputPort` properties to `true`.

Input Arguments

x — Log-likelihood ratios

column vector

Log-likelihood ratios, specified as an N -by-1 column vector containing the soft-decision output from demodulation. N is the number of bits in the LDPC codeword before modulation. Each element is the log-likelihood ratio for a received bit. Element values are more likely to be 0 if the log-likelihood ratio is positive. The first K elements correspond to the information-part of the input message.

Data Types: `double`

Output Arguments

y — Decoded data

column vector

Decoded data, returned as a column vector. The `DecisionMethod` property specifies whether the object outputs hard decisions or soft decisions (log-likelihood ratios).

- If the `OutputValue` property is set to `'Information part'`, the output includes only the information-part of the received log-likelihood ratio vector.
- If the `OutputValue` property is set to `'Whole codeword'`, the output includes the whole log-likelihood ratio vector.

Data Types: `double` | `logical`

numiter — Number of executed decoding iterations

positive integer

Number of executed decoding iterations, returned as a positive integer.

Dependencies

To enable this output, set the `NumIterationsOutputPort` property to `true`.

parity — Final parity checks

column vector

Final parity checks after decoding the input LDPC code, returned as an $(N-K)$ -by-1 column vector. N is the number of bits in the LDPC codeword before modulation. K is the length of the uncoded message.

Dependencies

To enable this output, set the `FinalParityChecksOutputPort` property to `true`.

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Common to All System Objects

<code>step</code>	Run System object algorithm
<code>release</code>	Release resources and allow changes to System object property values and input characteristics
<code>reset</code>	Reset internal states of System object

Examples

LDPC Encode and Decode QPSK-Modulated Signal Using GPU

Using a `comm.gpu.LDPCDecoder` System Object™ to decode the signal, transmit an LDPC-encoded, QPSK-modulated bit stream through an AWGN channel. After adding AWGN, demodulate and decode the received signal. Compute the error statistics for the reception of uncoded and LDPC-coded signals. For more information, see “Simulation Acceleration Using GPUs”.

Define simulation variables. Create an LDPC encoder configuration object and System objects for the LDPC decoder, QPSK modulator, and QPSK demodulators.

```
M = 4; % Modulation order (QPSK)
snr = [0.25,0.5,0.75,1.0,1.25];
numFrames = 10;
gpuLdpcDecoder = comm.gpu.LDPCDecoder;
encoderCfg = ldpcEncoderConfig(gpuLdpcDecoder.ParityCheckMatrix);
pskMod = comm.PSKModulator(M,'BitInput',true);
pskDemod = comm.PSKDemodulator(M,'BitOutput',true,...
    'DecisionMethod','Approximate log-likelihood ratio');
pskuDemod = comm.PSKDemodulator(M,'BitOutput',true,...
    'DecisionMethod','Hard decision');
errRate = zeros(1,length(snr));
uncErrRate = zeros(1,length(snr));
```

For each SNR setting and all frames, compute the error statistics for uncoded and LDPC-coded signals.

```
for ii = 1:length(snr)
    ttlErr = 0;
```

```

ttlErrUnc = 0;
pskDemod.Variance = 1/10^(snr(ii)/10); % Set variance using current SNR
for counter = 1:numFrames
    data = logical(randi([0 1],32400,1));
    % Transmit and receiver uncoded signal data
    mod_uncSig = pskMod(data);
    rx_uncSig = awgn(mod_uncSig,snr(ii), 'measured');
    demod_uncSig = pskuDemod(rx_uncSig);
    numErrUnc = biterr(data,demod_uncSig);
    ttlErrUnc = ttlErrUnc + numErrUnc;
    % Transmit and receive LDPC coded signal data
    encData = ldpcEncode(data,encoderCfg);
    modSig = pskMod(encData);
    rxSig = awgn(modSig,snr(ii), 'measured');
    demodSig = pskDemod(rxSig);
    rxBits = gpuldpcDecoder(demodSig);
    numErr = biterr(data,rxBits);
    ttlErr = ttlErr + numErr;
end
ttlBits = numFrames*length(rxBits);
uncErrRate(ii) = ttlErrUnc/ttlBits;
errRate(ii) = ttlErr/ttlBits;
end

```

Plot the error statistics for uncoded and LDPC-coded data.

```

plot(snr,uncErrRate,snr,errRate)
legend('Uncoded','LDPC coded')
xlabel('SNR (dB)')
ylabel('BER')

```

Algorithms

This object performs LDPC decoding using the belief propagation algorithm, also known as a message-passing algorithm.

Belief Propagation Decoding

The implementation of the belief propagation algorithm is based on the decoding algorithm presented by Gallager [2].

For transmitted LDPC-encoded codeword $c = c_0, c_1, \dots, c_{n-1}$, the input to the LDPC decoder is the log-likelihood ratio (LLR) value $L(c_i) = \log\left(\frac{\Pr(c_i = 0 \mid \text{channel output for } c_i)}{\Pr(c_i = 1 \mid \text{channel output for } c_i)}\right)$.

In each iteration, the key components of the algorithm are updated based on these equations:

$$L(r_{ji}) = 2 \operatorname{atanh} \left(\prod_{i' \in \mathcal{V}_{j,i}} \tanh \left(\frac{1}{2} L(q_{i'j}) \right) \right),$$

$L(q_{ij}) = L(c_i) + \sum_{j \in C_i \setminus i} L(r_{ji})$, initialized as $L(q_{ij}) = L(c_i)$ before the first iteration, and

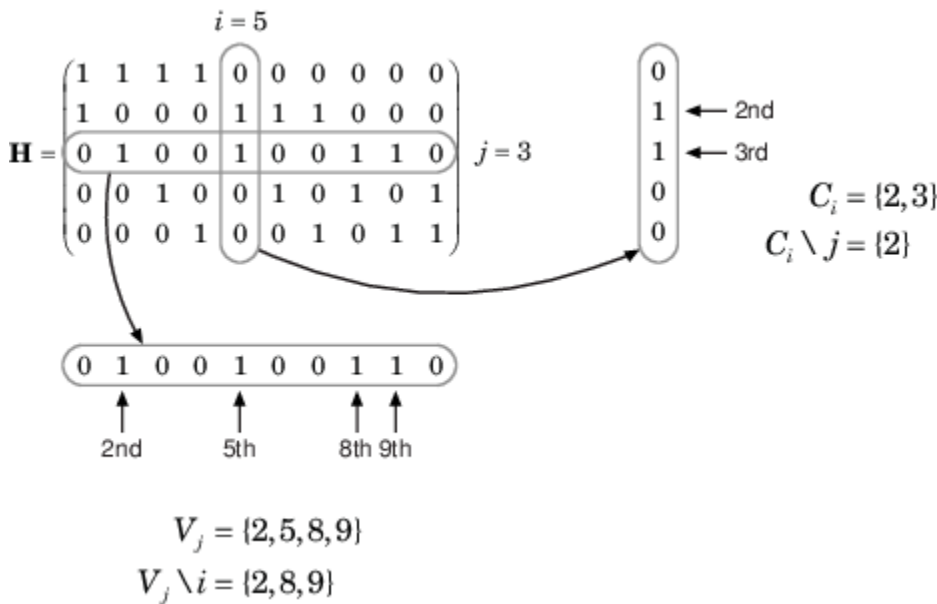

$$L(Q_i) = L(c_i) + \sum_{j \in C_i} L(r_{ji}).$$

At the end of each iteration, $L(Q_i)$ contains the updated estimate of the LLR value for transmitted bit c_i . The value $L(Q_i)$ is the soft-decision output for c_i . If $L(Q_i) < 0$, the hard-decision output for c_i is 1. Otherwise, the hard-decision output for c_i is 0.

If decoding is configured to stop when all of the parity checks are satisfied, the algorithm verifies the parity-check equation ($Hc' = 0$) at the end of each iteration. When all of the parity checks are satisfied, or if the maximum number of iterations is reached, decoding stops.

Index sets $C_i \setminus j$ and $V_j \setminus i$ are based on the parity-check matrix (PCM). Index sets C_i and V_j correspond to all nonzero elements in column i and row j of the PCM, respectively.

This figure shows the computation of these index sets in a given PCM for $i = 5$ and $j = 3$.

To avoid infinite numbers in the algorithm equations, $\operatorname{atanh}(1)$ and $\operatorname{atanh}(-1)$ are set to 19.07 and -19.07 , respectively. Due to finite precision, MATLAB returns 1 for $\tanh(19.07)$ and -1 for $\tanh(-19.07)$.

comm.gpu.PSKDemodulator

Package: comm

Demodulate using M-ary PSK method with GPU

Description

The GPU `PSKDemodulator` object demodulates an input signal using the M-ary phase shift keying (M-PSK) method.

Note To use this object, you must install a Parallel Computing Toolbox license and have access to an appropriate GPU. For more about GPUs, see “GPU Computing” (Parallel Computing Toolbox).

A GPU-based System object accepts typical MATLAB arrays or objects created using the `gpuArray` class. A GPU-based System object supports input signals with double- or single-precision data types. The output signal inherits its data type from the input signal.

- If the input signal is a MATLAB array, the System object handles data transfer between the CPU and the GPU. The output signal is a MATLAB array.
- If the input signal is a `gpuArray`, the data remains on the GPU. The output signal is a `gpuArray`. When the object is given a `gpuArray`, calculations take place entirely on the GPU, and no data transfer occurs. Passing `gpuArray` arguments provides increased performance by reducing simulation time. For more information, see “Establish Arrays on a GPU” (Parallel Computing Toolbox).

To demodulate a signal that was modulated using phase shift keying:

- 1 Define and set up your PSK demodulator object. See “Construction” on page 3-675.
- 2 Call `step` to demodulate the signal according to the properties of `comm.gpu.PSKDemodulator`. The behavior of `step` is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj, x)` and `y = obj(x)` perform equivalent operations.

Construction

`H = comm.gpu.PSKDemodulator` returns a GPU-based demodulator System object, `H`. This object demodulates the input signal using the M-ary phase shift keying (M-PSK) method.

`H = comm.gpu.PSKDemodulator(Name, Value)` creates a GPU-based M-PSK demodulator object, `H`, with the specified property set to the specified value. You can specify additional name-value pair arguments in any order as `(Name1, Value1, ..., NameN, ValueN)`

`H = comm.gpu.PSKDemodulator(M, PHASE, Name, Value)` creates a GPU-based M-PSK demodulator object, `H`, with the `ModulationOrder` property set to `M`, the `PhaseOffset` property set to `PHASE` and other specified property names set to the specified values. `M` and `PHASE` are value-only

arguments. To specify a value-only argument, you must also specify all preceding value-only arguments. You can specify name-value pair arguments in any order.

Properties

ModulationOrder

Number of points in signal constellation

Specify the number of points in the signal constellation as a positive, integer scalar. The default is 8.

PhaseOffset

Phase of zeroth point of constellation

Specify the phase offset of the zeroth point of the constellation, in radians, as a real scalar. The default is $\pi/8$.

BitOutput

Output data as bits

Specify whether the output consists of groups of bits or integer symbol values. When you set this property to true, the step method outputs a column vector of bit values with length equal to $\log_2(\text{ModulationOrder})$ times the number of demodulated symbols. When you set this property to false, the step method outputs a column vector, with a length equal to the input data vector that contains integer symbol values between 0 and ModulationOrder-1. The default is false.

SymbolMapping

Constellation encoding

Specify how the object maps an integer or group of $\log_2(\text{ModulationOrder})$ bits to the corresponding symbol as Binary | Gray | Custom. The default is Gray. When you set this property to Gray, the object uses a Gray-encoded signal constellation. When you set this property to Binary, the integer m ($0 \leq m \leq \text{ModulationOrder}-1$) maps to the complex value. This value is represented as $\exp(j*\text{PhaseOffset} + j*2*\pi*m/\text{ModulationOrder})$. When you set this property to Custom, the object uses the signal constellation defined in the CustomSymbolMapping property.

CustomSymbolMapping

Custom constellation encoding

Specify a custom constellation symbol mapping vector. The default is 0:7. This property must be a row or column vector of size ModulationOrder with unique integer values in the range [0, ModulationOrder-1]. The values must be of data type double. The first element of this vector corresponds to the constellation point at an angle of $0 + \text{PhaseOffset}$, with subsequent elements running counterclockwise. The last element corresponds to the constellation point at an angle of $-2\pi/\text{ModulationOrder} + \text{PhaseOffset}$. This property applies when you set the SymbolMapping property to Custom.

DecisionMethod

Demodulation decision method

Specify the decision method that the object uses as one of `Hard decision` | `Log-likelihood ratio` | `Approximate log-likelihood ratio`. The default is `Hard decision`. When you set `DecisionMethod` to `false`, the object always performs hard decision demodulation. This property applies when you set the `BitOutput` property to `true`.

VarianceSource

Source of noise variance

Specify the source of the noise variance as one of `Property` | `Input port`. The default is `Property`. This property applies when you set the `BitOutput` property to `true` and the `DecisionMethod` property to `Log-likelihood ratio` or `Approximate log-likelihood ratio`.

Variance

Specify the variance of the noise as a positive, real scalar. The default is `1`. If this value is very small (i.e., SNR is very high), then log-likelihood ratio (LLR) computations may yield `Inf` or `-Inf`. This occurs because the LLR algorithm computes the exponential value of very large or very small numbers using finite precision arithmetic. In such cases, use approximate LLR is recommended because its algorithm does not compute exponentials. This property applies when you set the `BitOutput` property to `true`, the `DecisionMethod` property to `Log-likelihood ratio` or `Approximate log-likelihood ratio`, and the `VarianceSource` property to `Property`. This property is tunable.

OutputDataType

Data type of output

When you set this property to `Full precision`, the output signal inherits its data type from the input signal.

Methods

`constellation` Calculate or plot ideal signal constellation
`step` Demodulate using M-ary PSK method

Common to All System Objects	
<code>release</code>	Allow System object property value changes

Algorithm

The GPU PSK Demodulator System object uses the same algorithm as the `comm.PSKDemodulator` System object. See `Decoding Algorithm` for details.

Examples

Transmit an LDPC-encoded, QPSK-modulated bit stream through an AWGN channel. Then demodulate, decode, and count errors.

16-PSK Modulation and Demodulation

Transmit an LDPC-encoded, QPSK-modulated bit stream through an AWGN channel.

Create a GPU-based PSK Modulator System object.

```
hMod = comm.gpu.PSKModulator(16, 'PhaseOffset',pi/16);
```

Create a GPU-based AWGN Channel System object with a signal-to-noise ratio of 15.

```
hAWGN = comm.gpu.AWGNChannel('NoiseMethod', ...  
    'Signal to noise ratio (SNR)', 'SNR',15);
```

Create a GPU-based PSK Demodulator System object.

```
hDemod = comm.gpu.PSKDemodulator(16, 'PhaseOffset',pi/16);
```

Create an error rate calculator System object.

```
hError = comm.ErrorRate;
```

Transmit a frame of data containing 50 symbols.

```
for counter = 1:100  
data = gpuArray.randi([0 hMod.ModulationOrder-1], 50, 1);
```

Run the simulation by using the step method to process data.

```
modSignal = step(hMod, data);  
noisySignal = step(hAWGN, modSignal);  
receivedData = step(hDemod, noisySignal);  
errorStats = step(hError, gather(data), gather(receivedData));  
end
```

Compute the error rate results.

```
fprintf('Error rate = %f\nNumber of errors = %d\n', ...  
    errorStats(1), errorStats(2))
```

GPU PSK Demodulator

Create GPU PSK modulator and demodulator pair.

```
gpuMod = comm.gpu.PSKModulator;  
gpuDemod = comm.gpu.PSKDemodulator;
```

Generate random data symbols. Modulate the data.

```
txData = randi([0 7],1000,1);  
txSig = gpuMod(txData);
```

Pass the signal through an AWGN channel.

```
rxSig = awgn(txSig,20);
```

Demodulate the received signal.

```
rxData = gpuDemod(rxSig);
```

Determine the number of symbol errors.

```
numSymErrors = symerr(txData,rxData)
```

```
numSymErrors =
```

`comm.PSKDemodulator` | `comm.gpu.PSKModulator`

Introduced in R2012a

constellation

Calculate or plot ideal signal constellation

Syntax

```
y = constellation(h)  
constellation(h)
```

Description

`y = constellation(h)` returns the numerical values of the constellation.

`constellation(h)` generates a constellation plot for the object.

Examples

Calculate Ideal Signal Constellation for `comm.gpu.PSKDemodulator`

Create a `comm.gpu.PSKDemodulator` System object, and then calculate its ideal signal constellation.

Create a `comm.gpu.PSKDemodulator` System object by entering the following at the MATLAB command line:

```
h = comm.gpu.PSKDemodulator
```

Calculate and display the ideal signal constellation by calling the `constellation` method.

```
a = constellation(h)
```

Plot Ideal Signal Constellation for `comm.gpu.PSKDemodulator`

Create a `comm.gpu.PSKDemodulator` System object, and then plot the ideal signal constellation.

Create a `comm.gpu.PSKDemodulator` System object by entering the following at the MATLAB command line:

```
h = comm.gpu.PSKDemodulator
```

Plot the ideal signal constellation by calling the `constellation` method.

```
constellation(h)
```

step

Demodulate using M-ary PSK method

Syntax

```
Y = step(H,X)
Y = step(H,X,VAR)
```

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(H,X)` demodulates data, `X`, with the GPU PSK Demodulator System object, `H`, and returns `Y`. Input `X` must be a scalar or a column vector with double- or single- precision data type. Depending on the `BitOutput` property value, output `Y` can be integer or bit valued.

`Y = step(H,X,VAR)` uses soft decision demodulation and noise variance `VAR`. This syntax applies when you set the `BitOutput` property to `true`, the `DecisionMethod` property to `Approximate log-likelihood ratio` or `Log-likelihood ratio`, and the `VarianceSource` property to `Input port`. The data type of input `VAR` must be double or single precision.

Note `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications. For more information on changing property values, see “System Design in MATLAB Using System Objects”.

comm.gpu.PSKModulator

Package: comm

Modulate using M-ary PSK method with GPU

Description

The GPU `PSKModulator` object modulates a signal using the M-ary phase shift keying method implemented on a graphics processing unit (GPU). The input is a baseband representation of the modulated signal. The input and output for this object are discrete-time signals. This object accepts a scalar-valued or column vector input signal.

Note To use this object, you must install a Parallel Computing Toolbox license and have access to an appropriate GPU. For more about GPUs, see “GPU Computing” (Parallel Computing Toolbox).

A GPU-based System object accepts typical MATLAB arrays or objects created using the `gpuArray` class. A GPU-based System object supports input signals with double- or single-precision data types. The output signal inherits its data type from the input signal.

- If the input signal is a MATLAB array, the System object handles data transfer between the CPU and the GPU. The output signal is a MATLAB array.
- If the input signal is a `gpuArray`, the data remains on the GPU. The output signal is a `gpuArray`. When the object is given a `gpuArray`, calculations take place entirely on the GPU, and no data transfer occurs. Passing `gpuArray` arguments provides increased performance by reducing simulation time. For more information, see “Establish Arrays on a GPU” (Parallel Computing Toolbox).

To modulate a signal using phase shift keying:

- 1 Define and set up your PSK modulator object. See “Construction” on page 3-682.
- 2 Call `step` to modulate the signal according to the properties of `comm.gpu.PSKModulator`. The behavior of `step` is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj, x)` and `y = obj(x)` perform equivalent operations.

Construction

`H = comm.gpu.PSKModulator` returns a GPU-based demodulator System object, `H`. This object modulates the input signal using the M-ary phase shift keying (M-PSK) method with soft decision using the approximate log-likelihood ratio algorithm.

`H = comm.gpu.PSKModulator(Name, Value)` creates a GPU-based M-PSK modulator object, `H`, with the specified property `Name` set to the specified `Value`. You can specify additional name-value pair arguments in any order as `(Name1, Value1, ..., NameN, ValueN)`

`H = comm.gpu.PSKModulator(M, PHASE, Name, Value)` creates a GPU-based M-PSK modulator object, `H`, with the `ModulationOrder` property set to `M`, the `PhaseOffset` property set to `PHASE` and other specified property `Names` set to the specified `Values`. `M` and `PHASE` are value-only arguments. To specify a value-only argument, you must also specify all preceding value-only arguments. You can specify name-value pair arguments in any order.

Properties

ModulationOrder

Number of points in signal constellation

Specify the number of points in the signal constellation as a positive, integer scalar. The default is 8.

PhaseOffset

Phase of zeroth point of constellation

Specify the phase offset of the zeroth point of the constellation, in radians, as a real scalar. The default is $\pi/8$.

BitInput

Assume bit inputs

Specify whether the input is bits or integers. The default is false. When you set this property to true, the step method input must be a column vector of bit values whose length is an integer multiple of $\log_2(\text{ModulationOrder})$. This vector contains bit representations of integers between 0 and $\text{ModulationOrder}-1$. The input data type can be numeric or logical. When you set the `BitInput` property to false, the step method input must be a column vector of integer symbol values between 0 and $\text{ModulationOrder}-1$. The data type of the input must be numeric.

SymbolMapping

Constellation encoding

Specify how the object maps an integer or group of $\log_2(\text{ModulationOrder})$ bits to the corresponding symbol as one of `Binary` | `Gray` | `Custom`. The default is `Gray`. When you set this property to `Gray`, the object uses a Gray-encoded signal constellation. When you set this property to `Binary`, the integer m ($0 \leq m \leq \text{ModulationOrder}-1$) maps to the complex value $\exp(j*\text{PhaseOffset} + j*2*\pi*m/\text{ModulationOrder})$. When you set this property to `Custom`, the object uses the signal constellation defined in the `CustomSymbolMapping` property.

CustomSymbolMapping

Custom constellation encoding

Specify a custom constellation symbol mapping vector. This property must be a row or column vector of size `ModulationOrder` with unique integer values in the range $[0, \text{ModulationOrder}-1]$. The values must be of data type double. The first element of this vector corresponds to the constellation point at an angle of $0 + \text{PhaseOffset}$, with subsequent elements running counterclockwise. The last element corresponds to the constellation point at an angle of $-2\pi/\text{ModulationOrder} + \text{PhaseOffset}$. This property applies when you set the `SymbolMapping` property to `Custom`. The default is `0:7`.

OutputDataType

Data type of output

Specify the output data type as one of `double` | `single`. The default is `double`.

Methods

<code>constellation</code>	Calculate or plot ideal signal constellation
<code>step</code>	Modulate using M-ary PSK method with GPU

Common to All System Objects	
<code>release</code>	Allow System object property value changes

Algorithm

The `GPU PSK Modulator System` object supports floating-point and integer input data types. This object uses the same algorithm as the `comm.PSKModulator System` object. See the Algorithms section of the `comm.PSKModulator` help page for details.

Examples

GPU PSK Modulator

Create binary data for 100, 4-bit symbols

```
data = randi([0 1],400,1);
```

Create a 16-PSK modulator System object with bits as inputs and Gray-coded signal constellation. Change the phase offset to $\pi/16$.

```
gpuMod = comm.gpu.PSKModulator(16,'BitInput',true);  
gpuMod.PhaseOffset = pi/16;
```

Modulate and plot the data

```
modData = gpuMod(data);  
scatterplot(modData)
```

constellation

Calculate or plot ideal signal constellation

Syntax

```
y = constellation(h)  
constellation(h)
```

Description

`y = constellation(h)` returns the numerical values of the constellation.

`constellation(h)` generates a constellation plot for the object.

Examples

Calculate Ideal Signal Constellation for `comm.gpu.PSKModulator`

Create a `comm.gpu.PSKModulator` System object, and then calculate its ideal signal constellation.

Create a `comm.gpu.PSKModulator` System object by entering the following at the MATLAB command line:

```
h = comm.gpu.PSKModulator
```

Calculate and display the ideal signal constellation by calling the `constellation` method.

```
a = constellation(h)
```

Plot Ideal Signal Constellation for `comm.gpu.PSKModulator`

Create a `comm.gpu.PSKModulator` System object, and then plot the ideal signal constellation.

Create a `comm.gpu.PSKModulator` System object by entering the following at the MATLAB command line:

```
h = comm.gpu.PSKModulator
```

Plot the ideal signal constellation by calling the `constellation` method.

```
constellation(h)
```

step

Modulate using M-ary PSK method with GPU

Syntax

$Y = \text{step}(H,X)$

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, $y = \text{step}(\text{obj}, x)$ and $y = \text{obj}(x)$ perform equivalent operations.

$Y = \text{step}(H,X)$ modulates the input data, X , using the GPU-based PSK modulator System object, H . The object returns the baseband modulated output Y . Depending upon the value of the `BitInput` property, input X can be an integer or bit-valued column vector with numeric or logical data types.

Note `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications. For more information on changing property values, see “System Design in MATLAB Using System Objects”.

comm.gpu.TurboDecoder

Package: comm.gpu

Decode input signal using turbo decoding with GPU

Note To use this object, you must install Parallel Computing Toolbox™ and have access to an appropriate GPU. For more about GPUs, see “GPU Computing” (Parallel Computing Toolbox).

Description

The `comm.gpu.TurboDecoder` System object decodes the input signal by using a parallel concatenated decoding scheme with a graphics processing unit (GPU). This decoding scheme uses the a-posteriori probability (APP) decoder as the constituent decoder. The constituent decoders use the same trellis structure and algorithm.

A GPU-based System object accepts typical MATLAB arrays or objects created using the `gpuArray` class. A GPU-based System object supports input signals with double- or single-precision data types. The output signal inherits its data type from the input signal.

- If the input signal is a MATLAB array, the System object handles data transfer between the CPU and the GPU. The output signal is a MATLAB array.
- If the input signal is a `gpuArray`, the data remains on the GPU. The output signal is a `gpuArray`. When the object is given a `gpuArray`, calculations take place entirely on the GPU, and no data transfer occurs. Passing `gpuArray` arguments provides increased performance by reducing simulation time. For more information, see “Establish Arrays on a GPU” (Parallel Computing Toolbox).

To decode an input signal using a turbo decoding scheme with GPU:

- 1 Create the `comm.gpu.TurboDecoder` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

Creation

Syntax

```
gpuTurboDec = comm.gpu.TurboDecoder
gpuTurboDec = comm.gpu.TurboDecoder(trellis,interlvrIndices,numIter)
gpuTurboDec = comm.gpu.TurboDecoder( ___,Name,Value)
```

Description

`gpuTurboDec = comm.gpu.TurboDecoder` creates a GPU-based turbo decoder System object. This object uses an APP constituent decoder to iteratively decode the parallel-concatenated convolutionally encoded input data.

`gpuTurboDec = comm.gpu.TurboDecoder(trellis,interlvrIndices,numIter)` sets the `TrellisStructure` property to `trellis`, the `InterleaverIndices` property to `interlvrIndices`, and the `NumIterations` property to `numIter`.

`gpuTurboDec = comm.gpu.TurboDecoder(___,Name,Value)` sets “Properties” on page 3-689 using one or more name-value arguments in addition to any of the input argument combinations in previous syntaxes. For example, `'NumIterations',10` specifies the number of decoding iterations used for each call to the System object.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects.

TrellisStructure — Trellis description of constituent convolutional code

`poly2trellis(4, [13 15], 13)` (default) | structure

Trellis description of the constituent convolutional code, specified as a structure that contains the trellis description for a rate K/N code. K is the number of input bit streams, and N is the number of output bit streams.

Note K must be 1 for the turbo coder. For more information, see “Coding Rate” on page 3-1364.

You can either use the `poly2trellis` function to create the trellis structure or create it manually. For more about this structure, see “Trellis Description of a Convolutional Code” and the `istrellis` function.

The trellis structure contains these fields.

numInputSymbols — Number of symbols input to encoder

2^K

Number of symbols input to the encoder, specified as an integer equal to 2^K , where K is the number of input bit streams.

Data Types: `double`

numOutputSymbols — Number of symbols output from encoder

2^N

Number of symbols output from the encoder, specified as an integer equal to 2^N , where N is the number of output bit streams.

Data Types: `double`

numStates — Number of states in encoder

power of 2

Number of states in the encoder, specified as a power of 2.

Data Types: double

nextStates — Next states

matrix of integers

Next states for all combinations of current states and current inputs, specified as a matrix of integers. The matrix size must be numStates-by- 2^K .

Data Types: double

outputs — Outputs

matrix of octal numbers

Outputs for all combinations of current states and current inputs, specified as a matrix of octal numbers. The matrix size must be numStates-by- 2^K .

Data Types: double

Data Types: struct

InterleaverIndicesSource — Source of interleaver indices

'Property' (default)

Source of interleaver indices, specified as 'Property'. The only valid setting for this property is Property, which uses the interleaver indices that you specify in the InterleaverIndices property.

Data Types: char | string

InterleaverIndices — Interleaver indices

(64:-1:1)' (default) | column vector of integers

Interleaver indices that define the mapping used to permute the codeword bits input to the decoder, specified as a column vector of integers. The vector must be of length L . Each element of the vector must be an integer in the range $[1, L]$ and must be unique. L is the length of the decoded output message, dec.

Data Types: double

Algorithm — Decoding algorithm

'True APP' (default)

Decoding algorithm, specified as 'True APP'. The only valid setting is 'True APP', which implements true APP decoding.

Data Types: char | string

NumIterations — Number of decoding iterations

6 (default) | positive integer

Number of decoding iterations, specified as a positive integer. This property sets the number of decoding iterations used for each call to the object.

Data Types: double

NumFrames — Number of independent frames

1 (default) | positive integer

Number of independent frames present in the input and output data vectors, specified as a positive integer.

The object segments the input vector into NumFrames segments and decodes them independently. The output contains NumFrames decoded segments.

Data Types: double

Usage

Syntax

```
dec = gpuTurboDec(codeword)
```

Description

`dec = gpuTurboDec(codeword)` decodes the input data by using the parallel concatenated convolutional coding scheme. If the host computer has a GPU configured, the processing utilizes the GPU. Otherwise, the processing uses the CPU. The output is the decoded data.

Input Arguments

codeword — Parallel concatenated codeword

column vector

Parallel concatenated codeword, specified as a column vector.

Data Types: double | single

Output Arguments

dec — Decoded message

binary-valued column vector

Decoded message, returned as a binary-valued column vector. The output signal is the same data type as the input. The object iterates and provides updates to the log-likelihood ratios (LLR) of the uncoded output bits. The output of the object is the hard-decision output of the final LLR update.

When the constituent convolutional code represents a rate $1/N$ code, the object sets the length `dec` to $(M-2 \times N_{\text{Tails}})/(2 \times N-1)$. M is the input vector length, and N_{Tails} is given by $\log_2(\text{TrellisStructure.numStates}) \times N$. The length of `dec` equals the length of the interleaver indices.

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Common to All System Objects

`step` Run System object algorithm

release Release resources and allow changes to System object property values and input characteristics
reset Reset internal states of System object

Examples

GPU-Based Turbo Encode and Decode BPSK Modulated Data

Transmit turbo-encoded data over a binary phase-shift keying (BPSK) modulated additive white Gaussian noise (AWGN) channel. Then, decode using an iterative turbo decoder and display errors.

Define a noise variable, establish a frame length of 256, and use the random stream so that the results are repeatable.

```
noiseVar = 4;  
frmLen = 256;  
s = RandStream('mt19937ar','Seed',11);  
intrlvrIndices = randperm(s,frmLen);
```

Create a turbo encoder System object™ with these properties.

```
tEnc = comm.TurboEncoder('TrellisStructure',poly2trellis(4,[13 15 17],13), ...  
                        'InterleaverIndices',intrlvrIndices);
```

Create a PSK Modulator System object.

```
modBPSK = comm.BPSKModulator;
```

Create an AWGN Channel System object.

```
channel = comm.AWGNChannel('NoiseMethod','Variance', ...  
                           'Variance',noiseVar);
```

Create a GPU-based Turbo Decoder System object. The trellis structure for the constituent convolutional code is poly2trellis(4, [13 15 17], 13).

```
tDec = comm.gpu.TurboDecoder('TrellisStructure',poly2trellis(4,[13 15 17],13), ...  
                             'InterleaverIndices',intrlvrIndices, ...  
                             'NumIterations',4);
```

Create an error rate System object.

```
errorRate = comm.ErrorRate;
```

Run the simulation. Convert the received signal to log-likelihood ratios for decoding. Compare original the data to the received data and then calculate the error rate results.

```
for frmIdx = 1:10  
    data = randi(s,[0 1],frmLen,1);  
    encodedData = tEnc(data);  
    modSignal = modBPSK(encodedData);  
    receivedSignal = channel(modSignal);  
    receivedBits = tDec(-2/(noiseVar/2)*real(receivedSignal));  
    errorStats = errorRate(data,receivedBits);  
end
```

Display the number of errors.

```
fprintf('Error rate = %f\nNumber of errors = %d\nTotal bits = %d\n', ...  
       errorStats(1), errorStats(2), errorStats(3));
```

```
Error rate = 0.000000  
Number of errors = 0  
Total bits = 2560
```

comm.gpu.ViterbiDecoder

Package: comm

Decode convolutionally encoded data using Viterbi algorithm with GPU

Note To use this object, you must install Parallel Computing Toolbox™ and have access to an appropriate GPU. For more about GPUs, see “GPU Computing” (Parallel Computing Toolbox).

Description

The `comm.gpu.ViterbiDecoder` System object decodes convolutionally encoded input symbols to produce binary output symbols by using Viterbi algorithm with a graphics processing unit (GPU).

A GPU-based System object accepts typical MATLAB arrays or objects created using the `gpuArray` class. A GPU-based System object supports input signals with double- or single-precision data types. The output signal inherits its data type from the input signal.

- If the input signal is a MATLAB array, the System object handles data transfer between the CPU and the GPU. The output signal is a MATLAB array.
- If the input signal is a `gpuArray`, the data remains on the GPU. The output signal is a `gpuArray`. When the object is given a `gpuArray`, calculations take place entirely on the GPU, and no data transfer occurs. Passing `gpuArray` arguments provides increased performance by reducing simulation time. For more information, see “Establish Arrays on a GPU” (Parallel Computing Toolbox).

To decode convolutionally encoded data using the Viterbi algorithm with a GPU:

- 1 Create the `comm.gpu.ViterbiDecoder` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

Creation

Syntax

```
gpuViterbiDec = comm.gpu.ViterbiDecoder
gpuViterbiDec = comm.gpu.ViterbiDecoder(trellis)
gpuViterbiDec = comm.gpu.ViterbiDecoder( ___,Name,Value)
```

Description

`gpuViterbiDec = comm.gpu.ViterbiDecoder` creates a GPU-based Viterbi decoder System object.

`gpuViterbiDec = comm.gpu.ViterbiDecoder(trellis)` sets the `TrellisStructure` property to `trellis`.

`gpuViterbiDec = comm.gpu.ViterbiDecoder(___, Name, Value)` sets “Properties” on page 3-695 using one or more name-value arguments in addition to any of the input argument combinations in previous syntaxes. For example, 'TerminationMethod', 'Continuous' specifies the termination method as continuous to save the internal state metric at the end of each frame for use with the next frame.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects.

TrellisStructure — Trellis structure of convolutional code

`poly2trellis(7,[171 133])` (default) | structure

Trellis description of the convolutional code, specified as a structure that contains the trellis description for a rate K/N code. K is the number of input bit streams, and N is the number of output bit streams.

You can either use the `poly2trellis` function to create the trellis structure or create it manually. For more about this structure, see “Trellis Description of a Convolutional Code” and the `istrellis` function.

The trellis structure contains these fields.

numInputSymbols — Number of symbols input to encoder

2^K

Number of symbols input to the encoder, specified as an integer equal to 2^K , where K is the number of input bit streams.

Data Types: `double`

numOutputSymbols — Number of symbols output from encoder

2^N

Number of symbols output from the encoder, specified as an integer equal to 2^N , where N is the number of output bit streams.

Data Types: `double`

numStates — Number of states in encoder

power of 2

Number of states in the encoder, specified as a power of 2.

Data Types: `double`

nextStates — Next states

matrix of integers

Next states for all combinations of current states and current inputs, specified as a matrix of integers. The matrix size must be numStates-by- 2^K .

Data Types: double

outputs — Outputs

matrix of octal numbers

Outputs for all combinations of current states and current inputs, specified as a matrix of octal numbers. The matrix size must be numStates-by- 2^K .

Data Types: double

Data Types: struct

InputFormat — Input format to decoder

'Unquantized' (default) | 'Hard' | 'Soft'

Input format to the decoder, specified as one of these values.

- 'Unquantized' — The input data must be a real-valued vector of double- or single-precision soft decision values that are unquantized. The object maps positive values to logical 0s and negative values to logical 1s.
- 'Hard' — The input must be a vector of hard decision values, which are 0s or 1s. The data type of the inputs must be double precision or single precision.
- 'Soft' — The input requires a vector of quantized soft decision values that are represented as integers between 0 and $2^{\text{SoftInputWordLength}} - 1$. The data type of the inputs must be double precision or single precision.

Data Types: char | string

SoftInputWordLength — Soft decision input word length

4 (default) | integer

Soft decision input word length that represents the number of bits for each quantized soft input value, specified as an integer.

Dependencies

To enable this property, set the InputFormat property to 'Soft'.

Data Types: double

InvalidQuantizedInputAction — Option to take action for invalid quantized input

'Ignore' (default)

Option to take action for an invalid quantized input, specified as 'Ignore'. The only valid setting is 'Ignore', which ignores out-of-range inputs.

Data Types: char | string

TracebackDepth — Traceback depth

34 (default) | integer in the range [0, 256]

Traceback depth, specified as an integer in the range [0, 256]. The traceback depth influences the decoding accuracy and delay. The number of zero symbols that precede the first decoded symbol in

the output represent a decoding delay. For more information, see “Traceback and Decoding Delay” on page 3-1389 and “Traceback Depth Estimates” on page 3-1389.

When you set the `TerminationMethod` property to `'Continuous'`, the decoding delay consists of `TracebackDepth` zero symbols or `TracebackDepth` zero bits for a rate $1/N$ convolutional code.

When you set the `TerminationMethod` property to `'Truncated'` or `'Terminated'`, no output delay is present. The `TracebackDepth` value must be less than or equal to the number of symbols in each input. If the code rate is $1/2$, a typical traceback depth value is about five times the constraint length of the code.

Data Types: `double`

TerminationMethod — Termination method of encoded frame

`'Continuous'` (default) | `'Truncated'` | `'Terminated'`

Termination method of the encoded frame, specified as one of these values.

- `'Continuous'` — The System object saves the internal state metric at the end of each frame for use with the next frame. The object treats each traceback path independently. Use this option when the input signal contains only one symbol.
- `'Truncated'` — The System object treats each frame independently. The traceback path starts at the state with the best metric and ends in the all-zeros state.
- `'Terminated'` — The System object treats each frame independently. The traceback path starts and ends in the all-zeros state.

Data Types: `char` | `string`

ResetInputPort — Option to enable decoder reset input

`false` or `0` (default) | `true` or `1`

Option to enable the decoder reset input, specified as a numeric or logical `0` (`false`) or `1` (`true`). Set this property to `true` to enable additional input to the object. When this additional reset input is a nonzero value, the internal states of the decoder reset to their initial conditions.

Dependencies

To enable this property, set the `TerminationMethod` property to `'Continuous'`.

Data Types: `logical` | `numeric`

DelayedResetAction — Option to delay output reset

`false` or `0` (default)

Option to delay the output reset, specified as a numeric or logical `0` (`false`). The only valid setting is `false`.

Data Types: `logical` | `numeric`

PuncturePatternSource — Source of puncture pattern

`'None'` (default) | `'Property'`

Source of the puncture pattern, specified as one of these values.

- `'None'` — The object does not apply puncturing.

- 'Property' — The object decodes the punctured codewords based on a puncture pattern vector that you specify in the PuncturePattern property.

Data Types: char | string

PuncturePattern — Puncture pattern vector

[1; 1; 0; 1; 0; 1] (default) | column vector

Puncture pattern vector to puncture the decoded data, specified as a column vector. The vector must contain 1s and 0s, where 0 indicates the position of the punctured bits. This puncture pattern must match the puncture pattern used by the convolutional encoder.

Dependencies

To enable this property, set the PuncturePatternSource property to 'Property'.

Data Types: double

ErasuresInputPort — Option to enable specification of erasures in input symbols

false or 0 (default)

Option to enable the specification of erasures in the input symbols, specified as a numeric or logical 0 (false). The only valid setting is false.

Data Types: logical | numeric

OutputDataType — Data type of output

'Full precision' (default)

Data type of the output, specified as 'Full precision'. The only valid setting is 'Full precision', which makes the output data type match the input data type.

Data Types: char | string

NumFrames — Number of independent frames

1 (default) | integer

Number of independent frames present in the input and output data vectors, specified as an integer.

The object segments the input vector into NumFrames segments and decodes them independently. The output contains NumFrames decoded segments.

Dependencies

To enable this property, set the TerminationMethod property to 'Truncated' or 'Terminated'.

Data Types: double

Usage**Syntax**

```
decmsg = gpuViterbiDec(codeword)
decmsg = gpuViterbiDec(codeword, resetstate)
```

Description

`decmsg = gpuViterbiDec(codeword)` decodes the GPU-based convolutionally encoded input data by using the GPU-based Viterbi decoding algorithm. The output is the decoded data.

`decmsg = gpuViterbiDec(codeword, resetstate)` specifies the input to reset the internal states of the decoder. To enable this syntax, set the `TerminationMethod` property to 'Continuous' and the `ResetInputPort` property to `true`.

Input Arguments

codeword — Convolutionally encoded message

column vector

Convolutionally encoded message, specified as a column vector. The data type and element value in the codeword depend on the value of the `InputFormat` property.

If the convolutional code uses an alphabet of 2^N possible output symbols, the length of this input vector must be $L \times N$ for some positive integer L .

Data Types: `double` | `single`

resetstate — Reset internal states of decoder

`false` or `0` (default) | `true` or `1`

Reset for internal states of the decoder, specified as a logical `0` (`false`) or `1` (`true`).

Dependencies

To enable this argument, set the `TerminationMethod` property to 'Continuous' and the `ResetInputPort` property to `true`.

Data Types: `double` | `logical`

Output Arguments

decmsg — Decoded message

binary-valued column vector

Decoded message, returned as a binary-valued column vector. This output vector has the same data type as input `codeword`.

If the decoded data uses an alphabet of 2^K possible output symbols, the length of this output vector is $L \times K$. L is the length of the input message.

Data Types: `double` | `single`

Object Functions

To use an object function, specify the `System` object as the first input argument. For example, to release system resources of a `System` object named `obj`, use this syntax:

```
release(obj)
```

Specific to `comm.gpu.ViterbiDecoder`

info Characteristic information of GPU-based Viterbi decoder

Common to All System Objects

step Run System object algorithm
release Release resources and allow changes to System object property values and input characteristics
reset Reset internal states of System object

Examples

GPU-Based Convolutionally Encode and Viterbi Decode 8-PSK Modulated Data

Create a GPU-based convolutional encoder System object.

```
conEnc = comm.gpu.ConvolutionalEncoder;
```

Create a GPU-based phase shift keying (PSK) modulator System object that accepts a bit input signal.

```
modPSK = comm.gpu.PSKModulator('BitInput',true);
```

Create a GPU-based additive white Gaussian noise (AWGN) channel System object with a signal-to-noise ratio of seven.

```
chan = comm.gpu.AWGNChannel('NoiseMethod','Signal to noise ratio (SNR)','SNR',7);
```

Create a GPU-based PSK demodulator System object that outputs a column vector of bit values.

```
demodPSK = comm.gpu.PSKDemodulator('BitOutput',true);
```

Create a GPU-based Viterbi decoder System object that accepts an input vector of hard decision values, which are zeros or ones.

```
vDec = comm.gpu.ViterbiDecoder('InputFormat','Hard');
```

Create an error rate System object that ignores 3 data samples before making comparisons. The received data lags behind the transmitted data by 34 samples.

```
error = comm.ErrorRate('ComputationDelay',3,'ReceiveDelay',34);
```

Run the simulation by using this for loop to process data.

```
for counter = 1:20
    data = randi([0 1],30,1);
    encodedData = conEnc(gpuArray(data));
    modSignal = modPSK(encodedData);
    receivedSignal = chan(modSignal);
    demodSignal = demodPSK(receivedSignal);
    receivedBits = vDec(demodSignal);
    errors = error(data,gather(receivedBits));
end
```

Display the number of errors.

```
errors(2)
```

ans = 1

gsmDownlinkConfig

Create GSM downlink TDMA frame configuration object

Description

The `gsmDownlinkConfig` object is a GSM downlink TDMA frame configuration object. Use `gsmDownlinkConfig` objects to create GSM downlink waveforms.

Creation

Syntax

```
cfggsmdl = gsmDownlinkConfig
cfggsmdl = gsmDownlinkConfig(sps)
cfggsmdl = gsmDownlinkConfig( ____,Name,Value)
```

Description

`cfggsmdl = gsmDownlinkConfig` creates a GSM downlink TDMA frame configuration object.

`cfggsmdl = gsmDownlinkConfig(sps)` sets the `SamplesPerSymbol` property to `sps`.

`cfggsmdl = gsmDownlinkConfig(____,Name,Value)` sets one or more name-value pair arguments using any of the previous syntaxes. For example, `'RiseTime',4` sets the burst rise time to 4 symbols. Enclose each property in quotes. Specify name-value pair arguments after all other input arguments.

Properties

SamplesPerSymbol — Samples per symbol

16 (default) | positive integer multiple of 4

Samples per symbol, specified as a positive integer multiple of 4.

Data Types: `double`

BurstType — Burst types

`["NB" "NB" "NB" "NB" "NB" "NB" "NB" "NB"]` (default) | string row vector with 8 elements | `"NB" | "FB" | "SB" | "Dummy" | "Off"`

Burst types for time slots 0-7 in the TDMA frame, specified as one of these options:

- Eight-element row vector where each value is `"NB"`, `"FB"`, `"SB"`, `"Dummy"`, or `"Off"` — Each element specifies the burst type for the corresponding time slot.
- `"NB"` — Transmit data using a normal burst for every time slot.
- `"FB"` — Transmit data using a frequency correction burst for every time slot.

- "SB" — Transmit data using a time synchronization burst for every time slot.
- "Dummy" — Transmit data using a dummy burst for every time slot.
- "Off" — All eight time slots contain no data.

For more information, see "GSM Frames, Time Slots, and Bursts" on page 3-715.

Note The `BurstType` property is an enumeration. To perform code generation, see "Code Generation" on page 3-736 and the "MEX Generation for GSM Downlink Waveform" on page 3-710 example.

Example: ["NB" "AB" "AB" "NB" "Off" "NB" "AB" "Off"] configures the frame to use normal bursts in time slots 0, 3, and 5, use access bursts in time slots 1, 2, and 6, and transmit no data in time slots 4 and 7.

TSC — Training sequence code

[0 1 2 3 4 5 6 7] (default) | eight-element row vector | integer in the range [0, 7]

Training sequence code (TSC) for normal bursts in time slots 0-7 in the TDMA frame, specified as one of these options:

- Eight-element row vector of integers in the range [0, 7] — Each element specifies the TSC value for the corresponding normal burst time slot.
- Integer in the range [0, 7] — Specifies the TSC value for every normal burst time slot.

For more information, see "Training Sequence Code (TSC)" on page 3-717.

Example: [5 7 0 0 0 0 0 0] configures the frame to use training sequence 5 in time slot 0, training sequence 7 in time slot 1, and training sequence 0 in time slots 2 through 7.

Dependencies

To enable this property for a time slot, set the corresponding element of `BurstType` to "NB".

Data Types: double

Attenuation — Power attenuation

[0 0 0 0 0 0 0 0] (default) | eight-element row vector | nonnegative integer

Power attenuation in dB for time slots 0-7 in the TDMA frame, specified as one of these options:

- Eight-element row vector of nonnegative integers — Each element specifies the attenuation power value for the corresponding time slot.
- Nonnegative integer — Specifies the power attenuation value for every time slot.

Example: [0 0 0 0 0 0 0 3] configures the frame to apply 0 dB attenuation to the burst signal power in time slot 0 through 6 and 3 dB of attenuation to the burst signal power in time slot 7.

Data Types: double

RiseTime — Burst rise time

2 (default) | positive scalar

Burst rise time in symbols, specified as a positive scalar in the range [1/SamplesPerSymbol, 29], where the increment resolution is 1/SamplesPerSymbol. The total ramp-up and ramp-down duration

$(\text{RiseTime} - \text{RiseDelay} + \text{FallTime} + \text{FallDelay})$ must be less than 9.25 symbols. The characteristic shape of the rising edge of the burst is sinusoidal.

For more information, see “GSM Frames, Time Slots, and Bursts” on page 3-715.

Data Types: double

RiseDelay — Burst rise delay

0 (default) | positive scalar

Burst rise delay in symbols, specified as a positive scalar in the range $[-10, 10]$, where the increment resolution is $1/\text{SamplesPerSymbol}$. The total ramp-up and ramp-down duration $(\text{RiseTime} - \text{RiseDelay} + \text{FallTime} + \text{FallDelay})$ must be less than 9.25 symbols. The burst rise delay is measured with respect to the start of the useful part of the burst. For more information, see “GSM Frames, Time Slots, and Bursts” on page 3-715.

When the burst rise delay is 0, the burst reaches full amplitude at the start of the useful part of the burst. When the burst rise delay is positive, the burst reaches full amplitude RiseDelay symbols after the start of the useful part. When the burst rise delay is negative, the burst reaches full amplitude RiseDelay symbols before the start of the useful part.

Data Types: double

FallTime — Burst fall time

2 (default) | positive scalar

Burst fall time in symbols, specified as a positive scalar in the range $[1/\text{SamplesPerSymbol}, 29]$, where the increment resolution is $1/\text{SamplesPerSymbol}$. The total ramp-up and ramp-down duration $(\text{RiseTime} - \text{RiseDelay} + \text{FallTime} + \text{FallDelay})$ must be less than 9.25 symbols. The characteristic shape of the falling edge of the burst is sinusoidal.

For more information, see “GSM Frames, Time Slots, and Bursts” on page 3-715.

Data Types: double

FallDelay — Burst fall delay

0 (default) | positive scalar

Burst fall delay in symbols, specified as a positive scalar in the range $[-10, 10]$, where the increment resolution is $1/\text{SamplesPerSymbol}$. The total ramp-up and ramp-down duration $(\text{RiseTime} - \text{RiseDelay} + \text{FallTime} + \text{FallDelay})$ must be less than 9.25 symbols. The burst fall delay is measured with respect to the end of the useful part of the burst. For more information, see “GSM Frames, Time Slots, and Bursts” on page 3-715.

When the burst fall delay is 0, the burst begins decreasing from full amplitude at the end of the useful part of the burst. When the burst fall delay is positive, the burst begins decreasing from full amplitude FallDelay symbols after the end of the useful part. When the burst fall delay is negative, the burst begins decreasing from full amplitude FallDelay symbols before the end of the useful part.

Data Types: double

Examples

Create GSM Downlink Waveform

Create a GSM downlink TDMA frame configuration object with default settings, and then create a GSM waveform containing one TDMA frame. The GSM TDMA frame has eight time slots, each separated by a guard period of 8.25 symbols or about 30.46×10^{-3} ms. Plot the GSM waveform.

Create a GSM downlink TDMA frame configuration object with default settings.

```
cfggsmdl = gsmDownlinkConfig

cfggsmdl =
  gsmDownlinkConfig with properties:

      BurstType: [NB    NB    NB    NB    NB    NB    NB    NB]
  SamplesPerSymbol: 16
           TSC: [0 1 2 3 4 5 6 7]
  Attenuation: [0 0 0 0 0 0 0 0]
    RiseTime: 2
   RiseDelay: 0
    FallTime: 2
   FallDelay: 0
```

Display information about the configured `gsmDownlinkConfig` object by using the `gsmInfo` function. Assign the sample rate to a variable, `Rs`, for use in computing the plot timescale.

```
wfInfo = gsmInfo(cfggsmdl)

wfInfo = struct with fields:
      SymbolRate: 2.7083e+05
      SampleRate: 4.3333e+06
  BandwidthTimeProduct: 0.3000
  BurstLengthInSymbols: 156.2500
      NumBurstsPerFrame: 8
  BurstLengthInSamples: 2500
  FrameLengthInSamples: 20000
```

```
Rs = wfInfo.SampleRate;
```

Create the GSM waveform by using the `gsmFrame` function, and then plot the GSM waveform.

```
waveform = gsmFrame(cfggsmdl);

t = (0:length(waveform)-1)/Rs*1e3;
subplot(2,1,1)
plot(t,abs(waveform))
grid on
axis([0 5 0 1.2])
title('GSM Downlink Waveform - Amplitude')
xlabel('Time (ms)')
ylabel('Amplitude')
subplot(2,1,2)
plot(t,unwrap(angle(waveform)))
grid on
title('GSM Downlink Waveform - Phase')
xlabel('Time (ms)')
ylabel('Phase (rad)')
```

Create GSM Downlink Waveform with Specified Samples per Symbol

Create a GSM downlink TDMA frame configuration object that specifies 8 samples per symbol, and then create a GSM waveform containing one GSM downlink TDMA frame. The GSM TDMA frame are eight time slots, each separated by a guard period of 8.25 symbols or about 30.46×10^{-3} ms separates each time slot. Plot the GSM waveform.

Create a GSM downlink TDMA frame configuration object, specifying 8 samples per symbols.

```
sps = 8;
cfggsmdl = gsmDownlinkConfig(sps)

cfggsmdl =
  gsmDownlinkConfig with properties:
    BurstType: [NB    NB    NB    NB    NB    NB    NB    NB]
    SamplesPerSymbol: 8
    TSC: [0 1 2 3 4 5 6 7]
    Attenuation: [0 0 0 0 0 0 0 0]
    RiseTime: 2
    RiseDelay: 0
    FallTime: 2
    FallDelay: 0
```

Display information about the configured `gsmDownlinkConfig` object by using the `gsmInfo` function. Assign the sample rate to a variable, `Rs`, for use in computing the plot timescale.

```
wfInfo = gsmInfo(cfggsmdl)

wfInfo = struct with fields:
    SymbolRate: 2.7083e+05
    SampleRate: 2.1667e+06
    BandwidthTimeProduct: 0.3000
    BurstLengthInSymbols: 156.2500
    NumBurstsPerFrame: 8
    BurstLengthInSamples: 1250
    FrameLengthInSamples: 10000
```

```
Rs = wfInfo.SampleRate;
```

Create the GSM waveform by using the `gsmFrame` function, and then plot the GSM waveform.

```
waveform = gsmFrame(cfggsmdl);

t = (0:length(waveform)-1)/Rs*1e3;
subplot(2,1,1)
plot(t,abs(waveform))
grid on
axis([0 5 0 1.2])
title('GSM Downlink Waveform - Amplitude')
xlabel('Time (ms)')
ylabel('Amplitude')
subplot(2,1,2)
plot(t,unwrap(angle(waveform)))
grid on
title('GSM Downlink Waveform - Phase')
xlabel('Time (ms)')
ylabel('Phase (rad)')
```

Create GSM Downlink Waveform with Specified Attenuation

Create two GSM downlink TDMA frame configuration objects. Specify default settings for the first `gsmDownlinkConfig` object and adjust the signal power per time slot for the second. Generate GSM waveforms for both configurations. Plot the waveforms to show the signal attenuation per time slot in the second waveform.

Create a GSM downlink TDMA frame configuration object with default settings.

```
cfggsmdl = gsmDownlinkConfig
```

```
cfggsmdl =  
gsmDownlinkConfig with properties:
```

```
    BurstType: [NB    NB    NB    NB    NB    NB    NB    NB]  
SamplesPerSymbol: 16  
      TSC: [0 1 2 3 4 5 6 7]  
Attenuation: [0 0 0 0 0 0 0 0]  
    RiseTime: 2  
    RiseDelay: 0  
    FallTime: 2  
    FallDelay: 0
```

Create another GSM downlink TDMA frame configuration object, adjusting the signal attenuation settings per time slot.

```
cfggsmdl2 = gsmDownlinkConfig('Attenuation',[1 0 3 4 5 6 4 2])

cfggsmdl2 =
    gsmDownlinkConfig with properties:
        BurstType: [NB    NB    NB    NB    NB    NB    NB    NB]
        SamplesPerSymbol: 16
        TSC: [0 1 2 3 4 5 6 7]
        Attenuation: [1 0 3 4 5 6 4 2]
        RiseTime: 2
        RiseDelay: 0
        FallTime: 2
        FallDelay: 0
```

Display information about the configured `gsmDownlinkConfig` object by using the `gsmInfo` function. Assign the sample rate to a variable, `Rs`, for use in computing the plot timescale.

```
wfInfo = gsmInfo(cfggsmdl)

wfInfo = struct with fields:
    SymbolRate: 2.7083e+05
    SampleRate: 4.3333e+06
    BandwidthTimeProduct: 0.3000
    BurstLengthInSymbols: 156.2500
    NumBurstsPerFrame: 8
    BurstLengthInSamples: 2500
    FrameLengthInSamples: 20000
```

```
Rs = wfInfo.SampleRate;
```

Create the GSM waveforms, containing one TDMA frame, by using the `gsmFrame` function. GSM TDMA frames have are eight time slots, each separated by a guard period of 8.25 symbols or about 30.46×10^{-3} ms separates each time slot. Plot each GSM waveform.

```
waveform = gsmFrame(cfggsmdl);
waveform2 = gsmFrame(cfggsmdl2);

t = (0:length(waveform)-1)/Rs*1e3;
subplot(2,1,1)
plot(t,[abs(waveform),abs(waveform2)])
grid on
axis([0 5 0 1.2])
title('GSM Downlink Waveform - Amplitude')
xlabel('Time (ms)')
ylabel('Amplitude')
subplot(2,1,2)
plot(t,[unwrap(angle(waveform)),unwrap(angle(waveform2))])
grid on
title('GSM Downlink Waveform - Phase')
xlabel('Time (ms)')
ylabel('Phase (rad)')
```

MEX Generation for GSM Downlink Waveform

Generate and run a GSM waveform MEX function from the helper function `createDownlinkWaveform`. The `createDownlinkWaveform` helper function creates a GSM downlink waveform.

Write MATLAB Function

Open `createDownlinkWaveform.m` to see the code. The `createDownlinkWaveform` helper function generates a GSM downlink waveform by using the `gsmDownlinkConfig` object and the `gsmInfo` and `gsmFrame` functions.

Generate GSM Waveform

Use the `createDownlinkWaveform` helper function to create a GSM waveform containing two TDMA frames, and then plot the waveform.

```
[x,t] = createDownlinkWaveform(2);

figure
subplot(2,1,1);
plot(t,abs(x));
grid on;
title('GSM Downlink Waveform - Amplitude');
```

```

xlabel('Time (ms)');
ylabel('Amplitude');
subplot(2,1,2);
plot(t,unwrap(angle(x)));
grid on;
title('GSM Downlink Waveform - Phase');
xlabel('Time (ms)');
ylabel('Phase (rad)')

```

Generate MEX Function

Code generation defaults to MEX code generation when you do not specify a build target. By default, codegen names the generated MEX function `createDownlinkWaveform_mex`. Generate a MEX function from the `createDownlinkWaveform` helper function, and then run the MEX function to create two TDMA frames.

```
codegen createDownlinkWaveform -args 3
```

Code generation successful.

Generate Waveform Using MEX Function

Run the MEX function and plot the results. Since the waveform is created using random data, the phase plot changes each time you run the `generateDownlinkFrame` helper function or `createDownlinkWaveform_mex` function.

```
[x,t] = createDownlinkWaveform_mex(2);
```

```

figure
subplot(2,1,1);
plot(t,abs(x));
grid on;
title('MEX - GSM Downlink Waveform - Amplitude');
xlabel('Time (ms)');
ylabel('Amplitude')
subplot(2,1,2);
plot(t,unwrap(angle(x)));
grid on;
title('MEX - GSM Downlink Waveform - Phase');
xlabel('Time (ms)');
ylabel('Phase (rad)')

```

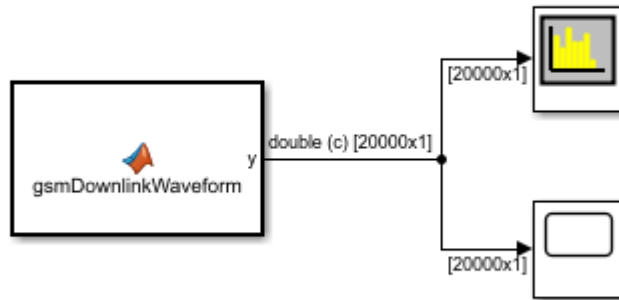

GSM Downlink Waveform Generation in Simulink

Model a GSM waveform generator in Simulink® by using the MATLAB® Function block and Communications Toolbox™ functions.

GSM Downlink Waveform Generation

The MATLAB Function (Simulink) block contains the `gsmDownlinkWaveform` function code. The code in the MATLAB Function block creates a GSM waveform by using the `gsmDownlinkConfig` object and the `gsmFrame` function.

GSM Uplink Waveform Generation and Visualization

Copyright 2019 The MathWorks, Inc.

The `gsmDownlinkConfig` object specifies 16 samples per symbol and the time slot configuration for the GSM downlink TDMA frame shown is this table.

Timeslot	Burst Type	Attenuation
0	Normal burst	0 dB
1	FrequencyCorrection burst	0 dB
2	Normal burst	3 dB
3	Synchronization burst	0 dB
4	No data	0 dB
5	Normal burst	6 dB
6	Dummy burst	0 dB
7	Normal burst	3 dB

The output waveform has 16 samples for each GMSK symbol. The `gsmFrame` function generates the samples of the waveform.

Explore the Model

In compliance with GSM standards 3GPP TS 45.001 and 3GPP TS 45.002, the sample time of the MATLAB Function block that contains the `gsmDownlinkWaveform` function code is set to the GSM symbol rate of $1625e3/6$ symbols per second. Display the current `gsmDownlinkConfig` object settings by using the `gsmInfo` function.

```
wfInfo =
```

```
struct with fields:
```

```

    SymbolRate: 2.7083e+05
    SampleRate: 4.3333e+06
    BandwidthTimeProduct: 0.3000
    BurstLengthInSymbols: 156.2500
    NumBurstsPerFrame: 8
    BurstLengthInSamples: 2500

```

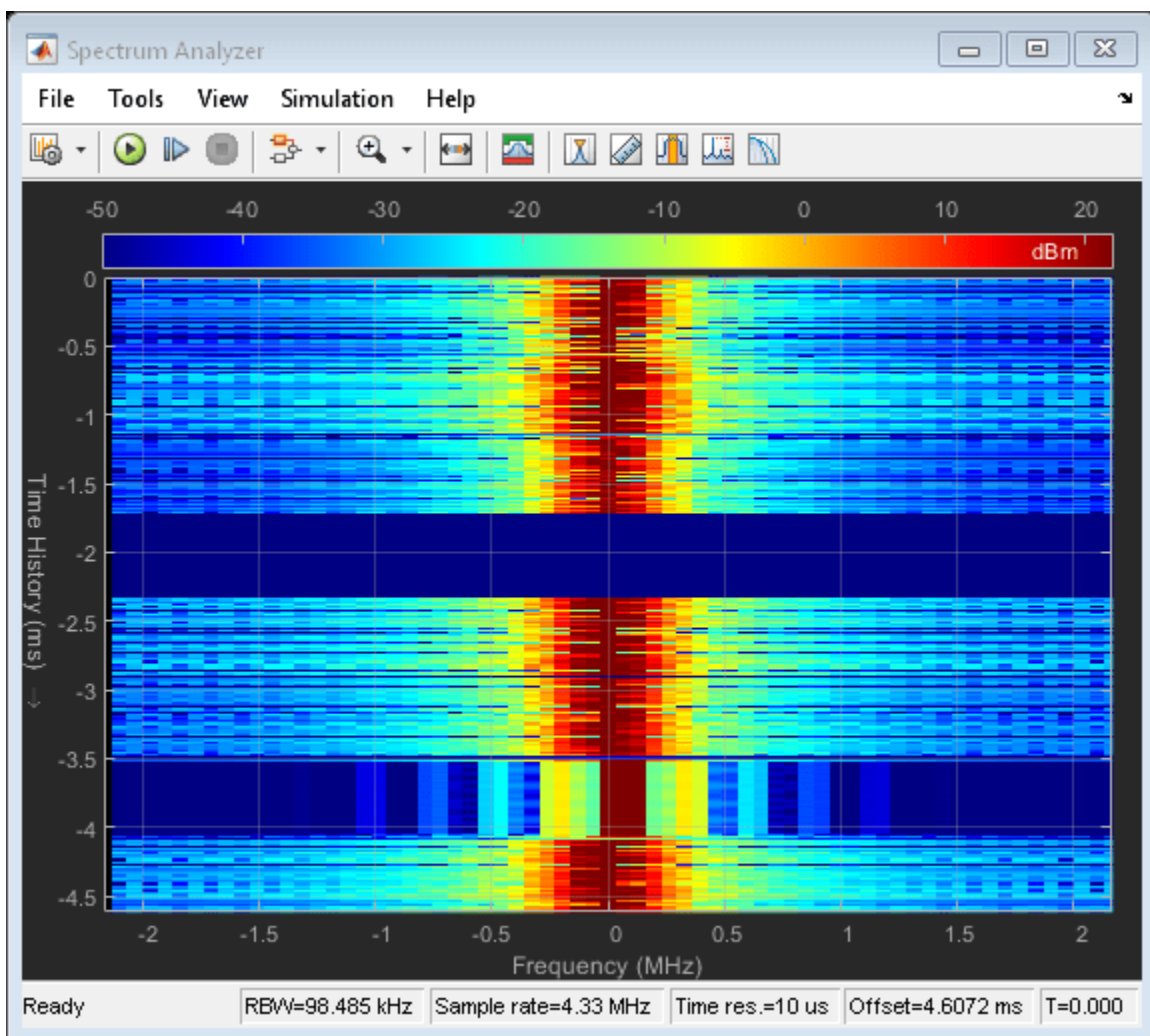

```
FrameLengthInSamples: 20000
```

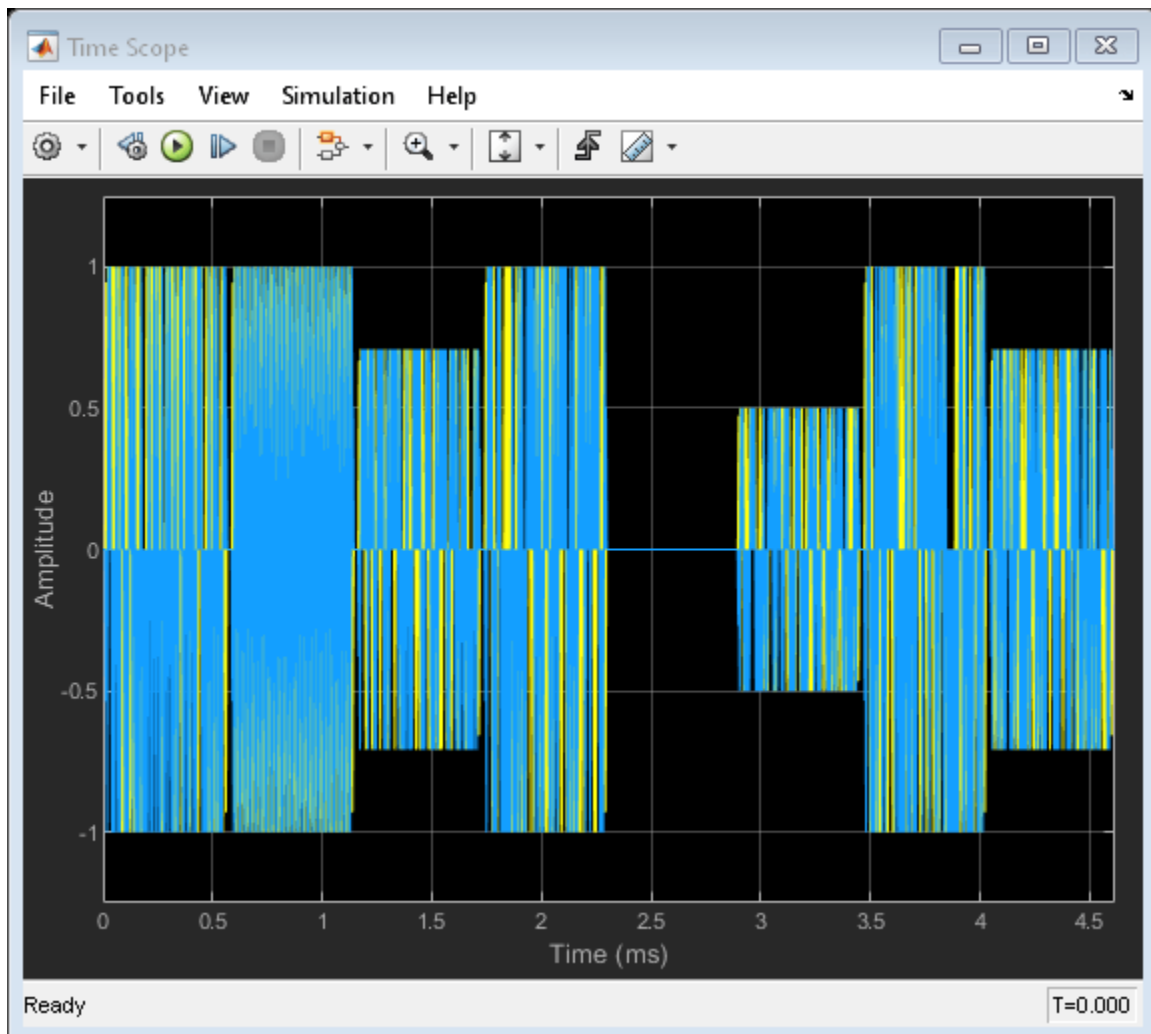

The model sample time of the MATLAB Function (Simulink) block is set to `wfInfo.FrameLengthInSamples/wfInfo.SampleRate`. To view the **Sample time** parameter, open the Block Parameters dialog box by right-clicking the MATLAB Function block and selecting **Block Parameters (Subsystem)**.

Before the simulation runs, you must configure the sample rate of the MATLAB Function block. The `PreLoadFcn` and `InitFcn` callback functions configure the MATLAB Function block by creating a `gsmDownlinkConfig` object and `wfInfo` structure. To view the callback functions, on the **Modeling** tab, in the **Setup** section, select **Model Settings > Model Properties**. Then, on the **Callbacks** tab, select the `PreLoadFcn` or `InitFcn` callback function in the **Model callbacks** pane.

Results

Display the time domain signal and the spectrogram by running the simulation.

More About

GSM Frames, Time Slots, and Bursts

In GSM, transmissions consist of TDMA frames. Each GSM TDMA frame consists of eight time slots. The transmission data content of a time slot is called a burst. As described in Section 5.2 of 3GPP TS 45.011, a GSM time slot has a 156.25-symbol duration when using the normal symbol period, which is a time interval of $15/26$ ms or about 576.9 microseconds. A guard period of 8.25 symbols or about 30.46 microseconds separates each time slot. The GSM standards describes a symbol as one bit period. Since GSM uses GMSK modulation, there is one bit per bit period. The transmission timing of a burst within a time slot is defined in terms of the bit number (BN). The BN refers to a particular bit period within a time slot. The bit with the lowest BN is transmitted first. BN0 is the first bit period, and BN156 is the last quarter-bit period.

This image from 3GPP TS 45.011 shows the relationship between different frame types and the relationship between different burst types.

This table shows the supported burst types and their characteristics.

Burst Type	Description	Link Direction	Useful Duration
NB	Normal burst	Uplink/Downlink	147
FB	Frequency correction burst	Downlink	147
SB	Synchronization burst	Downlink	147
Dummy	Dummy burst	Downlink	147
AB	Access burst	Uplink	87
Off	No burst sent	Uplink/Downlink	0

Useful duration, described in Section 5.2.2 of 3GPP TS 45.002, is a characteristic of GSM bursts. The useful duration, or useful part, of a burst is defined as beginning halfway through BN0 and ending half a bit period before the start of the guard period. The guard period is the period between bursts in successive time slots. This figure, from Section 2.2 of 3GPP TS 45.004, shows the leading and trailing ½ bit difference between the useful and active parts of the burst.

For more information, see “GSM TDMA Frame Parameterization for Waveform Generation”.

Training Sequence Code (TSC)

Normal bursts include a training sequence bits field assigned a bit pattern based on the specified TSC. For GSM, you can select one of these eight training sequences for normal burst type time slots.

Training Sequence Code (TSC)	Training Sequence Bits (BN61, BN62, ..., BN86)
0	(0,0,1,0,0,1,0,1,1,1,0,0,0,0,1,0,0,0,1,0,0,1,0,0,1,0,1,1,1)
1	(0,0,1,0,1,1,0,1,1,1,0,1,1,1,1,0,0,0,1,0,1,1,0,1,1,0,1,1,1)
2	(0,1,0,0,0,0,1,1,1,0,1,1,1,0,1,0,0,1,0,0,0,0,1,1,1,0)
3	(0,1,0,0,0,1,1,1,1,0,1,1,0,1,0,0,0,1,0,0,0,1,1,1,1,0)
4	(0,0,0,1,1,0,1,0,1,1,1,0,0,1,0,0,0,0,0,1,1,0,1,0,1,1)
5	(0,1,0,0,1,1,1,0,1,0,1,1,0,0,0,0,0,1,0,0,1,1,1,0,1,0)
6	(1,0,1,0,0,1,1,1,1,1,0,1,1,0,0,0,1,0,1,0,0,1,1,1,1,1)
7	(1,1,1,0,1,1,1,1,0,0,0,1,0,0,1,0,1,1,1,0,1,1,1,0,1,0)

For more information, see Section 5.2.3 in 3GPP TS 45.002.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- The `SamplesPerSymbol`, `RiseTime`, `RiseDelay`, `FallTime`, and `FallDelay` properties must be set when creating the object, and their settings are static in the generated code.
- The `BurstType` [property must be set using the enumeration type instead of the string representation. Use these `gsmDownlinkBurstType` enumerations: `gsmDownlinkBurstType.NB`, `gsmDownlinkBurstType.FB`, `gsmDownlinkBurstType.SB`, `gsmDownlinkBurstType.Dummy`, and `gsmUplinkBurstType.Off`. For example, this code assigns a frequency correction burst in time slot 2 and 5.

```
cfg = gsmDownlinkConfig
```

```
cfg =
```

```
gsmDownlinkConfig with properties:
```

```

    BurstType: [NB    NB    NB    NB    NB    NB    NB    NB]
SamplesPerSymbol: 16
          TSC: [0 1 2 3 4 5 6 7]
Attenuation: [0 0 0 0 0 0 0 0]
    RiseTime: 2
    RiseDelay: 0
    FallTime: 2
    FallDelay: 0

```

```
cfg.BurstType([2 5] +1) = gsmDownlinkBurstType.FB
```

```
cfg =
```

```
gsmDownlinkConfig with properties:
```

```

    BurstType: [NB    NB    FB    NB    NB    FB    NB    NB]
SamplesPerSymbol: 16
          TSC: [0 1 2 3 4 5 6 7]
Attenuation: [0 0 0 0 0 0 0 0]
    RiseTime: 2
    RiseDelay: 0
    FallTime: 2
    FallDelay: 0

gsmUplinkConfig

Create GSM uplink TDMA frame configuration object

Description

The `gsmUplinkConfig` object is a GSM uplink TDMA frame configuration object. Use `gsmUplinkConfig` objects to create GSM uplink waveforms.

Creation

Syntax

```
cfggsmul = gsmUplinkConfig
cfggsmul = gsmUplinkConfig(sps)
cfggsmul = gsmUplinkConfig( ____, Name, Value)
```

Description

`cfggsmul = gsmUplinkConfig` creates a GSM uplink TDMA frame configuration object.

`cfggsmul = gsmUplinkConfig(sps)` sets the `SamplesPerSymbol` property to `sps`.

`cfggsmul = gsmUplinkConfig(____, Name, Value)` sets one or more name-value pair arguments using any of the previous syntaxes. For example, `'RiseTime', 4` sets the burst rise time to 4 symbols. Enclose each property in quotes. Specify name-value pair arguments after all other input arguments.

Properties

SamplesPerSymbol — Samples per symbol

16 (default) | positive integer multiple of 4

Samples per symbol, specified as a positive integer multiple of 4.

Data Types: `double`

BurstType — Burst types

`["NB" "NB" "NB" "NB" "NB" "NB" "NB" "NB"]` (default) | string row vector with 8 elements | `"NB" | "AB" | "Off"`

Burst types for time slots 0-7 in the TDMA frame, specified as one of these options:

- Eight-element row vector where each value is `"NB"`, `"AB"`, or `"Off"` — Each element specifies the burst type for the corresponding time slot.
- `"NB"` — Transmit data using a normal burst for every time slot.
- `"AB"` — Transmit data using an access burst for every time slot.

- "Off" — All eight time slots contain no data.

For more information, see "GSM Frames, Time Slots, and Bursts" on page 3-733

Note The `BurstType` property is an enumeration. To perform code generation, see "Code Generation" on page 3-736 and the "MEX Generation for GSM Uplink Waveform" on page 3-728 example.

Example: ["NB" "AB" "AB" "NB" "Off" "NB" "AB" "Off"] configures the frame to use normal bursts in time slots 0, 3, and 5, use access bursts in time slots 1, 2, and 6, and transmit no data in time slots 4 and 7.

TSC — Training sequence code

[0 1 2 3 4 5 6 7] (default) | eight-element row vector | integer in the range [0, 7]

Training sequence code (TSC) for normal bursts in time slots 0-7 in the TDMA frame, specified as one of these options:

- Eight-element row vector of integers in the range [0, 7] — Each element specifies the TSC value for the corresponding normal burst time slot.
- Integer in the range [0, 7] — Specifies the TSC value for every normal burst time slot.

For more information, see "Training Sequence Code (TSC)" on page 3-735.

Example: [5 7 0 0 0 0 0 0] configures the frame to use training sequence 5 in time slot 0, training sequence 7 in time slot 1, and training sequence 0 in time slots 2 through 7.

Dependencies

To enable this property for a time slot, set the corresponding element of `BurstType` to "NB".

Data Types: double

Attenuation — Power attenuation

[0 0 0 0 0 0 0 0] (default) | eight-element row vector | nonnegative integer

Power attenuation in dB for time slots 0-7 in the TDMA frame, specified as one of these options:

- Eight-element row vector of nonnegative integers — Each element specifies the attenuation power value for the corresponding time slot.
- Nonnegative integer — Specifies the power attenuation value for every time slot.

Example: [0 0 0 0 0 0 0 3] configures the frame to apply 0 dB of attenuation to the burst signal power in time slot 0 through 6 and 3 dB of attenuation to the burst signal power in time slot 7.

Data Types: double

RiseTime — Burst rise time

2 (default) | positive scalar

Burst rise time in symbols, specified as a positive scalar in the range [1/SamplesPerSymbol, 29], where the increment resolution is 1/SamplesPerSymbol. The total ramp-up and ramp-down duration (RiseTime - RiseDelay + FallTime + FallDelay) must be less than 9.25 symbols. The characteristic shape of the rising edge of the burst is sinusoidal.

For more information, see “GSM Frames, Time Slots, and Bursts” on page 3-733.

Data Types: `double`

RiseDelay – Burst rise delay

0 (default) | positive scalar

Burst rise delay in symbols, specified as a positive scalar in the range [-10, 10], where the increment resolution is `1/SamplesPerSymbol`. The total ramp-up and ramp-down duration (`RiseTime - RiseDelay + FallTime + FallDelay`) must be less than 9.25 symbols. The burst rise delay is measured with respect to the start of the useful part of the burst. For more information, see “GSM Frames, Time Slots, and Bursts” on page 3-733.

When the burst rise delay is 0, the burst reaches full amplitude at the start of the useful part of the burst. When the burst rise delay is positive, the burst reaches full amplitude `RiseDelay` symbols after the start of the useful part. When the burst rise delay is negative, the burst reaches full amplitude `RiseDelay` symbols before the start of the useful part.

Data Types: `double`

FallTime – Burst fall time

2 (default) | positive scalar

Burst fall time in symbols, specified as a positive scalar in the range [`1/SamplesPerSymbol`, 29], where the increment resolution is `1/SamplesPerSymbol`. The total ramp-up and ramp-down duration (`RiseTime - RiseDelay + FallTime + FallDelay`) must be less than 9.25 symbols. The characteristic shape of the falling edge of the burst is sinusoidal.

For more information, see “GSM Frames, Time Slots, and Bursts” on page 3-733.

Data Types: `double`

FallDelay – Burst fall delay

0 (default) | positive scalar

Burst fall delay in symbols, specified as a positive scalar in the range [-10, 10], where the increment resolution is `1/SamplesPerSymbol`. The total ramp-up and ramp-down duration (`RiseTime - RiseDelay + FallTime + FallDelay`) must be less than 9.25 symbols. The burst fall delay is measured with respect to the end of the useful part of the burst. For more information, see “GSM Frames, Time Slots, and Bursts” on page 3-733.

When the burst fall delay is 0, the burst begins decreasing from full amplitude at the end of the useful part of the burst. When the burst fall delay is positive, the burst begins decreasing from full amplitude `FallDelay` symbols after the end of the useful part. When the burst fall delay is negative, the burst begins decreasing from full amplitude `FallDelay` symbols before the end of the useful part.

Data Types: `double`

Examples

Create GSM Uplink Waveform

Create a GSM uplink TDMA frame configuration object with default settings, and then create a GSM waveform containing one TDMA frame. GSM TDMA frames have eight time slots, each separated by a guard period of 8.25 symbols or about 30.46×10^{-3} ms. Plot the GSM waveform.

Create a GSM uplink TDMA frame configuration object with default settings.

```
cfggsmul = gsmUplinkConfig

cfggsmul =
  gsmUplinkConfig with properties:

      BurstType: [NB    NB    NB    NB    NB    NB    NB    NB]
SamplesPerSymbol: 16
      TSC: [0 1 2 3 4 5 6 7]
Attenuation: [0 0 0 0 0 0 0 0]
      RiseTime: 2
      RiseDelay: 0
      FallTime: 2
      FallDelay: 0
```

Display information about the configured `gsmUplinkConfig` object by using the `gsmInfo` function. Assign the sample rate to a variable, `Rs`, for use in computing the plot timescale.

```
wfInfo = gsmInfo(cfggsmul)

wfInfo = struct with fields:
      SymbolRate: 2.7083e+05
      SampleRate: 4.3333e+06
BandwidthTimeProduct: 0.3000
BurstLengthInSymbols: 156.2500
      NumBurstsPerFrame: 8
BurstLengthInSamples: 2500
FrameLengthInSamples: 20000
```

```
Rs = wfInfo.SampleRate;
```

Create the GSM waveform by using the `gsmFrame` function, and then plot the GSM waveform.

```
waveform = gsmFrame(cfggsmul);

t = (0:length(waveform)-1)/Rs*1e3;
subplot(2,1,1)
plot(t,abs(waveform))
grid on
axis([0 5 0 1.2])
title('GSM Uplink Waveform - Amplitude')
xlabel('Time (ms)')
ylabel('Amplitude')
subplot(2,1,2)
plot(t,unwrap(angle(waveform)))
grid on
title('GSM Uplink Waveform - Phase')
xlabel('Time (ms)')
ylabel('Phase (rad)')
```

Create GSM Uplink Waveform with Specified Samples per Symbol

Create a GSM uplink TDMA frame configuration object that specifies 4 samples per symbol, and then create a GSM waveform containing one GSM downlink TDMA frame. The GSM TDMA frame are eight time slots, each separated by a guard period of 8.25 symbols or about 30.46×10^{-3} ms separates each time slot. Plot the GSM waveform.

Create a GSM uplink TDMA frame configuration object, specifying 4 samples per symbols.

```
sps = 4;
cfggsmul = gsmUplinkConfig(sps)

cfggsmul =
  gsmUplinkConfig with properties:
      BurstType: [NB    NB    NB    NB    NB    NB    NB    NB]
      SamplesPerSymbol: 4
      TSC: [0 1 2 3 4 5 6 7]
      Attenuation: [0 0 0 0 0 0 0 0]
      RiseTime: 2
      RiseDelay: 0
      FallTime: 2
      FallDelay: 0
```

Display information about the configured `gsmUplinkConfig` object by using the `gsmInfo` function. Assign the sample rate to a variable, `Rs`, for use in computing the plot timescale.

```
wfInfo = gsmInfo(cfggsmul)

wfInfo = struct with fields:
    SymbolRate: 2.7083e+05
    SampleRate: 1.0833e+06
    BandwidthTimeProduct: 0.3000
    BurstLengthInSymbols: 156.2500
    NumBurstsPerFrame: 8
    BurstLengthInSamples: 625
    FrameLengthInSamples: 5000
```

```
Rs = wfInfo.SampleRate;
```

Create the GSM waveform by using the `gsmFrame` function, and then plot the GSM waveform.

```
waveform = gsmFrame(cfggsmul);

t = (0:length(waveform)-1)/Rs*1e3;
subplot(2,1,1)
plot(t,abs(waveform))
grid on
axis([0 5 0 1.2])
title('GSM Uplink Waveform - Amplitude')
xlabel('Time (ms)')
ylabel('Amplitude')
subplot(2,1,2)
plot(t,unwrap(angle(waveform)))
grid on
title('GSM Uplink Waveform - Phase')
xlabel('Time (ms)')
ylabel('Phase (rad)')
```

Create GSM Uplink Waveform with Specified Attenuation

Create two GSM uplink TDMA frame configuration objects. Specify default settings for the first `gsmUplinkConfig` object and adjust the signal power per time slot for the second. Generate GSM waveforms for both configurations. Plot the waveforms to show the signal attenuation per time slot in the second waveform.

Create a GSM uplink TDMA frame configuration object with default settings.

```
cfggsmul = gsmUplinkConfig
```

```
cfggsmul =  
gsmUplinkConfig with properties:
```

```
    BurstType: [NB    NB    NB    NB    NB    NB    NB    NB]  
SamplesPerSymbol: 16  
      TSC: [0 1 2 3 4 5 6 7]  
Attenuation: [0 0 0 0 0 0 0 0]  
    RiseTime: 2  
    RiseDelay: 0  
    FallTime: 2  
    FallDelay: 0
```

Create another GSM uplink TDMA frame configuration object, adjusting the signal attenuation settings per time slot.

```
cfggsmul2 = gsmUplinkConfig('Attenuation',[1 2 3 4 5 4 3 2])

cfggsmul2 =
  gsmUplinkConfig with properties:
      BurstType: [NB    NB    NB    NB    NB    NB    NB    NB]
  SamplesPerSymbol: 16
          TSC: [0 1 2 3 4 5 6 7]
  Attenuation: [1 2 3 4 5 4 3 2]
    RiseTime: 2
    RiseDelay: 0
    FallTime: 2
    FallDelay: 0
```

Display information about the configured `gsmUplinkConfig` object by using the `gsmInfo` function. Assign the sample rate to a variable, `Rs`, for use in computing the plot timescale.

```
wfInfo = gsmInfo(cfggsmul)

wfInfo = struct with fields:
      SymbolRate: 2.7083e+05
      SampleRate: 4.3333e+06
  BandwidthTimeProduct: 0.3000
  BurstLengthInSymbols: 156.2500
    NumBurstsPerFrame: 8
  BurstLengthInSamples: 2500
  FrameLengthInSamples: 20000
```

```
Rs = wfInfo.SampleRate;
```

Create the GSM waveforms, containing one TDMA frame, by using the `gsmFrame` function. GSM TDMA frames are eight time slots, each separated by a guard period of 8.25 symbols or about 30.46×10^{-3} ms. Plot each GSM waveform.

```
waveform = gsmFrame(cfggsmul);
waveform2 = gsmFrame(cfggsmul2);

t = (0:length(waveform)-1)/Rs*1e3;
subplot(2,1,1)
plot(t,[abs(waveform),abs(waveform2)])
grid on
axis([0 5 0 1.2])
title('GSM Uplink Waveform - Amplitude')
xlabel('Time (ms)')
ylabel('Amplitude')
subplot(2,1,2)
plot(t,[unwrap(angle(waveform)),unwrap(angle(waveform2))])
grid on
title('GSM Uplink Waveform - Phase')
xlabel('Time (ms)')
ylabel('Phase (rad)')
```

MEX Generation for GSM Uplink Waveform

Generate and run a GSM waveform MEX function from the helper function `createUplinkWaveform`. The `createUplinkWaveform` helper function creates a GSM uplink waveform.

Write MATLAB Function

Open `createUplinkWaveform.m` to see the code. The `createUplinkWaveform` helper function generates a GSM uplink waveform by using the `gsmUplinkConfig` object and the `gsmInfo` and `gsmFrame` functions.

Generate GSM Waveform

Use the `createUplinkWaveform` helper function to create a GSM waveform containing three TDMA frames, and then plot the waveform.

```
[x,t] = createUplinkWaveform(3);

figure
subplot(2,1,1);
plot(t,abs(x));
grid on;
title('GSM Uplink Waveform - Amplitude');
```

```

xlabel('Time (ms)');
ylabel('Amplitude');
subplot(2,1,2);
plot(t,unwrap(angle(x)));
grid on;
title('GSM Uplink Waveform - Phase');
xlabel('Time (ms)');
ylabel('Phase (rad)')

```

Generate MEX Function

Code generation defaults to MEX code generation when you do not specify a build target. By default, codegen names the generated MEX function `createUplinkWaveform_mex`. Generate a MEX function from the `createUplinkWaveform` helper function, and then run the MEX function to create three TDMA frames.

```
codegen createUplinkWaveform -args 3
```

Code generation successful.

Generate Waveform Using MEX Function

Run the MEX function and plot the results. Since the waveform is created using random data, the phase plot changes each time you run the `generateUplinkFrame` helper function or `createUplinkWaveform_mex` function.

```
[x,t] = createUplinkWaveform_mex(3);
```

```

figure
subplot(2,1,1);
plot(t,abs(x));
grid on;
title('MEX - GSM Uplink Waveform - Amplitude');
xlabel('Time (ms)');
ylabel('Amplitude')
subplot(2,1,2);
plot(t,unwrap(angle(x)));
grid on;
title('MEX - GSM Uplink Waveform - Phase');
xlabel('Time (ms)');
ylabel('Phase (rad)')

```

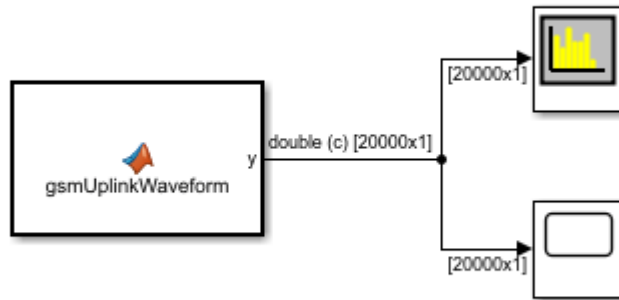

GSM Uplink Waveform Generation in Simulink

Model a GSM waveform generator in Simulink® by using the MATLAB® Function block and Communications Toolbox™ functions.

GSM Uplink Waveform Generation

The MATLAB Function (Simulink) block contains the `gsmUplinkWaveform` function code. The code in the MATLAB Function block creates a GSM waveform by using the `gsmUplinkConfig` object and the `gsmFrame` function.

GSM Uplink Waveform Generation and Visualization

Copyright 2019 The MathWorks, Inc.

The `gsmUplinkConfig` object specifies 16 samples per symbol and the time slot configuration for the GSM uplink TDMA frame shown is this table.

Timeslot	Burst Type	Attenuation
0	Normal burst	0 dB
1	Access burst	0 dB
2	Normal burst	3 dB
3	Normal burst	0 dB
4	No data	0 dB
5	Normal burst	6 dB
6	Normal burst	0 dB
7	Normal burst	3 dB

The output waveform has 16 samples for each GMSK symbol. The `gsmFrame` function generates the samples of the waveform.

Explore the Model

In compliance with GSM standards 3GPP TS 45.001 and 3GPP TS 45.002, the sample time of the MATLAB Function block that contains the `gsmUplinkWaveform` function code is set to the GSM symbol rate of $1625e3/6$ symbols per second. Display the current `gsmUplinkConfig` object settings by using the `gsmInfo` function.

```
wfInfo =
```

```
struct with fields:
```

```

    SymbolRate: 2.7083e+05
    SampleRate: 4.3333e+06
    BandwidthTimeProduct: 0.3000
    BurstLengthInSymbols: 156.2500
    NumBurstsPerFrame: 8
    BurstLengthInSamples: 2500

```

```
FrameLengthInSamples: 20000
```

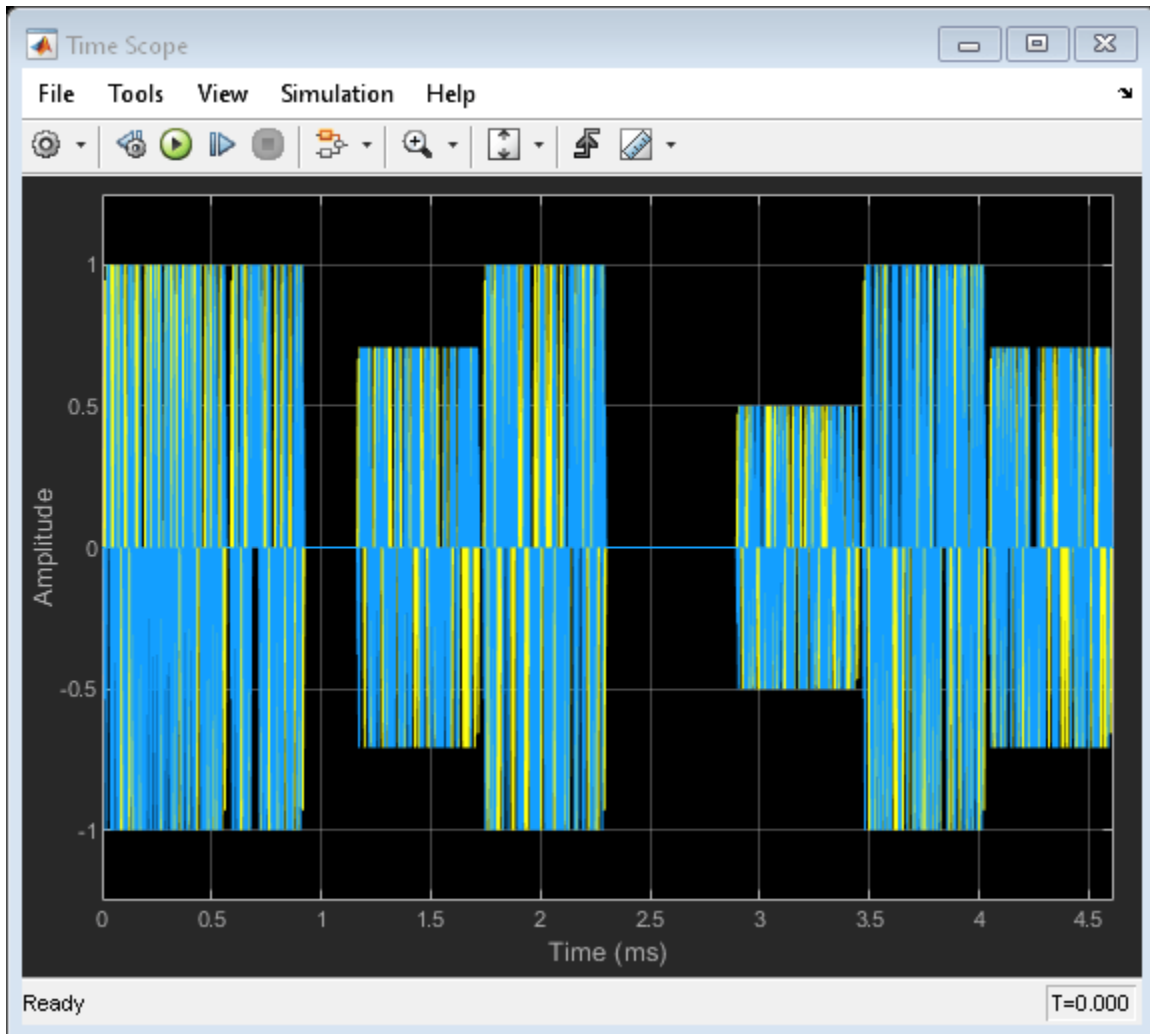

The model sample time of the MATLAB Function (Simulink) block is set to `wfInfo.FrameLengthInSamples/wfInfo.SampleRate`. To view the **Sample time** parameter, open the Block Parameters dialog box by right-clicking the MATLAB Function block and selecting **Block Parameters (Subsystem)**.

Before the simulation runs, you must configure the sample rate of the MATLAB Function block. The `PreLoadFcn` and `InitFcn` callback functions configure the MATLAB Function block by creating a `gsmUplinkConfig` object and `wfInfo` structure. To view the callback functions, on the **Modeling** tab, in the **Setup** section, select **Model Settings > Model Properties**. Then, on the **Callbacks** tab, select the `PreLoadFcn` or `InitFcn` callback function in the **Model callbacks** pane.

Results

Displays the time domain signal and the spectrogram by running the simulation.

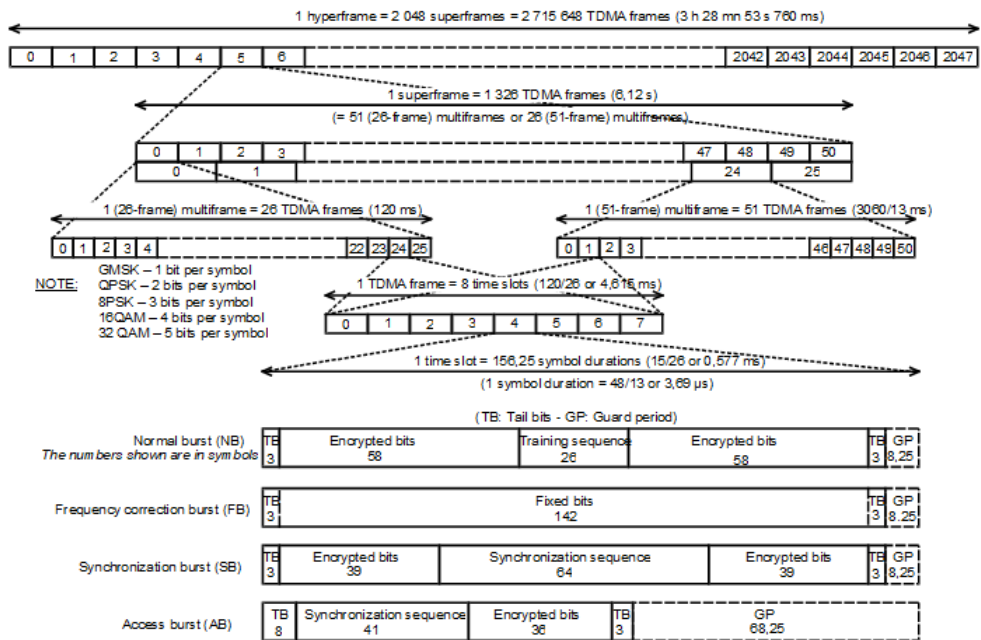

More About

GSM Frames, Time Slots, and Bursts

In GSM, transmissions consist of TDMA frames. Each GSM TDMA frame consists of eight time slots. The transmission data content of a time slot is called a burst. As described in Section 5.2 of 3GPP TS 45.011, a GSM time slot has a 156.25-symbol duration when using the normal symbol period, which is a time interval of $15/26$ ms or about 576.9 microseconds. A guard period of 8.25 symbols or about 30.46 microseconds separates each time slot. The GSM standards describes a symbol as one bit period. Since GSM uses GMSK modulation, there is one bit per bit period. The transmission timing of a burst within a time slot is defined in terms of the bit number (BN). The BN refers to a particular bit period within a time slot. The bit with the lowest BN is transmitted first. BN0 is the first bit period, and BN156 is the last quarter-bit period.

This image from 3GPP TS 45.011 shows the relationship between different frame types and the relationship between different burst types.

This table shows the supported burst types and their characteristics.

Burst Type	Description	Link Direction	Useful Duration
NB	Normal burst	Uplink/Downlink	147
FB	Frequency correction burst	Downlink	147
SB	Synchronization burst	Downlink	147
Dummy	Dummy burst	Downlink	147
AB	Access burst	Uplink	87
Off	No burst sent	Uplink/Downlink	0

Useful duration, described in Section 5.2.2 of 3GPP TS 45.002, is a characteristic of GSM bursts. The useful duration, or useful part, of a burst is defined as beginning halfway through BN0 and ending half a bit period before the start of the guard period. The guard period is the period between bursts in successive time slots. This figure, from Section 2.2 of 3GPP TS 45.004, shows the leading and trailing ½ bit difference between the useful and active parts of the burst.

For more information, see “GSM TDMA Frame Parameterization for Waveform Generation”.

Training Sequence Code (TSC)

Normal bursts include a training sequence bits field assigned a bit pattern based on the specified TSC. For GSM, you can select one of these eight training sequences for normal burst type time slots.

Training Sequence Code (TSC)	Training Sequence Bits (BN61, BN62, ..., BN86)
0	(0,0,1,0,0,1,0,1,1,1,0,0,0,0,1,0,0,0,1,0,0,1,0,0,1,0,1,1,1)
1	(0,0,1,0,1,1,0,1,1,1,0,1,1,1,1,0,0,0,1,0,1,1,0,1,1,1)
2	(0,1,0,0,0,0,1,1,1,0,1,1,1,0,1,0,0,1,0,0,0,0,1,1,1,0)
3	(0,1,0,0,0,1,1,1,1,0,1,1,0,1,0,0,0,1,0,0,0,1,1,1,1,0)
4	(0,0,0,1,1,0,1,0,1,1,1,0,0,1,0,0,0,0,0,1,1,0,1,0,1,1)
5	(0,1,0,0,1,1,1,0,1,0,1,1,0,0,0,0,0,1,0,0,1,1,1,0,1,0)
6	(1,0,1,0,0,1,1,1,1,1,0,1,1,0,0,0,1,0,1,0,0,1,1,1,1,1)
7	(1,1,1,0,1,1,1,1,0,0,0,1,0,0,1,0,1,1,1,0,1,1,1,1,0,0)

For more information, see Section 5.2.3 in 3GPP TS 45.002.

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- The `SamplesPerSymbol`, `RiseTime`, `RiseDelay`, `FallTime`, and `FallDelay` properties must be set when creating the object, and their settings are static in the generated code.
- The `BurstType` property must be set using the enumeration type instead of the string representation. Use these `gsmDownlinkBurstType` enumerations: `gsmDownlinkBurstType.NB`, `gsmDownlinkBurstType.AB`, and `gsmUplinkBurstType.Off`. For example, this code assigns an access burst in time slot 2 and 5.

```
cfg = gsmUplinkConfig
```

```
cfg =
```

```
gsmUplinkConfig with properties:
```

```

    BurstType: [NB    NB    NB    NB    NB    NB    NB    NB]
SamplesPerSymbol: 16
          TSC: [0 1 2 3 4 5 6 7]
Attenuation: [0 0 0 0 0 0 0 0]
    RiseTime: 2
    RiseDelay: 0
    FallTime: 2
    FallDelay: 0

```

```
cfg.BurstType([2 5] +1) = gsmUplinkBurstType.AB
```

```
cfg =
```

```
gsmUplinkConfig with properties:
```

```

    BurstType: [NB    NB    AB    NB    NB    AB    NB    NB]
SamplesPerSymbol: 16
          TSC: [0 1 2 3 4 5 6 7]
Attenuation: [0 0 0 0 0 0 0 0]
    RiseTime: 2
    RiseDelay: 0
    FallTime: 2
    FallDelay: 0

```

Topics

“GSM TDMA Frame Parameterization for Waveform Generation”

Introduced in R2019b

comm.HadamardCode

Package: comm

Generate Hadamard code

Description

The `HadamardCode` object generates a Hadamard code from a Hadamard matrix, whose rows form an orthogonal set of codes. You can use orthogonal codes for spreading in communication systems in which the receiver is perfectly synchronized with the transmitter. In these systems, the despreading operation is ideal, because the codes decorrelate completely.

To generate a Hadamard code:

- 1 Define and set up your Hadamard code object. See “Construction” on page 3-738.
- 2 Call `step` to generate a Hadamard according to the properties of `comm.HadamardCode`. The behavior of `step` is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj)` and `y = obj()` perform equivalent operations.

Construction

`H = comm.HadamardCode` creates a Hadamard code generator System object, `H`. This object generates Hadamard codes from a set of orthogonal codes.

`H = comm.HadamardCode(Name, Value)` creates a Hadamard code generator object, `H`, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as `(Name1, Value1, ..., NameN, ValueN)`.

Properties

Length

Length of generated code

Specify the length of the generated code as a numeric, integer scalar value with a power of two. The default is 64.

Index

Row index of Hadamard matrix

Specify the row index of the Hadamard matrix as a numeric, integer scalar value in the range $[0, 1, \dots, N-1]$. N is the value of the `Length` on page 3-0 property. The default is 60. An $N \times N$ Hadamard matrix, denoted as $P(N)$, is defined recursively as follows: $P(1) = [1]$ $P(2N) = [P(N) \ P(N); P(N) \ -P(N)]$ The $N \times N$ Hadamard matrix has the property that $P(N) \times P(N)' = N \times \text{eye}(N)$. The `step` method outputs code samples from the row of the Hadamard matrix that you specify in this property.

When you set this property to an integer k , the output code has exactly k zero crossings, for $k = 0, 1, \dots, N-1$.

SamplesPerFrame

Number of output samples per frame

Specify the number of Hadamard code samples that the `step` method outputs as a numeric, positive, integer scalar value. The default is 1.

When you set this property to a value of M , the `step` method outputs M samples of a Hadamard code of length N . N equals the length of the code that you specify in the `Length` on page 3-0 property.

OutputDataType

Data type of output

Specify the output data type as one of `double` | `int8`. The default is `double`.

Methods

`step` Generate Hadamard code

Common to All System Objects	
<code>release</code>	Allow System object property value changes
<code>reset</code>	Reset internal states of System object

Examples

Hadamard Code Sequence

Generate 10 samples of a Hadamard code sequence having a length of 128.

```
hadamard = comm.HadamardCode('Length',128,'SamplesPerFrame',10)
```

```
hadamard =  
    comm.HadamardCode with properties:
```

```
        Length: 128  
        Index: 60  
    SamplesPerFrame: 10  
    OutputDataType: 'double'
```

```
seq = hadamard()
```

```
seq = 10x1
```

```
    1  
    1  
    1  
    1  
   -1
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the Hadamard Code Generator block reference page. The object properties correspond to the block parameters, except:

- The object does not have a property to select frame based outputs.
- The object does not have a property that corresponds to the **Sample time** parameter.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

See “System Objects in MATLAB Code Generation” (MATLAB Coder).

`comm.WalshCode` | `comm.OVSFCode`

Introduced in R2012a

step

System object: comm.HadamardCode

Package: comm

Generate Hadamard code

Syntax

$Y = \text{step}(H)$

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj)` and `y = obj()` perform equivalent operations.

$Y = \text{step}(H)$ outputs a frame of the Hadamard code in column vector Y . Specify the frame length with the `SamplesPerFrame` property. The Hadamard code corresponds to one of the rows of an $N \times N$ Hadamard matrix, where N is a nonnegative power of 2, which you specify in the `Length` property. Use the `Index` property to choose the row of the Hadamard matrix. The `step` method outputs the code in a bi-polar format with 0 and 1 mapped to 1 and -1, respectively.

Note `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications. For more information on changing property values, see “System Design in MATLAB Using System Objects”.

comm.HDLCRCDetector

Package: comm

Detect errors in input data using CRC

Description

This HDL-optimized cyclic redundancy code (CRC) detector System object computes a checksum on the input data and compares the result against the input checksum. Instead of frame processing, the HDLCRCDetector System object processes streaming data. The object has frame synchronization control signals for both input and output data streams.

To compute and compare checksums:

- 1 Create the `comm.HDLCRCDetector` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

Creation

Syntax

```
CRCDet = comm.HDLCRCDetector  
CRCDet = comm.HDLCRCDetector(Name,Value)  
CRCDet = comm.HDLCRCDetector(poly,Name,Value)
```

Description

`CRCDet = comm.HDLCRCDetector` creates an HDL-optimized CRC detector System object, `CRCDet`, that detects errors in the input data according to a specified generator polynomial.

`CRCDet = comm.HDLCRCDetector(Name,Value)` sets properties using one or more name-value pairs. Enclose each property name in single quotes. For example,

```
CRCDet = comm.HDLCRCDetector('Polynomial',[1 0 0 0 1 0 0 0 0], ...  
'FinalXORValue',[1 1 0 0 0 0 0 0]);
```

specifies a CRC8 polynomial and an 8-bit value to XOR with the final checksum.

`CRCDet = comm.HDLCRCDetector(poly,Name,Value)` creates an HDL-optimized CRC detector System object, `CRCDet`, with the `Polynomial` property set to `poly`, and the other specified property names set to the specified values.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see *System Design in MATLAB Using System Objects*.

Polynomial — Generator polynomial

[1 0 0 0 1 0 0 0 0 0 0 1 0 0 0 0 1] (default) | binary vector

Generator polynomial, specified as a binary vector, with coefficients in descending order of powers. The vector length must be equal to the degree of the polynomial plus 1.

InitialState — Initial conditions of shift register

0 (default) | binary scalar | binary vector

Initial conditions of the shift register, specified as a binary, double-precision or single-precision scalar or vector. If you specify this property as a vector, the vector length is the degree of the generator polynomial that you specify in the `Polynomial` property. If you specify this property as a scalar, the object expands the value to a vector of length equal to the degree of the generator polynomial.

DirectMethod — Method of calculating checksum

false (default) | true

Method of calculating checksum, specified as a logical scalar. When this property is `true`, the object uses the direct algorithm for CRC checksum calculations.

To learn about direct and non-direct algorithms, see “Cyclic Redundancy Check Codes”.

ReflectInput — Input byte order

false (default) | true

Input byte order, specified as a logical scalar. When this property is `true`, the object flips the input data on a bitwise basis before it enters the shift register.

ReflectCRCChecksum — Checksum byte order

false (default) | true

Checksum byte order, specified as a logical scalar. When this property is `true`, the object flips the output CRC checksum around its center.

FinalXORValue — Checksum mask

0 (default) | binary scalar | binary vector

Checksum mask, specified as a binary, double- or single-precision data type scalar or vector. The object XORs the checksum with this value before appending the checksum to the input data. If you specify this property as a vector, the vector length is the degree of the generator polynomial that you specify in the `Polynomial` property. If you specify this property as a scalar, the object expands the value to a vector of length equal to the degree of the generator polynomial.

Usage

Syntax

```
[Y,startOut,endOut,validOut,err] = CRCn(X,startIn,endIn,validIn)
```

Description

`[Y, startOut, endOut, validOut, err] = CRCn(X, startIn, endIn, validIn)` computes CRC checksums for an input message `X` based on the control signals and compares the computed checksum with input checksum. If the two checksums are not equal, the output `err` is set to 1 (`true`).

Input Arguments**X — Input message and appended checksum**

binary column vector | scalar integer

Input message and appended checksum, specified as a binary vector or a scalar integer representing several bits. For example, vector input `[0, 0, 0, 1, 0, 0, 1, 1]` is equivalent to `uint8` input 19.

If the input is a vector, the data type can be `double` or `logical`. If the input is a scalar, the data type can be `unsigned integer` or `unsigned fixed-point` with 0 fractional bits (`fi([], 0, N, 0)`).

`X` can be part or all of the message to be checked.

The length of `X` must be less than or equal to the CRC length, and the CRC length must be divisible by the length of `X`.

The CRC length is the order of the polynomial that you specify in the `Polynomial` property.

Data Types: `double` | `uint8` | `uint16` | `uint32` | `logical` | `unsigned fi`

startIn — Start of input message

logical scalar

Start of the input message, specified as a logical scalar.

endIn — End of input message

logical scalar

End of the input message, specified as a logical scalar.

validIn — Validity of input data

logical scalar

Validity of input data, specified as a logical scalar. When `validIn` is 1 (`true`), the object computes the CRC checksum for input `X`.

Output Arguments**Y — Message with checksum removed**

binary column vector | scalar integer

Message with checksum removed, returned as a scalar integer or binary column vector with the same width and data type as input `X`.

startOut — Start of input message

logical scalar

Start of the input message, returned as a logical scalar.

endOut — End of input message

logical scalar

End of the input message, returned as a logical scalar.

validOut — Validity of input data

logical scalar

Validity of input data, returned as a logical scalar. When `validOut` is 1 (`true`), the output data `Y` is valid.

err — Checksum mismatch

logical scalar

Checksum mismatch, returned as a logical scalar. `err` is 1 (`true`) when the input checksum does not match the calculated checksum.

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Common to All System Objects

<code>step</code>	Run System object algorithm
<code>release</code>	Release resources and allow changes to System object property values and input characteristics
<code>reset</code>	Reset internal states of System object

Examples

CRC Encode and Decode for HDL

Encode and decode a signal using the HDL-optimized CRC generator and detector System objects. This example shows how to include each object in a function for HDL code generation.

Create a 32-bit message to be encoded, in two 16-bit columns.

```
msg = randi([0 1],16,2);
```

Run for 12 steps to accommodate the latency of both objects. Assign control signals for all steps. The first two samples are the valid data, and the remainder are processing latency.

```
numSteps = 12;
startIn = logical([1 0 0 0 0 0 0 0 0 0 0 0]);
endIn = logical([0 1 0 0 0 0 0 0 0 0 0 0]);
validIn = logical([1 1 0 0 0 0 0 0 0 0 0 0]);
```

Pass random input to the HDLCRCGenerator System object™ while it is processing the input message. The random data is not encoded because the input valid signal is 0 for steps 3 to 10.

```
randIn = randi([0, 1],16,numSteps-2);
dataIn = [msg randIn];
```

Write a function that creates and calls each System object™. You can generate HDL from these functions. The generator and detector objects both have a CRC length of 16 and use the default polynomial.

```
function [dataOut,startOut,endOut,validOut] = HDLCRC16Gen(dataIn,startIn,endIn,validIn)
%HDLCRC16Gen
% Generates CRC checksum using the comm.HDLCRCGenerator System object(TM)
% dataIn is a binary column vector.
% startIn, endIn, and validIn are logical scalar values.
% You can generate HDL code from this function.

persistent crcg16;
if isempty(crcg16)
    crcg16 = comm.HDLCRCGenerator()
end
[dataOut,startOut,endOut,validOut] = crcg16(dataIn,startIn,endIn,validIn);
end
```

```
function [dataOut,startOut,endOut,validOut,err] = HDLCRC16Det(dataIn,startIn,endIn,validIn)
%HDLCRC16Det
% Checks CRC checksum using the comm.HDLCRCDetector System object(TM)
% dataIn is a binary column vector.
% startIn, endIn, and validIn are logical scalar values.
% You can generate HDL code from this function.

persistent crcd16;
if isempty(crcd16)
    crcd16 = comm.HDLCRCDetector()
end
[dataOut,startOut,endOut,validOut,err] = crcd16(dataIn,startIn,endIn,validIn);
end
```

Call the CRC generator function. The encoded message is the original message plus a 16 bit checksum.

```
for i = 1:numSteps
    [dataOutGen(:,i),startOutGen(i),endOutGen(i),validOutGen(i)] = ...
        HDLCRC16Gen(logical(dataIn(:,i)),startIn(i),endIn(i),validIn(i));
end
```

crcg16 =

comm.HDLCRCGenerator with properties:

```
    Polynomial: [1 0 0 0 1 0 0 0 0 0 0 1 0 0 0 0 1]
    InitialState: 0
    DirectMethod: false
    ReflectInput: false
    ReflectCRCChecksum: false
    FinalXORValue: 0
```

Add noise by flipping a bit in the message.

```
dataOutNoise = dataOutGen;
dataOutNoise(2,4) = ~dataOutNoise(2,4);
```

Call the CRC detector function. The output of the detector is the input message with the checksum removed. If the input checksum was not correct, the `err` flag is set with the last word of the output.

```
for i = 1:numSteps
[dataOut(:,i),startOut(i),endOut(i),validOut(i),err(i)] = ...
    HDLCRC16Det(logical(dataOutNoise(:,i)),startOutGen(i),endOutGen(i),validOutGen(i));
end
```

```
crcd16 =
```

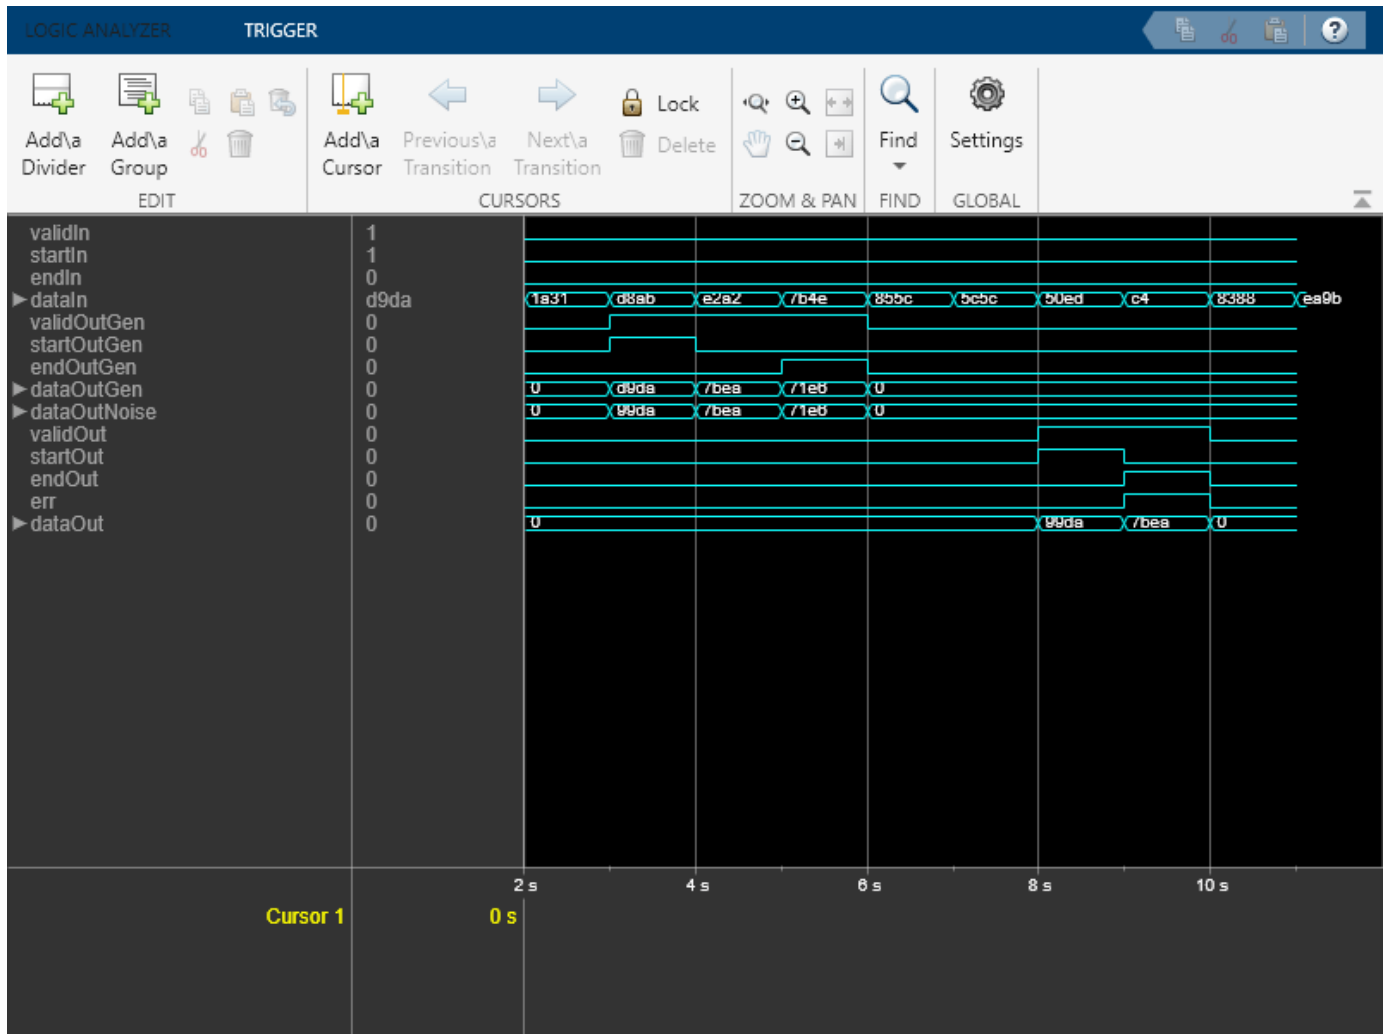

```
comm.HDLCRCDetector with properties:
```

```
    Polynomial: [1 0 0 0 1 0 0 0 0 0 0 1 0 0 0 0 1]
    InitialState: 0
    DirectMethod: false
    ReflectInput: false
    ReflectCRCChecksum: false
    FinalXORValue: 0
```

Use the **Logic Analyzer** to view the input and output signals.

```
channels = {'validIn','startIn','endIn',...
    {'dataIn','Radix','Hexadecimal'},...
    {'validOutGen','startOutGen','endOutGen',...
    {'dataOutGen','Radix','Hexadecimal'},...
    {'dataOutNoise','Radix','Hexadecimal'},...
    {'validOut','startOut','endOut','err',...
    {'dataOut','Radix','Hexadecimal'}}};
la = dsp.LogicAnalyzer('Name','CRC Encode and Decode','NumInputPorts',length(channels),...
    'BackgroundColor','Black','DisplayChannelHeight',8);

for ii = 1:length(channels)
    if iscell(channels{ii})
        % Display data signals as hexadecimal integers
        c = channels{ii};
        modifyDisplayChannel(la,ii,'Name',c{1},c{2},c{3})
        % Convert binary column vector to integer
        cVal = eval(c{1});
        dat2 = uint16(bit2int(cVal,size(cVal,1)));
        chanData{ii} = squeeze(dat2);
    else
        modifyDisplayChannel(la,ii,'Name',channels{ii})
        chanData{ii} = squeeze(eval(channels{ii}));
    end
end
la(chanData{:})
```

Algorithms

Timing Diagram

This waveform shows streaming data and the accompanying control signals for a CRC16 with 8-bit binary vector input. The input frames are contiguous. The output frames include space between them because the detector block removes the checksum word.

This waveform diagram shows continuous input data. Non-continuous data is also supported.

Initial Delay

The HDLCRCDetector System object introduces a latency on the output. You can compute the latency as follows, assuming the input data is continuous:

```
initialDelay = 3 * (CRCLength/inputDataWidth) + 2
```

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

This System object supports C/C++ code generation for accelerating MATLAB simulations, and for DPI component generation.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

double and single data types are supported for simulation, but not for HDL code generation.

To generate HDL code from predefined System objects, see “HDL Code Generation from Viterbi Decoder System Object” (HDL Coder).

comm.HDLCRCGenerator

Package: comm

Generate CRC code bits and append to input data

Description

This HDL-optimized cyclic redundancy code (CRC) generator System object generates cyclic redundancy code (CRC) bits. Instead of frame processing, the HDLCRCGenerator System object processes streaming data. The object has frame synchronization control signals for both input and output data streams.

To generate cyclic redundancy code bits:

- 1 Create the `comm.HDLCRCGenerator` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

Creation

Syntax

```
CRCGen = comm.HDLCRCGenerator  
CRCGen = comm.HDLCRCGenerator(Name,Value)  
CRCGen = comm.HDLCRCGenerator(poly,Name,Value)
```

Description

`CRCGen = comm.HDLCRCGenerator` creates an HDL-optimized CRC generator System object, `CRCGen`. This object generates CRC bits according to a specified generator polynomial and appends them to the input data.

`CRCGen = comm.HDLCRCGenerator(Name,Value)` sets properties using one or more name-value pairs. Enclose each property name in single quotes. For example,

```
CRCGen = comm.HDLCRCGenerator('Polynomial',[1 0 0 0 1 0 0 0 0], ...  
'FinalXORValue',[1 1 0 0 0 0 0 0]);
```

specifies a CRC8 polynomial and an 8-bit value to XOR with the final checksum.

`CRCGen = comm.HDLCRCGenerator(poly,Name,Value)` sets the `Polynomial` property to `poly`, and the other specified property names to the specified values.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see [System Design in MATLAB Using System Objects](#).

Polynomial — Generator polynomial

[1 0 0 0 1 0 0 0 0 0 0 1 0 0 0 0 1] (default) | binary vector

Generator polynomial, specified as a binary vector, with coefficients in descending order of powers. The vector length must be equal to the degree of the polynomial plus 1.

InitialState — Initial conditions of shift register

0 (default) | binary scalar | binary vector

Initial conditions of the shift register, specified as a binary, double-precision or single-precision scalar or vector. If you specify this property as a vector, the vector length is the degree of the generator polynomial that you specify in the `Polynomial` property. If you specify this property as a scalar, the object expands the value to a vector of length equal to the degree of the generator polynomial.

DirectMethod — Method of calculating checksum

false (default) | true

Method of calculating checksum, specified as a logical scalar. When this property is `true`, the object uses the direct algorithm for CRC checksum calculations.

To learn about direct and non-direct algorithms, see “[Cyclic Redundancy Check Codes](#)”.

ReflectInput — Input byte order

false (default) | true

Input byte order, specified as a logical scalar. When this property is `true`, the object flips the input data on a bitwise basis before it enters the shift register.

ReflectCRCChecksum — Checksum byte order

false (default) | true

Checksum byte order, specified as a logical scalar. When this property is `true`, the object flips the output CRC checksum around its center.

FinalXORValue — Checksum mask

0 (default) | binary scalar | binary vector

Checksum mask, specified as a binary, double- or single-precision data type scalar or vector. The object XORs the checksum with this value before appending the checksum to the input data. If you specify this property as a vector, the vector length is the degree of the generator polynomial that you specify in the `Polynomial` property. If you specify this property as a scalar, the object expands the value to a vector of length equal to the degree of the generator polynomial.

Usage

Syntax

```
[Y,startOut,endOut,validOut] = CRCn(X,startIn,endIn, validIn)
```

Description

`[Y, startOut, endOut, validOut] = CRCn(X, startIn, endIn, validIn)` generates CRC checksums for input message `X` based on control signals and appends the checksums to `X`.

Input Arguments**X — Input message**

binary column vector | scalar integer

Input message, specified as a binary vector or a scalar integer representing several bits. For example, vector input `[0, 0, 0, 1, 0, 0, 1, 1]` is equivalent to `uint8` input `19`.

If the input is a vector, the data type can be double or logical. If the input is a scalar, the data type can be unsigned integer or unsigned fixed-point with 0 fractional bits (`fi([], 0, N, 0)`).

`X` can be part or all of the message to be encoded.

The length of `X` must be less than or equal to the CRC length, and the CRC length must be divisible by the length of `X`.

The CRC length is the order of the polynomial that you specify in the `Polynomial` property.

Data Types: `double` | `uint8` | `uint16` | `uint32` | `logical` | `unsigned fi`

startIn — Start of input message

logical scalar

Start of the input message, specified as a logical scalar.

endIn — End of input message

logical scalar

End of the input message, specified as a logical scalar.

validIn — Validity of input data

logical scalar

Validity of input data, specified as a logical scalar. When `validIn` is 1 (`true`), the object computes the CRC checksum for input `X`.

Output Arguments**Y — Output message with appended checksum**

binary column vector | scalar integer

Output message, consisting of `X` with appended checksum, returned as a scalar integer or binary column vector with the same width and data type as input `X`.

startOut — Start of input message

logical scalar

Start of the input message, returned as a logical scalar.

endOut — End of input message

logical scalar

End of the input message, returned as a logical scalar.

validOut — Validity of input data

logical scalar

Validity of input data, returned as a logical scalar. When `validOut` is 1 (`true`), the output data `Y` is valid.

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Common to All System Objects

`step` Run System object algorithm

`release` Release resources and allow changes to System object property values and input characteristics

`reset` Reset internal states of System object

Examples

CRC Encode and Decode for HDL

Encode and decode a signal using the HDL-optimized CRC generator and detector System objects. This example shows how to include each object in a function for HDL code generation.

Create a 32-bit message to be encoded, in two 16-bit columns.

```
msg = randi([0 1],16,2);
```

Run for 12 steps to accommodate the latency of both objects. Assign control signals for all steps. The first two samples are the valid data, and the remainder are processing latency.

```
numSteps = 12;
startIn = logical([1 0 0 0 0 0 0 0 0 0 0 0]);
endIn = logical([0 1 0 0 0 0 0 0 0 0 0 0]);
validIn = logical([1 1 0 0 0 0 0 0 0 0 0 0]);
```

Pass random input to the HDLCRCGenerator System object™ while it is processing the input message. The random data is not encoded because the input valid signal is 0 for steps 3 to 10.

```
randIn = randi([0, 1],16,numSteps-2);
dataIn = [msg randIn];
```

Write a function that creates and calls each System object™. You can generate HDL from these functions. The generator and detector objects both have a CRC length of 16 and use the default polynomial.

```
function [dataOut,startOut,endOut,validOut] = HDLCRC16Gen(dataIn,startIn,endIn,validIn)
%HDLCRC16Gen
```

```
% Generates CRC checksum using the comm.HDLCRCGenerator System object(TM)
% dataIn is a binary column vector.
% startIn, endIn, and validIn are logical scalar values.
% You can generate HDL code from this function.
```

```
persistent crcg16;
if isempty(crcg16)
    crcg16 = comm.HDLCRCGenerator()
end
[dataOut,startOut,endOut,validOut] = crcg16(dataIn,startIn,endIn,validIn);
end
```

```
function [dataOut,startOut,endOut,validOut,err] = HDLCRC16Det(dataIn,startIn,endIn,validIn)
%HDLCRC16Det
```

```
% Checks CRC checksum using the comm.HDLCRCDetector System object(TM)
% dataIn is a binary column vector.
% startIn, endIn, and validIn are logical scalar values.
% You can generate HDL code from this function.
```

```
persistent crcd16;
if isempty(crcd16)
    crcd16 = comm.HDLCRCDetector()
end
[dataOut,startOut,endOut,validOut,err] = crcd16(dataIn,startIn,endIn,validIn);
end
```

Call the CRC generator function. The encoded message is the original message plus a 16 bit checksum.

```
for i = 1:numSteps
    [dataOutGen(:,i),startOutGen(i),endOutGen(i),validOutGen(i)] = ...
        HDLCRC16Gen(logical(dataIn(:,i)),startIn(i),endIn(i),validIn(i));
end
```

```
crcg16 =
```

```
comm.HDLCRCGenerator with properties:
```

```
    Polynomial: [1 0 0 0 1 0 0 0 0 0 0 1 0 0 0 0 1]
    InitialState: 0
    DirectMethod: false
    ReflectInput: false
    ReflectCRCChecksum: false
    FinalXORValue: 0
```

Add noise by flipping a bit in the message.

```
dataOutNoise = dataOutGen;
dataOutNoise(2,4) = ~dataOutNoise(2,4);
```

Call the CRC detector function. The output of the detector is the input message with the checksum removed. If the input checksum was not correct, the `err` flag is set with the last word of the output.

```

for i = 1:numSteps
[dataOut(:,i),startOut(i),endOut(i),validOut(i),err(i)] = ...
    HDLCRC16Det(logical(dataOutNoise(:,i)),startOutGen(i),endOutGen(i),validOutGen(i));
end

```

```
crcd16 =
```

```
comm.HDLCRCDetector with properties:
```

```

    Polynomial: [1 0 0 0 1 0 0 0 0 0 0 1 0 0 0 0 1]
    InitialState: 0
    DirectMethod: false
    ReflectInput: false
    ReflectCRCChecksum: false
    FinalXORValue: 0

```

Use the **Logic Analyzer** to view the input and output signals.

```

channels = {'validIn','startIn','endIn',...
    {'dataIn','Radix','Hexadecimal'},...
    'validOutGen','startOutGen','endOutGen',...
    {'dataOutGen','Radix','Hexadecimal'},...
    {'dataOutNoise','Radix','Hexadecimal'},...
    'validOut','startOut','endOut','err',...
    {'dataOut','Radix','Hexadecimal'}};
la = dsp.LogicAnalyzer('Name','CRC Encode and Decode','NumInputPorts',length(channels),...
    'BackgroundColor','Black','DisplayChannelHeight',8);

for ii = 1:length(channels)
    if iscell(channels{ii})
        % Display data signals as hexadecimal integers
        c = channels{ii};
        modifyDisplayChannel(la,ii,'Name',c{1},c{2},c{3})
        % Convert binary column vector to integer
        cVal = eval(c{1});
        dat2 = uint16(bit2int(cVal,size(cVal,1)));
        chanData{ii} = squeeze(dat2);
    else
        modifyDisplayChannel(la,ii,'Name',channels{ii})
        chanData{ii} = squeeze(eval(channels{ii}));
    end
end
la(chanData{:})

```

Algorithms

Timing Diagram

This waveform shows streaming data and the accompanying control signals for a CRC16 with an 8-bit binary vector input. To insert the checksum word, input frames must have enough space between them.

This waveform diagram shows continuous input data. The block also supports noncontinuous data. The output valid signal matches the input valid pattern.

Initial Delay

The HDLCRCGenerator System object introduces a latency on the output. You can compute the latency as follows, assuming the input data is continuous:

$$\text{initialDelay} = (\text{CRCLength}/\text{inputDataWidth}) + 2$$

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

This System object supports C/C++ code generation for accelerating MATLAB simulations, and for DPI component generation.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

`double` and `single` data types are supported for simulation, but not for HDL code generation.

To generate HDL code from predefined System objects, see “HDL Code Generation from Viterbi Decoder System Object” (HDL Coder).

comm.HDLRSDecoder

Package: comm

Decode message using Reed-Solomon decoder

Description

The HDL-optimized HDLRSDecoder System object recovers a message vector from a Reed-Solomon (RS) codeword vector. For proper decoding, the code and polynomial property values for this object must match those values in the corresponding encoder.

To recover a message vector from a Reed-Solomon codeword vector:

- 1 Create the `comm.HDLRSDecoder` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

Troubleshooting

- Each input frame must contain more than $(N-K)*2$ symbols and fewer than or exactly N symbols. The object infers a shortened code when the number of valid data samples between `startIn` and `endIn` is less than N . A shortened code still requires N cycles to perform the Chien search. If the input message is less than N symbols, leave a guard interval of at least $N - \text{size}$ inactive cycles before starting the next frame, where `size` is the message length.
- The decoder can operate on up to four messages at a time. If the object receives the start of a fifth message before completely decoding the first message, the object drops data samples from the first message. To avoid this issue, increase the number of inactive cycles between input messages.
- The generator polynomial is not specified explicitly. However, it is defined by the codeword length, the message length, and the B value for the starting exponent of the roots. To get the value of B from a generator polynomial, use the `genpoly2b` function.

Creation

Syntax

```
RSDec = comm.HDLRSDecoder
RSDec = comm.HDLRSDecoder(Name,Value)
RSDec = comm.HDLRSDecoder(N,K,Name,Value)
```

Description

`RSDec = comm.HDLRSDecoder` creates an HDL-optimized RS decoder System object, `RSDec`, that performs Reed-Solomon decoding.

`RSDec = comm.HDLRSDecoder(Name,Value)` sets properties using one or more name-value pairs. Enclose each property name in single quotes. For example,

```
comm.HDLRSDecoder('BSource','Property','B',2)
```

sets a starting power of 2 for the roots of the primitive polynomial.

`RSDec = comm.HDLRSDecoder(N,K,Name,Value)` sets the `CodewordLength` property to `N`, the `MessageLength` property to `K`, and other specified property names to the specified values.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects.

B — Starting power for roots of primitive polynomial

1 (default) | positive integer

Starting power for roots of the primitive polynomial, specified as a positive integer.

Dependencies

The object uses this value when you set `BSource` to `'Property'`.

BSource — Source of starting power for roots of primitive polynomial

'Auto' (default) | 'Property'

Source of the starting power for roots of the primitive polynomial, specified as either `'Property'` or `'Auto'`. When you select `'Auto'`, the object uses $B = 1$.

CodewordLength — Number of symbols, N, in RS codeword

7 (default) | positive integer

Number of symbols, N , in the RS codeword, specified as a positive integer. This value is rounded up to $2^M - 1$. M is the degree of the primitive polynomial, as specified by the `PrimitivePolynomialSource` and `PrimitivePolynomial` properties. The difference of `CodewordLength` - `MessageLength` must be an even integer.

If the value of this property is less than $2^M - 1$, the object assumes a shortened RS code.

If you set `PrimitivePolynomialSource` to `'Auto'`, then `CodewordLength` must be in the range $3 < \text{CodewordLength} \leq 2^{16} - 1$.

If you set `PrimitivePolynomialSource` to `'Property'`, then `CodewordLength` must be in the range $3 \leq \text{CodewordLength} \leq 2^M - 1$. M must be in the range $3 \leq M \leq 16$.

MessageLength — Message length, K

3 (default) | positive integer

Message length, K , specified as a positive integer. The difference of `CodewordLength` - `MessageLength` must be an even integer.

NumErrorsOutputPort — Enable number of errors output argument

false (default) | true

When you set this property to `true`, the object returns the number of corrected errors. The number of corrected errors is not valid when `errOut` is `true`, since there were more errors than could be corrected.

PrimitivePolynomialSource — Source of primitive polynomial

'Auto' (default) | 'Property'

Source of the primitive polynomial, specified as either 'Property' or 'Auto'.

- When you set this property to 'Auto', the object uses a primitive polynomial of degree $M = \text{ceil}(\log_2(\text{CodewordLength}+1))$, which is the result of `int2bit(primpoly(M),bpi)`, where bpi is the number of bits per integer.
- When you set this property to 'Property', you must specify a polynomial using the `PrimitivePolynomial` property.

PrimitivePolynomial — Primitive polynomial

[1 0 1 1] (default) | binary row vector

Primitive polynomial, specified as a binary row vector that represents a primitive polynomial over $\text{gf}(2)$ of degree M , in descending order of powers. The polynomial defines the finite field $\text{gf}(2^M)$ corresponding to the integers that form messages and codewords.

Dependencies

The object uses this value when you set `PrimitivePolynomialSource` to 'Property'.

Usage

Syntax

```
[Y,startOut,endOut,validOut,errOut] = RSDec(X,startIn,endIn,validIn)
[Y,startOut,endOut,validOut,errOut,numErrors] = RSDec(X,startIn,endIn,
validIn)
```

Description

`[Y,startOut,endOut,validOut,errOut] = RSDec(X,startIn,endIn,validIn)` decodes one encoded message symbol, X , and returns the decoded symbol Y . The `start` and `end` signals indicate the message frame boundaries. If `errOut` is 1 (`true`), then the object detected uncorrectable errors in the input frame.

`[Y,startOut,endOut,validOut,errOut,numErrors] = RSDec(X,startIn,endIn,validIn)` decodes the input data, and also returns the number of errors detected and corrected. To use this syntax, set the `NumErrorsOutputPort` property to `true`. If `errOut` is 1 (`true`), then the object detected uncorrectable errors in the output frame, and `numErrors` is invalid.

Input Arguments

X — Input message data or parity symbols

integer

Input message data and parity symbols, one symbol at a time, specified as an unsigned integer or `fi()` with any binary point scaling.

`double` type is allowed for simulation but not supported for HDL code generation.

Data Types: `double` | `uint8` | `uint16` | `uint32` | `fi`

startIn — Start of input data frame

logical scalar

Start of input data frame, specified as a logical scalar.

Data Types: `logical`

endIn — End of input data frame

logical scalar

End of input data frame, specified as a logical scalar.

Data Types: `logical`

validIn — Validity of input data

logical scalar

Validity of input data, specified as a logical scalar.

Data Types: `logical`

Output Arguments

Y — Message data symbols

integer

Message data symbols, returned one symbol at a time, as an integer with the same data type as the input message, `X`.

Data Types: `double` | `uint8` | `uint16` | `uint32` | `fi`

startOut — Start of output data frame

logical scalar

Start of output data frame, returned as a logical scalar.

Data Types: `logical`

endOut — End of output data frame

logical scalar

End of output data frame, returned as a logical scalar.

Data Types: `logical`

validOut — Validity of output data

logical scalar

Validity of output data, returned as a logical scalar.

Data Types: `logical`

errOut — Uncorrectable error in output data frame

logical scalar

Uncorrectable error in output data frame, returned as a logical scalar. This signal is 1 (`true`) when the message frame contains uncorrectable errors. In this case, the output data symbols are corrupted. This value is valid when `endOut` is 1 (`true`).

Data Types: `logical`

numErrors — Number of errors detected and corrected

integer

Number of errors detected and corrected, returned as an integer. This value is valid when `endOut` is 1 (`true`) and `errOut` is 0 (`false`).

Data Types: `uint8`

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Common to All System Objects

<code>step</code>	Run System object algorithm
<code>release</code>	Release resources and allow changes to System object property values and input characteristics
<code>reset</code>	Reset internal states of System object

Examples

Reed-Solomon Coding and Error Detection for HDL

Encode and decode a signal using Reed Solomon encoder and decoder System objects. This example shows how to include each object in a function for HDL code generation.

Create a random message to encode. This message is smaller than the codeword length to show how the objects support shortened codes. Pad the message with zeros to accommodate the latency of the decoder, including the Chien search.

```
messageLength = 188;  
dataIn = [randi([0,255],1,messageLength,'uint8') zeros(1,1024-messageLength)];
```

Write a function that creates and calls a `HDLRSEncoder` System object™ with an RS(255,239) code. This code is used in the IEEE® 802.16 Broadband Wireless Access standard. `B` is the starting power of the roots of the primitive polynomial. You can generate HDL from this function.

Note: This object syntax runs only in R2016b or later. If you are using an earlier release, replace each call of an object with the equivalent `step` syntax. For example, replace `myObject(x)` with `step(myObject,x)`.

```
function [dataOut,startOut,endOut,validOut] = HDLRSEnc80216(dataIn,startIn,endIn,validIn)  
%HDLRSEnc80216  
% Processes one sample of data using the comm.HDLRSEncoder System object(TM)
```

```

% dataIn is a uint8 scalar, representing 8 bits of binary data.
% startIn, endIn, and validIn are logical scalar values.
% You can generate HDL code from this function.

persistent rsEnc80216;
if isempty(rsEnc80216)
    rsEnc80216 = comm.HDLREncoder(255,239,'BSource','Property','B',0)
end
[dataOut,startOut,endOut,validOut] = rsEnc80216(dataIn,startIn,endIn,validIn);
end

```

Call the function to encode the message.

```

for ii = 1:1024
    messageStart = (ii==1);
    messageEnd = (ii==messageLength);
    validIn = (ii<=messageLength);
    [encOut(ii),startOut(ii),endOut(ii),validOut(ii)] = ...
        HDLREnc80216(dataIn(ii),messageStart,messageEnd,validIn);
end

```

rsEnc80216 =

```

comm.HDLREncoder with properties:
    CodewordLength: 255
    MessageLength: 239
    PrimitivePolynomialSource: 'Auto'
    PuncturePatternSource: 'None'
    BSource: 'Property'
    B: 0

```

Inject errors at random locations in the encoded message. Reed-Solomon can correct up to $(N - K)/2$ errors in each N symbols. So, in this example, the error correction capability is $(255 - 239)/2=8$ symbols.

```

numErrors = 8;
loc = randperm(messageLength,numErrors);
% encOut is qualified by validOut, use an offset for injecting errors
vi = find(validOut==true,1);
for i = 1:numErrors
    idx = loc(i)+vi;
    symbol = encOut(idx);
    encOut(idx) = randi([0 255],'uint8');
    fprintf('Symbol(%d): was 0x%x, now 0x%x\n',loc(i),symbol,encOut(idx))
end

```

```

Symbol(147): was 0x1f, now 0x82
Symbol(16): was 0x6b, now 0x82
Symbol(173): was 0x3, now 0xd1
Symbol(144): was 0x66, now 0xcb
Symbol(90): was 0x13, now 0xa4
Symbol(80): was 0x5a, now 0x60
Symbol(82): was 0x95, now 0xcf
Symbol(56): was 0xf5, now 0x88

```

Write a function that creates and calls a HDLRSDecoder System object™. This object must have the same code and polynomial as the encoder. You can generate HDL from this function.

```
function [dataOut,startOut,endOut,validOut,err] = HDLRSDec80216(dataIn,startIn,endIn,validIn)
%HDLRSDec80216
% Processes one sample of data using the comm.HDLRSDecoder System object(TM)
% dataIn is a uint8 scalar, representing 8 bits of binary data.
% startIn, endIn, and validIn are logical scalar values.
% You can generate HDL code from this function.

persistent rsDec80216;
if isempty(rsDec80216)
    rsDec80216 = comm.HDLRSDecoder(255,239,'BSource','Property','B',0)
end
[dataOut,startOut,endOut,validOut,err] = rsDec80216(dataIn,startIn,endIn,validIn);
end
```

Call the function to detect errors in the encoded message.

```
for ii = 1:1024
    [decOut(ii),decStartOut(ii),decEndOut(ii),decValidOut(ii),decErrOut(ii)] = ...
        HDLRSDec80216(encOut(ii),startOut(ii),endOut(ii),validOut(ii));
end
```

rsDec80216 =

```
comm.HDLRSDecoder with properties:
    CodewordLength: 255
    MessageLength: 239
    PrimitivePolynomialSource: 'Auto'
    BSource: 'Property'
    B: 0
    NumErrorsOutputPort: false
```

Select the valid decoder output and compare the decoded symbols to the original message.

```
decOut = decOut(decValidOut==1);
originalMessage = dataIn(1:messageLength);
if all(originalMessage==decOut)
    fprintf('All %d message symbols were correctly decoded.\n',messageLength)
else
    for jj = 1:messageLength
        if dataIn(jj)~=decOut(jj)
            fprintf('Error in decoded symbol(%d). Original 0x%x, Decoded 0x%x.\n',jj,dataIn(jj),decOut(jj))
        end
    end
end
```

All 188 message symbols were correctly decoded.

Encode message using Reed-Solomon encoder

Description

The HDL-optimized HDLRSEncoder System object creates a Reed-Solomon (RS) code with message and codeword lengths that you specify.

To encode a message using a Reed-Solomon code:

- 1 Create the `comm.HDLRSEncoder` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

Creation

Syntax

```
RSEnc = comm.HDLRSEncoder  
RSEnc = comm.HDLRSEncoder(Name,Value)  
RSEnc = comm.HDLRSEncoder(N,K,Name,Value)
```

Description

`RSEnc = comm.HDLRSEncoder` creates an HDL-optimized block encoder System object, `RSEnc`, that performs Reed-Solomon encoding in a streaming fashion for HDL.

`RSEnc = comm.HDLRSEncoder(Name,Value)` sets properties using one or more name-value pairs. Enclose each property name in single quotes. For example,

```
comm.HDLRSEncoder('BSource','Property','B',2)
```

sets a starting power of 2 for the roots of the primitive polynomial.

`RSEnc = comm.HDLRSEncoder(N,K,Name,Value)` sets the `CodewordLength` property to `N`, the `MessageLength` property to `K`, and other specified property names to the specified values.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see [System Design in MATLAB Using System Objects](#).

B — Starting power for roots of primitive polynomial

1 (default) | positive integer

Starting power for roots of the primitive polynomial, specified as a positive integer.

Dependencies

The object uses this value when you set BSource to 'Property'.

BSource — Source of starting power for roots of primitive polynomial

'Auto' (default) | 'Property'

Source of the starting power for roots of the primitive polynomial, specified as either 'Property' or 'Auto'. When you select 'Auto', the object uses $B = 1$.

CodewordLength — Number of symbols, N, in RS codeword

7 (default) | positive integer

Number of symbols, N , in the RS codeword, specified as a positive integer. This value is rounded up to $2^M - 1$. M is the degree of the primitive polynomial, as specified by the PrimitivePolynomialSource and PrimitivePolynomial properties. The difference of CodewordLength - MessageLength must be an even integer.

If the value of this property is less than $2^M - 1$, the object assumes a shortened RS code.

If you set PrimitivePolynomialSource to 'Auto', then CodewordLength must be in the range $3 < \text{CodewordLength} \leq 2^{16} - 1$.

If you set PrimitivePolynomialSource to 'Property', then CodewordLength must be in the range $3 \leq \text{CodewordLength} \leq 2^M - 1$. M must be in the range $3 \leq M \leq 16$.

MessageLength — Message length, K

3 (default) | positive integer

Message length, K , specified as a positive integer. The difference of CodewordLength - MessageLength must be an even integer.

PrimitivePolynomialSource — Source of primitive polynomial

'Auto' (default) | 'Property'

Source of the primitive polynomial, specified as either 'Property' or 'Auto'.

- When you set this property to 'Auto', the object uses a primitive polynomial of degree $M = \text{ceil}(\log_2(\text{CodewordLength} + 1))$, which is the result of $\text{int2bit}(\text{primpoly}(M, bpi))$, where bpi is the number of bits per integer.
- When you set this property to 'Property', you must specify a polynomial using the PrimitivePolynomial property.

PrimitivePolynomial — Primitive polynomial

[1 0 1 1] (default) | binary row vector

Primitive polynomial, specified as a binary row vector that represents a primitive polynomial over $\text{gf}(2)$ of degree M , in descending order of powers. The polynomial defines the finite field $\text{gf}(2^M)$ corresponding to the integers that form messages and codewords.

Dependencies

The object uses this value when you set `PrimitivePolynomialSource` to 'Property'.

PuncturePatternSource — Source of puncture pattern

'None' (default) | 'Property'

Source of the puncture pattern, specified as 'None' or 'Property'. If you set this property to 'None', then the object does not apply puncturing to the code. If you set this property to 'Property', then the object punctures the code based on a puncture pattern vector specified in the `PuncturePattern` property.

PuncturePattern — Pattern used to puncture encoded data

`[ones(2,1); zeros(2,1)]` (default) | binary column vector

Pattern used to puncture the encoded data, specified as a double-precision, binary column vector with a length of `CodewordLength - MessageLength`. The default is `[ones(2,1); zeros(2,1)]`. Zeros in the puncture pattern vector indicate the position of the parity symbols that are punctured or excluded from each codeword.

Dependencies

This property applies when you set the `PuncturePatternSource` property to 'Property'.

Usage**Syntax**

```
[Y,startOut,endOut,validOut] = RSEnc(X,startIn,endIn,validIn)
```

Description

`[Y,startOut,endOut,validOut] = RSEnc(X,startIn,endIn,validIn)` encodes one input message symbol, X, and returns one symbol of encoded data, Y. The `start` and `end` signals indicate the message frame boundaries. The object returns associated parity symbols at the end of each message frame.

Input Arguments**X — Input message symbol**

integer

Input message data, one symbol at a time, specified as an unsigned integer or `fi()` with any binary point scaling. The word length of each symbol must be `ceil(log2(CodewordLength+1))`.

`double` type is allowed for simulation but not supported for HDL code generation.

Data Types: `double` | `uint8` | `uint16` | `uint32` | `fi`

startIn — Start of input data frame

logical scalar

Start of input data frame, specified as a logical scalar.

Data Types: `logical`

endIn — End of input data frame

logical scalar

End of input data frame, specified as a logical scalar.

Data Types: `logical`**validIn — Validity of input data**

logical scalar

Validity of input data, specified as a logical scalar.

Data Types: `logical`**Output Arguments****Y — Output message data and parity symbols**

integer

Message data and parity symbols, returned one symbol at a time, as an integer with the same data type as the input message, *X*.Data Types: `double` | `uint8` | `uint16` | `uint32` | `fi`**startOut — Start of output data frame**

logical scalar

Start of output data frame, returned as a logical scalar.

Data Types: `logical`**endOut — End of output data frame**

logical scalar

End of output data frame, returned as a logical scalar.

Data Types: `logical`**validOut — Validity of output data**

logical scalar

Validity of output data, returned as a logical scalar.

Data Types: `logical`**Object Functions**To use an object function, specify the System object as the first input argument. Examples

Reed-Solomon Coding and Error Detection for HDL

Encode and decode a signal using Reed Solomon encoder and decoder System objects. This example shows how to include each object in a function for HDL code generation.

Create a random message to encode. This message is smaller than the codeword length to show how the objects support shortened codes. Pad the message with zeros to accommodate the latency of the decoder, including the Chien search.

```
messageLength = 188;  
dataIn = [randi([0,255],1,messageLength,'uint8') zeros(1,1024-messageLength)];
```

Write a function that creates and calls a `HDLRSEncoder` System object™ with an RS(255,239) code. This code is used in the IEEE® 802.16 Broadband Wireless Access standard. `B` is the starting power of the roots of the primitive polynomial. You can generate HDL from this function.

Note: This object syntax runs only in R2016b or later. If you are using an earlier release, replace each call of an object with the equivalent `step` syntax. For example, replace `myObject(x)` with `step(myObject,x)`.

```
function [dataOut,startOut,endOut,validOut] = HDLRSEnc80216(dataIn,startIn,endIn,validIn)  
%HDLRSEnc80216  
% Processes one sample of data using the comm.HDLRSEncoder System object(TM)  
% dataIn is a uint8 scalar, representing 8 bits of binary data.  
% startIn, endIn, and validIn are logical scalar values.  
% You can generate HDL code from this function.  
  
persistent rsEnc80216;  
if isempty(rsEnc80216)  
    rsEnc80216 = comm.HDLRSEncoder(255,239,'BSource','Property','B',0)  
end  
[dataOut,startOut,endOut,validOut] = rsEnc80216(dataIn,startIn,endIn,validIn);  
end
```

Call the function to encode the message.

```
for ii = 1:1024  
    messageStart = (ii==1);  
    messageEnd = (ii==messageLength);  
    validIn = (ii<=messageLength);  
    [encOut(ii),startOut(ii),endOut(ii),validOut(ii)] = ...  
        HDLRSEnc80216(dataIn(ii),messageStart,messageEnd,validIn);  
end
```

```
rsEnc80216 =  
    comm.HDLRSEncoder with properties:
```

```

        CodewordLength: 255
        MessageLength: 239
PrimitivePolynomialSource: 'Auto'
PuncturePatternSource: 'None'
        BSource: 'Property'
        B: 0

```

Inject errors at random locations in the encoded message. Reed-Solomon can correct up to $(N - K)/2$ errors in each N symbols. So, in this example, the error correction capability is $(255 - 239)/2=8$ symbols.

```

numErrors = 8;
loc = randperm(messageLength,numErrors);
% encOut is qualified by validOut, use an offset for injecting errors
vi = find(validOut==true,1);
for i = 1:numErrors
    idx = loc(i)+vi;
    symbol = encOut(idx);
    encOut(idx) = randi([0 255],'uint8');
    fprintf('Symbol(%d): was 0x%x, now 0x%x\n',loc(i),symbol,encOut(idx))
end

```

```

Symbol(147): was 0x1f, now 0x82
Symbol(16): was 0x6b, now 0x82
Symbol(173): was 0x3, now 0xd1
Symbol(144): was 0x66, now 0xcb
Symbol(90): was 0x13, now 0xa4
Symbol(80): was 0x5a, now 0x60
Symbol(82): was 0x95, now 0xcf
Symbol(56): was 0xf5, now 0x88

```

Write a function that creates and calls a HDLRSDecoder System object™. This object must have the same code and polynomial as the encoder. You can generate HDL from this function.

```

function [dataOut,startOut,endOut,validOut,err] = HDLRSDec80216(dataIn,startIn,endIn,validIn)
%HDLRSDec80216
% Processes one sample of data using the comm.HDLRSDecoder System object(TM)
% dataIn is a uint8 scalar, representing 8 bits of binary data.
% startIn, endIn, and validIn are logical scalar values.
% You can generate HDL code from this function.

    persistent rsDec80216;
    if isempty(rsDec80216)
        rsDec80216 = comm.HDLRSDecoder(255,239,'BSource','Property','B',0)
    end
    [dataOut,startOut,endOut,validOut,err] = rsDec80216(dataIn,startIn,endIn,validIn);
end

```

Call the function to detect errors in the encoded message.

```

for ii = 1:1024
    [decOut(ii),decStartOut(ii),decEndOut(ii),decValidOut(ii),decErrOut(ii)] = ...
        HDLRSDec80216(encOut(ii),startOut(ii),endOut(ii),validOut(ii));
end

```

```
rsDec80216 =  
  
    comm.HDLRSDecoder with properties:  
  
        CodewordLength: 255  
        MessageLength: 239  
        PrimitivePolynomialSource: 'Auto'  
        BSource: 'Property'  
        B: 0  
        NumErrorsOutputPort: false
```

Select the valid decoder output and compare the decoded symbols to the original message.

```
decOut = decOut(decValidOut==1);  
originalMessage = dataIn(1:messageLength);  
if all(originalMessage==decOut)  
    fprintf('All %d message symbols were correctly decoded.\n',messageLength)  
else  
    for jj = 1:messageLength  
        if dataIn(jj)~=decOut(jj)  
            fprintf('Error in decoded symbol(%d). Original 0x%x, Decoded 0x%x.\n',jj,dataIn(jj),decOut(jj))  
        end  
    end  
end
```

All 188 message symbols were correctly decoded.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

This System object supports C/C++ code generation for accelerating MATLAB simulations, and for DPI component generation.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

double and single data types are supported for simulation, but not for HDL code generation.

To generate HDL code from predefined System objects, see “HDL Code Generation from Viterbi Decoder System Object” (HDL Coder).

comm.HelicalDeinterleaver

Package: comm

Restore ordering of symbols using helical array

Description

The `HelicalDeinterleaver` object permutes the symbols in the input signal by placing them in a row-by-row array and then selecting groups helically to send to the output port.

To helically deinterleave input symbols:

- 1 Define and set up your helical deinterleaver object. See “Construction” on page 3-774.
- 2 Call `step` to deinterleave input symbols according to the properties of `comm.HelicalDeinterleaver`. The behavior of `step` is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`H = comm.HelicalDeinterleaver` creates a helical deinterleaver System object, `H`. This object restores the original ordering of a sequence that was interleaved using the helical interleaver System object.

`H = comm.HelicalDeinterleaver(Name,Value)` creates a helical deinterleaver object, `H`, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as `(Name1,Value1,...,NameN,ValueN)`.

Properties

NumColumns

Number of columns in helical array

Specify the number of columns in the helical array as a positive integer scalar value. The default is 6.

GroupSize

Size of each group of input symbols

Specify the size of each group of input symbols as a positive integer scalar value. The default is 4.

StepSize

Helical array step size

Specify number of rows of separation between consecutive input groups in their respective columns of the helical array. This property requires a positive integer scalar value. The default is 1.

InitialConditions

Initial conditions of helical array

Specify the value that is initially stored in the helical array as a numeric scalar value. The default is 0.

Methods

step Restore ordering of symbols using a helical array

Common to All System Objects	
release	Allow System object property value changes
reset	Reset internal states of System object

Examples

Helical Interleaving and Deinterleaving

Create helical interleaver and deinterleaver objects.

```
interleaver = comm.HelicalInterleaver('GroupSize',2,'NumColumns',3, ...
    'InitialConditions',-1);
deinterleaver = comm.HelicalDeinterleaver('GroupSize',2,'NumColumns',3, ...
    'InitialConditions',-1);
```

Generate random data. Interleave and then deinterleave the data.

```
[dataIn,dataOut] = deal([]);

for k = 1:10
    data = randi(7,6,1);
    intData = interleaver(data);
    deIntData = deinterleaver(intData);

    dataIn = cat(1,dataIn,data);
    dataOut = cat(1,dataOut,deIntData);
end
```

Determine the delay through the interleaver and deinterleaver pair.

```
intlvDelay = finddelay(dataIn,dataOut)

intlvDelay = 6
```

After taking the interleaving delay into account, confirm that the original and deinterleaved data are identical.

```
isequal(dataIn(1:end-intlvDelay),dataOut(1+intlvDelay:end))
```

```
ans = logical  
     1
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the Helical Deinterleaver block reference page. The object properties correspond to the block parameters.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

`comm.HelicalInterleaver` | `comm.MultiplexedDeinterleaver`

Introduced in R2012a

step

System object: comm.HelicalDeinterleaver

Package: comm

Restore ordering of symbols using a helical array

Syntax

$Y = \text{step}(H,X)$

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, $y = \text{step}(\text{obj}, x)$ and $y = \text{obj}(x)$ perform equivalent operations.

$Y = \text{step}(H,X)$ restores the original ordering of the sequence, X , that was interleaved using a helical interleaver and returns Y . The input X must be a column vector. The data type must be numeric, logical, or fixed-point (fi objects). Y has the same data type as X . The helical deinterleaver object uses an array for its computations. If you set the `NumColumns` property of the object to C , then the array has C columns and unlimited rows. If you set the `GroupSize` property to N , then the object accepts an input of length $C \times N$ and inserts it into the next N rows of the array. The object also places the value of the `InitialConditions` property into certain positions in the top few rows of the array. This accommodates the helical pattern and also preserves the vector indices of symbols that pass through the `HelicalInterleaver` and `HelicalDeinterleaver` objects. The output consists of consecutive groups of N symbols. The object selects the k -th output group in the array from column $k \bmod C$. This selection is of type helical because of the reduction modulo C and because the first symbol in the k -th group is in row $1+(k-1) \times s$, where s is the value for the `StepSize` property.

Note `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications. For more information on changing property values, see "System Design in MATLAB Using System Objects".

comm.HelicalInterleaver

Package: comm

Permute input symbols using helical array

Description

The `HelicalInterleaver` object permutes the symbols in the input signal by placing them in an array in a helical arrangement and then sending rows of the array to the output port.

To helically interleave input symbols:

- 1 Define and set up your helical interleaver object. See “Construction” on page 3-778.
- 2 Call `step` to interleave input symbols according to the properties of `comm.HelicalInterleaver`. The behavior of `step` is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`H = comm.HelicalInterleaver` creates a helical interleaver System object, `H`. This object permutes the input symbols in the input signal by placing them in an array in a helical arrangement.

`H = comm.HelicalInterleaver(Name,Value)` creates a helical interleaver object, `H`, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as `(Name1,Value1,...,NameN,ValueN)`.

Properties

NumColumns

Number of columns in helical array

Specify the number of columns in the helical array as a positive integer scalar value. The default is 6.

GroupSize

Size of each group of input symbols

Specify the size of each group of input symbols as a positive integer scalar value. The default is 4.

StepSize

Helical array step size

Specify the number of rows of separation between consecutive input groups in their respective columns of the helical array. This property requires as a positive integer scalar value . The default is 1.

InitialConditions

Initial conditions of helical array

Specify the value that is initially stored in the helical array as a numeric scalar value. The default is 0.

Methods

step Permute input symbols using a helical array

Common to All System Objects	
release	Allow System object property value changes

Examples

Helical Interleaving and Deinterleaving

Create helical interleaver and deinterleaver objects.

```
interleaver = comm.HelicalInterleaver('GroupSize',2,'NumColumns',3, ...
    'InitialConditions',-1);
deinterleaver = comm.HelicalDeinterleaver('GroupSize',2,'NumColumns',3, ...
    'InitialConditions',-1);
```

Generate random data. Interleave and then deinterleave the data.

```
[dataIn,dataOut] = deal([]);

for k = 1:10
    data = randi(7,6,1);
    intData = interleaver(data);
    deIntData = deinterleaver(intData);

    dataIn = cat(1,dataIn,data);
    dataOut = cat(1,dataOut,deIntData);
end
```

Determine the delay through the interleaver and deinterleaver pair.

```
intlVDelay = finddelay(dataIn,dataOut)

intlVDelay = 6
```

After taking the interleaving delay into account, confirm that the original and deinterleaved data are identical.

```
isequal(dataIn(1:end-intlVDelay),dataOut(1+intlVDelay:end))
```

```
ans = logical  
     1
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the Helical Interleaver block reference page. The object properties correspond to the block parameters.

`comm.HelicalDeinterleaver` | `comm.MultiplexedInterleaver`

Introduced in R2012a

step

System object: comm.HelicalInterleaver

Package: comm

Permute input symbols using a helical array

Syntax

$Y = \text{step}(H,X)$

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, $y = \text{step}(\text{obj}, x)$ and $y = \text{obj}(x)$ perform equivalent operations.

$Y = \text{step}(H,X)$ permutes input sequence, X , and returns interleaved sequence, Y . The input X must be a column vector. The data type must be numeric, logical, or fixed-point (fi objects). Y has the same data type as X . The helical interleaver object places the elements of X in an array in a helical fashion. If you set the `NumColumns` property of the object to C , then the array has C columns and unlimited rows. If you set the `GroupSize` property to N , then the object accepts an input of length $C \times N$ and partitions the input into consecutive groups of N symbols. The object places the k -th group in the array along column $k \bmod C$. This placement is of type helical because of the reduction modulo C and because the first symbol in the k -th group is in the row $1 + (k-1) \times s$, where s is the value for the `StepSize` property. Positions in the array that do not contain input symbols have default contents specified by the `InitialConditions` property. The object outputs $C \times N$ symbols from the array by reading the next N rows sequentially.

Note `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications. For more information on changing property values, see “System Design in MATLAB Using System Objects”.

comm.IntegerToBit

Package: comm

(Removed) Convert vector of integers to vector of bits

Note has been removed. Instead, use the `int2bit` function. For more information, see “Compatibility Considerations”.

Description

The `IntegerToBit` object maps each integer (or fixed-point value) in the input vector to a group of bits in the output vector.

To map integers to bits:

- 1 Define and set up your integer to bit object. See “Construction” on page 3-782.
- 2 Call `step` to map integers in the input vector to groups of bits in the output vector according to the properties of `comm.IntegerToBit`. The behavior of `step` is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj, x)` and `y = obj(x)` perform equivalent operations.

Construction

`H = comm.IntegerToBit` creates an integer-to-bit converter System object, `H`. This object maps a vector of integer-valued or fixed-point inputs to a vector of bits.

`H = comm.IntegerToBit(Name, Value)` creates an integer-to-bit converter object, `H`, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as `(Name1, Value1, ..., NameN, ValueN)`.

`H = comm.IntegerToBit(NUMBITS, Name, Value)` creates an integer-to-bit converter object, `H`. This object has the `BitsPerInteger` property set to `NUMBITS` and the other specified properties set to the specified values.

Properties

BitsPerInteger

Number of bits per integer

Specify the number of bits the System object uses to represent each input integer. You must set this property to a scalar integer between 1 and 32. The default is 3.

MSBFirst

Output bit words with first bit as most significant bit

Set this property to `true` to indicate that the first bit of the output bit words is the most significant bit (MSB). The default is `true`. Set this property to `false` to indicate that the first bit of the output bit words is the least significant bit (LSB).

SignedIntegerInput

Assume inputs are signed integers

Set this property to `true` if the integer inputs are signed. The default is `false`. Set this property to `false` if the integer inputs are unsigned. If the `SignedIntegerInput` on page 3-0 property is `false`, the input values must be between 0 and $(2^N)-1$. In this case, N is the value you specified in the `BitsPerInteger` on page 3-0 property. When you set this property to `true`, the input values must be between $-(2^{(N-1)})$ and $(2^{(N-1)})-1$.

OutputDataType

Data type of output

Specify output data type as one of `Full precision` | `Smallest unsigned integer` | `Same as input` | `double` | `single` | `int8` | `uint8` | `int16` | `uint16` | `int32` | `uint32` | `logical`. The default is `Full precision`.

When the input signal is an integer data type, you must have a Fixed-Point Designer user license to use this property in `Smallest unsigned integer` or `Full precision` mode.

When you set this property to `Full precision`, the object determines the output data type based on the input data type. If the input data type is double- or single-precision, the output data has the same data type as the input data. Otherwise, the output data type is determined in the same way as when you set this property to `Smallest unsigned integer`.

When you set this property to `Same as input`, and the input data type is numeric or fixed-point integer (fi object), the output data has the same data type as the input data.

Methods

`step` (Removed) Convert vector of integers to vector of bits

Common to All System Objects	
<code>release</code>	Allow System object property value changes

Compatibility Considerations

comm.IntegerToBit has been removed. Use int2bit instead.

Errors starting in R2021b

Use `int2bit` instead of `comm.IntegerToBit`.

Input types that are supported by `comm.IntegerToBit` are not inherently supported by functions. The code in this table shows decimal-to-binary conversion for various inputs using the recommended function.

Removed Feature	Recommended Replacement
<pre>% Default (left MSB) n = randi([1 100]); % Number of integers h1 = comm.IntegerToBit; bpi = h1.BitsPerInteger; x = randi([0,2^bpi-1],n,1); y = h1(x);</pre>	<pre>% Default (left MSB) n = randi([1 100]); % Number of integers bpi = 3; % Bits per integer x = randi([0,2^bpi-1],n,1); y = int2bit(x,bpi);</pre>
<pre>% Right MSB n = randi([1 100]); % Number of integers h2 = comm.IntegerToBit(... 'BitsPerInteger',5, ... 'MSBFirst',false); bpi = h2.BitsPerInteger; x = randi([0,2^bpi-1],n,1); y = h2(x);</pre>	<pre>% Right MSB n = randi([1 100]); % Number of integers bpi = 5; % Bits per integer x = randi([0,2^bpi-1],n,1); y = int2bit(x,bpi,false);</pre>
<pre>% Right MSB, signed input n = randi([1 100]); % Number of integers h3 = comm.IntegerToBit(... 'BitsPerInteger',8, ... 'MSBFirst',false, ... 'SignedIntegerInput',true); bpi = h3.BitsPerInteger; N = 2^bpi; x = randi([-N/2,N/2-1],n,1); y = h3(x);</pre>	<pre>% Right MSB, signed input n = randi([1 100]); % Number of integers bpi = 8; % Bits per integer N = 2^bpi; x = randi([-N/2,N/2-1],n,1); y = int2bit(x+(x<0)*N,bpi,false);</pre>

`dec2bin`

Introduced in R2012a

step

System object: comm.IntegerToBit

Package: comm

(Removed) Convert vector of integers to vector of bits

Note comm.IntegerToBit has been removed. Use int2bit instead.

Syntax

$Y = \text{step}(H,X)$

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, $y = \text{step}(\text{obj}, x)$ and $y = \text{obj}(x)$ perform equivalent operations.

$Y = \text{step}(H,X)$ converts integer input, X , to corresponding bits, Y . The input must be scalar or a column vector and the data type can be numeric or fixed-point (fi objects). The output is a column vector with length equal to $\text{length}(X) \times N$, where N is the value of the `BitsPerInteger` property. If any input value is outside the range of N , the object issues an error. If the `SignedIntegerInput` property is `false`, the input values must be between 0 and $(2^N)-1$. If you set the `SignedIntegerInput` property to `true`, the input values must be between $-(2^{(N-1)})$ and $(2^{(N-1)})-1$.

Note `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications. For more information on changing property values, see "System Design in MATLAB Using System Objects".

comm.IntegrateAndDumpFilter

Package: comm

Integrate discrete-time signal with periodic resets

Description

The `IntegrateAndDumpFilter` object creates a cumulative sum of the discrete-time input signal, while resetting the sum to zero according to a fixed schedule. When the simulation begins, the object discards the number of samples specified in the `Offset` property. After this initial period, the object sums the input signal along columns and resets the sum to zero every N_{input} samples, set by the `IntegrationPeriod` property. The reset occurs after the object produces output at that time step.

To integrate discrete-time signals with periodic resets:

- 1 Define and set up your integrate and dump filter object. See “Construction” on page 3-786.
- 2 Call `step` to integrate discrete-time signals according to the properties of `comm.IntegrateAndDumpFilter`. The behavior of `step` is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, $y = \text{step}(\text{obj}, x)$ and $y = \text{obj}(x)$ perform equivalent operations.

Construction

`H = comm.IntegrateAndDumpFilter` creates an integrate and dump filter System object, `H`. This object integrates over a number of samples in an integration period, and then resets at the end of that period.

`H = comm.IntegrateAndDumpFilter(Name, Value)` creates an integrate and dump filter object, `H`, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as `(Name1, Value1, ..., NameN, ValueN)`.

`H = comm.IntegrateAndDumpFilter(PERIOD, Name, Value)` creates an integrate and dump filter object, `H`. This object has the `IntegrationPeriod` property set to `PERIOD` and the other specified properties set to the specified values.

Properties

IntegrationPeriod

Integration period

Specify the integration period, in samples, as a positive, integer scalar value greater than 1. The integration period defines the length of the sample blocks that the object integrates between resets. The default is 8.

Offset

Number of offset samples

Specify a nonnegative, integer vector or scalar specifying the number of input samples that the object discards from each column of input data at the beginning of data processing. Discarding begins when you call the `step` method for the first time. The default is 0.

When you set the `Offset` on page 3-0 property to a nonzero value, the object outputs one or more zeros during the initial period while discarding input samples.

When you specify this property as a vector of length L , the i -th element of the vector corresponds to the offset for the i -th column of the input data matrix, which has L columns.

When you specify this property as a scalar value, the object applies the same offset to each column of the input data matrix. The offset creates a transient effect, rather than a persistent delay.

DecimateOutput

Decimate output

Specify whether the `step` method returns intermediate cumulative sum results or decimates intermediate results. The default is `true`.

When you set this property to `true`, the `step` method returns one output sample, consisting of the final integration value, for each block of `IntegrationPeriod` on page 3-0 input samples. If the inputs are $(K \times \text{IntegrationPeriod}) \times L$ matrices, then the outputs are $K \times L$ matrices.

When you set this property to `false`, the `step` method returns `IntegrationPeriod` output samples, comprising the intermediate cumulative sum values, for each block of `IntegrationPeriod` input samples. In this case, inputs and outputs have the same dimensions.

Fixed-Point Properties

FullPrecisionOverride

Full precision override for fixed-point arithmetic

Specify whether to use full precision rules. If you set `FullPrecisionOverride` to `true`, which is the default, the object computes all internal arithmetic and output data types using full precision rules. These rules provide the most accurate fixed-point numerics. It also turns off the display of other fixed-point properties because they do not apply individually. These rules guarantee that no quantization occurs within the object. Bits are added, as needed, to ensure that no roundoff or overflow occurs. If you set `FullPrecisionOverride` to `false`, fixed-point data types are controlled through individual fixed-point property settings. For more information, see “Full Precision for Fixed-Point System Objects” on page 3-790.

RoundingMethod

Rounding of fixed-point numeric values

Specify the rounding method as one of `Ceiling` | `Convergent` | `Floor` | `Nearest` | `Round` | `Simplest` | `Zero`. The default is `Floor`. This property applies only if the object is not in full precision mode.

OverflowAction

Action when fixed-point numeric values overflow

Specify the overflow action as one of `Wrap` | `Saturate`. The default is `Wrap`. This property applies only if the object is not in full precision mode.

AccumulatorDataType

Data type of accumulator

Specify the accumulator data type as one of `Full precision` | `Same as input` | `Custom`. The default is `Full precision`. When you set this property to `Full precision` the object automatically calculates the accumulator output word and fraction lengths. Set this property to `Custom` to specify the accumulator data type using the `CustomAccumulatorDataType` on page 3-0 property. This property applies when you set the `FullPrecisionOverride` on page 3-0 property to `false`.

CustomAccumulatorDataType

Fixed-point data type of accumulator

Specify the accumulator fixed-point type as a scaled `numericType` object with a signedness of `Auto`. The default is `numericType([], 32, 30)`. This property applies when you set the `FullPrecisionOverride` on page 3-0 property to `false` and the `AccumulatorDataType` on page 3-0 property to `Custom`.

OutputDataType

Data type of output

Specify the output fixed-point type as one of `Same as accumulator` | `Same as input` | `Custom`. The default is `Same as accumulator`. This property applies when you set the `FullPrecisionOverride` on page 3-0 property to `false`.

CustomOutputDataType

Fixed-point data type of output

Specify the output fixed-point type as a scaled `numericType` object with a signedness of `Auto`. The default is `numericType([], 32, 30)`. This property applies when you set the `FullPrecisionOverride` on page 3-0 property to `false` and the `OutputDataType` on page 3-0 property to `Custom`.

Examples

Pass Noisy Pulses Through Integrate and Dump Filter

Create an integrate and dump filter having an integration period of 20 samples.

```
intdump = comm.IntegrateAndDumpFilter(20);
```

Generate binary data.

```
d = randi([0 1],50,1);
```

Upsample the data, and pass it through an AWGN channel.

```
x = upsample(d,20);
y = awgn(x,25,'measured');
```

Pass the noisy data through the filter.

```
z = intdump(y);
```

Plot the original and filtered data. The integrate and dump filter removes most of the noise effects.

```
stairs([d z])
legend('Original Data','Filtered Data')
xlabel('Samples')
ylabel('Amplitude')
grid
```

More About

Full Precision for Fixed-Point System Objects

`FullPrecisionOverride` is a convenience property that, when you set to `true`, automatically sets the appropriate properties for an object to use full-precision to process fixed-point input.

For System objects, full precision, fixed-point operation refers to growing just enough additional bits to compute the ideal full precision result. This operation has no minimum or maximum range overflow nor any precision loss due to rounding or underflow. It is also independent of any hardware-specific settings. The data types chosen are based only on known data type ranges and not on actual numeric values. Full precision for System objects does not optimize coefficient values. When you set the `FullPrecisionOverride` property to `true`, the other fixed-point properties it controls no longer apply and any of their non-default values are ignored. These properties are also hidden. To specify individual fixed-point properties, first set `FullPrecisionOverride` to `false`.

Algorithms

This object implements the algorithm, inputs, and outputs described on the Integrate and Dump block reference page. The object properties correspond to the block parameters, except: The **Output intermediate values** parameter corresponds to the `DecimateOutput` on page 3-0 property.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

See “System Objects in MATLAB Code Generation” (MATLAB Coder).

Introduced in R2012a

step

System object: comm.IntegrateAndDumpFilter

Package: comm

Integrate discrete-time signal with periodic resets

Syntax

$Y = \text{step}(H,X)$

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, $y = \text{step}(\text{obj}, x)$ and $y = \text{obj}(x)$ perform equivalent operations.

$Y = \text{step}(H,X)$ periodically integrates blocks of N samples from the input data, X , and returns the result in Y . N is the number of samples that you specify in the `IntegrationPeriod` property. X is a column vector or a matrix and the data type is double, single or fixed-point (fi objects). X must have $K*N$ rows for some positive integer K , with one or more columns. The object treats each column as an independent channel with integration occurring along every column. The dimensions of output Y depend on the value you set for the `DecimateOutput` property.

Note `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications. For more information on changing property values, see “System Design in MATLAB Using System Objects”.

comm.KasamiSequence

Package: comm

Generate Kasami sequence

Description

The `comm.KasamiSequence` System object generates a sequence from the set of Kasami sequences. The Kasami sequences are a set of sequences that have cross-correlation properties. For more information, see “Kasami Sequences” on page 3-797.

To generate a Kasami sequence:

- 1 Create the `comm.KasamiSequence` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

Creation

Syntax

```
kasamiseq = comm.KasamiSequence  
kasamiseq = comm.KasamiSequence(Name,Value)
```

Description

`kasamiseq = comm.KasamiSequence` creates a `KasamiSequence` System object. This object generates a Kasami sequence.

`kasamiseq = comm.KasamiSequence(Name,Value)` sets “Properties” on page 3-792 using one or more name-value arguments. For example, `'Polynomial','z^8 + z^4 + z^3 + z^2 + 1'` specifies the generator polynomial.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see [System Design in MATLAB Using System Objects](#).

Polynomial — Generator polynomial

`'z^6 + z + 1'` (default) | character vector | string scalar | binary-valued row vector | integer-valued row vector

Generator polynomial, specified as one of these options:

- Character vector or string scalar of a polynomial whose constant term is 1. For more information, see “Representation of Polynomials in Communications Toolbox”.
- Binary-valued row vector that represents the coefficients of a polynomial in order of descending powers. The length of this vector must be $N + 1$, where N is the degree of the polynomial. The first and last entries must be 1, indicating a leading term with degree N and a constant term of 1.
- Integer-valued row vector of elements that represents the exponents for the nonzero terms of a polynomial in order of descending powers. The last entry must be 0, indicating a constant term of 1.

You can specify the primitive generator polynomial as a row vector of elements that represents the exponents for the nonzero terms of the polynomial in order of descending powers. Alternatively, you can also use the `primpoly` function to find the primitive polynomials for a Galois field or use the `gfprimck` function to check if a polynomial is a valid primitive polynomial.

Example: `'z^8 + z^4 + z^3 + z^2 + 1'`, `[1 0 0 0 1 1 1 0 1]`, and `[8 4 3 2 0]` represent the same polynomial: $z^8 + z^4 + z^3 + z^2 + 1$.

Data Types: `double` | `char` | `string`

InitialConditions — Initial conditions of shift register

`[0 0 0 0 0 1]` (default) | binary-valued scalar | binary-valued row vector

Initial conditions of the shift register, specified as one of these options:

- Binary-valued scalar — This value specifies the initial conditions of all cells in the shift register.
- Binary-valued row vector of length equal to the degree of the generator polynomial — Each element of the vector corresponds to the initial value of the corresponding cell in the shift register.

Note The scalar, or at least one element of the specified vector, requires a nonzero value for the object to generate a nonzero sequence.

Data Types: `double`

Index — Sequence index

0 (default) | integer | vector of the form `[k m]`

Sequence index, specified as an integer or vector of the form `[k m]` to select a Kasami sequence of interest from the set of possible sequences. Kasami sequences have a period equal to $N = 2^n - 1$, where n is a nonnegative even integer equal to the degree of the generator polynomial that you specify in the `Polynomial` property.

Two classes of Kasami sequences exist: those obtained from a small set and those obtained from a large set. You can choose a Kasami sequence from the small set by setting this property to an integer in the range $[0, 2^{n/2}-2]$. You can choose a sequence from the large set by setting this property to a vector of the form `[k m]`. k must be an integer in the range $[-2, 2^{n/2}-2]$, and m must be an integer in the range $[-1, 2^{n/2}-2]$. For more information, see “Kasami Sequences” on page 3-797.

Data Types: `double`

Shift — Sequence offset from starting point

0 (default) | integer

Sequence offset from the starting point, specified as an integer. The Kasami sequence has a period of $N = 2^n - 1$, where n is the degree of the generator polynomial that you specify in the `Polynomial` on page 3-0 property. The shift value is wrapped with respect to the sequence period.

Data Types: `double`

VariableSizeOutput — Option to enable variable-size outputs

`false` (default) | `true`

Option to enable variable-size outputs, specified as one of these numeric or logical values:

- `false` (0) -- Use the `SamplesPerFrame` property to specify the number of output samples per frame.
- `true` (1) -- Use the `outputsize` input argument to specify the output size of the Kasami sequence. The input value must be less than or equal to the value of the `MaximumOutputSize` property.

Data Types: `logical` | `double`

MaximumOutputSize — Maximum output size

`[10 1]` (default) | vector of the form `[m 1]`

Maximum output size of the Kasami sequence, specified as a vector of the form `[m 1]`, where m is a positive integer. The first element of the vector indicates the maximum size of the sequence, and the second element of the vector must be 1.

Example: `[10 1]` specifies a maximum output size of 10-by-1.

Dependencies

To enable this property, set the `VariableSizeOutput` property to 1 (`true`).

Data Types: `double`

SamplesPerFrame — Number of output samples per frame

1 (default) | positive integer

Number of output samples per frame, specified as a positive integer.

If you set this property to a value of M , then the output, which contains M samples of a Kasami sequence, has a period of $N = 2^n - 1$. The value n is the degree of the generator polynomial that you specify in the `Polynomial` on page 3-0 property.

Dependencies

To enable this property, set the `VariableSizeOutput` property to `false` (0).

Data Types: `double`

ResetInputPort — Option to enable input to reset sequence generator

`false` (default) | `true`

Option to enable generator reset input, specified as a logical or numeric `false` (0) or `true`(1). Set this property to `true` (1) to enable the `resetseq` input argument. The input argument resets the states of the Kasami sequence generator to the initial conditions that you specify in the `InitialConditions` on page 3-0 property.

Data Types: `logical` | `double`

OutputDataType — Data type of output Kasami sequence

'double' (default) | 'logical'

Data type of the output Kasami sequence, specified as 'double' or 'logical'.

Data Types: char | string

Usage**Syntax**

```

outsequence = kasamiseq()
outsequence = kasamiseq(outputsize)
outsequence = kasamiseq(resetseq)
outsequence = kasamiseq(outputsize, resetseq)

```

Description

`outsequence = kasamiseq()` generates a Kasami sequence.

`outsequence = kasamiseq(outputsize)` specifies the length of the output sequence.

To enable this syntax, set the `VariableSizeOutput` property to 1 (true).

`outsequence = kasamiseq(resetseq)` specifies a reset signal for the sequence generator.

To enable this syntax, set the `ResetInputPort` property to 1 (true).

`outsequence = kasamiseq(outputsize, resetseq)` specifies the length of the output sequence and the reset signal for the sequence generator.

To enable this syntax, set the `VariableSizeOutput` property to 1 (true) and the `ResetInputPort` property to 1 (true).

Input Arguments**outputsize — Length of output sequence**nonnegative integer | vector of the form [*n* 1]

Length of the output sequence, specified as a nonnegative integer or a vector of the form [*n* 1], where *n* is a positive integer. The first element of the vector indicates the length of the output frame, and the second element of the vector must be 1.

The scalar or the first element of the row vector must be less than or equal to the first element of the `MaximumOutputSize` property value.

Dependencies

To enable this input argument, set the `VariableSizeOutput` property to 1 (true).

Data Types: double

resetseq — Reset signal for sequence generator

nonzero scalar | numeric column vector

Reset signal for the sequence generator, specified as a scalar or a column vector with length equal to the number of samples per frame specified by the `SamplesPerFrame` property.

- When you specify this input as a nonzero scalar, the sequence generator resets to the specified initial conditions and then generates a new output frame.
- When you specify this input as a numeric column vector, the sequence generator resets to the specified initial conditions at each sample in the output frame that aligns with a nonzero value in this vector.

Dependencies

To enable this input argument, set the `ResetInputPort` property to `1 (true)`.

Data Types: `double`

Output Arguments

outSequence — Kasami sequence

column vector

Kasami sequence, returned as a column vector.

Data Types: `double`

Object Functions

To use an object function, specify the `System` object as the first input argument. For example, to release system resources of a `System` object named `obj`, use this syntax:

```
release(obj)
```

Common to All System Objects

<code>step</code>	Run <code>System</code> object algorithm
<code>release</code>	Release resources and allow changes to <code>System</code> object property values and input characteristics
<code>reset</code>	Reset internal states of <code>System</code> object

Examples

Spread BPSK Data with Kasami Sequence

Generate binary data, and then apply BPSK modulation to that data.

```
data = randi([0 1],10,1);  
modData = pskmod(data,2);
```

Create a Kasami sequence generator `System` object, specifying a generator polynomial $x^8 + x^4 + x^3 + x^2 + 1$, initial conditions of the shift register, and a Kasami sequence of length 255.

```
kasamiseq = comm.KasamiSequence('Polynomial',[8 4 3 2 0], ...  
    'InitialConditions',[0 0 0 0 0 0 0 1], 'SamplesPerFrame',255);
```

Generate the Kasami sequence, and then convert it to bipolar form.

```
kasSeq = kasamiseq();
kasSeq = 2*kasSeq - 1;
```

Apply a gain of $1/\sqrt{255}$ to ensure that the spreading operation does not increase the overall signal power.

```
kasSeq = kasSeq/sqrt(255);
```

Spread the BPSK data using the Kasami sequence.

```
spreadData = modData*kasSeq';
spreadData = spreadData(:);
```

Verify that the spread data sequence is 255 times longer than the input data sequence.

```
spreadingFactor = length(spreadData)/length(data)
```

```
spreadingFactor = 255
```

Verify that the spreading operation did not increase the signal power.

```
modSigPwr = sum(abs(modData).^2)/length(data)
```

```
modSigPwr = 1
```

```
spreadSigPwr = sum(abs(spreadData).^2)/length(data)
```

```
spreadSigPwr = 1.0000
```

More About

Kasami Sequences

Two sets of Kasami sequences exist: the *small set* and the *large set*. The large set contains all of the sequences in the small set. Only the small set is optimal in the sense of matching Welch's lower bound for correlation functions.

Kasami sequences have a period of $N = 2^n - 1$, where n is a nonnegative even integer. Let u be a binary sequence of length N , and let w be the sequence obtained by decimating u by $2^{n/2} + 1$. This piecewise function defines the small set of Kasami sequences. T is the left shift operator, m is the shift parameter for w , and \oplus denotes addition modulo 2.

$$K_s(u, n, m) = \begin{cases} u & m = -1 \\ u \oplus T^m w & m = 0, \dots, 2^{n/2} - 2 \end{cases}$$

The small set contains $2^{n/2}$ sequences.

For $\text{mod}(n, 4) = 2$, this piecewise function defines the large set of Kasami sequences. Let v be the sequence formed by decimating the sequence u by $2^{(n/2 + 1)} + 1$. k and m are the shift parameters for the sequences v and w , respectively.

$$K_L(u, n, k, m) = \begin{cases} u & k = -2; m = -1 \\ v & k = -1; m = -1 \\ u \oplus T^k v & k = 0, \dots, 2^n - 2; m = -1 \\ u \oplus T^m w & k = -2; m = 0, \dots, 2^{n/2} - 2 \\ v \oplus T^m w & k = -1; m = 0, \dots, 2^{n/2} - 2 \\ u \oplus T^k v \oplus T^m w & k = 0, \dots, 2^n - 2; m = 0, \dots, 2^{n/2} - 2 \end{cases}$$

The sequences described in the first three rows of K_L correspond to the Gold sequences for $\text{mod}(n, 4) = 2$. For a description of Gold sequences, see the `comm.GoldSequence` System object reference page. However, the Kasami sequences form a larger set than the Gold sequences alone.

The correlation functions for the sequences take on the values

$$\{-t(n), -s(n), -1, s(n) - 2, t(n) - 2\},$$

where

$$t(n) = 1 + 2^{(n+2)/2}, \text{ when } n \text{ is even and}$$

$$s(n) = \frac{1}{2}(t(n) + 1).$$

Polynomials for Generating Kasami sequences

Kasami sequences have a period of $N = 2^n - 1$, where n is a nonnegative even integer. This table lists some of the polynomials that you can use to generate the set of Kasami sequences.

n	N	Polynomial	Set
4	15	'z ⁴ + z + 1'	Small
6	63	'z ⁶ + z + 1'	Large
8	255	'z ⁸ + z ⁴ + z ³ + z ² + 1'	Small
10	1023	'z ¹⁰ + z ³ + 1'	Large
12	4095	'z ¹² + z ⁶ + z ⁴ + z + 1'	Small

Blocks

Kasami Sequence Generator

Introduced in R2012a

comm.LDPCDecoder

Package: comm

(Not recommended) Decode binary low-density parity-check (LDPC) code

Note is not recommended. Instead, use the `ldpcDecode` function. For more information, see “Compatibility Considerations”.

Description

The `comm.LDPCDecoder` System object uses the belief propagation algorithm to decode a binary LDPC code, which is input to the object as the soft-decision output (log-likelihood ratio of received bits) from demodulation. The object decodes generic binary LDPC codes where no patterns in the parity-check matrix are assumed. For more information, see “Belief Propagation Decoding” on page 3-805.

To decode an LDPC-encoded signal:

- 1 Create the `comm.LDPCDecoder` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

Creation

Syntax

```
ldpcdecoder = comm.LDPCDecoder
ldpcdecoder = comm.LDPCDecoder(parity)
ldpcdecoder = comm.LDPCDecoder( ____,Name,Value)
```

Description

`ldpcdecoder = comm.LDPCDecoder` creates a binary LDPC decoder System object. This object performs LDPC decoding based on the specified parity-check matrix.

`ldpcdecoder = comm.LDPCDecoder(parity)` sets the `ParityCheckMatrix` property to `parity` and creates an LDPC decoder System object. The `parity` input must be specified as described by the `ParityCheckMatrix` property.

`ldpcdecoder = comm.LDPCDecoder(____,Name,Value)` sets properties using one or more name-value pairs, in addition to inputs from any of the prior syntaxes. For example, `comm.LDPCDecoder('DecisionMethod','Soft decision')` configures an LDPC decoder System object to decode data using the soft-decision method and output log-likelihood ratios of data type `double`. Enclose each property name in quotes.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects.

ParityCheckMatrix — Parity-check matrix

`dvbs2ldpc(1/2)` (default) | sparse binary matrix | nonsparse index matrix

Parity-check matrix, specified as a sparse $(N - K)$ -by- N binary-valued matrix. N is the length of the received signal and must be in the range $(0, 2^{31})$. K is the length of the uncoded message and must be less than N . The last $(N - K)$ columns in the parity-check matrix must be an invertible matrix in the Galois field of order 2, `gf(2)`.

You can also specify the parity-check matrix as a two-column nonsparse index matrix, `I`, that defines the row and column indices of the 1s in the parity-check matrix such that `sparse(I(:,1),I(:,2),1)`.

This property accepts numeric data types. When you set this property to a sparse binary matrix, this property also accepts the `logical` data type.

The default value uses the `dvbs2ldpc` function to configure a sparse parity-check matrix for half-rate LDPC coding, as specified in the DVB-S.2 standard.

Example: `dvbs2ldpc(R, 'indices')` configures the index matrix for the DVB-S.2 standard, where `R` is the code rate, and `'indices'` specifies the output format of `dvbs2ldpc` as a two-column double-precision matrix that defines the row and column indices of the 1s in the parity-check matrix.

Data Types: `double` | `logical`

OutputValue — Output value format

`'Information part'` (default) | `'Whole codeword'`

Output value format, specified as one of these values:

- `'Information part'` — The object outputs a K -by-1 column vector containing only the information-part of the received log-likelihood ratio vector. K is the length of the uncoded message.
- `'Whole codeword'` — The object outputs an N -by-1 column vector containing the whole log-likelihood ratio vector. N is the length of the received signal.

N and K must align with the dimension of the $(N-K)$ -by- K parity-check matrix.

Data Types: `char`

DecisionMethod — Decision method

`'Hard decision'` (default) | `'Soft decision'`

Decision method used for decoding, specified as one of these values:

- `'Hard decision'` — The object outputs decoded data of data type `logical`.

- 'Soft decision' — The object outputs log-likelihood ratios of data type double.

Data Types: char

IterationTerminationCondition — Condition for iteration termination

'Maximum iteration count' (default) | 'Parity check satisfied'

Condition for iteration termination, specified as one of these values:

- 'Maximum iteration count' — Decoding terminates after the number of iterations specified by the `MaximumIterationCount` property.
- 'Parity check satisfied' — Decoding terminates after all parity checks are satisfied. If not all parity checks are satisfied, decoding terminates after the number of iterations specified by the `MaximumIterationCount` property.

Data Types: char

MaximumIterationCount — Maximum number of decoding iterations

50 (default) | positive integer

Maximum number of decoding iterations, specified as a positive integer.

Data Types: double

NumIterationsOutputPort — Output number of iterations executed

false (default) | true

Output number of iterations performed, specified as `false` or `true`. To output the number of iterations executed, set this property to `true`.

Data Types: logical

FinalParityChecksOutputPort — Output final parity checks

false (default) | true

Output final parity checks, specified as `false` or `true`. To output the final calculated parity checks, set this property to `true`.

Data Types: logical

Usage

Syntax

```
y = ldpcdecoder(x)
[y,numiter] = ldpcdecoder(x)
[y,parity] = ldpcdecoder(x)
[y,numiter,parity] = ldpcdecoder(x)
```

Description

`y = ldpcdecoder(x)` decodes input data using an LDPC code based on the default parity-check matrix.

`[y,numiter] = ldpcdecoder(x)` returns the decoded data, `y`, and number of iterations performed, `numiter`. To use this syntax, set the `NumIterationsOutputPort` property to `true`.

`[y,parity] = ldpcdecoder(x)` returns the decoded data, `y`, and final parity checks, `parity`. To use this syntax, set the `FinalParityChecksOutputPort` property to `true`.

`[y,numiter,parity] = ldpcdecoder(x)` returns the decoded data, number of iterations performed, and final parity checks. To use this syntax, set the `NumIterationsOutputPort` and `FinalParityChecksOutputPort` properties to `true`.

Input Arguments

x — Log-likelihood ratios

column vector

Log-likelihood ratios, specified as an N -by-1 column vector containing the soft-decision output from demodulation. N is the number of bits in the LDPC codeword before modulation. Each element is the log-likelihood ratio for a received bit. Element values are more likely to be 0 if the log-likelihood ratio is positive. The first K elements correspond to the information-part of the input message.

Data Types: `double`

Output Arguments

y — Decoded data

column vector

Decoded data, returned as a column vector. The `DecisionMethod` property specifies whether the object outputs hard decisions or soft decisions (log-likelihood ratios).

- If the `OutputValue` property is set to `'Information part'`, the output includes only the information-part of the received log-likelihood ratio vector.
- If the `OutputValue` property is set to `'Whole codeword'`, the output includes the whole log-likelihood ratio vector.

Data Types: `double` | `logical`

numiter — Number of executed decoding iterations

positive integer

Number of executed decoding iterations, returned as a positive integer.

Dependencies

To enable this output, set the `NumIterationsOutputPort` property to `true`.

parity — Final parity checks

column vector

Final parity checks after decoding the input LDPC code, returned as an $(N-K)$ -by-1 column vector. N is the number of bits in the LDPC codeword before modulation. K is the length of the uncoded message.

Dependencies

To enable this output, set the `FinalParityChecksOutputPort` property to `true`.

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Common to All System Objects

<code>step</code>	Run System object algorithm
<code>release</code>	Release resources and allow changes to System object property values and input characteristics
<code>reset</code>	Reset internal states of System object

Examples

LDPC Encode and Decode QPSK-Modulated Signal

Transmit an LDPC-encoded, QPSK-modulated bit stream through an AWGN channel. Demodulate and decode the received signal. Compute the error statistics for the reception of uncoded and LDPC-coded signals.

Define simulation variables. Create System objects for the LDPC encoder, LDPC decoder, QPSK modulator, and QPSK demodulators.

```
M = 4; % Modulation order (QPSK)
snr = [0.25,0.5,0.75,1.0,1.25];
numFrames = 10;
ldpcEncoder = comm.LDPCDecoder;
ldpcDecoder = comm.LDPCDecoder;
pskMod = comm.PSKModulator(M,'BitInput',true);
pskDemod = comm.PSKDemodulator(M,'BitOutput',true,...
    'DecisionMethod','Approximate log-likelihood ratio');
pskuDemod = comm.PSKDemodulator(M,'BitOutput',true,...
    'DecisionMethod','Hard decision');
errRate = zeros(1,length(snr));
uncErrRate = zeros(1,length(snr));
```

For each SNR setting and all frames, compute the error statistics for uncoded and LDPC-coded signals. The outer for loop processes each SNR value. The inner for loop processes frames of input data.

```
for ii = 1:length(snr)
    ttlErr = 0;
    ttlErrUnc = 0;
    pskDemod.Variance = 1/10^(snr(ii)/10);
    for counter = 1:numFrames
        data = logical(randi([0 1],32400,1));
        % Transmit and receiver uncoded signal data
        mod_uncSig = pskMod(data);
        rx_uncSig = awgn(mod_uncSig,snr(ii),'measured');
        demod_uncSig = pskuDemod(rx_uncSig);
        numErrUnc = biterr(data,demod_uncSig);
        ttlErrUnc = ttlErrUnc + numErrUnc;
        % Transmit and receive LDPC coded signal data
```

```

    encData = ldpcEncoder(data);
    modSig = pskMod(encData);
    rxSig = awgn(modSig,snr(ii),'measured');
    demodSig = pskDemod(rxSig);
    rxBits = ldpcDecoder(demodSig);
    numErr = biterr(data,rxBits);
    ttlErr = ttlErr + numErr;
end
ttlBits = numFrames*length(rxBits);
uncErrRate(ii) = ttlErrUnc/ttlBits;
errRate(ii) = ttlErr/ttlBits;
end

```

Run this code to plot the error statistics for uncoded and LDPC-coded data.

```

plot(snr,uncErrRate,snr,errRate)
legend('Uncoded','LDPC coded')
xlabel('SNR (dB)')
ylabel('BER')

```

Algorithms

This object performs LDPC decoding using the belief propagation algorithm, also known as a message-passing algorithm.

Belief Propagation Decoding

The implementation of the belief propagation algorithm is based on the decoding algorithm presented by Gallager [2].

For transmitted LDPC-encoded codeword $c = c_0, c_1, \dots, c_{n-1}$, the input to the LDPC decoder is the log-likelihood ratio (LLR) value $L(c_i) = \log \left(\frac{\Pr(c_i = 0 \mid \text{channel output for } c_i)}{\Pr(c_i = 1 \mid \text{channel output for } c_i)} \right)$.

In each iteration, the key components of the algorithm are updated based on these equations:

$$L(r_{ji}) = 2 \operatorname{atanh} \left(\prod_{i' \in V_{j \setminus i}} \tanh \left(\frac{1}{2} L(q_{i'j}) \right) \right),$$

$$L(q_{ij}) = L(c_i) + \sum_{j' \in C_i \setminus j} L(r_{ji'}), \text{ initialized as } L(q_{ij}) = L(c_i) \text{ before the first iteration, and}$$

$$L(Q_i) = L(c_i) + \sum_{j \in C_i} L(r_{ji}).$$

At the end of each iteration, $L(Q_i)$ contains the updated estimate of the LLR value for transmitted bit c_i . The value $L(Q_i)$ is the soft-decision output for c_i . If $L(Q_i) < 0$, the hard-decision output for c_i is 1. Otherwise, the hard-decision output for c_i is 0.

If decoding is configured to stop when all of the parity checks are satisfied, the algorithm verifies the parity-check equation ($H c' = 0$) at the end of each iteration. When all of the parity checks are satisfied, or if the maximum number of iterations is reached, decoding stops.

Index sets $C_i \setminus j$ and $V_j \setminus i$ are based on the parity-check matrix (PCM). Index sets C_i and V_j correspond to all nonzero elements in column i and row j of the PCM, respectively.

This figure shows the computation of these index sets in a given PCM for $i = 5$ and $j = 3$.

To avoid infinite numbers in the algorithm equations, $\operatorname{atanh}(1)$ and $\operatorname{atanh}(-1)$ are set to 19.07 and -19.07 , respectively. Due to finite precision, MATLAB returns 1 for $\tanh(19.07)$ and -1 for $\tanh(-19.07)$.

Compatibility Considerations

comm.LDPCDecoder is not recommended. Use ldpcDecode instead.

Not recommended starting in R2021b

Use `ldpcDecode` instead of `comm.LDPCDecoder`. To specify the LDPC code applied by the `ldpcDecode` function, use the configuration object returned by the `ldpcDecoderConfig` object.

The code in this table shows LDPC decoding inputs using the recommended function and configuration object.

Discouraged Feature	Recommended Replacement
<pre>% Decode using parity-check matrix (pcmatrix) dec = comm.LDPCDecoder(pcmatrix); dec.OutputValue = 'Whole codeword'; dec.DecisionMethod = 'Soft decision'; dec.MaximumIterationCount = 10; dec.IterationTerminationCondition = 'Parity check satisfied'; output = dec(LLR);</pre>	<pre>% Decode using parity-check matrix (pcmatrix) cfg = ldpcDecoderConfig(pcmatrix); output = ldpcDecode(LLR, cfg, 10, ... 'OutputFormat', 'whole', ... 'DecisionType', 'soft', ... 'Termination', 'early');</pre>

LDPC Decoder

Introduced in R2012a

comm.LDPCEncoder

Package: comm

(Not recommended) Encode binary low-density parity-check (LDPC) code

Note is not recommended. Instead, use the `ldpcEncode` function. For more information, see “Compatibility Considerations”.

Description

The `comm.LDPCEncoder` System object applies LDPC coding to a binary input message. LDPC codes are linear error control codes with sparse parity-check matrices and long block lengths that can attain performance near the Shannon limit.

To encode a binary LDPC code:

- 1 Create the `comm.LDPCEncoder` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

Creation

Syntax

```
ldpcencoder = comm.LDPCEncoder
ldpcencoder = comm.LDPCEncoder(parity)
ldpcencoder = comm.LDPCEncoder( ___,Name,Value)
```

Description

`ldpcencoder = comm.LDPCEncoder` creates a binary LDPC encoder System object. This object performs LDPC encoding based on the default parity-check matrix.

`ldpcencoder = comm.LDPCEncoder(parity)` sets the `ParityCheckMatrix` property to `parity` and creates an LDPC encoder System object. The `parity` input must be specified as described by the `ParityCheckMatrix` property.

`ldpcencoder = comm.LDPCEncoder(___,Name,Value)` sets properties using one or more name-value pairs, in addition to inputs from any of the prior syntaxes. For example, `comm.LDPCEncoder('ParityCheckMatrix',sparse(I(:,1),I(:,2),1))` configures an LDPC encoder System object to encode data using the parity matrix `sparse(I(:,1),I(:,2),1)`. Enclose each property name in quotes.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects.

ParityCheckMatrix — Parity-check matrix

`dvbs2ldpc(1/2)` (default) | sparse binary matrix | nonsparse index matrix

Parity-check matrix, specified as a sparse $(N - K)$ -by- N binary-valued matrix. N is the length of the output `codeword` vector, and must be in the range $(0, 2^{31})$. K is the length of the uncoded message and must be less than N . The last $(N - K)$ columns in the parity-check matrix must be an invertible matrix in the Galois field of order 2, `gf(2)`.

You can also specify the parity-check matrix as a two-column nonsparse index matrix, `I`, that defines the row and column indices of the 1s in the parity-check matrix such that `sparse(I(:,1),I(:,2),1)`.

This property accepts numeric data types. When you set this property to a sparse binary matrix, this property also accepts the `logical` data type.

The default value uses the `dvbs2ldpc` function to configure a sparse parity-check matrix for half-rate LDPC coding, as specified in the DVB-S.2 standard.

Note

- When the last $(N - K)$ columns of the parity-check matrix form a triangular matrix, forward or backward substitution is performed to solve the parity-check equation.
 - When the last $(N - K)$ columns of the parity-check matrix do not form a triangular matrix, a matrix inversion is performed to solve the parity-check equation. If a large matrix needs to be inverted, initializations or updates take more time.
-

Example: `dvbs2ldpc(R, 'indices')` configures the index matrix for the DVB-S.2 standard, where `R` is the code rate, and `'indices'` specifies the output format of `dvbs2ldpc` as a two-column double-precision matrix that defines the row and column indices of the 1s in the parity-check matrix.

Data Types: `double` | `logical`

Usage

Syntax

`codeword = ldpcencoder(message)`

Description

`codeword = ldpcencoder(message)` codes the input message using an LDPC code based on a parity-check matrix. The LDPC codeword output is a solution to the parity-check equation.

Input Arguments

message — Input message

binary column vector

Input message, specified as a K -by-1 column vector containing binary-valued elements. K is the length of the uncoded message.

Data Types: `double` | `logical`

Output Arguments

codeword — LDPC codeword

column vector

LDPC codeword, returned as an N -by-1 column vector. N is the number of bits in the LDPC codeword. The output signal inherits its data type from the input signal. The LDPC codeword output is a solution to the parity-check equation. The input message comprises the first K bits of the LDPC codeword output, and the parity check comprises the remaining $(N - K)$ bits.

Data Types: `double` | `logical`

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Common to All System Objects

<code>step</code>	Run System object algorithm
<code>release</code>	Release resources and allow changes to System object property values and input characteristics
<code>reset</code>	Reset internal states of System object

Examples

LDPC Encode and Decode QPSK-Modulated Signal

Transmit an LDPC-encoded, QPSK-modulated bit stream through an AWGN channel. Demodulate and decode the received signal. Compute the error statistics for the reception of uncoded and LDPC-coded signals.

Define simulation variables. Create System objects for the LDPC encoder, LDPC decoder, QPSK modulator, and QPSK demodulators.

```
M = 4; % Modulation order (QPSK)
snr = [0.25,0.5,0.75,1.0,1.25];
```

```

numFrames = 10;
ldpcEncoder = comm.LDPCDecoder;
ldpcDecoder = comm.LDPCDecoder;
pskMod = comm.PSKModulator(M,'BitInput',true);
pskDemod = comm.PSKDemodulator(M,'BitOutput',true,...
    'DecisionMethod','Approximate log-likelihood ratio');
pskuDemod = comm.PSKDemodulator(M,'BitOutput',true,...
    'DecisionMethod','Hard decision');
errRate = zeros(1,length(snr));
uncErrRate = zeros(1,length(snr));

```

For each SNR setting and all frames, compute the error statistics for uncoded and LDPC-coded signals. The outer for loop processes each SNR value. The inner for loop processes frames of input data.

```

for ii = 1:length(snr)
    ttlErr = 0;
    ttlErrUnc = 0;
    pskDemod.Variance = 1/10^(snr(ii)/10);
    for counter = 1:numFrames
        data = logical(randi([0 1],32400,1));
        % Transmit and receive uncoded signal data
        mod_uncSig = pskMod(data);
        rx_uncSig = awgn(mod_uncSig,snr(ii),'measured');
        demod_uncSig = pskuDemod(rx_uncSig);
        numErrUnc = biterr(data,demod_uncSig);
        ttlErrUnc = ttlErrUnc + numErrUnc;
        % Transmit and receive LDPC coded signal data
        encData = ldpcEncoder(data);
        modSig = pskMod(encData);
        rxSig = awgn(modSig,snr(ii),'measured');
        demodSig = pskDemod(rxSig);
        rxBits = ldpcDecoder(demodSig);
        numErr = biterr(data,rxBits);
        ttlErr = ttlErr + numErr;
    end
    ttlBits = numFrames*length(rxBits);
    uncErrRate(ii) = ttlErrUnc/ttlBits;
    errRate(ii) = ttlErr/ttlBits;
end

```

Run this code to plot the error statistics for uncoded and LDPC-coded data.

```

plot(snr,uncErrRate,snr,errRate)
legend('Uncoded','LDPC coded')
xlabel('SNR (dB)')
ylabel('BER')

```

Compatibility Considerations

comm.LDPCDecoder is not recommended. Use ldpcEncode instead.

Not recommended starting in R2021b

Use `ldpcEncode` instead of `comm.LDPCDecoder`. To specify the LDPC code applied by the `ldpcEncode` function, use the configuration object returned by the `ldpcEncoderConfig` object.

The code in this table shows LDPC encoding of data using the recommended function and configuration object.

Discouraged Feature	Recommended Replacement
<pre data-bbox="238 380 857 449">% Encode using parity-check matrix (pcmatrix) enc = comm.LDPC Encoder(pcmatrix); codeword = enc(infoBits);</pre>	<pre data-bbox="857 380 1471 449">% Encode using parity-check matrix (pcmatrix) cfg = ldpcEncoderConfig(pcmatrix); codeword = ldpcEncode(infoBits,cfg);</pre>

ldpcDecoderConfig

Create LDPC decoder configuration

Description

The `ldpcDecoderConfig` object is a configuration object for the `ldpcDecode` function. The object specifies the low-density parity-check (LDPC) matrix and read-only properties to provide information about the configured matrix.

Creation

Syntax

```
decodercfg = ldpcDecoderConfig
decodercfg = ldpcDecoderConfig(H)
decodercfg = ldpcDecoderConfig(H,alg)
decodercfg = ldpcDecoderConfig(encodercfg)
decodercfg = ldpcDecoderConfig(encodercfg,alg)
```

Description

`decodercfg = ldpcDecoderConfig` creates an LDPC decoder configuration object that specifies a rate 5/6 LDPC code from the WLAN 802.11 standard [1].

`decodercfg = ldpcDecoderConfig(H)` configures the output object setting the `ParityCheckMatrix` property `H`.

`decodercfg = ldpcDecoderConfig(H,alg)` configures the output object setting the `ParityCheckMatrix` property to `H` and the `Algorithm` property to `alg`.

`decodercfg = ldpcDecoderConfig(encodercfg)` sets properties based on the input `ldpcEncoderConfig` configuration object, `encodercfg`.

`decodercfg = ldpcDecoderConfig(encodercfg,alg)` sets properties based on the input `ldpcEncoderConfig` configuration object, `encodercfg`, and sets the `Algorithm` property to `alg`.

Validation of the object settings is performed when the `ldpcDecode` function is called with the object as an input.

Properties

ParityCheckMatrix — Parity-check matrix

sparse logical 108-by-648 matrix (default) | sparse logical $(N - K)$ -by- N matrix

Parity-check matrix, specified as a sparse logical $(N - K)$ -by- N matrix, where $N > K > 0$. N is the LDPC codeword block length. K is the number of information bits in the LDPC codeword. The default is the parity-check matrix of rate 5/6 LDPC code with a block length of 648 as specified in the WLAN

802.11 standard [1]. Specifically, the default is the sparse logical 108-by-648 matrix H output by the `ldpcQuasiCyclicMatrix` function in this code.

```
P = [
    17 13  8 21  9  3 18 12 10  0  4 15 19  2  5 10 26 19 13 13  1  0 -1 -1
     3 12 11 14 11 25  5 18  0  9  2 26 26 10 24  7 14 20  4  2 -1  0  0 -1
    22 16  4  3 10 21 12  5 21 14 19  5 -1  8  5 18 11  5  5 15  0 -1  0  0
     7  7 14 14  4 16 16 24 24 10  1  7 15  6 10 26  8 18 21 14  1 -1 -1  0
];
blockSize = 27;
H = ldpcQuasiCyclicMatrix(blockSize,P);
```

Data Types: `logical`

Algorithm — LDPC decoding algorithm

'bp' (default) | 'layered-bp' | 'norm-min-sum' | 'offset-min-sum'

LDPC decoding algorithm, specified as one of these values:

- 'bp' — Use “Belief Propagation Decoding” on page 3-817 algorithm.
- 'layered-bp' — Use “Layered Belief Propagation Decoding” on page 3-818 algorithm.
- 'norm-min-sum' — Use “Normalized Min-Sum Decoding” on page 3-819 algorithm.
- 'offset-min-sum' — Use “Offset Min-Sum Decoding” on page 3-819 algorithm.

Data Types: `char` | `string`

BlockLength — Block length

648 (default) | positive scalar

This property is read-only.

Block length of the LDPC codeword (N), specified as a positive scalar. N equals the number of columns in the parity-check matrix.

Data Types: `double`

NumInformationBits — Number of information bits

540 (default) | positive scalar

This property is read-only.

Number of information bits in the LDPC codeword (K), specified as a positive scalar. K equals the number of columns of the parity-check matrix minus the number of rows of the parity-check matrix.

Data Types: `double`

NumParityCheckBits — Number of parity-check bits

108 (default) | positive scalar

This property is read-only.

Number of parity-check bits in the LDPC codeword ($N - K$), specified as a positive scalar. $N - K$ equals the number of rows in the parity-check matrix.

Data Types: `double`

CodeRate — Code rate of LDPC code

5/6 (default) | positive scalar

This property is read-only.

Code rate of the LDPC code, specified as a positive scalar that is equal to NumInformationBits/BlockLength.

Data Types: double

NumRowsPerLayer — Number of rows per layer

108 (default) | positive scalar

This property is read-only.

Number of rows per layer, specified as a positive scalar. This property indicates the number of rows per layer when you use a layered decoding algorithm. Specifically, this property is the largest integer such that ParityCheckMatrix can be evenly split into consecutive submatrices in which at most one 1 exists in any column in any one of these submatrices.

```
ParityCheckMatrix(1:NumRowsPerLayer,:)
```

```
ParityCheckMatrix((NumRowsPerLayer + 1):2*NumRowsPerLayer,:)
```

```
ParityCheckMatrix((2*NumRowsPerLayer + 1):3*NumRowsPerLayer,:)
```

...

```
ParityCheckMatrix((end - NumRowsPerLayer + 1):end,:)
```

Dependencies

To enable this property set the Algorithm property to 'layered-bp', 'norm-min-sum', or 'offset-min-sum'.

Data Types: double

Examples**Decode Rate 3/4 LDPC Codewords**

Initialize parameters for the prototype matrix and block size to configure a rate 3/4 LDPC code specified in IEEE® 802.11. Create the parity-check matrix by using the ldpcQuasiCyclicMatrix function.

```
P = [
    16 17 22 24  9  3 14 -1  4  2  7 -1 26 -1  2 -1 21 -1  1  0 -1 -1 -1 -1
    25 12 12  3  3 26  6 21 -1 15 22 -1 15 -1  4 -1 -1 16 -1  0  0 -1 -1 -1
    25 18 26 16 22 23  9 -1  0 -1  4 -1  4 -1  8 23 11 -1 -1 -1  0  0 -1 -1
     9  7  0  1 17 -1 -1  7  3 -1  3 23 -1 16 -1 -1 21 -1  0 -1 -1  0  0 -1
    24  5 26  7  1 -1 -1 15 24 15 -1  8 -1 13 -1 13 -1 11 -1 -1 -1 -1  0  0
     2  2 19 14 24  1 15 19 -1 21 -1  2 -1 24 -1  3 -1  2  1 -1 -1 -1 -1  0
];
blockSize = 27;
pcmatrix = ldpcQuasiCyclicMatrix(blockSize,P);
```

Create LDPC encoder and decoder configuration objects, displaying their properties.

```
cfgLDPCEnc = ldpcEncoderConfig(pcmatrix)
```

```
cfgLDPCEnc =  
  ldpcEncoderConfig with properties:  
  
    ParityCheckMatrix: [162x648 logical]  
  
  Read-only properties:  
    BlockLength: 648  
    NumInformationBits: 486  
    NumParityCheckBits: 162  
    CodeRate: 0.7500
```

```
cfgLDPCDec = ldpcDecoderConfig(pcmatrix)
```

```
cfgLDPCDec =  
  ldpcDecoderConfig with properties:  
  
    ParityCheckMatrix: [162x648 logical]  
    Algorithm: 'bp'  
  
  Read-only properties:  
    BlockLength: 648  
    NumInformationBits: 486  
    NumParityCheckBits: 162  
    CodeRate: 0.7500
```

Transmit an LDPC-encoded, QPSK-modulated bit stream through an AWGN channel. Demodulate the signal, decode the received codewords, and then count bit errors. Use nested `for` loops to process multiple SNR settings and frames with and without LDPC forward error correction (FEC) coding of the transmitted data.

```
M = 4;  
maxnumiter = 10;  
snr = [20 6 3];  
numframes = 10;  
qpskmod = comm.PSKModulator(M, 'BitInput', true);  
qpskmod2 = comm.PSKModulator(M);  
  
ber = comm.ErrorRate;  
ber2 = comm.ErrorRate;  
  
for ii = 1:length(snr)  
  qpskdemod = comm.PSKDemodulator(M, 'BitOutput', true, ...  
    'DecisionMethod', 'Approximate log-likelihood ratio', ...  
    'Variance', 1/10^(snr(ii)/10));  
  qpskdemod2 = comm.PSKDemodulator(M);  
  for counter = 1:numframes  
    data = randi([0 1], cfgLDPCEnc.NumInformationBits, 1, 'int8');  
    % Transmit and receive with LDPC coding  
    encodedData = ldpcEncode(data, cfgLDPCEnc);  
    modSignal = qpskmod(encodedData);  
    receivedSignal = awgn(modSignal, snr(ii));  
    demodSignal = qpskdemod(receivedSignal);
```

```

    receivedBits = ldpcDecode(demodSignal, cfgLDPCDec, maxnumiter);
    errStats = ber(data, receivedBits);
    % Transmit and receive with no LDPC coding
    noCoding = qpskmod2(data);
    rxNoCoding = awgn(noCoding, snr(ii));
    rxBitsNoCoding = qpskdemod2(rxNoCoding);
    errStatsNoCoding = ber2(data, int8(rxBitsNoCoding));
end
fprintf(['SNR = %2d\n   Coded: Error rate = %1.2f, ' ...
        'Number of errors = %d\n'], ...
        snr(ii), errStats(1), errStats(2))
fprintf(['Noncoded: Error rate = %1.2f, ' ...
        'Number of errors = %d\n'], ...
        errStatsNoCoding(1), errStatsNoCoding(2))
end

SNR = 20
    Coded: Error rate = 0.00, Number of errors = 0
    Noncoded: Error rate = 0.00, Number of errors = 0

    Coded: Error rate = 0.00, Number of errors = 0
    Noncoded: Error rate = 0.02, Number of errors = 196

SNR = 3
    Coded: Error rate = 0.02, Number of errors = 353
    Noncoded: Error rate = 0.07, Number of errors = 976

```

Algorithms

LDPC decoding using one of these message-passing algorithms.

Belief Propagation Decoding

The implementation of the belief propagation algorithm is based on the decoding algorithm presented by Gallager [2].

For transmitted LDPC-encoded codeword $c = c_0, c_1, \dots, c_{n-1}$, the input to the LDPC decoder is the log-likelihood ratio (LLR) value $L(c_i) = \log \left(\frac{\Pr(c_i = 0 | \text{channel output for } c_i)}{\Pr(c_i = 1 | \text{channel output for } c_i)} \right)$.

In each iteration, the key components of the algorithm are updated based on these equations:

$$L(r_{ji}) = 2 \operatorname{atanh} \left(\prod_{i' \in \mathcal{V}_{ji}} \tanh \left(\frac{1}{2} L(q_{i'j}) \right) \right),$$

$L(q_{ij}) = L(c_i) + \sum_{j \in C_i \setminus j} L(r_{ji})$, initialized as $L(q_{ij}) = L(c_i)$ before the first iteration, and

$$L(Q_i) = L(c_i) + \sum_{j \in C_i} L(r_{ji}).$$

At the end of each iteration, $L(Q_i)$ contains the updated estimate of the LLR value for transmitted bit c_i . The value $L(Q_i)$ is the soft-decision output for c_i . If $L(Q_i) < 0$, the hard-decision output for c_i is 1. Otherwise, the hard-decision output for c_i is 0.

If decoding is configured to stop when all of the parity checks are satisfied, the algorithm verifies the parity-check equation ($Hc' = 0$) at the end of each iteration. When all of the parity checks are satisfied, or if the maximum number of iterations is reached, decoding stops.

Index sets $C_i \setminus j$ and $V_j \setminus i$ are based on the parity-check matrix (PCM). Index sets C_i and V_j correspond to all nonzero elements in column i and row j of the PCM, respectively.

This figure shows the computation of these index sets in a given PCM for $i = 5$ and $j = 3$.

To avoid infinite numbers in the algorithm equations, $\text{atanh}(1)$ and $\text{atanh}(-1)$ are set to 19.07 and -19.07 , respectively. Due to finite precision, MATLAB returns 1 for $\tanh(19.07)$ and -1 for $\tanh(-19.07)$.

Layered Belief Propagation Decoding

The implementation of the layered belief propagation algorithm is based on the decoding algorithm presented in Hocevar [3], Section II.A. The decoding loop iterates over subsets of rows (layers) of the PCM. For each row, m , in a layer and each bit index, j , the implementation updates the key components of the algorithm based on these equations:

(1) $L(q_{mj}) = L(q_j) - R_{mj}$,

(2) $A_{mj} = \sum_{\substack{n \in N(m) \\ n \neq j}} \psi(L(q_{mn}))$,

$$(3) s_{mj} = \prod_{\substack{n \in N(m) \\ n \neq j}} \text{sign}(L(q_{mn})),$$

$$(4) R_{mj} = -s_{mj}\psi(A_{mj}), \text{ and}$$

$$(5) L(q_j) = L(q_{mj}) + R_{mj}.$$

For each layer, the decoding equation (5) works on the combined input obtained from the current LLR inputs $L(q_{mj})$ and the previous layer updates R_{mj} .

Because only a subset of the nodes is updated in a layer, the layered belief propagation algorithm is faster compared to the belief propagation algorithm. To achieve the same error rate as attained with belief propagation decoding, use half the number of decoding iterations when you use the layered belief propagation algorithm.

Normalized Min-Sum Decoding

The implementation of the normalized min-sum decoding algorithm follows the layered belief propagation algorithm with equation (2) replaced by

$$A_{mj} = \min_{\substack{n \in N(m) \\ n \neq j}} (|L(q_{mn})| \cdot \alpha),$$

where α is in the range (0, 1] and is the scaling factor specified by the `MinSumScalingFactor` input argument to the `ldpcDecode` function. This equation is an adaptation of equation (4) presented in Chen [4].

Offset Min-Sum Decoding

The implementation of the offset min-sum decoding algorithm follows the layered belief propagation algorithm with equation (2) replaced by

$$A_{mj} = \max\left(\min_{\substack{n \in N(m) \\ n \neq j}} (|L(q_{mn})| - \beta), 0\right),$$

where $\beta \geq 0$ and is the offset specified by the `MinSumOffset` input argument to the `ldpcDecode` function. This equation is an adaptation of equation (5) presented in Chen [4].

Objects

`ldpcEncoderConfig`

Introduced in R2021b

LdpcEncoderConfig

Create LDPC encoder configuration

Description

The `LdpcEncoderConfig` object is a configuration object for the `LdpcEncode` function. The object specifies the low-density parity-check (LDPC) matrix and read-only properties to provide information about the configured matrix.

Creation

Syntax

```
encoderCfg = LdpcEncoderConfig
encoderCfg = LdpcEncoderConfig(H)
encoderCfg = LdpcEncoderConfig(decoderCfg)
```

Description

`encoderCfg = LdpcEncoderConfig` creates an LDPC encoder configuration object that specifies a rate 5/6 LDPC code from the WLAN 802.11 standard [1].

`encoderCfg = LdpcEncoderConfig(H)` configures the output object setting the `ParityCheckMatrix` property to `H`.

`encoderCfg = LdpcEncoderConfig(decoderCfg)` sets properties based on the input `LdpcDecoderConfig` configuration object, `decoderCfg`.

Validation of the object settings is performed when the `LdpcEncode` function is called with the object as an input.

Properties

ParityCheckMatrix — Parity-check matrix

sparse logical 108-by-648 matrix (default) | sparse logical $(N - K)$ -by- N matrix

Parity-check matrix, specified as a sparse logical $(N - K)$ -by- N matrix, where $N > K > 0$. The last $N - K$ rows of the parity-check matrix must be invertible in a Galois field of order 2. N is the LDPC codeword block length. K is the number of information bits in the LDPC codeword. The default is the parity-check matrix of rate 5/6 LDPC code with a block length of 648 as specified in the WLAN 802.11 standard [1]. Specifically, the default is the sparse logical 108-by-648 matrix `H` output by the `LdpcQuasiCyclicMatrix` function in this code.

```
P = [
 17 13  8 21  9  3 18 12 10  0  4 15 19  2  5 10 26 19 13 13  1  0 -1 -1
  3 12 11 14 11 25  5 18  0  9  2 26 26 10 24  7 14 20  4  2 -1  0  0 -1
 22 16  4  3 10 21 12  5 21 14 19  5 -1  8  5 18 11  5  5 15  0 -1  0  0
  7  7 14 14  4 16 16 24 24 10  1  7 15  6 10 26  8 18 21 14  1 -1 -1  0
```

```
];  
blockSize = 27;  
H = ldpcQuasiCyclicMatrix(blockSize,P);
```

Data Types: logical

BlockLength — Block length

648 (default) | positive scalar

This property is read-only.

Block length of the LDPC codeword (N), specified as a positive scalar. N equals the number of columns in the parity-check matrix.

Data Types: double

NumInformationBits — Number of information bits

540 (default) | positive scalar

This property is read-only.

Number of information bits in the LDPC codeword (K), specified as a positive scalar. K equals the number of columns of the parity-check matrix minus the number of rows of the parity-check matrix.

Data Types: double

NumParityCheckBits — Number of parity-check bits

108 (default) | positive scalar

This property is read-only.

Number of parity-check bits in the LDPC codeword ($N - K$), specified as a positive scalar. $N - K$ equals the number of rows in the parity-check matrix.

Data Types: double

CodeRate — Code rate of LDPC code

5/6 (default) | positive scalar

This property is read-only.

Code rate of the LDPC code, specified as a positive scalar that is equal to `NumInformationBits/BlockLength`.

Data Types: double

Examples

Encode Information Bits Using Rate 3/4 LDPC Code

Initialize parameters for the prototype matrix and block size to configure a rate 3/4 LDPC code specified in IEEE® 802.11. Create the parity-check matrix by using the `ldpcQuasiCyclicMatrix` function.

```
P = [16 17 22 24 9 3 14 -1 4 2 7 -1 26 -1 2 -1 21 -1 1 0 -1 -1 -1 -1  
25 12 12 3 3 26 6 21 -1 15 22 -1 15 -1 4 -1 -1 16 -1 0 0 -1 -1 -1
```

```

    25 18 26 16 22 23 9 -1 0 -1 4 -1 4 -1 8 23 11 -1 -1 -1 0 0 -1 -1
    9 7 0 1 17 -1 -1 7 3 -1 3 23 -1 16 -1 -1 21 -1 0 -1 -1 0 0 -1
    24 5 26 7 1 -1 -1 15 24 15 -1 8 -1 13 -1 13 -1 11 -1 -1 -1 -1 0 0
    2 2 19 14 24 1 15 19 -1 21 -1 2 -1 24 -1 3 -1 2 1 -1 -1 -1 -1 0
];
blockSize = 27;
pcmatrix = ldpcQuasiCyclicMatrix(blockSize,P);

```

Create an LDPC encoder configuration object, displaying its properties. Generate random information bits by using the `NumInformationBits` property of the configuration object to specify the number of information bits in an LDPC codeword. Encode the information bits by the LDPC code specified by the LDPC encoder configuration object.

```
cfgLDPCEnc = ldpcEncoderConfig(pcmatrix)
```

```

cfgLDPCEnc =
  ldpcEncoderConfig with properties:

    ParityCheckMatrix: [162x648 logical]

  Read-only properties:
    BlockLength: 648
    NumInformationBits: 486
    NumParityCheckBits: 162
    CodeRate: 0.7500

```

```

infoBits = rand(cfgLDPCEnc.NumInformationBits,1) < 0.5;
codeword = ldpcEncode(infoBits, cfgLDPCEnc);

```

comm.LTEMIMOChannel

Package: comm

(To be removed) Filter input signal through LTE MIMO multipath fading channel

Note `comm.LTEMIMOChannel` will be removed in a future release. Use `comm.MIMOChannel` instead.

Description

The `comm.LTEMIMOChannel` System object filters an input signal through an LTE multiple-input multiple-output (MIMO) multipath fading channel.

A specialization of the `comm.MIMOChannel` System object, the `comm.LTEMIMOChannel` System objects offers pre-set configurations for use with LTE link level simulations. In addition to the `comm.MIMOChannel` System object, the `comm.LTEMIMOChannel` System object also corrects the correlation matrix to be positive semi-definite, after rounding to 4-digit precision. This System object models Rayleigh fading for each of its links.

To filter an input signal using an LTE MIMO multipath fading channel:

- 1 Define and set up your LTE MIMO multipath fading channel object. See “Construction” on page 3-824.
- 2 Call `step` to filter the input signal using an LTE MIMO multipath fading channel according to the properties of `comm.LTEMIMOChannel`. The behavior of `step` is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj, x)` and `y = obj(x)` perform equivalent operations.

Construction

`H = comm.LTEMIMOChannel` creates a 3GPP Long Term Evolution (LTE) Release 10 specified multiple-input multiple-output (MIMO) multipath fading channel System object, `H`. This object filters a real or complex input signal through the multipath LTE MIMO channel to obtain the channel impaired signal.

`H = comm.LTEMIMOChannel(Name, Value)` creates an LTE MIMO multipath fading channel object, `H`, with the specified property `Name` set to the specified `Value`. You can specify additional name-value pair arguments in any order as `(Name1, Value1, ..., NameN, ValueN)`.

Properties

SampleRate

Input signal sample rate (Hertz)

Specify the sample rate of the input signal in hertz as a double-precision, real, positive scalar. The default value of this property is 30.72 MHz, as defined in the LTE specification.

Profile

Channel propagation profile

Specify the propagation conditions of the LTE multipath fading channel as one of EPA 5Hz | EVA 5Hz | EVA 70Hz | ETU 70Hz | ETU 300Hz, which are supported in the LTE specification Release 10. The default value of this property is EPA 5Hz.

This property defines the delay profile of the channel to be one of EPA, EVA, and ETU. This property also defines the maximum Doppler shift of the channel to be 5 Hz, 70 Hz, or 300 Hz. The Doppler spectrum always has a Jakes shape in the LTE specification. The EPA profile has seven paths. The EVA and ETU profiles have nine paths.

The following tables list the delay and relative power per path associated with each profile.

Extended Pedestrian A Model (EPA)

Excess tap delay [ns]	Relative power [db]
0	0.0
30	-1.0
70	-2.0
90	-3.0
110	-8.0
190	-17.2
410	-20.8

Extended Vehicular A Model (EVA)

Excess tap delay [ns]	Relative power [db]
0	0.0
30	-1.5
150	-1.4
310	-3.6
370	-0.6
710	-9.1
1090	-7.0
1730	-12.0
2510	-16.9

Extended Typical Urban Model (ETU)

Excess tap delay [ns]	Relative power [db]
0	-1.0

Excess tap delay [ns]	Relative power [db]
50	-1.0
120	-1.0
200	0.0
230	0.0
500	0.0
1600	-3.0
2300	-5.0
5000	-7.0

AntennaConfiguration

Antenna configuration

Specify the antenna configuration of the LTE MIMO channel as one of `1x2` | `2x2` | `4x2` | `4x4`. These configurations are supported in the LTE specification Release 10. The default value of this property is `2x2`.

The property value is in the format of N_t -by- N_r . N_t represents the number of transmit antennas and N_r represents the number of receive antennas.

CorrelationLevel

Spatial correlation strength

Specify the spatial correlation strength of the LTE MIMO channel as one of `Low` | `Medium` | `High`. The default value of this property is `Low`. When you set this property to `Low`, the MIMO channel is spatially uncorrelated.

The transmit and receive spatial correlation matrices are defined from this property according to the LTE specification Release 10. See the Algorithms section for more information.

AntennaSelection

Antenna selection

Specify the antenna selection scheme as one of `Off` | `Tx` | `Rx` | `Tx and Rx`, where `Tx` represents transmit antennas and `Rx` represents receive antennas. When you select `Tx` and/or `Rx`, additional input(s) are required to specify which antennas are selected for signal transmission. The default value of this property is `Off`.

RandomStream

Source of random number stream

Specify the source of random number stream as one of `Global stream` | `mt19937ar with seed`. The default value of this property is `Global stream`. When you set this property to `Global stream`, the current global random number stream is used for normally distributed random number generation. In this case, the `reset` method only resets the filters. If you set `RandomStream` to `mt19937ar with seed`, the object uses the `mt19937ar` algorithm for normally distributed random number generation. In this case, the `reset` method resets the filters and reinitializes the random number stream to the value of the `Seed` property.

Seed

Initial seed of mt19937ar random number stream

Specify the initial seed of an mt19937ar random number generator algorithm as a double-precision, real, nonnegative integer scalar. The default value of this property is 73. This property applies when you set the RandomStream property to mt19937ar with seed. The Seed reinitializes the mt19937ar random number stream in the reset method.

NormalizePathGains

Normalize path gains (logical)

Set this property to true to normalize the fading processes so that the total power of the path gains, averaged over time, is 0 dB. The default value of this property is true. When you set this property to false, there is no normalization for path gains.

NormalizeChannelOutputs

Normalize channel outputs (logical)

Set this property to true to normalize the channel outputs by the number of receive antennas. The default value of this property is true. When you set this property to false, there is no normalization for channel outputs.

PathGainsOutputPort

Enable path gain output (logical)

Set this property to true to output the channel path gains of the underlying fading process. The default value of this property is false.

Methods

reset (To be removed) Reset states of the LTEMIMOChannel object

step (To be removed) Filter input signal through LTE MIMO multipath fading channel

Common to All System Objects	
release	Allow System object property value changes

Examples

Configure MIMO Channel Object Using LTE MIMO Channel Object

Configure an equivalent MIMOChannel System Object using the LTEMIMOChannel System Object. Then, verify that the channel output and the path gain output from the two objects are the same.

Create a PSK Modulator System object™ to modulate randomly generated data.

```
pskModulator = comm.PSKModulator;
modData = pskModulator(randi([0 pskModulator.ModulationOrder-1],2e3,1));
```

Split modulated data into two spatial streams.

```
channelInput = reshape(modData,[2 1e3]).';
```

Create an LTEMIMOChannel System object with a 2-by-2 antenna configuration and a medium correlation level.

```
lteChan = comm.LTEMIMOChannel(...
    'Profile',          'EVA 5Hz',...
    'AntennaConfiguration', '2x2',...
    'CorrelationLevel',  'Medium',...
    'AntennaSelection',  'Off',...
    'RandomStream',     'mt19937ar with seed',...
    'Seed',             99,...
    'PathGainsOutputPort', true);
```

Warning: COMM.LTEMIMOCHANNEL will be removed in a future release. Use COMM.MIMOCHANNEL or LTEFAD.

Filter the modulated data using the LTEMIMOChannel System object, lteChan.

```
[LTEChanOut,LTEPathGains] = lteChan(channelInput);
```

Create an equivalent MIMOChannel System object, mimoChannel, using the properties of the LTEMIMOChannel System object, lteChan.

The KFactor, DirectPathDopplerShift and DirectPathInitialPhase properties only exist for the MIMOChannel System object. All other MIMOChannel System object properties also exist for the LTEMIMOChannel System object; however, some properties are hidden and read-only.

```
mimoChannel = comm.MIMOChannel( ...
    'SampleRate',lteChan.SampleRate, ...
    'PathDelays',lteChan.PathDelays, ...
    'AveragePathGains',lteChan.AveragePathGains, ...
    'NormalizePathGains',lteChan.NormalizePathGains, ...
    'FadingDistribution',lteChan.FadingDistribution, ...
    'MaximumDopplerShift',lteChan.MaximumDopplerShift, ...
    'DopplerSpectrum',lteChan.DopplerSpectrum, ...
    'SpatialCorrelationSpecification', ...
        lteChan.SpatialCorrelationSpecification, ...
    'SpatialCorrelationMatrix',lteChan.SpatialCorrelationMatrix, ...
    'AntennaSelection',lteChan.AntennaSelection, ...
    'NormalizeChannelOutputs',lteChan.NormalizeChannelOutputs, ...
    'RandomStream',lteChan.RandomStream, ...
    'Seed',lteChan.Seed, ...
    'PathGainsOutputPort',lteChan.PathGainsOutputPort);
```

Filter the modulated data using the equivalent mimoChannel object.

```
[MIMOChanOut, MIMOPathGains] = mimoChannel(channelInput);
```

Verify that the channel output and the path gain output from the two objects are the same.

```
sameChOutput = isequal(LTEChanOut,MIMOChanOut)
```

```
sameChOutput = logical
    1
```

```
samePathGains = isequal(LTEPathGains,MIMOPathGains)
```

```
samePathGains = logical
1
```

You can repeat the preceding process with `AntennaConfiguration` set to 4x2 or 4x4 and `CorrelationLevel` set to Medium or High for `lteChan`.

Algorithms

This System object is a specialized implementation of the `comm.MIMOChannel` System object. For additional algorithm information, see the `comm.MIMOChannel` System object help page.

Spatial Correlation Matrices

The following table defines the transmitter eNodeB correlation matrix.

	One Antenna	Two Antennas	Four Antennas
eNodeB Correlation	$R_{eNB} = 1$	$R_{eNB} = \begin{pmatrix} 1 & \alpha \\ \alpha^* & 1 \end{pmatrix}$	$R_{eNB} = \begin{pmatrix} 1 & \alpha^{1/9} & \alpha^{4/9} & \alpha \\ \alpha^{1/9*} & 1 & \alpha^{1/9} & \alpha^{4/9} \\ \alpha^{4/9*} & \alpha^{1/9*} & 1 & \alpha^{1/9} \\ \alpha^* & \alpha^{4/9*} & \alpha^{1/9*} & 1 \end{pmatrix}$

The following table defines the receiver UE correlation matrix.

	One Antenna	Two Antennas	Four Antennas
UE Correlation	$R_{UE} = 1$	$R_{UE} = \begin{pmatrix} 1 & \beta \\ \beta^* & 1 \end{pmatrix}$	$R_{UE} =$ $\begin{pmatrix} 1 & \beta^{1/9} & \beta^{4/9} & \beta \\ \beta^{1/9*} & 1 & \beta^{1/9} & \beta^{4/9} \\ \beta^{4/9*} & \beta^{1/9*} & 1 & \beta^{1/9} \\ \beta^* & \beta^{4/9*} & \beta^{1/9*} & 1 \end{pmatrix}$

The following table describes the R_{spat} channel spatial correlation matrix between the transmitter and receiver antennas.

Tx-by-Rx Configuration	Correlation Matrix
1-by-2	$R_{\text{spat}} = R_{UE} = \begin{bmatrix} 1 & \beta \\ \beta^* & 1 \end{bmatrix}$
2-by-2	$R_{\text{spat}} = R_{eNB} \otimes R_{UE} = \begin{bmatrix} 1 & \alpha \\ \alpha^* & 1 \end{bmatrix} \otimes \begin{bmatrix} 1 & \beta \\ \beta^* & 1 \end{bmatrix}$ $= \begin{bmatrix} 1 & \beta & \alpha & \alpha\beta \\ \beta^* & 1 & \alpha\beta^* & \alpha \\ \alpha^* & \alpha^*\beta & 1 & \beta \\ \alpha^*\beta^* & \alpha^* & \beta^* & 1 \end{bmatrix}$
4-by-2	$R_{\text{spat}} = R_{eNB} \otimes R_{UE} = \begin{bmatrix} 1 & \alpha^{1/9} & \alpha^{4/9} & \alpha \\ \alpha^{1/9*} & 1 & \alpha^{1/9} & \alpha^{4/9} \\ \alpha^{4/9*} & \alpha^{1/9*} & 1 & \alpha^{1/9} \\ \alpha^* & \alpha^{4/9*} & \alpha^{1/9*} & 1 \end{bmatrix}$ $\otimes \begin{bmatrix} 1 & \beta \\ \beta^* & 1 \end{bmatrix}$

Tx-by-Rx Configuration	Correlation Matrix
4-by-4	$R_{spat} = R_{eNB} \otimes R_{UE} = \begin{bmatrix} 1 & \alpha^{1/9} & \alpha^{4/9} & \alpha \\ \alpha^{1/9*} & 1 & \alpha^{1/9} & \alpha^{4/9} \\ \alpha^{4/9*} & \alpha^{1/9*} & 1 & \alpha^{1/9} \\ \alpha^* & \alpha^{4/9*} & \alpha^{1/9*} & 1 \end{bmatrix}$ $\otimes \begin{bmatrix} 1 & \beta^{1/9} & \beta^{4/9} & \beta \\ \beta^{1/9*} & 1 & \beta^{1/9} & \beta^{4/9} \\ \beta^{4/9*} & \beta^{1/9*} & 1 & \beta^{1/9} \\ \beta^* & \beta^{4/9*} & \beta^{1/9*} & 1 \end{bmatrix}$

Spatial Correlation Correction

Low Correlation		Medium Correlation		High Correlation	
α	β	α	β	α	β
0	0	0.3	0.9	0.9	0.9

To insure the correlation matrix is positive semi-definite after round-off to 4 digit precision, this System object uses the following equation:

$$R_{high} = [R_{spatial} + aI_n]/(1 + a)$$

Where

α represents the scaling factor such that the smallest value is used to obtain a positive semi-definite result.

For the 4-by-2 high correlation case, $\alpha=0.00010$.

For the 4-by-4 high correlation case, $\alpha=0.00012$.

The object uses the same method to adjust the 4-by-4 medium correlation matrix to insure the correlation matrix is positive semi-definite after rounding to 4 digit precision with $\alpha = 0.00012$.

`comm.MIMOChannel`

Introduced in R2012a

reset

System object: `comm.LTEMIMOChannel`

Package: `comm`

(To be removed) Reset states of the `LTEMIMOChannel` object

Note `comm.LTEMIMOChannel` will be removed in a future release. Use `comm.MIMOChannel` instead.

Syntax

`reset(H)`

Description

`reset(H)` resets the states of the `LTEMIMOChannel` object, `H`.

If you set the `RandomStream` property of `H` to `Global` stream, the `reset` method only resets the filters. If you set `RandomStream` to `mt19937ar` with `seed`, the `reset` method not only resets the filters but also reinitializes the random number stream to the value of the `Seed` property.

step

System object: `comm.LTEMIMOChannel`

Package: `comm`

(To be removed) Filter input signal through LTE MIMO multipath fading channel

Note `comm.LTEMIMOChannel` will be removed in a future release. Use `comm.MIMOChannel` instead.

Syntax

`Y = step(H,X)`
`[Y,PATHGAINS] = step(H,X)`

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(H,X)` filters input signal `X` through an LTE MIMO multipath fading channel and returns the result in `Y`. The input `X` can be a double- or single-precision data type scalar, vector, or 2-D matrix with real or complex values. `X` is of size N_s -by- N_t . N_s represents the number of samples and N_t represents the number of transmit antennas that must match the `AntennaConfiguration` property setting of `H`. `Y` is the output signal of size N_s -by- N_r . N_r represents the number of receive antennas that is specified by the `AntennaConfiguration` property of `H`. `Y` contains complex values with same precision as input signal.

`[Y,PATHGAINS] = step(H,X)` returns the LTE MIMO channel path gains of the underlying fading process in `PATHGAINS`. This applies when you set the `PathGainsOutputPort` property to `true`. `PATHGAINS` is of size N_s -by- N_p -by- N_t -by- N_r . N_p represents the number of discrete paths of the channel implicitly defined by the `Profile` property of `H`. `PATHGAINS` contains complex values with same precision as input signal.

Note `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications. For more information on changing property values, see “System Design in MATLAB Using System Objects”.

comm.MatrixDeinterleaver

Package: comm

(Removed) Deinterleave input symbols using permutation matrix

Compatibility

comm.MatrixDeinterleaver has been removed. Use `matdeintrlv` instead. For more information, see “Compatibility Considerations” on page 3-836.

Description

The `MatrixDeinterleaver` object performs block deinterleaving by filling a matrix with the input symbols column by column and then sending the matrix contents to the output port row by row. The number of rows and number of columns properties set the dimensions of the matrix that the object uses internally for computations.

To deinterleave input symbols using a permutation vector:

- 1 Define and set up your matrix deinterleaver object. See “Construction” on page 3-835.
- 2 Call `step` to deinterleave the input signal according to the properties of `comm.MatrixDeinterleaver`. The behavior of `step` is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`H = comm.MatrixDeinterleaver` creates a matrix deinterleaver System object, `H`. This object restores the original ordering of a sequence that was interleaved using the matrix interleaver object.

`H = comm.MatrixDeinterleaver(Name,Value)` creates a matrix deinterleaver object, `H`, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as `(Name1,Value1,...,NameN,ValueN)`.

`H = comm.MatrixDeinterleaver(N,M)` creates a matrix deinterleaver object, `H`. This object has the `NumRows` property set to `N`, the `NumColumns` property set to `M`.

Properties

NumRows

Number of rows of permutation matrix

Specify the number of permutation matrix rows as a scalar, positive integer. The default is 3.

NumColumns

Number of columns of permutation matrix

Specify the number of permutation matrix columns as a scalar, positive integer. The default is 4.

Methods

step (Removed) Deinterleave input symbols using permutation matrix

Common to All System Objects	
release	Allow System object property value changes

Examples

Matrix Interleaving and Deinterleaving

Create matrix interleaver and deinterleaver objects. Generate random data, interleave, and then deinterleave the data. Confirm the original and deinterleaved data are identical.

```
interleaver = comm.MatrixInterleaver('NumRows',2,'NumColumns',5);  
deinterleaver = comm.MatrixDeinterleaver('NumRows',2,'NumColumns',5);  
data = randi(7,10,1);intData = interleaver(data);  
deIntData = deinterleaver(intData);  
isequal(data,deIntData)
```

```
ans = 1
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the Matrix Deinterleaver block reference page. The object properties correspond to the block parameters.

Compatibility Considerations

comm.MatrixDeinterleaver has been removed

Errors starting in R2021b

comm.MatrixDeinterleaver has been removed. Use `matdeintrlv` instead.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

See “System Objects in MATLAB Code Generation” (MATLAB Coder).

Functions

`intrlv` | `deintrlv` | `matintrlv` | `matdeintrlv`

Introduced in R2012a

step

System object: `comm.MatrixDeinterleaver`

Package: `comm`

(Removed) Deinterleave input symbols using permutation matrix

Compatibility

`step` has been removed. Use `matdeintrlv` instead.

Syntax

`Y = step(H,X)`

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(H,X)` restores the original ordering of the sequence, `X`, that was interleaved using a block interleaver. The object fills a permutation matrix with the input symbols column by column and outputs the matrix contents row by row in the output, `Y`. The input `X` must be a column vector of length equal to `NumRows × NumColumns`. The data type for `X` can be numeric, logical, or fixed-point (fi objects). `Y` has the same data type as `X`.

Note `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications. For more information on changing property values, see “System Design in MATLAB Using System Objects”.

comm.MatrixInterleaver

Package: comm

(Removed) Permute input symbols using permutation matrix

Compatibility

comm.MatrixInterleaver has been removed. Use `matintrlv` instead. For more information, see “Compatibility Considerations” on page 3-840.

Description

The `MatrixInterleaver` object performs block interleaving by filling a matrix with the input symbols row by row and then outputs the matrix contents column-by-column.

To perform block interleaving using a permutation matrix:

- 1 Define and set up your matrix interleaver object. See “Construction” on page 3-839.
- 2 Call `step` to interleave the input symbols according to the properties of `comm.MatrixInterleaver`. The behavior of `step` is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`H = comm.MatrixInterleaver` creates a matrix interleaver System object, `H`. This object permutes the input by filling a permutation matrix with the input symbols row by row. The object then outputs the matrix contents column by column.

`H = comm.MatrixInterleaver(Name,Value)` creates a matrix interleaver object, `H`, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as `(Name1,Value1,...,NameN,ValueN)`.

`H = comm.MatrixInterleaver(N,M)` creates a matrix interleaver object, `H`. This object has the `NumRows` property set to `N`, the `NumColumns` property set to `M`.

Properties

NumRows

Number of rows of permutation matrix

Specify the number of permutation matrix rows as a scalar, positive integer. The default is 3.

NumColumns

Number of columns of permutation matrix

Specify the number of permutation matrix columns as a scalar, positive integer. The default is 4.

Methods

step (Removed) Permute input symbols using permutation matrix

Syntax

`Y = step(H,X)`

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(H,X)` permutes input sequence, `X`, and returns interleaved sequence, `Y`. The object fills a permutation matrix with the input symbols row by row and outputs the matrix contents column by column. The input `X` must be a column vector of length `NumRows × NumColumns` and the data type can be numeric, logical, or fixed-point (fi objects). `Y` has the same data type as `X`.

Note `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications. For more information on changing property values, see “System Design in MATLAB Using System Objects”.

comm.MatrixHelicalScanDeinterleaver

Package: comm

(Removed) Deinterleave input symbols by filling a matrix along diagonals

Compatibility

comm.MatrixHelicalScanDeinterleaver has been removed. Use `helscandeintrlv` instead. For more information, see “Compatibility Considerations” on page 3-845.

Description

The `MatrixHelicalScanDeinterleaver` object performs block deinterleaving by filling a matrix with the input symbols helically and then outputs the matrix contents row by row. The number of rows and number of columns properties represent the dimensions of the matrix that the object uses internally for computations.

To deinterleave the input symbols by filling a matrix with the input symbols helically and then outputting the matrix contents row-by-row:

- 1 Define and set up your matrix helical scan deinterleaver object. See “Construction” on page 3-843.
- 2 Call `step` to deinterleave the input signal according to the properties of `comm.MatrixHelicalScanDeinterleaver`. The behavior of `step` is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`H = comm.MatrixHelicalScanDeinterleaver` creates a matrix helical scan deinterleaver object, `H`. This object restores the original ordering of a sequence that was interleaved using the matrix helical scan interleaver System object.

`H = comm.MatrixHelicalScanDeinterleaver(Name,Value)` creates a matrix helical scan deinterleaver object, `H`, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as `(Name1,Value1,...,NameN,ValueN)`.

Properties

NumRows

Number of rows of permutation matrix

Specify the number of rows in the permutation matrix as a scalar, positive integer. The default is 64.

NumColumns

Number of columns of permutation matrix

Specify the number of columns in the permutation matrix as a scalar, positive integer. The default is 64.

StepSize

Slope of diagonals

Specify slope as a scalar integer between 0 and the value you specify in the NumRows on page 3-0 property. The default is 1. The slope value indicates the amount by which the row index increases as the column index increases by 1. When you set the value of this property to 0, the object does not interleave and the output matches the input.

Methods

step (Removed) Deinterleave input symbols by filling a matrix along diagonals

Common to All System Objects	
release	Allow System object property value changes

Examples

Matrix Helical Scan Interleaving and Deinterleaving

Create matrix helical scan interleaver and deinterleaver objects. Generate random symbols. Pass the data through the interleaver, and then pass that data through the deinterleaver. Display the original sequence, interleaved sequence and restored sequence. Confirm that the original and deinterleaved sequences are identical.

```
interleaver = ...
    comm.MatrixHelicalScanInterleaver('NumRows',4,'NumColumns',4);
deinterleaver = ...
    comm.MatrixHelicalScanDeinterleaver('NumRows',4,'NumColumns',4);
data = randi(7,16,1);
intData = interleaver(data);
deIntData = deinterleaver(intData);
[data intData deIntData]
isequal(data,deIntData)

ans = 1
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the Matrix Helical Scan Deinterleaver block reference page. The object properties correspond to the block parameters.

`Y = step(H,X)`

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(H,X)` restores the original ordering of the sequence, `X`. The object fills a permutation matrix with the input symbols in a helical fashion and output the contents row by row, and returns `Y`. The input `X` must be a `NumRows × NumColumns` long column vector and the data type can be numeric, logical, or fixed-point (fi objects). `Y` has the same data type as `X`.

Note `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications. For more information on changing property values, see “System Design in MATLAB Using System Objects”.

comm.MatrixHelicalScanInterleaver

Package: comm

(Removed) Permute input symbols by selecting matrix elements along diagonals

Compatibility

comm.MatrixHelicalScanInterleaver has been removed. Use `helscanintrlv` instead. For more information, see “Compatibility Considerations” on page 3-849.

Description

The `MatrixHelicalScanInterleaver` object performs block interleaving by filling a matrix with the input symbols row by row and then outputs the matrix contents helically. The number of rows and number of columns properties are the dimensions of the matrix that the object uses internally for computations.

To interleave the input signal by filling a matrix row-by-row with the input symbols and then outputting the matrix contents helically:

- 1 Define and set up your matrix helical scan interleaver object. See “Construction” on page 3-847.
- 2 Call `step` to interleave the input signal according to the properties of `comm.MatrixHelicalScanInterleaver`. The behavior of `step` is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj, x)` and `y = obj(x)` perform equivalent operations.

Construction

`H = comm.MatrixHelicalScanInterleaver` creates a matrix helical scan interleaver object, `H`. This object permutes the input by filling a permutation matrix with the input symbols row by row and then outputs the matrix contents helically.

`H = comm.MatrixHelicalScanInterleaver(Name, Value)` creates a matrix helical scan interleaver object, `H`, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as `(Name1, Value1, ..., NameN, ValueN)`.

Properties

NumRows

Number of rows of permutation matrix

Specify the number of rows in the permutation matrix as a scalar, positive integer. The default is 64.

NumColumns

Number of columns of permutation matrix

Specify the number of columns in the permutation matrix as a scalar, positive integer. The default is 64.

StepSize

Slope of diagonals

Specify slope as a scalar integer between 0 and the value you specify in the NumRows on page 3-0 property. The slope value represents the amount by which the row index increases as the column index increases by 1. When you set the value of this property to 0, the object does not interleave and the output matches the input. The default is 1.

comm.MemorylessNonlinearity

Package: comm

Apply memoryless nonlinearity to complex baseband signal

Description

The `comm.MemorylessNonlinearity` System object applies memoryless nonlinear impairments to a baseband signal. Use this System object to model memoryless nonlinear impairments caused by signal amplification in a radio frequency (RF) transmitter or receiver. For more information, see “Memoryless Nonlinear Impairments” on page 3-867.

To apply memoryless nonlinear impairments to a complex baseband signal:

- 1 Create the `comm.MemorylessNonlinearity` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

Creation

Syntax

```
mnl = comm.MemorylessNonlinearity
mnl = comm.MemorylessNonlinearity(Name,Value)
```

Description

`mnl = comm.MemorylessNonlinearity` creates a memoryless nonlinearity System object that models RF nonlinear impairments.

`mnl = comm.MemorylessNonlinearity(Name,Value)` specifies properties using one or more name-value pair arguments. Enclose each property name in quotes. For example, `'Method', 'Saleh model'` sets the modeling method to the Saleh method.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see [System Design in MATLAB Using System Objects](#).

Method — Nonlinearity modeling method

```
'Cubic polynomial' (default) | 'Hyperbolic tangent' | 'Saleh model' | 'Ghorbani model' | 'Modified Rapp model' | 'Lookup table'
```

Nonlinearity modeling method, specified as 'Cubic polynomial', 'Hyperbolic tangent', 'Saleh model', 'Ghorbani model', 'Modified Rapp model', or 'Lookup table'. For more information, see “Memoryless Nonlinear Impairments” on page 3-867.

Data Types: char | string

InputScaling — Input signal scaling factor

0 (default) | scalar

Input signal scaling factor in decibels, specified as a scalar. This property scales the power gain of the input signal.

Tunable: Yes

Dependencies

To enable this property, set the Method property to 'Saleh model' or 'Ghorbani model'.

Data Types: double

LinearGain — Linear gain

0 (default) | scalar

Linear gain in decibels, specified as a scalar. This property scales the power gain of the output signal.

Tunable: Yes

Dependencies

To enable this property, set the Method property to 'Cubic polynomial', 'Hyperbolic tangent', or 'Modified Rapp model'.

Data Types: double

T0ISpecification — Third-order nonlinearity specification for cubic polynomial

'IIP3' (default) | 'OIP3' | 'IP1dB' | 'OP1dB' | 'IPsat' | 'OPsat'

Third-order nonlinearity specification for cubic polynomial, specified as 'IIP3', 'OIP3', 'IP1dB', 'OP1dB', 'IPsat', or 'OPsat'. For more information, see “Cubic Polynomial Third-Order Coefficient” on page 3-869.

Dependencies

To enable this property, set the Method property to 'Cubic polynomial'.

Data Types: char | string

IIP3 — Third-order input intercept point

30 (default) | scalar

Third-order input intercept point in dBm, specified as a scalar.

Tunable: Yes

Dependencies

To enable this property, set the Method property to 'Cubic polynomial' or 'Hyperbolic tangent'.

Data Types: double

OIP3 — Third-order output intercept point

30 (default) | scalar

Third-order output intercept point in dBm, specified as a scalar.

Tunable: Yes

Dependencies

To enable this property, set the Method property to 'Cubic polynomial' and the TOISpecification property to 'OIP3'.

Data Types: double

IP1dB — One dB input compression point

30 (default) | scalar

One dB input compression point in dBm, specified as a scalar.

Tunable: Yes

Dependencies

To enable this property, set the Method property to 'Cubic polynomial' and the TOISpecification property to 'IP1dB'.

Data Types: double

OP1dB — One dB output compression point

30 (default) | scalar

One dB output compression point in dBm, specified as a scalar.

Tunable: Yes

Dependencies

To enable this property, set the Method property to 'Cubic polynomial' and the TOISpecification property to 'OP1dB'.

Data Types: double

IPsat — Input saturation point

30 (default) | scalar

Input saturation point in dBm, specified as a scalar.

Tunable: Yes

Dependencies

To enable this property, set the Method property to 'Cubic polynomial' and the TOISpecification property to 'IPsat'.

Data Types: double

OPsat — Output saturation point

30 (default) | scalar

Output saturation point in dBm, specified as a scalar.

Tunable: Yes

Dependencies

To enable this property, set the Method property to 'Cubic polynomial' and the TOISpecification property to 'OPsat'.

Data Types: double

AMPMConversion — Linear AM/PM conversion factor

10 (default) | scalar

Linear AM/PM conversion factor in degrees per decibel, specified as a scalar. For more information, see “Cubic Polynomial and Hyperbolic Tangent Model Methods” on page 3-869.

Tunable: Yes

Dependencies

To enable this property, set the Method property to 'Cubic polynomial' or 'Hyperbolic tangent'.

Data Types: double

AMAMPParameters — AM/AM parameters

[2.1587 1.1517] | [8.1081 1.5413 6.5202 -0.0718] | row vector

AM/AM parameters used to compute the amplitude gain for an input signal, specified as a row vector.

- When the Method property is set to 'Saleh model', this property must be a two-element vector that specifies alpha and beta values. In this case, the default value is [2.1587 1.1517].
- When the Method property is set to 'Ghorbani model', this property must be a four-element vector that specifies x_1 , x_2 , x_3 , and x_4 values. In this case, the default value is [8.1081 1.5413 6.5202 -0.0718].

For more information, see “Saleh Model Method” on page 3-871 and “Ghorbani Model Method” on page 3-872.

Tunable: Yes

Dependencies

To enable this property, set the Method property is set to 'Saleh model' or 'Ghorbani model'.

Data Types: double

AMPMPParameters — AM/PM parameters

[4.0033 9.1040] | [4.6645 2.0965 10.88 -0.003] | row vector

AM/PM parameters used to compute the phase change for an input signal, specified as a row vector.

- When the Method property is set to 'Saleh model', this property must be a two-element vector that specifies alpha and beta values. In this case, the default value is [4.0033 9.1040].
- When the Method property is set to 'Ghorbani model', this property must be a four-element vector that specifies y_1 , y_2 , y_3 , and y_4 values. In this case, the default value is [4.6645 2.0965 10.88 -0.003].

For more information, see “Saleh Model Method” on page 3-871 and “Ghorbani Model Method” on page 3-872.

Tunable: Yes

Dependencies

To enable this property, set the Method property is set to 'Saleh model' or 'Ghorbani model'.

Data Types: double

PowerLowerLimit — Input power lower limit

10 (default) | scalar

Input power lower limit in dBm, specified as a scalar less than the PowerUpperLimit property value. The AM/PM conversion scales linearly for input power values in the range [PowerLowerLimit, PowerUpperLimit]. If the input signal power is below the input power lower limit, the phase shift resulting from AM/PM conversion is zero. For more information, see “Cubic Polynomial and Hyperbolic Tangent Model Methods” on page 3-869.

Tunable: Yes

Dependencies

To enable this property, set the Method property is set to 'Cubic polynomial' or 'Hyperbolic tangent'.

Data Types: double

PowerUpperLimit — Input power upper limit

inf (default) | scalar

Input power upper limit in dBm, specified as a scalar greater than PowerLowerLimit. The AM/PM conversion scales linearly for input power values in the range [PowerLowerLimit, PowerUpperLimit]. If the input signal power is above the input power upper limit, the phase shift resulting from AM/PM conversion is constant. For more information, see “Cubic Polynomial and Hyperbolic Tangent Model Methods” on page 3-869.

Tunable: Yes

Dependencies

To enable this property, set the Method property is set to 'Cubic polynomial' or 'Hyperbolic tangent'.

Data Types: double

OutputScaling — Output signal scaling factor

0 (default) | scalar

Output signal scaling factor in decibels, specified as a scalar. This property scales the power gain of the output signal.

Tunable: Yes

Dependencies

To enable this property, set the Method property is set to 'Saleh model' or 'Ghorbani model'.

Data Types: double

Smoothness — Amplitude smoothness factor

0.5 (default) | scalar

Amplitude smoothness factor, specified as a scalar. For more information, see “Modified Rapp Model Method” on page 3-873.

Tunable: Yes

Dependencies

To enable this property, set the Method property is set to 'Modified Rapp model'.

Data Types: double

PhaseGainRadian — Phase gain for modified Rapp model

0 (default) | scalar

Phase gain for modified Rapp model in radians, specified as a scalar. A value of -0.45 is typical. For more information, see “Modified Rapp Model Method” on page 3-873.

Tunable: Yes

Dependencies

To enable this property, set the Method property is set to 'Modified Rapp model'.

Data Types: double

PhaseSaturation — Phase saturation for modified Rapp model

0.88 (default) | positive scalar

Phase saturation for modified Rapp model in radians, specified as a positive scalar. For more information, see “Modified Rapp Model Method” on page 3-873.

Tunable: Yes

Dependencies

To enable this property, set the Method property is set to 'Modified Rapp model'.

Data Types: double

PhaseSmoothness — Phase smoothness for modified Rapp model

3.43 (default) | positive scalar

Phase smoothness for modified Rapp model in radians, specified as a positive scalar. For more information, see “Modified Rapp Model Method” on page 3-873.

Tunable: Yes

Dependencies

To enable this property, set the Method property is set to 'Modified Rapp model'.

Data Types: double

OutputSaturationLevel — Output saturation level

1 (default) | positive scalar

Output saturation level, specified as a scalar. For more information, see “Modified Rapp Model Method” on page 3-873.

Tunable: Yes

Dependencies

To enable this property, set the Method property is set to 'Modified Rapp model'.

Data Types: double

Table — Amplifier characteristics lookup table

N -by- $[P_{in}, P_{out}, \Delta\Phi]$ matrix

Amplifier characteristics lookup table, specified as an N -by-3 matrix of measured power amplifier (PA) characteristics. Each row is of the form $[P_{in}, P_{out}, \Delta\Phi]$. P_{in} specifies the input signal in dBm, P_{out} specifies the output signal in dBm, and $\Delta\Phi$ specifies the output phase shift in degrees. The default value is $[-25, 5.16, -0.25; -20, 10.11, -0.47; -15, 15.11, -0.68; -10, 20.05, -0.89; -5, 24.79, -1.22; 0, 27.64, 5.59; 5, 28.49, 12.03]$.

The measured PA characteristics defined by this property are used to compute the AM/AM (in dBm/dBm) and AM/PM (in deg/dBm) nonlinear impairment characteristics.

Note To determine appropriate P_{out} and $\Delta\Phi$ values for any P_{in} values outside the range of values specified in the Table property, the System object applies linear extrapolation from the first two or last two $[P_{in}, P_{out}, \Delta\Phi]$ rows of Table.

Tunable: Yes

Dependencies

To enable this property, set the Method property to 'Lookup table'.

Data Types: double

Reference impedance — Reference impedance

1 (default) | positive scalar

Reference impedance in ohms, specified as a positive scalar. This value is used to convert voltage values to power values.

Tunable: Yes

Data Types: double

Usage

Syntax

```
outsig = mnl(insig)
```

Description

`outsig = mnl(insig)` applies memoryless nonlinear impairments to the input RF baseband signal.

Input Arguments

insig — Input RF baseband signal

scalar | column vector | matrix

Input RF baseband signal, specified as a scalar, column vector, or matrix.

Data Types: double

Output Arguments

outsig — Output RF baseband signal

scalar | column vector | matrix

Output RF baseband signal, returned as a scalar, column vector, or matrix. The output is of the same data type as the input.

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Specific to `comm.MemorylessNonlinearity`

<code>release</code>	Release resources and allow changes to System object property values and input characteristics
<code>clone</code>	Create duplicate System object

Examples

Show Amplification of Signal at Linear and Nonlinear Input Power Levels

Apply cubic polynomial nonlinearity to two 16-QAM signals. The first input signal power level is in the linear region of the amplifier power characteristic curve. The second input signal power level is in the nonlinear region of the amplifier power characteristic curve. Show the amplifier power characteristic curve and the constellation diagram for the amplified 16-QAM signals.

Initialize Simulation

Initialize variables for simulation and create System objects for a memoryless nonlinearity amplifier impairment and a constellation diagram. So that the constellation shows power compression only (and no phase rotation), configure the memoryless nonlinearity amplifier impairment with AM-PM distortion set to zero.

```

M = 16;           % Modulation order
sps = 4;         % Samples per symbol
pindBm = [12 25]; % Input power
gain = 10;       % Amplifier gain

amplifier = comm.MemorylessNonlinearity("Method","Cubic polynomial", ...
    "LinearGain",gain,"AMPMConversion",0,"ReferenceImpedance",50);
refConst = qammod([0:M-1],M);
axisLimits = [-gain gain];
constdiag = comm.ConstellationDiagram("NumInputPorts",2, ...
    "ChannelNames",["Linear" "Nonlinear"],"ShowLegend",true, ...
    "ReferenceConstellation",refConst, ...
    "XLimits",axisLimits,"YLimits",axisLimits);

```

Amplify and Plot Signal

Apply 16-QAM to an input signal of random data. Amplify the signal and use the `plot` function of the `comm.MemorylessNonlinearity` System object to show the output power and phase response curves. The first input signal power level is 12 dBm and is in the linear region of the amplifier power characteristic curve. The second input signal power level is 25 dBm and is in the nonlinear region of the amplifier power characteristic curve.

```

pin = 10.^((pindBm-30)/10); % Convert dBm to linear Watts
data = randi([0 M-1],1000,1);
modOut = qammod(data,M,"UnitAveragePower",true)*sqrt(pin*amplifier.ReferenceImpedance);
ampOut = amplifier(modOut);
plot(amplifier);

```

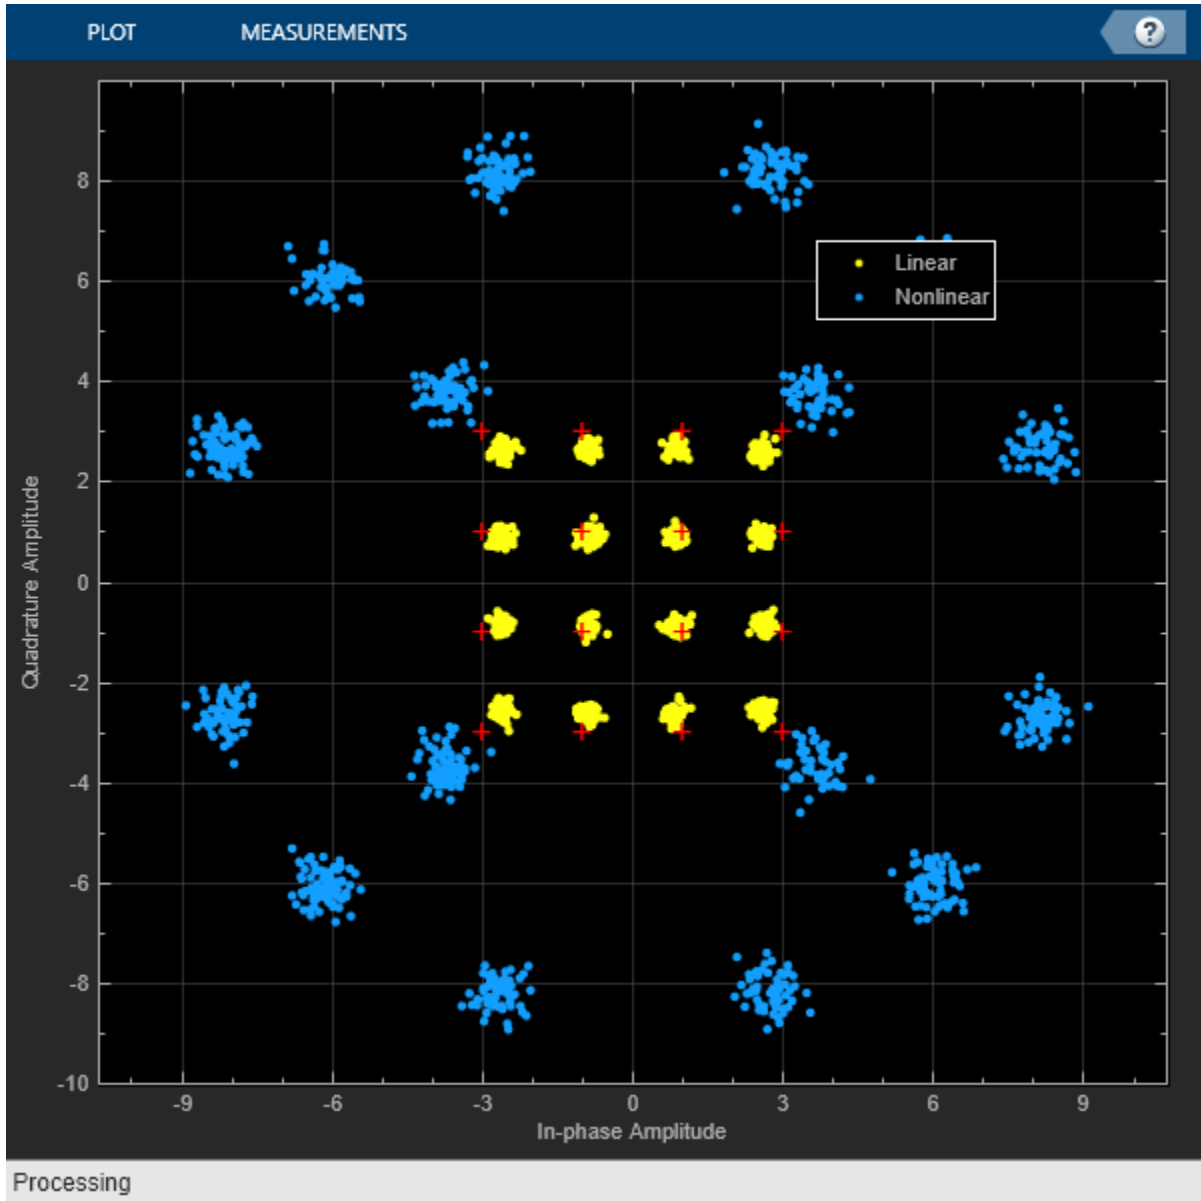

Add AWGN to the two amplified signals and show the constellation diagram for the signals.

```

snr = 25;
noisyLinOut = awgn(ampOut(:,1),snr,"measured");
noisyNonLinOut = awgn(ampOut(:,2),snr,"measured");
constdiag(noisyLinOut,noisyNonLinOut);

```

Apply Saleh Model of Power Amplifier Nonlinearity to 16-QAM Signal

Generate 16-QAM data with an average power of 10 mW and a reference impedance of 1 ohm. Pass the data through a nonlinear power amplifier (PA).

```

M = 16;
data = randi([0 (M - 1)]',1000,1);

```

```
avgPow = 1e-2;
minD = avgPow2MinD(avgPow,M);
```

Create a memoryless nonlinearity System object, specifying the Saleh model method.

```
saleh = comm.MemorylessNonlinearity('Method','Saleh model');
```

Generate modulated symbols and pass them through the PA nonlinearity model.

```
modData = (minD/2).*qammod(data,M);
y = saleh(modData);
```

Generate a scatter plot of the results.

```
scatterplot(y)
```

Average power normalization of input signal.

```
function minD = avgPow2MinD(avgPow,M)
% Average power to minimum distance
nBits = log2(M);
if (mod(nBits,2)==0)
% Square QAM
sf = (M - 1)/6;
else
% Cross QAM
if (nBits>4)
sf = ((31*M/32) - 1)/6;
```

```

        else
            sf = ((5*M/4) - 1)/6;
        end
    end
    minD = sqrt(avgPow/sf);
end

```

Nonlinear Amplifier Gain Compression

Plot the gain compression of a nonlinear amplifier for a 16-QAM signal.

Specify the modulation order and samples per symbol parameters.

```

M = 16;
sps = 4;

```

Model a nonlinear amplifier, by creating a memoryless nonlinearity System object with a 30 dB third-order input intercept point. Create a raised cosine transmit filter System object.

```

amplifier = comm.MemorylessNonlinearity('IIP3',30);
txfilter = comm.RaisedCosineTransmitFilter( ...
    'RolloffFactor',0.3,'FilterSpanInSymbols',6, ...
    'OutputSamplesPerSymbol',sps,'Gain',sqrt(sps));

```

Specify the input power in dBm and a reference impedance of 1 ohm. Convert the input power to W and initialize the gain vector.

```

pindBm = -5:25;
pin = 10.^((pindBm-30)/10);
gain = zeros(length(pindBm),1);

```

Execute the main processing loop, which includes these steps.

- Generate random data symbols.
- Modulate the data symbols and adjust the average power of the signal.
- Filter the modulated signal.
- Amplify the signal.
- Measure the gain.

```

for k = 1:length(pin)
    data = randi([0 (M - 1)],1000,1);
    modSig = qammod(data,M,'UnitAveragePower',true)*sqrt(pin(k));
    filtSig = txfilter(modSig);
    ampSig = amplifier(filtSig);
    gain(k) = 10*log10(mean(abs(ampSig).^2) / mean(abs(filtSig).^2));
end

```

Plot the amplifier gain as a function of the input signal power. The 1 dB gain compression point occurs for an input power of 18.5 dBm. To increase the point at which a 1 dB compression is observed, increase the third-order intercept point, `amplifier.IIP3`.

```

arrayplot = dsp.ArrayPlot('PlotType','Line','XLabel','Power In (dBm)', ...
    'XOffset',-5,'YLimits',[-5 5]);
arrayplot(gain)

```

Distort 16-QAM Signal with Measured Power Amplifier Nonlinearities

Apply nonlinear power amplifier (PA) characteristics with $50\ \Omega$ impedance to a 16-QAM signal. Load PA characteristics by setting the `Method` property to `'Lookup table'`. The `pa_performance_characteristics` helper function outputs the amplifier performance characteristics lookup table.

Define parameters for the modulation order, samples per symbol, and input power. Create random data.

```
M = 16; % Modulation order
sps = 4; % Samples per symbol
pindBm = -8; % Input power
pin = 10.^((pindBm-30)/10); % power in Watts
data = randi([0 (M - 1)],1000,1);
refdata = 0:M-1;
refconst = qammod(refdata,M,'UnitAveragePower',true);
paChar = pa_performance_characteristics();
```

Create a memoryless nonlinearity System object, a transmit filter System object, and a constellation diagram System object. The default lookup table values are used for the memoryless nonlinearity System object.

```

amplifier = comm.MemorylessNonlinearity('Method','Lookup table','Table',paChar,'ReferenceImpedance',100);
txfilter = comm.RaisedCosineTransmitFilter('RolloffFactor',0.3, ...
    'FilterSpanInSymbols',6,'OutputSamplesPerSymbol',sps,'Gain',sqrt(sps));
constellation = comm.ConstellationDiagram('SamplesPerSymbol',4, ...
    'Title','Amplified/Distorted Signal','NumInputPorts',2, ...
    'ReferenceConstellation', refconst,'ShowLegend',true, ...
    'ChannelNames',{'Filtered signal','Amplified signal'});

```

Modulate the random data. Filter and apply the nonlinear amplifier characteristics to the modulation symbols.

```

modSig = qammod(data,M,'UnitAveragePower',true)*sqrt(pin * amplifier.ReferenceImpedance);
filtSig = txfilter(modSig);
ampSig = amplifier(filtSig);

```

Compute input and output signal levels and the phase shift.

```

pSig = abs(ampSig).^2 / amplifier.ReferenceImpedance;
poutdBm = 10 * log10(pSig) + 30;
pfiltSig = abs(filtSig).^2 / amplifier.ReferenceImpedance;
simulated_pindBm = 10 * log10(pfiltSig) + 30;
phase = rad2deg(angle(ampSig.*conj(filtSig)));

```

Plot AM/AM characteristics, AM/PM characteristics, and the constellation results.

```

figure
set(gcf,'units','normalized','position',[.25 1/3 .5 1/3])
subplot(1,2,1)
plot(simulated_pindBm,poutdBm, '.');
hold on
plot(amplifier.Table(:,1),amplifier.Table(:,2), '.', 'Markersize',15);
xlabel('Input Power (dBm)')
ylabel('Output Power (dBm)');
grid on;
title('AM/AM Characteristics');
leglabel = {'Simulated results','Measurement'};
legend(leglabel,'Location','south');

subplot(1,2,2)
plot(simulated_pindBm,phase, '.');
hold on
plot(amplifier.Table(:,1),amplifier.Table(:,3), '.', 'Markersize',15);
legend(leglabel,'Location','south');
xlabel('Input Power (dBm)');
ylabel('Output Phase Shift (degrees)');
grid on;
title('AM/PM Characteristics');

```

For the purpose of constellation comparison, normalize the amplified signal and the filtered signal. Generate a constellation diagram of the filtered signal and amplified signal. The nonlinear amplifier characteristics cause compression of the amplified signal constellation compared to the filtered constellation.

```
filtSig = filtSig/mean(abs(filtSig)); % Normalized filtered signal
ampSig = ampSig/mean(abs(ampSig)); % Normalized amplified signal
constellation(filtSig,ampSig)
```

Helper Function

```
function paChar = pa_performance_characteristics()
```

The operating specification for the LDMOS-based Doherty amplifier are:

- A frequency of 2110 MHz
- A peak power of 300 W
- A small signal gain of 61 dB

Each row in `HAV08_Table` specifies P_{in} (dBm), gain (dB), phase shift (degrees) as derived from figure 4 of Hammi, Oualid, et al. "Power amplifiers' model assessment and memory effects intensity quantification using memoryless post-compensation technique." IEEE Transactions on Microwave Theory and Techniques 56.12 (2008): 3170-3179.

More About

Memoryless Nonlinear Impairments

Memoryless nonlinear impairments distort the amplitude and phase of the input signal. The amplitude distortion is amplitude-to-amplitude modulation (AM/AM) and the phase distortion is amplitude-to-phase modulation (AM/PM). These model methods are available for simulating the memoryless nonlinear impairment models.

Model Method	Memoryless Nonlinear Impairment
Cubic polynomial	Applies AM/AM and AM/PM
Hyperbolic tangent	
Saleh model	
Ghorbani model	

Model Method	Memoryless Nonlinear Impairment
Modified Rapp model	
Lookup table	Applies impairment according to $[P_{in}, P_{out}, \Delta\Phi]$ amplifier characteristics specified by the <code>Table</code> property

The modeled impairments apply the AM/AM and AM/PM distortions differently according to the model method you specify. The models apply the memoryless nonlinear impairment to the input signal by following these steps.

- 1 Multiply the signal by an input gain factor.

Note You can normalize the signal to 1 by setting the input scaling gain to the inverse of the input signal amplitude.

- 2 Split the complex signal into its magnitude and angle components. For real-valued input signals, the imaginary component is set to zero.
- 3 Apply an AM/AM distortion to the magnitude of the signal, according to the selected model method, to produce the magnitude of the output signal.
- 4 Apply an AM/PM distortion to the phase of the signal, according to the selected model method, to produce the angle of the output signal.
- 5 Combine the new magnitude and angle components into a complex signal. Then, multiply the result by an output gain factor.

The model methods apply AM/AM and AM/PM impairments as shown in this figure.

The lookup table method uses the power amplifier (PA) characteristics lookup table, specified as an N -by-3 matrix of measured PA characteristics. Each row is of the form $[P_{in}, P_{out}, \Delta\Phi]$. P_{in} specifies the PA input signal in dBm, P_{out} specifies the PA output signal in dBm, and $\Delta\Phi$ specifies the output phase shift in degrees. The measured PA characteristics defined by the `Table` property are used to compute the AM/AM (in dBm/dBm) and AM/PM (in deg/dBm) nonlinear impairment characteristics. The System object distorts the input signal by the computed AM/AM (in dBm/dBm) and AM/PM (in deg/dBm) values.

Note To determine appropriate P_{out} and $\Delta\Phi$ values for any P_{in} values outside the range of values specified in the `Table` property, the System object applies linear extrapolation from the first two or last two $[P_{in}, P_{out}, \Delta\Phi]$ rows of `Table`.

Cubic Polynomial and Hyperbolic Tangent Model Methods

This figure shows the AM/PM conversion behavior for the cubic polynomial and hyperbolic tangent model methods.

The AM/PM conversion scales linearly with an input power value between the lower and upper limits of the input power level. Outside this range, the AM/PM conversion is constant at the values corresponding to the lower and upper input power limits, which are zero and $(AM/PM \text{ conversion}) \times (\text{upper input power limit} - \text{lower input power limit})$, respectively.

Cubic Polynomial Third-Order Coefficient

The cubic polynomial model method uses linear power gain to determine the linear coefficient of a third order polynomial. The cubic polynomial model method then uses either the third order intercept point (IP3), the one dB compression point (P1dB), or the saturation power (Psat) to determine the third order coefficient of the polynomial.

This figure shows an example of the plot generated when you set the Method property to 'Cubic polynomial'.

The general form of cubic nonlinearity models the AM/AM characteristics as

$$F_{AM/AM}(|u|) = c_1 \times |u| + \frac{3}{4} c_3 \times |u|^3$$

where $F_{AM/AM}(|u|)$ is the magnitude of the output signal, $|u|$ is the magnitude of the input signal, c_1 is the coefficient of the linear gain term, and c_3 is the coefficient of the cubic gain term. The results for IIP3, OIP3, IP1dB, OP1dB, IPsat, and OPsat are taken from [6]. The coefficient c_3 values are given in this table.

Nonlinearity Type	Description	Equation
IIP3	Input power level at which the power from linear gain is equal to the power from a third-order nonlinearity	$c_3 = -\frac{4c_1}{3 \times 10^{[(IIP3 - 30)/10]}}$ where $IIP3$ is given in dBm.
OIP3	Output power level at which the power from linear gain is equal to the power from a third-order nonlinearity	$c_3 = -\frac{4c_1^3}{3 \times 10^{[(OIP3 - 30)/10]}}$ where $OIP3$ is given in dBm.
IP1dB	Input power level at which the output power is one dB less than the power from linear gain	$c_3 = -\frac{2c_1(10^{19/20} - 10)}{15 \times 10^{[(IP1dB - 30)/10]}}$ where $IP1dB$ is given in dBm.

Nonlinearity Type	Description	Equation
OP1dB	Output power level one dB less than the power from linear gain	$c_3 = -\frac{2c_1^3(10^{19/20} - 10)}{15 \times 10^{[(OP1dB - 30 - LGdB + 1)/10]}}$ <p>where <i>OP1dB</i> is given in dBm, and <i>LGdB</i> is the linear gain in dB</p>
IPsat	Input power at which the output power saturates	$c_3 = -\frac{4c_1}{9 \times 10^{[(IPsat - 30)/10]}}$ <p>where <i>IPsat</i> is given in dBm.</p>
OPsat	Output saturation power	$c_3 = -\frac{16c_1^3}{81 \times 10^{[(OPsat - 30)/10]}}$ <p>where <i>OPsat</i> is given in dBm.</p>

Saleh Model Method

This figure shows the AM/AM behavior (output voltage versus input voltage for the AM/AM distortion) and the AM/PM behavior (output phase versus input voltage for the AM/PM distortion) for the Saleh model method.

The AM/AM parameters, α_{AMAM} and β_{AMAM} , are used to compute the amplitude distortion of the input signal by using

$$F_{AMAM}(u) = \frac{\alpha_{AMAM} \times u}{1 + \beta_{AMAM} \times u^2},$$

where u is the magnitude of the scaled signal.

The AM/PM parameters, α_{AMPM} and β_{AMPM} , are used to compute the phase distortion of the input signal by using

$$F_{AMPM}(u) = \frac{\alpha_{AMPM} \times u^2}{1 + \beta_{AMPM} \times u^2},$$

where u is the magnitude of the scaled signal. The α and β parameters for AM/AM and AM/PM are similarly named but distinct.

Ghorbani Model Method

The Ghorbani model method applies AM/AM and AM/PM distortion as described in this section.

The AM/AM parameters (x_1 , x_2 , x_3 , and x_4) are used to compute the amplitude distortion of the input signal by using

$$F_{AMAM}(u) = \frac{x_1 u^{x_2}}{1 + x_3 u^{x_2}} + x_4 u,$$

where u is the magnitude of the scaled signal.

The AM/PM parameters (y_1 , y_2 , y_3 , and y_4) are used to compute the phase distortion of the input signal by using

$$F_{\text{AMPM}}(u) = \frac{y_1 u^{y_2}}{1 + y_3 u^{y_2}} + y_4 u,$$

where u is the magnitude of the scaled signal.

Modified Rapp Model Method

The modified Rapp model method applies AM/AM and AM/PM distortion as described in this section.

The amplitude and phase distortion of the input signal are given by

$$F_{\text{AMAM}}(u) = \frac{g_{\text{lin}} \times u}{\left(1 + \left(\frac{g_{\text{lin}} \times u}{O_{\text{sat}}}\right)^{2S}\right)^{1/2S}},$$

$$F_{\text{AMPM}}(u) = \frac{A u^q}{\left(1 + \left(\frac{u}{B}\right)^q\right)},$$

where:

- g_{lin} is $10^{(\text{LinearGain}/20)}$ and is the amplitude gain of the amplifier.
- u is the magnitude of the signal.
- S is the smoothness factor, specified by the Smoothness property.
- O_{sat} is the output saturation level, specified by the OutputSaturationLevel property.
- A is the phase gain in radians, specified by the PhaseGainRadian property.
- B is the phase saturation, specified by the PhaseSaturation property.
- q is the phase smoothness, specified by the PhaseSmoothness property.

comm.MER

Package: comm

Measure modulation error ratio

Description

The `comm.MER` (modulation error ratio) object measures the signal-to-noise ratio (SNR) in digital modulation applications. You can use MER measurements to determine system performance in communications applications. For example, determining whether a DVB-T system conforms to applicable radio transmission standards requires accurate MER measurements. The block measures all outputs in dB.

To measure modulation error ratio:

- 1 Define and set up your MER object. See “Construction” on page 3-875.
- 2 Call `step` to measure the modulation error ratio according to the properties of `comm.MER`. The behavior of `step` is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`MER = comm.MER` creates a modulation error ratio (MER) System object, `MER`. This object measures the signal-to-noise ratio (SNR) in digital modulation applications.

`MER = comm.MER(Name,Value)` creates an MER object with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as `(Name1,Value1,...,NameN,ValueN)`.

Example: `MER = comm.MER('ReferenceSignalSource','Estimated from reference constellation')` creates an object, `MER`, that measures the MER of a received signal by using a reference constellation.

Properties

ReferenceSignalSource

Reference signal source

Reference signal source, specified as either `'Input port'` (default) or `'Estimated from reference constellation'`. To provide an explicit reference signal against which the input signal is measured, set this property to `'Input port'`. To measure the MER of the input signal against a reference constellation, set this property to `'Estimated from reference constellation'`.

ReferenceConstellation

Reference constellation

Reference constellation, specified as a vector. This property is available when the `ReferenceSignalSource` property is 'Estimated from reference constellation'.

The default is `[0.7071 - 0.7071i; -0.7071 - 0.7071i; -0.7071 + 0.7071i; 0.7071 + 0.7071i]`, which corresponds to a standard QPSK constellation. You can derive constellation points by using modulation functions or objects. For example, to derive the reference constellation for a 16-QAM signal, you can use `qammod(0:15,16)`.

MeasurementIntervalSource

Measurement interval source

Measurement interval source, specified as one of the following: 'Input length' (default), 'Entire history', 'Custom', or 'Custom with periodic reset'. This property affects the RMS and maximum MER outputs only.

- To calculate MER using only the current samples, set this property to 'Input length'.
- To calculate MER for all samples, set this property to 'Entire history'.
- To calculate MER over an interval you specify and to use a sliding window, set this property to 'Custom'.
- To calculate MER over an interval you specify and to reset the object each time the measurement interval is filled, set this property to 'Custom with periodic reset'.

MeasurementInterval

Measurement interval

Measurement interval over which the MER is calculated, specified in samples as a real positive integer. This property is available when `MeasurementIntervalSource` is 'Custom' or 'Custom with periodic reset'. The default is 100.

AveragingDimensions

Averaging dimensions

Averaging dimensions, specified as a positive integer or row vector of positive integers. This property determines the dimensions over which the averaging is performed. For example, to average across the rows, set this property to 2. The default is 1.

The object supports variable-size inputs over the dimensions in which the averaging takes place. However, the input size for the nonaveraged dimensions must remain constant between `step` calls. For example, if the input has size `[4 3 2]` and `AveragingDimensions` is `[1 3]`, the output size is `[1 3 1]`, and the second dimension must remain fixed at 3.

MinimumMEROutputPort

Minimum MER measurement output port

Minimum MER measurement output port, specified as a logical scalar. To create an output port for minimum MER measurements, set this property to `true`. The default is `false`.

XPercentileMEROutputPort

X-percentile MER measurement output port

X-percentile MER measurement output port, specified as a logical scalar. To create an output port for X-percentile MER measurements, set this property to `true`. The X-percentile MER measurements persist until you reset the object. These measurements are calculated by using all of the input frames since the last reset. The default is `false`.

XPercentileValue

X-percentile value

X-percentile value above which X% of the MER measurements fall, specified as a real scalar from 0 to 100. This property applies when `XPercentileMEROutputPort` is `true`. The default is 95.

SymbolCountOutputPort

Symbol count output port

Symbol count output port, specified as a logical scalar. To output the number of accumulated symbols used to calculate the X-percentile MER measurements, set this property to `true`. This property is available when `XPercentileMEROutputPort` property is `true`. The default is `false`.

Methods

step Measure modulation error ratio

Common to All System Objects	
release	Allow System object property value changes
reset	Reset internal states of System object

Examples

Measure MER of Noisy 16-QAM Modulated Signal

Create an MER object which outputs minimum MER, 90-percentile MER, and the number of symbols.

```
mer = comm.MER('MinimumMEROutputPort',true, ...
    'XPercentileMEROutputPort',true,'XPercentileValue',90,...
    'SymbolCountOutputPort',true);
```

Generate random data. Apply 16-QAM modulation having unit average power. Pass the signal through an AWGN channel.

```
data = randi([0 15],1000,1);
refsym = qammod(data,16,'UnitAveragePower',true);
rxsym = awgn(refsym,20);
```

Determine the RMS, minimum, and 90th percentile MER values.

```
[MERdB,MinMER,PercentileMER,NumSym] = mer(refsym,rxsym)
```

```
MERdB = 20.1071
MinMER = 11.4248
PercentileMER = 16.5850
NumSym = 1000
```

Measure MER Using Reference Constellation

Generate random data symbols, and apply 8-PSK modulation.

```
d = randi([0 7],2000,1);
txSig = pskmod(d,8,pi/8);
```

Pass the modulated signal through an AWGN channel.

```
rxSig = awgn(txSig,30);
```

Create an MER object. Measure the MER using the transmitted signal as the reference.

```
mer = comm.MER;
mer1 = mer(txSig,rxSig);
```

Release the MER object. Set the object to use a reference constellation for making MER measurements.

```
release(mer)
mer.ReferenceSignalSource = 'Estimated from reference constellation';
mer.ReferenceConstellation = pskmod(0:7,8,pi/8);
```

Measure the MER using only the received signal as an input. Verify that it matches the result obtained with a reference signal.

```
mer2 = mer(rxSig);
[mer1 mer2]
```

```
ans = 1×2
```

```
30.0271 30.0271
```

Measure MER Using Custom Measurement Interval

Measure the MER of a noisy 8-PSK signal using two types of custom measurement intervals. Display the results.

Set the number of frames, M, and the number of subframes per frame, K.

```
M = 2;
K = 5;
```

Set the number of symbols in a subframe. Calculate the corresponding frame length.

```
sfLen = 100;
frmLen = K*sfLen
```

```
frmLen = 500
```

Create an MER object. Configure the object to use a custom measurement interval equal to the frame length.

```
mer1 = comm.MER('MeasurementIntervalSource','Custom', ...
    'MeasurementInterval',frmLen);
```

Configure the object to measure MER using an 8-PSK reference constellation.

```
mer1.ReferenceSignalSource = 'Estimated from reference constellation';
mer1.ReferenceConstellation = pskmod(0:7,8,pi/8);
```

Create an MER object, and configure it use a 500-symbol measurement interval with a periodic reset. Configure the object to measure MER using an 8-PSK reference constellation.

```
mer2 = comm.MER('MeasurementIntervalSource','Custom with periodic reset', ...
    'MeasurementInterval',frmLen);
mer2.ReferenceSignalSource = 'Estimated from reference constellation';
mer2.ReferenceConstellation = pskmod(0:7,8,pi/8);
```

Initialize the MER and signal-to-noise arrays.

```
merNoReset = zeros(K,M);
merReset = zeros(K,M);
snrdB = zeros(K,M);
```

Measure the MER for a noisy 8-PSK signal using both objects. The SNR increases by 1 dB from subframe to subframe. For `merNoReset`, the 500 most recent symbols are used to compute the estimate. In this case, a sliding window is used so that an entire data frame is used as the basis for the estimate. For `merReset`, the symbols are cleared each time a new frame is encountered.

```
for m = 1:M
    for k = 1:K
        data = randi([0 7],sfLen,1);
        txSig = pskmod(data,8,pi/8);
        snrdB(k,m) = k+(m-1)*K+7;
        rxSig = awgn(txSig,snrdB(k,m));
        merNoReset(k,m) = mer1(rxSig);
        merReset(k,m) = mer2(rxSig);
    end
end
```

Display the MER measured using the two approaches. The windowing used in the first case provides an averaging across the subframes. In the second case, the MER object resets after the first frame so that the calculated MER values more accurately reflect the current SNR.

```
stairs(snrdB(:),[merNoReset(:) merReset(:)])
xlabel('SNR (dB)')
ylabel('MER (%)')
legend('No Reset','Periodic Reset')
```

Measure MER Across Different Dimensions

Create OFDM modulator and demodulator objects.

```
ofdmmod = comm.OFDMModulator('FFTLength',32,'NumSymbols',4);
ofdmmod = comm.OFDMDemodulator('FFTLength',32,'NumSymbols',4);
```

Determine the number of subcarriers and symbols in the OFDM signal.

```
ofdmDims = info(ofdmmod);
numSC = ofdmDims.DataInputSize(1)

numSC = 21

numSym = ofdmDims.DataInputSize(2)

numSym = 4
```

Generate random symbols and apply QPSK modulation.

```
msg = randi([0 3],numSC,numSym);
modSig = pskmod(msg,4,pi/4);
```

OFDM modulate the QPSK signal. Pass the signal through an AWGN channel. Demodulate the noisy signal.

```
txSig = ofdmmod(modSig);
rxSig = awgn(txSig,10,'measured');
demodSig = ofdmmodem(rxSig);
```

Create an MER object, where the result is averaged over the subcarriers. Measure the MER. There are four entries corresponding to each of the 4 OFDM symbols.

```
mer = comm.MER('AveragingDimensions',1);
modErrorRatio = mer(demodSig,modSig)
```

```
modErrorRatio = 1x4
    10.9546    11.7781    13.2331    12.5573
```

Overwrite the MER object, where the result is averaged over the OFDM symbols. Measure the MER. There are 21 entries corresponding to each of the 21 subcarriers.

```
mer = comm.MER('AveragingDimensions',2);
modErrorRatio = mer(demodSig,modSig)
```

```
modErrorRatio = 21x1
    10.8828
    15.7292
    13.4323
    12.8910
    11.8733
    11.4374
    10.9259
     9.6960
     9.2397
    14.0779
     :
```

Measure the MER and average over both the subcarriers and the OFDM symbols.

```
mer = comm.MER('AveragingDimensions',[1 2]);
modErrorRatio = mer(demodSig,modSig)
```

```
modErrorRatio = 12.0817
```

Algorithms

MER is a measure of the SNR in a modulated signal calculated in dB. The *MER* over N symbols is

$$MER = 10 \cdot \log_{10} \left(\frac{\sum_{n=1}^N (I_k^2 + Q_k^2)}{\sum_{n=1}^N (e_k)} \right) \text{dB},$$

The *MER* for the k th symbol is

$$MER_k = 10 * \log_{10} \left(\frac{\frac{1}{N} \sum_{n=1}^N (I_k^2 + Q_k^2)}{e_k} \right) \text{ dB.}$$

The minimum *MER* represents the minimum *MER* value in a burst, or

$$MER_{\min} = \min_{k \in [1, \dots, N]} \{MER_k\},$$

where:

- $e_k = e_k = (I_k - \tilde{I}_k)^2 + (Q_k - \tilde{Q}_k)^2$
- I_k = In-phase measurement of the kth symbol in the burst
- Q_k = Quadrature phase measurement of the kth symbol in the burst
- I_k and Q_k represent ideal (reference) values. \tilde{I}_k and \tilde{Q}_k represent measured (received) symbols.

The block computes the X-percentile MER by creating a histogram of all the incoming MER_k values. The output provides the MER value above which X% of the MER values fall.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

Introduced in R2012a

step

System object: comm.MER

Package: comm

Measure modulation error ratio

Syntax

MERDB= step(MER,REFSYM,RXSYM)

MERDB = step(MER,RXSYM)

[____,MINMER] = step(____)

[____,XMER] = step(____)

[____,NUMSYM] = step(____)

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`MERDB= step(MER,REFSYM,RXSYM)` returns the measured MER, MERDB, of the received signal RXSYM, based on reference signal REFSYM. MER values are measured in dB.

REFSYM. REFSYM and RXSYM inputs are complex column vectors of equal dimensions and data type. The data type can be double, single, signed integer, or signed fixed point with power-of-two slope and zero bias. All outputs of the object are of data type double. To set the interval over which the MER is measured, use the `MeasurementIntervalSource` and `MeasurementInterval` properties.

`MERDB = step(MER,RXSYM)` returns the measured MER of received signal RXSYM based on a reference signal specified in the `ReceivedConstellation` property.

`[____,MINMER] = step(____)` returns the minimum MER, MINMER, given either of the two previous syntaxes.

To return minimum MER, set the `MinimumMEROutputPort` property to `true`. To set the interval over which MINMER is measured, use the `MeasurementIntervalSource` and `MeasurementInterval` properties.

`[____,XMER] = step(____)` returns the X-percentile MER, XMER.

To return the X-percentile MER, set the `XPercentileMEROutputPort` property to `true`. XMER is the MER above which X% of the measurements fall, where X is set by the `XPercentileValue` property. XMER is measured using all the input frames since the last reset.

`[____,NUMSYM] = step(____)` returns the number of symbols, NUMSYM, used to calculate the X-percentile MER.

To return NUMSYM, set the `SymbolCountOutputPort` to `true`. NUMSYM is measured using all the input frames since the last reset.

Note MER specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

comm.MIMOChannel

Package: comm

Filter input signal through MIMO multipath fading channel

Description

The `comm.MIMOChannel` System object filters an input signal through a multiple-input/multiple-output (MIMO) multipath fading channel. This object models Rayleigh and Rician fading and employs the Kronecker model for modeling the spatial correlation between the links. For processing details, see the Algorithms on page 3-912 section.

To filter an input signal through a MIMO multipath fading channel:

- 1 Create the `comm.MIMOChannel` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

Creation

Syntax

```
mimochannel = comm.MIMOChannel
mimochannel = comm.MIMOChannel(Name,Value)
```

Description

`mimochannel = comm.MIMOChannel` creates a MIMO frequency-selective or frequency-flat fading channel System object.

`mimochannel = comm.MIMOChannel(Name,Value)` sets properties using one or more name-value arguments. For example, `'SampleRate',2` sets the input signal sample rate to 2.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see [System Design in MATLAB Using System Objects](#).

SampleRate — Input signal sample rate

1 (default) | positive scalar

Input signal sample rate in hertz, specified as a positive scalar.

Data Types: `double`

PathDelays — Discrete path delay

0 (default) | scalar | row vector

Discrete path delay in seconds, specified as a scalar or row vector.

- When you set `PathDelays` to a scalar, the MIMO channel is frequency flat.
- When you set `PathDelays` to a vector, the MIMO channel is frequency selective.

The `PathDelays` and `AveragePathGains` properties must be the same length.

Data Types: `double`

AveragePathGains — Average path gains

0 (default) | scalar | row vector

Average path gains in decibels, specified as a scalar or row vector. The `AveragePathGains` and `PathDelays` properties must be the same length.

Data Types: `double`

NormalizePathGains — Normalize path gains

`true` or 1 (default) | `false` or 0

Normalize path gains, specified as one of these logical values:

- 1 (`true`) — The fading processes are normalized so that the total power of the path gains, averaged over time, is 0 dB.
- 0 (`false`) — The total power of the path gains is not normalized.

The `AveragePathGains` property specifies the average powers of the path gains.

Data Types: `logical`

FadingDistribution — Fading distribution

'Rayleigh' (default) | 'Rician'

Fading distribution to use for the channel, specified as 'Rayleigh' or 'Rician'.

Data Types: `char` | `string`

KFactor — K-factor of Rician fading channel

3 (default) | positive scalar | 1-by- N_p vector of nonnegative values

K-factor of a Rician fading channel, specified as a positive scalar or a 1-by- N_p vector of nonnegative values. N_p is the number of discrete path delays specified by the `PathDelays` property.

- When you set `KFactor` to a scalar, the first discrete path is a Rician fading process with a Rician K-factor of `KFactor`. Any remaining discrete paths are independent Rayleigh fading processes.
- When you set `KFactor` to a vector, the discrete path corresponding to a positive element of the `KFactor` vector is a Rician fading process with a Rician K-factor specified by that element. The discrete path corresponding to any zero-valued elements of the `KFactor` vector are Rayleigh fading processes. At least one element must be nonzero.

Dependencies

To enable this property, set the `FadingDistribution` property to 'Rician'.

Data Types: double

DirectPathDopplerShift — Doppler shifts for line-of-sight components

0 (default) | scalar | row vector

Doppler shifts for the line-of-sight components of the multipath Rician fading channel, specified as a scalar or row vector. Units are in hertz. This property must be the same size as the `KFactor` property.

- When you set `DirectPathDopplerShift` to a scalar, the value represents the line-of-sight component Doppler shift of the first discrete path. This path exhibits a Rician fading process.
- When you set `DirectPathDopplerShift` to a row vector, the discrete path corresponding to a positive element of the `KFactor` vector is a Rician fading process. The corresponding element of `DirectPathDopplerShift` specifies the line-of-sight component for the Doppler shift of that discrete path.

Dependencies

To enable this property, set the `FadingDistribution` property to 'Rician'.

Data Types: double

DirectPathInitialPhase — Initial phases for line-of-sight components

0 (default) | scalar | row vector

Initial phases for the line-of-sight components of the multipath Rician fading channel, specified as a scalar or row vector. Units are in radians. This property must be the same size as the `KFactor` property value.

- When you set `DirectPathInitialPhase` to a scalar, the value represents the line-of-sight component initial phase of the first discrete path. This path exhibits a Rician fading process.
- When you set `DirectPathInitialPhase` to a row vector, the discrete path corresponding to a positive element of the `KFactor` vector is a Rician fading process. The corresponding element of `DirectPathInitialPhase` specifies the line-of-sight component for the initial phase of that discrete path.

Dependencies

To enable this property, set the `FadingDistribution` property to 'Rician'.

Data Types: double

MaximumDopplerShift — Maximum Doppler shift for all channel paths

0.001 (default) | nonnegative scalar

Maximum Doppler shift for all channel paths, specified as a nonnegative scalar. Units are in hertz.

The maximum Doppler shift limit applies to each channel path. When you set this property to 0, the channel remains static for the entire input. You can use the `reset` object function to generate a new channel realization. The `MaximumDopplerShift` property value must be smaller than $\text{SampleRate}/10/f_c$ for each path, where f_c is the cutoff frequency factor of the path. For most Doppler spectrum types, the value of f_c is 1. For Gaussian and bi-Gaussian Doppler spectrum types, f_c is dependent on the Doppler spectrum structure fields. For more details about how f_c is defined, see the Cutoff Frequency Factor on page 3-913 section.

Data Types: `double`

DopplerSpectrum — Doppler spectrum shape for all channel paths

`doppler('Jakes')` (default) | Doppler spectrum structure | 1-by- N_p cell array of Doppler spectrum structures

Doppler spectrum shape for all channel paths, specified as a Doppler spectrum structure or a 1-by- N_p cell array of Doppler spectrum structures. These Doppler spectrum structures must be outputs of the `doppler` function. N_p is the number of discrete path delays specified by the `PathDelays` property. The `MaximumDopplerShift` property defines the maximum Doppler shift value that the `DopplerSpectrum` property permits when you specify the Doppler spectrum.

- When you set `DopplerSpectrum` to a single Doppler spectrum structure, all paths have the same specified Doppler spectrum.
- When you set `DopplerSpectrum` to a cell array of Doppler spectrum structures, each path has the Doppler spectrum specified by the corresponding structure in the cell array.

Specify options for the spectrum type by using the `spectType` input to the `doppler` function. If you set the `FadingTechnique` property to `'Sum of sinusoids'`, you must set `DopplerSpectrum` to `doppler('Jakes')`.

Dependencies

To enable this property, set the `MaximumDopplerShift` property to a positive scalar.

Data Types: `struct` | `cell`

SpatialCorrelationSpecification — Spatial correlation specification

`'Separate Tx Rx'` (default) | `'None'` | `'Combined'`

Spatial correlation specification, specified as `'Separate Tx Rx'`, `'None'`, or `'Combined'`.

- Choose `'Spatial Tx Rx'` to separately specify the transmit and receive spatial correlation matrices from which the number of transmit antennas (N_T) and number of receive antennas (N_R) are derived.
- Choose `'None'` to specify the number of transmit and receive antennas.
- Choose `'Combined'` to specify a single correlation matrix for the whole channel from which the product of N_T and N_R is derived.

Data Types: `char` | `string`

NumTransmitAntennas — Number of transmit antennas

2 (default) | positive integer

Number of transmit antennas, specified as a positive integer.

Dependencies

To enable this property, set the `SpatialCorrelationSpecification` property to `'None'` or `'Combined'`.

Data Types: `double`

NumReceiveAntennas — Number of receive antennas

2 (default) | positive integer

Number of receive antennas, specified as a positive integer.

Dependencies

To enable this property, set the `SpatialCorrelationSpecification` property to 'None' or 'Combined'.

Data Types: double

TransmitCorrelationMatrix — Spatial correlation of transmitter

[1 0; 0 1] (default) | N_T -by- N_T matrix | N_T -by- N_T -by- N_P array

Spatial correlation of the transmitter, specified as an N_T -by- N_T matrix or N_T -by- N_T -by- N_P array. N_T is the number of transmit antennas. N_P is the number of discrete path delays specified by the `PathDelays` property.

- If you set `PathDelays` to a scalar, the channel is frequency flat and `TransmitCorrelationMatrix` must be an N_T -by- N_T Hermitian matrix. The magnitude of any off-diagonal element must be no larger than the geometric mean of the two corresponding diagonal elements.
- If you set `PathDelays` to a vector, the channel is frequency selective and you can specify `TransmitCorrelationMatrix` as one of these options:
 - An N_T -by- N_T matrix. In this case, each path has the same transmit spatial correlation matrix.
 - An N_T -by- N_T -by- N_P array. In this case, each path has its own specified transmit spatial correlation matrix.

Dependencies

To enable this property, set the `SpatialCorrelationSpecification` property to 'Separate Tx Rx'.

Data Types: double

Complex Number Support: Yes

ReceiveCorrelationMatrix — Spatial correlation of receiver

[1 0; 0 1] (default) | N_R -by- N_R matrix | N_R -by- N_R -by- N_P array

Spatial correlation of the receiver, specified as an N_R -by- N_R matrix or N_R -by- N_R -by- N_P array. N_R is the number of receive antennas. N_P is the number of discrete path delays specified by the `PathDelays` property.

- If you set `PathDelays` to a scalar, the channel is frequency flat, and `ReceiveCorrelationMatrix` must be an N_R -by- N_R Hermitian matrix. The magnitude of any off-diagonal element must be no larger than the geometric mean of the two corresponding diagonal elements.
- If you set `PathDelays` to a vector, the channel is frequency selective and you can specify `ReceiveCorrelationMatrix` as one of these options:
 - An N_R -by- N_R matrix. In this case, each path has the same receive spatial correlation matrix.
 - An N_R -by- N_R -by- N_P array. In this case, each path has its own specified receive spatial correlation matrix.

Dependencies

To enable this property, set the `SpatialCorrelationSpecification` property to 'Separate Tx Rx'.

Data Types: double

Complex Number Support: Yes

SpatialCorrelationMatrix — Combined spatial correlation matrix

[1 0 0 0; 0 1 0 0; 0 0 1 0; 0 0 0 1] (default) | N_{TR} -by- N_{TR} matrix | N_{TR} -by- N_{TR} -by- N_P array

Combined spatial correlation matrix, specified as an N_{TR} -by- N_{TR} matrix or N_{TR} -by- N_{TR} -by- N_P array. $N_{TR} = (N_T \times N_R)$, and N_P is the number of discrete delay paths (the length of the `PathDelays` property).

- If `PathDelays` is a scalar, the channel is frequency flat, and `SpatialCorrelationMatrix` must be an N_{TR} -by- N_{TR} Hermitian matrix. The magnitude of any off-diagonal element must be no larger than the geometric mean of the two corresponding diagonal elements.
- If you set `PathDelays` to a vector, the channel is frequency selective and you can specify `SpatialCorrelationMatrix` as one of these options:
 - An N_{TR} -by- N_{TR} matrix. In this case, each path has the same combined spatial correlation matrix.
 - An N_{TR} -by- N_{TR} -by- N_P array. In this case, each path has its own specified combined spatial correlation matrix.

Dependencies

To enable this property, set the `SpatialCorrelationSpecification` property to 'Combined'.

Data Types: double

AntennaSelection — Antenna selection scheme

'Off' (default) | 'Tx' | 'Rx' | 'Tx and Rx'

Antenna selection scheme, specified as 'Off', 'Tx', 'Rx', or 'Tx and Rx'.

Tx represents transmit antennas, and Rx represents receive antennas. When you configure any antenna selection other than the default setting, the object requires one or more inputs to specify which antennas are selected for signal transmission. For more information, see [Antenna Selection](#) on page 3-913.

Data Types: char | string

NormalizeChannelOutputs — Normalize channel outputs

true or 1 (default) | false or 0

Normalize channel outputs, specified as one of these logical values:

- 1 (true) — The channel outputs are normalized by the number of receive antennas.
- 0 (false) — The channel outputs are not normalized.

Data Types: logical

ChannelFiltering — Channel filtering

true or 1 (default) | false or 0

Channel filtering, specified as one of these logical values:

- `1` (`true`) — The channel accepts an input signal and produces a filtered output signal.
- `0` (`false`) — The object does not accept an input signal, produces no filtered output signal, and outputs only channel path gains. You must specify the duration of the fading process by using the `NumSamples` property.

Data Types: `logical`

PathGainsOutputPort — Output channel path gains

`false` or `0` (default) | `true` or `1`

Output channel path gains, specified as a logical `0` (`false`) or `1` (`true`). Set this property to `true` to output the channel path gains of the underlying fading process.

Dependencies

To enable this property, set the `ChannelFiltering` property to `true`.

Data Types: `logical`

NumSamples — Number of samples

`100` (default) | nonnegative integer

Number of samples used for the duration of the fading process, specified as a nonnegative integer.

Tunable: Yes

Dependencies

To enable this property, set the `ChannelFiltering` property to `false`.

Data Types: `double`

OutputDataType — Path gain output data type

`'double'` (default) | `'single'`

Path gain output data type, specified as `'double'` or `'single'`.

Dependencies

To enable this property, set the `ChannelFiltering` property to `false`.

Data Types: `char` | `string`

FadingTechnique — Channel model fading technique

`'Filtered Gaussian noise'` (default) | `'Sum of sinusoids'`

Channel model fading technique, specified as `'Filtered Gaussian noise'` or `'Sum of sinusoids'`.

Data Types: `char` | `string`

NumSinusoids — Number of sinusoids

`48` (default) | positive integer

Number of sinusoids used to model the fading process, specified as a positive integer.

Dependencies

To enable this property, set the `FadingTechnique` property to `'Sum of sinusoids'`.

Data Types: `double`

InitialTimeSource — Source to control start time of fading process

`'Property'` (default) | `'Input port'`

Source to control the start time of the fading process, specified as `'Property'` or `'Input port'`.

- When you set `InitialTimeSource` to `'Property'`, set the initial time offset by using the `InitialTime` property.
- When you set `InitialTimeSource` to `'Input port'`, specify the start time of the fading process by using the `inittime` input argument. The input value can change in consecutive calls to the object.

Dependencies

To enable this property, set the `FadingTechnique` property to `'Sum of sinusoids'`.

Data Types: `char` | `string`

InitialTime — Initial time offset

`0` (default) | nonnegative scalar

Initial time offset for the fading model in seconds, specified as a nonnegative scalar.

`InitialTime` must be greater than the end time of the last frame. When `mod(InitialTime/SampleRate)` is nonzero, the object rounds the initial time offset up to the nearest sample position.

Dependencies

To enable this property, set the `FadingTechnique` property to `'Sum of sinusoids'` and the `InitialTimeSource` property to `'Property'`.

Data Types: `double`

RandomStream — Source of random number stream

`'Global stream'` (default) | `'mt19937ar with seed'`

Source of the random number stream, specified as `'Global stream'` or `'mt19937ar with seed'`.

- When you specify `'Global stream'`, the object uses the current global random number stream for normally distributed random number generation. In this case, the `reset` object function resets only the filters.
- When you specify `'mt19937ar with seed'`, the object uses the `mt19937ar` algorithm for normally distributed random number generation. In this case, the `reset` object function resets the filters and reinitializes the random number stream to the value of the `Seed` property.

Data Types: `char` | `string`

Seed — Initial seed of mt19937ar random number stream

`73` (default) | nonnegative integer

Initial seed of the mt19937ar random number stream, specified as a nonnegative integer. When you call the `reset` object function, it reinitializes the mt19937ar random number stream to the `Seed` value.

Dependencies

To enable this property, set the `RandomStream` property to `'mt19937ar with seed'`.

Data Types: `double`

Visualization — Channel visualization

`'Off'` (default) | `'Impulse response'` | `'Frequency response'` | `'Impulse and frequency responses'` | `'Doppler spectrum'`

Channel visualization, specified as `'Off'`, `'Impulse response'`, `'Frequency response'`, `'Impulse and frequency responses'`, or `'Doppler spectrum'`. When you set the channel visualization to a value other than `'Off'`, the selected channel characteristics, such as impulse response or Doppler spectrum, display in a separate window. For more information, see [Channel Visualization](#).

Dependencies

To enable this property, set the `FadingTechnique` property to `'Filtered Gaussian noise'`.

Data Types: `char` | `string`

AntennaPairsToDisplay — Transmit-receive antenna pair to display

`[1 1]` (default) | two-element row vector

Transmit-receive antenna pair to display, specified as a two element row vector. The first element corresponds to the desired transmit antenna, and the second element corresponds to the desired receive antenna. Only a single pair can be displayed.

Dependencies

To enable this property, set the `Visualization` property to `'Impulse response'`, `'Frequency response'`, `'Doppler spectrum'`, or `'Impulse and frequency responses'`.

Data Types: `double`

PathsForDopplerDisplay — Path for which Doppler spectrum is displayed

`1` (default) | positive integer in the range $[1, N_p]$

Path for which the Doppler spectrum is displayed, specified as an integer in the range $[1, N_p]$. N_p is the number of discrete path delays specified by the `PathDelays` property. Use this property to select the discrete path used in constructing a Doppler spectrum plot.

Dependencies

To enable this property, set the `Visualization` property to `'Doppler spectrum'`.

Data Types: `double`

SamplesToDisplay — Percentage of samples to display

`'25%'` (default) | `'10%'` | `'50%'` | `'100%'`

Percentage of samples to display, specified as `'25%'`, `'10%'`, `'50%'`, or `'100%'`. Increasing the percentage improves display accuracy at the expense of simulation speed.

Dependencies

To enable this property, set the Visualization property to 'Impulse response', 'Frequency response', or 'Impulse and frequency responses'.

Data Types: char | string

Usage

Syntax

```
y = mimochannel(x)
y = mimochannel(x,seltx)
y = mimochannel(x,selrx)
y = mimochannel(x,seltx,selrx)
y = mimochannel( ___,inittime)
[y,pathgains] = mimochannel( ___)

pathgains = mimochannel()
pathgains = mimochannel(seltx)
pathgains = mimochannel(selrx)
pathgains = mimochannel(seltx,selrx)
pathgains = mimochannel( ___,inittime)
```

Description

`y = mimochannel(x)` filters the input signal `x` through the MIMO fading channel and returns the result in `y`.

To enable this syntax, set the ChannelFiltering property to true.

`y = mimochannel(x,seltx)` filters the input signal through the MIMO fading channel by using the transmit antennas specified by `seltx`.

To enable this syntax set the AntennaSelection property to 'Tx'.

For example, this code shows how to select the first and third transmit antenna index as active.

```
mimochannel = comm.MIMOChannel('AntennaSelection','Tx');
seltx = [1 0 1];
...
y = mimochannel(x,seltx);
```

`y = mimochannel(x,selrx)` filters the input signal through the MIMO fading channel by using the receive antennas selected by `selrx`.

To enable this syntax set the AntennaSelection property to 'Rx'.

For example, this code shows how to select the second receive antenna index as active.

```
mimochannel = comm.MIMOChannel('AntennaSelection','Rx');
selrx = [0 1];
...
y = mimochannel(x,selrx);
```

`y = mimochannel(x,seltx,selrx)` filters the input signal through the MIMO fading channel by using the transmit and receive antennas selected by `seltx` and `selrx`.

To enable this syntax set the `AntennaSelection` property to `'Tx and Rx'`.

For example, this code shows how to select the first and second transmit antenna and the second receive antenna as active.

```
mimochannel = comm.MIMOChannel( ...
    'AntennaSelection','Tx and Rx');
seltx = [1 1];
selrx = [0 1];
...
y = mimochannel(x,selrx);
```

`y = mimochannel(____, inittime)` specifies a start time for the fading process in addition to an input argument combination from any of the previous syntaxes.

To enable this syntax, also set the `FadingTechnique` property to `'Sum of sinusoids'` and the `InitialTimeSource` property to `'Input port'`.

`[y,pathgains] = mimochannel(____)` also returns the MIMO channel path gains for antenna selection schemes using any of the input argument combinations in the previous syntaxes.

`pathgains = mimochannel()` returns the channel path gains of the underlying fading process. In this case, the channel requires no input signal and acts as a source of path gains.

To enable this syntax, set the `ChannelFiltering` property to `false`.

`pathgains = mimochannel(seltx)` returns the channel path gains of the underlying fading process by using the transmit antennas specified by `seltx`.

To enable this syntax set `ChannelFiltering` property to `false` and the `AntennaSelection` property to `'Tx'`.

`pathgains = mimochannel(selrx)` returns the channel path gains of the underlying fading process by using the transmit antennas specified by `selrx`.

To enable this syntax set the `ChannelFiltering` property to `false` and the `AntennaSelection` property to `'Rx'`.

`pathgains = mimochannel(seltx,selrx)` returns the channel path gains of the underlying fading process by using the transmit and receive antennas selected by `seltx` and `selrx`.

To enable this syntax set the `ChannelFiltering` property to `false` and the `AntennaSelection` property to `'Tx and Rx'`.

`pathgains = mimochannel(____, inittime)` specifies a start time for the fading process in addition to an input argument combination from any of the previous syntaxes.

To enable this syntax, also set the `FadingTechnique` property to `'Sum of sinusoids'` and the `InitialTimeSource` property to `'Input port'`.

Input Arguments

x — Input signal

scalar | vector | matrix

Input signal, specified as a scalar, an N_S -element column vector, or an N_S -by- N_T or N_S -by- N_{ST} matrix.

- N_S is the number of samples.
- N_T is the number of transmit antennas and is determined by the `TransmitCorrelationMatrix` or `NumTransmitAntennas` property values.
- N_{ST} is the number of selected transmit antennas and is determined by the number of elements that are set to 1 in the vector provided by the `selTx` input.

Data Types: single | double

Complex Number Support: Yes

selTx — Select active transmit antennas

1-by- N_T binary-valued vector

Select active transmit antennas, specified as a 1-by- N_T binary-valued vector. N_T is the number of transmit antennas. Elements set to 1 identify selected antenna indices, and the elements set to 0 identify nonselected antenna indices.

Data Types: single | double

selRx — Select active receive antennas

1-by- N_R binary-valued vector

Select active receive antennas, specified as a 1-by- N_R binary-valued vector. N_R is the number of receive antennas. Elements set to 1 identify selected antenna indices, and the elements set to 0 identify nonselected antenna indices.

Data Types: single | double

inittime — Initial time offset

0 (default) | nonnegative scalar

Initial time offset for the fading model in seconds, specified as a nonnegative scalar.

When `mod(inittime/SampleRate)` is nonzero, the initial time offset is rounded up to the nearest sample position.

Data Types: single | double

Output Arguments

y — Output signal

matrix

Output signal, returned as an N_S -by- N_R or N_S -by- N_{SR} matrix.

- N_S is the number of samples.
- N_R is the number of receive antennas and is determined by the `ReceiveCorrelationMatrix` or `NumReceiveAntennas` property values.
- N_{SR} is the number of selected receive antennas and is determined by the number of elements that are set to 1 in the vector provided by the `selRx` input.

pathgains — Output path gains N_S -by- N_P -by- N_T -by- N_R array

Output path gains, returned as an N_S -by- N_P -by- N_T -by- N_R array with NaN values for the unselected transmit-receive antenna pairs. `pathgains` contains complex values.

- N_S is the number of samples.
- N_P is the number of discrete path delays specified by the `PathDelays` property.
- N_T is the number of transmit antennas.
- N_R is the number of receive antennas.

When you set the `ChannelFiltering` property to `false`, the data type of this output has the same precision as the input signal `x`. When you set the `ChannelFiltering` property to `true`, the data type of this output is specified by the `OutputDataType` property.

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Specific to comm.MIMOChannel

info Characteristic information about fading channel object

Common to All System Objects

step	Run System object algorithm
release	Release resources and allow changes to System object property values and input characteristics
reset	Reset internal states of System object

Note

- If you set the `RandomStream` property of the object to `'Global stream'`, the `reset` object function resets the filters only.
- If you set `RandomStream` to `'mt19937ar with seed'`, the `reset` object function resets the filters and also reinitializes the random number stream to the value of the `Seed` property.

Examples**Pass QPSK Data Through 4-by-2 MIMO Channel**

Create a 4-by-2 MIMO channel by using the MIMO channel System object. Modulate and spatially encode data, and then pass the data through the channel.

Generate QPSK-modulated data.

```
data = randi([0 3],1000,1);  
modData = pskmod(data,4,pi/4);
```

Create an orthogonal space-time block encoder System object to encode the modulated data into four spatially separated streams. Then, encode the data.

```
ostbc = comm.OSTBCEncoder( ...  
    'NumTransmitAntennas',4, ...  
    'SymbolRate',1/2);  
txSig = ostbc(modData);
```

Create a MIMO channel System object, using name-value pairs to set the properties. The channel consists of two paths, each with a maximum Doppler shift of 5 Hz. Set the `SpatialCorrelationSpecification` property to 'None', which requires that you specify the number of transmit and receive antennas. Specify four transmit antennas and two receive antennas.

```
mimochannel = comm.MIMOChannel( ...  
    'SampleRate',1000, ...  
    'PathDelays',[0 2e-3], ...  
    'AveragePathGains',[0 -5], ...  
    'MaximumDopplerShift',5, ...  
    'SpatialCorrelationSpecification','None', ...  
    'NumTransmitAntennas',4, ...  
    'NumReceiveAntennas',2);
```

Pass the modulated and encoded signal through the MIMO channel.

```
rxSig = mimochannel(txSig);
```

Create a time vector, `t`, to use for plotting the power of the received signal.

```
ts = 1/mimochannel.SampleRate;  
t = (0:ts:(size(txSig,1)-1)*ts)';
```

Calculate and plot the power of the signal received by antenna 1.

```
pwrdB = 20*log10(abs(rxSig(:,1)));  
plot(t,pwrdB)  
title('Channel Response Power (dBW)')  
xlabel('Time (s)')  
ylabel('Power (dBW)')
```

Examine Spatial Correlation Characteristics of 2-by-2 Rayleigh Fading Channel

Generate path gains for a 2-by-2 Rayleigh fading channel and examine the spatial correlation characteristics of the channel realization. Use the `release` object function to unlock the object to set the `AntennaSelection` property to 'Tx and Rx' and then confirm the unselected transmit-receive antenna pairs.

Create a 2-by-2 MIMO channel System object with two discrete paths and channel filtering disabled. Each path has different transmit and receive correlation matrices, specified by the `TransmitCorrelationMatrix` and `ReceiveCorrelationMatrix` properties.

```
mimoChan = comm.MIMOChannel( ...
    'SampleRate',1000, ...
    'PathDelays',[0 1e-3], ...
    'AveragePathGains',[3 5], ...
    'NormalizePathGains',false, ...
    'MaximumDopplerShift',5, ...
    'TransmitCorrelationMatrix',cat(3,eye(2),[1 0.1;0.1 1]), ...
    'ReceiveCorrelationMatrix',cat(3,[1 0.2;0.2 1],eye(2)), ...
    'RandomStream','mt19937ar with seed', ...
    'Seed',33, ...
    'ChannelFiltering',false);
```

Generate channel response path gains using the MIMO channel object.

```
pathGains = mimoChan();
```

The transmit spatial correlation for the first discrete path at the first receive antenna is specified as an identity matrix in the `TransmitCorrelationMatrix` property. Confirm that the channel output `pathGains` exhibits the same statistical characteristics by using the `corrcoef` function to display the transmit spatial correlation for the first discrete path and the first receive antenna.

```
corrcoef(squeeze(pathGains(:,1,:,1)))
```

```
ans = 2×2 complex
```

```
1.0000 + 0.0000i -0.3391 + 0.4285i  
-0.3391 - 0.4285i 1.0000 + 0.0000i
```

The transmit spatial correlation for the second discrete path at the second receive antenna is specified as `[1 0.1;0.1 1]` in the `TransmitCorrelationMatrix` property. Confirm that the channel output `pathGains` exhibits the same statistical characteristics by using the `corrcoef` function to display the transmit spatial correlation for the second discrete path and the second receive antenna.

```
corrcoef(squeeze(pathGains(:,2,:,2)))
```

```
ans = 2×2 complex
```

```
1.0000 + 0.0000i -0.8989 - 0.2663i  
-0.8989 + 0.2663i 1.0000 + 0.0000i
```

The receive spatial correlation for the first discrete path at the second transmit antenna is specified as `[1 0.2;0.2 1]` in the `ReceiveCorrelationMatrix` property. Confirm that the channel output `pathGains` exhibits the same statistical characteristics by using the `corrcoef` function to display the receive spatial correlation for the first discrete path and the second transmit antenna.

```
corrcoef(squeeze(pathGains(:,1,2,:)))
```

```
ans = 2×2 complex
```

```
1.0000 + 0.0000i 0.9170 + 0.3141i  
0.9170 - 0.3141i 1.0000 + 0.0000i
```

The receive spatial correlation for the second discrete path at the first transmit antenna is specified as an identity matrix in the `ReceiveCorrelationMatrix` property. Confirm that the channel output `pathGains` exhibits the same statistical characteristics by using the `corrcoef` function to display the receive spatial correlation for the second discrete path and the first transmit antenna.

```
corrcoef(squeeze(pathGains(:,2,1,:)))
```

```
ans = 2×2 complex
```

```
1.0000 + 0.0000i 0.9227 - 0.3435i  
0.9227 + 0.3435i 1.0000 + 0.0000i
```

Display Impulse and Frequency Responses of Frequency-Selective Channel

Create a frequency-selective MIMO channel, and then display its impulse and frequency responses.

Set the sample rate to 10 MHz. Specify path delays and gains using the extended vehicular A (EVA) channel parameters. Set the maximum Doppler shift to 70 Hz.

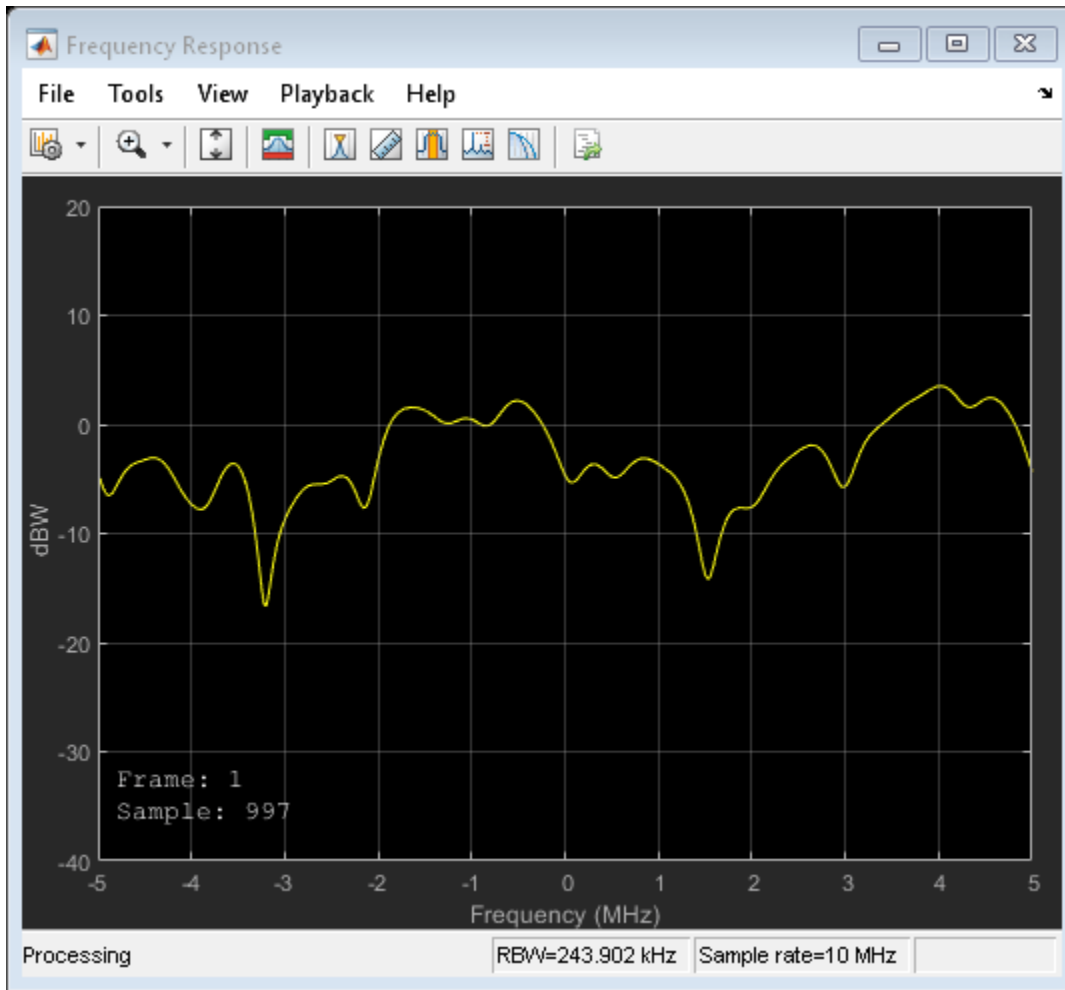

```
fs = 10e6; % Hz
pathDelays = [0 30 150 310 370 710 1090 1730 2510]*1e-9; % Seconds
avgPathGains = [0 -1.5 -1.4 -3.6 -0.6 -9.1 -7 -12 -16.9]; % dB
fD = 70; % Hz
```

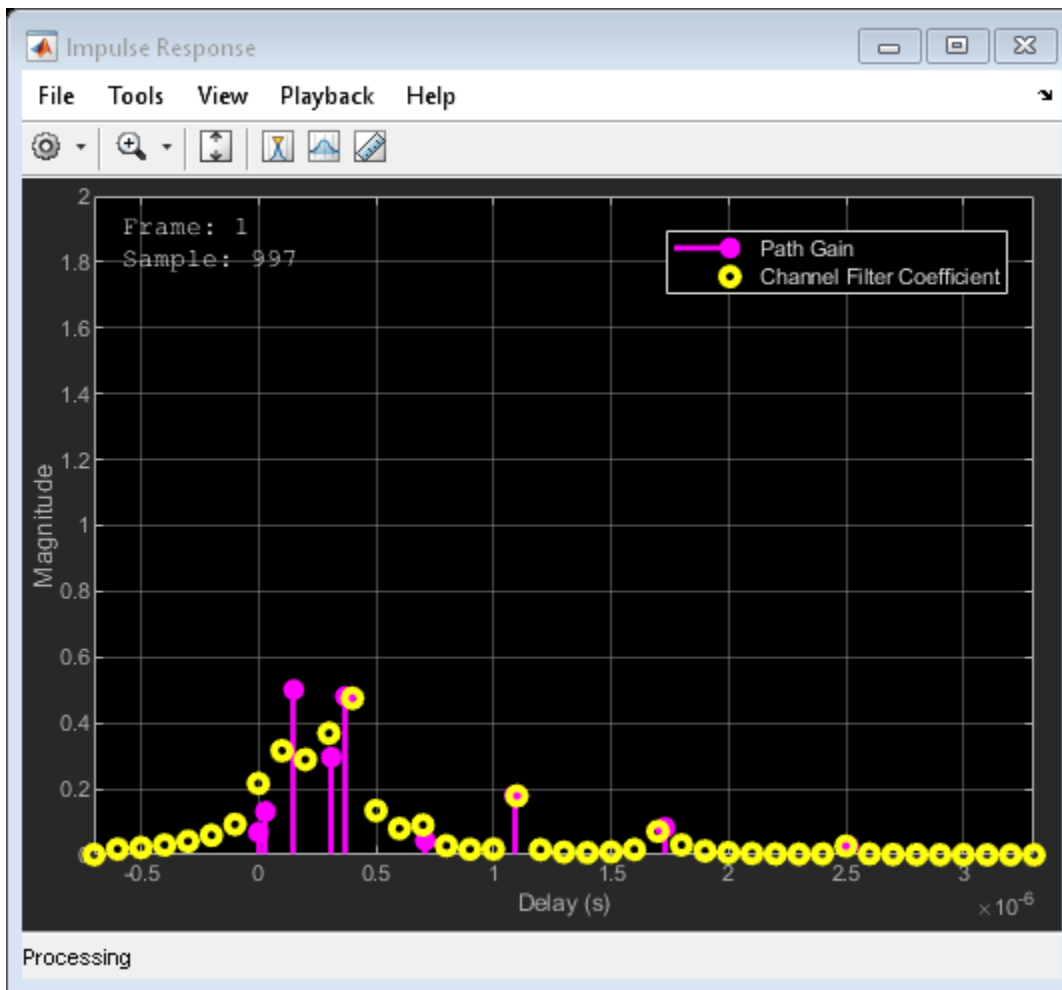

Create a 2-by-2 MIMO channel System object, specifying the previously defined parameters and setting channel visualization to plot the impulse and frequency responses. By default, the plot displays the antenna pair corresponding to first transmit and receive antennas.

```
mimoChan = comm.MIMOChannel('SampleRate',fs, ...
    'PathDelays',pathDelays, ...
    'AveragePathGains',avgPathGains, ...
    'MaximumDopplerShift',fD, ...
    'Visualization','Impulse and frequency responses');
```

Generate random binary data, and then pass it through the MIMO channel. The impulse response plot enables you to easily identify the individual paths and their corresponding filter coefficients. The frequency response plot shows the frequency-selective nature of the EVA channel.

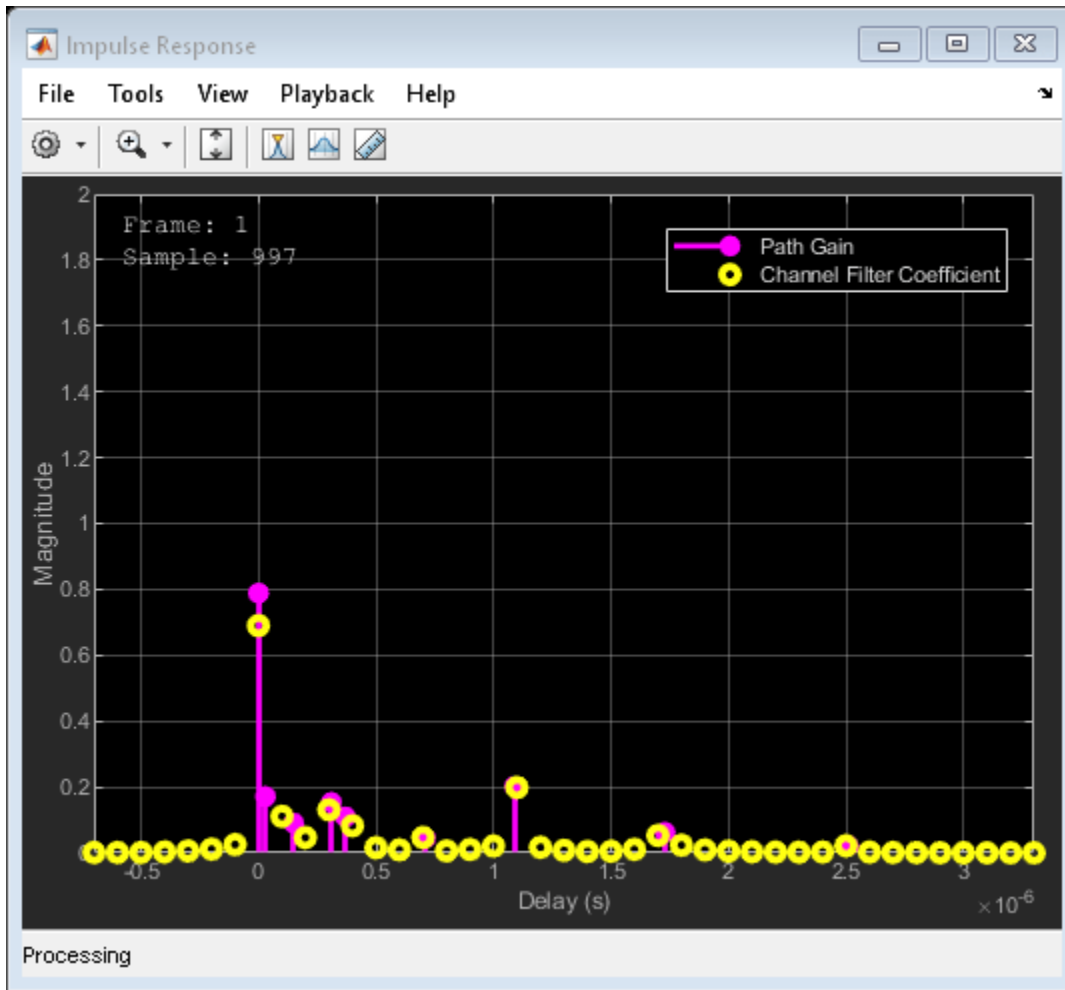

```
x = randi([0 1],1000,2);
y = mimoChan(x);
```

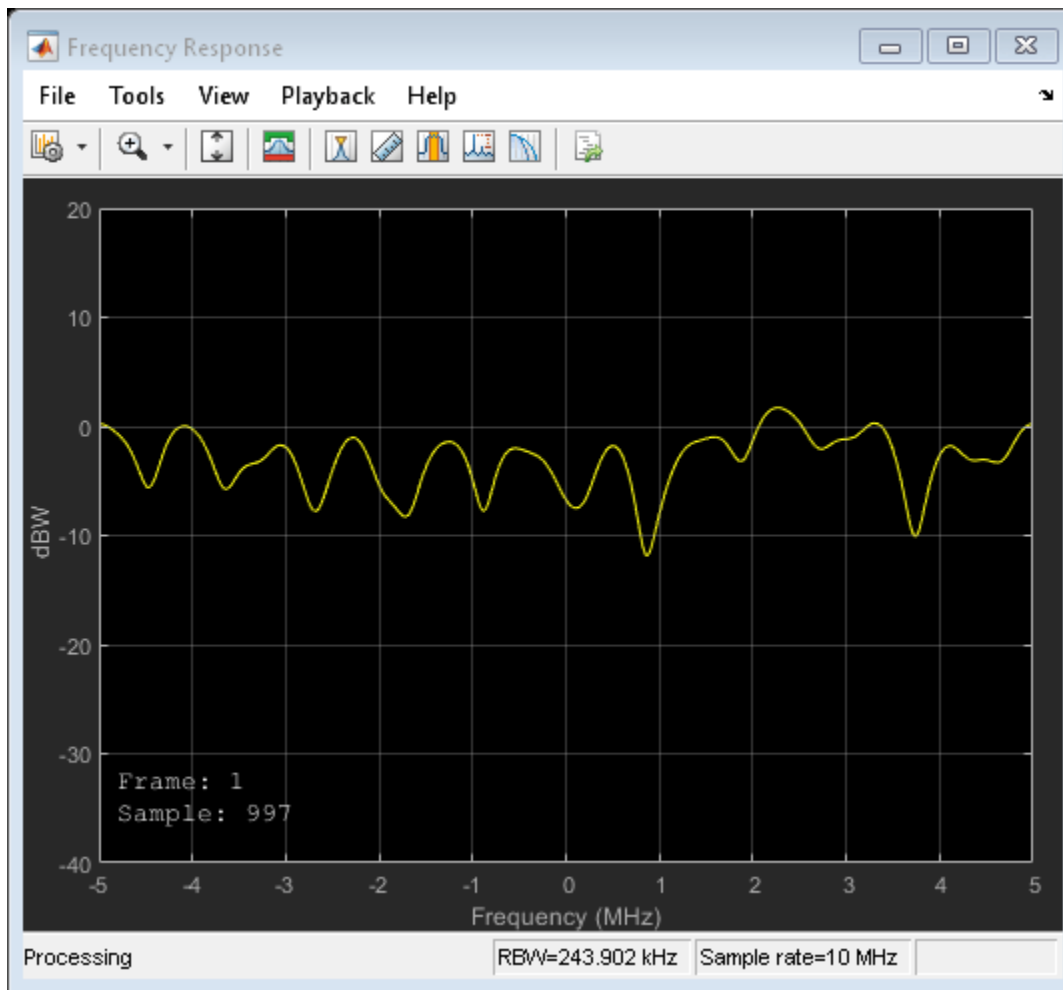

To view the antenna pair corresponding to the second transmit and first receive antennas, release the MIMO channel System object, and then set its `AntennaPairsToDisplay` property to `[2 1]`. Because the `AntennaPairsToDisplay` property is nontunable, to change its value, you must release the System object.

```
release(mimoChan)
mimoChan.AntennaPairsToDisplay = [2 1];
y = mimoChan(x);
```

Display Doppler for 2-by-2 MIMO Channel

Create and visualize the Doppler spectra of a MIMO channel that has two paths.

Construct a cell array of Doppler structures to be used in creating the channel. Set the Doppler spectrum of the first path to be bell shaped and the second path to be flat.

```
dp{1} = doppler('Bell');
dp{2} = doppler('Flat');
```

Create a 2-by-2 MIMO channel System object, specifying two paths and a maximum Doppler shift of 100 Hz, disabling the channel filtering, and enabling the visualization of the Doppler spectrum for the first Doppler path.

```
mimoChan = comm.MIMOChannel('SampleRate',1000, ...
    'PathDelays',[0 0.002], ...
    'AveragePathGains',[0 -3], ...
    'MaximumDopplerShift',100, ...
    'DopplerSpectrum',dp, ...
```

```

'ChannelFiltering',false, ...
'NumSamples',10000, ...
'Visualization','Doppler spectrum', ...
'PathsForDopplerDisplay',1);

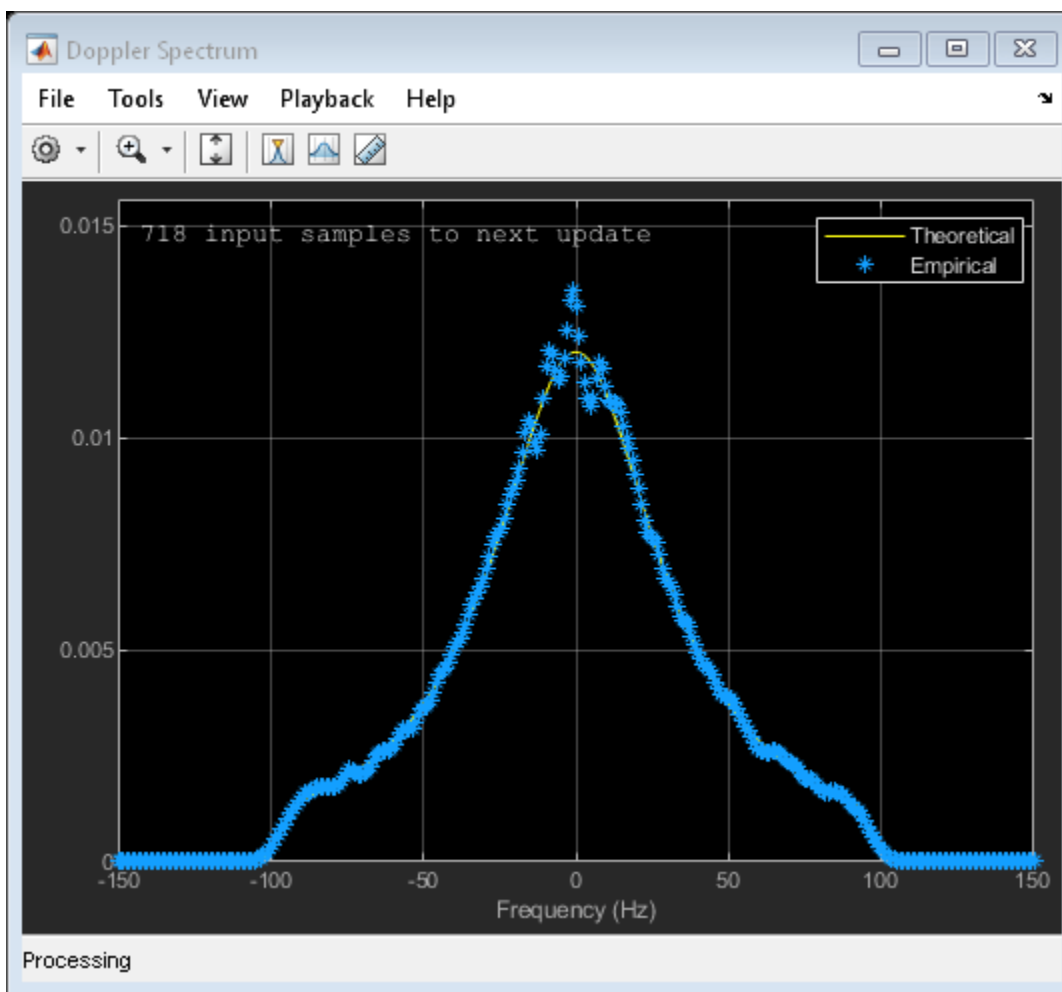

```

Use the MIMO channel to generate the Doppler spectrum of the first path. Because the Doppler spectrum plot does not update until its buffer is filled, call the MIMO channel object multiple times to help improve the accuracy of the estimate. Observe that the spectrum has a bell shape and that its minimum and maximum frequencies fall within the limits set by the `MaximumDopplerShift` property.

```

for k = 1:25
    mimoChan();
end

```

Release the MIMO channel object, and set its `PathsForDopplerDisplay` property to display the second path. Because the `PathsForDopplerDisplay` property is nontunable, to change its value, you must release the System object. Call the object multiple times to display the Doppler spectrum of the second path. The results show that the spectrum is flat.

```

release(mimoChan)
mimoChan.PathsForDopplerDisplay = 2;

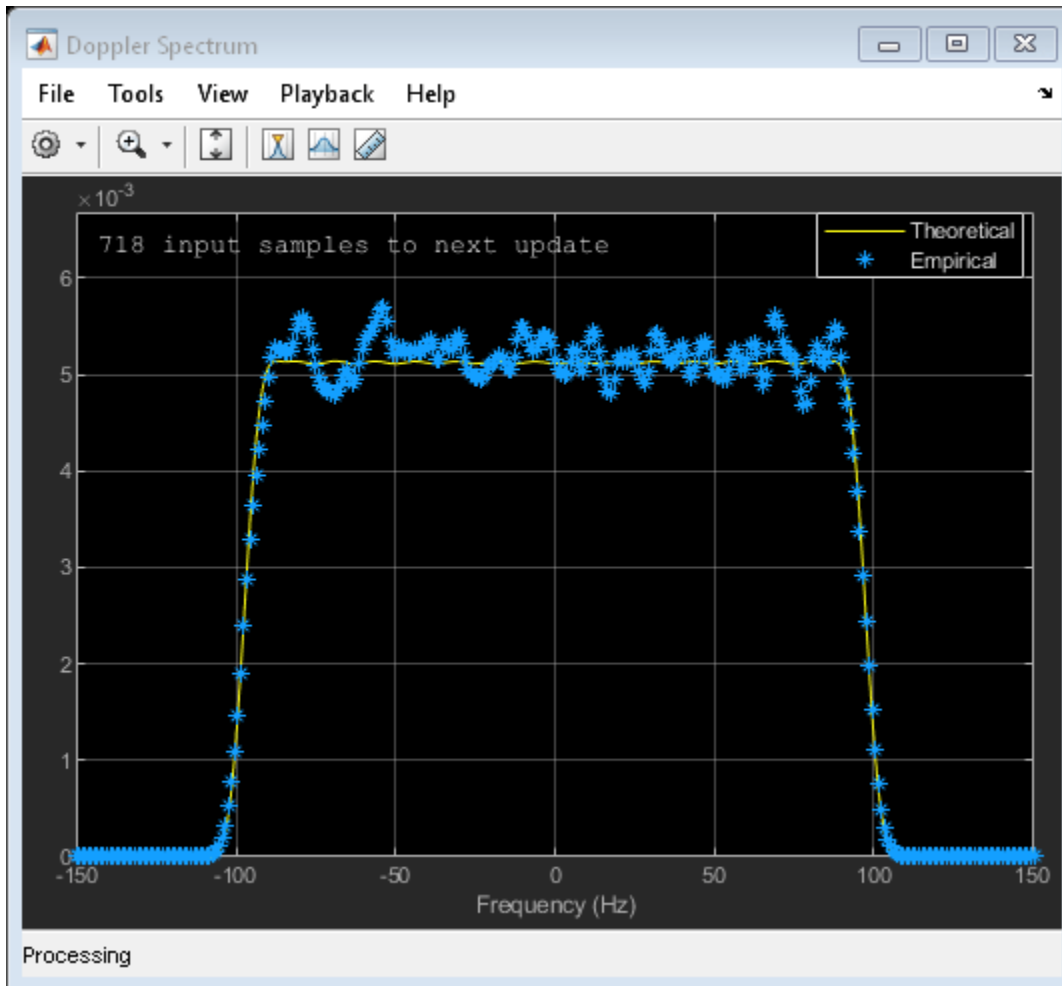

```

```

for k = 1:25
    y = mimoChan();
end

```

Model MIMO Channel Using Sum-of-Sinusoids Technique

Show that the channel state is maintained for discontinuous transmissions by using MIMO channel System objects configured to use the sum-of-sinusoids fading technique. Observe discontinuous channel response segments overlaid on a continuous channel response.

Set the channel properties.

```

fs = 1000;           % Sample rate (Hz)
pathDelays = [0 2.5e-3]; % Path delays (s)
pathPower = [0 -6]; % Path power (dB)
fD = 5;             % Maximum Doppler shift (Hz)
ns = 1000;         % Number of samples
nsdel = 100;       % Number of samples for delayed paths

```

Define a continuous time span and three discontinuous time segments over which to plot and view the channel response. View a 1000-sample continuous channel response starting at time 0 and three 100-sample channel responses starting at times 0.1, 0.4, and 0.7 seconds, respectively.

```
to0 = 0.0;
to1 = 0.1;
to2 = 0.4;
to3 = 0.7;
t0 = (to0:ns-1)/fs;      % Transmission 0
t1 = to1+(0:nsdel-1)/fs; % Transmission 1
t2 = to2+(0:nsdel-1)/fs; % Transmission 2
t3 = to3+(0:nsdel-1)/fs; % Transmission 3
```

Create a flat-fading 2-by-2 MIMO channel System object, disabling channel filtering and specifying a 1000 Hz sampling rate, the sum-of-sinusoids fading technique, and the number of samples to view. Specify a seed value so that results can be repeated. Use the default `InitialTime` property setting so that the fading channel is simulated from time 0.

```
mimoChan1 = comm.MIMOChannel('SampleRate',fs, ...
    'MaximumDopplerShift',fD, ...
    'RandomStream','mt19937ar with seed', ...
    'Seed',17, ...
    'FadingTechnique','Sum of sinusoids', ...
    'ChannelFiltering',false, ...
    'NumSamples',ns);
```

Create a clone of the MIMO channel System object. Change the number of samples for the delayed paths and the source for the initial time so that you can specify the fading channel offset time as an input argument when calling the System object.

```
mimoChan2 = clone(mimoChan1);
mimoChan2.InitialTimeSource = 'Input port';
mimoChan2.NumSamples = nsdel;
```

Save the path gain output for the continuous channel response by using the `mimoChan1` object and for the discontinuous delayed channel responses by using the `mimoChan2` object with initial time offsets provided as input arguments.

```
pg0 = mimoChan1();
pg1 = mimoChan2(to1);
pg2 = mimoChan2(to2);
pg3 = mimoChan2(to3);
```

Compare the number of samples processed by the two channels by using the `info` method. The results show that `mimoChan1` processed 1000 samples and that `mimoChan2` processed only 300 samples.

```
G = info(mimoChan1);
H = info(mimoChan2);
[G.NumSamplesProcessed H.NumSamplesProcessed]

ans = 1×2
```

```
    1000    300
```

Convert the path gains into decibels for the path corresponding to the first transmit and first receive antenna.

```

pathGain0 = 20*log10(abs(pg0(:,1,1,1)));
pathGain1 = 20*log10(abs(pg1(:,1,1,1)));
pathGain2 = 20*log10(abs(pg2(:,1,1,1)));
pathGain3 = 20*log10(abs(pg3(:,1,1,1)));

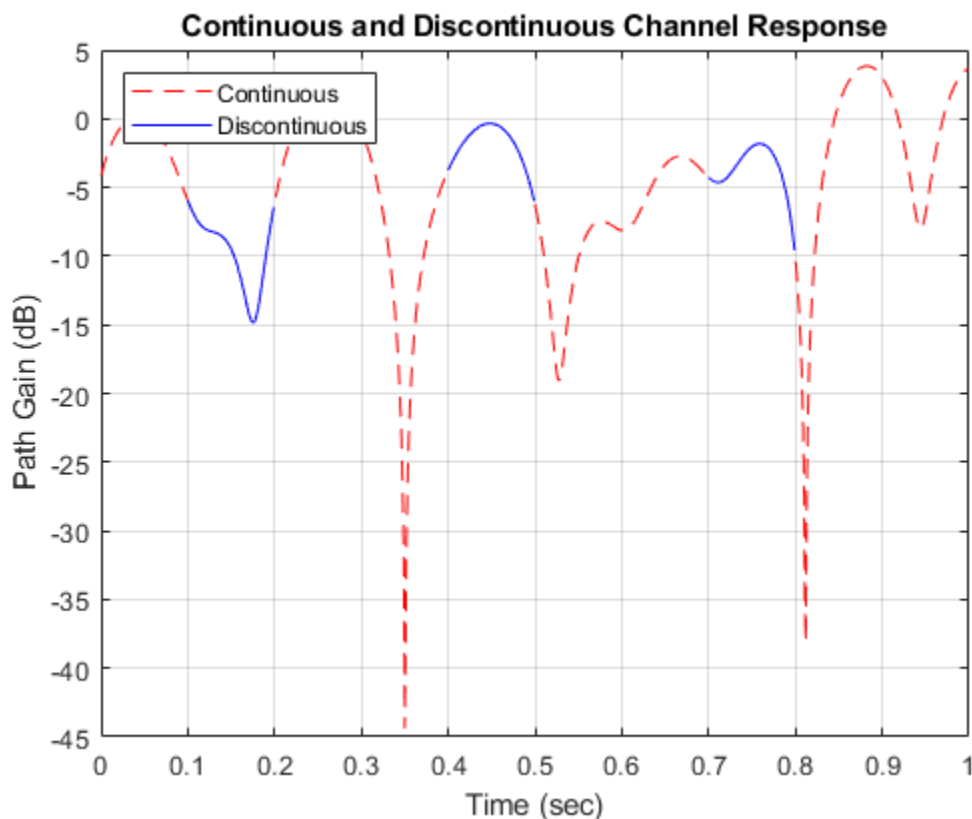

```

Plot the path gains for the continuous and discontinuous cases. The results show that the gains for the three segments match the gain for the continuous case. The alignment of the two shows that the sum-of-sinusoids technique is ideally suited to the simulation of packetized data because the channel characteristics are maintained even when data is not transmitted.

```

plot(t0,pathGain0,'r--')
hold on
plot(t1,pathGain1,'b')
plot(t2,pathGain2,'b')
plot(t3,pathGain3,'b')
grid
title('Continuous and Discontinuous Channel Response')
xlabel('Time (sec)')
ylabel('Path Gain (dB)')
legend('Continuous','Discontinuous','location','nw')

```

Calculate Execution Time Advantage Using Sum-of-Sinusoids Technique

Demonstrate the advantage of using the sum-of-sinusoids fading technique when simulating a channel with burst data.

Set the simulation parameters such that the sampling rate is 100 kHz, the total simulation time is 100 seconds, and the duty cycle for the burst data is 25%.

```
fs = 1e5; % Hz
tsim = 100; % seconds
dutyCycle = 0.25;
```

Create a flat-fading 2-by-2 MIMO channel System object, specifying the sample rate and using the default filtered Gaussian noise technique.

```
fgn = comm.MIMOChannel('SampleRate',fs);
```

Create a similar MIMO channel System object, specifying the same sample rate as the previous MIMO channel object but using the sum-of-sinusoids technique. Additionally specify 48 sinusoids and for the fading process start times to be given as an input argument.

```
sos = comm.MIMOChannel('SampleRate',fs, ...
    'FadingTechnique','Sum of sinusoids', ...
    'NumSinusoids',48, ...
    'InitialTimeSource','Input port');
```

Run a continuous sequence of random bits through the filtered Gaussian noise MIMO channel object. Use the `tic` and `toc` stopwatch timer functions to measure the execution time of the System object call.

```
tic
y = fgn(randi([0 1],fs*tsim,2));
tFGN = toc;
```

To transmit a data burst each second, pass random bits through the sum-of-sinusoids MIMO channel object by calling it inside of a `for` loop. Use the `tic` and `toc` stopwatch timer functions to measure the execution time.

```
tic
for k = 1:tsim
    z = sos(randi([0 1],fs*dutyCycle,2),0.5+(k-1));
end
tSOS = toc;
```

Compare the ratio of the sum-of-sinusoids execution time to the filtered Gaussian noise execution time. The ratio is less than one, which indicates that the sum-of-sinusoids technique is faster than the filtered Gaussian noise technique.

```
tSOS/tFGN
ans = 0.3323
```

Reciprocal Downlink and Uplink Transmissions in MIMO Channel

Using one MIMO channel System object™ and two identically configured channel filter System objects, switch a link-level simulation between 3-by-2 downlink and reciprocal 2-by-3 uplink signal transmissions.

Define system parameters.

```

modOrder = 256;           % Modulation order
Nant1 = 3;                % Number of 'transmit' antennas
Nant2 = 2;                % Number of 'receive' antennas
Rs = 1e6;                 % Sample rate
pd = [0 1.5 2.3]*1e-6;   % Path delays
frmLen = 1e3;             % Frame length

```

Create a MIMO channel System object™, configuring it for path gain generation by disabling channel filtering.

```

chan = comm.MIMOChannel( ...
    'SampleRate',Rs, ...
    'PathDelays',pd, ...
    'AveragePathGains',[1.5 1.2 0.2], ...
    'MaximumDopplerShift',300, ...
    'SpatialCorrelationSpecification','none', ...
    'NumTransmitAntennas',Nant1, ...
    'NumReceiveAntennas',Nant2, ...
    'ChannelFiltering',false, ...
    'NumSamples',frmLen);

```

Create identical channel filter System objects for both transmission directions: one channel filter for the Nant1-by-Nant2 downlink channel (3 transmit antennas to 2 receive antennas) and a reciprocal channel filter for the Nant2-by-Nant1 uplink channel (2 transmit antennas to 3 receive antennas).

```

chanFiltDownlink = comm.ChannelFilter( ...
    'SampleRate',Rs, ...
    'PathDelays',pd);
chanFiltUplink = clone(chanFiltDownlink);

```

Downlink Transmission

Generate random path gains for one frame of the downlink 3-by-2 channel. Pass randomly generated 256-QAM signals through the 3-by-2 downlink channel.

```

pgDownlink = chan();
x = qammod(randi([0 modOrder-1],frmLen,Nant1),modOrder);
yDL = chanFiltDownlink(x,pgDownlink);

```

Uplink Transmission

Switch the link direction. Run the channel object to generate another frame of path gains, permuting its 3rd (Tx) and 4th (Rx) dimensions for the reciprocal uplink 2-by-3 channel. Pass randomly generated 256-QAM signals through the 2-by-3 reciprocal uplink channel.

```

pgUplink = permute(chan(),[1 2 4 3]);
x = qammod(randi([0 modOrder-1],frmLen,Nant2),modOrder);
yUL = chanFiltUplink(x,pgUplink);

```

Downlink and Uplink Array Dimensions

Show the sizes of the downlink and uplink path gain arrays returned by the MIMO channel object as an N_S -by- N_P -by- N_T -by- N_R array.

- N_S is the number of samples.
- N_P is the number of path delays.

- N_T is the number of transmit antennas. Nant1 for downlink and Nant2 for uplink.
- N_R is the number of receive antennas. Nant2 for downlink and Nant1 for uplink.

```
size(pgDownlink)
```

```
ans = 1×4
```

```
    1000         3         3         2
```

```
size(pgUplink)
```

```
ans = 1×4
```

```
    1000         3         2         3
```

Show the size of the channel output matrices returned by the MIMO channel object as an N_S -by- N_R matrix. N_S is the number of samples. N_R is the number of receive antennas.

```
size(yDL)
```

```
ans = 1×2
```

```
    1000         2
```

```
size(yUL)
```

```
ans = 1×2
```

```
    1000         3
```

Algorithms

The fading processing per link is described in Methodology for Simulating Multipath Fading Channels and assumes the same parameters for all ($N_T \times N_R$) links of the MIMO channel. Each link comprises all multipaths for that link.

The Kronecker Model

The Kronecker model assumes that the spatial correlations at the transmit and receive sides are separable. Equivalently, the direction of departure (DoD) and directions of arrival (DoA) spectra are assumed to be separable. The full correlation matrix is:

$$R_H = E[R_t \otimes R_r]$$

- The \otimes symbol represents the Kronecker product.
- R_t is the correlation matrix at the transmit side, $R_t = E[H^H H]$, and is of size N_T -by- N_T .
- R_r is the correlation matrix at the receive side, $R_r = E[HH^H]$, and is of size N_R -by- N_R .

You can obtain a realization of the MIMO channel matrix as:

$$H = R_r^2 A R_t^2$$

A is an N_R -by- N_T matrix of independent identically distributed complex Gaussian variables with zero mean and unit variance.

Cutoff Frequency Factor

The cutoff frequency factor, f_c , is dependent on the type of Doppler spectrum.

- For any Doppler spectrum type other than Gaussian and bi-Gaussian, f_c equals 1.
- For a doppler('Gaussian') spectrum type, f_c equals `NormalizedStandardDeviation` $\times \sqrt{2\log 2}$.
- For a doppler('BiGaussian') spectrum type:
 - If the `PowerGains(1)` and `NormalizedCenterFrequencies(2)` field values are both 0, then f_c equals `NormalizedStandardDeviation(1)` $\times \sqrt{2\log 2}$.
 - If the `PowerGains(2)` and `NormalizedCenterFrequencies(1)` field values are both 0, then f_c equals `NormalizedStandardDeviation(2)` $\times \sqrt{2\log 2}$.
 - If the `NormalizedCenterFrequencies` field value is [0, 0] and the `NormalizedStandardDeviation` field has two identical elements, then f_c equals `NormalizedStandardDeviation(1)` $\times \sqrt{2\log 2}$.
 - In all other cases, f_c equals 1.

Antenna Selection

When the object is in antenna-selection mode, it uses these algorithms to process an input signal.

- All random path gains are always generated and keep evolving for each link, whether or not a given link is selected. The path gain values output for the nonselected links are populated with NaN.
- The spatial correlation applies to only the selected transmit and receive antennas, and the correlation coefficients are the corresponding entries in the transmit, receive, or combined correlation matrices. That is, the spatial correlation matrix for the selected transmit or receive antennas is a submatrix of the transmit, receive, or combined spatial correlation matrix property value.
- For signal paths that are associated with nonactive antennas, a signal with zero power is transmitted to the channel filter.
- Channel output normalization happens over the number of selected receive antennas.

comm.MLSEEqualizer

Package: comm

Equalize using maximum likelihood sequence estimation

Description

The `MLSEEqualizer` object uses the Viterbi algorithm to equalize a linearly modulated signal through a dispersive channel. The object processes input frames and outputs the maximum likelihood sequence estimate (MLSE) of the signal. This processing uses an estimate of the channel modeled as a finite impulse response (FIR) filter.

To equalize a linearly modulated signal and output the maximum likelihood sequence estimate:

- 1 Define and set up your maximum likelihood sequence estimate equalizer object. See “Construction” on page 3-915.
- 2 Call `step` to equalize a linearly modulated signal and output the maximum likelihood sequence estimate according to the properties of `comm.MLSEEqualizer`. The behavior of `step` is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj, x)` and `y = obj(x)` perform equivalent operations.

Construction

`H = comm.MLSEEqualizer` creates a maximum likelihood sequence estimation equalizer (MLSEE) System object, `H`. This object uses the Viterbi algorithm and a channel estimate to equalize a linearly modulated signal that has been transmitted through a dispersive channel.

`H = comm.MLSEEqualizer(Name, Value)` creates an MLSEE object, `H`, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as `(Name1, Value1, ..., NameN, ValueN)`.

`H = comm.MLSEEqualizer(CHANNEL, Name, Value)` creates an MLSEE object, `H`. This object has the `Channel` property set to `CHANNEL`, and the other specified properties set to the specified values.

Properties

ChannelSource

Source of channel coefficients

Specify the source of the channel coefficients as one of `Input port | Property`. The default is `Property`.

Channel

Channel coefficients

Specify the channel as a numeric, column vector containing the coefficients of an FIR filter. The default is `[1;0.7;0.5;0.3]`. The length of this vector determines the memory length of the channel. This must be an integer multiple of the samples per symbol, that you specify in the `SamplesPerSymbol` on page 3-0 property. This property applies when you set the `ChannelSource` on page 3-0 property to `Property`.

Constellation

Input signal constellation

Specify the constellation of the input modulated signal as a complex vector. The default is `[1+1i -1+1i -1-1i 1-1i]`.

TracebackDepth

Traceback depth of Viterbi algorithm

Specify the number of trellis branches (the number of symbols), the Viterbi algorithm uses to construct each traceback path. The default is 21. The traceback depth influences the decoding accuracy and delay. The decoding delay represents the number of zero symbols that precede the first decoded symbol in the output. When you set the `TerminationMethod` on page 3-0 property to `Continuous`, the decoding delay equals the number of zero symbols of this property. When you set the `TerminationMethod` property to `Truncated`, there is no output delay.

TerminationMethod

Termination method of Viterbi algorithm

Specify the termination method of the Viterbi algorithm as one of `Continuous` | `Truncated`. The default is `Truncated`. When you set this property to `Continuous`, the object initializes the Viterbi algorithm metrics of all the states to 0 in the first call to the `step` method. Then, the object saves its internal state metric at the end of each frame, for use with the next frame. When you set this property to `Truncated`, the object resets at every frame. The Viterbi algorithm processes each frame of data independently, resetting the state metric at the end of each frame. The traceback path always starts at the state with the minimum metric. The initialization of the state metrics depends on whether you specify a preamble or postamble. If you set the `PreambleSource` on page 3-0 property to `None`, the object initializes the metrics of all the states to 0 at the beginning of each data frame. If you set the `PreambleSource` property to `Property`, the object uses the preamble that you specify at the `Preamble` on page 3-0 property, to initialize the state metrics at the beginning of each data frame. When you specify a preamble, the traceback path ends at one of the states represented by that preamble. If you set the `PostambleSource` on page 3-0 property to `None`, the traceback path starts at the state with the smallest metric. If you set the `PostambleSource` property to `Property`, the traceback path begins at the state represented by the postamble that you specify at the `Postamble` on page 3-0 property. If the postamble does not decode to a unique state, the decoder identifies the smallest of all possible decoded states that are represented by the postamble. The decoder then begins traceback decoding at that state. When you set this property to `Truncated`, the `step` method input data signal must contain at least `TracebackDepth` on page 3-0 symbols, not including an optional preamble.

ResetInputPort

Enable equalizer reset input

Set this property to `true` to enable an additional input to the `step` method. The default is `false`. When this input is a nonzero, double-precision or logical scalar value, the object resets the states of

the equalizer. This property applies when you set the `TerminationMethod` on page 3-0 property to `Continuous`.

PreambleSource

Source of preamble

Specify the source of the preamble that is expected to precede the input signal. Choose from `None` | `Property`. The default is `None`. Set this property to `Property` to specify a preamble using the `Preamble` on page 3-0 property. This property applies when you set the `TerminationMethod` on page 3-0 property to `Truncated`.

Preamble

Preamble that precedes input signals

Specify a preamble that is expected to precede the data in the input signal as an integer, row vector. The default is `[0 3 2 1]`. The values of the preamble should be between 0 and $M-1$, where M is the length of the signal constellation that you specify in the `Constellation` on page 3-0 property. An integer value of $k-1$ in the vector corresponds to the k -th entry in the vector stored in the `Constellation` property. This property applies when you set the `TerminationMethod` on page 3-0 property to `Truncated` and the `PreambleSource` on page 3-0 property to `Property`.

PostambleSource

Source of postamble

Specify the source of the postamble that is expected to follow the input signal. Choose from `None` | `Property`. The default is `None`. Set this property to `Property` to specify a postamble in the `Postamble` on page 3-0 property. This property applies when you set the `TerminationMethod` on page 3-0 property to `Truncated`.

Postamble

Postamble that follows input signals

Specify a postamble that is expected to follow the data in the input signal as an integer row vector. The default is `[0 2 3 1]`. The values of the postamble should be between 0 and $M-1$. In this case, M indicates the length of the `Constellation` on page 3-0 property. An integer value of $k-1$ in the vector corresponds to the k -th entry in the vector specified in the `Constellation` property. This property applies when you set the `TerminationMethod` on page 3-0 property to `Truncated` and the `PostambleSource` on page 3-0 property to `Property`. The default is `[0 2 3 1]`.

SamplesPerSymbol

Number of samples per symbol

Specify the number of samples per symbol in the input signal as an integer scalar value. The default is 1.

Examples

MLSE Equalize QPSK Signal Through Dispersive Channel

This example shows how to use an MLSE equalizer to remove the effects of a frequency-selective channel.

Specify static channel coefficients.

```
chCoeffs = [.986; .845; .237; .12345+.311i];
```

Create an MLSE equalizer object. Create an error rate calculator object.

```
mlse = comm.MLSEEqualizer('TracebackDepth',10,...
    'Channel',chCoeffs,'Constellation',pskmod(0:3,4,pi/4));
errorRate = comm.ErrorRate;
```

The main processing loop includes these steps:

- Data generation
- QPSK modulation
- Channel filtering
- Signal equalization
- QPSK demodulation
- Error computation

```
for n = 1:50
    data= randi([0 3],100,1);
    modSignal = pskmod(data,4,pi/4,'gray');

    % Introduce channel distortion.
    chanOutput = filter(chCoeffs,1,modSignal);

    % Equalize the channel output and demodulate.
    eqSignal = mlse(chanOutput);
    demodData = pskdemod(eqSignal,4,pi/4,'gray');

    % Compute BER.
    errorStats = errorRate(data,demodData);
end
```

Display the bit error rate and the number of errors.

```
ber = errorStats(1)
numErrors = errorStats(2)
```

```
ber =
```

```
0
```

```
numErrors =
```

```
0
```

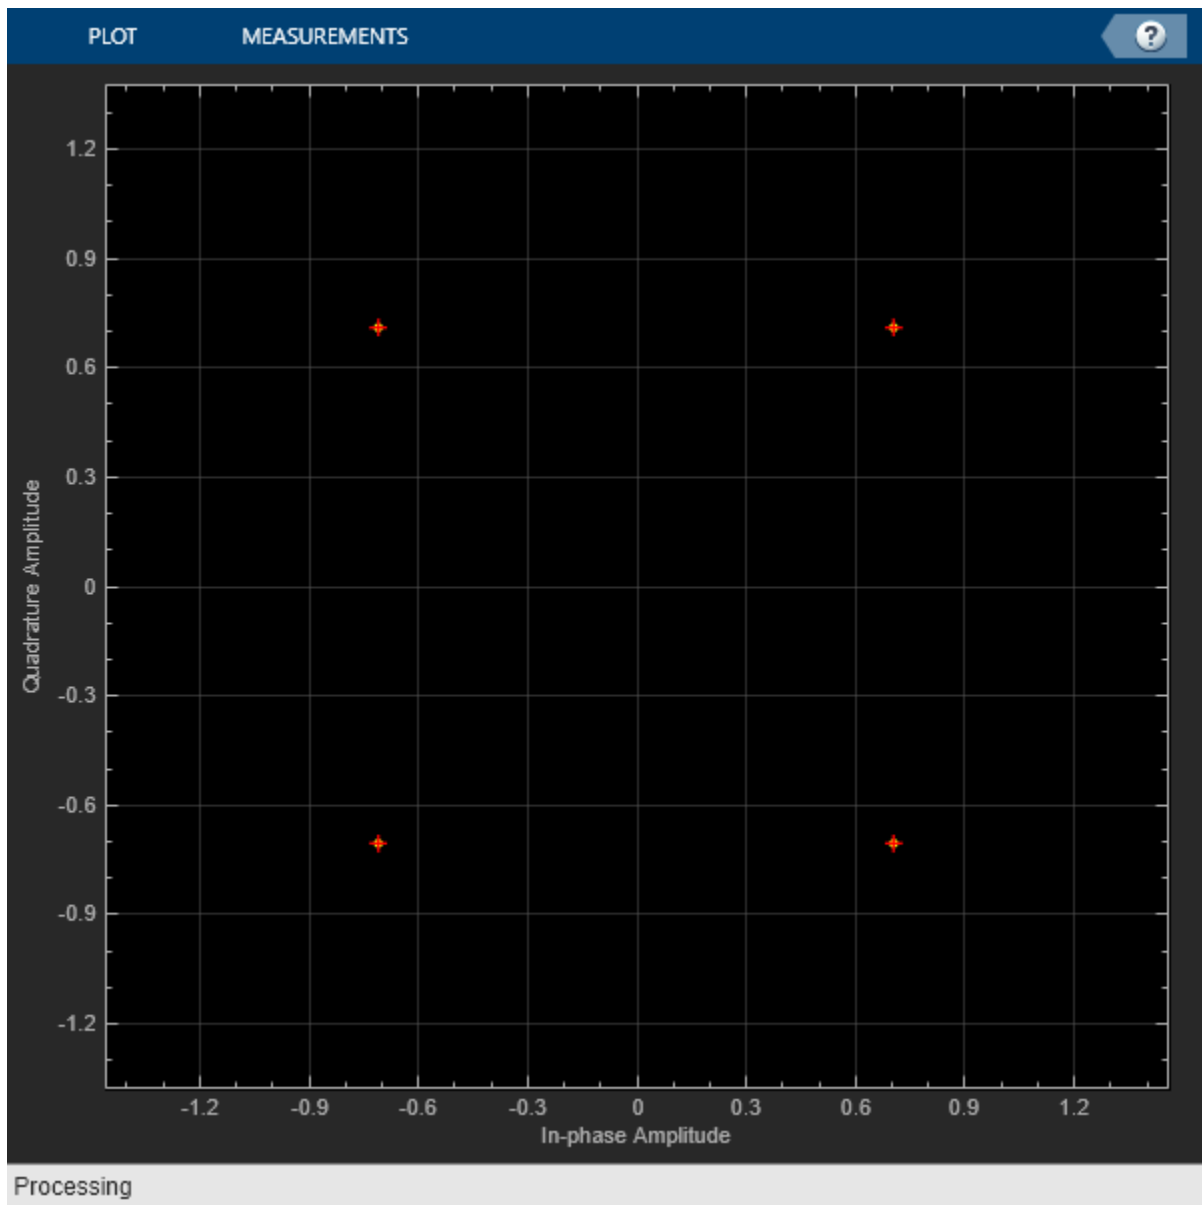

Plot the signal constellation prior to equalization.

```
constDiagram = comm.ConstellationDiagram;  
constDiagram(chanOutput)
```

Plot the signal constellation after equalization.

```
constDiagram(eqSignal)
```

The equalized symbols align perfectly with the QPSK reference constellation.

Algorithms

This object implements the algorithm, inputs, and outputs described on the MLSE Equalizer block reference page. The object properties correspond to the block parameters.

step

System object: comm.MLSEEqualizer

Package: comm

Equalize using maximum likelihood sequence estimation

Syntax

```
Y = step(H,X)
Y = step(H,X,CHANNEL)
Y = step(H,X,RESET)
```

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(H,X)` equalizes the linearly modulated data input, `X`, using the Viterbi algorithm. The `step` method outputs `Y`, the maximum likelihood sequence estimate of the signal. Input `X` must be a column vector of data type double or single.

`Y = step(H,X,CHANNEL)` uses `CHANNEL` as the channel coefficients when you set the `ChannelSource` property to 'Input port'. The channel coefficients input, `CHANNEL`, must be a numeric, column vector containing the coefficients of an FIR filter in descending order of powers of `z`. The length of this vector is the channel memory, which must be an integer multiple of the samples per input symbol specified in the `SamplesPerSymbol` property.

`Y = step(H,X,RESET)` uses `RESET` as the reset signal when you set the `TerminationMethod` property to 'Continuous' and the `ResetInputPort` property to true. The object resets when `RESET` has a non-zero value. `RESET` must be a double precision or logical scalar. You can combine optional input arguments when you set their enabling properties. Optional inputs must be listed in the same order as the order of the enabling properties. For example, `Y = step(H,X,CHANNEL,RESET)`.

Note `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications. For more information on changing property values, see "System Design in MATLAB Using System Objects".

comm.MSKDemodulator

Package: comm

Demodulate using MSK method and the Viterbi algorithm

Description

The `comm.MSKDemodulator` object demodulates a signal that was modulated using the minimum shift keying method. The object expects the input signal to be a baseband representation of a coherent modulated signal with no precoding. The initial phase offset property sets the initial phase of the modulated waveform.

To demodulate a signal that was modulated using minimum shift keying:

- 1 Define and set up your MSK demodulator object. See “Construction” on page 3-923.
- 2 Call `step` to demodulate the signal according to the properties of `comm.MSKDemodulator`. The behavior of `step` is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`H = comm.MSKDemodulator` creates a demodulator System object, `H`. This object demodulates the input minimum shift keying (MSK) modulated data using the Viterbi algorithm.

`H = comm.MSKDemodulator(Name, Value)` creates an MSK demodulator object, `H`, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as `(Name1, Value1, ..., NameN, ValueN)`.

Properties

BitOutput

Output data as bits

Specify whether the output consists of groups of bits or integer values. The default is `false`.

When you set this property to `false`, the `step` method outputs a column vector with a length equal to `N/SamplesPerSymbol` on page 3-0 . `N` represents the length of the input signal, which is the number of input baseband modulated symbols. The elements of the output vector are `-1` or `1`.

When you set the `BitOutput` on page 3-0 property to `true`, the `step` method outputs a binary column vector with a length equal to `N/SamplesPerSymbol`. The vector elements are bit values of `0` or `1`.

InitialPhaseOffset

Initial phase offset

Specify the initial phase offset of the input modulated waveform in radians as a real, numeric scalar value. The default is 0.

SamplesPerSymbol

Number of samples per input symbol

Specify the expected number of samples per input symbol as a positive, integer scalar value. The default is 8.

TracebackDepth

Traceback depth for Viterbi algorithm

Specify the number of trellis branches that the Viterbi algorithm uses to construct each traceback path as a positive, integer scalar value. The default is 16. The value of this property is also the output delay. This value indicates number of zero symbols that precede the first meaningful demodulated symbol in the output.

OutputDataType

Data type of output

Specify the output data type as one of `int8` | `int16` | `int32` | `double`, when you set the `BitOutput` on page 3-0 property to false. The default is `double`.

When you set the `BitOutput` property to true, specify the output data type as one of `logical` | `double`.

Methods

`step` Demodulate using MSK method and the Viterbi algorithm

Common to All System Objects	
<code>release</code>	Allow System object property value changes
<code>reset</code>	Reset internal states of System object

Examples**Demodulate an MSK Signal with Bit Inputs and Phase Offset**

```
% Create an MSK modulator, an AWGN channel, and an MSK demodulator. Use a
% phase offset of pi/4.
hMod = comm.MSKModulator('BitInput', true, ...
    'InitialPhaseOffset', pi/4);
hAWGN = comm.AWGNChannel('NoiseMethod', ...
    'Signal to noise ratio (SNR)', 'SNR', 0);
hDemod = comm.MSKDemodulator('BitOutput', true, ...
```

```

        'InitialPhaseOffset', pi/4);
% Create an error rate calculator, account for the delay caused by the Viterbi algorithm
hError = comm.ErrorRate('ReceiveDelay', hDemod.TracebackDepth);
for counter = 1:100
    % Transmit 100 3-bit words
    data = randi([0 1],300,1);
    modSignal = step(hMod, data);
    noisySignal = step(hAWGN, modSignal);
    receivedData = step(hDemod, noisySignal);
    errorStats = step(hError, data, receivedData);
end
fprintf('Error rate = %f\nNumber of errors = %d\n', ...
        errorStats(1), errorStats(2))

Error rate = 0.000000
Number of errors = 0

```

Map Binary Data to GMSK Signal

Map binary sequences of zeros and ones to the output of a GMSK modulator. This mapping also applies for MSK modulation.

Create a GMSK modulator that accepts binary inputs and has pulse length and samples per symbol values of 1.

```

gmskmodulator = comm.GMSKModulator('BitInput',true,'PulseLength',1, ...
        'SamplesPerSymbol',1);

```

Create an input sequence of all zeros. Modulate the sequence.

```

x = zeros(5,1);
y = gmskmodulator(x)

```

y = 5×1 complex

```

    1.0000 + 0.0000i
   -0.0000 - 1.0000i
   -1.0000 + 0.0000i
    0.0000 + 1.0000i
    1.0000 - 0.0000i

```

Determine the phase angle for each point. Use the `unwrap` function to show the trend.

```

theta = unwrap(angle(y))

theta = 5×1

```

```

    0
   -1.5708
   -3.1416
   -4.7124
   -6.2832

```

A sequence of zeros causes the phase to shift by $-\pi/2$ between samples.

Reset the modulator. Modulate an input sequence of all ones.

```
reset(gmskmodulator)
x = ones(5,1);
y = gmskmodulator(x)
```

y = 5×1 complex

```
1.0000 + 0.0000i
-0.0000 + 1.0000i
-1.0000 - 0.0000i
0.0000 - 1.0000i
1.0000 + 0.0000i
```

Determine the phase angle for each point. Use the `unwrap` function to show the trend.

```
theta = unwrap(angle(y))
```

theta = 5×1

```
0
1.5708
3.1416
4.7124
6.2832
```

A sequence of ones causes the phase to shift by $+\pi/2$ between samples.

Algorithms

This object implements the algorithm, inputs, and outputs described on the MSK Demodulator Baseband block reference page. The object properties correspond to the block parameters. For MSK the phase shift per symbol is $\pi/2$, which is a modulation index of 0.5.

Introduced in R2012a

step

System object: comm.MSKDemodulator

Package: comm

Demodulate using MSK method and the Viterbi algorithm

Syntax

$Y = \text{step}(H,X)$

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, $y = \text{step}(\text{obj}, x)$ and $y = \text{obj}(x)$ perform equivalent operations.

$Y = \text{step}(H,X)$ demodulates input data, X , with the MSK demodulator System object, H , and returns Y . X must be a double or single precision column vector with a length equal to an integer multiple of the number of samples per symbol you specify in the `SamplesPerSymbol` property.

Note `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications. For more information on changing property values, see “System Design in MATLAB Using System Objects”.

comm.MSKModulator

Package: comm

Modulate using MSK method

Description

The `MSKModulator` object modulates using the minimum shift keying method. The output is a baseband representation of the modulated signal. The `InitialPhaseOffset` property sets the initial phase of the output waveform, measured in radians.

To modulate a signal using minimum shift keying:

- 1 Define and set up your MSK modulator object. See “Construction” on page 3-928.
- 2 Call `step` to modulate the signal according to the properties of `comm.MSKModulator`. The behavior of `step` is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`H = comm.MSKModulator` creates a modulator System object, `H`. This object modulates the input signal using the minimum shift keying (MSK) modulation method.

`H = comm.MSKModulator(Name,Value)` creates an MSK modulator object, `H`, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as `(Name1,Value1,...,NameN,ValueN)`.

Properties

BitInput

Assume bit inputs

Specify whether the input is bits or integers. The default is `false`.

When you set the `BitInput` on page 3-0 property to `false`, the `step` method input must be a column vector with a double-precision or signed integer data type and of values equal to `-1` or `1`.

When you set the `BitInput` property to `true`, the `step` method input requires double-precision or logical data type column vector of 0s and 1s.

InitialPhaseOffset

Initial phase offset

Specify the initial phase of the modulated waveform in radians as a real, numeric scalar value. The default is 0.

SamplesPerSymbol

Number of samples per output symbol

Specify the upsampling factor at the output as a real, positive, integer scalar value. The default is 8. The upsampling factor indicates the number of output samples that the step method produces for each input sample.

OutputDataType

Data type of output

Specify output data type as one of `double` | `single`. The default is `double`.

Methods

`step` Modulate using MSK method

Common to All System Objects	
<code>release</code>	Allow System object property value changes
<code>reset</code>	Reset internal states of System object

Examples

Modulate an MSK Signal with Bit Inputs and Phase Offset

```
% Create an MSK modulator, an AWGN channel, and an MSK demodulator. Use a
% phase offset of pi/4.
hMod = comm.MSKModulator('BitInput', true, ...
    'InitialPhaseOffset', pi/4);
hAWGN = comm.AWGNChannel('NoiseMethod', ...
    'Signal to noise ratio (SNR)', 'SNR', 0);
hDemod = comm.MSKDemodulator('BitOutput', true, ...
    'InitialPhaseOffset', pi/4);
% Create an error rate calculator, account for the delay caused by the Viterbi algorithm
hError = comm.ErrorRate('ReceiveDelay', hDemod.TracebackDepth);
for counter = 1:100
    % Transmit 100 3-bit words
    data = randi([0 1], 300, 1);
    modSignal = step(hMod, data);
    noisySignal = step(hAWGN, modSignal);
    receivedData = step(hDemod, noisySignal);
    errorStats = step(hError, data, receivedData);
end
fprintf('Error rate = %f\nNumber of errors = %d\n', ...
    errorStats(1), errorStats(2))
```

```
Error rate = 0.000000
Number of errors = 0
```

Map Binary Data to GMSK Signal

Map binary sequences of zeros and ones to the output of a GMSK modulator. This mapping also applies for MSK modulation.

Create a GMSK modulator that accepts binary inputs and has pulse length and samples per symbol values of 1.

```
gmskmodulator = comm.GMSKModulator('BitInput',true,'PulseLength',1, ...  
                                   'SamplesPerSymbol',1);
```

Create an input sequence of all zeros. Modulate the sequence.

```
x = zeros(5,1);  
y = gmskmodulator(x)
```

y = 5×1 complex

```
1.0000 + 0.0000i  
-0.0000 - 1.0000i  
-1.0000 + 0.0000i  
0.0000 + 1.0000i  
1.0000 - 0.0000i
```

Determine the phase angle for each point. Use the `unwrap` function to show the trend.

```
theta = unwrap(angle(y))
```

theta = 5×1

```
0  
-1.5708  
-3.1416  
-4.7124  
-6.2832
```

A sequence of zeros causes the phase to shift by $-\pi/2$ between samples.

Reset the modulator. Modulate an input sequence of all ones.

```
reset(gmskmodulator)  
x = ones(5,1);  
y = gmskmodulator(x)
```

y = 5×1 complex

```
1.0000 + 0.0000i  
-0.0000 + 1.0000i  
-1.0000 - 0.0000i  
0.0000 - 1.0000i  
1.0000 + 0.0000i
```

Determine the phase angle for each point. Use the `unwrap` function to show the trend.

```
theta = unwrap(angle(y))
theta = 5×1
    0
    1.5708
    3.1416
    4.7124
    6.2832
```

A sequence of ones causes the phase to shift by $+\pi/2$ between samples.

GMSK vs. MSK

Compare Gaussian minimum shift keying (GMSK) and minimum shift keying (MSK) modulation schemes by plotting the eye diagram for GMSK with different pulse lengths and for MSK.

Set the samples per symbol variable.

```
sps = 8;
```

Generate random binary data.

```
data = randi([0 1],1000,1);
```

Create GMSK and MSK modulators that accept binary inputs. Set the `PulseLength` property of the GMSK modulator to 1.

```
gmskMod = comm.GMSKModulator('BitInput',true,'PulseLength',1, ...
    'SamplesPerSymbol',sps);
mskMod = comm.MSKModulator('BitInput',true,'SamplesPerSymbol',sps);
```

Modulate the data using the GMSK and MSK modulators.

```
modSigGMSK = gmskMod(data);
modSigMSK = mskMod(data);
```

Pass the modulated signals through an AWGN channel having an SNR of 30 dB.

```
rxSigGMSK = awgn(modSigGMSK,30);
rxSigMSK = awgn(modSigMSK,30);
```

Use the `eyediagram` function to plot the eye diagrams of the noisy signals. With the GMSK pulse length set to 1, the eye diagrams are nearly identical.

```
eyediagram(rxSigGMSK, sps, 1, sps/2)
```

`eyediagram(rxSigMSK,sps,1,sps/2)`

Set the `PulseLength` property for the GMSK modulator object to 3. Because the property is nontunable, the object must be released first.

```
release(gmskMod)
gmskMod.PulseLength = 3;
```

Generate a modulated signal using the updated GMSK modulator object and pass it through the AWGN channel.

```
modSigGMSK = gmskMod(data);
rxSigGMSK = awgn(modSigGMSK,30);
```

With continuous phase modulation (CPM) waveforms, such as GSMK, the waveform depends on values of the previous symbols as well as the present symbol. Plot the eye diagram of the GMSK signal to see that the increased pulse length results in an increase in the number of paths in the eye diagram.

```
eyediagram(rxSigGMSK,sps,1,sps/2)
```

Experiment by changing the `PulseLength` parameter of the GMSK modulator object to other values. If you set the property to an even number, you should set `gmskMod.InitialPhaseOffset` to $\pi/4$ and update the offset argument of the `eyediagram` function from `sps/2` to `0` for a better view of the modulated signal. In order to more clearly view the Gaussian pulse shape, you must use scopes that display the phase of the signal, as described in the “View CPM Phase Tree Using Simulink” example.

Algorithms

This object implements the algorithm, inputs, and outputs described on the MSK Demodulator Baseband block reference page. The object properties correspond to the block parameters. For MSK the phase shift per symbol is $\pi/2$, which is a modulation index of 0.5.

`comm.MSKDemodulator` | `comm.CPModulator` | `comm.CPMDemodulator`

Introduced in R2012a

step

System object: comm.MSKModulator

Package: comm

Modulate using MSK method

Syntax

$Y = \text{step}(H,X)$

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, $y = \text{step}(\text{obj}, x)$ and $y = \text{obj}(x)$ perform equivalent operations.

$Y = \text{step}(H,X)$ modulates input data, X , with the MSK modulator object, H . It returns the baseband modulated output, Y . Depending on the value of the `BitInput` property, input X can be a double precision, signed integer, or logical column vector. The length of output vector, Y , is equal to the number of input samples times the number of samples per symbol you specify in the `SamplesPerSymbol` property.

Note `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications. For more information on changing property values, see “System Design in MATLAB Using System Objects”.

comm.MSKTimingSynchronizer

Package: comm

Recover symbol timing phase using fourth-order nonlinearity method

Description

The `MSKTimingSynchronizer` object recovers the symbol timing phase of the input signal using a fourth-order nonlinearity method. This object implements a general non-data-aided feedback method that is independent of carrier phase recovery. This method requires prior compensation for the carrier frequency offset. This object is suitable for systems that use baseband minimum shift keying (MSK) modulation.

To recover the symbol timing phase of the input signal:

- 1 Define and set up your MSK timing synchronizer object. See “Construction” on page 3-937.
- 2 Call `step` to recover the symbol timing phase of the input signal according to the properties of `comm.MSKTimingSynchronizer`. The behavior of `step` is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`H = comm.MSKTimingSynchronizer` creates a timing phase synchronizer System object, `H`. This object recovers the symbol timing phase of the input signal using a fourth-order nonlinearity method.

`H = comm.MSKTimingSynchronizer(Name,Value)` creates an MSK timing synchronizer object, `H`, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as `(Name1,Value1,...,NameN,ValueN)`.

Properties

SamplesPerSymbol

Number of samples representing each symbol

Specify the number of samples that represent each symbol in the input signal as an integer-valued scalar greater than 1. The default is 4.

ErrorUpdateGain

Error update step size

Specify the step size for updating successive timing phase estimates as a positive, real scalar value. The default is 0.05. Typically, this number is less than $1/\text{SamplesPerSymbol}$ on page 3-0, which corresponds to a slowly varying timing phase. This property is tunable.

ResetInputPort

Enable synchronization reset input

Set this property to `true` to enable resetting the timing phase recovery process based on an input argument value. The default is `false`.

When you set this property to `true`, you must specify a reset input value to the `step` method.

When the reset input is a nonzero value, the object restarts the timing phase recovery process. When you set this property to `false`, the object does not restart.

ResetCondition

Condition for timing phase recovery reset

Specify the conditions to reset the timing phase recovery process as one of `Never` | `Every frame`. The default is `Never`.

When you set this property to `Never`, the phase recovery process never restarts. The object operates continuously, retaining information from one symbol to the next.

When you set this property to `Every frame`, the timing phase recovery restarts at the start of each frame of data. Thus, each time the object calls the `step` method. This property applies when you set the `ResetInputPort` on page 3-0 property to `false`.

Methods

`step` Recover symbol timing phase using fourth-order nonlinearity method

Common to All System Objects	
<code>release</code>	Allow System object property value changes
<code>reset</code>	Reset internal states of System object

Examples

Recover Timing Phase of MSK Signal

Create MSK modulator, variable fractional delay, and MSK timing synchronizer System objects.

```
mskMod = comm.MSKModulator('BitInput',true,'SamplesPerSymbol',14);
timingOffset = 0.2;
varDelay = dsp.VariableFractionalDelay;
mskTimingSync = comm.MSKTimingSynchronizer('SamplesPerSymbol',14,'ErrorUpdateGain', 0.05);
```

Main processing loop.

```
phEst = zeros(50,1);
for i = 1:50
    data = randi([0 1],100,1);    % Generate data
    modData = mskMod(data);      % Modulate data
```

```

% Apply timing offset error.
impairedData = varDelay(modData,timingOffset*14);
% Perform timing phase recovery.
[~,phase] = mskTimingSync(impairedData);
phEst(i) = phase(1)/14;
end

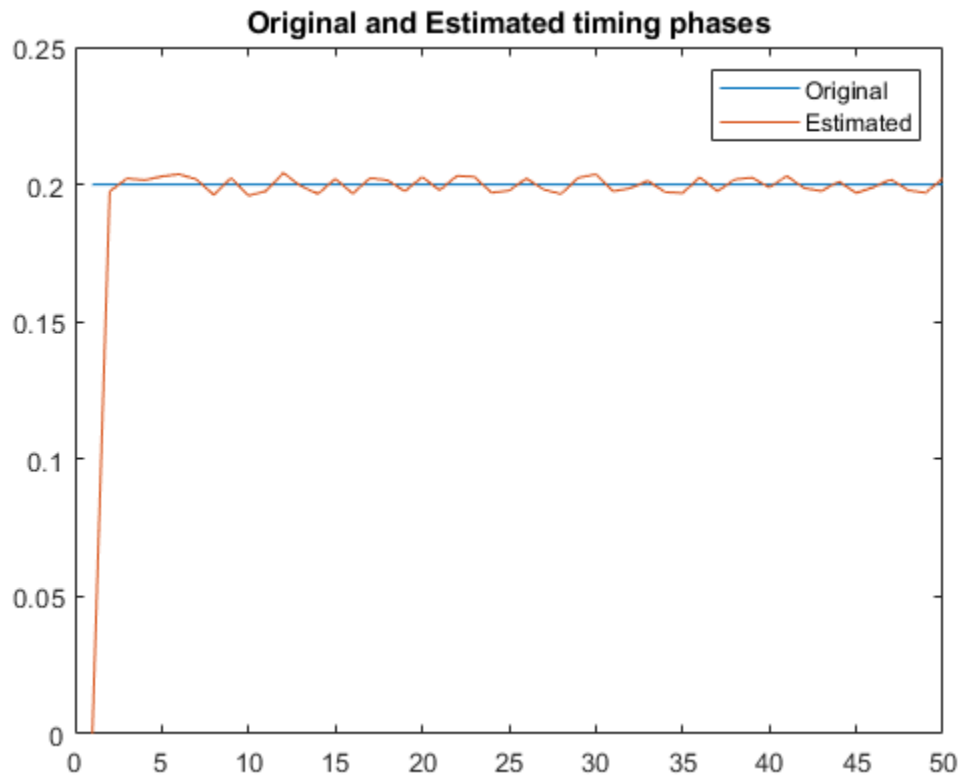

```

Plot the results.

```

plot(1:50,[0.2*ones(50,1) phEst]);
legend('Original','Estimated')
title('Original and Estimated timing phases');

```

Algorithms

This object implements the algorithm, inputs, and outputs described on the MSK-Type Signal Timing Recovery block reference page. The object properties correspond to the block parameters, except:

- The object corresponds to the MSK-Type Signal Timing Recovery block with the **Modulation type** parameter set to MSK.
- The **Reset** parameter corresponds to the ResetInputPort on page 3-0 and ResetCondition on page 3-0 properties.

Extended Capabilities

`comm.SymbolSynchronizer`

Introduced in R2012a

step

System object: comm.MSKTimingSynchronizer

Package: comm

Recover symbol timing phase using fourth-order nonlinearity method

Syntax

`[Y,PHASE] = step(H,X)`

`[Y,PHASE] = step(H,X,R)`

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`[Y,PHASE] = step(H,X)` recovers the timing phase and returns the time-synchronized signal, `Y`, and the estimated timing phase, `PHASE`, for input signal `X`. `X` must be a double or single precision complex column vector.

`[Y,PHASE] = step(H,X,R)` restarts the timing phase recovery process when you input a reset signal, `R`, that is non-zero. `R` must be a logical or double scalar. This syntax applies when you set the `ResetInputPort` property to true.

Note `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications. For more information on changing property values, see “System Design in MATLAB Using System Objects”.

comm.MultibandCombiner

Package: comm

Frequency-shift and combine signals

Description

The `comm.MultibandCombiner` System object interpolates, shifts input signals to the specified frequency bands, and then combines them into a single signal. For more information, see the “Algorithms” on page 3-947 section.

To frequency-shift and combine signals:

- 1 Create the `comm.MultibandCombiner` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

Creation

Syntax

```
multibandcombiner = comm.MultibandCombiner  
multibandcombiner = comm.MultibandCombiner(Name,Value)
```

Description

`multibandcombiner = comm.MultibandCombiner` creates a multiband combiner System object to frequency-shift and combine input signals.

`multibandcombiner = comm.MultibandCombiner(Name,Value)` sets properties using one or more name-value arguments. For example, `'InputSampleRate',2e6` specifies an input signal sample rate of 2 MHz.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see [System Design in MATLAB Using System Objects](#).

InputSampleRate — Input signal sample rate

1e6 (default) | positive scalar

Input signal sample rate in Hz, specified as a positive scalar.

Data Types: double

FrequencyOffsets — Frequency offsets

[0 1e6] (default) | scalar | 1-by- N_{chan} vector

Frequency offsets in Hz, specified as one of these options.

- Scalar — Each channel of the input signal is frequency-shifted by this scalar value.
- 1-by- N_{chan} vector — Each channel of the input signal is frequency-shifted by the corresponding value in this vector. N_{chan} is the number of channels in the input signal x .

Data Types: double

OutputSampleRateSource — Source of output sample rate

'Auto' (default) | 'Property'

Source of the output sample rate, specified as one of these values.

- 'Auto' — The object interpolates the input signals to ensure that the resulting sample rate of the signals is sufficient to avoid distorting the frequency content of the original signals after they are frequency-shifted to produce the output signal.
- 'Property' — Specify the output sample rate by using the OutputSampleRate property.

Data Types: char | string

OutputSampleRate — Output signal sample rate

3e6 (default) | positive scalar

Output signal sample rate in Hz, specified as a positive scalar.

Tips

To avoid distortion, specify this value to be greater than or equal to the automatically computed output sample rate. To determine the automatically computed output sample rate, first run the object with the OutputSampleRateSource property set to 'Auto'.

Dependencies

To enable this property, set the OutputSampleRateSource property to 'Property'.

Data Types: double

Usage

Syntax

```
y = multibandcombiner(x)
```

Description

$y = \text{multibandcombiner}(x)$ interpolates, frequency-shifts, and combines the input signal into one output signal.

Input Arguments

x — Input signals

N_{samp} -by- N_{chan} matrix

Input signals, specified as an N_{samp} -by- N_{chan} matrix. N_{samp} is the number of input samples per channel, and N_{chan} is the number of channels.

Data Types: double | single

Output Arguments

y — Output signal

N_{out} -by-1 vector

Output signal, returned as an N_{out} -by-1 vector of the same data type as input signal **x**. N_{out} is the number of output samples. For more information, see “Algorithms” on page 3-947.

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Specific to `comm.MultibandCombiner`

info Characteristic information about multiband combining

Common to All System Objects

step Run System object algorithm

release Release resources and allow changes to System object property values and input characteristics

reset Reset internal states of System object

Examples

Combine QPSK and GMSK Signals

Combine two 60 KHz frequency bands that are adjacent to each other.

Set simulation parameters.

```
M = 4;           % QPSK modulation
N = 2000;        % Frame length
Fs1 = 60e3;      % Input sample rate
```

Generate QPSK and GMSK signals.

```
data = randi([0,M-1],N,1);
modSig = pskmod(data,M,pi/4,'gray');
qpskTxFilter = comm.RaisedCosineTransmitFilter( ...
    OutputSamplesPerSymbol=2);
qpsksig = qpskTxFilter(modSig);
```

```
data = randi([0 1],N,1);
gmskMod = comm.GMSKModulator( ...
    BitInput=true, ...
    SamplesPerSymbol=2);
gmsksig = gmskMod(data);
```

Create a multiband combiner System object. Use the `info` object function to determine the output sample rate for the combined signal. Use this output sample rate when configuring the spectrum analyzer objects.

```
mbc = comm.MultibandCombiner( ...
    InputSampleRate=Fs1, ...
    FrequencyOffsets=[-30e3 30e3], ...
    OutputSampleRateSource='Auto');
mbcInfo = info(mbc);
Fs2 = mbcInfo.OutputSampleRate

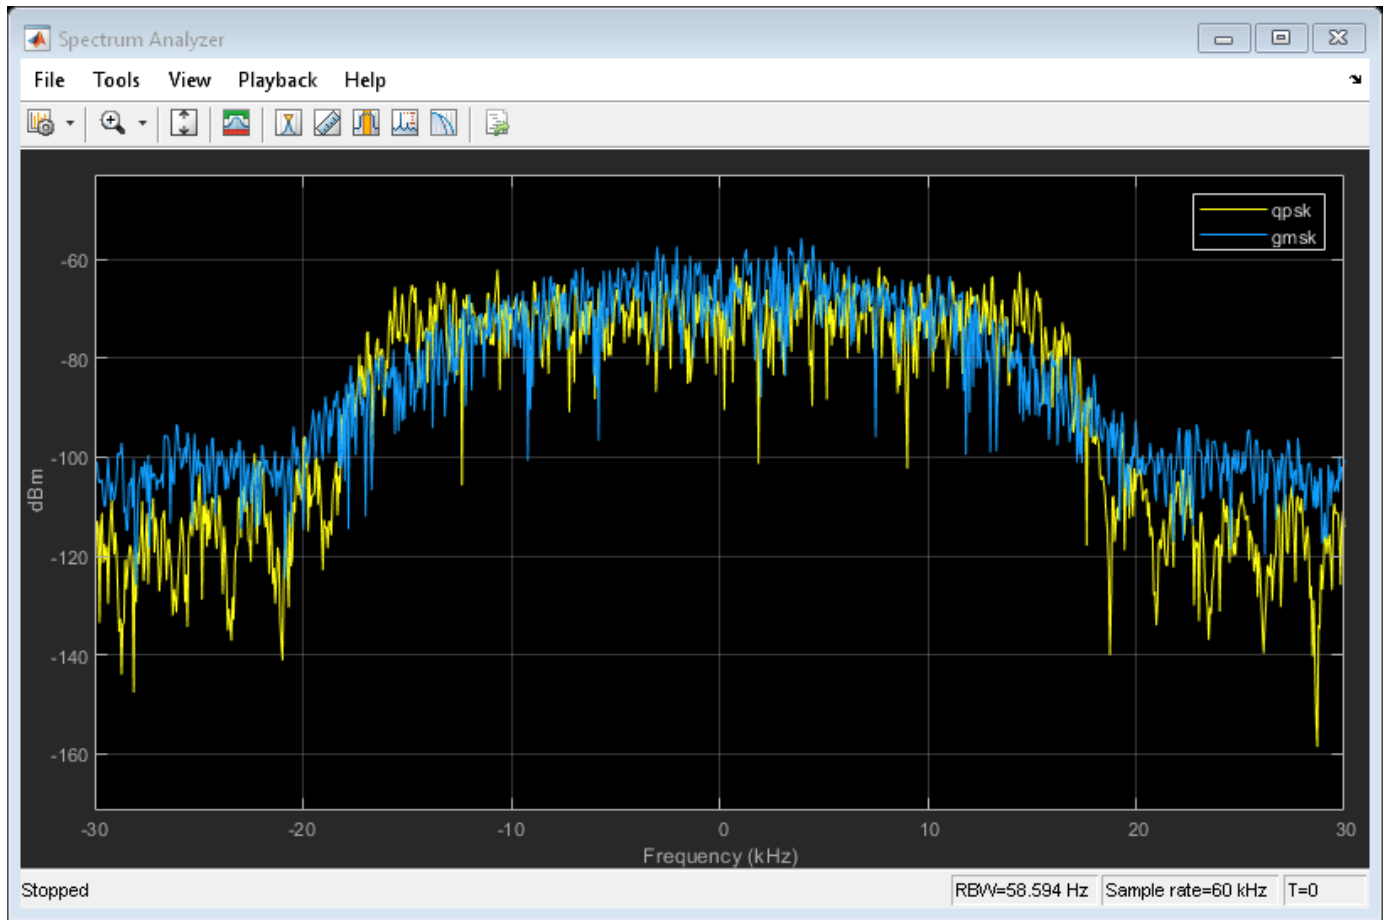

Fs2 = 120000
```

Use the multiband combiner object to interpolate, frequency-shift, and combine the two signals.

```
combinedsig = mbc([qpsksig,gmsksig]);
```

Create spectrum analyzer System objects. Use the spectrum analyzer objects to view the individual signals at 60 kHz and the combined signal at 120 kHz.

```
sa = dsp.SpectrumAnalyzer( ...
    NumInputPorts=2, ...
    SampleRate=Fs1, ...
    Method='Filter bank', ...
    AveragingMethod='Exponential', ...
    ShowLegend=true, ...
    ChannelNames={'qpsk','gmsk'});
sa(qpsksig,gmsksig);
sacombined = dsp.SpectrumAnalyzer( ...
    SampleRate=Fs2, ...
    Method='Filter bank', ...
    AveragingMethod='Exponential', ...
    ShowLegend=true, ...
    ChannelNames={'combined'});
sacombined(combinedsig);
release(sa)
```

`release(sacombined)`

Algorithms

Multiband Combiner

This figure shows how the multiband combiner algorithm processes input signal data.

When the output sample rate is greater than the input sample rate, the input signal is interpolated to avoid distortion in the frequency-shifted signal. Each column of the input signal is frequency-shifted by the corresponding value specified in the `FrequencyOffsets` property. The frequency-shifted signals are then added together into a single channel output signal. Each channel in the input must have the same number of samples.

Setting the `OutputSampleRateSource` to 'Auto' automatically configures the algorithm to compute the output sample rate as $R_O = R_I \times L$, where:

- R_O is the output sample rate `OutputSampleRate`.
- R_I is the input sample rate `InputSampleRate`.

- L is the interpolation factor and is computed as $L = \text{ceil}(2 \times B_{\text{max}}/R_f)$.
- B_{max} is the maximum bandwidth and is computed as $B_{\text{max}} = \max(\text{abs}(\text{FrequencyOffsets})) + (R_f/2)$.

Multiband Combining Delay

Multiband combining introduces a delay computed as $\text{delay} = \text{round}(\text{length}(\text{num})/2)$. The numerator coefficients, num , are computed as $\text{num} = \text{designMultirateFIR}(L,1)$, where L is the interpolation factor.

comm.MultiplexedDeinterleaver

Package: comm

Deinterleave symbols using set of shift registers with specified delays

Description

The `comm.MultiplexedDeinterleaver` System object deinterleaves the symbols in the input sequence by using a set of shift registers, each with its own specified delay. The deinterleaver uses N shift registers, where N is the number of elements in the vector specified by the `Delay` property. When a new input symbol enters the deinterleaver, the System object switches the commutator to a new register and shifts in the new symbol while shifting out the oldest symbol in that register. When the commutator reaches the N th register, upon the next new input, the System object returns to the first register. The multiplexed deinterleaver that is associated with the `comm.MultiplexedInterleaver` System object has the same number of registers as the interleaver. The delay in a particular deinterleaver register depends on the difference between the largest interleaver delay and the interleaver delay for the given register. For more information, see “Interleaving”.

To deinterleave the symbols in the input sequence:

- 1 Create the `comm.MultiplexedDeinterleaver` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

Creation

Syntax

```
muxdeinterleaver = comm.MultiplexedDeinterleaver
muxdeinterleaver = comm.MultiplexedDeinterleaver(Name,Value)
```

Description

`muxdeinterleaver = comm.MultiplexedDeinterleaver` creates a default multiplexed deinterleaver System object.

`muxdeinterleaver = comm.MultiplexedDeinterleaver(Name,Value)` sets the “Properties” on page 3-949 by using one or more name-value arguments. For example, `'InitialConditions',1` sets the initial conditions of shift registers to 1.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects.

Delay — Interleaver delay

[2; 0; 1; 3; 10] (default) | column vector of integers

Interleaver delay, specified as a column vector of integers. The values in this vector specify the lengths of the shift registers.

Data Types: double

InitialConditions — Initial conditions of shift registers

0 (default) | numeric scalar | column vector

Initial conditions of the shift registers, specified as one of these options.

- Numeric scalar — The default value is 0. The specified scalar applies to all shift registers.
- Column vector — The length of this vector must be equal to the length of the Delay property value. The *i*th initial condition applies to the *i*th shift register.

Data Types: double

Usage**Syntax**

```
deintrlvseq = muxdeinterleaver(intrlvseq)
```

Description

`deintrlvseq = muxdeinterleaver(intrlvseq)` deinterleaves the input sequence of symbols, `deintrlvseq`, by using a set of shift registers with delays specified by the Delay property. The System object returns the deinterleaved sequence, `deintrlvseq`.

Input Arguments**intrlvseq — Interleaved sequence of symbols**

column vector

Interleaved sequence of symbols, specified as a column vector. This sequence must be one that was interleaved using the `comm.MultiplexedInterleaver` System object.

Data Types: double | logical | fi

Output Arguments**deintrlvseq — Deinterleaved sequence of symbols**

column vector

Deinterleaved sequence of symbols, returned as a column vector with the same data type and size as the `intrlvseq` argument.

Data Types: double | logical | fi

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Common to All System Objects

<code>step</code>	Run System object algorithm
<code>release</code>	Release resources and allow changes to System object property values and input characteristics
<code>reset</code>	Reset internal states of System object

Examples

Interleave and Deinterleave Sequence

Create a multiplexed interleaver System object, specifying the interleaver delay.

```
interleaver = comm.MultplexedInterleaver('Delay',[1; 0; 2; 1]);
```

Create a multiplexed deinterleaver System object, specifying the interleaver delay.

```
deinterleaver = comm.MultplexedDeinterleaver('Delay',[1; 0; 2; 1]);
```

Generate a random data sequence. Pass the data sequence through the interleaver and then the deinterleaver.

```
[dataIn,dataOut] = deal([]); % Initialize data arrays
```

```
for index = 1:50
    data = randi([0 7],20,1);
    intrlvSequence = interleaver(data);
    deintrlvSequence = deinterleaver(intrlvSequence);
    % Save original data and deinterleaved data
    dataIn = cat(1,dataIn,data);
    dataOut = cat(1,dataOut,deintrlvSequence);
end
```

Determine the delay through the interleaver and deinterleaver.

```
delay = finddelay(dataIn,dataOut)
```

```
delay = 8
```

After accounting for the delay, confirm that the original and deinterleaved sequences are identical.

```
isequal(dataIn(1:end-delay),dataOut(delay+1:end))
```

```
ans = logical
     1
```

Permute symbols using set of shift registers with specified delays

Description

The `comm.MultplexedInterleaver` System object permutes the symbols in the input sequence by using a set of shift registers, each with its own delay value. For more information, see “Interleaving”.

To permute the symbols in the input sequence:

- 1 Create the `comm.MultplexedInterleaver` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

Creation

Syntax

```
muxinterleaver = comm.MultplexedInterleaver
muxinterleaver = comm.MultplexedInterleaver(Name,Value)
```

Description

`muxinterleaver = comm.MultplexedInterleaver` creates a default multiplexed interleaver System object. This System object permutes the symbols in the input sequence by using a set of shift registers with specified delays. The `muxinterleaver` System object consists of N registers, each with a specified delay. With each new input symbol, the System object switches the commutator to a new register and shifts in the new symbol while shifting out the oldest symbol in that register. When the commutator reaches the N th register, upon the next new input, the commutator returns to the first register.

`muxinterleaver = comm.MultplexedInterleaver(Name,Value)` sets the “Properties” on page 3-953 by using one or more name-value arguments. For example, `'InitialConditions',1` sets the initial conditions of the shift registers to 1.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

Delay — Interleaver delay

[2; 0; 1; 3; 10] (default) | column vector of integers

Interleaver delay, specified as a column vector of integers. The values in this vector specify the lengths of the shift registers.

Data Types: double

InitialConditions — Initial conditions of shift registers

0 (default) | numeric scalar | column vector

Initial conditions of the shift registers, specified as one of these options.

- Numeric scalar — The default value is 0. The specified scalar applies to all shift registers.
- Column vector — The length of this vector must be equal to the length of the Delay property value. The *i*th initial condition applies to the *i*th shift register.

Data Types: double

Usage**Syntax**

```
intrlvseq = muxinterleaver(inputseq)
```

Description

`intrlvseq = muxinterleaver(inputseq)` permutes the input sequence of symbols, `inputseq`, by using a set of shift registers with delays specified by the Delay property. The System object returns the interleaved sequence, `intrlvseq`.

Input Arguments**inputseq — Sequence of symbols**

column vector

Sequence of symbols, specified as a column vector.

Data Types: double | logical | fi

Output Arguments**intrlvseq — Interleaved sequence of symbols**

column vector

Interleaved sequence of symbols, returned as a column vector with the same data type and size as the `inputseq` input.

Data Types: double | logical | fi

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Common to All System Objects

comm.OQPSKDemodulator

Package: comm

Demodulation using OQPSK method

Description

The `comm.OQPSKDemodulator` object applies pulse shape filtering to the input waveform and demodulates it using the offset quadrature phase shift keying (OQPSK) method. For more information, see “Pulse Shaping Filter” on page 3-964. The input is a baseband representation of the modulated signal.

For information about delays incurred by modulator-demodulator pair processing, see “Modulation Delays” on page 3-963.

To demodulate a signal that is OQPSK modulated:

- 1 Create the `comm.OQPSKDemodulator` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

Creation

Syntax

```
oqpskdemod = comm.OQPSKDemodulator
oqpskdemod = comm.OQPSKDemodulator(mod)
oqpskdemod = comm.OQPSKDemodulator(Name,Value)
oqpskdemod = comm.OQPSKDemodulator(phase,Name,Value)
```

Description

`oqpskdemod = comm.OQPSKDemodulator` creates a demodulator System object. This object can jointly match-filter and decimate a waveform, and demodulate it using the offset quadrature phase shift keying (OQPSK) method.

`oqpskdemod = comm.OQPSKDemodulator(mod)` creates a demodulator System object with symmetric configuration to the OQPSK modulator object, `mod`.

`oqpskdemod = comm.OQPSKDemodulator(Name,Value)` sets properties using one or more name-value pairs. Enclose each property name in single quotes.

Example: `comm.OQPSKDemodulator('BitOutput',true)`

`oqpskdemod = comm.OQPSKDemodulator(phase,Name,Value)` sets the `PhaseOffset` property of the created object to `phase` and sets any other specified `Name, Value` pairs.

Example: `comm.OQPSKDemodulator(0.5*pi, 'SamplesPerSymbol', 2)`

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects.

PhaseOffset — Phase of zeroth point of signal constellation

0 (default) | scalar

Phase offset from $\pi/4$, specified as a scalar in radians. The phase offset is applied to the zeroth point of the signal constellation before delay of quadrature component. After the OQPSK imaginary-component delay the signal is normalized with unity power.

Example: 'PhaseOffset', $\pi/4$ aligns the zeroth point of the QPSK signal constellation point on the axes, $\{(1,0), (0,j), (-1,0), (0,-j)\}$.

Data Types: double

BitOutput — Option to output data as bits

false (default) | true

Option to output data as bits, specified as `false` or `true`.

- When you set this property to `false`, the object outputs a column vector of integer values with a length equal to the number of demodulated symbols. The output values are integer representations of two bits and range from 0 to 3.
- When you set this property to `true`, the object outputs a binary column vector of bit values. The output vector length is twice as long as the number of input symbols.

Data Types: logical

SymbolMapping — Signal constellation bit mapping

'Gray' (default) | 'Binary' | custom 4-element numeric vector of integers with values from 0 to 3

Signal constellation bit mapping, specified as 'Gray', 'Binary', or a custom 4-element numeric vector of integers with values from 0 to 3.

Setting	Constellation Mapping for Integers	Constellation Mapping for Bits	Comment								
Gray	<table border="1" style="border-collapse: collapse; text-align: center;"> <tr> <td style="border: none;">1</td> <td style="border: none;">0</td> </tr> <tr> <td style="border: none;">3</td> <td style="border: none;">2</td> </tr> </table>	1	0	3	2	<table border="1" style="border-collapse: collapse; text-align: center;"> <tr> <td style="border: none;">01</td> <td style="border: none;">00</td> </tr> <tr> <td style="border: none;">11</td> <td style="border: none;">10</td> </tr> </table>	01	00	11	10	The signal constellation mapping is Gray-encoded.

Data Types: char | double

PulseShape — Filtering pulse shape

'Half sine' (default) | 'Normal raised cosine' | 'Root raised cosine' | 'Custom'

Filtering pulse shape, specified as 'Half sine', 'Normal raised cosine' | 'Root raised cosine', or 'Custom'.

Data Types: char

RolloffFactor — Raised cosine filter rolloff factor

0.2 (default) | scalar

Raised cosine filter rolloff factor, specified as a scalar from 0 to 1.

Dependencies

This property is enabled when PulseShape is 'Normal raised cosine' or 'Root raised cosine'.

Data Types: double

FilterSpanInSymbols — Filter length

10 (default) | scalar

Filter length in symbols, specified as a scalar. An ideal raised cosine filter has an infinite impulse response. However, to realize a practical implementation of this filter, the object truncates the impulse response to FilterSpanInSymbols symbols.

Dependencies

This property is enabled when PulseShape is 'Normal raised cosine' or 'Root raised cosine'.

Data Types: double

FilterNumerator — FIR filter numerator

[0.7071 0.7071] (default) | row vector

FIR filter numerator, specified as a row vector.

Dependencies

This property is enabled when PulseShape is 'Custom'.

Data Types: double

SamplesPerSymbol — Number of samples per symbol

4 (default) | positive even integer

Number of samples per symbol, specified as a positive even integer.

Data Types: double

OutputDataType — Data type assigned to output

'double' (default) | 'single' | 'uint8'

Data type assigned to output, specified as 'double', 'single', or 'uint8'.

Data Types: char

Usage**Syntax**

```
outsignal = oqpskdemod(waveform)
```

Description

`outsignal = oqpskdemod(waveform)` returns the demodulated output signal. The object produces one output symbol for each input pulse.

Input Arguments**waveform — Received waveform**

scalar | column vector

Received waveform, specified as a complex scalar or column vector.

Data Types: double

Complex Number Support: Yes

Output Arguments**outsignal — Demodulated signal**

integer vector | bit vector

Demodulated signal, returned as an N_S -element integer vector or bit vector, where N_S is the number of samples.

The received waveform is pulse shaped according to the configuration properties PulseShape and SamplesPerSymbol. The setting of the BitOutput property determines the interpretation of the received waveform.

Data Types: double

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Common to All System Objects

<code>step</code>	Run System object algorithm
<code>release</code>	Release resources and allow changes to System object property values and input characteristics
<code>reset</code>	Reset internal states of System object

Examples

OQPSK Signal in AWGN

Create an OQPSK modulator and demodulator pair. Create an AWGN channel object having two bits per symbol.

```
oqpskmod = comm.OQPSKModulator('BitInput',true);
oqpskdemod = comm.OQPSKDemodulator('BitOutput',true);
channel = comm.AWGNChannel('EbNo',4,'BitsPerSymbol',2);
```

Create an error rate calculator. To account for the delay between the modulator and demodulator, set the `ReceiveDelay` property to 2.

```
errorRate = comm.ErrorRate('ReceiveDelay',2);
```

Process 300 frames of data looping through these steps.

- Generate vectors with 100 elements of random binary data.
- OQPSK-modulate the data. The data frames are processed as 50 sample frames of 2-bit binary data.
- Pass the modulated data through the AWGN channel.
- OQPSK-demodulate the data.
- Collect error statistics on the frames of data.

```
for counter = 1:300
    txData = randi([0 1],100,1);
    modSig = oqpskmod(txData);
    rxSig = channel(modSig);
    rxData = oqpskdemod(rxSig);
    errorStats = errorRate(txData,rxData);
end
```

Display the error statistics.

```
ber = errorStats(1)
```

```
ber = 3.3336e-05
```

```
numErrors = errorStats(2)
```

```
numErrors = 1
numBits = errorStats(3)
numBits = 29998
```

OQPSK Signal with Root Raised Cosine Filtering

Perform OQPSK modulation and demodulation and apply root raised cosine filtering to a waveform.

System initialization

Define simulation parameters and create objects for OQPSK modulation and demodulation.

```
sps = 12; % samples per symbol
bits = randi([0, 1], 800, 1); % transmission data

modulator = comm.OQPSKModulator( ...
    'BitInput',true, ...
    'SamplesPerSymbol',sps, ...
    'PulseShape','Root raised cosine');
demodulator = comm.OQPSKDemodulator(modulator);
```

Waveform transmission and reception

Use the `modulator` object to apply OQPSK modulation and transmit filtering to the input data.

```
oqpskWaveform = modulator(bits);
```

Pass the waveform through a channel.

```
snr = 0;
rxWaveform = awgn(oqpskWaveform,snr);
```

Use the `demodulator` object to apply receive filtering and OQPSK demodulation to the waveform.

```
demodData = demodulator(rxWaveform);
```

Compute the bit error rate to confirm the quality of the data recovery.

```
delay = (1+modulator.BitInput)*modulator.FilterSpanInSymbols;
[~, ber] = biterr(bits(1:end-delay), demodData(delay+1:end))

ber = 0
```

Soft-Decision OQPSK Modulation-Demodulation

Use the `qamdemod` function to simulate soft decision output for OQPSK-modulated signals.

Generate an OQPSK modulated signal.

```
sps = 4;
msg = randi([0 1],1000,1);
```

```
oqpskMod = comm.OQPSKModulator('SamplesPerSymbol',sps,'BitInput',true);
oqpskSig = oqpskMod(msg);
```

Add noise to the generated signal.

```
impairedSig = awgn(oqpskSig,15);
```

Perform Soft-Decision Demodulation

Create QPSK equivalent signal to align in-phase and quadrature.

```
impairedQPSK = complex( ...
    real(impairedSig(1+sps/2:end-sps/2)), ...
    imag(impairedSig(sps+1:end)));
```

Apply matched filtering to the received OQPSK signal.

```
halfSinePulse = sin(0:pi/sps:(sps)*pi/sps);
matchedFilter = dsp.FIRDecimator(sps, halfSinePulse, ...
    'DecimationOffset',sps/2);
filteredQPSK = matchedFilter(impairedQPSK);
```

To perform soft demodulation of the filtered OQPSK signal use the `qamdemod` function. Align symbol mapping of `qamdemod` with the symbol mapping used by the `comm.OQPSKModulator`, then demodulate the signal.

```
oqpskModSymbolMapping = [1 3 0 2];
demodulated = qamdemod(filteredQPSK,4,oqpskModSymbolMapping, ...
    'OutputType','llr');
```

More About

Modulation Delays

Digital modulation and demodulation objects incur delays between their inputs and outputs that result in an offset in the arrival sample of the received data. When comparing transmitted data with received data, such as when plotting or computing error statistics, you must take system delays into account. As shown here, the OQPSK modulation-demodulation delay varies depending on the pulse shaping filter and the input/output settings of the object pairs.

Pulse Shape	Input/Output Data (*)	End-to-End Delay Incurred by an OQPSK Modulator-Demodulator Object Pair (in samples)
'Half sine' or 'Custom'	Integer	1
	Bit	2
'Normal raised cosine' or 'Root raised cosine'	Integer	FilterSpanInSymbols
	Bit	2*FilterSpanInSymbols

(*) Set the data type property (`BitInput` for modulation or `BitOutput` for demodulation) to `false` for integer data and `true` for bit data.

Pulse Shaping Filter

The OQPSK modulation scheme requires oversampling of two or greater in order to delay (or offset) the quadrature channel by 90 degrees. This oversampling is achieved through interpolation filtering implemented by pulse shaping.

Phase Modulation

Introduced in R2012a

comm.OQPSKModulator

Package: comm

Modulation using OQPSK method

Description

The `comm.OQPSKModulator` object modulates the input signal using the offset quadrature phase shift keying (OQPSK) method and applies pulse shape filtering to the output waveform. For more information, see “Pulse Shaping Filter” on page 3-972. The output is a baseband representation of the modulated signal.

For information about delays incurred by modulator-demodulator pair processing, see “Modulation Delays” on page 3-972.

To modulate a signal using offset quadrature phase shift keying:

- 1 Create the `comm.OQPSKModulator` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

Creation

Syntax

```
oqpskmod = comm.OQPSKModulator
oqpskmod = comm.OQPSKModulator(demod)
oqpskmod = comm.OQPSKModulator(Name,Value)
oqpskmod = comm.OQPSKModulator(phase,Name,Value)
```

Description

`oqpskmod = comm.OQPSKModulator` creates a modulator System object. This object applies offset quadrature phase shift keying (OQPSK) modulation and pulse shape filtering to the input signal.

`oqpskmod = comm.OQPSKModulator(demod)` creates a modulator System object with symmetric configuration to the OQPSK demodulator object, `demod`.

`oqpskmod = comm.OQPSKModulator(Name,Value)` sets properties using one or more name-value pairs. Enclose each property name in single quotes.

Example: `comm.OQPSKModulator('BitInput',true)`

`oqpskmod = comm.OQPSKModulator(phase,Name,Value)` sets the `PhaseOffset` property of the created object to `phase` and sets any other specified `Name, Value` pairs.

Example: `comm.OQPSKModulator(0.5*pi,'SymbolMapping','Binary')`

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects.

PhaseOffset — Phase of zeroth point of signal constellation

0 (default) | scalar

Phase offset from $\pi/4$, specified as a scalar in radians. The phase offset is applied to the zeroth point of the signal constellation before delay of quadrature component. After the OQPSK imaginary-component delay, the signal is normalized with unity power.

Example: `'PhaseOffset', pi/4` aligns the zeroth point of the QPSK signal constellation point on the axes, $\{(1,0), (0,j), (-1,0), (0,-j)\}$.

Data Types: `double`

BitInput — Option to provide input in bits

false (default) | true

Option to provide input in bits, specified as `false` or `true`.

- When this property is set to `false`, the input values must be integer representations of two-bit input segments and range from 0 to 3.
- When this property is set to `true`, the input must be a binary vector of even length. Element pairs are binary representations of integers.

Data Types: `logical`

SymbolMapping — Signal constellation bit mapping

'Gray' (default) | 'Binary' | custom 4-element numeric vector of integers with values from 0 to 3

Signal constellation bit mapping, specified as `'Gray'`, `'Binary'`, or a custom 4-element numeric vector of integers with values from 0 to 3.

Setting	Constellation Mapping for Integers	Constellation Mapping for Bits	Comment								
Gray	<table border="1" style="border-collapse: collapse; text-align: center;"> <tr> <td style="border: none;">1</td> <td style="border: none;">0</td> </tr> <tr> <td style="border: none;">3</td> <td style="border: none;">2</td> </tr> </table>	1	0	3	2	<table border="1" style="border-collapse: collapse; text-align: center;"> <tr> <td style="border: none;">01</td> <td style="border: none;">00</td> </tr> <tr> <td style="border: none;">11</td> <td style="border: none;">10</td> </tr> </table>	01	00	11	10	The signal constellation mapping is Gray-encoded.

Data Types: char | double

PulseShape — Filtering pulse shape

'Half sine' (default) | 'Normal raised cosine' | 'Root raised cosine' | 'Custom'

Filtering pulse shape, specified as 'Half sine', 'Normal raised cosine', 'Root raised cosine', or 'Custom'.

Data Types: char

RolloffFactor — Raised cosine filter rolloff factor

0.2 (default) | scalar

Raised cosine filter rolloff factor, specified as a scalar from 0 to 1.

Dependencies

This property is enabled when PulseShape is 'Normal raised cosine' or 'Root raised cosine'.

Data Types: double

FilterSpanInSymbols — Filter length

10 (default) | scalar

Filter length in symbols, specified as a scalar. An ideal raised cosine filter has an infinite impulse response. However, to realize a practical implementation of this filter, the object truncates the impulse response to FilterSpanInSymbols symbols.

Dependencies

This property is enabled when PulseShape is 'Normal raised cosine' or 'Root raised cosine'.

Data Types: double

FilterNumerator — FIR filter numerator

[0.7071 0.7071] (default) | row vector

FIR filter numerator, specified as a row vector.

Dependencies

This property is enabled when PulseShape is 'Custom'.

Data Types: double

SamplesPerSymbol — Number of samples per symbol

4 (default) | positive even integer

Number of samples per symbol, specified as a positive even integer.

Data Types: double

OutputDataType — Data type assigned to output

'double' (default) | 'single'

Data type assigned to output, specified as 'double' or 'single'.

Data Types: char

Usage**Syntax**

```
waveform = oqpskmod(insignal)
```

Description

`waveform = oqpskmod(insignal)` returns baseband-modulated output. The output waveform is pulse shaped according to the configuration properties PulseShape and SamplesPerSymbol.

Input Arguments**insignal — Input signal**

integer column vector | bit column vector

Input signal, specified as an N_S -element column vector of integers or bits, where N_S is the number of samples.

The setting of the BitInput property determines the interpretation of the input vector.

Data Types: double

Output Arguments**waveform — Output waveform**

vector

Output waveform, returned as a vector. The output waveform is pulse-shaped according to the configuration properties PulseShape and SamplesPerSymbol.

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Common to All System Objects

step Run System object algorithm
 release Release resources and allow changes to System object property values and input characteristics
 reset Reset internal states of System object

Examples

OQPSK Signal in AWGN

Create an OQPSK modulator and demodulator pair. Create an AWGN channel object having two bits per symbol.

```
oqpskmod = comm.OQPSKModulator('BitInput',true);
oqpskdemod = comm.OQPSKDemodulator('BitOutput',true);
channel = comm.AWGNChannel('EbNo',4,'BitsPerSymbol',2);
```

Create an error rate calculator. To account for the delay between the modulator and demodulator, set the ReceiveDelay property to 2.

```
errorRate = comm.ErrorRate('ReceiveDelay',2);
```

Process 300 frames of data looping through these steps.

- Generate vectors with 100 elements of random binary data.
- OQPSK-modulate the data. The data frames are processed as 50 sample frames of 2-bit binary data.
- Pass the modulated data through the AWGN channel.
- OQPSK-demodulate the data.
- Collect error statistics on the frames of data.

```
for counter = 1:300
    txData = randi([0 1],100,1);
    modSig = oqpskmod(txData);
    rxSig = channel(modSig);
    rxData = oqpskdemod(rxSig);
    errorStats = errorRate(txData,rxData);
end
```

Display the error statistics.

```
ber = errorStats(1)
ber = 3.3336e-05
numErrors = errorStats(2)
numErrors = 1
numBits = errorStats(3)
numBits = 29998
```

Create OQPSK Modulator Using Demodulator

Use an OQPSK demodulator object to initialize an OQPSK modulator object while creating it.

Create an OQPSK demodulator, assigning it a phase offset of $\frac{1}{2}\pi$.

```
phase = 0.5*pi;  
oqpskdemod = comm.OQPSKDemodulator(phase)
```

```
oqpskdemod =  
comm.OQPSKDemodulator with properties:
```

```
Modulation  
PhaseOffset: 1.5708  
SymbolMapping: 'Gray'  
BitOutput: false
```

```
Filtering  
PulseShape: 'Half sine'  
SamplesPerSymbol: 4
```

```
OutputDataType: 'double'
```

Use the demodulator object to initialize an OQPSK modulator while creating it.

```
oqpskmod = comm.OQPSKModulator(oqpskdemod)
```

```
oqpskmod =  
comm.OQPSKModulator with properties:
```

```
Modulation  
PhaseOffset: 1.5708  
SymbolMapping: 'Gray'  
BitInput: false
```

```
Filtering  
PulseShape: 'Half sine'  
SamplesPerSymbol: 4
```

```
OutputDataType: 'double'
```

OQPSK Signal with Root Raised Cosine Filtering

Perform OQPSK modulation and demodulation and apply root raised cosine filtering to a waveform.

System initialization

Define simulation parameters and create objects for OQPSK modulation and demodulation.

```
sps = 12; % samples per symbol  
bits = randi([0, 1], 800, 1); % transmission data
```

```

modulator = comm.OQPSKModulator( ...
    'BitInput',true, ...
    'SamplesPerSymbol',sps, ...
    'PulseShape','Root raised cosine');
demodulator = comm.OQPSKDemodulator(modulator);

```

Waveform transmission and reception

Use the `modulator` object to apply OQPSK modulation and transmit filtering to the input data.

```
oqpskWaveform = modulator(bits);
```

Pass the waveform through a channel.

```
snr = 0;
rxWaveform = awgn(oqpskWaveform,snr);
```

Use the `demodulator` object to apply receive filtering and OQPSK demodulation to the waveform.

```
demodData = demodulator(rxWaveform);
```

Compute the bit error rate to confirm the quality of the data recovery.

```
delay = (1+modulator.BitInput)*modulator.FilterSpanInSymbols;
[~, ber] = biterr(bits(1:end-delay), demodData(delay+1:end))
```

```
ber = 0
```

Soft-Decision OQPSK Modulation-Demodulation

Use the `qamdemod` function to simulate soft decision output for OQPSK-modulated signals.

Generate an OQPSK modulated signal.

```
sps = 4;
msg = randi([0 1],1000,1);
oqpskMod = comm.OQPSKModulator('SamplesPerSymbol',sps,'BitInput',true);
oqpskSig = oqpskMod(msg);
```

Add noise to the generated signal.

```
impairedSig = awgn(oqpskSig,15);
```

Perform Soft-Decision Demodulation

Create QPSK equivalent signal to align in-phase and quadrature.

```
impairedQPSK = complex( ...
    real(impairedSig(1+sps/2:end-sps/2)), ...
    imag(impairedSig(sps+1:end)));
```

Apply matched filtering to the received OQPSK signal.

```
halfSinePulse = sin(0:pi/sps:(sps)*pi/sps);
matchedFilter = dsp.FIRDecimator(sps, halfSinePulse, ...
```

```
'DecimationOffset',sps/2);
filteredQPSK = matchedFilter(impairedQPSK);
```

To perform soft demodulation of the filtered OQPSK signal use the `qamdemod` function. Align symbol mapping of `qamdemod` with the symbol mapping used by the `comm.OQPSKModulator`, then demodulate the signal.

```
oqpskModSymbolMapping = [1 3 0 2];
demodulated = qamdemod(filteredQPSK,4,oqpskModSymbolMapping, ...
    'OutputType','llr');
```

More About

Modulation Delays

Digital modulation and demodulation objects incur delays between their inputs and outputs that result in an offset in the arrival sample of the received data. When comparing transmitted data with received data, such as when plotting or computing error statistics, you must take system delays into account. As shown here, the OQPSK modulation-demodulation delay varies depending on the pulse shaping filter and the input/output settings of the object pairs.

Pulse Shape	Input/Output Data (*)	End-to-End Delay Incurred by an OQPSK Modulator-Demodulator Object Pair (in samples)
'Half sine' or 'Custom'	Integer	1
	Bit	2
'Normal raised cosine' or 'Root raised cosine'	Integer	FilterSpanInSymbols
	Bit	2*FilterSpanInSymbols
(*) Set the data type property (<code>BitInput</code> for modulation or <code>BitOutput</code> for demodulation) to <code>false</code> for integer data and <code>true</code> for bit data.		

Pulse Shaping Filter

The OQPSK modulation scheme requires oversampling of two or greater in order to delay (or offset) the quadrature channel by 90 degrees. This oversampling is achieved through interpolation filtering implemented by pulse shaping.

Phase Modulation

Introduced in R2012a

comm.OSTBCCombiner

Package: comm

Combine inputs using orthogonal space-time block code

Description

The `OSTBCCombiner` object combines the input signal (from all of the receive antennas) and the channel estimate signal to extract the soft information of the symbols encoded by an OSTBC. The input channel estimate does not need to be constant and can vary at each call to the `step` method. The combining algorithm uses only the estimate for the first symbol period per codeword block. A symbol demodulator or decoder would follow the Combiner object in a MIMO communications system.

To combine input signals and extract the soft information of the symbols encoded by an OSTBC:

- 1 Define and set up your OSTBC combiner object. See “Construction” on page 3-974.
- 2 Call `step` to Combine inputs using an orthogonal space-time block code according to the properties of `comm.OSTBCCombiner`. The behavior of `step` is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`H = comm.OSTBCCombiner` creates an orthogonal space-time block code (OSTBC) combiner System object, `H`. This object combines the input signal (from all of the receive antennas) with the channel estimate signal to extract the soft information of the symbols encoded by an OSTBC.

`H = comm.OSTBCCombiner(Name,Value)` creates an OSTBC Combiner object, `H`, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as `(Name1,Value1,...,NameN,ValueN)`.

`H = comm.OSTBCCombiner(N,M,Name,Value)` creates an OSTBC Combiner object, `H`. This object has the `NumTransmitAntennas` property set to `N`, the `NumReceiveAntennas` property set to `N`, and the other specified properties set to the specified values.

Properties

NumTransmitAntennas

Number of transmit antennas

Specify the number of antennas at the transmitter as 2 | 3 | 4. The default is 2.

SymbolRate

Symbol rate of code

Specify the symbol rate of the code as $3/4$ | $1/2$. The default is $3/4$. This property applies when the `NumTransmitAntennas` on page 3-0 property is greater than 2. For 2 transmit antennas, the symbol rate defaults to 1.

NumReceiveAntennas

Number of receive antennas

Specify the number of antennas at the receiver as a double-precision, real, scalar integer value from 1 to 8. The default is 1.

Fixed-Point Properties

RoundingMethod

Rounding of fixed-point numeric values

Specify the rounding method as `Ceiling` | `Convergent` | `Floor` | `Nearest` | `Round` | `Simplest` | `Zero`. The default is `Floor`.

OverflowAction

Action when fixed-point numeric values overflow

Specify the overflow action as one of `Wrap` | `Saturate`. The default is `Wrap`. This property specifies the action to be taken in case of overflow. Such overflow occurs if the magnitude of a fixed-point calculation result does not fit into the range of the data type and scaling that stores the result.

ProductDataType

Data type of product

Specify the product data type as one of `Full precision` | `Custom`. The default is `Full precision`.

CustomProductDataType

Fixed-point data type of product

Specify the product fixed-point type as a scaled `numericType` object with a signedness of `Auto`. The default is `numericType([], 32, 16)`. This property applies when you set the `ProductDataType` property to `Custom`.

AccumulatorDataType

Data type of accumulator

Specify the accumulator data type as `Full precision` | `Same as product` | `Custom`. The default is `Full precision`.

CustomAccumulatorDataType

Fixed-point data type of accumulator

Specify the accumulator fixed-point type as a scaled `numericType` object with a signedness of `Auto`. The default is `numericType([], 32, 16)`. This property applies when you set the `AccumulatorDataType` property to `Custom`.

EnergyProductDataType

Data type of energy product

Specify the complex energy product data type as one of `Full precision | Same as product | Custom`. The default is `Full precision`. This property sets the data type of the complex product in the denominator to calculate the total energy in the MIMO channel.

CustomEnergyProductDataType

Fixed-point data type of energy product

Specify the energy product fixed-point type as a scaled `numericType` object with a signedness of `Auto`. The default is `numericType([], 32, 16)`. This property applies when you set the `EnergyProductDataType` property to `Custom`.

EnergyAccumulatorDataType

Data type of energy accumulator

Specify the energy accumulator data type as one of `Full precision | Same as energy product | Same as accumulator | Custom`. The default is `Full precision`. This property sets the data type of the summation in the denominator to calculate the total energy in the MIMO channel.

CustomEnergyAccumulatorDataType

Fixed-point data type of energy accumulator

Specify the energy accumulator fixed-point type as a scaled `numericType` object with a signedness of `Auto`. The default is `numericType([], 32, 16)`. This property applies when you set the `EnergyAccumulatorDataType` property to `Custom`.

DivisionDataType

Data type of division

Specify the division data type as one of `Same as accumulator | Custom`. The default is `Same as accumulator`. This property sets the data type at the output of the division operation. The setting normalizes diversity combining by the total energy in the MIMO channel.

CustomDivisionDataType

Fixed-point data type of division

Specify the division fixed-point type as a scaled `numericType` object with a signedness of `Auto`. The default is `numericType([], 32, 16)`. This property applies when you set the `DivisionDataType` property to `Custom`.

Common to All System Objects	
release	Allow System object property value changes

Examples

Encode with OSTBC and Calculate Errors

Determine the bit error rate for a QPSK signal employing OSTBC encoding when transmitted through a 4x2 MIMO channel. Perfect channel estimation is assumed to be used by the OSTBC combiner.

Define the system parameters.

```
numTx = 4;           % Number of transmit antennas
numRx = 2;           % Number of receive antennas
Rs = 1e6;            % Sampling rate (Hz)
tau = [0 2e-6];      % Path delays (sec)
pdb = [0 -10];       % Average path gains (dB)
maxDopp = 30;        % Maximum Doppler shift (Hz)
numBits = 12000;     % Number of bits
SNR = 6;             % Signal-to-noise ratio (dB)
```

Set the random number generator to its default state to ensure repeatable results.

```
rng default
```

Create a QPSK modulator System object™. Set the BitInput property to true and the SymbolMapping property to Gray.

```
hMod = comm.QPSKModulator(...
    'BitInput',true,...
    'SymbolMapping','Gray');
```

Create a corresponding QPSK demodulator System object. Set the SymbolMapping property to Gray and the BitOutput property to true.

```
hDemod = comm.QPSKDemodulator(...
    'SymbolMapping','Gray',...
    'BitOutput',true);
```

Create an OSTBC encoder and combiner pair, where the number of antennas is specified in the system parameters.

```
hOSTBCEnc = comm.OSTBCEncoder(...
    'NumTransmitAntennas',numTx);

hOSTBCComb = comm.OSTBCCombiner(...
    'NumTransmitAntennas',numTx,...
    'NumReceiveAntennas',numRx);
```

Create a flat 4x2 MIMO Channel System object, where the channel characteristics are set using name-value pairs. The path gains are made available to serve as a perfect channel estimate for the OSTBC combiner.

```
hChan = comm.MIMOChannel(...  
    'SampleRate',Rs,...  
    'PathDelays',tau,...  
    'AveragePathGains',pdb,...  
    'MaximumDopplerShift',maxDopp,...  
    'SpatialCorrelationSpecification','None',...  
    'NumTransmitAntennas',numTx,...  
    'NumReceiveAntennas',numRx,...  
    'PathGainsOutputPort',true);
```

Create an AWGN channel System object in which the noise method is specified as a signal-to-noise ratio.

```
hAWGN = comm.AWGNChannel(...  
    'NoiseMethod','Signal to noise ratio (SNR)',...  
    'SNR',SNR,...  
    'SignalPower',1);
```

Generate a random sequence of bits.

```
data = randi([0 1],numBits,1);
```

Apply QPSK modulation.

```
modData = step(hMod,data);
```

Encode the modulated data using the OSTBC encoder object.

```
encData = step(hOSTBCEnc,modData);
```

Transmit the encoded data through the MIMO channel and add white noise by using the `step` functions of the MIMO and AWGN channel objects, respectively.

```
[chanOut,pathGains] = step(hChan,encData);  
rxSignal = step(hAWGN,chanOut);
```

Sum the `pathGains` array along the number of paths (2nd dimension) to form the channel estimate. Apply the `squeeze` function to make its dimensions conform with those of `rxSignal`.

```
chEst = squeeze(sum(pathGains,2));
```

Combine the received MIMO signal and its channel estimate using the `step` function of the OSTBC combiner object. Demodulate the combined signal.

```
combinedData = step(hOSTBCComb,rxSignal,chEst);  
receivedData = step(hDemod,combinedData);
```

Compute the number of bit errors and the bit error rate.

```
[numErrors,ber] = biterr(data,receivedData)
```

```
numErrors = 11
```

```
ber = 9.1667e-04
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the OSTBC Combiner block reference page. The object properties correspond to the block parameters.

comm.OSTBCEncoder

Introduced in R2012a

step

System object: comm.OSTBCCCombiner

Package: comm

Combine inputs using orthogonal space-time block code

Syntax

$Y = \text{step}(H, X, \text{CEST})$

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, $y = \text{step}(\text{obj}, x)$ and $y = \text{obj}(x)$ perform equivalent operations.

$Y = \text{step}(H, X, \text{CEST})$ combines the received data, X , and the channel estimate, CEST , to extract the symbols encoded by an OSTBC. Both X and CEST are complex-valued and of the same data type, which can be double, single, or signed fixed point with power-of-two slope and zero bias. When the `step` method input X has double or single precision, the output, Y , has the same data type as the input. The input channel estimate can remain constant or can vary during each codeword block transmission. The combining algorithm uses the estimate only for the first symbol period per codeword block.

The time domain length, $T/\text{SymbolRate}$, must be a multiple of the codeword block length. T is the output symbol sequence length in the time domain. Specifically, when you set the `NumTransmitAntennas` property to 2, $T/\text{SymbolRate}$ must be a multiple of two. When you set the `NumTransmitAntennas` property greater than 2, $T/\text{SymbolRate}$ must be a multiple of four. For an input of $T/\text{SymbolRate}$ rows by `NumReceiveAntennas` columns, the input channel estimate, CEST , must be a matrix of size $T/\text{SymbolRate}$ by `NumTransmitAntennas` by `NumReceiveAntennas`. In this case, the extracted symbol data, Y , is a column vector with T elements. Input matrix size can be F by $T/\text{SymbolRate}$ by `NumReceiveAntennas`, where F is an optional dimension (typically frequency domain) over which the combining calculation is independent. In this case, the input channel estimate, CEST , must be a matrix of size F by $T/\text{SymbolRate}$ by `NumTransmitAntennas` by `NumReceiveAntennas`. The extracted symbol data, Y , is an F rows by T columns matrix.

Note `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications. For more information on changing property values, see “System Design in MATLAB Using System Objects”.

comm.OSTBCEncoder

Package: comm

Encode input using orthogonal space-time block code

Description

The OSTBCEncoder object encodes an input symbol sequence using orthogonal space-time block code (OSTBC). The block maps the input symbols block-wise and concatenates the output codeword matrices in the time domain.

To encode an input symbol sequence using an orthogonal space-time block code:

- 1 Define and set up your OSTBC encoder object. See “Construction” on page 3-981.
- 2 Call `step` to encode an input symbol sequence according to the properties of `comm.OSTBCEncoder`. The behavior of `step` is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`H = comm.OSTBCEncoder` creates an orthogonal space-time block code (OSTBC) encoder System object, `H`. This object maps the input symbols block-wise and concatenates the output codeword matrices in the time domain.

`H = comm.OSTBCEncoder(Name,Value)` creates an OSTBC encoder object, `H`, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as `(Name1,Value1,...,NameN,ValueN)`.

`H = comm.OSTBCEncoder(N,Name,Value)` creates an OSTBC encoder object, `H`. This object has the `NumTransmitAntennas` property set to `N`, and the other specified properties set to the specified values.

Properties

NumTransmitAntennas

Number of transmit antennas

Specify the number of antennas at the transmitter as 2 | 3 | 4. The default is 2.

SymbolRate

Symbol rate of code

Specify the symbol rate of the code as one of $3/4$ | $1/2$. The default is $3/4$. This property applies when you set the `NumTransmitAntennas` on page 3-0 property to greater than 2. For 2 transmit antennas, the symbol rate defaults to 1.

Fixed-Point Properties

OverflowAction

Action when fixed-point numeric values overflow

Specify the overflow action as one of `Wrap` | `Saturate`. The default is `Wrap`. This property specifies the action to be taken in the case of an overflow. Such overflow occurs when the magnitude of a fixed-point calculation result does not fit into the range of the data type and scaling that stores the result.

Methods

`step` Encode input using orthogonal space-time block code

Common to All System Objects	
<code>release</code>	Allow System object property value changes

Examples

Encode BPSK Modulated Data with OSTBC

Generate random binary data, modulate using the BPSK modulation scheme, and encode the modulated data using OSTBC.

Generate an 8-by-1 vector of random binary data.

```
data = randi([0 1],8,1);
```

Create BPSK Modulator System object and modulated the data using the `step` function.

```
bpskMod = comm.BPSKModulator;
modData = bpskMod(data);
```

Create an OSTBC Encoder and encode the modulated signal. As the default number of transmit antennas is 2, you can see that `encData` is an 8-by-2 vector.

```
ostbcEnc = comm.OSTBCEncoder;
encData = ostbcEnc(modData)
```

`encData = 8×2 complex`

```
-1.0000 + 0.0000i -1.0000 + 0.0000i
 1.0000 + 0.0000i -1.0000 - 0.0000i
 1.0000 + 0.0000i -1.0000 + 0.0000i
 1.0000 + 0.0000i  1.0000 + 0.0000i
-1.0000 + 0.0000i  1.0000 + 0.0000i
-1.0000 + 0.0000i -1.0000 - 0.0000i
 1.0000 + 0.0000i -1.0000 + 0.0000i
 1.0000 + 0.0000i  1.0000 + 0.0000i
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the OSTBC Encoder block reference page. The object properties correspond to the block parameters.

When this object processes variable-size signals:

- If the input signal is a column vector, the first dimension can change, but the second dimension must remain fixed at 1.
- If the input signal is a matrix, both dimensions can change.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

See “System Objects in MATLAB Code Generation” (MATLAB Coder).

comm.OSTBCCombiner

Introduced in R2012a

step

System object: comm.OSTBCEncoder

Package: comm

Encode input using orthogonal space-time block code

Syntax

$Y = \text{step}(H,X)$

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, $y = \text{step}(\text{obj}, x)$ and $y = \text{obj}(x)$ perform equivalent operations.

$Y = \text{step}(H,X)$ encodes the input data, X , using OSTBC encoder object, H . The input is a complex-valued column vector or matrix of data type `double`, `single`, or signed fixed-point with power-of-two slope and zero bias. The step method output, Y , is the same data type as the input data. The time domain length, T , of X must be a multiple of the number of symbols in each codeword matrix. Specifically, when you set the `NumTransmitAntennas` property is 2 or the `SymbolRate` property is $1/2$, T must be a multiple of two and when the `SymbolRate` property to $3/4$, T must be a multiple of three. For a time or spatial domain input of T rows by one column, the encoded output data, Y , is a $(T/\text{SymbolRate})$ -by-`NumTransmitAntennas` matrix. The input matrix size can be F rows by T columns, where F is the additional dimension (typically the frequency domain) over which the encoding calculation is independent. In this case, the output is an F -by- $(T/\text{SymbolRate})$ -by-`NumTransmitAntennas` matrix.

Note `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications. For more information on changing property values, see “System Design in MATLAB Using System Objects”.

comm.OVSFCode

Package: comm

Generate OVSF code

Description

The `OVSFCode` object generates an orthogonal variable spreading factor (OVSF) code from a set of orthogonal codes. OVSF codes were first introduced for 3G communication systems. They are primarily used to preserve orthogonality between different channels in a communication system.

To generate an OVSF code:

- 1 Define and set up your OVSF code object. See “Construction” on page 3-985.
- 2 Call `step` to generate an OVSF code according to the properties of `comm.OVSFCode`. The behavior of `step` is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj, x)` and `y = obj(x)` perform equivalent operations.

Construction

`H = comm.OVSFCode` creates an orthogonal variable spreading factor (OVSF) code generator System object, `H`. This object generates an OVSF code.

`H = comm.OVSFCode(Name, Value)` creates an OVSF code generator object, `H`, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as `(Name1, Value1, ..., NameN, ValueN)`.

Properties

SpreadingFactor

Length of generated code

Specify the length of the generated code as an integer scalar value with a power of two. The default is 64.

Index

Index of code of interest

Specify the index of the desired code from the available set of codes that have the spreading factor specified in the `SpreadingFactor` on page 3-0 property. This property must be an integer scalar in the range 0 to `SpreadingFactor-1`. The default is 60.

OVSF codes are defined as the rows of an n -by- n matrix, C_n , where n is the value specified in the `SpreadingFactor` property.

You can define the matrix C_n recursively as follows:

First, define $C_1 = [1]$.

Next, assume that C_n is defined and let $C_n(k)$ denote the k -th row of C_n .

Then, $C_{2n} = [C_n(0) \ C_n(0); C_n(0) \ -C_n(0); \dots; C_n(n-1) \ C_n(n-1); C_n(n-1) \ -C_n(n-1)]$.

C_n is only defined for values of n that are a power of 2. Set this property to a value of k to choose the k -th row of the C matrix as the code of interest.

SamplesPerFrame

Number of output samples per frame

Specify the number of OVSF code samples that the `step` method outputs as a numeric, positive, integer scalar value. The default is 1. If you set this property to a value of M , then the `step` method outputs M samples of an OVSF code of length N . N is the length of the OVSF code that you specify in the `SpreadingFactor` on page 3-0 property.

OutputDataType

Data type of output

Specify output data type as one of `double` | `int8`. The default is `double`.

Methods

`step` Generate OVSF code

Common to All System Objects	
<code>release</code>	Allow System object property value changes
<code>reset</code>	Reset internal states of System object

Examples

Generate 10 samples of an OVSF code with a spreading factor of 64.

```
hOVSF = comm.OVSFCode('SamplesPerFrame', 10, 'SpreadingFactor', 64);
seq = step(hOVSF)
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the OVSF Code Generator block reference page. The object properties correspond to the block parameters, except:

- The object does not have a property to select frame based outputs.
- The object does not have a property that corresponds to the **Sample time** parameter.

`comm.HadamardCode` | `comm.WalshCode`

Introduced in R2012a

step

System object: comm.OVSFCode

Package: comm

Generate OVSF code

Syntax

$Y = \text{step}(H)$

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, $y = \text{step}(\text{obj}, x)$ and $y = \text{obj}(x)$ perform equivalent operations.

$Y = \text{step}(H)$ outputs a frame of the OVSF code in column vector Y . Specify the frame length with the `SamplesPerFrame` property.

Note `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications. For more information on changing property values, see “System Design in MATLAB Using System Objects”.

comm.PAMDemodulator

Package: comm

(Not recommended) Demodulate using M-ary PAM method

Note comm.PAMDemodulator is not recommended. Use pamdemod instead.

Description

The PAMDemodulator object demodulates a signal that was modulated using M-ary pulse amplitude modulation. The input is a baseband representation of the modulated signal.

To demodulate a signal that was modulated using M-ary pulse amplitude modulation:

- 1 Define and set up your PAM demodulator object. See “Construction” on page 3-988.
- 2 Call `step` to demodulate the signal according to the properties of `comm.PAMDemodulator`. The behavior of `step` is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj, x)` and `y = obj(x)` perform equivalent operations.

Construction

`H = comm.PAMDemodulator` creates a demodulator System object, `H`. This object demodulates the input signal using the M-ary pulse amplitude modulation (M-PAM) method.

`H = comm.PAMDemodulator(Name, Value)` creates an M-PAM demodulator object, `H`, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as `(Name1, Value1, ..., NameN, ValueN)`.

`H = comm.PAMDemodulator(M, Name, Value)` creates an M-PAM demodulator object, `H`. This object has the `ModulationOrder` property set to `M`, and the other specified properties set to the specified values.

Properties

ModulationOrder

Number of points in signal constellation

Specify the number of points in the signal constellation as a positive, integer scalar value. The default is 4. When you set the `BitOutput` on page 3-0 property to `false`, this value must be even. When you set the `BitOutput` property to `true`, this value requires an integer power of two.

BitOutput

Output data as bits

Specify whether the output consists of groups of bits or integer symbol values. The default is `false`.

When you set this property to `true` the `step` method outputs a column vector of bit values with length equal to $\log_2(\text{ModulationOrder on page 3-0})$ times the number of demodulated symbols.

When you set this property to `false`, the `step` method outputs a column vector, with length equal to the input data vector. This value contains integer symbol values between 0 and $\text{ModulationOrder}-1$.

SymbolMapping

Constellation encoding

Specify how the object maps an integer or group of $\log_2(\text{ModulationOrder on page 3-0})$ bits to the corresponding symbol as one of `Binary` | `Gray`. The default is `Gray`.

When you set this property to `Gray`, the object uses a Gray-encoded signal constellation.

When you set this property to `Binary`, the integer m , between $0 \leq m \leq (\text{ModulationOrder}-1)$ maps to the complex value $2^{m-\text{ModulationOrder}+1}$.

NormalizationMethod

Constellation normalization method

Specify the method used to normalize the signal constellation as one of `Minimum distance between symbols` | `Average power` | `Peak power`. The default is `Minimum distance between symbols`.

MinimumDistance

Minimum distance between symbols

Specify the distance between two nearest constellation points as a positive, real, numeric scalar value. The default is 2. This property applies when you set the `NormalizationMethod on page 3-0` property to `Minimum distance between symbols`.

AveragePower

Average power of constellation

Specify the average power of the symbols in the constellation as a positive, real, numeric scalar value. The default is 1. This property applies when you set the `NormalizationMethod on page 3-0` property to `Average power`.

PeakPower

Peak power of constellation

Specify the maximum power of the symbols in the constellation as a positive, real, numeric scalar value. The default is 1. This property applies when you set the `NormalizationMethod on page 3-0` property to `Peak power`.

OutputDataType

Data type of output

Specify the output data type as one of `Full precision` | `Smallest unsigned integer` | `double` | `single` | `int8` | `uint8` | `int16` | `uint16` | `int32` | `uint32`. The default is `Full precision`.

When you set this property to `Full precision`, and the input data type is `single` or `double` precision, the output data has the same data type that of the input.

When the input signal is an integer data type, you must have a Fixed-Point Designer user license to use this property in `Smallest unsigned integer` or `Full precision` mode.

When the input data is of a fixed-point type, the output data type behaves as if you had set the `OutputDataType` on page 3-0 property to `Smallest unsigned integer`.

When you set the `BitOutput` on page 3-0 property to `true`, then `logical` data type becomes a valid option.

Fixed-Point Properties

FullPrecisionOverride

Full precision override for fixed-point arithmetic

Specify whether to use full precision rules. If you set `FullPrecisionOverride` to `true`, which is the default, the object computes all internal arithmetic and output data types using full precision rules. These rules provide the most accurate fixed-point numerics. It also turns off the display of other fixed-point properties because they do not apply individually. These rules guarantee that no quantization occurs within the object. Bits are added, as needed, to ensure that no roundoff or overflow occurs. If you set `FullPrecisionOverride` to `false`, fixed-point data types are controlled through individual fixed-point property settings. For more information, see “Full Precision for Fixed-Point System Objects” on page 3-992.

DenormalizationFactorDataType

Data type of denormalization factor

Specify the denormalization factor data type as one of `Same word length as input` | `Custom`. The default is `Same word length as input`.

CustomDenormalizationFactorDataType

Fixed-point data type of denormalization factor

Specify the denormalization factor fixed-point type as an `unscaled numeric type` object with a signedness of `Auto`. The default is `numeric type ([], 16)`. This property applies when you set the `DenormalizationFactorDataType` on page 3-0 property to `Custom`.

ProductDataType

Data type of product

Specify the product data type as one of `Full precision` | `Custom`. The default is `Full precision`. When you set this property to `Full precision` the object calculates the full-precision product word and fraction lengths. This property applies when you set the `FullPrecisionOverride` on page 3-0 property to `false`.

CustomProductDataType

Fixed-point data type of product

Specify the product fixed-point type as an unscaled `numericType` object with a signedness of `Auto`. The default is `numericType([], 32)`. This property applies when you set the `FullPrecisionOverride` on page 3-0 property to `false` and the `ProductDataType` on page 3-0 property to `Custom`.

ProductRoundingMethod

Rounding of fixed-point numeric value of product

Specify the product rounding method as one of `Ceiling` | `Convergent` | `Floor` | `Nearest` | `Round` | `Simplest` | `Zero`. The default is `Floor`. This property applies when the object is not in a full precision configuration

ProductOverflowAction

Action when fixed-point numeric value of product overflows

Specify the product overflow action as one of `Wrap` | `Saturate`. The default is `Wrap`. This property applies when the object is not in a full precision configuration.

SumDataType

Data type of sum

Specify the sum data type as one of `Full precision` | `Same as product` | `Custom`. The default is `Full precision`. When you set this property to `Full precision`, the object calculates the full-precision sum word and fraction lengths. This property applies when you set the `FullPrecisionOverride` on page 3-0 property to `false`

CustomSumDataType

Fixed-point data type of sum

Specify the sum fixed-point type as an unscaled `numericType` object with a signedness of `Auto`. The default is `numericType([], 32)`. This property applies when you set the `FullPrecisionOverride` on page 3-0 property to `false` and the `SumDataType` on page 3-0 property to `Custom`.

Methods

<code>constellation</code>	(Not recommended) Calculate or plot ideal signal constellation
<code>step</code>	(Not recommended) Demodulate using M-ary PAM method

Common to All System Objects

<code>release</code>	Allow System object property value changes
----------------------	--

Examples

Modulate and demodulate a signal using 16-PAM modulation.

```
hMod = comm.PAMModulator(16);
hAWGN = comm.AWGNChannel('NoiseMethod', ...
    'Signal to noise ratio (SNR)', ...
    'SNR',20, 'SignalPower', 85);
hDemod = comm.PAMDemodulator(16);
%Create an error rate calculator
hError = comm.ErrorRate;
for counter = 1:100
    % Transmit a 50-symbol frame
    data = randi([0 hMod.ModulationOrder-1],50,1);
    modSignal = step(hMod, data);
    noisySignal = step(hAWGN, modSignal);
    receivedData = step(hDemod, noisySignal);
    errorStats = step(hError, data, receivedData);
end
fprintf('Error rate = %f\nNumber of errors = %d\n', ...
    errorStats(1), errorStats(2))
```

Compatibility Considerations

comm.PAMDemodulator is not recommended

comm.PAMDemodulator is not recommended. Use pamdemod instead.

```
n = 10000; % Number of symbols to process
M = 8; % Modulation order
x = randi([0 M-1],n,1); % Create message signal.

%% Using PAM modulation and demodulation system objects
pammodObj = comm.PAMModulator(M);
pamdmodObj = comm.PAMDemodulator(M);
yOld = pammodObj(x); % Modulate.
% ... channel filtering ...
zOld = pamdmodObj(complex(y)); % Demodulate.

%% Using PAM modulation and demodulation functions
yNew = pammod(x,M); % Modulate.
% ... channel filtering ...
zNew = pamdemod(y,M); % Demodulate.
```

More About

Full Precision for Fixed-Point System Objects

FullPrecisionOverride is a convenience property that, when you set to `true`, automatically sets the appropriate properties for an object to use full-precision to process fixed-point input.

For System objects, full precision, fixed-point operation refers to growing just enough additional bits to compute the ideal full precision result. This operation has no minimum or maximum range overflow nor any precision loss due to rounding or underflow. It is also independent of any hardware-specific settings. The data types chosen are based only on known data type ranges and not on actual numeric values. Full precision for System objects does not optimize coefficient values. When you set the FullPrecisionOverride property to `true`, the other fixed-point properties it controls no longer apply and any of their non-default values are ignored. These properties are also hidden. To specify individual fixed-point properties, first set FullPrecisionOverride to `false`.

Algorithms

This object implements the algorithm, inputs, and outputs described on the M-PAM Demodulator Baseband block reference page. The object properties correspond to the block parameters.

step

System object: comm.PAMDemodulator

Package: comm

(Not recommended) Demodulate using M-ary PAM method

Note comm.PAMDemodulator is not recommended. Use pamdemod instead.

Syntax

$Y = \text{step}(H,X)$

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, $y = \text{step}(\text{obj}, x)$ and $y = \text{obj}(x)$ perform equivalent operations.

$Y = \text{step}(H,X)$ demodulates data, X , with the M-PAM demodulator System object, H , and returns Y . Input X must be a scalar or column vector. The data type of the input can be double or single precision, signed integer, or signed fixed point (fi objects). Depending on the `BitOutput` property value, output Y can be integer or bit valued.

Note `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications. For more information on changing property values, see “System Design in MATLAB Using System Objects”.

comm.PAMModulator

Package: comm

(Not recommended) Modulate using M-ary PAM method

Note comm.PAMModulator is not recommended. Use pammod instead.

Description

The PAMModulator object modulates using M-ary pulse amplitude modulation. The output is a baseband representation of the modulated signal. The M-ary number parameter, M, represents the number of points in the signal constellation and requires an even integer.

To modulate a signal using M-ary pulse amplitude modulation:

- 1 Define and set up your PAM modulator object. See “Construction” on page 3-997.
- 2 Call `step` to modulate the signal according to the properties of `comm.PAMModulator`. The behavior of `step` is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj, x)` and `y = obj(x)` perform equivalent operations.

Construction

`H = comm.PAMModulator` creates a modulator System object, H. This object modulates the input signal using the M-ary pulse amplitude modulation (M-PAM) method.

`H = comm.PAMModulator(Name, Value)` creates an M-PAM modulator object, H, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as `(Name1, Value1, ..., NameN, ValueN)`.

`H = comm.PAMModulator(M, Name, Value)` creates an M-PAM modulator object, H. This object has the `ModulationOrder` property set to M and the other specified properties set to the specified values.

Properties

ModulationOrder

Number of points in signal constellation

Specify the number of points in the signal constellation as a positive, integer scalar value. The default is 4. When you set the `BitInput` on page 3-0 property to `false`, `ModulationOrder` must be even. When you set the `BitInput` property to `true`, `ModulationOrder` must be an integer power of two.

BitInput

Assume bit inputs

Specify whether the input is in bits or integers. The default is `false`.

When you set this property to `true`, the `step` method input requires a column vector of bit values whose length is an integer multiple of `log2(ModulationOrder on page 3-0)`. This vector contains bit representations of integers between `0` and `ModulationOrder-1`.

When you set this property to `false`, the `step` method input must be a column vector of integer symbol values between `0` and `ModulationOrder-1`.

SymbolMapping

Constellation encoding

Specify how the object maps an integer or group of `log2(ModulationOrder on page 3-0)` input bits to the corresponding symbol as one of `Binary` | `Gray`. The default is `Gray`.

When you set this property to `Gray`, the object uses a Gray-encoded signal constellation.

When you set this property to `Binary`, the input integer m , between $0 \leq m \leq \text{ModulationOrder}-1$ maps to the complex value $2^{m - \text{ModulationOrder} + 1}$.

NormalizationMethod

Constellation normalization method

Specify the method used to normalize the signal constellation as one of `Minimum distance between symbols` | `Average power` | `Peak power`. The default is `Minimum distance between symbols`.

MinimumDistance

Minimum distance between symbols

Specify the distance between two nearest constellation points as a positive, real, numeric scalar value. The default is 2. This property applies when you set the `NormalizationMethod on page 3-0` property to `Minimum distance between symbols`.

AveragePower

Average power of constellation

Specify the average power of the symbols in the constellation as a positive, real, numeric scalar value. The default is 1. This property applies when you set the `NormalizationMethod on page 3-0` property to `Average power`.

PeakPower

Peak power of constellation

Specify the maximum power of the symbols in the constellation as a positive, real, numeric scalar value. The default is 1. This property applies when you set the `NormalizationMethod on page 3-0` property to `Peak power`.

OutputDataType

Data type of output

Specify the output data type as one of `double` | `single` | `Custom`. The default is `double`.

Fixed-Point Properties

CustomOutputDataType

Fixed-point data type of output

Specify the output fixed-point type as a `numericType` object with a signedness of `Auto`. The default is `numericType([],16)`. This property applies when you set the `OutputDataType` on page 3-0 property to `Custom`.

Methods

<code>constellation</code>	(Not recommended) Calculate or plot ideal signal constellation
<code>step</code>	(Not recommended) Modulate using M-ary PAM method

Common to All System Objects

<code>release</code>	Allow System object property value changes
----------------------	--

Examples

Modulate data using 16-PAM modulation, and visualize the data in a scatter plot.

```
% Create binary data for 100, 4-bit symbols
data = randi([0 1],400,1);
% Create a 16-PAM modulator System object with bits as inputs and
% Gray-coded signal constellation
hModulator = comm.PAMModulator(16,'BitInput',true);
% Modulate and plot the data
modData = step(hModulator, data);
constellation(hModulator)
```

Compatibility Considerations

comm.PAMModulator is not recommended

`comm.PAMModulator` is not recommended. Use `pammod` instead.

```
n = 10000; % Number of symbols to process
M = 8; % Modulation order
x = randi([0 M-1],n,1); % Create message signal.

%% Using PAM modulation and demodulation system objects
pammodObj = comm.PAMModulator(M);
pamdemodObj = comm.PAMDemodulator(M);
yOld = pammodObj(x); % Modulate.
% ... channel filtering ...
zOld = pamdemodObj(complex(y)); % Demodulate.
```

```
%% Using PAM modulation and demodulation functions
yNew = pammod(x,M); % Modulate.
% ... channel filtering ...
zNew = pamdemod(y,M); % Demodulate.
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the M-PAM Modulator Baseband block reference page. The object properties correspond to the block parameters.

step

System object: comm.PAMModulator

Package: comm

(Not recommended) Modulate using M-ary PAM method

Note comm.PAMModulator is not recommended. Use pammod instead.

Syntax

$Y = \text{step}(H,X)$

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, $y = \text{step}(\text{obj}, x)$ and $y = \text{obj}(x)$ perform equivalent operations.

$Y = \text{step}(H,X)$ modulates input data, X , with the M-PAM modulator System object, H . It returns the baseband modulated output, Y . Depending on the value of the `BitInput` property, input X can be an integer or bit valued column vector with numeric, logical, or fixed-point data types.

Note `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications. For more information on changing property values, see "System Design in MATLAB Using System Objects".

comm.PhaseFrequencyOffset

Package: comm

Apply phase and frequency offsets to input signal

Description

The `PhaseFrequencyOffset` object applies phase and frequency offsets to an incoming signal.

To apply phase and frequency offsets to the input signal:

- 1 Create the `comm.PhaseFrequencyOffset` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

Creation

Syntax

```
pfo = comm.PhaseFrequencyOffset  
pfo = comm.PhaseFrequencyOffset(Name=Value)
```

Description

`pfo = comm.PhaseFrequencyOffset` creates a phase and frequency offset System object. This object applies phase and frequency offsets to an input signal.

`pfo = comm.PhaseFrequencyOffset(Name=Value)` creates a phase and frequency offset object with each specified property set to the specified value. For example, `SampleRate=20` sets a sample rate of 20 Hz. You can specify additional name-value pair arguments in any order as `(Name1=Value1,...,NameN=ValueN)`.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see [System Design in MATLAB Using System Objects](#).

PhaseOffset — Phase offset

0 (default) | scalar | row or column vector | matrix

Phase offset in degrees, specified as numeric scalar, an M -by-1 or 1-by- N numeric vector, or an M -by- N numeric matrix. For more information, see “[Interdependent Property-Input Dimensions](#)” on page 3-1008.

Tunable: Yes

Data Types: double

FrequencyOffsetSource — Frequency offset source

"Property" (default) | "Input port"

Frequency offset source, specified as one of these values

- "Property" — Specify the frequency offset using the FrequencyOffset property.
- "Input port" — Specify the frequency offset in the foffset input argument.

FrequencyOffset — Frequency offset

0 (default) | scalar | row or column vector | matrix

Frequency offset in Hz, specified as a numeric scalar, a numeric row or column vector, or a numeric matrix.

For more information, see “Interdependent Property-Input Dimensions” on page 3-1008.

Tunable: Yes

Dependency

To enable this property, set the FrequencyOffsetSource property to "Property".

Data Types: double

SampleRate — Sample rate

1 (default) | positive scalar

Sample rate of the input signal in Hz, specified as a positive scalar.

Data Types: double

Usage

Syntax

```
y = pfo(x)
y = pfo(x, foffset)
```

Description

$y = \text{pfo}(x)$ applies phase and frequency offsets to input signal x . To use this syntax, set the FrequencyOffsetSource to "Property".

$y = \text{pfo}(x, \text{foffset})$ specifies the frequency offset to apply to x . To use this syntax, set the FrequencyOffsetSource to "Input port".

Input Arguments

x — Input signal

scalar | row or column vector | matrix

Input signal, specified as a numeric scalar, a numeric row or column vector, or a numeric matrix. For more information, see “Interdependent Property-Input Dimensions” on page 3-1008.

Data Types: `single` | `double`

foffset — Frequency offset

scalar | row or column vector | matrix

Frequency offset in Hz, specified as a numeric scalar, a numeric row or column vector, or a numeric matrix. For more information, see the description of the `FrequencyOffset` property and “Interdependent Property-Input Dimensions” on page 3-1008.

Dependency

To enable this input, set the `FrequencyOffsetSource` property to “Input port”.

Data Types: `single` | `double`

Output Arguments**y — Output signal**

scalar | row or column vector | matrix

Output signal, returned with the same dimensions and data type as `x`.

Data Types: `single` | `double`

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Common to All System Objects

<code>step</code>	Run System object algorithm
<code>release</code>	Release resources and allow changes to System object property values and input characteristics
<code>reset</code>	Reset internal states of System object

Examples**Introduce Phase Offset to 16-QAM Signal**

Introduce a phase offset to a 16-QAM signal and view its effect on the constellation.

Create a phase frequency offset System object™, setting the phase offset to 30 degrees.

```
pfo = comm.PhaseFrequencyOffset(PhaseOffset=30);
```

Generate random symbols and apply 16-QAM modulation.

```
M = 16;  
data = (0:M-1)';  
x = qammod(data,M);
```

Plot the 16-QAM constellation.

```
scatterplot(x);  
title("Original Constellation")  
xlim([-5 5])  
ylim([-5 5])
```

Introduce a phase offset and plot the offset constellation.

```
y = pfo(x);  
scatterplot(y);  
title("Constellation After Phase Offset")  
xlim([-5 5])  
ylim([-5 5])
```

More About

Interdependent Property-Input Dimensions

This table outlines the interdependency of property-to-input argument dimensions.

Number of Dimensions	Data I/O Dimension	Frame Size	Number of Channels	Frequency/Phase Offset Property Dimension	Frequency Offset Input Argument Dimension
Any	Scalar	1	1	Scalar	Scalar
2	M -by-1	M	1	M -by-1 1-by- M 1-by-1	M M -by-1 1 1-by-1

Number of Dimensions	Data I/O Dimension	Frame Size	Number of Channels	Frequency/Phase Offset Property Dimension	Frequency Offset Input Argument Dimension
2	1-by- N	1	N	N -by-1 1-by- N 1-by-1	N 1-by- N 1 1-by-1
2	M -by- N	M	N	M -by- N N -by-1 1-by- N M -by-1 1-by- M 1-by-1	M -by- N N 1-by- N 1 1-by-1 M M -by-1

For example:

- When you specify a scalar offset property, the object applies the same offset to all elements of the input signal
- When you specify a 2-by-1 offset property for a 2-by-3 input signal (one offset value per sample), the object applies the same sample offset across the three channels.
- When you specify a 1-by-3 offset property for a 2-by-3 input signal (one offset value per channel), the same channel offset is applied across the two samples of a channel.
- When you specify a 2-by-3 offset property for a 2-by-3 input signal (one offset value per sample for each channel), the offsets are applied element-wise to the input signal.

Algorithms

If the input signal is $u(t)$, then the output signal is

$$y(t) = u(t) \cdot \left(\cos\left(2\pi \int_0^t f(\tau) d\tau + \varphi(t)\right) + j \sin\left(2\pi \int_0^t f(\tau) d\tau + \varphi(t)\right) \right),$$

where $f(t)$ is the frequency offset, and $\varphi(t)$ is the phase offset.

The discrete-time output is given by

$$y(0) = u(0)(\cos(\varphi(0)) + j \sin(\varphi(0))) \text{ and}$$

$$y(i) = u(i) \left(\cos\left(2\pi \sum_{n=0}^{i-1} f(n)\Delta t + \varphi(i)\right) + j \sin\left(2\pi \sum_{n=0}^{i-1} f(n)\Delta t + \varphi(i)\right) \right),$$

where $i > 0$, and Δt is the sample time.

`comm.ThermalNoise` | `comm.PhaseNoise` | `comm.MemorylessNonlinearity` | `frequencyOffset`

Introduced in R2012a

comm.PhaseNoise

Package: comm

Apply phase noise to baseband signal

Description

The `comm.PhaseNoise` System object adds phase noise to a complex signal. This object emulates impairments introduced by the local oscillator of a wireless communication transmitter or receiver. The object generates filtered phase noise according to the specified spectral mask and adds it to the input signal. For a description of the phase noise modeling, see “Algorithms” on page 3-1017.

To add phase noise using a `comm.PhaseNoise` object:

- 1 Create the `comm.PhaseNoise` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

Creation

Syntax

```
phznnoise = comm.PhaseNoise
phznnoise = comm.PhaseNoise(Name,Value)
phznnoise = comm.PhaseNoise(level,offset,samplerate)
```

Description

`phznnoise = comm.PhaseNoise` creates a phase noise System object with default property values.

`phznnoise = comm.PhaseNoise(Name,Value)` creates a phase noise object with the specified property `Name` set to the specified `Value`. You can specify additional name-value pair arguments in any order as `(Name1,Value1,...,NameN,ValueN)`.

`phznnoise = comm.PhaseNoise(level,offset,samplerate)` creates a phase noise object with the phase noise level, frequency offset, and sample rate properties specified as value-only arguments. When specifying a value-only argument, you must specify all preceding value-only arguments.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see [System Design in MATLAB Using System Objects](#).

Level — Phase noise level

[-80 -100] (default) | vector of negative scalars

Phase noise level in decibels relative to carrier per hertz (dBc/Hz), specified as a vector of negative scalars. The `Level` and `FrequencyOffset` properties must have the same length.

Data Types: double

FrequencyOffset — Frequency offset

[2000 20000] (default) | vector of positive increasing values

Frequency offset in Hz, specified as a vector of positive increasing values. The maximum frequency offset value must be less than $F_s/2$, where F_s represents the `SampleRate` property value.

The `Level` and `FrequencyOffset` properties must have the same length.

Data Types: double

SampleRate — Sample rate

1e6 (default) | positive scalar

Sample rate in Hz, specified as a positive scalar greater than two times the maximum value specified by the `FrequencyOffset` property.

Data Types: double

RandomStream — Source of random stream

'Global stream' (default) | 'mt19937ar with seed'

Source of the random stream, specified as 'Global stream' or 'mt19937ar with seed'. If `RandomStream` is set to 'mt19937ar with seed', the mt19937ar algorithm is used for normally distributed random number generation, in which case the `reset` method reinitializes the random number stream to the value of the `Seed` property.

Data Types: char | string

Seed — Initial seed2137 (default) | positive scalar less than 2^{32}

Initial seed for `RandomStream`, specified as a positive scalar less than 2^{32} .

Dependencies

To enable this property, set `RandomStream` to 'mt19937ar with seed'.

Data Types: double

Usage**Syntax**

```
out = phznoise(in)
```

Description

`out = phznoise(in)` adds phase noise, specified by the `phznoise` System object, to the input signal. The result is returned in `out`.

Input Arguments

in — Input signal

vector | matrix

Input signal, specified as an N_S -by-1 numeric vector or N_S -by- M numeric matrix. N_S is the number of samples and M is the number of channels.

Data Types: double | single

Complex Number Support: Yes

Output Arguments

out — Output signal

vector | matrix

Output signal, returned as a complex-valued signal with the same data type and size as the input signal.

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Specific to comm.PhaseNoise

visualize Visualize spectrum mask of phase noise

Common to All System Objects

step Run System object algorithm

release Release resources and allow changes to System object property values and input characteristics

reset Reset internal states of System object

Examples

Phase Noise Effects on 16-QAM Signal

Add a phase noise vector and frequency offset vector to a 16-QAM signal. Then plot the signal.

Create a phase noise System object.

```
pnoise = comm.PhaseNoise('Level',-50,'FrequencyOffset',20);
```

Generate modulated symbols.

```
M = 16; % From 16-QAM
data = randi([0 M-1],1000,1);
modData = qammod(data,M);
```

Use `pnoise` to apply phase noise. Plot the impaired data.

```
y = pnoise(modData);
scatterplot(y)
```

View Phase Noise Effects on Signal Spectrum

View the effects of phase noise on a 10 MHz sine wave by using a spectrum analyzer. Adjust the resolution bandwidth of the spectrum analyzer to see its impact on the visualized spectral noise.

Initialize variables for the simulation.

```
fc = 1e6; % Carrier frequency in Hz
fs = 4e6; % Sample rate in Hz.
phNzLevel = [-85 -118 -125 -145]; % in dBc/Hz
phNzFreqOff = [1e3 9.5e3 19.5e3 195e3]; % in Hz
Nspf = 6e6; % Number of Samples per frame
freqSpan = 400e3; % in Hz, for spectrum computation
```

Create sine wave, phase noise, and spectrum analyzer objects.

```
sinewave = dsp.SineWave('Amplitude',1, ...
    'Frequency',fc, ...
    'SampleRate',fs, ...
    'SamplesPerFrame',Nspf, ...
    'ComplexOutput',true);
pnoise = comm.PhaseNoise('Level',phNzLevel, ...
```

```

    'FrequencyOffset',phNzFreqOff, ...
    'SampleRate',fs);
spectrumscopeRBW1 = dsp.SpectrumAnalyzer( ...
    'NumInputPorts',2, ...
    'SampleRate',fs, ...
    'FrequencySpan','Span and center frequency', ...

    'YLimits',[-150 10], ...
    'Title','Resolution Bandwidth 1 Hz', ...
    'Position',[79 147 605 374]);
spectrumscopeRBW10 = dsp.SpectrumAnalyzer( ...
    'NumInputPorts',2, ...
    'SampleRate',fs, ...
    'FrequencySpan','Span and center frequency', ...
    'CenterFrequency',fc, ...
    'Span',freqSpan, ...
    'RBWSource','Property', ...
    'RBW',10, ...
    'SpectrumType','Power density', ...
    'SpectralAverages',10, ...
    'SpectrumUnits','dBW', ...
    'YLimits',[-150 10], ...
    'Title','Resolution Bandwidth 10 Hz', ...
    'Position',[685 146 605 376]);

```

To analyze the spectrum and phase noise, the example includes two spectrum analyzer objects, with 1 Hz and 10 Hz resolution bandwidths, respectively. The spectrum analyzer objects use the default Hann windowing setting, the units are set to dBW/Hz, and the number of spectral averages is set to 10.

```

x = sinewave();
y = pnoise(x);

```

When the resolution bandwidth is 1 Hz, the dBW/Hz view for the spectrum analyzer shows the tone at 0 dBW/Hz. The spectrum analyzer object corrects for the power spreading effect of the Hann windowing. Results show the visual average of the phase noise match the specified phase noise spectrum.

```

spectrumscopeRBW1(x,y)

```

When the resolution bandwidth is 10 Hz, the dBW/Hz view for the spectrum analyzer shows the tone at -10 dBW/Hz. The tone energy of the sine wave is now spread across 10 Hz instead of 1 Hz, so the sine wave PSD level reduces by 10 dB. With the resolution bandwidth at 10 Hz, the visual average of the phase noise still achieves the phase noise defined by the phase noise object.

With the resolution bandwidth increased from 1 Hz to 10 Hz, the spectrum analyzer object still corrects for the power spreading effect of the Hann window, and it achieves better spectral averaging with the wider resolution bandwidth. For more information, see "Why Use Windows?"

`spectrumscopeRBW10(x,y)`

Calculate the RMS phase noise in degrees between the pure and noisy sine waves. In the general case, the pure signal must be time aligned with the noisy signal to accurately determine the phase error. However, in this case, the periodicity of the sine wave makes this step unnecessary.

```
ph_err = unwrap(angle(y) - angle(x));
rms_ph_nz_deg = rms(ph_err)*180/pi();
sprintf('The computed RMS phase noise is %3.2f degrees.\n', ...
        rms_ph_nz_deg)
```

```
ans =
    'The computed RMS phase noise is 0.18 degrees.'
```

Algorithms

The output signal, y_k , is related to input sequence x_k by $y_k = x_k e^{j\varphi_k}$, where φ_k is the phase noise. The phase noise is filtered Gaussian noise such that $\varphi_k = f(n_k)$, where n_k is the noise sequence and f represents a filtering operation.

To model the phase noise, define the power spectrum density (PSD) mask characteristic by specifying scalar or vector values for the frequency offset and phase noise level.

- For a scalar frequency offset and phase noise level specification, an IIR digital filter computes the spectrum mask. The spectrum mask has a $1/f$ characteristic that passes through the specified point.
- For a vector frequency offset and phase noise level specification, an FIR filter computes the spectrum mask. The spectrum mask is interpolated across $\log_{10}(f)$. It is flat from DC to the lowest frequency offset, and from the highest frequency offset to half the sample rate.

IIR Digital Filter

For the IIR digital filter, the numerator coefficient is

$$\lambda = \sqrt{2\pi f_{\text{offset}} 10^{L/10}},$$

where f_{offset} is the frequency offset in Hz and L is the phase noise level in dBc/Hz. The denominator coefficients, γ_i , are recursively determined as

$$\gamma_i = (i - 2.5) \frac{\gamma_{i-1}}{i - 1},$$

where $\gamma_1 = 1$, $i = \{1, 2, \dots, N_t\}$, and N_t is the number of filter coefficients. N_t is a power of 2, from 2^7 to 2^{19} . The value of N_t grows as the phase noise offset decreases towards 0 Hz.

FIR Filter

For the FIR filter, the phase noise level is determined through $\log_{10}(f)$ interpolation for frequency offsets over the range $[df, f_s / 2]$, where df is the frequency resolution and f_s is the sample rate. The phase noise is flat from 0 Hz to the smallest frequency offset, and from the largest frequency offset to $f_s / 2$. The frequency resolution is equal to $\frac{f_s}{2} \left(\frac{1}{N_t} \right)$, where N_t is the number of coefficients, and is a power of 2 less than or equal to 2^{16} . If $N_t < 2^8$, a time domain FIR filter is used. Otherwise, a frequency domain FIR filter is used.

The algorithm increases N_t until these conditions are met:

- The frequency resolution is less than the minimum value of the frequency offset vector.
- The frequency resolution is less than the minimum difference between two consecutive frequencies in the frequency offset vector.

- The maximum number of FIR filter taps is 2^{16} .

comm.PNSequence

Package: comm

Generate a pseudonoise (PN) sequence

Description

The `comm.PNSequence` System object generates a sequence of pseudorandom binary numbers using a linear-feedback shift register (LFSR). This object implements LFSR using a simple shift register generator (SSRG, or Fibonacci) configuration. Pseudonoise sequences are typically used for pseudorandom scrambling and in direct-sequence spread-spectrum systems.

To generate a PN sequence:

- 1 Create the `comm.PNSequence` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

Creation

Syntax

```
pnSequence = comm.PNSequence  
pnSequence = comm.PNSequence(Name, Value)
```

Description

`pnSequence = comm.PNSequence` creates a pseudonoise (PN) sequence generator System object. This object generates a sequence of pseudorandom binary numbers using a linear-feedback shift register (LFSR).

`pnSequence = comm.PNSequence(Name, Value)` sets properties using one or more name-value pairs. Enclose each property name in quotes. For example, `'Mask', 1` specifies a one sample offset of the output sequence from the starting point.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see [System Design in MATLAB Using System Objects](#).

Polynomial — Generator polynomial

'z⁶ + z + 1' (default) | character vector | string scalar | binary row vector | integer vector

Generator polynomial that determines the feedback connections of the shift register, specified as one of these options:

- Character vector or string scalar of a polynomial whose constant term is 1. For more information, see “Representation of Polynomials in Communications Toolbox”.
- Binary-valued row vector that represents the coefficients of the polynomial in order of descending powers. The length of this vector must be $N + 1$, where N is the degree of the polynomial. The first and last entries must be 1, indicating the leading term with degree N and a constant term of 1.
- Integer-valued row vector of elements that represent the exponents for the nonzero terms of the polynomial in order of descending powers. The last entry must be 0, indicating a constant term of 1.

For more information, see “Simple Shift Register Generator” on page 3-1031.

Example: 'z^8 + z^2 + 1', [1 0 0 0 0 0 1 0 1], and [8 2 0] represent the same polynomial, $p(z) = z^8 + z^2 + 1$.

Data Types: double | char

InitialConditionsSource — Source of initial conditions

'Property' (default) | 'Input port'

Source of the initial conditions used for the shift register of the PN sequence, specified as one of these values:

- 'Property' — Specify PN sequence generator initial conditions by using the InitialConditions property.
- 'Input port' — Specify PN sequence generator initial conditions by using the initcond input argument.

Data Types: char

InitialConditions — Initial conditions of shift register

[0 0 0 0 0 1] (default) | binary scalar | binary vector

Initial conditions used for the shift register of the PN sequence generator when the simulation starts, specified as a binary-valued scalar or binary-valued vector.

- If you set this property to a scalar, the initial value of all cells in the shift register are the specified scalar value.
- If you set this property to a vector, each element of the vector corresponds to the initial value of the corresponding cell in the shift register. The length of the vector must equal the degree of the generator polynomial specified by the Polynomial property.

For more information, see “Simple Shift Register Generator” on page 3-1031.

Note For the object to generate a nonzero sequence, at least one element of the initial conditions for the first or second preferred PN sequence generator must be nonzero. Specifically, the initial state of at least one of the shift registers must be nonzero.

Dependencies

To enable this property, set `InitialConditionsSource` to `'Property'`.

Data Types: `double`

MaskSource — Source of mask to shift PN sequence

`'Property'` (default) | `'Input port'`

Source of the mask that determines the shift of the PN sequence, specified as one of these:

- `'Property'` — Specify the mask by using the `Mask` property.
- `'Input port'` — Specify the mask by using the `maskvec` input argument.

Data Types: `char`

Mask — Mask to shift PN sequence

`0` (default) | integer scalar | binary vector

Mask that determines how the PN sequence is shifted from its starting point, specified as an integer scalar or a binary vector.

- When you set this property to an integer scalar, the value is the length of the shift. The object wraps shift values that are negative or greater than the length of the PN sequence.
- When you set this property to a binary vector, its length must equal the degree of the generator polynomial specified by the `Polynomial` property.

For more information, see “Shifting PN Sequence Starting Point” on page 3-1032. The mask vector can be calculated using the `shift2mask` function.

Dependencies

To enable this property, set `MaskSource` to `'Property'`.

VariableSizeOutput — Enable variable-size outputs

`false` (default) | `true`

Enable variable-size outputs, specified as a numeric or logical `0` (`false`) or `1` (`true`). To enable variable-size outputs by using the `outputsize` input argument, set this property to `true`. The enabled input specifies the output size of the PN sequence. The input value must be less than or equal to the value of the `MaximumOutputSize` property.

When you set this property to `false`, the `SamplesPerFrame` property specifies the number of output samples.

MaximumOutputSize — Maximum output size

`[10 1]` (default) | vector of the form `[m 1]`

Maximum output frame size, specified as a vector of the form `[m 1]`, where `m` is a positive integer. The first element of the vector indicates the maximum length of the output frame and the second element of the vector must be `1`.

Example: `[20 1]` specifies a maximum frame output size of 20-by-1.

Dependencies

To enable this property, set `VariableSizeOutput` to `true`.

SamplesPerFrame — Number of samples output per frame

1 (default) | positive integer

Number of samples output per frame, specified as a positive integer. If you set this property to a value of M , then the object outputs M samples of a PN sequence that has a period of $N = 2^n - 1$, where n represents the degree of the generator polynomial that the `Polynomial` specifies.

If you set the `BitPackedOutput` property to `false`, the samples are bits from the PN sequence. If you set the `BitPackedOutput` property to `true`, then the output corresponds to `SamplesPerFrame` groups of bit-packed samples.

ResetInputPort — Enable generator reset input`false` (default) | `true`

Enable the generator reset input, specified as a numeric or logical 0 (`false`) or 1 (`true`). To enable the ability to reset the sequence generator using the `resetseq` input argument, set this property to `true`. This input resets the states of the PN sequence generator to the initial conditions specified in the `InitialConditions` property. For more information, see “Resetting a Signal” on page 3-1032.

Dependencies

To enable this property, set `InitialConditionsSource` to 'Property'.

BitPackedOutput — Output bit-packed words`false` (default) | `true`

Option to output bit-packed words, specified as `false` or `true`. Set this property to `true` to enable bit-packed outputs.

When `BitPackedOutput` is `true`, the object outputs a column vector of length M , which contains most-significant-bit (MSB) first integer representations of bit words of length P . M is the number of samples per frame specified in the `SamplesPerFrame` property. P is the size of the bit-packed words specified in the `NumPackedBits` property.

Note The first bit from the left in the bit-packed word contains the most significant bit for the integer representation.

NumPackedBits — Number of bits per bit-packed word

8 (default) | integer in the range [1, 32]

Number of bits packed into each output data word, specified as an integer in the range [1, 32].

Dependencies

To enable this property, set `BitPackedOutput` to `true`.

SignedOutput — Output signed bit-packed words`false` (default) | `true`

Set this property to `true` to obtain signed, bit-packed, output words. In this case, a 1 in the most significant bit (sign bit) indicates a negative value. The property indicates negative numbers in a two's complement format.

Dependencies

To enable this property, set `BitPackedOutput` to `true`.

OutputDataType — Data type of output

'double' (default) | 'logical' | 'Smallest unsigned integer' | 'Smallest integer'

Output data type, specified as one of these values:

- When `BitPackedOutput` is set to `false`, `OutputDataType` can be 'double', 'logical', or 'Smallest unsigned integer'.
- When `BitPackedOutput` is set to `true`, `OutputDataType` can be 'double' or 'Smallest integer'.

Note You must have a Fixed-Point Designer user license to use this property in 'Smallest unsigned integer' or 'Smallest integer' mode.

Dependencies

The valid settings for this property depend on the setting of the `BitPackedOutput` property.

Usage**Syntax**

```
outSequence = pnSequence()  
outSequence = pnSequence(initcond)  
outSequence = pnSequence(maskvec)  
outSequence = pnSequence(outputsize)  
outSequence = pnSequence(resetseq)  
outSequence = pnSequence(initcond,maskvec,outputsize)  
outSequence = pnSequence(maskvec,outputsize,resetseq)
```

Description

`outSequence = pnSequence()` outputs a frame of the PN sequence in a column vector based on the configured object.

`outSequence = pnSequence(initcond)` uses `initcond` as the initial conditions for the PN sequence of the linear-feedback shift register.

To enable this syntax, set the `InitialConditionsSource` property to 'Input port'.

`outSequence = pnSequence(maskvec)` uses the `maskvec` input to specify the mask vector that determines how the PN sequence is shifted from its starting point.

To enable this syntax, set the `MaskSource` property to 'Input port'.

`outSequence = pnSequence(outputsize)` uses `outputsize` as the output size.

To enable this syntax, set the `VariableSizeOutput` property to `true`.

`outSequence = pnSequence(resetseq)` uses `resetseq` as the reset signal.

To enable this syntax, set the `InitialConditionsSource` property to 'Property' and the `ResetInputPort` property to true.

`outSequence = pnSequence(initcond,maskvec,outputsize)`

To enable this syntax, set the `InitialConditionsSource` property to 'Input port', the `ResetInputPort` property to false, the `MaskSource` property to 'Input port', and the `VariableSizeOutput` property to true.

`outSequence = pnSequence(maskvec,outputsize,resetseq)`

To enable this syntax, set the `InitialConditionsSource` property to 'Property', the `MaskSource` property to 'Input port', the `VariableSizeOutput` property to true, the `ResetInputPort` property to true.

Input Arguments

initcond — Initial register conditions used for shift register

binary-valued scalar | binary-valued vector

Initial conditions used for the shift register when the simulation starts, specified as a binary-valued scalar or binary-valued vector.

- If you set this property to a scalar, the initial value of all cells in the shift register are the specified scalar value.
- If you set this input to a vector, each element of the vector corresponds to the initial value of the corresponding cell in the shift register. The length of the vector must equal the degree of the generator polynomial specified by the `Polynomial` property.

Note For the object to generate a nonzero sequence, at least one element of the initial condition for the PN sequence generator must be nonzero. Specifically, the initial state of at least one of the shift registers must be nonzero.

Example: `outSequence = pnSequence([1 1 0])` corresponds to possible initial register states for a PN sequence generator specified by a generator polynomial of degree 3.

Data Types: double

maskvec — Mask vector

binary vector

Mask that determines how the PN sequence is shifted from its starting point, specified as a binary vector. The length of the vector must equal the degree of the `Polynomial` property.

outputsize — Length of output sequence

nonnegative integer | vector of the form `[n 1]`

Length of output sequence, specified as a nonnegative integer, n , or a vector of the form `[n 1]`, where n is a positive integer. The first element of the vector indicates the length of the output frame and the second element of the vector must be 1.

The scalar or the first element of the row vector must be less than or equal to the first element of the `MaximumOutputSize` property value.

resetseq — Reset PN sequence generator

scalar | column vector

Reset sequence generator, specified as a scalar or a column vector with length equal to the number of samples per frame specified by the `SamplesPerFrame` property.

- When you specify this input as a nonzero scalar, the object resets to the specified initial conditions and then generates a new output frame.
- When you specify this input as a column vector, the object resets to the specified initial conditions at each sample in the output frame that aligns with a nonzero value in the reset vector.

For more information, see “Resetting a Signal” on page 3-1032.

Output Arguments

outSequence — PN Sequence

column vector

PN sequence generated by the object, returned as a column vector.

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Common to All System Objects

<code>step</code>	Run System object algorithm
<code>release</code>	Release resources and allow changes to System object property values and input characteristics
<code>reset</code>	Reset internal states of System object

Examples

Configuring a PN Sequence Generator

When configuring a PN sequence generator System object™, you have options regarding how to express the polynomial and the mask. This figure defines a PN sequence generator with a generator polynomial $p(z) = z^6 + z + 1$ and a mask $m(z) = z^5 + z^4 + z^2 + 1$. The example shows a few of the formatting options available to define the generator polynomial and the mask when you configure the PN sequence generator in this figure.

You can input the polynomial exponents of z for the nonzero terms of the polynomial in descending order of powers and the mask as a binary vector.

```
pnseq1 = comm.PNSequence('Polynomial',[6 1 0], ...
    'Mask',[1 1 0 1 0 1], 'SamplesPerFrame',20)
```

```
pnseq1 =
  comm.PNSequence with properties:
    Polynomial: [6 1 0]
    InitialConditionsSource: 'Property'
    InitialConditions: [0 0 0 0 0 1]
    MaskSource: 'Property'
    Mask: [1 1 0 1 0 1]
    VariableSizeOutput: false
    SamplesPerFrame: 20
    ResetInputPort: false
    BitPackedOutput: false
    OutputDataType: 'double'
```

You can input the polynomial exponents as a binary-valued row vector that represents the coefficients of the polynomial in order of descending powers.

```
pnseq2 = comm.PNSequence('Polynomial',[1 0 0 0 0 1 1], ...
    'Mask',[1 1 0 1 0 1], 'SamplesPerFrame',20)
```

```
pnseq2 =
  comm.PNSequence with properties:
    Polynomial: [1 0 0 0 0 1 1]
    InitialConditionsSource: 'Property'
    InitialConditions: [0 0 0 0 0 1]
    MaskSource: 'Property'
    Mask: [1 1 0 1 0 1]
    VariableSizeOutput: false
    SamplesPerFrame: 20
    ResetInputPort: false
    BitPackedOutput: false
```

```
OutputDataType: 'double'
```

You can also define the mask as a scalar value using the `mask2shift` function.

```
mask2shift ([1 0 0 0 0 1 1],[1 1 0 1 0 1])
ans = 22
pnseq3 = comm.PNSequence('Polynomial',[1 0 0 0 0 1 1], ...
    'Mask',22,'SamplesPerFrame',20)
pnseq3 =
    comm.PNSequence with properties:
        Polynomial: [1 0 0 0 0 1 1]
    InitialConditionsSource: 'Property'
    InitialConditions: [0 0 0 0 0 1]
    MaskSource: 'Property'
    Mask: 22
    VariableSizeOutput: false
    SamplesPerFrame: 20
    ResetInputPort: false
    BitPackedOutput: false
    OutputDataType: 'double'
```

Use each PN sequence object to generate a frame of 20 samples and compare the generated sequences.

```
out_1 = pnseq1();
out_2 = pnseq2();
out_3 = pnseq3();
isequal(out_1,out_2)

ans = logical
     1

isequal(out_1,out_3)

ans = logical
     1
```

Generate Maximal Length PN Sequences

Generate a 14-sample frame of a maximal length PN sequence given generator polynomial, $x^3 + x^2 + 1$.

Generate PN sequence data by using the `comm.PNSequence` object. The sequence repeats itself as it contains 14 samples while the maximal sequence length is only 7 samples ($2^3 - 1$).

```
pnSequence = comm.PNSequence('Polynomial',[3 2 0], ...
    'SamplesPerFrame',14,'InitialConditions',[0 0 1]);
```

```
x1 = pnSequence();
[x1(1:7) x1(8:14)]
```

```
ans = 7×2
```

```
1    1
0    0
0    0
1    1
1    1
1    1
0    0
```

Create another maximal length sequence based on the generator polynomial, $x^4 + x + 1$. As it is a fourth order polynomial, the sequence repeats itself after 15 samples ($2^4 - 1$).

```
pnSequence2 = comm.PNSequence('Polynomial','x^4+x+1', ...
    'InitialConditions',[0 0 0 1], 'SamplesPerFrame',30);
```

```
x2 = pnSequence2();
[x2(1:15) x2(16:30)]
```

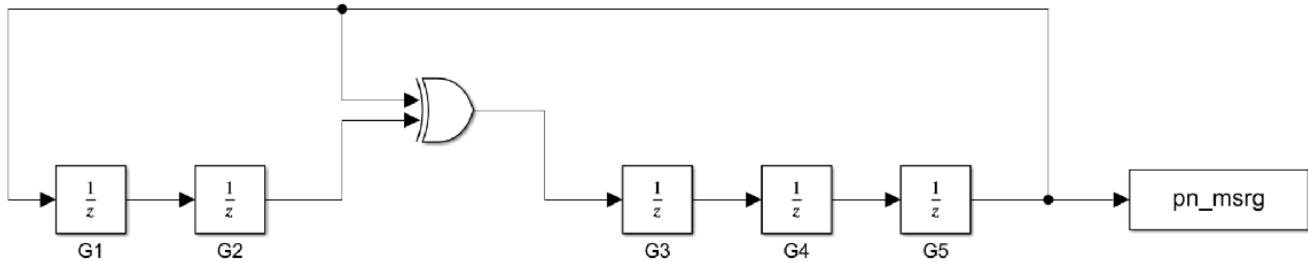

```
ans = 15×2
```

```
1    1
0    0
0    0
0    0
1    1
0    0
0    0
1    1
1    1
0    0
⋮
```

Generate Galois Linear-Feedback Shift Register Output

The `comm.PNSequence` System object implements a linear-feedback shift register (LFSR) using a simple shift register generator (SSRG, or Fibonacci configuration). This configuration differs from the modular shift register generator (MSRG, or Galois configuration) by a phase difference, that can be determined empirically from the System object.

This phase difference can be specified as the `Mask` parameter for the `comm.PNSequence` System object to generate the equivalent MSRG configuration output. The block diagram represents the implementation of a 5-bit LFSR in the Galois (MSRG) configuration.

Load the file `GaloisLFSR`. The file contains the following variables that define the properties and output PN sequence of the 5-bit Galois LFSR:

- `polyVec`: Generator polynomial
- `polySize`: Degree of the generator polynomial
- `initStates`: Initial conditions of the shift register
- `maskVar`: Mask to shift the PN sequence
- `pn_msrg`: Output PN sequence of maximal length, from the 5-bit Galois LFSR

load `GaloisLFSR`

Generate PN sequence data by using the `comm.PNSequence` object with the same set of properties used to implement the 5-bit Galois LFSR. Compare this PN sequence with the output of the 5-bit Galois LFSR. The two sequences differ by a phase shift.

```
pnSequence = comm.PNSequence( ...
    'Polynomial',polyVec, ...
    'InitialConditions',initStates,...
    'Mask',maskVar, ...
    'SamplesPerFrame',2^polySize-1);
pn = pnSequence();
isequal(pn,pn_msrg)

ans = logical
     0
```

Compute the phase shift between the two configurations. Set the value of the `Mask` property based on this phase shift.

```
for i = 1:length(pn)
    exp_pn = [pn(i:end);pn(1:(i-1))];
    if isequal(exp_pn,pn_msrg)
        break
    end
end
maskVar = i-1;
```

Generate PN sequence data by using the `comm.PNSequence` System object with the modified `Mask` property value. Compare this sequence with the output of the 5-bit Galois LFSR. The two sequences are now equal.

```
pnSequence_mod = comm.PNSequence( ...
    'Polynomial',polyVec, ...
```

```

    'InitialConditions',initStates,...
    'Mask',maskVar, ...
    'SamplesPerFrame',2^polySize-1);
pn_mod = pnSequence_mod();
isequal(pn_mod,pn_msrg)

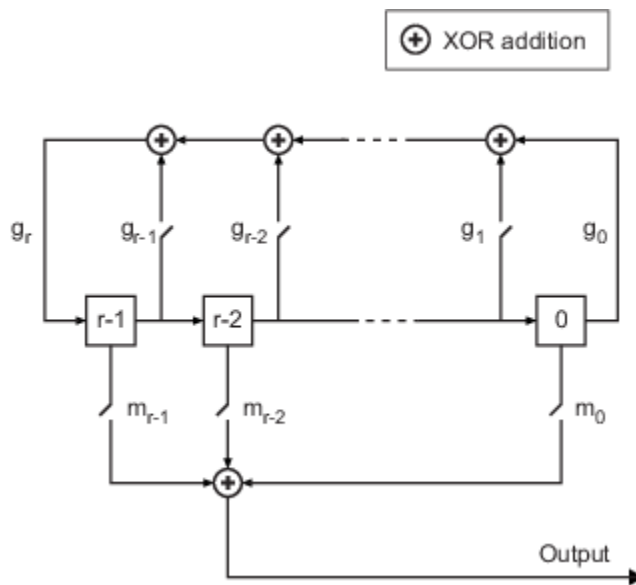

ans = logical
     1

```

More About

Simple Shift Register Generator

A linear-feedback shift register (LFSR), implemented as a simple shift register generator (SSRG), is used to generate PN sequences. This type of shift register is also known as a Fibonacci implementation.

The Polynomial property determines the feedback connections of the shift register. It is a primitive binary polynomial in z , $g_r z^r + g_{r-1} z^{r-1} + g_{r-2} z^{r-2} + \dots + g_0$. For the coefficient, $g_{k=0}$ to r , the coefficient g_k is 1 if there is a connection from the k th register to the adder. The leading term, g_r , and the constant term, g_0 , of the Polynomial property must be 1 because the polynomial must be primitive. The InitialConditions property specifies the initial values of the registers. For example, the following table indicates two sets of parameter values that correspond to a generator polynomial of $p(z) = z^8 + z^2 + 1$.

Quantity	Example 1	Example 2
Polynomial	$g1 = [1 \ 0 \ 0 \ 0 \ 0 \ 0 \ 1 \ 0 \ 1]$	$g2 = [8 \ 2 \ 0]$
Degree of generator polynomial	8, which is $\text{length}(g1) - 1$	8
InitialConditions	$[1 \ 0 \ 0 \ 0 \ 0 \ 0 \ 1 \ 0]$	$[1 \ 0 \ 0 \ 0 \ 0 \ 0 \ 1 \ 0]$

Each time you call the object, all r registers in the generator update their values according to the value of the incoming arrow to the shift register. The adders perform addition modulo 2. The output of the LFSR reflects the sum of all connections in the m mask vector.

The **Mask** property, m , determines the shift of the PN sequence starting point. For more information, see “Shifting PN Sequence Starting Point” on page 3-1032.

Shifting PN Sequence Starting Point

To shift the starting point of the PN sequence, specify the **Mask** property as:

- An integer representing the length of the shift.

The default **Mask** setting of 0 corresponds to no shift. As illustrated in the LFSR shift register diagram in “Simple Shift Register Generator” on page 3-1031, there is no shift when the only connection is along the arrow labeled m_0 .

This table shows the shift that occurs when you set **Mask** to 0 versus a positive integer d .

	T = 0	T = 1	T = 2	...	T = d	T = d+1
Shift = 0	x_0	x_1	x_2	...	x_d	x_{d+1}
Shift = d	x_d	x_{d+1}	x_{d+2}	...	x_{2d}	x_{2d+1}

- A binary vector whose length is equal to the degree of the generator polynomial. The LFSR shift register diagram in “Simple Shift Register Generator” on page 3-1031 shows **Mask** specified as a mask vector, m . The binary vector must have N elements, where N is the degree of the generator polynomial. To calculate the mask vector, use the `shift2mask` function.

The binary vector corresponds to a polynomial in z , $m_{r-1}z^{r-1} + m_{r-2}z^{r-2} + \dots + m_1z + m_0$, of degree at most $r - 1$. The mask vector that corresponds to a shift of d is the vector that represents $m(z) = z^d$ modulo $g(z)$, where $g(z)$ is the generator polynomial.

For example, if the degree of the generator polynomial is 4, then the mask vector that corresponds to $d = 2$ is [0 1 0 0], which represents the polynomial $m(z) = z^2$.

Resetting a Signal

To reset the PN generator sequence, you must first set the **ResetInputPort** property to `true`. Suppose that the system object generates a PN sequence of [1 0 0 1 1 0 1 1] when there is no reset. When the reset signal [0 0 0 1] is passed as an input argument to the object, the PN sequence is reset at the fourth bit, because the fourth bit of the reset signal is a 1.

Sequences of Maximum Length

To generate a maximum length sequence for a generator polynomial that has the degree r , set **Polynomial** to a value from the following table. The maximum sequence length is $2^r - 1$.

r	Generator Polynomial	r	Generator Polynomial	r	Generator Polynomial	r	Generator Polynomial
2	[2 1 0]	15	[15 14 0]	28	[28 25 0]	41	[41 3 0]
3	[3 2 0]	16	[16 15 13 4 0]	29	[29 27 0]	42	[42 23 22 1 0]
4	[4 3 0]	17	[17 14 0]	30	[30 29 28 7 0]	43	[43 6 4 3 0]
5	[5 3 0]	18	[18 11 0]	31	[31 28 0]	44	[44 6 5 2 0]
6	[6 5 0]	19	[19 18 17 14 0]	32	[32 31 30 10 0]	45	[45 4 3 1 0]
7	[7 6 0]	20	[20 17 0]	33	[33 20 0]	46	[46 21 10 1 0]
8	[8 6 5 4 0]	21	[21 19 0]	34	[34 15 14 1 0]	47	[47 14 0]
9	[9 5 0]	22	[22 21 0]	35	[35 2 0]	48	[48 28 27 1 0]
10	[10 7 0]	23	[23 18 0]	36	[36 11 0]	49	[49 9 0]
11	[11 9 0]	24	[24 23 22 17 0]	37	[37 12 10 2 0]	50	[50 4 3 2 0]
12	[12 11 8 6 0]	25	[25 22 0]	38	[38 6 5 1 0]	51	[51 6 3 1 0]
13	[13 12 10 9 0]	26	[26 25 24 20 0]	39	[39 8 0]	52	[52 3 0]
14	[14 13 8 4 0]	27	[27 26 25 22 0]	40	[40 5 4 3 0]	53	[53 6 2 1 0]

For more information about the shift register configurations that these polynomials represent, see *Digital Communications* by John Proakis.[1].

comm.KasamiSequence | comm.GoldSequence

Blocks

PN Sequence Generator

Introduced in R2008a

comm.PreambleDetector

Package: comm

Detect preamble in data

Description

The `comm.PreambleDetector` System object detects a preamble in an input data sequence. A preamble is a set of symbols or bits used in packet-based communication systems to indicate the start of a packet. The preamble detector object finds the location corresponding to the end of the preamble.

To detect a preamble in an input data sequence:

- 1 Create a `comm.PreambleDetector` object and set the properties of the object.
- 2 Call `step` to detect the presence of a preamble.

Note Alternatively, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj, x)` and `y = obj(x)` perform equivalent operations.

Construction

`prbdet = comm.PreambleDetector` creates a preamble detector object, `prbdet`, using the default properties.

`prbdet = comm.PreambleDetector(Name, Value)` specifies additional properties using `Name, Value` pairs. Unspecified properties have default values.

`prbdet = comm.PreambleDetector(prb, Name, Value)` specifies the preamble, `prb` in addition to those properties specified by using `Name, Value` pairs.

Example:

```
prbdet = comm.PreambleDetector('Input', 'Bit', 'Detections', 'First');
```

Properties

Input — Type of input data

'Symbol' (default) | 'Bit'

Type of input data, specified as 'Symbol' or 'Bit'. For binary inputs, set this parameter to 'Bit'. For all other inputs, set this parameter to 'Symbol'. Symbol data can be of data type `single` or `double` while bit data can, in addition, support the `Boolean`, `int8`, and `uint8` data types.

Preamble — Preamble sequence

[1+1i; 1-1i] (default) | column vector

Preamble sequence, specified as a real or complex column vector. The object uses this sequence to detect the presence of the preamble in the input data. If `Input` is 'Bit', the preamble must be a binary sequence. If `Input` is 'Symbol', the preamble can be any real or complex sequence.

Data Types: `double` | `single` | `logical` | `int8` | `uint8`

Threshold – Detection threshold

3 (default) | nonnegative scalar

Detection threshold, specified as a nonnegative scalar. When the computed detection metric is greater than or equal to `Threshold`, the preamble is detected. This property is available when `Input` is set to 'Symbol'. Tunable.

Detections – Number of preambles to detect

'All' (default) | 'First'

Number of preambles to detect, specified as 'All' or 'First'.

- 'All' – Detects all the preambles in the input data sequence.
- 'First' – Detect only the first preamble in the input data sequence.

Methods

`step` Detect preamble in data

Common to All System Objects	
<code>release</code>	Allow System object property value changes
<code>reset</code>	Reset internal states of System object

Examples

Detect Preamble from Binary Data Sequence

Specify a six-bit preamble.

```
prb = [1 0 0 1 0 1]';
```

Create a preamble detector object using preamble `prb` and taking bit inputs.

```
prbdet = comm.PreambleDetector(prb, 'Input', 'Bit');
```

Generate a binary data sequence containing two preambles and using random bits to represent the data fields.

```
pkt = [prb; randi([0 1],10,1); prb; randi([0 1],10,1)];
```

Locate the indices of the two preambles. The indices correspond to the end of the preambles. The detector correctly identified indices 6 and 22 as the end of the two preambles inserted in the sequence.

```
idx = prbdet(pkt)
```

```
idx = 2×1
     6
    22
```

Find Preamble for Fractional Sample Delay

Using a preamble sequence with good correlation properties, find the last sample of the preamble for a transmitted data frame in a stream of delayed received data.

Define the preamble with a length of 17 by using the ninth root of the Zadoff-Chu sequence. Generate a transmission signal by concatenating several samples from a random signal, the preamble, and a random signal of 100 samples.

```
M = 16; % 16-QAM modulation
preamble = zadoffChuSeq(9,17);
x = randi([0 M-1],100,1);
xmod = qammod(x,M,UnitAverage=true);
txsig = [xmod(23:30); preamble; xmod];
```

Create a variable fractional delay System object. Introduce a variable fractional delay of 82.3 samples. To return the full frame when executing the variable fractional delay object, add zero padding at the end of the transmitted signal. Add AWGN to the transmitted signal.

```
vfd = dsp.VariableFractionalDelay;
samplesToDelay = 82.3;
txsigdelayed = vfd([txsig; zeros(ceil(samplesToDelay),1)],samplesToDelay);

SNR = 40;
rxsig = awgn(txsigdelayed,SNR);
```

Create a preamble detector System object, specifying the preamble, the threshold level, and output of the index for the first detection. For the conditions in the example, setting the threshold to 60% of the total magnitude of the preamble samples finds the correct index for the preamble. Run the preamble detection object, returning the preamble index and detection metric.

```
thr = 0.6*sum(abs(preamble).^2);
preambleDet = comm.PreambleDetector( ...
    Preamble=preamble, ...
    Threshold=thr, ...
    Detections='First');
[idx,detmet] = preambleDet(rxsig);
idx
```

```
idx = 107
```

The detection metric is the absolute value of the cross-correlation of the preamble and the input signal. The cross-correlation peak should align with the returned preamble index. To confirm the returned index has identified the preamble, plot the returned cross-correlation values and compare the returned index value to the peak in the cross-correlation values.

```
plot(detmet)
```

Detect Preamble in Noisy QPSK Signal

Create a preamble and apply QPSK modulation.

```
p1 = [0 1 2 3 3 2 1 0]';
p = [p1; p1];
prb = pskmod(p,4,pi/4,'gray');
```

Create a `comm.PreambleDetector` object using preamble `prb`.

```
prbdet = comm.PreambleDetector(prb)

prbdet =
  comm.PreambleDetector with properties:
    Input: 'Symbol'
    Preamble: [16x1 double]
    Threshold: 3
    Detections: 'All'
```

Generate a sequence of random symbols. The first sequence represents the last 20 symbols from a previous packet. The second sequence represents the symbols from the current packet.

```
d1 = randi([0 3],20,1);
d2 = randi([0 3],100,1);
```

Modulate the two sequences.

```
x1 = pskmod(d1,4,pi/4,'gray');
x2 = pskmod(d2,4,pi/4,'gray');
```

Create a sequence of modulated symbols consisting of the remnant of the previous packet, the preamble, and the current packet.

```
y = [x1; prb; x2];
```

Add white Gaussian noise.

```
z = awgn(y,10);
```

Determine the preamble index and the detection metric.

```
[idx,detmet] = prbdet(z);
```

Calculate the number of elements in `idx`. Because the number of elements is greater than one, the detection threshold is too low.

```
numel(idx)
```

```
ans = 80
```

Display the five largest detection metrics.

```
detmetSort = sort(detmet,'descend');
detmetSort(1:5)
```

```
ans = 5×1
```

```
16.3115
```

```
13.6900
```

```
10.5698
```

```
9.1920
```

```
8.9706
```

Increase the threshold and determine the preamble index. The result of 36 corresponds to the sum of the preamble length (16) and the remaining samples in the previous packet (20). This indicates that the preamble has been successfully detected.

```
prbdet.Threshold = 15;
```

```
idx = prbdet(z)
```

```
idx = 36
```

Algorithms

Bit Inputs

When the input data is composed of bits, the preamble detector uses an exact pattern match.

Symbol Inputs

When the input data is composed of symbols, the preamble detector uses a cross-correlation algorithm. A finite impulse response (FIR) filter, in which the coefficients are specified from the

preamble, computes the cross-correlation between the input data and the preamble. When a sequence of input samples match the preamble, the filter output reaches its peak. The index of the peak corresponds to the end of the preamble sequence in the input data. See Discrete FIR Filter for further information on the FIR filter algorithm.

The cross-correlation values that are greater than or equal to the specified threshold are reported as peaks.

- If the detection threshold is too low, the algorithm will detect false peaks, or, in the extreme case, detect as many detected peaks as there are input samples.
- If the detection threshold is too high, the algorithm will miss detecting peaks, or, in the extreme case, detect no peaks.

Consequently, the selection of the detection threshold is critical.

`comm.CarrierSynchronizer` | `comm.CoarseFrequencyCompensator` |
`comm.SymbolSynchronizer`

Introduced in R2016b

step

System object: comm.PreambleDetector

Package: comm

Detect preamble in data

Syntax

```
idx = step(prbdet,x)
[idx,detmet] = step(prbdet,x)
idx = prbdet(x)
[idx,detmet] = prbdet(x)
```

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`idx = step(prbdet,x)` returns the location of the end of the preamble in data sequence `x`, using preamble detector `prbdet`. The index is of data type `double`.

`[idx,detmet] = step(prbdet,x)` also returns the detection metric, `detmet`. This syntax is available when the Input property is 'Symbol'. `detmet` has the same dimensions and data type as `x`.

The output, `detmet`, is determined by one of these algorithms:

- If either the preamble or input data is complex, the detection metric is the absolute value of the cross-correlation of the preamble and the input signal.
- If both the preamble and input data are real, the detection metric is the cross-correlation of the preamble and the input signal.

`idx = prbdet(x)` is equivalent to the first syntax.

`[idx,detmet] = prbdet(x)` is equivalent to the second syntax.

Note `prbdet` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

Introduced in R2016b

comm.PSKCoarseFrequencyEstimator

Package: comm

(Removed) Estimate frequency offset for PSK signal

Note has been removed. Use `comm.CoarseFrequencyCompensator` instead.

Description

The `PSKCoarseFrequencyEstimator` System object estimates frequency offset for a PSK signal.

To estimate frequency offset for a PSK signal:

- 1 Define and set up your PSK coarse frequency estimator object. See “Construction” on page 3-1042.
- 2 Call `step` to estimate frequency offset for a PSK signal according to the properties of `comm.PSKCoarseFrequencyEstimator`. The behavior of `step` is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj, x)` and `y = obj(x)` perform equivalent operations.

Construction

`H = comm.PSKCoarseFrequencyEstimator` creates a PSK coarse frequency offset estimator object, `H`. This object uses an open-loop technique to estimate the carrier frequency offset in a received PSK signal.

`H = comm.PSKCoarseFrequencyEstimator(Name, Value)` creates a PSK coarse frequency offset estimator object, `H`, with the specified property `Name` set to the specified `Value`. You can specify additional name-value pair arguments in any order as `(Name1, Value1, ..., NameN, ValueN)`.

Properties

ModulationOrder

Modulation order the object uses

Specify the modulation order of the PSK signal as a positive, real scalar of data type `double`. This value must be a positive power of 2. The default is 4.

Algorithm

Estimation algorithm to object uses

Specify the estimation algorithm as one of `FFT-based` or `Correlation-based`. The default is `FFT-based`.

FrequencyResolution

Desired frequency resolution (Hz)

Specify the desired frequency resolution for offset frequency estimation as a positive, real scalar of data type double. This property establishes the FFT length used to perform spectral analysis, and must be less than or equal to half the `SampleRate` on page 3-0 property. This property applies only if the `Algorithm` property is FFT-based. The default is 0.001.

MaximumOffset

Maximum measurable frequency offset (Hz)

Specify the maximum measurable frequency offset as a positive, real scalar of data type double. The default is 0.05.

The value of this property must be less than `SampleRate` on page 3-0 / `ModulationOrder` on page 3-0 . It is recommended that `MaximumOffset` on page 3-0 be less than or equal to `SampleRate` on page 3-0 / (4 * `ModulationOrder` on page 3-0). This property is active only if the `Algorithm` property is Correlation-based.

SampleRate

Sample rate (Hz)

Specify the sample rate in samples per second as a positive, real scalar of data type double. The default is 1.

Methods

step (Removed) Estimate frequency offset for PSK signal

Common to All System Objects	
release	Allow System object property value changes
reset	Reset internal states of System object

When using `reset`, note `comm.PSKCoarseFrequencyEstimator` has been removed. Use `comm.CoarseFrequencyCompensator` instead.

Examples

Compare Frequency Offset Estimation and Correction Methods for QPSK Signal

Estimate and correct for a frequency offset in a QPSK signal using the recommended `comm.CoarseFrequencyCompensator` System object. Compare frequency correction results to a workflow using the `comm.PSKCoarseFrequencyEstimator` System object.

Set example parameters.

```
nSym = 2048;    % Number of input symbols
M = 4;         % Modulation order
```

```
fs = 80000;      % Sampling frequency (Hz)
freqRez = 1;    % Frequency resolution (Hz)
freqOff = -2000; % Frequency offset
```

Create System objects for these operations:

```
% Square root raised cosine transmit filter
txfilter = comm.RaisedCosineTransmitFilter;
% Phase frequency offset - one to apply a frequency offset and a second
% that takes the frequency offset estimate as an input to correct the
% offset.
pfo = comm.PhaseFrequencyOffset('FrequencyOffset',freqOff, ...
    'SampleRate',fs);
pfoCorrect = comm.PhaseFrequencyOffset(...
    'FrequencyOffsetSource','Input port', ...
    'SampleRate',fs);
% PSK coarse frequency estimator
frequencyEst = comm.PSKCoarseFrequencyEstimator(...
    'SampleRate',fs,'FrequencyResolution',freqRez);

Error: comm.PSKCoarseFrequencyEstimator has been removed.
Use comm.CoarseFrequencyCompensator instead.

% Coarse frequency compensator
freqComp = comm.CoarseFrequencyCompensator('Modulation','QPSK', ...
    'SampleRate',fs,'FrequencyResolution',freqRez);
```

Generate a QPSK signal, filter the signal, apply the frequency offset, and pass the signal through the AWGN channel.

```
data = randi([0 M-1],nSym,1);
modData = pskmod(data,M,pi/4); % Generate QPSK signal
txFiltData = txfilter(modData); % Apply Tx filter
offsetData = pfo(txFiltData); % Apply frequency offset
rxData = awgn(offsetData,25); % Pass through AWGN channel
```

This example does not apply receive filtering. In general, when the frequency offset is high, it is beneficial to apply coarse frequency compensation prior to receive filtering because filtering suppresses energy in the useful spectrum.

Compare the results for estimating and correcting the frequency offset by:

- Using the `frequencyEst` object to estimate the frequency offset and `pfoCorrect` to compensate for the frequency offset.
- Using the `freqComp` object estimate and apply compensation to the signal.

Observe the frequency offset estimate returned by both estimation methods.

```
estFreqOffset1
estFreqOffset2

estFreqOffset1 =
    -2.0000e+03
estFreqOffset2 =
    -2.0000e+03
```

Confirm the maximum resulting difference between the two compensation methods is negligible.

```
max(compensatedData1-compensatedData2)
```

ans =

1.4710e-13 + 9.1149e-14i

comm.CoarseFrequencyCompensator | comm.PhaseFrequencyOffset | dsp.FFT

Introduced in R2013b

step

System object: `comm.PSKCoarseFrequencyEstimator`

Package: `comm`

(Removed) Estimate frequency offset for PSK signal

Note `comm.PSKCoarseFrequencyEstimator` has been removed. Use `comm.CoarseFrequencyCompensator` instead.

Syntax

`Y = step(H,X)`

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(H,X)` estimates the carrier frequency offset of the input `X` and returns the result in `Y`. `X` must be a complex column vector of data type `double`. The `step` method outputs the estimate `Y` as a scalar of type `double`.

Note `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications. For more information on changing property values, see “System Design in MATLAB Using System Objects”.

comm.PSKDemodulator

Package: comm

Demodulate using M-ary PSK method

Description

The `comm.PSKDemodulator` object demodulates a signal that was modulated using the M-ary phase shift keying (M-PSK) method. The input is a baseband representation of the modulated signal.

To demodulate a signal that was modulated using the M-PSK method:

- 1 Create the `comm.PSKDemodulator` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

Creation

Syntax

```
mpskdemod = comm.PSKDemodulator
mpskdemod = comm.PSKDemodulator(Name=Value)
mpskdemod = comm.PSKDemodulator(M,phase,Name=Value)
```

Description

`mpskdemod = comm.PSKDemodulator` creates a System object to demodulate input M-PSK signals.

`mpskdemod = comm.PSKDemodulator(Name=Value)` sets properties using one or more name-value arguments. For example, `DecisionMethod="Hard decision"` specifies demodulation using the hard-decision method.

`mpskdemod = comm.PSKDemodulator(M,phase,Name=Value)` sets the `ModulationOrder` property set to `M`, the `PhaseOffset` property to `phase`, and optional name-value arguments. Specify `phase` in radians.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see [System Design in MATLAB Using System Objects](#).

ModulationOrder — Number of points in signal constellation

8 (default) | positive integer

Number of points in signal constellation, specified as a positive integer.

Data Types: `double`

PhaseOffset — Phase of zeroth point in constellation

`pi/8` (default) | scalar

Phase of the zeroth point in the constellation in radians, specified as a scalar.

Example: `PhaseOffset=0` aligns the QPSK signal constellation points on the axes $\{(1,0), (0,j), (-1,0), (0,-j)\}$.

Data Types: `double`

BitOutput — Option to output data as bits

`0` or `false` (default) | `1` or `true`

Option to output data as bits, specified as a logical `0` (`false`) or `1` (`true`).

- Set this property to `false` to output symbols as integer values in the range $[0, (\text{ModulationOrder} - 1)]$ with length equal to the input data vector.
- Set this property to `true` to output a column vector of bit values with length equal to $\log_2(\text{ModulationOrder})$ times the number of demodulated symbols.

Data Types: `logical`

SymbolMapping — Symbol encoding

`'Gray'` (default) | `'Binary'` | `'Custom'`

Symbol encoding mapping of constellation bits, specified as `'Gray'`, `'Binary'`, or `'Custom'`. Each integer or group of $\log_2(\text{ModulationOrder})$ bits corresponds to one symbol.

- When you set this property to `'Gray'`, the object uses a Gray-encoded signal constellation.
- When you set this property to `'Binary'`, the signal constellation maps to the complex value $e^{j(\text{PhaseOffset} + (2m/\text{ModulationOrder}))}$, where m is an integer in the range $[0, (\text{ModulationOrder} - 1)]$.
- When you set this property to `'Custom'`, the object uses the signal constellation defined in the `CustomSymbolMapping` property.

CustomSymbolMapping — Custom symbol encoding

`0:7` (default) | vector

Custom symbol encoding, specified as a vector with length equal to the value of `ModulationOrder` and unique integer values in the range $[0, (\text{ModulationOrder} - 1)]$. The first element of this vector corresponds to the constellation point at an angle of $\theta + \text{PhaseOffset}$, with subsequent elements running counterclockwise. The last element corresponds to the constellation point at an angle of $-2\pi/\text{ModulationOrder} + \text{PhaseOffset}$.

Dependencies

To enable this property, set the `SymbolMapping` property to `'Custom'`.

Data Types: `double`

DecisionMethod — Demodulation decision method

`'Hard decision'` (default) | `'Log-likelihood ratio'` | `'Approximate log-likelihood ratio'`

Demodulation decision method, specified as 'Hard decision', 'Log-likelihood ratio', or 'Approximate log-likelihood ratio'. When you set the BitOutput property to false, the object always performs hard-decision demodulation.

Dependencies

To enable this property, set the BitOutput property to true.

VarianceSource — Source of noise variance

'Property' (default) | 'Input port'

Source of noise variance, specified as 'Property' or 'Input port'.

Dependencies

To enable this property, set the BitOutput property to true and the DecisionMethod property to 'Log-likelihood ratio' or 'Approximate log-likelihood ratio'.

Variance — Noise variance

1 (default) | positive scalar

Noise variance, specified as a positive scalar.

Tunable: Yes

Tips

The exact LLR algorithm computes exponentials using finite precision arithmetic. For computations involving very large positive or negative magnitudes, the exact LLR algorithm yields:

- Inf or -Inf if the noise variance is a very large value
- NaN if the noise variance and signal power are both very small values

The approximate LLR algorithm does not compute exponentials. You can avoid Inf, -Inf, and NaN results by using the approximate LLR algorithm.

Dependencies

To enable this property, set the BitOutput property to true, the DecisionMethod property to 'Log-likelihood ratio' or 'Approximate log-likelihood ratio', and the VarianceSource property to 'Property'.

Data Types: double

OutputDataType — Data type of output

'Full precision' (default) | 'Smallest unsigned integer' | 'double' | ...

Data type of the output, specified as 'Full precision', 'Smallest unsigned integer', 'double', 'single', 'int8', 'uint8', 'int16', 'uint16', 'int32', or 'uint32', 'logical'.

- When the input data type is single or double precision and you set the BitOutput property to true, the DecisionMethod property to 'Hard decision', and the OutputDataType property to 'Full precision', the output has the same data type as that of the input.
- When the input data is of a fixed-point type, the output data type behaves as if you had set the OutputDataType property to 'Smallest unsigned integer'.
- When you set BitOutput to true and the DecisionMethod property to 'Hard Decision', then 'logical' data type is a valid option.

- When you set the `BitOutput` property to `true` and the `DecisionMethod` property to `'Log-likelihood ratio'` or `'Approximate log-likelihood ratio'`, the output data type is the same as that of the input and the input data type must be single or double precision.

Dependencies

To enable this property, set the `BitOutput` property to `false` or set the `BitOutput` property to `true` and the `DecisionMethod` property to `'Hard decision'`.

Fixed-Point Properties**DerotateFactorDataType — Data type of derotate factor**

`'Same word length as input'` (default) | `'Custom'`

Data type of the derotate factor, specified as `'Same word length as input'` or `'Custom'`. The object uses the derotate factor in the computations only when the `ModulationOrder` property is 2, 4, or 8, the input signal is a fixed-point type, and the `PhaseOffset` property has a nontrivial value.

- For `ModulationOrder` = 2, the phase offset is trivial if it is a multiple of $\pi/2$.
- For `ModulationOrder` = 4, the phase offset is trivial if it is an even multiple of $\pi/4$.
- For `ModulationOrder` = 8, there are no trivial phase offsets.

Dependencies

To enable this property, set the `BitOutput` property to `false` or set the `BitOutput` property to `true` and the `DecisionMethod` property to `'Hard decision'`.

CustomDerotateFactorDataType — Fixed-point data type of derotate factor

`numerictype([],16)` (default) | `unscaled numerictype object`

Fixed-point data type of the derotate factor, specified as an `unscaled numerictype` object with a `Signedness` of `Auto`. The word length must be a value in the range [2, 128].

Dependencies

To enable this property, set the `DerotateFactorDataType` property to `'Custom'`.

Data Types: `numerictype` object

Usage**Syntax**

```
y = mpskdemod(x)
y = mpskdemod(x,var)
```

Description

`y = mpskdemod(x)` applies M-PSK demodulation to the input signal and returns the demodulated signal.

`y = mpskdemod(x,var)` uses soft decision demodulation and noise variance `var`. This syntax applies when you set the `BitOutput` property to `true`, the `DecisionMethod` property to `'Approximate log-likelihood ratio'` or `'Log-likelihood ratio'`, and the `VarianceSource` property to `'Input port'`.

Input Arguments

x — M-PSK-modulated signal

scalar | column vector

M-PSK-modulated signal, specified as a scalar or column vector.

Dependencies

The object accepts inputs with a signed integer data type or signed fixed point (`sfi`) objects when you set the `ModulationOrder` property to a value less than or equal to 8 and you set the `BitOutput` property to `false` or you set the `DecisionMethod` property to `'Hard decision'` and the `BitOutput` property to `true`.

Data Types: `double` | `single` | `int` | `fi`

var — Noise variance

scalar

Noise variance, specified as a scalar.

Dependencies

To enable this argument, set the `VarianceSource` property to `'Input port'`, the `BitOutput` property to `true`, and the `DecisionMethod` property to `'Approximate log-likelihood ratio'` or `'Log-likelihood ratio'`.

Data Types: `single` | `double`

Output Arguments

y — Output signal

scalar | column vector

Output signal, returned as a scalar or column vector. To specify whether the object outputs values as integers or bits, use the `BitOutput` property. To specify the output data type, use the `OutputDataType` property.

Object Functions

To use an object function, specify the `System` object as the first input argument. For example, to release system resources of a `System` object named `obj`, use this syntax:

```
release(obj)
```

Specific to comm.PSKDemodulator

`constellation` Calculate or plot ideal signal constellation

Common to All System Objects

`step` Run `System` object algorithm

`release` Release resources and allow changes to `System` object property values and input characteristics

`reset` Reset internal states of `System` object

Examples

16-PSK with Custom Symbol Mapping

Create 16-PSK modulator and demodulator System objects™ that use custom symbol mapping. Estimate the BER in an AWGN channel and compare the performance to a theoretical Gray-coded PSK system.

Create a custom symbol mapping for the 16-PSK modulation scheme. The 16 integer symbols must have values in the range [0, 15].

```
custMap = [0 2 4 6 8 10 12 14 15 13 11 9 7 5 3 1];
```

Create a 16-PSK modulator and demodulator pair having custom symbol mapping defined by the array `custMap`.

```
pskModulator = comm.PSKModulator(16,'BitInput',true, ...
    'SymbolMapping','Custom','CustomSymbolMapping',custMap);
pskDemodulator = comm.PSKDemodulator(16,'BitOutput',true, ...
    'SymbolMapping','Custom','CustomSymbolMapping',custMap);
```

Display the modulator constellation.

```
constellation(pskModulator)
```

Create an AWGN channel System object for use with 16-ary data.

```
awgnChannel = comm.AWGNChannel('BitsPerSymbol',log2(16));
```

Create an error rate object to track the BER statistics.

```
errorRate = comm.ErrorRate;
```

Initialize the simulation vectors. Vary E_b/N_0 from 6 to 18 dB in 1 dB steps.

```
ebnoVec = 6:18;
ber = zeros(size(ebnoVec));
```

Estimate the BER by modulating binary data, passing it through an AWGN channel, demodulating the received signal, and collecting the error statistics.

```
for n = 1:length(ebnoVec)

    % Reset the error counter for each Eb/No value
    reset(errorRate)
    % Reset the array used to collect the error statistics
    errVec = [0 0 0];
    % Set the channel Eb/No
    awgnChannel.EbNo = ebnoVec(n);

    while errVec(2) < 200 && errVec(3) < 1e7
        % Generate a 1000-symbol frame
        data = randi([0 1],4000,1);
        % Modulate the binary data
        modData = pskModulator(data);
        % Pass the modulated data through the AWGN channel
        rxSig = awgnChannel(modData);
        % Demodulate the received signal
        rxData = pskDemodulator(rxSig);
        % Collect the error statistics
        errVec = errorRate(data,rxData);
    end

    % Save the BER data
    ber(n) = errVec(1);
end
```

Generate theoretical BER data for an AWGN channel using the `berawgn` function.

```
berTheory = berawgn(ebnoVec,'psk',16,'nondiff');
```

Plot the simulated and theoretical results. The 16-PSK modulation BER performance of the simulated custom symbol mapping is not as good as the theoretical prediction curve for Gray codes.

```
figure
semilogy(ebnoVec,[ber; berTheory])
xlabel('Eb/No (dB)')
ylabel('BER')
grid
legend('Simulation','Theory','location','ne')
```

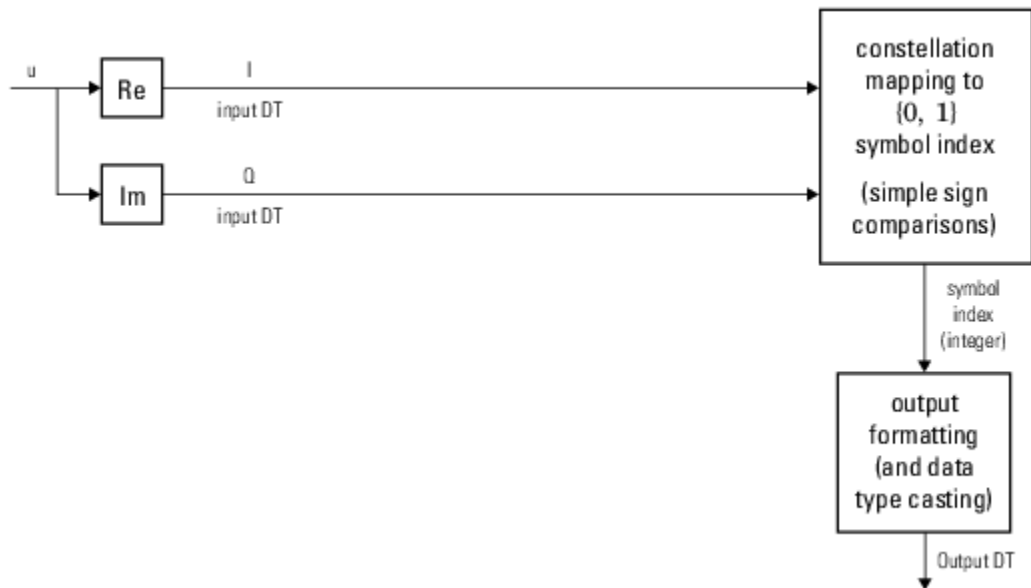

More About

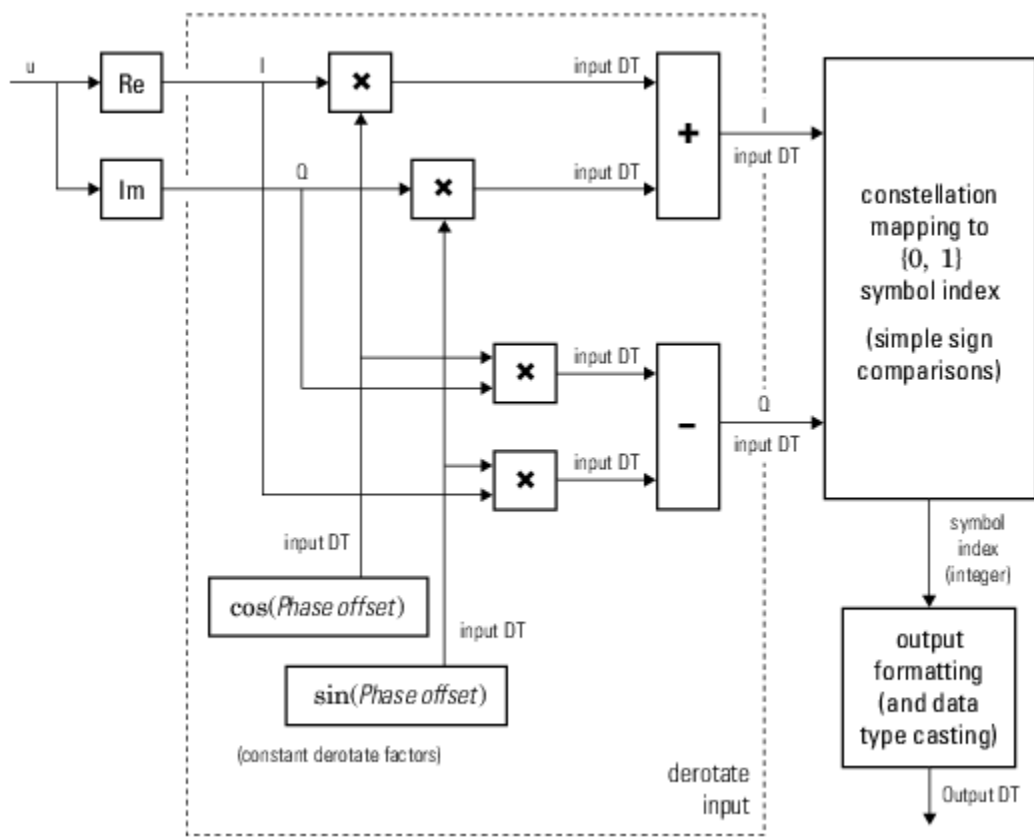

Hard-Decision BPSK Demodulation

The signal preprocessing required for BPSK demodulation depends on the configuration.

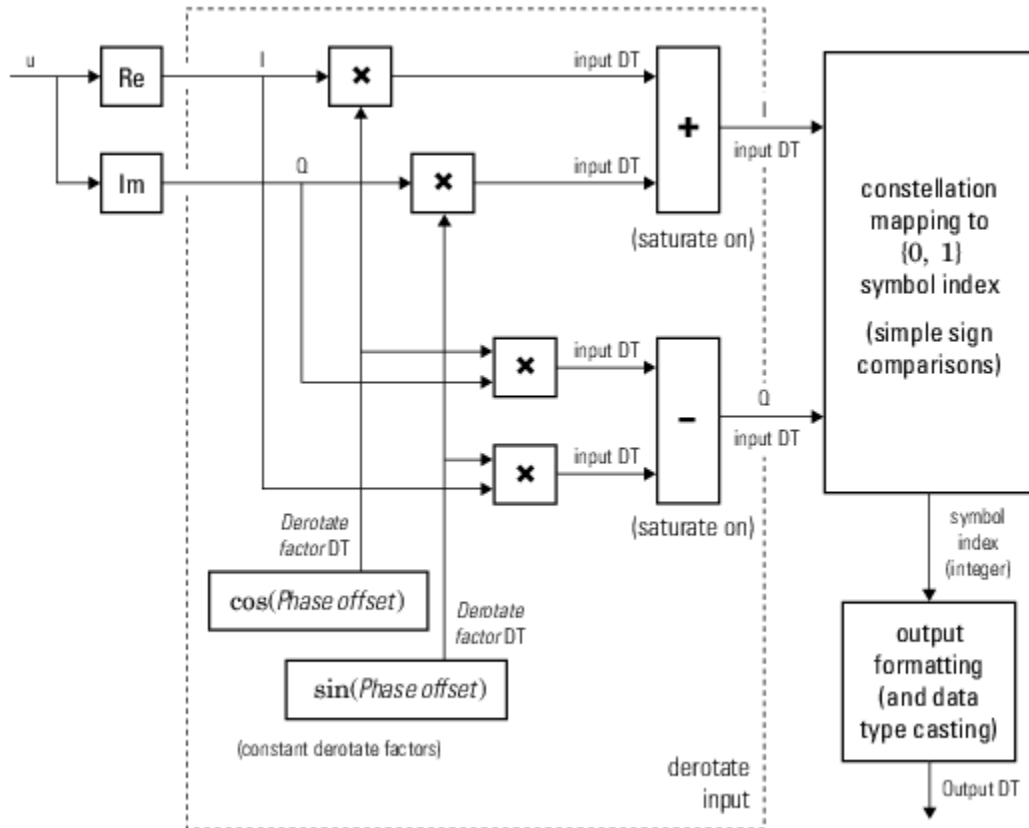

This figure shows the hard-decision BPSK demodulation signal diagram for the trivial phase offset (multiple of $\pi/2$) configuration.

This figure shows the hard-decision BPSK demodulation floating point signal diagram for the nontrivial phase offset configuration.

This figure shows the hard-decision BPSK demodulation fixed-point signal diagram for the nontrivial phase offset configuration.

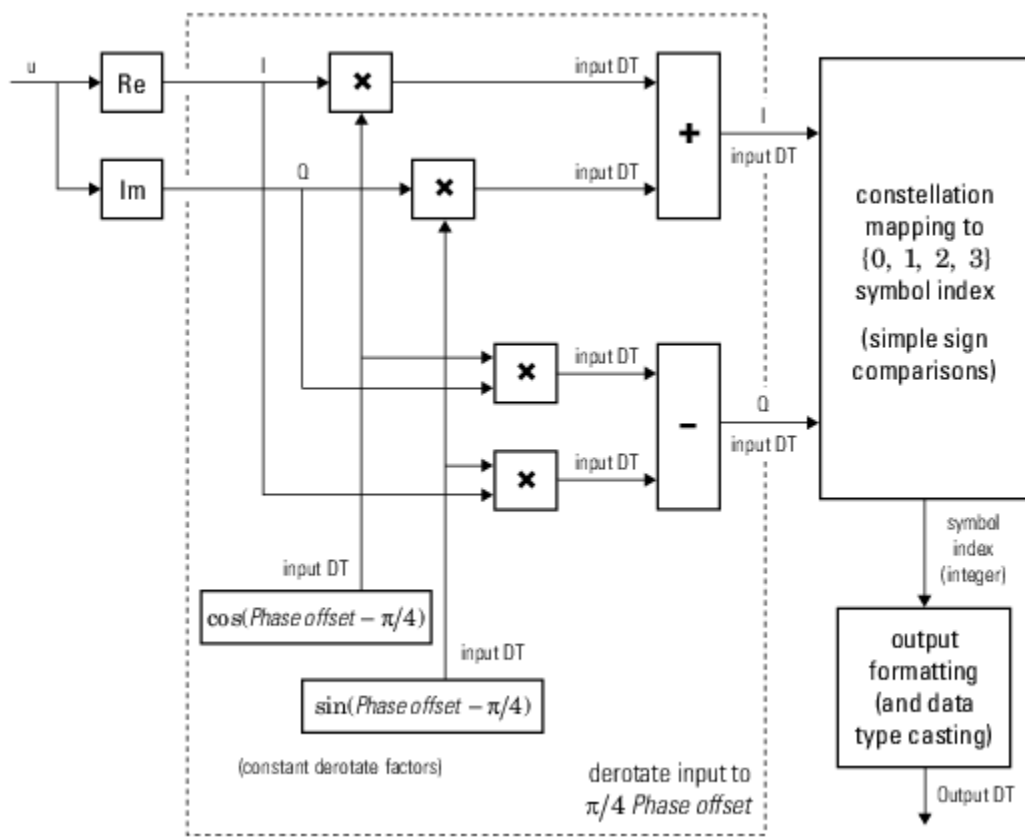

Hard-Decision QPSK Demodulation

The signal preprocessing required for QPSK demodulation depends on the configuration.

This figure shows the hard-decision QPSK demodulation signal diagram for the trivial phase offset (odd multiple of $\pi/4$) configuration.

This figure shows the hard-decision QPSK demodulation floating point signal diagram for the nontrivial phase offset configuration.

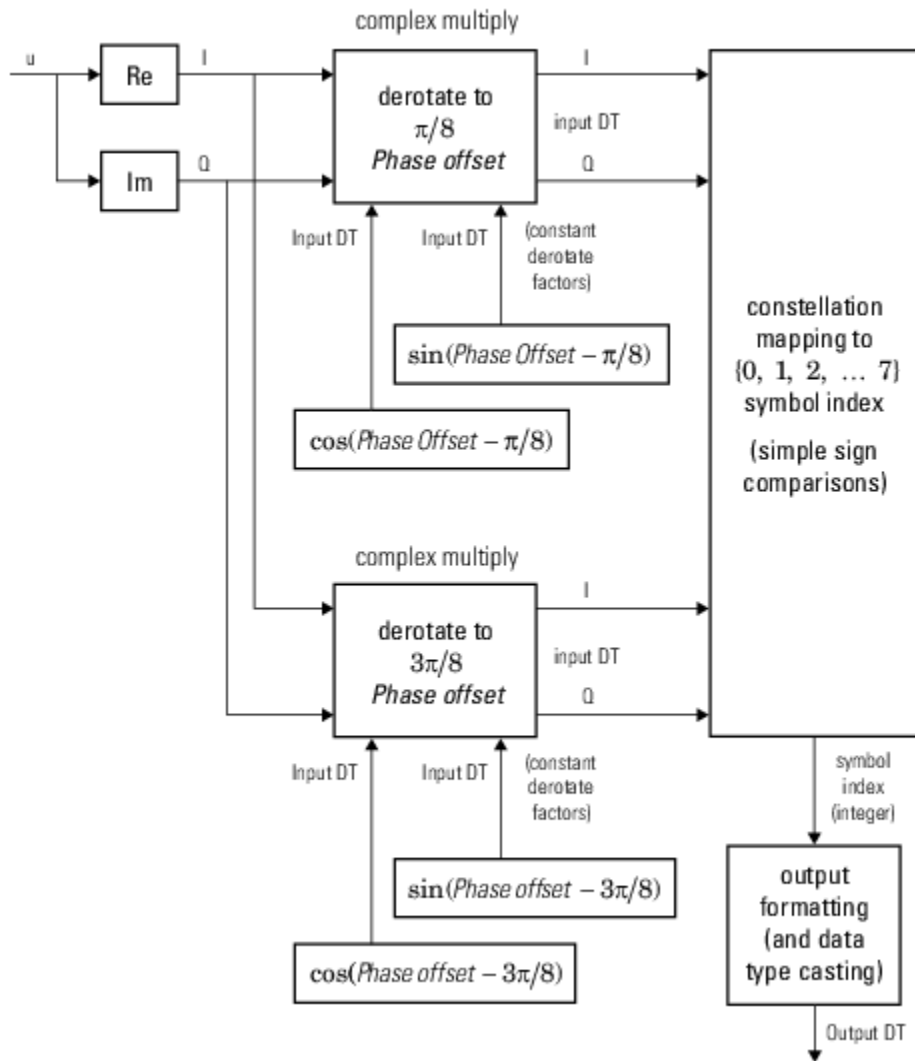

This figure shows the hard-decision QPSK demodulation fixed-point signal diagram for the nontrivial phase offset configuration.

Hard-Decision Higher-Order PSK

The signal preprocessing required for higher-order ($M \geq 8$) demodulation depends on the configuration.

This figure shows the hard-decision 8-PSK demodulation floating point signal diagram for the nontrivial phase offset configuration.

This figure shows the hard-decision 8-PSK demodulation for the fixed-point signal diagram for the nontrivial phase offset configuration.

This figure shows the hard-decision M-PSK demodulation ($M > 8$) floating point signal diagram for the nontrivial phase offset configuration.

In order to improve speed and implementation costs for $M > 8$, no derotation arithmetic is performed for trivial phase offsets (specifically, when the phase offset is 0, $\pi/2$, π , or $3\pi/2$).

Also, for $M > 8$, only inputs of type `double` and `single` are supported.

Soft-Decision M-PSK Demodulation

For soft demodulation, two soft-decision log-likelihood ratio (LLR) algorithms are available: exact LLR and approximate LLR. The exact LLR algorithm is more accurate but has slower execution speed than the approximate LLR algorithm. For further description of these algorithms, see the "Soft-Decision Demodulation" topic.

Note The exact LLR algorithm computes exponentials using finite precision arithmetic. For computations involving very large positive or negative magnitudes, the exact LLR algorithm yields:

- `Inf` or `-Inf` if the noise variance is a very large value

- NaN if the noise variance and signal power are both very small values

The approximate LLR algorithm does not compute exponentials. You can avoid Inf, -Inf, and NaN results by using the approximate LLR algorithm.

M-PSK Demodulator Baseband

Introduced in R2012a

comm.PSKModulator

Package: comm

Modulate signal using M-PSK method

Description

The `PSKModulator` System object modulates using the M-ary phase shift keying (M-PSK) method. The output is a baseband representation of the modulated signal.

To modulate a signal by using the M-PSK method:

- 1 Create the `comm.PSKModulator` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

Creation

Syntax

```
mpskmod = comm.PSKModulator  
mpskmod = comm.PSKModulator(Name,Value)  
mpskmod = comm.PSKModulator(M,phase,Name,Value)
```

Description

`mpskmod = comm.PSKModulator` creates a modulator System object `mpskmod`, that modulates the input signal using the M-ary phase shift keying (M-PSK) method.

`mpskmod = comm.PSKModulator(Name,Value)` creates an M-PSK modulator object `mpskmod`, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as `(Name1,Value1,...,NameN,ValueN)`.

`mpskmod = comm.PSKModulator(M,phase,Name,Value)` creates a M-PSK modulator object `mpskmod` using the modulation order specified in `M`. The object's `PhaseOffset` property is set to `phase`, and the other specified properties are set to the specified values.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see [System Design in MATLAB Using System Objects](#).

ModulationOrder — Number of points in signal constellation

8 (default) | positive integer scalar

Number of points in the signal constellation, specified as a positive, integer scalar.

Data Types: double

PhaseOffset — Phase of zeroth point of constellation $\pi/8$ (default) | finite real-valued scalar

Phase of the zeroth point of the constellation in radians, specified as a finite real-valued scalar.

Data Types: double

BitInput — Option to provide input in bits

0 or false (default) | 1 or true

Option to provide input in bits, specified as a numeric or logical 0 (false) or 1 (true).

- If you set this property to 0 (false), the input values must be integer representations of two-bit input segments and range between 0 to 3.
- If you set this property to 1 (true), the input must be a binary vector of even length. Element pairs are binary representations of integers.

Data Types: logical | char

SymbolMapping — Signal constellation bit mapping

'Gray' (default) | 'Binary' | 'Custom'

Signal constellation bit mapping, specified as 'Gray', 'Binary', or 'Custom'.

- 'Gray' — Use this value to specify Gray-encoded signal constellation mapping.
- 'Binary' — The integer m must be in the range $[0, \text{ModulationOrder} - 1]$ and map to the complex value $\exp(j(\text{PhaseOffset} + 2\pi m/\text{ModulationOrder}))$
- 'Custom' — Use this value to specify the signal constellation mapping by using the CustomSymbolMapping property.

Data Types: char | double

CustomSymbolMapping — Custom constellation encoding

[0 1 2 3 4 5 6 7] (default) | row vector | column vector

Custom constellation encoding, specified as a row vector or column vector of values in the range $[0, \text{ModulationOrder} - 1]$. The length of this vector must be equal to the ModulationOrder property value. The first element of this vector corresponds to the constellation point at an angle of PhaseOffset, with subsequent elements running counterclockwise. The last element corresponds to the constellation point at an angle of $-2\pi/\text{ModulationOrder} + \text{PhaseOffset}$.

Dependencies

To enable this property, set the SymbolMapping property to 'Custom'.

Data Types: double

OutputDataType — Output datatype

'double' (default) | 'single' | 'Custom'

Output data type, specified as either 'double', 'single' or 'Custom'.

Data Types: char | string

Fixed-Point Properties

CustomOutputDataType — Fixed-point data type of output

numericType([],16) (default) | numericType object

Fixed-point data type of the output signal, specified as a numericType object with its Signedness property set to Auto. To create this type of object, use the numericType function.

Dependencies

To enable this property, set the OutputDataType property to 'Custom'.

Usage

Syntax

```
mpsksignal = mpskmod(insignal)
```

Description

mpksignal = mpskmod(insignal) modulates the input signal by using the M-PSK method. The output is the modulated M-PSK baseband signal.

Input Arguments

insignal — Input signal

column vector

Input signal, specified as a column vector of integers or bits. The vector must be of length N_S , where N_S is the number of samples.

The setting of the BitInput property determines the interpretation of the input vector.

Data Types: double

Output Arguments

mpksignal — M-PSK modulated baseband signal

vector

M-PSK modulated baseband signal, returned as a vector.

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named obj, use this syntax:

```
release(obj)
```

Specific to comm.PSKModulator

constellation Calculate or plot ideal signal constellation

Common to All System Objects

step Run System object algorithm

release Release resources and allow changes to System object property values and input characteristics

reset Reset internal states of System object

Examples

Add White Gaussian Noise to 8-PSK Signal

Modulate an 8-PSK signal, add white Gaussian noise, and plot the signal to visualize the effects of the noise.

Create a M-PSK modulator System object™. The default modulation order for the object is 8.

```
pskModulator = comm.PSKModulator;
```

Modulate the signal.

```
modData = pskModulator(randi([0 7],2000,1));
```

Add white Gaussian noise to the modulated signal by passing the signal through an additive white Gaussian noise (AWGN) channel.

```
channel = comm.AWGNChannel('EbNo',20,'BitsPerSymbol',3);
```

Transmit the signal through the AWGN channel.

```
channelOutput = channel(modData);
```

Plot the noiseless and noisy data by using scatter plots to visualize the effects of the noise.

```
scatterplot(modData)
```

```
scatterplot(channelOutput)
```

Change the EbNo property to 10 dB to increase the noise.

```
channel.EbNo = 10;
```

Pass the modulated data through the AWGN channel.

```
channelOutput = channel(modData);
```

Plot the channel output. You can see the effects of increased noise.

```
scatterplot(channelOutput)
```

16-PSK with Custom Symbol Mapping

Create 16-PSK modulator and demodulator System objects™ that use custom symbol mapping. Estimate the BER in an AWGN channel and compare the performance to a theoretical Gray-coded PSK system.

Create a custom symbol mapping for the 16-PSK modulation scheme. The 16 integer symbols must have values in the range [0, 15].

```
custMap = [0 2 4 6 8 10 12 14 15 13 11 9 7 5 3 1];
```

Create a 16-PSK modulator and demodulator pair having custom symbol mapping defined by the array `custMap`.

```
pskModulator = comm.PSKModulator(16,'BitInput',true, ...
    'SymbolMapping','Custom','CustomSymbolMapping',custMap);
pskDemodulator = comm.PSKDemodulator(16,'BitOutput',true, ...
    'SymbolMapping','Custom','CustomSymbolMapping',custMap);
```

Display the modulator constellation.

```
constellation(pskModulator)
```

Create an AWGN channel System object for use with 16-ary data.

```
awgnChannel = comm.AWGNChannel('BitsPerSymbol', log2(16));
```

Create an error rate object to track the BER statistics.

```
errorRate = comm.ErrorRate;
```

Initialize the simulation vectors. Vary E_b/N_0 from 6 to 18 dB in 1 dB steps.

```
ebnoVec = 6:18;
ber = zeros(size(ebnoVec));
```

Estimate the BER by modulating binary data, passing it through an AWGN channel, demodulating the received signal, and collecting the error statistics.

```
for n = 1:length(ebnoVec)
    % Reset the error counter for each Eb/No value
    reset(errorRate)
    % Reset the array used to collect the error statistics
    errVec = [0 0 0];
    % Set the channel Eb/No
    awgnChannel.EbNo = ebnoVec(n);

    while errVec(2) < 200 && errVec(3) < 1e7
        % Generate a 1000-symbol frame
        data = randi([0 1], 4000, 1);
```

```

% Modulate the binary data
modData = pskModulator(data);
% Pass the modulated data through the AWGN channel
rxSig = awgnChannel(modData);
% Demodulate the received signal
rxData = pskDemodulator(rxSig);
% Collect the error statistics
errVec = errorRate(data,rxData);
end

% Save the BER data
ber(n) = errVec(1);
end

```

Generate theoretical BER data for an AWGN channel using the `berawgn` function.

```
berTheory = berawgn(ebnoVec, 'psk', 16, 'nondiff');
```

Plot the simulated and theoretical results. The 16-PSK modulation BER performance of the simulated custom symbol mapping is not as good as the theoretical prediction curve for Gray codes.

```

figure
semilogy(ebnoVec,[ber; berTheory])
xlabel('Eb/No (dB)')
ylabel('BER')
grid
legend('Simulation','Theory','location','ne')

```

Algorithms

The block outputs a baseband signal by mapping input bits or integers to complex symbols according to the following:

$$s_n(t) = \exp\left(j\pi\left(\frac{2n+1}{M}\right)\right); \quad n \in \{0, 1, \dots, M-1\}.$$

This applies when a natural binary ordering is used. Another common mapping is Gray coding, which has the advantage that only one bit changes between adjacent constellation points. This results in better bit error rate performance. For 8-PSK modulation with Gray coding, the mapping between the input and output symbols is shown.

Input	Output
0	0 (000)
1	1 (001)
2	3 (011)
3	2 (010)
4	6 (110)
5	7 (111)
6	5 (101)
7	4 (100)

The corresponding constellation diagram follows.

When the input signal is composed of bits, the block accepts binary-valued inputs that represent integers. The block collects binary-valued signals into groups of $\log_2(M)$ bits.

M-PSK Modulator Baseband

Introduced in R2012a

comm.PSKTCMDemodulator

Package: comm

Demodulate convolutionally encoded data mapped to M-ary PSK signal constellation

Description

The `PSKTCMDemodulator` object uses the Viterbi algorithm to decode a trellis-coded modulation (TCM) signal that was previously modulated using a PSK signal constellation.

To demodulate a signal that was modulated using trellis-coded modulation:

- 1 Define and set up your PSK TCM demodulator object. See “Construction” on page 3-1075.
- 2 Call `step` to demodulate the signal according to the properties of `comm.PSKTCMDemodulator`. The behavior of `step` is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`H = comm.PSKTCMDemodulator` creates a trellis-coded, M-ary phase shift, keying (PSK TCM) demodulator System object, `H`. This object demodulates convolutionally encoded data that has been mapped to an M-PSK constellation.

`H = comm.PSKTCMDemodulator(Name, Value)` creates a PSK TCM demodulator object, `H`, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as `(Name1, Value1, ..., NameN, ValueN)`.

`H = comm.PSKTCMDemodulator(TRELLIS, Name, Value)` creates a PSK TCM demodulator System object, `H`. This object has the `TrellisStructure` property set to `TRELLIS` and the other specified properties set to the specified values.

Properties

TrellisStructure

Trellis structure of convolutional code

Specify `trellis` as a MATLAB structure that contains the trellis description of the convolutional code. Use the `istrellis` function to check whether the trellis structure is valid. The default is the result of `poly2trellis([1 3], [1 0 0; 0 5 2])`.

TerminationMethod

Termination method of encoded frame

Specify the termination method as one of `Continuous` | `Truncated` | `Terminated`. The default is `Continuous`.

When you set this property to `Continuous`, the object saves the internal state metric at the end of each frame. The next frame uses the same state metric. The object treats each traceback path independently. If the input signal contains only one symbol, use `Continuous` mode.

When you set this property to `Truncated`, the object treats each input vector independently. The traceback path starts at the state with the best metric and always ends in the all-zeros state.

When you set property to `Terminated`, the object treats each input vector independently, and the traceback path always starts and ends in the all-zeros state.

TracebackDepth

Traceback depth for Viterbi decoder

Specify the scalar, integer number of trellis branches to construct each traceback path. The default is 21. The traceback depth influences the decoding accuracy and delay. The decoding delay is the number of zero symbols that precede the first decoded symbol in the output.

When you set the `TerminationMethod` on page 3-0 property to `Continuous`, the decoding delay consists of `TracebackDepth` zero symbols or `TracebackDepth`× K zero bits for a rate K/N convolutional code.

When you set the `TerminationMethod` property to `Truncated` or `Terminated`, no output delay occurs and the traceback depth must be less than or equal to the number of symbols in each input vector.

ResetInputPort

Enable demodulator reset input

Set this property to `true` to enable an additional input to the `step` method. The default is `false`. When this additional reset input is a nonzero value, the internal states of the encoder reset to initial conditions. This property applies when you set the `TerminationMethod` on page 3-0 property to `Continuous`.

ModulationOrder

Number of points in signal constellation

Specify the number of points in the signal constellation used to map the convolutionally encoded data as a positive, integer scalar value. The number of points must be 4, 8, or 16. The default is 8. The `ModulationOrder` on page 3-0 property value must equal the number of possible input symbols to the convolutional decoder of the PSK TCM demodulator object. The `ModulationOrder` property must equal 2^N for a rate K/N convolutional code.

OutputDataType

Data type of output

Specify output data type as `logical` | `double`. The default is `double`.

Methods

step Demodulate convolutionally encoded data mapped to M-ary PSK constellation

Common to All System Objects	
release	Allow System object property value changes
reset	Reset internal states of System object

Examples

Demodulate Noisy PSK QAM Data

Modulate and demodulate data using 8-PSK TCM modulation in an AWGN channel. Estimate the resulting error rate.

Define a trellis structure with four input symbols and eight output symbols.

```
t = poly2trellis([5 4],[23 35 0; 0 5 13]);
```

Create modulator and demodulator System objects™ using trellis, t, having modulation order 8.

```
hMod = comm.PSKTCMModulator(t,'ModulationOrder',8);
hDemod = comm.PSKTCMDemodulator(t,'ModulationOrder',8, ...
    'TracebackDepth',16);
```

Create an AWGN channel object.

```
hAWGN = comm.AWGNChannel('NoiseMethod','Signal to noise ratio (SNR)', ...
    'SNR',7);
```

Create an error rate calculator with delay in bits equal to TracebackDepth times the number of bits per symbol.

```
hError = comm.ErrorRate('ReceiveDelay',...
    hDemod.TracebackDepth*log2(t.numInputSymbols));
```

Generate random binary data and modulate with 8-PSK TCM. Pass the modulated signal through the AWGN channel and demodulate. Calculate the error statistics.

```
for counter = 1:10
    % Transmit frames of 250 2-bit symbols
    data = randi([0 1],500,1);
    % Modulate
    modSignal = step(hMod,data);
    % Pass through AWGN channel
    noisySignal = step(hAWGN,modSignal);
    % Demodulate
    receivedData = step(hDemod,noisySignal);
    % Calculate error statistics
    errorStats = step(hError,data,receivedData);
end
```

Display the BER and the number of bit errors.

```
fprintf('Error rate = %5.2e\nNumber of errors = %d\n', ...  
       errorStats(1),errorStats(2))
```

```
Error rate = 2.17e-02  
Number of errors = 108
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the M-PSK TCM Decoder block reference page. The object properties correspond to the block parameters.

Introduced in R2012a

step

System object: comm.PSKTCMDemodulator

Package: comm

Demodulate convolutionally encoded data mapped to M-ary PSK constellation

Syntax

$Y = \text{step}(H,X)$
 $Y = \text{step}(H,X,R)$

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, $y = \text{step}(\text{obj}, x)$ and $y = \text{obj}(x)$ perform equivalent operations.

$Y = \text{step}(H,X)$ demodulates the PSK modulated input data, X , and uses the Viterbi algorithm to decode the resulting demodulated, convolutionally encoded bits. X must be a complex, double or single precision column vector. The `step` method outputs a demodulated, binary data column vector, Y . When the convolutional encoder represents a rate K/N code, the length of the output vector is $K \times L$, where L is the length of the input vector, X .

$Y = \text{step}(H,X,R)$ resets the decoder to the all-zeros state when you input a reset signal, R that is non-zero. R must be a double precision or logical, scalar integer. This syntax applies when you set the `ResetInputPort` property to true.

Note `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications. For more information on changing property values, see "System Design in MATLAB Using System Objects".

comm.PSKTCMModulator

Convolutionally encode binary data and map using M-ary PSK signal constellation

Description

The `PSKTCMModulator` object implements trellis-coded modulation (TCM) by convolutionally encoding the binary input signal and then mapping the result to a PSK signal constellation.

To modulate a signal using trellis-coded modulation:

- 1 Define and set up your PSK TCM modulator object. See “Construction” on page 3-1080.
- 2 Call `step` to modulate the signal according to the properties of `comm.PSKTCMModulator`. The behavior of `step` is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`H = comm.PSKTCMModulator` creates a trellis-coded M-ary phase shift keying (PSK TCM) modulator System object, `H`. This object convolutionally encodes a binary input signal and maps the result to an M-PSK constellation.

`H = comm.PSKTCMModulator(Name, Value)` creates a PSK TCM encoder object, `H`, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as `(Name1, Value1, ..., NameN, ValueN)`.

`H = comm.PSKTCMModulator(TRELLIS, Name, Value)` creates a PSK TCM encoder object, `H`. This object has the `TrellisStructure` property set to `TRELLIS` and the other specified properties set to the specified values.

Properties

TrellisStructure

Trellis structure of convolutional code

Specify `trellis` as a MATLAB structure that contains the trellis description of the convolutional code. Use the `istrellis` function to check whether a trellis structure is valid. The default is the result of `poly2trellis([1 3], [1 0 0; 0 5 2])`.

TerminationMethod

Termination method of encoded frame

Specify the termination method as one of `Continuous` | `Truncated` | `Terminated`. The default is `Continuous`.

When you set this property to `Continuous`, the object retains the encoder states at the end of each input vector for use with the next input vector.

When you set this property to `Truncated`, the object treats each input vector independently. The encoder is reset to the all-zeros state at the start of each input vector.

When you set this property to `Terminated`, the object treats each input vector independently. However, for each input vector, the object uses extra bits to set the encoder to the all-zeros state at the end of the vector. For a rate K/N code, the `step` method outputs the vector with a length given by $y = N \times (L + S)/K$, where $S = \text{constraintLength}-1$ (or, in the case of multiple constraint lengths, $S = \text{sum}(\text{constraintLength}(i)-1)$). L indicates the length of the input to the `step` method.

ResetInputPort

Enable modulator reset input

Set this property to `true` to enable an additional input to the `step` method. The default is `false`. When this additional reset input is a nonzero value, the internal states of the encoder reset to initial conditions. This property applies when you set the `TerminationMethod` on page 3-0 property to `Continuous`.

ModulationOrder

Number of points in signal constellation

Specify the number of points in the signal constellation used to map the convolutionally encoded data as a positive integer scalar value equal to 4, 8, or 16. The default is 8. The value of the `ModulationOrder` on page 3-0 property must equal the number of possible output symbols from the convolutional encoder of the PSK TCM modulator. Thus, the value for the `ModulationOrder` property must equal 2^N for a rate K/N convolutional code.

OutputDataType

Data type of output

Specify the output data type as one of `double` | `single`. The default is `double`.

Methods

`step` Convolutionally encode binary data and map using M-ary PSK constellation

Common to All System Objects	
<code>release</code>	Allow System object property value changes
<code>reset</code>	Reset internal states of System object

Examples

Modulate Data Using 8-PSK TCM Modulation

Modulate random data using 8-PSK TCM modulation and display the constellation diagram.

Create binary data.

```
data = randi([0 1],1000,1);
```

Define a trellis structure with four input symbols and eight output symbols.

```
t = poly2trellis([5 4],[23 35 0; 0 5 13]);
```

Create an 8-PSK TCM modulator object using the trellis structure variable, `t`.

```
hMod = comm.PSKTCMModulator(t,'ModulationOrder',8);
```

Modulate and plot the data.

```
modData = step(hMod,data);  
scatterplot(modData);
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the M-PSK TCM Decoder block reference page. The object properties correspond to the block parameters.

Extended Capabilities

Introduced in R2012a

step

System object: comm.PSKTCMModulator

Package: comm

Convolutionally encode binary data and map using M-ary PSK constellation

Syntax

```
Y = step(H,X)  
Y = step(H,X,R)
```

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(H,X)` convolutionally encodes and modulates the input binary data column vector, `X`, and returns the encoded and modulated data, `Y`. `X` must be of data type numeric, logical, or unsigned fixed point of word length 1 (fi object). When the convolutional encoder represents a rate K/N code, the length of the input vector, `X`, must be $K \times L$, for some positive integer L . The `step` method outputs a complex column vector, `Y`, of length L .

`Y = step(H,X,R)` resets the encoder of the PSK TCM modulator object to the all-zeros state when you input a reset signal, `R`, that is non-zero. `R` must be a double precision or logical scalar integer. This syntax applies when you set the `ResetInputPort` property to `true`.

Note `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications. For more information on changing property values, see “System Design in MATLAB Using System Objects”.

comm.QAMCoarseFrequencyEstimator

Package: comm

(Removed) Estimate frequency offset for QAM signal

Note comm.QAMCoarseFrequencyEstimator has been removed. Use comm.CoarseFrequencyCompensator instead.

Description

The QAMCoarseFrequencyEstimator System object estimates frequency offset for a QAM signal.

To estimate frequency offset for a QAM signal:

- 1 Define and set up your QAM Coarse Frequency Estimator object. See “Construction” on page 3-1085.
- 2 Call step to estimate frequency offset for a QAM signal according to the properties of comm.QAMCoarseFrequencyEstimator. The behavior of step is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the step method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, $y = \text{step}(\text{obj}, x)$ and $y = \text{obj}(x)$ perform equivalent operations.

Construction

$H = \text{comm.QAMCoarseFrequencyEstimator}$ creates a rectangular QAM coarse frequency offset estimator object, H. This object uses an open-loop, FFT-based technique to estimate the carrier frequency offset in a received rectangular QAM signal.

$H = \text{comm.QAMCoarseFrequencyEstimator}(\text{Name}, \text{Value})$ creates a rectangular QAM coarse frequency offset estimator object, H, with the specified property Name set to the specified Value. You can specify additional name-value pair arguments in any order as (Name1, Value1, ..., NameN, ValueN).

Properties

FrequencyResolution

Desired frequency resolution (Hz)

Specify the desired frequency resolution for offset frequency estimation as a positive, real scalar of data type double. This property establishes the FFT length that the object uses to perform spectral analysis. The value for this property must be less than or equal to half the SampleRate on page 3-0 property. The default is 0.001.

SampleRate

Sample rate (Hz)

Specify the sample rate in samples per second as a positive, real scalar of data type double. The default is 1.

Methods

step (Removed) Estimate frequency offset for QAM signal

Common to All System Objects	
release	Allow System object property value changes
reset	Reset internal states of System object

When using reset, note `comm.QAMCoarseFrequencyEstimator` has been removed. Use `comm.CoarseFrequencyCompensator` instead.

Examples

Compare Frequency Offset Estimation and Correction Methods for 16-QAM Signal

Estimate and correct for a frequency offset in a 16-QAM signal using the recommended `comm.CoarseFrequencyCompensator` System object. Compare frequency correction results to a workflow using the `comm.QAMCoarseFrequencyEstimator` System object.

Set example parameters.

```
nSym = 2048;    % Number of input symbols
M = 16;        % Modulation order
fs = 80000;    % Sampling frequency (Hz)
freqRez = 1;  % Frequency resolution (Hz)
freqOff = -3000; % Frequency offset
```

Create System objects for these operations:

```
% Square root raised cosine transmit filter
txfilter = comm.RaisedCosineTransmitFilter;
% Phase frequency offset - one to apply a frequency offset and a
% second that takes the frequency offset estimate as an input to correct
% the offset.
pfo = comm.PhaseFrequencyOffset('FrequencyOffset',freqOff, ...
    'SampleRate',fs);
pfoCorrect = comm.PhaseFrequencyOffset(...
    'FrequencyOffsetSource','Input port', ...
    'SampleRate',fs);
% QAM coarse frequency estimator
frequencyEst = comm.QAMCoarseFrequencyEstimator(...
    'SampleRate',fs, ...
    'FrequencyResolution',freqRez);

Error: comm.QAMCoarseFrequencyEstimator has been removed.
Use comm.CoarseFrequencyCompensator instead.

% Coarse frequency compensator
freqComp = comm.CoarseFrequencyCompensator('Modulation','QAM', ...
    'SampleRate',fs,'FrequencyResolution',freqRez);
```

Generate a 16-QAM signal, filter the signal, apply the frequency offset, and pass the signal through the AWGN channel.

```
data = randi([0 M-1],nSym,1);
modData = qammod(data,M,'UnitAveragePower',true); % Generate QAM signal
txFiltData = txfilter(modData); % Apply Tx filter
offsetData = pfo(txFiltData); % Apply frequency offset
rxData = awgn(offsetData,25,'measured'); % Pass through AWGN channel
```

This example does not apply receive filtering. In general, when the frequency offset is high, it is beneficial to apply coarse frequency compensation prior to receive filtering because filtering suppresses energy in the useful spectrum.

Compare the results for estimating and correcting the frequency offset by:

- Using the `frequencyEst` object to estimate the frequency offset and `pfoCorrect` to compensate for the frequency offset.
- Using the `freqComp` object estimate and apply compensation to the signal.

Observe the frequency offset estimate returned by both estimation methods.

```
estFreqOffset1
estFreqOffset2
```

```
estFreqOffset1 =
-3.0000e+03
estFreqOffset2 =
-3.0000e+03
```

Confirm the maximum resulting difference between the two compensation methods is negligible.

```
max(compensatedData1-compensatedData2)
```

```
ans =
```

```
-1.3051e-13 - 1.7614e-13i
```

Introduced in R2013b

step

System object: `comm.QAMCoarseFrequencyEstimator`

Package: `comm`

(Removed) Estimate frequency offset for QAM signal

Note `comm.QAMCoarseFrequencyEstimator` has been removed. Use `comm.CoarseFrequencyCompensator` instead.

Syntax

`Y = step(H,X)`

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(H,X)` estimates the carrier frequency offset of the input `X` and returns the result in `Y`. `X` must be a complex column vector of data type `double`. The `step` method outputs the estimate `Y` as a scalar of type `double`.

Note `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications. For more information on changing property values, see "System Design in MATLAB Using System Objects".

comm.QPSKDemodulator

Package: comm

Demodulate using QPSK method

Description

The `comm.QPSKDemodulator` object demodulates a signal that was modulated using the quadrature phase shift keying (QPSK) method. The input is a baseband representation of the modulated signal.

To demodulate a signal that was modulated using the QPSK method:

- 1 Create the `comm.QPSKDemodulator` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

Creation

Syntax

```
qpskdemod = comm.QPSKDemodulator  
qpskdemod = comm.QPSKDemodulator(Name=Value)  
qpskdemod = comm.QPSKDemodulator(phase=Name, Value)
```

Description

`qpskdemod = comm.QPSKDemodulator` creates a System object to demodulate input QPSK signals.

`qpskdemod = comm.QPSKDemodulator(Name=Value)` sets properties using one or more name-value arguments. For example, `DecisionMethod="Hard decision"` specifies demodulation using the hard-decision method.

`qpskdemod = comm.QPSKDemodulator(phase=Name, Value)` sets the `PhaseOffset` property to `phase`, and optional name-value arguments. Specify `phase` in radians.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see [System Design in MATLAB Using System Objects](#).

PhaseOffset — Phase of zeroth point in constellation

`pi/4` (default) | scalar

Phase of the zeroth point in the constellation in radians, specified as a scalar.

Example: PhaseOffset=0 aligns the QPSK signal constellation points on the axes $\{(1,0), (0,j), (-1,0), (0,-j)\}$.

Data Types: double

BitOutput — Option to output data as bits

0 or false (default) | 1 or true

Option to output data as bits, specified as a logical 0 (false) or 1 (true).

- Set this property to false to output symbols as integer values in the range [0, 3] with length equal to the input data vector length.
- Set this property to true to output a column vector of bit values with length equal to twice the input data vector length.

Data Types: logical

SymbolMapping — Symbol encoding

'Gray' (default) | 'Binary'

Symbol encoding mapping of constellation bits, specified as 'Gray' or 'Binary'.

Setting	Constellation Mapping for Integers	Constellation Mapping for Bits	Comment								
Gray	<table border="1"> <tr> <td>1</td> <td>0</td> </tr> <tr> <td>3</td> <td>2</td> </tr> </table>	1	0	3	2	<table border="1"> <tr> <td>01</td> <td>00</td> </tr> <tr> <td>11</td> <td>10</td> </tr> </table>	01	00	11	10	Map symbols using Gray-coded ordering.
1	0										
3	2										
01	00										
11	10										
Binary	<table border="1"> <tr> <td>1</td> <td>0</td> </tr> <tr> <td>2</td> <td>3</td> </tr> </table>	1	0	2	3	<table border="1"> <tr> <td>01</td> <td>00</td> </tr> <tr> <td>10</td> <td>11</td> </tr> </table>	01	00	10	11	Map symbols using natural binary-coded ordering. The signal constellation maps to the complex value $e^{j(\text{PhaseOffset} + (2\pi m/4))}$, where m is an integer in the range [0, 3].
1	0										
2	3										
01	00										
10	11										

DecisionMethod — Demodulation decision method

'Hard decision' (default) | 'Log-likelihood ratio' | 'Approximate log-likelihood ratio'

Demodulation decision method, specified as 'Hard decision', 'Log-likelihood ratio', or 'Approximate log-likelihood ratio'. When you set the BitOutput property to false, the object always performs hard-decision demodulation.

Dependencies

To enable this property, set the BitOutput property to true.

VarianceSource — Source of noise variance

'Property' (default) | 'Input port'

Source of noise variance, specified as 'Property' or 'Input port'.

Dependencies

To enable this property, set the `BitOutput` property to `true` and the `DecisionMethod` property to 'Log-likelihood ratio' or 'Approximate log-likelihood ratio'.

Variance — Noise variance

1 (default) | positive scalar

Noise variance, specified as a positive scalar.

Tunable: Yes

Tips

The exact LLR algorithm computes exponentials using finite precision arithmetic. For computations involving very large positive or negative magnitudes, the exact LLR algorithm yields:

- `Inf` or `-Inf` if the noise variance is a very large value
- `NaN` if the noise variance and signal power are both very small values

The approximate LLR algorithm does not compute exponentials. You can avoid `Inf`, `-Inf`, and `NaN` results by using the approximate LLR algorithm.

Dependencies

To enable this property, set the `BitOutput` property to `true`, the `DecisionMethod` property to 'Log-likelihood ratio' or 'Approximate log-likelihood ratio', and the `VarianceSource` property to 'Property'.

Data Types: `double`

OutputDataType — Data type of output

'Full precision' (default) | 'Smallest unsigned integer' | 'double' | ...

Data type of the output, specified as 'Full precision', 'Smallest unsigned integer', 'double', 'single', 'int8', 'uint8', 'int16', 'uint16', 'int32', or 'uint32', 'logical'.

- When the input data type is single or double precision and you set the `BitOutput` property to `true`, the `DecisionMethod` property to 'Hard decision', and the `OutputDataType` property to 'Full precision', the output has the same data type as that of the input.
- When the input data is of a fixed-point type, the output data type behaves as if you had set the `OutputDataType` property to 'Smallest unsigned integer'.
- When you set `BitOutput` to `true` and the `DecisionMethod` property to 'Hard Decision', then 'logical' data type is a valid option.
- When you set the `BitOutput` property to `true` and the `DecisionMethod` property to 'Log-likelihood ratio' or 'Approximate log-likelihood ratio', the output data type is the same as that of the input and the input data type must be single or double precision.

Dependencies

To enable this property, set the `BitOutput` property to `false` or set the `BitOutput` property to `true` and the `DecisionMethod` property to 'Hard decision'.

Fixed-Point Properties

DerotateFactorDataType — Data type of derotate factor

'Same word length as input' (default) | 'Custom'

Data type of the derotate factor, specified as 'Same word length as input' or 'Custom'. The object uses the derotate factor in the computations only when the input signal is a fixed-point type and the PhaseOffset property has a value that is not an even multiple of $\pi/4$.

Dependencies

To enable this property, set the BitOutput property to false or set the BitOutput property to true and the DecisionMethod property to 'Hard decision'.

CustomDerotateFactorDataType — Fixed-point data type of derotate factor

numerictype([],16) (default) | unscaled numerictype object

Fixed-point data type of the derotate factor, specified as an unscaled numerictype object with a Signedness of Auto.

Dependencies

To enable this property, set the DerotateFactorDataType property to 'Custom'.

Data Types: numerictype object

Usage

Syntax

```
y = qpskdemod(x)
y = qpskdemod(x,var)
```

Description

`y = qpskdemod(x)` applies QPSK demodulation to the input signal and returns the demodulated signal.

`y = qpskdemod(x,var)` uses soft decision demodulation and noise variance `var`. This syntax applies when you set the BitOutput property to true, the DecisionMethod property to 'Approximate log-likelihood ratio' or 'Log-likelihood ratio', and the VarianceSource property to 'Input port'.

Input Arguments

x — QPSK-modulated signal

scalar | column vector

QPSK-modulated signal, specified as a scalar or column vector.

Dependencies

The object accepts inputs with a signed integer data type or signed fixed point (sfi) objects when you set the BitOutput property to false or you set the DecisionMethod property to 'Hard decision' and the BitOutput property to true.

Data Types: `double` | `single` | `int` | `fi`

var — Noise variance

scalar

Noise variance, specified as a scalar.

Dependencies

To enable this argument, set the `VarianceSource` property to `'Input port'`, the `BitOutput` property to `true`, and the `DecisionMethod` property to `'Approximate log-likelihood ratio'` or `'Log-likelihood ratio'`.

Data Types: `single` | `double`

Output Arguments**y — Output signal**

scalar | column vector

Output signal, returned as a scalar or column vector. To specify whether the object outputs values as integers or bits, use the `BitOutput` property. To specify the output data type, use the `OutputDataType` property.

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Specific to `comm.QPSKDemodulator`

`constellation` Calculate or plot ideal signal constellation

Common to All System Objects

`step` Run System object algorithm

`release` Release resources and allow changes to System object property values and input characteristics

`reset` Reset internal states of System object

Examples**Plot QPSK Reference Constellation**

Create a QPSK modulator.

```
mod = comm.QPSKModulator;
```

Determine the reference constellation points.

```
refC = constellation(mod)
```

```
refC = 4×1 complex
```

```

0.7071 + 0.7071i
-0.7071 + 0.7071i
-0.7071 - 0.7071i
0.7071 - 0.7071i

```

Plot the constellation.

```
constellation(mod)
```

Create a QPSK demodulator having phase offset set to 0.

```
demod = comm.QPSKDemodulator(0);
```

Plot the reference constellation. The `constellation` method works for both modulator and demodulator objects.

```
constellation(demod)
```

BER Estimate of QPSK Signal

Create a QPSK modulator and demodulator pair that operate on bits.

```
qpskModulator = comm.QPSKModulator('BitInput',true);
qpskDemodulator = comm.QPSKDemodulator('BitOutput',true);
```

Create an AWGN channel object and an error rate counter.

```
channel = comm.AWGNChannel('EbNo',4,'BitsPerSymbol',2);
errorRate = comm.ErrorRate;
```

Generate random binary data and apply QPSK modulation.

```
data = randi([0 1],1000,1);
txSig = qpskModulator(data);
```

Pass the signal through the AWGN channel and demodulate it.

```
rxSig = channel(txSig);
rxData = qpskDemodulator(rxSig);
```

Calculate the error statistics. Display the BER.

```

errorStats = errorRate(data,rxData);

errorStats(1)

ans = 0.0100

```

Log-Likelihood Ratio (LLR) Demodulation

This example shows the BER performance improvement for QPSK modulation when using log-likelihood ratio (LLR) instead of hard-decision demodulation in a convolutionally coded communication link. With LLR demodulation, one can use the Viterbi decoder either in the unquantized decoding mode or the soft-decision decoding mode. Unquantized decoding, where the decoder inputs are real values, though better in terms of BER, is not practically viable. In the more practical soft-decision decoding, the demodulator output is quantized before being fed to the decoder. It is generally observed that this does not incur a significant cost in BER while significantly reducing the decoder complexity. We validate this experimentally through this example.

For a Simulink™ version of this example, see “LLR vs. Hard Decision Demodulation in Simulink”.

Initialization

Initialize simulation parameters.

```

M = 4;                % Modulation order
k = log2(M);         % Bits per symbol
bitsPerIter = 1.2e4; % Number of bits to simulate
EbNo = 3;           % Information bit Eb/No in dB

```

Initialize coding properties for a rate 1/2, constraint length 7 code.

```

codeRate = 1/2;      % Code rate of convolutional encoder
constLen = 7;       % Constraint length of encoder
codeGenPoly = [171 133]; % Code generator polynomial of encoder
tblen = 32;        % Traceback depth of Viterbi decoder
trellis = poly2trellis(constLen,codeGenPoly);

```

Create a `comm.ConvolutionalEncoder` System object™ by using `trellis` as an input.

```

enc = comm.ConvolutionalEncoder(trellis);

```

Modulator and Channel

Create a `comm.QPSKModulator` and two `comm.QPSKDemodulator` System objects. Configure the first demodulator to output hard-decision bits. Configure the second to output LLR values.

```

qpskMod = comm.QPSKModulator('BitInput',true);
demodHard = comm.QPSKDemodulator('BitOutput',true,...
    'DecisionMethod','Hard decision');
demodLLR = comm.QPSKDemodulator('BitOutput',true,...
    'DecisionMethod','Log-likelihood ratio');

```

The signal going into the AWGN channel is the modulated encoded signal. To achieve the required noise level, adjust the E_b/N_0 for coded bits and multi-bit symbols. Calculate the SNR value based on the E_b/N_0 value you want to simulate.

```
SNR = convertSNR(EbNo,"ebno","BitsPerSymbol",log2(M),"CodingRate",codeRate);
```

Viterbi Decoding

Create `comm.ViterbiDecoder` objects to act as the hard-decision, unquantized, and soft-decision decoders. For all three decoders, set the traceback depth to `tblen`.

```
decHard = comm.ViterbiDecoder(trellis,'InputFormat','Hard', ...  
    'TracebackDepth',tblen);
```

```
decUnquant = comm.ViterbiDecoder(trellis,'InputFormat','Unquantized', ...  
    'TracebackDepth',tblen);
```

```
decSoft = comm.ViterbiDecoder(trellis,'InputFormat','Soft', ...  
    'SoftInputWordLength',3,'TracebackDepth',tblen);
```

Calculating the Error Rate

Create `comm.ErrorRate` objects to compare the decoded bits to the original transmitted bits. The Viterbi decoder creates a delay in the decoded bit stream output equal to the traceback length. To account for this delay, set the `ReceiveDelay` property of the `comm.ErrorRate` objects to `tblen`.

```
errHard = comm.ErrorRate('ReceiveDelay',tblen);  
errUnquant = comm.ErrorRate('ReceiveDelay',tblen);  
errSoft = comm.ErrorRate('ReceiveDelay',tblen);
```

System Simulation

Generate `bitsPerIter` message bits. Then convolutionally encode and modulate the data.

```
txData = randi([0 1],bitsPerIter,1);  
encData = enc(txData);  
modData = qpskMod(encData);
```

Pass the modulated signal through an AWGN channel.

```
[rxSig,noiseVariance] = awgn(modData,SNR);
```

Before using a `comm.ViterbiDecoder` object in the soft-decision mode, the output of the demodulator needs to be quantized. This example uses a `comm.ViterbiDecoder` object with a `SoftInputWordLength` of 3. This value is a good compromise between short word lengths and a small BER penalty. Define partition points for 3-bit quantization.

```
demodLLR.Variance = noiseVariance;  
partitionPoints = (-1.5:0.5:1.5)/noiseVariance;
```

Demodulate the received signal and output hard-decision bits.

```
hardData = demodHard(rxSig);
```

Demodulate the received signal and output LLR values.

```
LLRData = demodLLR(rxSig);
```

Hard-decision decoding

Pass the demodulated data through the Viterbi decoder. Compute the error statistics.

```
rxDataHard = decHard(hardData);
berHard = errHard(txData,rxDataHard);
```

Unquantized decoding

Pass the demodulated data through the Viterbi decoder. Compute the error statistics.

```
rxDataUnquant = decUnquant(LLRData);
berUnquant = errUnquant(txData,rxDataUnquant);
```

Soft-decision decoding

Pass the demodulated data to the `quantiz` function. This data must be multiplied by -1 before being passed to the quantizer, because, in soft-decision mode, the Viterbi decoder assumes that positive numbers correspond to 1s and negative numbers to 0s. Pass the quantizer output to the Viterbi decoder. Compute the error statistics.

```
quantizedValue = quantiz(-LLRData,partitionPoints);
rxDataSoft = decSoft(double(quantizedValue));
berSoft = errSoft(txData,rxDataSoft);
```

Running Simulation Example

Simulate the previously described communications system over a range of E_b/N_0 values by executing the simulation file `simLLRvsHD`. It plots BER results as they are generated. BER results for hard-decision demodulation and LLR demodulation with unquantized and soft-decision decoding are plotted in red, blue, and black, respectively. A comparison of simulation results with theoretical results is also shown. Observe that the BER is only slightly degraded by using soft-decision decoding instead of unquantized decoding. The gap between the BER curves for soft-decision decoding and the theoretical bound can be narrowed by increasing the number of quantizer levels.

This example may take some time to compute BER results. If you have the Parallel Computing Toolbox™ (PCT) installed, you can set `usePCT` to `true` to run the simulation in parallel. In this case, the file `LLRvsHDwithPCT` is run.

To obtain results over a larger range of E_b/N_0 values, modify the appropriate supporting files. Note that you can obtain more statistically reliable results by collecting more errors.

```
usePCT = false;
if usePCT && license('checkout','Distrib_Computing_Toolbox') ...
    && ~isempty(ver('parallel'))
    LLRvsHDwithPCT(1.5:0.5:5.5,5);
else
    simLLRvsHD(1.5:0.5:5.5,5);
end
```

Appendix

The following functions are used in this example:

- `simLLRvsHD.m` — Simulates system without PCT.
- `LLRvsHDwithPCT.m` — Simulates system with PCT.
- `simLLRvsHDPCT.m` — Helper function called by `LLRvsHDwithPCT`.

More About

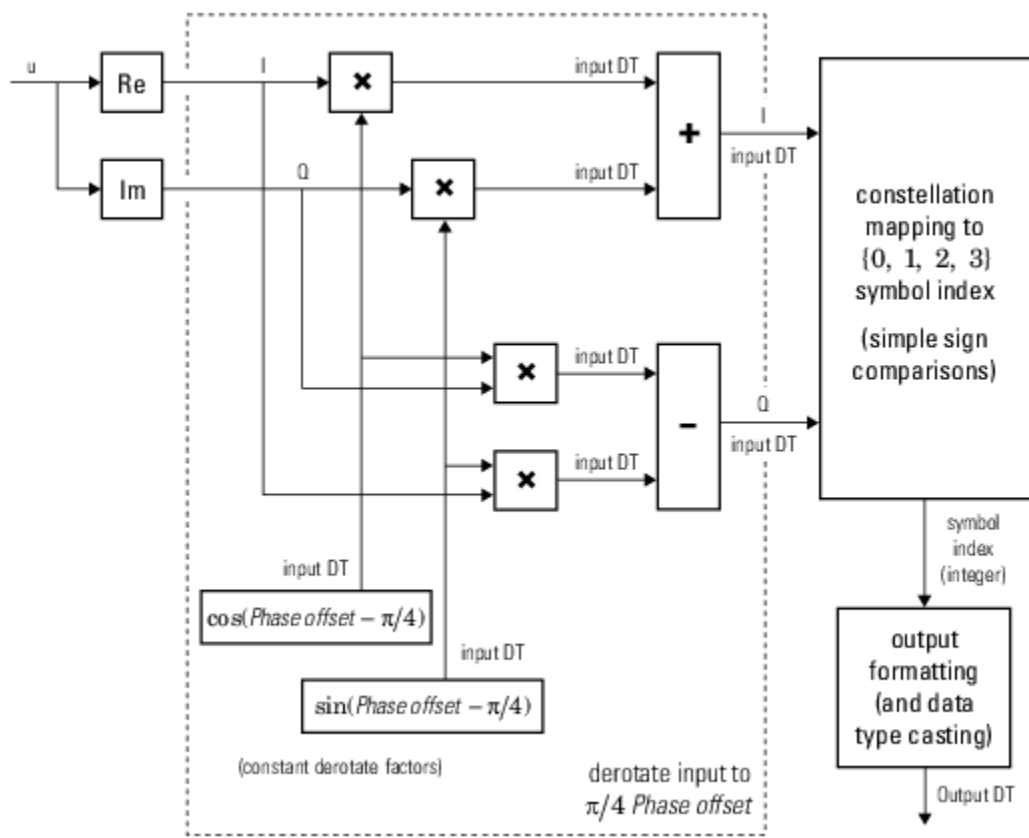

Hard-Decision QPSK Demodulation

The signal preprocessing required for QPSK demodulation depends on the configuration.

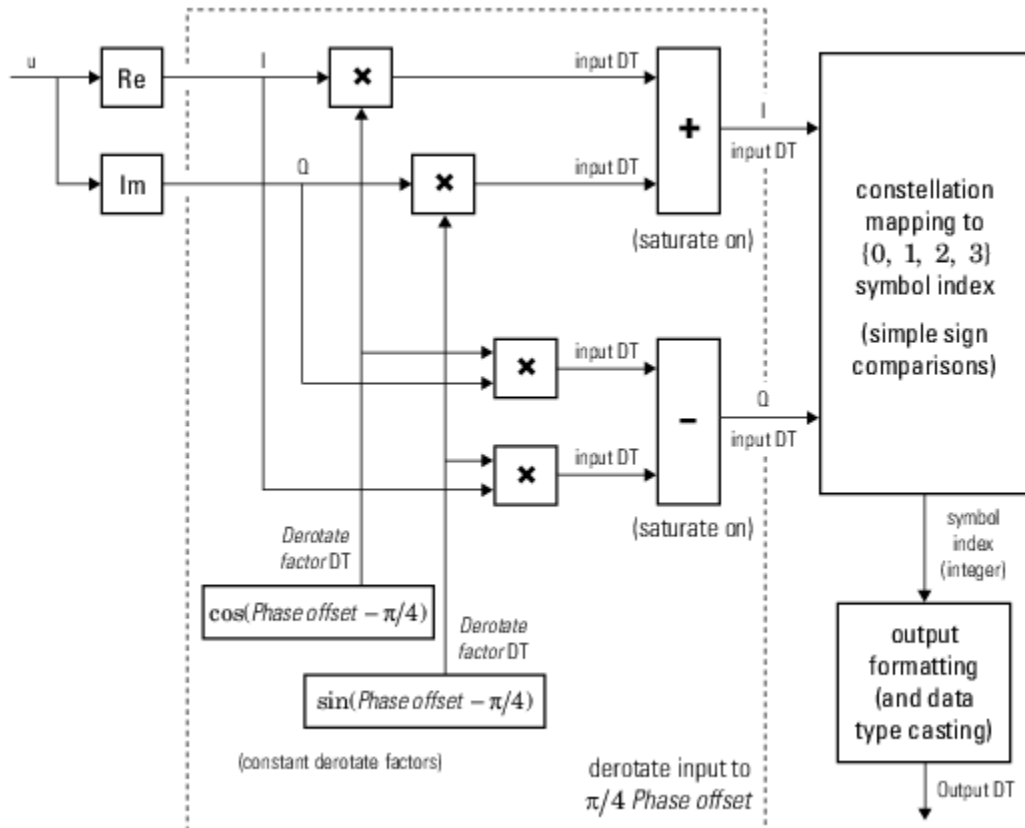

This figure shows the hard-decision QPSK demodulation signal diagram for the trivial phase offset (odd multiple of $\pi/4$) configuration.

This figure shows the hard-decision QPSK demodulation floating point signal diagram for the nontrivial phase offset configuration.

This figure shows the hard-decision QPSK demodulation fixed-point signal diagram for the nontrivial phase offset configuration.

Soft-Decision QPSK Demodulation

For soft demodulation, two soft-decision log-likelihood ratio (LLR) algorithms are available: exact LLR and approximate LLR. The exact LLR algorithm is more accurate but has slower execution speed than the approximate LLR algorithm. For further description of these algorithms, see the “Soft-Decision Demodulation” topic.

Note The exact LLR algorithm computes exponentials using finite precision arithmetic. For computations involving very large positive or negative magnitudes, the exact LLR algorithm yields:

- Inf or $-\text{Inf}$ if the noise variance is a very large value
- NaN if the noise variance and signal power are both very small values

The approximate LLR algorithm does not compute exponentials. You can avoid Inf , $-\text{Inf}$, and NaN results by using the approximate LLR algorithm.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

See “System Objects in MATLAB Code Generation” (MATLAB Coder).

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

double and single data types are supported for simulation, but not for HDL code generation.

QPSK Demodulator Baseband | M-PSK Demodulator Baseband

Introduced in R2012a

comm.QPSKModulator

Package: comm

Modulate using QPSK method

Description

The `comm.QPSKModulator` object modulates a signal using the quadrature phase shift keying (QPSK) method. The output is a baseband representation of the modulated signal.

To modulate using the QPSK method:

- 1 Create the `comm.QPSKModulator` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

Creation

Syntax

```
qpskmod = comm.QPSKModulator  
qpskmod = comm.QPSKModulator(Name,Value)  
qpskmod = comm.QPSKModulator(phase,Name,Value)
```

Description

`qpskmod = comm.QPSKModulator` creates a System object to modulate input signals using the QPSK method.

`qpskmod = comm.QPSKModulator(Name,Value)` sets properties using one or more name-value arguments. For example, `'OutputDataType'='single'` specifies output of the modulated signal values in single precision data type.

`qpskmod = comm.QPSKModulator(phase,Name,Value)` sets the `PhaseOffset` property to phase and optional name-value arguments. Specify phase in radians.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see [System Design in MATLAB Using System Objects](#).

PhaseOffset — Phase offset of zeroth point in constellation

`pi/4` (default) | scalar

Phase of zeroth point of the signal constellation in radians, specified as a scalar.

Example: 'PhaseOffset', 0 aligns the QPSK signal constellation points on the axes, {(1,0), (0,j), (-1,0), (0,-j)}.

Data Types: double

BitInput — Option to provide input in bits

0 or false (default) | 1 or true

Option to provide input in bits, specified as a logical 0 (false) or 1 (true).

- When this property is set to false, the input values must be integer representations of two-bit input segments in the range [0, 3].
- When this property is set to true, the input must be a binary vector of even length. Element pairs are binary representations of integers.

Data Types: logical

SymbolMapping — Symbol encoding

'Gray' (default) | 'Binary'

Symbol encoding mapping of constellation bits, specified as 'Gray' or 'Binary'.

Setting	Constellation Mapping for Integers	Constellation Mapping for Bits	Comment								
Gray	<table border="1"> <tr><td>1</td><td>0</td></tr> <tr><td>3</td><td>2</td></tr> </table>	1	0	3	2	<table border="1"> <tr><td>01</td><td>00</td></tr> <tr><td>11</td><td>10</td></tr> </table>	01	00	11	10	Map symbols using Gray-coded ordering.
1	0										
3	2										
01	00										
11	10										
Binary	<table border="1"> <tr><td>1</td><td>0</td></tr> <tr><td>2</td><td>3</td></tr> </table>	1	0	2	3	<table border="1"> <tr><td>01</td><td>00</td></tr> <tr><td>10</td><td>11</td></tr> </table>	01	00	10	11	Map symbols using natural binary-coded ordering. The signal constellation maps to the complex value $e^{j(\text{PhaseOffset} + (2\pi m/4))}$, where m is an integer in the range [0, 3].
1	0										
2	3										
01	00										
10	11										

Data Types: char

OutputDataType — Data type assigned to output

'double' (default) | 'single' | 'Custom'

Data type assigned to output, specified as 'double', 'single', or 'Custom'.

Data Types: char

Fixed-Point Properties

CustomOutputDataType — Fixed-point data type of output

numericType([], 16) (default) | numericType object

Fixed-point data type of output, specified as a `numericType` object with a signedness of `Auto`.

Dependencies

This property applies when you set the `OutputDataType` property to `'Custom'`.

Usage**Syntax**

```
y = qpskmod(x)
```

Description

`y = qpskmod(x)` returns baseband-modulated output.

Input Arguments**x — Input signal**

integer column vector | bit column vector

Input signal, specified as an N_S -element column vector of integers or bits, where N_S is the number of samples.

The setting of the `BitInput` property determines the interpretation of the input vector.

Data Types: `double` | `int8` | `logical` | `fi`

Output Arguments**y — Output QPSK-modulated signal**

vector

Output QPSK-modulated signal, returned as a complex-valued vector.

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Specific to `comm.QPSKModulator`

`constellation` Calculate or plot ideal signal constellation

Common to All System Objects

<code>step</code>	Run System object algorithm
<code>release</code>	Release resources and allow changes to System object property values and input characteristics
<code>reset</code>	Reset internal states of System object

Examples

Plot QPSK Reference Constellation

Create a QPSK modulator.

```
mod = comm.QPSKModulator;
```

Determine the reference constellation points.

```
refC = constellation(mod)
```

```
refC = 4x1 complex
    0.7071 + 0.7071i
   -0.7071 + 0.7071i
   -0.7071 - 0.7071i
    0.7071 - 0.7071i
```

Plot the constellation.

```
constellation(mod)
```

Create a QPSK demodulator having phase offset set to 0.

```
demod = comm.QPSKDemodulator(0);
```

Plot the reference constellation. The `constellation` method works for both modulator and demodulator objects.

```
constellation(demod)
```

Phase Noise on QPSK Signal

Create a QPSK modulator object and a phase noise object.

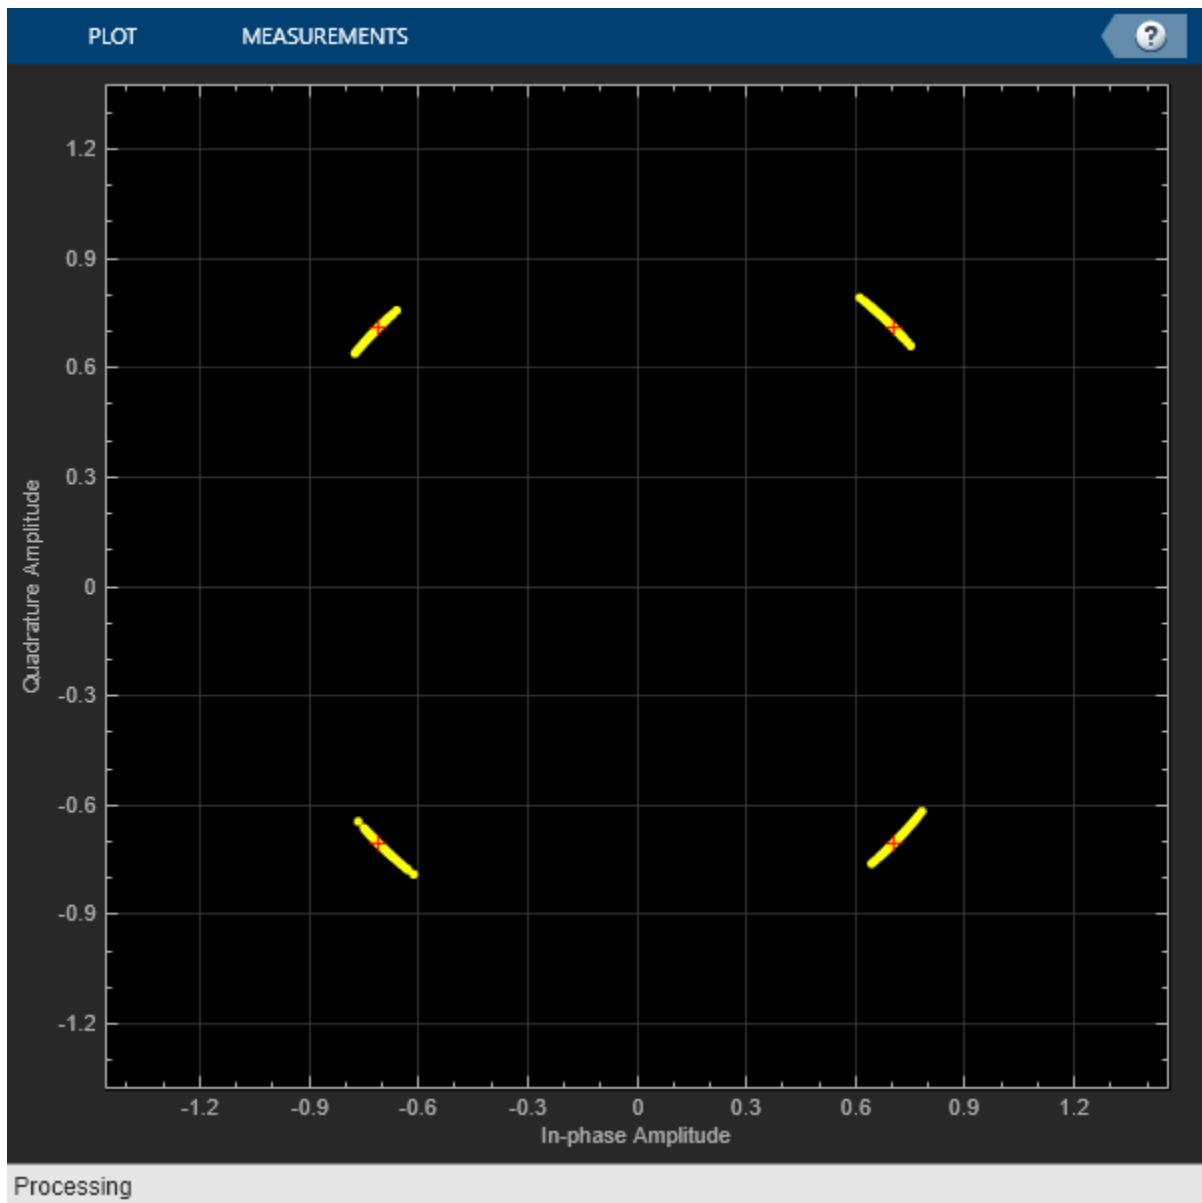

```
qpskmod = comm.QPSKModulator;
phNoise = comm.PhaseNoise( ...
    Level=-55, ...
    FrequencyOffset=20, ...
    SampleRate=1000);
```

Generate random QPSK data. Pass the signal through the phase noise object.

```
d = randi([0 3],1000,1);
x = qpskmod(d);
y = phNoise(x);
```

Display the constellation diagram of the QPSK signal. The phase noise has introduced a rotational distortion on the constellation diagram.

```
constDiagram = comm.ConstellationDiagram;
constDiagram(y)
```

Create QPSK Modulator Object with Bit Input

Create QPSK modulator object setting the BitInput property to true. Display the properties.

```
qpskmod = comm.QPSKModulator('BitInput',true)
```

```
qpskmod =  
comm.QPSKModulator with properties:
```

```
PhaseOffset: 0.7854  
BitInput: true  
SymbolMapping: 'Gray'
```

```
OutputDataType: 'double'
```

Determine the reference constellation points.

```
refC = constellation(qpskmod)
```

```
refC = 4×1 complex
    0.7071 + 0.7071i
   -0.7071 + 0.7071i
   -0.7071 - 0.7071i
    0.7071 - 0.7071i
```

Plot the constellation. Since BitInput is true, the constellation symbols are label with bit values.

```
constellation(qpskmod)
```

Create QPSK modulator object with default properties settings. Display the properties.

```
qpskmod2 = comm.QPSKModulator
```

```
qpskmod2 =
comm.QPSKModulator with properties:
```

```
PhaseOffset: 0.7854
BitInput: false
```

```
SymbolMapping: 'Gray'
OutputDataType: 'double'
```

Plot constellation with default settings. Since `BitInput` is false, the constellation symbols are labeled with integer values.

```
constellation(qpskmod2)
```

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

See “System Objects in MATLAB Code Generation” (MATLAB Coder).

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

`double` and `single` data types are supported for simulation, but not for HDL code generation.

QPSK Modulator Baseband

Introduced in R2012a

comm.RaisedCosineReceiveFilter

Package: comm

Apply pulse shaping by decimating signal using raised-cosine FIR filter

Description

The `comm.RaisedCosineReceiveFilter` System object applies pulse shaping by decimating an input signal using a raised-cosine finite impulse response (FIR) filter. The FIR filter has $(\text{FilterSpanInSymbols} \times \text{InputSamplesPerSymbol} + 1)$ tap coefficients.

To apply pulse shaping by decimating an input signal using a raised-cosine FIR filter:

- 1 Create the `comm.RaisedCosineReceiveFilter` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

Creation

Syntax

```
rxfilter = comm.RaisedCosineReceiveFilter
rxfilter = comm.RaisedCosineReceiveFilter(Name,Value)
```

Description

`rxfilter = comm.RaisedCosineReceiveFilter` returns a raised-cosine FIR receive filter System object, which decimates the input signal using a raised-cosine FIR filter. The filter uses an efficient polyphase FIR decimation structure and has unit energy.

`rxfilter = comm.RaisedCosineReceiveFilter(Name,Value)` sets properties using one or more name-value pairs. Enclose each property name in quotes. For example, `comm.RaisedCosineReceiveFilter('RolloffFactor',0.3)` configures a raised-cosine receive filter System object with the roll-off factor set to 0.3.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see [System Design in MATLAB Using System Objects](#).

Shape — Filter shape

Square root (default) | Normal

Filter shape, specified as 'Square root' or 'Normal'.

Data Types: char | string

RolloffFactor — Roll-off factor

0.2 (default) | scalar in the range [0, 1]

Roll-off factor, specified as a scalar in the range [0, 1].

Data Types: double

FilterSpanInSymbols — Filter span in symbols

10 (default) | positive integer

Filter span in symbols, specified as a positive integer. The object truncates the infinite impulse response (IIR) of an ideal raised-cosine filter to an impulse response that spans the number of symbols specified by this property.

Data Types: double

InputSamplesPerSymbol — Input samples per symbol

8 (default) | positive integer

Input samples per symbol, specified as a positive integer.

Data Types: double

DecimationFactor — Decimation factor

8 (default) | integer

Decimation factor, specified as an integer in the range [1, InputSamplesPerSymbol]. This value must evenly divide into InputSamplesPerSymbol. The sampling rate of the output signal is reduced by the decimation factor such that $\text{length}(y)/\text{length}(x)$ is equal to DecimationFactor. For a matrix input signal, the number of input rows must be a multiple of the decimation factor.

Data Types: double

DecimationOffset — Decimation offset

0 (default) | integer

Decimation offset, specified as an integer in the range [0, (DecimationFactor - 1)]. This property specifies the number of filtered samples the object discards before downsampling.

Data Types: double

Gain — Linear filter gain

1 (default) | positive scalar

Linear filter gain, specified as a positive scalar. The object designs a raised-cosine filter that has unit energy and then applies the linear filter gain to obtain final tap coefficient values.

Data Types: double

Usage

Syntax

```
y = rxfilter(x)
```

Description

`y = rxfilter(x)` applies pulse shaping by decimating an input signal using a raised cosine FIR filter. The output consists of decimated signal values.

Input Arguments

x — Input signal

column vector | matrix

Input signal, specified as a column vector or a K_i -by- N matrix. K_i is the number of input samples per signal channel, and N is the number of signal channels.

For a K_i -by- N matrix input, the object processes columns of the input matrix as N independent channels.

Data Types: double | single

Output Arguments

y — Output signal

column vector | matrix

Output signal, returned as a column vector or a K_o -by- N matrix. K_o is equal to $K_i / \text{DecimationFactor}$. K_i is the number of input samples per signal channel, and N is the number of signal channels.

The System object filters each channel over time and generates a K_o -by- N output matrix. The output signal is the same data type as the input signal.

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Specific to `comm.RaisedCosineReceiveFilter`

<code>info</code>	Information about filter System object
<code>coeffs</code>	Coefficients for filters
<code>cost</code>	Computational cost of implementing filter System object
<code>freqz</code>	Frequency response of discrete-time filter
<code>fvtool</code>	Plot frequency response of filter
<code>grpdelay</code>	Group delay response of discrete-time filter
<code>impz</code>	Impulse response of discrete-time filter
<code>order</code>	Order of discrete-time filter System object

Common to All System Objects

step	Run System object algorithm
release	Release resources and allow changes to System object property values and input characteristics
reset	Reset internal states of System object

Examples

Filter Signal Using Square-Root-Raised-Cosine Receive Filter

Filter the output of a square-root-raised-cosine (SRRC) transmit filter by using a matched SRRC receive filter. The input signal has eight samples per symbol.

Create an SRRC transmit filter object, setting the number of output samples per symbol to 8.

```
txfilter = comm.RaisedCosineTransmitFilter('OutputSamplesPerSymbol',8);
```

Create an SRRC receive filter, setting the number of input samples per symbol to 8 and the decimation factor to 8.

```
rxfilter = comm.RaisedCosineReceiveFilter('InputSamplesPerSymbol',8, ...  
    'DecimationFactor',8);
```

Use the `coeffs` function to determine the filter coefficients for both filters.

```
txCoef = coeffs(txfilter);  
rxCoef = coeffs(rxfilter);
```

Launch the filter visualization tool and display the magnitude responses of the two filters. The results show that the responses are the same.

```
fvt = fvtool(txCoef.Numerator,1,rxCoef.Numerator,1);  
legend(fvt,'Tx Filter','Rx Filter')
```

Generate a random bipolar signal. Interpolate the signal by using the SRRC transmit filter object.

```
preTx = 2*randi([0 1],100,1) - 1;
y = txfilter(preTx);
```

Decimate the signal by using the SRRC receive filter object.

```
postRx = rxfilter(y);
```

The filter delay is equal to the filter span. Accounting for the filter delay, adjust the plotted samples to compare the pre-Tx filter signal with the post-Rx filter signal. Because the combined receive and the transmit RRC filters generate a matched filter pair, the two signals overlap one another.

```
delay = txfilter.FilterSpanInSymbols;
x = (1:(length(preTx)-delay));
plot(x,preTx(1:end-delay),x,postRx(delay+1:end))
legend('Pre-Tx filter','Post-Rx filter')
```

Specify Filter Span of Square-Root-Raised-Cosine Receive Filter

Decimate a bipolar signal using a square-root-raised-cosine (SRRC) filter whose impulse response is truncated to filter a span of six symbol durations.

Create a SRRC transmit FIR filter, setting the filter span to six symbols. The object truncates the impulse response to six symbols.

```
txfilter = comm.RaisedCosineTransmitFilter('FilterSpanInSymbols',6);
```

Generate a random bipolar signal . Filter the signal by using the SRRC transmit FIR filter object.

```
x = 2*randi([0 1],25,1) - 1;
y = txfilter(x);
```

Create a matched SRRC receive filter object.

```
rxfilter = comm.RaisedCosineReceiveFilter('FilterSpanInSymbols',6);
```

Launch the filter visualization tool to show the impulse response of the receive filter.

```
fvtool(rxfilter,'Analysis','impulse')
```

Filter the output signal from the transmit filter by using the matched SRRRC receive filter object.

```
r = rxfilter(y);
```

Plot the interpolated signal. The results show a delay equal to the filter span (six symbols) before data passes through the filter.

```
stem(r)
```

Create Square-Root-Raised-Cosine Receive Filter with Unity Passband Gain

Create a square-root-raised-cosine (SRRC) receive filter object. Use FVTool to plot the filter response. The results show that the linear filter gain is greater than unity. Specifically, the passband gain is more than 0 dB.

```
rxfilter = comm.RaisedCosineReceiveFilter;  
fvtool(rxfilter)
```

Use the `coeffs` object function to obtain the filter coefficients and adjust the filter gain to unit energy.

```
b = coeffs(rxfilter);
```

Because a filter with unity passband gain must have filter coefficients that sum to 1, set the linear filter gain to the inverse of the sum of the filter tap coefficients, `b.Numerator`.

```
rxfilter.Gain = 1/sum(b.Numerator);
```

Verify that the resulting filter coefficients sum to 1.

```
bNorm = coeffs(rxfilter);
sum(bNorm.Numerator)
```

```
ans = 1.0000
```

Plot the filter frequency response. The results now show that the passband gain is 0 dB, which is unity gain.

```
fvtool(rxfilter)
```

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

See “System Objects in MATLAB Code Generation” (MATLAB Coder).

The `comm.RaisedCosineReceiveFilter` System object supports SIMD code generation using Intel AVX2 technology under these conditions:

- Input signal is real-valued with real filter coefficients.
- Input signal is complex-valued with real or complex filter coefficients.
- Input signal has a data type of `single` or `double`.

The SIMD technology significantly improves the performance of the generated code. For details, see “Generate SIMD Code for MATLAB Functions” (Embedded Coder).

Apply pulse shaping by interpolating signal using raised-cosine FIR filter

Description

The `comm.RaisedCosineTransmitFilter` System object applies pulse shaping by interpolating an input signal using a raised cosine finite impulse response (FIR) filter. The FIR filter has $(\text{FilterSpanInSymbols} \times \text{OutputSamplesPerSymbol} + 1)$ tap coefficients.

To apply pulse shaping by interpolating an input signal using a raised cosine FIR filter:

- 1 Create the `comm.RaisedCosineTransmitFilter` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

Creation

Syntax

```
txfilter = comm.RaisedCosineTransmitFilter  
txfilter = comm.RaisedCosineTransmitFilter(Name,Value)
```

Description

`txfilter = comm.RaisedCosineTransmitFilter` returns a raised cosine transmit FIR filter System object, which interpolates an input signal using a raised cosine FIR filter. The filter uses an efficient polyphase FIR interpolation structure and has unit energy.

`txfilter = comm.RaisedCosineTransmitFilter(Name,Value)` sets properties using one or more name-value pairs. Enclose each property name in quotes. For example, `comm.RaisedCosineTransmitFilter('FilterSpanInSymbols',15)` configures a raised cosine transmit filter System object with the filter span set to 15 symbols.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see [System Design in MATLAB Using System Objects](#).

Shape — Filter shape

'Square root' (default) | 'Normal'

Filter shape, specified as 'Square root' or 'Normal'.

Data Types: char | string

RolloffFactor — Roll-off factor

0.2 (default) | scalar in the range [0, 1]

Roll-off factor, specified as a scalar in the range [0, 1].

Data Types: double

FilterSpanInSymbols — Filter span in symbols

10 (default) | positive integer

Filter span in symbols, specified as a positive integer. The object truncates the infinite impulse response (IIR) of an ideal raised-cosine filter to an impulse response that spans the number of symbols specified by this property.

Data Types: double

OutputSamplesPerSymbol — Output samples per symbol

8 (default) | positive integer

Output samples per symbol, specified as a positive integer.

Data Types: double

Gain — Linear filter gain

1 (default) | positive scalar

Linear filter gain, specified as a positive scalar. The object designs a raised-cosine filter that has unit energy and then applies the linear filter gain to obtain final tap coefficient values.

Data Types: double

Usage

Syntax

```
y = txfilter(x)
```

Description

`y = txfilter(x)` applies pulse shaping by interpolating an input signal using a raised cosine FIR filter. The output consists of interpolated signal values.

Input Arguments

x — Input signal

column vector | matrix

Input signal, specified as a column vector or a K_1 -by- N matrix. K_1 is the number of input samples per signal channel, and N is the number of signal channels.

For a K_1 -by- N matrix input, the object processes columns of the input matrix as N independent channels.

Data Types: `double` | `single`

Output Arguments

y — Output signal

`column vector` | `matrix`

Output signal, returned as a column vector or a K_o -by- N matrix. K_o is equal to $K_i \times \text{OutputSamplesPerSymbol}$. K_i is the number of input samples per signal channel, and N is the number of signal channels.

The object interpolates and filters each channel over the first dimension and then generates a K_o -by- N output matrix. The output signal is the same data type as the input signal.

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Specific to `comm.RaisedCosineTransmitFilter`

<code>info</code>	Information about filter System object
<code>coeffs</code>	Coefficients for filters
<code>cost</code>	Computational cost of implementing filter System object

<code>impz</code>	Impulse response of discrete-time filter
<code>order</code>	Order of discrete-time filter System object

Common to All System Objects

<code>step</code>	Run System object algorithm
<code>release</code>	Release resources and allow changes to System object property values and input characteristics
<code>reset</code>	Reset internal states of System object

Examples

Interpolate Signal Using Square-Root-Raised-Cosine Filter

Interpolate a signal using square-root-raised-cosine (SRRC) transmit filter object and display the spectrum of the filtered signal.

Create random bipolar symbols at a symbol rate of 1e6 symbols per second.

```
data = 2*randi([0 1],1e6,1) - 1;
```

Create a SRRC transmit filter object. The default sets the filter to a square-root shape and the number of samples per symbol to 8.

```
txfilter = comm.RaisedCosineTransmitFilter
```

```
txfilter =
  comm.RaisedCosineTransmitFilter with properties:
          Shape: 'Square root'
      RolloffFactor: 0.2000
  FilterSpanInSymbols: 10
  OutputSamplesPerSymbol: 8
          Gain: 1
```

Filter the data by using the SRRC filter.

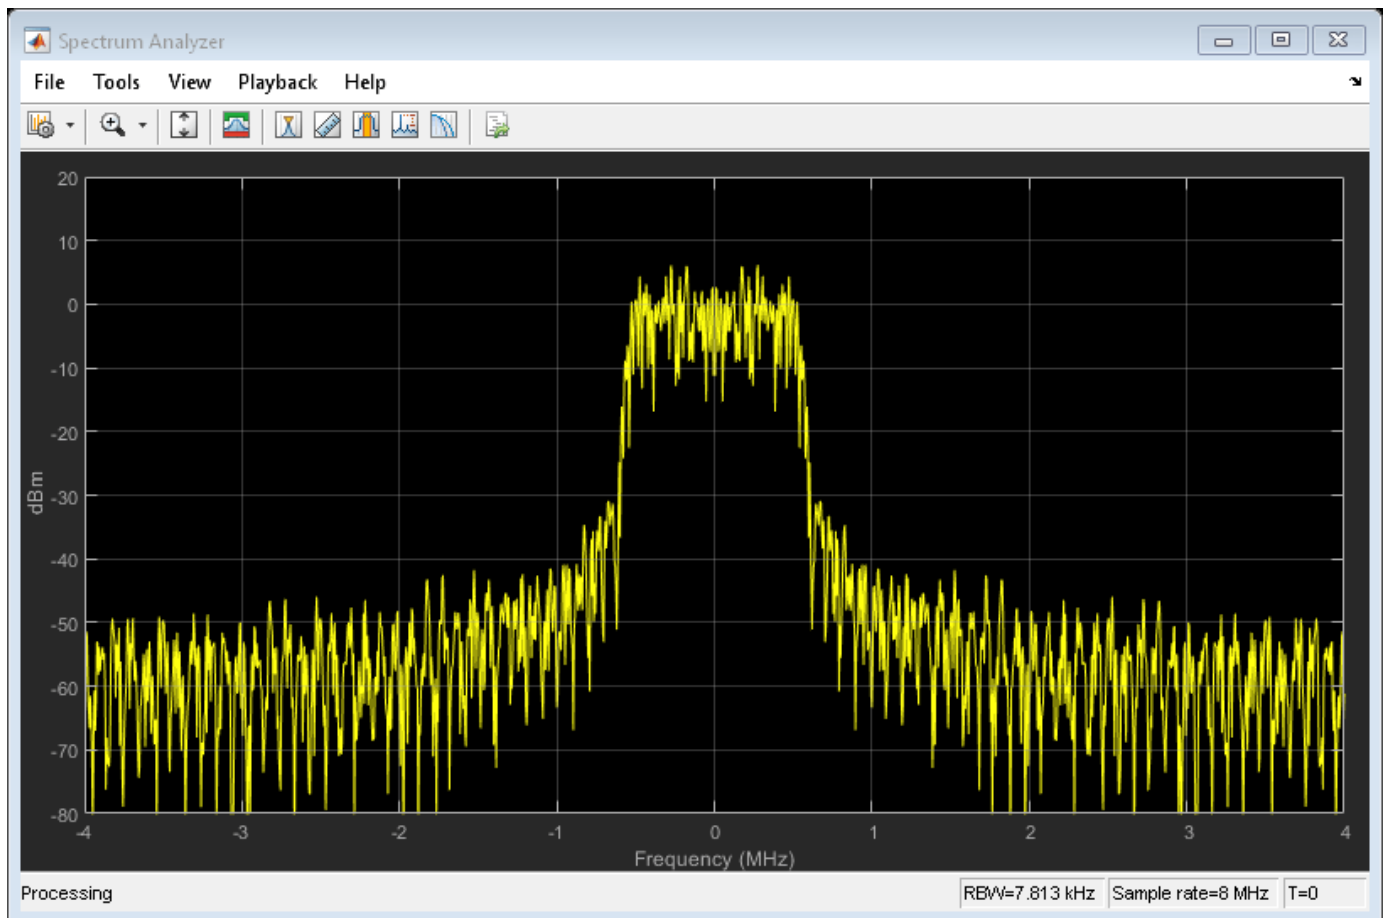

```
filteredData = txfilter(data);
```

Create a spectrum analyzer object with an 8e6 sampling rate. This sampling rate matches the sampling rate of the filtered signal.

```
spectrumAnalyzer = dsp.SpectrumAnalyzer('SampleRate',8e6);
```

View the spectrum of the filtered signal by using the spectrum analyzer object.

```
spectrumAnalyzer(filteredData)
```

Examine Effect of Filter Span on Magnitude Response

Create interpolated signals from a square-root-raised-cosine (SRRC) filter with various filter spans. Examine the magnitude response of the various filter designs.

Create SRRC filter objects setting various filter spans. Use the `coeffs` object function to obtain the filter coefficients.

```
txfilt2 = comm.RaisedCosineTransmitFilter('FilterSpanInSymbols',2);
txfilt4 = comm.RaisedCosineTransmitFilter('FilterSpanInSymbols',4);
txfilt6 = comm.RaisedCosineTransmitFilter('FilterSpanInSymbols',6);
txfilt8 = comm.RaisedCosineTransmitFilter('FilterSpanInSymbols',8);
txfilt16 = comm.RaisedCosineTransmitFilter('FilterSpanInSymbols',16);

taps2 = coeffs(txfilt2).Numerator;
taps4 = coeffs(txfilt4).Numerator;
taps6 = coeffs(txfilt6).Numerator;
taps8 = coeffs(txfilt8).Numerator;
taps16 = coeffs(txfilt16).Numerator;
```

Launch the filter visualization tool to show the magnitude response for various filter spans. Specify a sample rate of 1 kHz. Display the two-sided centered response.

```
fvt = fvtool(taps2,1,taps4,1,taps8,1,taps16,1);
fvt.Fs = 1e3;
fvt.FrequencyRange = '[-Fs/2, Fs/2]';
legend(fvt,'Span 2 symbols','Span 4 symbols', ...
        'Span 8 symbols','Span 10 symbols')
```

Create Square-Root-Raised-Cosine Transmit Filter with Unity Passband Gain

Create a square-root-raised-cosine (SRRC) transmit filter System object™, and then plot the filter response. The results show that the linear filter gain is greater than unity. Specifically, the passband gain is greater than 0 dB.

```
txfilter = comm.RaisedCosineTransmitFilter;
fvtool(txfilter)
```

Obtain the filter coefficients by using the `coeffs` object function and adjust the filter gain to unit energy.

```
b = coeffs(txfilter);
```

Because a filter with unity passband gain must have filter coefficients that sum to 1, set the linear filter gain to the inverse of the sum of the filter tap coefficients, `b.Numerator`.

```
txfilter.Gain = 1/sum(b.Numerator);
```

Verify that the resulting filter coefficients sum to 1.

```
bNorm = coeffs(txfilter);
sum(bNorm.Numerator)
```

```
ans = 1.0000
```

Plot the filter frequency response again. The results now show that the passband gain is 0 dB, which is unity gain.

```
fvtool(txfilter)
```

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

See “System Objects in MATLAB Code Generation” (MATLAB Coder).

The `comm.RaisedCosineTransmitFilter` System object supports SIMD code generation using Intel AVX2 technology under these conditions:

- Input signal is real-valued with real filter coefficients.
- Input signal is complex-valued with real or complex filter coefficients.
- Input signal has a data type of `single` or `double`.

The SIMD technology significantly improves the performance of the generated code. For details, see “Generate SIMD Code for MATLAB Functions” (Embedded Coder).

comm.RayleighChannel

Package: comm

Filter input signal through multipath Rayleigh fading channel

Description

The `comm.RayleighChannel` System object filters an input signal through the multipath Rayleigh fading channel. For more information on fading model processing, see the Methodology for Simulating Multipath Fading Channels section.

To filter an input signal through a multipath Rayleigh fading channel:

- 1 Create the `comm.RayleighChannel` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

Creation

Syntax

```
rayleighchan = comm.RayleighChannel  
rayleighchan = comm.RayleighChannel(Name,Value)
```

Description

`rayleighchan = comm.RayleighChannel` creates a frequency-selective or frequency-flat multipath Rayleigh fading channel System object. This object filters a real or complex input signal through the multipath channel to obtain a channel-impaired signal.

`rayleighchan = comm.RayleighChannel(Name,Value)` sets properties using one or more name-value arguments. For example, `'SampleRate', 2` sets the input signal sample rate to 2.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see [System Design in MATLAB Using System Objects](#).

SampleRate — Input signal sample rate

1 (default) | positive scalar

Input signal sample rate in hertz, specified as a positive scalar.

Data Types: double

PathDelays — Discrete path delay

0 (default) | scalar | row vector

Discrete path delay in seconds, specified as a scalar or row vector.

- When you set PathDelays to a scalar, the channel is frequency flat.
- When you set PathDelays to a vector, the channel is frequency selective.

The PathDelays and AveragePathGains properties must be the same length.

Data Types: double

AveragePathGains — Average gains of discrete paths

0 (default) | scalar | row vector

Average gains of the discrete paths in decibels, specified as a scalar or row vector. The AveragePathGains and PathDelays properties must be the same length.

Data Types: double

NormalizePathGains — Normalize average path gains

true or 1 (default) | false or 0

Normalize average path gains, specified as one of these logical values:

- 1 (true) — The fading processes are normalized so that the total power of the path gains, averaged over time, is 0 dB.
- 0 (false) — The total power of the path gains is not normalized.

The AveragePathGains property specifies the average powers of the path gains.

Data Types: logical

MaximumDopplerShift — Maximum Doppler shift for all channel paths

0.001 (default) | nonnegative scalar

Maximum Doppler shift for all channel paths, specified as a nonnegative scalar. Units are in hertz.

The maximum Doppler shift limit applies to each channel path. When you set this property to 0, the channel remains static for the entire input. You can use the reset object function to generate a new channel realization. The MaximumDopplerShift property value must be smaller than $\text{SampleRate}/10/f_c$ for each path. f_c is the cutoff frequency factor of the path. For most Doppler spectrum types, the value of f_c is 1. For Gaussian and bi-Gaussian Doppler spectrum types, f_c is dependent on the Doppler spectrum structure fields. For more details about how f_c is defined, see the “Cutoff Frequency Factor” on page 3-1150 section.

Data Types: double

DopplerSpectrum — Doppler spectrum shape for all channel paths

doppler('Jakes') (default) | Doppler spectrum structure | 1-by- N_p cell array of Doppler spectrum structures

Doppler spectrum shape for all channel paths, specified as a Doppler spectrum structure or a 1-by- N_p cell array of Doppler spectrum structures. These Doppler spectrum structures must be outputs of the

form returned from the `doppler` function. N_p is the number of discrete delay paths specified by the `PathDelays` property. The `MaximumDopplerShift` property defines the maximum Doppler shift value that the `DopplerSpectrum` property permits when you specify the Doppler spectrum..

- When you set `DopplerSpectrum` to a single Doppler spectrum structure, all paths have the same specified Doppler spectrum.
- When you set `DopplerSpectrum` to a cell array of Doppler spectrum structures, each path has the Doppler spectrum specified by the corresponding structure in the cell array.

Specify options for the spectrum type by using the `specType` input to the `doppler` function. If you set the `FadingTechnique` property to `'Sum of sinusoids'`, you must set `DopplerSpectrum` to `doppler('Jakes')`.

Dependencies

To enable this property, set the `MaximumDopplerShift` property to a positive scalar.

Data Types: `struct` | `cell`

ChannelFiltering — Channel filtering

`true` or `1` (default) | `false` or `0`

Channel filtering, specified as one of these logical values:

- `1` (`true`) — The channel accepts an input signal and produces a filtered output signal.
- `0` (`false`) — The object does not accept an input signal, produces no filtered output signal, and outputs only channel path gains. You must specify the duration of the fading process by using the `NumSamples` property.

Data Types: `logical`

PathGainsOutputPort — Output channel path gains

`false` or `0` (default) | `true` or `1`

Output channel path gains, specified as a logical `0` (`false`) or `1` (`true`). Set this property to `true` to output the channel path gains of the underlying fading process.

Dependencies

To enable this property, set the `ChannelFiltering` property to `true`.

Data Types: `logical`

NumSamples — Number of samples

`100` (default) | nonnegative integer

Number of samples used for the duration of the fading process, specified as a nonnegative integer.

Tunable: Yes

Dependencies

To enable this property, set the `ChannelFiltering` property to `false`.

Data Types: `double`

OutputDataType — Path gain output data type

`'double'` (default) | `'single'`

Path gain output data type, specified as 'double' or 'single'.

Dependencies

To enable this property, set the ChannelFiltering property to false.

Data Types: char | string

FadingTechnique — Channel model fading technique

'Filtered Gaussian noise' (default) | 'Sum of sinusoids'

Channel model fading technique, specified as 'Filtered Gaussian noise' or 'Sum of sinusoids'.

Data Types: char | string

NumSinusoids — Number of sinusoids used

48 (default) | positive integer

Number of sinusoids used to model the fading process, specified as a positive integer.

Dependencies

To enable this property, set the FadingTechnique property to 'Sum of sinusoids'.

Data Types: double

InitialTimeSource — Source to control start time of fading process

'Property' (default) | 'Input port'

Source to control the start time of the fading process, specified as 'Property' or 'Input port'.

- When you set InitialTimeSource to 'Property', set the initial time offset by using the InitialTime property.
- When you set InitialTimeSource to 'Input port', specify the start time of the fading process by using the inittime input argument. The input value can change in consecutive calls to the object.

Dependencies

To enable this property, set the FadingTechnique property to 'Sum of sinusoids'.

Data Types: char | string

InitialTime — Initial time offset

0 (default) | nonnegative scalar

Initial time offset for the fading model in seconds, specified as a nonnegative scalar.

When $\text{mod}(\text{InitialTime}/\text{SampleRate})$ is nonzero, the initial time offset is rounded up to the nearest sample position.

Dependencies

To enable this property, set the FadingTechnique property to 'Sum of sinusoids' and the InitialTimeSource property to 'Property'.

Data Types: double

RandomStream — Source of random number stream`'Global stream'` (default) | `'mt19937ar with seed'`

Source of the random number stream, specified as `'Global stream'` or `'mt19937ar with seed'`.

- When you specify `'Global stream'`, the object uses the current global random number stream for normally distributed random number generation. In this case, the `reset` object function resets only the filters.
- When you specify `'mt19937ar with seed'`, the object uses the `mt19937ar` algorithm for normally distributed random number generation. In this case, the `reset` object function resets the filters and reinitializes the random number stream to the value of the `Seed` property.

Data Types: `char` | `string`

Seed — Initial seed of mt19937ar random number stream`73` (default) | nonnegative integer

Initial seed of the `mt19937ar` random number stream generator algorithm, specified as a nonnegative integer. When you call the `reset` object function, it reinitializes the `mt19937ar` random number stream to the `Seed` value.

Dependencies

To enable this property, set the `RandomStream` property to `'mt19937ar with seed'`.

Data Types: `double`

Visualization — Channel visualization`'Off'` (default) | `'Impulse response'` | `'Frequency response'` | `'Impulse and frequency responses'` | `'Doppler spectrum'`

Channel visualization, specified as `'Off'`, `'Impulse response'`, `'Frequency response'`, `'Impulse and frequency responses'`, or `'Doppler spectrum'`. For more information, see the “Channel Visualization” on page 3-1151 section.

Dependencies

To enable this property, set the `FadingTechnique` property to `'Filtered Gaussian noise'`.

Data Types: `char` | `string`

PathsForDopplerDisplay — Path used for displaying Doppler spectrum`1` (default) | positive integer

Path used for displaying the Doppler spectrum, specified as a positive integer in the range $[1, N_p]$. N_p is the number of discrete delay paths specified by the `PathDelays` property. Use this property to select the discrete path used in constructing a Doppler spectrum plot.

Dependencies

To enable this property, set the `Visualization` property to `'Doppler spectrum'`.

Data Types: `double`

SamplesToDisplay — Percentage of samples to display`'25%'` (default) | `'10%'` | `'50%'` | `'100%'`

Percentage of samples to display, specified as '25%', '10%', '50%', or '100%'. Increasing the percentage improves display accuracy at the expense of simulation speed.

Dependencies

To enable this property, set the Visualization property to 'Impulse response', 'Frequency response', or 'Impulse and frequency responses'.

Data Types: char | string

Usage

Syntax

```
y = rayleighchan(x)
y = rayleighchan(x, inittime)
[y, pathgains] = rayleighchan( ___ )
```

```
pathgains = rayleighchan()
pathgains = rayleighchan(inittime)
```

Description

`y = rayleighchan(x)` filters the input signal `x` through a multipath Rayleigh fading channel and returns the result in `y`.

To enable this syntax, set the ChannelFiltering property to `true`.

`y = rayleighchan(x, inittime)` specifies a start time for the fading process.

To enable this syntax, set the FadingTechnique property to 'Sum of sinusoids' and the InitialTimeSource property to 'Input port'.

`[y, pathgains] = rayleighchan(___)` also returns the channel path gains of the underlying multipath Rayleigh fading process in `pathgains` using any of the input argument combinations in the previous syntaxes.

To enable this syntax, set the PathGainsOutputPort property set to `true`.

`pathgains = rayleighchan()` returns the channel path gains of the underlying fading process. In this case, the channel requires no input signal and acts as a source of path gains.

To enable this syntax, set the ChannelFiltering property to `false`.

`pathgains = rayleighchan(inittime)` returns the channel path gains of the underlying fading process beginning at the specified initial time. In this case, the channel requires no input signal and acts as a source of path gains.

To enable this syntax, set the FadingTechnique property to 'Sum of sinusoids', the InitialTimeSource property to 'Input port', and the ChannelFiltering property to `false`.

Input Arguments

x — Input signal

N_S -by-1 vector

Input signal, specified as an N_S -by-1 vector, where N_S is the number of samples.

Data Types: `single` | `double`

Complex Number Support: Yes

inittime — Initial time offset

0 | nonnegative scalar

Initial time offset in seconds, specified as a nonnegative scalar.

When `mod(inittime/SampleRate)` is nonzero, the initial time offset is rounded up to the nearest sample position.

Data Types: `single` | `double`

Output Arguments

y — Output signal

N_S -by-1 vector

Output signal, returned as an N_S -by-1 vector of complex values with the same data precision as the input signal `x`. N_S is the number of samples.

pathgains — Output path gains

N_S -by- N_P matrix

Output path gains, returned as an N_S -by- N_P matrix. N_S is the number of samples. N_P is the number of discrete delay paths specified by the `PathDelays` property. `pathgains` contains complex values.

When you set the `ChannelFiltering` property to `false`, the data type of this output has the same precision as the input signal `x`. When you set the `ChannelFiltering` property to `true`, the data type of this output is specified by the `OutputDataType` property.

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Specific to comm.RayleighChannel

`info` Characteristic information about fading channel object

Common to All System Objects

`step` Run System object algorithm

`release` Release resources and allow changes to System object property values and input characteristics

`reset` Reset internal states of System object

Examples

Produce Same Rayleigh Channel Outputs Using Two Random Number Generation Methods

Produce the same multipath Rayleigh fading channel response by using two different methods for random number generation. The multipath Rayleigh fading channel System object includes two methods for random number generation. You can use the current global stream or the mt19937ar algorithm with a specified seed. By interacting with the global stream, the System object can produce the same outputs from these two methods.

Create a PSK modulator System object to modulate randomly generated data.

```
pskModulator = comm.PSKModulator;
insig = randi([0,pskModulator.ModulationOrder-1],1024,1);
channelInput = pskModulator(insig);
```

Create a multipath Rayleigh fading channel System object, specifying the random number generation method as the my19937ar algorithm and the random number seed as 22.

```
rayleighchan = comm.RayleighChannel( ...
    'SampleRate',10e3, ...
    'PathDelays',[0 1.5e-4], ...
    'AveragePathGains',[2 3], ...
    'NormalizePathGains',true, ...
    'MaximumDopplerShift',30, ...
    'DopplerSpectrum',{doppler('Gaussian',0.6),doppler('Flat')}, ...
    'RandomStream','mt19937ar with seed', ...
    'Seed',22, ...
    'PathGainsOutputPort',true);
```

Filter the modulated data by using the multipath Rayleigh fading channel System object.

```
[chanOut1,pathGains1] = rayleighchan(channelInput);
```

Set the System object to use the global stream for random number generation.

```
release(rayleighchan);
rayleighchan.RandomStream = 'Global stream';
```

Set the global stream to have the same seed that you specified when creating the multipath Rayleigh fading channel System object.

```
rng(22)
```

Filter the modulated data by using the multipath Rayleigh fading channel System object again.

```
[chanOut2,pathGains2] = rayleighchan(channelInput);
```

Verify that the channel and path gain outputs are the same for each of the two methods.

```
isequal(chanOut1,chanOut2)
```

```
ans = logical
     1
```

```
isequal(pathGains1,pathGains2)
```

```
ans = logical
     1
```

Display Impulse and Frequency Responses of Multipath Rayleigh Fading Channel

Display the impulse and frequency responses of a frequency-selective multipath Rayleigh fading channel that is configured to disable channel filtering.

Define simulation variables. Specify path delays and gains by using the ITU pedestrian B channel configuration.

```
fs = 3.84e6; % Sample rate in Hz
pathDelays = [0 200 800 1200 2300 3700]*1e-9; % in seconds
avgPathGains = [0 -0.9 -4.9 -8 -7.8 -23.9]; % dB
fD = 50; % Max Doppler shift in Hz
```

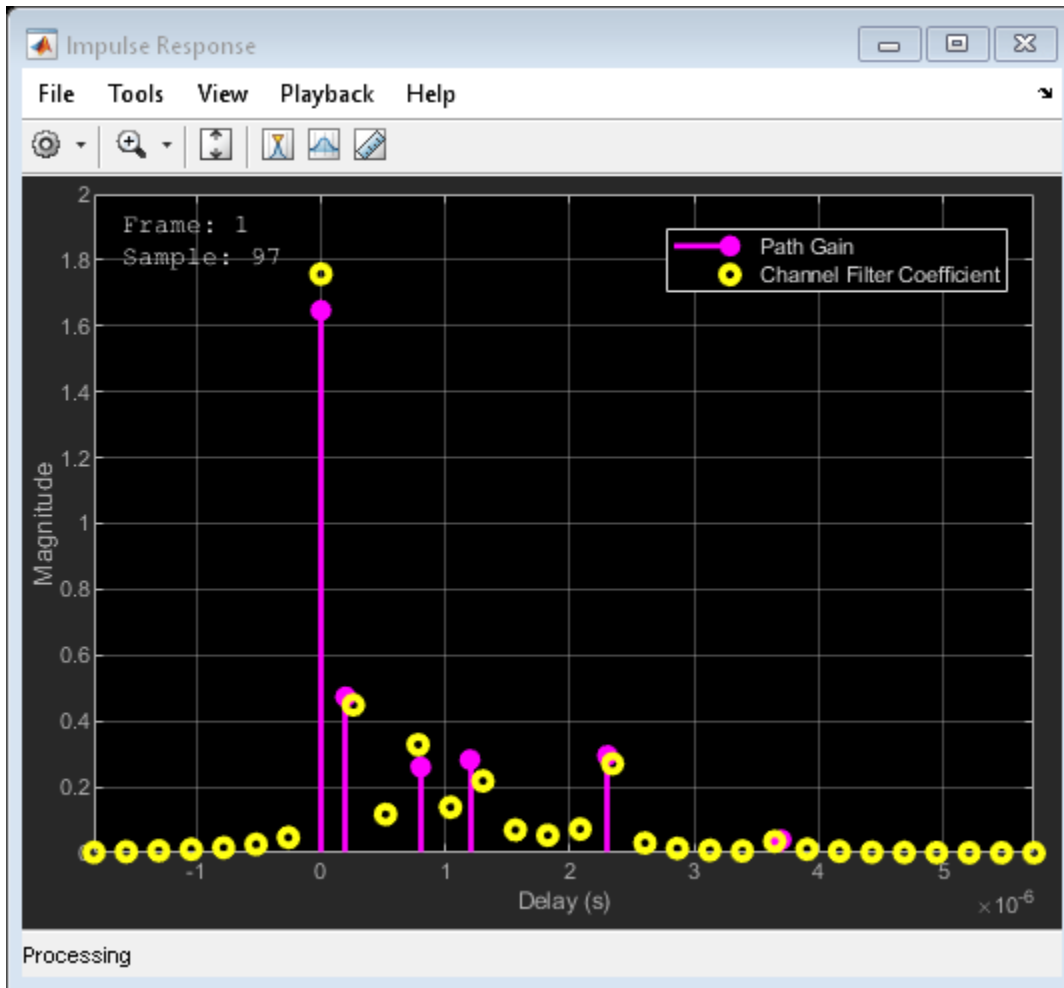

Create a multipath Rayleigh fading channel System object to visualize the impulse response and frequency response plots.

```
rayleighchan = comm.RayleighChannel('SampleRate',fs, ...
    'PathDelays',pathDelays, ...
    'AveragePathGains',avgPathGains, ...
    'MaximumDopplerShift',fD, ...
    'ChannelFiltering',false, ...
    'Visualization','Impulse and frequency responses');
```

Visualize the channel response by running the multipath Rayleigh fading channel System object with no input signal. The impulse response plot enables you to identify the individual paths and their corresponding filter coefficients. The frequency response plot shows the frequency-selective nature of the ITU pedestrian B channel.

```
rayleighchan();
```

Model Multipath Rayleigh Fading Channel by Using Sum-of-Sinusoids Technique

Show that the channel state is maintained for discontinuous transmissions by using multipath Rayleigh fading channel System objects that use the sum-of-sinusoids technique. Observe discontinuous channel response segments overlaid on a continuous channel response.

Set the channel properties.

```
fs = 1000;           % Sample rate (Hz)
pathDelays = [0 2.5e-3]; % In seconds
pathPower = [0 -6]; % In dB
fd = 5;             % Maximum Doppler shift (Hz)
ns = 1000;         % Number of samples
nsdel = 100;       % Number of samples for delayed paths
```

Define a continuous time span and three discontinuous time segments over which to plot and view the channel response. View a 1000-sample continuous channel response that starts at time 0 and three 100-sample channel responses that start at times 0.1, 0.4, and 0.7 seconds, respectively.

```

to0 = 0.0;
to1 = 0.1;
to2 = 0.4;
to3 = 0.7;
t0 = (to0:ns-1)/fs;      % Transmission 0
t1 = to1+(0:nsdel-1)/fs; % Transmission 1
t2 = to2+(0:nsdel-1)/fs; % Transmission 2
t3 = to3+(0:nsdel-1)/fs; % Transmission 3

```

Create a frequency-flat multipath Rayleigh fading System object, specifying a 1000 Hz sampling rate, the sum-of-sinusoids fading technique, disabled channel filtering, and the number of samples to view. Specify a seed value so that results can be repeated. Use the default `InitialTime` property setting so that the fading channel is simulated from time 0.

```

rayleighchan1 = comm.RayleighChannel('SampleRate',fs, ...
    'MaximumDopplerShift',fD, ...
    'RandomStream','mt19937ar with seed', ...
    'Seed',17, ...
    'FadingTechnique','Sum of sinusoids', ...
    'ChannelFiltering',false, ...
    'NumSamples',ns);

```

Create a clone of the multipath Rayleigh fading channel System object. In the cloned object, set the number of samples to view for the delayed paths. Also configure the initial time source as an input so that you can specify the fading channel offset time as an input argument when using the System object.

```

rayleighchan2 = clone(rayleighchan1);
rayleighchan2.NumSamples = nsdel;
rayleighchan2.InitialTimeSource = 'Input port';

```

Save the path gain output for the continuous channel response by using the `rayleighchan1` object and for the discontinuous delayed channel responses by using the `rayleighchan2` object with initial time offsets are provided as input arguments.

```

pg0 = rayleighchan1();
pg1 = rayleighchan2(to1);
pg2 = rayleighchan2(to2);
pg3 = rayleighchan2(to3);

```

Compare the number of samples processed by the two channels by using the `info` object function. The `rayleighchan1` object processed 1000 samples, while the `rayleighchan2` object processed only 300 samples.

```

G = info(rayleighchan1);
H = info(rayleighchan2);
[G.NumSamplesProcessed H.NumSamplesProcessed]

```

```
ans = 1×2
```

```
    1000    300
```

Convert the path gains into decibels.

```

pathGain0 = 20*log10(abs(pg0));
pathGain1 = 20*log10(abs(pg1));

```

```
pathGain2 = 20*log10(abs(pg2));
pathGain3 = 20*log10(abs(pg3));
```

Plot the path gains for the continuous and discontinuous cases. The gains for the three segments match the gain for the continuous case. Because the channel characteristics are maintained even when data is not transmitted, the alignment of the two plots shows that the sum-of-sinusoids technique is suited to the simulation of packetized data.

```
plot(t0,pathGain0,'r--')
hold on
plot(t1,pathGain1,'b')
plot(t2,pathGain2,'b')
plot(t3,pathGain3,'b')
grid
xlabel('Time (sec)')
ylabel('Path Gain (dB)')
legend('Continuous','Discontinuous','location','nw')
title('Continuous and Discontinuous Transmission Path Gains')
```

Reproduce Multipath Rayleigh Fading Channel Response

Reproduce the multipath Rayleigh fading channel output across multiple frames by using the `ChannelFilterCoefficients` property returned by the `info` object function of the `comm.RayleighChannel` System object.

Create a multipath Rayleigh fading channel System object, defining two paths. Generate data to pass through the channel.

```
rayleighchan = comm.RayleighChannel( ...
    'SampleRate',1000, ...
    'PathDelays',[0 1.5e-3], ...
    'AveragePathGains',[0 -3], ...
    'PathGainsOutputPort',true)
```

```
rayleighchan =
    comm.RayleighChannel with properties:
```

```
        SampleRate: 1000
        PathDelays: [0 0.0015]
    AveragePathGains: [0 -3]
    NormalizePathGains: true
    MaximumDopplerShift: 1.0000e-03
        DopplerSpectrum: [1x1 struct]
    ChannelFiltering: true
    PathGainsOutputPort: true
```

Show all properties

```
data = randi([0 1],600,1);
```

Pass data through the channel. Assign the ChannelFilterCoefficients property value to the variable `coeff`. Within a for loop, calculate the fractional delayed input signal at the path delay locations stored in `coeff`, apply the path gains, and sum the results for all of the paths. Compare the output of the multipath Rayleigh fading channel System object (`chanout1`) to the output reproduced using the path gains and the ChannelFilterCoefficients property of the multipath Rayleigh fading channel System object (`chanout2`).

```
chaninfo = info(rayleighchan);
coeff = chaninfo.ChannelFilterCoefficients;
Np = length(rayleighchan.PathDelays);
state = zeros(size(coeff,2)-1,size(coeff,1));
nFrames = 10;
chkChan = zeros(nFrames,1);
for jj = 1 : nFrames
    data = randi([0 1],600,1);
    [chanout1,pg] = rayleighchan(data);
    fracdelaydata = zeros(size(data,1),Np);
    % Calculate the fractional delayed input signal.
    for ii = 1:Np
        [fracdelaydata(:,ii),state(:,ii)] = ...
            filter(coeff(ii,:),1,data,state(:,ii));
    end
    % Apply the path gains and sum the results for all of the paths.
    % Compare the channel outputs.
    chanout2 = sum(pg .* fracdelaydata,2);
    chkChan(jj) = isequal(chanout1,chanout2);
end
chkChan'
```

```
ans = 1x10
```

```
    1    1    1    1    1    1    1    1    1    1
```

Verify Autocorrelation of Rayleigh Channel Path Gains

Verify that the autocorrelation of the path gain output from the Rayleigh channel System object is a Bessel function. The results in [1] on page 3-0 and Appendix A of [2] on page 3-0 , show that when the autocorrelation of the path gain outputs is a Bessel function, the Doppler spectrum is Jakes-shaped.

Initialize simulation parameters.

```
Rsym = 9600;           % Input symbol rate (symbols/s)
sps = 10;             % Number of samples per input symbol
Fs = sps*Rsym;       % Input sampling frequency (samples/s)
Ts = 1/Fs;           % Input sampling period (s)
numsym = 1e6;        % Number of input symbols to simulate
numsamp = numsym*sps; % Number of channel samples to simulate
fd = 100;            % Maximum Doppler frequency shift (Hz)
num_acsamp = 5000;   % Number of samples of autocovariance
                    % of complex fading process calculated
numtx = 1;           % Number of transmit antennas
numrx = 1;           % Number of receive antennas
numsin = 48;         % Number of sinusoids
frmLen = 10000;
numFrames = numsamp/frmLen;
```

Configure a Rayleigh channel System object.

```
chan = comm.RayleighChannel( ...
    'FadingTechnique','Sum of sinusoids', ...
    'NumSinusoids',numsin, ...
    'RandomStream','mt19937ar with seed', ...
    'PathDelays',0, ...
    'AveragePathGains',0, ...
    'SampleRate',Fs, ...
    'MaximumDopplerShift',fd, ...
    'PathGainsOutputPort',true);
```

Apply DPSK modulation to a random bit stream.

```
tx = randi([0 1],numsamp,numtx); % Random bit stream
dpskSig = dpskmod(tx,2);         % DPSK signal
```

Pass the modulated signal through the channel.

```
outsig = zeros(numsamp,numrx);
pg_rx = zeros(numsamp,numrx,numtx);
for frmNum = 1:numFrames
    [outsig((1:frmLen)+(frmNum-1)*frmLen,:),pathGains] = ...
        chan(dpskSig((1:frmLen)+(frmNum-1)*frmLen,:));
    for i = 1:numrx
        pg_rx((1:frmLen)+(frmNum-1)*frmLen,i,:) = ...
            pathGains(:, :, :, i);
    end
end
```

Using the channel path gains received per antenna, compute the autocovariance of the fading process for each transmit-receive path.

```

autocov = zeros(frmLen+1,numrx,numtx);
autocov_normalized_real = zeros(num_acsamp+1,numrx,numtx);
autocov_normalized_imag = zeros(num_acsamp+1,numrx,numtx);
for i = 1:numrx
    % Compute autocovariance of simulated complex fading process
    for j = 1:numtx
        autocov(:,i,j) = xcov(pg_rx(:,i,j),num_acsamp);
        % Real part of normalized autocovariance
        autocov_normalized_real(:,i,j) = ...
            real(autocov(num_acsamp+1:end,i,j) ...
                / autocov(num_acsamp+1,i,j));
        % Imaginary part of normalized autocovariance
        autocov_normalized_imag(:,i,j) = ...
            imag(autocov(num_acsamp+1:end,i,j) ...
                / autocov(num_acsamp+1,i,j));
    end
end

```

Compute the theoretical autocovariance of the complex fading process by using the `besselj` function.

```

Rrr = zeros(1,num_acsamp+1);
for n = 1:1:num_acsamp+1
    Rrr(n) = besselj(0,2*pi*fd*(n-1)*Ts);
end
Rrr_normalized = Rrr/Rrr(1);

```

Display the autocovariance to compare the results from the Rayleigh channel System object and the `besselj` function.

```

subplot(2,1,1)
plot(autocov_normalized_real,'b-')
hold on
plot(Rrr_normalized,'r-')
hold off
legend('comm.RayleighChannel', ...
    'Bessel function of the first kind')
title('Autocovariance of Real Part of Rayleigh Process')
subplot(2,1,2)
plot(autocov_normalized_imag)
legend('comm.RayleighChannel')
title('Autocovariance of Imaginary Part of Rayleigh Process')

```

As computed below, the mean square error comparing the results from the Rayleigh channel object versus the Bessel function is insignificant.

```
act_mse_real = ...
    sum((autocov_normalized_real-repmat(Rrr_normalized.',1,numrx,numtx)).^2,1) ...
    / size(autocov_normalized_real,1)
```

```
act_mse_real = 7.0043e-08
```

```
act_mse_imag = sum((autocov_normalized_imag-0).^2,1) ...
    / size(autocov_normalized_imag,1)
```

```
act_mse_imag = 4.1064e-07
```

Compare PDF of Empirical and Theoretical Rayleigh Channel

Compute and plot the empirical and theoretical probability density function (PDF) for a Rayleigh channel with one path.

Initialize parameters and create a Rayleigh channel System object that does not apply channel filtering.

```
Ns = 1.92e6;
Rs = 1.92e6;
dopplerShift = 2000;

chan = comm.RayleighChannel( ...
    'SampleRate',Rs, ...
    'PathDelays',0, ...
    'AveragePathGains',0, ...
    'MaximumDopplerShift',dopplerShift, ...
    'ChannelFiltering',false, ...
    'NumSamples',Ns, ...
    'FadingTechnique','Sum of sinusoids');
```

Compute and plot the empirical and theoretical PDF for the Rayleigh channel.

```
figure;
hold on;

% Empirical PDF plot
gain = chan();
pd = fitdist(abs(gain),'Kernel','Bandwidth',.01);
r = 0:.1:3;
y = pdf(pd,r);
plot(r,y)

% Theoretical PDF plot
exp_pdf_amplitude = raylpdf(r,0.7);
plot(r,exp_pdf_amplitude)
legend('Empirical','Theoretical')
title('Empirical and Theoretical PDF Curves')
```

More About

Cutoff Frequency Factor

The cutoff frequency factor, f_c , is dependent on the type of Doppler spectrum.

- For any Doppler spectrum type other than Gaussian and bi-Gaussian, f_c equals 1.
- For a doppler('Gaussian') spectrum type, f_c equals $\text{NormalizedStandardDeviation} \times \sqrt{2\log 2}$.
- For a doppler('BiGaussian') spectrum type:
 - If the PowerGains(1) and NormalizedCenterFrequencies(2) field values are both 0, then f_c equals $\text{NormalizedStandardDeviation}(1) \times \sqrt{2\log 2}$.
 - If the PowerGains(2) and NormalizedCenterFrequencies(1) field values are both 0, then f_c equals $\text{NormalizedStandardDeviation}(2) \times \sqrt{2\log 2}$.
 - If the NormalizedCenterFrequencies field value is [0, 0] and the NormalizedStandardDeviation field has two identical elements, then f_c equals $\text{NormalizedStandardDeviation}(1) \times \sqrt{2\log 2}$.
 - In all other cases, f_c equals 1.

Channel Visualization

The `comm.RayleighChannel` System object enables visualization of the channel impulse response, frequency response, and Doppler spectrum.

Note

- The displayed and specified path gain locations can differ by as much as 5% of the input sample time.
 - The visualization display speed is controlled by the combination of the `SamplesToDisplay` property and the **Reduce Updates to Improve Performance** scope menu item found in **Playback**. Reducing the percentage of samples to display and enabling reduced updates can speed up the rendering of the visualization scope.
 - If you close the visualization scopes, calls to the System object execute at normal speed.
 - Code generation is available only when you set the `Visualization` property to 'Off'.
-

Impulse Response

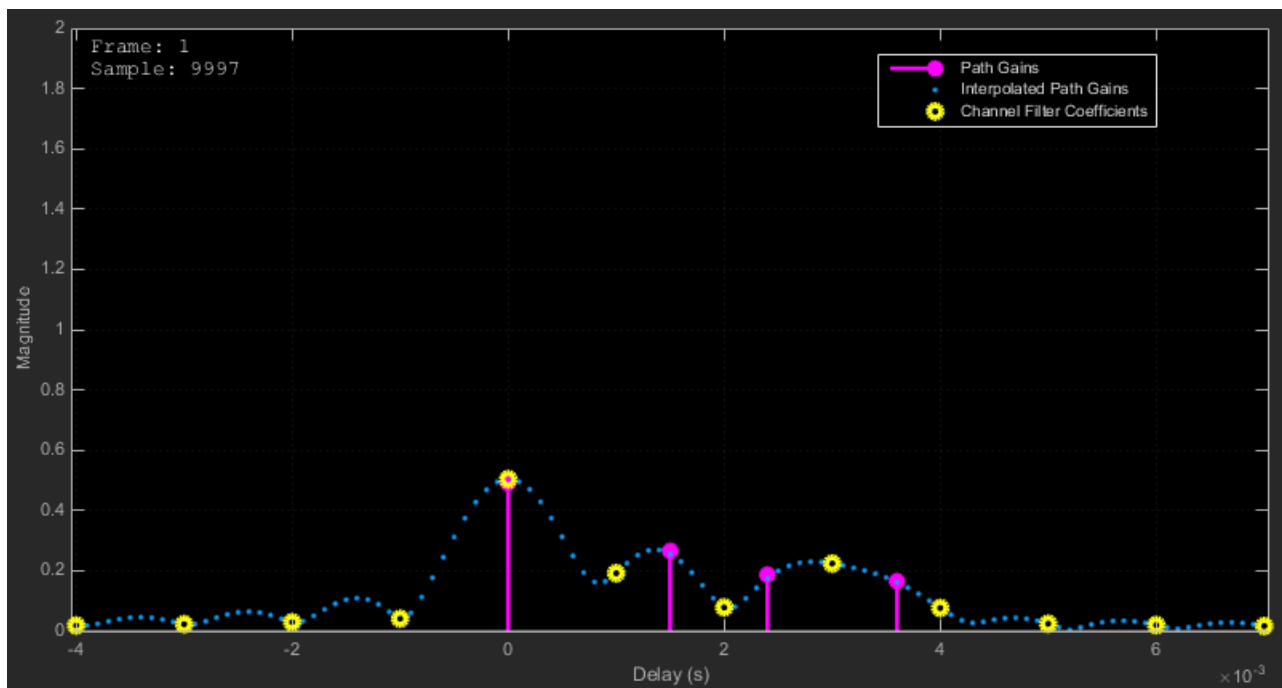

The impulse response scope displays the path gains, channel filter coefficients, and interpolated path gains. The path gains occur at time instances that correspond to the specified `PathDelays` property and might not be aligned with the input sampling time. The scope uses channel filter coefficients to model the channel. The coefficients are interpolated from the actual path gains and are aligned with the input sampling time. The path gains overlap the filter coefficients for cases where the path gains are aligned with the sampling time. Sinc interpolation is used to connect the channel filter coefficients and is shown as the interpolated path gains. These points are used solely for display purposes and not used in subsequent channel filtering. For a flat fading channel (one path), the sinc interpolation curve is not displayed. For all impulse response plots, the frame and sample numbers are shown in the upper-left corner of the scope.

The impulse response plot shares the same toolbar and menus as the `dsp.ArrayPlot` System object.

When the specified path gains align with the sample rate, the path gains and the channel filter coefficients overlap. In this figure, the impulse response shows that the path gains overlap the filter coefficients.

If the specified path gains are not aligned with the sample rate, the path gains and the channel filter coefficients do not overlap. In this figure, the filter coefficients are equally distributed. Because the path gains are not aligned with the sample rate, the path gains do not overlap with the channel filter coefficients.

This figure shows the impulse response for a frequency-flat channel without displaying the interpolated path gains.

Frequency response

The frequency response scope displays the multipath Rayleigh fading channel spectrum by taking a discrete Fourier transform of the channel filter coefficients. The frequency response plot shares the same toolbar and menus as the `dsp.SpectrumAnalyzer` System object.

The y-axis limits of the plot are computed based on the `NormalizePathGains` and `AveragePathGains` properties of the `comm.RayleighChannel` System object.

This table shows other selected default spectrum settings. You can change these settings from their default values by using the **Spectrum Settings** in **View** .

Spectrum Settings	Value
Type in Main options	Power
Window length in Main options	Channel filter length
NFFT in Main options	512
Window in Window options	Rectangular
Units in Trace options	dBW

This figure shows the frequency response plot for a frequency-selective channel.

Doppler Spectrum

The Doppler spectrum plot displays the theoretical Doppler spectrum and the empirically determined data points. The theoretical data is displayed as a line for the case of nonstatic channels and as a point for static channels. The empirical data is shown as * symbols. Before the empirical plot is updated, the internal buffer must be completely filled with filtered Gaussian samples. The empirical plot is the running mean of the spectrum that is calculated from each full buffer. For nonstatic channels, the number of input samples that is needed before the next update is displayed in the upper-left corner of the plot. The number of samples that is needed is a function of the sample rate and the maximum Doppler shift. For static channels, the text "Reset fading channel for next update" is displayed.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- To generate C code, set the `DopplerSpectrum` property to a single Doppler spectrum structure.
- Code generation is available only when you set the `Visualization` property to 'Off'.
- See "System Objects in MATLAB Code Generation" (MATLAB Coder).

comm.RayTracingChannel

Package: comm

Filter signal through multipath fading channel defined by propagation rays

Description

The `comm.RayTracingChannel` System object filters a signal through a multipath fading channel that is defined by propagation rays. For more information, see the “Channel Impulse Response” on page 3-1171 section.

To filter an input signal through a fading channel defined by propagation rays:

- 1 Create the `comm.RayTracingChannel` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

Creation

Syntax

```
rtchan = comm.RayTracingChannel
rtchan = comm.RayTracingChannel(Name,Value)
rtchan = comm.RayTracingChannel(rays,tx,rx)
```

Description

`rtchan = comm.RayTracingChannel` creates a ray-tracing fading channel System object, which defines the multipath environment using a set of propagation rays.

`rtchan = comm.RayTracingChannel(Name,Value)` sets properties using one or more name-value arguments. For example, `'SampleRate',1e6` sets the sample rate to 1 MHz.

`rtchan = comm.RayTracingChannel(rays,tx,rx)` creates a ray-tracing fading channel System object given inputs `rays`, `tx`, and `rx`.

- `rays`, specified as a set of `comm.Ray` objects, is used to set the `PropagationRays` property.
- `tx`, specified as a `txsite` object, is used to set the `TransmitArray` and `TransmitArrayOrientationAxes` properties.
- `rx`, specified as an `rxsite`, is used to set the `ReceiveArray` and `ReceiveArrayOrientationAxes` properties.

When you use this syntax, to configure other properties set their values after creating the System object. For example, see “Configure Sample Rate for Ray Tracing Channel” on page 3-1169.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see *System Design in MATLAB Using System Objects*.

SampleRate — Input signal sample rate

10000000 (default) | positive scalar

Input signal sample rate in hertz, specified as a positive scalar. The “Configure Sample Rate for Ray Tracing Channel” on page 3-1169 example shows workflows to set the sample rate.

Data Types: `double`

PropagationRays — Propagation rays

`comm.Ray` object (default) | row vector of `comm.Ray` objects | row cell array of `comm.Ray` objects

Propagation rays, specified as a `comm.Ray` object, a row vector of `comm.Ray` objects, or a row cell array of `comm.Ray` objects. This property specifies the propagation rays between the transmit and receive antenna arrays. All of the specified `comm.Ray` objects must have the same `Frequency` property setting. Any of the specified `comm.Ray` objects that have their `PathSpecification` property set to 'Locations' must have the same `CoordinateSystem`, `TransmitterLocation`, and `ReceiverLocation` property settings.

For code generation, the `PropagationRays` property must be a cell array of `comm.Ray` objects.

Data Types: `object` | `cell`

MinimizePropagationDelay — Option to force zero minimum propagation delay

`true` or `1` (default) | `false` or `0`

Option to force zero minimum propagation delay, specified as a logical `1` (`true`) or `0` (`false`). Set this property to `true` to subtract the minimum propagation delay from all of the propagation delays of the rays to force zero minimum delay. For more information, see the “Tips” on page 3-1171 section.

Data Types: `logical` | `double`

TransmitArray — Transmit antenna array

`arrayConfig` object (default) | `phased.IsotropicAntennaElement` System object | phased array antenna System object

Transmit antenna array, specified as one of these options.

- When you set `TransmitArray` to an `arrayConfig` object, you can adjust the `Size` property of the `arrayConfig` object to have the transmit array represent a uniform rectangular array (URA), uniform linear array (ULA), or single `phased.IsotropicAntennaElement` System object. The default configuration for an `arrayConfig` object is a 2-by-2 URA with an element spacing of 0.5 m.
- When you configure the `TransmitArray` to use a phased array antenna System object, you must have the “Phased Array System Toolbox” product. For a list of these additional supported values, see the “Phased Array Antenna Options” on page 3-1171 section.

TransmitArrayOrientationAxes — Orientation axes of transmit antenna array

eye(3) (default) | 3-by-3 unitary matrix

Orientation axes of the transmit antenna array, specified as a 3-by-3 unitary matrix indicating the rotation from the local coordinate system (LCS) to the global coordinate system (GCS). If the `comm.Ray` objects defined in the `PropagationRays` property set the `CoordinateSystem` property to 'Geographic', the GCS is the East-North-Up (ENU) coordinate system at the transmitter.

Data Types: double

ReceiveArray — Receive antenna array

arrayConfig object | phased.IsotropicAntennaElement System object | phased array antenna System object | ...

Receive antenna array, specified as one of these options.

- When you set `ReceiveArray` to an `arrayConfig` object, you can adjust the `Size` property of the `arrayConfig` object to have the receive array represent a uniform rectangular array (URA), uniform linear array (ULA), or single `phased.IsotropicAntennaElement` System object. The default configuration for an `arrayConfig` object is a 2-by-2 URA with an element spacing of 0.5 m.
- When you set `ReceiveArray` to a phased array antenna System object configuration, you must have the “Phased Array System Toolbox” product. For a list of these additional supported values, see the “Phased Array Antenna Options” on page 3-1171 section.

ReceiveArrayOrientationAxes — Orientation axes of receive antenna array

eye(3) (default) | 3-by-3 unitary matrix

Orientation axes of the receive antenna array, specified as a 3-by-3 unitary matrix indicating the rotation from the LCS to the GCS. If the `comm.Ray` objects defined in the `PropagationRays` property set the `CoordinateSystem` property to 'Geographic', the GCS is the East-North-Up (ENU) coordinate system at the receiver.

Data Types: double

ReceiverVirtualVelocity — Receive antenna array instantaneous velocity

[1; 1; 0] (default) | three-element column vector

Receive antenna array instantaneous velocity in the GCS in m/s, specified as a three-element column vector of the form $[x; y; z]$. The three elements in this vector specify the x-, y-, and z-velocity, respectively. If the `comm.Ray` objects defined in the `PropagationRays` property set the `CoordinateSystem` property to 'Geographic', the GCS is the East-North-Up (ENU) coordinate system at the receiver.

Data Types: double

NormalizeImpulseResponses — Option to normalize channel impulse responses

true or 1 (default) | false or 0

Option to normalize channel impulse responses, specified as a logical 1 (true) or 0 (false). Set this property to `true` to normalize the gains of CIRs to 0 dB from each transmit array element to each receive array element.

Data Types: logical

NormalizeChannelOutputs — Option to normalize channel outputs by number of receive elements`true` or `1` (default) | `false` or `0`

Option to normalize channel outputs by the number of receive elements, specified as a logical `1` (`true`) or `0` (`false`). Set this property to `true` to normalize the channel output by the number of receive array elements.

Data Types: `logical`

ChannelFiltering — Channel filtering`true` or `1` (default) | `false` or `0`

Channel filtering, specified as one of these logical values:

- `1` (`true`) — The channel accepts an input signal and produces a filtered output signal.
- `0` (`false`) — The object does not accept an input signal, produces no filtered output signal, and outputs only channel impulse responses. You must specify the duration of the fading process by using the `NumSamples` property.

Data Types: `logical` | `double`

NumSamples — Number of samples`100` (default) | nonnegative integer

Number of samples used for the duration of the channel impulse responses, specified as a nonnegative integer.

Tunable: Yes

Dependencies

To enable this property, set the `ChannelFiltering` property to `false`.

Data Types: `double`

OutputDataType — Channel impulse response output data type`'double'` (default) | `'single'`

Channel impulse response output data type, specified as `'double'` or `'single'`.

Dependencies

To enable this property, set the `ChannelFiltering` property to `false`.

Data Types: `char` | `string`

Usage**Syntax**

```
y = rtchan(x)
y = rtchan(x,starttime)
[y,cir] = rtchan(____)

cir = rtchan()
```

```
cir = rtchan(starttime)
```

Description

`y = rtchan(x)` filters the input signal through a multipath fading channel defined by a set of propagation rays and returns the result in `y`.

`y = rtchan(x, starttime)` specifies the start time of the input signal. When the last and current frames are not continuous in time, the System object resets the channel filter states.

`[y, cir] = rtchan(___)` also returns the channel impulse response using an input argument combination from either of the prior syntaxes.

`cir = rtchan()` returns the channel impulse response. To enable this syntax, set the `ChannelFiltering` property to `false`.

`cir = rtchan(starttime)` specifies the start time for the channel impulse response generation. To enable this syntax set the `ChannelFiltering` property to `false`.

Input Arguments

x — Input signal

N_S -by- N_T matrix

Input signal, specified as an N_S -by- N_T matrix.

- N_S is the number of samples.
- N_T is the number of transmit array elements.

Data Types: `single` | `double`

Complex Number Support: Yes

starttime — Start time

0 (default) | nonnegative scalar

Start time of input signal in seconds, specified as a nonnegative scalar.

When `mod(starttime/SampleRate)` is nonzero, the start time is rounded up to the nearest sample position. The start time must be greater than the end time of the last frame processed by the channel. You can use the `info` function to obtain the end time of the last processed frame.

Data Types: `double`

Output Arguments

y — Output signal

N_S -by- N_R matrix

Output signal, returned as an N_S -by- N_R matrix.

- N_S is the number of samples.
- N_R is the number of receive array elements.

`y` is the same data type as input `x`.

cir — Channel impulse response N_S -by- N_P -by- N_T -by- N_R array

Channel impulse response, returned as an N_S -by- N_P -by- N_T -by- N_R array.

- N_S is the number of samples. When you set the `ChannelFiltering` property to `true`, N_S is the length of the input. When you set `ChannelFiltering` to `false`, N_S is specified by the `NumSamples` property.
- N_P is the number of paths (specifically, the number of rays as indicated by the length of the `PropagationRays` property).
- N_T is the number of transmit array elements.
- N_R is the number of receive array elements.

When you set `ChannelFiltering` to `true`, the data type for this output is the same data type as input `x`. When you set `ChannelFiltering` to `false`, the data type for this output is specified by the `OutputDataType` property.

For more information, see the “Channel Impulse Response” on page 3-1171 section.

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Specific to comm.RayTracingChannel

<code>info</code>	Characteristic information about ray-tracing channel
<code>showProfile</code>	Plot temporal and spatial profiles of ray-tracing channel
<code>clone</code>	Create duplicate System object
<code>isLocked</code>	Determine if System object is in use

Common to All System Objects

<code>step</code>	Run System object algorithm
<code>release</code>	Release resources and allow changes to System object property values and input characteristics
<code>reset</code>	Reset internal states of System object

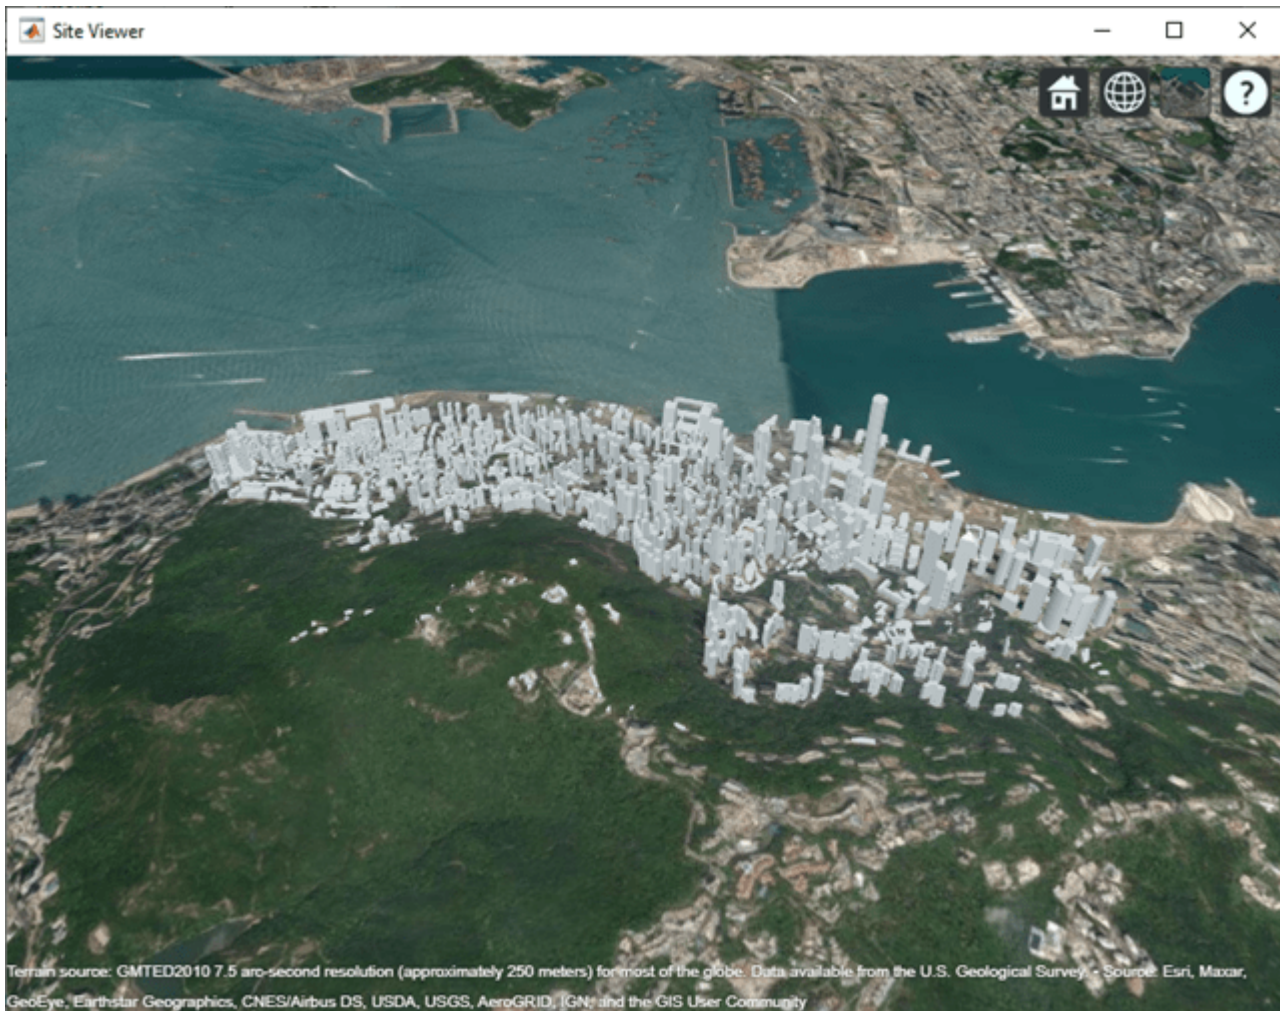

Examples

Remove Minimum Propagation Path Delay from Multipath Ray Trace Channel

Show the impact of not forcing the smallest propagation delay to be zero for a multipath channel model. Filter signals through a multipath ray tracing channel between two sites in Hong Kong, China. Build two multipath channel models by using the result from ray tracing. For the first ray tracing channel model, force the minimum propagation delay to zero. For the second ray tracing channel model, do not force the minimum propagation delay to zero.

Create a Site Viewer map display of buildings in Hong Kong. For more information about the OSM file, see [1] on page 3-0 .

```
sv = siteviewer("Buildings","hongkong.osm");
```

```
tx = txsite( ...
    "Latitude",22.2789, ...
    "Longitude",114.1625, ...
    "AntennaAngle",30, ... % Azimuth angle
    "AntennaHeight",10, ...
    "TransmitterFrequency",28e9);
rx = rxsite( ...
    "Latitude",22.2799, ...
    "Longitude",114.1617, ...
    "AntennaAngle",120, ... % Azimuth angle
    "AntennaHeight",1);
```

Create a ray tracing propagation model with up to two reflections using the image method. Perform ray tracing to find rays by using the propagation model.

```
pm = propagationModel("raytracing", ...
    "Method","image", ...
    "MaxNumReflections",2);
rays = raytrace(tx,rx,pm);
```

Create a channel model using the calculated rays in between the transmitter and receiver sites. The default configuration forces zero minimum propagation delay. Show the temporal and spatial profiles of the channel.

```
rtchan = comm.RayTracingChannel(rays{1},tx,rx);
rtchan.SampleRate = 50e6;
showProfile(rtchan);
```

Angle of Departure

Angle of Arrival

Create a clone of the ray tracing channel model and reconfigure it to not force zero minimum propagation delay. Show the temporal and spatial profiles of the channel. The angle of departure and arrival plots do not change, but the power delay profile plot shows the updated delay profile result when the minimum delay profile is not forced to zero.

```
rtchandelayed= clone(rtchan);
rtchandelayed.MinimizePropagationDelay = false;
showProfile(rtchandelayed);
```

Filter randomly generated 16-QAM signals through the channel models. Display the leading 15 elements of `y` and `ydelayedm`, which are output by the ray tracing channel objects `rtchan` and `rtchandelayed`, respectively. The leading samples in the delayed signal, `ydelayed`, are all zeros. When you model your communications system, you must account for this signal delay to avoid losing trailing signal data.

```
M = 16;           % Modulation order
frmLen = 1e3;    % Frame length
numTx = rtchan.info.NumTransmitElements;

x = qammod(randi([0,M-1], frmLen, numTx), M);
y = rtchan(x);
numTxdelayed = rtchandelayed.info.NumTransmitElements;
x = qammod(randi([0,M-1], frmLen, numTxdelayed), M);
ydelayed = rtchandelayed(x);
y(1:15)
```

```
ans = 15×1 complex
```

```

Appendix

[1] The OSM file is downloaded from <https://www.openstreetmap.org>, which provides access to crowd-sourced map data all over the world. The data is licensed under the Open Data Commons Open Database License (ODbL), <https://opendatacommons.org/licenses/odbl/>.

Show Multipath Ray Trace Channel Modeling in Conference Room

Filter signals through a multipath ray tracing channel model between two sites in a conference room. Build the multipath channel model by using the result from ray tracing.

Define a 3-D map for a conference room with one table and four chairs by using a standard tessellation language (STL) data file. Define a transmitter site close to the wall and a receiver site above the table.

```
mapFileName = "conferenceroom.stl";

tx = txsite('cartesian', ...
    'AntennaPosition', [-1.45; -1.4; 2.3], ...
    'TransmitterFrequency', 2.8e9);
rx = rxsite('cartesian', ...
    'AntennaPosition', [.6; .2; 1.0]);
```

Use the `siteviewer` object and the `show` object function to visualize the 3-D scenario. The transmitter and receiver sites are colored in red and blue, respectively.

```
siteviewer(SceneModel=mapFileName);
show(tx, 'ShowAntennaHeight', false);
show(rx, 'ShowAntennaHeight', false);
```

Create a ray tracing propagation model with up to three reflections using the shooting-bouncing-rays (SBR) method. Perform ray tracing to find rays by using the propagation model.

```
pm = propagationModel('raytracing', ...
    'CoordinateSystem', 'cartesian', ...
```

```

    'Method','sbr', ...
    'MaxNumReflections',3);
rays = raytrace(tx,rx,pm,'Map',mapFileName);

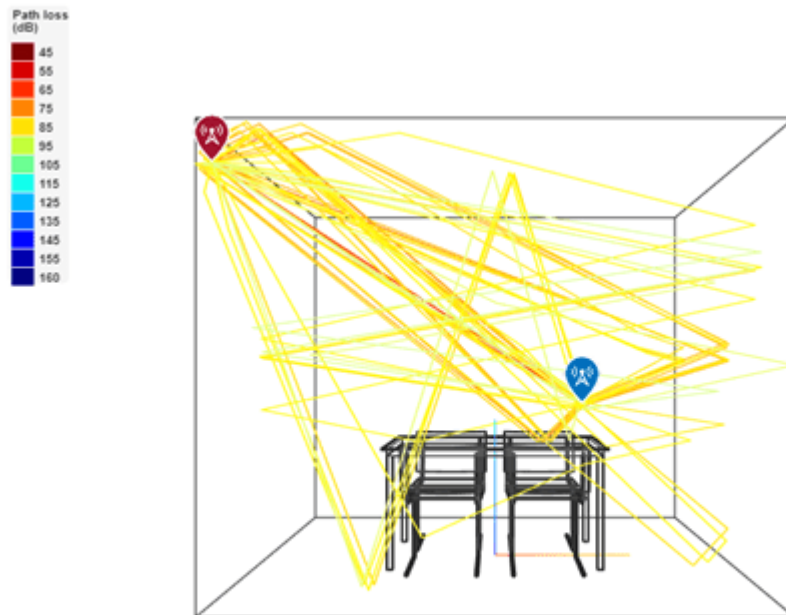

```

Extract the computed rays from the returned cell array, and then plot the rays. Each ray is colored based on its path loss value.

```

rays = rays{1,1};
plot(rays)

```

Create a channel model using the calculated rays in between the transmitter and receiver sites. Show the temporal and spatial profiles of the channel.

```

rtchan = comm.RayTracingChannel(rays,tx,rx);
showProfile(rtchan);

```

Filter randomly generated 16-QAM signals through the channel. With the default sample rate of 10^6 , the channel frequency response is flat. Increasing the sample rate to 10^9 results in a frequency selective channel. Show the filtered signal for the flat frequency response channel and the frequency selective channel in a constellation diagram.

```
M = 16;           % Modulation order
frmLen = 1e3;    % Frame length

numTx = rtchan.info.NumTransmitElements;
x = qammod(randi([0,M-1],frmLen,numTx),M);
y_samprate10e6 = rtchan(x);

release(rtchan);
rtchan.SampleRate = 1e9;
y_samprate1e9 = rtchan(x);
constellationdiag = comm.ConstellationDiagram( ...
    NumInputPorts=2, ...
    ChannelNames={ ...
        'Flat frequency response channel','Frequency selective channel'}, ...
    XLimits=[-5 5], ...
    YLimits=[-5 5], ...
    ReferenceConstellation=qammod(0:M-1,M));
constellationdiag(y_samprate10e6(:),y_samprate1e9);
```

Configure Sample Rate for Ray Tracing Channel

To modify the sample rate of the ray tracing channel, you can set the `SampleRate` property by using a name-value argument when you create the object or you can create a channel model by using the rays and site and set the `SampleRate` property after you create the object.

Set Sample Rate when Creating Ray Tracing Channel Object

Create a ray tracing channel model, specifying the sample rate as 20 MHz.

```
rtchan1 = comm.RayTracingChannel(SampleRate=2e7)
```

```

rtchan1 =
  comm.RayTracingChannel with properties:
      SampleRate: 20000000
      PropagationRays: [1x1 comm.Ray]
      MinimizePropagationDelay: true
      TransmitArray: [1x1 arrayConfig]
      TransmitArrayOrientationAxes: [3x3 double]
      ReceiveArray: [1x1 arrayConfig]
      ReceiveArrayOrientationAxes: [3x3 double]
      ReceiverVirtualVelocity: [3x1 double]
      NormalizeImpulseResponses: true
      NormalizeChannelOutputs: true
      ChannelFiltering: true

```

Set Sample Rate After Creating Ray Tracing Channel Object

Create a channel model by using the transmitter site, receiver site, and calculated rays between the sites. After creating the object, set the sample rate to 20 MHz.

```

tx = txsite( ...
    "Latitude",22.2789, ...
    "Longitude",114.1625, ...
    "AntennaAngle",30, ...           % Azimuth angle
    "AntennaHeight",10, ...
    "TransmitterFrequency",28e9);
rx = rxsite( ...
    "Latitude",22.2799, ...
    "Longitude",114.1617, ...
    "AntennaAngle",120, ...         % Azimuth angle
    "AntennaHeight",1);
pm = propagationModel("raytracing", ...
    "Method","sbr", ...
    "MaxNumReflections",3);
rays = raytrace(tx,rx,pm);

rtchan2 = comm.RayTracingChannel(rays{1},tx,rx);
rtchan2.SampleRate = 2e7

```

```

rtchan2 =
  comm.RayTracingChannel with properties:
      SampleRate: 20000000
      PropagationRays: [1x2 comm.Ray]
      MinimizePropagationDelay: true
      TransmitArray: [1x1 arrayConfig]
      TransmitArrayOrientationAxes: [3x3 double]
      ReceiveArray: [1x1 arrayConfig]
      ReceiveArrayOrientationAxes: [3x3 double]
      ReceiverVirtualVelocity: [3x1 double]
      NormalizeImpulseResponses: true
      NormalizeChannelOutputs: true
      ChannelFiltering: true

```

After configuring the channel object, you would typically filter a modulated signal through the channel. Here a 16-QAM signal is passed through the `rtchan2` ray tracing channel.

```

modOrd = 16;
frmLen = 1e3;
numTx = rtchan2.info.NumTransmitElements;
x = qammod(randi([0,modOrd-1],frmLen,numTx),modOrd);
y = rtchan2(x);

```

More About

Channel Impulse Response

The channel impulse response contains the computed Doppler fading over all rays individually. The phases of individual rays change over time, and their combination contributes to the channel fading. The rate of phase change depends on the angle between the receiver velocity and the angle of arrival (AoA) of the individual ray.

Phased Array Antenna Options

If you have the “Phased Array System Toolbox” product, you can specify any of these phased array antenna System object configurations for the TransmitArray and ReceiveArray properties.

- phased.IsotropicAntennaElement
- phased.NRAntennaElement
- phased.CustomAntennaElement
- phased.URA with the Element property set to a phased.IsotropicAntennaElement, phased.NRAntennaElement, or phased.CustomAntennaElement System object
- phased.ULA with the Element property set to a phased.IsotropicAntennaElement, phased.NRAntennaElement, or phased.CustomAntennaElement System object
- phased.ConformalArray with the Element property set to a phased.IsotropicAntennaElement, phased.NRAntennaElement, or phased.CustomAntennaElement System object
- phased.NRRectangularPanelArray with the ElementSet property set to a phased.IsotropicAntennaElement, phased.NRAntennaElement, or phased.CustomAntennaElement System object

Tips

- When you set the MinimizePropagationDelay property to true, the System object shifts all propagation delay paths to remove the amount of delay that is associated with the minimum propagation delay path. Shifting the paths removes potential leading zeros in the channel output and eliminates the need to account for the delay to receive the trailing signal samples.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

- For code generation, the PropagationRays property must be a cell array of comm.Ray objects.
- For comm.Ray objects, when you set the PathSpecification property to 'Locations' and the LineOfSight property to false, the Type field setting must be the same (either all 'Reflection' or all 'Diffraction') in the structures specified by the Interactions property for each individual comm.Ray object.

comm.RBDSWaveformGenerator

Package: comm

Generate RDS/RBDS waveform

Description

The `comm.RBDSWaveformGenerator` System object generates configurable standard-compliant baseband RDS/RBDS waveforms in MATLAB. RDS/RBDS waveforms supplement FM radio stations with additional textual information, such as song title, artist name, and station description. The RDS/RBDS signal lies in the 57-kHz band of the baseband FM radio signal.

Use this object to generate a waveform containing RadioText Plus (RT+) information and register a custom encoding implementation for an Open Data Application (ODA). You can also specify the time, data, and the program type. The object supports short, scrolling 8-character text, and longer 32-character or 64-character text.

To generate baseband RDS/RBDS waveforms:

- 1 Create a `comm.RBDSWaveformGenerator` object and set the properties of the object.
- 2 Call `step` to generate the waveform.

Note Alternatively, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`rbdsngen = comm.RBDSWaveformGenerator` creates an RDS/RBDS waveform generator object, `rbdsngen`, using the default properties.

`rbdsngen = comm.RBDSWaveformGenerator(Name,Value)` specifies additional properties using `Name,Value` pairs. Unspecified properties have default values.

Example:

```
rbdsngen = comm.RBDSWaveformGenerator( ...
    'GroupsPerFrame',20,'SamplesPerSymbol',10, ...
    'SendRadioTextPlus',true);
```

Properties

If a property is listed as tunable, then you can change its value even when the object is locked.

SamplesPerSymbol — Number of samples per symbol

10 (default) | positive even integer

Number of samples per symbol (bit), specified as a positive even integer. Half of the samples represent one amplitude level of Manchester coding. The other half of the samples represent the opposite level.

GroupsPerFrame — Number of groups per output frame

10 (default) | scalar integer

Number of groups per output frame, specified as a scalar integer. Each group is 104 symbols (bits) long.

RadioText — Long text conveyed with type 2A groups

'Long text' (default) | character vector

Radio text conveyed with type 2A groups, specified as a character vector that is up to 64 characters long. The object transmits the specified text four characters at a time, using type 2A groups.

Tunable: Yes

ProgramServiceName — Label of the program service

'ShortTxt' (default) | character vector

Label of the program service, specified as a character vector that is up to eight characters long. This information is conveyed as a short text with type 0A groups, two characters at a time.

Tunable: Yes

ProgramIdentificationCode — Program identification code

[0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0] (default) | 16-bit row vector

Program identification (PI) code, specified as a 16-bit row vector. In North America, the PI code conveys the call letters of the station. Example call letters include 'WABC' and 'KXYZ'.

To generate North American PI codes for a station's call letters, use the `callLettersToPICode` method.

ProgramType — Program type

'No program type or undefined' (default) | character vector

Program type, specified as a character vector containing one of the 31 values allowed by the RDS/RBDS standard. For a list of program types that the RDS/RBDS standard allows in North America, see [1].

Tunable: Yes

ProgramTypeName — Program type name

' ' (default) | character vector

Program type name, specified as a character vector that is up to eight characters long. This text further characterizes the program type, such as 'Football' for the program type 'Sports'. The object conveys the program type name using type 10A groups. If this property is empty, then no 10A groups are generated.

Tunable: Yes

SendDateTime — Option to advertise date and time

false (default) | true

Option to advertise the date and time, specified as either `false` or `true`. When you set this property to `true`, one 4A group is periodically generated every 685 groups (once a minute).

AlternativeFrequencies — Alternative frequencies

`[]` (default) | row vector

Alternative frequencies, specified as a row vector in MHz. This information is conveyed with type 0A groups. It indicates other transmitters broadcasting the same program in the same or adjacent reception areas. With this information, receivers can switch to a different frequency with better reception.

SendRadioTextPlus — Option to send RT+ information

`false` (default) | `true`

Option to transmit RadioText Plus (RT+) information, specified as a scalar logical. When you set this property to `true`, the RT+ ODA information is advertised with type 3A groups. In addition, the RT+ content types, specified in `RadioTextType1`, `RadioTextType2`, and the two RT+ substrings indexed by `RadioTextIndices` are conveyed with the open-format type 11A group.

RadioTextType1 — Content type of first RT+ substring

`'Item.Artist'` (default) | character vector

Content type of the first RT+ substring, specified as a character vector. Allowed values are the class names specified in the RT+ standard. For more details, see [2].

Tunable: Yes

RadioTextType2 — Content type of second RT+ substring

`'Item.Title'` (default) | character vector

Content type of the second RT+ substring, specified as a character vector. Allowed values are the class names specified in the RT+ standard. For more details, see [2].

Tunable: Yes

RadioTextIndices — Start and end indices of RT+ substrings

`[1 2; 3 4]` (default) | 2-by-2 matrix of positive integers

Start and end indices of RT+ substrings, specified as a 2-by-2 matrix of positive integers. The first column indexes the beginning of each RT+ substring. The second column indexes the end of each substring.

Tunable: Yes

Common to All System Objects	
reset	Reset internal states of System object

Examples

Generate a Basic RBDS Waveform

Generate a basic RBDS waveform, FM modulate the waveform with an audio signal, and then demodulate the waveform.

Each frame of the RBDS waveform contains 19 groups, with a group length of 104 bits (symbols) each. Set the number of samples per RBDS symbol to 10. Therefore, the number of samples in each frame of RBDS waveform is $104 \times 10 \times 19 = 19,760$. According to the RBDS standard, the bit rate is 1187.5 Hz. So, the RBDS sample rate = $1187.5 \times$ samples per RBDS symbol. Set the audio frame rate to $40 \times 1187.5 = 47,500$.

```
groupLen = 104;
sps = 10;
groupsPerFrame = 19;
rbdsFrameLen = groupLen*sps*groupsPerFrame;
afrRate = 40*1187.5;
rbdsRate = 1187.5*sps;
outRate = 4*57000;

afr = dsp.AudioFileReader('rbds_capture_47500.wav','SamplesPerFrame',rbdsFrameLen*afrRate/rbdsRate);
rbds = comm.RBDSWaveformGenerator('GroupsPerFrame',groupsPerFrame,'SamplesPerSymbol',sps);

fmMod = comm.FMBroadcastModulator('AudioSampleRate',afr.SampleRate,'SampleRate',outRate,...
    'Stereo',true,'RBDS',true,'RBDSsamplesPerSymbol',sps);
fmDemod = comm.FMBroadcastDemodulator('SampleRate',outRate,...
    'Stereo',true,'RBDS',true,'PlaySound',true);
scope = timescope('SampleRate',outRate,'YLimits',10^-2*[-1 1]);
```

Get the audio input and generate the RBDS waveform. FM modulate the stereo audio with the RBDS waveform, add noise, and FM demodulate the audio and RBDS waveforms. View the demodulated RBDS waveform in the time scope.

```
for idx = 1:7
    input = afr(); % get current audio input
    rbdsWave = rbds(); % generate RBDS info at the same configured rate
    yFM = fmMod([input input], rbdsWave); % FM modulate stereo audio with RBDS info
    rcv = awgn(yFM, 40); % add noise
    [audioRcv, rbdsRcv] = fmDemod(rcv); % FM demodulate the audio and RBDS waveforms
    scope(rbdsRcv);
end
```

Generate RBDS Waveform with RadioText Plus Information

Create a `comm.RBDSWaveformGenerator` System object™ with 20 groups per frame and 10 samples per symbol. Add the Radio Text plus (RT+) information, such as artist name and song, title, to the waveform. Indicate the start and end of the RT+ substrings by using the `RadioTextIndices` property.

```
rbds = comm.RBDSWaveformGenerator('GroupsPerFrame',20,'SamplesPerSymbol',10,...
    'SendRadioTextPlus', true);
rbds.RadioText = 'MyArtist - MySongTitle';
rbds.RadioTextType1 = 'Item.Artist';
rbds.RadioTextType2 = 'Item.Title';
rbds.RadioTextIndices = [1 8; 12 22];
for idx = 1:10
    rbds.step();
end
```

Register a Custom Encoding Implementation

Register a custom encoding implementation for an Open Data Application (ODA) by using the `registerODA` method of the `comm.RBDSWaveformGenerator` System object™. Set the ODA ID to 'CD46', which is the ID for the traffic message channel. The allocated group type is 8A.

```
rbds = comm.RBDSWaveformGenerator();  
odaID = 'CD46';  
allocatedGroupType = '8A';
```

This example uses the following templates as a starting point for custom encoding implementation.

```
mainProcessingFcn = @CustomODAEncodingMain;  
fcn3A             = @CustomODAEncoding3A;  
registerODA(rbds,odaID,allocatedGroupType,mainProcessingFcn,fcn3A);  
s = info(rbds);  
s.ODAMap
```

ans=2x1 struct array with fields:

```
    ID  
  GroupType  
FunctionMain  
Function3A
```

Configure RBDS Waveforms with Date and Time Information

Generate RBDS waveform with date and time information, the program type, and alternative frequencies. The `comm.RBDSWaveformGenerator` object uses type 4A groups for date and time information, type 10A groups for the program type information, and type 0A groups for alternative frequencies. View the waveform in a spectrum analyzer.

```
rbds = comm.RBDSWaveformGenerator('GroupsPerFrame',1000);  
scope = dsp.SpectrumAnalyzer('SampleRate',1187.5*rbds.SamplesPerSymbol,'YLimits',[-140 20]);  
rbds.SendDateTime = true;           % send type 4A groups  
rbds.ProgramType = 'Sports';  
rbds.ProgramTypeName = 'Football'; % send type 10A groups  
rbds.AlternativeFrequencies = [99.1 102.5]; % info sent in type 0A groups  
wave = rbds.step();  
scope(wave)
```

Algorithms

`comm.RBDSWaveformGenerator` generates waveforms according to the RDS/RBDS standard [1]. The RDS/RBDS standard consists of three layers: physical layer, data-link layer, and session and application layer.

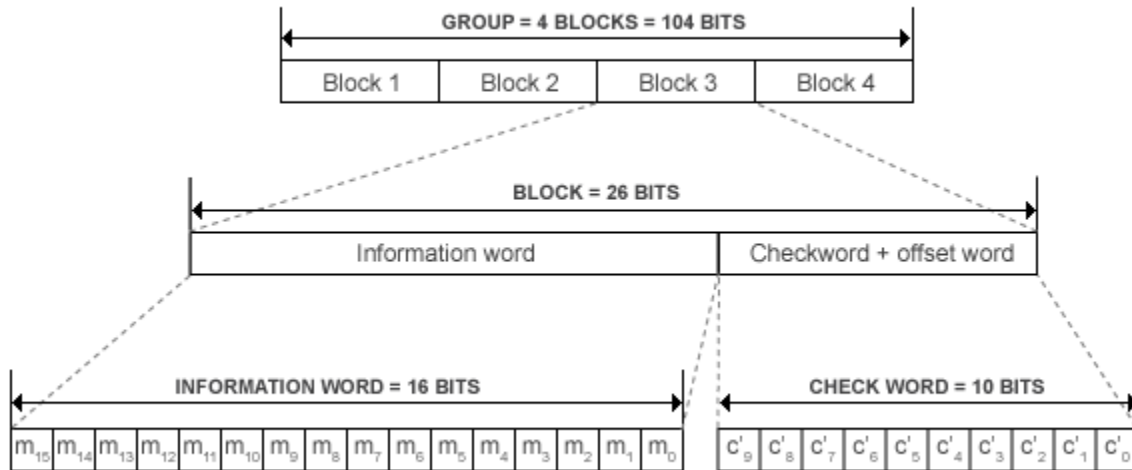

Physical Layer

The physical layer (first layer) converts the data-link bits to an analog waveform by conducting differential encoding and biphase symbol encoding (Manchester encoding) and pulse-shaping filtering.

Data-Link Layer

The data-link layer (second layer) performs (26,16) cyclic encoding shortened from (341,331) encoding [1]. The second layer is responsible for error detection, error correction, and the establishment of group-level synchronization. Each group of RDS/RBDS frames contains four blocks of 26 bits (that is 104 bits) each. Each block contains an information word and a check word. Each information word contains 16 bits, and each check word contains 10 bits.

Here is the baseband coding structure for the RDS/RBDS waveform. For more details, see [1].

For each block, a unique offset word is modulo-2 added to the checkword bits. The added offset word provides a group and block synchronization system in the receiver (decoder). Because the addition of the offset is reversible in the decoder, the normal additive error-correcting and detecting properties of the basic code are unaffected.

Session and Application Layer

The first block in every group contains a program identification (PI) code. The first four bits of the second block of every group are allocated to a four-bit code. This code specifies the application of the group. Groups are referred to as types 0-15 according to the binary weighting $A_3 = 8, A_2 = 4, A_1 = 2, A_0 = 1$. The fifth bit of the second block, B_0 , defines the version of the application. If $B_0 = 0$, the version of the group is A. The PI code in this version is inserted into block 1 only. Example group types include 0A, 1A, 2A, 3A, and 4A.

The Program Type code and Traffic Program Identification (PI) occupy fixed locations in block 2 of every group.

Group Types

Group Type	Group Type Code/Version					Description
	A ₃	A ₂	A ₁	A ₀	B ₀	
0A	0	0	0	0	0	Basic station information. Short, usually scrolling text, up to 8 characters long. Transmitted 2 characters at a time.
2A	0	0	1	0	0	Radio text. Long text, up to 64 characters long. Transmitted 4 characters at a time.
3A	0	0	1	1	0	Specification of used Open Data Applications and their allocation group type. Example: Radio Text Plus information is sent using 11A group.
4A	0	1	0	0	0	Date and time. Optional group that can be transmitted once in every 685 groups (once a minute).
10A	1	0	1	0	0	Program type name. Example: Football for ProgramType = 'Sports'.
11A	1	0	1	1	0	Open Data Applications. Example: RadioText Plus (RT+).

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

See “System Objects in MATLAB Code Generation” (MATLAB Coder).

In addition, the following limitations apply when you generate code that contains this System object or when you use this object in a MATLAB function block.

- The group type 4A cannot be transmitted in the generated code.
- The registerODA method is not supported.
- The ProgramType property is not tunable.

Objects

comm.FMBroadcastModulator | comm.FMBroadcastDemodulator

Introduced in R2017a

callLettersToPICode

System object: comm.RBDSWaveformGenerator

Package: comm

Convert North-American call letters to binary PI code

Syntax

```
picode = callLettersToPICode(rbdsgen, callLetters)
```

Description

`picode = callLettersToPICode(rbdsgen, callLetters)` returns the 16-bit program identification (PI) code that corresponds to `callLetters`. Acceptable call letter formats are 3-character or 4-character vectors beginning with 'K' or 'W'.

Introduced in R2017a

registerODA

System object: comm.RBDSWaveformGenerator

Package: comm

Register a custom encoding implementation for an ODA

Syntax

```
registerODA(rbdsgen,odaID,group,handleMain,handle3A)
```

Description

`registerODA(rbdsgen,odaID,group,handleMain,handle3A)` associates the Open Data Application (ODA) specified by the hexadecimal ID `odaID`, with the type `group` groups generated by `rbdsgen`. The four 16-bit information words of these groups are generated by the function `handleMain`. The third information word of type 3A groups, which is ODA-specific, is generated by the function `handle3A`.

Introduced in R2017a

step

System object: `comm.RBDSWaveformGenerator`

Package: `comm`

Generate RDS/RBDS waveform

Syntax

```
y = step(rbdsgen)
```

Description

Note Alternatively, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj, x)` and `y = obj(x)` perform equivalent operations.

`y = step(rbdsgen)` outputs a frame of the baseband RDS/RBDS waveform in column vector `y`. The waveform contains the number of 104-bit groups, specified in the `GroupsPerFrame` property of the object. Each symbol is oversampled according to the `SamplesPerSymbol` property. Thus, the output length is `SamplesPerSymbol × 104 × GroupsPerFrame` samples. The object uses an internal scheduler to determine the order and frequency of the transmitted group types.

Note `rbdsgen` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications, such as dimensions, complexity, and data type of the input data. If you change a nontunable property or an input specification, the System object issues an error. To change nontunable properties or inputs, you must first call the `release` method to unlock the object.

Introduced in R2017a

comm.RectangularQAMDemodulator

Package: comm

(To be removed) Demodulate using rectangular QAM signal constellation

Note `comm.RectangularQAMDemodulator` will be removed in a future release. Use `qamdemod` instead. For more information, see “Compatibility Considerations”.

Description

The `RectangularQAMDemodulator` object demodulates a signal that was modulated using quadrature amplitude modulation with a constellation on a rectangular lattice.

To demodulate a signal that was modulated using quadrature amplitude modulation:

- 1 Define and set up your rectangular QAM demodulator object. See “Construction” on page 3-1185.
- 2 Call `step` to demodulate the signal according to the properties of `comm.RectangularQAMDemodulator`. The behavior of `step` is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`H = comm.RectangularQAMDemodulator` creates a demodulator System object, `H`. This object demodulates the input signal using the rectangular quadrature amplitude modulation (QAM) method.

`H = comm.RectangularQAMDemodulator(Name, Value)` creates a rectangular QAM demodulator object, `H`, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as `(Name1, Value1, ..., NameN, ValueN)`.

`H = comm.RectangularQAMDemodulator(M, Name, Value)` creates a rectangular QAM demodulator object, `H`. This object has the `ModulationOrder` property set to `M`, and the other specified properties set to the specified values.

Properties

ModulationOrder

Number of points in signal constellation

Specify the number of points in the signal constellation as scalar value with a positive, integer power of two. The default is 16.

PhaseOffset

Phase offset of constellation

Specify the phase offset of the signal constellation, in radians, as a real scalar value. The default is 0.

BitOutput

Output data as bits

Specify whether the output consists of groups of bits or integer symbol values. When you set this property to `true` the `step` method outputs a column vector of bit values whose length equals $\log_2(\text{ModulationOrder on page 3-0})$ times the number of demodulated symbols. When you set this property to `false`, the `step` method outputs a column vector with a length equal to the input data vector. This vector contains integer symbol values between 0 and `ModulationOrder-1`. The default is `false`.

SymbolMapping

Constellation encoding

Specify how the object maps an integer or group of $\log_2(\text{ModulationOrder on page 3-0})$ bits to the corresponding symbol as one of `Binary` | `Gray` | `Custom`. The default is `Gray`. When you set this property to `Gray`, the object uses a Gray-coded signal constellation. When you set this property to `Binary`, the object uses a natural binary-coded constellation. When you set this property to `Custom`, the object uses the signal constellation defined in the `CustomSymbolMapping on page 3-0` property.

CustomSymbolMapping

Custom constellation encoding

Specify a custom constellation symbol mapping vector. The default is `0:15`. This property is a row or column vector with a size of `ModulationOrder on page 3-0` and with unique integer values in the range `[0, ModulationOrder-1]`. The values must be of data type `double`. The first element of this vector corresponds to the top-leftmost point of the constellation, with subsequent elements running down column-wise, from left to right. The last element corresponds to the bottom-rightmost point. This property applies when you set the `SymbolMapping on page 3-0` property to `Custom`.

NormalizationMethod

Constellation normalization method

Specify the method used to normalize the signal constellation as `Minimum distance between symbols` | `Average power` | `Peak power`. The default is `Minimum distance between symbols`.

MinimumDistance

Minimum distance between symbols

Specify the distance between two nearest constellation points as a positive, real, numeric scalar value. The default is 2. This property applies when you set the `NormalizationMethod on page 3-0` property to `Minimum distance between symbols`.

AveragePower

Average power of constellation

Specify the average power of the symbols in the constellation as a positive, real, numeric scalar value. The default is 1. This property applies when you set the `NormalizationMethod` on page 3-0 property to `Average power`.

PeakPower

Peak power of constellation

Specify the maximum power of the symbols in the constellation as a positive, real, numeric scalar value. The default is 1. This property applies when you set the `NormalizationMethod` on page 3-0 property to `Peak power`.

DecisionMethod

Demodulation decision method

Specify the decision method the object uses as `Hard decision` | `Log-likelihood ratio` | `Approximate log-likelihood ratio`. The default is `Hard decision`. When you set the `BitOutput` on page 3-0 property to `false` the object always performs hard-decision demodulation. This property applies when you set the `BitOutput` property to `true`.

VarianceSource

Source of noise variance

Specify the source of the noise variance as `Property` | `Input port`. The default is `Property`. This property applies when you set the `BitOutput` on page 3-0 property to `true` and the `DecisionMethod` on page 3-0 property to `Log-likelihood ratio` or `Approximate log-likelihood ratio`.

Variance

Noise variance

Specify the variance of the noise as a positive, real scalar value. The default is 1. If this value is very small (i.e., SNR is very high), log-likelihood ratio (LLR) computations may yield `Inf` or `-Inf`. This result occurs because the LLR algorithm computes the exponential of very large or very small numbers using finite-precision arithmetic. In such cases, using approximate LLR is recommended because its algorithm does not compute exponentials. This property applies when you set the `BitOutput` on page 3-0 property to `true`, the `DecisionMethod` on page 3-0 property to `Log-likelihood ratio` or `Approximate log-likelihood ratio`, and the `VarianceSource` on page 3-0 property to `Property`. This property is tunable.

OutputDataType

Data type of output

Specify the output data type as `Full precision` | `Smallest unsigned integer` | `double` | `single` | `int8` | `uint8` | `int16` | `uint16` | `int32` | `uint32`. The default is `Full precision`.

This property applies only when you set the `BitOutput` on page 3-0 property to `false` or when you set the `BitOutput` property to `true` and the `DecisionMethod` on page 3-0 property to `Hard`

decision. In this case, when the `OutputDataType` on page 3-0 property is set to `Full precision`, and the input data type is single- or double-precision, the output data has the same data type as the input.

When the input data is of a fixed-point type, the output data type behaves as if you had set the `OutputDataType` property to `Smallest unsigned integer`.

When you set the `BitOutput` property to `true` and the `DecisionMethod` property to `Hard Decision`, then logical data type becomes a valid option.

When you set the `BitOutput` property to `true` and the `DecisionMethod` property to `Log-likelihood ratio` or `Approximate log-likelihood ratio`, the output data type is the same as that of the input. In this case, that data type can only be single- or double-precision.

Fixed-Point Properties

FullPrecisionOverride

Full precision override for fixed-point arithmetic

Specify whether to use full precision rules. If you set `FullPrecisionOverride` to `true`, which is the default, the object computes all internal arithmetic and output data types using full precision rules. These rules provide the most accurate fixed-point numerics. It also turns off the display of other fixed-point properties because they do not apply individually. These rules guarantee that no quantization occurs within the object. Bits are added, as needed, to ensure that no roundoff or overflow occurs. If you set `FullPrecisionOverride` to `false`, fixed-point data types are controlled through individual fixed-point property settings. For more information, see “Full Precision for Fixed-Point System Objects” on page 3-1190.

DerotateFactorDataType

Data type of derotate factor

Specify the derotate factor data type as `Same word length as input` | `Custom`. The default is `Same word length as input`. This property applies when you set the `BitOutput` on page 3-0 property to `false`, or when you set the `BitOutput` property to `true` and the `DecisionMethod` on page 3-0 property to `Hard decision`. The object uses the derotate factor in the computations only when the step method input is of a fixed-point type and the `PhaseOffset` on page 3-0 property has a value that is not a multiple of $\pi/2$.

CustomDerotateFactorDataType

Fixed-point data type of derotate factor

Specify the derotate factor fixed-point type as an `unscaled numeric type` object with a signedness of `Auto`. The default is `numeric type([], 16)`. This property applies when you set the `DerotateFactorDataType` on page 3-0 property to `Custom`.

DenormalizationFactorDataType

Data type of denormalization factor

Specify the denormalization factor data type as `Same word length as input` | `Custom`. The default is `Same word length as input`. This property applies when you set the `BitOutput` on

page 3-0 property to false or when you set the `BitOutput` property to true and the `DecisionMethod` on page 3-0 property to Hard decision.

CustomDenormalizationFactorDataType

Fixed-point data type of denormalization factor

Specify the denormalization factor fixed-point type as an unscaled `numericType` object with a signedness of Auto. The default is `numericType([], 16)`. This property applies when you set the `DenormalizationFactorDataType` on page 3-0 property to Custom.

ProductDataType

Data type of product

Specify the product data type as `Full precision | Custom`. The default is `Full precision`. This property applies when you set the `BitOutput` on page 3-0 property to false or when you set the `BitOutput` property to true and the `DecisionMethod` on page 3-0 property to Hard decision.

CustomProductDataType

Fixed-point data type of product

Specify the product fixed-point type as an unscaled `numericType` object with a signedness of Auto. The default is `numericType([], 32)`. This property applies when you set the `ProductDataType` on page 3-0 property to Custom.

ProductRoundingMethod

Rounding of fixed-point numeric value of product

Specify the product rounding method as `Ceiling | Convergent | Floor | Nearest | Round | Simplest | Zero`. The default is `Floor`. This property applies when the object is not in a full precision configuration, when you set the `BitOutput` on page 3-0 property to false or when you set the `BitOutput` property to true and the `DecisionMethod` on page 3-0 property to Hard decision.

ProductOverflowAction

Action when fixed-point numeric value of product overflows

Specify the product overflow action as `Wrap | Saturate`. The default is `Wrap`. This property applies when the object is not in a full precision configuration, when you set the `BitOutput` on page 3-0 property to false or when you set the `BitOutput` property to true and the `DecisionMethod` on page 3-0 property to Hard decision.

SumDataType

Data type of sum

Specify the sum data type as `Full precision | Same as product | Custom`. The default is `Full precision`. This property applies when you set the `FullPrecisionOverride` on page 3-0 property to false, when you set the `BitOutput` on page 3-0 property to false or when you set the `BitOutput` property to true and the `DecisionMethod` on page 3-0 property to Hard decision.

CustomSumDataType

Fixed-point data type of sum

Specify the sum fixed-point type as an unscaled numeric type object with a signedness of Auto. The default is numeric type ([], 32). This property applies when you set the FullPrecisionOverride on page 3-0 property to false or when you set the SumDataType on page 3-0 property Custom.

Methods

step	(To be removed) Demodulate using rectangular QAM method

Common to All System Objects	
release	Allow System object property value changes

More About

Full Precision for Fixed-Point System Objects

FullPrecisionOverride is a convenience property that, when you set to true, automatically sets the appropriate properties for an object to use full-precision to process fixed-point input.

For System objects, full precision, fixed-point operation refers to growing just enough additional bits to compute the ideal full precision result. This operation has no minimum or maximum range overflow nor any precision loss due to rounding or underflow. It is also independent of any hardware-specific settings. The data types chosen are based only on known data type ranges and not on actual numeric values. Full precision for System objects does not optimize coefficient values. When you set the FullPrecisionOverride property to true, the other fixed-point properties it controls no longer apply and any of their non-default values are ignored. These properties are also hidden. To specify individual fixed-point properties, first set FullPrecisionOverride to false.

Algorithms

This object implements the algorithm, inputs, and outputs described on the Rectangular QAM Demodulator Baseband block reference page. The object properties correspond to the block parameters.

Compatibility Considerations

comm.RectangularQAMDemodulator will be removed in a future release. Use qamdmod instead.

Not recommended starting in R2018b

Constellation normalization by PeakPower and AveragePower (other than unit average power) as supported by comm.RectangularQAMModulator and comm.RectangularQAMDemodulator is not inherently provided by functions. To perform peak power and average power normalization using qammod and qamdmod functions, you can use these utility functions to scale symbols from peak or average power normalization to minimum distance normalization.

```

function minD = pkPow2MinD(pkPow,M)
% Peak power to minimum distance
nBits = log2(M);
if (mod(nBits,2)==0)
    % Square QAM
    sf = 0.5*M - sqrt(M) + 0.5;
else
    % Cross QAM
    mBy32 = M/32;
    if (nBits > 4)
        sf = (13 * mBy32) - (5 * sqrt(mBy32)) + 0.5;
    else
        sf = (20 * mBy32) - (6 * sqrt(mBy32)) + 0.5;
    end
end
minD = sqrt(pkPow/sf);
end

function minD = avgPow2MinD(avgPow,M)
% Average power to minimum distance
nBits = log2(M);
if (mod(nBits,2)==0)
    % Square QAM
    sf = (M - 1)/6;
else
    % Cross QAM
    if (nBits > 4)
        sf = ((31 * M / 32) - 1) / 6;
    else
        sf = ((5 * M / 4) - 1) / 6;
    end
end
minD = sqrt(avgPow/sf);
end

```

Peak Power Normalization for Hard Decision

This example compares computation of peak power normalization for hard decision by using the `qammod` and `qamdemod` functions and the `pkPow2MinD` utility function.

```

% QAM alternative for "Peak power" normalization method for
% hard decision output when using functions.
M = 128;
pkPow = 5;
minD = pkPow2MinD(pkPow,M);

modObj = comm.RectangularQAMModulator('ModulationOrder',M, ...
    'NormalizationMethod','Peak power', ...
    'PeakPower',pkPow);
demodObj = comm.RectangularQAMDemodulator('ModulationOrder',M, ...
    'NormalizationMethod','Peak power', ...
    'PeakPower',pkPow);

% Check 1 - Verify that the two constellations are same by
% comparing symbols.
constellationS0 = modObj([0:M-1]');
constellationFcn = qammod([0:M-1]',M);
scaledConstellationFcn = (minD/2) .* constellationFcn;
err = constellationS0 - scaledConstellationFcn;
maxConstellationErr = max(abs(err))

maxConstellationErr =
    0

```

Check 2 - Modulate and demodulate symbols using the System objects.

```
x = randi([0,M-1],100,1);
y1 = modObj(x);
z1 = demodObj(y1);
objModDemodOutputIsEqual = isequal(x,z1)
```

```
objModDemodOutputIsEqual =
    logical
     1
```

% Check 3 - Demodulate the modulator System object output
% using the qamdemod function.

```
y1ScaledForFcn = (2/minD) .* y1;
z2 = qamdemod(y1ScaledForFcn,M);
objModFcnDemodIsEqual = isequal(x,z2)
```

```
objModFcnDemodIsEqual =
    logical
     1
```

% Check 4 - Demodulate the qammod output using the
% demodulator System object.

```
y2 = qammod(x,M);
y2ScaledForS0 = (minD/2) .* y2;
z3 = demodObj(y2ScaledForS0);
fcnModObjDemodIsEqual = isequal(x,z3)
```

```
fcnModObjDemodIsEqual =
    logical
     1
```

Average Power Normalization for Hard Decision

This example compares computation of average power normalization for hard decision by using the qammod and qamdemod functions and the avgPow2MinD utility function..

% QAM alternative for "Average power" normalization method for
% hard decision output when using functions.

```
M = 64;          % Modulation order
avgPow = 100;   % Average constellation power
```

```
minD = avgPow2MinD(avgPow,M);
```

```
modObj = comm.RectangularQAMModulator('ModulationOrder',M, ...
    'NormalizationMethod','Average power', ...
    'AveragePower',avgPow);
demodObj = comm.RectangularQAMDemodulator('ModulationOrder',M, ...
    'NormalizationMethod','Average power', ...
    'AveragePower',avgPow);
```

% Check 1 - Verify that the two constellations are same by
% comparing symbols.

```
constellationS0 = modObj([0:M-1]');
constellationFcn = qammod([0:M-1]',M);
scaledConstellationFcn = (minD/2) .* constellationFcn;
err = constellationS0 - scaledConstellationFcn;
maxConstellationErr = max(abs(err))
```

```
maxConstellationErr =
     0
```

Check 2 - Modulate and demodulate symbols using the System objects.

```
x = randi([0,M-1],100,1);
y1 = modObj(x);
```

```

z1 = demodObj(y1);
objModDemodOutputIsEqual = isequal(x,z1)

objModDemodOutputIsEqual =
    logical
     1

% Check 3 - Demodulate the modulator System object output
% using the qamdemod function.
y1ScaledForFcn = (2/minD) .* y1;
z2 = qamdemod(y1ScaledForFcn,M);
objModFcnDemodIsEqual = isequal(x,z2)

objModFcnDemodIsEqual =
    logical
     1

% Check 4 - Demodulate the qammod output using the
% demodulator System object.
y2 = qammod(x,M);
y2ScaledForS0 = (minD/2) .* y2;
z3 = demodObj(y2ScaledForS0);
fcnModObjDemodIsEqual = isequal(x,z3)

fcnModObjDemodIsEqual =
    logical
     1

Functions

qamdmod | genqamdmod

Objects

comm.GeneralQAMDemodulator

Introduced in R2012a

constellation

System object: `comm.RectangularQAMDemodulator`

Package: `comm`

(To be removed) Calculate or plot ideal signal constellation

Note `comm.RectangularQAMDemodulator` will be removed in a future release. Use `qamdemod` instead.

Syntax

```
y = constellation(h)
constellation(h)
```

Description

`y = constellation(h)` returns the numerical values of the constellation.

`constellation(h)` generates a constellation plot for the object.

Examples

Plot QAM Reference Constellations

Plot QAM reference constellation using the `qammod` and `qamdemod` functions. Show that the `'PlotConstellation',true` Name,Value pair property works for both `qammod` and `qamdemod` functions. Also show the symbol ordering for Gray and binary code ordering by representing the data in binary format.

Create symbols for a 16-QAM modulator.

```
M = 16; % For 16-QAM
refSym = (0:M-1)';
```

Plot the reference constellation using the `qammod` function.

```
qammod(refSym,M,'PlotConstellation',true);
```

The default symbol order is Gray code ordering. To highlight the Gray symbol mapping, replot the reference constellation using binary input type. When you specify 'InputType', 'bit', the input signal must contain binary values, and the number of rows must be an integer multiple of $\log_2(M)$. Transpose the input vector so that the input symbols map to the column vectors.

```
biRefSym = de2bi(refSym);
qammod(biRefSym',M,'PlotConstellation',true,'InputType','bit');
```

Replot the reference constellation using binary-coded symbol ordering.

```
biRefSym = de2bi(refSym);  
qammod(biRefSym',M,'bin','PlotConstellation',true,'InputType','bit');
```

Create symbols for a 64-QAM modulator.

```
M = 64; % For 64-QAM
refSym = (0:M-1);
```

Plot the reference constellation using the `qamdemod` function.

```
qamdemod(refSym,M,'PlotConstellation',true);
```

step

System object: `comm.RectangularQAMDemodulator`

Package: `comm`

(To be removed) Demodulate using rectangular QAM method

Note `comm.RectangularQAMDemodulator` will be removed in a future release. Use `qamdemod` instead.

Syntax

`Y = step(H,X)`

`Y = step(H,X,VAR)`

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(H,X)` demodulates the input data, `X`, with the rectangular QAM demodulator System object, `H`, and returns, `Y`. Input `X` must be a scalar or a column vector with double or single precision data type. When `ModulationOrder` is an even power of two and you set the `BitOutput` property to `false` or, when you set the `DecisionMethod` to `Hard decision` and the `BitOutput` property to `true`, the data type of the input can also be signed integer, or signed fixed point (fi objects). Depending on the `BitOutput` property value, output `Y` can be integer or bit valued.

`Y = step(H,X,VAR)` uses soft decision demodulation and noise variance `VAR`. This syntax applies when you set the `BitOutput` property to `true`, the `DecisionMethod` property to `Approximate log-likelihood ratio` or `Log-likelihood ratio`, and the `VarianceSource` property to `Input port`. The data type of input `VAR` must be double or single precision.

Note `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications. For more information on changing property values, see “System Design in MATLAB Using System Objects”.

comm.RectangularQAMModulator

Package: comm

(To be removed) Modulate using rectangular QAM signal constellation

Note `comm.RectangularQAMModulator` will be removed in a future release. Use `qammod` instead. For more information, see “Compatibility Considerations”.

Description

The `RectangularQAMModulator` object modulates using M-ary quadrature amplitude modulation with a constellation on a rectangular lattice. The output is a baseband representation of the modulated signal. This block accepts a scalar or column vector input signal.

To modulate a signal using quadrature amplitude modulation:

- 1 Define and set up your rectangular QAM modulator object. See “Construction” on page 3-1204.
- 2 Call `step` to modulate the signal according to the properties of `comm.RectangularQAMModulator`. The behavior of `step` is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`H = comm.RectangularQAMModulator` creates a modulator object, `H`. This object modulates the input using the rectangular quadrature amplitude modulation (QAM) method.

`H = comm.RectangularQAMModulator(Name, Value)` creates a rectangular QAM modulator object, `H`, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as `(Name1, Value1, ..., NameN, ValueN)`.

`H = comm.RectangularQAMModulator(M, Name, Value)` creates a rectangular QAM modulator object, `H`. This object has the `ModulationOrder` property set to `M`, and the other specified properties set to the specified values.

Properties

ModulationOrder

Number of points in signal constellation

Specify the number of points in the signal constellation as scalar value that is a positive integer power of two. The default is 16.

PhaseOffset

Phase offset of constellation

Specify the phase offset of the signal constellation, in radians, as a real scalar value. The default is 0.

BitInput

Assume bit inputs

Specify whether the input is bits or integers. The default is `false`. When you set this property to `true`, the `step` method input requires a column vector of bit values. The length of this vector must be an integer multiple of $\log_2(\text{ModulationOrder on page 3-0})$. This vector contains bit representations of integers between 0 and `ModulationOrder-1`. When you set this property to `false`, the `step` method input must be a column vector of integer symbol values between 0 and `ModulationOrder-1`.

SymbolMapping

Constellation encoding

Specify how the object maps an integer or group of $\log_2(\text{ModulationOrder on page 3-0})$ input bits to the corresponding symbol as `Binary` | `Gray` | `Custom`. The default is `Gray`. When you set this property to `Gray`, the System object uses a Gray-coded signal constellation. When you set this property to `Binary`, the object uses a natural binary-coded constellation. When you set this property to `Custom`, the object uses the signal constellation defined in the `CustomSymbolMapping on page 3-0` property.

CustomSymbolMapping

Custom constellation encoding

Specify a custom constellation symbol mapping vector. The default is `0:15`. This property is a row or column vector with a size of `ModulationOrder on page 3-0`. This vector has unique integer values in the range `[0, ModulationOrder-1]`. These values must be of data type `double`. The first element of this vector corresponds to the top-leftmost point of the constellation, with subsequent elements running down column-wise, from left to right. The last element corresponds to the bottom-rightmost point. This property applies when you set the `SymbolMapping on page 3-0` property to `Custom`.

NormalizationMethod

Constellation normalization method

Specify the method used to normalize the signal constellation as `Minimum distance between symbols` | `Average power` | `Peak power`. The default is `Minimum distance between symbols`.

MinimumDistance

Minimum distance between symbols

Specify the distance between two nearest constellation points as a positive, real, numeric scalar value. The default is 2. This property applies when you set the `NormalizationMethod on page 3-0` property to `Minimum distance between symbols`.

AveragePower

Average power of constellation

Specify the average power of the symbols in the constellation as a positive, real, numeric scalar value. The default is 1. This property applies when you set the `NormalizationMethod` on page 3-0 property to `Average power`.

PeakPower

Peak power of constellation

Specify the maximum power of the symbols in the constellation as a positive real, numeric scalar value. The default is 1. This property applies when you set the `NormalizationMethod` on page 3-0 property to `Peak power`.

OutputDataType

Data type of output

Specify the output data type as `double` | `single` | `Custom`. The default is `double`.

Fixed-Point Properties

CustomOutputDataType

Fixed-point data type of output

Specify the output fixed-point type as a `numericType` object with a signedness of `Auto`. The default is `numericType([], 16)`. This property applies when you set the `OutputDataType` on page 3-0 property to `Custom`.

Methods

- `constellation` (To be removed) Calculate or plot ideal signal constellation
- `step` (To be removed) Modulate using rectangular QAM method

Common to All System Objects	
<code>release</code>	Allow System object property value changes

Algorithms

This object implements the algorithm, inputs, and outputs described on the Rectangular QAM Modulator Baseband block reference page. The object properties correspond to the block parameters.

Compatibility Considerations

`comm.RectangularQAMModulator` will be removed in a future release. Use `qammod` instead.
Not recommended starting in R2018b

Constellation normalization by `PeakPower` and `AveragePower` (other than unit average power) as supported by `comm.RectangularQAMModulator` and `comm.RectangularQAMDemodulator` is not

inherently provided by functions. To perform peak power and average power normalization using `qammod` and `qamdemod` functions, you can use these utility functions to scale symbols from peak or average power normalization to minimum distance normalization.

```
function minD = pkPow2MinD(pkPow,M)
% Peak power to minimum distance
    nBits = log2(M);
    if (mod(nBits,2)==0)
        % Square QAM
        sf = 0.5*M - sqrt(M) + 0.5;
    else
        % Cross QAM
        mBy32 = M/32;
        if (nBits > 4)
            sf = (13 * mBy32) - (5 * sqrt(mBy32)) + 0.5;
        else
            sf = (20 * mBy32) - (6 * sqrt(mBy32)) + 0.5;
        end
    end
    end
    minD = sqrt(pkPow/sf);
end
```

```
function minD = avgPow2MinD(avgPow,M)
% Average power to minimum distance
    nBits = log2(M);
    if (mod(nBits,2)==0)
        % Square QAM
        sf = (M - 1)/6;
    else
        % Cross QAM
        if (nBits > 4)
            sf = ((31 * M / 32) - 1) / 6;
        else
            sf = ((5 * M / 4) - 1) / 6;
        end
    end
    end
    minD = sqrt(avgPow/sf);
end
```

Peak Power Normalization for Hard Decision

This example compares computation of peak power normalization for hard decision by using the `qammod` and `qamdemod` functions and the `pkPow2MinD` utility function.

```
% QAM alternative for "Peak power" normalization method for
% hard decision output when using functions.
M = 128;
pkPow = 5;
minD = pkPow2MinD(pkPow,M);

modObj = comm.RectangularQAMModulator('ModulationOrder',M, ...
    'NormalizationMethod','Peak power', ...
    'PeakPower',pkPow);
demodObj = comm.RectangularQAMDemodulator('ModulationOrder',M, ...
    'NormalizationMethod','Peak power', ...
    'PeakPower',pkPow);

% Check 1 - Verify that the two constellations are same by
% comparing symbols.
constellationS0 = modObj([0:M-1]');
constellationFcn = qammod([0:M-1]',M);
scaledConstellationFcn = (minD/2) .* constellationFcn;
err = constellationS0 - scaledConstellationFcn;
maxConstellationErr = max(abs(err))
```

```

maxConstellationErr =
    0

Check 2 - Modulate and demodulate symbols using the System objects.

Functions

qammod | genqammod

Objects

comm.GeneralQAMModulator

Introduced in R2012a

constellation

System object: `comm.RectangularQAMModulator`

Package: `comm`

(To be removed) Calculate or plot ideal signal constellation

Note `comm.RectangularQAMModulator` will be removed in a future release. Use `qammod` instead.

Syntax

```
y = constellation(h)
constellation(h)
```

Description

`y = constellation(h)` returns the numerical values of the constellation.

`constellation(h)` generates a constellation plot for the object.

Examples

Plot QAM Reference Constellations

Plot QAM reference constellation using the `qammod` and `qamdemod` functions. Show that the `'PlotConstellation,true'` Name,Value pair property works for both `qammod` and `qamdemod` functions. Also show the symbol ordering for Gray and binary code ordering by representing the data in binary format.

Create symbols for a 16-QAM modulator.

```
M = 16; % For 16-QAM
refSym = (0:M-1)';
```

Plot the reference constellation using the `qammod` function.

```
qammod(refSym,M,'PlotConstellation',true);
```

The default symbol order is Gray code ordering. To highlight the Gray symbol mapping, replot the reference constellation using binary input type. When you specify 'InputType', 'bit', the input signal must contain binary values, and the number of rows must be an integer multiple of $\log_2(M)$. Transpose the input vector so that the input symbols map to the column vectors.

```
biRefSym = de2bi(refSym);
qammod(biRefSym',M,'PlotConstellation',true,'InputType','bit');
```

Replot the reference constellation using binary-coded symbol ordering.

```
biRefSym = de2bi(refSym);  
qammod(biRefSym',M,'bin','PlotConstellation',true,'InputType','bit');
```

Create symbols for a 64-QAM modulator.

```
M = 64; % For 64-QAM
refSym = (0:M-1);
```

Plot the reference constellation using the `qamdemod` function.

```
qamdemod(refSym,M,'PlotConstellation',true);
```

step

System object: `comm.RectangularQAMModulator`

Package: `comm`

(To be removed) Modulate using rectangular QAM method

Note `comm.RectangularQAMModulator` will be removed in a future release. Use `qammod` instead.

Syntax

`Y = step(H,X)`

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(H,X)` modulates input data, `X`, with the rectangular QAM modulator object, `H`. It returns the baseband modulated output, `Y`. Depending on the value of the `BitInput` property, input `X` can be an integer or bit valued column vector with numeric, logical, or fixed-point data types.

Note `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications. For more information on changing property values, see "System Design in MATLAB Using System Objects".

comm.RectangularQAMTCMDemodulator

Package: comm

Demodulate convolutionally encoded data mapped to rectangular QAM signal constellation

Description

The `RectangularQAMTCMDemodulator` object uses the Viterbi algorithm to decode a trellis-coded modulation (TCM) signal that was previously modulated using a rectangular QAM signal constellation.

To demodulate convolutionally encoded data mapped to a rectangular QAM signal constellation:

- 1 Define and set up your rectangular QAM TCM demodulator object. See “Construction” on page 3-1220.
- 2 Call `step` to demodulate the signal according to the properties of `comm.RectangularQAMTCMDemodulator`. The behavior of `step` is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`H = comm.RectangularQAMTCMDemodulator` creates a trellis-coded, rectangular, quadrature amplitude (QAM TCM) demodulator System object, `H`. This object demodulates convolutionally encoded data that has been mapped to a rectangular QAM constellation.

`H = comm.RectangularQAMTCMDemodulator(Name, Value)` creates a rectangular, QAM TCM, demodulator object, `H`, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as `(Name1, Value1, ..., NameN, ValueN)`.

`H = comm.RectangularQAMTCMDemodulator(TRELLIS, Name, Value)` creates a rectangular QAM TCM demodulator object, `H`. This object has the `TrellisStructure` property set to `TRELLIS`, and the other specified properties set to the specified values.

Properties

TrellisStructure

Trellis structure of convolutional code

Specify `trellis` as a MATLAB structure that contains the trellis description of the convolutional code. Use the `istrellis` function to check whether a structure is a valid trellis. The default is the result of `poly2trellis([3 1 1], [5 2 0 0; 0 0 1 0; 0 0 0 1])`.

TerminationMethod

Termination method of encoded frame

Specify the termination method as `Continuous` | `Truncated` | `Terminated`. The default is `Continuous`.

When you set this property to `Continuous`, the object saves the internal state metric at the end of each frame. The next frame uses the same state metric. The object treats each traceback path independently. If the input signal contains only one symbol, you should use `Continuous` mode.

When you set this property to `Truncated`, the object treats each input vector independently. The traceback path starts at the state with the best metric and always ends in the all-zeros state.

When you set this property to `Terminated`, the object treats each input vector independently, and the traceback path always starts and ends in the all-zeros state.

TracebackDepth

Traceback depth for Viterbi decoder

Specify the scalar, integer number of trellis branches to construct each traceback path. The default is 21. The Traceback depth parameter influences the decoding accuracy and delay. The decoding delay is the number of zero symbols that precede the first decoded symbol in the output.

When you set the `TerminationMethod` property to `Continuous`, the decoding delay consists of `TracebackDepth` zero symbols or `TracebackDepth`× K zero bits for a rate K/N convolutional code.

When you set the `TerminationMethod` property to `Truncated` or `Terminated`, no output delay occurs and the traceback depth must be less than or equal to the number of symbols in each input vector.

ResetInputPort

Enable demodulator reset input

Set this property to `true` to enable an additional input to the `step` method. The default is `false`. When this additional reset input is a nonzero value, the internal states of the encoder reset to initial conditions. This property applies when you set the `TerminationMethod` property to `Continuous`.

ModulationOrder

Number of points in signal constellation

Specify the number of points in the signal constellation used to map the convolutionally encoded data as a positive, integer scalar value. The number of points must be 4, 8, 16, 32, or 64. The default is 16. The `ModulationOrder` property value must equal the number of possible input symbols to the convolutional decoder of the rectangular QAM TCM demodulator object. The `ModulationOrder` must equal 2^N for a rate K/N convolutional code.

OutputDataType

Data type of output

Specify output data type as `logical` | `double`. The default is `double`.

Methods

step Demodulate convolutionally encoded data mapped to rectangular QAM constellation

Common to All System Objects	
release	Allow System object property value changes
reset	Reset internal states of System object

Examples

Modulate and Demodulate Using Rectangular 16-QAM TCM

Modulate and demodulate data using 16-QAM TCM in an AWGN channel. Estimate the BER.

Create QAM TCM modulator and demodulator System objects™.

```
hMod = comm.RectangularQAMTCMModulator;
hDemod = comm.RectangularQAMTCMDemodulator('TracebackDepth',16);
```

Create an AWGN channel object.

```
hAWGN = comm.AWGNChannel('EbNo',5);
```

Determine the delay through the QAM TCM demodulator. The demodulator uses the Viterbi algorithm to decode the TCM signal that was modulated using rectangular QAM. To accurately calculate the bit error rate, the delay through the decoder must be known.

```
bitsPerSymbol = log2(hDemod.TrellisStructure.numInputSymbols);
delay = hDemod.TracebackDepth*bitsPerSymbol;
```

Create an error rate calculator object with the `ReceiveDelay` property set to `delay`.

```
hErrorCalc = comm.ErrorRate('ReceiveDelay',delay);
```

Generate binary data and modulate with 16-QAM TCM. Pass the signal through an AWGN channel and demodulate. Calculate the error statistics. The loop runs until either 100 bit errors are encountered or 1e7 total bits are transmitted.

```
% Initialize the error results vector.
errStats = [0 0 0];

while errStats(2) < 100 && errStats(3) < 1e7
    % Transmit frames of 200 3-bit symbols
    txData = randi([0 1],600,1);
    % Modulate
    txSig = step(hMod,txData);
    % Pass through AWGN channel
    rxSig = step(hAWGN,txSig);
    % Demodulate
    rxData = step(hDemod,rxSig);
    % Collect error statistics
    errStats = step(hErrorCalc,txData,rxData);
end
```

Display the error data.

```
fprintf('Error rate = %4.2e\nNumber of errors = %d\n', ...  
       errStats(1),errStats(2))
```

```
Error rate = 1.94e-03  
Number of errors = 100
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the Rectangular QAM TCM Decoder block reference page. The object properties correspond to the block parameters.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

Introduced in R2012a

step

System object: `comm.RectangularQAMTCMDemodulator`

Package: `comm`

Demodulate convolutionally encoded data mapped to rectangular QAM constellation

Syntax

```
Y = step(H,X)  
Y = step(H,X,R)
```

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(H,X)` demodulates the rectangular QAM modulated input data, `X`, and uses the Viterbi algorithm to decode the resulting demodulated, convolutionally encoded bits. `X` must be a complex, double or single precision column vector. The `step` method outputs a demodulated, binary data column vector, `Y`. When the convolutional encoder represents a rate K/N code, the length of the output vector is $K*L$, where L is the length of the input vector, `X`.

`Y = step(H,X,R)` resets the decoder to the all-zeros state when you input a reset signal, `R` that is non-zero. `R` must be a double precision or logical, scalar integer. This syntax applies when you set the `ResetInputPort` property to `true`.

Note `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications. For more information on changing property values, see “System Design in MATLAB Using System Objects”.

comm.RectangularQAMTCMModulator

Package: comm

Convolutionally encode binary data and map using rectangular QAM signal constellation

Description

The `RectangularQAMTCMModulator` object implements trellis-coded modulation (TCM) by convolutionally encoding the binary input signal and mapping the result to a rectangular QAM signal constellation.

To convolutionally encode binary data and map the result using a rectangular QAM constellation:

- 1 Define and set up your rectangular QAM TCM modulator object. See “Construction” on page 3-1225.
- 2 Call `step` to modulate the signal according to the properties of `comm.RectangularQAMTCMModulator`. The behavior of `step` is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`H = comm.RectangularQAMTCMModulator` creates a trellis-coded, rectangular, quadrature amplitude (QAM TCM) System object, `H`. This object convolutionally encodes a binary input signal and maps the result to a rectangular QAM constellation.

`H = comm.RectangularQAMTCMModulator(Name, Value)` creates a rectangular QAM TCM modulator object, `H`, with each specified property set to the specified value. You can specify additional name-value pair arguments in any order as `(Name1, Value1, ..., NameN, ValueN)`.

`H = comm.RectangularQAMTCMModulator(TRELLIS, Name, Value)` creates a rectangular QAM TCM modulator object, `H`. This object has the `TrellisStructure` property set to `TRELLIS` and the other specified properties set to the specified values.

Properties

TrellisStructure

Trellis structure of convolutional code

Specify `trellis` as a MATLAB structure that contains the trellis description of the convolutional code. Use the `istrellis` function to check whether a structure is a valid trellis. The default is the result of `poly2trellis([3 1 1], [5 2 0 0; 0 0 1 0; 0 0 0 1])`.

TerminationMethod

Termination method of encoded frame

Specify the termination method as `Continuous` | `Truncated` | `Terminated`. The default is `Continuous`.

When you set this property to `Continuous`, the object retains the encoder states at the end of each input vector for use with the next input vector.

When you set this property to `Truncated`, the object treats each input vector independently. The encoder is reset to the all-zeros state at the start of each input vector.

When you set this property to `Terminated`, the object treats each input vector independently. For each input vector, the object uses extra bits to set the encoder to the all-zeros state at the end of the vector. For a rate K/N code, the `step` method outputs the vector with a length given by $y = N \times (L + S)/K$, where $S = \text{constraintLength}-1$ (or, in the case of multiple constraint lengths, $S = \text{sum}(\text{constraintLength}(i)-1)$). L is the length of the input to the `step` method.

ResetInputPort

Enable modulator reset input

Set this property to true to enable an additional input to the `step` method. The default is `false`. When you set the reset input to the `step` method to a nonzero value, the object resets the encoder to the all-zeros state. This property applies when you set the `TerminationMethod` on page 3-0 property to `Continuous`.

ModulationOrder

Number of points in signal constellation

Specify the number of points in the signal constellation used to map the convolutionally encoded data as a positive integer scalar value equal to 4, 8, 16, 32, or 64. The default is 16. The value of the `ModulationOrder` on page 3-0 property must equal the number of possible output symbols from the convolutional encoder of the QAM TCM modulator. Thus, the value for the `ModulationOrder` property must equal 2^N for a rate K/N convolutional code.

OutputDataType

Data type of output

Specify the output data type as one of `double` | `single`. The default is `double`.

Methods

`step` Convolutionally encode binary data and map using rectangular QAM constellation

Common to All System Objects	
<code>release</code>	Allow System object property value changes
<code>reset</code>	Reset internal states of System object

Examples

Modulate Data Using Rectangular QAM TCM

Modulate data using rectangular 16-QAM TCM modulation and display the scatter plot.

Generate random binary data. The length of the data vector must be an integer multiple of the number of input streams into the encoder, $\log_2(8) = 3$.

```
data = randi([0 1],3000,1);
```

Create a modulator System object™ and use its step function to modulate the data.

```
hMod = comm.RectangularQAMTCMModulator;  
modData = step(hMod,data);
```

Plot the modulated data.

```
scatterplot(modData)
```

Algorithms

This object implements the algorithm, inputs, and outputs described on the Rectangular QAM TCM Encoder block reference page. The object properties correspond to the block parameters.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

`comm.RectangularQAMTCMDemodulator` | `comm.GeneralQAMTCModulator` |
`comm.ConvolutionalEncoder`

Introduced in R2012a

step

System object: `comm.RectangularQAMTCMModulator`

Package: `comm`

Convolutionally encode binary data and map using rectangular QAM constellation

Syntax

```
Y = step(H,X)
Y = step(H,X,R)
```

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`Y = step(H,X)` convolutionally encodes and modulates the input data numeric or logical column vector `X`, and returns the encoded and modulated data, `Y`. `X` must be of data type numeric, logical, or unsigned fixed point of word length 1 (fi object). When the convolutional encoder represents a rate K/N code, the length of the input vector, `X`, must be $K \times L$, for some positive integer L . The `step` method outputs a complex column vector, `Y`, of length L .

`Y = step(H,X,R)` resets the encoder of the rectangular QAM TCM modulator object to the all-zeros state when you input a non-zero reset signal, `R`. `R` must be a double precision or logical, scalar integer. This syntax applies when you set the `ResetInputPort` property to `true`.

Note `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications. For more information on changing property values, see "System Design in MATLAB Using System Objects".

comm.RicianChannel

Package: comm

Filter input signal through multipath Rician fading channel

Description

The `comm.RicianChannel` System object filters an input signal through a multipath Rician fading channel. For more information on fading model processing, see the Methodology for Simulating Multipath Fading Channels section.

To filter an input signal through a multipath Rician fading channel:

- 1 Create the `comm.RicianChannel` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

Creation

Syntax

```
ricianchan = comm.RicianChannel  
ricianchan = comm.RicianChannel(Name,Value)
```

Description

`ricianchan = comm.RicianChannel` creates a frequency-selective or frequency-flat multipath Rician fading channel System object. This object filters a real or complex input signal through the multipath channel to obtain a channel-impaired signal.

`ricianchan = comm.RicianChannel(Name,Value)` sets properties using one or more name-value arguments. For example, `'SampleRate',2` sets the input signal sample rate to 2.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see [System Design in MATLAB Using System Objects](#).

SampleRate — Input signal sample rate

1 (default) | positive scalar

Input signal sample rate in hertz, specified as a positive scalar.

Data Types: `double`

PathDelays — Discrete path delay

0 (default) | scalar | row vector

Discrete path delay in seconds, specified as a scalar or row vector.

- When you set `PathDelays` to a scalar, the channel is frequency flat.
- When you set `PathDelays` to a vector, the channel is frequency selective.

The `PathDelays` and `AveragePathGains` properties must be the same length.

Data Types: `double`

AveragePathGains — Average gains of discrete paths

0 (default) | scalar | row vector

Average gains of the discrete paths in decibels, specified as a scalar or row vector. The `AveragePathGains` and `PathDelays` properties must be the same length.

Data Types: `double`

NormalizePathGains — Normalize average path gains

`true` or 1 (default) | `false` or 0

Normalize average path gains, specified as one of these logical values:

- 1 (`true`) — The fading processes are normalized so that the total power of the path gains, averaged over time, is 0 dB.
- 0 (`false`) — The total power of the path gains is not normalized.

The `AveragePathGains` property specifies the average powers of the path gains.

Data Types: `logical`

KFactor — K-factor of Rician fading channel

3 (default) | positive scalar | 1-by- N_p vector of nonnegative values

K-factor of Rician fading channel, specified as a positive scalar or a 1-by- N_p vector of nonnegative values. N_p is the number of discrete path delays specified by the `PathDelays` property.

- When you set `KFactor` to a scalar, the first discrete path is a Rician fading process with a Rician K-factor of `KFactor`. Any remaining discrete paths are independent Rayleigh fading processes.
- When you set `KFactor` to a vector, the discrete path corresponding to a positive element of the `KFactor` vector is a Rician fading process with a Rician K-factor specified by that element. The discrete path corresponding to any zero-valued elements of the `KFactor` vector are Rayleigh fading processes. At least one element must be nonzero.

Data Types: `double`

DirectPathDopplerShift — Doppler shifts for line-of-sight components

0 (default) | scalar | row vector

Doppler shifts for the line-of-sight components of the multipath Rician fading channel, specified as a scalar or row vector. Units are in hertz. This property must be the same size as the `KFactor` property.

- When you set `DirectPathDopplerShift` to a scalar, the value represents the line-of-sight component Doppler shift of the first discrete path. This path exhibits a Rician fading process.
- When you set `DirectPathDopplerShift` to a row vector, the discrete path corresponding to a positive element of the `KFactor` vector is a Rician fading process. The corresponding element of `DirectPathDopplerShift` specifies the line-of-sight component for the Doppler shift of that discrete path.

Data Types: `double`

DirectPathInitialPhase — Initial phases for line-of-sight components

`0` (default) | `scalar` | `row vector`

Initial phase for the line-of-sight components of a multipath Rician fading channel, specified as a scalar or row vector. Units are in radians. This property must be the same size as the `KFactor` property.

- When you set `DirectPathInitialPhase` to a scalar, the value represents the line-of-sight component initial phase of the first discrete path. This path exhibits a Rician fading process.
- When you set `DirectPathInitialPhase` to a row vector, the discrete path corresponding to a positive element of the `KFactor` vector is a Rician fading process. The corresponding element of `DirectPathInitialPhase` specifies the line-of-sight component initial phase of that discrete path.

Data Types: `double`

MaximumDopplerShift — Maximum Doppler shift for all channel paths

`0.001` (default) | `nonnegative scalar`

Maximum Doppler shift for all channel paths, specified as a nonnegative scalar. Units are in hertz.

The maximum Doppler shift limit applies to each channel path. When you set this property to `0`, the channel remains static for the entire input. You can use the `reset` object function to generate a new channel realization. The `MaximumDopplerShift` property value must be smaller than $\text{SampleRate}/10/f_c$ for each path. f_c is the cutoff frequency factor of the path. For most Doppler spectrum types, the value of f_c is 1. For Gaussian and bi-Gaussian Doppler spectrum types, the value of f_c is dependent on the Doppler spectrum structure fields. For more details about how f_c is defined, see the “Cutoff Frequency Factor” on page 3-1247 section.

Data Types: `double`

DopplerSpectrum — Doppler spectrum shape for all channel paths

`doppler('Jakes')` (default) | `Doppler spectrum structure` | `1-by- N_p cell array of Doppler spectrum structures`

Doppler spectrum shape for all channel paths, specified as a Doppler spectrum structure or a `1-by- N_p` cell array of Doppler spectrum structures. These Doppler spectrum structures must be outputs of the form returned from the `doppler` function. N_p is the number of discrete delay paths specified by the `PathDelays` property. The `MaximumDopplerShift` property defines the maximum Doppler shift value that the `DopplerSpectrum` property permits when you specify the Doppler spectrum.

- When you set `DopplerSpectrum` to a single Doppler spectrum structure, all paths have the same specified Doppler spectrum.
- When you set `DopplerSpectrum` to a cell array of Doppler spectrum structures, each path has the Doppler spectrum specified by the corresponding structure in the cell array.

Specify options for the spectrum type by using the `specType` input to the `doppler` function. If you set the `FadingTechnique` property to 'Sum of sinusoids', you must set `DopplerSpectrum` to `doppler('Jakes')`.

Dependencies

To enable this property, set the `MaximumDopplerShift` property to a positive scalar.

Data Types: `struct` | `cell`

ChannelFiltering — Channel filtering

`true` or `1` (default) | `false` or `0`

Channel filtering, specified as one of these logical values:

- `1` (`true`) — The channel accepts an input signal and produces a filtered output signal.
- `0` (`false`) — The object does not accept an input signal, produces no filtered output signal, and outputs only channel path gains. You must specify the duration of the fading process by using the `NumSamples` property.

Data Types: `logical`

PathGainsOutputPort — Output channel path gains

`false` or `0` (default) | `true` or `1`

Output channel path gains, specified as a logical `0` (`false`) or `1` (`true`). Set this property to `true` to output the channel path gains of the underlying fading process.

Dependencies

To enable this property, set the `ChannelFiltering` property to `true`.

Data Types: `logical`

NumSamples — Number of samples

`100` (default) | nonnegative integer

Number of samples used for the duration of the fading process, specified as a nonnegative integer.

Tunable: Yes

Dependencies

To enable this property, set the `ChannelFiltering` property to `false`.

Data Types: `double`

OutputDataType — Path gain output data type

'double' (default) | 'single'

Path gain output data type, specified as 'double' or 'single'.

Dependencies

To enable this property, set the `ChannelFiltering` property to `false`.

Data Types: `char` | `string`

FadingTechnique — Channel model fading technique

'Filtered Gaussian noise' (default) | 'Sum of sinusoids'

Channel model fading technique, specified as 'Filtered Gaussian noise' or 'Sum of sinusoids'.

Data Types: char | string

NumSinusoids — Number of sinusoids

48 (default) | positive integer

Number of sinusoids used to model the fading process, specified as a positive integer.

Dependencies

To enable this property, set the FadingTechnique property to 'Sum of sinusoids'.

Data Types: double

InitialTimeSource — Source to control start time of fading process

'Property' (default) | 'Input port'

Source to control the start time of the fading process, specified as 'Property' or 'Input port'.

- When you set InitialTimeSource to 'Property', set the initial time offset by using the InitialTime property.
- When you set InitialTimeSource to 'Input port', specify the start time of the fading process by using the inittime input argument. The input value can change in consecutive calls to the object.

Dependencies

To enable this property, set the FadingTechnique property to 'Sum of sinusoids'.

Data Types: char | string

InitialTime — Initial time offset

0 (default) | nonnegative scalar

Initial time offset for the fading model in seconds, specified as a nonnegative scalar.

When $\text{mod}(\text{InitialTime}/\text{SampleRate})$ is nonzero, the initial time offset is rounded up to the nearest sample position.

Dependencies

To enable this property, set the FadingTechnique property to 'Sum of sinusoids' and the InitialTimeSource property to 'Property'.

Data Types: double

RandomStream — Source of random number stream

'Global stream' (default) | 'mt19937ar with seed'

Source of the random number stream, specified as 'Global stream' or 'mt19937ar with seed'.

- When you specify 'Global stream', the object uses the current global random number stream for normally distributed random number generation. In this case, the reset object function resets only the filters.
- When you specify 'mt19937ar with seed', the object uses the mt19937ar algorithm for normally distributed random number generation. In this case, the reset object function resets the filters and reinitializes the random number stream to the value of the Seed property.

Data Types: char | string

Seed — Initial seed of mt19937ar random number stream

73 (default) | nonnegative integer

Initial seed of the mt19937ar random number stream generator algorithm, specified as a nonnegative integer. When you call the reset object function, it reinitializes the mt19937ar random number stream to the Seed value.

Dependencies

To enable this property, set the RandomStream property to 'mt19937ar with seed'.

Data Types: double

Visualization — Channel visualization

'Off' (default) | 'Impulse response' | 'Frequency response' | 'Impulse and frequency responses' | 'Doppler spectrum'

Channel visualization, specified as 'Off', 'Impulse response', 'Frequency response', 'Impulse and frequency responses', or 'Doppler spectrum'. For more information, see the “Channel Visualization” on page 3-1248 section.

Dependencies

To enable this property, set the FadingTechnique property to 'Filtered Gaussian noise'.

Data Types: char | string

PathsForDopplerDisplay — Path used for displaying Doppler spectrum

1 (default) | positive integer

Path used for displaying the Doppler spectrum, specified as a positive integer in the range $[1, N_p]$. N_p is the number of discrete delay paths specified by the PathDelays property. Use this property to select the discrete path used in constructing a Doppler spectrum plot.

Dependencies

To enable this property, set the Visualization property to 'Doppler spectrum'.

Data Types: double

SamplesToDisplay — Percentage of samples to display

'25%' (default) | '10%' | '50%' | '100%'

Percentage of samples to display, specified as '25%', '10%', '50%', or '100%'. Increasing the percentage improves display accuracy at the expense of simulation speed.

Dependencies

To enable this property, set the `Visualization` property to 'Impulse response', 'Frequency response', or 'Impulse and frequency responses'.

Data Types: char | string

Usage

Syntax

```
y = ricianchan(x)
y = ricianchan(x, inittime)
[y, pathgains] = ricianchan( ___ )
```

```
pathgains = ricianchan()
pathgains = ricianchan(inittime)
```

Description

`y = ricianchan(x)` filters input signal `x` through a multipath Rician fading channel and returns the result in `y`.

To enable this syntax, set the `ChannelFiltering` property to `true`.

`y = ricianchan(x, inittime)` specifies a start time for the fading process.

To enable this syntax, set the `FadingTechnique` property to 'Sum of sinusoids' and the `InitialTimeSource` property to 'Input port'.

`[y, pathgains] = ricianchan(___)` also returns the channel path gains of the underlying multipath Rician fading process in `pathgains` using any of the input argument combinations in the previous syntaxes.

To enable this syntax, set the `PathGainsOutputPort` property to `true`.

`pathgains = ricianchan()` returns the channel path gains of the underlying fading process. In this case, the channel requires no input signal and acts as a source of path gains.

To enable this syntax, set the `ChannelFiltering` property to `false`.

`pathgains = ricianchan(inittime)` returns the channel path gains of the underlying fading process beginning at the specified initial time. In this case, the channel requires no input signal and acts as a source of path gains.

To enable this syntax, set the `FadingTechnique` property to 'Sum of sinusoids', the `InitialTimeSource` property to 'Input port', and the `ChannelFiltering` property to `false`.

Input Arguments

x — Input signal

N_S -by-1 vector

Input signal, specified as an N_S -by-1 vector, where N_S is the number of samples.

Data Types: `single` | `double`
 Complex Number Support: Yes

inittime — Initial time offset

0 | nonnegative scalar

Initial time offset in seconds, specified as a nonnegative scalar.

When `mod(inittime/SampleRate)` is nonzero, the initial time offset is rounded up to the nearest sample position.

Data Types: `single` | `double`

Output Arguments

y — Output signal

N_S -by-1 vector

Output signal, returned as an N_S -by-1 vector of complex values with the same data precision as input signal `x`. N_S is the number of samples.

pathgains — Output path gains

N_S -by- N_P matrix

Output path gains, returned as an N_S -by- N_P matrix. N_S is the number of samples. N_P is the number of discrete delay paths specified by the `PathDelays` property. `pathgains` contains complex values.

When you set the `ChannelFiltering` property to `false`, the data type of this output has the same precision as the input signal `x`. When you set the `ChannelFiltering` property to `true`, the data type of this output is specified by the `OutputDataType` property.

Object Functions

To use an object function, specify the `System` object as the first input argument. For example, to release system resources of a `System` object named `obj`, use this syntax:

```
release(obj)
```

Specific to comm.RicianChannel

`info` Characteristic information about fading channel object

Common to All System Objects

<code>step</code>	Run <code>System</code> object algorithm
<code>release</code>	Release resources and allow changes to <code>System</code> object property values and input characteristics
<code>reset</code>	Reset internal states of <code>System</code> object

Examples

Produce Same Rician Channel Outputs Using Two Random Number Generation Methods

Produce the same multipath Rician fading channel response by using two different methods for random number generation. The multipath Rician fading channel `System` object includes two methods

for random number generation. You can use the current global stream or the mt19937ar algorithm with a specified seed. By interacting with the global stream, the System object can produce the same outputs from the two methods.

Create a PSK modulator System object to modulate randomly generated data.

```
pskModulator = comm.PSKModulator;  
insig = randi([0,pskModulator.ModulationOrder-1],1024,1);  
channelInput = pskModulator(insig);
```

Create a multipath Rician fading channel System object, specifying the random number generation method as the my19937ar algorithm and the random number seed as 73.

```
ricianchan = comm.RicianChannel( ...  
    'SampleRate',1e6, ...  
    'PathDelays',[0.0 0.5 1.2]*1e-6, ...  
    'AveragePathGains',[0.1 0.5 0.2], ...  
    'KFactor',2.8, ...  
    'DirectPathDopplerShift',5.0, ...  
    'DirectPathInitialPhase',0.5, ...  
    'MaximumDopplerShift',50, ...  
    'DopplerSpectrum',doppler('Bell', 8), ...  
    'RandomStream','mt19937ar with seed', ...  
    'Seed',73, ...  
    'PathGainsOutputPort',true);
```

Filter the modulated data by using the multipath Rician fading channel System object.

```
[RicianChanOut1,RicianPathGains1] = ricianchan(channelInput);
```

Set the System object to use the global stream for random number generation.

```
release(ricianchan);  
ricianchan.RandomStream = 'Global stream';
```

Set the global stream to have the same seed that you specified when creating the multipath Rician fading channel System object.

```
rng(73)
```

Filter the modulated data by using the multipath Rician fading channel System object again.

```
[RicianChanOut2,RicianPathGains2] = ricianchan(channelInput);
```

Verify that the channel and path gain outputs are the same for each of the two methods.

```
isequal(RicianChanOut1,RicianChanOut2)
```

```
ans = logical  
     1
```

```
isequal(RicianPathGains1,RicianPathGains2)
```

```
ans = logical  
     1
```

Display Impulse and Frequency Responses of Multipath Rician Fading Channel

Display the impulse and frequency responses of a frequency-selective multipath Rician fading channel that is configured to disable channel filtering.

Define simulation variables. Specify path delays and gains by using the ITU pedestrian B channel configuration.

```
fs = 3.84e6; % Sample rate in Hz
pathDelays = [0 200 800 1200 2300 3700]*1e-9; % in seconds
avgPathGains = [0 -0.9 -4.9 -8 -7.8 -23.9]; % dB
kfact = 10; % Rician K-factor
fD = 50; % Max Doppler shift in Hz
```

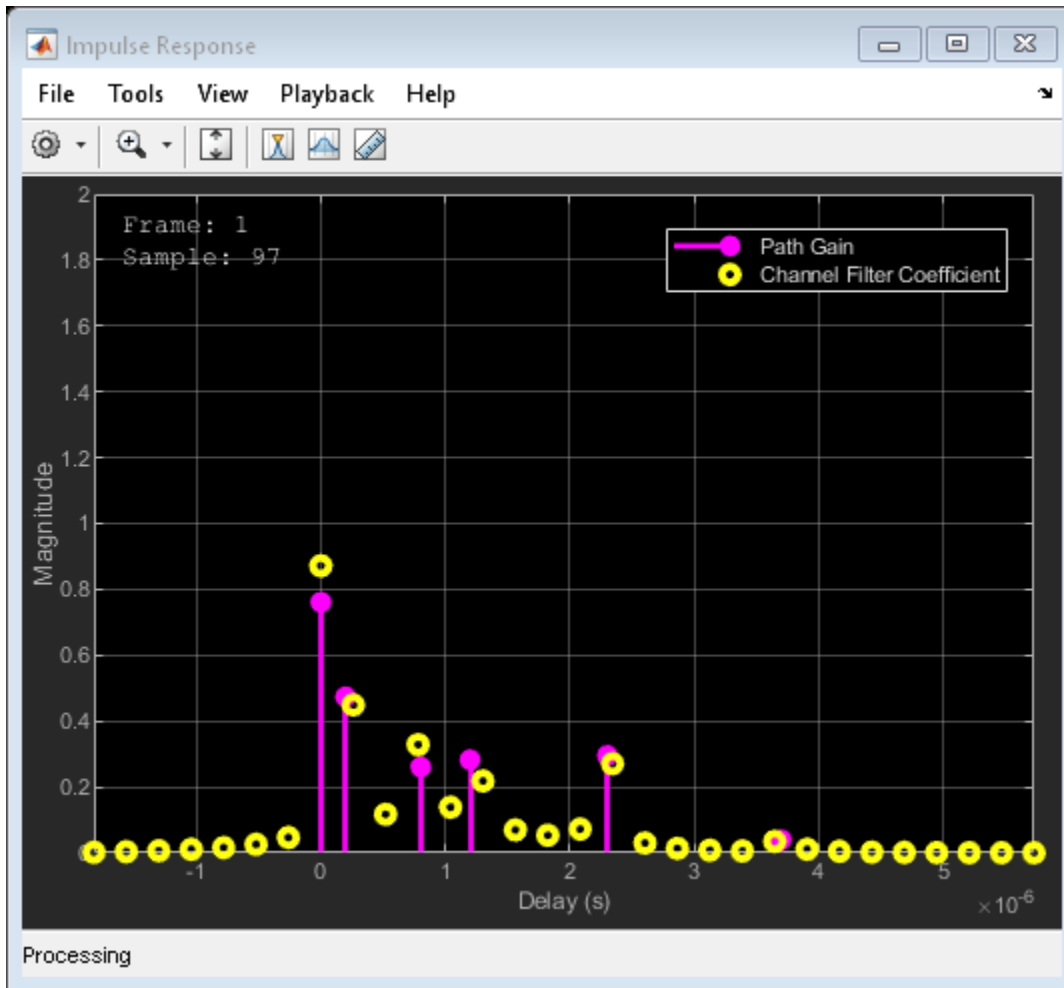

Create a multipath Rician fading channel System object to visualize the impulse response and frequency response plots.

```
ricianChan = comm.RicianChannel('SampleRate',fs, ...
    'PathDelays',pathDelays, ...
    'AveragePathGains',avgPathGains, ...
    'KFactor',kfact, ...
    'MaximumDopplerShift',fD, ...
    'ChannelFiltering',false, ...
    'Visualization','Impulse and frequency responses');
```

Visualize the channel response by running the multipath Rician fading channel System object with no input signal. The impulse response plot enables you to identify the individual paths and their corresponding filter coefficients. The frequency response plot shows the frequency-selective nature of the ITU pedestrian B channel.

```
ricianChan();
```

Model Rician Channel Using Sum-of-Sinusoids Technique

Show that the channel state is maintained for discontinuous transmissions by using multipath Rician fading channel System objects configured to use the sum-of-sinusoids fading technique. Observe discontinuous channel response segments overlaid on a continuous channel response.

Set the channel properties.

```
fs = 1000; % Sample rate in Hz
pathDelays = [0 2.5e-3]; % In seconds
pathPower = [0 -6]; % In dB
fd = 5; % Maximum Doppler shift in Hz
ns = 1000; % Number of samples
nsdel = 100; % Number of samples for delayed paths
```

Define a continuous time span and three discontinuous time segments over which to plot and view the channel response. View a 1000-sample continuous channel response that starts at time 0 and three 100-sample channel responses that start at times 0.1, 0.4, and 0.7 seconds, respectively.

```
to0 = 0.0;
to1 = 0.1;
to2 = 0.5;
to3 = 0.8;
t0 = (to0:ns-1)/fs;      % Transmission 0
t1 = to1+(0:nsdel-1)/fs; % Transmission 1
t2 = to2+(0:nsdel-1)/fs; % Transmission 2
t3 = to3+(0:nsdel-1)/fs; % Transmission 3
```

Create a frequency-flat multipath Rician fading System object, specifying a 1000 Hz sampling rate, the sum-of-sinusoids fading technique, disabled channel filtering, and the number of samples to view. Specify a seed value so that results can be repeated. Use the default `InitialTime` property setting so that the fading channel is simulated from time 0.

```
ricianchan1 = comm.RicianChannel('SampleRate',fs, ...
    'MaximumDopplerShift',fD, ...
    'RandomStream','mt19937ar with seed', ...
    'Seed',17, ...
    'FadingTechnique','Sum of sinusoids', ...
    'ChannelFiltering',false, ...
    'NumSamples',ns);
```

Create a clone of the multipath Rician fading channel System object. Set the number of samples for the delayed paths. Set the source for the initial time so that you can specify the fading channel offset time as an input argument when using the System object.

```
ricianchan2 = clone(ricianchan1);
ricianchan2.InitialTimeSource = 'Input port';
ricianchan2.NumSamples = nsdel;
```

Save the path gain output for the continuous channel response by using the `ricianchan1` object and for the discontinuous delayed channel responses by using the `ricianchan2` object with the initial time offsets provided as input arguments.

```
pg0 = ricianchan1();
pg1 = ricianchan2(to1);
pg2 = ricianchan2(to2);
pg3 = ricianchan2(to3);
```

Compare the number of samples processed by the two channels by using the `info` object function. The `ricianchan1` object processed 1000 samples, while the `ricianchan2` object processed only 300 samples.

```
G = info(ricianchan1);
H = info(ricianchan2);
[G.NumSamplesProcessed H.NumSamplesProcessed]
```

```
ans = 1×2
      1000      300
```

Convert the path gains into decibels.

```
pathGain0 = 20*log10(abs(pg0));
pathGain1 = 20*log10(abs(pg1));
pathGain2 = 20*log10(abs(pg2));
pathGain3 = 20*log10(abs(pg3));
```

Plot the path gains for the continuous and discontinuous cases. The gains for the three segments match the gain for the continuous case. Because the channel characteristics are maintained even when data is not transmitted, the alignment of the two plots shows that the sum-of-sinusoids technique is suited to the simulation of packetized data.

```
plot(t0,pathGain0,'r--')
hold on
plot(t1,pathGain1,'b')
plot(t2,pathGain2,'b')
plot(t3,pathGain3,'b')
grid
xlabel('Time (s)')
ylabel('Path Gain (dB)')
legend('Continuous','Discontinuous','location','nw')
title('Continuous and Discontinuous Transmission Path Gains')
```

Reproduce Multipath Rician Fading Channel Response

Reproduce the multipath Rician fading channel output by using the `ChannelFilterCoefficients` property returned by the `info` object function of the `comm.RicianChannel` System object.

Create a multipath Rician fading channel System object, defining two paths. Generate data to pass through the channel.

```
ricianchan = comm.RicianChannel( ...
    'SampleRate',1000, ...
    'PathDelays',[0 1e-3], ...
    'AveragePathGains',[0 -2], ...
    'PathGainsOutputPort',true)

ricianchan =
    comm.RicianChannel with properties:

        SampleRate: 1000
        PathDelays: [0 1.0000e-03]
        AveragePathGains: [0 -2]
        NormalizePathGains: true
        KFactor: 3
        DirectPathDopplerShift: 0
        DirectPathInitialPhase: 0
        MaximumDopplerShift: 1.0000e-03
        DopplerSpectrum: [1x1 struct]
        ChannelFiltering: true
        PathGainsOutputPort: true
```

Show all properties

```
data = randi([0 1],600,1);
```

Pass data through the channel. Assign the ChannelFilterCoefficients property value to the variable `coeff`.

```
[chanout1,pg] = ricianchan(data);
chaninfo = info(ricianchan)
```

```
chaninfo = struct with fields:
    ChannelFilterDelay: 0
    ChannelFilterCoefficients: [2x2 double]
    NumSamplesProcessed: 600
```

```
coeff = chaninfo.ChannelFilterCoefficients;
```

Calculate the fractional delayed input signal at the path delay locations stored in `coeff`.

```
Np = length(ricianchan.PathDelays);
fracdelaydata = zeros(size(data,1),Np);
for ii = 1:Np
    fracdelaydata(:,ii) = filter(coeff(ii,:),1,data);
end
```

Apply the path gains and sum the results for all paths.

```
chanout2 = sum(pg .* fracdelaydata,2);
```

Compare the output of the multipath Rician fading channel System object to the output reproduced using the path gains and the ChannelFilterCoefficients property of the multipath Rician fading channel System object.

```
isequal(chanout1,chanout2)
```

```
ans = logical
     1
```

Compare PDF of Empirical and Theoretical Rician Channel

Compute and plot the empirical and theoretical probability density function (PDF) for a Rician channel with one path.

Initialize parameters and create a Rician channel System object that does not apply channel filtering.

```
Ns = 1.92e6;
Rs = 1.92e6;
dopplerShift = 2000;
KFactor = -3; % In dB
KFactorLin = 10.^(KFactor/10); % Linear units
```

```
chan = comm.RicianChannel( ...
    'SampleRate',Rs, ...
    'PathDelays',0, ...
    'KFactor',KFactorLin, ...
    'AveragePathGains',0, ...
    'MaximumDopplerShift',dopplerShift, ...
    'ChannelFiltering',false, ...
    'NumSamples',Ns, ...
    'FadingTechnique','Sum of sinusoids');
```

Compute and plot the empirical and theoretical PDF for the Rician channel.

```
figure;
hold on;

% Empirical PDF plot
gain = chan();
pd = fitdist(abs(gain),'Kernel','BandWidth',.01);
r = 0:.1:3;
y = pdf(pd,r);
plot(r,y)

% Theoretical PDF plot
s = sqrt(KFactorLin)/sqrt(KFactorLin+1);
sigma = sqrt(1/2)/sqrt(KFactorLin+1);
exp_pdf_amplitude = pdf('Rician',r,s,sigma);
plot(r,exp_pdf_amplitude)
legend('Empirical','Theoretical')
title('Empirical and Theoretical PDF Curves')
```

Compare CDF of Empirical and Theoretical Rician Channel

Compute and plot the empirical and theoretical cumulative distribution function (CDF) for a Rician channel with one path.

Initialize parameters and create a Rician channel System object that does not perform channel filtering.

```
Ns = 1.92e6;
Rs = 1.92e6;
dopplerShift = 2000;
KFactor = -3; % In dB
KFactorLin = 10.^(KFactor/10); % Linear units
```

```
chan = comm.RicianChannel( ...
    'SampleRate',Rs, ...
    'PathDelays',0, ...
    'KFactor',KFactorLin, ...
    'AveragePathGains',0, ...
    'MaximumDopplerShift',dopplerShift, ...
    'ChannelFiltering',false, ...
    'NumSamples',Ns, ...
    'FadingTechnique','Sum of sinusoids');
```

Compute and plot the empirical and theoretical CDF for the Rician channel. Compute the empirical CDF by using the path gains.

```
% Empirical CDF plot
g = chan();
ecdf(abs(g));
hold on;

% Theoretical CDF plot
r = 0:.1:3;
s = sqrt(KFactorLin)/sqrt(KFactorLin+1);
sigma = sqrt(1/2)/sqrt(KFactorLin+1);
exp_cdf_amplitude = cdf('Rician',r,s,sigma);
plot(r,exp_cdf_amplitude)
legend('Emp','Theor')
title('Empirical and Theoretical CDF Curves')
```

More About

Cutoff Frequency Factor

The cutoff frequency factor, f_c , is dependent on the type of Doppler spectrum.

- For any Doppler spectrum type other than Gaussian and bi-Gaussian, f_c equals 1.
- For a doppler('Gaussian') spectrum type, f_c equals NormalizedStandardDeviation $\times \sqrt{2\log 2}$.

- For a doppler('BiGaussian') spectrum type:
 - If the PowerGains(1) and NormalizedCenterFrequencies(2) field values are both 0, then f_c equals $\text{NormalizedStandardDeviation}(1) \times \sqrt{2\log 2}$.
 - If the PowerGains(2) and NormalizedCenterFrequencies(1) field values are both 0, then f_c equals $\text{NormalizedStandardDeviation}(2) \times \sqrt{2\log 2}$.
 - If the NormalizedCenterFrequencies field value is [0,0] and the NormalizedStandardDeviation field has two identical elements, then f_c equals $\text{NormalizedStandardDeviation}(1) \times \sqrt{2\log 2}$.
 - In all other cases, f_c equals 1.

Channel Visualization

The `comm.RicianChannel` System object enables visualization of the channel impulse response, frequency response, and Doppler spectrum.

Note

- The displayed and specified path gain locations can differ by as much as 5% of the input sample time.
 - The visualization display speed is controlled by the combination of the `SamplesToDisplay` property and the **Reduce Updates to Improve Performance** scope menu item found in **Playback**. Reducing the percentage of samples to display and enabling reduced updates can speed up the rendering of the visualization scope.
 - If you close the visualization scopes, calls to the System object execute at normal speed.
 - Code generation is available only when you set the `Visualization` property to 'Off'.
-

Impulse Response

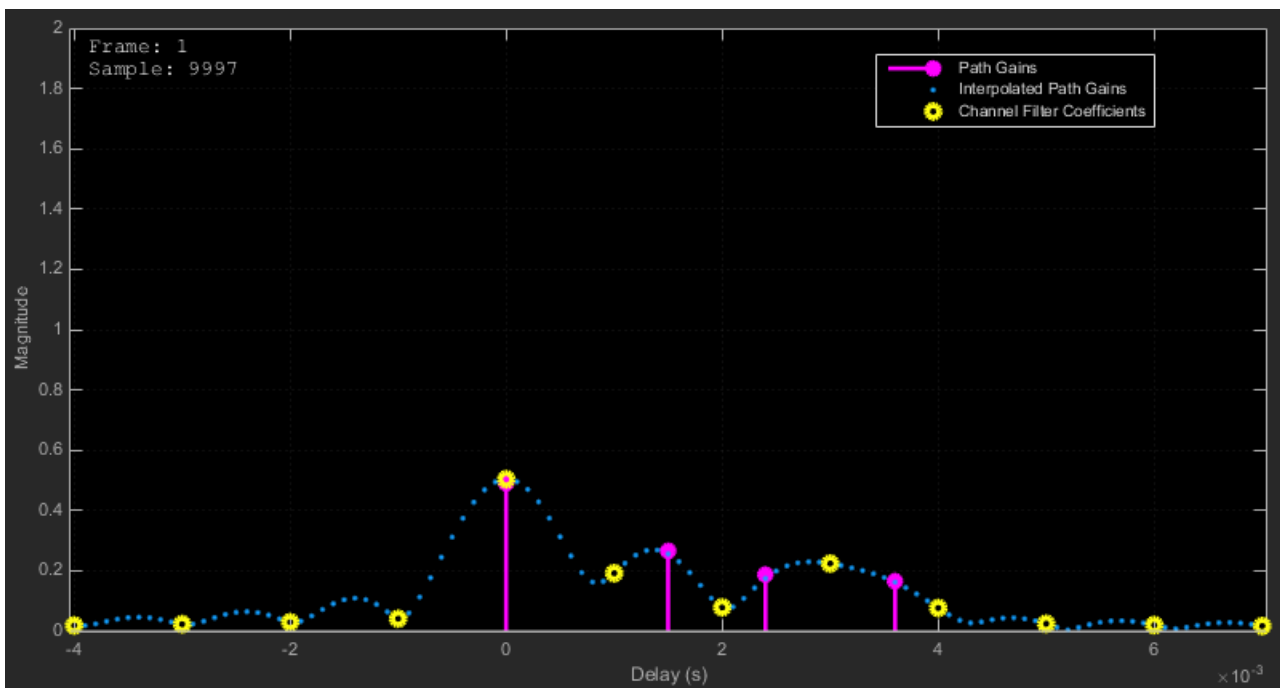

The impulse response scope displays the path gains, channel filter coefficients, and interpolated path gains. The path gains occur at time instances that correspond to the specified `PathDelays` property and might not be aligned with the input sampling time. The scope uses channel filter coefficients to model the channel. The coefficients are interpolated from the actual path gains and are aligned with the input sampling time. The path gains overlap the filter coefficients for cases where the path gains are aligned with the sampling time. Sinc interpolation is used to connect the channel filter coefficients and is shown as the interpolated path gains. These points are used solely for display purposes and not used in subsequent channel filtering. For a flat fading channel (one path), the sinc interpolation curve is not displayed. For all impulse response plots, the frame and sample numbers are shown in the upper-left corner of the scope.

The impulse response plot shares the same toolbar and menus as the `dsp.ArrayPlot` System object.

When the specified path gains align with the sample rate, the path gains and the channel filter coefficients overlap. In this figure, the impulse response shows that the path gains overlap the filter coefficients.

If the specified path gains are not aligned with the sample rate, the path gains and the channel filter coefficients do not overlap. In this figure, the filter coefficients are equally distributed. Because the path gains are not aligned with the sample rate, the path gains do not overlap with the channel filter coefficients.

This figure shows the impulse response for a frequency-flat channel without displaying the interpolated path gains.

Frequency response

The frequency response scope displays the multipath Rayleigh fading channel spectrum by taking a discrete Fourier transform of the channel filter coefficients. The frequency response plot shares the same toolbar and menus as the `dsp.SpectrumAnalyzer` System object.

The y-axis limits of the plot are computed based on the `NormalizePathGains` and `AveragePathGains` properties of the `comm.RicianChannel` System object.

This table shows other selected default spectrum settings. You can change these settings from their default values by using the **Spectrum Settings** in **View** .

Spectrum Settings	Value
Type in Main options	Power
Window length in Main options	Channel filter length
NFFT in Main options	512
Window in Window options	Rectangular
Units in Trace options	dBW

This figure shows the frequency response plot for a frequency-selective channel.

Doppler Spectrum

The Doppler spectrum plot displays the theoretical Doppler spectrum and the empirically determined data points. The theoretical data is displayed as a line for the case of nonstatic channels and as a point for static channels. The empirical data is shown as * symbols. Before the empirical plot is updated, the internal buffer must be completely filled with filtered Gaussian samples. The empirical plot is the running mean of the spectrum that is calculated from each full buffer. For nonstatic channels, the number of input samples that is needed before the next update is displayed in the upper-left corner of the plot. The number of samples that is needed is a function of the sample rate and the maximum Doppler shift. For static channels, the text "Reset fading channel for next update" is displayed.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- To generate C code, set the `DopplerSpectrum` property to a single Doppler spectrum structure.
- Code generation is available only when you set the `Visualization` property to 'Off'.
- See "System Objects in MATLAB Code Generation" (MATLAB Coder).

Methodology for Simulating Multipath Fading Channels

Introduced in R2013b

comm.RSDecoder

Package: comm

Decode data using Reed-Solomon decoder

Description

The `RSDecoder` object recovers a message vector from a Reed-Solomon codeword vector. For proper decoding, the property values for this object should match the property values in the corresponding RS Encoder object.

To decode data using a Reed-Solomon decoding scheme:

- 1 Define and set up your Reed-Solomon decoder object. See “Construction” on page 3-1254.
- 2 Call `step` to decode data according to the properties of `comm.RSDecoder`. The behavior of `step` is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`dec = comm.RSDecoder` creates a block decoder System object, `dec`. This object performs Reed-Solomon (RS) decoding.

`dec = comm.RSDecoder(N,K)` creates an RS decoder object, `dec` with the `CodewordLength` property set to `N` and the `MessageLength` property set to `K`.

`dec = comm.RSDecoder(N,K,GP)` creates an RS decoder object, `dec` with the `CodewordLength` property set to `N`, the `MessageLength` property set to `K`, and the `GeneratorPolynomial` property set to `GP`.

`dec = comm.RSDecoder(N,K,GP,S)` creates an RS decoder object, `dec` with the `CodewordLength` property set to `N`, the `MessageLength` property set to `K`, the `GeneratorPolynomial` property set to `GP`, and the `ShortMessageLength` property set to `S`.

`dec = comm.RSDecoder(N,K,GP,S,Name,Value)` creates an RS decoder object, `dec` with the `CodewordLength` property set to `N`, the `MessageLength` property set to `K`, the `GeneratorPolynomial` property set to `GP`, and each specified property `Name` set to the specified `Value`.

`dec = comm.RSDecoder(Name,Value)` creates an RS decoder object, `dec`, with each specified property name set to the specified value. You can specify additional name-value pair arguments in any order as `(Name1,Value1,...,NameN,ValueN)`.

Properties

Note The input and output signal lengths are listed in “Input and Output Signal Lengths in BCH and RS System Objects” on page 3-94 on the `comm.BCHDecoder` reference page.

BitInput

Assume that input is bits

Specify whether the input comprises bits or integers. The default is `false`.

- When you set this property to `false`, the input data value to run the object must be a numeric, column vector of integers. Running the object outputs an encoded data output vector. The output result is a column vector of integers. Each symbol that forms the input message and output codewords is an integer in the range $[0, 2^M - 1]$. These integers correspond to an element of the finite Galois field $\text{gf}(2^M)$. M is the degree of the primitive polynomial that you specify with the `PrimitivePolynomialSource` and `PrimitivePolynomial` properties.
- When you set this property to `true`, the input value must be a numeric, column vector of bits. The encoded data output result is a column vector of bits.

CodewordLength

Codeword length

Specify the codeword length of the RS code in symbols as a double-precision, positive, integer scalar value. The default is 7.

For a full-length RS code, the value of this property must be $2^M - 1$, where M is an integer such that $3 \leq M \leq 16$.

MessageLength

Message length

Specify the message length in symbols as a double-precision positive integer scalar value. The default is 3.

ShortMessageLengthSource

Short message length source

Specify the source of the shortened message as `Auto` or `Property`.

- When you set this property to `Auto`, the RS code is defined by the `CodewordLength`, `MessageLength`, `GeneratorPolynomial`, and `PrimitivePolynomial` properties.

When you set this property to `Property`, you must specify the `ShortMessageLength` property, which is used with the other properties to define the RS code. The default is `Auto`.

ShortMessageLength

Shortened message length

Specify the length of the shortened message in symbols as a double-precision positive integer scalar whose value must be less than or equal to `MessageLength`. The default is 3.

When `ShortMessageLength < MessageLength`, the RS code is shortened.

GeneratorPolynomialSource

Source of generator polynomial

Specify the source of the generator polynomial as `Auto` or `Property`. The default is `Auto`.

- When you set this property to `Auto`, the object automatically chooses the generator polynomial. The object calculates the generator polynomial based on the value of the `PrimitivePolynomial` property.
- When you set this property to `Property`, you must specify a generator polynomial using the `GeneratorPolynomial` property.

GeneratorPolynomial

Generator polynomial

Specify the generator polynomial for the RS code as a double-precision integer row vector or as a Galois field row vector. The Galois field row vector entries must be in the range $[0, 2^M - 1]$ and represent a generator polynomial in descending order of powers. Each coefficient is an element of the Galois field $\text{gf}(2^M)$, represented in integer format. The length of the generator polynomial must be `CodewordLength - MessageLength + 1`. The default is the result of `rsgenpoly(7, 3, [], [], 'double')`, which corresponds to `[1 3 1 2 3]`.

When you use this object to generate code, you must set the generator polynomial to a double-precision integer row vector.

This property applies when you set `GeneratorPolynomialSource` to `Property`.

CheckGeneratorPolynomial

Enable generator polynomial checking

Set this property to `true` to perform a generator polynomial check. The default is `true`.

This check verifies that $X^{\text{CodewordLength} + 1}$ is divisible by the generator polynomial specified in the `GeneratorPolynomial` property. For codes with generator polynomials of high degree, disabling the check speeds up processing. As a best practice, perform the check at least once before setting this property to `false`.

A valid generator polynomial is given by $(X - \alpha^B) \times (X - \alpha^{(B+1)}) \times \dots \times (X - \alpha^{(B + \text{CodewordLength} - \text{MessageLength} - 1)})$, where α is a root of the primitive polynomial and B is an integer. If the value of B is 1, then you can set this property to `false`. Otherwise, always set this property to `true`. For more information about B , see the `rsgenpoly` function reference page.

This property applies when you set `GeneratorPolynomialSource` to `Property`.

PrimitivePolynomialSource

Source of primitive polynomial

Specify the source of the primitive polynomial as `Auto` or `Property`. The default is `Auto`.

- When you set this property to `Auto`, the object uses a primitive polynomial of degree $M = \text{ceil}(\log_2(\text{CodewordLength} + 1))$.
- When you set this property to `Property`, you must specify a polynomial using `PrimitivePolynomial`.

PrimitivePolynomial

Primitive polynomial

Specify the primitive polynomial that defines the finite field $\text{gf}(2^M)$ corresponding to the integers that form messages and codewords. The default is the result of `int2bit(primpoly(3),4)'`, which is `[1 0 1 1]` or the polynomial $x^3 + x + 1$. Specify this property as a double-precision, binary, row vector that represents a primitive polynomial over $\text{gf}(2)$ of degree M in descending order of powers.

This property applies when you set `PrimitivePolynomialSource` to `Property`.

PuncturePatternSource

Source of puncture pattern

Specify the source of the puncture pattern as `None` or `Property`. The default is `None`.

- When you set this property to `None`, the object does not apply puncturing to the code.
- When you set this property to `Property`, the object punctures the code based on a puncture pattern vector specified in `PuncturePattern`.

PuncturePattern

Puncture pattern vector

Specify the pattern used to puncture the encoded data as a double-precision, binary column vector of length $(\text{CodewordLength} - \text{MessageLength})$. The default is `[ones(2,1); zeros(2,1)]`. Zeros in the puncture pattern vector indicate the position of the parity symbols that are punctured or excluded from each codeword.

This property applies when you set `PuncturePatternSource` to `Property`.

ErasuresInputPort

Enable erasures input

Set this property to `true` to specify a vector of erasures as an input when running the object. The default is `false`. The erasures input must be a double-precision or logical binary column vector that indicates which symbols of the input codewords to erase. The length of the erasures vector is explained in "Input and Output Signal Lengths in BCH and RS System Objects" on page 3-94.

When you set this property to `false`, the object assumes no erasures.

NumCorrectedErrorsOutputPort

Enable number of corrected errors output

Set this property to `true` to obtain the number of corrected errors as an output when running the object. The default is `true`. A nonnegative value in the i -th element of the error output vector, denotes the number of corrected errors in the i -th input codeword. A value of `-1` in the i -th element of

the error output vector indicates that a decoding error occurred for that codeword. A decoding error occurs when an input codeword has more errors than the error correction capability of the RS code.

OutputDataType

Data type of output

Specify the output data type as `Same as input`, `double`, or `logical`. The default is `Same as input`.

This property applies when you set `BitInput` to `true`.

Methods

`step` Decode data using a Reed-Solomon decoder

Common to All System Objects

<code>release</code>	Allow System object property value changes
----------------------	--

Examples

Transmit an RS-Encoded, 8-DPSK-Modulated Symbol Stream

Transmit an RS-encoded, 8-DPSK-modulated symbol stream through an AWGN channel. Then, demodulate, decode, and count errors.

```
enc = comm.RSEncoder;
mod = comm.DPSKModulator('BitInput',false);
chan = comm.AWGNChannel(...
    'NoiseMethod','Signal to noise ratio (SNR)','SNR',10);
demod = comm.DPSKDemodulator('BitOutput',false);
hDdecec = comm.RSDecoder;
errorRate = comm.ErrorRate('ComputationDelay',3);

for counter = 1:20
    data = randi([0 7], 30, 1);
    encodedData = step(enc, data);
    modSignal = step(mod, encodedData);
    receivedSignal = step(chan, modSignal);
    demodSignal = step(demod, receivedSignal);
    receivedSymbols = step(hDdecec, demodSignal);
    errorStats = step(errorRate, data, receivedSymbols);
end

fprintf('Error rate = %f\nNumber of errors = %d\n', ...
    errorStats(1), errorStats(2))
```

```
Error rate = 0.115578
Number of errors = 69
```

Estimate BER of QPSK in AWGN with Reed-Solomon Coding

Transmit Reed-Solomon encoded data using QPSK over an AWGN channel. Demodulate and decode the received signal and collect error statistics. Compute theoretical bit error rate (BER) for coded and noncoded data. Plot the BER results to compare performance.

Define the example parameters.

```
rng(1993);      % Seed random number generator for repeatable results
M = 4;          % Modulation order
bps = log2(M); % Bits per symbol
N = 7;          % RS codeword length
K = 5;          % RS message length
```

Create modulator, demodulator, AWGN channel, and error rate objects.

```
pskModulator = comm.PSKModulator('ModulationOrder',M,'BitInput',true);
pskDemodulator = comm.PSKDemodulator('ModulationOrder',M,'BitOutput',true);
awgnChannel = comm.AWGNChannel('BitsPerSymbol',bps);
errorRate = comm.ErrorRate;
```

Create a (7,5) Reed-Solomon encoder and decoder pair which accepts bit inputs.

```
rsEncoder = comm.RSEncoder('BitInput',true,'CodewordLength',N,'MessageLength',K);
rsDecoder = comm.RSDecoder('BitInput',true,'CodewordLength',N,'MessageLength',K);
```

Set the range of E_b/N_0 values and account for RS coding gain. Initialize the error statistics matrix.

```
ebnoVec = (3:0.5:8)';
ebnoVecCodingGain = ebnoVec + 10*log10(K/N); % Account for RS coding gain
errorStats = zeros(length(ebnoVec),3);
```

Estimate the bit error rate for each E_b/N_0 value. The simulation runs until either 100 errors or 10^7 bits is encountered. The main simulation loop processing includes encoding, modulation, demodulation, and decoding.

```
for i = 1:length(ebnoVec)
    awgnChannel.EbNo = ebnoVecCodingGain(i);
    reset(errorRate)
    while errorStats(i,2) < 100 && errorStats(i,3) < 1e7
        data = randi([0 1],1500,1); % Generate binary data
        encData = rsEncoder(data); % RS encode
        modData = pskModulator(encData); % Modulate
        rxSig = awgnChannel(modData); % Pass signal through AWGN
        rxData = pskDemodulator(rxSig); % Demodulate
        decData = rsDecoder(rxData); % RS decode
        errorStats(i,:) = errorRate(data,decData); % Collect error statistics
    end
end
```

Fit a curve to the BER data using `berfit`. Generate an estimate of QPSK performance with and without coding using the `bercoding` and `berawgn` functions.

```
berCurveFit = berfit(ebnoVecCodingGain,errorStats(:,1));
berwCoding = bercoding(ebnoVec,'RS','hard',N,K,'psk',M,'nondiff');
berNoCoding = berawgn(ebnoVec,'psk',M,'nondiff');
```

Plot the RS coded BER data, curve fit of the BER data, theoretical performance with RS coding, and theoretical performance without RS coding. The (7,5) RS code improves the E_b/N_0 required to achieve a 10^{-2} bit error rate by approximately 1.2 dB.

```
semilogy(ebnoVecCodingGain,errorStats(:,1),'b*', ...
ebnoVecCodingGain,berCurveFit,'c-',ebnoVecCodingGain,berwCoding,'r',ebnoVec,berNoCoding)
ylabel('BER')
xlabel('Eb/No (dB)')
legend('RS coded BER','Curve Fit','Theory with coding','Theory no coding')
grid
```

Transmit a Shortened RS-Encoded, 256-QAM-Modulated Symbol Stream

Transmit a shortened RS-encoded, 256-QAM-modulated symbol stream through an AWGN channel. Then demodulate, decode, and count errors.

Set the parameters for the Reed-Solomon code, where N is the codeword length, K is the nominal message length, and S is the shortened message length. Set the modulation order, M , and the number of frames, L .

```
N = 255;
K = 239;
S = 188;
```

```
M = 256;
L = 50;
```

Create an AWGN channel System object and an error rate System object.

```
awgnChan = comm.AWGNChannel('NoiseMethod','Signal to noise ratio (Eb/No)', ...
    'EbNo',15,'BitsPerSymbol',log2(M));
errorRate = comm.ErrorRate('ComputationDelay',3);
```

Create the Reed-Solomon generator polynomial from the DVB-T standard.

```
gp = rsgenpoly(N,K,[],0);
```

Create a Reed-Solomon encoder and decoder pair using the shortened message length, *S*, and the DVB-T generator polynomial, *gp*.

```
enc = comm.RSEncoder(N,K,gp,S);
dec = comm.RSDecoder(N,K,gp,S);
```

Generate random symbol frames whose length equals one message block. Encode, modulate, apply AWGN, demodulate, decode, and collect statistics.

```
for counter = 1:L
    data = randi([0 1],S,log2(M));
    encodedData = step(enc,bi2de(data));
    modSignal = qammod(encodedData,M,'UnitAveragePower',true);
    rxSignal = awgnChan(modSignal);
    demodSignal = qamdemod(rxSignal,M,'UnitAveragePower',true);
    rxBits = dec(demodSignal);
    dataOut = de2bi(rxBits);
    errorStats = errorRate(data(:),dataOut(:));
end
```

Display the error rate and number of errors.

```
fprintf('Error rate = %5.2e\nNumber of errors = %d\n', ...
    errorStats(1), errorStats(2))
```

```
Error rate = 2.01e-02
Number of errors = 1509
```

Reed-Solomon Coding with Erasures

This example shows how to configure the `comm.RSEncoder` and `comm.RSDecoder` System objects to perform Reed-Solomon (RS) block coding with erasures when simulating a communications system. RS decoders can correct both errors and erasures. A receiver that identifies the most unreliable symbols in a given codeword can generate erasures. When a receiver erases a symbol, it replaces that symbol with a zero. The receiver then passes a flag to the decoder, indicating that the symbol is an erasure, not a valid code symbol. In addition, an encoder can generate punctures for which specific parity symbols are always removed from its output. The decoder, which knows the puncture pattern, inserts zeros in the puncture positions and treats those symbols as erasures. The decoder treats encoder-generated punctures and receiver-generated erasures the exact same way when it decodes a symbol. Puncturing also has the added benefit of making the code rate more flexible, at the expense of some error correction capability. Shortened codes achieve the same code rate flexibility without degrading the error correction performance, given the same demodulator input energy per

bit to noise power spectral density ratio (E_b/N_0). Note that puncturing is the removal of parity symbols from a codeword, and shortening is the removal of message symbols from a codeword.

This example shows the simulation of a communication system consisting of a random source, an RS encoder, a 64-QAM modulator, an AWGN channel, a 64-QAM demodulator, and an RS decoder. It includes analysis of RS coding with erasures by comparing the channel bit error rate (BER) performance versus the coded BER performance. This example obtains Channel BER by comparing inputs for the QAM modulator to outputs from the QAM demodulator and obtains Coded BER by comparing inputs for the RS encoder to outputs from the RS decoder.

Initialization

The `helperRSCodingConfig.m` helper function initializes simulation parameters, and configures the `comm.AWGNChannel` and `comm.ErrorRate` System objects used to simulate the communications system. The uncoded E_b/N_0 ratio is set `EbNoUncoded = 15` dB. Criteria to stop the simulation stop are defined to stop the simulation if 500 errors occur or a maximum `5e6` bits are transmitted.

```
helperRSCodingConfig;
```

Configure RS Encoder/Decoder

This example uses a (63,53) RS code operating with a 64-QAM modulation scheme. This code can correct $(63-53)/2 = 5$ errors, or it can alternatively correct $(63-53) = 10$ erasures. For each codeword at the output of the 64-QAM demodulator, the receiver determines the six least reliable symbols using the `helperRSCodingGetErasures.m` helper function. The indices that point to the location of these unreliable symbols are passed as an input to the RS decoder. The RS decoder treats these symbols as erasures resulting in an error correction capability of $(10-6)/2 = 2$ errors per codeword.

Create a `comm.RSEncoder` System object and set the `BitInput` property to false to specify that the encoder inputs and outputs are integer symbols.

```
N = 63; % Codeword length
K = 53; % Message length
rsEncoder = comm.RSEncoder(N,K,'BitInput',false);
numErasures = 6;
```

Create a `comm.RSDecoder` System object matching the configuration of the `comm.RSEncoder` object.

```
rsDecoder = comm.RSDecoder(N,K,'BitInput',false);
```

Set the `ErasuresInputPort` property to true to specify erasures as an input to the decoder object.

```
rsDecoder.ErasuresInputPort = true;
```

Set the `NumCorrectedErrorsOutputPort` property to true so that the decoder outputs the number of corrected errors. A non negative value in the error output denotes the number of corrected errors in the input codeword. A value of -1 in the error output indicates a decoding error. A decoding error occurs when the input codeword has more errors than the error correction capability of the RS code.

```
rsDecoder.NumCorrectedErrorsOutputPort = true;
```

Run Stream Processing Loop

Simulate the communications system for an uncoded E_b/N_0 ratio of 15 dB. The uncoded E_b/N_0 is the ratio that would be measured at the input of the channel if there was no coding in the system.

The signal going into the AWGN channel is the encoded signal, so you must convert the uncoded E_b/N_0 values so that they correspond to the energy ratio at the encoder output. This ratio is the coded E_b/N_0 ratio. If you input K symbols to the encoder and obtain N output symbols, then the energy relation is given by the K/N rate. Set the `EbNo` property of the AWGN channel object to the computed coded E_b/N_0 value.

```
EbNoCoded = EbNoUncoded + 10*log10(K/N);
channel.EbNo = EbNoCoded;
```

Loop until the simulation reaches the target number of errors or the maximum number of transmissions.

```
chanErrorStats = zeros(3,1);
codedErrorStats = zeros(3,1);
correctedErrors = 0;
while (codedErrorStats(2) < targetErrors) && ...
    (codedErrorStats(3) < maxNumTransmissions)
```

The data symbols transmit one message word at a time. Each message word has K symbols in the $[0 N]$ range.

```
data = randi([0 N],K,1);
```

Encode the message word. The encoded word, `encData`, is $(N - \text{numPunc})$ symbols long.

```
encData = rsEncoder(data);
```

Modulate encoded data and add noise. Then demodulate channel output.

```
modData = qammod(encData,M);
chanOutput = channel(modData);
demodData = qamdemod(chanOutput,M);
```

Use the `helperRSCodingGetErasures.m` helper function to find the 6 least reliable symbols and generate an erasures vector. The length of the erasures vector must be equal to the number of symbols in the demodulated codeword. A one in the i th element of the vector erases the i th symbol in the codeword. Zeros in the vector indicate no erasures.

```
erasuresVec = helperRSCodingGetErasures(chanOutput,numErasures);
```

Decode the data. Log the number of errors corrected by the RS decoder.

```
[estData,errs] = rsDecoder(demodData,erasuresVec);
if (errs >= 0)
    correctedErrors = correctedErrors + errs;
end
```

When computing the channel and coded BERs, convert integers to bits.

```
chanErrorStats(:,1) = ...
    chanBERCalc(reshape(de2bi(encData,log2(M))',[],1),reshape(de2bi(demodData,log2(M))',[],1));
codedErrorStats(:,1) = ...
    codedBERCalc(reshape(de2bi(data,log2(M))',[],1),reshape(de2bi(estData,log2(M))',[],1));
end
```

The error rate measurement objects, `chanBERCalc` and `codedBERCalc`, output 3-by-1 vectors containing BER measurement updates, the number of errors, and the total number of bit

transmissions. Display the channel BER, the coded BER and the total number of errors corrected by the RS decoder.

```
chanBitErrorRate = chanErrorStats(1)
chanBitErrorRate = 0.0017
codedBitErrorRate = codedErrorStats(1)
codedBitErrorRate = 0
totalCorrectedErrors = correctedErrors
totalCorrectedErrors = 882
```

You can add a for loop around the processing loop above to run simulations for a set of E_b/N_0 values. Simulations were run offline for uncoded E_b/N_0 values in 4:15 dB, target number of errors equal to 5000, and maximum number of transmissions equal to 50e6. The results from the simulation are shown. The channel BER is worse than the theoretical 64-QAM BER because E_b/N_0 is reduced by the code rate.

Summary

This example utilized several System objects to simulate a 64-QAM communications system over an AWGN channel with RS block coding. It showed how to configure the RS decoder to decode symbols with erasures. System performance was measured using channel and coded BER curves obtained using error rate measurement System objects.

Helper functions used in this example:

- `helperRSCodingConfig.m`
- `helperRSCodingGetErasures.m`

Reed-Solomon Coding with Erasures and Punctures

This example shows how to configure the `comm.RSEncoder` and `comm.RSDecoder` System objects to perform Reed-Solomon (RS) block coding with erasures and puncture codes when simulating a communications system. An encoder can generate punctures to remove specific parity symbols from its output. Given the puncture pattern, the decoder inserts zeros in the puncture positions and treats those symbols as erasures. The decoder treats encoder-generated punctures and receiver-generated erasures in exactly the same way when it decodes. Puncturing has the added benefit of making the code rate more flexible, at the expense of some error correction capability.

This example shows the simulation of a communication system consisting of a random source, an RS encoder, a 64-QAM modulator, an AWGN channel, a 64-QAM demodulator, and an RS decoder. It includes analysis of RS coding with erasures and puncturing by comparing the channel bit error rate (BER) performance versus the coded BER performance. This example obtains Channel BER by comparing inputs for the QAM modulator to outputs from the QAM demodulator. This example obtains Coded BER by comparing inputs for the RS encoder to outputs from the RS decoder.

Initialization

The `helperRSCodingConfig.m` helper function initializes simulation parameters, and configures the `comm.AWGNChannel` and `comm.ErrorRate` System objects used to simulate the communications system. The uncoded E_b/N_0 ratio, `EbNoUncoded` is set to 15 dB. Criteria to stop the simulation are defined to stop the simulation if 500 errors occur or a maximum 5×10^6 bits are transmitted.

```
helperRSCodingConfig;
```

Configure RS Encoder/Decoder

This example uses the same (63,53) RS code operating with a 64-QAM modulation scheme that is configured for erasures and code puncturing. The RS algorithm decodes receiver-generated erasures and corrects encoder-generated punctures. For each codeword, the sum of the punctures and erasures cannot exceed twice the error-correcting capability of the code.

Create a `comm.RSEncoder` System object and set the `BitInput` property to false to specify that the encoder inputs and outputs are integer symbols.

```
N = 63; % Codeword length
K = 53; % Message length
rsEncoder = comm.RSEncoder(N,K, 'BitInput', false);
numErasures = 6;
```

Create a `comm.RSDecoder` System object matching the configuration of the `comm.RSEncoder` object. Then set the `ErasuresInputPort` property to true to specify erasures as an input to the decoder object.

```
rsDecoder = comm.RSDecoder(N,K, 'BitInput', false);
rsDecoder.ErasesuresInputPort = true;
```

To enable code puncturing, set the `PuncturePatternSource` property to 'Property' and set the `PuncturePattern` property to the desired puncture pattern vector. The same puncture vector must be specified in both the encoder and decoder. This example punctures two symbols from each codeword. Values of 1 in the puncture pattern vector indicate nonpunctured symbols, and values of 0 indicate punctured symbols.

```
numPuncs = 2;
rsEnc.PuncturePatternSource = 'Property';
rsEnc.PuncturePattern = [ones(N-K-numPuncs,1); zeros(numPuncs,1)];

rsDec.PuncturePatternSource = 'Property';
rsDec.PuncturePattern = rsEnc.PuncturePattern;
```

Run Stream Processing Loop

Simulate the communications system for an uncoded E_b/N_0 ratio of 15 dB. The uncoded E_b/N_0 is the ratio that would be measured at the input of the channel if there was no coding in the system.

The signal going into the AWGN channel is the encoded signal, so you must convert the uncoded E_b/N_0 values so that they correspond to the energy ratio at the encoder output. This ratio is the coded E_b/N_0 ratio. If you input K symbols to the encoder and obtain N output symbols, then the energy relation is given by the K/N rate. Since the length of the codewords generated by the RS encoder is reduced by the number of punctures specified in the puncture pattern vector, the value of the coded E_b/N_0 ratio needs to be adjusted to account for these punctures. In this example, The number of output symbols is $(N - \text{numPuncs})$ and the uncoded E_b/N_0 ratio relates to the coded E_b/N_0 as shown below. Set the `EbNo` property of the AWGN channel object to the computed coded E_b/N_0 value.

```
EbNoCoded = EbNoUncoded + 10*log10(K/(N - numPuncs));
channel.EbNo = EbNoCoded;
```

Loop until the simulation reaches the target number of errors or the maximum number of transmissions.

```
chanErrorStats = zeros(3,1);
codedErrorStats = zeros(3,1);
correctedErrors = 0;
while (codedErrorStats(2) < targetErrors) && ...
    (codedErrorStats(3) < maxNumTransmissions)
```

The data symbols transmit one message word at a time. Each message word has K symbols in the $[0 N]$ range.

```
data = randi([0 N],K,1);
```

Encode the message word. The encoded word, `encData`, is $(N - \text{numPunc})$ symbols long.

```
encData = rsEncoder(data);
```

Modulate encoded data and add noise. Then demodulate channel output.

```
modData = qammod(encData,M);
chanOutput = channel(modData);
demodData = qamdemod(chanOutput,M);
```

Use the `helperRSCodingGetErasures.m` helper function to find the 6 least reliable symbols and generate an erasures vector. The length of the erasures vector must be equal to the number of

symbols in the demodulated codeword. A one in the i th element of the vector erases the i th symbol in the codeword. Zeros in the vector indicate no erasures.

```
erasuresVec = helperRSCodingGetErasures(chanOutput,numErasures);
```

Decode the data. Log the number of errors corrected by the RS decoder.

```
[estData,errs] = rsDecoder(demodData,erasuresVec);
if (errs >= 0)
    correctedErrors = correctedErrors+errs;
end
```

When computing the channel and coded BERs, convert integers to bits.

```
chanErrorStats(:,1) = ...
    chanBERCalc(reshape(de2bi(encData,log2(M))',[],1),reshape(de2bi(demodData,log2(M))',[],1),1);
codedErrorStats(:,1) = ...
    codedBERCalc(reshape(de2bi(data,log2(M))',[],1),reshape(de2bi(estData,log2(M))',[],1));
end
```

The error rate measurement objects, `chanBERCalc` and `codedBERCalc`, output 3-by-1 vectors containing BER measurement updates, the number of errors, and the total number of bit transmissions. Display the channel BER, the coded BER and the total number of errors corrected by the RS decoder.

```
chanBitErrorRate = chanErrorStats(1)

chanBitErrorRate = 0.0015

codedBitErrorRate = codedErrorStats(1)

codedBitErrorRate = 0

totalCorrectedErrors = correctedErrors

totalCorrectedErrors = 632
```

You can add a for loop around the processing loop above to run simulations for a set of E_b/N_0 values. Simulations were run offline for uncoded E_b/N_0 values in 4:15 dB, target number of errors equal to 5000, and maximum number of transmissions equal to 50×10^6 . This figure compares results achieved for

- RS coding with only erasures
- RS coding with erasures and puncturing
- Theoretical BER for 64-QAM

The coded E_b/N_0 is slightly higher than the channel E_b/N_0 , so the channel BER is slightly better in the punctured case. On the other hand, the coded BER is worse in the punctured case, because the two punctures reduce the error correcting capability of the code by one, leaving it able to correct only $(10 - 6 - 2) / 2 = 1$ error per codeword.

Summary

This example utilized functions and System objects to simulate a 64-QAM communications system over an AWGN channel with RS block coding. It showed how to configure the RS encoder/decoder System objects to obtain punctured codes. System performance was measured using channel and coded BER curves obtained using error rate measurement System objects.

Helper functions used in this example:

- `helperRSCodingConfig.m`
- `helperRSCodingGetErasures.m`

Reed-Solomon Coding with Erasures, Punctures, and Shortening

This example shows how to configure the `comm.RSEncoder` and `comm.RSDecoder` System objects to perform Reed-Solomon (RS) block coding to shorten the (63,53) code to a (28,18) code. The simulation of a communication system consisting of a random source, an RS encoder, a 64-QAM modulator, an AWGN channel, a 64-QAM demodulator, and an RS decoder is presented.

The effects of RS coding with erasures, puncturing, and shortening are analyzed by comparing the channel bit error rate (BER) performance versus the coded BER performance. This example obtains Channel BER by comparing inputs for the QAM modulator to outputs from the QAM demodulator and obtains Coded BER by comparing inputs for the RS encoder to outputs from the RS decoder. Puncturing is the removal of parity symbols from a codeword, and shortening is the removal of

message symbols from a codeword. Puncturing has the benefit of making the code rate more flexible, at the expense of some error correction capability. Shortened codes achieve the same code rate flexibility without degrading the error correction performance for the same demodulator input E_b/N_0 .

Initialization

The `helperRSCodingConfig.m` helper function initializes simulation parameters, and configures the `comm.AWGNChannel` and `comm.ErrorRate` System objects used to simulate the communications system. The uncoded E_b/N_0 ratio is set `EbNoUncoded = 15 dB`. Criteria to stop the simulation stop are defined to stop the simulation if 500 errors occur or a maximum 5×10^6 bits are transmitted.

```
helperRSCodingConfig;
```

Configure RS Encoder/Decoder

This example uses a (63,53) RS code operating with a 64-QAM modulation scheme. The RS coding operation includes erasures, puncturing, and code shortening. This example shows how to shorten the (63,53) code to a (28,18) code.

To shorten a (63,53) code by 10 symbols to a (53,43) code, you can simply enter 53 and 43 for the `CodewordLength` and `MessageLength` properties, respectively (since $2\lceil\log_2(53 + 1)\rceil - 1 = 63$). However, to shorten it by 35 symbols to a (28,18) code, you must explicitly specify that the symbols belong to the Galois field $GF(26)$. Otherwise, the RS blocks will assume that the code is shortened from a (31,21) code (since $2\lceil\log_2(28 + 1)\rceil - 1 = 31$).

Create a pair of `comm.RSEncoder` and `comm.RSDecoder` System objects so that they perform block coding with a (28,18) code shortened from a (63,53) code that is configured to input and output integer symbols. Configure the decoder to accept an erasure input and two punctures. For each codeword at the output of the 64-QAM demodulator, the receiver determines the six least reliable symbols using the `helperRSCodingGetErasures.m` helper function. The indices that point to the location of these unreliable symbols are passed as an input to the RS decoder.

```
N = 63; % Codeword length
K = 53; % Message length
S = 18; % Shortened message length
numErasures = 6;
numPuncs = 2;
rsEncoder = comm.RSEncoder(N, K, 'BitInput', false);
rsDecoder = comm.RSDecoder(N, K, 'BitInput', false, 'ErasuresInputPort', true);
rsEncoder.PuncturePatternSource = 'Property';
rsEncoder.PuncturePattern = [ones(N-K-numPuncs,1); zeros(numPuncs,1)];
rsDecoder.PuncturePatternSource = 'Property';
rsDecoder.PuncturePattern = rsEncoder.PuncturePattern;
```

Set the shortened codeword length and message length values.

```
rsEncoder.ShortMessageLength = S;
rsDecoder.ShortMessageLength = S;
```

Specify the field of $GF(2^6)$ in the RS encoder/decoder System objects, by setting the `PrimitivePolynomialSource` property to 'Property' and the `PrimitivePolynomial` property to a 6th degree primitive polynomial.

```
primPolyDegree = 6;
rsEncoder.PrimitivePolynomialSource = 'Property';
```

```
rsEncoder.PrimitivePolynomial = de2bi(primpoly(primPolyDegree, 'nodisplay'), 'left-msb');
rsDecoder.PrimitivePolynomialSource = 'Property';
rsDecoder.PrimitivePolynomial = de2bi(primpoly(primPolyDegree, 'nodisplay'), 'left-msb');
```

Run Stream Processing Loop

Simulate the communications system for an uncoded E_b/N_0 ratio of 15 dB. The uncoded E_b/N_0 is the ratio that would be measured at the input of the channel if there was no coding in the system.

The signal going into the AWGN channel is the encoded signal, so you must convert the uncoded E_b/N_0 values so that they correspond to the energy ratio at the encoder output. This ratio is the coded E_b/N_0 ratio. If you input K symbols to the encoder and obtain N output symbols, then the energy relation is given by the K/N rate. The value of the coded E_b/N_0 ratio needs to be adjusted to account for shortened and punctured codewords. The number of output symbols is $(N - \text{numPuncs} - S)$ and the uncoded E_b/N_0 ratio relates to the coded E_b/N_0 as shown below. Set the `EbNo` property of the AWGN channel object to the computed coded E_b/N_0 value.

```
EbNoCoded = EbNoUncoded + 10*log10(S/(N - numPuncs - K + S));
channel.EbNo = EbNoCoded;
```

Loop until the simulation reaches the target number of errors or the maximum number of transmissions.

```
chanErrorStats = zeros(3,1);
codedErrorStats = zeros(3,1);
correctedErrors = 0;
while (codedErrorStats(2) < targetErrors) && ...
    (codedErrorStats(3) < maxNumTransmissions)
```

The data symbols transmit one message word at a time. Each message word has $K-S$ symbols in the $[0, 2^{\text{primPolyDegree}}-1]$ range.

```
data = randi([0 2^primPolyDegree-1], S, 1);
```

Encode the shortened message word. The encoded word `encData` is $(N - \text{numPuncs} - S)$ symbols long.

```
encData = rsEncoder(data);
```

Modulate encoded data and add noise. Then demodulate channel output.

```
modData = qammod(encData, M);
chanOutput = channel(modData);
demodData = qamdemod(chanOutput, M);
```

Use the `helperRSCodingGetErasures.m` helper function to find the 6 least reliable symbols and generate an erasures vector. The length of the erasures vector must be equal to the number of symbols in the demodulated codeword. A one in the i th element of the vector erases the i th symbol in the codeword. Zeros in the vector indicate no erasures.

```
erasuresVec = helperRSCodingGetErasures(chanOutput, numErasures);
```

Decode the data. Log the number of errors corrected by the RS decoder.

```
[estData, errs] = rsDecoder(demodData, erasuresVec);
if (errs >= 0)
```

```

        correctedErrors = correctedErrors + errs;
    end

```

When computing the channel and coded BERs, convert integers to bits.

```

    chanErrorStats(:,1) = ...
        chanBERCalc(reshape(de2bi(encData,log2(M))',[],1), ...
            reshape(de2bi(demodData,log2(M))',[],1));
    codedErrorStats(:,1) = ...
        codedBERCalc(reshape(de2bi(data,log2(M))',[],1), ...
            reshape(de2bi(estData,log2(M))',[],1));
end

```

The error rate measurement objects, `chanBERCalc` and `codedBERCalc`, output 3-by-1 vectors containing BER measurement updates, the number of errors, and the total number of bit transmissions. Display the channel BER, the coded BER, and the total number of errors corrected by the RS decoder.

```

chanBitErrorRate = chanErrorStats(1)

chanBitErrorRate = 0.0036

codedBitErrorRate = codedErrorStats(1)

codedBitErrorRate = 9.6599e-05

totalCorrectedErrors = correctedErrors

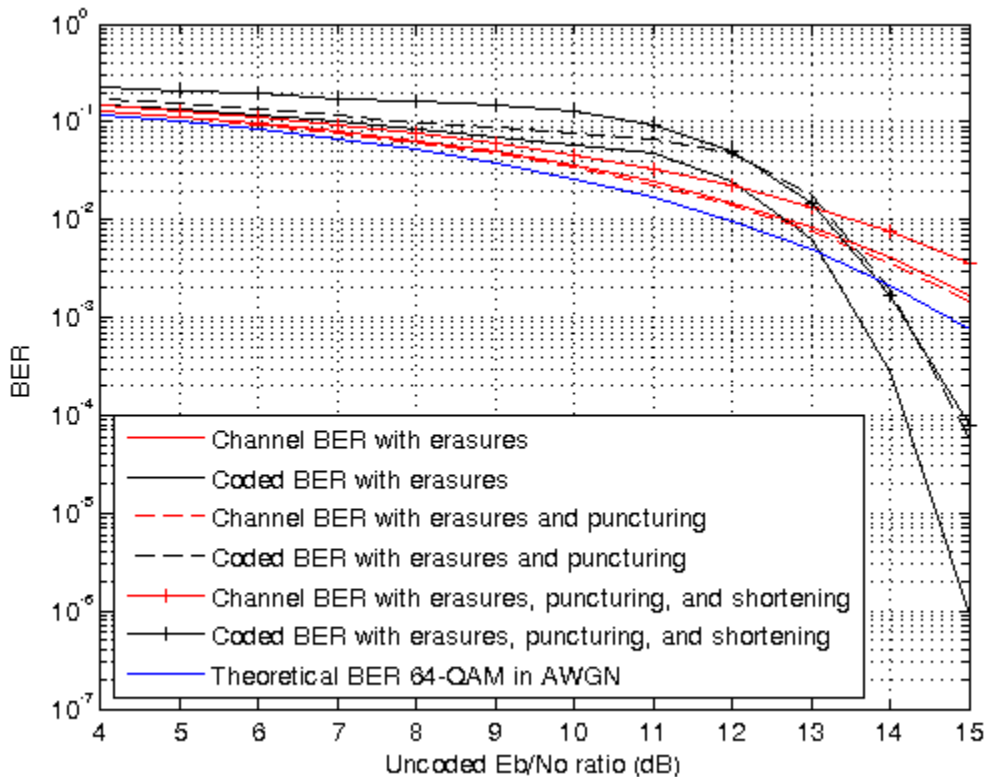

totalCorrectedErrors = 1436

```

You can add a for loop around the processing loop above to run simulations for a set of E_b/N_0 values. Simulations were run offline for uncoded E_b/N_0 values in 4:15 dB, target number of errors equal to 5000, and maximum number of transmissions equal to 50×10^6 . This figure compares results achieved for

- RS coding with only erasures
- RS coding with erasures and puncturing
- RS coding with erasures, puncturing, and shortening
- Theoretical BER for 64-QAM

The channel BER with shortening because the coded E_b/N_0 is degraded. This degraded coded E_b/N_0 occurs because the code rate of the shortened code is lower than that of the nonshortened code. Shortening also results in degraded coded BER, most noticeably at lower E_b/N_0 values.

Summary

This example utilized several System objects to simulate a 64-QAM communications system over an AWGN channel with a shortened RS block code. It showed how to configure the RS decoder to shorten a (63,53) code to a (28,18) code. System performance was measured using channel and coded BER curves obtained using error rate measurement System objects.

Helper functions used in this example:

- `helperRSCodingConfig.m`
- `helperRSCodingGetErasures.m`

Algorithms

This object implements the algorithm, inputs, and outputs described in "Algorithms for BCH and RS Errors-only Decoding".

Topics

“Reed-Solomon Codes”

Introduced in R2012a

step

System object: `comm.RSDecoder`

Package: `comm`

Decode data using a Reed-Solomon decoder

Syntax

```
[Y,ERR] = step(H,X)
Y = step(H,X)
Y = step(H,X,ERASURES)
```

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

`[Y,ERR] = step(H,X)` decodes the encoded input data, `X`, into the output vector `Y` and returns the number of corrected symbols in output vector `ERR`. The value of the `BitInput` property determines whether `X` is a vector of integers or bits with a numeric, logical, or fixed-point data type. The input and output length of the `step` function equal the values listed in “Input and Output Signal Lengths in BCH and RS System Objects” on page 3-94. This syntax applies when you set the `NumCorrectedErrorsOutputPort` property to `true`. A value of `-1` in the i -th element of the error output vector indicates that a decoding error occurred for that codeword.

`Y = step(H,X)` decodes the encoded data, `X`, into the output vector `Y`. This syntax applies when you set the `NumCorrectedErrorsOutputPort` property to `false`.

`Y = step(H,X,ERASURES)` uses the binary column input vector, `ERASURES`, to erase the symbols of the input codewords. The elements in `ERASURES` must be of data type `double` or `logical`. Values of `1` in the `ERASURES` vector correspond to erased symbols, and values of `0` correspond to non-erased symbols. This syntax applies when you set the `ErasuresInputPort` property to `true`.

Note `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications. For more information on changing property values, see “System Design in MATLAB Using System Objects”.

comm.RSEncoder

Package: comm

Encode data using Reed-Solomon encoder

Description

The RSEncoder object creates a Reed-Solomon code with message and codeword lengths you specify.

To encode data using a Reed-Solomon encoding scheme:

- 1 Define and set up your Reed-Solomon encoder object. See “Construction” on page 3-1275.
- 2 Call `step` to encode data according to the properties of `comm.RSEncoder`. The behavior of `step` is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`enc = comm.RSEncoder` creates a block encoder System object, `enc`. This object performs Reed-Solomon (RS) encoding.

`enc = comm.RSEncoder(N,K)` creates an RS encoder object, `enc`, with the `CodewordLength` property set to `N` and the `MessageLength` property set to `K`.

`enc = comm.RSEncoder(N,K,GP)` creates an RS encoder object, `enc`, with the `CodewordLength` property set to `N`, the `MessageLength` property set to `K`, and the `GeneratorPolynomial` property set to `GP`.

`enc = comm.RSEncoder(N,K,GP,S)` creates an RS encoder object, `enc`, with the `CodewordLength` property set to `N`, the `MessageLength` property set to `K`, the `GeneratorPolynomial` property set to `GP`, and the `ShortMessageLength` property set to `S`.

`enc = comm.RSEncoder(N,K,GP,S,Name,Value)` creates an RS encoder object, `enc`, with the `CodewordLength` property set to `N`, the `MessageLength` property set to `K`, the `GeneratorPolynomial` property set to `GP`, the `ShortMessageLength` property set to `S`, and each specified property `Name` set to the specified `Value`.

`enc = comm.RSEncoder(Name,Value)` creates an RS encoder object, `enc`, with each specified property name set to the specified value. You can specify additional name-value pair arguments in any order as `(Name1,Value1,...,NameN,ValueN)`.

Properties

Note The input and output signal lengths are listed in “Input and Output Signal Lengths in BCH and RS System Objects” on page 3-94 on the `comm.BCHDecoder` reference page.

BitInput

Assume that input is bits

Specify whether the input comprises bits or integers. The default is `false`.

When you set this property to `false`, the input data value when running the object must be a numeric, column vector of integers. Each symbol that forms the input message and output codewords is an integer in the range $[0, 2^M-1]$. These integers correspond to an element of the finite Galois field $gf(2^M)$, where M is the degree of the primitive polynomial that you specify with the `PrimitivePolynomialSource` and `PrimitivePolynomial` properties.

When you set this property to `true`, the input value must be a numeric, column vector of bits. The encoded data output result is a column vector of bits.

CodewordLength

Codeword length

Specify the codeword length of the RS code as a double-precision positive integer scalar value. The default is 7.

For a full-length RS code, the value of this property must be 2^M-1 , where M is an integer in the range $[3, 16]$.

MessageLength

Message length

Specify the message length as a double-precision positive integer scalar value. The default is 3.

ShortMessageLengthSource

Short message length source

Specify the source of the shortened message as `Auto` or `Property`. The default is `Auto`.

- When you set this property to `Auto`, the RS code is defined by the `CodewordLength`, `MessageLength`, `GeneratorPolynomial`, and `PrimitivePolynomial` properties.
- When you set this property to `Property`, you must specify the `ShortMessageLength` property to be used with the other properties to define the RS code.

ShortMessageLength

Shortened message length

Specify the length of the shortened message as a double-precision positive integer scalar whose value must be less than or equal to `MessageLength`. The default is 3.

When `ShortMessageLength < MessageLength`, the RS code is shortened.

GeneratorPolynomialSource

Source of generator polynomial

Specify the source of the generator polynomial as `Auto` or `Property`. The default is `Auto`.

- When you set this property to `Auto`, the object chooses the generator polynomial automatically. The object calculates the generator polynomial based on the value of the `PrimitivePolynomial` property.
- When you set this property to `Property`, you must specify a generator polynomial using the `GeneratorPolynomial` property.

GeneratorPolynomial

Generator polynomial

Specify the generator polynomial for the RS code as a double-precision integer row vector or as a Galois row vector. The Galois field row vector entries must be in the range $[0, 2^M-1]$ and represent a generator polynomial in descending order of powers. Each coefficient is an element of the Galois field $gf(2^M)$, represented in integer format. The length of the generator polynomial must be `CodewordLength - MessageLength + 1`. The default is the result of `rsgenpoly(7,3,[],[], 'double')`, which corresponds to `[1 3 1 2 3]`.

This property applies when you set `GeneratorPolynomialSource` to `Property`.

CheckGeneratorPolynomial

Enable generator polynomial checking

Set this property to `true` to perform a generator polynomial check. The default is `true`.

This check verifies that $X^{\text{CodewordLength}} + 1$ is divisible by the generator polynomial specified in the `GeneratorPolynomial` property. For codes with generator polynomials of high degree, disabling the check speeds up processing. As a best practice, perform the check at least once before setting this property to `false`.

This property applies when `GeneratorPolynomialSource` is set to `Property`.

PrimitivePolynomialSource

Source of primitive polynomial

Specify the source of the primitive polynomial as `Auto` or `Property`. The default is `Auto`.

- When you set this property to `Auto`, the object uses a primitive polynomial of degree $M = \text{ceil}(\log_2(\text{CodewordLength}+1))$.
- When you set this property to `Property`, you must specify a polynomial using the `PrimitivePolynomial` property.

PrimitivePolynomial

Primitive polynomial

Specify the primitive polynomial that defines the finite field $gf(2^M)$ corresponding to the integers that form messages and codewords. Specify this property as a double-precision, binary row vector that represents a primitive polynomial over $gf(2)$ of degree M in descending order of powers.

If `CodewordLength` is less than 2^M-1 , the object uses a shortened RS code. The default is the result of `int2bit(primpoly(3),4)'`, which is `[1 0 1 1]` or the polynomial x^3+x+1 .

This property applies when you set `PrimitivePolynomialSource` to `Property`.

PuncturePatternSource

Source of puncture pattern

Specify the source of the puncture pattern as `None` or `Property`. The default is `None`.

- When you set this property to `None`, the object does not apply puncturing to the code.
- When you set this property to `Property`, the object punctures the code based on a puncture pattern vector specified in the `PuncturePattern` property.

PuncturePattern

Puncture pattern vector

Specify the pattern used to puncture the encoded data as a double-precision, binary column vector with a length of $(\text{CodewordLength} - \text{MessageLength})$. The default is `[ones(2,1); zeros(2,1)]`. Zeros in the puncture pattern vector indicate the position of the parity symbols that are punctured or excluded from each codeword.

This property applies when you set the `PuncturePatternSource` property to `Property`.

OutputDataType

Data type of output

Specify the output data type as `Same as input`, `double`, or `logical`. The default is `Same as input`.

This property applies when you set the `BitInput` property to `true`.

Methods

`step` Encode data using a Reed-Solomon encoder

Common to All System Objects	
<code>release</code>	Allow System object property value changes

Examples

Transmit an RS-Encoded, 8-DPSK-Modulated Symbol Stream

Transmit an RS-encoded, 8-DPSK-modulated symbol stream through an AWGN channel. Then, demodulate, decode, and count errors.

```
enc = comm.RSEncoder;
mod = comm.DPSKModulator('BitInput',false);
chan = comm.AWGNChannel(...
    'NoiseMethod','Signal to noise ratio (SNR)','SNR',10);
demod = comm.DPSKDemodulator('BitOutput',false);
hDdecec = comm.RSDecoder;
errorRate = comm.ErrorRate('ComputationDelay',3);
```

```

for counter = 1:20
    data = randi([0 7], 30, 1);
    encodedData = step(enc, data);
    modSignal = step(mod, encodedData);
    receivedSignal = step(chan, modSignal);
    demodSignal = step(demod, receivedSignal);
    receivedSymbols = step(hDdecec, demodSignal);
    errorStats = step(errorRate, data, receivedSymbols);
end

fprintf('Error rate = %f\nNumber of errors = %d\n', ...
        errorStats(1), errorStats(2))

Error rate = 0.115578
Number of errors = 69

```

Estimate BER of QPSK in AWGN with Reed-Solomon Coding

Transmit Reed-Solomon encoded data using QPSK over an AWGN channel. Demodulate and decode the received signal and collect error statistics. Compute theoretical bit error rate (BER) for coded and noncoded data. Plot the BER results to compare performance.

Define the example parameters.

```

rng(1993);      % Seed random number generator for repeatable results
M = 4;          % Modulation order
bps = log2(M); % Bits per symbol
N = 7;          % RS codeword length
K = 5;          % RS message length

```

Create modulator, demodulator, AWGN channel, and error rate objects.

```

pskModulator = comm.PSKModulator('ModulationOrder',M,'BitInput',true);
pskDemodulator = comm.PSKDemodulator('ModulationOrder',M,'BitOutput',true);
awgnChannel = comm.AWGNChannel('BitsPerSymbol',bps);
errorRate = comm.ErrorRate;

```

Create a (7,5) Reed-Solomon encoder and decoder pair which accepts bit inputs.

```

rsEncoder = comm.RSEncoder('BitInput',true,'CodewordLength',N,'MessageLength',K);
rsDecoder = comm.RSDecoder('BitInput',true,'CodewordLength',N,'MessageLength',K);

```

Set the range of E_b/N_0 values and account for RS coding gain. Initialize the error statistics matrix.

```

ebnoVec = (3:0.5:8)';
ebnoVecCodingGain = ebnoVec + 10*log10(K/N); % Account for RS coding gain
errorStats = zeros(length(ebnoVec),3);

```

Estimate the bit error rate for each E_b/N_0 value. The simulation runs until either 100 errors or 10^7 bits is encountered. The main simulation loop processing includes encoding, modulation, demodulation, and decoding.

```

for i = 1:length(ebnoVec)
    awgnChannel.EbNo = ebnoVecCodingGain(i);
    reset(errorRate)

```

```

while errorStats(i,2) < 100 && errorStats(i,3) < 1e7
    data = randi([0 1],1500,1);           % Generate binary data
    encData = rsEncoder(data);           % RS encode
    modData = pskModulator(encData);     % Modulate
    rxSig = awgnChannel(modData);        % Pass signal through AWGN
    rxData = pskDemodulator(rxSig);      % Demodulate
    decData = rsDecoder(rxData);         % RS decode
    errorStats(i,:) = errorRate(data,decData); % Collect error statistics
end
end

```

Fit a curve to the BER data using `berfit`. Generate an estimate of QPSK performance with and without coding using the `bercoding` and `berawgn` functions.

```

berCurveFit = berfit(ebnoVecCodingGain,errorStats(:,1));
berwCoding = bercoding(ebnoVec, 'RS', 'hard', N, K, 'psk', M, 'nondiff');
berNoCoding = berawgn(ebnoVec, 'psk', M, 'nondiff');

```

Plot the RS coded BER data, curve fit of the BER data, theoretical performance with RS coding, and theoretical performance without RS coding. The (7,5) RS code improves the E_b/N_0 required to achieve a 10^{-2} bit error rate by approximately 1.2 dB.

```

semilogy(ebnoVecCodingGain,errorStats(:,1), 'b*', ...
    ebnoVecCodingGain,berCurveFit, 'c-', ebnoVecCodingGain,berwCoding, 'r', ebnoVec,berNoCoding)
ylabel('BER')
xlabel('Eb/No (dB)')
legend('RS coded BER', 'Curve Fit', 'Theory with coding', 'Theory no coding')
grid

```

Transmit a Shortened RS-Encoded, 256-QAM-Modulated Symbol Stream

Transmit a shortened RS-encoded, 256-QAM-modulated symbol stream through an AWGN channel. Then demodulate, decode, and count errors.

Set the parameters for the Reed-Solomon code, where N is the codeword length, K is the nominal message length, and S is the shortened message length. Set the modulation order, M , and the number of frames, L .

```
N = 255;
K = 239;
S = 188;
M = 256;
L = 50;
```

Create an AWGN channel System object and an error rate System object.

```
awgnChan = comm.AWGNChannel('NoiseMethod','Signal to noise ratio (Eb/No)', ...
    'EbNo',15,'BitsPerSymbol',log2(M));
errorRate = comm.ErrorRate('ComputationDelay',3);
```

Create the Reed-Solomon generator polynomial from the DVB-T standard.

```
gp = rsgenpoly(N,K,[],0);
```

Create a Reed-Solomon encoder and decoder pair using the shortened message length, S , and the DVB-T generator polynomial, gp .

```
enc = comm.RSEncoder(N,K,gp,S);  
dec = comm.RSDecoder(N,K,gp,S);
```

Generate random symbol frames whose length equals one message block. Encode, modulate, apply AWGN, demodulate, decode, and collect statistics.

```
for counter = 1:L  
    data = randi([0 1],S,log2(M));  
    encodedData = step(enc,bi2de(data));  
    modSignal = qammod(encodedData,M,'UnitAveragePower',true);  
    rxSignal = awgnChan(modSignal);  
    demodSignal = qamdemod(rxSignal,M,'UnitAveragePower',true);  
    rxBits = dec(demodSignal);  
    dataOut = de2bi(rxBits);  
    errorStats = errorRate(data(:),dataOut(:));  
end
```

Display the error rate and number of errors.

```
fprintf('Error rate = %5.2e\nNumber of errors = %d\n', ...  
    errorStats(1), errorStats(2))
```

```
Error rate = 2.01e-02  
Number of errors = 1509
```

Reed-Solomon Coding with Erasures

This example shows how to configure the `comm.RSEncoder` and `comm.RSDecoder` System objects to perform Reed-Solomon (RS) block coding with erasures when simulating a communications system. RS decoders can correct both errors and erasures. A receiver that identifies the most unreliable symbols in a given codeword can generate erasures. When a receiver erases a symbol, it replaces that symbol with a zero. The receiver then passes a flag to the decoder, indicating that the symbol is an erasure, not a valid code symbol. In addition, an encoder can generate punctures for which specific parity symbols are always removed from its output. The decoder, which knows the puncture pattern, inserts zeros in the puncture positions and treats those symbols as erasures. The decoder treats encoder-generated punctures and receiver-generated erasures the exact same way when it decodes a symbol. Puncturing also has the added benefit of making the code rate more flexible, at the expense of some error correction capability. Shortened codes achieve the same code rate flexibility without degrading the error correction performance, given the same demodulator input energy per bit to noise power spectral density ratio (E_b/N_0). Note that puncturing is the removal of parity symbols from a codeword, and shortening is the removal of message symbols from a codeword.

This example shows the simulation of a communication system consisting of a random source, an RS encoder, a 64-QAM modulator, an AWGN channel, a 64-QAM demodulator, and an RS decoder. It includes analysis of RS coding with erasures by comparing the channel bit error rate (BER) performance versus the coded BER performance. This example obtains Channel BER by comparing inputs for the QAM modulator to outputs from the QAM demodulator and obtains Coded BER by comparing inputs for the RS encoder to outputs from the RS decoder.

Initialization

The `helperRSCodingConfig.m` helper function initializes simulation parameters, and configures the `comm.AWGNChannel` and `comm.ErrorRate` System objects used to simulate the communications system. The uncoded E_b/N_0 ratio is set $E_bNoUncoded = 15$ dB. Criteria to stop the simulation are defined to stop the simulation if 500 errors occur or a maximum $5e6$ bits are transmitted.

```
helperRSCodingConfig;
```

Configure RS Encoder/Decoder

This example uses a (63,53) RS code operating with a 64-QAM modulation scheme. This code can correct $(63-53)/2 = 5$ errors, or it can alternatively correct $(63-53) = 10$ erasures. For each codeword at the output of the 64-QAM demodulator, the receiver determines the six least reliable symbols using the `helperRSCodingGetErasures.m` helper function. The indices that point to the location of these unreliable symbols are passed as an input to the RS decoder. The RS decoder treats these symbols as erasures resulting in an error correction capability of $(10-6)/2 = 2$ errors per codeword.

Create a `comm.RSEncoder` System object and set the `BitInput` property to false to specify that the encoder inputs and outputs are integer symbols.

```
N = 63; % Codeword length
K = 53; % Message length
rsEncoder = comm.RSEncoder(N,K, 'BitInput', false);
numErasures = 6;
```

Create a `comm.RSDecoder` System object matching the configuration of the `comm.RSEncoder` object.

```
rsDecoder = comm.RSDecoder(N,K, 'BitInput', false);
```

Set the `ErasuresInputPort` property to true to specify erasures as an input to the decoder object.

```
rsDecoder.ErasuresInputPort = true;
```

Set the `NumCorrectedErrorsOutputPort` property to true so that the decoder outputs the number of corrected errors. A non negative value in the error output denotes the number of corrected errors in the input codeword. A value of -1 in the error output indicates a decoding error. A decoding error occurs when the input codeword has more errors than the error correction capability of the RS code.

```
rsDecoder.NumCorrectedErrorsOutputPort = true;
```

Run Stream Processing Loop

Simulate the communications system for an uncoded E_b/N_0 ratio of 15 dB. The uncoded E_b/N_0 is the ratio that would be measured at the input of the channel if there was no coding in the system.

The signal going into the AWGN channel is the encoded signal, so you must convert the uncoded E_b/N_0 values so that they correspond to the energy ratio at the encoder output. This ratio is the coded E_b/N_0 ratio. If you input K symbols to the encoder and obtain N output symbols, then the energy relation is given by the K/N rate. Set the `EbNo` property of the AWGN channel object to the computed coded E_b/N_0 value.

```
EbNoCoded = EbNoUncoded + 10*log10(K/N);
channel.EbNo = EbNoCoded;
```

Loop until the simulation reaches the target number of errors or the maximum number of transmissions.

```
chanErrorStats = zeros(3,1);
codedErrorStats = zeros(3,1);
correctedErrors = 0;
while (codedErrorStats(2) < targetErrors) && ...
    (codedErrorStats(3) < maxNumTransmissions)
```

The data symbols transmit one message word at a time. Each message word has K symbols in the $[0 N]$ range.

```
data = randi([0 N],K,1);
```

Encode the message word. The encoded word, `encData`, is $(N - \text{numPunc})$ symbols long.

```
encData = rsEncoder(data);
```

Modulate encoded data and add noise. Then demodulate channel output.

```
modData = qammod(encData,M);
chanOutput = channel(modData);
demodData = qamdemod(chanOutput,M);
```

Use the `helperRSCodingGetErasures.m` helper function to find the 6 least reliable symbols and generate an erasures vector. The length of the erasures vector must be equal to the number of symbols in the demodulated codeword. A one in the i th element of the vector erases the i th symbol in the codeword. Zeros in the vector indicate no erasures.

```
erasuresVec = helperRSCodingGetErasures(chanOutput,numErasures);
```

Decode the data. Log the number of errors corrected by the RS decoder.

```
[estData,errs] = rsDecoder(demodData,erasuresVec);
if (errs >= 0)
    correctedErrors = correctedErrors + errs;
end
```

When computing the channel and coded BERs, convert integers to bits.

```
chanErrorStats(:,1) = ...
    chanBERCalc(reshape(de2bi(encData,log2(M))',[],1),reshape(de2bi(demodData,log2(M))',[],1));
codedErrorStats(:,1) = ...
    codedBERCalc(reshape(de2bi(data,log2(M))',[],1),reshape(de2bi(estData,log2(M))',[],1));
end
```

The error rate measurement objects, `chanBERCalc` and `codedBERCalc`, output 3-by-1 vectors containing BER measurement updates, the number of errors, and the total number of bit transmissions. Display the channel BER, the coded BER and the total number of errors corrected by the RS decoder.

```
chanBitErrorRate = chanErrorStats(1)

chanBitErrorRate = 0.0017

codedBitErrorRate = codedErrorStats(1)

codedBitErrorRate = 0
```

```
totalCorrectedErrors = correctedErrors
```

```
totalCorrectedErrors = 882
```

You can add a for loop around the processing loop above to run simulations for a set of E_b/N_0 values. Simulations were run offline for uncoded E_b/N_0 values in 4:15 dB, target number of errors equal to 5000, and maximum number of transmissions equal to 50e6. The results from the simulation are shown. The channel BER is worse than the theoretical 64-QAM BER because E_b/N_0 is reduced by the code rate.

Summary

This example utilized several System objects to simulate a 64-QAM communications system over an AWGN channel with RS block coding. It showed how to configure the RS decoder to decode symbols with erasures. System performance was measured using channel and coded BER curves obtained using error rate measurement System objects.

Helper functions used in this example:

- helperRSCodingConfig.m
- helperRSCodingGetErasures.m

Reed-Solomon Coding with Erasures and Punctures

This example shows how to configure the `comm.RSEncoder` and `comm.RSDecoder` System objects to perform Reed-Solomon (RS) block coding with erasures and puncture codes when simulating a communications system. An encoder can generate punctures to remove specific parity symbols from its output. Given the puncture pattern, the decoder inserts zeros in the puncture positions and treats those symbols as erasures. The decoder treats encoder-generated punctures and receiver-generated erasures in exactly the same way when it decodes. Puncturing has the added benefit of making the code rate more flexible, at the expense of some error correction capability.

This example shows the simulation of a communication system consisting of a random source, an RS encoder, a 64-QAM modulator, an AWGN channel, a 64-QAM demodulator, and an RS decoder. It includes analysis of RS coding with erasures and puncturing by comparing the channel bit error rate (BER) performance versus the coded BER performance. This example obtains Channel BER by comparing inputs for the QAM modulator to outputs from the QAM demodulator. This example obtains Coded BER by comparing inputs for the RS encoder to outputs from the RS decoder.

Initialization

The `helperRSCodingConfig.m` helper function initializes simulation parameters, and configures the `comm.AWGNChannel` and `comm.ErrorRate` System objects used to simulate the communications system. The uncoded E_b/N_0 ratio, `EbNoUncoded` is set to 15 dB. Criteria to stop the simulation stop are defined to stop the simulation if 500 errors occur or a maximum 5×10^6 bits are transmitted.

```
helperRSCodingConfig;
```

Configure RS Encoder/Decoder

This example uses the same (63,53) RS code operating with a 64-QAM modulation scheme that is configured for erasures and code puncturing. The RS algorithm decodes receiver-generated erasures and corrects encoder-generated punctures. For each codeword, the sum of the punctures and erasures cannot exceed twice the error-correcting capability of the code.

Create a `comm.RSEncoder` System object and set the `BitInput` property to false to specify that the encoder inputs and outputs are integer symbols.

```
N = 63; % Codeword length
K = 53; % Message length
rsEncoder = comm.RSEncoder(N,K,'BitInput',false);
numErasures = 6;
```

Create a `comm.RSDecoder` System object matching the configuration of the `comm.RSEncoder` object. Then set the `ErasuresInputPort` property to true to specify erasures as an input to the decoder object.

```
rsDecoder = comm.RSDecoder(N,K,'BitInput',false);
rsDecoder.ErasuresInputPort = true;
```

To enable code puncturing, set the `PuncturePatternSource` property to 'Property' and set the `PuncturePattern` property to the desired puncture pattern vector. The same puncture vector must be specified in both the encoder and decoder. This example punctures two symbols from each codeword. Values of 1 in the puncture pattern vector indicate nonpunctured symbols, and values of 0 indicate punctured symbols.

```
numPuncs = 2;
rsEnc.PuncturePatternSource = 'Property';
```

```
rsEnc.PuncturePattern = [ones(N-K-numPuncs,1); zeros(numPuncs,1)];
rsDec.PuncturePatternSource = 'Property';
rsDec.PuncturePattern = rsEnc.PuncturePattern;
```

Run Stream Processing Loop

Simulate the communications system for an uncoded E_b/N_0 ratio of 15 dB. The uncoded E_b/N_0 is the ratio that would be measured at the input of the channel if there was no coding in the system.

The signal going into the AWGN channel is the encoded signal, so you must convert the uncoded E_b/N_0 values so that they correspond to the energy ratio at the encoder output. This ratio is the coded E_b/N_0 ratio. If you input K symbols to the encoder and obtain N output symbols, then the energy relation is given by the K/N rate. Since the length of the codewords generated by the RS encoder is reduced by the number of punctures specified in the puncture pattern vector, the value of the coded E_b/N_0 ratio needs to be adjusted to account for these punctures. In this example, The number of output symbols is $(N - \text{numPuncs})$ and the uncoded E_b/N_0 ratio relates to the coded E_b/N_0 as shown below. Set the `EbNo` property of the AWGN channel object to the computed coded E_b/N_0 value.

```
EbNoCoded = EbNoUncoded + 10*log10(K/(N - numPuncs));
channel.EbNo = EbNoCoded;
```

Loop until the simulation reaches the target number of errors or the maximum number of transmissions.

```
chanErrorStats = zeros(3,1);
codedErrorStats = zeros(3,1);
correctedErrors = 0;
while (codedErrorStats(2) < targetErrors) && ...
    (codedErrorStats(3) < maxNumTransmissions)
```

The data symbols transmit one message word at a time. Each message word has K symbols in the $[0 N]$ range.

```
data = randi([0 N],K,1);
```

Encode the message word. The encoded word, `encData`, is $(N - \text{numPunc})$ symbols long.

```
encData = rsEncoder(data);
```

Modulate encoded data and add noise. Then demodulate channel output.

```
modData = qammod(encData,M);
chanOutput = channel(modData);
demodData = qamdemod(chanOutput,M);
```

Use the `helperRSCodingGetErasures.m` helper function to find the 6 least reliable symbols and generate an erasures vector. The length of the erasures vector must be equal to the number of symbols in the demodulated codeword. A one in the i th element of the vector erases the i th symbol in the codeword. Zeros in the vector indicate no erasures.

```
erasuresVec = helperRSCodingGetErasures(chanOutput,numErasures);
```

Decode the data. Log the number of errors corrected by the RS decoder.

```
[estData,errs] = rsDecoder(demodData,erasuresVec);  
if (errs >= 0)  
    correctedErrors = correctedErrors+errs;  
end
```

When computing the channel and coded BERs, convert integers to bits.

```
chanErrorStats(:,1) = ...  
    chanBERCalc(reshape(de2bi(encData,log2(M))',[],1),reshape(de2bi(demodData,log2(M))',[],1),1);  
codedErrorStats(:,1) = ...  
    codedBERCalc(reshape(de2bi(data,log2(M))',[],1),reshape(de2bi(estData,log2(M))',[],1));  
end
```

The error rate measurement objects, `chanBERCalc` and `codedBERCalc`, output 3-by-1 vectors containing BER measurement updates, the number of errors, and the total number of bit transmissions. Display the channel BER, the coded BER and the total number of errors corrected by the RS decoder.

```
chanBitErrorRate = chanErrorStats(1)  
chanBitErrorRate = 0.0015  
codedBitErrorRate = codedErrorStats(1)  
codedBitErrorRate = 0  
totalCorrectedErrors = correctedErrors  
totalCorrectedErrors = 632
```

You can add a for loop around the processing loop above to run simulations for a set of E_b/N_0 values. Simulations were run offline for uncoded E_b/N_0 values in 4:15 dB, target number of errors equal to 5000, and maximum number of transmissions equal to 50×10^6 . This figure compares results achieved for

- RS coding with only erasures
- RS coding with erasures and puncturing
- Theoretical BER for 64-QAM

The coded E_b/N_0 is slightly higher than the channel E_b/N_0 , so the channel BER is slightly better in the punctured case. On the other hand, the coded BER is worse in the punctured case, because the two punctures reduce the error correcting capability of the code by one, leaving it able to correct only $(10 - 6 - 2) / 2 = 1$ error per codeword.

Summary

This example utilized functions and System objects to simulate a 64-QAM communications system over an AWGN channel with RS block coding. It showed how to configure the RS encoder/decoder System objects to obtain punctured codes. System performance was measured using channel and coded BER curves obtained using error rate measurement System objects.

Helper functions used in this example:

- helperRSCodingConfig.m
- helperRSCodingGetErasures.m

Reed-Solomon Coding with Erasures, Punctures, and Shortening

This example shows how to configure the `comm.RSEncoder` and `comm.RSDecoder` System objects to perform Reed-Solomon (RS) block coding to shorten the (63,53) code to a (28,18) code. The simulation of a communication system consisting of a random source, an RS encoder, a 64-QAM modulator, an AWGN channel, a 64-QAM demodulator, and an RS decoder is presented.

The effects of RS coding with erasures, puncturing, and shortening are analyzed by comparing the channel bit error rate (BER) performance versus the coded BER performance. This example obtains Channel BER by comparing inputs for the QAM modulator to outputs from the QAM demodulator and obtains Coded BER by comparing inputs for the RS encoder to outputs from the RS decoder. Puncturing is the removal of parity symbols from a codeword, and shortening is the removal of

message symbols from a codeword. Puncturing has the benefit of making the code rate more flexible, at the expense of some error correction capability. Shortened codes achieve the same code rate flexibility without degrading the error correction performance for the same demodulator input E_b/N_0 .

Initialization

The `helperRSCodingConfig.m` helper function initializes simulation parameters, and configures the `comm.AWGNChannel` and `comm.ErrorRate` System objects used to simulate the communications system. The uncoded E_b/N_0 ratio is set `EbNoUncoded = 15 dB`. Criteria to stop the simulation stop are defined to stop the simulation if 500 errors occur or a maximum 5×10^6 bits are transmitted.

```
helperRSCodingConfig;
```

Configure RS Encoder/Decoder

This example uses a (63,53) RS code operating with a 64-QAM modulation scheme. The RS coding operation includes erasures, puncturing, and code shortening. This example shows how to shorten the (63,53) code to a (28,18) code.

To shorten a (63,53) code by 10 symbols to a (53,43) code, you can simply enter 53 and 43 for the `CodewordLength` and `MessageLength` properties, respectively (since $2\lceil\log_2(53 + 1)\rceil - 1 = 63$). However, to shorten it by 35 symbols to a (28,18) code, you must explicitly specify that the symbols belong to the Galois field $GF(2^6)$. Otherwise, the RS blocks will assume that the code is shortened from a (31,21) code (since $2\lceil\log_2(28 + 1)\rceil - 1 = 31$).

Create a pair of `comm.RSEncoder` and `comm.RSDecoder` System objects so that they perform block coding with a (28,18) code shortened from a (63,53) code that is configured to input and output integer symbols. Configure the decoder to accept an erasure input and two punctures. For each codeword at the output of the 64-QAM demodulator, the receiver determines the six least reliable symbols using the `helperRSCodingGetErasures.m` helper function. The indices that point to the location of these unreliable symbols are passed as an input to the RS decoder.

```
N = 63; % Codeword length
K = 53; % Message length
S = 18; % Shortened message length
numErasures = 6;
numPuncs = 2;
rsEncoder = comm.RSEncoder(N, K, 'BitInput', false);
rsDecoder = comm.RSDecoder(N, K, 'BitInput', false, 'ErasuresInputPort', true);
rsEncoder.PuncturePatternSource = 'Property';
rsEncoder.PuncturePattern = [ones(N-K-numPuncs,1); zeros(numPuncs,1)];
rsDecoder.PuncturePatternSource = 'Property';
rsDecoder.PuncturePattern = rsEncoder.PuncturePattern;
```

Set the shortened codeword length and message length values.

```
rsEncoder.ShortMessageLength = S;
rsDecoder.ShortMessageLength = S;
```

Specify the field of $GF(2^6)$ in the RS encoder/decoder System objects, by setting the `PrimitivePolynomialSource` property to 'Property' and the `PrimitivePolynomial` property to a 6th degree primitive polynomial.

```
primPolyDegree = 6;
rsEncoder.PrimitivePolynomialSource = 'Property';
```

```
rsEncoder.PrimitivePolynomial = de2bi(primpoly(primPolyDegree, 'nodisplay'), 'left-msb');
rsDecoder.PrimitivePolynomialSource = 'Property';
rsDecoder.PrimitivePolynomial = de2bi(primpoly(primPolyDegree, 'nodisplay'), 'left-msb');
```

Run Stream Processing Loop

Simulate the communications system for an uncoded E_b/N_0 ratio of 15 dB. The uncoded E_b/N_0 is the ratio that would be measured at the input of the channel if there was no coding in the system.

The signal going into the AWGN channel is the encoded signal, so you must convert the uncoded E_b/N_0 values so that they correspond to the energy ratio at the encoder output. This ratio is the coded E_b/N_0 ratio. If you input K symbols to the encoder and obtain N output symbols, then the energy relation is given by the K/N rate. The value of the coded E_b/N_0 ratio needs to be adjusted to account for shortened and punctured codewords. The number of output symbols is $(N - \text{numPuncs} - S)$ and the uncoded E_b/N_0 ratio relates to the coded E_b/N_0 as shown below. Set the `EbNo` property of the AWGN channel object to the computed coded E_b/N_0 value.

```
EbNoCoded = EbNoUncoded + 10*log10(S/(N - numPuncs - K + S));
channel.EbNo = EbNoCoded;
```

Loop until the simulation reaches the target number of errors or the maximum number of transmissions.

```
chanErrorStats = zeros(3,1);
codedErrorStats = zeros(3,1);
correctedErrors = 0;
while (codedErrorStats(2) < targetErrors) && ...
    (codedErrorStats(3) < maxNumTransmissions)
```

The data symbols transmit one message word at a time. Each message word has $K-S$ symbols in the $[0, 2^{\text{primPolyDegree}}-1]$ range.

```
data = randi([0 2^primPolyDegree-1], S, 1);
```

Encode the shortened message word. The encoded word `encData` is $(N - \text{numPuncs} - S)$ symbols long.

```
encData = rsEncoder(data);
```

Modulate encoded data and add noise. Then demodulate channel output.

```
modData = qammod(encData, M);
chanOutput = channel(modData);
demodData = qamdemod(chanOutput, M);
```

Use the `helperRSCodingGetErasures.m` helper function to find the 6 least reliable symbols and generate an erasures vector. The length of the erasures vector must be equal to the number of symbols in the demodulated codeword. A one in the i th element of the vector erases the i th symbol in the codeword. Zeros in the vector indicate no erasures.

```
erasuresVec = helperRSCodingGetErasures(chanOutput, numErasures);
```

Decode the data. Log the number of errors corrected by the RS decoder.

```
[estData, errs] = rsDecoder(demodData, erasuresVec);
if (errs >= 0)
```

```
        correctedErrors = correctedErrors + errs;
    end
```

When computing the channel and coded BERs, convert integers to bits.

```
    chanErrorStats(:,1) = ...
        chanBERCalc(reshape(de2bi(encData,log2(M))',[],1), ...
            reshape(de2bi(demodData,log2(M))',[],1));
    codedErrorStats(:,1) = ...
        codedBERCalc(reshape(de2bi(data,log2(M))',[],1), ...
            reshape(de2bi(estData,log2(M))',[],1));
end
```

The error rate measurement objects, `chanBERCalc` and `codedBERCalc`, output 3-by-1 vectors containing BER measurement updates, the number of errors, and the total number of bit transmissions. Display the channel BER, the coded BER, and the total number of errors corrected by the RS decoder.

```
chanBitErrorRate = chanErrorStats(1)
chanBitErrorRate = 0.0036
codedBitErrorRate = codedErrorStats(1)
codedBitErrorRate = 9.6599e-05
totalCorrectedErrors = correctedErrors
totalCorrectedErrors = 1436
```

You can add a for loop around the processing loop above to run simulations for a set of E_b/N_0 values. Simulations were run offline for uncoded E_b/N_0 values in 4:15 dB, target number of errors equal to 5000, and maximum number of transmissions equal to 50×10^6 . This figure compares results achieved for

- RS coding with only erasures
- RS coding with erasures and puncturing
- RS coding with erasures, puncturing, and shortening
- Theoretical BER for 64-QAM

The channel BER with shortening because the coded E_b/N_0 is degraded. This degraded coded E_b/N_0 occurs because the code rate of the shortened code is lower than that of the nonshortened code. Shortening also results in degraded coded BER, most noticeably at lower E_b/N_0 values.

Summary

This example utilized several System objects to simulate a 64-QAM communications system over an AWGN channel with a shortened RS block code. It showed how to configure the RS decoder to shorten a (63,53) code to a (28,18) code. System performance was measured using channel and coded BER curves obtained using error rate measurement System objects.

Helper functions used in this example:

- `helperRSCodingConfig.m`
- `helperRSCodingGetErasures.m`

Algorithms

This object implements the algorithm, inputs, and outputs described in "Algorithms for BCH and RS Errors-only Decoding".

Topics

“Reed-Solomon Codes”

Introduced in R2012a

step

System object: comm.RSEncoder

Package: comm

Encode data using a Reed-Solomon encoder

Syntax

$Y = \text{step}(H,X)$

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, $y = \text{step}(\text{obj}, x)$ and $y = \text{obj}(x)$ perform equivalent operations.

$Y = \text{step}(H,X)$ encodes the numeric column input data vector, X , and returns the encoded data, Y . The value of the `BitInput` property determines whether X is a vector of integers or bits with a numeric, logical, or fixed-point data type. The input and output length of the `step` function equal the values listed in the table in “Input and Output Signal Lengths in BCH and RS System Objects” on page 3-94.

Note `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications. For more information on changing property values, see “System Design in MATLAB Using System Objects”.

comm.SampleRateOffset

Package: comm

Apply sample rate offset to signal

Description

The `comm.SampleRateOffset` System object applies a sample rate offset to the input signal. Applying a sample rate offset is equivalent to changing the ADC clock rate.

To apply a sample rate offset to a signal:

- 1 Create the `comm.SampleRateOffset` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

Creation

Syntax

```
sro = comm.SampleRateOffset  
sro = comm.SampleRateOffset(offset)  
sro = comm.SampleRateOffset(Offset=offset)
```

Description

`sro = comm.SampleRateOffset` creates a sample rate offset System object.

`sro = comm.SampleRateOffset(offset)` sets the `Offset` property to the value of the `offset` input argument.

`sro = comm.SampleRateOffset(Offset=offset)` sets the `Offset` property to the value specified by `offset`.

Properties

Offset — Sample rate offset

10 (default) | scalar

Sample rate offset in parts per million (ppm), specified as a scalar greater than $-1e6$.

Data Types: double

Usage

Syntax

```
y = sro(x)
```

Description

`y = sro(x)` applies the sample rate offset configured by `sro` to the input signal and returns the resulting signal.

Input Arguments

x — Input signal

scalar | vector | matrix

Input signal, specified as a scalar, an N_S element column vector, or an N_S -by- N_C matrix. N_S is the number of time samples. N_C is the number of channels. For matrix input signals, the sample rate offset is applied independently to each column.

Data Types: double | single

Complex Number Support: Yes

Output Arguments

y — Output signal

scalar | vector | matrix

Output signal, returned as a scalar or matrix with the same dimension and data type as input signal `x`.

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Common to All System Objects

<code>step</code>	Run System object algorithm
<code>release</code>	Release resources and allow changes to System object property values and input characteristics
<code>reset</code>	Reset internal states of System object

Examples

Apply Sample Rate Offset to 16-QAM Signal

Set parameters and an input signal.

```
M = 16;                % Modulation order
offset = 50;           % Parts per million
```

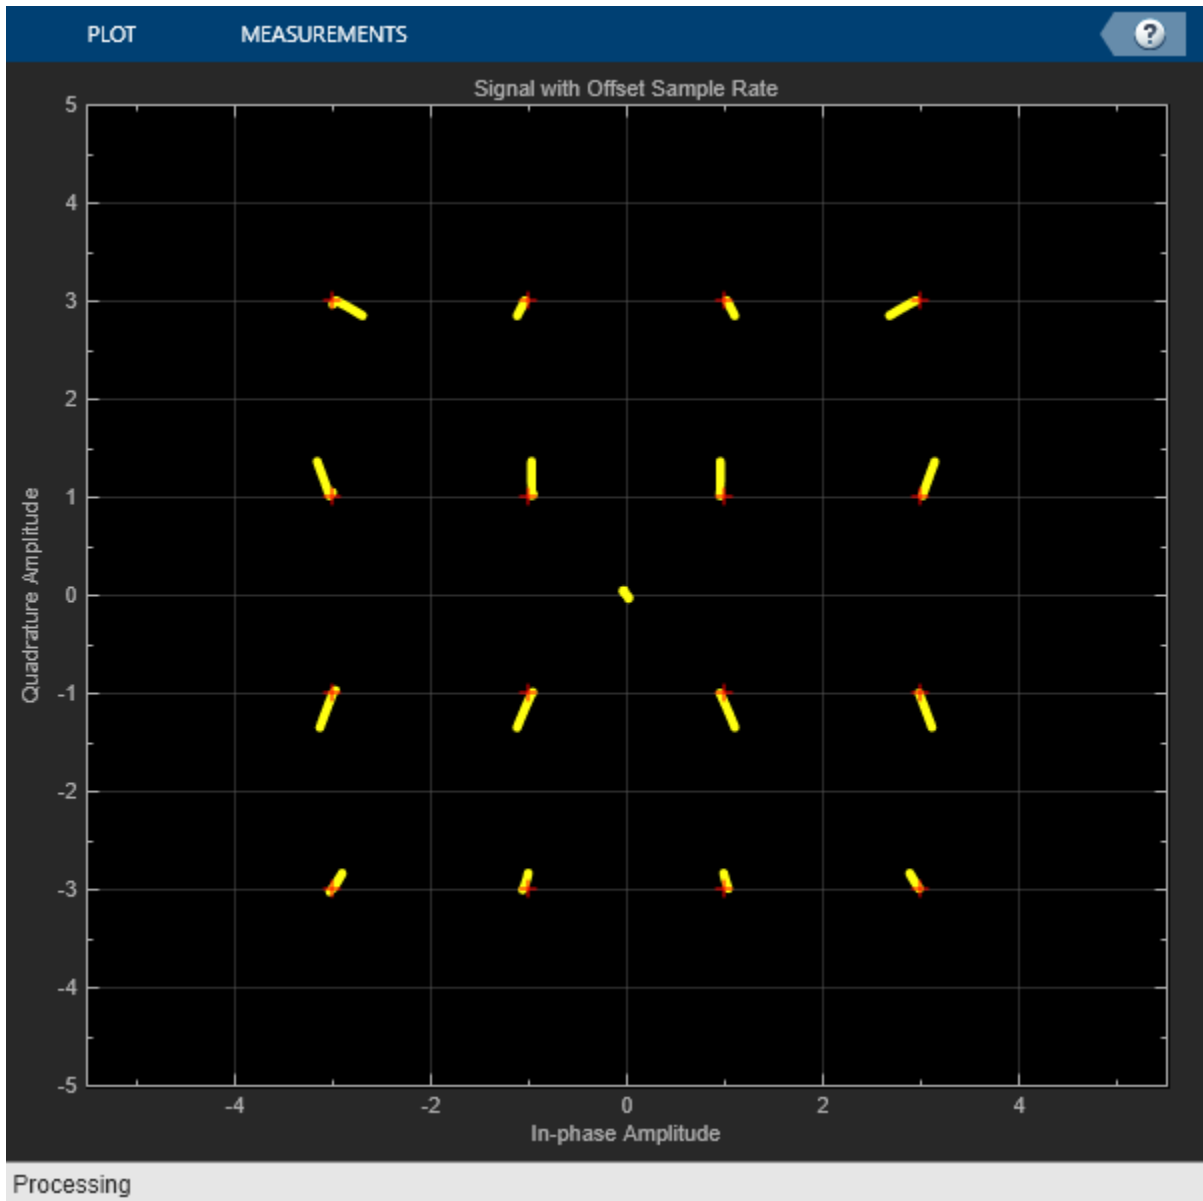

```
data = (0:M-1)';           % Input signal
refconst = qammod(data,M); % Reference constellation points
```

Create sample rate offset and constellation diagram System objects.

```
sro = comm.SampleRateOffset(offset);
constdiagram = comm.ConstellationDiagram( ...
    'ReferenceConstellation',refconst, ...
    'XLimits',[-5 5], ...
    'YLimits',[-5 5], ...
    'Title','Signal with Offset Sample Rate');
```

Apply 16-QAM modulation to random data, and then apply a sample rate offset to the modulated signal. Plot the reference constellation and the signal with offset sample rate offset.

```
modData = qammod(repmat(data,100,1),M);
impairedData = sro(modData);
constdiagram(impairedData)
```

Apply Sample Rate Offset to Sine Wave

Apply sample rate offsets to a 30 kHz single tone sine wave. Confirm the offset by computing the frequency difference between the transmitted tone and the received tone after applying positive and negative sample rate offsets.

Generate a single tone at 30 kHz.

```
f = 30e3;
samplerate = 100e3;
src = dsp.SineWave('Frequency',f, ...
    'SampleRate',samplerate, ...
```

```
    'SamplesPerFrame',10000, ...  
    'ComplexOutput',true);  
txsig = src();
```

Verify the frequency of the tone.

```
freqtx = samplerate * ...  
    (mean(angle(txsig(2:end) ./ txsig(1:end-1)))/(2*pi))  
  
freqtx = 3.0000e+04
```

Apply a sample rate offset of 20 ppm to the transmission tone (txsig). Increasing the sample rate offset is equivalent to increasing the ADC clock rate.

```
sro = comm.SampleRateOffset(20);  
rxsig = sro(txsig);
```

Find the frequency of the received tone (rxsig) after offsetting the sample rate. To skip samples with transient effects, ignore the first 100 samples.

```
freqrx = samplerate * ...  
    (mean(angle(rxsig(101:end) ./ rxsig(100:end-1)))/(2*pi))  
  
freqrx = 2.9999e+04
```

Increasing the ADC clock rate, decreases the frequency of the received tone. To show that the frequency of the received tone decreases by approximately 20 ppm, compare the frequency of the transmitted tone to the frequency of the received tone.

```
freqchangeppm = (freqrx-freqtx)/freqtx*1e6  
  
freqchangeppm = -19.9365
```

Apply a sample rate offset of -30 ppm to the transmission tone (txsig). Decreasing the sample rate offset is equivalent to decreasing the ADC clock rate.

```
sro = comm.SampleRateOffset(-30);  
rxsig = sro(txsig);
```

Find the frequency of the received tone (rxsig) after offsetting the sample rate. To skip samples with transient effects, ignore the first 100 samples.

```
freqrx = samplerate * ...  
    (mean(angle(rxsig(101:end) ./ rxsig(100:end-1)))/(2*pi))  
  
freqrx = 3.0001e+04
```

Decreasing the ADC clock rate, increases the frequency of the received tone. To show that the frequency of the received tone increases by approximately 30 ppm, compare the frequency of the transmitted tone to the frequency of the received tone.

```
freqchangeppm = (freqrx-freqtx)/freqtx*1e6  
  
freqchangeppm = 30.0736
```

Display Impact of Sample Rate Offset on Received QPSK Signal

Display the effects of a sample rate offset in the receiver on a QPSK signal.

Transmit frames containing a fixed preamble and random payload. In the receiver, use the preamble to find the beginning of a frame, and then demodulate the payload and measure the EVM. With a constant nonzero sample rate offset, the EVM varies from frame to frame with a consistent periodicity.

Initialize configuration parameters and create pulse-shaping filter objects for the transmitter and receiver.

```
numFrames = 200;
numSymbolsPerFrame = 4096;
preambleLength = 64;
payloadLength = numSymbolsPerFrame - preambleLength;
modulationOrder = 4;

rolloff = 0.2;
filterSpan = 10;
samplesPerSymbol = 8;
txFilter = comm.RaisedCosineTransmitFilter(RolloffFactor=rolloff, ...
    FilterSpanInSymbols=filterSpan, ...
    OutputSamplesPerSymbol=samplesPerSymbol);
rxFilter = comm.RaisedCosineReceiveFilter(RolloffFactor=rolloff, ...
    FilterSpanInSymbols=filterSpan, ...
    InputSamplesPerSymbol=samplesPerSymbol,DecimationFactor=1);
```

Use a Gold sequence for the preamble. Map the Gold sequence to $0.7071 + 0.7071i$ and $-0.7071 - 0.7071i$ in the QPSK constellation.

```
goldSeq = comm.GoldSequence(SamplesPerFrame=preambleLength);
preamble = goldSeq();
preamble(preamble==1)=2;
preambleModOut = pskmod(preamble,modulationOrder,pi/modulationOrder);
```

Generate a time-domain reference signal for the preamble.

```
preambleRefDelayed = rxFilter( ...
    txFilter([preambleModOut;zeros(filterSpan,1)]));
preambleRef = preambleRefDelayed( ...
    filterSpan*samplesPerSymbol+(1:samplesPerSymbol*preambleLength));
```

Generate a random payload and transmit signal.

```
txPayload = pskmod( ...
    randi([0 modulationOrder-1],payloadLength,numFrames), ...
    modulationOrder, ...
    pi/modulationOrder);
txFrames = reshape([ repmat(preambleModOut,1,numFrames);txPayload],[],1);
txSig = txFilter([txFrames;zeros(payloadLength,1)]);
```

Apply a 0.8 ppm sample rate offset to the received signal.

```
simulatedSRO = 0.8;
sro = comm.SampleRateOffset(simulatedSRO);
rxSig = rxFilter(sro(txSig));
```

Use a matched filter to find the preamble.

```
matchedFilterResponse = conj(flipud(preambleRef));
matchedFilterOutMag = abs(filter(matchedFilterResponse,1,rxSig));
```

Find the peak locations and plot the first ten peaks.

```
threshold = max(matchedFilterOutMag)*0.7;
[~, peakLocations] = findpeaks(matchedFilterOutMag, ...
    MinPeakHeight=threshold, ...
    MinPeakDistance=preambleLength*samplesPerSymbol);
plot(matchedFilterOutMag)
title('Matched Filter Output (Magnitude)')
xlabel('Sample')
axis([0 numSymbolsPerFrame*samplesPerSymbol*10 ...
    -0.15*max(matchedFilterOutMag) 1.25*max(matchedFilterOutMag)]);
grid on
```

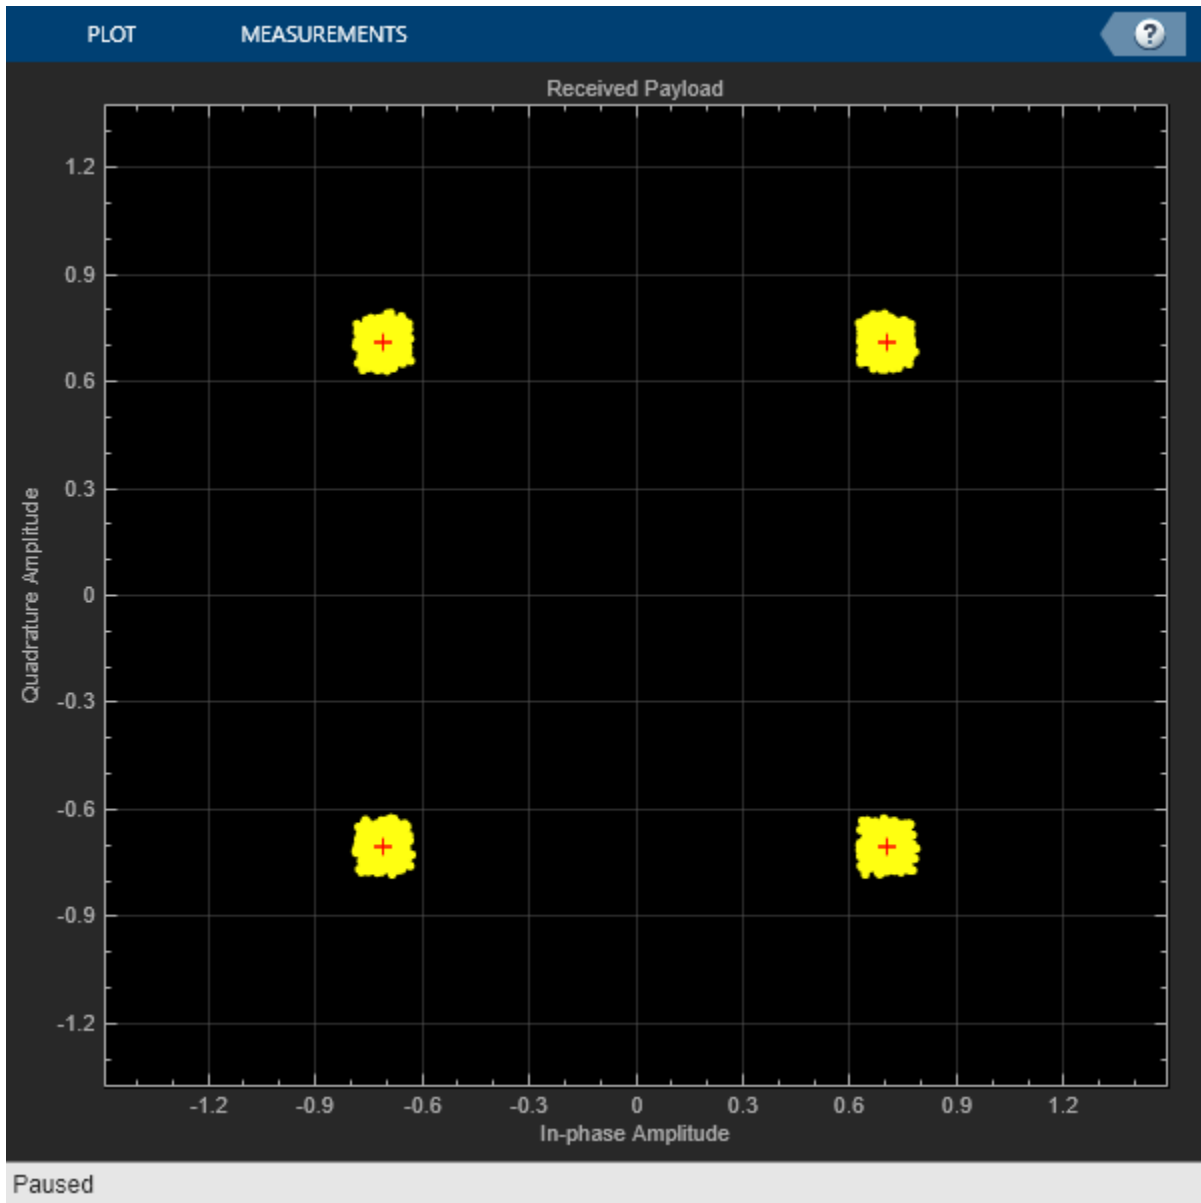

Locate the frames and examine the received data by plotting the computed EVM value and the received signal constellation. Estimate the sample rate offset. For a more accurate estimate, you can increase the number of transmitted frames.

```
frameDelay = peakLocations - length(preambleRef);
constDiag = comm.ConstellationDiagram(Title='Received Payload', ...
    Position=[20 70 600 600]);
evm = comm.EVM;
evmScope = timescope(TimeUnits='none',TimeSpan=length(frameDelay), ...
    YLabel='EVM (%)',YLimits=[0 15],TimeAxisLabels='none', ...
```

```
Position=[650 120 800 500]);  
for i = 1:length(frameDelay)  
    rxFrame = rxSig(frameDelay(i) + ...  
        (1:samplesPerSymbol:numSymbolsPerFrame*samplesPerSymbol));  
    evmScope(evm(txPayload(:,i),rxFrame(preambleLength+1:end)));  
    constDiag(rxFrame(preambleLength+1:end));  
    pause(0.1)  
end
```

```

peakSpacings = diff(peakLocations);
nominalPeakSpacing = numSymbolsPerFrame*samplesPerSymbol;
estimatedSR0 = (mean(peakSpacings)/nominalPeakSpacing-1)*1e6

estimatedSR0 = 0.7668

```

comm.Scrambler

Package: comm

Scramble input signal

Description

The comm.Scrambler object scrambles a scalar or column vector input signal.

This schematic shows the scrambler operation. The adders operate modulo N , where N is the value specified by the Calculation base property.

At each time step, the input causes the contents of the registers to shift sequentially. Using the Polynomial property, you specify the on or off state for each switch in the scrambler.

To scramble an input signal:

- 1 Create the comm.Scrambler object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

Creation

Syntax

```
scrambler = comm.Scrambler
scrambler = comm.Scrambler(base,poly,cond)
scrambler = comm.Scrambler( ___,Name,Value)
```

Description

`scrambler = comm.Scrambler` creates a scrambler System object. This object scrambles the input data by using a linear feedback shift register that you specify with the Polynomial property.

`scrambler = comm.Scrambler(base,poly,cond)` creates the scrambler object with the CalculationBase property set to `base`, the Polynomial property set to `poly`, and the InitialConditions property set to `cond`.

Example: `comm.Scrambler(8, '1 + z^-2 + z^-3 + z^-5 + z^-7', [0 3 2 2 5 1 7])` sets the calculation base to 8, and the scrambler polynomial and initial conditions as specified.

`scrambler = comm.Scrambler(___, Name, Value)` sets properties using one or more name-value pairs and either of the previous syntaxes. Enclose each property name in single quotes.

Example: `comm.Scrambler('CalculationBase', 2)`

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects.

CalculationBase — Range of input data

4 (default) | nonnegative integer

Range of input data used in the scrambler for modulo operations, specified as a nonnegative integer. The input and output of this object are integers from 0 to `CalculationBase - 1`.

Data Types: `double`

Polynomial — Connections for linear feedback shift registers

'1 + z^-1 + z^-2 + z^-4' (default) | character vector | integer vector | binary vector

Connections for linear feedback shift registers in the scrambler, specified as a character vector, integer vector, or binary vector. The `Polynomial` property defines if each switch in the scrambler is on or off. Specify the polynomial as:

- A character vector, such as '1 + z^-6 + z^-8'. For more details on specifying polynomials in this way, see Character Representation of Polynomials.
- An integer vector, such as [0 -6 -8], listing the scrambler coefficients in order of descending powers of z^{-1} , where $p(z^{-1}) = 1 + p_1z^{-1} + p_2z^{-2} + \dots$
- A binary vector, such as [1 0 0 0 0 0 1 0 1], listing the powers of z that appear in the polynomial that have a coefficient of 1. In this case, the order of the scramble polynomial is one less than the binary vector length.

Example: '1 + z^-6 + z^-8', [0 -6 -8], and [1 0 0 0 0 0 1 0 1] all represent this polynomial:

$$p(z^{-1}) = 1 + z^{-6} + z^{-8}$$

Data Types: `double` | `char`

InitialConditionsSource — Initial conditions source

'Property' (default) | 'Input port'

- 'Property' - Specify scrambler initial conditions by using the `InitialConditions` property.
- 'Input port' - Specify scrambler initial conditions by using an additional input argument, `initcond`, when calling the object.

Data Types: char

InitialConditions — Initial conditions of scrambler registers

[0 1 2 3] (default) | nonnegative integer vector

Initial conditions of scrambler registers when the simulation starts, specified as a nonnegative integer vector. The length of `InitialConditions` must equal the order of the Polynomial property. The vector element values must be integers from 0 to `CalculationBase - 1`.

Dependencies

This property is available when `InitialConditionsSource` is set to 'Property'.

ResetInputPort — Scrambler state reset port

false (default) | true

Scrambler state reset port, specified as `false` or `true`. If `ResetInputPort` is `true`, you can reset the scrambler object by using an additional input argument, `reset`, when calling the object.

Dependencies

This property is available when `InitialConditionsSource` is set to 'Property'.

Usage**Syntax**

```
scrambledOut = scrambler(signal)
scrambledOut = scrambler(signal,initcond)
scrambledOut = scrambler(signal,reset)
```

Description

`scrambledOut = scrambler(signal)` scrambles the input signal. The output is the same data type and length as the input vector.

`scrambledOut = scrambler(signal,initcond)` provides an additional input with values specifying the initial conditions of the linear feedback shift register.

This syntax applies when you set the `InitialConditionsSource` property of the object to 'Input port'.

`scrambledOut = scrambler(signal,reset)` provides an additional input indicating whether to reset the state of the scrambler.

This syntax applies when you set `InitialConditionsSource` to 'Property' and `ResetInputPort` to `true`.

Input Arguments**signal — Input signal**

column vector

Input signal, specified as a column vector.

Example: `scrambledOut = scrambler([0 1 1 0 1])`

Data Types: `double` | `logical`

initcond — Initial register conditions

nonnegative integer column vector

Initial scrambler register conditions when the simulation starts, specified as a nonnegative integer column vector. The length of `initcond` must equal the order of the Polynomial property. The vector element values must be integers from 0 to `CalculationBase - 1`.

Example: `scrambledOut = scrambler(signal,[0 1 1 0])` corresponds to possible initial register states for a scrambler with a polynomial order of 4 and a calculation base of 2 or higher.

Data Types: `double`

reset — Reset initial state of scrambler

scalar

Reset the initial state of the scrambler when the simulation starts, specified as a scalar. When the value of `reset` is nonzero, the object is reset before it is called.

Example: `scrambledOut = scrambler(signal,0)` scrambles the input signal without resetting the scrambler states.

Data Types: `double`

Output Arguments

out — Scrambled output

column vector

Scrambled output, returned as a column vector with the same data type and length as `signal`.

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Common to All System Objects

<code>step</code>	Run System object algorithm
<code>release</code>	Release resources and allow changes to System object property values and input characteristics
<code>reset</code>	Reset internal states of System object

Examples

Scramble and Descramble Data

Scramble and descramble 8-ary data using `comm.Scrambler` and `comm.Descrambler` System objects™ having a calculation base of 8.

Create scrambler and descrambler objects, specifying the calculation base, polynomial, and initial conditions using input arguments. The scrambler and descrambler polynomials are specified with different but equivalent data formats.

```
N = 8;
scrambler = comm.Scrambler(N,'1 + z^-2 + z^-3 + z^-5 + z^-7', ...
    [0 3 2 2 5 1 7]);
descrambler = comm.Descrambler(N,[1 0 1 1 0 1 0 1], ...
    [0 3 2 2 5 1 7]);
```

Scramble and descramble random integers. Display the original data, scrambled data, and descrambled data sequences.

```
data = randi([0 N-1],5,1);
scrData = scrambler(data);
deScrData = descrambler(scrData);
[data scrData deScrData]
```

```
ans = 5×3
```

```
     6     7     6
     7     5     7
     1     7     1
     7     0     7
     5     3     5
```

Verify that the descrambled data matches the original data.

```
isequal(data,deScrData)
```

```
ans = logical
     1
```

Scramble and Descramble Data with Changing Initial Conditions

Scramble and descramble quaternary data while changing the initial conditions between function calls.

Create scrambler and descrambler System objects having a calculation base of 4. Set the `InitialConditionsSource` property to 'Input port' so you can set the initial conditions as an argument to the object.

```
N = 4;
scrambler = comm.Scrambler( ...
    N,'1 + z^-3', ...
    'InitialConditionsSource','Input port');
descrambler = comm.Descrambler( ...
    N,'1 + z^-3', ...
    'InitialConditionsSource','Input port');
```

Preallocate memory for the error vector which will be used to store errors output by the `symerr` function.

```
errVec = zeros(10,1);
```

Scramble and descramble random integers while changing the initial conditions, `initCond`, each time the loop executes. Use the `symerr` function to determine if the scrambling and descrambling operations result in symbol errors.

```
for k = 1:10
    initCond = randperm(3)';
    data = randi([0 N-1],5,1);
    scrData = scrambler(data,initCond);
    deScrData = descrambler(scrData,initCond);
    errVec(k) = symerr(data,deScrData);
end
```

Examine `errVec` to verify that the output from the descrambler matches the original data.

`errVec`

`errVec = 10x1`

```
0
0
0

Scrambler

Introduced in R2012a

comm.SphereDecoder

Package: comm

Decode input using sphere decoder

Description

The Sphere Decoder System object decodes the symbols sent over N_T antennas using the sphere decoding algorithm.

To decode input symbols using a sphere decoder:

- 1 Define and set up your sphere decoder object. See “Construction” on page 3-1312.
- 2 Call `step` to decode input symbols according to the properties of `comm.SphereDecoder`. The behavior of `step` is specific to each object in the toolbox.

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Construction

`H = comm.SphereDecoder` creates a System object, `H`. This object uses the sphere decoding algorithm to find the maximum-likelihood solution for a set of received symbols over a MIMO channel with N_T transmit antennas and N_R receive antennas.

`H = comm.SphereDecoder(Name, Value)` creates a sphere decoder object, `H`, with the specified property name set to the specified value. `Name` must appear inside single quotes ("). You can specify several name-value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

`H = comm.SphereDecoder(CONSTELLATION, BITTABLE)` creates a sphere decoder object, `H`, with the `Constellation` property set to `CONSTELLATION`, and the `BitTable` property set to `BITTABLE`.

Properties

Constellation

Signal constellation per transmit antenna

Specify the constellation as a complex column vector containing the constellation points to which the transmitted bits are mapped. The default setting is a QPSK constellation with an average power of 1. The length of the vector must be a power of two. The object assumes that each transmit antenna uses the same constellation.

BitTable

Bit mapping used for each constellation point.

Specify the bit mapping for the symbols that the `Constellation` property specifies as a numerical matrix. The default is `[0 0; 0 1; 1 0; 1 1]`, which matches the default `Constellation` property value.

The matrix size must be `[ConstellationLength bitsPerSymbol]`. `ConstellationLength` represents the length of the `Constellation` property. `bitsPerSymbol` represents the number of bits that each symbol encodes.

InitialRadius

Initial search radius of the decoding algorithm.

Specify the initial search radius for the decoding algorithm as either `Infinity` | `ZF Solution`. The default is `Infinity`.

When you set this property to `Infinity`, the object sets the initial search radius to `Inf`.

When you set this property to `ZF Solution`, the object sets the initial search radius to the zero-forcing solution. This calculation uses the pseudo-inverse of the input channel when decoding. Large constellations and/or antenna counts can benefit from the initial reduction in the search radius. In most cases, however, the extra computation of the `ZF Solution` will not provide a benefit.

DecisionType

Specify the decoding decision method as either `Soft` | `Hard`. The default is `Soft`.

When you set this property to `Soft`, the decoder outputs log-likelihood ratios (LLRs), or soft bits.

When you set this property to `Hard`, the decoder converts the soft LLRs to bits. The hard-decision output logical array follows the mapping of a zero for a negative LLR and one for all other values.

Methods

`step` Decode received symbols using sphere decoding algorithm

Common to All System Objects	
<code>release</code>	Allow System object property value changes

Examples

Decode Using a Sphere Decoder

Modulate a set of bits using 16-QAM constellation. Transmit the signal as two parallel streams over a MIMO channel. Decode using a sphere decoder with perfect channel knowledge.

Specify the modulation order, the number of transmitted bits, the E_b/N_0 ratio, and the symbol mapping.

```
bps = 4; % Bits per symbol
M = 2^bps; % Modulation order
nBits = 1e3*bps;
```

```
ebno = 10;
symMap = [11 10 14 15 9 8 12 13 1 0 4 5 3 2 6 7];
```

Generate and display the symbol mapping of the 16-QAM modulator by using the `qammod` function and the custom symbol map.

```
sym = qammod(symMap(1:M)',M,symMap, ...
    'UnitAveragePower',true,'PlotConstellation',true);
```

Convert the decimal value of the symbol map to binary bits using the left bit as the most significant bit (msb). The M-by-bps matrix `bitTable` is used by the sphere decoder.

```
bitTable = int2bit(symMap, bps)';
```

Create a 2x2 MIMO Channel System object with `PathGainsOutputPort` set to `true` to use the path gains as a channel estimate. To ensure the repeatability of results, set the object to use the global random number stream.

```
mimo = comm.MIMOChannel( ...
    'PathGainsOutputPort',true, ...
    'RandomStream','Global stream');
```

Create an AWGN Channel System object.

```
awgnChan = comm.AWGNChannel('EbNo', ebno, 'BitsPerSymbol', bps);
```

Create a Sphere Decoder System object that processes bits using hard-decision decoding. Configure using the custom bit table and symbol map.

```
sphDec = comm.SphereDecoder('Constellation',sym, ...
    'BitTable',bitTable, 'DecisionType', 'Hard');
```

Create an error rate System object.

```
berRate = comm.ErrorRate;
```

Set the global random number generator seed.

```
rng(37)
```

Generate a random data stream.

```
data = randi([0 1],nBits,1);
```

Modulate the data and reshape it into two streams to be used with the 2x2 MIMO channel.

```
modData = qammod(data,M,symMap, ...
    'InputType','bit', 'UnitAveragePower',true);
modData = reshape(modData,[],2);
```

Pass the modulated data through the MIMO fading channel and add AWGN.

```
[fadedSig,pathGains] = mimo(modData);
rxSig = awgnChan(fadedSig);
```

Decode the received signal using pathGains as a perfect channel estimate.

```
decodedData = sphDec(rxSig,squeeze(pathGains));
```

Convert the decoded hard-decision data, which is a logical matrix, into a double column vector to enable the calculation of error statistics. Calculate and display the bit error rate and the number of errors.

```
dataOut = double(decodedData(:));
errorStats = berRate(data,dataOut);
errorStats(1:2)
```

```
ans = 2×1
```

```
    0.0380
   152.0000
```

Algorithm

This object implements a soft-output max-log a posteriori probability (APP) MIMO detector by means of a soft-output Schnorr-Euchner sphere decoder (SESD), implemented as single tree search (STS) tree traversal. The algorithm assumes the same constellation and bit table on all of the transmit antennas. Given as inputs, the received symbol vector and the estimated channel matrix, the algorithm outputs the log-likelihood ratios (LLRs) of the transmitted bits.

The algorithm assumes a MIMO system model with N_T transmit antennas and N_R receive antennas where N_T symbols are simultaneously sent, expressed as:

$$y = Hs + n.$$

where y is the received symbols, H is the MIMO channel matrix, s is the transmitted symbol vector, and n is the thermal noise.

The MIMO detector seeks the maximum-likelihood (ML) solution, \hat{s}_{ML} , such that:

$$\hat{s}_{ML} = \underset{s \in O}{\operatorname{argmin}} \|y - Hs\|^2$$

where O is the complex-valued constellation from which the N_T elements of s are chosen.

Soft detection also computes a log-likelihood ratio (LLR) for each bit that serves as a measure of the reliability of the estimate for each bit. The LLR is calculated as using the max-log approximation:

$$L(x_{j,b}) = \min_{s \in x_{j,b}^{(0)}} \|y - Hs\|^2 - \min_{s \in x_{j,b}^{(1)}} \|y - Hs\|^2$$

λ^{ML}
 $\lambda^{\overline{ML}}$

where

- $L(x_{j,b})$ is the LLR estimate for each bit.
- $x_{j,b}$ is each sent bit, the b th bit of the j th symbol.
- $x_{j,b}^{(0)}$ and $x_{j,b}^{(1)}$ are the disjoint sets of vector symbols that have the b th bit in the label of the j th scalar symbol equal to 0 and 1, respectively. The two λ symbols denotes the distance calculated as norm squared., specifically:
 - λ^{ML} is the distance \hat{s}_{ML} .
 - $\lambda^{\overline{ML}}$ is the distance to the counter-hypothesis, which denotes the binary complement of the b th bit in the binary label of the j th entry of \hat{s}_{ML} , specifically the minimum of the symbol set $x_{j,b}^{\overline{ML}}$, which contains all of the possible vectors for which the b th bit of the j th entry is flipped compared to the same entry of \hat{s}_{ML} .

Based on whether $x_{j,b}^{\overline{ML}}$ is 0 or 1, the LLR estimate for bit $x_{j,b}$ is computed as follows:

$$L(x_{j,b}) = \begin{cases} \lambda^{ML} - \lambda_{j,b}^{\overline{ML}}, & x_{j,b}^{ML} = \\ \lambda_{j,b}^{\overline{ML}} - \lambda^{ML}, & x_{j,b}^{ML} = \end{cases}$$

The design of a decoder strives to efficiently find \hat{s}_{ML} , λ^{ML} , and $\lambda_{j,b}^{\overline{ML}}$.

This search can be converted into a tree search by means of the sphere decoding algorithms. To this end, the channel matrix is decomposed into $H = QR$ by means of a QR decomposition. Left-multiplying y by Q^H , the problem can be reformulated as:

$$\lambda^{ML} = \arg \min_{s \in \mathcal{O}} \|\bar{y} - Rs\|$$

$$\lambda_{j,b}^{\overline{ML}} = \underset{s \in \mathcal{X}_{j,b}}{\operatorname{argmin}} \|\bar{y} - Rs\|^2$$

Using this reformulated problem statement, the triangular structure of R can be exploited to arrange a tree structure such that each of the leaf nodes corresponds to a possible s vector and the partial distances to the nodes in the tree can be calculated cumulatively adding to the partial distance of the parent node.

In the STS algorithm, the λ^{ML} and $\lambda_{j,b}^{\overline{ML}}$ metrics are searched concurrently. The goal is to have a list containing the metric λ^{ML} , along with the corresponding bit sequence x^{ML} and the metrics $x_{j,b}^{(ML)}$ of all counter-hypotheses. The sub-tree originating from a given node is searched only if the result can lead to an update of either λ^{ML} or $\lambda_{j,b}^{\overline{ML}}$.

The STS algorithm flow can be summarized as:

- 1** If when reaching a leaf node, a new ML hypothesis is found ($d(x) < \lambda^{ML}$), all $\lambda_{j,b}^{\overline{ML}}$ for which $x_{j,b} = x_{j,b}^{\overline{ML}}$ are set to λ^{ML} which now turns into a valued counter-hypothesis. Then, λ^{ML} is set to the current distance, $d(x)$.
- 2** If $d(x) \geq \lambda^{ML}$, only the counter-hypotheses have to be checked. For all j and b for which ($d(x) < \lambda^{ML}$) and $x_{j,b} = x_{j,b}^{\overline{ML}}$, the decoder updates $\lambda_{j,b}^{\overline{ML}}$ to be $d(x)$.
- 3** A sub-tree is pruned if the partial distance of the node is bigger than the current $\lambda_{j,b}^{\overline{ML}}$ which may be affected when traversing the subtree.
- 4** The STS concludes once all of the tree nodes have been visited once or pruned.

Limitations

- The output LLR values are not scaled by the noise variance. For coded links employing iterative coding (LDPC or turbo) or MIMO OFDM with Viterbi decoding, the output LLR values should be scaled by the channel state information to achieve better performance.

Introduced in R2013a

step

System object: comm.SphereDecoder

Package: comm

Decode received symbols using sphere decoding algorithm

Syntax

$Y = \text{step}(H, \text{RXSYMBOLS}, \text{CHAN})$

Description

Note Starting in R2016b, instead of using the `step` method to perform the operation defined by the System object, you can call the object with arguments, as if it were a function. For example, $y = \text{step}(\text{obj}, x)$ and $y = \text{obj}(x)$ perform equivalent operations.

$Y = \text{step}(H, \text{RXSYMBOLS}, \text{CHAN})$ decodes the received symbols, `RXSYMBOLS`, using the sphere decoding algorithm. The algorithm can be employed to decode N_s channel realizations in one call, where in each channel realization, N_r symbols are received.

The inputs are:

`RXSYMBOLS`: a $[N_s \ N_r]$ complex double matrix containing the received symbols.

`CHAN`: a $[N_s \ N_t \ N_r]$ or $[1 \ N_t \ N_r]$ complex double matrix representing the fading channel coefficients of the flat-fading MIMO channel. For the $[N_s \ N_t \ N_r]$ case, the object applies each channel matrix to each N_r symbol set. For the block fading case, i.e., when the size of `CHAN` is $[1 \ N_t \ N_r]$, the same channel is applied to all of the received symbols.

The output Y , which depends on the setting of the `DecisionType` property, is a double matrix containing the Log-Likelihood Ratios (LLRs) of the decoded bits or the bits themselves. For both cases, the size of the output is $[N_s * \text{bitsPerSymbol} \ N_t]$, where `bitsPerSymbol` represents the number of bits per transmitted symbol, as determined by the `BitTable` property.

Note `obj` specifies the System object on which to run this `step` method.

The object performs an initialization the first time the `step` method is executed. This initialization locks nontunable properties and input specifications. For more information on changing property values, see “System Design in MATLAB Using System Objects”.

comm.SymbolSynchronizer

Package: comm

Correct symbol timing clock skew

Description

The `comm.SymbolSynchronizer` System object corrects symbol timing clock skew between a single-carrier transmitter and receiver for PAM, PSK, QAM, and OQPSK modulation schemes. For more information, see “Symbol Synchronization Overview” on page 3-1338.

Note The input signal operates on a sample-rate basis and the output signal operates on a symbol-rate basis.

To correct symbol timing clock skew:

- 1 Create the `comm.SymbolSynchronizer` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

Creation

Syntax

```
symbolSync = comm.SymbolSynchronizer
symbolSync = comm.SymbolSynchronizer(Name,Value)
```

Description

`symbolSync = comm.SymbolSynchronizer` creates a symbol synchronizer System object for correcting the clock skew between a single-carrier transmitter and receiver.

`symbolSync = comm.SymbolSynchronizer(Name,Value)` sets properties using one or more name-value pairs. For example, `comm.SymbolSynchronizer('Modulation','OQPSK')` configures the symbol synchronizer System object for an OQPSK-modulated input signal. Enclose each property name in quotes.

Tunable `DampingFactor`, `NormalizedLoopBandwidth`, and `DetectorGain` properties enable you to optimize synchronizer performance in your simulation loop without releasing the object.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects.

Modulation — Modulation type

'PAM/PSK/QAM' (default) | 'OQPSK'

Modulation type, specified as 'PAM/PSK/QAM' or 'OQPSK'.

Tunable: No

Data Types: char | string

TimingErrorDetector — Timing error detector method

Zero-Crossing (decision-directed) (default) | Gardner (non-data-aided) | Early-Late (non-data-aided) | Mueller-Muller (decision-directed)

Timing error detector method, specified as Zero-Crossing (decision-directed), Gardner (non-data-aided), Early-Late (non-data-aided), or Mueller-Muller (decision-directed). This property assigns the timing error detection scheme used in the synchronizer. For more information, see “Timing Error Detection (TED)” on page 3-1339.

Tunable: No

Data Types: char | string

SamplesPerSymbol — Samples per symbol

2 (default) | integer greater than 1

Samples per symbol, specified as an integer greater than 1. For more information, see N_{sps} in “Loop Filter” on page 3-1342.

Tunable: No

Data Types: double

DampingFactor — Damping factor of loop filter

1 (default) | positive scalar

Damping factor of the loop filter, specified as a positive scalar. For more information, see ζ in “Loop Filter” on page 3-1342.

Tunable: Yes

Data Types: double | single

NormalizedLoopBandwidth — Normalized bandwidth of loop filter

0.01 (default) | scalar in the range (0, 1)

Normalized bandwidth of the loop filter, specified as a scalar in the range (0, 1). The loop bandwidth is normalized to the sample rate of the input signal. For more information, see $B_n T_s$ in “Loop Filter” on page 3-1342.

Note To ensure the symbol synchronizer locks, set the NormalizedLoopBandwidth property to a value less than 0.1.

Tunable: Yes

Data Types: double | single

DetectorGain — Phase detector gain

2.7 (default) | positive scalar

Phase detector gain, specified as a positive scalar. For more information, see K_p in “Loop Filter” on page 3-1342.

Tunable: Yes

Data Types: double | single

Usage

Note For versions earlier than R2016b, use the `step` function to run the System object™ algorithm. The arguments to `step` are the object you created, followed by the arguments shown in this section.

For example, `y = step(obj,x)` and `y = obj(x)` perform equivalent operations.

Syntax

`symbols = symbolSync(samples)`

Description

`symbols = symbolSync(samples)` corrects symbol timing clock skew between a single-carrier transmitter and receiver based on the input samples and outputs synchronized symbols.

- The input operates on a sample-rate basis and the output signal operates on a symbol-rate basis.
- You can tune the `DampingFactor`, `NormalizedLoopBandwidth`, and `DetectorGain` properties to improve the synchronizer performance.

Input Arguments

samples — Input samples

scalar (default) | column vector

Input samples, specified as a scalar or column vector of a PAM-, PSK-, QAM-, or OQPSK-modulated single-carrier signal.

Data Types: double | single

Complex Number Support: Yes

Output Arguments

symbols — Synchronized symbols

column vector

Synchronized symbols, returned as a variable-sized column vector. The output symbols inherit the data type from the input samples. For an input with dimensions N_{samp} -by-1, this output has dimensions N_{sym} -by-1. N_{sym} is approximately equal to N_{samp} divided by N_{sps} , where N_{sps} is equal to the `SamplesPerSymbol` property value. The output length is truncated if it exceeds the maximum output

size of $\left\lceil \frac{N_{\text{samp}}}{N_{\text{sps}}} \times 1.1 \right\rceil$.

timingErr — Estimated timing error

scalar in the range [0, 1] | column vector of elements in the range [0, 1]

Estimated timing error for each input sample, returned as a scalar in the range [0, 1] or column vector of elements in the range [0, 1]. The estimated timing error is normalized to the input sample rate. `timingErr` has the same data type and size as input samples.

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Specific to `comm.SymbolSynchronizer`

`clone` Create duplicate System object
`isLocked` Determine if System object is in use

Common to All System Objects

`step` Run System object algorithm
`release` Release resources and allow changes to System object property values and input characteristics
`reset` Reset internal states of System object

Examples**Correct Symbol Timing Error of QPSK-Modulated Signal**

Correct a fixed symbol timing error on a noisy QPSK-modulated signal. Check the bit error rate (BER) of the synchronized received signal.

Initialize simulation parameters.

```
M = 4;                % Modulation order for QPSK  
nSym = 5000;        % Number of symbols in a packet  
sps = 4;            % Samples per symbol  
timingErr = 2;      % Samples of timing error  
snr = 15;           % Signal-to-noise ratio (dB)
```

Create root raised cosine (RRC) transmit and receive filter System objects.

```
txfilter = comm.RaisedCosineTransmitFilter( ...  
    'OutputSamplesPerSymbol',sps);  
rxfilter = comm.RaisedCosineReceiveFilter( ...  
    'InputSamplesPerSymbol',sps,'DecimationFactor',2);
```

Create a symbol synchronizer System object to correct the timing error.

```
symbolSync = comm.SymbolSynchronizer;
```

Generate random M-ary symbols and apply QPSK modulation.

```
data = randi([0 M-1],nSym,1);
modSig = pskmod(data,M,pi/4);
```

Create a delay object to introduce a fixed timing error of 2 samples. Because the transmit RRC filter outputs 4 samples per symbol, 1 sample is equivalent to a 1/4 symbol through the fixed delay and channel.

```
fixedDelay = dsp.Delay(timingErr);
fixedDelaySym = ceil(fixedDelay.Length/sps); % Round fixed delay to nearest integer in symbols
```

Filter the modulated signal through a transmit RRC filter by using the `txfilter` object. Apply a signal timing error by using the `fixedDelay` object.

```
txSig = txfilter(modSig);
delaySig = fixedDelay(txSig);
```

Pass the delayed signal through an AWGN channel with a 15 dB signal-to-noise ratio.

```
rxSig = awgn(delaySig,snr,'measured');
```

Filter the modulated signal through a receive RRC filter by using the `rxfilter` object. Display the scatter plot. Due to the timing error, the received signal does not align with the expected QPSK reference constellation.

```
rxSample = rxfilter(rxSig);
scatterplot(rxSample(1001:end),2)
```

Correct the symbol timing error by using the `symbolSync` object. Display the scatter plot. The synchronized signal now aligns with the expected QPSK constellation.

```
rxSync = symbolSync(rxSample);
scatterplot(rxSync(1001:end),2)
```

Demodulate the QPSK signal.

```
recData = pskdemod(rxSync,M,pi/4);
```

Compute, in symbols, the total system delay due to the fixed delay and the transmit and receive RRC filters.

```
sysDelay = dsp.Delay(fixedDelaySym + txfilter.FilterSpanInSymbols/2 + ...
    rxfilter.FilterSpanInSymbols/2);
```

Compute the BER, taking into account the system delay.

```
[numErr,ber] = biterr(sysDelay(data),recData)
```

```
numErr = 10
```

```
ber = 1.0000e-03
```

Correct Symbol Timing Error of BPSK-Modulated Signal

Correct a fixed symbol timing error on a noisy BPSK transmission signal. Check the bit error rate (BER) of the synchronized received signal.

Initialize simulation parameters.

```
M = 2;           % Modulation order for BPSK
nSym = 20000;   % Number of symbols in a packet
sps = 4;       % Samples per symbol
timingErr = 2;  % Samples of timing error
snr = 15;      % Signal-to-noise ratio (dB)
```

Create root raised cosine (RRC) transmit and receive filter System objects.

```
txfilter = comm.RaisedCosineTransmitFilter(...
    'OutputSamplesPerSymbol',sps);
rxfilter = comm.RaisedCosineReceiveFilter(...
    'InputSamplesPerSymbol',sps,'DecimationFactor',1);
```

Create a symbol synchronizer System object™ to correct the timing error.

```
symbolSync = comm.SymbolSynchronizer(...
    'SamplesPerSymbol',sps, ...
    'NormalizedLoopBandwidth',0.01, ...
    'DampingFactor',1.0, ...
    'TimingErrorDetector','Early-Late (non-data-aided)');
```

Generate random data symbols and apply BPSK modulation.

```
data = randi([0 M-1],nSym,1);
modSig = pskmod(data,M);
```

Create a delay object to introduce a fixed timing error of 2 samples. Because the transmit RRC filter outputs 4 samples per symbol, 1 sample is equivalent to a 1/4 symbol through the fixed delay and channel.

```
fixedDelay = dsp.Delay(timingErr);
fixedDelaySym = ceil(fixedDelay.Length/sps); % Round fixed delay to nearest integer in symbols
```

Filter the modulated signal through a transmit RRC filter by using the txfilter object. Apply a signal timing error by using the fixedDelay object.

```
txSig = txfilter(modSig);
delayedSig = fixedDelay(txSig);
```

Pass the delayed signal through an AWGN channel.

```
rxSig = awgn(delayedSig,snr,'measured');
```

Filter the modulated signal through a receive RRC filter by using the rxfilter object. Display the scatter plot. Due to the timing error, the received signal does not align with the expected BPSK reference constellation.

```
rxSample = rxfilter(rxSig);
scatterplot(rxSample(10000:end),2)
```

Correct the symbol timing error by using the `symbolSync` object. Display the scatter plot. The synchronized signal now aligns with the expected BPSK constellation.

```
rxSync = symbolSync(rxSample);  
scatterplot(rxSync(10000:end),2)
```

Demodulate the BPSK signal.

```
recData = pskdemod(rxSync,M);
```

Compute, in symbols, the total system delay due to the fixed delay and the transmit and receive RRC filters.

```
sysDelay = dsp.Delay(fixedDelaySym + txfilter.FilterSpanInSymbols/2 + ...
    rxfilter.FilterSpanInSymbols/2);
```

Compute the BER, taking into account the system delay.

```
[numErr1,ber1] = biterr(sysDelay(data),recData)
```

```
numErr1 = 8
```

```
ber1 = 4.0000e-04
```

Correct Symbol Timing and Doppler Offsets

Correct symbol timing and frequency offset errors by using the `comm.SymbolSynchronizer` and `comm.CarrierSynchronizer` System objects.

Configuration

Initialize simulation parameters.

```
M = 16;           % Modulation order
nSym = 2000;     % Number of symbols in a packet
sps = 2;         % Samples per symbol
spsFilt = 8;     % Samples per symbol for filters and channel
spsSync = 2;    % Samples per symbol for synchronizers
lenFilt = 10;    % RRC filter length
```

Create a matched pair of root raised cosine (RRC) filter System objects for transmitter and receiver.

```
txfilter = comm.RaisedCosineTransmitFilter('FilterSpanInSymbols',lenFilt, ...
    'OutputSamplesPerSymbol',spsFilt,'Gain',sqrt(spsFilt));
rxfilter = comm.RaisedCosineReceiveFilter('FilterSpanInSymbols',lenFilt, ...
    'InputSamplesPerSymbol',spsFilt,'DecimationFactor',spsFilt/2,'Gain',sqrt(1/spsFilt));
```

Create a phase-frequency offset System object to introduce a 100 Hz Doppler shift.

```
doppler = comm.PhaseFrequencyOffset('FrequencyOffset',100, ...
    'PhaseOffset',45,'SampleRate',1e6);
```

Create a variable delay System object to introduce timing offsets.

```
varDelay = dsp.VariableFractionalDelay;
```

Create carrier and symbol synchronizer System objects to correct for Doppler shift and timing offset, respectively.

```
carrierSync = comm.CarrierSynchronizer('SamplesPerSymbol',spsSync);
symbolSync = comm.SymbolSynchronizer(...
    'TimingErrorDetector','Early-Late (non-data-aided)', ...
    'SamplesPerSymbol',spsSync);
```

Create constellation diagram System objects to view the results.

```
refConst = qammod(0:M-1,M,'UnitAveragePower',true);
cdReceive = comm.ConstellationDiagram('ReferenceConstellation',refConst, ...
    'SamplesPerSymbol',spsFilt,'Title','Received Signal');
cdDoppler = comm.ConstellationDiagram('ReferenceConstellation',refConst, ...
    'SamplesPerSymbol',spsSync,'Title','Frequency Corrected Signal');
cdTiming = comm.ConstellationDiagram('ReferenceConstellation',refConst, ...
    'SamplesPerSymbol',spsSync,'Title','Frequency and Timing Synchronized Signal');
```

Main Processing Loop

The main processing loop:

- Generates random symbols and applies QAM modulation.
- Filters the modulated signal.
- Applies frequency and timing offsets.
- Passes the transmitted signal through an AWGN channel.
- Filters the received signal.
- Corrects the Doppler shift.
- Corrects the timing offset.

```
for k = 1:15
    data = randi([0 M-1],nSym,1);
    modSig = qammod(data,M,'UnitAveragePower',true);
```

```
txSig = txfilter(modSig);  
  
txDoppler = doppler(txSig);  
txDelay = varDelay(txDoppler,k/15);  
  
rxSig = awgn(txDelay,25);  
  
rxFiltSig = rxfilter(rxSig);  
rxCorr = carrierSync(rxFiltSig);  
rxData = symbolSync(rxCorr);  
end
```

Visualization

Plot the constellation diagrams of the received signal, frequency corrected signal, and frequency and timing synchronized signal. Specific constellation points cannot be identified in the received signal and can be only partially identified in the frequency corrected signal. However, the timing and frequency synchronized signal aligns with the expected QAM constellation points.

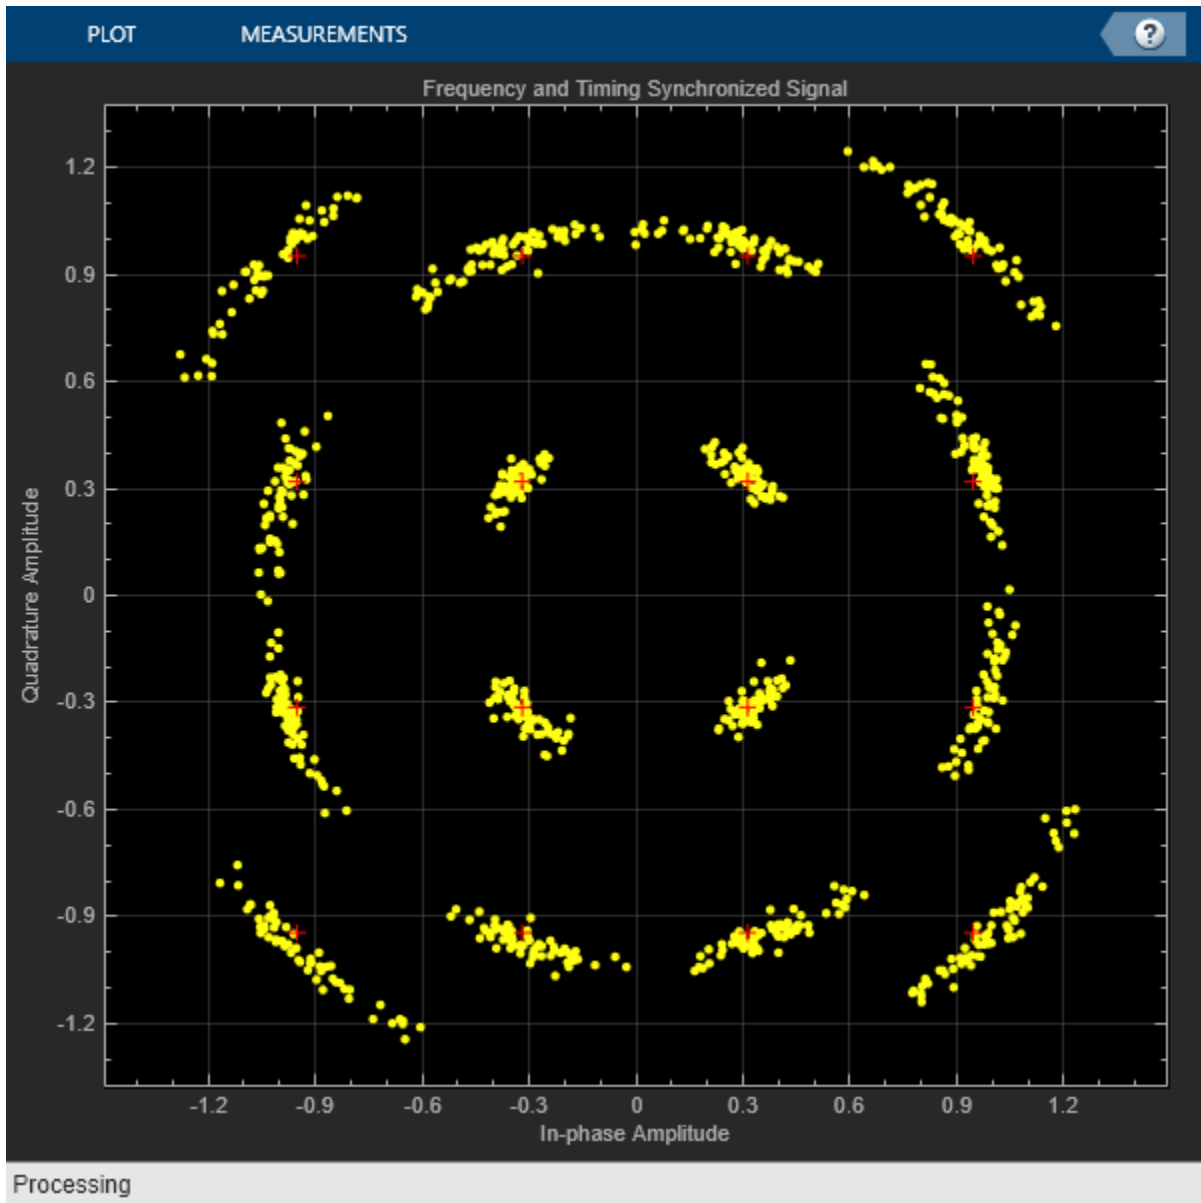

```
cdReceive(rxSig)
```

`cdDoppler(rxCorr)`

```
cdTiming(rxData)
```

Timing Error for Noisy 8-PSK Signal

Correct a monotonically increasing symbol timing error on a noisy 8-PSK signal. Display the normalized timing error.

Initialize simulation parameters.

```
M = 8;           % Modulation order
nSym = 5000;    % Number of symbol in a packet
sps = 2;       % Samples per symbol
nSamp = sps*nSym; % Number of samples in a packet
```

Create root raised cosine (RRC) transmit and receive filter System objects.

```
txfilter = comm.RaisedCosineTransmitFilter( ...
    'OutputSamplesPerSymbol',sps);
rxfilter = comm.RaisedCosineReceiveFilter( ...
    'InputSamplesPerSymbol',sps, ...
    'DecimationFactor',1);
```

Create a variable fractional delay System object™ to introduce a monotonically increasing timing error.

```
varDelay = dsp.VariableFractionalDelay;
```

Create a symbol synchronizer System object to correct the timing error.

```
symbolSync = comm.SymbolSynchronizer(...
    'TimingErrorDetector','Mueller-Muller (decision-directed)', ...
    'SamplesPerSymbol',sps);
```

Generate random 8-ary symbols and apply 8-PSK modulation.

```
data = randi([0 M-1],nSym,1);
modSig = pskmod(data,M,pi/8);
```

Filter the modulated signal through a raised cosine transmit filter and apply a monotonically increasing timing delay.

```
vdelay = (0:1/nSamp:1-1/nSamp)';
txSig = txfilter(modSig);
delaySig = varDelay(txSig,vdelay);
```

Pass the delayed signal through an AWGN channel with a 15 dB signal-to-noise ratio.

```
rxSig = awgn(delaySig,15,'measured');
```

Filter the modulated signal through a receive RRC filter. Display the scatter plot. Due to the timing error, the received signal does not align with the expected 8-PSK reference constellation.

```
rxSample = rxfilter(rxSig);
scatterplot(rxSample,sps)
```

Correct the symbol timing error by using the `symbolSync` object. Display the scatter plot. The synchronized signal now aligns with the expected 8-PSK constellation.

```
[rxSym,tError] = symbolSync(rxSample);  
scatterplot(rxSym(1001:end))
```

Plot the timing error estimate. Over time, the normalized timing error increases to 1 sample.

```
figure
plot(vdelay,tError)
xlabel('Time (s)')
ylabel('Timing Error (samples)')
```

More About

Symbol Synchronization Overview

The symbol timing synchronizer algorithm is based on a phased lock loop (PLL) algorithm that consists of four components:

- Timing error detector (TED)
- Interpolator
- Interpolation controller
- Loop filter

For OQPSK modulation, the in-phase and quadrature signal components are first aligned (as in QPSK modulation) using a state buffer to cache the last half symbol of the previous input. After initial alignment, the remaining synchronization process is the same as for QPSK modulation.

This block diagram shows an example of a timing synchronizer. In the figure, the symbol timing PLL operates on $x(t)$, the received sample signal after matched filtering. The symbol timing PLL outputs the symbol signal, $x(kT_s + \hat{\tau})$, after correcting for the clock skew between the transmitter and receiver.

Timing Error Detection (TED)

The symbol timing synchronizer supports non-data-aided TED and decision-directed TED methods. This table shows the timing estimate expressions for the TED method options.

TED Method	Expression
Zero-crossing (decision-directed)	$e(k) = x((k - 1/2)T_s + \hat{\tau})[\hat{a}_0(k - 1) - \hat{a}_0(k)] + y((k - 1/2)T_s + \hat{\tau})[\hat{a}_1(k - 1) - \hat{a}_1(k)]$
Gardner (non-data-aided)	$e(k) = x((k - 1/2)T_s + \hat{\tau})[x((k - 1)T_s + \hat{\tau}) - x(kT_s + \hat{\tau})] + y((k - 1/2)T_s + \hat{\tau})[y((k - 1)T_s + \hat{\tau}) - y(kT_s + \hat{\tau})]$
Early-late (non-data-aided)	$e(k) = x(kT_s + \hat{\tau})[x((k + 1/2)T_s + \hat{\tau}) - x((k - 1/2)T_s + \hat{\tau})] + y(kT_s + \hat{\tau})[y((k + 1/2)T_s + \hat{\tau}) - y((k - 1/2)T_s + \hat{\tau})]$
Mueller-Muller (decision-directed)	$e(k) = \hat{a}_0(k - 1)x(kT_s + \hat{\tau}) - \hat{a}_0(k)x((k - 1)T_s + \hat{\tau}) + \hat{a}_1(k - 1)y(kT_s + \hat{\tau}) - \hat{a}_1(k)y((k - 1)T_s + \hat{\tau})$

The non-data-aided TED (Gardner and early-late) methods use received samples without any knowledge of the transmitted signal or the results of the channel estimation. Non-data-aided TED is used to estimate the timing error for signals with modulation schemes that have constellation points aligned with the in-phase or quadrature axis. Examples of signals suitable for the Gardner or early-late methods include QPSK-modulated signals with a zero phase offset that has points at $\{1+0i, 0+1i, -1+0i, 0-1i\}$ and BPSK-modulated signals with a zero phase offset.

The early-late method is similar to the Gardner method but the Gardner method performs better in systems with high SNR values because it has lower self noise than the early-late method.

- **Gardner method** — The Gardner method is a non-data-aided feedback method that is independent of carrier phase recovery. It is used for baseband systems and modulated carrier systems. More specifically, this method is used for systems that use a linear modulation type with Nyquist pulses that have an excess bandwidth between approximately 40% and 100%. Examples

include systems that use PAM, PSK, QAM, or OQPSK modulation and that shape the signal using raised cosine filters whose rolloff factor is between 0.4 and 1. In the presence of noise, the performance of this timing recovery method improves as the excess bandwidth increases (or rolloff factor increases in the case of a raised cosine filter). The Gardner method is similar to the early-late gate method.

- **Early-late method** — The early-late method is a non-data-aided feedback method. It is used for systems that use a linear modulation type such as PAM, PSK, QAM, or OQPSK modulation. For example, systems using a raised cosine filter with Nyquist pulses. In the presence of noise, the performance of this timing recovery method improves as the excess bandwidth of the pulse increases (or rolloff factor increases in the case of a raised cosine filter).

The decision-directed TED (zero-crossing and Mueller-Muller) methods use the `sign` function to estimate the in-phase and quadrature components of received samples, which results in lower computational complexity than the non-data-aided TED methods.

- **Zero-crossing method** — The zero-crossing method is a decision-directed technique that requires 2 samples per symbol at the input to the synchronizer. It is used in low-SNR conditions for all values of excess bandwidth and in moderate-SNR conditions for moderate excess bandwidth factors in the approximate range [0.4, 0.6].
- **Mueller-Muller method** — The Mueller-Muller method is a decision-directed feedback method that requires prior recovery of the carrier phase. When the input signal has Nyquist pulses (for example, when using a raised cosine filter), the Mueller-Muller method has no self noise. For narrowband signaling in the presence of noise, the performance of the Mueller-Muller method improves as the excess bandwidth factor of the pulse decreases.

Because the decision-directed methods (zero-crossing and Mueller-Muller) estimate timing error based on the sign of the in-phase and quadrature components of signals passed to the synchronizer, they are not recommended for constellations that have points with either a zero in-phase or a quadrature component. $x(kT_s + \hat{\tau})$ and $y(kT_s + \hat{\tau})$ are the in-phase and quadrature components of the input signals to the timing error detector, where $\hat{\tau}$ is the estimated timing error. The Mueller-Muller method coefficients $\hat{a}_0(k)$ and $\hat{a}_1(k)$ are the estimates of $x(kT_s + \hat{\tau})$ and $y(kT_s + \hat{\tau})$. The timing estimates are made by applying the `sign` function to the in-phase and quadrature components and are used for only the decision-directed TED methods.

Interpolator

The time delay is estimated from the fixed-rate samples of the matched filter, which are asynchronous with the symbol rate. Because the resulting samples are not aligned with the symbol boundaries, an interpolator is used to "move" the samples. Because the time delay is unknown, the interpolator must be adaptive. Moreover, because the interpolant is a linear combination of the available samples, it can be thought of as the output of a filter.

The interpolator uses a piecewise parabolic interpolator with a Farrow structure and coefficient α set to $1/2$ (see Rice, Michael, *Digital Communications: A Discrete-Time Approach*).

Interpolation Control

Interpolation control provides the interpolator with the basepoint index and fractional interval. The basepoint index is the sample index nearest to the interpolant. The fractional interval is the ratio of the time between the interpolant and its basepoint index and the interpolation interval.

Interpolation is performed for every sample, and a strobe signal is used to determine if the interpolant is output. The synchronizer uses a modulo-1 counter interpolation control to provide the strobe and the fractional interval for use with the interpolator.

Loop Filter

The synchronizer uses a proportional-plus integrator (PI) loop filter. The proportional gain, K_1 , and the integrator gain, K_2 , are calculated by

$$K_1 = \frac{-4\zeta\theta}{(1 + 2\zeta\theta + \theta^2)K_p}$$

and

$$K_2 = \frac{-4\theta^2}{(1 + 2\zeta\theta + \theta^2)K_p}.$$

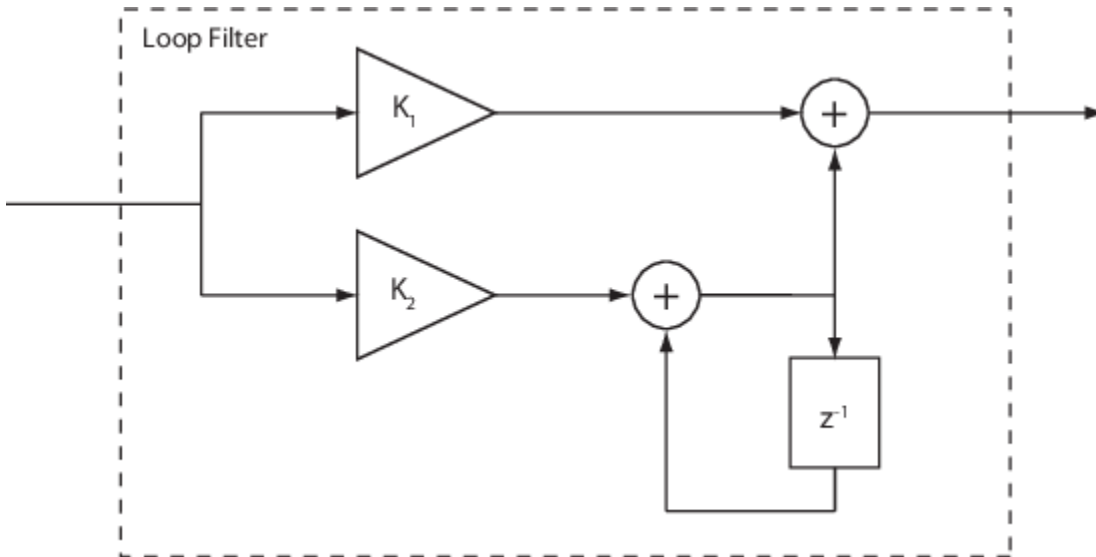

The interim term, θ , is given by

$$\theta = \frac{\frac{B_n T_s}{N_{\text{sps}}}}{\zeta + \frac{1}{4\zeta}},$$

where:

- N_{sps} is the number of samples per symbol.

- ζ is the damping factor.
- $B_n T_s$ is the normalized loop bandwidth.
- K_p is the detector gain.

Objects

comm.CarrierSynchronizer

Blocks

Symbol Synchronizer

Introduced in R2015a

comm.ThermalNoise

Package: comm

Add thermal noise to signal

Description

The `comm.ThermalNoise` System object object simulates the effects of thermal noise on a complex baseband signal. For more information, see “Algorithms” on page 3-1350.

To add thermal noise to a complex baseband signal:

- 1 Create the `comm.ThermalNoise` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

Creation

Syntax

```
noise = comm.ThermalNoise  
noise = comm.ThermalNoise(Name=Value)
```

Description

`noise = comm.ThermalNoise` creates a receiver thermal noise System object. This object adds thermal noise to the complex baseband input signal.

`noise = comm.ThermalNoise(Name=Value)` sets properties using one or more name-value arguments. For example, `SampleRate=2` sets the input signal sample rate to 2.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see [System Design in MATLAB Using System Objects](#).

NoiseMethod — Method used to set noise power

'Noise temperature' (default) | 'Noise figure' | 'Noise factor'

Method used to set the noise power, specified as 'Noise temperature', 'Noise figure', or 'Noise factor'.

NoiseTemperature — Receiver noise temperature

290 (default) | nonnegative scalar

Receiver noise temperature, specified in kelvins as a nonnegative scalar. Noise temperature is typically used to characterize receivers because the input noise temperature can vary and is often less than 290 K.

Tunable: Yes**Dependencies**

To enable this property, set the `NoiseMethod` property to 'Noise temperature'.

Data Types: double

NoiseFigure — Noise figure

3.01 (default) | nonnegative scalar

Noise figure in dB, specified as a nonnegative scalar. Noise figure describes the performance of a receiver and does not include the effect of the antenna. It is defined only for an input noise temperature of 290 K. The noise figure is the dB equivalent of the noise factor.

Tunable: Yes**Dependencies**

To enable this property, set the `NoiseMethod` property to 'Noise figure'.

Data Types: double

NoiseFactor — Noise factor2 (default) | scalar ≥ 1

Noise factor, specified as a scalar greater than or equal to 1. Noise factor describes the performance of a receiver and does not include the effect of the antenna. It is defined only for an input noise temperature of 290 K. The noise factor is the linear equivalent of the noise figure.

Tunable: Yes**Dependencies**

To enable this property, set the `NoiseMethod` property to 'Noise factor'.

Data Types: double

ReferenceLoad — Reference load

1 (default) | positive scalar

Reference load in ohms, specified as a positive scalar. The reference load value is used to compute the voltage levels based on the signal and noise power levels.

Tunable: Yes

Data Types: double

SampleRate — Sample rate

1 (default) | positive scalar

Sample rate in Hz, specified as a positive scalar. The object computes the variance of the noise added to the input signal as $kT \times \text{SampleRate}$. The value k is Boltzmann's constant and T is the noise temperature specified explicitly or implicitly via one of the noise methods.

Data Types: `double`

Add290KAntennaNoise — Option to add 290 K antenna noise

`false` or `0` (default) | `true` or `1`

Option to add 290 K antenna noise to the input signal, specified as a logical `0` (`false`) or `1` (`true`). To add 290 K antenna noise, set this property to `true`. The total noise applied to the input signal is the sum of the circuit noise and the antenna noise.

Dependencies

To enable this property, set the `NoiseMethod` property to `'Noise factor'` or `'Noise figure'`.

Usage**Syntax**

```
outsignal = noise(insignal)
```

Description

`outsignal = noise(insignal)` adds thermal noise to the complex baseband input signal `insignal` and returns the result in `outsignal`.

Input Arguments**insignal — Input signal**

scalar | column vector

Baseband signal, specified as a scalar or column vector of complex values.

Data Types: `single` | `double`

Complex Number Support: Yes

Output Arguments**outsignal — Output signal**

scalar | column vector

Output signal, returned as a scalar or column vector of complex values with the same length and data type as the input signal.

Data Types: `single` | `double`

Complex Number Support: Yes

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Common to All System Objects

step Run System object algorithm
 release Release resources and allow changes to System object property values and input characteristics
 reset Reset internal states of System object

Examples

Add Thermal Noise to QPSK Signal

Create a thermal noise object with a noise temperature of 290 K and a sample rate of 5 MHz.

```
thNoise = comm.ThermalNoise('NoiseTemperature',290,'SampleRate',5e6);
```

Generate QPSK modulated data with an output power of 20 dBm.

```
data = randi([0 3],1000,1);
modData = (10^((20-30)/20)) * pskmod(data,4,pi/4);
```

Attenuate the signal by the free space path loss assuming a 1000 m link distance and a carrier frequency of 2 GHz.

```
d = 1000;                             % m
f = 2e9;                             % Hz
c = 3e8;                             % m/s
fsl = (4*pi*d*f/c)^2;
rxData = modData/sqrt(fsl);
```

Add thermal noise to the signal. Plot the noisy constellation.

```
noisyData = thNoise(rxData);
scatterplot(noisyData)
```

Add Antenna and Receiver Thermal Noise to 16-QAM Signal

Create a thermal noise object with a 5 dB noise figure and a 10 MHz sample rate. Include 290 K antenna noise.

```
thermalNoise = comm.ThermalNoise('NoiseMethod','Noise figure', ...
    'NoiseFigure',5, ...
    'SampleRate',10e6, ...
    'Add290KAntennaNoise',true);
```

Generate QPSK modulated data with an output power of 1 W.

```
data = randi([0 15],1000,1);
modSig = qammod(data,16,'UnitAveragePower',true);
```

Attenuate the signal by the free space path loss assuming a 1 km link distance and a 5 GHz carrier frequency.

```
d = 1000; % m
f = 5e9; % Hz
c = 3e8; % m/s
fsl = (4*pi*d*f/c)^2;
rxSig = modSig/sqrt(fsl);
```

Add thermal noise to the signal and plot its constellation.

```
noisySig = thermalNoise(rxSig);  
scatterplot(noisySig)
```

Estimate the SNR.

```
mer = comm.MER;  
snrEst1 = mer(rxSig,noisySig)
```

```
snrEst1 = 22.6611
```

Decrease the noise figure to 0 dB and plot the resultant received signal. The signal is not completely noiseless because antenna noise is included.

```
thermalNoise.NoiseFigure = 0;  
noisySig = thermalNoise(rxSig);  
scatterplot(noisySig)
```

Estimate the SNR. The SNR is 5 dB higher than in the first case, which is expected given the 5 dB decrease in the noise figure.

```
snrEst2 = mer(rxSig,noisySig)
snrEst2 = 27.8658
snrEst2 - snrEst1
ans = 5.2047
```

Algorithms

Wireless receiver performance is often expressed as a noise factor or figure. The noise factor is defined as the ratio of the input signal-to-noise ratio, S_i/N_i to the output signal-to-noise ratio, S_o/N_o , such that

$$F = \frac{S_i/N_i}{S_o/N_o} .$$

Given the receiver gain G and receiver noise power N_{ckt} , the noise factor can be expressed as

$$F = \frac{S_i/N_i}{GS_i/(N_{ckt} + GN_i)}$$

$$= \frac{N_{ckt} + GN_i}{GN_i} .$$

The IEEE defines the noise factor assuming that noise temperature at the input is T_0 , where $T_0 = 290$ K. The noise factor is then

$$\begin{aligned} F &= \frac{N_{ckt} + GN_i}{GN_i} \\ &= \frac{GkBT_{ckt} + GkBT_0}{GkBT_0} \\ &= \frac{T_{ckt} + T_0}{T_0} . \end{aligned}$$

T_{ckt} is the equivalent input noise temperature of the receiver and is expressed as

$$T_{ckt} = T_0(F - 1) .$$

The overall noise temperature of an antenna and receiver T_{sys} is

$$T_{sys} = T_{ant} + T_{ckt} ,$$

where T_{ant} is the antenna noise temperature.

The noise figure NF is the dB equivalent of the noise factor and can be expressed as

$$NF = 10\log_{10}(F) .$$

The noise power can be expressed as

$$N = kTB = V^2/R ,$$

where V is the noise voltage expressed as

$$V^2 = kTBR ,$$

and R is the reference load.

comm.TurboDecoder

Package: comm

Decode input signal using parallel concatenated decoding scheme

Description

The `comm.TurboDecoder` System object uses a parallel concatenated decoding scheme to decode a coded input signal. The input signal is typically the soft-decision output from the baseband demodulation operation. For more information, see “Parallel Concatenated Convolutional Decoding Scheme” on page 3-1363.

To decode an input signal using a parallel concatenated decoding scheme:

- 1 Create the `comm.TurboDecoder` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

Creation

Syntax

```
turbodec = comm.TurboDecoder  
turbodec = comm.TurboDecoder(trellis,interlvrindices,numiter)  
turbodec = comm.TurboDecoder( ___,Name,Value)
```

Description

`turbodec = comm.TurboDecoder` creates a turbo decoder System object. This object uses the *a-posteriori* probability (APP) constituent decoder to iteratively decode the parallel-concatenated convolutionally encoded input data.

`turbodec = comm.TurboDecoder(trellis,interlvrindices,numiter)` creates a turbo decoder System object with the `TrellisStructure`, `InterleaverIndices`, and `numiter`, respectively. The `trellis` input must be specified as described by the `TrellisStructure` property. The `interlvrindices` input must be specified as described by the `InterleaverIndices` property. The `numiter` input must be specified as described by the `NumIterations` property.

`turbodec = comm.TurboDecoder(___,Name,Value)` sets properties using one or more name-value pairs in addition to any input argument combination from previous syntaxes. Enclose each property name in quotes. For example, `comm.TurboDecoder('InterleaverIndicesSource','Input port')` configures a turbo decoder System object with the interleaver indices to be supplied as an input argument to the System object when it is called.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects.

TrellisStructure — Trellis description of constituent convolutional code

`poly2trellis(4,[13 15],13)` (default) | structure

Trellis description of the constituent convolutional code, specified as a structure that contains the trellis description for a rate K/N code. K is the number of input bit streams, and N is the number of output bit streams.

Note K must be 1 for the turbo coder. For more information, see “Coding Rate” on page 3-1364.

You can either use the `poly2trellis` function to create the trellis structure or create it manually. For more about this structure, see “Trellis Description of a Convolutional Code” and the `istrellis` function.

The trellis structure contains these fields.

numInputSymbols — Number of symbols input to encoder

2^K

Number of symbols input to the encoder, specified as an integer equal to 2^K , where K is the number of input bit streams.

Data Types: `double`

numOutputSymbols — Number of symbols output from encoder

2^N

Number of symbols output from the encoder, specified as an integer equal to 2^N , where N is the number of output bit streams.

Data Types: `double`

numStates — Number of states in encoder

power of 2

Number of states in the encoder, specified as a power of 2.

Data Types: `double`

nextStates — Next states

matrix of integers

Next states for all combinations of current states and current inputs, specified as a matrix of integers. The matrix size must be `numStates-by- 2^K` .

Data Types: `double`

outputs – Outputs

matrix of octal numbers

Outputs for all combinations of current states and current inputs, specified as a matrix of octal numbers. The matrix size must be $\text{numStates-by-}2^K$.

Data Types: double

Data Types: struct

InterleaverIndicesSource – Source of interleaver indices

'Property' (default) | 'Input port'

Source of interleaver indices, specified as 'Property' or 'Input port'.

- When you set this property to 'Input port', the object executes using the input argument `interlvrindices` when you call the object. The vector length and values for the interleaver indices and coded input signal can change with each call to the object.
- When you set this property to 'Property', the object executes using the interleaver indices that you specified with the `InterleaverIndices` property when configuring the object.

Data Types: char | string

InterleaverIndices – Interleaver indices

(64:-1:1) .' (default) | column vector of integers

Interleaver indices that define the mapping used to permute the codeword bits input to the decoder, specified as a column vector of integers. The vector must be of length L . Each element of the vector must be an integer in the range $[1, L]$ and must be unique. L is the length decoded output message, `decmsg`. Each element of the vector must be an integer in the range $[1, L]$ and must be unique.

Dependencies

To enable this property, set the `InterleaverIndicesSource` property to 'Property'.

Data Types: double

InputIndicesSource – Source of input indices

'Auto' (default) | 'Property' | 'Input port'

Source of input indices, specified as 'Auto', 'Property', or 'Input port'.

- When you set this property to 'Auto', the object computes input indices that assume the second systematic stream is punctured and all tail bits are included in the input.
- When you set this property to 'Property', the object uses the input indices that you specify for the `InputIndices` property.
- When this property is set to 'Input port', the object executes using the input indices specified by the input argument `inindices`. The vector length and values for the input indices and the coded input signal can change with each call to the object.

Data Types: char | string

InputIndices – Input indices`getTurboIOIndices(64,2,3)` (default) | column vector of integers

Input indices for the bit ordering and puncturing used on the fully encoded data, specified as a column vector of integers. The length of this property must equal the length of the input data vector codeword.

Dependencies

To enable this property, set the `InputIndicesSource` property to `'Property'`.

Data Types: `double`

Algorithm — Decoding algorithm

`'True APP'` (default) | `'Max*'` | `'Max'`

Decoding algorithm, specified as `'True APP'`, `'Max*'`, or `'Max'`. When you set this property to `'True APP'`, the object implements true APP decoding. When you set this property to `'Max*'` or `'Max'`, the object uses approximations to increase the speed of the computations. For more information, see “APP Decoder” on page 3-1364.

Data Types: `char` | `string`

NumScalingBits — Number of scaling bits

3 (default) | integer in the range [0, 8]

Number of scaling bits, specified as an integer in the range [0, 8]. This property sets the number of bits the constituent decoders use to scale the input data to avoid losing precision during computations. The constituent decoders multiply the input by $2^{\text{NumScalingBits}}$ and divide the pre-output by the same factor. For more information, see “APP Decoder” on page 3-1364.

Dependencies

To enable this property, set the `Algorithm` property to `'Max*'`.

Data Types: `double`

NumIterations — Number of decoding iterations

6 (default) | positive integer

Number of decoding iterations, specified as a positive integer. This property sets the number of decoding iterations used for each call to the object. The object iterates and provides updates to the log-likelihood ratios (LLR) of the uncoded output bits. The output of the object is the hard-decision output of the final LLR update.

Data Types: `double`

Usage

Syntax

```
decmsg = turbodec(codeword)
decmsg = turbodec(codeword,interlvindices)
decmsg = turbodec(codeword,interlvindices,inindices)
```

Description

`decmsg = turbodec(codeword)` decodes the input codeword using the parallel concatenated convolutional decoding scheme that is specified by the trellis structure and interleaver indices.

`turbodec` returns the binary decoded data. For more information, see “Parallel Concatenated Convolutional Decoding Scheme” on page 3-1363.

`decmsg = turbodec(codeword, interlvrindices)` additionally specifies the interleaver indices. To enable this syntax, set the `InterleaverIndicesSource` property to `'Input port'`. The interleaver indices define the mapping used to permute the input at the decoder.

`decmsg = turbodec(codeword, interlvrindices, inindices)` additionally specifies the bit ordering and puncturing used on the fully encoded data. To enable this syntax, set the `InputIndicesSource` property to `'Input port'`. The input indices vector values must be relative to the fully encoded data, including the tail bits for the coding scheme for all streams.

Input Arguments

codeword — Parallel concatenated codeword

column vector

Parallel concatenated codeword, specified as a column vector of length M , where M is the length of the parallel concatenated codeword.

Data Types: `double` | `single`

interlvrindices — Interleaver indices

column vector of integers

Interleaver indices, specified as a column vector of integers. The vector must be of length L , where L is the length of the decoded output message, `decmsg`. Each element of the vector must be an integer in the range $[1, L]$ and must be unique. The interleaver indices define the mapping used to permute the input bits at the decoder.

Tunable: Yes

Dependencies

To enable this property, set the `InterleaverIndicesSource` property to `'Input port'`.

Data Types: `double`

inindices — Input indices

column vector of integers

Input indices for the bit ordering and puncturing used on the fully encoded data, specified as a column vector of integers. The length of the `inindices` vector must equal the length of the input data vector `codeword`. Element values in the `inindices` vector must be relative to the fully encoded data, including the tail bits for the coding scheme for all streams.

Dependencies

To enable this argument, set the `InputIndicesSource` property to `'Input port'`.

Data Types: `double`

Output Arguments

decmsg — Decoded message

binary column vector

Decoded message, returned as a binary column vector of length L , where L is the length of the decoded output message. This output signal is the same as data type of the codeword input.

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Common to All System Objects

<code>step</code>	Run System object algorithm
<code>release</code>	Release resources and allow changes to System object property values and input characteristics
<code>reset</code>	Reset internal states of System object

Examples

Define Output and Input Indices for Full-Length and Punctured Turbo Coding

Define output indices by using the `OutputIndices` property for turbo encoding and define the input indices by using the `InputIndices` property for turbo decoding. Show full-length punctured encoding and decoding for a rate 1/2 code and 10-bit block length.

Initialize Parameters

Define parameters to initialize the encoder.

```
blkLen = 10;
trellis = poly2trellis(4,[13 15],13);
n = log2(trellis.numOutputSymbols);
mLen = log2(trellis.numStates);
```

Full-Length Encoding and Decoding

Initialize variables and turbo encoding and decoding System objects for full-length coding. Turbo encode and decode the message. Display the turbo coding rate. Check the length of the coded output versus the length of the output indices vector.

```
fullOut = (1:(mLen+blkLen)*2*n)';
outLen = length(fullOut);
netRate = blkLen/outLen;
data = randi([0 1],blkLen,1);
intIndices = randperm(blkLen);

turboEnc = comm.TurboEncoder('TrellisStructure',trellis);
turboEnc.InterleaverIndices = intIndices;
turboEnc.OutputIndicesSource = 'Property';
turboEnc.OutputIndices = fullOut;

turboDec = comm.TurboDecoder('TrellisStructure',trellis);
turboDec.InterleaverIndices = intIndices;
turboDec.InputIndicesSource = 'Property';
```

```
turboDec.InputIndices = fullOut;
encMsg = turboEnc(data);      % Encode
disp(['Turbo coding rate: ' num2str(netRate)])
Turbo coding rate: 0.19231
encOutLen = length(encMsg)    % Display encoded length
encOutLen = 52
isequal(encOutLen,outLen)     % Check lengths

ans = logical
     1

rxMsg = turboDec(2*encMsg-1); % Decode
isequal(data, rxMsg)         % Compare bits with decoded bits

ans = logical
     1
```

Punctured Encoding and Decoding

Specify the output indices for puncturing of the second systematic stream by using the `getTurboIOIndices` function. Initialize variables and turbo encoding and decoding System objects for punctured coding. Turbo encode and decode the message. Display the turbo coding rate. Check the length of the coded output versus the length of the output indices vector.

```
puncOut = getTurboIOIndices(blkLen,n,mLen);
outLen = length(puncOut);
netRate = blkLen/outLen;
data = randi([0 1],blkLen,1);
intIndices = randperm(blkLen);

turboEnc = comm.TurboEncoder('TrellisStructure',trellis);
turboEnc.InterleaverIndices = intIndices;
turboEnc.OutputIndicesSource = 'Property';
turboEnc.OutputIndices = puncOut;

turboDec = comm.TurboDecoder('TrellisStructure',trellis);
turboDec.InterleaverIndices = intIndices;
turboDec.InputIndicesSource = 'Property';
turboDec.InputIndices = puncOut;

encMsg = turboEnc(data);      % Encode
disp(['Turbo coding rate: ' num2str(netRate)])
Turbo coding rate: 0.25641
encOutLen = length(encMsg) % Display encoded length
encOutLen = 39
```

```

isequal(encOutLen, outLen) % Check lengths
ans = logical
     1

rxMsg = turboDec(2*encMsg-1); % Decode
isequal(data, rxMsg)          % Compare bits with decoded bits
ans = logical
     1

```

Compare Full and Punctured Outputs

The output of the encoder interlaces the individual bit streams. The third bit of every 4-bit tuple is removed from the full-length code to produce the punctured code. This third output bit stream corresponds to the second systematic bit stream. Display the indices of the full-length code and the indices of the punctured code to show that the third bit of every 4-bit tuple is punctured.

```

fullOut'
ans = 1x52
      1      2      3      4      5      6      7      8      9     10     11     12     13     14     15     16

puncOut'
ans = 1x39
      1      2      4      5      6      8      9     10     12     13     14     16     17     18     20     21

```

Transmit and Receive Turbo-Encoded Data over BPSK-Modulated AWGN Channel

Simulate the transmission and reception of BPSK data over an AWGN channel by using turbo encoding and decoding.

Specify simulation parameters, and then compute the effective coding rate and noise variance. For BPSK modulation, E_S/N_0 equals E_b/N_0 because the number of bits per symbol (bps) is 1. To ease reuse of this code for other modulation schemes, calculations in this example include the bps terms. Define the packet length, trellis structure, and number of iterations. Calculate the noise variance using E_S/N_0 and the code rate. Set the random number generator to its default state to ensure that the results are repeatable.

```

modOrd = 2; % Modulation order
bps = log2(modOrd); % Bits per symbol
EbNo = 1; % Energy per bit to noise power spectral density ratio in dB
EsNo = EbNo + 10*log10(bps); % Energy per symbol to noise power spectral density ratio in dB

L = 256; % Input packet length in bits
trellis = poly2trellis(4,[13 15 17],13);
numiter = 4;

```

```
n = log2(trellis.numOutputSymbols);
numTails = log2(trellis.numStates)*n;
M = L*(2*n - 1) + 2*numTails; % Output codeword packet length
rate = L/M; % Coding rate
```

```
snrdB = EsNo + 10*log10(rate); % Signal to noise ratio in dB
noiseVar = 1./(10.^(snrdB/10)); % Noise variance
```

```
rng default
```

Generate random interleaver indices.

```
intrlvrIndices = randperm(L);
```

Create a turbo encoder and decoder pair. Use the defined trellis structure and random interleaver indices. Configure the decoder to run a maximum of four iterations.

```
turboenc = comm.TurboEncoder(trellis,intrlvrIndices);
turbodec = comm.TurboDecoder(trellis,intrlvrIndices,numiter);
```

Create a BPSK modulator and demodulator pair, where the demodulator outputs soft bits determined using an LLR method.

```
bpskmod = comm.BPSKModulator;
bpskdemod = comm.BPSKDemodulator('DecisionMethod','Log-likelihood ratio', ...
    'Variance',noiseVar);
```

Create an AWGN channel object and an error rate object.

```
awgnchan = comm.AWGNChannel('NoiseMethod','Variance','Variance',noiseVar);
errrate = comm.ErrorRate;
```

The main processing loop performs these steps.

- 1 Generate binary data.
- 2 Turbo encode the data.
- 3 Modulate the encoded data.
- 4 Pass the modulated signal through an AWGN channel.
- 5 Demodulate the noisy signal by using LLR to output soft bits.
- 6 Turbo decode the demodulated data. Because the bit mapping from the demodulator is opposite of the mapping expected by the turbo decoder, the decoder input must use the inverse of the demodulated signal.
- 7 Calculate the error statistics.

```
for frmIdx = 1:100
    data = randi([0 1],L,1);
    encodedData = turboenc(data);
    modSignal = bpskmod(encodedData);
    receivedSignal = awgnchan(modSignal);
    demodSignal = bpskdemod(receivedSignal);
    receivedBits = turbodec(-demodSignal);
    errorStats = errrate(data,receivedBits);
end
```

Display the error data.

```
fprintf('Bit error rate = %5.2e\nNumber of errors = %d\nTotal bits = %d\n', errorStats)
```

```
Bit error rate = 2.34e-04
Number of errors = 6
Total bits = 25600
```

Perform Turbo Coding on 16-QAM Signal in AWGN Channel

Simulate an end-to-end communication link by using a 16-QAM signal and turbo codes in an AWGN channel. Inside a frame processing loop, packet sizes are randomly selected to be 500, 1000, or 1500 bits. Because the packet size varies, the interleaver indices are provided to the turbo encoder and decoder as an input argument of their associated System object. Compare turbo coded bit error rate results to uncoded bit error rate results.

Initialize Simulation

Set the modulation order and range of E_b/N_0 values. Compute the number of bits per symbol and the energy per symbol to noise ratio (E_s/N_0) based on the modulation order and E_b/N_0 . To get repeatable results, seed the random number.

```
modOrder = 16;           % Modulation order
bps = log2(modOrder);    % Bits per symbol
EbNo = (2:0.5:4);       % Energy per bit to noise power spectral density ratio in dB
EsNo = EbNo + 10*log10(bps); % Energy per symbol to noise power spectral density ratio in dB
rng(1963);
```

Create a turbo encoder and decoder pair. Because the packet length varies for each frame, specify that the interleaver indices be supplied by an input argument of the System object when executed. Specify that the decoder perform four iterations.

```
turboEnc = comm.TurboEncoder('InterleaverIndicesSource','Input port');
turboDec = comm.TurboDecoder('InterleaverIndicesSource','Input port','NumIterations',4);
trellis = poly2trellis(4,[13 15 17],13);
n = log2(turboEnc.TrellisStructure.numOutputSymbols);
numTails = log2(turboEnc.TrellisStructure.numStates)*n;
```

Create an error rate object.

```
errRate = comm.ErrorRate;
```

Main Processing Loop

The frame processing loop performs these steps.

- 1 Select a random packet length, and generate random binary data.
- 2 Compute the output codeword length and coding rate.
- 3 Compute the signal to noise ratio (SNR) and noise variance.
- 4 Generate interleaver indices.
- 5 Turbo encode the data.
- 6 Apply 16-QAM modulation, and normalize the average signal power.
- 7 Pass the modulated signal through an AWGN channel.

- 8 Demodulate the noisy signal by using an LLR method, output soft bits, and normalize the average signal power.
- 9 Turbo decode the data. Because the bit mapping order from the demodulator is opposite the mapping order expected by the turbo decoder, the decoder input must use the inverse of the demodulated signal.
- 10 Calculate the error statistics.

```
ber = zeros(1,length(EbNo));
for k = 1:length(EbNo)
    % numFrames = 100;
    errorStats = zeros(1,3);
    %for pktIdx = 1:numFrames
    L = 500*randi([1 3],1,1); % Packet length in bits
    M = L*(2*n - 1) + 2*numTails; % Output codeword packet length
    rate = L/M; % Coding rate for current packet
    snrdB = EsNo(k) + 10*log10(rate); % Signal to noise ratio in dB
    noiseVar = 1./(10.^(snrdB/10)); % Noise variance

    while errorStats(2) < 100 && errorStats(3) < 1e7
        data = randi([0 1],L,1);
        intrlvrIndices = randperm(L);
        encodedData = turboEnc(data,intrlvrIndices);
        modSignal = qammod(encodedData,modOrder, ...
            'InputType','bit','UnitAveragePower',true);
        rxSignal = awgn(modSignal,snrdB);
        demodSignal = qamdemod(rxSignal,modOrder,'OutputType','llr', ...
            'UnitAveragePower',true,'NoiseVariance',noiseVar);
        rxBits = turboDec(-demodSignal,intrlvrIndices); % Demodulated signal is negated
        errorStats = errRate(data,rxBits);
    end
    % Save the BER data and reset the bit error rate object
    ber(k) = errorStats(1);
    reset(errRate)
end
```

Plot Results

Plot the bit error rate and compare it to the uncoded bit error rate.

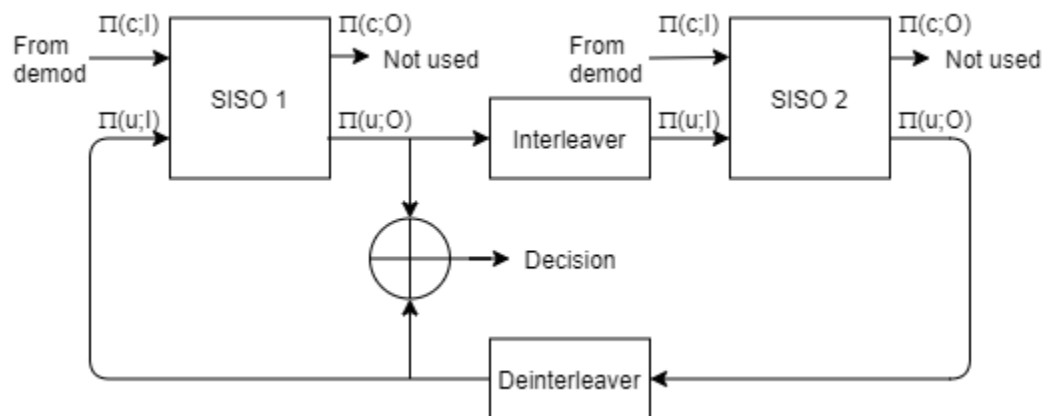

```
semilogy(EbNo,ber,'-o')
grid
xlabel('Eb/No (dB)')
ylabel('Bit Error Rate')
uncodedBER = berawgn(EbNo,'qam',modOrder); % Estimate of uncoded BER
hold on
semilogy(EbNo,uncodedBER)
legend('Turbo','Uncoded','location','sw')
```

More About

Parallel Concatenated Convolutional Decoding Scheme

The turbo decoder uses a parallel concatenated convolutional decoding scheme to decode a coded input signal. The parallel concatenated decoding scheme uses an iterative “APP Decoder” on page 3-1364 with two constituent decoders, an interleaver, and a deinterleaver. This figure shows the decoding scheme. Typically, the decoder input data comes from the demodulator output.

The two constituent decoders use the same trellis structure and decoding algorithm. The soft-input soft-output APP decoders (SISO 1 and SISO 2) output an updated sequence of log-likelihoods of the

encoder input bits, $\pi(u;O)$. The sequence is based on the received sequence of log-likelihoods of the channel (coded) bits, $\pi(c;I)$, and code parameters.

The decoder iteratively updates these likelihoods for a fixed number of decoding iterations and then outputs the decision bits. The interleaver used in the decoder is identical to the interleaver used in the encoder. The deinterleaver performs the inverse permutation with respect to the interleaver. The decoder does not assume knowledge of the tail bits and excludes these bits from the iterations.

For more information, see “Coding Rate” on page 3-1364.

APP Decoder

The `comm.TurboDecoder` System object implements the soft-input soft-output APP decoding algorithm according to [1] and [2].

The 'True APP' option of the `Algorithm` property implements APP decoding as per equations 20-23 in section V of [1]. To gain speed, the 'Max*' and 'Max' values of the `Algorithm` property approximate expressions like $\log \sum_i \exp(a_i)$ by other quantities. The 'Max' option uses $\max(a_i)$ as the approximation. The 'Max*' option uses $\max(a_i)$ plus a correction term given by the expression $\ln(1 + \exp(-|a_i - 1 - a_i|))$.

Setting the `Algorithm` property to 'Max*' enables the `NumScalingBits` property of this System object. This property denotes the number of bits by which this System object scales the data it processes (multiplies the input by $2^{\text{NumScalingBits}}$ and divides the pre-output by the same factor). Use this property to avoid losing precision during computations.

Coding Rate

In general, the coding rate of a constituent convolutional code is represented as a rate K / N code. K is the number of input bit streams. N is the number of output bit streams.

Note K must be 1 to use the `comm.TurboEncoder` and `comm.TurboDecoder` System objects. Alternatively, the “High Rate Convolutional Codes for Turbo Coding” example performs turbo coding for K greater than 1 by using the `comm.ConvolutionalEncoder` and `comm.APPDecoder` System objects.

The decoder accepts an M -element column vector input signal and returns an L -element column vector containing the decoded binary output message. L is the interleaver block length. M is the length of the parallel concatenated codeword.

For a given input trellis, when you set the `InputIndicesSource` property to 'Auto', M and L are related by $L = (M - 2 \times \text{numTails}) / (2 \times N - 1)$, where:

- $\text{numTails} = \log_2(\text{trellis.numStates}) \times N$
- $N = \log_2(\text{trellis.numOutputSymbols})$. For a rate 1 / 2 trellis, $N = 2$.

For more information about trellis structures, see the `poly2trellis` function. For more information about the constituent decoders, see “Parallel Concatenated Convolutional Decoding Scheme” on page 3-1363.

Package: comm

Encode input signal using parallel concatenated encoding scheme

Description

The `comm.TurboEncoder` System object applies a parallel concatenated encoding scheme to a binary input message. This coding scheme uses two convolutional encoders and appends the termination bits at the end of the encoded data bit stream. For more information, see “Parallel Concatenated Convolutional Encoding Scheme” on page 3-1377.

To encode a binary input message using a parallel concatenated encoding scheme:

- 1 Create the `comm.TurboEncoder` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

Creation

Syntax

```
turboenc = comm.TurboEncoder  
turboenc = comm.TurboEncoder(Name,Value)  
turboenc = comm.TurboEncoder(trellis,interlvrindices)
```

Description

`turboenc = comm.TurboEncoder` creates a turbo encoder System object. This object performs turbo encoding using the default object configuration.

`turboenc = comm.TurboEncoder(Name,Value)` sets properties using one or more name-value pairs. For example, `comm.TurboEncoder('InterleaverIndicesSource','Input port')` configures a turbo encoder System object with the interleaver indices to be supplied as an input argument to the System object when it is called. Enclose each property name in quotes.

`turboenc = comm.TurboEncoder(trellis,interlvrindices)` creates a turbo encoder System object with the `TrellisStructure` and `InterleaverIndices` properties set to `trellis` and `interlvrindices`, respectively. The `trellis` input must be specified as described by the `TrellisStructure` property. The `interlvrindices` input must be specified as described by the `InterleaverIndices` property.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects.

TrellisStructure — Trellis description of constituent convolutional code

`poly2trellis(4,[13 15],13)` (default) | structure

Trellis description of the constituent convolutional code, specified as a structure that contains the trellis description for a rate K/N code. K is the number of input bit streams, and N is the number of output bit streams.

Note K must be 1 for the turbo coder. For more information, see “Coding Rate” on page 3-1378.

You can either use the `poly2trellis` function to create the trellis structure or create it manually. For more about this structure, see “Trellis Description of a Convolutional Code” and the `istrellis` function.

The trellis structure contains these fields.

numInputSymbols — Number of symbols input to encoder

2^K

Number of symbols input to the encoder, specified as an integer equal to 2^K , where K is the number of input bit streams.

Data Types: `double`

numOutputSymbols — Number of symbols output from encoder

2^N

Number of symbols output from the encoder, specified as an integer equal to 2^N , where N is the number of output bit streams.

Data Types: `double`

numStates — Number of states in encoder

power of 2

Number of states in the encoder, specified as a power of 2.

Data Types: `double`

nextStates — Next states

matrix of integers

Next states for all combinations of current states and current inputs, specified as a matrix of integers. The matrix size must be `numStates-by-2^K`.

Data Types: `double`

outputs — Outputs

matrix of octal numbers

Outputs for all combinations of current states and current inputs, specified as a matrix of octal numbers. The matrix size must be `numStates-by-2^K`.

Data Types: double

Data Types: struct

InterleaverIndicesSource — Source of interleaver indices

'Property' (default) | 'Input port'

Source of interleaver indices, specified as 'Property' or 'Input port'.

- When you set this property to 'Property', the object executes using the interleaver indices that you specified with the InterleaverIndices property when configuring the object.
- When you set this property to 'Input port', the object executes using the input argument `interlvrindices` when you call the object. The vector length and values for the interleaver indices and binary input message can change with each call to the object.

Data Types: char | string

InterleaverIndices — Interleaver indices

(64:-1:1).' (default) | column vector of integers

Interleaver indices, specified as a column vector of integers. The vector must be of length L , where L is the length of the binary input message. Each element of the vector must be an integer in the range $[1, L]$ and must be unique. The interleaver indices define the mapping used to permute the input bits at the encoder.

Tunable: Yes

Dependencies

To enable this property, set the InterleaverIndicesSource property to 'Property'.

Data Types: double

OutputIndicesSource — Source of output indices

'Auto' (default) | 'Property' | 'Input port'

Source of output indices, specified as 'Auto', 'Property', or 'Input port'.

- When you set this property to 'Auto', the object computes output indices that puncture the second systematic stream and include all tail bits.
- When you set this property to 'Property', the object uses the output indices that you specify for the OutputIndices property.
- When you set this property to 'Input port', the object executes using the output indices specified by the input argument `outindices`. The vector length and values for the output indices, and the coded output signal can change with each call to the object.

Data Types: char | string

OutputIndices — Output indices

`getTurboIOIndices(64,2,3)` (default) | column vector of integers

Output indices for the bit ordering and puncturing used on the fully encoded data, specified as a column vector of integers. The number of bits output from the encoder equals the length of this property. The maximum length must not exceed the fully encoded length of $(L+mLen) \times N \times 2$, where L is the input block length, $mLen$ is the memory length, and N is the number of encoded streams for the constituent coder.

Dependencies

To enable this property, set the `OutputIndicesSource` property to 'Property'.

Data Types: `double`

Usage

Syntax

```
codeword = turboenc(message)
codeword = turboenc(message,interlvrindices)
codeword = turboenc(message,interlvrindices,outindices)
```

Description

`codeword = turboenc(message)` encodes the input message using the parallel concatenated convolutional encoding scheme specified by the trellis structure and interleaver indices. `turboenc` returns the binary encoded codeword. `message` and `codeword` are column vectors of numeric, logical, or unsigned fixed-point values with word length 1 (`fi` object). For more information, see “Parallel Concatenated Convolutional Encoding Scheme” on page 3-1377.

`codeword = turboenc(message,interlvrindices)` additionally specifies the interleaver indices. `interlvrindices` must be a column vector containing integers in the range $[1, L]$ with no repeated values. L is the length of the binary input message, `message`. This syntax applies when the `InterleaverIndicesSource` property is set to 'Input port'. The interleaver indices define the mapping used to permute the input bits at the encoder.

`codeword = turboenc(message,interlvrindices,outindices)` additionally specifies the bit ordering and puncturing used when encoding the message data. To enable this syntax, set the `OutputIndicesSource` property to 'Input port'. The output indices vector values must be relative to the fully encoded data for the coding scheme, including the tail bits for all streams.

Input Arguments

message — Input message

binary column vector

Input message, specified as a binary column vector of length L , where L is the length of the uncoded input message.

Data Types: `double` | `int8` | `fi(data,0,1)`

interlvrindices — Interleaver indices

column vector of integers

Interleaver indices, specified as a column vector of integers. The vector must be of length L , where L is the length of the binary input message. Each element of the vector must be an integer in the range $[1, L]$ and must be unique. The interleaver indices define the mapping used to permute the input bits at the encoder.

Dependencies

To enable this argument, set the `InterleaverIndicesSource` property to 'Input port'.

Data Types: double

outindices — Output indices

column vector of integers

Output indices for the bit ordering and puncturing used on the fully encoded data, specified as a column vector of integers. Element values in the `outindices` vector must be relative to the fully encoded data for the coding scheme, including the tail bits for all streams.

Dependencies

To enable this argument, set the `OutputIndicesSource` property to `'Input port'`.

Data Types: double

Output Arguments**codeword — Parallel concatenated codeword**

binary column vector

Parallel concatenated codeword, returned as a binary column vector of length M , where M is the number of bits in the parallel concatenated codeword. This output inherits its data type from the message input.

Data Types: double | int8 | `fi(data,0,1)`

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

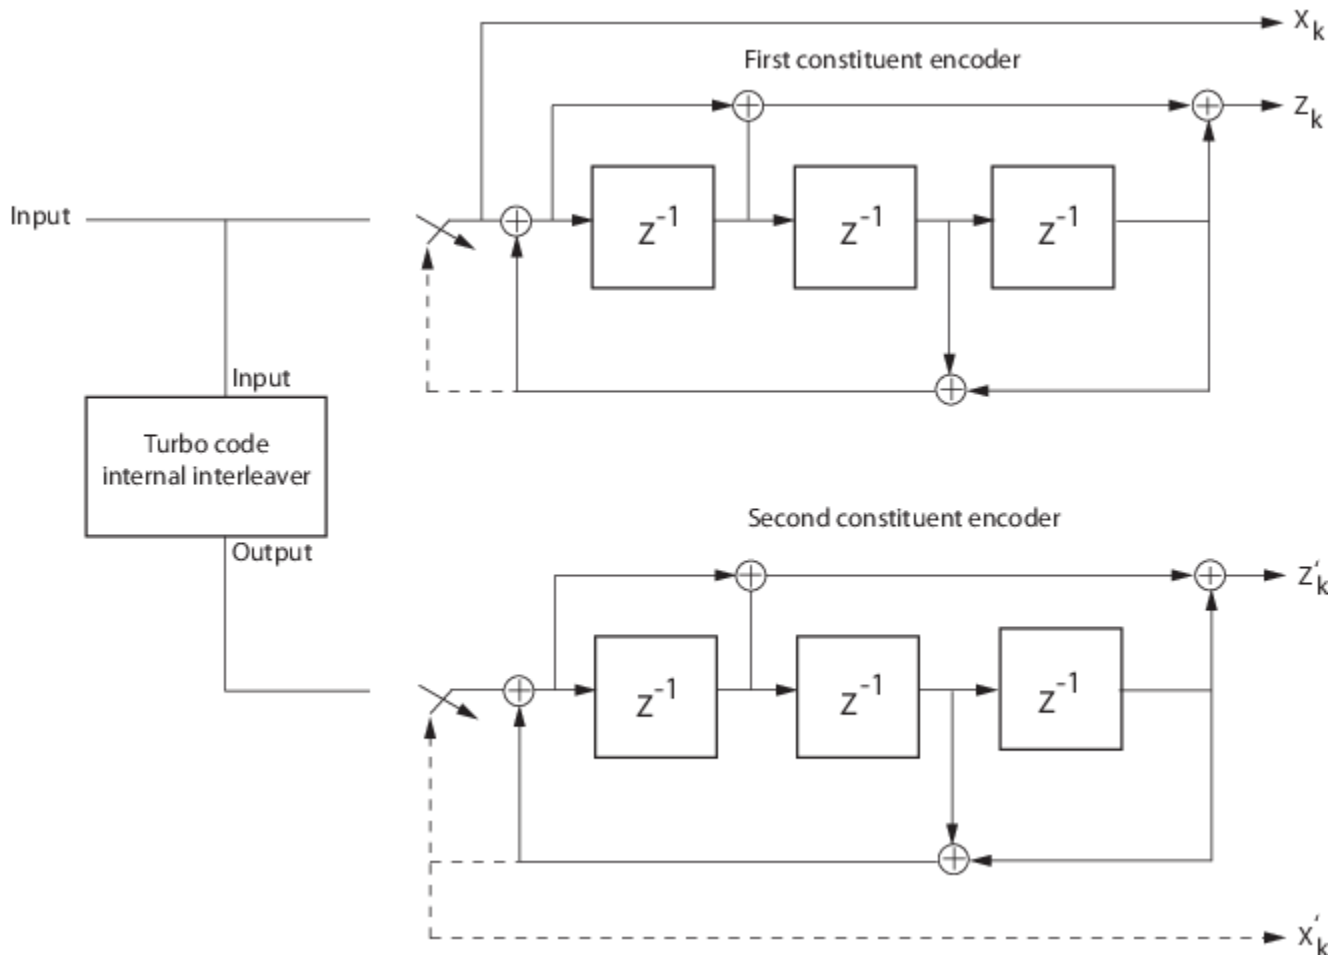

```
release(obj)
```

Common to All System Objects

<code>step</code>	Run System object algorithm
<code>release</code>	Release resources and allow changes to System object property values and input characteristics
<code>reset</code>	Reset internal states of System object

Examples**Perform Rate 1/3 Turbo Code Encoding**

Encode an input message by using a rate 1/3 turbo encoder configuration with the default trellis structure, `poly2trellis(4,[13 15],13)`, as represented in this figure.

For an input message with 64 bits, the codeword output from the encoder is 204 bits. The first 192 bits output correspond to the three 64 bit streams, interlaced as X_k , Z_k , and Z'_k . The systematic bit stream, X_k , and parity bit stream, Z_k , are from the first encoder and the parity bit stream, Z'_k , is from the second encoder. When the switches are in the lower position, signals follow the dashed lines and the last 12 bits correspond to the tail bits from the two encoders. The first group of six bits (three systematic bits and three parity bits) are the output tail bits from the first constituent encoder. The second group of six bits (three systematic bits and three parity bits) are the output tail bits from the second constituent encoder.

Create a turbo encoder using the default settings. Generate a frame of binary message data, and then encode the message data.

```
rng default
turboenc = comm.TurboEncoder;
frameLen = 64; % Frame length
data = randi([0 1], frameLen, 1);
encData = turboenc(data);
codewordLen = length(encData);
```

Compute the coding rate. Due to the tail bits, the encoder output code rate is slightly less than 1/3.

```
codingrate = frameLen/codewordLen
```

```
codingrate = 0.3137
```

Define Output Indices for Full-Length and Punctured Turbo Coding

Define output indices by using the `OutputIndices` property. Show full-length encoded output and punctured encoded output for a rate 1/2 code and 10-bit block length.

Initialize Parameters

Define parameters to initialize the encoder.

```
blkLen = 10;  
trellis = poly2trellis(4,[13 15],13);  
n = log2(trellis.numOutputSymbols);  
mLen = log2(trellis.numStates);
```

Full-Length Encoded Output

Initialize variables and a turbo encoder System object for full-length coding. Display the turbo coding rate. Check the length of the coded output versus the length of the output indices vector.

```
fullOut = (1:(mLen+blkLen)*2*n)';  
outLen = length(fullOut);  
netRate = blkLen/outLen;  
data = randi([0 1],blkLen,1);  
intIndices = randperm(blkLen);  
  
turboEnc = comm.TurboEncoder('TrellisStructure',trellis);  
turboEnc.InterleaverIndices = intIndices;  
turboEnc.OutputIndicesSource = 'Property';  
turboEnc.OutputIndices = fullOut;  
  
encMsg = turboEnc(data); % Encode  
  
disp(['Turbo coding rate: ' num2str(netRate)])  
Turbo coding rate: 0.19231  
  
encOutLen = length(encMsg) % Display encoded length  
encOutLen = 52  
  
isequal(encOutLen,outLen) % Check lengths  
  
ans = logical  
     1
```

Punctured Encoded Output

Specify the output indices for puncturing of the second systematic stream by using the `getTurboIOIndices` function. Initialize variables and a turbo encoder System object for punctured coding. Display the turbo coding rate. Check the length of the coded output versus the length of the output indices vector.

```
puncOut = getTurboIOIndices(blkLen,n,mLen);  
outLen = length(puncOut);
```

```

netRate = blkLen/outLen;
data = randi([0 1],blkLen,1);
intIndices = randperm(blkLen);

turboEnc = comm.TurboEncoder('TrellisStructure',trellis);
turboEnc.InterleaverIndices = intIndices;
turboEnc.OutputIndicesSource = 'Property';
turboEnc.OutputIndices = puncOut;

encMsg = turboEnc(data); % Encode

disp(['Turbo coding rate: ' num2str(netRate)])
Turbo coding rate: 0.25641

encOutLen = length(encMsg) % Display encoded length
encOutLen = 39

isequal(encOutLen, outLen) % Check lengths

ans = logical
     1

```

Compare Full and Punctured Outputs

The output of the encoder interlaces the individual bit streams. The third bit of every 4-bit tuple is removed from the full-length code to produce the punctured code. This third output bit stream corresponds to the second systematic bit stream. Display the indices of the full-length code and the indices of the punctured code to show that the third bit of every 4-bit tuple is punctured.

```

fullOut'
ans = 1×52
     1     2     3     4     5     6     7     8     9    10    11    12    13    14    15    16

puncOut'
ans = 1×39
     1     2     4     5     6     8     9    10    12    13    14    16    17    18    20    21

```

Transmit and Receive Turbo-Encoded Data over BPSK-Modulated AWGN Channel

Simulate the transmission and reception of BPSK data over an AWGN channel by using turbo encoding and decoding.

Specify simulation parameters, and then compute the effective coding rate and noise variance. For BPSK modulation, E_S/N_0 equals E_b/N_0 because the number of bits per symbol (bps) is 1. To ease reuse of this code for other modulation schemes, calculations in this example include the bps terms. Define the packet length, trellis structure, and number of iterations. Calculate the noise variance using E_S/N_0 and the code rate. Set the random number generator to its default state to ensure that the results are repeatable.

```
modOrd = 2; % Modulation order
bps = log2(modOrd); % Bits per symbol
EbNo = 1; % Energy per bit to noise power spectral density ratio in dB
EsNo = EbNo + 10*log10(bps); % Energy per symbol to noise power spectral density ratio in dB

L = 256; % Input packet length in bits
trellis = poly2trellis(4,[13 15 17],13);
numiter = 4;
n = log2(trellis.numOutputSymbols);
numTails = log2(trellis.numStates)*n;
M = L*(2*n - 1) + 2*numTails; % Output codeword packet length
rate = L/M; % Coding rate

snrdB = EsNo + 10*log10(rate); % Signal to noise ratio in dB
noiseVar = 1./(10.^(snrdB/10)); % Noise variance
```

```
rng default
```

Generate random interleaver indices.

```
intrlvrIndices = randperm(L);
```

Create a turbo encoder and decoder pair. Use the defined trellis structure and random interleaver indices. Configure the decoder to run a maximum of four iterations.

```
turboenc = comm.TurboEncoder(trellis,intrlvrIndices);
turbodec = comm.TurboDecoder(trellis,intrlvrIndices,numiter);
```

Create a BPSK modulator and demodulator pair, where the demodulator outputs soft bits determined using an LLR method.

```
bpskmod = comm.BPSKModulator;
bpskdemod = comm.BPSKDemodulator('DecisionMethod','Log-likelihood ratio', ...
    'Variance',noiseVar);
```

Create an AWGN channel object and an error rate object.

```
awgnchan = comm.AWGNChannel('NoiseMethod','Variance','Variance',noiseVar);
errrate = comm.ErrorRate;
```

The main processing loop performs these steps.

- 1 Generate binary data.
- 2 Turbo encode the data.
- 3 Modulate the encoded data.
- 4 Pass the modulated signal through an AWGN channel.
- 5 Demodulate the noisy signal by using LLR to output soft bits.
- 6 Turbo decode the demodulated data. Because the bit mapping from the demodulator is opposite of the mapping expected by the turbo decoder, the decoder input must use the inverse of the demodulated signal.
- 7 Calculate the error statistics.

```
for frmIdx = 1:100
    data = randi([0 1],L,1);
    encodedData = turboenc(data);
```

```

    modSignal = bpskmod(encodedData);
    receivedSignal = awgnchan(modSignal);
    demodSignal = bpskdemod(receivedSignal);
    receivedBits = turbodec(-demodSignal);
    errorStats = errrate(data,receivedBits);
end

```

Display the error data.

```
fprintf('Bit error rate = %5.2e\nNumber of errors = %d\nTotal bits = %d\n', errorStats)
```

```

Bit error rate = 2.34e-04
Number of errors = 6
Total bits = 25600

```

Perform Turbo Coding on 16-QAM Signal in AWGN Channel

Simulate an end-to-end communication link by using a 16-QAM signal and turbo codes in an AWGN channel. Inside a frame processing loop, packet sizes are randomly selected to be 500, 1000, or 1500 bits. Because the packet size varies, the interleaver indices are provided to the turbo encoder and decoder as an input argument of their associated System object. Compare turbo coded bit error rate results to uncoded bit error rate results.

Initialize Simulation

Set the modulation order and range of E_b/N_0 values. Compute the number of bits per symbol and the energy per symbol to noise ratio (E_s/N_0) based on the modulation order and E_b/N_0 . To get repeatable results, seed the random number.

```

modOrder = 16;           % Modulation order
bps = log2(modOrder);    % Bits per symbol
EbNo = (2:0.5:4);       % Energy per bit to noise power spectral density ratio in dB
EsNo = EbNo + 10*log10(bps); % Energy per symbol to noise power spectral density ratio in dB
rng(1963);

```

Create a turbo encoder and decoder pair. Because the packet length varies for each frame, specify that the interleaver indices be supplied by an input argument of the System object when executed. Specify that the decoder perform four iterations.

```

turboEnc = comm.TurboEncoder('InterleaverIndicesSource','Input port');
turboDec = comm.TurboDecoder('InterleaverIndicesSource','Input port','NumIterations',4);
trellis = poly2trellis(4,[13 15 17],13);
n = log2(turboEnc.TrellisStructure.numOutputSymbols);
numTails = log2(turboEnc.TrellisStructure.numStates)*n;

```

Create an error rate object.

```
errRate = comm.ErrorRate;
```

Main Processing Loop

The frame processing loop performs these steps.

- 1 Select a random packet length, and generate random binary data.

- 2 Compute the output codeword length and coding rate.
- 3 Compute the signal to noise ratio (SNR) and noise variance.
- 4 Generate interleaver indices.
- 5 Turbo encode the data.
- 6 Apply 16-QAM modulation, and normalize the average signal power.
- 7 Pass the modulated signal through an AWGN channel.
- 8 Demodulate the noisy signal by using an LLR method, output soft bits, and normalize the average signal power.
- 9 Turbo decode the data. Because the bit mapping order from the demodulator is opposite the mapping order expected by the turbo decoder, the decoder input must use the inverse of the demodulated signal.
- 10 Calculate the error statistics.

```

ber = zeros(1,length(EbNo));
for k = 1:length(EbNo)
    % numFrames = 100;
    errorStats = zeros(1,3);
    %for pktIdx = 1:numFrames
    L = 500*randi([1 3],1,1);           % Packet length in bits
    M = L*(2*n - 1) + 2*numTails;     % Output codeword packet length
    rate = L/M;                       % Coding rate for current packet
    snrdB = EsNo(k) + 10*log10(rate); % Signal to noise ratio in dB
    noiseVar = 1./(10.^(snrdB/10));   % Noise variance

    while errorStats(2) < 100 && errorStats(3) < 1e7
        data = randi([0 1],L,1);
        intrlvrIndices = randperm(L);
        encodedData = turboEnc(data,intrlvrIndices);
        modSignal = qammod(encodedData,modOrder, ...
            'InputType','bit','UnitAveragePower',true);
        rxSignal = awgn(modSignal,snrdB);
        demodSignal = qamdmod(rxSignal,modOrder,'OutputType','llr', ...
            'UnitAveragePower',true,'NoiseVariance',noiseVar);
        rxBits = turboDec(-demodSignal,intrlvrIndices); % Demodulated signal is negated
        errorStats = errRate(data,rxBits);
    end
    % Save the BER data and reset the bit error rate object
    ber(k) = errorStats(1);
    reset(errRate)
end

```

Plot Results

Plot the bit error rate and compare it to the uncoded bit error rate.

```

semilogy(EbNo,ber,'-o')
grid
xlabel('Eb/No (dB)')
ylabel('Bit Error Rate')
uncodedBER = berawgn(EbNo,'qam',modOrder); % Estimate of uncoded BER
hold on
semilogy(EbNo,uncodedBER)
legend('Turbo','Uncoded','location','sw')

```

More About

Parallel Concatenated Convolutional Encoding Scheme

The turbo encoder uses a parallel concatenated convolutional encoding scheme to encode a binary input signal. The coding scheme uses two constituent encoders and one internal interleaver as shown in this figure. Each constituent encoder is terminated independently by tail bits.

The `OutputIndicesSource` property specifies the source for the output indices used for symbol puncturing and repetition.

- When you set the `OutputIndicesSource` property to 'Auto', the object computes the output indices. In this case, the constituent encoders have a rate $1/N$ code, and the number of bits output from the turbo encoder is $L \times (2 \times N - 1) + (2 \times \text{numTails})$. L is the input vector length, and numTails is given by $\log_2(\text{TrellisStructure.numStates}) \times N$. The tail bits due to the termination are appended at the end after the encoded input bits.

The coding scheme uses two identical constituent encoders and one internal interleaver. Each constituent encoder is terminated independently by tail bits. The output of the turbo encoder consists of the systematic (X) and parity (Z) bit streams of the first encoder and only the parity (Z') bit streams of the second encoder. Tail bits are appended at the end for all streams.

- When you set the `OutputIndicesSource` property to 'Input port' or 'Property', you specify the output indices with the `outindices` input argument or the `OutputIndices` property, respectively. In this case, the object runs using the output indices you specify. The output indices are specified relative to the fully encoded output for all streams.

The output of the turbo encoder consists of the systematic (X and X') and parity (Z and Z') bit streams of first and second constituent encoders. The number of bits output equals the vector length of the output indices you provide.

For more information, see “Coding Rate” on page 3-1378 and “Tail bits” on page 3-1379.

Coding Rate

In general, the coding rate of a constituent convolutional code is represented as a rate K/N code. K is the number of input bit streams. N is the number of output bit streams.

Note K must be 1 to use the `comm.TurboEncoder` and `comm.TurboDecoder` System objects. Alternatively, the “High Rate Convolutional Codes for Turbo Coding” example performs turbo coding for K greater than 1 by using the `comm.ConvolutionalEncoder` and `comm.APPDecoder` System objects.

The encoder accepts an L -element column vector input signal and returns an M -element column vector output signal. The effective code rate of the turbo encoder is L / M . L is the length of the binary input message, and M is the number of bits output in the parallel concatenated codeword.

- When you set the `OutputIndicesSource` property to 'Auto', systematic bits from the second encoder (X , shown in the figure found in “Parallel Concatenated Convolutional Encoding Scheme” on page 3-1377) are not output to the parallel concatenated codeword. For a given trellis, M and L are related by $M = L \times (2 \times N - 1) + 2 \times numTails$, where $numTails$ is the number of tail bits. For more information, see “Tail bits” on page 3-1379.
- When you set the `OutputIndicesSource` property to 'Input port' or 'Property', M equals the length of the output indices vector specified by the `outindices` input argument or the `OutputIndices` property, respectively.

Tail bits

The turbo encoder treats each input independently. For each input message, extra bits are used to set the encoder states to an all-zeros state. Each constituent encoder is terminated independently by tail bits. The turbo encoder output consists of the interlaced systematic and parity streams, with the tail bits multiplexed to the end of the encoded data streams.

The number of tail bits, $numTails$, output by each constituent encoder depends on values in the trellis structure used by each coder.

- $numTails = \log_2(\text{trellis.numStates}) \times N$
- $N = \log_2(\text{trellis.numOutputSymbols})$. For a rate 1 / 2 trellis, $N = 2$.

For more information about trellis structures, see `poly2trellis`. For more information about the constituent encoders, see “Parallel Concatenated Convolutional Encoding Scheme” on page 3-1377.

comm.ViterbiDecoder

Package: comm

Decode convolutionally encoded data using Viterbi algorithm

Description

The `comm.ViterbiDecoder` System object decodes convolutionally encoded input symbols to produce binary output symbols by using the Viterbi algorithm.

To decode convolutionally encoded data using the Viterbi algorithm:

- 1 Create the `comm.ViterbiDecoder` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

Creation

Syntax

```
viterbidecoder = comm.ViterbiDecoder
viterbidecoder = comm.ViterbiDecoder(trellis)
viterbidecoder = comm.ViterbiDecoder( ___,Name,Value)
```

Description

`viterbidecoder = comm.ViterbiDecoder` creates a Viterbi decoder System object. This object uses the Viterbi algorithm to decode convolutionally encoded input data.

`viterbidecoder = comm.ViterbiDecoder(trellis)` sets the `TrellisStructure` property set to `trellis`.

`viterbidecoder = comm.ViterbiDecoder(___,Name,Value)` sets “Properties” on page 3-1381 using one or more name-value arguments in addition to any argument combinations in previous syntaxes. For example, `'TerminationMethod','Continuous'` specifies the termination method as continuous to save the internal state metric at the end of each frame for use with the next frame.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see [System Design in MATLAB Using System Objects](#).

TrellisStructure — Trellis structure of convolutional code`poly2trellis(7, [171 133]) (default) | structure`

Trellis description of the convolutional code, specified as a structure that contains the trellis description for a rate K/N code. K is the number of input bit streams, and N is the number of output bit streams.

You can either use the `poly2trellis` function to create the trellis structure or create it manually. For more about this structure, see “Trellis Description of a Convolutional Code” and the `istrellis` function.

The trellis structure contains these fields.

numInputSymbols — Number of symbols input to encoder 2^K

Number of symbols input to the encoder, specified as an integer equal to 2^K , where K is the number of input bit streams.

Data Types: `double`

numOutputSymbols — Number of symbols output from encoder 2^N

Number of symbols output from the encoder, specified as an integer equal to 2^N , where N is the number of output bit streams.

Data Types: `double`

numStates — Number of states in encoder

power of 2

Number of states in the encoder, specified as a power of 2.

Data Types: `double`

nextStates — Next states

matrix of integers

Next states for all combinations of current states and current inputs, specified as a matrix of integers. The matrix size must be `numStates-by-2K`.

Data Types: `double`

outputs — Outputs

matrix of octal numbers

Outputs for all combinations of current states and current inputs, specified as a matrix of octal numbers. The matrix size must be `numStates-by-2K`.

Data Types: `double`

Data Types: `struct`

InputFormat — Input format to decoder`'Unquantized' (default) | 'Hard' | 'Soft'`

Input format to the decoder, specified as `'Unquantized'`, `'Hard'`, or `'Soft'`.

- 'Unquantized' — The input data must be a real-valued vector of double- or single-precision soft values that are unquantized. The object maps positive values to logical 1s and negative values to logical 0s
- 'Hard' — The input must be a vector of hard decision values, which are 0s or 1s. The data type of the inputs must be double precision, single precision, logical, or numeric.
- 'Soft' — The input requires a vector of quantized soft values that are represented as integers between 0 and $2^{\text{SoftInputWordLength}} - 1$. The data type of the inputs must be double precision, single precision, logical, or numeric. Alternatively, you can specify the data type as an unsigned and unscaled fixed-point object using the (fi) with a word length equal to the word length that you specify for the `SoftInputWordLength` property. 0 is considered as most confident 0 and $2^{\text{SoftInputWordLength}} - 1$ as the most confident 1.

Data Types: char | string

SoftInputWordLength — Soft input word length

4 (default) | integer

Soft input word length that represents the number of bits for each quantized soft input value, specified as an integer.

Dependencies

To enable this property, set the `InputFormat` property to 'Soft'.

Data Types: double

InvalidQuantizedInputAction — Option to take action for invalid quantized input

'Ignore' (default) | 'Error'

Option to take action for invalid quantized input (that is, when input values are out of range), specified as 'Ignore' or 'Error'. Set this property to 'Error' so that the object generates an error when the quantized input values are out of range.

Dependencies

To enable this property, set the `InputFormat` property to 'Soft' or 'Hard'.

Data Types: char | string

TracebackDepth — Traceback depth

34 (default) | integer

Traceback depth, specified as an integer. The traceback depth influences the decoding accuracy and delay. The number of zero symbols that precede the first decoded symbol in the output represent a decoding delay. For more information, see “Traceback and Decoding Delay” on page 3-1389 and “Traceback Depth Estimates” on page 3-1389.

When you set the `TerminationMethod` property to 'Continuous', the decoding delay consists of $\text{TracebackDepth} \times K$ zero bits for a rate K/N convolutional code. K is the number of input symbols, and N is the number of output symbols.

When you set the `TerminationMethod` property to 'Truncated' or 'Terminated', no output delay is present.

Data Types: double

TerminationMethod — Termination method of encoded frame`'Continuous'` (default) | `'Truncated'` | `'Terminated'`

Termination method of the encoded frame, specified as one of these values.

- `'Continuous'` — The System object saves the internal state metric at the end of each frame for use with the next frame. The object treats each traceback path independently.
- `'Truncated'` — The System object treats each frame independently. The traceback path starts at the state with the best metric and ends in the all-zeros state.
- `'Terminated'` — The System object treats each frame independently. The traceback path always starts and ends in the all-zeros state.

Data Types: `char` | `string`

ResetInputPort — Option to enable decoder reset input`false` or `0` (default) | `true` or `1`

Option to enable the decoder reset input, specified as a logical `1`(`true`) or `0` (`false`). Set this property to `1` (`true`) to the object. When this additional reset input is a nonzero value, the internal states of the decoder reset to their initial conditions.

Dependencies

To enable this property, set the `TerminationMethod` property to `'Continuous'`.

Data Types: `logical`

DelayedResetAction — Option to delay output reset`false` or `0` (default) | `true` or `1`

Option to delay the output reset, specified as one of these logical values.

- `1` (`true`) — The reset of the internal states of the decoder occurs after the object computes the decoded data.
- `0` (`false`) — The reset of the internal states of the decoder occurs before the object computes the decoded data.

Dependencies

To enable this property, set the `ResetInputPort` property to `true`.

Data Types: `logical`

PuncturePatternSource — Source of puncture pattern`'None'` (default) | `'Property'`

Source of the puncture pattern, specified as one of these values.

- `'None'` — The object does not apply puncturing.
- `'Property'` — The object decodes the punctured codewords based on a puncture pattern vector that you specify in the `PuncturePattern` property.

Data Types: `char` | `string`

PuncturePattern — Puncture pattern vector`[1;1;0;1;0;1]` (default) | column vector

Puncture pattern vector to puncture the decoded data, specified as a column vector. The vector must contain 1s and 0s, where 0 indicates the position of the punctured bits. This puncture pattern must match the puncture pattern used by the convolutional encoder.

Dependencies

To enable this property, set the `PuncturePatternSource` property to 'Property'.

Data Types: `double`

ErasuresInputPort — Option to enable the specification of erasures in the input symbols

`false` or 0 (default) | `true` or 1

Option to enable the specification of erasures in the input symbols, specified as one of these numeric or logical values.

- 1 (`true`) — When you call the System object, it specifies a vector of erasures when calling it. This vector indicates which symbols of the input codewords to erase. Values of 1 indicate erased bits. The decoder does not update the branch metric for the erasures in the incoming data stream. The erasures input must be a double precision or logical column vector. The length of the erasure vector must equal the length of the input data.
- 0 (`false`) — The System object assumes no erasures.

Data Types: `logical`

OutputDataType — Data type of output

`full precision` (default) | `integer` | `binary value` | `smallest unsigned integer`

Data type of the output, specified as a full precision, integer, binary value, or smallest unsigned integer.

When the input signal is an integer data type, you must have a Fixed-Point Designer user license to use this property in `Smallest unsigned integer` or `Full precision` mode.

Data Types: `char`

StateMetricDataType — Data type of state metric

'`Full precision`' (default) | '`Custom`'

Data type of the state metric, specified as '`Full precision`' or '`Custom`'

When you set this property to '`Full precision`', the object sets the state metric fixed-point type to `numericType([],16)`.

- When you set the `InputFormat` property to '`Hard`', the input data must be a column vector. This vector comprises unsigned, fixed-point numbers (`fi` objects) of word length 1 to enable fixed-point Viterbi decoding. Based on this input (either a 0 or 1), the object calculates the internal branch metrics using an unsigned integer of word length L . In this case, L is the number of output bits as specified by the trellis structure.
- When you set the `InputFormat` property to '`Soft`', the input data must be a column vector. This vector comprises unsigned, fixed point numbers (`fi` objects) of word length N . In this case, N is the number of soft-decision bits specified by the `SoftInputWordLength` property.

When you call the System object, the data inputs must be integers in the range from 0 to 2^N-1 . The object calculates the internal branch metrics using an unsigned integer of word length $L = (N + N_{out} - 1)$. In this case, N_{out} is the number of output bits as specified by the trellis structure.

Dependencies

To enable this property, set the `InputFormat` property to 'Hard' or 'Soft'.

Data Types: `char`

CustomStateMetricDataType — Fixed-point data type of state metric

`numerictype([],16)` (default) | `unscaled numerictype` (Fixed-Point Designer) object

Fixed-point data type of the state metric, specified as an `unscaled numerictype` (Fixed-Point Designer) object with a signedness of `Auto`.

Dependencies

To enable this property, set the `StateMetricDataType` property to 'Custom'.

Data Types: `numeric`

Usage**Syntax**

```
decmsg = viterbidecoder(codeword)
decmsg = viterbidecoder(codeword,erasures)
decmsg = viterbidecoder(codeword,resetstate)
```

Description

`decmsg = viterbidecoder(codeword)` decodes the convolutionally encoded input data, `codeword`, by using the Viterbi algorithm. `decmsg` is the decoded data.

`decmsg = viterbidecoder(codeword,erasures)` specifies symbols of the input codewords for the object to erase. To enable this syntax, set the `ErasuresInputPort` property to `1` (`true`).

`decmsg = viterbidecoder(codeword,resetstate)` specifies the input to reset the internal states of the decoder. To enable this syntax, set the `TerminationMethod` property to 'Continuous' and the `ResetInputPort` property to `1` (`true`).

Input Arguments**codeword — Convolutionally encoded message**

numeric-valued column vector

Convolutionally encoded message, specified as a numeric-valued column vector. The data type and element value in `codeword` depend on how you set the `InputFormat` property.

If the convolutional code uses an alphabet of 2^N possible output symbols, the length of this input vector must be $L \times N$ for some positive integer L .

Data Types: `double`

erasures — Erasure symbols in codeword

binary-valued vector

Erasure symbols in the codeword, specified as a binary-valued vector. The elements in `erasures` must be of data type `double` or `logical`. Values of `1` in the `erasures` vector correspond to erased

symbols, and values of 0 correspond to nonerased symbols. The length of the codeword must equal the length of erasures.

Dependencies

To enable this argument, set the `ErasuresInputPort` property to 1 (`true`).

resetstate — Reset for internal states of decoder

false or 0 (default) | true or 1

Reset for internal states of the decoder, specified as a numeric or logical 1 (`true`) or 0 (`false`).

Dependencies

To enable this argument, set the `TerminationMethod` property to 'Continuous' and the `ResetInputPort` property to `true`.

Data Types: double | logical

Output Arguments

decmsg — Decoded message

binary-valued column vector

Decoded message, returned as a binary-valued column vector. This output vector has the same data type as the `OutputDataType` property.

If the decoded data uses an alphabet of 2^K possible output symbols, the length of this output vector is $L \times K$.

Object Functions

To use an object function, specify the `System` object as the first input argument. For example, to release system resources of a `System` object named `obj`, use this syntax:

```
release(obj)
```

Common to All System Objects

<code>step</code>	Run <code>System</code> object algorithm
<code>release</code>	Release resources and allow changes to <code>System</code> object property values and input characteristics
<code>reset</code>	Reset internal states of <code>System</code> object

Examples

Encode and Decode 8-DPSK Modulated Data

Transmit a convolutionally encoded 8 differential phase shift keying (DPSK) modulated bit stream through an additive white Gaussian noise (AWGN) channel. Then, demodulate and decode the modulated bit stream using a Viterbi decoder.

Create the necessary `System` objects.

```
conEnc = comm.ConvolutionalEncoder;
modDPSK = comm.DPSKModulator('BitInput',true);
```

```
chan = comm.AWGNChannel('NoiseMethod','Signal to noise ratio (SNR)','SNR',10);
demodDPSK = comm.DPSKDemodulator('BitOutput',true);
vDec = comm.ViterbiDecoder('InputFormat','Hard');
error = comm.ErrorRate('ComputationDelay',3,'ReceiveDelay',34);
```

Process the data by following these steps.

- 1 Generate random bits.
- 2 Convolutionally encode the data.
- 3 Apply DPSK modulation.
- 4 Pass the modulated signal through an AWGN channel.
- 5 Demodulate the noisy signal.
- 6 Decode the data using a Viterbi algorithm.
- 7 Collect error statistics.

```
for counter = 1:20
    data = randi([0 1],30,1);
    encodedData = conEnc(data);
    modSignal = modDPSK(encodedData);
    receivedSignal = chan(modSignal);
    demodSignal = demodDPSK(receivedSignal);
    receivedBits = vDec(demodSignal);
    errors = error(data,receivedBits);
end
```

Display the number of errors.

```
errors(2)
ans = 3
```

Convolutionally Encode and Viterbi Decode with Puncture Pattern Matrix

Encode and decode a sequence of bits using a convolutional encoder and a Viterbi decoder with a defined puncture pattern. Verify that the input and output bits are identical.

Define a puncture pattern matrix, and then reshape it into vector form for use with the encoder and decoder System objects.

```
pPatternMat = [1 0 1;1 1 0];
pPatternVec = reshape(pPatternMat,6,1);
```

Create a convolutional encoder and a Viterbi decoder in which the puncture pattern is defined by pPatternVec.

```
conEnc = comm.ConvolutionalEncoder('PuncturePatternSource','Property','PuncturePattern',pPatternMat);
viDec = comm.ViterbiDecoder('InputFormat','Hard','PuncturePatternSource','Property',...
    'PuncturePattern',pPatternVec);
```

Create an error rate counter with the appropriate receive delay.

```
error = comm.ErrorRate('ReceiveDelay',viDec.TracebackDepth);
```

Encode a sequence of random bits, and then decode the encoded message.

```
dataIn = randi([0 1],600,1);
dataEncoded = conEnc(dataIn);
dataOut = viDec(dataEncoded);
```

Verify that no errors exist in the output data.

```
errStats = error(dataIn,dataOut);
errStats(2)

ans = 0
```

More About

Traceback and Decoding Delay

The traceback depth influences the decoding delay. The decoding delay is the number of zero symbols that precede the first decoded symbol in the output.

- For the continuous operating mode, the decoding delay is equal to the number of traceback depth symbols.
- For the truncated or terminated operating mode, the decoding delay is zero. In this case, the traceback depth must be less than or equal to the number of symbols in each input.

Traceback Depth Estimates

As a general estimate, a typical traceback depth value is approximately two to three times $(ConstraintLength - 1) / (1 - coderate)$. The constraint length of the code, $ConstraintLength$, is equal to $(\log_2(trellis.numStates) + 1)$. The $coderate$ is equal to $(K / N) \times (\text{length}(PuncturePattern) / \text{sum}(PuncturePattern))$.

K is the number of input symbols, N is the number of output symbols, and $PuncturePattern$ is the puncture pattern vector.

For example, applying this general estimate, results in these approximate traceback depths.

- A rate 1/2 code has a traceback depth of $5(ConstraintLength - 1)$.
- A rate 2/3 code has a traceback depth of $7.5(ConstraintLength - 1)$.
- A rate 3/4 code has a traceback depth of $10(ConstraintLength - 1)$.
- A rate 5/6 code has a traceback depth of $15(ConstraintLength - 1)$.

comm.WalshCode

Package: comm

Generate bipolar Walsh code

Description

The `comm.WalshCode` System object generates a bipolar Walsh code from an orthogonal set of codes.

To generate a Walsh code:

- 1 Create the `comm.WalshCode` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

Creation

Syntax

```
walshCode = comm.WalshCode  
walshCode = comm.WalshCode(Name=Value)
```

Description

`walshCode = comm.WalshCode` creates a Walsh code generator System object. This object generates a Walsh code from a set of orthogonal codes.

`walshCode = comm.WalshCode(Name=Value)` sets properties using one or more name-value arguments. For example, `Length=11` specifies a Walsh code of length 11.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see [System Design in MATLAB Using System Objects](#).

Length — Length of generated code

64 (default) | power-of-two integer

Length of generated code, specified as a power-of-two integer.

Data Types: `double`

Index — Index of desired code

60 (default) | integer in the range [0, $N-1$]

Index of desired code, from the available set of codes, specified as an integer in the range [0, $N-1$]. N is the value of the Length property.

The number of zero crossings in the generated code equals the value of the specified index.

Data Types: double

SamplesPerFrame — Samples per output frame

1 (default) | positive integer

Samples per output frame, specified as a positive integer. If you set this property to M , the object outputs a frame containing M samples using the Walsh code specified by the Index property. The object repeats the Walsh code sequence, as needed, to reach M samples. For more information, see “Algorithms” on page 3-1394 section.

Data Types: double

OutputDataType — Output data type

double (default) | int8

Output data type, specified as double or int8.

Usage**Syntax**

```
y = walshCode
```

Description

`y = walshCode` outputs a bipolar Walsh code frame as a column vector. If the frame length exceeds the Walsh code length, the object fills the frame by repeating the Walsh code. For more information, see the “Algorithms” on page 3-1394 section.

Output Arguments**y — Walsh code**

column vector

Walsh code, returned as a column vector.

The code is in a bipolar format with 0 and 1 mapped to 1 and -1. Set the data type of the output with the OutputDataType property.

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Common to All System Objects

step Run System object algorithm
 release Release resources and allow changes to System object property values and input characteristics
 reset Reset internal states of System object

Examples

Generate Walsh Code Sequence

Generate a Walsh code of length 128. Specify the sequence with 16 samples per frame.

```
walsh = comm.WalshCode;
walsh.Length = 128;
walsh.SamplesPerFrame = 16;
disp(walsh)
```

comm.WalshCode with properties:

```
        Length: 128
          Index: 60
SamplesPerFrame: 16
  OutputDataType: 'double'
```

Display the bipolar Walsh code.

```
seq = walsh()
```

```
seq = 16×1
```

```

  1
  :
```

Walsh Code Sequence at Desired Index

Generate a Walsh code of length 256. Set the index of the desired code to 64 and the code sequence to 4 samples per frame.

```
walsh = comm.WalshCode;
walsh.Length = 256;
walsh.Index = 64;
walsh.SamplesPerFrame = 4;
disp(walsh)
```

`comm.WalshCode` with properties:

```
Length: 256
Index: 64
SamplesPerFrame: 4
OutputDataType: 'double'
```

Display the bipolar Walsh code.

```
seq = walsh()
```

```
seq = 4×1
```

```
1
1
-1
-1
```

Algorithms

Walsh codes are defined as a set of N codes, denoted W_j , for $j = 0, 1, \dots, N - 1$, which have the following properties:

- W_j takes on the values +1 and -1.
- $W_j[0] = 1$ for all j .
- W_j has exactly j zero crossings, for $j = 0, 1, \dots, N - 1$.
- $W_j W_k^T = \begin{cases} 0 & j \neq k \\ N & j = k \end{cases}$
- Each code W_j is either even or odd with respect to its midpoint.

Walsh codes are defined using a Hadamard matrix of order N , where N is a nonnegative power of 2 that you specify in the `Length` property. The `comm.WalshCode` System object outputs a row of the Hadamard matrix. Use the `Index` property to choose the row of the Hadamard matrix. If you set the `Index` property equal to an integer j , the output code has exactly j zero crossings, for $j = 0, 1, \dots, N - 1$.

Note, however, that the indexing in Walsh code is different from the indexing in Hadamard code.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

Walsh Code Generator

Introduced in R2012a

comm.WINNER2Channel

Package: comm

Filter input signal through WINNER II fading channel

Note Download Required: To use , first download the WINNER II Channel Model for Communications Toolbox add-on.

Description

The `comm.WINNER2Channel` System object filters an input signal through a WINNER II fading channel. The object utilizes the basic model defined and provided by the WINNER II Channel Models [1].

To filter an input signal through a WINNER II fading channel:

- 1 Create the `comm.WINNER2Channel` object and set its properties.
- 2 Call the object with arguments, as if it were a function.

To learn more about how System objects work, see [What Are System Objects?](#)

Creation

Syntax

```
winchannel = comm.WINNER2Channel  
winchannel = comm.WINNER2Channel(Name,Value)  
winchannel = comm.WINNER2Channel(cfgModel)  
winchannel = comm.WINNER2Channel(cfgModel,cfgLayout)
```

Description

`winchannel = comm.WINNER2Channel` creates a WINNER II fading channel System object to model single or multiple links. `winchannel` generates channel coefficients using the WINNER II spatial channel model (SCM). It also filters a real or complex input signal through the fading channel for each link.

`winchannel = comm.WINNER2Channel(Name,Value)` specifies properties using one or more name-value arguments. For example, `'NormalizeChannelOutputs','false'` specifies to not normalize the channel outputs.

`winchannel = comm.WINNER2Channel(cfgModel)` sets the `ModelConfig` property to `cfgModel`.

`winchannel = comm.WINNER2Channel(cfgModel,cfgLayout)` set the `LayoutConfig` property to `cfgLayout`.

Properties

Unless otherwise indicated, properties are *nontunable*, which means you cannot change their values after calling the object. Objects lock when you call them, and the `release` function unlocks them.

If a property is *tunable*, you can change its value at any time.

For more information on changing property values, see System Design in MATLAB Using System Objects.

ModelConfig — WINNER II model parameter configuration

`winner2.wimparset` (default) | structure

WINNER II model parameter configuration, specified as a structure. You can either use the `winner2.wimparset` function to create the default model configuration structure or create it manually. The Winner II channel model parameter configuration contains these fields.

NumTimeSamples — Number of time samples

100 (default) | scalar

Number of time samples, specified as a scalar.

Note If the number of samples in the input signal (N_S) does not match `NumTimeSamples`, then update `NumTimeSamples` to match N_S .

Data Types: `double`

FixedPdpUsed — Option to use predefined path delays and powers for specific scenarios

'no' (default) | 'yes'

Option to use predefined path delays and powers for specific scenarios, specified as 'no' or 'yes'.

FixedAnglesUsed — Option to use predefined path AoDs and AoAs for specific scenarios

'no' (default) | 'yes'

Option to use predefined path angles of departure (AoDs) and angles of arrival (AoAs) for specific scenarios, specified as 'no' or 'yes'.

IntraClusterDsUsed — Option to divide each of the two strongest clusters into three subclusters per link

'yes' (default) | 'no'

Option to divide each of the two strongest clusters into three subclusters per link, specified as 'yes' or 'no'.

PolarisedArrays — Option to use dual-polarized arrays

'yes' (default) | 'no'

Option to use dual-polarized arrays, specified as 'yes' or 'no'.

UseManualPropCondition — Option to use manually defined propagation conditions

'yes' (default) | 'no'

Option to use manually defined propagation conditions, specified as 'yes' or 'no'. Set this field to 'yes' to enforce the use of manually defined propagation conditions (LOS or NLOS) of the PropagConditionVector field. Set this field to 'no' to draw propagation conditions from predefined LOS probabilities.

CenterFrequency — Carrier frequency

5.25e9 (default) | scalar

Carrier frequency in Hz, specified as a scalar.

Data Types: double

UniformTimeSampling — Option to enforce uniform time sampling

'no' (default) | 'yes'

Option to enforce uniform time sampling, specified as 'no' or 'yes'.

SampleDensity — Number of time samples per half wavelength

2e6 (default) | scalar

Number of time samples per half wavelength, specified as a scalar.

Data Types: double

DelaySamplingInterval — Sampling interval

5e-9 (default) | scalar

Sampling interval, specified as a scalar indicating the input signal sample time in seconds. DelaySamplingInterval defines the sampling grid to which the path delays are rounded.

- A value of 0 seconds indicates no rounding on path delays. When performing channel filtering, the object sets DelaySamplingInterval to 0 to obtain the original path delays.
- Ignore any nonzero value of DelaySamplingInterval. Specifically, the path delays values that are not rounded to be multiples of the DelaySamplingInterval values and are nonzero.

Data Types: double

ShadowingModelUsed — Option to use shadow fading

'no' (default) | 'yes'

Option to use shadow fading, specified as 'no' or 'yes'.

PathLossModelUsed — Option to use path loss model

'no' (default) | 'yes'

Option to use path loss model, specified as 'no' or 'yes'.

PathLossModel — Path loss model

'pathloss' (default) | character vector

Path loss model, specified as a character vector representing a valid function name. Path loss model uses the internal pathloss function from the "WINNER II Channel" add-on to model the path loss.

Dependencies

To enable this property, set the PathLossModelUsed field to 'yes'.

Data Types: char

PathLossOption — Wall material

'CR_light' (default) | 'CR_heavy' | 'RR_light' | 'RR_heavy'

Wall material, specified as 'CR_light', 'CR_heavy', 'RR_light', or 'RR_heavy'. This field indicates the wall material for the A1 scenario NLOS path loss calculation.

Dependencies

To enable this property, set the PathLossModelUsed field to 'yes'.

Data Types: char

RandomSeed — Seed for random number generators

[] (default) | scalar

Seed for random number generators, specified as a scalar or empty brackets. Empty brackets, [], indicate the use of global random stream.

Data Types: double

Data Types: struct

LayoutConfig — WINNER II layout parameter configuration

winner2.layoutparset (default) | structure

WINNER II layout parameter configuration, specified as a structure. You can either use the winner2.layoutparset function to create the default layout configuration structure or create it manually. The Winner II channel layout parameter configuration contains these fields.

Stations — Active stations

row vector of structures (default)

Active stations, specified as a row vector of structures describing the antenna arrays for active stations. Stations is created from the arrays input. The row ordering specifies base station (BS) sectors first, followed by mobile stations (MS). The assignment of BS sector and MS positions is random. The BS sectors have no velocity. Each MS has a velocity of about 1.42 m/s with a randomly assigned direction.

Data Types: struct

NofSect — Number of sectors

vector (default)

Number of sectors, specified as a vector indicating the number of sectors in each BS.

Data Types: double

Pairing — BS to MS pairing

2-by- N_L matrix (default)

BS to MS pairing, specified as a 2-by- N_L matrix, where N_L specifies the number of links to be modeled. For BS and MS row ordering, see the Stations field.

Data Types: double

ScenarioVector — Spatial scenario1 (default) | 1-by- N_L vector | scalar

Spatial scenario, specified as a 1-by- N_L vector of scenario numbers. The default is 1, which specifies scenario A1.

The scenario numbers map as {1=A1, 2=A2, 3=B1, 4=B2, 5=B3, 6=B4, 10=C1, 11=C2, 12=C3, 13=C4, 14=D1, 15=D2a}.

For more information, see Section 2.3 of WINNER II Channel Models [1].

PropagConditionVector — Propagation conditions1 (default) | 1-by- N_L vector | scalar

Propagation conditions, specified as a 1-by- N_L vector. For each link, specify LOS as 1 and NLOS as 0.

Data Types: double

StreetWidth — Street width20 (default) | 1-by- N_L vector | scalar

Street width, specified as a 1-by- N_L vector of identical values that specify the average width (in meters) of the streets. Use `StreetWidth` for the path loss model of the B1 and B2 scenarios. For the scenario number mapping, see the `ScenarioVector` field.

Dependencies

To enable this property, set the `PathLossModelUsed` field to 'yes'.

Data Types: double

Dist1 — Distances from BS to last LOS pointNaN (default) | 1-by- N_L vector

Distances from the BS to the last LOS point, specified as a 1-by- N_L vector. Use the `Dist1` field for the path loss model of the B1 and B2 scenarios. The default value of NaN indicates that the distance is randomly determined in the path loss function. For the scenario number mapping, see the `ScenarioVector` field.

For more information, see Figure 4-3 of WINNER II Channel Models [1].

Dependencies

To enable this property, set the `PathLossModelUsed` field to 'yes'.

Data Types: double

NumFloors — Floor numbers1 (default) | 1-by- N_L vector | scalar

Floor numbers where the indoor BS or MS is located, specified as a 1-by- N_L vector. Use the `NumFloors` field for the path loss model of the A2 and B4 scenarios only. For the scenario number mapping, see the `ScenarioVector` field.

Dependencies

To enable this property, set the `PathLossModelUsed` field to 'yes'.

Data Types: double

NumPenetratedFloors — Number of floors penetrated

0 (default) | 1-by- N_L vector | scalar

Number of floors penetrated between the BS and the MS, specified as a 1-by- N_L vector. Use the `NumPenetratedFloors` field for the NLOS path loss model of the A1 scenario. For the scenario number mapping, see the `ScenarioVector` field.

For more information, see Table 4-4 of WINNER II Channel Models [1].

Dependencies

To enable this property, set the `PathLossModelUsed` field to 'yes'.

Data Types: double

Data Types: struct

NormalizeChannelOutputs — Option to normalize channel outputs

'true' (default) | 'false'

Option to normalize channel outputs, specified as 'true' or 'false'. Set this property to 'true' to normalize the channel outputs by the number of receive antennas at the MS for each link.

For more information, see “Channel Power” on page 3-1405.

Data Types: char | string

Usage

Syntax

```
outsignal = winchannel(insignal)
[outsignal,pathgains] = winchannel(insignal)
```

Description

`outsignal = winchannel(insignal)` filters the input signal through a WINNER II fading channel and returns the resulting signal.

`[outsignal,pathgains] = winchannel(insignal)` also returns the channel path gains of the underlying fading process.

Input Arguments

insignal — Input signal

N_L -by-1 cell array | N_S -by- N_T matrix

Input signal, specified as an N_L -by-1 cell array or an N_S -by- N_T matrix. N_L is the number of links, as specified by the `LayoutConfig` property of the `winchannel` object. The i th element of the `insignal` argument must be an N_S -by- $N_T(i)$ matrix of data type `double`.

- N_S is the number of samples to be generated and must be the same value for all elements of the `insignal` argument.

- N_T is the number of transmit antennas at the BS for the i th link, as specified by the `LayoutConfig` property of the `winchannel` object.

Output Arguments

outsignal — Output signal

N_L -by-1 cell array (default)

Output signal, returned as an N_L -by-1 cell array. If the channel has only one link or if all links have the same number of transmit antennas, the `insignal` argument must be an N_S -by- N_T matrix, and the i th element of the `outsignal` argument is an N_S -by- $N_R(i)$ matrix. $N_R(i)$ is the number of receive antennas at the MS for the i th link, as specified by the `LayoutConfig` property of the `winchannel` object.

pathgains — Channel path gains

N_L -by-1 cell array (default)

Channel path gains, returned as an N_L -by-1 cell array.

The i th element of the `pathgains` argument is an $N_R(i)$ -by- $N_T(i)$ -by- $N_P(i)$ -by- N_S array of complex values of data type `double`. $N_P(i)$ is the number of paths for the i th link, as specified by the `LayoutConfig` property of the `winchannel` object.

N_R , N_T , and N_P are link-specific. N_S is the same for all of the links.

Object Functions

To use an object function, specify the System object as the first input argument. For example, to release system resources of a System object named `obj`, use this syntax:

```
release(obj)
```

Common to All System Objects

<code>step</code>	Run System object algorithm
<code>release</code>	Release resources and allow changes to System object property values and input characteristics
<code>reset</code>	Reset internal states of System object

Note When you use the `reset` object function, if the `ModelConfig.RandomSeed` property of object is empty, `reset` resets the filters only. Otherwise, `reset` resets the filters and reinitializes the random number stream to the value of the `ModelConfig.RandomSeed` field.

Examples

Simulate WINNER II Channel with Two Mobile Stations

Simulate a system that has two MSs connected to one BS. One MS is 8 meters away from the BS, and the other is 20 meters away from the BS. Send the impulse signals through the two links. The spectrum of the received signals at the MS shows frequency selectivity.

Specify a random number generator seed for repeatability.

```
rng(100);
```

Initialize the frame length and sample rate.

```
frmLen = 1024;
```

Configure the winner II channel layout parameters.

```
BSAA = winner2.AntennaArray('UCA',8,0.02); % UCA-8 antenna array for BS
MSAA1 = winner2.AntennaArray('ULA',2,0.01); % ULA-2 antenna array for MS
MSAA2 = winner2.AntennaArray('ULA',4,0.005); % ULA-4 antenna array for MS
MSIdx = [2 3];
BSIdx = {1};
NL = 2;
maxRange = 100;
rndSeed = 101;
cfgLayout = winner2.layoutparset(MSIdx,BSIdx,NL, ...
    [BSAA,MSAA1,MSAA2],maxRange,rndSeed);
```

Adjust BS and MS positions.

```
cfgLayout.Stations(1).Pos(1:2) = [10, 10];
cfgLayout.Stations(2).Pos(1:2) = [18, 10]; % 8 meters away from BS
cfgLayout.Stations(3).Pos(1:2) = [22, 26]; % 20 meters away from BS
```

Specify the NLOS for both links.

```
cfgLayout.Pairing = [1 1; 2 3];
cfgLayout.PropagConditionVector = [0 0];
```

Configure the winner II channel model parameters.

```
cfgModel = winner2.wimparset;
cfgModel.NumTimeSamples = frmLen; % Frame length
cfgModel.IntraClusterDsUsed = 'no'; % No cluster splitting
cfgModel.SampleDensity = 2e5; % For lower sample rate
cfgModel.PathLossModelUsed = 'yes'; % Turn on path loss
cfgModel.ShadowingModelUsed = 'yes'; % Turn on shadowing
```

Create a WINNER II fading channel System object.

```
winChannel = comm.WINNER2Channel(cfgModel,cfgLayout);
```

Get system information.

```
chanInfo = info(winChannel)
```

```
chanInfo = struct with fields:
    NumLinks: 2
    NumBSElements: [8 8]
    NumMSElements: [2 4]
    NumPaths: [16 16]
    SampleRate: [1.0000e+07 1.0000e+07]
    ChannelFilterDelay: [7 7]
    NumSamplesProcessed: 0
```

Get the number of transmitters and sample rate of the system.

```
numTx = chanInfo.NumBSElements(1);
Rs = chanInfo.SampleRate(1);
```

Create a spectrum analyzer System object.

```
SA = dsp.SpectrumAnalyzer('SampleRate',Rs, ...
    'YLimits',[-170, -100],'ShowLegend',true, ...
    'ChannelNames',{'MS 1 (8 meters away)','MS 2 (20 meters away)'});
```

Pass impulse signals through the two links and show the spectra of the received signals at the two MSs.

```
for i = 1:10
    x = [ones(1,numTx);
        zeros(frmLen-1,numTx)];
    y = winChannel(x);
    SA([y{1}(:,1),y{2}(:,1)]);
end
```

More About

WINNER II Sampling Rate

The signal sample rate (R_S) for generating channel coefficients and performing channel filtering is calculated per link using the mobile station speed (V_{MS}), half wavelength distance, and sample density. The sample rate for each link is available as a field in the output of the info object function.

$$R_S = V_{MS} / (C / F_{center} / 2 / N_{SD})$$

- For the MS speed: V_{MS} ,
 - When you set the `ModelConfig.UniformTimeSampling` field to 'no', V_{MS} is the speed of the MS for the corresponding link, derived from the `LayoutConfig.Stations(i).Velocity` field.
 - When you set the `ModelConfig.UniformTimeSampling` field to 'yes', V_{MS} is the maximum speed of the MS for all links.
- C is the speed of light (2.99792458e8 m/s).
- F_{center} is the `ModelConfig.CenterFrequency` field.
- N_{SD} is the `ModelConfig.SampleDensity` field.

Channel Power

These conditions apply to the channel power of the `comm.WINNER2Channel` System object:

- When path loss and shadowing are off, path gains are normalized. Specifically, path gains are normalized when you set the `ModelConfig.ShadowingModelUsed` and `ModelConfig.PathLossModelUsed` fields to 'no'.
- When you set the `NormalizeChannelOutputs` property to 'true', the average gain of the channel is 0 dB.

rxsite

Create RF receiver site

Description

Use the `rxsite` object to create a radio frequency receiver site.

A receiver consists of an RF circuit and an antenna, where the antenna intercepts radio waves and converts them to a current that is decoded by the RF circuit (e.g. demodulated) into a signal. Key characteristics of a receiver include its sensitivity and its antenna radiation pattern.

Creation

Syntax

```
rx = rxsite
rx = rxsite(coordsys)
rx = rxsite(Name,Value)
```

Description

`rx = rxsite` creates a radio frequency receiver site.

`rx = rxsite(coordsys)` creates a receiver site with coordinate system set to 'geographic' or 'cartesian'.

`rx = rxsite(Name,Value)` sets properties using one or more name-value pairs. For example, `rx = rxsite('Name','RX Site')` creates a receiver site with name `RX Site`. Enclose each property name in quotes.

Create a 1-by- N array of receiver sites by specifying a property value as an array of N columns. Other property values must be specified with either 1 or N columns. The `Name`, `Latitude`, and `Longitude` properties may be specified as either a row vector or column vector with N elements. The `CoordinateSystem` property must be a string scalar or a character vector.

Properties

Name — Site name

character vector | string | row or column vector

Site name, specified as a character vector or as a row or column vector or as a string.

Example: 'Name','Site 3'

Example: `rx.Name = 'Site 3'`

Example: If you want to assign multiple values then - `names = ["Fenway Park","Faneuil Hall","Bunker Hill Monument"]`; `rx = rxsite('Name',names)`

Data Types: char | string

CoordinateSystem — Coordinate system of site location

'geographic' (default) | 'cartesian'

Coordinate system of the site location, specified as 'geographic' or 'cartesian'. If this property is 'geographic', the site location is defined using the properties `Latitude`, `Longitude`, and `AntennaHeight`. If this property is 'cartesian', the site location is defined using `AntennaPosition`.

Example: 'CoordinateSystem','cartesian'

Example: `tx.CoordinateSystem = 'cartesian'`

Latitude — Site latitude coordinates

42.3021 (default) | numeric scalar | row or column vector

Site latitude coordinates, specified as a numeric scalar or a row or column vector in the range of range -90 to 90. Coordinates are defined using Earth ellipsoid model WGS-84. Latitude is the north/south angle.

Example: 'Latitude',45.098

Example: `rx.Latitude = 45.098`

Example: If you want to assign multiple values then - `latitude = [42.3467,42.3598,42.3763]; rx = rxsite('Latitude',latitude)`

Dependencies

To use this property, `CoordinateSystem` must be set to 'geographic'.

Longitude — Site longitude coordinates

-71.3764 (default) | numeric scalar | row or column vector

Site longitude coordinates, specified as a numeric scalar or a row or column vector. Coordinates are defined using Earth ellipsoid model WGS-84. Longitude is the east/west angle.

Example: 'Longitude',-68.890

Example: `rx.Longitude = -68.890`

Example: If you want to assign multiple values then - `longitude = [-71.0972,-71.0545,-71.0611]; rx = rxsite('Longitude',longitude)`

Dependencies

To use this property, `CoordinateSystem` must be set to 'geographic'.

Antenna — Antenna element or array

'isotropic' (default) | object | row vector

Antenna element or array specified as one of these:

- 'isotropic' to model an antenna that radiates uniformly in all directions.
- An `arrayConfig` object.
- If you have Antenna Toolbox™, an antenna element from the “Antenna Catalog” (Antenna Toolbox).

- If you have Phased Array System Toolbox™, any antenna object in “Antennas, Microphones, and Sonar Transducers” (Phased Array System Toolbox) or any array object in “Array Geometries and Analysis” (Phased Array System Toolbox).

Example: 'Antenna',cfgArray, where cfgArray is an arrayConfig object

Example: rx.Antenna = arrayConfig('Size',[8 1]); specifies an 8-element ULA along z-axis

AntennaAngle — Angle of antenna local X-axis

0 (default) | numeric scalar | 2-by-1 vector | 2-by-*N* matrix

Angle of antenna local Cartesian coordinate system X-axis, specified as a numeric scalar representing azimuth angle in degrees or a 2-by-1 vector representing both azimuth and elevation angles with each element unit in degrees.

The azimuth angle is measured counterclockwise to the antenna X-axis, either from the east (for geographical sites) or from the global X-axis around the global Z-axis (for Cartesian sites).

The elevation angle is measured from the horizontal plane or X-Y plane to the antenna X-axis in the range -90 to 90 degrees.

Example: 'AntennaAngle',25

Example: tx.AntennaAngle = [25,-80]

AntennaHeight — Antenna height above surface

1 (default) | non-negative numeric scalar | row vector

Antenna height from the ground or building surface, specified as a non-negative numeric scalar in meters. Maximum value for this property is 6,371,000 m.

If the site coincides with the building, the height is measured from the top of the building to the center of the antenna. Otherwise,the height is measured from ground elevation to the center of the antenna.

Example: 'AntennaHeight',25

Example: rx.AntennaHeight = 15

Dependencies

To use this property, CoordinateSystem must be set to 'geographic'.

Data Types:

AntennaPosition — Position of antenna center

[0;0;0] (default) | 3-by-1 vector

Position of the antenna center, specified as a 3-by-1 vector representing [x;y;z] Cartesian coordinates with each element in meters.

Example: 'AntennaPosition',[0;2;4]

Example: tx.AntennaPosition = [0;2;4]

Dependencies

To use this property, choose CoordinateSystem must be set to 'cartesian'.

Data Types:

SystemLoss — System loss

0 (default) | nonnegative numeric scalar | row vector

System loss, specified as a non-negative numeric scalar or a row vector in dB.

System loss includes transmission line loss and any other miscellaneous system losses.

Example: 'SystemLoss',10

Example: rx.SystemLoss = 10

Data Types:

ReceiverSensitivity — Minimum received power to detect signal

-100 (default) | numeric scalar | row vector

Minimum received power to detect the signal, specified as a numeric scalar or a row vector in dBm.

Example: 'ReceiverSensitivity',-80

Example: rx.ReceiverSensitivity = -80

Data Types: double

Object Functions

show	Show site in Site Viewer
hide	Hide site from Site Viewer
distance	Distance between sites
angle	Angle between sites
elevation	Elevation of site
location	Coordinates at distance and angle from site
sigstrength	Received signal strength
los	Display or compute line-of-sight (LOS) visibility status
link	Display or compute communication link status
pattern	Display antenna radiation pattern in Site Viewer

Examples**Default Receiver Site**

Create and show the default receiver site.

```
rx = rxsite
```

```
rx =
```

```
rxsite with properties:
```

```

        Name: 'Site 2'
        Latitude: 42.3021
        Longitude: -71.3764
        Antenna: 'isotropic'
        AntennaAngle: 0
        AntennaHeight: 1
        SystemLoss: 0
        ReceiverSensitivity: -100
```

show(rx)

[arrayConfig](#) | [txsite](#) | [siteviewer](#)

Introduced in R2019b

siteviewer

Create Site Viewer

Description

Display transmitter sites, receiver sites, and RF propagation visualizations by using a `siteviewer` object. By default, Site Viewer displays a 3-D view of the globe. When you display sites on the globe, they are referenced to geographic coordinates. You can customize the globe using custom terrain, high-zoom-level or custom basemaps, and buildings.

You can also import and view 3-D models represented by standard tessellation language (STL) files or triangulation objects. When you display sites on a 3-D model, they are referenced to Cartesian coordinates.

Site Viewer requires hardware graphics support for WebGL™.

Creation

Syntax

```
viewer = siteviewer
viewer = siteviewer(Name, Value)
```

Description

`viewer = siteviewer` creates a Site Viewer.

`viewer = siteviewer(Name, Value)` specifies Site Viewer properties using name-value arguments. For example, import and view a 3-D model file by using the `SceneModel` name-value argument.

Properties

Site Viewer

Name — Caption to display on map viewer window

'Site Viewer' (default) | character vector | string scalar

Caption to display on map viewer window, specified as a character vector or a string scalar.

Data Types: `char` | `string`

Position — Size and location of map viewer window in pixels

four-element integer-valued vector

Size and location of map viewer window in pixels, specified as a four-element integer-valued vector in the form `[left bottom width height]`. The default value depends on the screen resolution such that the window lies in the center of the screen with a width of 800 pixels and a height of 600 pixels.

Data Types: double

CoordinateSystem — Coordinate reference system

'geographic' (default) | 'cartesian'

This property is read-only.

Coordinate reference system, specified as 'geographic' or 'cartesian'. The value of CoordinateSystem depends on how you create the Site Viewer.

- By default, the value of CoordinateSystem is 'geographic' and visualizations are referenced to the WGS84 reference ellipsoid.
- When you create the Site Viewer by specifying the SceneModel argument, the value of CoordinateSystem is 'cartesian' and coordinates are referenced to Cartesian coordinates.

When CoordinateSystem is 'geographic', you can view the latitude and longitude coordinates for a location by right-clicking the map and selecting **Show Location**. To remove the location, right-click and select **Remove Location**.

Data Types: char | string

Geographic Coordinate System

Basemap — Map imagery used to visualize sites

'satellite' (default) | 'openstreetmap' | 'streets' | 'streets-light' | 'streets-dark' | 'topographic' | ...

Map imagery used to visualize sites, specified as one of the basemap names in this table or as a custom basemap defined using the addCustomBasemap function.

	<p>'satellite' (default)</p> <p>Full global basemap composed of high-resolution satellite imagery.</p> <p>Hosted by Esri.</p> <p>Earthstar Geograph CNES/Airbus DS</p>		<p>'openstreetmap'</p> <p>Street map provided by OpenStreetMap.</p> <p>OpenStreetMap contributors</p>
---	--	--	---

	<p>'streets'</p> <p>General-purpose road map that emphasizes accurate, legible styling of roads and transit networks.</p> <p>Hosted by Esri.</p> <p>Esri South Africa, HERE, Garmin, NGA, USGS</p>		<p>'streets-light'</p> <p>Map designed to provide geographic context while highlighting user data on a light background.</p> <p>Hosted by Esri.</p> <p>Esri South Africa, HERE, Garmin, NGA, USGS</p>
	<p>'streets-dark'</p> <p>Map designed to provide geographic context while highlighting user data on a dark background.</p> <p>Hosted by Esri.</p> <p>Esri, HERE, Garmin, NGA, USGS</p>		<p>'topographic'</p> <p>General-purpose map with styling to depict topographic features.</p> <p>Hosted by Esri.</p> <p>Esri South Africa, HERE, Garmin, USGS, NGA</p>
	<p>'landcover'</p> <p>Map that combines satellite-derived land cover data, shaded relief, and ocean-bottom relief. The light, natural palette is suitable for thematic and reference maps.</p> <p>Created using Natural Earth.</p>		<p>'colorterrain'</p> <p>Shaded relief map blended with a land cover palette. Humid lowlands are green and arid lowlands are brown.</p> <p>Created using Natural Earth.</p>

	<p>'grayterrain'</p> <p>Terrain map in shades of gray. Shaded relief emphasizes both high mountains and micro-terrain found in lowlands.</p> <p>Created using Natural Earth.</p>		<p>'bluegreen'</p> <p>Two-tone, land-ocean map with light green land areas and light blue water areas.</p> <p>Created using Natural Earth.</p>
	<p>'grayland'</p> <p>Two-tone, land-ocean map with gray land areas and white water areas.</p> <p>Created using Natural Earth.</p>		<p>'darkwater'</p> <p>Two-tone, land-ocean map with light gray land areas and dark gray water areas. This basemap is installed with MATLAB.</p> <p>Created using Natural Earth.</p>

The basemaps hosted by Esri update periodically. As a result, you might see differences in your visualizations over time.

Alignment of boundaries and region labels are a presentation of the feature provided by the data vendors and do not imply endorsement by MathWorks®.

This property applies only when `CoordinateSystem` is 'geographic'.

Data Types: `char` | `string`

Terrain — Data on which to visualize sites and perform terrain calculations

'gmted2010' (default) | 'none' | character vector | scalar

Data on which to visualize sites and perform terrain calculations, specified as a character vector or a scalar previously added using `addCustomTerrain` or one of the following options:

- 'none' — Terrain elevation is 0 everywhere.
- 'gmted2010' — USGS GMTED2010 terrain data. This option requires an internet connection.

This property applies only when `CoordinateSystem` is 'geographic'.

This property is read-only after you create the Site Viewer.

For limitations, see “Limitations” on page 3-1427.

Data Types: `char` | `string`

Buildings — Name of OpenStreetMap (.osm) file to use as buildings data

`string scalar` | `character vector`

Name of the OpenStreetMap (.osm) file to use as buildings data, specified as a string scalar or a character vector. The file must be in the current directory, in a directory on the MATLAB path. You can also use a full or relative path to the file to specify the data. By default, this value is empty.

This property applies only when `CoordinateSystem` is `'geographic'`.

This property is read-only after you create the Site Viewer.

For limitations, see “Limitations” on page 3-1427.

Data Types: `char` | `string`

Cartesian Coordinate System

SceneModel — Name of 3-D model file or triangulation

`character vector` | `string scalar` | `triangulation object`

Name of the 3-D model file or triangulation, specified as a string scalar, a character vector, or a triangulation object.

When `SceneModel` is the name of a 3-D model file, you must specify an STL file with extension `.stl`. The form of `SceneModel` depends on the location of your file.

- If the file is in your current folder or in a folder on the MATLAB path, then specify the name of the file, such as `'myFile.stl'`.
- If the file is not in the current folder or in a folder on the MATLAB path, then specify the full or relative path name, such as `'C:\myfolder\myFile.stl'` or `'dataDir\myFile.stl'`.

This property applies only when `CoordinateSystem` is `'cartesian'`.

This property is read-only after you create the Site Viewer.

Data Types: `char` | `string`

Transparency — Transparency of model

`scalar in the range [0, 1]`

Transparency of the model, specified as a scalar in the range `[0, 1]`, where `0` is transparent and `1` is opaque. The default is `0.1` when `ShowEdges` is `1` (`true`), and `1` otherwise.

This property applies only when `CoordinateSystem` is `'cartesian'`.

Data Types: `double`

ShowOrigin — Option to show origin

`true` or `1` (default) | `false` or `0`

Option to show the origin of the model, specified as numeric or logical `1` (`true`) or `0` (`false`). The x-axis appears in red, the y-axis appears in green, and the z-axis appears in blue. The z-axis of the scene points up.

This property applies only when `CoordinateSystem` is `'cartesian'`.

Data Types: `logical`

ShowEdges — Option to show edges of model

`true` or `1` (default) | `false` or `0`

Option to show the edges of the model using black lines, specified as numeric or logical `1` (`true`) or `0` (`false`). Site Viewer defines edges as two adjacent facets with normals that differ by more than two degrees.

This property applies only when `CoordinateSystem` is `'cartesian'`.

This property is read-only after you create the Site Viewer.

Data Types: `logical`

Object Functions

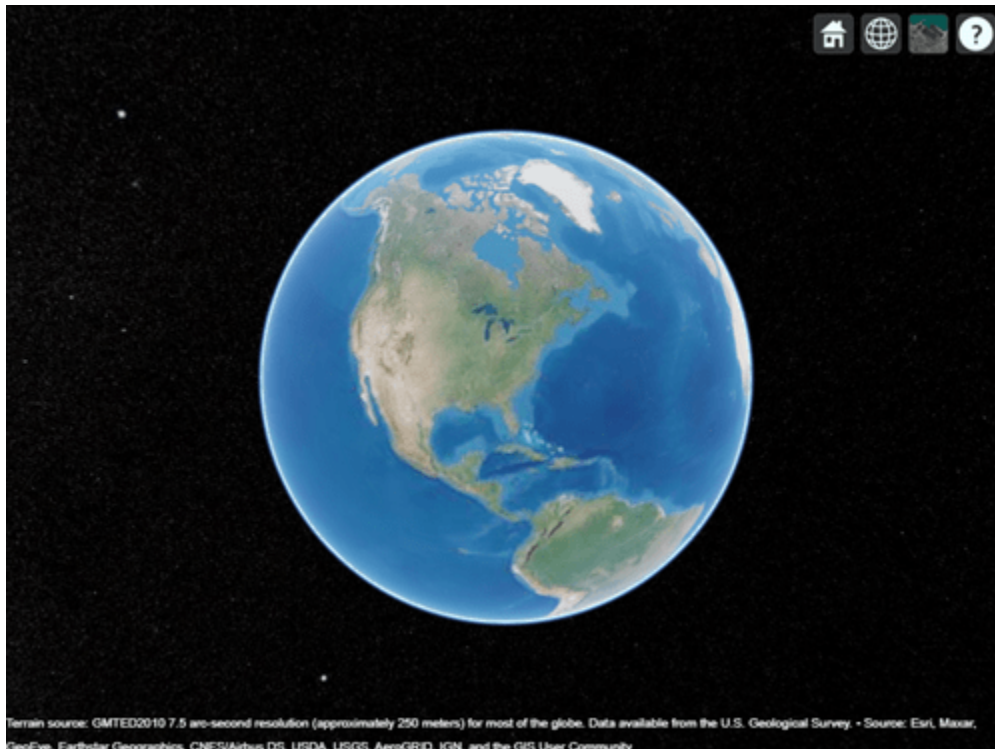

`clearMap` Clear plots
`close` Close Site Viewer

Examples

Default Site Viewer Map Display

Create a default Site Viewer.

```
viewer = siteviewer;
```

Pan by left-clicking and dragging, zoom by right-clicking and dragging or by using the scroll wheel, and rotate the visualization by clicking the middle button and dragging or by pressing **Ctrl** and left-clicking or dragging. View the coordinates for a location by right-clicking and selecting **Show location**.

For this example, navigate to a region containing New England and view the coordinates for a location near Cape Cod.

A gray marker appears at the location you selected. Remove the marker by right-clicking the location and selecting **Remove location**.

Site Viewer with 3-D Model

Import and view an STL file. The file models a small conference room with one table and four chairs.

```
viewer = siteviewer("SceneModel", "conferenceroom.stl");
```

Pan by left-clicking, zoom by right-clicking or by using the scroll wheel, and rotate the visualization by clicking the middle button and dragging or by pressing **Ctrl** and left-clicking and dragging.

View Transmitter Site On Site Viewer

Launch a Site Viewer with streets basemap.

```
viewer = siteviewer("Basemap", "streets");
```

View a transmitter site on this map.

```
tx = txsite;  
show(tx)
```

Compare Coverage Maps

Launch two Site Viewer windows. One Site Viewer window uses the terrain model and the other window does not use the terrain model.

```
viewer1 = siteviewer("Terrain","gmted2010","Name","Site Viewer (Using Terrain)");  
viewer2 = siteviewer("Terrain","none","Name","Site Viewer (No Terrain)");
```

Create a transmitter site.

```
tx = txsite;
```

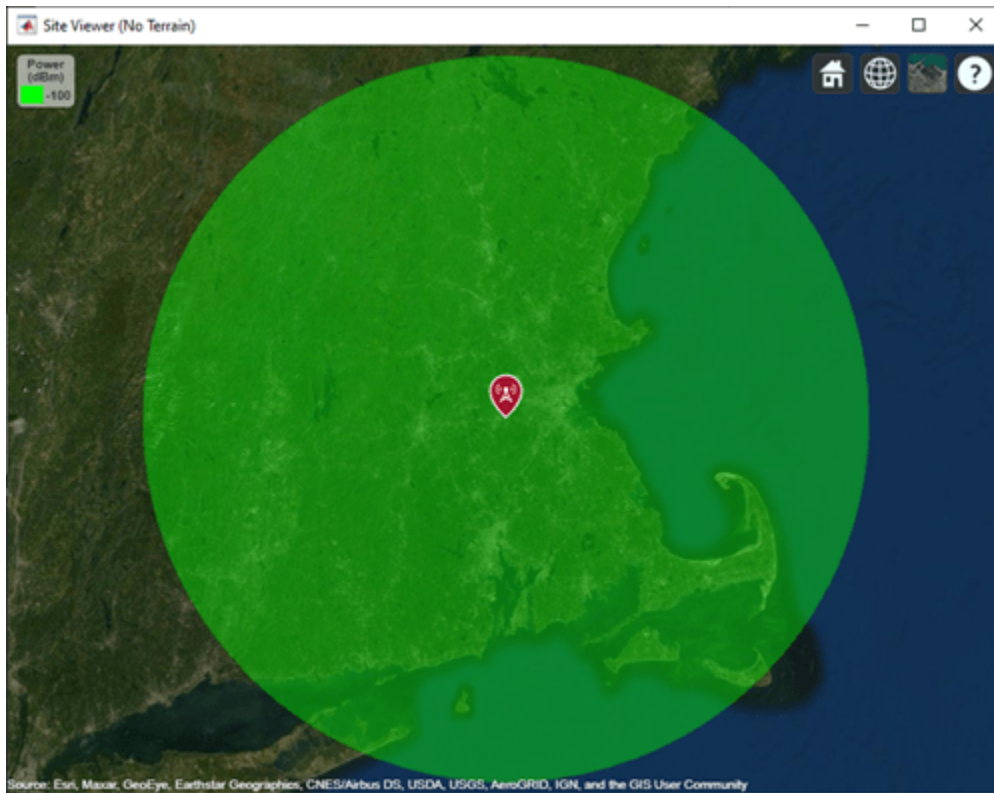

Generate a coverage map on each window. The map with terrain uses the Longley-Rice propagation model by default.

```
coverage(tx,"Map",viewer1)
```

The map without terrain uses the free-space model by default.

coverage(tx, "Map", viewer2)

Site Viewer with Buildings

Launch Site Viewer with a basemap and buildings file for Manhattan. For more information about the osm file, see [1] on page 3-0 .

```
viewer = siteviewer("Basemap","openstreetmap",...  
                  "Buildings","manhattan.osm");
```

Show a transmitter site on a building.

```
tx = txsite("Latitude",40.7107,...  
           "Longitude",-74.0114,...  
           "AntennaHeight",50);  
show(tx)
```

Appendix

[1] The osm file is downloaded from <https://www.openstreetmap.org>, which provides access to crowd-sourced map data all over the world. The data is licensed under the Open Data Commons Open Database License (ODbL), <https://opendatacommons.org/licenses/odbl/>.

Add and Remove a Custom Basemap

Add a custom basemap to view locations on an OpenTopoMap® basemap, then remove the custom basemap from siteviewer.

Initialize simulation variables to:

- Define the name that you will use to specify your custom basemap.
- Specify the website that provides the map data. The first character of the URL indicates which server to use to get the data. For load balancing, the provider has three servers that you can use: a, b, or c.
- Create an attribution to display on the map that gives credit to the provider of the map data. Web map providers might define specific requirements for the attribution.
- Define a display name for the custom map.

```
name = 'opentopomap';  
url = 'a.tile.opentopomap.org';  
copyright = char(uint8(169));  
attribution = copyright + "OpenStreetMap contributors";  
displayName = 'Open Topo Map';
```

Use `addCustomBasemap` to load the custom basemap, and then create a `siteviewer` object that loads the custom basemap.

```
addCustomBasemap(name,url,'Attribution',attribution,'DisplayName',displayName)
viewer = siteviewer('Basemap',name);
```

After a custom basemap is added to `siteviewer`, the custom map is available for future calls to `siteviewer`. Note the 'Open Topo Map' icon in the Imagery tab.

```
siteviewer;
```

Use `removeCustomBasemap` to remove the custom basemap from future calls to `siteviewer`. Note the 'Open Topo Map' icon is no longer available in the Imagery tab.

```
removeCustomBasemap(name)  
siteviewer;
```

Limitations

Terrain

- Default terrain access requires an internet connection. If no internet connection exists, then Site Viewer automatically uses 'none' in the property Terrain.
- Custom DTED terrain files for use with `addCustomTerrain` must be acquired outside of MATLAB for example by using USGS EarthExplorer.
- When using custom terrain, analysis is restricted to the terrain region. For example, an error occurs if you are trying to show a transmitter or receiver site outside of the region.

Buildings

- OpenStreetMap files obtained from <https://www.openstreetmap.org> represent crowd-sourced map data, and the completeness and accuracy of the buildings data may vary depending on the map location.
- When downloading data from <https://www.openstreetmap.org>, select an export area larger than the desired area to ensure that all expected building features are fully captured. Building features at the edge of the selected export area may be missing.
- Building geometry and features are interpreted from the file according to the recommendations of OpenStreetMap for 3-D buildings.

MATLAB Online

- In MATLAB Online™, if you refresh the URL, then the Site Viewer window remains open but the visualizations disappear.

More About

Site Viewer Navigation

You can interactively navigate Site Viewer by using your mouse.

- Pan by left-clicking and dragging.
- Zoom by scrolling or by right-clicking and dragging.
- Tilt and rotate by holding **Ctrl** and dragging or by middle-clicking and dragging.

When `CoordinateSystem` is 'geographic', you can restore the default view by selecting  **Restore View** from the toolbar.

Dimension Picker

When `CoordinateSystem` is 'geographic', you can choose between three view options by using the **Dimension Picker** in the toolbar.

-  **3-D View** — A smooth globe. This is the default view.
-  **2-D View** — A flat map in the Mercator projection.
-  **Columbus View** — A flat map in the Mercator projection that supports tilt and rotation.

Some interactions are not supported for **2-D View** and **Columbus View**.

Topics

“RF Propagation and Visualization”

Introduced in R2019b

txsite

Create RF transmitter site

Description

Use the `txsite` object to create a radio frequency transmitter site.

A transmitter consists of an RF circuit and an antenna, where the RF circuit excites the antenna with a signal and power. Key characteristics of a transmitter include its output power, operating frequency, and antenna radiation pattern.

Creation

Syntax

```
tx = txsite
tx = txsite(coordsys)
tx = txsite( ___,Name,Value)
```

Description

`tx = txsite` creates a radio frequency transmitter site.

`tx = txsite(coordsys)` creates a transmitter site with the specified coordinate system. You can specify either 'geographic' or 'cartesian' coordinate system.

`tx = txsite(___,Name,Value)` sets properties using one or more name-value pairs. For example, `tx = txsite('Name','TX Site')` creates a transmitter site with the name `TX Site`. Enclose each property name in quotes.

You can create multiple transmitter sites by using `Name`, `Latitude`, and `Longitude` properties. For example: `names = ["Fenway Park","Faneuil Hall","Bunker Hill Monument"]; lats = [42.3467,42.3598,42.3763]; lons = [-71.0972,-71.0545,-71.0611];`. The `CoordinateSystem` property must be a string scalar or a character vector.

Properties

Name — Site name

character vector | string | row or column vector

Site name, specified as a character vector or string or as a row or column vector of N elements. Specifying name as a row or column vector creates multiple sites.

Example: 'Name','Site 2'

Example: `tx.Name = 'Fenway Park'`

Example: `names = ["Fenway Park","Faneuil Hall","Bunker Hill Monument"]; tx = txsite('Name',names)`

Data Types: char | string

CoordinateSystem — Coordinate system used to site location

'geographic' (default) | 'cartesian'

Coordinate system used to the site location, specified as 'geographic' or 'cartesian'. If you specify 'geographic', the site location is defined using the Latitude, Longitude, and AntennaHeight properties. If you specify 'cartesian', the site location is defined using the AntennaPosition property.

Example: 'CoordinateSystem','cartesian'

Example: tx.CoordinateSystem = 'cartesian'

Latitude — Site latitude coordinates

42.3001 (default) | numeric scalar in the range [-90 90] | row or column vector

Site latitude coordinates, specified as a numeric scalar in the range of -90 to 90, or as a row or column vector of N elements in the range [-90 90]. Specifying latitude as a row or column vector creates multiple sites. The coordinates are defined using the world geodesic system of 1984 (WGS-84) reference ellipsoid. Latitude specifies north-south position.

Example: 'Latitude',45.098

Example: tx.Latitude = 45.098

Example: latitude = [42.3467,42.3598,42.3763]; tx = txsite('Latitude',latitude)

Dependencies

To enable this property, set CoordinateSystem to 'geographic'.

Longitude — Site longitude coordinates

-71.3504 (default) | numeric scalar in the range [-180 180] | row or column vector

Site longitude coordinates, specified as a numeric scalar in the range [-180 180] or as a row or column vector of N elements in the range [-180 180]. Specifying longitude as a row or column vector creates multiple sites. The coordinates are defined using the world geodesic system of 1984 (WGS-84) reference ellipsoid. Longitude specifies the east-west the position.

Example: 'Longitude',-68.890

Example: tx.Longitude = -71.0972

Example: longitude = [-71.0972,-71.0545,-71.0611]; tx = txsite('Longitude',longitude)

Dependencies

To enable this property, set the CoordinateSystem to 'geographic'.

Antenna — Antenna element or array

'isotropic' (default) | object | row vector

Antenna element or array specified as one of these options.

- 'isotropic' to model an antenna that radiates uniformly in all directions.
- An arrayConfig object.

- If you have Antenna Toolbox, an antenna element from the “Antenna Catalog” (Antenna Toolbox).
- If you have Phased Array System Toolbox, any antenna object in “Antennas, Microphones, and Sonar Transducers” (Phased Array System Toolbox) or any array object in “Array Geometries and Analysis” (Phased Array System Toolbox).

Example: 'Antenna',cfgArray, where cfgArray is an arrayConfig object

Example: tx.Antenna = arrayConfig('Size',[8 1]); specifies an 8-element ULA along z-axis

AntennaAngle — Antenna X-axis angle

0 (default) | numeric scalar | 2-by-1 vector | 2-by-*N* matrix

Antenna X-axis angle defined with reference to a local Cartesian coordinate system, specified as a numeric scalar representing an azimuth angle in degrees or as a 2-by-1 vector or a 2-by-*N* matrix representing both azimuth and elevation angles with each element unit in degrees.

The azimuth angle is measured counterclockwise from the east along the antenna X-axis (for geographical sites) or from the global X-axis around the global Z-axis (for Cartesian sites). Specify the azimuth angle between -180 to 180. degrees.

The elevation angle is measured from antenna X-axis along the horizontal or XY plane. Specify the elevation angle between -90 to 90 degrees.

Example: 'AntennaAngle',25

Example: tx.AntennaAngle = [25,-80]

AntennaHeight — Antenna height above surface

10 (default) | nonnegative numeric scalar | row vector

Antenna height from the ground or building surface, specified as a nonnegative numeric scalar in meters. Maximum value for this property is 6,371,000 m.

If the site location coincides with the building location, the antenna height is measured from the top of the building to the center of the antenna. Otherwise, the height is measured from ground elevation to the center of the antenna.

Example: 'AntennaHeight',25

Example: tx.AntennaHeight = 15

Dependencies

To enable this property, set CoordinateSystem to 'geographic'.

Data Types:

AntennaPosition — Position of antenna center

[0;0;0] (default) | 3-by-1 vector

Position of the antenna center, specified as a 3-by-1 vector representing X-, Y-, and Z-axis Cartesian coordinates with each element in meters.

Example: 'AntennaPosition',[0;2;4]

Example: tx.AntennaPosition = [0;2;4]

Dependencies

To enable this property, set `CoordinateSystem` to `'cartesian'`.

Data Types:

SystemLoss – System loss

0 (default) | nonnegative scalar | row vector

System loss, specified as a nonnegative scalar in dB.

System loss includes transmission line loss and any other miscellaneous system losses.

Example: `'SystemLoss',10`

Example: `txsite.SystemLoss = 10`

Data Types:

TransmitterFrequency – Transmitter operating frequency

1.9000e+09 (default) | positive scalar | row vector

Transmitter operating frequency, specified as a positive scalar in Hz. in the range [1e3 200e9].

Example: `'TransmitterFrequency',30e9`

Example: `txsite.TransmitterFrequency = 30e9`

Data Types: double

TransmitterPower – Signal power at transmitter output

10 (default) | positive scalar

Signal power at transmitter output, specified as a positive scalar in watts. The transmitter out is connected to the antenna.

Example: `'TransmitterPower',30`

Example: `txsite.TransmitterPower = 30`

Data Types: double

Object Functions

<code>show</code>	Show site in Site Viewer
<code>hide</code>	Hide site from Site Viewer
<code>distance</code>	Distance between sites
<code>angle</code>	Angle between sites
<code>elevation</code>	Elevation of site
<code>location</code>	Coordinates at distance and angle from site
<code>los</code>	Display or compute line-of-sight (LOS) visibility status
<code>coverage</code>	Display or compute coverage map
<code>sinr</code>	Display or compute signal-to-interference-plus-noise (SINR) ratio
<code>pattern</code>	Display antenna radiation pattern in Site Viewer

Examples

Default Transmitter Site

Create a transmitter site at a latitude of 42.3001 degrees and a longitude of -71.3504 degrees.

```
tx = txsite("Name","MathWorks Apple Hill", ...  
           "Latitude",42.3001,"Longitude",-71.3504)
```

```
tx =  
  txsite with properties:  
    Name: 'MathWorks Apple Hill'  
  CoordinateSystem: 'geographic'  
    Latitude: 42.3001  
    Longitude: -71.3504  
    Antenna: 'isotropic'  
  AntennaAngle: 0  
  AntennaHeight: 10  
    SystemLoss: 0  
  TransmitterFrequency: 1.9000e+09  
    TransmitterPower: 10
```

View the coverage of the site.

```
pattern(tx)
```

CloseIn

Close-in propagation model

Description

Model the behavior of electromagnetic radiation from a point of transmission as it travels through urban macro cell scenarios [1] by using a `CloseIn` object. Close-in propagation models have no enforced frequency range.

Creation

Create a `CloseIn` object by using the `propagationModel` function.

Properties

ReferenceDistance — Free-space reference distance

1 (default) | scalar

Free-space reference distance, specified as a scalar in meters.

Note The close-in model is valid for distances greater than or equal to the `ReferenceDistance`. Path loss is 0 for distances less than `ReferenceDistance`.

Data Types: `double`

PathLossExponent — Path loss exponent

2.9 (default) | scalar

Path loss exponent, specified as a scalar.

Data Types: `double`

Sigma — Standard deviation

5.7 (default) | scalar

Standard deviation of the zero-mean Gaussian random variable, specified as a scalar in decibels (dB).

Data Types: `double`

NumDataPoints — Number of data points

1869 (default) | integer

Number of data points of the zero-mean Gaussian random variable, specified as an integer.

Data Types: `double`

Object Functions

pathloss Path loss of radio wave propagation
range Range of radio wave propagation
add Add propagation models

Examples

Model Coverage Using Close-In Model

Display the coverage area for a transmitter using the close-in propagation model.

```
pm = propagationModel("close-in");  
tx = txsite("Name", "Apple Hill", "Latitude", 42.3001, "Longitude", -71.3604);  
coverage(tx, pm)
```

Fog

Fog propagation model

Description

Model the behavior of electromagnetic radiation from a point of transmission as it travels through fog or clouds [1] by using a Fog object. Propagation models for fog are valid from 10 to 1000 GHz, assume line-of-sight (LOS) conditions, and disregard terrain, the curvature of the Earth, and other obstacles.

Creation

Create a Fog object by using the `propagationModel` function.

Properties

Temperature – Air temperature

15 (default) | scalar

Air temperature, specified as a scalar in degrees Celsius (C).

Data Types: `double`

WaterDensity – Liquid water density

0.5 (default) | scalar

Liquid water density, specified as a scalar in grams per cubic meter (g/m³).

Data Types: `double`

Object Functions

`pathloss` Path loss of radio wave propagation

`range` Range of radio wave propagation

`add` Add propagation models

Examples

Model Coverage in Thick Fog

Display the coverage area for a transmitter in thick fog.

Create a propagation model for fog. Specify the water density as 0.5 grams per cubic meter.

```
pm = propagationModel("fog", "WaterDensity", 0.5);
```

Create a transmitter site. Display the coverage area for the transmitter. Propagation models for fog require transmitter frequencies between 10 and 1000 GHz.

```
tx = txsite("Name","Apple Hill","TransmitterFrequency",1e10, ...
"Latitude",42.3001,"Longitude",-71.3604);
coverage(tx,pm)
```

Gas

Gas propagation model

Description

Model the behavior of electromagnetic radiation from a point of transmission as it travels through gas [1] by using a Gas object. Propagation models for gas are valid from 1 to 1000 GHz, assume line-of-sight (LOS) conditions, and disregard terrain, the curvature of the Earth, and other obstacles.

Creation

Create a Gas object by using the `propagationModel` function.

Properties

Temperature — Air temperature

15 (default) | scalar

Air temperature, specified as a scalar in degrees Celsius (C).

Data Types: `double`

AirPressure — Dry air pressure

101300 (default) | scalar

Dry air pressure, specified as a scalar in pascals (Pa).

Data Types: `double`

WaterDensity — Water vapor density

7.5 (default) | scalar

Water vapor density, specified as a scalar in grams per cubic meter (g/m^3).

Data Types: `double`

Object Functions

LongleyRice

Longley-Rice propagation model

Description

Model the behavior of electromagnetic radiation from a point of transmission over irregular terrain, including buildings, by using the Longley-Rice model, also known as the Irregular Terrain Model (ITM) [1]. Represent the model by using a `LongleyRice` object.

The Longley-Rice model:

- Is valid from 20 MHz to 20 GHz.
- Calculates path loss from free-space loss, terrain and obstacle diffraction, ground reflection, atmospheric refraction, and tropospheric scatter.
- Provides path loss estimates by combining physics with empirical data.

Creation

Create a `LongleyRice` object by using the `propagationModel` function.

Properties

AntennaPolarization — Polarization of transmitter and receiver antennas

"horizontal" (default) | "vertical"

Polarization of transmitter and receiver antennas, specified as "horizontal" or "vertical". This object assumes both antennas have the same polarization. The model uses this value to calculate path loss due to ground reflection.

Data Types: `char` | `string`

GroundConductivity — Conductivity of ground

0.005 (default) | scalar

Conductivity of the ground, specified as a scalar in siemens per meter (S/m). The model uses this value to calculate path loss due to ground reflection. The default value corresponds to average ground.

Data Types: `double`

GroundPermittivity — Relative permittivity of ground

15 (default) | scalar

Relative permittivity of the ground, specified as a scalar. Relative permittivity is expressed as a ratio of absolute material permittivity to the permittivity of vacuum. The model uses this value to calculate the path loss due to ground reflection. The default value corresponds to average ground.

Data Types: `double`

AtmosphericRefractivity — Atmospheric refractivity near ground

301 (default) | scalar in N-Units

Atmospheric refractivity near the ground, specified as a scalar in “N-Units” on page 3-1447. The model uses this value to calculate the path loss due to refraction through the atmosphere and tropospheric scatter. The default value corresponds to average atmospheric conditions.

Data Types: double

ClimateZone — Radio climate zone

"continental-temperate" (default) | "equatorial" | "continental-subtropical" | "maritime-subtropical" | "desert" | "maritime-over-land" | "maritime-over-sea"

Radio climate zone, specified as one of these options:

- "continental-temperate"
- "equatorial"
- "continental-subtropical"
- "maritime-subtropical"
- "desert"
- "maritime-over-land"
- "maritime-over-sea"

The model uses this value to calculate the variability due to changing atmospheric conditions. The default value corresponds to average atmospheric conditions in a particular climate zone.

Data Types: char | string

TimeVariabilityTolerance — Time variability tolerance level

0.5 (default) | scalar in the range [0.001, 0.999]

Time variability tolerance level of the path loss, specified as a scalar in the range [0.001, 0.999]. Time variability occurs due to changing atmospheric conditions. This value gives the required system reliability expressed as the fraction of time during which the actual path loss is expected to be less than or equal to the model prediction.

Data Types: double

SituationVariabilityTolerance — Situation variability tolerance level

0.5 (default) | scalar in the range [0.001, 0.999]

Situation variability tolerance level of the path loss, specified as a scalar in the range [0.001, 0.999]. Situation variability occurs due to uncontrolled or hidden random variables. This value gives the required system confidence expressed as the fraction of similar situations for which the actual path loss is expected to be less than or equal to the model prediction.

Data Types: double

Object Functions

pathloss Path loss of radio wave propagation
add Add propagation models

Examples

Model Coverage Using Longley-Rice Model

Display the coverage area for a transmitter using the Longley-Rice model.

```
pm = propagationModel("longley-rice");  
tx = txsite("Name","Apple Hill","Latitude",42.3001,"Longitude",-71.3604);  
coverage(tx,pm,"SignalStrengths",-100:-5)
```

Increase the time and situation variability tolerance levels from 0.5 (the default) to 0.9. Display the coverage area for the transmitter using the updated propagation model.

```
pm.TimeVariabilityTolerance = 0.9;  
pm.SituationVariabilityTolerance = 0.9;  
coverage(tx,pm,"SignalStrengths",-100:5)
```

The coverage area is smaller for the model with higher variability tolerance levels.

More About

N-Units

The refractive index of air, n , is related to the dielectric constants of the gas constituents of an air mixture. The numerical value of n is only slightly larger than 1. To make the calculation more convenient, you can use N units, which are given by the formula: $N = (n - 1) \times 10^6$.

Rain

Rain propagation model

Description

Model the behavior of electromagnetic radiation from a point of transmission as it travels through rain [1] by using a `Rain` object. Propagation models for rain are valid from 1 to 1000 GHz, assume line-of-sight (LOS) conditions, and disregard terrain, the curvature of the Earth, and other obstacles.

Creation

Create a `Rain` object by using the `propagationModel` function.

Properties

RainRate — Rain rate

16 (default) | nonnegative scalar

Rain rate, specified as a nonnegative scalar in millimeters per hour (mm/h).

Data Types: `double`

Tilt — Polarization tilt angle of signal

0 (default) | scalar

Polarization tilt angle of the signal, specified as a scalar in degrees.

Data Types: `double`

Object Functions

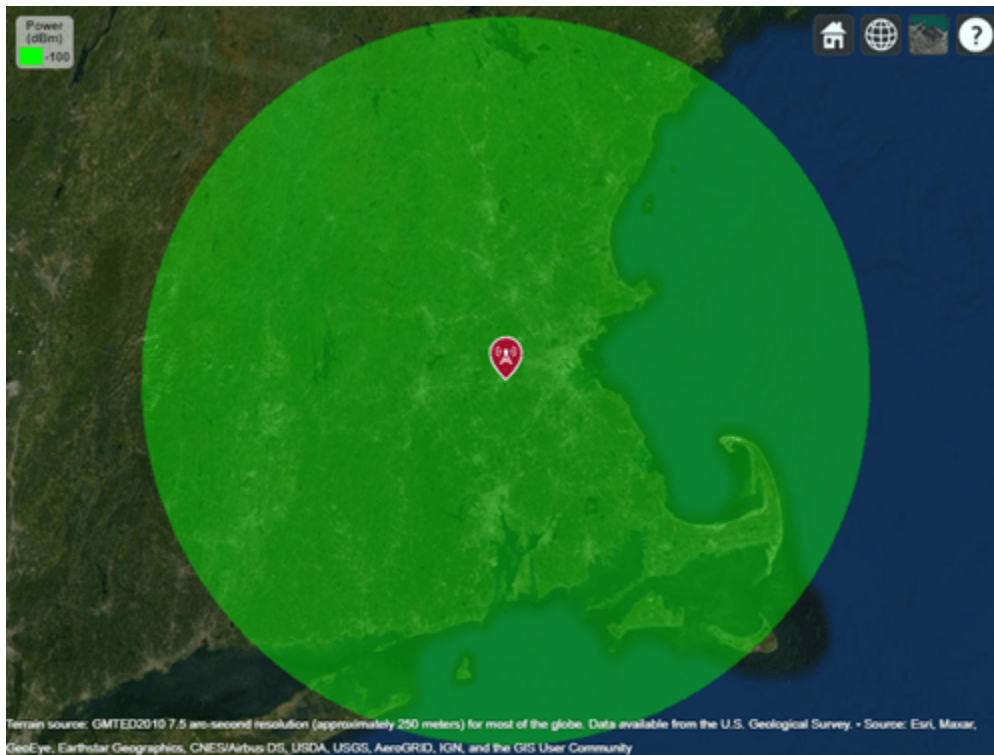

<code>pathloss</code>	Path loss of radio wave propagation
<code>range</code>	Range of radio wave propagation
<code>add</code>	Add propagation models

Examples

Model Coverage in Heavy Rain

Display the coverage area for a transmitter in heavy rain. Specify the rain rate as 50 millimeters per hour.

```
pm = propagationModel("rain", "RainRate", 50);
tx = txsite("Name", "Apple Hill", "Latitude", 42.3001, "Longitude", -71.3604);
coverage(tx, pm)
```

RayTracing

Ray tracing propagation model

Description

Ray tracing models compute propagation paths using 3-D environment geometry [1][2]. Represent a ray tracing model by using a `RayTracing` object.

Ray tracing models:

- Are valid from 100 MHz to 100 GHz.
- Compute multiple propagation paths. Other propagation models compute only single propagation paths.
- Support 3-D outdoor and indoor environments.
- Determine the path loss and phase shift of each ray using electromagnetic analysis, including tracing the horizontal and vertical polarizations of a signal through the propagation path. The path loss includes free-space loss and reflection losses. For each reflection, the model calculates losses on the horizontal and vertical polarizations by using the Fresnel equation, the incident angle, and the relative permittivity and conductivity of the surface material [3][4] at the specified frequency.

You can create ray tracing models that use either the shooting and bouncing rays (SBR) method on page 3-1458 or the image method on page 3-1459.

Creation

Create a `RayTracing` object by using the `propagationModel` function.

Properties

Ray Tracing

Method — Ray tracing method

"sbr" (default) | "image"

Ray tracing method, specified as one of these values:

- "sbr" — Use the shooting and bouncing rays (SBR) method on page 3-1458, which supports up to 10 path reflections. SBR calculates approximate propagation paths. The SBR method is generally faster than the image method. The model calculates path loss from free-space loss plus reflection losses due to material and antenna polarizations.
- "image" — Use the image method on page 3-1459, which supports up to 2 path reflections and calculates exact propagation paths. The model calculates path loss from free-space loss plus reflection losses due to material and antenna polarizations.

Specify the maximum number of path reflections by using the `MaxNumReflections` property.

For more information about differences between the image and SBR methods, see “Choose a Propagation Model”.

Data Types: `char` | `string`

AngularSeparation — Angular separation of launched rays

`"medium"` (default) | `"high"` | `"low"`

Angular separation of launched rays, specified as one of these values:

- `"high"` — Rays have an angular separation in the range [0.9912, 1.1845], measured in degrees, so that the model launches 40,962 rays.
- `"medium"` — Rays have an angular separation in the range [0.4956, 0.5923], measured in degrees, so that the model launches 163,842 rays.
- `"low"` — Rays have an angular separation in the range [0.2478, 0.2961], measured in degrees, so that the model launches 655,362 rays.

Because the model launches more rays, ray tracing analysis with low angular separation can require more time than ray tracing analysis with high angular separation.

Tips

When creating coverage maps using the `coverage` function, you can improve the results by choosing a lower angular separation.

Dependencies

To enable the angular separation of launched rays, you must specify the `Method` property as `"sbr"`.

Data Types: `char` | `string`

MaxNumReflections — Maximum number of path reflections

2 (default) | integer in the range [0,10]

Maximum number of path reflections to search for using ray tracing, specified as an integer. Supported values depend on the value of the `Method` property.

- When `Method` is `"image"`, supported values are 0, 1, and 2.
- When `Method` is `"sbr"`, supported values are in the range [0, 10].

Data Types: `double`

CoordinateSystem — Coordinate system of map and site location

`"geographic"` (default) | `"cartesian"`

Coordinate system of the site location, specified as `"geographic"` or `"cartesian"`. If you specify `"geographic"`, define material types by using the `BuildingsMaterial` and `TerrainMaterial` properties. If you specify `"cartesian"`, define material types by using the `SurfaceMaterial` property.

Data Types: `string` | `char`

Buildings Material

BuildingsMaterial — Surface material of geographic buildings

`"concrete"` (default) | `"perfect-reflector"` | `"brick"` | `"wood"` | `"glass"` | `"metal"` | `"custom"`

Surface material of geographic buildings, specified as one of these values: "perfect-reflector", "concrete", "brick", "wood", "glass", "metal", or "custom". The model uses the material type to calculate reflection loss where propagation paths reflect off of building surfaces. For more information, see "ITU Permittivity and Conductivity Values for Common Materials" on page 3-1460.

When BuildingsMaterial is "custom", specify the material permittivity and conductivity by using the BuildingsMaterialPermittivity and BuildingsMaterialConductivity properties.

Dependencies

To enable BuildingsMaterial, you must set CoordinateSystem to "geographic".

Data Types: char | string

BuildingsMaterialPermittivity — Relative permittivity of surface materials of buildings

5.31 (default) | nonnegative scalar

Relative permittivity of the surface materials of the buildings, specified as a nonnegative scalar. Relative permittivity is expressed as a ratio of absolute material permittivity to the permittivity of vacuum. The model uses this value to calculate path loss due to reflection. The default value corresponds to concrete at 1.9 GHz.

Dependencies

To enable BuildingsMaterialPermittivity, you must set CoordinateSystem to "geographic" and BuildingsMaterial to "custom".

Data Types: double

BuildingsMaterialConductivity — Conductivity of surface materials of buildings

0.0548 (default) | nonnegative scalar

Conductivity of the surface materials of the buildings, specified as a nonnegative scalar in siemens per meter (S/m). The model uses this value to calculate path loss due to reflection. The default value corresponds to concrete at 1.9 GHz.

Dependencies

To enable BuildingsMaterialConductivity, you must set CoordinateSystem to "geographic" and BuildingsMaterial to "custom".

Data Types: double

Terrain Material

TerrainMaterial — Surface material of geographic terrain

"concrete" (default) | "perfect-reflector" | "brick" | "water" | "vegetation" | "loam" | "custom"

Surface material of the geographic terrain, specified as one of these values: "perfect-reflector", "concrete", "brick", "water", "vegetation", "loam", or "custom". The model uses the material type to calculate reflection loss where propagation paths reflect off of terrain surfaces. For more information, see "ITU Permittivity and Conductivity Values for Common Materials" on page 3-1460.

When TerrainMaterial is "custom", specify the material permittivity and conductivity by using the TerrainMaterialPermittivity and TerrainMaterialConductivity properties.

Dependencies

To enable `TerrainMaterial`, you must set `CoordinateSystem` to "geographic".

Data Types: char | string

TerrainMaterialPermittivity — Relative permittivity of terrain materials

5.31 (default) | nonnegative scalar

Relative permittivity of the terrain material, specified as a nonnegative scalar. Relative permittivity is expressed as a ratio of absolute material permittivity to the permittivity of vacuum. The model uses this value to calculate path loss due to reflection. The default value corresponds to concrete at 1.9 GHz.

Dependencies

To enable `TerrainMaterialPermittivity`, you must set `CoordinateSystem` to "geographic" and `TerrainMaterial` to "custom".

Data Types: double

TerrainMaterialConductivity — Conductivity of terrain materials

0.0548 (default) | nonnegative scalar

Conductivity of the terrain material, specified as a nonnegative scalar in siemens per meter (S/m). The model uses this value to calculate path loss due to reflection. The default value corresponds to concrete at 1.9 GHz.

Dependencies

To enable `TerrainMaterialConductivity`, you must set `CoordinateSystem` to "geographic" and set `TerrainMaterial` to "custom".

Data Types: double

Surface Material**SurfaceMaterial — Surface material of Cartesian map surface**

"plasterboard" (default) | "perfect-reflector" | "ceilingboard" | "chipboard" | "floorboard" | "concrete" | "brick" | "wood" | "glass" | "metal" | "water" | "vegetation" | "loam" | "custom"

Surface material of Cartesian map surface, specified as one of these values:

"plasterboard", "perfect-reflector", "ceilingboard", "chipboard", "floorboard", "concrete", "brick", "wood", "glass", "metal", "water", "vegetation", "loam", or "custom". The model uses the material type to calculate reflection loss where propagation paths reflect off of surfaces. For more information, see "ITU Permittivity and Conductivity Values for Common Materials" on page 3-1460.

When `SurfaceMaterial` is "custom", specify the material permittivity and conductivity by using the `SurfaceMaterialPermittivity` and `SurfaceMaterialConductivity` properties.

Dependencies

To enable `SurfaceMaterial`, you must set `CoordinateSystem` to "cartesian".

Data Types: char | string

SurfaceMaterialPermittivity – Relative permittivity of surface materials

2.94 (default) | nonnegative scalar

Relative permittivity of the surface material, specified as a nonnegative scalar. Relative permittivity is expressed as a ratio of absolute material permittivity to the permittivity of vacuum. The model uses this value to calculate path loss due to reflection. The default value corresponds to plaster board at 1.9 GHz.

Dependencies

To enable `SurfaceMaterialPermittivity`, you must set `CoordinateSystem` to "cartesian" and `SurfaceMaterial` to "custom".

Data Types: double

SurfaceMaterialConductivity – Conductivity of surface materials

0.0183 (default) | nonnegative scalar

Conductivity of the surface material, specified as a nonnegative scalar in siemens per meter (S/m). The model uses this value to calculate path loss due to reflection. The default value corresponds to plaster board at 1.9 GHz.

Dependencies

To enable `SurfaceMaterialConductivity`, you must set `CoordinateSystem` to "cartesian" and set `SurfaceMaterial` to "custom".

Data Types: double

Object Functions

`pathloss` Path loss of radio wave propagation
`add` Add propagation models

Examples**Model Propagation Paths Using SBR and Image Methods**

Show reflected propagation paths in Chicago by using the SBR and image methods.

Create a Site Viewer with buildings in Chicago. For more information about the osm file, see [1] on page 3-0 .

```
viewer = siteviewer("Buildings", "chicago.osm");
```

Create a transmitter site on a building and a receiver site near another building.

```
tx = txsite("Latitude",41.8800, ...
           "Longitude",-87.6295, ...
           "TransmitterFrequency",2.5e9);
show(tx)
rx = rxsite("Latitude",41.8813452, ...
           "Longitude",-87.629771, ...
           "AntennaHeight",30);
show(rx)
```

Create a ray tracing model. Use the image method and calculate paths with up to one reflection. Then, display the propagation paths.

```
pm = propagationModel("raytracing", "Method", "image", ...  
    "MaxNumReflections", 1);  
raytrace(tx, rx, pm)
```

For this ray tracing model, there is one propagation path from the transmitter to the receiver.

Update the ray tracing model to use the SBR method and to calculate paths with up to two reflections. Display the propagation paths.

```
pm.Method = "sbr";  
pm.MaxNumReflections = 2;  
clearMap(viewer)  
raytrace(tx, rx, pm)
```

The updated ray tracing model shows three propagation paths from the transmitter to the receiver.

Appendix

[1] The osm file is downloaded from <https://www.openstreetmap.org>, which provides access to crowd-sourced map data all over the world. The data is licensed under the Open Data Commons Open Database License (ODbL), <https://opendatacommons.org/licenses/odbl/>.

Model Coverage Using Ray Tracing

Create a Site Viewer with buildings in Chicago. For more information about the .osm file, see [1] on page 3-0 .

```
viewer = siteviewer("Buildings","chicago.osm");
```

Create a transmitter site on a building and a receiver site near another building.

```
tx = txsite("Latitude",41.8800, ...
           "Longitude",-87.6295, ...
           "TransmitterFrequency",2.5e9);
show(tx)
```

Create a ray tracing model. By default, ray tracing models use the SBR method. Set the maximum number of reflections to 2. Then, display the coverage map.

```
pm = propagationModel("raytracing","Method","sbr", ...
                     "MaxNumReflections",2);
coverage(tx,pm,"SignalStrengths",-100:5)
```

Appendix

[1] The .osm file is downloaded from <https://www.openstreetmap.org>, which provides access to crowd-sourced map data all over the world. The data is licensed under the Open Data Commons Open Database License (ODbL), <https://opendatacommons.org/licenses/odbl/>.

More About

Shooting and Bouncing Rays Method

The shooting and bouncing rays (SBR) method supports calculation of approximate propagation paths for up to 10 path reflections. The locations of receiver sites calculated by the SBR method are not exact. The accuracy of the calculated propagation paths decreases as the length of the paths increases.

Computational complexity increases linearly with the number of reflections. As a result, the SBR method is generally faster than the image method.

This figure illustrates the SBR method for calculating propagation paths from a transmitter, T_x , to a receiver, R_x .

The SBR method launches many rays from a geodesic sphere centered at Tx . The geodesic sphere enables the model to launch rays that are approximately uniformly spaced.

Then, the method traces every ray from Tx and can model different types of interactions between the rays and surrounding objects, such as reflections, diffractions, refractions, and scattering. Note that the implementation considers only reflections.

- When a ray hits a flat surface, shown as R , the ray reflects based on the law of reflection.
- When a ray hits an edge, shown as D , the ray spawns many diffracted rays based on the law of diffraction [5][6]. Each diffracted ray has the same angle with the diffracting (sharp) edge as the incident ray. The diffraction point then becomes a new launching point and the SBR method traces the diffracted rays in the same way as the rays launched from Tx . A continuum of diffracted rays forms a cone around the diffracting edge, which is commonly known as a Keller cone [6]. The current implementation of the SBR method does not consider diffractions.

For each launched ray, the method surrounds Rx with a sphere, called a reception sphere, with a radius that is proportional to the angular separation of the launched rays and the distance the ray travels. If the ray intersects the sphere, then the model considers the ray a valid path from Tx to Rx .

Image Method

The image method supports up to two path reflections and calculates exact propagation paths. Computational complexity increases exponentially with the number of reflections.

This figure illustrates the image method for calculating the propagation path of a single reflection ray for the same transmitter and receiver as the SBR method. The image method locates the image of Tx with respect to a planar reflection surface, Tx' . Then, the method connects Tx' and Rx with a line segment. If the line segment intersects the planar reflection surface, shown as R in the figure, then a valid path from Tx to Rx exists. The method determines paths with multiple reflections by recursively extending these steps.

ITU Permittivity and Conductivity Values for Common Materials

ITU-R P.2040-1 [3] and ITU-R P.527-5 [4] present methods, equations, and values used to calculate real relative permittivity, conductivity, and complex relative permittivity for common materials.

- For information about the values computed for building materials specified in ITU-R P.2040-1, see `buildingMaterialPermittivity`.
- For information about the values computed for terrain materials specified in ITU-R P.527-5, see `earthSurfacePermittivity`.

Compatibility Considerations

Default modeling method is shooting and bouncing rays method

Behavior changed in R2021b

Starting in R2021b, when you create a propagation model using the syntax `propagationModel('raytracing')`, MATLAB returns a `RayTracing` model with the `Method` value set to `'sbr'` and two reflections (instead of `'image'` and one reflection, as in previous releases).

To create ray tracing propagation models that use the image method, use the syntax `propagationModel('raytracing','Method','image')`.

propagationData

Create RF propagation data from measurements

Description

Use the `propagationData` object to import and visualize geolocated propagation data. The measurement data can be path loss data, signal strength measurements, signal-to-noise-ratio (SNR) data, or cellular information.

Creation

Syntax

```
pd = propagationData(filename)
pd = propagationData(table)

pd = propagationData(latitude,longitude,varname,varvalue)
pd = propagationData( __ ,Name,Value)
```

Description

`pd = propagationData(filename)` creates a propagation data object by reading data from a file specified by `filename`.

`pd = propagationData(table)` creates a propagation data container object from a table object specified by `table`.

`pd = propagationData(latitude,longitude,varname,varvalue)` creates a propagation data container object using `latitude` and `longitude` coordinates with data specified using `varname` and `varvalue`.

`pd = propagationData(__ ,Name,Value)` sets properties using one or more name-value pairs. Enclose each property name in quotes.

Input Arguments

filename — Name of file containing propagation data

character vector | string scalar

Name of the file containing propagation data, specified as a character vector or a string scalar. The file must be in the current directory, in a directory on the MATLAB path, or be specified using a full or relative path. The file must be compatible with the `readtable` function. Call the `readtable` function if customized parameters are required to import the file and then pass the `table` object to the `propagationData` object.

Propagation data in the file must have one variable corresponding to the latitude values, one variable corresponding to longitude values, and at least one variable containing numeric data.

Data Types: `string` | `char`

table — Table containing propagation data

table object

Table containing propagation data, specified as a table object.

Propagation data in the file must have one variable corresponding to the latitude values, one variable corresponding to longitude values, and at least one variable containing numeric data.

Data Types: table

latitude — Latitude coordinate values

vector

Latitude coordinate values, specified as a vector in decimal degrees with reference to Earth's ellipsoid model WGS-84. The latitude coordinates must be in the range [-90 90].

Data Types: double

longitude — Longitude coordinate values

vector

Longitude coordinate values, specified as a vector in decimal degrees with reference to earth's ellipsoid. model WGS-84.

Data Types: double

varname — Variable name

character vector | string scalar

Variable name, specified as a character vector or a string scalar. This variable name must correspond to the variable with numeric data other than latitude or longitude. The variable name and the corresponding values are stored as a column in the Data property table object.

Data Types: string | char

varvalue — Variable values

numeric vector

Variable values, specified as a numeric vector. The numeric vectors must be the same size as latitude and longitude. The variable name and corresponding values are stored as a column in the Data property table object.

Data Types: double

Output Arguments**pd — Propagation data**

propagationData object

Propagation data, returned as a propagationData object.

Properties**Name — Propagation data name**

'Propagation Data' (default) | character vector | string scalar

Propagation data name, specified as a character vector or string scalar.

Example: 'Name', 'propdata'

Example: pd.Name = 'propdata'

Data Types: char | string

Data — Propagation data table

scalar table object

This property is read-only.

Propagation data table, specified as a scalar table object containing a column corresponding to latitude coordinates, a column corresponding to longitude coordinates, and one or more columns corresponding to associated propagation data.

Data Types: table

DataVariableName — Name of data variable to plot

character vector | string scalar

Name of the data variable to plot, specified as a character vector or string scalar corresponding to a variable name in the **Data** table used to create propagation data container object. The variable name must correspond to a variable with numeric data and cannot correspond to the latitude or longitude variables. The default value for this property is the name of the first numeric data variable name in the **Data** table that is not a latitude or longitude variable.

Data Types: char | string

Object Functions

plot	Display RF propagation data in Site Viewer
contour	Display contour map of RF propagation data in Site Viewer
location	Coordinates of RF propagation data
getDataVariable	Get data variable values
interp	Interpolate RF propagation data

Examples

Compute Signal Strength Data in Urban Environment

Launch Site Viewer with basemaps and building files for Manhattan. For more information about the osm file, see [1] on page 3-0 .

```
viewer = siteviewer("Basemap","streets_dark",...  
    "Buildings","manhattan.osm");
```

Show a transmitter site on a building.

```
tx = txsite("Latitude",40.7107,...  
           "Longitude",-74.0114,...  
           "AntennaHeight",80);  
show(tx)
```

Create receiver sites along nearby streets.

```
latitude = [linspace(40.7088, 40.71416, 50), ...
            linspace(40.71416, 40.715505, 25), ...
            linspace(40.715505, 40.7133, 25), ...
            linspace(40.7133, 40.7143, 25)]';
longitude = [linspace(-74.0108, -74.00627, 50), ...
             linspace(-74.00627, -74.0092, 25), ...
             linspace(-74.0092, -74.0110, 25), ...
             linspace(-74.0110, -74.0132, 25)]';
rxs = rxsite("Latitude", latitude, "Longitude", longitude);
```

Compute signal strength at each receiver location.

```
signalStrength = sigstrength(rxs, tx)';
```

Create a `propagationData` object to hold computed signal strength data.

```
tbl = table(latitude, longitude, signalStrength);
pd = propagationData(tbl);
```

Plot the signal strength data on a map as colored points.

```
legendTitle = "Signal" + newline + "Strength" + newline + "(dB)";
plot(pd, "LegendTitle", legendTitle, "Colormap", parula);
```

Appendix

[1] The osm file is downloaded from <https://www.openstreetmap.org>, which provides access to crowd-sourced map data all over the world. The data is licensed under the Open Data Commons Open Database License (ODbL), <https://opendatacommons.org/licenses/odbl/>.

Capacity Map Using SINR Data

Define names and locations of sites around Boston.

```
names = ["Fenway Park", "Faneuil Hall", "Bunker Hill Monument"];
lats = [42.3467, 42.3598, 42.3763];
lons = [-71.0972, -71.0545, -71.0611];
```

Create an array of transmitter sites.

```
txs = txsite("Name", names, ...
            "Latitude", lats, ...
            "Longitude", lons, ...
            "TransmitterFrequency", 2.5e9);
show(txs)
```

Create a signal-to-interference-plus-noise-ratio (SINR) map, where signal source for each location is selected as the transmitter site with the strongest signal.

```
sv1 = siteviewer("Name", "SINR map");  
sincr(txs, "MaxRange", 5000)
```

Return SINR propagation data.

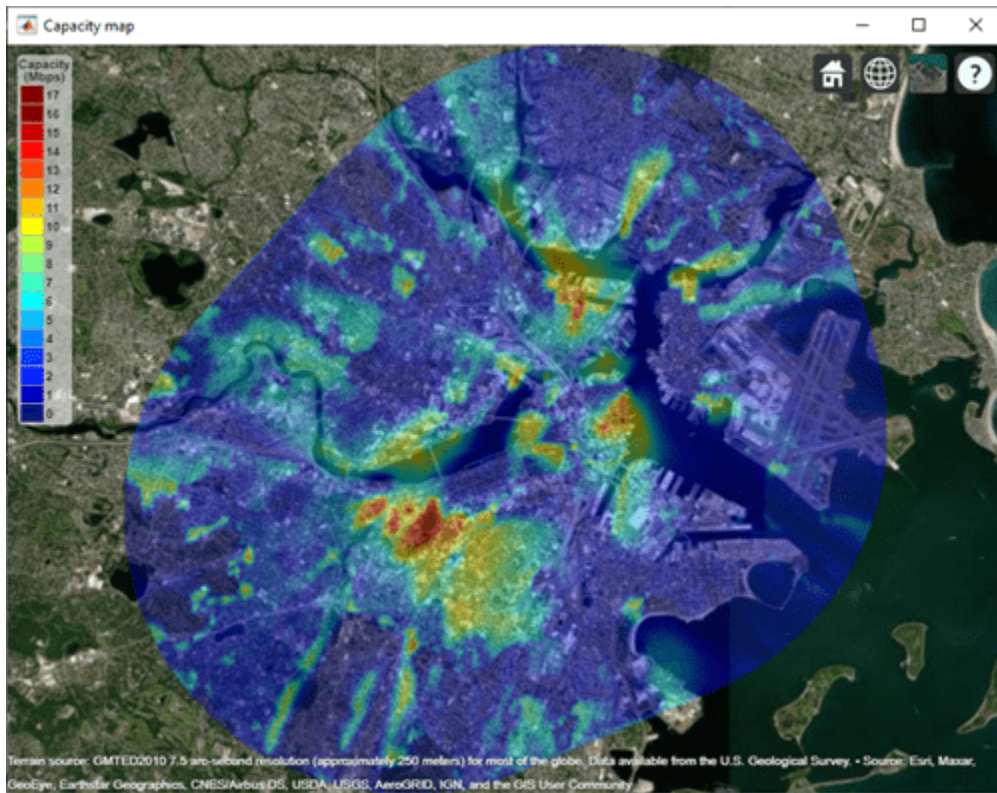

```
pd = sinr(txs,"MaxRange",5000);
[sinrDb,lats,lons] = getDataVariable(pd,"SINR");
```

Compute capacity using the Shannon-Hartley theorem.

```
bw = 1e6; % Bandwidth is 1 MHz
sinrRatio = 10.^(sinrDb./10); % Convert from dB to power ratio
capacity = bw*log2(1+sinrRatio)/1e6; % Unit: Mbps
```

Create new propagation data for the capacity map and display the contour plot.

```
pdCapacity = propagationData(lats,lons,"Capacity",capacity);
sv2 = siteviewer("Name","Capacity map");
legendTitle = "Capacity" + newline + "(Mbps)";
contour(pdCapacity,"LegendTitle",legendTitle);
```

Introduced in R2020a

comm.Ray

Create RF propagation ray

Description

The `comm.Ray` object is a container object for the properties of a propagation ray. The object contains the geometric and electromagnetic information of a radio wave propagating from one point to another point in the space.

Creation

Typically you create `comm.Ray` objects by using the `raytrace` function.

Syntax

```
ray = comm.Ray
ray = comm.Ray(Name, Value)
```

Description

`ray = comm.Ray` creates a ray object that initializes properties for a propagation ray.

`ray = comm.Ray(Name, Value)` sets properties using one or more name-value pair arguments. Enclose each property name in quotes. For example, `comm.Ray('CoordinateSystem', 'Geographic', 'TransmitterLocation', [40.730610, -73.935242, 0])` specifies the geographic coordinate system and a transmitter located in New York City.

Properties

PathSpecification — Propagation path specification method

'Locations' (default) | 'Delay and angles'

Propagation path specification method, specified as one of these values.

- 'Locations' — The ray object path between waypoints are conveyed as (x, y, z) coordinate points by the `TransmitterLocation`, `ReceiverLocation`, and, if applicable, `ReflectorLocations` properties.
- 'Delay and angles' — The ray object path between waypoints are conveyed by the `PropagationDelay`, `AngleOfDeparture`, and `AngleOfArrival` properties.

Data Types: `char` | `string`

CoordinateSystem — Coordinate system

'Cartesian' (default) | 'Geographic'

Coordinate system, specified as 'Cartesian' or 'Geographic'. When you set the `CoordinateSystem` property to 'Geographic', the coordinate system is defined relative to the

WGS-84 Earth ellipsoid model and the object defines angles relative to the local East-North-Up (ENU) coordinate system at the transmitter and receiver.

Dependencies

To enable this property, set the `PathSpecification` property to `'Locations'`.

Data Types: `char` | `string`

SystemScale — Cartesian coordinate system scale

1 (default) | positive scalar

Cartesian coordinate system scale in meters, specified as a positive scalar.

Dependencies

To enable this property, set the `PathSpecification` property to `'Locations'` and the `CoordinateSystem` property to `'Cartesian'`.

Data Types: `double`

TransmitterLocation — Transmitter location

[0;0;0] (default) | three-element numeric column vector

Transmitter location, specified as a three-element numeric column vector of coordinates in one of these forms.

- `[x; y; z]` — This form applies when you set the `CoordinateSystem` property to `'Cartesian'`. The object does not perform range validation for `x`, `y`, and `z`.
- `[latitude; longitude; height]` — This form applies when you set the `CoordinateSystem` property to `'Geographic'`. `latitude` must be in the range `[-90, 90]`. The object does not perform range validation for `longitude` and `height`. `height` is referenced to the ellipsoid defined by the World Geodetic System of 1984 (WGS84).

Dependencies

To enable this property, set the `PathSpecification` property to `'Locations'`.

Data Types: `double`

ReceiverLocation — Receiver location

[10;10;10] (default) | three-element numeric column vector

Receiver location, specified as a three-element numeric column vector of coordinates in one of these forms.

- `[x; y; z]` — This form applies when you set the `CoordinateSystem` property to `'Cartesian'`. The object does not perform range validation for `x`, `y`, and `z`.
- `[latitude; longitude; height]` — This form applies when you set the `CoordinateSystem` property to `'Geographic'`. `latitude` must be in the range `[-90, 90]`. The object does not perform range validation for `longitude` and `height`. `height` is referenced to the ellipsoid defined by the World Geodetic System of 1984 (WGS84).

Dependencies

To enable this property, set the `PathSpecification` property to `'Locations'`.

Data Types: `double`

LineOfSight – Line of sight

true or 1 (default) | false or 0

Line of sight, specified as a logical value of 1 (true) or 0 (false) to indicate whether the ray is a line-of-sight ray.

Dependencies

To enable this property, set the PathSpecification property to 'Locations'.

Data Types: logical

Interactions – Ray-surface interactions1-by- N_I structure

Ray-surface interactions along the propagation path, specified as a 1-by- N_I structure containing these fields. N_I is the number of interactions.

Type – Type of ray-surface interaction

'Reflection' (default) | 'Diffraction'

Type of ray-surface interaction, specified as 'Reflection' or 'Diffraction'.

Data Types: char | string

Location – Location

[10;10;0] (default) | 3-by-1 numeric vector

Location, specified as a 3-by-1 numeric vector containing the coordinates of one interaction point on the ray.

- When the CoordinateSystem property is set to 'Cartesian', the form is [x; y; z]. The object does not perform range validation for x, y, and z.
- When the CoordinateSystem property is set to 'Geographic', the form is [latitude; longitude; height]. The latitude must be in the range [-90, 90]. The object does not perform range validation for longitude and height. height is referenced to the ellipsoid defined by the World Geodetic System of 1984 (WGS84).

Data Types: double

Dependencies

To enable this property, set the PathSpecification property to 'Locations' and the LineOfSight property to 0 (false).

Data Types: struct

PropagationDelay – Propagation delay

5.7775e-08 | nonnegative scalar

Propagation delay in seconds, specified as a nonnegative scalar. The default value is computed using the default values of the TransmitterLocation and ReceiverLocation properties for a line-of-sight ray.

- When you set the PathSpecification property to 'Locations', this property is read-only and the value is derived from TransmitterLocation, ReceiverLocation and, if applicable, the Interactions.

- When you set the `PathSpecification` property to 'Delay and angles', this property is configurable.

Data Types: double

PropagationDistance — Propagation distance

17.3205 | nonnegative scalar

This property is read-only.

Propagation distance in meters, specified as a nonnegative scalar. The default value is computed using the default values of the `TransmitterLocation` and `ReceiverLocation` properties for a line-of-sight ray.

- When you set the `PathSpecification` property to 'Locations', the value is derived from `TransmitterLocation`, `ReceiverLocation` and, if applicable, the `Interactions`.
- When you set the `PathSpecification` property to 'Delay and angles', the value is derived from `PropagationDelay`.

Data Types: double

AngleOfDeparture — Angle of departure

[45; 35.2644] | numeric vector of the form [az; el]

Angle of departure in degrees of the ray at the transmitter, specified as a numeric vector of the form [az; el]. The azimuth angle, *az*, is measured from the positive x-axis counterclockwise and must be in the range (-180, 180]. The elevation angle, *el*, is measured from the x-y plane and must be in the range [-90, 90]. The default value is computed using the default values of the `TransmitterLocation` and `ReceiverLocation` properties for a line-of-sight ray.

- When you set the `PathSpecification` property to 'Delay and angles', this property is configurable.
- When you set the `PathSpecification` property to 'Locations', this property is read-only and the value is derived from `TransmitterLocation`, `ReceiverLocation` and, if applicable, the `Interactions`.
- When `CoordinateSystem` is set to 'Geographic', the angles are defined with reference to the local East-North-Up (ENU) coordinate system at transmitter.

Data Types: double

AngleOfArrival — Angle of arrival

[-135; -35.2644] | numeric vector of the form [az; el]

Angle of arrival in degrees of the ray at the receiver, specified as a numeric vector of the form [az; el]. The azimuth angle, *az*, is measured from the positive x-axis counterclockwise and must be in the range (-180, 180]. The elevation angle, *el*, is measured from the x-y plane and must be in the range [-90, 90]. The default value is computed using the default values of the `TransmitterLocation` and `ReceiverLocation` properties for a line-of-sight ray.

- When you set the `PathSpecification` property to 'Delay and angles', this property is configurable.
- When you set the `PathSpecification` property to 'Locations', this property is read-only and the value is derived from `TransmitterLocation`, `ReceiverLocation` and, if applicable, the `Interactions`.

- When `CoordinateSystem` is set to 'Geographic', the angles are defined with reference to the local East-North-Up (ENU) coordinate system at receiver.

Data Types: double

NumInteractions — Number of ray-surface interactions

0 (default) | nonnegative integer

This property is read-only.

Number of ray-surface interactions for the ray object from the transmitter to the receiver, specified as a nonnegative integer. The value is derived from `LineOfSight` and, if applicable, the `Interactions`.

Dependencies

To enable this property, set the `PathSpecification` property to 'Locations'.

Data Types: double

Frequency — Signal frequency

1.9e+09 (default) | positive scalar

Signal frequency in Hz, specified as a positive scalar.

Data Types: double

PathLossSource — Path loss source

'Free space model' (default) | 'Custom'

Path loss source, specified as 'Free space model' or 'Custom'.

Data Types: char | string

PathLoss — Path loss

62.7941 | nonnegative scalar

Path loss in dB, specified as a nonnegative scalar. The default value is computed using the default values of the `TransmitterLocation` and `ReceiverLocation` properties for a line-of-sight ray.

- When you set the `PathLossSource` property to 'Free space model', the `PathLoss` property is read-only and derived from the `PropagationDistance` and `Frequency` properties by using the free space propagation model.
- When you set the `PathLossSource` property to 'Custom', you can set the `PathLoss` property, independent of the geometric properties.

Data Types: double

PhaseShift — Phase shift

4.8537 | numeric scalar

Phase shift in radians, specified as a numeric scalar. The default value is computed using the default values of the `TransmitterLocation` and `ReceiverLocation` properties for a line-of-sight ray.

- When you set the `PathLossSource` property to 'Free space model', the `PhaseShift` property is read-only and derived from the `PropagationDistance` and `Frequency` properties by using the free space propagation model.

- When you set the PathLossSource property to 'Custom', you can set the PhaseShift property, independent of the geometric properties.

Data Types: double

Object Functions

plot (rays) Display RF propagation rays in Site Viewer

Examples

Perform Ray Tracing Between Two Sites in Hong Kong

Perform ray tracing between two sites in Hong Kong, generating a cell array containing comm.Ray objects. The comm.Ray objects contain the geometric and electromagnetic information for the radio wave propagation paths from the transmitter site to the receiver site.

Create a Site Viewer map, loading building data for Hong Kong. For more information about the osm file, see [1] on page 3-0 .

```
viewer = siteviewer('Buildings','hongkong.osm');
```

Specify transmitter and receiver sites.

```
tx = txsite('Latitude',22.2789,'Longitude',114.1625, ...  
           'AntennaHeight',10,'TransmitterPower',5, ...  
           'TransmitterFrequency',28e9);  
rx = rxsite('Latitude',22.2799,'Longitude',114.1617, ...
```

```

    'AntennaHeight',1);
show(tx);
show(rx);

```

Specify a ray tracing propagation model that uses the SBR method with up to three reflections.

```

pm = propagationModel('raytracing', ...
    'Method','sbr', ...
    'MaxNumReflections',3);

```

Perform ray tracing between the sites, generating `comm.Ray` objects in a cell array. For the specified transmitter and receiver sites, performing ray tracing results in a 1-by-1 cell array containing three ray objects in a row vector.

```

rays = raytrace(tx,rx,pm)

rays = 1x1 cell array
      {1x13 comm.Ray}

```

Display the properties of the first `comm.Ray` object. The `LineOfSight` property value is 1, and the `NumInteractions` property value is 0. This combination indicates that the ray defines a line-of-sight path.

```

rays{1}(1)

ans =
    Ray with properties:

        PathSpecification: 'Locations'
        CoordinateSystem: 'Geographic'
    TransmitterLocation: [3x1 double]
    ReceiverLocation: [3x1 double]
        LineOfSight: 1
        Frequency: 2.8000e+10
    PathLossSource: 'Custom'
        PathLoss: 104.2656
        PhaseShift: 4.6406

    Read-only properties:
    PropagationDelay: 4.6442e-07
    PropagationDistance: 139.2294
    AngleOfDeparture: [2x1 double]
    AngleOfArrival: [2x1 double]
    NumInteractions: 0

```

Display the properties of the second and third `comm.Ray` objects. The `LineOfSight` property values are 0, and the `NumInteractions` property values are greater than 0. This combination indicates that the rays define reflected paths.

```

rays{1}(2)

ans =
    Ray with properties:

        PathSpecification: 'Locations'
        CoordinateSystem: 'Geographic'

```

```
TransmitterLocation: [3×1 double]
ReceiverLocation: [3×1 double]
LineOfSight: 0
Interactions: [1×1 struct]
    Frequency: 2.8000e+10
    PathLossSource: 'Custom'
    PathLoss: 106.2236
    PhaseShift: 0.0788
```

```
Read-only properties:
    PropagationDelay: 4.6492e-07
    PropagationDistance: 139.3787
    AngleOfDeparture: [2×1 double]
    AngleOfArrival: [2×1 double]
    NumInteractions: 1
```

`rays{1}(3)`

`ans =`

Ray with properties:

```
PathSpecification: 'Locations'
CoordinateSystem: 'Geographic'
TransmitterLocation: [3×1 double]
ReceiverLocation: [3×1 double]
LineOfSight: 0
Interactions: [1×1 struct]
    Frequency: 2.8000e+10
    PathLossSource: 'Custom'
    PathLoss: 120.0733
    PhaseShift: 4.9316
```

```
Read-only properties:
    PropagationDelay: 1.1327e-06
    PropagationDistance: 339.5744
    AngleOfDeparture: [2×1 double]
    AngleOfArrival: [2×1 double]
    NumInteractions: 1
```

Visualize ray tracing results.

```
plot(rays{1});
```

Appendix

[1] The osm file is downloaded from <https://www.openstreetmap.org>, which provides access to crowd-sourced map data all over the world. The data is licensed under the Open Data Commons Open Database License (ODbL), <https://opendatacommons.org/licenses/odbl/>.

Plot Propagation Rays Between Sites in Chicago

Return ray tracing results in `comm.Ray` objects and plot the ray propagation paths after relaunching the Site Viewer map.

Create a Site Viewer map, loading building data for Chicago. For more information about the osm file, see [1] on page 3-0 .

```
viewer = siteviewer('Buildings', 'chicago.osm');
```

Create a transmitter site on one building and a receiver site on another building. Use the `los` function to show the line of sight path between the transmitter and receiver sites.

```
tx = txsite( ...  
    'Latitude',41.8800, ...  
    'Longitude',-87.6295, ...  
    'TransmitterFrequency',2.5e9);  
rx = rxsite( ...  
    'Latitude',41.881352, ...  
    'Longitude',-87.629771, ...  
    'AntennaHeight',30);  
los(tx,rx);
```

Perform ray tracing for up to two reflections. For the configuration defined, ray tracing returns a cell array containing the ray objects. Close the Site Viewer map.

```
pm = propagationModel( ...
    'raytracing', ...
    'Method','sbr', ...
    'MaxNumReflections',2);
rays = raytrace(tx,rx,pm)

rays = 1x1 cell array
    {1x3 comm.Ray}

rays{1}(1,1)

ans =
    Ray with properties:
        PathSpecification: 'Locations'
        CoordinateSystem: 'Geographic'
        TransmitterLocation: [3x1 double]
        ReceiverLocation: [3x1 double]
        LineOfSight: 0
        Interactions: [1x1 struct]
            Frequency: 2.5000e+09
            PathLossSource: 'Custom'
            PathLoss: 94.1067
            PhaseShift: 1.1472

    Read-only properties:
```

```
PropagationDelay: 5.7089e-07
PropagationDistance: 171.1479
AngleOfDeparture: [2×1 double]
AngleOfArrival: [2×1 double]
NumInteractions: 1
```

```
rays{1}(1,2)
```

```
ans =
```

```
Ray with properties:
```

```
PathSpecification: 'Locations'

PathLossSource: 'Custom'
PathLoss: 101.8769
PhaseShift: 2.8594
```

```
Read-only properties:
```

```
PropagationDelay: 5.9279e-07
PropagationDistance: 177.7143
AngleOfDeparture: [2×1 double]
AngleOfArrival: [2×1 double]
NumInteractions: 2
```

```
rays{1}(1,3)
```

```
ans =
```

```
Ray with properties:
```

```
PathSpecification: 'Locations'
CoordinateSystem: 'Geographic'
TransmitterLocation: [3×1 double]
ReceiverLocation: [3×1 double]
LineOfSight: 0
Interactions: [1×2 struct]
Frequency: 2.5000e+09
PathLossSource: 'Custom'
PathLoss: 99.1597
PhaseShift: 4.6635
```

```
Read-only properties:
```

```
PropagationDelay: 6.3790e-07
PropagationDistance: 191.2388
AngleOfDeparture: [2×1 double]
AngleOfArrival: [2×1 double]
NumInteractions: 2
```

```
close(viewer);
```

You can plot the rays without performing ray tracing again. Create another Site Viewer map with the same buildings. Show the transmitter and receiver sites. Using the previously returned cell array of

ray objects, plot the reflected rays between the transmitter site and the receiver site. The plot function can plot the path for ray objects collectively or individually. For example, to plot rays for the only second ray object, specify rays{1}(1,2). This figure plot all paths for all the ray objects.

```
siteviewer('Buildings', 'chicago.osm');
los(tx,rx);
plot(rays{:}, 'Type', 'power', ...
      'TransmitterSite', tx, 'ReceiverSite', rx);
```

Appendix

[1] The osm file is downloaded from <https://www.openstreetmap.org>, which provides access to crowd-sourced map data all over the world. The data is licensed under the Open Data Commons Open Database License (ODbL), <https://opendatacommons.org/licenses/odbl/>.

Compatibility Considerations

ReflectionLocations and NumReflections properties have been removed

Errors starting in R2021b

The ReflectionLocations and NumReflections properties have been removed. To accommodate reflections, use the Interactions property to replace the ReflectionLocations property and use the NumInteractions property to replace the NumReflections property.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Topics

“Choose a Propagation Model”

Introduced in R2020a

tdmsDatastore

Datastore for collection of TDMS-files

Description

Use the `TDMSDatastore` object to access data from a collection of TDMS-files.

Creation

Syntax

```
tdmsds = tdmsDatastore(location)
tdmsds = tdmsDatastore(__,Name=Value)
```

Description

`tdmsds = tdmsDatastore(location)` creates a `TDMSDatastore` object based on a TDMS-file or a collection of files in the folder specified by `location`. Within the folder, all files with the extension `.tdms` are included in the datastore.

`tdmsds = tdmsDatastore(__,Name=Value)` specifies function options and properties of `tdmsds` using optional name-value pairs.

Input Arguments

location — Location of TDMS datastore files

string | character vector | cell array

Location of TDMS datastore files, specified as a string, character vector, or cell array identifying either files or folders. The path can be relative or absolute, and can contain the wildcard characters `?` and `*`. If `location` specifies a folder, the datastore includes all files in that folder with the extension `.tdms`.

Example: `"C:\data\tdms_set1"`

Data Types: `char` | `string` | `cell`

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1, ..., NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

You can specify file information or object "Properties" on page 3-1486. Allowed options are `IncludeSubfolders`, `AlternateFileSystemRoots`, and the properties `SelectedChannelGroup`, `SelectedChannels`, `RowTimes`, and `ReadSize`.

Example: `SelectedChannelGroup="Acceleration"`

IncludeSubfolders — Include files in subfolders

false (default) | true

Include files in subfolders, specified as a logical. Specify `true` to include files in each folder and recursively in subfolders.

Example: `IncludeSubfolders=true`

Data Types: `logical`

AlternateFileSystemRoots — Root paths for different platforms

string array | cell array

Root paths to the TDMS-files for different platforms, specified as an array of strings.

Example: `AlternateFileSystemRoots=["Z:\datasets", "/tdms/datasets"]`

Data Types: `char` | `string` | `cell`

Properties**Files — Files included in datastore**

char | string | cell

This property is read-only.

Files included in the datastore, specified as a character vector or string identifying a relative or absolute path to a file or folder. The wildcard characters `?` and `*` are supported. All TDMS-files in the specified folder are included in the datastore. The property value is stored as a string vector of file names.

Example: `"file*.tdms"`

Data Types: `char` | `string`

ChannelList — All channels present in first TDMS-file

table

This property is read-only.

All channels present in first TDMS-file, returned as a table.

Those channels targeted for reading must have the same name and belong to the same channel group in each file of the TDMS datastore.

Data Types: `table`

SelectedChannelGroup — Channel group containing the channels to read from

string | char

Channel group containing the channels to read from, specified as a string or character vector.

Example: `"Torque"`

Data Types: `string` | `char`

SelectedChannels — Names of channels to read

char | string | cell

Names of channels to read, specified as a character vector, string, or array of either. The channels must be in the channel group specified by `SelectedChannelGroup` in each file of the TDMS datastore.

Example: `["Torque1" "Torque2"]`

Data Types: `char` | `string` | `cell`

RowTimes — Times associated with rows of table

`datetime` | `duration` | `channel name`

Times associated with rows of the table, specified as a selected time channel name, a `datetime` vector, or a `duration` vector. Setting this property causes the `read` and `readall` functions to output a cell array of timetables. Each time element labels a row in the output timetable.

Example: `duration(seconds([1:1000]/1000))`

Data Types: `datetime` | `duration` | `string`

ReadSize — Size of data returned by read

`20000` (default) | `numeric` | `"file"`

Size of data returned by the `read` function, specified as `"file"` or a numeric value. A string value of `"file"` causes a read of one TDMS-file at a time; a numeric value specifies the number of records to read. The `readall` function ignores this property.

If you change the `ReadSize` property value after creating the `TDMSDatastore` object, the datastore resets.

Example: `5000`

Data Types: `double` | `string` | `char`

Object Functions

<code>read</code>	Read data in TDMS datastore
<code>readall</code>	Read all data in TDMS datastore
<code>preview</code>	Read first 8 records from TDMS datastore
<code>hasdata</code>	Determine if data is available to read from TDMS datastore
<code>reset</code>	Reset TDMS datastore to initial state
<code>combine</code>	Combine data from multiple datastores
<code>transform</code>	Transform datastore

Examples

Read Data from a TDMS Datastore

Create a TDMS datastore from all the TDMS-files in the folder `C:\data\tdms`, and read the data into tables.

Set up the datastore and view its channel list.

```
td = tdmsDatastore("C:\data\tdms");
td.ChannelList(:,1:4)
```

```
ans =
```

6x4 table

ChannelGroupNumber	ChannelGroupName	ChannelGroupDescription	ChannelName
1	"Acceleration"	"CGAcceleration"	"Acceleration1"
1	"Acceleration"	"CGAcceleration"	"Acceleration2"
2	"Force"	"CGForce"	"Force1"
2	"Force"	"CGForce"	"Force2"
3	"Torque"	"CGTorque"	"Torque1"
3	"Torque"	"CGTorque"	"Torque2"

Read all available data.

```
td.SelectedChannelGroup = "Force"
data_set = readall(td)
```

data_set =

1x3 cell array

```
{9936x2 table} {9936x2 table} {9936x2 table}
```

View the data from the first channel group.

```
data_set{1}
```

ans =

9936x2 table

Acceleration1	Acceleration2
-1.9851	0
-3.9702	0
11.911	1.5521
5.9553	-1.5521
1.9851	-4.6562
5.9553	4.6562
3.9702	-1.5521
3.9702	-4.6562
13.896	0
:	:
-4.8046	-2.2609
-4.8046	6.7826
-7.2068	2.2609
-7.2068	4.5218
-7.2068	6.7826
-2.4023	9.0435
-2.4023	4.5218
-9.6091	2.2609
-12.011	4.5218

Display all 9936 rows.

Read all available data for the channel group Force.

```
td.SelectedChannelGroup = "Force";
data_set = readall(td)
```

```
data_set =  
    1×1 cell array  
    {9936×2 table}
```

Read 500 entries of data.

```
td.ReadSize = 500;  
data_set = read(td)
```

```
data_set =  
    1×1 cell array  
    {500×2 table}
```

Limitations

- TDMS functions are supported on Windows platforms only.
- As a special case of a datastore, the `TDMSDatastore` object does not support the following functionality:
 - Partitioning for parallel computing
 - Shuffling

The NI TDMS File Format

Introduced in R2022a

Object Functions

info

Package: comm

Characteristic information about baseband file reader

Syntax

```
S = info(bbr)
```

Description

`S = info(bbr)` returns a structure containing characteristic information about the specified baseband file reader.

Examples

Display Baseband File Reader Characteristic Information

Configure a baseband file reader object to read the `baseband_samples_1ghz.bb` baseband signal file. Then read the characteristic information of the baseband file reader by using the `info` object function.

```
bbr = comm.BasebandFileReader('baseband_samples_1ghz.bb');  
info(bbr)
```

```
ans = struct with fields:  
    NumSamplesInData: 10000  
        DataType: 'double'  
    NumSamplesRead: 0
```

Release the baseband file reader object and reconfigure the object to read the `ais_capture.bb` baseband signal file. Then, read the characteristic information about the reconfigured baseband file reader object by using the `info` object function.

```
release(bbr)  
bbr = comm.BasebandFileReader('ais_capture.bb');  
info(bbr)
```

```
ans = struct with fields:  
    NumSamplesInData: 262144  
        DataType: 'single'  
    NumSamplesRead: 0
```

Input Arguments

bbr — Baseband file reader

`comm.BasebandFileReader` System object

Baseband file reader, specified as a `comm.BasebandFileReader` System object.

Output Arguments

S — Characteristic information about baseband file reader

structure

Characteristic information about the baseband file reader, returned as a structure containing these fields.

NumSamplesInData — Total number of baseband data samples

positive integer

Total number of baseband data samples in the file, returned as a positive integer.

Data Types: double

Data Type — Data type of baseband signal

'double' | 'single' | 'uint8' | 'uint16' | 'uint32' | 'uint64' | 'int8' | 'int16' | 'int32' | 'int64'

Data type of the baseband signal in the file, returned as 'double', 'single', 'uint8', 'uint16', 'uint32', 'uint64', 'int8', 'int16', 'int32', or 'int64'.

NumSamplesRead — Number of samples read

nonnegative integer

Number of samples read from the file, returned as a nonnegative integer. The returned value does not exceed the value of the `NumSamplesInData` property of the baseband file reader when the `CyclicRepetition` property in that object is `false`.

Data Types: double

Functions

`info`

Introduced in R2016b

info

Package: comm

Characteristic information about baseband file writer

Syntax

```
S = info(bbw)
```

Description

`S = info(bbw)` returns a structure containing characteristic information about the specified baseband file writer.

Note All fields are determined and viewable after the object is run and locked. When the object is unlocked, only the `Filename` and `NumSamplesWritten` fields are available and viewable.

Examples

Write Baseband Signal to File

Create a baseband file writer object specifying a sample rate of 1 kHz and a 0 Hz center frequency.

```
bbw = comm.BasebandFileWriter('baseband_data.bb',1000,0);
```

Save the date for today in the `Metadata` structure.

```
bbw.Metadata = struct('Date',date);
```

Generate two channels of QPSK-modulated data.

```
d = randi([0 3],1000,2);  
x = pskmod(d,4,pi/4,'gray');
```

Write the baseband data to file `baseband_data.bb`.

```
bbw(x)
```

Display information about the baseband file writer. Then, release the object.

```
info(bbw)
```

```
ans = struct with fields:  
    Filename: 'C:\TEMP\Bdoc22a_1891349_13144\ibC86E06\18\tp5291867b\comm-ex66490302\bas  
    SamplesPerFrame: 1000  
    NumChannels: 2  
    DataType: 'double'  
    NumSamplesWritten: 1000
```

```
release(bbw)
```

Create a baseband file reader object to read the saved data. Display the metadata from the file.

```
bbr = comm.BasebandFileReader('baseband_data.bb', ...
    'SamplesPerFrame',100);
bbr.Metadata
ans = struct with fields:
    Date: '27-Feb-2022'
```

Read the data from the file.

```
z = [];
while ~isDone(bbr)
    y = bbr();
    z = cat(1,z,y);
end
```

Display information about the baseband file reader. Then, release object.

```
info(bbr)
ans = struct with fields:
    NumSamplesInData: 1000
    DataType: 'double'
    NumSamplesRead: 1000
```

```
release(bbr)
```

Confirm that the original modulated data x , matches the data z , read from file `baseband_data.bb`.

```
isequal(x,z)
ans = logical
     1
```

Input Arguments

bbw — Baseband file writer

`comm.BasebandFileWriter` System object

Baseband file writer, specified as a `comm.BasebandFileWriter` System object.

Output Arguments

S — Characteristic information about baseband file writer

structure

Characteristic information about the baseband file writer, returned as a structure containing these fields.

Filename — Name of baseband file to write

character vector

Name of the baseband file to write, returned as a character vector. The filename shows the absolute path.

Data Types: char

SamplesPerFrame — Number of samples in each frame

positive integer

Number of samples in each frame, returned as a positive integer.

Dependencies

To enable this field, you must first run the baseband file writer object.

Data Types: double

NumChannels — Number of channels in baseband signal

positive integer

Number of channels in the baseband signal written to the file, returned as a positive integer.

Dependencies

To enable this field, you must first run the baseband file writer object.

Data Types: double

DataType — Data type of baseband signal

'double' | 'single' | 'uint8' | 'uint16' | 'uint32' | 'uint64' | 'int8' | 'int16' | 'int32' | 'int64'

Data type of the baseband signal written to the file, returned as 'double', 'single', 'uint8', 'uint16', 'uint32', 'uint64', 'int8', 'int16', 'int32', or 'int64'.

Dependencies

To enable this field, you must first run the baseband file writer object.

NumSamplesWritten — Total number of baseband data samples written

positive integer

Total number of baseband data samples written to the file, returned as a positive integer. This field returns the smaller of the total number of samples processed by and the value of the NumSamplesToWrite property of the input baseband file writer object.

Data Types: double

Functions

info

Introduced in R2016b

getPercentileRelativePower

Package: comm

Relative power value for given percentile using CCDF

Syntax

```
R = getPercentileRelativePower(ccdf,P)
```

Description

`R = getPercentileRelativePower(ccdf,P)` returns the relative power value of a signal for the specified percentile value P . The input `ccdf` specifies the complementary cumulative distribution function (CCDF) curves of the signal of interest. The function returns the power level by which the signal is above its average power P percent of the time. A percentile of $P = 100$ corresponds to a probability of 1.0. For the i th channel in the input signal, the function evaluates the inverse of the corresponding CCDF curve at probability value $P(i)/100$.

Before calling the `getPercentileRelativePower` function, you must obtain the CCDF curves of the signal of interest by calling the `ccdf` System object on the signal.

Examples

Obtain CCDF Curves and Relative Power Levels

Generate a unit variance AWGN signal and a dual-tone signal.

```
n = [0:5e3-1].';
s1 = randn(5e3,1); % AWGN signal
s2 = sin(0.01*pi*n) + sin(0.03*pi*n); % Dual-tone signal
```

Create a CCDF measurement object.

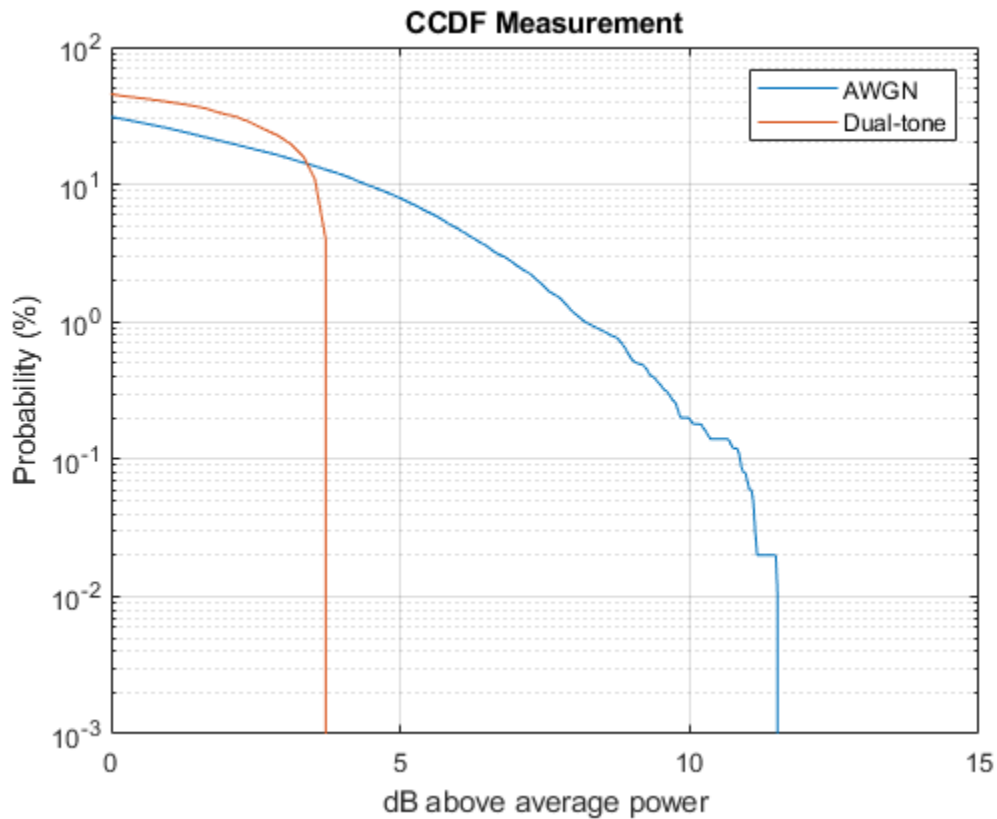

```
ccdf = comm.CCDF;
```

Obtain the CCDF curves of the signals.

```
ccdf([s1 s2]);
```

Plot the resulting curves.

```
plot(ccdf)
legend('AWGN', 'Dual-tone')
```

Find the relative power levels of the signals. The AWGN signal is 8.1929 dB above its average power 1 percent of the time. The dual-tone signal is 3.5493 dB above its average power 10 percent of the time.

```
RPW = getPercentileRelativePower(ccdf,[1 10])
```

```
RPW = 2×1
```

```
8.1923
3.5493
```

Input Arguments

ccdf — CCDF measurements

comm.CCDF System object

CCDF measurements, specified as a `comm.CCDF System` object. The object must contain CCDF curves. To obtain CCDF curves, call the object on the input signal of interest.

P — Percentile

numeric scalar | numeric row vector

Percentile, specified as one of these options.

- Numeric scalar in the range [0, 100] — The function evaluates the inverse of each CCDF curve at probability value $P/100$.
- Numeric row vector with values in the range [0, 100] — The function evaluates the inverse of the i th CCDF curve in the input `ccdf` at probability value $P(i)/100$.

Output Arguments

R — Relative power value

numeric column vector

Relative power value, returned as a numeric column vector. $R(i)$ is the relative power value returned for the channel corresponding to i th CCDF curve in the input `ccdf`. The `ccdf.PowerUnits` property specifies whether the relative power value is returned in a dB scale or linear scale.

Data Types: `double`

Objects

`comm.CCDF`

Functions

`getProbability` | `plot`

Introduced in R2012a

getProbability

Package: comm

Probability of relative power value using CCDF

Syntax

```
P = getProbability(ccdf,R)
```

Description

`P = getProbability(ccdf,R)` returns the probability, as a percentage in the range [0, 100], that the power level of a signal is above its average power by the specified level `R`. The input `ccdf` specifies the complementary cumulative distribution function (CCDF) curves of the signal of interest. For the i th channel in the input signal, the function evaluates the corresponding CCDF curve at relative power value $R(i)$.

Before calling the `getProbability` function, you must obtain the CCDF curves of the signal of interest by calling the `ccdf` System object on the signal.

Examples

Obtain CCDF Curves and Probabilities

Generate a unit variance AWGN signal and a dual-tone signal.

```
n = [0:5e3-1].';  
s1 = randn(5e3,1); % AWGN signal  
s2 = sin(0.01*pi*n) + sin(0.03*pi*n); % Dual-tone signal
```

Create a CCDF measurement object.

```
ccdf = comm.CCDF;
```

Obtain the CCDF curves of the signals.

```
ccdf([s1 s2]);
```

Plot the resulting CCDF curves.

```
plot(ccdf)  
legend('AWGN', 'Dual-tone')
```

Find the probability that the AWGN signal power is 5 dB above its average power and the probability that the dual-tone signal power is 3 dB above its average power.

```
P = getProbability(ccdf,[5 3])
```

```
P = 2×1
```

```
7.9551
21.1421
```

Input Arguments

ccdf — CCDF measurements

comm.CCDF System object

CCDF measurements, specified as a `comm.CCDF` System object. The object must contain CCDF curves. To obtain CCDF curves, call the object on the input signal of interest.

R — Relative power value

numeric scalar | numeric row vector

Relative power value, specified as one of these options.

- Numeric scalar — The function evaluates each CCDF curve at the relative power value R.

- Numeric row vector — The function evaluates the i th CCDF curve in the input `ccdf` at relative power value $R(i)$.

The `ccdf.PowerUnits` property specifies whether the relative power value is returned in a dB scale or linear scale.

Data Types: `double`

Output Arguments

P — CCDF probability of relative power value

numeric column vector

CCDF probability of the relative power value, returned as a numeric column vector with values in the range $[0, 100]$. A value of 100 corresponds to a probability of 1.0. $P(i)/100$ is the probability value of the channel corresponding to the i th CCDF curve in the input `ccdf`.

Data Types: `double`

Objects

`comm.CCDF`

Functions

`getPercentileRelativePower` | `plot`

Introduced in R2012a

plot

Package: comm

2-D line plots of CCDF curves

Syntax

```
lines = plot(ccdf)
lines = plot(ccdf,Name,Value)
```

Description

`lines = plot(ccdf)` creates 2-D line plots corresponding to the complementary cumulative distribution function (CCDF) curves of a signal of interest specified by `ccdf`. The number of curves is equal to the number of channels in the signal. The function returns a column vector of chart line objects corresponding to the plots.

Before calling the `plot` function, you must obtain the CCDF curves of the signal of interest by calling the `ccdf` System object on the signal.

`lines = plot(ccdf,Name,Value)` specifies options using one or more name-value arguments. For a complete list of name-value arguments, see [Line Properties](#). For example, `plot(ccdf, 'LineWidth', 2)` creates the plots such that the line width of each curve is 2 points.

Examples

Obtain CCDF Curves for 16-QAM and QPSK Signals

Generate 16-QAM and QPSK modulated signals.

```
qamTxSig = qammod(randi([0 15],20e3,1),16,'UnitAveragePower',true);
qpskTxSig = pskmod(randi([0 3],20e3,1),4,pi/4);
```

Pass the signals through an AWGN channel.

```
qamRxSig = awgn(qamTxSig,15);
qpskRxSig = awgn(qpskTxSig,15);
```

Create a CCDF measurement object enabling outputs for the average power measurements and peak power measurements.

```
ccdf = comm.CCDF(...
    'AveragePowerOutputPort',true, ...
    'PeakPowerOutputPort',true);
```

Obtain the CCDF measurements of the two waveforms.

```
[ccdfy,ccdfx,avg,peak] = ccdf([qamRxSig qpskRxSig]);
```

Plot the CCDF curves for both signals.

```
plot(ccdf)
legend('16-QAM', 'QPSK')
```

Input Arguments

ccdf — CCDF measurements

comm.CCDF System object

CCDF measurements, specified as a comm.CCDF System object. The object must contain CCDF curves. To obtain the CCDF curves, call the object on the input signal of interest.

Output Arguments

Lines — Plotted CCDF curves

column vector of Line objects

Plotted CCDF curves, returned as a column vector of Line objects. The length of this vector is equal to the number of CCDF curves specified by the input ccdf. These Line objects uniquely identify the plotted 2-D CCDF curves. Use these objects to query and modify the properties of the curves in the plots. For a complete list of object properties, see Line Properties.

info

Package: comm

Characteristic information about fading channel object

Syntax

```
infostruct = info(obj)
```

Description

`infostruct = info(obj)` returns a structure containing characteristic information about the fading channel System object.

Examples

Get comm.RayleighChannel Info

Use the `info` object function to get information from a `comm.RayleighChannel` object.

Create a Rayleigh channel object and some data to pass through the channel.

```
rayleighchan = comm.RayleighChannel('SampleRate',1000,'PathDelays',[0 0],'AveragePathGains',[0 0])
```

```
rayleighchan =  
    comm.RayleighChannel with properties:
```

```
        SampleRate: 1000  
        PathDelays: [0 0]  
    AveragePathGains: [0 0]  
    NormalizePathGains: true  
    MaximumDopplerShift: 1.0000e-03  
        DopplerSpectrum: [1x1 struct]  
    ChannelFiltering: true  
    PathGainsOutputPort: false
```

```
Show all properties
```

```
data = randi([0 1],600,1);
```

Check the Rayleigh channel object information.

```
info(rayleighchan)
```

```
ans = struct with fields:  
    ChannelFilterDelay: 0  
    ChannelFilterCoefficients: [2x1 double]  
    NumSamplesProcessed: 0
```

Pass data through the channel and check the object information again.

```

rayleighchan(data);
info(rayleighchan)

ans = struct with fields:
    ChannelFilterDelay: 0
    ChannelFilterCoefficients: [2x1 double]
    NumSamplesProcessed: 600

```

Release the object so you can update attributes. Add a 1.5e-3 second path delay to the second delay path.

```

release(rayleighchan)
rayleighchan.PathDelays = [0 1.5e-3]

rayleighchan =
    comm.RayleighChannel with properties:

        SampleRate: 1000
        PathDelays: [0 0.0015]
        AveragePathGains: [0 0]
        NormalizePathGains: true
        MaximumDopplerShift: 1.0000e-03
        DopplerSpectrum: [1x1 struct]
        ChannelFiltering: true
        PathGainsOutputPort: false

    Show all properties

```

Pass data through the channel and check the object information again.

```

rayleighchan(data);
info(rayleighchan)

ans = struct with fields:
    ChannelFilterDelay: 6
    ChannelFilterCoefficients: [2x16 double]
    NumSamplesProcessed: 600

```

Get comm.RicianChannel Info

Use the `info` object function to get information from a `comm.RicianChannel` object.

Create a Rician channel object and some data to pass through the channel.

```

ricianchan = comm.RicianChannel('SampleRate',500)

ricianchan =
    comm.RicianChannel with properties:

        SampleRate: 500
        PathDelays: 0
        AveragePathGains: 0
        NormalizePathGains: true

```

```
        KFactor: 3
DirectPathDopplerShift: 0
DirectPathInitialPhase: 0
    MaximumDopplerShift: 1.0000e-03
        DopplerSpectrum: [1x1 struct]
    ChannelFiltering: true
    PathGainsOutputPort: false
```

Show all properties

```
data = randi([0 1],600,1);
```

Check the Rician channel object information.

```
info(ricianchan)
```

```
ans = struct with fields:
    ChannelFilterDelay: 0
ChannelFilterCoefficients: 1
    NumSamplesProcessed: 0
```

Pass data through the channel and check the object information again.

```
ricianchan(data);
info(ricianchan)
```

```
ans = struct with fields:
    ChannelFilterDelay: 0
ChannelFilterCoefficients: 1
    NumSamplesProcessed: 600
```

Release the object so you can update attributes. Add a second path delay with a delay of 3.1e-3 second and an average path gain of -3 dB.

```
release(ricianchan)
ricianchan.PathDelays = [0 3.1e-3];
ricianchan.AveragePathGains = [0 -3]
```

```
ricianchan =
comm.RicianChannel with properties:

    SampleRate: 500
    PathDelays: [0 0.0031]
    AveragePathGains: [0 -3]
    NormalizePathGains: true
        KFactor: 3
DirectPathDopplerShift: 0
DirectPathInitialPhase: 0
    MaximumDopplerShift: 1.0000e-03
        DopplerSpectrum: [1x1 struct]
    ChannelFiltering: true
    PathGainsOutputPort: false
```

Show all properties

Pass data through the channel and check the object information again.

```
ricianchan(data);
info(ricianchan)

ans = struct with fields:
    ChannelFilterDelay: 6
    ChannelFilterCoefficients: [2x16 double]
    NumSamplesProcessed: 600
```

Get comm.MIMOChannel Info

Use the `info` object function to get information from a `comm.MIMOChannel` object.

Create a MIMO channel object and some data to pass through the channel.

```
mimo = comm.MIMOChannel('SampleRate',1000);
data = randi([0 1],600,2);
```

Check the MIMO channel object information.

```
info(mimo)

ans = struct with fields:
    ChannelFilterDelay: 0
    ChannelFilterCoefficients: 1
    NumSamplesProcessed: 0
```

Pass data through the channel and check the object information again.

```
mimo(data);
info(mimo)

ans = struct with fields:
    ChannelFilterDelay: 0
    ChannelFilterCoefficients: 1
    NumSamplesProcessed: 600
```

Release the object so you can update attributes. Add a $2.5e-3$ second path delay. Recheck the object information.

```
release(mimo)
mimo.PathDelays = 2.5e-3;
info(mimo)

ans = struct with fields:
    ChannelFilterDelay: 5
    ChannelFilterCoefficients: [-0.0326 0.0403 -0.0504 0.0646 -0.0861 ... ]
    NumSamplesProcessed: 0
```

Model MIMO Channel Using Sum-of-Sinusoids Technique

Show that the channel state is maintained for discontinuous transmissions by using MIMO channel System objects configured to use the sum-of-sinusoids fading technique. Observe discontinuous channel response segments overlaid on a continuous channel response.

Set the channel properties.

```
fs = 1000;           % Sample rate (Hz)
pathDelays = [0 2.5e-3]; % Path delays (s)
pathPower = [0 -6]; % Path power (dB)
fD = 5;             % Maximum Doppler shift (Hz)
ns = 1000;         % Number of samples
nsdel = 100;       % Number of samples for delayed paths
```

Define a continuous time span and three discontinuous time segments over which to plot and view the channel response. View a 1000-sample continuous channel response starting at time 0 and three 100-sample channel responses starting at times 0.1, 0.4, and 0.7 seconds, respectively.

```
to0 = 0.0;
to1 = 0.1;
to2 = 0.4;
to3 = 0.7;
t0 = (to0:ns-1)/fs; % Transmission 0
t1 = to1+(0:nsdel-1)/fs; % Transmission 1
t2 = to2+(0:nsdel-1)/fs; % Transmission 2
t3 = to3+(0:nsdel-1)/fs; % Transmission 3
```

Create a flat-fading 2-by-2 MIMO channel System object, disabling channel filtering and specifying a 1000 Hz sampling rate, the sum-of-sinusoids fading technique, and the number of samples to view. Specify a seed value so that results can be repeated. Use the default `InitialTime` property setting so that the fading channel is simulated from time 0.

```
mimoChan1 = comm.MIMOChannel('SampleRate',fs, ...
    'MaximumDopplerShift',fD, ...
    'RandomStream','mt19937ar with seed', ...
    'Seed',17, ...
    'FadingTechnique','Sum of sinusoids', ...
    'ChannelFiltering',false, ...
    'NumSamples',ns);
```

Create a clone of the MIMO channel System object. Change the number of samples for the delayed paths and the source for the initial time so that you can specify the fading channel offset time as an input argument when calling the System object.

```
mimoChan2 = clone(mimoChan1);
mimoChan2.InitialTimeSource = 'Input port';
mimoChan2.NumSamples = nsdel;
```

Save the path gain output for the continuous channel response by using the `mimoChan1` object and for the discontinuous delayed channel responses by using the `mimoChan2` object with initial time offsets provided as input arguments.

```
pg0 = mimoChan1();
pg1 = mimoChan2(to1);
pg2 = mimoChan2(to2);
pg3 = mimoChan2(to3);
```

Compare the number of samples processed by the two channels by using the `info` method. The results show that `mimoChan1` processed 1000 samples and that `mimoChan2` processed only 300 samples.

```
G = info(mimoChan1);
H = info(mimoChan2);
[G.NumSamplesProcessed H.NumSamplesProcessed]

ans = 1×2

      1000      300
```

Convert the path gains into decibels for the path corresponding to the first transmit and first receive antenna.

```
pathGain0 = 20*log10(abs(pg0(:,1,1,1)));
pathGain1 = 20*log10(abs(pg1(:,1,1,1)));
pathGain2 = 20*log10(abs(pg2(:,1,1,1)));
pathGain3 = 20*log10(abs(pg3(:,1,1,1)));
```

Plot the path gains for the continuous and discontinuous cases. The results show that the gains for the three segments match the gain for the continuous case. The alignment of the two shows that the sum-of-sinusoids technique is ideally suited to the simulation of packetized data because the channel characteristics are maintained even when data is not transmitted.

```
plot(t0,pathGain0,'r--')
hold on
plot(t1,pathGain1,'b')
plot(t2,pathGain2,'b')
plot(t3,pathGain3,'b')
grid
title('Continuous and Discontinuous Channel Response')
xlabel('Time (sec)')
ylabel('Path Gain (dB)')
legend('Continuous','Discontinuous','location','nw')
```

Input Arguments

obj — System object to get information from

System object

System object to get information from, specified as a `comm.MIMOChannel`, `comm.RayleighChannel`, or `comm.RicianChannel` System object.

Output Arguments

infostruct — Structure containing object information

structure

Structure containing these fields with information about the System object.

ChannelFilterDelay — Channel filter delay

positive integer

Channel filter delay in samples, returned as a positive integer.

ChannelFilterCoefficients — Channel filter coefficients

matrix

Channel filter coefficients, returned as a matrix. The coefficient matrix is used to convert path gains to channel filter tap gains for each sample and each pair of transmit and receive antennas.

NumSamplesProcessed — Number of samples processed by the channel object

positive integer

Number of samples processed by the channel object since the last reset, returned as a positive integer.

LastFrameTime — Last frame ending time

positive scalar

Last frame ending time in seconds, returned as a positive scalar. Use this value to confirm the simulation time.

Dependencies

This property applies when the `FadingTechnique` property is 'Sum of sinusoids' and the `InitialTimeSource` property is 'Input port'.

Introduced in R2012a

coeffs

Package: comm

Coefficients for filters

Syntax

```
coefInfo = coeffs(rcfilter)
coefInfo = coeffs(rcfilter, 'Arithmetic', arithType)
```

Description

`coefInfo = coeffs(rcfilter)` obtain the coefficients for the specified filter System object.

`coefInfo = coeffs(rcfilter, 'Arithmetic', arithType)` analyzes the filter System object based on the arithmetic specified in `arithType`.

Examples

Obtain Coefficients of Raised Cosine Filters

Create a receive raised cosine filter and obtain its numerator coefficients.

```
rxfilter = comm.RaisedCosineReceiveFilter('FilterSpanInSymbols', 25);
srx = coeffs(rxfilter)
```

```
srx = struct with fields:
    Numerator: [9.0942e-04 8.5589e-04 6.1364e-04 2.3196e-04 -2.0735e-04 ... ]
```

Calculate the expected number of numerator coefficients and confirm the value equals the length of `srx.Numerator`.

```
numcoefs = rxfilter.FilterSpanInSymbols * rxfilter.InputSamplesPerSymbol + 1
```

```
numcoefs = 201
```

```
isequal (numcoefs, length(srx.Numerator))
```

```
ans = logical
     1
```

Display the first ten coefficients.

```
srx.Numerator(1:10)
```

```
ans = 1×10
     10-3 ×
```

```
    0.9094    0.8559    0.6136    0.2320   -0.2074   -0.6071   -0.8759   -0.9486   -0.8021   -0.4
```

Display the impulse response of the receive raised cosine filter.

```
impz(srx.Numerator)
```

Create a transmit raised cosine filter and obtain its numerator coefficients.

```
txfilter = comm.RaisedCosineTransmitFilter('RolloffFactor',0.5);
stx = coeffs(txfilter);
```

Display the first ten filter coefficients.

```
stx.Numerator(1:10)
```

```
ans = 1×10
```

```
-0.0002    0.0011    0.0021    0.0024    0.0018    0.0004   -0.0014   -0.0029   -0.0036   -0.0044
```

Display the impulse response of the transmit raised cosine filter.

```
impz(stx.Numerator)
```

Input Arguments

rcfilter — Input filter

`comm.RaisedCosineReceiveFilter` System object | `comm.RaisedCosineTransmitFilter` System object

Input filter, specified as one of these of filter System objects.

- `comm.RaisedCosineReceiveFilter`
- `comm.RaisedCosineTransmitFilter`

arithType — Arithmetic type

'double' (default) | 'single' | 'Fixed'

Arithmetic used in the filter analysis, specified as 'double', 'single', or 'Fixed'. When you do not specify the arithmetic type and the filter System object is unlocked, the analysis tool assumes a double-precision filter. When you do not specify the arithmetic type and the System object is locked, the function performs the analysis based on the data type of the locked input.

The 'Fixed' value applies to filter System objects with fixed-point properties only.

When you specify this input as 'Fixed' and the filter object has the data type of the coefficients set to 'Same word length as input', the arithmetic analysis performed depends on whether the System object is unlocked or locked.

- If the System object is unlocked, the analysis object function cannot determine the data type of the coefficients. The function assumes that the data type of the coefficients is signed, has a 16-bit word length, and is autoscaled. The function performs fixed-point analysis based on this assumption.
- If the System object is locked -- When the input data type is 'double' or 'single', the analysis object function cannot determine the data type of the coefficients. The function assumes that the data type of the coefficients is signed, has a 16-bit word length, and is autoscaled. The function performs fixed-point analysis based on this assumption.

To check if the System object is locked or unlocked, use the `isLocked` function.

When you specify this input as 'Fixed' and the filter object has the data type of the coefficients set to a custom numeric type, the object function performs fixed-point analysis based on the custom numeric data type.

Data Types: `char` | `string`

Output Arguments

coefInfo — Filter coefficient information

structure

Filter coefficient information, returned as a structure containing the filter coefficients in the `Numerator` field. When the filter uses fixed-point arithmetic, the function returns additional information about the filter. This information includes the arithmetic setting and details about the filter internals.

cost

Package: comm

Computational cost of implementing filter System object

Syntax

```
filtcost = cost(rcfilter)
filtcost = cost(rcfilter,'Arithmetic',arithType)
```

Description

`filtcost = cost(rcfilter)` returns a structure of fields that contain information about the computational cost of implementing the specified filter.

`filtcost = cost(rcfilter,'Arithmetic',arithType)` specifies the type of arithmetic that the function uses to evaluate the filter response.

Examples

Compute Cost of RRC Filter

Compute the cost of implementing various root-raised-cosine (RRC) filters that are created by using a `comm.RaisedCosineTransmitFilter` System object™. Increasing the filter span or output samples per symbol increases the cost of implementing the filter.

```
rrcFilt = comm.RaisedCosineTransmitFilter( ...
    "FilterSpanInSymbols",20, ...
    "OutputSamplesPerSymbol",8);
costFilt = cost(rrcFilt)
```

```
costFilt = struct with fields:
    NumCoefficients: 161
    NumStates: 20
    MultiplicationsPerInputSample: 161
    AdditionsPerInputSample: 153
```

```
rrcFilt = comm.RaisedCosineTransmitFilter( ...
    "FilterSpanInSymbols",200, ...
    "OutputSamplesPerSymbol",8);
costFilt = cost(rrcFilt)
```

```
costFilt = struct with fields:
    NumCoefficients: 1601
    NumStates: 200
    MultiplicationsPerInputSample: 1601
    AdditionsPerInputSample: 1593
```

```
rrcFilt = comm.RaisedCosineTransmitFilter( ...
    "FilterSpanInSymbols",200, ...
```

```

    "OutputSamplesPerSymbol",16);
costFilt = cost(rrcFilt)

costFilt = struct with fields:
    NumCoefficients: 3201
    NumStates: 200
    MultiplicationsPerInputSample: 3201
    AdditionsPerInputSample: 3185

```

Input Arguments

rcfilter — Filter

comm.RaisedCosineReceiveFilter System object | comm.RaisedCosineTransmitFilter System object

Filter, specified as one of these System objects.

- comm.RaisedCosineReceiveFilter
- comm.RaisedCosineTransmitFilter

arithType — Arithmetic type

'double' (default) | 'single' | 'Fixed'

Arithmetic used in the filter analysis, specified as 'double', 'single', or 'Fixed'. When you do not specify the arithmetic type and the filter System object is unlocked, the analysis tool assumes a double-precision filter. When you do not specify the arithmetic type and the System object is locked, the function performs the analysis based on the data type of the locked input.

The 'Fixed' value applies to filter System objects with fixed-point properties only.

When you specify this input as 'Fixed' and the filter object has the data type of the coefficients set to 'Same word length as input', the arithmetic analysis performed depends on whether the System object is unlocked or locked.

- If the System object is unlocked, the analysis object function cannot determine the data type of the coefficients. The function assumes that the data type of the coefficients is signed, has a 16-bit word length, and is autoscaled. The function performs fixed-point analysis based on this assumption.
- If the System object is locked -- When the input data type is 'double' or 'single', the analysis object function cannot determine the data type of the coefficients. The function assumes that the data type of the coefficients is signed, has a 16-bit word length, and is autoscaled. The function performs fixed-point analysis based on this assumption.

To check if the System object is locked or unlocked, use the `isLocked` function.

When you specify this input as 'Fixed' and the filter object has the data type of the coefficients set to a custom numeric type, the object function performs fixed-point analysis based on the custom numeric data type.

Data Types: char | string

Output Arguments

filtcost – Cost estimate

structure

Cost estimate, returned as a structure containing these fields.

Field	Description
NumCoefficients	Number of filter coefficients (excluding coefficients with values 0, 1, or -1)
NumStates	Number of filter states
MultiplicationsPerInputSample	Number of multiplication operations performed for each input sample
AdditionsPerInputSample	Number of addition operations performed for each input sample

Data Types: struct

info

Package: comm

Information about filter System object

Syntax

```

filtInfo = info(rcfilter)
filtInfo = info(rcfilter,infoType)
filtInfo = info( __ , 'Arithmetic',arithType)

```

Description

`filtInfo = info(rcfilter)` obtains information about the specified filter System object. The type of information returned by the function depends on the filter type and configuration.

`filtInfo = info(rcfilter,infoType)` obtains the amount of filter information as specified by `infoType`.

`filtInfo = info(__ , 'Arithmetic',arithType)` analyzes the filter System object based on the arithmetic specified in `arithType`. Specify this option with any of the input combinations from previous syntaxes.

For more input options, see the `info` function.

Examples

Obtain Raised Cosine Filter Information

Obtain short-format and long-format information about a raised cosine filter.

```

txfilter = comm.RaisedCosineTransmitFilter;
info(txfilter)

ans = 10x62 char array
'Discrete-Time FIR Multirate Filter (real)                '
'-----'
'Filter Structure      : Direct-Form FIR Polyphase Interpolator'
'Interpolation Factor : 8                                   '
'Polyphase Length     : 11                                 '
'Filter Length        : 81                                 '
'Stable               : Yes                                 '
'Linear Phase         : Yes (Type 1)                       '
'                     :                                     '
'Arithmetic           : double                             '

info(txfilter,'Long')

ans = 17x62 char array
'Discrete-Time FIR Multirate Filter (real)                '

```

Input Arguments

rcfilter — Input filter

`comm.RaisedCosineReceiveFilter` System object | `comm.RaisedCosineTransmitFilter` System object

Input filter, specified as one of these of filter System objects.

- `comm.RaisedCosineReceiveFilter`
- `comm.RaisedCosineTransmitFilter`

infoType — Amount of information to display

'short' (default) | 'long'

Amount of filter information to display, specified as one of these values.

- 'short' -- The function displays the basic filter information. This information is the same as the information output by `info(rcfilter)`.
- 'long' -- The function returns this information about the filter.
 - Specifications such as the filter structure and filter order.
 - Information about the design method and options.
 - Performance measurements, such as the passband cutoff or stopband attenuation, for the filter response.
 - Cost of implementing the filter in terms of operations required to apply the filter to data.

When the filter uses fixed-point arithmetic, the function returns additional information about the filter. This information includes the arithmetic setting and details about the filter internals.

Data Types: `char` | `string`

arithType — Arithmetic type

'double' (default) | 'single' | 'Fixed'

Arithmetic used in the filter analysis, specified as 'double', 'single', or 'Fixed'. When you do not specify the arithmetic type and the filter System object is unlocked, the analysis tool assumes a

double-precision filter. When you do not specify the arithmetic type and the System object is locked, the function performs the analysis based on the data type of the locked input.

The 'Fixed' value applies to filter System objects with fixed-point properties only.

When you specify this input as 'Fixed' and the filter object has the data type of the coefficients set to 'Same word length as input', the arithmetic analysis performed depends on whether the System object is unlocked or locked.

- If the System object is unlocked, the analysis object function cannot determine the data type of the coefficients. The function assumes that the data type of the coefficients is signed, has a 16-bit word length, and is autoscaled. The function performs fixed-point analysis based on this assumption.
- If the System object is locked -- When the input data type is 'double' or 'single', the analysis object function cannot determine the data type of the coefficients. The function assumes that the data type of the coefficients is signed, has a 16-bit word length, and is autoscaled. The function performs fixed-point analysis based on this assumption.

To check if the System object is locked or unlocked, use the `isLocked` function.

When you specify this input as 'Fixed' and the filter object has the data type of the coefficients set to a custom numeric type, the object function performs fixed-point analysis based on the custom numeric data type.

Data Types: `char` | `string`

Output Arguments

filtInfo – Filter information

character array

Filter information, returned as a character array.

- When you set the `infoType` input to 'short', the function displays basic filter information.
- When you set the `infoType` input to 'long', the function displays this.
 - Specifications such as the filter structure and filter order.
 - Information about the design method and options.
 - Performance measurements, such as the passband cutoff or stopband attenuation, for the filter response.
 - Cost of implementing the filter in terms of operations required to apply the filter to data.

When the filter uses fixed-point arithmetic, the function returns additional information about the filter. The information includes the arithmetic setting and details about the filter internals.

fvtool

Package: comm

Plot frequency response of filter

Syntax

```
fvtool(rcfilter)
fvtool(rcfilter,options)
fvtool(____,Name,Value)
```

Description

`fvtool(rcfilter)` plots the magnitude response of the specified filter.

`fvtool(rcfilter,options)` plots the response that is specified by options.

For example, to plot the impulse response of the specified filter, set options to 'impulse'.

```
fvtool(rcfilter,'impulse');
```

`fvtool(____,Name,Value)` specifies additional options using one or more name-value arguments in addition to any input argument combination from the previous syntaxes.

For more input options, see the **FVTool** function.

Examples

Create Square-Root-Raised-Cosine Transmit Filter with Unity Passband Gain

Create a square-root-raised-cosine (SRRC) transmit filter System object™, and then plot the filter response. The results show that the linear filter gain is greater than unity. Specifically, the passband gain is greater than 0 dB.

```
txfilter = comm.RaisedCosineTransmitFilter;
fvtool(txfilter)
```

Obtain the filter coefficients by using the `coeffs` object function and adjust the filter gain to unit energy.

```
b = coeffs(txfilter);
```

Because a filter with unity passband gain must have filter coefficients that sum to 1, set the linear filter gain to the inverse of the sum of the filter tap coefficients, `b.Numerator`.

```
txfilter.Gain = 1/sum(b.Numerator);
```

Verify that the resulting filter coefficients sum to 1.

```
bNorm = coeffs(txfilter);
sum(bNorm.Numerator)
```

```
ans = 1.0000
```

Plot the filter frequency response again. The results now show that the passband gain is 0 dB, which is unity gain.

```
fvtool(txfilter)
```

Input Arguments

rcfilter – Filter

`comm.RaisedCosineReceiveFilter` System object | `comm.RaisedCosineTransmitFilter` System object

Filter, specified as one of these System objects.

- `comm.RaisedCosineReceiveFilter`
- `comm.RaisedCosineTransmitFilter`

options – Filter analysis options

'magnitude' (default) | 'phase' | 'freq' | 'grpdelay' | 'phasedelay' | 'impulse' | 'step' | 'polezero' | 'coefficients' | 'info' | 'magestimate' | 'noisepower'

Filter analysis options, specified as one of these values:

- 'magnitude' -- Magnitude response
- 'phase' -- Phase response
- 'freq' -- Frequency response
- 'grpdelay' -- Group delay
- 'phasedelay' -- Phase delay

- 'impulse' -- Impulse response
- 'step' -- Step response
- 'polezero' -- Pole zero plot
- 'coefficients' -- Coefficients vector
- 'info' -- Filter information
- 'magestimate' -- Magnitude response estimate
- 'noisepower' -- Round-off noise power spectrum

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1, ..., NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose Name in quotes.

Example: `fvtool(rcfilter,'Arithmetic','single')`

Fs — Sampling rate

scalar

Sampling rate, specified as a scalar. This value, F_s , determines the Nyquist interval $[-F_s/2, F_s/2]$ in which the function shows the frequency response of the filters in the channelizer.

Data Types: `single` | `double`

Arithmetic — Arithmetic type

'double' (default) | 'single' | 'Fixed'

Specify the arithmetic used during analysis. The analysis tool assumes a double-precision filter when the arithmetic input is not specified and the filter System object is unlocked. The 'Arithmetic' property set to 'Fixed' applies only to filter System objects with fixed-point properties.

When you specify this argument as 'Fixed', the function plots the double-precision reference filter and the quantized version of the filter. The function uses the `CoefficientsDataType` property of the respective filter System object to create the quantized version of the filter analysis values in options except for these:

- 'magestimate' -- Magnitude response estimate
- 'noisepower' -- Round-off noise power spectrum

For these two analysis options, the function uses all of the fixed-point settings to analyze the quantized version of the filter.

freqz

Package: comm

Frequency response of discrete-time filter

Syntax

```
[filtresp,w] = freqz(rcfilter)
[filtresp,w] = freqz(rcfilter,n)
[filtresp,w] = freqz( ___, 'Arithmetic',arithType)

freqz(rcfilter)
```

Description

`[filtresp,w] = freqz(rcfilter)` returns `filtresp`, the complex frequency response of the specified filter. The output `w` contains the frequencies (in radians per sample) at which the function evaluates the frequency response.

`[filtresp,w] = freqz(rcfilter,n)` returns the complex frequency response of the specified filter and the corresponding frequencies at `n` points that are equally spaced around the upper-half of the unit circle (from 0 to π).

This function uses the transfer function that is associated with the specified filter to calculate the frequency response of the filter with the current coefficient values.

`[filtresp,w] = freqz(___, 'Arithmetic',arithType)` specifies the type of arithmetic that the function uses to evaluate the filter response. You can use any input combination from the previous syntaxes.

`freqz(rcfilter)` plots the magnitude and unwrapped phase of the frequency response of the specified filter by using the `fvtool` object function.

For more input options, see the `freqz` function.

Examples

Evaluate RRC Filter Frequency Response

Evaluate the frequency response of an RRC filter.

Create a transmit RRC filter System object™. Evaluate the frequency response by using the `freqz` object function.

```
rrcFilt = comm.RaisedCosineTransmitFilter( ...
    "FilterSpanInSymbols",30, ...
    "RolloffFactor",0.25);
freqz(rrcFilt)
```

Input Arguments

rcfilter – Filter

`comm.RaisedCosineReceiveFilter` System object | `comm.RaisedCosineTransmitFilter` System object

Filter, specified as one of these System objects.

- `comm.RaisedCosineReceiveFilter`
- `comm.RaisedCosineTransmitFilter`

n – Number of points over which the frequency response is computed

8192 (default) | positive integer

Number of points over which the frequency response is computed, specified as positive integer. For faster computations (performed using FFTs), specify `n` as a power of two.

Data Types: double

arithType – Arithmetic type

'double' (default) | 'single' | 'Fixed'

Arithmetic used in the filter analysis, specified as 'double', 'single', or 'Fixed'. When you do not specify the arithmetic type and the filter System object is unlocked, the analysis tool assumes a

double-precision filter. When you do not specify the arithmetic type and the System object is locked, the function performs the analysis based on the data type of the locked input.

The 'Fixed' value applies to filter System objects with fixed-point properties only.

When you specify this input as 'Fixed' and the filter object has the data type of the coefficients set to 'Same word length as input', the arithmetic analysis performed depends on whether the System object is unlocked or locked.

- If the System object is unlocked, the analysis object function cannot determine the data type of the coefficients. The function assumes that the data type of the coefficients is signed, has a 16-bit word length, and is autoscaled. The function performs fixed-point analysis based on this assumption.
- If the System object is locked -- When the input data type is 'double' or 'single', the analysis object function cannot determine the data type of the coefficients. The function assumes that the data type of the coefficients is signed, has a 16-bit word length, and is autoscaled. The function performs fixed-point analysis based on this assumption.

To check if the System object is locked or unlocked, use the `isLocked` function.

When you specify this input as 'Fixed' and the filter object has the data type of the coefficients set to a custom numeric type, the object function performs fixed-point analysis based on the custom numeric data type.

Data Types: `char` | `string`

Output Arguments

filtresp — Frequency response

column vector

Frequency response, returned as a complex-valued column vector of length n . The function evaluates the frequency response at n points that are equally spaced around the upper-half of the unit circle (from 0 to π).

Data Types: `double`

w — Frequencies used for frequency response evaluation

column vector

Frequencies used for frequency response evaluation, returned as a column vector of length n . Unit are in radians per sample. The frequencies are equally spaced around the upper-half of the unit circle (from 0 to π).

Data Types: `double`

Tips

- Several ways exist for analyzing the frequency response of filters. The `freqz` function accounts for quantization effects in the filter coefficients but does not account for quantization effects in filtering arithmetic. To account for the quantization effects in filtering arithmetic, see the `noisepsd` function.
- For faster computations (performed using FFTs), specify n , the number of points over which the function computes the frequency response, as a power of two.

Algorithms

The `freqz` function calculates the frequency response for a filter from the filter transfer function $Hq(z)$. The complex-valued frequency response is calculated by evaluating $Hq(e^{j\omega})$ at discrete values of ω . The input argument `n` specifies the number of equally-spaced points around the upper-half of the unit circle at which the function evaluates the frequency response.

- When you do not specify scalar sampling frequency `fs` as an input argument, the frequency ranges from 0 to π radians per sample.
- When you specify scalar sampling frequency `fs` as an input argument to `freqz`, the frequency ranges from 0 to `fs/2` Hz. For more information about `fs`, see the `freqz` function.

grpdelay

Package: comm

Group delay response of discrete-time filter

Syntax

```
[gd,w] = grpdelay(rcfilter)
[gd,w] = grpdelay(rcfilter,n)
[gd,w] = grpdelay( ____, 'Arithmetic', arithType)
```

```
grpdelay(rcfilter)
```

Description

`[gd,w] = grpdelay(rcfilter)` returns `gd`, the group delay of the specified filter based on the filter coefficients. The output `w` contains the frequencies (in radians per sample) at which the function evaluates the group delay. The group delay is defined as $-\frac{d}{dw}(\text{angle}(w))$.

`[gd,w] = grpdelay(rcfilter,n)` returns the group delay of the specified filter and the corresponding frequencies at `n` points that are equally spaced around the upper-half of the unit circle (from 0 to π).

`[gd,w] = grpdelay(____, 'Arithmetic', arithType)` computes the group delay of the filter System object, specifies the type of arithmetic that the function uses to compute the group delay. You can use any input combination from the previous syntaxes.

`grpdelay(rcfilter)` plots the group delay of the specified filter by using the `fvtool` object function.

For more input options, see the `grpdelay` function.

Examples

Compute Group Delay of RRC Filter

Compute the group delay of an RRC filter.

```
rcfilter = comm.RaisedCosineTransmitFilter;
gd = grpdelay(rcfilter,32);
gd(1:5)'
```

```
ans = 1×5
```

```
40    40    40    40    40
```

Input Arguments

rcfilter — Filter

`comm.RaisedCosineReceiveFilter` System object | `comm.RaisedCosineTransmitFilter` System object

Filter, specified as one of these System objects.

- `comm.RaisedCosineReceiveFilter`
- `comm.RaisedCosineTransmitFilter`

n — Number of points over which the group delay is computed

8192 (default) | positive integer

Number of points over which the group delay is computed, specified as a positive integer. For faster computations (performed using FFTs) specify `n` as a power of two.

Data Types: double

arithType — Arithmetic type

'double' (default) | 'single' | 'Fixed'

Arithmetic used in the filter analysis, specified as 'double', 'single', or 'Fixed'. When you do not specify the arithmetic type and the filter System object is unlocked, the analysis tool assumes a double-precision filter. When you do not specify the arithmetic type and the System object is locked, the function performs the analysis based on the data type of the locked input.

The 'Fixed' value applies to filter System objects with fixed-point properties only.

When you specify this input as 'Fixed' and the filter object has the data type of the coefficients set to 'Same word length as input', the arithmetic analysis performed depends on whether the System object is unlocked or locked.

- If the System object is unlocked, the analysis object function cannot determine the data type of the coefficients. The function assumes that the data type of the coefficients is signed, has a 16-bit word length, and is autoscaled. The function performs fixed-point analysis based on this assumption.
- If the System object is locked -- When the input data type is 'double' or 'single', the analysis object function cannot determine the data type of the coefficients. The function assumes that the data type of the coefficients is signed, has a 16-bit word length, and is autoscaled. The function performs fixed-point analysis based on this assumption.

To check if the System object is locked or unlocked, use the `isLocked` function.

When you specify this input as 'Fixed' and the filter object has the data type of the coefficients set to a custom numeric type, the object function performs fixed-point analysis based on the custom numeric data type.

Data Types: char | string

Output Arguments

gd — Group delay

column vector

Group delay, returned as a column vector of length n .

Data Types: `double`

w – Frequencies used for group delay evaluation

column vector

Frequencies in radians/sample used for group delay evaluation, returned as a column vector of length n . Unit are in radians per sample. The frequencies are equally spaced around the upper-half of the unit circle (from 0 to π).

Data Types: `double`

Tips

- For faster computations (performed using FFTs), specify n , the number of points over which the function computes the group delay, as a power of two.

impz

Package: comm

Impulse response of discrete-time filter

Syntax

```
[impresp,t] = impz(rcfilter)
[impresp,t] = impz(rcfilter,n)
[impresp,t] = impz(rcfilter,n,fs)
[impresp,t] = impz(rcfilter,[],fs)
[impresp,t] = impz( ____, 'Arithmetic',arithType)
```

```
impz(rcfilter)
```

Description

`[impresp,t] = impz(rcfilter)` returns `impresp`, the impulse response of the specified filter. The output `t` represents the sample intervals and equals `[0 1 2 ...k-1]'`. `k` is the number of filter coefficients.

`[impresp,t] = impz(rcfilter,n)` computes the impulse response at `floor(n)` 1 second intervals. In this case, `t` equals `(0:floor(n) - 1)'`.

`[impresp,t] = impz(rcfilter,n,fs)` computes the impulse response at `floor(n)` `1/fs` second intervals. In this case, `t` equals `(0:floor(n) - 1)/fs`.

`[impresp,t] = impz(rcfilter,[],fs)` computes the impulse response at `k` `1/fs` second intervals. `k` is the number of filter coefficients. In this case, `t` equals `(0:k - 1)/fs`.

`[impresp,t] = impz(____, 'Arithmetic',arithType)` specifies the type of arithmetic that the function uses to evaluate the impulse response. You can use any input combination from the previous syntaxes.

`impz(rcfilter)` plots the magnitude and unwrapped phase of the impulse response of the specified filter by using the `fvtool` object function.

You can use the `impz` object function for real and complex filters. When you omit the output arguments, `impz` plots only the real part of the impulse response.

For more input options, see the Signal Processing Toolbox™ `impz` function.

Examples

Evaluate RRC Filter Impulse Response

Evaluate the impulse response of an RRC filter.

Create a transmit RRC filter System object™. Evaluate the impulse response by using the `impz` object function.

```
rcfilter = comm.RaisedCosineTransmitFilter;
impz(rcfilter)
```

Input Arguments

rcfilter — Filter

`comm.RaisedCosineReceiveFilter` System object | `comm.RaisedCosineTransmitFilter` System object

Filter, specified as one of these System objects.

- `comm.RaisedCosineReceiveFilter`
- `comm.RaisedCosineTransmitFilter`

n — Number of filter coefficients

positive integer

Number of filter coefficients, specified as a positive integer. This value determines the length of the output impulse response vector, `impResp`.

Data Types: double

fs — Sampling frequency

1 (default) | positive scalar

Sampling frequency that the function uses to compute the impulse response, specified as a positive scalar.

Data Types: `double`

arithType — Arithmetic type

`'double'` (default) | `'single'` | `'Fixed'`

Arithmetic used in the filter analysis, specified as `'double'`, `'single'`, or `'Fixed'`. When you do not specify the arithmetic type and the filter System object is unlocked, the analysis tool assumes a double-precision filter. When you do not specify the arithmetic type and the System object is locked, the function performs the analysis based on the data type of the locked input.

The `'Fixed'` value applies to filter System objects with fixed-point properties only.

When you specify this input as `'Fixed'` and the filter object has the data type of the coefficients set to `'Same word length as input'`, the arithmetic analysis performed depends on whether the System object is unlocked or locked.

- If the System object is unlocked, the analysis object function cannot determine the data type of the coefficients. The function assumes that the data type of the coefficients is signed, has a 16-bit word length, and is autoscaled. The function performs fixed-point analysis based on this assumption.
- If the System object is locked -- When the input data type is `'double'` or `'single'`, the analysis object function cannot determine the data type of the coefficients. The function assumes that the data type of the coefficients is signed, has a 16-bit word length, and is autoscaled. The function performs fixed-point analysis based on this assumption.

To check if the System object is locked or unlocked, use the `isLocked` function.

When you specify this input as `'Fixed'` and the filter object has the data type of the coefficients set to a custom numeric type, the object function performs fixed-point analysis based on the custom numeric data type.

Data Types: `char` | `string`

Output Arguments

impresp — Impulse response

column vector

Impulse response, returned as a column vector of length `n`. If `n` is not specified, the length of the impulse response vector equals the number of coefficients in the filter.

Data Types: `double`

t — Sample intervals

column vector

Sample intervals in seconds, returned as a column vector of equally spaced points. Units are in seconds. The syntax used determines the range of the output.

Data Types: `double`

order

Package: comm

Order of discrete-time filter System object

Syntax

```
filtOrder = order(rcfilter)
```

Description

`filtOrder = order(rcfilter)` returns the order of the filter System object. The order depends on the filter structure and the reference double-precision floating-point coefficients.

Examples

Determine Group Delay for RRC Filter Pair

Create a square root raised cosine (RRC) filter pair using the `comm.RaisedCosineTransmitFilter` and `comm.RaisedCosineReceiveFilter` System objects. Determine the group delay of the overall filter pair.

```
txrcfilt = comm.RaisedCosineTransmitFilter
```

```
txrcfilt =  
comm.RaisedCosineTransmitFilter with properties:
```

```
          Shape: 'Square root'  
    RolloffFactor: 0.2000  
    FilterSpanInSymbols: 10  
    OutputSamplesPerSymbol: 8  
          Gain: 1
```

```
rxrcfilt = comm.RaisedCosineReceiveFilter
```

```
rxrcfilt =  
comm.RaisedCosineReceiveFilter with properties:
```

```
          Shape: 'Square root'  
    RolloffFactor: 0.2000  
    FilterSpanInSymbols: 10  
    InputSamplesPerSymbol: 8  
    DecimationFactor: 8  
    DecimationOffset: 0  
          Gain: 1
```

```
groupDelay = order(txrcfilt)/2 + order(rxrcfilt)/2
```

```
groupDelay = 80
```

Input Arguments

rcfilter — Input filter

`comm.RaisedCosineReceiveFilter` System object | `comm.RaisedCosineTransmitFilter` System object

Input filter, specified as one of these of filter System objects.

- `comm.RaisedCosineReceiveFilter`
- `comm.RaisedCosineTransmitFilter`

Output Arguments

filtOrder — Filter order

scalar

Filter order, returned as a scalar. The order depends on the filter structure and the reference double-precision floating-point coefficients.

Data Types: `double`

Information about FM broadcast modulator or demodulator

Syntax

```
fmbInfo = info(fmb)
```

Description

`fmbInfo = info(fmb)` returns a structure containing information for the `comm.FMBroadcastModulator` or `comm.FMBroadcastDemodulator` System object

Note

- The modulator input sequence length for the audio input must be a multiple of `AudioDecimationFactor`.
 - The modulator input sequence length for the RDS/RBDS input must be a multiple of `RBDSDecimationFactor`.
 - When `RBDS` is `true`, the demodulator input sequence length must be a multiple of `AudioDecimationFactor` and `RBDSDecimationFactor`.
 - When `RBDS` is `false`, the demodulator input sequence length must be a multiple of `AudioDecimationFactor`.
-

Examples

Plot Spectrum of FM Broadcast Modulate and Demodulate Streaming Audio Signals

Modulate and demodulate an audio signal with the FM broadcast modulator and demodulator System objects. Plot the frequency responses to compare the input and demodulated audio signals.

Load the audio file `guitartune.wav` by using an audio file reader System object™. Set the samples per frame to 44,100, which is large enough to include the entire audio file.

```
audiofilereader = dsp.AudioFileReader('guitartune.wav', ...
    'SamplesPerFrame',44100);
x = audiofilereader();
```

Create spectrum analyzer System objects to plot the spectra of the modulated and demodulated signals.

```
SAudio = dsp.SpectrumAnalyzer( ...
    'SampleRate',44100, ...
```

```
    'ShowLegend',true, ...
    'Title','Audio Signal', ...
    'ChannelNames',{'Input signal' 'Demodulated signal'});
SAfm = dsp.SpectrumAnalyzer( ...
    'SampleRate',152e3, ...
    'Title','FM Broadcast Signal');
```

Create FM broadcast modulator and demodulator objects. Set the sample rate of the output audio signal to match the sample rate of the input audio signal. Configure the demodulator to match the specified modulator.

```
fmbMod = comm.FMBroadcastModulator( ...
    'AudioSampleRate',audiofilereader.SampleRate, ...
    'SampleRate',200e3);
fmbDemod = comm.FMBroadcastDemodulator(fmbMod)
```

```
fmbDemod =
  comm.FMBroadcastDemodulator with properties:

    SampleRate: 200000
  FrequencyDeviation: 75000
  FilterTimeConstant: 7.5000e-05
    AudioSampleRate: 44100
    PlaySound: false
    Stereo: false
    RBDS: false
```

The length of the sequence input to the object must be an integer multiple of the decimation factor. To determine the audio decimation factor of the filter in the modulator and demodulator, use the `info` object function.

```
info(fmbMod)
```

```
ans = struct with fields:
    AudioDecimationFactor: 441
  AudioInterpolationFactor: 2000
    RBDSDecimationFactor: 19
  RBDSInterpolationFactor: 320
```

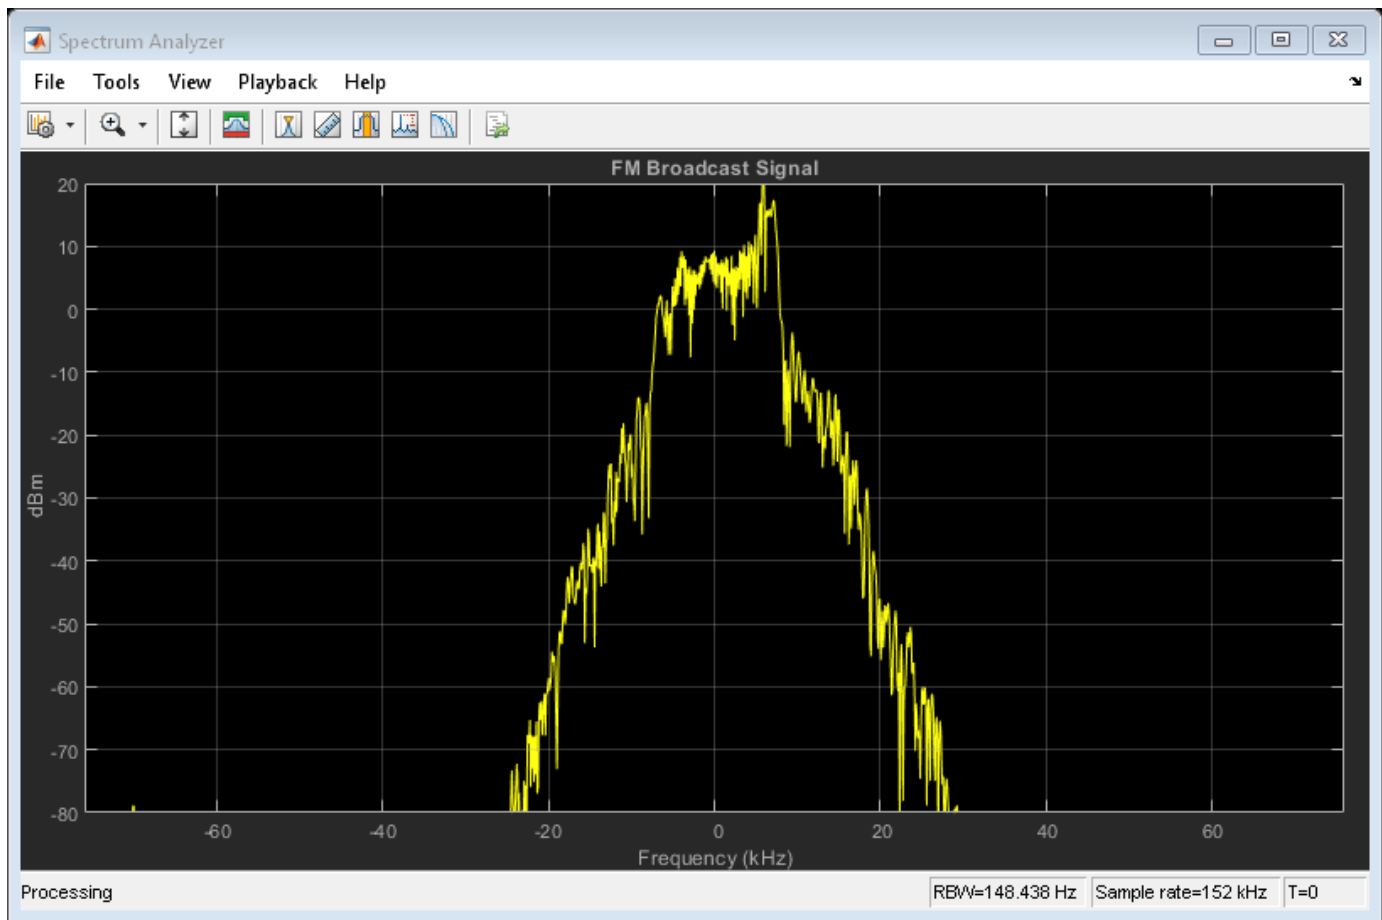

```
info(fmbDemod)
```

```
ans = struct with fields:
    AudioDecimationFactor: 50
  AudioInterpolationFactor: 57
    RBDSDecimationFactor: 50
  RBDSInterpolationFactor: 57
```

The audio decimation factor of the modulator is a multiple of the audio frame length of 44,100. The audio decimation factor of the demodulator is an integer multiple of the 200,000 samples data sequence length of the modulator output.

Modulate the audio signal and plot the spectrum of the modulated signal.

```
y = fmbMod(x);
SAfm(y)
```

Demodulate the modulated audio signal and plot the resultant spectrum. Compare the input signal spectrum with the demodulated signal spectrum. The spectra are similar except that the demodulated signal has smaller high-frequency components.

```
z = fmbDemod(y);  
SAudio([x z])
```

Input Arguments

fmb — FM broadcast object

`comm.FMBroadcastModulator` System object | `comm.FMBroadcastDemodulator` System object

FM broadcast object, specified as one of these System objects.

- `comm.FMBroadcastModulator`
- `comm.FMBroadcastDemodulator`

Output Arguments

fmbInfo — FM broadcast object information

structure

FM broadcast object information, returned as a structure containing these fields.

Field	Description
<code>AudioDecimationFactor</code>	Decimation factor of the audio modulator or demodulator filter.

Field	Description
AudioInterpolationFactor	Interpolation factor of the audio modulator or demodulator filter.
RBDSDecimationFactor	Decimation factor of the RDS/RBDS modulator or demodulator filter.
RBDSInterpolationFactor	Interpolation factor of the RDS/RBDS modulator or demodulator filter.

info

Package: comm

Characteristic information of GPU-based Viterbi decoder

Syntax

```
infostruct = info(gpuVitDec)
```

Description

`infostruct = info(gpuVitDec)` returns characteristic information of the specified graphics processing unit (GPU) based Viterbi decoder.

Examples

Get Characteristic Information of GPU-based Viterbi Decoder

Create a GPU-based Viterbi decoder System object™ that accepts an input vector of hard decision values, which are zeros or ones.

```
gpuVitDec = comm.gpu.ViterbiDecoder('InputFormat','Hard');
```

Get the characteristic information of the GPU-based Viterbi decoder.

```
infostruct = info(gpuVitDec)  
  
infostruct = struct with fields:  
    AcquisitionDepth: 70
```

Input Arguments

gpuVitDec — GPU-based Viterbi decoder

`comm.gpu.ViterbiDecoder` System object

GPU-based Viterbi decoder, specified as a `comm.gpu.ViterbiDecoder` System object.

Output Arguments

infostruct — Characteristic information

structure

Characteristic information of the input GPU-based Viterbi decoder, returned as a structure that contains this field.

AcquisitionDepth — Acquisition depth used in GPU implementation

integer

Acquisition depth used in the GPU implementation, returned as an integer.

The acquisition depth is the number of depunctured codewords that are used to overlap subsequences of the received data in the GPU implementation of the Viterbi decoder. For unpunctured codes, `AcquisitionDepth` is the greater of ten times the constraint length or two times the `TracebackDepth` property of the decoder. For punctured codes, `AcquisitionDepth` is scaled by a multiple of the number of codewords in the puncture pattern vector.

info

Package: comm

Characteristic information about multiband combining

Syntax

```
mbcInfo = info(multibandcombiner)
```

Description

`mbcInfo = info(multibandcombiner)` returns a structure containing characteristic information about the multiband combiner.

Examples

Show Multiband Combiner Characteristic Information

Create a multiband combiner System object™ and show the characteristic information for the configured object.

Create a multiband combine object. Use the `info` object function to view the characteristic information.

```
mutlibandcombiner = comm.MultibandCombiner()
```

```
mutlibandcombiner =  
    comm.MultibandCombiner with properties:
```

```
        InputSampleRate: 1000000  
        FrequencyOffsets: [0 1000000]  
        OutputSampleRateSource: 'Auto'
```

```
info(mutlibandcombiner)
```

```
ans = struct with fields:  
    OutputSampleRate: 3000000  
        Delay: 36
```

Input Arguments

multibandcombiner — Multiband combiner

`comm.MultibandCombiner` System object

Multiband combiner, specified as a `comm.MutlibandCombiner` System object.

Output Arguments

mbcInfo — Multiband combiner characteristic information

structure

Multiband combiner characteristic information, returned as a structure containing these fields. The multiband combiner is specified by the input `multibandcombiner`.

OutputSampleRate — Sample rate of output signal

positive scalar

Sample rate of the output signal in Hz, returned as a positive scalar.

Delay — Delay between input and output

positive scalar

Delay between input and output signals in samples at the output sampling rate.

plot

Package: comm

Plot nonlinearity AM/AM and AM/PM characteristics

Syntax

```
plot(mnl)
plot(mnl, 'Gain')
mnlplot = plot( __ )
```

Description

`plot(mnl)` plots the output signal power and the phase change versus the input signal power. This syntax is equivalent to `plot(mnl, 'Pout')`.

`plot(mnl, 'Gain')` plots the gain and the phase change versus the input signal power.

`mnlplot = plot(__)` returns a handle to the figure containing the generated plot. Specify an input argument combination from any of the previous syntaxes.

Examples

Plot Output Response for Amplifier Model

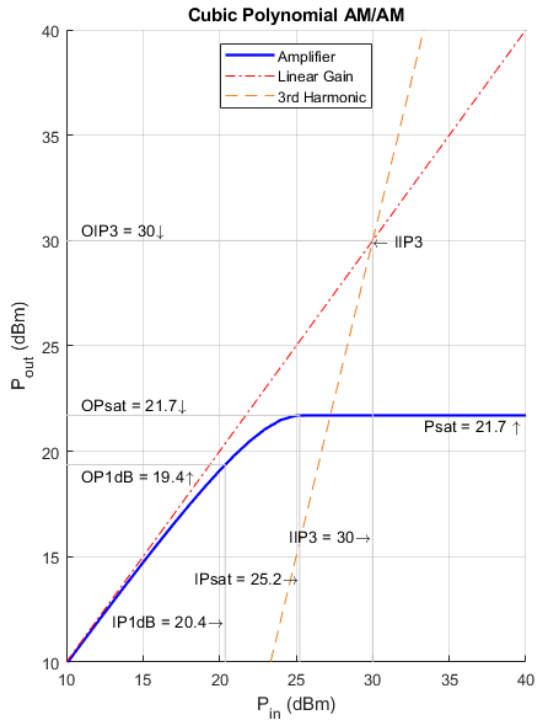

Plot the amplifier output power and phase response for various model methods.

Create a memoryless nonlinearity impairment System object™ for each of the nonlinearity modeling methods.

```
ampCubicPoly= comm.MemorylessNonlinearity('Method','Cubic polynomial');
ampHyperbolic = comm.MemorylessNonlinearity('Method','Hyperbolic tangent');
ampGhorbani = comm.MemorylessNonlinearity('Method','Ghorbani model');
ampSaleh = comm.MemorylessNonlinearity('Method','Saleh model');
ampModRapp = comm.MemorylessNonlinearity('Method','Modified Rapp model');
ampLookupTable = comm.MemorylessNonlinearity('Method','Lookup table','ReferenceImpedance',50);
```

Use the `plot` object function of the `comm.MemorylessNonlinearity` System object to show the response curves for the output power and phase for the each of the amplifier models.

```
plot(ampCubicPoly);
```

plot(ampHyperbolic);

```
plot(ampSaleh);
```

```
plot(ampLookupTable);
```

```
plot(ampGhorbani);
```

```
plot(ampModRapp);
```

Input Arguments

mn1 – Memoryless nonlinearity

`comm.Memoryless Nonlinearity System` object

Memoryless nonlinearity, specified as a `comm.MemorylessNonlinearity System` object.

Output Arguments

mn1plot – Plot figure

Figure object

Plot figure, returned as a `Figure` object created using the `figure` function. Use the `Figure` object to query or modify properties of the figure after it is created.

See Also

`comm.MemorylessNonlinearity`

Introduced in R2021a

constellation

Package: comm

Calculate or plot ideal signal constellation

Syntax

```
symbols = constellation(obj)
constellation(obj)
```

Description

`symbols = constellation(obj)` returns the numerical values of the constellation.

`constellation(obj)` generates a constellation plot for the object.

Examples

Plot QPSK Reference Constellation

Create a QPSK modulator.

```
mod = comm.QPSKModulator;
```

Determine the reference constellation points.

```
refC = constellation(mod)
```

```
refC = 4×1 complex
```

```
 0.7071 + 0.7071i
-0.7071 + 0.7071i
-0.7071 - 0.7071i
 0.7071 - 0.7071i
```

Plot the constellation.

```
constellation(mod)
```

Create a QPSK demodulator having phase offset set to θ .

```
demod = comm.QPSKDemodulator(theta);
```

Plot the reference constellation. The `constellation` method works for both modulator and demodulator objects.

```
constellation(demod)
```

Calculate BPSK Modulator Reference Constellation

Create a BPSK Modulator System object™ and calculate the reference constellation values.

Create a `comm.BPSKModulator` System object.

```
h = comm.BPSKModulator;
```

Calculate and display the reference constellation values by calling the `constellation` function.

```
refC = constellation(h)
```

```
refC = 2×1 complex
```

```
 1.0000 + 0.0000i  
-1.0000 + 0.0000i
```

Plot PSK Reference Constellation

Create a PSK modulator.

```
mod = comm.PSKModulator;
```

Determine the reference constellation points.

```
refC = constellation(mod)
```

```
refC = 8x1 complex
    0.9239 + 0.3827i
    0.3827 + 0.9239i
   -0.3827 + 0.9239i
   -0.9239 + 0.3827i
   -0.9239 - 0.3827i
   -0.3827 - 0.9239i
    0.3827 - 0.9239i
    0.9239 - 0.3827i
```

Plot the constellation.

```
constellation(mod)
```

Create a PSK demodulator having modulation order 16.

```
demod = comm.PSKDemodulator(16);
```

Plot its reference constellation. The constellation method works for both modulator and demodulator objects.

```
constellation(demod)
```

Plot BPSK Modulator Reference Constellation

Create a BPSK Modulator System object™ and plot the reference constellation.

Create a `comm.BPSKModulator` System object.

```
bpsk = comm.BPSKModulator;
```

Plot the reference constellation by calling the `constellation` function.

```
constellation(bpsk)
```

Calculate Reference Signal Constellation for BPSK Demodulator

Create a BPSK Demodulator System object™ and calculate its reference constellation.

```
bpskDemod = comm.BPSKDemodulator;
```

Calculate and display the reference signal constellation by calling the `constellation` function.

```
refC = constellation(bpskDemod)
```

```
refC = 2×1 complex
```

```
1.0000 + 0.0000i  
-1.0000 + 0.0000i
```

Plot BPSK Demodulator Reference Signal Constellation

Create a BPSK Demodulator System object™ and then plot the reference signal constellation.

```
bpskDemod = comm.BPSKDemodulator;
```

Plot the reference constellation by calling the `constellation` function.

```
constellation(bpskDemod)
```

Input Arguments

obj — System object to return constellation for

System object

System object to return constellation for, specified as a modulator System object.

Data Types: object

Output Arguments

symbols — Constellation points

complex vector (default)

Constellation points, returned as a complex vector.

Data Types: double | single

Complex Number Support: Yes

info

Package: comm

Characteristic information about ray-tracing channel

Syntax

```
chanInfo = info(rtchan)
```

Description

`chanInfo = info(rtchan)` returns a structure containing characteristic information about the input ray-tracing channel.

Examples

Return Information for Ray-Tracing Channel Between Two Sites in Hong Kong

Perform ray tracing between two sites in Hong Kong, China, build a multipath channel model using the ray-tracing result, and view the ray-tracing channel information.

Create a Site Viewer map display of buildings in Hong Kong. For more information about the osm file, see [1] on page 4-0 .

```
sv = siteviewer("Buildings","hongkong.osm");
```

Create transmitter and receiver sites.

```
tx = txsite( ...
    "Latitude",22.2789, ...
    "Longitude",114.1625, ...
    "AntennaAngle",30, ... % azimuth angle
    "AntennaHeight",10, ...
    "TransmitterFrequency",28e9);
rx = rxsite( ...
    "Latitude",22.2799, ...
    "Longitude",114.1617, ...
    "AntennaAngle",120, ... % azimuth angle
    "AntennaHeight",1);
```

Perform ray tracing to find rays with up to 2 reflections.

```
pm = propagationModel("raytracing", ...
    "Method",'sbr', ...
    "MaxNumReflections",3);
rays = raytrace(tx,rx,pm);
```

Create a channel model by using the transmitter site, receiver site, and calculated rays between the sites. Return information from the ray-tracing channel.

```
rtchan = comm.RayTracingChannel(rays{1},tx,rx);
info(rtchan)
```

```
ans = struct with fields:
    CarrierFrequency: 2.8000e+10
    CoordinateSystem: 'Geographic'
    TransmitArrayLocation: [3×1 double]
    ReceiveArrayLocation: [3×1 double]
    NumTransmitElements: 1
    NumReceiveElements: 1
    ChannelFilterDelay: 4
    ChannelFilterCoefficients: [12×30 double]
    NumSamplesProcessed: 0
    LastFrameTime: 0
```

Appendix

[1] The osm file is downloaded from <https://www.openstreetmap.org>, which provides access to crowd-sourced map data all over the world. The data is licensed under the Open Data Commons Open Database License (ODbL), <https://opendatacommons.org/licenses/odbl/>.

Input Arguments

rtchan — Ray-tracing channel

`comm.RayTracingChannel` System object

Ray-tracing channel, specified as a `comm.RayTracingChannel` System object.

Output Arguments

chanInfo — Ray tracing channel characteristic information

structure

Ray tracing channel characteristic information, returned as a structure containing these fields. The ray tracing channel is specified by the input `rtchan`.

CarrierFrequency — Carrier frequency

positive scalar

Carrier frequency in Hz, returned as a positive scalar.

CoordinateSystem — Coordinate system

'Cartesian' | 'Geographic'

Coordinate system, returned as 'Cartesian' or 'Geographic'. Any `comm.Ray` objects, specified by the `PropagationRays` property of the `rtchan` input, that have their `PathSpecification` property set to 'Locations', must have the same `CoordinateSystem` property setting.

Dependencies

This property applies when at least one `comm.Ray` object in the `PropagationRays` property of the `rtchan` input has `PathSpecification` set to 'Locations'.

TransmitArrayLocation — Transmit array location

three element column vector

Transmit array location, returned as a three element column vector. Any `comm.Ray` objects, specified by the `PropagationRays` property of the `rtchan` input, that have their `PathSpecification` property set to 'Locations', must have the same `TransmitterLocation` property setting.

Dependencies

This property applies when at least one `comm.Ray` object in the `PropagationRays` property of the `rtchan` input has `PathSpecification` set to 'Locations'.

ReceiveArrayLocation — Receive array location

three element column vector

Receive array location, returned as a three element column vector. Any `comm.Ray` objects, specified by the `PropagationRays` property of the `rtchan` input, that have their `PathSpecification` property set to 'Locations', must have the same `ReceiverLocation` property setting.

Dependencies

This property applies when at least one `comm.Ray` object in the `PropagationRays` property of the `rtchan` input has `PathSpecification` set to 'Locations'.

NumTransmitElements — Number of elements in transmit array

positive integer

Number of elements in the transmit array, returned as a positive integer.

NumReceiveElements — Number of elements in receive array

positive integer

Number of elements in the receive array, returned as a positive integer.

ChannelFilterDelay — Channel filter delay

nonnegative integer

Channel filter delay in samples, returned as a nonnegative integer.

ChannelFilterCoefficients — Channel filter coefficients

N_P -by- N_H matrix

Channel filter coefficients, returned as an N_P -by- N_H matrix. This coefficient matrix is used to convert channel impulse responses to channel filter tap gains for each sample, and then for each pair of transmit and receive antenna elements. N_P is the number of paths (specifically, the number of rays as indicated by the length of the `PropagationRays` property of the `rtchan` input). N_H is the number of impulse response samples (specifically, the number of channel filter taps).

NumSamplesProcessed — Number of samples processed by channel object

nonnegative integer

Number of samples processed by the channel object since its last reset, returned as a nonnegative integer.

LastFrameTime — End time of last frame

nonnegative integer

End time of last frame in seconds, returned as a nonnegative integer.

arrayConfig | comm.Ray | comm.RayTracingChannel

Functions

showProfile

Introduced in R2020b

showProfile

Package: comm

Plot temporal and spatial profiles of ray-tracing channel

Syntax

```
showProfile(rtchan)
showProfile(rtchan, 'ArrayPattern', false)
```

Description

`showProfile(rtchan)` plots the power delay profile (PDP), angle of departure (AoD), and angle of arrival (AoA) information for the ray-tracing channels in a single figure with three subplots.

- The PDP subplot is derived from the propagation delay, path loss, phase shift, pattern gain at transmit array and pattern gain at receive array for each ray specified by the `PropagationRays` property of the `rtchan` input.
- The AoD and AoA subplots show the 3-D directions of the rays in the local coordinate system (LCS).
 - When the `TransmitArray` or `ReceiveArray` properties are objects from the “Phased Array System Toolbox” software, the AoD and AoA subplots also show the directivity pattern of the arrays.

`showProfile(rtchan, 'ArrayPattern', false)` optionally turns off the directivity pattern in the AoD and AoA subplots. This option applies only when the `TransmitArray` or `ReceiveArray` property in the `comm.RayTracingChannel` System object are objects from the “Phased Array System Toolbox” software.

Examples

Show Temporal and Spatial Profiles of Ray-Tracing Channel

Perform ray-tracing between two sites in Chicago. Build a multipath channel model using the ray tracing result, and show the temporal and spatial profiles of the channel.

Launch Site Viewer with buildings in Chicago. For more information about the `osm` file, see [1] on page 4-0 .

```
viewer = siteviewer("Buildings", "chicago.osm");
```

Create a transmitter site, a receiver site, and a SBR ray tracing propagation model for up to five reflections.

```
tx = txsite('Latitude', 41.8800, ...
           'Longitude', -87.6295, ...
           'AntennaAngle', 30, 'AntennaHeight', 10, ...
           'TransmitterFrequency', 28e9);
```

```
rx = rxsite('Latitude',41.881352, ...  
          'Longitude',-87.629771, ...  
          'AntennaHeight',30);  
pm = propagationModel("raytracing", ...  
                     "Method","sbr", ...  
                     "MaxNumReflections",5);
```

Show obstructed line of sight.

```
los(tx,rx)
```

Show reflected propagation paths using ray tracing.

```
raytrace(tx,rx,pm)
```

Perform ray tracing to find rays between the transmitter and receiver sites for the specified SBR propagation model. Create a channel model using transmitter site, receiver site, and calculated rays between the sites. Show temporal and spatial profiles of the channel.

```
rays = raytrace(tx,rx,pm);  
rtchan = comm.RayTracingChannel(rays{1},tx,rx);  
showProfile(rtchan);
```

Angle of Departure

Angle of Arrival

Introduced in R2020b

hide

Package: comm

Hide scope window

Syntax

```
hide(scope)
```

Description

`hide(scope)` hides the window of the System object scope.

Examples

Hide and Show Scope

Create a `comm.ConstellationDiagram` object.

```
scope = comm.ConstellationDiagram;
```

Hide the constellation diagram scope window.

```
if(isVisible(scope))  
    hide(scope)  
end
```

Show the constellation diagram scope window.

```
if(~isVisible(scope))  
    show(scope)  
end
```

Hide the constellation diagram scope window again.

```
if(isVisible(scope))  
    hide(scope)  
end
```

Hide and Show Constellation Diagram

Generate a 16-QAM reference constellation and a signal to display.

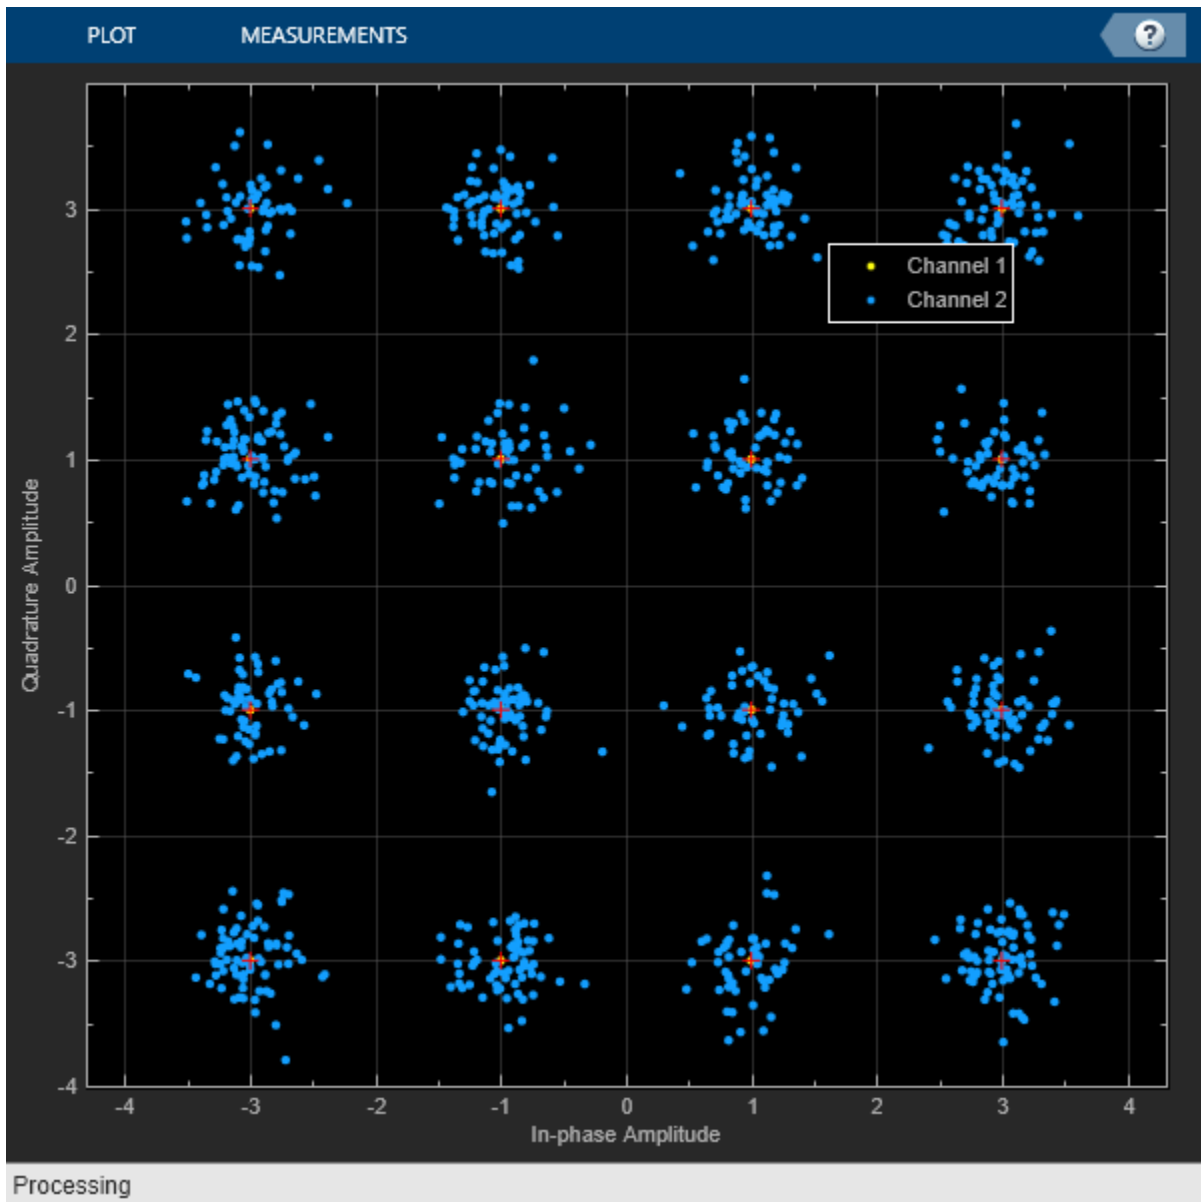

```
M = 16;  
xRef = (0:M-1)';  
refConst = qammod(xRef,M);  
signal = randi([0 M-1],1000,1);
```

Create a constellation diagram System object™, specifying the constellation reference points and axes limits using name-value pairs.

```
scope = comm.ConstellationDiagram('ReferenceConstellation',refConst, ...
    'XLimits',[-4 4],'YLimits',[-4 4]);
```

Modulate the random data signal using QAM. Add Gaussian white noise to the QAM symbols. Display the QAM symbols and noisy symbols with the constellation diagram object.

```
sym = qammod(signal,M);
rcv = awgn(sym,20,'measured');
scope([sym rcv]);
```

Hide the constellation diagram scope window.

```
if(isVisible(scope))
    hide(scope)
end
```

Show the constellation diagram scope window.

```
if(~isVisible(scope))
    show(scope)
end
```

Clear the workspace variables.

```
clear scope sym rcv M refConst signal xRef
```

Input Arguments

scope — Scope System object

scope System object

Scope System object, specified as a `comm.ConstellationDiagram` System object.

Example: `scope = comm.ConstellationDiagram;`

See Also

Functions

`isVisible` | `show`

Objects

`comm.ConstellationDiagram`

Introduced in R2013a

isVisible

Package: comm

Determine visibility of scope window

Syntax

```
visibility = isVisible(scope)
```

Description

`visibility = isVisible(scope)` returns a logical to verify in the System object scope is open. `visibility` is 1 if the scope window is open and 0 otherwise.

Examples

Hide and Show Scope

Create a `comm.ConstellationDiagram` object.

```
scope = comm.ConstellationDiagram;
```

Hide the constellation diagram scope window.

```
if(isVisible(scope))  
    hide(scope)  
end
```

Show the constellation diagram scope window.

```
if(~isVisible(scope))  
    show(scope)  
end
```

Hide the constellation diagram scope window again.

```
if(isVisible(scope))  
    hide(scope)  
end
```

Hide and Show Constellation Diagram

Generate a 16-QAM reference constellation and a signal to display.

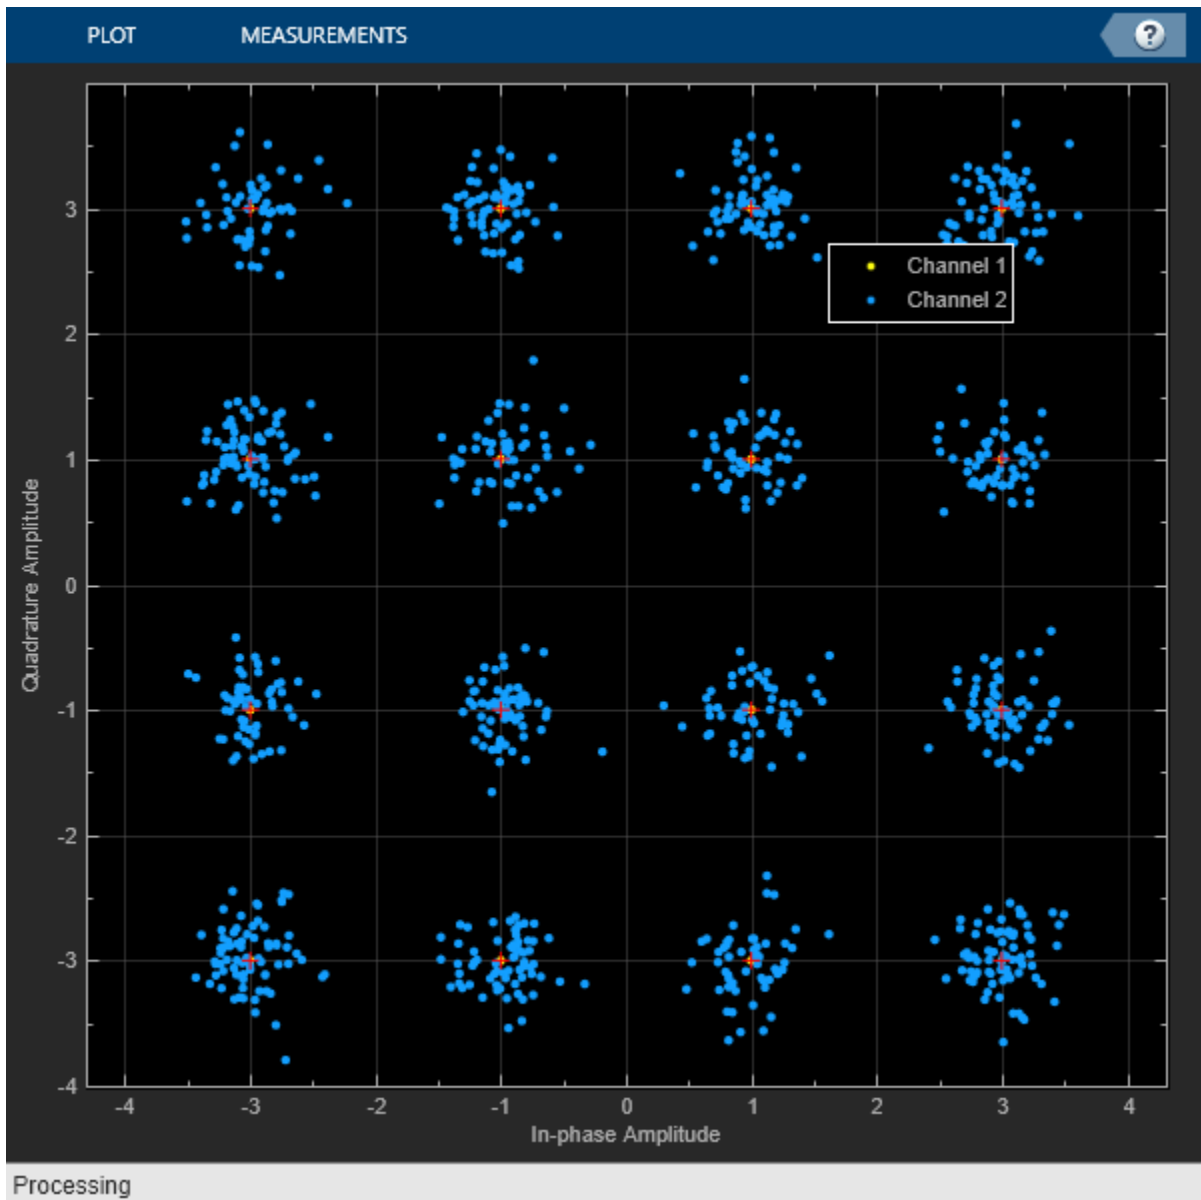

```
M = 16;  
xRef = (0:M-1)';  
refConst = qammod(xRef,M);  
signal = randi([0 M-1],1000,1);
```

Create a constellation diagram System object™, specifying the constellation reference points and axes limits using name-value pairs.

```
scope = comm.ConstellationDiagram('ReferenceConstellation',refConst, ...
    'XLimits',[-4 4],'YLimits',[-4 4]);
```

Modulate the random data signal using QAM. Add Gaussian white noise to the QAM symbols. Display the QAM symbols and noisy symbols with the constellation diagram object.

```
sym = qammod(signal,M);
rcv = awgn(sym,20,'measured');
scope([sym rcv]);
```

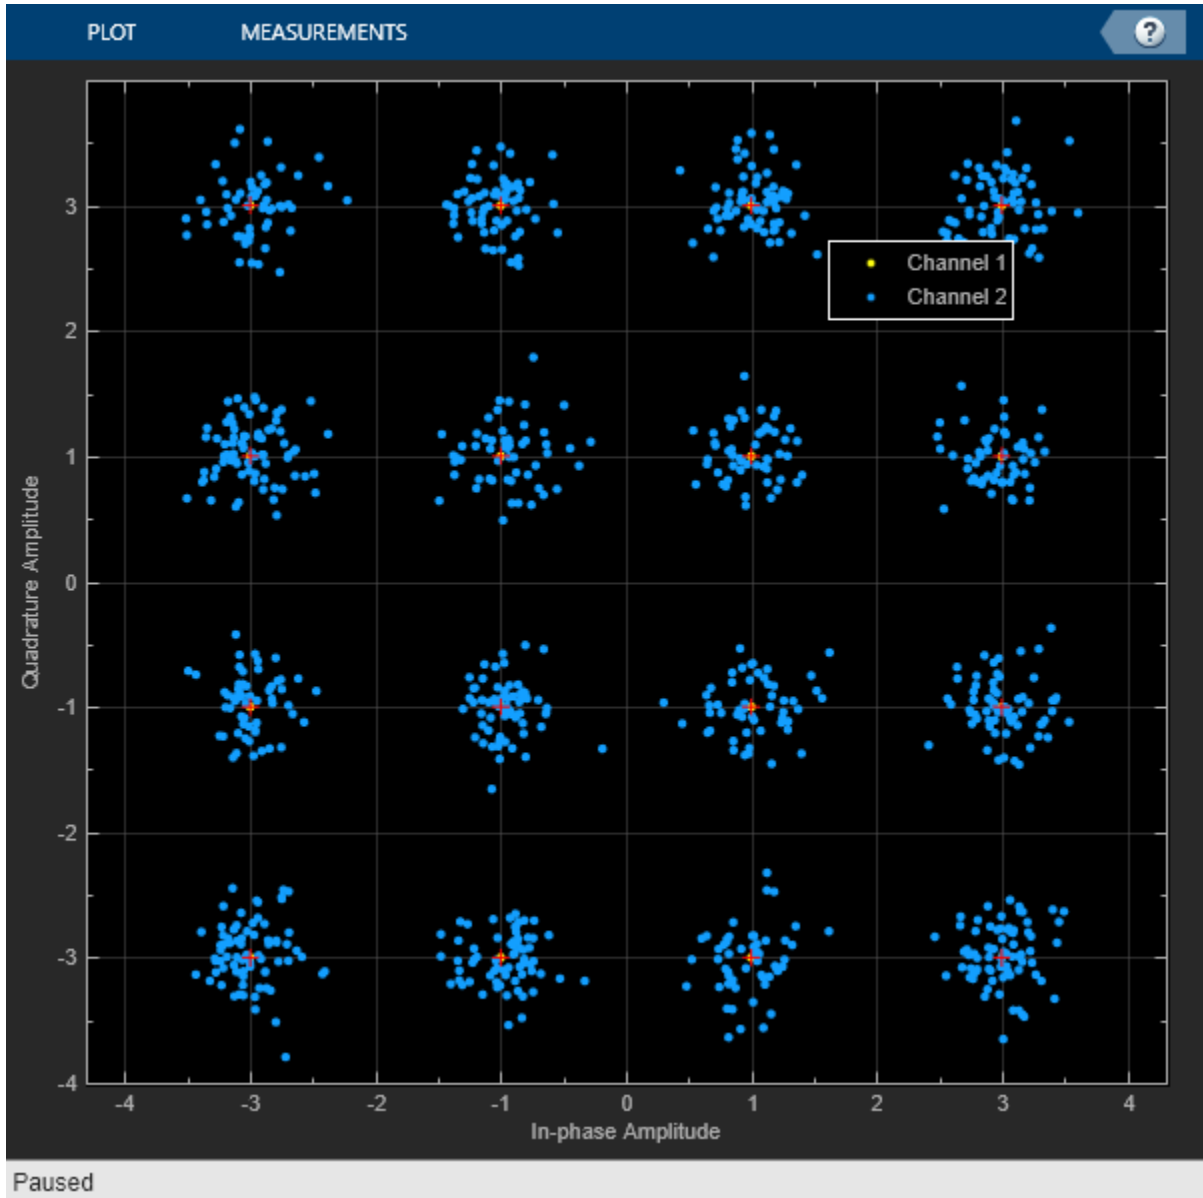

Hide the constellation diagram scope window.

```
if(isVisible(scope))  
    hide(scope)  
end
```

Show the constellation diagram scope window.

```
if(~isVisible(scope))  
    show(scope)  
end
```

Clear the workspace variables.

```
clear scope sym rcv M refConst signal xRef
```

Input Arguments

scope — Scope System object

scope System object

Scope System object, specified as a `comm.ConstellationDiagram` or `comm.EyeDiagram` System object.

Example: `scope = comm.ConstellationDiagram;`

See Also

Functions

`show` | `hide`

Objects

`comm.ConstellationDiagram` | `comm.EyeDiagram`

Introduced in R2013a

show

Package: comm

Show scope window

Syntax

```
show(scope)
```

Description

`show(scope)` shows the window of the System object scope.

Examples

Hide and Show Scope

Create a `comm.ConstellationDiagram` object.

```
scope = comm.ConstellationDiagram;
```

Hide the constellation diagram scope window.

```
if(isVisible(scope))  
    hide(scope)  
end
```

Show the constellation diagram scope window.

```
if(~isVisible(scope))  
    show(scope)  
end
```

Hide the constellation diagram scope window again.

```
if(isVisible(scope))  
    hide(scope)  
end
```

Hide and Show Constellation Diagram

Generate a 16-QAM reference constellation and a signal to display.

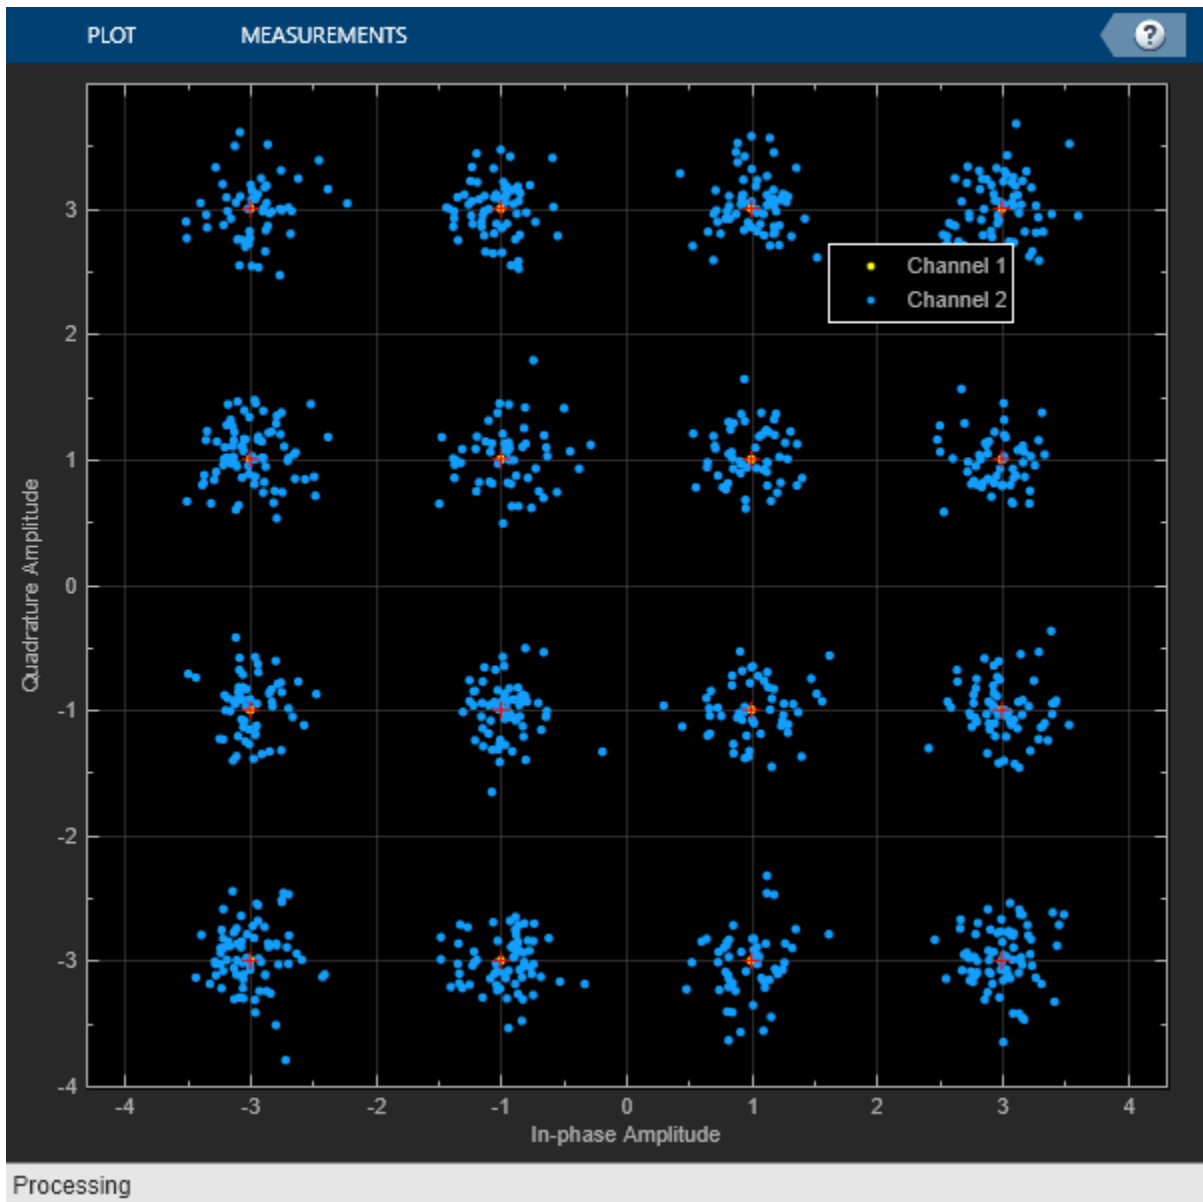

```
M = 16;  
xRef = (0:M-1)';  
refConst = qammod(xRef,M);  
signal = randi([0 M-1],1000,1);
```

Create a constellation diagram System object™, specifying the constellation reference points and axes limits using name-value pairs.

```
scope = comm.ConstellationDiagram('ReferenceConstellation',refConst, ...
    'XLimits',[-4 4],'YLimits',[-4 4]);
```

Modulate the random data signal using QAM. Add Gaussian white noise to the QAM symbols. Display the QAM symbols and noisy symbols with the constellation diagram object.

```
sym = qammod(signal,M);
rcv = awgn(sym,20,'measured');
scope([sym rcv]);
```

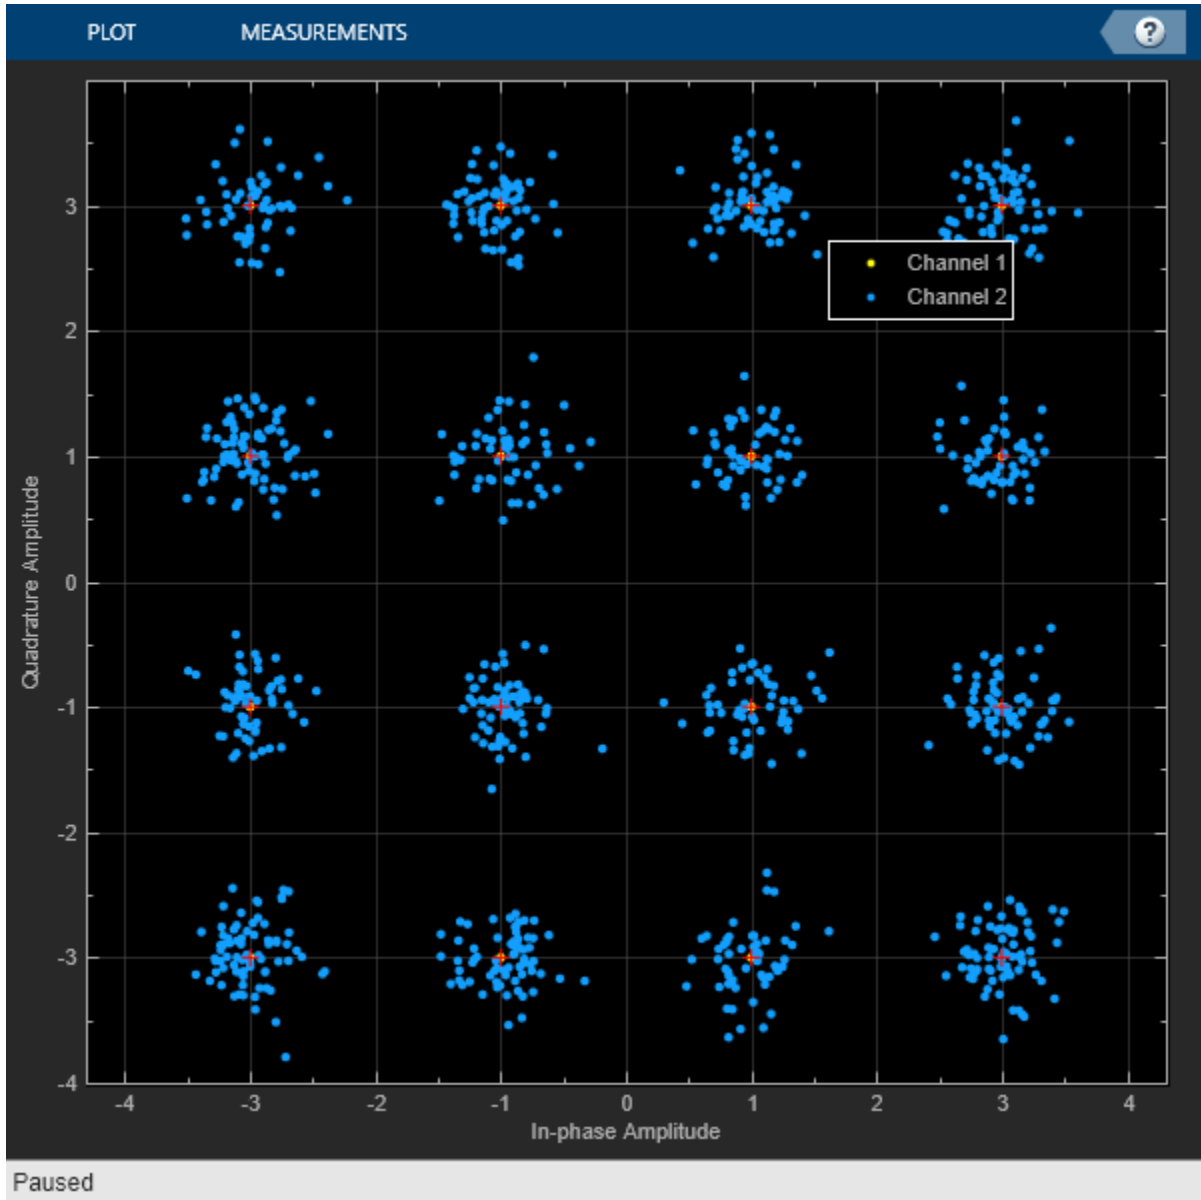

Hide the constellation diagram scope window.

```
if(isVisible(scope))  
    hide(scope)  
end
```

Show the constellation diagram scope window.

```
if(~isVisible(scope))  
    show(scope)  
end
```

Clear the workspace variables.

```
clear scope sym rcv M refConst signal xRef
```

Input Arguments

scope — Scope System object

scope System object

Scope System object, specified as a `comm.ConstellationDiagram` System object.

Example: `scope = comm.ConstellationDiagram;`

See Also

Functions

`hide` | `isVisible`

Objects

`comm.ConstellationDiagram`

Introduced in R2013a

info

System object: `comm.WINNER2Channel`

Package: `comm`

Display information about `WINNER2Channel` object

Note Download Required: To use , first download the WINNER II Channel Model for Communications Toolbox add-on.

Syntax

```
s = info(obj)
```

Description

`s = info(obj)` returns a structure containing information about the `Winner2Channel` System object characteristics. The information structure contains:

- `NumLinks` - Number of links in the system
- `NumBSElements` - Number of transmit antennas at the BS for each link
- `NumMSElements` - Number of receive antennas at the MS for each link
- `NumPaths` - Number of delay paths for each link
- `SampleRate` - Sample rate for each link
- `ChannelFilterDelay` - Channel filter delay per link, measured in samples
- `NumSamplesProcessed` - Number of samples the channel has processed since the last reset

Introduced in R2016b

info

Package: comm

Provide dimensioning information for OFDM modulator

Syntax

```
infostruct = info(hMod)
```

Description

`infostruct = info(hMod)` returns the input, pilot, and output data dimensions for the specified OFDM modulator System object.

Examples

Determine OFDM Modulator Data Dimensions

Get the OFDM modulator data dimensions by using the `info` object function.

Construct an OFDM modulator System object™ with user-specified pilot indices, an inserted DC null, and specify two transmit antennas.

```
hMod = comm.OFDMModulator('NumGuardBandCarriers',[4;3], ...
    'PilotInputPort',true, ...
    'PilotCarrierIndices',cat(3,[12; 26; 40; 54], ...
    [11; 25; 39; 53]), ...
    'InsertDCNull',true, ...
    'NumTransmitAntennas',2);
```

Use the `info` object function to get the modulator input data, pilot input data, and output data sizes.

```
info(hMod)

ans = struct with fields:
    DataInputSize: [48 1 2]
    PilotInputSize: [4 1 2]
    OutputSize: [80 2]
```

Input Arguments

hMod — OFDM modulator

System object

OFDM modulator, specified as a `comm.OFDMModulator` System object.

Output Arguments

infostruct — Dimensions of structure for OFDM modulator

struct

Dimensions of structure for OFDM modulator, returned as a structure containing these fields.

DataInputSize — Dimensions of input data

3-D array

Dimensions of input data, returned as a 3-D array of numeric values. The dimensions of this field are $N_{\text{data}}\text{-by-}N_{\text{sym}}\text{-by-}N_{\text{t}}$, where N_{data} is the number of data subcarriers such that $N_{\text{data}} = N_{\text{FFT}} - N_{\text{leftG}} - N_{\text{rightG}} - N_{\text{DCNull}} - N_{\text{pilot}} - N_{\text{custNull}}$.

For variable definitions, see Variable Definitions.

PilotInputSize — Dimensions of the pilot input data

3-D array

Dimensions of the pilot input array, returned as a 3-D array of numeric values. The output dimensions of this field are $N_{\text{pilot}}\text{-by-}N_{\text{sym}}\text{-by-}N_{\text{t}}$.

OutputSize — Dimensions of modulator output data

3-D array

Dimensions of the modulator output data, returned as a 3-D array of numeric values. The dimensions of this field are $((N_{\text{FFT}} + N_{\text{CP}}) \times N_{\text{sym}})\text{-by-}N_{\text{t}}$.

For variable definitions, see Variable Definitions.

Data Types: struct

More About

List of Variables

The variables mentioned in this table are defined in this table:

Variable Definitions

Variable	Description
N_{FFT}	Number of subcarriers
N_{leftG}	Number of subcarriers in the left guard band
N_{rightG}	Number of subcarriers in the right guard band
N_{DCNull}	Number of subcarriers in the DC null (either 0 or 1)
N_{pilot}	Number of pilot subcarriers
N_{custNull}	Number of subcarriers used for custom nulls (applies only when the PilotCarrierIndices property of input hMod is a 3-D array)
N_{t}	Number of transmit antennas
N_{CP}	Length of cyclic prefix.

Objects

comm.OFDMModulator

Introduced in R2014a

info

Package: comm

Return characteristic information about channel filter

Syntax

```
infostruct = info(chanFilt)
```

Description

`infostruct = info(chanFilt)` returns a structure containing characteristic information about the `comm.ChannelFilter` System object.

Examples

Determine Channel Filter Structure Dimensions

In a distributed MIMO system, send the same signal from two geographically separate transmitters (Tx) and combine the received signals at one single receiver (Rx) to explore spatial diversity. The two Txs are not co-located and they experience different multipath (path delays) to the Rx. Specify the path delays respectively.

```
delay1 = [0 1.5 2.3 5.2 6.6];  
delay2 = [0 3.7 6.2];
```

Configure one channel filter object per Tx.

```
chanFilt1 = comm.ChannelFilter('PathDelays', delay1);  
chanFilt2 = comm.ChannelFilter('PathDelays', delay2);
```

Use the `info` object function to get the `ChannelFilterDelay` and `ChannelFilterCoefficients`.

```
info(chanFilt1)
```

```
ans = struct with fields:  
    ChannelFilterDelay: 6  
    ChannelFilterCoefficients: [5x21 double]
```

```
info(chanFilt2)
```

```
ans = struct with fields:  
    ChannelFilterDelay: 4  
    ChannelFilterCoefficients: [3x19 double]
```

Input Arguments

chanFilt — Channel filter

System object

Channel filter, specified as a `comm.ChannelFilter` System object.

Output Arguments

infostruct — Characteristic information about channel filter

struct

Characteristic information about channel filter, returned as a structure containing these fields:

ChannelFilterDelay — Channel filter delay

positive real scalar

Channel filter delay, returned as a positive real scalar.

Data Types: `double`

ChannelFilterCoefficients — Channel filter coefficients

vector | matrix

Channel filter coefficients, returned as a vector or a matrix.

Data Types: `double`

Objects

`comm.ChannelFilter`

Introduced in R2020b

showResourceMapping

Package: comm

Show the subcarrier mapping of the OFDM symbols created by the OFDM modulator System object

Syntax

```
showResourceMapping(hMod)
showResourceMapping(hMod,ci)
```

Description

`showResourceMapping(hMod)` shows a visualization of the subcarrier mapping for the OFDM symbols created by the OFDM modulator System object.

`showResourceMapping(hMod,ci)` uses the values in input `ci` to number the subcarrier indices that the function displays. The subcarrier indices are numbered from 1 to ciN_{FFT} , where N_{FFT} is the number of FFT points.

Examples

Create and Modify OFDM Modulator

Create and display an OFDM modulator System object™ with default property values.

```
hMod = comm.OFDMModulator

hMod =
comm.OFDMModulator with properties:

    FFTLength: 64
NumGuardBandCarriers: [2x1 double]
    InsertDCNull: false
    PilotInputPort: false
CyclicPrefixLength: 16
    Windowing: false
    NumSymbols: 1
NumTransmitAntennas: 1
```

Modify the number of subcarriers and symbols.

```
hMod.FFTLength = 128;
hMod.NumSymbols = 2;
```

Verify that the number of subcarriers and the number of symbols changed.

```
disp(hMod)

comm.OFDMModulator with properties:
```

```

        FFTLength: 128
    NumGuardBandCarriers: [2x1 double]
        InsertDCNull: false
        PilotInputPort: false
    CyclicPrefixLength: 16
        Windowing: false
        NumSymbols: 2
    NumTransmitAntennas: 1

```

Use the `showResourceMapping` object function to show the mapping of data, pilot, and null subcarriers in the time-frequency space.

```
showResourceMapping(hMod)
```

Input Arguments

hMod — System object to visualize

`comm.OFDMModulator` System object

OFDM modulator, specified as a `comm.OFDMModulator` System object.

ci — Subcarrier indices to visualize

`[1, ..., NFFT]` (default) | two-element row vector of integers

Subcarrier indices to visualize, specified as a two-element row vector of integers. `ci` should satisfy $\text{diff}(\text{ci}) = N_{\text{FFT}} - 1$.

info

Package: comm

Characteristic information about carrier synchronizer

Syntax

```
infostruct = info(carrSynch)
```

Description

`infostruct = info(carrSynch)` returns a structure containing characteristic information for the CarrierSynchronizer System object.

Examples

Determine Carrier Synchronizer Loop Parameters

Create a carrier synchronizer object.

```
csync = comm.CarrierSynchronizer;
```

Determine the normalized pull-in range, the maximum frequency lock delay, and the maximum phase lock delay by using the `info` method.

```
syncInfo = info(csync)
```

```
syncInfo = struct with fields:
  NormalizedPullInRange: 0.0628
  MaxFrequencyLockDelay: 1.5787e+04
  MaxPhaseLockDelay: 130
```

The normalized pull-in range is 0.0628 rad/sec. Convert the pull-in range to Hz. This represents the maximum normalized frequency offset that can be corrected by the carrier synchronizer.

```
foffsetmax = syncInfo.NormalizedPullInRange/(2*pi)
```

```
foffsetmax = 0.0100
```

The time to acquire a frequency lock is 15787 s, and the time to acquire a phase lock is 130 s.

The overall acquisition time, `Tlock`, is well approximated by the sum of the frequency and phase lock terms.

```
Tlock = syncInfo.MaxFrequencyLockDelay + syncInfo.MaxPhaseLockDelay
```

```
Tlock = 1.5917e+04
```

Input Arguments

carrSynch — System object to get information from

System object

System object to get information from.

Output Arguments

infostruct — Structure containing object information

struct

Structure containing these fields with information about the System object.

NormalizedPullInRange — Normalized pull in range

scalar

Normalized pull in range in radians, returned as a scalar. `NormalizedPullInRange` is the largest frequency offset (rad), normalized by the loop bandwidth, for which the synchronizer can acquire lock.

MaxFrequencyLockDelay — Maximum frequency lock delay

positive integer

Maximum frequency lock delay, returned as a positive integer. `MaxFrequencyLockDelay` is the number of samples required for the synchronizer to acquire frequency lock.

MaxPhaseLockDelay — Maximum phase lock delay

positive integer

Maximum phase lock delay, returned as a positive integer. `MaxPhaseLockDelay` is the number of samples required for the synchronizer to acquire phase lock.

info

Package: comm

Characteristic information about the equalizer object

Syntax

```
infostruct = info(obj)
```

Description

`infostruct = info(obj)` returns a structure containing characteristic information for the System object.

Examples

Display Decision Feedback Equalizer Latency

Display latency value for a decision feedback equalizer object.

Create a decision feedback equalizer object.

```
dfe = comm.DecisionFeedbackEqualizer;
```

Display latency value for a decision feedback equalizer object by using the `info` object function.

```
info(dfe)
```

```
ans = struct with fields:  
    Latency: 2
```

Input Arguments

obj — System object to get information from

System object

System object to get information from.

Output Arguments

infostruct — Structure containing object information

structure

Structure containing fields with information about the System object.

Latency — Equalizer latency

scalar

Equalizer latency, returned as a scalar.

Introduced in R2012a

maxstep

Package: comm

Maximum step size for LMS equalizer convergence

Syntax

```
mumax = maxstep(eq,x)
```

Description

`mumax = maxstep(eq,x)` predicts a bound on the step size to provide convergence of the mean values of the coefficients of the equalizer defined by the `eq` System object. The set input signal sequences in `x` are assumed to have zero mean or nearly so.

Examples

Decision Feedback Equalize BPSK-Modulated Signal

Create a BPSK modulator and an equalizer System object™, specifying a decision feedback LMS equalizer having eight forward taps, five feedback taps, and a step size of 0.03.

```
bpsk = comm.BPSKModulator;
eqdfe_lms = comm.DecisionFeedbackEqualizer('Algorithm','LMS', ...
    'NumForwardTaps',8,'NumFeedbackTaps',5,'StepSize',0.03);
```

Change the reference tap index of the equalizer.

```
eqdfe_lms.ReferenceTap = 4;
```

Build a set of test data. Receive the data by convolving the signal.

```
x = bpsk(randi([0 1],1000,1));
rxsig = conv(x,[1 0.8 0.3]);
```

Use `maxstep` to find the maximum permitted step size.

```
mxStep = maxstep(eqdfe_lms,rxsig)
```

```
mxStep = 0.1028
```

Equalize the received signal. Use the first 200 symbols as the training sequence.

```
y = eqdfe_lms(rxsig,x(1:200));
```

Input Arguments

eq — Equalizer object

System object

Equalizer object, specified as a `comm.LinearEqualizer` or `comm.DecisionFeedbackFEqualizer` System object.

x — Input signal

column vector

Input signal, specified as a column vector. The input signal vector length must be equal to an integer multiple of the `InputSamplesPerSymbol` property. For more information, see “Symbol Tap Spacing” on page 3-414.

Data Types: `double`

Complex Number Support: Yes

Output Arguments**mumax — Prediction of maximum step size for LMS equalizer convergence**

scalar

Prediction of maximum step size for LMS equalizer convergence, returned as a scalar.

See Also**Objects**

`comm.LinearEqualizer` | `comm.DecisionFeedbackEqualizer`

Introduced in R2019a

mmseweights

Package: comm

Linear equalizer MMSE tap weights

Syntax

```
weights = mmseweights(eq, chTaps, EbN0)
```

Description

`weights = mmseweights(eq, chTaps, EbN0)` calculated minimum mean squared error (MMSE) solution for the linear equalizer, `eq` System object given the channel delay taps, `chTaps`, and signal to noise ratio, `EbN0`.

Examples

Calculate MMSE Weights for Linear Equalizer

Calculate the minimum mean squared error (MMSE) solution and use the weights for the linear equalizer taps weights.

Initialize simulation variables.

```
M = 4; % QPSK
numSymbols = 10000;
numTrainingSymbols = 1000;
chtaps = [1 0.5*exp(1i*pi/6) 0.1*exp(-1i*pi/8)];
EbN0 = 20;
```

Generate QPSK modulated symbols. Apply delayed multipath channel filtering and AWGN impairments to the symbols.

```
data = randi([0 M-1], numSymbols, 1);
tx = pskmod(data, M, pi/4);
rx = awgn(filter(chtaps, 1, tx), 25, 'measured');
```

Create a linear equalizer System object configured to use CMA algorithm and input the taps weights. Calculate the MMSE weights. Set the initial tap weights to the calculated MMSE weights. Equalize the impaired symbols.

```
eq = comm.LinearEqualizer('Algorithm', 'CMA', 'AdaptWeights', false, 'InitialWeightsSource', 'Property
```

```
eq =
```

```
comm.LinearEqualizer with properties:
```

```

    Algorithm: 'CMA'
    NumTaps: 5
    StepSize: 0.0100
    Constellation: [0.7071 + 0.7071i -0.7071 + 0.7071i ... ]
    InputSamplesPerSymbol: 1
```

```
    AdaptWeightsSource: 'Property'  
      AdaptWeights: false  
InitialWeightsSource: 'Property'  
  InitialWeights: [5x1 double]  
  WeightUpdatePeriod: 1
```

```
wgts = mmseweights(eq,chtaps,EbN0)
```

```
wgts = 5x1 complex
```

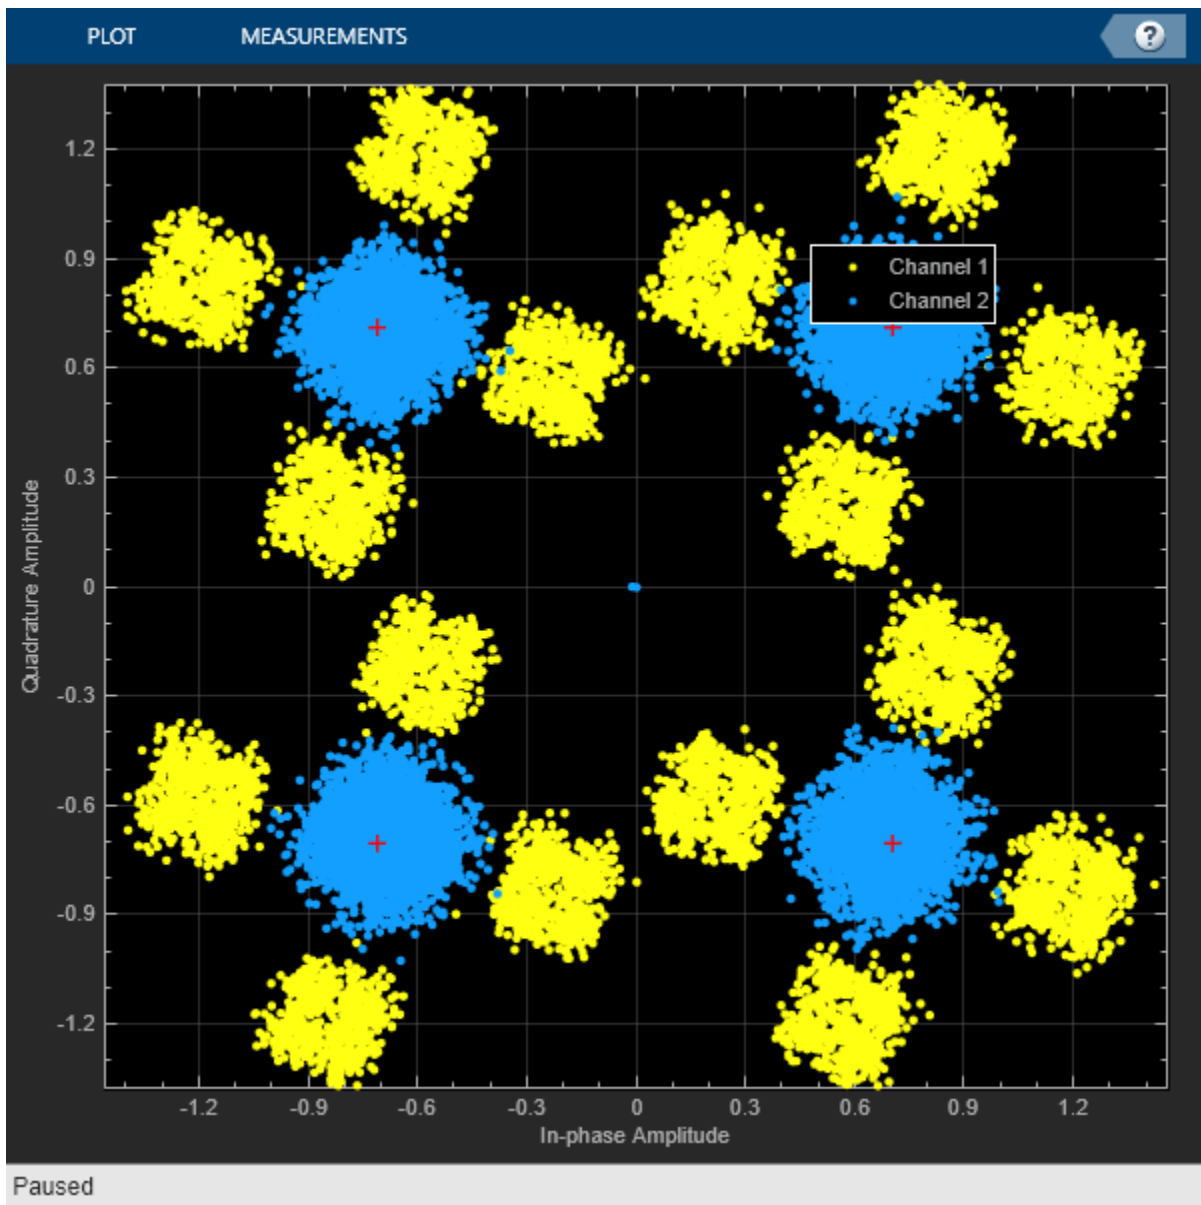

```
 0.0005 - 0.0068i  
 0.0103 + 0.0117i  
 0.9694 - 0.0019i  
-0.3987 + 0.2186i  
 0.0389 - 0.1756i
```

```
eq.InitialWeights = wgts;
```

```
[y,err,weights] = eq(rx);
```

Plot constellation of impaired and equalized symbols.

```
constell = comm.ConstellationDiagram('NumInputPorts',2);  
constell(rx,y)
```

Plot the equalizer error signal and compute the error vector magnitude of the equalized symbols.

```
plot(abs(err))  
grid on; xlabel('Symbols'); ylabel('|e|')
```

```
errevm = comm.EVM;
evm = errevm(tx,y)
```

```
evm = 139.1636
```

Plot equalizer tap weights.

```
subplot(3,1,1); stem(real(weights)); ylabel('real(weights)'); xlabel('Tap'); grid on; axis([1 8
line([eq.NumTaps+0.5 eq.NumTaps+0.5], [-0.5 1], 'Color', 'r', 'LineWidth', 1)
title('Equalizer Tap Weights')
subplot(3,1,2); stem(imag(weights)); ylabel('imag(weights)'); xlabel('Tap'); grid on; axis([1 8
line([eq.NumTaps+0.5 eq.NumTaps+0.5], [-0.5 1], 'Color', 'r', 'LineWidth', 1)
subplot(3,1,3); stem(abs(weights)); ylabel('abs(weights)'); xlabel('Tap'); grid on; axis([1 8 -0
line([eq.NumTaps+0.5 eq.NumTaps+0.5], [-0.5 1], 'Color', 'r', 'LineWidth', 1)
```

Input Arguments

eq — Equalizer object

System object

Equalizer object, specified as a `comm.LinearEqualizer` System object.

chTaps — Channel delay taps

vector

Channel delay taps, specified as a vector.

Data Types: `double`

Complex Number Support: Yes

EbN0 — Signal to noise ratio

scalar

Signal to noise ratio of the channel, specified as a scalar.

Data Types: `double`

Output Arguments

weights — **Weights for linear equalizer**

vector

Weights for linear equalizer, returned as a vector.

See Also

Objects

`comm.LinearEqualizer`

Introduced in R2019a

visualize

Package: comm

Visualize spectrum mask of phase noise

Syntax

```
visualize(phznoise)
```

Description

`visualize(phznoise)` displays the magnitude response of the filter defined by the `comm.PhaseNoise` System object. The function uses the **FVTool** function to display the magnitude response.

Examples

Visualize Spectrum Mask of Phase Noise

Create a phase noise object and display the spectral mask.

```
pnoise = comm.PhaseNoise( ...  
    Level=[-40 -70], ...  
    FrequencyOffset=[100 200], ...  
    SampleRate=1000);  
visualize(pnoise)
```

Input Arguments

phznoise — Phase noise

`comm.PhaseNoise` System object

Phase noise that defines the spectrum mask that is displayed, specified as a `comm.PhaseNoise` System object.

Tools

FVTool

Objects

`comm.PhaseNoise`

Introduced in R2012a

addCustomTerrain

Add custom terrain data

Syntax

```
addCustomTerrain(terrainName,files)
addCustomTerrain( ____,Name,Value)
```

Description

`addCustomTerrain(terrainName,files)` adds the terrain data specified with a user-defined `terrainName` and `files`. You can use this function to add custom terrain data in Site Viewer and other RF propagation functions. You can access the custom terrain data in the current and future sessions of MATLAB until you call `removeCustomTerrain`.

Note In Antenna Toolbox, `addCustomTerrain` function converts terrain elevation data from orthometric to ellipsoidal for visualization and when performing Euclidean distance or angle calculations between locations for example for free space path loss.

`addCustomTerrain(____,Name,Value)` adds custom terrain data with additional options specified by one or more name-value pairs.

Examples

Site Viewer Maps Using Custom Terrain

Add terrain for a region around Boulder, CO. The DTED file was downloaded from the "SRTM Void Filled" data set available from the U.S. Geological Survey.

```
dtedfile = "n39_w106_3arc_v2.dt1";
attribution = "SRTM 3 arc-second resolution. Data available " + ...
    "from the U.S. Geological Survey.";
addCustomTerrain("southboulder",dtedfile,"Attribution",attribution)
```

Use the custom terrain name in Site Viewer.

```
viewer = siteviewer("Terrain","southboulder");
```

Create a site with the terrain region.

```
mtzion = txsite("Name","Mount Zion", ...  
               "Latitude",39.74356, ...  
               "Longitude",-105.24193, ...  
               "AntennaHeight", 30);  
show(mtzion)
```

Create a coverage map of the area within 20 km of the transmitter site.

```
coverage(mtzion, ...  
  "MaxRange", 20000, ...  
  "SignalStrengths", -100: -5)
```

Remove the custom terrain.

```
close(viewer)
removeCustomTerrain("southboulder")
```

Input Arguments

terrainName — User-defined identifier for terrain data

string scalar | character vector

User-defined identifier for terrain data, specified as a string scalar or a character vector.

Data Types: char | string

files — List of DTED files

string scalar | character vector | cell array of character vectors

List of DTED files, specified as a string scalar, a character vector or a cell array of character vectors.

Note If you specify multiple files, they must combine to define a complete rectangular geographic region. If not, you must set the name-value pair 'FillMissing' to 'true'.

Data Types: char | string

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1, . . . , NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose Name in quotes.

Example: `'FillMissing',true`

Attribution — Attribution of custom terrain data

character vector | string scalar

Attribution of custom terrain data, specified as a character vector or a string scalar. The attribution is displayed on the Site Viewer map. By default, the value is empty.

Data Types: `char` | `string`

FillMissing — Fill data of missing files with value 0

false (default) | true

Fill data of missing files with value 0, specified as `true` or `false`. Missing file values are required to complete a rectangular geographic region with the input files.

Data Types: `logical`

WriteLocation — Name of folder to write extracted terrain files to

character vector | string scalar

Name of folder to write extracted terrain files to, specified as a character vector or a string scalar. The folder must exist and have write permissions. By default, `addCustomTerrain` writes extracted terrain files to a temporary folder that it generates using the `tempname` function.

Data Types: `char` | `string`

Tips

- You can find and download DTED files by using EarthExplorer, a data portal provided by the US Geological Survey (USGS). From the list of data sets, search for DTED files by selecting **Digital Elevation**, **SRTM**, and then **SRTM 1 Arc-Second Global** and **SRTM Void Filled**.

`removeCustomTerrain` | `siteviewer`

Introduced in R2019b

angle

Angle between sites

Syntax

```
[az,el] = angle(site1,site2)
[az,el] = angle(site1,site2,path)
[az,el] = angle( ___,Name,Value)
```

Description

`[az,el] = angle(site1,site2)` returns the azimuth and elevation angles between `site1` and `site2`.

`[az,el] = angle(site1,site2,path)` returns the angles using a specified path type, either a Euclidean or great circle path.

`[az,el] = angle(___,Name,Value)` returns the azimuth and elevation angles with additional options specified by name-value arguments.

Examples

Angle Between Sites

Create transmitter and receiver sites.

```
tx = txsite('Name','MathWorks','Latitude',42.3001,'Longitude',-71.3504);
rx = rxsite('Name','Fenway Park','Latitude',42.3467,'Longitude',-71.0972);
```

Get the azimuth and elevation angles between the sites.

```
[az,el] = angle(tx,rx)
```

```
az = 14.0142
```

```
el = -0.2816
```

Get the azimuth angle between sites in degrees clockwise from north.

```
azFromEast = angle(tx,rx); % Unit: degrees counter-clockwise from east
azFromNorth = -azFromEast + 90 % Convert angle to clockwise from north
```

```
azFromNorth = 75.9858
```

Angle Between Sites When Path is Great Circle

Create transmitter and receiver sites.

```
tx = txsite('Name','MathWorks','Latitude',42.3001,'Longitude',-71.3504);
rx = rxsite('Name','Fenway Park','Latitude',42.3467,'Longitude',-71.0972);
```

Get the azimuth and elevation angles between the sites.

```
[az,el] = angle(tx,rx,'greatcircle')
```

```
az = 14.0635
```

```
el = 0
```

Input Arguments

site1,site2 — Transmitter or receiver site

txsite object | rxsite object

Transmitter or receiver site, specified as a txsite or rxsite object. You can use array inputs to specify multiple sites.

path — Measurement path type

'euclidean' | 'greatcircle'

Measurement path type, specified as one of the following:

- 'euclidean' — Use the shortest path through space connecting the antenna center positions of the sites.
- 'greatcircle' — Use the shortest path on the surface of the earth connecting the latitude and longitude locations of the sites. This path uses a spherical Earth model.

Data Types: char

Name-Value Pair Arguments

Specify optional pairs of arguments as Name1=Value1,...,NameN=ValueN, where Name is the argument name and Value is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose Name in quotes.

Example: 'Map','siteviewer1'

Map — Map for visualization or surface data

siteviewer object | triangulation object | string scalar | character vector

Map for visualization or surface data, specified as a siteviewer object, a triangulation object, a string scalar, or a character vector. Valid and default values depend on the coordinate system.

Coordinate System	Valid map values	Default map value
'geographic'	<ul style="list-style-type: none"> • A siteviewer object^a. • A terrain name, if the function is called with an output argument. Valid terrain names are 'none', 'gmted2010', or the name of the custom terrain data added using <code>addCustomTerrain</code>. 	<ul style="list-style-type: none"> • The current siteviewer object or a new siteviewer object if none are open. • 'gmted2010', if the function is called with an output.
'cartesian'	<ul style="list-style-type: none"> • 'none'. • A siteviewer object. • The name of an STL file. • A triangulation object. 	<ul style="list-style-type: none"> • 'none'.

^a Alignment of boundaries and region labels are a presentation of the feature provided by the data vendors and do not imply endorsement by MathWorks.

Data Types: `char` | `string`

Output Arguments

az — Azimuth angle between sites

M-by-*N* arrays

Azimuth angle between `site1` and `site2`, returned as *M*-by-*N* arrays in degrees. *M* is the number of sites in `site1` and *N* is the number of sites in `site2`. The azimuth angle is expressed in degrees counter-clockwise from the east (for geographic sites), or from the global x-axis around the global z-axis (for Cartesian sites), ranging from -180 to 180 degrees.

e1 — Elevation angle between sites

M-by-*N* arrays

Elevation angle between `site1` and `site2`, returned as *M*-by-*N* arrays in degrees. *M* is the number of sites in `site2` and *N* is the number of sites in `site1`. The elevation angle is expressed in degrees from the horizontal (or X-Y) plane, ranging from -90 to 90 degrees.

When you specify the path type as 'greatcircle', the elevation angle is always zero.

`distance`

Introduced in R2019b

clearMap

Clear plots

Syntax

```
clearMap(viewer)
```

Description

`clearMap(viewer)` removes all plots from the specified Site Viewer.

Examples

View Transmitter Site On Site Viewer

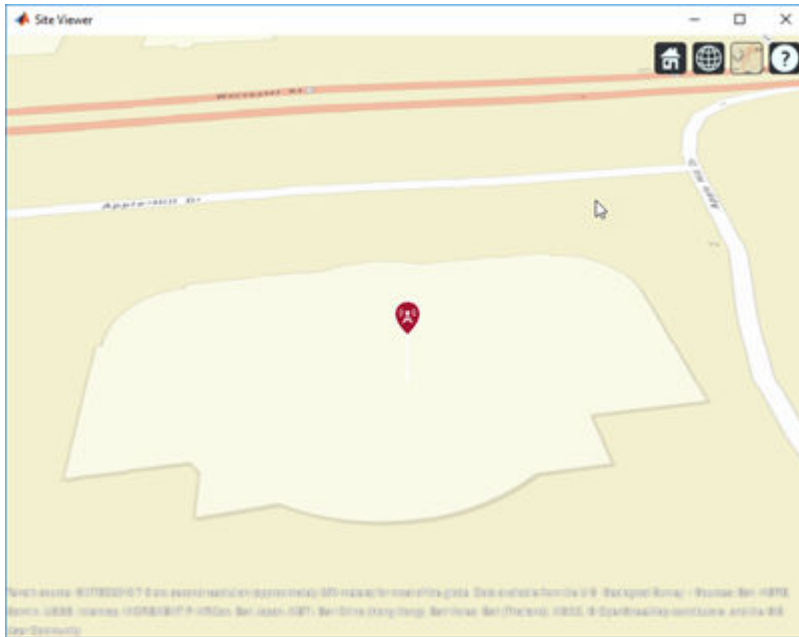

- 1 Launch a Site Viewer with streets basemap.

```
viewer = siteviewer("Basemap", "streets");
```

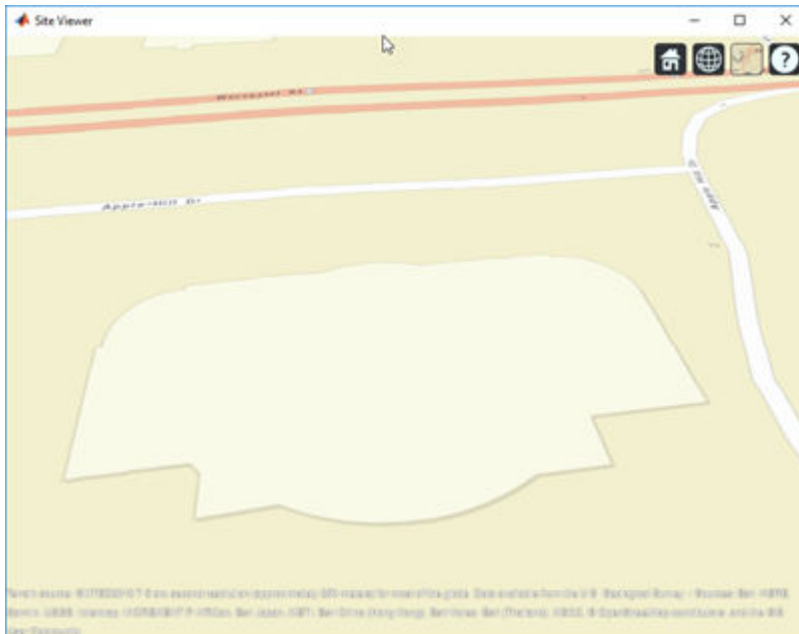

- 2 View a transmitter site on this map.

```
tx = txsite;  
show(tx)
```

3 Clear the map.

```
t = timer('TimerFcn',@(~,~)disp('Fired.'), 'StartDelay', 3);  
start(t)  
wait(t)  
clearMap(viewer)
```

Input Arguments

viewer — Map viewer for visualizing transmitter or receiver sites
siteviewer object

Map viewer for visualizing transmitter or receiver sites, specified as a `siteviewer` object.¹

See Also

`close` | `siteviewer`

Introduced in R2019b

¹ Alignment of boundaries and region labels are a presentation of the feature provided by the data vendors and do not imply endorsement by MathWorks.

close

Close Site Viewer

Syntax

```
close(viewer)
```

Description

`close(viewer)` closes the Site Viewer window and deletes the handle.

Examples

Compare Coverage Maps

Launch two Site Viewer windows. One Site Viewer window uses the terrain model and the other window does not use the terrain model.

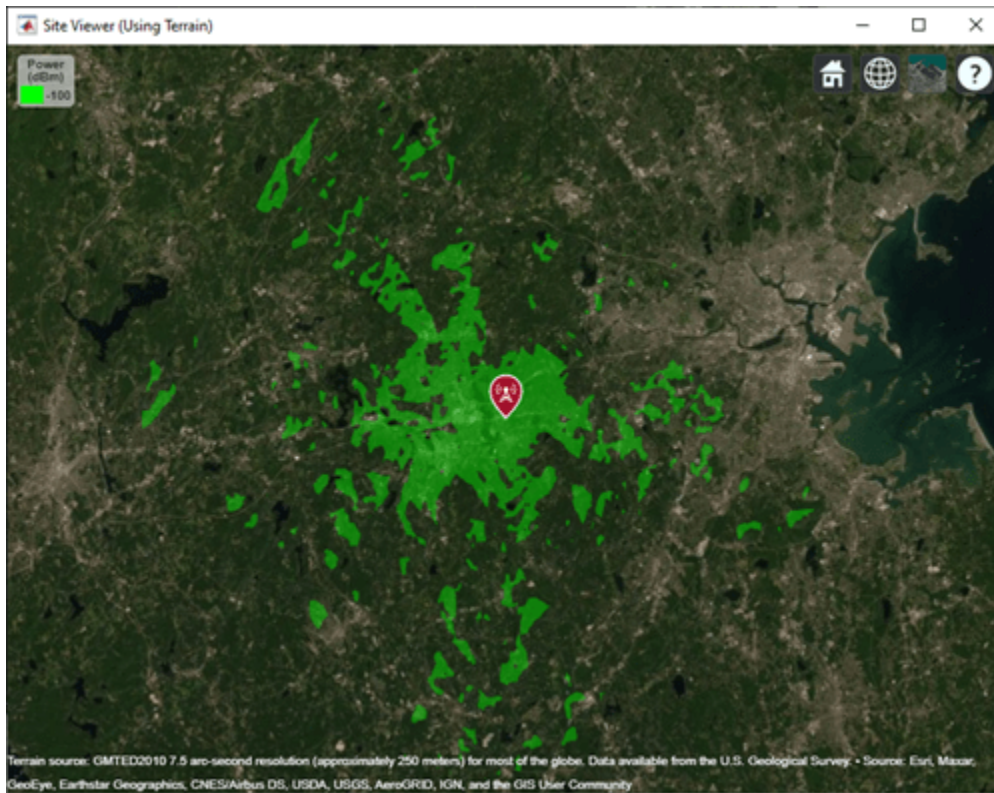

```
viewer1 = siteviewer("Terrain","gmted2010","Name","Site Viewer (Using Terrain)");  
viewer2 = siteviewer("Terrain","none","Name","Site Viewer (No Terrain)");
```

Create a transmitter site.

```
tx = txsite;
```

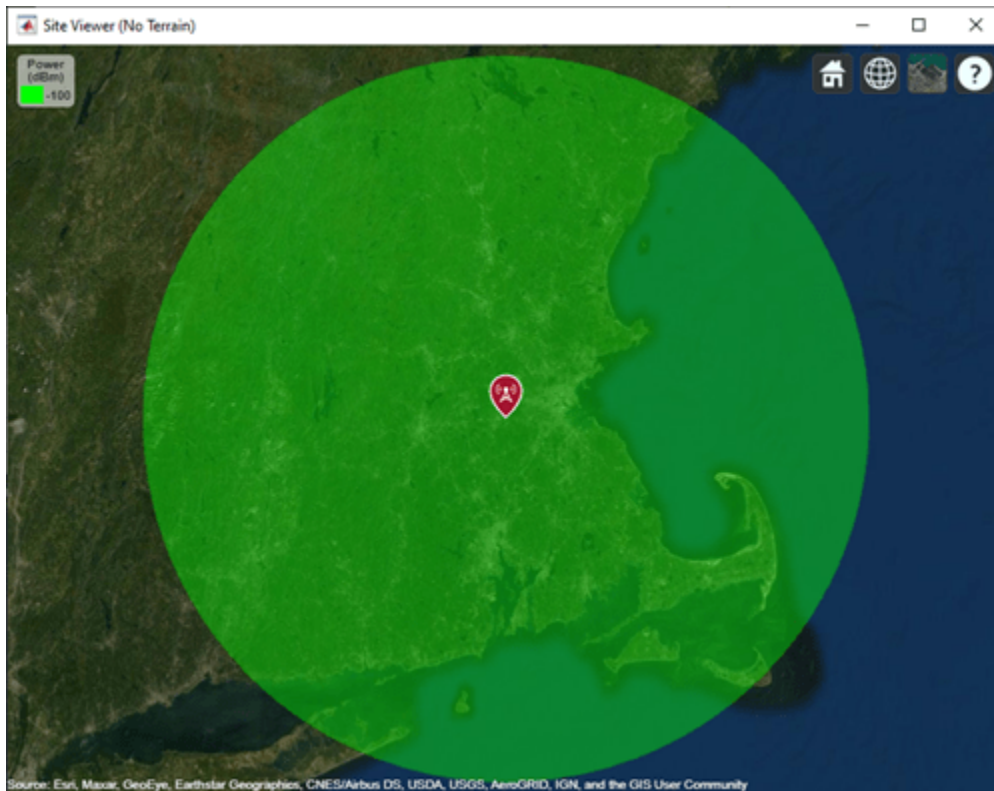

Generate a coverage map on each window. The map with terrain uses the Longley-Rice propagation model by default.

```
coverage(tx,"Map",viewer1)
```

The map without terrain uses the free-space model by default.

coverage(tx, "Map", viewer2)

Input Arguments

viewer — Map viewer for visualizing transmitter or receiver sites

siteviewer object

Map viewer for visualizing transmitter or receiver sites, specified as a siteviewer object.²

See Also

clearMap | siteviewer

Introduced in R2019b

² Alignment of boundaries and region labels are a presentation of the feature provided by the data vendors and do not imply endorsement by MathWorks.

contour

Display contour map of RF propagation data in Site Viewer

Syntax

```
contour(pd)
contour( ____,Name,Value)
```

Description

`contour(pd)` creates a filled contour plot in the current Site Viewer. Contours are colored according to data values of corresponding locations.

`contour(____,Name,Value)` creates a filled contour map with additional options specified by name-value pair arguments.

Examples

Capacity Map Using SINR Data

Define names and locations of sites around Boston.

```
names = ["Fenway Park","Faneuil Hall","Bunker Hill Monument"];
lats = [42.3467,42.3598,42.3763];
lons = [-71.0972,-71.0545,-71.0611];
```

Create an array of transmitter sites.

```
txs = txsite("Name",names,...
            "Latitude",lats,...
            "Longitude",lons, ...
            "TransmitterFrequency",2.5e9);
show(txs)
```

Create a signal-to-interference-plus-noise-ratio (SINR) map, where signal source for each location is selected as the transmitter site with the strongest signal.

```
sv1 = siteviewer("Name", "SINR map");  
sincr(txs, "MaxRange", 5000)
```

Return SINR propagation data.

```
pd = sinr(txs,"MaxRange",5000);
[sinrDb,lats,lons] = getDataVariable(pd,"SINR");
```

Compute capacity using the Shannon-Hartley theorem.

```
bw = 1e6; % Bandwidth is 1 MHz
sinrRatio = 10.^(sinrDb./10); % Convert from dB to power ratio
capacity = bw*log2(1+sinrRatio)/1e6; % Unit: Mbps
```

Create new propagation data for the capacity map and display the contour plot.

```
pdCapacity = propagationData(lats,lons,"Capacity",capacity);
sv2 = siteviewer("Name","Capacity map");
legendTitle = "Capacity" + newline + "(Mbps)";
contour(pdCapacity,"LegendTitle",legendTitle);
```

Input Arguments

pd — Propagation data

propagationData object (default)

Propagation data, specified as a propagationData object.

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1, ..., NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose Name in quotes.

Example: 'Type', 'power'

DataVariableName — Data variable to contour map

DataVariableName (default) | character vector | string scalar

Data variable to contour map, specified as the comma-separated pair consisting of 'DataVariableName' and a character vector or a string scalar corresponding to a variable name in the data table used to create the propagation data container object pd.

Data Types: char | string

Type — Type of value to plot

'custom' (default) | 'power' | 'efield' | 'sinr' | 'pathloss'

Type of value to plot, specified as the comma-separated pair consisting of 'Type' and one of the values in the 'Type' column:

Type	ColorLimits	LegendTitle
'custom'	[min(Data) max(Data)]	''
'power'	[-120 -5]	'Power (dBm)'
'efield'	[20 135]	'E-field (dBuV/m)'
'sinr'	[-5 20]	'SINR (dB)'
'pathloss'	[45 160]	'Path loss (dB)'

The default value for Levels is a linearly spaced vector bounded by ColorLimits.

Data Types: char | string

Levels – Data value levels to plot

numeric vector

Data value levels to plot, specified as the comma-separated pair consisting of 'Levels' and numeric vector. Each level is displayed as a different colored, filled contour on the map. The colors are selected using Colors if specified, or else Colormap and ColorLimits. Data points with values below the minimum level are not included in the plot.

The default value for Levels is a linearly spaced vector bounded by ColorLimits.

Data Types: double

Colors – Colors of data points

M-by-3 array of RGB | array of strings | cell array of character vectors

Colors of the filled contours, specified as the comma-separated pair consisting of 'Colors' and an *M*-by-3 array of RGB (red, blue, green) or an array of strings, or a cell array of character vectors. Colors are assigned element-wise to values in Levels for coloring the corresponding points. Colors cannot be used with Colormap and ColorLimits.

Data Types: double | char | string

Colormap – Color map for coloring points

'jet(256)' (default) | predefined colormap name | *M*-by-3 array of RGB triplets

Colormap for the coloring points, specified as the comma-separated pair consisting of 'Colormap' and a predefined colormap name or an *M*-by-3 array of RGB (red, blue, green) triplets that define *M* individual colors. Colormap cannot be used with Colors.

Data Types: double | char | string

ColorLimits – Color limits for color map

two-element vector

Color limits for the colormap, specified as the comma-separated pair consisting of 'ColorLimits' and a two-element vector of the form [min max]. The color limits indicate the data level values that map to the first and last colors in the colormap. ColorLimits cannot be used with Colors.

Data Types: double

Transparency — Transparency of contour map`0.4 (default) | numeric scalar in the range of [0,1]`

Transparency of the contour plot, specified as a numeric scalar in the range [0,1], where 0 is completely transparent and 1 is completely opaque.

Data Types: `double`

ShowLegend — Show color legend on map`true (default) | false`

Show color legend on map, specified as the comma-separated pair consisting of 'ShowLegend' and true or false.

Data Types: `logical`

LegendTitle — Title of color legend`character vector | string scalar`

Title of color legend, specified as the comma-separated pair consisting of 'LegendTitle' and a character vector or a string scalar.

Data Types: `string | char`

Map — Map for surface data`siteviewer object`

Map for surface data, specified as the comma-separated pair consisting of 'Map' and a `siteviewer` object.³ The default value is the current Site Viewer or a new Site Viewer, if none is open.

Data Types: `char | string`

See Also`plot | interp | getDataVariable`**Introduced in R2020a**

³ Alignment of boundaries and region labels are a presentation of the feature provided by the data vendors and do not imply endorsement by MathWorks.

coverage

Display or compute coverage map

Syntax

```
coverage(txs)
coverage(txs,propmodel)
coverage(txs,rx)
coverage(txs,rx,propmodel)
coverage( ____,Name,Value, ____ )
pd = coverage(txs, ____ )
```

Description

`coverage(txs)` displays the coverage map for the specified transmitter site in the current Site Viewer. Each colored contour of the map defines an area where the corresponding signal strength is transmitted to the mobile receiver.

Note This function only supports antenna sites with `CoordinateSystem` property set to `'geographic'`.

`coverage(txs,propmodel)` displays the coverage map based on the specified propagation model. The default propagation model is `'longley-rice'` when terrain is in use and `'freespace'` when terrain is not used.

`coverage(txs,rx)` displays the coverage map based on the receiver site properties.

`coverage(txs,rx,propmodel)` displays the coverage map based on the receiver site properties and specified propagation model.

`coverage(____,Name,Value, ____)` displays the coverage map using additional options specified by the `Name,Value` pairs.

`pd = coverage(txs, ____)` returns computed coverage data in the propagation data object, `pd`. No plot is displayed and any graphical only name-value pairs are ignored.

Examples

Coverage Map of Transmitter

Create a transmitter site at MathWorks headquarters.

```
tx = txsite('Name','MathWorks', ...
           'Latitude', 42.3001, ...
           'Longitude', -71.3503);
```

Show the coverage map.

coverage(tx)

Coverage Map Using Transmitter and Receiver

Create a transmitter site at MathWorks headquarters.

```
tx = txsite('Name','MathWorks', ...
           'Latitude', 42.3001, ...
           'Longitude', -71.3503);
```

Create a receiver site at Fenway Park with an antenna height of 1.2 m and system loss of 10 dB.

```
rx = rxsite('Name','Fenway Park', ...
           'Latitude', 42.3467, ...
           'Longitude', -71.0972, 'AntennaHeight', 1.2, 'SystemLoss', 10);
```

Calculate the coverage area of the transmitter using a close-in propagation model.

```
coverage(tx, rx, 'PropagationModel', 'closein')
```

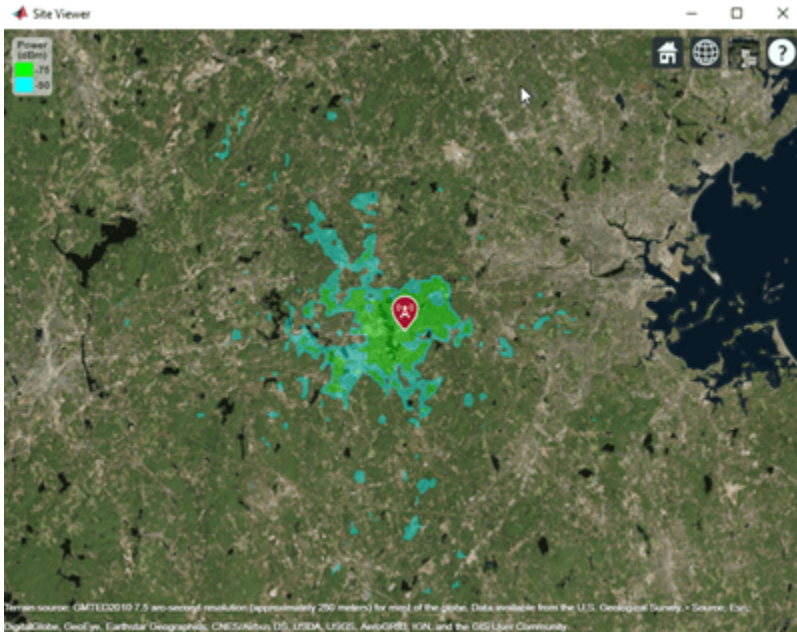

Coverage Map for Strong and Weak Signals

Define strong and weak signal strengths with corresponding colors.

```
strongSignal = -75;
strongSignalColor = "green";
weakSignal = -90;
weakSignalColor = "cyan";
```

Create a transmitter site and display the coverage map.

```
tx = txsite('Name','MathWorks', ...
    'Latitude',42.3001, ...
    'Longitude',-71.3503);
coverage(tx, ...
    'SignalStrengths',[strongSignal,weakSignal], ...
    'Colors', [strongSignalColor,weakSignalColor])
```

Combined Coverage Map of Multiple Transmitters

Define the names and the locations of sites around Boston.

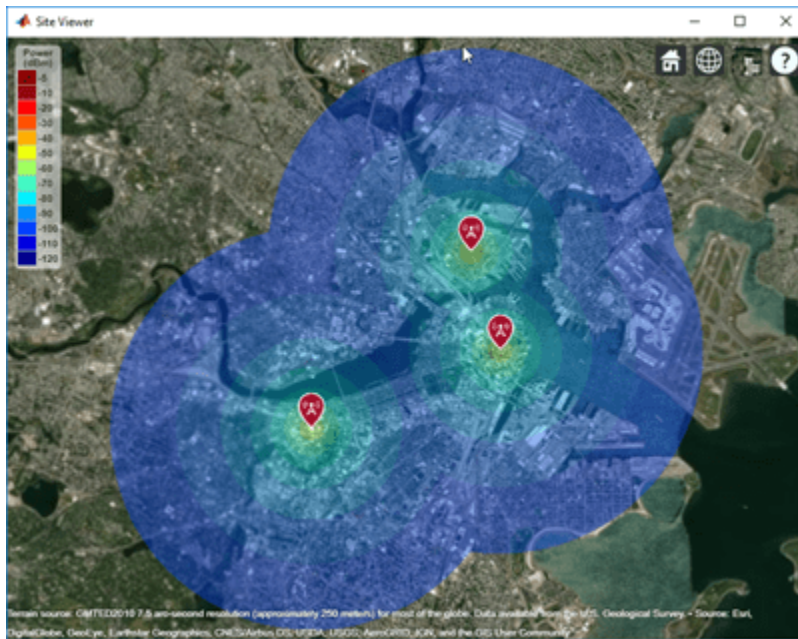

```
names = ["Fenway Park", "Faneuil Hall", "Bunker Hill Monument"];
lats = [42.3467, 42.3598, 42.3763];
lons = [-71.0972, -71.0545, -71.0611];
```

Create the transmitter site array.

```
txs = txsite('Name', names, ...
            'Latitude', lats, ...
            'Longitude', lons, ...
            'TransmitterFrequency', 2.5e9);
```

Display the combined coverage map for multiple signal strengths, using close-in propagation model.

```
coverage(txs, 'close-in', 'SignalStrengths', -100:5:-60)
```

Coverage Map Using Longley-Rice and Ray Tracing Method

Launch Site Viewer using buildings in Chicago. For more information about the osm file, see [1] on page 4-0 .

```
viewer = siteviewer("Buildings","chicago.osm");
```

Create a transmitter site on the building.

```
tx = txsite('Latitude',41.8800, ...  
           'Longitude',-87.6295, ...  
           'TransmitterFrequency',2.5e9);  
show(tx)
```

Coverage Map Using Longley-Rice Propagation Model

Create a coverage map of the city using the Longley-Rice propagation model.

```
coverage(tx, "SignalStrengths", -100:-5, "MaxRange", 250, "Resolution", 1)
```

Longley-Rice models over-the-rooftops propagation along vertical slices and obstructions tend to dominate the coverage region.

Coverage Map Using Ray Tracing Propagation Model and Image Method

Create a coverage map of the city by using a ray tracing propagation model that uses the image method. Calculate line-of-sight and single-reflection propagation paths.

```
pmImage = propagationModel("raytracing", "Method", "image", ...  
    "MaxNumReflections", 1);  
coverage(tx, pmImage, "SignalStrengths", -100:-5, ...  
    "MaxRange", 250, "Resolution", 2)
```

This coverage map shows new regions that are in service due to reflected propagation paths.

Coverage Map Using Ray Tracing Propagation Model and SBR Method

Create a coverage map of the city by using a ray tracing propagation model that uses the shooting and bouncing rays (SBR) method, which is generally faster than the image method. Increase the maximum number of path reflections to 2.

```
pmSBR = propagationModel("raytracing", "Method", "sbr", ...
    "MaxNumReflections", 2);
coverage(tx, pmSBR, "SignalStrengths", -100:-5, ...
    "MaxRange", 250, "Resolution", 2)
```

This coverage map shows new regions that are in service due to the additional reflected propagation paths.

Appendix

[1] The osm file is downloaded from <https://www.openstreetmap.org>, which provides access to crowd-sourced map data all over the world. The data is licensed under the Open Data Commons Open Database License (ODbL), <https://opendatacommons.org/licenses/odbl/>.

Input Arguments

txs — Transmitter sites

`txsite` object | array of `txsite` objects

Transmitter site, specified as a `txsite` object. Use array inputs to specify multiple sites.

This function only supports plotting antenna sites when `CoordinateSystem` property is set to 'geographic'.

rx — Receiver site

`rxsite` object

Receiver site, specified as a `rxsite` object.

This function only supports plotting antenna sites when `CoordinateSystem` property is set to 'geographic'.

propmodel — Propagation model

character vector | string

Propagation model, specified as a character vector or string. You can also use the name-value pair 'PropagationModel' to specify this parameter. You can also use the `propagationModel` function to define this input. The default propagation model is 'longley-ricc' when terrain is enabled and 'freespace' when terrain is disabled.

Data Types: char | string

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1, ..., NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose Name in quotes.

Example: 'Type', 'power'

Type — Type of signal strength to compute

'power' (default) | 'efield'

Type of signal strength to compute, specified as the comma-separated pair consisting of 'Type' and 'power' or 'efield'.

When type is 'power', `SignalStrengths` is expressed in power units (dBm) of the signal at the mobile receiver input. When type is 'efield', `SignalStrengths` is expressed in electric field strength units (dB μ V/m) of signal wave incident on the antenna.

The coverage function is not supported for ray tracing models when 'Type' is 'efield'.

Data Types: char

SignalStrengths — Signal strengths to display on coverage map

numeric vector

Signal strengths to display on coverage map, specified as the comma-separated pair consisting of 'SignalStrengths' and a numeric vector.

Each strength uses different colored filled contour on the map. The default value is -100 dBm if the 'Type' name-value pair is 'power' and 40 dB μ V/m if 'Type' is 'efield'.

Data Types: double

PropagationModel — Propagation model to use for path loss calculations

'longley-ricc' (default) | 'freespace' | 'close-in' | 'rain' | 'gas' | 'fog' | 'raytracing' | propagation model created with `propagationModel`

Propagation model to use for the path loss calculations, specified as the comma-separated pair consisting of 'PropagationModel' and one of the following:

- 'freespace' — Free space propagation model
- 'rain' — Rain propagation model
- 'gas' — Gas propagation model
- 'fog' — Fog propagation model
- 'close-in' — Close-in propagation model

- 'longley-rice' — Longley-Rice propagation model
- 'tirem' — Tirem propagation model
- 'raytracing' — Ray tracing propagation model that uses the shooting and bouncing rays (SBR) method
- A propagation model created with the `propagationModel` function

The default propagation model is 'longley-rice' when terrain is enabled and 'freespace' when terrain is disabled.

Terrain propagation models, including 'longley-rice' and 'tirem', are only supported for sites with a `CoordinateSystem` value of 'geographic'.

Data Types: char

MaxRange — Maximum range of coverage map from each transmitter site

numeric scalar

Maximum range of coverage map from each transmitter site, specified as a positive numeric scalar in meters representing great circle distance. `MaxRange` defines the region of interest on the map to plot. The default value is automatically computed based on the type of propagation model.

Type of Propagation Model	MaxRange
Atmospheric or empirical	Range of minimum value in <code>SignalStrengths</code> .
Terrain	30 km or distance to the furthest building.
Ray tracing	500 m

For more information about the types of propagation models, see “Choose a Propagation Model”.

Data Types: double

Resolution — Resolution of coverage map

'auto' (default) | numeric scalar

Resolution of coverage map, specified as the comma-separated pair consisting of 'Resolution' and a numeric scalar in meters.

The resolution of 'auto' computes the maximum value scaled to 'MaxRange'. Decreasing the resolution increases the quality of the coverage map and the time required to create it.

Data Types: char | double

ReceiverGain — Mobile receiver gain

2.1 (default) | numeric scalar

Mobile receiver gain, specified as the comma-separated pair consisting of 'ReceiverGain' and a numeric scalar in dB. The receiver gain value includes the mobile receiver antenna gain and system loss.

The receiver gain computes received signal strength when the 'Type' is 'power'.

If receiver site argument `rx` is passed to `coverage`, the default value is the maximum gain of the receiver antenna with the system loss subtracted. Otherwise the default value is 2.1.

Data Types: char | double

ReceiverAntennaHeight — Mobile receiver antenna height above ground elevation

1 (default) | numeric scalar

Mobile receiver antenna height above ground elevation, specified as the comma-separated pair consisting of 'ReceiverAntennaHeight' and a numeric scalar in meters.

If receiver site argument `rx` is passed to `coverage`, the default value is the `AntennaHeight` of the receiver. Otherwise the default value is 1.

Data Types: `double`**Colors — Colors of filled contours on coverage map***M*-by-3 array of RGB triplets | array of strings | cell array of character vectors

Colors of filled contours on coverage map, specified as the comma-separated pair consisting of 'Colors' and one of the following:

- An *M*-by-3 array of RGB triplets whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range $[0, 1]$; for example, $[0.4 \ 0.6 \ 0.7]$.
- An array of strings such as `["red" "green" "blue"]` or `["r" "g" "b"]`.
- A cell array of character vectors such as `{'red', 'green', 'blue'}` or `{'r', 'g', 'b'}`.

Colors are assigned element-wise to 'SignalStrengths' values for coloring the corresponding filled contours.

'Colors' cannot be used with 'ColorLimits' or 'ColorMap'.

This table contains the color names and equivalent RGB triplets for some common colors.

Color Name	Short Name	RGB Triplet	Appearance
'red'	'r'	[1 0 0]	
'green'	'g'	[0 1 0]	
'blue'	'b'	[0 0 1]	
'cyan'	'c'	[0 1 1]	
'magenta'	'm'	[1 0 1]	
'yellow'	'y'	[1 1 0]	
'black'	'k'	[0 0 0]	
'white'	'w'	[1 1 1]	

Data Types: `char` | `string` | `double`**ColorLimits — Color limits for colormap**

two-element vector

Color limits for colormap, specified as the comma-separated pair consisting of 'ColorLimits' and a two-element vector of type `[min max]`.

The color limits indicate the signal level values that map to the first and last colors on the colormap.

The default value is `[-120 -5]` if the 'Type' name-value pair is 'power' and `[20 135]` if 'Type' is 'efields'.

'ColorLimits' cannot be used with 'Color'.

Data Types: double

ColorMap — Colormap filled contours for coverage map

'jet' (default) | predefined color map | M -by-3 array of RGB triplets

Colormap filled contours on coverage map, specified as the comma-separated pair consisting of 'ColorMap' and a predefined colormap or M -by-3 array of RGB triplets, where M defines individual colors.

'ColorMap' cannot be used with 'Colors'.

Data Types: char | double

ShowLegend — Show signal strength color legend on map

true (default) | false

Show signal strength color legend on map, specified as the comma-separated pair consisting of 'ShowLegend' and true or false.

Data Types: logical

Transparency — Transparency of coverage map

0.4 (default) | numeric scalar

Transparency of coverage map, specified as the comma-separated pair consisting of 'Transparency' and a numeric scalar in the range 0 to 1. 0 is transparent and 1 is opaque.

Data Types: double

Map — Map for visualization of surface data

siteviewer object

Map for visualization of surface data, specified as the comma-separated pair consisting of 'Map' and a siteviewer object.⁴

Data Types: char | string

Output Arguments

pd — Coverage data

propagationData object

Coverage data, returned as a propagationData object consisting of *Latitude* and *Longitude*, and a signal strength variable corresponding to the plot type. Name of the propagationData is "Coverage Data".

Compatibility Considerations

'raytracing' propagation models use SBR method

Behavior changed in R2021b

⁴ Alignment of boundaries and region labels are a presentation of the feature provided by the data vendors and do not imply endorsement by MathWorks.

Starting in R2021b, when you use the `coverage` function and specify the `propmodel` argument or `PropagationModel` name-value argument as `'raytracing'`, the function uses the shooting and bouncing rays (SBR) method and calculates up to two reflections. In previous releases, the `coverage` function uses the image method and calculates up to one reflection.

To display or compute coverage maps using the image method instead, create a propagation model by using the `propagationModel` function. Then, use the `coverage` function with the propagation model as input. This example shows how to update your code.

```
pm = propagationModel('raytracing','Method','image');  
coverage(txs,pm)
```

For information about the SBR and image methods, see “Choose a Propagation Model”.

Starting in R2021b, all RF Propagation functions use the SBR method by default and calculate up to two reflections. For more information, see “Default modeling method is shooting and bouncing rays method” on page 4-210.

`link` | `sigstrength` | `sinr` | `propagationModel`

Introduced in R2019b

distance

Distance between sites

Syntax

```
d = distance(site1,site2)
d = distance(site1,site2,path)
d = distance( ____,Name,Value)
```

Description

`d = distance(site1,site2)` returns the distance in meters between `site1` and `site2`.

`d = distance(site1,site2,path)` returns the distance using a specified path type, either a Euclidean or great circle path.

`d = distance(____,Name,Value)` returns the distance with additional options specified by name-value arguments.

Examples

Distance Between Transmitter and Receiver Site

Create transmitter and receiver sites.

```
tx = txsite('Name','MathWorks','Latitude',42.3001,'Longitude',-71.3504);
rx = rxsite('Name','Fenway Park','Latitude',42.3467,'Longitude',-71.0972);
```

Get the Euclidean distance in km between the sites.

```
dme = distance(tx,rx)
```

```
dme = 2.1504e+04
```

```
dkm = dme / 1000
```

```
dkm = 21.5037
```

Get the great circle distance between the two sites.

```
dmg = distance(tx,rx,'greatcircle')
```

```
dmg = 2.1451e+04
```

Input Arguments

site1,site2 — Transmitter or receiver site

txsite object | rxsite object

Transmitter or receiver site, specified as a `txsite` or `rxsite` object. You can use array inputs to specify multiple sites.

path — Measurement path type

'euclidean' | 'greatcircle'

Measurement path type, specified as one of the following:

- 'euclidean' — Use the shortest path through space that connects the antenna center positions of the sites.
- 'greatcircle' — Use the shortest path on the surface of the earth that connects the latitude and longitude locations of the sites. This path uses a spherical Earth model.

Data Types: char

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1, ..., NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose Name in quotes.

Example: 'Map', 'siteviewer1'

Map — Map for visualization or surface data

siteviewer object | triangulation object | string scalar | character vector

Map for visualization or surface data, specified as a `siteviewer` object, a `triangulation` object, a string scalar, or a character vector. Valid and default values depend on the coordinate system.

Coordinate System	Valid map values	Default map value
'geographic'	<ul style="list-style-type: none"> • A <code>siteviewer</code> object^a. • A terrain name, if the function is called with an output argument. Valid terrain names are 'none', 'gmted2010', or the name of the custom terrain data added using <code>addCustomTerrain</code>. 	<ul style="list-style-type: none"> • The current <code>siteviewer</code> object or a new <code>siteviewer</code> object if none are open. • 'gmted2010', if the function is called with an output.
'cartesian'	<ul style="list-style-type: none"> • 'none'. • A <code>siteviewer</code> object. • The name of an STL file. • A <code>triangulation</code> object. 	<ul style="list-style-type: none"> • 'none'.

^a Alignment of boundaries and region labels are a presentation of the feature provided by the data vendors and do not imply endorsement by MathWorks.

Data Types: char | string

Output Arguments

d — Distance between sites

M-by-*N* numeric array

Distance between sites, returned as an *M*-by-*N* numeric array in meters, where *M* is the number of sites in `site2` and *N* is the number of sites in `site1`.

See Also

`angle`

Introduced in R2019b

elevation

Elevation of site

Syntax

```
z = elevation(site)
z = elevation( ____,Name,Value)
```

Description

`z = elevation(site)` returns the ground or building surface elevation of antenna site in meters. Elevation is measured relative to mean sea level using earth gravitational model, EGM-96. If the site coincides with a building, elevation is measured at the top of the building. Otherwise, elevation is measured at the ground.

This function only supports antenna sites with a `CoordinateSystem` property value of `'geographic'`.

`z = elevation(____,Name,Value)` returns the ground elevation of the antenna in meters with additional options specified by name-value arguments.

Examples

Elevation at Mount Washington

Compute and display the elevation at Mount Washington in meters.

```
mtwash = txsite('Name','Mt Washington','Latitude',44.2706, ...
               'Longitude',-71.3033);
z = elevation(mtwash)

z = 1.8704e+03
```

Input Arguments

site — Transmitter or receiver site

txsite or rxsite object | array of txsite or rxsite objects

Transmitter or receiver site, specified as a txsite or rxsite object or an array of txsite or rxsite objects.

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1, ..., NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose Name in quotes.

Example: 'Map', 'siteviewer1'

Map — Map for visualization or surface data

siteviewer object | string scalar | character vector

Map for visualization or surface data, specified as one of the following:

- A `siteviewer` object.⁵
- A terrain name if the function is called with an output argument. Valid terrain names are 'none', 'gmted2010', or the name of the custom terrain data added using `addCustomTerrain`.

The default value is:

- The current `siteviewer` object or a new `siteviewer` object if none are open.
- 'gmted2010' if called with an output.

Data Types: char | string

Output Arguments

z — Ground or building surface elevation of antenna site

M-by-1 matrix

Ground or building surface elevation of the antenna site, returned as an *M*-by-1 matrix with each element unit in meters. *M* is the number of sites in `site`.

Functions

distance | angle

Objects

txsite | rxsite

Introduced in R2019b

⁵ Alignment of boundaries and region labels are a presentation of the feature provided by the data vendors and do not imply endorsement by MathWorks.

getDataVariable

Get data variable values

Syntax

```
datavariabale = getDataVariable(pd)
[datavariabale,lat,lon] = getDataVariable(pd)
[ ___ ] = getDataVariable(pd,varname)
```

Description

`datavariabale = getDataVariable(pd)` returns the values of the data points in the propagation data object. The data is processed such that the missing values are removed and duplicate location data are replaced with mean values.

`[datavariabale,lat,lon] = getDataVariable(pd)` returns the location coordinates of the data points in the propagation data object.

`[___] = getDataVariable(pd,varname)` returns the values of the data points corresponding to the `varname` variable.

Examples

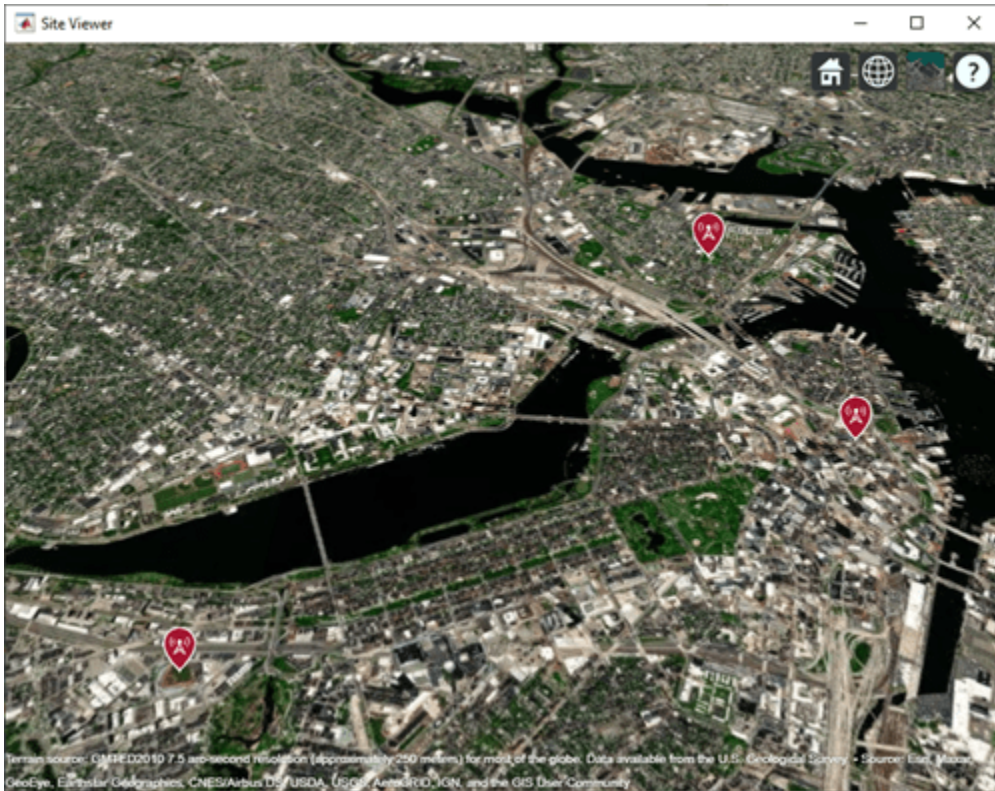

Capacity Map Using SINR Data

Define names and locations of sites around Boston.

```
names = ["Fenway Park","Faneuil Hall","Bunker Hill Monument"];
lats = [42.3467,42.3598,42.3763];
lons = [-71.0972,-71.0545,-71.0611];
```

Create an array of transmitter sites.

```
txs = txsite("Name",names,...
            "Latitude",lats,...
            "Longitude",lons, ...
            "TransmitterFrequency",2.5e9);
show(txs)
```

Create a signal-to-interference-plus-noise-ratio (SINR) map, where signal source for each location is selected as the transmitter site with the strongest signal.

```
sv1 = siteviewer("Name", "SINR map");  
sincr(txs, "MaxRange", 5000)
```

Return SINR propagation data.

```
pd = sinr(txs,"MaxRange",5000);
[sinrDb,lats,lons] = getDataVariable(pd,"SINR");
```

Compute capacity using the Shannon-Hartley theorem.

```
bw = 1e6; % Bandwidth is 1 MHz
sinrRatio = 10.^(sinrDb./10); % Convert from dB to power ratio
capacity = bw*log2(1+sinrRatio)/1e6; % Unit: Mbps
```

Create new propagation data for the capacity map and display the contour plot.

```
pdCapacity = propagationData(lats,lons,"Capacity",capacity);
sv2 = siteviewer("Name","Capacity map");
legendTitle = "Capacity" + newline + "(Mbps)";
contour(pdCapacity,"LegendTitle",legendTitle);
```

Input Arguments

pd — Propagation data

propagationData object (default)

Propagation data, specified as a propagationData object.

varname — Variable name in data table

character vector | string scalar

Variable name in the data table, specified as a character vector or a string scalar. This variable name must correspond to a variable with numeric data other than the latitude or longitude data.

Output Arguments

datavariable — Values of data points

column vector

Values of data points in the propagation data object, returned as a column vector.

lat — Latitude of data points

M -by-1 vector

Latitude of data points, returned as an M -by-1 vector with each element unit in degrees.

lon — Longitude of data points*M*-by-1 vector

Longitude of data points, returned as an *M*-by-1 matrix with each element unit in degrees. The output is wrapped so that the values are in the range `[-180 180]`.

hide

Hide site from Site Viewer

Syntax

```
hide(site)
hide( ____,Name,Value)
```

Description

`hide(site)` hides the location of the specified antenna site from the current Site Viewer.

`hide(____,Name,Value)` hides the site with additional options specified by one or more name-value pairs.

Examples

Show and Hide Transmitter Site

Create and show a transmitter site.

```
tx = txsite('Name','MathWorks Apple Hill',...
           'Latitude',42.3001, ...
           'Longitude',-71.3504);
show(tx)
```

Hide the transmitter site.

```
hide(tx)
```

Show and Hide Sites with Cartesian Coordinates

Import and view an STL file. The file models a small conference room with one table and four chairs.

```
viewer = siteviewer('SceneModel','conferenceroom.stl');
```

Create a transmitter site near the upper corner of the room and a receiver site above the table. Specify the position using Cartesian coordinates in meters. Then, visualize the sites.

```
tx = txsite('cartesian', ...
    'AntennaPosition',[-1.46; -1.42; 2.1]);
rx = rxsite('cartesian', ...
    'AntennaPosition',[0.3; 0.3; 0.85]);
```

```
show(tx)
show(rx)
```

Pan by left-clicking, zoom by right-clicking or by using the scroll wheel, and rotate the visualization by clicking the middle button and dragging or by pressing **Ctrl** and left-clicking and dragging.

Hide the sites.

```
hide(tx)  
hide(rx)
```

Input Arguments

site — Transmitter or receiver site

txsite or rxsite object | array of txsite or rxsite objects

Transmitter or receiver site, specified as a txsite or rxsite object or an array of txsite or rxsite objects.

Name-Value Pair Arguments

Specify optional pairs of arguments as Name1=Value1, . . . , NameN=ValueN, where Name is the argument name and Value is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose Name in quotes.

Example: 'Map', 'siteviewer1'

Map — Map for visualization of surface data

siteviewer object

Map for visualization of surface data, specified as a siteviewer object.⁶

Data Types: char | string

show

Introduced in R2019b

⁶ Alignment of boundaries and region labels are a presentation of the feature provided by the data vendors and do not imply endorsement by MathWorks.

interp

Interpolate RF propagation data

Syntax

```
interpvalue = interp(pd,lat,lon)
interpvalue = interp(pd,Name,Value)
```

Description

`interpvalue = interp(pd,lat,lon)` returns interpolated values from the propagation data for each query point specified in latitude and longitude vectors. The interpolation is performed using a scattered data interpolation method. Values corresponding to query points outside the data region are assigned a NaN.

`interpvalue = interp(pd,Name,Value)` returns interpolated values with additional options specified by name-value pair arguments.

Examples

Transmitter Site Service Areas

Define names and locations of sites around Boston.

```
names = ["Fenway Park","Faneuil Hall","Bunker Hill Monument"];
lats = [42.3467,42.3598,42.3763];
lons = [-71.0972,-71.0545,-71.0611];
```

Create array of transmitter sites.

```
txs = txsite("Name", names,...
            "Latitude",lats,...
            "Longitude",lons, ...
            "TransmitterFrequency",2.5e9);
```

Compute received power data for each transmitter site.

```
maxr = 20000;
pd1 = coverage(txs(1),"MaxRange",maxr);
pd2 = coverage(txs(2),"MaxRange",maxr);
pd3 = coverage(txs(3),"MaxRange",maxr);
```

Compute rectangle containing locations of all data.

```
locs = [location(pd1); location(pd2); location(pd3)];
[minlatlon, maxlatlon] = bounds(locs);
```

Create grid of locations over rectangle.

```
gridlength = 300;
latv = linspace(minlatlon(1),maxlatlon(1),gridlength);
```

```
lonv = linspace(minlatlon(2),maxlatlon(2),gridlength);
[lons,lats] = meshgrid(lonv,latv);
lats = lats(:);
lons = lons(:);
```

Get data for each transmitter at grid locations using interpolation.

```
v1 = interp(pd1,lats,lons);
v2 = interp(pd2,lats,lons);
v3 = interp(pd3,lats,lons);
```

Create propagation data containing minimum received power values.

```
minReceivedPower = min([v1 v2 v3],[],2,"includenan");
pd = propagationData(lats,lons,"MinReceivedPower",minReceivedPower);
```

Plot minimum received power, which shows the weakest signal received from any transmitter site. The area shown may correspond to the service area of triangulation using the three transmitter sites.

```
sensitivity = -110;
contour(pd,"Levels",sensitivity:-5,"Type","power")
```

Input Arguments

pd — Propagation data

propagationData object (default)

Propagation data, specified as a propagationData object.

Lat — Latitude coordinate values

vector

Latitude coordinate values, specified as a vector in decimal degrees with reference to Earth's ellipsoid. model WGS-84. The latitude coordinates must be in the range [-90 90].

Lon — Longitude coordinate values

vector

Longitude coordinate values, specified as a vector in decimal degrees with reference to Earth's ellipsoid. model WGS-84.

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1, ..., NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose Name in quotes.

Example: 'Method', 'linear'

DataVariableName — Data variable to interpolate

character vector | string scalar

Data variable to interpolate, specified as the comma-separated pair consisting of 'DataVariableName' and a character vector or string scalar corresponding to a variable name in the data table used to create the `propagationData` container object. The default value is the `DataVariableName` property in the `propagationData`.

Data Types: `char` | `string`

Method — Method used to interpolate data

'natural' (default) | 'nearest' | 'linear'

Method used to interpolate data, specified as the comma separated-pair consisting 'Method' and one of the following:

- 'natural' - Natural neighbor interpolation
- 'linear' - Linear interpolation
- 'nearest' - Nearest neighbor interpolation

Data Types: `char` | `string`

Output Arguments**interpvalue — Interpolated values from propagation data**

numeric vector

Interpolated values from the propagation data for each query point specified in latitude and longitude vectors, returned as a numeric vector.

Introduced in R2020a

link

Display or compute communication link status

Syntax

```
link(rx,tx)
link(rx,tx,propmodel)
link( ____,Name,Value)
status = link( ____)
```

Description

`link(rx,tx)` displays a one-way point-to-point communication link between a receiver site and transmitter site in the current Site Viewer. The plot is color coded to identify the link success status.

`link(rx,tx,propmodel)` displays the communication link based on the specified propagation model.

`link(____,Name,Value)` displays a communication link using additional options specified by `Name,Value` pairs.

`status = link(____)` returns the success status of the communication link as `true` or `false`.

Examples

Communication Link Between Geographic Transmitter and Receiver

Create a transmitter site.

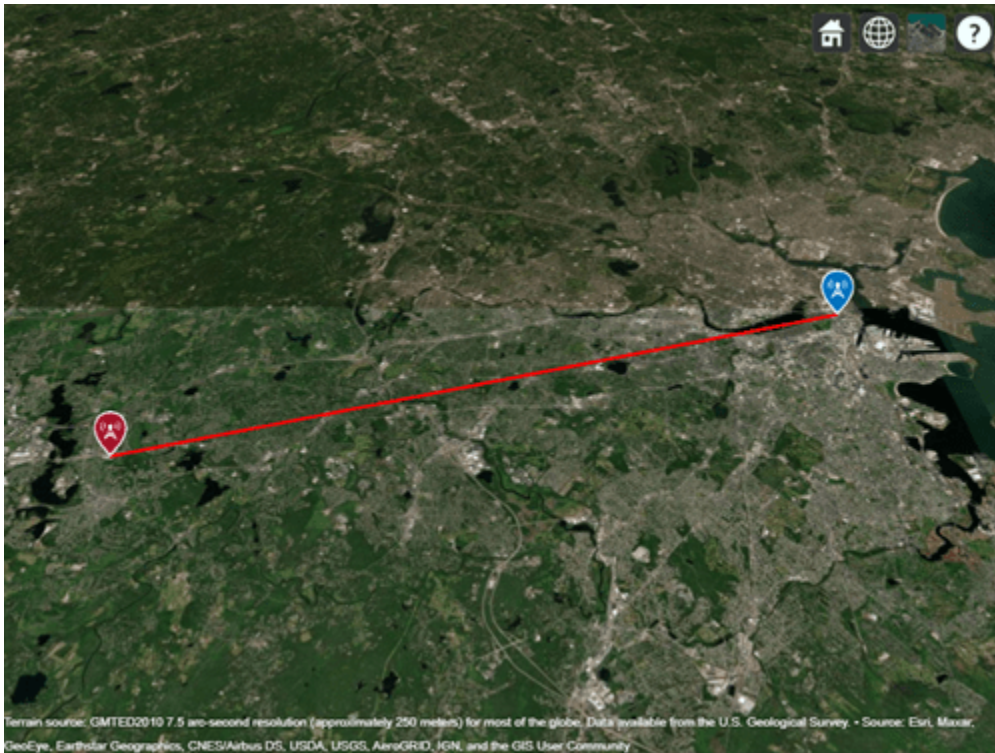

```
tx = txsite("Name","MathWorks", ...
           "Latitude",42.3001, ...
           "Longitude",-71.3503);
```

Create a receiver site with a sensitivity defined in dBm.

```
rx = rxsite("Name","Boston", ...
           "Latitude",42.3601, ...
           "Longitude",-71.0589, ...
           "ReceiverSensitivity",-90);
```

Plot the communication link between the transmitter and the receiver.

```
link(rx,tx)
```

Communication Link Between Cartesian Transmitter and Receiver

Import and view an STL file. The file models a small conference room with one table and four chairs.

```
viewer = siteviewer('SceneModel', 'conferenceroom.stl');
```

Create a transmitter site near the upper corner of the room and a receiver site above the table. Specify the position using Cartesian coordinates in meters.

```
tx = txsite('cartesian', ...  
           'AntennaPosition', [-1.46; -1.42; 2.1]);  
rx = rxsite('cartesian', ...  
           'AntennaPosition', [0.3; 0.3; 0.85]);
```

Plot the communication link between the transmitter and the receiver.

```
link(rx, tx)
```

Pan by left-clicking, zoom by right-clicking or by using the scroll wheel, and rotate the visualization by clicking the middle button and dragging or by pressing **Ctrl** and left-clicking and dragging.

Input Arguments

rx — Receiver site

`rxsite` object | array of `rxsite` objects

Receiver site, specified as a `rxsite` object. You can use array inputs to specify multiple sites.

tx — Transmitter site

`txsite` object | array of `txsite` objects

Transmitter site, specified as a `txsite` object. You can use array inputs to specify multiple sites.

propmodel — Propagation model

character vector | string | propagation model created with `propagationModel`

Propagation model, specified as a character vector, a string, or a propagation model created with the `propagationModel` function. The default value depends on the coordinate system used by the input sites.

Coordinate System	Default propagation model value
'geographic'	<ul style="list-style-type: none"> 'longley-rice' when you use a terrain. 'freespace' when you do not use a terrain.

Coordinate System	Default propagation model value
'cartesian'	<ul style="list-style-type: none"> ' freespace ' when Map is set to none. ' raytracing ' when Map is set to the name of an STL file or a triangulation object. The default ray tracing model uses the shooting and bouncing rays (SBR) method.

You can also specify the propagation model by using the 'PropagationModel' name-value pair argument.

Name-Value Pair Arguments

Specify optional pairs of arguments as Name1=Value1,...,NameN=ValueN, where Name is the argument name and Value is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose Name in quotes.

Example: 'Type', 'power'

PropagationModel — Propagation model to use for path loss calculations

'longley-ric' (default) | 'freespace' | 'close-in' | 'rain' | 'gas' | 'fog' | 'raytracing' | propagation model created with propagationModel

Propagation model to use for the path loss calculations, specified as the comma-separated pair consisting of 'PropagationModel' and one of the following:

- ' freespace ' — Free space propagation model
- ' rain ' — Rain propagation model
- ' gas ' — Gas propagation model
- ' fog ' — Fog propagation model
- ' close-in ' — Close-in propagation model
- ' longley-ric ' — Longley-Rice propagation model
- ' tirem ' — Tirem propagation model
- ' raytracing ' — Ray tracing propagation model that uses the shooting and bouncing rays (SBR) method
- A propagation model created with the propagationModel function

The default propagation model is 'longley-ric' when terrain is enabled and 'freespace' when terrain is disabled.

Terrain propagation models, including 'longley-ric' and 'tirem', are only supported for sites with a CoordinateSystem value of 'geographic'.

Data Types: char

SuccessColor — Color of successful links

'green' (default) | RGB triplet | character vector | string scalar

Color of successful links, specified as the comma-separated pair consisting of 'SuccessColor' and one of the following:

- An RGB triplet whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range [0,1]; for example, [0.4 0.6 0.7].
- A character vector such as 'red' or 'r'.
- A string scalar such as "red" or "r".

This table contains the color names and equivalent RGB triplets for some common colors.

Color Name	Short Name	RGB Triplet	Appearance
'red'	'r'	[1 0 0]	
'green'	'g'	[0 1 0]	
'blue'	'b'	[0 0 1]	
'cyan'	'c'	[0 1 1]	
'magenta'	'm'	[1 0 1]	
'yellow'	'y'	[1 1 0]	
'black'	'k'	[0 0 0]	
'white'	'w'	[1 1 1]	

Data Types: char | string | double

FailColor – Color of unsuccessful links

'red' (default) | RGB triplet | character vector | string scalar

Color of unsuccessful links, specified as the comma-separated pair consisting of 'FailColor' and one of the following:

- An RGB triplet whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range [0,1]; for example, [0.4 0.6 0.7].
- A character vector such as 'red' or 'r'.
- A string scalar such as "red" or "r".

This table contains the color names and equivalent RGB triplets for some common colors.

Color Name	Short Name	RGB Triplet	Appearance
'red'	'r'	[1 0 0]	
'green'	'g'	[0 1 0]	
'blue'	'b'	[0 0 1]	
'cyan'	'c'	[0 1 1]	
'magenta'	'm'	[1 0 1]	
'yellow'	'y'	[1 1 0]	
'black'	'k'	[0 0 0]	
'white'	'w'	[1 1 1]	

Data Types: char | string | double

Map – Map for visualization or surface data

siteviewer object | triangulation object | string scalar | character vector

Map for visualization or surface data, specified as a `siteviewer` object, a `triangulation` object, a string scalar, or a character vector. Valid and default values depend on the coordinate system.

Coordinate System	Valid map values	Default map value
'geographic'	<ul style="list-style-type: none"> A <code>siteviewer</code> object^a. A terrain name, if the function is called with an output argument. Valid terrain names are 'none', 'gmted2010', or the name of the custom terrain data added using <code>addCustomTerrain</code>. 	<ul style="list-style-type: none"> The current <code>siteviewer</code> object or a new <code>siteviewer</code> object if none are open. 'gmted2010', if the function is called with an output.
'cartesian'	<ul style="list-style-type: none"> 'none'. A <code>siteviewer</code> object. The name of an STL file. A <code>triangulation</code> object. 	<ul style="list-style-type: none"> 'none'.

^a Alignment of boundaries and region labels are a presentation of the feature provided by the data vendors and do not imply endorsement by MathWorks.

Data Types: `char` | `string`

Output Arguments

status — Success status of communication link

M-by-*N* array

Success status of communication links, returned as an *M*-by-*N* arrays. *M* is the number of transmitter sites and *N* is the number of receiver sites.

Compatibility Considerations

'raytracing' propagation models use SBR method

Behavior changed in R2021b

Starting in R2021b, when you use the `link` function and specify the `propmodel` argument or `PropagationModel` name-value argument as 'raytracing', the function uses the shooting and bouncing rays (SBR) method and calculates up to two reflections. In previous releases, the `link` function uses the image method and calculates up to one reflection.

To display or compute communication link status using the image method instead, create a propagation model by using the `propagationModel` function. Then, use the `link` function with the propagation model as input. This example shows how to update your code.

```
pm = propagationModel('raytracing', 'Method', 'image');
link(rx,tx,pm)
```

For information about the SBR and image methods, see “Choose a Propagation Model”.

Starting in R2021b, all RF Propagation functions use the SBR method by default and calculate up to two reflections. For more information, see “Default modeling method is shooting and bouncing rays method” on page 4-210.

sigstrength | coverage | sinr | los | propagationModel

Introduced in R2019b

location

Coordinates at distance and angle from site

Syntax

```
sitelocation = location(site)
[lat,lon] = location(site)
[___] = location(site,distance,azimuth)
```

Description

`sitelocation = location(site)` returns the site location of the antenna.

`[lat,lon] = location(site)` returns the latitude and longitude of the antenna site.

This syntax only supports antenna sites with a `CoordinateSystem` property value of `'geographic'`.

`[___] = location(site,distance,azimuth)` returns the new location achieved by moving the antenna site by the distance specified in the direction of the azimuth angle. The location is calculated by moving along a great circle path using a spherical Earth model.

This syntax only supports antenna sites with a `CoordinateSystem` property value of `'geographic'`.

Examples

Location of Antenna Site

Create a site 1 km north of a given site.

Create the first transmitter site.

```
tx = txsite('Name','MathWorks', ...
           'Latitude',42.3001, ...
           'Longitude',-71.3504);
```

Calculate the location 1 km north of the first site.

```
[lat,lon] = location(tx,1000,90)
```

```
lat = 42.3091
```

```
lon = -71.3504
```

Create a second transmitter site at the location specified by `lat` and `lon`.

```
tx2 = txsite('Name','Second transmitter', ...
            'Latitude',lat, ...
            'Longitude',lon);
```

Show the two transmitter sites.

```
show([tx, tx2])
```

Input Arguments

site — Antenna site

scalar | array

Antenna site, specified as a scalar or an array. It is either a txsite or a rxsite object. For more information, see txsite, and rxsite

Note If distance or azimuth is a vector, then site must be a scalar.

distance — Distance to move antenna site

scalar | vector

Distance to move antenna site, specified as a scalar or vector in meters.

azimuth — Azimuth angle

scalar | vector

Azimuth angle, specified as a scalar or vector in degrees. Azimuth angle is measured counterclockwise from due east.

Output Arguments

siteLocation — Location of antenna site

M-by-2 matrix

Location of antenna site, returned as an *M*-by-2 matrix with each element unit in degrees. *M* is the number of sites in `site`. The location value includes the latitude and longitude of the antenna site.

If the antenna site has the `CoordinateSystem` property set to 'geographic', *L* is a 1-by-2 vector in degrees latitude and longitude. The output longitude is wrapped so that values are in the range [-180 180]. If `SITE` has `CoordinateSystem` set to 'cartesian', *L* is a 1-by-3 vector.

lat — Latitude of one or more antenna sites

M-by-1 vector

Latitude of one or more antenna sites, returned as an *M*-by-1 vector with each element unit in degrees. *M* is the number of sites in `site`.

lon — Longitude of one or more antenna sites

M-by-1 matrix

Longitude of one or more antenna sites, returned as an *M*-by-1 matrix with each element unit in degrees. *M* is the number of sites in `site`. The output is wrapped so that the values are in the range [-180 180].

`distance` | `angle` | `txsite` | `rxsite`

Introduced in R2019b

los

Display or compute line-of-sight (LOS) visibility status

Syntax

```
los(site1,site2)
los(site1,site2,Name,Value)
vis = los(site1,site2,Name,Value)
```

Description

`los(site1,site2)` displays the line-of-sight (LOS) visibility from site 1 to site 2 in the current Site Viewer. The plot is color coded to identify the visibility of the points along the line.

`los(site1,site2,Name,Value)` sets properties using one or more name-value pairs. For example, `los(site1,site2,'ObstructedColor','red')` displays the LOS in red to show blocked visibility.

`vis = los(site1,site2,Name,Value)` returns the status of the LOS visibility.

Examples

LOS from a Transmitter Site to a Receiver Site

Create a transmitter site with an antenna of height 30 m and a receiver site at ground level.

```
tx = txsite("Name","MathWorks Apple Hill",...
           "Latitude",42.3001,"Longitude",-71.3504,"AntennaHeight",30);
rx = rxsite("Name","MathWorks Lakeside", ...
           "Latitude",42.3021,"Longitude",-71.3764);
```

Plot the LOS between the two sites.

```
los(tx,rx)
```

LOS from a Transmitter Site to Two Receiver Sites

Create a transmitter site with an antenna of height 30 m and two receiver sites with antennas at ground level.

```
tx = txsite("Name", "MathWorks Apple Hill", ...
           "Latitude", 42.3001, "Longitude", -71.3504, "AntennaHeight", 30);
```

```
names = ["Fenway Park", "Bunker Hill Monument"];
lats = [42.3467, 42.3763];
lons = [-71.0972, -71.0611];
```

Create the receiver site array.

```
rxs = rxsite("Name", names, ...
            "Latitude", lats, ...
            "Longitude", lons);
```

Plot the LOSs to the receiver sites. The red portion of the LOS represents obstructed visibility.

```
los(tx, rxs)
```

LOS Between Cartesian Sites

Import and view an STL file. The file models a small conference room with one table and four chairs.

```
viewer = siteviewer("SceneModel", "conferenceroom.stl");
```

Create a transmitter site near the upper corner of the room and a receiver site above the table. Specify the position using Cartesian coordinates in meters.

```
tx = txsite("cartesian", ...  
           "AntennaPosition", [-1.46; -1.42; 2.1]);  
rx = rxsite("cartesian", ...  
           "AntennaPosition", [0.3; 0.3; 0.85]);
```

Plot the LOS between the transmitter and the receiver.

```
los(rx, tx)
```

Pan by left-clicking, zoom by right-clicking or by using the scroll wheel, and rotate the visualization by clicking the middle button and dragging or by pressing **Ctrl** and left-clicking and dragging.

Plot Propagation Rays Between Sites in Chicago

Return ray tracing results in `comm.Ray` objects and plot the ray propagation paths after relaunching the Site Viewer map.

Create a Site Viewer map, loading building data for Chicago. For more information about the osm file, see [1] on page 4-0 .

```
viewer = siteviewer('Buildings','chicago.osm');
```

Create a transmitter site on one building and a receiver site on another building. Use the `los` function to show the line of sight path between the transmitter and receiver sites.

```
tx = txsite( ...  
    'Latitude',41.8800, ...  
    'Longitude',-87.6295, ...  
    'TransmitterFrequency',2.5e9);  
rx = rxsite( ...  
    'Latitude',41.881352, ...  
    'Longitude',-87.629771, ...  
    'AntennaHeight',30);  
los(tx,rx);
```

Perform ray tracing for up to two reflections. For the configuration defined, ray tracing returns a cell array containing the ray objects. Close the Site Viewer map.

```
pm = propagationModel( ...
    'raytracing', ...
    'Method','sbr', ...
    'MaxNumReflections',2);
rays = raytrace(tx,rx,pm)

rays = 1x1 cell array

```

```
close(viewer);
```

You can plot the rays without performing ray tracing again. Create another Site Viewer map with the same buildings. Show the transmitter and receiver sites. Using the previously returned cell array of

ray objects, plot the reflected rays between the transmitter site and the receiver site. The plot function can plot the path for ray objects collectively or individually. For example, to plot rays for the only second ray object, specify rays{1}(1,2). This figure plot all paths for all the ray objects.

```
siteviewer('Buildings', 'chicago.osm');
los(tx,rx);
plot(rays{:}, 'Type', 'power', ...
     'TransmitterSite', tx, 'ReceiverSite', rx);
```

Appendix

[1] The osm file is downloaded from <https://www.openstreetmap.org>, which provides access to crowd-sourced map data all over the world. The data is licensed under the Open Data Commons Open Database License (ODbL), <https://opendatacommons.org/licenses/odbl/>.

Input Arguments

site1 — Source antenna site

txsite object | rxsite object

Source antenna site, specified as a txsite object or a rxsite object. Site 1 must be a single site object.

site2 — Target antenna site

txsite object | rxsite object | vector of txsite or rxsite objects

Target antenna site, specified as a txsite object or a rxsite object. Site 2 can be a single site object or a vector of multiple site objects.

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1, ..., NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` in quotes.

Example: `'ObstructedColor','blue'`

VisibleColor — Plot color for successful visibility

`'green'` (default) | RGB triplet | character vector | string scalar

Plot color for successful visibility, specified as one of the following:

- An RGB triplet whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range $[0, 1]$; for example, $[0.4 \ 0.6 \ 0.7]$.
- A character vector such as `'red'` or `'r'`.
- A string scalar such as `"red"` or `"r"`.

This table contains the color names and equivalent RGB triplets for some common colors.

Color Name	Short Name	RGB Triplet	Appearance
'red'	'r'	[1 0 0]	
'green'	'g'	[0 1 0]	
'blue'	'b'	[0 0 1]	
'cyan'	'c'	[0 1 1]	
'magenta'	'm'	[1 0 1]	
'yellow'	'y'	[1 1 0]	
'black'	'k'	[0 0 0]	
'white'	'w'	[1 1 1]	

ObstructedColor — Plot color for blocked visibility

`'red'` (default) | RGB triplet | character vector | string scalar

Plot color for blocked visibility, specified as one of the following:

- An RGB triplet whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range $[0, 1]$; for example, $[0.4 \ 0.6 \ 0.7]$.
- A character vector such as `'red'` or `'r'`.
- A string scalar such as `"red"` or `"r"`.

This table contains the color names and equivalent RGB triplets for some common colors.

Color Name	Short Name	RGB Triplet	Appearance
'red'	'r'	[1 0 0]	
'green'	'g'	[0 1 0]	
'blue'	'b'	[0 0 1]	

Color Name	Short Name	RGB Triplet	Appearance
'cyan'	'c'	[0 1 1]	
'magenta'	'm'	[1 0 1]	
'yellow'	'y'	[1 1 0]	
'black'	'k'	[0 0 0]	
'white'	'w'	[1 1 1]	

Resolution — Sampling distance between two sites

'auto' (default) | numeric scalar

Resolution of sample locations used to compute line-of-sight visibility, specified as 'auto' or a numeric scalar expressed in meters. Resolution defines the distance between samples on the great circle path using a spherical Earth model. If Resolution is 'auto', the function computes a value based on the distance between the sites.

Map — Map for visualization or surface data

siteviewer object | triangulation object | string scalar | character vector

Map for visualization or surface data, specified as a siteviewer object, a triangulation object, a string scalar, or a character vector. Valid and default values depend on the coordinate system.

Coordinate System	Valid map values	Default map value
'geographic'	<ul style="list-style-type: none"> A siteviewer object^a. A terrain name, if the function is called with an output argument. Valid terrain names are 'none', 'gmted2010', or the name of the custom terrain data added using addCustomTerrain. 	<ul style="list-style-type: none"> The current siteviewer object or a new siteviewer object if none are open. 'gmted2010', if the function is called with an output.
'cartesian'	<ul style="list-style-type: none"> 'none'. A siteviewer object. The name of an STL file. A triangulation object. 	<ul style="list-style-type: none"> 'none'.

^a Alignment of boundaries and region labels are a presentation of the feature provided by the data vendors and do not imply endorsement by MathWorks.

Data Types: char | string

Output Arguments

vis — Status of LOS visibility

true or 1 | false or 0 | *n*-by-1 logical array

Status of LOS visibility, returned as logical 1 (true) or 0 (false). If there are multiple target sites, the function returns a logical array of *n*-by-1.

pathloss

Package: rfprop

Path loss of radio wave propagation

Syntax

```
pl = pathloss(propmodel,rx,tx)
pl = pathloss(____,Name,Value)
[pl,info] = pathloss(____)
```

Description

`pl = pathloss(propmodel,rx,tx)` returns the path loss of radio wave propagation at the receiver site from the transmitter site.

`pl = pathloss(____,Name,Value)` returns the path loss using additional options specified by Name,Value pairs.

`[pl,info] = pathloss(____)` returns the path loss and the information about the propagation paths.

Examples

Path Loss of Receiver In Heavy Rain

Specify the transmitter and the receiver sites.

```
tx = txsite('Name','MathWorks Apple Hill', ...
    'Latitude',42.3001,'Longitude',-71.3504, ...
    'TransmitterFrequency', 2.5e9);
```

```
rx = rxsite('Name','Fenway Park', ...
    'Latitude',42.3467,'Longitude',-71.0972);
```

Create the propagation model for heavy rainfall rate.

```
pm = propagationModel('rain','RainRate',50)
```

```
pm =
    Rain with properties:
```

```
    RainRate: 50
    Tilt: 0
```

Calculate the pathloss at the receiver using the rain propagation model.

```
pl = pathloss(pm,rx,tx)
```

```
pl = 127.3208
```

Input Arguments

propmodel — Propagation model

propagation model object

Propagation model, specified as a propagation model object. Use the `propagationModel` function.

Data Types: object

rx — Receiver site

rxsite object

Receiver site, specified as a rxsite object. You can use array inputs to specify multiple sites.

Data Types: char

tx — Transmitter site

txsite object

Transmitter site, specified as a txsite object. You can use array inputs to specify multiple sites.

Data Types: char

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1, ..., NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose Name in quotes.

Example: 'Map', 'none'

Map — Map for visualization or surface data

siteviewer object | triangulation object | string scalar | character vector

Map for visualization or surface data, specified as a siteviewer object, a triangulation object, a string scalar, or a character vector. Valid and default values depend on the coordinate system.

Coordinate System	Valid map values	Default map value
'geographic'	<ul style="list-style-type: none"> A siteviewer object^a. A terrain name, if the function is called with an output argument. Valid terrain names are 'none', 'gmted2010', or the name of the custom terrain data added using <code>addCustomTerrain</code>. 	<ul style="list-style-type: none"> The current siteviewer object or a new siteviewer object if none are open. 'gmted2010', if the function is called with an output.

Coordinate System	Valid map values	Default map value
'cartesian'	<ul style="list-style-type: none"> 'none'. A <code>siteviewer</code> object. The name of an STL file. A <code>triangulation</code> object. 	<ul style="list-style-type: none"> 'none'.

^a Alignment of boundaries and region labels are a presentation of the feature provided by the data vendors and do not imply endorsement by MathWorks.

Data Types: `char` | `string`

Output Arguments

pL — Path loss

scalar | M -by- N arrays

Path loss, returned as a scalar or M -by- N cell arrays containing a row vector of path loss values in decibels. M is the number of TX sites and N is the number of RX sites.

Path loss is computed along the shortest path through space connecting the transmitter and receiver antenna centers.

For terrain propagation models, path loss is computed using terrain elevation profile that is computed at sample locations on the great circle path between the transmitter and the receiver. If `Map` is a `siteviewer` object with buildings specified, the terrain elevation is adjusted to include the height of the buildings.

info — Information corresponding to each propagation path

M -by- N structure array | M -by- N cell array containing vector of structures in each cell

Information corresponding to each propagation path, returned as a M -by- N cell array containing vector of structures in each cell for ray tracing propagation models and M -by- N structure array for all other propagation models. The field and values for the structures are:

- `PropagationDistance` — Total distance of propagation path returned as a double scalar in meters.
- `AngleOfDeparture` — Angle of departure of signal from transmitter site antenna returned as a 2-by-1 double vector of azimuth and elevation angles in degrees.
- `AngleOfArrival` — Angle of arrival of signal at receiver site antenna returned as a 2-by-1 double vector of azimuth and elevation angles in degrees.
- `NumReflections` — Number of reflections undergone by signal along propagation path, returned specified as 0, 1, or 2. This field and value is only for ray tracing propagation models.

Angle values in this structure are defined using the local East-North-Up coordinate system of the antenna when `CoordinateSystem` is set to `geographic`. Angle values in this structure are defined using global Cartesian coordinate system when `CoordinateSystem` is set to `cartesian`. Azimuth angle is measured either from east (when `'geographic'`) or from the global x-axis around the global z-axis (when `'cartesian'`). Elevation angle is measured from the horizontal (or X-Y) plane to the x-axis of the antenna in the range -90 to 90.

`propagationModel` | `range`

Introduced in R2019b

plot

Display RF propagation data in Site Viewer

Syntax

```
plot(pd)
plot( ____,Name,Value)
```

Description

`plot(pd)` displays propagation data in the current Site Viewer. Each data point is displayed as a circular marker that is colored according to the corresponding value.

`plot(____,Name,Value)` displays the propagation data with additional options specified by name-value pair arguments.

Examples

Compute Signal Strength Data in Urban Environment

Launch Site Viewer with basemaps and building files for Manhattan. For more information about the `osm` file, see [1] on page 4-0 .

```
viewer = siteviewer("Basemap","streets_dark",...
    "Buildings","manhattan.osm");
```

Show a transmitter site on a building.

```
tx = txsite("Latitude",40.7107,...
           "Longitude",-74.0114,...
           "AntennaHeight",80);
show(tx)
```

Create receiver sites along nearby streets.

```
latitude = [linspace(40.7088, 40.71416, 50), ...
            linspace(40.71416, 40.715505, 25), ...
            linspace(40.715505, 40.7133, 25), ...
            linspace(40.7133, 40.7143, 25)]';
longitude = [linspace(-74.0108, -74.00627, 50), ...
             linspace(-74.00627, -74.0092, 25), ...
             linspace(-74.0092, -74.0110, 25), ...
             linspace(-74.0110, -74.0132, 25)]';
rxs = rxsite("Latitude", latitude, "Longitude", longitude);
```

Compute signal strength at each receiver location.

```
signalStrength = sigstrength(rxs, tx)';
```

Create a propagationData object to hold computed signal strength data.

```
tbl = table(latitude, longitude, signalStrength);
pd = propagationData(tbl);
```

Plot the signal strength data on a map as colored points.

```
legendTitle = "Signal" + newline + "Strength" + newline + "(dB)";
plot(pd, "LegendTitle", legendTitle, "Colormap", parula);
```

Appendix

[1] The osm file is downloaded from <https://www.openstreetmap.org>, which provides access to crowd-sourced map data all over the world. The data is licensed under the Open Data Commons Open Database License (ODbL), <https://opendatacommons.org/licenses/odbl/>.

Input Arguments

pd — Propagation data

propagationData object (default)

Propagation data, specified as a propagationData object.

Name-Value Pair Arguments

Specify optional pairs of arguments as Name1=Value1, . . . , NameN=ValueN, where Name is the argument name and Value is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose Name in quotes.

Example: 'Type', 'power'

DataVariableName — Data variable to plot

pd.DataVariableName (default) | character vector | string scalar

Data variable to plot, specified as the comma-separated pair consisting of 'DataVariableName' and a character vector or a string scalar corresponding to a variable name in the data table used to create

the propagation data container object `pd`. The default value is dynamic and corresponds to the `DataVariableName` property of the `propagationData` object.

Data Types: `char` | `string`

Type — Type of value to plot

'custom' (default) | 'power' | 'efield' | 'sinr' | 'pathloss'

Type of value to plot, specified as the comma-separated pair consisting of 'Type' and one of the values in the Type column:

Type	ColorLimits	LegendTitle
'custom'	[min(Data) max(Data)]	' '
'power'	[-120 -5]	'Power (dBm)'
'efield'	[20 135]	'E-field (dBuV/m)'
'sinr'	[-5 20]	'SINR (dB)'
'pathloss'	[45 160]	'Path loss (dB)'

The default value for `Levels` is a linearly spaced vector bounded by `ColorLimits`.

Data Types: `char` | `string`

Levels — Data value levels to plot

numeric vector

Data value levels to plot, specified as the comma-separated pair consisting of 'Levels' and a numeric vector. The propagation data is binned according to `Levels`. The data in each bin is color coded according to the corresponding level. The colors are selected using `Colors` if specified, or else `Colormap` and `ColorLimits`. Data points with values below the minimum level are not included in the plot.

The default value for `Levels` is a linearly spaced vector bounded by `ColorLimits`.

Data Types: `double`

Colors — Colors of data points

M-by-3 array of RGB | array of strings | cell array of character vectors

Colors of the data points, specified as the comma-separated pair consisting of 'Colors' and an *M*-by-3 array of RGB (red, blue, green) or an array of strings, or a cell array of character vectors. Colors are assigned element-wise to values in `Levels` for coloring the corresponding points. Colors cannot be used with `Colormap` and `ColorLimits`.

Data Types: `double` | `char` | `string`

Colormap — Color map for coloring points

'jet(256)' (default) | predefined colormap name | *M*-by-3 array of RGB triplets

Colormap for the coloring points, specified as the comma-separated pair consisting of 'Colormap' and a predefined colormap name or an *M*-by-3 array of RGB (red, blue, green) triplets that define *M* individual colors. `Colormap` cannot be used with `Colors`.

Data Types: `double` | `char` | `string`

ColorLimits — Color limits for color map

two-element vector

Color limits for the colormap, specified as the comma-separated pair consisting of 'ColorLimits' and a two-element vector of the form [min max]. The color limits indicate the data level values that map to the first and last colors in the colormap. ColorLimits cannot be used with Colors.

Data Types: double

MarkerSize — Size of data markers

10 (default) | positive numeric scalar

Size of data markers plotted on the map, specified as the comma-separated pair consisting of 'MarkerSize' and a positive numeric scalar in pixels.

Data Types: double

ShowLegend — Show color legend on map

true (default) | false

Show color legend on map, specified as the comma-separated pair consisting of 'ShowLegend' and true or false.

Data Types: logical

LegendTitle — Title of color legend

character vector | string scalar

Title of color legend, specified as the comma-separated pair consisting of 'LegendTitle' and a character vector or a string scalar.

Data Types: string | char

Map — Map for surface data

siteviewer object

Map for surface data, specified as the comma-separated pair consisting of 'Map' and a siteviewer object.⁷ The default value is the current Site Viewer or a new Site Viewer, if none is open.

Data Types: char | string

See Also**Introduced in R2020a**

⁷ Alignment of boundaries and region labels are a presentation of the feature provided by the data vendors and do not imply endorsement by MathWorks.

location

Coordinates of RF propagation data

Syntax

```
datalocation = location(pd)
[lat,lon] = location(pd)
```

Description

`datalocation = location(pd)` returns the location coordinates of the data points in the propagation data object.

`[lat,lon] = location(pd)` returns the latitude and longitude of the propagation data object

Examples

Transmitter Site Service Areas

Define names and locations of sites around Boston.

```
names = ["Fenway Park", "Faneuil Hall", "Bunker Hill Monument"];
lats = [42.3467,42.3598,42.3763];
lons = [-71.0972,-71.0545,-71.0611];
```

Create array of transmitter sites.

```
txs = txsite("Name", names,...
            "Latitude",lats,...
            "Longitude",lons, ...
            "TransmitterFrequency",2.5e9);
```

Compute received power data for each transmitter site.

```
maxr = 20000;
pd1 = coverage(txs(1), "MaxRange",maxr);
pd2 = coverage(txs(2), "MaxRange",maxr);
pd3 = coverage(txs(3), "MaxRange",maxr);
```

Compute rectangle containing locations of all data.

```
locs = [location(pd1); location(pd2); location(pd3)];
[minlatlon, maxlatlon] = bounds(locs);
```

Create grid of locations over rectangle.

```
gridlength = 300;
latv = linspace(minlatlon(1),maxlatlon(1),gridlength);
lonv = linspace(minlatlon(2),maxlatlon(2),gridlength);
[lons,lats] = meshgrid(lonv,latv);
lats = lats(:);
lons = lons(:);
```

Get data for each transmitter at grid locations using interpolation.

```
v1 = interp(pd1,lats,lons);
v2 = interp(pd2,lats,lons);
v3 = interp(pd3,lats,lons);
```

Create propagation data containing minimum received power values.

```
minReceivedPower = min([v1 v2 v3],[],2,"includenan");
pd = propagationData(lats,lons,"MinReceivedPower",minReceivedPower);
```

Plot minimum received power, which shows the weakest signal received from any transmitter site. The area shown may correspond to the service area of triangulation using the three transmitter sites.

```
sensitivity = -110;
contour(pd,"Levels",sensitivity:-5,"Type","power")
```

Input Arguments

pd — Propagation data

propagationData object (default)

Propagation data, specified as a propagationData object.

Output Arguments

dataLocation — Location coordinates of data points

M-by-2 matrix

Location of antenna site, returned as an M -by-2 matrix with each element unit in degrees. M is the number of rows in the data table with valid latitude and longitude values. Duplicate locations are not removed.

lat — Latitude of data points

M -by-1 vector

Latitude of data points, returned as an M -by-1 vector with each element unit in degrees.

lon — Longitude of data points

M -by-1 vector

Longitude of data points, returned as an M -by-1 matrix with each element unit in degrees. The output is wrapped so that the values are in the range $[-180\ 180]$.

See Also

Introduced in R2020a

propagationModel

Create RF propagation model

Syntax

```
pm = propagationModel(modelname)
pm = propagationModel( ___,Name,Value)
```

Description

`pm = propagationModel(modelname)` creates an RF propagation model for the specified model.

`pm = propagationModel(___,Name,Value)` specifies options using name-value arguments. For example, `pm = propagationModel('rain','RainRate',96)` creates a rain propagation model with a rain rate of 96 mm/h.

Examples

Signal Strength of Receiver in Heavy Rain

Specify transmitter and receiver sites.

```
tx = txsite('Name','MathWorks Apple Hill',...
    'Latitude',42.3001, ...
    'Longitude',-71.3504, ...
    'TransmitterFrequency', 2.5e9);

rx = rxsite('Name','Fenway Park',...
    'Latitude',42.3467, ...
    'Longitude',-71.0972);
```

Create the propagation model for a heavy rainfall rate.

```
pm = propagationModel('rain','RainRate',50)
```

```
pm =
    Rain with properties:
```

```
    RainRate: 50
    Tilt: 0
```

Calculate the signal strength at the receiver using the rain propagation model.

```
ss = sigstrength(rx,tx,pm)
```

```
ss = -87.1559
```

Longley-Rice Propagation Model

Create a default transmitter site.

```
tx = txsite;
```

Create a Longley-Rice propagation model by using the `propagationModel` function.

```
pm = propagationModel("longley-rice", "TimeVariabilityTolerance", 0.7)
```

```
pm =
```

```
LongleyRice with properties:
```

```
    AntennaPolarization: 'horizontal'  
    GroundConductivity: 0.0050  
    GroundPermittivity: 15  
    AtmosphericRefractivity: 301  
    ClimateZone: 'continental-temperate'  
    TimeVariabilityTolerance: 0.7000  
    SituationVariabilityTolerance: 0.5000
```

Find the coverage of the transmitter site by using the defined propagation model.

```
coverage(tx, "PropagationModel", pm)
```

Input Arguments

modelName — Name of propagation model

' freespace ' | ' rain ' | ' gas ' | ' fog ' | ' close-in ' | ' longley-rice ' | ' tirem ' | ' raytracing '

Name of propagation model, specified as one of these:

- ' freespace ' — Free space propagation model.
- ' rain ' — Rain propagation model. For more information, see [3].
- ' gas ' — Gas propagation model. For more information, see [6].
- ' fog ' — Fog propagation model. For more information, see [2].
- ' close-in ' — Close-in propagation model typically used in urban macro-cell scenarios. For more information, see [1].

Note The close-in model implements a statistical path loss model and can be configured for different scenarios. The default values correspond to an urban macro-cell scenario in a non-line-of-sight (NLOS) environment.

- ' longley-rice ' — Longley-Rice propagation model. This model is also known as Irregular Terrain Model (ITM). You can use this model to calculate point-to-point path loss between sites over an irregular terrain, including buildings. Path loss is calculated from free-space loss, terrain diffraction, ground reflection, refraction through atmosphere, tropospheric scatter, and atmospheric absorption. For more information and list of limitations, see [4].

Note The Longley-Rice model implements the point-to-point mode of the model, which uses terrain data to predict the loss between two points.

- ' tirem ' — Terrain Integrated Rough Earth Model™ (TIREM™). You can use this model to calculate point-to-point path loss between sites over an irregular terrain, including buildings. Path loss is calculated from free-space loss, terrain diffraction, ground reflection, refraction through atmosphere, tropospheric scatter, and atmospheric absorption. This model needs access to an external TIREM library. The actual model is valid from 1 MHz to 1000 GHz. But with Antenna Toolbox elements and arrays the frequency range is limited to 200 GHz.
- ' raytracing ' — A multipath propagation model that uses ray tracing analysis to compute propagation paths and corresponding path losses. Path loss is calculated from free-space loss, reflection loss due to material, and antenna polarization loss. You can perform ray tracing analysis using the shooting and bouncing rays (SBR) method or the image method. Specify a method using the ' Method ' property. The SBR method includes effects from surface reflections but does not include effects from diffraction, refraction, or scattering. The image method considers surface reflection only. Both ray tracing methods are valid for a frequency range of 100 MHz to 100 GHz. For information about differences between the image and SBR methods, see “Choose a Propagation Model”. Use the raytrace function to compute and plot the propagation paths between the sites.

Dependencies

Specifying ' tirem ' requires Antenna Toolbox.

Data Types: char

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1, ..., NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose Name in quotes.

Example: `propagationModel("rain", "RainRate", 50)` sets the rate of rainfall in the rain propagation model to 50 millimeters per hour.

Each type of propagation model object supports a different set of properties. For a full list of the properties and their descriptions for a propagation model type, see the associated object page.

Type of Propagation Model	Object Page
' freespace '	FreeSpace
' rain '	Rain
' gas '	Gas
' fog '	Fog
' close-in '	CloseIn
' longley-rice '	LongleyRice
' tirem '	TIREM
' raytracing '	RayTracing

Output Arguments

pm — Propagation model

FreeSpace object | Rain object | Gas object | Fog object | CloseIn object | ...

Propagation model, returned as a FreeSpace, Rain, Gas, Fog, CloseIn, LongleyRice, TIREM, or RayTracing object.

Compatibility Considerations

Default modeling method is shooting and bouncing rays method

Behavior changed in R2021b

Starting in R2021b, when you create a propagation model using the syntax `propagationModel('raytracing')`, MATLAB returns a RayTracing model with the Method value set to 'sbr' and two reflections (instead of 'image' and one reflection as in previous releases).

To create ray tracing propagation models that use the image method, use the syntax `propagationModel('raytracing', 'Method', 'image')`.

propagationModel('raytracing-image-method') syntax will be removed in a future release

Warns starting in R2022a

The `propagationModel('raytracing-image-method')` syntax will be removed in a future release.

Use the `propagationModel('raytracing', 'Method', 'image')` syntax to use the image ray tracing method. Alternatively, using the `propagationModel('raytracing')` syntax sets the ray tracing method to SBR.

Topics

"Choose a Propagation Model"

Introduced in R2019b

range

Package: rfprop

Range of radio wave propagation

Syntax

```
r = range(propmodel,tx,pl)
```

Description

`r = range(propmodel,tx,pl)` returns the range of radio wave propagation from the transmitter site.

Examples

Range of Transmitter In Heavy Rain

Specify transmitter and receiver sites.

```
tx = txsite('Name','MathWorks Apple Hill',...
           'Latitude',42.3001, ...
           'Longitude',-71.3504, ...
           'TransmitterFrequency', 2.5e9);
```

```
rx = rxsite('Name','Fenway Park',...
           'Latitude',42.3467, ...
           'Longitude',-71.0972);
```

Create the propagation model for heavy rainfall rate.

```
pm = propagationModel('rain','RainRate',50)
```

```
pm =
  Rain with properties:
```

```
    RainRate: 50
         Tilt: 0
```

Calculate the range of transmitter using the rain propagation model and a path loss of 127 dB.

```
r = range(pm,tx,127)
```

```
r = 2.0747e+04
```

Input Arguments

propmodel — Propagation model

propagation model object

Propagation model, specified as a propagation model object. Use the `propagationModel` function.

Data Types: `object`

tx — Transmitter site

`txsite` object

Transmitter site, specified as a `txsite` object. You can use array inputs to specify multiple sites.

Data Types: `char`

pL — Path loss

scalar

Path loss, specified as a scalar in decibels.

Data Types: `double`

Output Arguments

r — range

scalar | M -by-1 arrays

Range, returned as a scalar or M -by-1 array with each element in meters. M is the number of TX sites.

Range is the maximum distance for which the path loss does not exceed the value of the specified `pL`.

See Also

`propagationModel` | `pathloss`

Introduced in R2019b

raytrace

Display or compute RF propagation rays

Syntax

```
raytrace(tx,rx)
raytrace(tx,rx,propmodel)
raytrace( ____,Name,Value)
rays = raytrace( ____ )
```

Description

The `raytrace` function plots or computes propagation paths by using ray tracing with surface geometry defined by the 'Map' property. Each plotted propagation path is color-coded according to the received power (dBm) or path loss (dB) along the path. The ray tracing analysis includes surface reflections but does not include effects from diffraction, refraction, or scattering. Operational frequency for this function is from 100 MHz to 100 GHz. For more information, see "Choose a Propagation Model".

`raytrace(tx,rx)` displays the propagation paths from the transmitter site (`tx`) to the receiver site (`rx`) in the current Site Viewer by using the shooting and bouncing rays (SBR) method with up to two reflections.

`raytrace(tx,rx,propmodel)` displays the propagation paths from the transmitter site (`tx`) to the receiver site (`rx`) based on the specified propagation model. To input building and terrain materials to calculate path loss, create a 'raytracing' propagation model using the `propagationModel` function and set the properties to specify building materials.

`raytrace(____,Name,Value)` specifies options using one or more name-value arguments in addition to the input arguments in previous syntaxes.

`rays = raytrace(____)` returns the propagation paths in rays.

Examples

Obstructed and Reflected Paths Using Ray Tracing

Show reflected propagation paths in Chicago using the ray tracing analysis with the SBR method

Launch Site Viewer with buildings in Chicago. For more information about the osm file, see [1] on page 4-0 .

```
viewer = siteviewer("Buildings","chicago.osm");
```

Create a transmitter site on a building and a receiver site near another building.

```
tx = txsite("Latitude",41.8800, ...
           "Longitude",-87.6295, ...
           "TransmitterFrequency",2.5e9);
```

```
show(tx)
rx = rxsite("Latitude",41.8813452, ...
           "Longitude",-87.629771, ...
           "AntennaHeight",30);
show(rx)
```

Show obstruction to line-of-sight.

```
los(tx,rx)
```

Show reflected propagation path using ray tracing with up to two reflections.

```
raytrace(tx,rx)
```

Appendix

[1] The osm file is downloaded from <https://www.openstreetmap.org>, which provides access to crowd-sourced map data all over the world. The data is licensed under the Open Data Commons Open Database License (ODbL), <https://opendatacommons.org/licenses/odbl/>.

Signal Strength Using Ray Tracing Propagation Model

Launch Site Viewer with buildings in Chicago. For more information about the osm file, see [1] on page 4-0 .

```
viewer = siteviewer("Buildings", "chicago.osm");
```

Create a transmitter site on a building.

```
tx = txsite('Latitude',41.8800, ...
           'Longitude',-87.6295, ...
           'TransmitterFrequency',2.5e9);
```

Create a receiver site near another building.

```
rx = rxsite('Latitude',41.881352, ...
           'Longitude',-87.629771, ...
           'AntennaHeight',30);
```

Compute the signal strength by using a ray tracing propagation model. By default, the ray tracing model uses the SBR method, and performs line-of-sight and two-reflection analysis.

```
pm = propagationModel("raytracing");
ssTwoReflections = sigstrength(rx,tx,pm)
```

```
ssTwoReflections = -52.4056
```

Plot the propagation paths for SBR with up to two reflections.

```
raytrace(tx,rx,pm)
```

Compute signal strength with analysis up to two reflections, where total received power is the cumulative power of all propagation paths

```
pm.MaxNumReflections = 5;
ssFiveReflections = sigstrength(rx,tx,pm)
```

```
ssFiveReflections = -51.8927
```

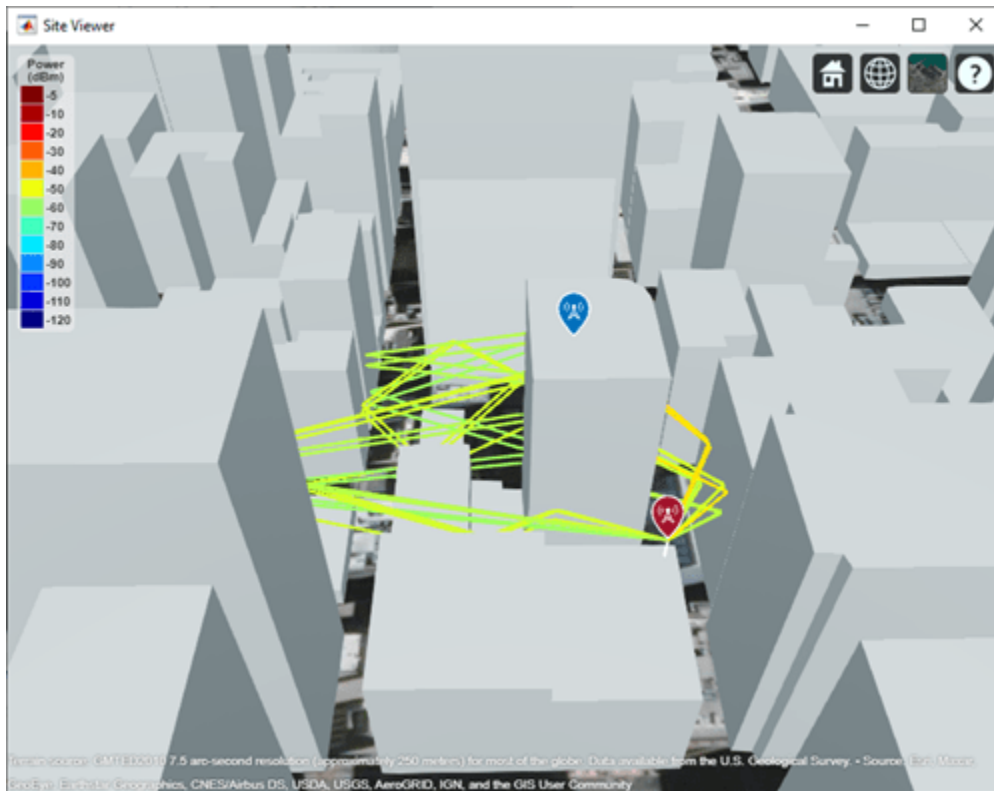

Observe the effect of material by replacing default concrete material with perfect reflector.

```
pm.BuildingsMaterial = 'perfect-reflector';
ssPerfect = sigstrength(rx,tx,pm)
```

```
ssPerfect = -38.8614
```

Plot the propagation paths for SBR with up to five reflections.

```
raytrace(tx,rx,pm)
```

Appendix

[1] The osm file is downloaded from <https://www.openstreetmap.org>, which provides access to crowd-sourced map data all over the world. The data is licensed under the Open Data Commons Open Database License (ODbL), <https://opendatacommons.org/licenses/odbl/>.

Path Loss Due to Material Reflection and Atmosphere

Path loss due to material reflection and atmosphere in Hong Kong. Configure ray tracing to use the shooting and bouncing rays (SBR) method with up to 5 reflections.

Launch Site Viewer with buildings in Hong Kong. For more information about the osm file, see [1] on page 4-0 .

```
viewer = siteviewer("Buildings", "hongkong.osm");
```

Define transmitter and receiver sites to model a small cell scenario in a dense urban environment.

```
tx = txsite("Name","Small cell transmitter", ...
    "Latitude",22.2789, ...
    "Longitude",114.1625, ...
    "AntennaHeight",10, ...
    "TransmitterPower",5, ...
    "TransmitterFrequency",28e9);
rx = rxsite("Name","Small cell receiver", ...
    "Latitude",22.2799, ...
    "Longitude",114.1617, ...
    "AntennaHeight",1);
```

Create a ray tracing propagation model for perfect reflection with up to 5 reflections. Specify the ray tracing method as shooting and bouncing rays (SBR).

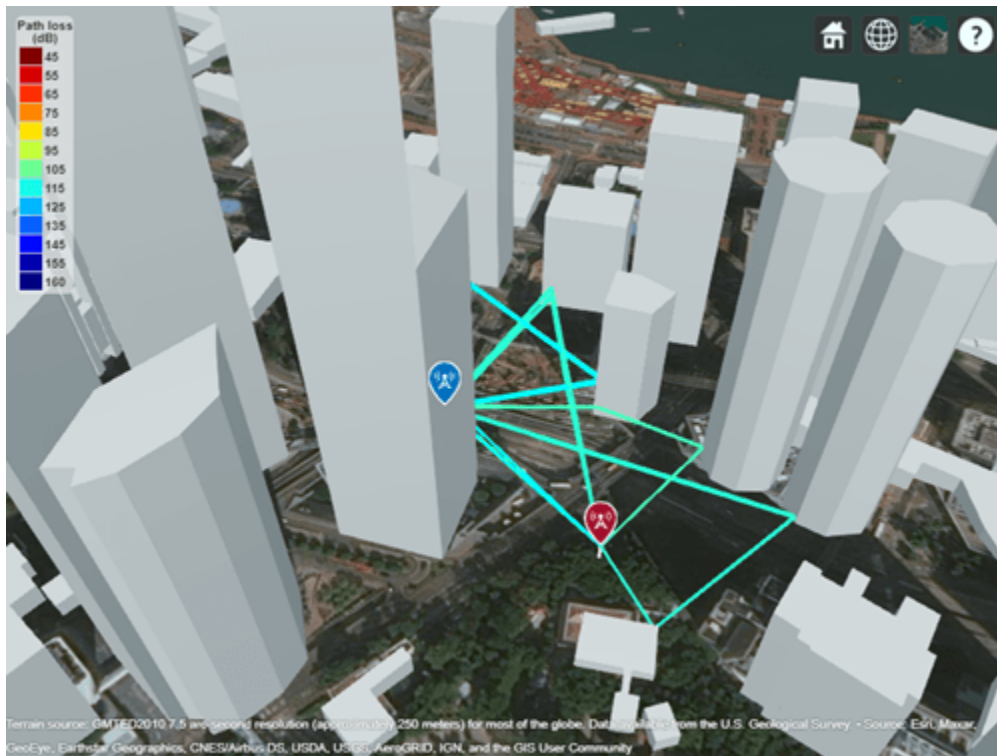

```
pm = propagationModel("raytracing", ...
    "Method","sbr", ...
    "AngularSeparation","low", ...
    "MaxNumReflections",5, ...
    "BuildingsMaterial","perfect-reflector", ...
    "TerrainMaterial","perfect-reflector");
```

Visualize the propagation paths and compute corresponding path losses.

```
raytrace(tx,rx,pm,"Type","pathloss")
raysPerfect = raytrace(tx,rx,pm,"Type","pathloss");
plPerfect = [raysPerfect{1}.PathLoss]

plPerfect = 1x15
```

Recompute and visualize the propagation paths after configuring material reflection loss by setting building and terrain material types in the propagation model. The first value is unchanged because it corresponds to the line-of-sight propagation path.

```
pm.BuildingsMaterial = "glass";
pm.TerrainMaterial = "concrete";
raytrace(tx,rx,pm,"Type","pathloss")
raysMtrls = raytrace(tx,rx,pm,"Type","pathloss");
plMtrls = [raysMtrls{1}.PathLoss]
```

```
plMtrls = 1x15
```

104.2656 106.2236 119.3577 121.5812 122.2841 121.4389 127.0060 122.4593 122.7023 122.0

Recompute and visualize the propagation paths with atmospheric loss by adding atmospheric propagation models.

```
pm = pm + propagationModel("rain") + propagationModel("gas");
raytrace(tx,rx,pm,"Type","pathloss")
raysAtmospheric = raytrace(tx,rx,pm,"Type","pathloss");
plAtmospheric = [raysAtmospheric{1}.PathLoss]
```

```
plAtmospheric = 1x15
```

```
105.3245 107.2834 121.9430 123.4766 124.8711 124.0280 129.7238 124.3557 125.2930 125.7
```

Appendix

[1] The osm file is downloaded from <https://www.openstreetmap.org>, which provides access to crowd-sourced map data all over the world. The data is licensed under the Open Data Commons Open Database License (ODbL), <https://opendatacommons.org/licenses/odbl/>.

Visualize Ray Tracing in Conference Room

This example shows how to:

- Scale an STL file so that the model uses units of meters.
- View the scaled model in Site Viewer.
- Use ray tracing to calculate and display propagation paths from a transmitter to a receiver.

While Cartesian `txsite` and `rxsite` objects require position coordinates in meters, STL files might use other units. If your STL file does not use meters, you must scale the model before importing it into Site Viewer.

Read an STL file as a `triangulation` object. The file models a small conference room with one table and four chairs.

```
TR = stlread("conferenceroom.stl");
```

Scale the coordinates and create a new `triangulation` object. For this example, assume that the conversion factor from the STL units to meters is 0.9.

```
scale = 0.9;
scaledPts = TR.Points * scale;
TR_scaled = triangulation(TR.ConnectivityList,scaledPts);
```

View the new triangulation object using Site Viewer. Alternatively, you can save the new triangulation object as an STL file by using the `stlwrite` function.

```
viewer = siteviewer('SceneModel',TR_scaled);
```

Create and display a transmitter site close to the wall and a receiver site under the table. Specify the position using Cartesian coordinates in meters.

```
tx = txsite("cartesian", ...
    "AntennaPosition",[-1.25; -1.25; 1.9], ...
    "TransmitterFrequency",2.8e9);
show(tx,"ShowAntennaHeight",false)

rx = rxsite("cartesian", ...
    "AntennaPosition",[0.3; 0.2; 0.5]);
show(rx,"ShowAntennaHeight",false)
```

Pan by left-clicking, zoom by right-clicking or by using the scroll wheel, and rotate the visualization by clicking the middle button and dragging or by pressing **Ctrl** and left-clicking and dragging.

Create a ray tracing propagation model for Cartesian coordinates. Specify the ray tracing method as shooting and bouncing rays (SBR). Calculate rays that have up to 2 reflections. Set the surface material to wood.

```
pm = propagationModel("raytracing", ...  
    "CoordinateSystem", "cartesian", ...  
    "Method", "sbr", ...  
    "MaxNumReflections", 2, ...  
    "SurfaceMaterial", "wood");
```

Calculate the propagation paths and return the result as a `comm.Ray` object. Extract and plot the rays.

```
r = raytrace(tx, rx, pm);  
r = r{1};  
plot(r)
```

View information about a ray by clicking on it.

Input Arguments

tx — Transmitter site

`txsite` object | array of `txsite` objects

Transmitter site, specified as a `txsite` object or an array of `txsite` objects. If the receiver sites are specified as arrays, then the propagation paths are plotted from each transmitter to each receiver site.

rx — Receiver site

`rxsite` object | array of `rxsite` objects

Receiver site, specified as a `rxsite` object or an array of `rxsite` objects. If the transmitter sites are specified as arrays, then the propagation paths are plotted from each transmitter to each receiver site.

propmodel — Propagation model

character vector | string | ray tracing propagation model created with `propagationModel`

Propagation model, specified as a character vector, a string, or a ray tracing propagation model created with the `propagationModel` function. The default is `'raytracing'`, a ray tracing propagation model that uses the SBR method with the maximum number of reflections set to 2.

To specify a ray tracing propagation model that calculates different numbers of reflections, create a `RayTracing` object by using the `propagationModel` function and set the `MaxNumReflections` property.

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1, . . . , NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose Name in quotes.

Example: `'Type', 'power'`

Type — Type of quantity to plot

`'power'` (default) | `'pathloss'`

Type of quantity to plot, specified as the comma-separated pair consisting of `'Type'` and `'power'` in dBm or `'pathloss'` in dB.

When you specify `'power'`, each path is color-coded according to the received power along the path. When you specify `'pathloss'`, each path is color-coded according to the path loss along the path.

Friis equation is used to calculate the received power:

$$P_{rx} = P_{tx} + G_{tx} + G_{rx} - L - L_{tx} - L_{rx}$$

where:

- P_{rx} is the received power along the path.
- P_{tx} is the transmit power defined in `tx.TransmitterPower`.
- G_{tx} is the antenna gain of tx in the direction of the angle-of-departure (AoD).
- G_{rx} is the antenna gain of rx in the direction of the angle-of-arrival (AoA).
- L is the path loss calculated along the path.
- L_{tx} is the system loss of the transmitter defined in `tx.SystemLoss`.
- L_{rx} is the system loss of the receiver defined in `rx.SystemLoss`.

Data Types: `char`

PropagationModel — Type of propagation model for ray tracing analysis

`'raytracing'` (default) | ray tracing propagation model created with `propagationModel`

Type of propagation model for ray tracing analysis, specified as the comma-separated pair consisting of `'PropagationModel'` and `'raytracing'` or a ray tracing propagation model created with the `propagationModel` function. If you specify `'raytracing'`, then the `raytrace` function calculates propagation paths by using the SBR method with up to 2 reflections for the ray tracing propagation model object configuration

To perform ray tracing analysis using the image method instead, specify a propagation model created using the `propagationModel` function. This code shows how to create a propagation model that uses the image method.

```
pm = propagationModel('raytracing', 'Method', 'image');
```

For information about differences between the image and SBR methods, see “Choose a Propagation Model”.

Data Types: `char`

ColorLimits — Color limits for colormap

two-element numeric row vector

Color limits for colormap, specified as the comma-separated pair consisting of 'ColorLimits' and a two-element numeric row vector of the form [min max]. The units and default values of the color limits depend on the value of the 'Type' parameter:

- 'power' - Units are in dBm, and the default value is [-120 -5].
- 'pathloss' - Units are in dB, and the default value is [45 160].

The color limits indicate the values that map to the first and last colors in the colormap. Propagation paths with values below the minimum color limit are not plotted.

Data Types: double

Colormap — Colormap for coloring propagation paths'jet' (default) | predefined color map name | M -by-3 array of RGB

Colormap for coloring propagation paths, specified as the comma-separated pair consisting of 'Colormap' and a predefined color map name or an M -by-3 array of RGB (red, blue, green) triplets that define M individual colors.

Data Types: char | double

ShowLegend — Show color legend on map

true (default) | false

Show color legend on map, specified as the comma-separated pair consisting of 'ShowLegend' and true or false.

Data Types: logical

Map — Map for visualization or surface data

siteviewer object | triangulation object | string scalar | character vector

Map for visualization or surface data, specified as a siteviewer object, a triangulation object, a string scalar, or a character vector. Valid and default values depend on the coordinate system.

Coordinate System	Valid map values	Default map value
'geographic'	<ul style="list-style-type: none"> • A siteviewer object^a. • A terrain name, if the function is called with an output argument. Valid terrain names are 'none', 'gmted2010', or the name of the custom terrain data added using addCustomTerrain. 	<ul style="list-style-type: none"> • The current siteviewer object or a new siteviewer object if none are open. • 'gmted2010', if the function is called with an output.

Coordinate System	Valid map values	Default map value
'cartesian'	<ul style="list-style-type: none"> 'none'. A <code>siteviewer</code> object. The name of an STL file. A <code>triangulation</code> object. 	<ul style="list-style-type: none"> 'none'.

a Alignment of boundaries and region labels are a presentation of the feature provided by the data vendors and do not imply endorsement by MathWorks.

Data Types: `char` | `string`

Output Arguments

rays — Ray configuration object

M-by-*N* cell array

Ray configuration, returned as a *M*-by-*N* cell array where *M* is the number of transmitter sites and *N* is the number of receiver sites. Each cell element is a row vector of `comm.Ray` objects representing all the rays found between the corresponding transmitter site and receiver site. Within each row vector, the `comm.Ray` objects with the same transmitter to receiver interactions types are grouped together, groups are sorted alphabetically and then by ascending number of reflections. In each group, the rays are ordered by increasing propagation distance.

Compatibility Considerations

raytrace function uses SBR method

Behavior changed in R2021b

Starting in R2021b, the `raytrace` function uses the shooting and bouncing rays (SBR) method and calculates up to two reflections by default. In previous releases, the `raytrace` function uses the image method and calculates up to one reflection.

To display or compute RF propagation rays using the image method instead, create a propagation model by using the `propagationModel` function. Then, use the `raytrace` function with the propagation model as input. This example shows how to update your code.

```
pm = propagationModel('raytracing', 'Method', 'image');
raytrace(tx, rx, pm)
```

For information about the SBR and image methods, see “Choose a Propagation Model”.

Starting in R2021b, all RF Propagation functions use the SBR method by default and calculate up to two reflections. For more information, see “Default modeling method is shooting and bouncing rays method” on page 4-210.

NumReflections name-value argument will be removed

Warns starting in R2022a

The `NumReflections` name-value argument will be removed in a future release. The `NumReflections` name-value argument now only applies for the image ray tracing method. Instead, create a propagation model by using the `propagationModel` function with its `MaxNumReflections` name-value argument. Then, use the `raytrace` function with the propagation model as an input. This example shows the recommended workflow.

```
pm = propagationModel('raytracing', ...  
    'Method','image','MaxNumReflections',2);  
rays = raytrace(tx,rx,pm);
```

Topics

“Choose a Propagation Model”

Introduced in R2019b

removeCustomTerrain

Remove custom terrain data

Syntax

```
removeCustomTerrain(terrainName)
```

Description

`removeCustomTerrain(terrainName)` removes the custom terrain data specified by the user-defined `terrainName`. You can use this function to remove terrain data that is no longer needed. The terrain data to be removed must have been previously added using `addCustomTerrain`.

Examples

Site Viewer Maps Using Custom Terrain

Add terrain for a region around Boulder, CO. The DTED file was downloaded from the "SRTM Void Filled" data set available from the U.S. Geological Survey.

```
dtedfile = "n39_w106_3arc_v2.dt1";  
attribution = "SRTM 3 arc-second resolution. Data available " + ...  
             "from the U.S. Geological Survey.";  
addCustomTerrain("southboulder",dtedfile,"Attribution",attribution)
```

Use the custom terrain name in Site Viewer.

```
viewer = siteviewer("Terrain","southboulder");
```

Create a site with the terrain region.

```
mtzion = txsite("Name","Mount Zion", ...  
               "Latitude",39.74356, ...  
               "Longitude",-105.24193, ...  
               "AntennaHeight", 30);  
show(mtzion)
```

Create a coverage map of the area within 20 km of the transmitter site.

```
coverage(mtzion, ...  
         "MaxRange", 20000, ...  
         "SignalStrengths", -100: -5)
```

Remove the custom terrain.

```
close(viewer)  
removeCustomTerrain("southboulder")
```

Input Arguments

terrainName — User-defined identifier for terrain data

string scalar | character vector

User-defined identifier for terrain data previously added using `addCustomTerrain`, specified as a string scalar or a character vector.

Data Types: `char` | `string`

See Also

`addCustomTerrain` | `siteviewer`

Introduced in R2019b

add

Package: rfprop

Add propagation models

Syntax

```
pmc = add(propmodel1,propmodel2)
```

Description

`pmc = add(propmodel1,propmodel2)` adds propagation model objects `propmodel1` and `propmodel2` and returns a composite propagation model object `pmc` which contains `propmodel1` and `propmodel2`.

Note

- The syntax `propmodel1+propmodel2` can be used in place of `add`.
 - A composite propagation model cannot contain more than one propagation model object of the same class.
 - A composite propagation model cannot contain more than one propagation model object which includes effects of free-space loss.
-

Examples

Signal Strength Over Terrain Using Composite Propagation Model

Specify the transmitter and the receiver sites.

```
tx = txsite("Name","Fenway Park", ...  
           "Latitude",42.3467, ...  
           "Longitude",-71.0972, ...  
           "TransmitterFrequency",6e9);  
rx = rxsite("Name","Bunker Hill Monument", ...  
           "Latitude",42.3763, ...  
           "Longitude",-71.0611);
```

Calculate signal strength using default Longley-Rice model.

```
ss1 = sigstrength(rx,tx)
```

```
ss1 = -80.9353
```

Create composite propagation model with Longley-Rice and specific atmospheric propagation models.

```
pm = propagationModel("longley-rice") + ...  
     propagationModel("gas") + propagationModel("rain");
```

Calculate signal strength using composite propagation model.

```
ss2 = sigstrength(rx,tx,pm)
```

```
ss2 = -81.2259
```

Input Arguments

propmodel1 — Propagation model

character vector | string

Propagation model, specified as a character vector or string. You can also use the `propagationModel` function to define this input.

Data Types: `char` | `string`

propmodel2 — Propagation model

character vector | string

Propagation model, specified as a character vector or string. You can also use the `propagationModel` function to define this input.

Data Types: `char` | `string`

Output Arguments

pmc — Composite propagation model

composite `propagationModel` function object

Composite propagation model, `composite propagationModel` function object

The path loss computed by `pmc` is the sum of path losses computed by `propmodel1` and `propmodel2`. If either `propmodel1` or `propmodel2` is a ray tracing model, then `pmc` is also a ray tracing model where path losses from rain, gas, or fog models in the composite are added to the path loss computed for each propagation path.

`propagationModel` | `range`

Introduced in R2020a

pattern

Display antenna radiation pattern in Site Viewer

Syntax

```
pattern(tx)
pattern(rx, frequency)
pattern( ____, Name, Value)
```

Description

`pattern(tx)` displays the 3-D antenna radiation pattern for the transmitter site `txsite` in the current Site Viewer. Signal gain value (dBi) in a particular direction determines the color of the pattern.

`pattern(rx, frequency)` displays the 3-D radiation pattern for the receiver site `rxsite` for the specified frequency.

`pattern(____, Name, Value)` displays the 3-D radiation pattern with additional options specified by name-value pair arguments.

Examples

Single Transmitter Site Pattern

Define and visualize the radiation pattern of a single transmitter site.

```
tx = txsite;
pattern(tx)
```

Pattern for Cartesian Transmitter

Import and view an STL file. The file models a small conference room with one table and four chairs.

```
viewer = siteviewer('SceneModel', 'conferenceroom.stl');
```

Create a transmitter site that uses a three-element uniform linear array (ULA) with an element spacing of 0.05 meters. Specify the position using Cartesian coordinates in meters.

```
cfgArray = arrayConfig("Size", [3 1], "ElementSpacing", 0.05);
tx = txsite("cartesian", ...
    "AntennaPosition", [0; 0; 2.1], ...
    "Antenna", cfgArray);
```

Display the antenna pattern. Specify the size of the pattern plot as 0.4 meters.

```
pattern(tx, "Transparency", 0.6, "Size", 0.4)
```

Pan by left-clicking, zoom by right-clicking or by using the scroll wheel, and rotate the visualization by clicking the middle button and dragging or by pressing **Ctrl** and left-clicking and dragging.

Tilt the antenna by updating the `AntennaAngle` property of the transmitter. Display the updated pattern.

```
tx.AntennaAngle = [0 90];  
pattern(tx, "Transparency", 0.6, "Size", 0.4)
```

Input Arguments

tx — Transmitter site

txsite object

Transmitter site, specified as a txsite object.

rx — Receiver site

rxsite object

Receiver site, specified as a rxsite object.

frequency — Frequency to calculate radiation pattern

positive scalar

Frequency to calculate radiation pattern, specified as a positive scalar.

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1, ..., NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose Name in quotes.

Example: `'Size', 2`

Size — Size of pattern plot

'auto' (default) | numerical scalar

Size of the pattern plot, specified as a numerical scalar in meters. This parameter represents the distance between the antenna position and the point on the plot with the highest gain.

The default value depends on the `CoordinateSystem` property of the `siteviewer` object. When `CoordinateSystem` is `'geographic'`, the default size is 50 meters. When `CoordinateSystem` is `'cartesian'`, the default size is approximately 1/6 of the scene model size.

Data Types: `double`

Transparency — Transparency of pattern plot

0.4 (default) | real number in the range of [0,1]

Transparency of the pattern plot, specified as a real number in the range of [0,1], where 0 is completely transparent and 1 is completely opaque.

Data Types: `double`

Colormap — Colormap for coloring of pattern plot

'jet(256)' (default) | predefined colormap name | *M*-by-3 array of RGB triplets

Colormap for coloring of the pattern plot, specified as a predefined colormap name or an *M*-by-3 array of RGB (red, blue, green) triplets that define *M* individual colors.

Data Types: `double`

Resolution — Resolution of 3-D pattern

'high' (default) | 'low' | 'medium'

Resolution of 3-D map, specified as `'low'`, `'medium'`, or `'high'`. This property controls the visual quality and the time taken to plot the pattern where the value of `'low'` corresponds to the fastest and the least detailed pattern.

Data Types: `double`

Map — Map for visualization of surface data

`siteviewer` object

Map for visualization of surface data, specified as a `siteviewer` object.⁸

Data Types: `char` | `string`

See Also

`coverage`

Introduced in R2019b

⁸ Alignment of boundaries and region labels are a presentation of the feature provided by the data vendors and do not imply endorsement by MathWorks.

show

Show site in Site Viewer

Syntax

```
show(site)
show(site,Name,Value)
```

Description

`show(site)` displays the location of the specified transmitter or receiver site using a marker in the current Site Viewer.

`show(site,Name,Value)` displays `site` with additional options specified by one or more name-value arguments.

Examples

Default Receiver Site

Create and show the default receiver site.

```
rx = rxsite
rx =
    rxsite with properties:
        Name: 'Site 2'
        Latitude: 42.3021
        Longitude: -71.3764
        Antenna: 'isotropic'
        AntennaAngle: 0
        AntennaHeight: 1
        SystemLoss: 0
        ReceiverSensitivity: -100

show(rx)
```

Show and Hide Transmitter Site

Create and show a transmitter site.

```
tx = txsite('Name','MathWorks Apple Hill',...  
           'Latitude',42.3001, ...  
           'Longitude',-71.3504);  
show(tx)
```

Hide the transmitter site.

hide(tx)

Show and Hide Sites with Cartesian Coordinates

Import and view an STL file. The file models a small conference room with one table and four chairs.

```
viewer = siteviewer('SceneModel', 'conferenceroom.stl');
```

Create a transmitter site near the upper corner of the room and a receiver site above the table. Specify the position using Cartesian coordinates in meters. Then, visualize the sites.

```
tx = txsite('cartesian', ...  
           'AntennaPosition', [-1.46; -1.42; 2.1]);  
rx = rxsite('cartesian', ...  
           'AntennaPosition', [0.3; 0.3; 0.85]);
```

```
show(tx)  
show(rx)
```

Pan by left-clicking, zoom by right-clicking or by using the scroll wheel, and rotate the visualization by clicking the middle button and dragging or by pressing **Ctrl** and left-clicking and dragging.

Hide the sites.

```
hide(tx)  
hide(rx)
```

Input Arguments

site — Transmitter or receiver site

txsite or rxsite object | array of txsite or rxsite objects

Transmitter or receiver site, specified as a txsite or rxsite object or an array of txsite or rxsite objects.

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1, ..., NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose Name in quotes.

Example: 'ClusterMarkers', true

Icon — Image file

character vector

Image file, specified as a character vector.

Data Types: char

IconSize — Width and height of icon

36-by-36 (default) | 1-by-2 vector of positive numeric values

Width and height of the icon, specified as a 1-by-2 vector of positive numeric values in pixels.

IconAlignment — Vertical position of icon relative to site

'top' (default) | 'center' | 'bottom'

Vertical position of icon relative to site, specified as:

- 'bottom' - Aligns the icon below the site antenna position.
- 'center' - Aligns the center of the icon to the site antenna position.
- 'top' - Aligns the icon above the site antenna position.

ClusterMarkers — Combine nearby markers into groups or clusters

true | false

Combine nearby markers into groups or clusters, specified as true or false.

Data Types: char

Map — Map for visualization of surface data

siteviewer object

Map for visualization of surface data, specified as a siteviewer object.⁹

Data Types: char | string

ShowAntennaHeight — Option to show line from site to surface

true or 1 (default) | false or 0

Option to show a white line from the site down to the nearest surface, specified as numeric or logical 1 (true) or 0 (false).

Data Types: logical

See Also

hide

Introduced in R2019b

⁹ Alignment of boundaries and region labels are a presentation of the feature provided by the data vendors and do not imply endorsement by MathWorks.

sigstrength

Received signal strength

Syntax

```
ss = sigstrength(rx,tx)
ss = sigstrength(rx,tx,propmodel)
ss = sigstrength( ____,Name,Value)
```

Description

`ss = sigstrength(rx,tx)` returns the signal strength at the receiver site due to the transmitter site.

`ss = sigstrength(rx,tx,propmodel)` returns the signal strength at the receiver site using the specified propagation model. Specifying a propagation model is the same as specifying the 'PropagationModel' name-value argument.

`ss = sigstrength(____,Name,Value)` returns the signal strength using additional options specified by name-value arguments and either of the previous syntaxes.

Examples

Received Power and Link Margin at Receiver

Create a transmitter site.

```
tx = txsite('Name','Fenway Park', ...
           'Latitude', 42.3467, ...
           'Longitude', -71.0972);
```

Create a receiver site with sensitivity defined (in dBm).

```
rx = rxsite('Name','Bunker Hill Monument', ...
           'Latitude', 42.3763, ...
           'Longitude', -71.0611, ...
           'ReceiverSensitivity', -90);
```

Calculate the received power and link margin. Link margin is the difference between the receiver's sensitivity and the received power.

```
ss = sigstrength(rx,tx)
ss = -71.1414
margin = abs(rx.ReceiverSensitivity - ss)
margin = 18.8586
```

Signal Strength Using Ray Tracing Propagation Model

Launch Site Viewer with buildings in Chicago. For more information about the osm file, see [1] on page 4-0 .

```
viewer = siteviewer("Buildings","chicago.osm");
```

Create a transmitter site on a building.

```
tx = txsite('Latitude',41.8800, ...
           'Longitude',-87.6295, ...
           'TransmitterFrequency',2.5e9);
```

Create a receiver site near another building.

```
rx = rxsite('Latitude',41.881352, ...
           'Longitude',-87.629771, ...
           'AntennaHeight',30);
```

Compute the signal strength by using a ray tracing propagation model. By default, the ray tracing model uses the SBR method, and performs line-of-sight and two-reflection analysis.

```
pm = propagationModel("raytracing");
ssTwoReflections = sigstrength(rx,tx,pm)
```

```
ssTwoReflections = -52.4056
```

Plot the propagation paths for SBR with up to two reflections.

```
raytrace(tx,rx,pm)
```

Compute signal strength with analysis up to two reflections, where total received power is the cumulative power of all propagation paths

```
pm.MaxNumReflections = 5;
ssFiveReflections = sigstrength(rx,tx,pm)
```

```
ssFiveReflections = -51.8927
```

Observe the effect of material by replacing default concrete material with perfect reflector.

```
pm.BuildingsMaterial = 'perfect-reflector';
ssPerfect = sigstrength(rx,tx,pm)
```

```
ssPerfect = -38.8614
```

Plot the propagation paths for SBR with up to five reflections.

```
raytrace(tx,rx,pm)
```

Appendix

[1] The osm file is downloaded from <https://www.openstreetmap.org>, which provides access to crowd-sourced map data all over the world. The data is licensed under the Open Data Commons Open Database License (ODbL), <https://opendatacommons.org/licenses/odbl/>.

Input Arguments

rx — Receiver site

`rxsite` object | array of `rxsite` objects

Receiver site, specified as a `rxsite` object. You can use array inputs to specify multiple sites.

tx — Transmitter site

`txsite` object | array of `txsite` objects

Transmitter site, specified as a `txsite` object. You can use array inputs to specify multiple sites.

propmodel — Propagation model

character vector | string | propagation model created with `propagationModel`

Propagation model, specified as a character vector, a string, or a propagation model created with the `propagationModel` function. The default value depends on the coordinate system used by the input sites.

Coordinate System	Default propagation model value
'geographic'	<ul style="list-style-type: none"> 'longley-rice' when you use a terrain. 'freespace' when you do not use a terrain.
'cartesian'	<ul style="list-style-type: none"> 'freespace' when Map is set to none. 'raytracing' when Map is set to the name of an STL file or a triangulation object. The default ray tracing model uses the shooting and bouncing rays (SBR) method.

You can also specify the propagation model by using the 'PropagationModel' name-value pair argument.

Name-Value Pair Arguments

Specify optional pairs of arguments as Name1=Value1, ..., NameN=ValueN, where Name is the argument name and Value is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose Name in quotes.

Example: 'Type', 'power'

Type — Type of signal strength to compute

'power' (default) | 'efield'

Type of signal strength to compute, specified as the comma-separated pair consisting of 'Type' and 'power' or 'efield'.

When type is 'power', signal strength is expressed in power units (dBm) of the signal at the mobile receiver input. When type is 'efield', signal strength is expressed in electric field strength units (dB μ V/m) of signal wave incident on the antenna.

The sigstrength function is not supported for ray tracing models when 'Type' is 'efield'.

Data Types: char | string

PropagationModel — Propagation model to use for path loss calculations

'longley-rice' (default) | 'freespace' | 'close-in' | 'rain' | 'gas' | 'fog' | 'raytracing' | propagation model created with propagationModel

Propagation model to use for the path loss calculations, specified as the comma-separated pair consisting of 'PropagationModel' and one of the following:

- 'freespace' — Free space propagation model
- 'rain' — Rain propagation model
- 'gas' — Gas propagation model
- 'fog' — Fog propagation model
- 'close-in' — Close-in propagation model
- 'longley-rice' — Longley-Rice propagation model
- 'tirem' — Tirem propagation model

- 'raytracing' — Ray tracing propagation model that uses the shooting and bouncing rays (SBR) method
- A propagation model created with the `propagationModel` function

The default propagation model is 'longley-ricc' when terrain is enabled and 'freespace' when terrain is disabled.

Terrain propagation models, including 'longley-ricc' and 'tirem', are only supported for sites with a `CoordinateSystem` value of 'geographic'.

Data Types: char

Map — Map for visualization or surface data

`siteviewer` object | `triangulation` object | string scalar | character vector

Map for visualization or surface data, specified as a `siteviewer` object, a `triangulation` object, a string scalar, or a character vector. Valid and default values depend on the coordinate system.

Coordinate System	Valid map values	Default map value
'geographic'	<ul style="list-style-type: none"> • A <code>siteviewer</code> object^a. • A terrain name, if the function is called with an output argument. Valid terrain names are 'none', 'gmted2010', or the name of the custom terrain data added using <code>addCustomTerrain</code>. 	<ul style="list-style-type: none"> • The current <code>siteviewer</code> object or a new <code>siteviewer</code> object if none are open. • 'gmted2010', if the function is called with an output.
'cartesian'	<ul style="list-style-type: none"> • 'none'. • A <code>siteviewer</code> object. • The name of an STL file. • A <code>triangulation</code> object. 	<ul style="list-style-type: none"> • 'none'.

^a Alignment of boundaries and region labels are a presentation of the feature provided by the data vendors and do not imply endorsement by MathWorks.

Data Types: char | string

Output Arguments

ss — Signal strength

M-by-*N* array

Signal strength, returned as *M*-by-*N* array in dBm. *M* is the number of transmitter sites and *N* is the number of receiver sites.

Compatibility Considerations

'raytracing' propagation models use SBR method

Behavior changed in R2021b

Starting in R2021b, when you use the `sigstrength` function and specify the `propmodel` argument or `PropagationModel` name-value argument as 'raytracing', the function uses the shooting and

bouncing rays (SBR) method and calculates up to two reflections. In previous releases, the `sigstrength` function uses the image method and calculates up to one reflection.

To calculate received signal strength using the image method instead, create a propagation model by using the `propagationModel` function. Then, use the `sigstrength` function with the propagation model as input. This example shows how to update your code.

```
pm = propagationModel('raytracing','Method','image');  
ss = sigstrength(rx,tx,pm)
```

For information about the SBR and image methods, see “Choose a Propagation Model”.

Starting in R2021b, all RF Propagation functions use the SBR method by default and calculate up to two reflections. For more information, see “Default modeling method is shooting and bouncing rays method” on page 4-210.

See Also

[link](#) | [sinr](#) | [propagationModel](#)

Introduced in R2019b

sinr

Display or compute signal-to-interference-plus-noise (SINR) ratio

Syntax

```
sinr(txs)
sinr(txs,propmodel)
sinr( ____,Name,Value)
pd = sinr(txs, ____)
r = sinr(rxs,txs, ____)
```

Description

`sinr(txs)` displays the signal-to-interference-plus-noise ratio (SINR) for transmitter sites `txs` in the current Site Viewer. The map contours are generated using SINR values computed for receiver site locations on the map. For each location, the signal source is the transmitter site in `TXS` with the greatest signal strength. The remaining transmitter sites in `txs` with the same transmitter frequency act as sources of interference. If `txs` is scalar or there are no sources of interference the resultant map displays signal-to-noise ratio (SNR).

This function only supports plotting for antenna sites with a `CoordinateSystem` property value of `'geographic'`.

`sinr(txs,propmodel)` displays the SINR map with the propagation model set to the value in `propmodel`.

`sinr(____,Name,Value)` sets properties using one or more name-value pairs, in addition to the input arguments in previous syntaxes. For example, `sinr(txs, 'MaxRange', 8000)` sets the range from the site location at 8000 meters to include in the SINR map region.

`pd = sinr(txs, ____)` returns computed SINR data in the propagation data object, `pd`. No plot is displayed and any graphical only name-value pairs are ignored.

`r = sinr(rxs,txs, ____)` returns the `sinr` in dB computed at the receiver sites due to the transmitter sites.

Examples

SINR Map for Multiple Transmitters

Define names and location of sites in Boston.

```
names = ["Fenway Park","Faneuil Hall","Bunker Hill Monument"];
lats = [42.3467,42.3598,42.3763];
lons = [-71.0972,-71.0545,-71.0611];
```

Create a transmitter site array.

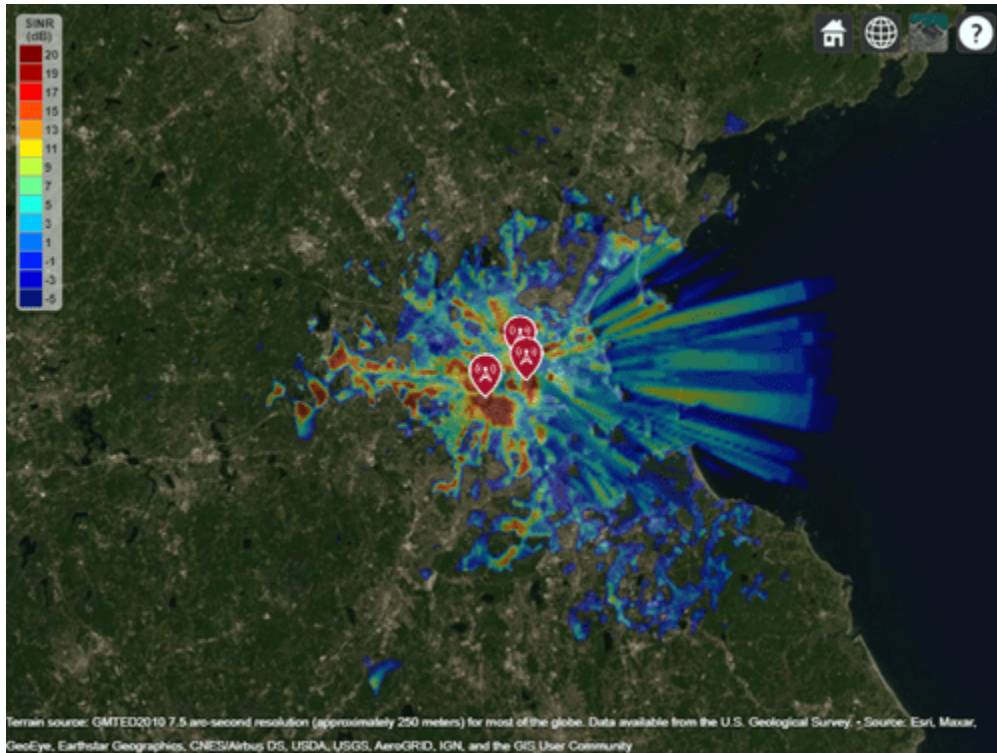

```
txs = txsite("Name", names,...
            "Latitude",lats,...
```

```
"Longitude",lons, ...
"TransmitterFrequency",2.5e9);
```

Display the SINR map, where signal source for each location is selected as the transmitter site with the strongest signal.

```
sinr(txs)
```

Input Arguments

txs — Transmitter sites

txsite object | array of txsite objects

Transmitter site, specified as a txsite object. Use array inputs to specify multiple sites.

This function only supports plotting antenna sites when CoordinateSystem property is set to 'geographic'.

rxs — Receiver sites

rxsite object | array of rxsite objects

Receiver site, specified as a rxsite object. Use array inputs to specify multiple sites.

This function only supports plotting antenna sites when CoordinateSystem property is set to 'geographic'.

propmodel — Propagation model

character vector | string | propagation model created with propagationModel

Propagation model, specified as a character vector, a string, or a propagation model created with the `propagationModel` function. The default value depends on the coordinate system used by the input sites.

Coordinate System	Default propagation model value
'geographic'	<ul style="list-style-type: none"> 'longley-rice' when you use a terrain. 'freespace' when you do not use a terrain.
'cartesian'	<ul style="list-style-type: none"> 'freespace' when Map is set to none. 'raytracing' when Map is set to the name of an STL file or a triangulation object. The default ray tracing model uses the shooting and bouncing rays (SBR) method.

You can also specify the propagation model by using the 'PropagationModel' name-value pair argument.

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1, ..., NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose Name in quotes.

Example: 'MaxRange', 8000

General

SignalSource — Signal source of interest

'strongest' (default) | transmitter site object

Signal source of interest, specified as the comma-separated pair consisting of `SignalSource` and 'strongest' or as a transmitter site object. When the signal source of interest is 'strongest', the transmitter with the greatest signal strength is chosen as the signal source of interest for that location. When computing `sinr`, `SignalSource` can be a `txsite` array with equal number of elements `rxs` where each transmitter site element defines the signal source for the corresponding receiver site.

PropagationModel — Propagation model to use for path loss calculations

'longley-rice' (default) | 'freespace' | 'close-in' | 'rain' | 'gas' | 'fog' | 'raytracing' | propagation model created with `propagationModel`

Propagation model to use for the path loss calculations, specified as the comma-separated pair consisting of 'PropagationModel' and one of the following:

- 'freespace' — Free space propagation model
- 'rain' — Rain propagation model
- 'gas' — Gas propagation model
- 'fog' — Fog propagation model
- 'close-in' — Close-in propagation model
- 'longley-rice' — Longley-Rice propagation model

- 'tirem' — Tirem propagation model
- 'raytracing' — Ray tracing propagation model that uses the shooting and bouncing rays (SBR) method
- A propagation model created with the `propagationModel` function

The default propagation model is 'longley-rice' when terrain is enabled and 'freespace' when terrain is disabled.

Terrain propagation models, including 'longley-rice' and 'tirem', are only supported for sites with a `CoordinateSystem` value of 'geographic'.

Data Types: char

ReceiverNoisePower — Total noise power at receiver

-107 (default) | scalar

Total noise power at receiver, specified as the comma-separated pair consisting of 'ReceiverNoisePower' and a scalar in dBm. The default value assumes that the receiver bandwidth is 1 MHz and receiver noise figure is 7 dB.

$$N = -174 + 10 \cdot \log(B) + F$$

where,

- N = Receiver noise in dBm
- B = Receiver bandwidth in Hz
- F = Noise figure in dB

ReceiverGain — Receiver gain

2.1 (default) | scalar

Mobile receiver gain, specified as the comma-separated pair consisting of 'ReceiverGain' and a scalar in dB. The receiver gain values include the antenna gain and the system loss. If you call the function using an output argument, the default value is computed using `rxs`.

ReceiverAntennaHeight — Receiver antenna height

1 (default) | scalar

Receiver antenna height above the ground, specified as the comma-separated pair consisting of 'ReceiverAntennaHeight' and a scalar in meters. If you call the function using an output argument, the default value is computed using `rxs`.

Map — Map for visualization or surface data

siteviewer object | triangulation object | string scalar | character vector

Map for visualization or surface data, specified as a `siteviewer` object, a `triangulation` object, a string scalar, or a character vector. Valid and default values depend on the coordinate system.

Coordinate System	Valid map values	Default map value
'geographic'	<ul style="list-style-type: none"> • A siteviewer object^a. • A terrain name, if the function is called with an output argument. Valid terrain names are 'none', 'gmted2010', or the name of the custom terrain data added using addCustomTerrain. 	<ul style="list-style-type: none"> • The current siteviewer object or a new siteviewer object if none are open. • 'gmted2010', if the function is called with an output.
'cartesian'	<ul style="list-style-type: none"> • 'none'. • A siteviewer object. • The name of an STL file. • A triangulation object. 	<ul style="list-style-type: none"> • 'none'.

^a Alignment of boundaries and region labels are a presentation of the feature provided by the data vendors and do not imply endorsement by MathWorks.

Data Types: char | string

For Plotting SINR

Values — Values of SINR for display

[-5:20] (default) | numeric vector

Values of SINR for display, specified as the comma-separated pair consisting of 'Values' and a numeric vector. Each value is displayed as a different colored, filled on the contour map. The contour colors are derived using Colormap and ColorLimits.

MaxRange — Maximum range of coverage map from each transmitter site

numeric scalar

Maximum range of coverage map from each transmitter site, specified as a positive numeric scalar in meters representing great circle distance. MaxRange defines the region of interest on the map to plot. The default value is automatically computed based on the type of propagation model.

Type of Propagation Model	MaxRange
Atmospheric or empirical	30 km
Terrain	30 km or distance to the furthest building.
Ray tracing	500 m

For more information about the types of propagation models, see “Choose a Propagation Model”.

Data Types: double

Resolution — Resolution of receiver site locations used to compute SINR values

'auto' (default) | numeric scalar

Resolution of receiver site locations used to compute SINR values, specified as the comma-separated pair consisting of 'Resolution' and 'auto' or a numeric scalar in meters. The resolution defines the maximum distance between the locations. If the resolution is 'auto', sinr computes a value scaled to MaxRange. Decreasing the resolution increases the quality of the SINR map and the time required to create it.

Colormap — Colormap for coloring filled contours`'jet'` (default) | M -by-3 array of RGB triplets

Colormap for coloring filled contours, specified as the comma-separated pair consisting of `'ColorMap'` and an M -by-3 array of RGB triplets, where M is the number of individual colors.

ColorLimits — Color limits for color maps`[-5 20]` (default) | two-element vector

Color limits for color maps, specified as the comma-separated pair consisting of `'ColorLimits'` and a two-element vector of the form `[min max]`. The color limits indicate the SINR values that map to the first and last colors in the colormap.

ShowLegend — Show signal strength color legend on map`'true'` (default) | `'false'`

Show signal strength color legend on map, specified as the comma-separated pair consisting of `'ShowLegend'` and `'true'` or `'false'`.

Transparency — Transparency of SINR map`0.4` (default) | numeric scalar

Transparency of SINR map, specified as the comma-separated pair consisting of `'Transparency'` and a numeric scalar in the range 0-1. If the value is zero, the map is completely transparent. If the value is one, the map is completely opaque.

Output Arguments**`r` — Signal to interference plus noise ratio at the receiver**

numeric vector (default)

Signal to interference plus noise ratio at the receiver due to the transmitter sites, returned as a numeric vector. The vector length is equal to the number of receiver sites.

Data Types: `double`**`pd` — SINR data**`propagationData` object

SINR data, returned as a `propagationData` object consisting of *Latitude* and *Longitude*, and a signal strength variable corresponding to the plot type. Name of the `propagationData` is "SINR Data".

Compatibility Considerations**'raytracing' propagation models use SBR method***Behavior changed in R2021b*

Starting in R2021b, when you use the `sinr` function and specify the `propmodel` argument or `PropagationModel` name-value argument as `'raytracing'`, the function uses the shooting and bouncing rays (SBR) method and calculates up to two reflections. In previous releases, the `sinr` function uses the image method and calculates up to one reflection.

To display or compute the SINR using the image method instead, create a propagation model by using the `propagationModel` function. Then, use the `sinr` function with the propagation model as input. This example shows how to update your code.

```
pm = propagationModel('raytracing', 'Method', 'image');  
sinr(txs, pm)
```

For information about the SBR and image methods, see “Choose a Propagation Model”.

Starting in R2021b, all RF Propagation functions use the SBR method by default and calculate up to two reflections. For more information, see “Default modeling method is shooting and bouncing rays method” on page 4-210.

`coverage` | `propagationModel`

Introduced in R2019b

plot (rays), plot

Package: comm

Display RF propagation rays in Site Viewer

Syntax

```
plot(rays)
plot(rays, Name, Value)
```

Description

`plot(rays)` plots the propagation paths for ray objects in the Site Viewer map.

`plot(rays, Name, Value)` plots the propagation paths for ray objects in the Site Viewer map with additional options specified by one or more name-value pair arguments.

Examples

Plot Propagation Rays Between Sites in Chicago

Return ray tracing results in `comm`. Ray objects and plot the ray propagation paths after relaunching the Site Viewer map.

Create a Site Viewer map, loading building data for Chicago. For more information about the osm file, see [1] on page 4-0 .

```
viewer = siteviewer('Buildings', 'chicago.osm');
```

Create a transmitter site on one building and a receiver site on another building. Use the `los` function to show the line of sight path between the transmitter and receiver sites.

```
tx = txsite( ...
    'Latitude',41.8800, ...
    'Longitude',-87.6295, ...
    'TransmitterFrequency',2.5e9);
rx = rxsite( ...
    'Latitude',41.881352, ...
    'Longitude',-87.629771, ...
    'AntennaHeight',30);
los(tx,rx);
```

Perform ray tracing for up to two reflections. For the configuration defined, ray tracing returns a cell array containing the ray objects. Close the Site Viewer map.

```
pm = propagationModel( ...
    'raytracing', ...
    'Method','sbr', ...
    'MaxNumReflections',2);
rays = raytrace(tx,rx,pm)

rays = 1x1 cell array
      {1x3 comm.Ray}

    NumInteractions: 2
```

```
close(viewer);
```

You can plot the rays without performing ray tracing again. Create another Site Viewer map with the same buildings. Show the transmitter and receiver sites. Using the previously returned cell array of

ray objects, plot the reflected rays between the transmitter site and the receiver site. The plot function can plot the path for ray objects collectively or individually. For example, to plot rays for the only second ray object, specify rays{1}(1,2). This figure plot all paths for all the ray objects.

```
siteviewer('Buildings', 'chicago.osm');
los(tx,rx);
plot(rays{:}, 'Type', 'power', ...
     'TransmitterSite', tx, 'ReceiverSite', rx);
```

Appendix

[1] The osm file is downloaded from <https://www.openstreetmap.org>, which provides access to crowd-sourced map data all over the world. The data is licensed under the Open Data Commons Open Database License (ODbL), <https://opendatacommons.org/licenses/odbl/>.

Input Arguments

rays — Ray configuration object

comm.Ray object

Ray configuration, specified as one comm.Ray object or a vector of comm.Ray objects. Each object must have the PathSpecification property set to "Locations".

Data Types: comm.Ray

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1, . . . , NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose Name in quotes.

Example: `plot(rays, "Type", "pathloss", "ColorLimits", [-100 0])` adds the propagation path specified in `rays` to the current Site Viewer and adjusts the default color limits.

Type — Quantity type to plot

"pathloss" (default) | "power"

Quantity type to plot, specified as "pathloss" or "power". Based on the value specified for `Type`, the color applied along the path maps to the path loss in dB or the power in dBm of the signal along the path.

Data Types: char | string

TransmitterSite — Transmitter site

txsite object

Transmitter site, specified as a txsite object.

Dependencies

Applies only when `Type` is set to "power".

Data Types: char

ReceiverSite — Receiver site

rxsite object

Receiver site, specified as an rxsite object.

Dependencies

Applies only when `Type` is set to "power".

Data Types: char

ColorLimits — Colormap color limits

[-120 -5] or [45 160] (default) | 1-by-2 numeric vector

Color limits for colormap, specified as a 1-by-2 numeric vector, [*min*, *max*], where *min* represents the lower saturation limit and *max* represents the upper saturation limit. The default is [-120 -5] when `Type` is set to 'power' and [45 160] when `Type` is set to 'pathloss'.

Data Types: double

Colormap — Colormap applied to propagation path

'jet' (default) | *M*-by-3 numeric array

Colormap applied to propagation path, specified as an *M*-by-3 numeric array of RGB (red,green,blue) triplets that define *M* individual colors.

Data Types: double | char | string

ShowLegend — Show color legend on map`true (default) | false`

Show color legend on map, specified as `true` or `false`.

Data Types: `logical`

Map — Map for visualization and surface data`siteviewer` object

Map for visualization and surface data, specified as a `siteviewer` object.¹⁰ The default is the current `siteviewer` object, or if no Site Viewer is open a new `siteviewer` object opens.

Data Types: `siteviewer` object

See Also**Functions**`raytrace`**Objects**`comm.Ray` | `siteviewer`**Introduced in R2020a**

¹⁰ Alignment of boundaries and region labels are a presentation of the feature provided by the data vendors and do not imply endorsement by MathWorks.

hasdata

Package: matlab.io.datastore

Determine if data is available to read from TDMS datastore

Syntax

```
tf = hasdata(tdmsds)
```

Description

`tf = hasdata(tdmsds)` returns logical 1 (true) if there is data available to read from the TDMS datastore specified by `tdmsds`. Otherwise, it returns logical 0 (false).

Examples

Check TDMS Datastore for Readable Data

In a while-loop, use `hasdata` to determine if there is any more data to read at the current location.

```
tdmsds = tdmsDatastore(tdmsDatastore("C:\data\tdms"));  
while hasdata(tdmsds)  
    m = read(tdmsds);  
    :  
end
```

Input Arguments

tdmsds — TDMS datastore

TDMSDatastore object

TDMS datastore, specified as a TDMSDatastore object.

Example: `tdmsds = tdmsDatastore("C:\data\tdms")`

Output Arguments

tf — Indicator of data to read

1 | 0

Indicator of data to read, returned as a logical 1 (true) or 0 (false).

Limitations

- TDMS functions are supported on Windows platforms only.

See Also

Functions

tdmsDatastore | read | reset

preview

Package: matlab.io.datastore

Read first 8 records from TDMS datastore

Syntax

```
data = preview(tdmsds)
```

Description

`data = preview(tdmsds)` returns the first 8 records from TDMS datastore `tdmsds`, without changing the current read position in the datastore.

Examples

Examine Preview of TDMS Datastore

```
tdmsds = tdmsds = tdmsDatastore("C:\data\tdms");  
data = preview(tdmsds)
```

```
data =
```

```
1x3 cell array
```

```
{8x2 table} {8x2 table} {8x2 table}
```

```
data{3}
```

```
ans =
```

```
8x2 table

Functions

tdmsDatastore | read | readall | hasdata

Introduced in R2022a

read

Package: matlab.io.datastore

Read data in TDMS datastore

Syntax

```
data = read(tdmsds)
[data,info] = read(tdmsds)
```

Description

`data = read(tdmsds)` reads data from the files in the TDMS datastore `tdmsds`, and returns a cell array of tables or timetables. Each element of the cell array corresponds to a channel group in the datastore file `data`.

The `read` function returns a subset of data from the datastore. The size of the subset is determined by the `ReadSize` property of the datastore object. On the first call, `read` starts reading from the beginning of the datastore, and subsequent calls continue reading from the endpoint of the previous call. Use `reset` to read from the beginning again.

The function returns a cell array of tables or a cell array of timetables, depending on the value of the `tdmsds.RowTimes` property. See “Read TDMS-File Data into Timetables” on page 4-274.

`[data,info] = read(tdmsds)` also returns the output argument `info`, with information and metadata about the extracted data.

Examples

Read Datastore by Files

Read data from a TDMS datastore one file at a time. Set the read size and read the first data set.

```
tdmsds = tdmsDatastore("C:\data\tdms",ReadSize="file");
data1 = read(tdmsds);
```

Read the second file and view information about the data.

```
[data2,info2] = read(tdmsds);
info2
```

```
info2 =
  struct with fields:
    Filename: "C:\data\tdms\Turbine_002.tdms"
    FileSize: 172098
    Offset: 0
```

Read TDMS-File Data into Timetables

By providing a vector of durations, you can read TDMS-file data into timetables.

Define a vector of 1000 elements of 1 ms duration. Set up the datastore object to read 1000 records (ReadSize) and return a timetable (RowTimes).

```
durvec = milliseconds(1:1000);
tdmsds = tdmsDatastore("C:\data\tdms",ReadSize=1000,RowTimes=durvec)
```

```
tdmsds =
```

```
TDMSDatastore with properties:
```

```
Files: ["C:\data\tdms\Turbine_001.tdms" "C:\data\tdms\Turbine_002.tdms"
ChannelList: [6x8 table]
SelectedChannelGroup: [0x0 string]
SelectedChannels: [0x0 string]
RowTimes: [0.001 sec 0.002 sec 0.003 sec 0.004 sec 0.005 sec 0.006 sec 0.007 sec 0.008 sec]
ReadSize: 1000
```

Read 1000 records from the datastore into timetables.

```
dd = read(tdmsds)
```

```
dd =
```

```
1x3 cell array
```

```
{1000x2 timetable} {1000x2 timetable} {1000x2 timetable}
```

View part of one of the timetables.

```
dd{1}
```

```
ans =
```

```
1000x2 timetable
```

Display all 1000 rows.

Input Arguments

tdmsds – TDMS datastore

TDMSDatastore object

TDMS datastore, specified as a TDMSDatastore object.

Example: `tdmsds = tdmsDatastore("C:\data\tdms")`

Output Arguments

data – Output data

cell array of tables

Output data, returned as a cell array of tables from the TDMS records.

info – Information about data

structure array

Information about the data source file, returned as a structure with the following fields:

Filename
FileSize
Offset

The `offset` field indicates the position of the data in the file.

Limitations

- TDMS functions are supported on Windows platforms only.

Functions

`tdmsDatastore` | `reset` | `preview` | `readall` | `hasdata`

Introduced in R2022a

readall

Package: matlab.io.datastore

Read all data in TDMS datastore

Syntax

```
data = readall(tdmsds)
```

Description

`data = readall(tdmsds)` reads all the data in the datastore specified by `tdmsds`, and returns a cell array of tables or timetables. Each element of the cell array corresponds to a channel group in the datastore file data.

The function returns a cell array of tables or a cell array of timetables, depending on the value of the `tdms.RowTimes` property. See `tdmsDatastore`.

After the `readall` function returns all the data, it resets `tdmsds` to point to the beginning of the datastore.

Examples

Read All the Data in a Datastore

Read all the data from a multiple file TDMS datastore into an array of tables.

Set up datastore and read all its data.

```
tdmsds = tdmsDatastore("C:\data\tdms");
data = readall(td)
```

```
data =
```

```
1×3 cell array
```

```
{9936×2 table} {9936×2 table} {9936×2 table}
```

View part of the data.

```

Functions

`tdmsDatastore` | `read` | `preview`

Introduced in R2022a

reset

Package: matlab.io.datastore

Reset TDMS datastore to initial state

Syntax

```
reset(tdmsds)
```

Description

`reset(tdmsds)` resets the TDMS datastore specified by `tdmsds` to its initial read state, where no data has been read from it. Resetting allows you to reread from the same datastore.

Examples

Reset TDMS Datastore

Reset a TDMS datastore so that you can read from it again.

```
tdmsds = tdmsDatastore("C:\data\tdms");  
data = read(tdmsds);  
:  
reset(tdmsds);  
data = read(tdmsds);
```

Input Arguments

tdmsds — TDMS datastore

TDMSDatastore object

TDMS datastore, specified as a TDMSDatastore object.

Example: `tdmsds = tdmsDatastore("C:\data\tdms")`

Limitations

- TDMS functions are supported on Windows platforms only.

Blocks

A-Law Compressor

Implement A-law compressor for source coding

Library

Source Coding

Description

The A-Law Compressor block implements an A-law compressor for the input signal. The formula for the A-law compressor is

$$y = \begin{cases} \frac{A|x|}{1 + \log A} \operatorname{sgn}(x) & \text{for } 0 \leq |x| \leq \frac{V}{A} \\ \frac{V(1 + \log(A|x|/V))}{1 + \log A} \operatorname{sgn}(x) & \text{for } \frac{V}{A} < |x| \leq V \end{cases}$$

where A is the A-law parameter of the compressor, V is the peak signal magnitude for x , \log is the natural logarithm, and sgn is the sign function.

The most commonly used A value is 87.6.

The input can have any shape or frame status. This block processes each vector element independently.

Parameters

A value

The A-law parameter of the compressor.

Peak signal magnitude

The peak value of the input signal. This is also the peak value of the output signal.

Introduced before R2006a

A-Law Expander

Implement A-law expander for source coding

Library

Source Coding

Description

The A-Law Expander block recovers data that the A-Law Compressor block compressed. The formula for the A-law expander, shown below, is the inverse of the compressor function.

$$x = \begin{cases} \frac{y(1 + \log A)}{A} & \text{for } 0 \leq |y| \leq \frac{V}{1 + \log A} \\ \exp(|y|(1 + \log A)/V - 1) \frac{V}{A} \operatorname{sgn}(y) & \text{for } \frac{V}{1 + \log A} < |y| \leq V \end{cases}$$

The input can have any shape or frame status. This block processes each vector element independently.

Parameters

A value

The A-law parameter of the compressor.

Peak signal magnitude

The peak value of the input signal. This is also the peak value of the output signal.

Match these parameters to the ones in the corresponding A-Law Compressor block.

Algebraic Deinterleaver

Restore ordering of input symbols using algebraically derived permutation

Library

Block sublibrary of Interleaving

Description

The Algebraic Deinterleaver block restores the original ordering of a sequence that was interleaved using the Algebraic Interleaver block. In typical usage, the parameters in the two blocks have the same values.

The **Number of elements** parameter, N , indicates how many numbers are in the input vector. This block accepts a column vector input signal.

The block accepts the following data types: `int8`, `uint8`, `int16`, `uint16`, `int32`, `uint32`, `boolean`, `single`, `double`, and fixed-point. The output signal inherits its data type from the input signal.

The **Type** parameter indicates the algebraic method that the block uses to generate the appropriate permutation table. Choices are `Takehita-Costello` and `Welch-Costas`. Each of these methods has parameters and restrictions that are specific to it; these are described on the reference page for the Algebraic Interleaver block.

Parameters

Type

The type of permutation table that the block uses for deinterleaving. Choices are `Takehita-Costello` and `Welch-Costas`.

Number of elements

The number of elements, N , in the input vector.

Multiplicative factor

The factor the block uses to compute the corresponding interleaver's cycle vector. This field appears only when you set **Type** to `Takehita-Costello`.

Cyclic shift

The amount by which the block shifts indices when creating the corresponding interleaver's permutation table. This field appears only when you set **Type** to `Takehita-Costello`.

Primitive element

An element of order N in the finite field $GF(N+1)$. This field appears only if **Type** is set to `Welch-Costas`.

General Block Deinterleaver | Algebraic Interleaver

Introduced before R2006a

Algebraic Interleaver

Reorder input symbols using algebraically derived permutation table

Library

Block sublibrary of Interleaving

Description

The Algebraic Interleaver block rearranges the elements of its input vector using a permutation that is algebraically derived. The **Number of elements** parameter, N , indicates how many numbers are in the input vector. This block accepts a column vector input signal.

The block accepts the following data types: `int8`, `uint8`, `int16`, `uint16`, `int32`, `uint32`, `boolean`, `single`, `double`, and `fixed-point`. The output signal inherits its data type from the input signal.

The **Type** parameter indicates the algebraic method that the block uses to generate the appropriate permutation table. Choices are `Takeshita-Costello` and `Welch-Costas`. Each of these methods has parameters and restrictions that are specific to it:

- If you set **Type** to `Welch-Costas`, then $N + 1$ must be prime. The **Primitive element** parameter is an integer, A , between 1 and N that represents a primitive element of the finite field $\text{GF}(N + 1)$. This means that every nonzero element of $\text{GF}(N + 1)$ can be expressed as A raised to some integer power.

In a Welch-Costas interleaver, the permutation maps the integer k to $\text{mod}(A^k, N + 1) - 1$.

- If you set **Type** to `Takeshita-Costello`, then N must be 2^m for some integer m . The **Multiplicative factor** parameter, k , must be an odd integer less than N . The **Cyclic shift** parameter, h , must be a nonnegative integer less than N .

A Takeshita-Costello interleaver uses a length- N *cycle vector* whose n th element is

$$c(n) = \text{mod}\left(k \cdot \frac{n \cdot (n - 1)}{2}, N\right) + 1, n$$

for integers n between 1 and N . The intermediate permutation function is obtained by using the following relationship:

$$\Pi(c(n)) = c(n + 1)$$

where

$$n = 1:N$$

The interleaver's actual permutation vector is the result of cyclically shifting the elements of the permutation vector, π , by the **Cyclic shift** parameter, h .

Parameters

Type

The type of permutation table that the block uses for interleaving.

Number of elements

The number of elements, N , in the input vector.

Multiplicative factor

The factor used to compute the interleaver's cycle vector. This field appears only if **Type** is set to Takeshita-Costello.

Cyclic shift

The amount by which the block shifts indices when creating the permutation table. This field appears only if **Type** is set to Takeshita-Costello.

Primitive element

An element of order N in the finite field $GF(N+1)$. This field appears only if **Type** is set to Welch-Costas.

Align Signals

(Removed) Align two signals by finding delay between them

Compatibility

Align Signals Block has been removed. Instead, use the Find Delay block to find delays and the Delay block to apply delays. For more information, see “Compatibility Considerations” on page 5-11.

Library

Utility Blocks

Description

The Align Signals block aligns two signals by finding the delay between them. This is useful when you want to compare a transmitted and received signal to determine the bit error rate, but do not know the delay in the received signal. This block accepts a column vector or matrix input signal. For a matrix input, the block aligns each channel independently.

The s1 input port receives the original signal, while the s2 input port receives a delayed version. The two input signals must have the same dimensions and sample times. The block calculates the delay between the two signals, and then

- Delays the first signal, s1, by the calculated value, and outputs it through the port labeled s1 del.
- Outputs the second signal s2 without change through the port labeled s2.
- Outputs the delay value through the port labeled delay.

See “Delays” for more information about signal delays.

The block's **Correlation window length** parameter specifies how many samples of the signals the block uses to calculate the cross-correlation. The delay output is a nonnegative integer less than the **Correlation window length**.

As the **Correlation window length** is increased, the reliability of the computed delay also increases. However, the processing time to compute the delay increases as well.

You can make the Align Signals block stop updating the delay after it computes the same delay value for a specified number of samples. To do so, select **Disable recurring updates**, and enter a positive integer in the **Number of constant delay outputs to disable updates** field. For example, if you set **Number of constant delay outputs to disable updates** to 20, the block will stop recalculating and updating the delay after it calculates the same value 20 times in succession. Disabling recurring updates causes the simulation to run faster after the target number of constant delays occurs.

Tips for Using the Block Effectively

- Set the **Correlation window length** parameter sufficiently large so that the computed delay eventually stabilizes at a constant value. If the computed delay is not constant, you should increase **Correlation window length**. If the increased value of **Correlation window length** exceeds the duration of the simulation, then you should also increase the duration of the simulation accordingly.
- If the cross-correlation between the two signals is broad, then **Correlation window length** should be much larger than the expected delay, or else the algorithm might stabilize at an incorrect value. For example, a CPM signal has a broad autocorrelation, so it has a broad cross-correlation with a delayed version of itself. In this case, the **Correlation window length** value should be much larger than the expected delay.
- If the block calculates a delay that is greater than 75 percent of **Correlation window length**, the signal *s1* is probably delayed relative to the signal *s2*. In this case, you should switch the signal lines leading into the two input ports.
- If you use the Align Signals block with the Error Rate Calculation block, you should set the **Receive delay** parameter of the Error Rate Calculation block to 0 because the Align Signals block compensates for the delay. Also, you might want to set the Error Rate Calculation block's **Computation delay** parameter to a nonzero value to account for the possibility that the Align Signals block takes a nonzero amount of time to stabilize on the correct amount by which to delay one of the signals.

Parameters

Correlation window length

The number of samples the block uses to calculate the cross-correlations of the two signals.

Disable recurring updates

Selecting this option causes the block to stop computing the delay after it computes the same delay value for a specified number of samples.

Number of constant delay outputs to disable updates

A positive integer specifying how many times the block must compute the same delay before ceasing to update. This field appears only if **Disable recurring updates** is selected.

Algorithm

The Align Signals block finds the delay by calculating the cross-correlations of the first signal with time-shifted versions of the second signal, and then finding the index at which the cross-correlation is maximized.

Compatibility Considerations

Align Signals Block has been removed

Errors starting in R2021b

Align Signals Block has been removed. Instead, use the Find Delay block to find delays and the Delay block to apply delays.

APP Decoder

Decode convolutional code using a posteriori probability (APP) method

Library

Convolutional sublibrary of Error Detection and Correction

Description

The APP Decoder block performs a posteriori probability (APP) decoding of a convolutional code.

Input Signals and Output Signals

The input $L(u)$ represents the sequence of log-likelihoods of encoder input bits, while the input $L(c)$ represents the sequence of log-likelihoods of code bits. The outputs $L(u)$ and $L(c)$ are updated versions of these sequences, based on information about the encoder.

If the convolutional code uses an alphabet of 2^n possible symbols, this block's $L(c)$ vectors have length $Q*n$ for some positive integer Q . Similarly, if the decoded data uses an alphabet of 2^k possible output symbols, then this block's $L(u)$ vectors have length $Q*k$.

This block accepts a column vector input signal with any positive integer for Q .

If you only need the input $L(c)$ and output $L(u)$, you can attach a Simulink Ground block to the input $L(u)$ and a Simulink Terminator block to the output $L(c)$.

This block accepts `single` and `double` data types. Both inputs, however, must be of the same type. The output data type is the same as the input data type.

Specifying the Encoder

To define the convolutional encoder that produced the coded input, use the **Trellis structure** parameter. This parameter is a MATLAB structure whose format is described in “Trellis Description of a Convolutional Code”. You can use this parameter field in two ways:

- If you have a variable in the MATLAB workspace that contains the trellis structure, enter its name as the **Trellis structure** parameter. This way is preferable because it causes Simulink to spend less time updating the diagram at the beginning of each simulation, compared to the usage described next.
- If you want to specify the encoder using its constraint length, generator polynomials, and possibly feedback connection polynomials, use a `poly2trellis` command within the **Trellis structure** field. For example, to use an encoder with a constraint length of 7, code generator polynomials of 171 and 133 (in octal numbers), and a feedback connection of 171 (in octal), set the **Trellis structure** parameter to

```
poly2trellis(7,[171 133],171)
```

To indicate how the encoder treats the trellis at the beginning and end of each frame, set the **Termination method** parameter to either `Truncated` or `Terminated`. The `Truncated` option indicates that the encoder resets to the all-zeros state at the beginning of each frame. The `Terminated` option indicates that the encoder forces the trellis to end each frame in the all-zeros state. If you use the Convolutional Encoder block with the **Operation mode** parameter set to `Truncated` (reset every frame), use the `Truncated` option in this block. If you use the Convolutional Encoder block with the **Operation mode** parameter set to `Terminate trellis by appending bits`, use the `Terminated` option in this block.

Specifying Details of the Algorithm

You can control part of the decoding algorithm using the **Algorithm** parameter. The `True APP` option implements a posteriori probability decoding as per equations 20–23 in section V of [1]. To gain speed, both the `Max*` and `Max` options approximate expressions like

$$\log \sum_i \exp(a_i)$$

by other quantities. The `Max` option uses $\max(a_i)$ as the approximation, while the `Max*` option uses $\max(a_i)$ plus a correction term given by $\ln(1 + \exp(-|a_{i-1} - a_i|))$ [3].

The `Max*` option enables the **Scaling bits** parameter in the dialog box. This parameter is the number of bits by which the block scales the data it processes internally (multiplies the input by $(2^{\text{numScalingBits}})$ and divides the pre-output by the same factor). Use this parameter to avoid losing precision during the computations.

Parameters

Trellis structure

MATLAB structure that contains the trellis description of the convolutional encoder.

Termination method

Either `Truncated` or `Terminated`. This parameter indicates how the convolutional encoder treats the trellis at the beginning and end of frames.

Algorithm

Either `True APP`, `Max*`, or `Max`.

Number of scaling bits

An integer between 0 and 8 that indicates by how many bits the decoder scales data in order to avoid losing precision. This field is active only when **Algorithm** is set to `Max*`.

Disable L(c) output port

Select this check box to disable the secondary block output, `L(c)`.

AGC

Adaptively adjust gain for constant signal-level output

Library: Communications Toolbox / RF Impairments Correction

Description

The automatic gain controller (AGC) block adaptively adjusts its gain to achieve a constant signal level at the output.

This icon shows the AGC block with the optional Px port.

Ports

Input

In — Input signal

column vector

Input signal, specified as a column vector.

Data Types: `single` | `double` | `int` | `uint`

Output

y — Output signal

N_S -element column vector

Output signal, returned as an N_S -element column vector. N_S is the length of the input signal. The output signal is the same data type as the input signal.

Px — Power level estimate

N_S -element column vector

Power level estimate, returned as an N_S -element column vector. N_S is the length of the input signal. You can use `powerLevel` as an energy detector output.

Dependencies

To enable this port, select the **Enable output of estimated input power** parameter.

Parameters

Step size — Step size for gain updates

0.01 | positive scalar

Step size for gain updates, specified as a positive scalar. Increasing the step size enables the AGC to respond more quickly to changes in the input signal level but increases variation in the output signal level after reaching steady-state operation. For more information, see “AGC Performance Criteria” on page 5-19.

Desired output power (W) — Target output power level

1 | positive scalar

Target output power level, specified as a positive scalar. The power level is measured in watts referenced to 1 ohm.

Averaging length — Length of the averaging window

100 | positive integer

Length of the averaging window in samples, specified as a positive integer. For more information on how the averaging length influences the variance of the AGC output signal in steady-state operation and the execution speed, see “Tips” on page 5-19.

Maximum power gain (dB) — Maximum power gain

60 (default) | positive scalar

Maximum power gain in decibels, specified as a positive scalar. Large gain adjustments can cause clipping when a small input signal power suddenly increases. Use this property to avoid large gain adjustments by limiting the gain that the AGC applies to the input signal. For an example, see “Compare AGC Performance for Different Maximum Gains”.

Enable output of estimated input power — Option to output estimated input power

off (default) | on

Select this check box to provide an output port, Px, that returns an estimate of the input signal power.

Simulate using — Type of simulation to run

Interpreted execution (default) | Code generation

Type of simulation to run, specified as Interpreted execution or Code generation.

- **Interpreted execution** -- Simulate the model by using the MATLAB interpreter. This option requires less startup time than the **Code generation** method, but the speed of subsequent simulations is slower. In this mode, you can debug the source code of the block.
- **Code generation** -- Simulate the model by using generated C code. The first time you run a simulation, Simulink generates C code for the block. The C code is reused for subsequent simulations unless the model changes. This option requires additional startup time, but the speed of the subsequent simulations is faster than **Interpreted execution**.

Block Characteristics

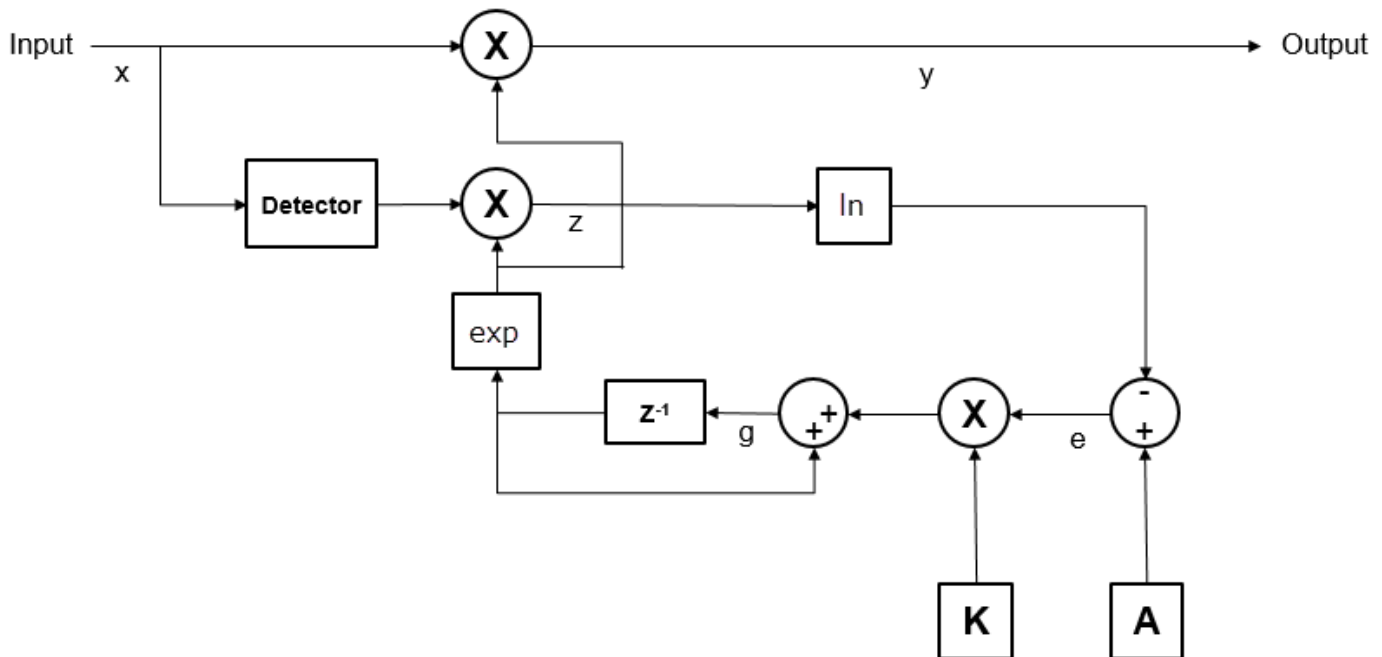

Data Types	double single
-------------------	-----------------

Multidimensional Signals	no
Variable-Size Signals	yes

More About

Logarithmic-Loop AGC

The AGC implementation uses a logarithmic feedback loop. As this figure of the logarithmic-loop AGC algorithm shows, the output signal is the product of the input signal and the exponential of the loop gain. The error signal is the difference between the reference level and the product of the logarithm of the detector output and the exponential of the loop gain. After multiplying by the step size, the AGC passes the error signal to an integrator.

The logarithmic-loop AGC performs well for a variety of signal types, including amplitude modulation. The “AGC Detector” on page 5-19 is applied to the input signal, which improves convergence times, but increases signal power variation at the detector input. Large signal variation at the detector input is acceptable for floating-point systems.

Mathematically, the algorithm is summarized as

$$\begin{aligned}
 y(n) &= x(n) \cdot \exp(g(n-1)), \\
 z(n) &= D(x(n)) \cdot \exp(2g(n-1)), \\
 e(n) &= A - \ln(z(n)), \text{ and} \\
 g(n) &= g(n-1) + K \cdot e(n),
 \end{aligned}$$

where:

- x is the input signal.

- y is the output signal.
- g is the loop gain.
- $D(\bullet)$ is the detector function.
- z is the detector output.
- A is the reference value.
- e is the error signal.
- K is the step size.

AGC Detector

The AGC detector output, z , computes a square law detector given by

$$z(m) = \frac{1}{N} \sum_{n=mN}^{(m+1)N-1} |y(n)|^2,$$

where N is the update period. The square law detector produces an output proportional to the square of the input signal y .

AGC Performance Criteria

Increasing the step size decreases the attack time and decay times, but it also increases gain pumping.

- Attack time — The duration taken for the AGC to respond to an increase in the input amplitude
- Decay time — The duration taken for the AGC to respond to a decrease in the input amplitude
- Gain pumping — The variation in the gain value during steady-state operation

Tips

- This block is designed for streaming applications.
- If the signal amplitude does not change within the frame, you can simulate an ideal AGC by calculating the average gain desired for a frame of samples. Then, apply the gain to each sample in the frame.
- If you use the AGC with higher order QAM signals, you might need to reduce the variation in the gain during steady-state operation. Inspect the constellation diagram at the output of the AGC during steady-state operation. You can increase the averaging length to avoid frequent gain adjustments. An increase in averaging length reduces execution speed.

Introduced in R2013a

AWGN Channel

Add white Gaussian noise to input signal

Library: Communications Toolbox / Channels

Description

The AWGN Channel block adds white Gaussian noise to the input signal. It inherits the sample time from the input signal.

Ports

Input

In — Input data signal

vector | matrix

Input data signal, specified as an N_S -by-1 vector or an N_S -by- N_C matrix.

N_S represents the number of samples in the input signal. N_C represents the number of channels, as determined by the number of columns in the input signal matrix. Both N_S and N_C can be equal to 1.

The block adds frames of length- N_S Gaussian noise to each of the N_C channels, using a distinct random distribution per channel.

Data Types: double | single

Complex Number Support: Yes

Var — Variance of additive white Gaussian noise

positive scalar | vector

Variance of additive white Gaussian noise, specified as a positive scalar or a 1-by- N_C vector. N_C represents the number of channels, as determined by the number of columns in the input signal matrix. For more information, see “Specifying the Variance Directly or Indirectly” on page 5-25.

Dependencies

To enable this port, set Mode to Variance from port.

Data Types: double

Output

Out — Output data signal

vector | matrix

Output data signal for the AWGN channel, returned as a vector or matrix. The datatype and dimensions of `Out` match those of the input signal, `In`.

Parameters

Initial seed — Noise generator initial seed

67 (default) | positive scalar | vector

Noise generator initial seed, specified as a positive scalar or a 1-by- N_C vector.

This block uses the Random Source block to generate noise. Random numbers are generated using the Ziggurat method (V5 RANDN algorithm). The block reuses the same initial seeds every time you rerun the simulation, so that this block outputs the same signal each time you run a simulation.

When the input signal is complex, the block creates random data as:

```
randData = randn(2*NS,NC)
noise = randData(1:2:end) + 1i(randData(2:2:end))
```

N_S is the number of samples and N_C is the number of channels.

You can specify different seed values for each DLL build.

Tunable: Yes

Mode — Variance mode

Signal to noise ratio (Eb/No) (default) | Signal to noise ratio (Es/No) | Signal to noise ratio (SNR) | Variance from mask | Variance from port

Variance mode, specified as Signal to noise ratio (Eb/No), Signal to noise ratio (Es/No), Signal to noise ratio (SNR), Variance from mask, or Variance from port. For more information, see “Relationship Among Eb/No, Es/No, and SNR Modes” on page 5-24 and “Specifying the Variance Directly or Indirectly” on page 5-25.

Eb/No (dB) — Ratio of information bit energy per symbol to noise power spectral density

10 (default) | scalar | vector

Ratio of information bit energy per symbol to noise power spectral density in decibels, specified as a scalar or vector. The information bit energy is the magnitude without channel coding.

Tunable: Yes

Dependencies

To enable this parameter, set Mode to Eb/No.

Es/No (dB) — Ratio of information symbol energy per symbol to noise power spectral density

10 (default) | scalar | vector

Ratio of information symbol energy per symbol to noise power spectral density in decibels, specified as a scalar or vector. The information bit energy is the magnitude without channel coding.

Tunable: Yes

Dependencies

To enable this parameter, set Mode to Es/No.

SNR (dB) — Ratio of signal power to noise power

10 (default) | scalar | vector

Ratio of signal power to noise power in decibels, specified as a scalar or vector.

Tunable: Yes

Dependencies

To enable this parameter, set Mode to SNR.

Number of bits per symbol — Number of bits in each input symbol

1 (default) | scalar | vector

Number of bits in each input symbol, specified as a scalar or vector.

Dependencies

To enable this parameter, set Mode to Eb/No.

Input signal power, referenced to 1 ohm (watts) — Mean square power of input

1 (default) | scalar | vector

Mean square power of the input in watts, specified as a scalar or vector.

- When Mode is Eb/No or Es/No, the parameter is the mean square power of the input symbols.
- When Mode is SNR, this parameter is the mean square power of the input samples.

Tunable: Yes

Dependencies

To enable this parameter, set Mode to Eb/No, Es/No, or SNR.

Symbol period (s) — Duration of an information channel

1 (default) | positive scalar | vector

Duration of an information channel symbol in seconds, specified as a positive scalar or vector. The duration of the information channel is measured without channel coding.

Dependencies

To enable this parameter, set Mode to Eb/No or Es/No.

Variance — Variance of white Gaussian noise

1 (default) | scalar | vector

Variance of the white Gaussian noise, specified as a scalar or vector. For more information, see “Specifying the Variance Directly or Indirectly” on page 5-25.

Tunable: Yes

Dependencies

To enable this parameter, set Mode to Variance from mask.

Block Characteristics

Data Types	double single
Multidimensional Signals	no
Variable-Size Signals	no

Tips

- You can tune parameters in normal mode, accelerator mode, or rapid accelerator mode.
- Unless otherwise indicated, parameters are *nontunable*.
 - For nontunable parameters, when you use the Simulink Coder™ rapid simulation (RSIM) target to build an RSIM executable, you cannot change their values without recompiling the model.
 - If a parameter is *tunable*, you can change its value at any time. This is useful for Monte Carlo simulations in which you run the simulation multiple times (such as on multiple computers) with different amounts of noise.

Algorithms**Relationship Among Eb/No, Es/No, and SNR Modes**

For uncoded complex input signals, the AWGN Channel block relates E_b/N_0 , E_s/N_0 , and SNR according to these equations:

$$E_s/N_0 = (T_{\text{sym}}/T_{\text{samp}}) \cdot \text{SNR}$$

$$E_s/N_0 = E_b/N_0 + 10\log_{10}(k) \text{ in dB}$$

- E_s represents the signal energy in joules.
- E_b represents the bit energy in joules.
- N_0 represents the noise power spectral density in watts/Hz.
- T_{sym} represents the Symbol period (s) parameter of the block in Es/No mode.
- k represents the number of information bits per input symbol, Number of bits per symbol.
- T_{samp} represents the inherited sample time of the block, in seconds.

For real signal inputs, the AWGN Channel block relates E_s/N_0 and SNR according to this equation:

$$E_s/N_0 = 0.5 (T_{\text{sym}}/T_{\text{samp}}) \cdot \text{SNR}$$

Note

- All values of power assume a nominal impedance of 1 ohm.
- The equation for the real case differs from the corresponding equation for the complex case by a factor of 2. Specifically, the object uses a noise power spectral density of $N_0/2$ watts/Hz for real input signals, versus N_0 watts/Hz for complex signals.

For more information, see “AWGN Channel Noise Level”.

Specifying the Variance Directly or Indirectly

To directly specify the variance of the noise generated by AWGN Channel, specify the Mode as:

- **Variance from mask**, where you specify the variance in the dialog box. The value must be positive.
- **Variance from port**, where you provide the variance as an input to the block. The variance input must be positive, and its sampling rate must equal that of the input signal.

For **Variance from mask** and **Variance from port** mode:

- If the variance is a scalar, then all signal channels are uncorrelated but share the same variance.
- If the variance is a vector whose length is the number of channels in the input signal, then each element represents the variance of the corresponding signal channel.

Note If you apply complex input signals to the AWGN Channel block, then it adds complex zero-mean Gaussian noise with the calculated or specified variance. The variance for each quadrature component of the complex noise is half of the calculated or specified value.

To specify the variance indirectly, that is, to have the block calculate the variance, specify the Mode as:

- **Signal to noise ratio (Eb/No)**, where the block calculates the variance from these quantities that you specify in the dialog box:
 - Eb/No (dB), the ratio of bit energy to noise power spectral density
 - Number of bits per symbol
 - Input signal power, referenced to 1 ohm (watts), the actual power of the symbols at the input of the block
 - Symbol period (s)
- **Signal to noise ratio (Es/No)**, where the block calculates the variance from these quantities that you specify in the dialog box:
 - Es/No (dB), the ratio of signal energy to noise power spectral density
 - Input signal power, referenced to 1 ohm (watts), the actual power of the symbols at the input of the block
 - Symbol period (s)
- **Signal to noise ratio (SNR)**, where the block calculates the variance from these quantities that you specify in the dialog box:
 - SNR (dB), the ratio of signal power to noise power
 - Input signal power, referenced to 1 ohm (watts), the actual power of the samples at the input of the block

Changing the symbol period in the AWGN Channel block affects the variance of the noise added per sample, which also causes a change in the final error rate.

$$\text{NoiseVariance} = \frac{\text{SignalPower} \times \text{SymbolPeriod}}{\text{SampleTime} \times 10^{\frac{\text{Es/No}}{10}}}$$

Tip Select the symbol period equal to the symbol period of the model. The value depends on what constitutes a symbol and what the oversampling applied to it is. For example, a symbol could have 3 bits and be oversampled by 4. For more information, see “AWGN Channel Noise Level”.

Barker Code Generator

Generate bipolar Barker Code

Library: Communications Toolbox
 Communications Toolbox / Comm Sources / Sequence
 Generators

Description

The Barker Code Generator block generates a bipolar Barker code. The short length and low correlation sidelobes make Barker codes useful for frame synchronization in digital communications systems. For more information, see “Barker Codes” on page 5-28.

Ports

Output

output — Barker code frame

column vector

Barker code frame, returned as a column vector. If the frame length exceeds the Barker code length, the block fills the frame by repeating the Barker code.

Dependencies

Set the data type of the output with the **Output data type** parameter.

Parameters

Code length — Length of generated code

7 (default) | 1 | 2 | 3 | 4 | 5 | 11 | 13

Length of the generated code, specified as 1, 2, 3, 4, 5, 7, 11, or 13. For more information, see “Barker Codes” on page 3-77.

Example: 2 outputs the Barker code [-1;1].

Data Types: double

Sample time — Output sample time

1 (default) | -1 | positive scalar

Positive scalars specify the time in seconds between each sample of the output signal. If you set the **Sample time** to -1, the output signal inherits the sample time from downstream. For information on the relationship between the **Sample time** and **Samples per frame** parameters, see “Sample Timing” on page 5-29.

Samples per frame — Samples per output frame

1 (default) | positive integer

Samples per output frame, specified as a positive integer. If **Samples per frame** is M , the block outputs a frame containing M samples comprised of length N Barker code sequences. N is the length of the generated code, which is set by the **Code length** parameter. When M is not an integer multiple of N , consecutive frames maintain continuity of the Barker code across frame boundaries.

For information on the relationship between **Sample time** and **Samples per frame**, see “Sample Timing” on page 5-29.

Data Types: double

Output data type — Output data type

double (default) | int8

Output data type, specified as double or int8.

Data Types: char | string

Simulate using — Type of simulation to run

Code generation (default) | Interpreted execution

Type of simulation to run, specified as Code generation or Interpreted execution.

- **Code generation** -- Simulate the model by using generated C code. The first time you run a simulation, Simulink generates C code for the block. The C code is reused for subsequent simulations unless the model changes. This option requires additional startup time, but the speed of the subsequent simulations is faster than **Interpreted execution**.
- **Interpreted execution** -- Simulate the model by using the MATLAB interpreter. This option requires less startup time than the **Code generation** method, but the speed of subsequent simulations is slower. In this mode, you can debug the source code of the block.

Block Characteristics

Data Types	double integer
Multidimensional Signals	no
Variable-Size Signals	no

More About

Barker Codes

Barker codes have a maximum autocorrelation sequence, which has off-peak autocorrelations no larger than 1.

A correlation sidelobe is the correlation of a codeword with a time-shifted version of itself. The correlation sidelobe, C_k , for a k -symbol shift of an N -bit code sequence, $\{X_j\}$, is

$$C_k = \sum_{j=1}^{N-k} X_j X_{j+k}$$

For $j=1, 2, 3, \dots, N$, X_j is an individual code symbol that is equal to +1 or -1. The adjacent symbols are assumed to be 0.

The output code is in a bipolar format with 0 and 1 mapped to 1 and -1. The maximum known Barker code length is 13. The short length and low correlation sidelobes make Barker codes useful for frame synchronization in digital communications systems. The Barker code generator outputs the Barker codes listed in this table.

Barker Code Length	Barker Code	Sidelobe Level
1	[-1]	0 dB
2	[-1; 1]	-6 dB
3	[-1; -1; 1]	-9.5 dB
4	[-1; -1; 1; -1]	-12 dB
5	[-1; -1; -1; 1; -1]	-14 dB
7	[-1; -1; -1; 1; 1; -1; 1]	-16.9 dB
11	[-1; -1; -1; 1; 1; 1; -1; 1; 1; -1; 1]	-20.8 dB
13	[-1; -1; -1; -1; -1; 1; 1; -1; -1; 1; -1; 1; -1]	-22.3 dB

Sample Timing

The time between output updates is equal to the product of the **Samples per frame** and **Sample time** parameter values. For example, if **Sample time** and **Samples per frame** each equal 1, the block outputs a sample every second. If you increase **Samples per frame** to 10, then the block outputs a 10-by-1 vector every 10 seconds. This ensures that the equivalent output rate is not dependent on the **Samples per frame** parameter.

Compatibility Considerations

Existing models automatically update this block to current version

Behavior changed in R2020a

Starting in R2020a, Simulink no longer allows you to use the Barker Code Generator block version available before R2015b.

Existing models automatically update to load the Barker Code Generator block version announced in “Source blocks output frames of contiguous time samples but do not use the frame attribute” in the R2015b Release Notes. For more information on block forwarding, see “Maintain Compatibility of Library Blocks Using Forwarding Tables” (Simulink).

Objects

comm.BarkerCode

Introduced before R2006a

Baseband File Reader

Read baseband signals from file

Library: Communications Toolbox / Comm Sources

Description

The Baseband File Reader block reads a signal from a baseband file. A baseband file is a specific type of binary file written by the Baseband File Writer block. Baseband signals are typically downconverted from a nonzero center frequency to 0 Hz. The block automatically reads the sample rate, center frequency, number of channels, and any descriptive data.

Input/Output Ports

Output

Data — Baseband signal

scalar | vector | matrix

Baseband signal, returned as a scalar, vector, or matrix. The signal is read from the file specified by the **Baseband file name** parameter. The sample time is either inherited from the file or can be set by the **Sample Time (s)** parameter.

Data Types: `double`

EOF — End-of-file indicator

logical scalar

End-of-file indicator, returned as a logical scalar. The output is `true` when the **Repeatedly read the file** parameter is `false` and the entire file has been read. To enable this port, select the **Output end-of-file indicator** parameter.

Parameters

Baseband file name — Name of file from which data is read

`example.bb` (default) | character vector

Specify the name of the baseband file as a character vector.

Click **Browse** to locate the baseband file you want to read. Click **File Info** to display this information:

- File name
- Sample rate
- Center frequency
- Number of samples

- Number of channels
- Data type
- Any metadata fields

Data Types: char

Inherit sample time from file – Select source of sample time

on (default) | off

Select this check box to inherit the sample time from the file specified by **Baseband file name**.

Sample time (s) – Block sample time

1 (default) | positive scalar

Specify the block sample time in seconds as a positive scalar. To enable this parameter, clear the **Inherit sample time from file** check box.

Samples per frame – Number of samples per output frame

100 (default) | positive integer scalar

Number of samples per output frame, specified as a positive integer or Inf. When this parameter is Inf, the output frame contains all of the samples in the baseband file.

Repeatedly read the file – Continuously loop data from file

off (default) | on

Select this check box to repeatedly read the contents of the baseband file. When the end of the file is reached:

- The block outputs zeros, if the **Repeatedly read the file** parameter is not selected (off).
- The block outputs samples from the beginning of the file, if the **Repeatedly read the file** parameter is selected (on).

Simulate using – Type of simulation to run

Code generation (default) | Interpreted execution

Type of simulation to run, specified as Code generation or Interpreted execution.

- **Code generation** -- Simulate the model by using generated C code. The first time you run a simulation, Simulink generates C code for the block. The C code is reused for subsequent simulations unless the model changes. This option requires additional startup time, but the speed of the subsequent simulations is faster than **Interpreted execution**.
- **Interpreted execution** -- Simulate the model by using the MATLAB interpreter. This option requires less startup time than the **Code generation** method, but the speed of subsequent simulations is slower. In this mode, you can debug the source code of the block.

Block Characteristics

Data Types	double integer single

Blocks

Baseband File Writer

Introduced in R2016b

Baseband File Writer

Write baseband signals to file

Library: Communications Toolbox / Comm Sinks

Description

The Baseband File Writer block writes a baseband signal to a specific type of binary file. Baseband signals are typically down-converted from a nonzero center frequency to 0 Hz. Sample rate, which is determined by the input signal sample time and frame size, and center frequency are saved when the signal is written to a file.

Input/Output Ports

Input

Port_1 — Baseband signal

scalar | vector | matrix

This port accepts a baseband signal to be saved under the filename specified by the **Baseband file name** parameter. The saved signal is always complex.

Data Types: single | double

Parameters

Baseband file name — Name of file in which data is saved

untitled.bb (default) | character vector

Specify the name of the baseband file as a character vector.

To specify the location where the file is saved, click **Browse**.

Center frequency (Hz) — Center frequency of the baseband signal

1e8 (default) | nonnegative scalar

Specify the center frequency in Hz as a nonnegative scalar.

Metadata in a structure — Data describing the baseband signal

struct() (default) | structure

Specify data describing the baseband signal as a structure. If the signal has no descriptive data, this parameter is an empty structure. The structure can contain any number of fields. Field names have no restrictions, but the field values must be numeric, logical, or character data types having any dimension.

Number of latest samples to write — Number of samples to write`inf` (default) | positive scalar

Specify the number to write. If this parameter is `inf`, all samples are saved. Otherwise, only the last N samples are saved, where N is specified by this parameter.

Simulate using — Select simulation mode`Code generation` (default) | `Interpreted execution`**Code generation**

On the first model run, simulate and generate code for the block using only MATLAB functions supported for code generation. If the structure of the block does not change, subsequent model runs do not regenerate the code.

Interpreted execution

Simulate model using all supported MATLAB functions. Choosing this option can slow simulation performance.

Block Characteristics

Data Types	<code>double</code> <code>integer</code> <code>single</code>
Multidimensional Signals	<code>no</code>
Variable-Size Signals	<code>no</code>

Tips

- The Baseband File Writer block writes baseband signals to uncompressed binary files. To share these files, you can compress them to a zip file using the `zip` function. For more information, see “Create and Extract from Zip Archives”.

Baseband File Reader

Introduced in R2016b

Baseband PLL

(To be removed) Implement baseband phase-locked loop

Note will be removed in a future release. To design voltage-controlled oscillators (VCOs) and phase-locked loops (PLLs), use the “Phase-Locked Loops” (Mixed-Signal Blockset) blocks.

Library

Components sublibrary of Synchronization

Description

The Baseband PLL (phase-locked loop) block is a feedback control system that automatically adjusts the phase of a locally generated signal to match the phase of an input signal. Unlike the Phase-Locked Loop block, this block uses a baseband method and does not depend on a carrier frequency.

This PLL has these three components:

- An integrator used as a phase detector.
- A filter. You specify the filter's transfer function using the **Lowpass filter numerator** and **Lowpass filter denominator** parameters. Each is a vector that gives the respective polynomial's coefficients in order of descending powers of s .

To design a filter, you can use the Signal Processing Toolbox functions `cheby1`, and `cheby2`. The default filter is a Chebyshev type II filter whose transfer function arises from the command below.

```
[num, den] = cheby2(3,40,100,'s')
```

- A voltage-controlled oscillator (VCO). You specify the sensitivity of the VCO signal to its input using the **VCO input sensitivity** parameter. This parameter, measured in Hertz per volt, is a scale factor that determines how much the VCO shifts from its quiescent frequency.

This block accepts a sample-based scalar signal. The input signal represents the received signal. The three output ports produce:

- The output of the filter
- The output of the phase detector
- The output of the VCO

This model is nonlinear; for a linearized version, use the Linearized Baseband PLL block.

For more information, “Phase-Locked Loops”.

Parameters

Lowpass filter numerator

The numerator of the lowpass filter's transfer function, represented as a vector that lists the coefficients in order of descending powers of s .

Lowpass filter denominator

The denominator of the lowpass filter's transfer function, represented as a vector that lists the coefficients in order of descending powers of s .

VCO input sensitivity (Hz/V)

This value scales the input to the VCO and, consequently, the shift from the VCO's quiescent frequency.

“Phase-Locked Loops”

Introduced before R2006a

BCH Decoder

Decode BCH code to recover binary vector data

Library: Communications Toolbox / Error Detection and Correction / Block

Description

The BCH Decoder block recovers a binary message vector from a binary BCH codeword vector. For proper decoding, the **Codeword length, N** and **Message length, K** parameter values in this block must match the parameters in the corresponding BCH Encoder block. The full-length values of N and K must produce a valid narrow-sense BCH code.

If the encoder is processing multiple codewords per frame, then the same puncture pattern holds for all codewords. The input and output signal lengths are listed in "Input and Output Signal Length in BCH Blocks" on page 5-41.

See "Tips" on page 5-43 for information about valid N values, valid (N,K) pairs, and error-correcting capabilities for a given BCH code.

If decoding fails, the message portion of the decoder input is returned unchanged as the decoder output.

The sample times of all input and output signals are equal.

This icon shows optional ports.

Ports

Input

In — Encoded message

binary column vector

Encoded message, specified as a binary column vector. The encoded message is a BCH code with message length K and codeword length (N - number of punctures).

Data Types: single | double | int8 | int16 | int32 | uint8 | uint16 | uint32 | Boolean

Era — Erasure vector

binary column vector

Erasure vector, specified as a binary column vector that is the same length as **In**. Erasure values of 1 correspond to erased bits in the same position in the codeword. Values of 0 correspond to bits that are not erased.

Dependencies

To enable this port, select **Enable erasures input port**.

Data Types: `double` | `Boolean`

Output

Out — Decoded message

binary column vector

Decoded message, returned as a binary column vector input signal with an integer multiple of **Message length, K** elements or **Shortened message length, S** elements if the code is shortened. Each group of input elements represents one codeword to decode. The input and output signal lengths are listed in the “Input and Output Signal Length in BCH Blocks” on page 5-41 table.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean`

Err — Decoding errors

integer vector

Decoding errors, returned as an integer vector that indicates the number of errors detected during decoding of the codeword. A negative integer indicates that the block detected more errors than it could correct by using the coding scheme.

Dependencies

To enable this port, select **Output number of corrected errors**.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean`

For more information, see “Supported Data Types” on page 5-43.

Parameters

Codeword length, N — Codeword length

15 (default) | integer

Codeword length, specified as an integer of the form $N = 2^M - 1$, where M is an integer from 3 through 16. For more information, see “Tips” on page 5-43.

Message length, K — Message length

5 (default) | integer

Message length, specified as an integer. The (N, K) pair must produce a narrow-sense BCH code.

Shortened message length, S — Shortened message length

5 (default) | integer

Shortened message length, specified as an integer. When you specify this parameter, provide full-length N and K values to specify the (N, K) code that is shortened to an $(N - K + S, S)$ code.

Dependencies

To enable this parameter, select **Specify shortened message length**.

Generator polynomial — Generator polynomial

'X¹⁰ + X⁸ + X⁵ + X⁴ + X² + X + 1' (default) | polynomial character vector | binary row vector | binary Galois row vector

Generator polynomial, specified as one of the following:

- A polynomial character vector — For more information, see “Representation of Polynomials in Communications Toolbox”.
- A binary row vector that represents the coefficients of the generator polynomial in order of descending power.
- A binary Galois row vector that represents the coefficients of the generator polynomial in order of descending power.

Example: 'X¹⁰ + X⁸ + X⁵ + X⁴ + X² + X + 1', which is equivalent to `bchgenpoly(15,5)`

Dependencies

To enable this parameter, select **Specify generator polynomial**.

Primitive polynomial — Primitive polynomial

'X⁴ + X + 1' (default) | polynomial character vector | binary row vector

Primitive polynomial in order of descending power. It is a polynomial of order M that defines the finite Galois field GF(2), specified as one of the following:

- A polynomial character vector — For more information, see “Representation of Polynomials in Communications Toolbox”.
- A binary row vector that represents the coefficients of the generator polynomial in order of descending power.

Example: 'X⁴ + X + 1', which is the primitive polynomial used for a (15,5) code, `ppoly = primpoly(4, 'nodisplay'); int2bit(ppoly, ceil(log2(max(ppoly))))'`

Dependencies

To enable this parameter, select **Specify primitive polynomial**.

Disable generator polynomial checking — Option to disable generator polynomial checking

on (default) | off

Select this parameter to disable generator polynomial check.

Each time a model initializes, the block performs a polynomial check. This check verifies that $X^N + 1$ is divisible by the specified generator polynomial, where N represents the full codeword length. For larger codes, disabling the check speeds up the simulation process.

Tip Always run the check at least once before disabling this feature.

Dependencies

To enable this parameter, select **Specify generator polynomial**.

Puncture vector – Puncture vector

[ones(8,1); zeros(2,1)] (default) | column vector

Puncture vector, specified as a binary column vector of length $N-K$. Element indices with 1s represent data symbol indices that pass through the block unaltered. Element indices with 0s represent data symbol indices that get punctured, or removed, from the data stream. For more information, see “Puncturing and Erasures” on page 5-42.

Dependencies

To enable this parameter, select **Puncture code**.

Enable erasures input port – Option to enable erasures input port

off (default) | on

Selecting this check box enables the erasures port, Era.

Through the port, you can input a binary column vector that is $1/M$ times as long as the codeword input.

Erasure values of 1 correspond to erased symbols in the same position in the bit-packed codeword. Values of 0 correspond to nonerased symbols. For more information, see “Puncturing and Erasures” on page 5-42.

Output number of corrected errors – Option to enable port to output number of corrected errors

off (default) | on

Selecting this check box enables an additional output port, Err, which indicates the number of errors the block corrected in the input codeword.

Block Characteristics

Data Types	Boolean double integer single
Multidimensional Signals	no
Variable-Size Signals	no

More About**Input and Output Signal Length in BCH Blocks**

This table shows how to compute the input and output signal lengths for the BCH encoder and decoder blocks.

The notation $y = c * x$ denotes that y is an integer multiple of x .

Specify Shortened Message Length, S	BCH Encoder	BCH Decoder
off	Input Length: $c * K$ Output Length: $c * (N - P)$	Input Length: $c * (N - P)$ Output Length: $c * K$ Erasures Length: $c * (N - P)$
on	Input Length: $c * S$ Output Length: $c * (N - K + S - P)$	Input Length: $c * (N - K + S - P)$ Output Length: $c * S$ Erasures Length: $c * (N - K + S - P)$

- N is the codeword length
- K is the message length
- S is the shortened message length
- P is the number of punctures value, and is equal to the number of zeros in the puncture vector.

Puncturing and Erasures

1s and 0s have precisely opposite meanings for the puncture and erasure vectors.

In a puncture vector,

- 1 means that the data symbol is passed through the block unaltered.
- 0 means that the data symbol is to be punctured, or removed, from the data stream.

In an erasure vector,

- 1 means that the data symbol is to be replaced with an erasure symbol.
- 0 means that the data symbol is passed through the block unaltered.

These conventions apply to both the encoder and the decoder. For more information, see “Shortening, Puncturing, and Erasures”.

Supported Data Types

Port	Supported Data Types
In	<ul style="list-style-type: none"> • Double-precision floating point • Boolean • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers
Out	<ul style="list-style-type: none"> • Double-precision floating point • Boolean • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers
Era	<ul style="list-style-type: none"> • Double-precision floating point • Boolean
Err	<ul style="list-style-type: none"> • Double-precision floating point • Boolean • 8-, 16-, and 32-bit signed integers • 8-, 16-, and 32-bit unsigned integers

Pair Block

BCH Encoder — Encodes data using BCH algorithm.

Tips

- To generate the list of valid (N,K) pairs along with the corresponding values of the error-correction capability, run `bchnumerr(N)`.
- Valid values for $N = 2^M - 1$, where M is an integer from 3 through 16. The maximum allowable value of N is 65,535.

Algorithms

This block implements the algorithm, inputs, and outputs described in “Algorithms for BCH and RS Errors-only Decoding”.

BCH Encoder

Create BCH code from binary vector data

Library: Communications Toolbox / Error Detection and Correction / Block

Description

The BCH Encoder block creates a BCH code with message length K and codeword length (N - number of punctures).

If the encoder is processing multiple codewords per frame, then the same puncture pattern holds for all codewords. The input and output signal lengths are listed in “Input and Output Signal Length in BCH Blocks” on page 5-47.

See “Tips” on page 5-48 for information about valid N values, valid (N,K) pairs, and error-correcting capabilities for a given BCH code.

Ports

Input

In — Message to encode

binary column vector

Message to encode, specified as a binary column vector input signal with an integer multiple of **Message length, K** elements or **Shortened message length, S** elements if the code is shortened. Each group of input elements represents one message word to encode. The input and output signal lengths are listed in “Input and Output Signal Length in BCH Blocks” on page 5-47.

Data Types: single | double | int8 | int16 | int32 | uint8 | uint16 | uint32 | Boolean

Output

Out — Encoded message

binary column vector

Encoded message, returned as a binary column vector. The encoded message is a BCH code with message length K and codeword length (N - number of punctures).

Data Types: single | double | int8 | int16 | int32 | uint8 | uint16 | uint32 | Boolean

For more information, see “Supported Data Types” on page 5-48.

Parameters

Codeword length, N — Codeword length

15 (default) | integer

Codeword length, specified as an integer of the form $N = 2^M - 1$, where M is an integer from 3 through 16. For more information, see “Tips” on page 5-48.

Message length, K — Message length

5 (default) | integer

Message length, specified as an integer. The (N, K) pair must produce a narrow-sense BCH code.

Shortened message length, S — Shortened message length

5 (default) | integer

Shortened message length, specified as an integer. When you specify this parameter, provide full-length N and K values to specify the (N, K) code that is shortened to an $(N - K + S, S)$ code.

Dependencies

To enable this parameter, select **Specify shortened message length**.

Generator polynomial — Generator polynomial

' $X^{10} + X^8 + X^5 + X^4 + X^2 + X + 1$ ' (default) | polynomial character vector | binary row vector | binary Galois row vector

Generator polynomial, specified as one of the following:

- A polynomial character vector — For more information, see “Representation of Polynomials in Communications Toolbox”.
- A binary row vector that represents the coefficients of the generator polynomial in order of descending power.
- A binary Galois row vector that represents the coefficients of the generator polynomial in order of descending power.

Example: ' $X^{10} + X^8 + X^5 + X^4 + X^2 + X + 1$ ', which is equivalent to `bchgenpoly(15,5)`

Dependencies

To enable this parameter, select **Specify generator polynomial**.

Primitive polynomial — Primitive polynomial

' $X^4 + X + 1$ ' (default) | polynomial character vector | binary row vector

Primitive polynomial in order of descending power. It is a polynomial of order M that defines the finite Galois field $GF(2)$, specified as one of the following:

- A polynomial character vector — For more information, see “Representation of Polynomials in Communications Toolbox”.
- A binary row vector that represents the coefficients of the generator polynomial in order of descending power.

Example: ' $X^4 + X + 1$ ', which is the primitive polynomial used for a (15,5) code, `ppoly = primpoly(4, 'nodisplay'); int2bit(ppoly, ceil(log2(max(ppoly))))'`

Dependencies

To enable this parameter, select **Specify primitive polynomial**.

Disable generator polynomial checking – Option to disable generator polynomial checking

on (default) | off

Select this parameter to disable generator polynomial check.

Each time a model initializes, the block performs a polynomial check. This check verifies that $X^N + 1$ is divisible by the specified generator polynomial, where N represents the full codeword length. For larger codes, disabling the check speeds up the simulation process.

Tip Always run the check at least once before disabling this feature.

Dependencies

To enable this parameter, select **Specify generator polynomial**.

Puncture vector – Puncture vector

[ones(8,1); zeros(2,1)] (default) | binary column vector

Puncture vector, specified as a binary column vector of length $N-K$. Element indices with 1s represent data symbol indices that pass through the block unaltered. Element indices with 0s represent data symbol indices that get punctured, or removed, from the data stream. For more information, see “Shortening, Puncturing, and Erasures”.

Note 1s and 0s have precisely opposite meanings for the puncture and erasure vectors. For an erasure vector, 1 means that the data symbol is to be replaced with an erasure symbol, and 0 means that the data symbol is passed through the block unaltered. This convention applies to both the encoder and the decoder.

Dependencies

To enable this parameter, select **Puncture code**.

Bernoulli Binary Generator

Generate Bernoulli-distributed random binary numbers

Library: Communications Toolbox / Comm Sources / Random Data Sources

Description

The Bernoulli Binary Generator block generates random binary numbers using a Bernoulli distribution. Use this block to generate random data bits to simulate digital communication systems and obtain performance metrics such as bit error rate. The Bernoulli distribution with parameter p produces zero with probability p and one with probability $1-p$. The Bernoulli distribution has mean value $1-p$ and variance $p(1-p)$. The **Probability of zero** parameter specifies p and can be any real number in range $[0, 1]$.

The output signal can be a column or row vector, two-dimensional matrix, or scalar. The number of rows in the output signal corresponds to the number of samples in one frame and is set by the **Samples per frame** parameter. The number of columns in the output signal corresponds to the number of channels and is set by the number of elements in the **Probability of zero** parameter. For more details, see “Sources and Sinks” in *Communications Toolbox User's Guide*

Ports

Output

Out — Output data signal

scalar | vector | matrix

Output data signal, returned as a scalar, vector, or matrix.

Data Types: double

Parameters

Probability of zero — Probability of generating zero at output

0.5 (default) | integer in the range $[0, 1]$ | vector of integers in the range $[0, 1]$

Probability of zero must be in the range of $[0, 1]$. The number of elements in the **Probability of zero** parameter corresponds to the number of independent channels output from the block. The Bernoulli distribution with parameter p produces zero with probability p and one with probability $1-p$.

Source of initial seed — Source of initial seed for random number generator

Auto (default) | Parameter

Select Parameter to use the **Initial seed** parameter to specify the initial seed for the random number generator.

Note When the **Source of initial seed** parameter is set to Auto and the **Simulate using** parameter is set to Code generation, the random number generator uses an initial seed of zero. In this case, the block generates the same random numbers each time it is started. To ensure that the model uses different initial seeds, set **Simulate using** parameter to Interpreted execution. If you run Interpreted execution in Rapid accelerator mode, then the model behaves the same as Code generation mode.

Dependencies

Select Auto for the block to use the global random number stream as the initial seed. For more information, see “Managing the Global Stream Using RandStream” and “Random Number Generators”.

Initial seed — Initial seed for random number generator

nonnegative scalar

If you set the **Initial seed** parameter to a constant value, then the resulting sequence is repeatable.

Dependencies

To enable this parameter, set the **Source of initial seed** to Parameter.

Sample time — Sample time of output signal

1 (default) | -1 | positive scalar

Positive scalars specify the time in seconds between each sample of the output signal. If you set the **Sample time** to -1, the output signal inherits the sample time from downstream. For information on the relationship between the **Sample time** and **Samples per frame** parameters, see “Sample Timing” on page 5-52.

Samples per frame — Samples per frame of output signal

1 (default) | positive scalar

Samples per frame in one channel of the output signal, specified as a positive integer. For information on the relationship between **Sample time** and **Samples per frame**, see “Sample Timing” on page 5-52.

Output data type — Data type of output signal

double (default) | boolean

Select the data type for the output signal.

Simulate using — Type of simulation to run

Code generation (default) | Interpreted execution

Type of simulation to run, specified as Code generation or Interpreted execution.

- **Code generation** -- Simulate the model by using generated C code. The first time you run a simulation, Simulink generates C code for the block. The C code is reused for subsequent simulations unless the model changes. This option requires additional startup time, but the speed of the subsequent simulations is faster than Interpreted execution.
- **Interpreted execution** -- Simulate the model by using the MATLAB interpreter. This option requires less startup time than the Code generation method, but the speed of subsequent simulations is slower. In this mode, you can debug the source code of the block.

Block Characteristics

Data Types	Boolean double integer single
Multidimensional Signals	no
Variable-Size Signals	no

More About

Sample Timing

The time between output updates is equal to the product of the **Samples per frame** and **Sample time** parameter values. For example, if **Sample time** and **Samples per frame** each equal 1, the block outputs a sample every second. If you increase **Samples per frame** to 10, then the block outputs a 10-by-1 vector every 10 seconds. This ensures that the equivalent output rate is not dependent on the **Samples per frame** parameter.

Compatibility Considerations

Bernoulli Binary Generator block update supported in Upgrade Advisor

Behavior changed in R2020a

Starting in R2020a, Bernoulli Binary Generator block allows you to use the Upgrade Advisor. You can update to the block version announced in R2015b or keep the block version available before R2015b.

- Use the Upgrade Advisor to update existing models that include the Bernoulli Binary Generator block.
- Behavior of the random number generator is changed. The statistics are improved. For more information, see “Source blocks output frames of contiguous time samples but do not use the frame attribute” in the R2015b Release Notes.

Binary Cyclic Decoder

Decode systematic cyclic code to recover binary vector data

Library

Block sublibrary of Error Detection and Correction

Description

The Binary Cyclic Decoder block recovers a message vector from a codeword vector of a binary systematic cyclic code. For proper decoding, the parameter values in this block should match those in the corresponding Binary Cyclic Encoder block.

This block accepts a column vector input signal containing N elements, where N is the codeword length. The output signal is a column vector containing K elements, where K is the message length of the cyclic code.

You can determine the systematic cyclic coding scheme in one of two ways:

- To create an $[N,K]$ code, enter N and K as the first and second dialog parameters, respectively. The block computes an appropriate generator polynomial, namely, `cyclpoly(N,K,'min')`.
- To create a code with codeword length N and a particular degree- $(N-K)$ binary *generator polynomial*, enter N as the first parameter and a polynomial character vector or a binary vector as the second parameter. The vector represents the generator polynomial by listing its coefficients in order of ascending exponents. You can create cyclic generator polynomials using the Communications Toolbox `cyclpoly` function.

For information about the data types each block port supports, see the “Supported Data Type” on page 5-54 table on this page.

Parameters

Codeword length N

The codeword length N , which is also the input vector length.

Message length K , or generator polynomial

Either the message length, which is also the input vector length, a polynomial character vector, or a binary vector that represents the generator polynomial for the code.

Binary Cyclic Encoder

Create systematic cyclic code from binary vector data

Library

Block sublibrary of Error Detection and Correction

Description

The Binary Cyclic Encoder block creates a systematic cyclic code with message length K and codeword length N .

This block accepts a column vector input signal containing K elements. The output signal is a column vector containing N elements.

You can determine the systematic cyclic coding scheme in one of two ways:

- To create an $[N,K]$ code, enter N and K as the first and second dialog parameters, respectively. The block computes an appropriate generator polynomial, namely, `cyclpoly(N,K,'min')`.
- To create a code with codeword length N and a particular degree- $(N-K)$ binary *generator polynomial*, enter N as the first parameter and a polynomial character vector or a binary vector as the second parameter. The vector represents the generator polynomial by listing its coefficients in order of ascending exponents. You can create cyclic generator polynomials using the Communications Toolbox `cyclpoly` function.

For information about the data types each block port supports, see the “Supported Data Type” on page 5-56 table on this page.

Parameters

Codeword length N

The codeword length, which is also the output vector length.

Message length K , or generator polynomial

Either the message length, which is also the input vector length, a polynomial character vector, or a binary vector that represents the generator polynomial for the code.

Binary-Input RS Encoder

Create Reed-Solomon code from binary vector data

Library: Communications Toolbox / Error Detection and Correction / Block

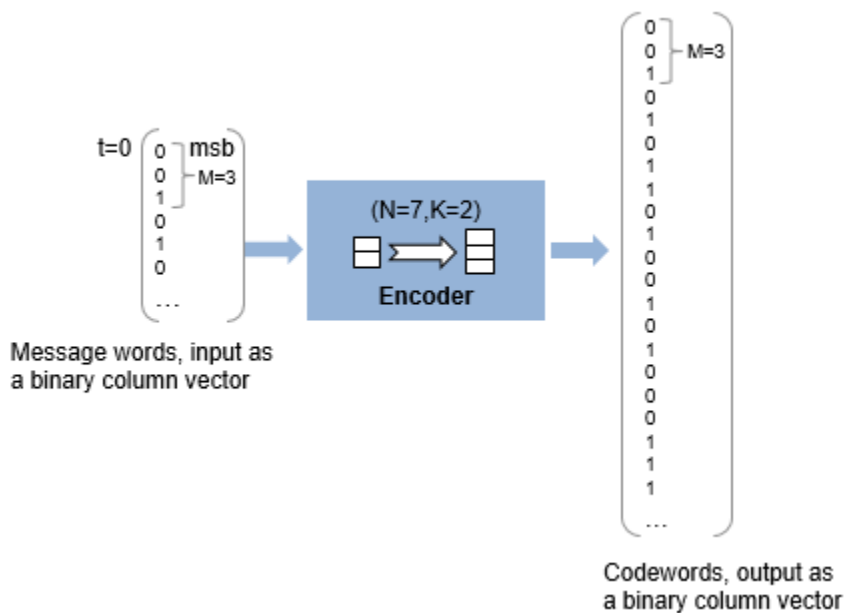

Description

The Binary-Input RS Encoder block creates a Reed-Solomon code.

The symbols for the code are binary sequences of length M , corresponding to elements of the Galois field $GF(2^M)$. The first bit in each symbol is the most significant bit.

Suppose $M = 3$, $N = 2^3 - 1 = 7$, and $K = 2$. Then a message is a vector of length 2 whose entries are integers between 0 and 7. A corresponding codeword is a vector of length 7 whose entries are integers between 0 and 7. The following figure illustrates possible input and output signals to this block when codeword length $N=7$ and message word length $K=2$. Since $N=2^M-1$, when $N=7$, the symbol length, $M=3$.

Each input message word is a binary vector of length 6, that represents 2 three-bit integers. Each corresponding output codeword is a binary vector of length 21 that represents 7 three-bit integers. For more information, see “Input and Output Signal Length in RS Blocks” on page 5-60.

Ports

Input

In — Message

binary column vector

Message in bits, specified as one of the following:

- When there is no message shortening, a $(N_C \times K \times M)$ -by-1 binary column vector.
- When there is message shortening, a $(N_C \times S \times M)$ -by-1 binary column vector.

N_C is the number of message words, K is the **Message length K (symbols)**, M is the number of bits per symbol, and S is the **Shortened message length S (symbols)**.

Note The number of decoded message words equals the number of codewords.

For more information, see “Input and Output Signal Length in RS Blocks” on page 5-60.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `ufix(1)`

Output

Out — Reed-Solomon codeword

binary column vector

Reed-Solomon codeword in bits, returned as an $(N_C \times (N - K + S - P) \times M)$ -by-1 binary column vector. N_C is the number of codewords, N is the **Codeword length N (symbols)**, K is the **Message length K (symbols)**, S is the **Shortened message length S (symbols)**, P is the number of punctures per codeword, and M is the number of bits per symbol.

For more information, see “Input and Output Signal Length in RS Blocks” on page 5-60.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `ufix(1)`

For more information, see “Supported Data Types” on page 5-62.

Parameters

Codeword length N (symbols) — Codeword length

7 (default) | integer

Codeword length in symbols, specified as an integer.

For more information, see “Restrictions on the M and the Codeword Length N” on page 5-61 and “Input and Output Signal Length in RS Blocks” on page 5-60.

Message length K (symbols) — Message word length

3 (default) | integer

Message word length in symbols, specified as an integer in the range $[1, N-2]$, where N is the codeword length.

Shortened message length S (symbols) – Shortened message word length

3 (default) | integer

Shortened message word length in symbols, specified as an integer, such that $S \leq K$. When **Shortened message length S (symbols) < Message length K (symbols)**, the Reed-Solomon code is shortened.

You still specify N and K values for the full-length (N, K) code but the decoding is shortened to an $(N - K + S, S)$ code.

Dependencies

To enable this parameter, select **Specify shortened message length**.

Generator polynomial – Generator polynomial
`rsgenpoly(7, 3, [], [], 'double')` (default) | polynomial character vector | binary row vector
| binary Galois row vector

Generator polynomial with values from 0 to $2^M - 1$, in order of descending power, specified as one of the following:

- A polynomial character vector. For more information, see “Representation of Polynomials in Communications Toolbox”.
- An integer row vector that represents the coefficients of the generator polynomial in order of descending power.
- An integer Galois row vector that represents the coefficients of the generator polynomial in order of descending power.

Each coefficient is an element of the Galois field defined by the primitive polynomial. For more information, see “Specify the Generator Polynomial” on page 5-61.

Example: `[1 3 1 2 3]`, which is equivalent to `rsgenpoly(7,3)`

Dependencies

To enable this parameter, select **Specify generator polynomial**.

Primitive polynomial – Primitive polynomial
`'X^3 + X + 1'` (default) | polynomial character vector | binary row vector

Primitive polynomial in order of descending power. This polynomial is of order M and defines the finite Galois field $GF(2^M)$ corresponding to the integers that form message words and codewords. Specify the primitive polynomial as one of the following:

- A polynomial character vector. For more information, see “Representation of Polynomials in Communications Toolbox”.
- A binary row vector that represents the coefficients of the generator polynomial.

For more information, see “Restrictions on the M and the Codeword Length N” on page 5-61.

Example: `'X^3 + X + 1'`, which is the primitive polynomial used for a (7,3) code, `ppoly = primpoly(3, 'nodisplay'); int2bit(ppoly, ceil(log2(max(ppoly))))'`

Dependencies

To enable this parameter, select **Specify primitive polynomial**.

Puncture vector – Puncture vector

[ones(2,1); zeros(2,1)] (default) | binary column vector

Puncture vector, specified as an $(N-K)$ -by-1 binary column vector. Element indices with 1s represent data symbol indices that pass through the block unaltered. Element indices with 0s represent data symbol indices that get punctured, or removed, from the data stream. For more information, see “Puncturing and Erasures” on page 5-62.

Dependencies

To enable this parameter, select **Puncture code**.

Output data type – Output type of the block

Same as input (default) | boolean | double

Output type of the block, specified as Same as input, boolean, or double.

Block Characteristics

Data Types	Boolean double fixed point ^a integer single
Multidimensional Signals	no
Variable-Size Signals	no

^a ufix(1) only.

More About**Input and Output Signal Length in RS Blocks**

The Reed-Solomon code has a message word length, K , or shortened message word length, S . The codeword length is $N - K + S - P$, where N is the full codeword length and P is the number of punctures per codeword. When there is no message shortening, the codeword length expression reduces to $N - P$, because $K = S$. If the decoder is processing multiple codewords per frame, then the same puncture pattern holds for all codewords.

This table provides expressions for the input and output signal lengths for the Reed-Solomon encoder and decoder.

The notation $y = N_C \times x$ denotes that y is an integer multiple of x .

	Input, Erasure, and Output Vector Lengths	
RS Block Coder	No Message Shortening Used	Message Shortening Used
Binary-Input RS Encoder	Input Length (bits): $N_C \times K \times M$ Output Length (bits): $N_C \times (N-P) \times M$	Input Length (bits): $N_C \times S \times M$ Output Length (bits): $N_C \times (N-K+S-P) \times M$

RS Block Coder	Input, Erasure, and Output Vector Lengths	
	No Message Shortening Used	Message Shortening Used
Binary-Output RS Decoder	Input Length (bits): $N_C \times (N-P) \times M$ Erasures Length (symbols): $N_C \times (N-P)$ Output Length (bits): $N_C \times K \times M$	Input Length (bits): $N_C \times (N-K+S-P) \times M$ Erasures Length (symbols): $N_C \times (N-K+S-P)$ Output Length (bits): $N_C \times S \times M$

- N is the codeword length.
- K is the message word length.
- S is the shortened message word length.
- N_C is the number of codewords (and message words).
- P is the number of punctures per codeword, and is equal to the number of zeros in the puncture vector.
- M is the degree of the primitive polynomial. Each group of M bits represents an integer between 0 and 2^M-1 that belongs to the finite Galois field $GF(2^M)$.

For more information on representing data for Reed-Solomon codes, see “Integer Format (Reed-Solomon Only)”.

Also, see “Restrictions on the M and the Codeword Length N ” on page 5-61.

Restrictions on the M and the Codeword Length N

- If you do not select **Specify primitive polynomial**, valid values for the codeword length, N , are from 7 to 65535. In this case, the block uses the default primitive polynomial of degree $M = \text{ceil}(\log_2(N+1))$. You can display the default primitive polynomial by running `primpoly(ceil(log2(N+1)))`.
- If you select **Specify primitive polynomial**, valid values for the primitive polynomial degree, M , are from 3 to 16. The valid values for N in this case are from 7 to 2^M-1 . Selecting **Specify primitive polynomial** enables you to specify the primitive polynomial that defines the finite field $GF(2^M)$, which corresponds to the values that form message words and codewords.

Specify the Generator Polynomial

Select **Specify generator polynomial** to enable the **Generator polynomial** parameter for specifying the generator polynomial of the Reed-Solomon code. Enter an integer row vector with element values from 0 to 2^M-1 . The vector represents a polynomial, in descending order of powers, whose coefficients are elements of $GF(2^M)$ represented in integer format. For more information about integer and binary format, see “Integer Format (Reed-Solomon Only)”. The generator polynomial must be equal to a polynomial with this factored form:

$$g(x) = (x+\alpha^b)(x+\alpha^{b+1})(x+\alpha^{b+2})\dots(x+\alpha^{b+N-K-1})$$

α is the primitive element of the Galois field over which the input message is defined, and b is an integer.

If you do not select **Specify generator polynomial**, the block uses the default generator polynomial, corresponding to $b=1$, for Reed-Solomon encoding. You can display the default generator polynomial by running `rsgenpoly`.

- If you are using the default primitive polynomial (**Specify primitive polynomial** is not selected), the default generator polynomial is `rsgenpoly(N,K)`, where $N = 2^M - 1$.
- If you are not using the default primitive polynomial (**Specify primitive polynomial** is selected) and you specify the primitive polynomial as `poly`, the generator polynomial is `rsgenpoly(N,K,poly)`.

Note The degree of the generator polynomial is $N - K$, where N is the codeword length and K is the message word length.

Puncturing and Erasures

1s and 0s have precisely opposite meanings for the puncture and erasure vectors.

In a puncture vector,

- 1 means that the data symbol is passed through the block unaltered.
- 0 means that the data symbol is to be punctured, or removed, from the data stream.

In an erasure vector,

- 1 means that the data symbol is to be replaced with an erasure symbol.
- 0 means that the data symbol is passed through the block unaltered.

These conventions apply to both the encoder and the decoder. For more information, see “Shortening, Puncturing, and Erasures”.

Binary Linear Decoder

Decode linear block code to recover binary vector data

Library

Block sublibrary of Error Detection and Correction

Description

The Binary Linear Decoder block recovers a binary message vector from a binary codeword vector of a linear block code.

The **Generator matrix** parameter is the generator matrix for the block code. For proper decoding, this should match the **Generator matrix** parameter in the corresponding Binary Linear Encoder block. If N is the codeword length of the code, then **Generator matrix** must have N columns. If K is the message length of the code, then the **Generator matrix** parameter must have K rows.

This block accepts a column vector input signal containing N elements. This block outputs a column vector with a length of K elements.

The decoder tries to correct errors, using the **Decoding table** parameter. If **Decoding table** is the scalar 0, then the block defaults to the table produced by the Communications Toolbox function `syndtable`. Otherwise, **Decoding table** must be a 2^{N-K} -by- N binary matrix. The r th row of this matrix is the correction vector for a received binary codeword whose syndrome has decimal integer value $r-1$. The syndrome of a received codeword is its product with the transpose of the parity-check matrix.

For information about the data types each block port supports, see the “Supported Data Type” on page 5-65 table on this page.

Parameters

Generator matrix

Generator matrix for the code; same as in Binary Linear Encoder block.

Decoding table

Either a 2^{N-K} -by- N matrix that lists correction vectors for each codeword's syndrome; or the scalar 0, in which case the block defaults to the table corresponding to the **Generator matrix** parameter.

Binary-Output RS Decoder

Decode Reed-Solomon code to recover binary vector data

Library: Communications Toolbox / Error Detection and Correction / Block

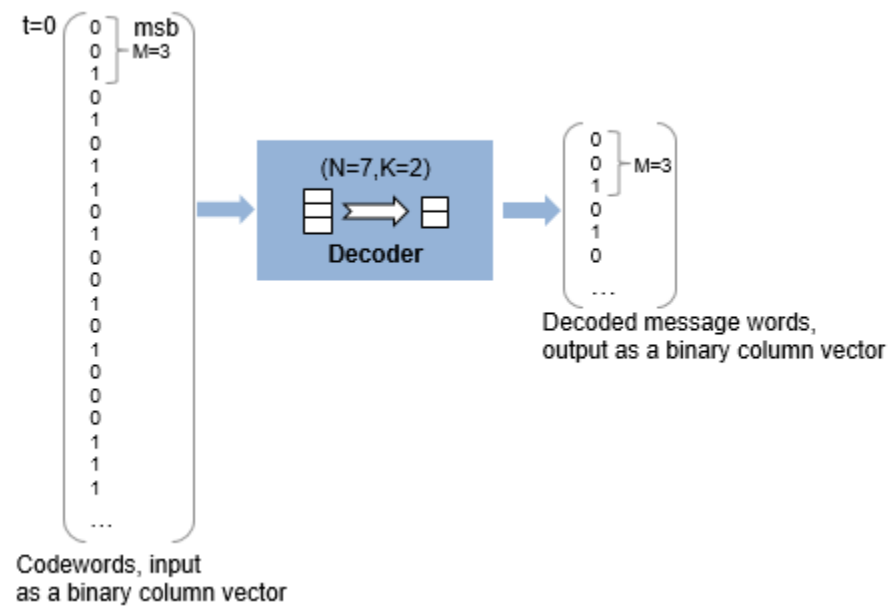

Description

The Binary-Output RS Decoder block recovers a binary message vector from a binary Reed-Solomon codeword vector. For proper decoding, the parameter values in this block must match parameter values in the corresponding Binary-Input RS Encoder block.

The symbols for the code are binary sequences of length M , corresponding to elements of the Galois field $GF(2^M)$. The first bit in each symbol is the most significant bit.

This figure shows the decoder input-output word length for codeword length $N=7$ and message word length $K=2$. Since $N=2^M-1$, when $N=7$, the symbol length, $M=3$.

Each input codeword is a binary vector of length 21 that represents 7 three-bit integers. Each corresponding output message word is a binary vector of length 6, that represents 2 three-bit integers. For more information, see “Input and Output Signal Length in RS Blocks” on page 5-72.

This icon shows all ports, including optional ones:

Ports

Input

In — Reed-Solomon codeword

binary column vector

Reed-Solomon codeword in bits, specified as an $(N_C \times (N - K + S - P) \times M)$ -by-1 binary column vector. N_C is the number of codewords, N is the **Codeword length N (symbols)**, K is the **Message length K (symbols)**, S is the **Shortened message length S (symbols)**, P is the number of punctures per codeword, and M is the number of bits per symbol.

For more information, see “Input and Output Signal Length in RS Blocks” on page 5-72.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `ufix(1)`

Era — Erasure vector

binary column vector

Erasure vector in symbols, specified as an $(N_C \times (N - K + S - P))$ -by-1 binary column vector. N_C is the number of codewords, N is the **Codeword length N (symbols)**, K is the **Message length K (symbols)**, S is the **Shortened message length S (symbols)**, P is the number of punctures per codeword, and M is the number of bits per symbol.

Erasure values of 1 correspond to erased bits in the same position in the codeword. Values of 0 correspond to bits that are not erased. For more information, see “Puncturing and Erasures” on page 5-74.

Dependencies

To enable this port, select **Enable erasures input port**.

Data Types: `double` | `Boolean`

Output

Out — Decoded message

binary column vector

Decoded message in bits, returned as one of the following:

- When there is no message shortening, a $(N_C \times K \times M)$ -by-1 binary column vector.
- When there is message shortening, a $(N_C \times S \times M)$ -by-1 binary column vector.

N_C is the number of message words, K is the **Message length K (symbols)**, M is the number of bits per symbol, and S is the **Shortened message length S (symbols)**.

Note The number of decoded message words equals the number of codewords.

For more information, see “Input and Output Signal Length in RS Blocks” on page 5-72.

Data Types: single | double | int8 | int16 | int32 | uint8 | uint16 | uint32 | Boolean | ufix(1)

Err — Decoding errors

integer vector

Symbol decoding errors, returned as an integer vector with N_C elements, where N_C is the number of codewords. This port indicates the number of symbol errors detected during decoding of each codeword. A negative integer indicates that the block detected more errors than it could correct by using the specified coding scheme.

Note An (N,K) Reed-Solomon code can correct up to $\text{floor}((N-K)/2)$ symbol errors (not bit errors) in each codeword. When a received codeword contains more than $(N-K)/2$ symbol errors, a decoding failure occurs.

Dependencies

To enable this port, select **Output number of corrected symbol errors**.

Data Types: double

For more information, see “Supported Data Types” on page 5-74.

Parameters

Codeword length N (symbols) — Codeword length

7 (default) | integer

Codeword length in symbols, specified as an integer.

For more information, see “Restrictions on M and Codeword Length N” on page 5-73 and “Input and Output Signal Length in RS Blocks” on page 5-72.

Message length K (symbols) — Message word length

3 (default) | integer

Message word length in symbols, specified as an integer in the range $[1, N-2]$, where N is the codeword length.

Shortened message length S (symbols) — Shortened message word length

3 (default) | integer

Shortened message word length in symbols, specified as an integer, such that $S \leq K$. When **Shortened message length S (symbols) < Message length K (symbols)**, the Reed-Solomon code is shortened.

You still specify N and K values for the full-length (N, K) code but the decoding is shortened to an $(N-K+S, S)$ code.

Dependencies

To enable this parameter, select **Specify shortened message length**.

Generator polynomial — Generator polynomial

`rsgenpoly(7, 3, [], [], 'double')` (default) | polynomial character vector | binary row vector
| binary Galois row vector

Generator polynomial with values from 0 to 2^M-1 , in order of descending power, specified as one of the following:

- A polynomial character vector. For more information, see “Representation of Polynomials in Communications Toolbox”.
- An integer row vector that represents the coefficients of the generator polynomial in order of descending power.
- An integer Galois row vector that represents the coefficients of the generator polynomial in order of descending power.

Each coefficient is an element of the Galois field defined by the primitive polynomial. For more information, see “Specify the Generator Polynomial” on page 5-73.

Example: `[1 3 1 2 3]`, which is equivalent to `rsgenpoly(7,3)`

Dependencies

To enable this parameter, select **Specify generator polynomial**.

Primitive polynomial — Primitive polynomial

`'X^3 + X + 1'` (default) | polynomial character vector | binary row vector

Primitive polynomial in order of descending power. This polynomial is of order M and defines the finite Galois field $GF(2^M)$ corresponding to the integers that form message words and codewords. Specify the primitive polynomial as one of the following:

- A polynomial character vector. For more information, see “Representation of Polynomials in Communications Toolbox”.
- A binary row vector that represents the coefficients of the generator polynomial.

For more information, see “Restrictions on M and Codeword Length N ” on page 5-73.

Example: `'X^3 + X + 1'`, which is the primitive polynomial used for a (7,3) code, `ppoly = primpoly(3, 'nodisplay'); int2bit(ppoly, ceil(log2(max(ppoly))))'`

Dependencies

To enable this parameter, select **Specify primitive polynomial**.

Puncture vector — Puncture vector

`[ones(2,1); zeros(2,1)]` (default) | binary column vector

Puncture vector, specified as an $(N-K)$ -by-1 binary column vector. Element indices with 1s represent data symbol indices that pass through the block unaltered. Element indices with 0s represent data symbol indices that get punctured, or removed, from the data stream. For more information, see “Puncturing and Erasures” on page 5-74.

Dependencies

To enable this parameter, select **Punctured code**.

Enable erasures input port — Enable erasures input port

off (default) | on

Selecting this check box enables the erasures port, **Era**. For more information, see “Puncturing and Erasures” on page 5-74.

Output number of corrected symbol errors — Enable port to output number of corrected symbol errors

off (default) | on

Selecting this check box enables an additional output port, **Err**, which indicates the number of symbol errors the block corrected in the input codeword.

Output data type — Output type of the block

Same as input (default) | boolean | double

Output type of the block, specified as Same as input, boolean, or double.

Block Characteristics

Data Types	Boolean double fixed point ^a integer single
Multidimensional Signals	no
Variable-Size Signals	no

^a ufix(1) only.

More About**Input and Output Signal Length in RS Blocks**

The Reed-Solomon code has a message word length, K , or shortened message word length, S . The codeword length is $N - K + S - P$, where N is the full codeword length and P is the number of punctures per codeword. When there is no message shortening, the codeword length expression reduces to $N - P$, because $K = S$. If the decoder is processing multiple codewords per frame, then the same puncture pattern holds for all codewords.

This table provides expressions for the input and output signal lengths for the Reed-Solomon encoder and decoder.

The notation $y = N_C \times x$ denotes that y is an integer multiple of x .

	Input, Erasure, and Output Vector Lengths	
RS Block Coder	No Message Shortening Used	Message Shortening Used
Binary-Input RS Encoder	Input Length (bits): $N_C \times K \times M$ Output Length (bits): $N_C \times (N-P) \times M$	Input Length (bits): $N_C \times S \times M$ Output Length (bits): $N_C \times (N-K+S-P) \times M$
Binary-Output RS Decoder	Input Length (bits): $N_C \times (N-P) \times M$ Erasures Length (symbols): $N_C \times (N-P)$ Output Length (bits): $N_C \times K \times M$	Input Length (bits): $N_C \times (N-K+S-P) \times M$ Erasures Length (symbols): $N_C \times (N-K+S-P)$ Output Length (bits): $N_C \times S \times M$

- N is the codeword length.
- K is the message word length.
- S is the shortened message word length.
- N_C is the number of codewords (and message words).
- P is the number of punctures per codeword, and is equal to the number of zeros in the puncture vector.
- M is the degree of the primitive polynomial. Each group of M bits represents an integer between 0 and 2^M-1 that belongs to the finite Galois field $GF(2^M)$.

For more information on representing data for Reed-Solomon codes, see “Integer Format (Reed-Solomon Only)”.

Also, see “Restrictions on M and Codeword Length N ” on page 5-73.

Restrictions on M and Codeword Length N

- If you do not select **Specify primitive polynomial**, valid values for the codeword length, N , are from 7 to 65535. In this case, the block uses the default primitive polynomial of degree $M = \text{ceil}(\log_2(N+1))$. You can display the default primitive polynomial by running `primpoly(ceil(log2(N+1)))`.
- If you select **Specify primitive polynomial**, valid values for the primitive polynomial degree, M , are from 3 to 16. The valid values for N in this case are from 7 to 2^M-1 . Selecting **Specify primitive polynomial** enables you to specify the primitive polynomial that defines the finite field $GF(2^M)$, which corresponds to the values that form message words and codewords.

Specify the Generator Polynomial

Select **Specify generator polynomial** to enable the **Generator polynomial** parameter for specifying the generator polynomial of the Reed-Solomon code. Enter an integer row vector with element values from 0 to 2^M-1 . The vector represents a polynomial, in descending order of powers,

whose coefficients are elements of $GF(2^M)$ represented in integer format. For more information about integer and binary format, see “Integer Format (Reed-Solomon Only)”. The generator polynomial must be equal to a polynomial with this factored form:

$$g(x) = (x+\alpha^b)(x+\alpha^{b+1})(x+\alpha^{b+2})\dots(x+\alpha^{b+N-K-1})$$

α is the primitive element of the Galois field over which the input message is defined, and b is an integer.

If you do not select **Specify generator polynomial**, the block uses the default generator polynomial, corresponding to $b=1$, for Reed-Solomon encoding. You can display the default generator polynomial by running `rsgenpoly`.

- If you are using the default primitive polynomial (**Specify primitive polynomial** is not selected), the default generator polynomial is `rsgenpoly(N,K)`, where $N = 2^M - 1$.
- If you are not using the default primitive polynomial (**Specify primitive polynomial** is selected) and you specify the primitive polynomial as `poly`, the generator polynomial is `rsgenpoly(N,K,poly)`.

Note The degree of the generator polynomial is $N - K$, where N is the codeword length and K is the message word length.

Puncturing and Erasures

1s and 0s have precisely opposite meanings for the puncture and erasure vectors.

In a puncture vector,

- 1 means that the data symbol is passed through the block unaltered.
- 0 means that the data symbol is to be punctured, or removed, from the data stream.

In an erasure vector,

- 1 means that the data symbol is to be replaced with an erasure symbol.
- 0 means that the data symbol is passed through the block unaltered.

These conventions apply to both the encoder and the decoder. For more information, see “Shortening, Puncturing, and Erasures”.

Introduced before R2006a

Binary Symmetric Channel

Introduce binary errors

Library: Communications Toolbox / Channels

Description

The Binary Symmetric Channel block introduces errors to the input signal transmitted through a binary symmetric channel. The errors are introduced based on the specified Error probability. For more information, see “Tips” on page 5-77.

Ports

Input

Input — Input signal

column vector | matrix

Input signal, specified as a column vector or an N_S -by- N_C matrix of `Boolean` values. N_S is the number of samples per channel. N_C is the number of independent data channels. For more information, see “Tips” on page 5-77.

Output

Output — Binary output signal

column vector | matrix

Binary output signal, returned as a column vector or matrix with the same dimensions as `Input`. The output signal is a version of the input signal that has been modified by introducing random errors based on the specified Error probability. To set the output data type, use Output data type.

Err — Error locations

column vector | matrix

Error locations, returned as a column vector or matrix with the same dimensions as `Input`. Element values in `Err` are 1 or 0, where:

- 1 indicates that the corresponding element in `Output` has an error.
- 0 indicates that the corresponding element in `Output` does not have an error.

The data type of `Err` is the same as `Output`, as set by Output data type.

Dependencies

To enable this port, select Output error vector.

Parameters

Error probability — Probability of error occurrence

0.05 (default) | scalar

Probability of error occurrence for the input signal elements, specified as a scalar in the range [0,1]. The probability of error applies independently for each element.

Output error vector — Option to output error locations

on (default) | off

To enable the Err output port to the block, select this parameter.

Output data type — Output data type

double (default) | single | boolean

Select the output data type as double, single, or boolean. This parameter sets the output data type for both the **Output** and **Err** ports.

Initial seed — Initial seed

71 (default) | integer

Initial seed value for the random number generator used by the block, specified as an integer. The block uses the mt19937ar algorithm to generate uniformly distributed random numbers. For details about the mt19937ar algorithm, see “Creating and Controlling a Random Number Stream”.

Simulate using — Type of simulation to run

Code generation (default) | Interpreted execution

Type of simulation to run, specified as:

- **Code generation** -- Simulate the model using generated C code. The first time you run a simulation, Simulink generates C code for the block. The C code is reused for subsequent simulations as long as the model does not change. This option requires additional startup time.
- **Interpreted execution** -- Simulate the model using the MATLAB interpreter. This option shortens startup time. In Interpreted execution mode, you can debug the source code of the block.

Block Characteristics

Data Types	Boolean double fixed point integer single
Multidimensional Signals	no
Variable-Size Signals	no

Tips

- When the input consists of not Boolean values, Binary Symmetric Channel converts zero-valued elements to 0 and converts nonzero-valued elements to 1.
- The Binary Symmetric Channel block creates and uses an independent RandStream to provide a random number stream for probability determination.

- To generate repeatable results, use the same Initial seed value.
- To generate independent probability statistics, set different Initial seed values for multichannel signals, multiple processing chains, or simulation runs.

Compatibility Considerations

Random Number Generation

Behavior changed in R2018b

To improve statistical properties, the Binary Symmetric Channel block uses the `mt19937ar` algorithm with `RandStream`. The Binary Symmetric Channel block accepts a single scalar value for the Initial seed parameter.

Bipolar to Unipolar Converter

Map bipolar signal into unipolar signal in range [0, M-1]

Library

Utility Blocks

Description

The Bipolar to Unipolar Converter block maps the bipolar input signal to a unipolar output signal. If the input consists of integers in the set $\{-M+1, -M+3, -M+5, \dots, M-1\}$, where M is the **M-ary number** parameter, then the output consists of integers between 0 and $M-1$. This block is only designed to work when the input value is within the set $\{-M+1, -M+3, -M+5, \dots, M-1\}$, where M is the **M-ary number** parameter. If the input value is outside of this set of integers the output may not be valid.

The table below shows how the block's mapping depends on the **Polarity** parameter.

Polarity Parameter Value	Output Corresponding to Input Value of k
Positive	$(M-1+k)/2$
Negative	$(M-1-k)/2$

Parameters

M-ary number

The number of symbols in the bipolar or unipolar alphabet.

Polarity

A value of **Positive** causes the block to maintain the relative ordering of symbols in the alphabets. A value of **Negative** causes the block to reverse the relative ordering of symbols in the alphabets.

Output Data Type

The type of bipolar signal produced at the block's output.

The block supports the following output data types:

- Inherit via internal rule
- Same as input
- double
- int8
- uint8
- int16

- uint16
- int32
- uint32
- boolean

When the parameter is set to its default setting, `Inherit via internal rule`, the block determines the output data type based on the input data type.

- If the input signal is floating-point (either `single` or `double`), the output data type is the same as the input data type.
- If the input data type is not floating-point:
 - Based on the **M-ary number** parameter, the output data type is the ideal unsigned integer output word length required to contain the range $[0\ M-1]$ and is computed as follows:
$$\text{ideal word length} = \text{ceil}(\log_2(M))$$
 - The block sets the output data type to be an unsigned integer, based on the smallest word length (in bits) that can fit best the computed ideal word length.

Note The selections in the “Hardware Implementation Pane” (Simulink) pane pertaining to word length constraints do not affect how this block determines output data types.

Examples

If the input is `[-3; -1; 1; 3]`, the **M-ary number** parameter is 4, and the **Polarity** parameter is **Positive**, then the output is `[0; 1; 2; 3]`. Changing the **Polarity** parameter to **Negative** changes the output to `[3; 2; 1; 0]`.

If the value for the **M-ary number** is 2^8 the block gives an output of `uint8`.

If the value for the **M-ary number** is 2^8+1 the block gives an output of `uint16`.

BPSK Demodulator Baseband

Demodulate BPSK-modulated data

Library: Communications Toolbox / Modulation / Digital Baseband
Modulation / PM
Communications Toolbox HDL Support / Modulation / PM

Description

The BPSK Demodulator Baseband block demodulates a signal that was modulated using the binary phase shift keying method. The input is a baseband representation of the modulated signal. This block accepts a scalar or column vector input signal. The input signal must be a discrete-time complex signal. The block maps the points $\exp(j\theta)$ or $-\exp(j\theta)$ to 0 and 1, respectively. The `Phase offset` (rad) parameter specifies the value of θ .

Ports

Input

In — BPSK-modulated signal

scalar | vector | matrix

BPSK-modulated signal, specified as a scalar, vector, or matrix. When this input is a matrix, each column is treated as an independent channel. This port is unnamed until the `Var` port is enabled. When the noise variance or signal power result in computations involving extreme positive or negative magnitudes, see “BPSK Soft Demodulation” on page 5-85 for demodulation decision type considerations.

Data Types: double | single | fixed point

Complex Number Support: Yes

Var — Noise Variance

positive scalar | vector of positive values

Noise variance, specified as a positive scalar or vector of positive values. When the noise variance or signal power result in computations involving extreme positive or negative magnitudes, see “BPSK Soft Demodulation” on page 5-85 for demodulation decision type considerations.

Dependencies

To enable this parameter, set the **Noise variance source** parameter to `Port`.

Data Types: double

Output

Out — Demodulated signal

scalar | vector

Demodulated signal, returned as a scalar or vector. If the output is a scalar, the value is an integer. If the output is a vector, it is an integer-valued or binary-valued vector.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean`

Parameters

Main

Decision type — Decision type

`Hard decision` (default) | `Log-likelihood ratio` | `Approximate log-likelihood ratio`

Decision type used during demodulation, specified as `Hard decision`, `Log-likelihood ratio` or `Approximate log-likelihood ratio`. For algorithm details, see the “Exact LLR Algorithm” and “Approximate LLR Algorithm” topics.

The output matches the data type of the input values when **Decision type** is set to `Log-likelihood ratio` or `Approximate log-likelihood ratio`.

Noise variance source — Noise variance source

`Dialog` (default) | `Port`

Noise variance source, specified as `Dialog` or `Port`.

- `Dialog` — The noise variance is set using the `Noise variance` parameter.
- `Port` — The noise variance is set using the `Var` input port.

Noise variance — Noise Variance

`1` (default) | `positive scalar` | `vector of positive values`

Noise variance, specified as a positive scalar or vector of positive values.

- When specified as a scalar, that value is used on all elements in the input signal.
- When specified as a vector, the vector length must be equal to the number of columns in the input signal. Each noise variance vector element is applied to its corresponding column in the input signal.

When the noise variance or signal power result in computations involving extreme positive or negative magnitudes, see “BPSK Soft Demodulation” on page 5-85 for demodulation decision type considerations.

This parameter is tunable in normal mode, accelerator mode and rapid accelerator mode. If you use the Simulink Coder rapid simulation (RSIM) target to build an RSIM executable, then you can tune the parameter without recompiling the model. This is useful for Monte Carlo simulations, in which you run the simulation multiple times (perhaps on multiple computers) with different amounts of noise.

Tunable: Yes

Dependencies

To enable this parameter, set the `Decision type` parameter to set to either `Log-likelihood ratio` or `Approximate log-likelihood ratio` and set the **Noise variance source** parameter to `Dialog`.

Phase offset (rad) — Phase of zeroth point

0 (default) | real-valued scalar

Phase of the zeroth point, specified as a real-valued scalar. Units are in radians.

Example: $\pi/4$

Data Types**Output data type — Output data type**

Inherit via internal rule (default) | Smallest unsigned integer | double | single | ...

Output data type, specified as one of these options

- When you set the **Decision type** parameter to **Hard decision**:
 - **Inherit via internal rule** — The block inherits the output data type from the input port. If the input is a floating-point type (**single** or **double**), the output data type is the same as the input data type. If the input data type is fixed-point, the output data type works as if you set this parameter to **Smallest unsigned integer**.
 - **Smallest unsigned integer** — The block selects the output data type based on the settings used in the **Hardware Implementation** pane of the Configuration Parameters dialog box of the model. If you select ASIC/FPGA in the **Hardware Implementation** pane, the output data type is the ideal minimum one-bit size, that is, **ufix(1)**. For all other selections, the output data type is an unsigned integer with the smallest available word length large enough to fit one bit, usually corresponding to the size of a character (for example, **uint8**).
 - **double**
 - **single**
 - **int8**
 - **uint8**
 - **int16**
 - **uint16**
 - **int32**
 - **uint32**
 - **boolean**
- When you set the **Decision type** parameter to **Log-likelihood ratio** or **Approximate log-likelihood ratio** — The block inherits the output data type matches the data type of the input.

Derotate factor — Derotate factor

Same word length as input (default) | Specify word length

Derotate factor, specified as Same word length as input or Specify word length.

Dependencies

This parameter applies only when the input is fixed-point and the **Phase offset (rad)** parameter is not a multiple of $\pi/2$.

Block Characteristics

Data Types	Boolean double fixed point ^{a, b} integer single
Multidimensional Signals	no
Variable-Size Signals	yes

a Fixed-point inputs must be signed.

b ufix(1) only at the output when ASIC/FPGA is selected in the Hardware Implementation Pane.

More About

BPSK Hard-Decision Demodulation

When applying hard demodulation, the input signal type and phase offset are considered.

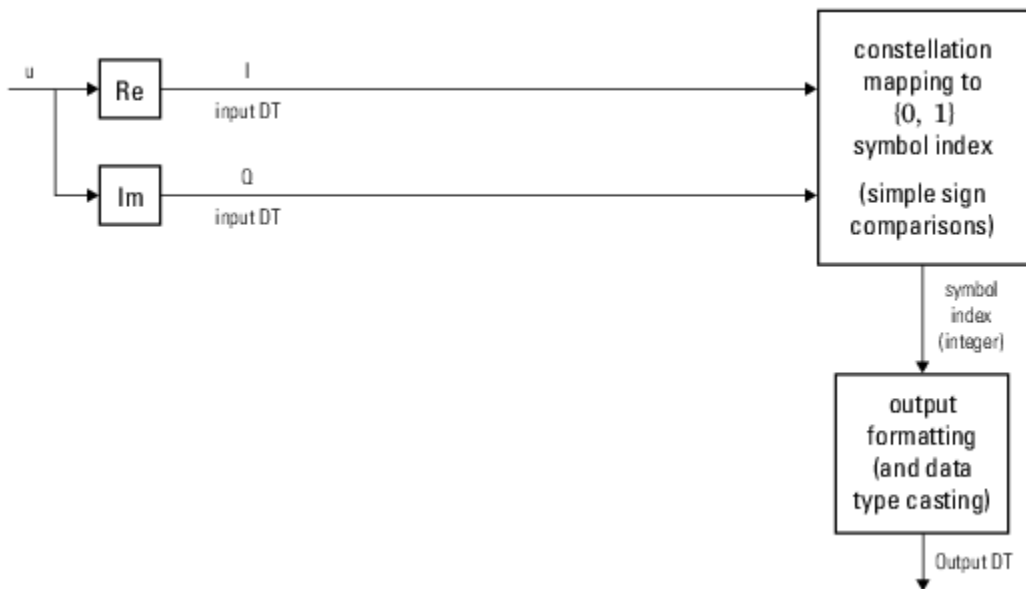

This figure shows the hard decision BPSK demodulator for a floating-point or fixed-point signal and trivial phase offset (multiple of $\pi/2$)

This figure shows the hard decision BPSK demodulator for a floating-point signal and nontrivial phase offset

This figure shows the hard decision BPSK demodulator for a fixed-point signal and nontrivial phase offset

BPSK Soft Demodulation

For soft demodulation, two soft-decision log-likelihood ratio (LLR) algorithms are available: exact LLR and approximate LLR. The exact LLR algorithm is more accurate but has slower execution speed than the approximate LLR algorithm. For further description of these algorithms, see the “Soft-Decision Demodulation” topic.

Note The exact LLR algorithm computes exponentials using finite precision arithmetic. For computations involving very large positive or negative magnitudes, the exact LLR algorithm yields:

- Inf or -Inf if the noise variance is a very large value
- NaN if the noise variance and signal power are both very small values

The approximate LLR algorithm does not compute exponentials. You can avoid Inf, -Inf, and NaN results by using the approximate LLR algorithm.

BPSK Modulator Baseband

Modulate using BPSK method

Library: Communications Toolbox / Modulation / Digital Baseband
Modulation / PM
Communications Toolbox HDL Support / Modulation / PM

Description

The BPSK Modulator Baseband block modulates a signal by using the binary phase shift keying (BPSK) method. The output is a baseband representation of the modulated signal. The input signal must be a discrete-time binary-valued signal. If the input bit is 0 or 1, then the modulated symbol is $\exp(j\theta)$ or $-\exp(j\theta)$, respectively. The Phase offset (rad) parameter specifies the value of θ in radians.

Ports

Input

In — Input data

scalar | vector

Input signal, specified as a scalar or vector with element values in the range $[0, M - 1]$, where M is the modulation order. If you specify a binary vector, the number of elements must be an integer multiple of the number of bits per symbol. The number of bits per symbol is equal to $\log_2(M)$.

Data Types: single | double | int8 | int16 | int32 | uint8 | uint16 | uint32 | Boolean

Output

Out — BPSK-modulated baseband signal

scalar | vector

BPSK-modulated baseband signal, returned as a complex-valued scalar or vector.

Data Types: single | double | fixed point

Parameters

Main

Phase offset (rad) — Phase offset of zeroth point

0 (default) | scalar

Phase offset of the zeroth point of the constellation in radians, specified as a scalar.

Example: `pi/4`

Data Types

Output data type — Output data type

double (default) | single | Inherit via back propagation | fixdt(1,16) | fixdt(1,16,0) | <data type expression>

Output data type, specified as one of these options.

- double
- single
- Inherit via back propagation — The block matches the output data type and scaling to the next block in the model
- fixdt(1,16)
- fixdt(1,16,0)
- <data type expression> — Enables parameters for which you specify additional details

Block Characteristics

Data Types	Boolean double fixed point ^{a, b} integer single
Multidimensional Signals	no
Variable-Size Signals	yes

^a $\text{ufix}(\text{ceil}(\log_2(M)))$ only at the input for M-ary modulation.

^b Fixed-point outputs must be signed.

More About

Constellation Visualization

Click **View Constellation** on the block mask to visualize a signal constellation for the specified block parameters. Parameter settings must be applied before viewing a constellation. For more information, see “View Constellation of Modulator Block”.

Algorithms

Phase modulation is a linear baseband modulation technique in which the message modulates the phase of a constant amplitude signal. Binary Phase Shift Keying (BPSK) is a two phase modulation scheme, where the 0's and 1's in a binary message are represented by two different phase states in the carrier signal

$$s_n(t) = \sqrt{\frac{2E_b}{T_b}} \cos(2\pi f_c t + \phi_n),$$

for $(n-1)T_b \leq t \leq nT_b$, $n = 1, 2, 3, \dots$ where:

- $\phi_n = \pi m$, $m \in \{0, 1\}$.
- E_b is the energy per bit.
- T_b is the bit duration.

- f_c is the carrier frequency.

In MATLAB, the baseband representation of a BPSK signal is

$$s_n(t) = e^{-i\phi_n} = \cos(\pi n).$$

The BPSK signal has two phases: 0 and π . The probability of a bit error in an AWGN channel is

$$P_b = Q\left(\sqrt{\frac{2E_b}{N_0}}\right),$$

where N_0 is the noise power spectral density.

Carrier Synchronizer

Compensate for carrier frequency offset

Library

Synchronization

Description

The Carrier Synchronizer block compensates for carrier frequency and phase offsets using a closed-loop approach for BPSK, QPSK, OQPSK, 8-PSK, QAM, and PAM modulation schemes. The block accepts a single input port. To obtain an estimate of the phase error in radians, select the **Estimated phase error output port** check box. The block accepts a sample- or frame-based complex input signal and returns a complex output signal and a real phase estimate. The block outputs have the same dimensions as the input.

Note

- This block does not resolve phase ambiguities created by the synchronization algorithm. As indicated in this table, the potential phase ambiguity introduced by the synchronizer depends on the modulation type:

Modulation	Phase Ambiguity (degrees)
'BPSK' or 'PAM'	0, 180
'OQPSK', 'QPSK', or 'QAM'	0, 90, 180, 270
'8PSK'	0, 45, 90, 135, 180, 225, 270, 315

- For best results, apply carrier synchronization to non-oversampled signals.

Parameters

Modulation

Specify the modulation type as BPSK, QPSK, OQPSK, 8PSK, QAM, or PAM.

Modulation phase offset

Specify the method used to calculate the modulation phase offset as either Auto or Custom.

- Auto applies the traditional offset for the specified modulation type.

Modulation	Phase Offset (radians)
BPSK, QAM, or PAM	0
QPSK or OQPSK	$\pi/4$
8PSK	$\pi/8$

- Custom enables the **Custom phase offset (radians)** parameter.

Custom phase offset (radians)

Specify the phase offset in radians as a real scalar. This parameter is available only when **Modulation phase offset** is set to Custom.

Samples per symbol

Specify the number of samples per symbol as a positive integer scalar.

Damping factor

Specify the damping factor of the loop as a positive real finite scalar.

Normalized loop bandwidth

Specify the normalized loop bandwidth as a real scalar between 0 and 1. The bandwidth is normalized by the sample rate of the carrier synchronizer block.

Estimated phase error output port

Select this check box to provide the estimated phase error to an output port.

Simulate using

Select the simulation mode.

Code generation

On the first model run, simulate and generate code for the block using only MATLAB functions supported for code generation. If the structure of the block does not change, subsequent model runs do not regenerate the code.

Interpreted execution

Simulate model using all supported MATLAB functions. Choosing this option can slow simulation performance.

Algorithms

This block implements the algorithm, inputs, and outputs described on the `comm.CarrierSynchronizer` reference page. The object properties correspond to the block parameters.

Examples

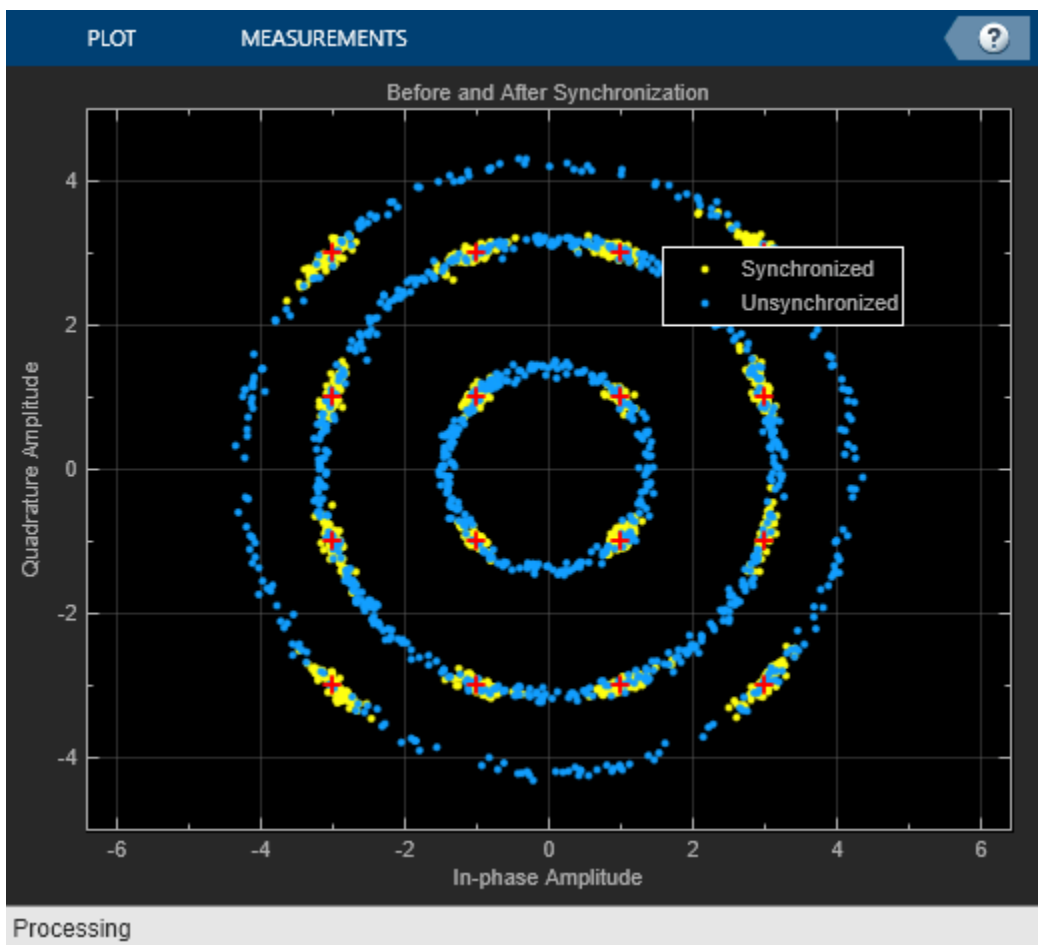

Correct for Frequency and Phase Offset

Correct for a phase and frequency offset imposed on a noisy 16-QAM channel by using the Carrier Synchronizer block.

The `doc_qamcarriersync` model configures a 16-QAM signal, filters the signal through a noisy AWGN channel, adds phase and frequency offset, and then corrects the offsets by using the Carrier Synchronizer block.

The constellation diagram shows the signal constellation before and after carrier synchronization. Before synchronization, the signal appears as a spiral pattern that results from a phase and frequency offset. After the carrier synchronizer converges to a solution, the signal symbols are grouped around the reference constellation.

Experiment with the parameters in the Phase/Frequency Offset and Carrier Synchronizer blocks. By varying these parameters, you can change how quickly the output conforms to an ideal 16-QAM

constellation. If the signal does not converge to the expected constellation, additional measures can be taken to achieve successful recovery.

Supported Data Types

Port	Supported Data Types
Signal Input	<ul style="list-style-type: none"> • Double-precision floating point • Single-precision floating point
Signal Output	<ul style="list-style-type: none"> • Double-precision floating point • Single-precision floating point
Phase Error Estimate	<ul style="list-style-type: none"> • Double-precision floating point • Single-precision floating point

Charge Pump PLL

(To be removed) Implement charge pump phase-locked loop using digital phase detector

Note will be removed in a future release. To design voltage-controlled oscillators (VCOs) and phase-locked loops (PLLs), use the “Phase-Locked Loops” (Mixed-Signal Blockset) blocks.

Library

Components sublibrary of Synchronization

Description

The Charge Pump PLL (phase-locked loop) block automatically adjusts the phase of a locally generated signal to match the phase of an input signal. It is suitable for use with digital signals.

This PLL has these three components:

- A sequential logic phase detector, also called a digital phase detector or a phase/frequency detector.
- A filter. You specify the filter transfer function using the **Lowpass filter numerator** and **Lowpass filter denominator** parameters. Each is a vector that gives the respective polynomial's coefficients in order of descending powers of s .

To design a filter, use functions such as `butter`, `cheby1`, and `cheby2` in Signal Processing Toolbox software. The default filter is a Chebyshev type II filter whose transfer function arises from the command below.

```
[num, den] = cheby2(3,40,100,'s')
```

- A voltage-controlled oscillator (VCO). You specify characteristics of the VCO using the **VCO input sensitivity**, **VCO quiescent frequency**, **VCO initial phase**, and **VCO output amplitude** parameters.

This block accepts a sample-based scalar input signal. The input signal represents the received signal. The three output ports produce:

- The output of the filter
- The output of the phase detector
- The output of the VCO

A sequential logic phase detector operates on the zero crossings of the signal waveform. The equilibrium point of the phase difference between the input signal and the VCO signal equals π . The sequential logic detector can compensate for any frequency difference that might exist between a VCO and an incoming signal frequency. Hence, the sequential logic phase detector acts as a frequency detector.

For more information, “Phase-Locked Loops”.

Parameters

Lowpass filter numerator

The numerator of the lowpass filter transfer function, represented as a vector that lists the coefficients in order of descending powers of s .

Lowpass filter denominator

The denominator of the lowpass filter transfer function, represented as a vector that lists the coefficients in order of descending powers of s .

VCO input sensitivity (Hz/V)

This value scales the input to the VCO and, consequently, the shift from the **VCO quiescent frequency** value. The units of **VCO input sensitivity** are Hertz per volt.

VCO quiescent frequency (Hz)

The frequency of the VCO signal when the voltage applied to it is zero. This should match the frequency of the input signal.

VCO initial phase (rad)

The initial phase of the VCO signal.

VCO output amplitude

The amplitude of the VCO signal.

CMA Equalizer

(Removed) Equalize using constant modulus algorithm

Note has been removed. Use Linear Equalizer instead.

Library

Equalizers

Description

The CMA Equalizer block uses a linear equalizer and the constant modulus algorithm (CMA) to equalize a linearly modulated baseband signal through a dispersive channel. During the simulation, the block uses the CMA to update the weights, once per symbol. If the **Number of samples per symbol** parameter is 1, then the block implements a symbol-spaced equalizer; otherwise, the block implements a fractionally spaced equalizer.

When using this block, you should initialize the equalizer weights with a nonzero vector. Typically, CMA is used with differential modulation; otherwise, the initial weights are very important. A typical vector of initial weights has a 1 corresponding to the center tap and zeros elsewhere.

Input and Output Signals

The **Input** port accepts a scalar-valued or column vector input signal. The **Desired** port receives a training sequence with a length that is less than or equal to the number of symbols in the **Input** signal.

You can configure the block to have one or more of the extra ports listed in the table below.

Port	Meaning	How to Enable
Err output	$y(R - y ^2)$, where y is the equalized signal and R is a constant related to the signal constellation	Select Output error .
Wts output	A vector listing the weights after the block has processed either the current input frame or sample.	Select Output weights .

Algorithms

Referring to the schematics in “Adaptive Equalizers”, define w as the vector of all weights w_i and define u as the vector of all inputs u_i . Based on the current set of weights, w , this adaptive algorithm creates the new set of weights given by

$$(\text{LeakageFactor}) w + (\text{StepSize}) u^*e$$

where the $*$ operator denotes the complex conjugate.

Equalizer Delay

The delay between the transmitter's modulator output and the CMA equalizer output is typically unknown (unlike the delay for other adaptive equalizers in this product). If you need to determine the delay, you can use the Find Delay block.

Parameters

Number of taps

The number of taps in the filter of the equalizer.

Number of samples per symbol

The number of input samples for each symbol.

When you set this parameter to 1, the filter weights are updated once for each symbol, for a symbol spaced (i.e. T-spaced) equalizer. When you set this parameter to a value greater than one, the weights are updated once every N^{th} sample, for a fractionally spaced (i.e. T/N-spaced) equalizer.

Signal constellation

A vector of complex numbers that specifies the constellation for the modulation.

Step size

The step size of the CMA.

Leakage factor

The leakage factor of the CMA, a number between 0 and 1. A value of 1 corresponds to a conventional weight update algorithm, and a value of 0 corresponds to a memoryless update algorithm.

Initial weights

A vector that lists the initial weights for the taps.

Output error

If you check this box, the block outputs the error signal described in the table above.

Output weights

If you check this box, the block outputs the current weights.

References

[1] Haykin, Simon, *Adaptive Filter Theory*, Third Ed., Upper Saddle River, N.J., Prentice-Hall, 1996.

Compatibility Considerations

CMA Equalizer has been removed

Errors starting in R2022a

- CMA Equalizer has been removed. Use Linear Equalizer instead with the adaptive algorithm set to CMA.
- The Linear Equalizer block does not have a leakage factor parameter. This is equivalent to setting the **Leakage factor** parameter to 1 in the CMA Equalizer block.

For more information, see the "Adaptive Equalizers" topic.

Coarse Frequency Compensator

Compensate for carrier frequency offset for PAM, PSK, or QAM

Library

Synchronization

Description

The Coarse Frequency Compensator block compensates for a carrier frequency offset for BPSK, QPSK, OQPSK, 8-PSK, PAM, and QAM modulation schemes. The block accepts a single input signal. To obtain an estimate of the frequency offset in Hz, select the **Estimated frequency offset output port** check box. The block accepts a sample- or frame-based complex input signal and returns a complex output signal and a real frequency offset estimate. The output signal has the same dimensions as the input signal. The frequency offset estimate is a scalar.

Parameters

Modulation type of input signal

Specify the modulation type as BPSK, QPSK, OQPSK, 8PSK, PAM, or QAM.

The default setting is QAM.

Estimation algorithm

Specify the frequency offset estimation algorithm as FFT-based or Correlation-based. This parameter appears when **Modulation type of input signal** is BPSK, QPSK, 8PSK, or PAM.

The table shows the allowable combinations of the modulation type and the estimation algorithm.

Modulation	FFT-Based Algorithm	Correlation-Based Algorithm
BPSK, QPSK, 8PSK, PAM	✓	✓
OQPSK, QAM	✓	

Frequency resolution (Hz)

Specify the frequency resolution in Hz as a positive real scalar. This option is available when the FFT-based algorithm is used. The default setting is 0.001 Hz.

Samples per symbol

Specify the number of samples per symbol as a positive integer scalar greater than or equal to 4. The default setting is 4.

Maximum frequency offset (Hz)

Specify the maximum frequency offset in Hz as a positive real scalar. This option is appears when you set **Estimation algorithm** to Correlation-based. The default setting is 0.05 Hz.

Estimated frequency offset output port

Select this check box to provide the estimated frequency offset to an output port. The default for this parameter is selected.

Simulate using

Select the simulation mode.

Code generation

On the first model run, simulate and generate code for the block using only MATLAB functions supported for code generation. If the structure of the block does not change, subsequent model runs do not regenerate the code.

If the simulation mode is Code generation, System objects accept a maximum of nine inputs.

Interpreted execution

Simulate your model using all supported MATLAB functions. Choosing this option can slow simulation performance.

The default setting is Code generation.

Algorithms

This block implements the algorithm, inputs, and outputs described on the `comm.CoarseFrequencyCompensator` reference page. The object properties correspond to the block parameters.

Examples**Correct for Frequency and Phase Offset**

Correct for a frequency offset imposed on a noisy 8-PSK channel by using the Coarse Frequency Compensator block.

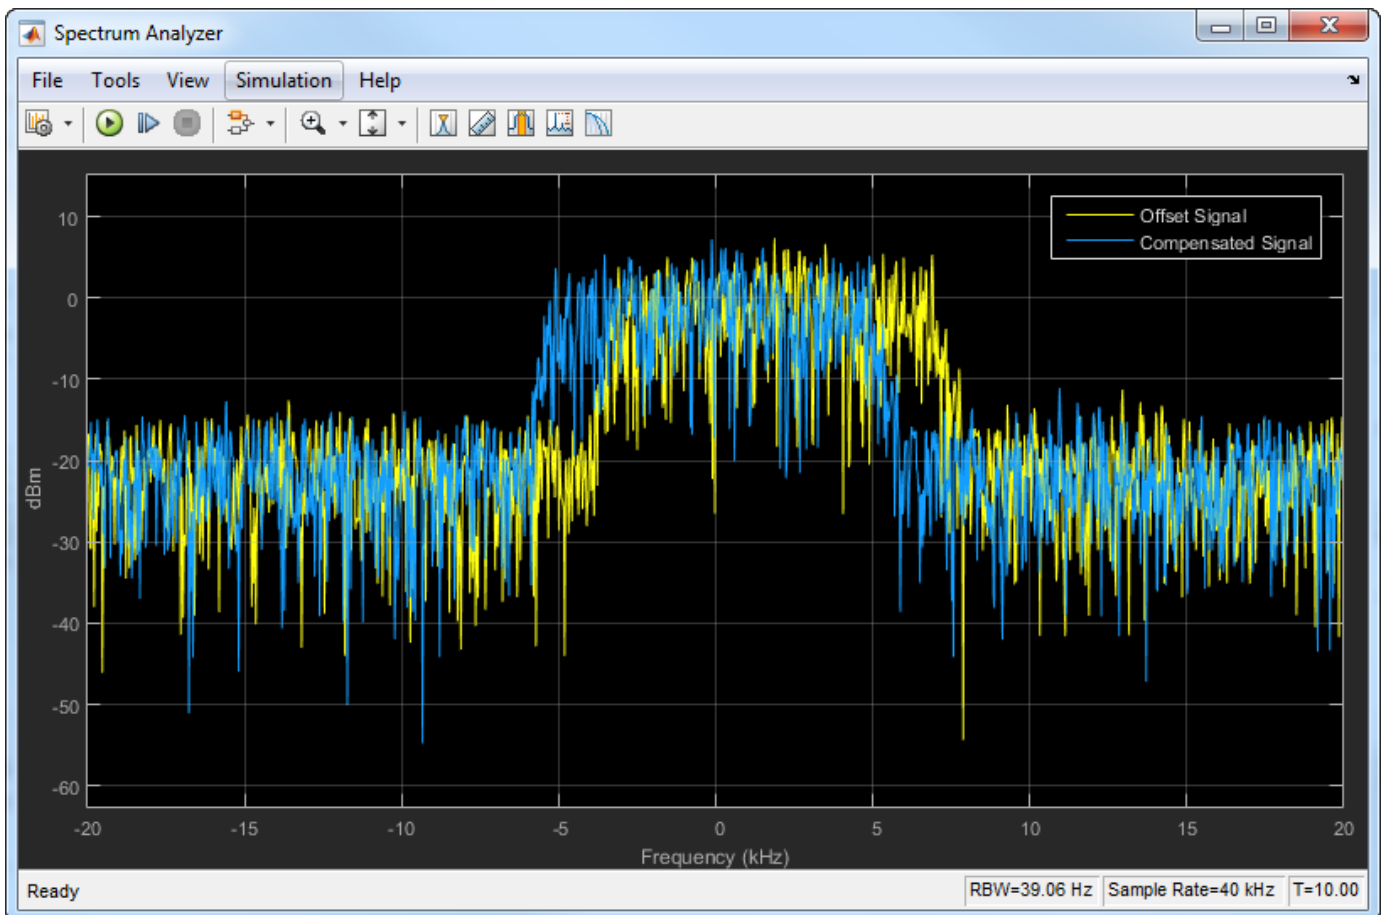

Open the `doc_coarsefreqcomp` model.

Open the dialog boxes to verify these parameter values:

- Random Integer Generator — **Sample time** is 1e-4, which is equivalent to a 10 ksym/sec symbol rate.
- Raised Cosine Transmit Filter — **Output samples per symbol** is 4.
- AWGN Channel — **Mode** is Signal to noise ratio (SNR) and **SNR (dB)** is 20.
- Phase/Frequency Offset — **Frequency offset (Hz)** is 2000.
- Coarse Frequency Compensator — **Estimation algorithm** is FFT-based and **Frequency resolution (Hz)** is 1.

Run the model. The Spectrum Analyzer block shows both the frequency offset signal and the compensated signal. In addition, the Display block shows the estimate of the frequency offset. Observe that the spectrum plot shows that the Coarse Frequency Compensator correctly centers the signal around 0 Hz. Additionally, the display shows that the estimated frequency offset is 2000 Hz.

Adjust the parameters in the Phase/Frequency Offset and Coarse Frequency Compensator blocks and see their effect on frequency compensation performance.

Supported Data Types

Port	Supported Data Types
Signal Input	<ul style="list-style-type: none"> • Double-precision floating point • Single-precision floating point

Complex Phase Difference

Phase difference between two complex signals

Library: Communications Toolbox / Utility Blocks

Description

The Complex Phase Difference block computes the phase difference in radians between the second input signal and the first input signal. The elements of the output are between $-\pi$ and π . This block independently processes each pair of corresponding elements.

Ports

Input

In1 — First input signal

scalar | column vector | matrix

First input signal, specified as a scalar, column vector, or matrix. If both input signals are nonscalar, they must be the same dimension.

Note This block processes complex signals. Real values at the input ports are type cast to complex values with $+j0$ complex components.

Data Types: double | single

Complex Number Support: Yes

In2 — Second input signal

scalar | column vector | matrix

Second input signal, specified as a scalar, column vector, or matrix. If both input signals are nonscalar, they must be the same dimension. **In2** must be the same data type as **In1**.

Note This block processes complex signals. Real values at the input ports are type cast to complex values with $+j0$ complex components.

Data Types: double | single

Output

Out1 — Phase shift difference

scalar | column vector | matrix

Phase shift difference in radians, returned as a scalar, column vector, or matrix. If either input signal is nonscalar, the output signal dimension matches the dimension of the nonscalar input signal. The

output is the phase difference between the second input signal and the first input signal. The elements of the output signal are between $-\pi$ and π and are the same data type as the input signals.

Complex Phase Shift

Apply complex phase shift to complex signal

Library: Communications Toolbox / Utility Blocks

Description

The Complex Phase Shift block applies a complex phase shift to a complex signal. This block independently processes each pair of corresponding elements.

Ports

Input

In — Input signal

scalar | column vector | matrix

Input signal, specified as a scalar, column vector, or matrix.

Note This block processes and outputs complex signals. Real values at the input port are type cast to complex values with $+j0$ complex components.

Data Types: double | single

Complex Number Support: Yes

Ph — Phase shift

scalar | column vector | matrix

Phase shift in radians, specified as a scalar, column vector, or matrix. If the phase shift is nonscalar, it must have the same dimension as the signal at port **In**.

Data Types: double

Output

Out1 — Phase-shifted signal

scalar | column vector | matrix

Phase-shifted signal, returned as a complex-valued scalar, column vector, or matrix. This output is the same dimension and data type as the input signal.

Constellation Diagram

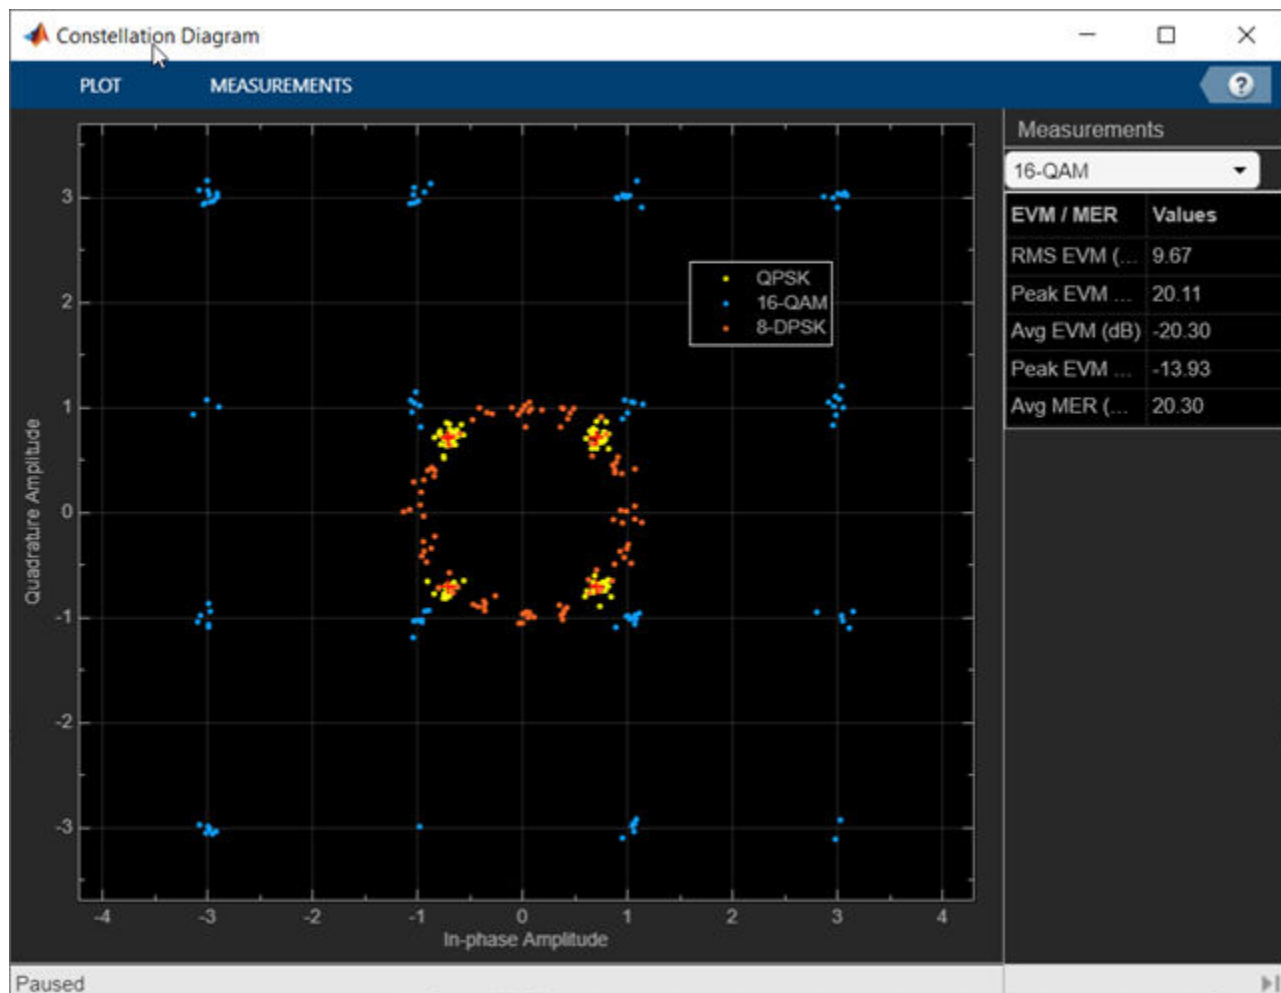

Display and analyze input signals in IQ-plane

Library: Communications Toolbox / Comm Sinks
 Communications Toolbox HDL Support / Comm Sinks

Description

The Constellation Diagram block displays real- and complex-valued floating- and fixed-point signals in the IQ plane. Use this block to perform qualitative and quantitative analysis on modulated single-carrier signals. Specifically, the IQ-plane displays the in-phase and quadrature components of modulated signals on the real and imaginary axis of an xy-plot.

In the Constellation Diagram window, you can:

- Input and plot multiple signals on a single constellation diagram. To define a reference constellation for each input signal, use the **Reference Constellation** parameter.
- Select signals in the legend to toggle visibility of individual channels. To display the legend, use the **Legend** parameter on the **Plot** tab. For a multichannel signal, specify the input as a matrix with individual signals defined in the columns of the matrix.
- Display calculated error vector magnitude (EVM) and modulation error ratio (MER) measurements for individual signals. To view and configure the measurements, select **EVM/MER** on the **Measurements** tab. When multiple signals are input, you can select which signal to use for measurements in the **Channel** section.

Ports

Input

In_1, ..., In_N — Signals (as separate ports)

column vectors | matrices

Signals, specified as separate arguments of N_{sym} -by-1 column vectors or N_{sym} -by- N_{channel} matrices. N_{sym} is the number of symbols, and N_{channel} is the number of input signal channels. Signals can have different data types and dimensions.

You must specify N input ports, where N is the **Number of input ports** parameter value. You can visualize up to 20 individual or collective signal channels in the constellation diagram. For example, if you create a two-channel signal for every input, then you can define up to 10 input ports.

Example: `[-1 + 1i; -1 - 1i; 1 + 1i; 1 - 1i]` specifies a four-symbol input signal.

Data Types: `double`

Complex Number Support: Yes

Parameters

Plot

In the **Plot** tab, you can adjust settings of the constellation diagram configuration, simulate the model, take a snapshot of the plot, copy the display, and print the figure. Parameters unique to the constellation diagram scope are described.

Settings — Constellation diagram settings

button

On the **Plot** tab, click **Settings** to open the Configuration Plot Settings window. This window includes parameter subsections to configure the data and axes, labels, and color and styling. Parameters unique to the constellation diagram are described on this page.

Number of input ports — Number of input ports on scope block

1 (default) | integer in the range [1, 20]

Specify the number of input ports on the scope block as an integer in the range [1, 20].

The total number of input signal channels cannot exceed 20. When you specify multichannel input signals, the total number of input signal channels limits the maximum number of input ports.

Samples per symbol — Number of samples used to represent each symbol

1 (default) | positive integer

Specify the number of samples used to represent each symbol as a positive integer. The signal is downsampled by the value of this parameter before it is plotted.

Offset — Number of samples to skip before plotting points

0 (default) | nonnegative integer

Specify the number of samples to skip before plotting points as a nonnegative integer less than the **Samples per symbol** parameter value. This value specifies the number of samples to skip when **Samples per symbol** is greater than 1.

Symbols to display — Maximum number of symbols to display

Input frame length (default) | positive integer

Specify the maximum number of symbols to display by selecting `Input frame length` or specifying a positive integer. To specify a positive integer, select and then replace `<user-defined>` with your desired value. Use this parameter to limit the maximum number of symbols that the constellation diagram displays when you input long signals. The block plots the most recently received symbols.

Reference Constellation — Reference constellation configuration

button

On the **Plot** tab or **Measurements** tab, click **Reference Constellation**, to open the Reference Constellation window. This window includes parameters to configure the reference constellation for each input port.

Show reference constellations — Option to display reference constellations

on (default) | off

Select this parameter to show reference constellations on the plot.

Input — Select input port

1 (default) | positive integer

Configure the reference constellation parameters for the specified input port.

Each input port has its own reference constellation. For a multichannel input signal, the block applies a single reference constellation for all signals in that input port.

Reference constellation — Reference constellation

Custom (default) | BPSK | 8-PSK | 16-QAM | 64-QAM | 256-QAM

Specify the reference constellation by selecting `Custom`, `BPSK`, `QPSK`, `8-PSK`, `16-QAM`, `64-QAM`, or `256-QAM`. To specify a custom value, first select `Custom`. Then in the **Custom value** parameter, replace the entry with your custom vector of symbol values.

Each input port had its own reference constellation. For a multichannel input signal, the block applies a single reference constellation for all signals in that input port.

The EVM/MER measurements use the specified reference constellation to calculate the signal quality of the modulated input signal. For more information about the signal quality measurements, see “EVM and MER Measurements” on page 5-114.

Custom value — Input reference constellation

[0.7071+0.7071i -0.7071+0.7071i -0.7071-0.7071i 0.7070-0.7071i] (default) | vector

Specify the reference constellation for an input as a vector that defines symbol values for the custom modulation scheme.

Dependencies

To enable this parameter, set the **Reference constellation** parameter to Custom Reference Constellation.

Data Types: char | double

Complex Number Support: Yes

Constellation normalization — Normalization method

Average power (default) | Minimum distance | Peak power

Specify the normalization method that the block uses for the constellation diagram by selecting Average power, Minimum distance, or Peak power.

Dependencies

To enable this parameter, set the **Reference constellation** parameter to 16-QAM, 64-QAM, or 256-QAM.

Average reference power — Average power of reference constellation

1 (default) | positive scalar

Specify the average power of the reference constellation as a positive scalar. The average power is referenced to a one-ohm load. Units are in watts.

Dependencies

To enable this parameter, set the **Reference constellation** parameter to BPSK, QPSK, 8-PSK, 16-QAM, 64-QAM, or 256-QAM.

Reference phase offset (rad) — Phase offset of reference constellation

scalar

Specify the phase offset of the reference constellation as a scalar. Units are in radians.

Dependencies

To enable this parameter, set the **Reference constellation** parameter to BPSK, QPSK, 8-PSK, 16-QAM, 64-QAM, or 256-QAM.

- The default value is 0 for BPSK, 16-QAM, 64-QAM, and 256-QAM.
- The default value is $\pi/4$ for 8-PSK.
- The default value is $\pi/8$ for QPSK.

Legend — Option to display legend

button

On the **Plot** tab, click **Legend** to toggle the display of the legend. The names listed in the legend are the names for signals connected to input ports as specified in the model. The legend does not display until the model runs with an input signal.

In the scope legend, click a signal name to toggle the signal visibility in the scope.

Trajectory — Option to display signal trajectory

button

On the **Plot** tab, click **Trajectory** to toggle the display of the trajectory. Select this parameter to display the trajectory between constellation points for the plotted signals.

Measurements

In the **Measurements** tab, you can select the active channel, configure the signal quality measurements, and toggle the **Measurements** pane.

For more information about the signal quality measurements, see “EVM and MER Measurements” on page 5-114.

Channel

Channel — Active input channel

name of first channel in first port (default) | list of channels

Select the active input channel for measurements from the list of input channels. Click **EVM/MER** to display the signal quality measurements for the active channel.

The total number of input signal channels cannot exceed 20. When you specify multichannel input signals, the total number of input signal channels limits the maximum permitted value for the **Number of input ports** parameter.

Measurements

Measurement Interval — Duration of EVM and MER measurement

Current display (default) | All displays | positive integer

Specify the duration of the EVM and MER measurement in symbols by selecting **Current Display**, or **All displays** or by specifying a positive integer. To specify a positive integer, select and then replace <user-defined> with your desired value. The value must be a positive value in the range [1, **Symbols to display**). The block computes measurements after the number of input data samples exceeds the measurement interval.

EVM Normalization — Normalization method

Average constellation power (default) | Peak constellation power

Specify the normalization method that the block uses for the EVM normalization by selecting **Average constellation power** or **Peak constellation power**.

Reference Constellation — Reference constellation configuration

button

On the **Plot** tab or **Measurements** tab, click **Reference Constellation**, to open the Reference Constellation window. This window includes parameters to configure the reference constellation for each input port. For parameter descriptions, see the **Reference Constellation** parameter in the “Plot” on page 5-110 section.

EVM/MER — Option to display signal quality measurements pane

button

On the **Measurements** tab, click **EVM/MER** to toggle display the signal quality measurements pane. For more information, see “EVM and MER Measurements” on page 5-114.

Block Characteristics

Data Types	Boolean double enumerated fixed point integer single
Direct Feedthrough	no
Multidimensional Signals	no
Variable-Size Signals	yes
Zero-Crossing Detection	no

More About

EVM and MER Measurements

The **Measurements** pane displays the EVM and MER signal quality measurement settings and the calculation results for the specified signal channel.

- EVM — An error vector is a vector in the IQ plane from the ideal constellation point to the actual point at the receiver. The EVM calculations include root mean square (RMS), peak, and average values.

You can normalize the EVM_{RMS} and EVM_{Average} calculations by the average or peak constellation power method as computed using these algorithms.

EVM Normalization Method	Algorithm
Average constellation power	$EVM_k = 100\sqrt{\frac{e_k}{P_{\text{avg}}}}$ <p>EVM_{RMS}, in percent, for average constellation power normalization:</p> $EVM_{\text{RMS}}(\%) = 100\sqrt{\frac{\frac{1}{N} \sum_{k=1}^N (e_k)}{P_{\text{avg}}}}$
Peak constellation power	$EVM_k = 100\sqrt{\frac{e_k}{P_{\text{max}}}}$ <p>EVM_{RMS}, in percent, for peak constellation power normalization:</p> $EVM_{\text{RMS}}(\%) = 100\sqrt{\frac{\frac{1}{N} \sum_{k=1}^N (e_k)}{P_{\text{max}}}}$

The **Measurements** pane shows the RMS and peak *EVM* in percent and the average and peak *EVM* decibels for the selected input channel. The *EVM* in decibels is computed as $EVM \text{ (dB)} = 10 \cdot \log_{10}(EVM_{\text{MS}}) = 20 \cdot \log_{10}(EVM_{\text{RMS}})$, where:

- $e_k = (I_k - \tilde{I}_k)^2 + (Q_k - \tilde{Q}_k)^2$
- I_k is the in-phase value of the k th symbol in the input vector.
- Q_k is the quadrature phase value of the k th symbol in the input vector.
- I_k and Q_k represent ideal (reference) symbol values. \tilde{I}_k and \tilde{Q}_k represent measured (received) symbol values.
- N is the input vector length.
- P_{avg} is the value for average constellation power.
- P_{max} is the value for peak constellation power.
- $EVM_{\text{RMS}} = \sqrt{EVM_{\text{MS}}}$

The maximum *EVM* value in a vector is $EVM_{\text{max}} = \max_{k \in [1, \dots, N]} \{EVM_k\}$, where k is the k th symbol in a vector of length N .

- *MER* — *MER* is the ratio of the average power of the transmitted signal to the average power of the error vector. The **Measurements** pane indicates average *MER* measurement result in decibels for the selected signal channel.

MER is a measure of the SNR in a modulated signal, calculated in dB. The *MER* over N symbols is

$$MER = 10 \cdot \log_{10} \left(\frac{\sum_{n=1}^N (I_k^2 + Q_k^2)}{\sum_{n=1}^N (e_k)} \right) \text{ dB},$$

where:

- $e_k = (I_k - \tilde{I}_k)^2 + (Q_k - \tilde{Q}_k)^2$
- I_k is the in-phase value of the k th symbol in the input vector.
- Q_k is the quadrature phase value of the k th symbol in the input vector.
- I_k and Q_k represent ideal (reference) values. \tilde{I}_k and \tilde{Q}_k represent measured (received) symbols.

Programmatic Configuration

You can programmatically configure the scope properties with callbacks or within scripts by using a scope configuration object as described in “Control Scope Blocks Programmatically” (Simulink).

Continuous-Time VCO

(To be removed) Implement voltage-controlled oscillator

Note will be removed in a future release. To design voltage-controlled oscillators (VCOs) and phase-locked loops (PLLs), use the “Phase-Locked Loops” (Mixed-Signal Blockset) blocks.

Library

Components sublibrary of Synchronization

Description

The Continuous-Time VCO (voltage-controlled oscillator) block generates a signal with a frequency shift from the **Quiescent frequency** parameter that is proportional to the input signal. The input signal is interpreted as a voltage. If the input signal is $u(t)$, then the output signal is

$$y(t) = A_c \cos\left(2\pi f_c t + 2\pi k_c \int^t u(\tau) d\tau + \varphi\right)$$

where A_c is the **Output amplitude** parameter, f_c is the **Quiescent frequency** parameter, k_c is the **Input sensitivity** parameter, and φ is the **Initial phase** parameter.

This block uses a continuous-time integrator to interpret the equation above.

The input and output are both sample-based scalar signals.

Parameters

Output amplitude

The amplitude of the output.

Quiescent frequency

The frequency of the oscillator output when the input signal is zero.

Input sensitivity

This value scales the input voltage and, consequently, the shift from the **Quiescent frequency** value. The units of **Input sensitivity** are Hertz per volt.

Initial phase

The initial phase of the oscillator in radians.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Convolutional Deinterleaver

Restore ordering of symbols that were permuted using shift registers

Library

Convolutional sublibrary of Interleaving

Description

The Convolutional Deinterleaver block recovers a signal that was interleaved using the Convolutional Interleaver block. Internally, this block uses a set of shift registers. The delay value of the k^{th} shift register is $(N-k)$ times the **Register length step** parameter. The number of shift registers, N , is the value of the **Rows of shift registers** parameter. The parameters in the two blocks must have the same values.

This block accepts a scalar or column vector input signal, which can be real or complex. The output signal has the same sample time as the input signal.

This block accepts the following data types: `int8`, `uint8`, `int16`, `uint16`, `int32`, `uint32`, `boolean`, `single`, `double`, and `fixed-point`.

Parameters

Rows of shift registers

The number of shift registers that the block uses internally.

Register length step

The difference in symbol capacity of each successive shift register, where the last register holds zero symbols.

Initial conditions

Indicates the values that fill each shift register at the beginning of the simulation (except for the last shift register, which has zero delay).

- When you select a scalar value for **Initial conditions**, the value fills all shift registers (except for the last one)
- When you select a column vector with a length equal to the **Rows of shift registers** parameter, each entry fills the corresponding shift register.

The value of the first element of the **Initial conditions** parameter is unimportant, since the last shift register has zero delay.

Examples

For an example that uses this block, see “Convolutional Interleaving”.

Pair Block

Convolutional Interleaver

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic.

HDL Architecture

You can generate HDL code for the Convolutional Deinterleaver block using a shift-register-based implementation, or a RAM-based implementation.

The default implementation for the Convolutional Deinterleaver block is shift register-based. To suppress generation of reset logic, set the implementation parameter `ResetType` to 'none'. When you set `ResetType` to 'none', reset is not applied to the shift registers.

When registers are not fully loaded, mismatches between Simulink and the generated code occur for some number of samples during the initial phase. To avoid spurious test bench errors, determine the number of samples required to fill the shift registers. Set the **Ignore output data checking (number of samples)** option accordingly. (If you are using the command-line interface, you can use the `IgnoreDataChecking` property for this purpose.)

When you select the RAM implementation for a Convolutional Deinterleaver block, HDL Coder uses RAM resources instead of shift registers.

HDL Block Properties

ConstrainedOutputPipeline	Number of registers to place at the outputs by moving existing delays within your design. Distributed pipelining does not redistribute these registers. The default is 0. For more details, see “ConstrainedOutputPipeline” (HDL Coder).
InputPipeline	Number of input pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “InputPipeline” (HDL Coder).
OutputPipeline	Number of output pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “OutputPipeline” (HDL Coder).
ResetType	Suppress reset logic generation. The default is default, which generates reset logic. See also “ResetType” (HDL Coder).

Restrictions

When you select the RAM implementation:

- Double or single data types are not supported for either input or output signals.
- You must set **Initial conditions** for the block to zero.
- At least two rows of interleaving are required.

Introduced before R2006a

Convolutional Encoder

Create convolutional code from binary data

Library

Convolutional sublibrary of Error Detection and Correction

Description

The Convolutional Encoder block encodes a sequence of binary input vectors to produce a sequence of binary output vectors. This block can process multiple symbols at a time.

This block can accept inputs that vary in length during simulation. For more information about variable-size signals, see “Variable-Size Signal Basics” (Simulink).

Input and Output Sizes

If the encoder takes k input bit streams (that is, it can receive 2^k possible input symbols), the block input vector length is $L*k$ for some positive integer L . Similarly, if the encoder produces n output bit streams (that is, it can produce 2^n possible output symbols), the block output vector length is $L*n$.

This block accepts a column vector input signal with any positive integer for L . For variable-size inputs, the L can vary during simulation. The operation of the block is governed by the **Operation mode** parameter.

For both its inputs and outputs for the data ports, the block supports **double**, **single**, **boolean**, **int8**, **uint8**, **int16**, **uint16**, **int32**, **uint32**, and **ufix1**. The port data types are inherited from the signals that drive the block. The input reset port supports **double** and **boolean** typed signals.

Specifying the Encoder

To define the convolutional encoder, use the **Trellis structure** parameter. This parameter is a MATLAB structure whose format is described in “Trellis Description of a Convolutional Code”. You can use this parameter field in two ways:

- If you have a variable in the MATLAB workspace that contains the trellis structure, enter its name in the **Trellis structure** parameter. This way is preferable because it causes Simulink to spend less time updating the diagram at the beginning of each simulation, compared to the usage described next.
- If you want to specify the encoder using its constraint length, generator polynomials, and possibly feedback connection polynomials, use a `poly2trellis` command in the **Trellis structure** parameter. For example, to use an encoder with a constraint length of 7, code generator polynomials of 171 and 133 (in octal numbers), and a feedback connection of 171 (in octal), set the **Trellis structure** parameter to

```
poly2trellis(7,[171 133],171)
```

The encoder registers begin in the all-zeros state. Set the **Operation mode** parameter to **Reset on nonzero input via port** to reset all encoder registers to the all-zeros state during the simulation. This selection opens a second input port, labeled **Rst**, which accepts a scalar-valued input signal. When the input signal is nonzero, the block resets before processing the data at the first input port. To reset the block after it processes the data at the first input port, select **Delay reset action to next time step**.

Parameters

Trellis structure

MATLAB structure that contains the trellis description of the convolutional encoder.

Operation mode

In **Continuous** mode, the block retains the encoder states at the end of each input, for use with the next frame.

In **Truncated (reset every frame)** mode, the block treats each input independently. The encoder states are reset to all-zeros state at the start of each input.

Note When this block outputs sequences that vary in length during simulation and you set the **Operation mode** to **Truncated (reset every frame)** or **Terminate trellis by appending bits**, the block's state resets at every input time step.

In **Terminate trellis by appending bits** mode, the block treats each input independently. For each input frame, extra bits are used to set the encoder states to all-zeros state at the end of the frame. The output length is given by $y = n \cdot (x + s)/k$, where x is the number of input bits, and $s = \text{constraint length} - 1$ (or, in the case of multiple constraint lengths, $s = \text{sum}(\text{ConstraintLength}(i) - 1)$).

Note This block works for cases $k \geq 1$, where it has the same values for constraint lengths in each input stream (e.g., constraint lengths of [2 2] or [7 7] will work, but [5 4] will not).

In **Reset on nonzero input via port** mode, the block has an additional input port, labeled **Rst**. When the **Rst** input is nonzero, the encoder resets to the all-zeros state.

Delay reset action to next time step

When you select **Delay reset action to next time step**, the Convolutional Encoder block resets after computing the encoded data. This check box only appears when you set the **Operation mode** parameter to **Reset on nonzero input via port**.

The delay in the reset action allows the block to support HDL code generation. In order to generate HDL code, you must have an HDL Coder license.

Output final state

When you select **Output final state**, the second output port signal specifies the output state for the block. The output signal is a scalar, integer value. You can select **Output final state** for all operation modes except **Terminate trellis by appending bits**.

Specify initial state via input port

When you select **Specify initial state via input port** the second input port signal specifies the starting state for every frame in the block. The input signal must be a scalar, integer value.

Specify initial state via input port appears only in Truncated operation mode.

Puncture code

Selecting this option opens the field **Puncture vector**.

Puncture vector

Vector used to puncture the encoded data. The puncture vector is a pattern of 1s and 0s where the 0s indicate the punctured bits. This field appears when you select **Punctured code**.

Puncture Pattern Examples

For some commonly used puncture patterns for specific rates and polynomials, see the last three references listed on this page.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic.

HDL Architecture

This block has a single, default HDL architecture.

HDL Block Properties

ConstrainedOutputPipeline	Number of registers to place at the outputs by moving existing delays within your design. Distributed pipelining does not redistribute these registers. The default is 0. For more details, see “ConstrainedOutputPipeline” (HDL Coder).
InputPipeline	Number of input pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “InputPipeline” (HDL Coder).
OutputPipeline	Number of output pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “OutputPipeline” (HDL Coder).

Restrictions

- Input data requirements:
 - Must be sample-based,
 - Must have a `boolean` or `ufix1` data type.
- HDL Coder supports only the following coding rates:
 - $\frac{1}{2}$ to $\frac{1}{7}$
 - $\frac{2}{3}$
- The coder supports only constraint lengths for 3 to 9.
- Specify **Trellis structure** by the `poly2trellis` function.
- The coder supports the following **Operation mode** settings:
 - `Continuous`
 - `Reset on nonzero input via port`

If you select this mode, you must select the **Delay reset action to next time step** option. When you select this option, the Convolutional Encoder block finishes its current computation before executing a reset.
- You cannot generate HDL for this block inside a Resettable Synchronous Subsystem.

Introduced before R2006a

Convolutional Interleaver

Permute input symbols using set of shift registers

Library

Convolutional sublibrary of Interleaving

Description

The Convolutional Interleaver block permutes the symbols in the input signal. Internally, it uses a set of shift registers. The delay value of the k th shift register is $(k-1)$ times the **Register length step** parameter. The number of shift registers is the value of the **Rows of shift registers** parameter.

The **Initial conditions** parameter indicates the values that fill each shift register at the beginning of the simulation (except for the first shift register, which has zero delay). If **Initial conditions** is a scalar, then its value fills all shift registers except the first; if **Initial conditions** is a column vector whose length is the **Rows of shift registers** parameter, then each entry fills the corresponding shift register. The value of the first element of the **Initial conditions** parameter is unimportant, since the first shift register has zero delay.

This block accepts a scalar or column vector input signal, which can be real or complex. The output signal has the same sample time as the input signal.

The block can accept the data types `int8`, `uint8`, `int16`, `uint16`, `int32`, `uint32`, `boolean`, `single`, `double`, and fixed-point. The data type of this output will be the same as that of the input signal.

Parameters

Rows of shift registers

The number of shift registers that the block uses internally.

Register length step

The number of additional symbols that fit in each successive shift register, where the first register holds zero symbols.

Initial conditions

The values that fill each shift register when the simulation begins.

Examples

For an example that uses this block, see “Convolutional Interleaving”.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic.

HDL Architecture

You can generate HDL code for the Convolutional Interleaver block using a shift-register-based implementation, or a RAM-based implementation.

The default implementation for the Convolutional Interleaver block is shift register-based. To suppress generation of reset logic, set the implementation parameter `ResetType` to 'none'. When you set `ResetType` to 'none', reset is not applied to the shift registers.

When registers are not fully loaded, mismatches between Simulink and the generated code occur for some number of samples during the initial phase. To avoid spurious test bench errors, determine the number of samples required to fill the shift registers. Set the **Ignore output data checking (number of samples)** option accordingly. (If you are using the command-line interface, you can use the `IgnoreDataChecking` property for this purpose.)

When you select the RAM implementation for a Convolutional Interleaver block, HDL Coder uses RAM resources instead of shift registers.

HDL Block Properties

ConstrainedOutputPipeline	Number of registers to place at the outputs by moving existing delays within your design. Distributed pipelining does not redistribute these registers. The default is 0. For more details, see “ConstrainedOutputPipeline” (HDL Coder).
InputPipeline	Number of input pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “InputPipeline” (HDL Coder).
OutputPipeline	Number of output pipeline stages to insert in the generated code. Distributed pipelining and constrained output pipelining can move these registers. The default is 0. For more details, see “OutputPipeline” (HDL Coder).
ResetType	Suppress reset logic generation. The default is default, which generates reset logic. See also “ResetType” (HDL Coder).

Restrictions

When you select the RAM implementation:

- Double or single data types are not supported for either input or output signals.
- You must set **Initial conditions** for the block to zero.
- At least two rows of interleaving are required.

Introduced before R2006a

CPFSK Demodulator Baseband

Demodulate CPFSK-modulated data

Library

CPM, in Digital Baseband sublibrary of Modulation

Description

The CPFSK Demodulator Baseband block demodulates a signal that was modulated using the continuous phase frequency shift keying method. The input to this block is a baseband representation of the modulated signal. The **M-ary number** parameter, M , is the size of the input alphabet. M must have the form 2^K for some positive integer K .

This block supports multi-h **Modulation index**. See CPM Modulator Baseband for details.

Integer-Valued Signals and Binary-Valued Signals

When you set the **Output type** parameter to `Integer`, then the block produces odd integers between $-(M-1)$ and $M-1$.

When you set the **Output type** parameter to `Bit`, then the block produces groupings of K bits. Each grouping is called a *binary word*.

In binary output mode, the block first maps each input symbol to an intermediate value as in the integer output mode. The block then maps the odd integer k to the nonnegative integer $(k+M-1)/2$. Finally, the block maps each nonnegative integer to a binary word, using a mapping that depends on whether the **Symbol set ordering** parameter is set to `Binary` or `Gray`.

This block accepts a scalar-valued or column vector input signal with a data type of `single` or `double`.

Single-Rate Processing

In single-rate processing mode, the input and output signals have the same port sample time. The block implicitly implements the rate change by making a size change at the output when compared to the input. The input width must be an integer multiple of the **Samples per symbol** parameter value, and the input can be a column vector.

- When you set **Output type** to `Bit`, the output width is K times the number of input symbols.
- When you set **Output type** to `Integer`, the output width is the number of input symbols.

Multirate Processing

In multirate processing mode, the input and output signals have different port sample times. The input must be a scalar. The output symbol time is the product of the input sample time and the **Samples per symbol** parameter value.

- When you set **Output type** to **Bit**, the output width equals the number of bits per symbol.
- When you set **Output type** to **Integer**, the output is a scalar.

Traceback Depth and Output Delays

Internally, this block creates a trellis description of the modulation scheme and uses the Viterbi algorithm. The **Traceback depth** parameter, D , in this block is the number of trellis branches that the algorithm uses to construct each traceback path. D influences the output delay, which is the number of zero symbols that precede the first meaningful demodulated value in the output.

- When you set the **Rate options** parameter to **Allow multirate processing**, and the model uses a variable-step solver or a fixed-step solver with the **Tasking Mode** parameter set to **SingleTasking**, then the delay consists of $D+1$ zero symbols.
- When you set the **Rate options** parameter to **Enforce single-rate processing**, then the delay consists of D zero symbols.

The optimal **Traceback depth** parameter value is dependent on minimum squared Euclidean distance calculations. Alternatively, a typical value, dependent on the number of states, can be chosen using the “five-times-the-constraint-length” rule, which corresponds to $5 \cdot \log_2(\text{numStates})$.

For the definition of the number of states, see CPM Demodulator Baseband Help page.

Parameters

M-ary number

The size of the alphabet.

Output type

Determines whether the output consists of integers or groups of bits.

Symbol set ordering

Determines how the block maps each integer to a group of output bits. This field is active only when **Output type** is set to **Bit**.

Modulation index

Specify the modulation index $\{h_i\}$. The default is 0.5 . The value of this property must be a real, nonnegative scalar or column vector.

This block supports multi-h **Modulation index**. See CPM Modulator Baseband for details.

Phase offset (rad)

The initial phase of the modulated waveform.

Samples per symbol

The number of input samples that represent each modulated symbol, which must be a positive integer. For more information, see “Upsample Signals and Rate Changes” in *Communications Toolbox User's Guide*.

Rate options

Select the rate processing method for the block.

- **Enforce single-rate processing** — When you select this option, the input and output signals have the same port sample time. The block implements the rate change by making a size change at the output when compared to the input. The output width is the number of symbols (which is given by dividing the input length by the **Samples per symbol** parameter value when the **Output type** parameter is set to Integer).
- **Allow multirate processing** — When you select this option, the input and output signals have different port sample times. The output period is the same as the symbol period and equals the product of the input period and the **Samples per symbol** parameter value.

For more information, see Single-Rate Processing and Multirate Processing in the Description section of this page.

Traceback depth

The number of trellis branches that the CPFSK Demodulator Baseband block uses to construct each traceback path.

Output datatype

The output data type can be boolean, int8, int16, int32, or double.

Supported Data Types

Port	Supported Data Types
Input	<ul style="list-style-type: none"> • Double-precision floating point • Single-precision floating point
Output	<ul style="list-style-type: none"> • Double-precision floating point • Boolean (When Output type set to Bit) • 8-, 16-, and 32-bit signed integers (When Output type set to Integer)

CPFSK Modulator Baseband

Modulate using continuous phase frequency shift keying method

Library

CPM, in Digital Baseband sublibrary of Modulation

Description

The CPFSK Modulator Baseband block modulates a signal using the continuous phase frequency shift keying method. The output is a baseband representation of the modulated signal. The **M-ary number** parameter, M , represents the size of the input alphabet. M must have the form 2^K for some positive integer K .

This block supports multi-h **Modulation index**. See CPM Modulator Baseband for details.

Integer-Valued Signals and Binary-Valued Signals

When you set the **Input type** parameter to `Integer`, the block accepts odd integers between $-(M-1)$ and $M-1$.

When you set the **Input type** parameter to `Bit`, the block accepts groupings of K bits. Each grouping is called a *binary word*. The input vector length must be an integer multiple of K .

In binary input mode, the block maps each binary word to an integer between 0 and $M-1$, using a mapping scheme that depends on whether you set the **Symbol set ordering** parameter to `Binary` or `Gray`. The block then maps the integer k to the intermediate value $2k-(M-1)$ and proceeds as if it operates in the integer input mode. For more information, see “Integer-Valued Signals and Binary-Valued Signals”.

This block accepts a scalar-valued or column vector input signal. If you set **Input type** to `Bit`, then the input signal can also be a vector of length K .

Single-Rate Processing

In single-rate processing mode, the input and output signals have the same port sample time. The block implicitly implements the rate change by making a size change at the output when compared to the input. In this mode, the input to the block can be multiple symbols.

- When you set **Input type** to `Integer`, the input can be a column vector, the length of which is the number of input symbols.
- When you set **Input type** to `Bit`, the input must be a column vector with a width that is an integer multiple of K , the number of bits per symbol.

The output width equals the product of the number of input symbols and the **Samples per symbol** parameter value.

Multirate Processing

In multirate processing mode, the input and output signals have different port sample times. In this mode, the input to the block must be one symbol.

- When you set **Input type** to `Integer`, the input must be a scalar.
- When you set **Input type** to `Bit`, the input width must equal the number of bits per symbol.

The output sample time equals the symbol period divided by the **Samples per symbol** parameter value.

Parameters

M-ary number

The size of the alphabet.

Input type

Indicates whether the input consists of integers or groups of bits.

Symbol set ordering

Determines how the block maps each group of input bits to a corresponding integer. This field is active only when **Input type** is set to `Bit`.

Modulation index

Specify the modulation index $\{h_i\}$. The default is 0.5. The value of this property must be a real, nonnegative scalar or column vector.

This block supports multi-h **Modulation index**. See CPM Modulator Baseband for details.

Phase offset (rad)

The initial phase of the output waveform, measured in radians.

Samples per symbol

The number of output samples that the block produces for each integer or binary word in the input, which must be a positive integer. For all non-binary schemes, as defined by the pulse shapes, this value must be greater than 1.

For more information, see “Upsample Signals and Rate Changes”.

Rate options

Select the rate processing option for the block.

- **Enforce single-rate processing** — When you select this option, the input and output signals have the same port sample time. The block implements the rate change by making a size change at the output when compared to the input. The output width equals the product of the number of symbols and the **Samples per symbol** parameter value.
- **Allow multirate processing** — When you select this option, the input and output signals have different port sample times. The output sample time equals the symbol period divided by the **Samples per symbol** parameter value.

Output data type

Select the data type of the output signal. The output data type can be `single` or `double`.

Supported Data Types

Port	Supported Data Types
Input	<ul style="list-style-type: none"> • Double-precision floating point • Boolean (When Input type set to Bit) • 8-, 16-, and 32-bit signed integers (When Input type set to Integer)
Output	<ul style="list-style-type: none"> • Double-precision floating point • Single-precision floating point

CPM Demodulator Baseband

Demodulate signal using CPM method and Viterbi algorithm

Library: Communications Toolbox / Modulation / Digital Baseband
Modulation / CPM

Description

The CPM Demodulator Baseband block demodulates an input signal that was modulated using the continuous phase modulation (CPM) method.

CPM is a modulation method with memory. The block processing includes a correlator followed by a maximum-likelihood sequence detector (MLSD) that searches the paths through the state trellis for the minimum Euclidean distance path. The block uses the Viterbi algorithm to perform MLSD.

For more information about this demodulation and the filtering applied, see “CPM Demodulation” on page 5-139 and “Pulse Shape Filtering” on page 5-140.

Ports

Input

In — Input signal

scalar | column vector

Input signal, specified as a scalar or column vector. The length of the input signal must be an integer multiple of the number of samples per symbol specified in the **Samples per symbol** parameter. For more information, see “Integer-Valued and Binary-Valued Output Signals” on page 5-141.

Data Types: double | single

Output

Out — Output signal

scalar | column vector

Output signal, returned as a scalar or column vector. For more information, see “Integer-Valued and Binary-Valued Output Signals” on page 5-141.

Supported Data Types

- Double-precision floating point
- Boolean (when **Output type** is set to Bit)
- 8-, 16-, and 32-bit signed integers (when **Output type** is set to Integer)

Data Types: double | Boolean | int8 | int16 | int32

For more information on the processing rates, see “Single-Rate Processing” on page 5-141, and “Multirate Processing” on page 5-142.

Parameters

M-ary number — Modulation order

4 (default) | positive integer

Modulation order indicating the alphabet size, specified as a positive integer that is a nonzero power of two. M must have the form 2^K for some positive integer K , where K is the number of bits per symbol.

Output type — Determines whether output consists of integers or groups of bits

Integer (default) | Bit

Determines whether the output consists of integers or groups of bits, specified as Integer or Bit.

Symbol set ordering — Bit mapping

Binary (default) | Gray

Bit mapping, specified as Binary or Gray.

- Set this parameter to Binary to map symbols using natural binary-coded ordering.
- Set this parameter to Gray to map symbols using Gray-coded ordering.

For more information, see “Integer-Valued and Binary-Valued Output Signals” on page 5-141.

Dependencies

To enable this parameter, set **Output type** to Bit.

Modulation index — Modulation index $\{h_i\}$

0.5 (default) | nonnegative scalar | column vector

Modulation index $\{h_i\}$, specified as a nonnegative scalar or column vector.

$\{h\}$ represents a sequence of modulation indices. For more information, see “CPM Demodulation” on page 5-139.

Frequency pulse shape — Type of pulse shaping

Rectangular (default) | Raised Cosine | Spectral Raised Cosine | Gaussian | Tamed FM

Type of pulse shaping used to smooth the phase transitions of the modulated signal, specified as Rectangular, Raised Cosine, Spectral Raised Cosine, Gaussian, or Tamed FM. For more information on the filtering options, see “Pulse Shape Filtering” on page 5-140.

Main lobe pulse duration (symbol intervals) — Main lobe duration

1 (default) | positive integer

Main lobe duration of the largest lobe in the spectral raised cosine pulse, specified as a positive integer representing the number of symbol intervals used by the demodulator to pulse-shape the modulated signal.

Dependencies

To enable this parameter, set **Frequency pulse shape** to Spectral Raised Cosine.

Rolloff — Rolloff factor of spectral raised cosine pulse shape

0.2 (default) | scalar in the range [0, 1]

Rolloff factor of the spectral raised cosine pulse, specified as a scalar in the range [0, 1].

Dependencies

To enable this parameter, set **Frequency pulse shape** to Spectral Raised Cosine.

BT product — Product of bandwidth and symbol time of Gaussian pulse

0.3 (default) | positive scalar

Product of the bandwidth and symbol time of the Gaussian pulse shape, specified as a positive scalar. Use **BT product** to reduce the bandwidth, at the expense of increased intersymbol interference.

Dependencies

To enable this parameter, set **Frequency pulse shape** to Gaussian.

Pulse length (symbol intervals) — Length of frequency pulse shape

1 (default) | positive integer

Frequency pulse shape length, specified as a positive scalar. For more information on the frequency pulse length, refer to *LT* in “Pulse Shape Filtering” on page 5-140.

Symbol prehistory — Data symbols used before the start of simulation

1 (default) | scalar | vector

Symbol prehistory, specified as scalar or vector with odd integer elements in the range [- (**M-ary number** - 1), (**M-ary number** - 1)]. This parameter defines the data symbols used by the modulator prior to the first call of the block in reverse chronological order. When you specify this parameter as a vector, the length must be (**Pulse length (symbol intervals)** - 1).

Phase offset (rad) — Initial phase offset

0 (default) | scalar

Initial phase offset in radians of the modulated waveform, specified as a scalar.

Samples per symbol — Symbol sampling rate

8 (default) | positive scalar

Symbol sampling rate, specified as a positive scalar. This parameter represents the number of samples output for each integer or binary word input. For all nonbinary schemes, as defined by the pulse shapes, this value must be greater than 1.

For more information, see “Upsample Signals and Rate Changes”.

Rate options — Block processing rate

Enforce single-rate processing (default) | Allow multirate processing

Block processing rate, specified as one of these options:

- **Enforce single-rate processing** — The input and output signals have the same port sample time. The block implements the rate change by making a size change at the output when compared to the input. The output width is the number of symbols (which is given by dividing the input length by the **Samples per symbol** parameter value when the **Output type** parameter is set to Integer).

- **Allow multirate processing** — The input and output signals have different port sample times. The output period is the same as the symbol period and equals the product of the input period and the **Samples per symbol** parameter value.

Traceback depth — Traceback depth for Viterbi algorithm

16 (default) | positive integer

Traceback depth for the Viterbi algorithm, specified as a positive integer representing the number of trellis branches that the Viterbi algorithm uses to construct each traceback path. The value of this parameter is also the output delay and the number of zero symbols that precede the first meaningful demodulated symbol in the output. For more information, see “Traceback Depth and Output Delays” on page 5-142.

Output data type — Output data type

double (default) | boolean | int8 | int16 | int32

Output data type, specified as double, boolean, int8, int16, or int32. For more information, see **Supported Data Types** in OutOut.

Block Characteristics

Data Types	Boolean double integer single
Multidimensional Signals	no
Variable-Size Signals	no

More About

CPM Demodulation

The CPM demodulation method process consists of a correlator followed by a maximum-likelihood sequence detector (MLSD) that searches the paths through the state trellis for the minimum Euclidean distance path. When the modulation index is rational ($h = m / p$), a finite number of phase states exist in the symbol. The implementation uses the Viterbi algorithm to perform MLSD.

$\{h_i\}$ is a sequence of modulation indices that moves cyclically through a set of indices $\{h_0, h_1, h_2, \dots, h_{H-1}\}$.

- $h_i = m_i / p_i$ is the modulation index in proper rational form.
- m_i is the numerator of the modulation index.
- p_i is the denominator of the modulation index.
- m_i and p_i are relatively prime positive numbers.
- The least common multiple (LCM) of $\{p_0, p_1, p_2, \dots, p_{H-1}\}$ is denoted as p .
- $h_i = m'_i / p$.

$\{h_i\}$ determines the number of phase states,

$$\text{numPhaseStates} = \begin{cases} p, & \text{for all even } m'_i \\ 2p, & \text{for any odd } m'_i \end{cases}$$

and affects the number of trellis states,

$$numStates = numPhaseStates \times M^{(L-1)},$$

- L is the pulse length.
- M is the modulation order.

CPM Method

The input to the demodulator is a baseband representation of the modulated signal:

$$s(t) = \exp\left[j 2\pi \sum_{i=0}^n \alpha_i h_i q(t - iT)\right], \text{ and}$$

$$nT < t < (n + 1)T.$$

- $\{\alpha_i\}$ is a sequence of M -ary data symbols selected from the alphabet $\pm 1, \pm 3, \pm(M-1)$.
- M must have the form 2^k for some positive integer k , where M is the modulation order and specifies the size of the symbol alphabet.
- $\{h_i\}$ is a sequence of modulation indices, and h_i moves cyclically through a set of indices $\{h_0, h_1, h_2, \dots, h_{H-1}\}$. When $H=1$, only one modulation index exists, h_0 , which is denoted as h .

Pulse Shape Filtering

The CPM method uses pulse shaping to smooth the phase transitions of the modulated signal. The function $q(t)$ is the phase response obtained from the frequency pulse, $g(t)$, through this relation:

$$q(t) = \int_{-\infty}^t g(t) dt.$$

The specified frequency pulse shape corresponds to these pulse shape expressions for $g(t)$.

Pulse Shape	Expression
Rectangular	$g(t) = \begin{cases} \frac{1}{2LT}, & 0 \leq t \leq LT \\ 0 & \text{otherwise} \end{cases}$
Raised Cosine	$g(t) = \begin{cases} \frac{1}{2LT} \left[1 - \cos\left(\frac{2\pi t}{LT}\right) \right], & 0 \leq t \leq LT \\ 0 & \text{otherwise} \end{cases}$
Spectral Raised Cosine	$g(t) = \frac{1}{L_{main}T} \frac{\sin\left(\frac{2\pi t}{L_{main}T}\right) \cos\left(\beta \frac{2\pi t}{L_{main}T}\right)}{\frac{2\pi t}{L_{main}T} \left[1 - \left(\frac{4\beta}{L_{main}T} t\right)^2 \right]}, \quad 0 \leq \beta$ ≤ 1

Pulse Shape	Expression
Gaussian	$g(t) = \frac{1}{2T} \left\{ Q \left[2\pi B_b \frac{t - \frac{T}{2}}{\sqrt{\ln 2}} \right] - Q \left[2\pi B_b \frac{t + \frac{T}{2}}{\sqrt{\ln 2}} \right] \right\}, \text{ where}$ $Q(t) = \int_{-\infty}^{\infty} \frac{1}{\sqrt{2\pi}} e^{-\tau^2/2} d\tau$
Tamed FM (tamed frequency modulation)	$g(t) = \frac{1}{8} [g_0(t - T) + 2g_0(t) + g_0(t + T)], \text{ where}$ $g_0(t) \approx \frac{1}{T} \left[\frac{\sin(\frac{\pi t}{T})}{\frac{\pi t}{T}} - \frac{\pi^2}{24} \frac{2\sin(\frac{\pi t}{T}) - \frac{2\pi t}{T} \cos(\frac{\pi t}{T}) - (\frac{\pi t}{T})^2 \sin(\frac{\pi t}{T})}{(\frac{\pi t}{T})^3} \right]$

- L_{main} is the main lobe pulse duration in symbol intervals.
- β is the roll-off factor of the spectral raised cosine.
- B_b is the product of the bandwidth and the Gaussian pulse.
- The duration of the pulse, LT , is the pulse length in symbol intervals. As defined by the expressions, the spectral raised cosine, Gaussian, and tamed FM pulse shapes have infinite length. For all practical purposes, LT specifies the truncated finite length.

For more information on pulse shape filtering, see [1]

Integer-Valued and Binary-Valued Output Signals

When the **Output type** parameter is set to Integer:

- The block produces odd integers between $-(M-1)$ and $M-1$. The modulation order, M , is specified by the **M-ary number** parameter.
- The **Output datatype** parameter cannot be set to `boolean`.

When the **Output type** parameter is set to Bit:

- The block produces groupings of k -length binary words. The binary word mapping options are natural binary-coded ordering or Gray-coded ordering.
- The **Output datatype** can only be `double` or `boolean`.
- In binary output mode, the block processing follows this procedure:
 - 1 Maps each input symbol to an intermediate value, as in the integer output mode.
 - 2 Maps the odd integer L to the nonnegative integer $(L+M-1)/2$.
 - 3 Maps each nonnegative integer to a binary word, using Binary or Gray mapping, as specified by the **Symbol set ordering** parameter.

Single-Rate Processing

In single-rate processing mode, the input and output signals have the same port sample time. The block implicitly implements the rate change by making a size change at the output when compared to the input. The input width must be an integer multiple of the **Samples per symbol** parameter value, and the input can be a column vector.

- When you set **Output type** to `Bit`, the output width is K times the number of input symbols.

- When you set **Output type** to Integer, the output width is the number of input symbols.

Multirate Processing

In multirate processing mode, the input and output signals have different port sample times. The input must be a scalar. The output symbol time is the product of the input sample time and the **Samples per symbol** parameter value.

- When you set **Output type** to Bit, the output width equals the number of bits per symbol.
- When you set **Output type** to Integer, the output is a scalar.

Traceback Depth and Output Delays

The traceback depth is the number of trellis branches used to construct each traceback path. Traceback depth influences the output delay, which is the number of zero symbols that precede the first meaningful demodulated value in the output.

The optimal traceback depth setting depends on minimum squared Euclidean distance calculations. Alternatively, you can choose a typical value, dependent on the number of states, using the five-times-the-constraint-length rule, which corresponds to $5\log_2(\text{numStates})$.

For a binary raised cosine pulse shape with a pulse length of 3 and $h=2/3$, applying this rule ($5\log_2(3 \times 2^2) = 18$) gives a result that is close to the optimum value of 20.

- When the **Rate options** parameter is set to Allow multirate processing, and the model uses a variable-step solver or a fixed-step solver with the **Tasking Mode** parameter set to SingleTasking, then the delay vector consists of (**Traceback depth**+1) zero-value symbols.
- When the **Rate options** parameter is set to Enforce single-rate processing, the delay vector consists of **Traceback depth** zero-value symbols.

CPM Modulator Baseband

Modulate signal using CPM method

Library: Communications Toolbox / Modulation / Digital Baseband
Modulation / CPM

Description

The CPM Modulator Baseband block modulates an input signal using the continuous phase modulation (CPM) method. The output of the modulator is a baseband representation of the modulated signal.

For more information about the modulation and the filtering applied, see “CPM Modulation” on page 5-147 and “Pulse Shape Filtering” on page 5-147.

Ports

Input

In — Input signal

scalar | column vector

Input signal, specified as a scalar or column vector.

When the **Input type** parameter is set to **Integer**, the block accepts odd integers in the range $[-(M-1), (M-1)]$. M is the modulation order which is specified by the **M-ary number** parameter.

When the **Input type** parameter is set to **Bit**, the block accepts binary-valued inputs that represent integers. The block collects binary-valued signals into groups of $k = \log_2(M)$ bits. k is the number of bits per symbol and M is the modulation order. The input vector length must be an integer multiple of k . The block maps each group of k bits onto a symbol, as specified by the **Symbol set ordering** parameter. For each group of k bits, the block outputs one modulated symbol, oversampled by the **Samples per symbol** parameter value.

Supported Data Types

- Double-precision floating point
- Boolean is permitted when **Input type** is set to **Bit**
- 8-, 16-, and 32-bit signed integers are permitted when **Input type** is set to **Integer**

Data Types: double | Boolean | int8 | int16 | int32

Output

Out — Output signal

scalar | column vector

Output signal, returned as a scalar or column vector.

- When the **Input type** parameter is set to `Integer`, the block outputs one modulated symbol for each input symbol.
- When the **Input type** parameter is set to `Bit`, the block outputs one modulated symbol for each group of k bits.

In both cases, the modulated symbols are oversampled by the **Samples per symbol** parameter value.

Data Types: `double` | `single`

For more information on the processing rates, see “Single-Rate Processing” on page 5-149, and “Multirate Processing” on page 5-149.

Parameters

M-ary number — Modulation order

4 (default) | power of two scalar

Modulation order, specified as a power-of-two scalar. The modulation order, $M = 2^k$ specifies the number of points in the signal constellation, where k is a positive integer indicating the number of bits per symbol.

Input type — Integer or group of bits input indicator

`Integer` (default) | `Bit`

Indicates whether the input consists of integers or groups of bits, specified as `Integer` or `Bit`.

Symbol set ordering — Symbol mapping

`Binary` (default) | `Gray`

Symbol mapping of bit inputs, specified as `Binary` or `Gray`.

- Set this parameter to `Binary` to map symbols using natural binary-coded ordering.
- Set this parameter to `Gray` to map symbols using Gray-coded ordering.

For more information, see “Symbol Sets” on page 5-148.

Dependencies

To enable this parameter, set **Input type** to `Bit`.

Modulation index — Modulation index $\{h_i\}$

0.5 (default) | nonnegative scalar | column vector

Modulation index $\{h_i\}$, specified as a nonnegative scalar or column vector.

$\{h\}$ represents a sequence of modulation indices. For more information, see “CPM Modulation” on page 5-147.

Frequency pulse shape — Type of pulse shaping

`Rectangular` (default) | `Raised Cosine` | `Spectral Raised Cosine` | `Gaussian` | `Tamed FM`

Type of pulse shaping used to smooth the phase transitions of the modulated signal, specified as `Rectangular`, `Raised Cosine`, `Spectral Raised Cosine`, `Gaussian`, or `Tamed FM`. For more information on the filtering options, see “Pulse Shape Filtering” on page 5-147.

Main lobe pulse duration (symbol intervals) – Main lobe duration

1 (default) | positive integer

Main lobe duration of the largest lobe in the spectral raised cosine pulse, specified as a positive integer representing the number of symbol intervals used by the modulator to pulse-shape the modulated signal.

Dependencies

To enable this parameter, set **Frequency pulse shape** to Spectral Raised Cosine.

Rolloff – Rolloff factor of spectral raised cosine pulse shape

0.2 (default) | nonnegative scalar

Rolloff factor of the spectral raised cosine pulse, specified as a scalar from 0 to 1.

Dependencies

To enable this parameter, set **Frequency pulse shape** to Spectral Raised Cosine.

BT product – Product of bandwidth and symbol time of Gaussian pulse shape

0.3 (default) | positive scalar

Product of the bandwidth and symbol time of the Gaussian pulse shape, specified as a positive scalar. Use **BT product** to reduce the bandwidth, at the expense of increased intersymbol interference.

Dependencies

To enable this parameter, set **Frequency pulse shape** to Gaussian.

Pulse length (symbol intervals) – Length of frequency pulse shape

1 (default) | positive integer

Length of the frequency pulse shape in symbol intervals, specified as a positive integer. For more information on the frequency pulse length, refer to *LT* in “Pulse Shape Filtering” on page 5-147.

Symbol prehistory – Data symbols used before the start of simulation

1 (default) | scalar | vector

Symbol prehistory, specified as scalar or vector with odd integer elements in the range $[-(\mathbf{M}\text{-ary number} - 1), (\mathbf{M}\text{-ary number} - 1)]$. This parameter defines the data symbols used by the modulator prior to the first call of the block in reverse chronological order. When you specify this parameter as a vector, the length must be $(\mathbf{Pulse length (symbol intervals)} - 1)$.

Phase offset (rad) – Initial phase offset

0 (default) | scalar

Initial phase offset in radians of the modulated waveform, specified as a scalar.

Samples per symbol – Symbol sampling rate

8 (default) | positive scalar

Symbol sampling rate, specified as a positive scalar. This parameter represents the number of samples output for each integer or binary word input. For all nonbinary schemes, as defined by the pulse shapes, this value must be greater than 1.

For more information, see “Upsample Signals and Rate Changes”.

Rate options — Block processing rate

Enforce single-rate processing (default) | Allow multirate processing

Block processing rate, specified as one of these options:

- **Enforce single-rate processing** — The input and output signals have the same sample time. The block implements the rate change by making a size change at the output when compared to the input. The output width equals the product of the number of symbols and the **Samples per symbol** parameter value.
- **Allow multirate processing** — The input and output signals have different sample times. The output sample time equals the symbol period divided by the **Samples per symbol** parameter value.

Output data type — Output data type

double (default) | single

Output data type, specified as double or single.

Block Characteristics

Data Types	Boolean double integer single
Multidimensional Signals	no
Variable-Size Signals	no

More About**CPM Modulation**

The output of the modulator is a baseband representation of the modulated signal:

$$s(t) = \exp\left[j 2\pi \sum_{i=0}^n \alpha_i h_i q(t - iT)\right], \text{ and}$$

$$nT < t < (n + 1)T.$$

- $\{\alpha_i\}$ is a sequence of M -ary data symbols selected from the alphabet $\pm 1, \pm 3, \pm(M-1)$.
- M must have the form 2^k for some positive integer k , where M is the modulation order and specifies the size of the symbol alphabet.
- $\{h_i\}$ is a sequence of modulation indices, and h_i moves cyclically through a set of indices $\{h_0, h_1, h_2, \dots, h_{H-1}\}$. When $H=1$, only one modulation index exists, h_0 , which is denoted as h .

h_i specifies the modulation index. When h_i varies from interval to interval, the block operates in multi- h . To ensure a finite number of phase states, h_i must be a rational number.

Pulse Shape Filtering

The CPM method uses pulse shaping to smooth the phase transitions of the modulated signal. The function $q(t)$ is the phase response obtained from the frequency pulse, $g(t)$, through this relation:

$$q(t) = \int_{-\infty}^t g(t) dt.$$

The specified frequency pulse shape corresponds to these pulse shape expressions for $g(t)$.

Pulse Shape	Expression
Rectangular	$g(t) = \begin{cases} \frac{1}{2LT}, & 0 \leq t \leq LT \\ 0 & \text{otherwise} \end{cases}$
Raised Cosine	$g(t) = \begin{cases} \frac{1}{2LT} \left[1 - \cos\left(\frac{2\pi t}{LT}\right) \right], & 0 \leq t \leq LT \\ 0 & \text{otherwise} \end{cases}$
Spectral Raised Cosine	$g(t) = \frac{1}{L_{\text{main}}T} \frac{\sin\left(\frac{2\pi t}{L_{\text{main}}T}\right) \cos\left(\beta \frac{2\pi t}{L_{\text{main}}T}\right)}{\frac{2\pi t}{L_{\text{main}}T} \left[1 - \left(\frac{4\beta}{L_{\text{main}}T}t\right)^2 \right]}, \quad 0 \leq \beta \leq 1$
Gaussian	$g(t) = \frac{1}{2T} \left\{ Q \left[2\pi B_b \frac{t - \frac{T}{2}}{\sqrt{\ln 2}} \right] - Q \left[2\pi B_b \frac{t + \frac{T}{2}}{\sqrt{\ln 2}} \right] \right\}, \text{ where}$ $Q(t) = \int_{-\infty}^{\infty} \frac{1}{\sqrt{2\pi}} e^{-\tau^2/2} d\tau$
Tamed FM (tamed frequency modulation)	$g(t) = \frac{1}{8} [g_0(t - T) + 2g_0(t) + g_0(t + T)], \text{ where}$ $g_0(t) \approx \frac{1}{T} \left[\frac{\sin\left(\frac{\pi t}{T}\right)}{\frac{\pi t}{T}} - \frac{\pi^2}{24} \frac{2\sin\left(\frac{\pi t}{T}\right) - \frac{2\pi t}{T} \cos\left(\frac{\pi t}{T}\right) - \left(\frac{\pi t}{T}\right)^2 \sin\left(\frac{\pi t}{T}\right)}{\left(\frac{\pi t}{T}\right)^3} \right]$

- L_{main} is the main lobe pulse duration in symbol intervals.
- β is the roll-off factor of the spectral raised cosine.
- B_b is the product of the bandwidth and the Gaussian pulse.
- The duration of the pulse, LT , is the pulse length in symbol intervals. As defined by the expressions, the spectral raised cosine, Gaussian, and tamed FM pulse shapes have infinite length. For all practical purposes, LT specifies the truncated finite length.

For more information on pulse shape filtering, see [1].

Symbol Sets

In binary input mode, the block processing follows this procedure.

- 1 Divide the input bits into k -length bit words and map each to an integer, L , in the range $[0, M - 1]$. Where $k = \mathbf{log2}(M)$ and M is the modulation order specified by the M-ary number parameter. The binary word mapping options are natural binary-coded ordering or Gray-coded ordering, as specified by the Symbol set ordering parameter.
- 2 Map each integer L to signed integers, as $2L - (M - 1)$.
- 3 Proceed with modulation processing as in the integer input mode.

Single-Rate Processing

In single-rate processing mode, the input and output signals have the same port sample time. In this mode, the input to the block can be multiple symbols. The block implicitly implements the rate change by making a size change at the output when compared to the input.

- When you set **Input type** to **Integer**, the input can be a scalar or a column vector with the length equal to the number of input symbols.
- When you set **Input type** to **Bit**, the input width must be an integer multiple of the number of bits per symbol.

The output width equals $N_{\text{Sym}} \times N_{\text{SPS}}$, where N_{Sym} is the number of symbols in the frame and N_{SPS} is the number of samples per symbol.

Multirate Processing

In multirate processing mode, the input and output signals have different port sample times. In this mode, the input to the block must be one symbol.

- When you set **Input type** to **Integer**, the input must be a scalar.
- When you set **Input type** to **Bit**, the input width must equal the number of bits per symbol.

The output sample time equals $T_{\text{Sym}} / N_{\text{SPS}}$, where T_{Sym} is the symbol period and N_{SPS} is the number of samples per symbol.

CPM Phase Recovery

(Removed) Recover carrier phase using 2P-Power method

Note CPM Phase Recovery has been removed. Use the Carrier Synchronizer block instead.

Library

Carrier Phase Recovery sublibrary of Synchronization

Description

The CPM Phase Recovery block recovers the carrier phase of the input signal using the 2P-Power method. This feedforward, non-data-aided, clock-aided method is suitable for systems that use these types of baseband modulation: continuous phase modulation (CPM), minimum shift keying (MSK), continuous phase frequency shift keying (CPFSK), and Gaussian minimum shift keying (GMSK). This block is suitable for use with blocks in the Baseband Continuous Phase Modulation library.

If you express the modulation index for CPM as a proper fraction, $h = K / P$, then P is the number to which the name "2P-Power" refers. The observation interval parameter must be an integer multiple of the input signal vector length.

The 2P-Power method assumes that the carrier phase is constant over a series of consecutive symbols, and returns an estimate of the carrier phase for the series. The **Observation interval** parameter is the number of symbols for which the carrier phase is assumed constant. This number must be an integer multiple of the input signal's vector length.

Input and Output Signals

This block accepts a scalar or column vector input signal of type `double` or `single`. The input signal represents a baseband signal at the symbol rate, so it must be complex-valued and must contain one sample per symbol.

The outputs are as follows:

- The output port labeled **Sig** gives the result of rotating the input signal counterclockwise, where the amount of rotation equals the carrier phase estimate. The **Sig** output is thus a corrected version of the input signal, and has the same sample time and vector size as the input signal.
- The output port labeled **Ph** outputs the carrier phase estimate, in degrees, for all symbols in the observation interval. The **Ph** output is a scalar signal.

Note Because the block internally computes the argument of a complex number, the carrier phase estimate has an inherent ambiguity. The carrier phase estimate is between $-90/P$ and $90/P$ degrees and might differ from the actual carrier phase by an integer multiple of $180/P$ degrees.

Delays and Latency

The block's algorithm requires it to collect symbols during a period of length **Observation interval** before computing a single estimate of the carrier phase. Therefore, each estimate is delayed by

Observation interval symbols and the corrected signal has a latency of **Observation interval** symbols, relative to the input signal.

Parameters

P

The denominator of the modulation index for CPM ($h = K / P$) when expressed as a proper fraction.

Observation interval

The number of symbols for which the carrier phase is assumed constant. The observation interval parameter must be an integer multiple of the input signal vector length.

When this parameter is exactly equal to the vector length of the input signal, then the block always works. When the integer multiple is not equal to 1, on the **Simulation** tab, select **Model Settings**. Then in the **Solver > Solver selection** section, choose **Type: Fixed-step** and clear the **Treat each discrete rate as a separate task** checkbox.

Algorithm

If the symbols occurring during the observation interval are $x(1)$, $x(2)$, $x(3)$, ..., $x(L)$, then the resulting carrier phase estimate is

$$\frac{1}{2P} \arg \left\{ \sum_{k=1}^L (x(k))^{2P} \right\}$$

where the arg function returns values between -180 degrees and 180 degrees.

Data Mapper

Map integer symbols from one coding scheme to another

Library: Communications Toolbox / Utility Blocks

Description

The Data Mapper block accepts integer inputs and maps them to integer outputs. The mapping types include: binary to Gray coded, Gray coded to binary, and user defined. Additionally, a pass through option is available.

Gray coding is an ordering of binary numbers such that all adjacent numbers differ by only one bit.

Input/Output Ports

Input

Port_1 — Input port

scalar | column vector | matrix

Input signal, specified as a scalar, vector, or matrix of integers. Elements of the input signal must be nonnegative values. The block truncates noninteger values to integer values. When the input is a matrix, the columns are treated as independent channels.

Data Types: double | single | int8 | int16 | int32 | uint8 | uint16 | uint32

Output

Port_2 — Output signal

scalar | column vector | matrix
